below 0 °C. The reaction mixture was decomposed by the addition of dil hydrochloric acid (50 ml), extracted with chloroform (50 ml×3), washed with brine, dried over anhydrous sodium sulfate, and concentrated. The residue was chromatographed on silica gel to give 33 mg (21%) of **5**, mp 154.5—156 °C (lit,[5] 155—156 °C) and 110 mg (78%) of 1,5-dimethoxynaphthalene. Here obtained **5** did not depress the melting point of an authentic sample[5] of **5** on admixture.

B. Hydrolysis of 6. A mixture of **6** (0.534 g, 2 mmol), Cu powder (20 mg), and Cu_2O powder (60 mg) in aqueous sodium hydroxide (2.5 M (1M=1 mol dm^{-3}), 100 ml) was stirred at 150 °C for 3 h in a stainless-steel autoclave. The reaction mixture was filtered, washed with chloroform, and the filtrate was acidified with hydrochloric acid and extracted with chloroform. The usual work-up and purification of the crude product by silica gel chromatography gave **5** (65 mg, 16%) (mp 155—156 °C) and 1,5-dimethoxynaphthalene (54 mg, 14%).

1,4-Dimethoxynaphthalene (**7**) and 1,4,5-trimethoxynaphthalene (**9**) (mp 120—121 °C, lit,[10] 119 °C) were prepared in 87 and 86% yield, respectively, by a similar method for synthesis of 1,5-dimethoxynaphthalene by Benthey et al.[11] **7**: mp 86.5—87.5 °C (hexane); IR (KBr) 1622, 1590, 1380, 1270, 1235, 1095, 1082, and 1020 cm^{-1}; ^1H NMR δ=3.85 (s, 6H, 2×OCH_3), 6.56 (s, 2H, ArH), 7.45 (m, 2H, ArH), and 8.21 (m, 2H, ArH); MS, *m/z* 188 (M^+), 173 (M^+-CH_3), and 145. Calcd for $C_{12}H_{12}O_2$: C, 76.57; H, 6.43%. Found: C, 76.97; H, 6.43%.

1,4-Dimethoxy-2-naphthalenecarbaldehyde (8). A solution of **7** (0.98 g, 5.21 mmol) in chloroform (19 ml) was added to a mixture of phosphoryl chloride (8.27 g, 53.9 mmol) and *N,N*-dimethylformamide (3.89 g, 53.2 mmol). The mixture was refluxed for 80 h and decomposed by the addition of ice water, and extracted with chloroform. After the usual work-up, the residue was chromatographed on silica gel to give 1.12 g (99.6%) of **8**. Recrystallization from hexane gave orange crystals, mp 119.5—120.0 °C. IR (KBr) 1675 (C=O), 1598, 1385, 1375, 1130, and 1100 cm^{-1}; ^1H NMR δ=3.98, 4.06 (each s, 3H, OCH_3), 7.09 (s, 1H, ArH-3), 7.38 (m, 2H, ArH), 8.18 (m, 2H, ArH), and 10.56 (s, 1H, CHO); MS, *m/z* 216 (M^+), 201 (M^+-CH_3), 173, and 145. Calcd for $C_{13}H_{12}O_3$: C, 72.21; H, 5.59%. Found: C, 71.89; H, 5.64%.

Formylation of 9 by a Vilsmeier Reaction. A mixture of **9** (961 mg, 4.41 mmol) in chloroform (20 ml) with $POCl_3$ (3.38 g, 22.0 mmol) and DMF (1.61 g, 22.0 mmol) was allowed to react for 10 h in the same manner as the formylation of **7** and gave 867 mg (80%) of 4,5,8-trimethoxy-1-naphthalenecarbaldehyde (**10**) and 140 mg (13%) of 1,4,8-trimethoxy-2-naphthalenecarbaldehyde (**3**).

10: Mp 186.5—187.5 °C (benzene-hexane (2:1)); IR (KBr) 1660 (C=O), 1610, 1590, 1065, and 1028 cm^{-1}; ^1H NMR δ=3.92, 3.93, 4.02 (each s, 3H, OCH_3), 6.90 (s, 2H, ArH-6,7), 6.91 (d, *J*=8.6 Hz, 1H, ArH-3), 7.93 (d, *J*=8.6 Hz, 1H, ArH-2), and 10.89 (s, 1H, CHO); MS, *m/z* 246 (M^+), 231 (M^+-CH_3), and 119. Calcd for $C_{14}H_{14}O_4$: C, 68.28; H, 5.73%. Found: C, 68.11; H, 5.78%.

3: Mp 90—91 °C (hexane) (lit,[2] 89—89 °C). IR (KBr) 1672 (C=O), 1620, 1607, 1583, 1382, and 1080 cm^{-1}; ^1H NMR δ=3.95, 4.01, 4.06 (each s, 3H, OCH_3), 6.99 (dd, *J*=7.9 and 1.2 Hz, 1H, ArH-7), 7.16 (s, 1H, ArH-3), 7.48—7.65 (2d, *J*=8.3 and 7.9 Hz, 1H, ArH-6), 7.92 (dd, *J*=8.3 and 1.2 Hz, 1H, ArH-5), and 10.57 (s, 1H, CHO); MS, *m/z* 246 (M^+), 231, 203, and 188. Calcd for $C_{14}H_{14}O_4$: C, 68.28; H, 5.73%. Found: C, 68.18; H, 5.78%.

Formylation of 5. The reaction of **5** (209 mg, 1.02 mmol) in chloroform (20 ml) with $POCl_3$ (800 mg, 5.1 mmol) and DMF (374 mg, 5.1 mmol) was carried out over 10 h using the same procedure mentioned above for the formylation of **7**, and gave 146 mg (62%) of 4,8-dimethoxy-1-naphthyl formate (**11**) and 56 mg (24%) of 1-hydroxy-4,8-dimethoxy-2-naphthalenecarbaldehyde (**12**).

11: Mp 137—138.5 °C (hexane); IR (KBr) 1730 (ester C=O), 1595, 1405, 1370, 1260, 1145, 1055, 845, 790, and 750 cm^{-1}; ^1H NMR δ=3.90, 3.98 (each s, 3H, OCH_3), 6.75 (d, *J*=8.3 Hz, 1H, ArH-3), 6.88 (dd, *J*=7.9 and 1.3 Hz, 1H, ArH-7), 7.06 (d, *J*=8.3 Hz, 1H, ArH-2), 7.33—7.47 (2d, *J*=9.3 and 7.9 Hz, 1H, ArH-6), 7.97 (dd, *J*=9.3 and 1.3 Hz, 1H, ArH-5), and 8.33 (s, 1H, HCO-); MS, *m/z* 232 (M^+), 204, 189, and 174. Calcd for $C_{13}H_{12}O_4$: C, 67.23; H, 5.21%. Found: C, 65.98; H, 5.12%.

12: Mp 117.5—118.5 °C (hexane); IR (KBr) 1655 (C=O), 1627, 1610, 1470, 1390, 1257, 1065 cm^{-1}; ^1H NMR δ=3.96, 4.10 (each s, 3H, OCH_3), 6.93 (dd, *J*=7.9 and 1.3 Hz, 1H, ArH-7), 7.07 (s, 1H, ArH-3), 7.44—7.57 (2d, *J*=8.3 and 7.9 Hz, 1H, ArH-6), 7.87 (dd, *J*=8.3 and 1.3 Hz, 1H, ArH-5), 10.23 (s, 1H, OH), and 10.52 (s, 1H, CHO); MS, *m/z* 232 (M^+), 217, 199, and 189. Calcd for $C_{13}H_{12}O_4$: C, 67.23; H, 5.21%. Found: C, 67.14; H, 5.24%.

Duff Reaction of 5. A mixture of **5** (204 mg, 1 mmol), hexamethylenetetramine (140 mg, 1 mmol), *p*-toluenesulfonic acid monohydrate (190 mg, 1 mmol), and acetic acid (5 ml) was refluxed for 3 h, decomposed by water and extracted with chloroform. The chloroform solution was washed with brine, dried over anhydrous sodium sulfate, and concentrated. The residue was chromatographed on silica gel to give 142 mg (61%) of **12**. Recrystallization from hexane gave an analytical sample, mp 117.5—118 °C, which did not depress the melting point of the above **12** on admixture.

Methylation of 12. A mixture of **12** (957 mg, 4.12 mmol), methyl *p*-toluenesulfonate (4.74 g, 6.18 mmol), sodium carbonate (3.30 g, 31 mmol) in *o*-dichlorobenzene (12 ml) was refluxed for 2 h. Water was added and the system was extracted with chloroform. After the usual work-up, the residue was purified by silica-gel chromatogaraphy and gave 960 mg (95%) of **3**. Recrystallization from hexane gave an analytical sample, mp 89—90 °C, which did not depress the melting point of **3** from the formylation of **9**.

The Dehalogenation of *vic*-Dihaloalkanes to Alkenes with Sodium Trithiocarbonate or Sodium Dithiocarbonate in the Presence of Phase-Transfer Catalysts

Akira SUGAWARA,* Atsushi NAKAMURA, Akitoshi ARAKI, and Ryu SATO*,†
Department of Industrial Chemistry, Tsuruoka Technical College, Tsuruoka, Yamagata 997

(Received March 6, 1989)

Synopsis. The reductive dehalogenation of *vic*-dihaloalkanes with aqueous sodium trithiocarbonate or sodium dithiocarbonate in the presence of a phase-transfer catalyst gave the corresponding alkenes in high yields under mild conditions.

There have been numerous reports on the methods of synthesizing various organic compounds using phase-transfer catalysts.[1] These phase-transfer systems have been effectively used to prepare many organosulfur compounds, such as sulfides[2] and dithiocarbonates.[3] Recently, we ourselves have also reported the synthesis of alkyl, aryl, alkanediyl, and cyclic trithiocarbonates in the presence of phase-transfer catalysts (PTC).[4] For the dehalogenations of *vic*-dihaloalkanes to alkenes, several procedures using a variety of reagents have been developed hitherto.[5] An interesting dehalogenation was provided by Nakayama and his co-workers.[6] They showed an effective dehalogenation of *vic*-dibromoalkanes to alkenes using aqueous sodium sulfide in the presence of a phase-transfer catalyst. The use of sodium hydrogensulfide has also been reported.[7] In the course of our investigations of the chemistry of various trithiocarbonates, we have now found that *vic*-dihaloalkanes such as 1,2-dibromo-1,2-diphenylethane (**1**) are reductively dehalogenated under mild conditions by treatment with sodium trithiocarbonate or sodium dithiocarbonate in the presence of PTC to give the corresponding alkenes in excellent yields (Scheme 1).

As shown in Table 1, the present reaction proceeded smoothly in the phase-transfer system when the mixture was stirred for a short period between 0 °C and room temperature. Consequently, we could obtain several alkenes from *vic*-dihaloalkanes in high yields. Trioctylmethylammonium chloride (TOMAC) was employed as a typical PTC and gave favorable results. It should be noted that the reaction of *meso*-1,2-dibromo-1,2-diphenylethane (**1a**) gave *trans*-stilbene (**2a**) exclusively (Entry 1, Table 1), whereas the *dl*-1,2-dibromo-1,2-diphenylethane (**1b**) afforded a mixture of *cis*- and *trans*-stilbene (Entry 7). No alkene was formed in the absence of PTC (Entry 4). In addition, the treatment of the *vic*-dihaloalkane (**1**) with aq. NaOH alone did not give any alkenes (Entry 6). When sodium trithiocarbonate was used as the reducing reagent, the reaction could be monitored by the decolorization of the orange color of the reaction mixture. The dehalogenation of **1a** was completely inhibited by the addition of a radical scavenger such as *N'*,*N'*-diphenyl-*N*-picrylhydrazyl to the reaction system. In the dark, we could also observe considerable retardation (Entries 1 and 2). Furthermore, the reaction of **1b** with sodium trithiocarbonate was greatly accelerated by the irradiation of a 300 W ref-lamp (Entry 8). Based on these results, the present reaction seems not to proceed through the E2-type mechanism proposed by Landini for the dehalogenation of *vic*-dihaloalkanes with sodium sulfide in the presence of PTC,[7] but through a radical mechanism involving one electron transfer which is similar to that proposed by Kormblum for the reductive elimi-

nation of *vic*-dinitro compounds to alkenes (Scheme 2).[8]

It is noteworthy that the elimination-type reaction (E) predominates over nucleophilic substitution (S_N) for the reaction of even *vic*-dihaloalkanes bearing an electron-withdrawing group, such as phenyl and carbonyl groups with sodium trithiocarbonate (Scheme 3).

As has been mentioned above, we succeeded in a new reductive dehalogenation of *vic*-dihaloalkanes to alkenes in the phase-transfer system. We wish to emphasize that the present procedure has several advantages, namely, efficiency of conversion, simplicity of operation, and mild conditions.

Experimental

The IR spectra were obtained on a Jasco IR-G spectrometer, while the NMR spectra were measured with a Varian Gemini-200 spectrometer (200 MHz) in $CDCl_3$, using TMS as the internal standard. The elemental analyses were determined with a Yanagimoto MT-3 apparatus. The ref-lamp used was a National REF-300W. All the melting points are uncorrected.

General Procedure. To a solution of *meso*-1,2-dibromo-1,2-diphenylethane (2 mmol) in benzene (5 ml) we added a 30% aqueous Na_2CS_3 solution (6 mmol) and trioctylmethylammonium chloride (0.08 mmol), the mixture was then stirred for 10 min at room temperature. After the completion of the reaction, the organic layer was washed with water and then dried over sodium sulfate. The residue obtained by the evaporation of the solvent was passed through a short silica gel column, using dichloromethane as the eluent, to give *trans*-stilbene in a 100% yield. The structure of the products was characterized by ^1H NMR, IR, and elemental analyses. The physical and spectral data of the alkenes were also compared with those authentic samples.[9-13]

4-Phenyl-1,3-dithiolane-2-thione: Mp 83—85 °C; IR (KBr) 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ=4.10 (m, 2H, CH_2), 5.65 (m, 1H, CH), and 7.40 (m, 5H, arom). Found: C, 50.61; H, 3.96%. Calcd for $C_9H_8S_3$: C, 50.87; H, 3.77%.

The Enantiomeric Purity of (*S*)- and (*R*)-4-Methylfarnesols Synthesized from Artificial Substrates by Means of a Farnesyl Diphosphate Synthase Reaction

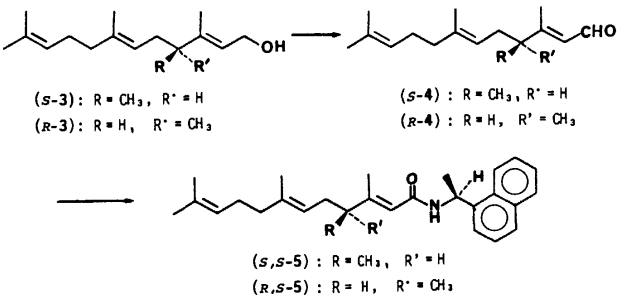
Shin-ichi OHNUMA, Tanetoshi KOYAMA, and Kyozo OGURA*
Chemical Research Institute of Non-Aqueous Solutions, Tohoku University, Katahira, Sendai 980
(Received March 8, 1989)

Synopsis. Both (*S*)- and (*R*)-4-methylfarnesols, synthesized respectively from (*E*)- and (*Z*)-3-methyl-3-pentenyl diphosphates by means of farnesyl diphosphate synthase reactions, were demonstrated to be of almost 100% enantiomeric purity.

Although the utilization of enzymes to prepare chiral compounds of synthetic value is well documented,[1] only a limited number of studies have dealt with enzymes catalyzing carbon-to-carbon-bond formation. We have previously demonstrated the synthetic value of pig-liver farnesyl diphosphate synthase, showing that this enzyme can be used to prepare both (*S*)- and (*R*)-4-methylfarnesols and their homologues directly by the type of C-C bond-forming reactions[2] shown in Scheme 1. We have also synthesized insect metabolites and related compounds using some of these products as chiral synthons.[3-5] However, the enantiomeric purities of the 4-methylfarnesols synthesized by this enzymatic method remained to be determined accurately, though roughly opposite ORD spectra were previously observed for these alcohols.[2] We here wish to report evidence to show that the enantiomeric excesses of these alcohols are both almost 100%.

Results and Discussion

In order to determine the enantiomeric excess of the products derived from (*E*)- (**1**) and (*Z*)-3-methyl-3-pentenyl diphosphate (**2**), we first examined the conversion of racemic (2*E*,6*E*)-4-methylfarnesol (**3**) into diastereomeric derivatives that could be separated from each other. The racemic alcohol **3** was synthesized as follows: The Wittig reaction of 3-geranyl-2-butanone (**6**) with diethyl ethoxycarbonylmethylphosphonate gave a mixture of the *Z*,*E*- and *E*,*E*-isomers of ethyl 4-methylfarnesate, from which ethyl (*RS*)-(2*E*,6*E*)-4-methylfarnesate (**7**) was purified by silica-gel chromatography. Racemic **3** was then obtained by the $LiAlH_4$ reduction of **7**. The alcohol **3** was oxidized with MnO_2 to the aldehyde **4**, which was then oxidized with $NaClO_2$[6] to give (2*E*,6*E*)-4-methylfarnesic acid (**8**) in a quantitative yield. A chromatographic analysis of the methyl ester derived from **8** showed that no isomerization to the 2*Z* isomer had taken place during the oxidation. The oxidation of **4** was also carried out in D_2O so that epimerization could be monitored; it was confirmed by mass spectrometry that no deuterium was incorporated into the acid. The acid was then treated with (*S*)-1-(1-naphthyl)ethylamine in the presence of dicyclohexyl-



Scheme 2. Conversion of (*S*)- and (*R*)-4-methylfarnesols to the corresponding acid amides.

carbodiimide to give a diastereomeric mixture of the corresponding amides, which could subsequently be well separated from each other by means of HPLC. Then, the (*S*)-4-methylfarnesol [(*S*)-**3**] and its *R* enantiomer [(*R*)-**3**], synthesized by the farnesyl diphosphate synthase method, were similarly converted into the corresponding amides, (*S,S*)-**5** and (*R,S*)-**5** respectively. As is shown in Fig. 1, the chromatography of the amides derived from the *S* and *R* isomers indicated that both (*S*)- and (*R*)-4-methylfarnesols had high enantiomeric purities. In other words, the introduction of a methyl group on either the *E* or the *Z* side of C-4 of isopentenyl diphosphate does not disturb the stereochemical course of the C-C bond formation.

The CD spectra of the (*S*)-4-methylfarnesal [(*S*)-**4**] and its *R* enantiomer [(*R*)-**4**], which are perfectly antipodal, also support the high optical purities of these compounds (Fig. 2).

Experimental

The (*S*)-1-(1-naphthyl)ethylamine was purchased from Aldrich. The alkaline phosphatase was obtained from Boehringer-Mannheim. The (*E*)-3-methyl-3-pentenyl diphosphate (**1**), its *Z* isomer (**2**), and geranyl diphosphate were prepared from the corresponding alcohols by diphosphorylation according to the method of Poulter et al.[7]

3-Geranyl-2-butanone (6). A solution of geranyl chloride (5.0 g, 28.9 mmol) in 30 ml of absolute ethanol was added, drop by drop, to a solution of the sodium compound of ethyl 2-methylacetoacetate (ethyl 2-methylacetoacetate, 4.59 g, 31.0 mmol; sodium ethoxide, 2.95 g, 43.4 mmol; and absolute ethanol, 170 ml) under a nitrogen atmosphere at 0 °C. After stirring has been continued at room temperature for 12 h, water was added and the mixture was extracted with hexane. The hexane extract was washed with saturated solutions of NH_4Cl and NaCl and dried over $MgSO_4$. The solvent was evaporated, and the residue was chromatographed on a column of silica gel. Elution with hexane/ethyl acetate (10/1) gave 6.75 g (83.4%) of ethyl 2-geranyl-2-methyl-3-oxobutanoate. A mixture of the ester (6.54 g, 23.2 mmol), 2 M KOH (150 ml; 1 M=1 mol dm^{-3}), and ethanol (25 ml) was stirred overnight at room temperature, after which the mixture was acidified and extracted with diethyl ether. The ether extract was worked up routinely to give **6** (4.82 g, 99%).

Ethyl (*RS*)-(2*E*,6*E*)-4-Methylfarnesate (7). To a suspension of NaH (1.06 g, 44 mmol) in dry benzene we added diethyl ethoxycarbonylmethylphosphonate (5.26 g, 23 mmol) and **6** (4.42 g, 21.3 mmol); the mixture was stirred at room temperature for 1 h and then at 65 °C overnight. Water and hexane were then added, and the mixture was shaken. The organic layer was treated as usual to give a mixture (22/3) of **7** and its 2*Z* isomer (1.50 g, 24%), from which the 2*E* isomer **7** was purified by HPLC on silica gel with hexane/ethyl acetate (200/1).

(*RS*)-4-Methylfarnesol (3). Ethyl 4-methylfarnesate (**7**, 194.2 mg, 0.7 mmol) was added under a nitrogen atmosphere to a suspension of $LiAlH_4$ (55.7 mg, 1.4 mmol) in diethyl ether (10 ml), after which the mixture was stirred at 0 °C. The reaction mixture was worked up routinely, and the product was purified by silica-gel chromatography with hexane/ethyl acetate (5/1). The yield of (*RS*)-**3** was 152.7 mg; 93%.

(*RS*)-4-Methylfarnesic Acid (8). A solution of $NaH_2PO_4 \cdot 2H_2O$ (107.0 mg, 0.68 mmol) and $NaClO_2$ (80.0 mg, 0.88 mmol) in water (0.81 ml) was added, drop by drop, to a stirred solution of (*RS*)-4-methylfarnesal (**4**, 21.3 mg), obtained by the MnO_2 oxidation of (*RS*)-**3** in *t*-butyl alcohol (1.9 ml) and 2-methyl-2-butene (0.5 ml). After being stirred at room temperature for 50 min, the mixture was diluted with water and extracted with hexane. The hexane extract was then purified by chromatography on silica gel with hexane/ethyl acetate (5/1) to give **8** in a quantitative yield.

For the reaction in D_2O, $NaD_2PO_4 \cdot 2D_2O$ and $(CH_3)_3COD$ were used instead of $NaH_2PO_4 \cdot 2H_2O$ and *t*-butyl alcohol.

***N*-[(*S*)-1-(1-Naphthyl)ethyl]-(*S*)-4-methylfarnesamide [(*S,S*)-5] and *N*-[(*S*)-1-(1-Naphthyl)ethyl]-(*R*)-4-methylfarnesamide [(*R,S*)-5].** (*S*)-1-(1-Naphthyl)ethylamine (7.5 mg, 0.044 mmol) was added to a solution of dicyclohexylcarbodiimide (9.9 mg, 0.048 mmol) and (*RS*)-4-methylfarnesic acid (**8**, 10.0 mg, 0.04 mmol) in dichloromethane, after which the mixture was stirred at room temperature overnight. The reaction mixture was then extracted with diethyl ether, and the extract was washed with saturated solutions of NH_4Cl, $NaHCO_3$, and NaCl. After the removal of the solvent, the residue was purified by silica-gel chromatography to give a diastereomeric mixture of the amides in a 23% yield.

Enzymatic Synthesis of (*S*)-4-Methylfarnesol [(*S*)-3] and Its *R* Enantiomer [(*R*)-3]. The enzymatic synthesis was carried out essentially by the same procedure as has been described previously,[2] except for the scale of incubation. The incubation volumes were 1.8 dm^3 and 7.2 dm^3 for the syntheses of (*S*)-**3** and (*R*)-**3** respectively. The yields of (*S*)-**3** and (*R*)-**3** were 24.8 mg and 47.0 mg respectively.

(*S*)-4-Methylfarnesal [(*S*)-4] and Its *R* Enantiomer [(*R*)-4]. Manganese dioxide (20 equiv) was added to a solution of (*S*)-**3** (24.8 mg) or (*R*)-**3** (47.0 mg) in dichloromethane, and the mixture was stirred at room temperature overnight. After the mixture had then been filtered, the filtrate was concentrated and the product was purified by silica-gel chromatography. The yields were both quantitative.

Conversion of (*S*)-4 and (*R*)-4 to Amides (*S,S*)-5 and (*R,S*)-5. (*S*)-4-Methylfarnesic acid [(*S*)-**8**, 15.4 mg] and its *R* enantiomer [(*R*)-**8**, 24.5 mg], which had been obtained respectively from (*S*)-**4** and (*R*)-**4** by $NaClO_2$ oxidation in D_2O, were treated with cyclohexylcarbodiimide as has been described for the reaction of (*RS*)-4-methylfarnesic acid (**8**).

HPLC Separation of (*S,S*)-5 and (*R,S*)-5. The separation of the diastereomeric amides, (*S,S*)-**5** and (*R,S*)-**5**, was performed by chromatography on a 4.6×250 mm column of Zorbax Sil with hexane/ethyl acetate saturated with water (30/1) at a flow rate of 2 ml min^{-1}. The enantiomeric

purities of (*S*,*S*)-**5** and (*R*,*S*)-**5** were both more than 98% ee.

This work was supported by the Asahi Glass Foundation for industrial technology, by special coordination funds of the Science and Technology Agency, and by a Grant-in-Aid for Scientific Research No. 63616502 from the Ministry of Education, Science and Culture. We wish to thank Dr. Nobuyuki Harada of this Institute for his help in the CD spectral measurements.

(Received March 20, 1989)

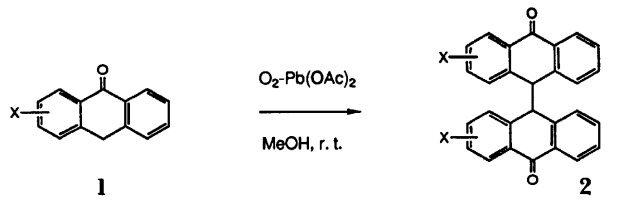
Synopsis. Anthrones were oxidatively dimerized with oxygen in the presence of $Pb(OAc)_2$ giving 9,9′-bianthracene-10,10′(9*H*,9′*H*)-diones. The dimerization proceeds under mild reaction conditions, and gives products in good yields. Binaphthacenedione and bipentacenedione were also synthesized.

9′9-Bianthracene-10,10′(9*H*,9*H*)-diones and their derivatives possess interesting chemical, physical, or biological properties. For example, sennosides are natural purgatives,[1] and photochromism, thermochromism, or piezochromism of $\Delta^{10,10'}$-bianthrone, dehydro derivative of 9,9′-bianthracene-10,10′(9*H*, 9′*H*)-dione, has been known.[2] As for the synthesis of 9,9′-bianthracene-10,10′(9*H*,9′*H*)-diones, oxidative dimerization of anthrones has been conducted using several oxidants,[1-6] of which $FeCl_3$ was most frequently employed.[1a,2a,3] Although the dimerization can be carried out with oxygen more conveniently,[7] the reaction was sluggish, and relatively strong basic conditions were required for promotion. During our investigations on the synthesis of polycyclic aromatic compounds,[8] a novel oxygen-induced dimerization of anthrones, which proceeds under mild reaction conditions, was found.

When 2-methoxycarbonyl-3-methoxycarbonylmethyl-1,9-anthracenediol (**1a**)[8f] was treated with $Pb(OAc)_2$ in methanol at room temperature, oxidative dimerization reaction proceeded smoothly and 4,4′-dihydroxy-3,3′-bis(methoxycarbonyl)-2,2′-bis(methoxycarbonylmethyl)-9,9′-bianthracene-10,10′(9*H*,9′*H*)-dione (**2a**) was obtained in quantitative yield. The use of $Cd(OAc)_2$ gave **2a** in lower yield. Other metal acetates were less effective. Under oxygen atmosphere the reaction was accelerated. Although mass spectra of **2a** showed the parent peak corresponding to the monomer, the dimeric structure was determined by conversion to acetate **3a** or methyl ether **4a**, which gave parent peaks of dimers (Scheme 1). ^1H NMR spectra of **1a** showed the presence of two stereoisomers. Since **1a** exists in keto-form, they are *meso*- and *dl*-isomers concerning 9- and 9′-chiral centers.[9]

Several other anthrones were oxidatively dimerized in the presence of $Pb(OAc)_2$ in good yields (Table 1). Under the reaction conditions, 1,8-dihydroxyanthrone (**1c**) gave dimer **2c** of thermodynamically less stable *pseudoaxial-pseudoaxial*-type conformation rather than *pseudoequatorial-pseudoequatorial*-type.[7b] Two stereoisomers synthesized by the dimerization of anthrone **1d** or 12-naphthacenone **1e** were separable by silica gel chromatography. Equilibration between *meso*- and *dl*-isomer was not observed. The intercon-

Table 1. Oxidative Dimerization of Anthrones



1 2

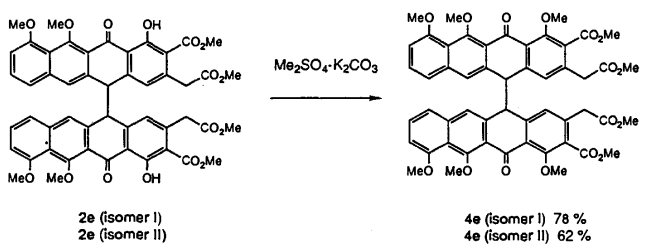
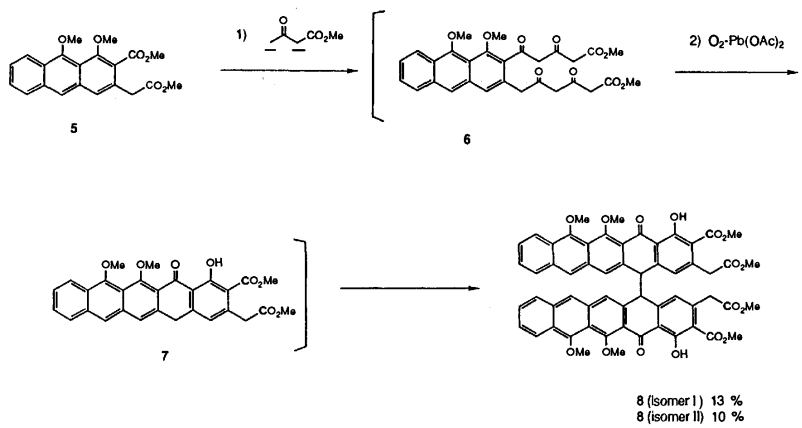


Scheme 2.



Scheme 3.

version did not proceed even under basic conditions. Each of the two isomers of **2e** gave distinct methylated product at 1-hydroxy group by treating with dimethyl sulfate and K_2CO_3 (Scheme 2). It is presumed that enolization is inhibited by severe steric repulsion between 12-hydroxyl group and substituents at 1- and 11-position in the planar structure of enol form. The behavior of **2e** is contrasted to that of **2a** lacking 8-substituent, which readily aromatized to **4a** (Cf. Scheme 1).

The dimerization reaction was applied to pentacenone **7** formed from dimethoxyanthracene **5** (Scheme 3). According to the reactions developed in our laboratory,[8] **5** was treated with methyl acetoacetate dianion followed by $Pb(OAc)_2$, and 5,5′-dipentacene-14,14′(5*H*,5′*H*)-dione (**8**) was obtained as a separable mixture of two stereoisomers. Here, $Pb(OAc)_2$ serves as the promoter of intramolecular condensation of polyketide intermediate **6** and oxidative dimerzation of **7**.

Experimental

Melting points were not corrected. NMR spectra were obtained on a JEOL JNM-FX-60. Chemical shift values are given in ppm relative to internal Me_4Si. IR spectra were recorded on a Shimadzu IR-408. High-resolution mass spectra were taken with JEOL JMS-DX-300. UV spectra were obtained on a Hitachi Model 150-20 double beam spectrophotometer.

1,1′-Dihydroxy-2,2′-bis(methoxycarbonyl)-3,3′-bis(methoxycarbonylmethyl)-10,10′,11,11′-tetramethoxy-5,5′-binaphthacene-12,12′(5*H*,5′*H*)-dione (2e). A mixture of (**1e**,[8f] 60 mg, 0.13 mmol) and $Pb(OAc)_2 \cdot 3H_2O$ (184 mg, 0.68 mmol) in methanol (4 mL) was stirred overnight vigorously. The mixture was filtered, and washed with dichloromethane. Solvents were removed in vacuo, and the residue was chromatographed on silica gel to give 16 mg (26%) of Isomer I (with higher R_f) and 19 mg (32%) of Isomer II (with lower R_f). Isomer I: Mp 222—225 °C ($CHCl_3$-hexane). ^1H NMR ($CDCl_3$) δ=3.57 (6H, s), 3.77 (6H, s), 3.90 (4H, s), 3.94 (6H, s), 3.98 (6H, s), 4.59 (2H, s), 6.36 (2H, s), 6.83 (2H, d, J=7 Hz), 7.04 (2H, s), 7.06 (2H, d, J=7 Hz), 7.50 (2H, t, J=7 Hz), 12.99 (2H, s). IR (KBr) 3400, 1740, 1720, 1630, 1605 cm^{-1}. HRMS Calcd for $C_{25}H_{22}O_8$: 450.1314. Found: 450.1282 (M/2+H). Isomer II: Mp 228—230 °C ($CHCl_3$-hexane). ^1H NMR ($CDCl_3$) δ=3.70 (16H, s), 3.92 (6H, s), 3.98 (6H, s), 4.66 (2H, s), 6.36 (2H, s), 6.85 (2H, d, J=8 Hz), 6.98 (2H, s), 7.09 (2H, d, J=8 Hz), 7.47 (2H, t, J=8 Hz), 12.94 (2H, s). IR (KBr) 3300, 1735, 1710, 1630, 1610 cm^{-1}. HRMS Calcd for $C_{25}H_{22}O_8$: 450.1314. Found: 450.1321 (M/2+H).

4,4′-Dihydroxy-3,3′-bis(methoxycarbonyl)-2,2′-bis(methoxycarbonylmethyl)-9,9′-bianthracene-10,10′(9*H*,9′*H*)-dione (2a). ^1H NMR ($CDCl_3$) δ=3.71 (5H, s), 3.74 (5 H, s), 3.93 (3H, s), 3.96 (3H, s), 4.61 (1H, s), 4.63 (1H, s), 6.33 (1H, s), 6.3—6.9 (2H, m), 6.68 (1H, s), 7.2—7.5 (4H, m), 7.7—8.0 (2H, m), 12.83 (1H, s), 12.88 (1H, s). IR (KBr) 3400, 1735, 1630, 1595 cm^{-1}. HRMS Calcd for $C_{19}H_{16}O_6$: 340.0947. Found: 340.0950 (M/2+H).

9,9′-Bianthracene-10,10′(9*H*,9′*H*)-dione (2b). Mp 270—272 °C decomp ($CHCl_3$). Lit, 264—266 °C decomp.[10] ^1H NMR spectra was identical to the reported data.[10]

4,4′,8,8′-Tetrahydroxy-9,9′-bianthracene-10,10′ (9*H*,9′*H*)-dione (2c). Mp 237 °C decomp (benzene). Lit, 230 °C decomp.[7b] ^1H NMR was identical to the reported data of *pseudoaxial-pseudoaxial*-type conformation.[7b]

4,4′-Dihydroxy-5,5′-dimethoxy-3,3′-bis(methoxycarbonyl)-2,2′-bis(methoxycarbonylmethyl)-9,9′-bianthracene-10,10′(9*H*,9′*H*)-dione (2d). Isomer I (with higher R_f): Mp 185—186 °C ($CHCl_3$-hexane). ^1H NMR ($CDCl_3$) δ=3.74 (6H, s), 3.81 (4H, s), 3.85 (6H, s), 3.95 (6H, s), 4.51 (2H, s), 5.88 (2H, d, J=7 Hz), 6.87 (2 H, s), 6.88 (2H, d, J=7 Hz), 7.26 (2H, t, J=7 Hz), 12.93 (2H, s). IR (KBr) 3500, 1735, 1620 cm^{-1}. UV ($CHCl_3$) λ_{max} 353 nm. HRMS Calcd for $C_{20}H_{18}O_7$: 370.1052. Found: 370.1079 (M/2+H). Isomer II (with lower R_f): Mp 192—194 °C ($CHCl_3$-hexane). ^1H NMR ($CDCl_3$) δ=3.65 (4H, s), 3.70 (6H, s), 3.92 (12H, s), 4.48 (2H, s), 6.25 (2H, s), 6.44 (2H, d, J=8 Hz), 6.93 (2H, s), 7.40 (2H, t, J=8 Hz), 12.87 (2H, s). IR (KBr) 3400, 1735, 1625 cm^{-1}. UV ($CHCl_3$) λ_{max} 353 nm. HRMS Calcd for $C_{20}H_{18}O_7$: 370.1052. Found: 370.1043 (M/2+H).

3,3′-Bis(methoxycarbonyl)-2,2′-bis(methoxycarbonylmethyl)-4,4′,10,10′-tetramethoxy-9,9′-bianthracene (4a). Under a nitrogen atmosphere, a mixture of **2a** (68 mg, 0.21 mmol), K_2CO_3 (119 mg, 0.86 mmol), dimethyl sulfate (0.5 mL), and acetone (5 mL) was stirred at reflux for 3 h. Then 2 M hydrochloric acid (1 M=1 mol dm^{-3}) was added, and organic materials were extracted twice with chloroform. Combined extracts were washed with water and brine, dried (Na_2SO_4), concentrated, and chromatographed on silica gel to give **4a** (41 mg, 53%). Mp 167—172 °C ($CHCl_3$-hexane). ^1H NMR ($CDCl_3$) δ=3.46 (10H, s), 3.96 (6H, s), 4.16 (6H, s), 4.22 (6H, s), 6.76 (2H, s), 6.7—7.6 (6H, m), 8.53 (2H, d, J=8 Hz). IR (KBr) 1740 cm^{-1}. UV ($CHCl_3$) λ_{max} 417, 395, 375, 269 nm. HRMS Calcd for $C_{42}H_{38}O_{12}$: 734.2364. Found: 734.2403.

1,1′,10,10′,11,11′-Hexamethoxy-2,2′-bis(methoxycarbon-

yl)-3,3′-bis(methoxycarbonylmethyl)-5,5′-binaphthacene-12,12′(5*H*,5′*H*)-dione (4e). Two isomers I and II of **2e** were methylated in 78 and 62% yields, respectively. **4e** (isomer I) synthesized from **2e** (isomer I): Mp 239—242 °C ($CHCl_3$-hexane). ^1H NMR ($CDCl_3$) δ=3.68 (6H, s), 3.70 (6H, s), 3.90 (6H, s), 3.91 (12H, s), 3.96 (4H, s), 4.53 (2H, s), 6.61 (2H, s), 6.7—7.1 (4H, m), 6.96 (2H, s), 7.36 (2H, t, J=8 Hz). IR (KBr) 1735, 1675, 1615, 1595, 1560 cm^{-1}. UV ($CHCl_3$) λ_{max} 383 nm. HRMS Calcd for $C_{26}H_{23}O_8$: 463.1392. Found: 463.1374 (M/2). **4e** (isomer II) synthesized from **2e** (isomer II): Mp 259—262 °C ($CHCl_3$-hexane). ^1H NMR ($CDCl_3$) δ=3.64 (10H, s), 3.73 (6H, s), 3.87 (6H, s), 3.89 (6H, s), 3.99 (6H, s), 4.57 (2H, s), 6.58 (2H, s), 6.7—7.2 (4H, m), 6.98 (2H, s), 7.42 (2H, t, J=7Hz). IR (KBr) 1740, 1685, 1620, 1600, 1565 cm^{-1}. UV ($CHCl_3$) λ_{max} 382 nm. HRMS Calcd for $C_{26}H_{24}O_8$: 464.1471. Found: 464.1494 (M/2+H).

3,3′-Bis(methoxycarbonyl)-2,2′-bis(methoxycarbonylmethyl)-4,4′,10,10′-tetraacetoxy-9,9′-bianthracene (3a). Under a nitrogen atmosphere, a mixture of **2a** (34 mg, 0.10 mmol), a catalytic amount of 4-dimethylaminopyridine, pyridine (2 mL), and acetic anhydride (0.5 mL) was stirred overnight at room temperature. Saturated aqueous $KHSO_4$ was added and organic materials were extracted twice with chloroform. Organic layer was washed with saturated aqueous $NaHCO_3$ and brine, dried (Na_2SO_4), concentrated, and chromatographed on silica gel to give **3a** (34 mg, 82%). Mp 140—144 °C (benzene-hexane). ^1H NMR ($CDCl_3$) δ=2.50 (6H, s), 2.65 (6H, s), 3.45 (6H, s), 3.60 (4H, s), 3.87 (6H, s), 6.8—7.7 (6H, m), 6.94 (2H, s), 8.08 (2H, d, J=8Hz). IR (KBr) 1770, 1730, 1615 cm^{-1}. MS 847 (M+H)

1,1′-Dihydroxy-2,2′-bis(methoxycarbonyl)-3,3′-bis(methoxycarbonylmethyl)-12,12′,13,13′-tetramethoxy-5,5′-bipentacene-14,14′(5*H*,5′*H*)-dione (8). Under a nitrogen atmosphere, a THF (4 mL) solution of methyl acetoacetate dianion[11] was prepared from methyl acetoacetate (132 mg, 1.7 mmol), sodium hydride (42 mg, 1.9 mmol), and hexane solution (1.1 mL) of butyllithium (1.7 mmol). Methyl 4,10-dimethoxy-3-methoxycarbonyl-2-anthraceneacetate (**5**,[8f] 78 mg, 0.21 mmol) in THF (2 mL) was added at 0 °C, and stirring was continued for 2 h at room temperature. The reaction mixture was poured on cooled 2 M hydrochloric acid, and organic materials were extracted twice with ethyl acetate. The combined organic layer was washed with water and brine, dried (Na_2SO_4), and concentrated. Methanol (2 mL) and $Pb(OAc)_2 \cdot 3H_2O$ (380 mg, 1.0 mmol) were added to the residue, and the mixture was stirred vigorously for 3 h at room temperature. Then, 2 M hydrochloric acid was added, and organic materials were extracted twice with ethyl acetate. Organic layer was washed with water and brine, dried (Na_2SO_4), concentrated, and chromatographed on silica gel giving isomer I (10 mg, 10%) and isomer II (13 mg, 13%) of **8**. Isomer I (with higher R_f): Mp 170—172 °C (AcOEt-hexane). ^1H NMR ($CDCl_3$) δ=3.67 (6H, s), 3.81 (6H, s), 3.93 (4H, s), 3.99 (12H, s), 4.62 (2H, s), 6.59 (2H, s), 7.09 (2H, s), 7.3—7.6 (4H, m), 7.87 (2H, s), 7.7—8.0 (2H, m), 8.1—8.4 (2H, m), 12.79 (2H, s). IR (KBr) 3400, 1735, 1630, 1600 cm^{-1}. UV ($CHCl_3$) λ_{max} 455, 339, 281, 258 nm. HRMS Calcd for $C_{29}H_{24}O_8$: 500.1470. Found: 500.1461 (M/2+H). Isomer II (with lower R_f): Mp 156—157 °C (AcOEt-hexane). ^1H NMR ($CDCl_3$) δ=3.72 (16H, s), 3.94 (6H, s), 4.01 (6H, s), 4.76 (2H, s), 6.40 (2H, s), 7.25 (2H, s), 7.4—7.7 (4H, m), 7.7—8.0 (2H, m), 7.88 (2H, s), 8.2—8.5 (2H, m), 12.90 (2H, s). IR(KBr) 3400, 1735, 1625, 1600 cm^{-1}. UV ($CHCl_3$) λ_{max} 454, 339, 264 nm. HRMS Calcd for $C_{29}H_{24}O_8$: 500.1470. Found: 500.1468 (M/2+H).

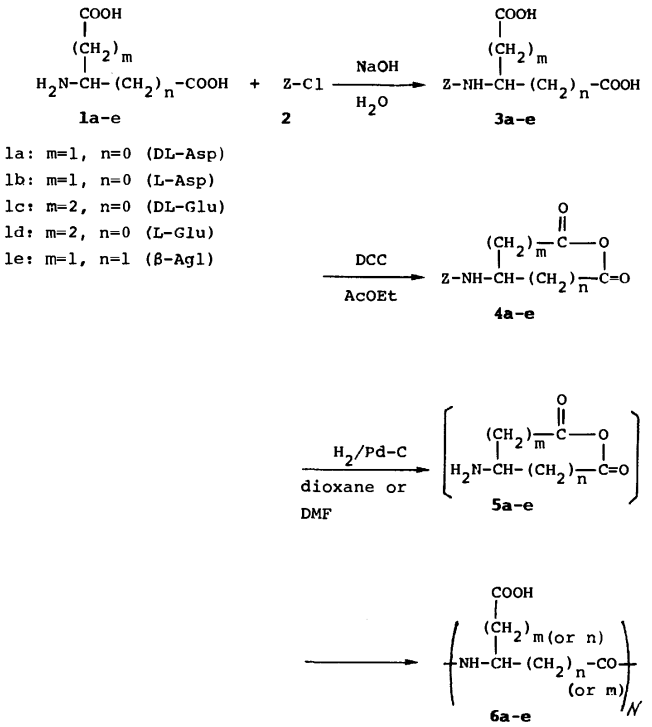
Syntheses of Polypeptides by Hydrogenolysis of *N*-Benzyloxycarbonyl-Amino Acid Anhydrides

Toratane MUNEGUMI, Yan-Qing MENG, and Kaoru HARADA*
Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305
(Received March 27, 1989)

Synopsis. When anhydrides of *N*-benzyloxycarbonyl-DL-aspartic acid (Z-DL-Asp), Z-L-Asp, *N*-Z-DL-glutamic acid (Z-DL-Glu), Z-L-Glu, and *N*-Z-3-aminoglutaric acid (Z-β-Agl) were hydrogenolyzed in *N*,*N*-dimethylformamide (DMF), polypeptides were obtained in high yields. Hydrogenolyses of Z-DL-Glu and Z-L-Glu in dioxane gave pyroglutamic acid.

Although there are many investigations on the syntheses of polyamino acids, there have been few studies on the polymerization of amino acid anhydrides because of their instability and difficulty of isolation.[1] One way to overcome this difficulty would be to generate the amino acid anhydride in situ,[1-3] which would then react with each other to form polypeptides. The hydrogenation of 2-azidosuccinic anhydride in dioxane to afford polyaspartic acid has been reported.[2] However, the molecular weight and the structure of the product were not characterized in detail.[2] Aspartic acid anhydride was considered as the intermediate (actual monomer) in the polymerization.

In this paper, we wish to describe the polymerization reactions of amino acid anhydrides generated by the hydrogenolyses of anhydrides of *N*-benzyloxycarbonyl-DL-aspartic acid (Z-DL-Asp), Z-L-Asp, Z-DL-glutamic acid (Z-DL-Glu), Z-L-Glu, and Z-3-aminoglutaric acid (Z-β-Agl) in dioxane or *N*,*N*-dimethylformamide (DMF) over palladium on charcoal. Benzyloxycarbonyl (Z) group is a convenient protecting group and is easily removable by catalytic hydrogenolysis without any side reactions.[5] The Z-amino acid anhydrides (**4a—e**) were prepared and then hydrogenolyzed as shown in Scheme 1. The catalytic hydrogenolyses were carried out at room temperature in dioxane or DMF for 72 h. After hydrogenolysis, the solution obtained by filtration of the reaction mixture was evaporated and the residual product was purified by gel filtration.



Scheme 1. Preparation of Z-amino acid anhydride and polymerization reaction by hydrogenolyses. Z: benzyloxycarbonyl-, β-Agl: 3-aminoglutaric acid, DCC: dicyclohexylcarbodiimide, AcOEt: ethyl acetate, DMF: *N*,*N*-dimethylformamide.

Results and Discussion

The yields of polypeptides, reaction conditions, amino acid recovery in acid-hydrolysates are listed in Table 1. Catalytic hydrogenolyses of Z-DL-Asp anhydride (**4a**) and Z-L-Asp anhydride (**4b**) in dioxane or DMF gave white powder whose molecular weights were estimated to be in the range of 3000 to 5000 by means of G-25 gel filtration. Amino acid recoveries after acid-hydrolysis were more than 90%. The IR spectrum of the white powder showed typical absorption bands of acidic polypeptides (1700 cm^{-1}: carboxylic acid; 1640 cm^{-1}: amide I; 1540 cm^{-1}: amide II).

Hydrogenolyses of anhydrides (**4c—e**) of Z-DL-Glu(**3c**), Z-L-Glu (**3d**), and Z-3-aminoglutaric acid (**3e**) in DMF gave peptides similar to those obtained after hydrogenolysis of Z-Asp anhydrides (**4a—b**). However, Z-DL-Glu anhydride (**4c**) and Z-L-Glu anhydride were hydrogenolyzed in dioxane to afford pyroglutamic acid in high yields (79, 80%). The hydrogenolysis of Z-L-Glu anhydride (**4d**) in glacial acetic acid or ethyl acetate also gave pyroglutamic acid.[4]

Although the polymerization reactions were carried out at room temperature, it is important to estimate the optical purity of Asp composing the poly-L-Asp, due to the possibility of racemization during the polymerization. If optically pure poly-L-Asp was obtained, it would be an interesting material for various studies. The actual ratio of D-Asp to L-Asp in the poly-L-Asp obtained from Z-L-Asp anhydride (**4b**) which was optically pure was determined by the gas chromatographic resolution of the derivatives of the enantiomers in the hydrolysate of the poly-L-Asp. Figure 1 shows the amino acid recovery and the D/L ratio of Asp against the hydrolysis time in 6 M HCl (1 M=1 mol dm^{-3}) at 110 °C. Free amino acid recovery reached 90% after 8 hours' hydrolysis. The D/L ratio of Asp increased proportionally with the hydrolysis time. After 8 hours' hydrolysis, the D/L ratio was 5%.

Table 1. Formation of Polypeptides by Hydrogenolyses of Z-Amino Acid Anhydrides (**4a—e**) in Dioxane or *N,N*-Dimethylformamide (DMF)

Substrate	Solvent	Product[a]	Yield/%[b]	AAA/%[c]	Elemental analysis/%	(C	H	N)

a) Molecular weights of polypeptides estimated by GPC were 3000—5000. b) Yield is expressed by the molar ratio of amino acid residue in product to substrate. c) Amino acid recovery in hydrolysate of polypeptide.

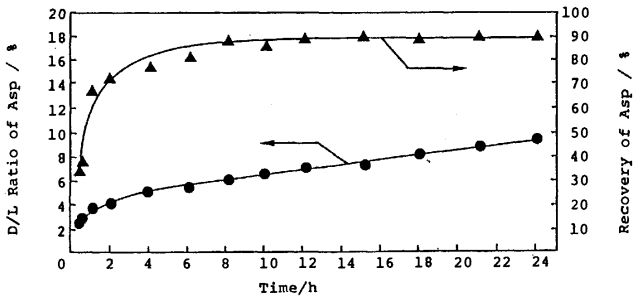

Fig. 1. Recovery and D/L ratio of Asp in acid-hydrolysate of the polypeptide which was obtained by the hydrogenolysis of Z-Asp anhydride (**4b**) in DMF.

The actual D/L ratio (3%) in poly-Asp before hydrolysis was estimated by extrapolating the value of D/L ratio to 0 hour. The existence of small amount of D-Asp(3%) would be due to the following three reasons: (1) racemization of L-Asp during the polymerization, (2) racemization during the hydrolysis of poly-Asp, and (3) existence of D-Asp in the starting material (Z-L-Asp anhydride). The third one would be negligible, because the optical purity of Z-L-Asp anhydride was almost 100% according to the gas chromatographic analysis of the derivative (*N*-trifluoroacetyl-Asp isopropyl ester) from Z-L-Asp anhydride. Similar experiments were carried out for the polypeptides derived from Z-L-Glu anhydride (**4d**) to show almost same racemization (3%).

In the present paper, we demonstrate a new synthetic method of polypeptides using catalytic hydrogenolysis. According to the best of our knowledge, this report would afford the first examples of the syntheses of poly-Glu and poly-β-Agl by hydrogenolysis of the corresponding amino acid anhydrides. Further characterizations such as determination of the ratios of β- or γ-carboxyl group to α-carboxyl group in the side chains are under investigation.

Experimental

All the melting points were not corrected. Optical rotations were measured with a JASCO DIP Polarimeter. All the gas chromatographic analyses were carried out with a Hitachi 163 gas chromatograph, and the peaks on the chromatograms were integrated with a Sic Chromatocoda 11. NMR spectra were measured on a JEOL FT-100 NMR spectrometer. IR spectra were measured with a Jasco Infrared spectrometer. Palladium on charcoal (5%) was purchased from Nippon Engelhald.

Materials. Amino Acids (1a—d). DL-Aspartic acid (**1a**), L-aspartic acid (**1b**), DL-glutamic acid (**1c**), and L-glutamic acid (**1d**) were purchased from Wako Pure Chemical Company. 3-Aminoglutaric acid (**1e**) was prepared by heating glutaconic acid monohydrate (Aldrich Chemical Company) and ammonia. Yield, 60%. Mp 274 °C (decomposed).

Preparation of Z-Amino Acids (3a—e). Z-Amino acids **3a—e** were prepared from benzyloxycarbonyl chloride (**2**) and amino acids (**1a—e**) by the manner in the literature.[5] **3a:** Yield, 63%, Mp 85—88 °C. **3b:** Yield, 89%, Mp 117—118 °C. $[\alpha]_D$ +8.8, *c* 1.0 (acetic acid). **3c:** Yield, 72%, Mp 117—119 °C. **3d:** Yield, 90%, Mp 112—113 °C. $[\alpha]_D^{25}$ −0.76 (*c* 10, acetic acid). **3e:** Yield, 73%, Mp 157—159 °C. ^{1}H NMR (CD_3OD): δ=2.59 (4H, d, *J*=6.4 Hz), 4.32 (1H, t, *J*=6.8 Hz), 5.06 (2H, s), 7.32 (5H, s). IR (KBr): 3350, 1720, 1540, 1430, 1240—1300 cm^{-1}. Calcd for $C_{13}H_{15}NO_6$: C, 55.51; H, 5.37; N, 4.99%. Found: C, 55.49; H, 5.01; N, 4.99%.

Preparation of Z-Amino Acid Anhydrides (4a—e).[5-7] **4a.**[5,6] To a cooled ethyl acetate solution (150 ml) of Z-DL-

Asp (**3a**) (13.3 g, 50 mmol), was added dicyclohexylcarbodiimide (DCC) (11.3 g, 55 mmol) dissolved in 50 ml ethyl acetate. The cyclization reaction was carried out for 1 h at 0 °C and for 24 h at room temperature. After usual work-up, Z-DL-Asp anhydride (**4a**) was obtained. Yield, 89%. Mp 120—122 °C. ^{1}H NMR ($CDCl_3$): δ=2.23 (2H, m), 4.36—4.64 (1H, m), 5.15 (2H,s), 7.36 (5H, s). IR (KBr): 3400, 1860, 1780, 1700, 1540, 1260 cm^{-1}. Calcd for $C_{12}H_{11}NO_5$: C, 57.83; H, 4.44; N, 5.62%; Found: C, 58.08; H, 4.68; N, 5.88%. **4b**, Yield, 98%. Mp 106—107 °C. $[\alpha]_D^{25}$ −29.1 (*c* 1.0, acetic acid). ^{1}H NMR ($CDCl_3$): δ=2.23 (2H, m), 4.36—4.64 (1H, m), 5.15 (2H, s), 7.36 (5H, s). IR (KBr): 3400, 1860, 1780, 1700, 1540, 1260 cm^{-1}. Calcd for $C_{12}H_{11}NO_5$: C, 57.83; H, 4.44; N, 5.62%; Found: C, 58.22; H, 4.50; N, 5.57%. **4c**, Yield, 96%. Mp 103—105 °C. ^{1}H NMR ($CDCl_3$) δ=1.8—2.2 (2H, m), 2.8—3.1 (2H, m), 4.3—4.6 (1H, m), 5.15 (2H, s), 5.6 (1H, br), 7.36 (1H, s). IR (KBr): 3400, 1820, 1770, 1730, 1540, 1260 cm^{-1}. Calcd for $C_{13}H_{13}NO_6$: C, 59.31; H, 4.97; N, 5.32%; Found: C, 59.04; H, 5.01; N, 5.27%. **4d**, Yield, 60%. Mp 76—77 °C. $[\alpha]_D^{20}$ −41.6 (*c* 9.98, acetic acid). ^{1}H NMR ($CDCl_3$): δ=1.8—2.2 (2H, m), 2.8—3.1 (2H, m), 4.3—4.6 (1H, m), 5.15 (2H, s), 5.6 (1H, br), 7.36 (1H, s). IR (KBr): 3400, 1820, 1770, 1730, 1540 cm^{-1}. Calcd for $C_{13}H_{13}NO_6$: C, 59.31; H, 4.98; N, 5.32%. Found: C, 59.19; H, 5.07; N, 5.35%. **4e**, Yield, 73%. Oil. ^{1}H NMR (DMSO-d_6): δ=2.64—3.20 (4H, m), 4.00—4.20 (1H, m), 5.04 (2H, s), 7.35 (5H, s), 7.90 (1H, br). IR (KBr): 3350, 1820, 1780, 1700, 1540, 1220—1280 cm^{-1}. Calcd for $C_{13}H_{13}NO_6$: C, 59.31; H, 5.98; N, 5.32%. Found: C, 59.71; H, 5.73; N, 5.64%.

Hydrogenolyses of Z-Amino Acid Anhydrides (4a—e) Followed by Polymerization. Z-DL-Asp anhydride (**4a**) (747 mg, 3.0 mmol) was dissolved in 5.0 ml dioxane or DMF, and was hydrogenolyzed over 5% palladium on charcoal (0.34 g) for 72 h under hydrogen atmosphere. After 3 hours' heating at 40 °C, the reaction mixture was filtered and the filtrate was evaporated in vacuo to give a residual product. The product was dissolved in water and was lyophilyzed to give white powder. The resulted white powder was dissolved in 5 ml of 0.5 M acetic acid and was loaded into a Sephadex column (G-10). Elution was carried out with 0.5 M acetic acid. The fractions which have the absorption at UV 230 nm and did not show ninhydrin color on TLC, were lyophilized to give white solid. Other Z-amino acid anhydrides (**4b**—e) were hydrogenolyzed by the similar manner to that described for **4a**.

Estimation of Molecular Weight of Polypeptides (6a—e). Molecular weights of all the purified polypeptides were estimated with Sephadex G-25 using 0.1 M sodium phosphate buffer (pH 6.8). The polypeptides were eluted earlier than oxidized Insulin (A and B chains, MW ca. 3000)[8] and later than the size exlusion limit (MW 5000) of this gel.

Determination of D/L Ratio of Asp in the Poly-L-Asp. The purified polypeptide **6b** (10 mg) was dissolved in 5 ml 6 M HCl and the solution in a sealed tube under vacuum was heated at 110 °C for 1 to 24 h. The D/L ratios of Asp were determined by the gas chromatographic resolution of enantiomeric *N*-trifluoroacetyl-Asp isopropyl esters using a chiral glass capillary column (Chirasil-Val[9] III).

The Absolute Configuration of 4,6-Decadiyne-1,3,8-triol Isolated from *Gymnopilus spectabilis*

Masaru HASHIMOTO, Mitsutoshi YANAGIYA, Toshikatsu OKUNO,† and Haruhisa SHIRAHAMA*
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
†Department of Agricultural Chemistry, Faculty of Agriculture, Hirosaki University, Aomori 036
(Received April 3, 1989)

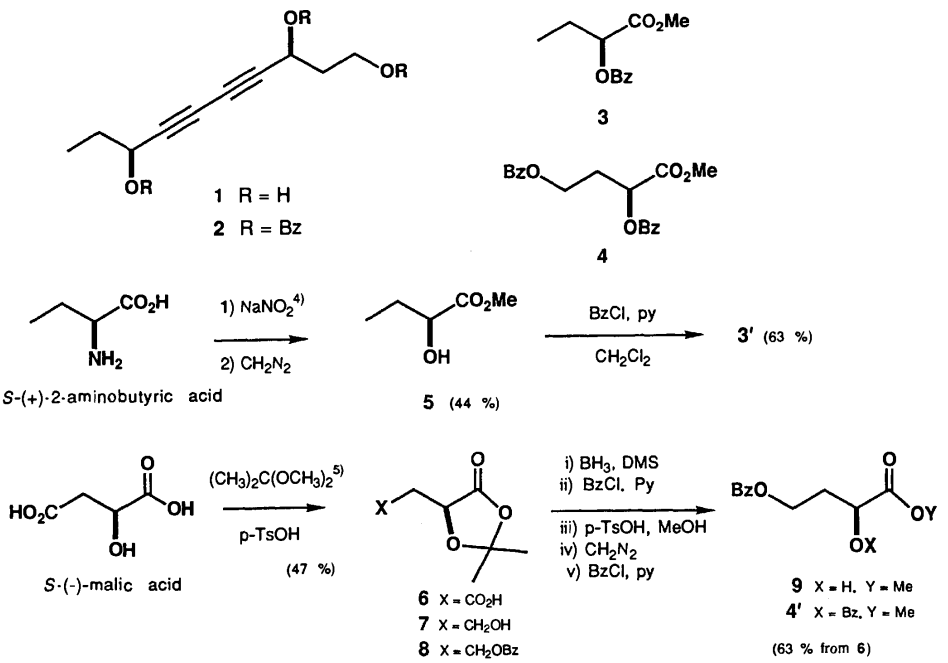
Synopsis. The absolute configuration of 4,6-decadiyne-1,3,8-triol, isolated from *Gymnopilus spectabilis*, was established as (3*S*,8*S*) by the comparison of degradated compounds with synthetic ones.

A toxic mushroom *Gymnopilus spectabilis* has been widely known for unique and curious biological activity in Japan. It has been said if you would eat it erroneously, you should laugh out loudly and could not stop doing. Therefore, the mushroom was named "Big laughter mushroom" (Ohwaraitake in Japanese). Chemical constituents of this mushroom have been studied by two groups, Matsumoto's[1] and Nozoe's,[2,3] and they reported previously isolations and structural elucidations of bitter principles, gymnopilines, gymnoprenols[1,2] and 4,6-decadiyne-1,3,8-triol (**1**).[3] Now we wish to describe absolute configuration of compound **1**.

Decadiynetriol **1**, which was newly extracted from the mushroom, was converted to tribenzoate **2** in 78% yield and then ozonolysis of **2** was performed. After decomposition of the ozonide with hydrogen peroxide, the products were treated with diazomethane to give a mixture of two esters which was separated on silica-gel TLC plate developed by 20% ether-hexane to afford methyl 2-benzoyloxybutyrate (**3**) (R_f=0.45, $[\alpha]_D^{21}$ −1.7° (*c* 0.80, $CHCl_3$), $\Delta\varepsilon_{228}^{24}$ +5.0 (*c* 4.5×10^{-4} mol l^{-1}, MeOH)) and methyl 2,4-bis(benzoyloxy)butyrate (**4**) (R_f=0.30, $[\alpha]_D^{21}$ −20° (*c* 1.2, $CHCl_3$)) in 36 and 45% yield, respectively. On the other hand, they were also prepared from commercially available and optically active compounds. Through a known procedure,[4] (*S*)-(+)-2-aminobutyric acid was converted in 44% yield to hydroxy ester **5**, and it was benzoylated to give methyl (2*S*)-(−)-2-benzoyloxybutyrate (**3′**) ($[\alpha]_D^{22}$ −1.5° (*c* 1.6, $CHCl_3$), $\Delta\varepsilon_{228}^{24}$ +4.4 (3.4×10^{-4} mol l^{-1}, MeOH)) in 63% yield. Acetonide **6**, synthesized from (*S*)-(−)-malic acid in 47% yield by also known method,[5] was subjected to the following sequential reactions: i) reduction with borane dimethyl sulfide complex, ii) benzoylation of hydroxyl group, iii) removal of acetonide protective group under acidic conditions, iv) esterification with CH_2N_2, v) benzoylation of hydroxyl group, to yield methyl (2*S*)-2,4-bis(benzoyloxy)-butyrate (**4′**) ($[\alpha]_D^{23}$ −21° (*c* 1.0, $CHCl_3$)) was obtained in 65% over all yield. Both synthetic products **3′** and **4′** were identical with degradation products **3** and **4**, respectively, on spectral data (NMR, IR, and MS) including optical rotation and chromatographic behavior. Absolute configurations of both **3** and **4** were thus represented as *S*. Accordingly the stereochemistry of the natural product **1** should be assigned to 3*S* and 8*S* configurations.

Experimental

Melting point was uncorrected. All ^{1}H NMR spectra were measured on a Hitachi R-90H spectrometer in $CDCl_3$, and ^{13}C NMR spectrum was determined on a JEOL JNM-GX 270 spectrometer in CD_3OD. IR spectra were recorded



on a JASCO IR-S spectrophotometer. Optical rotations were obtained by JASCO DIP-360 digital polarimeter, and CD spectra by JASCO J-20A automatic recording spectropolarimeter. High and low mass spectra were recorded on a JEOL JMS-DX 303 spectrometer.

4,6-Decadiyne-1,3,8-triol (1).[3] The mushroom, Gymnopilus spectabilis, was collected in Aomori prefecture and **1** was isolated as colorless oil in 0.027% from fresh fruit bodies: $[\alpha]_D^{23}$ −5.8° (*c* 1.7, MeOH); ^{13}C NMR δ=9.76 (q), 31.72 (t), 41.30 (t), 59.05 (t), 60.20 (d), 64.31 (d), 68.93 (s), 69.09 (s), 81.25 (s), and 81.61 (s); FD-MS *m/z* 183 (M^++H) and 165 ((M^++H−H_2O), base peak).

(3*S*,8*S*)-1,3,8-Trisbenzoyloxy-4,6-decadiyne (2). 4,6-Decadiynetriol **1** (9.0 mg, 0.049 mmol) was treated with pyridine (0.20 ml) and benzoyl chloride (50 mg, 0.35 mmol) in dichloromethane (0.50 ml). After 6 h stirring, the mixture was poured into 0.5% citric acid solution and extracted with ether. The ethereal solution was washed with brine, dried (Na_2SO_4) and concentrated. Chromatography of the obtained oil on silica gel (2 g) with 50% hexane-ether gave tribenzoate **2** as amorphous solid (19 mg, 0.038 mmol, 78%): mp 97—102 °C; $[\alpha]_D^{21}$ +4.70° (*c* 1.7, $CHCl_3$); ^{1}H NMR δ=1.07 (3H, t, *J*=7 Hz), 1.94 (2H, quint, *J*=7 Hz), 2.38 (2H, q, *J*=6 Hz), 4.54 (2H, t, *J*=7 Hz), 5.59 (1H, t, *J*=7 Hz), 5.88 (1H, t, *J*=6 Hz), and 7—8 (15H); IR (Nujol) 1730, 1690, 1270, 1095, and 710 cm^{-1}; EI-MS *m/z* 494 (M^+) and 105 ($C_6H_5CO^+$, base peak); Found: *m/z* 494.1777, Calcd for $C_{31}H_{26}O_6$: M, 494.1730.

Oxidative Degradatioon of 1,3,8-Trisbenzoyloxy-4,6-decadiyne (2). To a dichloromethane solution (10 ml) of tribenzoate **2** (40 mg, 0.080 mmol), ozone gas was bubbled for 20 min at 0 °C. After removal of excess ozone by bubbling of oxygen, 30% hydrogen peroxide (0.10 ml) was added and the mixture was stirred for 20 min to decompose the ozonide product. Dimethyl sulfide (2.0 ml) was added to decompose excess peroxide. The solvent was removed and an obtained oil was diluted with methanol (10 ml). An ethereal solution of diazomethane was added until yellow color did not disappear. The mixture was diluted with ether, washed with water and brine, dried (Na_2SO_4) and concentrated. The purification of the oil by preparative TLC (silica gel) with 20% ether-hexane gave methyl 2-benzoyloxybutyrate (**3**) as a colorless oil (6.5 mg, 0.029 mmol, 36%) and methyl 2,4-bis(benzoyloxy)butyrate (**4**) as a colorless oil (13 mg, 0.036 mmol, 45%).

Methyl 2-Benzoyloxybutyrate (3): R_f=0.45 (silica gel, 20% ether-hexane); $[\alpha]_D^{21}$ −1.7° (*c* 0.80, $CHCl_3$) $\Delta\varepsilon_{228}^{24}$ +5.0 (*c* 4.5×10^{-4} mol l^{-1}, MeOH); ^{1}H NMR δ=1.09 (3H, t, *J*=7 Hz), 2.02 (2H, dq, *J*=6 and 7 Hz), 3.77 (3H, s), 5.21 (1H, t, *J*=6 Hz), 7.5 (3H, m), and 8.0 (2H, m); IR (film) 1760, 1730, 1115, and 715 cm^{-1}; EI-MS *m/z* 222 (M^+) and 105 ($C_6H_5CO^+$, base peak); Found: *m/z* 222.0887, Calcd for $C_{12}H_{14}O_4$: M, 222.0892.

Methyl 2,4-Bis(benzoyloxy)butyrate (4): R_f=0.30 (silica gel, 20% ether-haxane); $[\alpha]_D^{21}$ −21° (*c* 1.2, $CHCl_3$); ^{1}H NMR δ=2.48 (2H, q, *J*=7 Hz), 3.73 (3H, s), 4.54 (2H, t, *J*=6 Hz), 5.49 (1H, t, *J*=6 Hz), 7.5 (6H, m), and 8.0 (4H, m); IR (film) 1760, 1730, 1605, 765, and 715 cm^{-1}; EI-MS *m/z* 342 (M^+), 310 (M^+−MeOH), and 105 ($C_6H_5CO^+$, base peak); Found *m/z* 342.1102, Calcd for $C_{19}H_{18}O_6$: M, 342.1103.

Methyl (2*S*)-2-Benzoyloxybutyrate (3′). A solution of methyl (2*S*)-2-hydroxybutyrate (**5**) (43 mg, 0.41 mmol), pyridine (0.20 ml), and benzoyl chloride (60 mg, 0.43 mmol) in dichloromethane (1.0 ml) was stirred at room temperature for 10 h. The mixture was poured into water and extracted with ether. The organic layer was washed with brine, dried (Na_2SO_4), and concentrated. Chromatography of the residue on silica gel (3 g) with 15% ether-hexane gave benzoate **3′** as a colorless oil (68 mg, 63%); $[\alpha]_D^{22}$ −1.5° (*c* 1.6, $CHCl_3$), $\Delta\varepsilon_{228}^{24}$ +4.4 (3.4×10^{-4} mol l^{-1}, MeOH); Found: *m/z* 222.0905, Calcd for $C_{12}H_{14}O_4$: M, 222.0892.

Methyl (2*S*)-2,4-Bis(benzoyloxy)butyrate (4′). Borane dimethyl sulfide complex (2.0 ml, 21 mmol) was added to THF solution (50 ml) of (3S)-3,4-*O*-isopropyliden-4-oxobutyric acid (**6**) (1.0 g, 5.7 mmol) at 0 °C. After 5 h stirring, methanol was added slowly to decompose excess hydride. The mixture was poured into brine and extracted with chloroform. The organic solution was dried (Na_2SO_4), concentrated to afford an alcohol **7** (870 mg, 5.3 mmol, 93%): ^{1}H NMR δ=1.52, 1.65 (each 3H, s), 2.00 (2H, q, *J*=6 Hz), 2.31 (1H, brs), 3.81 (2H, s, *J*=6 Hz), and 4.55 (1H, dd, *J*=6 and 8 Hz).

To the dichloromethane solution (10 ml) of the alcohol **7** (870 mg, 5.3 mmol), pyridine (0.80 ml, 10 mmol) and benzoyl chloride (1.0 g, 7.1 mmol) were added at 0 °C. The mixture was allowed to warm to room temperature and was stirred for 12 h. The mixture was poured into water and extracted with ether. The ethereal solution was washed with brine, dried (Na_2SO_4), and concentrated to give a benzoyl ester **8** (1.3 g, 5.0 mmol, 94%): ^{1}H NMR δ=1.53, 1.57 (each 3H, s), 2.27 (2H, m), 4.50 (3H, m), 7.1—7.7 (3H), and 7.9—8.2 (2H).

The ester **8** (1.3 g, 5.0 mmol) was treated with *p*-TsOH (10 mg) in methanol (15 ml) for 10 h. To this solution, ethereal solution of diazomethane was added until yellow color did not disappear, and the solvent was removed to yield ester **9**: ^{1}H NMR δ=2.23 (2H, m), 2.92 (1H, brs), 3.24 (3H, s), 4.54 (2H, m), 7.2—7.6 (3H), and 7.9—8.2 (2H). The obtained ester **9** was stirred with benzoyl chloride (1.0 ml, 7.1 mmol) and pyridine (0.80 ml, 10 mmol) in dichloromethane (15 ml) at room temperature for 10 h. The mixture was poured into water and extracted with ether. The ethereal solution was washed with sat. $CuSO_4$ aqueous solution and brine, dried (Na_2SO_4), and concentrated. Chromatography of the residue on 40 g of silica gel with 25% ether-hexane gave 2,4-bis(benzoyloxy)butyrate **4′** as a colorless oil (1.3 g, 3.7 mmol, 74% through 2 steps): $[\alpha]_D^{23}$ −21° (*c* 1.0, $CHCl_3$); Found: *m/z* 342.1094, Calcd for $C_{12}H_{14}O_4$: M, 342.1103.

The Effect of Starting Source on the Concentration Distribution of Nickel Supported on Alumina

Tadahiro FUJITANI, Osamu UEKI, and Etsuro ECHIGOYA*
Department of Industrial Chemistry, Chiba Institute of Technology,
Tsudanuma, Narashino, Chiba 275
(Received March 2, 1989)

Synopsis. The concentration profile and particle size of nickel supported on alumina spheres were easily controlled by varying the starting source materials of the impregnation solution. Further, the reduction behavior of nickel oxide supported on alumina was influenced by the starting nickel source material.

The catalyst activity and selectivity of supported metal catalyst are strongly influenced by the amount of metal, the size of dispersed metal particles, the preparation method and the support composition. In particular, to improve the catalyst activity and durability it is necessary to control the distribution of metal particles in the catalyst. The control of a radial distribution of metal particles in the catalyst was easily achieved by changing factors as the impregnation period,[1] the pH of impregnation solution[2] and used additives.[3,4] However, only a few investigations have been reported about the effect of the source material on the physical properties and reactivity of the catalysts.[5,6]

In this paper, we wish to report on the effect of the starting source material on the metal particle distribution and physical properties of nickel supported on alumina sphere catalysts.

Experimental

The Ni/Al_2O_3 catalysts were prepared by impregnation of γ-alumina (JRC-ALO-3 supplied by Catalysis Society of Japan) with aqueous solution of the nickel salts (nickel acetate, nickel formate, nickel chloride and nickel nitrate) or aqueous ammonia (28%) of a nickel carbonate and the solution was evaporated at 100 °C. The impregnated samples were calcined in air at 450 °C for 2 h and, subsequently, reduced in a stream of hydrogen at 450 °C for 2 h. Typical properties of the support are given in Table 1. Nickel concentration profiles along the diameter of the catalyst cross section were measured by EPMA (JEOL JCXA-733). The catalyst was embedded in a thermoplastic resin. After solidification, raping film sheets were used to grind off the catalyst particles so as to expose the cross section. The sample was coated with a layer of carbon by vacuum deposition. The particle size of nickel was measured by TEM (Hitachi H-9000H). Finely ground catalyst particles were suspended in ethanol and then scooped up with a micromesh. These particles were dried under vacuum and used as a specimen. The reduction behavior of the catalyst was measured by TPR. Typically, 50-mg samples were used. Prior to reduction, each sample was dried for one hour in a stream of helium at 300 °C. On cooling the sample to room temperature, helium was replaced by hydrogen, then, the reactor temperature was raised (1 °C min^{-1}) and the hydrogen consumption was measured. The total nickel content in each catalyst was determined by chelate titration. A sample solution was prepared by dissolving the nickel of the catalyst in hydrochloric acid and filtering.

Table 1. Physical Properties of JRC-ALO-3[7,8]

Composition	γ-alumina
BET surface area/m^2g^{-1}	121
Modal pore diameter /nm	10.0
Specific pore volume/m^3g^{-1}	5.28×10^{-7}
Average diameter/mm	3.0—3.2

Results and Discussion

First, the nickel concentration profile and total nickel contents in the alumina sphere of the prepared Ni/Al_2O_3 using various nickel solution were measured as shown in the Fig. 1. The nickel concentration profile in the support can be classified into two types. In the first type, the nickel atoms were uniformly distributed over the whole of alumina sphere (A and B). In the second type, the nickel atoms were concentrated in the vicinity of the outer surface of alumina sphere (C, D, and E). Further, the band widths of the nickel atom in the second-type concentration profile were changed by the starting source materials. In the case of nickel carbonate, the nickel atoms were sharply distributed on the outer surface of the alumina sphere. The thickness of the nickel band was estimated to be about 100 μm. On the other hand, the position of the nickel band seems to spread toward the center of the alumina sphere when nickel acetate and nickel formate were used. The Ni/Al ratio of impregnant was 50/950 but the total nickel contents of these catalysts were different from those of the starting source materials. The total nickel contents obtained by chelate titration were in good agreement with the analytical data from EPMA response for nickel. The differences of the nickel concentration profile and total nickel contents in the alumina sphere were attributed to the adsorption rate of nickel complex ion into the alumina.[9]

The particle sizes of the nickel metal in the catalysts were observed by TEM as shown in Fig. 2. In the case of the catalysts prepared from nickel nitrate, nickel acetate and nickel chloride, the nickel metal particles were highly dispersed in an even size around 5 nm on the alumina spheres. On the other hand, the nickel metal particles of the catalysts prepared from nickel carbonate and nickel formate were observed in the form of larger crystallites. The nickel concentration profile produced from nickel acetate in alumina sphere was similar to that from nickel formate as shown in Fig. 1, but they differed from one another in the nickel particle size.

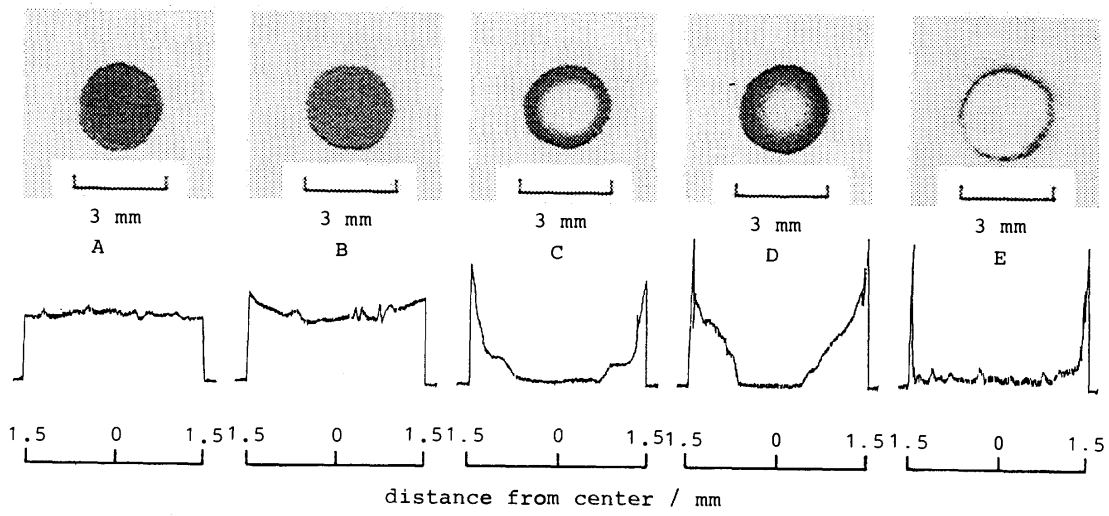

Fig. 1. Distribution of Ni atom in the catalysts measured by EPMA.
A: nickel nitrate (Ni/Al=37/923), B: nickel chloride (Ni/Al=36/924), C: nickel formate (Ni/Al=32/928), D: nickel acetate (Ni/Al=28/972), E: nickel carbonate (Ni/Al=19/981).

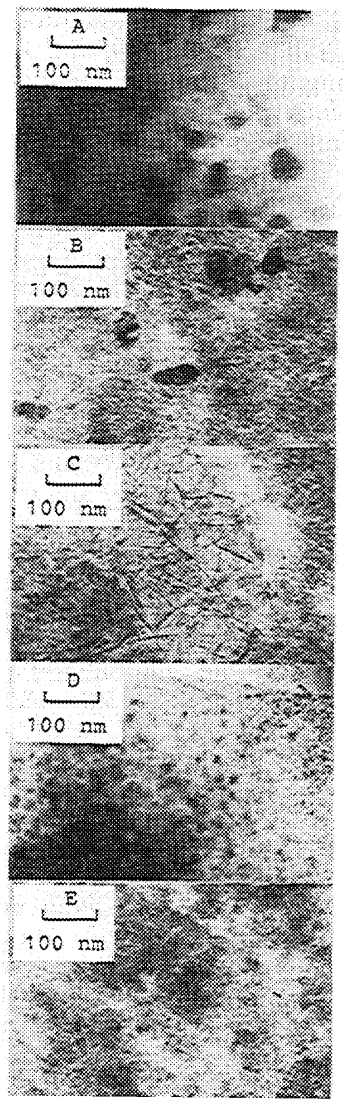

Fig. 2. TEM photograph of Ni in the catalyst reduced at 500 °C for 3 h.
A: nickel formate, B: nickel carbonate, C: nickel chloride, D: nickel acetate, E: nickel nitrate.

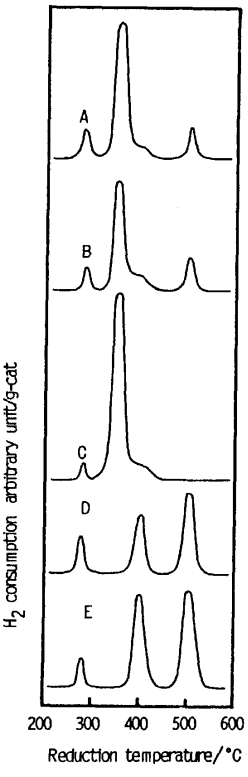

Fig. 3. TPR spectrum of supported nickel catalysts.
A: nickel nitrate, B: nickel acetate, C: nickel chloride, D: nickel formate, E: nickel carbonate.

The chemical interaction between nickel oxide and alumina was measured by TPR. Figure 3 shows the TPR spectrum change in relation to starting nickel source materials. The reduction peak of nickel oxide appeared at 280 °C. The main reduction peaks of the catalysts prepared from nickel nitrate, nickel chloride and nickel acetate were observed at 350 °C and a small peak appeared at 500 °C, while the main reduction peaks of the catalysts prepared from nickel carbonate and nickel formate appeared at 400 and 500 °C. It

was found that the reduction of the catalysts prepared from nickel carbonate and nickel formate became very difficult compared with those prepared from nickel nitrate, nickel chloride and nickel acetate. The results from the morphology investigation on the nickel/γ-alumina catalysts[10] indicated that the difficulty in the reduction of the nickel oxide were responsible for the formation of nickel aluminate precursor and large nickel crystallites were produced by its reduction. According to the experimental results in Figs. 2 and 3, the nickel aluminate precursor was plausibly formed when nickel carbonate and nickel formate were used as starting source materials.

It is concluded that the starting nickel source has the remarkably effects on the nickel concentration profile and nickel particle size in the alumina spheres which are used as a support, when preparing the catalyst by the impregnation method.

Hydrogenation of Carbon Dioxide on Unpromoted and Potassium-Promoted Iron Catalysts

Min-Dar LEE,* Jyh-Fu LEE, and Chau-Shang CHANG
Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan 10764, Republic of China
(Received October 7, 1988)

Synopsis. The promotional effect of potassium was studied on catalytic behavior of iron in CO_2 hydrogenation. A higher product selectivity toward light olefins and long-chain hydrocarbons was obtained on promoted catalyst than on unpromoted catalyst. This can be attributed to the enhancement of carburization on iron catalyst by potassium, as evidenced by Mössbauer spectroscopy and temperature-programmed decarburization.

The catalytic hydrogenation of CO has been extensively studied because it is an important step in utilization of coal as a carbon source. However, the hydrogenation of CO_2 has gained considerably less attention.[1-5] Previous studies indicated that the hydrogenation of CO_2 to hydrocarbons (HC) is proceeded via two elementary steps in series.[5-7] CO_2 first reacts with H_2 to form CO and H_2O, so-called reverse water-gas shift (RWGS) reaction, followed by Fischer-Tropsch (F-T) reaction in which CO is further hydrogenated to HC. Since iron-based catalysts are widely used in the industrial shift reaction as well as F-T reaction,[8,9] iron should be a potential catalyst for the hydrogenation of CO_2 to HC. On the other hand, potassium has long been known as an effective promoter of iron-based catalysts for the production of olefins and long-chain hydrocarbons in F-T reaction with enhanced water-gas-shift activity.[10] Accordingly, it is expected that potassium will also exhibit remarkable promotional effect in CO_2 hydrogenation.

In the present work, hydrogenation of CO_2 was carried out on the unpromoted and potassium-promoted iron catalysts. The bulk phase changes of catalysts during reaction were characterized by Mössbauer spectroscopy. Comparison between the relative stabilities of carbon deposits on used catalysts was accomplished by temperature-programmed decarburization. All the experimental evidences are helpful to elucidate the promotional effect of potassium on iron catalyst in CO_2 hydrogenation.

Experimental

Iron oxide was prepared by slowly adding ammonium hydroxide into an aqueous iron(III) nitrate solution until pH of 8.5 was reached. The precipitate was vacuum dried overnight at 393 K and calcined at 773 K for 24 h. To prepare potassium-promoted catalyst (with potassium loading of 3 atom%), calcined iron oxide was impregnated with an aqueous solution of potassium carbonate to incipient wetness followed by further calcination at 773 K for 3 h. Two catalyst samples are designated as Fe and K/Fe, respectively.

Prior to reaction tests, the calcined samples were reduced in situ in flowing hydrogen at 773 K for 15 h. The reactions were carried out in a tubular flow reactor at 593 K under 101 kPa or 1013 kPa, using a H_2/CO_2 (4/1 mole ratio) mixture of 600 cm^3(NTP) $h^{-1}g^{-1}$ (based on unreduced catalysts) as feed gas. Effluent gas from the reactor was analyzed by a gas chromatograph equipped with Porapak Q columns and both thermal conductivity detector (TCD) and flame ionization detector (FID).

In each of the temperature-programmed decarburization (TPDC) runs, the catalyst of 0.1 g was subjected to a H_2/CO_2 feed gas of 10 $cm^3 min^{-1}$ under 101 kPa. After a certain period, the catalyst bed was purged with helium for 2 min followed by quickly cooling down to room temperature. The gas stream was then switched to hydrogen and temperature increased to 773 K at 5 K min^{-1} to evolve carbon deposits on the catalyst. Continuous detection of any H_2-evolved carbon by FID gives a TPDC profile.

All ^{57}Fe-Mössbauer spectra were recorded at room temperature with a ^{57}Co(Rh) source oscillating in constant acceleration mode. The hyperfine spectrum of a natural iron foil was used to calibrate the velocity scale. After computer folding, each spectrum consisted of 512 points and was fitted with Lorentzian lines using a nonlinear regression program.[11]

Results and Discussion

The Mössbauer spectra show a single sextet with a hyperfine field of 330 kOe for both freshly reduced Fe

Table 1. Conversion and Product Selectivity in CO_2 Hydrogenation[a]

Catalyst	Reaction pressure	CO_2 conv.	Yield of CO	Yield of HC	HC distribution/carbon %					Olefin/paraffin ratio in C_2—C_4
	kPa	%	%	%	CH_4	C_2	C_3	C_4	C_{5+}	
Fe	101	21.6	17.1	4.5	66.5	18.3	9.2	3.3	2.7	0.90
Fe	1013	32.0	7.5	24.5	33.1	15.6	15.2	9.9	26.2	0.21
K/Fe	101	19.2	18.7	0.5	59.4	15.8	11.4	5.8	7.6	6.4
K/Fe	1013	34.7	6.3	28.4	19.7	12.6	16.9	14.5	36.3	5.3

a) Reaction conditions: temp=593 K, H_2/CO_2=4/1 (mole ratio), GHSV=600 $cm^3 h^{-1} g^{-1}$. Data were taken after 24 h reaction (101 kPa) and 48 h reaction (1013 kPa).

and K/Fe catalysts, indicating that all iron atoms exist in the form of α-Fe before reaction. The BET surface areas of these two catalysts are nearly the same (14 ± 2 $m^2\ g^{-1}$). However, CO uptake at 195 K by K/Fe catalyst (0.8 $\mu mol\ g^{-1}$) is far less than that by Fe catalyst (4.5 $\mu mol\ g^{-1}$), consistent with the picture in which a large portion of iron surface is covered by potassium.[12]

The conversion and product selectivity of CO_2 hydrogenation on both catalysts are listed in Table 1 for comparison. The promotional effect of potassium was reflected in the higher selectivity toward light olefins and long-chain hydrocarbons on K/Fe catalyst. This catalytic result can be satisfactorily explained from the viewpoint that the carburization (in contrast to hydrogenation) on iron catalyst was enhanced by potassium during CO_2 hydrogenation.

Figure 1 shows the Mössbauer spectra of used catalysts after CO_2/H_2 reactions. During computer fitting, seven sextets attached to four components (α-Fe, Fe_3O_4, θ-Fe_3C, and χ-Fe_5C_2) are taken into consideration. Based on the assumption that the recoil-free fraction of ^{57}Fe nuclei in γ-ray resonance absorption is the same for all components, the percentages of spectral peak areas (see Table 2) represent directly the distribution of iron atoms in individual components.

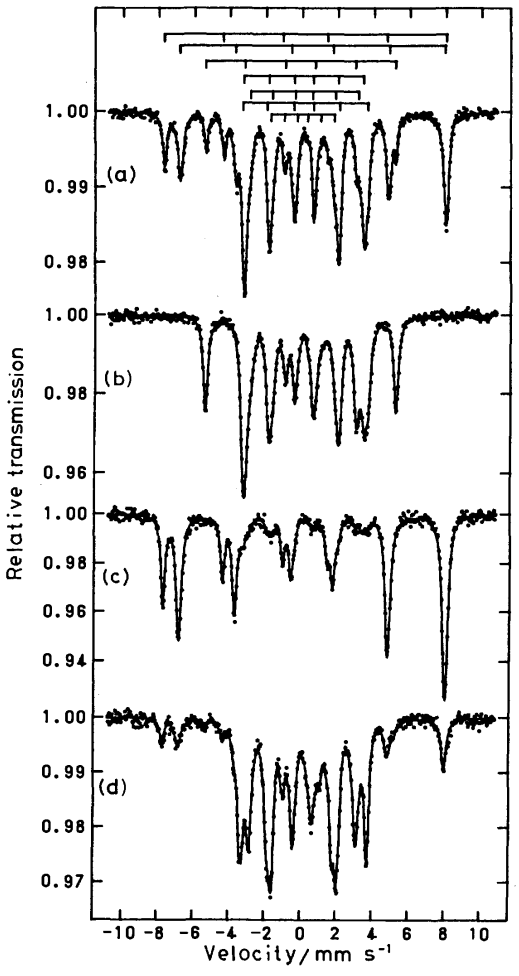

Fig. 1. Mössbauer spectra of (a) Fe and (b) K/Fe catalysts after CO_2/H_2 reaction under 101 kPa for 24 h, and (c) Fe and (d) K/Fe catalysts after CO_2/H_2 reaction under 1013 kPa for 48 h. The seven identifications shown for the (a) spectrum represent, from top down respectively, the tetrahedral and octahedral sites in Fe_3O_4, α-Fe, θ-Fe_3C, and I, II, and III sites in χ-Fe_5C_2.

Metallic iron catalysts will be oxidized (to Fe_3O_4) as well as carburized (to χ-Fe_5C_2 or θ-Fe_3C) during CO_2 hydrogenation. For a given catalyst, high reaction pressure favors the formation of Fe_3O_4. Since H_2O is the common product in both elementary steps (RWGS and F-T reactions) of overall CO_2 hydrogenation, high conversion of CO_2 especially with increased HC yield leads to abundant H_2O production. Therefore, it is believed that the preference for Fe_3O_4 formation under elevated pressure is due to the oxidation of metallic iron by H_2O.

The bulk carburization of iron catalyst is enhanced in the presence of potassium promoter. Not only carbide phases are more preferable on K/Fe catalyst than on Fe catalyst for given reaction conditions, but the relative dominance of carbide phases shifts from θ-Fe_3C to χ-Fe_5C_2. The χ-Fe_5C_2 phase is known to be less stable than θ-Fe_3C phase,[13,14] and its formation requires a lower H_2/CO feed ratio in CO hydrogenation. However, CO is an intermediate product instead of reactant in CO_2 hydrogenation. This in turn leads to a high ratio of H_2/CO on the catalyst surface, which is a favorable condition for θ-Fe_3C formation.

Table 2. Peak Area Percentages of Spectral Contributions Shown in Fig. 1

Spectrum	α-Fe	Fe_3O_4	θ-Fe_3C	χ-Fe_5C_2
(a)	7.4	33.9	33.2	25.5
(b)	28.8	—	25.9	45.3
(c)	—	86.8	6.7	6.5
(d)	2.3	14.1	—	83.6

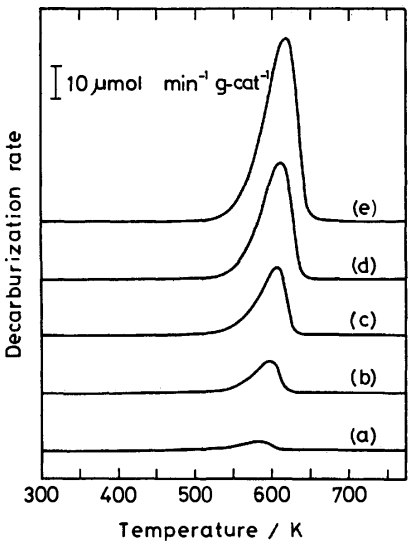

Fig. 2. Temperature-programmed decarburization profiles (with a heating rate of 5 K min^{-1}) of Fe catalyst after CO_2/H_2 reaction for (a) 2, (b) 5, (c) 10, (d) 20, and (e) 40 min.

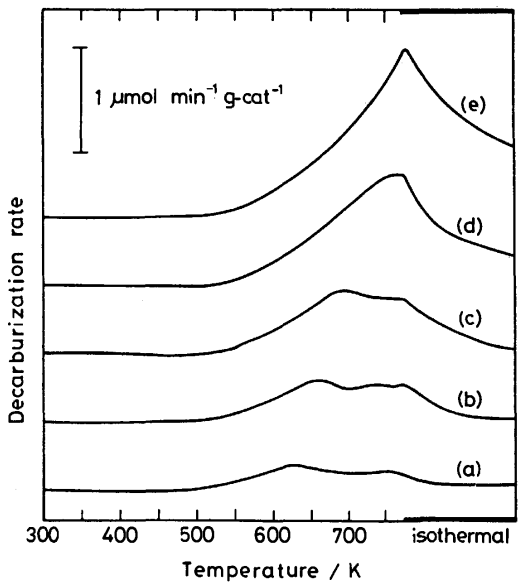

Fig. 3. Temperature-programmed decarburization profiles (with a heating rate of 5 K min^{-1}) of K/Fe catalyst after CO_2/H_2 reaction for (a) 2, (b) 5, (c) 10, (d) 20, and (e) 40 min.

The enhancement of carburization on K/Fe catalyst destroys this condition to some extent, and hence χ-Fe_5C_2 is more likely to form.

The relative stabilities of carbon deposits on used catalysts are also reflected by the peak temperatures of TPDC profiles. The higher peak temperature implies the more stable carbon deposits, and vice versa. Figures 2 and 3 show the TPDC profiles of Fe and K/Fe catalysts, respectively, after subjecting to CO_2/H_2 reaction for various times between 2 and 40 min.

All TPDC profiles for Fe catalyst show a single peak with peak temperature shifting from 587 K to 621 K when reaction time increases from 2 to 40 min. As shown in Fig. 2, most carbon deposits are evolved in the temperature range between 500 K and 650 K. In contrast, multiple peaks can be observed on the TPDC profiles of K/Fe catalyst if reaction time is shorter than 10 min, indicating that more than one forms of carbon deposits exist with different reactivities toward hydrogen. The distribution of carbon deposits with various stabilities makes the TPDC peaks of K/Fe catalyst much broader, regardless of the take-off temperature of TPDC peaks close to that of Fe catalyst. As the reaction time further increases, overlapping between unresolved TPDC peaks tends to combine in a single but even broader peak with peak temperature higher than 770 K. Since the temperature rise was stopped at 773 K in TPDC experiments and then held isothermally at that temperature, the decarburization rate turns to drop due to the decrease of driving force.

In summary, it is no doubt that carbon deposits on K/Fe catalyst are more stable than on Fe catalyst upon comparing the corresponding TPDC peak temperatures. The existence of more stable carbon deposits provides another evidence for the enhancement of carburization on iron catalyst by potassium promoter. This promotional effect of potassium also leads to the preference for bulk phase changes of K/Fe catalyst to carbides rather than oxides, as observed in Mössbauer spectroscopy, and bears the responsibility for the higher product selectivity of light olefins and long-chain hydrocarbons in CO_2 hydrogenation.

The authors wish to thank Dr. Teng-Yuan Dong (Institute of Chemistry, Academia Sinica) for his generosity of providing the Mössbauer spectrometer and assistance in the spectroscopic experiments. Financial support of this work by National Science Council (grant NSC77-0402-E002-05) is gratefully acknowledged.

Potentiometric Determination of Some Aliphatic Aldehydes Using the Silver/Sulfide Ion-Selective Electrode

M. Tarek M. ZAKI* and M. H. FAWZY
Department of Chemistry, Faculty of Science, Ain Shams University, Abbassia, Cairo, Egypt
(Received October 14, 1988)

Synopsis. A simple, selective and reproducible method for the potentiometric determination of some aliphatic aldehydes is described. The method is based on oxidation of the aldehydes with silver oxide packed in a column. The formed silver salts of the fatty acids are eluted with water and the silver ion concentration is determined with a silver/sulfide ion-selective electrode using either a calibration graph or a standard addition technique. The effects of experimental variables and the interference of other organic functional groups are investigated. Samples containing up to 5.0 mg aldehyde are analyzed with an average recovery of 98.5% and 98.4% using the proposed techniques, respectively.

Potentiometric methods for aldehyde determination are based on either condensation or oxidation-reduction reactions. In the methods involving condensation reactions, an excess of hydrazine or hydroxyl amine derivatives is added, and the unreacted reagent is back titrated with a suitable titrant. Siggia and Stahl[1] treated aldehydes with excess 1,1-dimethylhydrazine in methanol or ethylene glycol medium. The unused reagent was titrated with hydrochloric acid in methanol. Berka and Zyka[2,3] used 2,4-dinitrophenylhydrazine. The formed hydrazone was separated and the unreacted reagent was titrated with chloramine T in presence of potassium bromide. Moreover, Langmair[4] utilized hydroxylamine hydrochloride as reagent and sodium hydroxide as titrant. However, the former methods lacks selectivity.

On the other hand, Siggia and Segal[5] reported a macro method based on oxidation with Tollens reagent. The residual silver ions were potentiometrically titrated with potassium iodide solution. However, the reagent is unstable and the method is not suitable for adaptation to the micro scale.[6,7]

Application of ion-selective electrodes for end point detection was also reported. Formaldehyde was determined by reaction with iodine-iodide solution in alkaline medium.[8] After acidification, the mixture was titrated with silver nitrate solution using the iodide ion-selective electrode. Moreover, Ma and Hassan[9] reported that the amperometric method of Ikeda[10] for formaldehyde determination with potassium cyanide may be adapted potentiometrically by titrating the unreacted cyanide ions with silver nitrate solution using the cyanide or silver/sulfide ion-selective electrode.

In the present work, the optimum conditions for aliphatic aldehyde determination based on oxidation with silver(I) ions followed by potentiometric measurement using the silver/sulfide ion-selective electrode were investigated. The reagent, silver oxide-butylamine complex, which was recommended by Siggia et al.[11] for the volumetric determination of aldehydes has been tested. However, an invariably low recovery was obtained. To overcome this problem, a potentiometric study based on prior oxidation with silver oxide[12] packed in a column has been carried out. The eluted silver salts of fatty acids were determined with the silver/sulfide ion-selective electrode using either a calibration graph or a known addition technique.

Experimental

Instrumentation and Reagents. An Orion Model EA 920 pH/ISE meter fitted with Orion silver/sulfide ion-selective electrode (Model 94-16) and Orion double-junction reference electrode (Model 90-02) were used for potential measurements.

Silver oxide of 99% purity (Aldrich Chem.) was used to pack two-thirds of a column (1 cm diam. ×15 cm). The filled column was washed several times with twice-distilled water before introducing the samples.

Potassium nitrate solution, 4 M (1 M=1 mol dm^{-3}), was used as ionic strength adjustor (ISA).

Procedure. Introduce 5 ml of the sample solution, containing up to 5.0 mg of the aldehyde in water or 1,4-dioxane, into the column. Elute with water to make a total volume of 40 ml. Collect the eluent in 250-ml beaker. Add 60 ml water and determine the silver ion concentration using the silver/sulfide-double junction reference electrode system by either of the following techniques:

1-Calibration Graph Technique: The electrode calibration graph was established using 100 ml each of the 10^{-1} to 10^{-5} M silver nitrate solution in water or 5% dioxane-water according to the solvent used for the tested sample. To each solution, 2.0 ml of ISA was added before the potential measurement. A linear calibration graph was obtained over the entire range studied.

To the eluted solution, 2.0 ml of ISA was added and the potential was measured. A blank experiment was carried out under identical conditions. The calibration graph was used to determine the silver ion concentration equivalent to the aldehyde sample.

2-Known Addition Technique: Add 2.0 ml of ISA to the eluent, place the electrodes and stir thoroughly. Measure the relative millivolt. Set the reading to zero by turning the calibration control or record the potential reading, if the reading cannot be set to zero. Prepare a standard solution about ten folds as concentrated as the sample concentration under investigation. Add 2.0 ml of ISA to each 100 ml standard. Add 10.0 ml of the standard to the sample and stir thoroughly. Record the potential difference (ΔE). If the meter could not be zeroed in the former step, subtract the second reading from the first to get (ΔE). Calculate the silver ion concentration in the sample which is equivalent to the aldehyde using the equation:

$$C_0=\frac{C_sV_s}{V_0+V_s}\left[10^{-\Delta E/S}-\left(\frac{V_0}{V_0+V_s}\right)\right]^{-1}$$

where C_0 and C_s are the molar concentrations of the sample

Table 1. Potentiometric Determination of Some Aliphatic Aldehydes Using The Silver/Sulfide Ion-Selective Electrode

Sample	Carbonyl group(%)				
	Calcd	Electrode calibration method		Standard addition method	
		Found	Recovery	Found	Recovery
Formaldehyde solution (37 wt.%)	93.33	91.56	98.1	91.44	98.0
		91.58	98.1	91.53	98.1
		91.64	98.2	91.55	98.1
Acetaldehyde	63.64	62.79	98.7	62.69	98.1
		62.85	98.8	62.76	98.6
		62.91	98.9	62.80	98.7
Propion-aldehyde	48.28	47.67	98.7	47.66	98.7
		47.76	98.9	47.72	98.8
		47.81	99.0	47.74	98.9
Butanal	38.89	38.35	98.6	38.29	98.5
		38.36	98.6	38.34	98.6
		38.38	98.7	38.35	98.6
Pentanal	32.56	32.01	98.3	31.98	98.2
		32.05	98.4	31.99	98.2
		32.08	98.5	32.03	98.4
Hexanal	28.00	27.42	97.9	27.37	97.8
		27.48	98.1	27.40	97.9
		27.51	98.3	27.43	98.0

and the standard, V_0 and V_s the corresponding volumes and S is the electrode slope in mV per ten-fold change in concentration. C_0 may also be calculated using the equation:

$$C_0 = QC_s$$

where Q is the value from the known table.[13]

Results and Discussion

The aim of this work was to accomplish the optimum conditions for aliphatic aldehyde determination by oxidation with silver(I) ions. The low recovery obtained using silver oxide-butylamine complex[11] as reagent and silver/sulfide ion-selective electrode for the end point detection, may be attributed to the presence of free amine which affect the sensor membrane. Therefore, an external column packed with silver oxide was utilized as oxidizing agent.

Selection of Conditions. Aliphatic aldehydes are oxidized with silver oxide to the corresponding silver salt of the fatty acids according to the equation:

$$2\ RCHO + 3\ Ag_2O_{(s)} = 2\ RCOOAg + H_2O + 4\ Ag_{(s)}$$

Water, methanol, ethanol, 1-propanol, 2-propanol, and 1,4-dioxane were tested as solvents for aldehyde samples. Water was suitable for aldehydes of low molecular weight. On the other hand, aldehydes of relatively high molecular weight were best dissolved in 1,4-dioxane. Using alcohols as solvents were accompanied by a slight increase in the blank values. This is presumably due to the partial oxidation of this alcohols with silver oxide.

The effect of water volume necessary for eluting the formed fatty acid silver salts was investigated. 20 ml of water was sufficient to elute the formed silver formate or acetate. However, 35 ml of water was required to elute the salts formed by oxidation of higher aldehydes such as pentanal or hexanal. Larger volumes of water than that was accompanied by increasing the blank value due to the solubility of silver oxide. Therefore, 35 ml of water was recommended to elute all samples.

Anal sis of Aldehyde. The results obtained for the analysis of some aldehydes using the calibration graph and the standard addition techniques are summarized in Table 1. Average recoveries of 98.49% and 98.37% with a relative standard deviation of 0.32% and 0.33% were obtained, respectively. On the other hand, the analysis of higher aliphatic aldehydes such as octanal and decanal, in addition to aromatic aldehydes gave low recoveries. This may be due to a nonstoichiometric oxidation with silver oxide or incomplete elution of the formed fatty acid silver salts.

Interferences. The extent of interference from other organic functional groups was investigated. Alcohols (methanol, ethanol, 1-propanol, 2-propanol, and 2-methyl-2-propanol), ketones (acetone, 2-butanone, 3-pentanone, 2-hexanone, and 4-methyl-2-pentanone), amides (formamide, acetamide, and *N,N*-dimethylformamide), imides (succinimide), and hydrogen peroxide did not interfere.

However, acids and esters interfered. Esters undergo partial hydrolysis to form the corresponding fatty acid silver salts. Therefore, a preliminary separation of these compounds was required before aldehyde determination.

1:1:1 Inclusion Compounds of β-Cyclodextrin with Fluorene and Alcohols or Nitriles in Aqueous Solution

Sanyo HAMAI
Department of Physics, Miyazaki Medical College, Kiyotake, Miyazaki 889-16
(Received December 8, 1988)

Fluorene forms a 1:1 inclusion compound (FC) with β-cyclodextrin (CDx) in aqueous solution. From electronic absorption and emission spectra, FC has been found to further associate with alcohol (from ethanol to 1-pentanol) or nitrile (from propionitrile to hexanenitrile) to form a 1:1:1 inclusion compound. An equilibrium constant (K_3) for the formation of the 1:1:1 inclusion compound from FC and alcohol, and that (K_4) from fluorene and a 1:1 inclusion compound of CDx with alcohol have been determined. Upon going from ethanol to 1-pentanol, the value of K_4 increases, reaches a maximum at 1-propanol, and then decreases while K_3 monotonously increases with an increase in the alkyl-chain length of alcohol. For nitriles, K_3 and K_4 have also been evaluated. In this case, the largest K_4 value is seen for propionitrile and butyronitrile, while K_3 increases with increasing the alkyl-chain length of nitrile.

In the β-cyclodextrin (CDx)–alcohol–pyrene and CDx–alcohol–acenaphthene systems, we have found that association occurs between alcohol and a 1:1 inclusion compound of CDx with pyrene or acenaphthene.[1,2] From fluorescence lifetime measurements, Nelson et al. have proposed that 2-methyl-2-propanol is associated with a CDx–pyrene 1:1 inclusion compound.[3] Such behavior of the 1:1 inclusion compound of pyrene or acenaphthene seems to be reasonable since these aromatic guests are too large to bind deeply into the CDx cavity. From comparisons of equilibrium constants for the formation of a ternary 1:1:1 inclusion compound, it was concluded that 1-propanol, among primary alcohols, fits most snugly into the void interior space of the CDx cavity which already accommodates pyrene or acenaphthene.[1,2] These results suggest that the fit of two guest molecules of different kinds into the CDx cavity plays an important role in forming the 1:1:1 inclusion compound.

From a stereochemical point of view, the whole body of a fluorene molecule is anticipated to be deeply incorporated into the cavity, thereby the interior dimension of the cavity being thoroughly occupied by fluorene. Under such circumstances, it seems to be difficult for a 1:1 inclusion compound of CDx with fluorene to associate with an additional alcohol molecule. Thus, in order to further clarify the nature of 1:1:1 inclusion compounds of CDx, we investigated whether or not the CDx–fluorene 1:1 inclusion compound complexes with additional alcohol or nitrile by means of measurements of absorption and fluorescence spectra.

Experimental

Fluorene purchased from Tokyo Kasei was recrystallized twice from ethanol. β-Cyclodextrin (CDx) from Nakarai was recrystallized three times from water. Alcohols (from methanol to hexanol) and nitriles (from acetonitrile to hexanenitrile) were distilled under atmospheric or reduced pressure. Fluorene aqueous solutions were prepared according to the same method as that used for pyrene.[4] The fluorene concentration of sample solutions was (6—7)×10^{-6} mol dm^{-3}. Aerated sample solutions were employed throughout this work. Absorption spectra were run on a Shimadzu UV-260 spectrophotometer. Fluorescence spectra were recorded on a Shimadzu RF-501 spectrofluorometer equipped with a cooled Hamamatsu R-943 photomultiplier, and were corrected for the spectral response of the fluorometer. All measurements were made at 25±0.1 °C, unless otherwise noted.

Results and Discussion

1:1 Inclusion Compound of CDx with Fluorene.

Figure 1 shows the absorption spectra of fluorene aqueous solutions containing various concentrations of CDx. The addition of CDx resulted in red shifts of absorption peaks and the appearance of isosbestic points at 294 and 299 nm. The spectral change is attributed to the formation of a 1:1 inclusion compound (FC) of CDx with fluorene:

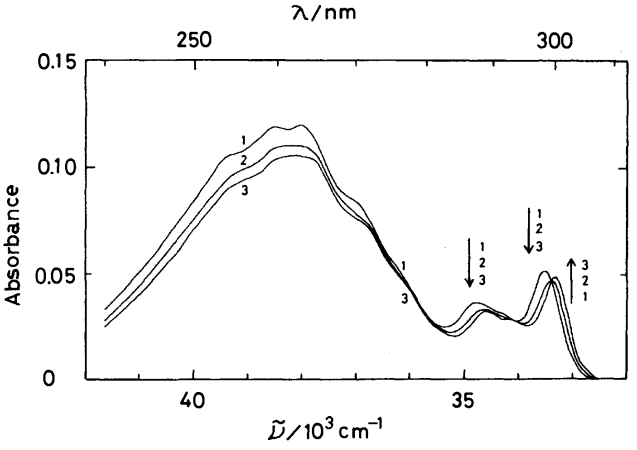

Fig. 1. Absorption spectra of fluorene (ca. 6×10^{-6} mol dm^{-3}) in the presence of CDx. Concentration of CDx: (1) 0 mol dm^{-3}; (2) 8.4×10^{-4} mol dm^{-3}; (3) 4.2×10^{-3} mol dm^{-3}.

$$FL + CDx \underset{}{\overset{K_1}{\rightleftharpoons}} FC, \quad (1)$$

where FL represents fluorene, and K_1 is an equilibrium constant for the formation of FC. From the absorbance change of fluorene,[5] K_1 has been determined to be 1200±100 mol^{-1} dm^3. This value is nearly twice that for naphthalene (685 mol^{-1} dm^3)[5] and one to two orders of magnitude greater than those for pyrene (7.6 mol^{-1} dm^3)[1] and acenaphthene (76±5 mol^{-1} dm^3).[2] Since pyrene and acenaphthene cannot bind deeply into the CDx cavity owing to the steric hindrance, smaller K_1 values are obtained. A naphthalene ring fully enters the cavity,[6] resulting in the relatively large value of K_1. A comparison between these K_1 values suggests that in FC the hydrophobic interaction occurs between CDx and fluorene, i.e., as expected above, the whole body of a nearly prolate fluorene molecule deeply penetrates into the CDx cavity. An examination of a space-filling molecular model supports such a picture of FC. When CDx is added to a fluorene aqueous solution, the intensity ratio of the 304-nm peak to the 312-nm peak in the fluorene fluorescence is enhanced. This change in the fluorescence spectra also shows the complex formation between CDx and fluorene. From the fluorescence intensity change caused by the addition of CDx, a K_1 value (1100±100 mol^{-1} dm^3) similar to that obtained from the absorption method was evaluated.[7]

1:1:1 Inclusion Compounds of CDx with Fluorene and Alcohols. Figure 2 illustrates the absorption spectra of fluorene aqueous solutions containing both CDx (4.2×10^{-3} mol dm^{-3}) and varying amounts of 1-butanol (Bu). Isosbestic points are observed at 256, 261, 286, 290, 298, and 301 nm, and a new shoulder appears at ca. 303 nm, which locates at longer wavelengths than the 0–0 band of fluorene in water or in water containing CDx. Upon cooling to 5 °C, this shoulder becomes a sharp peak at 304 nm. Such spectral changes have never been observed in the absence of CDx. Consequently, the absorption change shown in Fig. 2 can be interpreted in terms of the formation of a ternary inclusion compound composed of CDx, fluorene, and Bu. This conclusion is consistent with Scypinsky and Cline Love's suggestion that CDx, 1,2-dibromoethane, and fluorene forms a ternary complex.[8] Figure 3 exhibits the normalized fluorescence of fluorene in aqueous solutions contain-

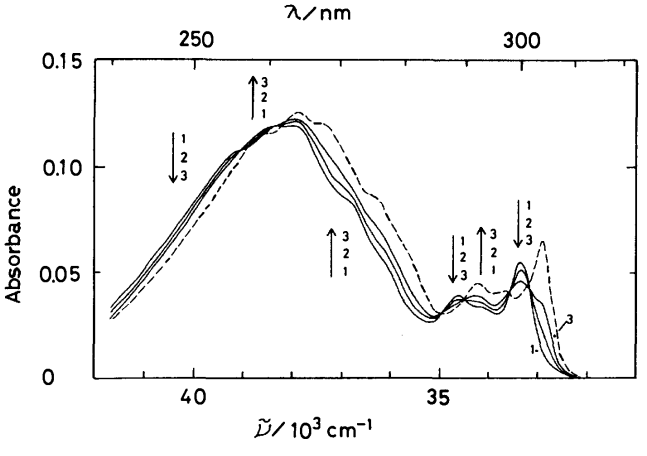

Fig. 2. Absorption spectra of fluorene (ca. 6×10^{-6} mol dm^{-3}) aqueous solutions containing CDx (4.2×10^{-3} mol dm^{-3}) and varying concentrations of Bu at 25 °C and the absorption spectrum (----) of a fluorene solution containing CDx (4.2×10^{-3} mol dm^{-3}) and Bu (1.09×10^{-1} mol dm^{-3}) at 5 °C. Concentration of Bu: (1) 0 mol dm^{-3}; (2) 3.28×10^{-2} mol dm^{-3}; (3) 1.09×10^{-1} mol dm^{-3}.

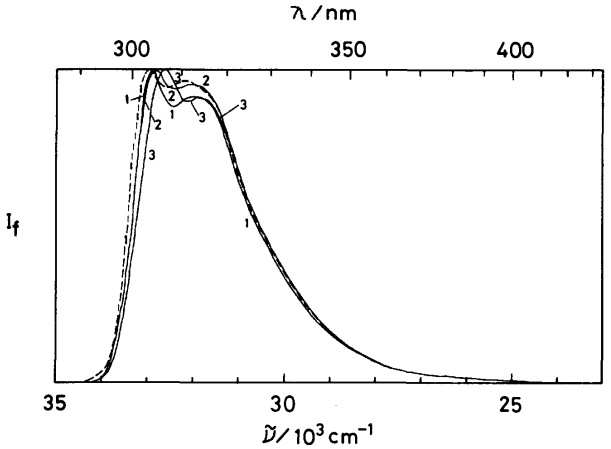

Fig. 3. Normalized fluorescence spectra of fluorene (ca. 6×10^{-6} mol dm^{-3}) aqueous solutions containing CDx (4.2×10^{-3} mol dm^{-3}) and varying concentrations of Bu. For comparison, the normalized fluorescence spectrum (----) of fluorene in aqueous solution is also shown. Concentration of Bu: (1) 0 mol dm^{-3}; (2) 2.19×10^{-2} mol dm^{-3}; (3) 1.09×10^{-1} mol dm^{-3}. λ_{ex}=298 nm.

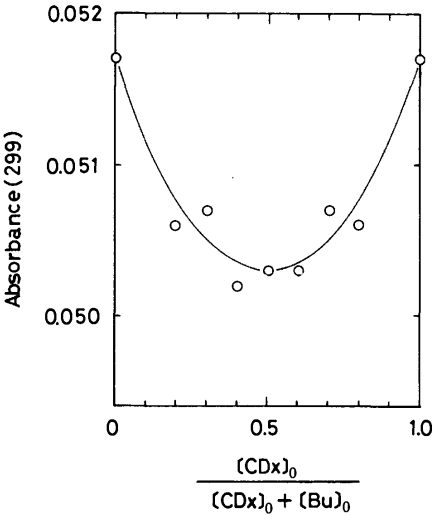

Fig. 4. Continuous variation plot under the condition of $[CDx]_0+[Bu]_0=1\times10^{-2}$ mol dm^{-3}. The observed wavelength is 299 nm. The fluorene concentration is ca. 6.5×10^{-6} mol dm^{-3}.

ing both CDx (4.2×10^{-3} mol dm^{-3}) and varying concentrations of Bu. Upon the addition of Bu, the fluorescence maximum is shifted to longer wavelengths. The red shift in the fluorescence spectrum shown in Fig. 3 corresponds to that in the absorption spectrum in Fig. 2. In order to determine the stoichiometry of the ternary inclusion compound responsible for the red shifts in the absorption and fluorescence spectra, we applied a continuous variation method,[1,4] in which the absorbance at 299 nm was monitored as a function of the molar fraction of CDx under the condition that a sum of the initial concentrations of CDx and Bu was held constant at 1×10^{-2} mol dm^{-3} while the fluorene concentration was fixed. The experimental results are shown in Fig. 4. Although there is some scatter of the data, a minimum at a molar fraction of 0.5 evidently indicates a 1:1 stoichiometry concerning CDx and Bu. When Bu less than 5×10^{-2} mol dm^{-3} is added to a fluorene solution containing CDx (4.2×10^{-3} mol dm^{-3}), the absorbance at 305 nm is proportional to the Bu concentration, indicating that the ternary inclusion compound contains only one Bu molecule. From these results, the ternary inclusion compound can be assigned to a 1:1:1 inclusion compound (FBC) of CDx with fluorene and Bu. Such 1:1:1 inclusion compounds including alcohol have already been reported for the cases of pyrene and acenaphthene.[1,2] The formation of FBC is represented by the following equilibria:

$$\text{Bu} + \text{CDx} \underset{}{\overset{K_2}{\rightleftharpoons}} \text{BC}, \tag{2}$$

$$\text{FC} + \text{Bu} \overset{K_3}{\rightleftharpoons} \text{FBC}, \tag{3}$$

and

$$\text{FL} + \text{BC} \overset{K_4}{\rightleftharpoons} \text{FBC}, \tag{4}$$

where BC is a 1:1 inclusion compound of CDx with Bu, and K_2, K_3, and K_4 are equilibrium constants for the formation of BC, FBC from FC and Bu, and FBC from fluorene and BC, respectively. As in the case of the CDx-alcohol-pyrene system,[1] K_3 can be determined from a comparison of the observed fluorescence intensities, which are a function of the Bu concentration, with curves calculated by assuming three parameters. By using an instrumental constant a, the fluorescence quantum yield ϕ, the molar absorption coefficient ε at the excitation wavelength, and subscripts 1, 2, and 3 which stand for fluorene, FC, and FBC, respectively, one can write the fluorene fluorescence intensity I_f as[1]

$$I_f = A - B/(C + [\text{Bu}]_0), \tag{5}$$

where $A=a\phi_3\varepsilon_3[\text{FL}]_0$, $B=a\{\phi_3\varepsilon_3K_1K_3[\text{CDx}]_0(1+K_1[\text{CDx}]_0)(1+K_2[\text{CDx}]_0)[\text{FL}]_0/K_1K_3[\text{CDx}]_0-(\phi_1\varepsilon_1+\phi_2\varepsilon_2K_1[\text{CDx}]_0)(1+K_2[\text{CDx}]_0)[\text{FL}]_0/K_1K_3[\text{CDx}]_0\}$, and $C=(1+K_1[\text{CDx}]_0)(1+K_2[\text{CDx}]_0)/K_1K_3[\text{CDx}]_0$. Here, subscript 0 refers to the initial concentration. The least-squares fit of a simulation curve was obtained when $A=110$, $B=3.07$ mol dm^{-3}, and $C=0.0573$ mol dm^{-3} (Fig. 5). From this C value, the K_1 value determined in this study, and the K_2 value reported by Matsui and Mochida,[9] K_3 was evaluated to be 22 ± 1 mol^{-1} dm^3. From a relationship $K_1K_3=K_2K_4$, K_4 was estimated to be 1900 ± 200 mol^{-1} dm^3. These K_3 and K_4 values are given in Table 1.

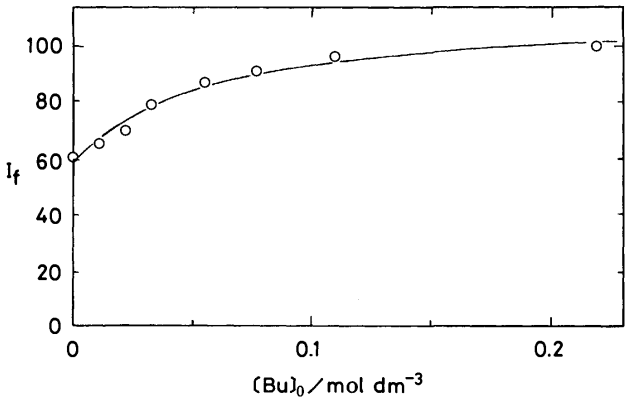

Fig. 5. Comparison between observed fluorescence intensities of fluorene (ca. 6×10^{-6} mol dm^{-3}) and a least-squares fit curve calculated with assumed parameters $A=110$, $B=3.07$ mol dm^{-3}, and $C=0.0573$ mol dm^{-3}. The maximum fluorescence intensity is normalized to 100. $[\text{CDx}]_0=4.2\times10^{-3}$ mol dm^{-3}. $\lambda_{ex}=303$ nm.

The addition of alcohols from ethanol to 1-pentanol to fluorene aqueous solutions with CDx results in an absorption change similar to that shown in Fig. 2, indicating the formation of 1:1:1 inclusion compounds containing alcohol.[10] For alcohols other than Bu, K_3 and K_4 have similarly been evaluated, and are also summarized in Table 1. As the alkyl chain of alcohol is lengthened, K_3 monotonously increases like K_2. On the other hand, the largest K_4 is obtained for 1-propanol, and K_4 is reduced when the alkyl chain of alcohol is shortened or lengthened relative to that of 1-propanol. Such characteristics of K_3 and K_4 are quite similar to those obtained for the CDx-alcohol-pyrene and CDx-alcohol-acenaphthene systems.[1,2] In the 1:1 inclusion compound of pyrene or acenaphthene, the CDx cavity which accommodates pyrene or acenaphthene has a void space, while in the 1:1 inclusion compound of fluorene there is no void dimension inside the cavity since the cavity is fully occupied by fluorene. From the stereochemical standpoint, it is surprising that an additional guest, alcohol, can associate with the CDx-fluorene 1:1 inclusion compound. Therefore, owing to the formation of the 1:1:1 inclusion compound of fluorene, a fluorene molecule within the CDx cavity may protrude from the cavity to some extent to make a void space for an additional alcohol molecule. In the case of fluorene, the K_3 values are two to three orders of magnitude smaller than those for the pyrene or

Table 1. Equilibrium Constants for the Formation of 1:1 and 1:1:1 Inclusion Compounds

	K_2/mol^{-1} dm^3	K_3/mol^{-1} dm^3	K_4/mol^{-1} dm^3
Ethanol	0.93[a]	0.94±0.05	1400±100
1-Propanol	3.72[a]	7.9±0.4	3000±300
1-Butanol	16.6[a]	22±1	1900±200
1-Pentanol	63.1[a]	78±3	1800±200
Propionitrile	3.8±0.3	3.6±0.2	1300±200

a) Data of Matsui and Mochida (Ref. 9).

acenaphthene system,[1,2,11] indicating that the complexation reaction between the CDx-fluorene 1:1 inclusion compound and additional alcohol is not so favorable as that between a CDx-pyrene or CDx-acenahthene 1:1 inclusion compound and alcohol. The same is true for K_4.[12]

As mentioned above, at low temperatures the 0-0 absorption band of the 1:1:1 inclusion compound appears at 304 nm. This peak wavelength is rather abnormal because fluorene exhibits the peak of the 0-0 band at 301, 300, 300, 301, 300, 300, 299, and 298 nm in cyclohexane (ε=2.02), 1,4-dioxane (ε=2.21), ethyl acetate (ε=6.02), dichloromethane (ε=9.08), ethanol (ε=24.3), methanol (ε=32.6), acetonitrile (ε=37.5), and water (ε=78.5), respectively. For the S_2 absorption band of pyrene in the CDx-alcohol-pyrene 1:1:1 inclusion compound, the 0-0 band is also located at longer wavelengths than that in any solvent.[1] The abnormally large red shifts of the absorption peaks in the CDx-alcohol-fluorene and -pyrene 1:1:1 inclusion compounds may be interpreted in terms of a kind of microheterogeneous solvent effect. One part of a long fluorene molecule in the 1:1:1 inclusion compound is extruded out of the CDx cavity to the very polar water medium, and the other part of the fluorene molecule resides in the CDx cavity, being in contact with the alkyl chain of an alcohol molecule entering the cavity. Therefore, one end of the fluorene molecule experiences a very polar environment, and the other end of the fluorene molecule is in a relatively nonpolar environment owing to both the hydrophobicity of the inner wall of the CDx cavity and that of the alkyl chain of an alcohol molecule entering the CDx cavity. Under such circumstances, the excited state of fluorene may be lowered in energy relative to that in a uniform environment (neat solvent), since π electrons delocalize more easily in the excited state than in the ground state. As a consequence, the 0-0 band of fluorene in the 1:1:1 inclusion compound is shifted to the red relative to that in any neat solvent.

1:1:1 Inclusion Compounds of CDx with Fluorene and Nitriles. The association of FC with nitriles from propionitrile to hexanenitrile has been confirmed from the observations of absorption and fluorescence spectral changes similar to those for solutions containing alcohol.[13] This finding is consistent with Turro et al.'s suggestion that a ternary complex is formed among CDx, acetonitrile, and 1-halonaphthalene.[14] On the basis of a competition method,[2,9] K_2 values for the nitriles have been evaluated and are listed in Table 1. From comparisons between the observed fluorescence intensities and intensity curves which have been calculated according to Eq. 5, K_3 and K_4 for the nitriles have been determined (Table 1). Both K_2 and K_3 increase as the alkyl chain of nitrile is lengthened. These K_2 and K_3 values are several times greater than those for alcohols possessing the same alkyl group, indicating the stronger hydrophobicity of nitrile than that of alcohol. However, the K_4 values for the nitriles are rather small compared with those for the corresponding alcohols. The largest K_4 is seen both for propionitrile and butyronitrile, and K_4 decreases on going from butyronitrile to hexanenitrile. It should be noted that K_4 for propionitrile with a shorter alkyl chain than 1-propanol, whose K_4 is the largest in the alcohol series, has a maximum value in the nitrile series. These findings may imply that in the 1:1:1 inclusion compound the orientation and/or location of a nitrile molecule within the CDx cavity is slightly different from that of the alcohol molecule.

The author is grateful to Professor Fumio Hirayama for his valuable discussion.

A Transition Sequence of Complex Oscillations in a Chemical Oscillation Model Showing Chaos

Makoto MORITA, Kazutoshi IWAMOTO, and Manabu SENŌ*
Institute of Industrial Science, University of Tokyo,
7-22-1, Roppongi, Minato-ku, Tokyo 106
(Received January 25, 1989)

A three-variable model system exhibiting complex oscillations was analyzed. Our analysis reveals a bifurcation structure of complex oscillations including chaotic oscillations. The bifurcation structure reproduces well the transition sequences of oscillatory states observed in the experiments of the Belousov–Zhabotinskii reaction and the chlorite oscillators. The transition sequence to chaotic oscillations in our model system shows period-doubling sequences. When the number F is defined as a ratio of the number of large amplitude to the total number of oscillations per period in the complex oscillation, the number constitutes a monotonous, stepwise-increasing function of a control parameter. The sequence of the complex oscillations is described well by the Farey arithmetric. Also, the average flux of reaction was found to change abruptly at the bifurcation points of the complex oscillations.

In recent years much attention has been paid on the complex oscillations and the chaotic oscillations in the oscillating chemical reactions, and numerous experimental and theoretical studies have been made.[1–4] The complex oscillations were first investigated by Belousov and Zhabotinskii,[5] and Hudson et al. reexamined in detail the Belousov–Zhabotinskii (BZ) reaction in a continuous flow reactor and confirmed that the complex oscillations continued steadily.[6,7] Their experiments exhibited various types of complex oscillations and chaotic oscillations depending on the flow rate of the reactant solutions. Similar phenomena have been also observed in various chlorite oscillators.[8,9] Every complex oscillation reported hitherto is composed of a combination of small and large amplitude oscillations per period. Theoretical investigations on the appearance of complex oscillations have been also performed. Especially, studies on the modified Oregonator[10] may be the most representative.[11–14]

In a previous paper we proposed a simple model to explain chemical oscillations.[15] Moreover, with some modification of the original model system, we constituted a new model system showing some complex oscillations consisting of concatenating small and large amplitude oscillations and explained a mechanism for occurrence of such complex oscillations.[16]

Recently, transition sequences of complex oscillations have been observed in careful and detailed experiments.[17–19] To understand these transition sequences of periodic states, theoretical studies have been carried out by means of one-dimensional maps[20–22] and model systems.[23,24] Many experimental and theoretical efforts have been made to establish the theory of bifurcation structures in oscillating chemical reactions, but still now we can say that bifurcation structures including chaotic oscillations have not been adequately understood.

In the present paper we report a bifurcation structure of complex oscillations including chaotic oscillations by analyzing our simple model with three variables. The model exhibits a quite similar transition sequence of the complex oscillations observed in the BZ reaction[6,7,17–19] and the chlorite oscillators.[8,9] All the complex oscillations appear in the region between the singly small amplitude oscillation and the singly large amplitude oscillation. Mode locking is observed in the transition sequence of complex oscillations. And combined complex oscillations and chaotic oscillations were observed between two stable complex oscillations. The transition sequence from a complex to the chaotic oscillation was period doubling. A complex oscillation becomes unstable with an increase in a control parameter value and a 2-cycle period oscillation appears and then, when the parameter increases, 2^2, 2^3,…, 2^k-cycle oscillations appear and finally an aperiodic state (chaotic oscillation) is followed. When the control parameter increases further, the aperiodic state becomes unstable and a 3-cycle oscillations appears. This sequence was predicted by Li and Yorke.[25]

When an oscillatory state is characterized by a number F, the ratio of the number of large amplitude peaks to the total number of peaks per period, F is a monotonous stepwise-increasing function of a control parameter and forms a staircase similar to the so-called "devil's staircase".[26] The transition sequence of complex oscillations is described well by Farey series.[27]

In order to consider meanings of the staircase structure, the average flux of reaction of each oscillatory state was calculated and a distinct relationship between the oscillatory state and the average flux of reaction was found.

The main purpose of this paper is to show the global feature of the bifurcation structure in our model. Details of respective cases will appear somewhere.

The Model

In a previous paper, we proposed a two-variable chemical system exhibiting temporal oscillations.[15] In a succeeding paper of it, a three-variable model system exhibiting complex oscillations was derived by some modification of the original system and its behavior was analyzed.[16] In this paper, the modified system was investigated in order to make clear the bifurcation structure of the complex oscillations including chaotic oscillations. The system is consisting of the following chemical reactions;[16]

$$\mathrm{P} + \mathrm{Z} \xrightarrow{k_1} \mathrm{E} + \mathrm{Z}, \qquad \text{(R1)}$$

$$\mathrm{E} + \mathrm{X} \xrightarrow{k_2} \mathrm{R} + \mathrm{X}, \qquad \text{(R2)}$$

$$\mathrm{A} + 2\mathrm{X} + \mathrm{E} \underset{k_4}{\overset{k_3}{\rightleftharpoons}} 3\mathrm{X} + \mathrm{E}, \qquad \text{(R3)}$$

$$\mathrm{B} + \mathrm{X} \underset{k_6}{\overset{k_5}{\rightleftharpoons}} \mathrm{C}, \qquad \text{(R4)}$$

$$\mathrm{Q} \xrightarrow{k_7} \mathrm{Z}, \qquad \text{(R5)}$$

$$\mathrm{Z} + \mathrm{X} \xrightarrow{k_8} \mathrm{D} + \mathrm{X}, \qquad \text{(R6)}$$

where A, B, P, and Q are reactants, C, D, and R are products and E, X, and Z, are intermediates. In the model the concentrations of all the reactants and the products are assumed to be constant, keeping the system effectively far from equilibrium. For simplicity, the symbols for the chemical species are used also to denote their concentrations. The differential equations describing the dynamic behavior of this model are given by applying the law of mass action to Reactions (R1)—(R6);

$$\frac{dE}{dt} = k_1PZ - k_2EX, \qquad (1)$$

$$\frac{dX}{dt} = k_3AEX^2 - k_4EX^3 - k_5BX + k_6C, \qquad (2)$$

$$\frac{dZ}{dt} = k_7Q - k_8XZ. \qquad (3)$$

k_i's denote forward or backward rate constants for Reactions (R1)—(R6). The numerical values of k_1 through k_8, A, B, C, and Q are given as follows: k_1=1.0, k_2=5.0, k_3=100.0, k_4=50.0, k_5=10.0, k_6=1.0, k_7=0.1, k_8=0.4, A=1.3, B=5.0, C=5.3, and Q=1.0. Equations 1—3 were calculated by the double-precision Runge-Kutta-Gill method with a digital computer. P is set as a control parameter and every calculation was carried out by assigning a proper value of P.

Bifurcation Structures of Complex Oscillations

According to the results of linearized stability analysis, the steady state of the present chemical system is unstable in the region, $1.034<P<14.21$. The differential equations (Eqs. 1—3) were solved numerically to confirm the occurrence of sustained oscillations at these unstable steady states. Complex oscillations formed from combinations of small and large amplitude oscillations appear, as an example is illustrated in Fig. 1. A mechanism for the occurrence of the complex oscillations has been proposed in the preceding paper.[16] Figure 1(a) shows the temporal change of the intermediate X at P=1.13. This complex oscillations is formed by concatenating one large amplitude and four small amplitude oscillations per period. Figure 1(b) shows a three-dimensional view of this complex oscillation. A common feature of the complex oscillations observed in our system is that they consist of periodic repetitions of a basic pattern of a large amplitude oscillation followed by some small amplitude oscillations. Therefore, these typical complex oscillations can be characterized by a number n, the total number of peaks per period. The notation $\pi(n)$ is used hereafter to describe the complex oscillation formed from the combination of one large peak and $(n-1)$ small peaks per period. The oscillation shown in Fig. 1 is $\pi(5)$.

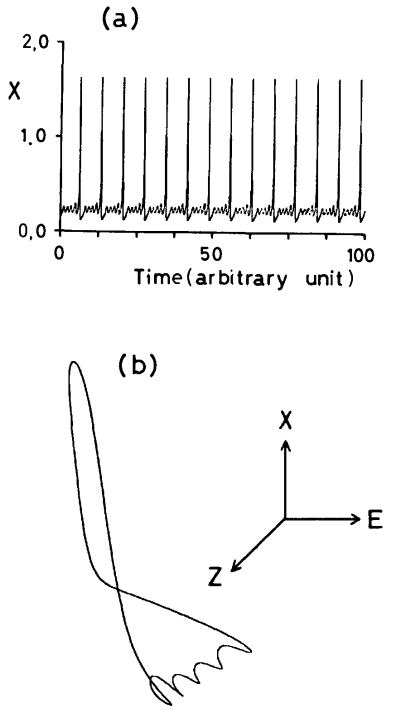

Fig. 1. A behavior of the complex oscillation $\pi(5)$ in our model. (a) Temporal change X vs. time, (b) three dimensional view in the E-X-Z space. P=1.13.

Figure 2 shows the relationship between the number n and the parameter P. With an increase in the value of P, the number of small peaks per period decreases by one. Here, $\pi(1)$ represents a single, large amplitude oscillation. It is noteworthy that the mode locking exerts in these oscillations and the number n is a

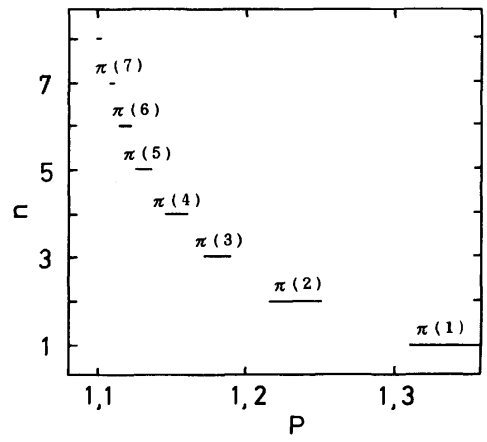

Fig. 2. A mode locking structure of complex oscillations. Relationship between the control parameter P and the number n which characterizes the states of complex oscillations.

staircase-like function of P. The oscillation region of $\pi(n)$ and the transition region between $\pi(n+1)$ and $\pi(n)$ become larger for the smaller number of n.

The property of mode locking has been noticed also in the BZ reaction[17-19] and a one-dimensional map has been utilized to describe the sequence of oscillatory states in the BZ reaction.[20] The mode locking behaviors have been occasionally observed in nonlinear systems having 2-torus attractor,[28-34] even though we do not confirm the existence of two distinct oscillators in these systems.

More complex oscillations appear in the parameter range between $\pi(n)$ and $\pi(n-1)$. They are a periodic oscillation formed from the combination of $\pi(n)$ and $\pi(n-1)$ per period and a chaotic oscillation. Typical examples are shown in Fig. 3. Figure 3(a) shows a periodic oscillation where $\pi(2)$ and $\pi(3)$ appear alternately. Hereafter we call this type oscillation as a combined complex oscillation and designate as $\pi(3)\pi(2)$ for an example. Figure 3(b) shows a more complicated periodic oscillation consisting of a 3-cycle oscillation of $\pi(2)$ and a 1-cycle oscillation of $\pi(3)$ per period. The general notation of these combined complex oscillations is $[\pi(n)]^k[\pi(n-1)]^m$; a periodic oscillation formed from the combination of k-cycle oscillation of $\pi(n)$ and m-cycle oscillation of $\pi(n-1)$. The combined complex oscillation shown in Fig. 3(b) is $[\pi(3)][\pi(2)]^3$. Noteworthily, almost all the combined complex oscillations between the regions of $\pi(n)$ and $\pi(n-1)$ consist of the combination of $\pi(n)$ and $\pi(n-1)$. Moreover, a chaotic oscillation observed in this region consists of aperiodic repetitions of $\pi(n)$ and $\pi(n-1)$, as Fig. 3(c) illustrates. However, there are some exceptional cases where the chaotic oscillations in the region between $\pi(n)$ and $\pi(n-1)$ consist of not only $\pi(n)$ and $\pi(n-1)$ but also $\pi(k)$ with k except for n and $n-1$. An example is shown in Fig. 3(d). On a chaotic oscillation we will explain in detail the bifurcation

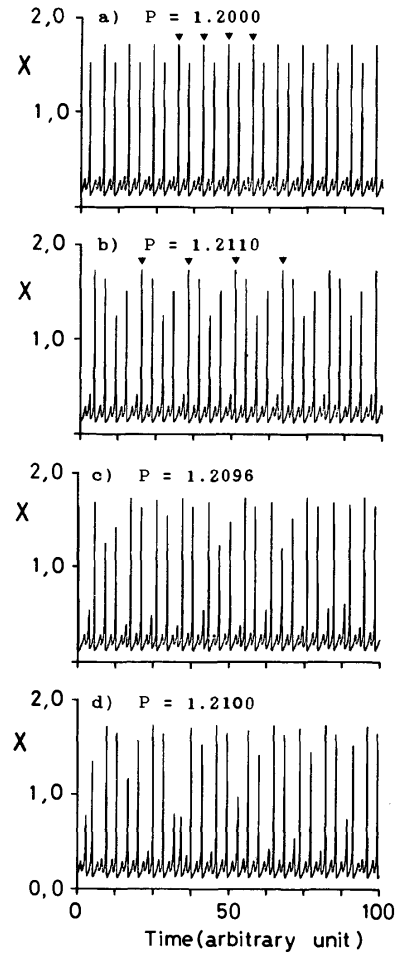

Fig. 3. The combined complex oscillations and the chaotic oscillations. (a) P=1.20: $\pi(3)\pi(2)$, (b) P=1.211: $[\pi(3)][\pi(2)]^3$, (c) P=1.2096 and (d) P=1.21: chaos. Each mark above the oscillations shows the period.

structure in the following papers.

In order to explain the transition sequence including combined complex oscillations and chaotic oscillations, we put a suitable rational between n and $n-1$ to a periodic oscillation of $[\pi(n)]^k[\pi(n-1)]^m$ and plot against P on the n-P two-dimensional phase diagram, as seen in Fig. 4. The mode locking is observed again. The combined complex oscillation of $\pi(n)\pi(n-1)$ occupies a larger region between $\pi(n)$ and $\pi(n-1)$ than other combined complex oscillations of $[\pi(n)]^k[\pi(n-1)]^m$ ($k \neq m$). Every chaotic oscillation takes place in a very limited region. Figure 5 shows an outline of the transition sequence of oscillatory states between $\pi(2)$ and $\pi(1)$. Figure 6 shows the examples of corresponding oscillation states. The oscillation $\pi(2)$ (a) bifurcates successively to $[\pi(2)]^2$ (b), $[\pi(2)]^4$ (c), $[\pi(2)]^8$ (d),$\cdots$, resulting in an aperiodic oscillation (e) formed from $\pi(2)$, as P increases. When P increased beyond over the chaotic region, a 3-cycle oscillation $[\pi(2)]^3$ (f) and a different type chaotic oscillation (g) were found to appear without any period-doubling sequence. The

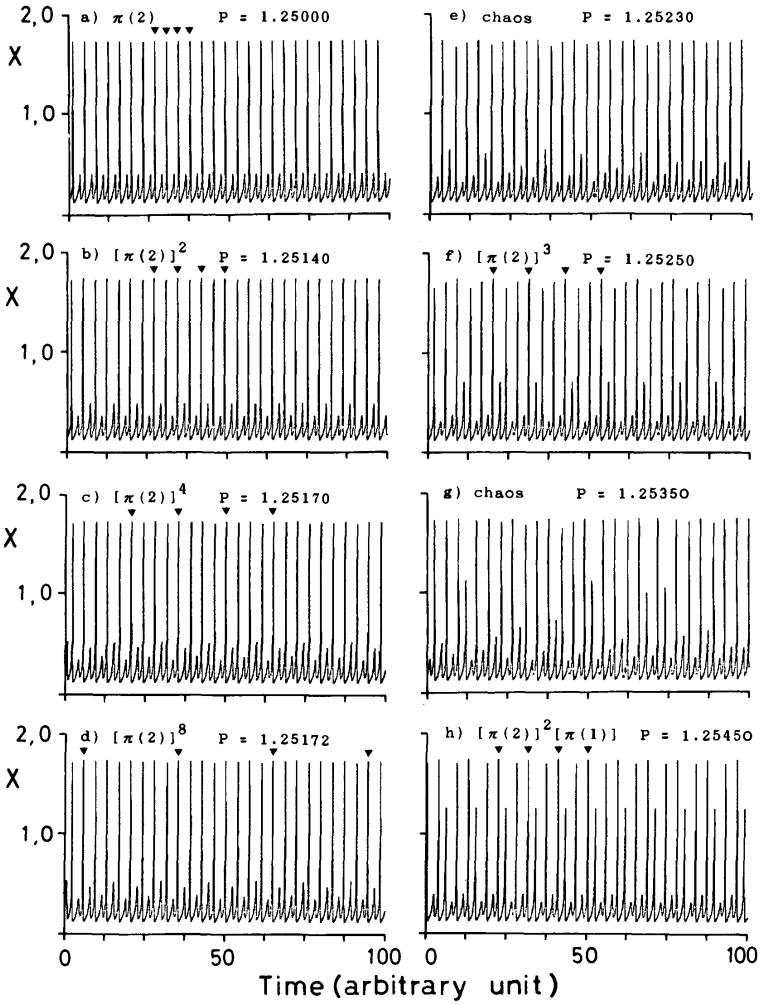

Fig. 6. A transition sequence of oscillations between $\pi(2)$ and $[\pi(2)]^2[\pi(1)]$. Each mark above the oscillations shows the period.

latter chaotic oscillation consists of a combination of $\pi(2)$ and $\pi(1)$. Then, the system leads a combined complex oscillation $[\pi(2)]^2[\pi(1)]$ (h) formed by concatenating $\pi(2)$ and $\pi(1)$, which shows period-doubling as an increase in P till it becomes unstable. After repetitions of these processes, $\pi(2)\pi(1)$ and finally $\pi(1)$ occur.

The transition sequence from $\pi(n)$ to $\pi(n-1)$ with an increasing P can be summarized as follows:

$$\begin{aligned}&\pi(n) \to [\pi(n)]^2 \to [\pi(n)]^4 \to \to \text{chaos} \to [\pi(n)]^3 \\ &\to \text{chaos} \to \to \to [\pi(n)]^k[\pi(n-1)]^m\,(k>m) \to \to \text{chaos} \to \\ &\to \pi(n)\pi(n-1) \to \to \text{chaos} \to \to [\pi(n)]^k[\pi(n-1)]^m\,(k<m) \\ &\to \to \text{chaos} \to [\pi(n-1)]^3 \to \to \text{chaos} \to [\pi(n-1)]^4 \\ &\to [\pi(n-1)]^2 \to \pi(n-1),\end{aligned}$$

where $[\pi(n)]^k$ is a k-cycle oscillation of $\pi(n)$.

According to Maselko and Swinney,[18,19] we define a following number F which characterizes each complex oscillation;

$$F = L/(L + S),$$

where S and L are respectively the numbers of small and large amplitude oscillations per period. For examples, the complex oscillation $\pi(n)$ has the number of $F=1/n$ and the combined complex oscillation $\pi(n)\pi(n-1)$ has $F=2/(2n-1)$. Of course, some of the different oscillations have the same value of F; e.g. both $\pi(2)$ and $[\pi(2)]^2$ have $F=1/2$.

Figure 7 shows the relationship between F and P, where F forms a staircase as a function of P. F equals 1/2 in a discrete wide range of P. The regions having the values of 1/3, 2/3, 1/4, and 3/4 are also clearly distinguishable. $F=1/2$ represents a series of periodic states formed from $\pi(2)^n$, where n=1, 2, 4, 8,·····5, 3 (Sarkovskii sequence).[36] Similarly, 1/3, 2/3, and 1/4, respectively show $\pi(3)^n$, $[\pi(2)\pi(1)]^n$, and $\pi(4)^n$, where n=1, 2, 4, 8,···5, 3. Aperiodic states (chaotic oscillations) are thus included in this figure, but the case shown in Fig. 6(g) is difficult to define its value of F and to show in this figure. This staircase is similar

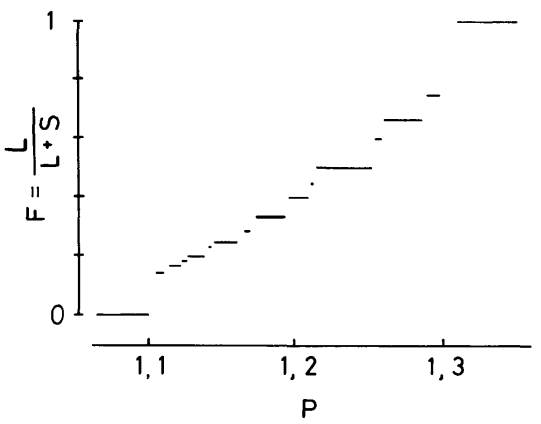

Fig. 7. A staircase behavior of the number F vs. P.

to the "devil's staircase".[26] The devil's staircase has as infinite self-similar staircase structure and is a representative example of fractal, which has been often observed in nonlinear systems. For examples, the one-dimensional Ising model[31] and the sine circle map[32,33] exhibit the devil's staircase.

Recently, Maselko and Swinney have found a similar staircase in the BZ reaction.[18,19] They studied two types of sequences, a complex oscillation composed of two basic patterns and that of three basic patterns. The former sequence is in conformity with the experimental results by Hudson et al. These sequences could be well reproduced in our model.

It has been noticed that the ordering of the number F is related to the Farey series,[18,19,30] when the system has the staircase structure. The Farey series is given by the following procedure; starting with two fractions, 0/1 and 1/1, we get a new fraction according to the following equation.

$$a/b \oplus c/d = (a + c)/(b + d).$$

The first Farey series is 0/1, 1/1, the second is 0/1, 1/2, 1/1, the third is 0/1, 1/3, 1/2, 2/3, 1/1, and so forth. The series of F in Fig. 7 is in a good agreement with the Farey series. It is noteworthy that the complex oscillation having a smaller denominator in the Farey number occupies the wider region. 0/1 and 1/1 represent the single oscillations with a smaller and a larger amplitude, respectively.

Relationship between Oscillatory States and the Average Flux of Reaction

As described above, the transition sequence of complex oscillations in the BZ reaction could be simulated by means of our system. The transition behavior suggests us that there should exist some quantities that change discontinuously at the transition, like entropy or heat capacity in the ordinary phase transition of first or second order. Although it is not yet confirmed that such a quantity exists in the dynamic transition point, we tried to calculate the flux of reaction and examine its relationship to the oscillation states, because the system concerned is a non-equilibrium state far from equilibria and the flux of reaction is one of the essential quantities that characterize the dynamic state of system and determine the entropy production rate. In the case of the one-dimensional Ising model, it has been proved that the staircase structure appears under the conditions that the total energy of the system should be minimized at a given magnetization.[31] Thus, we intend to find a useful quantity like the total energy in the Ising model to explain the staircase structure. Here, we examine the relation between each oscillatory state and its flux of reaction. The average flux of reaction was determined from the integrated flux of the reaction for a

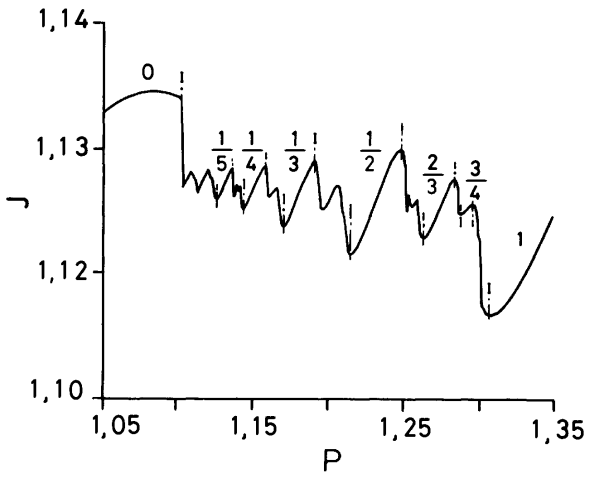

Fig. 8. Relationship between P and average flux of reaction. The values of F for the representative states are given in the figure.

sufficiently long period divided by the integration time.

Figure 8 shows the relationship between P and J, where J is the consuming rate of P ($J=k_1PZ$). Compared with Fig. 7, the average flux J increases monotonously in the region of a (combined) complex oscillation and start to decrease where the period-doubling sequence begins to occur. That is, the inflection point from an increase to a decrease in J coincides perfectly with the starting point of changing from a complex oscillation toward the next one. In some cases where a periodic oscillation changes to a chaotic oscillation without showing any period-doubling sequence, the changes in J are drastic. The value of J would exhibit the same tendency as the value of entropy production rate.[37] Further investigations are needed.

Transition Sequences of Oscillatory States of a Model Chemical System Showing Chaotic Oscillations

Makoto MORITA, Kazutoshi IWAMOTO, and Manabu SENŌ*
Institute of Industrial Science, University of Tokyo,
7-22-1, Roppongi, Minato-ku, Tokyo 106
(Received March 24, 1989)

The transition sequence from a complex oscillation or a combined complex oscillation to a chaotic oscillation of a three-variable model system of chemical reactions were studied through analyses of the bifurcation diagrams. Period-doubling sequences, discontinuous transitions between two different oscillation states, and intermittency-type pseudo-periodic oscillations were observed. A pseudo-periodic oscillation appears when a combined complex oscillation changes to a new oscillatory state under some transition conditions. By changing the conditions, the discontinuous transition becomes to occur, leading the hysteresis behavior of transition.

Aperiodic behavior (chaotic oscillation) in chemical reactions has been observed in the peroxidase-catalyzed oxidation of NADH,[1] the Belousov-Zhabotinskii (BZ) reaction,[2-11] and the chlorite–thiosulfate reaction.[12,13] Some periodic-chaotic sequences have been carefully examined for the BZ reaction and the chlorite oscillators carried out in a continuous flow stirred tank reactor (CSTR).

A chemical reaction model which exhibits chaotic oscillations was first proposed by Rössler[14] in 1976. The Rössler model is a chemical system with three variables and its chaotic behavior has been fully investigated through numerical calculations. The Oregonator[15] is the most well-known model for the BZ reaction and, however, any attempt to find out chaotic oscillations for the three-variable Oregonator has not yet succeeded. Turner et al. modified the original Oregonator to make up a new model having four variables and showed the appearance of chaotic oscillations.[7] On the other hand, Tomita and Tsuda proved for a three-variable model of the BZ reaction to show chaotic oscillations by introducing flow terms.[17]

Some routes from periodic oscillations to chaotic oscillations have been uncovered; period doubling,[16] intermittency,[18] and quasi-periodicity[19] are typical examples. The intermittency,[8,10] and the quasi-periodicity[20] have been experimentally observed in the BZ reaction. The period-doubling sequence from the oscillating state with a single amplitude to the chaotic state was found experimentally in the BZ reaction by Simoyi et al.[9] and numerically in the modified Oregonator by Ringland and Turner.[21] But the route from a complex oscillation or a combined complex oscillation to a chaotic oscillation is not yet examined.

The BZ reaction is the most well-known experimental system which exhibits chaotic oscillations. Swinney et al. examined in detail the transition sequence using CSTR and found a staircase relationship by plotting the Firing number F against the residence time of the flow reactor as a control parameter. The BZ reaction in CSTR shows complicated oscillations made of L cycles of large amplitude oscillations and S cycles of small amplitude oscillations and the Firing number of the oscillation is defined as $F=L/(L+S)$.

In our preceeding paper,[22] a three-variable model chemical system was studied and its bifurcation structures from a complex oscillation to a chaotic or a combined complex oscillation have been reported. When the transition sequence was displayed by the relationship of the firing number F with a control parameter, according to the way of Swinney et al., the resulting staircase behavior of F is very similar to the staircase diagram observed experimentally in the BZ reaction. This result strongly suggests a similarity of the mathematical structure between the BZ reaction and the present model. Thus, it is expected that the detailed analyses of the present model give us a more detailed prospect of the transition sequence in the BZ reaction.

In this paper, the model chemical system of three variables was studied through numerical calculation and period-doubling sequences from complex or combined complex oscillations to chaotic oscillations was demonstrated. Here, the terms, "complex oscillation" and "combined complex oscillation", are defined as follows.[22] A complex oscillation is an oscillatory state combining of one large amplitude oscillation and $n-1$ small amplitude oscillations. The symbol $\pi(n)$ is used to note this complex oscillation. The term of combined complex oscillation is used for a combination of two or more complex oscillations and the symbol $\pi(m)\pi(n)$ is for a combined complex oscillation consisting of complex oscillations $\pi(m)$ and $\pi(n)$. Now, the detailed structure of transition sequence of the model chemical system will be investigated by using a bifurcation diagram, which is made by plotting the peak height of each pulse in a periodic or an aperiodic state on a two-dimensional phase plane. There appear a period-doubling sequence, a discontinuous transition between a combined complex oscillation and a pseudo-periodic oscillation, and an intermittency-type pseudo-periodic oscillation. The term of "pseudo-periodic oscillation" is hereafter used

when we can not determine whether the oscillation is chaotic or not. A discontinuous change implies usually a hysteresis correlation and coexistence of two different oscillatory states. This phenomenon, which is called birhythmicity, has been found in the experimental[23] and the computational works.[24] However, this is the first paper reporting the birhythmicity between a combined complex oscillation and a pseudo-periodic oscillation.

Chemical Oscillation Model

In the present investigations, the system consisting of the following chemical reactions is considered. This model system has been proposed in a previous paper.[22]

$$\mathrm{P} + \mathrm{Z} \xrightarrow{k_1} \mathrm{E} + \mathrm{Z}, \quad \text{(R1)}$$

$$\mathrm{E} + \mathrm{X} \xrightarrow{k_2} \mathrm{R} + \mathrm{X}, \quad \text{(R2)}$$

$$\mathrm{A} + 2\mathrm{X} + \mathrm{E} \underset{k_4}{\overset{k_3}{\rightleftharpoons}} 3\mathrm{X} + \mathrm{E}, \quad \text{(R3)}$$

$$\mathrm{B} + \mathrm{X} \underset{k_6}{\overset{k_5}{\rightleftharpoons}} \mathrm{C}, \quad \text{(R4)}$$

$$\mathrm{Q} \xrightarrow{k_7} \mathrm{Z}, \quad \text{(R5)}$$

$$\mathrm{Z} + \mathrm{X} \xrightarrow{k_8} \mathrm{D} + \mathrm{X}, \quad \text{(R6)}$$

where A, B, P, and Q are reactants, C, D, and R are products and E, X, and Z are intermediates. Then, three differential equations concerning the concentrations of E, X, and Z will describe the time behavior of the system;

$$\frac{dE}{dt} = k_1PZ - k_2EX, \quad (1)$$

$$\frac{dX}{dt} = k_3AEX^2 - k_4EX^3 - k_5BX + k_6C, \quad (2)$$

$$\frac{dZ}{dt} = k_7Q - k_8XZ. \quad (3)$$

The following values are substituted in respective parameters and the equations are solved numerically by the aid of FACOM M380 (Fujitsu). These values were selected to afford a chaotic behavior of oscillations. The value of P is selected as a variable for the calculation. A=1.3, B=5.0, C=5.3, Q=1.0, k_1=1.0, k_2=5.0, k_3=100.0, k_4=50.0, k_5=10.0, k_6=1.0, k_7=0.1, and k_8=0.4.

Results and Discussion

Period-Doubling Sequence. By solving Eqs. 1—3 numerically, complex oscillations, combined complex oscillations and chaotic oscillations were confirmed to appear in a range $1.08 \leqq P \leqq 1.31$, and the global profile of the transition sequence has been reported in a preceding paper.[22] Some characteristics of transition sequences were studied by the aid of bifurcation diagrams, which are made by plotting the peak value of X of every pulse in an oscillatory state. The bifurcation diagram shown in Fig. 1 is obtained on increasing the value of P stepwise from 1.250 to 1.262. In solving Eqs. 1—3 numerically for each P value, the final values of E, X, and Z in a preceeding step with a given value of P were used for the initial values of the calculation for the next step of P.

Figure 1 shows the transition sequence from the complex oscillation $\pi(2)$ to the combined complex oscillation $\pi(2)\pi(1)$, passing through the combined complex oscillations $[\pi(2)]^2\pi(1)$ and $[\pi(2)]^3\pi(1)$. The notation $[\pi(m)]^i[\pi(n)]^j$ means a combined complex

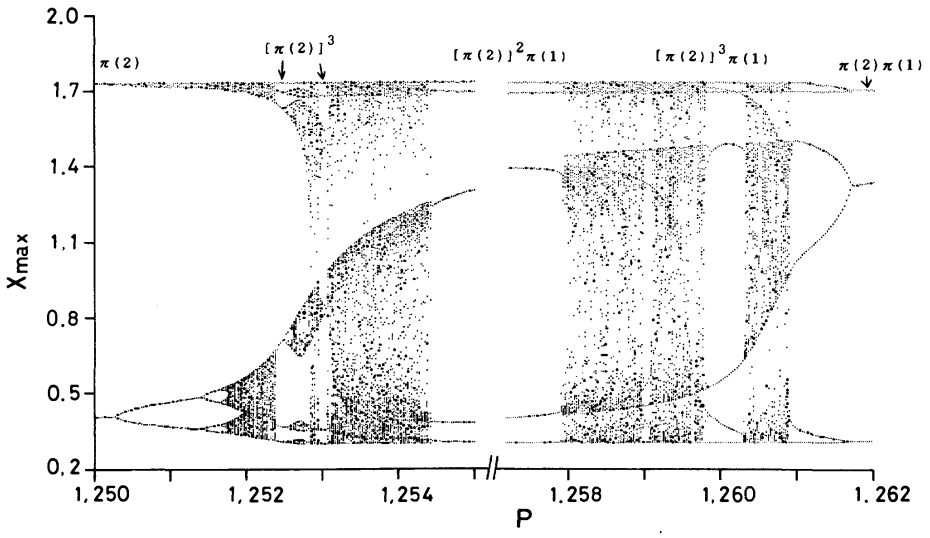

Fig. 1. A bifurcation diagram displaying from $\pi(2)$ to $\pi(2)\pi(1)$. The regimes of respective oscillations are noted.

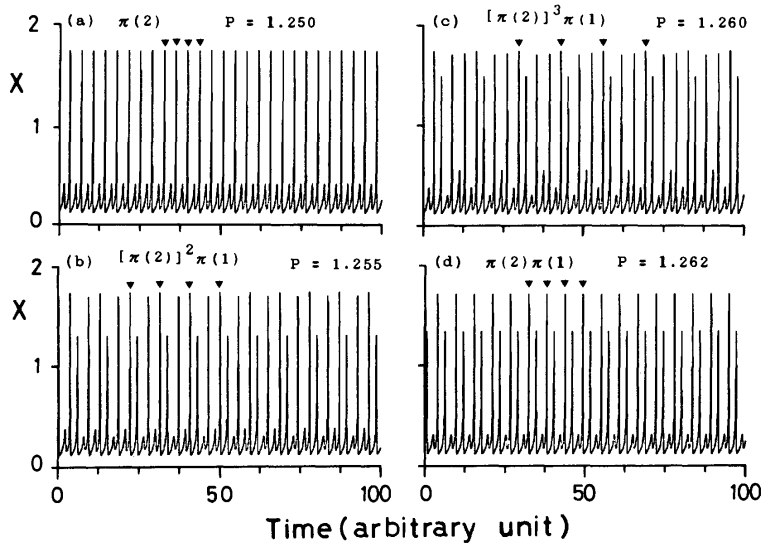

Fig. 2. Representative periodic oscillations designated in Fig. 1. Marks above the oscillations show the period.

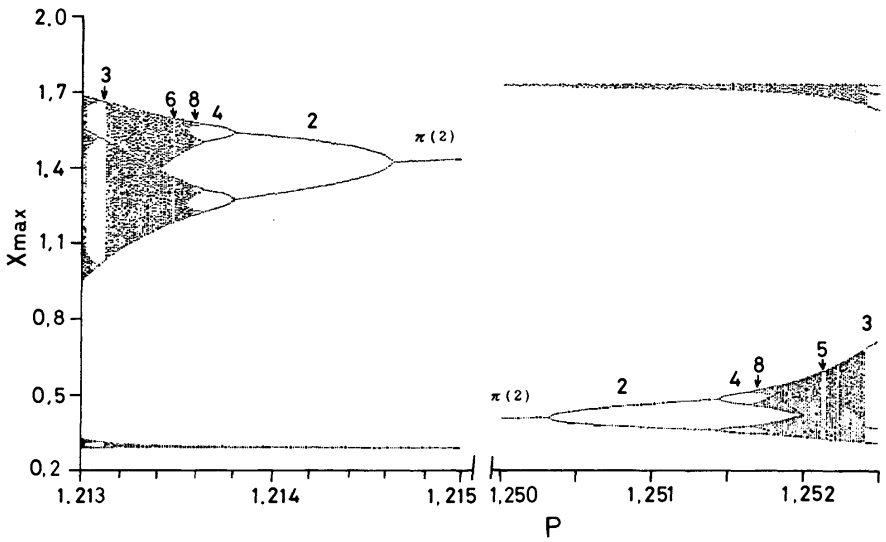

Fig. 3. Period-doubling sequences of the complex oscillation π(2) for increasing and decreasing P. The 2^n-cycle oscillations of π(2) are marked with n. Windows of 6, 5, and 3-cycle oscillations can be seen.

oscillation consisting of i-cycle $\pi(m)$ and j-cycle $\pi(n)$.[22] The oscillation behavior of π(2), $[\pi(2)]^2\pi(1)$, $[\pi(2)]^3\pi(1)$, and $\pi(2)\pi(1)$ are shown in Fig. 2. As shown in the preceding paper,[22] the number F defined as $F=L/(L+S)$ according to Maselko and Swinney,[25] where S and L are respectively the numbers of small and large amplitude oscillations per period, is staircase-like increasing function against P, when only the conspicuous oscillations with large regimes on P are selected. In detail, however, the values of F for the oscillations π(2), $[\pi(2)]^2\pi(1)$, $[\pi(2)]^3\pi(1)$, and $\pi(2)\pi(1)$ with an increase of P are 1/2, 3/5, 4/7, and 2/3, respectively, and this order is not an increasing order. That is, this series of oscillations is out of the rule of staircase-like increasing function of F. Similar trends are occasionally seen in the fine structures of the bifurcation diagram of the present model. Experimentally such a trend has never been observed but probably could be found by a careful experiment.

A period-doubling sequence is clearly seen in Fig. 1. The complex oscillation π(2) appears at $P=1.250$. As P increases, π(2) becomes unstable and diverges to the 2-cycle oscillation of π(2) (i.e. $[\pi(2)]^2$). The right hand figure of Fig. 3 displays an enlarged view of this

region. With a further increase in P, $[\pi(2)]^2$ develops to the 4-cycle oscillation of $\pi(2)$ (i.e. $[\pi(2)]^4$), followed by the higher order 2-cycle oscillations. The range of P of 2^n-cycle oscillation of $\pi(2)$ becomes steeply narrower as n increases, and finally a chaotic oscillation appears. According to Li and Yorke,[26] a chaotic oscillation resulting from the sequence of infinitely high order 2-cycle oscillations is a typical example of the chaotic oscillations. The chaotic oscillations are shown as a diffuse and vertical distribution of dots in the diagram. The bifurcation diagram shown in Fig. 3 is partly broken by "windows" of 6-cycle and 5-cycle oscillations of $\pi(2)$ and is very similar to that of May's system with a typical period-doubling bifurcation.[27]

Feigenbaum[17] showed that an asymptotic limit of the ratio $(P_n-P_{n-1})/(P_{n+1}-P_n)$, where P_n is the parameter value at which the n^{th} doubling bifurcation begins, is a universal number called Feigenbaum's constant, i.e., $\delta=4.6692\cdots$. The values of P_n in the present model are: $P_1=1.250332$, $P_2=1.251452$, $P_3=1.2516700$, $P_4=1.2517154$, and $P_5=1.2517252$. The P_n with $n\geqq 6$ could not be determined. From these values, the ratio $(P_4-P_3)/(P_5-P_4)=4.6\pm0.1$, being fairly in agreement with Feigenbaum's constant.

The bifurcation diagram in the region from $P=1.213$ to 1.215 is shown in the left hand of Fig. 3, where the similar period-doubling bifurcation takes place in a decreasing direction of P. Thus, it was concluded that the complex oscillation $\pi(2)$ changes to a chaotic oscillation through the period-doubling bifurcation with both the increasing and the decreasing directions of P.

For the cases of $\pi(n)$ ($n=1$, 3, 4, 5, and 6), the period-doubling sequences were always observed, so that we can conclude that a complex oscillation diverges to another oscillatory state through a period-doubling sequence. The period-doubling sequence of $\pi(1)$ is clearly seen in Fig. 4.

Intermittency-Type Pseudo-Periodic Oscillation. As the value of P increases up to 1.255, the complex oscillation $\pi(2)$ changes to the combined complex oscillation $[\pi(2)]^2\pi(1)$, where the F value changes from 1/2 to 3/5. That is, the mixing of $\pi(2)$ with $\pi(1)$ should take place after the period-doubling sequence of $\pi(2)$. Similarly, when the combined complex oscillation $[\pi(2)]^2\pi(1)$ changes to the following oscillatory state having a different value of F with an increase in P, the mixing of some oscillatory component into $[\pi(2)]^2\pi(1)$ would take place, resulting in a change in the F value. The bifurcation diagram of Fig. 5 shows a sudden transition at about $P=1.257886$, where $[\pi(2)]^2\pi(1)$ enters into a new oscillatory state. The sudden change in the distribution of dots should be noticed and the period-doubling sequence is not observed in this case. The oscillations before and after the transition are also shown in Fig. 5. After the transition the regular oscillation $[\pi(2)]^2\pi(1)$ is occasionally disturbed by two or three repetitions of irregular oscillation. The irregular oscillation happens to appear intermittently. This type of oscillation is called hereafter as "intermittency-type pseudo-periodic oscillation", because we can not definitely determine whether it is chaotic or not.

Figure 1 shows many transitions which seem to be discontinuous. Some of them were investigated in detail and found to be the transitions with intermittency-type pseudo-periodic oscillations. We can say that this type of transition occurs when a combined complex oscillation changes to a new oscillatory state

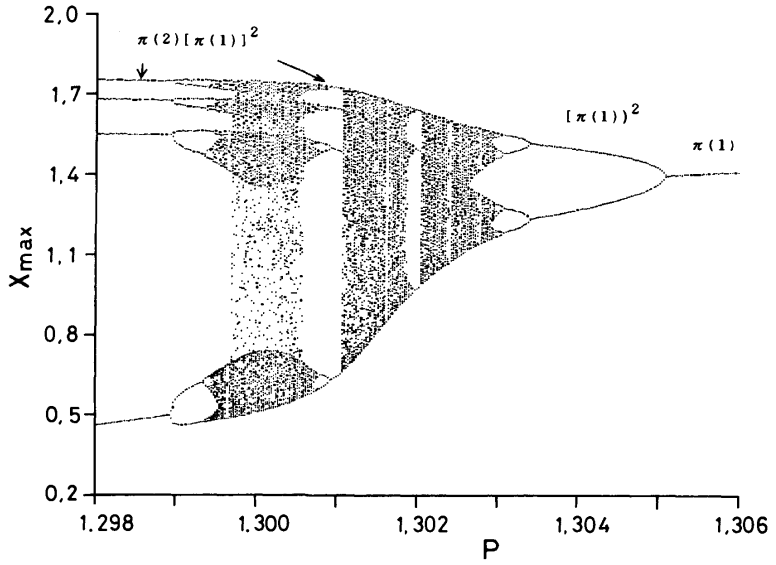

Fig. 4. A bifurcation diagram displaying from $\pi(2)[\pi(1)]^2$ to $\pi(1)$ with the period-doubling sequence of $\pi(1)$.

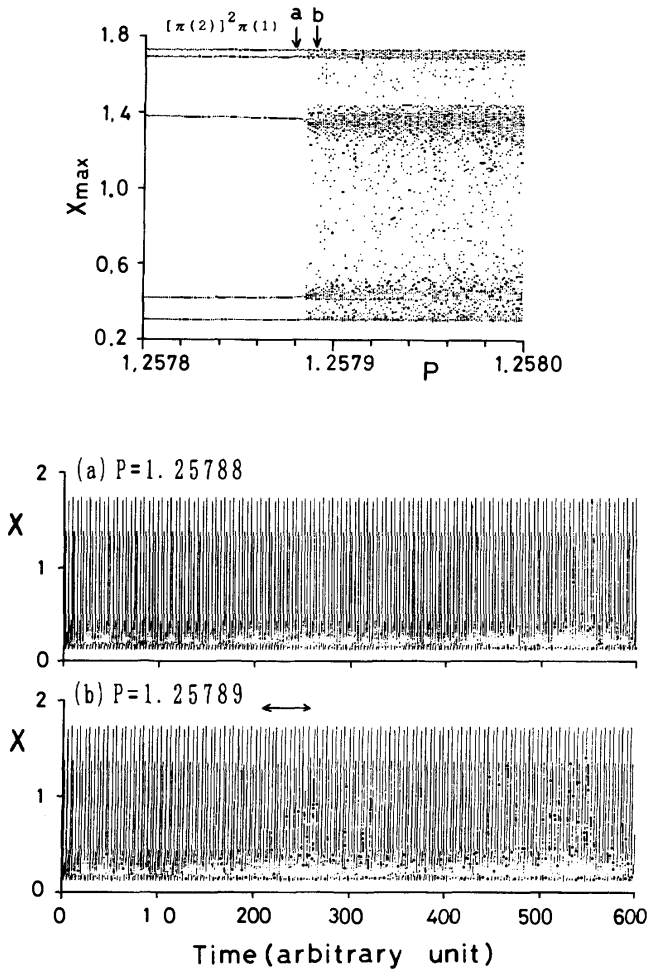

Fig. 5. A bifurcation diagram showing a sudden transition from $[\pi(2)]^2\pi(1)$ to a new oscillatory state and oscillatory behaviors before and after the sudden transition. (a) P=1.25788 and (b) P=1.25789. The bar in (b) indicates the region where $[\pi(2)]^2\pi(1)$ is disturbed.

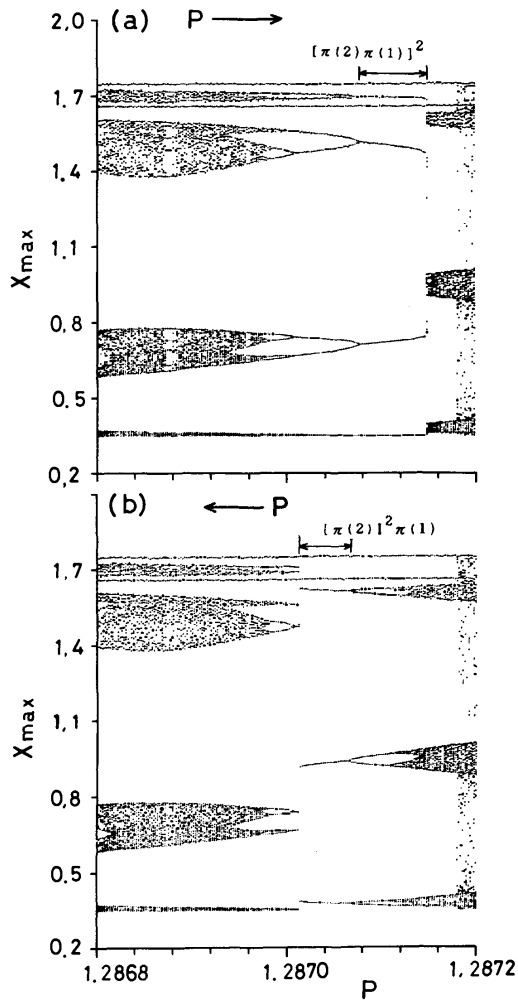

Fig. 6. Dependence of the bifurcation diagram on the direction of change in P. (a) P is increasing, and (b) P is decreasing.

with a different F value. Now we face a question whether the intermittency-type pseudo-periodic oscillation occurs always in a transition state from an oscillatory state to another with a change in F. The answer is that it is not always true. A different type of transition behavior will be shown in the next section.

Birhythmicity. A discontinuous change is observed at about P=1.28714 in a sequence of the combined complex oscillations $\pi(2)\pi(1)$. At this point, the birhythmicity appears and one of two different oscillations is realized depending on the initial conditions of calculation. This result suggests strongly the existence of hysteresis behavior of oscillations as for the changing direction of P. Figure 6 displays the dependence of the bifurcation diagram on the changing direction of P. The transition is discontinuous and hysteresis behavior is clearly shown. Interestingly, the F values of the coexisting oscillations, $[\pi(2)\pi(1)]^2$ and $[\pi(2)]^2\pi(1)$, are different one another and the correlation of F vs. P shows also hysteresis. The transition from $[\pi(2)\pi(1)]^2$ to $[\pi(2)]^2\pi(1)$ occurs at P=1.287148 as P increases, and the reverse transition does at P=1.287012 as P decreases, without showing any intermittency-type pseudo-periodic oscillations.

The hysteresis behavior could be related to a cusp-type catastrophy with a folded phase plane in a three dimensional phase space. Thus, an interpretation of birhythmicity is undertaken with a three-dimensional profile. Figure 7 shows bifurcation diagrams at the discontinuous transition with various values of A. When A=1.286, $[\pi(2)\pi(1)]^2$ changes to $[\pi(2)]^2\pi(1)$, passing through a sudden transition. In this case no hysteresis is observed. When the value of A increases further, the region of pseudo-periodic oscillations becomes narrower and finally disappears, as shown in Fig. 10(b). When the value of A increases further, hysteresis behavior begins to appear.

On the basis of these computations, a schematic profile of the folded phase plane leading these bifurcation diagrams would be drawn as shown in Fig.

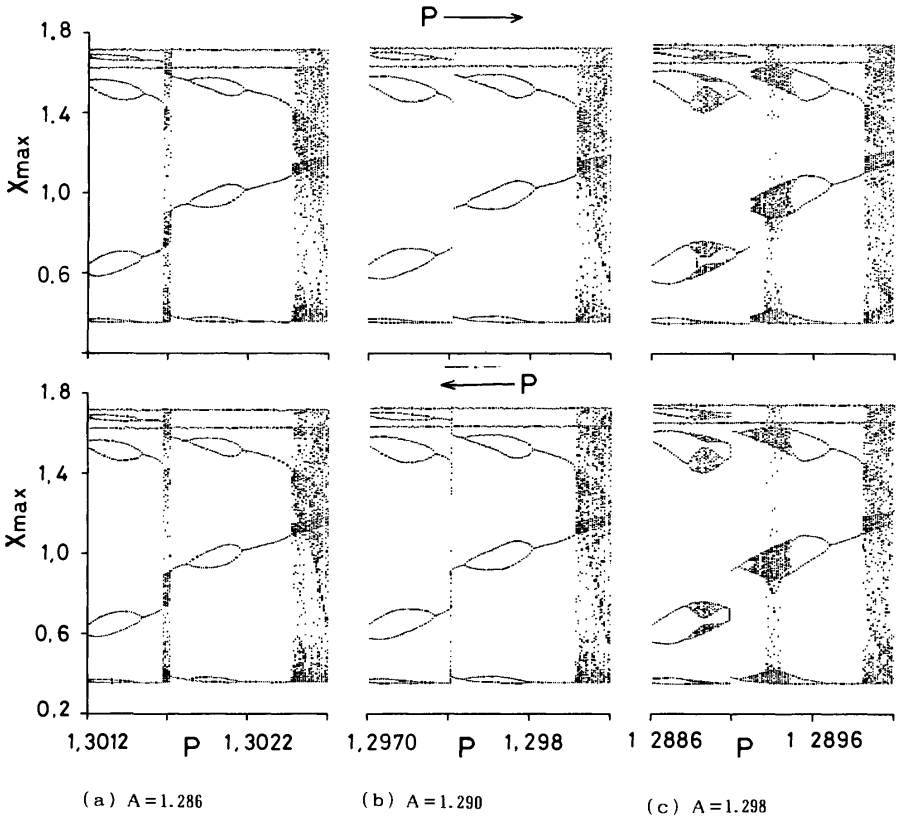

Fig. 7. Bifurcation diagrams with various values of A. In case (a), a sudden transition takes place and no hysteresis is observed. In case (b), the region of intermittecy-type pseudo-periodic oscillation almost disappeared, but no hysteresis is observed. In case (c), a transition accompanied by hysteresis is observed.

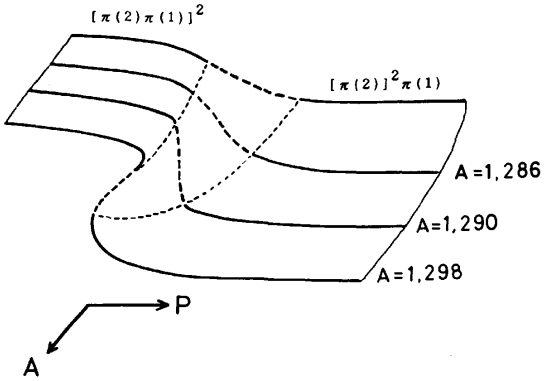

Fig. 8. A phase portrait with a casp catastrophy inferred from the bifurcation diagrams in Fig. 7. The dashed part of each line shows the region of an intermittency-type pseudo-periodic oscillation. The perpendicular coordinate is used to figure the respective states of oscillation.

8. The transition region from $[\pi(2)\pi(1)]^2$ to $[\pi(2)]^2\pi(1)$ is shown by dotted lines. As the value of A increases, the transition region becomes concaved more steeply and finally folded completely between the oscillatory states of $[\pi(2)\pi(1)]^2$ and $[\pi(2)]^2\pi(1)$. Under the latter conditions, the transition between the two combined complex oscillations takes place without showing any pseudo-periodic oscillation, and the birhythmicity is caused by the hysteresis nature of a folded phase plane.

(Received January 30, 1989)

A method of calculating the excited state MCSCF electronic wave function by constraining it to be orthogonal to the predetermined ground state wave function was applied to calculate wave functions of the Li-H_2 system near the center of a conical intersection of the lowest two potential energy surfaces. Combined with an additional nonorthogonal configuration interaction process, it has proved to be an efficient method to get systems of wave functions that are continuous throughout whole geometries. Qualitative characters of wave functions near the center of potential crossing previously inferred have been reconfirmed.

Nonadiabatic transition is a key process to all physicochemical phenomena involving electronically excited states. It participates in every process where electronic energy is converted in to other kinds of energy. Its detailed mechanism, particularly how electrons will behave at the moment of transition, is of great theoretical interest.[1-9,18,35,37,38] Quenching of the fluorescence of alkali metal atoms by simple molecules is a prototype of relevant phenomena and suitable for detailed theoretical investigation, and has been the subject of many experimental and theoretical works.[10-43]

Many authors[25-28,41-43] have applied the classical trajectory method to potential energy surfaces calculated by some semiempirical methods. In those studies, discussion was often neglected on the nature of wave functions and detailed shapes of potential surfaces in the nonadiabatic region were often neglected. In ab initio calculation of wave functions[44,47-50,52,53] also, most concern has been given to detailed shapes of potential energy surfaces in their crossing regions and not to the nature of wave functions themselves.

For the Li-H_2 system, ab initio calculations of wave functions using large basis sets have been reported only for limited geometries.[34,36,38] Neither calculation of complete three-dimensional potential hypersurfaces nor analysis of wave functions near the center of their conical intersection[35] has hitherto been carried out by anyone including ourselves, despite their importance for detailed understanding of the nonadiabatic process. This is mainly because, as reported in the preceding paper,[54] direct MCSCF calculations of excited states for such geometries suffer convergence difficulties. Even if fortuitous convergence has been achieved, potential energy surfaces thus obtained often show apparent irregularities near crossing geometry, yielding electron density maps inadequate to excited states. Such cases have usually been treated by the state averaged MCSCF (SA-MCSCF) method.[44-53]† Using the method with weight factor 0.5 for lower accompanying states, we have obtained[54] smooth potential curves for the ground and excited states, but they lie somewhat higher than the corresponding curves obtained by the ordinary MCSCF method. Moreover, we have not been able to obtain SA-MCSCF functions if we use the weight factor 0.0 for lower states. This leaves some ambiguity in wave function obtained. To overcome these difficulties, we have introduced a new alternative method[54] to obtain excited MCSCF wave functions. It amounts to minimizing the energy requiring the function to be orthogonal[55] to a predetermined MCSCF ground state (hereafter, this method will be abbreviated as OC-MCSCF).

OC-MCSCF gives exactly the same function outside the crossing region as the conventional MCSCF method, and gives potential surfaces which seem to stand for smooth interpolations of potential surfaces obtained in the left and right sides of the crossing region, just as the SA-MCSCF method does, but energies are, in general, lower than those obtained by the SA-MCSCF method. The above-mentioned achievement of the present method has been gained by sacrificing, for general C_s geometries,[54] the generalized Brillouin theorem[56] to some extent. (SA-MCSCF functions with nonzero weight factors for lower accompanying states also may not fulfill the theorem.) Moreover, excited MCSCF function(s) in the potential crossing region may, in general, not be properly

† Other methods of calculating correlated wave functions, such as Cluster Expansion Methods, CEPA, and MP2, are left aside here, and treatments in the MCSCF domain are discussed.

hamiltonian-orthogonal to the ground MCSCF function independently calculated for the same geometry. Thus, in our scheme,[54] a final nonorthogonal configuration interaction process (NCI) is taken from among all CSF's constituting the pair of ground and excited MCSCF functions. This guarantees the mutual orthogonality and hamiltonian-orthogonality of the final pair of MCSCF functions.

In this paper, we report the whole unified potential surfaces for the Li-H_2 system thus obtained. The nature of wave functions will also be discussed using suitable electron density maps.

Method of Calculation

The geometric parameters are shown in Fig. 1. The basis functions are the same as used in an earlier work.[38] Dill and Pople's 5-21G basis set was used for Li atom, and for H atoms the 4-31G basis set of Ditchfield et al.[58] was augmented by p-polarization functions of exponent 1.0 before use. All calculations were done with C_s symmetry of molecular orbitals. No further symmetry constraint was applied to orbitals even in higher symmetric geometries than C_{2v}. This was necessary to avoid any discontinuities in potential surfaces.[35,38] The selection of CSF was of CAS[59] type. The inactive space consisted of 1a′ orbital, and the active space consisted of (2a′—6a′) and 1a″ orbitals. Orbitals from 7a′ to 15a′ and 2a″, 3a″, and 4a″ were taken to be virtual. The resulting 45 CSF's corresponded to those of the minimal basis full valence calculation.

Ground state MCSCF functions were calculated by the standard one-step Newton-Raphson procedure using an exponetial formalism incorporated with a mode control and a mode damping process.[60] Near the center of the conical intersection of the ground and the excited state potential energy surface, each excited state wave function was calculated with a constraint of being orthogonal to the corresponding ground state wave function, by using a slight modification of the original MCSCF program, as reported in the preceding paper.[54] When the geometry was far from the critical geometry, both the constrained and the unconstrained program gave exactly the same result.

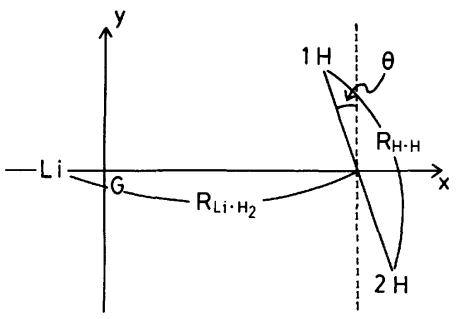

Fig. 1. Geometrical parameters for the Li-H_2 system.

In practice, we adopted the natural orbital expansion for all MCSCF functions to make their expressions unique since CAS wave function forms are invariant to any orbital rotations in the active space.

Then, we adopted the nonorthogonal configuration interaction for all CSF's (45×2=90 in all) constituting the primary pair of ground and excited MCSCF wave functions to get the final expression of states

$$\Psi = \sum_{i=1}^{N} A_i^{(G)} \Phi_i^{(G)} + \sum_{i=1}^{N} A_i^{(E)} \Phi_i^{(E)},$$

where $\Phi_i^{(G)}$'s are the CSF's obtained for the ground MCSCF function, and $\Phi_i^{(E)}$'s are those for the excited MCSCF function. $A_i^{(G)}$'s and $A_i^{(E)}$'s are taken freely to make $<\Psi|H|\Psi>$ stationary under a sole condition of $<\Psi|\Psi>=1$.

Results and Discussion

1 C_{2v} Geometry. (1) Potential Energy Curves in the Immediate Neighborhood of the Center of Intersection: Figure 2 shows the total energies of the system calculated by the method described above along some reaction coordinate defined earlier[38] on the C_{2v} potential energy surface. The solid lines show the results before NCI and the chain lines show those after NCI. The ground state energies (filled circles in Fig. 2) were obtained directly by the usual MCSCF method,

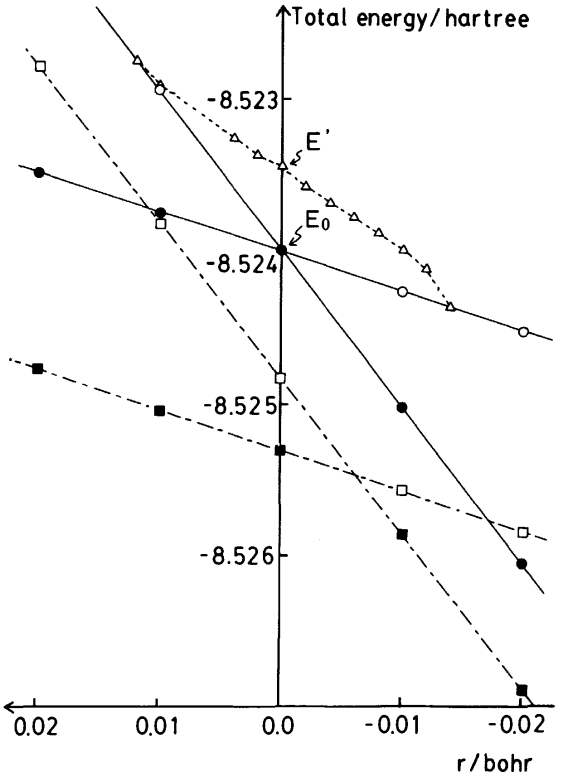

Fig. 2. Comparison of potential energy curves near the point P along the reaction coordinate r calculated by conventional MCSCF: (●, △), OC-MCSCF: (○), OC-MCSCF+NCI: (■, □).

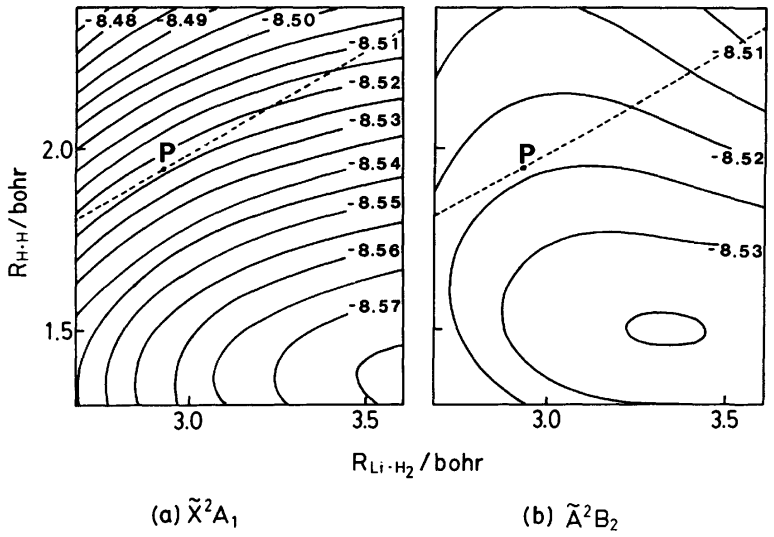

Fig. 3. Contour plots of the two lowest potential energy surfaces near their crossing seam (broken lines). Energies are given in hartrees. *P* is the lowest point on the crossing seam.

while the excited state energies (open circles in Fig. 2) were obtained by OC-MCSCF using the corresponding ground state as reference. As seen in the figure, no irregularities occur in the OC-MCSCF curve as is usually reported in SA-MCSCF calculations.[44,48–50,52,53]†† The open triangles in the figure indicate energies of excited states when the constraint was not applied. When the geometry was relatively far from the *P* point, i.e., $r \gtrsim 0.01$ or $r \lesssim -0.015$ bohr, open triangles fell on the open circles, and the wave functions with and without constraint were identical after the MO's were transformed to natural orbitals. As we see from the 3a′ natural orbital electron density maps in Figs. 5(a) and (b), for example at $r=0$, the symmetry of the wave functions by the method are correctly of C_{2v}, even though no C_{2v} constraint was put on the MO form. The typical energy lowering by the NCI was 7×10^{-4} hartree at the *P* point. For further details see Ref. 54.

(2) C_{2v} Potential Energy Surfaces in the Crossing Region: Figure 3 shows the lowest two potential energy surface contour maps thus obtained for a wider range of geometries around the central point of the crossing region. The broken lines indicate the crossing seam between the surfaces. The location and energy of the *P* point (the lowest point on the seam) are $R_{Li\text{-}H_2}=2.9344$ and $R_{H\text{-}H}=1.9520$ bohr, respectively. It lies 1.1×10^{-3} hartree lower than the energy of $Li(^2P)+H_2(^1\Sigma_g^+)$. The depth of the pond on the excited state potential surface is 1.26×10^{-2} hartree, and its bottom is located at ($R_{Li\text{-}H_2}=3.35$, $R_{H\text{-}H}=1.55$ bohr). These values deviate somewhat from the values of Hobza and Schleyer.[34] The difference may be due mainly to the basis set quality, but may also have resulted from the small NCI size adopted in the work. Even the size of the wave function set used in the present NCI may be sufficient in improving both qualities and some of the energies of MCSCF functions in the vicinity of the potential crossing center, but for other geometries it is rather insufficient. Increasing the size of NCI would have no difficulty and may improve the whole of the unified potential surfaces. The results will be reported in future papers. The main additional task in OC-MCSCF plus NCI procedure over the usual MCSCF procedure is the construction of second order transition density matrix elements between the ground and the excited state. This did not cause any methodological difficulties, but required about 20% extra CPU time over the ordinary procedure in iterations.

It should be noted that we have found a small dip in the C_{2v} ground state potential energy surface. It is located at ($R_{Li\text{-}H_2}=11.8$, $R_{H\text{-}H}=1.4$ bohr) and has a depth of 8.2 μhartree. It probably corresponds to the van der Waals interaction of $Li(^2S)$ and $H_2(^1\Sigma_g^+)$. A minimum also is observed in our $C_{\infty v}$ calculations at ($R_{Li\text{-}H_2}=12.3$, $R_{H\text{-}H}=1.4$ bohr), and its depth is 5.2 μhartree. Hobza and Schleyer[34] also reported a minimum on their potential energy surface for $C_{\infty v}$ symmetry ($R_{Li\text{-}H_2}=11.4$, $R_{H\text{-}H}=1.4$ bohr, 30 μhartree†††).

2 C_s Geometry. The OC-MCSCF method was most effective in computing the excited states in C_s geometries. Figure 4 shows part of the various poten-

†† In this case also, we got smooth SA curves some 5×10^{-3} hartree shifted upwards relative to the OC-MCSCF excited and ground state curves. (cf. Ref. 54)

††† Referring to Table 1 of Ref. 34, we obtain the numerical value for the depth given above, instead of "13 kcal mol^{-1}" given in the text of that paper.

tial curves obtained by three methods, conventional MCSCF, OC-MCSCF, and OC-MCSCF+NCI, when the H_2 molecule was rotated from the C_{2v} geometry of the point P with R_{Li-H_2} and R_{H-H} kept fixed. The actual calculation was started from $\theta=90°$ ($C_{\infty v}$) and proceeded step by step down to $\theta=0°$ by using the converged MC function at a previous geometry as the 0th approximation of iteration. The OC-MCSCF function at $\theta=90°$ was obtained from the function at ($R_{Li-H_2}=3.0$, $R_{H-H}=1.4$ bohr, $\theta=90°$), the latter function being calculated in the opposite direction, i.e., by starting from ($R_{Li-H_2}=3.0$, $R_{H-H}=1.4$ bohr, $\theta=0°$, C_{2v}) and increasing θ up to 90°. At the last geometry, there was no ambiguity in identifying the ground and excited state MCSCF functions since they are sufficiently outside the geometric region where the usual MCSCF procedure shows irregularities.

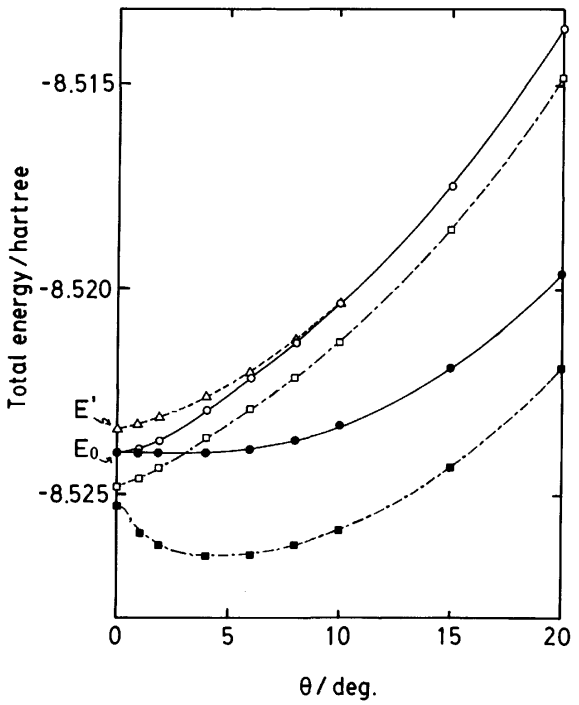

Fig. 4. Potential energy curves of the ground state and the first excited state vs. rotation angle θ from the C_{2v} geometry at point P. R_{Li-H_2} and R_{H-H} are fixed constant. Conventional MCSCF: (●, △), OC-MCSCF: (○), OC-MCSCF+NCI: (■, □).

In Fig. 4, as θ decreases from 20°, the MCSCF excited state curve deviates upward from the OC-MCSCF curve and reaches the energy E', somewhat higher than that of the MCSCF ground state at $\theta=0°$ (E_0). The energy E' is equal to the energy of the excited state obtained by an MCSCF calculation on C_{2v} geometries (E' in Fig. 2). An electron density map analysis also has shown that the MCSCF excited state thus obtained has no correct C_{2v} symmetry. These reveal the inadequateness of the conventional MCSCF method for the central portion of potential crossing geometries. (We have made many other attempts by starting with different 0th approximations or using different algorithms, but none of them has been successful.) On the other hand, the OC-MCSCF curve reaches E_0 just at $\theta=0°$ and there occur no discontinuities between the C_{2v} and C_s potentials. After the MO's were converted to natural orbitals, the OC-MCSCF function at $\theta=0°$ was identical with that obtained in section 1-(1). The 3a'

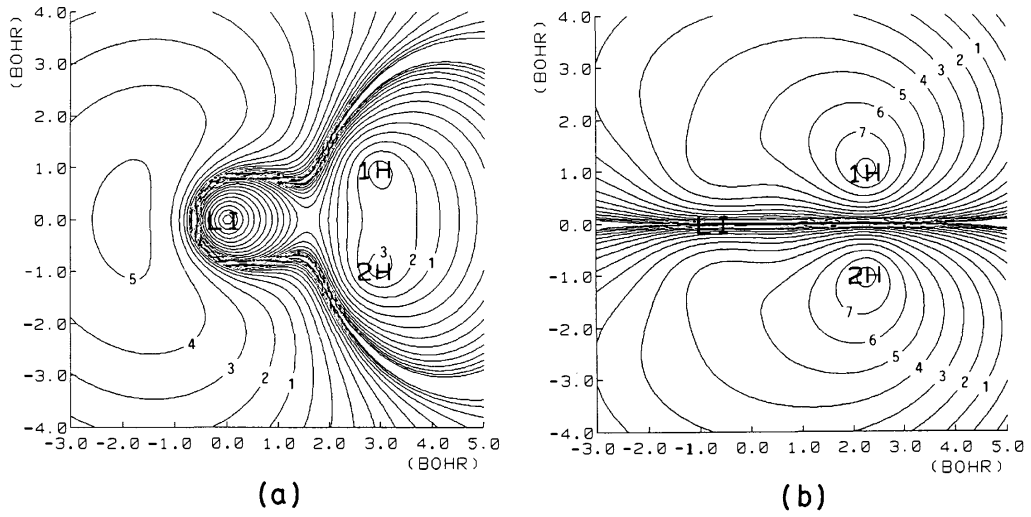

Fig. 5. Contour plots of 3a' natural orbital electron density maps at P (a) the $\tilde{X}^2A_1$ state obtained by conventional MCSCF and (b) $\tilde{A}^2B_2$ state obtained by OC-MCSCF. The numbers 1, 2, ···, and 7 beside the contours indicate electron density of 6.325×10^{-4}, 1.125×10^{-3}, 2.000×10^{-3}, 3.556×10^{-3}, 6.325×10^{-3}, 1.125×10^{-2}, 2.000×10^{-2} electrons bohr^{-3}, respectively.

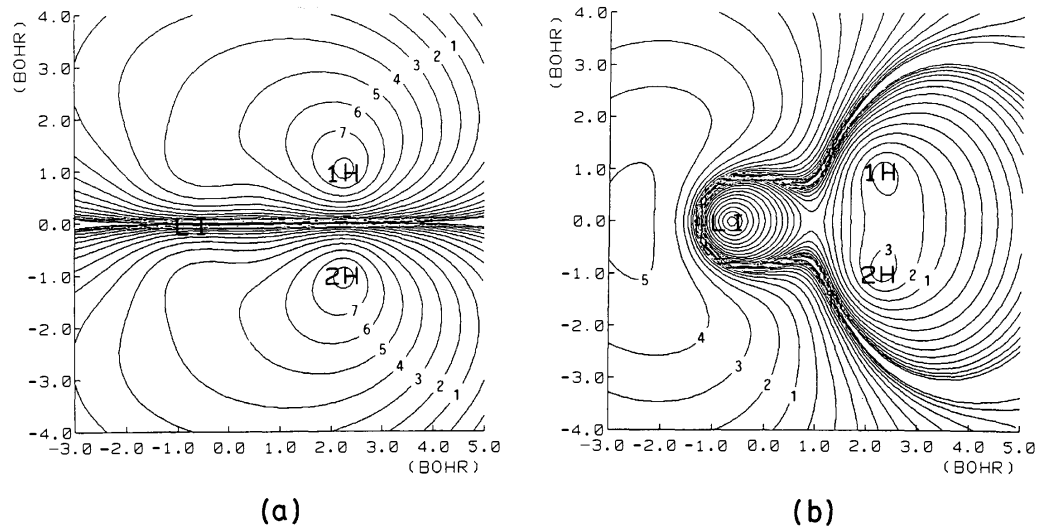

Fig. 6. Similar maps as in Fig. 5, after NCI.

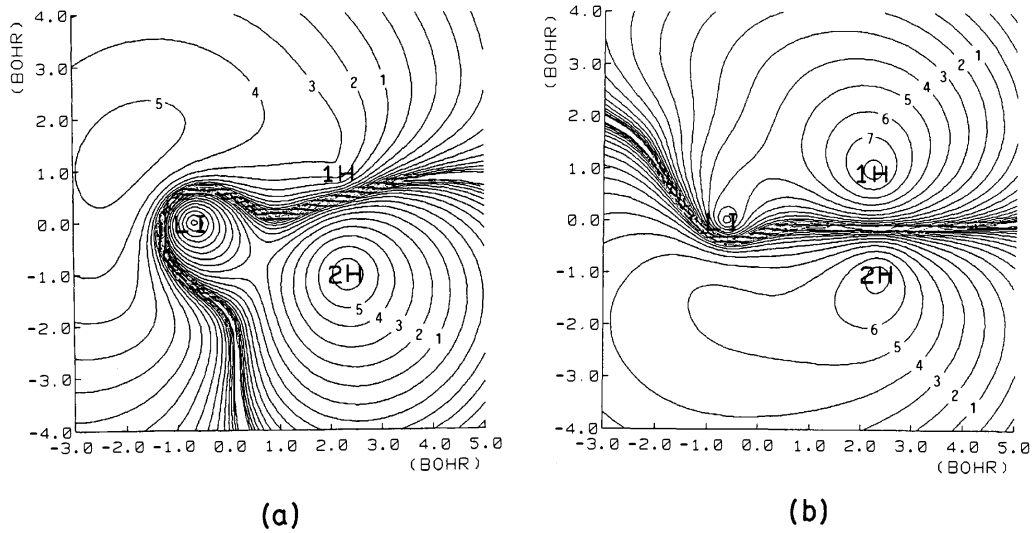

Fig. 7. Contour plots of 3a′ natural orbital electron density maps at a geometry where H_2 is rotated 4.0° from the geometry of P with $R_{Li\text{-}H_2}$ and $R_{H\text{-}H}$. (a) the $1^2A'$ state obtained by conventional MCSCF and (b) $2^2A'$ state obtained by OC-MCSCF. Figures besides contours have the same meaning as in Fig. 6.

natural orbital electron density maps of the ground and excited states are thus identical with Figs. 5(a) and (b), which show the correct symmetry of the functions.

As seen in Fig. 4, the NCI splits the energies of the almost degenerate OC-MCSCF function pair at $\theta=0°$. As a consequence, the intersection of the $^2A_1$ and $^2B_2$ curves in C_{2v} geometry shifts somewhat, as seen in Fig. 2. At the same time, we get small but definite energy improvements (cf. section 1-(1)) at the geometry.

Common to all results reported hitherto,[35,37,38] there is a minimum (at $\theta=5°$ with a depth of 4.4×10^{-3} hartree relative to $\theta=0°$) in the ground state curve, while the excited state curve increases monotonically as θ increases.

Figures 6(a) and (b) are the 3a′ natural orbital electron density maps of the pair states at $\theta=0°$ after NCI. They also show C_{2v} symmetry.†††† Figures 7(a) and (b) show similar density maps taken at $\theta=4.0°$ before NCI. It is seen that both the functions have their own unique natures widely differing from each other. It is a favorable feature for them to be the basis of the succeeding NCI step since as we are inclined to gather a maximum degree of information from the

†††† The interchange between the $^2A_1$ and $^2B_2$ state energies is due to the shift of the P point noted above.

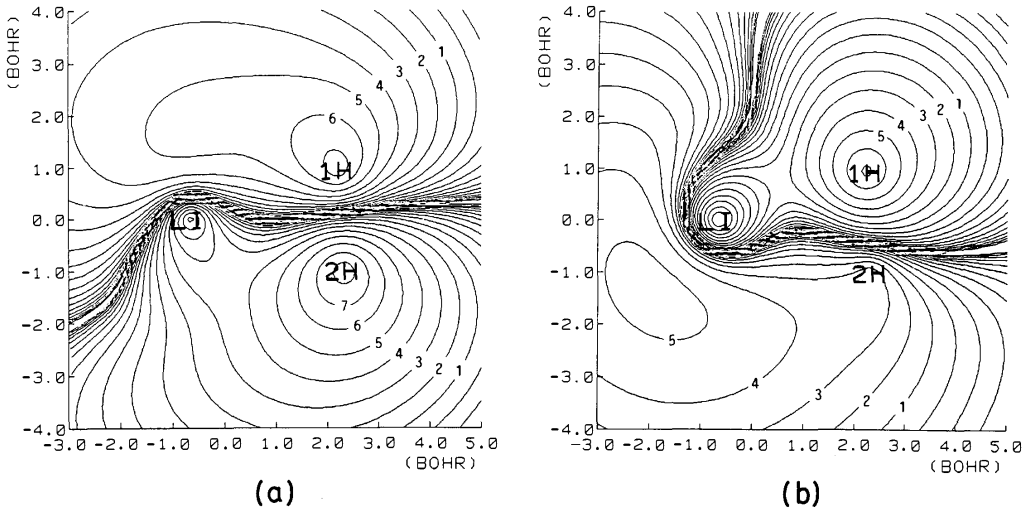

Fig. 8. Similar maps as in Fig. 7, after NCI.

primary MCSCF function of limited size to construct final functions. In this connection, Hosteny and Hagstrom[61] and Petsalakis et al.[62,63] have argued that the effect of NCI may be comparable to that of an ordinary large size CI when the two sets of CSF's differ considerably. Figures 8(a) and (b) are the maps after the NCI. The improvement by NCI of the main features of these maps had turned out not to be very significant,†††† and the features of the final function are in good agreement with those reported earlier for less quantitative calculations (minimal basis valence CAS,[33,35] minimal basis full CI,[37] and SCF+NCI[38] using the same basis set as the present one) with respect to the bonding nature of the shorter Li–H in the ground state and the bonding nature of the longer Li–H in the excited state.

In order to obtain certain cross sections of the three dimensional hypersurfaces, we carried out similar calculations starting with many geometries for the reaction coordinate of section 1-(1). Using some interpolation techniques, these results were combined to give two sheets of potential energy surfaces. Figure 9 is a computer graphical representation of these surfaces. The outlook of these surfaces is very much the same as reported earlier,[35] but it is now more quantitative.

Conclusion

In summary, the OC-MCSCF and the additional NCI procedure described in this and the preceding paper provide an effective means of constructing excited state MCSCF functions and of the corresponding ground state functions in geometries where their potential energy surface fall close to each other or even cross with each other. The potential energy surfaces and the functions themselves connect continuously with the ones calculated by the ordinary MCSCF procedure outside the critical region, and no discontinuities occur between them. The excited state function is strictly orthogonal and hamiltonian orthogonal to its corresponding ground state function. The method is general, and only a little extra work over the ordinary method is required in constructing the second order transition density matrix. Further, by extension of the size of NCI, the method may give us unified MCSCF functions and potential surfaces which are good throughout a wide range of geometries, not restricted to the nonadiabatic region. The geometrical symmetries of the wave functions tested for the present special case seem to be reasonable.

Conclusions reported in earlier papers concerning

†††† The apparent interchange between the characteristics of $1^2A'$ and $2^2A'$ maps is for the same reason as given in the footnote.††††

the behavior of wave functions of the Li-H_2 system in the nonadiabaic region have been reconfirmed in the present more quantitative calculations.

The authors wish to thank Professor Keiji Morokuma of the Institute for Molecular Science and Dr. Shigeki Kato of the University of Tokyo. The calculations were carried out at the Computer Center of the IMS, Okazaki National Research Institutes, at the Computer Center of the University of Tokyo, and at the Information Science Research Center of Aoyama Gakuin University.

(Received February 16, 1989)

Stabilization of ZnO photoanodes was investigated using ZnO thin film electrodes under controlled potential in various pH solutions; the effects of light intensity and agitation were also studied. The photocorrosion of ZnO photoanodes was suppressed at sufficiently cathodic potentials and/or at low light intensity. Agitation of solution also suppressed photocorrosion. On the basis of the experimental results, the mechanism of the stabilization in high pH solutions is discussed and a model is proposed.

Zinc oxide (ZnO) is one of the most popular semiconductor photoelectrodes. Although it shows a large anodic photocurrent, it has been difficult to use ZnO for solar energy conversion[1] or photoelectrochemical synthesis[2-4] because of its photocorrosion.[5-10] We recently showed that ZnO photoanodes could be stabilized in high pH solutions,[11,12] but the mechanism of the stabilization still remains unknown. On the other hand, the photocorrosion of ZnO can be used for other applications such as imaging systems,[13] and micro-processing of ZnO for optoelectric devices.[14,15] In these systems, it is necessary to control film thickness, and therefore speed of the photocorrosion, during the photoetching process. Thus it is still important to understand the details of the mechanism of the photocorrosion of ZnO photoelectrodes. In the present work we studied the effects of pH of the solution, electrode potential, light intensity, and agitation of the solution on the photocorrosion of ZnO photoelectrode. We have developed a new simple technique for monitoring the dissolution of ZnO electrode. ZnO thin films on transparent SnO_2-coated glass were used as photoelectrodes. A change in thickness of the ZnO film was detected by observing a change in interference colors. In addition, the surface morphology could be monitored with a scanning electron microscope. The experimental results are explained in terms of competition between the photocorrosion of ZnO and the oxidation of hydroxide ion in the electrolyte solution.

Experimental

A ZnO thin film was deposited onto a SnO_2-coated glass (Asahi Glass Co., Ltd.) by a spray-pyrolysis technique.[16] Figure 1 shows the structure of the ZnO film electrode. The thickness of the film was estimated to be 200±20 nm. X-Ray diffraction analyses showed that the c-axis was oriented vertically to the surface. The photocorrosion of ZnO was investigated under a controlled bias in a solution of $NaClO_4$ (0.2 mol dm^{-3}) containing an adequate amount of NaOH for pH control. A He-Cd laser (Kinmon Denki Co., Ltd. wavelength 325 nm, output 8 mW) was used as a light source; the diameter of the light beam was controlled with a quartz lens so that the incident photon flux was maintained constant.

The amount of charge passed, C, which resulted in the dissolution of the irradiated spot of the ZnO films, can be calculated as follows:

$$C = \frac{\pi \cdot r^2 \cdot d \cdot D \cdot n \cdot F}{4 \cdot M} \quad (1)$$

Here r is beam diameter, d thickness of the films, D the specific gravity of ZnO, n number of electrons transferred, F the Faraday constant, and M formular weight of ZnO. For $n=2$, $r=1.2\pm0.1$ mm, and $d=200\pm20$ nm, C is 2—4 mC. However, the photocurrent from SnO_2 must be taken into account as a background. Thus, characterization of the electrode surface was carried out after a charge of 5 mC was passed, which took several minutes under the present conditions.

The relation between the interference color and the thickness of the film can be written as follows

$$4 \cdot n \cdot d = (2 \cdot M + 1) \cdot \lambda \quad (2)$$

Here, d is the thickness of the film, n the refractive index of

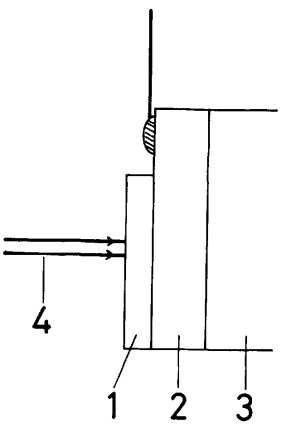

Fig. 1. The structure of the ZnO film electrode. 1: ZnO film, 2: SnO_2 layer, 3: glass substrate, 4: laser beam.

ZnO, λ the wave length of the interference light, and M an integral constant. Since the refractive index of ZnO is about 2.0, $\lambda=8\cdot d$ when $M=0$, and a change in λ of ca. 40—50 nm can be detected by the observation with naked eyes. Thus a thickness change of 5 nm could be easily detected. When the interference color of the irradiated spot was the same as that of the substrate SnO_2 film, it was judged that the ZnO film had completely been removed. When there was no change in the interference color after the irradiation, it was regarded that photocorrosion did not occur. Between these two cases, it was concluded that incomplete photocorrosion had occurred.

Results

Figure 2 shows the typical current-time curves for the following three cases; no ptotocorrosion, incomplete photocorrosion and complete photocorrosion. Since the power of the light beam was 8 mW and the irradiated area was 1.3 ± 10^{-2} cm^2, the light intensity was calculated to be 0.6 W cm^{-2}. The quantum efficiency of the ZnO photoelectrodes used here is 40—70% in ordinary circumstances. However, the total quantum efficiency was decreased to 10—20% under these experimental conditions, because the light intensity was so high that the recombination of the carrier occurred. In addition, I_{ph} was not saturated at the potential regions employed here. Thus, it is reasonable that the I_{ph} values observed here were smaller than that expected from the amount of incident photons. When the photocorrosion did not occur (Fig. 2(a)), I_{ph} was almost constant. Figure 2(b) corresponds to the cases with incomplete photocorrosion. I_{ph} initially showed a large decrease and then became almost constant. These two results imply that reaction other than photocorrosion takes place at the electrode surface. This reaction is the oxidation of OH^- ions to gaseous oxygen. However, we could not visually detect gas evolution because of the small photocurrent. Figure 2(c) shows the case of complete photocorrosion; I_{ph} exhibited a large decrease after an initial small increase. The photocorrosion roughens the electrode surface, and thus increases the surface area. This is the reason why I_{ph} increases at first. The thickness of the ZnO film decreases with the occurrence of photocorrosion, and consequently I_{ph} decreases. A small constant I_{ph} is probably due to I_{ph} from the SnO_2 substrate.

It was found that pH of the solution, electrode

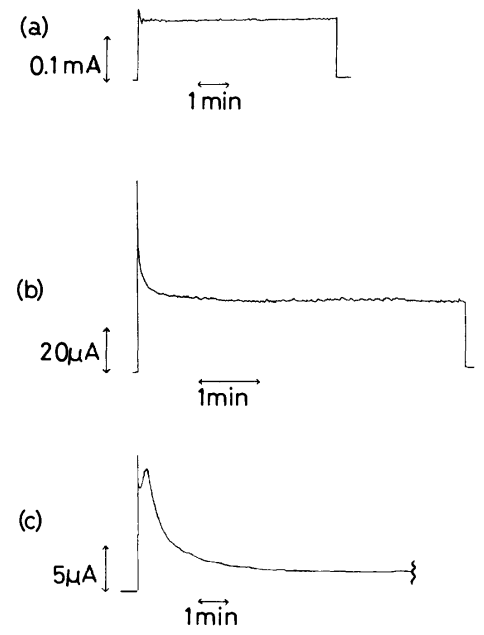

Fig. 2. Typical current-time curves: light intensity 0.6 W cm^{-2}. (a) pH 13, −0.3 V vs. SCE: no photocorrosion. (b) pH 12, −0.1 V vs. SCE: incomplete photocorrosion. (c) pH 11, 0.0 V vs. SCE: complete photocorrosion.

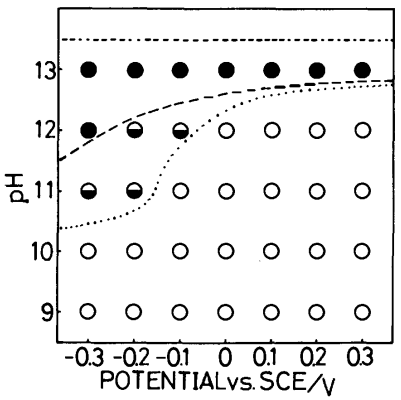

Fig. 3. Summary of the effects of pH and potential. ○: complete photocorrosion. ◒: incomplete photocorrosion. ●: no photocorrosion.

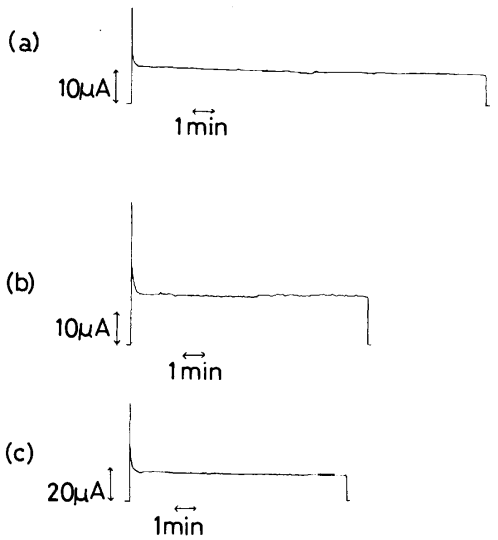

Fig. 4. Photocurrent-time curve in a pH 12 solution, light intensity 0.6 W cm^{-2}. (a) potential −0.3 V vs. SCE. (b) potential −0.2 V vs. SCE. (c) potential −0.1 V vs. SCE.

potential, light intensity and agitation of the solution affected the photocorrosion of ZnO. The effects of the electrode potential and pH of the solution are summarized in Fig. 3 (light intensity 0.6 W cm^{-2}, in stationary solution). The effect of electrode potential was apparent in the region near 0 V vs. SCE. The I_{ph} increases with the electrode potential in this potential region. From pH 7 to 10, the photocorrosion was observed for all the applied potentials. The photocorrosion was incomplete at −0.3 V vs. SCE for pH 11 and at −0.2 to −0.1 V vs. SCE for pH 12. The photocorrosion was not observed at −0.3 V vs. SCE for pH 12 and in the potential region from −0.3 to −0.8 V vs. SCE for pH 13.

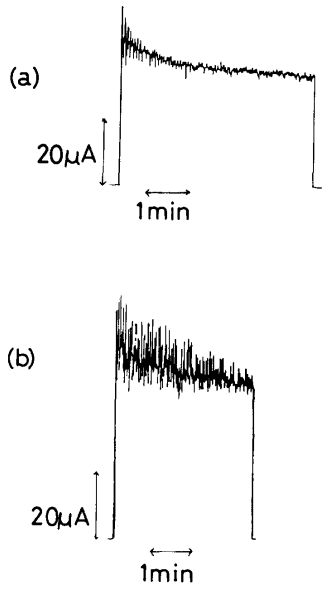

Fig. 5. Photocurrent-time curve in an agitated solution, pH 12, light intensity 0.6 W cm^{-2}. (a) potential −0.1 V vs. SCE. (b) potential 0.0 V vs. SCE.

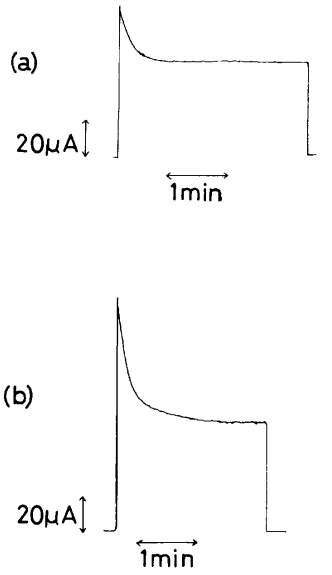

Fig. 6. Photocurrent-time curve in pH 12 solution, light intensity 0.1 W cm^{-2}. (a) Potential −0.1 V vs. SCE. (b) Potential 0.0 V vs. SCE.

The effects of agitation and light intensity are shown in Figs. 4—6. Photocorrosion was observed in a stationary solution of pH 12 when the light intensity was 0.6 W cm^{-2} and the electrode potential was −0.1 V vs. SCE (Fig. 4(c)), but it was not observed when the solution was agitated (Fig. 5(a)) or when the light intensity was 0.1 W cm^{-2} (Fig. 6(a)).

Discussion

Here we consider the competition reaction between the photocorrosion and the oxidation of OH^- ions in order to explain the experimental results observed. The photocorrosion of ZnO and the oxidation of OH^- can be summarized by Eqs. 3—8.

$$ZnO + h\nu \longrightarrow ZnO + p^+ + e^- \tag{3}$$

$$ZnO + 2p^+ \longrightarrow Zn^{2+} + \cdot O \quad \text{(slow)} \tag{4}$$

$$OH^- + p^+ \longrightarrow \cdot OH \quad \text{(slow)} \tag{5}$$

$$Zn^{2+} + nH_2O \longrightarrow Zn^{2+}(H_2O)_n \quad \text{(fast)} \tag{6}$$

$$2\cdot O \longrightarrow O_2 \quad \text{(fast)} \tag{7}$$

$$2\cdot OH \longrightarrow H_2O + 1/2O_2 \quad \text{(fast)} \tag{8}$$

We did not consider the chemical dissolution of ZnO which takes place at extremely high pH and low pH. The rate-determining step of the photocorrosion is given by Eq. 4 and that of the oxidation of OH^- by Eq. 5. Now, we write the rate of the reaction (4) as V_1 and that of the reaction (5) as V_2. According to this model, the current efficiency of the ZnO decomposition, C_d becomes as follows,

$$C_d = \frac{V_1}{V_1 + V_2} \tag{9}$$

The steady state is attained with respect to the surface concentrations of OH^- ion and p^+ when the photocurrent is constant with time. These conditions are satisfied when the thickness of the ZnO films is sufficiently larger than that of the space charge layer, or when the photocorrosion does not occur. The following relations hold under the steady state;

$$I_p = V_1 + V_2 \tag{10}$$

$$f = V_2 \tag{11}$$

Here I_p and f denote the photocurrent density and the current density induced by the flux of OH^- ion, respectively. We obtain the following equation by using Eqs. 9—11.

$$C_d = \frac{I_p - f}{I_p}$$

$$= 1 - \frac{f}{I_p} \quad (12)$$

This analysis shows that C_d is determined by I_p and f. I_p is a function of the electrode potential and the light intensity. The flux f is a function of the thickness of the diffusion layer (d), concentration of OH^- ion in bulk ($[OH^-]_b$) and at surface ($[OH^-]_s$). The conditions where the photocorrosion does not occur, that is, $C_d=0$ can be realized when $I_p=f$. When diffusion along the surface is neglected, f can be approximately expressed as

$$f = \frac{D}{d} \cdot F \cdot ([OH^-]_b - [OH^-]_s) \quad (13)$$

Here D is the diffusion coefficient of OH^- ions, F the Faraday constant. We write the f as f_{max} when $[OH^-]_s$ is zero. Under the conditions where d and $[OH^-]_s$ are constant, f_{max} is constant. When I_p is equal or smaller than f_{max}, $I_p=f$ is approximately realized, and consequently C_d becomes zero. When I_p is larger than f_{max}, $I_p=f$ cannot be realized then $C_d=1-f_{max}/I_p>0$, and photocorrosion occurs.

From the experimental results, we can make a quantitative analysis. The diffusion coefficient of OH^- ion, D, was estimated from the molar conductivity, to be ca. 3×10^{-5} cm^2 s^{-2}. The thickness of diffusion layer, d, can be estimated from the time needed for the photocurrent to become constant. It was ca. 3×10^{-3} cm when the light intensity was 0.6 W cm^{-2} for pH 12 ($[OH^-]_b=1\times10^{-2}$ mol l^{-1}), and photocorrosion was not observed. Under this condition, f_{max} becomes ca. 1×10^{-3} A cm^{-2}. We can compare this estimation with the results of Figs. 4(a) and 4(b). Photocorrosion was not observed for Fig. 4(a) where $I_p=8.8\times10^{-4}$ A cm^{-2}, and photocorrosion was observed for Fig. 4(b) where $I_p=1.2\times10^{-3}$ A cm^{-2}. These results support our competition model.

In an agitated solution of pH 12 (Fig. 5), photocorrosion was not observed even when I_p was 3.0×10^{-3} A cm^{-2} (Fig. 5(a)), but was observed when I_p was 4.2×10^{-3} A cm^{-2} (Fig. 5(b)). This result shows that the f_{max} value was 3—4 times larger than that in a stationary solution. This is because d was decreased by the agitation.

In the case where the light intensity was 0.1 W cm^{-2}, photocorrosion did not occur when I_p was 6.6×10^{-4} A cm^{-2} (Fig. 6(a)), but was observed when I_p was 8.8×10^{-4} A cm^{-2} (Fig. 6(b)). From the time needed for the photocurrent to become constant, d was estimated to be 4×10^{-2} cm, and f_{max} was calculated to be 7×10^{-4} A cm^{-2}. This f_{max} value is smaller than that estimated from Figs. 4(a) and 4(b). In the potential region employed in these experiments, the photocurrent was not saturated, so a large part of the energy of the incident photons was converted into heat. Thus, there was heat convection around the irradiated spot. In a stationary solution, this heat convection reduces the thickness of the diffusion layer. Thus when the light intensity is large, heat convection will be intense and the thickness of the diffusion layer will be small. Hence f_{max} for the light intensity of 0.1 W cm^{-2} became smaller than that for the light intensity of 0.6 W cm^{-2}.

Conclusion

Photocorrosion of ZnO is suppressed when the concentration of OH^- ion at the surface is large or when the concentration of p^+ at the surface is small. These results can be explained in terms of competition reaction between the oxidation of OH^- ion and the photocorrosion of ZnO.

We would like to thank Professor B. H. Loo for his kind advice and appreciate financial support from the Ministry of Education, Science and Culture, Grant-in-Aid.

The Phase Transition of Quaternary Fluoroalkyl Halide Salts of 1,4-Diazabicyclo[2.2.2]octane

Tohru TERADA, Takashi NOGAMI,* and Yasuhiko SHIROTA
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565
(Received April 3, 1989)

The solid-solid phase transition of quaternary halide salts of 1,4-diazabicyclo[2.2.2]octane (DABCO) was investigated by DSC, Raman spectroscopies, and the measurements of the ionic conductivity of the halide anions. The DABCO salts studied are classified into two; one is the salt possessing both fluoroalkyl and alkyl groups, and the other the ones possessing the same fluoroalkyl groups at both ends of the molecule. The former molecule exhibited a gradual increase of the ionic conductivity above the transition temperature. The ionic conductivity of the former molecule was higher than that of the latter molecules and the symmetric quaternary alkyl halide salts of DABCO. These facts were explained by a spacer effect of the fluoroalkyl group. The temperature dependence of the Raman spectra of the former salt established that the fluoroalkyl group was much more rigid than the alkyl group, and that the molecular movement took place mainly at the alkyl group and the DABCO portion in the high temperature phase. One of the latter type of molecules exhibited a conductivity jump around the transition temperature.

The phase transition of a series of quaternary alkyl halide salts of 1,4-diazabicyclo[2.2.2]octane (DABCO) was investigated by DSC, IR and Raman spectroscopies, NMR, and the measurements of the ionic conductivities of halide anions.[1-8] The phase transition of the quaternary DABCO salts containing tetrafluoroborate anion has also been reported recently.[9] These materials exhibit conformational change of the alkyl group in the high temperature phase in the solid. A conductivity jump of the halide anion was observed by up to three orders of magnitude around the transition temperature. These materials also showed the disappearance of optical anisotropy in the high temperature phase, and in some cases they remained in a metastable state after having been heated above the transition temperature and then cooled to room temperature. These switching properties of the ionic conductivities[10] and optical and thermodynamic properties may be applicable to some temperature and memory devices.

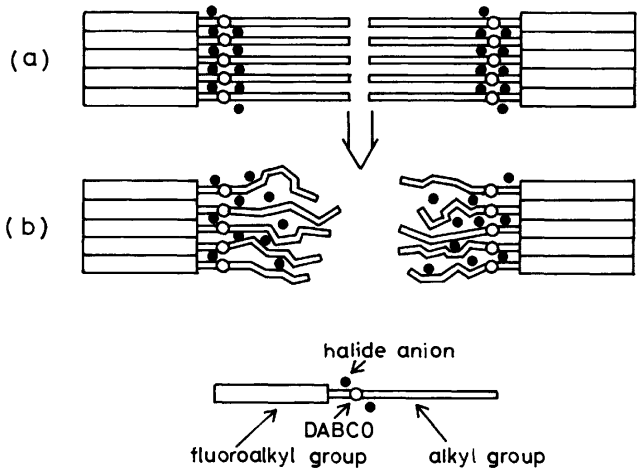

Fig. 1. Schematic drawing of the proposed molecular arrangement, spacer effect, and molecular motion of C_n^F-DABCO-C_n-X_2 in a solid. (a) Low temperature phase, (b) high temperature phase.

A variety of amphipatic materials containing both long alkyl and fluoroalkyl chains as hydrophobic parts were synthesized, and their physicochemical properties investigated.[11] These studies established that the fluoroalkyl and alkyl groups tend to separate from each other in the solid; in other words, the fluoroalkyl chains arrange parallel to one another, and so do the alkyl chains.[12] In general, the fluoroalkyl chain forms a helical structure, and the fluorine atoms surround the C-C backbone.[13] The structural difference of the fluoroalkyl chain from the alkyl chain results in the more rigid structure of the former chain than of the latter. Moreover, the fluoroalkyl group is bulkier than the alkyl group. Thus, the quaternary halide salt of DABCO containing both the fluoroalkyl and the alkyl groups (C_n^F-DABCO-C_n-X_2) may possess the molecular arrangement shown schematically in Fig. 1(a). The bulkier fluoroalkyl groups function as spacers in the solid, so that the less bulky alkyl groups may move relatively freely in the high temperature phase (Fig. 1(b)). On the other hand, the molecular motion of the alkyl group may be retarded in the case

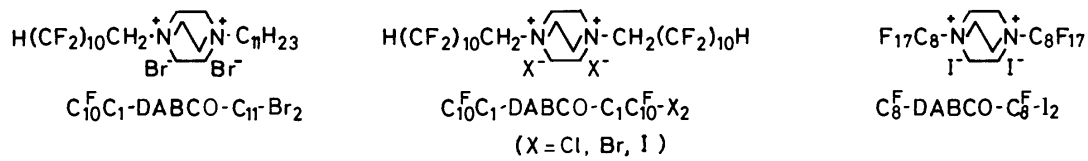

Fig. 2. Quaternary DABCO halide salts.

of the DABCO salts possessing two alkyl groups at both sides of the molecule (C_n-DABCO-C_n-X_2) because of the closed-packed molecular arrangements. Thus, C_n^F-DABCO-C_n-X_2 may show higher halide anion conductivity than C_n-DABCO-C_n-X_2. We are also interested in the difference of the molecular motion between the alkyl and fluoroalkyl groups in the solid. Bearing these assumptions in mind, we have synthesized the two types of quaternary DABCO halide salts shown in Fig. 2; one is a quaternary DABCO bromide salt containing both fluoroalkyl and alkyl groups in the molecule, and the other the symmetric quaternary DABCO halide salts containing two fluoroalkyl groups in the molecule. The names of the molecules in Fig. 2 are abbreviated to $C_{10}^F C_1$-DABCO-C_{11}-Br_2, $C_{10}^F C_1$-DABCO-$C_1 C_{10}^F$-X_2 (X=Cl, Br, I), and C_8^F-DABCO-C_8^F-I_2.

Experimental

$C_{10}^F C_1$-DABCO-C_{11}-Br_2. $H(CF_2)_{10}CH_2OH$ (1.2 g, 2.3 mmol) was dissolved in benzene (50 cm^3) containing several drops of pyridine, and thionyl bromide (0.5 g, 2.4 mmol) wad added dropwise to this solution at 0 °C. The solution was heated gradually to 60 °C, stirred for 8 h at this temperature, and allowed to cool to room temperature. The solvent was distilled out using an evaporator, and the residual white powder was recrystallized from a mixed solvent of benzene and hexane to obtain $H(CF_2)_{10}CH_2Br$ (0.54 g, 40%). Quaternary undecylbromide salt of DABCO (C_{11}-DABCO-Br)[3] (0.7 g) and $H(CF_2)_{10}CH_2Br$ (1.2 g) so obtained were dissolved in benzene (50 cm^3) and the solution was stirred for 24 h at 60 °C, and then cooled by ice. The precipitate was collected, and recrystallized from benzene (22% yield, 0.41 g).

$C_{10}^F C_1$-DABCO-$C_1 C_{10}^F$-Cl_2. $H(CF_2)_{10}CH_2Cl$ was obtained (62% yield) by the same method as the synthesis of $H(CF_2)_{10}CH_2Br$. Thionyl chloride was used instead of thionyl bromide. DABCO (0.06 g, 0.5 mmol) and $H(CF_2)_{10}CH_2Cl$ (0.6 g, 1.1 mmol) were dissolved in benzene (50 cm^3) and the solution was stirred for 12 h at 60 °C. Subsequently the same procedure as that described for the synthesis of $C_{10}^F C_1$-DABCO-C_{11}-Br_2 was adopted (75% yield, 0.49 g).

$C_{10}^F C_1$-DABCO-$C_1 C_{10}^F$-Br_2. This was synthesized by the same method as that described for the corresponding chloride salt (73% yield).

$C_{10}^F C_1$-DABCO-$C_1 C_{10}^F$-I_2. $H(CF_2)_{10}CH_2Cl$ (1.2 g, 2.2 mmol), DABCO (0.12 g, 1.1 mmol), and potassium iodide (2 g, 20 mmol) was dissolved in the mixed solvent of ethanol and water (1:1, 50 cm^3), and the solution was refluxed for 12 h. The precipitate was collected, and recrystallized from benzene (68% yield, 1.0 g).

C_8^F-DABCO-C_8^F-I_2. The ethanol solution (50 cm^3) of $C_8F_{17}I$ (1.2 g, 2.2 mmol) and DABCO (0.12 g, 1.1 mmol) was stirred for 6 h at room temperature.[14] The solution was then cooled by ice to yield a white precipitate. It was collected, and recrystallized from benzene (82% yield, 1.08 g).

Measurements. DSC, and ionic conductivities were measured by the methods described previously.[2] The temperature dependence of the Raman spectra was measured by the method described previously.[7] R-500 Laser Spectrometer (Japan Spectroscopic Co., Ltd.) was used as a monochromator, and a GLS/GLG argon ion laser (514.5 nm) (Nippon Electric Co., Ltd.) as an excitation source. Since all of the materials were unstable above ca. 40 °C in air, all of the measurements were made in a sealed cell under nitrogen atmosphere.

Results and Discussion

DSC Measurements of $C_{10}^F C_1$-DABCO-C_{11}-Br_2. Figure 3 shows the DSC curve of $C_{10}^F C_1$-DABCO-C_{11}-Br_2 measured with a scan rate of 5 °C min^{-1}. It showed an endothermic signal at 38 °C (extrapolated onset temperature) when heated from room temperature. When the sample was cooled after having been heated above 50 °C, a much broader exothermic signal was observed. The succeeding heating/cooling cycles gave signals almost identical with those of Fig. 3. Thus, a phase transition occurred at 38 °C, and the initial low temperature phase recovered gradually when the temperature was lowered from the high temperature phase to room temperature. The transition temperature (T_c), transition enthalpy (ΔH), and transition entropy ($\Delta S=\Delta H/T_c$) are shown in Table 1. This material decomposed at 83 °C in an inert atmosphere. This is a much lower decomposition temperature than that of the corresponding C_{11}-DABCO-C_{11}-Br_2.[2] It may be caused by the weak C-N bond energy between DABCO-nitrogen and the fluoroalkyl carbon due to the inductive effect of the fluoroalkyl group.[14]

Ionic Conductivities of $C_{10}^F C_1$-DABCO-C_{11}-Br_2. The temperature dependence of the ionic conductivities of $C_{10}^F C_1$-DABCO-C_{11}-Br_2 was measured for a compressed pellet sample by an AC impedance method,[2] in order to see the effect of the phase transition on the ionic conductivities. This type of quaternary DABCO-halide salt was found to be a halide anion conductor by the fact that the ionic conductivity did not change at all on applying a DC current if the halide anions were injected from the electrode.[1] Figure 4 shows the plot of the ionic conductivity of $C_{10}^F C_1$-DABCO-C_{11}-Br_2 against the

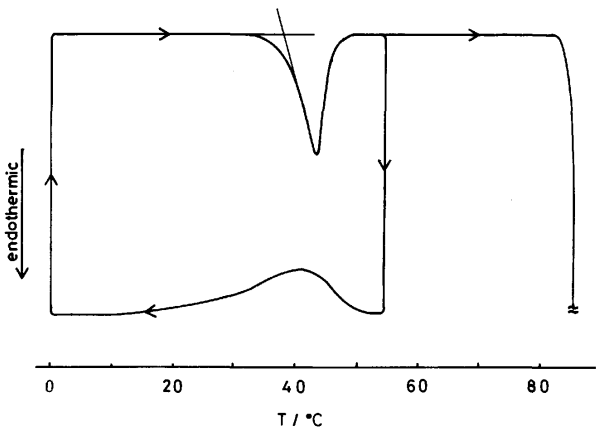

Fig. 3. DSC thermogram of $C_{10}^F C_1$-DABCO-C_{11}-Br_2.

Table 1. Materials, Transition Temperatures (T_c), Transition Enthalpies (ΔH), Transition Entropies (ΔS), and Ratios of Halide Anion Conductivities (σ_h/σ_l) Below and Above Transition Temperatures

Materials	T_c	ΔH	ΔS	σ_h/σ_l
	°C	kJ mol^{-1}	J mol^{-1} K^{-1}	
$C^F_{10}C_1$-DABCO-C_{11}-Br_2	38	38.3	123	a)
$C^F_{10}C_1$-DABCO-$C_1C^F_{10}$-Cl_2	63	109.6	326	120
$C^F_{10}C_1$-DABCO-$C_1C^F_{10}$-Br_2	93	47.5	130	b)
$C^F_{10}C_1$-DABCO-$C_1C^F_{10}$-I_2	96	51.0	138	b)
C^F_8-DABCO-C^F_8-I_2	89	58.3	161	c)

a) Since a gradual increase in the ionic conductivity was observed above the transition temperature, it was difficult to estimate the value of the conductivity jump. b) No conductivity jump was observed. c) Because of the decomposition of the material at a few degrees above the transition temperature, the σ_h/σ_l value could not be estimated.

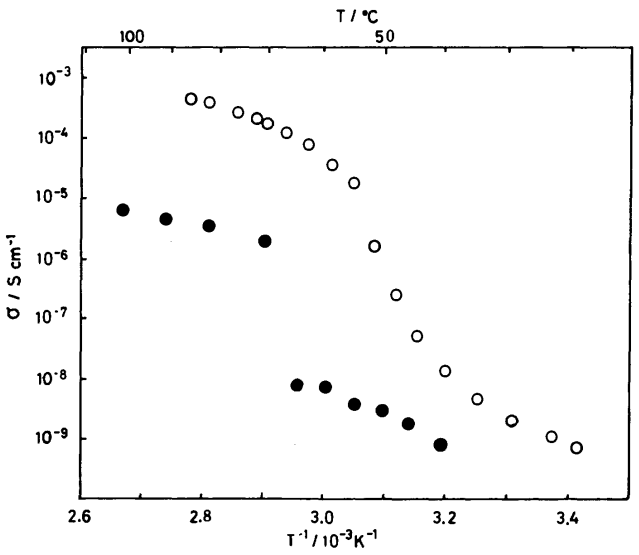

Fig. 4. Temperature dependence of the ionic conductivities of bromide anion. ○ $C^F_{10}C_1$-DABCO-C_{11}-Br_2, ● C_{11}-DABCO-C_{11}-Br_2.

reciprocal temperature. This figure also shows the same plot of C_{11}-DABCO-C_{11}-Br_2 (transition temperature=72 °C[2]) for the sake of comparison. The bromide anion conductivities of $C^F_{10}C_1$-DABCO-C_{11}-Br_2 were always higher than those of C_{11}-DABCO-C_{11}-Br_2, probably due to the spacer effect of the fluoroalkyl group as described in the Introduction (see also Fig. 1). The ionic conductivity of the former material approached to 10^{-3} S cm^{-1} in the high temperature phase, and this value was higher by about two orders of magnitude than those of the symmetric DABCO salts, C_n-DABCO-C_n-Br_2 ($10 \leqq n \leqq 22$).[2] The temperature dependence of the ionic conductivity of $C^F_{10}C_1$-DABCO-C_{11}-Br_2 was different from that of C_{11}-DABCO-C_{11}-Br_2; the latter material showed a conductivity jump by a factor of 630 around the transition temperature.[2] On the other hand, the former material did not show a conductivity jump, but showed a gradual increase of the ionic conductivity in the range of 40—60 °C, which was initiated by the phase transition at 38 °C. These results are explained as follows. In the case of C_{11}-DABCO-C_{11}-Br_2, the alkyl group could not move vigorously due to the closed-packed molecular arrangement in the low temperature phase. When the sample was heated to the transition temperature, the movement of the alkyl chain was released suddenly to give rise to the conductivity jump. On the other hand, the movement of the alkyl chain of $C^F_{10}C_1$-DABCO-C_{11}-Br_2 could be excited more easily due to the spacer effect of the fluoroalkyl group (Fig. 1). Thus, the gradual increase of the ionic conductivity was caused by a facile excitation of the movement of the alkyl group with the elevation of the temperature. This assumption was confirmed by Raman spectroscopy (vide infra).

Raman Spectroscopy of $C^F_{10}C_1$-DABCO-C_{11}-Br_2. Generally, Raman and IR bands broaden as the amount of the thermal motion increases in the solid.[15] In order to clarify the molecular motion in more detail and to relate it to the results of DSC and the measurements of the ionic conductivities, Raman spectra of $C^F_{10}C_1$-DABCO-C_{11}-Br_2 were measured in the low (13 °C) and high (65 °C) temperature phases (Fig. 5). Since the band at 732 cm^{-1} (C-C stretching mode of the fluoroalkyl group)[16] hardly changed at both temperatures, hardly any molecular movement at the fluoroalkyl group accompanied the conformational change. This assumption was confirmed by the almost constant Raman profiles of the CF_2 stretching modes, (1308, 1360, and 1372 cm^{-1}).[16] Slight line broadning was observed at 65 °C for the Raman bands of the CF_2 vibrational modes (306 and 385 cm^{-1}),[16] which indicates that a rotational movement of the fluoroalkyl group was excited to some extent in the high temperature phase.

In contrast to the small change of the Raman bands of the CF_2 vibrational modes, the Raman bands at 1064 and 1132 cm^{-1} (skeltal vibration of the alkyl group[7]) decreased their intensities appreciably in the high temperature phase. This fact suggests that vigorous motions accompany the conformational change occurring at the alkyl group in the high temperature phase.

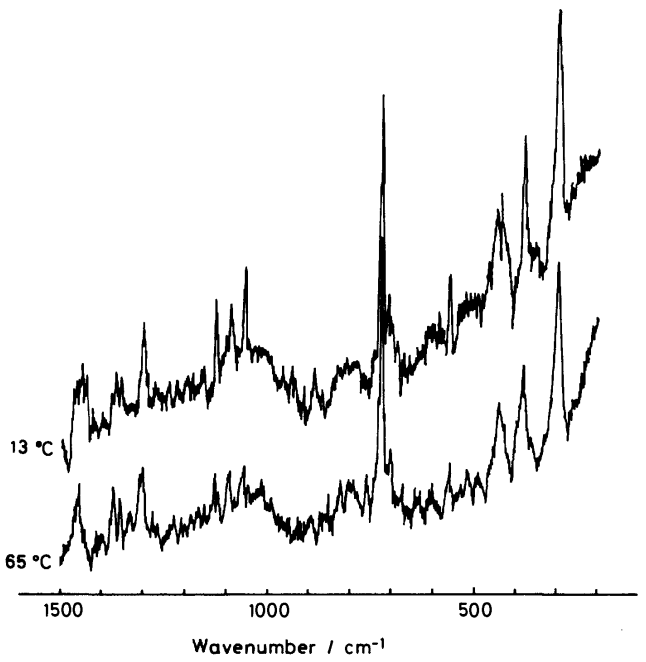

Fig. 5. Raman spectra of $C_{10}^{F}C_1$-DABCO-C_{11}-Br_2 below and above the transition temperature.

As to the Raman bands ascribable to the DABCO portion,[7] the band at 714 cm^{-1} (NC_4 symmetric stretching mode) decreased its intensity at 65 °C, and the band at 890 cm^{-1} (NC_4 degenerate stretching mode) observed in the low temperature phase disappeared almost completely at 65 °C. This suggests that the rotational movement of the DABCO portion was excited in the high temperature phase.

Summarizing the above experimental results, the molecular movement sets in mainly at the alkyl group and DABCO portion at the transition temperature. On the other hand, only a slight rotational movement seems to be excited at the fluoroalkyl group. Thus, the prediction of the molecular motion illustrated in Fig. 1 was confirmed by Raman spectroscopy.

Phase Transition of Symmetric Quaternary Fluoroalkyl Halide Salts of DABCO. The phase transitions of the symmetric quaternary fluoroalkyl halide salts of DABCO, $C_{10}^{F}C_1$-DABCO-$C_1C_{10}^{F}$-X_2 (X=Cl, Br, I), and C_8^F-DABCO-C_8^F-I_2, were also investigated by DSC, Raman spectroscopy, and the measurements of the ionic conductivities of the halide anions in order to compare them with those of $C_{10}^{F}C_1$-DABCO-C_{11}-Br_2 and C_n-DABCO-C_n-X_2. These materials showed reversible DSC signals. Table 1 summarizes the transition temperatures (T_c), transition enthalpies (ΔH), and transition entropies (ΔS) obtained by the DSC measurements in a nitrogen atmosphere. C_8^F-DABCO-C_8^F-I_2 decomposed at 93 °C, just above the transition temperature (89 °C), in an inert atmosphere. The exceptionally instability of C_8^F-DABCO-C_8^F-I_2 may be associated with a weak C-N bond energy caused by an inductive effect of fluorine atoms. Temperature dependences of the halide anion conductivities of $C_{10}^{F}C_1$-DABCO-$C_1C_{10}^{F}$-X_2 (X=Cl, Br, I) were measured, and only the chloride salt showed a conductivity jump (σ_h/σ_l) by a factor of about 120 (Table 1).[17] This value was much smaller than those observed for the corresponding symmetric quaternary alkyl halide salts of DABCO.[2] These facts suggest that the molecular motion of $C_{10}^{F}C_1$-DABCO-$C_1C_{10}^{F}$-X_2 (X=Cl, Br, I) is less vigorous than that of C_{11}-DABCO-C_{11}-X_2 (X=Cl, Br, I) in the high temperature phases. In order to confirm this, the temperature dependence of the Raman spectra of $C_{10}^{F}C_1$-DABCO-$C_1C_{10}^{F}$-Br_2 (not shown here) was measured below and above (16 °C and 103 °C) the transition temperature (93 °C). The Raman band at 732 cm^{-1} (C-C stretching of fluoroalkyl group) hardly changed for the high temperature phase. This suggests that the amount of molecular motion of the fluoroalkyl group is small even for the high temperature phase. Since the Raman intensities ascribable to the $-CH_2$-DABCO-CH_2- portion were weak, no further detailed analysis could be mode. The phase transition may be caused by the molecular motion of $-CH_2$-DABCO-CH_2- portion and/or by the change of the molecular packing in the solid. The small σ_h/σ_l values of $C_{10}^{F}C_1$-DABCO-$C_1C_{10}^{F}$-X_2 (X=Cl, Br, I) could be related to the rigid molecular structure of the fluoroalkyl group.

We are grateful to Professor Shigekazu Kusabayashi and Dr. Shunsuke Takeneka, Faculty of Engineering, Osaka University, for allowing us to use the DSC apparatus. The present work was supported by a Grant-in-Aid for Special Project Research on Chemical Sensors (No. 62217014) from the Ministry of Education, Science and Culture.

14) Symmetric quaternary alkyl halide salts of DABCO were usually synthesized by refluxing methanol solution of alkyl halide and DABCO for about 36 h. The much milder condition for the synthesis of C_8^F-DABCO-C_8^F-I_2 exemplifies that a nucleophilic attack of the lone-pair of DABCO nitrogen to the fluoroalkyl carbon takes place more easily than that to the alkyl carbon, due to the inductive effect of fluorine atoms.

On the Intrinsic Difference between Topological Aromaticity and So-Called Quasi-Aromaticity

Hiroshi ICHIKAWA,* Jun-ichi AIHARA,† and Siegfried DAEHNE††
Hoshi College of Pharmacy, Shinagawa, Tokyo 142
†Department of Chemistry, Faculty of Sciences, Shizuoka University, Shizuoka 422
††Central Institute of Physical Chemistry, Academy of Sciences of the GDR,
1199 Berlin-Adlershof, Rudower Chaussee 5, GDR
(Received April 6, 1989)

In an attempt to understand the intrinsic difference between topological aromaticity and so-called quasi-aromaticity, the authors examined the potential energy and the kinetic energy of electrons in 6-π-acyclic polymethine-like molecules (**5**—**7**), benzene (**8**), and hexatriene (**9**) as a reference structure. Protonation interrupts π conjugation; the energetic difference from the non-protonated structure depends on the conjugative stabilization energy. Such a difference from the reference system corresponds to extra stabilization. Analysis of this difference showed that benzene increases the kinetic energy by interrupting its conjugation more than hexatriene while polymethine-like molecules increase the potential energy by doing so. This indicates that extra stabilizaion in benzene is produced by lowering the kinetic energy of electrons. In marked contrast with this that in polymethine-like molecules is due to lowering the potential energy. Analogous results were obtained in the ten-π-electron systems (**10**—**13**). The authors discussed the inappropriateness of the term "quasi-aromatic" for polymethinic resonance stabilization.

Aromatic compounds have been characterized by the tendency to undergo substitution reactions.[1] Such a characteristic is really applicable to many cyclic conjugated compounds and has been studied topologically[2] as well as by a variety of molecular orbital methods.[3-5] Atoms are arranged in an aromatic compound in such a manner that they induce an appreciable amount of so-called topological resonance energy. This kind of aromaticity will be referred to as topological aromaticity.

It is noteworthy that substitution reactions take place not only in many cyclic but also in some acyclic systems, e.g. some of which not only undergo very easily electrophilic substitution but also nucleophilic substitution followed by a cleavage of the C-C bond.[6] Lloyd and Marshall proposed that molecules should be called quasi-aromatic if they are acyclic conjugated π electron systems with chemical properties typical of aromatic compounds.[7] At the same time Daehne et al. showed that conjugated chain-shaped molecules consisting of n atoms and $n\pm1$ π electrons have unique features which are not comparable to those of aromatic compounds.[8] Therefore, they introduced the term ideal polymethine state to describe the typical properties of resonance stabilized molecular chains. The quantum chemical foundation of this ideal state was given by Fabian and Hartmann.[9] Among such "quasi-aromatics" or "polymethinic" compounds are the 2,3-dihydro-1*H*-1,4-diazepinium salts (**1**),[7,10] α,ω-diazapolymethinium ions (**2**),[8a,11] and transition-metal chelates of diketones (**3**).[12] Noteworthy, however, is that extra stabilization energy scarcely arises from these systems: So-called topological resonance energy is negligible.[13] Recently, Aihara[14] as well as Klein[15] pointed out that quasi-aromatic compounds can be rationalized in terms of Gimarc's topological charge stabilization rule.[16] Our problem is what then is the intrinsic difference between topological aromaticity on the one hand and quasi-aromaticity or polymethinic resonance stabilization or "polymethinicity" on the other hand.

Theory

Molecular energy (E) consists of the electronic energy and the energy of nuclear motion. The kinetic energy of nuclear motion may be treated separately as far as the Born-Oppenheimer approximation operates.[17] Therefore, important energies are the potential energy (V) and the kinetic energy of electrons (T). Those energies can be easily obtained by the ab initio Hartree-Fock theory.

At the optimized structure the system holds the virial relationship, $V=-2T$, as far as all bond lengths, with which the geometry is determined together with bond angles, are optimized with respect to the total energy. As a matter of fact, it is not easy to obtain such a wave function without artificially scaling it. Fortunately, this is not necessary in most case, since we only need the changes of the energy components. For example, the energy difference (by an MO method with any split-valence basis set) between any two sets of geometry-optimized conformations was shown to satisfy the relationship, $\Delta V=-2\Delta T$ (the virial theorem of difference), where ΔT and ΔV are the differences of the kinetic energy and the potential energy.[18c] This shows that the virial errors caused by an inappropriate wave function are cancelled in the differences. The effectiveness of the use of these differences has been discussed in detail[18] and successfully applied in the analyses of π bond formation and conjugations between a π electron system and its substituent.

Now consider a perturbed state such that a proton is loosely put on one of the carbon atoms of the conjugated system. Such a perturbation leads to changes in the total energy and its components, where the simple virial relationship of difference no longer holds, since the system is not in the state of the optimized geometry. Our strategy is to analyze those energy changes by protonation. The basis sets adopted here are 6-31G[19] and 4-31G,[20] which are suitable for the practical analysis of such large molecular systems as those studied here.[18c]

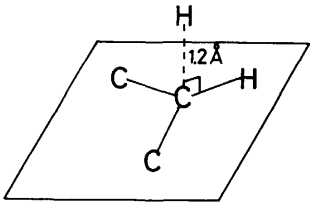
Results and Discussion

Intrinsic Difference of Resonance Stabilizations. We examined the effect of protonation on individual energy terms of π conjugated acyclic compounds (**4**—**7**, **10**, **11**) as well as benzene (**8**) and naphthalene (**12**). Protonation interrupts π conjugation; the difference from the non-protonated structure (ΔE) may depend on the resonance stabilization energy. Analysis of the energy changes in ΔE may reveal the origin of resonance stabilization. In determining the degree of resonance stabilization, e.g. topological aromaticity, of a given compound, one needs the reference structure. The reference structure is considered to have the *standard* conjugation and can be a measure of any type of π conjugation. For cyclic unsaturated hydrocarbons, the linear unsaturated hydrocarbon with the same number of double bonds has once been used as the reference structure.[4] Such a reference structure has later been replaced by a hypothetical structure constructed with bonds of an appropriate infinitely large conjugated system.[2] Although the latter reference structure is desirable, it is not applicable to the present problem. Therefore, we adopted hexatriene (**9**) and decapentaene (**12**) as the reference structures for the six-π-electron and ten-π-electron systems, respectively.

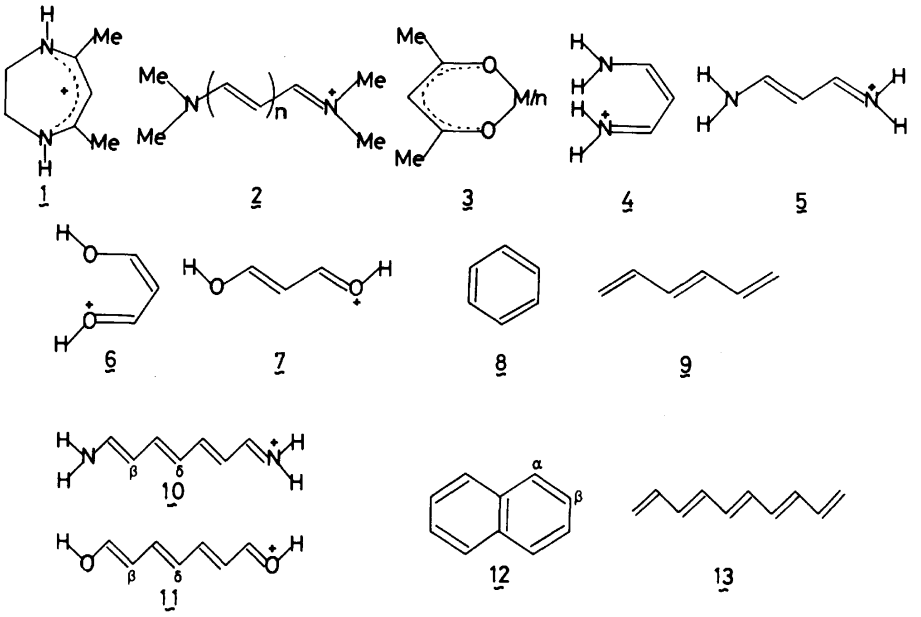
The proton can be placed at any distance from the carbon atom to give a perturbation with shorter distances leading to larger energy changes. Shown in tables are the case where proton was placed 1.2 Å vertically above a carbon atom on the molecular plane (Scheme 2).

Table 1 shows the total energy and its components in the six-π-electron systems. As for the protonated systems only the deviation from the intact systems is recorded. The last column shows the difference in energy from the reference system. In all cases protonation increases the kinetic energy and decreases the potential energy. The latter is larger, resulting in lower total energy by protonation. This is a natural consequence that reflects a localization of π electrons by a broken conjugation.

The energy difference from the reference system is important as is true for determining the degree of aromaticity. Namely, the difference from the reference system corresponds to *extra* stabilization. As shown in



Scheme 2.



Scheme 1.

the last column of Table 1, benzene increases the kinetic energy by interrupting its conjugation more than hexatriene while acyclic conjugated molecules increase the potential energy by doing so. This indicates that resonance stabilization in benzene is produced by the kinetic energy of electrons. In marked contrast with this, that in polymethine-like molecules is due to the potential energy.

Analogous results for the ten-π-electron systems are presented in Table 2. Possible sites of protonation in **10** and **11** are at β and δ carbons. In harmony with the six-π-electron systems, ten-π-electron polymethines give higher potential energy than the corresponding reference structures by protonation while naphthalene gives higher kinetic energy by protonation.

Concluding Remarks

Ichikawa and Ebisawa reported that thermodynamic stability of a topological aromatic system is given by the lowered kinetic energy of π electrons.[5c] The present results for benzene and naphthalene are in good accord with this interpretation of topological aromaticity. From the present study, we come to the conclusion that the resonance stabilization of acyclic conjugated molecules is intrinsically different from that of topological aromatics. Stabilization of topological aromatics is given by the lowered kinetic energy of π electrons whereas that of acyclic polymethine-like molecules by the potential energy. From the above reason the term "quasi-aromatic" connected with resonance-stabilized chain-shaped molecules seems to us misleading, whereas designation such as ideal polymethine state, polymethinic resonance stabilization, or "polymethinicity" much better describe the situation. We caution, however, against over-emphasizing the charge stabilization rule, because there are

Kinetics and Mechanism of the Substitution of β-Diketonates for Acetylacetonate in Bis(acetylacetonato)(trimethyl phosphate)-dioxouranium(VI)

Yoshiko UDAGAWA, Hiroshi TOMIYASU,* Woo-Sik JUNG,†
Tae Yoon EOM,† and Hiroshi FUKUTOMI††

(Received March 1, 1989)

Kinetics of the substitution of β-diketonates for one acetylacetonate in $UO_2(acac)_2tmp$ (acac= acetylacetonate, tmp=trimethyl phosphate) has been studied in tmp by spectrophotometric methods. The reactions proceed through intermediate complexes $UO_2(acac)_2HB$, where HB denotes various β-diketones. The formation of the intermediates are followed by intramolecular proton transfer processes from coordinated HB to one of two acac in $UO_2(acac)_2HB$. The proton-transfer step for various HB can be classified into two groups owing to the difference in the values of rate constants k_2, i.e. the substitutions of Hbza, Hhpd, and Hdbm and those of Hbta, Htta, and Htfa, k_2 of the former group giving the order of $10^{-3}\,s^{-1}$, while that of the latter the order of $10^{-1}\,s^{-1}$, at 25 °C, where Hbza=benzoylacetone, Hhpd=3,5-heptanedione, Hdbm=dibezoylmethane, Hbta=benzoyltrifluoroacetone, Htta=2-thenoyltrifluoroacetone, and Htfa=trifluoroacetylacetone. This can be well explained in view of the acidity of β-diketones. The addition of amphiprotic solvents, such as water and alcohols, accelerates the substitution rates, and the observed first-order rate constant k_{obsd} is expressed by $k_{obsd}=k_2+k_c[solvent]$. In the case of the addition of alcohols, k_c increases in the order: *n*-BuOH<*i*-PrOH<*n*-PrOH<EtOH<MeOH. This is the reverse order of autoprotolysis constants of these alcohols. Kinetic isotope effects k_c^H/k_c^D for the substitution of Hbza in tmp in the presence of H_2O (or D_2O) and CH_3OH (or CH_3OD) were determined to be 2.5 and 1.8, respectively.

In a previous paper,[1] we reported the kinetics of the substitution of dibenzoylmethanate for one acac in $UO_2(acac)_2L$, where L denotes dmso (dimethyl sulfoxide), dmf (*N*,*N*-dimethylformamide) and tmp, and proposed that the reaction started with the formation of an intermediate complex $UO_2(acac)_2Hdbm$, followed by a relatively slow proton-transfer process from coordinated Hdbm to acac. A similar proton-transfer process was also found to control the rates of β-diketonate exchange reactions in U(IV) and Th(IV) complexes.[2-4] However, the rates of these exchange reactions are much faster than those of β-diketonates in dioxouranium(VI) in spite of the similarity of the reaction mechanism.

This paper presents further information on the kinetics of the substitutions of various β-diketonates for acac in $UO_2(acac)_2tmp$. The reaction can be expressed by:

$$UO_2(acac)_2tmp + \beta\text{-diketone} \xrightarrow[\text{in tmp}]{} UO_2(acac)(\beta\text{-diketonato})tmp + Hacac.$$

The effect of water and alcohols on the rates of substitution and the kinetic isotope effects were also investigated. The kinetic results are compared with those of the previous paper.[1]

Experimental

The complex $UO_2(acac)_2tmp$ was synthesized by the same method as described previously.[1] Hacac and tmp were distilled under reduced pressure, and Hbza and Htta were recrystallized from ethanol and methanol, respectively, and dried under vacuum before use. Htfa, Hhpd, and Hbta were used without further purification. Methanol, ethanol, propanol, 2-propanol, and butanol were dried over 3- or 4-A Molecular Sieves. Merck 99.8 atom% deuterium oxide and 98 atom% methanol-d_1 were used. The water content of the solvent was below 5×10^{-3} M (M=mol dm^{-3}) as determined by Karl-Fisher titration after each kinetic run, and this degree of water content has no significant influence on the reaction rates.

The kinetic measurements were carried out on a JASCO UNIDEC-505 spectrophotometer with thermostated cell compartments (±0.2 °C) and 1-cm quartz cells for slow reaction or a Union Giken RA-401 stopped-flow spectrophotometer for fast reactions. The kinetic experiments were done under pseudo-first-order conditions ($[UO_2(acac)_2tmp]\gg[\beta\text{-diketone}]$). The rate of the replacement of one coordinated acac in $UO_2(acac)_2tmp$ was given by $k_{obsd}[\beta\text{-diketone}]_{enol}$, where $[\beta\text{-diketone}]_{enol}$ refers to the concentration of β-diketone in the enol form and k_{obsd} refers to the rate constant for the substitution of each acac. The pseudo-first-order rate constant k_{app} was determined from the slope in plots of $\ln(A_f-A_t)$ versus time t, where A_t and A_f are absorbances at time t and infinity, respectively at the wavelength 440 nm which gives the largest absorption change by the ligand substitution. Since $UO_2(acac)_2tmp$ involves two acac molecules, each suffering the substitution in an equal probability, k_{obsd} is the half of k_{app}. Kinetic runs were performed at least twice.

Results and Discussion

Figure 1 shows that k_{obsd} for the substitution of Hbza for acac in $UO_2(acac)_2tmp$ are independent of the concentrations of complex $[UO_2(acac)_2tmp]$. The values of k_{obsd} at various temperatures are given in Table 1. For the substitution of Htta, k_{obsd} increases linearly with $[UO_2(acac)_2tmp]$ in the low region of $[UO_2(acac)_2tmp]$, but tends to saturate in the high region. However, as seen in Fig. 2, plots of $1/k_{obsd}$ against

$1/[UO_2(acac)_2tmp]$ give straight lines with intercepts yielding the expression:

$$1/k_{obsd} = q + r/[UO_2(acac)_2tmp] \quad (1)$$

where q and r are constants. The same tendency was observed for the substitutions of Htfa, Hhta, and Hhpd. The data are summarized in Table 2 with the values of q and r.

The results in the present study can be well-explained by a mechanism (Fig. 3) proposed in the previous paper.[1] In this mechanism, the reaction is initiated with the fast equilibrium between UO_2-$(acac)_2tmp$ (**I**) and β-diketone in the enol form HB,[5] followed by the intramolecular proton-transfer process from coordinated HB to one of two chelated acac. According to the neutron diffraction study on UO_2-$(acac)_2Hacac$,[6] Hacac is coordinated to uranium atom via a keto oxygen atom, and the plane of Hacac is located at 32.5 °C to the pentagonal equatorial plane. The structure of intermediate **II** could be similar to that of $UO_2(acac)_2Hacac$. Based on the above mechanism, assuming that the proton-transfer process (k_2 path) is the rate-determining step, k_{obsd} is given by

$$k_{obsd} = k_2K_1[UO_2(acac)_2tmp]/(1 + K_1[UO_2(acac)_2tmp] \quad (2a)$$

or

$$k_{obsd}^{-1} = 1/k_2 + 1/(k_2K_1[UO_2(acac)_2tmp]) \quad (2b)$$

where $K_1=[UO_2(acac)_2HB]/([UO_2(acac)_2tmp][HB])$. In the limiting case $K_1[UO_2(acac)_2tmp]\gg1$, Eq. 2a can be simplified as $k_{obsd}=k_2$, i.e. k_{obsd} is independent of $[UO_2(acac)_2tmp]$. This is the case for the substitution of Hbza. Equation 2b is basically the same as Eq. 1, and parameters k_2 and K_1 are determined by these equations for the substitutions of Htta, Htfa, Hhpd, and Hbta. The results are listed in Tables 1 and 2. In these tables, the substitutions of HB can be classified into two groups owing to the difference of k_2 values: one is the substitutions of Hbza and Hhpd, and the other those of Htta, Htfa, and Htfa, k_2 of these groups being the order of 10^{-3} and 10^{-1} s^{-1}, respectively. The substitution of Hdbm[1] belongs to the former group. Since the k_2 path corresponds to the proton-transfer process from HB to coordinated acac, it is likely that k_2 increases with increasing acidity of HB. The acidity of HB was evaluated from data of pK_a in water-dioxane mixture (75 wt% dioxane) at 30 °C,[7,8] because pK_a of HB was not available in tmp. The values of k_2 at 25 °C and pK_a of HB are summarized in Table 3. In this table the pK_a values are considerably smaller, i.e. HB is more acidic, in the latter group. These facts indicate that the acidity of HB plays an important role for the k_2 process.

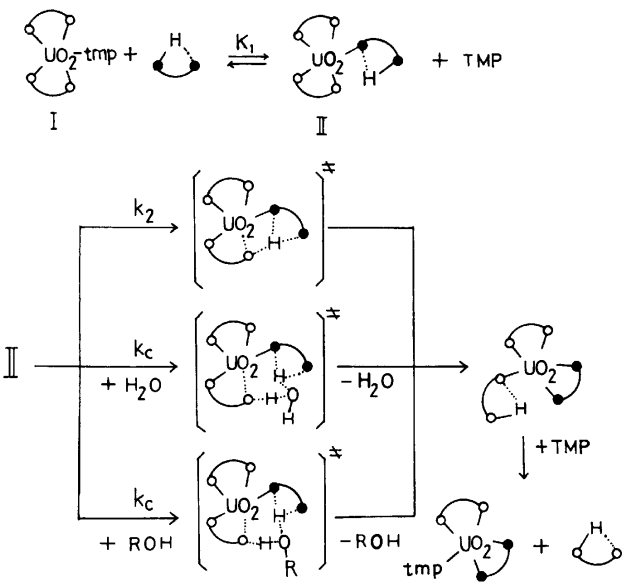

Fig. 3. Possible mechanism of the substitution of β-diketonates for acac in $UO_2(acac)_2tmp$ in tmp. HO⌒O and H●⌒● represent Hacac and β-diketone in the enol form, respectively.

In order to examine the steric hindrance of entering HB for the substitution rate, the substitution of Hbza is compared with that of Hdbm, because Hdbm is

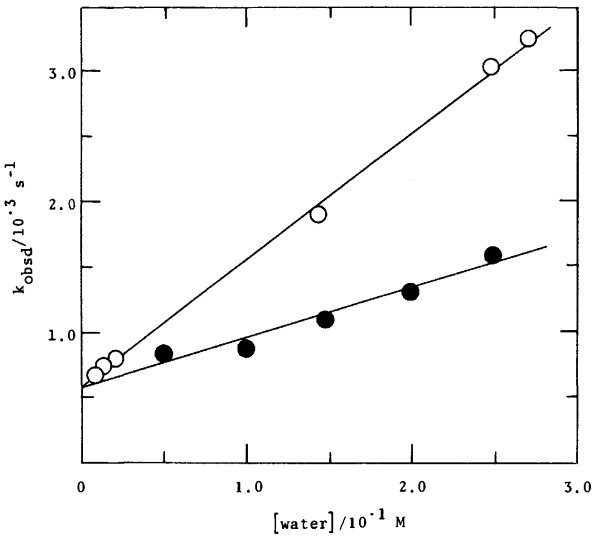

Fig. 4. Plots of k_{obsd} versus [Water] for the substitution of Hbza for acac in $UO_2(acac)_2tmp$ at 25 °C: (○) H_2O; (●) D_2O.

much bulkier in size than Hbza and their pK_a values are similar. In Table 1, k_2 for Hbza is 5.30×10^{-4} s^{-1} at 24 °C, while 2.19×10^{-3} s^{-1} for Hdbm at the same temperature.[1] The results that the rate is even faster for the substitution of the bulkier ligand suggest that the steric hindrance is of no significant effect.

The effect of adding water (<0.3 M) and various alcohols (<0.05 M) on the rates was investigated for the substitution of Hbza. As seen in Fig. 4, k_{obsd} increases linearly with the concentration of H_2O (D_2O). The similar linearlity was also found for all alcohols studied. Therefore, k_{obsd} can be expressed by:

$$k_{obsd} = k_2 + k_c[S] \quad (3)$$

where [S] denotes the concentrations of water and alcohols. The second-order rate constant k_c is listed in Table 4, together with the autoprotolysis constant pK_{auto}. In the case of the addition of alcohols, k_c shows a tendency to decrease with increasing pK_{auto}. This suggests that the k_c process in Fig. 3 is related to the amphiprotic property of alcohols, i.e. the ability of acting as a proton-donor and -acceptor through hydrogen bonding with intermediate **II**. Since K_{auto} is the product of the acidity constant ($ROH=RO^-+H^+$) and the constant for proton accepting equilibrium ($ROH+H^+=ROH_2^{2+}$) expressed by: $K_{auto}=[RO^-][ROH_2^{2+}]$, the role of each individual property of proton-donating or -accepting for the k_c process can not be determined strictly from these data. If the acceptor number[14] is allowed to estimate the acid strength for prototype acids, the acidity of alcohols decreases in the order: MeOH>EtOH>*i*-PrOH, e.g. as a mutter of fact, pK_a of MeOH and EtOH are 16.68 and 18.88, respectively,[9] indicating that the ability of proton donating of alcohols appears to be important. Water seems to behave differently, because the geometric configuration of intermediate II involving water differs from that of the intermediate involving alcohols.

a) Ref. 9. b) Ref. 13.

The replacement of adding H_2O and CH_3OH by D_2O and CH_3OD lowers the k_c values (Table 4) and the kinetic isotope effects k_c^H/k_c^D for H_2O/D_2O and CH_3OH/CD_3OD are determined to be 2.5 and 1.8, respectively. These values are substantially small compared with the direct proton transfer in the acac-exchange reaction.[11] Since proton transfers proceed from entering HB to leaving acac through water or alcohols, this indirect proton transfer might reduce the isotope effect in the presence of these amphiprotic solvents, particularly in such cases where proton-donor and -acceptor atoms are unsymmetrically located. This is experimentally evidenced by the fact that the smaller the difference in the acidity between two acids, HX and HY, (i.e. the more symmetrical the transition state) the larger the kinetic isotope effect for the proton-transfer reaction X^- and HY or Y^- and HX.[10]

The activation parameters of the k_2 path for the various β-diketonates are listed in Table 5. Although

there is no consistency in ΔH^* in a series of the substitutions, the change in k_2 is relatively small. This is attributed to the compensation effect[12] between ΔH^* and ΔS^*, which might be resulted from the polarization of intermediate **II** as acac···$H^{\delta+}$–$B^{\delta-}$, i.e. the larger polarization could reduce the ΔH^* values because of the weakened HB bonds and could make ΔS^* more negative as well owing to an increase of solvation towards the intermediate.

This work is partly supported by a Grant-in-Aid for General Scientific Research No. 62470039 from the Ministry of Education, Science and Culture.

An X-Ray Diffraction Study on the Stucture of 18-Crown-6 Ether Complexes with Alkali Metal Ions in Aqueous Solution

Kazuhiko OZUTSUMI,§ Masahiko NATSUHARA,† and Hitoshi OHTAKI*
Coordination Chemistry Laboratories, Institute for Molecular Science, Myodaiji, Okazaki 444
†Department of Electronic Chemistry, Tokyo Institute of Technology at Nagatsuta, Nagatsuta-cho 4259, Midori-ku, Yokohama 227
(Received April 14, 1989)

The structure of 1,4,7,10,13,16-hexaoxacyclooctadecane (18-crown-6) and its complexes with alkali metal ions in aqueous solution has been investigated by X-ray diffraction and Raman spectroscopic methods at 25 °C. The X-ray scattering data and Raman spectrum for an aqueous 18-crown-6 solution show that free 18-crown-6 has a conformation of C_i or D_{3d} symmetry. The molecule seems to be flexible and may be present as a mixture of the two conformations in aqueous solution. The structure of the lithium complex was not conclusive because of a weak scattering power of lithium atoms and weak complex formation between lithium ion and 18-crown-6. The sodium 18-crown-6 complex is estimated to have a structure similar to that found in crystal. The 18-crown-6 ring within the complex adopts the C_i conformation, where five oxygen atoms within 18-crown-6 coordinate to sodium ion at the equatorial position and an oxygen atom within 18-crown-6 and a water molecule at the axial one. The structure of the potassium complex is also similar to that in crystal in which the D_{3d} conformation is taken. Potassium ion is located at the center of the mean plane of 18-crown-6 and one or two water molecules solvate potassium ion above and/or below the plane of 18-crown-6. It is suggested that the structure of the caesium complex is with either C_i or D_{3d} symmetry, where caesium ion is apart from the mean plane of 18-crown-6. The rubidium complex was not examined because of a strong fluorescent X-ray emission from rubidium atoms when studied. The 18-crown-6 ring in the sodium and potiassium complexes is rather rigid probably because the cavity of the ring well fits to the metal ions, while the ring coordinating to large caesium ion becomes more flexible than that in the sodium and potassium complexes due to weaker interaction with caesium ion.

Synthetic macrocyclic polyethers (crown ethers) can be good model compounds of ionophores such as nonactin and valinomycin in biological systems because of the similarity in structure and ion selectivity. Metal complexes with polyethers are also useful in organic syntheses since they increase the nucleophilic reactivity of halide ions by solubilizing metal halides in many organic solvents. In these respects, complexation equilibria of metal ions with crown ethers have extensively been investigated in various solvents.[1] Many complexes with crown ethers have also been isolated and their structures in crystal have been determined.[2]

It has been found that the conformational change of valinomycin occurs in the course of complexation with potassium ion in methanol.[3] Crown ethers seem to be similarly flexible in solution and thus the structure determined in crystal may sometimes be different from that in solution. The flexibility of the crown ring may play an important role in the complexation with metal ions. However, thermodynamic quantities of crown ether complexes in solution have been interpreted on the basis of their structures in crystal because of insufficient structural information of the complexes in solution. It has also been shown that the stability constants of crown ether complexes are strongly dependent on properties of solvents.[1] Solvation of the complexes is also an important factor for the stability and reactivity of the complexes as well as the conformation of the ring structure in solution. Thus, we aimed at determining the structure of 1,4,7,10,13,16-hexaoxacyclooctadecane (18-crown-6) complexes with alkali metal ions, as well as the structure of the free ligand, in aqueous solution by employing X-ray diffraction and Raman spectroscopic methods in order to obtain more direct structural information in solution.

The structure of 18-crown-6[4] and its 1:1 complexes with monovalent cations[5-13] has been determined in crystal. Two ring oxygen atoms and two water molecules coordinate to lithium ion in the $LiClO_4 \cdot$(18-crown-6)$\cdot 2H_2O$ crystal.[13] Other cations are all coordinated with six oxygen atoms within 18-crown-6 and the seventh and/or eighth coordination sites of metal ions are occupied by anions in most complexes in crystal. The sites may, however, be occupied by solvent molecules in solution.

The most stable conformation of free 18-crown-6 in an isolated state was evaluated to be the one with C_i symmetry from a molecular mechanical study,[14] and the conformation has also been found in the 18-crown-6 crystal.[4] On the other hand, in aqueous solution the most stable conformation is proposed to be with D_{3d} symmetry by the Monte Carlo simulation.[15] The different structures of the 18-crown-6 ether in solution and in crystal are due to solvation of the compound with water molecules in the former. The C_i conformation was found in the NaSCN–18-crown-6 complex in crystal[7] and the D_{3d} conformation was observed in other 18-crown-6 complexes with monovalent cations including lithium ion.[5,6,8-13] The most

stable conformation of 18-crown-6 within the sodium and potassium complexes in an isolated state without any hydrated water molecules was found to be C_1 and D_{3d}, respectively, by the molecular mechanical calculations.[14] It is suggested that the D_{3d} conformation is more stable than the C_1 conformation in the potassium complex with two water molecules coordinating to metal ions, while the energy difference between the C_1 and D_{3d} conformations was very small in the sodium complex according to the same method.[14] Thus it is seen that the solvation of 18-crown-6 greatly affects its conformation in solution. The structures of free 18-crown-6 and the complexes in various states reported so far by employing different methods are summarized in Table 1.

Although the conformation of 18-crown-6 in solution has so far been investigated by the dipole moment[16] and Raman spectral measurements,[17,18] no direct structual data of the solvated complexes have been given. An EXAFS measurement for the rubidium complex in solution has been carried out,[19] but the structure analysis is still incomplete. In the present paper we report the structural data of 18-crown-6 complexes with alkali metal ions, except rubidium ion, in aqueous solution studied by the X-ray diffraction method in order to obtain information on both conformation and solvation of the complexes. The structure of the rubidium complex was not determinable by the present method because of a strong fluorescent X-ray radiation. Raman spectroscopic measurements were also carried out to obtain additional information of the structure of the complexes.

Experimental

Preparation of Sample Solutions. NISSO 18-crown-6 (99%) was used without further purification and dried at room temperature under a reduced pressure. Alkali chlorides of reagent grade were recrystallized once from water.

Six sample solutions were prepared for the X-ray diffraction measurements. Solution A was an aqueous 18-crown-6 solution. Solutions B through F were prepared by dissolving alkali chlorides and 18-crown-6 in water. Concentrations of chloride ions in the test solutions were gravimetrically determined as AgCl. Concentrations of alkali metal ions in the solutions were evaluated from the stoichiometry of the salts used. Concentrations of 18-crown-6 were calculated from the weighted amounts of 18-crown-6. Densities of the solutions were measured by using pycnometer. The composition of the solutions is listed in Table 2.

X-Ray Scattering Measurements. X-Ray scattering measurements were performed on a JEOL θ-θ type diffractometer by using Mo $K\alpha$ radiation (λ=71.07 pm). The method of measurements and data treatments were described elsewhere.[20] The accessible range of scattering angle 2θ was from 2° to 140°, which corresponded to the scattering variable s ($=4\pi\lambda^{-1}\sin\theta$) range of 0.3×10^{-2} to 16.6×10^{-2} pm^{-1}. Times required to accumulate 80000 counts were recorded at each angle of 2θ and the measurement was repeated three times over the whole angle range.

The reduced intensities $i(s)$ were obtained by subtracting independent coherent scatterings from the measured intensities $I(s)$ as follows:

$$i(s) = KI(s) - \sum_j n_j[\{f_j(s) + \Delta f_j'\}^2 + (\Delta f_j'')^2], \quad (1)$$

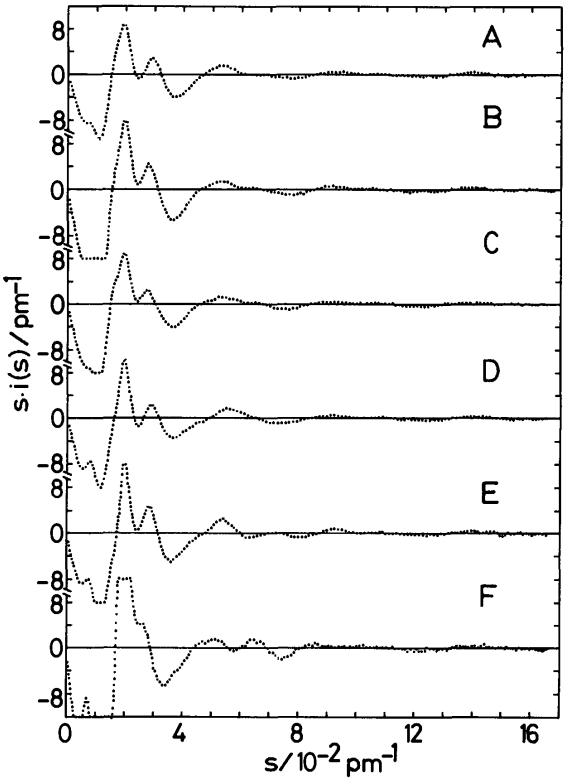

Fig. 1. The reduced intensities multiplied by s for solutions A through F.

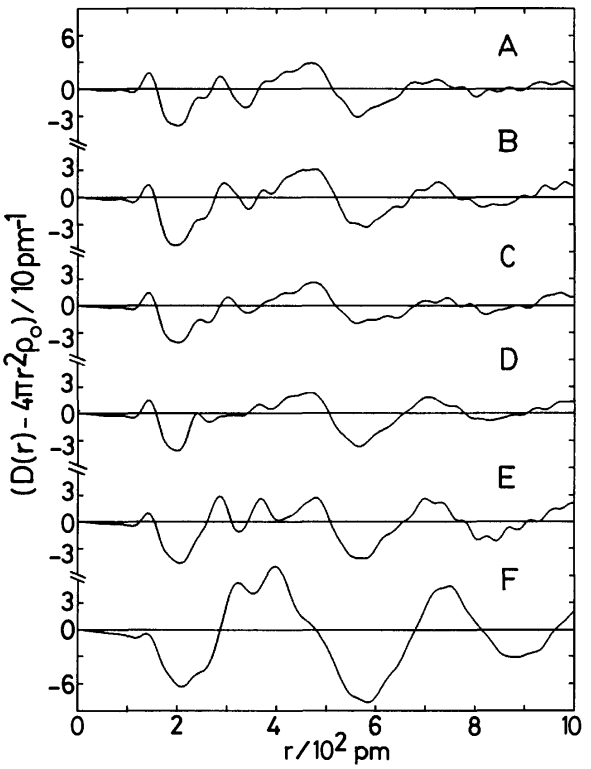

Fig. 2. The differential radial distribution curves, $D(r)-4\pi r^2\rho_0$, for solutions A through F.

where K stands for a normalization factor of the measured intensities to the absolute ones. n_j is the number of atom j in a stoichiometric volume V of the test solutions. $f_j(s)$ represents the atomic scattering factor at s, and $\Delta f_j'$ and $\Delta f_j''$ denote the real and imaginary parts of anomalous dispersion, respectively, of atom j. The reduced intensities multiplied by s for the sample solutions are shown in Fig. 1.

The radial distribution function $D(r)$ was calculated by the Fourier transform of the reduced intensities according to Eq. 2:

$$D(r) = 4\pi r^2 \rho_0 + \frac{2r}{\pi}\int_0^{s_{max}} s\cdot i(s)\cdot M(s)\cdot \sin(rs)\mathrm{d}s, \quad (2)$$

where ρ_0 ($=\{\sum n_j\cdot f_j(0)\}^2/V$) is the average scattering density in a stoichiometric volume of the sample solution and s_{max} represents the maximum s-value attained in the measurement ($s_{max}=16.6\times10^{-2}$ pm^{-1}). The modification function $M(s)$ is given as

$$M(s) = \frac{\sum_j n_j\{(f_j(0)+\Delta f_j')^2+(\Delta f_j'')^2\}}{\sum_j n_j\{(f_j(s)+\Delta f_j')^2+(\Delta f_j'')^2\}}\cdot\exp(-ks^2). \quad (3)$$

The damping factor k was chosen as 100 pm^2 in the present case. The $(D(r)-4\pi r^2\rho_0)$ curves for the test solutions are depicted in Fig. 2.

A least-squares calculation for the refinement of the structure parameters was applied to the reduced intensities so as to minimize the error-square sum U,

$$U = \sum_{s_{min}}^{s_{max}} s^2\{i(s)_{obsd} - i(s)_{calcd}\}^2. \quad (4)$$

The theoretical intensities $i(s)_{calcd}$ arising from the interatomic interactions in the solutions are obtained as follows:

$$i(s)_{calcd} = \sum_{\substack{p\\p\neq q}}\sum_{q} n_{pq}[\{f_p(s)+\Delta f_p'\}\{f_q(s)+\Delta f_q'\}+(\Delta f_p'')(\Delta f_q'')] \times \frac{\sin(r_{pq}s)}{r_{pq}s}\cdot\exp(-b_{pq}s^2), \quad (5)$$

where r_{pq}, b_{pq}, and n_{pq} represent the distance, the temperature factor, and the frequency factor of the atom-pair p-q, respectively.

All calculations were performed by using programs KURVLR[21] and NLPLSQ.[22]

Raman Spectroscopic Measurements. Raman spectra for solutions A through F were measured by JEOL JRS-400T laser Raman spectrophotometer equipped with an Ar^+ ion laser (Spectra-Physics Model 125 laser) using 514.5 nm excited line at the Instrumental Center of the Institute for Molecular Science.

Results and Discussion

Raman Spectra. Figure 3 shows the Raman spectra for solutions A through F. Conformations of C_i, C_1, and D_{3d} symmetry have been known for the 18-crown-6 ring in the crystalline state. The C_i and C_1 conformations have been found in the crystals of pure 18-crown-6 and the NaSCN–18-crown-6 complex, respectively.[4,7] The D_{3d} symmetry is observed in various metal complexes with 18-crown-6 in crys-

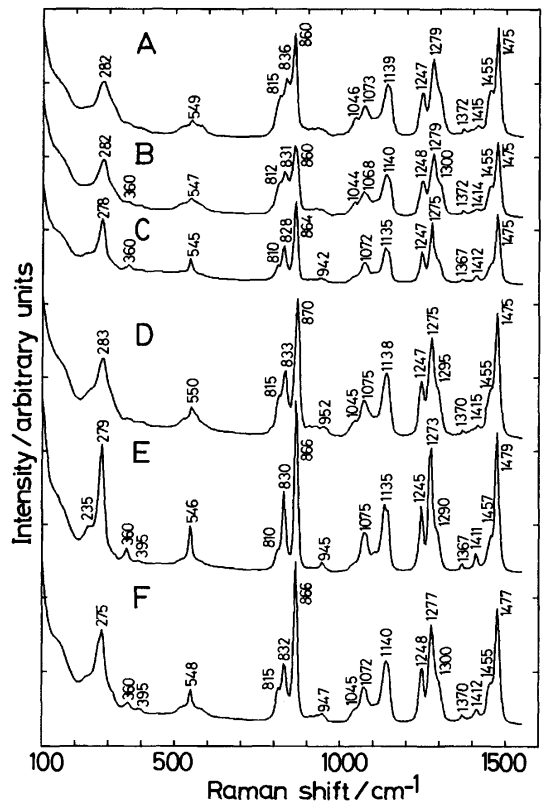

Fig. 3. The Raman spectra for solutions A through F.

tal.[5,6,8-13] The Raman spectrum of pure 18-crown-6 in the solid state which has the conformation of the C_i symmetry has been reported,[17,18] in which strong bands appeared at 271, 320, 415, 580, 824, 868, 892, and 988 cm^{-1}. However, the bands at 320, 415, 580, 824, 892, and 988 cm^{-1} are not observed in the spectrum of the solution sample of free 18-crown-6 (see Fig. 3). On the other hand, the band at 549 cm^{-1} observed for the solution sample is not seen in the spectrum of the crystal having the C_i conformation. No Raman spectroscopic data are available for pure 18-crown-6 with other conformations in the solid state and no direct comparison may be possible between the spectrum of free 18-crown-6 in Fig. 3 and those of metal complexes, because coordination of the ligating atoms of the crown ring to metal ions usually strongly influences vibrational modes of the ligand molecule. It is thus conclusive from the Raman spectra that 18-crown-6 in solution has not the conformation of the C_i symmetry and probably it takes either C_1 or D_{3d} symmetry, or is present as a mixture of the two. This result agrees with the conclusion of the C_i conformation which is the least stable in aqueous solution according to the Monte Carlo simulation for the conformation of 18-crown-6.[15]

The band at 550 cm^{-1} becomes sharper when an alkali metal ion is introduced in the ring (see Fig. 3,B—F).

Table 3. Interatomic Distances (r) below 500 pm and the Frequency Factors (n) of the Relevant Atom-Pairs within 18-Crown-6 of Different Conformations[a]

Interaction	r/pm C_i	C_1	D_{3d}	n

C···O (C_6···O_1)	488	453	499	12

a) The distances are averaged ones.

A composite band around 860 cm^{-1} found in an aqueous 18-crown-6 solution (solution A) consists of two distinct bands at 836 and 860 cm^{-1} and a small peak at 815 cm^{-1}. The highest peak among the three, the band at ca. 860 cm^{-1}, shifts toward the high frequency side when an alkali metal ion is combined with the ligand. The order of the Raman shift is Li<Na>K≈Cs, but it is not very clear when we take into account the uncertaintiy of the measurement (±2 cm^{-1}). However, the shape of the band at 860 cm^{-1} seems to be very closely related to the stabilities of the metal complexes,[23,24] i.e., the sharpness of the peak changes in the order: free <Li<Na<K>Cs. The same trend can also be observed in the band shapes at ca. 280, 550, 1275, and 1475 cm^{-1}.

Radial Distribution Functions. 18-Crown-6 Solution. The radial distribution curve for an aqueous 18-crown-6 solution (solution A) is depicted in Fig. 2,A. Three large peaks appear around 140, 280, and 480 pm in the curve. In order to analyze the radial distribution function of solution A, intramolecular atomic distances for the conformations with C_i, C_1, and D_{3d} symmetry are calculated from the structural data of 18-crown-6,[4] NaSCN-18-crown-6,[7] and KSCN-18-crown-6[8] crystals, respectively. The interatomic distances obtained from the data of RbSCN-18-crown-6[11] and CsSCN-18-crown-6[12] crystals, in both of which the 18-crown-6 molecule adopts the D_{3d} conformation, are almost the same as those estimated from the structure of the KSCN-18-crown-6 crystal. The results are summarized in Table 3. For the sake of convenience in the following discussions, the atoms within an 18-crown-6 molecule are numbered as shown in Fig. 4.

From the table it is seen that the first peak at 140 pm is attributed to the C-H, C-O, and C-C bonds within 18-crown-6 molecules and the O-H bonds within

water molecules. The second peak at 280 pm with a shoulder at 240 pm includes peaks due to nonbonding intramolecular interactions such as $C_2\cdots H_3$, $O_1\cdots H_1$, $C_3\cdots O_1$, $C_3\cdots C_5$, $O_1\cdots O_4$, $O_4\cdots H_1$, and $C_5\cdots H_3$ ones within 18-crown-6 molecules. Conformations of 18-crown-6 are very insensitive to the distances. It should be noted that the C···H and O···H interactions can not be neglected in the course of the analysis in spite of the weak scattering power of hydrogen atom, since the frequency factors for the interactions are very large (Table 3). The large peak around 480 pm is mainly due to various intramolecular interactions of

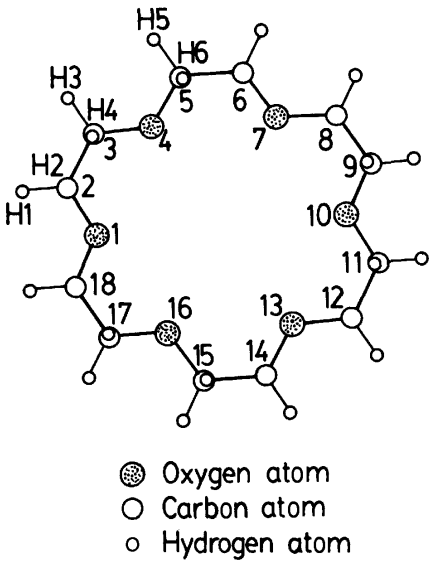

Fig. 4. The numbering of atoms within 18-crown-6.

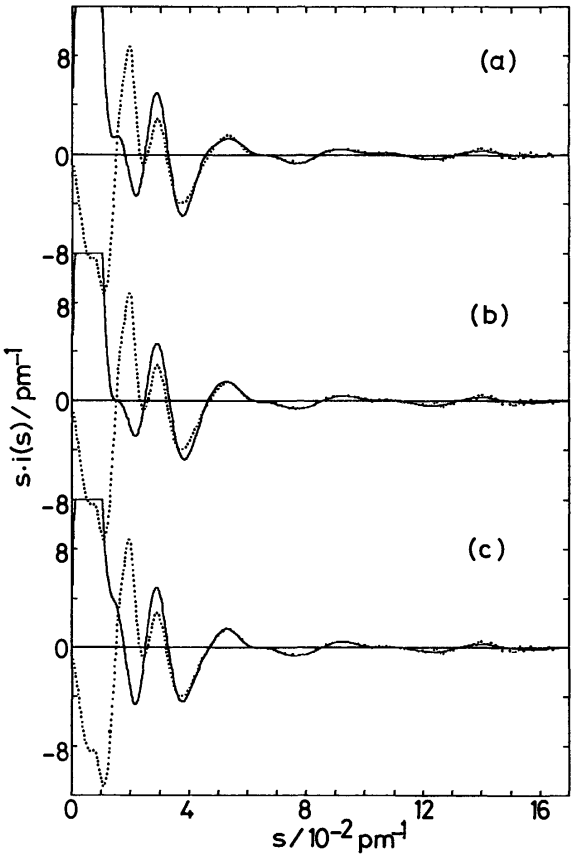

Fig. 5. The $s\cdot i(s)$ curve for solution A. The observed values are shown by the dotted lines and the calculated ones by assuming (a) C_i, (b) C_1, and (c) D_{3d} conformations of 18-crown-6 are drawn by the solid lines.

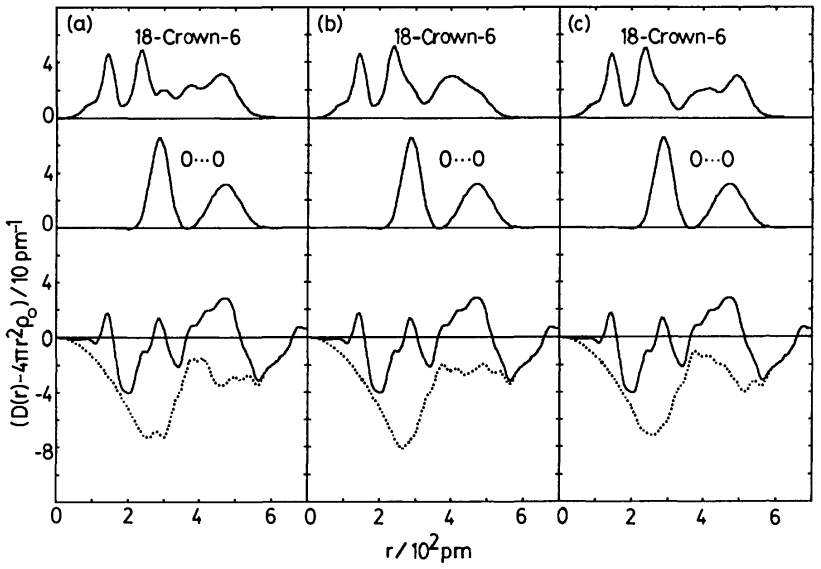

Fig. 6. The $(D(r)-4\pi r^2\rho_0)$ curve for solution A. The peak shapes for intramolecular interactions within 18-crown-6 are calculated on the basis of (a) C_i, (b) C_1, and (c) D_{3d} conformations of 18-crown-6 (upper part). The dotted lines (lower part) represent the residual curves after subtraction of the theoretical peak shapes owing to the intramolecular interactions within 18-crown-6 and the O···O interactions of hydrated 18-crown-6 and of bulk water.

18-crown-6, the distances being varied depending on the conformations of 18-crown-6. The O···O interactions between water molecules in the bulk may appear also around 280 and 460 pm.[25]

In order to draw the theoretical reduced intensities and radial distribution curves by using the parameter values given in Table 3, the root mean square amplitudes Δr_{pq} of the atom-pairs were assumed to be 5% of the corresponding atom-pair distances, which have been evaluated from the results of solution X-ray diffraction measurements so far examined for non-bonding interatomic interactions which have a separation of one to two atoms in between. The temperature factors b_{pq} were thus calculated as $b_{pq}=(\Delta r_{pq})^2/2$. In the course of the calculations, hydration of oxygen atoms in 18-crwon-6 was teken into account on the basis of the hydration model proposed by the Monte Carlo simulation.[15] The O···O contacts of bulk water were also considered.[25] In Figs. 5 and 6 are shown the reduced intensities and radial distribution curves, respectively, thus calculated, all of which reasonably reproduce the experimental ones. Therefore, it is not conclusive which conformation predominantly exists in aqueous solution from the present X-ray scattering data, but the D_{3d} conformation (Fig. 5,C) seems to give the best fit result. According to the Raman spectroscopic measurement described in the preceding section, the C_1 and D_{3d} conformations are possible to be present, and the C_i conformation was not acceptable.

The peaks due to the intramolecular interactions of 18-crown-6 are large and comparable to those for O···O interactions of bulk water, and therefore, we must be careful to analyze peaks due to the intramolecular structure of 18-crown-6 complexes in the following sections with a reasonable evaluation of structure parameters for interactions between water molecules in the bulk, as well as those between atoms in the 18-crown-6 molecule.

LiCl and 18-Crown-6 Solutions. The $s\cdot i(s)$ (Figs. 1,B and C) and $(D(r)-4\pi r^2\rho_0)$ curves (Figs. 2,B and C) of aqueous LiCl solutions with 18-crown-6 (solutions B and C) are analyzed by the similar method to that employed for solution A. The C_i, C_1, and D_{3d} conformations of 18-crown-6 were assumed at each calculation. As pointed out in the preceding section, complexation between lithium ion and 18-crown-6 was weak, and an only part of the whole lithium ions in the solution is trapped into the crown ring. In this calculation hydration of oxygen atoms in 18-crown-6 was not taken into consideration. The octahedral hydration model of chloride ion given in the literature was assumed.[26] The Li–O interactions arising from the hydration of free lithium ion and from the complex between lithium ion and 18-crown-6 were neglected in the course of the calculation because of the weak scattering power of lithium atom and its low concentration in the solution. The results for solution B calculated by using different assumptions of the C_i, C_1, and D_{3d} conformations are shown in Fig. 7 and practically the same results were also obtained for solution C. It may be rather difficult to draw a definite conclusion from the reduced intensities because all cases seem to give similar fits between experimental and calculated results. We may say that the D_{3d} symmetry (Fig. 7,C) gave the best fit result among the three, but this is not conclusive. The Raman spectroscopic data indicated that either the C_1 or D_{3d} conformation or both are possible for the lithium 18-crown-6 complex in solution (see Fig. 3).

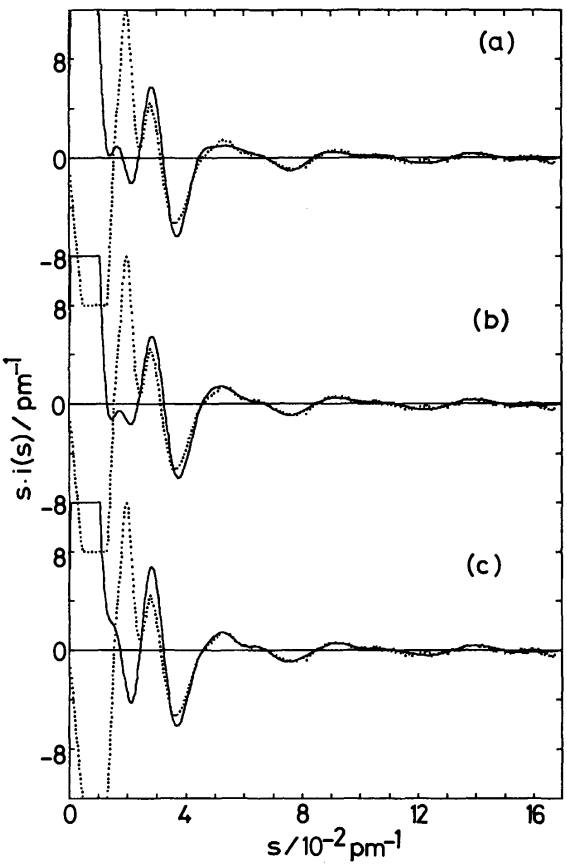

Fig. 7. The $s\cdot i(s)$ curve for solution B. The observed values are shown by the dotted lines and the calculated ones by assuming (a) C_i, (b) C_1, and (c) D_{3d} conformations of 18-crown-6 are drawn by the solid lines.

NaCl and 18-Crown-6 Solution. The $(D(r)-4\pi r^2\rho_0)$ curve for solution D depicted in Fig. 2,D is also analyzed by assuming three structural models (C_i, C_1, and D_{3d}) for the conformation of the 18-crown-6 ring in the sodium complex. In the C_i model sodium ion is located at the center of gravity of the six oxygen atoms in the ring and then is moved along the axis which is perpendicular to the mean plane defined by the six oxygen atoms in 18-crown-6. The position of sodium ion is determined so that the distance between the sodium ion and the nearest oxygen atom is ca. 245 pm,

which is estimated from the peak position in the radial distribution curve (Fig. 2,D). Two hydrated water molecules at the same distance from sodium ion are also taken into consideration in order to explain the peak area at ca. 245 pm. The 18-crown-6 ring in the sodium complex with thiocyanate ion as the counter anion in crystal has the C_i conformation, i.e., sodium ion is surrounded by five oxygen atoms (O_1 to O_{13}) in the equatorial plane and an oxygen atom (O_{16}) and a water molecule coordinate at the axial site.[7] For the D_{3d} conformation two model structures are examined: in one model sodium ion is located at the center of the six oxygen atoms within 18-crown-6 with D_{3d} symmetry, the structure corresponding to that found in KSCN–18-crown-6 crystal[8] and, thus, the Na–O distance is ca. 280 pm. In the other model sodium ion contacts with two oxygen atoms at the distance of 240—250 pm in the mean plane of 18-crown-6. In both cases two hydrated water molecules above and below the plane are taken into consideration.

Among the structure models examined, the theoretical values based on the C_i model gave the best agreement with the experimental ones as shown in Fig. 8. The C_i and D_{3d} models do not fit to the observed curves. From these results we concluded that the structure of the sodium complex in aqueous solution is with the C_i conformation which is similar to that in the solid state with one hydrated water molecule.

The structure parameters of the Na–18-crown-6 complex could not be well refined by a least-squares calculation using reduced intensities because of the low concentration of sodium ion and the relatively weak scattering power of sodium atom, since the contribution of intramolecualr structure of 18-crown-6 to the intensity values is very large.

KCl and 18-Crown-6 Solution. The differential radial distribution curve for solution E (Fig. 2,E) shows two distinct peaks at 280 and 360 pm which are not observable in solutions A through D. The peaks may thus be ascribed to the K–O and K···C interactions within the K–18-crown-6 complex.

The $(D(r)-4\pi r^2\rho_0)$ curve for solution E was

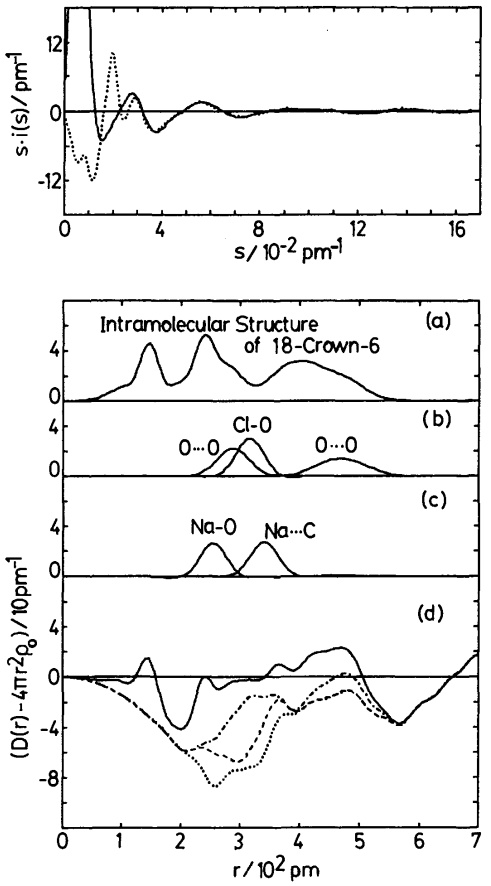

Fig. 8. The $s\cdot i(s)$ and $(D(r)-4\pi r^2\rho_0)$ curves for solution D. The observed $s\cdot i(s)$ values are shown by the dotted line and calculated ones by the solid line (above). The observed radial distribution curve is drawn by the solid line, and chain, dashed, and dotted ones represent the residual curves after subtraction of calculated peak shapes in (a), (b), and (c), respectively (below).

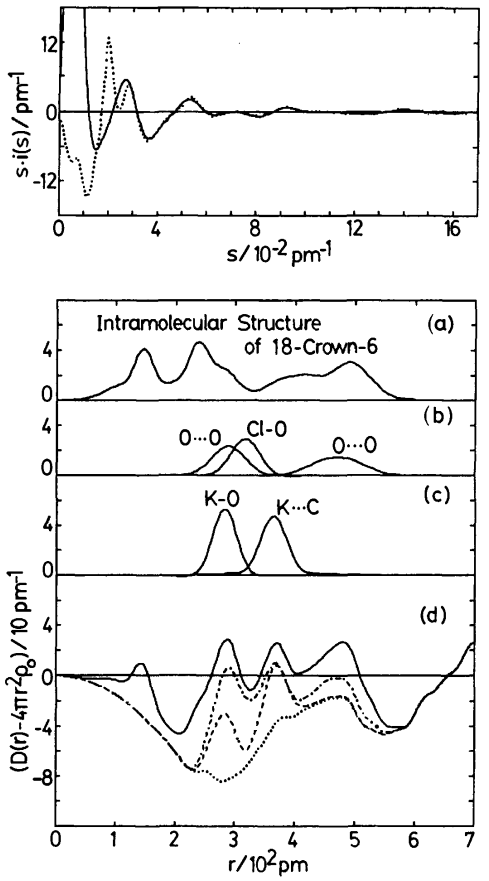

Fig. 9. The $s\cdot i(s)$ and $(D(r)-4\pi r^2\rho_0)$ curves for solution E. The observed $s\cdot i(s)$ values are shown by the dotted line and calculated ones by the solid line (above). The observed radial distribution curve is drawn by the solid line, and chain, dashed, and dotted ones represent the residual curves after subtraction of calculated peak shapes in (a), (b), and (c), respectively (below).

analyzed in a similar manner to that employed in previous sections on the basis of three conformational models of 18-crown-6. For the C_i conformation, the same model as that employed for solution D was used. The distance between potassium ion and the nearest oxygen atom was taken to be ca. 280 pm. In the C_1 model potassium ion was moved along the line which is perpendicular to the mean plane defined by five oxygen atoms within 18-crown-6 through the center of gravity of these atoms, and in the course of this procedure, the K–O distance to the nearest oxygen atom within 18-crown-6 was assumed to be approximately 280 pm which were evaluated from the peak position in the $(D(r)-4\pi r^2 \rho_0)$ curve. The conformation with D_{3d} symmetry was adopted which has been found in the KSCN–18-crown-6 crystal.[8] In all cases two water molecules bound to potassium ion at the distance of ca. 280 pm are taken into account. In these examinations the D_{3d} model gave the best-fit result. In Fig. 9 the reduced intensities and radial distrubution curve drawn on the basis of the D_{3d} model are shown, in which theoretical curves well reproduced the experimental ones. Reduced intensity curves calculated from the C_i and C_1 models gave large discrepancies from the experimental ones. Thus the most plausible structure of the potassium complex was concluded to be the one with D_{3d} symmetry.

Since the contribution of interatomic interactions in 18-crown-6 and in the bulk water to the reduced intensities and radial distribution curve becomes almost comparable to those of K–O and K···C interactions (see Fig. 9), the direct analysis of the curve for the structural parameters of the K–O and K···C interactions may be largely affected by the assumption for the Cl–O distance and the hydration number of chloride ion in aqueous solution, which has been reported to be concentration dependent,[27] as well as for the interatomic interactions in 18-crown-6 and in the bulk water. Therefore, the structure parameters for the potassium 18-crown-6 complex were evaluated by the following procedure: we first subtracted the reduced intensities for solution C containing 2 mol dm^{-3} lithium chloride, in which almost the same concentrations of 18-crown-6, chloride ion, and water molecule as in solution E are contained, from those of solution E. By this procedure the short-range interatomic interactions in 18-crown-6 below 300 pm, hydrated chloride ions and the bulk water, except for those of the metal–oxygen interactions, were eliminated. The contribution of long-range interatomic interactions in 18-crown-6 would entirely be eliminated when the conformation of 18-crown-6 in the potassium complex was the same as that in the lithium complex. Even if their conformations are different, the difference in the long-range interatomic interactions may be small enough to obtain the structure parameters for the potassium complex with a reasonable accuracy, because the contribution of K–O and K···C interactions to the difference reduced intensities $\Delta\{s\cdot i(s)\}$ is much larger. The Li–O and Li···C interactions in case of solution C may be neglected because of the weak scattering power of lithium atom. The difference reduced intensities $\Delta\{s\cdot i(s)\}$ and difference radial distribution curve $\Delta D(r)$ are shown in Fig. 10. The $\Delta D(r)$ curve shows two distinct peaks at 278 and 360 pm which should be due to the K–O and K···C interactions, respectively. The areas under the peaks correspond to ca. seven K–O bonds and ca. twelve K···C interactions.

A least-squares calculation was finally applied to the $\Delta\{s\cdot i(s)\}$ curve in the high-angle region to optimize the structural parameters of the potassium 18-crown-6 complex. The conformation of 18-crown-6 within the potassium complex was assumed to be D_{3d} on the basis of the analysis of the radial distribution curve in the course of the refinements. Two types of the calculations were performed in the refinements: in the type I calculation, the conformation of 18-crown-6 in solution C was assumed to be the same as that in

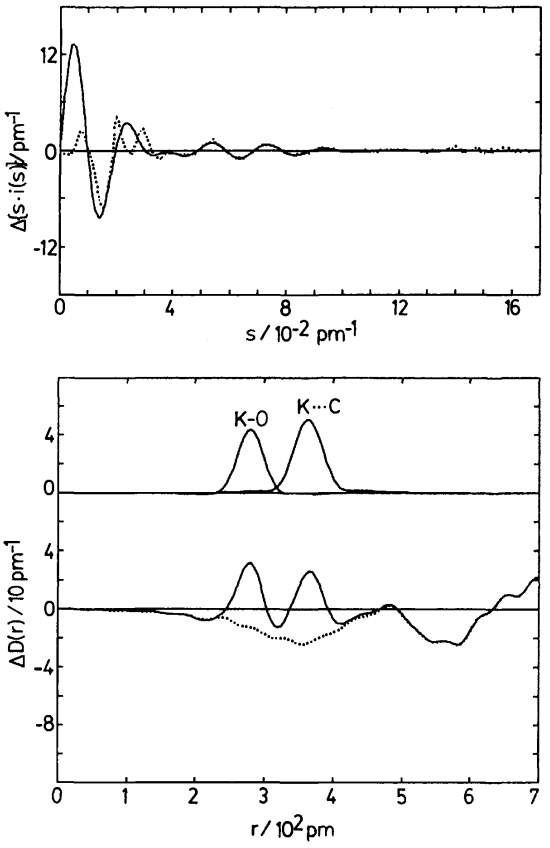

Fig. 10. The difference reduced intensities $\Delta\{s\cdot i(s)\}$ and difference radial distribution curve $\Delta D(r)$ for solution E. The observed $\Delta\{s\cdot i(s)\}$ values are shown by the dotted line and calculated ones by the solid line (above). The observed $\Delta D(r)$ curve is drawn by the solid line and the residual curve after subtraction of calculated peak shapes by the dotted line (below).

Table 4. Least-Squares Refinements for the Structure Parameters of the Potassium 18-Crown-6 Complex in Aqueous Solution with Different Models

Interaction	Parameter	I	II	Proposed length
K-O	r/pm	278(1)	276(1)	277(2)
	$b/10^2$ pm^2	6(1)	12(2)	
	n	5.5(4)	8.2(6)	
K···C	r/pm	363(1)	356(1)	360(4)
	$b/10^2$ pm^2	14(1)	14(1)	
	n	12[a]	12[a]	
	U/pm^{-2}	4.9	5.1	

a) The values were kept constant during the calculation.

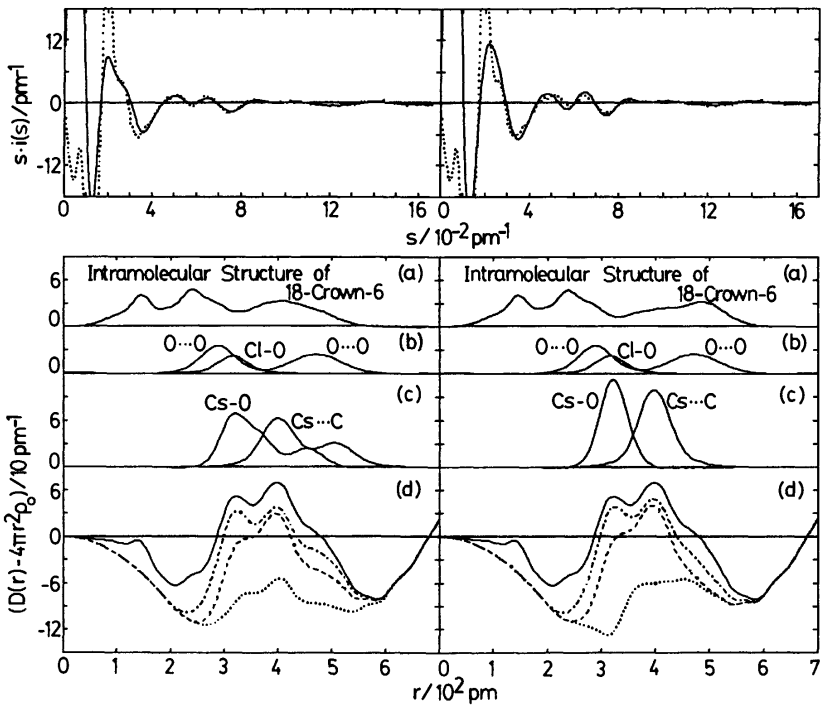

Fig. 11. The $s \cdot i(s)$ and $(D(r)-4\pi r^2\rho_0)$ curves for solution F. The theoretical curves are calculated on the basis of the C_1 (left) and D_{3d} (right) conformations. The observed $s \cdot i(s)$ values are shown by the dotted line and calculated ones by the solid line (above). The observed radial distribution curve is drawn by the solid line, and chain, dashed, and dotted ones represent the residual curves after subtraction of calculated peak shapes in (a), (b), and (c), respectively (below).

solution E (D_{3d} conformation). On the other hand, in the type II treatment, the conformations of 18-crown-6 in solutions C and E were different, the former 18-crown-6 adopting the C_1 conformation, and hence the structural difference between the two complexes must be taken into consideration. The results are summarized in Table 4 and very similar results were obtained by both treatments. The structural difference between lithium and potassium complexes did not thus affect the structure determination of the potassium complex even if their structures were different. The K-O and K···C distances determined are 277(2) and 360(4) pm, respectively, and therefore, potassium ion is located at the center of 18-crown-6. The frequecy factor for the K-O bond is estimated to be 6—8, which suggests that one or two water molecules solvate potassium ion above and/or below the mean plane of 18-crown-6 with D_{3d} symmetry.

CsCl and 18-Crown-6 Solution. The $(D(r)-4\pi r^2\rho_0)$ curve for solution F depicted in Fig. 2,F shows two large peaks around 310 and 390 pm. The peaks are assignable to the Cs-O and Cs···C interactions within the caesium 18-crwon-6 complex.

The radial distribution function for solution F was analyzed by a similar procedure to that employed for solution E. The Cs-O distance to the nearest oxygen atom within 18-crown-6 was set to be 315 pm in the three models examined (C_i, C_1, and D_{3d} models). Two water molecules with the same distance from the caesium ion were also taken into consideration in

order to explain the large area under the peak at 310 pm. Among the structure models examined, both C_1 and D_{3d} models rather reasonably reproduced the experimental values as depicted in Fig. 11. Therefore, it is not conclusive from the result which conformation is taken in the complex. Both can also exist as a mixture of two type conformations in the solution. The latter explanation seems to be likely because Cs–O interactions are rather weak and the Raman bands in the CsCl–18-crown-6 solution are broader than those of KCl–18-crown-6 solution.

The refinement of the structure parameters for the Cs–O and Cs···C interactions within the caesium complex was also performed by the similar method to that applied to the case of the potassium complex. In this case the reduced intensities of solution B were subtracted from those of solution F because the composition of the two solutions is very similar. The difference reduced intensities $\Delta\{s\cdot i(s)\}$ and difference radial distribution curve $\Delta D(r)$ are shown in Fig. 12. In the observed $\Delta D(r)$ curve two large broad peaks are found around 320 and 400 pm owing to the Cs–O and Cs···C interactions, respectively, which are less separated than those for the potassium complex. This suggests that the temperature factors for both Cs–O and Cs···C interactions are larger than those of K–O and K···C interactions. The large temperature factors of the Cs–O and Cs···C pairs certainly arise from their weak interactions, and thus the Cs–O and Cs···C distances may fluctuate to a relatively large extent. In the crystal of CsSCN–18-crown-6 each of the Cs–O and Cs···C distances can be devided into two groups, i.e., three shorter Cs–O distances of 306 pm and three longer ones of 324 pm, and five shorter Cs···C distances of 377 pm and seven longer ones of 398 pm.[12] Therefore, we tried to separate the peaks in the radial distribution curve into four major ones on the basis of the crystallographic data. However, any combination of the interatomic distances and temperature factors was not successful to reproduce the experimental curves by using four kinds of interactions. Three different Cs–O bonds and two different Cs···C interactions, at least, were needed in order to explain the experimental result according to the least-squares calculations for the $\Delta\{s\cdot i(s)\}$ values when we adopted the C_1 conformation of the 18-crown-6 structure. On the other hand, only two interactions, one Cs–O and one Cs···C, were sufficient to interprete the difference reduced intensities of the solution on the basis of the D_{3d} symmetry model (see Table 5).

The structure parameters finally refined by a least-squares calculation using the high-angle region of the $\Delta\{s\cdot i(s)\}$ values are summarized in Table 5. Both models almost equally reproduce the experimental

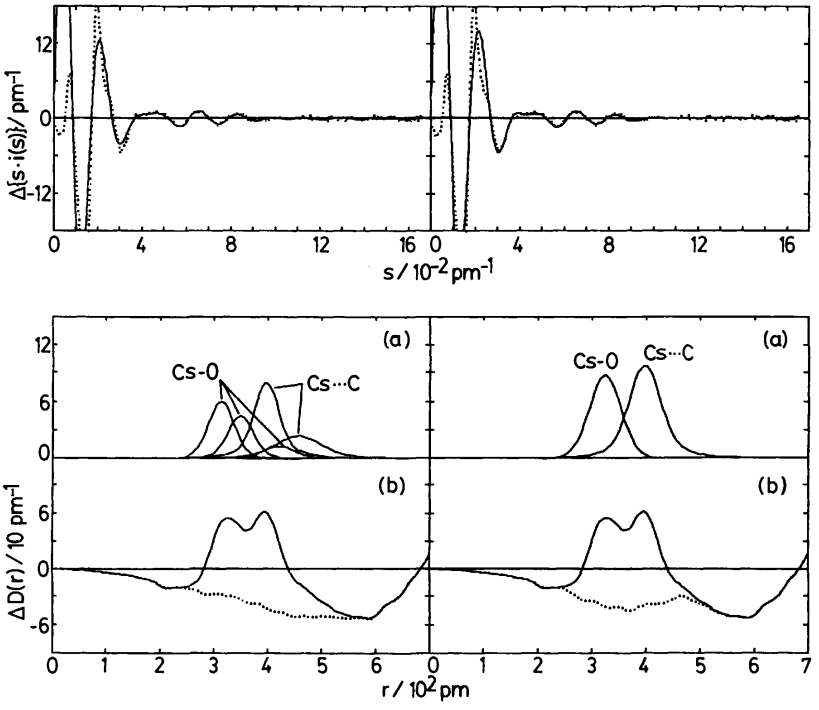

Fig. 12. The difference reduced intensities $\Delta\{s\cdot i(s)\}$ and difference radial distribution curve $\Delta D(r)$ for solution F. The theoretical curves are calculated on the basis of the C_1 (left) and D_{3d} (right) conformations. The observed $\Delta\{s\cdot i(s)\}$ values are shown by the dotted line and calculated ones by the solid line (above). The observed $\Delta D(r)$ curve is drawn by the solid line and the residual curve after subtraction of calculated peak shapes by the dotted line (below).

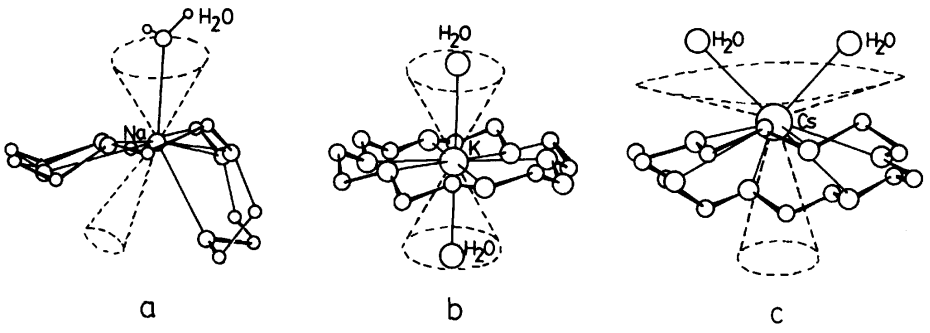

Fig. 13. Proposed structures of hydrated 18-crown-6 alkali metal complexes. Broken lines indicate corn angles above and below the metal ion in the complexes. (a) Sodium complex with C_1 conformation of the 18-crown-6 ring, (b) Potassium complex with D_{3d} conformation, (c) One of the possible structure of the caesium complex which has the D_{3d} conformation.

Table 5. Least-Squares Refinements for the Structure Parameters of the Caesium 18-Crown-6 Complex in Aqueous Solution with Different Models of the Crown-Ring Structure

Interaction	Parameter	C_1	D_{3d}
Cs–O	r/pm	312(2)	321(1)
	$b/10^2$ pm^2	13(2)	27(4)
	n	4[a,b]	7.1(4)
Cs–O	r/pm	348(5)	—
	$b/10^2$ pm^2	13(5)	—
	n	3[a]	—
Cs–O	r/pm	419(43)	—
	$b/10^2$ pm^2	25[a]	—
	n	1[a]	—
Cs···C	r/pm	396(3)	394(1)
	$b/10^2$?pm^2	15(4)	29(2)
	n	8[a]	12[a]
Cs···C	r/pm	453(20)	—
	$b/10^2$ pm^2	71(54)	—
	n	4[a]	—
	$U/10$ pm^{-2}	1.1	1.2

a) The values were kept constant during the calculation. b) The value was varied from 2 to 6 but practically the same Cs–O and Cs···C distances were obtained.

curve. Therefore it is concluded that Cs–18-crown-6 complex with different conformations C_1 and D_{3d} can be present, and the Cs–18-crown-6 complex takes either C_1 or D_{3d} conformation, or has a structure of their mixture in the solution. Since a large caesium ion cannot accommodate in the hole of the 18-crown-6 ring and is located appart from the mean plane of the ring, the ring may be more flexible than that in the sodium and potassium complexes, in which these ions are kept at the center of the ring, and thus, the latter explanation (mixture model) cannot be rejected from the conclusion. Since the frequency factor for the Cs–O bond in the D_{3d} model converged to 7.1(4), the caesium ion may be solvated with one to two water molecules in the solution.

In Fig. 13 plausible structures are depicted for the alkali metal complexes with 18-crown-6 in aqueous solution examined, except fot the lithium complex whose structure was not estimated from the present work. Broken lines in the figure indicate corn angles around the central metal ions which are drawn by taking into account the van der Waals radii of oxygen, carbon, and hydrogen atoms in the 18-crown-6 ring. It is seen from the corn angles, it may be possible that only one water molecule combines with sodium ion in the complex. In the potassium complex, two water molecules can approach the central ion. For the caesium complex, about two water molecules can interact with caesium ion from one side of the crown ring.

The work has been financially supported by the Grant-in-Aid for Scientific Research No. 63612005 (Macromolecular Complexes) from the Ministry of Education, Science and Culture. Computer calculations were carried out at the computer center of the Institute for Molecular Science in Okazaki.

The Thermal Decomposition of Ammonium Strontium *cyclo*-Tri-, *cyclo*-Tetra-, and *cyclo*-Hexaphosphate

Atsushi TAKENAKA,* Itaru MOTOOKA,† and Hiroyuki NARIAI
Department of Industrial Chemistry, Yonago National College of Technology, Otakazuna, Hikona-cho, Yonago, Tottori 683
†Department of Chemistry, Faculty of General Education, Kobe University, Tsurukabuto, Nada-ku, Kobe 657
(Received May 11, 1988)

Ammonium strontium *cyclo*-triphosphate $Sr(NH_4)P_3O_9 \cdot 3H_2O$ [P_{3m}], *cyclo*-tetraphosphate $Sr(NH_4)_2P_4O_{12}$ [P_{4m}], and *cyclo*-hexaphosphate $Sr_2(NH_4)_2P_6O_{18} \cdot 7H_2O$ [P_{6m}] were prepared by a wet method. The thermal decomposition of the *cyclo*-phosphates was investigated by means of TG-DTA, HPLC-FIA, X-ray analysis, and IR spectrometry. Streams of humid air and dry nitrogen gas were used to clarify the effect of humidity on the pyrolysis. The decomposition of the ring structure of P_{3m} and P_{4m} was accompanied by the elimination of ammonia. Although P_{6m} lost some of the waters of crystallization without any change in the structure, the ring was cleaved by the release of the other waters of crystallization. Regardless of the *cyclo*-phosphates, the final crystalline product was β-$Sr(PO_3)_2$, with a long-chain anion. The formation of β-$Sr(PO_3)_2$ was facilitated by water vapor in the cases of P_{3m} and P_{6m}. Unlike the pyrolysis of $(NH_4)_6P_6O_{18} \cdot 1.5H_2O$ and $(NH_4)_4P_4O_{12}$, it was unlikely that P_{3m}, P_{4m}, and P_{6m} were decomposed to produce oligophosphate radicals. They were probably hydrolyzed to oligophosphates; then, polyphosphates were formed by the condensation of the oligophosphates.

In general, the formation and the structure of condensed phosphates depend on the temperature and the time of heating, the cooling rate of the melts, and the pressure of water vapor in the atmosphere.[1-7] Moreover, it is known that the valence and the radius of the constituent metal ion also affect the structures of condensed phosphates.[8]

We reported in a previous paper[9] that ammonium *cyclo*-tetra- and *cyclo*-hexaphosphates decomposed to produce ammonium polyphosphate through some lower-condensed phosphate radicals. If such a mechanism as a radical decomposition-polymerization depends on the radius of the constituent cation, it is of interest to study the thermal decomposition of ammonium metal(II) *cyclo*-phosphate, prepared by replacing the ammonium ion of the ammonium *cyclo*-phosphates with a bivalent metal ion having a radius close to that of the ammonium ion.

Though the strontium ion has a radius somewhat less than that of the ammonium ion,[10] an attempt to produce ammonium strontium *cyclo*-hexaphosphate (P_{6m}) in solution was successful. However, we could not prepare ammonium barium (which has a radius[10] close to that of the ammonium ion) *cyclo*-hexaphosphate by a wet method. Therefore, we chose strontium as the metal ion to substitute for the ammonium ion.

Durif et al. prepared ammonium strontium *cyclo*-tetraphosphate by a solid-state reaction, and then investigated it crystallographically.[11] Ammonium strontium *cyclo*-triphosphate, synthesized through a solid-state reaction, was studied by means of IR spectroscopy by Serazetdinov et al.[12] However, ammonium strontium *cyclo*-hexaphosphate has not yet been reported. The purpose of this work is to study the thermal decomposition of P_{6m}, in connection with the effect of humidity in the atmosphere, as well as the thermal decompositions of ammonium strontium *cyclo*-tri- (P_{3m}) and *cyclo*-tetraphosphate (P_{4m}), both prepared by the wet method.

Experimental

Chemicals. Guaranteed-grade reagents were used unless otherwise stated.

Determination of Strontium, Nitrogen, Phosphorus, and the Water of Crystallization. The strontium was determined by means of a replacement titration technique, in which Mg-EDTA and Eriochrome Black T(EBT) were employed.[13] The nitrogen content was obtained by means of an ammonia-distillation method.[14]

The strontium ions were precipitated as strontium oxalate[15] or removed by the use of a cation-exchange resin, Amberlite IR-120B.[16] Then, phosphates were hydrolyzed with diluted hydrochloric acid.[17] The resultant phosphates were determined colorimetrically.[18]

A sample was mixed with zinc oxide. The mixture was heated to a constant weight at 650 °C.[19] The amount of the water of crystallization could be determined by subtracting the weight loss due to the evolution of ammonia and the water arising from the NH_4^+ ions, calculated from the nitrogen content, from the total weight loss of the mixture.

X-Ray Diffractometry. The X-ray diffraction patterns were recorded on a Rigaku Denki Geigerflex X-ray diffractometer, RAD-IA, using nickel-filtered Cu $K\alpha$ radiation.

Thermal Analysis. About 20 mg of the sample was placed in a platinum pan. The thermal analyses (TG-DTA) were carried out at the heating rate of 2.5 °C min^{-1} on a Rigaku High-temperature-type Thermal Analyser, 8076 D1. The measurements were performed in stationary air or in a stream of dry N_2 gas at 50 cm^3 min^{-1}. The dry N_2 gas was introduced for 30 min before the measurements.

HPLC-Flow Injection Analysis (HPLC-FIA). The ratio of individual phosphates was determined according to the method in the literature.[9]

IR Spectrophotometry. The IR spectra were recorded on a JASCO IR spectrophotometer, IR-700, by the use of a Nujol-mull method.

Thermal Decomposition. The thermal decomposition

was carried out in a way similar to that previously reported,[9] although a stream of dry N_2 gas (50 cm^3 min^{-1}) was used instead of that of dry air.

The amount of ammonia evolved by the pyrolysis was determined as follows. The effluent gas (dry nitrogen or humid air) was introduced continuously into 30 cm^3 of a 0.01 mol dm^{-3} sulfuric acid at 50 cm^3 min^{-1}. When the furnace had reached the required temperature, the sample was taken out quickly and the gas (dry nitrogen or humid air) was passed into the acid for a further 10 min to absorb any ammonia remaining in the furnace. The ammonia absorbed in the solution was determined by means of a back-titration technique, using a 0.02 mol dm^{-3} sodium hydroxide solution and Methyl Red as an indicator.

Preparation of Ammonium Strontium *cyclo*-Phosphates. **Ammonium Strontium *cyclo*-Triphosphate Trihydrate $Sr(NH_4)P_3O_9 \cdot 3H_2O$:** Twenty mmol (5.8188 g) of $(NH_4)_3P_3O_9$,[21] prepared by means of the ammoniation of $Na_3P_3O_9 \cdot H_2O$,[22] were dissolved in 80 cm^3 of water. This solution was then mixed with 40 cm^3 (20 mmol) of a 0.5 mol dm^{-3} strontium chloride aqueous solution, and the mixture was stirred for 30 min. The precipitate was filtered off and washed with cold water, 50% (v/v) ethanol–water, and then methanol. The product was air-dried. Found: Sr, 21.88; N, 3.33; P, 23.95; H_2O, 14.28%. Calcd for $Sr(NH_4)P_3O_9 \cdot 3H_2O$: Sr, 22.10; N, 3.53; P, 23.43; H_2O, 13.62%. The X-ray diffraction data are listed in Table 1. Ninety-three per cent of the P atoms were found by HPLC-FIA to be present as *cyclo*-$P_3O_9^{3-}$.

Ammonium Strontium *cyclo*-Tetraphosphate $Sr(NH_4)_2P_4O_{12}$: Fifteen mmol (5.82 g) of anhydrous $(NH_4)_4P_4O_{12}$,[21] obtained from $Na_4P_4O_{12} \cdot 4H_2O$,[23] were dissolved in 60 cm^3 of water. Fifteen-cm^3 (7.5 mmol) of the 0.5 mol dm^{-3} strontium chloride solution was then added, and the mixture was stirred. After 1 h, the precipitate was filtered off, washed, and dried as described above. At least 92% of the P atoms were in the form of *cyclo*-tetraphosphate. The X-ray diffraction pattern was in agreement with that of $Sr(NH_4)_2P_4O_{12}$, reported by Durif et al.[11] The elemental analyses also suggested that the product was anhydrous $Sr(NH_4)_2P_4O_{12}$.

Ammonium Strontium *cyclo*-Hexaphosphate Heptahydrate $Sr_2(NH_4)_2P_6O_{18} \cdot 7H_2O$: Five mmol (3.045 g) of $(NH_4)_6P_6O_{18} \cdot 1.5H_2O$ were dissolved in 30 cm^3 of water.[9] Then the solution was mixed with 20 cm^3 (10 mmol) of the 0.5 mol dm^{-3} strontium chloride solution. The mixture was stirred for 30 min. The precipitate was then filtered off, washed, and dried as above. Found: Sr, 21.87; N, 3.32; P, 23.03; H_2O, 15.57%. Calcd for $Sr_2(NH_4)_2P_6O_{18} \cdot 7H_2O$: Sr, 21.61; N, 3.45; P, 22.91; H_2O, 15.53%. At least 97% of the P atoms were found as *cyclo*-$P_6O_{18}^{6-}$ ions. The X-ray diffraction data are shown in Table 2.

Results and Discussion

Thermal Decomposition of Ammonium Strontium *cyclo*-Triphosphate $Sr(NH_4)P_3O_9 \cdot 3H_2O$. Figure 1 shows the thermal analyses (TG-DTA) in stationary air and in a stream of N_2 gas. Strong endothermic peaks with a weight loss appeared at 130 °C in both atmospheres. In stationary air (humid atmosphere), there was an endothermic peak at about 340 °C and an exothermic peak at about 355 °C. These peaks shifted to 360 and 390 °C respectively in a stream of dry N_2 gas (dry atmosphere).

The amount of the individual phosphate in the products obtained by heating up to the temperature indicated by arrows in Fig. 1, changed as is shown in Fig. 2. The *cyclo*-triphosphate anion of P_{3m} was not decomposed, at least not until 250 °C. Figure 3 represents the amount of ammonia evolved by heating P_{3m}, as a function of the temperature. Since ammonia

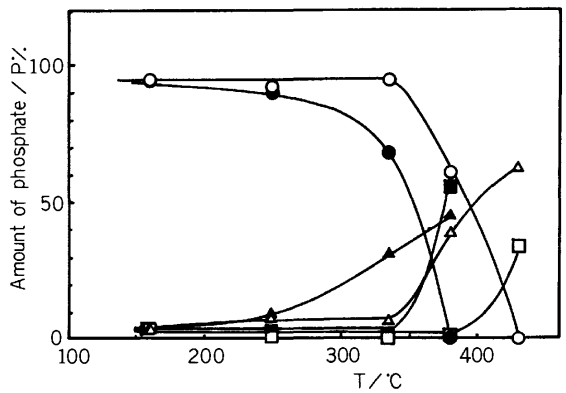

Fig. 2. Amounts of phosphates in the decomposition products of $Sr(NH_4)P_3O_9 \cdot 3H_2O$. ○ and ●: *cyclo*-Triphosphate observed in the dry and the humid atmospheres, respectively; □ and ■: oligophosphates with the chain length less than three, observed in the dry and the humid atmospheres respectively; △ and ▲: polyphosphates with the chain length more than four, in the dry and the humid atmospheres respectively.

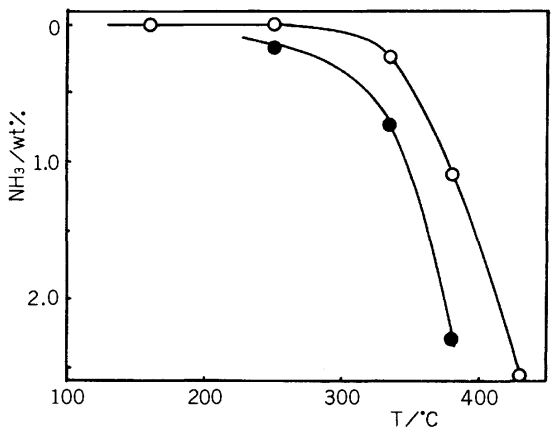

Fig. 3. Amount of ammonia evolved by heating $Sr(NH_4)P_3O_9 \cdot 3H_2O$. ○: Measured in the dry atmosphere, ●: in the humid atmosphere.

was not evolved up to 250 °C in the dry atmosphere, the endothermic peak at 130 °C was attributed to the elimination of the water of crystallization. The corresponding TG-loss (13.1%) was close to the calculated value (13.62%).

Figure 3 shows that the water vapor accelerated the evolution of ammonia. A similar "catalytic effect" of the water vapor was reported in the reaction of calcium oxide with ammonium chloride.[24]

The product obtained by heating up to 380 °C in the dry atmosphere contained many P_{3m} anions, and the evolution of ammonia was clearly observed above 335 °C. It was supposed that not the cleavage of the P_{3m} anions but the evolution of ammonia from P_{3m} caused the endothermic peak at 360 °C.

Since the decomposition of P_{3m} was influenced by the humidity, as is shown in Fig. 2, and since neither an increase in weight nor a corresponding exothermal peak may be seen in Fig. 1, P_{3m} can not be thought to form oligophosphate radicals.[9] Therefore, polyphosphates with a chain length of more than four must be produced through the condensation of oligophosphates.

Considerable ammonia was lost at 380 and 430 °C in the humid and dry atmospheres respectively (Fig. 3). It is expected that the product became acidic and that a vigorous hydrolytic reaction took place at 380 and 430 °C. Obviously, the total quantities of the oligophosphates with a chain length of less than three, which were considered to be the initial hydrolytic products of P_{3m} (or perhaps the oligophosphates are produced from the polyphosphates), were greater at 380 and 430 °C (Fig. 2).

Although the products from 160 to 380 °C under dry conditions did not change X-ray diffractometrically, the sample heated up to 380 °C was somewhat amorphous. The X-ray diffraction pattern of the product obtained by heating up to 430 °C under the dry condition agreed with that of β-$Sr(PO_3)_2$ with a long-chain anion. Consequently, the exothermic peak at 390 °C (or 355 °C for the humid conditions) was attributable to the following reaction (1), although the temperature was lower than 430 °C, as has been observed by Ropp et al.:[20]

$$Sr(PO_3)_2\,[\text{amorphous}] \longrightarrow \beta\text{-}Sr(PO_3)_2\,[\text{crystalline}] \quad (1)$$

The thermal decomposition may be summarized as follows (the water of crystallization was lost at 130 °C):

$$Sr(NH_4)P_3O_9 \cdot 3H_2O \longrightarrow Sr(NH_4)P_3O_9 + 3H_2O \quad (2)$$

Above 335 °C (or 250 °C for the humid conditions), polyphosphates began to form, accompanied by the evolution of ammonia (Figs. 2 and 3). Therefore, the following reaction takes place above that temperature:

$$Sr(NH_4)P_3O_9 \longrightarrow Sr(PO_3)_2\,[\text{amorphous}] + (NH_4)_{1-n}H_n(PO_3)\,[\text{amorphous}] + nNH_3 \quad (3)$$

where $Sr(PO_3)_2$ and $(NH_4)_{1-n}H_n(PO_3)$ are polyphosphates. They are formed through the condensation of oligophosphates. At a higher temperature (430 and 380 °C respectively), because of the loss of ammonia, the hydrolysis becomes vigorous enough to produce an appreciable amount of oligophosphates, as has been mentioned above.

Thermal Decomposition of Ammonium Strontium *cyclo*-Hexaphosphate $Sr_2(NH_4)_2P_6O_{18}\cdot 7H_2O$. Figure 4 shows the results of thermal analyses in the dry and humid atmospheres. The products, heated up to the temperatures indicated by the arrows in Fig. 4, were analyzed. Heating up to 200 °C, irrespective of the conditions, did not cause any ammonia-elimination. Consequently, the two large endothermic peaks below 130 °C and the set of endothermic peaks from 130 to 200 °C were considered to result from the elimination of the water of crystallization. The two large endothermic peaks were shifted to a higher temperature by an enhanced partial pressure of water vapor.

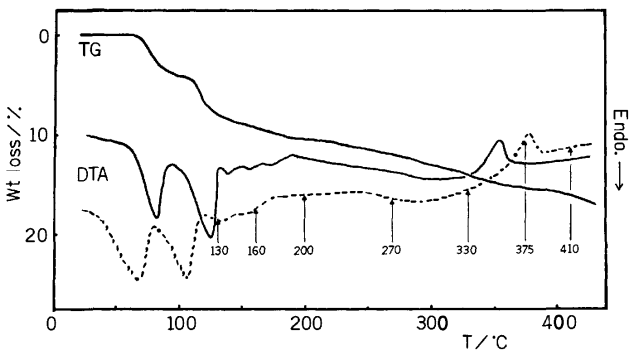

Fig. 4. TG-DTA analyses of $Sr_2(NH_4)_2P_6O_{18}\cdot 7H_2O$ measured in the two different atmospheres. Solid line (—): TG and DTA in stationary air, dotted line (---): DTA in a stream of dry N_2 gas.

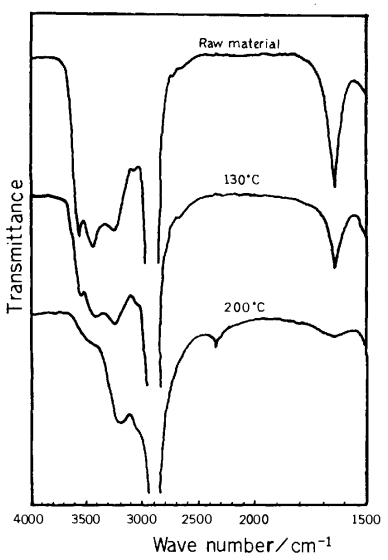

Fig. 5. IR spectra of the products at 130 and 200°C of $Sr_2(NH_4)_2P_6O_{18}\cdot 7H_2O$ in dry atmosphere.

There were absorptions at 3560 cm^{-1} in the IR spectra of P_{6m} and the product heated up to 130 °C (Fig. 5). These absorptions (as high as 3580 cm^{-1}) were attributed to the "interstitial" water molecules, loosely held in the crystal lattice.[25] The sharp and strong band at 1640 cm^{-1} of P_{6m} was also assigned to these water molecules.[25] The "interstitial" water may be identical with the so-called "Zeolitic Water."[26,27] Since the *cyclo*-hexaphosphate anion was not cleaved (Fig. 6), and since the structure of the products did not change X-ray diffractometrically until 130 °C (though the diffraction lines became weak), the endothermic peaks below 130 °C can be regarded as being caused by the elimination of a part of the interstitial water molecules.

The decomposition of P_{6m} was found not to be dependent on the humidity, and neither an increase in weight nor the corresponding exothermic reaction was observed (Figs. 6 and 4). Thus, P_{6m} could not be presumed to produce oligophosphate radicals as in the pyrolysis of $(NH_4)_6P_6O_{18}\cdot 1.5H_2O$.[9] Therefore, it was probably cleaved by hydrolysis. The absorptions at 1640, 3440, and 3560 cm^{-1} almost disappeared in the sample heated to 200 °C (Fig. 5). Consequently, P_{6m} was considered to lose the water of crystallization completely. The appearance of the peak at 2360 cm^{-1}, assigned to P-OH stretching,[25,28] certainly resulted from the hydrolysis.

The exothermic peak at around 375 °C in the dry atmosphere was shifted to a lower temperature (about 350 °C) in the humid atmosphere. The X-ray diffractogram showed that the phase transition from

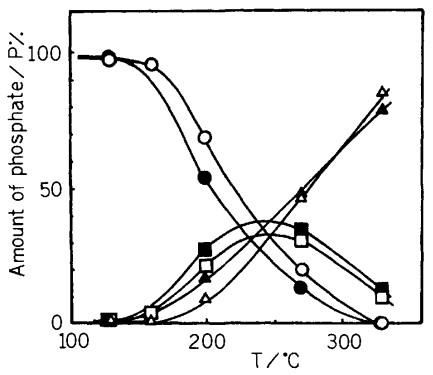

Fig. 6. Amounts of phosphates in the products of $Sr_2(NH_4)_2P_6O_{18}\cdot 7H_2O$. ○ and ●: *cyclo*-Hexaphosphate observed in the dry and the humid atmospheres, respectively; □ and ■: oligophosphates with the chain length less than six, observed in the dry and the humid atmospheres respectively; △ and ▲: polyphosphates with the chain length more than seven, in the dry and the humid atmospheres respectively.

amorphous $Sr(PO_3)_2$ to β-$Sr(PO_3)_2$ was exothermic. McGilvery and Scott reported that water vapor facilitated the crystallization of sodium triphosphate, and that water was considered to promote the diffusion of the sodium ions.[5] In a similar way, the diffusion of the strontium ion in the amorphous phase, which was produced before the exothermic peak, might also be facilitated by water vapor, so that the crystallization of β-$Sr(PO_3)_2$ occurred under the humid conditions at a lower temperature.

Thermal Decomposition of Ammonium Strontium *cyclo*-Tetraphosphate $Sr(NH_4)_2P_4O_{12}$. The thermal analysis shows only the large endothermic peak at about 375 °C; this temperature was not influenced by the humidity. The endothermic peak corresponds to the elimination of ammonia from P_{4m}. The decomposition of P_{4m} was accompanied by the elimination of ammonia—analogously to the cleavage of P_{3m}.

The products above 375 °C always contained β-$Sr(PO_3)_2$. No exothermic peak caused by the transition of amorphous $Sr(PO_3)_2$ to β-$Sr(PO_3)_2$ was recognized; the endothermic peak may be supposed to conceal it.

Compared to the cases of $(NH_4)_6P_6O_{18}\cdot 1.5H_2O$ (215 °C) and $(NH_4)_4P_4O_{12}$ (238 °C),[9] the decomposition temperatures of P_{6m} (330 °C) and P_{4m} (420 °C) were heightened by the replacement of the NH_4^+ ion with the Sr^{2+} ion. The ring anions of all the ammonium strontium *cyclo*-phosphates studied (P_{3m}, P_{4m}, and P_{6m}) decomposed, accompanied by a weight loss. No corresponding exothermic peak attributable to the incorporation of water molecules, suggesting the radical formation,[9] was observed in the respective thermal analysis. The decompositions of $(NH_4)_6P_6O_{18}\cdot 1.5H_2O$ and $(NH_4)_4P_4O_{12}$ to the oligophosphate radicals were not influenced by the humidity,[9] whereas the degradation of P_{3m} and P_{6m} depended on the water vapor (Figs. 2 and 6); thus, P_{3m} and P_{6m} were not supposed to bring about a radical decomposition-polymerization. On the other hand, P_{4m} decomposed irrespective of the humidity. However, its thermal analysis showed no increase in weight and no exothermic peak. Accordingly, P_{4m} also could not be proved to produce oligophosphate radicals thermally. In conclusion, the radical decomposition-polymerization of *cyclo*-phosphates probably has no definite relation to the radius of the constituent cation.

The authors wish to thank Miss Fumine Shitani and Mr. Toshihiro Sumioka, who were students in the present college, for their helpful assistance.

Equilibrium and Kinetic Studies of the Iron(III) Complex with *N*-Pyridoxylidene-L-tryptophan: Electronic Absorption and Circular Dichroism Spectral Characteristics, Stability, and Formation and Ligand-Substitution Reaction Mechanisms

Hideyuki KUNO, Ken-ichi OKAMOTO,† Jinsai HIDAKA,† and Hisahiko EINAGA*
Institute of Materials Science, University of Tsukuba, Tsukuba, Ibaraki 305
†Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305
(Received October 24, 1988)

Studies have been made of the electronic absorption and circular dichroism (CD) spectral characteristics, thermodynamic stability, and formation and ligand-substitution reaction kinetics of an iron(III) complex with *N*-pyridoxylidene-L-tryptophan (Hpdx-L-Htrp). The 1:2 (metal:ligand) complex forms in an acidic aqueous solution with the stability constant (β_2) of $\log \beta_2 = 18.38 \pm 0.10$ mol^{-2} dm^6 (0.50 mol dm^{-3} (NaCl), 25 °C). The complex shows a characteristic CD spectrum in the charge-transfer region. The kinetics were studied by a stopped-flow CD method in a 0.50 mol dm^{-3} aqueous NaCl solution at 25 °C. The formation of the complex proceeds through six parallel pathways of Fe^{3+}, $FeOH^{2+}$, and $FeCl^{2+}$ with H_2pdx-L-Htrp$^+$ and H_2pdx-L-trp, with the coordination of the carboxylato group to iron(III) as the rate-determining step. The ligand-substitution reaction of the complex by ethylenediamine-*N*,*N*,*N*′,*N*′-tetraacetic acid depends neither on the entering ligand nor on the hydrogen-ion concentration. The dissociation of a coordinated Hpdx-L-trp$^-$ from [Fe(Hpdx-L-trp)$_2$]$^+$ is concluded to be the rate-determining step. The reaction mechasnisms are discussed in detail.

Metal complexes containing Schiff bases of pyridoxal and optically active amino acids have attracted great attention as reaction intermediates since the pioneering work by Metzler and Snell[1] on the nonenzymatic transamination of the Schiff base of pyridoxal and glutamic acid. This is because these complexes play an important role not only in the transamination, but also in the racemization, decarboxylation, and related reactions, of the amino acids. Many studies have been made since that time of the structures of these Schiff-base complexes of various sorts of metal ions and amino acids; an iron(III) complex with pyridoxal and DL-valine has been isolated in the crystalline state, and its structure has been determined by the X-ray diffraction method.[2] However, little have been known on the reaction kinetics and mechanism as well as on the thermodynamic stability of these complexes.

In the present work, the formation and ligand-substitution reactions of the iron(III) complex with a Schiff base of pyridoxal and L-tryptophan(*N*-pyridoxylidene-L-tryptophan, Hpdx-L-Htrp) were investigated by means of the stopped-flow circular dichroism (CD) method. The iron(III) complex with Hpdx-L-Htrp was chosen here because the Schiff-base ligand forms quantitatively over a wide range of acidities and because the iron(III) complex is stable to coordinated-ligand reactions during a kinetic investigation. The reactions were studied in a 0.50 mol dm^{-3} aqueous sodium chloride solution in order to make it possible to compare the present work's to those in the literature data on *N*-pyridoxylidene-L(and/or D)-amino acids. The reaction mechanisms of the formation and ligand-substitution by ethylenediamine-*N*,*N*,*N*′,*N*′-tetraacetic acid (EDTA, H_4edta) of the iron(III) complex will be discussed in detail.

Experimental

Reagents. The analytical-grade reagents of pyridoxal (as hydrochloride) and L-tryptophan were supplied by the Tokyo Kasei Kogyo Co., Ltd., Tokyo, and the Wako Pure Chemicals Ind., Ltd., Osaka, and by the Kanto Chemical Co., Ltd., respectively. The Hpdx-L-Htrp was prepared by the condensation of pyridoxal and L-tryptophan in an aqueous solution in the usual manner. The ligand was characterized by the elemental analysis. A stock solution of iron(III) was prepared from $(NH_4)Fe(SO_4)_2 \cdot 12H_2O$ and was acidified with the minimum quantity of sulfuric acid necessary to prevent the hydrolysis of iron(III). The absence of traces of iron(II) was checked on the the stock solution by means of a reaction with 2,2′-bipyridine. The other reagents used were of an analytical or equivalent grade.

Measurements. The electronic absorption and CD spectra were recorded on a JASCO spectrophotometer, model UVIDEC-1M, and a JASCO spectropolarimeter, model J-500C. The protonation, stability, and rate constants were determined in a 0.50 mol dm^{-3} aqueous NaCl solution at 25.0±0.1 °C.

The pH of the solution was measured with an Orion Research digital pH meter, model 801A, with glass and saturated calomel electrodes. The hydrogen-ion concentration, $-\log [H^+]$, was calculated from the pH value, pH_{meas}, according to Eq. 1:

$$-\log [H^+] = pH_{meas} + \log f_{H^+} \quad (1)$$

The coefficient, f_{H^+}, was estimated on the basis of the literature procedure[3] by defining a solution containing 0.0100 mol dm^{-3} of HCl and 0.4900 mol dm^{-3} of NaCl at 25 °C as having $-\log [H^+] \equiv 2.00$.

The kinetic runs were carried out on the JASCO spectropolarimeter, to which were attached a stopped-flow apparatus, model SFC-5, a data processor, model DP-500, and a Watanabe Sokki X-Y recorder, model WX-441. The formation reaction was studied at 600 nm by following the

CD-intensity change with the time under the pseudo-first-order kinetic conditions for the metal-ion concentration. The ligand-substitution reaction of the iron(III) complex with Hpdx-L-Htrp by EDTA was studied at the same wavelength under the pseudo-first-order kinetic conditions used for the iron(III) complex concentration. These conditions satisfied the requirement that the CD intensity depends linearly on the concentration of the iron(III) complex with Hpdx-L-Htrp. This complex was stable enough to show no racemization of the coordinated ligand during the kinetic runs.

The observed rate constant, k_{obsd}, was calculated from the slope of the linear relation, $-\ln(\Delta E_t - \Delta E_\infty)$ vs. t, on the basis of Eq. 2:

$$\ln\{(\Delta E_0 - \Delta E_\infty)/(\Delta E_t - \Delta E_\infty)\} = k_{obsd}t \qquad (2)$$

where ΔE_0, ΔE_t, and ΔE_∞ stand for the CD intensities at the initial state, at time t, and at equilibrium, respectively. Good straight lines were obtained for the formation and lignd-substitution reactions for more than three half-life periods.

Results and Discussion

Electronic Absorption and CD Spectra. Figure 1 shows the electronic absorption and the CD spectra of the iron(III) complex, with the corresponding values for Hpdx-L-Htrp and the free ligand shown for the sake of comparison. The iron(III) complex gives new absorption bands as shoulders near 18×10^3 and 23×10^3 cm^{-1} assignable to the $t_{2g}(O_h)\leftarrow\pi$ and $\pi_2^*\leftarrow e_g(O_h)$ charge-transfer transitions, and a shoulder near 28×10^3 cm^{-1} and bands around 35×10^3 cm^{-1} assignable to the $\pi_1^*\leftarrow\pi$ (azomethine chromophore) and $\pi_2^*\leftarrow\pi$ (pyridine and indole ring chromophores) transitions of the coordinated ligand.[4-14] The CD spectrum of the iron(III) complex shows new negative and positive bands at 16.6×10^3 and 19.1×10^3 cm^{-1} in the $t_{2g}(O_h)\leftarrow\pi$ transition region due to a diastereoisomeric pair of the complex, Δ_{LL}-spiral and Λ_{LL}-spiral,[15] with the meridional (mer) coordination[2,16-19] of Hpdx-L-Htrp. The relatively large magnitude of the $\Delta\varepsilon$ on the CD spectrum indicates that one of the diastereoisomers is present in solution in preference to the other and that the CD spectral pattern in the $t_{2g}(O_h)\leftarrow\pi$ transition region reflects the total concentration of the complex.

Hence, the absorption and CD spectral bands in the wavenumber region below 21×10^3 cm^{-1} can be used for the thermodynamic and kinetic studies of the iron(III) complex with Hpdx-L-Htrp.

Stability. The protonation constants of Hpdx-L-Htrp were determined spectrophotometrically for $K_{a(phOH)}$ (=[Hpdx-L-trp$^-$]/[H$^+$][pdx-L-trp^{2-}]) at the absorption maximum of the pdx-L-trp^{2-} species (394 nm) and for $K_{a(pyNH)}$ (=[H$_2$pdx-L-trp]/[H$^+$][Hpdx-L-trp$^-$]) at that of the Hpdx-L-trp$^-$ species (390 nm), exept for $K_{a(COOH)}$ (=[H$_2$pdx-L-Htrp$^+$]/[H$^+$][H$_2$pdx-L-trp]), which was estimated separately (vide infra) because of the very small spectral changes on protonation to the H$_2$pdx-L-trp sepcies. The data are summarized in Table 1.

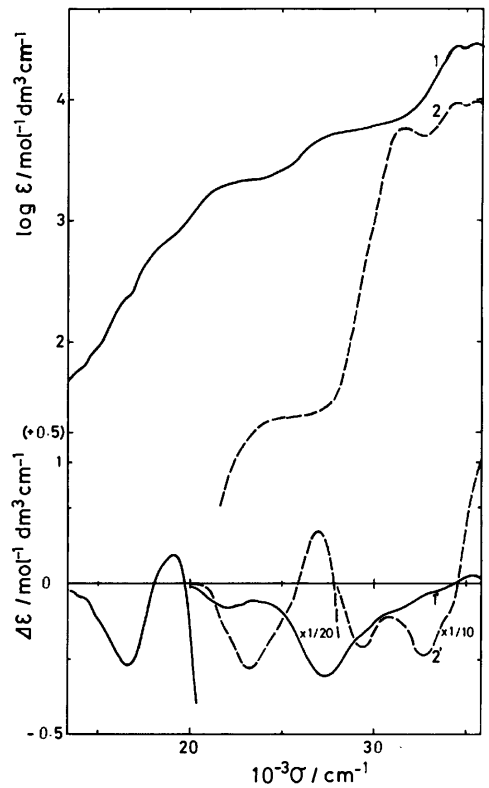

Fig. 1. Electronic absorption and CD spectra of iron(III) complex with Hpdx-L-Htrp in aqueous solution. 1,1': [Fe(Hpdx-L-trp)$_2$]$^+$; and 2,2': H$_2$pdx-L-trp species. The complex was used after isolation as a solid (Anal.($C_{38}H_{38}N_6O_8Cl_2FeCl\cdot H_2O$) C,H,N,Fe).

Table 1. Protonation and Stability Constants

	$\log K_{a(COOH)}$	$\log K_{a(pyNH)}$	$\log K_{a(phOH)}$
	mol^{-1} dm^3	mol^{-1} dm^3	mol^{-1} dm^3
Hpdx-L-Htrp[a]	2.30±0.05	4.10±0.05	8.24±0.05
	$\log\beta_1$	$\log\beta_2$	
	mol^{-1} dm^3	mol^{-2} dm^6	
[Fe(Hpdx-L-trp)$_2$]$^+$	9.65±0.10	18.38±0.10	

0.50 mol dm^{-3} (NaCl), 25 °C. a) The $K_{a(COOH)}$, $K_{a(pyNH)}$, and $K_{a(phOH)}$ of the ligand refer to the protonations at the carboxylate oxygen, pyridyl nitrogen, and phenolate oxygen respectively.

The stability constants of the iton(III) complex with Hpdx-L-Htrp were determined spectrophotometrically at 450 nm under the experimental conditions of $C_L \gg C_M$ (C_L and C_M are the total concentrations of iron(III) and Hpdx-L-Htrp; C_M is of the order of 10^{-4} mol dm^{-3}). By taking into consideration the hydrolysis constant ($\log K^{11}_{OH} = -2.72$ mol dm^{-3} (0.50 mol dm^{-3} ($NaClO_4$), 25 °C; $K^{11}_{OH} = [FeOH^{2+}][H^+]/[Fe^{3+}]$)[20,21] and the chloro complex formation constant ($\log \beta^1_{Cl} = 0.64$ mol^{-1} dm^3 (0.50 mol dm^{-3}(—), 25 °C; $\beta^1_{Cl} = [FeCl^{2+}]/[Fe^{3+}][Cl^-]$)[22] of iron(III), and the protonation constants of Hpdx-L-Htrp, the following relations can be derived[23] for the bis-ligand complex:

$$\log (A_{max} - A)/(A - A_{min}) = 2 \log \{k_{a(phOH)}[H^+] (K_{a(COOH)}[H^+] + 1)\} + \log (1 + K^{11}_{OH}[H^+]^{-1} + \beta^1_{Cl}[Cl^-]) - \log \beta_2 C_L^2 \quad (3)$$

and for the mono-ligand complex:

$$\log (A_{max}' - A)/(A - A_{min}) = \log \{k_{a(phOH)}[H^+] (K_{a(COOH)}[H^+] + 1)\} + \log (1 + K^{11}_{OH}[H^+]^{-1} + \beta^1_{Cl}[Cl^-]) - \log \beta_1 C_L \quad (4)$$

Here, A_{max} stands for the absorbance of a solution in which the bis-ligand complex forms quantitatively: A_{max}', for that of a solution in which the mono-ligand complex forms quantitatively; A_{min}, for that of a solution containing the ligand alone, and A, for that of a solution in which the bis-ligand or the mono-ligand complex and the free ligand coexist.

The experimental data are depicted in Fig. 2. Good linear relations with a slope of unity were obtained above $-\log [H^+]$ of 2.3 (cf. line 1) and below 1.9 (cf. line 2) with a suitable assumption of the value of A_{max}' between the absorbance and the hydrogen-ion-concentration terms of Eqs. 3 and 4, respectively. The stability constants for the bis-ligand complex (β_2) and the mono-ligand complex (β_1) are summarized in Table 1.

The behavior of pyridyl nitrogen during the complex formation should also be discussed. In a weakly acidic aqueous solution, the principal complex formation reaction equilibrium can be expressed as follows ($C_L \gg C_M$):

$$Fe^{3+} + 2\,H_2pdx\text{-}L\text{-}trp \rightleftharpoons [Fe(Hpdx\text{-}L\text{-}trp)_2]^+ + 2H^+ \quad (5)$$

Here, pyridyl nitrogen was assumed still to be protonated in the coordinated ligand, because a reasonable analysis of the experimental data on absorbance vs. the hydrogen-ion concentration based on the formation of $[Fe(pdx\text{-}L\text{-}trp)_2]^-$ and the liberation of four protons per complex instead of Eq. 5 was unsuccessful. This means that the coordination of

Dependence of k_{obsd} on $[H^+]$, on C_L, and on $[Cl^-]$. 1: C_L: 7.50×10^{-3} mol dm^{-3}; C_M: 2.50×10^{-4} mol dm^{-3}; 0.50 mol dm^{-3} (NaCl). 2: C_M: 2.50×10^{-4} mol dm^{-3}; $[H^+]$: 1.05×10^{-2} mol dm^{-3}; 0.50 mol dm^{-3} (NaCl). 3: C_M: 2.50×10^{-4} mol dm^{-3}; $[H^+]$: 8.10×10^{-4} mol dm^{-3}; 0.50 mol dm^{-3} (NaCl). 4: C_L: 7.50×10^{-3} mol dm^{-3}; C_M: 2.50×10^{-4} mol dm^{-3}; $[H^+]$: 7.18×10^{-3} (◐), 1.05×10^{-2} (○), and 1.28×10^{-2} mol dm^{-3} (◑); $[NaCl]+[NaClO_4]$: 0.50 mol dm^{-3}. 25 °C; and λ: 600 nm.

Hpdx-L-Htrp to iron(III) has little influence on the basicity of pyridyl nitrogen.

Formation-Reaction Kinetics. Experimental data on the relations between k_{obsd} and $[H^+]$, k_{obsd} and C_L, and k_{obsd} and $[Cl^-]$ under the conditions of $C_L \gg C_M$ are given in Fig. 3. The linear relation between k_{obsd} and C_L at constant $[H^+]$ and $[Cl^-]$ values, which can be extrapolated to the point of origin, indicates that the coordination of the first Hpdx-L-Htrp to iron(III) corresponds to the rate-determining step.

In the formation of the mono-ligand complex as the rate-determining step, six reaction pathways contributing Fe^{3+}, $FeOH^{2+}$, and $FeCl^{2+}$ for the metal ion and H_2pdx-L-Htrp$^+$ and H_2pdx-L-trp for the ligand are possible by taking into consideration the protonation constants of the ligand, the hydrolysis constant of iron(III), and the stability constants of the chloro and the Hpdx-L-Htrp complexes, and the rapid attainment of equilibria for the protolytic processes[3] as compared with the complex formation process. The following rate equation can be derived under the pseudo-first-order kinetic conditions for C_M:

$$d[[Fe(Hpdx\text{-}L\text{-}trp)_2]^+]/dt = k_{obsd}([[Fe(Hpdx\text{-}L\text{-}trp)_2]^+]_\infty - [[Fe(Hpdx\text{-}L\text{-}trp)_2]^+]) \quad (6)$$

$$k_{obsd}(1 + K^{11}_{OH}[H^+]^{-1} + \beta^1_{Cl}[Cl^-])(K_{a(COOH)}[H^+] + 1)\, C_L^{-1} = (k_{31} + k_{21(Cl)}\beta^1_{Cl}[Cl^-])K_{a(COOH)}[H^+] + k_{30} + k_{20(Cl)}\beta^1_{Cl}[Cl^-] + k_{21}K^{11}_{OH}K_{a(COOH)} + k_{20}K^{11}_{OH}[H^+]^{-1} \quad (7)$$

Here, k_{ij} is the rate constant for the reaction pathway of $[Fe(OH)_{3-i}]^{i+}$ (i=2 and 3), and $k_{2i(Cl)}$, that for the pathway of $FeCl^{2+}$ with H_2pdx-L-H$_j$trp^{j+} (j=0 and 1).

The experimental data given in Fig. 3 indicate that k_{obsd} is constant in the case of changes in $[Cl^-]$ within the limits of experimental error and that the k_{obsd} value can be classified by acidity region: that in the higher-acidity region, where the contribution of the pathway of k_{20} can be neglected, and that in the lower-acidity region, where that of the pathways of k_{31} and $k_{21(Cl)}$ can be neglected. Firstly, the data in the higher-acidity region ($-\log [H^+] < 2.4$) were analyzed at a constant $[Cl^-]$ under the assumption of a suitable numerical value of $K_{a(COOH)}$ so that a good linear relation could be obtained between $k_{obsd}(1+K^{11}_{OH}[H^+]^{-1}+\beta^1_{Cl}[Cl^-])(K_{a(COOH)}[H^+]+1)\, C_L^{-1}$ and $[H^+]$. Secondly, by using the $K_{a(COOH)}$ value thus estimated and the intercept, which is equal to the $k_{30}+k_{20(Cl)}\beta^1_{Cl}[Cl^-]+k_{21}K^{11}_{OH}K_{a(COOH)}$ derived from the above relation, the data in the lower-acidity region ($-\log [H^+] > 2.4$) were analyzed for the linear relation between $k_{obsd}(1+K^{11}_{OH}[H^+]^{-1}+\beta^1_{Cl}[Cl^-])(K_{a(COOH)}[H^+]+1)\, C_L^{-1}$ and $[H^+]^{-1}$. Finally, $k_{31}K_{a(COOH)}+k_{21(Cl)}\beta^1_{Cl}K_{a(COOH)}[Cl^-]$ and $k_{30}+k_{21}K^{11}_{OH}K_{a(COOH)}+k_{20(Cl)}\beta^1_{Cl}[Cl^-]$ were plotted against $[Cl^-]$ to obtain the individual rate constant. Those of k_{31}, $k_{31(Cl)}$, k_{20}, $k_{20(Cl)}$, and $k_{30}+k_{21}K^{11}_{OH}K_{a(COOH)}$, the last of which cannot be separated because of the proton ambiguity (vide infra), are summarized in Table 2.

Many kinetic data have been reported[24] for the iron(III) complexes with various sorts of ligands. The rate constant for the pathway of Fe^{3+} with H_2pdx-L-Htrp$^+$, k_{31}, is in close proximity to the constants for the reaction pathways of Fe^{3+} with aliphatic carboxylic acids. This fact indicates that the coordination of Hpdx-L-Htrp to iron(III) proceeds through the donation of the carboxylato group of the amino acid moiety rather than the phenolato group of the pyridoxal moiety, because the analysis of kinetic data by using $K_{a(phOH)}$ instead of $K_{a(COOH)}$ gave an extremely small and unreasonable magnitude of k_{31}. Furthermore, this close proximity in the rate constants substantiates the fact that the rate-determining step of the reaction of iron(III) with Hpdx-L-Htrp lines in the coordination of the first ligand to iron(III), because the rate constants for Fe^{3+} with these carboxylic acid ligands have been determined on the mono(carboxylato)iron(III) complexes.[25-32]

Contrary to k_{31}, k_{20} is considerably smaller than the value of $FeOH^{2+}$ with $ClCH_2COO^-$ (k_{20}: $(4.1\pm0.2)\pm10^4$ mol^{-1} dm^3 s^{-1} (1 mol dm^{-3}($NaClO_4$), 25 °C).[25] The magnitude of k_{20} reflects the fact that the carboxylato group of H_2pdx-L-trp ligand species may not be free, but hydrogen-bonded. There is a possibility of an intramolecular hydrogen bond between the hydroxyl and the carboxylato groups for the enol imine form and also between the imino hydrogen and the carboxylato group for the keto enamine form of Hpdx-L-Htrp. This role of the intramolecular hydrogen bond is substantiated by a comparison of the rate constant for $FeOH^{2+}$ with $ClCH_2COO^-$ (k_{20}: vide supra) with that for $FeOH^{2+}$ with the monoprotonated salicylato ligand (k_{21}: 2.9×10^3 mol^{-1} dm^3 s^{-1} (0.1 mol dm^{-3}

Table 2. Rate Constants for the Iron(III) Complex with Hpdx-L-Htrp

Pathway	k_{ij} / mol^{-1} dm^3 s^{-1}
$Fe^{3+}+H_2$pdx-L-Htrp$^+$ (k_{31})	10.1±0.3
$Fe^{3+}+H_2$pdx-L-trp and $FeOH^{2+}+H_2$pdx-L-Htrp$^+$ ($k_{30}+k_{21}K^{11}_{OH}K_{a(COOH)}$)	21.3±0.6
$FeCl^{2+}+H_2$pdx-L-Htrp$^+$ ($k_{21(Cl)}$)	11.7±0.3
$FeCl^{2+}+H_2$pdx-L-trp ($k_{20(Cl)}$)	11.5±0.3
$FeOH^{2+}+H_2$pdx-L-trp (k_{20})	32.5±0.3
$[Fe(Hpdx\text{-}L\text{-}trp)_2]^+$ ($+H_2O$) ($k_{-3\bar{1}}$)	2.9±0.3[a]

0.50 mol dm^{-3} (NaCl), 25 °C. a) $k_{-3\bar{1}}$/s^{-1}.

($LiClO_4$), 25 °C[31] and (1.4±0.1) $\times 10^4$ mol^{-1} dm^3 s^{-1} (1.0 mol dm^{-3} (KNO_3), 25 °C[32]). The progress of the reaction through the donation of the carboxylato group indicates that there are no fundamental differences in the kinetics of the enol imine and the keto enamine forms of Hpdx-L-Htrp.

The rate constant, $k_{21(Cl)}$, is very close to k_{31}, as can be expected from independence of k_{obsd} on [Cl^-] at constant C_L and [H^+] values. There have been several papers[33-36] concerning with kinetics of Fe^{3+} with Cl^-; the rate-determining step for the formation of $FeCl^{2+}$ from Fe^{3+} and Cl^- has been concluded to be the release of a water molecule from the primary coordination sphere of iron(III).[33,35] The kinetic data (k/mol^{-1} dm^3 s^{-1} ($Fe^{3+}+Cl^-$): 9.4±1.0[33] and 4.8±0.4;[36] and k/s^{-1} ($FeCl^{2+}+H_2O$): 2.3±0.2[33] and 3.2±0.2[36] (1.0 mol dm^{-3},[33] and 1.5 mol dm^{-3} ($NaClO_4$), 25 °C[36]) and the ^{35}Cl and ^{17}O NMR spectral data[34,35] on the exchange of a water molecule and a chloride ion between the primary coordination sphere of the chloro and aqua iron(III) complex species and the bulk solvent establish that the exchange process, together with the protolytic reaction of $Fe^{3+} \rightleftharpoons FeOH^{2+}+H^+$, is rapid enough for us to regard the process as a reversible pre-equilibrium for the kinetic process of Fe^{3+} with Hpdx-L-Htrp. Our experimental data on the close proximity of $k_{21(Cl)}$ to k_{31} support this deduction: The coordinated chloro ligand makes no intrinsic contribution to the coordination reaction kinetics of Hpdx-L-Htrp to iron(III).

The deduction mentioned above indicates that k_{21} can be estimated from the composite rate constants of $k_{30}+k_{21}K_{OH}^{11}K_{a(COOH)}$ given in Table 2, because k_{30} can reasonably be assumed to be equal to $k_{20(Cl)}$. The value of k_{21} thus calculated was 26±6 mol^{-1} dm^3 s^{-1}.

It can be summarized that the formation of the iron(III) complex with Hpdx-L-Htrp proceeds through the parallel pathways of Fe^{3+}, $FeOH^{2+}$, and $FeCl^{2+}$ with H_2pdx-L-Htrp$^+$ and H_2pdx-L-trp via the coordination of the carboxylato group to iron(III) as the mechanistic rate-determining step. This coordination of the carboxylato group follows the rapid coordination of the azomethine nitrogen and the phenolato oxygen to form an intermediate, Fe(Hpdx-L-trp)$^{2+}$, with five- and six-membered fused chelate rings. The coordination of the second Hpdx-L-Htrp to the intermediate proceeds in just the same way as that of the first one, but in a more rapid way as a result of the labilization[3,37] of the remaining coordinated water molecules in Fe(Hpdx-L-trp)$^{2+}$ to complete the thermodynamically more stable [Fe(Hpdx-L-trp)$_2$]$^+$.

Ligand-Substitution Reaction Kinetics. Fe(Hpdx-L-trp)^2]$^+$ gives a ligand-substitution with EDTA to form Fe(edta)$^-$ quantitatively in an acidic aqueous solution under the experimental conditions of $C_{edta} \gg C_M$ and $2C_L > C_M$. The ligand-substitution reaction was of the first order with respect to the starting complex concentration, as has been described in the Experimental section. The relations between k_{obsd} and C_{edta}, between k_{obsd} and [H^+], and between k_{obsd} and C_L are given in Table 3. The k_{obsd} depends neither on C_{edta}, C_L, nor [H^+]; the ligand-substitution reaction proceeds by means of the dissociation of one of the Hpdx-L-trp$^-$ ligands from [Fe(Hpdx-L-trp)$_2$]$^+$ to form Fe(Hpdx-L-trp)$^{2+}$ as an intermediate as the rate-determining step:

Table 3. Kinetic Data of the Ligand-Substitution Reaction

[H^+]	C_{edta}	C_L	k_{obsd}
10^3 mol dm^{-3}	10^2 mol dm^{-3}	10^3 mol dm^{-3}	s^{-1}

4.57	0.500	3.50	3.07
4.57	0.500	4.00	2.86

C_M: 1.00×10^{-4} mol dm^{-3}, 0.50 mol dm^{-3} (NaCl), 25 °C.

$$-d[[Fe(Hpdx\text{-}L\text{-}trp)_2]^+]/dt = k_{obsd}[[Fe(Hpdx\text{-}L\text{-}trp)_2]^+] \quad (8)$$

$$k_{obsd} = k_{-3\bar{1}} \quad (9)$$

The rate constant, $k_{-3\bar{1}}$, as estimated from Table 3, is given in Table 2.

The ligand-substitution reaction of [Fe(Hpdx-L-trp)$_2$]$^+$ with EDTA belongs to a simple aquation, because the reaction is of zeroth order with respect to the entering and leaving ligand concentrations, which fact rules out the liberation of the second ligand from Fe(Hpdx-L-trp)$^{2+}$ or its mixed-ligand complex with EDTA as an intermediate as the rate-determining step. Furthermore, the pathway of [Fe(Hpdx-L-trp)$_2$]$^+$+H^+ and analogous proton-assisted pathways, which are anticipated from the formation reaction kinetics, are impracticable in the present ligand-substitution reaction. Only the pathway of [Fe(Hpdx-L-trp)$_2$]$^+$ (+H_2O) to form Fe(Hpdx-L-trp)$^{2+}$ and Hpdx-L-trp$^-$, the latter of which will rapidly protonate to form H_2pdx-L-trp and H_2pdx-L-Htrp$^+$, is practicable. The mechanistic rate-determining step may be the dissociation from the central metal atom of the carboxylato group of the coordinated ligand in the thermodynamically more stable [Fe(Hpdx-L-trp)$_2$]$^+$ by taking the kinetic characteristics of the formation and the basicity of the ligating groups on Hpdx-L-Htrp into consideration.

In conclusion, *N*-pyridoxylidene-L-tryptophan forms a 1:2 (metal: ligand) complex with iron(III) of a high thermodynamic stability and lability. The coordination of the ligand proceeds through six parallel pathways of Fe^{3+}, $FeOH^{2+}$, and $FeCl^{2+}$ with H_2pdx-L-Htrp$^+$ and H_2pdx-L-trp, with the donation of the carboxylato oxygen to iron(III) as the rate-determining step. This coordinated ligand leaves the central metal atom dissociatively, even in the presence of other multidentate ligands, through the pathway of Fe(Hpdx-L-trp)$^{2+}$ and Hpdx-L-trp$^-$, with cleavage of the carboxylato oxygen-iron(III) bond as the rate-determining step.

(Received March 24, 1989)

Cyclic voltammograms of glassy carbon electrode modified with iron-sulfur and iron-selenium clusters $(Bu_4N)_2[Fe_4X_4(YC_6H_4\text{-}p\text{-}t\text{-}C_4H_9)_4]$ (X, Y=S, Se) show the stable (2−/3−) redox couple in water, and the peak potentials of those redox waves are shifted by the change of pH due to reversible protonations not only of the oxidized but also of the reduced clusters. The electron transfer between the cluster and the glassy carbon plate is also influenced by the protonation equilibrium. A retardation of the electron transfer caused by the protonation of the cluster may be associated with a reorganization energy required in the redox reaction of the protonated cluster.

Synthetic Fe_4S_4 clusters with arene- and alkanethiolate ligands as models of 4Fe ferredoxins show reversible or pseudo-reversible $[Fe_4S_4]^{2+/+}$ redox couple not only in organic solvents but also in aqueous solutions.[1] On the other hand, some of biological redox reactions mediated by iron sulfur proteins involve a multi-electron transfer process such as NO_3^-[2] and SO_4^{2-}[3]-reductions, CO_2-assimilation,[4] and N_2-fixation.[5] Among those multi-electron reductions, N_2 fixation is especially interested in the viewpoint of the fact that N_2 is reduced with eight electrons to afford NH_3 and H_2, where unstable N_2H_2 is proposed as a reaction intermediate.[6] The construction of a catalytic system which can transport electrons rapidly to the reaction center, therefore, is desired in order to simulate multi-electron reductions involving unstable intermediates, otherwise the reaction intermediate may be decomposed without affording the final reduction product. In accordance with this view, six- and eight-electron reductions of RN_3 (R=CH_2CH_2OH) affording N_2H_4 and NH_3 via N_2H_2 can be achieved by using glassy carbon electrodes modified with $[Fe_6Mo_2S_8(SPh)_9]^{3-}$,[7] $[Fe_3MoS_4(SPh)_3(quinone)]_2^{4-}$,[8] and $[Fe_4S_4(SPh)_4]^{2-}$[8] under the controlled potential electrolysis at −1.25 V vs. SCE in H_2O, whereas the same clusters can catalyze only the two-electron reduction of RN_3 affording RNH_2 and N_2 under the electrolysis at the same potential in a homogeneous MeOH/THF solution. The superiority of the heterogeneous electrolysis to the homogeneous one with respect to a multi-electron reduction of RN_3 may be ascribed to an efficient multi-electron transfer to the cluster directly attached to the electrode in the former. Thus a multi-electron reduction involving unstable reaction intermediates can be achieved by a catalytic system which is provided with the ability of transport multi-electrons rapidly to the reaction center. On the basis of the fact that 4Fe ferredoxins mediate multi-electron transfer processes in biological reductions, synthetic Fe_4S_4 cluster modified electrodes may be applicable as redox catalysts to a wide range of reductions involving a multi-electron process. It seems, therefore, to be very important to elucidate the factor determining the rate of the electron transfer in the cluster-modified electrodes.

Experimental

General Procedure and Materials. All manipulations were carried out under N_2 atmosphere. Iron-sulfur and iron-selenium clusters $(Bu_4N)_2[Fe_4S_4(SC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]$ ($(Bu_4N)_4$-[4FeSS]), $(Bu_4N)_2[Fe_4S_4(SeC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]$ ($(Bu_4N)_2$[4FeSSe]), $(Bu_4N)_2[Fe_4Se_4(SC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]$ ($(Bu_4N)_2$[4FeSeS]), and $(Bu_4N)_2[Fe_4Se_4(SeC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]$ ($(Bu_4N)_2$[4FeSeSe]) were prepared according to a literature.[9] Commercially available guaranteed reagents grades of NaOH and H_3PO_4 were used without further purification. Glassy carbon electrodes modified with a cluster (1×10^{-9}—1×10^{-6}mol cm^{-2}) were prepared by addition of a given amount of a CH_3CN solution of each cluster (1.0 mmol dm^{-3}) on a polished surface of the glassy carbon plates (1.0 cm^2) by syringe techniques and dried for ca. 30 min under dry N_2 stream.[7]

Physical Measurements. Cyclic voltammograms of cluster-modified electrodes were obtained at 298 K in H_2O by using a Hokuto Denko potentialstat HB-401, a Hokuto Denko function generator HB-107, and a Yokogawa Electric X-Y recorder 3077. H_3PO_4–NaOH was used as a supporting electrolyte in aqueous solutions.

Results and Discussion

Cyclic Voltammograms of Glassy Carbon Electrodes Modified with Clusters. It has been reported that Fe_4S_4 clusters attached covalently to a SnO_2 electrode[10] and incorporated in electrode-bound ion-exchange polymer[11] undergo a pseudo-reversible or reversible redox reaction in organic solvents. Compared with those Fe_4S_4 cluster-coated electrodes, the current cluster-modified electrode can be quite easily prepared. The cyclic voltammogram of the glassy carbon electrode modified with $(Bu_4N)_2[Fe_4S_4(SC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]$ ([4FeSS]/GC; 1×10^{-8} mol cm^{-2}) in water (pH 11.9) at 10 mV s^{-1} shows an anodic wave at −0.93 V vs. SCE together with a strong cathodic current at potentials more negative than −1.2 V due to not only the reduction of the cluster modified on the glassy carbon plate but also the evolution of H_2 catalyzed by the

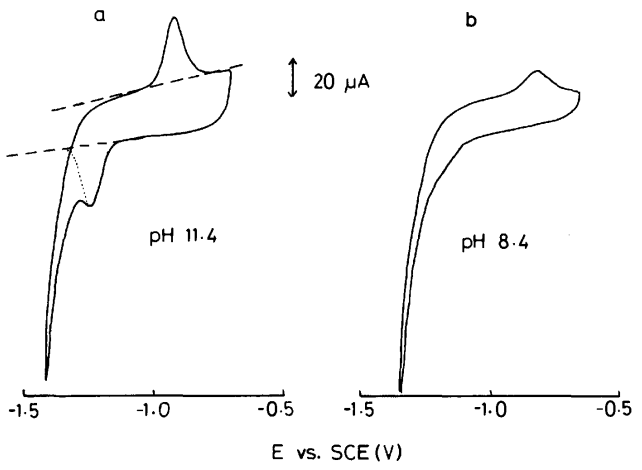

Fig. 1. Cyclic voltammograms of the glassy carbon electrode modified with $(Bu_4N)_2[Fe_4S_4(SC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]$ (1.0×10^{-8} mol dm^{-2}) in H_2O at pH 11.4 (a) and at pH 8.4 (b), dE/dt=10 mV s^{-1}; a dotted line (a) represents the pattern of the anodic wave.

reduced species of the cluster[12] (a solid line in Fig. 1a). The cyclic voltammogram of the [4FeSS/GC] was unchanged essentially even in a multi-scanning for 1 h. Thus, the Fe_4S_4 cluster modified on the GC plates stably undergoes a redox reaction in water. The cathodic wave at −1.24 V is almost superimposable on the anodic one at −0.93 V (a dotted line in Fig. 1a).[13] In addition, the electricity calculated from the area of the anodic wave corresponded to the number of $[4FeSS]^{2-}$ molecules modified on the electrode with the ratio of electron/molecule=1.00±0.02. These results clearly indicate that almost all the clusters undergo the $[4FeSS]^{2-/3-}$ redox reaction (Eq. 1) on the GC plate.

$$[Fe_4S_4(SC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]^{2-} + e^- \rightleftharpoons [Fe_4S_4(SC_6S_4(SC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]^{3-} \quad (1)$$

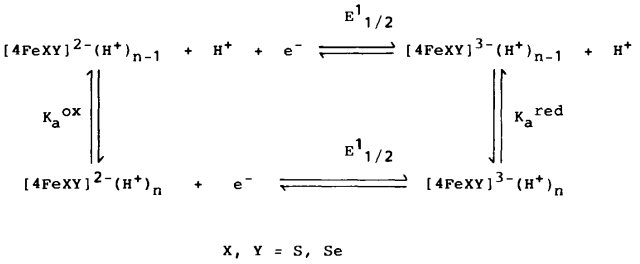
On the other hand, the change of pH of the aqueous phase from 11.4 to 8.3 causes a shift of the anodic wave from −0.93 to −0.82 V with decreasing the electricity of the wave at the same scanning rate (10 mV s^{-1}). At the same time, the cathodic wave was almost concealed by the anodic shift of the threshold potential of H_2 evolution (Fig. 1b). Such the change of the cyclic voltammogram of [4FeSS]/GC at pH 8.3 results from neither the decomposition nor stripping off the cluster from the GC plate since the cyclic voltammogram of [4FeSS]/GC at pH 11.4 was regenerated when the pH was put back to 11.4. The cyclic voltammograms of glassy carbon electrodes modified with $(Bu_4N)_2[Fe_4S_4(SeC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]$, $(Bu_4N)_2[Fe_4Se_4(SC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]$, and $(Bu_4N)_2[Fe_4Se_4(SeC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]$ ([4FeSSe]/GC, [4FeSeS]/GC, and [4FeSeSe]/GC, respectively) also exhibit the similar pH dependence as that of [4FeSS]/GC in H_2O.

The redox reaction of the Fe_4S_4 cluster-modified electrode is accompanied by the transport of the counter ion of the cluster between the redox center on the GC plate and the contacting aqueous electrolyte solutions. The migration of the counter ion of the cluster for the charge neutrality, therefore, largely influences the stability of the cluster modified electrodes. For example, the cyclic voltammogram of a glassy carbon plate modified with $(Et_4N)_4[Fe_4S_4(SC_6H_5)_4]$ was essentially consistent with that with the [4FeSS]/GC (Fig. 1). The anodic wave of the former, however, was almost disappeared in the multi-scanning cyclic voltammogram for 30 min, while the decrease in the anodic peak current of the glassy carbon electrode modified with $(Bu_4N)_2[Fe_4S_4(SC_6H_5)_4]$ was about 20% in the multi-scanning cyclic voltammogram for 1 h. Thus, a bulky counter ion of the cluster stabilizes the modified electrode. In addition, the Bu_4N^+ salt of the Fe_4S_4 cluster with the terminal ligand $SC_6H_4\text{-}p\text{-}t\text{-}Bu$ in place of SC_6H_5 further improved the stability of the cluster-modified electrode, as described in a previous section. It should be mentioned that the cyclic voltammogram of the Fe_4S_4 cluster-modified electrode did not show any redox couple of the cluster in the case a bulky Bu_4NClO_4 was used as an electrolyte in pure H_2O.[14] This fact clearly indicates that the charge neutrality in the [4FeXY]/GC (X, Y=S, Se) is maintained by the transport of Na^+ from the aqueous NaOH–H_3PO_4 buffer solution rather than that by H^+.[15] If the diffusion coefficient of Na^+ in the [4FeXY]/GC is assumed to be constant in the experimental pH region, the pH dependent cyclic voltammogram of [4FeXY]/GC (see Fig. 1a and 1b) is ascribed to the change of the proton concentrations in the aqueous phase. In accordance with this, not only oxidized but also reduced species of the current clusters undergo reversible protonation reactions in aqueous Triton X-100 micellar and poly[2-(dimethylamino)hexanamide] (PDACA) solutions.[9] The pH dependent redox behavior of the [4FeXY]/GC, therefore, also can be associated with such the reversible protonation of the clusters modified on the GC plate.

Not only the pattern of the cyclic voltammogram but also the peak potentials of the $[4FeXY]^{2-/3-}$ redox couples are altered by the change of proton concentrations in the aqueous phase. The anodic and cathodic peak potentials (E_{pa} and E_{pc}, respectively) of the [4FeXY]/GC at various pH, therefore, are depicted in Fig. 2, where E_{pa} and E_{pc} were determined at the sweep rate 10 mV s^{-1} in order to minimize the effect of the sweep rate on those peak potentials.[16] Although the E_{pc} value in the neutral pH region was not determined accurately due to the cathodic current of the H_2 evolution, the dependence of the E_{pc} values on pH is consistent with that of the E_{pa} on pH; the E_{pa} and E_{pc} values of the [4FeSS]/GC and the [4FeSeS]/GC show a tendency to level off in the pH region lower and higher than around 9.5 and 10.5, respectively and a shift by −60 mV/pH in the intermediate pH region (Fig. 2a).

Such the characteristic curves of Fig. 2a can be explained in terms of the reversible protonation of not only $[4FeXS]^{2-}$ but also $[4FeXS]^{3-}$ (X=S, Se) modified on the GC plate as similar to that of those clusters solubilized in an aqueous PDACA solution.[9] The turning points of Fig. 2a can, therefore, be associated with the pK_a values of the cluster. From the consideration of the basicity of $[4FeXS]^{2-}$ and $[4FeXS]^{3-}$, the protonation of $[4FeXS]^{3-}$ should take place in higher pH region than that of $[4FeXS]^{2-}$. The turning points in the plots of E_{pa} vs. pH (or E_{pc} vs. pH) around pH 10.5 and 9.5 in Fig. 2a, therefore, are assigned to the pK_a^{red} and pK_a^{ox} values of the protonated (3−) and (2−) states of the clusters, respectively. The shift of the E_{pa} and E_{pc} values of the [4FeXS]/GC by −60 mV/pH in the pH region from the pK_a^{red} to pK_a^{ox} values, therefore, is caused by the dissociation of one proton upon the oxidation of the protonated $[4FeXY]^{3-}$ to $[4FeXY]^{2-}$, and the association of one proton to $[4FeXY]^{3-}$ formed by the reduction of $[4FeXY]^{2-}$. On the basis of the preceding discussion, the turning points observed at around 10.5 (Fig. 2b) in the plots of E_{pa} and E_{pc} values of the [4FeXSe]/GC (X=S, Se) against pH can be assigned to their pK_a^{ox} values. The continuous shift by −60 mV/pH of the E_{pa} and E_{pc} values of those clusters above pH 10.5, therefore, is reasonably explained by the pK_a^{red} values of the protonated $[4FeXSe]^{3-}$ (X=S, Se) being larger than 12. It should be noticed that the relation between E_{pa} and E_{pc} of the cluster and pH affords only the information about the difference in the number of protons attached to the (2−) and (3−) states of the cluster. The total number of protons bonded to $[4FeXY]^{2-}$ and $[4FeXY]^{3-}$ is not clear in the present study so that the protonation equilibriums of [4FeXY]/GC are depicted by Scheme 1, where n, E_1, E_2 are the total number of protons bonded to the clusters in a given pH, the redox potential of the $[4FeXY]^{2-/3-}(H^+)_{n-1}$, and that of the $[4FeXY]^{2-/3-}(H^+)_n$.[17]

Table 1 summarizes the pK_a^{red} and pK_a^{ox} of the [4FeXY]/GC obtained from the turning points of the plots of E_{pa}^{ox} vs. pH of Fig. 2 together with those values determined in an aqueous PDACA solution.[9] Although the pK_a^{red} values of the protonated $[4FeXSe]^{3-}$ could not be determined in the present study, the pK_a^{ox} values are divided into two groups; around 9.5 for $[4FeSS]^{2-}$ and $[4FeSeS]^{2-}$, and around 10.5 for $[4FeSSe]^{2-}$



Scheme 1.

Table 1. pK_a Values of the Oxidized and Reduced Cluster Modified on a Glassy Carbon Plate and Solubilized in an Aqueous PDACA Solution

Cluster	pK_a^{ox}	pK_a^{red}
$[Fe_4S_4(SC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]^{2-}$	9.6 (5.9)[a]	11.4 (8.8)
$[Fe_4Se_4(SC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]^{2-}$	9.2 (5.9)	10.5 (7.3)
$[Fe_4S_4(SeC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]^{2-}$	10.4 (6.9)	(8.8)
$[Fe_4Se_4(SeC_6H_4\text{-}p\text{-}t\text{-}Bu)_4]^{2-}$	10.6 (6.7)	(7.3)

a) Values in parentheses are in a PDACA solution.[9]

and [4FeSeSe]$^{2-}$. Such a pK_a^{ox} difference may be explained in terms of the difference of terminal sulfur and selenium rather than that of the Fe_4X_4 core (X=S, Se), suggesting that the protonation of [4FeXY]$^{2-}$ modified on the glassy carbon plate takes place on the terminal sulfur or selenium atom. It is worthy to note that both pK_a^{red} and pK_a^{ox} values of the [4FeXY]/GC are fairly larger than those of the clusters solubilized in aqueous PDACA solution (values in parentheses in Table 1). This result suggests that the hydrophobicity around the cluster modified on the GC plates in H_2O is less than that in an aqueous PDACA solution.

Rate Constants of the Electron Transfer between Clusters and Glassy Carbon Plates. As described in a previous section, the electricity consumed in the anodic and cathodic waves of the [4FeSS]/GC at pH 11.4 is equal to the amount of [4FeSS]$^{2-}$ modified on the GC plates, while the electricity of the anodic wave at pH 8.4 is much smaller than the amount of [4FeSS]$^{2-}$ (Fig. 1). This discrepancy may result from the fact that the reduction of the cluster is followed by H_2 evolution catalyzed by the resultant [4FeXY]$^{3-}$. Even if all the clusters modified on the GC plate participate in the redox reaction, the agreement between the electricity consumed in those redox waves and the amount of [4FeXY]$^{2-}$ modified is realized only when the rate of the electron transfer (k_s) between the cluster and the GC plate is much faster than that of H_2 evolution, otherwise most of electrons transferred to [4FeXY]$^{2-}$ from the GC plates are consumed by H_2 evolution prior to the anodic process of [4FeXY]$^{3-}$ in the GC plate. Accordingly, in a case of k_s being slower than the rate of H_2 evolution, the electricity released in the anodic wave of the [4FeXY]/GC is smaller than the amount of [4FeXY]$^{2-}$ modified on the GC plate. The rate of H_2 evolution apparently increases with decreasing pH. The rate of the electron transfer in the [4FeXY]/GC was evaluated under the assumption that H_2 evolution catalyzed by the reduced cluster does not disturb seriously the rate of the electron transfer.

The values of the peak separation between anodic and cathodic waves (ΔE_p) of an adsorbed species is frequently used as the criterion for kinetics in the electron transfer between the electrode and the redox center. For rapid kinetics in the electron transfer, $\Delta E_p=0$ is expected at any scan rate.[18] The present clusters, however, shows a fairly large ΔE_p values (300—400 mV) even at sweep rate 10 mV s^{-1} (Fig. 1), and both E_{pa} and E_{pc} are dependent on sweep rates. In the present study, both oxidized and reduced clusters are attached to the GC plate. When a redox center in a modified electrode is distributed homogeneously without any special interaction with the neighboring one, the rate constant of electron transfer k_s is expressed by Eq. 2,[19]

$$\log k_s = \alpha \log(1-\alpha) + (1-\alpha)\log \alpha - \log (RT/nFv) - \alpha(1-\alpha)nF\Delta E_p/2.3RT \quad (2)$$

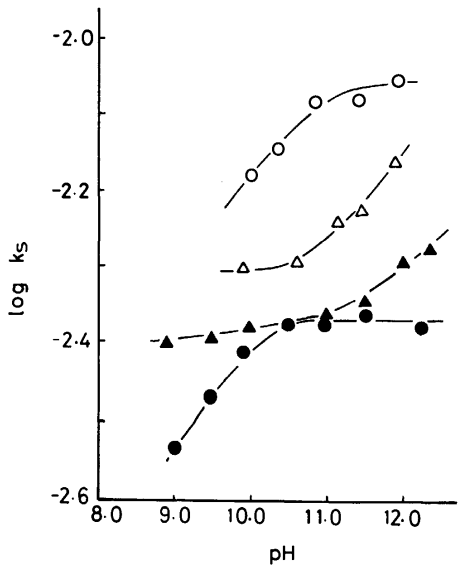

Fig. 3. The rate constant of the electron transfer (k_s) of the [4FeXY]/GC (X,Y=S,Se) at various pH; X,Y=S,S (O), SeS (●), SSe (△), and SeSe (▲).

where α, R, T, n, F, and v are the transfer coefficient, the gas constant, temperature, the Faraday constant, and the sweep rate. The value of α was obtained by the half width of the anodic wave (α=62.5 mV/$\delta_{1/2}$).[20] As mentioned in previous section, the cathodic wave of the (2−/3−) redox couple in the neutral region is almost completely concealed by H_2 evolution catalyzed by the (3−) state of the cluster, the k_s value, therefore, was determined in a limited pH region, where E_{pc} can be determined accurately. The plot of k_s obtained vs. pH is depicted in Fig. 3, which clearly shows the tendency of the decrease of k_s with increasing pH and the presence of the turning points close to the pK_a^{red} and pK_a^{ox} values of each [4FeXY]/GC (compare Fig. 2 with Fig. 3). Taking account the fact that protons in aqueous phase does not function as a counter ion in the redox reaction of the [4FeXY]/GC, the protonation of not only [4FeXY]$^{2-}$ but also [4FeXY]$^{3-}$ may cause a retardation of the rate of the electron transfer. Thus, the decrease of the electricity consumed in the anodic wave with decreasing pH (Fig. 1) may be caused by the retardation of the electron transfer, resulting from the protonation of the [4FeXY]/GC. It has been elucidated that the structure of $[Fe_4S_4(SC_6H_5)_4]^{2-}$ is nearly D_{2d} core symmetry with four short and eight longer Fe-S bonds approximately parallel to and perpendicular to the $\bar{4}$ axis,[21] while that of $[Fe_4S_4(SC_6H_5)_4]^{3-}$ is idealized D_{2d} core symmetry with four long Fe-S bonds approximately parallel to the $\bar{4}$ axis.[22] The similar structural change between [4FeXY]$^{2-}$ and [4FeXY]$^{3-}$ should be caused by the redox reaction of the [4FeXY]/GC. Such a reorganization process involved in the redox reaction of a Fe_4S_4 cluster may hardly influence on the rate of electron transfer in a certain Fe_4S_4 cluster-modified electrode since $[Fe_4S_4(SC_6H_5\text{-}p\text{-}n\text{-}C_8H_{17})_4]^{2-}$ adsorbed

on an Hg electrode undergoes a similar protonation reaction in an aqueous lecithin vesicle solution and exhibits a reversible (2−/3−) redox couple with $\Delta E_p=0$ at any scan rates in neutral and weak acidic conditions.[23] The distinct difference in the rate of the electron transfer in the redox reactions between $[Fe_4S_4(SC_6H_5\text{-}p\text{-}n\text{-}C_8H_{17})_4]^{2-}$ adsorbed on an Hg electrode and $[Fe_4X_4(Y_4C_6H_4\text{-}p\text{-}t\text{-}Bu)_4]^{2-}$ (X, Y=S, Se) modified on a GC plate may be associated with the form of the cluster; the former exists as a monomeric form on the Hg electrode, while the latter exists as the solid form on the GC plate. The rate-determining step of the electron transfer in the present study may, therefore, involve the structural change of the cluster in the solid state. The agreement of the turning points in the plots of k_s vs. pH with the pK_a^{ox} and pK_a^{red} values of those clusters suggests that protonation of the [4FeXY]/GC increases the reoganization energy of the cluster in the solid state.

13) In the case the amount of the cluster on the GC plate is more than 10^{-6} mol cm^{-2}, the electricity in the anodic wave of the [4FeSS]/GC is fairly smaller than the expected value even at pH 11.4 due to a poor conductivity of the cluster.

14) $(Bu_4N)_2$[4FeSS] is irreversibly oxidized around 0 V vs. SCE in DMF. However, the [4FeSS]/GC showed no anodic wave at potentials more positive than 0 V vs. SCE in H_2O, since Bu_4N^+ may be completely fixed on the GC plate.

15) The reduction of $(Bu_4N)_2$[4FeSS] on the GC plate results in the formation of $(Bu_4N)_2Na$[4FeSS].

16) Both E_{pa} and E_{pc} values depend on the sweep rate, but the turning points of Fig. 2 is essentially independent on the sweep rates in the range of 10 to 100 mV s^{-1}.

17) The half wave potential for the overall electrode reaction can be written as follows;[9]

$$E_{1/2} = E^1_{1/2} + (RT/F)\ln[K_{ox}(K_{red} + [H]^+)/(K_{red}(K_{ox} + [H]^+))]$$

or

$$E_{1/2} = E^2_{1/2} + (RT/F)\ln[(K_{red} + [H]^+)/(K_{ox} + [H]^+)]$$

Synthesis and Chromogenic Properties of Disulfonated (1-Naphthyl)(2-quinolyl)-methanone 5-Nitro-2-pyridylhydrazone and Its Application to the Spectrophotometric and Analogue-Derivative Spectrophotometric Determination of Trace Amounts of Zinc†

Hajime ISHII,* Katsunori KOHATA, Tsugikatsu ODASHIMA, and Yoshiaki KAWAMONZEN
Chemical Research Institute of Non-Aqueous Solutions, Tohoku University, Katahira, Sendai, Miyagi 980
(Received March 25, 1989)

A water-soluble hydrazone, disulfonated (1-naphthyl)(2-quinolyl)methanone 5-nitro-2-pyridylhydrazone (NQNPH), in which one nitro group and two sulfo groups are introduced for the purpose of increasing sensitivity and solubility in water, has been synthesized and its chromogenic property and reactivity with metal ions investigated. NQNPH reacts with various metal ions including zinc(II) to form 1:2 (metal:ligand) colored stable complexes with high molar absorptivities. On this basis, sensitive and practical spectrophotometric and analogue-derivative spectrophotometric methods for the determination of trace amounts of zinc with NQNPH have been proposed. The zinc(II)–NQNPH complex is formed quantitatively in the pH range 6.9—9.6 and its absorption spectrum shows an absorption maximum at 516 nm. Beer's law is obeyed over the range 0.07—1.5 ppm of zinc and the apparent molar absorptivity of the complex is 4.33×10^4 dm^3 mol^{-1} cm^{-1} at 516 nm. The proposed method was applied to the determination of zinc in Kuroko and water samples, with satisfactory results. In addition, the acid dissociation constants of NQNPH and the overall formation constant of its zinc complex were also determined spectrophotometrically.

In the course of a series of studies on the synthesis of hydrazone compounds as highly sensitive and selective reagents and their analytical application, recently we synthesized five kinds of water-soluble hydrazones derived from 2-(3-sulfobenzoyl)pyridine[1,2] and reported that one of them, (2-pyridyl)(3-sulfophenyl)-methanone 2-pyrimidylhydrazone, is a very useful reagent for the determination of iron at sub-ppm levels by spectrophotometry[1] and flow injection analysis.[3] Furthermore, we also synthesized a series of water-soluble hydrazones, in which various substituents were introduced to the 5-position of the pyridine ring in the hydrazine moiety of (2-pyridyl)(3-sulfophenyl)-methanone 2-pyridylhydrazone synthesized by Going et al.,[4] and found that, of those hydrazones, (2-pyridyl)(3-sulfophenyl)methanone 5-nitro-2-pyridyl-hydrazone having an electron-withdrawing nitro group is a very favorable spectrophotometric reagent in both sensitivity and selectivity for the determination of metals, especially for that of cobalt.[5]

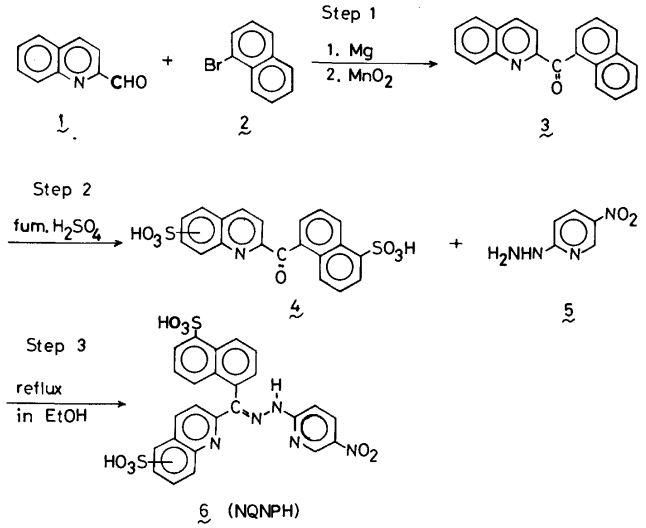
In the work presented here disulfonated (1-naphthyl)-(2-quinolyl)methanone 5-nitro-2-pyridylhydrazone (NQNPH) which has one nitro group and two sulfo groups in its molecule was synthesized from a viewpoint of the development of the hydrazone reagent which is more soluble in water as well as sensitive to metal ions and properties of the hydrazone and its metal complexes were investigated in detail. On the basis of the results, a spectrophotometric method for the determination of trace amounts of zinc has been developed and applied successfully to the determination of zinc in Kuroko, a kind of mineral containing copper, lead and zinc as major constituents, and water samples, as examples. Further, the proposed method could be made more sensitive by the introduction of an analogue-derivative spectrophotometric technique.

† Presented in part at the 48th Symposium on Analytical Chemistry, Toba, June, 1987.

Experimental

Synthesis of NQNPH. NQNPH was synthesized according to Scheme 1 as follows.

Synthesis of 2-(1-Naphthoyl)quinoline (3): Manganese dioxide (activated under vacuum at 110 °C for 2 days, 67.6 g, 0.773 mol) was added to the chloroform solution (300 cm^3) of (1-naphthyl)(2-quinolyl)methanol (9.6 g, 0.034 mol) which was obtained by the Grignard method[6] using 1-bromonaphthalene (**2**) (16.6 g, 0.773 mol), magnesium turnings (3.86 g, 0.159 mol) and 2-quinolinecarbaldehyde (**1**) (10.5 g, 0.067 mol).[7] The reaction mixture was refluxed for 5 h. After cooling the mixture was filtered through a Celite pad and concentrated to yield a yellow solid, which was



6 (NQNPH)

Scheme 1.

recrystallized from benzene to give a pure pale yellow 2-(1-naphthoyl)quinoline (**3**) [9.21 g (92.8%)]. Mp: 139 °C. Found: C, 84.76; H, 4.81; N, 5.39%. Calcd. for $C_{20}H_{13}ON$: C, 84.78; H, 4.63; N, 5.65%. IR (KBr): $\nu_{C=O}$ 1650 cm^{-1}.

Synthesis of Disulfonated 2-(1-Naphthoyl)quinoline (4): 2-(1-Naphthoyl)quinoline (**3**) (6 g, 0.021 mol) and fuming sulfuric acid (25% SO_3, 30 cm^3) were placed in a round bottom flask with a tight stopper and the mixture was stirred at 90 °C for 138 h. Fuming sulfuric acid (20 cm^3) was added, the temperature was raised to 110 °C and the stirring was continued for additional 72 h. Furthermore fuming sulfuric acid (10 cm^3) was added. After the stirring was continued for additional 27 h, the reaction mixture was cooled and cautiously poured into ethanol (120 cm^3) under cooling. Addition of ethyl acetate (6 dm^3) with sufficient stirring caused the precipitate as a dark brown solid. The mixture was filtered, washed with acetone and dried overnight at 60 °C under reduced pressure to yield a dark brown solid (**4**) (13 g), which still contained water and sulfuric acid. This material was used in the next step without purification. IR (KBr): $\nu_{C=O}$ 1670 cm^{-1}, ν_{SO_2} 1240—1140, 1040—1020 cm^{-1}.

Synthesis of Disulfonated (1-Naphthyl)(2-quinolyl)-methanone 5-Nitro-2-pyridylhydrazone (NQNPH) (6): 5-Nitro-2-pyridylhydrazine (**5**) (2.09 g, 0.014 mol) in hot ehtanol (450 cm^3) was added to a hot ethanol solution (100 cm^3) of disulfonated 2-(1-naphthoyl)quinoline (**4**) (7 g) and the mixture was refluxed for 5 h. After cooling a dark brown solid was obtained by concentration of the mixture. This solid was purified in a column of silica gel by elution with 2-propanol–ethyl acetate–water (2+3+1, v/v). Appropriate fractions [R_f=0.42 in 2-propanol–ethyl acetate–water (2+3+2, v/v)] were collected and concentrated to afford an orange yellow solid. This purification was repeated for several times to give 3.5 g in total. Mp>350 °C, IR (KBr): $\nu_{C=O}$ 1670 cm^{-1} (disappeared), ν_{NO_2} 1540, 1340 cm^{-1}, ν_{SO_2} 1240—1180, 1040 cm^{-1}.

Reagents. All reagents used were of analytical-reagent grade unless stated otherwise. All solutions were prepared with distilled, deionized water.

NQNPH solution. A 1.25×10^{-3} M (1 M=1 mol dm^{-3}) aqueous solution was prepared using synthesized NQNPH. This solution was standardized by photometric titration with a standard copper(II) solution at pH 5.5 and at 530 nm.

Standard zinc(II) solution. A 1×10^{-2} M stock solution was prepared by dissolving metallic zinc (99.999% pure) in a sufficient volume of hydrochloric acid (1+1) to give an acidity of about 0.1 M in the final solution. Working solutions were prepared by dilution of this solution with water.

Buffer solutions. 1 M Chloroacetic acid–1 M sodium chloroacetate, 1 M acetic acid–1 M sodium acetate, 0.5 M tris(hydroxymethyl)aminomethane–0.5 M hydrochloric acid, 1 M aqueous ammonia–1 M ammonium chloride or 0.5 M boric acid–0.5 M sodium carbonate system was used according to the pH value required.

Apparatus. For measurements of the absorbance, the absorption spectrum and the derivative absorption spectrum, the same instruments as those stated in an earlier paper[5] were used. Infrared spectra were obtained on a JASCO A-3 IR spectrometer. Thin-layer chromatography (TLC) was carried out on 0.2-mm E. Merck 60F-254 precoated silica-gel plates. For column chromatography, E. Merck silica gel 60 (70—230 mesh) was used.

Procedures. Determination of Zinc by Ordinary Spectrophotometry: Place a sample or standard solution containing up to 30 μg of zinc(II) in a 25-cm^3 calibrated flask. Add 5 cm^3 of 0.5 M tris(hydroxymethyl)aminomethane–0.5 M hydrochloric acid buffer solution (pH 7.2), suitable masking agents if necessary and 2 cm^3 of 1.25×10^{-3} M NQNPH solution, and dilute to the mark with water. After allowing to stand for about 10 min, measure the absorbance of the resultant solution at 516 nm against a reagent blank prepared under the same conditions using 1-cm cells.

Determination of Zinc by Second-Derivative Spectrophotometry: When the zinc content of the solution prepared by the procedure described under ordinary spectrophotometry is too low to give a measureable absorbance, record the second-derivative spectrum from 600 to 400 nm against a reagent blank by using a combination of both first- and second-order differentiation circuits (No. 6 of Refs. 8 and 9) and a scan speed of 300 nm min^{-1} and measure the second-derivative absorbance (the vertical distance from a peak to a trough or that from the base line to a trough of the peak).

Dissolution and Pretreatment of Kuroko Samples: Decompose sample and prepare the sample solution according to JIS method:[10] To 10—40 mg of sample add 15 cm^3 each of concentrated nitric and hydrochloric acids and heat to decompose the sample. Add 2 cm^3 of sulfuric acid (1+1) and evaporate to dryness. After cooling to room temperature, dissolve the residue in about 50 cm^3 of hydrochloric acid (1+50), heat for a few minutes to dissolve the soluble salts, filter into a 200-cm^3 calibrated flask, wash with hot water, and dilute to the mark with water after cooling to room temperature. Use an appropriate aliquot of the resultant solution to the determination.

Results and Discussion

Identification of the Hydrazone. Identification of the product was carried out at two stages in the course of synthesis.

Disulfonated 2-(1-Naphthoyl)quinoline (4): A TLC test on the product obtained at step 2 revealed that the product consists of two position isomers of the sulfo group on quinoline ring [R_f=0.26 and 0.18 respectively in 2-propanol–ethyl acetate–water (2+3+2, v/v)]. The faster-migrating product was obtained mainly on a reaction mixture sulfonated for 23 h and decreased gradually with the addition of fuming sulfuric acid and the passage of time. On the other hand, the slower-migrating one increased gradually and became main finally. The faster- and slower-migrating products presumed to be 2-(5-sulfo-1-naphthoyl)-5-quinolinesulfonic acid and 2-(5-sulfo-1-naphthoyl)-8-quinolinesulfonic acid, respectively, because 5-sulfoquinoline migrated faster (R_f=0.45) than 8-sulfoquinoline (R_f=0.39) in 2-propanol–ethyl acetate–water (2+3+2, v/v). However, the position of sulfo group on quinoline ring could not be decided.

NQNPH (6): Neither of the elemental analysis, the determination of water content by Karl Fischer's

method, the mass spectrum (FAB) and the NMR spectrum of the final product gave reliable results in spite of trials because the product is hygroscopic and has large molecular weight and two sulfo groups. However, the hydrolysis of this product with concentrated nitric acid at room temperature for two days gave the starting ketone, disulfonated 2-(1-naphthoyl)-quinoline (**4**). On the basis of the result, this product is presumed to be a target hydrazone.

The number of sulfo groups of NQNPH (**6**) was determined by the ion-pair extraction method with zephiramine as an ion-pair-forming reagent, that is, solutions of pH 7.8 containing a fixed amount of NQNPH and various amounts of zephiramine were shaken for 24 h with an equal volume of benzene to the aqueous phase and then the absorbances of the organic and aqueous phases were measured, in which the absorbance of the latter was measured after the addition of sufficient amounts of zinc(II) as a color-forming reagent. The results are shown in Fig. 1, from

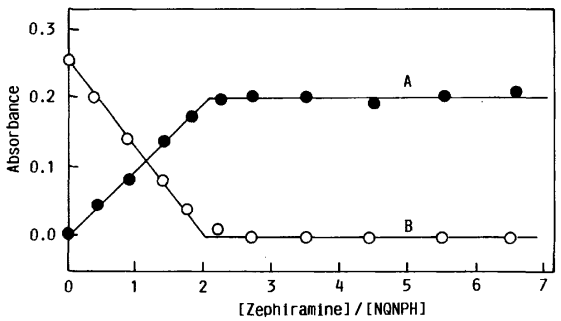


Fig. 1. Determination of the number of sulfo groups of NQNPH by the ion-pair extraction method. NQNPH, 7.2×10^{-5} M; pH 7.8; shaking time, 24 h. A, Benzene phase measured at 430 nm against benzene; B, water phase measured at 516 nm against water.

which the composition of the ion pair of NQNPH and zephiramine is found to be 1:2. This indicates that the number of sulfo groups of NQNPH is two.

Properties and Characteristics of the Hydrazone. NQNPH is hygroscopic, but remains unchanged for more than one year when stored in a desiccator. It is very soluble in water as expected beforehand and also soluble in polar solvents such as ethanol, *N*,*N*-dimethylformamide, and dimethyl sulfoxide, but insoluble in less or nonpolar solvents. Its aqueous solution is very stable.

As is apparent from the structure, NQNPH is a tribasic acid as well as a triacidic base, having six dissociable hydrogens in acidic solutions above 1 M. However, in less acidic solutions, the de-protonations from the C=N nitrogen and the sulfo groups are complete. Hence NQNPH exists in solution in any of the following forms, depending on pH:

$$H_3L \overset{K_{a4}}{\rightleftharpoons} H_2L^- \overset{K_{a5}}{\rightleftharpoons} HL^{2-} \overset{K_{a6}}{\rightleftharpoons} L^{3-} \quad (1)$$

where L denotes the undissociable part of the hydrazone and K_{a4}, K_{a5}, and K_{a6} are the acid dissociation constants.

The acid dissociation constants were determined spectrophotometrically at ionic strengths of 0.2 for K_{a5} and K_{a6} and 3.0 for K_{a4}, and at 25±0.1 °C. The values obtained for K_{a4}, K_{a5}, and K_{a6} were $10^{-0.80}$, $10^{-4.80}$, and $10^{-10.93}$, respectively. The K_{a4} and K_{a5} may be assigned to the de-protonation of the protonated pyridine-nitrogen and quinoline-nitrogen, respectively, whereas the K_{a6} corresponds to that of the secondary amino group. The contribution of the electron-withdrawing nitro group on the pyridine ring to the value of K_{a4} is found to be remarkable. A species distribution diagram of NQNPH prepared on the basis of these acid dissociation constants is shown in Fig. 2.

Table 1. Reactivity of NQNPH with Metal Ions

Metal ion	pH 4		pH 7		pH 10

Zn(II)	—	—	516	43300	516	41400

Standing time: 30 min.

Reactivity of the Hydrazone. The reactivity of NQNPH with various metal ions at pH 4, 7, and 10 were investigated, the results being summarized in Table 1. NQNPH is found to react with cadmium(II), cobalt(II), copper(II), iron(II), nickel(II), palladium(II), zinc(II), etc. to form colored stable complexes with high molar absorptivities. So the complexation reaction of NQNPH with these metal ions was investigated somewhat in detail. Absorption spectra of the complexes are shown in Fig. 3. Experimental results concerning the effect of pH on the complexations are indicated in Fig. 4. Absorption maxima of the complexes and optimum pH ranges for the complexations obtained from these results are summarized in Table 2 along with apparent molar absorptivities and compositions of the complexes determined by both the continuous variation and the molar ratio methods. These results suggest that NQNPH may be useful for the sensitive determination of these metals. Hence conditions for the complexation with zinc(II) and spectrophotometric determination of zinc at sub-ppm levels utilizing this complexation were investigated in detail at the outset in the subsequent work.

Zn(II)-NQNPH	516	43300	1:2	6.9— 9.6

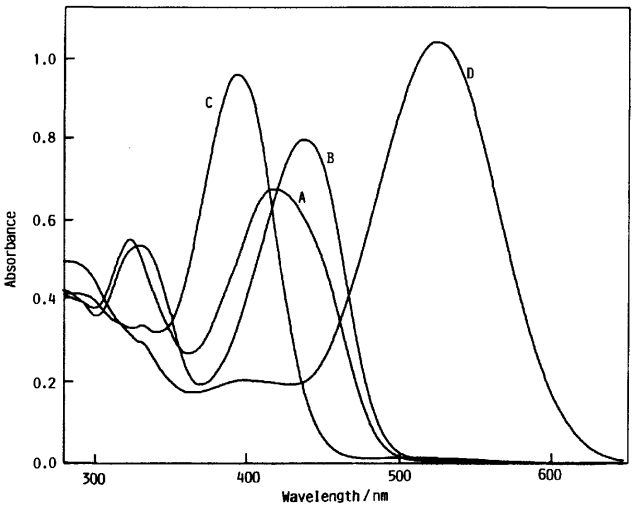

Fig. 5. Absorption spectra of NQNPH at pH (A), 0; (B), 3; (C), 8; and (D), 13.7. NQNPH, 4.1×10^{-5} M; reference, water.

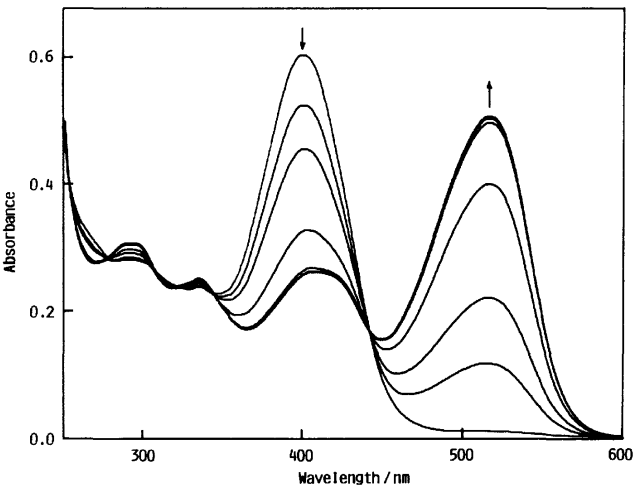

Fig. 6. Absorption spectra of the zinc(II)-NQNPH system. NQNPH, 2.3×10^{-5} M; pH, 7.0; reference, water. Arrows indicate spectral trends observed when changing the NQNPH to zinc(II) ratio from 1:0 to 1:3.2.

Studies of the Zinc(II)-NQNPH System. Absorption Spectra: Figure 5 shows absorption spectra of NQNPH at pH 0, 3, 8, and 13.7, in which spectra A, B, C, and D correspond to H_3L, H_2L^-, HL^{2-}, and L^{3-},

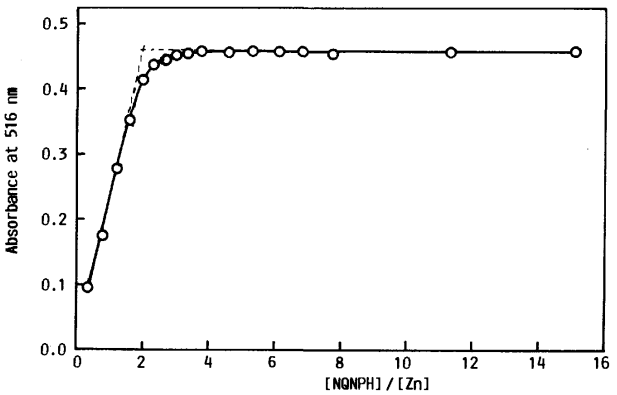

Fig. 7. Effect of NQNPH concentration. Zn(II), 693 ppb (1.1×10^{-5} M); pH, 7.2; reference, reagent blank.

respectively, taking Fig. 2 into consideration. Figure 6 exhibits the spectral change in the complexation between zinc(II) and NQNPH at pH 7.0, from which it is found that the absorption maximum shifts from 400 to 516 nm on complexation. In addition, the absorption due to NQNPH itself is very small at the latter wavelength, which is favorable for the zinc determination.

Effect of pH: As shown in Fig. 4 and Table 2, a constant and maximum absorbance is obtained over the pH range 6.9—9.6. The use of tris(hydroxymethyl)-aminomethane-hydrochloric acid buffer (pH 7.2) is recommended because the phosphate buffer interferes with the zinc determination.

Effect of NQNPH Concentration: The effect of the NQNPH concentration on the complexation was investigated. The results was shown in Fig. 7, from which it is found that a 4-fold molar excess of NQNPH is necessary for the complete complexation and an excess of NQNPH does not interfere. In addition, this result suggests the formation of a 1:2 (metal: ligand) complex.

Stability of the Complex: Under the recommended conditions, zinc(II) reacts almost instantaneously with NQNPH to form a complex at room temperature. The complex formed is very stable, the absorbance remaining constant even after 20 h.

Calibration Graph, Sensitivity and Precision: A linear calibration graph passing through the origin

Table 3. Tolerance Limits for Other Metal Ions in the Determination of 15.9 μg of Zinc

Tolerance limit		No masking agent added	Masking agent added
Above	1000 μg	Mg(II), Cr(VI)	Ag(I),[a] Hg(II)[a]
	500 μg	Ca(II), V(V)	
	200 μg	Al(III)	Fe(III),[b] Cu(II)[c]
	100 μg	Cr(III)	
	50 μg	Ti(IV)	V(IV),[d] Mn(II),[b] Pd(II),[c] Pd(II)[a]
	20 μg		Co(II),[e] Ni(II),[f] Cd(II)[a]
	10 μg	Mn(II), Ag(I), Hg(II)	V(IV),[b] Co(II)[f]
	5 μg	V(IV)	
	2 μg	Pd(II), Pb(II)	
	1 μg	Fe(III), Cd(II)	
Below	1 μg	Fe(II), Co(II), Ni(II), Cu(II)	
Above	100 mg	Br^-, Cl^-, I^-, ClO_4^-, NO_3^-, SCN^-, SO_4^{2-}, Acetate	
	50 mg	F^-, $S_2O_3^{2-}$	
	20 mg	Tartrate	
	10 mg	PO_4^{3-}	
	1 mg	Oxalate	
Below	1 mg	Citrate, EDTA	

a) 3 ml of 50% potassium iodide solution was added. b) 4 ml of 4% sodium fluoride solution was added. c) 5 ml of 10% thiourea solution was added. d) 1 ml of 2.5% sodium tartrate solution was added. e) 1 ml of 10% sodium perborate solution and 1.5 ml of sodium acetate solution were added. f) 0.7 ml of 5×10^{-3} M *N*-(dithiocarboxy)sarcosine solution was added.

was obtained by the recommended procedure. The equation for the line obtained by a least-squares treatment was

$$\text{Zn(ppm)} = 1.51A \quad (2)$$

where A is the absorbance. The optimum range for the zinc determination is 0.1—1.5 ppm in the solution measured. The apparent molar absorptivity calculated from Eq. 2 is 4.33×10^4 M^{-1} cm^{-1}.

Ten standard solutions containing 638 ppb of zinc(II) were analyzed by the recommended procedure. The results gave a relative standard deviation of 0.29%.

Effect of Diverse Ions: The effect of diverse ions on the determination of zinc were studied by adding a known amount of the ion in question to a solution containing 15.9 μg of zinc(II) and following the recommended procedure. An error of ±3% in the absorbance reading was considered tolerable. The results are summarized in Table 3. Many ions including cadmium(II), cobalt(II), copper(II), iron(II and III), lead(II), manganese(II), mercury(II), nickel(II), palladium(II), silver(I), vanadium(IV), oxalate, citrate, and EDTA interfered with the determination when no masking agent is added, but the other ions scarcely or did not interfere. Of these interfering ions, iron(III), manganese(II) and a small amount of vanadium(IV) can be masked with sodium fluoride, cadmium(II), lead(II), mercury(II), and silver(I) with thiourea, nickel(II) and a small amount of cobalt(II) with *N*-(dithiocarboxy)sarcosine, vanadium(IV) with sodium tartrate, and cobalt(II) with sodium perborate and ammonium acetate.

In addition, the removal of interferences caused by several ions which coexist at the same time was also examined. For example, a calibration graph prepared in the presence of each 30 μg of copper(II), iron(III), and lead(II) and by using thiourea, sodium fluoride, and potassium iodide as masking agents for these ions was in good agreement with that prepared in the absence of these interferents within an error of 3%. This suggests that the selectivity in the proposed method can be improved enough to apply it to the analysis of practical samples.

Use of Analogue-Derivative Spectrophotometry to Improve Sensitivity. Derivative spectrophotometry using the analogue differentiation circuit enhances the sensitivity of ordinary spectrophotometry,[8,9] so second-derivative spectrophotometry was applied here to the determination of zinc.

Selection of Conditions for Measurements: In second-derivative spectrophotometry both the time constant of the analogue differentiation circuit and the scan speed of the spectrophotometer considerably affect the sensitivity and selectivity, so both need to be optimized to give a well resolved large peak. Figure 8 shows the second-derivative spectra of the zinc(II)–NQNPH complex measured with various scan speeds and circuit numbers. A combination of circuit No. 6 (which has the largest time constant, 2.0 s, the time constant increasing with circuit number in our apparatus) and a scan speed of 300 nm min^{-1} was found to give the best sensitivity and resolution (i.e., selectivity) for the zinc determination.

Calibration Graph: The calibration graph prepared under the recommended conditions by plotting the second-derivative absorbance versus the zinc concentration is linear and passes through the origin

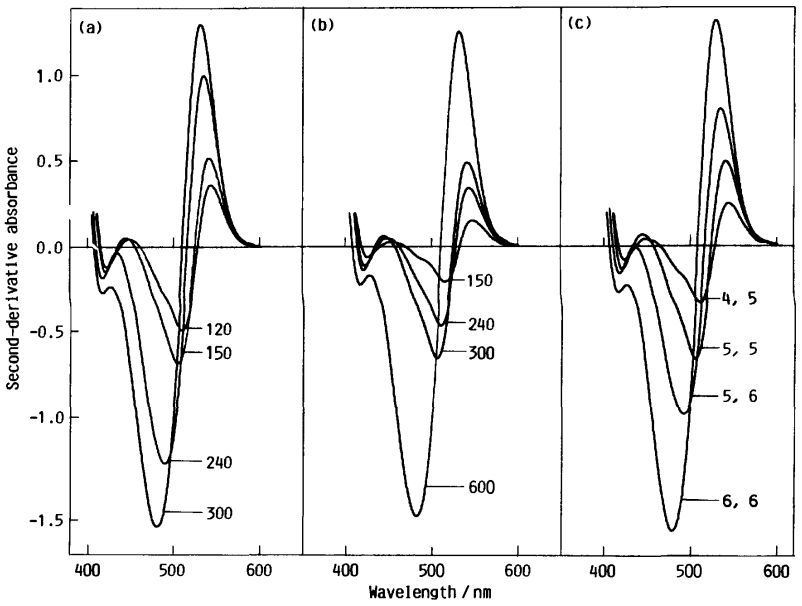

Fig. 8. Influence of (a), (b) scan speed [with circuits all No. 6 in (a) and all No. 5 in (b)] and (c) circuit number (with scan speed 300 nm min^{-1}) on second-derivative spectra of zinc(II)-NQNPH complex solution. Zn(II), 319 ppb (4.9×10^{-6} M); NQNPH, 1.0×10^{-4} M; pH, 7.2; reference, reagent blank. Numerical values indicate scan speeds in (a) and (b) and first- and second-differentiation circuits in (c).

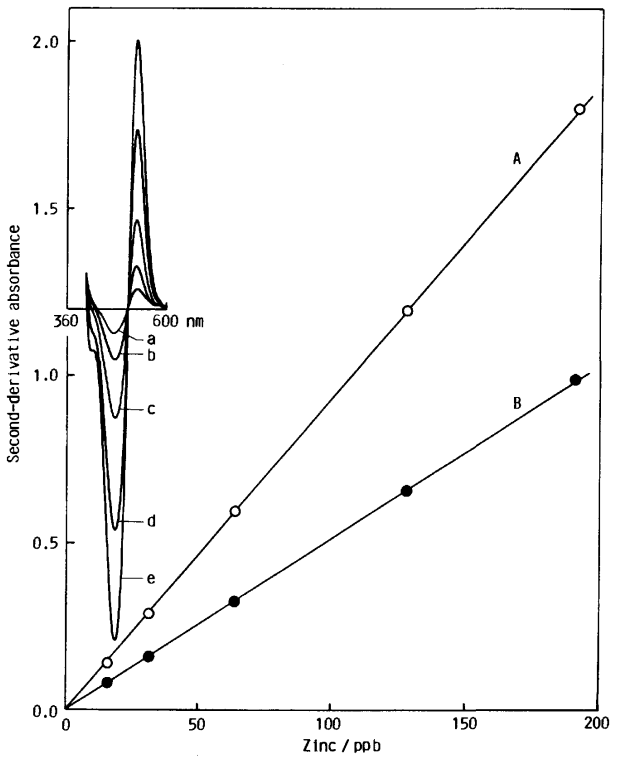

Fig. 9. Calibration graph for zinc in second-derivative spectrophotometry. A, Peak-to-trough values plotted; B, base line-to-trough values plotted. Circuits, all No. 6; scan speed, 300 nm min^{-1}; slit width, 1 nm; recorder sensitivity, ×1; reference, reagent blank; NQNPH, 1.0×10^{-4} M. Zn(II)—a, 15.9; b, 31.9; c, 63.8; d, 128; and e, 191 ppb.

when either the peak to trough values or the base line to trough values are plotted, as shown in Fig. 9. The equation for the lines were

$$\text{Zn(ppb)} = 107D \quad (3)$$

$$\text{Zn(ppb)} = 194D \quad (4)$$

where D is the second-derivative absorbance converted into absorbance. It will be seen that zinc at levels as low as 16 ppb can easily be determined in this way.

Practical Applications. To confirm the usefulness of the proposed method, zinc in Kuroko and water samples was determined. The results are summarized in Table 4 together with those by atomic absorption spectrometry carried out for comparison. Both sets of results are in good agreement.

Composition of the Complex. The molar composition of the zinc(II)-NQNPH complex formed under the conditions for the determination of zinc was examined by both the molar ratio and the continuous variation methods. Both method indicated the formation of a 1 : 2 (metal : ligand) complex. As an example, the result by the continuous variation method is shown in Fig. 10.

Formation Constant of the Complex. The formation constant of the zinc(II)-NQNPH complex formed under the recommended conditions was determined spectrophotometrically by the equilibrium shift method.[11]

Table 4. Determination of Zinc in Kuroko and Water Samples

Sample	Zinc content		
	Proposed method		Atomic absorption method[a]
	Individual values	Average	
Kuroko A	19.4% 18.8%	19.1%	19.0%
Kuroko B	9.19% 8.90%	9.05%	9.07%
Tap water	34 ppb 34 ppb 33 ppb	34 ppb	35 ppb[b]
Hirose river water	18 ppb 19 ppb 19 ppb	19 ppb	20 ppb[b]

a) By JIS K-0102 (1981) p. 155. b) Before the determination samples were concentrated by evaporation to 1/20 of the initial volume.

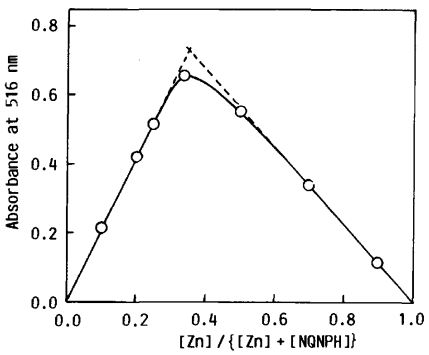

Fig. 10. Continuous variation graph for the zinc(II)–NQNPH system. [Zn]+[NQNPH]=4.88×10⁻⁵ M; pH, 7.2; reference, reagent blank.

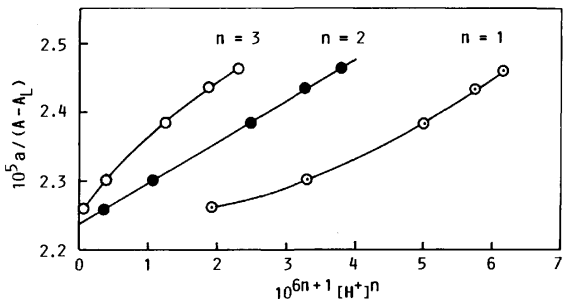

Fig. 11. Plots of $a/(A-A_L)$ versus $[H^+]^n$. Zn(II) (=a), 9.75×10⁻⁶ M; NQNPH (=b), 3.39×10⁻⁴ M; wavelength, 516 nm; ionic strength, 0.2 ($NaClO_4$); temperature, 25±0.1 °C.

The complexation equilibrium between zinc(II) and NQNPH may be expressed as

$$Zn^{2+} + nHL^{2-} \rightleftharpoons ZnL_n^{(3n-2)-} + nH^+ \quad (5)$$

$$K_{eq} = [ZnL_n^{(3n-2)-}][H^+]^n/[Zn^{2+}][HL^{2-}]^n \quad (6)$$

where K_{eq} denotes the equilibrium constant of the complexation reaction. If the initial concentration of the ligand, b, is much higher than that of the metal ion, a, Eq. 6 can be approximated as

$$K_{eq} = x[H^+]^n/(a-x)b^n \quad (7)$$

where x is the equilibrium concentration of the complex formed. As described above, the system obeys Beer's law additively over the wavelength range of interest, it can be deduced that

$$A = \varepsilon_L(b-nx) + \varepsilon_C x \quad (8)$$

where ε_L and ε_C are molar absorptivities of the ligand and the complex at a specified wavelength, respectively, and A is the total absorbance of the solution. From Eqs. 7 and 8, Eq. 9 can finally be obtained:

$$a/(A-A_L) = [H^+]^n/(\varepsilon_C - n\varepsilon_L)K_{eq}b^n + 1/(\varepsilon_C - n\varepsilon_L) \quad (9)$$

where A_L is the absorbance of the solution of the ligand alone. Equation 9 implies that at constant values of a and b there should be a linear relationship between the terms $a/(A-A_L)$ and $[H^+]^n$, from which the value of n can be estimated. Such a relation was experimentally obtained when assuming n is equal to 2, as shown in Fig. 11. This reveals the formation of a 1:2 (metal:ligand) complex, which is in accordance with the result by the continuous variation method indicated above. Thus the complexation reaction of zinc(II) with NQNPH may reasonably be expressed as

$$Zn^{2+} + 2HL^{2-} \rightleftharpoons ZnL_2^{4-} + 2H^+ \quad (5')$$

$$K_{eq} = [ZnL_2^{4-}][H^+]^2/[Zn^{2+}][HL^{2-}]^2 \quad (6')$$

The value of K_{eq} obtained from Eq. 9 and the

experimental data when assuming $n=2$ in Fig. 11 was $10^{-4.49}$.

The overall formation constant, β_2, of the complex defined by

$$Zn^{2+} + 2L^{3-} \rightleftharpoons ZnL_2^{4-} \quad (10)$$

$$\beta_2 = [ZnL_2^{4-}]/[Zn^{2+}][L^{3-}]^2 \quad (11)$$

can be calculated from the values of K_{eq} and the acid dissociation constant of the ligand, K_{a6}, as follows:

$$\beta_2 = K_{eq}/K_{a6}^2 = 10^{-4.49}/(10^{-10.93})^2 = 10^{17.37}$$

Conclusion

A water-soluble hydrazone, NQNPH, was synthesized and its chromogenic properties and reactivity with metal ions were investigated. This hydrazone, the synthesis of which was somewhat complicated, was very soluble in water as expected beforehand and reacted with transition metal ions to give complexes with high molar absorptivities as well as water-soluble hydrazones reported earlier by us.[1,2,5] On the basis of results of fundamental experiments, spectrophotometric and analogue-derivative spectrophotometric methods for the determination of trace amounts of zinc have been proposed and applied successfully to the analysis of mineral and water samples. The proposed methods offer the advantages of simplicity, rapidity, reasonable selectivity and high sensitivity. Very high sensitivity was attained on employing second-derivative spectrophotometry. In addition, the acid dissociation constants of NQNPH and the formation constant of the zinc(II)–NQNPH complex were determined spectrophotometrically.

A Highly Sensitive Fiber-Optic Immunosensor Using a Metal-Complex Compound as a Chemiluminescent Catalyst

Tadashi HARA,* Kazuhiko TSUKAGOSHI, Akihiro ARAI, and Yuji IMASHIRO
Department of Chemical Engineering, Faculty of Engineering, Doshisha University, Karasuma Imadegawa, Kamigyo-ku, Kyoto 602
(Received March 28, 1989)

A highly sensitive fiber-optic immunosensor using an antibody-immobilized optical fiber was developed and introduced into a chemiluminescence complex catalyst immunoassay (CLCCIA) which had been reported by the authors in a previous paper. After optimization of the experimental conditions, human serum albumin as model protein was determined by both competitive immunoassay and sandwich immunoassay, using the fiber-optic immunosensor. Human serum albumin could be determined in the concentration range 1×10^{-4}—1×10^{-1} g dm^{-3} with a lower limit of 400 pg by competitive immunoassay while in the concentration range 1×10^{-5}—1×10^{-1} g dm^{-3} with a lower limit of 40 pg by sandwich immunoassay. The new fiber-optic immunosensor developed by the authors can be characterized as follows: 1) Highly sensitive for the determination of a small amount of protein, 2) applicable to a wide concentration range of protein sample, 3) feasible with a microvolume of sample, 4) suitable for automated operation, and 5) excellent regarding safety, cost, and treatment.

A new immunoassay, chemiluminescence complex catalyst immunoassay (CLCCIA), in which iron(III) 2,9,16,23-tetrakis(chlorocarbonyl)phtalocyanine (TCCP-Fe(III)) was used as a labeling agent, was previously developed by the authors[1-3] using the fact that TCCP-Fe(III) markedly accelerates the chemiluminescene (CL) reaction between 5-amino-2,3-dihydro-1,4-phthalazinedione (luminol) and hydrogen peroxide (H_2O_2). Their immunoassays were carried out by a batchwise method, a flow-through method, and a chromatographic method using antibody-immobilized glass beads. The CLCCIA was highly sensitive and superior regarding safety, cost, and easy treatment to radioimmunoassay and enzyme immunoassay.

An optical fiber has recently been applied to a chemical sensor and a biosensor since the optical fiber makes in situ and in vivo measurements possible and allows very weak light to transfer without any accompanying light loss. However, a few reports have been published with regard to a fiber-optic immunosensor in which an antibody is directly immobilized on the plain end of an optical fiber,[4,5] or a CL reaction is used for the determination of an antigen.[6-8]

In the present study, an attempt was made to develop a new fiber-optic immunosensor using an antibody-immobilized optical fiber and to introdue it into CLCCIA. The fiber-optic immunosensor gave satisfactory results regarding sensitivity for detection, concentration range for determination, amount of sample, and cost.

Experimental

Reagents. All reagents were of commercially available special grade. Ion-exchanged water was distilled before use.

A 1.0×10^{-3} mol dm^{-3} luminol solution contained 1.8×10^{-1} mol dm^{-3} sodium carbonate, 2.0×10^{-1} mol dm^{-3} sodium hydrogencarbonate, and 1.0×10^{-3} mol dm^{-3} ethylenediaminetetraacetic acid (EDTA). A 7.5×10^{-3} mol dm^{-3} H_2O_2 solution was prepared by diluting 30 wt% H_2O_2 with water.

Since the purpose of the present study was to describe the establishment of a new immunoassay methodology, all experiments were carried out using easily available and inexpensive human serum albumin (HSA) as model protein. Rabbit anti-HSA (DAKO) was used without further purification. HSA (MilesLabolatories, Inc.), bovine serum albumin (BSA)(Sigma Chemical Co.), human serum γ-globulin-(HγG)(Sigma Chemical Co.), bovine serum γ-globulin (BγG) (Sigma Chemical Co.), bovine serum α-globulin (BαG) (INC Pharmaceuticals, Inc.), and ovalbumin (Ova)(Sigma Chemical Co.) were dissolved and diluted with a phoshate buffer solution consisting of 2.78×10^{-3} mol dm^{-3} potassium dihydrogenphosphate, 5.56×10^{-3} mol dm^{-3} disodiumhydrogenphosphate, and 0.05 wt% sodium azide (pH 7.3) (Buff-A) or a Buff-A containing 1 wt% BSA (Buff-B).

Iron(III) 2,9,16,23-tetracarboxyphtalocyanine (TCP-Fe(III)) and TCCP-Fe(III) were synthesized as described in the previous paper.[1,9] TCCP-Fe(III) was used as a labeling reagent. TCP-Fe(III) was used to optimize the conditions for the measurement of the CL intensity because TCCP-Fe(III) was hydrolyzed in water and changed to TCP-Fe(III).

Preparation of labeled HSA and labeled anti-HSA were carried out as described in previous papers.[1,3] The concentrations of these albumins were determined on the basis of the calibration curves of their absorbance.

Preparation of the Optical Fiber Immobilized with Anti-HSA. The plain end of an optical fiber (GC. 800/1000L, Fujikura Co.; 1 mm i.d.×5 cm) was polished with a sand paper (1200 CC-CW, SANKYO RIKAGAKU Co.) and was followed by the immobilization of anti-HSA, as described in the literature.[4,10] After the end part of an optical fiber was activated by strong mineral acid, the surface was treated by 3-(2,3-epoxypropoxy)propyltrimethoxysilane, and anti-HSA was immobilized by a periodic acid method on the surface, followed by the reduction of the imine-type bond to the amine-type bond by sodium borohydride. The antibody-immobilized optical fiber, thus obtained, was washed by Buff-A and stored at 4 °C in Buff-B. According to the present procedure, 160 pieces of antibody-immobilized optical fibers were obtained using 10 mg of antibody.

Apparatus and Procedure. Both the competitive immunoassay and sandwich immunoassay are schematically shown in Fig. 1.

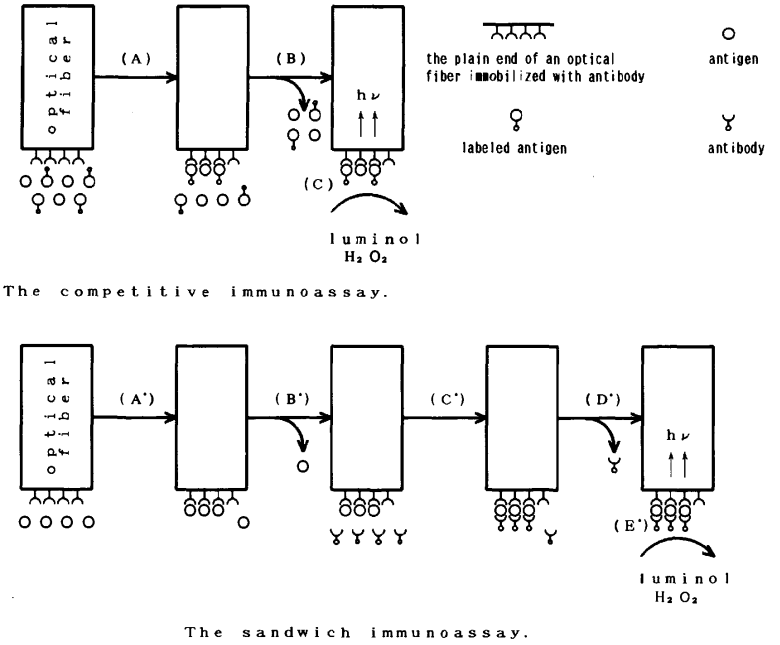

Fig. 1. Schematic diagram of the immunoassay. (A),(A'),(C'): Antigen-antibody reaction, (B),(B'),-(D'): separation of bound and free fractions, and (C),(E'): measurement of CL intensity.

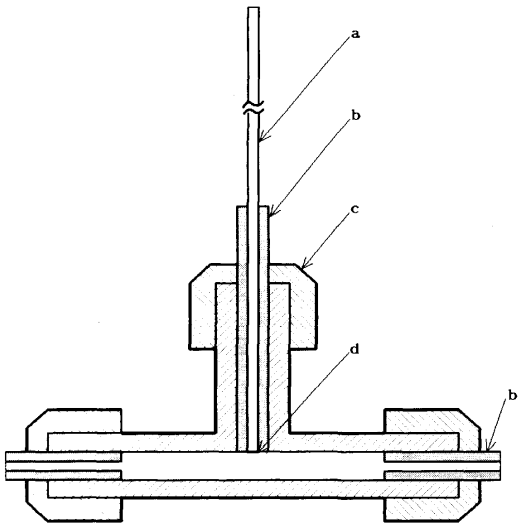

Fig. 2. The cell set with an optical fiber. a: optical fiber, b: silicone tube (3 mm o.d.×1 mm i.d.), c: Teflon-made three-way joint (3 mm i.d.), and d: immobilized antibody.

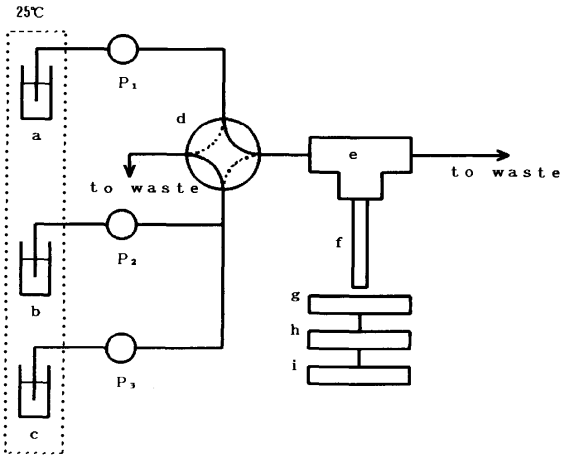

Fig. 3. Schematic flow diagram of a fiber-optic immunosensor. a: Buffer solution, b: H_2O_2 solution, c: luminol solution, d: four-way cock, e: cell, f: optical fiber, g: photomultiplier, h: photoncounter, i: integrator, and P_1, P_2, P_3: pump.

Competitive immunoassay was carried out as follows: The end part of an antibody-immobilized optical fiber was immersed in a mixed solution containing 2.4 ng of labeled HSA in 4 mm^3 of Buff-B and a definite amount of HSA in 4 mm^3 of Buff-B, and was made to react with antigen (HSA) in the mixed solution at 4 °C for 2 hours (A). The optical fiber was twice washed with 50 mm^3 of Buff-C (2.78×10^{-3} mol dm^{-3} potassium dihydrogenphosphate, 5.56×10^{-3} mol dm^{-3} disodium hydrogenphosphate) (B) and positioned in the cell as shown in Fig. 2. Sandwich immunoassay was carried out as follows: The end part of an antibody-immobilized optical fiber was immersed in a solution containing a definite amount of HSA in 4 mm^3 Buff-B, and was made to react with antigen (HSA) in the solution at 25 °C for 2 hours (A'). The optical fiber was twice washed with 50 mm^3 of Buff-B (B') and was made to react with 12 ng of labeled HSA in 4 mm^3 of Buff-A at 4 °C for 4 hours (C'). The optical fiber was positioned in the cell as shown in Fig. 2 after washing twice with 50 mm^2 Buff-C (D').

The CL emitted from the surface of the optical fiber set to the cell was measured ((C) and (E')) in accordance with the following procedure: The measurement of the CL intensity was made using the immunosensor system shown in Fig. 3 in which all the tubes and connectors were made of Teflon. Each solution of Buff-C (a), H_2O_2 (b), and luminol (c) was fed at a flow rate of 1.5, 0.25, and 0.25 cm^3 min^{-1} by means of pumps (P_1), (P_2), and (P_3) (Atto, SJ1211). The optical fiber set to the cell was washed with Buff-C for 1 min and fed with a mixed solution of H_2O_2 and luminol by operating a four-way cock (d). The CL emitted from the surface of the optical fiber was immediately detected with the photon-counter (h) and was integrated for 1 min with the integrator (i) to give the CL intensity as a peak area (V s).

Results and Disccusion

Determination of Analysis Conditions. An adequate investigation was not made in previous studies,[1-3,9] regarding the type and pH of the buffer solution used for a luminol solution in the lunimol-H_2O_2-TCP-Fe(III) system. To improve the sensitivity of immunoassay, a CL system by which TCP-Fe(III) could be determined more sensitively was necessary. Then, the type and pH used for a luminol solution were optimized. The apparatus used for this experiment is shown schematically in Fig. 4. Each solution of luminol, H_2O_2 and carrier(Buff-C) was fed at a flow rate of 2.0, 2.0, and 0.5 $cm^{-3}min^{-1}$. A 50 mm^3 portion of a 1.0×10^{-8} mol dm^3 TCP-Fe(III) catalyst solution was injected into the line of carrier solution through the sampling loop and six-way cock. The CL intensity of the solution passing through the flow-cell (0.8 mm i.d.×45 cm; poly (vinyl chloride) tube) was detected with a photoncounter and recorded on a recoder. The peak area obtained by injecting the catalyst sample solution was integrated with the integrator to give the CL intensity as a peak area (V s). As can be seen from the experimental results (Fig. 5) obtained using the above-mentioned apparatus, the CL intensity showed a maximum value when a 0.2 mol dm^{-3} carbonate buffer solution (pH 10.8) was used. Since the value of the base line which corresponded to the CL intensity due to both a luminol solution and a H_2O_2 solution in the absence of a catalyst solution was large, a 1.0×10^{-2}—1.0×10^{-4} mol dm^{-3} EDTA solution was added to a luminol solution so as to minimize the value of the base line. The relationship between the EDTA concentration and the value of the base line or the CL intensity of a TCP-Fe(III) catalyst solution was obtained. The addition of the EDTA solution lowered the value of the base line by one-hundred times, but had almost no affect on the catalytic activity of the

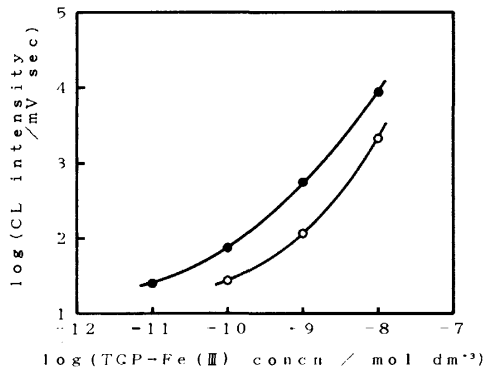

Fig. 6. The relationship between concentration of TCP-Fe(III) and CL intensity.
●: The present luminol solution and O: the conventional luminol solution.

TCP-Fe(III) solution. Therefore, the detection limit of TCP-Fe(III) using the present luminol solution consisting of 1.0×10^{-3} mol dm^{-3} EDTA in a 0.2 mol dm^{-3} carbonate buffer solution (pH 10.8), was about one-tenth that of TCP-Fe(III) using the luminol solution mentioned in a previous paper.[3] Two calibration curves for TCP-Fe(III) using the present luminol solution and same luminol solution as in the previous paper[3] were shown in Fig. 6.

The relationship between the CL intensity and the flow rate of a 1:1 mixed solution of a luminol solution and a H_2O_2 solution was examined by the measuring system shown in Fig. 3. In this experiment the CL emitted from an antibody-immobilized optical fiber, which had been made to react with 4 mm^3 of 1.0×10^{-2} g dm^{-3} labeled HSA at 4 °C for 20 min, was measured for 1 min at various flow rates of the 1:1 mixed solution of a luminol solution and a H_2O_2 solution. The maxium CL intensity was observed when the flow rate of the 1:1 mixed solution was 0.5 cm^3 min^{-1}; the change of the CL intensity in the flow rate range of 0.1—2.0 cm^3 min^{-1} was within 10%. A flow rate of 0.5 cm^3 min^{-1} was used for the experiment.

The relationship between the repetitive use and the activity change of an antibody-immobilized optical fiber was examined as follows: The antibody-immobilized optical fiber was made to react with 4 mm^3 of 1.0×10^{-2} g dm^{-3} labeled HSA at 4 °C for 20 min and the CL emitted from the optical fiber was measured for 1 min. Then, the labeled HSA was eluted with a 8.0×10^{-3} mol dm^{-3} hydrochloric acid —3.0×10^{-2} mol dm^{-3} potassium chloride buffer solution (pH 2.3), and the antibody-immobilized optical fiber was subjected to the next immune reaction, followed by measuring (using a similar method as before) the CL. This operation was repeated severall times. According to the obtained results, about a 20% reduction of the CL intensity was observed for one-time use. A newly prepared antibody-immobilized optical fiber was used for every measurement in the present study.

The conditions necessary for the immune reaction (A) in competitive and the immune reaction (C′) in sandwich immunoassay were chosen by taking the reaction time and nonspecific adsorption into consideration,[11,12] as follows: Immune reaction (A) 3.0×10^{-3} g dm^{-3} labeled HSA, 4 °C, and 2 hours; immune reaction (C′) 3.0×10^{-2} g dm^{-3} labeled anti-HSA, 4 °C, and 4 hours.

The relationship between the reaction time and the CL intensity was examined for the immune reaction (A′) in sandwich immunoassay. The immune reaction (A′) was found to almost attain equilibrium in 2 hours. Therefore, the immnue reaction (A′) in the subsequent experiment was carried out for 2 hours. The relationship between the sample amount used for sandwich immunoassay and the CL intensity was examined. The CL intensity was nearly definite for a sample solution of more than 4 mm^3. Therefore, a 4 mm^3 sample solution was used in the subsequent experiment.

Calibration Curve of HSA. The calibration curve for HSA was obtained by competitive immunoassay under the optimized conditions mentioned above (Fig. 7). HSA could be determined in the concentration range 1×10^{-4}—1×10^{-1} g dm^{-3}, with a lower limit of 400 pg. The coefficient of variation for five analyses of a 1.0×10^{-3} g dm^{-3} HSA solution was 6.5%.

The calibration curve for HSA was also obtained by sandwich immunoassay under the optimized conditions mentioned above (Fig. 8). HSA could be determined in the concentration range 1×10^{-5}—1×10^{-1} g dm^{-3}, with the lower limit of 40 pg. The

Table 1. Selectivity of a Fiber-Optic Immunosensor

Protein	Relative CL intensity
HSA	1.00
HγG	0.14
BγG	0.07
BγG	0.00
Ova	0.00

Protein concn=1.0×10^{-2} g dm^{-3}.

coefficient of variation for five analyses of a 1.0×10^{-3} g dm^{-3} HSA solution was 5.0%. Though sandwich immunoassay was a tedious method, it was about 10 times more sensitive than competitive immunoasay.

Selectivity. The selectivity of the fiber-optic immunosensor in sandwich immunoassay was examined by measuring the adsorption amount of various proteins onto an anti-HSA immobilized optical fiber (Table 1). Each 1.0×10^{-2} g dm^{-3} of protein was used throughout this experiment and the relative CL intensity was shown based on the CL intensity of HSA (=1.00). As can be seen from Table 1, BαG and Ova showed no nonspecific adsorption, whereas HγG and BγG showed somewhat nonspecific adsorption with values of 0.14 and 0.07. Such nonspecific adsorption would be decreased by the ues of a monoclonal antibody, since a polyclonal antibody was used in the present experiment.

Comparison with Other Methods. The method for the determination of protein, which is based on the combination of CLCCIA and an immune column, has already been reported by the authors.[3] The concentration range for the determination of protein, the detection limit, and the sample amount necessary for the determination mentioned in the paper[3] were 2.5×10^{-5}—5×10^{-3} g dm^{-3}, 5 ng, and 200 mm^3, while those in the sandwich immunoassay in the present study were 1×10^{-5}—1×10^{-1} g dm^{-3}, 40 pg, and 4 mm^3.

Sepaniak et al. reported the determination of IgG in the concentration range 3.7×10^{-4}—1.8×10^{-1} g dm^{-3} by use of a fiber-optic immunosensor (D-I)[4] with fluorescence detection in which an antibody was directly immobilized on the plain end of an optical fiber. Aizawa et al. also reported the determination of protein in the concentration range 6.9×10^{-2}—2.1 g dm^{-3} HSA using a fiber-optic immunosensor (D-II)[6,7] with electro-chemical luminescence detection and in the concentration range 1×10^{-6}—1×10^{-2} g dm^{-3} IgG they used a fiber-optic immunosensor (D-III)[8] with chemiluminescence detection, in which an aromatic hydrocarbon or enzyme was used as a labeling agent, though the antibody was not directly immobilized on an optical fiber. In the present study, a highly sensitive immunosensor using an optical fiber immobilized with antibody directly on its plain end was newly developed; it was introduced into CLCCIA using a synthetic metal-complex catalyst for CL reaction as a labeling agent. The sensitivity of the present method was inferior to that of D-III but superior to those of D-I and D-II by more than 10 times.

The new fiber-optic immunosensor was characterized by the followings: 1) Highly sensitive for the determination of a small amount of protein, 2) applicable to a wide concentration range of protein sample, 3) feasible with a microvolume of sample, 4) suitable for the automation of operation, and 5) excellent regarding safety, cost, and treatment.

The authors wish to thank Mr. Masakatsu Imaki (Horiba, Ltd.) for providing the apparatus necessary for the present study.

The present study was supported by a Grant-in-Aid for General Scientific Research No. 63550567 from the Ministry of Education, Science and Culture.

(Received February 18, 1989)

The temperature dependence and associated decay kinetics of the high energy band centered at 380 nm in the fluorescence spectrum of 1,6-diphenyl-1,3,5-hexatriene in a nonpolar solvent were investigated. Below 150 K the emission intensity at 380 nm relative to that of a sharp band near 400 nm was very small. Above this temperature the intensity at 380 nm increased with increasing temperature. The fluorescence decay analysis of this band showed two components with decay times of 62 ps and 13.4 ns. The 62 ps component was assigned to the prompt fluorescence of the S2 (1Bu*) state and 13.4 ns component to a delayed type fluorescence from the same state after establishment of a thermal equilibrium with lower S1 (1Ag*) state.

When a molecule is used as a fluorescence probe in biological systems it is essential that its photophysical properties are clearly understood so that the information provided by the probe is correct and most useful. 1,6-Diphenyl-1,3,5-hexatriene (DPH) has been employed as a fluorescence probe for the elucidation of the order and dynamics of membrane systems.[1-3] It is representative of the diphenyl derivatives of linear polyenes and considerable data about their photophysical properties have been reported.[4,5] It has been adequately shown that DPH has anomalous fluorescence properties.[6] The fluorescence properties of DPH has a large Stokes shift and its radiative lifetime when estimated from Strickler-Berg relationships[7] is far smaller than that obtained experimentally.[8] A large number of investigations of DPH photophysics have been directed at understanding origin of these anomalies. It has been shown that the 1Ag* state is the emitting state.[9] Birks and co-workers[10] suggested that the fluorescence occured from the symmetrically forbidden 1Ag*-1Ag transition, which borrowed intensity from the dipole allowed 1Bu*-1Ag transition. They proposed that the energy difference between the 1Bu* and 1Ag* state and conformational changes in the excited state were controlling factors for the photophysical processes of diphenylpolyenes such as diphenylbutadiene (DPB) and diphenyloctatetraene (DPO). While this rationalization appears to be reasonable, Alford, Palmer,[11,12] Itoh and Kohler[13] in their investigations of the fluorescence spectra of DPH and its derivatives assigned a band near 380 nm to the 1Bu*-1Ag transition. Furthermore, recent picosecond transient absorption studies on DPH suggested a thermal equilibrium exists between the S2 and S1 states.[14] In this report we present a detailed study of the temperature dependence and fluorescence decay kinetics of the high enegry band.

Materials and Methods

all-trans-1,6-Diphenyl-1,3,5-hexatriene (Sigma Chemical Co. St. Louis Mo.) was purified by vacuum sublimation. Its purity and photochemical decomposition was checked by measuring its absorption spectrum before and after any fluorescence measurements. Methylcyclohexane (MCH) (Distilled in glass quality, Caledon Lab, Georgetown, Ont) was used without further purification and shown to be free of any fluorescence impurities.

Fluorescence decay measurements were performed with a frequency doubled Spectra-Physics synchronously pumped and cavity dumped laser system (E_x=295 nm or 310 nm) and methods of time correlated single photon counting techniques. The instrumentation and the methods of data analysis used have been described in detail.[15] The emission bandpass was 4 nm. A Perkin-Elmer MPF-44A spectrofluorometer equipped with a DCSU-2 microprocessor correction unit was used for measurement of the fluorescence spectra. The fluorometer was connected through an analog to digital converter to a Commodore PET minicomputer for the storage and manipulation of the fluorescence spectra. The fluorometer was equipped with a thermostable cell holder. Low temperature (<0 °C) spectra were recorded using a NRCC built quartz Dewar assembly the temperature of which was controlled by blowing cold nitrogen gas into the Dewar. The samples in this latter case were in a suprasil quartz tube. The excitation and emission bandpasses were 2 nm and 2 nm respectively. All samples were deoxygenated by flushing with oxygen free nitrogen. Absorption spectra were measured on Cary 118 spectrophotometer.

Results

The fluorescence spectrum of DPH in a MCH glass at 77 K has three sharp bands at 397, 425, and 445 nm and a shoulder at 480 nm (Fig. 1). Above 147 K the MCH solution is liquid. The spectrum at 150 K again has three sharp transitions at 401, 426, and 450 nm which are red shifted relative to the bands in the 77 K spectrum. At 150 K and 77 K the emission intensity between 360 nm and 390 nm was negligible when

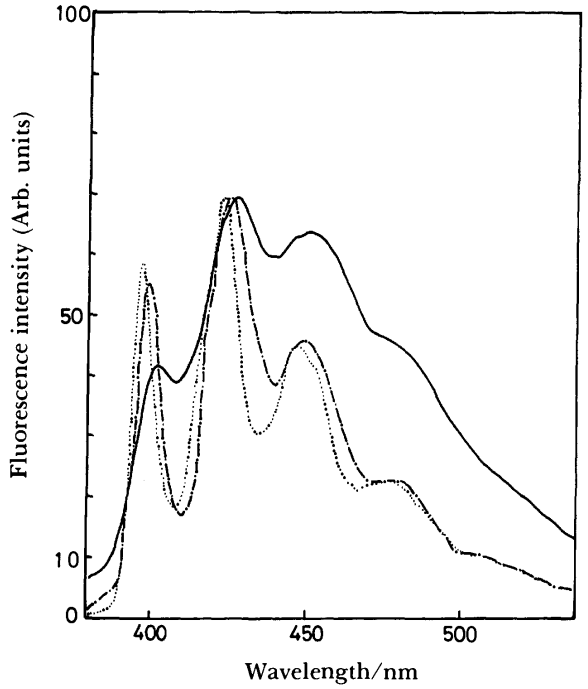

Fig. 1. Fluorescence spectra of DPH in MCH. -----; 77 K, ----; 150 K, —; 293 K.

compared to the intensity of the band above 390 nm. As the temperature increased the position of the bands remained constant, however the band widths broadened and the intensities of the long wavelength bands (426, 450, and 482 nm) increased. At the same time, a shoulder became evident at a wavelength below the

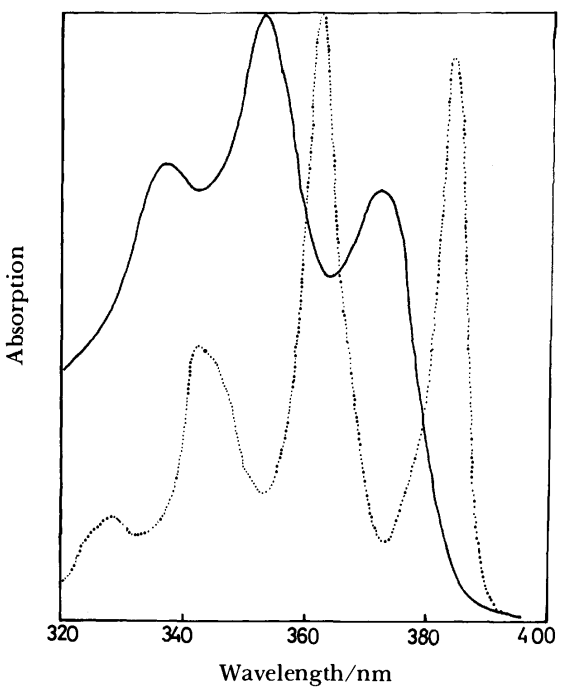

Fig. 3. Absorption spectra of DPH in MCH at 77 K (-----) and 293 K (—). See text.

400 nm band. Figure 2 shows the high energy edge of the DPH fluorescence spectrum in MCH solution at 183, 233, 279, and 313 K. The emission intensity in this region increased as the temperature increased. The peak position and the band width of the high energy emission band, measured at 279 K was estimated to be 380 nm and 970 cm^{-1} respectively by curve fitting assuming Gaussian band shapes. Because of the broadening of the 400 nm band, it is difficult to determine the precise peak position of the high energy band at high temperature. But this band apparently undergoes a shift to the lower energy side with decreasing temperature. This contrasts with the behavior of the main fluorescence bands above 400 nm.

The absorption spectrum of DPH in MCH at 77 K has sharp bands at 327, 342, 362, and 384 nm and no absorption was detected around 400 nm (Fig. 3). Usually the excitation spectrum is used for the investigation of absorbance at 77 K. But that is correct only when the sample concentration is extremely low. The spectrum shown in Fig. 3 was obtained from the intersection of the straight line log $(I(\lambda)/I(\lambda_0))$-[DPH] plot of the following equation

$$\log\{I(\lambda)/I(\lambda_0)\} = \log\{\varepsilon(\lambda)/\varepsilon(\lambda_0)\} - \{\varepsilon(\lambda) - \varepsilon(\lambda_0)\}cd$$

where $I(\lambda)$ and $I(\lambda_0)$ are fluorescence intensities excited by λ and λ_0 and ε, c and d are absorption coefficient, DPH concentration and optical path length, respectively.[16] The absorption spectrum of DPH at temperature above 293 K has peaks at 337 nm, at 353 nm and 372 nm which are blue shifted relative to the 77 K

spectrum. As reported earlier[8] these bands undergo small shifts to higher energy with increasing temperature. The emission band at the high energy edge (380 nm) overlaps the lowest energy band of the absorption spectra.

The fluorescence decay of DPH in MCH was measured over the full spectral region. Between 400 nm and 550 nm the fluorescence decayed with single exponential decay kinetics (Fig. 4 upper). Below 400 nm, in the high energy fluorescence spectral region, DPH showed the double exponential decay kinetics (Fig. 4 middle and lower) with lifetimes of 13.38 ns (T_1) and 62 ps (T_2). The fluorescence decay parameters of DPH are summarized in Table 1. Because T_2 is short and its fractional fluorescence is small, close attention was paid to eliminate the possibility that this component was due to light scattering or emission from quartz cuvette or solvent impurities. From the relation between the steady state fluorescence intensity, $F_{ss}(\lambda)$ and the fluorescence decay kinetics, the fast decay component $F_s(\lambda)$ is extracted as follows,

$$F_s(\lambda) = F_{ss}(\lambda)R(\lambda)\ T_2/(R(\lambda)\ T_2 + T_1)$$

where $R(\lambda)$ is the ratio of the normalized preexponential factor. The time resolved spectrum of DPH fluorescence in the high energy spectral region gives a

clear peak at 377 nm (Fig. 5). This peak position is coincident with the high energy peak of the steady state DPH fluorescence spectra estimated by a curve fitting procedure. In experiments using the third harmonics (353 nm) from the neodymium laser it was observed that the fluorescence of DPH had a decay component which decayed to 70 percent of the maximum fluorescence within 30 ps after excitation.[17] This component corresponds to the 62 ps component which we observed. The time evolution of the transient absorption spectra of DPH shown by Rullière and Declémy supports the assignment of the fast decay component of DPH fluorescence to the S_2-S_0 transition.[14]

Discussion

Because the 1Ag*-1Ag transition is symmetrically forbidden, it is presumed that the absorption spectrum of DPH is due to the 1Bu*-1Ag transition. Therefore the spectral overlap at temperature 150 K in the 380 nm region would support the assignment of this latter emission band originating from the 0-0 level of the same transition. Further since the 1Ag* state is lower in energy than the 1Bu* state in DPH in nonpolar solvents the 401 nm band in the 150 K fluorescence spectrum can be assigned to the 0-0 band of the 1Ag*-1Ag transition.

We agree that the increase in the 380 nm fluorescence intensity with temperature is indicative, as Alford and Palmer suggested, requires that a thermal equilibrium be established between the S_2 (1Bu*) and S_1 (1Ag*) states. Using the data obtained at several different temperatures it is possible to estimate the energy difference between these states from the relationship proposed by Parker[18]:

$$I(380)/I(401) = A\exp(-E_0/kT)$$

where $I(380)$ and $I(401)$ represent the fluorescence intensities at 380 nm and 401 nm respectively, A is a temperature independent constant which include a frequency factor and a radiative lifetime, and the other terms, k, and T have their usual definitions. A plot of the natural logarithm of the intensity ratio against $1/T$ is shown in Fig. 6; an excellent straight line was obtained with a slope having a value for E_0=630 cm^{-1} (0.078 eV). This value is coresponds to the energy difference E(1Bu*)−E(1Ag*) of DPH in hexane at zero temperature reported by Itoh and Kohler.[13] The energy difference between the 1Bu* and 1Ag* state can also be estimated from the 0-0 bands of the fluorescence spectra. This gives a value of 840 cm^{-1} which is in close agreement with the value obtained above. It is noteworthy that Cehelnik et al. in a study of the temperature quenching of the fluorescence of DPH in MCH (E_m=400 nm) found a value of 7.1 kJ mol^{-1} (596 cm^{-1}) which is close to the value which we report

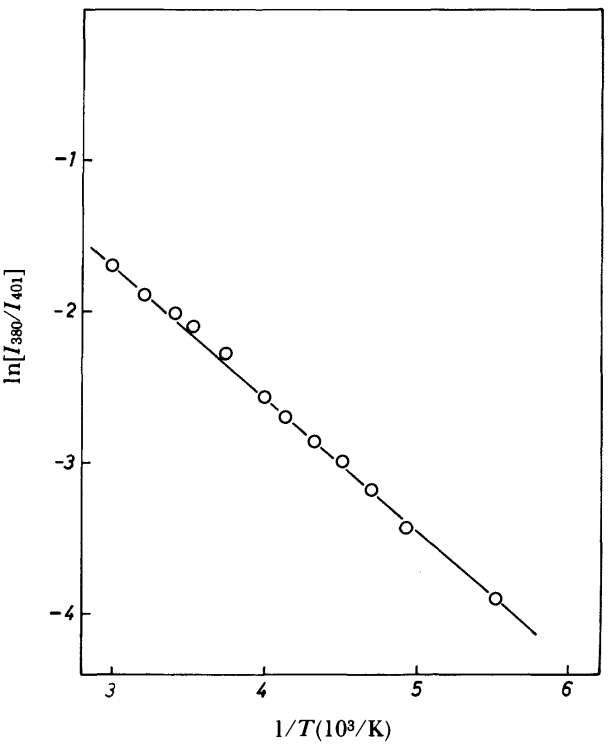

Fig. 6. Plot of ln (I_{380}/I_{401}) against $1/T$, I_{380} and I_{401} are fluorescence intensities at 380 and 401 nm, respectively.

herein. This is strong evidence that the main nonradiative deactivation pathway of the 1Ag* state is a thermally activated process occuring through the 1Bu* state.

We propose that the fluorescence decay results may be rationalized according to the following scheme. We attribute the 62 ps component, which is only observed at wavelengths below 400 nm, to prompt emission from the initially excited 1Bu* state. We have not been able to detect any evidence of a short component at longer wavelengths. This may be due either to the lack of such a contribution at lower energies or to a very small contribution (<0.2% of a 13.40 ns component) which cannot be detected. The signal 13.4 ns component which is observed above 400 nm is assigned to the emission from the 1Ag* state. The 13.4 ns component, which is observed below 400 nm, is attributed to a delayed type emission from the 1Bu* state after thermal repopulation from the 1Ag* state. At present we cannot rule out the possibility that the fluorescence above 400 nm includes 1Bu* emission. If it did however we might expect to detect a 62 ps component due to the prompt fluorescence from this state. As stated above this might make a negligible contribution to the fluorescence in this region.

The value of the radiative lifetime, τ_r, of DPH from the 1Bu*-1Ag transition, estimated by the Strickler-Berg method was 1.6 ns. The short lifetime, 62 ps, in these experiment is much less than the theoretical

value. However, it is reasonable to attribute the shorter value to internal conversion processes between the 1Bu* and 1Ag* states.

In summary we have resolved the temporal behavior of the 380 nm transition and have confirmed the assignment of this band as the 1Bu*–1Ag transition. The model of a thermal equilibrium between the S_2 (1Bu*) and S_1 (1Ag*) excited state is consistent with all the data. We consider that their relationship and the role they play in the photophysical processes in DPH are clarified so that a better understanding of these processes in lipid system where DPH is used as a probe of order and dynamics is possible.

The Addition of the Cyanide Ion to the *N*-Methyl-3-carbamoylpyridinium Ion in Reversed Micelles

Ayako GOTO* and Hiroshi KISHIMOTO†
Department of Chemistry, University of Shizuoka, 395 Yada, Shizuoka 422
†Faculty of Pharmaceutical Sciences, Nagoya City University, Tanabe-dori, Mizuho-ku, Nagoya 467
(Received February 22, 1989)

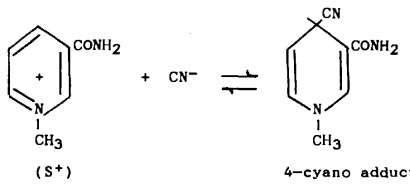
The addition reaction of the cyanide ion to the *N*-methyl-3-carbamoylpyridinium ion was carried out in reversed micelle systems, and the functions of the electric charge of surfactants and of the entrapped water in the micelle were studied by measuring the rate and equilibrium constants. Reversed micelles formed by hexadecyltrimethylammonium bromide (HTAB), a cationic surfactant, not only enhanced the reaction, but also stabilized the product, 4-cyano-1,4-dihydro-*N*-methylnicotinamide (P), which is thermodynamically unstable in aqueous media. This was in contrast to sodium 1,2-bis(2-ethylhexyloxycarbonyl)ethanesulfonate (AOT), an anionic surfactant, reversed micelles. In both reversed micelle systems the reaction could be controlled by varying the water content, although neither is favorable for the reaction at a higher water content. From the distribution measurements and spectroscopic studies, it can be suggested that the reaction occurred preferably in the micellar phase, especially in the water pool. Three kinds of effects were proposed for interpreting the enhancement as compared to the reaction in aqueous systems. The first was the local concentration of reaction species in the water pools, and the second was the lower micropolarity of water pools. The third concerned the electric nature of the surfactant and reactant ions.

The active site of enzyme provides a specific microenvironment, one in which the nature of the medium, such as the pH, the polarity and the viscosity, is quite different from that of bulk water, resulting in the enhancement of the reactivity of the substrates. Thus, the reaction pathway, the rate, and the equilibrium of an enzyme-substrate complex reaction can be controlled by adjusting the physicochemical conditions of the microenvironment.[1] From the physicochemical point of view, the issue of the microenvironment is very interesting to study.

Some reversed micelles[2-5] afford to substrates a microenvironment similar to that afforded by enzymes, because the water in the interior cores of reversed micelles is considered to be less polar and more viscous than in the bulk phase, so that the water pools in the reversed micelles might subrogate the active sites of enzymes for substrates. It has also been proposed, for the reversed micelles formed out of some kinds of functionalyzed surfactants, that the interfaces between the water pools and the hydrophilic groups of the surfactants inside of the micelles are activated and that the inner surfaces of the micelles can mimic the active sites of enzymes.[6] It must be noted here that, contrary to the cases of aqueous micelle systems, in reversed micelle systems the reactivity of substrates can easily be controlled by changing the content of water in the systems and by adjusting the physicochemical properties of the water in the pools.

Baumrucker et al.[7] and Bunton et al.[8] found that the rate and equilibrium constants for the addition of cyanide ion to a series of *N*-alkyl-3-carbamoylpyridinium ions remarkably increased in aqueous micelle systems with normal alkyltrimethylammonium salts and 3-(dodecyldimethylammonio)-1-propanesulfonate as surfactants.

In this work, we wish to report on an addition reaction similar to the one mentioned above, but carried out in some reversed micelle systems. As a reacting cation, the water-soluble *N*-methyl-3-carbamoylpyridinium (S^+) ion was used. The stoichiometric relation is shown by Eq. 1. We examined the functions of the electric charge of the surfactants and the entrapped water in the micelles by measuring the rate and equilibrium constants of the reactions as well as the stability of the product, the i.e., 4-cyano-1,4-dihydro-*N*-methylnicotinamide or simply, the 4-cyano adduct (P).



(1)

Experimental

Materials. The *N*-methyl-3-carbamoylpyridinium chloride (S) was obtained from Wako Chemicals and was twice recrystallized from methanol (MeOH). The water used was distilled by the use of an all-glass distillation apparatus. The sodium cyanide was of reagent grade. The chloroform and 2,2,4-trimethylpentane (isooctane) were dried and stored over a type 4A Molecular Sieve which had been activated by heating at 200 °C under reduced pressure for several hours and, then cooled in vacuo over silica gel; they were used as soon as possible.

The hexadecyltrimethylammonium bromide (HTAB), the cationic surfactant, was commercially obtained and was twice recrystallized from acetone–MeOH. The sodium 1,2-bis(2-ethylhexylcarbonyl)ethane sulfonate (AOT), the anionic surfactant, was obtained from Nikko Chemicals; its purity was more than 99.9%. Both the surfactants were dried at 60 °C in vacuo over P_2O_5 and used immediately.

Preparation of Solutions I and II. Each reversed micelle

system was formed by adding a ternary mixture of an organic solvent, a surfactant, and S (Solution I) to a quaternary mixture of an organic solvent, water, a surfactant, and NaCN (Solution II). The HTAB was dissolved in chloroform/isooctane mixture (3:2 volume ratio). The AOT was dissolved in isooctane. Each solution will hereafter be denoted as a mother solution.

Then, to prepare Solution I, a relatively small amount of the S/MeOH solution was dissolved in the mother solution. The concentration of HTAB or AOT in the mother solution before dissolving the S/MeOH solution was always kept at 0.2 M (1 M=1 mol dm^{-3}). The concentration of S in Solution I was in the range from 2 to 4×10^{-4} M, corresponding to the amount and concentration of the MeOH solution of S. The content of MeOH was within a 0.5% volume ratio. Special care was taken to exclude moisture during the above procedures. To prepare Solution II, various amounts of NaCN aqueous solutions were added, solubilized in the mother solution, and kept at 1×10^{-2} M. However, the molar ratio of water to HTAB or AOT in this solution was variable.

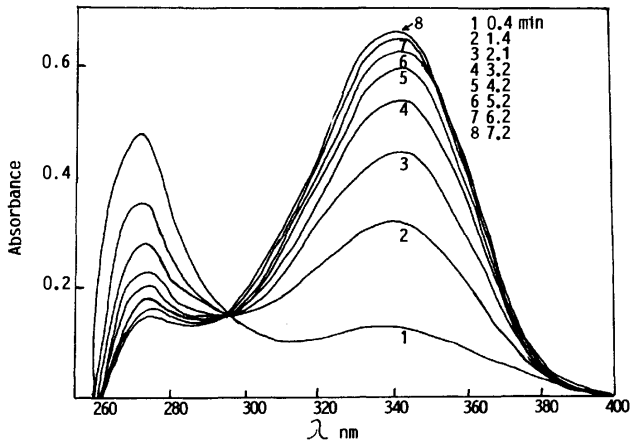


Fig. 1. Ultraviolet spectra of HTAB reversed micelle solution containing *N*-methyl-3-carbamoylpyridinium chloride and sodium cyanide at various reaction time. [HTAB]=0.2 M, R=2.7, $[NaCN]_{aq}$= 0.06 M.

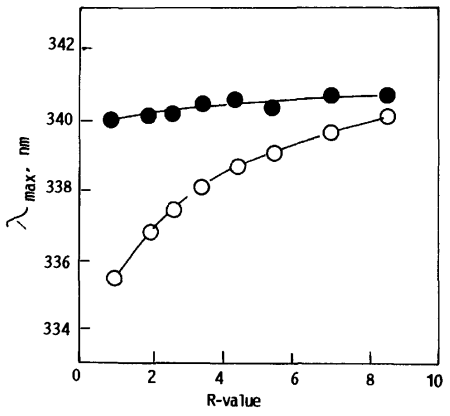

Fig. 2. The wavelength of maximum absorption, λ_{max}, of 4-cyano-1,4-dihydro-*N*-methylnicotinamide, P, in reversed micelles. ●, 0.2 M HTAB; ○, 0.2 M AOT.

By mixing equal amounts of Solutions I and II, we prepared the system for Reaction 1. In Solution II and the resultant reaction system, water was estimated to induce the formation and/or the growth of reversed micelles, which might not have appeared or developed yet, in the mother solution and also in Solution I. Solutions I and II as well as their mixed systems were found to be transparent and colorless.

Kinetics. Kinetic measurements were carried out spectrophotometrically with the aid of a Shimazu UV-265 spectrophotometer thermoregulated at 25±0.1 °C. The addition reaction (Reaction 1) was followed by measuring the OD (optical density) at 340 nm, where the absorption maximum of the reaction product, P, was found nearby, as is shown in Fig. 1. Although the wavelength of maximum absorption, λ_{max}, of P depended upon the composition of the reaction system, its variation was rather slight (Fig. 2) and, was considered to be tolerable in fixing the measured wave length of absorption at 340 nm for the kinetic study.

The reaction was initiated by the addition of 1.5 ml of a substrate solution (Solution I) to 1.5 ml of a cyanide solution (Solution II) in a moisture-proof cell in the spectrophotometer.

Distribution Measurement. The distribution of S between chloroform and aqueous phase was examined as follows, although the organic phase was different from that in the reversed micelle systems. Aqueous solutions of S with concentrations of 3×10^{-4}, 3×10^{-3}, and 3×10^{-2} M were prepared. Equal volumes of one of the aqueous solutions and chloroform were mixed in a vial, which was then sealed with a screw cap and vigorously shaken for about 12 hours at 25 °C. After the vial has been allowed to stand until the two liquid phases had completely separated, the solute concentration in the aqueous phase was determined spectrophotometrically.

Results and Discussion

Rate and Equilibrium Constants of the Addition Reaction in Reversed Micelles. In the reaction mixture, the initial concentrations S^+ and cyanide ions, $[S^+]^i$ and $[CN^-]^i$, were $1—2\times10^{-4}$ M and 5×10^{-3} M respectively. Within 30 min, all the reactions were regarded as having reached their final states, as may be seen in Figs. 1 and 3a. In aqueous systems, a remarkable spectral shift from 340 nm to 320 nm, which suggested the formation of the 2- or 6-cyano adduct, were observed.[9] However, in reversed micelle systems, no spectral change was observed, even after 2 hours, suggesting that less rearrangement of the 4-cyano adduct to the 6- or 2-cyano adduct occurs. Since $[CN^-]^i$ was sufficiently higher than $[S^+]^i$, Reaction 1 was expected to proceed with a pseudo first order in the earlier stage of the reaction. To examine this expectation, we traced the reaction in the plot of log ($OD^f_{340}-OD_{340}$) vs. time, where OD_{340} is the measured optical density at 340 nm and where OD^f_{340} denotes the value of OD_{340}, when the reaction was estimated to be at its final state. As may be seen in Fig. 3b, all the plots were linear with a correlation

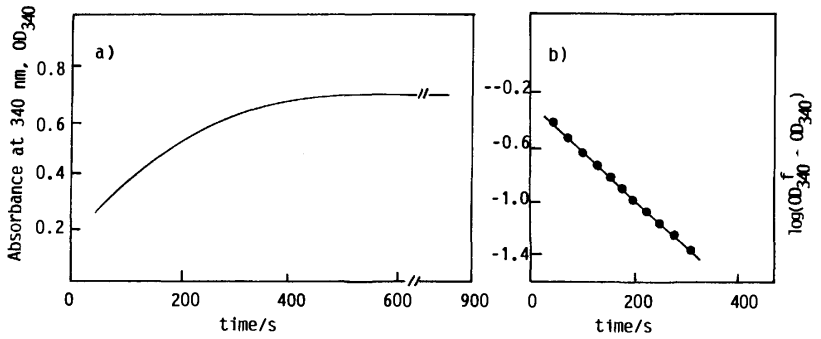

Fig. 3. Determination of first-order rate constants for the addition reaction. a) Absorption change at 340 nm at time; b) Plots of log (OD^{f}_{340}—OD_{340}) against time.

coefficient of 0.998 or over. Therefore, Reaction 1 in this work might be analyzed, at least mathematically, according to a pseudo first order rate equation with respect to the S^+ ion. The rate constant, k_{ob}, can be given as the negative slope of the above-mentioned plot.

The reversibility of Reaction 1 was examined as follows. When the reaction was considered to be practically completed after 30 min, we added a small amount of 1 M acetic acid and found that the absorbance at 265 nm increased according to the decrease in $[CN^-]$. Also, we found that the absorbance at 340 nm increased when we added NaCN. From the above results, we could conclude that the reaction is reversible. Therefore, the effect of the backward reaction on k_{ob} was considered. According to Lindquist and Cordes,[9] who worked on the reversible addition reaction of the CN^- ion to the 4-position of the *N*-methyl-3-carbamoylpyridinium ion in the aqueous micelle systems, we have:

$$k_2 = k_{ob}/([CN^-] + K^{-1}), \quad (2)$$

where K is the equilibrium constant of Reaction 1 and can be given by Eq. 3 in terms of the equilibrium concentrations of the P, CN^-, and S^+ ions, which are written as $[P]^{eq}$, $[CN^-]^{eq}$, and $[S^+]^{eq}$ respectively.

$$K = [P]^{eq}/([CN^-]^{eq}\cdot[S^+]^{eq}) \quad (3)$$

Here, the quantities, k_2, k_{ob}, and K must be the apparent ones, because these values were determined on the basis of the concentrations of the reacting species, which were evaluated over the total volume of the system, while the systems in this work are heterogeneous from the microscopical point of view and so the chemical species would be unevenly distributed or localized.

When $[CN^-]^i$ is sufficiently higher than $[S^+]^i$, the value of $[CN^-]^{eq}$ in Eq. 3 can be approximately substituted by a constant, $[CN^-]^i$. The ratio of $[P]^{eq}$ to $[S^-]^{eq}$ is approximately equal to the ratio, $OD^{f}_{340}/(\varepsilon_{340}\cdot[S^+]^i - OD^{f}_{340})$, at the reaction equlibrium. The symbol ε_{340} represents the molar extinction coefficient of P at 340 nm. For the value of OD_{340} at the reaction equilibrium, we adopted the value of OD^{f}_{340}. The value of ε_{340}, which is considered to be constant through each measurement, was determined following the usual procedure from the relationship between the absorbance of P at 340 nm and that of the S^+ ion at 265 nm in the course of the reaction, where the isosbestic point was always observed. This also indicates that Reaction 1 proceeds stoichiometrically in reversed micelles, while the succeeding reaction scarcely proceeds at all, reflecting the formation of the 2- or 6-cyano adduct.

Equation 3 reduced to Eq. 4 for the experimental determination of K:

$$K = OD^{f}_{340}/(\varepsilon_{340}\cdot[S^+]^i - OD^{f}_{340})[CN^-]^i \quad (4)$$

Then, we estimated the value of k_2 for each course of reaction, according to Eq. 2. As k_{ob} and $[CN^-]$, we adopted, respectively, the value of k_{ob} in the earlier stage of reaction and the value of $[CN^-]^i$.

We estimated the values of k_2 and K in the reversed micelle systems under the initial conditions that the concentrations of the surfactant and the CN^- ion were 0.2 M and 5×10^{-3} M respectively. The ratio of the water to the surfactant, R, was varied from less than unity to nearly ten. We show the plots of k_2 and K vs. R in Figs. 4 and 5. It was found that the formation of P is greatly favored in the reversed micelles, especially with smaller R values, compared with the reaction in pure water, where k_2 and K are estimated to be 0.016 $M^{-1}s^{-1}$ and 0.238 M^{-1} respectively.[9] In the reversed micelle systems with HTAB or AOT as the surfactant, the value of k_2 reached a thousand times or a hundred times, respectively, as much as the value in pure water, while a several or ten thousand-fold increase in K was estimated at the maximum. However, the values of k_2 and K both decreased with

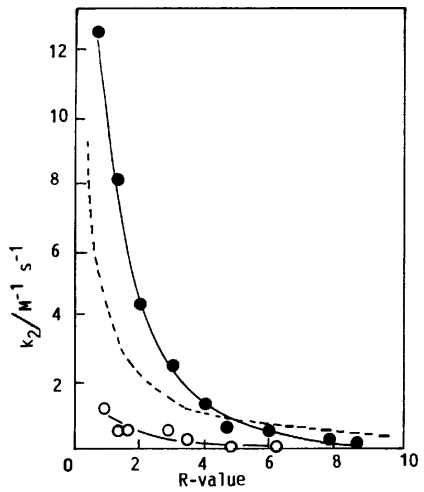

Fig. 4. Second-order rate constants, k_2, for the addition reaction in reversed micelles as a function of R-value at 25 °C. ●, 0.2 M HTAB; ○, 0.2 M AOT; broken line, a theoretical plot which took account of the localization effect of reactants.

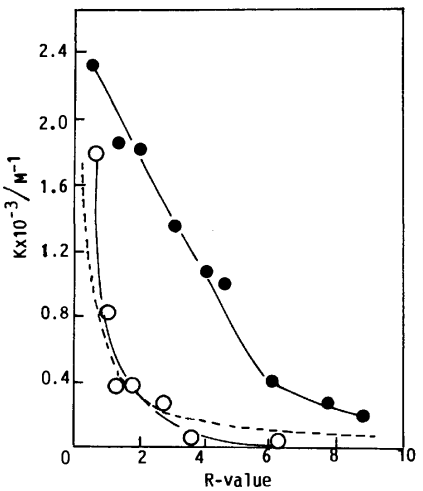

Fig. 5. Equilibrium constants, K, for the addition reaction in reversed micelles as a function of R-value at 25 °C. ●, 0.2 M HTAB; ○, 0.2 M AOT; broken line, a theoretical plot which took account of the localization effect of reactants.

the increase in R, as is seen in Figs. 4 and 5. The inconstancy of k_2 and K may be interpreted as reflecting the heterogeneity of the reversed micelle systems and the nature of the microenvironment surrounding each chemical species concerned.

Location of the Addition Reaction in the Reversed Micelle Systems. From the thermodynamic or macroscopic point of view, the presence of micelle yields no new phase. However, in order to elucidate the nature of any reaction concerned with the micelle, we should discuss the reaction from the microscopic point of view, which divides the reaction system into a number of subphases. For Reaction 1, therefore, we divided each reversed micelle system into two subphases, i.e.,

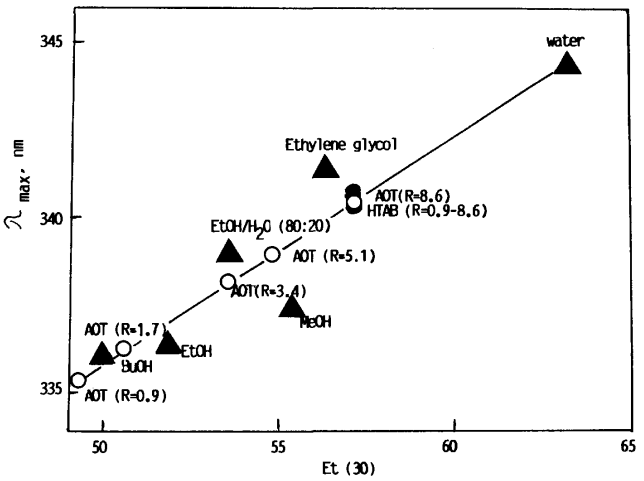

Fig. 6. Absorption maxima of 4-cyano-1,4-dihydro-*N*-methylnicotinamide, P, in several solvents as a function of the Dimroth's solvent-polarity parameter, Et(30). ▲, various solvents; ●, 0.2 M HTAB; ○, 0.2 M AOT.

the bulk phase and a pseudophase in colloidal dispersion. The former phase consists of an organic medium and various solutes, while the latter one, hereafter called the "micellar phase", consists mainly of a surfactant, water, and solutes. A small amount of a surfactant is dissolved in the bulk phase, with its concentration at cmc. The micellar phase will be subdivided into the outer shell, which mainly consists of the surfactant, and the water pool. In the detailed discussion, the water will be distinguished between that bound to the ionic heads of the surfactants at the inner surface of the micelle and the other water which constitutes the water pool.[10] Here, we will call the former the "interface zone", and the latter, the "center zone".

In the distribution measurements of S, the concentration ratio of the S^+ ion in chloroform to water was found to be less than 0.05. The ratio for the CN^- ion may be expected to be much less than that for the S^+ ion, in view of the more polar structure of the CN^- ion than the S^+ ion. Therefore, the greater parts of the reactants, the S^+ and CN^- ions, were estimated to be present preferably in the micellar phase, especially in the water pool.

To estimate the location of P in reversed micelle systems, we applied to these systems the relation between the value of λ_{max} and the polarity of the surrounding medium adjacent to P. First, Reaction 1 was carried out in various solvents, and the value of the λ_{max} of P was measured. The value in each solvent was then plotted against the Dimroth's solvent polarity parameter, Et(30), as is shown by the solid triangles in Fig. 6.[11] From the values of the λ_{max} of P in various HTAB or AOT reversed micelle systems, as may be seen in Fig. 2, we could read the corresponding values of Et(30) of the reversed micelle systems on the

calibration line in Fig. 6.

Since the reversed micelle system is microscopically heterogeneous, the Et(30) value of a reversed micelle system is considered to be the average of the Et(30) values for the microenvironments. Therefore, the estimated value of Et(30) from the measurement of λ_{max} would approximately disclose the average location of P.

In the HTAB reversed micelle systems with various R values, it was found that the λ_{max} of P or Et(30) remains nearly constant halfway between water and MeOH (Figs. 2 and 6). In other words, the environment around P is like the MeOH–water mixture in terms of the polarity. Concerning the polarity of the MeOH–water mixture, we show the plots of the λ_{max} of P in the mixture against its composition in Fig. 7. According to Sunamoto et al.,[5b] the micropolarity of the water pool in HTAB reversed micelles with smaller values of R can be estimated to be near to that of MeOH from the fluorescence maximum of *O*-methylpyranine. Therefore, it seems that it can be roughly concluded that the P in the HTAB reversed micelle systems is in the water pool. The question is where P exists inside the water pool with respect to its microscopic location. If P is dissolved homogeneously throughout in the water pool, the value of the λ_{max} of P in the HTAB reversed micelle systems would vary between those in MeOH and water with the variation in R, since the nature of the water pool must approach that of the bulk water with the increase in R, while approaching that of MeOH with the decrease in R. The results shown in Figs. 2 and 6 deviate the homogeneous distribution of P in the water pool. Also, it can be deduced, from an argument similar to that above, that P is not concentrated in the center zone of the water pool. The true situation is possibly some kind of localized concentration of P near the interface zone of the water pool, and the interface zone is not much affected by the variation in R. The penetration of P into the palisade layer of the surfactant might be a result of the electrically neutral and hydrophobic nature of P. The nearly constant value of λ_{max} has previously been explained. The fact that the value of λ_{max} of P in the HTAB reversed micelles is not the same as that in MeOH, but lies halfway between those in MeOH and water, suggests that the value of λ_{max} depends not only on the polarity of the medium, but also on the specific interaction between solute and medium. Thus, the result on *O*-methylpyranine seems to differ somewhat from the result on P in this work.

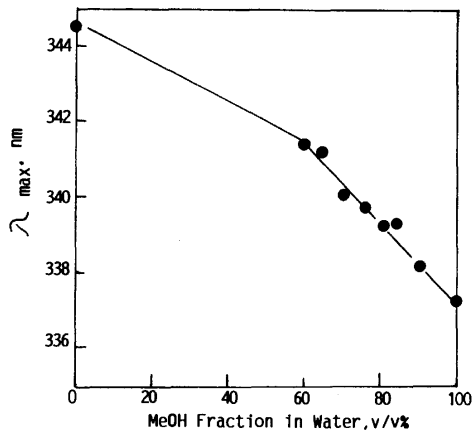

Fig. 7. The wavelength of maximum absorption, λ_{max}, of 4-cyano-1,4-dihydro-*N*-methylnicotinamide, P, in mixed solvents of MeOH–H_2O.

In the AOT reversed micelle systems, the dependency of λ_{max} or Et(30) on R was remarkable in comparison with the HTAB reversed micelle systems. Also, it was found that the λ_{max} in the AOT systems is always shorter than in the HTAB systems and that the microenvironment of P in the AOT systems is lower in polarity than that in the HTAB systems. Sunamoto et al.[5b] estimated that the polarity of water pools in the AOT reversed micelles is intermediate between those of MeOH and water, while that in the HTAB reversed systems is nearly that of MeOH, as has already been mentioned. In other words, the polarity of the water pools themselves in the AOT reversed micelles is higher than that in the HTAB reversed micelles; this is contrary to the case of the microenvironment of P. From the above facts, it can be deduced that the greater of the P in the AOT reversed systems is much more concentrated in the interface zone of the water pool, and is surrounded by a more nonpolar or hydrophobic environment, than in the HTAB reversed systems. That is, the P in an AOT micelle might exist mainly in or near the palisade layer of the surfactant, with its polar head turned toward the center of the water pool. The remarkable variation in the λ_{max} of P with the variation of R suggests a gradual change in the surfactant shell of the AOT micelle, which forms entirely, or at least in large part, of the microenvironment of P. It seems most likely that an increase or decrease in R is accompanied by an increase or decrease of the micellar size, which causes the molecular packing of the surfactant shell to tighten or loosen. In the micelle of a smaller size, which is supposed to have a more loosely packed shell, P must penetrate more deeply inside the surfactant shell or the palisade layer of the micelle.

From the location of the reaction species, the main fields of the forward and backward processes in Reaction 1 were identified approximately as follows. The forward reaction, in which S^+ and CN^- ions are the principal species, proceeds in the interior of the water pool, while the backward one, with the P proceeds in the outer sphere of the water pool. The discrepancy in site between the two opposing reactions might require some modification of Eqs. 2 and 3, which need the same sites for both reactions. Therefore, the following discussion of the values of k_2 and K,

which are based on Eqs. 2 and 3, might be regarded as rather qualitative and might have to be modified by taking into account, e.g., the transport or the diffusion process of the reaction species between the different sites.

Factors Responsible for the Enhancement of the Addition Reaction in Reversed Micelle Systems. Three kinds of effects may be proposed for interpreting the enhancement of the addition reaction in the reversed micelle systems as compared to that in the aqueous systems. The first is the local concentration of reaction species in the water pool rather than in the whole volume of each system. When the reaction is a bimolecular process, as it was in this work, the localization of the reaction species results in the enhancement of the reaction rate and equilibrium (k_2 and K) by the factor of the effective concentration to nominal, e.g., by a multiplication factor of about 300 and 40 times for R at 1 and 10 respectively.

The actual enhancement deviated more or less from the expectation; we took account of the concentration effect and adopted the values obtained by Lindquist and Cordes[9] for the reaction in pure water as the basis of comparison. The expected values are shown in Figs. 4 and 5. The deviation differed in degree between the results in the HTAB and AOT systems. Since S^+ and CN^- are presumed to be dissolved in the water pool, the difference in the reaction constants between the HTAB and AOT systems can be partly attributed to the difference in nature between the water pools of the two systems. As has already been established,[5b] the micropolarity of the water pools at a small water content is near to that of MeOH for the HTAB reversed micelles and intermediate between those of MeOH and water for the AOT reversed micelles. The lower micropolarity of the water pools seems to contribute to the enhancement of the reaction in the HTAB systems. Although Lamborg et al.[16] have reported that the addition of a 1-methylpyridinium compound with the cyanide ion was strongly dependent upon the dielectric constant of the solvent, it has not yet been studied quantitatively. Therefore, in order to examine the relation between the polarity of a medium and the reactivity, we measured the values of k_2 and K of the addition reaction in the mixed solvents of MeOH and water, as is shown in Figs. 8 and 9. As the fraction of MeOH in the solvent, i.e., the polarity of the medium, approaches that of pure MeOH, the values of k_2 and K were found to increase with the acceleration. Thus, the significantly high values of k_2 and K in the HTAB systems at lower R were elucidated, at least quantitatively. For the AOT systems, the effect of the micropolarity of the water pools on the addition reaction seems to be negligible, judging from the results in Figs. 8 and 9, which shar the polarity halfway between MeOH and water.

The third effect is connected with the electric nature

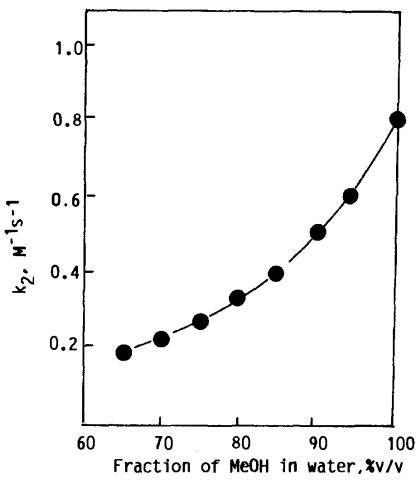

Fig. 8. Second-order rate constants, k_2, for the addition reaction in MeOH–H_2O mixed solvents at 25 °C.

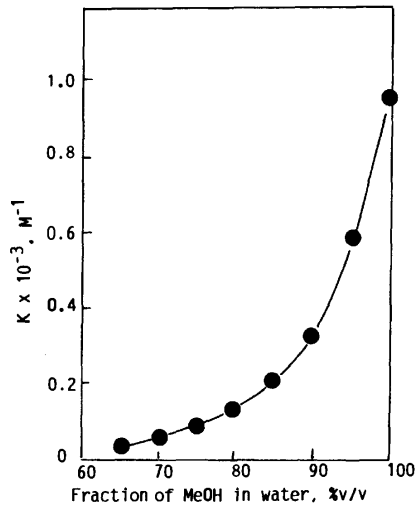

Fig. 9. Equilibrium constants, K, for the addition reaction in MeOH–H_2O mixed solvents at 25 °C.

of the surfactant and the reactant ions. No doubt, the electrostatic attraction and/or repulsion between various ions plays a principal role in determining the spatial distribution of the reactant ions in the water pools and will affect the addition reaction. It can be supposed in each HTAB reversed micelle that the S^+ and CN^- ions are concentrated in the center zone and near the interface zone of the water pool due to the electrostatic repulsion and to the attraction with the cationic head of the surfactant respectively. The above situation might serve to attenuate the first and second kinds of effects, i.e., localized concentration of the reactants and the lowering of the polarity of microenvironment, on the reaction in the reversed micelle systems with relatively large R values. However, with a decrease in R, the concentration of CN^- ions will soon become saturated in the interface zone and increase throughout the region of the water pool, since [CN^-] in this work

is set relatively high (5×10^{-3} M). Then, the above-mentioned attenuating effect will disappear. With a very small R, the repulsion between the S^+ ion and the cationic head might promote the forward reaction, that is, a charge neutralization, and result in a significant increase in k_2 and K.

Similarly to the case of the HTAB systems, but with the inverse type of ionic distribution, it can be supposed in each AOT micelle that the CN^- and S^+ ions have a tendency to concentrate in the center zone and near the interface zone of the water pool respectively. At higher R values, the divided concentrations of both reactant ions would contribute to the values of k_2 and K in the AOT reversed micelle systems, much like those in the HTAB systems. At very small R values, the situation must be the same as between both kinds of reversed micelle systems; i.e., there is a significant increase in k_2 and K. However, in the intermediate region of R, there are some differences between the two reversed micelle systems in the distribution patterns of the ions in the water pools. In other words, the saturation of CN^- ions in the center zone of the water pool in the AOT systems may be expected to occur somewhat later than the saturation in the interface zones of the HTAB systems. The difference in porofile between the plots for the HTAB and AOT systems, as is seen in Figs. 4 and 5, is considered to be due to the differences in R for the saturation of CN^- ions between the respectively preferred zones.

The Stability of the 4-Cyano Adduct in Reversed Micelles. Lindquist and Cordes[9] reported that the peak near 345 nm slowly decreased in magnitude, while, at the same time, a new absorption peak appeared near 305 nm together with increased absorption near 265 nm, they suggested that the spectral shift might be a rearrangement of P to the 6- and 2-cyano adduct, as has already been described. Therefore, it was supposed that P is not stable thermodynamically in an aqueous medium.[9] It can be considered that the stability of P in MeOH is higher than in an aqueous medium, but such a spectral shift was observed in concentrated MeOH (95%) after 48 hours (Fig. 10). As the water fraction in the mixed solvents of MeOH–H_2O increased, a remarkable shift from 340 to 310 nm was observed. The 4-cyano adduct, P, formed in AOT reversed micelles was relatively stable, thus making it possible to estimate the equilibrium constant approximately, but a distinct spectral shift was observed after 2 hours (Fig. 10). It was supposed that AOT itself acts against the P as a base, resulting in the formation of nitrile.[14]

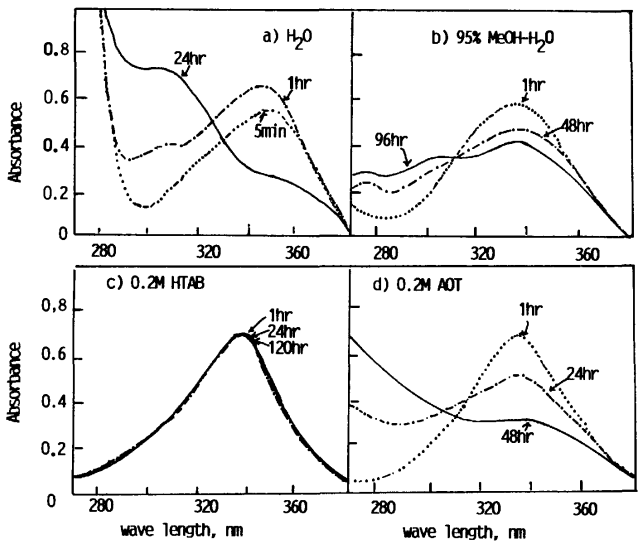

Fig. 10. Ultraviolet spectra for solutions containing initially *N*-methyl-3-carbamoylpyridinium chloride and sodium cyanide. a) H_2O; [S]=6.3×10^{-4} M, [NaCN]=5.0×10^{-1} M, b) 95%MeOH–H_2O, c) 0.2 M HTAB (R=1.0) and d) 0.2MAOT (R=1.0); [S]= 1.5×10^{-4} M, [NaCN]=5.0×10^{-3} M.

On the other hand, such a spectral shift was not observed in HTAB reversed micelles even after they had stood 5 days. It can thus be concluded that the P in HTAB reversed micelles is especially stable. This shows that the microenvironment surrounding the P in HTAB reversed micelles contributes to the stability of the P, most likely because of the specific nature of the water pool.

In conclusion, it became evident that the reaction field provided by HTAB reversed micelles not only enhanced the addition reaction, but also stabilized the P, which is thermodynamically unstable in an aqueous medium. This is in contrast to the AOT reversed micelle system. These results might be related to the postulate that a cationic charge, such as the lysine residue of alcohol dehydrogenase located very close to the bound NADH may protect the NADH from hydration decay.[15] Therefore, it is not too much to say that the HTAB reversed micelle systems provide a field advantageous for synthesizing the dihydro compounds, for the dihydro-compounds produced by the addition of the cyanide ion to pyridinium salt or isoquinolinium salt are usually less stable and can not easily be isolated.[12,17]

Also, it should be noted that reversed micelle systems can control the addition reaction by varying the water content, although they may be unfavorable for reactions at higher water contents.

Limitation of Absorbance Measurement by Using Photoacoustic Method

Masahide TERAZIMA* and Tohru AZUMI
Department of Chemistry, Faculty of Science, Tohoku University, Sendai 980
(Received March 3, 1989)

The solute dependence of the photoacoustic (PA) signal intensity has been examined. The results show that the PA signal intensity depends not only on the released energy, but also on the nature of the solute. This means that the absorbance of an unknown sample cannot be precisely measured by comparing the PA signal intensity with that of a standard solution containing a different solute.

Photothermal techniques, such as thermal lens (TL)[2,3] and photoacoustic (PA),[4-6] have been utilized for the sensitive detection of weak absorptions. In order to obtain absorptivity in a quantitative manner, the light energy absorbed by a solution should be obtained from the signal intensity. However, since the TL and PA signal intensities depend on the various physical properties of the solution (vide infra) and experimental conditions, it is extremely difficult, if not impossible, to determine the absorbed energy from the signal intensity. In view of this difficulty, one usually tries to estimate the absorbed energy by comparing the signal intensity with that of a standard sample of known absorbance.[4-15] This comparison method is based on the theoretical expectation[4-8] that, provided that the proper correction for the energy loss due to radiative emission and photochemical reaction is made, the signal intensity should be proportional only to the absorbed energy in the series of experimental data obtained with the same experimental setup. In particular, since the signal intensity of the sample is compared with that of the standard solution, which usually contains a different solute, the signal intensity should not depend on the nature of the solute if the released energy is identical.

Even though this comparison method is frequently used in both the PA and TL methods,[4-15] we found in a previous study that the absorbance of a sample cannot be precisely measured, at least by the TL method.[1] This result was based on the fact that the TL signal intensity depends not only on the releasing energy but also on the nature of the solute. Namely, the assumption which is essential for the capability of the quantitative measurement has been revealed to be invalid. We have suggested that the solute dependence of the TL signal comes from the vibrational mode dependence of the vibration to the translation energy transfer rate.[1]

As an extension of this TL experiment, we attempted in the present work to study the PA signal and its correlation with the TL signal by using a simultaneous PA and TL measuring system. As described in detail below, we found that the PA signal intensity also depends on the solute. This means that the PA signal intensity of a solution cannot be calibrated by using a standard sample solution containing a different solute.

Experimental

The apparatus of the TL experiment described previously[1] was modified so as to perform simultaneous measurements of both the TL and PA signals (Fig. 1). For the PA detector, a piezoelectric transducer (PZT) of a lead zirconate-lead titanate cylinder (Tohoku Kinzoku Co. N-6) poled axially was used. It was mounted inside a metal case, essentially the same as designed by Patel and Tam.[17] The transducer was directly attached to the wall of the square cell from the outside with a thin vacuum grease layer to facilitate acoustic coupling. The signal from the transducer was amplified by a wide-band preamplifier (PAR, Model 115) with a voltage gain of 10. The signal from the amplifier was fed into a transient digitizer (Iwatsu Co., DM901) and averaged by a microcomputer (NEC, PC-9801). For the excitation light source, a nitrogen laser (Molectron UV-24) was used. The laser power was 3 μJ/pulse. In the case of 400-nm excitation, a dye laser (Molectron, DLII-14P) pumped by the nitrogen laser was used for the light source. The laser beam, focused using a 20-cm focal-length lens, passed through the sample cell at the distance 5 mm from the PA detector. Since the PA signal intensity slightly depended on the volume of the sample in the cell, we use a fixed volume (3.5 cm^3) of the sample for the measurement.

Chemicals and purification procedures were the same as previously reported.[1] The concentrations of the sample solutions were adjusted so that the absorbance at 337.1 nm

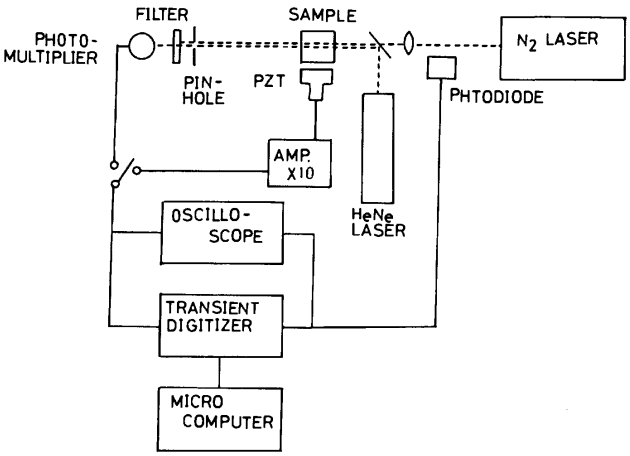

Fig. 1. Block diagram of the experimental setup for thermal lens and photoacoustic measurement in simultaneously.

was 0.1±0.01. Therefore, the concentration of each solution varied, depending on the molar extinction coefficient at 337.1 nm.

Method

If the assumptions described below are satisfied, the electronic signal from a PZT is given by[8,9]

$$I_{PA} = K\frac{v^2\beta}{C_P}(1 - 10^{-A})H, \quad (1)$$

where K is a constant that depends on the geometrical parameters as well as on the response properties of the PZT, but not on the nature of the solute. Further, C_p, β, A, and v denote the molar heat capacity at constant pressure, the thermal expansion coefficient, the absorbance of the sample, and acoustic velocity, respectively. The factor $(1-10^{-A})H$ represents the releasing energy from the sample as the radiationless transition. H is expressed by[1]

$$H = H_0\left(1 - \frac{E_s}{E_{ex}}\phi_f - \frac{\Delta H}{E_{ex}}\phi_{reac}\right), \quad (2)$$

where E_{ex}, E_s, and H_0 are the photon energy of the pulsed laser, the photon energy of the fluorescence, and the laser power which is used to excite the solute, respectively. Further, ϕ_f is the quantum yield of the fluorescence and ϕ_{reac} is a quantum yield of the photochemical reaction. The quantity ΔH is the enthalpy difference between the reactant and the product. For air-saturated samples, any radiative decay due to phosphorescence can be neglected.

The assumptions which were used to derive Eq. 1 are as follows:[8,9]

(a) A thin cylindrical excitation (week absorption of the sample),

(b) $w^2/D \gg t_a$, (3)

(c) $t_a \gg t_p$, (4)

and

(d) $t_a \gg t_{nr}$. (5)

Here t_p, t_{nr}, and t_a are the pulse length of the excitation laser, the relaxation time from the excited state, and an acoustic transit time to travel across the laser illuminated region in the sample, respectively. Further, D and w are the thermal diffusion coefficient and the laser spot size, respectively.

The PA signal intensity should be solute independent as long as Eq. 1 is valid, since Eq. 1 was derived from thermodynamic equations, in which there are no solute dependent factors. Previously, investigators have taken it for granted that Eq. 1 is valid for many molecules under real experimental conditions. Our goal in this study was to check whether or not Eq. 1 is valid under our experimental condition. We define the corrected signal intensity as

$$S_{PA} = I_{PA}/(1 - 10^{-A})H = K\frac{v^2\beta}{C_p}. \quad (6)$$

If the thermal properties (β, C_v, v) of a solution are essentially identical to those of the solvent, S_{PA} should not depend on the solutes as long as Eq. 1 is valid. We measured S_{PA} for many organic solutes in the same solvent (benzene).

The TL signal intensity (I_{TL}) and the corrected intensity (S_{TL}), defined previously,[1] are given here again for convenience:

$$I_{TL} = \frac{I(t=0) - I(t=\infty)}{I(t=0)} \quad (7)$$

and

$$S_{TL} = I_{TL}/(1 - 10^{-A})H, \quad (8)$$

where $I(t=0)$ and $I(t=\infty)$ are the intensity of the cw monitoring laser just after the solute is excited by the pulsed laser and that after the sufficiently long time compared with the heat diffusion time in the solution, respectively.

Results

A typical PA siganl is shown in Fig. 2. There is no detectable signal from the pure solvent; we therefore conclude that there is no signal from the wall of the cell or due to scattered light. The peak height of the first minimum in the PA signal is an arbitrary measure of the amplitude of the signal (I_{PA})(Fig. 2), because the first maximum peak is easily disturbed by the electric noise coming from the excitation laser. The relative I_{PA}

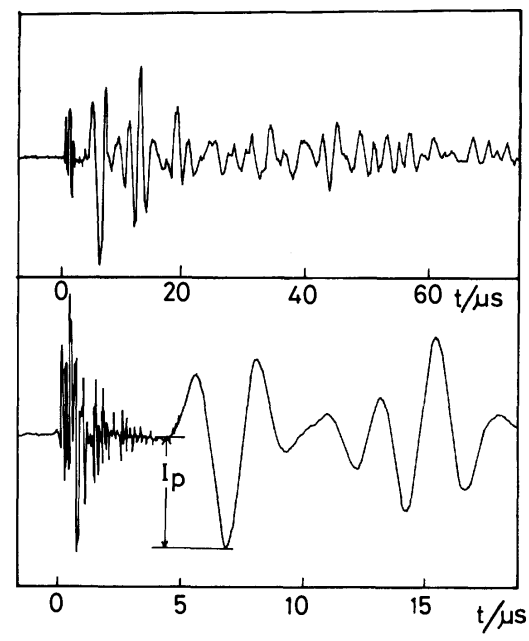

Fig. 2. Single pulse trace of the PA signal. The signal intensity (I_{PA}) which we measured is also represented.

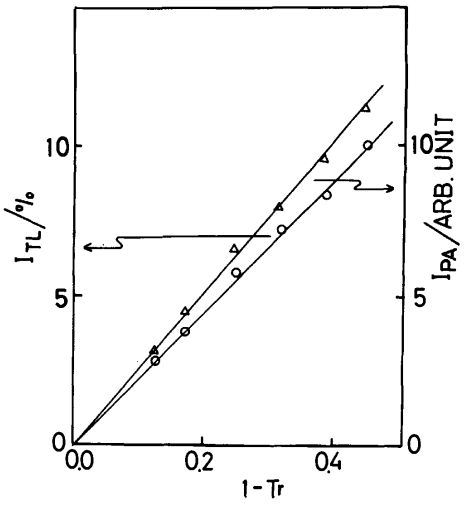

Fig. 3. Plot of the thermal lens and photoacoustic signal intensity vs. $(1-T_r)$, where T_r is the transmittance of the benzophenone in benzene at 337.1 nm.

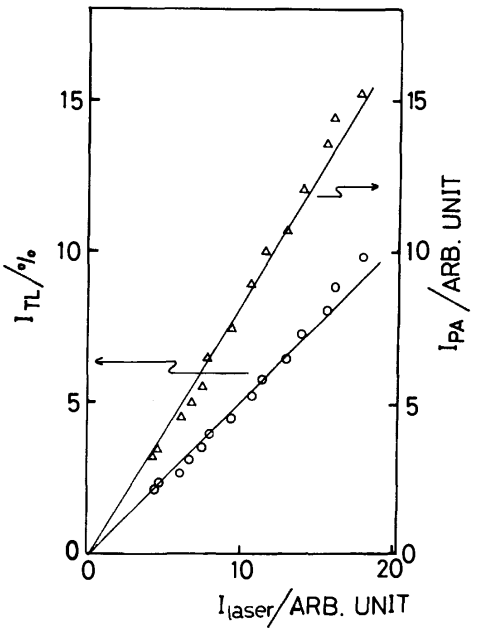

Fig. 4. Plot of the thermal lens and photoacoustic signal intensity vs. the excitation laser power for benzophenone in benzene.

values were reproducible within 5%.

First, we checked the linerity of our system for the PA and TL measurements. Figure 3 shows the signal intensity of PA and TL against $(1-10^{-A})$. The linear dependence of the PA and TL signal intensities on the laser power is shown in Fig. 4. Within the range of concentrations and laser powers which we used there was no saturation effect. These results rationalize the validity of Eq. 6.

Table 1 summarizes the relative PA (S^r_{PA}) and TL(S^r_{TL}) signal intensities observed for various solutes in benzene. The signal intensity of benzophenone is set to be 1.00; that is,

$$S^r_{PA} = S_{PA}(\text{sample})/S_{PA}(\text{benzophenone})$$

and

$$S^r_{TL} = S_{TL}(\text{sample})/S_{TL}(\text{benzophenone}).$$

The correction parameters for fluorescence and photochemical reactions are the same as those listed previously.[1)]

Table 1. The Corrected TL (S_{TL}) and PA (S_{PA}) Signal Intensity for Various Solutes in Benzene
S_{PA} and S_{TL} of benzophenone is set to be 1.00.

Solute	S_{PA}	S_{TL}

Discussion

The Validity of Eq. 1. According to Eq. 1, the PA signal intensity should be proportional to the releasing energy. Further, if the releasing energy, experimental configuration and thermal properties (β, v, C_p) are identical, the PA signal intensity should be identical. The results listed in Table 1 are, however, inconsistent with this prediction.

Before we doubt the validity of Eq. 1, we should check the solute dependence of the factors which affect the signal intensity. We will first check the thermal properties of the solutions. In dilute solutions, as in this case, the thermal properties of the solution are considered to be almost identical to those of the pure solvent. Actually, we have already confirmed that the thermal properties which affect the TL signal intensity (thermal diffusivity, thermal conductivity and dn/dT; where n and T denote the refractive index and temperature, respectively) are almost identical to those

Table 2. The PA Signal Intensity (I_{PA}) of Mixed Solutions to Examine the Solute Effect on the Thermal Properties of the Solvent
The excitation wavelength is 400.0 nm. I_{PA} of 9,10-dibromoanthracene (DBA) is set to be 1.00 as reference.

	I_{PA}
9,10-Dibromoanthracene (DBA)	1.00
DBA+anthracene	0.95
DBA+benzophenone	0.99
DBA+quinoxaline	0.95
DBA+stilbene	0.98

of the pure solvent.[1] Here, we examine whether the thermal properites which affect the PA signal (β, v, C_p) are similarly identical to those of a pure solvent.

The principle is as follows: If the thermal properties of a solution are different from those of a pure solvent upon adding a solute (solute A), the PA signal intensity which comes from another solute (solute B) with solute A should be different from that of solute B without solute A. We used 9,10-dibromoanthracene (DBA) as solute B. We choose benzophenone, stilbene, quinoxaline, and anthracence for solute A. A dye laser at 400 nm was used to excite only solute B, not solute A. Note that only DBA possesses an absorption band at 400 nm. We prepared two kinds of solutions. One solution contained only solute B, whose absorbance at 400 nm was adjusted to 0.1. The other solution contained solute B of the same concentration as solute A, whose absorbance at 337.1 nm was adjusted to 0.1, identical to the previous experiment (Table 1). If the PA signal intensity of the solution contained both A and B is different from that of the solution contained only solute B, it means that solute A changes the thermal properties of the solution from those of a pure solvent. The observed S_{PA}, summarized in Table 2, does not depend on whether or not solute A is contained within the experimental error. This result shows that the thermal properties which affect the PA signal intensity are almost identical to those of a pure solvent. Therefore, the solute dependence (Table 1) cannot be explained by the solute effect on the thermal properties of the solvent.

Other trivial factors, such as multiphoton and/or transient absorption and scattering processes, can be neglected under our conditions, as confirmed previously.[1]

The S_{TL} values listed in Table 1 are almost identical to the values reported in Ref. 1. In that paper, we conclude that the dissipation of thermal energy as pressure waves does not play an important role in the solute dependence of the TL signal intensity. If the thermal energy dissipation as pressure waves is the origin of the solute dependence of the TL signal, a solute which gives a small S_{TL} should give a large S_{PA}. However, such a negative correlation was not found, as shown in Fig. 5. This result supports the previous

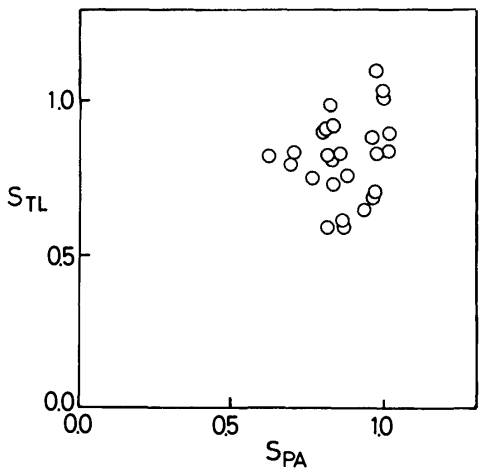

Fig. 5. Plot of the corrected TL (S_{TL}) vs. PA (S_{PA}) signal intensity for various solutions listed in Table 1.

conclusion.[1]

The Origin of the Solute Dependence. According to the above discussion, the solute dependence of S_{PA} means that Eq. 1 does not hold under our experimental conditions. In this section, we discuss the origin of the solute dependence by checking the assumptions on which Eq. 1 is based.

Under our experimental conditions, the first (a thin cylindrical excitation), the second (Eq. 3) and the third (Eq. 4) assumptions were considered to be adequate on the basis of parameters $w \approx 1$ mm, $D \approx 10^{-3}$ cm^2 s^{-1}, $t_a \approx 4 \times 10^{-7}$ s, and $t_p \approx 1 \times 10^{-8}$ s. Furthermore, these conditions should not depend on the nature of the solute, as considered in the previous section (Table 2). Therefore, the solute dependence is not due to a violation of these conditions. The factor t_{nr} of Eq. 5 represents the relaxation time of the energy transfer from the electronic energy of the solute to the translational energy of the solvent. If t_{nr} is longer than 500 ns, this quantity can be measured from the rise time of the TL signal and the adequacy of the fourth condition checked. Unfortunately, we found that the rise times of the TL signal of these solutions which we investigated are determined by the time constant of the TL signal (500 ns) in our experimental apparatus. We can therefore only say that t_{nr} is shorter than 500 ns. Although we cannot conclude the invalidity of the fourth condition exclusively, we may suggest that the remaining condition, i.e. the fourth condition (Eq. 5), could be the reason for the solute dependence; namely, the fourth condition does not hold for some solutes. The experimental support for this assumption is now in progress.

The observed solute dependence of the PA signal intensity means that the quantitative measurement by the PA method using a reference solute is not precious. In order to measure the absorbance precisely, the solute of the reference sample should be the same

solute as the sample, or the solute-dependent factor should be corrected before the PA signal intensity is compared. For practical purposes, we suggest that the signal intensity of the PA signal should be expressed empirically be

$$I_{PA} = K' \frac{v^2 \beta}{C_p} (1 - 10^{-A})H, \quad (9)$$

where K' depends on the nature of the solute.

Conclusion

Our experimental results show that not only the TL signal but also the PA signal intensity depends on the solute, even if the releasing energy and the experimental configuration are identical. This fact means that absorbance measurements by the TL and PA method are not precious unless the signal intensity is calibrated using the same solute.

The authors are grateful to Mr. Makoto Kobayashi and Miss. Michiko Horiguchi for technical assistance.

Studies of Collectors. XI.[1] The Preparation of Cyclic Polyamine-Type Surfactants and Application to Ion-Flotation Collectors

Kimiho YAMADA, Yoshifumi KOIDE,* Hiroshi YAMANOKUCHI, Masaki OHMURA, and Hideto SHOSENJI

Department of Applied Chemistry, Faculty of Engineering, Kumamoto University, Kurokami, Kumamoto 860

(Received April 3, 1989)

Inclusion-type surfactants bearing cyclic dioxopolyamine ($R_n$doN$_4$, $R_n$doN$_5$) or cyclic polyamine ($R_{12}N_4$, 2.4R-N$_6$, Ls6.8N$_6$) were prepared and then investigated as ion-flotation collectors. The surface tensions of the surfactant solutions were 30—40 dyn cm^{-1}. The molecular areas of the surfactants in the aqueous solutions, as calculated from the Gibbs adsorption isotherm, were discussed in connection with the structures of the $R_n$doN$_4$ and its Cu^{2+} complex. Heavy metal ions were floated with $R_n$doN$_4$ or $R_n$doN$_5$. The highest floatabilities of Cu^{2+} and Ni^{2+} were in the pH range of 10—12, while that of Fe^{3+} was in the pH range of 6—10. Furthermore, similar characteristics of the metal floatabilities were obtained by using $R_{12}N_4$ and alkylated linear polyamine. The flotation using $R_n$doN$_4$ or $R_n$doN$_5$ was done by the complex formation, but that using $R_{12}N_4$ or 2.4R-N$_6$ was done by the neutralization of the complex with OH^-. The selectivities in pH 4—8 were $Cu^{2+}>Ni^{2+}>Fe^{3+}>Zn^{2+}$ when $R_n$doN$_4$ was used and $Fe^{3+}>Cu^{2+}>Ni^{2+}>Zn^{2+}$ when $R_n$doN$_5$ was used.

Inclusion compounds, such as cyclodextrin[2] and crown ether, have recently been reported as new functional materials.[3] These compounds form stable complexes, and the complex formations are highly selective. Some amphiphilic crown ethers have been prepared, and their alkali metal complexes have been examined as phase-transfer catalysts.[4]

Moreover, specific chelating surfactants have been applied to ion-flotation collectors.[5] High selectivity is usually a matter of great importance in ion-flotation. Therefore, the inclusion compounds capable of capturing such heavy metal ions as cyclic polyamine, particularly the dianion-type ligand of cyclic dioxopolyamine, which forms an uncharged complex with Cu^{2+} and Ni^{2+},[6] are very attractive. The capturing ability becomes more effective upon the introduction of a long alkyl group, because the ligand is densely adsorbed at the gas-liquid interface of the bubble; thus, the heavy metal ions must be highly concentrated on the ligand-condensed foams. In this study, the long-alkyl-substituted cyclic dioxopolyamines and cyclic polyamines are prepared, and their surface activities and their characteristics as ion-flotation collectors are investigated.

N-Alkylethylenediamine and *N*-dodecyldiethylenetriamine have previously been used as ion-flotation collectors.[7] However, ion-flotation collectors of cyclic polyamine-type surfactants have not yet been investigated, except for 1,4,8,11-tetraazacyclotetradecane, used as a carrier in the transportation.[6,8]

Experimental

Materials. Long-alkyl-substituted cyclic dioxopolyamines were prepared by reference to the method described in the literature.[9] The condensation of dimethyl alkylmalonate[10] with 3,7-diazanonane-1,9-diamine[11] gave the cyclic dioxohexamine derivatives (R_{12}doN$_4$, R_{18}doN$_4$), while the condensation with 3,6,10-triazaundecane-1,11-diamine gave the cyclic dioxopentamine derivatives (R_{12}doN$_5$, R_{18}doN$_5$). The preparation of the cyclic dioxohexamine bearing a dodecyl group, R_{12}doN$_4$, was done as follows: 0.1 mol of 3,7-diazanonane-1,9-diamine and 0.1 mol of dimethyl dodecylmalonate were dissolved in 100 cm^3 of methanol, after which the mixture was refluxed for 5 d. The resulting white precipitates, R_{12}doN$_4$, was purified by recrystallization from acetone. Yield, 30%. R_{18}doN$_4$ and $R_n$doN$_5$ were prepared by a similar procedure; the R_{12}doN$_5$ and R_{18}doN$_5$ were deposited out by adding hydrochloric acid, and then the precipitate was recrystallized from 50% methanol. Yields: R_{18}doN$_4$, 28%; R_{12}doN$_5$, 25%; R_{18}doN$_5$, 35%. Their structures were confirmed by the IR spectra (Shimadzu IR-408), the ^{1}H NMR spectra (JEOL JMN-MH-100), and elementary analyses (Yanako CHN Corder MT-3). Mp: R_{12}doN$_4$ 85—88 °C, R_{18}doN$_4$ 99—102 °C, R_{12}doN$_5$·3HCl 184—188 °C, R_{18}doN$_5$·3HCl 235—240 °C. IR (KBr): ν_{NH} 3300, ν_{CH} 2900, ν_{CO} 1650, δ_{NH} 1540, δ_{CH} 1460 cm^{-1}. ^{1}H NMR: $R_n$doN$_4$ in $CDCl_3$ δ=0.9 (3H, t, CH_3-CC-), 1.3 (methylene in alkane), 1.8 (4H, -CCH$_2$C-, -CCH$_2$C<), 2.7 (8H, -CCH$_2$NCH$_2$C-), 3.2—3.4 {5H, -COCH(C-)CO-, -CONCH$_2$C-}; $R_n$doN$_5$·3HCl in D_2O δ=0.8 (3H, t, CH_3CC-), 1.3 (methylene in alkane), 1.8 (2H, -CCH$_2$C<), 3.0 {H, -COCH(C-)CO-}, 3.4 (4H, -CONCH$_2$C-), 3.5—3.6 (12H, -CCH$_2$N$^+$CH$_2$C-). R_{12}doN$_4$ Found: C, 63.89; H, 10.70; N, 13.15%; Calcd for $C_{22}H_{44}O_2N_4\cdot 0.9H_2O$: C, 63.89; H, 11.18; N, 13.54%. R_{18}doN$_4$ Found: C, 65.85; H, 11.32; N, 11.08%; Calcd for $C_{28}H_{56}N_4O_2\cdot 1.7H_2O$: C, 65.74; H, 11.71; N, 10.96%. R_{12}doN$_5$·3HCl Found: C, 50.82; H, 9.35; N, 12.28%; Calcd for $C_{23}H_{47}O_2N_5\cdot 3HCl\cdot 0.5H_2O$: C, 50.82; H, 9.45; N, 12.88%. R_{18}doN$_5$·3HCl Found: C, 56.13; H, 9.84; N, 11.04%; Calcd for $C_{29}H_{53}N_5O_2\cdot 3HCl$: C, 56.79; H, 9.22; N, 11.42%.

Cyclic tetramine bearing a dodecyl group, $R_{12}N_4$, was prepared from the R_{12}doN$_4$. The R_{12}doN$_4$ was reduced with a large excess of a reductant, B_2H_6, in refluxing tetrahydrofuran for 24 h. After the treatment with hydrochloric acid, the salts ($R_{12}N_4\cdot 4HCl$) were recrystallized from 80% methanol. Yield, 25%. $R_{12}N_4\cdot 4HCl$ Mp: 218—221 °C. IR (KBr): ν_{NH} 3300, ν_{CH} 2900, δ_{NH} 1610, δ_{CH} 1450, ν_{CN} 1050—1030 cm^{-1}. ^{1}H NMR (CF_3COOH): δ=0.9 (3H, t, CH_3CC-), 1.3—1.9 (methylene and methylidyne in alkane), 3.6—3.9 (16H,

$-CCH_2N^+CH_2C-$). $R_{12}N_4$ Found: C, 51.54; H, 9.86; N, 10.11%; Calcd for $C_{22}H_{48}N_4 \cdot 4HCl$: C, 51.32; H, 10.20; N, 10.89%.

Cyclic hexamine, [18]aneN$_6$, was prepared according to the procedure described in the literature.[12,13] [18]aneN$_6$ Found: C, 28.55; H, 7.61; N, 16.44%; Calcd for $C_{12}H_{30}N_6 \cdot 6HCl \cdot 1.5H_2O$: C, 28.55; H, 7.80; N, 16.64%. The [18]aneN$_6$ bearing 2.4 mol of the dodecanoyl groups, 2.4R-N$_6$, was obtained by the treatment of [18]aneN$_6$ with a 2.8-fold mol portion of dodecanoyl chloride. The number of the side chain was determined by the ratios based on the ^{1}H NMR spectra and the elementary analyses. ^{1}H NMR ($CDCl_3$): δ=0.9 (3H, t, CH_3CC-), 1.2 (methylene in alkane), 2.7—3.4 (24H, $-NCH_2CH_2N-$). 2.4R-N$_6$ Found: C, 67.57; H, 11.31; N, 11.44%; Calcd for $C_{40.8}H_{82.8}N_6O_{2.47} \cdot 0.8HCl$: C, 67.58; H, 11.62; N, 11.59%.

A telomer bearing 6.8 mol of [18]aneN$_6$, Ls6.8N$_6$, was derived from an acrylic acid-type telomer (LsnAc). The LsnAc was prepared by the radical telomerization of acrylic acid by a procedure similar to that described previously;[14] it was refined by reprecipitations with hexane after having been dissolved in ether, after which the insoluble telomer in the ether was filtered off. The conditions of telomerization are shown in Table 1. The molar ratios of 1-dodecanethiol to acrylic acid (β) are correlated to the polymerization degrees (Pn), because the chain transfer of the growing radical to 1-dodecanethiol is affected by the β. The Pn of the telomers were: $Pn^{-1}=0.71\times\beta-0.018$ (insoluble in ether); $Pn^{-1}=0.71\times\beta+0.090$ (soluble in ether). The structures of the telomers were determined by IR, ^{1}H NMR, and elementary analyses. An example (Ls8.5Ac) is as follows; IR (KBr): ν_{CH} 2900, ν_{CO} 1700 cm^{-1}; ^{1}H NMR{DCON(CD_3)$_2$}: δ=0.9 (3H, t, CH_3CC-), 1.3 (methylene in alkane), 10 (8.5H, -COOH); Ls8.5Ac Found: C, 54.9; H, 7.58%; Calcd for $C_{12}H_{25}S(CH_2CHCOOH)_{8.5}H$: C, 55.26; H, 7.43%. Then, the carboxyl groups of Ls8.5Ac were converted into chloroformyl groups by treatment with an excess of thionyl chloride.[15] The conversion was confirmed by IR (KBr) and ^{1}H NMR spectroscopy. The ν_{CO} frequencies, based on the carboxyl group (1700 cm^{-1}), were shifted to high ν_{CO} frequencies based on the chloroformyl group (1750—1800 cm^{-1}), and the proton signal of the carboxyl group (δ=10) disappeared. The telomer bearing 8.5 mol of chloroformyl groups was treated with an amount of [18]aneN$_6$ equimolar to the unit chloroformyl group in a refluxing toluene solution. After the toluene has been evaporated, the residue was washed with cold water and then acetone. The structure of the telomer bearing 6.8 mol of [18]aneN$_6$, Ls6.8N$_6$1.7Ac, was confirmed by IR, ^{1}H NMR, and elementary analyses. IR (KBr): ν_{CO} 1630 cm^{-1}; ^{1}H NMR(D_2O): δ=0.9 (3H, t, CH_3CC-), 1.2 (methylene in alkane), 3.8 (methylene in [18]aneN$_6$), the ratio of [18]aneN$_6$ to the dodecyl group, as determined by the peak areas, was 6.8; Ls6.8N$_6$1.7Ac Found N/C ratio(%/%)=0.42: Calcd for $C_{12}H_{25}S(CH_2CHCOC_{12}H_{29}N_6)_{6.8}(CH_2CHCOOH)_{1.7}H \cdot 5HCl$ N/C(%/%)=0.40.

The abbreviations of these cyclic polyamine-type surfactants are shown in Fig. 1.

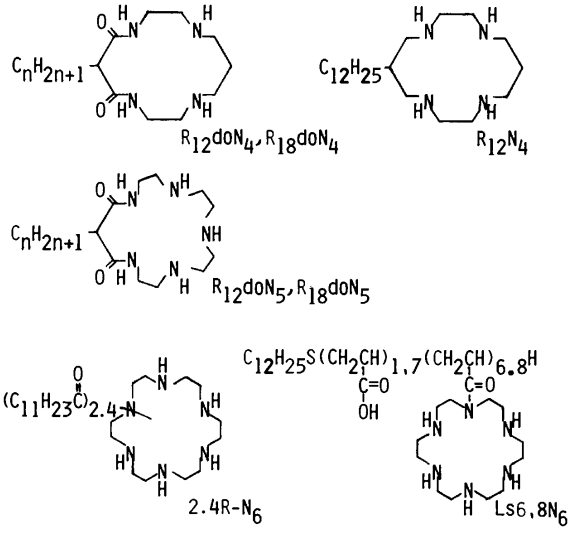

Fig. 1. The structures and the abbreviations.

a) Acrylic acid, 0.4 mol; LSH: 1-Dodecanethiol, β=LSH/(acrylic acid); 2,2′-azobisisobutyronitrile, 0.289 g; ethanol, 300 cm^3. Temp: 78 °C, time: 3 h. b) Sol: Telomer soluble in ether, Insol: telomer insoluble in ether. Pn: Polymerization degree.

Apparatus and Procedures. The flotation apparatus was the same as that previously reported.[5] The cyclic polyamine-type surfactant was added to 500 cm^3 of a metal solution (Cu^{2+}, Ni^{2+}, Fe^{3+}, Zn^{2+}, Hg^{2+}) in a flotation vessel, and then air was introduced into the solution through a sintered-glass disk (No. 4) at the bottom of the vessel at the rate of 30—40 cm^3 min^{-1} for 20 min. The floatabilities of the metal ions were calculated using the following formula:

$$F(\%) = \frac{a_0 - a_1}{a_0} \times 100$$

where a_0 and a_1 denote the initial and final metal concentrations respectively.

Results and Discussion

Surface Activities of R_ndoN_4. The synthesized compounds bear a hydrophobic long alkyl group and a hydrophilic polyamine residue, so the surface activities were investigated. The surface tension of the $R_{12}doN_4$ solution, as measured by a Wilhelmy (Shimadzu ST-1) surface tension balance, is shown in Fig. 2 (1 dyn=1×10^{-5} N). The lowering of the surface tension was more at pH 10 or in the presence of Cu^{2+}, as compared with that at pH 4. The lowering ceased in about 10 h, and the value become nearly constant. Therefore, the following measurements were carried out until the surface tension became constant (longer than 10 h).

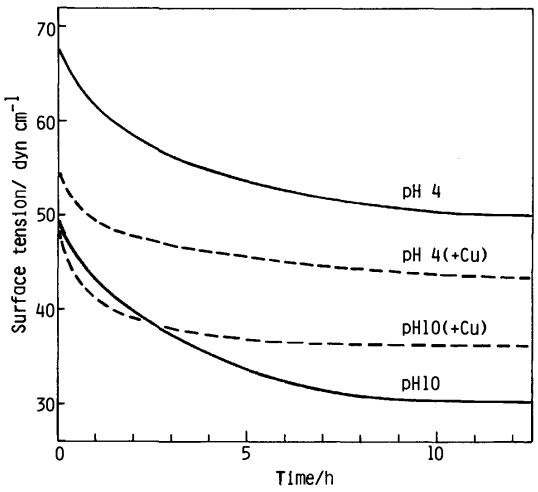

Fig. 2. Surface tension curves of $R_{12}doN_4$ at 20°C.
Concn at pH 4: [$R_{12}doN_4$]=4.8×10^{-5} mol dm^{-3}, [$R_{12}doN_4$]+[Cu^{2+}]=(4.7+4.7)×10^{-5} mol dm^{-3}.
Concn at pH 10: [$R_{12}doN_4$]=6.3×10^{-5} mol dm^{-3}, [$R_{12}doN_4$]+[Cu^{2+}]=(4.8+4.8)×10^{-5} mol dm^{-3}.

The relations between the surface tension and the concentration of R_ndoN_4 are shown in Fig. 3. $R_{12}doN_4$ at pH 10 had an excellent ability to lower the surface tension. The critical micellar concentration (cmc) was 1×10^{-4} M (1 M=1 mol dm^{-3}); this was confirmed also by the conductometric titration. However, the cmc at pH 4 was not observed in concentrations below 3.8×10^{-4} M. The $R_{12}doN_4$ in the presence of Cu^{2+} had an excellent lowering ability, and the surface tensions at pH 4 and 10 were nearly the same in value. $R_{18}doN_4$ was soluble in a solution acidic enough for its surface tension to be measured, but not at pH 10. The addition of Cu^{2+} to the $R_{18}doN_4$ solution made the surface tension lower, even at pH 10, and the two surface-tension curves at pH 4 and 10 became nearly the same.

The $R_{12}doN_4$-Ni^{2+} complex had as much lowering ability as the Cu^{2+} complex. However, the Fe^{3+} complex at pH 10 was deposited, and the surface tension was not lowered so much {[$R_{12}doN_4$]+[Fe^{3+}]=(4.7+4.7)×10^{-5} M: 42 dyn cm^{-1}, which is not shown in the figure}. The formation of the Cu^{2+} and Ni^{2+} complexes was confirmed over the pH range of 4.5—10,[16] but that of the Fe^{3+} complex has not yet been confirmed. The Fe^{3+} complex would be less stable and

a) Wilhelmy surface-tension balance; temp: 20°C.

so would be hydrolyzed easily, or the $R_{12}doN_4$ might bind to the Fe^{3+} hydroxide.

The surface-tension curves of hydrophilic R_ndoN_5 were located in higher concentrations than the curves of R_ndoN_4. The relations of the surface tension between the $R_{12}doN_5$, the $R_{18}doN_5$, and their Cu^{2+} complexes were similar to those between the corresponding $R_{12}doN_4$, $R_{18}doN_4$, and their Cu^{2+} complexes.

Molecular Area. The surfactants (R_ndoN_4 and its Cu^{2+} complex) are oriented on the surface layer of the solutions. Therefore, the mole numbers of the vertical surfactants(Γ) per unit area (cm^2) were calculated from the Gibbs adsorption isotherm on the basis of the lowering of the surface tension(γ):[17]

$$\Gamma = \frac{1}{RT} \times \frac{d\gamma}{d \ln C}$$

Then, the areas of the cross-section of a surfactant molecule were calculated from the mole number. The areas (S) are shown in Table 2, together with their surface activities. The S values when soluble in water lead to a small error. However, it is reasonable to estimate the relative areas in connection with the structures of the R_ndoN_4 and its Cu^{2+} complex.

The areas of $R_{12}doN_4$ were 82 $Å^2$ mol^{-1} at pH 4 and 57 $Å^2$ mol^{-1} at pH 10; that of $R_{18}doN_4$ was 77 $Å^2$ mol^{-1} at pH 4, but has unmeasured at pH 10. The $R_{12}doN_4$ and $R_{18}doN_4$ in the acidic solution of pH 4 are cationic. Therefore, the area of $R_{12}doN_4$ at pH 4 would be widened because of the solvation and the electrostatic repulsion, while the area of $R_{18}doN_4$ at pH 4 would become narrower than that of $R_{12}doN_4$ at pH 4 because of the additional aggregation based on the van der Waals force of a longer alkyl chain.

The area of R_ndoN_4 in the presence of Cu^{2+} became smaller than that in the absence of Cu^{2+}. The $R_{12}doN_4$-Cu^{2+} and $R_{18}doN_4$-Cu^{2+} complexes had nearly the same S values, and the two areas at pH 10 (46—48 $Å^2$ mol^{-1}) were smaller than those at pH 4 (66—67 $Å^2$ mol^{-1}). Dioxo[14]aneN_4 is known to form the uncharged Cu^{2+} complex above pH 4.5.[16] Therefore, the R_ndoN_4 at pH 10 would form the uncharged Cu^{2+} complex with a tighter aggregation.

Thus, it was proved that the long-alkyl-substituted cyclic dioxopolyamine and its metal complexes have the ability to lower the surface tension.

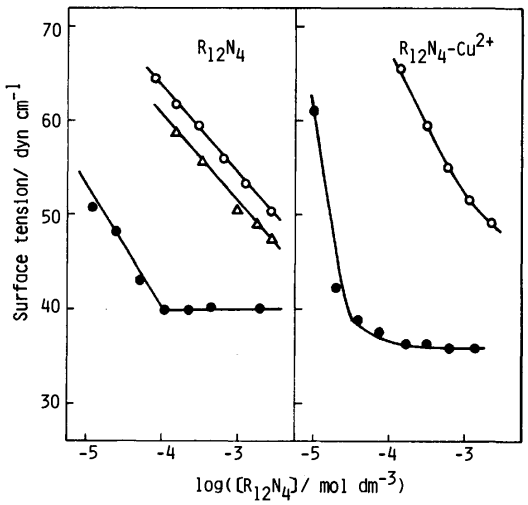

Fig. 4. Surface tension of $R_{12}N_4$. $[R_{12}N_4]$=$[Cu^{2+}]$, temp: 20°C. ○: pH 4, △: pH 7, ●: pH 10.

Surface Activities of $R_{12}N_4$. The reduction product of $R_{12}doN_4$, $R_{12}N_4$, also made the surface tension lower. The surface tension, as measured by Du Noüy surface-tension balance, is shown in Fig. 4. At pH 4 and 7, the surface tension lowered with the increase in the concentration, and the cmc was not observed over the concentration range below 3×10^{-3} M. The surface tension at pH 10 fell to 40 dyn cm^{-1}, and the cmc was nearly 10^{-4} M. The addition of Cu^{2+} lowered the surface tension a little, and the cmc at pH 10 shifted to a lower concentration. The calculated S values of $R_{12}N_4$ were 95 $Å^2$ mol^{-1} at pH 4 and 66 $Å^2$ mol^{-1} at pH 10, while those of the Cu^{2+} complex were 48—53 $Å^2$ mol^{-1} at pH 4 and 39 $Å^2$ mol^{-1} at pH 10. The 2.4R-N_6 and Ls6.8N_6 showed a lowering of the surface tension (2.4R-N_6 34—37 dyn cm^{-1}, Ls6.8N_6 42 dyn cm^{-1}); their Cu^{2+} complexes had a similar surface tension. The S values at pH 7 were 72 $Å^2$ mol^{-1} for 2.4R-N_6 and 42 $Å^2$ mol^{-1} for the Cu^{2+} complex. The differences in the areas are probably caused by the tightness of the aggregation based on the complex formation. However, the S values of Ls6.8N_6 and its Cu^{2+} complex were both 92 $Å^2$ mol^{-1} at pH 7. The same wide areas are probably caused by the weak

aggregation based on the similar great repulsion of the 1.7 mol of carboxylate ion in Ls6.8N_6 and its Cu^{2+} complex.

Ion-Flotation. The four metal ions (Cu^{2+}, Ni^{2+}, Fe^{3+}, Zn^{2+}) in water were separated by the method of ion-flotation using these surfactants. $R_{12}doN_4$ and $R_{18}doN_4$ showed almost the same floatabilities of the metal ions, as is shown in Fig. 5. The dioxo[14]aneN_4-metal complexes when the equimolar dioxo[14]aneN_4 was added to the 10^{-4} M of the metal ion were calculated from the data of the stability constants.[18] The 1:1 species were in the pH range above 4.6 for Cu^{2+} and above 7 for Ni^{2+}. Therefore, the alkylated R_ndoN_4 would complex and float with Cu^{2+} or Ni^{2+} in that pH region. R_ndoN_5 exhibited slightly different floatabilities from those obtained by using R_ndoN_4, e.g., Fe^{3+} in pH 5—6 (Fig. 6). R_ndoN_5 is more hydrophilic than R_ndoN_4, so that the differences in the floatabilities are caused by their HLB.

The collector characteristics of the alkylated reduction product ($R_{12}N_4$) and the polyalkylated 2.4R-N_6 ([18]aneN_6 bearing 2.4 mol of dodecyl groups) are shown in Fig. 7. The stability constants (log K) of the cyclic polyamine-Cu^{2+} complexes are known to be far greater than those of the cyclic dioxopolyamine-Cu^{2+} complexes.[18,19] The pk_a and log K(Cu^{2+} complex) have been reported as follows: dioxo[14]aneN_4 pk_{a1} 5.97, pk_{a2} 9.57, log K 1.0; dioxo[16]aneN_5 $pk_{a1}<2$, pk_{a2} 8.69, pk_{a3} 9.01;[18] [14]aneN_4 pk_{a1} 0.9, pk_{a2} 1.61, pk_{a3} 10.62, pk_{a4} 11.59, log K 27.2; [18]aneN_6 pk_{a1} ca. 1, pk_{a2} ca. 2, pk_{a3} 4.30, pk_{a4} 9.01, pk_{a5} 9.51, pk_{a6} 10.46, log K 21.6.[19]

Then, the stabilities of the $R_{12}doN_4$-Cu^{2+} and $R_{12}N_4$-Cu^{2+} complexes were confirmed by pH titration with a NaOH solution. The titration curves of the $R_{12}doN_4$ and $R_{12}N_4$ showed the end points based on the acid dissociation (pk_a) at two and four equimolar quantities of NaOH respectively. From the two pH-titration curves in the presence of Cu^{2+}, it was concluded that the Cu^{2+} complex of $R_{12}N_4$ is far more stable than the complex of $R_{12}doN_4$, while the $R_{12}doN_4$ forms uncharged complexes with divalent Cu^{2+}.

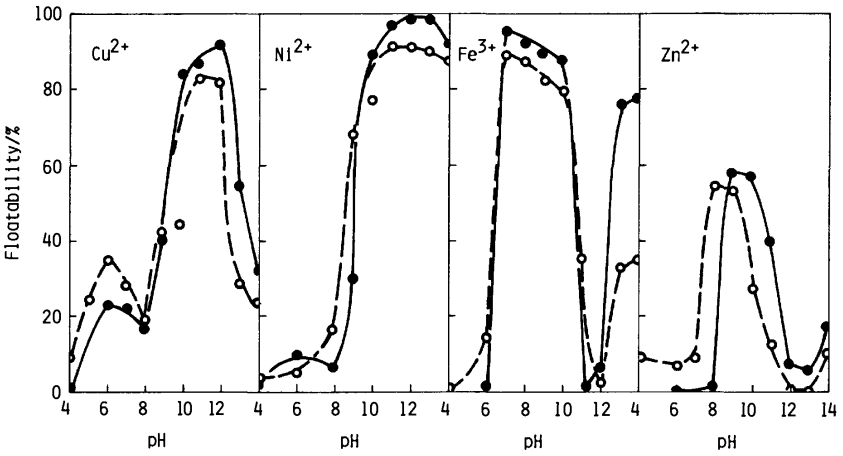

Fig. 5. Flotation by using R_ndoN_4. [Metal ion], [R_ndoN_4]=10^{-4} mol dm^{-3}. O: $R_{12}doN_4$, ●: $R_{18}doN_4$.

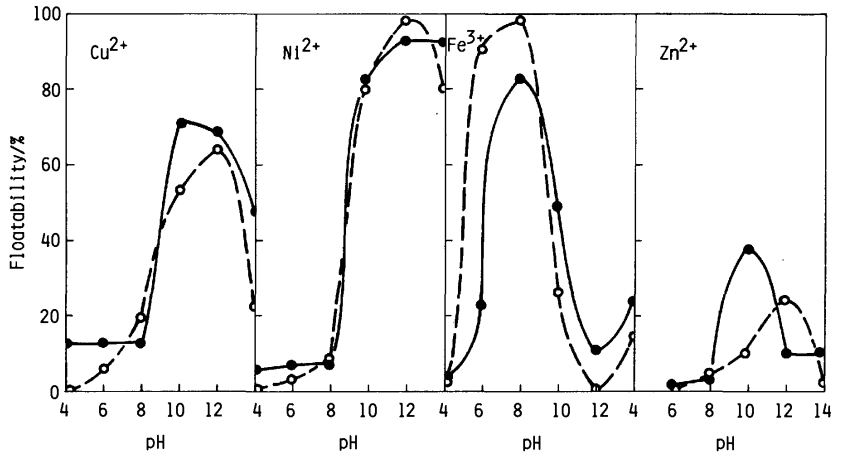

Fig. 6. Flotation by using R_ndoN_5. [Metal ion], [R_ndoN_5]=10^{-4} mol dm^{-3}. O: $R_{12}doN_5$, ●: $R_{18}doN_5$.

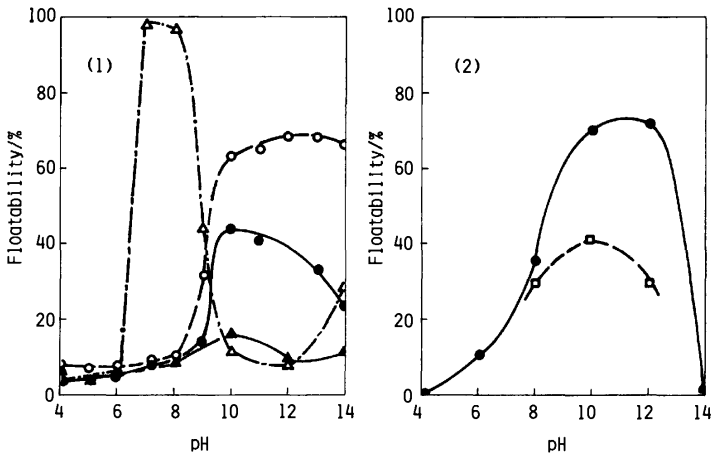

Fig. 7. Flotation by using $R_{12}N_4$ and 2.4R-N_6. (1): [Metal ion], $[R_{12}N_4]=10^{-4}$ mol dm^{-3}. (2): [Metal ion], [2.4R-N_6]$=3\times10^{-5}$ mol dm^{-3}. ●: Cu^{2+}, O: Ni^{2+}, △: Fe^{3+}, ▲: Zn^{2+}, □: Hg^{2+}.

Therefore, the pk_a values of $R_n$doN$_4$, $R_n$doN$_5$, $R_{12}N_4$, and 2.4R-N_6, and the log$K$ values of their metal complexes, are comparable to those of the corresponding cyclic dioxopolyamine, cyclic polyamine, and the metal complexes.

However, neither Cu^{2+} nor the other metal ions was floated so highly by using $R_{12}N_4$, and the floatability of Cu^{2+} by using 2.4R-N_6 in the alkaline region was similar to that when $R_n$doN$_4$ or $R_n$doN$_5$ was used. The floatable $R_{12}N_4$-metal and 2.4R-N_6-metal complexes in that alkaline region are the neutralized species with OH^-. The telomer bearing 6.8 mol of [18]aneN$_6$, Ls6.8N$_6$, formed soluble metal complexes and did not make the metal ions float.

Thus, the variation in the complex forms, that is, the variation in their HLB values, fairly affected the floatabilities. The floated complexes were surface-active. The HLB values were calculated according to the Oda equation[20] on the basis of the postulated structures. The HLB values were R_{12}doN$_4$-Cu 9, R_{12}doN$_5$-Cu 10, and $(R_{12}N_4\text{-Cu})^{2+}\cdot2(OH)^-$ 14. The values of the complexes proved to be in the HLB range of 4—14 suitable for ion flotation, as has been reported previously.[21] Therefore, they must be floated.

Flotation Using Polyamine. *N*-Alkylethylenediamine and *N*-dodecyldiethylenetriamine have been placed in an ion-flotation collector.[7] The complexation of the cyclic polyamine differs much from that of the linear polyamine. Therefore, the collector characteristics of the alkylated cyclic polyamines were compared with those of the linear polyamine-type surfactants. The flotation of Cu^{2+} is shown in Fig. 8.[7,22] All the floatabilities were roughly similar, in spite of the great differences in the stability constants. The Cu^{2+} complexes of linear polyamines should be neutralized with OH^- in the alkaline region, and then the complexes come to be in the HLB range of 4—14.

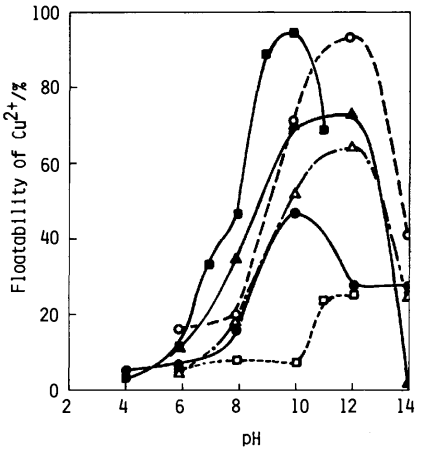

Fig. 8. Flotation of Cu^{2+} by using polyamine-type surfactants. O: R_{12}doN$_4$, △: R_{12}doN$_5$, ●: $R_{12}N_4$, ▲: 2.4R-N_6, □: *N*-dodecylethylenediamine, ■: *N*-dodecyldiethylenetriamine.

Therefore, the complexes should be floated in the alkaline region, and all the collector characteristics will resemble each other.

Selectivity. The selectivity of metal ions is a matter of great practical importance in separation. Therefore, the selective flotation from a metal-ion mixture (Fe^{3+}, Cu^{2+}, Ni^{2+}, Zn^{2+}) was examined. The flotations by using R_{18}doN$_4$ and R_{18}doN$_5$ in pH 4—8 are shown in Fig. 9. The selectivities by using R_{18}doN$_4$ or R_{12}doN$_4$ were $Cu^{2+}>Ni^{2+}>Fe^{3+}>Zn^{2+}$; this order differed from that by using R_{18}doN$_5$ or R_{12}doN$_5$ ($Fe^{3+}>Cu^{2+}>Ni^{2+}>Zn^{2+}$). The coordination numbers of Cu^{2+} and Fe^{3+} are usually 4 and 6 respectively. Therefore, it was considered that the $R_n$doN$_4$-Cu^{2+} complex was saturated, while the $R_n$doN$_5$-Cu^{2+}, R_{18}doN$_4$-Fe^{3+}, and R_{18}doN$_5$-Fe^{3+} complexes (or compounds) were not. The unsaturated R_{18}doN$_5$-Cu^{2+}

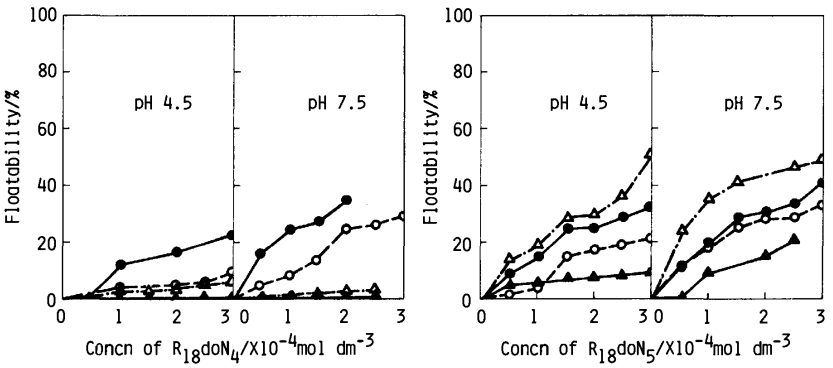

Fig. 9. Selectivities using $R_{18}doN_x$ at pH 4.5 and 7.5. Metal ions mixture: Cu^{2+}, Ni^{2+}, Fe^{3+}, Zn^{2+} (each 10^{-4} mol dm^{-3}). ●: Cu^{2+}, ○: Ni^{2+}, △: Fe^{3+}, ▲: Zn^{2+}.

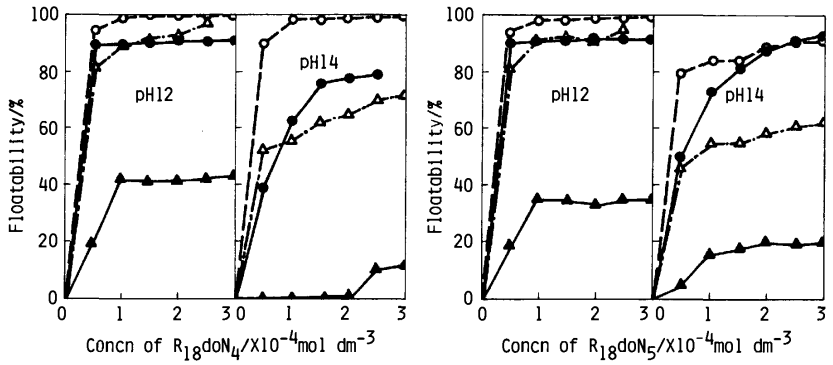

Fig. 10. Selectivities using $R_{18}doN_x$ in alkaline. Metal ions mixture: Cu^{2+}, Ni^{2+}, Fe^{3+}, Zn^{2+} (each 10^{-4} mol dm^{-3}). ●: Cu^{2+}, ○: Ni^{2+}, △: Fe^{3+}, ▲: Zn^{2+}.

complex is more hydrophilic than the saturated $R_{18}doN_4$-Cu^{2+} complex, because of its one more amine. Moreover, the unsaturated Fe^{3+} complexes are cationic and are hydrolyzed easily above pH 3—4. The cationic $R_{18}doN_4$ and $R_{18}doN_5$ might bind to the colloidal Fe^{3+} hydroxide. Therefore, the $R_{18}doN_4$-Cu^{2+} complex would be more hydrophobic than the $R_{18}doN_4$-Fe^{3+} compound. This tendency agreed with the hydrophobic properties in the surface tension; that is, the lowering of the surface tension of the hydrophobic $R_{12}doN_4$-Cu^{2+} complex at pH 4 (Fig. 3) began at a lower concentration of $R_{12}doN_4$ than did that of the $R_{12}doN_4$-Fe^{3+} compound at pH 4 (the surface-tension curve, which is not shown, was nearly the same as the curve of the $R_{12}doN_4$ in the absence of Fe^{3+}). On the other hand, the $R_{18}doN_5$-Fe^{3+} complex, the cyclic dioxopentamine compound, should be less hydrophilic than the Cu^{2+} complex. Therefore, the hydrophobic Cu^{2+} and Fe^{3+} complexes would be selectively floated by using R_ndoN_4 and R_ndoN_5 respectively. However, the same selectivities were observed in the pH range of 12—14, even though the floatabilities (Ni^{2+}>Cu^{2+}>Fe^{3+}>Zn^{2+}) were high, as is shown in Fig. 10. Metal ions form polyhydroxo complexes in a strongly alkaline solution. The log K values of the metal-hydroxo complexes are Ni^{2+} 3.08, Cu^{2+} 6.66, Fe^{3+} 11.17, and Zn^{2+} 5.04;[23] the Ni^{2+} hydroxide is the least stable among these metal ions. Therefore, the conditional stability constants of the $R_{18}doN_4$-Ni^{2+} and the $R_{18}doN_5$-Ni^{2+} complexes in the pH range of 12—14 would become the largest, and then Ni^{2+} would be floated most. Figures 5 and 6 also illustrate that the hydrophobic properties (HLB) of the Cu^{2+} and Fe^{3+} complexes developed in the floatabilities at pH 5—6, while the stabilities of the Ni^{2+} complex developed in the floatabilities above pH 12. On the other hand, the Cu^{2+} was extracted and transported selectively by using $R_{16}doN_4$ from a mixture of Cu^{2+}, Fe^{3+}, Ni^{2+}, and Zn^{2+} because of the formation of the most stable complex.[6] Therefore, the selectivities in the ion-flotaion markedly differed from those in the extraction and transportation.

Thus, it is concluded that the cyclic polyamine-type surfactants have excellent surface-activities and that the flotation using the cyclic dioxopolyamine-type surfactant was done by means of the complex formation, while that using the cyclic polyamine or linear polyamine was done by means of the neutralization of

the complex with OH^-. Furthermore, the selective flotation has been proved to be attributable to the hydrophobic properties (smaller HLB) of the metal complexes in the HLB range of 4—14 rather than to the stability.

The authors are grateful to Assistant Professor Akinori Jyo for his useful suggestions and to Mr. Shunji Hayashi and Mr. Norihito Maehara for their help in the experiments.

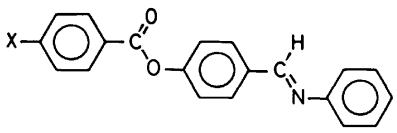
Effects of Polysubstitution on Mesomorphic Properties: Chloro and Methyl Derivatives of *N*-[4-(4-Substituted benzoyloxy)benzylidene]anilines

Hiroyuki HASEGAWA, Tatsuya MASUDA, Yoshio MATSUNAGA,*
Sachiko SEO, and Kazuaki YASUHARA
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received April 12, 1989)

The effects of mono-, di-, and trichloro substitution of the aniline moiety on the nematic-isotropic transition temperature of *N*-[4-(4-X-substituted benzoyloxy)benzylidene]anilines, where X=CH_3O, CH_3, or Cl, have been studied, while paying particular attention to the vicinal chlorines. While the substituent on the 2 or 3 position of the aniline moiety lowers the transition temperature of the parent compound and the 4-chloro derivative, the 2,3-dichloro derivative shows a temperature higher than that of either the 2- or 3-chloro derivative. Moreover, the transition temperature of the 2,3,4-trichloro derivative exceeds that of the 3,4-dichloro derivative and is a little below that of the 2,4-dichloro isomer. In contrast, the introduction of 4-substituent increases the temperature, regardless of the position(s) of the other substituent(s). Methyl substitution exerts effects closely similar to those described above.

The effects of polysubstitution on mesomorphic thermal stabilities have been the subjects of many studies.[1] These studies have demonstrated that lateral substitution of a mesomorphic compound causes a pronounced lowering of the mesomorphic transition temperature. Therefore, the increased intermolecular separation seems to decrease the intermolecular cohesion to an extent outweighing any enhancement in these cohesive forces arising from increased polarity and polarizability. It has been concluded that the effects of two substituents are approximately additive.[2] However, Young et al. have noted that the transition temperature drops more slowly with each additional substituent when the molecule contains three or four substituents.[3] A survey of the literatures revealed that the substituents in almost all cases are located on different aromatic rings or are not bonded to the neighboring carbon atoms if they are located on the same ring. The work by Panse et al. on 4-(4-alkoxybenzoyloxy)-4′-alkylazobenzenes includes some exceptional cases.[4] For instance, the nematic–isotropic (N-I) transition temperature of the 2,3-dimethyl derivative was recorded to be 215 °C when the terminal substituents were butoxyl and butyl groups, respectively. This value is appreciably higher than that of the corresponding 3-methyl derivative, 183 °C. Moreover, the effects of two lateral cyano groups introduced into the neighboring positions on the mesomorphic behavior of four esters were described by Osman.[5] He concluded that the second substituent has little effect on the clearing point since it fills the space produced by the introduction of the first one and does not increase the intermolecular separation.

We have undertaken systematic examinations of the effects of substituents attached to the neighboring carbon atoms in the same benzene ring on the thermal stability of mesophases. As the decreases in thermal stability of the mesophase by the introduction of lateral substituent(s) are often large, the thermal stabilities of mesophases and the temperature ranges over which the mesophases exist must be considerable, if one is to study the effects of di- and polysubstitution upon the mesomorphic transition temperatures. For this purpose, we have chosen *N*-[4-(4-substituted benzoyloxy)benzylidene]anilines (**1**) as the parent compounds and methyl and/or chloro substituent(s) to be introduced to the aniline moieties. The van der Waals radii of these two substituents are about 0.23 and 0.18 nm respectively; however, the difference in the radius is almost cancelled by the difference in the ring-X bond length; these two are expected to affect the thermal stability of mesophase nearly to the same extent when they are employed as lateral substituents.[1] The stable or metastable nematic phase may hopefully be detected with the selected compounds, since *N*-[4-(4-methoxybenzoyloxy)benzylidene]-4-methylaniline has been reported to exhibit a nematic phase over the temperature range from 129 to 274.5 °C and the 4-chloro analog from 165 to 274 °C.[6,7]



1

Experimental

Materials. 4-(4-X-substituted benzoyloxy)benzaldehydes were prepared by reacting 4-X-substituted benzoyl chlorides and 4-hydroxybenzaldehyde in the presence of pyridine. The Schiff's bases were synthesized by condensing the above-mentioned benzaldehydes with appropriate anilines in ethanol. The products were recrystallized from ethanol, benzene, or the mixtures until constant transition temperatures were obtained.

Measurements. Transition temperatures were determined by calorimetric curves recorded with a Rigaku Thermoflex differential scanning calorimeter at a heating or cooling rate of 5 °C min^{-1}. Enthalpy changes were estimated by comparing the peak areas with that due to the melting of indium, 3.26 kJ mol^{-1}. When no mesophase was detectable,

the virtual transition temperature was estimated by the extrapolation of the clearing point curve in the binary system with 4,4′-azoxydianisole.

Results and Discussion

The transition temperatures and the associated enthalpy changes of the monofluoro, monochloro, monobromo, monoiodo, and monomethyl derivatives of *N*-[4-(4-methoxybenzoyloxy)benzylidene]aniline (X=CH_3O) are summarized in Table 1. Here, crystalline, nematic, and isotropic phases are denoted by K, N, and I respectively. Gray and Worrall have shown that the clearing point (N-I transition temperature) of 3′-substituted 4′-octyloxybiphenyl-4-carboxylic acids decreases smoothly with increasing the molecular breadth.[8] Gray and his coworkers have also studied the mesomorphic properties of 2′- and 3′-X-substituted 4-[(4-alkoxybenzylidene)amino]biphenyls.[9] The 2′-isomers give much larger depressions of the clearing point because of a twisting effect superimposed on a broadening effect. In our case, a twisting effect is essentially absent and the substituent on the 2 position of the aniline moiety may be less exposed than that on the 3 position, because the lines defining the molecular breadth have their positions determined by the stereochemistry of the -COO- and -CH=N- units. The substituent on the 3 position is so effective in reducing the temperature that the mesophase is eliminated when chlorine, bromine, and iodine atoms are employed. In these cases, the virtual transition temperature estimated by the extrapolation of the clearing point curve in the binary system with 4,4′-azoxydianisole is listed in Table 1. As a result, the depression of the clearing point by the 2-chloro substituent was found to be 59 °C and that by the 3-substitution 82 °C. The methyl substitution results in similar differences.

Table 2 presents the transition temperatures and the associated enthalpy changes of the dichloro and trichloro derivatives of *N*-[4-(4-methoxybenzoyloxy)-benzylidene]aniline. The change in the clearing point by the chloro substituents is well demonstrated by the diagram shown in Fig. 1a. The 4-substitution promotes the thermal stability of the mesophase in the 2-chloro, 3-chloro, and 2,3-dichloro derivatives. The extents are not much different from that found with the parent compound. Furthermore, the depression of the transition temperature of the 4-chloro derivative by the 2- or 3-substitution appears to be similar to those arising from the substitution on the parent compound. Thus, the effects are approximately additive in these cases. Serious deviations from the additivity rule are clearly seen when the thermal stability of mesophase is compared between the 2,3-dichloro derivative and the 2- or 3-chloro derivative, and also between the 2,3,4-trichloro derivative and the 2,4- or 3,4-dichloro derivative. Namely, the 2,3-dichloro derivative exhibits a temperature higher than either the 2-chloro or the 3-chloro derivative. Stabilization by the second substituent is about twice as large when the first one is located on the 3 position. A similar, but less pronounced, tendency is found among the trichloro and dichloro derivatives mentioned above.

While the clearing point of the monomethyl derivative is close to that of the corresponding monochloro derivative, the difference is somewhat larger among the disubstituted compounds (see Table 2). The changes in the transition temperature by methyl substitution are summarized in Fig. 1b. It may be noted that all of the compounds employed in this

figure exhibit a stable or metastable mesophase; in other words, all of the transition temperatures are measurable. The mesophase is promoted by 4-methyl substitution as much as by the 4-chloro substitution presented in Fig. 1a. Moreover, the phase of the 4-methyl derivative is destabilized by 2- or 3-methyl substitution to an extent which is well compared with that given by the corresponding chloro derivative. Since the 2,3-dimethyl derivative exhibits an N-I transition temperature higher by 19 °C than the 2,3-dichloro derivative, the deviation from the additivity rule observed in Fig. 1b is more striking than that given in Fig. 1a.

The resemblance in the mesomorphic behavior between the chloro and methyl derivatives indicates that dispersive forces play a major role compared with dipole attractive forces, as pointed out by Osman.[5] This conclusion is supported by our additional data on the 2-methyl-3-chloro and 3-chloro-4-methyl derivatives. Their clearing points are in the order; 2,3-dichloro<2-methyl-3-chloro<2,3-dimethyl and 3,4-dimethyl<3-chloro-4-methyl<3,4-dichloro, respectively.

The thermodynamic data for compounds with X=CH_3 are presented in Table 3 and the changes in the clearing point are given in Fig. 2a. As the 2-chloro, 3-chloro, and 2,3-dichloro derivatives are not mesogenic, the changes involving these derivatives may not be very accurate. Nevertheless, the general feature in Fig. 2a is in good agreement with those found in Figs. 1a and b. The enhancement in the thermal stability of mesophase by the 4-chloro substituent seems to be more pronounced than that in the previously-described series. As demonstrated by the clearing points of the 4-chloro, 2,4-dichloro, and 3,4-dichloro derivatives, the 3-chloro substituent is more efficient to reduce the clearing point than the 2-chloro substituent. The difference in the clearing point between the 2,3,4-trichloro derivative and the 2,4-dichloro or 3,4-dichloro derivative contrasts markedly with the above-mentioned and definitely indicates that the anomaly is caused by the substituents located at the 2 and 3 positions. It must be added that the 2-methyl-3-chloro derivative is not mesogenic in conformity with the behavior of the 2,3-dichloro derivative. The clearing

point given by the 3-chloro-4-methyl derivative is lower than that of the 3,4-dichloro derivative.

Table 4 summarizes the effect of chloro substitution on the mesomorphic behavior of compounds with X=Cl. These compounds are unique in the sense that all the substituents are chlorine atoms. This situation is reflected by some irregularities in the thermal behavior. Compared with the compound listed in Table 3, the clearing point of the parent compound is higher by 22 °C. In contrast, the mesophase of the 3,4-dichloro derivative in the present series is transformed into an isotropic liquid at a temperature lower by 9 °C and that of the 2,3,4-trichloro derivative by 6 °C. The clearing point exhibited by the remaining two, the 4-chloro and 2,4-dichloro derivatives, is almost the same as that of the corresponding methyl compound. Thus, the compounds carrying only chloro substituents do not seem follow the well-known order of nematic group efficiency for terminal substituents.

The thermal stability of mesophase varies by the substitution as shown in Fig. 2b. In this series too, no mesophase is detectable for the 2-chloro, 3-chloro, and 2,3-dichloro derivatives. It seems to be reasonable to see that the clearing point of the 2,4-dichloro derivative is much higher than that of the 3,4-dichloro derivative. Therefore, the observation that the 2-chloro and 3-chloro substituents contribute nearly equally in reducing the clearing point of the parent compound looks very strange and might be ascribed to the uncertainties in the virtual clearing points of these chloro derivatives. Even so, the anomalously high thermal stabilities in the 2,3-dichloro and 2,3,4-trichloro derivatives are firmly demonstrated by this diagram.

The following general comments may be made about the results presented in this work. The terminal substituent (the substituent on the 4 position) promotes the thermal stability of mesophase irrespective of the presence of a lateral substituent, even when the latter is bonded to the neighboring carbon atom. In these cases, the effects of the terminal and lateral

substituents are roughly additive. When two lateral substituents are bonded to the neighboring carbon atoms (the 2 and 3 positions), the effects deviate greatly from the additivity rule. The second substituent is accommodated, more or less, in the space produced by the introduction of the first one; therefore, it may be possible that the enhancement of the intermolecular cohesion arising from the increased polarizability outweighs the decrease in the cohesion due to the increased intermolecular separation. If the nature of substituents is markedly different from that in the compounds studied here, the outcome may become less significant, as reported by Osman.[5]

The presence of a short-range order of the molecular positions in the nematic phase, such as the smectic C-type and one-dimensional correlation along the nematic director, has been pointed out in addition to the long-range orientational order along the director.[10,11] Furthermore, a molecule with a polar terminal substituent is known to exhibit a strong tendency to molecular association.[12] The terminal substituents employed in the present work are so different in polarity from each other that the favorable relative arrangement of the molecules in the nematic phase may not be identical. Consequently, it seems reasonable that compounds carrying X=Cl exhibit a thermal behavior somewhat anomalous compared with those carrying the other substituents.

Determination of Individual Partial Molar Volumes of Ions in Water from Measurements of Ultrasonic Vibration Potentials

Nobuo TAKENAKA and Kiyoshi ARAKAWA*
Research Institute of Applied Electricity, Hokkaido University, Sapporo 060
(Received April 27, 1989)

A new apparatus for measurements of ionic vibration potentials generated by the propagation of ultrasonic waves through electrolyte solutions was constructed, and used for the determination of partial molar volumes of ions in aqueous solutions of uni-univalent electrolytes. The apparatus, based on the method of ultrasonic vibration potentials (Zana and Yeager), was improved in two points through the introduction of the Doppler effect: a small measuring cell (about 50 cm^3) and very low noises (50 nV). Then, measurements of temperature variation of ultrasonic vibration potentials have become possible. Partial molar volumes of hydrogen, alkali metal, and halide ions in water were determined in the range of temperature, 15—45 °C.

The ionic partial molar volume has turned out to be a very useful tool in elucidating the nature of ion-solvent interactions in electrolyte solutions.[1,2] For the direct experimental determination of partial molar volumes of individual ions, the method of ultrasonic vibration potentials (UVP) has been found to be the still unique experimental means available to obtain those data. The theoretical basis of the method of UVP was given by Debye,[3] and others,[4,5] formerly, and Zana and Yeager[6] constructed the experimental apparatus for the measurements of UVP in 1967.

In the apparatus used by Zana et al.[6,7] the measuring unit was, however, too large in its size and therefore measurements have been confined near room temperature only. Then, we have undertaken to improve the experimental method of UVP given first by Zana and others, especially aiming at obtaining the data at various temperatures.

Theory and Experimental Procedures

Theory. In a sound field the difference in the dynamical responses between cations and anions within an electrolyte solution produces an alternating potential (ionic vibration potential/ultrasonic vibration potential).

The forces acting on an ion (the jth type) within the solution are expressed as follows,[3,6]

$$e_jE - \mu_j(u_j - u_0) + d_0v_j\frac{\partial u_0}{\partial t} = m_j\frac{\partial u_j}{\partial t}. \quad (1)$$

m_j, e_j, v_j, and u_j, is the mass, the charge, the volume, and the velocity of the ion, respectively. μ_j is the frictional coefficient acting on the ion, d_0 and u_0 the density and the velocity of the solvent molecule, E the strength of the field, and t time.

The Poisson equation is

$$\varepsilon\frac{\partial E}{\partial x} = \Sigma n_je_j, \quad (2)$$

where ε is the permittivity of the medium, n_j the number density of the jth ions, and x the coordinate (the propagation distance of the sound wave), and the equation of continuity becomes

$$\frac{\partial n_j}{\partial t} + \frac{\partial(n_ju_j)}{\partial x} = 0. \quad (3)$$

The velocity of the ion and solvent in the sound field is expressed as

$$u_j = a_je^{i(\omega t - kx)}, \quad (4a)$$

$$u_0 = a_0e^{i(\omega t - kx)}, \quad (4b)$$

where ω and k is the angular frequency and the propagation constant of the sound wave, and $k=\omega/c$ (c; sound velocity). Here, we define α_j as

$$\alpha_j = \frac{a_jm_j - a_0d_0v_j}{m_j - d_0v_j} = \frac{a_jm_j - a_0d_0v_j}{w_j}, \quad (5)$$

and the UVP becomes

$$\Phi = -\int E\mathrm{d}x = \Phi_0e^{i(\omega t - kx)}. \quad (6)$$

In the following we treat the case of solutions of uni-univalent electrolyte, where suffixes 1 and 2 denote cations and anions, respectively. Then we can derive the equation of UVP from Eqs. 1—6[6]

$$\Phi_0F = c(\alpha_1W_1t_1 - \alpha_2W_2t_2)f(\omega), \quad (7)$$

and

$$f(\omega) = (\sigma/\varepsilon\omega)/[1 + (\sigma/\varepsilon\omega)^2]^{1/2},$$

where F is the Faraday constant, σ the electrolytic conductivity, and t_i (i=1,2) the transport number at the concentration. When the concentration is not so extremly dilute and the sound frequency is not so high, $f(\omega)$ is safely regarded as $f(\omega)=1$[3] and the factor in Eq. 7 can be eliminated. In Eq. 7 W_i (i=1,2) originally defined in Eq. 5 is expressed as molar quantities.

Here, according to Zana et al.,[6] we use following notations with respect to the molar mass of solvated ions,

$$M_i = M_{i0} + M_{iw}, \quad i = 1, 2, \quad (8)$$

where M_{i0} is the molar mass of bare ions and M_{iw} that of solvents solvated to ions. Then, apparent molar volumes of ions φ_i are

$$\varphi_i = V_i - M_{iw}/d_0, \quad i = 1, 2, \tag{9}$$

and the apparent molar volume of the salts φ is

$$\varphi = \varphi_1 + \varphi_2.$$

From Eqs. 7, 8, and 9,

$$\varphi_1 = \frac{1}{d_0(\alpha_1 t_1 + \alpha_2 t_2)} \times [\alpha_1 t_1 M_{10} - \alpha_2 t_2 M_{20} + d_0 \alpha_2 t_2 \varphi - \frac{\Phi_0 F}{c}], \tag{10a}$$

$$\varphi_2 = \frac{1}{d_0(\alpha_1 t_1 + \alpha_2 t_2)} \times [\alpha_2 t_2 M_{20} - \alpha_1 t_1 M_{10} + d_0 \alpha_1 t_1 \varphi + \frac{\Phi_0 F}{c}]. \tag{10b}$$

At this step, if we take for

$$\alpha_1 = \alpha_2 = a_0 \quad (\text{this means } a_1 = a_2 = a_0), \tag{11}$$

Eqs. 10 become

$$\varphi_1 = \frac{1}{d_0}(t_1 M_{10} - t_2 M_{20}) + t_2 \varphi - \frac{\Phi_0 F}{a_0 d_0 c}, \tag{12a}$$

$$\varphi_2 = \frac{1}{d_0}(t_2 M_{20} - t_1 M_{10}) + t_1 \varphi + \frac{\Phi_0 F}{a_0 d_0 c}. \tag{12b}$$

Eqs. 12a and 12b are quite identical with those given and used by Zana et al.[6,7] The introduction of the assumption, Eq. 11, means an approximation that, in the derivation of Eqs. 12, the factor $\partial u_j/\partial t$ in the right hand side of Eq. 1 is replaced by $\partial u_0/\partial t$ at this step. Then we adopt here another approximation instead of Eq. 11 as follows,

$$\alpha_1 = \alpha_2 = \alpha \quad (\neq a_0). \tag{13}$$

Using Eq. 13, Eqs. 10a and 10b become respectively

$$\varphi_1 = \frac{1}{d_0}(t_1 M_{10} - t_2 M_{20}) + t_2 \varphi - \frac{\Phi_0 F}{\alpha d_0 c}, \tag{14a}$$

$$\varphi_2 = \frac{1}{d_0}(t_2 M_{20} - t_1 M_{10}) + t_1 \varphi + \frac{\Phi_0 F}{\alpha d_0 c}. \tag{14b}$$

We use Eqs. 14a and 14b here instead of Eqs. 12a and 12b. That is, we measure Φ_0 for two electrolyte solutions containing common ions, for example, NaCl and LiCl, at the same concentration and from the two values of Φ_0, using Eqs. 14a and 14b, we can determine the magnitudes of φ_{Na^+}, φ_{Li^+}, φ_{Cl^-}, and α.

Apparatus and Experimental Procedures. The block diagram of the apparatus constructed is shown in Fig. 1. A 1 MHz ultrasonic wave is propagated in the cell through a transducer by excitation from the 1 MHz oscillator, and the UVP is produced within the sample solution. The detector consists of two iridium needles (0.127 mm ϕ) held parallel. In order to detect the UVP, it is rotated in the sample and fixed at an angle where the distance between two needles along the sound wave becomes $\lambda/2$ (λ: the wavelength of the sound wave), and then, as the result of the Doppler effect of the ultrasonic wave by moving the cell back and forth with a constant velocity of $10^{-6}c$, the UVP of $2\Phi_0$ (frequency 1 M±1 Hz) is produced in the sample and detected between two needles.

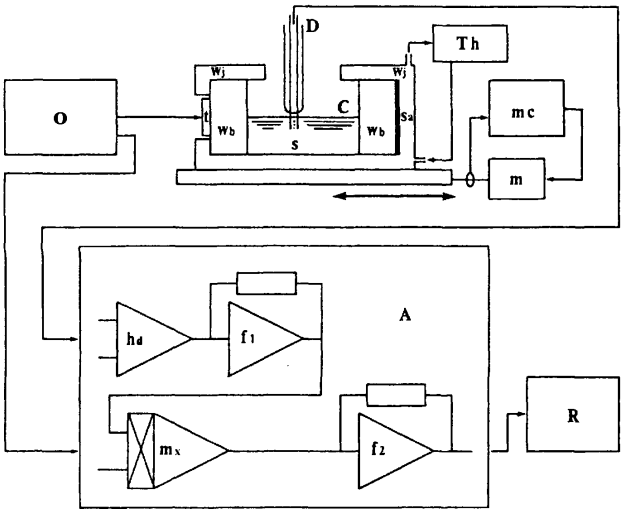

Fig. 1. Block diagram of the apparatus. O: oscillator, C: cell; t transducer (20 mmϕ, ceramics), s sample, w_b buffer (water), s_a sound absorber (butyl rubber), w_j water jacket, m motor, mc motor controller, D: detector, A: amplifier; h_d high input impedance differential amplifier, m_x mixer, f_1 bandpass filter (1 MHz), f_2 bandpass filter (1 Hz), R: recorder, T_h: thermostat.

In the detecting device circuit, the UVP, via a high input impedance amplifier, is mixed with a direct output from the oscillator, and then, is converted to a 1 Hz wave and 2 M±1 Hz wave, where the leakage from power sources is converted to a non-alternating current drift and 2 MHz wave. These all waves are lead to a bandpass filter with a central frequency of 1 Hz, and we can easily take out the 1 Hz component only from the UVP. This 1 Hz component is recorded by a recorder of ordinary type, where the total gain of 5000 is required in the amplification device on the whole.

In the device described above, a part of the differential amplifier with high input impedance is shown in Fig. 2.

A typical pattern of UVP recorded for a solution of NaI is shown in Fig. 3. The wave shows the UVP after frequency conversion to 1 Hz. The straight broken line in the figure shows the position of the cell in its movement: the point (a) denotes the starting point and the point (b) the end point. If the cell comes to the end of the path, the cell is stopped and the UVP vanishes. The UVP pattern at the right half in Fig. 3, shows that

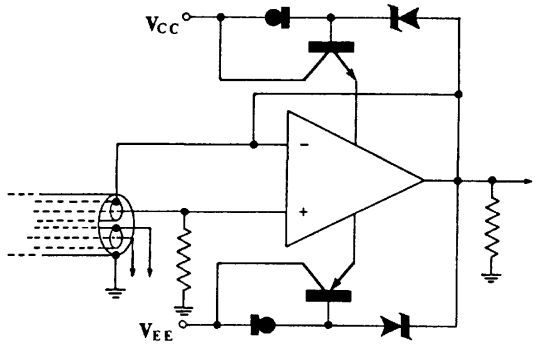

Fig. 2. A part of high input impedance differential amplifier. The amplifier made by a combination of bootstrap and driven shield circuit.

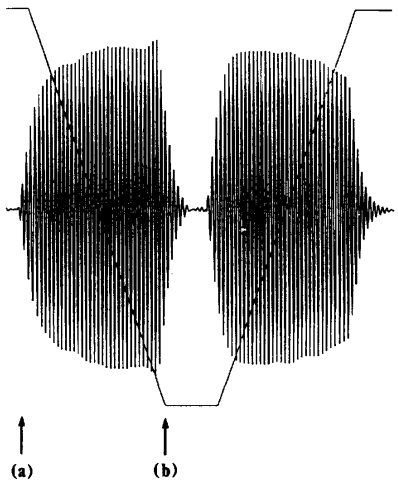

Fig. 3. Typical pattern of UVP recorded (NaI, 0.01 mol dm^{-3}).

on the backward shift of the cell.

The noise level in our device is below 50 nV. This noise level is of the order of 1/100, or so, of that observed in the apparatus used by Zana and Yeager.[6,7]

Results and Discussion

We have chosen a pair of salts, LiCl and NaCl, as a standard pair of samples to be measured in the present experiment according to the theoretical procedure using Eqs. 14a and 14b. In applying the procedure, the effectiveness of the approximation, Eq. 13, must be taken into consideration. Too large values of Φ_0 are supposed to violate the approximation. Then, the magnitude of Φ_0 should be not too large. The pair of LiCl and NaCl fits the condition in addition to the merit that the Φ_0 for the pair is determined with high accuracy.

We measured the magnitudes of UVP, Φ_0, for the NaCl solution as well as for the LiCl solution at the same concentrations, and determined the values of φ_{Na^+}, φ_{Li^+}, φ_{Cl^-}, and Φ_0/α. The observed values of Φ_0 at 15—45 °C are given in Table 1. The accuracy of those at $C>0.1$ mol dm^{-3}, is found to be smaller than ±5%. The magnitudes of Φ_0 and Φ_0/α at 25 °C are shown in Fig. 4. The increasing trend of UVP with decrease of concentration at low concentrations, $C\leqq 0.1$ mol dm^{-3}, is clearly seen in the figure, which was pointed out by Hunter et al.[8,9] previously. Then for the analysis below, we used the data at $C>0.1$ mol dm^{-3}, where, with respect to the transport number of ions and the apparent molar volume of salts, literature values were used.[10–15] The literature values of transport numbers and apparent molar volumes are shown in Table 2.

The values of φ_{Li^+}, φ_{Na^+}, φ_{Cl^-}, and α obtained at 25 °C are given in Table 3. The magnitudes of φ_{Na^+}, at

various temperatures are given as circles in Fig. 5, where the thin solid lines and dashed lines represent the values determined according to the best-fit procedure with the following formula[2] and those of the partial molar volumes obtained.

$$\varphi_{Na^+} = \varphi^0_{Na^+} + \frac{A}{2}\sqrt{C} + BC, \qquad (15a)$$

Table 4. Comparison of Values for Partial Molar Volumes at Infinite Dilution at 25°C

Ions	$\overline{V}^0_{ion}$/cm^3 mol^{-1}		
	This work	Zana-Yeager	Hirakawa
H^+	−5.0±0.3	−5.4±0.2	(−6.26—−0.32)
Li^+	−6.0±0.3	−11.2±1.2	(−13.02—−1.29)
Na^+	−6.3±0.3	−7.4±1.9	(−9.46—−1.45)
K^+	3.9±0.3	3.4±0.6	(3.56— 9.23)
Rb^+	9.0±0.3	9.0±0.7	(7.50— 17.0)
Cs^+	16.2±0.3	15.5±0.3	(10.25— 24.90)
F^-	3.9±0.3	3.3±1.0	(−4.47— 4.05)
Cl^-	22.9±0.3	23.7±1.2	(14.0 — 23.21)
Br^-	29.8±0.3	30.2±0.2	(17.68— 30.13)
I^-	41.1±0.5	41.4±0.9	(33.47— 40.95)

$$A = F^2 e \frac{10^2}{2\pi}\left(\frac{1}{20\varepsilon RT}\right)^{1/2}\left(\frac{\partial \ln\varepsilon}{\partial p} - \frac{\beta}{3}\right), \qquad (15b)$$

where A is the Debye-Hückel constant, B the material constant, β the isothermal compressibility.

The accuracy of each quantity is ±0.2, ±0.3, ±0.7** cm^3 mol^{-1} for φ_{ion}, φ^0_{ion} ($\equiv\overline{V}^0_{ion}$), and $\overline{V}_{ion}$ respectively.

The magnitudes of $\overline{V}^0_{Li^+}$, $\overline{V}^0_{Na^+}$, and $\overline{V}^0_{Cl^-}$ thus determined as well as those for other ions obtained from the values and $\overline{V}^0$ (partial molar volume of salts at infinite dilution) are given in Table 4, together with those of Zana-Yeager and Hirakawa[16] for comparison. Hirakawa constructed an apparatus for the measurement of the sedimentation potential in ionic solutions and obtained individual ionic partial molar volumes. The method of the sedimentation potential is essentially identical with the method of ultrasonic vibration potentials in principle, though vibration frequency is 100 Hz.[16]

As seen in Table 4, the values of the present work are found to be coincided with those of Zana and Yeager within the deviation of 1 cm^3 mol^{-1}, except for the case of Li^+. In the case of $\overline{V}^0_{Li^+}$, the absolute magnitudes of the values are found to deviate each other. Zana-Yeager's value of $|\overline{V}^0_{Li^+}|$ is clearly too large, being taken into consideration of the fact that in the case of the values of $\overline{V}^0_{Cl^-}$ as a counter ion, those of ours and Zana-Yeager's coincide within experimental errors. In Table 5, the present data are compared with the values calculated by the empirical formula of Mukerjee[17] and

** The accuracy of $\overline{V}_{ion}$ depends on the concentration. This value is that at C=0.25 mol dm^{-3}.

Table 5. Comparison of Values for Partial Molar Volumes with those from Empirical Formula

I^-	40.7	41.1	42.0	42.4

that of Conway et al.[18] The coincidence is fairly good on the whole.

Concerning the temperature dependence of partial molar volumes of ions at infinite dilution, the values for univalent ions at various temperatures are given in Table 6, where the accuracy of those is ±0.3 cm^3 mol^{-1} throughout all the temperature range observed. As seen in the table, the values for alkali metal ions except for Li^+ are clearly observed to increase with increasing temperature as well as those for H^+, while those for Li^+ and Cl^- are held to be nearly constant in this temperature range. For other halide ions, Br^- and I^-, the values increase very slowly with increase of temperature.

(Received April 22, 1989)

Distribution constant ($K_{D,L}$) of 16-crown-5 (16C5) and overall extraction equilibrium constants (K_{ex}) of uni- and bivalent metal picrates with 16C5 were determined between benzene and water at 25 °C. The K_{ex} values were analyzed by four fundamental equilibria, extraction constant of picric acid, $K_{D,L}$, formation constant in water and ion-pair extraction constant ($K_{ex,ip}$) with a picrate ion of the 16C5-metal ion complex. The K_{ex} value of 16C5 for the uni- and bivalent metal ions decreases in the order $Ag^+ > Na^+ > Tl^+ > K^+ > Rb^+ > Cs^+ > Li^+$ and $Pb^{2+} > Ba^{2+} \geq Sr^{2+} > Ca^{2+}$, respectively. Size-fit relationship holds for extraction-selectivity of 16C5 toward alkali metal ions, but it does not hold for that toward alkaline earth metal ions. Factors influencing extractability and extraction-selectivity of 16C5 for metal ions were discussed from the viewpoint of molecular grounds. $K_{ex,ip}$ value of 16C5 varies with a cation of the same charge held in the cavity. $K_{ex,ip}$ values of 16C5-metal picrate complexes were compared with those of 15-crown-5-metal picrate complexes. Various effects on ion-pair extractability of a 16C5-metal ion complex with a picrate anion were explained.

16-Crown-5 (16C5) and 15-crown-5 (15C5) have the same number of donor oxygen atoms. However, 15C5 has a symmetrical structure, whereas 16C5 has a less symmetrical structure, which is caused by an introduction of an extra methylene group into the 15C5 ring. It has been reported that 16C5 shows much higher selectivity for Na^+ among alkali metal ions than 15C5 in both homogeneous[1] and liquid-liquid extraction systems.[2] The higher selectivity of 16C5 for Na^+ was explained in terms of cavity size and orientation of the donor oxygen atoms through examination of CPK molecular models; namely, Na^+ is better accommodated in the cavity of 16C5 than in the cavity of 15C5, and the donor oxygen atoms of 16C5 arrange more nicely around Na^+ compared with 15C5.

In this study, in order to clarify the role of 16C5 in the metal ion-extraction process, overall extraction equilibrium constants of uni- and bivalent metal picrates with 16C5 were determined between benzene and water at 25 °C and analyzed by four constituent equilibria. The data on 16C5 were compared in detail with those of 15C5.

Experimental

Materials. The preparation of 16C5 was just the same as that described in the previous paper.[2a] Benzene, picric acid, $LiOH \cdot H_2O$, NaOH, KOH, $AgNO_3$, $TlNO_3$, $Mg(NO_3)_2 \cdot 6H_2O$, $Ca(NO_3)_2 \cdot 4H_2O$, $Sr(OH)_2 \cdot 8H_2O$, $Ba(OH)_2 \cdot 8H_2O$, and $Pb(NO_3)_2$ were analytical-grade reagents. Rubidium and caesium hydroxides were reagent-grade. Benzene was washed three times with distilled water. The purities of $AgNO_3$ and the other nitrates were determined by KCl and EDTA titrations, respectively. The concentrations of solutions of the hydroxides and picric acid were determined by neutralization titration.

The experimental procedures were almost the same as those described in previous papers.[3,4] Extractions were conducted at 25±0.2 °C. Concentrations of 16C5, metal salts, and picric acid were 2.8×10^{-5}—7.9×10^{-2} M (1 M= 1 mol dm^{-3}), 4.1×10^{-3}—1.8×10^{-1} M, and 3.3×10^{-3}—1.1×10^{-2} M, respectively. For nitrate and Cs systems, the extractions were carried out at pH 2.2—2.9. For all the other systems, the extractions were performed at pH 6.8—12.1.§ Concentrations of extracted Li, Na, K, Sr, and Ba were determined by a UV-spectrophotometer; those of extracted Rb, Cs, Ag, Tl, Ca, and Pb were determined by an atomic absorption spectrophotometer. It was impossible to extract any Mg into the benzene phase.

The Distribution Coefficient of 16C5. A 13 ml benzene solution of 16C5 (2.6×10^{-5}—1.5×10^{-3} M) and an equal volume of distilled water in a stoppered glass tube (volume 30 ml) were shaken in a thermostated water bath at 25± 0.2 °C for 2 h and centrifuged. A portion 12 ml of the benzene phase and an equal volume of an aqueous solution (pH 10.7—11.3) containing NaOH (1.1×10^{-1} M) and picric acid (1.0×10^{-1} M) were placed in a stoppered glass tube (No. 1), agitated, and centrifuged. A portion ($12-2n$) ml of the aqueous phase in the stoppered glass tube (No. n) and an equal volume of benzene were placed in a stoppered glass tube (No. $(n+1)$), shaken, and centrifuged. This procedure was repeated until $n=4$. The picrate in the benzene phase in the stoppered glass tube (No. n) was back-extracted into ($12-2n$) ml of 0.01 M NaOH aqueous solution (volume ratio 1:1), and the picrate concentration was determined spectrophotometrically ($\lambda_{max}=356$ nm, $\varepsilon=1.45\times10^4$ cm^{-1} M^{-1}). This procedure was repeated until $n=5$. The total concentration of the extracted 16C5-sodium picrate complex in a series of these extractions was calculated. The total concentration of the extracted 16C5 complex was assumed to be equal to the concentration of 16C5 which distributed itself into the 13 ml benzene phase. The distribution coefficient value of 16C5 is 0.397±0.004, which is the average of 22 measurements.

Results

In an equilibrium between a benzene solution of a

§ These experiments were designed to study extraction of a 1:1 16C5:metal ion complex with a picrate ion.

crown ether (L) and an aqueous solution of a metal ion (M^{m+}) and a picrate ion (A^-), the equilibrium constants are defined as

$$K_{ex} = [MLA_m]_o[H^+]^m/[M^{m+}][L]_o[HA]_o^m, \quad (1)$$

$$K_{D,L} = [L]_o/[L], \quad (2)$$

$$K_{ex}(HA) = [HA]_o/[H^+][A^-], \quad (3)$$

$$K_{ML} = [ML^{m+}]/[M^{m+}][L], \quad (4)$$

$$K_{ex,ip} = [MLA_m]_o/[ML^{m+}][A^-]^m, \quad (5)$$

where the subscript "o" and the lack of subscript denote the organic and the aqueous phase, respectively. The overall extraction equilibrium constant (K_{ex}) can be written as

$$K_{ex} = K_{ML}K_{ex,ip}K_{D,L}^{-1}K_{ex}(HA)^{-m}. \quad (6)$$

The distribution ratio of the metal is represented by

$$D = [MLA_m]_o/([M^{m+}] + [ML^{m+}]). \quad (7)$$

In the case of $[M^{m+}] \gg [ML^{m+}]$, Eq. 7 is transformed into

$$D = K_{ex}K_{ex}(HA)^m[L]_o[A^-]^m. \quad (8)$$

For the univalent metal ion system, $\log(D/[A^-])$ vs. $\log[L]_o$ plot in Fig. 1 shows a straight line with a slope of 1 in every case. This indicates that 16C5 forms a 1:1 complex with the univalent metal ion. For the bivalent metal ion system, $\log(D/[A^-]^2)$ vs. $\log[L]_o$ plot in Fig. 2 always shows a line with a slope of 1. This indicates that 16C5 forms a 1:1 complex with the bivalent metal ion.

From the mass balances, $[L]_o$, $[M^{m+}]$, and $[HA]_o$ are given by

$$[L]_o = ([L]_t - [MLA_m]_o)/(\alpha + \beta[M^{m+}]), \quad (9)$$

$$[M^{m+}] = ([M]_t - [MLA_m]_o)/(1 + \beta[L]_o), \quad (10)$$

$$[HA]_o = ([HA]_t - m[MLA_m]_o)/\{1 + ([H^+]^{-1} + K_{HA})K_{ex}(HA)^{-1}\}, \quad (11)$$

where the subscript "t" denotes the total concentration, $\alpha = 1 + K_{D,L}^{-1}$, and $\beta = K_{ML}K_{D,L}^{-1}$. For all the systems except for the cases of Li^+, Rb^+, Cs^+, and Ca^{2+}, K_{ex} values were determined by using $[L]_o$ values of Eq. 9, $[M^{m+}]$ values of Eq. 10, and $[HA]_o$ values of Eq. 11; for the Li^+, Rb^+, Cs^+, and Ca^{2+} systems, K_{ex} values were determined, neglecting the terms, $\beta[M^{m+}]$ of Eq. 9 and $\beta[L]_o$ of Eq. 10. Values of $K_{ex}(HA)$ and K_{HA} at 25 °C are 247[3] and 1.9$_5$,[5] respectively, where K_{HA} is an association constant of picric acid in water and $K_{HA} = [HA]/[H^+][A^-]$. Equilibrium constants are summarized in Table 1.

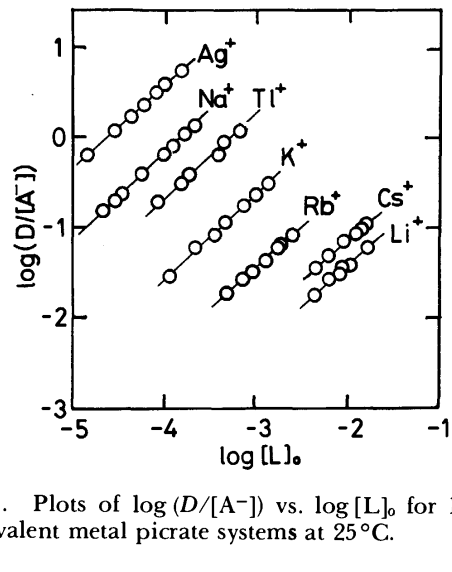

Fig. 1. Plots of $\log(D/[A^-])$ vs. $\log[L]_o$ for 16C5–univalent metal picrate systems at 25 °C.

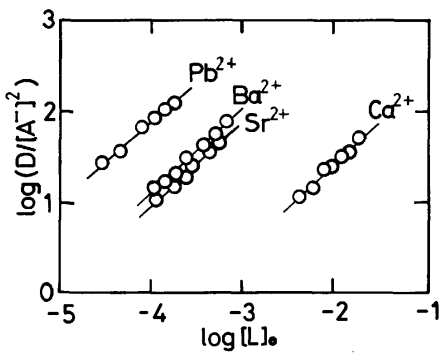

Fig. 2. Plots of $\log(D/[A^-]^2)$ vs. $\log[L]_o$ for 16C5–bivalent metal picrate systems at 25 °C.

Discussion

$\log K_{D,L}$ values at 25 °C of 12-crown-4 (12C4), 15C5, and 18-crown-6 (18C6) between benzene and water are −0.82,[8] -0.80_6,[3,4] and -1.19_8,[3,4] respectively. From $\log K_{D,L}$ values of 12C4, 15C5, 18C6, and 16C5, the contribution of an ether oxygen atom to $\log K_{D,L}$ (Π_o) at 25 °C between benzene and water can be evaluated by using the Π_{CH_2} value (0.48_5[9]), where Π_{CH_2} is the contribution of a methylene group to extraction constants of ion pairs of tetraalkylammonium ions with picrate anions at 25 °C between benzene and water; namely, $\Pi_o = (\log K_{D,L} - \Pi_{CH_2} \times a)/b$, a and b denoting the number of methylene groups and ether oxygen atoms, respectively. Π_o values are −1.17, -1.13_1, -1.16_9, and −1.147 for 12C4, 15C5, 18C6, and 16C5, respectively. They are nearly equal. The Π_o value is −1.15 on the average. From these empirical parameters, the $\log K_{D,L}$ value of 16C5 at 25 °C between benzene and water can be estimated to be -0.41_5. This is in accord with the experimental $\log K_{D,L}$ value of 16C5 (-0.401 ± 0.004).

The difference in $\log K_{D,L}$ values between 16C5 and

a) R. D. Shannon and C. T. Prewitt, *Acta Crystallogr., Sect. B*, **25**, 925 (1969).

15C5 corresponds to Π_{CH_2}. It is interesting that the difference (0.40[5]) between the two neutral crown ethers is consistent with the Π_{CH_2} value (0.48[5]) determined by ion-pair extraction constants of tetraalkylammonium picrates.

Table 1 shows that $\log K_{ex}$ value of 16C5 for the univalent metal ions decreases in the order $Ag^+>Na^+>Tl^+>K^+>Rb^+>Cs^+>Li^+$. This indicates that, for the alkali metal ions, the more closely the metal ion fits into the 16C5 cavity (cavity radius 0.9 Å[1]), the more extractable the 16C5-metal ion complex is (size-fit concept); Ag^+, which has a more favorable size for the 16C5 cavity than Tl^+, is more extractable with 16C5 than Tl^+. The $\log K_{ex}$-value sequence of 16C5 for the univalent metal ions is identical with that of 15C5. However, 16C5 shows higher extraction selectivity for Ag^+ and Na^+ than for the other univalent metal ions, compared with 15C5; furthermore, extraction selectivity of 16C5 is higher for Ag^+ than for Na^+, compared with 15C5. For univalent metals M_1 and M_2, and crown ethers L_1 and L_2, $\Delta(\Delta\log K_{ex}(M_1-M_2))(L_1-L_2)$, $\Delta(\Delta\log K_{ML}(M_1-M_2))(L_1-L_2)$, and $\Delta(\Delta\log K_{ex,ip}(M_1-M_2))(L_1-L_2)$ are defined as follows; $\Delta(\Delta\log K_{ex}(M_1-M_2))(L_1-L_2)=(\Delta\log K_{ex}(M_1-M_2))_{L_1}-(\Delta\log K_{ex}(M_1-M_2))_{L_2}$, where $(\Delta\log K_{ex}(M_1-M_2))_L=(\log K_{ex}(M_1))_L-(\log K_{ex}(M_2))_L=(\Delta\log K_{ML}(M_1-M_2))_L+(\Delta\log K_{ex,ip}(M_1-M_2))_L$, where $(\Delta\log K_{ML}(M_1-M_2))_L=\log K_{M_1L}-\log K_{M_2L}$ and $(\Delta\log K_{ex,ip}(M_1-M_2))_L=(\log K_{ex,ip}(M_1))_L-(\log K_{ex,ip}(M_2))_L$, where $(\log K_{ex}(M))_L$ and $(\log K_{ex,ip}(M))_L$ are $\log K_{ex}$ and $\log K_{ex,ip}$ of a L-MA complex, respectively. $\Delta(\Delta\log K_{ML}(M_1-M_2))(L_1-L_2)=(\Delta\log K_{ML}(M_1-M_2))_{L_1}-(\Delta\log K_{ML}(M_1-M_2))_{L_2}$. $\Delta(\Delta\log K_{ex,ip}(M_1-M_2))(L_1-L_2)=(\Delta\log K_{ex,ip}(M_1-M_2))_{L_1}-(\Delta\log K_{ex,ip}(M_1-M_2))_{L_2}$. Thus, $\Delta(\Delta\log K_{ex}(M_1-M_2))(L_1-L_2)=\Delta(\Delta\log K_{ML}(M_1-M_2))(L_1-L_2)+\Delta(\Delta\log K_{ex,ip}(M_1-M_2))(L_1-L_2)$. Both positive $\Delta(\Delta\log K_{ML}(Ag-Na))(16C5-15C5)$ and $\Delta(\Delta\log K_{ex,ip}(Ag-Na))(16C5-15C5)$ values are responsible for higher extraction selectivity of 16C5 for Ag^+ than for Na^+, compared with 15C5.§§ 16-Crown-5 shows higher extraction selectivity for Ag^+ or Na^+ than for Tl^+ and K^+ in comparison with 15C5. This is attributed to the fact that, although $\Delta(\Delta\log K_{ex,ip}(M_1-M_2))(L_1-L_2)$ value is negative, $\Delta(\Delta\log K_{ML}(M_1-M_2))(L_1-L_2)$ value is positive and $\Delta(\Delta\log K_{ML}(M_1-M_2))(L_1-L_2)$ is larger than $|\Delta(\Delta\log K_{ex,ip}(M_1-M_2))(L_1-L_2)|$ (M_1=Ag or Na; M_2=Tl or K; L_1=16C5 and L_2=15C5). From the above discussion, it can be concluded that higher extraction selectivity of 16C5 for Ag^+ than for Na^+, Tl^+, and K^+ and that for Na^+ than for Tl^+ and K^+ in comparison with 15C5 are dependent on higher selectivity in water of 16C5 for Ag^+ than for Na^+, Tl^+, and K^+ and that for Na^+ than for Tl^+ and K^+, compared with 15C5, respectively.

$\log K_{ex}$-, $\log K_{ML}$-, and $\log K_{ex,ip}$-value sequences of 16C5 for Na^+, K^+, Ag^+, and Tl^+ are identical ($Ag^+>Na^+>Tl^+>K^+$), whereas it does not hold for

§§ Detailed explanations are as follows. The difference in $\log K_{ML}$ values of 16C5 between Ag^+ and Na^+ (0.32) is larger than the corresponding difference of 15C5 (0.24). The difference in $\log K_{ex,ip}$ values of 16C5 between Ag^+ and Na^+ (0.45) is larger than the corresponding difference of 15C5 (0.31). These two positive contributions are responsible for the fact that the difference in $\log K_{ex}$ values of 16C5 between Ag^+ and Na^+ (0.761) is larger than the corresponding difference of 15C5 (0.55).

15C5.

For a given metal ion, the following relationship can be derived from Eq. 6;

$$\log\{K_{ex}(L_1)/K_{ex}(L_2)\} = \log(K_{ML_1}/K_{ML_2}) + \log\{K_{ex,ip}(L_1)/K_{ex,ip}(L_2)\} - \log(K_{D,L_1}/K_{D,L_2}). \quad (12)$$

16-Crown-5 shows lower extractability for the univalent metal ion except for Ag^+ than does 15C5 (Table 1). For Na^+, K^+, and Tl^+, this is ascribed to the fact log $(K_{D,L_1}/K_{D,L_2})$>log (K_{ML_1}/K_{ML_2})+log $\{K_{ex,ip}(L_1)/K_{ex,ip}(L_2)\}$; greater extractability of 16C5 for Ag^+ than that of 15C5 is attributable to the fact that log $\{K_{ex,ip}(L_1)/K_{ex,ip}(L_2)\}$>log $(K_{D,L_1}/K_{D,L_2})$ and the log (K_{ML_1}/K_{ML_2}) value is positive, where L_1=16C5 and L_2=15C5.

log K_{ex}-value sequences of 16C5 for the bivalent metal ions are $Pb^{2+}>Ba^{2+}\geq Sr^{2+}>Ca^{2+}$ (Table 1). The size-fit concept does not hold for the extractability of 16C5 for the alkaline earth metal ions. Although stability of the 16C5–Pb^{2+} complex in water is much lower than that of 16C5–Sr^{2+} and Ba^{2+} complexes, the 16C5–Pb^{2+} complex is the most extractable among all the 16C5–bivalent metal ion complexes. This is entirely due to much the largest log $K_{ex,ip}$ value of the 16C5–Pb^{2+} complex. log K_{ex}-value sequence of 16C5 for the bivalent metal ions except for Ba^{2+} is identical with that of 15C5. The value of $(\Delta\log K_{ML}(Sr-Ba))_L+(\Delta\log K_{ex,ip}(Sr-Ba))_L$ is negative when L=16C5 and positive when L=15C5, which are responsible for the slightly larger log K_{ex} value of Ba^{2+} of 16C5 than that of Sr^{2+} and the smaller log K_{ex} value of Ba^{2+} of 15C5 than that of Sr^{2+}, respectively.

Extractability of 16C5 for the bivalent metal ion is lower than that of 15C5. It can be seen from Table 1 and Eq. 12 that, for Sr^{2+}, Ba^{2+}, and Pb^{2+}, the term log $(K_{D,L_1}/K_{D,L_2})$ plays a very important role in the lower extractability of 16C5 compared with 15C5, where L_1=16C5 and L_2=15C5; namely, the smaller log K_{ex} value of 16C5 than that of 15C5 is largely or completely due to the higher lipophilicity of 16C5 compared with 15C5.

log $K_{ex,ip}$ value of 16C5 varies with a cation of the same charge (Table 1). The same trend is found for 15C5.

From Gibbs free energies of hydration ($\Delta G_h°$/kJ mol^{-1}) of Na^+ (−411.3) and K^+ (−338),[10] the interaction of Na^+ with water is much stronger than that of K^+. The interaction with water of Na^+ trapped in the 16C5 cavity is expected to be stronger than that of K^+. Association constant of Na^+ with a picrate ion in water is smaller than that of K^+.[11] Association constant with a picrate ion of Na^+ trapped in the 16C5 cavity is expected to be smaller than that of K^+. Hence, $K_{ex,ip}$ value of the Na^+–16C5 complex is anticipated to be smaller than that of the K^+ complex. However, $K_{ex,ip}$ value of 16C5 is larger for Na^+ than for K^+ (Table 1). From the structure of the 16C5 complex with the univalent metal ion trapped in the cavity, anion- and solvent-contact are possible in respective directions perpendicular to the plane of the 16C5 ring. Consequently, it is concluded from the above discussion that the larger $K_{ex,ip}$ value of the Na^+–16C5 complex than that of the K^+ complex is ascribed to negligible effect of water on association of the Na^+–16C5 complex with a picrate ion and/or weak interaction with water of the Na^+ complex. The same discussion holds for the cases of 15C5–Na^+ and –K^+ complexes. A Na^+ ion has a more suitable size for the 16C5 cavity than does a Ag^+ ion; $-\Delta G_h°$ of Ag^+ (479.1 kJ mol^{-1})[10] is larger than that of Na^+; but, $K_{ex,ip}$ value of 16C5 is greater for Ag^+ than for Na^+. The larger $K_{ex,ip}$ value of the Ag^+–16C5 complex may be attributed to the specific interaction with benzene of the Ag^+ ion[12] in the 16C5 complex and stronger association with a picrate ion and/or weaker interaction with water of the Ag^+ complex compared with the case of the Na^+ complex. The same discussion holds for the cases of 15C5–Na^+ and –Ag^+ complexes.

For a crown ether–bivalent metal ion complex, two picrate anion-contacts with the cation are possible in respective directions perpendicular to the plane of the ring. Sr^{2+} and Pb^{2+} are nearly equal in size and larger than the 16C5- and 15C5-cavity. Therefore, it can be considered that the size of the MLA_2 complex of Pb^{2+} is nearly equal to that of the corresponding MLA_2 complex of Sr^{2+}. $-\Delta G_h°$ values of Sr^{2+} (1447 kJ mol^{-1})[10] and Pb^{2+} (1497 kJ mol^{-1})[10] are almost the same. However, in each case of 16C5 and 15C5, $K_{ex,ip}$ is greater for Pb^{2+} than for Sr^{2+}. This is probably attributable to stronger interaction with the two picrate anions of the Pb^{2+} complex compared with the corresponding Sr^{2+} complex.

From Table 1, $K_{ex,ip}$ value of a univalent metal ion increases with an increase in the size of crown ether (15C5<16C5); but, it is not always true for the cases of the bivalent metal ions. The difference in log $K_{ex,ip}$ values of a univalent metal ion between 16C5 and 15C5 is 0.28—0.59, which is roughly constant. This indicates that an increment of log $K_{ex,ip}$ value per a methylene group is about 0.44 (on the average), which is nearly equal to the Π_{CH_2} value (0.48_5). $K_{ex,ip}$ consists of two fundamental equilibria, namely, $K_{ex,ip}=K_{MLA}K_{D,MLA}$ ($K_{MLA}=[MLA]/[ML^+][A^-]$, $K_{D,MLA}=[MLA]_o/[MLA]$). Since $K_{D,MLA}$ is a partition constant of a neutral complex MLA between benzene and water, an increment of log $K_{D,MLA}$ per a methylene group is evaluated to be about 0.49 on the basis of Π_{CH_2} value (0.48_5). It thus appears from the above discussion that log K_{MLA} values of 16C5 and 15C5 complexes with the same univalent metal ion are roughly equal.

Since MLA_2 is a neutral complex, the K_{D,MLA_2} value probably increases with an increase in the size of the crown ether (15C5<16C5), where $K_{D,MLA_2}=[MLA_2]_o/[MLA_2]$. The differences in log $K_{ex,ip}$ values between

16C5 and 15C5 for Pb^{2+} and Ba^{2+} are larger than and are comparable to the Π_{CH_2} value, respectively. This indicates that K_{MLA_2} values of 16C5 for Pb^{2+} and Ba^{2+} are greater than and roughly equal to those of 15C5, respectively, where $K_{MLA_2}=[MLA_2]/[ML^{2+}][A^-]^2$. Whereas, the log $K_{ex,ip}$ value of the 16C5–Sr^{2+} complex is smaller than that of the 15C5–Sr^{2+} complex. This indicates that the K_{MLA_2} value of the 16C5 complex is much smaller than that of the 15C5 complex.

For 15C5, log $K_{ex,ip}$ value of Sr^{2+} is larger than that of Ba^{2+}; but, the reverse is found for 16C5. It seems that, in each case of 16C5 and 15C5, the MLA_2 complexes of Sr^{2+} and Ba^{2+} are almost the same in size. Therefore, K_{D,MLA_2} values of Sr^{2+} and Ba^{2+} of the same crown ether can be expected to be nearly equal. It thus appears that the K_{MLA_2} value of Sr^{2+} for 15C5 is greater than that of Ba^{2+}, whereas the reverse is true for 16C5, which is caused by an extra methylene group in the 16C5 ring.

We thank Mr. Masanao Nagamori of this laboratory for his experimental assistance.

(Received April 27, 1989)

A simple, rugged home-built scanning tunneling microscope for operation in both air and liquid that uses a Z-stage micrometer to provide coarse mechanical positioning is described. The construction of this STM was accomplished at low cost without precision machining. The tunneling current is typically acquired within 10—15 minutes. The atomic resolving power of our STM has been demonstrated by a cleaved HOPG at a 15-Hz scanning rate in air. There was no use of plate-stack-type isolators, due to the high rigidness of the tunneling unit. The STM image of a HOPG in ultrapure water was also observed with a glass-coated tip. Images of a pc-Ag electrode in 0.1 mol dm^{-3} KCl demonstrate stable operation in a liquid solution. The lateral drift was shown to be less than 0.13 nm min^{-1} for operation in liquid, estimated by subsequent imaging of the same area. This STM is easy to handle and has a suitable design for in situ electrode surface characterization.

Scanning tunneling microscope (STM) and associated techniques are beginning to be incorporated into the field of electrochemistry. To date, surface chemistry is poorly understood on account of the limited measuring conditions and resolving power of available tools. The currently developing scanning tunneling microscope is a suitable instrument for investigating the surfaces of conducting materials at the nanometer scale under various environments.[1] A number of designs for scanning tunneling microscopes (STMs) have been published since the pioneering work of Binnig and Rohrer.[2] Among them, Sonnenfeld and Hansma[3] have demonstrated that STM could be used to study surfaces immersed in liquid solutions. The investigations of Hansma's group have opened up the field for in situ observations of surface structures at the solid/liquid interface.[4] Bard et al.,[5] Arvia et al.,[6] and Itaya et al.[7] were the first groups to apply the STM in the field of electrochemistry. Considerable attention has recently been focused on in situ observations.[8] To apply STM to the particular interests of electrochemistry, suitable STM needs to be constructed. Much effort has been expended on ingenious designs of STM. However, the construction of our STM was accomplished at low cost without precision machining. Here, we present the design of a simple, rugged home-built STM for operation in both air and liquid. It has a suitable design for studying electrochemical processes in situ. The emphasis of this paper is on the STM itself.

Experimental

Tunnel Unit Design. The basic principle for construction of a tunneling unit is simplicity and rigidness. Figure 1 shows a schematic illustration of our tunneling unit. The unit comprises essentially two main parts. The lower part is a high-precision, vertical-translation Z-stage (Σ-303-(2), Sigmakohki Co., Ltd., Japan) and a four-legged piezoactuator (Fuji Ceramics, Co., Ltd., Japan) which is attached to a motionless part of the Z-stage. The upper part is a tripod scanner fixed inside a stainless-steel enclosure which is rigidly screwed to the stage. At the top of the unit, a current-sensitive preamplifier is installed so as to decrease electronic noise. Our unit has several advantages: (1) no precision machining is required, (2) unit fabrication can be accomplished at low cost, (3) exchanging both the tip and the sample is facile, (4) different areas can be observed by sliding the enclosure across the stage, and (5) for operation in liquid, the tip approaches the vertical direction from above the sample.

Tunneling Tip and Sample Setting. Commercially available Pt-Ir tips with a diameter 250 μm (Longreach Scientific Resources Co., Ltd., USA) were used. This type tip was slightly bent and mounted within a steatite tip holder by inserting it into a steel tube made from a hypodermic needle. A sample is attached with silver paint to

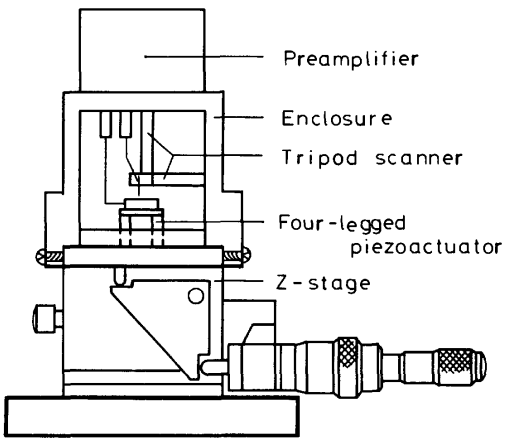

Fig. 1. A schematic cross-sectional view of the tunnel unit.

quartz glass which is glued with epoxy to the top of a four-legged piezoactuator.

Coarse and Fine Adjustment. The Z-stage micrometer with a 0.5 μm resolution provides a simple coarse adjustment mechanism that brings the tip into the operating range of the four-legged piezoactuator, while being observed by an optical microscope of 100 magnification. After coarse positioning the tip mechanically with the Z-stage micrometer from the sample, the Z-stage is clamped by a screw so as to prevent any backlash. The tunneling current is automatically detected by raising the sample under the control of the four-legged piezoactuator in connection with a personal computer (PC98VX4, NEC, Japan) while operating a feedback control of the Z-piezoactuator. The four-legged piezoactuator provides displacements from −2.0 μm to +2.0 μm by a stable dc voltage source (M107, Systron Donner, USA) with an accuracy of 0.002%. The feedback voltage applied to the Z-piezoactuator is in the range between +250 V to −250 V, determined by the feedback gain. The full voltage range of the feedback response of the Z-piezoactuator corresponds to a tip motion of 1.0 μm. The tunneling current is typically acquired within 10—15 minutes without crashing the tip into the sample; no additional precision mechanisms are employed.

3-Dimension Scanning. Prototype tripod piezoelectric actuators (three orthogonal piezoelectric rods) are being used for a 3-dimensional scanner. *X*, *Y*, and *Z* PZT-piezoelectric arms ((C-8), Fuji ceramics Co., Ltd., Japan) have the same characteristics with a resonance frequency of 140 kHz, an electrostatic capacity of 180 pF, and a curie temperature of 210 °C. The three (*X*, *Y*, *Z*) piezoelectric arms are attached to a steatite ($MgO \cdot SiO_2$) tip holder with epoxy. Calibration of the piezoelectric sensitivity is performed by the STM image of a highly oriented pyrolytic graphite (HOPG), as described later. Its sensitivity is 2.0 nm V^{-1}.

Vibration Isolation. Vibration isolation is provided by an air-suspension table with a resonance frequency of 1.8 and 2 Hz in the vertical and horizontal directions, respectively. The suitability of vibration isolation for our STM operation was checked with the cooperation of Meiritsuseiki Co., Ltd., Japan using an FFT analyser. A 15-kg circular weight is located on the air-suspension table; the tunneling unit sits on top of it. Neither a plate-stack type isolator nor a coil-spring type isolator was necessary, due to the high rigidness of the tunneling unit. The unit was installed in a shield box in order to avoid any acoustic or electronic noise.

Electronics. Figure 2 shows a block diagram of the electronic setup of STM and tunneling spectroscopy. Our electronic setup differs from the commonly used types mainly regarding three aspects: (1) the sample is a ground for all the electronics, (2) the tunneling bias is applied to the tip, and (3) the tunneling current is detected from the tip. The scanning rate in the X-direction can be changed from 0.1 Hz to 100 Hz by a function generator (FG-143, NF Electronic Instruments INC., Japan). A ramp generator was used for Y-scanning. Our STM is operated in an analog mode and images are monitored on a storage oscilloscope. It also has a computerized arrangement for tunneling spectroscopy, using a feedback hold mode at a point (Fig. 2). The tunneling current and bias are monitored by two transient memories (S210, Autonics, Japan); each is averaged by an averager (F601, Autonics, Japan). The digital data is transferred to a personal computer and can be calculated numerically. The surface density of states of a TiO_2(110) single crystal obtained by tunneling spectroscopy using our STM setup is discussed elsewhere.[9]

Sample. As a standard sample for STM study,[10] a cleaved HOPG single crystal (Nippon Carbon, Co., Ltd., Japan) was used to examine the resolving power of our STM.

Results and Discussion

STM Images in Air. In Figs. 3(a) and (c) we display images of a HOPG in air at a frequency of 5 and 15 Hz in the *X*-direction, respectively. These images were taken with a constant current mode over an area of 1.4×1.4 nm^2. The tunneling bias and current were set at +10 mV (tip positive) and 1 nA, respectively. The STM image (Fig. 3(a)) shows the atomic structure of graphite. It coincides with the surface crystallographic structure[11] in the same area depicted in Fig. 3(b). The geometrical configuration of the carbon atoms of graphite have three sites (Fig. 3(b)). At site A (●) the atoms in the two uppermost layers are atop. At site B (●) there is only an atom in the upper layer; at site C (○) the atom is only in the underneath layer.[10,11] The STM images in Figs. 3(a) and (c) show the atomic configuration of B site of graphite.[12] Therefore, our STM has a resolving power better than 0.25 nm in the lateral direction and 0.10 nm in the vertical direction, respectively. The STM has an atomic resolving power at a high X scanning rate (15 Hz) due to the rigidness of the tunneling unit (Fig. 3(c)). The time required for imaging was only 5 seconds. To observe the atomic corrugation, the rigid setting of the tunneling tip was a dominant factor. It is noteworthy that any dust attached to the tip of the needle or a sample can be stripped by flowing N_2 before imaging. We also in-

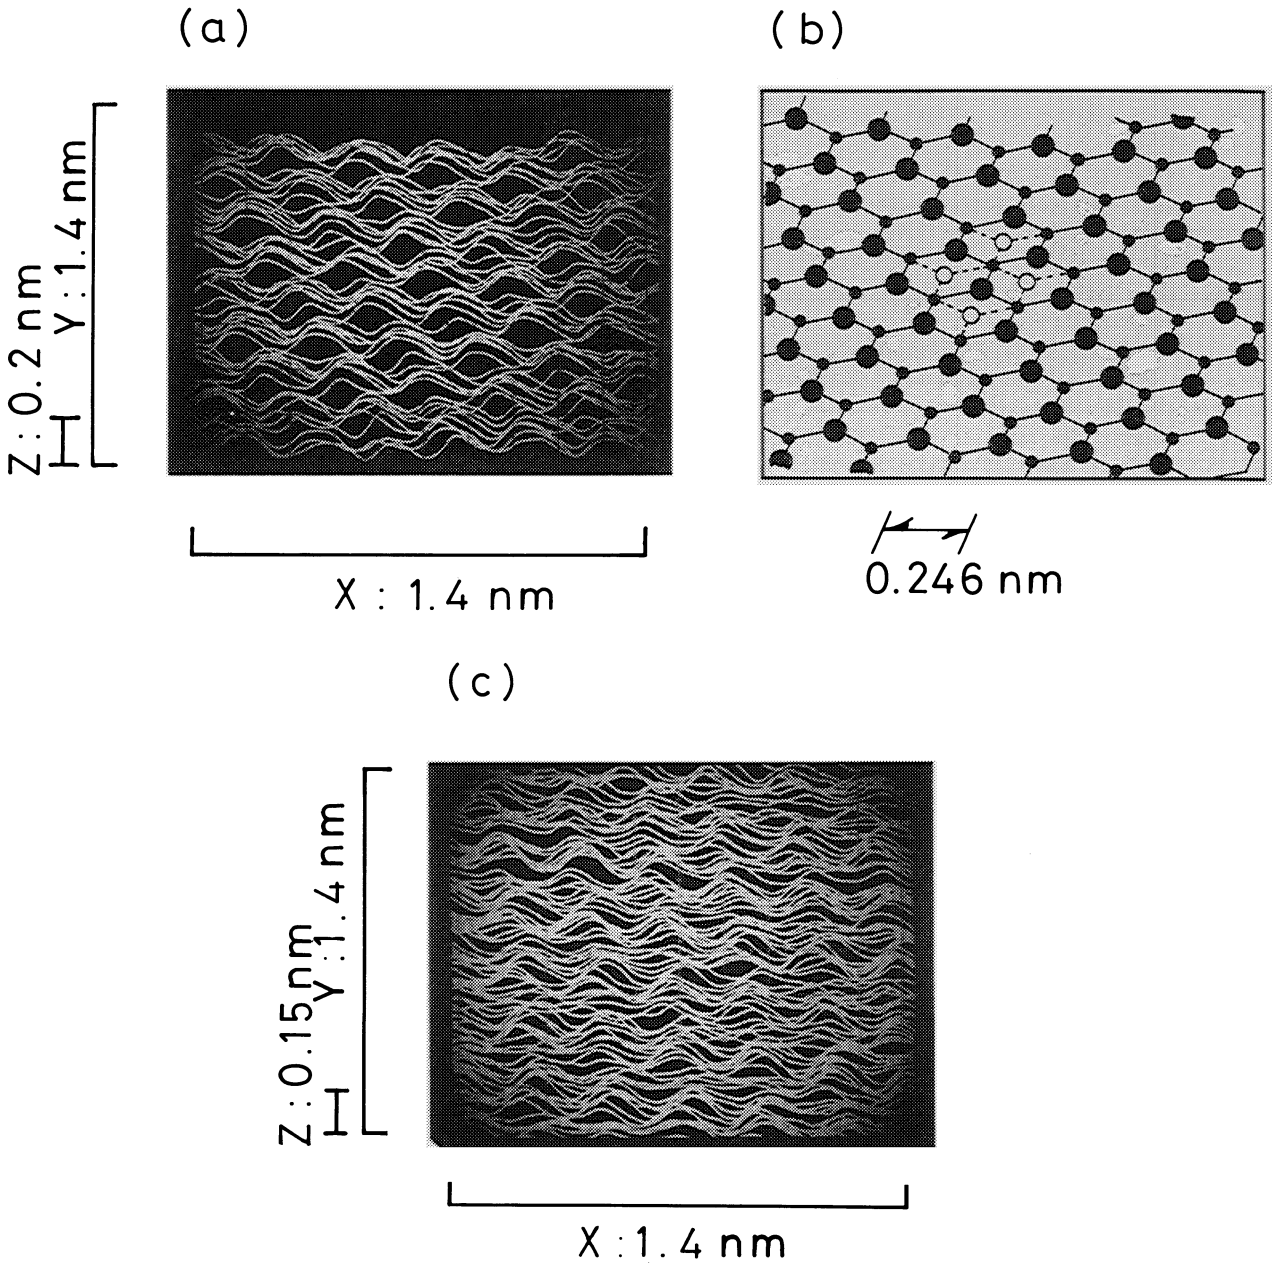

Fig. 3. Constant current images of a HOPG in air observed at a frequency of 5 Hz (a) and 15 Hz (c), respectively. Measuring conditions (1 nA, +10 mV (tip positive)). (b) is the surface crystallographic structure of graphite. A, B and C site are denoted •, ●, and ○, respectively.

vestigated the surface morphology of a polycrysalline (pc-) Ag (99.88%, The Japan Lamp Industies Co., Ltd.) in air. It is difficult to mechanically polish a soft metal like Ag with a SiO_2 powder because the SiO_2 abrasive sticks to the surface. In this work mechanical polishing was accomplished with wet lapping films containing alumina powder (9, 3, 1, 0.3 μm grain size) using Newdaiyalap (ML-451) with the cooperation of Maruto Co., Ltd., Japan. Figures 4(a) and (b) are STM images of pc-Ag in air at ambient pressure. Figure 4(b) was obtained by sliding the enclosure across the Z-stage after the observation of Fig. 4(a). A shallow surface was captured in the STM image (Fig. 4(a)); the surface was nearly flat over an area of $25 \times 20\ nm^2$. At different regions of the same sample (Fig. 4(b)), a 2-nm step as well as a tableland structure can be seen. Under air and ambient pressure, our STM draws the same profile of the surface during about 20 minutes.

STM Images in Liquids. To test the operation

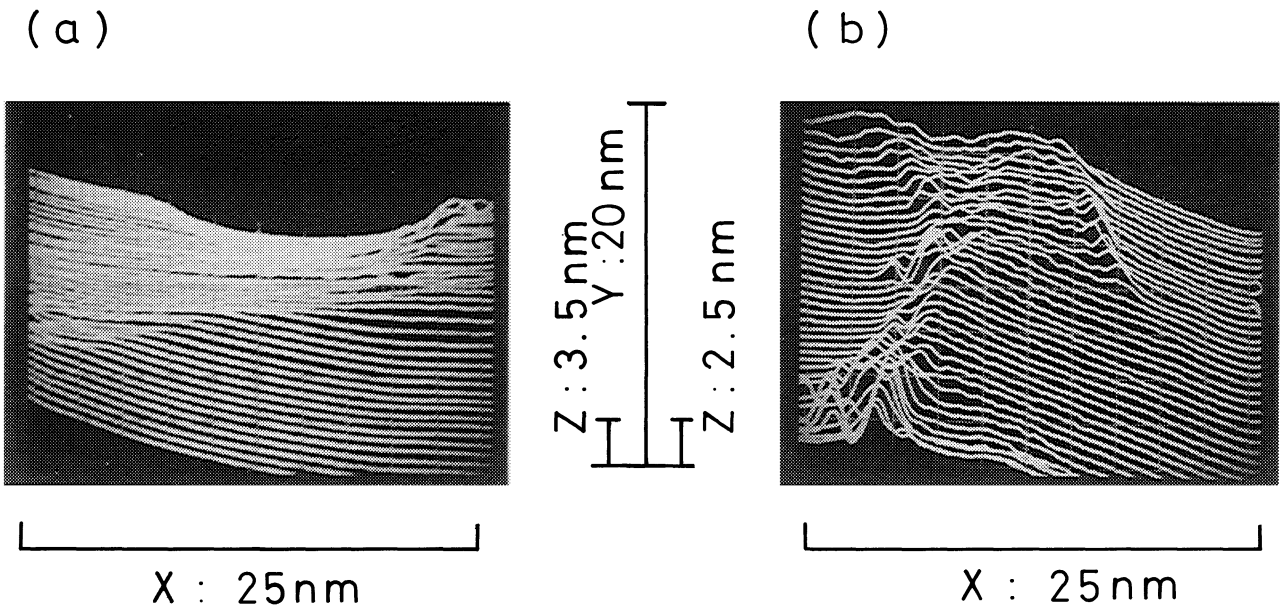

Fig. 4. STM images of a mechanically polished pc-Ag electrode in air. Measuring conditions 1 nA, +200 mV (tip positive), scan rate: 2 Hz). (a) and (b) were observed at different area.

in liquid we examined the HOPG sample in ultrapure water (UHQ, ELGA). Glass-coated Pt–Ir tips (Longreach Scientific Resources, USA) were used for measurements in liquid solutions. The exposed tip areas were determined by an electrochemical method[13] with an oxidation-limiting current of 1 m mol dm^{-3} of ferrocene in acetonitrile containing 0.2 m mol dm^{-3} TBAP. The exposed areas ranged typically between about 80 and 2 μm^2.[14] The glass-coated tip was rinsed in concd H_2SO_4 for 1 hour and ultra-pure water before use. The cleaved HOPG plate (5 mm×5 mm×1 mm thick) was attached to a Cu plate with silver paint. The exposed area of the Cu plate was covered with epoxy. A Teflon sheet (10 mm×10 mm×4 mm thick) with a hole of 8 mm diameter was attached above sample with epoxy. After the cell was carefully rinsed in 0.1 mol dm^{-3} H_2SO_4 and ultra-pure water, it was set on the four-logged piezoactuator with silver paint. Figure 5 shows the STM image (constant current mode) of the HOPG in the area of 1.3×1.7 nm^2 in ultrapure water. The tunneling current and bias were set at 8 nA and +10 mV (tip positive), respectively. The *X* scan rate (0.35 Hz) was reduced compared to the measuring condition under air in order to avoid any sway of water during tip scanning. The atomic corrugation of the HOPG was slightly distorted. The main reason of this distortion is the surface tension of water. The grass-coated tip was pulled by this force in the direction to the sample surface. A firm setting of the glass-coated tip is necessary in order to gain a good STM image under liquid with respect to the measurements under air. Following the above experiment, we examined a

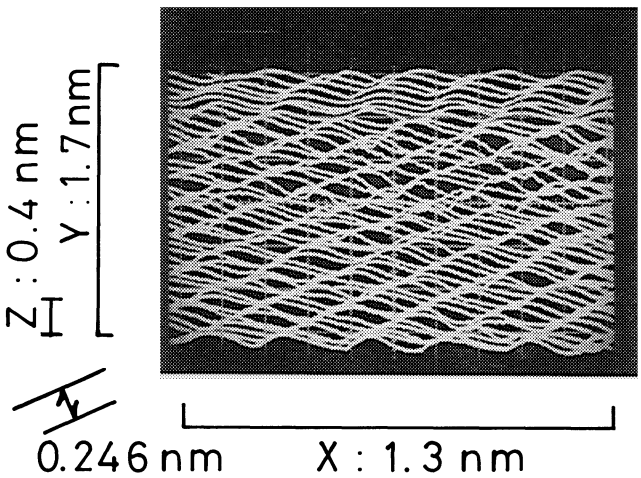

Fig. 5. STM image of a HOPG in ultra water. Measuring conditions (8 nA, +10 mV (tip positive), scan rate: 0.35 Hz).

pc-Ag surface in 0.1 mol dm^{-3} KCl. An Ag electrode cell was made with Teflon sheet. The cell was carefully rinsed in acetone and distilled water. Any electrochemical current was less than 100 pA in 0.1 mol dm^{-3} KCl and was suppressed by a factor of 50 under the tunneling current (5 nA) and the tunnel bias (+200 mV: tip positive). Figures 6(a) and (b) are STM images of a pc-Ag in 0.1 mol dm^{-3} KCl. Figure 6(b) was observed 10 minutes after the observation of Fig. 6(a). About a 2.5 nm "mountain range" structure in the top left-side and a small "hill" in the bottom right-side were found in both STM images. The long-term

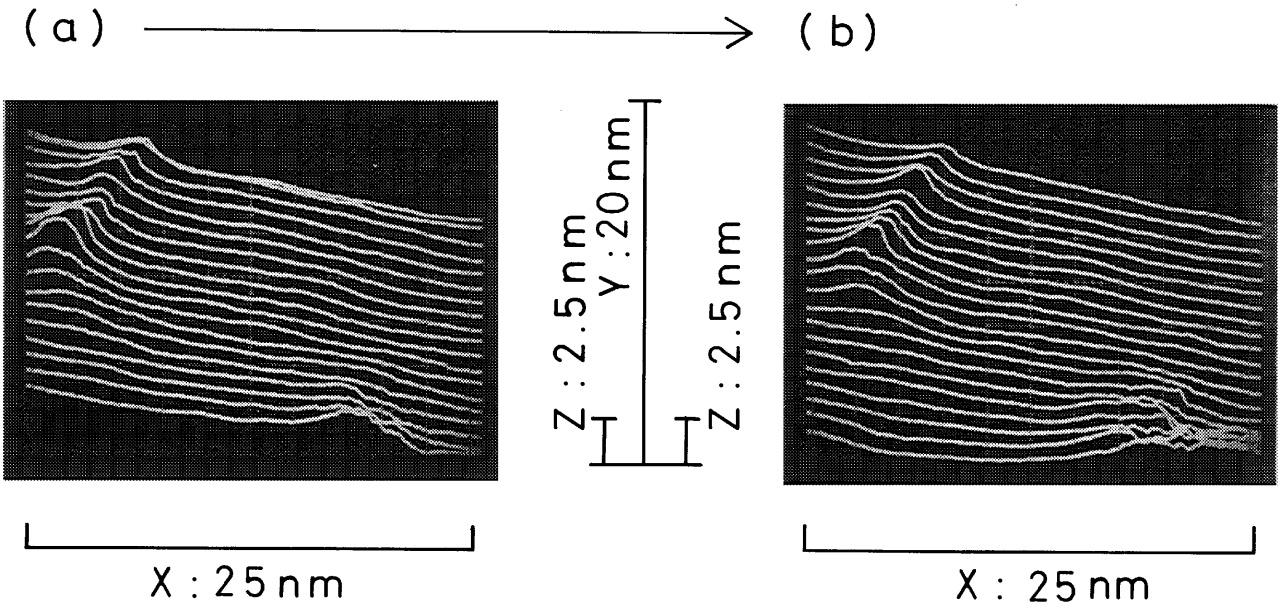

Fig. 6. STM images of a mechanically polished pc-Ag electrode in 0.1 mol dm^{-3} KCl. (b) was observed 10 minutes after the observation of (a). Measuring conditions (5 nA, +200 mV (tip positive), scan rate: 1 Hz).

stability of our STM in liquid is demonstrated as shown in Fig. 6. A lateral drift of less than ca. 0.13 nm min^{-1} in a salt water solution was estimated by subsequent imaging of the same area. For operation in liquid, it is necessary to rinse both the sample and the glass-coated tip carefully. In order to compare STM images observed in air and liquid, the following experiment was carried out. First, the surface of a pc-Ag electrode was imaged in air (Fig. 7(a)). After imaging in air, the tip was raised above the sample. A solution of 0.1 mol dm^{-3} KCl was carefully poured into the cell with Microsyringe (HAMILTON). The surface in the same area was then imaged in 0.1 mol dm^{-3} KCl (Fig. 7(b)). The X scan frequency of Figs. 7(a) and (b) were 2 and 1 Hz, respectively. The other measuring conditions were the same. A "mountain range" structure can be seen in both images (Figs. 7(a) and (b)). Both images draw the same surface profile, except for the offset. The appearance of a "hillock" in the top left-side in Fig. 7(b) was caused by drift when the liquid was poured into the cell. However, the "mountain range" in 0.1 mol dm^{-3} KCl (Fig. 7(b)) was higher than that in air (Fig. 7(a)) due to a current without a tunneling current. It seems that the more the exposed tip area is decreased, the greater does the resolving power of STM in the liquid solution increase. In addition, the large-area STM images of a pc-Ag have "island-like" structures.[15,16] The characterization of an electrochemically modified (ORC treatment) pc-Ag electrode with or without pyridine molecules in connection with surface-enhanced Raman scattering (SERS) has been discussed elsewhere.[15,16]

In conclusion, the rigid construction of an STM unit has demonstrated the atomic resolving power in both air and liquid solutions without additional precision mechanisms and careful vibration isolation. The STM is easy to handle and has a suitable design for in situ electrode surface characterization.

One part of this work was presented at the STM(II) meeting under Thin Film and Surface Physics of the Japan Society of Applied Physics, Dec., 12—14, 1988 at Atagawa, Japan.

One of the authors (K. S.) greatly acknowledges instructive discussions with Prof. Kingo Itaya (Tohoku Univ.) and Prof. Toshio Sakurai (Tokyo Univ.), and Prof. Osamu Nishikawa (Tokyo Institute of Technology) when he visited their laboratories. In addition, K. S. is grateful to Dr. Ichiro Otsuka (Tohoku Dental. Univ.) for useful discussions.

Racemization of Phenylalanine Coordinated to Bis(2,2′-bipyridine)-ruthenium(II) Complexes in Basic Aqueous Solutions

Takashi NAGAI
Laboratory of Chemistry, Nippon Medical School, Kosugi-chou, Nakahara-ku, Kawasaki 211
(Received January 31, 1989)

Racemization of the phenylalaninato ligand in Λ- and Δ-$[Ru(phe)(bpy)_2]^+$ (phe; phenylalaninate anion, bpy; 2,2′-bipyridine) complexes was found in basic aqueous solutions. It was proceeding without conformational change around the ruthenium ion in the dark. The equilibrium and rate constants of the racemization were determined in basic solutions at 100 °C. The reaction was base-catalyzed and not affected by photoexcitation of the complex ions.

The photochemical inversion of diastereoisomers of $[Ru(S\text{-am})(bpy)_2](ClO_4)_n$ (am; amino acidate anion) has been studied by Vagg et al.[1-5] They have reported that in aqueous solutions these complexes are photolabile and the inversion reaction around the metal ion occurs on irradiation of light. By contrast, these complexes are markedly stable in darkness: No inversion occurs even on boiling the complexes in aqueous solutions for a few hours. However, we found that the coordinated phenylalanine in $[Ru(phe)(bpy)_2]^+$ ion was gradually racemized in basic solutions in the dark. The rate and equilibrium constants of the racemization at 100 °C were determined by the use of the chromatographic method. Moreover, effects of photoexcitation of the complexes on the racemization were examined by light irradiation during the reaction.

Experimental

All materials used were of reagent grade, and used without further purification. The UV-visible spectra were obtained with a HITACHI 340 spectrophotometer. Circular dichroism (CD) spectra were obtained using a JASCO J-500 spectrophotometer.

Λ- and Δ-[Ru(*S*-phe)(bpy)$_2$]ClO$_4$ Hydrates. The mixture of Λ- and Δ-isomers was prepared and partially resolved by Vagg et al.[1,4] However, we prepared it by a different way and resolved it completely to obtain perchlorates of the Λ- and Δ-forms.

cis-$[Ru(CO_3)(bpy)_2]\cdot 3H_2O$[6] (1 g) was dissolved in 200 cm^3 of hot water, and (*S*)-phenylalanine (0.4 g) was added. The solution was stirred at 50 °C for 25 min in the dark. The deep-red solution was cooled, and then added on a short column (12.5 cm height×2.5 cm diameter) of SE-Toyopearl.[7] The adsorbed complexes were eluted with 0.2 mol dm^{-3} Na_2SO_4 to remove minor impurities. The main adsorption band was eluted, and the complexes in the eluate were precipitated by adding an excess of $NaClO_4$. The dark-red precipitate was filtered, washed with a small amount of water, and air-dried (yield 1.2 g).

The precipitate (0.7 g) was dissolved in 400 cm^3 of water, and placed on a column (56 cm height×2.6 cm diameter) of SE-Toyopearl. The adsorbed complex cations were washed with water and then eluted with 0.05 mol dm^{-3} sodium (*R*,*R*)-tartrate to develop two adsorption bands by the recycle chromatographic technique. The two bands were eluted separately, and each eluate was evaporated to about one-tenth of the initial volume by a rotary evaporator at about 40 °C, and then methanol was added to remove sodium (*R*,*R*)-tartrate. The filtrates were evaporated to take off the methanol, and dark-red crystals were precipitated by adding $NaClO_4$. The products were filtered off, washed with a small amount of water and dried under vacuum. All the above procedures were performed in the dark. The assignment of the absolute configuration of the complexes was determined by the sign of the peaks at about 290 nm of the CD spectrum in accordance with Vagg's report.[1] The products from the first and second adsorption bands were assigned to Δ- and Λ-isomers, respectively, and were used as the standard samples for measuring absorption and CD spectra in kinetic experiments.

Δ-Isomer. Found: Ru, 15.10; C, 49.04; H, 3.76; N, 9.86%. Calcd for Δ-$[Ru(S\text{-phe})(bpy)_2]ClO_4\cdot H_2O$: Ru, 14.54; C, 50.11; H, 4.06; N, 10.08%. ABS (H_2O) 492 nm (ε 9250); CD (H_2O) 350 nm (Δε −13.7). Λ-Isomer. Found: Ru, 13.60; C, 46.81; H, 3.57; N, 9.50%. Calcd for Λ-$[Ru(S\text{-phe})(bpy)_2]ClO_4\cdot 3H_2O$: Ru, 13.82; C, 47.64; H, 4.41; N, 9.58%. ABS (H_2O) 492 nm (ε 9250); CD (H_2O) 350 nm (Δε 16.1).

Starting Materials of Kinetic Experiments. A solution containing *cis*-$[Ru(CO_3)(bpy)_2]$ and (*S*)-phenylalanine was refluxed for 20 min at 100 °C. After cooling, a dark-red product was precipitated by adding $NaClO_4$. The product was identified as $[Ru(phe)(bpy)_2]ClO_4\cdot 2H_2O$ by the spectrophotometric methods, and it was found by the chromatographic separation that the product comprised four isomers which consisted of two predominant ones, Λ- and Δ-[Ru(*S*-phe)$(bpy)_2$]$ClO_4\cdot 2H_2O$, and two minor ones, Λ- and Δ-[Ru(*R*-phe)$(bpy)_2$]$ClO_4\cdot 2H_2O$, because of partial racemization of the coordinated phenylalanine.[8] This product was used as starting materials in the following experiments.

Rate Determination Procedures. The starting materials, $[Ru(phe)(bpy)_2]ClO_4\cdot 2H_2O$, of 0.2—0.25 mmol were dissolved in 100 cm^3 of a refluxing Sørensen buffer solution (0.05 mol dm^{-3} borax–0.1 mol dm^{-3} NaOH) at (100±2) °C in an atmosphere of nitrogen in darkness. In the case of a typical experiment, a 10 cm^3 aliquot of the reaction solution was taken out after 1 and 2 hours later and cooled in ice. The solution was added on a column (27 cm height×2 cm diameter) of SE-Toyopearl. The adsorbed complex cations were eluted with 0.1 mol dm^{-3} sodium (*R*,*R*)-tartrate, and completely resolved into two isomeric groups. One group contained Δ-$[Ru(S\text{-phe})(bpy)_2]^+$ (Δ-*S*) and Λ-$[Ru(R\text{-phe})(bpy)_2]^+$ (Λ-*R*) ions which were first eluted, and another contained Λ-$[Ru(S\text{-phe})(bpy)_2]^+$ (Λ-*S*) and Δ-[Ru(*R*-phe)-

$(bpy)_2]^+$ (Δ-R) ions which were secondly eluted. Decomposition products were negligible. An absorbance at 492 nm (ε=9250 for all of four isomers) gave the total concentration of the complexes, and a circular dichroism at 350 nm ($\Delta\varepsilon$=−13.7 for Δ-S, 16.1 for Λ-S, 13.7 for Λ-R, and −16.1 for Δ-R) reflected a ratio of the concentrations between two enantiomers in each eluate. The fractions of each isomer to the total complex ions were calculated from these spectrophotometric data and volumetric ratio of the two eluates as shown in Table 1. The data at t=0 were obtained from the chromatographic separation of the starting complex solution which was not refluxed. The data at equilibria were obtained from the refluxing solutions at pH 9.03 and 8.64 for 10 and 45 h, respectively. These reaction periods were more than ten times of half-lives estimated with effective rate constants (vide infra).

As regards racemization of the coordinated phenylalanine, the pseudo first-order rate constants, k_{AD}, k_{BD}, k_{AL}, and k_{BL}, were defined as follows:

$$\Delta\text{-}S \underset{k_{BD}}{\overset{k_{AD}}{\rightleftharpoons}} \Delta\text{-}R, \tag{1}$$

$$\Lambda\text{-}R \underset{k_{BL}}{\overset{k_{AL}}{\rightleftharpoons}} \Lambda\text{-}S. \tag{2}$$

In the present experiments, the fractions of the four isomers were obtained for each reaction time, and hence two integrated rate equations were yielded independently from both rates of disappearance of the reactant and appearance of the product with regard to one of the reversible reactions. The two expressions for the effective rate constant, k_{eff}, defined as sum of the rate constants for the forward and reverse directions of reaction (1), are

$$k_{eff} = \frac{1}{t}\cdot\ln\left(\frac{P[\Delta\text{-}S]_0 - P[\Delta\text{-}S]_e}{P[\Delta\text{-}S]_t - P[\Delta\text{-}S]_e}\right) \tag{3}$$

and

$$k_{eff} = \frac{1}{t}\cdot\ln\left(\frac{P[\Delta\text{-}R]_0 - P[\Delta\text{-}R]_e}{P[\Delta\text{-}R]_t - P[\Delta\text{-}R]_e}\right), \tag{4}$$

where P[A] is the fraction of A, and subscripts 0 and e refer to zero time and equilibrium conditions, respectively. The values evaluated by the two equations almost agreed with each other, and thereupon the mean value was adopted as k_{eff}. The rate constants, k_{AD} and k_{BD}, were calculated by

$$k_{eff} = k_{AD} + k_{BD} = k_{BD}\cdot(1 + K), \tag{5}$$

where K is the equilibrium constant defined as

$$K = P[\Delta\text{-}R]_e/P[\Delta\text{-}S]_e = P[\Delta\text{-}S]_e/P[\Delta\text{-}R]_e. \tag{6}$$

The each value of the fractions at equilibria ($P[\Delta\text{-}S]_e$, $P[\Delta\text{-}R]_e$, $P[\Lambda\text{-}S]_e$, and $P[\Lambda\text{-}R]_e$) was assumed to be the same for all runs at various pHs. The mean values of the corresponding fractions at pH 8.64 and 9.03 were adopted as the values at equilibria, and used to calculate the rate and equilibrium constants. The other rate constants, k_{AL} and k_{BL}, were similarly derived by using the fractions of the isomers in reaction (2). The values of each rate constant were calculated corresponding to two reaction times other than at equilibrium, and they were the same at respective pH values. The mean observed values of k_{AD}, k_{BD}, k_{AL}, and k_{BL} are summarized in Table 2.

The pH values at the reaction temperature, (100±2) °C, were estimated by extrapolation of the pH values measured at room temperature to those at 100 °C by reference to the temperature dependence data of pH of Sørensen buffer solution.

Experiments on effects of photoexcitation were carried out at pH 9.03. Light from 300 W short-arc type Xe lamp was focused on an area of about 4 cm diameter, and irradiated to the refluxing solution through a Pyrex glass vessel.

Results and Discussion

Table 1 shows that the (S)-phenylalaninato complexes, Δ-S and Λ-S, were predominant components of the starting materials. As the racemization of the coordinated phenylalanine proceeded, the fractions of the (R)-phenylalaninato complexes, $P[\Delta\text{-}R]$ and $P[\Lambda\text{-}R]$, increased. From Table 1, it is also seen that the fraction of Δ-isomers, $P[\Delta]$, or that of Λ-ones, $P[\Lambda]$, was always constant for all the dark reactions. Preliminary experiments revealed that no inversion around the metal ion was detected even though an isomer was refluxed in a neutral aqueous solution for four hours in the dark, and the results were the same with those by Vagg et al.[5] From such observations, we assumed the dark reaction paths as illustrated in Scheme 1.

Scheme 1 expresses that racemization occurs only on the amino carboxylato ligand (paths I and II), while the paths of the inversion reaction (paths III and IV) are intercepted by some energy barriers. Absence of the reactions through the paths III and IV was supported by the fact that both fractions of Δ- and Λ-isomers, $P[\Delta]$ and $P[\Lambda]$, were maintained constant in addition to the total concentration of the complexes. The enantiomers, Δ-S and Λ-R or Δ-R and Λ-S, are energetically equivalent. At equilibria the ratios of the fractions of the enantiomers, ($P[\Delta\text{-}S]_e/P[\Lambda\text{-}R]_e$) and ($P[\Delta\text{-}R]_e/P[\Lambda\text{-}S]_e$), were not unity but equal to ($P[\Delta]/P[\Lambda]$), which was always constant at 0.92±0.01 for the dark reactions. This is also explainable as a result of absence of the paths III and IV.

For each pH, the values of k_{AD} and k_{BD} agree with k_{AL} and k_{BL}, respectively, within experimental errors as shown in Table 2. Hence it is confirmed that the paths I and II are statically and dynamically identical reactions. Then the pseudo first-order rate constants k_A will be used for k_{AD} and k_{AL}, and k_B for k_{BD} and k_{BL} in the following. Since the stability of the two isomers in path I or II differed from each other, the magnitude of k_A did not coincide with that of k_B in each pH. It is suggested that Λ-S (or Δ-R) is more stable than Δ-S (or Λ-R), because k_A is greater than k_B. This is consistent with Vagg's report.[4,5] He has described that the main

factor to determining the stability of these complex species is the steric interaction between one of the bipyridine protons and amino acid side chain.

In Table 2, the rate constants at pH 9.03 are greater than the corresponding ones at pH 8.64 by a factor about 5. On the other hand, in Table 1, the equilibrium constants evaluated by Eq. 6 for these pH values are the same (K=1.9) and independent of pH. These results indicate that this is base-catalyzed reaction. Logarithms of k_A and k_B are plotted against pH in Fig. 1. The plots are linear and both slopes can be regarded as unity, and it is indicated that the racemization rates are the first-order with respect to OH^- concentration. Hence, the expressions for the rate law are

Nonirradiated	0.420	0.062	0.475	0.043	0.895	0.105

pH of the solution: 10.70; The reaction time: 2.3 h for both the irradiated and the nonirradiated reactions.

$$R_A = k_A'[OH^-][\Delta\text{-}S] = k_A'[OH^-][\Lambda\text{-}R] \quad (7)$$

and

$$R_B = k_B'[OH^-][\Lambda\text{-}S] = k_B'[OH^-][\Delta\text{-}R], \quad (8)$$

where R_A and R_B represent the rates for the faster and slower reactions, respectively, and k_A' and k_B' are the corresponding second-order rate constants. The values of k_A' and k_B' are derived from k_A and k_B,[9] as follows:

$$k_A' = (0.19 \pm 0.07)\ \text{mol}^{-1}\cdot\text{dm}^3\cdot\text{s}^{-1},$$

$$k_B' = (0.10 \pm 0.04)\ \text{mol}^{-1}\cdot\text{dm}^3\cdot\text{s}^{-1} \quad (\text{at } 100\,^\circ\text{C}).$$

Bada[11] has determined the racemization rate of free phenylalanine at pH 7.6:

$$\log k(\text{year}^{-1}) = 17.05 - 6208/T.$$

When T is 373 K, k is evaluated to $8.1\times10^{-8}\ \text{s}^{-1}$. On the other hand, extrapolation of the present data to pH 7.6 gives $k_A \simeq 4.4\times10^{-6}\ \text{s}^{-1}$ and $k_B \simeq 2.3\times10^{-6}\ \text{s}^{-1}$. These values of k_A and k_B are ca. 50 and ca. 30 times greater than the rate constant of free phenylalanine, respectively.

Widely, the rate of racemization of amino acids chelated to a metal ion or in proteins and peptides are of the first-order with respect to hydroxide ion concentration, while the free amino acids racemize with a small pH dependence in basic solutions.[10-12] Accordingly, the present results suggest that the coordinated phenylalanine racemizes without breaking bonds to the ruthenium ion. As for reaction mechanism, it would be the same as generally recognized base-catalyzed one: α-proton is abstracted by hydroxide ion to form a planar carbanion intermediate.[10-15]

When light was irradiated on the reaction system, the rapid reaction paths III and IV in Sheme 1 were induced. On the assumption that the equilibria for paths III and IV are established rapidly enough as compared to paths I and II, the system is apparently written by

$$S_{\text{total}} \underset{k_{ap}}{\overset{k_{ap}}{\rightleftarrows}} R_{\text{total}}, \quad (9)$$

where S_{total} refers (Δ-S+Λ-S) and R_{total} does (Δ-R+Λ-R), and k_{ap} is the apparent first-order rate constant. If the light has no effect on the paths I and II, k_{ap} can be yielded by using k_A and k_B for the dark reaction system. The relationship is expressed by

$$k_{ap} = (k_A + k_B\cdot K_{inv})/(K_{inv} + 1), \quad (10)$$

where K_{inv} is equilibrium constant for the inversion reaction paths III and IV and defined as

$$K_{inv} = P[\Lambda\text{-}S]_e/P[\Delta\text{-}S]_e = P[\Delta\text{-}R]_e/P[\Lambda\text{-}R]_e. \quad (11)$$

Considering energetic relationship of the isomers, K_{inv} is essentially the same with K for the racemization of the coordinated amino acid. The values of the rate constants of the dark reaction under pH 9.03, $k_A = 1.5\times10^{-4}\ \text{s}^{-1}$ and $k_B = 7.8\times10^{-5}\ \text{s}^{-1}$, and equilibrium constant, $K_{inv} = K = 1.9$, are substituted in Eq. 10 to yield $1.0\times10^{-4}\ \text{s}^{-1}$ for k_{ap}. On the other hand, k_{ap} was determined to be $9.9\times10^{-5}\ \text{s}^{-1}$ by using data under irradiation of light in Table 1. The two values agree very well with each other.

Effects of the irradiation on the racemization were also examined with solutions at pH 10.70 at room temperature where no racemization was expected to take place in the dark. Results in Table 3 show that the racemization is not caused even by the irradiation, although the inversion around the metal ion occured.

It is concluded that the racemization of the coordinated amino acid proceeds independently of the photoexcitation of the complex ions. Commonly, the racemization rate of an amino acid increases with increasing stability of the carbanion intermediate. The extent of the stability is influenced greatly by the electron-withdrawing power of the metal ion in complexes, when amino acid is chelated as a bidentate.[10,15] Photoexcited states of complexes such as ones studied have been considered to be ^{3}(MLCT) and (dd) excited states[16] which bring some electron deficient state on the central metal ion and some distortion on metal-ligand bonds, respectively. The excited states cause secondary reactions such as the photosensitized one and ligand substitutions. However, the present studies indicate that effects of the photoexcited states of the complexes are limited in the bis(2,2′-bipyridine)ruthenium moiety and do not extend to the α-carbon of the amino carboxylato ligand or events concerning the excited states are much faster than the racemization.

A Structural Study of a Series of Bis(2,3-alkanedione dioximato)-nickel(II) Complexes in the Crystal and the Liquid States by X-Ray Absorption Spectroscopy

Seiichi YAMASHITA, Yoshio YANASE, Toshio YAMAGUCHI, and Hisanobu WAKITA*
Department of Chemistry, Faculty of Science, Fukuoka University, Nanakuma, Jonan-ku, Fukuoka 814-01
(Received March 1, 1989)

The structures of a series of bis(2,3-alkanedione dioximato)nickel(II) complexes, [Ni(R,R′-dioxH)$_2$], with dioxH=C(=NOH)-C(=NO), R and R′=H(**A**), R=CH_3 and R′=H(**B**), CH_3(**C**), C_2H_5(**D**), n-C_3H_7(**E**), n-C_4H_9(**F**), n-C_5H_{11}(**G**), n-C_6H_{13}(**H**), or n-$C_{10}H_{21}$(**I**), were investigated in crystals, pyridine solution, and melt (160 °C) by means of extended X-ray absorption fine structure (EXAFS) and X-ray absorption near edge structure (XANES), magnetic susceptibility, and UV/visible spectra. The magnetic susceptibility of complexes **C**, **F**, and **H** in crystals revealed a diamagnetic character. The electronic spectra of crystalline samples **E**, **F**, and **H** changed with the alkyl substituents of the glyoximato ligands, while the corresponding spectra in a pyridine solution were very similar to each other, independent of the glyoximato ligands. The EXAFS data showed that the average Ni-N distance within nickel(II) glyoximato complexes is 1.85—1.88 Å, practically independent of the alkyl substituents of the glyoximato ligands. The XANES spectra were found to correlate with the molecular packing structures of nickel(II) glyoximato complexes in crystals, pyridine solutions, and melt.

A series of 2,3-alkanedione dioximes are known as a good precipitant for Ni(II) and Pd(II) ions. The crystal structures of bis(2,3-alkanedione dioximato) nickel(II) complexes (Fig. 1) were reported for bis(dioximato)nickel(II), [Ni(gH)$_2$],[1] bis(2,3-butanedione dioximato)nickel(II), [Ni(dmgH)$_2$],[2] and bis(2,3-pentanedione dioximato)nickel(II), [Ni(emgH)$_2$].[3] In the crystal structure of [Ni(dmgH)$_2$], planar Ni(II) complexes are stacked face to face along the c-axis to form Ni···Ni linear chains;[4] hereafter, this molecular packing structure is referred to as the cross-type[5] ((b) and (d) in Fig. 2). On the other hand, for the crystal structures of [Ni(gH)$_2$] and [Ni(emgH)$_2$], planar Ni(II) complexes are arrayed like the slats of a venetian blind; this molecular packing structure is referred to as the blind-type[5] ((a) and (c) in Fig. 2). The molecular packing structure of the blind-type for [Ni(emgH)$_2$] complex is transformed into the cross-type by heating.[5] On the other hand, bis(2,3-alkanedione dioximato)-nickel(II) complexes in pyridine, acetone, and alcohols solutions show the same red-orange color as that in the crystalline state,[6] suggesting that no solvent molecule coordinates to a central nickel(II) ion. Moreover, [Ni(R,R′-dioxH)$_2$] complexes with long alkyl chains R′ (**E**—**I**) can be melted and sublimed by heating.

In spite of the above interesting phenomena, there are no comprehensive structural analyses of a series of bis(2,3-alkanedione dioximato)nickel(II) complexes in crystals, solution, and melt. In the present paper, the structures of the [Ni(R,R′-dioxH)$_2$] complexes given in Table 1 have been investigated in solid, pyridine solution, and melt by EXAFS[7] and XANES[8] spectra, magnetic susceptibility,[9] and UV/visible spectral measurements, in particular, to examine the effect of the length of the alkyl chains in glyoximato ligands on the molecular structure of the Ni(II) complexes and to reveal structural differences between the Ni(II) complexes in the three states.

Experimental

Sample Preparation. A series of 2,3-alkanedione dioximes were prepared as reported in the literature[5] and recrystallized from a mixture of methanol and chloroform.

Bis(2,3-alkanedione dioximato)nickel(II) complexes (Table 1) were prepared in the following manner. An aqueous solution, saturated with $[Ni(CH_3COO)_2]4H_2O$, was added to a hot concentrated methanol solution of a dioxime ligand. The complex formed was recrystallized more than five times from a mixture of methanol and chloroform, and then dried in a vacuum desiccator. They were identified by ^{13}C NMR spectrometry, X-ray powder diffractometry and thermal analysis.

Magnetic Susceptibility Measurements. For crystalline powder of complexes **C**, **F**, and **H**, and a pyridine solution and melt of complex **F**, the magnetic susceptibility was measured by a hand-made thermomagnetic analysis (TMA) system equipped with a temperature control unit,[9] The voltage, the electric current, and the intensity of the magnetic field used in the measurements were 50 V, 7A, and 1.6 T, respectively. A reference compound used for calibration of TMA was powdery $[Ni(en)_3]S_2O_3$, which had been purified by recrystallization from water twice.

UV/Visible Spectral Measurements. UV/visible spectra were measured over the wavelength from 400 to 600 nm with a Hitachi spectrophotometer U-3200. The opal method was used for crystalline samples, while the liquid film method was employed for pyridine solutions.

X-Ray Absorption Measurements. X-Ray absorption measurements were performed at the BL-10B station of the Synchrotron Radiation Research Facility (the Photon Factory) in the National Laboratory for High Energy Physics (KEK). X-Ray absorption data were collected in the range from ca. 400 eV on the lower energy side of the nickel *K*-edge (8331.7 eV) to ca. 1800 eV on the higher energy side.

Table 1. Composition of $[Ni(R,R'\text{-dioxH})_2]$

	Complex	R	R′
A	$[Ni(gH)_2]$	H	H
B	$[Ni(mgH)_2]$	CH_3	H
C	$[Ni(dmgH)_2]$	CH_3	CH_3
D	$[Ni(emgH)_2]$	CH_3	C_2H_5
E	$[Ni(mprgH)_2]$	CH_3	n-C_3H_7
F	$[Ni(bmgH)_2]$	CH_3	n-C_4H_9
G	$[Ni(mpegH)_2]$	CH_3	n-C_5H_{11}
H	$[Ni(hxmgH)_2]$	CH_3	n-C_6H_{13}
I	$[Ni(decmgH)_2]$	CH_3	n-$C_{10}H_{21}$

The time to collect X-ray photons was 2 seconds at each measuring point. Crystalline samples were measured in a pellet form after powdering crystals with an agate mortar. Pyridine solution samples, prepared by dissolving crystalline Ni(II) complexes in distilled pyridine, were measured with a polyethylene pouch sandwiched by polyacrylate holders. Melting samples were measured at 160 °C by use of a metallic cell on a hot-plate.

EXAFS spectra were analysed as previously reported.[7] The structural parameters (the interatomic distance, the mean-square displacement, and the coordination number) were determined by a curve fitting method applied to Fourier filtered EXAFS spectra. The basic formula are described below.

The observed EXAFS spectrum, $\chi_{obsd}(k)$, is Fourier transformed to a function, $F(r)$, by the following equation.

$$F(r) = \int_{k_{min}}^{k_{max}} k^3 \cdot \chi_{obsd}(k) \cdot \exp(2ikr)\mathrm{d}k \quad (1)$$

$$= F_{re}(r) + iF_{im}(r), \quad (2)$$

where k is the photoelectron wavenumber, $F_{re}(r)$ and $F_{im}(r)$ are the real and imaginary parts of the $F(r)$ function, respectively. k_{max} and k_{min} are the upper and lower k-values used in the transform. The radial function, $|F(r)|$, is given as

$$|F(r)| = [F_{re}(r)^2 + F_{im}(r)^2]^{1/2}. \quad (3)$$

The calculated EXAFS spectrum, $\chi_{calcd}(k)$, is given as

$$\chi_{calcd}(k) = \sum_j [N_j/(k \cdot r_j^2)] \cdot |f_j(\pi, k)| \cdot \sin(2kr_j + \phi_j(k)) \cdot \exp(-2r_j/\lambda_j) \cdot \exp(-2\sigma_j^2 k^2), \quad (4)$$

where r_j is the distance from an absorbing to backscattering atoms in the j-th coordination shell, N_j the number of the backscattering atoms at r_j, σ_j^2 the mean square displacement, and λ_j the mean free path. $|f_j(\pi,k)|$ and $\phi_j(k)$ are, respectively, the backscattering amplitude and the phase shift of the atoms in the j-th shell. A curve fitting is performed to minimize an error-square sum, U, as

$$U = \sum[k^3 \cdot \chi_{filt}(k) - k^3 \cdot \chi_{calcd}(k)]^2, \quad (5)$$

where $\chi_{filt}(k)$ is the Fourier backfiltered EXAFS spectrum.

Results

Magnetic Susceptibilities. The measured magnetic susceptibility of complexes **C**, **F**, and **H** is listed in Table 2. In the case of crystalline samples **C**, **F**, and **H**,

Table 2. Magnetic Susceptibility Measured for Complexes **C**, **F**, and **H**. χ_{Ni}, μ_B, and T Are the Magnetic Susceptibility Per Mole of Ni Atom, Bohr Magneton, and Temperature Measured, Respectively

	Sample		$\chi_{Ni}/10^{-6}$ cm^3 mol^{-1}	μ_B/BM	T/°C
C	$[Ni(dmgH)_2]$	Crystal	−34.0		20
F	$[Ni(bmgH)_2]$	Crystal	−27.0		20
		Melt	4.45	0.12	160
		Solution[a]	125	0.54	20
H	$[Ni(hxmgH)_2]$	Crystal	−22.6		20

a) Pyridine solution.

the magnetic susceptibility per mole of Ni, χ_{Ni}, measured at 20 °C was all negative. On the other hand, the χ_{Ni} values of a melt of sample **F** at 160 °C and of a pyridine solution of sample **F** at 20 °C became both slightly positive.

UV/Visible Spectra. Figure 3 shows the electronic spectra for complexes **E**, **F**, and **H** in crystals and pyridine solutions. The spectra of the crystalline samples (solid lines in the figure) show different d–d transition bands in the wavelength range from 430 to 550 nm, depending on the complexes. For the corresponding pyridine solutions, however, all spectra (dashed lines) resemble each other with a shoulder at about 480 nm.

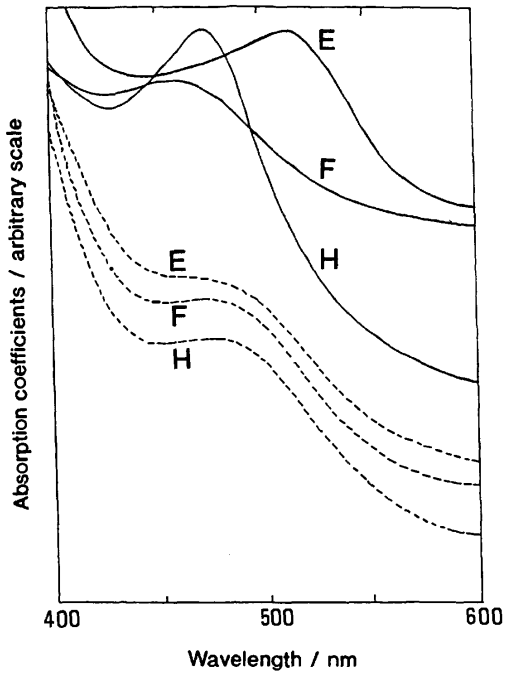

Fig. 3. UV/visible spectra of complexes **E**, **F**, and **H**. Solid lines; crystal, dashed lines; pyridine solution.

EXAFS Analysis. Figures 4 and 5 show the experimentally obtained $k^3\chi(k)$ curves of the crystalline powder of complexes **A**—**I**, and of pyridine solutions and melts of complexes **E**, **F**, and **H** respectively. The corresponding radial function curves (uncorrected for the phase shift) are shown in Figs. 6 and 7; the k range used in the Fourier transform was from 4.5 to 14.0 Å^{-1} for all the spectra. The prominent first peak at about 1.5 Å in each radial function is ascribable to Ni–N interactions within [Ni(R,R′-dioxH)$_2$] complexes. The second and third peaks observed at 2.5—4.0 Å should be ascribed to nonbonded Ni···C and Ni···O interactions within the complexes. The peaks appearing beside the sharp Ni–N peak are the side lobe.

In order to obtain the structural parameters of the Ni–N interactions, Fourier filtered EXAFS spectra were extracted for the first peak from 1.1 to 1.9 Å in the radial functions. Subsequently, the theoretical function of Eq. 4 was fitted to the filtered spectra from 5.5 to 13.0 Å^{-1} in the k space. The backscattering amplitude and phase shift for the Ni–N interaction were determined by a least-squares method for reference compound of known structure **A**. In the fits

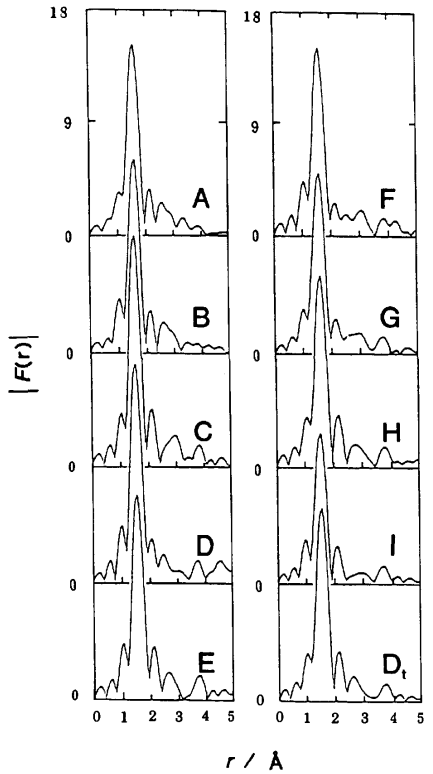

Fig. 6. The radial functions, $|F(r)|$, for crystalline samples **A**—**I** and $\mathbf{D_t}$. $\mathbf{D_t}$ is thermally transformed crystal **D**.

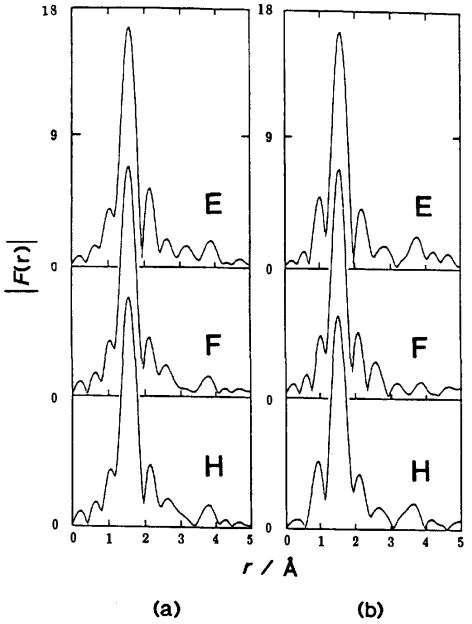

Fig. 7. The radial functions, $|F(r)|$, for solutions and melts of complexes **E**, **F**, and **H**. (a) Pyridine solutions (b) melts (160°C).

different Ni–N interactions in the crystal (1.87 and 1.88 Å) were treated as one-shell since the difference in the Ni–N distances was within the uncertainties in the EXAFS analysis; the average bond distance and the coordination number were fixed at 1.88 Å and 4,[1] respectively.

Table 3 summarizes the Ni–N interatomic distance within the complexes in crystals, pyridine solutions, and melts obtained from the curve-fittings. The Ni–N bond lengths fall within 1.85 — 1.88 Å independent of the alkyl substituents and the sample states.

In the curve fits of the Ni–N interactions for complexes **E**, **F**, and **H** in pyridine solutions the coordination numbers of four and six were tested for Ni(II)-coordination; the best fit was obtained only when the coordination number was four. This result shows that no pyridine molecules coordinate to a central nickel(II) ion. Therefore, in subsequent curve fits of pyridine solutions of complexes **E**, **F**, and **H** the coordination number was kept constant at four.

XANES Patterns. Figures 8 and 9 show, respectively, the XANES curves for crystals of complexes **A**—**I** and for pyridine solutions and melts of complexes **E**, **F**, and **H**. The XANES curves in the X-ray energy range from 8310 to 8380 eV can be classified into three kinds of patterns, which are referred subsequently to as α-, β-, and γ-patterns. In the three kinds of XANES

patterns were observed a pre-edge peak at 8330 eV and two peaks at 8348—8362 eV. The α-, β-, and γ-patterns correspond, respectively, to that of crystalline samples **A**, **B**, and **D**, that of crystalline samples **C**, **E**—**I**, and $\mathbf{D}_t$, and that of solution samples **E**, **F**, and **H**.

The α-pattern was characteristic of a shoulder at 8336 eV, while the β-pattern had a sharp peak at 8335 eV and a shoulder at 8342 eV. On the other hand, the γ-pattern observed for the pyridine solutions showed no distinct peak at 8335—8345 eV, but appreciable shoulders at 8337 and 8342 eV. The XANES curves of the melts of complexes **E**, **F**, and **H** showed the β-pattern.

Discussion

Crystalline State. As seen in Table 3, the Ni–N interatomic distances for crystalline samples **B**—**I** do not change significantly with the length of the alkyl substituents in the glyoximato ligands. In addition, the magnetic susceptibility (Table 2) of crystalline samples **C**, **F**, and **H** is all negative; thus, these [Ni(R,R′-dioxH)$_2$] complexes are diamagnetic in crystals. These experimental results indicate that the square planar NiN_4 skeleton within a series of the [Ni(R,R′-dioxH)$_2$] complexes is not significantly distorted in the solid state.

However, the XANES patterns (Fig. 8) of the crystalline [Ni(R,R′-dioxH)$_2$] complexes have shown different features (the α- and β-types) as mentioned in the previous section. The pre-edge peak due to the 1s→3d electron transition of nickel(II) ion observed at 8330 eV in all spectra does not show any remarkable change with respect to the shape and peak position. This fact indicates that the oxidation state of nickel atom in crystalline samples **B**—**I** is very similar to

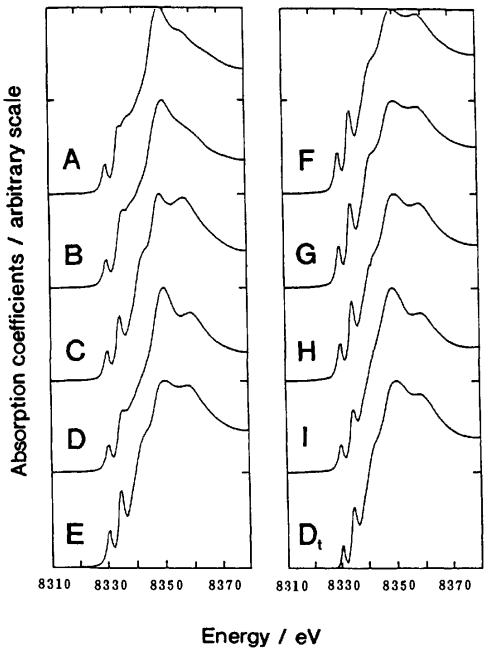

Fig. 8. The XANES spectra of crystalline samples **A**—**I** and $\mathbf{D}_t$. $\mathbf{D}_t$ is thermally transformed crystal **D**.

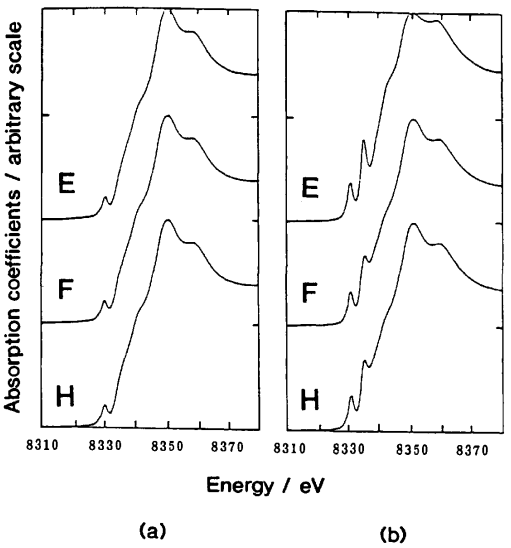

Fig. 9. The XANES spectra of solutions and melts of complexes **E**, **F**, and **H**. (a) Pyridine solutions, (b) melts (160°C).

Table 4. Packing Structures and XANES Patterns (Figs. 8 and 9) Found for [Ni(R,R′-dioxH)$_2$] Complexes in Crystals, Melts, and Pyridine Solutions. The α, β, and γ Refer to the Packing Types Described in the Text

	Complex	Crystal		Solution[a]	Melt[b]
		Packing	XANES	XANES	XANES
A	[Ni(gH)$_2$]	Blind	α		
B	[Ni(mgH)$_2$]		α

a) Pyridine solution. b) Measured at 160°C. c) Thermally transformed crystal **D**.

each other, independent of the length of the alkyl chains in glyoximato ligands. Therefore, the variation of the XANES curves may be due to the change in the electronic state of nickel(II) ion influenced by neighboring atoms: the change in the symmetry around Ni(II) ion and/or different multiple scattering processes arising from different surroundings of Ni(II) ion in the complexes, i.e. different crystal packings.

Table 4 compares the crystal packing structures of Ni(II) glyoximato complexes with their XANES patterns. According to the crystal structures reported,[1-3] the packing form of complexes **A** and **D** is of the blind-type ((a) and (c) in Fig. 2); the corresponding XANES curves show the α-pattern. On the other hand, complexes **C** and $\mathbf{D}_t$ have the cross-type packing structure ((b) and (d) in Fig. 2); their XANES curves belong to the β-pattern. The crystal structures of complexes **B** and **E**—**I** are not available in the literature. X-Ray diffraction patterns were measured for all the powdered samples **A**—**I**, but none of these was found to be isomorphic; thus the packing structures of complexes **B** and **E**—**I** could not be estimated from the X-ray powder patterns. It is suggested, however, from UV/visible spectral measurements[5] that the crystal packing of complex **E** is similar to that of complex **C** with the cross-type packing structure.

In spite of the above limited number of the crystal structures reported for [Ni(R,R′-dioxH)$_2$] complexes, we may discuss the correlation between the XANES patterns and the packing types in the crystal structure. As seen in Fig. 2, in the case of the packing structure of the blind-type, the axial sites above and below a central Ni atom are occupied by light (oxygen, nitrogen, and carbon) atoms, while for the packing structure of the cross-type nickel atoms in other layers are above and below a central Ni(II) ion. Thus, the different feature in the XANES spectra shown in Figs. 8 and 9 is probably ascribed to the different types of the interactions between an Ni(II) ion and the atoms present above and below the Ni(II) ion since the electronic state of Ni(II) glyoximato complexes or the multiple scattering process through different backscattering atoms will change. This conclusion is also supported from the experimental finding that the γ-pattern is observed for all pyridine solutions (Fig. 9), in which no pyridine molecule directly coordinates to a central nickel(II) ion.

On the basis of the above relation between the XANES patterns and the packing types we may presume a packing structure of the other complexes whose crystal structures are not known. Since the XANES curve of complex **B** shows the α-pattern, the complex probably has the blind-type packing structure. Similarly, from the XANES curves of complexes **E**—**I** showing the β-pattern, the packing structure of the complexes may be of the cross-type.

Solutions and Melts. Unlike the crystalline compounds, the solution and melt of sample **F** showed a slightly positive value (0.54 and 0.12 BM) of their magnetic susceptibility (Table 2). The positive magnetic susceptibility of bis(2-propanedione dioximato)nickel(II) in pyridine solution was reported to be 1.5 BM.[10]

In pyridine solutions the electronic spectra of the three complexes (**E**, **F**, and **H**) resemble each other (Fig. 3), independent of the length of the alkyl substituents, so do the XANES spectra (Fig. 9). From these experimental findings the complexes **E**, **F**, and **H** may have a similar NiN_4 moiety in pyridine solutions.

For melts of complexes **E**, **F**, and **H**, the Ni–N interatomic distances and the XANES patterns are similar to those in crystals (Table 3). The XANES spectra of the melts show the β-pattern, suggesting that the complex molecules in the melts still retain cross-type packing structure, similar to that found in the corresponding crystals.

The authors wish to thank Dr. Masaharu Nomura for his advice in the X-ray absorption spectral measurements and Dr. Mikiya I for his help in preparation of the compounds. This work has been performed under the approval of the Photon Factory Program Advisory Committee (Proposal No. 86-008). All the calculations were performed with an FACOM M-380 R computer at the Computer Center of Fukuoka University.

A Modified Vapor Saturation Method for Preparing Aqueous Solutions of Solid Aromatic Hydrocarbons

Isao SANEMASA,* Kazunari ISHIBASHI, Masaya KUMAMARU, and Toshio DEGUCHI
Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami 2-39-1, Kumamoto 860
(Received April 3, 1989)

An excess quantity of a solid hydrocarbon is dispersed in water, and then air is bubbled through the aqueous phase to produce the solute vapor. The vapor is introduced into a separate water phase and circulated in a closed system. Aqueous solutions saturated with some solid aromatic hydrocarbons can be prepared in a relatively short time without any need to remove solute microcrystals. It can be confirmed whether the solubility obeys Henry's law. The present method provides us with rough enthalpy of sublimation of a solute if its solubility follows Henry's law. Biphenyl, naphthalene, phenanthrene, and anthracene were examined as solutes.

We recently proposed a method to prepare aqueous solutions saturated with solid aromatic hydrocarbons.[1] The principle is as follows: a solid solute is added in excess to a suitable organic solvent so that a part of the solute is always present in solid state in the solvent, then, air is bubbled through the solvent, and the resulting vapor is introduced into water to circulate in a closed system. It was found that 1-octanol was the most suitable solvent for preparing aqueous solutions saturated with solid aromatic hydrocarbons.

The present work concerns a modification of the previous method. The organic solvent was not used here, but water was used to disperse solid solutes. This work aims to see whether or not the modification is successful and, if successful, to confirm whether Henry's law holds for some solid aromatic hydrocarbons.

Experimental

Materials. The solid aromatic hydrocarbons used as solutes are the same as those examined in the previous paper.[1] Distilled deionized water was used throughout this work.

Apparatus and Procedures. The apparatus used for preparing aqueous solutions saturated with solute vapor is essentially the same as that previously used,[2] except for some minor modification. The apparatus was composed of two main glass parts: a pear-shaped long-necked vessel of 50 cm^3 capacity in which ca. 0.5 g of solid hydrocarbon roughly powdered by agate mortar was placed together with ca. 20 cm^3 water (we call this vessel the "solute reservoir") and a separatory funnel of 200 cm^3 capacity in which 150 cm^3 water was placed (we call this funnel the "solubility flask"). These two vessels were connected with glass and Teflon tubes incorporated with a Viton diaphragm airpump (Iwaki Type AP-32 Z) and a round-bottom flask of 200 cm^3 capacity to trap fine solute powders.

The temperature of the solubility flask was held at 25±0.1 °C by circulating water from a thermostated water bath through a jacket surrounding the funnel. The solute reservoir and the trap-flask were immersed in a separate water bath kept constant at any desired temperature below 25 °C. The temperature of a chamber containing the assembled apparatus was always kept higher than that of the solute reservoir.

By means of the pump, air was bubbled at a flow rate of ca. 0.5 $dm^3\ min^{-1}$ through the solute reservoir via a glass capillary, and the resulting solute (and water) vapor was introduced through the trap-flask into water in the solubility flask to disperse via a glass capillary, and circulated in the closed system. After solubility equilibrium was attained, a suitable portion of the aqueous solution was transferred from the separatory funnel into a glass test tube, in which a 5 cm^3 portion of cyclohexane had previously been placed, and weighed; prior to the operation of stopcock attached to the funnel bottom, the funnel position was slightly lowered so as to allow air to enter the funnel through its top opening. Extractions were made after diluting the aqueous phase to 20 cm^3 with water.

The cyclohexane extract, after dehydrated with anhydrous sodium sulfate, was analyzed by UV absorption (biphenyl: 247.5, naphthalene: 285, phenanthrene: 250, anthracene: 251.5 nm) with a Hitachi 100-50 spectrophotometer and by fluorescence for anthracene (excitation 253.6, emission 378 nm) with a JASCO FP-770 spectrofluorometer.

For each solute, a calibration curve was prepared by extracting a 5 cm^3 portion of the standard cyclohexane solution containing a known amount of the solute with 20 cm^3 water.

Results and Discussion

The Time Required for Saturating Water with Solute Vapor. The circulation rate of solute vapor may affect the time for attaining the equilibrium solubility, and high circulation rates are desirable to reduce the time required. In the present work, however, the circulation rate was suppressed to be moderate, because at higher circulation rates extraordinarily high "solubility" values were sometimes observed probably due to accidental contamination with solute fine powders. The time necessary to saturate is as follows: 1 h for biphenyl and naphthalene, 6 h for phenanthrene, and 20 h for anthracene.

The term "equilibrium solubility" is used in this paper to describe the solubility obtained under the condition that the temperature of the solute reservoir differs from that of the solubility flask.

The equilibrium solubility can be attained from both directions: approaches from either lower or

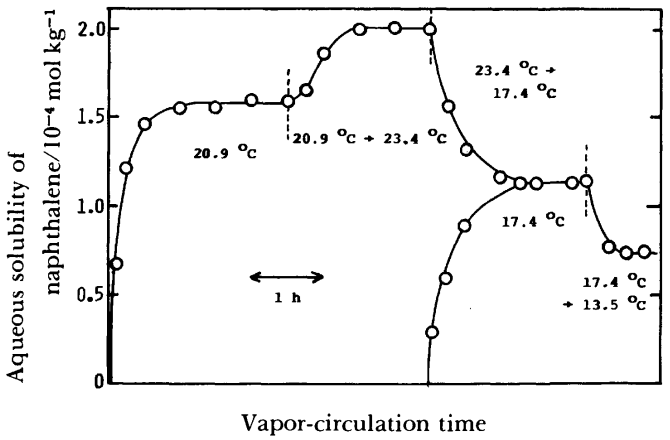

Fig. 1. Equilibrium solubility vs. vapor-circulation time. The temperature of solute reservoir in which solid naphthalene had been placed together with water was set as specified in Figure, while that of solubility flask was held constant at 25 °C.

Table 1. Equilibrium Solubility of Solid Aromatic Hydrocarbons in Water at 25 °C

Temperature of solute	Solute vapor pressure[a]	Equilibrium solubility[b]
°C	Pa	mol kg^{-1}
Biphenyl		
13.7	0.311	1.35×10^{-5}
20.1	0.621	2.60
23.1	0.852	3.48
24.9	1.03	4.25
Naphthalene		
16.6	4.60	1.05×10^{-4}
20.5	6.95	1.54
23.1	9.07	1.99
24.9	10.88	2.38
Anthracene		
10.9	1.08×10^{-4}	$0.329(0.389)\times10^{-7}$
15.2	2.06	0.646(2.22)
19.1	3.62	1.09(3.03)

15.4	0.711×10^{-2}	2.34×10^{-6}
20.7	1.36	4.09
21.9	1.57	4.33
23.0	1.79	5.18
24.2	2.07	5.91
25.0	2.27	6.22

a) The vapor pressure data of biphenyl,[3] naphthalene,[4] anthracene,[5] and phenanthrene,[5] are taken from the literature. b) Values of anthracene in the parentheses were obtained by UV absorption measurements, and these values are unreliable for the solubility data owing to some unknown impurities present in this hydrocarbon (see Text).

higher vapor pressure. This is illustrated in Fig. 1, which shows how naphthalene concentration in water at 25 °C varies with the circulation time after the temperature of the solute reservoir was changed.

Equilibrium Solubility and Solute Vapor Pressure. In Table 1 are given the equilibrium solubility values obtained under the experimental condition that the temperature of the solute reservoir was varied while that of the solubility flask was held constant at 25 °C. The equilibrium solubility of each solute is found to be proportional to the solute vapor pressure (Fig. 2). That is, solubility obeys Henry's law

$$P = K_H X_2, \quad (1)$$

where P is the partial pressure of the solute, X_2 is the mole fraction of the dissolved solute, and K_H is the Henry's law constant. Here, the solute in water being in equilibrium with the solid solute in the solute reservoir, we have taken the partial pressure of the solute to be equal to the vapor pressure of pure solid at the temperature of the solute reservoir. The vapor pressure at any desired temperature of each solid hydrocarbon, biphenyl,[3] naphthalene,[4] anthracene,[5] and phenanthrene,[5] has been estimated from the literature. The Henry's law constant at 25 °C and the aqueous solubility in mol kg^{-1} determined from K_H are summarized in Table 2. The solubility thus determined for the solute studied in this work is in reasonable agreement with that reported in our previous work and that cited therein.[1]

The Aqueous Solubility of Anthracene. In the beginning of this work, the anthracene solubility has been measured by the UV absorption method. Then, it appeared, as can be seen from Table 1, that the equilibrium solubility plotted against the anthracene vapor pressure, does not follow Henry's law, and that the solubility at 25 °C, 4.33×10^{-7} mol kg^{-1}, is two times larger than our previous value. We, then, adopted the fluorescence method to determine the concentration of anthracene, and found that Henry's law holds for this solute and that the solubility is in a reasonable agreement with our previous value.[1] We speculate that this is caused by some impurities present in anthracene and that the impurity is volatile and responds to UV absorption, but not to fluorescence measurements. The present method uses water as the disperse medium, and hence, some impurities are readily volatilized and dissolved into the separate water phase.

As was noted in the previous paper,[1] the literature data of anthracene solubility can be grouped into two well-defined values: 2.5 and 4.2×10^{-7} mol dm^{-3}. The lower value has been reported by researchers who adopted either the fluorescence technique[6] or the combination of HPLC-separation and absorption measurement.[7] This clearly indicates that some impurities are responsible for the higher solubility

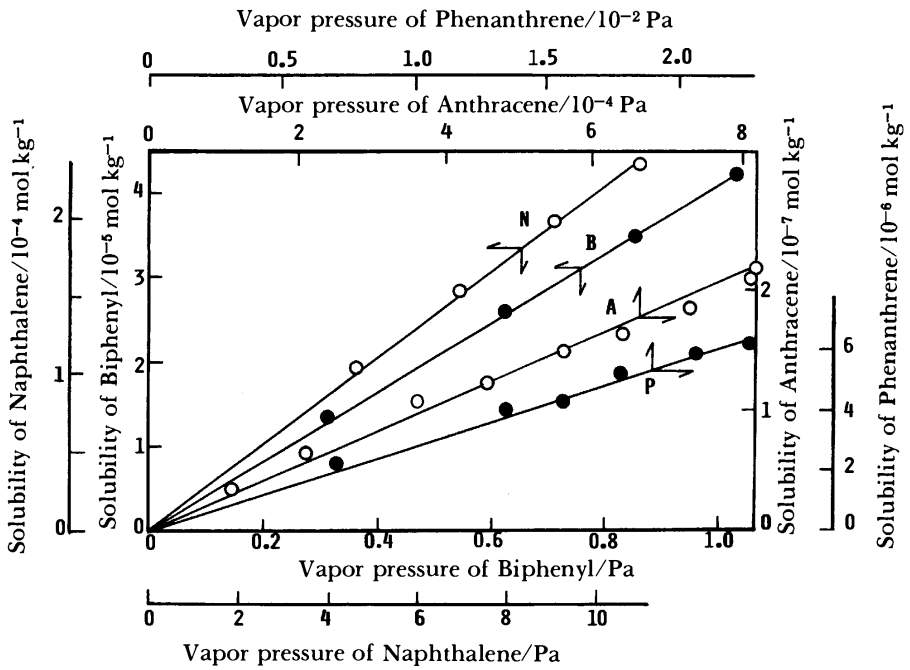

Fig. 2. Equilibrium solubility vs. solute vapor pressure. Biphenyl (B), naphthalene (N), anthracene (A), and phenanthrene (P).

Table 2. Henry's Law Constant and Aqueous Solubility at 25 °C

Solute	$P^{a)}$	$K_H{}^{b)}$	$S^{c)}$
	Pa	Pa	mol kg^{-1}
Biphenyl	1.04	1.34×10^{6}	4.30×10^{-5}
Naphthalene	10.98	2.52×10^{6}	2.42×10^{-4}
Anthracene	8.31×10^{-4}	2.11×10^{5}	2.18×10^{-7}
Phenanthrene	2.27×10^{-2}	1.96×10^{5}	6.45×10^{-6}

a) The vapor pressure of solid hydrocarbon at 25 °C taken from the literature. b) Henry's law constant determined in this work. c) The solubility of hydrocarbon in water estimated from K_H.

value of anthracene. May et al., who used the latter technique, assumed the impurity to be phenanthrene. If it is true, so long as the fluorescence technique is used, the presence of phenanthrene would increase considerably the apparent solubility of anthracene owing to the relatively high solubility of phenanthrene which also has fluorescence. We have analyzed both the cyclohexane extract of aqueous solution saturated with the vapor of anthracene and the cyclohexane solution of this solid hydrocarbon by gas chromatography (Shimadzu GC-14A, detector: FID, column packing: BBBT, temperature: 195 °C). As the result, phenanthrene was detected in neither of the cases.

In our previous study, where the UV absorption technique was employed, the value close to the present fluorescence result was obtained. This is probably due to that the impurities in the solid anthracene are soluble in such an organic solvent as 1-octanol. That is, they remain soluble in 1-octanol, while volatile in water.

The Utility of the Vapor Saturation Method. The use of a disperse medium is favorable for generating the vapor of the solute which exists as solid at ordinary temperatures. For this purpose, benzene and cyclohexane cannot be used,[1] but either 1-octanol or water is suitable. When water is used as the disperser, care should be taken, as was just mentioned above, of volatile impurities which might be present in the solid solute. The use of water as the disperser, however, makes the solubility system much simple, because the influence of 1-octanol, which is also dissolved in water, need not be considered.

We have studied aqueous solubility of volatile nonelectrolytes such as metallic mercury,[8] benzene and alkylbenzenes,[2] and iodine,[9] and demonstrated that the solute vapor circulation method is useful to determine experimentally whether the solute follows Henry's law. This is also the case for the solid aromatic hydrocarbons studied here. The present method has a potential application to such studies that

association of some hydrophobic solutes with aromatic hydrocarbons is to be determined in water by measuring the change of the solubility of aromatics.

The influence of temperature on the vapor pressure of a solid is given by the well-known equation

$$\mathrm{d} \ln P/\mathrm{d}T = \Delta H_{sub}/(RT^2), \quad (2)$$

where P is the sublimation vapor pressure, ΔH_{sub} is the enthalpy of sublimation, and T and R have usual meaning. As the concentration of a solid solute in the aqueous phase increases, the solute crystallizes out when the partial pressure of the solid solute equals its sublimation vapor pressure. This is the case for what happens in the solute reservoir in our present approach. We, therefore, take the vapor pressure, P, which appears in Eqs. 1 and 2, equal to each other in its physical quantity. Then, by combining Eqs. 1 and 2, ΔH_{sub} can be estimated for a solid hydrocarbon. Here, it is assumed that ΔH_{sub} is independent of temperature over the range studied. For each solute studied in this work, $\log X$ was plotted against T^{-1} (Fig. 3), and we get a straight line with a slope which corresponds to $-\Delta H_{sub}/(2.303\times8.314)$. The ΔH_{sub} value thus estimated over the temperature range of 15 to 25 °C is given in Table 3 together with some literature data. Reasonable agreements are found between data of this and the preceding works except for phenanthrene.

Two techniques have been used to prepare aqueous

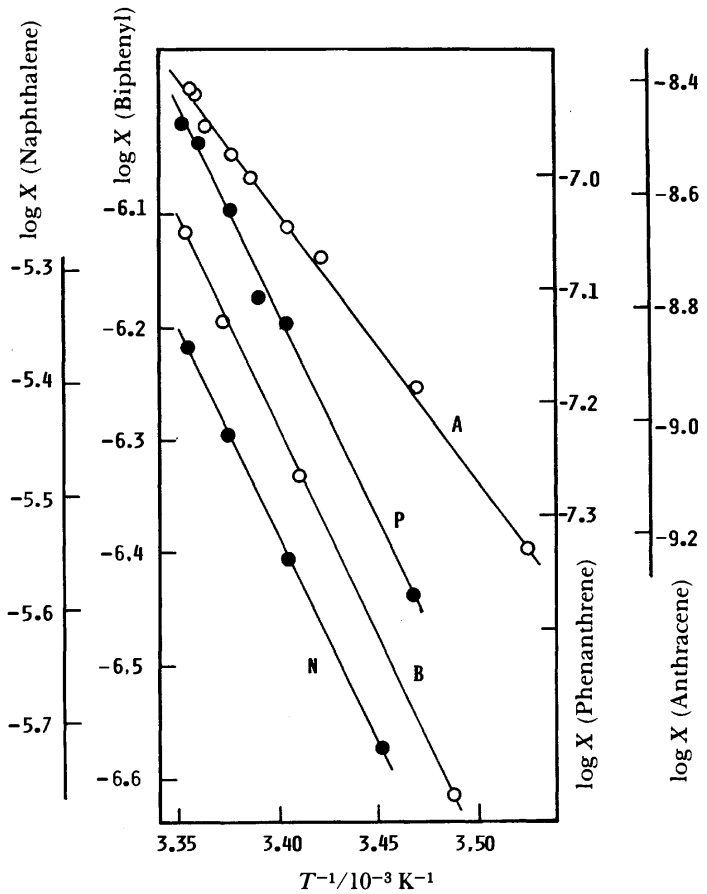

Fig. 3. $\log X$ vs. T^{-1}. X: equilibrium solubility at 25°C in mole fraction; T: absolute temperature of solute; biphenyl (B), naphthalene (N), anthracene (A), and phenanthrene (P).

Table 3. The Enthalpy of Sublimation Estimated from Equilibrium Solubility Over 15—25 °C

Solute	ΔH_{sub}/kJ mol^{-1}			
	This work	Literature data		
Biphenyl	72.4	72.8,[11]	75.8[3]	
Naphthalene	71.0	72.4,[5]	72.6,[12]	75.8[13]
Anthracene	90.9	91.8,[13]	103.8,[3]	104.5[12]
Phenanthrene	73.3	86.6,[3]	92.5,[12]	95.0[13]

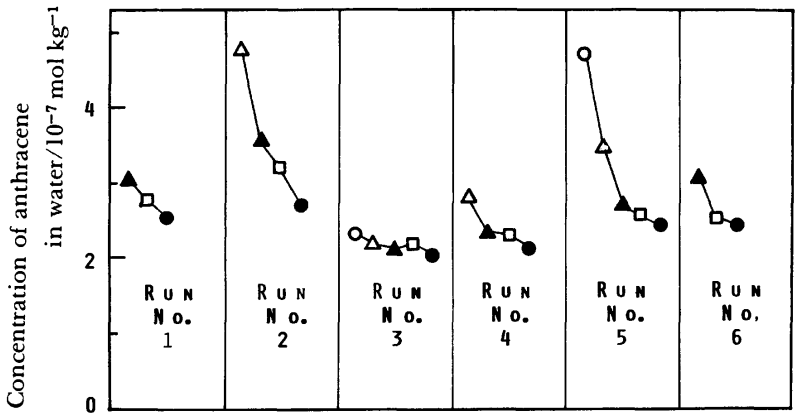

Fig. 4. Concentration of anthracene in water prepared by "shake-flask" technique, six replicated runs. The solid anthracene was stirred in water, and then, allowed to stand for 5(○), 7(△), 9(▲), 11(□), and 14 days(●).

solutions saturated with liquid or solid solutes: one is called "generator column,"[7] and the other "shake-flask." These techniques make the solute phase directly contact with water. The latter technique, most widely used for solubility studies, requires a long time to attain the solubility equilibrium and, subsequently, to settle the excess solute phase. In this work, we have also prepared aqueous solutions of anthracene by the conventional shake-flask method using the device described elsewhere,[10] to check the value obtained by the present solute vapor circulation method. The results of fluorescence measurements in six replicated runs are shown in Fig. 4. After an excess quantity of the solid hydrocarbon had been stirred in water for 24 h at 25 °C, the mixture was allowed to stand in the thermostated bath for two weeks, during which a portion of the aqueous phase was withdrawn periodically via a side-arm attached to the device. It was found that the solubility value approaches on standing for quite a long time the value obtained by the vapor circulation method. A "clear" aqueous phase appeared after the mixture was allowed to stand overnight. Nevertheless, considerably high "solubility" was observed. This is probably due to dispersion rather than true dissolution.

Advantages of the present method are (1) saturated solutions can be prepared in a relatively short time and (2) the removal of the excess solute phase is not required.

Hexacarbonylmolybdenum(0)-Induced Dechalcogenization of Allylic Sulfides, Sulfones, and Selenides: Nucleophilic Substitution and Reductive Dechalcogenization

Yoshiro MASUYAMA,* Kohji YAMADA, Soh-hei SHIMIZU, and Yasuhiko KURUSU

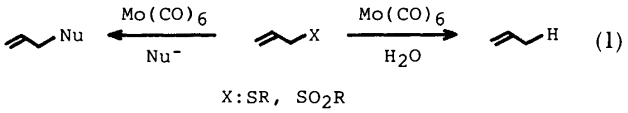
(Received February 13, 1989)

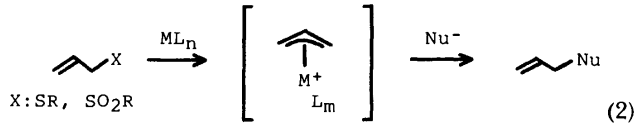
Hexacarbonylmolybdenum(0)-induced dechalcogenization of allylic sulfides **I**, sulfones **II**, and selenides **III** in refluxing dioxane, which led to nucleophilic substitutions with carbon nucleophiles. Attack of the relatively bulky nucleophile, 2-ethoxycarbonyl-2-sodiocyclopentanone occurred regioselectively at the less substituted end of the allyl unit after the dechalcogenization to give only one isomer. Attack of diethyl sodiomalonate to **I** and **III** occurred preferentially at γ-position, and that to **II** occurred preferentially at the more substituted end of the allyl unit after the desulfonylation. In the absence of the carbon nucleophiles, treatment of **I**, **II**, and **III** with $Mo(CO)_6$ in refluxing dioxane caused reductive dechalcogenization. Addition of H_2O accelerated the reductive dechalcogenization.

Organochalcogenides have made a great contribution to organic synthesis, due to the ability of the chalcogenide group to stabilize the adjacent carbanion.[1,2] In particular, allylic chalcogenides have been widely applied to the reactions with various electrophiles as reagents for three carbon homologation.[3] Since the chalcogenide-functional groups are rarely present in the final synthetic target, removal of the functional groups becomes an important subject. The representative removal methods are (1) β-elimination of the sulfide and selenide via oxidation[1,2] and of the sulfone under basic conditions[1,4] and (2) reductive defunctionalization of all groups with metal reagents.[1,5] The organochalcogen groups have not been generally utilized as the leaving groups in the nucleophilic substitutions with carbon nucleophiles. Use of a metal reagent, which has oxidizing-ability, may permit the nucleophilic substitution.[6] Hexacarbonylmolybdenum [$Mo(CO)_6$] seems to have both oxidizing and reducing abilities, since molybdenum has a variety of oxidation states between −2 and +6. In addition, molybdenum has thiophilicity. Thus, $Mo(CO)_6$ becomes an effective reagent for both the rare nucleophilic substitution (oxidation) and the reductive defunctionalization (reduction) of organosulfur compounds. The objective of our study is the development of an approach to this subject which has been achieved in allylic systems such as allylic sulfides and sulfones (Eq. 1).[7]



(1)

The early applications of the transition metal-promoted substitutions are represented by the nickel-catalyzed reaction of the allylic sulfides with Grignard reagents[8] and the palladium- or molybdenum-catalyzed reaction of the allylic sulfones with active methylene compounds.[9] These metal-promoted substitutions probably proceed via π-allylmetal complexes (Eq. 2).

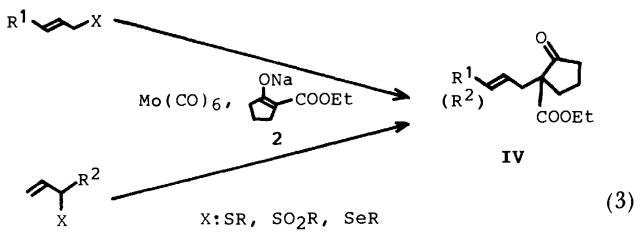


(2)

In both the nucleophilic substitutions and the reductive defunctionalizations of allylic sulfides, sulfones, and selenides with $Mo(CO)_6$, the properties of these organochalcogen groups should affect the coordination of olefins to molybdenum, namely the formation of π-allylmolybdenum complexes, to exhibit unique regiochemistry in the reaction of the allylic moieties.

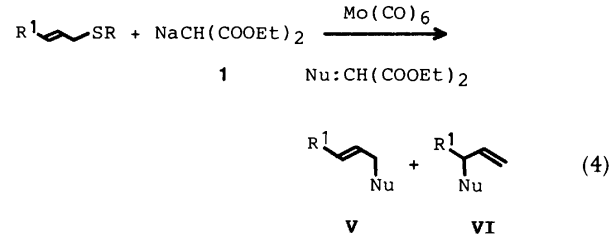
Results and Discussion

Nucleophilic Substitution. The $Mo(CO)_6$-induced nucleophilic substitution of allylic sulfides **I**, sulfones **II**, or selenides **III** with carbon nucleophiles, diethyl sodiomalonate (**1**) or 2-ethoxycarbonyl-2-sodiocyclopentanone (**2**) proceeded in refluxing dioxane under a nitrogen atmosphere to afford allylic alkylation products. The results are summarized in Table 1. In the reactions of **I** at 110 °C, use of dioxane as a solvent exhibited higher yield than that in solvents such as DMF and toluene, while the reaction did not occur in refluxing THF or benzene. Reactivity of **II** and **III** seems to be slightly higher than that of **I** in the nucleophilic substitution. Using any allylic compound mentioned above, the relatively bulky nucleophile **2** attacked regioselectively at the less substituted end of the allyl unit after the defunctionalization to produce only one isomer **IV** (Entries 4—7, 22—25, 35—38), as



(3)

shown in Eq. 3. The attack of nucleophile **1** to **I** occurred at γ-position (product **VI**) in preference to



(4)

α-position (product **V**) even in γ-substituted allyl sulfides (Entries 9, 10, 12, 13, Eq. 4). However, any steric hindrance of bulky substituent on γ-carbon should reduce the regioselectivity. The low reactivity of α-substituted allyl sulfides toward **1** is presumably attributable to preferential complexation of **1** and $Mo(CO)_6$,[10] since the bulky α-substituent disturbs that of the allyl sulfides and $Mo(CO)_6$. Thus, the results demonstrate that the reaction proceeds not via π-allylmolybdenum intermediate but via coordination of

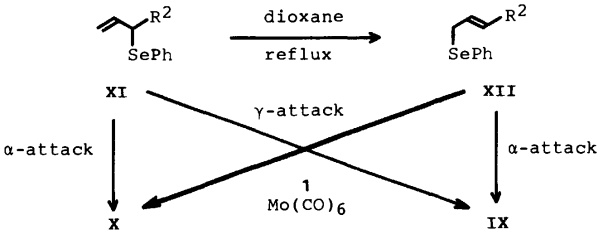
(5)

a sulfenyl group to molybdenum (chelate intermediate **VII**) (Eq. 5). Attack of **1** to α-substituted allyl sulfones occurred regioselectively at α-position, which is the more substituted end of the allyl unit, after the desulfonylation, contrary to the case of α-substituted allyl sulfides (Entries 19, 20, Eq. 5). Therefore, the intermediate derived from **II** and $Mo(CO)_6$ should be different from that derived from **I** and $Mo(CO)_6$. Since the nucleophilic substitution of π-allylmolybdenum complex, derived from allylic acetate and $Mo(CO)_6$, with dimethyl sodiomalonate has preferentially occurred at the more substituted end of the allyl unit,[10–12] π-allylmolybdenum intermediate **VIII** may be produced by the reaction of **II** with $Mo(CO)_6$, similarly to the case of π-allylpalladium complex prepared by that of **II** with $Pd(PPh_3)_4$ (Eq. 5).[9,13] In the case of γ-substituted allyl sulfones, the preparation of **VIII** may compete with that of the sulfide-like intermediate to afford the mixture of **a** and **b**, because bulky substituents on an olefin hindered π-coordination of the olefin (Entries 17, 18). γ-Substituted allyl selenides preferentially reacted with **1** at γ-position (Entries 29, 30). In contrast with α-substituted allyl sulfides, the γ-regioselective attack of **1** to α-substituted allyl selenides was not detected (Entries 31, 32). α-Substituted allyl selenides **XI** in refluxing dioxane easily caused [1,3] allylic shift of benzeneselenenyl group to produce γ-substituted allyl selenides **XII**.[14] In the reaction of **XI** with **1** in the presence of $Mo(CO)_6$, the [1,3] allylic shift should occur in preference to the nucleophilic substitution. Thus, the apparent attack of **1** at α-position of **XI** probably increased (Entries 31, 32, Eq. 6).



(6)

Reductive Dechalcogenization. The results of reductive dechalcogenization of 1-(3,4-methylenedioxybenzyl)allyl derivatives **17**, **18**, and **19** with $Mo(CO)_6$ are summarized in Table 2. These results demonstrated that reductive deselenenylation of allylic selenides with $Mo(CO)_6$ was easier than the corresponding reductive desulfenylation or desulfonylation. The addition of H_2O (or D_2O) accelerated the reductive dechalcogenization. Product **20c** was probably produced by the isomerization of **20b** with $Mo(CO)_6$, because elongation of the reaction time led to the increase of **20c**. Both the results of regioselectivity in deuteration with D_2O and the ratios of deuteration to protonation suggested that reaction mechanism of the reductive desulfonylation was different from that of

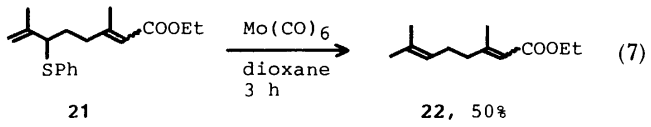
a) Isolated yields of a mixture of **20a**, **20b**, and **20c**. b) Ratio of isomers was determined by ^1H NMR (FX-200 or GX-270). c) The *E*/*Z* ratio of **20b** was ca 3/1 in every case. d) Complete deuteration occurred. e) The ratios of deuteration to protonation in every isomer were 13—15%. f) The ratios of deuteration to protonation in every isomer were 35—40%.

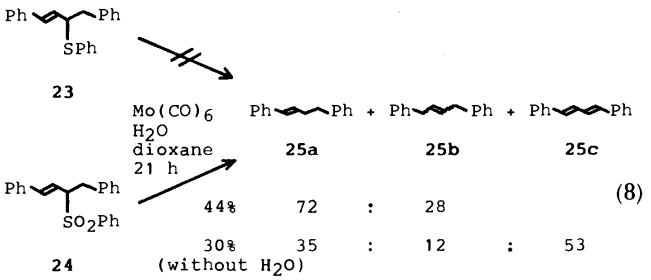
the reductive desulfenylation. The intermediates in the reductive dechalcogenizations seem to be the same as those in the corresponding nucleophilic substitutions. Deuteration scarcely occurred in the desulfenylation of **17** without H_2O in refluxing dioxane-d_8.[15]

The reductive desulfenylation of substrate **21**[16] proceeded more rapidly to give only one regioisomer **22** (Eq. 7). Even in the presence of nucleophile **1**, **21**



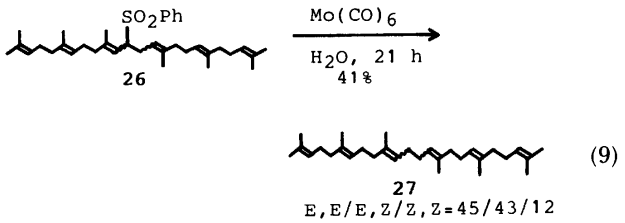
21 22, 50% (7)

did not cause nucleophilic substitution but did cause reductive desulfenylation. 1-Benzyl-3-phenylallyl sulfide **23** did not react with $Mo(CO)_6$, but the corresponding sulfone **24** caused reductive desulfonylation in the presence of H_2O to give **25a** and **25b** (Eq. 8). In



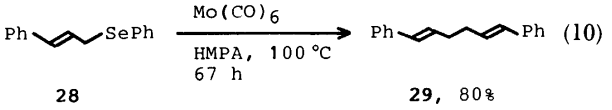
(8)

absence of H_2O, main product of the reaction was diene **25c**. Considering the ease of alkylation of allylic sulfones, the reductive desulfonylation could be applied to organic synthesis of alkene derivatives. This desulfonylation was applied to the synthesis of squalene (**27**) from allylic sulfone **26**[17] (Eq. 9).[18]



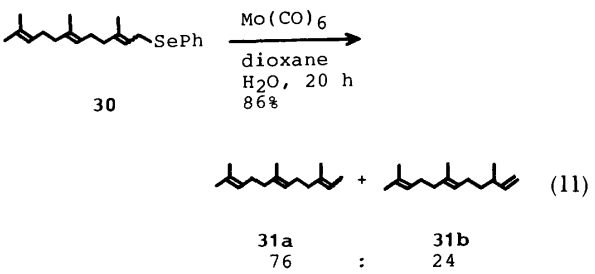
(9)

Cinnamyl phenyl selenide (**28**) did not cause the reductive deselenenylation in refluxing dioxane, but caused reductive allylic homocoupling at 100 °C in HMPA (Eq. 10). The reductive deselenenylation of



(10)

allylic selenide having trisubstituted olefin, farnesyl phenyl selenide (**30**), easily occurred in refluxing dioxane to give triene isomers **31a** and **31b** (Eq. 11).



(11)

Conclusion

Hexacarbonylmolybdenum-induced dechalcogenization of allylic sulfides, sulfones, and selenides, which led to nucleophilic substitution with carbon nucleophiles and reduction without the carbon nucleophiles. Yields in the nucleophilic substitution were not so high, since reductive dechalcogenization presumably occurred even in the presence of the carbon nucleophiles. $Mo(CO)_6$ could thus be used as both an oxidizing agent and a reducing agent in the dechalcogenization. The reactivity of sulfonyl and selenenyl groups with $Mo(CO)_6$ seems to be higher than that of sulfenyl groups with $Mo(CO)_6$. The regiochemistry in both the nucleophilic substitution and the reduction of allylic sulfones was different from that in reactions of both allylic sulfides and selenides. The intermediate should hence be different for allylic sulfones and for allylic sulfides and selenides. Both reactions of allylic sulfones probably proceeded via π-allylmolybdenum intermediates. In contrast with allylic sulfones, allylic sulfides and selenides should not form the corresponding π-allylmolybdenum intermediates, since the coordination of sulfenyl and selenenyl groups to molybdenum center was stronger than that of olefinic moiety.

Experimental

General. $Mo(CO)_6$ was purchased from Strem Chemicals, Inc. Benzenethiol, 2-pyridinethiol, sodium benzenesulfinate, sodium *p*-toluenesulfinate, 3-bromo-1-propene, 3-chloro-1-phenyl-1-propene, 1-chloro-2-butene, 3-chloro-2-methyl-1-propene, 1-iodobutane, iodomethane, benzyl bromide, diethyl malonate, methyl vinyl ketone, and ethyl diethoxyphosphinylacetate were purchased from Tokyo Chemical Industry Co., Ltd. Diphenyl diselenide was prepared by the reaction of phenylmagnesium bromide with selenium, followed by oxidation. 2-(Ethoxycarbonyl)-cyclopentanone was prepared by the Dieckmann condensation. Allyl and γ-substituted allyl sulfides, sulfones, and selenides were prepared by reactions of allylic halides with sodium thiolates, sulfinates, and selenolates, respectively. α-Substituted allyl sulfides and selenides were prepared by alkylation of the anion of the corresponding allylic compounds with alkyl halides.[3] α-Substituted allyl sulfones were prepared by molybdenum-catalyzed oxidation of the corresponding allylic sulfides with H_2O_2. Sodium hydride and potassium hydride were employed after removal of mineral oil from 60 wt.% dispersion NaH and 35 wt.% dispersion KH, respectively (Wako Pure Chemical Industries,

Ltd.). Sodium borohydride was purchased from Wako Pure Chemical Industries, Ltd. Dioxane, tetrahydrofuran, and toluene were distilled from sodium benzophenone ketyl. Purification of products was carried out by means of column chromatography (E. Merck, Silica gel 60). IR spectra were recorded on a Hitachi 260-50 spectrophotometer, ^{1}H NMR spectra on Hitachi R-22 and Jeolco FX-200 and GX-270 spectrometers, and mass spectra on a Jeolco JMS-D300 spectrometer.

General Procedure of Nucleophilic Substitution. To a solution of carbanion derived from diethyl malonate (0.16 g, 1.0 mmol) or 2-(ethoxycarbonyl)cyclopentanone (0.16 g, 1.0 mmol) with sodium hydride (29 mg, 1.2 mmol) in dry dioxane (5 ml) were added allylic compounds **I**, **II**, or **III** (1 mmol) and Mo(CO)$_6$ (1.1 mmol). This mixture was refluxed for 16—87 h under nitrogen atmosphere. The reaction mixture was diluted with chloroform (30 ml) and a precipitate was removed from the mixture by filtration. Evaporation of solvents and purification by column chromatography on silica gel using hexane/ethyl acetate (7/1) as eluent gave the product.

2-Ethoxycarbonyl-2-(2-propenyl)cyclopentanone (**3**): IR and ^{1}H NMR spectra corresponded with those of the authentic sample.[19]

2-[(*E*)-2-Butenyl]-2-(ethoxycarbonyl)cyclopentanone (**4**): IR and ^{1}H NMR spectra corresponded with those of the authentic sample.[19]

2-Ethoxycarbonyl-2-[(*E*)-3-phenyl-2-propenyl]cyclopentanone (**5**): IR (neat) 1750, 1715, 1220, 1150, 1020, 740, 690 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=1.25 (t, J=7.18 Hz, 3H), 1.85—2.87 (m, 8H), 4.16 (q, J=7.18 Hz, 2H), 6.09 (dt, J=15.7, 7.53 Hz, 1H), 6.45 (d, J=15.7 Hz, 1H), 7.15—7.36 (m, 5H). The IR and ^{1}H NMR spectra corresponded with those of one regioisomer of the authentic sample.[19]

2-Ethoxycarbonyl-2-(6-phenyl-2,5-hexadienyl)cyclopentanone (**6**): IR (neat) 1750, 1720, 1220, 1150, 1020, 740, 690 cm^{-1}. ^{1}H NMR (CCl_4) δ=1.21 (t, J=7.0 Hz, 3H), 1.74—2.70 (m, 8H), 2.84 (br. t, J=5.4 Hz, 2H), 4.06 (q, J=7.0 Hz, 2H), 5.16—5.68 (m, 2H), 6.01 (dt, J=15.4, 5.4 Hz, 1H), 6.28 (d, J=15.4 Hz, 1H), 7.02—7.32 (m, 5H). MS (70 eV) m/z (rel intensity) 312 (M^+; 0.4), 199 (39), 198 (48), 156 (100), 141 (32), 117 (79), 115 (41), 104 (54), 91 (76). Calcd for $C_{20}H_{24}O_3$: M, 312.1724. Found: m/z 312.1717.

2-Ethoxycarbonyl-2-(2-heptenyl)cyclopentanone (**7**): IR (neat) 1750, 1720, 1220, 1155 cm^{-1}. ^{1}H NMR (CCl_4) δ=0.89 (br. t, J=6.5 Hz, 3H), 1.24 (t, J=7.0 Hz, 3H), 1.22—1.42 (m, 4H), 1.75—2.70 (m, 10H), 4.15 (q, J=7.0 Hz, 2H), 5.06—5.70 (m, 2H). MS (70 eV) m/z (rel intensity) 252 (M^+; 6.8), 179 (41), 156 (91), 121 (100), 110 (44), 55 (43). Calcd for $C_{15}H_{24}O_3$: M, 252.1724. Found: m/z 252.1727.

2-(2-Cyclohexenyl)-2-(ethoxycarbonyl)cyclopentanone (**8**): IR (neat) 1750, 1720, 1220, 1155 cm^{-1}. ^{1}H NMR (CCl_4) δ=1.21 (t, J=7.0 Hz, 3H), 1.42—2.54 (m, 12H), 2.84—3.22 (br, 1H), 4.08 (q, J=7.0 Hz, 2H), 4.97—5.41 (m, 1H), 5.52—5.78 (m, 1H).

A mixture of diethyl 2-butenylmalonate and diethyl 1-methyl-2-propenylmalonate (**9**) (Entry 9 in Table 1): IR (neat) 1740, 1635, 1260, 1220, 1175, 1145, 1030 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=1.11 (d, J=6.84 Hz, 2.19H), 1.25, 1.27 (2t, J=7.18 Hz, 6H), 1.64 (d, J=6.22 Hz, 0.81H), 2.54—2.69 (m, 0.54H), 2.88—3.00 (m, 0.73H), 3.27 (d, J=8.89 Hz, 0.73H), 3.36 (t, J=7.70 Hz, 0.27H), 4.17, 4.22 (2q, J=7.18 Hz, 4H), 5.01 (dd, J=10.2, 2.60 Hz, 0.73H), 5.09 (dd, J=17.5, 2.60 Hz, 0.73H), 5.20—5.62 (m, 0.54H), 5.79 (ddd, J=17.5, 10.2, 7.86 Hz, 0.73H). MS (70 eV) m/z (rel intensity) 214 (M^+; 5.6), 141 (100), 140 (35), 123 (44), 113 (32), 112 (53), 95 (30), 55 (47). Calcd for $C_{11}H_{18}O_3$: M, 214.1204. Found: m/z 214.1198.

A mixture of diethyl 3-phenyl-2-propenylmalonate and diethyl 1-phenyl-2-propenylmalonate (**10**) (Entry 10 in Table 1): IR (neat) 1745, 1730, 1255, 1225, 1170, 1150 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=1.25 (t, J=7.18 Hz, 6H), 2.80 (dd, J=7.52, 7.18 Hz, 1H), 3.49 (t, J=7.52 Hz, 0.5H), 3.83 (d, J=10.9 Hz, 0.5H), 4.06—4.15 (m, 0.5H), 4.20 (q, J=7.18 Hz, 4H), 5.07 (d, J=10.2 Hz, 0.5H), 5.12 (d, J=17.0 Hz, 0.5H), 6.00 (ddd, J=17.0, 10.2, 8.12 Hz, 0.5H), 6.15 (dt, J=15.7, 7.18 Hz, 0.5H), 6.47 (d, J=15.7 Hz, 0.5H), 7.15—7.35 (m, 5H). MS (70 eV) m/z (rel intensity) 276 (M^+; 5.9), 203 (100), 175 (21), 129 (48), 117 (92), 115 (29). Calcd for $C_{16}H_{20}O_4$: M, 276.1360. Found: m/z 276.1358.

Diethyl 1-methyl-2-butenylmalonate (**11**): IR (neat) 1730, 1240, 1150 cm^{-1}. ^{1}H NMR (CCl_4) δ=1.00 (d, J=7.0 Hz, 3H), 1.21 (br. t, J=7.0 Hz, 6H), 1.58 (d, J=4.5 Hz, 3H), 2.64—2.86 (m, 1H), 3.02 (d, J=7.5 Hz, 1H), 4.05, 4.08 (2d, J=7.0 Hz, 4H), 5.00—5.67 (m, 2H).

A mixture of diethyl 1-butyl-2-butenylmalonate (**12**): IR (neat) 1730, 1240, 1150 cm^{-1}. ^{1}H NMR (CCl_4) δ=0.70—1.08 (br, 3H) 1.03 (d, J=6.0 Hz, 2.1H), 1.15—1.74 (m, 10.6H), 1.61 (d, J=5.6 Hz, 0.9H), 1.74—2.14 (m, 1.4H), 2.44—3.02 (m, 1H), 3.02—3.21 (m, 1H), 3.92—4.26 (m, 4H), 5.00—5.56 (m, 2H).

A mixture of diethyl 1-butyl-2-propenylmalonate and diethyl 2-heptenylmalonate (**13**) (Entry 32 in Table 1): IR (neat) 1750, 1725, 1240, 1150 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=0.80—0.95 (br, 3H), 1.15—1.45 (m, 11H), 1.95—2.03 (m, 1H), 2.57 (dd, J=6.60, 6.30 Hz, 1H), 2.83—2.90 (m, 0.5H), 3.30—3.42 (m, 1H), 4.18 (q, J=7.18 Hz, 4H), 5.03—5.14 (m, 1H), 5.25—5.74 (m, 1.5H). MS (70 eV) m/z (rel intensity) 256 (M^+; 6.5), 199 (81), 183 (83), 165 (42), 161 (30), 160 (100), 155 (30), 153 (38), 140 (34), 133 (36), 127 (39), 125 (43), 115 (31), 81 (37), 67 (34), 55 (87). Calcd for $C_{14}H_{24}O_4$: M, 256.1673. Found: m/z 256.1677.

Diethyl 2-propenylmalonate (**14**): IR (neat) 1725, 1270, 1115 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=1.27 (t, J=7.18 Hz, 6H), 2.61—2.67 (m, 2H), 3.42 (t, J=7.52 Hz, 1H), 4.20 (q, J=7.18 Hz, 4H), 5.06 (dd, J=10.3, 2.60 Hz, 1H), 5.12 (dd, J=17.1, 2.60 Hz, 1H), 5.78 (ddt, J=17.1, 10.3, 6.83 Hz, 1H). MS (70 eV) m/z (rel intensity) 200 (M^+; 3.0), 182 (30), 153 (39), 127 (40), 109 (36), 105 (100), 98 (32), 93 (29), 81 (27), 77 (53). Calcd for $C_{10}H_{16}O_4$: M, 200.1048. Found: m/z 200.1045.

Diethyl 1-benzyl-2-propenylmalonate (**15**): IR (neat) 1730, 1230, 1150 cm^{-1}. ^{1}H NMR (CCl_4) δ=1.21 (t, J=6.8 Hz, 6H), 2.43—2.92 (m, 3H), 3.25 (d, J=6.0 Hz, 1H), 4.09 (2q, J=6.8 Hz, 4H), 4.72—4.95 (m, 2H), 5.46—5.90 (m, 1H), 6.93—7.24 (m, 5H).

2-Ethoxycarbonyl-2-(4-phenyl-2-butenyl)cyclopentanone (**16**): IR (neat) 1745, 1720, 1220, 1150, 750, 700 cm^{-1}. ^{1}H NMR (CCl_4) δ=1.17 (t, J=7.2 Hz, 3H), 1.63—2.70 (m, 8H), 3.24 (d, J=6.4 Hz, 2H), 4.03 (q, J=7.2 Hz, 2H), 5.10—5.75 (m, 2H), 6.90—7.25 (m, 5H). MS (70 eV) m/z (rel intensity) 286 (M^+; 0.1), 131 (16), 130 (100), 129 (13), 121 (11), 91 (20). Calcd for $C_{18}H_{22}O_3$: M, 286.1568. Found: m/z 286.1565.

General Procedure of Reductive Dechalcogenization. A solution of allylic compound **I**, **II**, or **III** (1 mmol), Mo(CO)$_6$ (1.1 mmol), and H_2O (5 mmol) in dioxane (7 ml) was refluxed for 3—40 h under nitrogen atmosphere. The reaction mixture was diluted with chloroform (40 ml) and

precipitate material was removed from the mixture by filtration. Evaporation of solvents and purification by column chromatography on silica gel using hexane or hexane/ethyl acetate as eluent gave the product.

A mixture of 4-(3,4-methylenedioxyphenyl)-1-butene (**20a**), 1-(3,4-methylenedioxyphenyl)-2-butene (**20b**), and 1-(3,4-methylenedioxyphenyl)-1-butene (**20c**): ^{1}H NMR ($CDCl_3$) **20a**: δ=2.33 (m, 2H), 2.62 (t, J=7.42 Hz, 2H), 4.97 (br. d, J=10.9 Hz, 1H), 5.02 (br. d, J=18.0 Hz, 1H), 5.76—5.88 (m, 1H), 5.91 (s, 2H), 6.60 (br, 1H), 6.63 (br, 2H), **20b**: δ=1.67 (br. d, J=5.10 Hz, 3H), 3.22, 3.31 (E/Z=81/19, 2d, J=5.10, 5.79 Hz, 2H), 5.49—5.56 (m, 2H), 5.92 (s, 2H), 6.67 (br, 2H), 6.71 (s, 1H), **20c**: δ=1.07 (t, J=7.52 Hz, 3H), 2.19 (m, 2H), 5.90 (s, 2H), 6.08 (dt, J=15.6, 6.33 Hz, 1H), 6.28 (d, J=15.6 Hz, 1H), 6.73 (br, 2H), 6.89 (br, 1H). MS (70 eV) m/z (rel intensity) 176 (M^+, 93), 161 (29), 131 (100), 103 (46), 77 (22). Calcd for $C_{11}H_{12}O_2$: M, 176.0836. Found: m/z 176.0836.

Ethyl 3,7-dimethyl-2,6-octadienoate (**22**): ^{1}H NMR (CCl_4) δ=1.21 (t, J=7.2 Hz, 3H), 1.56 (s, 3H), 1.64 (s, 3H), 1.90—2.30 (m, 4H), 2.09 (s, 3H), 4.02 (q, J=7.2 Hz, 2H), 5.00 (m, 1H), 5.51 (br, 1H). The NMR spectrum corresponded with that of the authentic sample derived from 6-methyl-5-hepten-2-one and ethyl diethoxyphosphinylacetate with t-BuOK.

A mixture of stereoisomers of squalene (**27**): ^{1}H NMR ($CDCl_3$) δ=1.60, 1.68 (2s, 24H), 1.90—2.15 (m, 20H), 5.03—5.19 (m, 6H). The NMR spectrum corresponded with that of an authentic sample.[20] The isomer ratio was determined by GLPC [5% OV-17/Chromosorb W (AW-DMCS), 60—80 mesh, 2 m, He, 200 °C].[20]

1,6-Diphenyl-1,5-hexadiene (**29**): IR (KBr) 1590, 1480, 1180, 1065, 1015, 735 cm^{-1}. ^{1}H NMR (CCl_4) δ=2.23—2.38 (br, 4H), 6.07 (dt, J=16.0, 5.8 Hz, 2H), 6.35 (t, J=16.0 Hz, 2H), 6.90—7.25 (m, 10H). The IR and NMR spectra and retention time of GLPC [5% OV-17/Chromosorb W (AW-DMCS), 60—80 mesh, 2 m, He, 230 °C] corresponded with those of an authentic sample.[20]

A mixture of 2,6,10-trimethyl-2,6,10-dodecatriene (**31a**) and 3,7,11-trimethyl-1,6,10-dodecatriene (**31b**): IR (neat) 2960, 2920, 970 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=0.95 (d, J=6.96 Hz, 0.72H), 1.53—1.75 (m, 14.0H), 1.90—2.20 (br, 7.8H), 4.90 (dd, J=9.60, 2.20 Hz, 0.24H), 4.95 (d, J=16.0 Hz, 0.24H), 5.11 (t, J=5.38 Hz, 2H), 5.20 (q, J=6.70 Hz, 0.76H), 5.68 (ddd, J=16.0, 9.60, 7.80 Hz, 0.24H). MS (70 eV) m/z (rel intensity) 206 (M^+, 6), 137 (14), 123 (14), 81 (62), 69 (100), 55 (18). Calcd for $C_{15}H_{26}$: M, 206.2033. Found: m/z 206.2033.

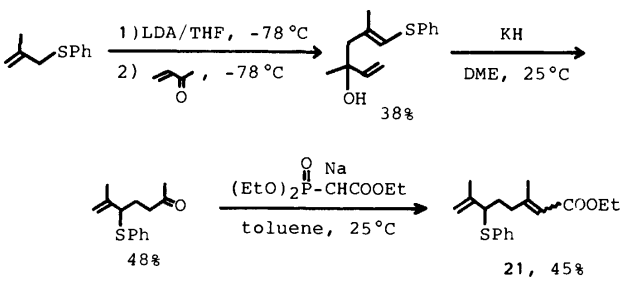
13) In order to detect π-allylmolybdenum intermediate **VIII**, ^{1}H NMR spectroscopic investigation was carried out in the reaction of allyl tolyl sulfone with $Mo(CO)_6$ in dioxane at 100 °C. The formation of **VIII** was not confirmed, since the reductive desulfonylation probably occurred rapidly. In a case of allyl phenyl sulfide, neither chelate intermediate **VII** nor π-allyl intermediate was detected.

A typical procedure of the [1,3] allylic shift of benzeneselenenyl group is as follows: 4-(3,4-methylenedioxyphenyl)-3-phenylseleno-1-butene (3.3 g, 10 mmol) was stirred for 23 h in refluxing dioxane. Evaporation of dioxane and purification by column chromatography (Wakogel C-200, hexane/AcOEt=20/1) gave 1-(3,4-methylenedioxyphenyl)-4-phenylseleno-2-butene (2.8 g, 85%). The [1,3] allylic shift of benzenesulfenyl group in α-substituted allyl sulfides did not occur under the same conditions; see: P. Brownbridge and S. Warren, *J. Chem. Soc., Chem. Commun.*, **1975**, 820.

15) In the reductive desulfenylation without adding H_2O, proton source was not detected.

16) Preparation of **21** was carried out in the following manner:



17) The isomer ratio (*E,E/E,Z/Z,E/Z,Z*) of allylic sulfone **26** was not determined by ^{1}H NMR.

A New Synthesis of 3-Hydroxy-2,5-dialkyl-1,4-benzoquinone from 3-Halo-3,6-dialkyl-1,2-cyclohexanedione Using Iodine-Copper(II) Acetate

C. Akira HORIUCHI* and Yasuto SUZUKI
Department of Chemistry, Rikkyo (St. Paul's) University, Nishi-Ikebukuro, Toshima-ku, Tokyo 171
(Received February 25, 1989)

The reaction of 3-iodo-3,6-dialkyl-1,2-cyclohexanedione (**2**) with iodine-copper(II) acetate in acetic acid-water (5:1) at 80 °C gave the respective 3-hydroxy-2,5-dialkyl-1,4-benzoquinone in 38—80% yields. On the other hand, the reaction of **2** with copper(II) acetate in acetic acid-water (10:1) under refluxing afforded the respective 3,3′-dihydroxy-2,2′,5,5′-tetraalkyl-4,4′-diphenoquinone (**5**) in 41—85% yields. In the case of 3-bromo-3,6-dialkyl derivative (**3**) with copper(II) acetate, the diphenoquinone derivatives and 3-hydroxy-2,5-dialkyl-1,4-benzoquinone were obtained.

3-Hydroxy-2,5-dialkyl-1,4-benzoquinones are important as intermediates,[1-4] and hydroxy-1,4-benzoquinone derivatives are known as natural products.[5-9] Much work has been reported on the syntheses of 3-hydroxy-2,5-dialkyl-1,4-benzoquinone.[1,2,10,11] However, all of these methods give only a low yield and involve several steps in preparing the starting materials. Diphenoquinone derivatives and 3,3′-dihydroxy-4,4′-diphenoquinones, both those having and not having alkyl groups, are often used as dyes, possessors of biological activity, electron acceptors, and synthetic intermediates.[12] 3,3′-Dihydroxy derivatives are prepared by one of the following methods: the reaction of 2-hydroxy-5-methoxybenzaldehyde with hydrogen peroxide-sodium hydroxide;[13] the reaction of 3-hydroxy-2,5-dimethyl-1,4-benzoquinone with boron trifluoride etherate;[3] or the Ullmann Reaction of 4-iodoveratrole.[14] Though these methods involve several steps to prepare the starting materials, they have been little afforded 3,3′-dihydroxy-2,2′,5,5′-tetraalkyl-4,4′-diphenoquinone. There has been no information concerning a direct synthesis from the cyclic 1,2-diketone derivative. In connection with our studies, we have found that iodine-copper(II) acetate in acetic acid is a useful reagent for the syntheses of some iodo compounds.[16] In a previous paper[17] we reported on a new synthesis of 3-hydroxy-2,5-dialkyl-1,4-benzoquinones using iodine-copper(II) acetate.

In the present paper we would like to report that the reaction of 3-bromo- and 3-iodo-3,6-dialkyl-1,2-cyclohexanedione with iodine-copper(II) acetate or copper(II) acetate in acetic acid-water gave the corresponding 3-hydroxy-2,5-dialkyl-1,4-benzoquinone or 3,3′-dihydroxy-2,2′,5,5′-tetraalkyldiphenoquinone, respectively.

The reaction of **2c—2e** with iodine (0.5 mol equiv)-copper(II) acetate (1.0 mol equiv) in acetic acid-water (5:1) at 80 °C for 5 h gave the 3-hydroxy-2,5-dialkyl-1,4-benzoquinone (47% for **4c**; 67% for **4d** and **4′d**; and 38% for **4e**). These 1,4-benzoquinones showed IR absorption at 3288—3296 (OH), 1656—1668 (C=O), 1634—1640 (C=O), and 1614—1616 cm^{-1} (C=C) in their IR spectra. The IR and UV spectra indicated that they had *p*-quinonoid structures with a hydroxyl group in the molecule. The ^1H NMR spectra of these hydroxy-1,4-benzoquinones (**4c—4e**) showed a doublet at δ 6.42 (J=0.70 Hz) for **4c**, a triplet at δ 6.49 (J=1.71 Hz) for **4d**, and a triplet at δ 6.46 (J=1.0 Hz) for **4e** assignable to the C_6-H. Compound **4′d** showed a doublet at δ 2.07 (J=1.71 Hz) and a triplet at δ 6.49 (J=1.71 Hz) in the ^1H NMR spectrum. Therefore, **4c**, **4d**, and **4e** were presumed to be 3-hydroxy-2,5-dialkyl-1,4-benzoquinone and **4′d** was presumed to be 5-hydroxy derivative. These were also supported by the ^{13}C NMR spectral data.

The reaction of 3-iodo-1,2-diketone (**2a**, **2b**, **2c**, **2d**, and **2e**) with copper(II) acetate (1.5 mol equiv.) in acetic acid-water (10:1) under refluxing for 4 h yielded reddish crystals (**5a**, **5b**, **5c**, **5d**, and **5e**) in a 41—82% yield, and 3-hydroxy-1,4-benzoquinones (**4a**, **4b**, **4c**, and **4e**) in a 3—14% yield. These compounds showed absorption at 3440—3480 (OH), 1650—1654 (C=O), 1636—1642 (C=O), and 1594—1600 cm^{-1} (C=C) in their IR spectra. The ^1H NMR spectra of these compounds showed a singlet at δ 6.89—7.00 due to the CH of the *p*-quinonoid structure. The UV spectra showed absorption at 406 nm due to diphenoquinone.

On the basis of the IR, ^1H NMR, UV, and HRMS spectral data for **5a**, **5b**, **5c**, **5d**, and **5e**, the structures of these diphenoquinones were determined to be 3,3′-dihydroxy-2,2′,5,5′-tetraalkyl-4,4′-diphenoquinone.

Table 1. Products and Isolated Yields (%) in the Reaction of 3-Iodo-1,2-cyclohexanedione (**2a—2e**) with Iodine-Copper(II) Acetate

$$2 \xrightarrow[\text{AcOH-H}_2\text{O}]{\text{I}_2\text{-Cu(OAc)}_2} 4$$

Substrate	Products (%)
2a	**4a** (80)
2b	**4b** (50) **7b** (34)
2c	**4c** (47)
2d	**4d**,**4′d** (67)[a]
2e	**4e** (38)

a) **4d**:**4′d**=60:40.

Table 2. Products and Isolated Yields (%) in the Reaction of 3-Iodo- (**2a**—**2e**) and 3-Bromo-1,2-cyclohexanedione (**3a**—**3e**) with Copper(II) Acetate

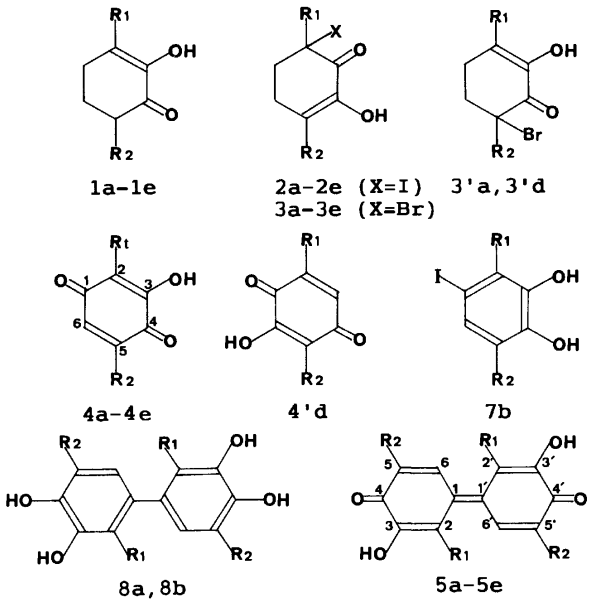
$$\textbf{2 or 3} \xrightarrow[\text{AcOH-H}_2\text{O}]{\text{Cu(OAc)}_2} \textbf{4 + 5}$$

Substrate	Products (%)	
2a	**4a** (3)	**5a** (43)
2b	**4b** (5)	**5b** (41)
2c	**4c** (12)	**5c** (82)
2d	**4d** (1)	**5d** (72)
2e	**4e** (14)	**5e** (44)
3a,3'a	**4a** (19)	**5a** (25)
3b	**4b** (22)	**5b** (21)
3c	**4c** (16)	**5c** (16)
3d,3'd	**4d,4'd** (8)[a]	**5d** (60)
3e	**4e** (15)	**5e** (41)

a) **4d**:**4'd**=59:41.

These were also supported by the ^{13}C NMR spectral data. The oxidation of 3,3',4,4'-tetrahydroxy-2,2',5,5'-tetraalkylbiphenyl (**8a** and **8b**) produced as an intermediate with copper(II) acetate yielded the diphenoquinone derivative (**5a** and **5b**).

On the other hand, to investigate the properties of other halogen, the reaction of 3-bromo-1,2-diketone (**3a**, **3b**, **3c**, **3d**, and **3e**) with copper(II) acetate was carried out. These reactions gave the hydroxyquinone (8—22%) and diphenoquinone (16—60%). In the case of diosphenol (**1a**) with bromine-copper(II) acetate, the hydroxyquinone (**4a**) (21%) was obtained. It seemed that these results indicated our previously proposed reaction pathway: 3-iodo-3,6-dialkyl-1,2-diketone⟶3,6-dialkyl-1,2-benzenediol⟶4-iodo derivative⟶4-hydroxy-1,2-diketone⟶3-hydroxy-1,4-benzoquinone. It is assumed that copper(I) iodide can not recycle, but copper(II) bromide is given by the reaction of copper(I) bromide and hydrogen bromide produced with oxygen in the air. Therefore, in the case of 3-bromo-1,2-diketone, it seemed that a considerable sum of hydroxy-1,4-benzoquinone was yielded by the reaction pathway mentioned above. In the absence of halogen, the coupling reaction occurs preferentially, rather than the following pathway: halogenation⟶hydrolysis⟶oxidation.



a:R_1=Me, R_2=i-Pr
b:R_1=R_2=Me
c:R_1=Me, R_2=Cyclohexyl
d:R_1=Me, R_2=Et
e:R_1=R_2=Et

Experimental

All the melting points are uncorrected. The IR apectra were measured using a Hitachi Model 270-30 grating infrared spectrometer. The NMR spectra were measured using JEOL FX 200 Model Spectrometer in deuteriochloroform with TMS as an internal standard. The high-resolution mass spectra were recorded at 75 eV on a JEOL JMS-O1SG-2 instrument with a direct inlet.

3,6-Dialkyl-1,2-cyclohexanedione (1a—1e). These compounds (**1a**—**1e**) were synthesized by the methods described in the literature.[18]

3-Iodo-3,6-dialkyl-1,2-cyclohexanedione (2a—2e). Diosphenol (**1a**) (0.50 g) in acetic acid-water (5:1) (48 ml) was treated with iodine (0.80 g) and copper(II) acetate (0.65 g) at room temperature for 8 h. The precipitated copper(I) iodide was removed by filtration, and the solvent was then removed under reduced pressure. The residue was poured into water and extracted with ether. The ethereal solution was washed successively with aqueous sodium hydrogencarbonate and with water, dried, and concentrated. Crystallization of the residue from ethanol gave needles of **2a** (0.80 g) (83%), mp 85—87 °C.[17]

2b: Yield 80%, mp 109—110 °C.[17]

2c: Yield 76%, mp 97—98 °C; IR (KBr): 3440, 1658, and 1624 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=2.11 (s, 3H), 2.75 (m, 1H), and 6.10 (s, 1H); ^{13}C NMR ($CDCl_3$): δ=190.6, 138.8, 138.2, 46.0, 41.6, 38.8, 30.9, 30.0, 29.4, 26.2, 26.1, 26.0, and 25.4. Found: *m/z* 334.042. Calcd for $C_{13}H_{19}O_2I$: M, 334.043.

2d: Yield 67%; mp 81—83 °C; IR (KBr): 3440, 1670, and 1626 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=0.96 (t, 3H), 1.94 (s, 3H), 2.04 (m, 2H), and 6.10 (s, 1H); ^{13}C NMR ($CDCl_3$): δ=189.4, 140.7, 130.0, 54.8, 37.1, 34.8, 30.8, 17.0, and 11.4. Found: *m/z* 279.995. Calcd for $C_9H_{13}O_2I$: M, 279.996.

2e: Yield 67%, mp 81—83 °C; IR (KBr): 3428, 1662, and 1630 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=1.00 (t, 3H), 1.10 (t, 3H), 1.93 (m, 2H), 2.40—2.55 (m, 2H), and 6.12 (s, 1H); ^{13}C NMR ($CDCl_3$): δ=189.8, 140.1, 135.0, 55.0, 37.2, 34.8, 28.4, 24.0, 11.5, and 11.3. Found: *m/z* 294.012. Calcd for $C_{10}H_{15}O_2I$: M, 294.012.

3-Bromo-3,6-dialkyl-1,2-cyclohexanedione (3a—3e). Diosphenol (**1a**) (1.00 g) in acetic acid (50 ml) was treated with bromine (0.997 g) at room temperature for 5 min. After the usual work-up, the resulting oil, upon crystallization from ethanol, gave mixtures (60:40) of 3-bromo- (**3a**) and 6-bromo-3-methyl-6-isopropyl-1,2-cyclohexanedione (**3'a**) (1.440 g) (98%), mp 51—53 °C; IR (KBr): 3440, 1660, and 1634 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=0.93 (d, 3H), 1.06 (d, 3H), 1.10 (d, 3H), 1.17 (d, 3H), 1.92 (s, 3H), 1.94 (d, 3H), 2.81 (m, 1H), 3.17 (m,

1H), 6.08 (s, 1H), and 6.14 (s, 1H); ^{13}C NMR ($CDCl_3$): δ=188.9, 187.9, 141.7, 139.7, 139.4, 130.5, 39.4, 34.7, 29.9, 28.1, 28.0, 27.9, 21.8, 19.9, 19.4, 18.3, 18.1, and 17.1. Found: *m/z* 246.027. Calcd for $C_{11}H_{15}O_2Br$: M, 246.026.

3b: Yield 95%; mp 99—101 °C; IR (KBr): 3436, 1668, and 1632 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=1.940 (s, 3H), 1.942 (s, 3H), and 6.05 (br s, 1H); ^{13}C NMR ($CDCl_3$): δ=188.2, 140.8, 131.0, 61.1, 39.2, 28.6, 27.9, and 17.1; MS *m/z* 218 (M^+) and 220 (M+2).

3c: Yield 79%; mp 107—108 °C; IR (KBr): 3440, 1668, and 1630 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=1.92 (s, 3H), 2.80 (m, 1H), and 6.04 (s, 1H); ^{13}C NMR ($CDCl_3$): δ=188.9, 139.5, 134.8, 61.1, 39.4, 38.8, 29.9, 29.5, 27.9, 26.18, 26.12, 26.06, and 22.8. Found: *m/z* 286.051. Calcd for $C_{13}H_{19}O_2Br$: M, 286.057.

3d, 3′d: Yield 89% (**3d**:**3′d**=60:40); mp 67—70 °C, 75—77 °C; IR (KBr): 3444, 1668, 1641, and 1630 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=1.02 (t, 3H), 1.10 (t, 3H), 1.94 (s, 3H), 1.95 (s, 3H), 6.04 (s, 1H), and 6.08 (s, 1H); ^{13}C NMR ($CDCl_3$): δ=188.6, 188.0, 141.3, 140.1, 136.2, 130.8, 67.0, 61.2, 39.4, 35.1, 32.4, 28.3, 27.9, 26.1, 24.1, 17.1, 11.3, and 9.6. Found: *m/z* 232.006. Calcd for $C_9H_{13}O_2Br$: M, 232.010.

3e: Yield 99%; 86—89 °C; IR (KBr): 3436, 1668, and 1632 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=1.02 (t, 3H), 1.10 (t, 3H), 1.98 (m, 2H), 2.45—2.57 (m, 2H), and 6.02 (s, 1H); ^{13}C NMR ($CDCl_3$): δ=188.4, 140.7, 136.0, 67.1, 35.2, 32.4, 25.8, 24.1, 11.3, and 9.6. Found: *m/z* 246.024. Calcd for $C_{10}H_{13}O_2Br$: M, 246.026.

Reaction of 3-Iodo-3-methyl-6-isopropyl-1,2-cyclohexanedione (2a) with Iodine-Copper(II) Acetate in Acetic Acid-Water. A mixture of **2a** (200 mg), iodine (160 mg), and copper(II) acetate monohydrate (140 mg) in acetic acid-water (5:1) (12 ml) was stirred at 80 °C for 5 h. The precipitated copper(I) iodide was removed by filtration, and the solvent was then removed under reduced pressure. The residue was poured into water and extracted with ether. The ethereal solution was washed successively with aqueous sodium hydrogencarbonate and with water, dried, and concentrated. Crystallization of the residue from ethanol gave needles of **4a** (150 mg) (80%), mp 167—168 °C (lit,[17] 167—168 °C). The IR and ^{1}H and ^{13}C NMR spectra[15] were identical with those of an authentic sample.

4b: Yield 50%; mp 138—140 °C (lit,[10] 141—142 °C). The IR and ^{1}H NMR spectra were identical with those of an authentic sample.

4c: Yield 47%; mp 130—132 °C; IR (KBr): 3296, 1668, 1640, and 1614 cm^{-1}; UV (EtOH): 270 (ε 1.08×10^4) and 425 nm (ε 0.97×10^3); ^{1}H NMR ($CDCl_3$): δ=1.92 (s, 3H), 2.65 (m, 1H), 6.16 (s, 1H), and 6.42 (d, *J*=0.70 Hz, 1H); ^{13}C NMR ($CDCl_3$): δ=194.0, 178.7, 151.7, 141.8, 132.3, 117.1, and 7.8. Found: *m/z* 220.112. Calcd for $C_{13}H_{16}O_3$: M, 220.110.

4d, 4′d: Yield 67% (**4d**:**4′d**=60:40); mp 124—126 °C; IR (KBr): 3288, 1658, 1634, and 1616 cm^{-1}; UV (EtOH): 266 (ε 1.31×10^4) and 405 nm (ε 1.39×10^3); ^{1}H NMR ($CDCl_3$): δ=1.07 (t, 3H), 1.15 (t, 3H), 1.94 (s, 3H), 2.07 (d, *J*=1.71 Hz, 3H), 2.40—2.54 (m, 4H), 6.49 (t, *J*=1.71 Hz, 1H), and 7.02 (br s, 2H); ^{13}C NMR ($CDCl_3$): δ=184.4, 183.7, 151.4, 146.3, 133.6, 117.1, 21.4, 12.6, and 7.9 (for **4d**); δ=184.4, 183.7, 150.9, 141.0, 135.4, 122.6, 16.1, 14.8, and 11.6 (for **4′d**). Found: *m/z* 166.065. Calcd for $C_9H_{10}O_3$: M, 166.063.

4e: Yield 38%; mp 115—116 °C; IR (KBr): 3288, 1656, 1634, and 1614 cm^{-1}; UV (EtOH): 266 (ε 1.31×10^4) and 405 nm (ε 1.39×10^3); ^{1}H NMR ($CDCl_3$): δ=1.00 (m, 6H), 2.48 (m, 4H), 6.46 (t, *J*=1.0 Hz, 1H), and 6.98 (s, 1H); ^{13}C NMR ($CDCl_3$): δ=187.6, 183.9, 150.8, 146.1, 133.8, 122.5, 21.4, 16.1, 12.6, and 11.6. Found: *m/z* 180.080. Calcd for $C_{10}H_{12}O_3$: M, 180.079.

Reaction of 3-Isopropyl-6-methyl-1,2-benzenediol (6) with Iodine-Copper(II) Acetate in Acetic Acid-Water (5:1). A mixture of **6** (109 mg), iodine (173 mg), and copper(II) acetate monohydrate (130 mg) in acetic acid-water (5:1) (12 ml) was stirred at 80 °C for 1 h. After the usual work-up, the resulting oil, upon crystallization from ethanol, gave **4a** as needles (101 mg), mp 167—168 °C.

Reaction of 4-Iodo-3,6-dimethyl-1,2-benzenediol (7d) with Iodine-Copper(II) Acetate in Acetic Acid-Water. A mixture of **7** (3.0 mg), iodine (1.5 mg), and copper(II) acetate (2.2 mg) in acetic acid-water (5:1) (0.3 ml) was stirred at 80 °C for 4 h. After the usual work-up, the resulting oil, upon crystallization from ethanol, gave **4b** as needles (0.9 mg), mp 138—140 °C.

Reaction of 3-Iodo-3-methyl-6-isopropyl-1,2-cyclohexanedione (2a) with Copper(II) Acetate in Acetic Acid-Water. 3-Iodo-1,2-diketone (**2a**) (300 mg) in acetic acid-water (10:1) (25 ml) was treated with copper(II) acetate (305 mg) under refluxing for 4 h. The precipitated copper(I) iodide was removed by filtration, and the solvent was then removed under reduced pressure. The residue was poured into water and extracted with chloroform. After a similar work-up, the resulting oil (217 mg) was chromatographed on silica gel (25 g). Elution with benzene-chloroform (5:1) (120 ml) gave 3-hydroxythymo-1,4-quinone (**4a**) as needles (6 mg) from ethanol, mp 167—168 °C. The second fraction, eluted by the same solvent (320 ml) gave 3,3′-dihydroxy-2,2′-dimethyl-5,5′-diisopropyl-4,4′-diphenoquinone (**5a**) as needles (72 mg) from ethanol, mp 238—240 °C; IR (KBr): 3470, 1650, 1640, 1594, and 840 cm^{-1}; UV ($CHCl_3$): 245 (ε 1.09×10^4) and 406 nm (ε 4.57×10^3); ^{1}H NMR ($CDCl_3$): δ=1.32 (t, 12H), 1.60 (br s, 2H), 2.08 (s, 3H), 2.36 (s, 3H), 3.46 (m, 2H), and 7.00 (s, 2H); ^{13}C NMR ($CDCl_3$): δ=179.5, 149.4, 135.0, 126.0, 124.4, 121.2, 26.7 (24.6), 22.7 (20.2), and 14.7. Found: *m/z* 328.168. Calcd for $C_{20}H_{24}O_4$: M, 328.168.

Reaction of 3-Iodo-3,6-dimethyl-1,2-cyclohexanedione (2b) with Copper(II) Acetate in Acetic Acid-Water. By practically the same method as that in the case of **2a** above, **2b** (300 mg) was treated with copper(II) acetate. After the usual work-up, the resulting oil (185 mg) was chromatographed on silica gel (25 g). Elution with benzene-chloroform (5:1) (250 ml) gave 3-hydroxy-2,5-dimethyl-1,4-benzoquinone (**4b**),as needles (9 mg) from ethanol, mp 138—140 °C. The second fraction, eluted by the same solvent (160 ml) gave 4-iodo-3,6-dimethyl-1,2-benzenediol (**7**) as needles (14 mg) from ethanol, mp 88—90 °C.[17] The third fraction, eluted by the same solvent (200 ml), on crystallization from ethanol gave 3,3′-dihydroxy-2,2′,5,5′-tetramethyl-4,4′-diphenoquinone (**5b**) as reddish needles (64 mg), mp 238—239 °C; IR (KBr): 3450, 1654, 1642, 1606, and 836 cm^{-1}; UV ($CHCl_3$): 246 (ε 1.96×10^4) and 406 nm (ε 8.87×10^3); ^{1}H NMR ($CDCl_3$): δ=1.59 (br s, 6H), 2.12 (s, 6H), 2.40 (s, 6H), and 6.96 (s, 2H); ^{13}C NMR ($CDCl_3$): δ=181.8, 150.0, 139.5, 131.1, 126.4, 124.6, 14.7, and 7.7. Found: *m/z* 272.104. Calcd for $C_{16}H_{16}O_4$: M, 272.105.

Reaction of 3-Iodo-6-cyclohexyl-3-methyl-1,2-cyclohexanedione (2c): The 3-iodo-1,2-dione (**2c**) (275 mg) in acetic acid-water was treated with copper(II) acetate to give 23 mg

of **4c** and 147 mg of **5c**.

5c: Reddish needles; mp 237—240 °C; IR (KBr): 3480, 1654, 1642, 1594, and 840 cm^{-1}; UV ($CHCl_3$): 244 (ε 1.92×10^4) and 406 nm (ε 8.16×10^3); ^1H NMR ($CDCl_3$): δ=1.61 (br s, 2H), 2.07 (s, 3H), 2.35 (s, 3H), 3.11 (m, 2H), and 6.98 (s, 2H); ^{13}C NMR ($CDCl_3$): δ=177.3, 148.0, 132.2, 124.5, 123.1, 120.5, and 7.8. Found: *m/z* 408.230. Calcd for $C_{26}H_{32}O_4$: M, 408.230.

Reaction of 3-Iodo-6-ethyl-3-methyl-1,2-cyclohexanedione (2d): The 3-iodo-1,2-dione (**2d**) (85 mg) in acetic acid–water was treated with copper(II) acetate. After a similar work-up, the resultant oil was chromatographed on silica gel (25 g). Elution with benzene–chloroform (10:1) (150 ml) gave 3,3′-dihydroxy-5,5′-diethyl-2,2′-dimethyl-4,4′-diphenoquinone (**5d**) as reddish needles (33 mg), mp 184—187 °C; IR (KBr): 3440, 1652, 1625, 1600, and 840 cm^{-1}; UV ($CHCl_3$): 245 (ε 2.18×10^4) and 406 nm (ε 9.57×10^3); ^1H NMR ($CDCl_3$): δ=1.15 (t, 3H), 1.28 (t, 3H), 1.54 (s, 2H), 2.11 (s, 3H), 2.38 (s, 3H), 2.64 (q, 2H), 2.77 (q, 2H), and 6.95 (s, 2H); ^{13}C NMR ($CDCl_3$): δ=179.2, 149.1, 135.8, 130.2, 124.1, 121.1, 22.4, 14.7, and 7.8. Found: *m/z* 300.135. Calcd for $C_{18}H_{20}O_4$: M, 300.136.

Reaction of 3-Iodo-3,6-diethyl-1,2-cyclohexanedione (2e): The 3-iodo-1,2-dione (**2e**) (483 mg) in acetic acid–water was treated with copper(II) acetate to give 44 mg of **4e** and 115 mg of **5e**.

5e: Reddish needles; mp 185—188 °C; IR (KBr): 3454, 1654, 1636, 1598, and 848 cm^{-1}; UV ($CHCl_3$): 245 (ε 2.18×10^4) and 406 nm (ε 9.46×10^3); ^1H NMR ($CDCl_3$): δ=1.15 (t, 6H), 1.31 (t, 6H), 1.71 (br s, 2H), 2.65 (q, 4H), 2.79 (q, 4H), and 6.89 (s, 2H); ^{13}C NMR ($CDCl_3$): δ=178.5, 148.6, 135.4, 129.9, 124.0, 120.6, 22.2, 15.9, 14.0, and 12.6. Found: *m/z* 328.168. Calcd for $C_{20}H_{24}O_4$: M, 328.168.

Reaction of 3,3′,4,4′-Tetrahydroxy-2,2′,5,5′-tetraalkylbiphenyl (8a,8b) with Copper(II) Acetate. The tetrahydroxybiphenyl (**8a** and **8b**) (50 mg) in acetic acid–water was treated with copper(II) acetate. After the usual work-up, crystallization from ethanol afforded needles of **5a** (46 mg), mp 238—240 °C and **5b** (44 mg), mp 238—239 °C.

Reaction of Diosphenol (1a) with Bromine and Copper(II) Acetate in Acetic Acid–Water. The diosphenol (**1a**) (600 mg) in acetic acid–water (5:1) (60 ml) was treated with bromine (570 mg) and copper(II) acetate (712 mg) under refluxing for 5 h. After the usual work-up, the resulting oil (552 mg) was chromatographed on silica gel (25 g). Elution with benzene–ether (10:1) (220 ml) gave **4a** as needles (134 mg), mp 167—168 °C.

Reaction of 3-Bromo-3,6-dialkyl-1,2-cyclohexanedione (3a—3e) with Copper(II) Acetate in Acetic Acid–Water. General Procedure. A mixture of 3-bromo-1,2-diketone (**3a—3e**) (1.00×10^{-3} mol), copper(II) acetate monohydrate (1.50×10^{-3}mol), and acetic acid–water (10:1) (16.5 ml) was stirred under refluxing for 4 h. After the usual work-up, the resulting oil was chromatographed on silica gel. Elution with benzene–chloroform (4:1) gave orange and reddish crystals from ethanol. These results are summarized in Table 2.

We are indebted to Research Laboratories of Toyo Jozo Co., Ltd. and Associate Professor Sukekatsu Nozaki, Josai University, for their measurements of the high resolution mass spectra. Thanks are also due to Associate Professor Yoshio Koike and Mr. Toshio Takayama, Kanagawa University, for the measurement of FT-NMR spectra.

Implications of Unusual Population Ratios in Rotational Isomers of 9-(4-Substituted Benzyl)-8,13-dichloro-1,4-dimethyltriptycenes and 4-Substituted 9-Benzyl-8,13-dichloro-1-methyltriptycenes: $CH_3\cdots\pi$ Hydrogen Bond[1)]

Yasufumi NAKAI, Katsuya INOUE, Gaku YAMAMOTO, and Michinori ŌKI*,#

(Received February 28, 1989)

Population ratios of rotational isomers in substituted 9-benzyl-8,13-dichloro-1-methyltriptycenes were examined by equilibration in solution. The *sc* isomers increase in their populations as the electron density on the 9-benzyl group increases and the acidity of the 1-methyl group increases. The *sc/ap* ratios were larger than 2, the statistical value, in all the compounds examined, except the 4-nitrobenzyl compound. By contrast, MM2 calculations show that the *sc* isomers are less stable than the *ap* by ca. 1 kcal mol^{-1}. This discrepancy together with the substitutent effects on populations of the rotamers are attributed to the presence of $CH_3\cdots\pi$ interactions in the *sc* forms that stabilize the system mainly by charge-transfer interactions but are not included in the MM2 calculations.

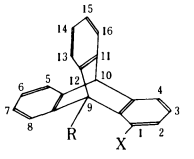
Since the π-systems act as base, though weak,[2)] it is possible to observe the presence of OH–π hydrogen bond[3)] and NH–π hydrogen bond.[4)] Because of the weakness of the basicity of the π-system, the proton donor must be rather strong to manifest the XH–π hydrogen bond. Since the CH group is a weak electron-acceptor, the CH–π interactions are seldom observed unless the C–H group is a strong acid: the presence of the interactions between the acetylenic CH group and π-systems has been reported.[5)]

Although the presence of hydrogen bond involving the CH group as an electron acceptor has been reported in various cases,[6)] evidence for the presence is often not decisive: in many cases, if a C–H group and an electron donor are placed within the sum of their van der Waals radii in crystals, the result is taken to imply the presence of the hydrogen bond.[7)] In solution, the situation is more complicated than in the solid, because there is no means to determine the distance between the two groups concerned.

Hirota and Nishio have worked for a long time in this area. Once they believed that the unusual population ratios of rotamers in 1-alkyl-2-arylethane derivatives were the indication of the presence of the CH–π interactions but later they interpreted the results by dispersion forces because MM2 calculations could reproduce the population ratios of those compounds.[8)] Although they recently reported that they observed the CD–π hydrogen bond in 2-methyl-4-phenyl-3-pentanone-2*d* by infrared spectroscopy, their experimental results are so unusual from the normal sense of hydrogen bond that it is not possible to take the results as firm evidence for the presence of the CH–π hydrogen bond: the C–D stretching absorption due to the hydrogen-bonded form appears at a higher frequency than the non-hydrogen-bonded C–D stretching and the hydrogen-bonded form is less stable than the non-hydrogen-bonded form.[9)] However, the CH–π hydrogen bond is theoretically possible, though weak.[10,11)]

It is understood that, because of the very weak nature of the CH–π hydrogen bond, if after all present, strong evidence for the presence of the CH–π hydrogen bond is difficult to obtain. The N–H stretching absorption is known not to be affected by the NH–π hydrogen bond.[12)] The CH–π hydrogen bond, being still weaker than the NH–π, is expected to not affect the C–H stretching absorption, though it is possible that the C–H stretching appears at a higher frequency than the normal C–H stretching because of the congestion.[13)] Although appearance of abnormal population ratios of rotational isomers can be taken as evidence for the presence of attractive interactions, like the *sc* isomers of 1,2-ethanedithiol,[14)] this kind of effect is manifested only when the attractive interaction is stronger than repulsive interactions in the very conformation. Because of the weak nature of the CH–π interaction, the interaction may not overcome the repulsive van der Waals interactions in a given conformer in which the CH–π interaction is possible. To observe enhanced populations due to weak CH–π interactions, we must design a system in which the van der Waals repulsion can be eliminated or balanced in various conformations.

It is not possible, of course, to construct such a system, but it is possible to construct a system that nearly conforms to the conditions mentioned above. That is the 1,9-disubstituted triptycenes (**1**). In this



1

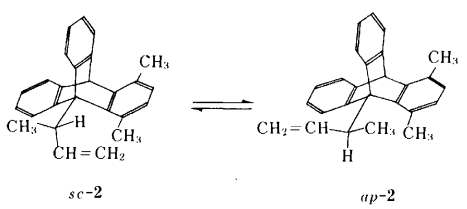
system, the atoms beta to the C_9 in the 9-substituent is placed unusually closely to the 1-substituent. X-Ray

Present address: Department of Chemistry, Faculty of Science, Okayama University of Science, Ridaicho, Okayama 700.

crystallographic data reveal that the distance is ca. 3.0 Å,[15] which is well within the sum of the van der Waals radii of the two groups concerned. If the 9-substituent is a primary alkyl group, it can rotate to assume another conformation, in which the atom beta to the 9-position is *ap* to the 1-substituent, when the distance between the substituent and the peri-carbon (8 or 13) is ca. 3.2 Å,[16] which is again within the sum of the van der Waals radii of the groups concerned. Although it is true that the distance between the two groups in the *ap* position is indeed a little longer than that in the *sc*[17] and the van der Waals replusion is more severe in the *sc* conformation than in the *ap*, yet it is also true that even in the *ap* conformation the van der Waals repulsion is severe, even though we neglect the presence of a hydrogen atom attached to the peri-carbon. Thus in this system, it can be expected that the severe van der Waals repulsion in the *sc* form is nearly equalled by that in the *ap*. Thus a weak interaction may be observed in this system as the unusual population ratios: that is, the *sc* form may be favored irrespective of the fact that sterically it is less favored.

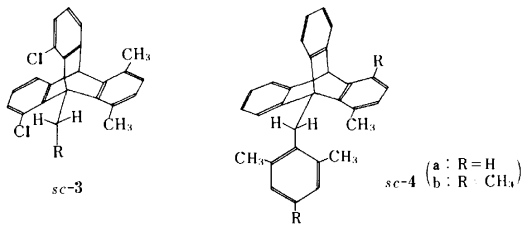
The reason why we could report the presence of weak molecular interactions by taking advantage of this system is indeed the feature of the structures mentioned above. It was possible to detect charge-transfer interactions between a methoxy-oxygen and benzene rings that do not carry electronegative groups,[18] those between a chloro or a methoxy-oxygen and a carbonyl group,[19] those between a methoxy-oxygen and a CH_2X group where the X is an electronegative group,[20] and $CH_3\cdots O$ hydrogen bond.[21] It is quite natural to expect that the system could be useful in manifesting the CH-π interactions.

We have had several experiences that might be explained by the presence of the $CH_3\cdots\pi$ interactions in the 1,9-disubstituted triptycenes. In 1,4-dimethyl-9-(1-methyl-2-propenyl)triptycene (**2**), the population ratio, *sc*/*ap*, of the rotamers is 1.52, whereas the ratio is ca. 0.8 when the 1-substituent of comound **2** is switched to a chloro, a bromo, or a methoxyl.[22] We have pointed out a possibility that the results might imply the presence of the CH-π hydrogen bond, although it is possible to argue that the unusual population could be caused by the bulkiness of the methyl group in the 9-substituent.



sc-2 *ap*-2

In 9-substituted 8,13-dichloro-1,4-dimethyltriptycenes (**3**), the *sc*/*ap* value is 2.0 or more if the 9-substituent carries a π-system beta to the 9-position, but it becomes 0.75 when the beta-substituent is a methyl.[23] Although it is possible again to argue that the results can be attributed to the steric repulsion due to the fact that a methyl is larger than a chloro and than a π-system, it is possible also to assume that the results are the indication that the *sc* conformation is stabilized by the presence of the CH-π interactions. Although the charge-transfer interaction between the chloro group and the π^*-system of the substituent may be claimed to be the cause, this interaction should favor the *ap* conformation rather than the *sc*.



sc-3 *sc*-4 (a : R=H, b : R=CH3)

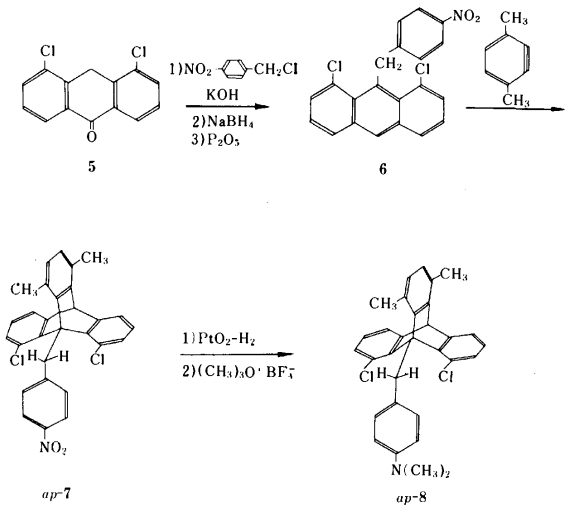
Another encouraging factor for the assumption of the presence of the CH-π interactions in this system is the failure of an empirical force field calculation in predicting the correct relative stability of the *sc* and the *ap* rotamers of 9-benzyl-1-methyltriptycene derivatives (**4**). Mislow and his co-workers calculated the stability by the empirical method to find that the *ap* conformer of 1-methyl-9-(2,6-dimethylbenzyl)triptycene (**4a**) is more stable than the *sc* form by 0.6 kcal mol^{-1} (1 cal=4.184 J). The experiment on the conformers of 1,4-dimethyl-9-(2,4,6-trimethylbenzyl)triptycene (**4b**) shows, in contrast, that the *sc* isomer is more stable than the *ap* by 0.8 kcal mol^{-1} or more.[24] The discrepancy may be taken as that the calculation is not reliable in this kind of congested molecules, but our experiences show that the calculations give correct tendency, though the value itself may not be correct.[25] It may indicate the presence of the CH-π interactions, because this type of charge-transfer interactions are not taken care of by the empirical calculations. We have thus felt that the assumption that the CH-π interactions are observed in this system is worthwhile to examine. This paper reports the results of such an examination.

We have selected the system of 9-benzyl-8,13-dichloro-1-methyltriptycenes for two reasons. One is that the system gives stable rotational isomers that can be separated at room temperature.[23] The advantage of this system is that we can equilibrate the rotational isomers by the classical method which is believed to afford reliable data. The other is that the chloro and the methyl groups are similar in size. This should give similar steric circumstances for both the *sc* and *ap* rotamers and the cancellation of the van der Waals repulsion in both rotamers is better than the case where there are no substituents in the 8,13-positions. The system involves two series of compounds: one is 9-(4-substituted benzyl)-1,4-dimethyltriptycenes which

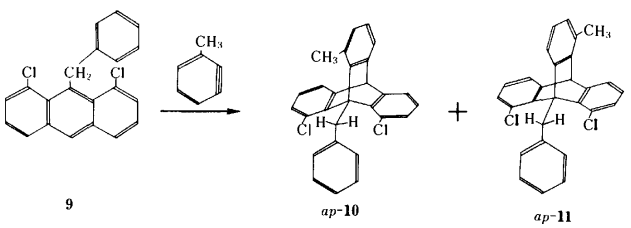
provide a variety of electron densities in the benzyl group and the other is 4-substituted 9-benzyl-1-methyltriptycenes which provide a variety of acidities of the 1-methyl group.

Syntheses

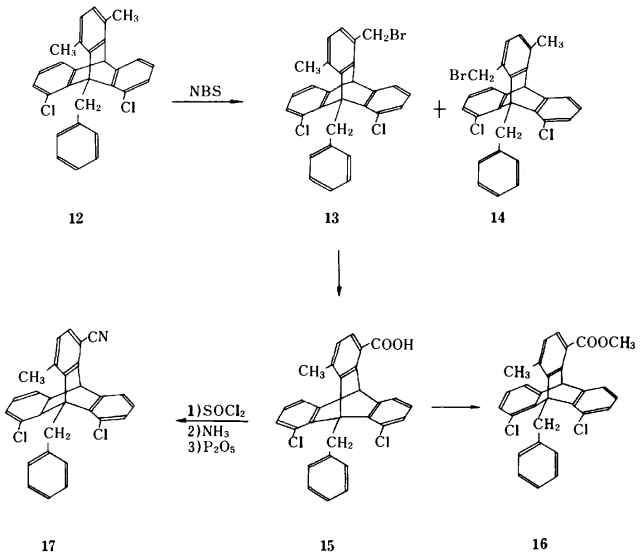
The method of synthesis of 1,4-dimethyl-9-(4-nitrobenzyl)triptycene (**7**) is essentially the same with that of the unsubstituted compound that has been published.[23] 4,5-Dichloro-9-anthrone (**5**) was treated with *p*-nitrobenzyl chloride and aqueous potassium hydroxide and the product was reduced with sodium tetrahydroborate and then dehydrated in the presence of phosphorus pentaoxide to afford 1,8-dichloro-9-(4-nitrobenzyl)anthracene (**6**). Treatment of the anthracene (**6**) with 3,6-dimethylbenzyne which was produced in situ from 3,6-dimethylanthranilic acid gave 8,13-dichloro-1,4-dimethyl-9-(4-nitrobenzyl)triptycene (**7**). Hydrogenation of the triptycene (**7**) in the presence of platinum oxide followed by methylation afforded 8,13-dichloro-9-[4-(dimethylamino)benzyl]-1,4-dimethyltriptycene (**8**).



Similarly 9-benzyl-1,8-dichloroanthracene (**9**) was treated with 3-methylbenzyne which was generated from 3-methylanthranilic acid to afford a mixture of 9-benzyl-8,13-dichloro-1-methyltriptycene (**10**) and its 4-methyl isomer (**11**). The assignment of the structures of **10** and **11** bases on the ^{1}H NMR data: the chemical shift of the methyl protons in the *sc* form of **10** is higher than that of **11** due to the ring current effect of the benzyl-benzene ring.

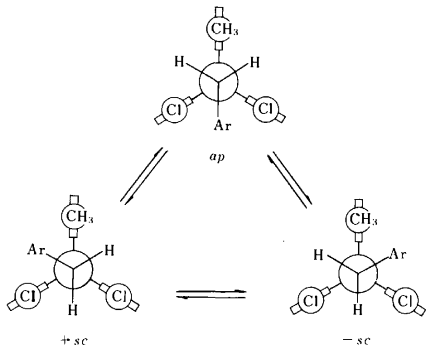


Treatment of 9-benzyl-8,13-dichloro-1,4-dimethyltriptycene (**12**) with *N*-bromosuccinimide afforded 9-benzyl-4-bromomethyl-8,13-dichloro-1-methyltriptycene (**13**) and 9-benzyl-1-bromomethyl-8,13-dichloro-1-methyltriptycene (**14**) together with other products. The identification of **13** and **14** was carried out again with the use of the chemical shift data of the methyl and the bromomethyl protons in ^{1}H NMR spectra that reflected the anisotropy effect of the benzyl-benzene ring. The 4-bromomethyl compound (**13**) was hydrolyzed and then oxidized with the Jones reagent to afford 9-benzyl-8,13-dichloro-4-carboxy-1-methyltriptycene (**15**). Compound **15** was methylated to give the methyl ester (**16**). Treatment of compound **15** with thionyl chloride followed by that with ammonia and then phosphorus pentaoxide afforded the corresponding nitrile (**17**).



Results and Discussion

The isomerization was carried out by heating solutions of the compounds in chloroform-*d* unless otherwise mentioned. The assignment of the conformations was performed by observing the singlet signal for the *ap* form and the AB quartet for the *sc* form in



Scheme 1. Rotational circuit.

the ^{1}H NMR spectra of the benzylic methylene protons as is clearly understood from the Newman-type projection in Scheme 1.

Although only one isomer was isolated by chromatography, the identity of the other isomer was confirmed by equilibration as well as their ^{1}H NMR spectra. The populations of isomers were estimated by the ^{1}H NMR spectra at 270 MHz. The equilibration data at 54 °C for the rotamers of the compounds in question are compiled in Tables 1 and 2 together with some relevant data.

In principle, the populations of one isomer can increase, if the rotamer is stabilized by an attractive interaction, or if other isomers are destabilized by a repulsive interaction or by structural deformation of the molecule. Although it is difficult to diagnose which is the case in general, the rotational barrier will give a clue for the diagnosis in this case because the transition state energy for rotation in the series of compounds can be assumed little different, if we take molecular interactions in the transition state only. Thus we decided to compare the barrier to rotation in the nitro compound (**7**) with that in the unsubstituted (**12**).[23] The kinetic data for the isomerization of the nitro compound (**7**) are compiled in Table 3.

The rate constants for isomerization, *sc*→*ap*, are ca. 1.7 times larger for the unsubstituted compound (**12**) than the nitro (**7**), whereas those for the *ap*→*sc* process are ca. 2.5 times faster for the former than the latter. Although *ap*-**7** isomerizes more sluggishly than *ap*-**12**, the tendency is also true for the *sc* conformer. The results may be interpreted to mean that the *sc* form of the nitro compound (**7**) is not specially destabilized, though its population decreases relatively from the unsusbstituted compound (**12**). We assume, therefore, that the population change in the series of compounds is mainly caused by repulsive and attractive interactions within the molecules without significant structural changes.

The main attractive forces and repulsive forces that may affect the populations of rotamers are van der Waals attractive force (dispersion force), charge-transfer interactions, van der Waals repulsions, and Coulombic interactions, both attractive and repulsive.

The data in Table 1 clearly indicate that, as the electron density on the benzyl-benzene ring increases, the *sc* form becomes favored. The results cannot be explained by the van der Waals repulsion because the high electron density on the benzyl-benzene means the bulkier π-system than the low electron-density one and

the methyl group is larger than the chloro group. In consideration of the Coulombic interactions, we may consider the bond dipoles of the C–Cl and the substituted benzene rings, because other parts of the molecule are hydrocarbons. Since the distance between the C–Cl bonds and the substituted benzyl-benzene rings are different in the *sc* form from those in the *ap*, the Coulombic interactions may change in one isomer from the other. However, to the first approximation, we neglect the difference, because the directions of the dipole of the substituted benzenes, 60° or 120°, relative to the C–Cl bonds do not change irrespective of the kind of rotamers. The dispersion force may be neglected to the first approximation from being the main factor that manifests the observed rotamer ratios, because the dispersion force is dependent on the polarizability and the ionization potential:[28] the high electron density means the high polarizability as well as the low ionization potential. In addition, we are comparing the rotamer distributions in a series of compounds: the comparison may cancel the change in the dispersion force. Thus the charge-transfer interactions between the CH_3 group and the π-system remain as a strong candidate that favors the *sc* conformation over the *ap*. However, it is possible to argue that, since the charge-transfer interaction[18] between the chloro group and the π^*-system of the benzyl group is expected to be stronger in the *ap* conformation than in the *sc*, especially in the case with electronegative substituents, the results are attributed to this type of charge-transfer. The argument cannot be ruled out by the data in Table 1.

The data in Table 2 suggest that, by and large, the *sc/ap* value increases as the 4-substituent becomes electronegative. Since the bulkiness of the 1-methyl group will not substantially change irrespective to the change in the electron density at the 1-position, the results cannot be explained by the van der Waals repulsions. Van der Waals attraction may also be neglected as a main factor that favors the *sc* form because the change in the force may again be small. The Coulombic interactions cannot be the factor that mainly controls the rotamer populations in this case because the dipole introduced by the 4-substituent must contribute equally to both the *sc* and *ap* rotamers. The results as well exclude the possibility that the charge-transfer interaction between the chloro substituent and the π^*-system is the main cause for the observed population ratios: if it were the case, the 4-substituent should affect the population ratios little. Thus the results strongly support the claim that we have observed the presence of the $CH_3\cdots\pi$ interactions.

Although the general trend that, as the acidity of the 1-methyl group becomes high, the *sc* form becomes favored relative to the *ap* form is apparent, close examination reveals some irregularities: the *K* value for the 4-methyl compound (**12**) is larger than that for the unsubstituted compound (**10**) and the *K* value for the 4-cyano compound (**17**) is smaller than that for the 4-methoxycarbonyl compound (**16**), even though the 4-methyl group increases the electron density on the 1-methyl group more than the 4-hydrogen and a cyano group is more electron-attracting than a methoxycarbonyl. We suspected that a small difference in dipole moments of the rotamers involved might be responsible to the irregular trend in the population ratios.

MM2 calculations show that the dipole moments of the rotamers of 9-benzyl-8,13-dichloro-1,4-dimethyltriptycene are indeed different, though the difference is small: *sc* 3.231 D and *ap* 3.157 D (1 D=3.3356×10^{-30} C m). Introduction of a substituent instead of the methyl at the 4-position will change the difference in the dipole moments of the rotamers. Thus we examined the solvent effect on the rotamer populations. The *sc/ap* values in dimethyl-d_6 sulfoxide were obtained as follows at 54.0 °C: 4-CH_3 2.0, 4-H 1.8, 4-CH_3OCO 3.0, 4-CN 2.4. Thus the *K* values all decrease in dimethyl sulfoxide relative to the value in chloroform and the irregular tendency is repeated. Thus at least dipole moments of the molecules are not the factors that cause the irregularities. Although further study is needed to clarify the point, the irregularities must be caused by the factors we have neglected in the discussion.

The total steric energies of the 4-substituted 9-benzyl-8,13-dichloro-1-methyltriptycenes as calculated by the MM2 method are shown in Table 4. The interesting point here is the fact that the *ap* forms of the series of comounds are ca. 1.0 kcal mol^{-1} more stable than the corresponding *sc* forms by calculations, irrespective of the kind of substituents, in sharp contrast to the experimental observation that the *sc* forms are more favored than the statistical value. From our experience in MM2 calculations, we under-

Table 4. Total Steric Energies of 4-Substituted 9-Benzyl-8,13-dichloro-1-methyltriptycene Rotamers as Calculated by MM2 Method

Compd	Subst	*ap*/kcal mol^{-1}	*sc*/kcal mol^{-1}	ΔE/kcal mol^{-1}
12	CH_3	28.462	29.539	1.077
10	H	28.208	29.216	1.008
16	$COCH_3$[a]	37.275	38.259	0.984
17	CN	27.397	28.445	1.052

a) This substituent was used instead of the methoxycarbonyl group, because the parameters for the latter were not available.

stand that the absolute values obtained by the method may not be reliable in the series of congested triptycenes, even for the ground states. However, it is also true that the relative values and the tendency of the stability of the ground state molecules are reproducible by the MM2 calculations.[25] Therefore, we believe the discrepancy between the MM2 calculations and the experimental results is significant. Since MM2 calculations take care of dispersion forces and the dipole interactions, the discrepancy must be attributed to the forces other than those mentioned. Thus the charge-transfer interactions are the most likely factor that stabilizes the *sc* form.

We conclude that the *sc* form of the triptycenes described in this paper is stabilized by the $CH_3\cdots\pi$ interactions. Although the $CH\cdots\pi$ interactions are known to be very weak by theoretical studies,[10,11] there are two points that render the observation of the presence of the $CH_3\cdots\pi$ interactions possible. They are the proximity of the two groups concerned that makes overlap of the orbitals concerned more effective than the normal cases and the near-cancellation of the repulsive forces in the triptycene rotamers due to the highly congested state in both rotamers. The unusual population ratios described in the introduction of this paper is now believed to include the contribution of this type of interactions at least to some extent. Although observation of normal hydrogen bonding is resulted by various factors including dipole interactions, charge transfer, and repulsive interactions, the contribution of dipole moment is rather small in the case of C–H bonds.[11] Thus the results presented in this paper can be the basis that there is the $CH_3\cdots\pi$ hydrogen bond in which charge transfer is the main stabilizing factor.

Experimental

Kinetics of Isomerization. The 4-nitrobenzyl compound (**7**) (*sc* or nearly pure *ap*) was dissolved in chloroform-*d* to make up ca. 1% (w/v) solutions. The kinetic data were obtained as described previously.[29] The analyses of the starting material and the product were performed by using a Waters HPLC apparatus (microporasil and hexane) equipped with a UV detector, *p*-nitrotoluene being used as an internal standard. The data were processed by assuming a reversible first order reaction.

Equilibration of Rotamers. The triptycenes were dissolved in either chloroform-*d* or dimethyl-d_6 sulfoxide to make up ca. 1% (w/v) solutions. The solution was sealed in an NMR sample tube and was heated by immersing into a boiling acetone bath. The populations of the rotamers were determined by integration of the methyl signals, of which assignment was confirmed by consulting the intensities of the signals due to benzylic methylene protons, in ^{1}H NMR spectra recorded on a JEOL GX270 spectrometer which operated at 270 MHz. The integration was carried out for several times and the data were treated statistically.

MM2 Calculations. The calculations were carried out with the use of an available program[30] by a HITAC M-280H computer at the Computer Center of the University of Tokyo. The parameters used for the chloro substituents were those reported from this laboratory some time ago.[31] Structural features of 1,9-disubstituted triptycenes, such as sharpening of the pyramid of which apex is C_9 with a base made up by C_{9a}–C_{8a}–C_{12} and widening of the dihedral angle that is made by two benzeno bridges flanking the beta atom of the 9-substituent (a phenyl in the cases described here), were reproducible.

4,5-Dichloro-10-(4-nitrobenzyl)anthrone. To a boiling solution of 3.29 g (12.5 mol) of 4,5-dichloroanthrone (**5**)[32] and 2.14 g (12.5 mmol) of *p*-nitrobenzyl chloride in 100 mL of methanol, was added 1.0 g (ca. 15 mmol) of potassium hydroxide (ca. 85% pure) in 40 mL of methanol in 2 h under a nitrogen atmosphere. The reaction mixture was allowed to cool with stirring and the precipitate was removed by filtration. The solvent was evaporated from the filtrate and the residue was recrystallized from tetrahydrofuran–methanol to afford pale yellow crystals, mp 200—201 °C, in 4.05 g (81%) yield. Found: C, 63.25; H, 3.30; N, 3.60; Cl, 17.33%. Calcd for $C_{21}H_{13}Cl_2NO_3$: C, 63.34; H, 3.29; N, 3.52; Cl, 17.80%. ^{1}H NMR ($CDCl_3$) δ=3.49 (2H, d, J=4.5 Hz), 5.41 (1H, t, J=4.5 Hz), 6.18 (2H, d, J=8.6 Hz), 7.2—8.0 (8H, m).

1,8-Dichloro-9-(4-nitrobenzyl)anthracene (6). To a solution of 5.58 g (14.0 mmol) of the foregoing anthrone in 200 mL of methanol, was added 3.0 g (79 mmol) of sodium tetrahydroborate in 3 portions with 10 min intervals. The mixture was stirred for further 10 min and the solvent was evaporated. The residue was treated with water and extracted with chloroform. The extract was dried over magnesium sulfate and the solvent was evaporated to give oily 4,5-dichloro-10-(4-nitrobenzyl)-9-anthranol which was apparently one isomer of the possible two according to the ^{1}H NMR spectrum ($CDCl_3$): δ=2.49 (1H, d, J=10.2 Hz), 3.21 (2H, d, J=5.6 Hz), 4.43 (1H, d, J=10.2 Hz), 5.18 (1H, t, J=5.6 Hz), 6.59 (2H, d, J=8.9 Hz), 7.1—7.6 (6H, m), 7.81 (2H, d, J=8.9 Hz).

The anthranol in 100 mL of carbon tetrachloride was heated with 15 g of phosphorus pentaoxide for 15 min. The solid was removed by filtration and was washed with hot carbon tetrachloride. The combined carbon tetrachloride solution was evaporated and the residue was submitted to silica-gel chromatography (hexane–dichloromethane eluent) to yield 1.23 g (23%) of the desired product which was purified by recrysallization from dichloromethane–hexane. Bright yellow crystals, mp 184—185 °C. Found: C, 66.14; H, 3.66; N, 3.73; Cl, 18.50%. Calcd for $C_{21}H_{13}Cl_2NO_2$: C, 65.59; H, 3.43; N, 3.66; Cl, 18.55%. ^{1}H NMR ($CDCl_3$) δ=5.71 (2H, s), 6.8—8.0 (10H, m), 8.45 (1H, s).

8,13-Dichloro-1,4-dimethyl-9-(4-nitrobenzyl)triptycene (7). To a boiling solution of 2.38 g (6.23 mmol) of the anthracene (**6**) and 6.0 mL (45 mmol) of isopentyl nitrite in 150 mL of dichloromethane were simultaneously added a solution of 3.00 g (18.2 mmol) of 3,6-dimethylanthranilic acid[33] in 80 mL of dichloromethane and that of 3.0 mL (22 mmol) of isopentyl nitrite in 20 mL of dichloromethane from two separatory funnels under a nitrogen atmosphere in 40 min and the whole was refluxed for 20 min. The solvent was evaporated and the residue was submitted to chromatography on silica gel (hexane–dichloromethane eluent). The

product was recrystallized from dichloromethane–hexane and was found to be a mixture of ca. 1:6 *sc* and *ap* isomers. Yield was 2.40 g (79%). Attempted purification of the *ap* isomer by recrystallization resulted in failure because the operation enriched the *sc* isomer. The *sc* isomer was obtained by chromatography (hexane–dichloromethane eluent) of the thermally equilibrated mixture of *sc* and *ap* forms on alumina, the mixture being obtained by heating a tetrahydrofuran solution under reflux for 6 h. The melting point was >300 °C. Found: C, 71.39; H, 4.55; N, 3.13; Cl, 14.34%. Calcd for $C_{29}H_{21}Cl_2NO_2$: C, 71.61; H, 4.35; N, 3.13; Cl, 14.58%. ^{1}H NMR ($CDCl_3$) δ=2.09 (3H, s), 2.58 (3H, s), 5.40 and 5.85 (2H, ABq, J=19.3 Hz), 5.60 (1H, s), 6.55—7.40 (9H, m), 7.65—7.8 (2H, m), 8.2—8.3 (1H, m).

The following ^{1}H NMR data ($CDCl_3$, δ) of the *ap* form were collected: 2.43 (3H, s), 2.84 (3H, s), 5.60 (2H, s), 5.64 (1H, s), 6.7—7.4 (9H, m), 7.65—7.8 (2H, m), 8.2—8.3 (1H, m).

8,13-Dichloro-9-[4-(dimethylamino)benzyl]-1,4-dimethyltriptycene (8). A suspension of 667 mg (1.37 mmol) of the nitrobenzyltriptycene (**7**, *sc*/*ap*=1.0) in 1:1 (v/v) dioxane–acetic acid was shaken under a hydrogen atmosphere in the presence of ca. 60 mg of platinum(IV) oxide for 12 h. For completion of the hydrogenation, it was necessary to add another portion of platinum oxide (60 mg) and to shake under hydrogen for 24 h. After removal of the catalyst by filtration, the solvents were evaporated and the residue was treated with aqueous sodium hydrogencarbonate. The mixture was extracted with dichloromethane and the solution was dried over magnesium sulfate. The product, after evaporation of the solvent, was used directly for the next reaction. The following ^{1}H NMR data were collected ($CDCl_3$, δ): *sc* form 2.19 (3H, s), 2.53 (3H, s), 3.38 (2H, br s), 5.13 and 5.57 (2H, ABq, J=18.9 Hz), 5.55 (1H, s), 6.1—7.4 (12H, m); *ap* form 2.37 (3H, s), 2.81 (3H, s), 3.38 (2H, br s), 5.37 (2H, s), 5.57 (1H, s), 6.1—7.4 (12H, m).

Trimethyloxonium tetrafluoroborate[34] (ca. 300 mg or ca. 2 mmol) was added to a solution of 625 mg (1.37 mmol) of the amine in 15 mL of dichloromethane and the mixture was stirred for 2 h at room temperature. The mixture was poured into a saturated solution of sodium hydrogencarbonate in water and then the aqueous layer was extracted with dichloromethane. After drying over magnesium sulfate, the solvent was evaporated and the residue was treated again with the Meerwein reagent as above. The product was chromatographed on alumina (hexane–dichloromethane eluent) to give 422 mg (64%) of the desired product, which was a mixture (*sc*/*ap*=2.0) of the rotamers.

The *sc* isomer was obtained in a pure form by semi-preparative HPLC (microporasil, 20:1 hexane-chloroform eluent), mp 280 °C (decomp). Found: C, 76.74; H, 5.32; N, 2.86; Cl, 14.43%. Calcd for $C_{31}H_{27}Cl_2N$: C, 76.86; H, 5.62; N, 2.89; Cl, 14.64%. ^{1}H NMR ($CDCl_3$) δ=2.19 (3H, s), 2.56 (3H, s), 2.87 (6H, s), 5.15 and 5.60 (2H, ABq, J=18.2 Hz), 5.56 (1H, s), 6.15—6.25 (2H, m), 6.5—7.4 (10H, m).

The following ^{1}H NMR data ($CDCl_3$, δ) of the *ap* form were collected: 2.41 (3H, s), 2.85 (3H, s), 2.88 (6H, s), 5.38 (2H, s), 5.58 (1H, s), 6.15—6.25 (2H, m), 6.5—7.4 (10H, m).

9-Benzyl-8,13-dichloro-1-methyltriptycene (10). 9-Benzyl-1,8-dichloroanthracene[23] (4 mmol) was similarly treated with 3-methylanthranilic acid[35] (9 mmol) and isopentyl nitrite in dichloromethane as described for the preparation of the nitro compound (**7**). The reaction afforded, after chromatography on silica gel (hexane–dichloromethane eluent), a 3:2:8 mixture of *sc*-**10**, *ap*-**10**, and 9-benzyl-8,13-dichloro-4-methyltriptycene (**11**). Most of the 4-methyl isomer (**11**) was removed by filtration after letting a solution of the mixture in dichloromethane to stand to evaporate the solvent. The filtrate was submitted to gel permeation chromatography (chloroform solvent) to separate **10** from **11**. The mixture of rotamers of **10** was resubmitted to GPC. Recycling 40 times did not give any of the pure rotamers. Recrystallization of the *sc*-enriched portion from 1:1 dichloromethane–hexane afforded crystals which consisted of 8:3 *sc* and *ap* rotamers and melted at 249.5—251.0 °C. Found: C, 78.36; H, 4.68; Cl, 16.88%. Calcd for $C_{28}H_{20}Cl_2$: C, 78.69; H, 4.72; Cl 16.59%. The following ^{1}H NMR data ($CDCl_3$, δ) were collected. *sc*: 2.17 (3H, s), 5.27 and 5.76 (2H, ABq, J=19.1 Hz), 6.4—7.7 (14H, m). *ap*: 2.89 (3H, s), 5.26 (1H, s), 5.51 (2H, s), 6.4—7.7 (14H, m).

The 4-methyl isomer (**11**) was submitted to recrystallization from 1:1 dichloromethane–hexane to give analytical sample, mp 227.0—228.0 °C. Found: C, 78.62; H, 4.89; Cl 16.82%. Calcd for $C_{28}H_{20}Cl_2$: C, 78.69; H, 4.72; Cl, 16.59%. This compound apparaently crystallized as *sc* forms. ^{1}H NMR ($CDCl_3$, 25 °C) δ=2.58 (3H, s), 5.60 (1H, s), 4.88 and 5.95 (2H, ABq, J=18.2 Hz), 6.50 (1H, br s), 6.7—7.5 (12 H, m), 7.58 (1H, br s). ^{1}H NMR spectra at other temperatures suggest that the isolated rotation of the benzylic phenyl group at −40 °C is slow but is taking place slowly at room temperature, whereas rotation about the C_9-to-substituent bond begins to take palce at 55 °C in chloroform-*d*: at −40 °C, δ=2.58 (3H, s), 5.60 (1H, s), 4.88 and 5.95 (2H, ABq, J=18.1 Hz), 6.49 (1H, d, J=8.5 Hz), 6.7—7.5 (12H, m), 7.68 (1H, d, J=8.5 Hz); at 55 °C, δ=2.57 (3H, s), 4.80 (1H, br d), 5.58 (1H, s), 5.94 (1H, br d), 6.6—7.4 (14H, m).

9-Benzyl-4-bromomethyl-8,13-dichloro-1-methyltriptycene (13). A mixture of 1.01 g (2.29 mmol) of 9-benzyl-8,13-dichloro-1,4-dimethyltriptycene (**12**)[23] (*sc*/*ap*=1.0), 0.45 g (2.5 mmol) of *N*-bromosuccinimide and a small amount of dibenzoyl peroxide in 60 mL of carbon tetrachloride was heated under reflux for 4 h. The mixture was cooled and the insoluble materials were removed by filtration. The solvent was evaporated in vacuo from the filtrate and the residue was submitted to chromatography on silica gel with the use of a medium-pressure liquid chromatograph (hexane–dichloromethane eluent). The order of elution was the unreacted material, *sc*-**13**, *ap*-**13**, *sc*-**14**, and *ap*-**14**. The total yield of *sc*-**13** and *ap*-**13** was 0.39 g (33%). The mixture of *sc*- and *ap*-**13** (*sc*/*ap*=2.0) was resubmitted to the medium-pressure chromatography to afford pure *sc*-**13**, mp 247.5—248.5 °C. Found: C, 66.89; H, 4.37; Cl, 13.58; Br, 15.30%. Calcd for $C_{29}H_{21}BrCl_2$: C, 66.95; H, 4.07; Cl, 13.63; Br, 15.36%. ^{1}H NMR ($CDCl_3$) δ=2.18 (3H, s), 4.73 and 4.85 (2H, ABq, J=10.3 Hz), 5.28 and 5.76 (2H, ABq, J=18.7 Hz), 5.77 (1H, s), 6.42 (1H, br d, J=8.1 Hz), 6.62 (1H, d, J=8.1 Hz), 6.8—7.6 (11H, m). The *ap*-**13** afforded the following ^{1}H NMR data ($CDCl_3$, δ): 2.89 (3H, s), 4.62 (2H, s), 5.51 (2H, s), 5.79 (1H, s), 6.42 (1H, br d, J=8.1 Hz), 6.62 (1H, d, J=8.1 Hz), 6.8—7.6 (11H, m).

9-Benzyl-4-carboxy-8,13-dichloro-1-methyltriptycene (15). To a solution of compound **13** (*sc*/*ap*=2.0, 268 mg or 0.514 mmol) in 10 mL of dimethyl sulfoxide, was added

2 mL of water and the whole was heated at 90—100 °C for 4 h. The mixture was poured into water and extracted with dichloromethane. The extract was dried over magnesium sulfate and the solvent was evaporated. The residue was taken up in 6 mL of acetone and, to this solution, the Jones reagent[36] was added at room temperature until the yellow color of Cr(VI) became persistent. The mixture was stirred for further 30 min at room temperature and the excess of the Cr(VI) was reduced with ethanol. The solid was removed by filtration and the filtrate was poured into water. The mixture was extracted with dichloromethane and the extract was dried over magnesium sulfate. Evaporation of the solvent afforded practically pure **15**, which was directly used for the next reaction, in 229 mg (95%) yield. The *sc*/*ap* value was 4.0. The following ^{1}H NMR data were collected ($CDCl_3$, δ): *sc* 2.28 (3H, s), 5.34 and 5.81 (2H, ABq, J=19.4 Hz), 6.35—6.4 (1H, m), 6.7—7.75 (14H, m); *ap* 2.98 (3H, s), 5.55 (2H, s), 6.35—6.4 (1H, m), 6.7—7.75 (14H, m).

9-Benzyl-8,13-dichloro-4-methoxycarbonyl-1-methyltriptycene (16). To a solution of 244 mg (0.517 mmol) of the carboxylic acid (**15**, *sc*/*ap*=4.0) in 15 mL of dichloromethane, was added diazomethane in ether,[37] prepared from *N*-methyl-*N*-nitroso-*p*-toluenesulfonamide, until the solution bore yellow tinge and then the mixture was stirred for 10 min at room temperature. The excess of diazomethane was destroyed with acetic acid and the mixture was poured into aqueous sodium hydrogencarbonate. The mixture was extracted with dichloromethane and the extract was dried over magnesium sulfate. The solvent was evaporated and the residue was submitted to preparative TLC (silica gel, hexane–dichloromethane eluent) to afford 211 mg (84%) of the desired product. The *sc* isomer was isolated by medium-pressure chromatography (silica gel, hexane-dichloromethane eluent). Mp 218.5—224.5 °C. Found: C, 74.42; H, 4.82; Cl, 14.40%. Calcd for $C_{30}H_{22}Cl_2O_2$: C, 74.23; H, 4.52; Cl, 14.61%. ^{1}H NMR ($CDCl_3$) δ=2.24 (3H, s), 4.00 (3H, s), 5.32 and 5.79 (2H, ABq, J=19.1 Hz), 6.3—6.4 (1H, m), 6.65—7.6 (13H, m).

ap-**16** exhibited the following ^{1}H NMR data ($CDCl_3$, δ): 2.94 (3H, s), 3.94 (3H, s), 5.52 (2H, s), 6.3—6.4 (1H, m), 6.65—7.6 (13H, m).

9-Benzyl-8,13-dichloro-4-cyano-1-methyltriptycene (17). To a suspension of 229 mg (0.486 mmol) of the acid (**15**) (*sc*/*ap*=4.0) in 10 mL of benzene was added 0.20 mL (2.7 mmol) of thionyl chloride. The mixture was stirred at room temperature for 1 h and then heated under reflux for 4 h. The benzene and the excess of the thionyl chloride were removed in vacuo and the residue was taken up in 2.5 mL of tetrahydrofuran. The solution was treated with 2 mL of concentrated aqueous ammonia for 2 h with ice-cooling. The whole was poured into water and extracted with dichloromethane. The extract was dried over magnesium sulfate and the solvent was evaporated. The residue, taken up in 10 mL of toluene, was heated with 2 g of phosphorus pentaoxide for 2 h under reflux. The solid was removed by filtration from the cooled mixture and the solvent was evaporated from the filtrate. The residue was submitted to preparative TLC (silica gel, hexane–dichloromethane eluent) to give 95 mg (43%) of the desired product (*sc*/*ap*=3.0). The *sc* form was separated by medium-pressure chromatography (silica gel, hexane–dichloromethane), mp 300.5—301.0 °C. Found: C, 76.82; H, 4.02; N, 2.93; Cl, 15.49%. Calcd for $C_{29}H_{19}Cl_2N$: C, 77.00; H, 4.23; N, 3.10; Cl, 15.67%. ^{1}H NMR ($CDCl_3$) δ=2.22 (3H, s), 5.25 and 5.79 (2H, ABq, J=19.4 Hz), 5.83 (1H, s), 6.3—6.4 (1H, m), 6.75—7.6 (12H, m). IR (KBr disc): 2225 cm^{-1}.

The following ^{1}H NMR data for *ap*-**17** were recorded ($CDCl_3$, δ): 2.94 (3H, s), 5.50 (2H, s), 5.80 (1H, s), 6.3—6.4 (1H, m), 6.75—7.6 (12H, m).

17) Since we neglect the presence of the peri-hydrogen in discussing the distance because of the uncertainty of the positions of the hydrogen atoms obtained by X-ray analysis, the distance between the beta atom of the 9-substituent and the peri-positions in the *ap* form may be even closer than the value mentioned above. However, it is also true that a bulky substituent prefers the *ap* position in the rotational isomers of the triptycene series. See the following paper for the references: M. Ōki, N. Takiguchi, S. (Received March 1, 1989)

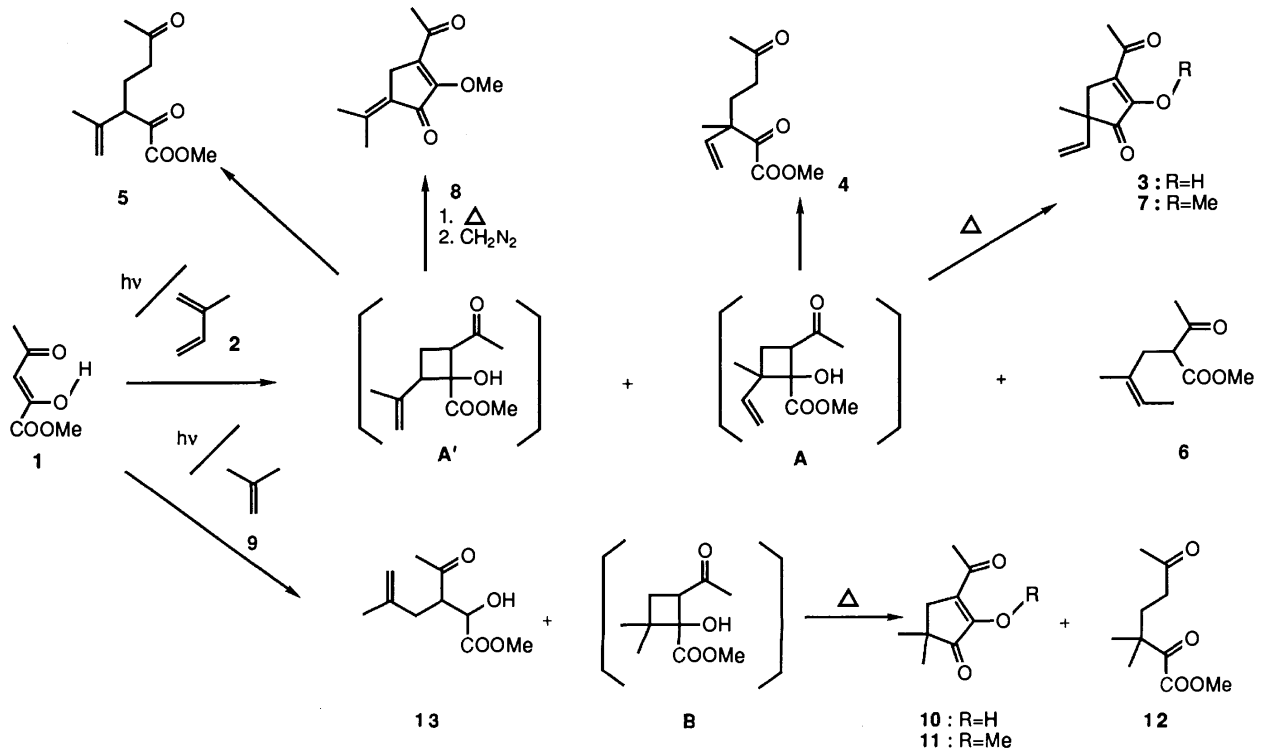
Pyrolysates obtained from the proto-photoadducts of methyl 2,4-dioxopentanoate with olefins were shown to be 3-acetyl-1,2-cyclopentanedione derivatives. One-pot formation of polyfunctionalized cyclopentane derivatives via a photocycloaddition has no precedence. Intentional preparation of the ring system was also achieved by a diethyl azodicarboxylate–triphenylphosphine treatment of the proto-adducts.

During our studies of the photochemical cycloadditions of methyl 2,4-dioxopentanoate with various olefins, we noticed the formation of by-products in variable yields. This paper deals with their structure elucidation.

As previously reported,[2] irradiation of methyl 2,4-dioxopentanoate (**1**) with isoprene (**2**) in ethyl acetate by means of a 400-W high-pressure mercury lamp through a Pyrex glass filter at 0 to 5 °C caused a smooth photocycloaddition to give photoadducts. When the whole mixture was thermolyzed at 180 °C, a new polar by-product (**3**) was isolated in 7% yields together with the expected 1,5-diketones (**4** and **5**) and a decarbonylated ene-reaction product (**6**),[3] 35, 15, and 14% yields, respectively. Upon treatment with ethereal diazomethane, **3** gave a methyl derivative (**7**) in good yield. On the basis of the molecular compositions, **3** and **7** were shown to be derived from 1 : 1-adducts of **1** to **2**. The IR spectrum of **7** revealed two carbonyl stretching bands at 1710 and 1660 cm^{-1}, while the ^1H NMR of **3** disclosed the presence of chelated β-hydroxy α,β-unsaturated ketone functions, δ=13.55. Both **3** and **7** revealed low-field shifted acetyl methyl signals at 2.39 and 2.51 in the ^1H NMR spectra. Other than these, there are signals ascribable to a singlet methyl on the sp^3-carbon and three olefinic protons. Therefore, **3** and **7** were deduced to be five-membered carbocyclic derivatives.

In order to detect corresponding thermolysate from isomeric proto-cycloadduct (**A'**), the entire reaction mixture was at first briefly treated with aqueous sodium hydrogen carbonate, methylated with diazomethane, and chromatographed on a silica-gel column.



Scheme 1.

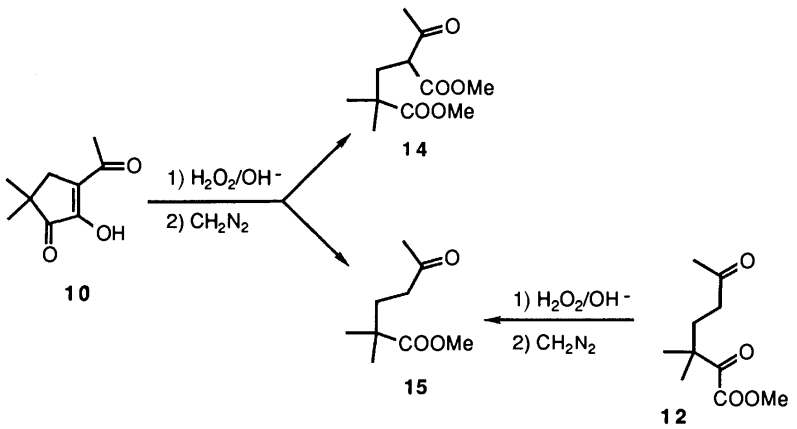
Indeed, together with **7** and **6**, a cyclopentenone derivative (**8**), in 0.8% yield, was isolated. The ^{1}H NMR spectrum of **8** revealed signals at 1.94 and 2.32 (each 3H, s), the latter of which suffered strong anisotropic and electric-field effects from the neighboring cisoid carbonyl group, indicating the presence of an isopropylidene group. The yield of **8** was much smaller than expected from the ratio of **4**:**5** (**7**:**8**=9:1; **4**:**5**=23:13). Therefore, the formation of this type of by-products is favorable for the photoadducts of 1,1-disubstituted ethenes.

Indeed, the photocycloaddition of **1** with 2-methylpropene (**9**)[4] gave a similar pyrolytic product (**10**) in 6% yield, which was characterized as a methyl derivative (**11**). The normal photoproduct (**12**) was isolated in 16% yield together with an ene-reaction product (**13**), whose structure was elucidated from the NMR evidence.

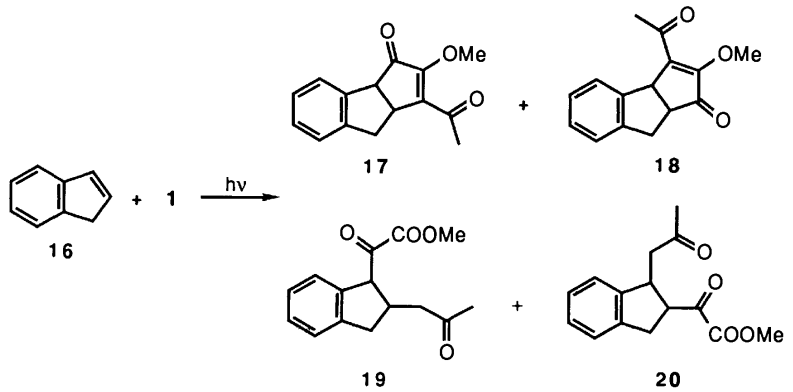
When **10** was treated with alkaline hydrogen peroxide[5] at room temperature, two acidic compounds were formed and their methyl esters were identified as dimethyl 4-acetyl-2,2-dimethylglutarate (**14**) and its decarboxylated methyl 2,2-dimethyl-5-oxohexanoate (**15**) by the NMR spectral analysis. The latter, **15**, was also formed by similar oxidation of **4**. Thus, the structure **11** must be 3-acetyl-2-methoxy-5,5-dimethyl-2-cyclopenten-1-one. Consequently, **3** and **10** should be derived from the proto-photoadducts (**A** and **B**) by a "retro-benzilic acid rearrangement"-type ring enlargement.

After deduction of the structures, our attention turned to a method for improving their formation. When the reaction mixture from **1** and **2** was treated with diethyl azodicarboxylate and triphenylphosphine[6] in ether at room temperature, the yields of **7** improved to 18% yield together with the expected **4** and **5**, in 28 and 13% yields, respectively. However, this alternative method was not always preferable; sometimes, the yields of cyclopentenones were lower than those of the pyrolytic workup. Nevertheless, by this alternative method, methyl ethers can be obtained directly by dehydration.

In addition, **1** and indene (**16**) gave, after similar irradiation and thermal treatment, the same type of methyl ethers (**17** and **18**) in 18 and 3% yields, respectively, along with the expected 2,6-dioxo ester (**19**) and previously undetected isomeric 2,6-dioxo ester (**20**).[7] The ^{1}H NMR spectrum of **17** revealed signals due to a methylene group and two methine protons, and the ^{13}C NMR showed two carbonyl carbon signals, suggesting the same carbon skeleton with **7**. The structure of **20** was deduced from an unequivocal



Scheme 2.



Scheme 3.

analysis of its ^{1}H NMR spectrum; i.e., the methylene protons adjacent to the acetyl group appear at 2.59 and 2.80 with mutual spin coupling of 18.7 Hz and additional coupling with a methine proton at 4.03. The coupling pattern of the methine proton, ddd (J=7.9, 7.8, 5.2 Hz), confirmed it to be benzylic.

Similar types of secondary products were obtained from various proto-photocycloadducts of **1** with olefins (Scheme 4). Namely, both conjugated olefins, cyclopentadiene (**21**),[8] and 2,3-dimethylbutadiene(**22**), and the isolated olefins, cyclopentene (**23**),[8] 2-methyl-2-butene (**24**), 2,3-dimethyl-2-butene (**25**), and 1-methylcyclohexene (**26**), respectively afforded the products in low, but reproducible, yields. They were characterized as methyl ethers after treatment with diazomethane. The physical properties of these products (**27** to **42**) are summarized in the experimental section. The yields of the rearranged compounds were relatively high, especially those from 1,1-disubstituted ethenes, which make the α-carbons to the α-hydroxy ester function quaternary in the proto-photoadducts. Occasionally, we have characterized other secondary products derived from the proto-adducts; one notable feature is methyl 2-(2-alkenyl)-3-oxobutyrates (**6** and **31**), from **2** and **22**, via photochemical retro-Prins cleavage,[3] and pyrolytic decarbonylation. These facts further showed the stability of these β-acetylcyclobutanol derivatives under the conditions mentioned above. An extreme case was a reaction with **25**; the proto-product, **38**, was detected in the photoproduct mixture, where expected diketone, **37**, was formed only after the thermolysis. The photoproducts from these olefins are listed in Scheme 4.

For a further confirmation of the rearranged structures, we carried out a two-dimensional C–H correlation NMR spectrum (C–H COSY) and long-

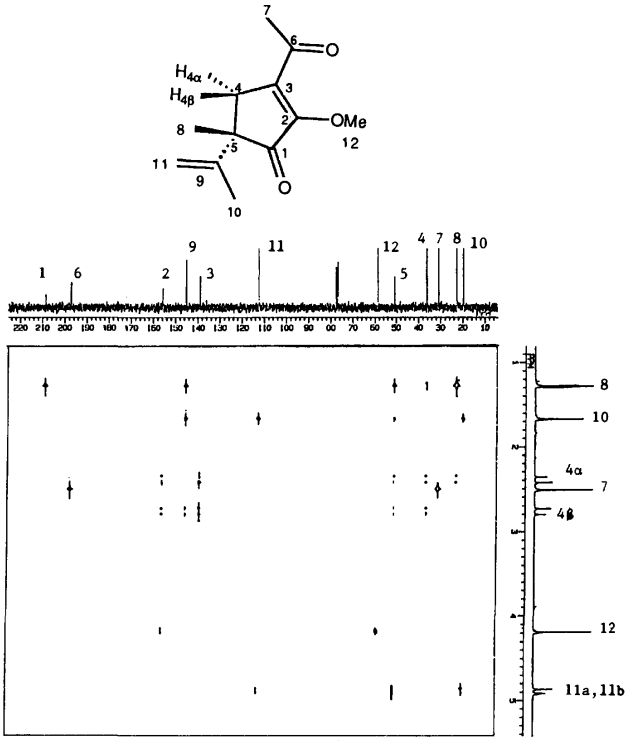


Fig. 1. Long-range C–H COSY spectrum of **29**. (Experimental conditions: observed frequency, 67.8 MHz; data points, 4 KX256; repetition, 80 scans; polarization transfer delay (τ_1), 50 ms (corresponding to J_{CH}=10 Hz) with second delay for proton decoupling (τ_2), 25 ms).

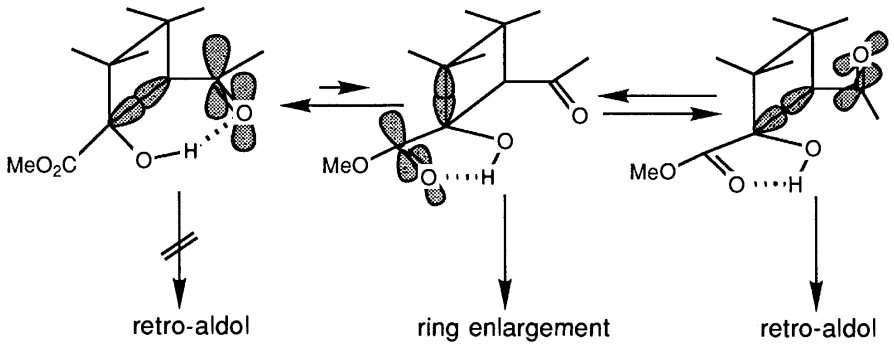


Scheme 5.

range C–H COSY analyses with **29** from the photo-adduct of **1** with **22**. The methoxyl proton signal revealed a correlation with an sp^2-carbon at δ=155.6 and the singlet methyl signal at 1.28 revealed a correlation with the carbonyl carbon signal at 208.4. Clearly, this carbonyl group exists at the α-position of the quaternary carbon bearing the methyl group; the methoxyl group is on the enol system (Fig. 1).

It is interesting that the formation of the by-products described in this paper constitutes a one-pot formation of the cyclopentane derivatives which carry several functional groups. Although a practical synthetic method of functional cyclopentane derivatives from various photocycloadducts of **1** has been developed by titanium(II) chloride condensation,[9] the derivatives described in this paper possess a different substitution pattern.[10] An improvement in the yields will be our next aim, for which the use of high-concentration conditions with olefins is favorable, as shown in the large-scale preparation of **3** (see Experimental); at present, about 50% of the proto-cycloadducts could be converted to the acetylcyclopentenone derivatives, according to a comparison of the product distributions.

Finally, it is also noteworthy that those sufficiently inert proto-cycloadducts of **1** towards retro-aldolization carry heavy substituents. The stable conformation of the proto-adduct is one having hydrogen bonding between the hydroxyl proton and carbonyl oxygen of the acetyl group, which is supported by a chemical shift of the hydroxy proton of **38** to at as low as δ=5.12. In this conformation, however, a retro-aldol reaction is stereoelectronically unfavored due to the perpendicular geometry of the C=O π-orbital and the breaking C–C bond. A steric repulsion from the adjacent substituents makes the orientation of methoxycarbonyl group favorable for ring enlargement, and the acetyl group was inhibited to change the conformation to one having the C=O π-orbital parallel to the breaking C–C bond in the retro-aldol process. This is one reason why the heavily substituted olefins give proto-photoadducts[11] and their transformation products.

Experimental

Elemental analyses were performed by Miss S. Hirashima, of Institute of Advanced Material Study, Kyushu University. The NMR spectra were measured in $CDCl_3$ with an FX 100 Model and a GSX 270H Model spectrometers, JEOL, and the chemical shift were expressed in δ values. The mass spectra were measured with a OISG-2 spectrometer, JEOL. IR spectra were measured with a Jasco IR-A 102 Model spectrometer as KBr disks, inserted liquid films, or in $CHCl_3$ solutions. The oxygen-free solvents for irradiations were obtained by careful distillation under an N_2 atmosphere.

Photoproducts of Low-Temperature Irradiation of 1 and 2. Isolation of 7 and 8. An EtOAc solution (30 cm^3) of **1** (480 mg) and **2** (11 cm^3) was irradiated by means of a 400-W high-pressure mercury lamp at −60 °C for 6 h. Then, the irradiation was stopped at the 74%-consumption of **1** (UV spectrometry) and the mixture was heated at 180 °C for 1 h, and the mixture was, after methylation with CH_2N_2, chromatographed on a silica-gel column to give **7** [a pale yellow oil, 34 mg; 7%. Found: *m/z*, 194.0941 (M^+). Calcd for $C_{11}H_{14}O_3$: 194.0942. ^{1}H NMR δ=1.26 (3H, s), 2.46 (1H, d, J=17.8 Hz), 2.51 (3H, s), 2.77 (1H, d, J=17.8 Hz), 4.17 (3H, s), 5.13 (1H, d, J=10.7 Hz), 5.14 (1H, d, J=17.3 Hz), and 5.78 (1H, dd, J=17.3, 10.7 Hz). ^{13}C NMR δ=22.4, 30.9, 35.9, 48.5, 58.6, 114.6, 138.1, 139.8, 155.1, 197.0, and 207.3. IR ν: 2950, 1710, 1660, 1610, 1380, 1220, 1180, 1040, 1020, and 920 cm^{-1}], **8** [yellow crystals, mp 110—111 °C, 4 mg; 0.8%. Found: *m/z*, 194.0982 (M^+). Calcd for $C_{11}H_{14}O_3$: 194.0942. ^{1}H NMR δ=1.94 (3H, s), 2.32 (3H, s), 2.50 (3H, s), 3.09 (2H, s), and 4.26 (3H, s). ^{13}C NMR δ=20.7, 22.9, 27.5, 30.9, 58.7, 127.5, 132.3, 152.2, 159.4, 192.3, and 197.4. IR ν: 2900, 1685, 1655, 1635, 1600, 1440, 1390, 1280, 1230, 1180, 1150, 1020, 950, 900, and 810 cm^{-1}], **4** (181 mg; 35%), **5** (79 mg; 15%), and decarbonylated **6** [a colorless oil, 63 mg; 14%. Found: *m/z*, 184.1101(M^+). Calcd for $C_{10}H_{16}O_3$: 184.1167. ^{1}H NMR δ=1.58 (3H, dq, J=7.0, 1.5 Hz), 1.67 (3H, q, J=1.5 Hz), 2.23 (3H, s), 2.56 (1H, dd, J=13.9, 7.3 Hz), 2.66 (1H, dd, J=13.9, 8.1 Hz), 3.64 (1H, dd, J=8.1, 7.3 Hz), 3.72 (3H, s), and 5.32 (1H, qm, J=7.0 Hz). ^{13}C NMR δ=13.4, 22.9, 29.1, 30.1, 52.4, 57.6, 122.7, 131.4, 170.2, and 202.8. IR ν: 2970, 2930, 1750, 1720, 1440, 1360, 1270, 1240, 1210, and 1150 cm^{-1}].

Large-Scale Irradiation of 1 with 2. A mixture of **1** (11.4 g) and **2** (150 cm^3) was irradiated by means of a 400-W high-pressure mercury lamp through a Pyrex-glass filter at 0 °C under an N_2 atmosphere. After 13 h, the mixture was

distilled in vacuo; the distillate solidified spontaneously was recrystallized from MeOH to give **3** [colorless crystals, mp 63—64 °C, 3.22 g; 22.7%. Found: C, 66.49; H, 6.75%. Calcd for $C_{10}H_{12}O_3$: C, 66.65; H, 6.71%. ^{1}H NMR δ=1.31 (3H, s), 2.39 (3H, s), 2.56 (1H, d, J=15.5 Hz), 2.86 (1H, d, 15.5 Hz), 5.12 (1H, dd, J=10, 0.5 Hz), 5.13 (1H, dd, J=17.5, 0.5 Hz), 5.80 (1H, dd, J=17.5, 10 Hz), and 13.55 (1H, br). ^{13}C NMR δ=23.5, 28.4, 36.5, 48.4, 114.8, 128.6, 139.2, 157.3, 201.3, and 205.3. IR ν: 3300, 1730, 1230, 930 cm^{-1}]. Silica-gel column chromatography of the residual mass in the bottom gave **4** (3.33 g; 20%),[2] and **5** (1.74 g; 10.4%).[2]

The CH_2N_2-Treatment of 3. Formation of 7. An ethereal solution (10 cm^3) of **3** (69 mg) was treated with an ethereal solution (10 cm^3) of CH_2N_2 to give **7** (70 mg; 94%).

Isolation of the Photoadducts from 1 and 2-Methylpropene (9).[5] Similarly, an EtOAc solution (50 cm^3) of **1** (960 mg) and **9** (1.2 g) was irradiated at −60 °C for 6 h to show 85%-consumption of **1**. One half of the mixture was diluted with *p*-cymene and refluxed for 1 h. After methylation with CH_2N_2, silica-gel column chromatography of the mixture gave **11** [a colorless oil, 39 mg; 8%. Found: m/z 182.0932 (M^+). Calcd for $C_9H_{12}O_3$: 182.0942. ^{1}H NMR δ=1.13 (6H, s), 2.45 (2H, s), 2.50 (3H, s), and 4.18 (3H, s). ^{13}C NMR δ=25.2 (2C), 30.8, 37.8, 41.8, 58.4, 138.3, 155.0, 197.2, and 210.8. IR ν: 2970, 2940, 2880, 1710, 1660, 1610, 1460, 1420, 1385, 1240, 1205, 1165, 1130, 1040, 960, 920, and 820 cm^{-1}], together with the ordinary product, **12** [a colorless oil, 144 mg; 25%. Found: m/z, 201.1125 (M^++1). Calcd for $C_{10}H_{17}O_4$: 201.1126. ^{1}H NMR δ=1.23 (6H, s), 1.94 (2H, dt, J=7.9, 1.5 Hz), 2.15 (3H, s), 2.40 (2H, tm, J=7.9 Hz), and 3.86 (3H, s). ^{13}C NMR δ=23.6 (2C), 29.9, 32.4, 38.8, 45.5, 52.4, 164.0, 201.1, and 207.7. IR ν: 2960, 1740, 1710, 1440, 1280, 1240, 1160, 1050, and 1030 cm^{-1}].

The rest of the mixture was directly chromatographed on a silica-gel column to give **13** [a colorless oil, 24 mg; 4%. Found: m/z 200.1045 (M^+). Calcd for $C_{10}H_{16}O_4$: 201.1048. ^{1}H NMR δ=1.82 (3H, br s), 2.21 (3H, s), 2.48 (2H, dm, J=7.7 Hz), 3.21 (1H, dt, J=7.7, 3.3 Hz), 3.35 (1H, dm, J=8.1 Hz), 3.85 (3H, s), 4,25 (1H, dd, J=8.1, 3.3 Hz), 4.87 (1H, br s), and 4.93 (1H, br s). ^{13}C NMR δ=22.2, 29.2, 36.0, 52.6, 52.7, 70.8, 113.8, 141.5, 174.2, and 211.0. IR ν: 3500, 2950, 1740, 1720, 1440, 1360, 1270, 1210, 1110, and 890 cm^{-1}], together with **12** (215 mg; 38%).

Hydrolysis of 11 to 10. An EtOH solution of **11** (48 mg) containing 2 M HCl (2 cm^3; 1 M=1 mol dm^{-3}) was refluxed for 1 h to give **10** [colorless needles, mp 98—100 °C, 43 mg; 96%. Found: C, 64.44; H, 7.13%. Calcd for $C_9H_{12}O_3$: C, 64.27; H, 7.19%. ^{1}H NMR δ=1.20 (6H, s), 2.40 (3H, s), 2.58 (2H, s), and 10.00 (1H, br s). ^{13}C NMR δ=25.2 (2C), 28.2, 38.4, 41.9, 128.4, 157.7, 201.8, and 208.4. IR ν: 3320, 2970, 1715, 1640, 1430, 1360, 1265, 1230, 1110, and 690 cm^{-1}].

Alkaline H_2O_2-Oxidation of 10 and Subsequent Methylation. Characterization of Dimethyl 4-Acetyl-2,2-dimethylglutarate (14) and Methyl 2,2-Dimethyl-5-oxohexanoate (15). An MeOH solution (3 cm^3) of **10** (8.4 mg) containing NaOH (13 mg) was treated with 35%-H_2O_2 (25 mg) at room temperature for 1 h. The mixture was then diluted with aq Na_2CO_3 and extracted with ether. The aqueous layer was acidified with dil HCl, and extracted with EtOAc, and methylated with ethereal CH_2N_2. Silica-gel column chromatography of the mixture afforded **15** [a colorless oil, 1.2 mg; 14%. Found: m/z, 172.1091 (M^+). Calcd for $C_9H_{16}O_3$: 172.1099. ^{1}H NMR δ=1.17 (6H, s), 1.81 (2H, m), 2.15 (3H, s), 2.40 (2H, m), and 3.67 (3H, s). ^{13}C NMR 25.1 (2C), 30.0, 33.9, 39.5, 41.6, 51.8, 177.9, and 208.3] and **14** [a colorless oil, 5.8 mg; 50%. Found: m/z, 231.1215 (M^++1). Calcd for $C_{11}H_{19}O_5$: 231.1231. ^{1}H NMR δ=1.18 (6H, s), 2.12 (1H, dd, J=14.7, 6.6 Hz), 2.22 (1H, dd, J=14.7, 5.1 Hz), 2.26 (3H, s), 3.55 (1H, dd, J=6.6, 5.1 Hz), 3.65 (3H, s), and 3.73 (3H, s). ^{13}C NMR δ=24.8, 25.7, 29.0, 37.5, 41.7, 51.9, 52.6, 56.4, 170.4, 177.4, and 202.4. IR ν: 2960, 1720, 1440, 1360, 1290, 1250, 1200, 1160, and 980 cm^{-1}].

H_2O_2-Oxidation of 12. An MeOH solution of **12** (20 mg) was briefly treated with 35%-H_2O_2 at room temperature for 10 min. The mixture was diluted with aq Na_2CO_3, from which neutral compound was removed by extraction with ether. After acidifying the aqueous solution with dil HCl, the acidic compounds were methylated with CH_2N_2, and collected via a silica-gel column chromatography to give **15**, which was identical with the sample obtained from **10** in every respect.

Isolation of 6 from the Photoproduct Mixture of 1 and 2 by Means of PPh_3-Diethyl Azodicarboxylate. The photoproduct mixture, immediately after the irradiation was treated with $(NCOOEt)_2$ and PPh_3 in ether (10 cm^3) at room temperature. The mixture was then diluted with ether and water, and extracted with ether. Silica-gel column chromatography of the organic extract afforded **6** (119 mg; 18%), which was identical with the authentic sample, together with **4** (189 mg; 27%) and **5** (95 mg; 13%).

Isolation of the Photoproducts of 1 and Indene (16).[6] Smilarly, an EtOAc solution (50 cm^3) of **1** (960 mg) and **16** (2.32 g) was irradiated at −60 °C for 6 h. The mixture was then divided into two parts. One of them was diluted with *p*-cymene (6 cm^3), and refluxed for 1 h. After methylation with CH_2N_2 silica-gel column chromatography of this mixture gave **17** [yellow crystals, mp 81—82 °C, 43 mg; 8%. Found: C, 74.44; H, 5.83%. Calcd for $C_{15}H_{14}O_3$: C, 74.36; H, 5.82%. ^{1}H NMR δ=2.47 (3H, s), 2.85 (1H, ddd, J=17.9, 3.3, 1.4 Hz), 3.45 (1H, dd, J=17.9, 10.0 Hz), 3.83 (1H, ddd, 10.0, 6.5, 3.3 Hz), 3.94 (1H, dd, J=6.5, 1.1 Hz), 4.15 (3H, s), and 7.14—7.50 (4H, m). ^{13}C NMR δ=31.3, 36.9, 55.1, 58.6, 124.9, 125.4, 127.0, 128.3, 137.5, 142.9, 143.1, 156.1, 197.2, and 204.1. IR ν: 3000, 2940, 2850, 1710, 1660, 1610, 1600, 1450, 1380, 1270, 1160, 1130, 1070, and 740 cm^{-1}] and **18** [a yellow oil, 16 mg; 3%. Found: m/z, 242.0948 (M^+). Calcd for $C_{15}H_{14}O_3$: 242.0942. ^{1}H NMR δ=2.51 (3H, s), 3.22—3.76 (3H, m), 4.16 (3H, s), 4.75 (1H, d, J=5.9 Hz), and 7.17—7.43 (4H, m). ^{13}C NMR δ=31.4, 33.3, 45.5, 48.0, 58.6, 125.1, 126.2, 127.0, 127.8, 141.5, 142.8, 143.6, 156.6, 197.4, and 208.1].

The rest of the photoproduct mixture was immediately passed through a silica-gel column to give the ordinary type products, **19**[6] and newly characterized **20** [a colorless oil, 17 mg; 3%. Found: m/z, 260.1041 (M^+). Calcd for $C_{15}H_{16}O_4$: 260.1048. ^{1}H NMR δ=2.06 (3H, s), 2.59 (1H, dd, J=18.7, 5.2 Hz), 2.80 (1H, dd, J=18.7, 7.8 Hz), 2.97 (1H, dd, J=16.1, 7.8 Hz), 3.34 (1H, dd, J=16.1, 10.0 Hz), 3.93 (3H, s), 4.03 (1H, ddd, J=7.9, 7.8, 5.2 Hz), 4.48 (1H, ddd, J=10.0, 7.9, 7.8 Hz), and 7.1—7.2 (4H, m). ^{13}C NMR δ=30.2, 33.4, 42.8, 45.2, 49.3, 53.2, 123.8, 124.7, 127.2, 127.4, 140.6, 144.4, 161.2, 194.7, and 207.8. IR ν: 2940, 1715, 1430, 1360, 1260, 1160, 1080, 750 cm^{-1}].

Isolation of Photoproducts from 1 and Cyclopentadiene (21).[7] Similarly, an EtOAc solution (30 cm^3) of **1** (480 mg) and **21** (660 mg) was irradiated at −60 °C for 6 h. The mixture was then diluted with *p*-cymene (6 cm^3) and

refluxed for 1 h. The mixture, after treatment with CH_2N_2, was chromatographed on a silica-gel column to give **27** [yellow crystals, mp 71—72 °C, 48 mg; 13%. Found: C, 69.00; H, 6.39%. Calcd for $C_{11}H_{12}O_3$: C, 68.74; H, 6.29%. ^{1}H NMR δ=2.15 (1H, br), 2.48 (3H, s), 2.85 (1H, br), 3.47 (1H, br), 3.57 (1H, m), 4.17 (3H, s), 5.63 (1H, m), and 5.74 (1H, m). ^{13}C NMR δ=31.3, 36.0, 37.3, 56.6, 58.6, 126.4, 133.8, 143.1, 155.8, 197.2, and 205.1] and **28** [as a mixture with **27**. 16 mg; ca. 4%. ^{1}H NMR δ=2.48 (3H, s), 2.54 (1H, br m), 2.63 (1H, br m), 3.03 (1H, m), 4.01 (1H, m), 4.17 (3H, s), 5.58 (1H, m), and 5.86 (1H, m)]. No other photoproduct was isolated by this work up.

Isolation of the Photoproducts from 1 and 2,3-Dimethylbutadiene (22). Similarly, an EtOAc solution (30 cm^3) of **1** (480 mg) and **22** (820 mg) was irradiated at −60 °C for 6 h to show 65%-consumption of **1**. The mixture was then diluted with *p*-cymene, and refluxed for 1 h. Silica-gel column chromatography of the methylated mixture afforded **29** [a pale-yellow oil, 27 mg; 6%. Found: *m/z*, 208.1102 (M^+). Calcd for $C_{12}H_{16}O_3$: 208.1099. ^{1}H NMR δ=1.28 (3H, s), 1.67 (3H, dd, *J*=1.5, 0.7 Hz), 2.39 (1H, d, *J*=18 Hz), 2.51 (3H, s), 2.76 (1H, d, *J*=18 Hz), 4.18 (3H, s), 4.87 (1H, q, *J*=0.7 Hz), 4.91 (1H, q, *J*=1.5 Hz). ^{13}C NMR δ=19.6, 22.6, 30.8, 36.1, 50.7, 58.5, 112.3, 138.8, 145.0, 155.6, 197.0, and 208.4. IR ν: 2950, 1700, 1660, 1610, 1380, 1220, 1180, 1160, 1140, 1020, 930, and 890 cm^{-1}] together with the ordinary product **30** [a colorless oil, 162 mg; 33%. Found: *m/z*, 226.1205 (M^+). Calcd for $C_{12}H_{18}O_4$: 226.1204. ^{1}H NMR δ=1.33 (3H, s), 1.73 (3H, s), 2.01—2.12 (2H, m), 2.13 (3H, s), 2.31—2.37 (2H, m), 3.79 (3H, s), 4.85 (1H, br m), and 5.08 (1H, br s). ^{13}C NMR δ=19.8, 20.0, 28.6, 30.0, 38.4, 52.3, 54.5, 114.8, 144.1, 163.2, 198.2, and 207.8. IR ν: 2950, 1740, 1720, 1640, 1440, 1360, 1280, 1160, 1020, and 900 cm^{-1}] and decarbonylated **31** [a colorless oil, 116 mg; 29%. Found: *m/z*, 198.1248 (M^+). Calcd for $C_{11}H_{18}O_3$: 198.1256. ^{1}H NMR δ=1.63 (6H, s), 1.66 (3H, s), 2.21 (3H, s), 2.58 (1H, dd, *J*=14.3, 8.7 Hz), 2.67 (1H, dd, *J*=14.3, 6.7 Hz), 3.61 (1H, dd, *J*=8.7, 6.7 Hz), and 3.71 (3H, s). ^{13}C NMR δ=18.0, 20.4, 20.8, 29.2, 33.1, 52.3, 58.1, 123.2, 127.9, 170.4, and 203.2. IR ν: 2950, 2920, 1740, 1720, 1430, 1355, 1265, 1220, 1190, and 1150 cm^{-1}].

Isolation of Photoproducts from 1 and Cyclopentene (23).[7] Similarly, an EtOAc solution (30 cm^3) of **1** (480 mg) and **23** (680 mg) was irradiated at −60 °C for 6 h; during that period 23% of **1** was consumed. The mixture was then diluted with *p*-cymene and refluxed for 1 h. Silica-gel column chromatography of the methylated mixture afforded **32** [yellow oil, 8 mg; 5%. Found: *m/z*, 194.0944 (M^+). Calcd for $C_{11}H_{14}O_3$: 194.0942. ^{1}H NMR δ=1.3 (1H, br), 1.5—1.9 (5H, m), 2.47 (3H, s), 2.71 (1H, ddd, *J*=9, 6, 2 Hz), 3.38 (1H, *J*=9, 6, 2 Hz), and 4.16 (3H, s). ^{13}C NMR δ=24.4, 29.6, 30.4, 31.3, 38.8, 49.1, 58.5, 143.7, 157.1, 197.3, and 209.2. IR ν: 2950, 2870, 1710, 1660, 1600, 1410, 1380, 1320, 1220, 1180, 1135, 1105, 1080, 1060, 1010, 960, 930, and 910 cm^{-1}] and the ordinary product **33**[7] [a colorless oil, a trace amount. ^{13}C NMR δ=23.5, 28.0, 30.2, 32.6, 38.2, 44.6, 48.8, 53.0, 161.9, 196.6, and 208.3].

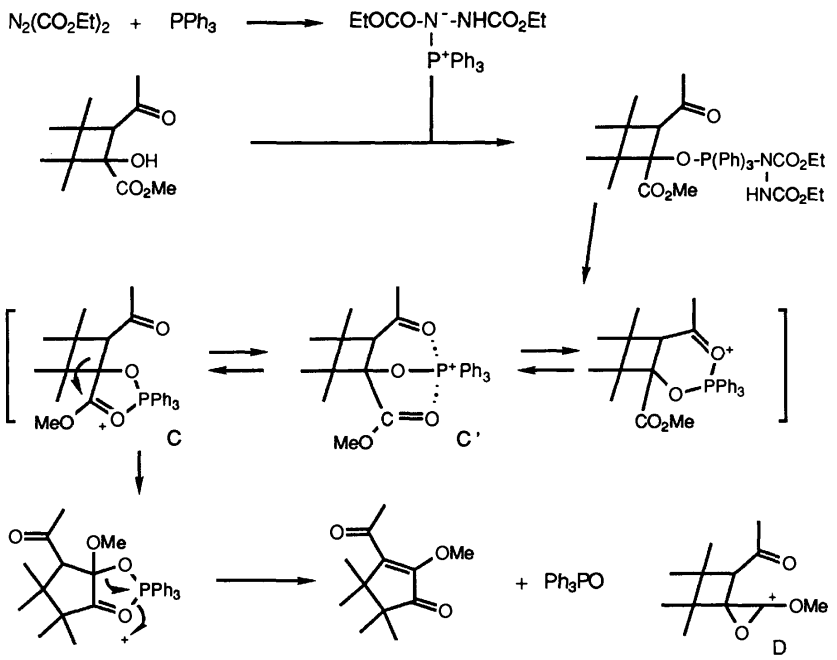
Isolation of the Photoproducts from 1 and 2-Methyl-2-butene (24). Similarly, **1** (480 mg) and **24** (700 mg) were irradiated at −60 °C for 6 h to consume 28% of **1**. The mixture was then refluxed in a *p*-cymene solution, and then chromatographed on a silica-gel column to give **34** [a pale-yellow oil, 30 mg; 16%. Found: *m/z*, 196.1089 (M^+). Calcd for $C_{11}H_{16}O_3$: 196.1099. ^{1}H NMR δ=1.04 (3H, d, *J*=7.0 Hz), 1.05 (3H, s), 1.12 (3H, s), 2.48 (3H, s), 2.79 (1H, q, *J*=7.0 Hz), and 4.14 (3H, s). ^{13}C NMR δ=16.5, 19.3, 27.6, 31.6, 41.0, 46.4, 58.5, 143.6, 154.9, 197.6, and 210.7. IR ν: 2975, 1710, 1660, 1610, 1450, 1380, 1235, 1160, 1130, 1030, and 940 cm^{-1}] and expected **35** [a colorless oil, 44 mg; 22%. Found: *m/z*, 214.1213 (M^+). Calcd for $C_{11}H_{18}O_4$: 214.1205. ^{1}H NMR δ=0.89 (3H, d, *J*=6.6 Hz), 1.12 (3H, s), 1.19 (3H, s), 2.14 (3H, s), 2.21 (1H, dd, *J*=16.9, 10.3 Hz), 2.41 (1H, dd, *J*=16.9, 2.8 Hz), 2.62 (1H, br m), and 3.85 (3H, s). IR ν: 2980, 1740, 1720, 1710, 1365, 1280, 1220, 1050, 1030, and 750 cm^{-1}].

Fractionation of the Photoproducts from 1 and 2,3-Dimethyl-2-butene (25). Similarly, an EtOAc solution (30 cm^3) of **1** (480 mg) and **25** (840 mg) was irradiated at −60 °C for 6 h to consume 33% of **1**. The mixture was then diluted with *p*-cymene and refluxed for 1 h. Silica-gel column chromatography of the methylated mixture afforded **36** [a pale-yellow oil, 35 mg; 15%. Found: *m/z* 210.1246 (M^+). Calcd for $C_{12}H_{18}O_3$: 210.1255. ^{1}H NMR δ=1.05 (6H, s), 1.17 (6H, s), 2.45 (3H, s), and 4.08 (3H, s). ^{13}C NMR δ=21.4 (2C), 24.2 (2C), 32.5, 43.1, 51.5, 58.5, 145.7, 155.2, 198.6, and 210.2. IR ν: 2975, 1710, 1670, 1600, 1450, 1370, 1280, 1210, 1160, and 1090 cm^{-1}], and a mixture (55 mg) of **37** [ca. 7%. ^{1}H NMR δ=1.13 (6H, s), 1.22 (6H, s), 2.15 (3H, s), and 2.56 (2H, s), and 3.84 (3H, s)], and **39** [17%. ^{1}H NMR δ=1.15 (3H, s), 1.18 (3H, s), 1.84 (3H, dd, *J*=1.3, 0.8 Hz), 2.15 (3H, s), 2.85 (1H, d, *J*=17.4 Hz), 3.15 (1H, d, *J*=17.4 Hz), 3.73 (3H, s), 3.81 (1H, s), 4.82 (1H, quint, *J*=0.8 Hz), and 4.96 (1H, qq, *J*=1.3, 0.8 Hz). ^{13}C NMR δ=22.5, 23.3, 23.6, 30.9, 44.8, 47.5, 52.3, 113.6, 149.9, 175.1, and 208.4].

Without a thermal treatment of the mixture, silica-gel column chromatography gave none of the expected **37**, but proto-product **38** [ca. 25%. ^{1}H NMR δ=0.97 (3H, s), 1.03 (3H, s), 1.19 (3H, s), 1.23 (3H, s), 2.13 (3H, s), 3.56 (1H, s), and 5.12 (1H, s). ^{13}C NMR δ=16.0, 21.5, 21.6, 24.8, 31.0, 42.0, 44.4, 52.0, 54.1, 80.2, 172.4, and 212.0] and ene-product **39** (12%). However, the isolation of these compounds was unsuccessful.

Isolation of the Photoproducts from 1 and 1-Methylcyclohexene (26). Similarly, an EtOAc solution (30 cm^3) of **1** (960 mg) and **26** (1.9 g) was irradiated at −60 °C for 6 h to consume 28% of **1**. One half of the mixture was then diluted with *p*-cymene, and refluxed for 1 h. Silica-gel column chromatography of the methylated mixture gave **40** [pale-yellow oil, 5 mg; 2%. Found: *m/z*, 222.1279 (M^+). Calcd for $C_{13}H_{18}O_3$: 222.1255. ^{1}H NMR δ=1.05 (3H, s), 1.1—1.3 (3H, m), 1.3—1.45 (2H, m), 1.5 (1H, br), 1.9 (1H, br), 2.48 (3H, s), 2.73 (1H, dd, *J*=7.5, 5.6 Hz), and 4.15 (3H, s). ^{13}C NMR δ=20.2, 20.3, 26.3, 27.9, 30.3, 31.3, 42.6, 46.9, 58.5, 143.0, 155.7, 197.4, and 210.5. IR ν: 2950, 2880, 1710, 1660, 1605, 1450, 1420, 1380, 1220, 1170, 1140, 1080, 1020, 960, 910, and 800 cm^{-1}] and the ordinary product, **41** [a colorless oil, a trace amount. Found: *m/z*, 241.1475 (M^++1). Calcd for $C_{13}H_{21}O_4$: 241.1439. ^{1}H NMR δ=1.29 (3H, s), 1.3—1.7 (7H, m), 2.04—2.16 (2H, m), 2.14 (3H, s), 2.52 (1H, dd, *J*=17.8, 9.5 Hz), 2.73 (1H, dd, *J*=17.8, 2.6 Hz), and 3.83 (3H, s). ^{13}C NMR δ=22.7, 23.5, 24.6, 27.8, 30.7, 35.1, 39.8, 44.9, 49.3, 52.3, 164.2, 201.8, and 208.1. IR ν: 2940, 2860, 1740, 1450, 1360, 1280, 1260, 1160, 1040, and 1010 cm^{-1}].

The rest of the photoreaction mixture was treated without thermolysis and chromatographed on a silica-gel column to give **41** (15 mg; 6%) and an ene-product, **42** [a colorless oil, 12 mg; 5%. Found: *m/z*, 240.1363 (M^+). Calcd for $C_{13}H_{20}O_4$: 240.1360. ^{1}H NMR δ=1.25—1.85 (6H, m), 2.11—2.22 (2H, m), 2.23 (3H, s), 2.94 (1H, dm, *J*=11.7 Hz), 3.36 (1H, dd,



Scheme 6.

J=11.7, 2.6 Hz), 3.47 (1H, d, J=8.8 Hz), 3.77 (3H, s), 4.28 (1H, dd, J=8.8, 2.6 Hz), 4.87 (2H, br s). ^{13}C NMR δ=21.9, 28.3, 30.5, 32.3, 32.9, 41.9, 52.6, 53.0, 70.8, 111.0, 147.7, 194.4, and 213.2. IR ν: 3500, 2930, 2860, 1740, 1720, 1440, 1360, 1250, 1220, 1160, and 1100 cm^{-1}].

3) Formation of **6** and **31** can be explained as the result of photochemical retro-Prins cleavage of their proto-cycloadducts as already described in our previous paper (H. Takeshita, K. Komiyama, and K. Okaishi, *Bull. Chem. Soc. Jpn.*, **58**, 2725 (1985)). However, for the present case, subsequent refluxing in *p*-cymene for 1 h caused spontaneous decarbonylation of the α-keto ester moiety to result in these products. Furthermore, it is interesting that 3-substituted 2,6-dioxoheptanoates were stable toward thermal decarbonylation under those conditions.

4) This olefin was employed for the synthesis of deoxytrisporone via the cycloaddition with methyl 2,4-dioxohexanoate. See H. Takeshita, S. Hatta, and T. Hatsui, *Bull. Chem. Soc. Jpn.*, **57**, 619 (1984).

5) E. Kyburz, B. Riniker, H. R. Schenk, H. Heusser, and O. Jeger, *Helv. Chim. Acta*, **36**, 1891 (1953); W. Baker, H. F. Bondy, J. Gumb, and D. Miles, *J. Chem. Soc.*, **1953**, 1615.

6) Triphenylphosphine-dimethylazodicarboxylate is a mild and neutral dehydrating agent leading to esters, lactones, cyclic esters and amines by activating the hydroxyl group (O. Mitsunobu, *Synthesis*, **1986**, 1). We are grateful to a referee who called our attention to a novelty of present application in respect of carbonyl group activation for dehydration. The reaction is likely to proceed via penta- or hexa-coordinated phosphorane intermediate (**C** or **C'**) rather than via oxiranyl cation (**D**) by participation of neighboring carbonyl group. Stereochemical feature is similar to that in pyrolytic dehydration (Scheme 6).

7) H. Takeshita, A. Mori, and T. Toyonaga, *Kyushu Daigaku Seisan Kagaku Kenkyusho Hokoku*, **64**, 25 (1976).

8) H. Takeshita, A. Mori, and Y. Toyonaga, *Bull. Chem. Soc. Jpn.*, **48**, 307 (1975).

9) N. Kato, K. Nakanishi, and H. Takeshita, *Bull. Chem. Soc. Jpn.*, **59**, 1125 (1986); H. Takeshita and N. Kato, *Yuki Gosei Kagaku Kyokai Shi*, **44**, 1081 (1986).

10) We should point out that, indeed, the metacycloaddition of benzene derivatives (P. A. Wender and G. B. Dreyer, *J. Am. Chem. Soc.*, **104**, 5805 (1982)) should belong to this category. Or, even photodimerization of phenylethyne to 1-phenylazulene (D. Bryce-Smith and J. E. Lodge, *J. Chem. Soc.*, **1963**, 15) and photoisomerization of barrelene to semibullvalene (H. E. Zimmermann, and G. L. Grunewald, *J. Am. Chem. Soc.*, **88**, 183 (1966)) are the cases. More versatile example was the intramolecular hydrogen abstraction and cyclization of α-diketones to acyloin derivatives (R. Bishop and N. K. Hamer, *J. Chem. Soc. C*, **1970**, 1193), though it is not the cycloaddition.

11) During our total synthesis of cuparene, such proto-product (**i**) from **1** and *p*-isopropenyltoluene was indeed isolated. See H. Takeshita, A. Mori, and S. Nakamura, *Bull. Chem. Soc. Jpn.*, **57**, 3152 (1984).

(Received March 3, 1989)

The reactions of 2-thiouracils and azauracils with ozone have been examined. 2-Thiouracils were ozonized to give the corresponding 4(3*H*)-pyrimidinones and uracils. Ozone attacks the thiocarbonyl moiety and the desulfurization process to give 4(3*H*)-pyrimidinones competes with the oxidation process to give uracils. 5-Azauracil was stable for ozone, while 6-azauracil readily reacted with ozone to give parabanic acid.

The ozonization of the C=S moiety has been reported to give the corresponding C=O and/or C=S=O moieties.[1] Interestingly, in our study on the ozonization of pyrimidine bases, 2-thiouracils were found to give 4(3*H*)-pyrimidinones as the main products. This is the first report on the transformation of C=S into the C–H moiety by ozone. The reaction of azauracils with ozone was also investigated.

Experimental

Instruments. Ozone was generated with a Nihon Ozon 0-1-2 ozonizer. Melting points were measured by a Yanagimoto micro melting point apparatus and uncorrected. NMR and mass spectra were recorded on JEOL JNM-GX 270 FT NMR and Shimadzu QP-1000 mass spectrometers, respectively. High-performance liquid chromatography was performed on a Jasco Familic 100N liquid chromatograph.

Materials. Uracil (**1a**) and azauracils (**11** and **12**) were purchased from Tokyo Kasei Kogyo Co., Ltd. and used without further purification. Thiouracils (**3a—g** and **5**), dithiouracil (**6**) and 2-methylthio-4(3*H*)-pyrimidinone (**7**) were synthesized as described in the literature. Their melting points and spectral data are as follows:

2-Thiouracil (**3a**): mp >300 °C (lit,[2] 340 °C); ^{1}H NMR (DMSO-d_6) δ=5.81 (d, J=7 Hz, 1H), 7.40 (d, J=7 Hz, 1H), 12.37 (br. s, 2H); MS (70 eV) m/z (rel intensity) 128 (M^+, 100).

5-Methyl-2-thiouracil (**3b**): mp 265—267 °C (lit,[3] 265—267 °C); ^{1}H NMR (DMSO-d_6) δ=1.77 (s, 3H), 7.31 (s, 1H), and 12.29 (br. s, 2H); MS(70 eV) m/z (rel intensity) 142 (M^+, 80) and 55 (100).

5-Ethyl-2-thiouracil (**3c**): mp 191—192 °C (lit,[4] 190—192 °C); ^{1}H NMR (DMSO-d_6) δ=1.01 (t, J=7 Hz, 3H), 2.21 (q, J=7 Hz, 2H), 7.21 (s, 1H), and 12.35 (br. s, 1H); MS (70 eV) m/z (rel intensity) 156 (M^+, 100).

6-Methyl-2-thiouracil (**3d**): mp >300 °C (lit,[4] >300 °C); ^{1}H NMR (DMSO-d_6) δ=2.06 (s, 3H), 5.68 (s, 1H), and 12.27 (br. s, 2H); MS (70 eV) m/z (rel intensity) 142 (96) and 44 (100).

3-Methyl-2-thiouracil (**3e**): mp 272—273 °C; ^{1}H NMR (DMSO-d_6) δ=3.52 (s, 3H), 5.94 (d, J=8 Hz, 1H), 7.44 (d, J=8 Hz, 1H), and 12.60 (br. s, 1H); MS (70 eV) m/z (rel intensity) 142 (M^+, 100).

1-Methyl-2-thiouracil (**3f**): mp 229 °C (lit,[5] 228 °C); ^{1}H NMR (DMSO-d_6) δ=3.56 (s, 3H), 5.91 (d, J=8 Hz, 1H), 7.83 (d, J=8 Hz, 1H), and 12.58 (br. s, 1H); MS (70 eV) m/z (rel intensity) 142 (M^+, 72) and 42 (100).

1,3-Dimethyl-2-thiouracil (**3g**): mp 104 °C (lit,[6] 103 °C); ^{1}H NMR (DMSO-d_6) δ=3.56 (s, 3H), 3.65 (s, 3H), 6.05 (d, J=8 Hz, 1H), and 7.97 (d, J=8 Hz, 1H); MS (70 eV) m/z (rel intensity) 156 (M^+, 72) and 42 (100).

4-Thiouracil (**5**): mp >300 °C (lit,[7] 317—321 °C); ^{1}H NMR (DMSO-d_6) δ=5.74 (d, J=8 Hz, 1H), 7.38 (d, J=8 Hz, 1H), and 12.20 (br. s, 2H); MS (70 eV) m/z (rel intensity) 128 (M^+, 100).

2,4-Dithiouracil (**6**): mp 267—273 °C (lit,[8] 265—275 °C); ^{1}H NMR (DMSO-d_6) δ=6.50 (d, J=7 Hz, 1H), 7.26 (d, J=7 Hz, 1H), 12.87 (br. s, 1H), and 13.62 (br. s, 1H); MS (70 eV) m/z (rel intensity) 144 (M^+, 100).

2-Methylthio-4(3*H*)-pyrimidinone (**7**): mp 190—192 °C (lit,[9] 198—199 °C); ^{1}H NMR (DMSO-d_6) δ=2.54 (s, 3H), 6.12 (d, J=7 Hz, 1H), and 7.89 (d, J=7 Hz, 1H); MS (70 eV) m/z (rel intensity) 142 (M^+, 100).

The purity of used materials was checked by TLC (SiO_2, AcOEt:Me_2CHOH:H_2O=75:16:9).

Ozonization Reaction. Ozonization was carried out with an ozone-oxygen mixture (O_3: 0.22 mmol min^{-1}, O_2: 200 ml min^{-1}) on 2 mmol of substrate in 100 ml of acetic acid at room temperature. The end point of the reaction was monitored by TLC (SiO_2, AcOEt:Me_2CHOH:H_2O=75:16:9). In order to remove the dissolved ozone, nitrogen gas (100 ml min^{-1}, 10 min) was bubbled into the solution, which was allowed to stand overnight. The disappearance of peroxide activity was checked by a KI test. The solution was concentrated on a rotary evaporator and chromatographed on preparative TLC (SiO_2, AcOEt:Me_2CHOH:H_2O=75:16:9). The isolated products were identified on the basis of their spectral data shown below: 5-Methyluracil (**1b**): mp >300 °C (lit,[10] 313—314 °C); ^{1}H NMR (DMSO-d_6) δ=1.71 (s, 3H), 7.24 (s, 1H), 10.57 (br. s, 1H), and 10.99 (br. s, 1H); MS (70 eV) m/z (rel intensity) 126 (M^+, 39) and 55 (100).

5-Ethyluracil (**1c**): mp 290 °C (lit,[11] 300—303 °C); ^{1}H NMR (DMSO-d_6) δ=0.99 (t, J=7 Hz, 3H), 2.16 (q, J=7 Hz, 2H), 7.16 (d, J=7 Hz, 1H), 10.61 (br. s, 1H), and 10.97 (br. s, 1H); MS (70 eV) m/z (rel intensity) 140 (M^+, 100).

6-Methyluracil (**1d**): mp >300 °C (lit,[12] 340 °C); ^{1}H NMR (DMSO-d_6) δ=2.00 (s, 3H), 5.31 (s, 1H), and 10.82 (br. s, 2H); MS (70 eV) m/z (rel intensity) 126 (M^+, 29) and 42 (100).

3-Methyluracil (**1e**): mp 169 °C (lit,[13] 174—175 °C); ^{1}H NMR (DMSO-d_6) δ=3.12 (s, 3H), 5.57 (d, J=7 Hz, 1H), 7.39 (dd, J=7 and 6 Hz, 1H), and 10.97 (br. s, 1H); MS (70 eV) m/z (rel intensity) 126 (M^+, 90) and 69 (100).

1-Methyluracil (**1f**): mp 178—182 °C (lit,[14] 232 °C); ^{1}H NMR (DMSO-d_6) δ=3.23 (s, 3H), 5.50 (dd, J=8 and 2 Hz, 1H), 7.58 (d, J=8 Hz, 1H), and 11.07 (br. s, 1H); MS (70 eV) m/z (rel intensity) 126 (M^+, 52) and 42 (100).

1,3-Dimethyluracil (**1g**): mp 122—123 °C (lit,[15] 122—124 °C); ^{1}H NMR (DMSO-d_6) δ=3.14 (s, 3H), 3.29 (s, 3H),

5.65 (d, J=8 Hz, 1H), and 7.65 (d, J=8 Hz, 1H); MS (70 eV) m/z (rel intensity) 140 (M^+, 91) and 42 (100).

1-Formyl-5-hydroxyhydantoin (**2**): mp 153—155 °C; ^{1}H NMR (DMSO-d_6) δ=5.47 (d, J=8 Hz, 1H), 7.56 (d, J=8 Hz, 1H, exchanges with D_2O), 8.95 (s, 1H), and 11.70 (br. s, 1H, exchanges with D_2O); ^{13}C NMR (DMSO-d_6) δ=75.8 (d), 154.2 (s), 158.9 (d), and 171.1 (s); MS (70 eV) m/z (rel intensity) 144 (M^+, 5), 116 (54), and 88 (100); MS (CI, 200 eV, isobutane) m/z 145 (MH^+, 100%); Found: m/z 144.0175. Calcd for $C_4H_4N_2O_4$: M^+, 144.0171.

4(3*H*)-Pyrimidinone (**4a**): mp 160—163 °C (lit,[16] 163—164 °C); ^{1}H NMR (DMSO-d_6) δ=6.31 (d, J=7 Hz, 1H), 7.89 (d, J=7 Hz, 1H), 8.16 (s, 1H), and 12.54 (br. s, 1H); ^{13}C NMR (DMSO-d_6) δ=115.9 (d), 150.5 (d), and 161.3 (s); MS (70 eV) m/z (rel intensity) 96 (M^+, 100).

5-Methyl-4(3*H*)-pyrimidinone (**4b**): mp 145—147 °C (lit,[17] 153—154 °C); ^{1}H NMR (DMSO-d_6) δ=2.13 (s, 3H), 7.89 (s, 1H), and 8.18 (s, 1H); ^{13}C NMR (DMSO-d_6) δ=13.7 (q), 126.7 (s), 148.8 (d), 152.1 (d), and 163.3 (s); MS (70 eV) m/z (rel intensity) 110 (M^+, 100).

5-Ethyl-4(3*H*)-pyrimidinone (**4c**): mp 88—90 °C; ^{1}H NMR (DMSO-d_6) δ=1.22 (t, J=7 Hz, 3H), 2.53 (q, J=7 Hz, 2H), 7.90 (s, 1H), 8.27 (s, 1H), and 9.39 (s, 1H); ^{13}C NMR (DMSO-d_6) δ=12.4 (q), 20.8 (t), 131.1 (s), 147.0 (d), 150.0 (d), and 164.0 (s); MS (70 eV) m/z (rel intensity) 124 (M^+, 100).

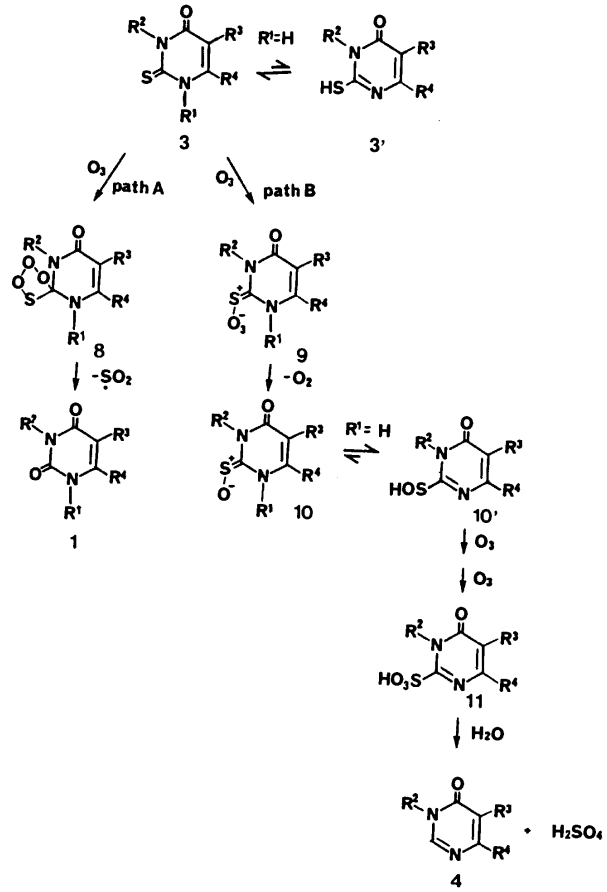
6-Methyl-4(3*H*)-pyrimidinone (**4d**): mp 145—147 °C (lit,[18] 149—150 °C); ^{1}H NMR (DMSO-d_6) δ=2.17 (s, 3H), 6.16 (s, 1H), and 8.08 (s, 1H); ^{13}C NMR (DMSO-d_6) δ=23.0 (q), 112.6 (d), 149.2 (d), 160.8 (d), and 164.3 (s); MS (70 eV) m/z (rel intensity) 110 (M^+, 100).

3-Methyl-4(3*H*)-pyrimidinone (**4e**): mp 118—120 °C (lit,[19] 121—122 °C); ^{1}H NMR (DMSO-d_6) δ=3.32 (s, 3H), 6.49 (d, J=7 Hz, 1H), 7.90 (d, J=7 Hz, 1H), and 8.21 (s, 1H); MS (70 eV) m/z (rel intensity) 110 (M^+, 42) and 42 (100).

Parabanic acid (**13**): mp 236—240 °C (lit,[20] 238—244 °C); ^{1}H NMR (DMSO-d_6) δ=11.75 (br. s, 2H); MS (70 eV) m/z (rel intensity) 114 (M^+, 72), 86 (64), and 43 (100). The purity of all products was checked by TLC (SiO_2, AcOEt:Me_2CHOH:H_2O=75:16:9). Analysis of products was carried out by HPLC (SS-10, AcOEt:Me_2CHOH:H_2O=75:16:9, 254 nm).

Results and Discussion

The ozonization reactions of uracil (**1a**), 2-thiouracils (**3a—d**), 4-thiouracil (**5**), and 2,4-dithiouracil (**6**) are summarized in Table 1. The reaction of uracil (**1a**) gave 1-formyl-5-hydroxyhydantoin (**2**) in a 29% yield (Run 1). Interestingly, the reaction of 1-unsubstituted 2-thiouracils **3a—e** under the same conditions gave the corresponding uracils **1a—e** and 4(3*H*)-pyrimidinones **4a—e** in 7—37 and 48—72% yields, respectively (Runs 2—6). The reaction of 1-methyl-2-thiouracils **3f,g** preferentially gave 1-methyluracils **1** in 19 and 47% yields, respectively (Runs 7 and 8). The ozonization of 4-thiouracil (**5**) gave only uracil (**1a**) in a 41% yield (Run 9). In the case of insoluble



Scheme 1.

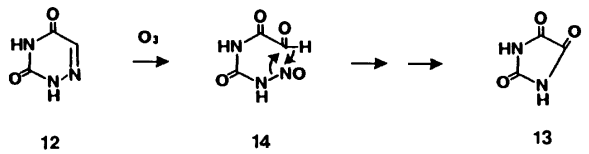
a) Ozonization was carried out with an ozone-oxygen mixture (O_3: 0.22 mmol min^{-1}, O_2: 200 ml min^{-1}) on 2 mmol of substrate in 100 ml of acetic acid at room temperature. b) 2,4-Dithiouracil (**6**) is insoluble in acetic acid under the conditions.



12 14 13

Scheme 2.

2,4-dithiouracil (**6**) in acetic acid, the reaction gave small amounts of uracil (**1a**) and 4(3*H*)-pyrimidinone (**4a**) (Run 10).

A proposed path for the formation of uracils **1** and 4(3*H*)-pyrimidinones **4** is shown in Scheme 1. It is clear that ozone preferentially attacks the thiocarbonyl moiety of 2-thiouracils **3** rather than the olefinic 5-6 bond. 2-Thiouracils **3** can be in equilibrium with the thiol form **3'** in solution. It has been reported that the thione form **3** is predominant under acidic conditions.[21] Besides the ozonization of 2-methylthio-4(3*H*)-pyrimidinone (**7**), which exists in thiol form, was complicated and gave neither uracil nor 4(3*H*)-pyrimidinone. Therefore, it is concluded that ozone reacts with the thione form **3**. In the ozonization of thiocarbonyl moiety, both 1,3-dipolar cycloaddition and electrophilic attack of ozone have been proposed.[1] In the cases of 1-unsubstituted 2-thiouracils **3a—e**, the former to give uracils **1a—e** competes with the latter to afford 4(3*H*)-pyrimidinones **4a—e**. 1,3-Dipolar cycloaddition of ozone to the C=S moiety gives the ozone-adduct **8** followed by the elimination of sulfur dioxide to give uracils **1** (path A). Electrophilic ozone attack on the S-atom gives the ozone-adduct **9** followed by deoxygenation to give sulfine **10**, which is in equilibrium with sulfenic acid **10'** (path B). This intermediate **10'** is further oxidized to give sulfonic acid **11**. Since a small amount of water is contained in the solvent, the sulfonic acid **11** is desulfurized to give 4(3*H*)-pyrimidinones **4a—e**. After the ozonization of 2-thiouracil (**3a**), the pH value of the solution was 1.5 and a sulfate ion was detected by the barium chromate-diphenylcarbonohydrazide method.[22] In the cases of 1-substituted 2-thiouracils **3f,g**, uracils **1f,g** are preferentially obtained via path A, because no equilibrium between sulfine **10** and sulfenic acid **10'** exists and the sulfines **10f,g** are further ozonized to give unidentified products. In the case of **3f**, 1-methyl-4(1*H*)-pyrimidinone was not detected.

5-Azauracil (**11**) was very stable for ozone under the same conditions, while 6-azauracil (**12**) readily reacted with ozone to give parabanic acid (**13**) in a 34% yield. Similarly, 5-azacytosine was stable for ozone, while 6-azacytosine readily reacted with ozone to give unidentified several compounds in low yields. A mechanism for the ozonization of 6-azauracil (**12**) is proposed in Scheme 2. The reaction of C=N bond with ozone gives the corresponding carbonyl and nitroso compounds.[23] The ozonization of 5-6 bond of 6-azauracil (**12**) may give the intermediate **14**, followed by the elimination of HNO (or HNO_2) to give parabanic acid (**13**). Nitrite and/or nitrate ions were detected by a sulfuric acid–iron(II) sulfate method.[24]

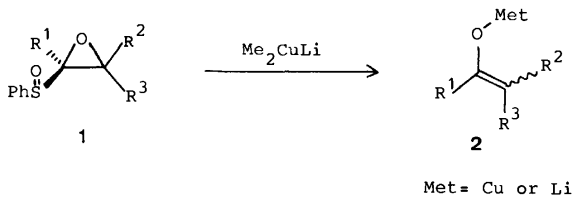
(Received March 17, 1989)

Enolates were generated from α,β-epoxy sulfoxides using lithium dimethylcuprate as an electron-transfer reagent. The enolates were trapped with several electrophiles, in which aldehydes reacted with the generated enolates giving aldols in good yields with high regioselectivity.

Enolates are the most fundamental intermediates in the chemistry of carbon–carbon bond formation. Such famous reactions as acetoacetic ester synthesis, aldol condensation, Claisen reaction, Dieckman condensation, Perkin reaction, and Robinson annulation are known to take place through enolates.[2)] Usually, enolates are generated from carbonyl compounds with strong bases, such as sodium hydride, metal alkoxides, or lithium diisopropylamide (LDA). In modern organic syntheses some other methods for the generation of metal enolates have been reported.[3)]

We recently reported novel synthetic methods from 1-chloroalkyl aryl sulfoxides and carbonyl compounds through α,β-epoxy sulfoxides **1**.[4)] In a study it was found that the β-position of **1** shows quite a high reactivity to various kinds of nucleophiles. In a search for another nucleophiles we found that lithium dialkylcuprates reacts with α,β-epoxy sulfoxides **1** to give enolates **2** (Scheme 1).



Scheme 1.

In this paper we report on details concerning a novel method for the generation of enolates **2** from **1** with lithium dimethylcuprate (Me_2CuLi) and the synthesis of aldols from **1**.[5)] We also refer to some trials to trap the generated enolates with *t*-butyldimethylsilyl chloride, acetyl chloride, and ethyl chloroformate.

Results and Discussion

The nucleophilic ring-opening of oxiranes by organocopper reagents is a very useful method for carbon–carbon bond formation.[6)] In some cases, however, the reaction of oxiranes with organocopper reagents shows a somewhat different aspect due to the electron-transferable nature of the reagents.[7)] For instance, Tamao et al. recently reported the deoxygenation of α,β-epoxy silanes with Grignard reagents catalyzed by copper giving vinylsilanes.[8)] This reaction was thought to proceed through a one-electron transfer from an organocopper reagent.

The treatment of α,β-epoxy sulfoxide **3**,[9)] which was synthesized from 1-chlorobutyl phenyl sulfoxide and benzaldehyde, was carried out with two equivalents of Me_2CuLi in ether at 0 °C for 3 h. The reaction was quenched with aqueous NH_4Cl to give 1-phenyl-2-pentanone **4** in 77% yield as the sole product. Interestingly, no methylated product was obtained. Among the alkylcopper reagents studied (Me_2CuLi, Bu_2CuLi, $Bu_2CuCNLi$, $Et_2CuMgBr$) Me_2CuLi was found to be the most useful. As a copper source,

6	**8**	ClCOOEt (5)	0°C, 1 h	 **13**	81

a) All reactions were carried out with three equivalents of Me_2CuLi in dry ether at 0°C then quenched with electrophile. b) Isolated yield after silica-gel column chromatography.

copper(I) bromide–dimethyl sulfide complex (CuBr·SMe_2)[10] was found to be the most effective. We thought that this reaction took place through an enolate. Indeed, by quenching the reaction with benzaldehyde instead of water, a mixture of aldols (**5** and **6**; **5**:**6**=1:4) was obtained in 41% yield (Scheme 2).[11]

In order to obtain further proof of the enolates, the reaction was carried out with other electrophiles using **7** and **8** as the α,β-epoxy sulfoxides. The reason for using **7** and **8** was to clarify the reactivity and regioselectivity of the generated enolates (Table 1).

Quenchig the enolates generated from **7** and **8** with chlorotrimethylsilane gave a mixture of silyl enol ethers; however their isolation was found to be difficult. With *t*-butyldimethylsilyl chloride, both enolates derived from **7** and **8** selectively gave a stereoisomeric mixture of silyl enol ether **9** in good yield, though the reaction was found to have no regiospecificity (Entries 1 and 2). The reaction of the enolates with acetyl chloride was somewhat interesting: it gave diacylated products (**10** and **11**) with high regioselectivity, though yields were not satisfactory (Entries 3 and 4). The reaction of the enolates with ethyl chloroformate regioselectively gave the enol carbonates (**12** and **13**) in moderate to good yields (Entries 5 and 6).

With some results of trapping the enolates with electrophiles in hand, our attention was again focused

10			H	—	—	2 h[c]	—[h]		—

a) All reactions were carried out in ether at 0°C. Unless otherwise noted, 3 equivalents of Me_2CuLi were used. b) Isolated yield. c) 4 equivalents of Me_2CuLi were used. d) 5 equivalents of Me_2CuLi were used. e) Threo/erythro=2/1. f) This reaction gave **20** with 1-phenyl-2-nonanone (39%). g) This reaction did not give aldol but 3-methyl-1-phenyl-2-butanone[4a] in 68% yield. h) The α,β-epoxy sulfoxide did not react with Me_2CuLi.

on the result with the carbonyl compound described above. As shown in Scheme 2, quenching the enolate obtained from **3** with benzaldehyde gave aldols **5** and **6** without regioselectivity. We thought that it is possible to obtain aldols with high regioselectivity if the reaction is carried out with some additives. House demonstrated that zinc chloride is quite useful as an additive for controling the aldol condensation.[12]

α,β-Epoxy sulfoxide **3** was treated with three equivalents of Me_2CuLi in ether at 0 °C for 40 min. After all of the starting materials disappeared, two equivalents of $ZnCl_2$ in ether[12a] followed by benzaldehyde were added to the reaction mixture. The desired aldol reaction took place quite smoothly to give **5** in 74% yield (Scheme 3). The stereochemical assignment of **5** was made by an examination of the vicinal coupling constant in the ^1H NMR. The coupling constant (J=9 Hz) of the proton at the carbon bearing a hydroxyl group clearly indicated that **5** was threo diastereomer.[12b,13] Though a trace amount of the erythro isomer was observed on ^1H NMR, this reaction was found to take place with complete regioselectivity. The representative examples of the synthesis of aldols from α,β-epoxy sulfoxides with Me_2CuLi and carbonyl compounds are listed in Table 2.

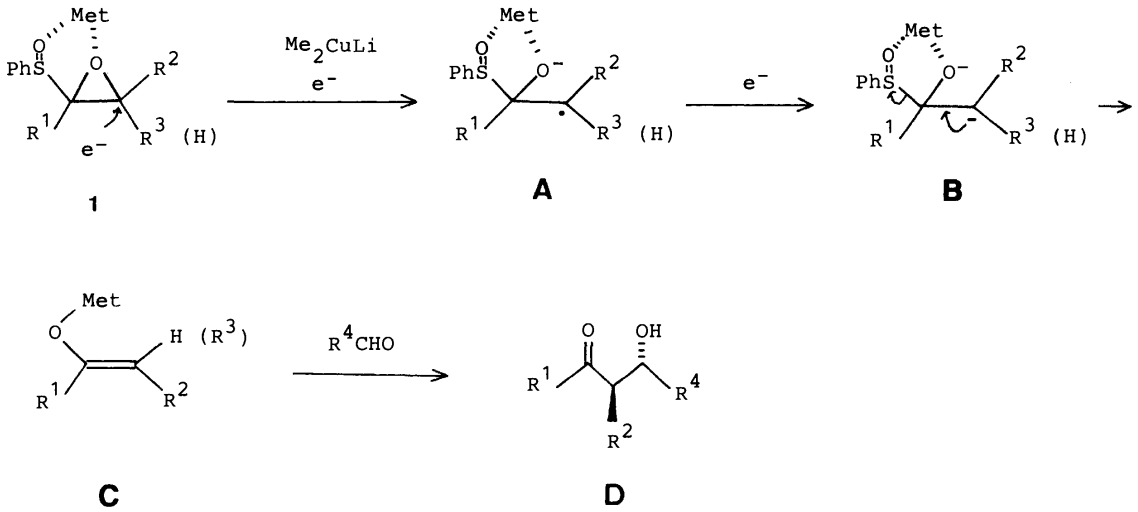
The important characteristics of the results shown in Table 2 are as follows: 1) The α,β-epoxy sulfoxides having a hydrogen at the β-carbon (R^3=H; they were synthesized from aldehydes) reacted smoothly with Me_2CuLi to give enolates in high yields, except Entry 10. 2) The α,β-epoxy sulfoxides having a branch at C-1 of R^1 showed quite a low reactivity with Me_2CuLi (Entry 10). 3) The α,β-epoxy sulfoxides having a phenyl group at the β-carbon showed a much higher reactivity with Me_2CuLi than other α,β-epoxy sulfoxides (Entries 6—8). 4) β-Disubstituted α,β-epoxy sulfoxide reacted very sluggishly with Me_2CuLi, giving enolate; however, the reaction of this enolate with benzaldehyde gave a complex mixture (Entry 9). 5) *threo*-Aldols were obtained exclusively or predominantly. 6) Acetone gave aldol in low yield (Entry 7). 7) In Entries 3, 8 and 4, 6, regioisomers of aldols (**16**, **5** and **17**, **19**, respectively) were synthesized in pure form; these results mean that these reactions are a kind of the directed aldol reaction.[3]

The possible mechanism of these reactions can be proposed as follows (Scheme 4). One electron transfer from Me_2CuLi to the α,β-epoxy sulfoxide **1** gives an anion radical intermediate **A**, which receives a second electron from Me_2CuLi to give a dianion intermediate **B**. Then elimination of the phenylsulfinyl group takes place to afford an enolate **C**. The enolate is trapped with electrophiles to give the product described in this paper. The stereochemistry of **C** in the aldol reaction is worth noting. Both isomers of the α,β-epoxy sulfoxides equally react with Me_2CuLi followed by aldehydes to afford *threo*-aldols. From these selectivities of the reaction, it can be presumed that the stereochemistry of the enolates is *E*, as shown in Scheme 4.[14]

Even though the reaction gave aldols with some limitation, we believe that the present method will prove to be valuable in the synthesis of aliphatic aldols with high regioselectivity.

Experimental

All melting points are uncorrected. The IR spectra were measured directly on a NaCl plate or KBr disks with a Hitachi 215 spectrometer. ^1H NMR spectra were measured in a $CDCl_3$ solution with a JEOL FX-100 spectrometer or Hitachi R-24B spectrometer using Me_4Si as an internal standard. Electron-impact mass spectra (MS) were obtained on a Hitachi M-80 double-focusing spectrometer at 70 eV by direct insertion. Silica gel BW-127 ZH (Fuji-Devison) containing a 2% fluoresence reagent (254) and a quartz column were used for column chromatography; products showing ultraviolet (UV) absorption were detected by UV



Scheme 4.

irradiation. Ether and THF were dried with benzophenone ketyl and distilled.

α,β-Epoxy Sulfoxides. All α,β-epoxy sulfoxides, except for **8** and the α,β-epoxy sulfoxide in Table 2 (Entry 3), were reported previously.[4,9] Two new α,β-epoxy sulfoxides were prepared from the aldehydes and 1-chloro-2-phenylethyl phenyl sulfoxide through chlorohydrins in the usual way.[4]

2,3-Epoxy-1-phenyl-2-phenylsulfinylpentane (Entry 3 in Table 2). *Z*-Isomer: Colorless semisolid, 44% overall yield. IR (neat): 1080 and 1050 (SO) cm^{-1}; ^1H NMR δ=1.10 (3H, t, *J*=6 Hz), 1.99 (2H, m), 2.52 (1H, d, *J*=15 Hz), 2.62 (1H, t, *J*=6 Hz), 3.55 (1H, d, *J*=15 Hz), and 6.8—7.9 (10H, m); MS *m/z* (%) 286 (M^+, 0.5), 161 (9), 126 (13), and 91 (100); Found: *m/z* 286.1023. Calcd for $C_{17}H_{18}O_2S$: M, 286.1026. *E*-Isomer: Colorless oil, 40% overall yield. IR (neat): 1080 and 1050 (SO) cm^{-1}; ^1H NMR δ=1.00 (3H, t, *J*=6 Hz), 1.58 (2H, m), 3.02 (2H, s), 3.68 (1H, t, *J*=6 Hz), and 6.8—7.9 (10H, m); MS *m/z* (%) 286 (M^+, 0.3), 161 (10), 126 (14), and 91 (100); Found: *m/z* 286.1017. Calcd for $C_{17}H_{18}O_2S$: M, 286.1025.

2,3-Epoxy-1-phenyl-2-phenylsulfinylnonane (8). *Z*-Isomer: Colorless oil, 43% overall yield. IR (neat): 1080 and 1050 (SO) cm^{-1}; ^1H NMR δ=0.90 (3H, t, *J*=6 Hz), 1.0—2.2 (10H, m), 2.53 (1H, d, *J*=15 Hz), 2.65 (1H, t, *J*=6 Hz), 3.58 (1H, d, *J*=15 Hz), and 6.7—7.9 (10H, m); MS *m/z* (%) 342 (M^+, trace), 217 (9), 126 (12), and 91 (100); Found: *m/z* 342.1655. Calcd for $C_{21}H_{26}O_2S$: M, 342.1653. *E*-Isomer: Colorless oil, 41% overall yield. IR (neat): 1080 and 1050 (SO) cm^{-1}; ^1H NMR δ=0.88 (3H, t, *J*=6 Hz), 1.0—1.7(10H, m), 3.04 (2H, s), 3.70 (1H, t, *J*=6 Hz), and 7.0—7.8 (10H, m); MS *m/z* (%) 342 (M^+, trace), 217 (9), 126 (11), and 91 (100); Found: *m/z* 342.1662. Calcd for $C_{21}H_{26}O_2S$: 342.1652.

1-Phenyl-2-pentanone (4). A solution of **3** (90 mg; 0.28 mmol) in 1 ml of dry ether was added to a solution of Me_2CuLi (0.56 mmol; prepared from MeLi and $CuBr \cdot SMe_2$ in ether at 0 °C) in ether (3 ml) at 0 °C under N_2. The reaction mixture was stirred at 0 °C for 3 h; the reaction was then quenched with sat. aq. NH_4Cl. The solution was extracted with ether and the organic layer was washed with sat. aq. NH_4Cl. The usual work-up followed by silica-gel column chromatography afforded 35 mg (77%) of **4** as a colorless oil. IR (neat): 1710 (CO) cm^{-1}; ^1H NMR δ=0.96 (3H, t, *J*=7 Hz), 1.58 (2H, m), 2.41 (2H, t, *J*=7 Hz), 3.66 (2H, s), and 7.0—7.4 (5H, m); MS *m/z* (%) 162 (M^+, 18), 91 (48), and 71 (100); Found: *m/z* 163.1062. Calcd for $C_{11}H_{14}O$: M, 163.1076.

2-(*t*-Butyldimethylsiloxy)-1-phenyl-1-nonene (9). A solution of **7** (69 mg; 0.2mmol) in 1 ml of dry ether was added to a solution of Me_2CuLi (0.6 mmol) in 1.5 ml of ether at 0 °C under N_2. The reaction mixture was stirred at 0 °C for 40 min. To the reaction mixture was added a solution of Et_3N (1 mmol) in 4 ml of dry THF followed by a solution of *t*-butyldimethylsilyl chloride (1 mmol) and HMPA (1 mmol) in 2 ml of THF. The solution was stirred at room temperature for 9 h. The reaction was quenched with H_2O and the whole was extracted with ether. The usual work-up followed by silica-gel column chromatography gave 60 mg (90%) of **9** (a mixture of *E/Z*=1/2) as a colorless oil. IR (neat): 1650 and 1255 cm^{-1}; ^1H NMR δ=−0.04, 0.00 (each 3H, s), 0.81 (9H, s), 0.7—1.0 (3H, m), 1.0—1.6 (12H, m), 2.08 (t, *J*=7 Hz, *E*-isomer), 2.32 (t, *J*=7 Hz, *Z*-isomer), 5.31 (s, vinyl-H, *Z*-isomer), 5.64 (s, vinyl-H, *E*-isomer), and 7.0—7.5 (5H, m); MS *m/z* (%) 332 (M^+, 25), 275 ($[M-C_4H_9]^+$, 100), and 191 (18); Found: *m/z* 332.2530. Calcd for $C_{21}H_{36}OSi$: M, 332.2527.

α,β-Epoxy sulfoxide **8** gave the same product on treatment with Me_2CuLi followed by *t*-butyldimethylsilyl chloride.

2-Acetoxy-3-phenyl-2-undecen-4-one (10). A solution of **7** (103 mg; 0.3 mmol) in 1 ml of ether was added to a solution of Me_2CuLi (0.9 mmol) in 2 ml of ether at 0 °C under N_2. The reaction mixture was stirred at 0 °C for 30 min. To this reaction mixture was added acetyl chloride (3 mmol); the mixture was first stirred at 0 °C for 1.5 h and then at room temperature for 1 h. The reaction was quenched with 1% aq. ammonia and the whole was extracted with ether. The usual work-up followed by silica-gel column chromatography afforded 48 mg (53%) of **10** as a colorless oil. Single isomer; *E/Z* not determined. IR (neat): 1770 and 1700 (CO) cm^{-1}; ^1H NMR δ=0.85 (3H, t, *J*=6 Hz), 1.0—1.6 (10H, m), 1.92 (3H, s), 2.19 (2H, m), 2.21 (3H, s), and 7.1—7.5 (5H, m); MS *m/z* (%): 302 (M^+, 6), 260 ($[M-C_2H_2O]^+$, 19), 242 (20), 176 (71), 161 (92), and 43 (100); Found: *m/z* 302.1880. Calcd for $C_{19}H_{26}O_3$: M, 302.1880.

2-Acetoxy-3-hexyl-5-phenyl-2-penten-4-one (11). A similar treatment of **8** with Me_2CuLi followed by acetyl chloride gave **11** as a *E/Z*-mixture (1:1) in 30% yield. Colorless oil; IR (neat): 1760 and 1690 (CO) cm^{-1}; ^1H NMR δ=0.86 (3H, t, *J*=6 Hz), 1.0—1.6 (8H, m), 1.8—2.5 (8H, m), 3.76, 3.83 (each bs, 2H, $PhC\underline{H_2}CO$-), and 7.0—7.4 (5H, m); MS *m/z* (%) 302 (M^+, 1), 260 ($[M-C_2H_2O]^+$, 2), 211 ($[M-PhCH_2]^+$, 16), and 169 (100); Found: *m/z* 302.1904. Calcd for $C_{19}H_{26}O_3$: M, 302.1881.

2-Ethoxycarbonyloxy-1-phenylnonene (12). A solution of **7** (69 mg; 0.2 mmol) in 1 ml of ether was added to a solution of Me_2CuLi (0.6 mmol) in 1.5 ml of ether at 0 °C under N_2. The reaction mixture was stirred at 0 °C for 30 min; then ethyl chloroformate (1 mmol) was added. The reaction mixture was stirred at 0 °C for 1.5 h; then the reaction was quenched with 1% aq. ammonia. The usual work-up followed by silica-gel column chromatography gave 30 mg (50%) of **12** (a mixture of *E/Z*; *E/Z*=2/1) as a colorles oil. IR (neat): 1765 (CO) and 1240 (COC) cm^{-1}; ^1H NMR δ=0.85 (3H, m, CH_3), 1.0—1.7 (13H, m), 2.28—2.60 (2H, m, $C=CC\underline{H_2}$), 4.0—4.2 (2H, m, $OC\underline{H_2}CH_3$), 5.90 (s, vinyl-H; Z), 6.33 (s, vinyl-H, E), and 7.0—7.5 (5H, m); MS *m/z* (%) 290 (M^+, 11), 218 ($[M-C_3H_4O_2]^+$, 21), 199 (15), 134 (43), and 91 (100); Found: *m/z* 290.1895. Calcd for $C_{18}H_{26}O_3$: M, 290.1881.

2-Ethoxycarbonyloxy-1-phenyl-2-nonene (13). A similar treatment of **8** with Me_2CuLi followed by ethyl chloroformate gave **13** as a *E/Z*-mixture (*E/Z*=3/2) in 81% yield. Colorless oil; IR (neat): 1760 (CO) and 1250 (COC) cm^{-1}; ^1H NMR δ=0.86 (3H, m, CH_3), 1.0—1.6 (11H, m), 1.6—2.1 (2H, m), 3.52 (3/5H, s, $PhC\underline{H_2}$), 3.85 (2/5H, s, $PhC\underline{H_2}$), 4.0—4.4 ($OC\underline{H_2}$–, and vinyl-H (*Z*), m), 4.95 (3/5H, t, *J*=7 Hz, vinyl-H (*E*)), and 7.0—7.6 (5H, m); MS *m/z* (%) 290 (M^+, 2), 207 (34), and 91 (100); Found: *m/z* 290.1893. Calcd for $C_{18}H_{26}O_3$: M, 290.1881.

General Procedure for the Preparation of Aldols from α,β-Epoxy Sulfoxides with Me_2CuLi Followed by Carbonyl Compounds: The synthesis of (1*R**,2*S**)-1-hydroxy-1,2-diphenyl-3-hexanone **5** from **3** is described. A solution of **3** (97 mg; 0.3 mmol) in 1 ml of ether was added to a solution of Me_2CuLi (0.9 mmol) in 2 ml of ether at 0 °C under N_2. The solution was stirred at 0 °C for 40 min. To this reaction

mixture was added a solution of $ZnCl_2$ in ether (0.6 mmol) followed by benzaldehyde (0.33 mmol). The reaction mixture was stirred for 10 min; then the reaction was quenched with sat. aq. NH_4Cl. The solution was extracted with ether-benzene. The usual work-up followd by column chromatography gave 67 mg (74%) of **5** as colorless needles. Mp 48.5—50.5 °C (AcOEt-hexane); IR (KBr): 3400 (OH) and 1705 (CO) cm^{-1}; ^1H NMR δ=0.81 (3H, t, J=7 Hz), 1.56 (2H, sextet, J=7 Hz), 2.37 (2H, t, J=7 Hz), 3.93 (1H, d, J=9 Hz), 5.18 (1H, d, J=9 Hz), and 6.7—7.3 (10H, m); MS m/z (%) 250 ($[M-H_2O]^+$, 0.8), 207 (0.5), 162 (28), and 70 (100); Found: C, 80.62; H, 7.51%. Calcd for $C_{18}H_{20}O_2$: C, 80.56; H, 7.51%.

4-Hydroxy-3-methyl-1,4-diphenyl-2-butanone (14). A threo/erythro (2/1) mixture; colorless oil; 80% yield. IR (neat): 3450 (OH) and 1720 (CO) cm^{-1}; ^1H NMR δ=0.88 (d, J=7 Hz threo), 1.07 (d, J=7 Hz, erythro), 2.8—3.2 (1H, m), 3.58 (s, PhC$\underline{H}_2$, erythro), 3.74 (s, PhC$\underline{H}_2$, threo), 4.69 (bd, J=9 Hz, threo), 4.90 (d, J=5 Hz, erythro), and 6.9—7.4 (10H, m); MS m/z (%): 254 (M^+, 4), 180 (6), 163 ($[M-PhCH_2]^+$, 17), 148 (44), and 107 (100); Found: m/z 254.1302. Calcd for $C_{17}H_{18}O_2$: M, 254.1305.

4-Hydroxy-3-methyl-1-phenyl-2-hexanone (15). A threo/erythro (2/1) mixture; colorless oil; 79% yield. IR (neat): 3475 (OH) and 1715 (CO) cm^{-1}; ^1H NMR δ=0.90 (3H, t, J=7 Hz), 1.12 (d, J=7 Hz, erythro), 1.13 (d, J=7 Hz, threo), 1.2—1.7 (2H, m), 2.5—2.9 (1H, m), 3.4—3.8 (1H, m), 3.77 (2H, s), and 7.0—7.4 (5H, m); MS m/z (%) 206 (M^+, 10), 148 ($[M-C_3H_6O]^+$, 13), 115 (72), and 91 (100); Found: m/z 206.1311. Calcd for $C_{13}H_{18}O_2$: M, 206.1305.

(3*R,4*S**)-3-Ethyl-4-hydroxy-1,4-diphenyl-2-butanone (16).** Colorless crystals; 53% yield; mp 59—60.5 °C (AcOEt-hexane). IR (KBr): 3405 (OH) and 1720 (CO) cm^{-1}; ^1H NMR δ=0.73 (3H, t, J=7 Hz), 1.1—1.8 (2H, m), 2.8—3.1 (1H, m), 3.63 (2H, s), 4.77 (1H, d, J=7 Hz), and 6.9—7.4 (10H, m); MS m/z (%) 268 (M^+, 2), 239 ($[M-C_2H_5]^+$, 1), 177 (22), 162 (25), and 91 (100); Found: C, 80.38; H, 7.51%. Calcd for $C_{18}H_{20}O_2$: C, 80.56; H, 7.51%.

A High Cis-Stereoselectivity in the Hydrogenation of 6-*t*-Butyltetrahydropyran-3-one and 2-*t*-Butyl-1,3-dioxan-5-one

Yasuhisa SENDA,*,† Toshiyuki TERASAWA, Jun-ichi ISHIYAMA, Shin-ichi KAMIYAMA, and Shin IMAIZUMI
Department of Engineering Science, Faculty of Engineering, Tohoku University, Aoba, Sendai 980
(Received April 20, 1989)

Stereochemistry in the hydrogenation of 4-*t*-butylcyclohexanone and the corresponding oxa- and dioxacyclohexanone was examined. A high cis selectivity was observed in the latter two compounds regardless of the catalyst metals used here. These results were explained in terms of intramolecular n_O–π_{CO} interaction, which was supported by ^{13}C NMR chemical shifts of the carbonyl carbons and CNDO/2 calculation.

The stereochemistry of hydrogenation of an unsaturated bond is frequently controlled by a heteroatom in a molecule. For instance, in allylic alcohols and ethers, hydrogens come into the unsaturated bond from the same side as the oxygen atom of the hydroxyl or the alkoxyl group. This is attributed to an interaction of the oxygen atom through the lone pair with the catalyst surface. This is called as the "directing effect" or "anchor effect".[1] However, in some cases, this effect does not necessarily appear. For methylene-1,3-dioxanes in which oxygen atoms and the double bond are placed at an appropriate position, the stereochemistry of the hydrogenation is such that the hydrogens add from the side opposite to the oxygen lone pair. This is interpreted in terms of intramolecular interaction between the nonbonding orbital of the oxygen and the olefinic π-orbital.[2]

In this paper, in order to investigate how the effect of an oxygen atom appears in the hydrogenation of cyclic ketones, 6-*t*-butyltetrahydropyran-3-one (**1**) and 2-*t*-butyl-1,3-dioxan-5-one (**2**) were hydrogenated in ethanol over several Group VIII transition metal catalysts and the stereochemistry was compared with that of 4-*t*-butylcyclohexanone (**3**). The results of the hydrogenation are tabulated in Table 1.

In the hydrogenation of **1** and **3**, Pd and Rh black catalysts behaved somewhat differently from other metal catalysts used in the present study. The main products of hydrogenation from **3** were saturated alcohol on Rh catalyst (Fig. 2) and saturated ether on Pd catalyst (Fig. 3) similar as the results obtained by Nishimura et al.[3] On the contrary, the saturated alcohol was the main products of hydrogenation from **1** on Pd catalyst under the same reaction conditions (Fig. 1).

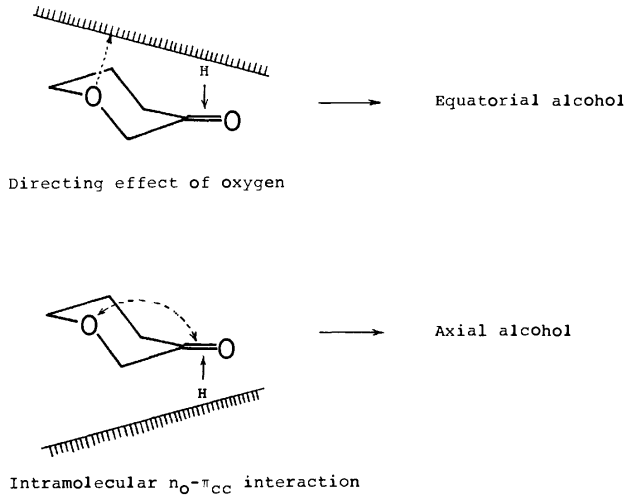
The stereochemistry of the hydrogenation of **3** over Group VIII transition metal black catalysts has been investigated in detail and was interpreted in terms of the Horiuti-Polanyi mechanism which is one of the most satisfactory theories.[4] The change in the product-controlling step depending on the catalysts coincides with a change in the ratio of the product. The Horiuti-Polanyi formulation of the mechanism of hydrogenation of unsaturated bonds may be represented by four elementary reactions, dissociation of hydrogen, adsorption of the substrate on the catalyst, first hydrogen transfer to the adsorbed species,



Scheme 1.

and second hydrogen transfer to the half-hydrogenated intermediate. The proportion of the stereoisomeric products will depend upon which of the elementary reactions is a product controlling step, because the geometry and/or composition of the several possible transition states differ from one another. When the product controlling step is the adsorption of the substrate on the catalyst or the first hydrogen transfer from the catalyst to the adsorbed species, the stereochemistry of the reaction is controlled by the interaction between the substrate and the catalyst. On the other hand, when the product controlling step is the second hydrogen transfer from the catalyst to the half-hydrogenated species, the stereochemistry is controlled by the relative stabilities of the two epimeric half-hydrogenated species.

The hydrogenation of **3** gave an excess cis product (55—77%) except in the case of Pt black on which the more stable one of the two possible products was predominant. This indicates that the stereochemistry is controlled by the steric interaction between the substrate and the catalysts other than Pt black catalysts.[5] Significantly high cis stereoselectivity was observed in the hydrogenation of **1** and **2** which contain the oxygen atom/atoms in the β-position with respect to the carbonyl carbon. Since geometries of the 1,3-dioxane and the tetrahydropyran skeleton are similar to the cyclohexane ring, formation of the trans products (equatorial alcohol) is expected by the introduction of the oxygen atom/atoms (Scheme 1).[1] The reaction, however, proceeded selectively to give cis saturated products. Such a high cis selectivity in the oxygen-containing substrates has been found in the hydrogenation of 2-*t*-butyl-5-methylene-1,3-dioxane and 2-*t*-butyl-5-methylenetetrahydropyran.[2]

In order to obtain information on the structure of these molecules, the substrates were subjected to ^{13}C NMR spectroscopy. The chemical shifts were tabulated in Table 2. The chemical shifts of the

	−10.0

The chemical shifts were taken from a) J. B. Stothers, "Carbon-13 NMR Spectroscopy," Academic Press Inc., New York (1972). b) Ref. 2.

carbonyl carbons were compared with those of the carbo-cyclic carbonyl compounds. When the oxygen atom/atoms were introduced in the cyclohexane ring, the shift effect of the oxygen on the β carbon was found to be −1.1 ppm for tetrahydropyran and −1.0 for 1,3-dioxane. Much larger high field shifts of carbonyl carbons which are β to the oxygen atom were practically observed in **1** and **2** (−3.4 ppm for **1** and −7.3 ppm for **2**, respectively) as shown in Table 3. Experimentally it has been found that the effects of substituents on ^{13}C chemical shifts are largely additive. Such high field shifts of the carbonyl carbons in an unsaturated system compared to a saturated one by the introduction of an oxygen atom/atoms indicate electron delocalization of π-electrons similar to those with 2-*t*-butyl-5-methylene-1,3-dioxane[2] and 2-*t*-butyl-5-methylenetetrahydropyran (Table 3). This implies an interaction between the oxygen lone pair and the carbon–oxygen double bond.

The semi-empirical calculations of **1**, **2**, and **3** were performed to compare the electron density of the carbonyl group by the CNDO/2 method which was successful in predicting the electron density of the double bond. Total and π-electron densities of the carbonyl group in each of the most stable chair conformations were obtained and the difference in electron densities can be calculated between compounds containing oxygen and the corresponding cyclohexanone. The δD_T (difference in the total electron density) values for carbonyl carbon are +0.0211 for **1** and +0.0425 for **2**, and for carbonyl oxygen are −0.0157 for **1** and −0.0301 for **2** compared to **3**. The δD_π (difference in the π-electron density) values for carbonyl carbon are +0.0103 for **1** and +0.0193 for **2**, and for carbonyl oxygen are −0.0203 for **1** and −0.0375 for **2** compared to **3** (Table 4). A good correlation was found between the δD values of the electron density and the $\Delta\delta$ values of the ^{13}C NMR chemical shifts. The carbonyl carbon resonances moved to a higher field with an increase in the electron density. Such calculations also support the presence of intramolecular orbital interaction between the oxygen atom and the unsaturated bond.

A high cis (axial alcohol) selectivity observed in the hydrogenation of **1** and **2** implies significant control exerted by the oxygen participation on the transition state of the adsorption of the substrate. The non-bonded electrons of the oxygen can stabilize any incipient charge which might result from a π-donation of an unsaturated carbon–oxygen bond on the metal surface. The enhanced effective electronegativity of the oxygen, therefore, induces the back-donation from the metal surface to the π^*-orbital of the carbonyl.

Table 4. Total and π-Electron Densities (D_T, D_π) of Carbonyl Group in 6-*t*-Butyltetrahydropyran-3-one (**1**), 2-*t*-Butyl-1,3-dioxan-5-one, and 4-*t*-Butylcyclohexanone (**3**) by CNDO/2 Calculation

		C=O				C=*O*

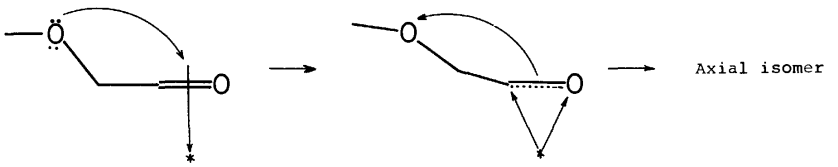
	D_π	0.8185			D_π	1.2538		



Scheme 2.

This results in a predominant adsorption from the equatorial side of the molecule (Schemes 1 and 2). Similarly, anchimeric assistance by long-range oxygen participation has also been found in the solvolytic reaction of 9-oxabicyclo[4.2.1]nonan-2-yl brosylates[6] and in some electrophilic reactions of 8-oxabicyclo-[4.3.0]non-3-enes.[7]

Chemical reduction with $LiAlH_4$ and $NaBH_4$ was also examined, and its stereochemistry made a sharp contrast with that of the hydrogenation (Table 1). Stereoselective formation of equatorial alcohols from **1** and **2** was consistent with the reduction of 2-phenyl-1,3-dioxan-5-one which was reported by Jochims et al.[8]

Experimental

6-*t*-Butyltetrahydropyran-3-one (1). The compound, **1** was prepared following two methods. (I) According to the method of Ancelmi et al.[9] by using trimethylacetaldehyde and 3-buten-1-ol as starting materials. (II) The hydroboration of 2-*t*-butyl-5,6-dihydro-4*H*-pyran which was prepared by the method of Anderson and Sepp[10] followed by the oxidation with pyridinium chlorochromate; bp 92—94 °C (12 mmHg; 1 mmHg≈133.322 Pa); ^{1}H NMR ($CDCl_3$) δ=0.95 (9H, s), 1.6—3.4 (5H, m), 3.95 (1H, bs), 4.05 (1H, bs). Found: C, 68.92; H, 10.37%. Calcd for $C_9H_{16}O_2$: C, 69.19; H, 10.32%.

2-*t*-Butyl-1,3-dioxan-5-one (2).[11] 2-*t*-Butyl-5-hydroxymethyl-5-nitro-1,3-dioxane[12] was converted to **2** by the hydrogenation of nitro group followed by sodium periodate oxidation.

Metal Black Catalyst. The metal black catalysts were prepared from the corresponding metal chloride or metal oxides by the methods reported in the literature.[13,14]

Catalytic Hydrogenation. The substrate (0.5 mmol) was stirred under hydrogen atmosphere in 3 ml ethanol at room temperature over a weighed catalyst. The reaction was followed gas chromatographically by analyzing aliquots of the reaction mixture at appropriate time intervals. The cis products from **1** and **2** over Rh catalyst were subjected to ^{13}C NMR analysis (the epimeric purity was 94 and 100%, respectively).

Metal Hydride Reduction. To a solution of 0.25 mmol of complex metal hydride in ether ($LiAlH_4$) or in 2-propanol ($NaBH_4$), ketone (1 mmol) was added at 0 °C. After the reaction mixture had been stirred for 30 min, water was added and the solution was subjected to gas chromatography. The trans products from **1** and **2** on $LiAlH_4$ reduction were subjected to ^{13}C NMR analysis (the epimeric purity was 92 and 93%, respectively).

NMR and Gas Chromatographic Analyses. ^{1}H NMR spectra were obtained with a JEOL JNM-MH-100 spectrometer and ^{13}C NMR spectra were obtained with a JEOL JNM-FX-60-Q spectrometer. Gas chromatographic analyses were performed with Hitachi 164 with a Goley column of PEG 4000 (45 m×0.25 mm for the products from **1** and **3**, and 30 m×0.25 mm for the products from **2**) at 130 °C.

A series of new trimethylsilyldiazenido complexes [MX(NNSiMe$_3$)(L)$_4$] (M=Mo: X=I; M=W: X=CF_3SO_3; L=PMe_2Ph or 1/2 dpe; dpe=$Ph_2PCH_2CH_2PPh_2$) and trimethylsilylhydrazido(2−) complexes [MX$_2$(NNHSiMe$_3$)-(PMe_2Ph)$_3$] (M=Mo: X=I or Br; M=W: X=CF_3SO_3) and [MX(NNHSiMe$_3$)(dpe)$_2$]X (M=Mo: X=I; M=W: X=CF_3SO_3) were prepared by treatment of dinitrogen complexes *cis*-[M(N$_2$)$_2$(PMe_2Ph)$_4$] or *trans*-[M(N$_2$)$_2$(dpe)$_2$] with Me$_3$SiX in benzene. The trimethylsilyl groups on the terminal nitrogen atoms were easily replaced by hydrogen by the reaction with MeOH or H_2O, affording, for example, diazenido and hydrazido(2−) complexes such as [WI(NNH)(dpe)$_2$] and [WI$_2$(NNH$_2$)(PMe_2Ph)$_3$] from [WI(NNSiMe$_3$)(dpe)$_2$] and *mer*-[WI$_2$(NNHSiMe$_3$)-(PMe_2Ph)$_3$], respectively. When reduced with excess Na in THF under N_2, complexes *trans*-[MI(NNSiMe$_3$)-(PMe_2Ph)$_4$] (M=Mo or W) and *mer*-[WI$_2$(NNHSiMe$_3$)(PMe_2Ph)$_3$] gave (Me$_3$Si)$_2$NH and NH_3 in substantial yields, accompanied by the regeneration of the parent dinitrogen complexes. Additional amount of NH_3 was obtained by the hydrolysis of the evaporated reaction mixture residue.

As the first demonstrated example of the Si–N bond formation from coordinated dinitrogen, we have recently reported the reaction of a series of tungsten dinitrogen complexes of the type [W(N$_2$)$_2$(L)$_4$] (L=tertiary phosphines) with Me$_3$SiI to give trimethylsilyldiazenido (NNSiMe$_3$) and trimethylsilylhydrazido(2−) (NNHSiMe$_3$) complexes, together with the X-ray structures of *trans*-[WI(NNSiMe$_3$)(PMe_2Ph)$_4$] (**1**) and *mer*-[WI$_2$(NNHSiMe$_3$)(PMe_2Ph)$_3$] (**2**).[2)] Here we wish

cis-[W(N$_2$)$_2$(PMe_2Ph)$_4$] (**5**) $\xrightarrow{Me_3SiI}$ *trans*-[WI(NNSiMe$_3$)(PMe_2Ph)$_4$] (**1**)

to report the results of the reaction of molybdenum dinitrogen complexes *cis*-[Mo(N$_2$)$_2$(PMe_2Ph)$_4$] (**3**) and *trans*-[Mo(N$_2$)$_2$(dpe)$_2$] (**4**, dpe=$Ph_2PCH_2CH_2PPh_2$) with Me$_3$SiI as well as the trimethylsilylation of tungsten dinitrogen complexes *cis*-[W(N$_2$)$_2$(PMe_2Ph)$_4$] (**5**) and *trans*-[W(N$_2$)$_2$(dpe)$_2$] (**6**) by using $CF_3SO_3SiMe_3$. Some properties and reactivities of trimethylsilylated dinitrogen complexes are also described.

Results and Discussion

Preparation of New Trimethylsilylated Dinitrogen Complexes. When treated with 1 equiv of Me$_3$SiI in benzene under rigorously dry conditions, complex **3** gave the trimethylsilyldiazenido complex *trans*-[MoI-(NNSiMe$_3$)(PMe_2Ph)$_4$](**7**) in moderate yield. Complex **3** is more reactive than its tungsten analogue **5**. Thus, the reaction proceeds smoothly even at room temperature, whereas complex **5** does react with Me$_3$SiI around 50 °C. In the case of complex **4**, the reaction is much slower than that of complex **3** under the same conditions and the reaction must be carried out at 50 °C by using 2 equiv of Me$_3$SiI to obtain [MoI-(NNSiMe$_3$)(dpe)$_2$]. As described in the preceding paper,[2)] removal of HI generated in situ by the reaction of Me$_3$SiI and adventitious moisture is necessary to isolate these trimethylsilyldiazenido complexes. On the other hand, if the freeze-pump-thaw cycles to remove HI are omitted, complexes **3** and **4** reacted with Me$_3$SiI (ca. 1.5 equiv for complex **3** and ca. 2 equiv for complex **4**) to give trimethylsilylhydrazido(2−) complexes *mer*-[MoI$_2$(NNHSiMe$_3$)(PMe_2Ph)$_3$](**8**) and [MoI-(NNHSiMe$_3$)(dpe)$_2$]I, respectively, although the isolated yields of these complexes were low. These

[Mo(N$_2$)$_2$(L)$_4$] (**3**: L = PMe_2Ph; **4**: L = 1/2dpe)
$\xrightarrow{Me_3SiI}$ [MoI(NNSiMe$_3$)(L)$_4$]
$\xrightarrow{Me_3SiI/HI}$ [MoI$_2$(NNHSiMe$_3$)(L)$_3$] (L = PMe_2Ph) or [MoI(NNHSiMe$_3$)(L)$_4$]I (L = 1/2dpe)

trimethylsilylated dinitrogen complexes of molybdenum are less stable than the corresponding tungsten complexes and decompose slowly at room temperature even when stored under an inert atmosphere in a solid state. The lower isolated yields of the molybdenum complexes than those of the tungsten analogues presumably result from the lower stability observed for the molybdenum complexes.

Spectroscopic data of the trimethylsilyldiazenido and trimethylsilylhydrazido(2−) complexes are shown in Table 1, which correspond well to those of tungsten complexes reported previously (Table 2). It is interesting to note that the trimethylsilyldiazenido complexes of molybdenum show ν(NN) bands at higher frequencies and ν(SiN) bands at lower frequencies than the corresponding tungsten analogues. According to the results of the X-ray analyses of complex **1** which demonstrate the linear W–N–N linkage and the unusually short Si–N bond length in the tri-

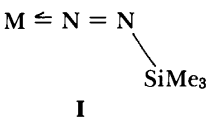
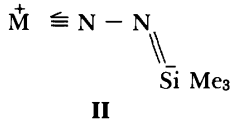
methylsilyldiazenido moiety, we previously proposed the presence of the contribution of structure **II** toward structure **I** considering the back donation from the metal.[2] The IR data described above indicate that the structure **II** contributes to a greater extent in the tungsten complexes than in the molybdenum analogues. This trend can be well explained by the stronger electron-donating ability of tungsten compared with molybdenum, which is commonly observed.



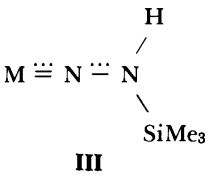
I



II

In contrast, trimethylsilylhydrazido(2−) complexes of molybdenum show ν(NN)[3] at lower frequencies in the IR spectra than those of the tungsten analogues. In this case also, the greater electron density is presumably donated into the π orbital(s) that spread(s) from the metal to the Si atom via the two nitrogen atoms for the tungsten complexes than the molybdenum analogues. However, this results in an increase of the N–N bond order in contrast to the above trimethylsilyldiazenido complexes. Thus, the structure of the trimethylsilylhydrazido(2−) ligand may best be described as **III**.

When treated with Me_3SiBr in place of Me_3SiI, complex **3** gave the corresponding trimethylsilylhydrazido-

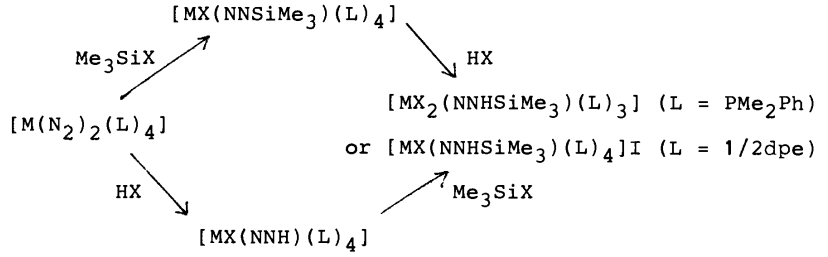


III

(2−) complex *mer*-[$MoBr_2(NNHSiMe_3)(PMe_2Ph)_3$] in low yield. However, no silylated complexes were obtained in the case of complex **5** under the same conditions. On the other hand, complex **5** can be readily converted into trimethylsilylhydrazido(2−) complex *mer*-[$W(CF_3SO_3)_2(NNHSiMe_3)(PMe_2Ph)_3$] by treatment with 3 equiv of $CF_3SO_3SiMe_3$. The reaction proceeded smoothly in benzene at room temperature. However, the trials to isolate the trimethylsilyldiazenido complex *trans*-[$W(CF_3SO_3)(NNSiMe_3)(PMe_2Ph)_4$] by using 1.5 equiv of $CF_3SO_3SiMe_3$ were not successful except for only one run. This is probably because the removal of CF_3SO_3H from $CF_3SO_3SiMe_3$ is very difficult compared to HI. As shown in Table 2, the IR and NMR data are consistent with the above structures. Treatment of complex **6** with 6 equiv of $CF_3SO_3SiMe_3$ at room temperature afforded a mixture of the trimethylsilyldiazenido complex [$W(CF_3SO_3)(NNSiMe_3)(dpe)_2$] and the trimethylsilylhydrazido(2−) complex [$W(CF_3SO_3)(NNHSiMe_3)(dpe)_2$][$CF_3SO_3$]. Appearance of two ν(NN) bands in the IR spectrum of the former complex probably results from the existence of two isomeric forms, for example cis and trans, in this complex. However, this compound is practically insoluble in common NMR solvents and further characterization of this complex was abandoned.

As described above, trimethylsilylhydrazido(2−) complexes can be isolated as the major products in the presence of HX (X=Br, I, CF_3SO_3) that is formed by the reaction of Me_3SiI or $CF_3SO_3SiMe_3$ with adventitious water. This is supported by the fact that when Me_3SiI (3 mol/W atom) in benzene was treated with MeOH (0.8 mol/W atom) first to generate HI in situ and then complex **5** was added to this mixture, the yield of complex **2** increased to 70%. Although this shows that the presence of HX is essential to form trimethylsilylhydrazido(2−) complexes, two reaction pathways are possible as shown below. The pathway which proceeds via [$MX(NNSiMe_3)(L)_4$] is supported by the fact that treatment of complex **1** with 1 equiv of HCl gas gave the trimethylsilylhydrazido(2−) complex [$WClI(NNHSiMe_3)(PMe_2Ph)_3$] which showed ν(NN) and ν(SiN) bands at 1334 and 845 cm^{-1} in its IR spectrum, respectively. On the other hand, the fact that an isolated diazenido complex [$WI(NNH)(dpe)_2$] reacted with Me_3SiI to give [$WI(NNHSiMe_3)(dpe)_2$]I in about 70% yield is indicative of the presence of the other pathway that includes the formation of diazenido complexes (MNNH) and the successive reaction with Me_3SiX. Thus both pathways are possible at present and the reaction course may depend upon the nature of the metals, the phosphines and the trimethylsilylating reagents. At least for the formation of complex **8**, the upper reaction pathway seems more plausible, since complex **7** was isolated as the major product from the reaction of complex **3** with Me_3SiI (2 mol/Mo atom) in the presence of 0.8 equiv of MeOH, whereas the formation of complex **8** was enhanced by the addition of 1.7 equiv of MeOH.

Reaction of Trimethylsilylated Dinitrogen Complexes with Water and Alcohols. As is well-known, trimethylsilyl group has a strong affinity with a fluoride anion and an oxygen atom. Thus, the reaction of complexes **1** and **2** with [n-Bu_4N]F were tried, but the purification of the products for full characterization was not successful. In contrast, treatment of complex **2** with about 4 equiv of water in benzene afforded the hydrazido(2−) complex *mer*-[$WI_2(NNH_2)(PMe_2Ph)_3$] (**9**) in 89% yield, as was expected. The similar reaction with a slightly excess of MeOH also resulted in the formation of complex **9** in 66% yield. Furthermore, the trimethylsilyldiazenido complex [$WI(NNSiMe_3)(dpe)_2$] reacted similarly with an almost stoichiometric amount of MeOH to give the diazenido complex [$WI(NNH)(dpe)_2$]. This is the only demonstrated method to derive diazenido complexes from dinitrogen complexes except for the reaction of hydrazido(2−) complexes with weak bases.[4] Diazenido complexes are regarded as an initial intermediate stage to reach ammonia and hydrazine from dinitrogen complexes. Although a series of diazenido complexes of type [$MX(NNH)(dpe)_2$] (M=W: X=F, Cl, Br; M=Mo: X=F, Br) are prepared by the reaction of the corresponding hydrazido(2−) complexes with weak bases, diazenido complexes with PMe_2Ph ligands



are not yet known. Therefore the reaction of complex **1** with water or MeOH was performed. However, the isolated product was only complex **9** (35% yield) for the former and *trans*-[WI(NNH_2)(PMe_2Ph)$_4$]I (15% yield) for the latter, respectively, and the formation of the diazenido complex [WI(NNH)(PMe_2Ph)$_4$] was not observed. It may be presumed that the diazenido complex initially formed was so unstable that it was converted into the hydrazido(2−) complex(es) by the disproportionation reaction. Formation of the dinitrogen complex **5** from the reaction of complex **1** with MeOH may support this reaction pathway, although the yield of complex **5** was quite low.

Redox Properties of Trimethylsilyldiazenido and Trimethylsilylhydrazido(2−) Complexes. Cyclic voltammograms of complexes **1** and **2** were recorded in THF-0.1 M [*n*-Bu_4N][BF_4] under Ar by using glassy carbon, Pt wire and Ag wire immersed in the electrolyte as the working, counter, and reference electrodes, respectively. Under the present conditions, one-electron transfer between (η^5-C_5H_5)$_2$Fe and (η^5-C_5H_5)$_2$Fe$^+$ occurs at the potential of +0.56 V. The solution of the trimethylsilyldiazenido complex **1** shows the irreversible oxidation wave at +1.16 V, which gradually weakened and shifted to the negative direction by the repetitive scans. During these scans appeared the new anodic and cathodic waves at +0.53 and +0.16 V, which may correspond to the redox processes assignable to the species generated by the irreversible oxidation of complex **1**. By the scan to the negative direction from 0 V, no distinctive reduction peaks were observed, although the reduction current itself increased significantly at the potentials below −1.8 V. On the other hand, the trimethylsilylhydrazido(2−) complex **2** shows the irreversible reduction and oxidation waves at −2.1 and +0.82 V, respectively.

Reduction of Trimethylsilylated Dinitrogen Complexes with Sodium Metal and Sodium Hydride. Several attempts have been made to reduce hydrazido(2−) and dialkylhydrazido(2−) complexes to obtain nitrogenous compounds, regenerating the parent dinitrogen complexes at the same time.[5,6] Now we have found that treatment of complex **1** with excess Na sand (0.5—1 mm diameter) in THF at 30 °C under Ar gave $(Me_3Si)_2NH$ and NH_3 in substantial yields, accompanied by the formation of free and coordinated dinitrogen. After hydrolysis of the evaporated reaction mixture residue, additional amount of NH_3 was detected in moderate yield. The total nitrogen balance of the products based on complex **1** as a unit of dinitrogen was 0.95. When this reaction was carried out under N_2, the parent dinitrogen complex **5** was regenerated in 55% yield. The reactions with Na metal proceeded analogously for the molybdenum trimethylsilyldiazenido complex (**7**), the results of which are summarized in Table 3.

$$\textit{trans}\text{-[MI(NNSiMe}_3\text{)(P)}_4\text{]} \xrightarrow[\text{THF}]{\text{Na}} N_2 + [M(N_2)_2(P)_4] + (Me_3Si)_2NH + NH_3 + NaNH_2 + (Me_3Si)NHNa + (Me_3Si)_2NNa + \cdots\cdots \quad (M = Mo, W;\ P = PMe_2Ph) \qquad (1)$$

About a half of the nitrogen atoms in the trimethylsilyldiazenido complexes are converted into the N_1 products in this reaction system, with the remainder forming N_2 gas (Eq. 1). Among these products, $(Me_3Si)_2NH$ might be formed by the disproportionation reaction between two unstable Me_3SiNH_2 molecules, the protons of which may be derived from THF and/or a trace amount of H_2O still remaining despite the employment of rigorously dry conditions. Major N_1 products which were detected as NH_3 after hydrolysis are presumably present as the sodium salts such as $NaNH_2$, $Me_3SiNHNa$, or $(Me_3Si)_2NNa$, since the addition of Et_3SiCl to the reaction mixture of complex **1** with Na for 22 h resulted in the formation of Et_3SiNH_2, $(Me_3Si)NH(SiEt_3)$, $(Et_3Si)_2NH$, and $(Me_3$-

a) Reaction conditions: complex, 0.14—0.17 mmol; THF, 5 ml; Na sand (0.5—1 mm diameter), 20 equiv of M atom; 30 °C, 22 h, in the dark. b) Determined by GLC. c) Not including free NH_3. In each run N_2H_4 was detected in low yields after distillation (ca. 0.06 mol per metal atom). d) Determined by GLC after thermal decomposition and/or by the IR spectrum of the evaporated residue. e) The parent dinitrogen complexes *cis*-[W(N_2)$_2$(PMe_2Ph)$_4$] (**5**) and *cis*-[Mo(N_2)$_2$(PMe_2Ph)$_4$] (**3**) were recovered in 55 and 45% yields, respectively, determined by the IR method. f) NaH was used in place of Na sand. g) *cis*-[W(N_2)$_2$(PMe_2Ph)$_4$] (**5**) were recovered in 36% yield.

$Si)_2N(SiEt_3)$ in the yields of 9%, 21%, 19%, and 6% per W atom, respectively. On the other hand, when complexes **1** and **7** were reduced with Na under Ar in the presence of excess Me_3SiCl, $(Me_3Si)_3N$ was formed as the principal product in the yields of 0.42 mol and 0.75 mol per metal atom, respectively. Based on these observations the catalytic conversion of molecular nitrogen into silylamines has been achieved very recently and details of this work have been reported separately.[7]

Reduction of the trimethylsilylhydrazido(2−) complex **2** with Na metal under the similar reaction conditions also produced $(Me_3Si)_2NH$ and NH_3 in substantial yields together with free N_2 and the parent dinitrogen complex **5** as shown in Table 3. Further NH_3 was detected in moderate yield after following hydrolysis. By the similar treatment under a nitrogen atmosphere, the recovery of the dinitrogen complex **5** increased to 36% per W atom.

When NaH was used as a reducing agent under Ar, about a half of the nitrogen atoms in complexes **1** and **7** were converted into gaseous N_2 and total yields of NH_3 resulting from the remaining nitrogen atoms did not exceed those obtained by the reactions using Na metal.

Experimental

Ganeral. All experiments were carried out under dry nitrogen atmosphere. All solvents were rigorously dried by Na wire or Na–benzophenone ketyl and distilled just before use. Complexes **1**,[2] **2**,[2] **4**,[8] **5**,[8,9] **6**,[8,10] and Me_3SiI[11] were prepared according to the literature methods. Trimethylsilyl triflate commercially obtained was used after being degassed. The IR spectra were recorded on a Hitachi 215 or a Shimadzu IR-400 spectrometer and ^1H and ^{31}P NMR spectra were on a JEOL JMN-GX-400 spectrometer. Quantitative analyses using GLC were carried out on a Hitachi K23, a Shimadzu GC-8A or a GC-14A Gas Chromatograph. GC-MS analyses were performed on a Shimadzu GC-MS QP-1000 spectrometer. Electrochemical measurements were carried out at ambient temperature under Ar by using Hokuto Denko instrumentation (HA-501 Potentiostat, and HB-105 Function Generator), a glassy-carbon working electrode, and a platinum wire counter electrode. Potentials were measured vs. a pseudo-reference electrode of a silver wire immersed in the electrolyte (0.1 M $[n\text{-}Bu_4N][BF_4]$–THF). The cyclic voltammogram recorded under these conditions with the scan rate of $0.2\ V\ s^{-1}$ showed the oxidation potential of ferrocene at $E_{1/2}$=+0.52 V.

Preparation of *cis*-$[Mo(N_2)_2(PMe_2Ph)_4]$(3). The reported method[8] was modified as follows. The mixture of Mg turnings (6 g) and a piece of I_2 was heated at 150 °C with stirring under reduced pressure for 2 h. After cooling to room temperature, THF (100 ml) and PMe_2Ph (2.85 ml, 20.0 mmol) were added. Then $MoCl_5$ (1.36 g, 5.00 mmol) was added slowly with stirring. The color of the reaction solution changed from pale brown to dark brown. After stirring overnight under N_2 (1 atm) the resultant mixture was filtered and the filtrate was dried up. The dark sticky residue was washed with MeOH, extracted with ether (200 ml) and the extract was cooled down to −20 °C. The yellow crystals deposited were filtered off, washed successively with hexane, MeOH, and ether, and then dried in vacuo (1.2 g, 32%).

The ^{15}N complex *cis*-$[Mo(^{15}N_2)_2(PMe_2Ph)_4]$ was prepared from complex **3** according to the published method.[12]

Preparation of *trans*-$[MoI(NNSiMe_3)(PMe_2Ph)_4]$ (7). Into a solution of Me_3SiI (32 μl, 0.225 mmol) in benzene (5 ml) carefully degassed by freeze (at −50 °C)-pump-thaw cycles was added complex **3** (165 mg, 0.234 mmol) and the resultant yellow solution was stirred for 8 h at room temperature in the dark. Trap to trap condensation of hexane (6 ml) on the red product solution gave red crystals, which were filtered off, washed with hexane and then dried in vacuo (57 mg, 28%). Found: C, 47.25; H, 6.51; N, 2.94; I, 13.98%. Calcd for $C_{35}H_{53}N_2IP_4SiMo$: C, 47.95; H, 6.11; N, 3.19; I, 14.41%.

Preparation of $[MoI(NNSiMe_3)(dpe)_2]$. Into a solution of Me_3SiI (80 μl, 0.56 mmol) in benzene (8 ml) carefully prepared as above was added complex **4** (270 mg, 0.284 mmol). After stirring overnight at 50 °C in the dark, the yellow orange suspension was reduced in volume to a half in vacuo. After trap to trap condensation of hexane (6 ml) on it, the yellow solid deposited was filtered off and dried in vacuo (42 mg, 13%). Found: C, 57.87; H, 4.94; N, 1.49%. Calcd for $C_{55}H_{57}N_2IP_4SiMo$: C, 58.94; H, 5.13; N, 1.49%.

Preparation of *mer*-$[MoI_2(NNHSiMe_3)(PMe_2Ph)_3]$ (8). Into a solution of complex **3** (154 mg, 0.219 mmol) in benzene (5 ml) was added Me_3SiI (49 μl, 0.344 mmol) and the mixture was stirred for 12 h at room temperature in the dark. The deep red solution obtained was filtered and hexane (10 ml) was added to the filtrate by trap to trap condensation. The black crystals precipitated were filtered off, washed with hexane and dried in vacuo (8 mg, 4%). Found: C, 37.10; H, 4.86; N, 2.77; I, 28.72%. Calcd for $C_{27}H_{43}N_2I_2P_3SiMo$: C, 37.43; H, 5.01; N, 3.23; I, 29.29%.

Addition of MeOH (20 μl, 0.493 mmol) into a mixture of Me_3SiI (80 μl, 0.562 mmol) and benzene before reaction with complex **3** (200 mg, 0.284 mmol) increased the yield of complex **8** to 15%.

Preparation of $[MoI(NNHSiMe_3)(dpe)_2]I\cdot C_6H_6$. Into a suspension of complex **4** (502 mg, 0.529 mmol) in benzene (10 ml) was added Me_3SiI (150 μl, 1.05 mmol) and the mixture was stirred for 20 h at 40 °C in the dark. The red product solution was separated from unreacted complex **4** by filtration and hexane (15 ml) was added to the filtrate. Dark yellow crystals deposited were filtered off, washed with hexane, and then dried in vacuo (93 mg, 13%). Found: C, 55.41; H, 5.22; N, 2.10; I, 18.18%. Calcd for $C_{61}H_{64}N_2I_2P_4SiMo$: C, 55.21; H, 4.87; N, 2.11; I, 19.12%.

Preparation of *mer*-$[MoBr_2(NNHSiMe_3)(PMe_2Ph)_3]$. Into a mixture of Me_3SiBr (38 μl, 0.29 mmol) and benzene (7 ml), complex **3** (122 mg, 0.173 mmol) was added to give a yellow solution. After 4 h, the red solution obtained was concentrated and hexane (5 ml) was condensed on it by trap to trap method. On cooling at −18 °C, red crystals precipitated together with crystals of the parent complex **3**. Only the red crystals were collected, washed with hexane and dried in vacuo (5 mg, 4%). Found: C, 42.01; H, 5.55; N, 3.54; Br, 20.73%. Calcd for $C_{27}H_{43}N_2Br_2P_3SiMo$: C, 41.98; H, 5.62; N, 3.62; Br, 20.69%.

Treatment of *cis*-$[W(N_2)_2(PMe_2Ph)_4]$(5) with $CF_3SO_3SiMe_3$.

Into a solution of complex **5** (283 mg, 0.358 mmol) in benzene (5 ml) was added $CF_3SO_3SiMe_3$ (0.195 ml, 1.01 mmol). After stirring for 10 h at room temperature, the resultant red solution was reduced in volume to about a quarter. Trap to trap condensation of hexane (7.5 ml) on it gave red needles of the trimethylsilylhydrazido(2−) complex *mer*-[$W(CF_3SO_3)_2(NNHSiMe_3)(PMe_2Ph)_3$], which were filtered off, washed with hexane and dried in vacuo. (196 mg, 37%). Found: C, 34.42; H, 4.53; N, 2.81%. Calcd for $C_{29}H_{43}O_6N_2F_6S_2P_3SiW$: C, 34.87; H, 4.35; N, 2.81%.

Analogous treatment of complex **5** with 1.5 equiv of $CF_3SO_3SiMe_3$ in benzene gave the trimethylsilyldiazenido complex *trans*-[$W(CF_3SO_3)(NNSiMe_3)(PMe_2Ph)_4$] only once in low yield but all other trials to reproduce this run were unsuccessful probably due to the impurity such as CF_3SO_3H present in the commercially obtained $CF_3SO_3SiMe_3$. Found: C, 44.18; H, 5.44; N, 2.25%. Calcd for $C_{36}H_{53}O_3N_2F_3P_4SSiW$: C, 43.82; H, 5.41; N, 2.84%.

Preparation of [$W(CF_3SO_3)(NNSiMe_3)(dpe)_2$] and [$W(CF_3SO_3)(NNHSiMe_3)(dpe)_2$][$CF_3SO_3$]. Into a suspension of complex **6** (246 mg, 0.237 mmol) in benzene (10 ml) was added $CF_3SO_3SiMe_3$ (0.27 ml, 1.5 mmol) and the mixture was stirred overnight. The resultant orange solution was concentrated to about a half volume and trap to trap condensation of hexane to it gave a mixture of a yellow solid and orange crystals. Removal of the slurry containing the yellow solid remained the orange crystals of the trimethylsilyldiazenido complex, which was washed with hexane and dried (231 mg, 79%). Found: C, 54.88; H, 4.68; N, 2.00%. Calcd for $C_{56}H_{57}O_3N_2F_3SP_4SiW$: C, 54.63; H, 4.68; N, 2.27%. The trimethylsilylhydrazido(2−) complex was isolated by filtration of the separated yellow slurry (42 mg, 13%). Found: C, 48.34; H, 3.90; N, 1.17%. Calcd for $C_{57}H_{58}O_6N_2F_6S_2P_4SiW$: C, 49.57; H, 4.24; N, 2.03%.

Reaction of *trans*-[$WI(NNSiMe_3)(PMe_2Ph)_4$] (1) with HCl Gas. Onto a frozen solution of complex **1** (158 mg, 0.164 mmol) in benzene (10 ml) was condensed HCl gas (107 ml/28 mmHg/22.5 °C, 0.163 mmol; 1 mmHg≈133.322 Pa) at −196 °C. The mixture was slowly warmed to room temperature and stirred for 24 h. The red product solution was concentrated to about 2 ml in vacuo and hexane (6 ml) was added to it by trap to trap condensation. The yellow solid of *mer*-[$WClI(NNHSiMe_3)(PMe_2Ph)_3$] was filtered off, washed with hexane and dried in vacuo (92 mg, 64%). IR (KBr disk): ν(NN), 1334; $\delta(Me_3Si)$, 1245; ν(SiN), 845 cm^{-1}.

Reaction of [$WI(NNH)(dpe)_2$] with Me_3SiI. Into a suspension of [$WI(NNH)(dpe)_2$] (207 mg, 0.182 mmol) in benzene (10 ml) was added Me_3SiI (54 μl, 0.379 mmol). The color of the mixture gradually changed from yellow to orange. After stirring for 6 h, the orange solid was filtered off, washed with hexane and dried in vacuo (199 mg). Major component of this solid was [$WI(NNHSiMe_3)(dpe)_2$]I, the yield of which was estimated to be about 70% by the IR spectrum. Further purification of the product was not successful because of its low solubility.

Reaction of *trans*-[$WI(NNSiMe_3)(PMe_2Ph)_4$] (1) with Water. Into a solution of complex **1** (119 mg, 0.123 mmol) in benzene was added H_2O (2.2 μl, 0.122 mmol) and the mixture was stirred for 17 h in the dark at room temperature. The red solution obtained was concentrated to about 1 ml and hexane (6 ml) was added to it. The brown solid deposited was filtered off and precipitated again from benzene/hexane. The yellow solid isolated was characterized as complex **9** by the IR spectrum and the analytical data (38 mg, 35%). Found: C, 33.01; H, 4.01; N, 3.07%. Calcd for $C_{24}H_{35}N_2I_2P_3W$: C, 32.67; H, 4.01; N, 3.18%.

Reaction of *mer*-[$WI_2(NNHSiMe_3)(PMe_2Ph)_3$] (2) with Water. Analogous treatment of complex **2** (112 mg, 0.116 mmol) in benzene (10 ml) with H_2O (7.5 μl, 0.414 mmol) gave the product suspension. The yellow solid separated by filtration was characterized as complex **9** by the IR spectrum (91 mg, 89%).

Reaction of *mer*-[$WI_2(NNHSiMe_3)(PMe_2Ph)_3$] (2) with MeOH. Into a solution of complex **2** (254 mg, 0.266 mmol) in benzene (5 ml) was added MeOH (13 μl, 0.322 mmol). The red solution changed rapidly to the brown suspension. After stirring for 20 h in the dark, complex **9** produced was filtered off, washed with benzene and dried in vacuo (145 mg, 66%).

Reaction of [$WI(NNSiMe_3)(dpe)_2$] with MeOH. Into a suspension of [$WI(NNSiMe_3)(dpe)_2$] (220 mg, 0.182 mmol) in benzene (15 ml) was added MeOH (7.8 μl, 0.193 mmol). After stirring for 35 h, the resultant suspension was filtered and the deep yellow solution obtained was concentrated to about 3 ml. Addition of hexane (7 ml) gave dark red crystals of [$WI(NNH)(dpe)_2$], which were filtered off, washed with hexane and dried in vacuo (42 mg, 20%). Found: C, 55.01; H, 4.30; N, 2.09; I, 11.54%. Calcd for $C_{52}H_{49}N_2IP_4W$: C, 54.94 H, 4.35; N, 2.46; I, 11.16%. IR (KBr disk): ν(NN), 1900 cm^{-1}.

Reaction of *trans*-[$WI(NNSiMe_3)(PMe_2Ph)_4$] (1) with MeOH. Analogous treatment of complex 1 (212 mg, 0.220 mmol) with MeOH (13 μl, 0.322 mmol) gave the brown solid of *trans*-[$WI(NNH_2)(PMe_2Ph)_4$]I (34 mg, 15%). From the filtrate were obtained small amounts of complexes **5** and **9**. However, isolation and characterization of the major product from this reaction mixture were not successful.

Reduction of Trimethylsilylated Dinitrogen Complexes. under Ar with Na: Onto a frozen mixture of THF (5—6 ml) and Na sand (0.5—1 mm diameter, ca. 20 mol excess) in a rigorously dried Schlenk tube with a volume of 35—40 ml, complex **1**, **2**, or **7** (0.12—0.17 mmol) and nonane as an internal standard were added under Ar. The mixture was warmed slowly and then stirred for 22 h in the dark at 30 °C. After determining the amounts of the evolved N_2 in the gaseous phase (Molecular Sieve 13X, 80—100 mesh, 3 mm ϕ×2.0 m stainless column) and $(Me_3Si)_2NH$ in the liquid phase (Silicone KF-96, 5% on Chromosorb W(AW-DMCS), 60—80 mesh, 2.6 mm ϕ×2.0 m glass column) by GLC, volatile materials were condensed into another Schlenk tube immersed in liquid nitrogen from the reaction mixture which was cooled down to −30—−40 °C to avoid the evaporation of $(Me_3Si)_2NH$. The trapped materials including free ammonia were treated with aqueous H_2SO_4 solution (0.5 mol dm^{-3}, 10 ml) and NH_3 was analyzed quantitatively by the indophenol method. As for the evaporated residue, the amount of the coordinated dinitrogen was determined by comparing the intensities of the ν(NN) band at 1910 cm^{-1} and the band at 1430 cm^{-1} assigned to the phenyl group in PMe_2Ph ligand and/or by the GLC analysis of the evolved N_2 gas after thermal decomposition of the residue at 160—170 °C for 1 h. After these procedure, the residue was treated with an aqueous KOH solution (40%, 10 ml) and NH_3 and N_2H_4 distilled into an aqueous H_2SO_4 solution were analyzed by indophenol and *p*-dimethylaminobenzaldehyde reagents, respectively.

Under N_2 with Na: The similar procedure to the reduction under Ar was carried out except for the determination of evolved N_2 gas by GLC.

Under Ar with NaH: The similar procedure was undertaken except that NaH (ca. 20 mol excess) was used in place of Na sand.

Reaction with Et_3SiCl after Reduction. After the similar treatment of complex **1** (141 mg, 0.146 mmol) with Na microdispersion (62 mg, 2.71 mmol) adding decane as an internal standard, the amount of $(Me_3Si)_2NH$ determined by GLC was 0.11 mol per W atom (Silicone OV-17, 5% on Chromosorb W(AW-DMCS), 60—80 mesh, 2.6 mmϕ×2.0 m glass column). Then Et_3SiCl (356 mg, 2.43 mmol) was added to the solution. After stirring for 2 days at room temperature, the amounts of Et_3SiNH_2, $(Me_3Si)NH(SiEt_3)$ (Silicone OV-17, 5% on Chromosorb W(AW-DMCS), 60—80 mesh, 2.6 mmϕ×2.0 m glass column), $(Et_3Si)_2NH$ and $(Me_3Si)_2N(SiEt_3)$ (Shimadzu HiCap-CBP10-M25-025, capillary column) in the solution were determined by GLC.

Reduction of *trans*-[MoI(NNSiMe$_3$)(PMe$_2$Ph)$_4$] (7) and *trans*-[WI(NNSiMe$_3$)(PMe$_2$Ph)$_4$] (1) with Na in the Presence of Excess Me_3SiCl. Into a degassed mixture of Na microdispersion (8—10 μm diameter, ca. 20 mol excess) and Me_3SiCl (ca. 20 mol excess) in THF (5 ml) at −78 °C, *mer*-[MoI(NNSiMe$_3$)(PMe$_2$Ph)$_4$] (**7**) (123 mg, 0.128 mmol) was added under Ar. After stirring for 22 h at room temperature in the dark, the unreacted Me_3SiCl and about a half of THF were removed by trap-to-trap method. Then the yield of $(Me_3Si)_3N$ in the residue was determined by GLC (Silicone OV-225, 2% on Chromosorb W(AW-DMCS), 80—100 mesh, 2.6 mmϕ×2.0 m glass column) using nonane as an internal standard (0.75 mol per Mo atom). In the presence of excess Me_3SiCl, the quantitative GLC analysis of $(Me_3Si)_3N$ was not successful under the conditions we examined.

By the similar treatment of complex **1**, $(Me_3Si)_3N$ was produced in the yield of 0.42 mol per W atom.

The financial support by the Ministry of Education of Japan and the Asahi Glass Foundation of Engineering Technology is greatly appreciated.

$2^A,2^B$-, $2^A,2^C$-, and $2^A,2^D$-Bis-*O*-(*p*-tolylsulfonyl)-β-cyclodextrins

Kahee FUJITA,* Takashi ISHIZU, Kyoko OSHIRO, and Ken-ichi OBE
Faculty of Pharmaceutical Sciences, Fukuyama University, Sanzo, Higashimura-cho, Fukuyama 729-02
(Received May 11, 1989)

A mixture of the title ditosylates was prepared by the reaction of β-cyclodextrin with dibutyltin oxide and tosyl chloride. Each ditosylate was isolated by reversed-phase column chromatography and the structure was assigned on the basis of conversion into a known compound or hydrolysis with Taka amylase A.

The introduction of two functional groups at the desired positions of cyclodextrins is an approach to the construction of enzyme (or receptor) mimics.[1-5] In this context the study of specific disulfonylation is important.

Tabushi et al.[6-9] reported the specific 6,6-di-*O*-sulfonylation of β-cyclodextrin (β-CD) and Boger and Knowles[10] demonstrated nonspecific 6,6,6-tri-*O*-sulfonylation of α-cyclodextrin (α-CD) but only the $6^A,6^C,6^E$ isomer was identified. Fujita et al.[11-14] prepared poly-6-*O*-sulfonylated α(or β or γ)-cyclodextrins by nonspecific sulfonylation.

Since Breslow et al.[15] demonstrated that β-CD modified with a pyridoxamine moiety on its secondary hydroxyl side[15] produced amino acids with opposite chirality to that produced from the corresponding 6-*O*-modified β-CD[16] in transamination reactions, disulfonylation of the secondary hydroxyl groups has been a challenging problem. However, there are few reliable methods for the specific sulfonylation of 3-OH or 2-OH.

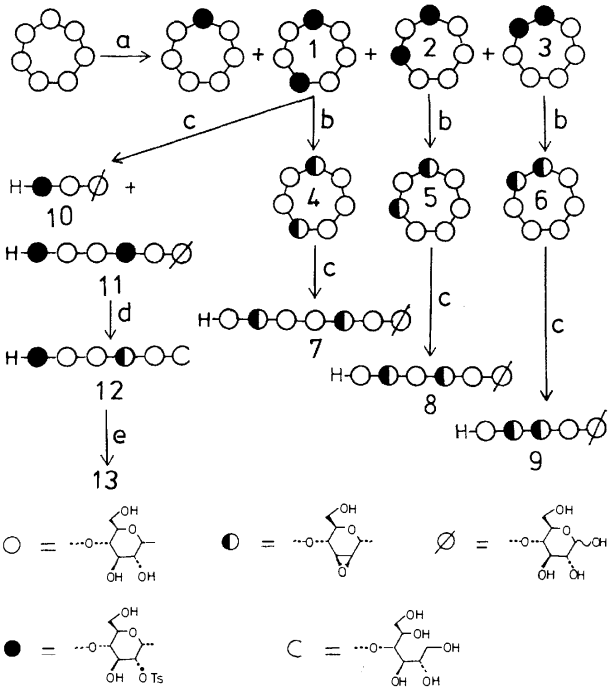
Fujita et al.[17] reported the preparation of 3-*O*-sulfonylated α- or β-CD by reaction with 2-naphthalenesulfonyl chloride in alkaline aqueous acetonitrile and its application for the preparation of $3^A,3^C$- and $3^A,3^D$-di-*O*-sulfonylated β-CDs.

Three methods have been reported for the 2-*O*-sulfonylation of β-CD. (a) Ueno and Breslow[18] prepared 2-*O*-(*p*-tosyl)-β-CD by the reaction of β-CD with *m*-nitrophenyl *p*-tosylate in alkaline aqueous *N,N*-dimethylformamide. (b) Fujita et al. reported that the reaction of α- or β-CD with *m*-nitrobenzenesulfonyl chloride[19] or 1-naphthalenesulfonyl chloride[20] in alkaline aqueous solution gave the corresponding 2-*O*-sulfonates. The reaction with *m*-nitrobenzenesulfonyl chloride was used to synthesize $2^A,2^X$-di-*O*-sulfonyl-α-CDs (X=B, C, and D). However, the reaction with 1-naphthalenesulfonyl chloride gave a low yield of 2-*O*-sulfonyl β-CD and the rate of reaction was too slow to allow further sulfonylation because of the competitive epoxidation of the monosulfonate. (c) Murakami et al.[21] reported the preparation of a 2-*O*-sulfonate by the use of dibutyltin oxide and the corresponding sulfonyl chloride in *N,N*-dimethylformamide.[22] Methods (a) and (b) did not allow accumulation of the disulfonates since the 2-*O*-sulfonylated β-CDs were converted into the epoxide, $(2^AS,3^AS)$-$2^A,3^A$-anhydro-β-CD.

Method (c), on the other hand, is carried out in dry *N,N*-dimethylformamide and offers a promise for the preparation of 2,2-di-*O*-sulfonylated β-CDs. We now describe its use for the preparation of $2^A,2^B$-, $2^A,2^C$-, and $2^A,2^D$-bis-*O*-(*p*-tosyl)-β-CDs by the reaction of β-CD.

Results and Discussion

Following the reaction of β-CD with dibutyltin oxide and *p*-toluenesulfonyl chloride in *N,N*-dimethylformamide, reversed-phase column chromatography of the products gave, in order of elution in reversed-phase HPLC, 2-*O*-*p*-tosyl (9.4%), $2^A,2^D$- (**1**, 3.6%), $2^A,2^C$- (**2**, 2.6%), and $2^A,2^B$-bis-*O*-(*p*-tosyl) (**3**, 1.8%) derivatives (Scheme 1). That **1**—**3** were ditosylates was confirmed by their fast-atom bombardment (hereafter abbreviated to FAB) mass spectra and by their



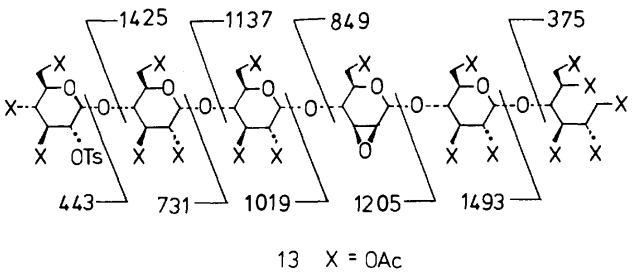
Scheme 1. Preparation and determination of the structure of $2^A,2^X$-bis-*O*-(*p*-tosyl)-β-cyclodextrins (**1**—**3**): (a) *p*-toluenesulfonyl chloride–Bu_2SnO–*N,N*-dimethylformamide, (b) $Ba(OH)_2$, (c) Taka amylase A, (d) $NaBH_4$, (e) Ac_2O–pyridine.

^{13}C NMR spectra which showed that two of the ^{13}C resonances were shifted up-field (see Experimental). However, the ^{13}C NMR spectra were not helpful in determining the regiochemistry of the sulfonylations.

Fujita et al.[19] reported that $2^A,2^X$-di-*O*-sulfonyl-α-CDs (X=B, C, and D) were converted easily into the corresponding ($2^AS,3^AS:2^XS,3^XS$)-$2^A,3^A:2^X,3^X$-dianhydro-α-CDs by treatment with aqueous alkali and that ($2^AS,3^AS:2^CS,3^CS$)-$2^A,3^A:2^C,3^C$-dianhydro-α-CD and ($2^AS,3^AS:2^BS,3^BS$)-$2^A,3^A:2^B,3^B$-dianhydro-α-CD were hydrolyzed by Taka amylase A to give ($2''S,3''S:2''''S,3''''S$)-$2'',3'':2'''',3''''$-dianhydromaltohexaose and ($2''S,3''S:2'''S,3'''S$)-$2'',3'':2''',3'''$-dianhydromaltopentaose, respectively, whereas ($2^AS,3^AS:2^DS,3^DS$)-$2^A,3^A:2^D,3^D$-dianhydro-α-CD was unaffected.

Following these procedures, **1**—**3** were treated with aqueous $Ba(OH)_2$ to give the corresponding diepoxides **4**—**6**. Although the ^{13}C NMR spectra of **4**—**6** were different from each other, they did not allow the structures to be assigned. The diepoxides **4**—**6** were hydrolyzed by Taka amylase A to give diepoxides (**7**—**9**) of maltoheptaose, maltohexaose, and maltopentaose, respectively, together with glucose (Scheme 1). The FAB mass spectra of **7**—**9** contained the corresponding molecular ions (see Experimental). The structures ($2''S,3''S:2''''S,3''''S$)-$2'',3'':2'''',3''''$-dianhydromaltohexaose and ($2''S,3''S:2'''S,3'''S$)-$2'',3'':2''',3'''$-dianhydromaltopentaose were assigned to **8** and **9**, respectively, by comparing the FAB mass spectra and retention times in reversed-phase HPLC with those of the authentic compounds which were prepared from ($2^AS,3^AS:2^XS,3^XS$)-$2^A,3^A:2^X,3^X$-dianhydro-α-CDs (X=B and C) as described above.[19] Therefore, **2** and **3** are the $2^A,2^C$- and $2^A,2^B$-ditosylate, respectively. Since there are only three 2,2-disulfonates, **1** must be the $2^A,2^D$ isomer and this was confirmed as follows.

Hydrolysis of 2-*O*-arylsulfonyl-β-CDs by Taka amylase A gives[20] $2''$-*O*-(arylsulfonyl)maltotrioses (**10**). However, enzymic hydrolysis of **1** gave the expected known compound **10**[20] only as a minor product. The major product was **11**. Reduction of **11** with aqueous $NaBH_4$ gave **12**, the FAB mass spectrum of which contained ($M+H^+$) ion at *m/z* 1129 demonstrating that one of the two tosylated sugar units had been converted into an epoxide and that the end group was a hexitol moiety. Treatment of **12** with acetic anhydride in pyridine gave the octadecaacetate **13**, the FAB mass spectral fragmentation of which (Scheme 2) demonstrated the tosyl and the epoxy groups were located at the first and fourth glucose units, respectively. Therefore, the identity of **1** is confirmed as $2^A,2^D$-bis-*O*-(*p*-tosyl)-β-CD.



13 X = OAc

Scheme. 2. FAB mass spectral fragmentation pattern of **13**.

The ditosylates **1**—**3** may serve as starting materials for the synthesis of specifically bifunctionalized β-CDs.

Experimental

General. ^{13}C NMR spectra were determined with a JEOL FX 100 (25 MHz) spectrometer. FAB mass spectra were recorded with a JEOL DX-300 data system. Merck Lobar prepacked columns of LiChroprep Rp18 (A 10 mm×240 mm and B 25 mm×310 mm) and Rp8 (C 37 mm×440 mm) were used for reversed-phase column chromatography. HPLC was performed on a HITACHI L-3000 instrument with a column (4.6 mm×250 mm) of TSKgel ODS-80TM (5 μm, TOSOH).

Preparation and Isolation of $2^A,2^X$-Bis-*O*-(*p*-tosyl)-β-CDs (1—3, X=B—D). A mixture of β-cyclodextrin (5.25 g, 4.63 mmol) and dibutyltin oxide (11.52 g, 46.3 mmol) in anhydrous *N,N*-dimethylformamide (35 mL) was stirred at 95—100 °C for 2 h under nitrogen. The mixture was cooled to 0 °C, triethylamine (5.61 g, 55.5 mmol) was added, followed dropwise by a solution of *p*-toluenesulfonyl chloride (8.84 g, 46.3 mmol) in anhydrous *N,N*-dimethylformamide (10 mL). The mixture was stirred for 10 h at room temp and then concentrated in vacuo to 20 mL. The residual yellow syrup was stirred vigorously with acetone (500 mL) for 20 min, the solid was collected, washed with acetone, and dried in vacuo. A solution in water (250 mL) was filtered and chromatographed on column C. After elution with aqueous 20% methanol (1 L), gradient elution from aqueous 30% methanol (1 L) to aqueous 60% methanol (1 L) was applied to give 2-*O*-(*p*-tosyl)-β-CD (561 mg, 9.4%) and a mixture of $2^A,2^X$-bis-*O*-(*p*-tosyl)-β-CDs (X=B—D). The mixture was concentrated in vacuo and chromatographed on column B with gradient elution from aqueous 40% methanol (1 L) to aqueous 60% methanol (1 L) to give $2^A,2^D$-(**1**, 240 mg, 3.6%), $2^A,2^C$-(**2**, 174 mg, 2.6%), and $2^A,2^B$-bis-*O*-(*p*-tosyl)-β-CD (**3**, 122 mg, 1.8%). ^{13}C NMR (Me_2SO-d_6, internal Me_4Si, characteristic nonaromatic carbons), **1** δ=59.8, 69.1, 71.9, 72.2, 72.9, 79.5, 81.4, 98.1 (two shifted C-1 resonances), 101.8, **2** δ=59.7, 69.2, 70.2, 72.0, 72.8, 79.6, 80.9, 81.4, 98.1 (two shifted C-1 resonances), 101.8, **3** δ=59.8, 68.8, 69.1, 71.9, 72.9, 79.2, 80.2, 81.1, 81.5, 97.1 (a shifted C-1 resonance), 97.7 (a shifted C-1 resonance), 101.8; FABMS *m/z* **1** 1443 ($M+H^+$), **2** 1443 ($M+H^+$), **3** 1443 ($M+H^+$).

Epoxidation of $2^A,2^X$-Bis-*O*-(*p*-tosyl)-β-CDs (1—3, X=B—D). A solution of **1** (30.8 mg) in 0.05 M $Ba(OH)_2$ (3 mL; 1 M=1 mol dm^{-3}) was stirred at room temperature for 1.5 h, then neutralized with 0.5 M H_2SO_4, filtered, applied to a column (2.6 cm×90 cm) of Bio-Gel P-2 (200—400 mesh, Bio-Rad Laboratories), and eluted with water to give ($2^AS,3^AS:2^DS,3^DS$)-$2^A,3^A:2^D,3^D$-dianhydro-β-CD **4** (23.1 mg, 74%).

Similarly, **2** (15.0 mg) and **3** (25.2 mg) gave ($2^AS,3^AS:2^CS,3^CS$)-$2^A,3^A:2^C,3^C$-dianhydro-β-CD (**5**, 11.3 mg, 84.8%) and ($2^AS,3^AS:2^BS,3^BS$)-$2^A,3^A:2^B,3^B$-dianhydro-β-CD (**6**, 17.8 mg, 97.8%),

respectively. ^{13}C NMR [D_2O, internal $Me_3Si(CH_2)_3SO_3Na$, characteristic absorptions] **4** δ=51.7, 56.5, 62.7, 63.5, 74.3, 75.0, 82.2, 82.6, 83.1, 100.0, 100.2, 103.9, **5** δ=51.9, 56.6, 62.7, 63.4, 74.3, 74.6, 82.3, 82.7, 83.2, 100.1, 103.6, 104.1, **6** δ=51.7, 52.2, 56.7, 62.8, 63.4, 74.4, 75.6, 82.8, 83.3, 99.0, 100.2, 103.0, 104.1; FABMS *m/z* **4** 1121 ($M+Na^+$), 1137 ($M+K^+$), **5** 1121 ($M+Na^+$), **6** 1099 ($M+H^+$), 1137 ($M+K^+$).

Hydrolysis of (2^A*S*,3^A*S*:2^X*S*,3^X*S*)-2^A,3^A:2^X,3^X-dianhydro-β-CD (4—6, X=B—D) with Taka Amylase A. A solution of (36 mg) and Taka amylase A [α-amylase Type X-A (Sigma), 36 mg] in 0.2 M acetate buffer (3 mL, pH 5.5) containing 0.01 M $CaCl_2$ was kept at 40 °C for 2 days, then heated at 100 °C for 10 min, filtered, applied to a column (2.6 cm×90 cm) of Bio-Gel P-2 and eluted with water to give (2″*S*,3″*S*:2⁗*S*,3⁗*S*)-2″,3″:2⁗,3⁗-dianhydromaltoheptaose (**7**, 17.6 mg, 48.2%).

Similarly, **5** (26 mg) and **6** (59 mg) gave (2″*S*,3″*S*:2⁗*S*,3⁗*S*)-2″,3″:2⁗,3⁗-dianhydromaltohexaose (**8**, 6.0 mg, 26.5%) and (2″*S*,3″*S*:2‴*S*,3‴*S*)-2″,3″:2‴,3‴-dianhydromaltopentaose (**9**, 32.0 mg, 88.8%), respectively. FABMS *m/z* **7** 1117 ($M+H^+$), 1139 ($M+Na^+$), **8** 955 ($M+H^+$), 977 ($M+Na^+$), 993 ($M+K^+$), **9** 793 ($M+H^+$), 815 ($M+Na^+$).

Hydrolysis of 2^A,2^D-Bis-*O*-(*p*-tosyl)-β-CD 1 with Taka Amylase A. A solution of **1** (60 mg) and Taka amylase A (180 mg) in 0.2 M acetate buffer (8 mL, pH 5.5) containing 0.01 M $CaCl_2$ was kept at 40 °C for 2 days, then worked-up as described above. The filtrate was chromatographed on column A. After elution of aqueous 5% methanol (50 mL), gradient elution from aqueous 10% methanol (500 mL) to aqueous 50% methanol (500 mL) was applied to give 2″-*O*-(*p*-tosyl)maltotriose (**10**, 9 mg, 32.9%) and 2″,2⁗″-bis-*O*-(*p*-tosyl)maltohexaose (**11**, 36.0 mg, 66.7%). FABMS *m/z* **10** 659 ($M+H^+$), 681 ($M+Na^+$), **11** 1299 ($M+H^+$), 1321 ($M+Na^+$).

Reduction of 2″,2⁗″-Bis-*O*-(*p*-tosyl)maltohexaose 11 with $NaBH_4$. A solution of **11** (15.5 mg) in aqueous 1% $NaBH_4$ (5 mL) was kept at room temp for 16 h, then neutralized with aqueous 5% HCl, filtered, and chromatographed on column A with gradient elution from aqueous 20% methanol (500 mL) to aqueous 50% methanol (500 mL) to give *O*-2-*O*-(*p*-tosyl)-α-D-glucopyranosyl-(1→4)-*O*-α-D-glucopyranosyl-(1→4)-*O*-α-D-glucopyranosyl-(1→4)-*O*-[(2*S*,3*S*)-2,3-anhydro-α-D-glucopyranosyl]-(1→4)-*O*-α-D-glucopyranosyl-(1→4)-D-glucitol (**12**, 7.5 mg, 55.9%). FABMS *m/z* 1129 ($M+H^+$).

A solution of **12** (3 mg) was treated conventionally with acetic anhydride (1.5 mL) in pyridine (1.5 mL) at room temp for 2 days. The crude product was purified by reversed-phase HPLC with gradient elution from aqueous 50% CH_3CN to aqueous 80% CH_3CN to give *O*-2-*O*-(*p*-tosyl)-α-D-glucopyranosyl-(1→4)-*O*-α-D-glucopyranosyl-(1→4)-*O*-α-D-glucopyranosyl-(1→4)-*O*-[(2*S*,3*S*)-2,3-anhydro-α-D-glucopyranosyl]-(1→4)-*O*-α-D-glucopyranosyl-(1→4)-D-glucitol octadecaacetate (**13**). FABMS *m/z* 1885 ($M+H^+$) (see Scheme 2).

We thank Japan Maize Products Co., Ltd. for a generous gift of β-cyclodextrin.

Pyrex-filtered photoirradiation of a thermally inert complex $CoH[PPh(OEt)_2]_4$ generated a coordinatively unsaturated active hydride species "$CoH[PPh(OEt)_2]_3$" ($CoHP_3$), which catalyzed hydrogen transfer from secondary alcohols to carbonyl compounds, such as ketones. Study of initial reaction-rate dependence of the hydrogen transfer on complex and substrate concentrations indicated that the reaction was initiated by coordination of the carbonyl compounds to the photogenerated $CoHP_3$ species, and these coordination was confirmed by the decay analysis of the transient $CoHP_3$ absorbance observed after laser flash photolysis. In addition, the rate-determining step of the hydrogen-transfer reaction was associated with the hydride transfer to the carbonyl carbon, at the stage of the transformation of hydrido (ketone or aldehyde) cobalt into alkoxo intermediate. Second-order coordination-rate constants k' of aldehydes and ketones to $CoHP_3$ ranged from 10^5 to 10^3 M^{-1} s^{-1}. The constants k' of aldehydes were considerably larger than those of ketones, where substantial steric repulsion by the bulky substituents introduced in place of the aldehyde hydrogen, was presumed to hinder the $CoHP_3$ approach to the carbonyl group.

Transition-metal hydride complexes have become an important class of compounds in organometallic chemistry, which play a key role in many homogeneous catalytic reactions[1] and have promise also in hydrogen and energy storage systems.[2] Moreover, their photochemical properties[3] have recently received much attention in view of photochemical hydrogen production from water[2a,b] and of photogeneration of highly reactive organometallic fragments.[4]

The hydridophosphonitecobalt(I) complex $CoH[PPh(OEt)_2]_4$ ($CoHP_4$) with an 18-electron configuration is thermally inert. However, Pyrex-filtered photoirradiation of the complex dissociates a phosphonite ligand $PPh(OEt)_2$ (P) from cobalt efficiently without cleavage of the hydrido–cobalt bond, and produces a coordinatively unsaturated transient of the hydride species "$CoH[PPh(OEt)_2]_3$" ($CoHP_3$).[5] The quantum yield for the $CoHP_3$ photogeneration is almost 1.0 at 337 nm.[5b] Furthermore, the species has shown high catalytic activities in double-bond migration of some allylic compounds such as *N,N*-diethylallylamine, and laser flash photolysis displayed the substrate coordination through C=C double bond to the species.[5c]

We now report the photoassisted intermolecular hydrogen transfer from secondary alcohols to carbonyl compounds such as ketones, as an another example of the catalytic reactions by the photogenerated $CoHP_3$ species. Some aspects of this work have appeared in a preliminary communication.[6]

Catalytic transfer hydrogenation using organic compounds as hydrogen sources seems to remain of current interest and secondary alcohols have most often been employed as the sources.[1b,7] In these reactions, homogeneous catalyst have been widely used, such as $RhCl(PPh_3)_3$, $RhH(PPh_3)_4$, $RuCl_2(PPh_3)_3$, and $RuH_2(PPh_3)_4$.[7] However, there were only a few descriptions on the hydrogen transfer catalyzed by photogenerated reactive organometallic species.[8]

Experimental

Materials and General Procedures. The complex $CoH[PPh(OEt)_2]_4$, $CoHP_4$ was prepared by the literature methods.[9] Benzene was treated with concentrated sulfuric acid until thiophene-free. After water washing, it was dried over anhydrous magnesium sulfate, and distilled from sodium under nitrogen. Toluene was purified similarly. For continuous irradiation, a high-pressure mercury lamp (400 W) was used with a Pyrex filter, and reactant solutions were placed at about 45 mm from the lamp.

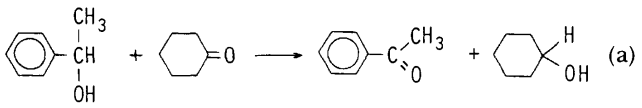
Catalytic Hydrogen Transfer and Product Analyses. Benzene solutions (5 cm^3) of $CoHP_4$ and substrates were degassed by freeze-pump-thaw cycles in a Pyrex Schlenk tube (18 mm^{ϕ}). After standing the solutions at 30 °C in the dark or under irradiation to proceed catalytic hydrogen transfer, the reaction mixture was analyzed by Shimadzu GC-8AIT(TCD) and GC-8APF(FID) gas chromatographs with Molecular Sieve 5A, polyethylene glycol 20M, Silicone SE-30, tetrakis-*O*-(2-cyanoethyl)pentaerythritol, and Thermon 3000 columns, together with JEOL model JMS-DX303 GC-mass and JNM-GX-400 NMR spectrometers. Other catalytic reactions described in this paper were conducted similarly.

Laser Flash Photolysis. A Molectron UV-400 nitrogen laser was used for excitation. A right-angle optical system using a 1×1 cm Pyrex cell was employed for the excitation-analysis set-up. The kinetic spectrophotometer and data collection system are described elsewhere.[10] Samples were deaerated by bubbling with argon for 20 min or by several freeze-pump-thaw cycles after transfer of solvent from a reservoir, containing

$LiAlH_4$, using a vacuum line. Second-order rate constants were obtained from the plots of pseudo-first-order rate constants vs. the substrate concentrations, and regarded as accurate to within ca. 10%.

Results and Discussion

Intermolecular Hydrogen Transfer from Secondary Alcohols to Ketones. The $CoHP_4$ complex was mixed with 50-fold moles of cyclohexanone and 1-phenylethanol in benzene, and the solution was irradiated at 30 °C for 8 h by use of a high-pressure Hg lamp with a Pyrex filter. Hydrogen transfer occurred from 1-phenylethanol to cyclohexanone affording acetophenone and cyclohexanol, and virtual stoichiometric relationship was found to hold among these four organic compounds.[6] The reaction mixture gave



(a)

a value of 0.77 for the molar ratio of cyclohexanol formed to that of cyclohexanone charged. Similar photocatalytic hydrogen transfer was performed also from cyclohexanol to acetophenone (i.e., backward hydrogen-transfer reaction of (a)), and afforded the reaction mixture of comparable composition to that of the forward hydrogen-transfer reaction, indicating equilibration among these alcohols and ketones.[6] Formation of pinacols and their derivatives was not observed under the present reaction conditions. No other products were detected on the basis of gas chromatography except a small amount of dissociated phosphonite and only trace of molecular hydrogen (less than 2% yield relative to $CoHP_4$).

In the absence of $CoHP_4$, the hydrogen transfer did not proceed even under irradiation, and addition of free phosphonite did not change the situation either. In the dark, the cobalt complex did not cause the hydrogen transfer at 30 °C in benzene at all. Accordingly, the hydrogen transfer of the present system was determined to be photoassisted. In consideration of the fact that the present hydrogen transfer proceeded only under photoirradiation of $CoHP_4$ and ceased immediately upon interruption of irradiation, it was evident that the photogenerated hydride species $CoHP_3$ played an important role in the catalytic cycle of the present hydrogen transfer, similarly to the photoassisted reactions of the olefin double-bond migration reported previously.[5a,c]

Dependence of the Hydrogen-Transfer Reaction-Rates on Concentrations of the Cobalt Complex and Substrates. For benzene solutions of 0.82 M†† 1-phenylethanol and cyclohexanone, the initial reaction rate of the hydrogen transfer became larger as the concentration of $CoHP_4$ increased from 0.16× to 0.82×10^{-2} M (Fig. 1). However, in the range above 0.82×10^{-2} M, the initial reaction rate did not change so much upon the further increase in the $CoHP_4$ concentration, and the rate seemed to approach one asymptotic value. This finding was attributed to the saturated photogeneration of the hydride $CoHP_3$ species due to total absorption of the incident light. Similar phenomenon was noticed also in the conversion of cyclohexanone to cyclohexanol after 4 h.

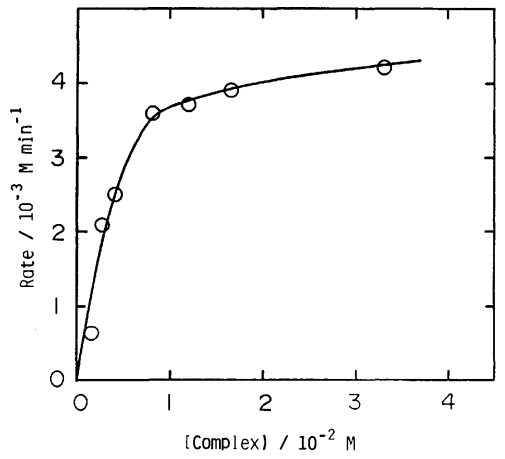


Fig. 1. Dependence of the initial rate of hydrogen transfer on the $CoH[PPh(OEt)_2]_4$ concentration. 1-Phenylethanol, 0.82 M; cyclohexanone, 0.82 M.

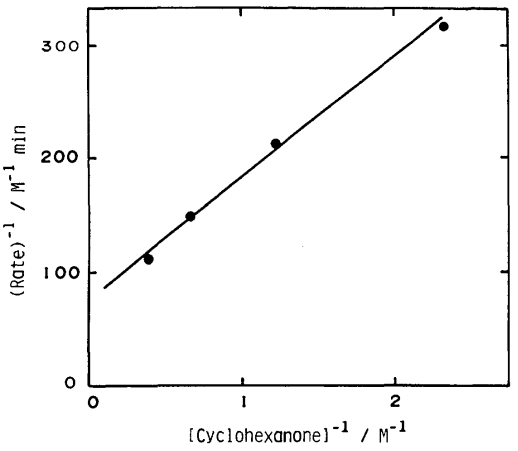

Fig. 2. Double reciprocal plots of the initial reaction rate against the cyclohexanone concentration. $CoH[PPh(OEt)_2]_4$, 0.0165 M; 1-phenylethanol, 0.82 M.

At the fixed concentrations of $CoHP_4$ (1.65×10^{-2} M) and 1-phenylethanol (0.82 M), we studied concentration effects of the cyclohexanone charged, and found that the reciprocal initial reaction rate bore a linear relationship with the reciprocal

$$\left[\frac{d[Y]}{dt}\right]_{t=0}^{-1} = \frac{1}{V} + \frac{K_m}{V} \times [S]_{t=0}^{-1},$$

S=cyclohexanone, t=time, Y=cyclohexanol,

$V=1.28\times10^{-2}$ M min^{-1}, $K_m=1.32$ M, Correlation coefficient=0.997

†† 1 M=1 mol dm^{-3}.

concentration of the cyclohexanone charged (Fig. 2). On the contrary, the initial reaction rate was practically independent of the concentration of 1-phenylethanol charged, as shown in Fig. 3, where the concentration ranged from 0.4 to 2.5 M.

As for the mechanism of the present hydrogen transfer, we propose the reaction pathway, which involves initial coordination of ketone to the $CoHP_3$ species photogenerated and the hydride transfer to the carbonyl carbon in ketone, forming an alkoxo intermediate. Subsequent reaction of the intermediate takes place with reactant alcohol to release product alcohol converted from the charged ketone, accompanied by transformation into another intermediate with the alkoxo group of the reactant alcohol. The latter intermediate is expected to afford product ketone and to regenerate the catalytic hydride $CoHP_3$ species through β-hydrogen elimination. As mentioned above (Fig. 2), the linear relationship was observed on the double reciprocal plots of the initial reaction rates and the concentrations of the ketones charged, in sharp contrast to the case of the alcohols where their concentrations did not affect significantly the initial reaction rates in the concentration range under discussion. By analogy with the Michaelis-Menten model,[11] this result supported coordination equilibrium of ketones to $CoHP_3$ in our proposed reaction pathway. Moreover, pulsed laser photolysis of $CoHP_4$ was performed in the presence of some substrates used in this study, and confirmed ketone coordination to the photogenerated $CoHP_3$ species (vide infra).

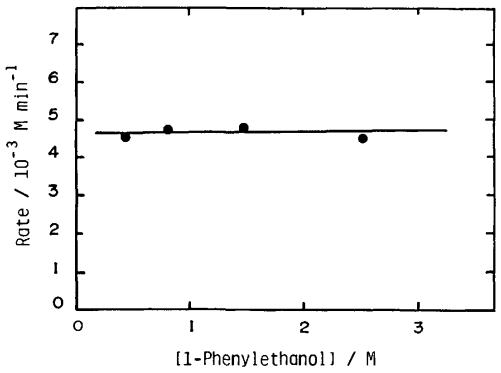

Fig. 3. Dependence of the initial reaction rate on the 1-phenylethanol concentration. CoH[PPh(OEt)2]4, 0.0165 M; cyclohexanone, 0.82 M.

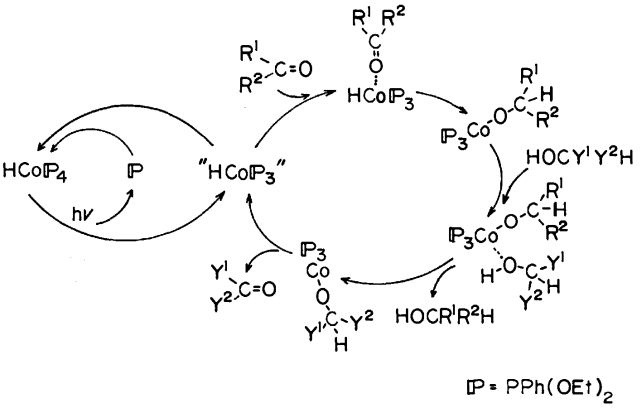

Hydrogen Transfer to 4-Alkyl-Substituted Cyclohexanones. 4-Alkyl-substituted cyclohexanones were employed as hydrogen acceptors in the photoassisted hydrogen-transfer reaction with the cobalt complex, to study stereoselectivity in reduction of the carbonyl groups. The hydrogen-transfer reaction of 1-phenylethanol with 4-methylcyclohexanone in benzene for 4 h gave 4-methylcyclohexanols with the cis/trans isomer ratio of about 2.1 in a 65% conversion, whereas similar reaction of neat 2-propanol showed the cis/trans ratio of 2.4 with the 87% conversion. For 4-*t*-butylcyclohexanone, the hydrogen-transfer reaction of 1-phenylethanol in benzene proceeded slowly to give 2.2 and 19% for the cis/trans value and the conversion, respectively. Free-energy difference between cis and trans 4-*t*-butylcyclohexanols has been described to be about 0.5 kcal mol^{-1},[12] which led to a value of 0.43 for the cis/trans ratio in the thermodynamically equilibrated state at 30 °C. It was determined that the present photoassisted hydrogen transfer with $CoHP_4$ afforded kinetically controlled product composition rather than thermodynamically controlled one, and preferred formation of thermodynamically less stable cis isomers. During the course of the probable transformation of hydrido(4-alkylcyclohexanone)cobalt species to cis and trans (4-alkylcyclohexyloxy)cobalt through hydride transfer to the carbonyl carbon, steric

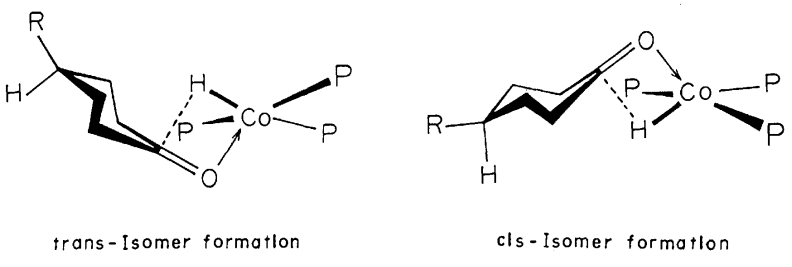

Fig. 4. Formation of trans and cis 4-substituted cyclohexanols.

approach control was presumed to prefer less sterically hindered pathway effectively, which afforded axial i.e. cis cyclohexanols.

Hydrogen Transfer to *p*-Substituted Benzaldehydes. In the hope to obtain some further clues to the present reaction mechanism, we performed the hydrogen transfer from neat 2-propanol to some *p*-substituted benzaldehydes, and studied substituent effect on the initial formation rates of the corresponding benzyl alcohols. Figure 5 shows good linear relationship of the logarithmic formation rates with the respective Hammett substituent constants σ_p^+. The reaction constant (the gradient of the linear relationship) ρ and the correlation coefficient were 1.348 and 0.997, respectively. Positive reaction constant ρ implys that the rate was enhanced by withdrawal of electron density from the reaction site. In connection with the above-described observation of the kinetically controlled hydrogen transfer to 4-alkyl-substituted cyclohexanones, this fact led us to conclude that the important rate-determining step was the hydride transfer to the carbonyl carbon with partial positive charge, at the stage of the transformation of hydrido-(aldehyde or ketone)cobalt into alkoxocobalt intermediate.[13] Subsequent reaction of the alkoxo intermediate with secondary reactant alcohols was assumed to be fast, in conformity with the finding that the initial hydrogen-transfer rate was not dependent apparently on the concentration of secondary alcohols charged (Fig. 3).

Laser Flash Photolysis and Substrate Coordination to $CoHP_3$. Laser flash photolysis of $CoHP_4$ was performed at 337 nm using a nitrogen laser in the presence of some substrates, such as cyclohexanone and 1-phenylethanol in benzene at room temperature. In the time-resolved absorption spectra, we monitored the decay of the transient bands of photogenerated $CoHP_3$ at 580 and 760 nm, due to recombination with free phosphonite and to substrate coordination. Table 1 summarizes the second-order coordination-rate constants k' of these and some related substrates.[5c,14]

$$-\frac{d[CoHP_3]}{dt} = k[CoHP_3][P] + k'[CoHP_3][\text{Substrate}]$$

P=$PPh(OEt)_2$, $k=1.4\times10^8\,M^{-1}s^{-1}$

The constants k' of ketones and aldehydes ranged from 10^5 to $10^8\ M^{-1}\ s^{-1}$, whereas those of the secondary alcohols were very small and undetermined explicitly. Therefore, this result confirmed the ketone coordination to the photogenerated $CoHP_3$ species, in the above-described reaction pathway concerning the photoassisted hydrogen transfer with $CoHP_4$. Moreover, Table 1 shows the constants k' of aldehydes were considerably larger than those of ketones. When the photogenerated $CoHP_3$ species approach the carbonyl groups in these compounds, interaction of the species was initiated with the HOMO of the groups, which expand mainly over the sp^2-hybrid plane,[15] as illustrated in Fig. 6. In the case of aldehydes, the $CoHP_3$ species can approach the carbonyl group easily through the less hindered side including the aldehyde hydrogen on the hybrid plane. However, in the case of ketones, substantial steric repulsion by the bulky

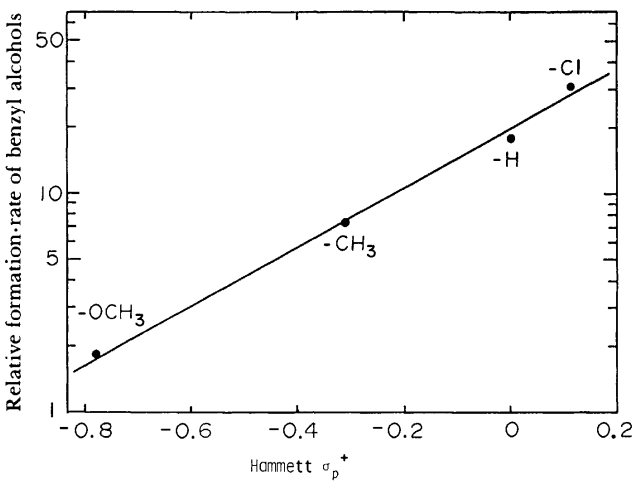

Fig. 5. Plots of the logarithmic formation rate of *p*-substituted benzyl alcohols against Hammett σ_p^+. $CoH[PPh(OEt)_2]_4$, 5×10^{-3} M; *p*-substituted benzaldehyde, 0.2 M; solvent, 2-propanol; temperature, 30°C.

Table 1. Second-Order Rate Constants k' ($M^{-1}\ s^{-1}$) for Coordination

	8.6×10^5		Negligible
	3.2×10^5		Negligible
	1.6×10^8		9.4×10^6
	1.1×10^8		9.1×10^6

substituents introduced in place of the aldehyde hydrogen, was presumed to hinder the $CoHP_3$ approach to the carbonyl group. Steric factor was described previously to be dominant in the magnitude of the constants k' for aliphatic amines.[14]

It is noteworthy also that methylenecyclohexane showed a comparable value of the rate constant to that of 2-phenylpropene, whereas the constant of cyclohexanone was larger than that of acetophenone by a factor of ca. 2.7. In the cases of the former two substrates of olefins, the $CoHP_3$ species was attracted by the olefinic π-bond electrons and approached the axial site over the sp^2-hybrid plane of the two double-bonded carbons. On the other hand for the ketones, the species approached the HOMO expanded mainly over the sp^2-hybrid plane of the carbonyl groups, and steric factor was assumed to work in this planar approach process.

Concluding Remarks

Photogenerated hydride transient $CoHP_3$ catalyzed intermolecular hydrogen transfer from secondary alcohols to carbonyl compounds such as ketones. The catalytic reaction was initiated by coordination of the carbonyl compounds to $CoHP_3$. The rate-determining step was associated with the hydride transfer to the carbonyl carbon, at the stage of the transformation of hydrido(ketone or aldehyde)cobalt into alkoxo intermediate.

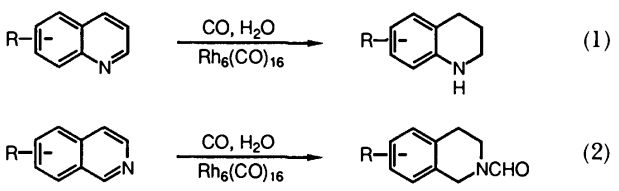
Rhodium Catalyzed Hydrogenation of Quinolines and Isoquinolines under Water-Gas Shift Conditions

Shun-Ichi MURAHASHI,* Yasushi IMADA, and Yoshiaki HIRAI
Department of Chemistry, Faculty of Engineering Science, Osaka University, Machikaneyama, Toyonaka, Osaka 560
(Received May 12, 1989)

Wide variety of quinolines and isoquinolines can be hydrogenated selectively in the nitrogen-containing ring by means of carbon monoxide and water in the presence of catalytic amount of rhodium carbonyl cluster. These reactions provide a useful method for the preparation of 1,2,3,4-tetrahydroquinolines and 1,2,3,4-tetrahydroisoquinolines which are key intermediates for the synthesis of isoquinoline alkaloids and other biologically active nitrogen compounds.

Polynuclear nitrogen heteroaromatic compounds, such as quinolines and isoquinolines are much contained in coal, oil shale, and tar sands.[1] Selective hydrogenation of these nitrogen heteroaromatics provides potential means for utilization of these natural resources, and various synthetic key intermediates can be obtained. 1,2,3,4-Tetrahydroquinoline derivatives are synthetic intermediates for drugs,[2] agrochemicals,[3] and dyes,[4] while 1,2,3,4-tetrahydroisoquinoline derivatives are useful precursors of isoquinoline alkaloids.[5] Water-gas shift reactions are of importance in view of energy problem because hydrogen can be generated from water and carbon monoxide, which is readily available from low-grade carbonaceous materials such as coal, oil shale, tar sands, and lignite.[6] The metal hydride species which are formed as intermediates of water-gas shift reactions, can be used directly as reducing agents. Therefore, the reduction of various substrates such as nitroarenes, carbonyl compounds, and α,β-unsaturated ketones and nitriles have been studied under water-gas shift conditions.[7]

We have found that hydrogenation of wide variety of quinolines and isoquinolines can be performed selectively under water-gas shift conditions as depicted by Eqs. 1 and 2.[8] The results are different from those obtained from the catalytic hydrogenations of nitrogen aromatics under molecular hydrogen.[9,10] Reduction of nitrogen heteroaromatics using carbon monoxide and water has been studied. Laine[11] reported that the reduction of pyridine to piperidine was catalyzed by rhodium complex. Fish and Kaezs reported that $Fe(CO)_5$[12,13] and $Mn_2(CO)_8(PBu_3)_2$[12] catalyzed the hydrogenation reaction in the presence of base such as KOH. As compared with these reports, we describe the full details of our reactions, which can be utilized for the selective hydrogenation of various types of substituted quinolines and isoquinolines.



Results and Discussion

Hydrogenation of Quinolines. Quinolines are hydrogenated selectively in the nitrogen containing ring to give 1,2,3,4-tetrahydroquinolines under water-gas shift conditions. The catalytic activity of various metal carbonyls was examined with respect to the reaction of quinoline (**1**). The representative results are shown in Table 1. Rhodium carbonyl cluster $Rh_6(CO)_{16}$ gave the best results. The exclusive product detected during the reaction was 1,2,3,4-tetrahydroquinoline (**2**), and neither 5,6,7,8-tetrahydroquinoline nor decahydroquinoline were obtained. Rhodium clusters such as $Rh_4(CO)_{12}$ and $[Rh(COD)Cl]_2$ and ruthenium clusters such as $Ru_3(CO)_{12}$ gave good results. Other metal carbonyls such as $W(CO)_6$ and $Fe(CO)_5$ did not produce the hydrogenated product under the present conditions. Although $Fe(CO)_5$ has been reported to be an active catalyst for the hydrogenation of quinoline in the presence of KOH,[13] the catalytic activity was not

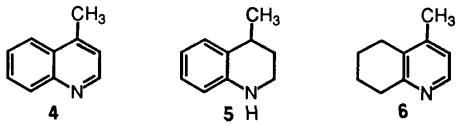
observed under the present conditions. The addition of bases enhances the catalytic activity of transition metal carbonyls under water-gas shift conditions.[14] The key point of the present reaction is that quinolines behave as bases to enhance the hydrogenation and are also reduced regioselectively in the nitrogen-containing ring. Most of the solvents examined such as, 2-methoxyethanol, toluene, dioxane, and dimethylformamide gave good results; however, chloroform retarded the reaction. Without a solvent **2** was obtained in low yields.

The representative results of the hydrogenation of quinolines under water-gas shift conditions are summarized in Table 2. In general, 1,2,3,4-tetrahydroquinolines are obtained selectively under the present reaction conditions. Substituted quinolines have been recovered under the conditions using $Fe(CO)_5$ catalyst.[13] It is noteworthy that 4-methylquinoline (**4**) can be converted into 4-methyl-1,2,3,4-tetrahydroquinoline (**5**) selectively (Entry 3) under the present water-gas shift conditions. In the nickel catalyzed hydrogenation of methyl substituted quinolines with molecular hydrogen, substituent on the benzene ring leads to exclusive formation of 1,2,3,4-tetrahydroquinolines, while substituent loading of the pyridine ring favors the formation of 5,6,7,8-tetrahydro compounds.[15] Typically, tetrahydroquinoline **5** was obtained selectively in 91% yield under the present reaction conditions. However, catalytic hydrogenation of **4** afforded a mixture of **5** and 4-methyl-5,6,7,8-tetrahydroquinoline (**6**) in 33% and 66% yields, respectively. The $Rh_6(CO)_{16}$ catalyzed hydrogenation of **4** under hydrogen (10 kg cm^{-2}) also gave **6** exclusively



(50% conversion). Moreover, the hydrogenation of 2,4-dimethylquinoline (**10**) under the present conditions gave 2,4-dimethyl-1,2,3,4-tetrahydroquinoline (**11**) exclusively in 89% yield (Entry 6), while the hydrogenation of **10** with nickel catalyst under molecular hydrogen gave **11** only in 20% yield along with 80% of 5,6,7,8-tetrahydroquinoline.[15] The cis/trans ratio of

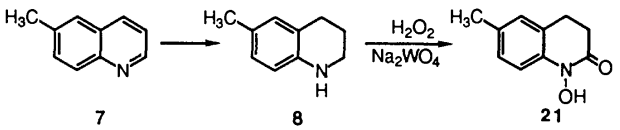
11 was determined to be 7/3 on the basis of ^1H and ^{13}C NMR analyses.

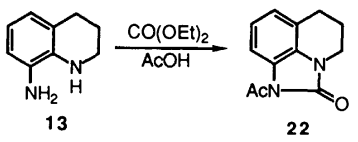
Quinolines bearing other functional groups also undergo the hydrogenation on the pyridine ring to give the corresponding 1,2,3,4-tetrahydroquinolines. These results are summarized in Table 3. 8-Nitroquinoline (**12**) was reduced under the rhodium catalyzed water-gas shift conditions (48 h) to give 8-amino-1,2,3,4-tetrahydroquinoline (**13**) exclusively (Entry 1), while the same reaction of **12** for shorter time (24 h) gave **13** and 8-aminoquinoline (**14**) in 61% and 16% yields, respectively. 8-Aminoquinoline **14** was also converted into **13** highly efficiently (Entry 2). Therefore, the reduction of the nitro group of **12** proceeds faster than that of the pyridine ring. 5-Aminoquinoline was also converted into 5-amino-1,2,3,4-tetrahydroquinoline (**15**) (Entry 3). The reaction of 2-quinolinecarboxylic acid afforded 2-methoxyethyl 1,2,3,4-tetrahydroquinoline-2-carboxylate (**16**) (Entry 4), which was formed by hydrogenation followed by esterification with 2-methoxyethanol. 6-Chloroquinoline (**17**) was converted into 6-chloro-1,2,3,4-tetrahydroquinoline (**18**) selectively without cleavage of carbon–halogen bond (Entry 5). By using this product, various functional groups can be introduced at 6-position of tetrahydroquinolines.

The tetrahydroquinolines thus obtained are valuable synthetic intermediates. Tungstate catalyzed oxidation of tetrahydroquinolines with hydrogen peroxide gives the corresponding hydroxamic acids,[16] which show antibacterial activity[17] and also are precursors of biologically active compounds, such as 3,4-dihydrocarbostyril compounds. Typically, the treatment of tetrahydroquinoline **8**, which was obtained from **7** in 96% yield, with aqueous 30% hydrogen peroxide in the presence of catalytic amount of Na_2WO_4 gave 1-hydroxy-6-methyl-1,2,3,4-tetrahydroquinolin-2-one (**21**)



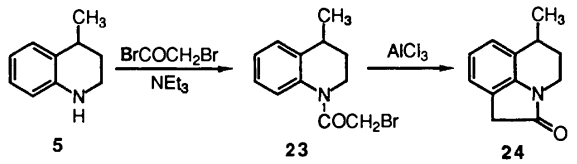
7 8 **21**

in 82% yield. Amino-1,2,3,4-tetrahydroquinolines are useful precursors of hair coloring compositions[4] and fungicides.[18] Treatment of **13** with diethyl carbonate in acetic acid gave 1,2,5,6-tetrahydroimidazoquinolin-2-one **22**.[18] Furthermore, the reaction of **5** with



13 22

bromoacetyl bromide followed by intramolecular alkylation gives 1,2,5,6-tetrahydropyrroloquinolin-2-one **24**, which has pharmacological activity and has been used as CNS depressant agents.[19]



5 23 24

Next, the reactivity of four 6-substituted quinolines, that is, quinoline (**1**), 6-methylquinoline (**7**), 6-chloroquinoline (**17**), and 6-methoxyquinoline (**19**) was compared. The results are listed in Table 4. Quinolines **1** and **17** were reduced completely within 5 h; however, the conversion of quinolines **7** and **19** were only 30% and 35% after 5 h and 70% and 80% after 10 h, respectively. The rate difference seems to reflect electronic requirement of substituents at the 6-position. Thus, electron withdrawing substituents such as chloro group accelerate the reaction, while electron donating substituents retard the reactivity.

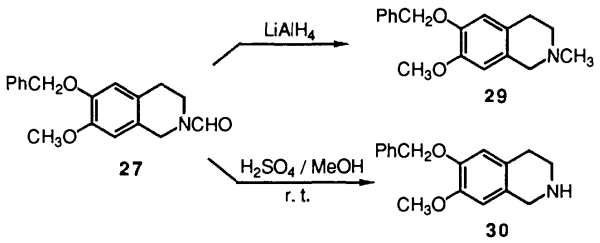
Table 4. Reactivity of Quinolines **1**, **7**, **17**, and **19** for the Hydrogenation[a]

Run time	Convn. of quinolines[b]/%			
	1	**17**	**7**	**19**
5 h	>98	>98	30	35
12 h			70	80
24 h			>98	>98

a) A mixture of quinoline (2.31 mmol), $Rh_6(CO)_{16}$ (0.0188 mmol), and water (0.5 ml) in 2-methoxyethanol (2 ml) was heated at 150 °C under the pressure of CO (56 kg cm^{-2}). b) Determined by 270 MHz ^{1}H NMR analysis.

Hydrogenation of Isoquinolines. Isoquinolines were converted into *N*-formyl-1,2,3,4-tetrahydroisoquinolines under the same conditions. Typically, the reaction of isoquinoline gave *N*-formyl-1,2,3,4-tetrahydroisoquinoline (**25**) in 69% isolated yield. When the same reaction was carried out for shorter reaction time, a mixture of **25** and 1,2,3,4-tetrahydroisoquinoline (**26**) was obtained, indicating that initial formation of **26** and subsequent *N*-formylation. The *N*-formylation of tetrahydroisoquinoline **26** may be due to higher basicity of nitrogen of **26** in comparison with **2**. Indeed, **25** was obtained from **26** in 76% yield under the same conditions. The representative results of the hydrogenation of isoquinolines are summarized in Table 5. It is noteworthy that benzyloxy group torelates the reaction, although benzyloxy group is readily removed by reductive cleavage under usual hydrogenation conditions. Thus, 6-benzyloxy-7-methoxyisoquinoline was converted into the corresponding *N*-formyl-6-benzyloxy-7-methoxy-1,2,3,4-tetrahydroisoquinoline (**27**) (Entry 2).

N-Formyltetrahydroisoquinolines thus obtained can be readily converted into *N*-methyltetrahydroisoquinolines upon treating with $LiAlH_4$. Thus, the reduction of **27** with $LiAlH_4$ gave 6-benzyloxy-7-methoxy-*N*-methyl-1,2,3,4-tetrahydroisoquinoline (**29**) selectively in 83% yield. *N*-Formyl group on 1,2,3,4-tetrahydroisoquinolines can be removed readily by acid catalyzed hydrolysis. Thus, when *N*-formyl compound **27** was allowed to react with sulfuric acid in methanol (1/9) at



27 29 30

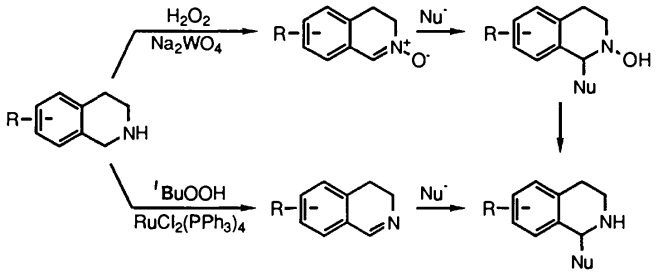
Table 5. Hydrogenation of Isoquinolines under Water-Gas Shift Conditions[a]

Entry	Isoquinoline	Tetrahydroisoquinoline	Yield[b]/%
1		 **25**	69
2		 **27**	65
3		 **28**	66

a) A mixture of isoquinoline (2.31 mmol), $Rh_6(CO)_{16}$ (0.0188 mmol), and water (0.5 ml) in 2-methoxyethanol (2 ml) was heated at 150 °C for 24 h under the pressure of CO (56 kg cm^{-2}). b) Isolated yield.

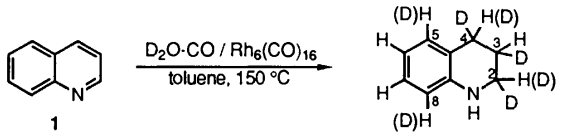
room temperature, 6-benzyloxy-7-methoxy-1,2,3,4-tetrahydroisoquinoline (**30**) was obtained in 95% yield. 6,7-Dimethoxy-1,2,3,4-tetrahydroisoquinoline (**31**) was also obtained upon hydrolysis of *N*-formyl-6,7-dimethoxy-1,2,3,4-tetrahydroisoquinoline (**28**) in 96% yield.

The tetrahydroisoquinolines thus obtained are quite useful synthetic intermediates. Introduction of substituents at position 1 of tetrahydroisoquinolines can be performed readily by using our recently developed methods, that is, oxidation of secondary amines to give either imines[20] or nitrones[21] and subsequent treatment of these intermediates with nucleophiles as shown in Scheme 1.



Scheme 1.

Mechanisms. The hydrogenation of quinoline **1** using deuterium oxide in place of water in toluene was examined. The product of deuterated 1,2,3,4-tetrahydroquinoline was analyzed by 270 MHz ^{1}H NMR spectroscopy, and the results were shown in Scheme 2. The product obtained after 5 h had 1.2 deuteriums at position 2, 1.0 deuterium at position 3, 1.2 deuteriums at position 4, and 0.2 deuterium at each positions 5 and 8. The product obtained after 24 h had 1.7 deuteriums at position 2, 1.0 deuterium at position 3, 1.2 deuteriums at position 4, and 0.9 deuterium at each positions 5 and 8. When 1,2,3,4-tetrahydroquinoline (**2**) was subjected to the same conditions for 5 h, the product had 0.1 deuterium at position 2 and 0.8 deuterium each at positions 5 and 8, and no deuterium incorporation was observed at positions 3 and 4 as shown in Scheme 3. Thus, water must be the hydrogen source in the present hydrogenation reaction, and each 1.0 deuterium was introduced at the positions of 2, 3, and 4. The deuterium incorporation at positions 5 and 8 may be due to the exchange of the aromatic hydrogen of **2** rather than **1**. The deuterium incorporation at positions 5 and 8 in **2** is noteworthy, although specific reason has not been clarified yet. The deuterium incorporation at position 2 in **2** is derived from dehydrogenation–hydrogenation process of **2** via intermediacy imine metal complex.[22,23]



position	2	3	4	5	8

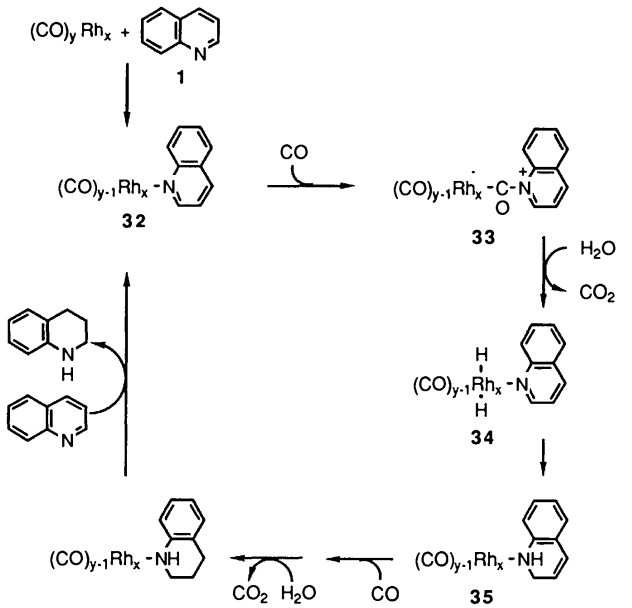
5 h	0.1	0	0	0.8	0.8

Scheme 3.

Although the exact nature of the active species still remains unspecified, a hydrido rhodium carbonyl species[24] seems to be the active catalyst. Recently Fish[25] reported that **1** reacts with mononuclear rhodium dication complex to form N-bounded rhodium–quinoline complex, while **2** complexes with π-bonding rather than N-bonding. Laine[26] and Fish[27] isolated ruthenium–quinoline complexes by the reaction of **1** with $Ru_3(CO)_{12}$, and the structure of the complexes has been characterized as triangle of ruthenium atoms with **1** bound to the cluster to the nitrogen and the 2-carbon atoms. The catalytic cycle is rationalized by assuming Scheme 4. The first step is the coordination of quinoline to the rhodium catalyst to give the N-bounded rhodium–quinoline complex **32**. Water-gas shift reactions induced by rhodium and ruthenium catalysts are promoted by amines, and hence amine-coordinated complexes have been considered to be active species.[14a,c] The water-gas shift reaction gives quinoline-coordinated rhodium hydride species **34**. Subsequent intramolecular addition of nitrogen-bounded rhodium hydride to the pyridine ring of



Scheme 4.

quinoline results in regioselective reduction to give **35**, Similar reaction of **35** with carbon monoxide and water gives 1,2,3,4-tetrahydroquinoline along with **32**.

In summary, the rhodium carbonyl cluster catalyzes the hydrogenation of a wide variety of quinolines by means of water and carbon monoxide. The hydrogenation proceeds regioselectively to give 1,2,3,4-tetrahydroquinolines efficiently. Similar treatment of isoquinolines affords the corresponding *N*-formyl-1,2,3,4-tetrahydroisoquinolines.

Experimental

General. All melting points were determined in capillary tubes and are uncorrected. IR spectra were recorded on a Hitachi 215 spectrometer. NMR spectra were obtained on JEOL JNM PMX-60SI (60 MHz for ^1H) and JEOL JNM GSX-270 (270 MHz for ^1H and 67.9 MHz for ^{13}C) spectrometers; chemical shifts (δ) were expressed in parts per million down field from tetramethylsilane. Analytical GLC evaluations of products mixtures were carried out on Shimadzu GC-9A flame ionization gas chromatograph by using a 1 m×4 mm analytical column (10% SE-30 on 60—80 mesh Uniport HP). Preparative TLC was performed on glass plates coated with Merck silica gel 60 PF_{254} (art. 7747). Mass spectra were obtained on a Hitachi RMS-4 or Shimadzu GCMS-QP1000 mass spectrometers. Elemental analyses were performed on a Yanagimoto MT-3 CHN corder.

Materials. $Rh_6(CO)_{16}$ (Nippon Engelhald Co., Ltd.) and other metal catalysts were commercially available and used as received, except $Fe(CO)_5$ which was distilled prior to use and $Mo(CO)_6$ which was sublimed prior to use. 2-Methoxyethanol was commercially available and used as received. Quinolines and isoquinolines were commercially available and used as received except 8-aminoquinoline, 5- and 8-nitroquinoline,[28] 6-benzyloxy-7-methoxyisoquinoline, and 6,7-dimethoxyisoquinoline[29] which were prepared according to the reported procedure.

Catalytic Activity of Various Metal Complexes. A mixture of quinoline (**1**), metal complex, H_2O (0.5 mL), and 2-methoxyethanol (2 mL) was heated at 150 °C for 12 h in a 10-mL stainless-steel autoclave under the pressure of CO (56 kg cm^{-2}). The conversion of **1** and the yield of 1,2,3,4-tetrahydroquinoline (**2**) were determined by the GLC analysis of the reaction mixture using an internal standard (dodecane). The results with various catalysts are shown in Table 1.

General Procedure for Hydrogenation of Quinolines and Isoquinoline under Water-Gas Shift Conditions. In a 10-mL stainless-steel autoclave equipped with a magnetic stirring bar were placed quinoline (2.31 mmol), $Rh_6(CO)_{16}$ (0.020 g, 0.0188 mmol), H_2O (0.5 mL, 27.8 mmol), and 2-methoxyethanol (2.0 mL). The autoclave was sealed and degassed by three 5 kg cm^{-2} pressurization/depressurization cycles with CO. The autoclave was then charged to 56 kg cm^{-2} of CO and heated with stirring a 150 °C for 24 h. After the autoclave was cooled to room temperature, the pressure was released. The reaction mixture was taken up with chloroform and filtered through a pad of Florisil (3 g, 14×55 mm). After removal of the solvent under reduced pressure, the product was purified by means of silica-gel column chromatography (ca. 5 g, eluents are described below) or Kugelrohr distillation. These results are summarized in Tables 2, 3, and 5.

1,2,3,4-Tetrahydroquinoline (2): Bp 126—127 °C/3 mmHg (1 mmHg≈133.3 Pa) (Kugelrohr); R_f 0.83 (SiO_2, ethyl acetate); ^1H NMR ($CDCl_3$, 270 MHz) δ=1.91 (2H, tt, J=6.3 and 5.8 Hz, H^3), 2.74 (2H, t, J=6.3 Hz, H^4), 3.26 (2H, t, J=5.8 Hz, H^2), 3.76 (1H, br-s, NH), 6.43 (1H, d, J=7.4 Hz, H^8), 6.58 (1H, t, J=7.2 Hz, H^6), and 6.90—6.98 (2H, m, H^5 and H^7).

Found: C, 81.26; H, 8.34; N, 10.41%. Calcd for $C_9H_{11}N$: C, 81.16; H, 8.33; N, 10.52%.

2-Methyl-1,2,3,4-tetrahydroquinoline (3): Bp 126 °C/5 mmHg (Kugelrohr); R_f 0.69 (SiO_2, ethyl acetate-hexane=1:4); IR (neat) 3400 (NH), 2940, 2860, 1615, 1500, 1320, and 775 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.19 (3H, d, J=6.3 Hz, CH_3), 1.57 (1H, dddd, J=12.8, 11.4, 9.9, and 5.5 Hz, H^{3a}), 1.91 (1H, dddd, J=12.8, 5.6, 3.5, and 2.9 Hz, H^{3e}), 2.71 (1H, ddd, J=16.4, 5.5, and 3.5 Hz, H^{4e}), 2.83 (1H, J=16.4, 11.4, and 5.6 Hz, H^{4a}), 3.38 (1H, ddq, J=9.9, 6.3, and 2.9 Hz, H^2), 3.60 (1H, br-s, NH), 6.45 (1H, dd, J=8.1 and 1.2 Hz, H^8), 6.59 (1H, ddd, J=7.3, 7.3, and 1.2 Hz, H^6), and 6.90—6.99 (2H, m, H^5 and H^7); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=22.6, 26.6, 30.2, 47.2, 114.0, 117.0, 121.1, 126.7, 129.3, and 144.8.

Found: C, 81.36; H, 8.80; N, 9.43%. Calcd for $C_{10}H_{13}N$: C, 81.58; H, 8.90; N, 9.52%.

4-Methyl-1,2,3,4-tetrahydroquinoline (5): Bp 150 °C/5 mmHg (Kugelrohr); IR (neat) 3400 (NH), 2960, 2860, 1610, 1585, 1500, 1360, 1315, 1070, and 740 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.25 (3H, d, J=7.1 Hz, CH_3), 1.62 (1H, dddd, J=12.8, 6.4, 6.4, and 3.8 Hz, H^{3e}), 1.92 (1H, J=12.8, 8.2, 5.3, and 4.2 Hz, H^{3a}), 2.80—2.92 (1H, m, H^4), 3.17 (1H, ddd, J=11.2, 6.4, and 4.2 Hz, H^{2e}), 3.25 (1H, ddd, J=11.2, 8.2, and 3.8 Hz, H^{2a}), 3.75 (1H, br-s, NH), 6.39 (1H, dd, J=7.9 and 1.2 Hz, H^8), 6.59 (1H, ddd, J=7.5, 7.5, and 1.2 Hz, H^6), 6.92 (1H, ddd, J=7.9, 7.5, and 1.2 Hz, H^7), and 7.01 (1H, d, J=7.5 Hz, H^5); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=22.6, 29.9, 30.2, 39.0, 114.1, 116.8, 126.5, 126.7, 128.3, and 144.3; mass spectrum (80 eV), m/z (relative intensity) 147 (M^+, 44), 146 (M^+-1, 10), 133 (100), and 118 (26).

Found: C, 81.46; H, 8.95; N, 9.46%. Calcd for $C_{10}H_{13}N$: C, 81.58; H, 8.90; N, 9.52%.

6-Methyl-1,2,3,4-tetrahydroquinoline (8): Bp 144—145 °C/5 mmHg (Kugelrohr); IR (neat) 3350 (NH), 3000, 2900, 2830, 1610, 1510, 1260, and 800 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.87—1.96 (2H, m, H^3), 2.19 (3H, s, CH_3), 2.72 (2 H, t, J=6.5 Hz, H^4), 3.25 (2H, t, J=5.5 Hz, H^2), 3.51 (1H, br-s, NH), 6.38 (1H, d, J=8.5 Hz, H^8), and 6.75—6.78 (2H, m, H^5 and H^7); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=20.4, 22.5, 26.9, 42.2, 114.5, 121.6, 126.2, 127.3, 130.1, and 142.4.

Found: C, 81.64; H, 8.80; N 9.44%. Calcd for $C_{10}H_{13}N$: C, 81.58; H, 8.90; N, 9.52%.

8-Methyl-1,2,3,4-tetrahydroquinoline (9): Bp 148—150 °C/5 mmHg (Kugelrohr); R_f 0.79 (SiO_2, ethyl acetate); IR (neat) 3400 (NH), 2930, 2840, 1600, 1490, 1360, 1310, 1270, 1190, 1110, 750, and 730 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.92 (2H, tt, J=6.4 and 5.5 Hz, H^3), 2.05 (3H, s, CH_3), 2.77 (2H, t, J=6.4 Hz, H^4), 3.34 (2H, t, J=5.5 Hz, H^2), 3.60 (1H, br-s, NH), 6.54 (1H, dd, J=7.4 and 7.4 Hz, H^6), and 6.80—6.88 (2H, m, H^5 and H^7); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=17.1, 22.1, 27.3, 42.3, 116.4, 120.8, 121.1, 127.3, 127.8, and 142.7.

Found: C, 81.60; H, 8.87; N, 9.41%. Calcd for $C_{10}H_{13}N$: C, 81.58; H, 8.90; N, 9.52%.

2,4-Dimethyl-1,2,3,4-tetrahydroquinoline (11): Bp 143—144 °C/4 mmHg (Kugelrohr); R_f 0.70 (SiO_2, ethyl acetate);

IR (neat) 3370 (NH), 3040, 2960, 2850, 1610, 1580, 1480, 1300, 1260, 1170, 1160, 1130, 1040, and 840 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.17 (3H×0.7, d, J=6.2 Hz, cis-2-CH_3), 1.19 (3H×0.3, d, J=6.2 Hz, trans-2-CH_3), 1.26 (3H×0.3, d, J=7.2 Hz, trans-4-CH_3), 1.31 (3H×0.7, d, J=6.7 Hz, cis-4-CH_3), 1.34 (1H×0.7, ddd, J=12.8, 11.2, and 11.1 Hz, cis-H^{3a}), 1.636 (1H×0.3, dd, J=6.5 and 4.0 Hz, trans-H^{3a}), 1.638 (1H×0.3, dd, J=7.5 and 5.0 Hz, trans-H^{3e}), 1.91 (1H×0.7, ddd, J=12.8, 5.3, and 2.6 Hz, cis-H^{3e}), 2.80—3.00 (1H, m, H^4), 3.30—3.55 (1H, m, H^2), 3.47 (1H, br-s, NH), 6.44 (1H×0.7, dd, J=7.9 and 1.2 Hz, cis-H^8), 6.47 (1H×0.3, dd, J=7.9 and 1.2 Hz, trans-H^8), 6.58—6.66 (1H×0.3, m, trans-H^6), 6.64 (1H×0.7, ddd, J=7.6, 7.5, and 1.2 Hz, cis-H^6), 6.91—6.99 (1H×0.3, m, trans-H^7), 6.96 (1H×0.7, ddd, J=7.9, 7.5, and 1.2 Hz, cis-H^7), 6.99—7.04 (1H×0.3, m, trans-H^5), and 7.12 (1H×0.7, ddd, J=7.6, 1.2, and 1.2 Hz cis-H^5); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=20.3 (cis-4-CH_3), 22.7 (2-CH_3), 24.8 (trans-4-CH_3), 30.1 (trans-C^4), 30.8 (cis-C^4), 37.1 (trans-C^3), 40.6 (cis-C^3), 42.3 (trans-C^2), 47.3 (cis-C^2), 113.9 (cis-C^8), 114.0 (trans-C^8), 116.9 (trans-C^6), 117.2 (cis-C^{6a}), 126.2 (C^{4a}), 126.6 (trans-C^7), 126.7 (cis-C^7), 126.8 (cis-C^5), 129.1 (trans-C^5), 144.1 (trans-C^{8a}), and 144.7 (cis-C^{8a}).

Found: C, 82.05; H, 9.39; N, 8.57%. Calcd for $C_{11}H_{15}N$: C, 81.93; H, 9.38; N, 8.69%.

8-Amino-1,2,3,4-tetrahydroquinoline (13): Bp 172 °C/5 mmHg (Kugelrohr); R_f 0.62 (SiO_2, ethyl acetate); IR (neat) 3330 (NH), 3050, 2930, 2850, 1600, 1500, 1330, 1290, 1250, 1180, 1100, 990, 760, and 730 cm^{-1}; ^1H NMR ($CDCl_3$, 60 MHz) δ=1.65—2.15 (2H, m, H^3), 2.73 (2H, t, J=6.0 Hz, H^4), 3.13 (3H, br-s, NH and NH_2), 3.10—3.43 (2H, m, H^2), and 6.50 (3H, s, ArH).

Found: C, 72.85; H, 8.20; N, 18.73%. Calcd for $C_9H_{12}N_2$: C, 72.94; H, 8.16; N, 18.90%.

5-Amino-1,2,3,4-tetrahydroquinoline (15): Mp 102 °C; R_f 0.76 (SiO_2, ethyl acetate); IR (Nujol) 2870, 1580, 1340, 1250, 1170, 1130, and 760 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.00 (2H, tt, J=6.6 and 5.4 Hz, H^3), 2.47 (2H, t, J=6.6 Hz, H^4), 3.23 (2H, t, J=5.4 Hz, H^2), 3.52 (3H, br-s, NH and NH_2), 5.99 (1H, d, J=7.9 Hz), 6.07 (1H, d, J=7.9 Hz), and 6.79 (1H, dd, J=7.9 and 7.9 Hz, H^7); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=21.5, 22.4, 41.4, 104.7, 105.6, 106.8, 127.0, 144.9, and 145.8.

Found: C, 72.77; H, 8.13; N, 18.82%. Calcd for $C_9H_{12}N_2$: C, 72.94; H, 8.16; N, 18.90%.

2-Methoxyethyl 1,2,3,4-Tetrahydroquinoline-2-carboxylate (16): Bp 230—232 °C/7 mmHg (Kugelrohr); R_f 0.81 (SiO_2, ethyl acetate); IR (neat) 3400 (NH), 2930, 1740 (C=O), 1610, 1590, 1500, 1200, 1120, 1040, and 740 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.01 (1H, dddd, J=12.9, 8.9, 8.9, and 5.5 Hz, H^{3a}), 2.31 (1H, dddd, J=12.9, 5.6, 5.6, and 3.8 Hz, H^{3e}), 2.74 (1H, ddd, J=16.5, 5.6, and 5.5 Hz, H^{4e}), 2.83 (1H, J=16.5, 8.9, and 5.6 Hz, H^{4a}), 3.38 (3H, s, OCH_3), 3.61 (2H, t, J=4.7 Hz), 4.0 (1H, br, NH), 4.08 (1H, dd, J=8.9 and 3.8 Hz, H^2), 4.33 (2H, t, J=4.7 Hz), 6.58 (1H, dd, J=7.9 and 0.9 Hz, H^8), 6.64 (1H, ddd, J=7.4, 7.3, and 1.2 Hz, H^6), and 6.92—7.03 (2H, m, H^5 and H^7); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=24.7, 25.8, 53.9, 59.0, 64.2, 70.3, 114.6, 117.6, 120.5, 127.0, 129.1, 143.0, and 173.3.

Found: C, 66.31; H, 7.27; N, 5.85%. Calcd for $C_{13}H_{17}NO_3$: C, 66.35; H, 7.30; N, 5.95%.

6-Chloro-1,2,3,4-tetrahydroquinoline (17): Reaction time was 12 h: IR (neat) 3400 (NH), 2930, 2840, 1600, 1580, 1495, 1470, 1350, 1300, 1270, 1180, 1080, 950, 890, and 800 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.89 (2H, tt, J=6.4 and 5.5 Hz, H^3), 2.71 (2H, t, J=6.4 Hz, H^4), 3.26 (2H, t, J=5.5 Hz, H^2), 3.75 (1H, br-s, NH), 6.36 (1H, dd, J=7.2 and 1.7 Hz, H^8), and 6.86—6.91 (2H, m, H^5 and H^7); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=21.6, 26.8, 41.7, 115.0, 120.8, 122.7, 126.3, 128.9, and 143.3.

17·HCl: Found: C, 52.89; H, 5.39; N, 6.82; Cl, 34.35%. Calcd for $C_9H_{11}NCl_2$: C, 52.97; H, 5.43; N, 6.86; Cl, 34.74%.

6-Methoxy-1,2,3,4-tetrahydroquinoline (20): Bp 162—168 °C/6 mmHg (Kugelrohr); IR (neat) 3380 (NH), 2940, 2840, 1520, 1470, 1300, 1260, 1240, 1200, 1160, 1040, and 810 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.86—1.95 (2H, m, H^3), 2.73 (2H, t, J=6.5 Hz, H^4), 3.20—3.25 (2H, m, H^2), 3.43 (1H, br-s, NH), 3.71 (3H, s, OCH_3), 6.42 (1H, d, J=8.4 Hz, H^8), and 6.53—6.60 (2H, m, H^5 and H^7); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=22.5, 27.2, 42.4, 55.8, 113.0, 115.0, 115.6, 122.9, 138.9, and 151.9.

Found: C, 73.68; H, 8.08; N , 8.46%. Calcd for $C_{10}H_{13}NO$: C, 73.59; H, 8.03; N, 8.58%.

2-Formyl-1,2,3,4-tetrahydroquinoline (25): R_f 0.44 (SiO_2 ethyl acetate); IR (neat) 2850, 1660 (C=O), 1440, 1400, 1190, 930, and 750 cm^{-1}; ^1H NMR ($CDCl_3$, 60 MHz) δ=2.90 (2H, t, J=6.0 Hz, H^4), 3.58 (2H×0.6, t, J=6.0 Hz, H^3), 3.73 (2H×0.4, t, J=6.0 Hz, H^3), 4.47 (2H×0.4, s, H^1), 4.62 (2H×0.6, s, H^1), 7.00 (4H, s, ArH), 8.10 (1H×0.6, s, NCHO), and 8.15 (1H×0.4, s, NCHO).

Found: C, 74.41; H, 6.80; N, 8.55%. Calcd for $C_{10}H_{11}NO$: C, 74.51; H, 6.88; N, 8.69%.

2-Formyl-6-benzyloxy-7-methoxy-1,2,3,4-tetrahydroisoquinoline (27): IR (neat) 2940, 1665 (C=O), 1620, 1520, 1450, 1260, 1225, 1115, 1020, 860, 750, and 700 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.72 (2H×0.4, t, J=6.1 Hz, H^4), 2.75 (2H×0.6, t, J=5.9 Hz, H^4), 3.57 (2H×0.6, t, J=5.9 Hz, H^3), 3.74 (2H×0.4, t, J=6.1 Hz, H^3), 3.84 (3H×0.6, s, OCH_3), 3.85 (3H×0.4, s, OCH_3), 4.44 (2H×0.4, s, H^1), 4.59 (2H×0.6, s, H^1), 5.10 (2H, s), 6.59 (1H×0.4, s), 6.62 (2H×0.6, s), 6.65 (1H×0.4, s), 7.26—7.45 (5H, m, Ph), 8.16 (1H×0.6, s, NCHO), and 8.22 (1H×0.4, s, NCHO); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=27.5, 29.2, 38.0, 42.0, 43.3, 47.1, 56.18, 56.24, 71.25, 71.32, 109.5, 110.0, 114.7, 114.8, 124.5, 124.7, 125.5, 126.4, 127.3, 127.86, 127.90, 128.5, 137.0, 137.1, 147.1, 148.9, 161.1, and 161.5; mass spectrum (80 eV), m/z (relative intensity) 297 (M^+, 4), 265 (3), 206 (M^+-CH_2Ph, 5), 178 (5), and 91 (100).

Found: C, 72.97; H, 6.68; N, 4.63%. Calcd for $C_{18}H_{19}NO_3$: C, 72.71; H, 6.44; N, 4.71%.

2-Formyl-6,7-dimethoxy-1,2,3,4-tetrahydroisoquinoline (28) Mp 127—128 °C; R_f 0.26 (SiO_2, ethyl acetate); ^1H NMR ($CDCl_3$, 270 MHz) δ=2.79 (2H×0.4, t, J=6.1 Hz, H^4), 2.83 (2H×0.6, t, J=5.8 Hz, H^4), 3.63 (2H×0.6, t, J=5.8 Hz, H^3), 3.78 (2H×0.4, t, J=6.1Hz, H^3), 3.85 (6H×0.6, s, OCH_3), 3.86 (6H×0.4, s, OCH_3), 4.47 (2H×0.4, s, H^1), 4.61 (2H×0.6, s, H^1), 6.58 (1H×0.4, s), 6.60 (2H×0.6, s), 6.62 (1H×0.4, s), 8.19 (1H×0.6, s, NCHO), and 8.25 (1H×0.4, s, NCHO); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=27.6, 29.3, 38.1, 42.0, 43.4, 47.1, 56.0, 56.05, 56.10, 108.9, 109.4, 111.7, 112.0, 123.8, 124.0, 125.4, 126.4, 148.0, 148.2, 148.3, 161.1, and 161.6.

Found: C, 65.02; H, 6.76; N, 6.07%. Calcd for $C_{12}H_{15}NO_3$: C, 65.13; H, 6.85; N, 6.33%.

Hydrogenation of 4 Using Molecular Hydrogen. A mixture of **4** (1.57 g, 11.0 mmol) and $Rh_6(CO)_{16}$ (0.024 g, 0.023 mmol) was heated at 200 °C for 20 h under the pressure of H_2 (10 kg cm^{-2}). After cooling to room temperature, the reaction mixture was taken up with ether and filtered. After removal of the solvent under reduced pressure, silica-gel column chromatography (ethyl acetate–hexane=3:7) afforded

4-methyl-5,6,7,8-tetrahydroquinoline (**6**) (0.680 g, 47%): R_f 0.50, (SiO_2, ethyl acetate); ^1H NMR ($CDCl_3$, 270 MHz) δ=1.82—1.88 (4H, m, H^6 and H^7), 2.20 (3H, s, CH_3), 2.64 (2H, t, J=6.1 Hz), 2.91 (2H, t, J=6.1 Hz), 6.89 (1H, d, J=4.8 Hz, H^3), and 8.22 (1H, d, J=4.8 Hz, H^2); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=18.8, 22.86, 22.91, 25.8, 33.0, 122.6, 131.1, 145.8, 146.1, and 156.7.

Oxidation of 8 to 1-Hydroxy-6-methyl-1,2,3,4-tetrahydroquinolin-2-one (21): To a mixture of **8** (0.270 g, 1.83 mmol) and sodium tungstate monohydrate (0.012 g, 0.04 mmol) in methanol (25 mL) was added dropwise 30% aqueous hydrogen peroxide (0.62 mL, 6.0 mmol) at 0 °C under nitrogen. The reaction mixture was stirred at room temperature for 24 h. After removal of methanol under reduced pressure, the solidified dark brown residue was extracted with dichloromethane (10 mL×4). The combined extracts were dried over sodium sulfate and evaporated. Silica-gel column chromatography (20×80 mm, dichloromethane–ether=9:1) gave **21** (0.267 g, 82%): mp 137.8—138.5 °C; R_f 0.35 (SiO_2, ether); IR (Nujol) 2900 (O-H), 1645 (C=O), 1285, 1245, 1215, 1080, 1025, 975, 890, 850, 820, and 740 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.30 (3H, s, CH_3), 2.72 (2H, dd, J=7.7 and 7.0 Hz, H^3), 2.90 (2H, dd, J=7.7 and 7.0 Hz, H^4), 6.95 (1H, s, H^5), 7.08 (1H, d, J=8.1 Hz), 7.25 (1H, d, J=8.1 Hz), and 8.0—10.0 (1H, br, OH); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=20.7, 24.6, 30.0, 113.0, 123.4, 128.08, 128.11, 133.4, 134.8, and 164.7.

Found: C, 67.88; H, 6.22; N, 7.83%. Calcd for $C_{10}H_{11}NO_2$: C, 67.78; H, 6.26; N, 7.91%.

Synthesis of 1-Acetyl-1,2,5,6-tetrahydro-4*H*-imidazo[4,5,1-*ij*]quinolin-2-one (22). In a 25-mL round-bottomed flask equipped with a reflux condenser were placed **13** (0.148 g, 1.00 mmol), diethyl carbonate (0.13 mL, 1.07 mmol), and acetic acid (5 mL). The mixture was stirred at 100 °C for 3 h. The reaction mixture was cooled to room temperature, basified with dilute aqueous ammonia, and extracted with chloroform (10 mL×3). The combined extracts were dried over sodium sulfate and evaporated. The residue was chromatographed on silica gel (20×80 mm, ethyl acetate–hexane=1:1 and methanol) to afford **22** (0.102 g, 49%) along with unreacted **13** (0.031 g, 21%). Thus, the yield based on consumed **13** is 62%: R_f 0.69 (SiO_2, methanol); ^1H NMR ($CDCl_3$, 60 MHz) δ=2.10 (2H, tt, J=5.5 and 6.0 Hz, H^5), 2.43 (3H, s, $NCOCH_3$), 2.85 (2H, t, J=5.5 Hz, H^6), 3.90 (2H, t, J=6.0 Hz, H^4), and 6.97—7.47 (3H, m, ArH); mass spectrum (70 eV), m/z (relative intensity) 172 (M^+-COCH_3, 100), 171 (90), 144 (14), and 130 (30).

Synthesis of 6-Methyl-1,2,5,6-tetrahydro-4*H*-pyrrolo[3,2,1-*ij*]quinolin-2-one (24). In a 50-mL round-bottomed flask were placed tetrahydroquinoline **5** (0.294 g, 2.00 mmol), bromoacetyl bromide (0.20 mL, 2.30 mmol), triethylamine (0.3 mL, 2.15 mmol), and benzene (10 mL). The reaction mixture was stirred at room temperature under argon atmosphere for 3 h. The resulting mixture was washed with water (10 mL×3) and dried over magnesium sulfate. After removal of the solvent under reduced pressure, column chromatography on silica gel (18×60 mm, ethyl acetate–hexane=1:1) gave 1-bromoacetyl-4-methyl-1,2,3,4-tetrahydroquinoline (**23**) (0.512 g, 96%).

In a 50-mL round-bottomed flask were placed **23** (0.128 g, 0.478 mmol) and aluminum chloride (0.190 g, 1.43 mmol). After the mixture was heated at 150 °C for 30 min, crushed ice was added to the reaction mixture. The resulting mixture was made alkaline with dilute aqueous ammonia and extracted with chloroform (10 mL×3). Combined organic layers were dried over magnesium sulfate. After removal of the solvent under reduced pressure, the residue was sublimed (110 °C, 5 mmHg, 10 h) to give **24** (0.058 g, 65%). **23**: R_f 0.91 (SiO_2, ethyl acetate); IR (neat) 2950, 2870, 1730, 1650, 1580, 1490, 1380, 1200, 1120, and 750 cm^{-1}; ^1H NMR ($CDCl_3$, 60 MHz) δ=1.26 (3H, d, J=6.0 Hz, CH_3), 1.90—2.30 (2H, m, H^3), 2.47—3.03 (1H, m, H^4), 3.70 (2H, t, J=5.0 Hz, H^2), 4.00 (2H, s, $COCH_2$), and 7.00—7.50 (4H, m, ArH). **24:** R_f 0.61 (SiO_2, ethyl acetate); ^1H NMR ($CDCl_3$, 270 MHz) δ=1.34 (3H, d, J=7.1 Hz, CH_3), 1.72 (1H, dddd, J=13.7, 8.7, 8.6, and 4.4 Hz, H^{5a}), 2.06 (1H, J=13.7, 6.7, 4.4, and 4.2 Hz, H^{5e}), 2.90—3.03 (1H, m, H^6), 3.50 (2H, s, H^1), 3.63 (1H, ddd, J=13.2, 8.6, and 4.2 Hz, H^{4a}), 3.85 (1H, ddd, J=13.2, 6.7, and 4.4 Hz, H^{4e}), 6.95 (1H, dd, J=7.6 and 7.6 Hz, H^8), and 7.05—7.12 (2H, m, H^7 and H^9); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=19.9, 29.3, 29.4, 36.7, 37.1, 122.0, 122.2, 123.3, 125.1, 125.2, 141.7, and 174.1.

Found: C, 76.62; H, 6.98; N, 7.50%. Calcd for $C_{12}H_{13}NO$: C, 76.96; H, 7.01; N, 7.48%.

Hydrogenation of 1 by Using Deuterium Oxide. The reaction of **1** with D_2O was carried out according to the general procedure by using toluene in place of 2-methoxyethanol. The product was analyzed by 270 MHz ^1H NMR and the results were shown in Scheme 2.

Preparation of 6-Benzyloxy-7-methoxy-2-methyl-1,2,3,4-tetrahydroisoquinoline (29). In a 200-mL three-necked flask equipped with a reflux condenser and a dropping funnel were placed lithium aluminum hydride (0.339 g, 0.892 mmol) and anhydrous tetrahydrofuran (15 mL). To the suspension was added cautiously a solution of **27** (1.34 g, 4.51 mmol) in anhydrous tetrahydrofuran (26 mL). After addition was complete, the reaction mixture was refluxed for 15 h. Stirring was continued while the mixture was cooled in an ice bath and a saturated aqueous solution of sodium sulfate was added cautiously until the hydrogen evolution ceased. The mixture was then filtered and evaporated to afford **29** (1.06 g, 83%). An analytical sample after recrystallization from hexane showed following properties: mp 93—94 °C; IR (Nujol) 3300 (N-H), 1610, 1520, 1225, 1130, 1010, 750, and 700 cm^{-1}; ^1H NMR ($CDCl_3$, 270 MHz) δ=2.44 (3H, s, CH_3), 2.64 (2H, t, J=5.9 Hz), 2.78 (2H, t, J=5.9 Hz), 3.50 (2H, s, H^1), 3.83 (s, 3H, OCH_3), 5.09 (2H, s, OCH_2Ph), 6.53 (1H, s), 6.63 (1H, s), and 7.25—7.50 (5H, m, Ph); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=28.7, 46.0, 52.9, 56.2, 57.6, 71.3, 110.2, 114.7, 125.9, 127.37, 127.41, 127.7, 128.5, 137.4, 146.9, and 148.1.

Preparation of 6-Benzyloxy-7-methoxy-1,2,3,4-tetrahydroisoquinoline (30). In a 50-mL round-bottomed flask were placed **28** (0.947 g, 3.18 mmol) and a mixture of sulfuric acid and methanol (1/9) (20 mL). After the mixture was stirred at room temperature for 48 h, the solution was basified with diluted aqueous ammonia. After methanol was removed under reduced pressure, the resulting aqueous solution was extracted with chloroform (10 mL×3). The combined organic layers were dried over sodium sulfate and evaporated to give **30**: mp 78 °C; ^1H NMR ($CDCl_3$, 270 MHz) δ=1.81 (1H, br-s, NH), 2.64 (2H, t, J=5.8 Hz), 3.08 (2H, t, J=5.8 Hz), 3.83 (3H, s, OCH_3), 3.93 (2H, s, H^1), 5.10 (2H, s, OCH_2Ph), 6.53 (1H, s), 6.61 (1H, s), and 7.25—7.46 (5H, m, Ph); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=28.6, 44.0, 48.0, 56.2, 71.4, 110.0, 115.3, 126.7, 127.3, 127.8, 128.5, 128.6, 137.4, 146.8, and 148.2; mass spectrum (80 eV), m/z (relative intensity) 269

(M^+, 9), 178 (M^+-CH_2Ph), 150 (27), and 91 (100).

Found: C, 75.49; H, 7.12; N, 5.04%. Calcd for $C_{17}H_{19}NO_2$: C, 75.81; H, 7.11; N, 5.20%.

6,7-Dimethoxy-1,2,3,4-tetrahydroisoquinoline (31). ^1H NMR ($CDCl_3$, 270 MHz) δ=2.02 (1H, br-s, NH), 2.71 (2H, t, J=5.9 Hz, H^4), 3.12 (2H, t, J=5.9 Hz, H^3), 3.83 (3H, s, OCH_3), 3.84 (3H, s, OCH_3), 3.94 (2H, s, H^1), 6.51 (1H, s), and 6.58 (1H, s); ^{13}C NMR ($CDCl_3$, 67.9 MHz) δ=28.7, 44.0, 48.0, 56.0, 109.3, 112.2, 126.6, 127.8, 147.4, and 147.6.

(−)-(9Z)-1,9-Heptadecadiene-4,6-diyn-3-ol as a Principal Component of the Resinous Sap of Evodiopanax innovans Nakai, Japanese Name, Takanotsume, and Its Role in an Ancient Golden Varnish of Japan[1)]

Akira TERADA,* Yasuhiro TANOUE, and Daishiro KISHIMOTO
Department of Chemistry, Faculty of Engineering, Kyushu Institute of Technology, Tobata, Kitakyushu 804
(Received November 30, 1988)

(−)-(9Z)-1,9-Heptadecadiene-4,6-diyn-3-ol was for the first time isolated in high yield (29%) from the resinous sap of Evodiopanax innovans Nakai, Araliaceae. This compound has been associated with the main polymerizable component of an ancient golden varnish. It has also been associated with a phytoalexin and a defense material which produces a water-insoluble coating film by photopolymerization under sunlight for a Takanotsume tree upon being wounded.

(−)-(9Z)-1,9-Heptadecadiene-4,6-diyn-3-ol, also called panaxynol,[2)] falcarinol,[3)] and carrotatoxin,[4)] was first isolated in high yield as the main component of the resinous sap of the Takanotsume tree; it was previously used as one of the GONZETSU paints in Japan. GONZETSU was a golden-colored, anticorrosive paint varnish (photopolymerizable by sunlight) used for armor suits and helmets in ancient Japan, Korea, and China.[5)] GONZETSU paint used in ancient Japan had been named as KOSHIABURA and was thought to be the resinous sap of the Koshiabura tree (Acanthopanax sciadophylloides French et. Sav., Araliaceae),[6)] though its correct origin remained unproven until recently.[7)]

Terada[8)] studied the historical documents concerning GONZETSU, as well as the floras of the Koshiabura tree and similar trees such as Kakuremino and Takanotsume trees, Araliaceae in Japan. He also investigated the chemical constituents of their resinous saps, arriving at the conclusion that in Korea and China during the T′ang dynasty the GONZETSU was called ŌSHITSU (yellow varnish), the resinous saps of trees of the Dendropanax genus (Araliaceae family; these plants belong to one and the same genus of Japanese Kakuremino tree, namely, Dendropanax morbifera Leb., in Korea, and Dendropanax chevalieri (Viquier) Merr., in Chechiang-Sheny of China). He also concluded that in Japan the resinous saps of trees of Koshiabura, Takanotsume, and Kakuremino (Dendropanax trifidus Makino) were used for the same purpose.[9)] The saps of the former two were the indigenous Japanese golden varnish GONZETSU; their fast-drying abilities were so valuable that they were exported to T′ang and Po-hai in ancient times.[9)] All of them were called either GONZETSU or KOSHIABURA in Japan, and were photosensitive paints which could harden under sunlight irradiation.[9)]

We have already reported on the chemical constituents of the resinous saps of Koshiabura and Japanese Kakuremino,[10,11)] and recently found that they contained polyacetylenic compounds.[12)] The present report deals with the detection of a polyacetylenic compound((−)-(9Z)-1,9-heptadecadiene-4,6-diyn-3-ol) as the main component of Takanotsume resinous sap as well as its sunlight polymerization and biological roles.

Results and Discussion

The ethanolic extract of Takanotsume sap (**1**) was a red brown oil, and showed conjugated polyacetylenic absorption bands in IR and UV which implied an ene-diyne conjugated system.[13)] Since this sample accompanied many mono- and sesquiterpenes and polymers and was very labile, catalytic hydrogenation at ordinary temperature and pressure was carried out and gave white crystals: $C_{17}H_{36}O$, mp 51.5—52 °C in 27% yield. ^{13}C NMR and other analytical evidence showed that this was 3-heptadecanol (**2**).

Repeated TLC separations of the crude sample (**1**) of polyacetylenes afforded an analytical sample, $C_{17}H_{24}O$ (**3**) in 29% yield, which showed $[\alpha]_D^{18}$ −36.93°; the IR spectrum was identical with that of (−)-(9Z)-1,9-heptadecadiene-4,6-diyn-3-ol, panaxynol, isolated and identified already by Takahashi et al.[2a)] from the Ginseng root (Panax ginseng C. A. Meyer) in 0.1% yield. This was also identical with the carrotatoxin isolated in a trace amount (between 10 and 20 ppm) as a natural toxicant from vegetable carrot (Daucus carota L.) by Crosby and Aharonson,[4)] and with falcarinol from Falcaria vulgaris Bernh and from many other Umbelliferae by Bohlmann et al.[3)] All of them were shown to be the same compound by Bently et al.[14)]

The MnO_2 oxidation of **3** resulted in the formation of (9Z)-1,9-heptadecadiene-4,6-diyn-3-one (**4**), also proving the existence of **3** in Takanotsume sap.

Compound **3** polymerizes in sunlight to produce a golden, transparent, hard film that is insoluble in solvents. In general, a conjugated polyacetylenic compound quickly polymerizes under daylight[15)] or UV-light irradiation,[16)] and the following polymer structure, like **5** in Fig. 1 for example, may be typical in the case of the conjugated diacetylene (**3**).[16)] Upon polymerization, the carbon-carbon double bonds in the R and R′ groups (Fig. 1) may be co-operative dur-

ing polymerization. The IR- and UV-absorption spectra of the dried film **5** are shown in Figs. 2 and 3, respectively, along with those of **3**.

The IR-absorption bands of the monomer **3** at 2255 (C≡C–C≡C, strong), 983 and 929 (vinyl), and 692 cm^{-1} (C=C, cis) were absent in the polymer film (**5**). Moreover, new characteristic bands of the polymer (**5**) appeared at 2195, 2155, and 2120 (C≡C–C=C, conjugated, all weak), and at 979 and 955 cm^{-1} (C=C, conjugated). Tieke et al. ascribed these phenomena to the C≡C-streching modes of the polymer backbone with various C–C-skeleton motions, judged from a large number of small peaks around them.[18] In addition, the structure of the polymer was supported by the finding of Baughman et al. that the polymer backbone was best represented by $(=C-C\equiv C-C=)_n$ from its Raman spectra.[19] These facts show that the polymer backbone is built up by a structure like **5** in Fig. 1.

The UV of polymer **5** in Fig. 3 shows a bathochromic shift and the polymer color is, therefore, a golden-yellow. Usually, to make Langmuir–Blodgett multilayers a number of conjugated diacetylenes are employed in solid state polymerization by irradiation of the UV light from a high-pressure mercury lamp; the

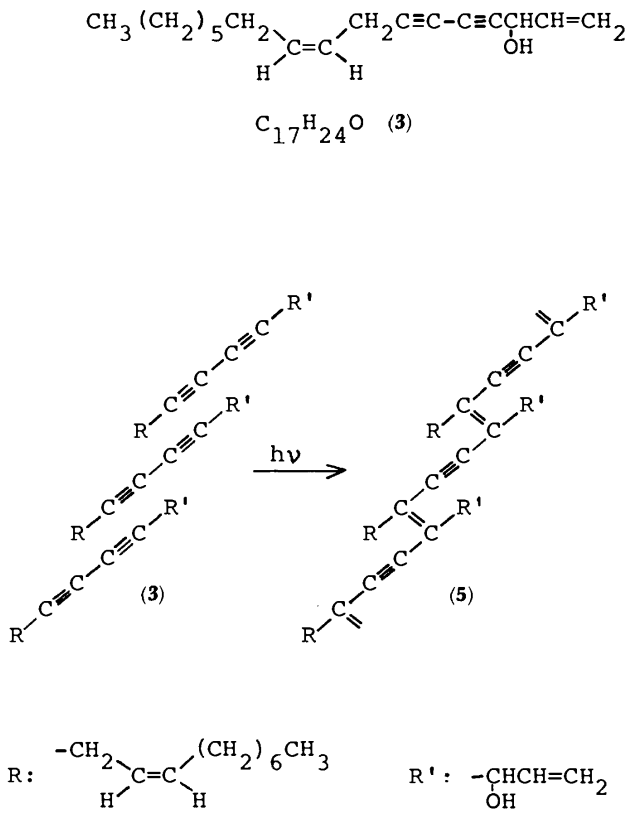

Fig. 1. Photopolymerization of **3**.

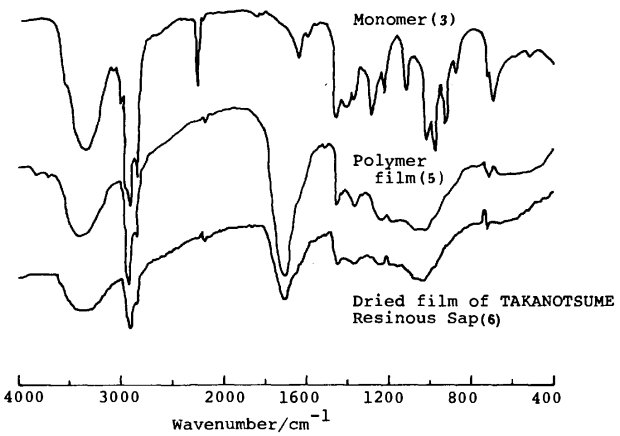

Fig. 2. IR of monomer **3**, polymer **5**, and dried film of TAKANOTSUME resinous sap.

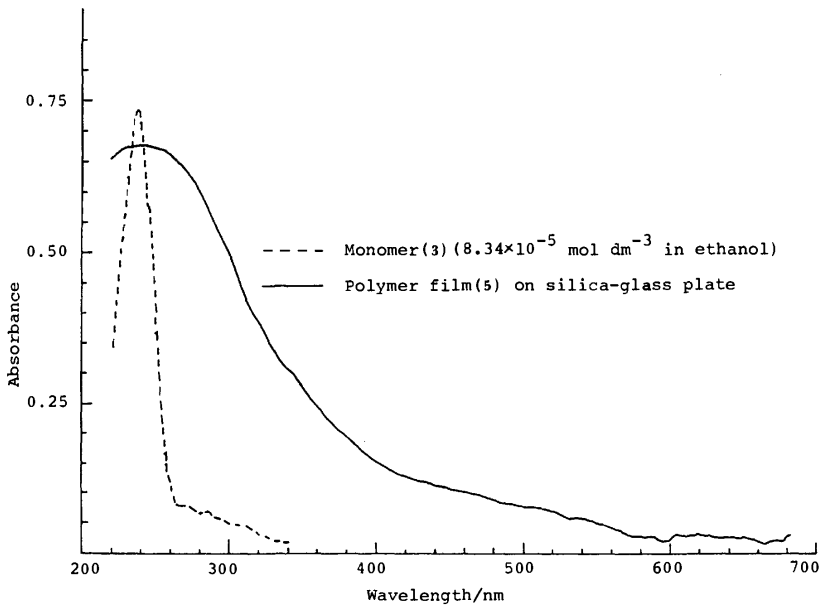

Fig. 3. UV of monomer **3** and polymer **5**.

reactions come to completion within a few minutes. These polymerizations proceed topochemically without any destruction of the layer structures, and appear as deep purple; this color changes irreversibly to red upon treatment with ethanol or chloroform.[16] Because the net-worked insoluble polymer **5**, which we obtained in this study, is not such a high-molecular-weight one and does not have such a stereoregularity, it therefore shows a golden-yellow color owing to the short-distance conjugation of carbon–carbon double and triple bonds in the polymer backbone. Krieger said that a polymer having a highly planar backbone is blue, that a slightly planar one is red, and that a highly nonplanar one is yellow.[20]

We also show the IR of a dried fim of Takanotsume sap in Fig. 2-**6**. This is almost the same with that of the polymer **5**.

The above-mentioned facts prove that this sap would be one of the old GONZETSU paint-compounds which made the old armors and helmets golden-colored, waterproof and anticorrosive.

Yoshioka et al.[21] have reported that the hexane extract of Takanotsume stems showed no conjugated polyacetylenic compound on its UV-spectral detection. Thus, our finding that compound **3** occurs only upon cutting the bark to obtain sap would suggest that this is a phytoalexin which can be used as an antiseptic. Dewit and Kodde have reported this compound **3**, falcarinol, as a phytoalexin, which was found in tomato (Lycopersicon esculentum) after incubation with Cladosporium fulvum.[22] Harding and Heale have found falcarinol to be one of the inhibitory compounds in the induced resistance response of carrot root slices; the compound was active against Botrysis cinerea.[23] We also suppose that the compound **3** that we obtained here acts effectively as defensive-type substance through a phytoalexin and also by forming a coating film over a raw wound. These phenomena suggest that compound **3** would play a similar role to Japanese lacquer urushiol found in the sap of Rhus verniciflua Stokes.

Otsuka et al. have found a strong inhibitory activity of the chloroform extract of roots of Panax ginseng C. A. Meyer against the formation of granulation tissue and proved that compound **3** and linoleic acid were the major active components.[24]

In Japan, especially in Northeast districts (Tohoku), some people have a well-established custom of eating the young leaves of Takanotsume. They also feed domestic animals the leaves since the tree is of little importance these days. Yasue et al.[25] have reported an accident in which some goats were poisened after eating this food. We suppose that since many polyacetylenic compounds are well known to be poisonous to fish,[26] and that compound **3** has been found as a natural toxicant by Crosby and Aharonson,[4] such a poisoning might suggest an accumulation of compound **3** as well as closely related polyacetylenic compounds in their food leaves.

We also conclude again that the occurrence of a great quantity of compound **3** in a wounded Takanotsume tree is for phytoalexin and serves as a barrier against the raw wound through polymerization; it then makes its own cure.

Experimental

Infrared and ultraviolet absorption spectra were recorded on Hitachi 260-30 infrared and Hitachi 139 UV spectrophotometers, respectively. ^1H and ^{13}C NMR spectra were obtained on a JEOL JNM-FX 60 spectrometer operated at 60 and 15.04 MHz, respectively. Mass spectra were determined on a JEOL DX-300 spectrometer. Mp's(corrected) were determined on a Yanagimoto micromelting point apparatus. TLC separations were performed by silica gel(Merck, 60 PF).

Ethanolic Extract of Takanotsume sap. Takanotsume sap was dissolved in ethanol, filtered and concentrated under diminished pressure to give an orange-yellow oil (**1**). IR (neat) 3380 (broad, OH), 2250 (sharp, -C≡C-), 2230 (weak, -C≡C-), 1640 (-C=C-), and 698 cm^{-1} (cis -CH=CH-). The benzene extract of **1** showed the UV_{max} (methanol) at 228, 237, 254, 269, and 285 nm. This orange-yellow oil (**1**) spread on a glass plate was dried under sunlight irradiation for half an hour,[1] resulting in the formation of a golden-colored, transparent, hard film.

Catalytic Hydrogenation of Ethanolic Extract of Takanotsume sap. Upon hydrogenation using a platinum black catalyst in ethanol under ambient temperature and atmospheric pressure, 1.740 g of the ethanolic extract (**1**) absorbed 551.6 ml of hydrogen and yielded 27% of white crystals, mp 51.5—52 °C, after purifications by silica-gel column chromatography and recrystallization from ethanol. The ^{13}C NMR data showed that this compound was an open chain alcohol, 3-heptadecanol (lit, mp 54—54.5 °C,[2a] 44—46 °C,[4]) and the IR spectral data well agreed with those reported.[4] IR (KBr) 3320, 3220 (each OH), 1473 (CH_2), 1380, 1348 (each CH_3), 1139 (OH), 948, and 723 cm^{-1}; MS *m/z* 256 (M^+), 238 ($M^+ - H_2O$), 227 ($M^+ - CH_3CH_2$), 197 ($C_{14}H_{29}$), 59 ($C_2H_5CH(OH)$); ^{13}C NMR ($CDCl_3$) δ=9.9 (q, C-1), 14.2 (q, C-17), 22.7 (t, C-16), 25.8 (t, C-5), 29.4 (t, C-6, C-14), 29.7 (t, C-7—C-13), 30.2 (t, C-2), 32.0 (t, C-15), 37.0 (t, C-4), and 73.4 (d, C-3). Found: C, 79.57; H, 14.34%. Calcd for $C_{17}H_{36}O$: C, 79.61; H, 14.15%.

Isolation of 3. An ethanolic extract of a fresh Takanotsume sap was repeatedly chromatographed by TLC and gave 29% of a light-yellow oil (**3**) (R_f=0.33, $CHCl_3$), $[\alpha]_D^{18}$ −36.93° (*c* 0.77, $CHCl_3$) (lit, −25.2°).[2a] UV(95%C_2H_5OH) λ_{max} 238 (ε=8700); IR (neat) 3330 (OH), 3090, 3020 (C=C-H), 2255 (C≡C), 1638 (C=C), 1118 (OH), 1015, 983, 930 (vinyl), and 698 cm^{-1} (cis -CH=CH-);[2d] MS *m/z* 244 (M^+, 6%) and 159 ($M^+ - [-(CH_2)_5CH_3]$); ^1H NMR ($CDCl_3$) δ=0.81 (3H, m, CH_3), 1.28 (10H, m, CH_2×5), 2.0 (2H, m, =CH-C<u>H</u>$_2$-), 3.12 (2H, d, *J*=6 Hz, ≡CC<u>H</u>$_2$-CH=), 4.88 (1H, d, *J*=4.8 Hz, C<u>H</u>OH), 5.4 (2H, m, vinyl CH_2=), 5.85 (1H, ddd, *J*=4.8, 9.4, 17 Hz, vinyl), and 5.45 (2H, m, -CH=CH-). Found: C, 83.08; H, 9.62%. Calcd for $C_{17}H_{24}O$: C, 83.55; H, 9.80%.

(9Z)-1,9-Heptadecadiene-4,6-diyn-3-one (4). By the procedure of Takahashi and Yoshikura,[2b] MnO_2 oxidation of 80 mg of **3** in hexane afforded 41 mg of a pure sample of **4**

after the usual work-up, a yellow oil. The IR was identical with those of Takahashi and Yoshikura[2b] and Bohlmann et al.[27] IR (neat) 3010 (C=CH), 2240 (C≡C), 1642 (C=O), 1614(C=C), 1462, 1402, 1311, 1272, 1163, 1078, 982, and 967 (vinyl), 905, 795, 703, and 686 cm^{-1} (cis C=C). There was no appearance of an OH band in the 3500—3300 cm^{-1} region.

Photopolymerization of 3. A sample of **3** was spread to a thickness of 20 μm on a glass plate using an applicator, and exposed directly to the sun for 1 h. Polymerization was almost completed within this time and the color changed to golden yellow (Fig. 1). The dried film showed 33 in hardness according to a Swoad-Rocker Hardness test (the hardness of the standard glass plate is provided as 100).[17] The IR and UV spectra are shown in Figs. 2 and 3, respectively.

The Catalytic Degradation Reaction of Polypropylene with Silica-Alumina

Yumiko ISHIHARA,* Hidesaburo NANBU, Chiemi IWATA,
Tadashi IKEMURA, and Tomoyuki TAKESUE
Department of Industrial Chemistry, College of Science and Technology, Nihon University,
1-8, Kanda-Surugadai, Chiyoda-ku, Tokyo 101
(Received March 2, 1989)

A detailed analysis was carried out on the catalytic degradation of polypropylene with silica-alumina, using a glass tube reactor (25ϕ×150 mm) at 180 to 300 °C and a N_2 flow rate of 120 ml min^{-1} over a period of 5 to 120 minutes. The ratio of C/S was from 0.1 to 6.0. The molecular weight of PP decreased slightly at about 160 °C by cationic degradation, but the decrease started at about 200 °C by radical degradation (without catalyst). The main chain of PP was remarkable weakened by the catalytic degradation with silica-alumina. Analysis of degradation products by ^{13}C NMR, FD-MS and variation in chain scission number clearly indicated the catalytic degradation of PP to occur in two stages. The first stage at low temperature is initiated by the addition of a proton released from the catalyst to weak links in the main chain. The second stage at high temperature occurs by attack a low-molecular-weight carbonium ion of the saturated degraded oligomer. These ions are closely involved in the production of irregular structural oligomers and their redegradation.

The degradation reaction of polymer is important for the synthesis of materials by polymeric reactions starting from a high polymer and studying the molecular design of functional, heat-resistant polymers and the stabilization of a general-purpose polymers.

Many studies in this area, especially on pyrolytic radical reactions, have been reported. However, only a few studies have been carried out cationic and anionic degradation reactions of polymers in the presence of a catalyst. A study using an oligomer fraction produced by degradation of polypropylene (briefly "PP") as a lubricating oil has been conducted.[1] The catalytic degradation of PP,[2,3] and reactions of nylon, polyisobutylene (briefly "PIB"), and polystyrene (briefly "PS")[4-6] have been recently studied. Gasification reactions are studied to determine the yields and composition of volatile matter while PP, PIB, nylon, and PS reactions are investigated to clarify main chain skeleton reactions as polymeric reactions.

The authors found unusual polymeric reactions of the latter type to take place. For instance, a unique polyindan[6] can be produced at high yield in the catalytic reaction of PS with aluminum chloride and the multibranched ethylene oligomer is produced in the catalytic reaction of polyethylene (briefly "PE") with silica-alumina.[7]

The above cationic degradations are remarkably different from conventional pyrolytic radical reactions. It is not possible to synthesis the polyindan and the multibranched oligomer mentioned above either by a radical reaction nor by ordinary monomer polymerization. The cationic and anionic degradation reactions of polymers may thus possibly hold promise for the synthesis of new materials. And considerable research should be directed to the basic cationic and anionic degradation reactions of polymers as pyrolytic radical reaction. The authors consequently conducted fundamental research on the cationic degradation reactions of polymers and the catalytic degradation of general-purpose polymers.

Experimental

The sample used for this study was prepared by pulverizing a commercially available isotactic PP (Biscol 330P manufactured by Sanyo Kasei; isotacticity; 90%; and $\bar{M}_n$ (by viscosity method)=16000), to 60 mesh or under, extracting in with heptane in a Soxlet extractor, for 6 hours and drying at 40 °C for 72 hours under vacuum.

The catalyst was prepared by pulverizing a commercially available silica-alumina catalyst (N-631L manufactured by Nikki Chemical; alumina content: 13 wt%) to a 100 mesh or less sintering it at 540 °C for 3 hours and then drying it in a flow of dried air. The activity of the catalyst was measured by butylamine titration.[8,9]

Experimental Operation and Procedure. A Pyrex glass tube reactor (outer diameter: 25 mm and length: 150 mm) connected to traps for recovering gaseous and liquid products as shown in Fig. 1 was used.

The experimental procedure was as follows: 2 g each of the sample and the catalyst were mixed by stirring at different temperatures and timings and 0.6 to 2 g of the sample and 0.2 to 4 g of the catalyst were mixed by stirring with different concentrations of the catalyst. The mixture was put in a

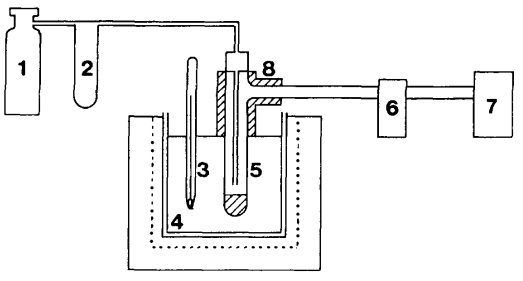

Fig. 1. Apparatus for the catalytic degradation: (1) N_2 cylinder, (2) manometer, (3) thermometer, (4) metal bath, (5) reactor, (6) trap for liquid fraction, (7) trap for gaseous product, (8) asbestos.

reactor; the reaction a value was maintained from 180 to 300 °C in an oil or metal bath; nitrogen was passed through the reactor at a flow rate of 120 ml min^{-1} for 5 to 120 minutes and the ratio of catalyst to sample (C/S) was varied from 0.1 to 6.

Analytical Method. A gas-liquid chromatograph (GC-8A of Shimadzu) was used.

The gaseous product was qualitatively analyzed by a comparison with the retention time of the standard gas and quantitatively analyzed by the absolute calibration curve method.[10]

A FT-IR spectrometer (Fourier transform infrared spectrophotometer of Nihon Denshi) was used. The range of wavelength for measurement was from 4000 to 400 cm^{-1}.

Parameter of the starting PP sample were determined by the Fourier transform infrared spectroscopic method.

Field desorption- (FD-) and field ionization-mass spectrometers (FI-MS) (RMU-7M of Hitachi) were used. The molecular weight distribution of the oligomer was determined by FD-MS. The molecular weight of low- and high-boiling fractions in the liquid product were determined by FI- and FD-MS, respectively.

The measuring conditions are shown in Table 1.

^1H and ^{13}C NMR (JUM FX-100 of Nihon Denshi) were used. The resonance frequencies of ^1H and ^{13}C NMR were 99.6 and 25.05 MHz, respectively.

The PP sample dissolved in 1,2,4-trichlorobenzene, benzene-*d* as the internally locking agent of the magnetic field and a small amount of hexamethyldisiloxane (HMDS) as the internal standard material were introduced into a 5 mm-NMR tube which was then deaereated by freezing, followed by a complete substitution with nitrogen and sealing. The oligomer dissolved in chloroform-*d* and a small amount of tetramethylsilane (TMS) as the internal standard material were put in a 5 mm-NMR tube.

The measuring conditions of ^1H and ^{13}C NMR are the same as in the previous paper.[10]

Method for the Assignment of ^{13}C NMR Signal. The addition rules of Grant-Paul,[11] Randall,[12] and Lindeman-Adams[13] are generally used for assigning ^{13}C NMR signals. In particular, the addition rule Grant-Paul is used for the ^{13}C NMR signal of PP. Nishioka et al.[14] calculated the average values of standard deviations in the structures with ethyl to hexyl or higher side chains.

In contrast, the addition rule of Lindeman-Adams has the following advantages: the standard deviation from the Lindeman-Adams method is intermediate between the values obtained from these three methods and the calculated value of a quaternary carbon atom can be obtained. Accordingly, in the present study, the addition rule of Lindeman-Adams was used mainly. For comparison, both these addition rules were used.

The addition rule is expressed as follows:

$$\delta c(K) = Bs + \sum^{4} D_M A_{SM} + \gamma_S N_3 + \Delta S N_4$$

where *B*, *A*, γ, and Δ=the respective additive parameters for the α-, β-, γ-, and δ-positions of C-k, *s*=number of carbon atoms directly bonding to C-k, D_M=total M carbon atoms bonding to C-k, and Nk3 (Nk4)=number of carbon atoms three (four) bonds away from C-k, that is, the γ-carbon atom (δ-carbon atom).

The parameters used in the addition rules are shown in Table 2.

Results and Discussion

Variation in the Number of Chain Scission of Polypropylene. Variation in the molecular weight of the main of PP was measured to examine its catalytic degradation reaction when using a silica-alumina catalyst.

The results are shown in Fig. 2. Decreasing molecular weight in the thermal degradation with non catalyst was observed at 200 °C. But, in the degradation of PP with the catalyst, the molecular weight sharply decreased from 16000 to 10000 at lower temperature in the experiment on variation in reaction temperature (open symbol). It slowly decreased from 10000 to 7500 at higher temperature. These trends are more pronounced for variation in time (closed symbol). The decrease in molecular weight at the early stage (lower temperature) of the catalytic degradation reaction thus appears to differ from that at the late stage (higher temperature).

The results are expressed as change in the number of main-chain scissions by rearranging the above results is shown in Table 3. The number of chain scissions was 0.45 from 180 to 220 °C, and 0.3 to 0.38 from 220 to 280 °C. Thus, the molecular weight decreased more sharply at the early stage. The number of chain scissions was 0.44 in the period from zero to 40

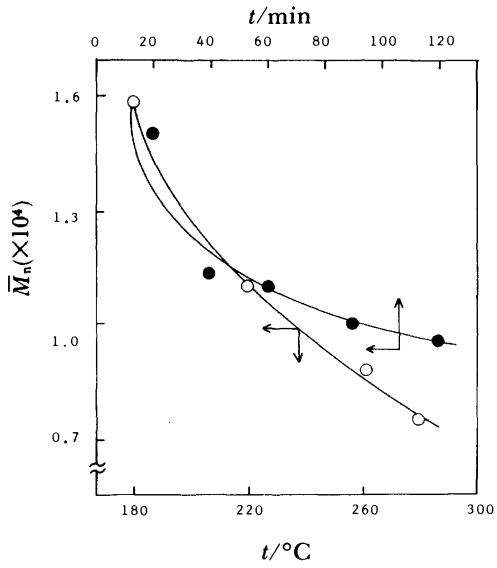

Fig. 2. Changes in the molecular weight ($\bar{M}_n$) of the degraded polymer. O: temp., ●: time.

Table 3. The Number of Main-Chain Scission of Catalytic Degraded Polymer

t/°C	180	220	260	280
Number of main-chain-scission	0	0.45	0.75	1.13

t/min	20	40	60	90	120
Number of main-chain-scission	0.06	0.44	0.48	0.56	0.60

Reaction conditions; time=60 min, C/S=1
Reaction conditions; temp=220°C, C/S=1.

minutes, and 0.14, only a third of the former in the period from 40 to 120 minutes. Chain scission thus takes place, more rapidly at the early stage than late stage. The molecular weight decreasing reaction at the early stage differed from that at the late stage.

The molecular weight decreasing reaction of PS was similar to the above reaction.

The molecular weight of PS decreased rapidly at the early stage and slowly at the late stage.[15] This rapid decrease is attributed to a low activation energy reaction caused by weak links in the main chain.[16] Since these weak links are more distinct in the main chain of PP than in that of PS, the initial reaction is possibly initiated by low activation energy in the same manner as in PS. It is thus likely, that the rapid decrease in molecular weight is caused by weak links in the same way as in PS. The weak links in the sample of this study are illustrated in Fig. 9.

These two molecular weight decreasing reactions were analyzed in terms of change in degraded product composition.

Yields of Degradation Products vs. Reaction Conditions. Figure 3 shows variation in the yields of the four main fractions, gas, liquid, grease (oligomer), and wax (low polymer). Another important product was carbon deposited on the catalyst.

The yield of wax (low polymer) linearly decreased with increase in reaction temperature, while that of the liquid sharply increases.

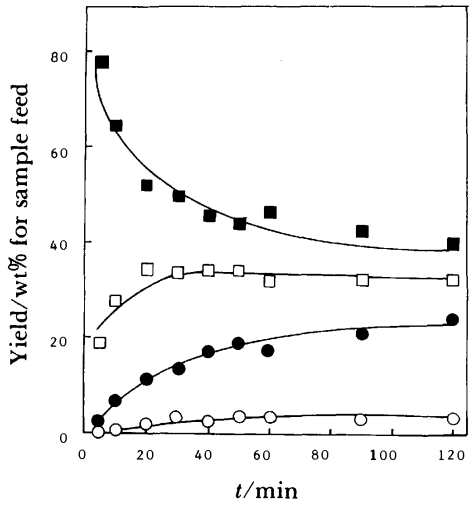

Fig. 6. Catalytic degradation product yield from PP. O: gas, ●: liquid, □: oligomer, ■: polymer. Reaction conditions: 220 °C, C/S=1.

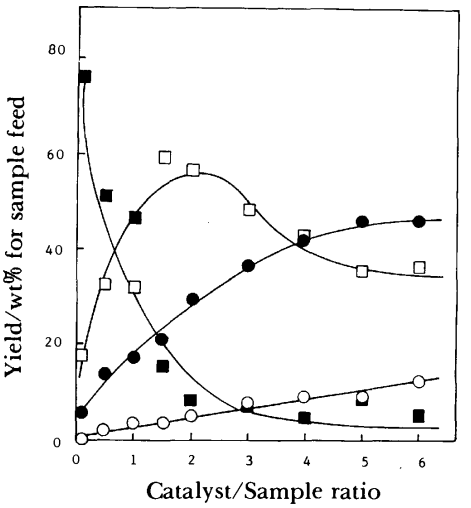

Fig. 7. Catalytic degradation product yield from PP. O: gas, ●: liquid, □: oligomer, ■: polymer. Reaction conditions: 220 °C, 60 min.

The results of FD-MS in Figs. 4 and 5 indicate the molecular weight distributions of the liquid and oligomer (mixture of grease and wax) fractions produced at 280 °C from 200 to 600, mainly at 360 and from 200 to 900, mainly at 450. Figure 4 shows the fraction (shown as····) produced at higher temperature to have a lower molecular weight, while that (shown as——) produced at lower temperatures, a higher molecular weight. Since the exhaust fume temperature in the higher temperature reaction system was high, the high boiling heavier fraction (oligomer) formed could flow out of the system. Phenomena such as reflux and redegradation way occur in the lower temperature reaction system, since the heavier fraction can hardly flow out. The molecular weight of the higher temperature reaction product should thus be higher than that of the lower temperature reaction product. This however, is the reverse of the above theory and at variance with the concept based on the boiling point of the reaction product in the reaction system.

This variance, however, may be resolved by considering that the oligomer redegradation to proceed at high temperature and the recombination-addition reactions of low-boiling products formed to occur during reflux in the long residence time at low temperature. Consequently, the molecular weights of the products become higher than those of products formed at high temperature. The molecules of a degradation product from an oligomer are smaller than those of the oligomer itself, and thus they move more easily toward the catalyst, should be more readily degraded and recombined. Evidence for this view is shown in Figs. 7 and 8.

The above results show PP to hardly be depolymerized in the catalytic degradation reaction, but to be

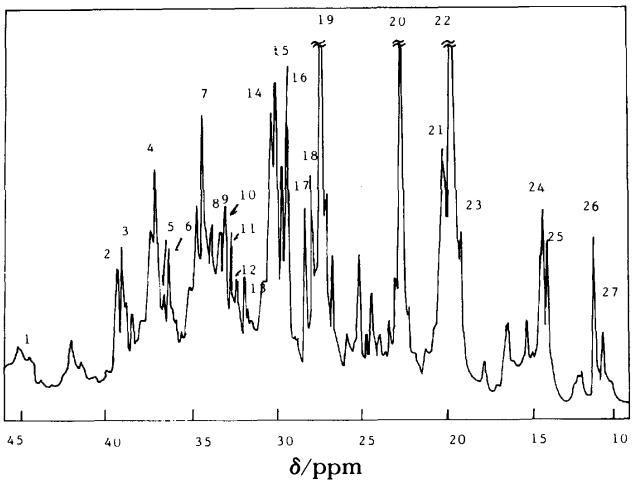

Fig. 8. ^{13}C NMR spectrum of the propylene oligomer (grease fraction). Reaction conditions: 220 °C, 60 min, C/S=1.

degraded through random scission. The yield of the component (propylene) produced by the depolymerization of PP was only 0.35 wt% the total yield.

The decrease in molecular weight of the main chain dominates at the early stage of the reaction mentioned above, while volatile matter is vigorously produced at the late stage. The catalytic degradation of PP was confirmed to occur in two stages remarkably different from each other. This reaction is similar to that of PS degradation. However, most of the reaction products in the latter half of the reaction of PS are olefinic monomers derived from depolymerization, while those of PP comprise a low-boiling liquid mixture of saturated hydrocarbons containing recombination and addition products as was shown by NMR analysis (in the later section).

The relationships among the four main fractions

and reaction time are shown in Fig. 6. They were all essentially the same the composition of each reaction product attained equilibrium during the catalytic degradation reaction. Each product thus appears to be formed in a simple reaction process. This, however, should be considered in relation to the catalyst concentration.

Variation in Degradation Products with Catalyst Concentration. The effect of the concentration of the catalyst was examined to elucidate the relationship between its activity and degradation. The results are shown in Fig. 7. The oligomer was degraded more than the liquid at a high concentration of catalyst (C/S=3) and the yield of polymer remarkably decreased as C/S exceeded 2 and the decrease was approximately 5.1 wt% at C/S of 4. The degradation reaction thus depends mainly the reaction temperature and catalytic concentration.

Since the oligomer with high-molecular mobility comes into contact more easily with the catalyst than the polymer with low molecular mobility and the oligomer is more rapidly degraded than the polymer an at extremely high concentration of catalyst, the yield of the oligomer is likely to drop. The yield of the oligomer, however, was not so much reduced as that of the polymer. The yield of gas and liquid should increase since the degradation reaction is accelerated more with increase in the concentration of catalyst. The yield of the oligomer did not decrease as shown in Fig. 7. This is probably because the oligomer was produced not only by degradation of the polymer but also by recombination or addition reaction of low-molecular components such as gaseous and liquid fractions. These results are essentially the same as those shown in Fig. 4.

These recombination reactions were confirmed by the chemical structures of the degraded products and the reaction of a model compound, 1-pentadecene. Thus, most of the olefin groups of the model compound are recombined, leading to increased molecular weight.[17] The reaction was quite different from the radical degradation reaction and characterized the cationic polymer degradation with the silica-alumina catalyst.

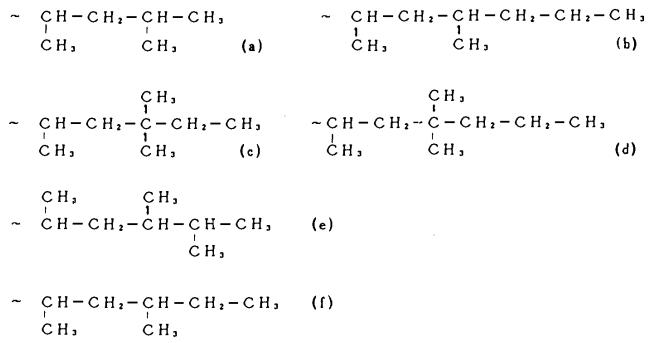
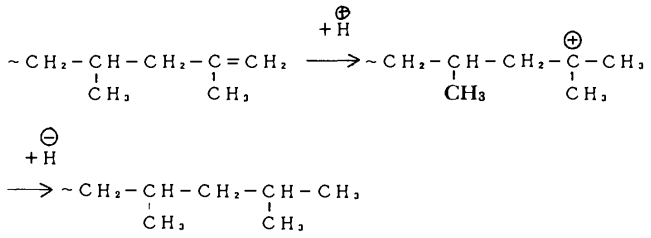
a) Chemical shifts calculated by Lindeman-Adams method. b) Peak No. in ^{13}C NMR spectrum of Fig. 8.

fraction produced at the late stage. The spectrum of the liquid fraction was nearly equal to that of the oligomer. The chemical structures of the products were assigned by calculation of the formulas.[11-13] The signals of the chain ends and chain skeletons of the main components are shown in Table 4. The relationship between the detailed structures and their signals are shown in Table 5.

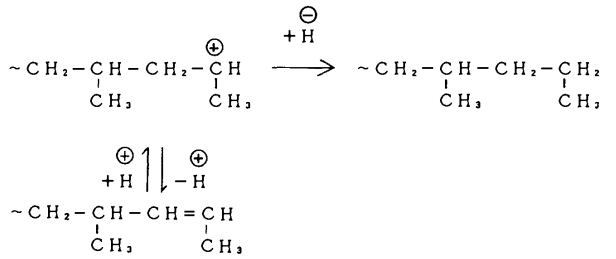
The chemial structures of the chain ends of the oligomer and liquid include the following six types:



Thus, the formation of these chain ends can be resonably explained on the basis of the following reaction schemes:



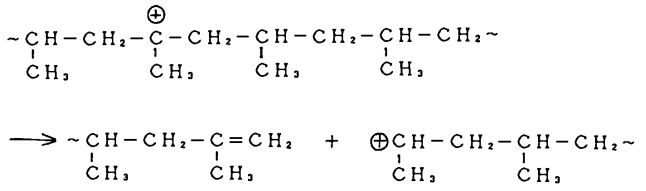
Scheme 1.



Scheme 2.

These chain end olefins with high affinity for protons are hydrogenated or saturated by the addition of a low-molecular-weight carbonium ion intermediate and the hydride ion ($\overset{\ominus}{H}$). The results of qualitative analysis indicated the chain ends of degradation products to be approximately hydrogenated. Moreover, the chain end of the degraded polymer includes only two types, (a) and (b), which are extremely simple compared to those of the oligomer and liquid. These two types of ends are also the main chain end structures of the oligomer fractions.

It is clear from the end structure of the main chain that main chain scission of the polymer is caused mainly by β-scission of the tertiary carbonium ion produced on the main chain according to the following scheme:



Scheme 3.

It was confirmed that the quaternary carbon atoms in (c) and (d) structures are produced in the oligomer and liquid fractions unlike those in the normal end structure. All these quaternary carbon atoms are found only in components produced in a high-temperature reaction. This proves that the oligomer and liquid fractions are produced by recombination of the low-molecular gaseous and liquid fractions. But they are not formed as internal carbon atoms in backbone chains and are located in the vicinity of the chain ends.

The concentration of quaternary carbon atoms seem high, considering the ratio of intensities of spectra. The chain end olefin (>C=CH$_2$ Scheme 1) is immediately attacked by a proton released from the catalyst or by a reaction intermediate possessing a tertiary carbonium ion formed from olefinic products consisting of the gaseous and liquid fractions.

The analytical results of the chemical structure of a catalytically degraded product of PP indicated the carbonium ion produced on the main chain to cause β-scission, and both the chain end olefin and the chain end high-molecular-weight carbonium ion to be saturated by hydrogenation or addition of activated low-molecular component.

The catalytic degradation reaction of PP occurs in two stages. The first stage is a low-temperature reaction initiated by the addition of a proton released from the catalyst to weak links in the main chain. The reaction should proceed using low activation energy. The formation of the carbonium ion on the main chain takes place at weak links in PP, which are the following functional groups included in the main chain.[18,19] These weak links in the starting sample in this study are shown by the FT-IR spectrum in Fig. 9. The functional groups confirmed in the sample are shown in the 1, 2, and 3 in figure. [1,2: >C=O, (1758, 1689 cm^{-1}), 3: olefin group, (1646 cm^{-1})]

These groups are easily attacked by protons, producing an on-chain a molecular weight decrease.

The second stage should be initiated by a higher activation energy than in the first stage reaction at high temperature. The chain ends of the oligomer

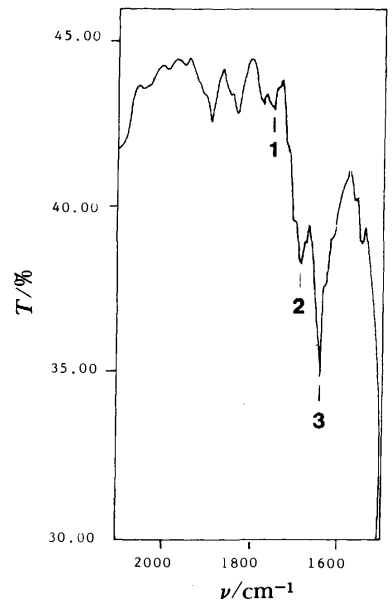


Fig. 9. FT-IR spectrum of the starting polypropylene

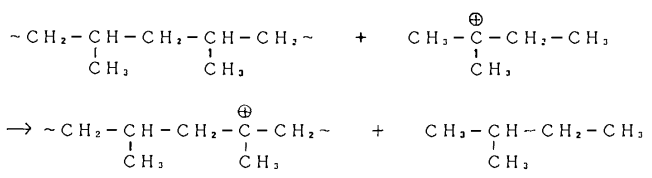
produced by the catalytic degradation reaction are saturated because the weak links (functional groups) were eliminated at the first stage of reaction. The oligomer is thus, chemically stable and contains no functional groups with affinity for a proton. The reaction which produces the on-chain carbonium ion causing the decrease in molecular weight of the saturated oligomer should require an extremely high activation energy. There is a wide difference in the activation energies required for producing the on-chain carbonium ion between the first and second stages of the reaction. Accordingly, the decreasing rate of molecular weight was determind in the two stages.

The results from variation in yields of the four fraction produced, FD-MS of liquid fraction and the determination of quaternary carbon atom by NMR indicate the lower molecular components including the liquid fraction to participate in the recombination reaction at low temperature but not the higher molecular weight components including the oligomer and polymer. The redegradation reaction of the chemically stable paraffinic oligomer is initiated by the intermolecular reaction with the intermediates of low-molecular-weight carbonium ion.

That is, in the reaction at high temperature, these ionic intermediates are formed by proton addition with olefinic gaseous and liquid products and also attack the on-chain tertiary carbon atoms of a saturated oligomer and degraded polymers. The activation energy of the reaction should be higher than that of the weak links.

These ionic intermediates are saturated by hydride ions extracted from the oligomer and polymer chains. Consequently, chain tertiary carbonium ions are again produced on the paraffinic oligomer and degraded polymers chains.

The intermolecular rearrangement of carbonium ions takes place on the surface of the catalyst. These reactions certainly require much higher activation energies than the addition reaction of protons to the weak links. The reaction of the intermolecular rearrangement of carbonium ion in the latter takes place as follows:



Scheme 4.

The schematic process of the catalytic degradation of PP using a silica-alumina catalyst involves the production of the on-chain carbonium ion initiated by the addition of protons to the weak links at the early stage and production of on-chain carbonium ion by the intermolecular rearrangement reaction of the low-molecular-weight carbonium ionic intermediates with tertiary carbon atoms in paraffinic oligomers at the late stage. The carbonium ionic intermediates of the low-molecular-weight fractions produced recombine with the low-molecular-weight olefinic fractions to increase the concentration of the oligomer fraction. In particular, it is clear that the intermediate of the low-molecular-weight tertiary carbonium ion is equally involved in the production of oligomer fraction with irregular structures. These reactions are quite different from the pyrolytic radical reaction of PP in which recombination of volatile matter is not important.[20]

(Received January 28, 1989)

Synopsis. The assignment of the nontotally symmetric g-type normal vibrations of [$^1H_4$]- and [$^2H_4$]pyrazines was reinvestigated through the analyses of the single vibronic level fluorescence spectrum. The assignment given in this work was consistent with the assignment made based on the polarization behavior of the phosphorescence spectrum.

In spite of a large number of works made on the assignment of the normal vibrations of pyrazine the assignment given for some of the nontotally symmetric vibrations has not been established yet.[1-7] Many workers made the assignment through the analyses of the Raman and infrared spectra.[1-4] Udagawa et al.[5] and McDonald and Rice[6] studied the assignment based on the analyses of the single vibronic level (SVL) fluorescence spectra and Azumi et al.[7,8] studied the assignment based on the polarization behavior of the phosphorescence spectrum. Their results are summarized in Table 1. The assignment given for the totally symmetric and ν_{10a} vibrations is established based on the various experimental results, while the assignment given for the ν_4, ν_5, and ν_{6b} is not consistent with each other.

Since the reasonable and definite assignment of the normal vibrations is very important for the study of the nature of the electronic excited states, the assignment of the ν_4, ν_5, and ν_{6b} vibrations is reinvestigated through the analyses of the SVL fluorescence and polarized Raman spectra of [$^1H_4$]- and [$^2H_4$]pyrazines in this work.

Experimental

Material. [$^2H_4$]Pyrazine was synthesized by exchange reaction of [$^1H_4$]pyrazine with D_2O using palladium asbestos as a catalyst. The sample was purified by repeated vacuum distillation.

Optical Measurements. The SVL fluorescence spectra were observed in vapor and in supersonic free jets. The excitation light source was a frequency doubled dye laser pumped by the second harmonic of a YAG laser (Qunta-Ray PDL-II DCR-11). The fluorescence spectrum dispersed by a 1.26 m monochromator (Spex. 1269) was detected by a photomultiplier tube (EMI 9789QB) and the signal was processed by a gated integrator (Stanford Research Systems SR 250).

The polarized Raman spectrum was observed with a laser Raman spectrophotometer (Jeol 400T) and the 514.5 nm beam from an Ar^+ ion laser, whose power was adjusted low enough because of high sublimation property of the pyrazine crystal. A single crystal grown by the Bridgman method was cut along the cleavage (101) plane, which will be referred to as the bc′ plane, where the c′ axis is taken to be inclined counterclockwise by 57.6° from the c axis in the ac plane.[9] The bb, c′c′, and bc′ polarized Raman spectra were observed by the back scattering method in the same way as described previously,[10] where the first and second letters refer to the polarization directions of the excitation and scattering lights, respectively.

Results and Discussion

Fluorescence Spectrum. The fluorescence excitation spectra of [$^1H_4$]- and [$^2H_4$]pyrazines observed in supersonic free jets are given in Fig. 1. The

assignment made on the vibronic bands is the same as that given by Udagawa et al.[5] except for the band at $0^0+509\,cm^{-1}$ in the [$^1H_4$]pyrazine spectrum and the weak band at $0^0+473\,cm^{-1}$ in [$^2H_4$]pyrazine, which was newly detected in this work. The SVL fluorescence spectra generated by pumping to the 0^0 level at 30875 (31032) cm^{-1}, to the $10a^1$ level at $0^0+383\,cm^{-1}$ ($0^0+293\,cm^{-1}$), and to the level at $0^0+509\,cm^{-1}$ ($0^0+473\,cm^{-1}$) are given in Fig. 2, where the first number refers to the frequency for [$^1H_4$]pyrazine and the number in parentheses to that for [$^2H_4$]pyrazine. The assignment given for the vibronic bands in the 0^0 and $10a^1$ SVL fluorescence spectra is exactly the same as that given by Udagawa et al. and McDonald and Rice, except for the bands at $0^0-755\,cm^{-1}$ and $10a^1-704\,cm^{-1}$ ($0^0-648\,cm^{-1}$, $0^0-886\,cm^{-1}$, $0^0-1008\,cm^{-1}$, and $10a^1-687\,cm^{-1}$). In the 0^0 SVL spectrum of pyrazine the 0_0^0 and totally symmetric vibronic bands showed parallel band envelope in correspondence with the out-of-plane transition moments, while the vibronic bands at $0^0-755\,cm^{-1}$ and $0^0-921\,cm^{-1}$ ($0^0-648\,cm^{-1}$ and $0^0-725\,cm^{-1}$) showed perpendicular band envelope as observed by Udagawa et al. This indicates that these vibronic bands are induced by the vibronic coupling through certain out-of-plane vibrations. Since the frequencies of 921 (725) cm^{-1} was already assigned to the ν_{10a} vibration of b_{1g} species,[5,6] the frequency of 755 (648) cm^{-1} should be assigned to one of the normal vibrations of b_{2g} species in the ground state.

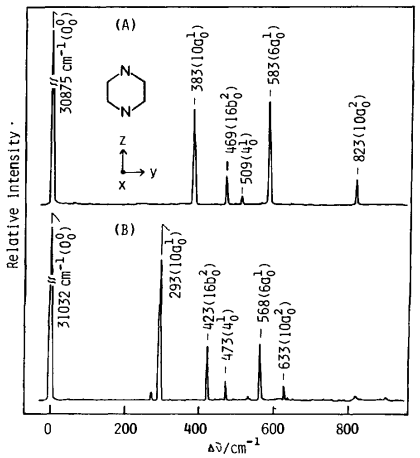

Fig. 1. Fluorescence excitation spectra of [$^1H_4$]- (A) and [$^2H_4$]- (B) pyrazines. The difference in wavenumber from the 0-0 band is expressed by $\Delta\tilde{\nu}$.

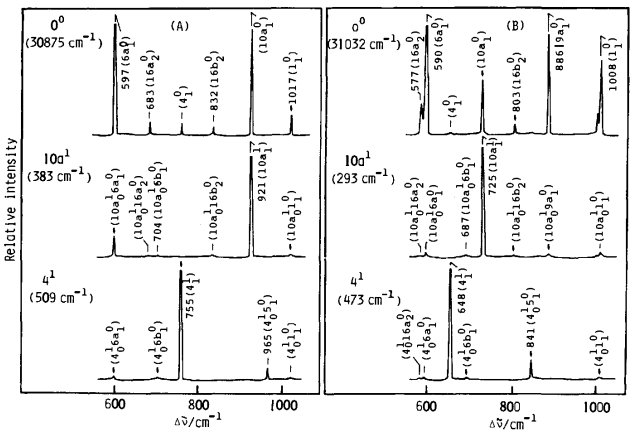

Fig. 2. SVL fluorescence spectra of [$^1H_4$]- (A) and [$^2H_4$]- (B) pyrazines. Excited level is indicated in the left hand side of the each spectrum. The difference in wavenumber from the exciting light is expressed by $\Delta\tilde{\nu}$.

In the $0^0+509\,cm^{-1}$, which will be written as ν_{509}, SVL spectrum of [$^1H_4$]pyrazine several bands were newly detected at $\nu_{509}-597\,cm^{-1}$, $\nu_{509}-704\,cm^{-1}$, and $\nu_{509}-965\,cm^{-1}$ in the fundamental vibrational region in addition to the band at $\nu_{509}-755\,cm^{-1}$ which was assigned to the 5_1^1 band by Udagawa and McDonald. In the $0^0+473\,cm^{-1}$ (ν_{473}) SVL spectrum of [$^2H_4$]pyrazine several bands were clearly observed at $\nu_{473}-577\,cm^{-1}$, $\nu_{473}-590\,cm^{-1}$, $\nu_{473}-648\,cm^{-1}$, $\nu_{473}-687\,cm^{-1}$, and $\nu_{473}-841\,cm^{-1}$. The assignment for the vibronic bands involving a_g vibrations was made straightforwardly by comparing the bands with the 0^0 SVL spectra and is given in Fig. 2.

For the nontotally symmetric vibrations the potential minimum would not change upon excitation and therefore the overlap integral of the vibrational wave functions of the ground and excited states $\langle X_i|X_j'\rangle$, which governs the transition probability, is close to δ_{ij}. Thus, the fact that the intensity of the band at $\nu_{509}-755\,cm^{-1}$ became strongest in the [$^1H_4$]pyrazine spectrum when the $0^0+509\,cm^{-1}$ level was excited indicates that the $509\,cm^{-1}$ band should be ascribed to the b_{2g} vibration in the $^3B_{3u}$ (n, π^*) state as indicated by Udagawa and McDonald. Similarly the fact that the intensity of the $\nu_{473}-648\,cm^{-1}$ band became strongest in the [$^2H_4$]pyrazine spectrum when the $0^0+473\,cm^{-1}$ level was excited indicates that the frequency of $473\,cm^{-1}$ should be assigned to the upper state b_{2g} vibration.

It was shown that two normal modes that belong to the same symmetry species and are effective to the vibronic coupling concerning to a certain electronic transition can exhibit Duschinski effect. In pyrazine the vibronic coupling between the $^1B_{3u}$ (n, π^*) and $^1B_{1u}$ (π, π^*) states can be induced through the ν_4 and ν_5 vibrations of b_{2g} species. The observations that the $\nu_{509}-965\,cm^{-1}$ ($\nu_{473}-841\,cm^{-1}$) band is the second strongest band in the fundamental vibrational region of the $0^0+509\,cm^{-1}$ ($0^0+473\,cm^{-1}$) SVL spectrum while the vibronic band involving the frequency of 965 (841) cm^{-1} was hardly detected in the 0^0 SVL spectrum and could not be detected in the $10a^1$ SVL spectrum as shown in Fig. 2 suggest that (1) the 965 (841) cm^{-1} band can be classified into the same symmetry species as that of the 755 (648) cm^{-1} band, (2) the 755 and 965 (648 and 841) cm^{-1} bands can be assigned to the ν_4 and ν_5 vibrations in the ground state, respectively, and (3) the 509 (473) cm^{-1} band can be assigned to the ν_4 vibration in the $^1B_{3u}$ (n, π^*) state.

The vibronic band involving the frequency of 704 (687) cm^{-1} was not observed in the 0^0 SVL spectrum but observed clearly in the $10a^1$ and 4^1 SVL spectra. Symmetry consideration suggests that this frequency

Table 2. Squares of Relative Values of Elements of the Raman Tensor for Pyrazine Crystal

	b_{1g}	b_{2g}	b_{3g}
$(A_{b\,b})^2$	0.50	0.00	0.00
$(A_{c'\,c'})^2$	0.04	0.12	0.70
$(A_{b\,c'})^2$	0.14	0.61	0.10

can be ascribed to one of the b_{3g} vibrations. The study of the normal vibrations of pyridine[11] and pyrimidine[12] suggests that the frequencies of 886 and 1008 cm^{-1} observed in the fluorescence spectrum of [$^2H_4$]pyrazine should be assigned to the ν_{9a} and ν_1 vibrations, respectively, although Udagawa et al. assigned these to the ν_1 and ν_{9a} vibrations, respectively.

The assignment given in this work for the vibronic bands observed in the fluorescence excitation and SVL fluorescence spectra is given in Figs. 1 and 2 and Table 1.

Polarized Raman Spectrum. Pyrazine crystallizes in the orthorhombic space group P_{mnn} with two molecules in the unit cell.[9] The matrix elements of the Raman tensor of the pyrazine crystal was calculated based on the simple oriented gas model approximation. The squares of relative values of the elements of the Raman tensor are given in Table 2. The bb, bc', and c'c' polarized Raman spectra of the [$^1H_4$]- and [$^2H_4$]pyrazine crystals are shown in Fig. 3. In the bb spectrum the Raman bands were observed at 1582 (1540), 1250 (899), 1017 (1003), 598 (591), and 943 (735) cm^{-1}. The first four bands can be assigned to the totally symmetric vibrations as already established by various workers. The band at 943 (735) cm^{-1} can be assigned to the ν_{10a} vibration based on the SVL fluorescence spectrum but the observed polarization behavior of this Raman band was not consistent with the expected behavior given in Table 2.

The Raman bands at 978 (840) and 756 (648) cm^{-1} observed in the c'c' and bc' spectra can be assigned to the ν_5 and ν_4 vibrations based on the SVL fluorescence spectrum, respectively, but the polarization behavior of these Raman bands did not entirely coincide with the expected behavior. The Raman bands at 1523 (1503), 1360 (1037), and 700 (674) cm^{-1} were observed in the c'c' and bc' spectra. The last band splits into doublets at 700 and 697 (674 and 671) cm^{-1} in the crystal, which may be caused by the factor group splitting. The first two Raman bands can be assigned to the ν_{8b} and ν_3 vibrations of the in-plane vibration of b_{3g} species, respectively, because of their higher frequencies than 1000 cm^{-1}. The last Raman band can be assigned to the ν_{6b} vibration of b_{3g} species because the corresponding frequency was not observed in the 0^0 SVL fluorescence spectrum but observed in the $10a^1$ and 4^1 SVL spectra. The observed polarization behavior of these b_{3g} vibrations did not entirely coincide with the expected one. The inconsistency of the observed and expected polarization behavior of the Raman bands may be ascribed to the characteristics in the pyrazine crystal which is invariably twinned on the (101) plane as indicated by Wheatley,[9] and therefore this suggests that the simple oriented gas model approximation cannot be applied to the analysis of the polarized Raman spectrum of the pyrazine crystal. Polarization behavior of the Raman bands can only give a reasonable evidence for the Raman bands observed in the bb spectrum being assigned to the a_g or b_{1g} vibration but not to the b_{2g} and b_{3g} vibrations since the vanishing values of the matrix elements for the b_{2g} and b_{3g} vibrations in the bb spectrum given in Table 2 result from the fact that the molecular z axis is parallel to the crystal a axis. The assignment made in this work, which is given in Figs. 2 and 3 and Table 1, is completely coincided with that made by Azumi et al. based on the polarized phosphorescence spectra of [$^1H_4$]- and [$^2H_4$]pyrazines.[7,8]

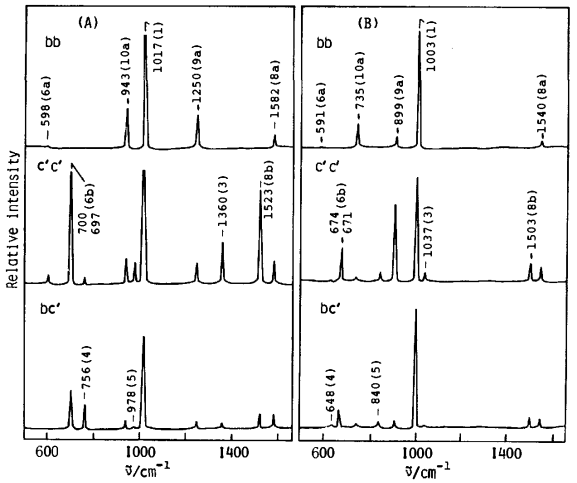

Fig. 3. Polarized Raman spectra of [$^1H_4$]- (A) and [$^2H_4$]- (B) pyrazine single crystals.

Formation of Magnesium and Chloroaluminium Phthalocyanine Thin Films Exhibiting an Intense Near-Infrared Absorption by Electrolysis of Surfactants with Ferrocenyl Moiety

Tetsuo SAJI
Department of Chemical Engineering, Tokyo Institute of Technology, Ohokayama, Meguro-ku, Tokyo 152
(Received February 6, 1989)

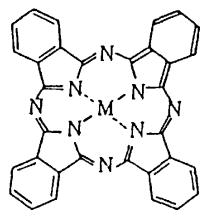
Synopsis. Magnesium or chloroaluminium phthalocyanine (**1** and **2**) was dispersed to the micellar solution formed by a non-ionic surfactant with ferrocenyl moiety (**3**). The thin films prepared by the controlled-potential electrolysis of the micellar solution exhibited an intense near-infrared absorption.

In recent years extensive researches have been carried out on organic compounds for laser recording materials.[1] The sublimed films of phthalocyanine compounds usually exhibit no strong absorption in the wavelength region over 800 nm of use for a laser diode light source.[2] After acid, organic solvent, or thermal treatments, the sublimed films of magnesium, aluminium, and vanadyl phthalocyanines show strong absorption in the near-infrared region.[3-6]

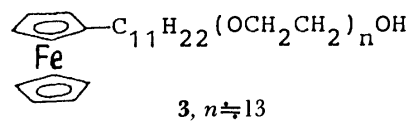
Recently, we have presented a novel technique for electrochemical formation of an organic thin film by electrolysis of cationic surfactants with ferrocenyl moiety (micelle disruption method).[7] We further reported thin films of phthalocyanine compounds MPc (M=H_2, Cu) by electrolysis of non-ionic surfactants with a ferrocenyl moiety (**3**), and showed that crystalline forms of CuPc thin films prepared by this technique are identical with those of CuPc powders dispersed in an aqueous solution of the surfactant.[8,9] The author will report the preparation of thin films of magnesium and chloroaluminium phthalocyanines (**1** and **2**) using this technique, which have an intense absorption peak in the near-infrared region and have been proposed as candidates for laser recording materials.[1]

Experimental

1 was obtained from Tokyo Kasei Co. **2** was given by Nippon Shokubai Kagaku Kogyo Co. The surfactant used was poly(oxyethylene) (**13**) 11-ferrocenylundecyl ether (average molecular weight≒900) (**3**).[10] The micellar solution of **1** was prepared in the following manner: An aqueous solution containing 1 mM **3**, 0.1 M LiBr, and 5 mM **1** was sonicated for 10 min and stirred for three days. This solution was allowed to stand for overnight. The supernatant of this



1, M=Mg
2, M=AlCl



3, n≒13

solution was used for preparing the films. The test solution for electronic absorption measurements was prepared by diluting this solution. The micellar solution of **2** was prepared in the same manner as that of **1**.

Controlled-potential electrolysis was done for of an aqueous solution containing 3.2 mM **1**, 1.0 mM **3**, and 0.1 M LiBr by indium tin oxide (ITO) electrode maintained at +0.50 V vs. SCE with slow stirring. When 2.0 mM **3** solution was used, **1** film did not grow up. If **3** is present in the solution which is unadsorbed on the surfaces of **1** particles, the film formation seems to be disturbed. After a definite amount of current passed through ITO electrode, the electrode was air-dried at room temperature overnight, then rinsed with distilled water. Electrochemical measurements were carried out at 25 °C under a nitrogen atmosphere.

Results and Discussion

Figure 1 shows the electronic absorption spectrum of 1.0 mM (1 M=1 mol dm^{-3}) aqueous solution of **1** (a), and that of **1** in ethanol solution (b). The absorption peaks in spectrum (b) are the same as those previously reported[11] and are attributable to the

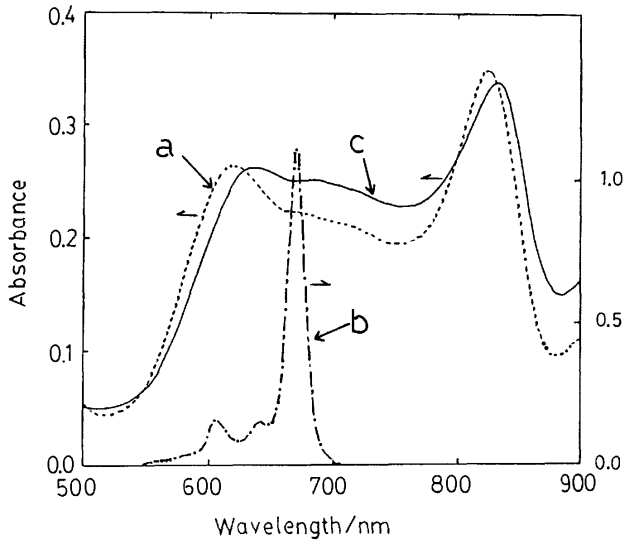


Fig. 1. Electronic absorption spectra of **1** in 1 mM **3**, and 0.1 M LiBr aqueous solution (a), in ethanol solution (b), and **1** film prepared by electrolysis of an aqueous solution containing 1 mM **3**, 3.2 mM **1**, and 0.1 M LiBr at ITO electrode maintained at +0.5 V vs. SCE for 1 h (c).

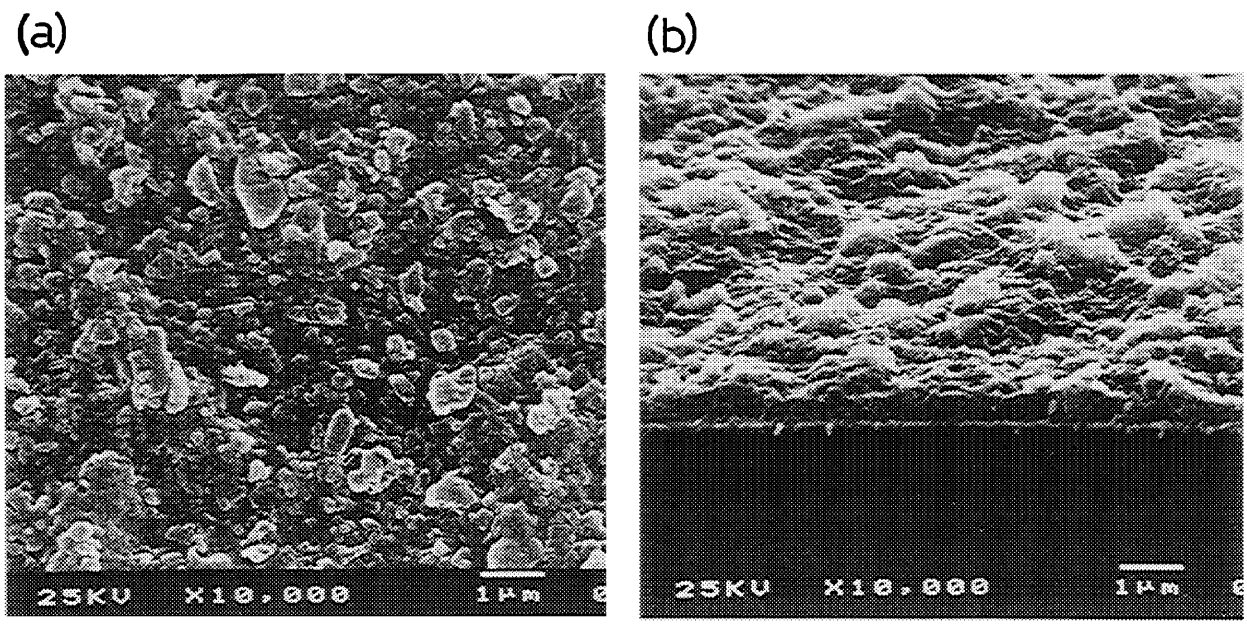

Fig. 2. SEM top (a) and cross sectional (b) views of **1** film prepared by the electrolysis of an aqueous solution containing 3.2 mM **1**, 1.0 mM **3**, and 0.1 M LiBr at ITO electrode maintained at +0.5 V vs. SCE for 14 h.

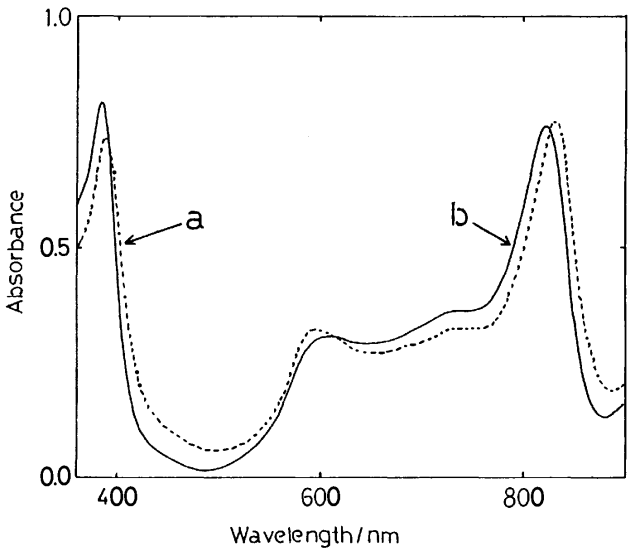

Fig. 3. Electronic absorption spectra of **2** in aqueous solution containing 2.0 mM **3** and 0.1 M LiBr (a), and **2** film prepared by the electrolysis of the same solution at ITO electrode maintained at +0.5 V vs. SCE for 3 h (b).

monomer.[12] The spectrum (a) consisting of a broad intense near-infrared peak at 827 nm suggests that the molecules of **1** in micellar solution exist in aggregates (particles).

The absorption spectrum of **1** film on the ITO electrode prepared by the electrolysis for 1 h consists of a broad intense near-infrared peak at 830 nm (Fig. 1-c).

Figure 2 shows the scanning electron micrographs (SEM) of the film on ITO. The crystals less than 1 μm in length were formed as shown in this figure. The SEM of the cross section of the film shows that the film thickness is approximately 0.5 μm (Fig. 2). This film thickness was easily controlled by changing the electrolysis time.

Figure 3-a shows the electronic absorption spectrum of **2** in 2.0 mM **3** (Fig. 3-b). The spectrum consists of an intense near-infrared peak at 828 nm. The thin film of **2** was prepared by the same method as that of **1**. The electronic absorption spectrum of **2** film (Fig. 3-b) consisted of an intense near-infrared peak at 822 nm.

Such near-infrared peaks of **1** and aluminium-phthalocyanine derivatives have been reported in the cases of treating these sublimed films with organic solvents.[3,4] These phenomena have been ascribed to a crystal form change, followed by dissolving of these compounds in the organic solvent. The formation of the films in our studies which show near-infrared peaks is relevant to the process of preparing these films: The cyrstal form of the particles dispersed in the surfactant solution is maintained in that of the film deposited on ITO electrode, because the electronic absorption spectrum of the film is similar to that of the micellar solution (Figs. 1 and 3).

The experimental results indicate that such an electrochemical method will give a technique for preparing **1** and **2** films which show near-infrared peaks without any further treatment.

We would like to thank Rokuro Ohki for the electron micrographs.

Synopsis. The influence of α-cyclodextrin (α-CD) on the electrochemistry of (ferrocenylmethyl)dodecyldimethylammonium bromide (**I**) was studied with a glassy carbon (GC) electrode. α-CD increases the apparent diffusion coefficient of **I**. This unusual effect is explained in terms of disruptive effect of α-CD on **I**'s aggregates. α-CD also influences, to some extent, **I**'s adsorption onto GC electrode when adsorbed from its micromolar aqueous solution.

The electrochemistry of redox active surfactants in aqueous solution has received some attention in the last few years.[1-5] Furthermore, their spontaneous aggregation on the surface of solid electrodes has recently been reported.[6-8]

Cyclodextrins (CDs) are torus shaped cyclic oligosaccharides having a hydrophobic cavity and a hydrophilic exterior. They can function as hosts for hydrophobic moieties of molecules dissolved in aqueous medium.[9] When CDs are added to a surfactant solution, they cause a decrease in the hydrophobicity of the solution. This is due to the inclusion of the hydrophobic alkyl chain of surfactant into the hydrophobic CD cavity.[10,11] Also, the solubility of a few electroreduced surfactants is known to increase by the presence of CD.[12,13]

In this report we show how α-CD influences the electrochemistry of redox active surfactants in aqueous solution. Although the effect of CDs on the behavior of redox inactive chromophore molecules in solution can be evaluated by, for example, UV-visible absorption and induced circular dichroism spectroscopies, that of redox active species can be examined by electrochemical methods, too. It appears not insignificant to show such an example. We chose here a functional surfactant with ferrocene (Fc) moiety, i.e. $FcCH_2N^+(CH_3)_2C_{12}H_{25}Br^-$ (**I**) and studied its properties and behavior in terms of electrochemistry. This molecule aggregates because it contains a long alkyl chain,[6] but is different from often studied viologen surfactants,[7,8] with which attractive interactions between viologen moieties may also cause aggregation.[14] The choice of α-CD, which is composed of six glucose units and has among CDs the smallest hydrophobic cavity with diameters of 0.47—0.52 nm,[9] is to lessen the probability of inclusion of the ferrocene moiety into the cyclodextrin cavity.

Experimental

Materials. **I** was synthesized by the reaction of [(dimethylamino)methyl]ferrocene (Aldrich) with dodecyl bromide (Tokyo Kasei) according to the literature.[1] The product was identified by elementary analysis. Found: C, 60.22; H, 8.70; N, 2.77%. Calcd for $C_{25}H_{42}NFeBr$: C, 60.08; H, 8.62; N, 2.85%. Li_2SO_4 was an extra pure reagent and was used as received. The water used for preparation of electrolyte solutions and sonication of electrodes was purified by a water purifier RO-10C (Tokyo Rikakikai Co., Ltd.).

Equipment and Procedures. Cyclic voltammetry and potential step chronoamperometry were performed using a potentiostat/galvanostat HA-501, an arbitrary function generator HB-105 (both Hokuto Denko), and a 3036 XY recorder (Yokogawa) connected with a water-jacketed three-compartment electrochemical cell at 25 °C. A spiral made of platinum wire served as the counter electrode and a saturated calomel electrode (SCE) as a reference one. As a working electrode a GC (Tokai Carbon GC-20) disc (0.071 cm^2 area) mounted in Teflon was used. It was polished using 0.3 and 0.05 μm β-alumina (Buehler). Each polishing step was followed by rinsing and sonication with water for more than 10 min. Then the electrode was immersed into a nitrogen-saturated solution and electrochemical measurements were performed. Apparent redox potentials (E°_{app}) were determined from cyclic voltammograms as midpotentials of cathodic and anodic peak potentials. Apparent diffusion coefficients (D_{app}) were determined by potential step chronoamperometry[15] by assuming one-electron process. The error of the above parameters was estimated to be 10 mV for E°_{app} and less than 20% for D_{app}.

Circular dichroism spectra were recorded on a JASCO-400X spectropolarimeter connected with a cell having an optical path of 10 mm.

Results and Discussion

The cyclic voltammograms recorded for the 2 mM (1 M=1 mol dm^{-3}) **I** and 0.2 M Li_2SO_4 aqueous solution in the absence and presence of 10 mM α-CD are presented in Fig. 1. It is obvious that **I** adsorbs weakly onto GC as onto Pt electrode.[1] The value of E°_{app} (0.427 V) determined in this particular case as being 0.029 V more positive than the cathodic peak potential, is within the error of experiment, being the same as in the case of Pt electrode.[1]

When the above experiment was performed in the 10 mM α-CD solution, the shape of the anodic peak changed. The 60 mV difference between cathodic and anodic peak potentials and the linear dependence of peak currents on the square root of scan rates in the scan rate range 0.01—0.2 V s^{-1} indicate that this couple is associated with a one-electron process, controlled by mass transport to the electrode.[15] The decrease in the anodic peak current, the shift of E°_{app} by 0.020 V in the anodic direction, and the slight increase in cathodic current in comparison to those determined in the absence of α-CD may be caused by a complexation

† On leave from the Institute of Physical Chemistry of Polish Academy of Sciences, Warszawa, Poland.

with α-CD and its influence on I's aggregation (see below).

The concentration dependences ($0.2 \leqq [\mathbf{I}] \leqq 4$ mM) of D_{app} and E°_{app} of **I** in the 10 mM α-CD and 0.2 M Li_2SO_4 aqueous solution are shown in Fig. 2. The D_{app} decreases slightly with the increase in [**I**] but it is larger than that in the absence of α-CD, except in the 0.2 mM **I** solution (compare also with Fig. 2 in Ref. 1). This behavior is opposite to that generally observed.[16] It has been shown that D_{app} is lower when molecules of redox probe aggregate than when aggregation does not occur.[1] Therefore, the effect of α-CD on the D_{app} of **I** may be caused by its disruptive effect on I's micelles (the twofold increase in critical micelle concentration (cmc) of tetraalkylammonium surfactants in the presence of CD has been explained similarly[10,11]).

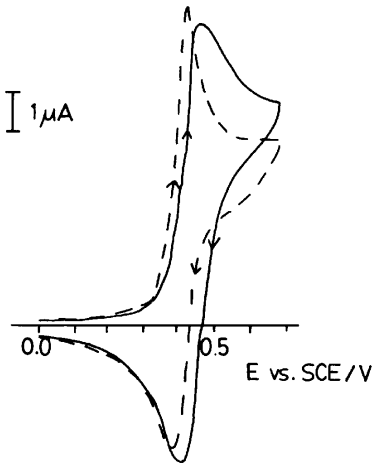

Fig. 1. The cyclic voltammograms recorded in 2 mM solution of **I** in 0.2 M Li_2SO_4 aqueous solution at GC electrode with scan rate 0.1 V s^{-1} (broken line). The same with 10 mM α-CD (solid line).

The D_{app} value estimated at the maximum concentration of **I** in the presence of α-CD is about 20% higher than that estimated in the absence of α-CD.[1] This may be due to the higher value of cmc as well as the smaller molecular weight of micelles in the presence of α-CD (the cmc values of **I** in the 0.2 M Li_2SO_4 in the absence and presence of α-CD are estimated to be, at 25 °C, ca. 0.5 mM[1] and ca. 2 mM (from Fig. 2), respectively). The D_{app} value estimated for the 0.2 mM solution of **I** is smaller than that estimated in the absence of α-CD. At this concentration **I** does not form aggregates[1] and this decrement in D_{app} may be ascribed only to CD complex formation.[16] The dependence of E°_{app} on [**I**] is similar to that evaluated in the absence of α-CD,[1] but E°_{app} is slightly shifted in the anodic direction. The anodic shift of E°_{app} in the 0.2 mM solution of **I** may indicate a stronger complexation of the reduced form of **I** by α-CD. At higher concentrations of **I**, the concentration dependence of E°_{app} may be caused by both aggregation and complexation.

Circular dichroism is induced when a chromophore is trapped in the cavity of CDs.[17] Accordingly, the lack of circular dichroism signals in the range of 200—500 nm in the 0.5 mM **I** and 10 mM α-CD solution indicates that the ferrocene chromophore is not included into the α-CD cavity.

The influence of CD on the surface aggregation of redox surfactants in solution has recently been mentioned.[8] Therefore, we performed a similar experiment with **I**. The cyclic voltammograms recorded at $[\mathbf{I}]/\mu M = 30$ in the 0.2 M Li_2SO_4 solution are presented in Fig. 3A. The linear dependence of anodic and cathodic peak currents (after subtraction of the current recorded in the electrolyte solution) on scan rate in the range 0.01—0.2 V s^{-1} indicates that **I** adsorbs onto the GC electrode from this solution. The E°_{app} value (+0.49 V) of the $\mathbf{I}^{0/+1}$ couple is shifted in the anodic direction by 0.13 V relative to that determined

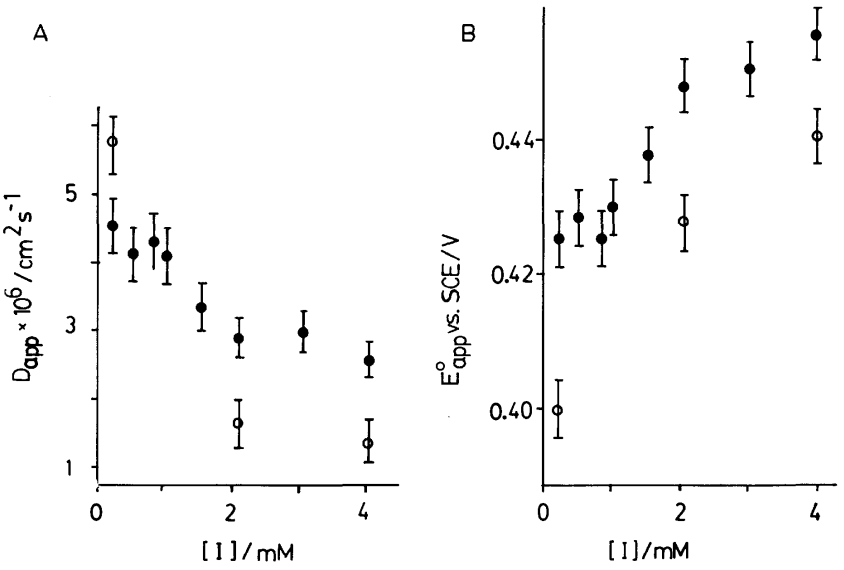

Fig. 2. The dependence of (A) D_{app} of **I** and (B) E°_{app} of $\mathbf{I}^{0/+1}$ couple on [**I**] in aqueous 0.2 M Li_2SO_4 (○). The same with 10 mM α-CD (●).

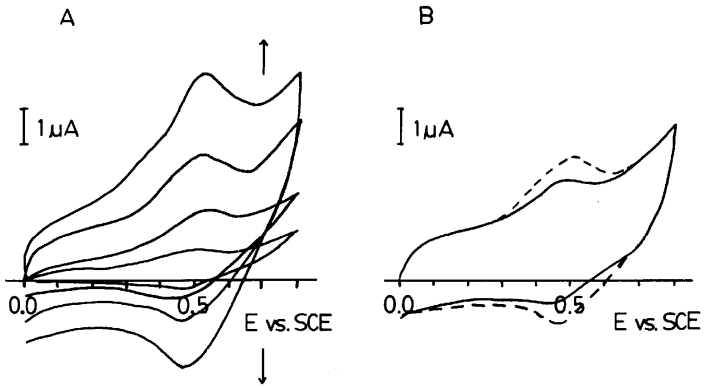

Fig. 3. The cyclic voltammograms recorded at GC electrode in 0.2 M Li_2SO_4 solution containing 30 μM of **I** (A) with scan rates 0.025, 0.05, 0.1, and 0.2 V s^{-1}, and (B) with the scan rate 0.1 V s^{-1} in the absence (broken line) and presence (solid line) of 0.5 mM α-CD.

for ferrocenyltrimethylammonium cation (0.36 V vs. SCE[18]). This indicates that, of the two redox forms, the oxidized one is more weakly bonded to the electrode. This may be caused by stronger repulsive interactions among head groups in the oxidized species of **I**. The differences between the anodic and cathodic peak potentials are equal to 0.04—0.06 V and their half widths (though difficult to estimate) are larger by more than 0.07 V than the theoretical value (0.091 V[19]). This indicates that the layer cannot be regarded as tightly packed, although the area per molecule (about 50 nm^2) is similar to that reported for the monolayer of (ferrocenylmethyl)octadecyldimethylammonium cations deposited on Au electrode by the Langmuir-Blodgett technique.[20]

When the experiments described above were performed in the 0.5 mM α-CD solution, i.e. at [α-CD]/[**I**]=17 (Fig. 3B), both the anodic and cathodic peak currents decreased by ca. 50%, and when [α-CD] was increased to ca. 10 mM ([α-CD]/[**I**]=ca. 3333), the two peaks disappeared. This behavior is different from that of viologen surfactant where 10-fold excess of α-CD was enough to prevent the surface aggregation onto Au electrode.[8] The formation constant of alkyl chain surfactant-α-CD complexes are about 10^3 dm^3 mol^{-1},[10,11] and it does not depend on the length of alkyl chain of surfactants when the chain contains more than 10 carbon atoms.[11] Therefore, it seems reasonable to assume a similar formation constant for **I**-α-CD complexes. If so, in the above experiments more than 90% of **I**'s molecules are considered to be complexed with α-CD. In spite of such a high degree of complexation, the decrease of adsorption is slight compared with other systems.[8] This may indicate the presence of some attractive interactions between **I** and hydrophilic GC surface. The lock of circular dichroism signals suggests no inclusion of ferrocenyl moiety. Accordingly, if some interaction exists between the electrode surface and **I**, **I**'s ferrocenyl group would be participating in the interaction.

Dielectric Properties of Dehydrated Ca_1Na_{10}-A and Na_{12}-A Zeolites

Tatsuo OHGUSHI,* Kenji NONAKA, Hiroyuki YOSHIDA, and Tetsuo TAKAISHI
Department of Materials Science, Toyohashi University of Technology, Toyohashi 440
(Received February 14, 1989)

Synopsis. Dielectric properties of completely dehydrated Ca_1Na_{10}-A and Na_{12}-A zeolites were studied. The properties of Ca_1Na_{10}-A bore close parallels to those of Na_{11}-ZK4 having almost the same cation distribution as Ca_1Na_{10}-A. The properties of Na_{12}-A were markedly different from those of Ca_1Na_{10}-A and the unusual behavior of the zeolite were attributed to a larger mobility of Na^+ ion on the 4-ring site.

Properties of Ca_xNa_{12-2x}-A zeolites ($0 \leq x \leq 6$) have been widely investigated, e.g., heats of gas-adsorption,[1] reactivities of oxygen in zeolite framework,[2] and heat-resistivities.[3] These properties of the zeolite at composition of $x=0$ were markedly different from those at $x \geq 1$ and the differences were correlated to the Na^+ ion near a 4-membered oxygen ring (abbreviated as 4-ring Na^+ ion), since the zeolite contains the 4-ring Na^+ ion at $x=0$ but not at $x \geq 1$ (Table 1). The unusual behavior of the 4-ring Na^+ ion may be directly studied by dielectric measurements, and thus the dielectric properties of Na_{12}-A and Ca_1Na_{10}-A were measured and compared with each other. It is one objective of the present work to study the unusual properties of Na_{12}-A.

Another subject is to investigate the similarities of the dielectric properties of the Ca_1Na_{10}-A and Na_{11}-ZK4 zeolites. Zeolite A is isostructural with zeolite ZK4, and Ca_1Na_{10}-A has the same cation distribution as Na_{11}-ZK4, except for a Ca^{2+} ion being used in the place of a Na^+ ion near a 6-ring (Table 1). Thus, the dielectric properties of Ca_1Na_{10}-A are expected to be similar to those observed in Na_{11}-ZK4.[7]

Experimental

The apparatus and the procedures used in the dielectric measurements were the same as in a previous paper.[8] A commercial 4A zeolite, $Na_{11.8}(AlO_2)_{11.8}(SiO_2)_{12.2} \cdot nH_2O$ (abbreviated as Na_{12}-A), was ion-exchanged with 0.1 mol dm^{-3} solution of $(CH_3COO)_2Ca$ at 353±0.5 K for 3 d, and the cation composition of zeolite after ion-exchange was determined to be $Ca_{1.05}Na_{9.7}(AlO_2)_{11.8}(SiO_2)_{12.2}$ (Ca_1Na_{10}-A), by EDTA titration of the ion exchange solution and from the material balance.

Complex dielectric constants ($\varepsilon^* = \varepsilon' - i\varepsilon''$) were measured as functions of frequency f and temperature T, in the ranges of 20—2×10^6 Hz and 273—653 K for Ca_1Na_{10}-A, and 50—2×10^6 Hz and 163—363 K for Na_{12}-A. In the present work, we did not require the absolute value of the dielectric constant and did not make the correction for the packing density of the sample disk, because we were concerned only with its dependence on the frequency and temperature.

Table 1. Cation Distribution[4-6]

Composition	8-Ring 3[a]	6-Ring 8[a]	4-Ring 12[a]
Na_{12}-A	3 Na^+	8 Na^+	1 Na^+
Ca_1Na_{10}-A	3 Na^+	1 Ca^{2+}+7 Na^+	0
Na_{11}-ZK4	3 Na^+	8 Na^+	0

a) Number of ring per pseudo unit cell. Each ring can accommodate only one cation.

Results

Spectra of the loss tangent for Ca_1Na_{10}-A are shown in Fig. 1, which contain two main losses, a loss peak in a higher frequency region and a peak-less loss in a lower region. A frequency, f_{tan}, at the peak of the loss tangent was determined and the activation energy, E_{tan}, of cation jump was found to be 87±2 kJ mol^{-1} from the slope of the plots of $\ln f_{tan}$ vs. $1/T$.

Cole-Cole plots (Fig. 2) showed, in a larger ε' region, a steep rise of ε''_{obs} which is usually attributed to a conductivity loss[9-11] (subscript obs denotes observed

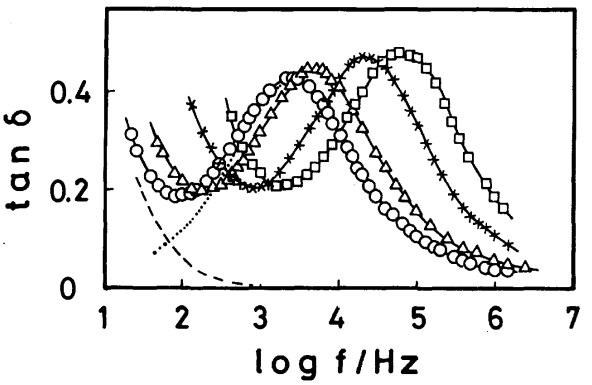

Fig. 1. Spectra of dielectric loss tangent for Ca_1Na_{10}-A zeolite. □: 657.7 K, ✳: 614.4 K, △: 566.8 K, ○: 543.8 K. Broken line for loss tangent of conduction, $\tan\delta_c = \varepsilon''_c/\varepsilon'_{obs}$, at 543.8 K ($\varepsilon''_c = \sigma/2\pi f\varepsilon_0$ with $\sigma = 2.1\times10^{-8}$ S m^{-1}). Dotted line for loss tangent of relaxation, $\tan\delta_r = \tan\delta_{obs} - \tan\delta_c$, at 543.8 K. Subscript obs denotes observed values.

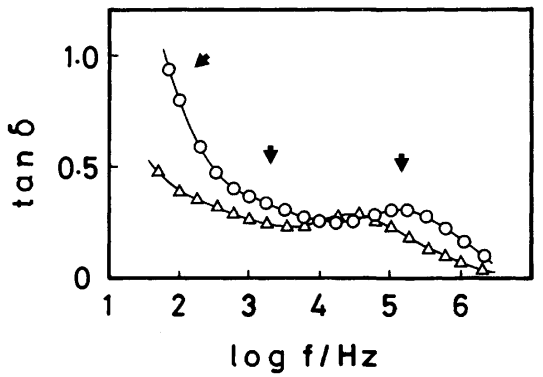

Fig. 3. Spectra of dielectric loss tangent for Na_{12}-A zeolite. O: 363.2 K, Δ: 331.0 K. Arrows denote losses in each frequency region of spectrum at 363.2 K, losses in the lower, middle and higher frequency regions.

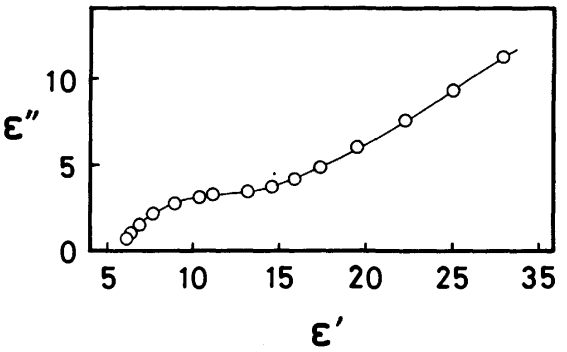

Fig. 4. Cole-Cole plots for Na_{12}-A zeolite at 363.2 K.

values). The loss part in the larger ε' region was described with the equation of the conductivity loss, $\varepsilon_c''=\sigma/2\pi f\varepsilon_0$, and was thereby assigned to the conductivity loss, where ε_c'' and ε_0 are the conductivity loss and the permittivity of vacuum, respectively, and σ an apparent dc conductivity. A plot of $\ln\sigma$ vs. $1/T$ gave $E_c=83\pm4$ kJ mol^{-1} for the conduction process. The observed loss was corrected for by subtracting the conductivity loss. The plots of ε_r'' $(=\varepsilon_{obs}''-\varepsilon_c'')$ vs. ε_{obs}' were well described with a single circular arc, except for the larger ε' region, as shown in Fig. 2. Hence, we concluded that the main part of ε_r'' contains only one relaxation loss. For the relaxation process, the activation energy, E_r, and the frequency factor, ω_0, were determined from plots of $\ln f_r$ vs. $1/T$, where f_r is the frequency at the maximum value of ε_r'' and ω_0 is defined as $\ln f_r=\ln\omega_0/2\pi-E_r/RT$. Their values were $E_r=87\pm3$ kJ mol^{-1} and $\log\omega_0=12.0\pm0.4$. If a relaxation process and a conduction process contain the same cation-jump, the equation of $E_r-E_c=RT$ holds true.[8] The present values of E_r and E_c satisfy this relationship, and thus it was concluded that both processes involve the same cation jump.

For Na_{12}-A zeolite, both ε_{obs}' and ε_{obs}'', at $T>400$ K, were too large to give useful data for analysis. The measurements were thereby limited to temperatures lower than 363 K. Representative spectra of the loss tangent and Cole-Cole plots are given in Figs. 3 and 4, respectively. The spectra of the loss tangent show that there are three kinds of losses, a loss peak in the higher frequency region, a large peak-less loss in the lower region, and a small loss in the middle region, though the last is less clear. The large loss in the larger ε' region, in Fig. 4, may be due to conduction. However, the loss part was not evaluated with the equation of conductivity loss owing to the loss in the middle region. Thus the Cole-Cole curve could not be separated into separate components. The activation energy of cation jump was thereby determined only from the spectra of loss tangent, and was $E_{tan}=48\pm4$ kJ mol^{-1}.

Discussion

Let us consider cation-jumps causing the losses observed in Ca_1Na_{10}-A. Allowed cation-jumps in Ca_1Na_{10}-A can be deduced from the cation distribution in the zeolite, since only jumps to sites unoccupied by cations are allowed. The cation distribution is essentially the same as in Na_{11}-ZK4 and thus the same type of cation-jumps as in Na_{11}-ZK4 are allowed, namely a jump from the 8- or 6-ring site to the 4-ring site, a jump from the 8-ring site to the neighboring sites in the same ring, and a jump between the 6-ring sites in the large cage side and in the soadalite cage side.[7] In the allowed jumps, the jump which can cause both relaxation and conductivity losses is only the jump of Na^+ ion between the 8- and 4-ring sites, since the cation can escape from the unit cell dimension only by repeating the jump of the 8-ring site → 4-ring site → another 8-ring site. Thus both relaxation and conductivity losses observed in Ca_1Na_{10}-A are assigned to the jump of Na^+ ion between the 8-ring and 4-ring sites.

The relaxation loss is characterized by $E_{tan}=87\pm2$ kJ mol^{-1}, $E_r=87\pm3$ kJ mol^{-1}, and $\log\omega_0=12.0\pm0.4$, and the conductivity loss by $E_c=83\pm4$ kJ mol^{-1}. These characteristics are respectively close to those for Na_{11}-ZK4 ($E_{tan}=89\pm2$ kJ mol^{-1}, $E_r=91\pm3$ kJ mol^{-1}, $\log\omega_0=12.1\pm0.4$ for the relaxation loss assigned to the jump between the 8- and 4-ring sites, and $E_c=86\pm4$ kJ mol^{-1} for the conductivity loss attributed to the jump of 8-ring → 4-ring → another 8-ring).[7] Hence, we can conclude that the dielectric properties of Ca_1Na_{10}-A bear close parallels to those of Na_{11}-ZK4.

In Na_{12}-A, the loss peak was observed at a lower temperature range of 273—363 K. Such a loss was not observed in Ca_1Na_{10}-A and Na_{11}-ZK4 zeolites lacking the 4-ring Na^+ ion. The loss is thereby peculiar to Na_{12}-A and is correlated to jumps of the 4-ring Na^+ ion. There are two kinds of jumps related to the 4-ring Na^+ ion, that is, one is the jump from the 4-ring site to the neighboring 4-ring site and another is the modification of the jump, from the 8- or 6-ring site to the 4-ring site, by the 4-ring Na^+ ion. If the Na^+ ion on the 4-ring site jumps to the nearest 4-ring site, the activation energy of the jump may be as small as $E_{tan}=48$ kJ mol^{-1}, since the cation has a weak affinity to the 4-ring site.[4,12] Thus the loss peak is most probably assigned to the jump of Na^+ ion between the 4-ring sites.

Conclusion

It was confirmed that the dielectric properties of Ca_1Na_{10}-A and Na_{11}-ZK4 zeolites are, in both the characteristic values and the jump mechanism, close to each other. The zeolite Na_{12}-A showed "unusual" behaviors also in dielectric properties. As can be seen from the small activation energy of jump of the 4-ring Na^+ ion, the unusual behavior has its origin in a larger mobility of the Na^+ ion on the 4-ring site.

Synopsis. From rate measurements with pulse surface reaction rate analysis, it was found that the methanation activity of Ni/TiO_2 was the same both in the SMSI and in the normal states.

On high-temperature reduction (namely at 773 K), titania-supported metals exhibit an interesting phenomenon which is known as a strong metal-support interaction (SMSI).[1] As a result of SMSI, a large part of the chemisorption ability for H_2 or CO is lost without any agglomeration of a supported metal.[2] While most reactions in which hydrogen is involved are suppressed on the catalyst in the SMSI state, it has been found that the hydrogenation of CO or methanation is enhanced by SMSI.[3] This enhanced activity was measured on the basis of the turnover frequency (TOF), which is determined by dividing the rate by the number of adsorption sites. The suppression of chemisorption, however, makes it difficult to count precisely the number of adsorption sites. Indeed, there seems to be controversy over the enhanced activity of the SMSI catalyst for CO hydrogenation.[4]

Different from the conventional TOF, we have found that pulse surface reaction rate analysis (PSRA) is relevant in examining the activity enhancement of the SMSI catalyst for CO hydrogenation.[5] Since adsorbed CO is an initial reacting species under conditions of PSRA, the CO adsorption step is not involved in this rate analysis. Therefore, if the number of adsorbed CO molecules is decreased only by methanation, but not by desorption, we can determine directly the rate constant per active site without any information about the number of active sites from the analysis of the dynamic behavior of the adsorbed CO or the CH_4 produced.[6] PSRA has a further advantage: the rate for the initial state of a catalyst can be measured with minimal influence of the H_2O produced, which can destroy the SMSI state.[7] In the previous study, by using PSRA, we revealed that SMSI increased the activity for the hydrogenation of adsorbed CO on titania-supported Pt and Pd, but not on titania-supported Rh, Ru, and Ir.[5] Compared to noble metals, studies about the effect of SMSI on CO hydrogenation over titania-supported base metals are limited.[3,4] In the present study, selecting Ni as the base metal, we examined the effect of SMSI on the hydrogenation of adsorbed CO on the basis of the rate constant per active site determined by PSRA.

Experimental

Catalyst. Ni/TiO_2 catalyst (metal loading, 20 wt%) was prepared by impregnating TiO_2 (Nippon Aerosil, P-25) with an aqueous solution of $Ni(NO_3)_2$ followed by drying and subsequent calcination. Before making rate and chemisorption measurements, the catalyst was reduced at different temperatures for 4 h. In order to obtain information about the extents both of reduction and of sintering, X-ray powder diffraction measurements were made using a Shimadzu Cu $K\alpha$ diffractometer (Shimadzu XD-3A).

Rate and Chemisorption Measurements. For the hydrogenation of adsorbed CO, the rate constant per active site was determined by PSRA in the manner described elsewhere.[5,6] The amount of CO chemisorbed on the catalyst was determined at 300 K using a conventional pulse adsorption apparatus.

Results and Discussion

Figure 1 shows the X-ray diffraction patterns for

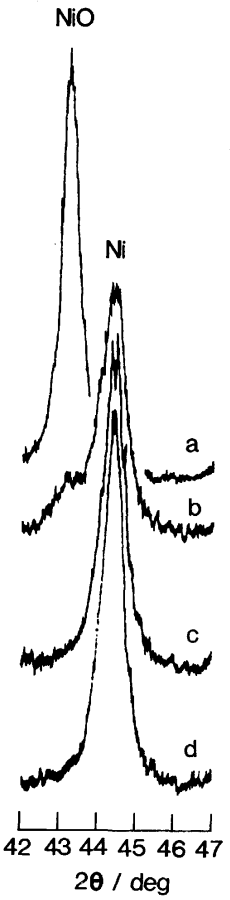

Fig. 1. X-Ray powder diffraction patterns for unreduced (a) and reduced Ni/TiO_2 catalysts. Reduction temperature: 573 K (b), 673 K (c), and 773 K (d).

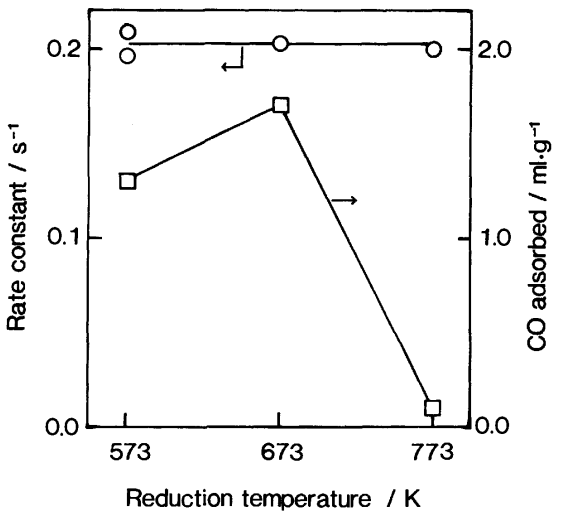

Fig. 2. Amount of CO adsorbed (□) and the rate constant per active site (○) on Ni/TiO_2 against the reduction temperature. Catalyst weight; 100 mg, reaction temperature; 453 K, flow rate of carrier gas; 40 cm^3 min^{-1}, amount of CO pulsed; 10 mm^3.

unreduced and reduced catalysts. Although most NiO is changed into Ni metal after reduction at 573 K, some of the NiO still remains unreduced. After reduction both at 673 and at 773 K, on the other hand, the NiO diffraction peak disappears, implying that complete reduction occurs. It is furthermore observable from X-ray diffraction patterns that the peak width at half height is almost the same at all reduction temperatures examined. This suggests that the particle size is hardly altered after reduction below 773 K.

The amount of CO adsorbed is shown in Fig. 2 as a function of the reduction temperature. A considerable amount of CO is adsorbed on the catalyst after reduction at 573 and 673 K, although the amount is smaller on reduction at 573 K than at 673 K. The lower amount of CO chemisorption on reduction at 573 K is ascribable to the incomplete reduction, as the X-ray diffraction shows (see Fig. 1). Contrary to this, CO chemisorption is suppressed almost completely after reduction at 773 K. Since reduction at 773 K did not cause the agglomeration of supported Ni metal particles, as described above, the drastic suppression of CO chemisorption should be attributed to SMSI.

Under experimental conditions of PSRA, a small amount of CO (usually 10 mm^3) pulsed via the H_2 carrier gas was immediately adsorbed on the catalyst and then hydrogenated selectively to CH_4. Analysis of the dynamics of the CH_4 produced permits us to determine the rate constant per active site.[5,6] The rate constant determined is also shown in Fig. 2 as a function of the reduction temperature. The rate constant is almost constant irrespective of the reduction temperature. Taking into account the fact that reduction at 773 K induces the SMSI state in the Ni/TiO_2, the results in Fig. 2 clearly indicates that the SMSI of this catalyst does not increase the rate constant per active site for the hydrogenation of adsorbed CO. It is interesting to compare the present results with the one previously obtained on noble metals.[5] Titania-supported Ni is very similar to titania-supported Rh, Ru, and Ir in a sense that their SMSI does not increase the activity for the hydrogenation of adsorbed CO.

It is now accepted that SMSI results from migration of TiO_x-suboxide species, formed by high-temperature reduction, onto the metal particles.[8] The suppression of CO chemisorption results from site blocking by the migrated TiO_x-suboxide, by which the number of adsorption sites is decreased. The influence of SMSI on CO hydrogenation has been attributed to this TiO_x-suboxide.[9] The suboxide takes part in C–O bond dissociation by bond formation between a titanium ion in a partially reduced state and an oxygen end of an adsorbed CO species. Due to the high affinity of the titanium ion in the reduced state for an oxygen atom, a C–O bond is readily dissociated, leading to an increase in the activity for CO hydrogenation. Since our Ni/TiO_2 is in the SMSI state after reduction at 773 K, the TiO_x-suboxide should be present on Ni metal particles. Nevertheless, this suboxide did not increase the activity for the hydrogenation of adsorbed CO. We have previously presented a possible explanation for the effect of the TiO_x-suboxide: the suboxide effectively takes part in the C–O bond dissociation on such a metal as Pt or Pd exhibiting a relatively low activity for CO hydrogenation. However, it does not work on a metal with high activity like Rh or Ru.[5] This may also explain the absence of the enhanced activity of Ni/TiO_2 in the SMSI state, because Ni is known to be one of the most active metals for CO hydrogenation.[10] This may again support our previous explanation.

Molecular Aggregation Structure of Barium Stearate Monolayer Based on Electron Microscopy

Tisato KAJIYAMA,* Kazuo UMEMURA, Motoko UCHIDA, Yushi OISHI, and Ryutaro TAKEI†
Department of Applied Chemistry, Faculty of Engineering, Kyushu University,

(Received May 18, 1989)

Synopsis. Aggregation structure of barium stearate monolayers prepared from a benzene solution at various surface pressures was investigated by using a transmission electron microscope. Two-dimensional crystallites of the monolayer were formed even at the surface pressure of 0 $mN \cdot m^{-1}$. The monolayer crystallites on the water surface became a continuous phase at 25 $mN \cdot m^{-1}$ and collapsed at 40 $mN \cdot m^{-1}$. The surface pressure-area isotherm represents an aggregating process of the small two-dimensional crystallites on the water surface, instead of a generally accepted concept on phase transitions among gas, liquid, and solid phases.

It has been generally accepted on the basis of π-A isotherm behavior that monolayer on the water surface is homogeneous at every surface pressure and also that the gaseous monolayer state at very low surface pressure converts into the liquid expanded one, liquid condensed one and finally the solid monolayer state with increasing surface pressure on the water surface. To ascertain this concept, morphology for monolayers prepared from various amphiphiles has been studied.[1-6] However, there has been no morphological observation with diffraction experiment for phase assignment of monolayers at various surface pressures.

In this study, the aggregation structure of barium stearate monolayer transferred onto a substrate at various surface pressures was investigated on the basis of electron microscopic observations, a bright field electron micrograph and an electron diffraction, ED pattern.

Experimental

Benzene solution of stearic acid was prepared at the concentration of 3.5×10^{-3} $mol \cdot l^{-1}$. The monolayer was spread on the water subphase containing 3×10^{-5} $mol \cdot l^{-1}$ of $BaCl_2$ and 4×10^{-4} $mol \cdot l^{-1}$ of $KHCO_3$ and then, compressed to a given surface pressure at the barrier speed of 48 $mm \cdot min^{-1}$. The subphase temperature, T_{sp} was maintained at 290±0.5 K. The monolayer was transferred onto a substrate by a horizontal lifting method at the surface pressure of 0 $mN \cdot m^{-1}$ or by a vertical lifting method at 10, 25 and 40 $mN \cdot m^{-1}$. The transfer rate was 10 $mm \cdot min^{-1}$. The prepared substrate was Formvar-covered electron microscope grids (200-mesh).[2] It was confirmed by an electron micrograph and an ED pattern that the substrate surface was smooth and the substrate itself was in an amorphous state. Therefore, this substrate was suitable for observation of the monolayer structure by using an electron microscope. Transmission electron micrographs were taken with a Hitachi H-500 electron microscope, operated at 75 kV and a beam current of 2.5 μA. Pt-carbon was vapor-deposited onto the monolayer samples with shadowing angle of 23°.

† On leave from Asahi Glass Electronic Products R&D Center Co., Ltd., Yokohama 221.

Results and Discussion

Figure 1 shows the surface pressure-area (π-A) isotherm for barium stearate monolayers spread on the buffered water at T_{sp} of 290 K. This temperature was much lower than the melting temperature, T_m of the monolayer which was estimated from the T_{sp} dependence of the maximum area modulus of the monolayer.[7] This isotherm showed a rapid rise of surface pressure with decreasing surface area. On the basis of a generally accepted concept, this π-A behavior is interpreted as that a gas state monolayer at very low surface pressure converts into a solid state monolayer at higher surface pressure without appearance of a liquid expanded state monolayer. The limiting area for the monolayer was 0.21 $nm^2 \cdot molecule^{-1}$. The value was close to the area of 0.20 $nm^2 \cdot molecule^{-1}$ which corresponded to the occupied cross-sectional area of closely packed hydrocarbon chains.

Figure 2 shows the bright field electron micrographs and the ED patterns of barium stearate monolayers which were spread from a benzene solution on the water surface and also, were transferred at the surface pressures of (a) 0, (b) 10, (c) 25, and (d) 40 $mN \cdot m^{-1}$. The transfer ratios at 10, 25, and 40 $mN \cdot m^{-1}$ were 0.9, 1.0, and 1.7, respectively. The direction of Pt-C shadowing is shown by an arrow. At 0 $mN \cdot m^{-1}$ (a), many isolated domains were observed in the bright field image. At 10 $mN \cdot m^{-1}$ (b), these domains covered almost all region of the water surface. The bright field image of the monolayer at 25 $mN \cdot m^{-1}$ (c) exhibited the fairly uniform, smooth, and continuous monolayer. The bright field image at 40 $mN \cdot m^{-1}$ (d) showed heterogeneous aggregation which was composed of

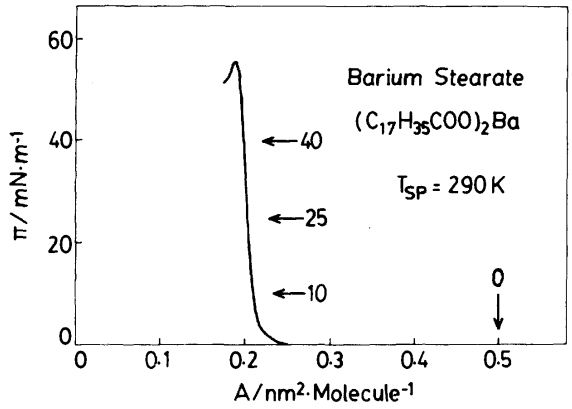

Fig. 1. π-A isotherm of barium stearate monolayer.

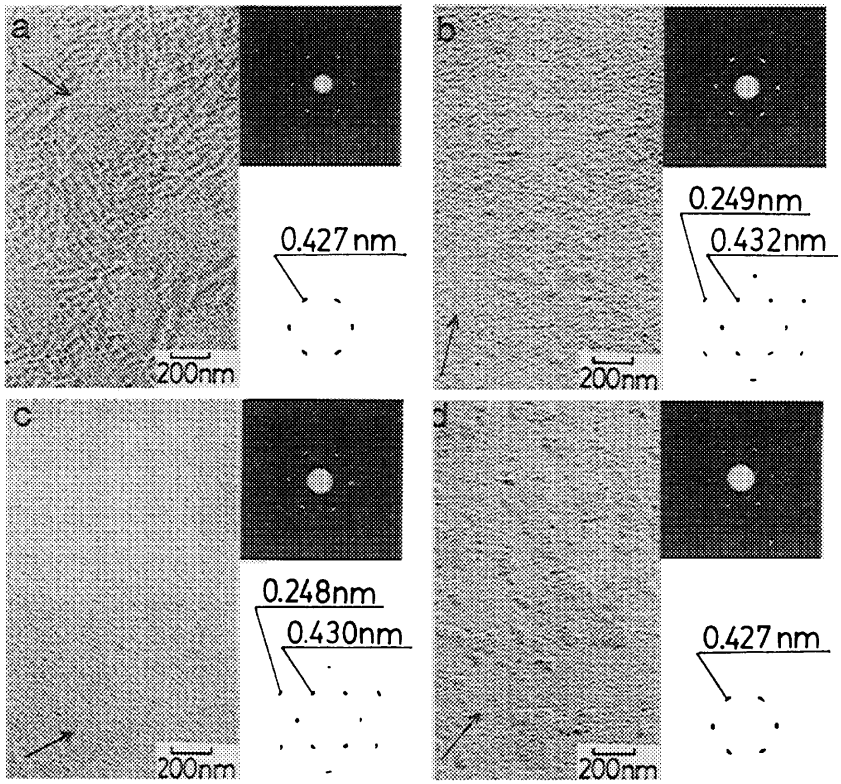

Fig. 2. Electron micrographs and electron diffraction patterns of barium stearate monolayers transferred at (a) 0 $mN \cdot m^{-1}$, (b) 10 $mN \cdot m^{-1}$, (c) 25 $mN \cdot m^{-1}$, and (d) 40 $mN \cdot m^{-1}$.

partially overlapped domains due to collapse of the monolayer. Figure 2(d) indicates that the monolayer starts to collapse at a lower surface pressure than the generally defined collapse pressure as the peak of the π-A isotherm. This partial collapse of monolayer cause the excess transfer of monolayer with the transfer ratio of 1.7 more than 1. The height of these overlapped domains was evaluated to be 5 nm from the shadowed length of Pt-C. Since the value of 5 nm corresponds to the thickness of a double layer of barium stearate, the monolayer collapses in a similar mechanism proposed by Ries.[8]

Every ED pattern of the monolayers transferred at the surface pressures of 0, 10, 25, and 40 $mN \cdot m^{-1}$ exhibited sharp crystalline spots with the spacing of 0.43 nm as shown in Fig. 2. At 10 and 25 $mN \cdot m^{-1}$, the crystalline spots with the spacing of 0.25 nm which is $1/\sqrt{3}$ of the spacing of 0.43 nm, were also observed in the ED patterns. These results indicate that the ED patterns are analyzed as a hexagonal structure and that the spacings of 0.43 and 0.25 nm are assigned to $(10\bar{1}0)$ and $(11\bar{2}0)$ reflections, respectively. When one molecule is assigned to the unit cell, the surface area occupied is estimated to be 0.21 $nm^2 \cdot molecule^{-1}$ which agrees with that found from the extrapolation of the π-A isotherm. It should be noted that the domains observed in the bright field image are in a crystalline state even at 0 $mN \cdot m^{-1}$ and also, that monolayer crystallites in a fairly wide area (corresponding to an electron beam diameter of several μm) aggregate with the crystallographically same orientation. Therefore, it is reasonable to consider that small two-dimensional crystallites grow right after spreading a solution on the water surface. The reason why crystallites arrange along their crystallographic direction on the water surface, is unknown at present. However, it is expected that crystallographic sintering at the boundary surfaces was caused from fusion or recrystallization at a higher surface pressure of 25 or 40 $mN \cdot m^{-1}$, resulting in formation of a large homogeneous two-dimensional single crystal (monolayer). For obtaining a larger single crystalline monolayer, it is necessary to anneal the monolayer on the water surface after compressing it to the surface pressure where the monolayer is morphological homogeneous.

The aggregation state of monolayer domains during compression is schematically shown in Fig. 3 in the case of T_{sp} lower than T_m. Barium stearate molecules form two-dimensional crystallites right after spreading a solution (at π_0) as mentioned above. The schematic crystallites are represented by the hatched domains in Fig. 3. The free area (white space) presented among crystallites is reduced with decreasing the surface area from A_0 to A_1. Contact between crystallites gives rise to an increase in surface pressure (at π_1). Monolayer crystallites in surface pressure range between π_1 and π_2 gather closer, resulting in the formation of a large-area monolayer at π_2. At a higher surface pressure than π_2,

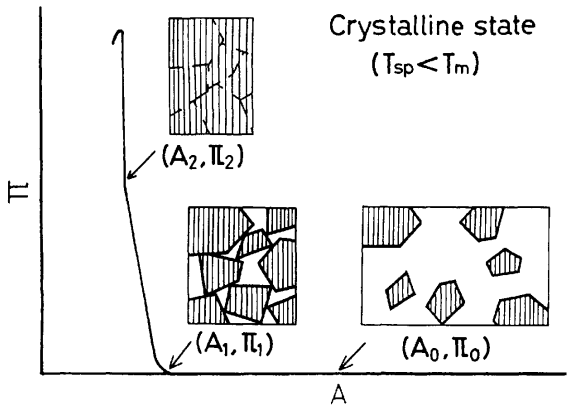

Fig. 3. Schematic representation of aggregation structure of monolayer during compression.

the monolayer starts to collapse locally, even though the surface pressure is lower than the generally defined collapse pressure as the peak of the π-A isotherm. Thus, in the case of barium stearate, a compression process on the water surface corresponds to an aggregation one of monolayer crystallites formed right after spreading a solution. The similar concept was also proposed by other researchers, on the basis of microscopic observations for a polydiacetylene monolayer,[9] dialkylammonium monolayer[10] and fatty acids or these salts.[11]

Conclusion

It became apparent that a molecular aggregation state in the barium stearate monolayer is quite different from the generally accepted concept based on the π-A isotherm. Barium stearate molecules aggregate in a crystalline state even at zero surface pressure when the subphase temperature is lower than the melting temperature of the monolayer. Therefore, the π-A isotherm represents an aggregating process of small two-dimensional crystallites on the water surface.

Evaluation of Oxidation of Vegetable Oils by Pyrolytic Sulfurization Gas Chromatography

Itsuro KAWAI* and Tadashi HARA†
Department of Applied Physics and Chemistry, Fukui Institute of Technology, Gakuen-3chome, Fukui 910
†Department of Chemical Engineering, Faculty of Engineering, Doshisha University, Karasuma Imadegawa, Kamigyo-ku, Kyoto 602
(Received November 29, 1988)

Synopsis. Oxygen determination by pyrolytic sulfurization gas chromatography[1-5] was applied to observe the degree of oxidation of vegetable oils. Oxidation deterioration of vegetable oil and the effect of antioxidants were evaluated.

Elemental analysis by use of pyrolytic sulfurization gas chromatography (PSGC), adopting the sulfur combustion method instead of the conventional oxygen combustion, has its prime feature in its ability to determine the oxygen content of a sample together with the contents of other constituent elements. This report deals with a study on the oxidation of vegetable oils performed as an application of this advantageous oxygen determination by PSGC. Both the oxidation deterioration of vegetable oils and the effect of antioxidants on it were investigated.

Experimental

Reagents. The sulfur used as a reaction agent together with a sample was obtained by purifying[6] commercially available sulfur (chemically pure) by the Bacon-Fanelli method. Drying oils (linseed, and soybean oils), a semidrying oil (sesame oil) and nondrying oils (olive, and castor oils) as the sample oils were obtained commercially. The aromatic antioxidants (*t*-butylhydroquinone, propyl gallate, and hydroquinone) were of JIS special grade quality.

Apparatus. A sampler, a displacement apparatus and an electric furnace were used. Gas chromatograms were taken on a Shimadzu GC-4B gas chromatograph.

Procedure. The oxidation test of the vegetable oils was made as follows: A sample oil (25 ml) was introduced into a 50 ml round-bottom flask, and oxidized by bubbling oxygen gas into it at a flow rate of 180 ml min^{-1} under agitation at 1400 rpm. At fixed time intervals after the start of the reaction, specimens (about 0.5 mg) were taken out and subjected to elemental analysis by PSGC. The measurements were made at different temperatures between 50 and 150 °C. Each type of drying, semidrying, and nondrying oils was used as the sample vegetable oil.

For the examination of the effect of antioxidants, sample oils containing 8.2×10^{-4} mol l^{-1} of antioxidants were used, and analysis by PSGC was made in the same way as for the oxidation test described above. The antioxidants used were aromatics.

The analytical conditions of PSGC were as follows: About 0.5 mg of a vegetable oil and 5 mg of sulfur were sampled into an ampoule, and allowed to react at a high temperature under a pressurized helium atmosphere. The reaction products were subjected to gas chromatography under the following conditions: Porapak QS 150 cm×4ϕ Teflon, Chromosorb 104 50 cm×4ϕ Teflon; column temperature 85 °C; carrier gas He 50 ml min^{-1}; and detector TCD.

Results and Discussion

Fats and oils generally consist of glycerides, which are susceptible to oxidation when they are of unsaturated types. Most of vegetable oils, in particular, strongly tend to be oxidized because of their being unsaturated glycerides.

Under the conditions adopted, the pyrolytic sulfurization products from vegetable oils were limited to three species (H_2S, COS, CS_2) regardless of the kinds of vegetable oil:

$$\text{Vegetable oil (C, H, O)} \xrightarrow[\text{Sulfur}]{950\,^\circ\text{C}} [H_2S, COS, CS_2]$$

where carbon contained in the sample was converted to carbonyl sulfide (COS) and carbon disulfide (CS_2); hydrogen to hydrogen sulfide (H_2S); and oxygen wholly to carbonyl sulfide (COS). Figure 1 shows the oxidation curves derived from the pyrograms, at an oxidation temperature of 100 °C, of typical vegetable oils. According to this figure, castor oil and sesame oil underwent no change under the conditions adopted for oxidation, conceivably because castor oil consists primarily of the triglyceride of hard-to-oxidize ricinoleic acid and sesame oil is accompanied by natural antioxidants. Elemental analysis data by PSGC of vegetable oils are shown in Table 1.

Figure 2 shows the oxidation curves for soybean oil

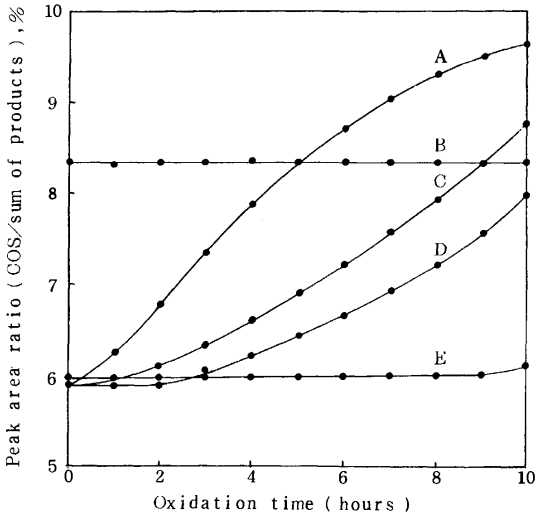

Fig. 1. Oxidation curves of vegetable oils.

Table 1. Analytical Results of Vegetable Oils

Sample	Oxidation time /h	Found (%)		
		C	H	O
Linseed oil	0	78.73	10.96	10.31
	10	73.81	10.17	16.02
Soybean oil	0	78.20	11.19	10.61
	10	74.15	10.90	14.95
Sesame oil	0	77.97	11.37	10.66
	10	77.78	11.43	10.79
Olive oil	0	78.07	11.43	10.50
	10	74.97	11.29	13.77
Castor oil	0	74.09	11.50	14.41
	10	74.60	11.08	14.32

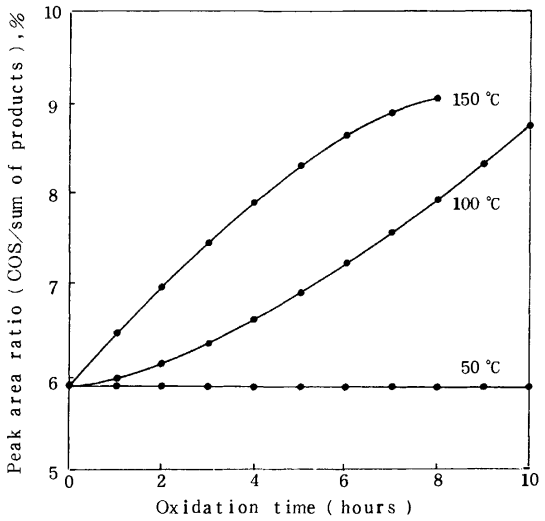

Fig. 2. Oxidation curves of soybean oil.

at varied oxidation temperatures of 50 °C, 100 °C, and 150 °C. As can be seen from this figure, oxidation of vegetable oils is markedly accelerated by the rise of temperature as with general chemical reactions.

The effect of antioxidants on the oxidation of vegetable oils was also investigated. Figure 3 shows the effects of antioxidants on the oxidation rate of soybean oil. The oxidation temperature was 100 °C and the concentration of each antioxidant was 8.24×10^{-4} mol l^{-1}. The same procedure may be applied to other vegetable oils. Figure 4 shows the effect of the concentration of the antioxidant (*t*-butylhydroquinone) on the induction period for soybean oil. The oxidation temperature was 100 °C. Figure 4 indicates that the induction period reaches a maximum when the concentration of *t*-butylhydroquinone is approximately 150 ppm. This procedure may be applied to other antioxidants.

One of the known methods for examining the degree of oxidation of a fat or an oil comprises measuring the weight gain caused by a reaction between the sample fat or oil and oxygen. The data obtained by this method agree well with the analytical data determined by PSGC.

The coefficient of variation in the peak area ratio of each sample vegetable oil calculated by effecting the

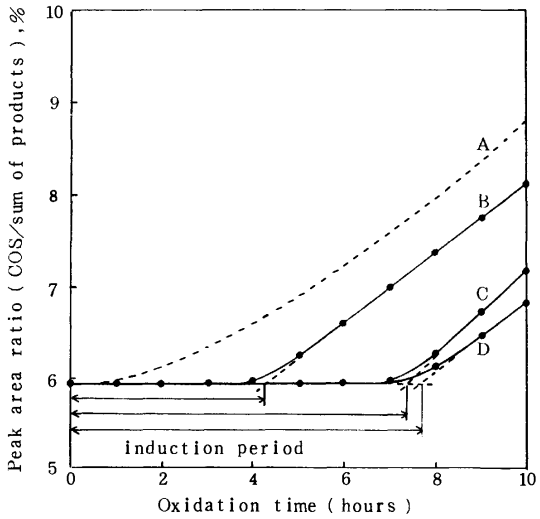

Fig. 3. Effect of antioxidants on the rate of oxidation of soybean oil.
Reaction temperature: 100 °C, and antioxidant concentration: 8.24×10^{-4} mol l^{-1}. A: oil alone, B: oil plus *t*-butylhydroquinone, C: oil plus propyl gallate, and D: oil plus hydroquinone.

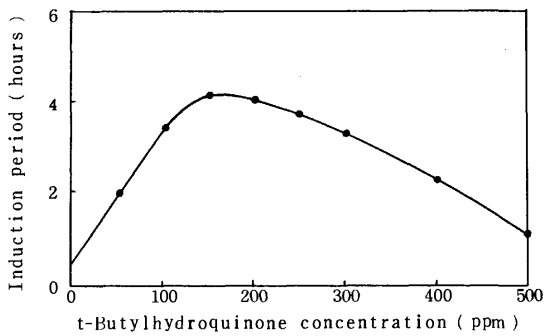

Fig. 4. Relationship between induction period and *t*-butylhydroquinone concentration for soybean oil.
Reaction temperature: 100 °C.

determination by PSGC six times did not exceed 0.5%. In view of this coefficient value, the method of this study can be considered fully suitable for oxidation tests on vegetable oils.

From the findings described above, this method can be considered useful in estimating the oxidation deterioration of vegetable oils and the effect of antioxidants on it. It can also be useful for food analyses and food control of fats and oils, because most of the vegetable oils for home use consist primarily of unsaturated glycerides susceptible to oxidation.

Sulfur Pressure Control in an H_2-Sulfur Vapor System

Hiroaki WADA
National Institute for Research in Inorganic Materials, Namiki 1-1, Tsukuba, Ibaraki 305
(Received December 17, 1988)

Synopsis. A direct sulfur pressure control method by a N_2-sulfur vapor system was modified by using an H_2-sulfur vapor system. A ratio of H_2S/H_2 in the atmosphere was found to be controlled very well in the range from 10^{-2} to 10^{-4} only by the temperature regulation.

A direct sulfur pressure control method by using a N_2-sulfur vapor system has been recently devised and applied to the equilibrium studies of several transition metal sulfides.[1-5] However, this has disadvantage that the lower limit of partial pressure of sulfur available is restricted to 10^{-4} atm because of shortage of accuracy in determination of sulfur content. An attempt has been made to control the partial pressure of sulfur more precisely by using an H_2-sulfur vapor system under the same conditions. This note is concerned with the experimental results obtained in the H_2-sulfur vapor system.

Experimental

Sulfur Pressure Control. The apparatus used for the equilibrium study is shown schematically in Fig. 1. All this apparatus is constructed of quartz glass. The heating systems are the same ones as those described in the previous paper.[2] Several hundred grams of sulfur (purity: 99.9999%) was kept in the round-bottom reservoir. After passing hydrogen gas through the apparatus for 12 h, sulfur was heated and changed to the molten state. Prior to use, the hydrogen gas was purified using DEOXO purifier (Engelhard Co.) in order to remove oxygen and water impurities. The saturated sulfur vapor over molten sulfur was transported to the upper part of the apparatus by hydrogen gas at a constant rate (3 cm^3 of H_2/s). The central zone of part B was held at the minimum temperature in all this apparatus so that the transported sulfur vapor from the reservoir became supersaturated and excess sulfur was condensed on the wall. Only sulfur vapor equilibrated at the minimum temperature zone (width: 10 cm) was carried to the upper part of apparatus. Then the sulfur was changed to hydrogen sulfide at temperatures higher than 773 K according to the reaction of $2H_2+S_2=2H_2S$. A desired partial pressure of hydrogen sulfide was easily obtained by controlling the temperature within ±0.5 K at the minimum temperature zone. At the outlet, L, hydrogen sulfide was absorbed in 0.8 M NaOH solution (1 M=1 mol dm^{-3}) and oxidized by H_2O_2 to SO_4^{2-} ion. Finally, the sulfur content was determined gravimetrically as $BaSO_4$.

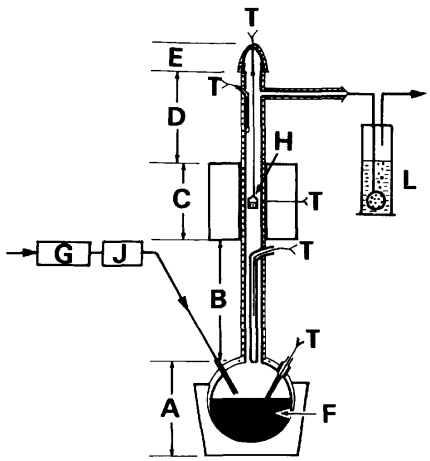

Fig. 1. Schematic diagram of apparatus. The heating systems are divided into five parts from A to E. A: Heating mantle. B: Nichrome wire (0.8 mm) is used for a winding to maintain the minimum temperature zone over the central portion of B. C: Reaction furnace. Pt-40% Rh wire (0.8 mm) is used. D: Nichrome wire (0.45 mm) is used. E: The cap is wound with Nichrome wire (0.8 mm). F: Sulfur. G: DEOXO purifier. H: Sulfide sample is suspended from the cap by strands of thin platinum wire (0.2 mm). J: Mass flow controller (SEC 310). L: NaOH solution. T: Chromel-alumel thermocouples.

Results and Discussion

The experimental results of the sulfur pressure measurements, in terms of the amount of collected sulfur at L, are presented in Table 1 and Fig. 2. The relationship between the total amount of sulfur brought by unit volume of hydrogen and the temperature of the minimum temperature zone is given very well by the following formula (least squares treatment): $\log(W/\mathrm{g\,dm^{-3}})=-4294/(T/\mathrm{K})+7.1852$, where the amount of collected sulfur is represented as W in g. The previous experimental data obtained in the N_2-sulfur vapor system[2] are also shown in Fig. 2 for comparison. Both data exhibit very similar linear relationships except for small difference in the absolute values. This fact indicates clearly that the sulfur pressure was controlled precisely by the temperature regulation at the minimum temperature

Table 1. Relationships between the Temperature of Minimum Temperature Zone, Weight of $BaSO_4$ and the Mass Flow Rate of Sulfur

Temperature / K	Weight of $BaSO_4$ / mg h^{-1}	Mass flow rate of sulfur (g dm^{-3} of H_2)
370	2.72	3.48×10^{-5}
385	9.30	1.19×10^{-4}
386	9.88	1.26×10^{-4}
394	16.50	2.08×10^{-4}
402	23.95	3.06×10^{-4}
403	26.60	3.40×10^{-4}
413	53.68	6.78×10^{-4}
422	74.55	9.54×10^{-4}
423	88.20	1.13×10^{-3}
472	887.79	1.19×10^{-2}

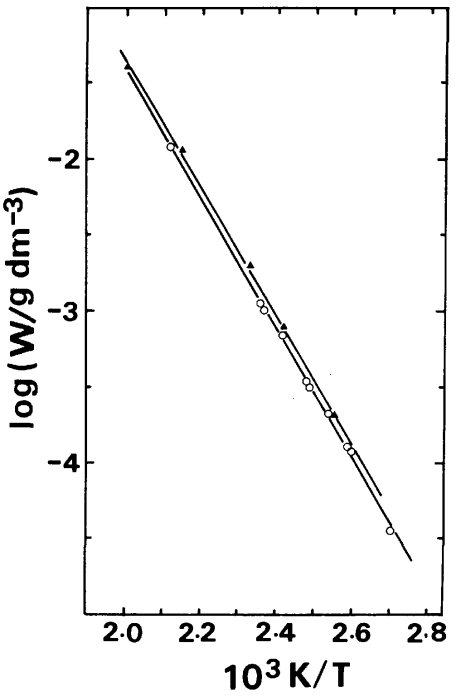

Fig. 2. Plot of log (W/g dm^{-3}) versus $1/T$. ○: H_2–sulfur vapor system, ▲: N_2–sulfur vapor system.

zone in the selected experimental system. The slightly lower values for the data points in the H_2–sulfur vapor system may be due to incomplete transportation of sulfur. One of the possible explanations for this phenomenon may be related to the fact that the viscosity of H_2 gas is much lower than that of N_2 gas.

According to Richardson and Jeffes,[6] the free energy for the reaction

$$H_2(g) + \frac{1}{2}S_2(g) = H_2S(g) \qquad (1)$$

is given by the following equation

$$\Delta G^\circ = -21570 + 11.79T. \qquad (2)$$

The equilibrium of Eq. 1 is represented as follows by using the equilibrium constant K

$$\log K = -\frac{\Delta G^\circ}{RT} = \log \frac{P_{H_2S}}{P_{S_2}^{1/2} P_{H_2}} . \qquad (3)$$

Rearranging Eq. 3, we obtain the following equation

$$\log P_{S_2} = 2\log \frac{P_{H_2S}}{P_{H_2}} + \frac{2\Delta G^\circ}{RT} . \qquad (4)$$

By varying the temperature of the minimum temperature zone H_2S/H_2 ratio could be varied between 10^{-2} and 10^{-4}. The assumptions were made to calculate the sulfur pressure that the sulfur species present in the gas phase is only the diatomic molecule S_2 and that the equilibrium has been established on the reaction Eq. 1 at the high temperatures. Corresponding to the variation of H_2S/H_2, $\log P_{S_2}$ was estimated to range from −8.54 to −12.54 at 973 K.

In an application of this method iron Chevrel phase compound $Fe_{1.25}Mo_6S_{7.75}$ has been subjected to an equilibrium study at 1273 K. The rhombohedral phase of $Fe_{1.25}Mo_6S_{7.75}$ was found to be stable in the range $-7.44 < \log P_{S_2} < -5.35$.

Mixed-Valence States in TCNQ Salts of 1′,1‴-Dibutyl-, 1′,1‴-Dipentylbiferrocene and Their Mixed Crystals

Satoru NAKASHIMA and Hirotoshi SANO*
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukasawa, Setagaya-ku, Tokyo 158
(Received January 20, 1989)

Synopsis. Mixed-valence states in TCNQ salts of 1′,1‴-dibutyl-, 1′,1‴-dipentylbiferrocene and their mixed crystals were investigated by Mössbauer spectroscopy. It was found that a valence delocalization of the mixed crystals was affected by the host lattice.

It is known that mixed-valence states of biferrocene derivatives are affected by counter anions,[1,2] and that intermolecular interactions play an important role in the mixed-valence states. It is also known that introduction of aromatic planar molecules as counter anions provides an interesting series of mixed-valence biferrocene derivatives.[3,4] In the present study, mixed-valence states in 7,7,8,8-tetracyanoquinodimethane (TCNQ) salts of 1′,1‴-dibutyl-, 1′,1‴-dipentylbiferrocene and their mixed crystals were inverstigated by means of Mössbauer spectroscopy.

Experimental

Materials. 1′,1‴-Dibutyl-,[5] 1′,1‴-dipentylbiferrocene,[6] and their TCNQ salts[3] were prepared according to the method previously reported. It was found from elemental analysis that the TCNQ salts consist of binuclear ferrocene and TCNQ in a molar ratio of 1:3. Found: C, 70.13; H, 4.25; N, 14.92%. Calcd for 1′,1‴-dibutylbiferrocenium$^+$(TCNQ)$_3^-$, $Fe_2C_{64}H_{46}N_{12}$: C, 70.21; H, 4.24; N, 15.35%. Found: C, 70.71; H, 4.69; N, 14.95%. Calcd for 1′,1‴-dipentylbiferrocenium$^+$(TCNQ)$_3^-$, $Fe_2C_{66}H_{50}N_{12}$: C, 70.60; H, 4.49; N, 14.97%. Mixed crystals were obtained by the following method. A mixture of 1′,1‴-dipentylbiferrocene (40.1 mg, 7.86×10^{-5} mol), and TCNQ (98.6 mg. 4.83×10^{-4} mol) was refluxed for 5 hours in 50 ml of acetonitrile under nitrogen and kept in a freezer for one night. Precipitates were filtered and collected as mixed crystals **1**. The filtrate was kept in the freezer for one night. Precipitates were filtered and collected as mixed crystals **2**. Found for mixed crystals **1**: C, 69.99; H, 4.34; N. 15.44%. Found for mixed crystals **2**: C, 70.12; H, 4.46; N, 15.24%. Calcd for 1:1 mixed crystals, $(Fe_2C_{28}H_{34})_{0.5}$-$(Fe_2C_{30}H_{38})_{0.5}(C_{12}H_4H_4)_3$=$Fe_2C_{65}H_{48}N_{12}$: C, 70.41; H, 4.36; N, 15.16%. It is found that the products consist of the sum of two kinds of binuclear ferrocenes (1′,1‴-dibutylbiferrocene+1′,1‴-dipentylbiferrocene) and TCNQ in the molar ratio of (ca. 0.5+ ca. 0.5): 3. It is difficult to determine definitely the ratio of 1′,1‴-dibutylbiferrocene to 1′,1‴-dipentylbiferrocene in the mixed crystals **1** and **2** from the elemental analysis data, because the difference between the butyl substituent and the pentyl substituent is small in the salts which have large molecular weight. X-Ray diffraction patterns of 1′,1‴-dipentylbiferrocenium$^+$(TCNQ)$_3^-$ shown in Fig. 1 are similar as a whole, suggesting that the salts are isomorphous and make a mixed crystal. The slight difference observed between them can be attributed to the difference of the alkyl group in their cations. The patterns of the mixed crystals **1** are more similar to 1′,1‴-dibutylbiferrocenium$^+$(TCNQ)$_3^-$, while those of mixed crystals **2** to 1′,1‴-dipentylbiferrocenium$^+$(TCNQ)$_3^-$, showing that mixed crystals **1** contain more 1′,1‴-dibutylbiferrocenium than dipentylbiferrocenium and mixed crystals **2** more 1′,1‴-dipentylbiferrocenium than dibutylbiferrocenium than dibutylbiferrocenium. The possibility to be a mixture but not to be mixed crystals is also rejected, based on the results on the Mössbauer spectra measurements (see Results and Discussion).

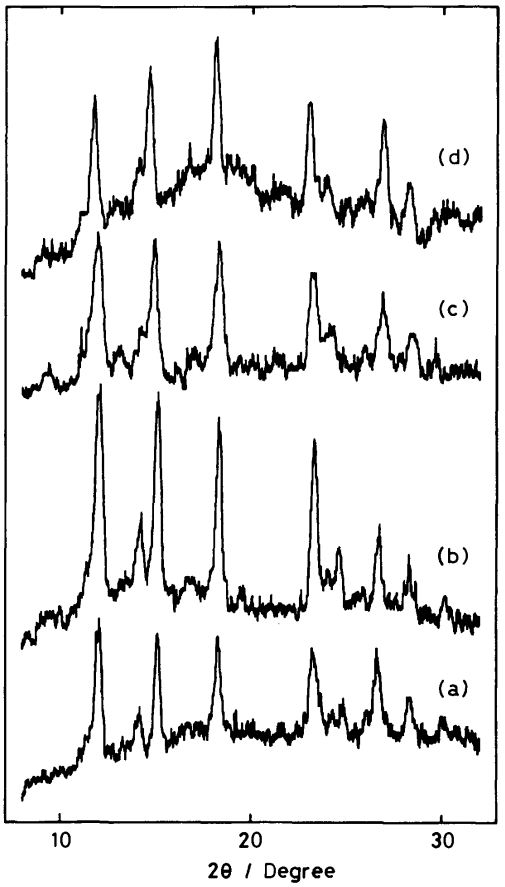

Fig. 1. X-Ray powder patterns (Cu K_α) for (a) 1′,1‴-dibutylbiferrocenium$^+$ (TCNQ)$_3^-$, (b) mixed crystals **1**, (c) mixed crystals **2**, and (d) 1′1‴-dipentylbiferrocenium$^+$ (TCNQ)$_3^-$.

Mössbauer Spectroscopic Measurements. A ^{57}Co(Rh) source moving in a constant-acceleration mode was used for Mössbauer spectroscopic measurements. Mössbauer spectra were obtained by using an Austin Science Associates Mössbauer spectrometer and a proportional counter. Isomer shift values were referred to metallic iron foil. Mössbauer parameters were obtained by least-squares fitting to Lorentian peaks.

Results and Discussion

Mössbauer spectra of 1′,1‴-dibutyl- and 1′,1‴-dipentylbiferrocenium$^+$(TCNQ)$_3^-$ are shown in Figs. 2 and 3, respectively. The Mössbauer spectrum of 1′,1‴-dibutylbiferrocenium$^+$(TCNQ)$_3^-$ at 5 K shows a

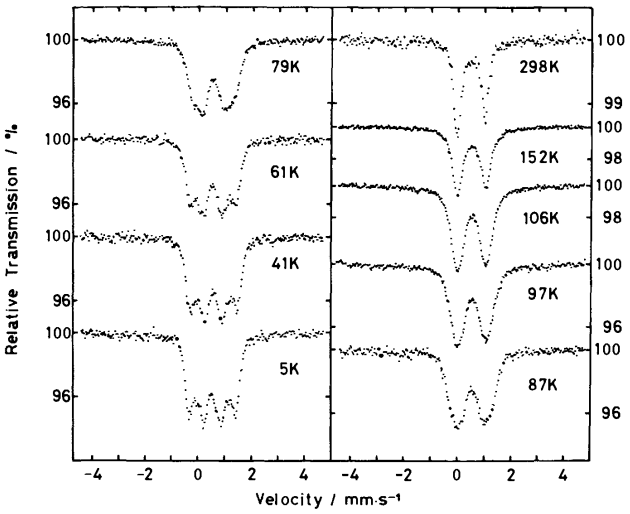

Fig. 2. Mössbauer spectra of 1′,1‴-dibutylbiferrocenium$^+$ $(TCNQ)_3^-$.

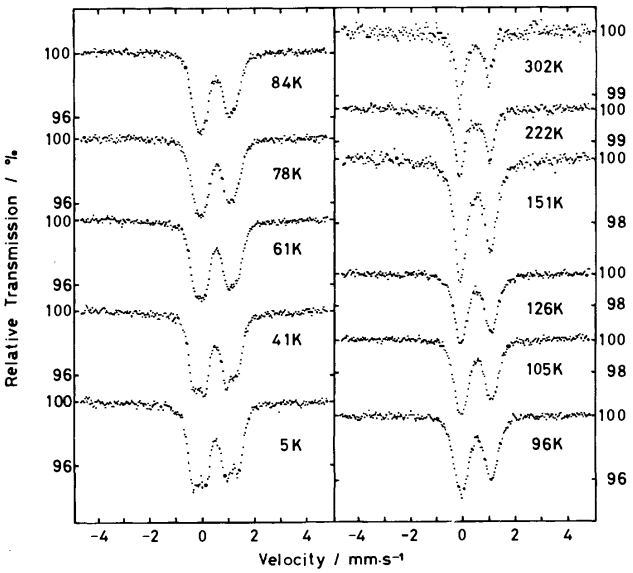

Fig. 4. Mössbauer spectra of mixed crystals **1**.

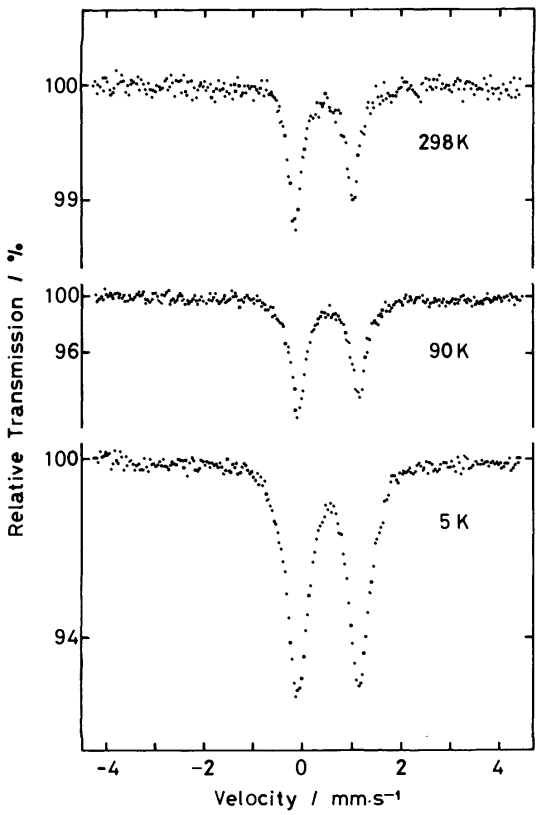

Fig. 3. Mössbauer spectra of 1′,1‴-dipentylbiferrocenium$^+$ $(TCNQ)_3^-$.

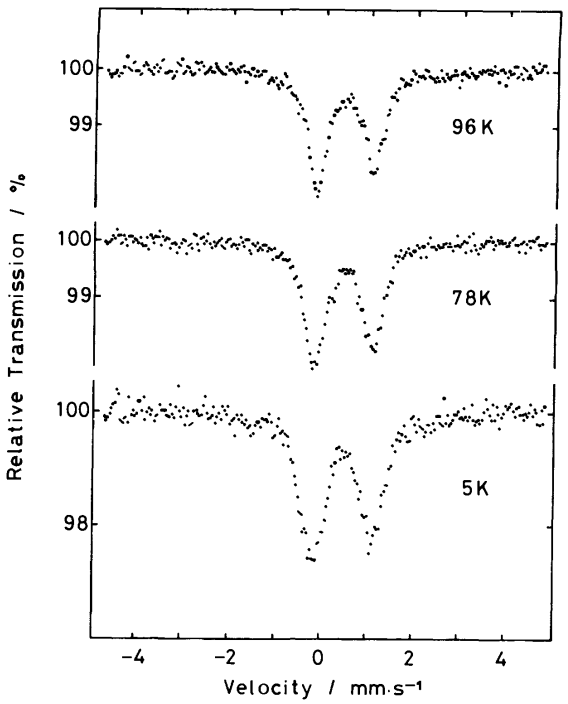

Fig. 5. Mössbauer spectra of mixed crystals **2**.

main component ascribed to a trapped-valence state together with a small component of averaged-valence state. The relative intensity of the doublet for the averaged-valence state increases with increasing temperature, as observed in 1′,1‴-bis(*o*-methylbenzyl)biferrocenium$^+$ $TCNE^-$ (TCNE=tetracyanoethylene).[4] 1′,1‴-Dipentylbiferrocenium$^+$ $(TCNQ)_3^-$ shows only the component of averaged-valence state in the whole temperature range from 5 to 298 K.

Mössbauer spectra of mixed crystals **1** and **2** are shown in Figs. 4 and 5, respectively, and the quadrupole splitting (Q. S.) values of all the salts studied in the present study are summarized in Fig. 6. Although the temperature dependence of the mixed-valence states in mixed crystals **1** is classified into a so-called coexisting type, as in the case of 1′,1‴-dibutylbiferrocenium$^+$$(TCNQ)_3^-$. The Q. S. value at 5 K (0.74 mm s^{-1}) of mixed crystals **1** is different from the value (0.55 mm s^{-1}) of 1′,1‴-dibutylbiferrocenium$^+$ $(TCNQ)_3^-$ at 5 K. In the coexisting region of the trapped- and averaged-valence state (at 5—126 K) in 1′,1‴-dibutylbiferrocenium$^+$$(TCNQ)_3^-$, the Q. S. val-

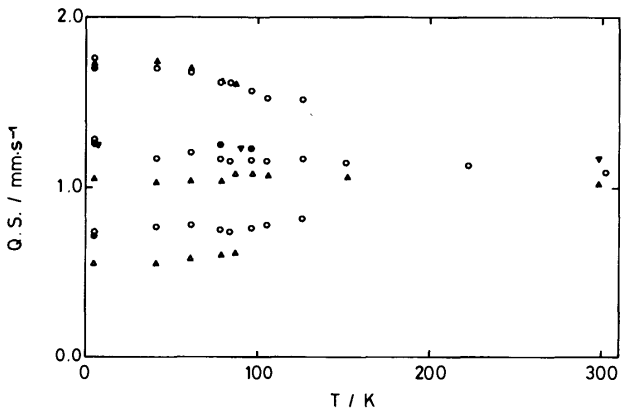

Fig. 6. Temperature dependences in the Q. S. values of 1′,1‴-dibutylbiferrocenium$^+$ $(TCNQ)_3^-$ (△), 1′,1‴-dipentylbiferrocenium$^+$ $(TCNQ)_3^-$ (▽), mixed crystals **1** (○), and mixed crystals **2** (●).

ues of the iron atoms in the averaged-valence state are close to an averaged value of the Q. S. values for the ferrocene-like doublet and ferrocenium-like doublet of their trapped-valence state and almost equal to the value at 302 K. The Q. S. values of the iron atoms in the averaged-valence state for mixed crystals **1** (e.g., 1.09 mm s^{-1} at 302 K) show averaged values of the values of 1′,1‴-dibutylbiferrocenium$^+$ $(TCNQ)_4^-$ (e.g., 1.02 mm s^{-1} at 298 K) and 1′,1‴-dipentylbiferrocenium$^+$ $(TCNQ)_3^-$ (e.g., 1.17 mm s^{-1} at 298 K) as expected for mixed crystals. The results reject the possibility of a mixture of the two salts obtained for the mixed crystals **1** because no line-broadening is found at higher temperatures. Mixed-valence states in mixed crystals **2** are similar to those in 1′,1‴-dipentylbiferrocenium$^+(TCNQ)_3^-$, although a small component assigned to the trapped-valence state coexists at 5 K. The Q. S. values of the trappped-valence state (1.79 mm s^{-1} and 0.72 mm s^{-1} at 5 K) are similar to those of mixed crystals **1** and are different from those of 1′,1‴-dibutylbiferrocenium$^+(TCNQ)_3^-$. The results found in the mixed crystals **2** also reject the possibility of a mixture of the component salts.

The results obtained in the present study indicate that the valence delocalization is affected by the crystal lattice, which is predominantly under the control of the host component, 1′,1‴-dibutylbiferrocenium$^+$ $(TCNQ)_3^-$ in mixed crystals **1** and of 1′,1‴-dipentylbiferrocenium$^+(TCNQ)_3^-$ in mixed crystals **2**.

We thank the Ministry of Education, Science and Culture of Japan for supporting a part of this work under a Grant-in-Aid for Scientific Research (No. 62790155).

Preparation and Characterization of Triethylenetetramine Cobalt(III) Complexes with 1,2-Ethanedithiolate or 1,2-Ethanedisulfinate

Takumi KONNO,* Hideki UMEHARA, Ken-ichi OKAMOTO, and Jinsai HIDAKA
Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305
(Received April 14, 1989)

Synopsis. Triethylenetetramine (trien) cobalt(III) complexes with 1,2-ethanedithiolate (edt) or 1,2-ethanedisulfinate (edsi) were prepared and characterized by absorption, CD, and ^{13}C NMR spectra. Each of the two complexes gave three possible geometrical isomers (cis-α, cis-β-*RR,SS*, and cis-β-*RS,SR*) which were separated and optically resolved by fractional crystallization and/or column chromatography.

In a previous paper[1] we reported the stereochemistry of triethylenetetramine (trien) cobalt(III) complexes with 1,3-propanedithiolate (pdt; $^{-}S(CH_2)_3S^{-}$) or 1,3-propanedisulfinate (pdsi; $^{-}O_2S(CH_2)_3SO_2^{-}$). Both complexes produced only the cis-α isomer, although three geometrical isomers (cis-α, cis-β-*RR,SS*, and cis-β-*RS,SR*)[2] are possible for the [Co(bidentate-*S,S*)(trien)]$^{+}$-type complexes. This note discusses the preparation and resolution of the trien cobalt(III) complexes with 1,2-ethanedithiolate (edt; $^{-}S(CH_2)_2S^{-}$) or 1,2-ethanedisulfinate (edsi; $^{-}O_2S(CH_2)_2SO_2^{-}$); three possible geometrical isomers were formed for each of the two complexes. These isomers were characterized on the basis of absorption, CD, and ^{13}C NMR spectra compared with those of the corresponding pdt and pdsi isomers.

Experimental

(1) Preparation and Resolution of Complexes. a) [Co(edt)(trien)]X (X=ClO_4 and I). To an ice-cold solution containing 3.1 g (0.01 mol) of *cis*-α- or *cis*-β-[$CoCl_2$(trien)]Cl[3] in 60 cm^3 of water was added an ice-cold solution containing 0.95 g (0.01 mol) of 1,3-propanedithiol in a mixture of a 1 mol dm^{-3} NaOH aqueous solution (20 cm^3) and methanol (20 cm^3). The mixture was stirred for 1 h in an ice bath. After removing the precipitate by filtration, to the filtrate was added 20 cm^3 of a saturated $NaClO_4$ solution; this mixture was kept in a refrigerator for 5 h. The precipitate which appeared was filtered off again. The filtrate was concentrated to one half its volume with a rotary evaporator below 25 °C and kept in a refrigerator overnight. The resulting black complex was collected by filtration and recrystallized from a small amount of water. It was found from absorption and ^{13}C NMR spectral measurements that this complex contained a mixture of *cis*-α-, *cis*-β-*RR,SS*-, and *cis*-β-*RS,SR*-[Co(edt)(trien)]$^{+}$. Attempts to separate the isomers using column chromatography were unsuccessful because of decomposition in the column. Yield: 64%. Found: C, 23.96; H, 5.63; N, 14.07%. Calcd for [Co(edt)(trien)]ClO_4=$C_8H_{22}N_4O_4S_2ClCo$: C, 24.22; H, 5.59; N, 14.12%.

The iodide salt was precipitated using 20 cm^3 of a saturated NaI solution instead of a saturated $NaClO_4$ solution. Black tetragonal crystals were obtained by recrystallization from a small amount of water. It was found from absorption and ^{13}C NMR spectral measurements that these crystals contained only the cis-α isomer. Yield: 20%. Found: C, 22.61; H, 5.27; N, 13.22%. Calcd for [Co(edt)(trien)] I=$C_8H_{22}N_4S_2CoI$: C, 22.64; H, 5.22; N, 13.20%

An excess amount (0.5 g) of $Na_2[Sb_2(d\text{-tart})_2]\cdot 5H_2O$ (*d*-tart=*d*-tartrate) was added with stirring to a solution containing 0.1 g of *cis*-α-[Co(edt)(trien)]I in 10 cm^3 of water. After the solution was stirred for 3 min at room temperature, 3 cm^3 of ethanol was added in an ice bath; the resulting black-brown precipitate of the $(-)_{580}^{CD}$-cis-α isomer was collected by filtration. The H_2O_2 oxidation product of the $(-)_{580}^{CD}$-cis-α showed identical absorption spectrum and CD patterns with $(-)_{460}^{CD}$-*cis*-α-[Co(edsi)(trien)]$^{+}$ (A-2 isomer) described in b), though the CD intensity of the former complex was smaller than that of the latter. This indicates that *cis*-α-[Co(edt)(trien)]$^{+}$ was partially resolved; the CD intensity of the $(-)_{580}^{CD}$-cis-α isomer is shown by an arbitrary scale in Fig. 1.

b) [Co(edsi)(trien)]ClO_4. An excess amount (8 cm^3) of a 5% H_2O_2 solution was added to a solution containing 0.5 g of [Co(edt)(trien)]ClO_4 in 20 cm^3 of water, followed by 1 cm^3 of a 30% $HClO_4$ solution. The mixture was stirred for 1 h in an ice bath and then kept in a refrigerator overnight. The resulting yellow powder (A-1) was collected by filtration. The filtrate was concentrated to one half its volume with a rotary evaporator below 24 °C and kept in a refrigerator overnight. After the yellow powder (A-1) was again removed by filtration, the filtrate was concentrated to one half its volume and kept in a refrigerator overnight. The deep-yellow needle crystals (A-2) which appeared were collected by filtration. Each of the A-1 and A-2 complexes was recrystallized from a small amount of water. It was found from the absorption and ^{13}C NMR spectral measurements that the A-1 complex contained a mixture of *cis*-β-*RR,SS*- and *cis*-β-*RS,SR*-[Co(edsi)(trien)]$^{+}$ and the A-2 one contained the cis-α isomer. A-1 complex: Yield: 28%. A-2 complex: Yield: 13%. Found for A-2: C, 20.15; H, 5.03; N, 11.65%. Calcd for [Co(edsi)(trien)]$ClO_4\cdot H_2O$=$C_8H_{22}N_4O_8S_2ClCo\cdot H_2O$: C, 20.07; H, 5.05; N, 11.70%.

An aqueous solution of the A-1 complex (cis-β-*RR,SS* and cis-β-*RS,SR*) was poured onto a Dowex 50W-X8 column (Na^{+} form, 200—400 mesh, 3 cm×20 cm). After sweeping the column with water, the adsorbed band was eluted with a 0.075 mol dm^{-3} $K_2[Sb_2(d\text{-tart})_2]$ solution. Two pairs of yellow bands, B-1 and B-2, were eluted in this order. It was found from the ^{13}C NMR spectral measurements that the earlier moving pair (B-1) contained *cis*-β-*RR,SS*-[Co(edsi)(trien)]$^{+}$ and the later moving one (B-2) contained the cis-β-*RS,SR* isomer. The formation ratio of the two isomers, B-1 (cis-β-*RR,SS*): B-2 (cis-β-*RS,SR*), was about 4:1. For each of the two pairs, the earlier moving and the later moving bands contained the $(-)_{470}^{CD}$ and $(+)_{470}^{CD}$ isomers respectively. The $(-)_{470}^{CD}$ isomer of B-1 (cis-β-*RR,SS*) was isolated as the perchlorate salt. The B-2 (cis-β-*RS,SR*) isomer was not isolated because of its poor yield, and the concentration of this isomer was evaluated by the method of plasma emission spectral analysis. Found for $(-)_{470}^{CD}$ B-1 isomer: C, 20.12; H, 5.06; N, 11.68%. Calcd for [Co(edsi)(trien)]$ClO_4\cdot H_2O$: C, 20.07; H, 5.07; N, 11.70%.

When the A-2 (cis-α) complex was chromatographed on a Dowex 50W-X8 column (Na^{+} form, 200—400 mesh, 3.0 cm× 20 cm) eluting with a 0.075 mol dm^{-3} $K_2[Sb_2(d\text{-tart})_2]$ solution, two deep yellow bands of the $(-)_{460}^{CD}$ and $(+)_{460}^{CD}$ isomers were eluted in this order. Each eluate was converted into the perchlorate salt using a QAE-Sephadex A-25 column (ClO_4^{-}

form, 2.5 cm×20 cm). The concentration of each isomer was evaluated on the basis of the absorption spectral datum of the racemic perchlorate salt.

(2) Measurements. The electronic absorption spectra were recorded on a JASCO UVIDEC-1 or UVIDEC-610 spectrophotometer and the CD spectra on a JASCO J-20 spectropolarimeter. All measurements were carried out in aqueous solution at room temperature. The concentration of *cis*-β-*RS,SR*-[Co(edsi)(trien)]$^+$ (B-2 isomer) was determined with a Jarrel-Ash Model-975 Plasma Atom Comp ICP spectrometer. The ^{13}C NMR spectra were recorded in deuterium oxide on a JEOL JNM-FX-100 NMR spectrometer at the probe temperature. Sodium 4,4-dimethyl-4-silapentane-1-sulfonate was used as an internal reference.

Results and Discussion

Three geometrical isomers (cis-α, cis-β-*RR,SS*, and cis-β-*RS,SR*)[2] are possible for each of [Co(edt)(trien)]$^+$ and [Co(edsi)(trien)]$^+$. The absorption spectrum of [Co(edt)(trien)]$^+$ isolated as the perchlorate or iodide salt is similar to that of *cis*-α-[Co(pdt)(trien)]$^+$ [1] in the whole region (Fig. 1). The edt complex exhibits the sulfur-to-metal charge transfer (SMCT) band at ca. 35×10^3 cm^{-1}, which is composed of two components. This absorption spectral behavior is characteristic for the cis(*S*)-type cobalt(III) complexes with two thiolato donor atoms.[4-7] For the three isomers of [Co(edsi)-(trien)]$^+$, which were derived from the perchlorate salt of [Co(edt)(trien)]$^+$ by the H_2O_2 oxidation reaction, the absorption spectral behavior agrees well with that of *cis*-α-[Co(pdsi)(trien)]$^+$ [1] in the whole region (Fig. 2). It has been established by X-ray structural analysis that the pdsi in *cis*-α-[Co(pdsi)(trien)]$^+$ coordinates through two sulfur atoms.[1] Accordingly, the present edsi complex can be assigned to the *S,S*-bonded isomer having the cis(*S*) geometry. The absorption spectrum of the edsi complex also shows an intense SMCT band consisting of two components at ca. 34×10^3 cm^{-1}.

The iodide salt of [Co(edt)(trien)]$^+$ exhibits four ^{13}C NMR signals at δ 36.84, 46.54, 57.86, and 58.83 due to the eight methylene carbon atoms in the complex, indicating the C_2 symmetry. Further, the H_2O_2 oxidation of the iodide salt gave *cis*-α-[Co(edsi)(trien)]$^+$ (A-2 complex, vide infra). A similar oxidation reaction of the thiolato cobalt(III) complexes has proceeded with retention of the geometrical configuration to form the sulfinato complexes.[1,8] These facts suggest that the iodide salt of [Co(edt) trien)]$^+$ is the cis-α isomer. The perchlorate salt of [Co(edt)(trien)]$^+$ shows twenty ^{13}C NMR signals in the region of δ 35—60, of which four signals are the same as those of the iodide salt. The H_2O_2 oxidation of the perchlorate salt produced *cis*-α-, *cis*-β-*RR,SS*-, and *cis*-β-*RS,SR*-[Co(edsi)(trien)]$^+$ (vide infra). Therefore, it is probable that the perchlorate salt of [Co(edt)(trien)]$^+$ is a mixture of the cis-α, cis-β-*RR,SS*, and cis-β-*RS,SR* isomers. In the ^{13}C NMR spectra of [Co(edsi)(trien)]$^+$ containing eight methylene carbon atoms, the A-1 and A-2 complexes exhibit fifteen and four (δ 45.61, 45.72, 58.78, and 59.65) signals respectively. The A-1 complex was separated into two isomers, B-1 and B-2, which show eight ^{13}C NMR signals (δ 43.83, 50.44, 51.68, 52.33, 56.12, 57.53, 58.40, and 60.68 for B-1, and δ 45.13, 47.84, 53.09, 53.20, 57.26, 59.43, 59.70, and 60.68 for B-2). These results indicate that the A-1 complex is a mixture of the cis-β-*RR,SS* and cis-β-*RS,SR* isomers (C_1 symmetry), while the A-2 complex is the cis-α isomer (C_2 symmetry). The ^{13}C NMR signals of the B-1 isomer appear at higher magnetic fields than those of the B-2 isomer. For [Co(NH$_3$)$_2$(trien)]$^{3+}$ [9] and [Co(CN)$_2$(trien)]$^+$,[10] the cis-β-*RR,SS* isomer commonly shows ^{13}C NMR signals at higher magnetic fields than those of the cis-β-*RS,SR* isomer. Therefore, it is tentatively assigned that the B-1 and B-2 isomers take

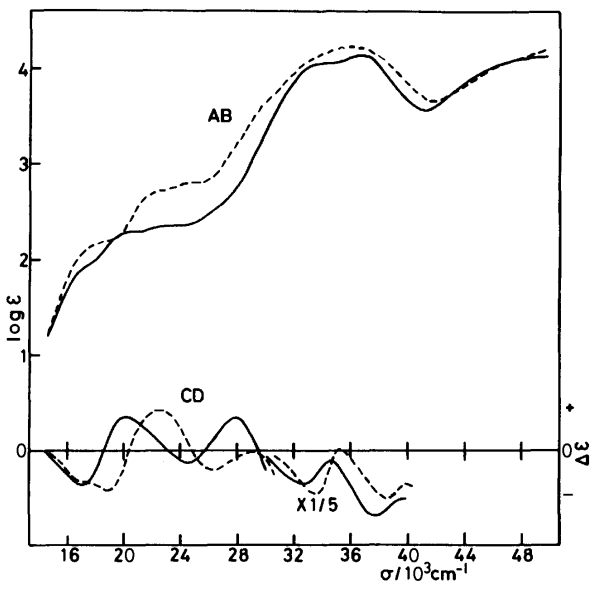

Fig. 1. Absorption and CD spectra of Δ-(−)$^{CD}_{580}$-*cis*-α-[Co(edt)(trien)]$^+$ (——) and Δ-*cis*-α-[Co(pdt)(trien)]$^+$ (-----). CD scale is arbitrary.

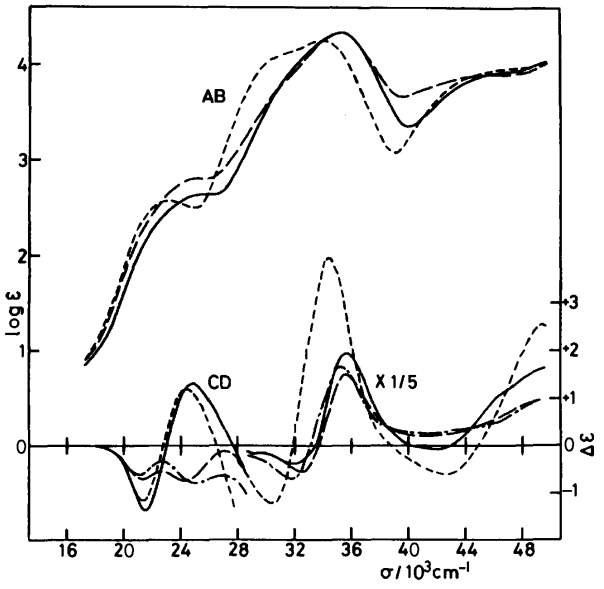

Fig. 2. Absorption and CD spectra of Δ-(−)$^{CD}_{460}$-*cis*-α-(——), Δ-(−)$^{CD}_{470}$-*cis*-β-*RR*- (———), Δ-(−)$^{CD}_{470}$-*cis*-β-*RS*-[Co(edsi)(trien)]$^+$ (—·—·—), and Δ-*cis*-α-[Co(pdsi)-(trien)]$^+$ (-----).

the cis-β-*RR,SS* and cis-β-*RS,SR* configurations respectively. The assignment for the two cis-β isomers is supported from a 4:1 formation ratio of the *RR,SS* (B-1) isomer to the *RS,SR* (B-2) isomer, which is an usual trend observed for $[CoX_2(trien)]^{n+}$ (X_2=$NH_2CH_2CO_2^-$,[11] $2NH_3$,[9] $2CN^-$,[10] and $2NCS^-$ [12]).

As shown in Fig. 2, the CD spectrum of $(-)_{460}^{CD}$-*cis*-α-[Co(edsi)(trien)]$^+$ is similar to that of Δ-*cis*-α-[Co(pdsi)(trien)]$^+$ over the whole region, whose absolute configuration has been determined by X-ray structural analysis.[1] Therefore, the $(-)_{460}^{CD}$-cis-α edsi isomer is assignable to the Δ configuration. The CD spectra of $(-)_{470}^{CD}$-*cis*-β-*RR,SS*- and $(-)_{470}^{CD}$-*cis*-β-*RS,SR*-[Co(edsi)(trien)]$^+$ quite resemble each other, showing the two negative CD bands in the first absorption band region (18—28$\times10^3$ cm^{-1}) and a negative and a positive band from lower energy in the SMCT band region (28—38$\times10^3$ cm^{-1}) (Fig. 2). This CD spectral pattern is the same as that of Δ-$(-)_{460}^{CD}$-*cis*-α-[Co(edsi)(trien)]$^+$, except for some deviation at the higher-energy side in the first absorption band region, suggesting that the two $(-)_{470}^{CD}$-cis-β edsi isomers also take the Δ configuration (Δ-cis-β-*RR* and Δ-cis-β-*RS*). The CD spectrum of $(-)_{580}^{CD}$-*cis*-α-[Co(edt)(trien)]$^+$ is similar to that of Δ-*cis*-α-[Co(pdt)(trien)]$^+$ [1] in the SMCT band regions (30—40$\times10^3$ cm^{-1}), although the intensities are shown by an arbitrary scale (Fig. 1). Furthermore, the oxidation product of $(-)_{580}^{CD}$-*cis*-α-[Co(edt)(trien)]$^+$ showed an identical CD pattern with that of Δ-*cis*-α-[Co(edsi)(trien)]$^+$. Accordingly, it is reasonable to assign that the $(-)_{580}^{CD}$-cis-α edt isomer takes the Δ configuration.

Reactive Langmuir-Blodgett Membrane for Biosensor Applications. Use of Succinimidyl Behenoate-Based Membranes as Support for Covalently Immobilizing α-Chymotrypsin

Jun-ichi ANZAI, Shouryu LEE, and Tetsuo OSA*
Pharmaceutical Institute, Tohoku University, Aobayama, Sendai 980
(Received May 1, 1989)

Synopsis. Succinimidyl behenoate was synthesized to prepare Langmuir-Blodgett (LB) membranes which possess reactive groups on the surface. The surface of the succinimidyl behenoate-based LB membrane could be covalently modified with α-chymotrypsin, for the purpose of biosensor applications.

Several groups have reported the use of Langmuir-Blodgett (LB) membranes for preparing enzyme sensors.[1-5] A prerequisite to construction of LB membrane-based enzyme sensors is to immobilize enzymes on or in the LB membrane deposited previously, or to deposit enzyme-containing monolayer using, for example, Fromherz-type trough. We have prepared an enzyme sensor by immobilizing penicillinase through adsorption on the surface of LB membrane deposited on a pH-sensitive field effect transistor (pH-ISFET). Penicillinase, fortunately, could be tightly adsorbed, through electrostatic or hydrophobic force of attraction, to the surface of the LB membrane. However, it is not always possible for enzymes to be adsorbed to the LB membrane surface without deactivation. In fact, we have observed poor reproducibility in potentiometric response for the pH-ISFETs covered with LB membranes adsorbing urease, trypsin, and α-chymotrypsin, presumably due to desorption or deactivation of enzymes. For these reasons, we have developed a reactive LB membrane which can covalently bind enzymes on the surface, using a fatty acid active ester, succinimidyl behenoate (**1**), as a membrane-forming amphiphile.

This paper reports the immobilization of α-chymotrypsin on the surface of LB membrane containing **1** which is deposited on the pH-ISFET and its use as an enzyme sensor.

Experimental

Materials. Succinimidyl behenoate (**1**) was prepared from *N*-hydroxysuccinimide (1.2 g) and behenic acid (3.4 g) in 50 ml chloroform using dicyclohexylcarbodiimide (2.1 g) as coupling reagent. The crude product was purified by repeated recrystallization from ethanol. 3.2 g (73%). Mp 98—99 °C. Found; C, 71.46; H, 10.59; N, 3.36%. Calcd for $C_{26}H_{47}NO_4$; C, 71.35; H, 10.82; N, 3.20%.

α-Chymotrypsin (EC 3.4.21.1) was obtained from Sigma Co. *N*-Acetyltyrosine ethyl ester (ATEE) was purchased from Research Organics Inc.

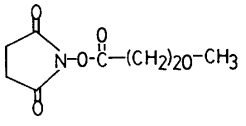

Chart 1. Succinimidyl behenoate **1**.

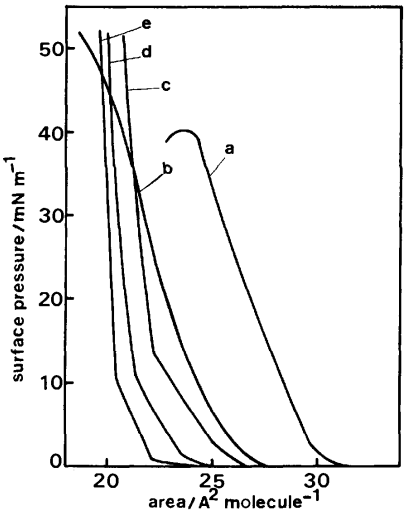

Fig. 1. π-*A* isotherms of **1** and **1**/1-octadecanol mixed monolayers on water at 17 °C. The contents of **1** in the monolayers were 100(a), 90(b), 40(c), 10(d), and 0 w/w%(e).

The procedure for the fabrication and the pH response of the pH-ISFET used are described elsewhere.[6,7]

Sensor Fabrication. The **1** or **1**/1-octadecanol mixed monolayer was spread with benzene on an aqueous subphase in a Langmuir trough (Kyowa Kaimenkagaku Co.). The water subphase was adjusted at ca. pH 7 with $BaCl_2$ and $KHCO_3$. The monolayer was deposited on the pH-ISFET precoated with 11-layer octadecanoic acid LB membrane, by dipping the probe vertically through the monolayer at 25 mN m^{-1}. After the monolayer had been removed from water surface, the probe was pulled up. By this treatment, the active ester groups should be located at the uppermost surface of the deposited LB layer, and, therefore, the surface is reactive to nucleophilic group such as amine. The deposition behavior of **1** and **1**/1-octadecanol membranes was elucidated by the deposition on the glass plate precoated with octadecanoic acid LB layer (1 cm×3 cm), since the small area of the pH-ISFET (ca. 1 mm×3 mm) inhibited precise measurement of deposition ratio.

The LB membrane-coated pH-ISFET, thus prepared, was immersed in a 0.5% α-chymotrypsin solution (1 mM phosphate buffer, pH 7.5, 1 M=1 mol dm^{-3}) for 4 h, in order to bind the enzyme onto the surface of LB membrane. The enzyme sensors prepared were rinsed thoroughly with the working buffer before use.

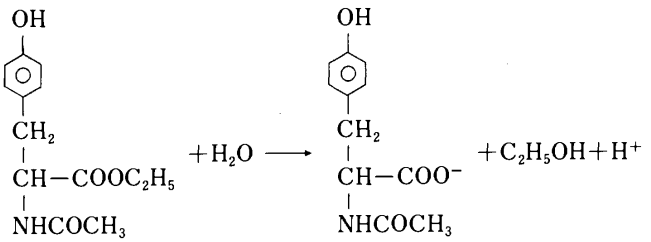
Results and Discussion

In Fig. 1, we display π-*A* diagrams of **1** monolayer together with the mixed monolayers of **1** and 1-octadecanol spread on water surface at 17 °C. Al-

though the **1** monolayer can be compressed up to about 40 mN m^{-1}, the π-A diagram does not afford clear indication of the formation of condensed monolayer of **1**. Basically the same π-A diagram as **1** was observed for the mixed monolayer with 90 w/w% **1**. These monolayers may assume expanded phase, not condensed one. On the other hand, the mixed monolayers with lower **1** content (10 and 40%) exhibited π-A diagrams with transition pressures at 11 — 14 mN m^{-1}, which are similar to that of 1-octadecanol monolayer, indicative of the formation of stable condensed phase.

We examined the deposition property of the monolayer on the glass plate precoated with octadecanoic acid LB layers. The deposition ratios of the **1** and mixed monolayers were measured by dipping the glass plate into the water subphase through the monolayer at 25 mN m^{-1}. The deposition ratios thus measured were 1.9 for **1** monolayer and 1.3, 1.0, and 1.1 for the mixed monolayers with **1** content of 90, 40, and 10%, respectively. Unexpectedly high values of deposition ratios for the monolayers of higher **1** content might come from the expanded nature of the **1** and 90% **1** monolayers on the water surface at 25 mN m^{-1}.

Figure 2 shows a typical response of the α-chymotrypsin-immobilized pH-ISFET which was prepared by the use of the probe covered with the mixed LB layer (**1** content; 90 w/w%) as well as a pH response of bared pH-ISFET. The potentiometric response of immobilized pH-ISFET became slow to compare with that of bared pH-ISFET. However, the probe exhibited a potentiometric response to *N*-acetyltyrosine ethyl ester (ATEE) (a model substrate of α-chymotrypsin), showing that the enzyme was immobilized without deactivation and catalyzed hydrolysis reaction of ATEE to change pH value at the surface of the pH-ISFET gate as follows:



ATEE

It is thought that amino residues in the enzyme attacked the active ester of LB layer to form amide linkage between them, in view of the fact that succinimidyl esters are widely used for modifying proteins[8] and covalently binding proteins on the solid support.[9] The potentiometric response of the sensor was fairly reproducible.

We also tried to immobilize α-chymotrypsin on the surface of 1-octadecanol LB layer deposited on the pH-ISFET, by immersing the probe in the enzyme solution (0.5%) in a similar manner. After rinsing the probe with the working buffer for ca. 1 h, we measured the potentiometric response of the sensor to 2 mM ATEE repeatedly and found that the ΔE_{gs} value

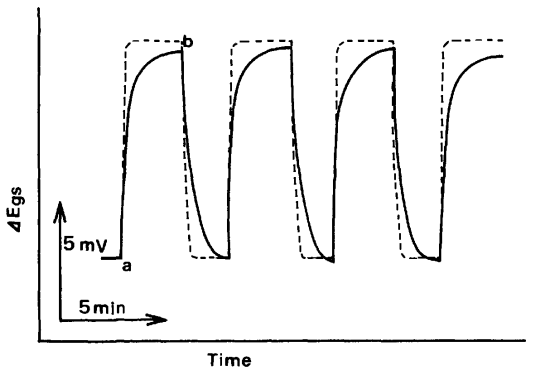


Fig. 2. A typical response of the α-chymotrypsin-immobilized ISFET for *N*-acetyltyrosine ethyl ester. The probe was immersed in the ATEE solution (2 mM) (a) and buffer solution (b). 2 mM buffer (pH 8.0) was used. High concentration samples (above 2 mM) of ATEE could not be prepared due to the low solubility. A response of bared pH-ISFET from pH 8.0 buffer to pH 7.8 buffer is shown in dashed line (---).

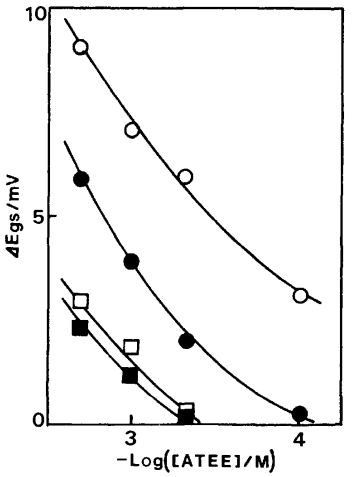

Fig. 3. Effects of **1** content in the LB membrane on the response of the sensor. The contents of **1** were 90(—○—), 40(—●—), 10(—□—), and 0 w/w%(—■—). 2 mM buffer (pH 8.0) was used. High concentration samples (above 2 mM) of ATEE could not be prepared due to the low solubility.

reduced gradually during the repeated use; ΔE_{gs}= ca. 2 mV after 4 measurements (data not shown). This clearly shows the essential role of the active ester to bind enzyme effectively.

The effects of **1** content in the mixed LB membrane on the response of the α-chymotrypsin-immobilized pH-ISFET were examined (Fig. 3). The potentiometric response was enhanced with increasing the **1** content in the LB membrane. This may be due to enchanced enzyme loading on the surface of higher **1** content. A small portion of enzyme seems to be adsorbed to the surface without formation of amide linkage, judging from the fact that the sensor prepared by the use of 1-octadecanol LB membrane showed a little response. The pure **1** LB layer was omitted from

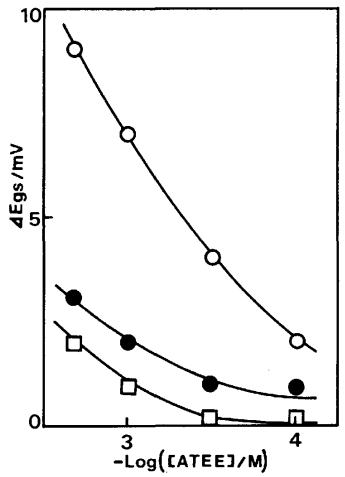

Fig. 4. Effects of pH of the sample solution on the response of the sensor. The pH values of the solutions were 8.0(—○—), 7.0(—●—), and 6.0(—□—).

the consideration, because the nonordered surface structure in deposited **1** layer was suggested by the anomalously high value of deposition ratio.

Figure 4 shows the response of the sensor prepared by the use of 90% **1** mixed LB membrane in pH 6, 7, and 8. The potentiometric response was higher in pH 8 medium, but, in pH 6 and 7 media, the response was lower. This may be due to the fact that the optimum pH of α-chymotrypsin is pH 8.0.[10]

It is a problem in the present method that the long-term stability of α-chymotrypsin immobilized is not satisfactory, which seems to depend on the conditions of measurement and storage. For instance, the catalytic activity of the sensor disappeared in a few days even if the sensor was stored in a 2 mM phosphate buffer (pH 8.0) at 4 °C. However, the long-term stability may be enhanced by the more suitable design of the LB membrane surface and the improvement of the storage conditions.

Thus, we have shown that succinimidyl behenoate is a useful material for the preparation of reactive LB membrane which can bind enzyme covalently on the surface, for the biosensor applications.

Preparation of Bicyclic Crown Ethers Containing Amide Groups: Coordination of the Oxygen Atoms of the Amide Groups

Takeshi KUMAGAI and Sadatoshi AKABORI*
Department of Chemistry, Faculty of Science, Toho University, Funabashi, Chiba 274
(Received October 29, 1988)

Synopsis. 9,12,23,26,31,36-Hexaoxa-1,6,15,20-tetraaza-3,4:17,18-dibenzotricyclo[18.8.5.5^{6,15}]octatriaconta-3,17-diene-2,5,16,19-tetraone (**7a**) was obtained by the reaction of phthaloyl dichloride with 1,4,10-trioxa-7,13-diazacyclopentadecane in 38% yield, and related compounds were prepared by a similar method. Compound **7a** showed high extraction abilities toward alkali, alkaline earth, and other metal cations (Ag^+, Tl^+, and Pb^{2+}), especially lithium and sodium cations.

Diazacrown ethers are well-known as complexing agents toward alkali and alkaline earth metal cations.[1] Especially, the complexing abilities of cryptand-type bicyclic crown ethers toward alkaline earth metal cations are considerably high.[2] We previously reported that cyclobutane-incorporated diazacrown ether **1**[3,4] had high complexing abilities toward alkali, alkaline earth, and other metal cations (Ag^+, Co^{2+}, Ni^{2+}, and Cu^{2+}) without remarkable selectivities. The structures of the complexes of cyclobutane-incorporated diazacrown ether **1** with lithium and/or mercury(II) were revealed by X-ray analyses.[3,4] The results suggested that the metal cation was not incorporated into the cavity of the crown ether moiety, but was coordinated by the oxygen atoms of the two amide groups. On the other hand, Vögtle et al.[5] isolated the 1:1 complexes of diazacrown ethers **2c**, **2d**, **3c**, and **3d** with Na^+ or K^+, and suggested that the metal cation was incorporated into the cavity of the crown ether moiety. However, they did not discuss the complexing ability of diamide **2a**, **2b**, **3a**, and **3b**. Noting these results, we were interested in the complexing abilities of the crown ethers containing amide groups. We therefore prepared the novel azacrown ethers **6b**, **6d**, **7a**, and **7c** in order to discuss their complexing abilities and the structures of their metal complexes.

Results and Discussion

Compound **7a** was prepared by the reaction of 1,4,10-trioxa-7,13-diazacyclopentadecane (**4a**) with phthaloyl dichloride (**5**) in the presence of triethylamine in 38% yield. Also, the compounds **6b**, **6d**, and **7c** were prepared by the similar methods, as described above. However, in these reactions compounds **6a**, **6c**, **7b**, and **7d** were not obtained. The ^1H NMR spectrum of **6b** showed the signals of methylene protons in the δ=4.38 to 2.88 region as a considerably complicated splitting pattern. The 2D COSY ^1H NMR spectrum of **6d** showed an interesting spectral pattern. As shown in Fig. 1, four protons (Ha and Hb), which were expected to be equivalent, appeared as four independent peaks. The signals of two protons (Ha), which are methylene protons adjacent to the nitrogen atoms and also close to the oxygen atoms of the carbonyl group, appeared at δ=4.36 (t, J=4.3 Hz, 1H) and 4.32 (t, J=4.3 Hz, 1H), whereas the other protons (Hb), which are attached to the same carbon atoms, are shifted upfield to δ=2.95 (q, J=3.8 Hz, 1H) and 2.91 (q, J=3.8 Hz, 1H). From the Corey-Pauling-Koltom

(CPK) molecular model, these unusual shifts of the methylene protons were attributed to a steric compression between the carbonyl group and the methylene protons adjacent to nitrogen atoms.[3] However, in the ^{1}H NMR spectra of **7a** and **7c**, the signals of the methylene protons did not give a well-separated pattern; therefore, those signals could not be assigned. The CPK molecular models suggest that the structures of **7a** and **7c** were sterically very crowded and that the mobility of the molecule was obstructed at ambient temperature.

The reaction of **6b** with mercury(II) thiocyanate gave 1:2 complex **8** in 22% yield, and its composition was defined by elemental analysis. In the ^{1}H and ^{13}C NMR spectra, however, only slight differences in the chemical shifts between **6b** and **8** were observed. In the ^{13}C NMR spectra, the chemical shift differences of all carbon atoms between compound **6b** and complex **8** were less than 1.0 ppm. The signals showed that the greatest chemical shift difference was due to the carbonyl carbon atoms, though only 0.98 ppm. These results suggested that if the crown ether moiety and the oxygen atoms of the amide groups are concerned with complexation, coordination becomes presumably very weak.

In the IR spectra, $\nu_{C=O}$ (1616 cm^{-1}) of **8** was shifted to a low wavenumber compared with that (1624 cm^{-1}) of **6b**, and $\nu_{C\equiv N}$ of **8** appeared at 2100 and 2075 cm^{-1}, whereas that of $Hg(SCN)_2$ showed only one absorption band at 2120 cm^{-1}. These results suggested a coordination of the oxygen atoms of the amide groups and the presence of the two kinds of thiocyanate anions. As shown in Fig. 2, the structure of complex **8** was thought to be such that the first of the two mercury atoms is coordinated by the two oxygen atoms of the amide groups, while the second is coordinated by the two nitrogen atoms of the thiocyanate anions of the first one, besides each of the counter anions.

The extraction abilities of the compounds **6b**, **6d**, **7a**, and **7c** toward alkali, alkaline earth, and other metal cations were determined by a method described by Pedersen.[6] However, this determination was carried out using a concentration of azacrown ethers of 7.0×10^{-3} mol dm^{-3}, instead of 7.0×10^{-4} mol dm^{-3}, in order to define the ion selectivities of these azacrown ethers. The results are summarized in Table 1. Compounds **6b** and **7a** showed significant extraction abilities toward alkali and alkaline earth metal cations. Especially, **7a** showed high selectivities toward Li^+(39%) and Na^+(65%). Also **7a** showed high extraction abilities toward Ag^+(49%), Tl^+(42%), and Pb^{2+}(24%). However, **6d** and **7c** showed low extraction

abilities and selectivities toward alkali and alkaline earth metal cations, although they showed high extraction abilities toward Ag^+, Tl^+, and Pb^{2+} cations. Restricted to alkali and alkaline earth metal cations, the significant extraction abilities of **6b** and **7a** may be attributed to an increased basicity of the carbonyl oxygen atoms due to the presence of the *o*-phenylene group. Furthermore, the lower complexing abilities of **6b** toward alkali and alkaline earth metal cations compared with those found in **7a** were presumably caused by difference in the number of carbonyl oxygen atoms. Therefore, compound **7b**, which contains four carbonyl groups as the binding site, showed a stronger affinity toward alkali and alkaline earth metal cations than those of compound **6b**, which contains two carbonyl groups.

Experimental

The melting points were uncorrected. The IR spectra were measured on a JASCO IRA-2 Diffraction Grating Infrared Spectrometer. The ^1H and ^{13}C NMR spectra were obtained on a JEOL GX400 Spectrometer, with TMS as an internal standard. Solvent extraction was carried out according to the method reported previously.[7]

Materials. All reagents and solvents were either commercial or prepared by the usual methods.

The Reaction of 4 with 5. To a solution of triethylamine (1.50 g, 15 mmol) in benzene (400 cm^3), the solution of phthaloyl dichloride (**5a**) (1.02 g, 5.0 mmol) in benzene (100 cm^3) and 1,4,10,13-tetraoxa-7,16-diazacyclooctadecane (**4b**) (1.00 g, 4.6 mmol) in benzene (100 cm^3) were added dropwise at the same rate over a period of 6 h and then stirred for 19 h at room temperature. The precipitated triethylamine hydrochloride was filtered off, and the filtrate was washed with aqueous 10% hydrochloric acid and then water. The mixture was dried by anhydrous magnesium sulfate and concentrated in vacuo. The residue was chromatographed on activated alumina using ethyl alcohol as an eluant. The first fraction was collected and the solvent was removed in vacuo. The residue was recrystallized from benzene to give **6b** as a colorless powder in 13% yield. Mp 216.0—217.0 °C. Synthesis of the 1*H*,5*H*-Naphtho[1,8-*ef*][1,3]dithiocin System

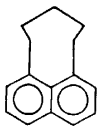
Toshihiro KAMADA,* Yasuo GAMA, and Nobuhide WASADA
National Chemical Laboratory for Industry, Higashi-1, Tsukuba, Ibaraki 305
(Received February 28, 1989)

Synopsis. The titled new pericyclized naphthalene system has been prepared in four steps from 1,8-naphthalenedicarboxylic anhydride in an overall yield of 35—78%. The key step in the synthesis employed a dithioacetal-cyclization reaction of 1,8-bis(mercaptomethyl)naphthalene with carbonyl compounds using boron trifluoride etherate as a catalyst.

Previously, we reported the synthesis of the 8,9,10,11-tetrahydro-7*H*-cycloocta[*de*]naphthalene system (**1**).[1,2] The successful synthesis of the carbocyclic ring of the eight-membered pericyclized naphthalene system has led us to investigate further the synthesis of heterocyclic analogs of this family of molecules. In this paper, a synthesis of new peri ring system, 1*H*,5*H*-naphtho[1,8-*ef*][1,3]dithiocin (**2**) is reported.



1

Lithium aluminum hydride reduction of the commercially available 1,8-naphthalenedicarboxylic anhydride readily gave 1,8-bis(hydroxymethyl)naphthalene (**3**) (85% yield).[2] Bromination of **3** with phosphorus tribromide in dioxane produced the dibromide **4** (94% yield), which, on treatment with thiourea, was converted to the dithiol **5** (99% yield).[3] Our approach to synthesis of the 1*H*,5*H*-naphtho[1,8-*ef*][1,3]dithiocin system then utilized a dithioacetal-cyclization reaction between **5** and carbonyl compounds. The reactions were carried out with a variety of aldehydes and ketones in chloroform using boron trifluoride etherate as a catalyst. Thus, treatment of **5** with paraformaldehyde (**6a**) yielded 1*H*,5*H*-naphtho[1,8-*ef*][1,3]dithiocin (**2a**) (44% yield) with the desired 1,3-dithiocin peri ring. Similarly, from paraldehyde (**6b**) and benzaldehyde (**6c**) were obtained 3-monosubstituted derivatives of **2a**—i.e., 3-methyl- (**2b**) (69% yield) and 3-phenyl- (**2c**) (97% yield) 1*H*,5*H*-naphtho[1,8-*ef*]dithiocins, respectively. Furthermore, ketones also underwent a ready dithioacetalization reaction on treatment with **5** to give rise to 3,3-disubtituted derivatives of **2a**—i.e., from acetone (**6d**), 2-butanone (**6e**), and acetophenone (**6f**) were obtained 3,3-dimethyl- (**2d**) (70% yield), 3-ethyl-3-methyl- (**2e**) (81% yield), and 3-methyl-3-phenyl- (**2f**) (60% yield) 1*H*,5*H*-naphtho[1,8-*ef*][1,3]dithiocins, respectively.

c; $R_1 = C_6H_5$, $R_2 = H$
d; $R_1 = R_2 = CH_3$
e; $R_1 = C_2H_5$, $R_2 = CH_3$
f; $R_1 = CH_3$, $R_2 = C_6H_5$

All the products obtained (**2a—f**) are listed in Table 1. Each of these new compounds gave elemental analysis and spectra (IR, NMR, MS) identical with its structure. (See Experimental).

Experimental

General. Melting points were taken on a microscopic hot-stage melting-point apparatus and are uncorrected. The R_f values were obtained on Merck Silica gel $60F_{254}$ (0.2 mm) with benzene as a solvent. The IR spectra were measured with a JASCO IR-G spectrometer using Nujol mulls calibrated with polystyrene. The ^1H NMR spectra were determined on a JEOL C-60 spectrometer (at 60 MHz) using chloroform-*d* as a solvent (ca. 10% solution) and tetramethylsilane as an internal standard. Mass spectra were obtained with a JEOL-01SG-2 instrument with a direct-inlet system operating at 75 eV.

1,8-Bis(hydroxymethyl)naphthalene (3). This was prepared from 1,8-naphthalenedicarboxylic anhydride in 85% yield as described previously.[2]

1,8-Bis(bromomethyl)naphthalene (4). This was ob-

Table 1. Synthesis of 1*H*,5*H*-Naphtho[1,8-*ef*][1,3]dithiocins (**2a**—f) from 1,8-Bis(mercaptomethyl)naphthalene (**5**) and Carbonyl Compounds (**6**)

Carbonyl compound (**6**)	R_1	R_2	Product (**2**)	Yield/%

tained in a more excellent yield than that reported[4] by using the procedure described below.

To a stirred suspension of the diol **3** (20.435 g) in dioxane (100 ml) was slowly added phosphorus tribromide (30 ml) at room temperature. After 25 h, water (300 ml) was added under cooling to decompose the excess reagent, and the resulting mixture, after further addition of water (1200 ml), was stirred at room temperature for an additional 1 h. The solid precipitated was then collected by filtration and crystallized from benzene to give the dibromide **4** (35 g, 94%) as colorless crystals; mp 131.5—132 °C (lit,[4] mp 130—131.5 °C); MS, *m/z* 314 (M^+=$C_{12}H_{10}Br^{79}Br^{81}$).

1,8-Bis(mercaptomethyl)naphthalene (5). This was prepared by a modification of the procedure previously reported.[3]

A mixture of the dibromide **4** (34.54 g) and thiourea (17.6 g) in 95% ethanol (580 ml) was boiled under reflux over a period of 4 h. After cooling the white precipitate of bis(isothiouronium) salt was collected. The salt was then added to a nitrogen-degassed solution of potassium hydroxide (180 g) in water (350 ml) and refluxed under nitrogen atmosphere for 1 h. After cooling and washing with benzene, the aqueous alkaline solution was slowly added with ice-cooling to a nitrogen-degassed 6 M-aqueous hydrochloric acid (1 M=1 mol dm^{-3}). The resulting cloudy solution was stirred for 30 min at room temperature. The white solid precipitated was collected by filtration to provide the dithiol **5** (23.8 g, 99%); mp 79—81 °C (lit,[3] mp 80—80.5 °C); IR (Nujol) 2557 cm^{-1} (S-H); ^1H NMR ($CDCl_3$) δ=1.84 (2H, t, J=6.1 Hz, SH), 4.42 (4H, d, J=6.1 Hz, $ArCH_2SH$), 7.36—7.91 (6H, m, ArH); MS, *m/z* 220 (M^+). This was shown (by IR, ^1H NMR, TLC) to be pure enough and employed without further purification for the following reactions.

Preparation of 1*H*,5*H*-Naphtho[1,8-*ef*][1,3]dithiocins (2a—f) by Reaction of the Dithiol 5 with Paraformaldehyde (6a), Paraldehyde (6b), Benzaldehyde (6c), Acetone (6d), 2-Butanone (6e), and Acetophenone (6f). General Procedure. To a stirred and cooled (0 °C) solution of the dithiol **5** (0.5 mmol) and aldehyde or ketone **6** (0.5 mmol) in chloroform (10 ml) there was added boron trifluoride etherate (2 mmol) under nitrogen atmosphere. After the mixture had been stirred at 0 °C for 2 h, it was allowed to warm to room temperature and was stirred for an additional 18 h. Water was then added and the mixture was extracted with ether. The ether layer was washed successively with 10% aqueous sodium hydroxide solution and water, and was evaporated after drying over magnesium sulfate. The resulting solid was purified by recrystallization from ethanol to afford the pure dithioacetal **2**.

1*H*,5*H*-Naphtho[1,8-*ef*][1,3]dithiocin (2a); colorless needles; mp 180.5—181 °C; R_f 0.51 (SiO_2/benzene); IR (Nujol) 3025, 1600, 1510, 835, 780, 770 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.55 (2H, s, C_9-CH_2), 4.69 (4H, broad signal, $ArCH_2$), 7.41—7.94 (6H, m, ArH); MS, *m/z* (relative intensity), 232 (M^+, 69), 186 (36), 185 (M^+—CH_3S, 100), 172 (96), 171 (61), 153 (70), 152 (51); Found: C, 67.29; H, 5.02%. Synopsis. The asymmetric alkylation of 2-methoxycarbonyl-1-indanone (**2**) and ethyl 2-methylacetoacetate (**5**) with an alkylsulfonium salt containing a sugar group were investigated. (*S*)-Ethyl 2-allyl-2-methylacetoacetate (**6b**) was obtained with up to 25% optical purity on alkylation of the enolate ion of **5** using the allyl(*p*-tolyl)sulfonio D-glucoside derivative (**1h**).

S-Adenosylmethionine (AdoMet) is an important biological methylating agent, which is the source of the methyl groups of such compounds as DNA, RNA, proteins, and biogenic amines.[1] A few stereochemical studies have been reported on the methylation reaction of phenolic oxygens with *S*-adenosylmethionine via S_N2-type process in enzymic systems.[2] In recent years, a few studies have been published on the alkylation reaction of oxygen nucleophiles such as carboxylate, nitrogen nucleophiles such as amines, and carbon nucleophiles (e.g. enolate ions of β-keto esters) with racemic alkylsulfonium salts.[3] More recently, we have reported the first examples of asymmetric alkylation of β-keto esters with optically active alkylsulfonium salts.[4] We now describe herein the synthesis of alkylsulfonium salts containing sugar groups, since *S*-adenosylmethionine has a sugar group at the α-position of the sulfur atom. The asymmetric alkylation of cyclic and acyclic β-keto esters using the sulfonium salts is also described.[5]

Alkylsulfonium salts containing sugar groups (**1a**—**k**) were prepared from D-glucose. The sulfonium salts (**1e** and **1i**) were shown to be diastereomeric mixtures on the sulfur atom by ^1H NMR analysis (see Experimental section). They could not be separated by recrystallization.

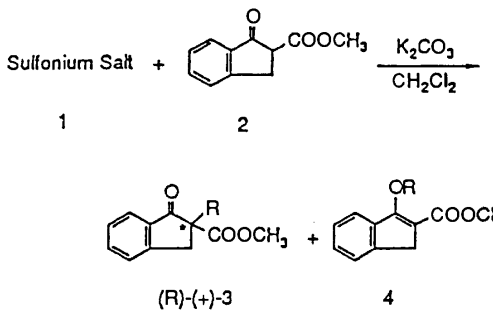
2-Methoxycarbonyl-1-indanone (**2**) was alkylated with a dimethylsulfonio D-glucoside derivative (**1a**) in the presence of anhydrous potassium carbonate in dichloromethane at room temperature for 3 days (Eq. 1). Purification of the reaction mixture by silica-gel chromatography gave *C*-methylated product, (*R*)-(+)-2-methyl-2-methoxycarbonyl-1-indanone (**3a**) (71% yield; o.p. 4.1%),[4] and the *O*-methylated product, **4a** (9% yield). In a similar manner, alkylation of **2** with diethylsulfonio D-glucoside derivative (**1b**) gave the *C*-ethylated product (*R*)-(+)-**3b** (77% yield; o.p. 4.7%),[4] and the *O*-ethylated product **4b** (12% yield).

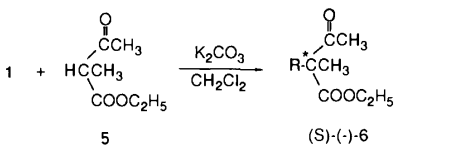
When the methyl(*p*-tolyl)sulfonio D-glucoside derivative (**1d**) was employed for the reaction with **2**, only the methyl group was introduced to the α-carbon and oxygen atom of **2** to give **3a** and **4a**, respectively. The major product **3a** was also optically active with *R*-configuration.



(1)

Similarly, the alkylation of **2** with the methyl(*p*-nitrophenyl)sulfonio D-glucoside derivative (**1e**) gave (*R*)-(+)-**3a** (78% yield; o.p. 6.6%) and product **4a** in 10% yield (Entry 4). Alkylation with arylethylsulfonium salts (**1f** and **1g**) gave (*R*)-(+)-**3b** in 71% yield (o.p. 5.3%) and (*R*)-(+)-**3b** in 74% yield (o.p. 11.9%), respectively (Entries 5 and 6). As shown in Entry 7, the exclusive *C*-allylation of **2** occurred without being accompanied by *O*-allylation. No significant effects on the optical yields were observed when the para-substituent on the aromatic ring was changed from a methyl group (**1d** and **1f**) to a nitro group (**1e** and **1g**).

The alkylation of ethyl 2-methylacetoacetate (**5**)



(2)

with alkylsulfonium salts containing sugar group **1** was also investigated (Eq. 2).

When ester **5** was alkylated with sulfonium salt (**1i**), it afforded the *C*-benzylated product (*S*)-(−)-**6a** in 49% yield (o.p. 4.7%).[6] Similarly, allylation of **5** with sulfonium salt (**1h**) gave *C*-allylated products (*S*)-(−)-**6b** in 18% yield (o.p. 25.0%). The results are sum-

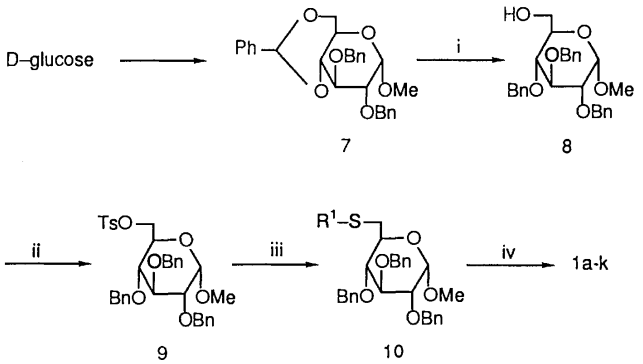
marized in Table 2.

As shown in Tables 1 and 2, we have achieved asymmetric alkylation using alkylsulfonium salts containing sugar groups, although this method has shown only a small enrichment of one enantiomer by an asymmetric induction effect. Two factors may be considered to explain this asymmetric induction: that is, the chiral transfer from the chiral sulfur atom of the sulfonium salt and the steric control by the sugar moiety. The former factor is not clear, since small asymmetric inductions were observed for the alkylation of **2** with dimethyl- and diethylsulfonium salts (**1a** and **1b**) and alkylarylsulfonium salts (**1e** and **1i**), although **1e** and **1i** were 1:1 diastereomeric mixtures. Accordingly, this asymmetric alkylation is mainly attributable to the steric control by the sugar portion when the enolate ion of **2** attacks at the alkyl carbon atom of the sulfonium salt via an S_N2 process. The S_N2 mechanism is supported by the fact that the ratio of *C*-methylated and *C*-ethylated product of **2** with ethylmethylsulfonium salt (**1c**) was 2.8:1.[7,8]

Experimental

The procedure for the preparation of sulfonium salts **1** is outlined in Scheme 1.

Preparation of Methyl 6-*O*-Tosyl-2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (9). A mixture of methyl 4,6-*O*-benzylidene-2,3-di-*O*-benzyl-α-D-glucopyranoside (**7**) (4.78 g), was prepared from D-glucose by the ordinary procedures, and lithium aluminum hydride (764 mg) in 55 cm^3 of dry CH_2Cl_2–Et_2O (7:4) was stirred and heated to reflux. After the addition of aluminum chloride (2.68 g) in 15 cm^3 of dry ether, the solution was refluxed again for 3 h to give methyl 2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (**8**) (4.67 g, 99% yield). To a pyridine solution (10 cm^3) of **8** (2.03 g) was added *p*-toluenesulfonyl chloride (1.27 g) at 0 °C, and the mixture



Scheme 1. Reagents: i, $LiAlH_4$–$AlCl_3$, CH_2Cl_2–Et_2O; ii, TsCl, pyridine; iii, R^1SH, EtOH–NaOEt; iv, R^2X–$AgClO_4$, CH_3CN.

was stirred for 1 day at room temperature to give methyl 6-*O*-tosyl-2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (**9**) (2.59 g, 96% yield); $[\alpha]_D$+24.8° (*c* 2.26, $CHCl_3$); ^1H NMR ($CDCl_3$) δ=2.24 (3H, s), 3.17 (3H, s), 3.23—4.93 (13H, m), 6.92—7.83 (19H, m); MS, *m/z* 618 (M^+); HRMS, Calcd for $C_{35}H_{38}O_8S$: M, 618.2286. Found: *m/z* 618.2260.

General Procedure for the Synthesis of 6-Deoxy-6-[alkylthio (or arylthio)]-α-D-glucopyranoside (10). The thiol (5 mmol) was added to an ethanol solution of sodium ethoxide with stirring. The mixture was cooled to 0 °C and **9** (4 mmol) was added to it. The reaction mixture was stirred for 1 h at 0 °C and for 24 h at room temperature to give 6-deoxy-6-[alkylthio (or arylthio)]-α-D-glucopyranoside (**10a—d**).

Methyl 6-Deoxy-6-(*p*-tolylthio)-2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (10a): 69% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=2.24 (3H, s), 3.32 (3H, s), 2.67—5.04 (7H, m), 4.38—5.04 (6H, m), 6.92 and 7.14 (4H, A_2B_2, *J*=8.4 Hz), 7.20 (15H, br-s); $[\alpha]_D$+22.3° (*c* 1.73, $CHCl_3$); MS, *m/z* 570 (M^+); Calcd for $C_{35}H_{38}O_5S$: C, 73.68, H, 6.72%. Found: C, 73.53, H, 6.79%.

Methyl 6-Deoxy-6-(*p*-nitrophenylthio)-2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (10b): 86% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=3.13—3.93 (6H, m), 3.28 (3H, s), 4.41—4.90 (6H, m), 5.06 (1H, d, *J*=3.6 Hz), 6.98 and 7.90 (4H, A_2B_2, *J*=8.4 Hz), 7.20 (15H, br-s); $[\alpha]_D$+24.1° (*c* 3.52, $CHCl_3$); MS, *m/z* 601 (M^+); HRMS, Calcd for $C_{34}H_{35}O_7NS$: M, 601.2132. Found: *m/z* 601.2238.

Methyl 6-Deoxy-6-(*p*-chlorophenylthio)-2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (10c): 96% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=2.60—3.96 (6H, m), 3.23 (3H, s), 3.32—4.73 (6H, m), 4.93 (1H, d, *J*=3.8 Hz), 7.00—7.10 (19H, m); $[\alpha]_D$+29.6° (*c* 1.95, $CHCl_3$); MS, *m/z* 590 (M^+); HRMS,

Calcd for $C_{34}H_{35}O_5SCl$: M, 590.1892. Found: *m/z* 590.1938.

Methyl 6-Deoxy-6-(methylthio)-2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (10d): 89% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=2.02 (3H, s), 2.32—2.83 (2H, m), 3.05—3.97 (3H, m), 3.29 (3H, s), 4.37—4.75 (7H, m), 4.92 (1H, d, *J*=4.0 Hz), 7.07 (10H, br-s), 7.12 (5H, br-s); $[\alpha]_D$+36.4° (*c* 5.77, $CHCl_3$); MS, *m/z* 494 (M^+); HRMS, Calcd for $C_{29}H_{34}O_5S$: M, 494.2126. Found: *m/z* 494.2153.

Methyl 6-Deoxy-6-(ethylthio)-2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (10e): 92% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=1.33 (3H, t, *J*=6.4 Hz), 2.37—2.87 (2H, m), 2.56 (2H, q, *J*=6.4 Hz), 3.68 (3H, s), 3.20—4.12 (3H, m), 4.83—4.47 (7H, m), 5.05 (1H, d, *J*=4.2 Hz), 7.23 (5H, s), 7.27 (10H, s); $[\alpha]_D$+40.0° (*c* 1.63, $CHCl_3$); MS, *m/z* 507 (M^+-1); HRMS, Calcd for $C_{30}H_{35}O_5S$ (M^+-1): 507.2204. Found: *m/z* 507.2208.

General Synthetic Procedure for Alkylaryl- and Dialkylsulfonium Salts Containing a Sugar Group (1a—k). To a mixture of silver perchlorate (2.5 g, 12 mmol) and sulfide **10** (12 mmol) in acetonitrile (15 cm^3) was added slowly an acetonitrile solution (5 cm^3) of alkyl iodide (60 mmol) at 0 °C. The mixture was stirred for 2 days at room temperature to give perchlorate salts of alkylaryl- and dialkylsulfonium containing sugar group (**1a—k**).

Perchlorate Salt of Methyl 6-Deoxy-6-(dimethylsulfonio)-2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (1a): 90% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=2.72 (3H, s), 2.81 (3H, s), 3.33 (3H, s), 3.17—4.07 (6H, m), 4.40—5.03 (7H, m), 7.23 (15H, br-s); $[\alpha]_D$+59.5° (*c* 2.55, $CHCl_3$). **1b**: 73% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=1.32 (3H, t, *J*=7.2 Hz), 1.36 (3H, t, *J*=7.2 Hz), 3.11—4.09 (10H, m), 3.33 (3H, m), 4.23—5.10 (7H, m), 7.23 (15H, br-s); $[\alpha]_D$+31.9° (*c* 8.63, $CHCl_3$). **1c**: 99% yield; Mp 131—132 °C; ^1H NMR ($CDCl_3$) δ=1.30 (3H, t, *J*=7.0 Hz), 2.73 (3H, s), 3.10—4.07 (8H, m), 3.30 (3H, s), 4.37—4.87 (6H, m), 4.93 (1H, d, *J*=6.6 Hz), 7.22 (15H, br-s); $[\alpha]_D$+58.9° (*c* 1.0, $CHCl_3$); Calcd for $C_{31}H_{39}O_9SCl$: C, 59.74, H, 6.32%. Found: C, 59.97, H, 6.71%. **1d**: 86% yield; colorless syrup; ^1H NMR (acetone-d_6) δ=2.40 (3H, s), 3.28 (3H, s), 3.37 (3H, s), 3.50—4.98 (13H, m), 7.20 (15H, br-s), 7.46 and 7.90 (4H, A_2B_2, *J*=8.4 Hz); $[\alpha]_D$+55.6° (*c* 1.18, acetone). **1e**: 82% yield; colorless syrup; ^1H NMR (acetone-d_6) δ=3.23 (1.5H, s), 3.29 (1.5H, s), 3.33 (3H, s), 3.15—4.20 (6H, m), 4.35—5.12 (7H, m), 7.15 (15H, br-s), 7.92 and 8.26 (4H, A_2B_2, *J*=8.0 Hz); $[\alpha]_D$+39.1° (*c* 1.08, acetone). **1f**: 91% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=1.20 (3H, t, *J*=7.2 Hz), 2.42 (3H, s), 3.23 (3H, s), 3.30—5.00 (15H, m), 7.22 (15H, br-s), 7.30 and 7.60 (4H, A_2B_2, *J*=8.2 Hz); $[\alpha]_D$+43.4° (*c* 2.17, acetone). **1g**: 68% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=1.52 (3H, t, *J*=8.0 Hz), 3.28 (3H, s), 3.13—4.16 (8H, m), 4.33—5.10 (7H, m), 7.13 (15H, br-s), 7.90 and 8.23 (4H, A_2B_2, *J*=8.0 Hz); $[\alpha]_D$+54.0° (*c* 1.04, acetone). **1h**: 99% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=2.38 (3H, s), 3.17 (3H, s), 3.13—4.00 (6H, m), 4.16—4.87 (9H, m), 5.33—5.60 (3H, m), 6.93 and 7.61 (4H, A_2B_2, *J*=8.0 Hz), 7.20 (15H, br-s); $[\alpha]_D$+38.3° (*c* 3.39, acetone). **1i**: 75% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=3.13 (1.5H, s), 3.21 (1.5H, s), 3.31—4.17 (6H, m), 4.27—5.03 (9H, m), 7.07—7.67 (24H, m); $[\alpha]_D$+17.3° (*c* 8.5, $CHCl_3$). **1j**: 85% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=2.38 (3H, s), 3.25 (3H, s), 3.47—4.97 (15H, m), 7.10—7.33 (20H, m), 7.45 and 7.88 (4H, A_2B_2, *J*=8.4 Hz); $[\alpha]_D$+38.2° (*c* 2.31, $CHCl_3$). **1k**: 92% yield; colorless syrup; ^1H NMR ($CDCl_3$) δ=3.19 (3H, s), 3.16—4.03 (7H, m), 4.17—5.10 (8H, m), 5.31—5.61 (3H, m), 6.95—7.80 (19H, m); $[\alpha]_D$+42.3° (*c* 1.53, $CHCl_3$).

General Procedure for Asymmetric Alkylation of β-Keto Ester 2 (or 5) with 1. A mixture of alkylsulfonium salts **1** (1 mmol), β-keto ester **6** (or **8**) (1 mmol) and anhydrous potassium carbonate (1.3 mmol) was stirred in dry dichloromethane (10 cm^3) at room temperature for 3 days. After filtration of insoluble materials, the alkylated products of the β-keto ester were purified by column chromatography (silica gel) and GPC. The optical purity and the absolute configuration were determined by ^1H NMR analysis for compound **3b** in the presence of chiral shift reagent ($Eu(hfc)_3$) and by HPLC analysis for compound **3a**, using an optically active column (DAICEL CHEMICAL CHIRALCEL CA-1; methanol as eluent): the results are listed in Table 1. The structures of **6a** and **6b** were determined on the basis of the following spectroscopic data and their optical purity and absolute configuration were determined in comparison with authentic samples.[6]

Ethyl 2-Benzyl-2-methylacetoacetate (6a); ^1H NMR ($CDCl_3$) δ=1.18 (3H, s), 1.18 (3H, t, *J*=7.0 Hz), 2.03 (3H, s), 3.03 (2H, d, *J*=5.0 Hz), 4.06 (2H, q, *J*=7.0 Hz), 6.90—7.23 (5H, m); MS, *m/z* 234 (M^+); HRMS, Calcd for $C_{14}H_{18}O_3$: M, 234.1255. Found: *m/z* 234.1248.

Ethyl 2-Allyl-2-methylacetoacetate (6b); ^1H NMR ($CDCl_3$) δ=1.23 (3H, s), 1.25 (3H, t, *J*=7.0 Hz), 2.03 (3H, s), 2.45 (2H, d, *J*=6.4 Hz), 4.03 (2H, q, *J*=7.0 Hz), 4.77—5.90 (3H, m); MS, *m/z* 184 (M^+); HRMS, Calcd for $C_{10}H_{16}O_3$: M, 184.1099. Found: *m/z* 184.1069.

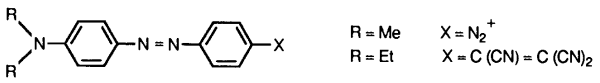
(Received March 17, 1989)

Synopsis. 2-Aryl-2,3-dihydro-3,3-dimethyl-5,6-cycloheptapyrazolediones with an electron-releasing group at C-4 on the benzene ring showed a bathochromic shift in acid solution, whereas the 4-ethoxycarbonylphenyl derivative showed a negative halochromism; 484 nm in ethyl acetate, 517, 566, and 600(sh) nm in trifluoroacetic acid, and 455 nm in concd sulfuric acid.

It is well-known that azo compounds in acidic solution show absorption maxima normally at longer wavelengths than those in neutral solution.[1] However, 4′-diazonio-4-(dimethylamino)azobenzene[2] and 4-(diethylamino)-4′-(tricyanovinyl)azobenzene[3] are outstanding in view of their negative halochromism, i.e., the absorption in acidic solution is at shorter wavelengths than that in neutral solution. We will describe here a new example showing a remarkably large negative halochromism.



Scheme 1.

2-Aryl-2,3-dihydro-3,3-dimethyl-5,6-cycloheptapyrazolediones, hinopurpurins (**1**), prepared from 4-isopropyltropolone and benzene diazonium salts,[4] are known to be stable dyes. Table 1 summarizes the oxidation-reduction potentials ($E^1_{1/2}$ and $E^2_{1/2}$), determined by cyclic voltammetry (CV), and the maxima of the visible absorption spectra. The remote substituents on the benzene ring influence both the potentials and the maxima. Since **1** can be regarded as a masked *p*-tropoquinone, the shapes of the voltammograms, as shown in Fig. 1, might be similar to those of *p*-tropoquinone derivatives.[5,6] This was indeed observed and the more electron-attractive the substituent, the higher were the potentials $E^1_{1/2}$ and $E^2_{1/2}$.

The absorption of **1a** did not change much on changing the solvent. However, the positions of the absorption of **1c** and **1d** were largely dependent on the solvent. Compounds **1b** and **1c** showed positive halochromism; i.e., 13 nm for **1b** and ca. 70 nm for **1c** between chloroform and concd sulfuric acid.

On the other hand, the absorption of **1d** showed a bathochromic shift (ca. 60 nm) in trifluoroacetic acid, whereas in concd sulfuric acid an unusually large negative shift was observed (111 nm between trifluoroacetic acid and concd sulfuric acid and 29 nm between ethyl acetate and concd sulfuric acid) with a decrease of the peak intensity. The wavelength of the absorption peak was ca. 30 nm shorter than that of **1a** in concd sulfuric acid and that of **1d** in ethyl acetate. This negative halochromism of **1d** was also observed in acidic methanol solutions. The reversibility of this color change was confirmed by changes of the acidity of methanol solutions.

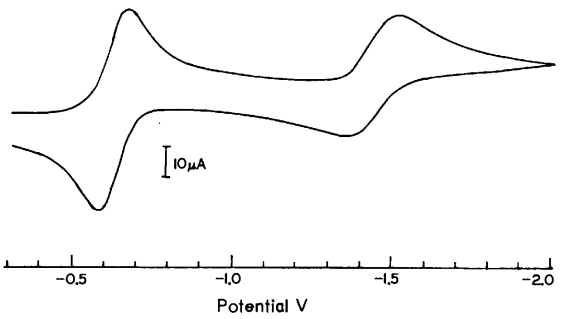


Fig. 1. CV curve of **1d**.

a) The CV were measured in anhydrous DMF with 0.1 M $(n\text{-Bu})_4NBF_4$ using Pyrex-glass sealed Pt wire as working and counter electrodes and standard Ag/AgCl as a reference electrode at 22—23 °C under N_2 atmosphere with a scan rate of 100 mV s^{-1}.

These phenomena could be explained as follows: There exist the following mesomeric forms (**1** and **1′**). In the ground state, the neutral form is predominant, whereas the ionic form is favored in the excited state. Since a large increase in the dipole moment of the molecule can be expected during the excitation, the energy level of the excited state will be markedly lowered, causing a bathochromic shift.[7] Furthermore, the protonated form (**2**) of **1** seems to be more stable than the neutral one due to the disappearance of the dipole repulsion on the α-diketone part and the formation of a tropolone structure. The electron-releasing substituents on the benzene ring assist this protonation to cause a bathochromic shift as observed in **1b** and **1c**. In the case of **1d**, the ethoxycarbonyl part might be also protonated in concd sulfuric acid. The doubly protonated species **3**, where charges are located at two terminal oxygens, has mesomeric forms such as **3′** and **3″**, the latter of which is a polar and less stable *p*-benzoquinone methide derivative. Accordingly, the excited state is more strongly destabilized than the ground state and the maxima of the absorption would become shorter than those of the neutral form.[7]

In view of recent interest in organic dyes for functional compounds, a rare negative halochromism with exceptionally large differences observed in easily available nonbenzenoid dyes is particularly noteworthy. Furthermore, azo compounds as functional dyes, recently became less attractive in view of their chemical instability; however, the present dyes, hinopurpurins, are stable towards air, light, and acid and base under ordinary conditions, having ring-closed to 5*H*-pyrazole system, and are promising materials.

Experimental

Preparation of Hinopurpurins. To a pyridine solution (5 cm^3) of 4-isopropyltropolone (400 mg, 2.44 mmol) was added drop by drop an aqueous solution of a diazotized amine (3 mmol) at 0 °C to 5 °C with stirring for 2 h. After the solution was diluted with water (40 cm^3), the precipitate was filtered and dried. An EtOH solution of 5-diazonio-4-isopropyltropolone was refluxed for 4 h and cooled to yield crystals by filtration.

1a: Reddish needles, 42%, mp 154—155 °C (from acetone-hexane; lit,[4] mp 148 °C); ^1H NMR ($CDCl_3$)[8] δ=1.75 (6H, s), 6.42 (1H, s), 6.75 (1H, d, *J*=12.1 Hz), 7.32 (1H, t, *J*=7.3 Hz), 7.46 (2H, dd, *J*=9.2, 7.3 Hz), 7.56 (2H, d, *J*=9.2 Hz), and 7.57 (1H, d, *J*=12.1 Hz); ^{13}C NMR ($CDCl_3$) δ=27.8 (2C), 75.7, 116.3, 119.4 (2C), 126.8, 127.4, 129.8 (2C), 132.7, 139.5, 142.9, 157.4, 182.7, and 184.3.

1b: Greenish needles, 52%, mp 256—267 °C (decomp) (from EtOH; lit,[4] mp 244 °C); ^1H NMR (pyridine-d_5) δ=1.60 (6H, s), 2.28 (3H, s), 6.70 (1H, s), 6.83 (1H, d, *J*=12.1 Hz), 7.27 (2H, d, *J*=8.4 Hz), 7.57 (2H, d, *J*=8.4 Hz), and 7.62 (1H, d, *J*=12.1 Hz); ^{13}C NMR (pyridine-d_5) δ=20.7, 27.2 (2C), 76.0, 116.7, 119.9 (2C), 127.3, 130.5 (2C), 132.6, 136.7, 137.7, 142.8, 157.4, 183.3, and 185.1.

(Received April 13, 1989)

Synopsis. Methyl 2,3,5,6,11,11b-Hexahydro-3-oxo-1*H*-indolizino[8,7-*b*]indole-5-carboxylate was converted into the tetrahydro, dihydro, and dehydro esters using *N*-bromosuccinimide. On treatment with acetic acid, the 6a-bromo indolenine derivative bearing a substituent on C-11b gave a mixture of 8- and 9-bromo compounds by migration of the bromine to the benzene ring, while the corresponding 6a-chloro derivative afforded the oxindole.

In the preceding paper, we reported the isolation of 2,3,5,6,11,11b-hexahydro-3-oxo-1*H*-indolizino[8,7-*b*]-indole-5-carboxylic acid and the 5,11b-dicarboxylic acid as the methyl esters **1** and **2** from *Clerodendron trichotomum* Thunb. The conversion of **1** into a blue pigment, trichotomine dimethyl ester (**3**), was achieved using *N*-bromosuccinimide (NBS) in *t*-BuOH, and the formation of **3** was suggested to proceed via the $\Delta^{1,11b}$-tetrahydro ester **4** derived from **5**.[1] The versatility of 3-halo-3*H*-indoles as intermediates in indole alkaloid synthesis is well documented in the literature.[2] This paper deals with the dehydrogenation of **1** by treatment with NBS and the reaction of 6a-halo derivatives **6a**, **b**, obtained from **2**, with acetic acid.

5 X=Br R=H
6a X=Br R=COOMe
6b X=Cl R=COOMe

Bromination of **1** with NBS in CH_2Cl_2 in the presence of K_2CO_3 followed by treatment with triethylamine (Et_3N) gave the $\Delta^{5,6}$-tetrahydro ester **7**. On the other hand, treatment of **1** with NBS in CH_2Cl_2 afforded **4**, from which Iwadare et al. synthesized **3** by autoxidation.[3] The formation of **4** from the initially formed **5** must be catalyzed by hydrogen bromide evolved and supports the intermediacy of **4** in the conversion of **1** into **3** with NBS in *t*-BuOH.

On heating with 5% palladium charcoal in toluene, **7** underwent dehydrogenation to the dihydro ester **8** (UV 329 nm, ε 10500), while on treatment with excess NBS in Et_3N–CH_2Cl_2 at 0 °C for 15 min, **7** was dehydrogenated to **8** and the dehydro ester **9** (UV 376 nm, ε 12800). In the latter reaction, a 6a-bromo derivative formed from **7** seems to undergo dehydrobromination to **8**, which might afford **9** by allylic bromination at C-1 followed by dehydrobromination. In the presence of MeOH, treatment of **7** with NBS in THF afforded the β-carboline **10** (UV 343 nm, ε 4000) presumably by methanolysis of the intermediate **8**. Compounds **8** and **9** were identical with those prepared in the following way. On heating with 2,3-dichloro-5,6-dicyano-*p*-benzoquinone in benzene, **1** underwent dehydrogenation to **9**, which gave **8** by catalytic reduction.

The properties of 6a-halo derivatives **6a**, **b** obtained from **2** were examined, since **6a**, **b** had a methoxycarbonyl group on C-11b and could not undergo such dehydrogenation reactions mentioned above.

Bromination of **2** with NBS gave **6a** as crystals (^{13}C NMR δ=56.5, C-6a). On treatment with Et_3N, **6a** gave the $\Delta^{5,6}$ diester **11**. On the other hand, treatment of **6a** with acetic acid afforded a separable mixture of bromo diesters **12** and **13** in a ratio of 2:5. The presence of bromine on C-8 of **12** and on C-9 of **13** was suggested from the ^1H NMR spectrum of **12** and **13**. The structure **13** was assigned to the major product, since the carbamate **14** formed from **13** with methyl chloroformate showed a singlet of C_{10}-proton at low field (δ=8.20) in the ^1H NMR spectrum. In 3-bromo-3*H*-indoles, migration of the bromine to the benzene ring was reported in the literature.[4] On further

treatment with NBS and then with acetic acid, the mixture of **12** and **13** yielded the 8,9-dibromo diester **15**.

After chlorination of **2** with *t*-butyl hypochlorite (*t*-BuOCl), the resulting **6b** was treated with acetic acid to afford the oxindole **16** (^{13}C NMR δ=58.9, C-6a). On treatment with *t*-BuOCl in EtOH-CH_2Cl_2, **2** gave the dichloroxindole **17**. The formation of **17** was rationalized by indole-oxindole rearrangement to **16** followed by chlorination of the benzene ring,[5] since **16** gave the chloroxindole **18** on treatment with *t*-BuOCl and then with EtOH, and **18** yielded **17** with *t*-BuOCl in EtOH-CH_2Cl_2.

Experimental[6]

Preparation of 7. To a stirred mixture of **1** (284 mg, 1.0 mmol), K_2CO_3 (0.50 g) and CH_2Cl_2 (30 ml) cooled to 0 °C was added dropwise a solution of NBS (214 mg, 1.2 mmol) in CH_2Cl_2 (10 ml). After stirring at 0 °C for 10 min, Et_3N (5 ml) was added. The mixture was stirred at room temperature for 7 h, and then filtered. The filtrate was concentrated under reduced pressure to leave a residue, which was dissolved in $CHCl_3$. The solution was washed with water, dried over Na_2SO_4, and concentrated under reduced pressure. Separation of the residue by column chromatography (SiO_2-$CHCl_3$) gave **7** (163 mg, 68% based on reacted **1**) and **1** (42 mg). **7**: mp 253—256 °C (MeOH); ^{1}H NMR (CD_3COCD_3) δ=2.28—3.00 (4H, m), 3.76 (3H, s), 5.30 (1H, m), 7.13—7.77 (4H, m), 7.47 (1H, s), and 10.95 (1H, br s). Found: *m/z* 282.1027. Calcd for $C_{16}H_{14}N_2O_3$: M, 282.1004.

Preparation of 4. To a stirred solution of **1** (142 mg, 0.50 mmol) in CH_2Cl_2 (30 ml) cooled to 0 °C was added dropwise a solution of NBS (134 mg, 0.75 mmol) in CH_2Cl_2 (10 ml). After stirring at 22 °C for 1 h, the solution was washed successively with water, aqueous $NaHCO_3$, and brine, and then dried over Na_2SO_4. Evaporation of the solvent and separation of the products by column chromatography (SiO_2-$CHCl_3$) gave **4**[3] (62 mg, 44%).

Dehydrogenation of 7. A mixture of **7** (50 mg), 5% Pd-C (20 mg) and toluene (70 ml) was refluxed with stirring for 10 h, and then filtered. Evaporation of the solvent and separation of the products by column chromatography (SiO_2, 1 vol% MeOH-$CHCl_3$) gave **8** (27 mg, 54%): mp 257—259 °C ($CHCl_3$-hexane); UV 240 (ε 49200), 264 (21700), 283 (sh, 14600), 317 (8880), and 329 nm (10500); ^{1}H NMR δ=3.26 (2H, t, *J*=7.6 Hz), 3.60 (2H, t, *J*=7.6 Hz), 4.08 (3H, s), 7.51—8.57 (4H, m), and 8.67 (1H, s). Found: *m/z* 280.0864. Calcd for $C_{16}H_{12}N_2O_3$: M, 280.0847.

Reaction of 7 with NBS. To a stirred solution of **7** (28 mg, 0.10 mmol) in Et_3N-CH_2Cl_2 (0.2—20 ml) cooled to 0 °C was added NBS (71 mg, 0.40 mmol). The solution was stirred at 0 °C for 15 min, and worked up in the usual way. Separation of the products by PTLC (SiO_2, 3 vol% MeOH-$CHCl_3$) afforded **8** (1 mg, 4%) and **9** (8 mg, 30%). **8** was identical with that obtained above by ^{1}H NMR and TLC comparisons. **9**: mp 272—273 °C ($CHCl_3$-hexane); UV 214 (ε 28800), 246 (32000), 268 (20100), 305 (sh, 7020), 345 (sh, 8820), 359 (14000), and 376 nm (12800); ^{1}H NMR δ=4.13 (3H, s), 7.05 (1H, d, *J*=9.9 Hz), 7.57—8.70 (4H, m), 8.17 (1H, d, *J*=9.9 Hz), and 8.88 (1H, s); MS *m/z* 278 (M^+). Anal. ($C_{16}H_{10}N_2O_3$) C, H, N.

Preparation of 10. To a stirred solution of **7** (20 mg, 0.07 mmol) in MeOH-THF (2—10 ml) cooled to 0 °C was added NBS (15 mg, 0.08 mmol). The solution was stirred at 0 °C for 30 min, and diluted with AcOEt (100 ml). The solution was worked up in the usual way to give **10** (15 mg, 68%): mp 179—181 °C ($CHCl_3$-hexane); UV 219 (ε 17000), 237 (24100), 270 (35900), 303 (7360), 330 (4430), and 343 nm (4000); ^{1}H NMR δ=2.99 (2H, t, *J*=6.4 Hz), 3.53 (2H, t, *J*=6.4 Hz), 3.67 (3H, s), 4.05 (3H, s), 7.32—8.18 (4H, m), 8.78 (1H, s), and 9.61 (1H, br s). Found: *m/z* 312.1116. Calcd for $C_{17}H_{16}N_2O_4$: M, 312.1109.

Dehydrogenation of 1. A mixture of **1** (284 mg, 1 mmol), DDQ (0.91 g, 4.0 mmol) and benzene (300 ml) was refluxed with stirring for 5 h, and filtered. The filtrate was worked up in the usual way. Separation of the products by column chromatography (SiO_2, 1 vol% MeOH-$CHCl_3$) gave **9** (79 mg, 28%), which was found to be identical with that obtained above by IR and ^{1}H NMR comparisons.

Catalytic Reduction of 9. A mixture of **9** (150 mg, 0.54 mmol), PtO_2 (30 mg), and dioxane (220 ml) was stirred under hydrogen atmosphere at room temperature overnight, and filtered. Evaporation of the solvent and separation of the residue by column chromatography (SiO_2-$CHCl_3$) gave **8** (125 mg, 83%), which was identical with that obtained above by IR and ^{1}H NMR comparisons.

Preparation of 6a. To a solution of **2** (342 mg, 1.0 mmol) in $CHCl_3$ (30 ml) was added a solution of NBS (196 mg, 1.1 mmol) in $CHCl_3$ (30 ml). The solution was kept at room temperature for 15 min and worked up in the usual way. Crystallization from $CHCl_3$-hexane gave **6a** (395 mg, 94%): mp 130—132 °C (decomp); ^{13}C NMR δ=29.5 (t), 29.8 (t), 33.1 (t), 49.4 (d), 52.6 (q), 53.1 (q), 56.5 (s), 67.4 (s), 122.1 (d), 123.3 (d), 127.6 (d), 130.5 (d), 138.5 (s), 152.1 (s), 168.3 (s), 169.7 (s), 175.2 (s), and 178.4 (s). Without further purification, **6a** was subjected to the next experiment.

Preparation of 11. A solution of **6a** (43 mg) in Et_3N-CH_2Cl_2 (0.5—1 ml) was allowed to stand at room temperature for 2 d, and concentrated under reduced pressure. Separation of the residue by PTLC (SiO_2-AcOEt) gave **11** (10 mg, 29%) and **2** (20 mg, 57%). **11**: mp 231—233 °C ($CHCl_3$-hexane); ^{1}H NMR δ=2.39—3.03 (4H, m), 3.70 (3H, s), 3.89 (3H, s), 7.20—7.67 (4H, m), 7.50 (1H, s), and 8.97 (1H, br s). Found: *m/z* 340.1061. Calcd for $C_{18}H_{16}N_2O_5$: M, 340.1058.

Preparation of 12 and 13. A solution of **6a** (210 mg) in AcOH (10 ml) was kept at 20 °C for 22 h, and concentrated under reduced pressure to leave an oil, which was dissolved in $CHCl_3$. The solution was washed with aqueous $NaHCO_3$ and dried over Na_2SO_4. Evaporation of the solvent gave an oil, which contained **12** and **13** in a ratio of 2:5 (determined by ^{1}H NMR). Separation of the products by column chromatography (SiO_2-$CHCl_3$) and PTLC (SiO_2, AcOEt-hexane, 2:1) gave **12** (26 mg, 12%) and **13** (89 mg, 42%). **12**: mp 186—188 °C ($CHCl_3$-hexane); ^{1}H NMR δ=2.17—2.98 (4H, m), 3.05 (1H, dd, *J*=16.0 and 7.0 Hz), 3.23 (1H, dd, *J*=16.0 and 1.8 Hz), 3.61 (3H, s), 3.85 (3H, s), 5.48 (1H, dd, *J*=7.0 and 1.8 Hz), 7.23 (C_{10}-H, d, *J*=8.6 Hz), 7.29 (C_9-H, dd, *J*=8.6 and 1.8 Hz), 7.62 (C_7-H, d, *J*=1.8 Hz), and 8.55 (1H, br s). Found: *m/z* 420.0320. Calcd for $C_{18}H_{17}N_2O_5Br$: M, 420.0320.

13: mp 176—178 °C (MeOH); ^{1}H NMR δ=2.17—2.98 (4H, m), 3.08 (1H, dd, *J*=16.1 and 7.3 Hz), 3.27 (1H, dd, *J*=16.1 and 1.2 Hz), 3.63 (3H, s), 3.86 (3H, s), 5.49 (1H, dd, *J*=7.3 and 1.2 Hz), 7.16 (C_8-H, dd, *J*=8.4 and 1.8 Hz), 7.32 (C_7-H, d, *J*=8.4 Hz), 7.37 (C_{10}-H, d, *J*=1.8 Hz), and 8.65 (1H, br s). Found: *m/z* 420.0300. Calcd for $C_{18}H_{17}N_2O_5Br$: M, 420.0320.

Conversion of 13 into 14. To a stirred solution of **13** (68 mg, 0.16 mmol) in DMF (3 ml) was added NaH (20 mg, 0.9 mmol). After stirring at room temperature for 20 min, methyl chloroformate (0.1 ml) was added. The mixture was stirred at room temperature for 2 h, and then poured into

aqueous NH_4Cl. The solution was worked up in the usual way to give **14** (50 mg, 65%): mp 112—114 °C (MeOH); ^1H NMR δ=2.03—3.33 (4H, m), 2.95 (1H, dd, J=16.5 and 8.1 Hz), 3.59 (1H, d, J=16.5 Hz), 3.64 (3H, s), 3.68 (3H, s), 4.03 (3H, s), 5.47 (1H, d, J=8.1 Hz), 7.38 (C_7-H, d, J=8.1 Hz), 7.44 (C_8-H, dd, J=8.1 and 1.6 Hz), and 8.20 (C_{10}-H, s). Found: m/z 478.0361. Calcd for $C_{20}H_{19}N_2O_7Br$: M, 478.0374.

Preparation of 15. As described above, a solution of **2** (103 mg, 0.30 mmol) in $CHCl_3$ (20 ml) was treated with a solution of NBS (59 mg, 0.33 mmol) in $CHCl_3$ (20 ml) to give **6a** quantitatively. Without crystallization, **6a** was dissolved in AcOH (10 ml) to yield a mixture of **12** and **13**. In the same way as mentioned above, the mixture of **12** and **13** was again treated with NBS (59 mg) and then AcOH (10 ml) to give **15** (95 mg, 63%): mp 232—233 °C (MeOH); ^1H NMR δ=2.18—2.99 (4H, m), 3.05 (1H, dd, J=16.1 and 7.3 Hz), 3.23 (1H, dd, J=16.1 and 0.7 Hz), 3.66 (3H, s), 3.88 (3H, s), 5.49 (1H, dd, J=7.3 and 0.7 Hz), 7.29 (C_{10}-H, s), 7.69 (C_7-H, s), and 8.90 (1H, br s). Found: m/z 497.9439. Calcd for $C_{18}H_{16}N_2O_5Br_2$: M, 497.9426.

Preparation of 16. To a solution of **2** (20 mg) in CH_2Cl_2 (2 ml) was added t-BuOCl (3 drops). The solution was kept at room temperature for 10 min and concentrated under reduced pressure to give **6b** quantitatively: ^{13}C NMR δ=29.5 (t), 33.3 (t), 48.6 (d), 52.6 (q), 53.0 (q), 67.1 (s), 67.5 (s), 122.0 (d), 123.1 (d), 127.7 (d), 130.7 (d), 137.9 (s), 152.8 (s), 168.5 (s), 170.0 (s), 175.2 (s), and 177.8 (s). Without further purification, **6b** was dissolved in AcOH (0.5 ml). The solution was allowed to stand at room temperature for 3 h and concentrated under reduced pressure. The residue was worked up in the usual way to give **16** (20 mg, 95%): mp 267—268 °C (MeOH); ^{13}C NMR δ=23.7 (t), 32.4 (t), 38.7 (t), 52.6 (q), 56.8 (d), 58.9 (s), 78.1 (s), 110.7 (d), 122.7 (d), 123.9 (d), 124.7 (s), 129.7 (d), 141.5 (s), 170.8 (s), 171.5 (s), 177.3 (s), and 179.1 (s). Found: m/z 358.1147. Calcd for $C_{18}H_{18}N_2O_6$: M, 358.1163.

Preparation of 17. To a solution of **2** (162 mg) in EtOH-CH_2Cl_2 (0.5—30 ml) was added t-BuOCl (1 ml). The solution was allowed to stand at room temperature for 2 d and concentrated under reduced pressure to give **17** (142 mg, 70%): mp 266—267 °C (EtOH); ^1H NMR (DMSO-d_6) δ= 1.70—2.95 (6H, m), 3.72 (6H, s), 4.78 (1H, t, J=8.4 Hz), 6.84 (C_7-H, d, J=1.8 Hz), 7.53 (C_9-H, d, J=1.8 Hz), and 11.38 (1H, br s). Found: m/z 426.0381. Calcd for $C_{18}H_{16}N_2O_6Cl_2$: M, 426.0383.

Preparation of 18. To a solution of **16** (14 mg) in CH_2Cl_2 (5 ml) was added t-BuOCl (2 drops). The solution was allowed to stand at room temperature for 18 h and concentrated under reduced pressure. Crystallization of the residue from EtOH gave **18**, mp >300 °C, (13 mg, 87%): ^1H NMR (DMSO-d_6) δ=1.70—2.90 (6H, m), 3.70 (6H, s), 4.77 (1H, t, J=8.4 Hz), 6.82 (C_7-H, d, J=2.1 Hz), 6.88 (C_{10}-H, d, J=8.4 Hz), 7.32 (C_9-H, dd, J=8.4 and 2.1 Hz), and 10.87 (1H, br s). Anal. ($C_{18}H_{17}N_2O_6Cl$) C, H, N.

Preparation of 17 from 18. To a mixture of **18** (24 mg) and EtOH-CH_2Cl_2 (0.1—10 ml) was added t-BuOCl (0.2 ml). The mixture was stirred at room temperature for 2 d and worked up as described above to give **17** (20 mg, 77%), which was found to be identical with that obtained as above.

A Synthetic Route to (±)-Humulone

Heitaro OBARA,* Jun-ichi ONODERA, Yoshihisa MACHIDA, and Shuji YADA
Department of Applied Chemistry, Faculty of Engineering, Yamagata University, Yonezawa 992
(Received April 14, 1989)

Synopsis. The synthesis of (±)-humulone was achieved by the prenylation of 2,3,4,6-tetrahydroxyisovalerophenone with 1-bromo-3-methyl-2-butene.

Humulone, an antibiotic and bitter costituent of hop (*Humulus lupulus* L.), was first isolated by Lintner and Schnell[1] in 1904; the structure was determined to be 3,5,6-trihydroxy-4,6-bis(3-methyl-2-butenyl)-2-(3-methyl-1-oxobutyl)-2,4-cyclohexadien-1-one (**6**) by the synthesis of its racemate[2] and on the basis of its spectral data.[3]

However, the method for synthesizing (±)-humulone is not applicable to the preparative purpose because of the tedious procedure and poor yield.[2] In this paper we wish to report a new synthetic route to (±)-humulone.

We first succeeded in the synthesis of model compounds of **6**, 3,5,6-trihydroxy-2-acetyl-4,6-dimethyl- and 3,5,6-trihydroxy-2-acetyl-4,6-diethyl-2,4-cyclohexadien-1-one (**3** and **4**), by the di-*C*-alkylation of 2,3,4,6-tetrahydroxyacetophenone (**2**)[4] with methyl or ethyl iodide in the presence of sodium hydride in dimethyl sulfoxide. This method was applied to the convenient synthesis of (±)-**6**.

(±)-Humulone was synthesized by the prenylation of 2,3,4,6-tetrahydroxyisovalerophenone (**5**) obtained by the acylation of 1,2,3,5-benzenetetrol (**1**)[5] with isovaleryl chloride by Friedel-Crafts reaction. The acylation of **1** with isovaleronitrile by the Hoesch reaction did not succeed. The IR and ^{1}H NMR spectra of this synthetic humulone and its *o*-phenylenediamine complex were identical with those of natural specimens.

It is assumed that this synthetic method is applicable to the preparation of such other hop constituents as cohumulone[6] or adhumulone.[7]

Experimental

The UV and IR spectra were recorded with Hitachi 100-50 spectrophotometer and Hitachi 215 spectrophotometers, respectively. The mass spectra were recorded with a Hitachi RMU-6M mass spectrometer. ^{1}H and ^{13}C NMR spectra were recorded with Hitachi R-600 spectrometer and Hitachi R-90H spectrometers using tetramethylsilane as an internal standard, respectively.

3,5,6-Trihydroxy-2-acetyl-4,6-dimethyl-2,4-cyclohexadien-1-one (3). To a mixture of **2** (3.68 g) and sodium hydride (1.6 g) in dry dimethyl sulfoxide (150 ml) was added methyl iodide (9.0 g) under cooling with cold water; the mixture was then stirred for 3 h at room temperature. The reaction mixture was poured into cold dilute hydrochloric acid and extracted with ethyl acetate. The extract was chromatographed on a column of silica gel with carbon tetrachloride–ethyl acetate–acetic acid (60:30:1) to afford **3** (2.36 g, 57%). Mp 153—154 °C (lit,[8] 150.5—151.5 °C). MS *m/z* 212 (M^+). ES λ_{max} (EtOH) 229, 321, and 358 nm (log ε=4.18, 4.09, and 4.01). IR (KBr) ν 3400, 3250, and 1660 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=1.58 and 1.84 (each 3H, s), 2.57 (3H, s), and 18.42 (1H, s). Found: C, 56.56, H, 5.74%, Calcd for $C_{10}H_{12}O_5$: C, 56.60, H, 5.70%.

3,5,6-Trihydroxy-2-acetyl-4,6-diethyl-2,4-cyclohexadien-1-one (4). Compound **4** (0.2 g, 17%) was obtained from **2** (0.92 g), sodium hydride (0.4 g), and ethyl iodide (2.34 g) by way of **3** as described above. Mp 106—107 °C. MS *m/z* 240 (M^+). ES λ_{max} (EtOH) 229, 322, and 358 nm (log ε=4.19, 4.08, and 3.97). IR (KBr) ν 3350, 3250, and 1660 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=0.97 (6H, m), 1.86 and 2.35 (each 2H, m), 2.52 (3H, s), 18.59 (1H, s). Found: C, 59.93, H, 6.89%, Calcd for $C_{12}H_{16}O_5$: C, 59.97, H, 6.71%.

2,3,4,6-Tetrahydroxyisovalerophenone (5). To a mixture of **1**[5] (9.0 g) and anhydrous aluminium chloride (10.0 g) in nitrobenzene (100 ml) was added isovaleryl chloride (6.6 g) at 0 °C; the mixture was then stirred for 3 days at room temperature. The reaction mixture was poured into cold 10% hydrochloric acid and extracted with ether. The ether was distilled away and the remaining nitrobenzene was taken off by steam distillation. The residue was chromatographed on a column of silica gel with benzene–ethyl acetate (3:1) to give **5** (4.44 g, 38%). Mp 167—168 °C. MS *m/z* 226 (M^+). ES λ_{max} (EtOH) 237 and 298 nm (log ε=3.94 and 4.28). ^{1}H NMR (DMSO-d_6) δ=0.92 (6H, d, J=7.0 Hz), 2.18 (1H, m), 2.90 (2H, d, J=7.0 Hz), 5.89 (1H, s), 11.12 and 12.19 (each 1H, s). Found: C, 58.55, H, 6.40%, Calcd for $C_{11}H_{14}O_5$: C, 58.40, H, 6.24%.

(±)-Humulone. To a mixture of **5** (2.0 g) and sodium hydride (0.64 g) in dry dimethyl sulfoxide (60 ml) was added 1-bromo-3-methyl-2-butene (2.8 g) under cooling with cold water; the mixture was then stirred for 2 h at room temperature. The reaction mixture was poured into cold dilute hydrochloric acid and extracted with ethyl acetate. The extract was chromatographed on silica gel with benzene–methyl acetate–acetic acid (300:20:1) to give (±)-**6** (1.06 g, 33%) as viscous pale brown oil. MS *m/z* 362 (M^+). ES λ_{max} (EtOH) 228, 327, and 356 nm (log ε=4.15, 4.03, and 3.95). IR (CCl_4) ν 3370, 2970, 2870, 1660, 1530, 1460, 1355, 1340, 1290, 1240, 1215, 1170, and 1100 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=0.98 and 1.02 (each 3H, d, J=7.0 Hz), 1.54 and 1.69 (12H, s), 2.17 (1H, m), 2.50, 2.70, and 3.09 (each 2H, d, J=7.0 Hz), 5.08 (2H, m), 18.89 (1H, s). ^{13}C NMR ($CDCl_3$) δ=17.7 and 17.8 (each q), 21.1 (d), 22.5, 22.8, 25.7, and 25.9 (each q), 26.4, 42.6, and 46.3 (each t), 78.8, 105.9, and 109.3 (each s), 115.7 and 121.0 (each d), 132.0, 137.9, 167.6, 190.6,

195.0, and 200.0 (each s). The IR and ^{1}H NMR spectra of this compound were completely identical with those of natural (−)-humulone.

(−)-Humulone. Natural humulone-*o*-phenylenediamine complex (0.5 g, mp 103 — 104 °C) was chromatographed on a column of silica gel with benzene–methyl acetate–acetic acid (300:20:1) as an eluent to give **(−)-humulone** (0.2 g), $[\alpha]_D$=−136.0° (*c* 1.39, chloroform), as a pale brown viscous solid.

***o*-Phenylenediamine Complex of (±)-6.** A mixed solution of **(±)-6** (167 mg) and *o*-phenylenediamine (50 mg) in benzene (7 ml) was allowed to stand overnight in a refrigerator. The resulting precipitate was recrystallized from benzene to afford the complex (42 mg, 20%) as light-yellow needles. Mp 104 — 105 °C (lit,[2] mp 105 — 106 °C). The IR and ^{1}H NMR spectra of this complex were completely identical with those of the natural specimen.

The authors express to their thanks to Mr. Masahiro Kowaka of KIRIN Brewery Co., Ltd., for his kind gift of natural sample. We are also grateful to Miss Mamiko Masuzawa and Mr. Kazuhiro Nagahara for their technical assistance.

New Approaches to Tetracyanoquinodimethane

Shunro YAMAGUCHI,* Kazuyuki MIYAMOTO, and Terukiyo HANAFUSA
The Institute of Scientific and Industrial Research, Osaka University, Ibaraki, Osaka 567
(Received April 25, 1989)

Synopsis. New synthetic methods of tetracyanoquinodimethane from terephthaloyl dichloride were presented. Conversion of terephthaloyl dichloride to 1,4-bis(dicyanobenzoyloxymethyl)benzene, followed by debenzoyloxylation and succeessive oxidation afforded TCNQ.

Tetracyanoquinodimethane (TCNQ) is an excellent electron acceptor and readily forms conducting charge-transfer complexes with various donors. Owing to the electrical properties of TCNQ charge-transfer complexes, several approaches to TCNQ have been developed[1] We wish to report the synthetic method of TCNQ from terephthaloyl dichloride in a few steps. Terephthaloyl dichloride was converted to terephthaloyl dicyanide (**3**) with copper(I) cyanide. The reaction of terephthaloyl dicyanide with potassium cyanide and benzoyl chloride under ultrasonic irradiation[2] yielded 1,4-bis(dicyanobenzoyloxymethyl)benzene (**4**). Compound **4** was also prepared by the treatment of terephthaloyl dichloride with potassium cyanide, benzoyl chloride, and 18-crown-6[3] in dichloromethane and water. These reactions were carried out under heterogeneous conditions. Conversion of compound **4** to TCNQ was achieved by four methods. i) Benzoyloxy group of compound **4** was removed electrochemically[4] to give 1,4-bis(dicyanomethyl)-benzene ($TCNQH_2$), and $TCNQH_2$ was oxidized with *N*-iodosuccinimide (NIS) to afford TCNQ. ii) Reduction of compound **4** with zinc dust in acetic acid, followed by the oxidation with *N*-iodosuccinimide gave TCNQ. iii) Conversion of compound **4** to TCNQ was effected with triphenylphosphine-bromine complex in chlorobenzene. iv) Flash pyrrolysis of compound **4** under reduced pressure also afforded TCNQ.

In these approaches, it may be noted that the starting material is terephthaloyl dichloride, all reagents are inexpensive, and the cyanation reagents are easy to handle.

Experimental

Melting points were uncorrected. IR spectra were obtained on Hitachi 260—10 spectrophotometer. ^1H NMR spectra were measured on a Bruker AM360 instrument and the chemical shifts are given in δ-values with respect to TMS used as internal standard. Mass spectra were taken on a JMS-DX300 mass spectrometer.

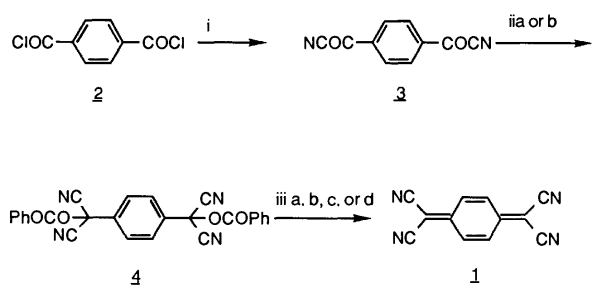
Terephthaloyl Dicyanide (3). The mixture of terephthaloyl dichloride (50.0 g, 0.25 mol) and CuCN (46.3 g, 0.52 mol) in dry acetonitrile (500 ml) was refluxed overnight. After removal of volatiles, the resulting residue was extracted with hot benzene (100 ml×3). The combined organic layer was evaporated and the resulting residue was sublimed under reduced pressure (1 Torr; 1 Torr=133.322 Pa, 100 °C) to give 42.1 g of a colorless powder. Yield 87%. Mp 142—145 °C (lit,[5] 140—142 °C).

1,4-Bis(dicyanobenzoyloxymethyl)benzene (4). The mixture of terephthaloyl dicyanide (1.0 g, 5.6 mmol), KCN (1.8 g, 27.6 mmol), and benzolyl chloride (4.0 g, 28.5 mmol) in dry acetonitrile (6.5 ml) was placed in a test tube fitted with a screw cap. Ultrasound irradiation of the mixture was performed at 50 °C for 3.5 h, immersed in an ultrasonic cleaner. The insoluble materials were filtered off and the filtrate was condensed under reduced pressure. The resulting residue was purified by silica-gel chromatography and recrystallized from acetonitrile to give 1.5 g, of colorless prisms. Yield 60%. Mp 232—235 °C, IR (KBr disk) 2245, 1740 cm^{-1}, ^1H NMR ($CDCl_3$) δ=8.13 (3 4H), 8.08—7.55 (m 10H). MS (*m/z*) M^+ 446. Calcd for $C_{26}H_{14}O_4N_4$: C, 69.95; H, 3.16; N, 12.55%. Found: C, 69.81; H, 3.23; N, 12.65%.

A mixture of terephthaloyl dicyanide (5.0 g, 27.8 mmol), KCN (9.0 g, 0.14 mmol), benzolyl chloride (20 g, 0.14 mmol), and 18-crown-6 (360 mg, 1.38 mmol) in dry acetonitrile (50 ml) and water (0.08 ml) was stirred for 5 h at room temperature. The insoluble materials were filtered off. After the same procedure mentioned above, 5.6 g of colorless prisms were obtained. Yield 45%. Mp 232—235 °C.

Tetracyanoquinodimethane (1). i) A 100 ml H-type divided electrolysis cell was fitted with a Pb anode and a carbon cathode. A solution of compound **4** (89 mg, 0.2 mmol) and tetraethylammonium tosylate (3.01 g, 10.6 mmol) in concd H_2SO_4 (0.2 ml) and CH_2Cl_2 (20 ml) was placed in the cathodic compartment and in the anodic compartment was placed the solution of tetraethylammonium tosylate (3.01 g, 10.6 mmol) in CH_2Cl_2 (20 ml). The stirred catholyte was electrochemically reduced at 20 mA (current density 6.7 mA cm^{-2}) with N_2 bubbling. After 4.2 mol^{-1} of electricity was passed through the reaction system, the catholyte was taken into a 50 ml round-bottomed flask, to which was added *N*-iodosuccinimide (90 mg, 4.0 mmol). The reaction mixture was stirred for 30 min, washed with H_2O (10 ml×2), dried over anhydrous Na_2SO_4, and the solvent was evaporated. The residue was purified by silica-gel chromatography to give 29 mg of orange microcrystals. Yield 71%. Mp 293—294 °C (lit;[1] 291—293 °C). ^1H NMR ($CDCl_3$) δ=7.38 (s, 4H). IR (Nujol) 2230 cm^{-1}.

ii) To a solution of compound **3** (100 mg, 0.22 mmol) in acetic acid (10 ml) and THF (10 ml) was added Zn dust (2.0 g). After stirring for 10 min at room temperature, the insoluble materials were filtered off and the filtrate was concentrated. The resulting residue was dissolved in acetonitrile



i) CuCN. ii a) KCN, PhCOCl, Ultra sound, ii b) KCN, PhCOCl, PTC
iii a) Electrolysis, NIS. iii b) Zn-AcOH, NIS, iii c) Ph_3PBr_2, iii d) pyrrolysis

Scheme 1. Approaches to TCNQ from terephthaloyl dichlonide.

(10 ml). To the solution was added NIS (120 mg, 0.53 mmol). The reaction mixture was stirred for 30 min at room temperature and then the solvent was evaporated. The residue was purified by silica-gel chromatography to afford 21 mg of orange microcrystals. Yield 46%. Mp 293—294 °C.

iii) To a solution of Ph_3P (131 mg, 0.50 mmol) in chlorobenzene (10 ml) was added bromine (88 mg, 0.55 mmol) and pale yellow crystals were formed. After the addition of compound **3** (100 mg, 0.55 mmol), the mixture was heated for 5 h. Removal of volatiles and purification of the residue by silica-gel chromatography gave 22 mg of orange microcrystals. Yiled 49%. Mp 293—294 °C.

iv) Compound **3** (100 mg, 0.22 mmol) was placed in a Pyrex tube of 0.8 mm diameter. The tube was heated at 750 °C under reduced pressure (0.3 Torr). The sublimated products were dissolved in dichloromethane and purified by chromatography to yield 9 mg of orange microcrystals. Yiled 19%. Mp 293—294 °C.

We wish to thank Dr. Ikuzo Nishiguchi, Osaka Municipal Technical Research Institute for providing tetraethylammonium tosylate.

(Received May 11, 1989)

Synopsis. The title synthetic method which undergoes without racemization, was explored employing sequential amidolysis with a secondary amine, alkylation with an alkyl halide under basic conditions, and reduction with sodium bis(methoxyethoxy)aluminium hydride.

In connection with our ongoing project on the synthesis of the carbapenem key intermediate (**1**),[1] a large quantity of optically pure (*S*)-2-benzyloxypropanal (**2a**)[2] was required as a synthetic intermediate. Initially, the requisite aldehyde (**2a**) could be prepared without racemization by benzylation of commercially available inexpensive ethyl (*S*)-lactate (**3**) with benzyl trichloroacetimidate followed by reduction of formed ethyl (*S*)-2-benzyloxypropionate (**4**) with diisobutylalminium hydride.[1] However, this synthetic scheme turned out to be unrewarding for a large scale preparation of **2a** since the reagent for benzylation is highly expensive. Accordingly, an alternative efficient method was sought which can readily produce **2a** by using inexpensive reagents.

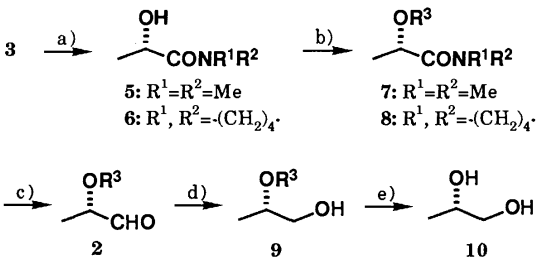
2a
1

While it has been uncovered that direct benzylation of **3** under basic conditions such as those employing benzyl bromide and sodium hydride in *N*,*N*-dimethylformamide, gives a low yield[3] of **4** and accompanies considerable racemization,[2c] we have now found that **2a** can be readily prepared without racemization by sequential amidolysis of **3** with a secondary amine, benzylation of the formed (*S*)-*N*,*N*-dialkyllactamide under basic conditions, and reduction of the amide group into an aldehyde moiety.

According to the reported method[4] with some modifications, preparation of (*S*)-*N*,*N*-dimethyllactamide (**5**) could be readily achieved in 93% yield by heating a mixture of **3** and liquid dimethylamine in a sealed tube at 70 °C. Benzylation of **5** was effected smoothly by treating with benzyl chloride and sodium hydride[5] or with benzyl chloride and sodium hydroxide[6] under usual phase-transfer conditions, giving rise to the *O*-benzyl derivative (**7a**) in 88 or 86% yield, respectively. Reduction of **7a** with sodium bis(2-methoxyethoxy)aluminium hydride (Vitride®),[7] furnished **2a** in 90% yield.

Since it had been reported that **2a** shows no constant value on measurement of the optical rotation due to its rapid hydration by moisture present in a solvent or air,[2a] determination of the optical purity of **2a** thus



a: R^3=Bn, **b**: R^3=*p*-$ClC_6H_4CH_2$,
c: R^3=*p*-$MeOC_6H_4CH_2$, **d**: R^3=$BnOCH_2$

a) For **5**, Me_2NH, 70°C, 93%. For **6**, see text. b) For **7**, RCl-NaH in DMF-THF, 0°C, 88% (for **7a**), 76% (for **7b**), 75% (for **7c**), 62% (for **7d**), or BnCl-aqNaOH, $BnBu_3NCl$ (cat.), 86% (for **7a**). For **8a**, see text. c) Vitride in THF-toluene, 0°C, 90% (for **2a**), 89% (for **2b**), 80% (for **2c**), 84% (for **2d**). d) $NaBH_4$, in EtOH, 0°C, 89% (for **9a**), 95% (for **9b**), 99% (for **9c**), 85% (for **9d**). e) H_2-Pd/C, HCl (cat.), 70% (from **9a**), 56% (from **9b**), 60% (from **9c**).

obtained was attempted at the stage of (*S*)-2-benzyloxy-1-propanol (**9a**). Thus, treatment of **2a** with sodium borohydride followed by acylation of **9a** with (*R*)- and (*S*)-2-methoxy-3,3,3-trifluoro-2-phenylpropionyl chloride (MTPACl),[8] yielded the (*R*)- and (*S*)-MTPA esters of **9a**, respectively. As the ^1H NMR spectrum of the (*R*)-MTPA ester showed no signals corresponding to those of the (*S*)-MTPA ester, it appeared obvious that **2a** could be produced without racemization.

Taking into account the reagents required for converting **3** into **2a**, the explored synthetic route is undoubtedly more economical than the previous method and can be readily applied to a large scale preparation of **2a**.

In order to extend the developed synthetic scheme to general preparation method of various types of (*S*)-2-alkoxypropanals (**2**) whose protective groups could be introduced under basic conditions, syntheses of **2b—d** were next examined. Thus, alkylation of **5** with *p*-methoxybenzyl chloride, *p*-chlorobenzyl chloride, or benzyloxymethyl chloride,[9] followed by reduction of the *O*-alkyl derivatives (**7b—d**) with Vitride®, smoothly produced **2b—d** in a similar manner to that described for the preparation of **2a**. Since (*S*)-1,2-propanediol (**10**) obtained from **2b**,c by sequential reduction with sodium borohydride and hydrogenolysis exhibited the same optical rotation values as that of **10** independently synthesized from **9a**, it appeared obvious that **2b**,c could be prepared without racemization similarly to **2a**.[10]

As mentioned above, we have succeeded in developing an efficient synthetic method of **2a** required for the synthesis of the carbapenem key intermediate and in extending the explored synthetic scheme to general preparation method of (*S*)-2-alkoxypropanals such as

2b—d.[11] Throughout these studies, **5** was solely used as the substrate for protection of the alcoholic functionality. However, it can be readily realized that (*S*)-*N*,*N*-tetramethylenelactamide (**6**) accessible from **3** and pyrrolidine can be utilized similarly to **5**. The successful preparation of **2a** from **6** by way of the *O*-benzyl derivative (**8a**) has already been briefly mentioned in the separate paper reporting an efficient synthesis of the carbapenem key intermediates.[1b]

Experimental

(*S*)-*N*,*N*-Dimethyllactamide (5). Anhyd dimethylamine (18.0 g, 0.400 mol) was added to **3** (39.6 g, 0.335 mol) in a sealed tube at 0 °C. The mixture was stirred in a sealed tube at 70 °C for 1 d and excess dimethylamine and resulting ethanol were removed in vacuo to afford an oily residue. Additional amount of anhyd dimethylamine (10.0 g, 0.222 mol) was added to the residue and the mixture was further stirred in a sealed tube at 70 °C for 1 d to complete the amidolysis. After complete removal of excess dimethylamine and resulting ethanol in vacuo, the oily residue was purified with distillation (77 °C, 1 mmHg, 1 mmHg=133.322 Pa) to afford **5** as a colorless oil (36.4 g, 93%), $[\alpha]_D^{20}$ +0.98° (*c* 2.03, $CHCl_3$). IR (neat): 3450, 3000, 2950, 1640, 1510, 1450, 1380, 1260, 1120, 1030 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.33 (3H, d *J*=6.6 Hz, Me), 2.99 (6H, s, NMe_2), 3.66 (1H, bs OH), 4.46 (1H, dq, *J*=6.6 Hz, CH). MS *m/z*: 117 $(M)^+$, 73 $(M-NMe_2)^+$.

(*S*)-*N*,*N*-Dimethyl-2-benzyloxypropionamide (7a). a) Preparation with Sodium Hydride and Benzyl Chloride. A solution of **5** (8.12 g, 69.3 mmol) in THF (10 ml) was added slowly to a suspension of sodium hydride (2.00 g, 83.3 mmol) in THF (50 ml) and DMF (36 ml) at 0 °C with vigorous stirring. After stirring for 2 h, the mixture was diluted with THF (15 ml) and DMF (8 ml) and stirred vigorously for additional 6.5 h. Benzyl chloride (8.80 ml, 76.5 mmol) was added to the mixture at 0 °C, and stirring was continued at the same temperature overnight. The resulting mixture was diluted with H_2O (50 ml) and extracted with AcOEt. The combined extracts were washed with satd aq NaCl and dried over anhyd $MgSO_4$. After filtration and concentration in vacuo, the residue was purified with distillation (140 °C, 1 mmHg) to give **7a** as a colorless oil (11.3 g, 88%), $[\alpha]_D^{20}$ −51.5° (*c* 2.90, $CHCl_3$). IR (neat): 3500, 3000, 2950, 1660, 1500, 1458, 1402, 1260, 1118, 700 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.42 (3H, d, *J*=6.6 Hz Me), 2.95, 3.03 (6H, two s, NMe_2), 4.34 (1H, q, *J*=6.7 Hz. CH), 4.40, 4.60 (2H, two d, *J*=each 11.7 Hz, $\underline{CH_2}Ph$), 7.32 (5H, s, Ph), MS *m/z*: 208 $(M+1)^+$, 135 $(M-\overline{CO}NMe_2)^+$.

b) Preparation with Sodium Hydroxide and Benzyl Chloride in the Presence of a Phase-Transfer Catalyst. Benzyltributylammonium chloride (0.156 g, 0.500 mmol), benzyl chloride (1.52 g, 12.0 mmol), and aq NaOH (50%, 2.80 g, 35.0 mmol) were successively added to a solution of **5** (1.17 g, 10.0 mmol) in CH_2Cl_2 (5.0 ml) at rt. After being vigorously stirred for 12 h, the mixture was diluted with CH_2Cl_2 (10 ml) and H_2O (5 ml). The aqueous layer was separated and the organic layer was washed successively with 1 mol dm^{-3} HCl, and satd aq NaCl, then dried over anhyd $MgSO_4$. After filtration and concentration in vacuo, the residue was purified with column chromatography (SiO_2, hexane–AcOEt 2:3) to give **7a** as a colorless oil (1.78 g, 86%). The ^1H NMR spectrum of this sample were identical with those of **7a** obtained in a).

(*S*)-*N*,*N*-Dimethyl-2-(*p*-chlorobenzyloxy)propionamide (7b). Treatments of **5** (0.828 g, 7.06 mmol) with *p*-chlorobenzyl chloride (1.37 g, 8.51 mmol) under the same conditions as described for the procedure a) of the preparation of **7a** from **5**, gave **7b** as a colorless oil (1.30 g, 76%) after purification with column chromatography (SiO_2, hexane–AcOEt 3:7). $[\alpha]_D^{20}$ −47.2° (*c* 2.05, $CHCl_3$). IR (neat): 3500, 3000, 2950, 1655, 1498, 1400, 1105, 1018, 810 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.43 (3H, d, *J*=6.8 Hz, Me), 2.96, 3.01 (6H, two s, NMe_2), 4.34 (1H, q, *J*=6.9 Hz, CH), 4.35, 4.56 (2H, two d, *J*=each 11.7 Hz, $\underline{CH_2}Ar$), 7.29 (4H, s, C_6H_4). MS *m/z*: 242 $(M+1)^+$, 125 $(CH_2C_6H_4Cl)^+$.

(*S*)-*N*,*N*-Dimethyl-2-(*p*-methoxybenzyloxy)propionamide (7c). (*S*)-*N*,*N*-Dimethyllactamide (**5**) (0.828 g, 7.06 mmol) was treated with *p*-methoxybenzyl chloride (1.37 g, 8.51 mmol) under the same conditions as described for the procedure a) of the preparation of **7a** from **5**, afforded **7c** as a colorless oil (1.17 g, 75%) after purification with column chromatography (SiO_2, hexane–AcOEt 1:1). $[\alpha]_D^{20}$ −55.6° (*c* 2.03, $CHCl_3$). IR (neat): 3550, 2950, 1650, 1242, 1100, 1030, 820 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.41 (3H, d, *J*=6.8 Hz, Me), 2.95, 3.05 (6H, two s, NMe_2), 3.80 (3H, s, OMe), 4.32 (1H, q, *J*=6.8 Hz, CH), 4.34, 4.53 (2H, two d, *J*=each 10.6 Hz, $\underline{CH_2}Ar$), 6.85, 7.26 (4H, two d, *J*=8.8 Hz, C_6H_4). MS *m/z*: 238 $(M+1)^+$, 198 $(M-NMe_2)^+$, 121.

(*S*)-*N*,*N*-Dimethyl-2-(benzyloxymethoxy)propionamide (7d). Treatments of **5** (0.847 g, 7.23 mmol) with benzyloxymethyl chloride (1.21 ml, 8.70 mmol) under the same conditions as described for the procedure a) of the preparation of **7a** from **5**, gave **7d** as a colorless oil (1.07 g, 62%) after purification with column chromatography (SiO_2, hexane–AcOEt 3:2). $[\alpha]_D^{20}$ −64.4° (*c* 2.62, $CHCl_3$). IR (neat): 3550, 3120, 3000, 1665, 1518, 1462, 1418, 1120, 1050, 760, 718 cm^{-1}. ^1H NMR ($CDCl_3$): 1.40 (3H, d, *J*=6.8 Hz, Me), 2.94, 3.04 (6H, two s, NMe_2), 4.61 (1H, q, *J*=6.8 Hz, CH), 4.63 (2H, s, OCH_2O), 4.74, 4.84 (2H, two d, *J*=each 7.8 Hz, $\underline{CH_2}Ph$), 6.85, 7.26 (4H, two d, *J*=8.8 Hz, C_6H_4). MS *m/z*: 238 $(M+1)^+$, 198 $(M-NMe_2)^+$, 121.

(*S*)-2-Benzyloxypropanal (2a). General procedure for the reduction with Vitride®. A 1.07 mol dm^{-3} solution of Vitride® in a mixture of toluene and THF (1.60 ml, 3.20 mmol) was added slowly to a solution of **7a** (1.12 g, 5.39 mmol) in THF (15 ml) at 0 °C. After stirring at the same temperature for 2.5 h, the reaction mixture was poured into 1 mol dm^{-3} HCl (15 ml) cooled in an ice bath and extracted with CH_2Cl_2. The combined extracts were washed successively with 0.3 mol dm^{-3} HCl, satd aq NaCl, satd aq $NaHCO_3$, and satd aq NaCl, then dried over anhyd $MgSO_4$. Filtration and concentration in vacuo gave a residue which was purified with bulb-to-bulb distillation (100 °C, 1 mmHg) to give **2a** as a colorless oil (0.800 g, 90%). IR (neat): 3470, 3058, 3000, 2950, 1740, 1500, 1456, 1380, 1210, 1100, 741, 702 cm^{-1}. ^1H NMR ($CDCl_3$): 1.32 (3H, d, *J*=6.8 Hz,Me), 3.88 (1H, dq, *J*=1.8, 6.8 Hz, Me$\underline{CH}$), 4.62 (2H, s, $\underline{CH_2}Ph$), 7.35 (5H, s, Ph), 9.66 (1H, d *J*=1.8 Hz,CHO). MS *m/z*: 181 $(M+OH)^+$, 135 $(M-CHO)^+$.

(*S*)-(*p*-Chlorobenzyloxy)propanal (2b). Reduction of **7b** (0.800 g, 3.31 mmol) performed in a similar manner to that described for the preparation of **2a**, gave **2b** as a colorless oil (0.586 g, 89%) after purification with column chromatography (SiO_2, hexane–AcOEt 97:3). IR (neat): 2990, 2860, 1738, 1490, 1082, 1010, 802 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.34 (3H, d, *J*=7.0 Hz, Me), 3.88 (1H, dq, *J*=1.7, 7.0 Hz, CH), 4.51, 4.65 (2H, two d, *J*=each 11.9 Hz, $\underline{CH_2}Ar$), 7.31 (4H, s, C_6H_4), 9.66 (1H, d, *J*=1.5 Hz, CHO). MS *m/z*: 169 $(M-CHO)^+$, 125 $(CH_2C_6H_4Cl)^+$.

(*S*)-(*p*-Methoxybenzyloxy)propanal (2c). Treatment of **7c** (0.427 g, 1.80 mmol) under the conditions similar to those described for the reduction of **7a** afforded **2c** as a colorless oil (0.278 g, 80%) after purification with column chromatography (SiO_2, hexane–AcOEt 24:1). IR (neat): 2950, 2850, 1728, 1610, 1518, 1250, 1030, 820 cm^{-1}. ^1H NMR ($CDCl_3$): δ= 1.30 (3H, d, *J*=7.0 Hz,Me), 3.80 (3H, s, MeO), 3.90 (1H, dq, *J*=1.8, 7.0 Hz, CH), 4.55 (2H, s, $\underline{CH_2}Ar$), 6.88, 7.29 (4H, two

d, J=8.8 Hz, C_6H_4), 9.62 (1H, d, J=1.8 Hz, CHO). MS m/z: 194 $(M)^+$, 121 $(M-CH_2C_6H_4OMe)^+$.

(*S*)-(Benzyloxymethoxy)propanal (2d). Reduction of **7d** (0.724 g, 3.05 mmol) carried out in a similar manner to that described for the preparation of **2a**, gave **2d** as a colorless oil (0.500 g, 84%) after purification with column chromatography (SiO_2, hexane–AcOEt 24:1—4:1). IR (neat): 3050, 2900, 1738, 1450, 1380, 1040, 740, 700 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.32 (3H, d, J=6.8 Hz, Me), 4.10 (1H, dq, J=1.5, 6.8 Hz, CH), 4.67 (2H, s, OCH_2O), 4.86 (2H, s, $\underline{CH_2}Ph$), 7.33 (5H, s, Ph), 9.64 (1H, d, J=1.5 Hz, CHO). MS m/z: 165 $(M-CHO)^+$.

(*S*)-2-Benzyloxy-2-propanol (9a). General procedure for the reduction with sodium borohydride. Sodium borohydride (0.166 g, 4.39 mmol) was added to a solution of **2a** (0.282 g, 1.72 mmol) in EtOH (2 ml) at 0 °C. After stirring for 2 h at the same temperature, the mixture was diluted with 1 mol dm^{-3} HCl to decompose the excess reducing agent and extracted with AcOEt. The combined extracts were washed successively with satd aq NaCl, satd aq $NaHCO_3$ and satd aq NaCl, then dried over anhyd $MgSO_4$. Filtration and concentration in vacuo gave an oily residue which was purified with column chromatography (SiO_2, hexane–AcOEt 4:1) to give **9a** as a colorless oil (0.272 g, 95%), $[\alpha]_D^{20}$ +44.7° (c 3.47, $CHCl_3$) [lit,[2b] $[\alpha]_D^{25}$ +43.1° (c 3, $CHCl_3$) lit,[2c] $[\alpha]_D$ +45.86° (c 6.4, $CHCl_3$)]. IR (neat): 3450, 3050, 2970, 2940, 2870, 1950, 1880, 1818, 1500, 1450, 1050, 700 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.15 (3H, d, J=6.0 Hz, Me), 2.41 (1H, bs, OH), 3.51—3.65 (3H, m, $CHCH_2O$), 4.44, 4.63 (2H, two d, J=each 11.7 Hz, $\underline{CH_2}Ph$), 7.31 (5H, bs, Ph). MS m/z: 166 $(M)^+$, 91, 65. The optical purity of this sample was determined by comparing the ^1H NMR spectra of its (*R*)- and (*S*)-MTPA esters prepared according to the method reported by Mosher et al.[8] The (*R*)- and (*S*)-MTPA esters of **9a** were obtained in 72% and 66% yields, respectively. The (*R*)-MTPA ester of **9a**: $[\alpha]_D^{20}$ +45.7° (c 1.35, $CHCl_3$). IR (neat): 3000, 2950, 1745, 1445, 1270, 1240, 1162, 1020, 700 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.21 (3H, d, J=6.4 Hz, Me), 3.54 (3H, dd, J=1.3, 2.4 Hz, MeO), 3.78—3.90 (1H, m, CH), 4.29—4.39 (2H, m, $CH\underline{CH_2}O$), 4.52 (2H, s, $\underline{CH_2}Ph$), 7.23—7.62 (10H, m, Ph×2). MS m/z: 382 $(M)^+$, 244. The (*S*)-MTPA esters of **9a**: $[\alpha]_D^{20}$ −32.7° (c 2.24, $CHCl_3$). IR (neat): 3000, 2950, 1742, 1442, 1270, 1240, 1160, 1020, 695 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.20 (3H, d, J=6.4 Hz, Me), 3.53 (3H, dd, J=1.2, 2.3 Hz, MeO), 3.77—3.90 (1H, m, CH), 4.33 (2H, d, J=5.7 Hz, $CH\underline{CH_2}O$), 4.51 (2H, s, $\underline{CH_2}Ph$), 7.22—7.61 (10H, m, Ph×2). MS m/z: 382 $(M)^+$, 244. The ^1H NMR spectrum of the (*R*)-MTPA ester showed no signals corresponding to the (*S*)-MTPA ester. Accordingly, it appeared obvious that **2a** could be prepared from **3** without racemization.

(*S*)-2-(*p*-Chlorobenzyloxy)-1-propanol (9b). Reduction of **2b** (0.408 g, 2.05 mmol) performed as described for the preparation of **9a** from **2a**, gave **9b** as a colorless oil (0.390 g, 95%) after purification with column chromatography. $[\alpha]_D^{20}$ +36.8° (c 1.72, $CHCl_3$). IR (neat): 3450, 2950, 1918, 1610, 1500, 1100, 890 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.17 (3H, d, J=6.2 Hz, Me), 2.00 (1H, bs, OH), 3.48—3.73 (3H, m, $CHCH_2O$), 4.44, 4.63 (2H, two d, J=each 11.8 Hz, $\underline{CH_2}Ar$), 7.31 (4H, bs, C_6H_4). MS m/z: 200 $(M)^+$, 125 $(CH_2C_6H_4Cl)^+$.

(*S*)-2-(*p*-Methoxybenzyloxy)-1-propanol (9c). Treatments of **2c** (0.216 g, 1.11 mmol) under the same conditions as described for the preparation of **9a** from **2a**, gave **9c** as a colorless oil (0.217 g, 99%) after purification with column chromatography. $[\alpha]_D^{20}$ +41.2° (c 4.10, $CHCl_3$). IR (neat): 3450, 2950, 1610, 1510, 1242, 1030, 820 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.15 (3H, d, J=5.2 Hz, Me), 2.20 (1H, br, OH), 3.44—3.74 (3H, m, $CHCH_2O$), 3.79 (3H, s, OMe), 4.38, 4.52 (2H, two d, J=each 11.2 Hz $\underline{CH_2}Ar$), 6.87, 7.26 (4H, two d, J=8.6 Hz, C_6H_4). MS m/z: 196 $(M)^+$, 152, 137.

(*S*)-2-(*p*-Benzyloxymethoxy)-1-propanol (9d). Reduction of **2d** (0.431 g, 2.17 mmol) under the same conditions described for the preparation of **9a** from **2a**, afforded **9d** as a colorless oil (0.361 g, 85%) after purification with column chromatography. $[\alpha]_D^{20}$ +51.8° (c 1.51, $CHCl_3$). IR (neat): 3460, 2950, 2900, 1458, 1380, 1040, 700 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.18 (3H, d, J=6.4 Hz, Me), 2.61 (1H, bs, OH), 3.53 (2H, m, $\underline{CH_2}OH$), 3.86 (1H, m, CH), 4.65 (2H, s, OCH_2O), 4.85 (2H, s, $\underline{CH_2}Ph$), 7.34 (5H, s, Ph). MS m/z: 181 $(M-Me)^+$, 165 $(M-CH_2OH)^+$.

(*S*)-1,2-Propanediol (10). Palladium on carbon (10%, 25.8 mg) and one drop of 5 mol dm^{-3} solution of HCl in EtOH were added to a solution of **9a** (0.204 g, 1.23 mmol) in EtOH (3 ml) and the mixture was stirred under a hydrogen atmosphere for 1 h. The catalyst was filtered off and the filtrate was concentrated in vacuo. The concentration residue was purified with bulb-to-bulb distillation (110 °C, 18 mmHg) to give **10** as a colorless oil (65.0 mg, 70%). By the same procedure as described above, **9b, c** could be derived to **10** (56% from **9b** and 60% from **9c**). $[\alpha]_D^{20}$ +27.4° (c 3.00, $CHCl_3$) (from **9a**), $[\alpha]_D^{20}$ +27.5° (c 2.38, $CHCl_3$) (from **9b**), $[\alpha]_D^{20}$ +28.0° (c 2.31, $CHCl_3$) (from **9c**), [lit,[12] $[\alpha]_D^{24.2}$ +30.0° (c 3.00, $CHCl_3$)]. These specific rotation values clearly confirmed that no racemization had taken place during the preparation of **2b,c** from **3**. IR (neat): 3400, 3000, 2950, 1650, 1140, 1040, 840 cm^{-1}. ^1H NMR ($CDCl_3$): δ=1.15 (3H, d, J=6.4 Hz, Me), 3.10 (2H, bs, OH×2), 3.38—3.99 (3H, m, $\underline{CHCH_2}O$). MS m/z: 61 $(M-Me)^+$, 59 $(M-OH)^+$.

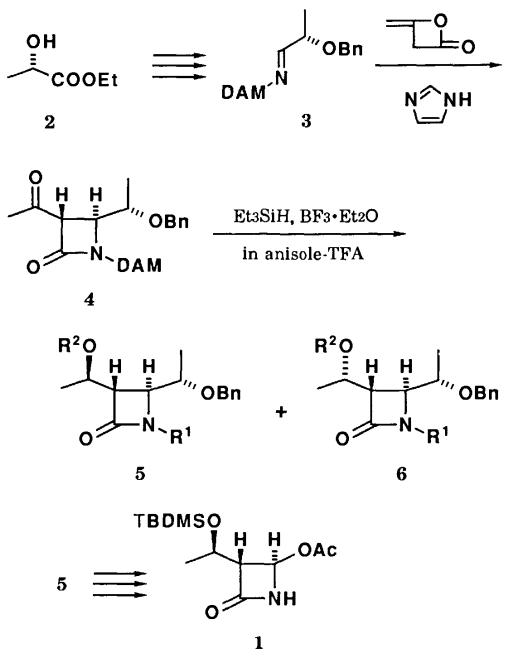
A Novel Use of the Ionic Hydrosilation in the Synthesis of Carbapenem Key Intermediate

Yuko KOBAYASHI, Yoshio ITO, and Shiro TERASHIMA*
Sagami Chemical Research Center, Nishi-Ohnuma, Sagamihara, Kanagawa 229
(Received May 18, 1989)

Synopsis. The ionic hydrosilation of the 3-acetyl-2-azetidinone derivative in the presence of boron trifluoride etherate was found to effect highly stereoselective reduction of the acetyl group (at most, 17:1), giving rise to the desired 3-[(*R*)-1-hydroxyethyl]-2-azetidinone derivative as a major product. Simultaneous reductive removal of the bis(*p*-methoxyphenyl)methyl group was also observed depending upon the reaction conditions.

We have recently succeeded in exploring an efficient synthetic route to the important carbapenem key intermediate (**1**) starting from commercially available and inexpensive ethyl (*S*)-lactate (**2**).[1] Thus, the 3-acetyl-2-azetidinone derivative (**4**) bearing the desired absolute stereochemistry could be produced stereoselectively by the [2+2]-cycloaddition of the chiral imine (**3**) derived from **2** with diketene. Subsequent reduction of **4** with K-selectride® or potassium triethylhydroborate according to the reported procedures,[2] afforded the 3-[(*R*)-1-hydroxyethyl]-2-azetidinone (**5a**) in a highly stereoselective manner, from which **1** could be readily elaborated by way of the *N*-unprotected 2-azetidinone and the 3-[(*R*)-1-(*t*-butyldimethylsilyloxy)ethyl]-2-azetidinone derivatives (**5b** and **5c**).

Since a number of the methods which may effect stereoselective reduction of **4** to **5a** are limited[3,4] and the reducing agents so far examined by us seem to be fairly expensive, another efficient reduction method was sought which can produce **5a** from **4** highly stereoselectively. After numerous experimentations surveying various reducing agents, we found that the ionic hydrosilation[5] of **4** underwent in a highly stereoselective manner, affording a good yield of **5a** or **5b** depending upon the reaction conditions.



DAM=(*p*-MeOC$_6$H$_4$)$_2$CH

a: R^1=DAM, R^2=H, b: R^1=R^2=H, c: R^1=H, R^2=TBDMS

Thus, when **4** was treated with triethylsilane in a mixture of trifluoroacetic acid (TFA) and anisole in the presence of a catalytic amount of boron trifluoride etherate ($BF_3 \cdot Et_2O$) (0.08 equivalent to the amount of triethylsilane used) at −10 °C, a mixture of **5a** and the 3-[(*S*)-1-hydroxyethyl]-2-azetidinone (**6a**) could be obtained in 71% combined yield along with a small amount of the mixture of **5b** and **6b** (10% combined yield). The formation ratio of **5a** to **6a** was determined as 8:1 by comparing the ^{1}H NMR spectrum of the mixture with those of authentic samples of **5a** and **6a**.[1] On the other hand, treatment of **4** with a mixture of TFA and anisole in the presence of $BF_3 \cdot Et_2O$ (0.35 equivalent to the amount of triethylsilane used) at 0 °C was found to effect simultaneous stereoselective reduction of the acetyl group and reductive removal of the bis(*p*-methoxyphenyl)methyl (DAM) group, giving rise to a mixture of **5b** and **6b** in 64% combined yield. The latter hydrosilation conditions is anticipated to be more severe than the former. The ratio of **5b** and **6b** could be determined as 17:1 by the ^{1}H NMR spectrum after conversion to a mixture of the *t*-butyldimethylsilyl (TBDMS) ethers (**5c** and **6c**). Independent syntheses of **6b**,**c** from **6a** which had already been converted to **5a** by the Mitsunobu reaction,[1] could rigorously establish the stereochemistries of **6b**,**c**.

In these ionic hydrosilation reactions, TFA and $BF_3 \cdot Et_2O$ were found to be essential. Thus, complex mixtures of the decomposition products were always produced in the absence of $BF_3 \cdot Et_2O$ probably due to slowdown of the reaction rate. Uses of other Lewis acids such as boron tribromide or titanium tetrachloride in place of $BF_3 \cdot Et_2O$ were shown to be unrewarding, giving rise to complex decomposition products. Additionally, the ionic hydrosilation reactions attempted using trichloroacetic acid or acetic acid as a protic acid in place of TFA resulted in simple recovery of **4**.

Thus, it appeared that the ionic hydrosilation holds promise as an effective method for reducing the acetyl group of **4** to the (*R*)-1-hydroxyethyl group in a highly stereoselective manner and affords a good yield of **5a** or **5b** depending upon the reaction conditions.[6] Furthermore, direct synthesis of **5b** from **4** may have high practical value since the DAM group of **5a** is removable only by oxidation with fairly expensive

cerium(IV) ammonium nitrate (CAN).

Experimental

General. All melting points were determined with a Yamato MP-21 melting point apparatus and were uncorrected. Measurements of optical rotaions were performed with a Horiba SEPA-200 automatic digital polarimeter. IR spectral measurements were carried out with a JASCO A-202 diffraction grating infrared spectrometer. ^{1}H NMR spectra were recorded with a Hitachi R-90H (90 MHz) and a Bruker AM spectrometer (400 MHz). All signals were expressed as ppm downfield from tetramethylsilane used as an internal standard (δ-value). Wakogel C-200 and C-300 kieselgel 60 were used as an adsorbent for column chromatography.

(3*S*,4*S*)-4-[(*S*)-1-Benzyloxyethyl]-1-[bis(*p*-methoxyphenyl)-methyl]-3-[(*R*)-1-hydroxyethyl]-2-azetidinone and Its 3-[(*S*)-1-Hydroxyethyl] Isomer (5a and 6a). Trifluoroacetic acid (0.640 ml, 8.31 mmol) and $BF_3 \cdot Et_2O$ (6.0 µl, 0.049 mmol) were added to a mixture of **4** (98.1 mg, 0.207 mmol), anisole (68.0 µl, 0.626 mmol), and triethylsilane (0.100 ml, 0.626 mmol) at −10 °C. After stirring at −25 °C for 1.5 h, the mixture was concentrated in vacuo and the concentration residue was diluted with aqueous NaOH and ether. The organic layer was separated and washed successively with 1 mol dm^{-3} HCl and saturated aqueous NaCl, then dried over anhydrous $MgSO_4$. Filtration and concentration in vacuo gave an oily residue, which was purified with column chromatography (SiO_2, CH_2Cl_2–AcOEt 1:0—2:1) to give a mixture of **5a** and **6a** (69.6 mg, 71%) from the less polar fraction. The ratio of **5a** to **6a** could be calculated as 8:1 by comparing the ^{1}H NMR spectrum of the mixture with those of authentic samples of **5a** and **6a**.[1)] A mixture of **5b** and **6b** (4.9 mg, 10%) was also isolated as the minor products from the more polar fraction. Comparison of the ^{1}H NMR spectrum of the mixture with those of pure samples of **5b** and **6b** (vide infra) obviously established the structures of the products (**5b** and **6b**).

(3*S*,4*S*)-4-[(*S*)-1-Benzyloxyethyl]-3-[(*R*)-1-hydroxyethyl]-2-azetidinone and Its 3-[(*S*)-1-Hydroxyethyl] Isomer (5b and 6b). Trifluoroacetic acid (0.690 ml) and $BF_3 \cdot Et_2O$ (25.0 µl, 0.203 mmol) were added to a mixture of **4** (0.106 g, 0.223 mmol), anisole (73.0 µl, 0.672 mmol), and triethylsilane (0.107 ml, 0.670 mmol) at 0 °C. After stirring at the same temperature overnight, the mixture was concentrated in vacuo and the residue was diluted with saturated aqueous $NaHCO_3$ and AcOEt. The organic layer was separated, washed successively with 1 mol dm^{-3} HCl and saturated aqueous NaCl, then dried over anhydrous $MgSO_4$. Filtration and concentration in vacuo gave an oily residue, which was purified with column chromatography (SiO_2, CH_2Cl_2–AcOEt 2:1) to give a mixture of **5b** and **6b** (35.5 mg, 64%). The stereochemistries of the reduction products were determined by converting the mixture of **5b** and **6b** to that of **5c** and **6c** in 84% yield under the same conditions as described for silylation of a pure sample of **6b** with *t*-butylchlorodimethylsilane. As **5c** had been obtained from **5a** by way of **5b**,[1)] an authentic sample of **6c** was prepared by silylation of a pure sample of **6b** (vide infra). The ratio of **5b** to **6b** could be calculated as 17:1 by the integration ratio of C_3-H in the ^{1}H NMR spectrum of the mixture (vide infra). A single recrystallization of the mixture of **5b** and **6b** from hexane–AcOEt readily afforded a pure sample of **5b**, mp 130.5 °C and $[\alpha]_D^{25}$+66.2° (*c* 1.24, $CHCl_3$) [lit,[1b)] mp 129—130 °C and $[\alpha]_D^{25}$+61.5° (*c* 1.45, $CHCl_3$)]. IR and ^{1}H NMR spectrum of this sample were also identical with those reported.[1b)] An authentic sample of **6b** was prepared by oxidation of **6a** with cerium(IV) ammonium nitrate (vide infra).

(3*S*,4*S*)-4-[(*S*)-1-Benzyloxyethyl]-3-[(*S*)-1-hydroxyethyl]-2-azetidinone (6b). Cerium(IV) ammonium nitrate (0.122 g, 0.222 mmol) was added to a solution of an authentic sample of **6a**[1)] (32.1 mg, 0.0675 mmol) in H_2O–MeCN (1:9) (0.2 ml) at −10 °C. The mixture was stirred vigorously at the same temperature for 2 h, then diluted with 1 mol dm^{-3} NaOH (0.45 ml). After stirring at rt for 1 h, the mixture was extracted with AcOEt. The combined organic extracts were washed with saturated aqueous NaCl, dried over anhydrous $MgSO_4$, filtered, and concentrated in vacuo. The concentration residue was purified with column chromatography (SiO_2, hexane–AcOEt 2:3) to give **6b** (9.9 mg, 60%). ^{1}H NMR ($CDCl_3$): 1.22 (3H, d, *J*=5.7 Hz, MeCHOBn), 1.31 (3H, d, *J*=6.4 Hz, MeCHOH), 2.2—2.4 (1H, br, OH), 2.84 (1H, m, C_3-H), 3.4—3.5 (2H, m, CHOBn and C_4-H), 4.07 (1H, m, CHOH), 4.41, 4.68 (2H, two d, *J*=11.9 Hz, PhCH$_2$), 6.20 (1H, bs, NH), 7.32 (5H, s, C_6H_5). This sample was used as an authentic sample of **6b** (vide supra).

(3*S*,4*S*)-4-[(*S*)-1-Benzyloxyethyl]-3-[(*S*)-1-(*t*-butyldimethylsilyloxy)ethyl]-2-azetidinone (6c). Imidazole (10.0 mg, 0.147 mmol) and *t*-butylchlorodimethylsilane (15.0 mg, 0.0995 mmol) were added to a solution of an authentic sample of **6b** (5.5 mg, 0.022 mmol) in DMF (0.1 ml). After stirring for 1 h, the mixture was diluted with H_2O and extracted with ether. The combined extracts were washed with saturated aqueous NaCl and dried over anhydrous $MgSO_4$. Filtration and concentration in vacuo gave a residue, which was purified with column chromatography (SiO_2, CH_2Cl_2) to give **6c** (7.8 mg, 98%). ^{1}H NMR ($CDCl_3$): 0.07 (6H, s, Me_2Si), 0.88 (9H, s, Me_3CSi), 1.22 (3H, d, *J*=6.2 Hz, MeCHOBn), 1.29 (3H, d, *J*=6.4 Hz, MeCHOSi), 2.88 (1H, m, C_3-H), 3.50 (2H, m, CHOBn and C_4-H), 4.17 (1H, m, CHOSi), 4.40, 4.67 (2H, two d, *J*=11.7 Hz, PhCH$_2$), 6.00 (1H, bs, NH), 7.32 (5H, s, C_6H_5). This was used as an authentic sample of **6c** (vide supra).

A Facile Preparation of 7-(Substituted amino)-6*H*-pyrrolo[3,4-*d*]-pyrimidine Derivatives[1)]

Michihiko NOGUCHI,* Yasutoshi KIRIKI, and Shoji KAJIGAESHI
Department of Industrial Chemistry, Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube 755
(Received May 15, 1989)

Synopsis. 6-Phenyl-7-(substituted amino)-6*H*-pyrrolo[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-diones **3** were obtained by the reaction of 5-formyl-1,3-dimethyl-6-[(substituted amino)-methyl]-2,4(1*H*,3*H*)-pyrimidinediones (**1**) with aniline (**2a**).

Recently, we reported a one-pot preparation of 6,7-dihydropyrido[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-dione derivatives (**D**) from the reaction of 5-formyl-1,3,6-trimethyl-2,4(1*H*,3*H*)-pyrimidinedione (**A**) with primary amines.[2)] The cycloaddition reaction of 5,6-dihydro-5,6-bis(methylene)-2,4(1*H*,3*H*)-pyrimidinedione **B**, generated via 1,5-hydrogen shift of **A**, and aldimines from **A** and amines yielding 5,6,7,8-tetrahydropyrido[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-dione **C** was the key step in this pyridopyrimidine synthesis.

In the continuation of the investigations on the preparation of fused pyrimidines, we wish to describe here a facile preparation of 7-(substituted amino)-6*H*-pyrrolo[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-dione derivatives from the reaction of 5-formyl-1,3-dimethyl-6-[(substituted amino)methyl]-2,4(1*H*,3*H*)-pyrimidinedione with primary amines.

Results and Discussion

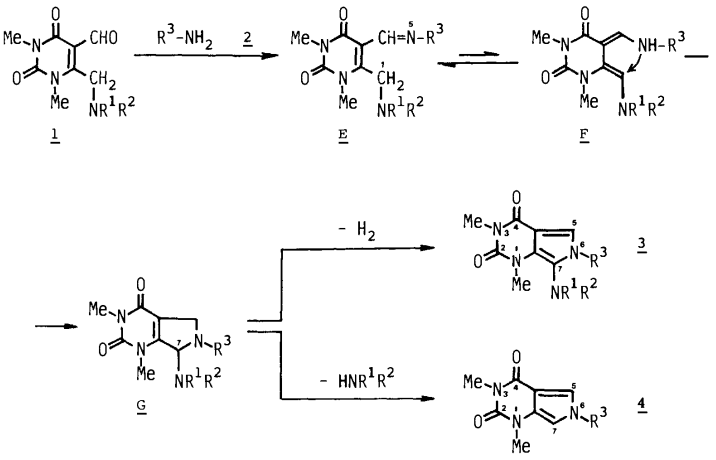
The reaction of 5-formyl-1,3-dimethyl-6-(morpholinomethyl)-2,4(1*H*,3*H*)-pyrimidinedione (**1a**) with aniline (**2a**) in benzene under reflux afforded 1,3-dimethyl-7-morpholino-6-phenyl-6*H*-pyrrolo[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-dione (**3a**) in 59% yield. The reaction of other 5-formyl-6-[(substituted amino)methyl]-2,4(1*H*,3*H*)-pyrimidinediones (**1**) with aniline (**2a**) was also examined. The reaction patterns depended on the kind of the substituted amino groups; the reaction of 6-[(1-pyrrolidinyl)methyl]- (**1b**) afforded only **3b**, the same type product as **3a**, while the reaction of 6-[(diethylamino)methyl]- (**1c**) and 6-[(*N*-methylanilino)methyl]- (**1d**) afforded 1,3-dimethyl-6-phenyl-6*H*-pyrrolo[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-dione (**4**)[3)] as a major product together with the corresponding 7-(substituted amino) derivatives **3c** and **3d**, respectively.

The structural elucidation of pyrrolopyrimidines **3** was accomplished on the basis of their spectral data comparing with those of **4**.

A pathway for these pyrrolopyrimidines **3** and **4** can be explained by the analogy to that for pyrido[3,4-*d*]pyrimidines **C** from **A** and primary amines. The 1,5-hydrogen shift of the aldimine **E** from **1** and aniline (**2a**) affords a 5-anilinomethylene-5,6-dihydro-6-[(substituted amino)methylene]-2,4(1*H*,3*H*)-pyrimidinedione intermediate (**F**). The 1,5-cyclization of **F** leads to a 6,7-dihydro-5*H*-pyrrolo[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-dione (**G**). The dehydrogenation of **G** gives the 7-(substituted amino) derivatives **3**, while the deamination of **G** gives pyrrolopyrimidine **4**.

The above pathway for the formation of **G** is related to that for 6-tosylamino-6*H*-pyrrolo[3,4-*d*]pyrimidine synthesis by the reaction of 1,2,3,4-tetrahydro-6-bromomethyl-1,3-dimethyl-2,4-dioxo-5-pyrimidinecarbaldehyde tosylhydrazone with triethylamine, in which the 1,5-cyclization of 1-azapentadienyl anion was proposed.[3)] The dehydrogenation of **G** leading to **3** is much of interest, because another process, the deamination leading to **4**, seems to be a favorable one. Although a plausible explanation for the results is not found yet, we suggest that the substituted amino group at the 7-position might stabilize the 6*H*-pyrrolo[3,4-*d*]pyrimidine system.

In order to survey the usefulness of this method, the



Scheme 1.

a) In dry benzene under reflux for 2 d. b) Based on isolated products.

reaction of **1a** with arylamines and benzylamine were examined. In these reaction the 7-(substituted amino)-6*H*-pyrrolo[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-diones **3e—j** were obtained in good to fair yields. These results are summarized in Table 1.

Although much attention has been focused on the pharmacological potentialities of pyrrolo[3,4-*d*]pyrimidine derivatives, few reports on their preparation were found.[3-5] We believe that our method based on the 1,5-cyclization of 5-anilinomethylene-5,6-dihydro-6-[(substituted amino)methylene]-2,4(1*H*,3*H*)-pyrimidinediones serves as a new entry into 7-(substituted amino)-6*H*-pyrrolo[3,4-*d*]pyrimidines.

Experimental[6]

The new starting materials **1b** and **1c** were prepared from the reaction of 5-formyl-1,3-dimethyl-6-bromomethyl-2,4-(1*H*,3*H*)-pyrimidinedione and corresponding amines similarly to the reported method.[3]

5-Formyl-1,3-dimethyl-6-[(1-pyrrolidinyl)methyl]-2,4(1*H*,3*H*)-pyrimidinedione (1b): Mp 123—125 °C. Found: C, 57.42; H, 7.00; N, 16.43%. Calcd for $C_{12}H_{17}N_3O_3$: C, 57.35; H, 6.82; N, 16.72%.

6-[(Diethylamino)methyl]-5-formyl-1,3-dimethyl-2,4(1*H*,3*H*)-pyrimidinedione (1c): 73—74 °C. Found: C, 57.14; H, 7.83; N, 16.64%. Calcd for $C_{12}H_{19}N_3O_3$: C, 56.90; H, 7.56; N, 16.59%.

The Reaction of 1 with Aniline (2a). General Procedure: The solution of **1c** (1 mmol) and aniline (**2a**)(1 mmol) in dry benzene (5 mL) was heated under reflux for 2 d, and the solvent was evaporated to dryness. The residue was subjected to column chromatography on silica gel to afford 109 mg (33%) of **3c** as elution of benzene/chloroform (1/1) to chloroform and 154 mg (53%) of **4** as elution of chloroform/ethyl acetate (4/1), respectively.

1,3-Dimethyl-7-morpholino-6-phenyl-6*H*-pyrrolo[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-dione (3a): Colorless prisms (benzene-ethanol); mp 218—219 °C; IR (KBr) cm^{-1}: 1690, 1640(CO); ^1H NMR ($CDCl_3$) δ=2.8—3.0, 3.4—3.7 (4H, each, 2m, $-CH_2-$), 3.40, 3.67 (3H, each, 2s, $-CH_3$), 7.19 (3H, s, 5-H), 7.3—7.6 (8H, total, m and s, phenyl and benzene); ^{13}C NMR ($CDCl_3$) δ=27.8, 31.5, 52.8, 67.0, 104.9 (4a-C), 118.2 (5-C), 120.8 (7a-C), 123.8 (7-C), 127.7, 128.3, 129.2 (benzene), 129.4, 139.3, 152.5 (2-C), 160.0 (4-C); MS *m/z*: 340 (M^+). Found: C, 66.79; H, 6.07; N, 14.81%. Calcd for $C_{18}H_{20}N_4O_3 \cdot 1/2C_6H_6$: C, 66.47; H, 6.12; N, 14.76%.

1,3-Dimethyl-6-phenyl-7-(1-pyrrolidinyl)-6*H*-pyrrolo[3,4-*d*]pyrimidine-2,4(1*H*,3*H*)-dione (3b): Colorless plates (hexane-ethanol); mp 226—227 °C; IR (KBr) cm^{-1}: 1680, 1640 (CO); ^1H NMR ($CDCl_3$) δ=1.6—1.8, 2.9—3.1 (4H, each, 2 m, $-CH_2-$), 3.41, 3.56 (3H, each, 2s, $-CH_3$), 7.28 (1H, s, 5-H), 7.3—7.6 (5H, m, phenyl); ^{13}C NMR ($CDCl_3$) δ=26.1, 27.8, 30.3, 53.4, 104.9, (4a-C), 117.2 (5-C), 120.2 (7a-C), 121.9 (7-C), 126.3, 128.5, 129.2, 139.0, 152.6 (2-C), 160.2 (4-C); MS *m/z*: 324 (M^+). (Received May 24, 1989)

Synopsis. Chlorinative cyclization of 4-(2-benzothiazolyldithio)azetidinones into 2β-(chloromethyl)penams has been successfully performed by treatment with aqueous sodium nitrite in a two-layer solution comprising aqueous hydrochloric acid and dichloromethane layers. Similarly, the corresponding 2β-(bromomethyl)penams can be obtained by use of aqueous hydrobromic acid in place of aqueous hydrochloric acid.

The nucleophilic substitution of the chlorine atom of 2β-(chloromethyl)penams **3** (X=Cl)[1] is a promising procedure for the synthesis of various 2β-(substituted methyl)penams and 3β-substituted cephams.[1c,2] The 2β-(chloromethyl)penams **3** (X=Cl) has been prepared by a two-step operation involving thermolysis of penicillanate 1-oxides **1** with 2-mercaptobenzothiazole leading to Kamiya's disulfide **2**[1a] and subsequent chlorinative cyclization with chlorine and copper(II) chloride (Scheme 1).[1a-c] In a practical sense, however, the hitherto known methods for the latter step (**2**—**3**) suffer from inevitable disadvantages due to the contamination of overchlorination products and/or difficulties in removing copper complexes generated in the reaction. Therefore, we needed a new device for the chlorinative cyclization of 4-(2-benzothiazolyldithio)-azetidinones **2** in high product selectivities without the tedious workup process. For this purpose, we have elaborated a unique two-layer system, comprising aqueous sodium nitrite-hydrochloric acid and dichloromethane as illustrated in Scheme 2 in which the chlorinative cyclization of **2** can be performed smoothly to afford **3** (X=Cl) in satisfactory yields.

The present method is characterized by the simple operation and the high yield of the product **3** (X=Cl). Into the two-layer solution comprising a dichloromethane solution of 4-dithioazetidinones **2** (R^1=R^2=H) and aqueous 22% hydrochloric acid was added portionwise aqueous 8% sodium nitrite. After being stirred for a few hours, the organic layer was separated and worked up in a conventional manner to afford 2β-(chloromethyl)-penams **3a**—**c** (R^1=R^2=H, X=Cl) together with bis(2-benzothiazoyl) disulfide **4** in good yields, (Table 1, Entries 1—3). Undesired side products, e.g. overchlorina-

a) Carried out with 8% aqueous sodium nitrite (1.1—2 equiv) in 22% hydrochloric acid (or 10% hydrobromic acid) and dichloromethane. b) PNB: *p*-nitrobenzyl; PMB: *p*-methoxybenzyl. c) Isolated yields. d) A mixture of **3h** and **7h** (56/44) was obtained after column chromatography.

tion products or β-lactam ring-opened products were not detected in the crude products. The isolation of the product **3** from the disulfide **4** can be easily performed by a fractional recrystallization from acetone and/or methanol.

The chlorinative cyclization of various 4-dithioazetidinones derivatives **2** was similarly performed in the two layer system (Entries 4—9). 3-Bromo-, 3,3-dibromo-, and 3-(phenylacetamido)azetidinones **2d—g** were transformed to the corresponding penicillanates **3d—g** in good yields.

In addition, the two-layer system can be applied successfully to the preparation of the corresponding 2β-(bromomethyl)penams **3** (X=Br) by use of hydrobromic acid in place of hydrochloric acid. The 2β-(bromomethyl)penams **3** are very susceptible to isomerization to 3β-bromocepham **7**; indeed, upon the chromatography on a silica gel, **3h** (R^1=R^2=H, X=Br) was partly isomerized to a mixture of **3h** and **7h** (55/44). Fortunately, pure 2β-(bromomethyl)penams **3** were obtained by fractional recrystallization from acetone and/or ether immediately after the reaction.

Although the reaction mechanism has not yet been clarified, nitrosyl halide (NOX) generated in the aqueous phase seems to play a significant role; thus, in an aqueous phase, sodium nitrite would react with hydrogen halide to generate nitrosyl halide, which moves to the organic phase and reacts with 4-dithioazetidinones **2**, generating tricyclo sulfonium ion **5** and nitroso intermediate **6**. In turn, the former would produce 2β-(halomethyl)penam **3** by the attack of halide ion on the 2β-methylene carbon of **5**, while the latter would undergo disproportionation and/or further reaction with 4-dithioazetidinones **2** to give dimer **4**.

Experimental

Melting points were determined with a Thomas-Hoover capillary apparatus and are uncorrected. IR spectra were recorded on a JASCO IRA-1 grating spectrophotometer. ^{1}H NMR spectra were taken on a Hitachi R-24 (60 MHz) and a JEOL MX-100 spectrometers (100 MHz) using tetramethylsilane as an internal standard. Mass spectra were obtained on a JEOL JMS-DX303 spectrometer. Microanalyses were performed in our laboratory.

General Procedure for Synthesis of 2β-(Chloromethyl)penams (Table 1, Entries 1—7). ***p*-Nitrobenzyl 2β-(Chloromethyl)-2α-methylpenam-3α-carboxylate (3a):** To a solution of *p*-nitrobenzyl [(*R*)-4-(2-benzothiazol-2-yldithio)-2-oxo-1-azetidinyl]isopropenylacetate (**2a**) (501 mg, 1 mmol) in dichloromethane (4 ml) and 22% hydrochloric acid (4 ml) was added sodium nitrite (76 mg, 1.1 mmol) in water (1 ml) portionwise at 0 °C. The stirring was continued for 2 h at 0 °C. The precipitates bis(2-benzothiazolyl) disulfide (**4**) were filtered and washed with a small amount of dichloromethane. The filtrates and washing were combined, washed with water, aqueous sodium hydrogencarbonate, and brine, and dried (Na_2SO_4). After concentration in vacuo, the residue was taken up with a small amount of acetone and insoluble materials were filtered off. The filtrate was again concentrated in vacuo and the residue was crystallized from ether to afford **3a**[1c] (337 mg, 91%); mp 104—105 °C; IR (KBr) 1780, 1775 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.49 (s, 3H, CH_3), 3.15 (dd, *J*=2 and 16 Hz, 1H, 6-H), 3.63 (dd, *J*=4 and 16 Hz, 1H, 6-H), 3.60 (s, 2H, CH_2Cl), 5.12 (s, 1H, 3-H), 5.30 (s, 2H, OCH_2), 5.40 (dd, *J*=2 and 4 Hz, 5-H), 7.57 (d, *J*=8 Hz, 2H, aromatic H), 8.26 (d, *J*=8 Hz, 2H, aromatic H).

Efficient Reduction of 2-Haloacetophenone Derivatives to the Corresponding Halohydrins by 9,10-Dihydro-10-methylacridine in the Presence of Titanium Tetrachloride. Comparison with the Reduction in the Presence of Perchloric Acid

Seiji MOCHIZUKI, Shunichi FUKUZUMI,* and Toshio TANAKA

Synopsis. 2-Haloacetophenone derivatives are reduced by an acid-stable NADH model compound, 9,10-dihydro-10-methylacridine, in the presence of $HClO_4$ in acetonitrile at 335 K to yield 10-methylacridinium ion and the parent acetophenone derivatives as well as halohydrins, while the reduction of 2-haloacetophenone derivatives in the presence of $TiCl_4$ in dichloromethane undergoes much more readily even at 298 K to yield the corresponding halohydrins selectively.

Acid catalysis is known to play an essential role in the efficient enzymatic reduction of carbonyl compounds by dihydronicotinamide adenine dinucleotide (NADH).[1] The catalytic center of the enzyme, zinc ion, is believed to act as a Lewis acid rather than a Brönsted acid.[1] Ohno et al.[2] reported that benzaldehyde is reduced to benzyl alcohol by an acid-stable NADH model compound, 1,2,4-trimethyl-3-(α-methylbenzylcarbamoyl)-1,4-dihydroquinoline, in the presence of a Lewis acid ($TiCl_4$ or $AlCl_3$) in tetrahydrofuran at room temperature in 12 h. The reduction of benzaldehyde derivative by acid-stable NADH model compounds is known to be catalyzed also by a Brönsted acid.[3,4]

We have recently reported that various nonactivated ketones[5] and α-halo ketones[6] can be reduced by an acid-stable NADH model compound, 9,10-dihydro-10-methylacridine ($AcrH_2$), in the presence of a Brönsted acid ($HClO_4$) in acetonitrile at 335 K to yield the corresponding halo alcohols and the parent ketones, respectively. The present work reports the comparison of the reactivities as well as the products in the reduction of 2-haloacetophenone derivatives by $AcrH_2$ in the presence of a Lewis acid ($TiCl_4$) with those in the presence of a Brönsted acid ($HClO_4$).

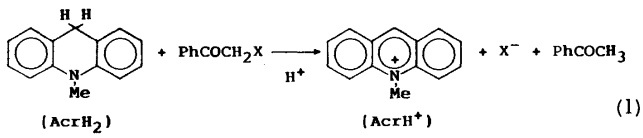
Experimental

Materials. 9,10-Dihydro-10-methylacridine ($AcrH_2$) was prepared from 10-methylacridinium iodide ($AcrH^+I^-$) by the reduction with $NaBH_4$ in methanol, and purified by recrystallization from methanol.[7] The dideuterated compound, [9,9-$^2H_2$]-9,10-dihydro-10-methylacridine ($AcrD_2$), was prepared from 10-methyl-9-acridone by the reduction with $LiAlD_4$.[8] 2-Bromoacetophenone and 2-chloroacetophenone were obtained commercially and purified by the standard methods.[9] 2-Bromo-4′-methoxyacetophenone and 2-bromo-4′-cyanoacetophenone were prepared from bromination of the corresponding acetophenone derivatives in methanol.[10] Styrene bromohydrins was prepared by the reaction of styrene with *N*-bromosuccinimide in water according to the literature.[11] Titanium tetrachloride, dichloromethane, and acetonitrile-d_3 were obtained commercially and used without further purification. Perchloric acid (70%) was obtained from Wako Pure Chemicals.

Reaction Procedure. Typically, $AcrH_2$ (6.0×10^{-5} mol) was added to an NMR tube that contained a deaerated acetonitrile-d_3 (CD_3CN) solution (0.60 cm^3) of 2-haloacetophenone (1.8×10^{-4} mol) and $HClO_4$ (1.8×10^{-4} mol). After the reactant solution was deaerated again by a stream of argon and sealed, the NMR tube was immersed in a water bath which was thermostatted at 335 K. In the case of the reduction of 2-haloacetophenone by $AcrH_2$ in the presence of $TiCl_4$, 2-haloacetophenone (2.0×10^{-3} mol) was firstly added to a deaerated solution of CD_2Cl_2 (0.05 cm^3) containing $AcrH_2$ (5.0×10^{-4} mol), and then $TiCl_4$ (1.3×10^{-3} mol) was added to the 2-haloacetophenone–$AcrH_2$ system under a stream of argon. The reaction was carried out also by changing the order of addition; $TiCl_4$ was firstly added to a CD_2Cl_2 solution of $AcrH_2$, and then 2-haloacetophenone was added to the $AcrH_2$–$TiCl_4$ system. The reaction was quenched by the addition of water (2.0×10^{-3} mol) after 2 min. The product yields were determined from the ^1H NMR spectra in CD_3CN (0.50 cm^3) by comparing with those of the authentic samples.[6] The NMR spectra were recorded using a Japan Electron Optics JNM-PS-100 NMR spectrometer (100 MHz).

Results and Discussion

An NADH model compound ($AcrH_2$) shows no reactivity towards 2-haloacetophenone ($PhCOCH_2X$; X=Br, Cl) in the dark at 335 K. When $HClO_4$ is added to the $AcrH_2$–$PhCOCH_2X$ system, $PhCOCH_2X$ is reduced by $AcrH_2$ at 335 K to yield 10-methylacridinium ion ($AcrH^+$) and acetophenone (Eq. 1) as well as



(1)

α-(halomethyl)benzenemethanol (Eq. 2). 2-Haloacetophenone is reduced by $AcrH_2$ much more readily even

$$ArcH_2 + PhCOCH_2X + H^+ \longrightarrow AcrH^+ + PhCH(OH)CH_2X \quad (2)$$

at 298 K in the presence of $TiCl_4$ in dichloromethane, and the corresponding halohydrin, α-(halomethyl)-benzenemethanol is obtained selectively in 70—80% yield with no dehalogenated compound in 2 min, when the reaction is quenched by water. Such selective formation of halohydrin seems interesting since the model systems that have so far been reported for the reduction of α-halo ketones undergo the reductive dehalogenation to yield parent ketones,[12] although the enzyme-mediated reduction of 2-haloacetophenone is known to yield the corresponding halo-

hydrin selectively.[13]

The reaction conditions and the yields of products are compared for the reduction of various 2-haloacetophenone derivatives by $AcrH_2$ in the presence of $HClO_4$ with those in the presence of $TiCl_4$ as shown in Table 1. The much higher reaction temperature and more prolonged reaction time are required for the reactions in the presence of $HClO_4$ brought to completion than those in the presence of $TiCl_4$. In the reduction of $PhCOCH_2X$ (X=Br, Cl) by $AcrH_2$ in the presence of $TiCl_4$, the yield of the oxidized product $AcrH^+$ is about the same as that of the reduced product, $PhCH(OH)CH_2X$ (Table 1). The prolonged reaction time (e.g., 10 min) did not improve the product yields.

When $AcrH_2$ is replaced by the 9,9-dideuterated analogue ($AcrD_2$) in the reduction of 2-haloacetophenone in the presence of $HClO_4$ and also in the reduction in the presence of $TiCl_4$, the deuterium is incorporated into α-(halomethyl)benzenemethanol in both cases (Table 1). In the case of the reduction in the presence of $HClO_4$, however, no deuterium is incorporated into the dehalogenated product, acetophenone. The acetophenone is further reduced by $AcrH_2$ to yield small amount of the corresponding alcohol in which the deuterium is incorporated (Table 1). The substitution of the α-carbon of $PhCOCH_2Br$ with an alkyl group for the reduction in the presence of $TiCl_4$ results in significant decrease in the yield of halohydrin, accompanied by the recovery of the reactant, although the yield of $AcrH^+$ is rather constant (Table 1).

In the absence of 2-haloacetophenone as well, $AcrH_2$ is readily oxidized by $TiCl_4$ to yield $AcrH^+$ (Table 1). In addition, no appreciable reduction of 2-haloacetophenone occurs upon the reversed addition; $AcrH_2$ is added to a dichloromethane solution of $TiCl_4$ firstly and then 2-haloacetophenone is added to the $AcrH_2$–$TiCl_4$ system. Thus, the reduction of $TiCl_4$ by $AcrH_2$ may take place firstly, and then a reduced titanium species, which would decompose in the absence of active substrates, may reduce 2-haloacetophenone derivatives to the corresponding halohydrins. The reduced titanium species may not be $TiCl_3$, since $TiCl_3$ is known to bring about reductive dehalogenation of 2-haloacetophenone to yield acetophenone exclusively.[14] In general, a Lewis acid such as $TiCl_4$ is known to activate carbonyl compounds in the reductions by various reductants.[15] Thus, a hydride transfer from $AcrH_2$ to 2-haloacetophenone may be mediated by $TiCl_4$ and facilitated by the interaction of α-halo ketones with $TiCl_4$. At present, however, the detection of a possible mediator such as a titanium hydride species by a low-temperature ^1H NMR measurement was unsuccessful. Other Lewis acids such as $SnCl_4$, $BF_3\cdot OEt_2$, and $AlCl_3$ were not effective for the reduction of α-halo ketones to halohydrins by $AcrH_2$.

The Selectivity of Sulfided NiW/Al_2O_3 Catalyst in the Hydrodesulfurization of Dibenzothiophene

Masatoshi NAGAI
Department of Chemical Engineering, Faculty of Technology, Tokyo University of Agriculture and Technology, Koganei, Tokyo 184
(Received March 17, 1989)

Synopsis. The selectivity of a sulfided NiW/Al_2O_3 catalyst for hydrodesulfurization has been studied at 300°C and 10.1 MPa total pressure. The presence of oxygen and sulfur compounds depressed the desulfurization of dibenzothiophene, but not the hydrogenation. The addition of large amounts of acridine improved the catalytic activity significantly for the desulfurization of dibenzothiophene to biphenyl while preventing hydrogenation.

The hydrodesulfurization of petroleum residue is widely practiced and the need for a similar technology for coal-derived liquids is well recognized. Heavy feedstocks contain small amounts of nitrogen compounds and sulfur compounds as impurities. Catalyst poisoning by nitrogen compounds is a serious problem during hydroprocessing treatment.

Several researchers have studied the effect of nitrogen compounds on the hydrodesulfurization reactions in order to obtain more detailed information about the poisoning mechanism. A previous study[1] revealed that the presence of nitrogen compounds depressed the hydrogenation of dibenzothiophene on a sulfided Mo/Al_2O_3 catalyst. Neither an increase in the conversion, nor an improvement in the catalytic activity for the desulfurization, was observed during the reaction. Cowley and Massoth[2] also found that the addition of pyridine greatly decreased the conversion of thiophene on a sulfided Mo/Al_2O_3 catalyst. Moreover, Urimoto and Sakikawa[3] reported that the presence of pyridine inhibited the hydrodesulfurization activity of MoS_2, WS_2, CoS, and NiS catalysts. Thus, the presence of nitrogen compounds greatly decreased the conversion, and diminished the catalytic activity of the molybdenum (or nickel or tungsten) sulfided catalyst which did not contain any promoting metals.

However, we have studied the poisoning effect of nitrogen compounds on the hydrodesulfurization of dibenzothiophene on a sulfided $NiMo/Al_2O_3$[4] and NiW/Al_2O_3[5] catalyst and found that the presence of large amounts of acridine markedly enhanced the desulfurization activity of the catalysts, together with a decrease in the hydrogenation activity. The behavior of these catalysts appeared to be different from the sulfided Mo/Al_2O_3 catalysts or metal sulfide catalysts without a promoter in the presence of nitrogen compounds.

In the present work, the hydrodesulfurization of dibenzothiophene on the sulfided NiW/Al_2O_3 catalyst at 300°C and 10.1 MPa total pressure was investigated in the presence of CS_2 and xanthene as well as acridine. The selectivity of the sulfided NiW/Al_2O_3 catalyst for hydrogenation and desulfurization is discussed.

Experimental

Acridine (Ultra pure grade, Tokyo Kasei Chemical), dibenzothiophene, xanthene and carbon disulfide (Extra pure grade), and xylene (Chemically pure grade) were used without purification. Hydrogen (99.9%, To-Ei Chemical) was passed through 13X Molecular Sieves before use. Hydrogen sulfide (99.5%) was used without purification.

Two grams of a NiW/Al_2O_3 (6.5%, NiO and 21% WO_3, Ketjenfine; 14—20 mesh) were packed into the central portion (length 3.6 cm) of the reactor and were oxidized in air at 450°C for more than 24 h. The catalyst was reduced in situ at 400°C for 4 h at a pressure of 10.1 MPa of hydrogen, then at 30 L h^{-1}. After presulfidation, the catalyst was sulfided at a 10% H_2S/H_2 atmosphere, then at 30 L h^{-1} and 400°C for 3 h. The experiment was carried out in a continuous-flow microreactor at 300°C and 10.1 MPa total pressure. The hydrogen (gas ntp)/dibenzothiophene ratio was 320. The weight hourly space velocity (WHSV) was 7.5. After a solution containing 5 wt% dibenzothiophene in xylene was introduced into the reactor, a steady state was achieved within about 3 h. This standard condition was run before the start of each set of experiments with a particular additive.

When measuring the selective effect on the hydrodesulfurization by an additive, a series of feeds containing increasing concentrations of additive was used. The catalyst attained steady activity within about 1 h when additive concentrations were increased. The liquid products were separated by a high-pressure separator into gaseous products. The liquid products, which had higher boiling points than xylene, were analyzed by FID gas chromatography. Biphenyl, cyclohexylbenzene, and 2-ethylbicyclo[4.4.0]decane were identified by comparisons with data from authentic samples by GC and high-resolution mass spectrometry. The hydrogenated dibenzothiophene compounds, cyclohexylbenzene and methyl- and dimethyl dibenzothiophene, were analyzed by GC-MS.

Results and Discussion

Promoting Effect of Acridine. The change in the product distribution in dibenzothiophene hydrodesulfurization in the presence of acridine at 300°C and 10.1 MPa total pressure is shown in Fig. 1. The concentrations of the unreacted dibenzothiophene and cyclohexylbenzene remained constant at 0.1 wt% of acridine, though but further additions led to a great increase in the conversion of dibenzothiophene. This observation indicates that a large amount of acridine enhances the selective desulfurization of dibenzothiophene to biphenyl and depresses hydrogenation. Above 320°C, conversion is not influenced by acridine. This appears to be caused either by diffusional limitations or by a competitive C–N hydrogenolysis of perhydroacridine, which is formed from acridine hydrogenation.

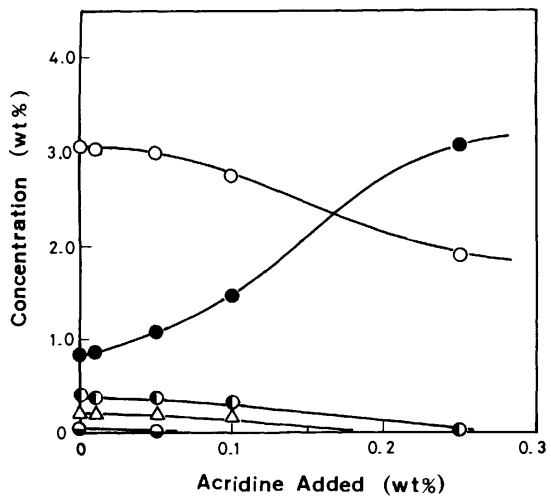

Fig. 1. Change in the product distribution of dibenzothiophene hydrodesulfurization on the addition of acridine at 300 °C. ◒, Methyl- and dimethyldibenzothiophene; ○, Dibenzothiopohene; ●, biphenyl; △, cyclohexylbenzene; ◐, 1,1′-bicyclohexyl, hydrogenated dibenzothiophenes, and other hydrocarbons which have higher boiling point than 1,1′-bicyclohexyl.

The addition of acridine greatly improved the carbon material balance on dibenzothiophene, even at higher temperatures, since the formation of the many small amounts of by-products decreased. The material balance was initially 29 and 57% at 320 and 360 °C, respectively, but rose to 80% after the addition of acridine.

Several authors have proposed shcemes for the electron-transfer reactions between nickel and tungsten ions responsible for generating the desulfurization sites.[1-8] Ni(II) ions should be more easily reduced than WS_2 by hydrogen:

$$\mathrm{Ni(II)} + \mathrm{e} = \mathrm{Ni(I)} \quad (1)$$

and

$$\mathrm{Ni(I)} + \mathrm{W(IV)} = \mathrm{Ni(II)} + \mathrm{W(III)}. \quad (2)$$

The removal of sulfur from dibenzothiophene by W(III) could be followed by reduction with hydrogen to complete the catalytic cycle

$$2\mathrm{W(III)} + \mathrm{RS} + (\mathrm{H_2}) = 2\mathrm{W(IV)} + \mathrm{RH_2} + \mathrm{S^{2-}}, \quad (3)$$

$$\mathrm{S^{2-}} + 4\mathrm{W(IV)} = 1/8\mathrm{S_8} + 4\mathrm{W(III)}, \quad (4)$$

or

$$2\mathrm{S^{2-}} + 2\mathrm{H_2} + 4\mathrm{W(IV)} = 2\mathrm{H_2S} + 4\mathrm{W(III)}. \quad (5)$$

The addition of acridine yielded sulfur in solution as well as a high desulfurization activity to the catalyst. When the reaction solution in the presence of 0.25 wt% acridine was cooled to 0 °C, the solution changed from colorless to orange. Sulfur precipitated from the solution within a couple of days. The orange color was caused by amine complexes,[9] such as hydrogenated acridine compounds with sulfur. The amines, to which acridine was easily hydrogenated, appears to help with the formation of sulfur from a sulfide anion to form an active site W(III) and/or with the desorption of hydrogen sulfide.

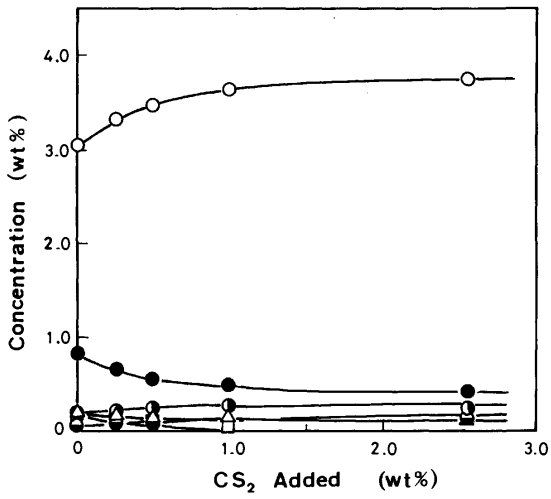

Fig. 2. Effect of CS_2 on product distribution of dibenzothiophene hydrodesulfurization at 300 °C. ◑, Hydrogenated dibenzothiophene compounds; □, 1,1′-bicyclohexyl and other hydrocarbons which have higher boiling point than 1,1′-bicyclohexyl. See Fig. 1 for the other symbols.

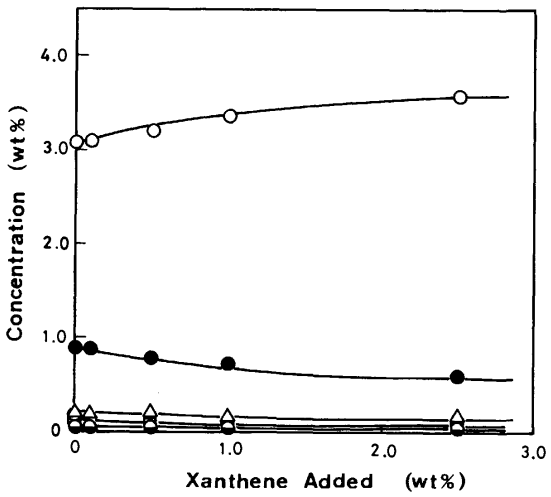

Fig. 3. Effect of xanthene on product distribution of dibenzothiophene hydrodesulfurization at 300 °C. See Fig. 1 for the symbols.

Depressing Effect of Carbon Disulfide and Xanthene. Figure 2 shows the effect of CS_2 on dibenzothiophene hydrodesulfurization at 10.1 MPa and 300 °C. The presence of CS_2 apparently depressed the desulfurization of dibenzothiophene to biphenyl and of hexahydrodibenzothiophene to cyclohexylbenzene. This result gives rise to an increase in concentration of tetrahydro- and hexahydrodibenzothiophene before desulfurization. The presence of an added sulfur compound depresses the desulfurization reaction along with a competitive adsorption of both dibenzothiophene and the hydrogenated compounds, but does not depress the hydro-

genation. Singhal et al.[10] and Broderick et al.[11] also found that H_2S (generated from CS_2) did not inhibit dibenzothiophene hydrogenation on the sulfided $CoMo/Al_2O_3$ catalysts.

The concentrations of methyl- and dimethyl dibenzothiophene was increased by the addition of CS_2. This result indicates that the presence of CS_2 enhanced the alkylation of dibenzothiophene and hampered the desulfurization. These compounds were produced in the reaction with the Co/HY zeolite catalyst,[12] which had stronger acid sites. Therefore, the sulfided NiW/Al_2O_3 catalyst appears to have stronger acid sites than the sulfided $NiMo/Al_2O_3$, $CoMo/Al_2O_3$, and Mo/Al_2O_3 catalysts.

The change in the products of dibenzothiophene hydrodesulfurization in the presence of xanthene at 300°C is shown in Fig. 3. The presence of xanthene depressed the formation of both biphenyl and cyclohexylbenzene with decreasing the conversion of dibenzothiophene, while methyldibenzothiophenes remained unchanged. Thus, the inhibitory effect of an oxygen compound on the sulfided NiW/Al_2O_3 catalyst closely parallels that of CS_2, except for an enhancement of the alkylation of dibenzothiophene.

These results indicated that there are two different sites on the sulfided NiW/Al_2O_3 catalyst; hydrogenation and desulfurization sites. Hydrogenation sites were inhibited by acridine but neither by CS_2 nor by xanthene, whereas desulfurization sites were promoted by acridine. The presence of a nitrogen compound promotes the catalytic activity of the sulfided NiW/Al_2O_3 catalyst for the desulfurization.

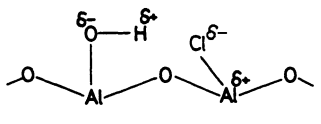
Isomerization of 1-Butene on High-Temperature-Chlorinated Alumina

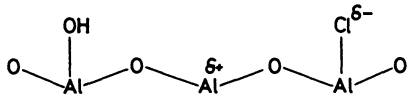
Akimi AYAME* and Goro SAWADA†
Department of Industrial Chemistry, Muroran Institute of Technology,
27-1 Mizumoto, Muroran, Hokkaido 050
(Received February 25, 1989)

Regarding aluminas chlorinated at 973—1223 K, which have only a Lewis acidic character without hydroxyl groups and basic sites, the IR spectra of the adsorbed 1-butene were measured and the isomerization of 1-butene and *cis*-2-butene was performed at 273—323 K. The obtained results were compared with those for aluminas dehydrated at the same temperatures. The IR spectra of the adsorbed 1-butene well resembled that of *cis*-2-butene, including the absence of peaks due to double-bond and π-allyl carbanion species, observed even after outgassing at 473 K. During isomerization at 273 K, the initial isomerization reaction rates and cis/trans ratios were greater than those for dehydrated alumina. The ratio decreased rapidly with increasing reaction temperature. The specific reaction rates and the ratio were independent of the chlorination temperature. In the isomerization of *cis*-2-butene the most thermodynamically unstable molecule, 1-butene, was formed preferentially. The obtained results could be interpreted by an isomerization mechanism through a doubly bonded intermediate, i.e., the allylic butenyl cation.

A high-temperature treatment of aluminas in air and/or in vacuo removes water molecules from the surfaces, resulting in aluminium cations with unsaturated coordination, isolated hydroxyl groups and oxygen anions on the surfaces. Consequently, Lewis acid, Brønsted acid and basic sites are formed.[1-5] On the other hand, it is known that by chlorination with hydrogen chloride, carbon tetrachloride, aluminium trichloride, and gaseous chlorine below 823 K the Lewis and Brønsted acid sites on γ and η-aluminas can be enhanced.[6-11] The effects are interpreted in terms of a decrease in the electron density of aluminium atoms which are directly linked to chlorine **I** or in the nearest position to the aluminium atom linked to chlorine **II**.



[I]



[II]

The authors studied the chlorination of γ-aluminas with dry chlorine at 773—1273 K as well as the surface characteristics of treated aluminas.[12] Chlorination effectively removed surface hydroxyl groups and sulfate ions. The obtained alumina surface had chlorine atoms (2—3 nm^{-2}) bonded with the tetrahedral aluminium cation, leading to the formation of strong Lewis acid sites with $H_0 \leqq -14.52$ and yielding intense IR peaks at 1628 and 1453 cm^{-1} in pyridine adsorption. The surface was, however, unable to form carbonate and bicarbonate ions in carbon dioxide adsorption. In the 1,2-epoxypropane isomerization, allyl alcohol promoted by an acid-base bifunctional catalysis was not produced, whereas the abstraction of an oxygen atom from the epoxide molecule by strong Lewis acid site took place in addition to the formation of propionaldehyde and acetone. Even in hydrogen chloride adsorption, there was no evidence for the formation of hydroxyl groups and water molecules.[13] These experimental results undoubtedly indicated that on high-temperature-chlorinated aluminas Brønsted acid and strong basic sites were absent; only

† Present address: Maruzen Petrochemical Co., Ltd., 3 Goi-Minami-Kaigan, Ichihara, Chiba 290.

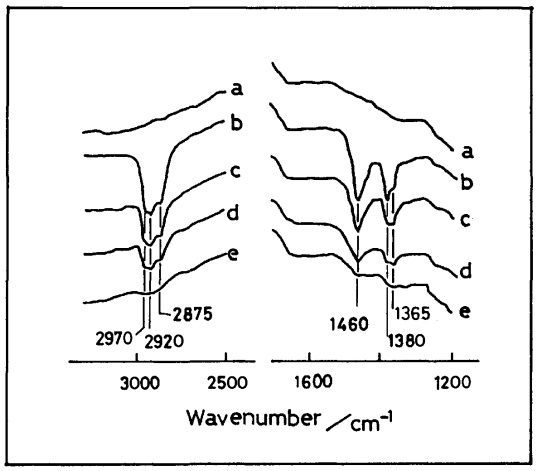

Fig. 2. IR spectra of 1-butene on alumina (ALO-4) chlorinated at 1073 K. (a) Background; (b) after exposed to 1-butene under 40 Torr for 15 min at room temperature; after outgassing for 30 min at (c) room temperature, (d) 373 K, and (e) 473 K.

Lewis acid sites were present. In addition, the strong Lewis acid sites tightly adsorbed benzene to form a π-complex with λ_{max}=294 nm and chloropropanes to the π-allyl cation, respectively, and promoted the isomerization of butane and cyclohexane to 2-methylpropane and methylcyclopentane with 100% selectivity, respectively, at 303 K.[13,14] Consequently, the chlorinated alumina is expected to be a solid Lewis superacid and to be used instead of homogeneous Lewis acids.

In the present work, in order to reveal the catalytic properties of chlorinated alumina, the infrared spectra of adsorbed 1-butene were measured and compared with those for the dehydrated aluminas; also, the isomerization of 1-butene and *cis*-2-butene was carried out. In this paper the 1-butene isomerization mechanism on a pure Lewis acidic surface is also discussed.

Experimental

Cylindrical γ-alumina JRC-ALO-4 (JRC represents the Japan Reference Catalyst[15]) was first crushed and sieved to obtain 16—32 and 100—150 mesh fractions; these were then washed with pure water and dried. Self-supported disks (13 mmϕ) prepared with the 100—150 mesh fraction were used in IR measurements and the 16—32 fraction in catalytic reactions. Commercial chlorine (Nissan Shoji Co., 99.4%) was purified by vacuum distillation, and 1-butene and *cis*-2-butene (Takachiho Chemicals, 99.0%) were used without special purification.

Chlorination of the samples was carried out with 100 Torr (1 Torr≈133.322 Pa) chlorine gas at temperatures between 973 and 1223 K for 1 h and then outgassed. Prior to chlorination, the samples were dehydrated at 773 K for 1 h in vacuo. During chlorination, an IR in situ cell made of a quartz glass tube and a highly pure alumina ceramics tube of 8 mmϕ i.d. (SSA-S, Nippon Ceramics Co.) were used. IR spectra were measured at room temperature using a Hitachi 215 transmission spectrometer. Isomerization reactions of 1-butene and *cis*-2-butene were performed using a fixed bed-closed circular reactor with a volume of about 550 ml. The reactant mixture comprised 1-butene (10 vol%) and helium (99.99% in purity; 90 vol%). The total pressure of the mixture was 300 Torr. The reactor comprised a U-type Pyrex glass tube (4 mmϕ i.d.) and the catalyst (0.1 g) supported by glass wool. The reaction temperature was between 273 and 323 K, and the reactant and product gases were analyzed by a gas chromatograph equipped with a column packed with propylene carbonate (15 wt%/Chromosorb G).

Results and Discussion

IR Spectra. The IR spectra of 1-butene and *cis*-2-butene adsorbed on the alumina dehydrated at 1073 K (Fig. 1). Spectrum b agreed with that on magnesium oxide pretreated at 773 K (reported by Baird and Lunsford[16]). In the spectra of 1-butene, the two peaks at 3015 and 1635 cm^{-1} were assigned to the terminal =C-H and the double-bond stretching vibrations, respectively. For *cis*-2-butene, these peaks appeared at 3020 and 1640 cm^{-1}. The 1405 cm^{-1} peak was due to the C-H deformation vibration of -CH=CH- in the cis configuration. A doublet band consisting of 1380 and 1365 cm^{-1} peaks was assigned to the resonating symmetrical deformation vibration of the C-H bond of two methyl groups in such hydrocarbon molecules as a molecule-like isopropyl group. All of the peaks described above were almost eliminated by outgassing at room temperature for 30 min. Figure 2 shows the IR spectra of the 1-butene adsorbed on alumina chlorinated at 1073 K. The spectra are very similar to that for *cis*-2-butene physically adsorbed on dehydrated alumina, also observed after outgassing at 473 K for 30 min. However, the peaks assigned to the double bond completely disappeared, the 1440 cm^{-1} peak due to the C-H deformation vibration was shifted to 1460 cm^{-1}, and a new 2970 cm^{-1} peak due to the C-H stretching vibration of the methyl group appeared. Further, the intensity ratio of the 1380 to 1460 cm^{-1} peak was 0.6—0.7, which was in accord with that for *cis*-2-butene (Fig. 1). These results indicate that 1-butene was strongly adsorbed on the strong Lewis acid sites to form such adsorbed species as **III** or **IV** via an intermolecular hydrogen-transfer reaction.

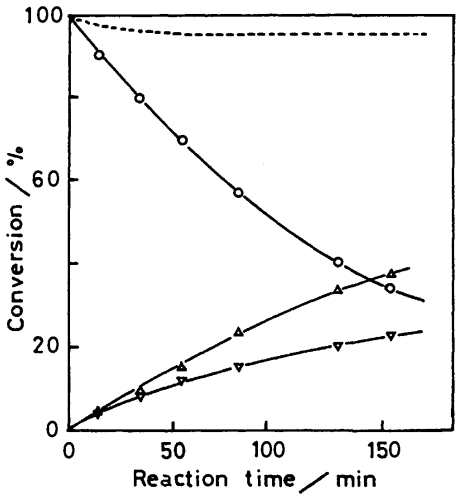

Fig. 4. Isomerization of 1-butene at 323 K on ALO-4 chlorinated at 1073 K. (○) 1-butene; (△) *cis*-2-butene; (▽) *trans*-2-butene; (----) total butene.

Geometrically, form **III** would be favorable, where *sL* indicates a possible strong Lewis acid site enhanced by chlorine bonding to the tetrahedral aluminium cation. In addition, the adsorbed species was likely to be desorbed at a higher reaction temperature, since the clear peaks assigned to oligomers or polymers were not observed. Along with the 1-butene adsorption, a new appearance of OH bands and peaks due to allylic species, which might arise from dissociation of the butene molecule, were undetected. However, on the dehydrated sample a small shift in the OH band to the low-frequency side was observed.

Isomerization of 1-Butene. Table 1 summarizes the initial isomerization reaction rates and obtained cis/trans ratios. The time courses of gas composition when a large conversion of 1-butene was obtained are shown in Figs. 3 and 4. The compositions were far apart from the thermodynamical equilibrium values of butenes: 4.1/70.7/25.2 for 1-butene/*trans*-2-butene/*cis*-2-butene. In every run, a loss in carbon balance was observed. An irreversibly adsorbed amount for 120 min decreased with an increasing reaction time and treatment temperature, being 1—7 and 3—15 mol% of 1-butene for the dehydrated and chlorinated aluminas, respectively. At every reaction temperature, the isomerization rates and cis/trans ratios for the chlorinated aluminas were greater than those for the dehydrated aluminas. Each reaction rate indicated a maximum at a chlorination temperature between 973 and 1073 K. The chlorination temperature dependence was very similar to that of the chlorine content for chlorinated alumina JRC-ALO-2.[12] The surface area decreased as a result of chlorination, as well as with an increase in the chlorination temperature. Consequently, the differences in the reaction rates between the two kinds of treated aluminas became increasingly large with increasing temperature. However, the specific isomerization rates and the cis/trans ratios were almost independent of the chlorination temperature (Fig. 5). Only the specific

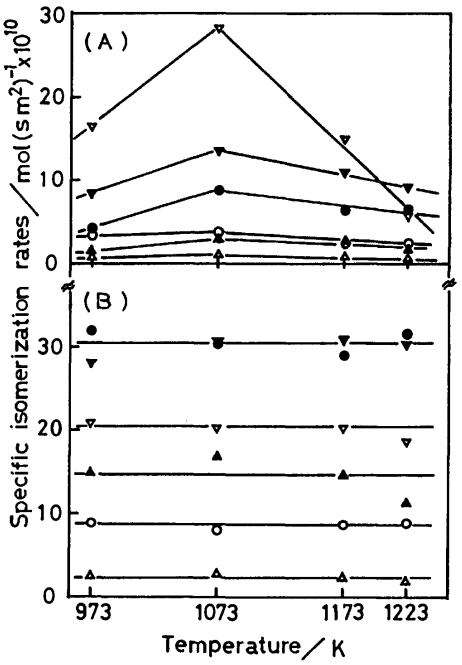

Fig. 5. Treatment temperature dependences of the isomerization reaction rates of 1-butene for (A) dehydrated and (B) chlorinated alumina (ALO-4). Reaction temperatures—273 K (▲ cis, △ trans); 296 K (● cis, ○ trans); 323 K (▼ cis, ▽ trans).

rate to *cis*-2-butene at 273 K varied with the chlorination temperature. This variation seems to reflect an unstable surface state caused by the accumulation of *cis*-2-butene tightly adsorbed in form **III** or **IV**. The number of chlorine atoms per unit surface area was almost constant (2.5 nm^{-2}) and did not depend on the chlorination temperature.[13] This result suggests that 1-butene isomerization is mainly catalyzed by the strong Lewis acid site, "*sL*".

Isomerization of *cis*-2-Butene. The isomerization of *cis*-2-butene was carried out at 273 K under the same reaction conditions as 1-butene (Table 2). The most unstable molecule, 1-butene, among the butenes was formed at 3.2—4.4 times the reaction rates for the dehydrated aluminas. However, the *trans*-2-butene formation rates for the two kinds of catalysts were of the same order. The trans/1 ratios (0.7—1.4) were abnormally small, being smaller than those for the dehydrated aluminas. Such low trans/1 ratios indicate that the rotation of the ^{2}C-^{3}C axis of adsorbed *cis*-2-butene is remarkedly depressed on chlorinated aluminas.

Mechanism. The cis/trans ratio and the trans/1 ratio obtained for dehydrated aluminas were almost in accord with the results reported by Gerberich and Hall and explained by the acid-base bifunctional and geometric isomerization mechanism via allylic butenyl ion intermediate.[17] Basset et al. reported that the π electrons of the double bond were delocalized to yield a dipole intermediate with partially negative and positive charges on ^{1}C and ^{4}C, respectively; they concluded that the repulsion between the positive methyl group and aluminium cation took place to give the high trans/1 ratio in *cis*-2-butene isomerization.[18] In addition, they explained the low trans/1 ratio for carbon tetrachloride-treated alumina by the classical carbonium ion mechanism. However, the cis/trans ratio in the 1-butene isomerization with the carbonium ion mechanism should be close to unity.[17,19] Regarding the chlorinated alumina which Basset et al. employed, oxygen ions with an electron-donor property, weak basic sites and strong Lewis acid sites were present because of adoption of a low chlorination temperature, 473 K.[18] In order to effectively eliminate hydroxyl groups and strong basic sites from the surfaces, a chlorination temperature of at least above 973 K was required.[12] On alumina chlorinated at such temperatures, the strong Lewis acid sites, "*sL*", were enhanced by chlorine bonding to aluminium cations; other weak sites were present. The presence of weak basic sites which would compensate the acidity is not necessarily denied. However, the surface had no ability to adsorb carbon dioxide to form carbonate and bicarbonate ions. In the adsorption of hydrogen chloride, a new OH stretching band at 3700 cm^{-1} and a deformation band of the O-H bond of H_2O at 1600 cm^{-1} clearly appeared on the dehydrated sample,

Table 2. Initial Reaction Rates and Trans/1 Ratio in *cis*-2-Butene Isomerization

Catalyst (0.1 g)	Treatment tempertature /K	Reaction temperature /K	Initial rates/mol $(g \cdot m^2)^{-1} \times 10^{10}$		Trans
			trans-2-Butene	1-Butene	1
Chlorinated	1073	273	2.45	1.80	1.38
	1173	273	1.91	2.61	0.73
ALO-4		296	6.52	3.84	1.71

	1223	273	2.04	2.84	0.74
Dehydrated	1073	273	2.81	0.56	5.02
	1173	273	1.97	0.59	3.33
ALO-4		296	11.7	1.97	6.00
		323	15.5	2.11	7.49
	1223	273	2.07	0.76	2.74

whereas on the chlorinated sample both bands were entirely undetected.[13] These results indicate the complete absence of oxygen ions and hydroxyl groups having an electron-donor character.

The cis/trans ratios obtained on the Lewis acidic surfaces (Table 1) were very great, being rather similar to those for basic metal oxides.[16,20] Dent and Kokes[21] and Chang et al.[22] studied the isomerization and adsorption of 1-butene on a partially dehydrated zinc oxide and concluded that the cis/trans ratio was 10.5 and the adsorbed butene formed a π-allyl carbanion species, which showed absorption peaks at 1550—1572 cm^{-1}. In addition, they confirmed, along with the π-allyl bands, the appearance of a new OH band at 3587 cm^{-1} arising from the dissociation of adsorbed butene, which was caused by strong basic sites. In the present study, there was no evidence for the formation of the π-allyl species or new OH groups. Thus, a mechanism involving a π-allyl carbanion intermediate is very difficult to justify for isomerization on chlorinated aluminas. Further, although the IR peaks assigned to the π-allyl cation can not be observed in Fig. 2, as well as in the case of more longer-time adsorption, it was ascertained that the adsorption of chloropropanes yielded an intense peak at 1533—1535 cm^{-1} due to the cation.[12] This indicates that the strong Lewis acid site abstracts, as a hydride ion, an allylic hydrogen of propene formed from chloropropanes by dehydrochlorination. Consequently, the high selectivity of 1-butene to *cis*-2-butene, as shown in Table 1, is considered to be illustrated by a mechanism via a doubly bonded intermediate, butenyl cation, similar to that presented by Tanaka and Ogasawara[8] (Fig. 6). The 1-butene molecule can approach very closely to the "*sL*" site because of the absence of hydroxyl groups and basic oxygen ions with a large electron cloud. The "*sL*" site abstracts the hydrogen atom on allylic carbon and the adjacent Lewis acid site attracts the terminal methylene carbon. When the intermediate **V** shifts to **VI**, the hybrid orbital of ^3C changes from sp^3 to sp^2. At the same time, the methyl group goes away from the surface due to its large electron cloud and the ^2C moves upward. Subsequently, during the shifting of π-electrons, the cis configuration would be completed. The IR spectra of 1-butene adsorbed on the "*sL*" site, coinciding with that of *cis*-2-butene, completely lost its double-bond character. This shows that a hydride shift and a ^2C-^3C axis rotation take place very fast. Intermediate **III**, corresponding to the spectra in Fig. 2, seems to be the most stable configuration of 1-butene and *cis*-2-butene molecules which approach very close to the surface, since two methyl groups on the same side are permitted to move somewhat away from the surface. The butenyl cation mechanism would lead to the high cis/trans ratio. The experimental value was about 6. Similar results were reported by Gerberich and Hall (about 5) regarding fluoridized alumina[17] and Tanaka and Ogasawara (about 6) regarding hydrogen chloride-treated alumina.[8] For *cis*-2-butene isomerization, intermediate **III** is first formed; however, the formation of a ^2C-^3C axis at rotation to give *trans*-2-butene is more difficult than a hydride shift from ^1C to ^3C, since the interaction between the "*sL*" site and the *cis*-2-butene molecule is very strong. The lower trans/1 ratios therefore seem to have been obtained. At high reaction temperatures, doubly bonded intermediate **III** would become easy to shift to a singly bonded *s*-butyl cation, i.e., trans configuration. Consequently, with increasing reaction temperature, the cis/trans ratio and the trans/1 ratio seem to decrease and increase, respectively.

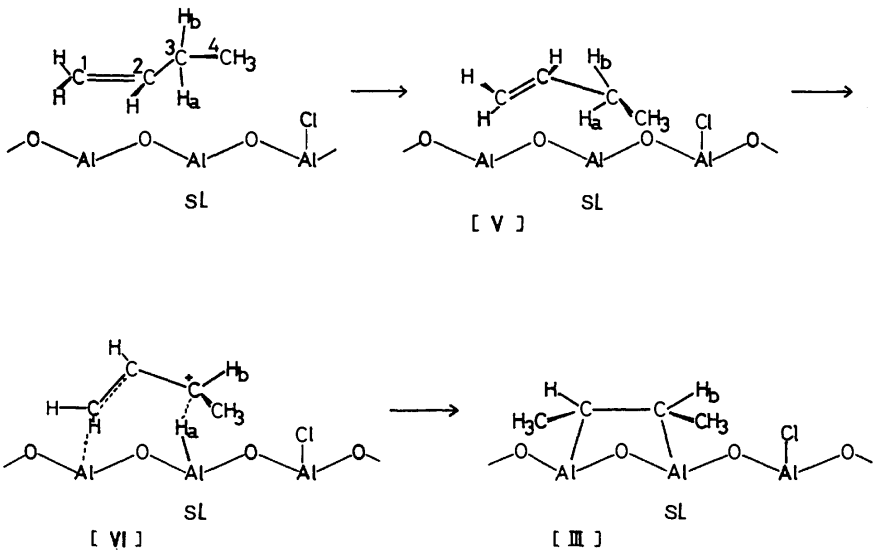

Fig. 6. Possible isomerization mechanism on the chlorinated aluminas.
The *sL* represents a possible strong Lewis acid site.

High-Resolution Solid-State ^{31}P NMR of Alkali Phosphates

Shigenobu HAYASHI* and Kikuko HAYAMIZU
National Chemical Laboratory for Industry, Tsukuba, Ibaraki 305
(Received March 27, 1989)

High-resolution solid-state ^{31}P NMR spectra have been measured for inorganic alkali phosphates with different condensations in the PO_4 units, and the isotropic chemical shift and anisotropy have been determined. The isotropic chemical shifts in alkali orthophosphates do not correlate directly with the cation size. The hydration effects have been carefully examined by means of a ^1H decoupling experiment and by the heat treatment of the materials, accompanied by thermogravimetric analysis. Hydration causes an upfield shift in Na_3PO_4, K_3PO_4, and $Na_4P_2O_7$, while it causes a downfield shift in Rb_3PO_4 and Cs_3PO_4. All the five peaks observed in the $K_4P_2O_7$ sample can be ascribed to anhydrous species; this is in contrast to the findings of previous works. The field-dependence experiments definitely demonstrate that the splittings in $K_4P_2O_7$ and $(KPO_3)_n$ are caused by inequivalent sites.

High-resolution solid-state NMR using magic-angle sample spinning (MAS)[1,2] has been used in a variety of fields recently.[3] Inorganic phosphates are constructed of PO_4 units, which are connected with each other by the sharing of their oxygen atoms. The PO_4 condensation can be expected to be identified by using ^{31}P MAS NMR, much as the SiO_4 condensation is identified by means of ^{29}Si MAS NMR.[4]

Several groups have studied ^{31}P MAS NMR in inorganic phosphates. Rothwell et al.[5] have studied some solid calcium phosphates as examples of mineralized tissues. Andrew et al.[6] and later Haubenreisser et al.[7] and Burlinson et al.[8] have studied sodium triphosphate. Grimmer and Haubenreisser[9] have reported the chemical shifts of PO_4 groups in potassium phosphates with different condensations. Duncan and Douglass[10] have studied several condensed phosphates. Mudrakovskii et al.[11] have measured the spectra of various I—IV-group orthophosphates and pyrophosphates. Turner et al.[12] have studied various orthophosphates and have tried to relate the chemical-shift values with some structural parameters. Prabhakar et al.[13] have measured the spectra of some sodium and potassium phosphates. As reviewed above, data on the ^{31}P MAS NMR spectra of alkali phosphates have been accumulated to some extent. However, the observed lines have not been assigned completely, and there remain some controversies in the assignments.

In the present work, we have measured the ^{31}P MAS NMR spectra of inorganic alkali phosphates and have determined the isotropic chemical shift and its anisotropy, being careful to take account of the effect of the hydration on the chemical-shift parameters. Since the aim of this paper is to present reliable data, we have attempted various measurements, such as ^1H dipolar decoupling and magnetic-field dependence, as well as the heat treatment of the materials.

Experimental

Materials. The materials were purchased from Nacalai Tesque, Inc. (Kyoto, Japan), unless otherwise noted. The $K_4P_2O_7$ was also obtained from the Aldrich Chemical Co. (Milwaukee, U. S. A.); the $Na_5P_3O_{10}$, from Wako Pure Chemical Industries, Ltd. (Osaka, Japan), and the $Rb_3PO_4 \cdot 4H_2O$ and $Cs_3PO_4 \cdot 2.4H_2O$, from the Soekawa Chemicals Co., Ltd. (Tokyo, Japan). The $Na_5P_3O_{10}$ and $K_5P_3O_{10}$ were also synthesized by heating mixtures of M_2HPO_4 and MH_2PO_4 (M=Na, K) at 550 °C.[14] The contents of water in the hydrated materials were checked by means of thermogravimetric analysis (TG). Their anhydrous samples were prepared by heating the hydrated phosphates at the evolution temperatures determined by TG. Three samples, $Na_6P_4O_{13}$, $(NaPO_3)_6$, and $(NaPO_3)_n$, are amorphous, as checked by powder X-ray diffraction.

NMR Measurements. The NMR spectra were measured mostly by the use of a Bruker MSL400 pulsed spectrometer, whose ^{31}P resonance frequency (ν_0) was 161.98 MHz. A JEOL FX200 pulsed spectrometer (ν_0=80.76 MHz) was also used to check the field dependence of the spectra. The probes were doubly tuned to ^{31}P and ^1H resonances, being capable of MAS (magic-angle sample spinning). The chemical shifts are given with respect to 85% H_3PO_4, with the higher-frequency side (i.e., the downfield side) being expressed as positive.

The ordinary single-pulse sequence was used. Typical measuring conditions were $\pi/4$ for the flip angle of the pulse and 10—20 s for the repetition time. A ^1H dipolar decoupling experiment was always performed to check the effect of the ^1H spins.

Since the ^{31}P nucleus has a large chemical-shift anisotropy in many cases, the isotropic peaks are accompanied by many spinning sidebands, especially in high magnetic fields such as used in this work. The isotropic peaks were identified by changing the spinning rate of the sample. The principal values of the chemical-shift tensor were evaluated from the intensities of the spinning sidebands by using the graphical method proposed by Herzfeld and Berger.[15] Q_n in the text denotes that the PO_4 unit shares n oxygen atoms with other PO_4 units. The accuracy of the isotropic chemical shift is about ±0.2 ppm, while that of the principal values of the shift tensor is about ±5 ppm.

Results and Discussion

Orthophosphates (Q_0). In orthophosphates, the PO_4 units are isolated from each other; they are denoted as Q_0. Some typical ^{31}P MAS NMR spectra

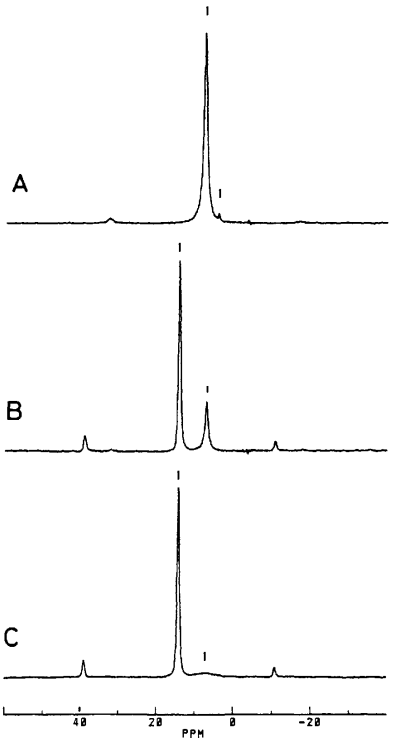

Fig. 1. ^{31}P MAS NMR spectra at ν_0=161.98 MHz of $Na_3PO_4 \cdot 10H_2O$ with ^1H dipolar decoupling (A) and its dehydrated sample with (B) and without (C) decoupling. Bars on top of the peak indicate the isotropic peaks.

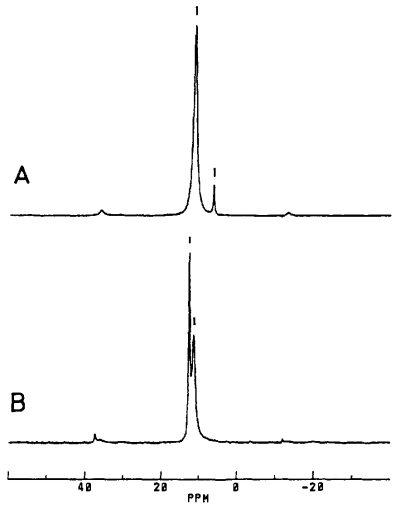

Fig. 2. ^{31}P MAS NMR spectra with ^1H dipolar decoupling of (A) $K_3PO_4 \cdot 3H_2O$ and (B) its dehydrated sample measured at ν_0=161.98 MHz. Bars on top of the peak indicate the isotropic peaks.

of alkali orthophosphates are shown in Figs. 1—3, while the parameters obtained are summarized in Table 1. Impurity peaks are usually omitted from the table if they can be identified. The procedures of the peak assignments will be described below, starting from the lightest cation.

Anhydrous Li_3PO_4 has an isotropic chemical shift

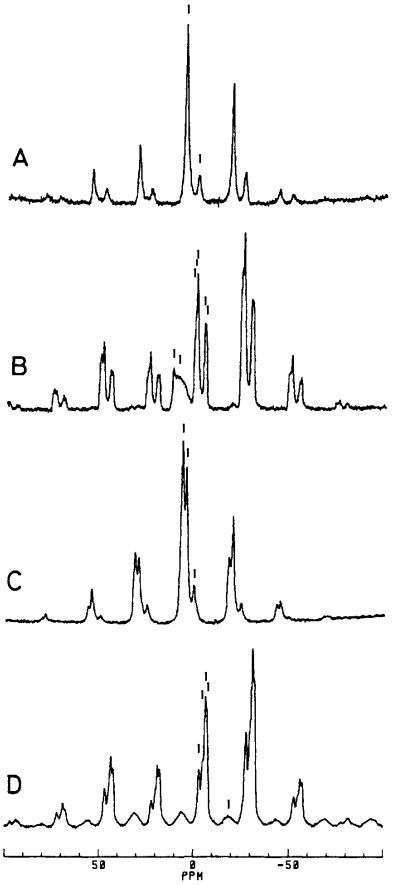

Fig. 3. ^{31}P MAS NMR spectra at ν_0=161.98 MHz of (A) $Rb_3PO_4 \cdot 4H_2O$ with decoupling, (B) its dehydrated sample without decoupling, (C) $Cs_3PO_4 \cdot 2.4H_2O$ with decoupling and (D) its dehydrated sample without decoupling. Bars on top of the peak indicate the isotropic peaks.

of 10.8 ppm, and its tensor is almost isotropic (spectra are not shown).

$Na_3PO_4 \cdot 10H_2O$ has an isotropic chemical shift of 7.7 ppm (Fig. 1A). The thermogravimetric analysis indicates that this sample has the above composition rather than that of $Na_3PO_4 \cdot 12H_2O$ nominated by the supplier. This peak interacts with the ^1H spins in the hydrated water through the dipole-dipole interaction. Another, very small peak is observed at 4.0 ppm; it does not interact with the ^1H spins. This peak disappears after the heat treatment at 210 °C and might be ascribed to much-hydrated species. Heavy hydration is considered to enhance the motion of the PO_4 unit, which can make the time average of the dipole-dipole interaction zero. The sample dehydrated at 210 °C for 0.5 h has isotropic peaks at 14.0 and 6.7 ppm (Fig. 1B). The 14.0 ppm peak is free from the dipolar interaction with the ^1H spins, while the 6.7 ppm peak interacts with the ^1H spins, as is demonstrated in Fig. 1C. The 14.0 ppm peak can be ascribed to anhydrous Na_3PO_4, and the 6.7 ppm peak, to the rehydrated material, $Na_3PO_4 \cdot 10H_2O$.

$K_3PO_4 \cdot 3H_2O$ has an isotropic chemical shift of 11.3

a) The following definitions are used; δ_i: isotropic shift, δ_1, δ_2, and δ_3: principal values of the shift tensor, $\Delta\delta$: shift anisotropy, and η: asymmetry factor in the shift tensor.

$$|\delta_3-\delta_i| \geqq |\delta_1-\delta_i| \geqq |\delta_2-\delta_i| \qquad \delta_i=(\delta_1+\delta_2+\delta_3)/3$$
$$\Delta\delta=\delta_3-(\delta_1+\delta_2)/2 \qquad \eta=(\delta_2-\delta_1)/(\delta_3-\delta_i)$$

b) Negative; its absolute value is less than 30 ppm. c) Not measured. d) Anhydrous species. e) Condensed phosphates might be present. f) Overlapping of the signals prevents accurate estimation.

ppm (Fig. 2A) which interacts with the ^{1}H spins. Another, small peak observed at 6.2 ppm might be ascribed to much-hydrated species, since it does not interact with ^{1}H and disappears after heat treatment at 300 °C. The sample dehydrated at 300 °C for 4.5 h has shifts of 12.5 and 11.3 ppm (Fig. 2B). The interaction with the ^{1}H spins is not found in the former peak, which can be ascribed to anhydrous K_3PO_4. On the other hand, the 11.3 ppm peak does interact with the ^{1}H spins and so can be ascribed to $K_3PO_4 \cdot 3H_2O$.

The above orthophosphates and their hydrates have little anisotropy (less than 30 ppm). The obtained shift parameters agree very well with some of the literature data, as is shown in Table 1. The presence of the rehydrated species in the dehydrated samples suggests that the anhydrous compounds are easily hydrated to form $Na_3PO_4 \cdot 10H_2O$ and $K_3PO_4 \cdot 3H_2O$, while such partially hydrated species as $Na_3PO_4 \cdot nH_2O$ (n=1—9) and $K_3PO_4 \cdot mH_2O$ (m=1,2) are not stable.

The $Rb_3PO_4 \cdot 4H_2O$ sample has two isotropic peaks, at 5.6 and −1.2 ppm (Fig. 3A). The former interacts with the ^{1}H spins, whereas the latter does not. This indicates that the 5.6 ppm peak can be ascribed to a hydrated species like $Rb_3PO_4 \cdot 4H_2O$ and the −1.2 ppm peak, to anhydrous Rb_3PO_4. The sample dehydrated at 400 °C for 2 h has seven isotropic peaks (Fig. 3B), none of which interact with the ^{1}H spins. The peaks at 0.5, −0.2, −0.9, −5.2, and −5.6 ppm can be ascribed to Rb_3PO_4, and the other small peaks at 11.3 and ca.7 ppm, to impurities. The broad linewidth of the 7 ppm peak suggests that a small amount of the amorphous phase was created by the heat treatment.

The $Cs_3PO_4 \cdot 2.4H_2O$ sample has three isotropic peaks (Fig. 3C). The 6.3 and 4.2 ppm peaks interact with the ^{1}H spins and can be ascribed to hydrated species. On the other hand, the −0.1 ppm peak does not interact with the ^{1}H spins and can be ascribed to anhydrous species. The sample dehydrated at 400 °C for 1.3 h has peaks at −3.1, −5.1, −6.4, −7.1, and −19 ppm (Fig. 3D). The peaks other than −19 ppm might be ascribed to Q_0, but the presence of the −19 ppm peak (Q_2) suggests that condensation was encouraged by the heat treatment. The broad linewidth of this peak suggests that an amorphous phase is formed.

In summary, the isotropic chemical shift does not

correlate with the cation radius directly in alkali orthophosphates. Hydration causes upfield shifts in Na_3PO_4 and K_3PO_4, while it leads to downfield shifts in Rb_3PO_4 and Cs_3PO_4. The shift tensors are not isotropic in the orthophosphates with larger cation sizes.

The crystal structure of the hydrated compounds has been studied for $Na_3PO_4 \cdot 12H_2O$.[16] Water molecules coordinate to the Na^+ ion, forming octahedra centered on the Na^+ ion. The PO_4^{3-} ion interacts with the Na^+ ion indirectly through the hydrated water. Thus, the chemical shift of the hydrated compound approaches the value of a Na_3PO_4 aqueous solution ranging from 5.4 to 6.0 ppm.[17] Also, in the other hydrated orthophosphates, water molecules are considered to coordinate to the cations, approaching the shift values near to that of an aqueous solution.

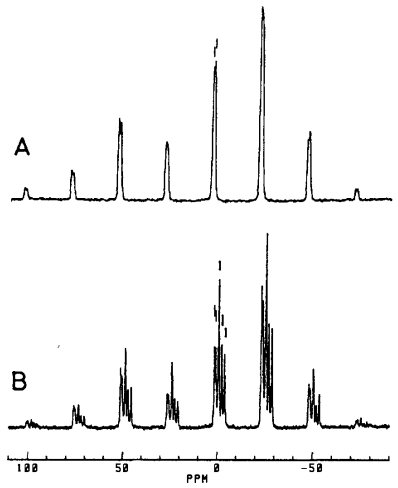

Fig. 4. ^{31}P MAS NMR spectra without ^1H dipolar decoupling of (A) $Na_4P_2O_7$, and (B) $K_4P_2O_7$, measured at ν_0=161.98 MHz. Bars on top of the peak indicate the isotropic peaks.

Pyrophosphates (Q_1-Q_1). Two PO_4 units are connected by sharing one oxygen atom in pyrophosphates. Figure 4 shows the spectra of pyrophosphates; the results are summarized in Table 2.

$Na_4P_2O_7$ has doublet peaks, whose isotropic chemical shifts were 3.0 and 2.2 ppm (Fig. 4A). No splitting was observed at the lower frequency of 80.76 MHz. Thus, the field-dependence measurement failed to elucidate the origin of the splitting. Duncan and Douglass[10] and Prabhakar et al.[13] have reported similar doublets. Duncan and Douglass[10] have interpreted, based on the X-ray diffraction study,[18] that this splitting is caused by inequivalent sites. The magnitudes of the splitting were found to be 1.2 ppm (100 Hz) at 81.015 MHz by Duncan and Douglass,[10] 1.1 ppm (130 Hz) at 121.495 MHz by Prabhakar et al.,[13] and 0.73 ppm (120 Hz) at 161.98 MHz by authors. The ^{31}P-^{31}P scalar coupling in solution is about 20 Hz,[17] much smaller than the observed splitting. Thus, we consider that the interpretation proposed by Duncan and Douglass is most reasonable. In other words, the two Q_1 units in the same Q_1-Q_1 group have different chemical shifts.

$Na_4P_2O_7 \cdot 10H_2O$ shows a similar splitting. The isotropic peaks are observed at −1.4 and −2.3 ppm. The two peaks show interaction with the ^1H spins, and the hydration causes an upfield shift in this compound. Water molecules take part in the sodium coordination, forming octahedra centered on the sodium cation.[19,20] The $P_2O_7^{4-}$ anion interacts with the octahedra through hydrogen bonds. Thus, the chemical shift of the hydrated compound approaches the value of the $Na_4P_2O_7$ aqueous solution (−5.5 to −7 ppm).[17]

On the other hand, five isotropic peaks are observed in $K_4P_2O_7$ (Fig. 4B). Their chemical shifts are 1.4, 0.7, −0.9, −2.5, and −4.0 ppm, and their intensity ratios are approximately 1 : 1 : 2 : 1 : 1. The field-

a) Symbols have the same meanings as in Table 1. b) Ascribed to $K_4P_2O_7$ according to the reference. c) Ascribed to $K_4P_2O_7 \cdot 3H_2O$ according to the reference.

dependence measurements definitely demonstrate that the five lines can be ascribed to inequivalent sites. The ^{1}H dipolar decoupling has no effect on the spectra, which indicates that no effective hydration takes place. None of the five lines change a position or intensity after heat treatment at 150 °C for 1 h. Therefore, all five lines can be ascribed to inequivalent sites in anhydrous $K_4P_2O_7$.

The sample obtained from Aldrich gives the same results as to the position, but the relative intensities of peaks differ from those in Nacalai's sample. Based on the principle that the intensity ratio of the peaks belonging to the same phase is constant, a detailed examination of the intensities suggests that three phases are mixed in these samples. The first phase has peaks at 1.4 and −4.0 ppm; the second, at 0.7 and −2.5 ppm, and the third, at −0.9 ppm. The Q_1 units in the same Q_1-Q_1 group have different chemical shifts in the first two phases, while they have the same chemical shift in the third phase.

On the other hand, Grimmer and Haubenreisser[9] have observed four lines— at −0.3, −2.2, −2.4, and −4.9 ppm. They tentatively ascribed the former two lines to anhydrous $K_4P_2O_7$, and the latter two, to $K_4P_2O_7 \cdot 3H_2O$. Duncan et al.[10] reported results similar to ours, but they ascribed their lines according to Grimmer and Haubenreisser,[9] except for the −1.8 ppm line. The above two groups gave the average parameters of anisotropy, probably because the lines were not well resolved. On the other hand, we can determine the anisotropy parameters of each line, since the lines are well separated.

Triphosphates (Q_1-Q_2-Q_1). Three PO_4 units are connected linearly in triphosphates. Figure 5 shows the spectra of triphosphates, and Table 3 summarizes the results.

Both the commercial and synthesized $Na_5P_3O_{10}$ samples have two isotropic peaks at 5.1 and −5.6 ppm; their intensities are 2.2 : 1 (Fig. 5A). The 5.1 ppm and the −5.6 ppm peaks can be ascribed to the end-chain (Q_1) and middle-chain (Q_2) PO_4 groups respectively.[6-8] The third sets of peaks, observed at 3.0 and 2.2 ppm, can be ascribed to the $Na_4P_2O_7$ contained as an impurity.

The synthesized $K_5P_3O_{10}$ sample has at least eight isotropic peaks— at 1.4, 0.3, −0.7, −2.7, −3.7, −16.3, −18.7, and −19.8 ppm (Figs. 5B and 5D). The three strong peaks can be ascribed to Q_1 (−0.7 and −3.7 ppm) and Q_2 (−18.7 ppm) in the Q_1-Q_2-Q_1 unit. The remaining, small peaks can be ascribed to other phases.

On the other hand, the commercial sample has at least six isotropic peaks— at 7.6, 6.8, −0.7, −3.5, −5.3, and −18.6 ppm (Figs. 5C and 5E). Upon the use of

a) Symbols have the same meanings as in Table 1. b) This peak might be ascribed to an impurity. c) This peak might be partly ascribed to an impurity.

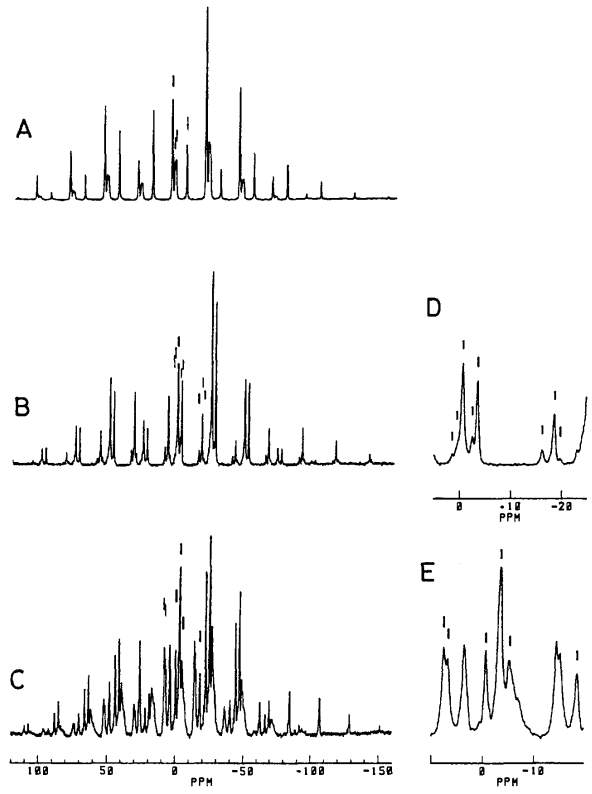

Fig. 5. ^{31}P MAS NMR spectra without ^{1}H dipolar decoupling of (A) $Na_5P_3O_{10}$ (commercial) (B) $K_5P_3O_{10}$ (synthesized), and (C) $K_5P_3O_{10}$ (commercial) measured at ν_0=161.98 MHz. (D) and (E) are expanded plots of the isotropic region of (B) and (C) respectively. Bars on top of the peak indicate the isotropic peaks.

^{1}H dipolar decoupling, the two peaks at 7.6 and 6.8 ppm collapse into one line, at 7.4 ppm, suggesting that the lines are split by the interaction with the ^{1}H spins. The field-dependence measurements demonstrate that the five peaks at 7.4, −0.7, −3.5, −5.3, and −18.6 ppm can be ascribed to inequivalent sites. The magnitudes and signs of the anisotropy suggest that the −18.6 ppm peak can be ascribed to Q_2, and the others, to Q_1. Heat treatment at 200 °C increased the intensities of the 7.4, −3.5, and −5.3 ppm peaks, while the others decreased relatively. This fact and the results on the synthesized sample lead to the following assignments. The −0.7, −3.5, and −18.6 ppm peaks are attributed to the triphosphate anion (Q_1-Q_2-Q_1). The two peaks at −3.5 and −5.3 ppm can be ascribed to Q_1 in the diphosphate anion (Q_1-Q_1), contained as an impurity. The −3.5 ppm peak consists of two components; thus, its intensity is strongest. However, the assignment of the 7.4 ppm peak is still ambiguous.

On the other hand, Grimmer and Haubenreisser[9] have reported the presence of three lines— at −1.2, −4.2, and −19.4 ppm. Duncan and Douglass[10] have reported similar results.

Tetraphosphates (Q_1-Q_2-Q_2-Q_1). Four PO_4 units are linearly linked in tetraphosphates. $Na_6P_4O_{13}$ has two isotropic signals, at 1.5 and −16.4 ppm (Fig. 6A and Table 4), which can be ascribed to Q_1 and Q_2 respectively. The X-ray diffraction results demonstrate that this sample is amorphous. Thus, the broad linewidth is produced by chemical-shift dispersion due to the disorderness in the amorphous material.

Metaphosphates (-Q_2-). In metaphosphates, many PO_4 units are linked by sharing two of the four oxygen atoms to form rings and chains. The spectra of the metaphosphates are shown in Fig. 6, while the shift parameters are summarized in Table 4.

$(NaPO_3)_n$ has an isotropic chemical shift of −19.9 ppm (Fig. 6B); it can be ascribed to the middle-chain PO_4 group (Q_2). A small peak was also observed at −6.2 ppm; it can be ascribed to the end-chain PO_4 group (Q_1). The linewidths are broad because of the amorphousness. Since the chemical-shift dispersion, which is the origin of the linewidth for this sample, is proportional to the static magnetic field (in Hz unit), lower-field measurements are useful in reducing the linewidth if the spinning rate of the sample is constant. The measurements at ν_0=80.76 MHz reveal the presence of the third, small components at about 1 ppm; they might be Q_1. The $(NaPO_3)_6$ sample shows similar results, as is shown in Table 4.

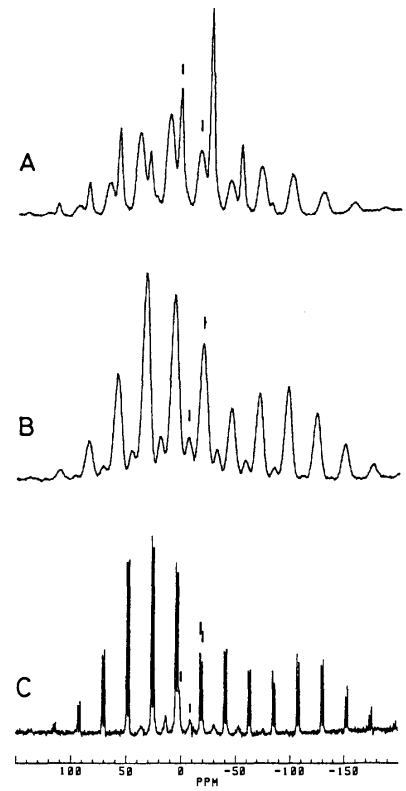

Fig. 6. ^{31}P MAS NMR spectra of (A) $Na_6P_4O_{13}$ and (B) $(NaPO_3)_n$ without ^{1}H dipolar decoupling and (C) $(KPO_3)_n$ with ^{1}H decoupling, measured at ν_0=161.98 MHz. Bars on top of the peak indicate the isotropic peaks.

$(KPO_3)_n$	−17.8, −19.8	—	—	—	NM	NM	Q_2	13

a) Symbols have the same meanings as in Table 1.

Duncan and Douglass[10] have reported results similar to ours. Prabhakar et al.[13] have reported five resonance lines— at −15.6, −18.5, −19.9, −24.1, and −26.8 ppm for $(NaPO_3)_n$. The lines were all ascribed to Q_2. Their sample is considered to be crystalline, in contrast to Duncan and Douglass's sample and to ours.

$(KPO_3)_n$ has two isotropic peaks, at −17.9 and −19.8 ppm (Fig. 6C), ascribed to the middle-chain (Q_2) group. The field-dependence experiments demonstrate that these two peaks are produced by two inequivalent sites. The X-ray diffraction study[21] supports the presence of two inequivalent sites. Grimmer and Haubenreisser[9] have reported the values of −18.5 and −20.7 ppm, while Prabhakar et al.[13] have reported the values of −17.8 and −19.8 ppm. Some other peaks were observed which can be ascribed to impurities. The peak at 4.1 ppm interacts with the ^{1}H spins and vanishes after the sample has been heated at 260 °C; it can be ascribed to hydrated species. Three peaks developed in the course of the experiment— at 0.8, −10.4, and −22.6 ppm. They have negligible anisotropy and no interaction with the ^{1}H spins. Heat treatments of the sample could not reduce the intensities of these peaks. From the above observations, they can be ascribed to decomposed species formed by hydrolysis. By analogy with the solution data,[17] the 0.8 ppm peak can be ascribed to Q_0; the −10.4 ppm peak, to Q_1, and the −22.6 ppm peak, to Q_2.

Summary

The ^{31}P chemical shift and its anisotropy in each Q_n species have been discussed previously.[6-13] The present work generally confirms the previous results. An upfield shift in Q_n is observed as n increases. The Q_0 group in M_3PO_4 usually has an isotropic shift-tensor. On the other hand, the Q_1 group usually has an axially-symmetric tensor or an asymmetric factor lower than 0.3. The Q_2 group has a non-axially symmetric tensor with asymmetric factors between 0.3 and 0.6. The magnitudes of the anisotropy, $|\Delta\delta|$, are 100—160 and 170—240 ppm for the Q_1 and Q_2 respectively, while the signs of $\Delta\delta$ are opposite for the two groups.

In the present work, new data on the orthophosphates of Rb and Cs are presented. These orthophosphates have considerably greater magnitudes of anisotropy than the other orthophosphates. Although the data from Li to Cs have been collected, the isotropic chemical shift does not correlate directly with the cation size.

The hydration effects have been carefully examined by means of the ^{1}H decoupling experiment and heat treatment of the materials, accompanied by thermogravimetric analysis. The coexistence of Na_3PO_4 and $Na_3PO_4 \cdot 10H_2O$ demonstrates that the stable hydrate contains 10 H_2O in a quantity not less than 10. Similar phenomena are observed in K_3PO_4 and its hydrate, $K_3PO_4 \cdot 3H_2O$. Hydration causes upfield shifts in Na_3PO_4, K_3PO_4, and $Na_4P_2O_7$, while it causes downfield shifts in Rb_3PO_4 and Cs_3PO_4. Although previous works[9,10] have suggested that two peaks in the spectra of $K_4P_2O_7$ are attributable to its hydrate, our experiment demonstrates that all five peaks can be ascribed to anhydrous $K_4P_2O_7$. In the hydrated compounds, water molecules coordinate to alkali cations, and the phosphate anions interact with the cations indirectly through the water molecules. This situation is similar to that in an aqueous solution; thus, the chemical shifts of the hydrated compounds approach the values in the aqueous solution.

The field-dependence experiment can clearly demonstrate whether the splitting is caused by inequiva-

lent sites or by spin-spin coupling. The splittings in $K_4P_2O_7$ and $(KPO_3)_n$ are caused by inequivalent sites. The doublets in $Na_4P_2O_7$ and its hydrate are also considered to be caused by inequivalent sites, but no experimental evidence was obtained.

Finally, the present work has revealed that some materials contain coexisting phases and/or impurities. The ^1H decoupling experiment, the field-dependence measurements, and the heat treatment of the material can help very much in the confirmation of the impurity, as is demonstrated by the complicated spectra of commercial $K_5P_3O_{10}$.

The Fluorescence Quenching of Zinc Porphyrins with the ω-[4-(4-Pyridyl)pyridinio]alkyl Group

Kohshin TAKAHASHI,* Tetsuo TERASHIMA, Teruhisa KOMURA, and Hiroto IMANAGA
Department of Chemistry and Chemical Engineering, Faculty of Technology,
Kanazawa University, Kodatsuno, Kanazawa 920
(Received April 10, 1989)

The fluorescence of parent porphyrins in $ZnPC_2bpy^+(n)$, ($PC_2bpy^+(n)$, 5-[*n*-[2-[4-(4-pyridyl)pyridinio]ethoxyl]phenyl]-10,15,20-triphenylporphyrin bromide, n=2,3, and 4), and $ZnPC_8bpy^+(3)$, ($PC_8bpy^+(3)$, 5-[3-[8-[4-(4-pyridyl) pyridinio]octyloxy]phenyl]-10,15,20-triphenylporphyrin bromide), was effectively quenched in non-coordinating solvents, such as *o*-dichlorobenzene and dichloromethane, because the pyridyl group in bpy^+ (ω-[4-(4-pyridyl)pyridinio]alkyl group) was coordinated to zinc in porphyrin. On the other hand, the fluorescence of parent porphyrins in $ZnPC_2bpy^+(3)$, $ZnPC_2bpy^+(4)$, and $ZnPC_8bpy^+$ (3) was partly quenched in such coordinating solvents as *N*,*N*-dimethylformamide and pyridine. However, only the fluorescence of the parent porphyrin in $ZnPC_2bpy^+(2)$ was effectively quenched, even in coordinating solvents. The hydrophobic interaction between the porphyrin ring and bpy^+ in $ZnPC_2bpy^+(2)$ may be considerably large, for bpy^+ in $ZnPC_2bpy^+(2)$ is covalently linked to the ortho position of the phenyl group in ZnTPP, (TPP 5,10,15,20-tetraphenylporphyrin), by a short chain. The emission was effectively quenched by the photoinduced electron transfer from the porphyrin ring to bpy^+, because the axial coordination or the hydrophobic interaction gave bpy^+ access to the porphyrin ring.

A metalloporphyrin covalently bound to an electron acceptor is very interesting as a model of the photoinduced electron transfer that occurs in photosynthetic reaction centers. Furthermore, the study of the photophysical properties of electron acceptor-linked metalloporphyrins is very important in order to produce, in the future, a molecular device for the conversion of solar to chemical and/or electrical energy. The emission properties and the photoinduced electron transfer mechanism have been reported on porphyrins covalently bound to quinone or viologen by a flexible chain.[1-5] An investigation of the photoinduced electron transfer of porphyrins covalently linked to an electron acceptor by a rigid spacer exhibited the importance of distance and orientation between the two reactants.[6-8] The application of an external magnetic field[9,10] and multistep electron transfer[11-14] were examined in order to form a long-lived ion-pair in electron acceptor-linked porphyrins. The photoinduced electron transfer of a porphyrin covalently linked to tetracyanonaphtoquinodimethane[15] or a macrotetracyclic cryptate containing the silver(I) ion[16] was also investigated. Recently, we found the photoinduced electron transfer of a zinc porphyrin with an *N*-methylpyridinio group covalently linked to the meso position in the porphyrin ring.[17]

Blondeel et al.[5] reported that the fluorescence quenching efficiency of a zinc porphyrin covalently linked to bpy^+ by a flexible chain was almost the same as that of a viologen-linked porphyrin, although bpy^+ have a smaller electron affinity than the viologen. In the present paper, we report that the zinc porphyrins (shown in Fig. 1) have different conformations in different solvents because of the axial coordination and the hydrophobic interaction between the porphyrin ring and bpy^+, and also that the fluorescence quantum yield is dependent on the conformation.

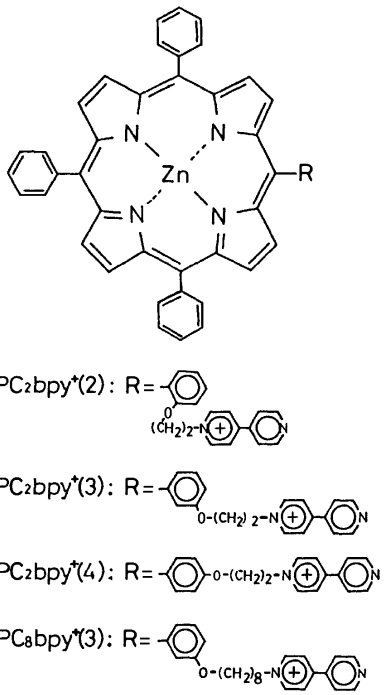

Fig. 1. Structures and abreviations of zinc porphyrins.

Experimental

5-(2-, 3-, and 4-Hydroxyphenyl)-10,15,20-triphenylporphyrins were synthesized and purified by the literature method.[18] The zinc porphyrins were also synthesized by the literature method.[19] The products were purified by column chromatography on alumina. $ZnPC_2Br(n)$, ($PC_2Br(n)$, 5-(*n*-(2-bromoethoxy)phenyl)-10,15,20-triphenylporphyrin, n=2, 3, and 4) and $ZnPC_8Br(3)$, ($PC_8Br(3)$, 5-(3-(8-bromooctyloxy)phenyl)-10,15,20-triphenylporphyrin), were synthesized

and purified by the literature method.[20] $ZnPC_2bpy^+(n)$ and $ZnPC_8bpy^+(3)$ were synthesized by heating a mixture of $ZnPC_2Br(n)$ (or $ZnPC_8Br(3)$) and 4,4'-bipyridine in *N,N*-dimethylformamide (DMF) at 100 °C for 24 hours.[10] The products were purified by column chromatography on silica. Calcd for $C_{56}H_{51}N_6O_7BrZn(ZnPC_2bpy^+(3)\ 6H_2O)$(MW. 1065.34): C, 63.14; H, 4.82; N, 7.89%. Found: C, 63.37; H, 4.26; N, 7.63%. Calcd for $C_{62}H_{55}N_6O_3BrZn(ZnPC_8bpy^+(3)\ 2H_2O)$(MW.1077.44): C, 69.12; H, 4.96; N, 7.80%. Found: C, 68.64; H, 4.84; N, 7.57%. 1-Methyl-4-(4-pyridyl)pyridinium bromide was synthesized and purified by the literature method.[21] Tetraethylammonium perchlorate (Et_4NClO_4) was used after a double recrystallization from water. DMF was distilled twice under reduced pressure in a N_2 atmosphere after dehydration, using Molecular Sieves (4A1/16) and barium oxide. The other solvents were used after distillation.

The absorption spectra were recorded on a Hitachi U-3210 spectrophotometer. The emission and excitation spectra were taken on a Shimadzu RF-540 spectrofluorometer equipped with a Hamamatsu Photonics R928 photomultiplier. The spectral response was corrected by the use of the standard solutions.[22,23] The quantum yields of the emissions in air-equilibrated solutions were determined with reference to the yield of ZnTPP in benzene ($\phi_f^{S1}=0.033$[24]), using the optical dilute method.[25] Cyclic voltammetry was performed in a N_2-purged solution, using a Pt disk (diameters; 1 mm) as the working electrode, a Pt wire as the counter electrode, and Ag/0.1 M $AgNO_3$ in acetonitrile as the reference electrode (1 M=1 mol dm^{-3}). Potential control was obtained by using a Hokuto Denko HA-501 potentiostat and a HB-104 function generator. Cyclic voltammograms were recorded on a Yokogawa 3025 X-Y recorder. The half-wave potentials, measured at the scan rate of 50 mV s^{-1}, were the averages of the cathodic and anodic peak potentials.

Results and Discussion

Inter- and Intramolecular Axial Coordination of Zinc Porphyrins Covalently Linked to bpy^+ by a Flexible Chain. $ZnPC_2bpy^+(2)$, $ZnPC_2bpy^+(3)$, and $ZnPC_8bpy^+(3)$ were slightly soluble, while $ZnPC_2bpy^+(4)$ was insoluble, in non-coordinating solvents, such as *o*-dichlorobenzene (*o*-DCB) and CH_2Cl_2. However, the porphyrins were soluble in coordinating solvents, such as DMF and pyridine.

The addition of pyridine to ZnTPP in *o*-DCB gave rise to a red shift of the absorption peak in the B and Q regions because of the formation of a monopyridine complex.[26] On the other hand, in *o*-DCB, the absorption peaks in the B and Q regions of bpy^+-linked zinc porphyrins were observed at longer wavelengths than those of ZnTPP; also, the Soret bands of bpy^+-linked zinc porphyrins exhibited very broad spectra, with very small molar extinction coefficients at the absorption peak, in comparison with the Soret band of ZnTPP. The absorption spectrum of $ZnPC_2bpy^+(3)$ in *o*-DCB exhibited the characteristic Soret splitting. However, when pyridine was added to the *o*-DCB solution, the Soret bands of the bpy^+-linked zinc porphyrins became sharp. The absorption spectra of ZnTPP, $ZnPC_2bpy^+(3)$, and $ZnPC_8bpy^+(3)$ in *o*-DCB and DMF are shown in Fig. 2, while the absorption spectral features of zinc porphyrin derivatives in different solvents are summarized in Table 1. The intensity ratios of the Q(0,0) and Q(1,0) bands (ε (0,0)/ε (1,0)) for ZnTPP were larger in DMF, pyridine, alcohols, acetonitrile, and nitromethane than in CH_2Cl_2 and *o*-DCB. These results suggested that the solvent molecules, such as DMF, pyridine, alcohols, acetonitrile, and nitromethane, were coordinated to zinc in ZnTPP.[27] The spectral profiles of $ZnPC_2Br(n)$ and $ZnPC_8Br(3)$ in all the solvents were similar to that of ZnTPP, but an enhancement of ε (0,0)/ε (1,0) and a red shift of the B and Q bands for bpy^+-linked zinc porphyrins were observed in the non-coordinating solvents, such as *o*-DCB and CH_2Cl_2.

The above results suggest that the pyridyl group in bpy^+-linked zinc porphyrins was coordinated to zinc in the same or another porphyrin. From the Soret splitting of $ZnPC_2bpy^+(3)$ in *o*-DCB, we tentatively proposed a dimer model of $ZnPC_2bpy^+(3)$ in a non-coordinating solvent, as is shown in Fig. 3a. We previously reported that the Soret band of a zinc porphyrin with a pyridyl group consisted of two components in CH_2Cl_2 because of two intermolecular axial coordinations between the pyridyl group and zinc in porphyrin.[28] Furthermore, Tabushi et al. reported that a gable porphyrin exhibited the same Soret splitting; they inferred that the splitting was due

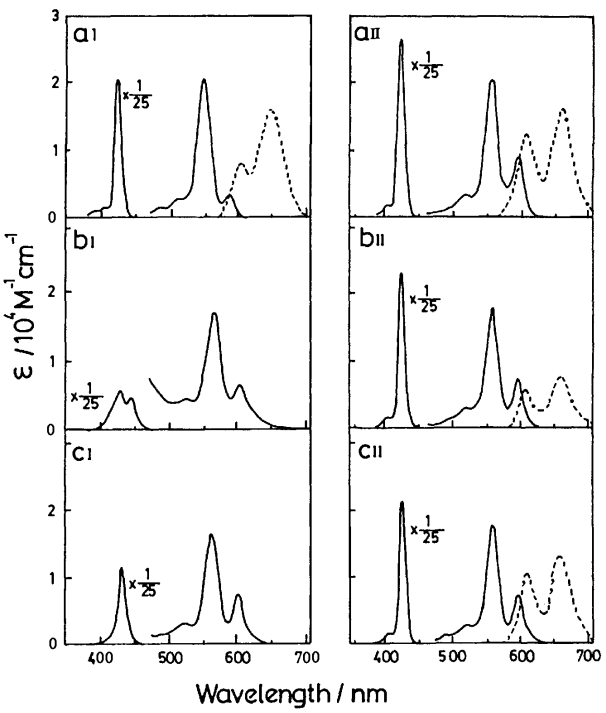

Fig. 2. Absorption (——) and fluorescence (----) spectra of ZnTPP (a), $ZnPC_2bpy^+(3)$ (b) and $ZnPC_8bpy^+(3)$ (c) in *o*-DCB(I) and DMF(II) at room temperature.

a) The intensity ratio of the Q(0,0) and Q(1,0) bands. b) The values in parentheses are the molar extinction coefficients ($\varepsilon/10^4$ M^{-1} cm^{-1}).

to the nearly perpendicular orientation between two porphyrin rings, which caused a relatively weak π-π interaction between them.[29] The dimer of $ZnPC_2bpy^+(3)$ in *o*-DCB can be formed by two intermolecular axial coordinations between the pyridyl group and Zn in porphyrin, while the π-π interaction between two porphyrin rings may be relatively weak. The absorption spectra in the Soret region of $ZnPC_2bpy^+(3)$ in *o*-DCB distinctly changed in the range from 25 to 65 °C, although the absorption spectra in the Q region hardly changed at all. Figure 4 shows the temperature-dependence of the absorption spectra in the Soret region of $ZnPC_2bpy^+(3)$ in *o*-DCB. The absorption spectra indicated two isosbestic points—at 417 and 439 nm. The absorbance of the absorption peak at 447 nm decreased with an increase in the temperature, while that of the absorption peak at 431 nm increased. The Soret splitting consequently disappeared at a relatively high temperature. The temperature-dependence of the Soret band was probably attributable to the temperature-dependence of the conformation between the two porphyrin rings.

In nitromethane and acetonitrile, an enhancement of ε (0,0)/ε (1,0) and a red shift of the B and Q bands for $ZnPC_8bpy^+(3)$ were observed, while no spectral change in $ZnPC_2bpy^+(n)$ was observed. The pyridyl group in $ZnPC_8bpy^+(3)$ with a long-flexible chain can be coordinated to zinc in porphyrin, even in nitromethane and acetonitrile, which have a relatively strong power of coordination. Therefore, we tentatively proposed a model of an intramolecular axial coordination for $ZnPC_8bpy^+(3)$ in a non-coordinating

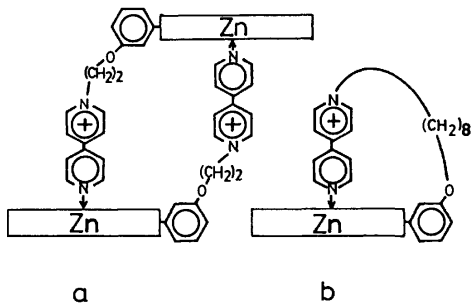

Fig. 3. Typical schematic axial coordination models of $ZnPC_2bpy^+$ (3) (a) and $ZnPC_8bpy^+$ (3) (b). □ Denotes porphyrin ring, and N→Zn coordination between Zn and N(pyridyl group).

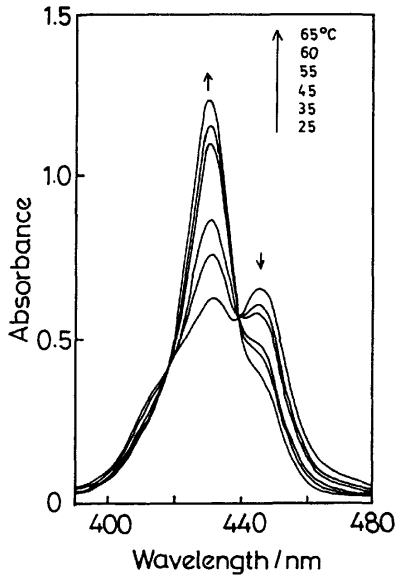

Fig. 4. Temperature-dependence of Soret absorption spectra of 4.1×10^{-6} M $ZnPC_2bpy^+$ (3) in *o*-DCB.

solvent, as is shown in Fig. 3b. Such a model was also supported by the emission properties of $ZnPC_8bpy^+$(3), which will be discussed below.

Since an enhancement of ε (0,0)/ε (1,0) and a red shift of the B and Q bands for $ZnPC_2bpy^+$(2) was observed only in a non-coordinating solvent, such as *o*-DCB, it was inferred that a pyridyl group in $ZnPC_2bpy^+$(2) was also coordinated to zinc in porphyrin only in a non-coordinating solvent. We presumed an intramolecular axial coordination for $ZnPC_2bpy^+$(2) as well as for $ZnPC_8bpy^+$(3) because of the covalent linkage of bpy^+ to the ortho position of the phenyl group in ZnTPP.

Solvent Effects of Fluorescence Properties. When a zinc porphyrin is covalently linked to bpy^+ by a flexible chain, the lowest singlet excited state (S_1) is partly quenched in coordinating solvents, as has been reported by Blondeel et al.[5] On the other hand, the S_1 excited states of parent porphyrins in the bpy^+-linked zinc porphyrins are effectively quenched in non-coordinating solvents; also, only the S_1 excited states of parent porphyrins in $ZnPC_2bpy^+$(2) are effectively quenched, even in coordinating solvents. The S_1 emission spectra of ZnTPP, $ZnPC_2bpy^+$(3), and $ZnPC_8bpy^+$(3) in DMF and *o*-DCB are shown in Fig. 2. Tables 2 and 3 summarize the quantum yields and the relative quantum yields (ϕ/ϕ_0) of S_1 emissions of zinc porphyrins in different solvents, where ϕ and ϕ_0 denote the quantum yields of S_1 emissions of a bpy^+-linked porphyrin and ZnTPP respectively. Since the fluorescence quantum yields of $ZnPC_2Br(n)$ and $ZnPC_8Br$(3) were similar to that of ZnTPP, bpy^+ in bpy^+-linked zinc porphyrins can be said to act as a quencher.

Table 4 summarizes the redox potentials of zinc porphyrin derivatives and Me-bpy^+(1-methyl-4-(4-pyridyl)pyridinium bromide) in DMF. The porphyrin rings in zinc porphyrins were oxidized around 0.4V vs. Ag^+/Ag and were reduced around −1.8 V. The ω-[4-(4-pyridyl)pyridinio]alkyl groups (bpy^+) in bpy^+-linked zinc porphyrins were reduced around −1.3 V. The oxidation potentials in the S_1 excited state ($E(P^+/P_{s1}^*)$), which are estimated from the oxidation potential in the ground state and from the excitation energy from the ground state to the S_1 excited state, are also summarized in Table 4. The photoinduced electron transfer from the porphyrin ring to bpy^+ can occur because the value of $E(P^+/$

P_{s1}^*.) is more negative than the reduction potential of bpy$^+$.

The S_1 excited states of parent porphyrins in bpy$^+$-linked zinc porphyrins were effectively quenched in non-coordinating solvents, and the very weak fluorescence spectra were almost entirely consistent with the fluorescence spectra of ZnTPP despite the axial coordination of the pyridyl group in bpy$^+$. The excitation spectra of the S_1 emissions of bpy$^+$-linked zinc porphyrins in non-coordinating solvents did not agree with the absorption spectra, but they did agreed with the absorption spectrum of ZnTPP. These results show that the fluorescence of parent porphyrins in bpy$^+$-linked zinc porphyrins was completely quenched when the pyridyl group in bpy$^+$ was coordinated to zinc in porphyrin, and also that the pyridyl group in bpy$^+$ was only slightly dissociated from zinc in porphyrin, even in non-coordinating solvents. Hence, the fluorescence quantum yield of a bpy$^+$-linked zinc porphyrin in a non-coordinating solvent must be an apparent one. The addition of 4,4′-bipyridine to ZnTPP in benzene gave rise to a red shift of the absorption and fluorescence peaks because of the axial coordination of 4,4′-bipyridine to zinc in porphyrin, and caused a slight decrease in the fluorescence quantum yield (0.022 in benzene containing 0.06 M 4,4′-bipyridine). These results suggest that the photoinduced electron transfer from the porphyrin ring to bpy$^+$ effectively occurred, for the axial coordination of the pyridyl group in bpy$^+$ to zinc in porphyrin gave bpy$^+$ access to the porphyrin ring.

Figure 5a shows the Soret absorption spectra of $ZnPC_2bpy^+$(3) in *o*-DCB containing DMF. The absorption spectra indicated two isosbestic points—at 420 and 440 nm. Figure 5b shows the dependence of the value of I/I_0 for $ZnPC_2bpy^+$(3) in *o*-DCB on the concentration of DMF, where I and I_0 denote the fluorescence quantum yields in the presence and in the absence of a coordinating solvent molecule at an excitation wavelength which is an isosbestic point of the absorption spectra respectively. The addition of DMF to the *o*-DCB solution caused a dissociation between the pyridyl group and zinc in the bpy$^+$-linked zinc porphyrin and an increase in the value of I/I_0. Furthermore, when 0.03M pyridine was added to the *o*-DCB solutions, the I/I_0 values for $ZnPC_2bpy^+$(3) and $ZnPC_8bpy^+$(3) were 22 and 14 respectively; also, a red shift of the fluorescence peaks and a change in the intensity ratio of the Q(0,0) and Q(0,1) fluorescence bands were observed. The zinc porphyrins was probably emitted only when the pyridyl group in bpy$^+$ was dissociated from the zinc in porphyrin.

In nitromethane and acetonitrile, the fluorescence quantum yields of $ZnPC_8bpy^+$(3) were considerably smaller than those of $ZnPC_2bpy^+$(3) (Table 2). When 0.03 M pyridine was added to the nitromethane solutions, the value of I/I_0 for $ZnPC_8bpy^+$(3) was 10, although the fluorescence quantum yield of $ZnPC_2bpy^+$(3) hardly changed. These results suggest that, in nitromethane and acetonitrile, the pyridyl group in $ZnPC_8bpy^+$(3) was coordinated to zinc in the same porphyrin as is shown in Fig. 3b, but that the pyridyl group in $ZnPC_2bpy^+$(3) was not.

The fluorescence quantum yields of $ZnPC_2bpy^+$(3)

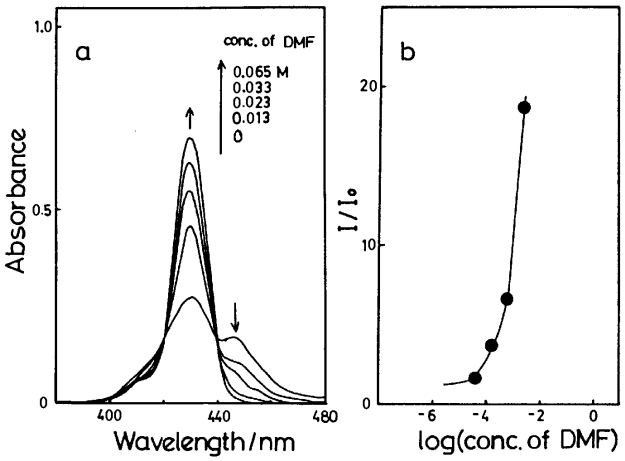

Fig. 5. The dependence of Soret absorption spectra (a) and I/I_0 (b) for 1.7×10^{-6} M $ZnPC_2bpy^+$ (3) in *o*-DCB on the concentration of DMF at room temperature, where I and I_0 denote the fluorescence quantum yields in the presence and the absence of DMF at the excitation wavelength of 420 nm (isosbestic point).

and $ZnPC_8bpy^+$(3) were larger in DMF and pyridine than in *o*-DCB and CH_2Cl_2; also, in DMF and pyridine, the fluorescence quantum yields of $ZnPC_8bpy^+$(3) were larger than those of $ZnPC_2bpy^+$(3) (Table 2). The zinc porphyrins in coordinating solvents probably had a conformation in which the bpy^+ was remote from the porphyrin ring. However, the S_1 excited states of the zinc porphyrins were quenched more effectively in alcohols than in DMF and pyridine (Table 2). The hydrophobic interaction between the porphyrin ring and bpy^+ may be larger in alcohols than in DMF and pyridine. On the other hand, even in coordinating solvents, the fluorescence of the parent porphyrin in $ZnPC_2bpy^+$(2) was effectively quenched (Table 3). The reduction potential of bpy^+ in $ZnPC_2bpy^+$(2) was more positive than those of bpy^+ in other bpy^+-linked zinc porphyrins; also, the reduction potential of the porphyrin ring in $ZnPC_2bpy^+$(2) was more negative (Table 4). The hydrophobic interaction between the porphyrin ring and bpy^+ may be larger in $ZnPC_2bpy^+$(2) than in other zinc porphyrins, for the bpy^+ in $ZnPC_2bpy^+$(2) is covalently linked to the ortho position of the phenyl group in ZnTPP by a short chain; thus, the interaction can easily cause the photoinduced electron transfer.

(Received May 1, 1989)

Interactions of a basic tripeptide, lysyl-tryptophyl-lysine (LTL) with dimyristoylphosphatidylserine (DMPS) were investigated by fluorescence spectroscopy. An interacting LTL-DMPS complex assumes two distinctly different conformations in the lipid bilayer depending on the thermotropic phase of lipid. At temperatures below the gel-liquid crystalline phase-transition temperature (T_c), LTL binds to the polar head groups of DMPS through electrostatic force, and the tryptophan residue is located on the surface of the membrane because of the rigidity of the head groups. Above T_c, it assumes a conformation such that the tryptophan residue slips deeply into the DMPS bilayer. The temperature dependence of the fluorescence quenching by acrylamide supported the penetration of the tryptophan upon the phase transition of DMPS. A fluorescence decay analysis based on the photophysical deactivation mechanism of tryptophan residue has revealed a peculiar interaction of LTL with DMPS in the bilayer.

Recently, much attention has been paid to the peptide-lipid interaction because many small peptides, when brought to interact with membrane systems, exert significant biological effects or display important physiological functions. Investigations of their interactions provide information on the relationship between their structures and functions.[1,2] Fluorescence spectroscopy is endowed with some functions which have been proved useful for such studies. Since only tyrosine and tryptophan residues give efficient fluorescence, they provide a specific intrinsic probe for properties of the peptide-lipid system.

A tripeptide, LTL, has attracted a great deal of interest because of its intrinsic fluorescence due to tryptophan and the positively charged lysine residues which are responsible for electrostatic interactions with the negatively charged head group of phospholipid bilayers. There is evidence that upon LTL's binding with phosphatidylserine, the fluorescence emission spectrum shifted to shorter wavelengths accompanying a marked enhancement in quantum yield, and such a change in fluorescence spectrum has been interpreted as being due to a change in the environment of the indole ring of tryptophan.[3] These results directed us to carry out detailed studies on binding properties of LTL with the phospholipid bilayer. The present paper reports of fluorescence spectroscopic studies on interactions of LTL with DMPS above and below the transition temperature of the phospholipid.

Materials and Methods

LTL and 1,6-diphenylhexatriene (DPH) were purchased from Aldrich Chemicals Co. and purified by recrystallization and sublimation, respectively. DMPS obtained from Avanti Polar Lipid Inc. was used without further purification. The other reagents used throughout the present experiment were of analytical grade.

Unilamellar Vesicles of DMPS. Unilamellar vesicles of DMPS were prepared by the method of Barenholz,[4] and the concentration of DMPS was determined by the method of Bartlett.[5]

Fluorescence Spectra. Fluorescence measurements of LTL and its complex with DMPS vesicles were carried out on a Perkin-Elmer spectrofluorometer MPF-44 equipped with a DCSU-2 microprocessor correction unit. Analog signals were passed into an ADC interfaced to a Commodore minicomputer having a Commodore 2040 disk driver for data storage. For spectroscopic analysis of LTL-DMPS interactions, a small aliquot of DMPS vesicles was added to 2 ml of LTL solution in Tris-acetate buffer at a given pH. This was done in such a manner that the concentration of the remaining LTL is kept constant. Unless otherwise specified, fluorescence was measured with excitation at 280 nm and with 3 nm bandpath. Samples were kept at a constant temperature (±0.5 °C) by circulating water through a thermostated bath.

Fluorescence Decay Analysis. Fluorescence decay measurements were performed by use of the technique of time correlated single photon counting. A synchronously pumped dye laser and a cavity dumper system were employed as the excitation source operating at 825 kHz and with 15 ps pulse width. Detection of emissions was performed on a photomultiplier after their successive passage through a polarizer at the magic angle and a monochromater with 4 nm bandpath. The wavelength dependence of the instrument responce was corrected by using an emission from terphenyl. Data were accumulated in 1024 channels of a multichannel analyzer with a channel width of 21.6 ps, and analyzed by the nonlinear least squares iterative deconvolution method based on the Marquardt algorism. The adequacy of exponential decay fitting was examined by inspection of weighted residual plots and other statistical parameters. The details of the instrumentation and the method of data analysis were described in our previous paper.[6]

Results

Fluorescence Spectra of LTL in the Absence and Presence of DMPS Vesicles. Figure 1 shows fluorescence spectra of free LTL and its complex with DMPS

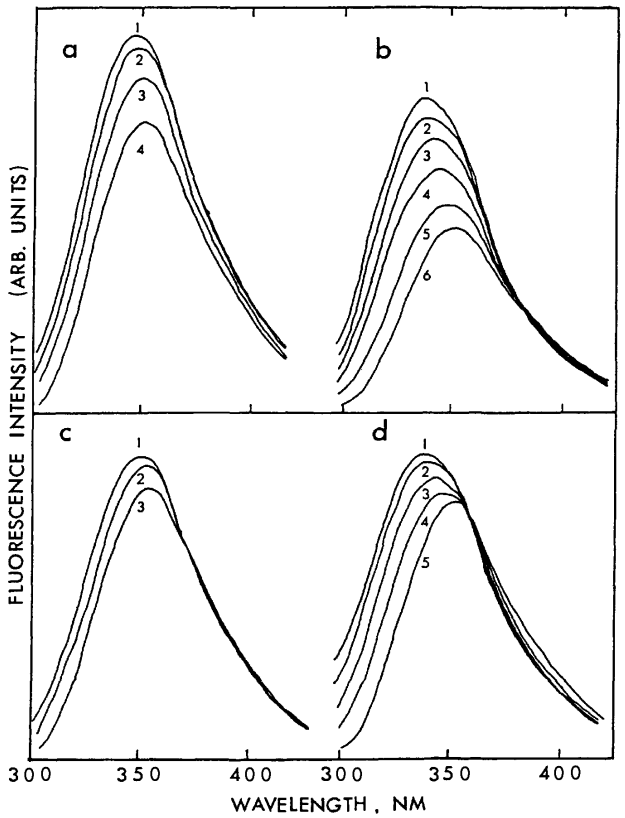

Fig. 1. Fluorescence spectra of LTL in the presence of DMPS vesicles in 20 mM Tris-acetate buffer: LTL concentration, 12.5 μM; (a) pH 5.0; 25 °C; DMPS concentration; 1, 200 μM; 2, 100 μM; 3, 50 μM; 4, 0 μM; (b) pH 5.0; 45 °C; DMPS concentration; 1, 150 μM; 2, 100 μM; 3, 75 μM; 4, 50 μM; 5, 25 μM; 6, 0 μM; (c) pH 7.0; 25 °C; DMPS concentration; 1, 150 μM; 2, 50 μM; 3, 0 μM; (d) pH 7.0; 45 °C; DMPS concentration; 1, 250 μM; 2, 200 μM; 3, 100 μM; 4, 50 μM; 5, 0 μM.

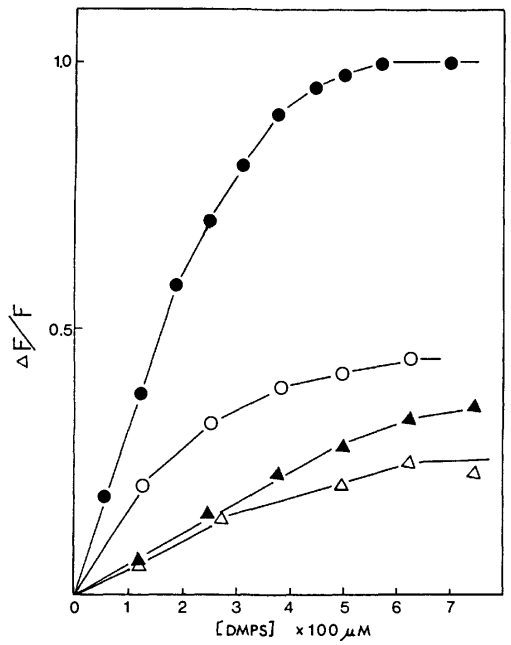

Fig. 2. Relative increase of LTL fluorescence intensity ($\Delta F/F$) on the addition of DMPS: —●—, pH 5.0 at 45 °C; —○—, pH 5.0 at 25 °C; —▲—, pH 7.0 at 45 °C; —△—, pH 7.0 at 25 °C; LTL concentration, 12.5 μM.

at different pHs and temperatures. The fluorescence spectrum of free LTL excited at 280 nm has a maximum at 352 nm. Upon addition of DMPS, the spectrum shifted to shorter wavelengths and the fluorescence intensity increased with increasing concentration of DMPS. From the variation of the fluorescence, titration curves for the binding of LTL to DMPS under various conditions were constructed by plotting $\Delta F/F$ values against the concentration of DMPS, where F is the fluorescence intensity of free LTL and ΔF is the difference in the fluorescence intensities between free and bound LTLs. As shown in Fig. 2, $\Delta F/F$ values increased with increasing concentration of DMPS and reached a plateau for all samples. It is noticeable that the titration curve was varied with pH and temperature. The $\Delta F/F$ values at pH 5.0 were larger than those at pH 7.0, and increased with increasing temperature. Ratios of the maximal fluorescence $\Delta F^{max}/F$ of the LTL-DMPS complex to that of free LTL were obtained at different pHs and temperatures. At pH 5.0 and 26 °C, the $\Delta F^{max}/F$ value was 1.45 and the emission maximum was 348 nm. The emission maximum shifted to 335 nm and the $\Delta F^{max}/F$ value increased to 2.0 with increasing temperature from 26 to 45 °C. Such shift of emission maximum and increase in $\Delta F^{max}/F$ value were also observed when measurement was done at pH 7.0. The maximum shifted from 348 to 340 nm and the $\Delta F^{max}/F$ value increased from 1.30 to 1.40. For better understanding of the nature of the binding of LTL to DMPS vesicles, experiments were done at various temperatures with an LTL-DMPS complex in which the LTL molecule was completely saturated with DMPS vesicles. As shown in Fig. 3, the fluorescence intensity of the LTL-DMPS complex decreased markedly with elevation of temperature from 25 to 36 °C, whereas the emission maximum remained unchanged. On elevation of temperature from 36 to 39 °C, the emission maximum shifted to 335 nm and the fluorescence intensity increased to the same level as at 25 °C. A further elevation of temperaure led to decrease in the fluorescence intensity without any noticeable change in the emission maximum. In the insert of Fig. 3, emission maxima of the LTL-DMPS complex at pHs 5.0 and 7.0 are plotted against temperature, in comparison with similar plots for free LTL. The emission maximum of free LTL remained unchanged when temperature was increased from 25 to 60 °C. Contrary to this, the emission maxima of the LTL-DMPS complex at pHs 5.0 and 7.0 shifted to the shorter wavelength side abruptly at 26 and 36 °C, respectively.

Figure 4 shows the temperature dependence of the

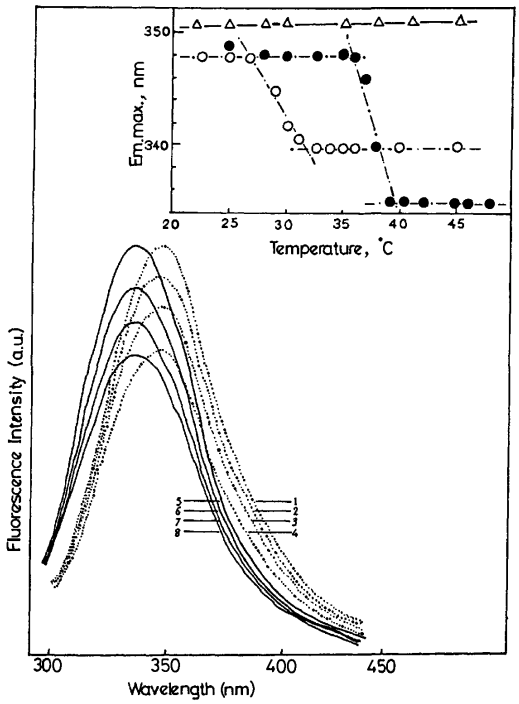

Fig. 3. Temperature dependence of fluorescence spectrum of bound LTL at pH 5.0: 1, 25; 2, 28; 3, 31; 4, 36; 5, 39; 6, 42; 7, 45; 8, 48 °C; Insert, temperature dependence of the fluorescence maximum of LTL; —△—, free LTL at pH 5.0; —○—, bound LTL at pH 7.0; —●—, bound LTL at pH 5.0.

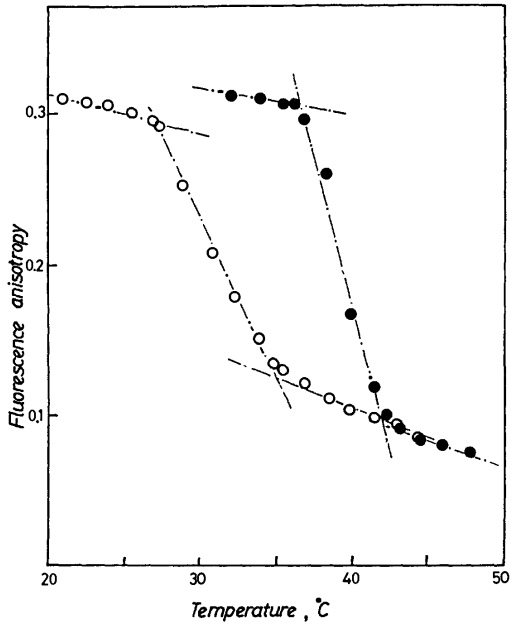

Fig. 4. Fluorescence anisotropy of DPH in DMPS vesicles: —○—, pH 7.0; —●—, pH 5.0; [DMPS]/[DPH]=1000.

fluorescence anisotropy of DPH in DMPS vesicles. When the temperature of gel-liquid crystalline phase transition (T_c) was evaluated from the midpoint of the anisotropy change as shown in Fig. 4, the T_c of DMPS was found to be 39 °C at pH 5.0 and 31 °C at pH 7.0.

Kinetics of Fluorescence Decay. The fluorescence decay kinetics of LTL was analyzed according to the equation

$$F(t)=\sum_j A_j \exp(-t/T_j), \quad (1)$$

where $F(t)$, A_j, and T_j are the fluorescence intensity at t, normalized preexponential factor, and lifetime of the jth component, respectively. The fluorescence decay of LTL in the presence of DMPS vesicles obeys the double exponential kinetics. As shown in Fig. 5, an analysis using the double exponential kinetics has

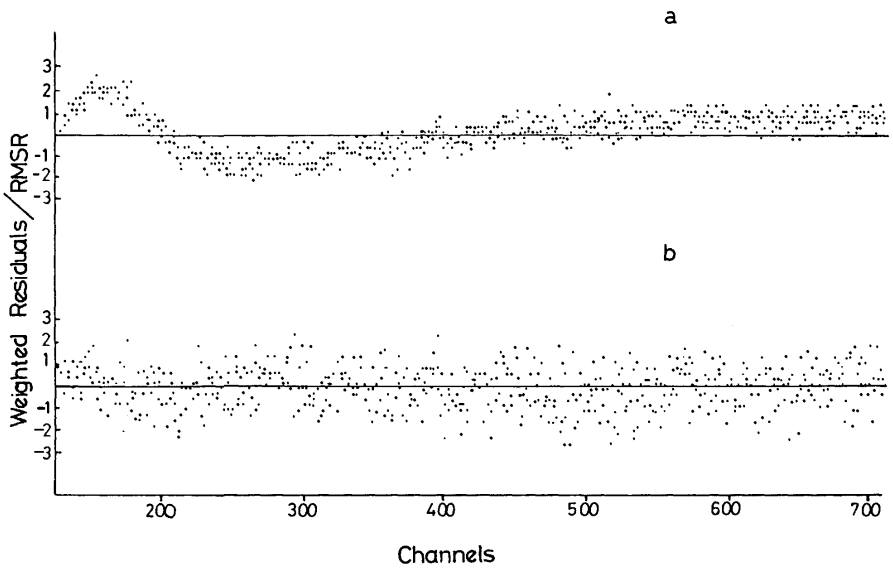

Fig. 5. Plots of weighted residuals after iterative convolution of the fluorescence decay of the bound LTL ([DMPS]/[LTL]=50, 30 °C, pH=5.0) for the best fits: (a) single exponential decay function; (b) double exponential decay function. E_m=335 nm, 22 ps/channel.

Table 1. Kinetic Parameters of the Fluorescence Decay of LTL

	pH	Temp/°C	T_1/ns[a)]	T_2/ns[a)]	A_1	A_2
Buffer	5.0	26	2.24	0.90	0.51	0.51

a) Standard error=0.02 (for T_1), and 0.03 (for T_2), the weighted root mean square residuals (RMSR) of all measurements are within 1.0±0.1. RMSR=$[1/N\sum_i^C 1/R_{ie}\,(R_{ie}-R_{ic})^2/R_{ie}]^{1/2}$, where N is the number of degrees of freedom, C is the number of channels, and R_{ie} and R_{ic} are, respectively, the experimental and calculated numbers of counts in the ith channel.

revealed that the weighted residuals (RMSR) distribute homogeneously and that the root mean square residuals are nearly 1.0 (panel b), whereas the single exponential analysis gives an extremely heterogeneous distribution of the residuals (panel a). The decay of free LTL also perfectly fits to the double exponential kinetics. The resulting decay parameters are summarized in Table 1. The two preexponential factors (A_1 and A_2) of LTL, whether free or bound, are positive and the emission wavelength dependence of the decay parameters could not be observed over the entire fluorescence spectrum region (310—450 nm). The temperature dependence of the lifetime of free LTL is different from that of the LTL-DMPS complex. When $1/T_1$ and $1/T_2$ of free LTL are plotted against $1/T$, straight lines are obtained as shown in Fig. 6. On the other hand, the lifetime of bound LTL was prolonged temporally at the phase-transition temperature of DMPS vesicles. Although the prolongation of the two lifetimes of bound LTL at pH 7.0 at the phase transition temperature was not so large as at pH 5.0, clear deviation from a linear line is observed with the plots of $\ln[1/T_1, 1/T_2]$ against $1/T$. The fluorescence decays of free and bound LTL can be described in terms of the same type of kinetics (double exponential kinetics). But the decay parameters of free LTL are modified by the binding with DMPS vesicles. A comparison of the lifetime of free LTL with that of bound LTL has revealed that at each temperature in the presence of vesicles the longer lifetime is prolonged, the shorter becoming still shorter. This suggests a peculiar interaction of LTL with DMPS vesicles.

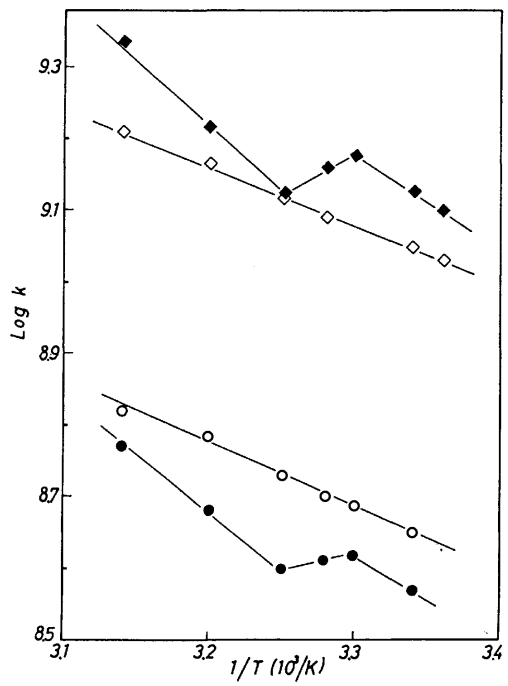

Fig. 6. Temperature dependence of the fluorescence decay constant of LTL at pH 5.0: —◆—, short lived component of bound LTL; —◇—, short lived component of free LTL; —●—, long lived component of bound LTL; —○—, long lived component of free LTL; [DMPS]/[LTL]=50; $k=1/T_1, 1/T_2$.

Solute Quenching of Tryptophan Fluorescence. The fluorescence intensity of bound LTL was measured in the presence of acrylamide, and quenching data were analyzed in accordance with the Stern-Volmer plot based on the equation

$$F_0/F=1+k_qT_{av}[Q] \quad (2)$$

where F_0 and F are the fluorescence intensities in the absence of acrylamide and in its presence at concentration [Q], respectively, k_q is the quenching constant, and T_{av} is the weighted mean lifetime of bound LTL which is defined as $T_{av}=(A_1T_1+A_2T_2)/(A_1+A_2)$. In the plots of F_0/F versus the concentration of acrylamide, straight lines were obtained for all the samples as shown in Fig. 7. In Fig. 8, quenching constants (k_q) are plotted against temperature. Quenching constants of free LTL increase linearly with elevation of temperature. However, reflection points are found at the T_c of DMPS (29 °C at pH 7.0 and 38 °C at pH 5.0) in the plots given for the LTL-DMPS complex, and k_q values increase above the phase transition

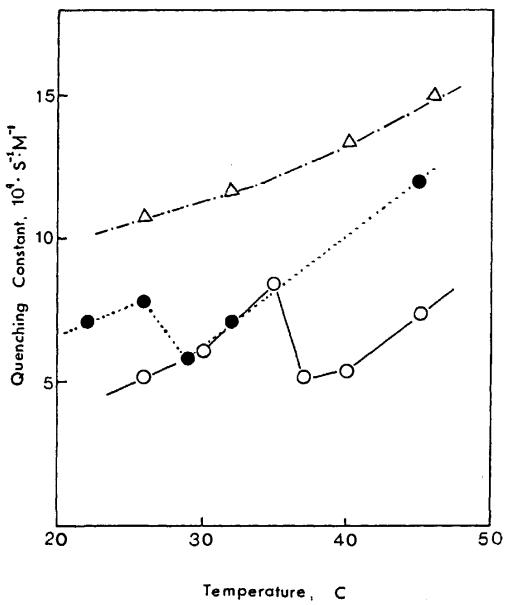

Fig. 8. Temperature dependence of quenching constant for the fluorescence of bound and free LTL: ---△---, free LTL at pH 5.0; —○—, bound LTL at pH 5.0; ---●---, bound LTL at 7.0; [DMPS]/[LTL]=50; Weighted mean lifetimes were used for evaluating the quenching constant (see text).

temperatures.

Discussion

The results presented here provide some insight into the property of the binding of LTL, a tripeptide, to DMPS vesicles. In this work, the intrinsic fluorescence of LTL due to the tryptophan residue was advantageously utilized to analyze the peptide-lipid interaction. As demonstrated here, the binding of LTL to DMPS vesicles induces a shift of the fluorescence emission maximum and change in the fluorescence intensity of LTL (Fig. 1). Such a change in the fluorescence spectrum of LTL can be interpreted as being due to a change in the environment of the tryptophan residue caused by the binding with DMPS vesicles. It is noteworthy that the interaction of LTL with DMPS vesicles, resulting in change in fluorescence spectrum, is greatly influenced by temperature (Fig. 2). Below the phase-transition temperature of DMPS vesicles, the binding of LTL to DMPS induced only a slight shift of emission maximum, whereas large shift of emission maximum was observed above the phase-transition temperature (Fig. 3). Such a difference in the fluorescence spectra of the LTL-DMPS complex observed below and above T_c is attributable to the difference in the behavior of the tryptophan residue in the phospholipid between the gel and liquid crystalline phases. It is postulated that in the temperature range below the T_c of DMPS vesicles, the indole side chain of the tryptophan residue of the peptide would slip into the environment of the acyl chain moiety of DMPS vesicles which is less polar than that in the aqueous medium, but that it would still remain near the head group, i.e., the phosphatidylserine moiety of the DMPS molecule. It is plausible that in the liquid crystalline phase of DMPS vesicles, the packing of the phospholipid is less dense than in the gel phase, which facilitates the penetration of the indole side chain of tryptophan into DMPS vesicles. Such a view is consistent with our previously postulated model in which the gel phase of phospholipid is so tightly packed as to prevent the entry of the indole ring into the acyl moiety of the phospholipid bilayer. NMR studies on lipid-water systems[8,9] have indicated that phosphatidylserine has a rigid head group as compared to phosphatidylcholine and phosphatidylethanolamine, and that the distance of head groups between DMPS molecules in the vesicles is made longer when the phase transition of vesicles occurs. In the solute quenching experiment, the quenching constant for tryptophan fluorescence in the LTL-DMPS complex was reduced at the phase-transition temperature of DMPS vesicles both at pHs 5.0 and 7.0 (Fig. 4). Such a change in the quenching constant as observed at T_c might be explained by change in the distance between head groups in DMPS molecules in vesicles as suggested by NMR measurements.

The phase-transition temperature of DMPS evaluated from the fluorescence anisotropy of DPH is 39 °C at pH 5.0 and 31 °C at pH 7.0 (Fig. 4). These values are in good agreement with those obtained from phase-transition titration curves using spin probe.[10] However, the apparent transition temperatures estimated from the shift of the emission maximum of the LTL-DMPS complex are lower than the T_c values obtained by the fluorescence anisotropy of DPH (the

insert in Fig. 3). The discrepancy of the transition temperatures of DMPS vesicles observed between the two methods may be due to perturbation to the order of the acyl chains in DMPS vesicles caused by the binding with LTL. It has been reported that an electrostatic binding of positively charged molecules to DMPS led to a marked increase in the T_c of phospholipid.[11] In the present case, however, the T_c of DMPS was reduced after DMPS's binding with LTL. There may be differences in modes of binding to phospholipid between LTL and other cationic molecules.

The time resolved fluorescence study also supports the penetration of the tryptophan residue into deeper sites of the membrane on phase transition. The prolongation of the fluorescence lifetime on phase transition is coincident with the solvent polarity dependence of the fluorescence lifetime of indole which is the chromophore of tryptophan residue. The mean lifetime of indole in nonpolar solvent is longer than in aqueous solution, although the radiative lifetime is almost the same.[12]

The double exponential decay kinetics from a single fluorophore arises from the existence of a ground state equilibrium, since the preexponential terms are both positive and their ratio is nearly constant over the entire fluorescence spectrum of LTL. It is confirmed that three rotamers around C_α-C_β of tryptophan residue are responsible for the multiexponential fluorescence decay since they give heterogeneous microenvironments to LTL in association with the decay of the excited singlet state. The indole rings of two rotamers (rotamers I and III) are adjacent to the C_α-carbonyl group and -H or -NH. The other rotamer (rotamer II) has a structure such that the indole is not close to the carbonyl group. C_α-Carbonyl group is an efficient intramolecular quencher in indole derivatives (A. G. Szabo and D. T. Krajcarski, unpublished observation). According Szabo et al.,[12,13] therefore, the longer lived component can be assigned to rotamer II, and rotamers I and III account for the shorter lifetime. The dual fluorescence emission can be rationalized if the quenching efficiences of rotamers I and III are similar to each other or if their interconversion is very rapid. On the basis of the above assignment, the biphasic effect (prolongation of T_1 and shortening of T_2) of the binding on the fluorescence lifetimes of LTL suggests a peculiar interaction between LTL and DMPS. It is clear that the prolongation of T_1 of free LTL by the binding with DMPS is caused by the decrease in polarity of the environment around the indole side chain. The indole side chain of T_2 component also must be under the same conditions. However, clear shortening of T_2 was observed to be caused by the binding with DMPS. This suggests that some quenching interaction which works effectively for rotamer I and III is created by the binding with DMPS. For such specific interaction, we postulate a structural distortion of LTL resulting in the enhancement of the quenching efficiency of C_α carbonyl group. The indole ring could be more accessible to the carbonyl group by the distortion induced by the binding. Since the quenching by the carbonyl group is not involved in the decay channel of rotamer II, the fluorescence lifetime of rotamer II is free from such an effect. Some contribution due to the intermolecular quenching by DMPS should be examined closely. But it seems unreasonable, because the quenching by any groups of DMPS such as carboxyl group is not so efficient as carbonyl group. If DMPS acted as an efficient quencher, we could not observe the increase in the fluorescence quantum yield of LTL with the binding with DMPS as shown in Figs. 1 and 2.

The steady state and time resolved fluorescence studies have consistently described the phase dependence of the interactions between LTL and DMPS vesicles. Further, it has been suggested that structural change of LTL is induced by the binding with the membrane. The present results can give no fine detailed structure of LTL in the membrane. But increase of our knowledge on the photophysics of tryptophan by means of improved instrumentation could contribute to solving the problems we have proposed here.

The Preparation, Stereochemistry, and Oxidation of 2-Pyridinethiolato Cobalt(III) Complexes, and the Crystal Structure of [Co(2-pyridinethiolato)(en)$_2$](ClO$_4$)$_2$

Masakazu KITA,*,† Kazuaki YAMANARI, and (the late) Yoichi SHIMURA
Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received January 27, 1989)

A series of mixed complexes $[Co(pyt)_{3-n}(diamine)_n]^{n+}$ (n=0, 1, and 2; pyt=2-pyridinethiolate(1−) and diamine=ethylenediamine, (*R*)-propylenediamine, or 2,2′-bipyridine) have been prepared and characterized by means of their visible and ultraviolet absorption, circular dichroism, and magnetic circular dichroism spectra. In the [Co(pyt)$_3$] or [Co(pyt)$_2$(diamine)]$^+$ complex, only one geometrical isomer, *mer(S)* or *trans(S)* respectively, has been obtained. The [Co(pyt)(en)$_2$](ClO$_4$)$_2$ complex, which was spontaneously resolved, had an orthorhombic space group of $P2_12_12_1$, with a=12.406(1), b=12.754(1), c=11.621(4) Å, V=1838.7(6) Å^3, and Z=4. The refinement of 2276 reflections (Mo $K\alpha$ radiation) led to R=0.049. The Co–N bond trans to the pyt sulfur atom was longer by 0.023(11) Å than the cis one. The novel oxidation product [Co(2-pyridinesulfenato-*N*,*S*)(en)$_2$]$^{2+}$ was photochemically converted into the *N*,*O*-chelated linkage-isomer [Co(2-pyridinesulfenato-*N*,*O*)(en)$_2$]$^{2+}$ in the solid state, accompanied by ring-expansion from a four- to a five-membered chelate ring.

We have long been interested in the synthesis and stereochemistry of cobalt(III)[1] and rhodium(III)[2] complexes containing various kinds of bidentate-*N*,*S* ligands, such as 2-aminoethanethiol (=Haet), L-cysteine, L-cysteine methyl ester, and their oxidation derivatives. We previously prepared only *fac(S)* isomers of the [M(III)(bidentate-*N*,*S*)$_3$] (M=Co(III) and Rh(III)) type complexes. On the other hand, 2-pyridinethiolate(1−)(=pyt), which is an aromatic bidentate-*N*,*S* ligand and which forms a 4-membered chelate ring on coordination, showed a different stereochemical preference, as was reported in our preliminary papers.[3,4]

This paper will describe the preparation and characterization of a series of cobalt(III) complexes containing pyt [Co(pyt)$_{3-n}$(diamine)$_n$]$^{n+}$ (diamine= ethylenediamine(=en), (*R*)-propylenediamine(=R-pn), or 2,2′-bipyridine(=bpy); n=0, 1, or 2) by means of their electronic absorption, circular dichroism (CD), magnetic circular dichroism (MCD), and ^{13}C NMR spectra. In the complexes of [Co(pyt)$_3$] or [Co(pyt)$_2$(diamine)]$^+$, one geometrical isomer, *mer(S)* or *trans(S)* respectively, was obtained. These results are quite different from those obtained from complexes with aliphatic *N*,*S*-ligands. The crystal structure of [Co(pyt)(en)$_2$](ClO$_4$)$_2$ revealed the trans influence (trans lengthening) induced by the pyt sulfur donor atom. The difference in the electronic structures of the pyt and aet complexes is discussed on the basis of the X-ray crystal data. The orange sulfenato complex, which is the oxidation product of [Co(pyt)(en)$_2$](ClO$_4$)$_2$, changed photochemically into a green one in the solid state. These complexes were characterized as novel linkage isomers with a *N*,*S*- and *N*,*O*-chelate as the basis of the X-ray photoelectron spectra (XPS).

Experimental

Preparation, Separation, and Optical Resolution of 2-Pyridinethiolato Complexes. Most of the complexes were prepared by a redox reaction between di-2-pyridyl disulfide and the cobalt(II) ion.

(1) [Co(pyt)(en)$_2$](ClO$_4$)$_2$: Into a solution of Co(ClO$_4$)$_2$·6H$_2$O) (17.0 g, 0.046 mol) in 30 cm^3 of ethanol we stirred a solution of ethylenediamine (6.0 g, 0.1 mol) in 40 cm^3 of ethanol. To the resulting solution we then immediately added a solution of di-2-pyridyl disulfide (5.0 g, 0.023 mol) in 100 cm^3 of ethanol, after which the mixture was stirred at ca. 50 °C for 2 h. The resulting brown precipitate was filtered and washed with ethanol (100 cm^3) and diethyl ether (100 cm^3). The precipitate was recrystallized by dissolving it in hot water (ca. 70 °C), filtering it, and cooling it to ca. 5 °C. At this stage, the orthorhombic brown crystals of [Co(pyt)(en)$_2$](ClO$_4$)$_2$ obtained were spontaneously resolved, as was confirmed by the CD spectrum of the aqueous solution, which contained one crystal, and by the following X-ray crystallographic data with a chiral space group. The yield was 18.0 g (80%). Found: C, 22.27; H, 4.20; N, 14.41%. Calcd for [Co(pyt)(en)$_2$](ClO$_4$)$_2$=$C_9H_{20}N_5O_8SCl_2Co$: C, 22.14; H, 4.13; N, 14.35%.

For optical resolution, a solution of $K_2[Sb_2\{(R,R)\text{-}C_4H_2O_6\}_2]\cdot 3H_2O$ (1.4 g, 0.002 mol) in 30 cm^3 of water was added to a solution of [Co(pyt)(en)$_2$](ClO$_4$)$_2$ (2.0 g, 0.004 mol) in 30 cm^3 of water. Immediately, crystals of *Λ*[Co(pyt)(en)$_2$][$Sb_2\{(R,R)\text{-}C_4H_2O_6\}_2$]·5H$_2$O which showed a positive CD peak at 588 nm began to deposit, they were filtered off. Ten grams of NaClO$_4$ were then added to the filtrate, and the solution was cooled to induce crystallization. The crystals of *Δ*-[Co(pyt)(en)$_2$](ClO$_4$)$_2$ were collected and recrystallized from hot water. Found for the *Λ*-diastereomer: C, 22.38; H, 3.65; N, 7.61%. Calcd for *Λ*-[Co(pyt)(en)$_2$][$Sb_2\{(R,R)\text{-}C_4H_2O_6\}_2$]·5H$_2$O=$C_{17}H_{34}N_5O_{17}SCoSb_2$: C, 22.32; H, 3.75; N, 7.65%. Found for the *Δ*-complex: C, 22.30; H, 4.13; N, 14.32%. Calcd for *Δ*-[Co(pyt)(en)$_2$](ClO$_4$)$_2$=$C_9H_{20}N_5O_8SCl_2Co$: C, 22.14; H, 4.13; N, 14.35%.

(2) [Co(pyt)$_2$(en)]ClO$_4$: This complex was obtained as a by-product (1.0 g, 5%) from the mother liquor in the above preparation, but was prepared in a higher yield by the following method. Di-2-pyridyl disulfide (1.5 g, 0.0068

mol) was stirred into a solution of $Co(ClO_4)_2 \cdot 6H_2O$ (5.0 g, 0.0135 mol) in 50 cm^3 of ethanol. To this solution we then added a mixed solution of 2-pyridinethiol (1.5 g, 0.0135 mol) and ethylenediamine (1.0 g, 0.0166 mol) in 50 cm^3 of ethanol. After a few minutes, a green precipitate began to deposit. The mixture was stirred at ca. 50 °C for 2 h. The resulting green precipitate was filtered and washed with cold water (below 5 °C) until the washings were no longer brown. The precipitate was then recrystallized from water (ca. 70 °C). Columnar green crystals with a metallic luster were thus collected (4.3 g, 72%). Found: C, 32.98; H, 3.69; N, 12.81%. Calcd for $[Co(pyt)_2(en)]ClO_4=C_{12}H_{16}N_4O_4S_2ClCo$: C, 32.85; H, 3.67; N, 12.77%.

(3) [Co(pyt)$_3$]: This nonelectrolyte complex was effectively prepared by the reaction of freshly prepared CoO(OH) (0.015 mol) with 2-pyridinethiol (5.0 g, 0.045 mol) in 200 cm^3 of ethanol-water (1 : 1). The dark brown orthorhombic crystals of $[Co(pyt)_3]$ (5.0 g, 90%) were collected by filtration and recrystallized by dissolving them in dimethyl silfoxide (DMSO) and by then adding water. The yield was 4.7 g (80%). Found: C, 46.27; H, 3.18; N, 10.92%. Calcd for $[Co(pyt)_3]=C_{15}H_{12}N_3S_3Co$: C, 46.27; H, 3.18; N, 10.79%.

(4) [Co(pyt)$_2$(R-pn)]ClO$_4$: A bis(2-pyridinethiolato) complex containing (*R*)-propylenediamine $[Co(pyt)_2(R\text{-}pn)]ClO_4$ was prepared by the same procedure as that used for $[Co(pyt)_2(en)]ClO_4$ except for the use of R-pn instead of en. A pair of green diastereomers, *Λ*-$[Co(pyt)_2(R\text{-}pn)]ClO_4$ (more soluble in ethanol) and *Δ*-$[Co(pyt)_2(R\text{-}pn)]ClO_4$ (less soluble in ethanol), was obtained. Found for the *Λ*-diastereomer: C, 34.34; H, 4.00; N, 12.17%. Found for the *Δ*-diastereomer: C, 34.74; H, 4.04; N, 12.47%. Calcd for *Λ*- or *Δ*-$[Co(pyt)_2(R\text{-}pn)]ClO_4=C_{13}H_{18}N_4O_4S_2ClCo$: C, 34.48; H, 4.01; N, 12.37%.

(5) [Co(pyt)(bpy)$_2$](ClO$_4$)$_2$: Into a solution of $Co(ClO_4)_2 \cdot 6H_2O$ (7.3 g, 0.020 mol) in 30 cm^3 of water we stirred a solution of 2,2′-bipyridine (6.2 g, 0.040 mol) in 40 cm^3 of hot ethanol. To the solution we then immediately added a solution of di-2-pyridyl disulfide (2.2 g, 0.010 mol) in 100 cm^3 of ethanol, after which the mixture was stirred at ca. 70 °C for 2 h. The resulting brown precipitate was filtered and washed with ethanol (100 cm^3) and diethyl ether (100 cm^3). The precipitate was recrystallized from water (ca. 70 °C). The yield was 12 g (85%). Found: C, 42.22; H, 3.22; N, 9.66%. Calcd for $[Co(pyt)(bpy)_2](ClO_4)_2 \cdot 1.5H_2O=C_{25}H_{23}N_5O_{9.5}SCl_2Co$: C, 42.45; H, 3.28; N, 9.90%.

(6) [Co(pyt)$_2$(bpy)]ClO$_4$: Di-2-pyridyl disulfide (2.0 g, 0.0091 mol) was stirred into a solution of $Co(ClO_4)_2 \cdot 6H_2O$ (7.3 g, 0.020 mol) in 60 cm^3 of water-ethanol (1 : 3). To this solution we then added a mixed solution of 2-pyridinethiol (2.0 g, 0.0182 mol) and 2,2′-bipyridine (4.0 g, 0.0256 mol) in 50 cm^3 of ethanol. The mixture was stirred at ca. 70 °C for 2 h. The resulting brown-green precipitate was filtered and washed with hot water until the washings were no longer brown. The precipitate was recrystallized from methanol. Needle-like yellow-green crystals were collected (5.0 g, 47%). Found: C, 44.85; H, 3.09; N, 10.42%. Calcd for $[Co(pyt)_2(bpy)]ClO_4=C_{20}H_{16}N_4O_4S_2ClCo$: C, 44.91; H, 3.01; N, 10.47%.

Oxidation of [Co(pyt)(en)$_2$](ClO$_4$)$_2$ and Photoisomerization of the Oxidation Product. A solution of 30% aqueous H_2O_2 (10 g) and 60% aqueous $HClO_4$ (10 g) was stirred into a solution of *Δ*-$[Co(pyt)(en)_2](ClO_4)_2$ (5 g) in 50 cm^3 of DMSO below 5 °C to give an orange solution instantly. To the resulting solution we immediately added a mixture of diethyl ether (700 cm^3) and ethanol (300 cm^3). Orange crystals appeared on the inside wall of a beaker in a few minutes; they were filtered. The yield was ca. 1 g. Found: C, 21.44; H, 3.93; N, 13.53%. Calcd for $(-)^{CD}_{507}$-$[Co(pyse)(en)_2](ClO_4)_2=C_9H_{20}N_5O_9SCl_2Co$: C, 21.44; H, 4.00; N, 13.89% (Hpyse=2-pyridinesulfenic acid).

The orange pyse complex immediately turned a green one in the solid state upon exposure to the sun or a fluorescence lamp. The results of an elemental analysis of the photoproduct were identical with the original formula $[Co(pyse)(en)_2](ClO_4)_2$. The DMSO or aqueous solution of the orange complex became dark brownish within several tens minutes, even in the dark. Such a color change in solution was caused probably by redox decomposition and/or solvolysis. However, the green pyse complex was stable in an aqueous or DMSO solution at room temperature.

Measurements. The visible and ultraviolet absorption spectra were measured on a Hitachi 330 spectrophotometer. The CD spectra were recorded on a JASCO MOE-1 spectropolarimeter, and the MCD spectra on the same instrument in 1.5 T magnetic field. The absorption, CD, and MCD measurements were carried out in DMSO and H_2O solutions at the low- and high-energy regions respectively. The XPS data were recorded on a Shimadzu HIPS 70 apparatus. The binding energies relative to the Fermi level were determined by referring to the Na-2s (64.0 eV) and S-$2p_{3/2}$ (169.5 eV) values of Na_2SO_4 mixed with an appropriate amount of each sample. All the measurements were done at room temperature.

X-Ray Study of [Co(pyt)(en)$_2$](ClO$_4$)$_2$. A brown crystal (0.40×0.39×0.33 mm) of the title compound was used for the data collection. Crystal data: orthorhombic, $P2_12_12_1$, a=12.406(1), b=12.754(1), c=11.621(4) Å, and V=1838.7(6) Å^3, D_{calcd}= 1.76, D_{obsd}=1.80 g cm^{-3}, and Z=4. It is very interesting that this complex is spontaneously resolvable, for in the corresponding aet complex the perchlorate forms a conglomerate.[5] The diffraction intensities were measured using a Rigaku four-circle diffractometer, with graphite monochromatized Mo$K\alpha$ radiation (λ=0.71069 Å). μ(Mo$K\alpha$)= 13.80 cm^{-1} and no absorption correction was applied. Within the range of $24° < 2\theta < 55°$, 2276 independent reflections ($I < 3\sigma(I)$) were obtained. All the computations were performed on a HITAC M-200H computer at the Computer Center of the Institute for Molecular Science using the Universal Crystallographic Computation Program System UNICS III.[6] The structure was solved by the usual heavy-atom method. The positions of ten hydrogen atoms were identified in subsequent difference Fourier maps, but the others could not be determined. The positional parameters of the hydrogen atoms, the anisotropic thermal parameters for all the non-hydrogen atoms, and the complete list of $|F_o|$ and $|F_c|$ values are deposited as Document No. 8892 at the Office of the Editor of the Bull. Chem. Soc. Jpn.

Results and Discussion

Characterization and Stereochemistry of 2-Pyridinethiolato Complexes. The electronic strucutre of the Hpyt compound in acidic conditions is considered to be comparable to that of the pyt-*N,S* ligand in a metal complex. In a 0.1 mol dm^{-3} $HClO_4$ solution, the absorption spectrum of the Hpyt compound showed

Table 1. Absorption Spectral Data

a) Wavenumbers are given in 10^3 cm^{-1} units, and log ε (in parentheses), in mol^{-1} dm^3 cm^{-1}, while sh means a shoulder.

two intense absorption bands, at ca. 27000 and ca. 36000 cm^{-1} (Table 1). The energetically lower and higher bands can be assigned to the π^*(py)$\leftarrow$n(s) and π^*(py)$\leftarrow\pi$(py) transitions respectively (py=pyridine). Such bands can also be expected to appear in the spectra of the pyt complexes.

The absorption, CD, and MCD spectra of $[Co(pyt)(en)_2](ClO_4)_2$ (Fig. 1 and Tables 1, 2, and 3) are quite similar to those of $[Co(aet)(en)_2](ClO_4)_2$[7,8] (aet=2-aminoethanethiolato) in the spin-allowed first d-d transition band region. The shoulder at ca. 17000 cm^{-1} in the CD spectrum (or the positive MCD peak at 17330 cm^{-1}) and the negative CD peak at 19800 cm^{-1} are assigned to the components generated from the $^1E\leftarrow{}^1A_1$ transition in the C_{4v} symmetry on the CoN_5S geometry. These splittings have been ascribed by Houlding et al.[8,9] to the perturbation of the p-like lone pair of the two remaining lone-pairs on the sulfur atom. The positive CD band and the negative MCD one at ca. 22000 cm^{-1} are assigned to the $^1A_2\leftarrow{}^1A_1$ (C_{4v}) transition. The energy peaks at ca. 12000 and 14000 cm^{-1} in the CD and MCD spectra are assigned to the spin-forbidden d-d transition, $^3T_{1g}\leftarrow{}^1A_{1g}$ and $^3T_{2g}\leftarrow{}^1A_{1g}(O_h)$ respectively. The bands at 30000, 35000, and 39000 cm^{-1} in the absorption spectra (in H_2O) can be assigned to π^*(py)$\leftarrow$n(S), σ^*(Co)$\leftarrow\sigma$(S), and π^*(py)$\leftarrow\pi$(py) transitions respectively on the basis of the spectrum-pattern similarity of the Hpyt compound under acidic conditions.

The absorption and MCD spectra of $[Co(pyt)(bpy)_2](ClO_4)_2$ (Tables 1 and 3) are quite similar to those of $[Co(aet)(en)_2](ClO_4)_2$ and $[Co(pyt)(en)_2](ClO_4)_2$ in the spin-allowed first d-d transition region. The positive MCD peak at 15900 cm^{-1} and the negative one at 20400 cm^{-1} of $[Co(pyt)(bpy)_2](ClO_4)_2$ are energetically lower by ca. 1400 and ca. 1900 cm^{-1} respectively, than the corresponding peaks of $[Co(pyt)(en)_2](ClO_4)_2$; tentatively, the difference can be attributed to the destabilization of the Co dπ orbitals by the pi-donor character of bpy ligand.

The absorption and MCD spectra of $[Co(pyt)_2(en)]ClO_4$, and the absortion and CD spectra of *Λ*- and *Δ*-$[Co(pyt)_2(R\text{-}pn)]ClO_4$, are shown in Figs. 2 and 3 respectively. For the former en complex, three geometrical isomers, *C*$_2$-*cis*(*S*), *C*$_1$-*cis*(*S*), and *trans*(*S*), are possible. However, only one green isomer was obtained for $[Co(pyt)_2(en)]^+$, as for $[Co(pyt)_2(R\text{-}pn)]^+$. The bis(pyt) complexes are assigned to a *trans*(*S*) isomer on the basis of the fair agreement of the absorption spectra of the *trans*(S)-$[Co(thiolato)_2(amine)_4]^+$-type complexes[10] in the spin allowed first d-d transition region. The intense transitions, π^*(py)$\leftarrow$n(S) at 28000 cm^{-1} and σ^*(Co)$\leftarrow\sigma$(S) at 32000 cm^{-1}, were considerably red-shifted compared with those of

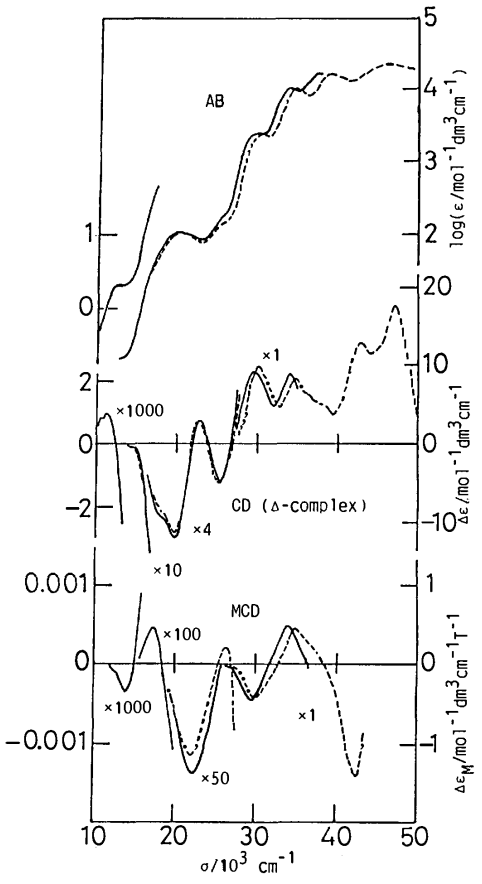

Fig. 1. Absorption, CD (for *Δ*-complex), and MCD spectra of $(Co(pyt)(en)_2](ClO_4)_2$ (—— in DMSO and ----in H_2O).

$[Co(pyt)(en)_2](ClO_4)_2$; tentatively, this may be attributed to the destabilizations of the sulfur nonbonding and sigma-donor orbitals by the mutual 'trans-influence' of the *trans*-*S* donors, whereas the π^*(py)← π(py) transition (38000 cm^{-1}) does not shift.

The absorption and MCD spectra of $[Co(pyt)_2(bpy)]ClO_4$ (Tables 1 and 3) were similar to those of *trans*(*S*)-$[Co(pyt)_2(en)]ClO_4$ in the spin-allowed first d-d transition region. Therefore, the bpy complex is also assigned to the *trans*(*S*) isomer.

Figure 4 shows the absorption and MCD spectra of $[Co(pyt)_3]$. In this complex, only one of the two possible geometrical isomers, *fac*(*S*) and *mer*(*S*), was obtained. This dark brown complex is assigned to a *mer*(*S*) isomer on the basis of the ^{13}C NMR spectrum in the $CDCl_3$ solution, which showed eight resonances; 116.87[b], 125.48[b], 135.45, 135.94, 136.59, 147.10[b], 149.48[b], and 150.41[b] ppm (b=broad), whereas only five signals are expected for the *fac*(*S*) geometry. The splitting pattern of the MCD spectrum in the first d-d transition region (14300, 17900, and 21200 cm^{-1}) also supports this assignment.

The Crystal Structure of $[Co(pyt)(en)_2](ClO_4)_2$. Figure 5 shows the numbering of the title complex ion. The atomic parameters and the bond distances and angles are listed in Tables 4 and 5. The complex has a distorted octahedral structure around Co center. The bite angle of the 4-membered pyt ligand 72.9(2)° is rather narrower than a right angle. The bond length of the Co-N(5) sited trans to pyt's sulfur is 1.993(6) Å, while the average of the Co-N(2) and Co-N(4) sited cis to the sulfur is 1.970(9) Å; that is, the difference is 0.023(11) Å. The trans-influence of the pyt thiolate is less by 0.041(10) Å than that of the aet thiolate in the corresponding complex.[11] The smaller trans influence of the pyt thiolate may be interpreted in terms of the decrease in the orbital interaction between the Co 3d and the sulfur lone pair

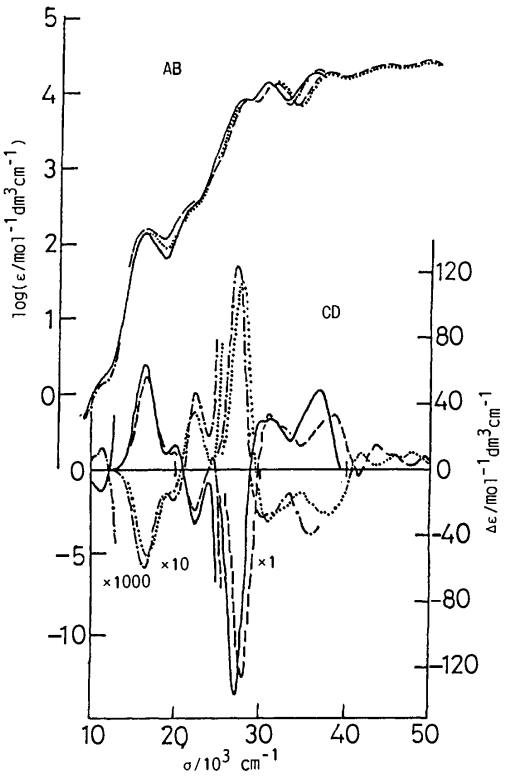

Fig. 3. Absorption and CD spectra of *Λ*-[Co(pyt)$_2$(R-pn)]ClO_4 (—— in DMSO and ---- in H_2O) and *Δ*-[Co(pyt)$_2$(R-pn)]ClO_4 (— · — in DMSO and ····· in H_2O).

orbitals, on the basis of the narrower bite angle (72.9(2)°) compared to the aet one (88.8(2)°).[11] In addition, the resonance structure **b** (anion of 2(1*H*)-pyridinethione) in Fig. 6 contributes to the pyt complex, and the sigma-donor ability of the pyt thiolate becomes weak because of the lesser electron density of the sulfur atom compared to that of the aliphatic thiolato sulfur. This resonance contribution is in good agreement with the facts that the S-C(1) bond distance (1.754(7) Å) is rather shorter than the ali-

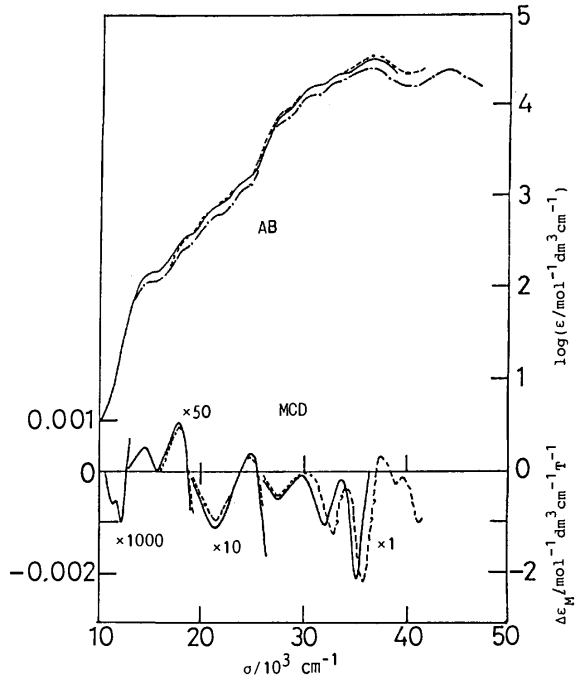

Fig. 4. Absorption and MCD spectra of [Co(pyt)$_3$] (—— in DMSO, ---- in CH_3OH, —·— in $(C_2H_5)_2O$).

phatic S-C one (1.818(8) Å)[11] and that the C(1)-C(2) and C(3)-C(4) bond distances (1.397(10) and 1.405 (14) Å respectively) are considerably longer than the C(2)-C(3) and C(4)-C(5) distances (1.355(12) and 1.362(11) Å respectively). This difference of the trans influence induced by **pyt** and **aet** may be related to the geometrical isomeric preference of the [Co(N-S)$_3$] and [Co(N-S)$_2$(N-N)]$^+$-type complexes. In fact, only the *fac* geometry has been obtained for the aet complexes [Co(aet)$_3$][1] and [Rh(aet)$_3$],[2] whereas only the *mer* geometry has been obtained for the pyt complexes [Co(pyt)$_3$] and [Rh(pyt)$_3$].[12] In the case of [Rh(6-

methyl-2-pyridinethiolato)$_3$],[13] only the fac geometry was isolated, but this is due to the steric effect of the 6-methyl groups. Thus, the aet thiolates with a relatively large trans-influence favor the cis disposition toward each other, but the pyt thiolates with a lesser trans influence make a trans disposition possible.

Characterization of the Oxidation Product [Co(pyse-*N,S*)(en)$_2$](ClO$_4$)$_2$ and Its Photoisomerization into [Co(pyse-*N,O*)(en)$_2$](ClO$_4$)$_2$. The H_2O_2 oxidation of the [Co(pyt)(en)$_2$](ClO$_4$)$_2$ in acid media resulted in an orange complex, which was characterized as the sulfenato-*N,S* complex [Co(pyse-*N,S*)(en)$_2$](ClO$_4$)$_2$ on the basis of its elemental analysis and absorption spectrum (Fig. 7). This orange complex changed into a green one photochemically in the solid state. Since the green complex has the same chemical composition, it is reasonable to consider that the linkage isomerization from *N,S*- to *N,O*-bonded is induced by to exposure light. The green complex exhibited a ligand-field transition at 16600 cm^{-1}, as is shown in Fig. 7.[14] Though the ligand-field strength of the oxygen atom of the *O*-bonded sulfenato complex is extraordinarily weak, this may be because of the repulsion between the oxygen and adjacent sulfur lone pairs. The pyse-*S,N* and -*O,N* complexes exhibit a characteristic intense absorption band at ca. 25000 cm^{-1} and ca. 26000 cm^{-1} respectively. All the known *S*-bonded sulfenato complexes showed a similar absorption band at ca. 27000 cm^{-1}. Such an intense band has generally been observed in complexes with the Co-X-Y array, where X and Y are oxygen and/or sulfur atom with lone-pair electrons.[15] The parent complex, [Co(pyt-*S,N*)(en)$_2$]$^{2+}$, did not show such an intense band in the region below 30000 cm^{-1}. On the other hand, both sulfenato complexes showed this intense band, as is consistent with the above strucutre assignments. The optically active complexes, $(-)^{CD}_{500}$-[Co(pyse-*S,N*)(en)$_2$]$^{2+}$ and its linkage isomer $(-)^{CD}_{603}$-[Co(pyse-*O,N*)(en)$_2$]$^{2+}$, are assigned to the *Δ* absolute configuration on the basis of the dominant negative CD sign at 19700 cm^{-1} and at 16600 cm^{-1} respectively in the first d-d band region.

The XPS spectra of the S-2p binding energy region for the orange and green isomers of [Co(pyse)-(en)$_2$](ClO$_4$)$_2$ are shown in Fig. 8. The orange complex exhibited a peak at 166.7 eV, with a shoulder at ca. 164 eV. The green complex showed a peak at 164.3 eV, with a shoulder at ca. 167 eV. These results indicate that the samples used for both measurements are mixtures of two species; that is, the pure orange complex should show a peak at 166.7 eV, and the pure green one, are at 164.3 eV. Since the *N,O*-coordinated pyse must show a lower sulfur binding energy because of the decrease in the partial charge on the sulfur atom as compared with the *N,S*-coordinated pyse, the orange and green isomers can be assigned to the *N,S*- and *N,O*-chelated structures respectively. Thus, the light irradiation of the 4-membered *N,S*-pyse complex caused the linkage isomerization in the solid state to give the *N,O*-chelated complex with the 5-membered ring. In general, the strain energy of a chelate ring is much eliminated in a 5-membered chelate as compared with a 4-membered one. Therefore, the present photoisomerization seems to be energetically favora-

ble. Photoisomerization has been reported in an aqueous solution of the sulfinato complex [Co(aesi-*N*,*S*)$(en)_2]^{2+}$ (Haesi=2-aminosulfinic acid), though the corresponding sulfenato complex [Co(aese-*N*,*S*)-$(en)_2]^{2+}$ (Haese=2-aminosulfenic acid) did not show any.[8]

Response and Application in Dipolar Aprotic Solvents of Ion-Selective Electrodes Based on Polyacrylamide Modified with Acyclic Poly(oxyethylene) Derivatives

Toshio NAKAMURA,* Hisakazu HIGUCHI, and Kosuke IZUTSU
Department of Chemistry, Faculty of Science, Shinshu University, Asahi, Matsumoto 390
(Received March 16, 1989)

The response of organic polymer membrane electrodes, constructed by coating a platinum disk with polyacrylamide (PAA) coupled to acyclic poly(oxyethylene) derivatives, tetraethylene glycol monododecyl ether (POE4) and hexaethylene glycol monododecyl ether (POE6) was studied in acetonitrile (AN) and *N,N*-dimethylformamide (DMF). The PAA-POE4 electrode showed Nernstian response to the lithium ion in AN and the magnesium and barium ions in DMF, while the PAA-POE6 electrode showed near Nernstian response to the barium ion in DMF. The PAA-POE4 electrode was applied to study the complexation of the lithium ion in AN with DMF. The formation constants, $\beta_1=17$ and $\beta_2=1.2\times10^2$, obtained agreed well with the values obtained previously with an univalent cation sensitive glass electrode. The response of the PAA-POE4 electrode in barium bis(2-ethylhexyl) sulfosuccinate ($Ba(DSS)_2$)-DMF solution has been studied and the results are explained by taking the conductometrically determined association constant ($K_{1A}=5.2\times10^2$) between Ba^{2+} and DSS^- ions.

Some types of ion-selective electrodes have been successfully used in physicochemical as well as in analytical studies of nonaqueous solutions.[1] Recently, we have developed some ion-selective electrodes for use in dipolar aprotic solvents.[2] One of these electrodes was used to study the complexing of the magnesium and barium ions in acetonitrile (AN) with other dipolar aprotic solvent molecules.[3] In the present paper the response and the application of the same type of ion-selective electrodes[2] constructed by coating a platinum disk with polyacrylamide (PAA) coupled to tetraethylene glycol monododecyl ether (POE4) or hexaethylene glycol monododecyl ether (POE6) are reported. The response behavior of the PAA-POE4 and PAA-POE6 electrodes to the lithium, magnesium and barium ions were investigated in several nonaqueous chemical systems. The PAA-POE4 elctrode was used to obtain the successive complex formation constants of the lithium ion in AN with *N,N*-dimethylformamide (DMF) to compare with the values obtained previously with a values obtained previously with a univalent cation sensitive glass electrode.[4] The response behavior of the PAA-POE4 electrode to barium bis(2-ethylhexyl) sulfosuccinate ($Ba(DSS)_2$) in DMF has been studied and the results are explained by taking the conductometrically determined association constant of the compound.

Experimental

Reagents. The sodium bis(2-ethylhexyl)sulfosuccinate was the product of Tokyo Kasei Kogyo Co., Ltd. and the barium bis(2-ethylhexyl) sulfosuccinate, $Ba(DSS)_2$, was prepared and purified according to the method of Kitahara et al.[5] Other reagents and solvents were the same as those in the previous report.[3]

Potentiometric Measurements. Most of the methods of the potentiometric measurements and the electrode construction were the same as those described in the previous report.[3] The responses of the electrodes were tested in the following Cell I,

Ag/10 mM $AgNO_3$+10 mM Et_4NClO_4 (D)//
50 mM Et_4NClO_4(D)//*C* $M(ClO_4)_x$ or $Ba(DSS)_2$+
10 mM Et_4NClO_4 (D)/PAA-POE4 or 6/Pt·····Cell I,

where $M(ClO_4)_x$ was the perchlorate of the cation to be tested (lithium, magnesium, or barium ion), D was AN or DMF, and *C* in mol dm^{-3}. A standard addition method was employed in obtaining calibration curves. Steady state potentials were read to ±0.1 mV. The electrode potentials were not significantly affected by change in the rate of the solution.

Conductivity Measurements. A conductivity meter of Toa Denpa Kogyo, Type CM-40S, equipped with an interval time unit IT-1S and a Yanagimoto conductivity cell, Type C, was used. The conductivity was also monitored simultaneously with a strip chart recorder, Yokogawa Denki type 3056. The $Ba(DSS)_2$-DMF solution of known concentration was added to the conductometric cell (cell constant 0.368_5) with a microburette (Gilmont Instruments, Inc., S1100A and S1200A).

Determination of the Complex Formation Constants. The successive complex formation constants of the lithium ion in AN with DMF were determined by potentiometric measurement in Cell II. The complexing solvent DMF was added to the cell with a microburette, 10 μl in each step, until its volume per cent reached 1%.

Ag/10 mM $AgNO_3$+10 mM Et_4NClO_4(AN)//
50 mM Et_4NClO_4(AN)//0.1 mM$LiClO_4$+
10 mM Et_4NClO_4(AN+DMF)/PAA-POE4/Pt···Cell II.

The potentiometric data were analyzed by the same method as that described in the previous report.[3]

Results

Responses of the Electrodes. The PAA-POE4 and PAA-POE6 electrodes were durable in AN and DMF for at least two weeks. The responses of these electrodes to lithium, magnesium, and barium ions are summarized in Table 1 and Fig. 1. The activity of

Table 1. The Responses of Organic Polymer Membrane Electrodes to Some Metal Ions in Nonaqueous Solvents at 25 °C

			PAA-POE4	
Li^+	0.60	AN	57.4	8×10^{-5}—6×10^{-3}
Mg^{2+}	0.65	DMF	30.4	2×10^{-5}—2×10^{-3}
Ba^{2+}	1.35	DMF	27.3	3×10^{-6}—3×10^{-4}
			PAA-POE6	
Ba^{2+}	1.35	DMF	26.1	1×10^{-5}—4×10^{-4}

a) r_c: Crystallographic ionic radius.

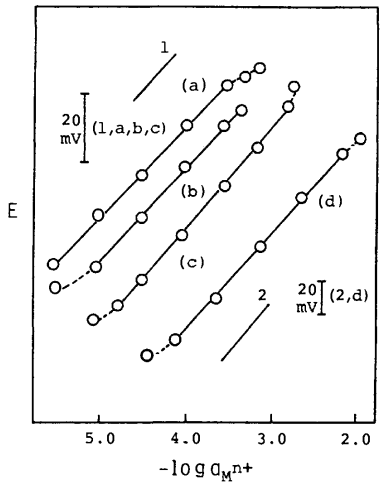

Fig. 1. Calibration curves in nonaqueous solvents at 25 °C. Lines 1 and 2, theoretical slope for bivalent cations (29.6 mV/$pa_{M^{2+}}$) and for univalent cation (59.2 mV/pa_{M^+}), respectively. (a) Ba^{2+} in DMF with PAA-POE4, (b) Ba^{2+} in DMF with PAA-POE6, (c) Mg^{2+} in DMF with PAA-POE4, (d) Li^+ in AN with PAA-POE4.

the metal ion, $a_{M^{x+}}$, was calculated by using the Debye-Hückel second approximation equation as previously described.[6] The results in Table 1 have not been corrected for the change in the liquid junction potential between the sample solution and the salt bridge of Cells I and II, but its effect seems to be small. The PAA-POE4 electrode could respond in a Nernstian way to the activities of the lithium ion in AN between the concentration range 7×10^{-5}—7×10^{-3} M (1M=1 mol dm^{-3}). The electrode could respond in Nernstian ways to the activities of the magnesium and barium ions in DMF between the concentration ranges 5×10^{-5}—1×10^{-2} M and 1×10^{-5}—1×10^{-3} M, respectively. The PAA-POE6 electrode showed near Nernstian response to the activity of the barium ion in DMF between the concentration range 3×10^{-5}—2×10^{-3} M.

Complexing of the Lithium Ion in AN with DMF. The complex formation constants of the lithium ion in AN with DMF were determined by measuring the emf change of Cell II. The relations between the potential change ΔE and the concentration of DMF, [D], and between R_1 and [D] (see Ref. 3) obtained in this experiment are shown in Fig. 2(a) and (b), respectively. Here $R_1 \equiv \{10^{\Delta E/59.16}-1\}/[D]=\beta_1+\beta_2[D]+\beta_3[D]^2+\cdots$. From the intercept and the slope of the straight line, $\beta_1=16$ and $\beta_2=1.5\times10^2$ are obtained (β_1 and β_2; see Ref. 3). The average values obtained in this experi-

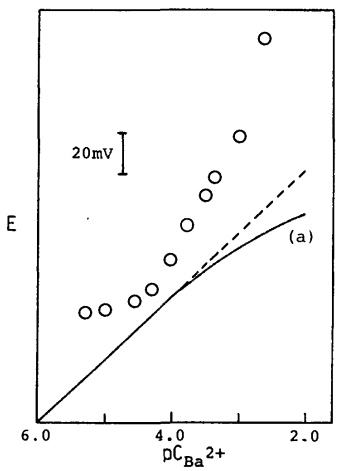

Fig. 3. Calculated potential curve vs. log $C_{Ba^{2+}}$ (curve (a)) and E (○) vs. log $C_{Ba^{2+}}$ relations of $Ba(DSS)_2$ in DMF with PAA-POE4 electrode under the coexistence of 10 mM Et_4NClO_4.

ment are shown in Table 2 with the results obtained previously by the use of an univalent cation-sensitive glass electrode.[4] The agreement between the results obtained with the two electrodes is excellent.

Potentiometric and Conductometric Behavior of $Ba(DSS)_2$ in DMF. (i) Potentiometry: The response of the PAA-POE4 electrode to the amphiphilic substance, $Ba(DSS)_2$, in DMF was measured using Cell I. The result is shown in Fig. 3 and curve (a) shows the calculated potential response to the barium ion in the solution of $Ba(DSS)_2$. The association constant of $Ba(DSS)_2$ in DMF used to elucidate the barium ion activity was obtained by the conductometric measurement shown below. When the concentration of the barium ion in DMF increased, the slope of the E-$pC_{Ba^{2+}}$ relation became steeper. The situation of the potential response of the PAA-POE4 electrode to the barium ion in $Ba(DSS)_2$-DMF solution, in which there was no Et_4NClO_4, was similar to that in Fig. 3 , but the potential change suddenly ceased at the highest concentration of the $Ba(DSS)_2$. **(ii) Conductometry:** The conductometric measurement was carried out to determine the association constant of $Ba(DSS)_2$ in DMF. The equivalent conductivities obtained are shown in Table 3. These values were used to get the association constant of Ba $(DSS)_2$ in DMF using the method of the Modified Fuoss-Edelson.[7] The activity coefficient of Ba^{2+}, y, was calculated using the Debye-Hückel second approximation equation[6] with ion-size parameters, a, of 10 Å and dielectric constant, ε, of 36.71 of DMF. The Modified Fuoss-Edelson plot obtained is shown in Fig. 4. Here the ΔF on the ordinate and the X on the abscissa in Fig. 4 are the same as those in Ref. 7 reported by Doe and Kitagawa. From the intercept and the slope of the straight line in Fig. 4, the limiting equivalent conductivity, Λ_0 of $Ba(DSS)_2$ in DMF and the 1 : 1 association constant between Ba^{2+} and DSS^-, K_{1A}, were obtained to be 54.8 and $5.2_4\times10^2$, respectively. The limiting equivalent conductivity of the barium ion in DMF used for the above calculation was 39.0[8] and that of the DSS^- in DMF was calculated to be 15.8.

Table 3. Equivalent Conductivity of $Ba(DSS)_2$ in DMF at 25 °C

Discussion

The PAA-POE4 electrode can respond to the activities of the lithium ion in AN and the magnesium and barium ions in DMF. The PAA-POE6 electrode may also be used to measure the barium ion activity in DMF.

The PAA-POE4 electrode was used to determine the successive complex formation constants of the lithium ion in AN with DMF and the results agreed well with those obtained previously[4] by the use of an univalent cation-sensitive glass electrode. The glass electrode has been proved to respond in the same way as the amalgam electrode to the variation in solvation energies of the lithium ions.[9] In the previous paper,[3] we also showed that the PAA-POE4 electrode and the barium amalgam electrode could give similar formation constants for the complexation of the barium ion in AN with DMF. These results show that at least in an AN-rich region the electrode can respond thermodynamically to the variation in solvation energies of these ions and can be applied to study the complex formation reaction of alkali and alkaline earth metal ions in AN with other basic aprotic solvents.

In the present study the association constant of the barium ion with DSS^- in the $Ba(DSS)_2$-DMF solution was found to be of the same order of magnitude as that of the barium ion with *p*-toluenesulfonate and more associated than with perchlorate.[8] Using the association constant, the response of the PAA-POE4 electrode in the $Ba(DSS)_2$-DMF solution was estimated theoretically. But, as in Fig. 3, the slope of the potential change was larger than the theoretical one. It may be due to the localization of the barium ion at the PAA-POE4 membrane surface: the hydrophilic sulfonate of the DSS^- seems to be directed to the hydrophilic organic membrane and to concentrate the counter ion, Ba^{2+}, to the vicinity of the membrane. In the absence of Et_4NClO_4 in Fig. 3, the potential suddenly ceased to change at the highest concentration of the $Ba(DSS)_2$ as shown in the Results section. The difference in the electrode responses in the presence and absence of Et_4NClO_4 might be explained by the role of anions. In order to investigate the response mecha-

nism of the PAA-POE4 electrode we prepared a glass filter membrane impregnated with PAA-POE4 and measured the ion transport across the membrane. A conductometric method was used to monitor the ionic transport. From the experiment, we found that the perchlorate ion can enter the membrane freely, while the entrance of the DSS^- into the membrane is fairly limited due to its larger size.[10] The sudden stop of the potential change in the absence of Et_4NClO_4 might be related to the difficulty for DSS^- to enter into the membrane. Probably sufficient anions should be present in the membrane to counterbalance the barium ion necessary for the proper electrode response. Some deficiency of anions would occur in the absence of Et_4NClO_4. In addition to this, it should also be taken into account that surface active substances (DSS^-) may change the property of the electrode surface and may interupt the response of the electrode.

Further studies are now being continued in this laboratory in order to elucidate the mechanism of the potential response at the polymer based ion-selective electrodes.

This work was supported in part by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

The Complexation Equilibria of Mercury(II) Ions with Macromonocyclic 16-Membered Dioxopentamine, 18-Membered Dioxohexamine, and Their Related Compounds

Mutsuo KODAMA* and Eiichi KIMURA†

Department of Chemistry, College of General Education, Hirosaki University, Bunkyo, Hirosaki 036

†Department of Medical Chemistry, Hiroshima University School of Medicine, Kasumi, Hiroshima 734

(Received April 3, 1989)

We have investigated the equilibria of complexation reactions of mercury(II) ions with 16-membered macrocyclic dioxopentamine (dioxo[16]aneN$_5$), 18-membered macrocyclic dioxohexamine (dioxo[18]aneN$_6$), and their related compounds by employing a polarographic method and pH-metric titration. Dioxo[16]aneN$_5$, dioxo[18]aneN$_6$, and other dioxo ligands except dioxotetramines were found to form solely 1 : 1 ratio mercury(II) complexes designated as $HgH_{-1}L^+$ with displacement of one amide proton, while the macrocyclic 16-membered monooxopentamine(monooxo[16]aneN$_5$) forms HgL^{2+} in addition to $HgH_{-1}L^+$. The substitution of amine nitrogen of dioxo[16]aneN$_5$ by the sulfur donor unexpectedly gave no increase in the stability of mercury(II) complex of dioxo ligand, $HgH_{-1}L^+$.

The macrocyclic dioxopolyamines possess novel ligand properties of saturated macrocyclic polyamines blended with oligopeptide features. They can accommodate certain metal ions such as Cu^{2+}, Ni^{2+}, and Co^{2+} in the macrocyclic cavities with simultaneous dissociation of the amide protons to afford 1 : 1 ratio complexes generally designated as $MH_{-1}L^+$ or $MH_{-2}L$.[1-3] However in reactions with Zn^{2+}, Cd^{2+}, and Pb^{2+} they undergo no deprotonation, giving a ML^{2+} complex.[4]

The mercury(II) ion is generally harmful to biological systems and an understanding of its action is of great importance. Its toxic action may be ascribable to the formation of protein complexes, which may block the enzymatic activity or change the conformation and the solubility of proteins. For a more detailed understanding of the toxic effect of mercury(II) ion on living systems, it is necessary to know the nature of the Hg(II)-protein interaction. It is not well known whether the mercury(II) ion can bind to the amide nitrogen atom of the peptide group, promoting the dissociation of the amide proton. In this paper we studied systematically the complexation reactions of mercury(II) ions with macrocyclic dioxopentamine and dioxohexamine using polarographic and pH-metric methods.

Though care should be taken in drawing conclusion about the Hg(II)-protein interaction from studies on low-molecular weight systems, the present equilibrium study on the complexation reactions of Hg(II) ions with macrocyclic dioxopolyamines might shed more light on the properties of Hg(II)-peptide interaction.

Experimental

Reagents. The macromonocyclic 18-membered dioxohexamine L^8 was synthesized as an intermediate to a saturated macrocyclic 18-membered hexamine, [18]aneN$_6$, by employing the method proposed by Tabushi et al.[5] All monooxo and dioxo ligands used in this study (Chart 1) were synthesized according to the reported method.[3]

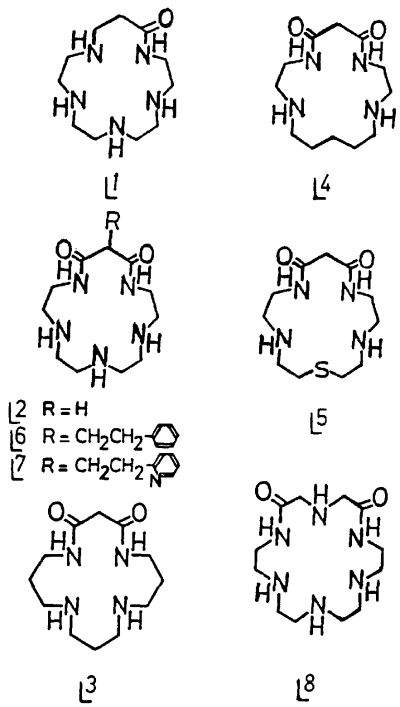

Chart 1.

Polarographic Method. All the polarograms were obtained with a Yanagimoto P-8 pen-recording polarograph or a manual polarograph similar to that of Kolthoff and Lingane.[6] The dropping mercury electrode (DME) had the open-circuit characteristics m=0.928 mg s^{-1} and t_d=4.75 s. in an air-free 0.10 mol·dm^{-3} $NaClO_4$ solution at a column height of 60 cm at 25°C. The polarographic procedures were the same as those applied to the previous mercury(II) complexes of macromonocyclic tetramine[7] and pentamines.[8] In order to maintain the solution pH constant, acetate (5.80>pH>4.00), tris. (8.20>pH>7.00), and borate (10.00>pH>8.20) buffers were used in this study.

Potentiometric Method. Potentiometric (pH-metric) titrations were performed with a Mettler automatic titrator at 25±0.10 °C under a nitrogen or argon atmosphere. The

mixed protonation constants (pK_a's) of the new dioxo ligands, L^3 and L^8, were determined by titrations with 0.100_0 mol·dm^{-3} carbonate-free tetraethylammonium hydroxide (TEAOH) or NaOH solution using a sample solution containing 10^{-3} mol·dm^{-3} ligand with an ionic strength made up to 0.20 mol·dm^{-3} using $NaClO_4$. The pK_a values for L^3 were 9.70 and 8.05, and those for L^8 were 8.70, 7.10, ca.2, and ca.1. The cumulative formation constants for the dioxopentamine and dioxohexamine complexes were also determined by titration with 0.100_0 mol·dm^{-3} TEAOH or NaOH solution of 10^{-3} mol·dm^{-3} equimolar mixture solution of Hg(II) and L^2·3HCl or L^8·4HCl salt. The change in the Na^+ concentration had no effect on the titration curves and polarograms. The values of $-\log[H^+]$ (for calculation of formation constants) were estimated from pH readings at an ionic strength (I)=0.20; $-\log[H^+]$=pH−0.13.

Results and Discussion

In tris.(0.050 mol·dm^{-3}) and borate (0.030 mol·dm^{-3}) buffer solutions all the macromonocyclic monooxopentamine, dioxopentamines, and dioxohexamine studied gave well defined anodic waves at DME. A typical polarogram obtained for the dioxo[16]aneN$_5$ (L^2) at pH=8.36 is shown in Fig. 1. Their polarographic behavior exept for the pH dependence of the half-wave potential were the same as those of the saturated macromonocyclic tetramines[7] and pentamines.[8] The reversible nature of the electrode processes was also confirmed by the ac polarographic method.[7,9]

The half-wave potential, $(E_{1/2})_L$, for the dioxo[16]aneN$_5$ shifted to more negative values on increasing the solution pH according to the relation (1) (Table 1 and Fig. 2), where $(\alpha_H)_L$ is defined as $1+[H^+]/K_3+[H^+]^2/K_3\cdot K_2+[H^+]^3/K_3\cdot K_2\cdot K_1$.[3]

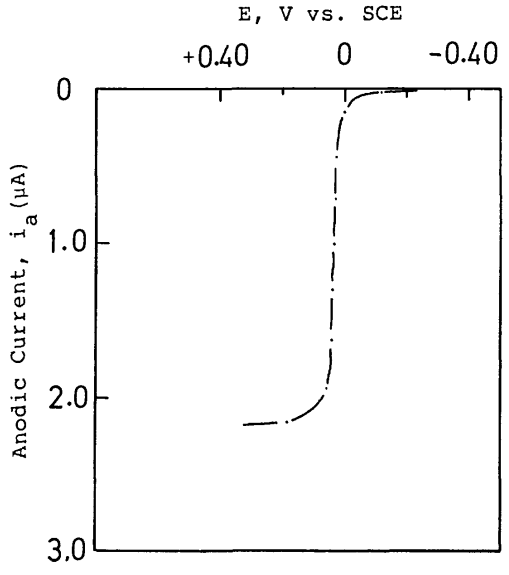

Fig. 1. Anodic dissolution wave at DME due to dioxo[16]aneN$_5$.
[dioxo[16]aneN$_5$]=0.40 mM, borate buffer 0.060 M, pH=8.36, I=0.20 M, 25 °C.

$$\frac{\Delta E_{1/2}}{\Delta\log(\alpha_H)_L\cdot[H^+]} = 30\ \text{mV} \quad (1)$$

The findings evidently indicate that only a 1 : 1 ratio mercury(II)-dioxo[16]aneN$_5$ complex designated as $HgH_{-1}L^+$ is formed in the Eq. 2 with simultaneous dissociation of one amide proton.

$$Hg + H_iL^{i+} \rightleftarrows HgH_{-1}L^+ + (i+1)H^+ \quad (2)$$

The half-wave potential is then expressed as in Eq. 3.

$$(E_{1/2})_L=\varepsilon^0_{Hg}+0.0296[\log f_{Hg}{}^{2+}-\log K_{HgH_{-1}L}+\log(\alpha_H)_L\cdot[H^+]]+0.0296\log(k_L/k_{HgH_{-1}L}) \quad (3)$$

Here, the diffusion current coefficients of the mercury(II)-dioxo[16]aneN$_5$ complex, $k_{HgH_{-1}L'}$ and of the various forms of dioxo[16]aneN$_5$, $k_{L'}$ can be assumed equal for approximation. In Eq. 3, ε^0_{Hg} is the ordinary formal standard potential[10] and a cumulative formation constant, $K_{HgH_{-1}L'}$ is defined as $[HgH_{-1}L^+]\cdot[H^+]/[Hg^{2+}]\cdot[L]$. In a similar way as those applied to the Hg(II)-saturated macrocyclic polyamine complexes,[7,8] the cumulative formation constant can be determined from the $E_{1/2}$ difference from the EDTA (Y^{4-}) system,[11] $\Delta E_{1/2}$, using the Eq. 4. Here, $(\alpha_H)_Y$

$$\log K_{HgH_{-1}L}=\frac{\Delta E_{1/2}}{0.0296}+\log K_{HgY}-\log(\alpha_H)_Y+\log(\alpha_H)_L\cdot[H^+] \quad (4)$$

is the (α_H) value for the EDTA system. With the aid of Eq. 4, $\log K_{HgH_{-1}L}$ value for the Hg(II)-dioxo[16]aneN$_5$ was determined to be 10.14. The reported $K_{HgY}(=[HgY^{2-}]/[Hg^{2+}]\cdot[Y^{4-}])$ and dissociation constants of EDTA (H_4Y^0) at ionic strength I=0.10 mol·dm^{-3} were corrected to I=0.20 mol·dm^{-3} by using the activity coefficients of the ions derived from the Davies relation.[12]

The complexation reactions of dioxo ligands with mercury(II) ions were also studied using the potentiometric method. A typical pH-metric titration curve for the 1.00×10^{-3} mol·dm^{-3} equimolar mixture of mercury(II) ion and dioxo[16]aneN$_5$ ($L^2\cdot3HCl$) is shown in Fig. 3. The complexation reaction occurs in a buffered region of pH 3.0—4.0. The titration data were found to be in best agreement with the concomitant formation of $HgH_{-1}L^+$ (Fig. 4). As was discussed in connection with the reactions of copper(II) ions with macrocyclic dioxotetramine,[13] the following theoretical relation can be expected for the $HgH_{-1}L^+$ formation. β_H in Eq. 5 has the same meaning as those used previously.[3] C_L and α are the

total concentration of L^2 and $a\cdot C_L+[H^+]$, respectively. Here, a means the fraction titrated. $K_{HgH_{-1}L}$ was determined from the slope of the straight line

$$K_{HgH_{-1}L}(4C_L-\alpha)^2\cdot(\alpha_H)_L=(\alpha\cdot(\alpha_H)_L-\beta_H\cdot C_L)\cdot(4(\alpha_H)_L-\beta_H)\cdot[H^+] \quad (5)$$

in Fig. 4 to be $10^{10.34}$ in a good agreement with that determined polarographically($10^{10.14}$).

Calculations for the simultaneous or separate formation of HgL^{2+} and $HgH_{-2}L^0$ and for the simultaneous formation of HgL^{2+} and $HgH_{-1}L^+$ were also made. However, the equation derived failed to fit the experimental data. Thus we concluded that neither HgL^{2+} nor $HgH_{-2}L^0$ is formed in this buffer region. The pH dependence of $(E_{1/2})_L$ for the anodic wave of dioxo[16]aneN$_5$ and the pH titration curve for the equimolar mixture solution of mercury(II) and dioxo[16]aneN$_5\cdot3HCl$ (shown in Fig. 3) can also be explained in terms of the formation of $HgL(OH)^+$ in which the dioxo[16]aneN$_5$ molecule might coordinate to the Hg(II) ion through its three amino nitrogens. Pure and Schwarzenbach reported that the mercury(II) ion can form a 1:1:1 ratio mixed diethylenetriamine (dien) complex including hydroxide anion, [Hg(dien)(OH)]$^+$.[14] The equilibrium constant (5.0×10^7) reported for the following reaction shows that the Hg(II)-dien complex can exist in the form of

$$[Hg(dien)(OH)]^+ + H^+ \rightleftarrows [Hg(dien)]^{2+}$$

$[Hg(dien)(OH)]^+$ only at pH's higher than 9. Thus, all the above facts lead us to choose the formation of a $HgH_{-1}L^+$ complex in which the amide group of dioxo[16]aneN$_5$ undergoes deprotonation. All the

polarographic and pH-metric behaviors of L^5, L^6, L^7, and L^8 were the same as those of the dioxo[16]aneN$_5$ system. Hence, an identical treatment of the experimental data was applied.

In the case of monooxo[16]aneN$_5$ (L^1) plots of anti-log $(\Delta E_{1/2}/0.0296+\log K_{HgY}-\log(\alpha_H)_Y+\log(\alpha_H)_L]$ against $[H^+]^{-1}$ gave a straight line with an intercept of finite value (Fig. 5). If only the $HgH_{-1}L^+$ complex is formed, the above plots should give a straight line which passes through the origin. Hence, the above linear relationship evidently indicates that under the present experimental conditions the monooxo-[16]aneN$_5$ ligand can form HgL^{2+} as well as $HgH_{-1}L^+$ as in the Reaction 6.

$$Hg+H_iL^{i+} \rightleftarrows \begin{cases} HgL^{2+}+iH^++2e^- \\ HgH_{-1}L^++(i+1)\cdot H^++2e^- \end{cases} \quad (6)$$

Thus the half-wave potential for the above electrode reaction should be given by Eq. 7. The product $K_{HgL}\cdot K^{-H}$ in Eq. 7 corresponds to $K_{HgH_{-1}L}$. From the

$$(E_{1/2})_L=\varepsilon^0_{Hg}+0.0296[\log f_{Hg^{2+}}-\log K_{HgL}\cdot(1+K^{-H}\cdot[H^+]) +\log(\alpha_H)_L+\log(k_L/k_{HgL})] \quad (7)$$

intercept and the slope of the straight line in Fig. 5,

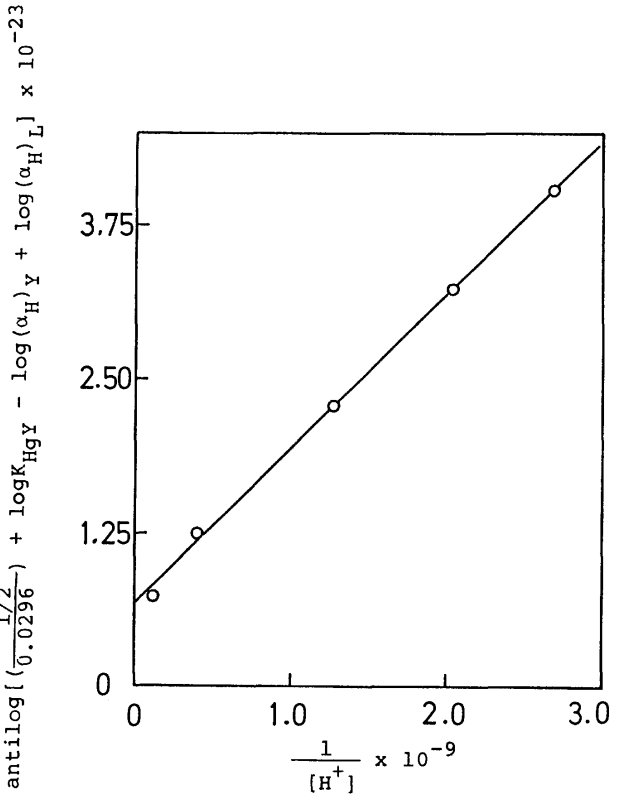

Fig. 5. Plots of antilog $[(\Delta E_{1/2}/0.0296)+\log K_{HgY}-\log(\alpha_H)_Y+\log(\alpha_H)_L]$ against $1/[H^+]$. [monooxo[16]aneN$_5$]=0.40 mM, Tris. or borate buffer 0.060 M, 9.75>pH>8.00, I=0.20 M, 25 °C.

K_{HgL}(=$[HgL^{2+}]/[Hg^{2+}][L]$) and $K_{HgH_{-1}L}$ values were determined to be 6.7×10^{22} and $1.2_6\times10^{14}$ respectively.

At pH's lower than 7.0 the anodic wave due to the uncomplexed dioxo macrocyclic polyamine merges into the mercury oxidation wave (background) completely. For this reason, it is impossible to study the complexation reaction at pH's lower than 7.0 by employing the polarographic technique. Two 16-membered macrocyclic dioxotetramines, L^3 and L^4, gave no anodic wave, suggesting that these dioxotetramines do not form stable mercury(II) complexes under the present experimental conditions.

As shown by the $K_{HgH_{-1}L}$ values in Table 2, $HgH_{-1}L^+$ complex of L^1 is more stable than that of L^2. This may suggest that in the complexation with Hg(II) ion L^1 can afford one more amine nitrogen atom than L^2. The $K_{HgH_{-1}L}$ values also show that the mercury(II) complex of L^8 is less stable than that of L^2. This probably suggests that the 18-membered macrocyclic ring is too large to place firmly nitrogen donors including deprotonated amide nitrogen atom for the stable Hg(II)-nitrogen bond formation. All the above findings may imply that in the macromonocyclic dioxopolyamine system, the presence of more than three amine nitrogen donors and a sufficiently large macrocyclic cavity which fits the mercury(II) ion size are essential for the formation of stable $HgH_{-1}L^+$ complexes.

The dioxo[16]aneN$_5$ system with extra-planar benzyl and pyridyl substituents (L^6 and L^7) also yielded stable $HgH_{-1}L^+$ complexes (Table 2). The appended pyridyl donor stabilizes the mercury(II) complexes of dioxo ligands. The affinity enhancement found may be accounted for by the additional coordination of the pyridyl nitrogen donor to the mercury(II) ion.

Mercury(II) forms strong complexes with thiol groups of proteins.[15] Serum albumin readily reacts with mercury(II) ions, forming the dimer, HgL_2, in which Hg(II) is coordinated to the single thiol group

Table 2. Cumulative Formation Constants, $K_{HgH_{-1}L}$, of Hg(II)-Macrocyclic Dioxopolyamine Complexes

I=0.20 M, 25 °C

a) At least three separate experiments were conducted for each system. b) Values determined potentiometrically.

of each protein molecule.[16] The Hg(II)-coordination of this group may also offer an explanation for its action as an enzyme inhibitor. We also studied the reaction of mercury(II) ion with dioxo[16]aneN$_4$S (L^5). As illustrated by the $K_{HgH_{-1}L}$ values in Table 2, the incorporation of a sulfur donor into the dioxo 16-membered macrocyclic frame, contrary to our expectation, gave no increase in the stability of Hg(II)-dioxo ligand complex. This trend was also true for the dioxo-free system.[17] The fact that the mercury(II) complex of dioxo[16]aneN$_4$S is thermodynamically less stable than that of dioxo[16]aneN$_5$ may be explained in terms of failure of the sulfur donor incorporated within the 16-membered cyclic frame to form a stable coordination bond with mercury(II) ion because of the cyclic nature of the ligand and of the larger sulfur donor size.

A typically soft metal ion, Cu(I), is reported to bind to the amide nitrogen atom of the peptide with the simultaneous dissociation of its proton.[18] Since the mercury(II) ion can form stronger complexes with peptides than Cu(I) ions, it is reasonable to believe that the mercury(II) ion may form such complexes with peptides. The present finding concerning the Hg(II)-macrocyclic dioxo ligand interaction lends strong support to the above argument. Though great care is required in drawing conclusion about the metal-protein interaction from the studies on the low-molecular weight system, the macrocyclic dioxo polyamines offer a useful model for the study of the metal-peptide interaction and thus, this is the first paper reporting the possibility of forming a mercury(II)-deprotonated amide nitrogen bond.

Association of Some Polynuclear Aromatic Hydrocarbons with Cyclodextrins in Aqueous Medium

Isao SANEMASA,* Tatsuyoshi TAKUMA, and Toshio DEGUCHI
Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami 2-39-1, Kumamoto 860
(Received April 12, 1989)

Complex formation using cyclodextrins (CyDs) as hosts and anthracene, phenanthrene, and naphthacene as guests has been studied in aqueous medium at 25 °C by measuring the guest volatilization rate. The results obtained are compared with those previously determined for benzene and naphthalene. Factors governing the host-guest association are discussed based on the dehydration energy of the guest derived from the Henry's law constant. It was suggested that van der Waals force is the main factor to stabilize the polynuclear aromatic hydrocarbons in the CyD cavity and that the contribution of hydrophobic interaction is less important. The additional van der Waals stabilization does not work fully for naphthacene of the longest molecular axis among the guests studied.

Cyclodextrins (CyDs) consist of glucopyranose units, forming cyclic oligosaccharides with different cavity size: α-, β-, and γ-CyD composed of 6, 7, and 8 units has the cavity diameter, 4.5—6.0, 6.0—8.0, and 8.0—10.0 Å, respectively. The interior of cavity is thought to be of hydrophobic environment, and, in aqueous medium, a wide variety of substances can be included therein as guests, if they are more or less hydrophobic in nature.[1]

In order to elucidate the CyD-guest binding forces and the complex formation process, many investigations have been made using hydrocarbons with polar derivatives.[2-5] In such studies, the use of hydrophobic guest substances without any polar group is desirable, because the presence of polar group in the guest molecule makes the contribution of hydrophobic effect uncertain.

Hydrophobic substances are in general only sparingly soluble in water and, moreover, some are volatile, so that it is difficult to use these solutes as guests. We have recently proposed a method that can be applied to such guests. The method is based on the facts that the guest molecules can be driven out to gaseous phase by introducing an inert gas at a constant flow rate into the aqueous solution and that the volatilization rate of guest decreases with increasing association with the host in aqueous medium. This method is applicable to such a system that the host-guest association rate is rapid compared with the guest volatilization rate. We have applied this method to benzene and alkylbenzenes,[6] and naphthalene and its methyl derivatives.[7] The host-guest spatial fitting was discussed on the basis of their association constants determined.

The present work is concerned with a further application of the method to such guests as anthracene, phenanthrene, and naphthacene. By combining the present results with the previous ones on benzene and naphthalene, we will get a better insight into the inclusion mechanism for polynuclear aromatic hydrocarbons.

Experimental

Materials and Preparation of Sample Solutions. Distilled deionized water was used throughout the experiments. Anthracene (Wako Pure Chemicals Co.), phenanthrene (Kodak Co.), and naphthacene (Tokyo Kasei Co.) as guests and cyclodextrins (α-, β-, and γ-CyD, Nakarai Chemical Co.) as hosts were of analytical reagent grade and used as received. An aqueous stock solution of each guest was prepared by adding an excess of each solid hydrocarbon to water and stirring for at least 24 h in the dark. After standing the mixture for at least 24 h, a portion of the saturated guest solution was transferred to a separatory funnel and the fluorescence of its chloroform extract was measured to determine the guest concentration using the following wavelengths: emission; 383, 367, and 479.1 nm, excitation; 260, 260, and 446.7 nm, for anthracene, phenanthrene, and naphthacene, respectively. Another portion of anthracene or phenanthrene aqueous solution was transferred to a 2.5 ϕ×25 cm cylindrical glass tube. A suitable amount of CyD, which had been dried over phosphorus pentaoxide under vacuum, was weighed and dissolved into the guest solution, and then the solution was diluted to 50

Table 1. The 1 : 1 (Host : Guest) Formation Constants at 25 °C[a]

	Concentration of CyD	Fraction(%) of guest	Formation constant
	10^{-2}mol dm^{-3}	volatilized	dm^3 mol^{-1}
Anthracene			
α-CyD	0.808—4.00	43	40±20
β-CyD	0.151—0.602	18	(2.3±0.2)×10^3
γ-CyD	1.50 —4.50	9	(1.5±0.2)×10^3
Phenanthrene			
α-CyD	1.82 —9.00	47	16±5
β-CyD	0.193—0.934	15	(1.5±0.3)×10^3
γ-CyD	0.800—3.20	8	(7.7±0.1)×10^2
Naphthacene			
β-CyD	0.100	3	3.4×10^3
γ-CyD	0.120	7	1.7×10^3

a) The concentration ranges of guest are, (5.00—17.8)×10^{-8} for anthracene, (5.7—19.1)×10^{-7} for phenanthrene, and (4.6—9.6)×10^{-9} for naphthacene, in mol dm^{-3}.

cm^3 with water. In the case of naphthacene, a 450 cm^3 portion of the guest aqueous solution was transferred to a round-bottom flask of 1 dm^3 capacity and diluted with water to 500 cm^3 after addition of CyD. The host and guest concentration ranges are given in Table 1.

Amberlite XAD-2 resin (Rohm and Hass) of 80—150 mesh size was used as an adsorbent of guest vapor.

Apparatus and Procedures. The apparatus and the experimental procedure were the same as those described in the previous paper.[7] Nitrogen gas was blown at a constant flow rate of 600 $cm^3 min^{-1}$ into the aqueous guest solution placed with or without CyD in the cylindrical glass tube or the round-bottom flask immersed in a bath thermostated at 25.0±0.1 °C. The N_2 gas leaving the sample solution was passed through a glass column of 0.5 ϕ×23 cm filled with XAD resin beads of 8 cm in length and the guest adsorbed on the resin within a fixed time was eluted out with $CHCl_3$ of 4 cm^3, and the amount of guest, ΔQ_ϕ, was determined by fluorescence measurement.

Results

Under the present experimental conditions that host molecules are always excess over guest molecules, the possible host:guest stoichiometric ratios are assumed to be 1 : 1 and 2 : 1. Then, the reactions that should be taken into account are:

$$\mathrm{CyD}+\phi \rightleftarrows \mathrm{CyD}\cdot\phi,\ K_1, \quad (1)$$

$$\mathrm{CyD}\cdot\phi+\mathrm{CyD} \rightleftarrows \mathrm{CyD_2}\cdot\phi,\ K_2, \quad (2)$$

and

$$\phi(\mathrm{aq}) \rightarrow \phi(\mathrm{gas}),\ k, \quad (3)$$

where ϕ refers to a guest molecule, K_1 and K_2 are the corresponding stepwise association constants, and k is the rate constant for the transfer of guest molecules from aqueous to gaseous phase.

We assume that the release of guest molecules at a constant N_2 flow rate is of first-order with respect to the concentration of free species present at any time t in the solution as follows:

$$dQ_\phi V^{-1}/dt = k[\phi], \quad (4)$$

where V is the volume of aqueous solution.

An equation to estimate K_1 and K_2 can be derived using the total concentrations of host (C_{CyD}) and guest (C_ϕ) and the amount of guest released from aqueous solution during the aeration time (Q_ϕ, the sum of ΔQ_ϕ from time 0 to t), in the same way as described in the previous paper.[7]

$$\ln(C_\phi - Q_\phi V^{-1}) = -kt/(1+K_1C_{CyD}+K_1K_2C_{CyD}^2)+\ln C_\phi$$
$$= -k't+\ln C_\phi, \quad (5)$$

where

$$k' = k/(1+K_1C_{CyD}+K_1K_2C_{CyD}^2). \quad (6)$$

Rearrangement of Eq. 6 yields:

$$1/k' = K_1K_2C_{CyD}^2/k + K_1C_{CyD}/k + 1/k. \quad (7)$$

The plots according to Eq. 5 for anthracene-β-CyD are shown in Fig. 1. The plots give straight lines over the aeration time employed; the volatilization rates of guest molecules dealt with in this work are much slower than those previously studied,[6,7] and hence the fraction of the amount of guest released

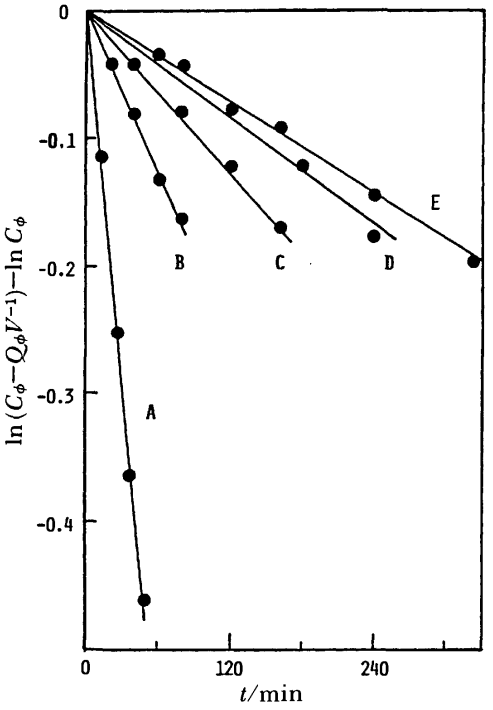

Fig. 1. Anthracene-β-CyD system. The plots of $\ln(C_\phi - Q_\phi V^{-1}) - \ln C_\phi$ vs. t with and without cyclodextrin. $C_{CyD}/10^{-3}$ mol dm^{-3}: (A) 0, (B) 1.51, (C) 3.01, (D) 4.49, (E) 6.02; C_ϕ: (5.00—17.8)×10^{-8} mol dm^{-3}.

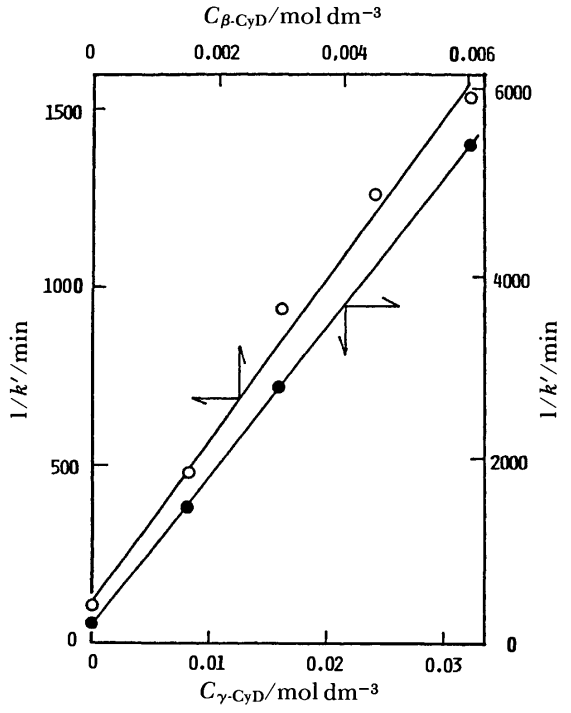

Fig. 2. The plots of $1/k'$ vs. C_{CyD}. Anthracene-β-CyD (○), phenanthrene-γ-CyD (●).

during the aeration is small (see Table 1). This linear relationship verifies the assumption that the volatilization of guest molecules follows a first-order reaction at a constant N_2 flow rate. Slopes of the resulting straight lines, k'(and k), were evaluated using the least-squares method. Typical $1/k'$ vs. C_{CyD} plots are shown in Fig. 2. The plots appeared to be linear for each host-guest combination studied; the K_2 can be neglected. In the case of naphthacene, measurements were made at a constant CyD concentration and the K_1 values were estimated from the average of three (for β-CyD) and two (for γ-CyD) runs. The K_1 values for this guest are, therefore, less reliable. The K_1 values determined in this work are summarized in Table 1. It should be noted that the K_1 values for α-CyD are less reliable because the difference between k and k' is small.

Discussion

Comparison of Association Constants with Literature Values. Vapor pressure,[8] fluorescence,[9-13] UV absorption,[14] and thin-layer chromatographic[15] methods have been used to evaluate CyD association constants with guests relevant to the present study. These are listed in Table 2. Our measurement provides reasonable values for benzene and naphthalene, while, for the other three guests, there is very large disagreement between ours and literature values. These differences probably arise from low solubility of guest substances in water. It is difficult to maintain the guest concentration in water constant owing to the adsorption of guest solute on the walls of glasswares including the cell.[16] Our method is suitable for these guests, because the accurate knowledge of the guest concentration in the aqueous medium is not essential, but what is required is the relative volatilization rate of the guest with and without CyD. While we have no criterion to judge which are more reliable, between ours and literature values, it seems to be helpful to clarify what factors govern the CyD-guest association.

The Inclusion Models. Since the cavity size of α-CyD is relatively small, a benzene ring associates only partly with the host. On the other hand, the other two hosts have sufficiently large cavity to accept linear-condensed benzene-ring compounds. Some water-soluble anthracene derivatives have been demonstrated to be accommodated in γ-CyD as dimer.[17] It seems probable, therefore, that γ-CyD with large internal cavity size includes two anthracene molecules. In this work, however, we have analyzed γ-CyD-anthracene system as a 1 : 1 complex according to the preceding stoichiometric study.[18] We simply postulate that naphthalene, anthracene, phenanthrene, and naphthacene are all axially included in β- and γ-CyD cavities. Inclusion models for anthracene are depicted in Fig. 3.

Factors Governing the Stability of Inclusion Complex. Hydrogen bonding, van der Waals forces, and hydrophobic interaction are generally accepted to be responsible for bonding of guest molecules to CyD

Table 2. Association Constants of 1 : 1 (Host : Guest) Complexation at 25 °C, Comparison with Those in Literatures

Guest-Host	Association constant/dm³ mol⁻¹	
	Our studies	Literature
Benzene-α-CyD	17[6]	31.6[8]
-β-CyD	1.2×10^2[6]	169,[8] 196[9]
-γ-CyD	12[6]	9.1[8]
Naphthalene-α-CyD	83[7]	
-β-CyD	6.3×10^2[7]	685,[10] 730,[11] 850,[12] 186[14]
-γ-CyD	1.3×10^2[7]	
Anthracene-β-CyD	2.3×10^3	420,[14] 32.39[15]
-γ-CyD	1.5×10^3	9.41[15]
Phenanthrene-β-CyD	1.5×10^3	170[13]
Naphthacene-β-CyD	3.4×10^3	221[14]

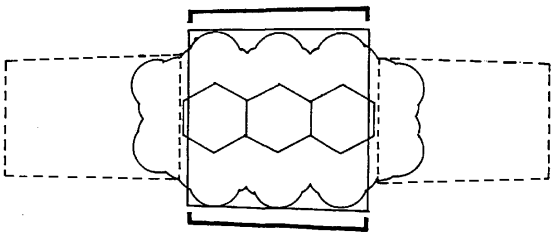

Fig. 3. Anthracene-CyD inclusion model. α-, β-, and γ-cyclodextrin cavities are drawn by dotted, thin solid, and thick solid lines, respectively.

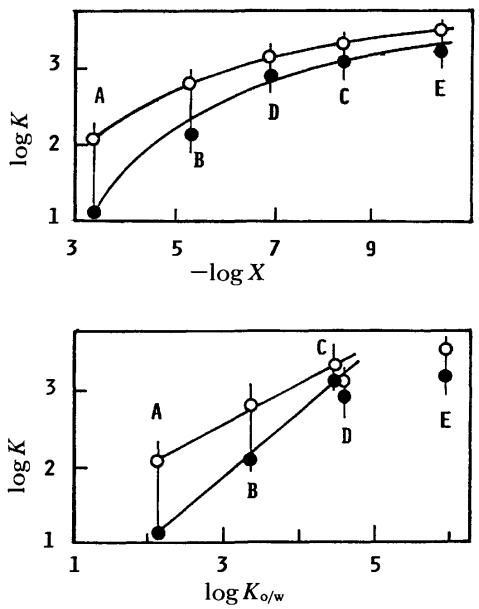

Fig. 4. The dependence of association constant (K) on the mole fraction solubility (X) of guest substance in water (upper), on the partition coefficient ($K_{o/w}$) of guest in 1-octanol/water (lower). Guest: benzene (A), naphthalene (B), anthracene (C), phenanthrene (D), naphthacene (E); β-CyD(○), γ-CyD (●).

cavity. The first one can be excluded in the present case because the guests under consideration have no ability to form hydrogen-bond with CyDs. Hydrophobic interaction has been thought to occur in an aqueous environment between the CyD interior wall and the guest molecule which has lower affinity with water.

It is a problem what should be chosen for an indication of guest hydrophobicity. For some homologous guest series, their solubility in water or their partition coefficient between 1-octanol (or chloroform) and water has been used as a measure of hydrophobicity: logarithmic values vs. $\log K$ plots give fairly good linear relationships.[19-21] Such plots are shown in Fig. 4, from which we can see that the association constant, K, increases with decreasing guest solubility in water or increasing partition coefficient in 1-octanol/water, $K_{o/w}$. A simple interpretation of the phenomena is that the more hydrophobic guest forms the more stable complex with CyD, but we need real reason.

Is a solute with lower solubility in water or larger $K_{o/w}$ value more hydrophobic? The partition coefficient is defined as the ratio of solute concentration in organic solvent to that in water at equilibrium. This coefficient has been measured for a wide variety of chemicals to relate it theoretically to the solute aqueous solubility or to predict the distribution of hydrophobic pollutants in aquatic environments.[22,23] For instance, chemicals with a large partition coefficient are liable to be accumulated into fish body.[24] The partition coefficient is often taken as a measure of the hydrophobic character of a solute,[25] but in a strict sense it is a measure of the relative solubility of the solute in organic solvent and in water, that is, a relative affinity of the solute between surrounding organic and water molecules.

An image of the host-guest association process is that a guest molecule is transferred from water to the hydrophobic environment leaving behind a structured cavity which collapses and redistributes.[26] The free-energy change associated with this process can be easily evaluated, if the hydrophobic environment is substituted for the gaseous phase. Using the Henry's law constant, K_H, $\Delta G_{dehyd}=-RT \ln K_H$. The K_H value is estimated for each guest from its partial vapor pressure and the mole fraction solubility in water at 25 °C. The free-energy change in the 1 : 1 complex formation, $\Delta G_{complex}$ ($=-RT \ln K_1$), is plotted against ΔG_{dehyd} in Fig. 5; a dotted line indicates that $\Delta G_{complex}=\Delta G_{dehyd}$.

For volatile solutes, the most suitable parameter of the hydrophobicity is K_H, a measure of free-energy necessary to carry a solute from aqueous medium to gaseous phase. According to $-\Delta G_{dehyd}$ values, benzene is more hydrophobic than naphthalene, and the latter is more hydrophobic than anthracene. This statement may be strange from the fact that the solubility of naphthalene in water (2.35×10^{-4} M at 25 °C; 1M=1 mol dm^{-3}) is lower two orders of magnitude than that of benzene (2.07×10^{-2} M), and that the solubility of anthracene (2.5×10^{-7} M) is lower three orders of magnitude than that of naphthalene. Such differences in the solubility arise from the difference in the saturated vapor pressure of the solute. The vapor pressure of benzene (1.26×10^{4} Pa at 25 °C) is higher three orders of magnitude than that of naphthalene (10.98 Pa), and the vapor pressure of the latter is higher four orders of magnitude than that of anthracene (8.31×10^{-4} Pa). This is also the case for phenanthrene and anthracene. The former is a little more hydrophobic than the latter in spite of the former aqueous solubility being thirty times larger than the latter.

It can be seen from Fig. 5 that the guests except benzene have considerably larger $-\Delta G_{complex}$ than $-\Delta G_{dehyd}$. If we postulate that a guest molecule is fully embraced in the CyD cavity and that the environment around the guest is a gaseous phase, $-\Delta G_{dehyd}$ for the guest will contribute fully to the $-\Delta G_{complex}$, that is, $-\Delta G_{dehyd}$ estimated from K_H is to be taken as the upper limit of the hydrophobic contribution.

For the guest substances studied here, hydrophobic interaction as a driving force of CyD complexation is not significant, because $-\Delta G_{complex}$ does not increase with $-\Delta G_{dehyd}$. It is van der Waals force that plays the major role to stabilize the complex for the guest of large size. The plots of $\log K$ vs. the total surface area of associating guest are shown in Fig. 6. Nearly

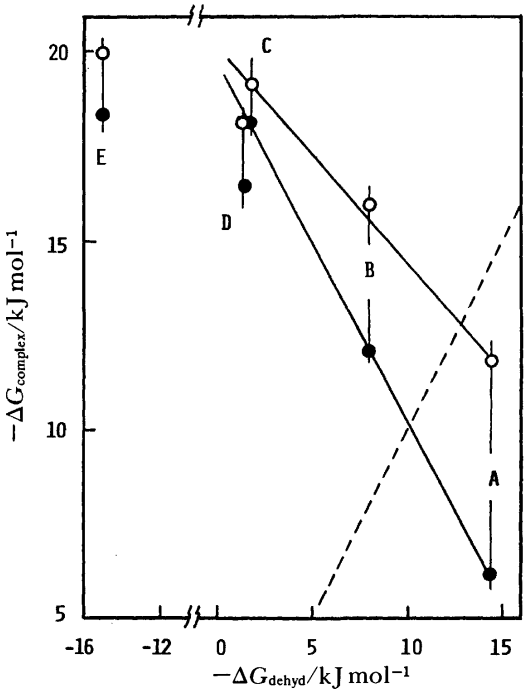

Fig. 5. Free energy changes of CyD-guest complexation and dehydration of guest. Signs and symbols are the same as those shown in Fig. 4.

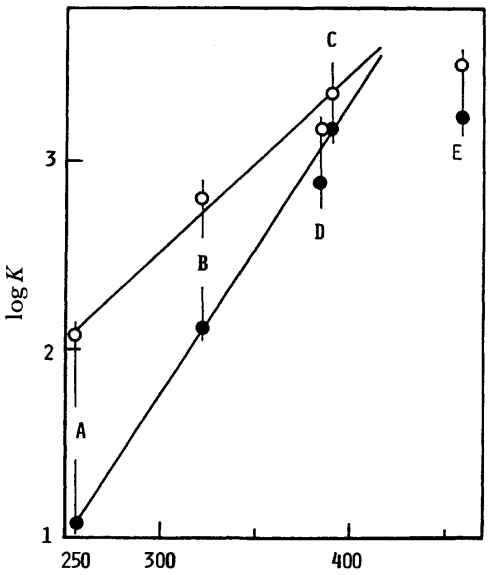

Fig. 6. The dependence of association constant on the surface area of guest molecule. The signs and symbols are the same as those shown in Fig. 4. Values of surface area are taken from Ref. 27.

linear relationships can be seen for β- and γ-CyD except phenanthrene and naphthacene. The increase in the axial length of guest molecule increases the host-guest contact area, leading to the increase in net stabilization. For naphthacene, however, the additional stabilization does not serve to any significant extent, probably because a considerable part of the molecule protrudes out of the CyD cavity. Anthracene and phenanthrene have approximately the same surface area, but the latter forms less stable complexes with CyDs. The reason cannot be fully given at present. Less favorable contact of phenanthrene to the CyD cavity wall may be partially responsible.

The tendency that a guest with the large partition coefficient forms more stable complex with CyD has been observed for guests of homologous series. The tendency is not due to the guest hydrophobicity, but due to the relative strength of guest-water and guest-organic solvent interactions. Intermolecular forces acting between the solute (or guest) and the surrounding solvent molecules (or CyD cavity wall) are similar in its character to each other, that is, the van der Waals forces.

(Received January 13, 1989)

In order to increase the applications of the water-soluble active ester method, water-soluble acylating reagents, [*p*-(benzyloxycarbonyloxy)phenyl]dimethylsulfonium methyl sulfate, [*p*-(*t*-butoxycarbonyloxy)-phenyl]dimethylsulfonium methyl sulfate and [*p*-(9-fluorenylmethyloxycarbonyloxy)phenyl]dimethyl-sulfonium methyl sulfate, were synthesized from of *p*-hydroxyphenyldimethylsulfonium methyl sulfate. These compounds had high solubility (more than 30%) in water and were found to act as excellent water-soluble acylating reagents for the synthesis of *N*-benzyloxycarbonyl, *N*-*t*-butoxycarbonyl, *N*-9-fluorenylmethyl-oxycarbonyl amino acid derivatives in aqueous solution. They converted dipeptides to *N*-acyl-dipeptides in aqueous media as well as amino acids. In addition, they were found to be efficient reagents for protecting the side chains of lysine, ornithine, and cysteine.

In 1987, we reported that *p*-hydroxyphenyldi-methylsulfonium methyl sulfate (HODSP) was found to be an excellent reagent for peptide synthesis in aqueous solution.[1] We also pointed out that HODSP has a high reactivity, as the same as that of conventional active ester reagents, such as *p*-nitrophenol or *N*-hydroxysuccinimide. By carrying out peptide synthesis in aqueous solution we can strictly control the pH during the reaction. This means that arginine residue, which has a guanide group in the side chain, can be treated while unprotected. By employing the HODSP active ester method, FMRFamide (Phe-Met-Arg-Phe-NH_2), a molluscan neuropeptide from the ganglia of the clam *Macrocallisa nimbosa*,[2] was synthesized.[3] The water-soluble active ester method is an ideal method for both Arg- and Met-containing peptide, such as FMRFamide. The peptide can be prepared without hydrogenation or HF deprotection, which is known to sometime severely damage the peptide during the final step. We prepared several FMRFamide analogs by using this water-soluble active ester method as well as naturally occurring FMRFamide.[4]

After we established peptide synthesis using water-soluble active ester, we then set out to develop new types of water-soluble acylating reagents. We selected three amino protecting groups (benzyl-oxycarbonyl-, *t*-butoxycarbonyl, and 9-fluorenyl-methyloxycarbonyl groups) which are widely used in peptide synthesis; their deprotecting conditions are all different. [*p*-(Benzyloxycarbonyloxy)phenyl]dimethyl-sulfonium methyl sulfate (**1**), [*p*-(*t*-butoxycarbonyloxy)-phenyl]dimethylsulfonium methyl sulfate (**2**), and [*p*-(9-fluorenylmethyloxycarbonyloxy)phenyl]dimethyl-sulfonium methyl sulfate (**3**) were prepared and practically allowed to react with amino acids in aqueous media. Furthermore, we applied these water-soluble acylating reagents to the selective side-chain protection of amino acids (lysine, ornithine, and cysteine). In this paper we discuss the utility and applicability of water-soluble acylating reagents in peptide synthesis.

† This is one part of studies on the water-soluble active ester method for peptide synthesis. The previous studies (part I, II, and III) appeared in this journal. See Refs. 1, 3, and 4.

Results and Discussion

Preparation of [*p*-Benzyloxycarbonyloxy)phenyl]dimethylsulfonium Methyl Sulfate (1), [*p*-(*t*-Butoxycarbonyloxy)phenyl]dimethylsulfonium Methyl Sulfate (2), and [*p*-(9-Fluorenylmethyloxycarbonyloxy)-phenyl]dimethylsulfonium Methyl Sulfate (3). Compounds **1**, **2**, and **3** were all easily synthesized from the reaction of HODSP with benzyloxycarbonyl chloride, di-*t*-butyl dicarbonate, and 9-fluorenylmethyloxy-carbonyl chloride, respectively, in CH_3CN. These compounds were stable and did not undergo decomposition when stored below 10 °C. Compounds **1**, **2**, and **3** were soluble in water (solubility:>30 wt%) and very soluble in DMF, alcohol, CH_3CN, and $CHCl_3$.

Preparation of Benzyloxycarbonyl, *t*-Butoxycarbonyl, 9-Fluorenylmethyloxycarbonyl Amino Acids Derivatives. In order to establish optimal conditions for the reaction between amino acids and **1**, **2**, or **3** in aqueous solution, the effect of five bases (NaOH, Na_2CO_3,

$NaHCO_3$, triethylamine, and pyridine) in acylation of alanine were first studied. It was found that all, except pyridine, promoted the reaction and sodium hydroxide and triethylamine gave the highest yield (83%) of *N*-(benzyloxycarbonyl)-L-alanine.

The reaction rate of **1** and **2** with glycine in aqueous solution at pH 7—10 was measured by HPLC. The rate of **1** and **2** with glycine in several concentrations was also measured. It was found that **1** and **2** gave Z-Gly and Boc-Gly in highest yield when they were treated at a pH concentration greater than 10 and 0.25 M (1 M=1 mol dm^{-3}), respectively. The benzyloxycarbonylation of glycine with **1** (0.25 M) came to completion within 2 h at pH 8. In the case of **2**, the reaction was over within 2 h at pH 10. These results showed that the standard conditions for the reaction involve using triethylamine as a base in aqueous solution at a pH and concentration greater than 10 and 0.25 M, respectively, at room temperature. The yield of *N*-acyl amino acid derivatives, prepared in aqueous solution, are shown in Tables 1, 2, and 3. *N*-Acyl amino acid derivatives were obtained in good yields from **1**, **2**, and **3** only in aqueous media. Even if an aqueous-acetonitrile system was employed for the solvent, the yields of *N*-aryl amino acid derivatives were still good. This result definitely shows that these water-soluble acylating reagents could be used as well as conventional *N*-acylating reagents. It is another merit of water-soluble acylating reagents that the unreacted reagents and HODSP, which forms during the reaction as a by-product, can easily be removed because of their high solubility in water.

We studied a possible side reaction, *N*-methylation, because HODSP has methyl sulfate as a counter anion. We collected some of the reaction mixture of the water-soluble acylating reagent and amino acid, and then carried out the deprotection procedure on that mixture; the resultant mixture was applied to HPLC. No *N*-methyl amino acid was found.

***N*-Acylation of Dipeptides in Aqueous Solution.** The active ester method is generally carried out under mild conditions rather than acid halides, acid anhy-

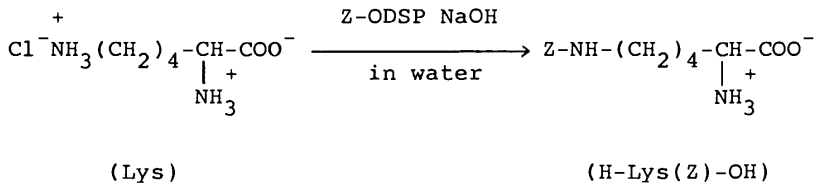
a) The reactions were carried out using water as solvent and triethylamine as a base. b) This reaction was carried out in water-acetonitrile.

drides or other condensing reagents. The water-soluble active ester can form an amide linkage under much milder conditions than other active esters. We can control the reactivity of the active ester by changing the pH.

N-Acylation of dipeptides in aqueous solution using **1**, **2**, or **3** were carried out. *N*-Acyl-dipeptides were obtained (Yield; Z-Phe-Gly-OH, 77%; Boc-Leu-



Scheme 1.

Val-OH, 70%; Fmoc-Gly-Gly-OH, 75%) in aqueous solution without any side reaction because the pH of these reaction mixtures was strictly controlled.

Selective Acylation of Amino Groups on the Side Chain of Lysine and Ornithine. The other merit of the reaction in water is that we could presume selective acylation of the amino group of side chains of lysine and ornithine. Compound **1** was allowed to react with lysine by controlling the pH of the reaction mixture automatically. The synthetic route of N^{ε}-(benzyloxycarbonyl)-L-lysine (H-Lys(Z)-OH) is shown in Scheme 1. We studied the yield of H-Lys(Z)-OH and Z-Lys(Z)-OH by changing the pH of the reaction. The amino group on the side chain of lysine was selectively benzyloxycarbonylated and H-Lys(Z)-OH was obtained only during one step by strictly controlling the pH of the reaction mixture. A small amount of Z-Lys(Z)-OH, which was produced at the same time, was easily washed out with ethyl acetate. Lysine was also treated with two equivalents of **1**. We recognized a selective formation of H-Lys(Z)-OH at pH 8 and 9. The highest yield of H-Lys(Z)-OH was obtained at pH 11.5 (63.6%); that condition kept the yield of Z-Lys(Z)-OH, a by-product, below 5.4%. The reaction with Z-OSu (dioxane-water as a solvent), which is a commercial benzyloxycarbonylating reagent, was then studied. A selective aminolysis reaction was not observed since the reaction requires organic solvents and the pH of the reaction mixture can not be accurately controlled.

Ornithine was treated with **1** under the same conditions. The same principle can also be applied to the selective benzyloxycarbonylation of the ω-amino group of ornithine. In the case of the reaction in two equal quantities of **1**, we recognized a selective benzyloxycarbonylation of δ-amino group as well as lysine. Presently, the synthetic route of H-Lys(Z)-(OH) or H-Orn(Z)-OH is first to form a Cu(II) complex of lysine or ornithine; they are then allowed to react with benzyloxycarbonyl chloride.[5-9] The Cu(II) complex is removed by hydrogen sulfide. This procedure requires three steps and decreases the yield of the product. By using of this water-soluble acylating reagent, H-Lys(Z)-OH or H-Orn(Z)-OH can be prepared in one step.

Preparation of *S*-(Benzyloxycarbonyl)-L-cysteine. The mercapto group in cysteine is too reactive to be left unprotected, since it is a stronger nucleophilic group than the amino group and is easily converted to disulfides by air oxidation as well. We investigated the reactivity of the mercapto group of cysteine at various pH's in aqueous media using **1**. *S*-(Benzyloxycarbonyl)-L-cysteine was obtained in one step at pH 6.0 or 6.5 (61%), as well as the case of selective acylation of lysine and ornithine, which have amino groups in their side chains.

We dealt with three typical *N*-protecting groups in peptide synthesis. We also showed that the introduction of those groups using the water-soluble active ester could be carried out successfully. It is clear that the water-soluble active ester method can be applied to other urethane-type amino-protecting groups. Additionally, side-chain-protected amino acids, such as H-Lys(Z)-OH, H-Orn(Z)-OH, and H-Cys(Z)-OH were prepared using the water-soluble active esters very easily. We believe that the water-soluble acylating reagent will also be a powerful tool for the chemical modification of proteins in aqueous solution without causing any conformational changing. We plan to show this elsewhere shortly.

Experimental

All melting points were uncorrected. IR spectra were recorded on a Hitachi 269-30 infrared spectrometer. NMR spectra were measured on a Hitachi R-24B (60 MHz) spectrometer. The chemical shifts are given in δ scale with tetramethylsilane as an internal standard. Amino acid analysis and detection of substances were performed by means of HPLC using JASCO TRI ROTER-V and UNIDEC-100V apparatus.

Synthesis of Z-ODSP(1), Boc-ODSP(2), and Fmoc-ODSP (3). HODSP (13.3 g, 50 mmol) was dissolved in CH_3CN (200 ml), and Et_3N (7.0 ml, 50 mmol) was added to the solution below 5 °C with stirring. After 10 min, Z-Cl, $(Boc)_2O$, or Fmoc-Cl (50 mmol) was added. The reaction mixture was stirred below 5 °C for 2—5 h and then the precipitated triethylammonium chloride or unreacted reagents was removed from the reaction mixture by filtration. The filter cake washed with CH_3CN, and combined filtrates were concentrated in vacuo to give products as crystalline solid, which was readily recrystallized from ethyl acetate.

Z-ODSP (1). Yield 90.0%; mp 78—80 °C. IR data ν_{max}^{KBr} 1760 cm^{-1} (ester C=O). ^1H NMR data (DMSO-d_6); δ=3.30 (s, 6H, $-S^+(CH_3)_2$), 3.42 (s, 3H, $CH_3SO_4^-$), 5.35 (s, 2H, benzyl CH_2), 7.41 (2.5H, C_6H_5), 7.92 (dd, 4H, J_1=31 Hz, J_2=6 Hz, $-O-C_6H_4-S<$). Found: C, 51.42; H, 4.58%. Calcd for $C_{17}H_{20}O_7S_2$: C, 51.51; H, 4.99%.

Boc-ODSP (2). Yield 80.0%; mp 118.5—121 °C. IR data ν_{max}^{KBr} 1760 cm^{-1} (ester C=O). ^1H NMR (DMSO-d_6); δ= 1.50 (s, 9H, *t*-butyl), 3.30 (s, 3H, $CH_3SO_4^-$), 3.40 (s, 6H,

$-S^+-(CH_3)_2$), 7.85 (dd, 4H, J_1=33 Hz, J_2=8 Hz, $-O-C_6H_4-S<$). Found: C, 45.78; H, 6.31%. Calcd for $C_{14}H_{22}O_7S_2$: C, 45.92; H, 6.00%.

Fmoc-ODSP (3). Yield 85.0%; mp 90.5—92 °C. IR data ν_{max}^{KBr} 1760 cm^{-1} ster C=O). ^1H NMR ($CDCl_3$); δ=3.41 (s, 6H, $-S^+(CH_3)_2$), 3.68 (s, 3H, $CH_3SO_4^-$), 4.30 (t, 1H, J=7 Hz, $>CH-CH_2-OCO_2-$), 4.54 (d, 2H, J=7 Hz, $>CH-CH_2-OCO_2-$), 7.24—7.81 (m, 10H, aromatic protons of Fmoc+right peaks of dd of $-O-C_6H_4-S<$), 8.15 (d, 2H, J=11 Hz, left peaks of dd of $-O-C_6H_4-S<$). Found: C, 60.96; H, 5.07%. Calcd for $C_{24}H_{24}O_7S_2$: C, 61.02; H, 5.12%.

***N*-Benzyloxycarbonyl Amino Acids, *N*-*t*-Butoxycarbonyl Amino Acids and *N*-(9-Fluorenylmethyloxycarbonyl) Amino Acids (General Method).** L-Amino acid (10 mmol) and Et_3N (12 mmol) were dissolved in water (10 ml) and Z-ODSP, Boc-ODSP, or Fmoc-ODSP (12 mmol) was added to the solution at room temperature with stirring. After 8—24 h, 1 M HCl or 20% citric acid was added to the solution and the pH of the solution was adjusted to 3.0. In the case of Fmoc-amino acids, water was added to the reaction mixture, then extracted with ether; the aqueous phase was acidified with 1 M HCl. The mixture was extracted with ethyl acetate. The solution was washed with water and then dried over anhydrous sodium sulfate. The filtrate was concentrated in vacuo. The residue was recrystallized from the solvents indicated. Side chain amino acid derivatives were prepared using different procedures.

Synthesis of *N*-Acyl Dipeptides. Z-Phe-Gly-OH. H-Phe-Gly-OH (1.07 g, 3 mmol) was adjusted to 10.0 by 1 M NaOH. Z-ODSP (1.44 g, 3.3 mmol) was added to a stirring solution and the reaction mixture was acidified with 20% citric acid. The mixture was extracted with ethyl acetate. The solution was then washed with water and dried over anhydrous sodium sulfate. The solution was concentrated and crystallized from ether; Yield 77%; mp 158—160 °C [lit, 159—161 °C].[33] Prepared similarly were the following dipeptide derivatives:

Z-Ile-Phe-OH. Yield 72%; mp 174—176 °C [lit, 175—176 °C].[34]

Boc-Leu-Val-OH. Yield 70%; mp 108—110 °C [lit, 109—111 °C].[35]

Fmoc-Gly-Gly-OH. Yield 75%; mp 176—177 °C [lit, 176—177 °C].[32]

Preparation of H-Lys(Z)-OH and H-Orn(Z)-OH. Lys·HCl (1.83 g, 10 mmol) and 2 M NaOH (5 ml) were dissolved in water (50 ml) and the pH of the solution was adjusted to 11.3 by 1 M HCl. Z-ODSP (6.4 g, 16 mmol) was added to a stirring solution below 20 °C, the pH being automatically maintained at the starting pH with 2 M NaOH for 30 min. The precipitate was filtered and washed with water and ethanol. By a similar procedure, H-Orn(Z)-OH (at pH 11.5) was obtained.

H-Lys(Z)-OH. Yield 63.6%; mp 250—253 °C; $[\alpha]_D^{25}$ +16.0° (*c* 1.0, 6 M HCl). Found: C, 59.92; H, 7.12; N, 9.94%. Calcd for $C_{14}H_{20}N_2O_4$: C, 59.98; H, 7.19; N, 9.99%.

H-Orn(Z)-OH. Yield 80%; mp 254—255 °C; $[\alpha]_D^{25}$+17.3° (*c* 0.7, 6 M HCl). Found: C, 58.57; H, 6.84; N, 10.42%. Calcd for $C_{13}H_{18}N_2O_4$: C, 58.63; H, 6.81; N, 10.52%.

Preparation of H-Cys(Z)-OH. Cys·HCl (10 mmol) and Et_3N (1.4 ml) were dissolved in water (50 ml) and pH of the solution was adjusted to 6.0 by 1 M HCl. Z-ODSP (10 mmol) was added to a stirred solution below 20 °C, the pH being automatically maintained at the starting pH with 2 M NaOH for 5 h. The precipitate was filtered and washed with water and ethanol. Yield 61%, mp 162—164 °C, $[\alpha]_D^{25}$—122° (*c* 1.0, DMF). Found: C, 51.72; H, 5.15; N, 5.41%. Calcd for $C_{11}H_{13}NO_4S$: C, 51.75; H, 5.13; N, 5.49%.

Determination of the Rate of Aminolysis. pH Effect: Gly or Val (5 mmol) was dissolved in water (10 ml) and the pH of the solution was adjusted to 7—10 by 2 M HCl. Z-ODSP (**1**, 5 mmol) was added to the solution and the total volume of the solution was increased up to 20 mol by water and stirred. The pH was automatically maintained at the starting pH with 2 M NaOH. At predetermined time intervals, 0.1 ml aliquots of the solution were withdrawn and diluted with 4% citric acid (1 ml) and distilled water (total volume, 100 ml). The consumption of Gly or Val was measured using HPLC (column, AApack Na; eluent, 0.1 M citrate buffer; pH 4.25; 60 °C).

Concentration Effect: Gly or Val (5 mmol) was dissolved in water and the concentration of the solution was adjusted to various concentrations (0.01—1 M). Z-ODSP (**1**, 5 mmol) was added to a solution and stirred. The pH was automatically maintained at the starting pH with 2 M NaOH. At determined time intervals, the same procedures were carried out as described above.

Syntheses and Structures of Indolo[6,7-*g*]indoles, a New Heteroaromatic System[1)]

Yoshinobu NAGAWA,* Midori GOTO, Koichi HONDA, and Hiroshi NAKANISHI
National Chemical Laboratory for Industry, 1-1, Higashi, Tsukuba, Ibaraki 305
(Received March 22, 1989)

Photolysis of 1,1′-(1,8-naphthylene)-bis(1*H*-1,2,3-triazole)s (**1**) in methanol has given new heteroaromatic system compounds, indolo[6,7-*g*]indoles (**2**). The spectral properties of these compounds were studied in comparison with those of the corresponding benz[*g*]indoles (**4**) obtained from the similar photolysis of 1-(1-naphthyl)-1*H*-1,2,3-triazoles (**3**). The ^{1}H NMR and IR spectra of **2** and **4** suggest the existence of a strong intramolecular hydrogen bonding in **2**. The X-ray crystallographic analysis of tetraethyl 1*H*, 10*H*-indolo[6,7-*g*]-indole-2,3,8,9-tetracarboxylate, **2a**, indicates that the molecule has almost twofold rotational symmetry, and the framework is distorted due to the steric overcrowding.

In order to know the properties of peri-substituted naphthalenes with heteroaromatic rings, we have synthesized novel 1,1′-(1,8-naphthylene)-bis(1*H*-1,2,3-triazole)s, which have triazole rings at 1 and 8 positions in the naphthalene ring, and investigated their structure by several spectroscopic analyses.[2)] According to the X-ray diffraction studies of these compounds, the naphthalene ring is considerably distorted owing to the steric repulsion between the two triazole rings.[3)] In addition to these studies, we have investigated photochemical reactions of these compounds. Products based on the interaction between the two triazole rings were expected, but they were not recognized in this reaction. Instead, new heteroaromatic system compounds, indolo[6,7-*g*]indoles, were produced by the denitrogenation from the triazole rings followed by the cyclization with the naphthalene ring.

In this paper, we describe the formation of these compounds by the photolysis of 1,1′-(1,8-naphthylene)-bis(1*H*-1,2,3-triazole)s (**1**) and their structural studies by spectroscopic analyses including X-ray crystallography.

Results and Discussion

Photolysis of Naphthyltriazoles. Irradiation of **1a** in methanol for 15 min afforded tetraethyl 1*H*,10*H*-indolo[6,7-*g*]indole-2,3,8,9-tetracarboxylate (**2a**), which was produced by the elimination of nitrogen molecules from two triazole rings and cyclization toward the naphthalene ring. There are several kinds of indoloindole structures possible depending on the mode of condensation of the two indole rings. Although indolo[3,2-*b*]indole[4)] and indolo[7,6-*g*]-indole[5)] are known, the indolo[6,7-*g*]indole skeleton has not yet been synthesized to our knowledge. A similar reaction was observed on photolysis of the corresponding monotriazoles (**3**). Irradiation of **3a** in methanol for 15 min gave diethyl 1*H*-benz[*g*]indole-2,3-dicarboxylate (**4a**) almost quantitatively. Only a few studies have been investigated about the photochemical reaction of triazoles.[6)] Burgess et al. reported the formation of ketenimine derivatives by the photolysis of 1,4,5-triphenyl-1*H*-1,2,3-triazole.[7)] On the other hand, 1*H*-azirine derivatives were detected by the pyrolysis of triazole rings.[8)] We presumed the formation of similar compounds to the present reaction, but could not detect them to any extent under the experimental conditions. The isopropoxycarbonyl derivatives **2b** and **4b** were also produced by similar photolyses from **1b** and **3b** in excellent yield.

Photolyses of **1** and **3** were followed by HPLC using an ODS column and methanol-water (90 : 10) as an eluent. The starting material (**3a**) disappeared completely after 2 min irradiation, while **1a** required 10 min for the complete decomposition. A similar difference was observed between **1b** and **3b**, indicating that triazolylnaphthalenes (**3**) decompose much faster than disubstituted ones (**1**). The decomposition of the triazole ring in **1** may be restricted by the adjacent triazole ring. As described above, 15 min irradiation of **1a** afforded indolo[6,7-*g*]indole derivatives, **2a**, while irradiation of **1a** for 2 min led to the intermediate diethyl 9-(4,5-diethoxycarbonyl-1*H*-1,2,3-triazol-

1-yl)-1*H*-benz[*g*]indole-2,3-dicarboxylate (**5a**), which was isolated from the solution. The amount of **5a** became maximum at 2 min irradiation and thereafter gradually decreased. Finally, **5a** could not detected after 15 min under the reaction condition.

Spectral Properties of Indoles. Spectral properties of **2a—b**, **4a—b**, and **5a—b** are listed in Table 1. In the ^{1}H NMR spectrum, the NH signal of **2a** is ca. δ 0.9 downfield from that of **4a**. This large low field shift is due to the intramolecular hydrogen bonding as well as the anisotropic effect between the two condensed indole rings. The N-H signal of **5a** is observed at ca. δ 2.3 upfield from that of **4a** in the ^{1}H NMR. The reason of this extremely upfield shift is due to the anisotropic effects of the triazole ring. Probably, the triazole ring is perpendicular to the benz[*g*]indole ring because of steric repulsion between the triazole ring and the pyrrole moiety. Then, the triazole ring faces toward the NH proton in short distance, and it makes such a large up-field shift.

In the IR spectrum, the N-H stretching frequency of **2a** is about 100 cm^{-1} lower than that of **4a**, which also suggests the existence of a strong intramolecular hydrogen bonding in **2a**. Since the IR spectra were measured in the very dilute concentration as low as 2 mM (1M=1 mol dm^{-3}), the effect of the intermolecular hydrogen bonding is ruled out for the low frequency shift. Owing to the enlargement of the condensed ring, the longest maximum wavelength band of **2a** shows about 30 nm red shift compared with that of **4a** in the UV spectrum. The spectral relationships observed for **2a**, **4a**, and **5a** as described above are also found in those between **2b**, **4b**, and **5b**. This means the substituted ester groups scarcely affect these spectroscopic properties.

Molecular and Crystal Structure of 2a. The molecular structure of **2a** with the atom numbering is presented by the ORTEP[9] drawing in Fig. 1. The selected bond distances and angles for **2a** are given in

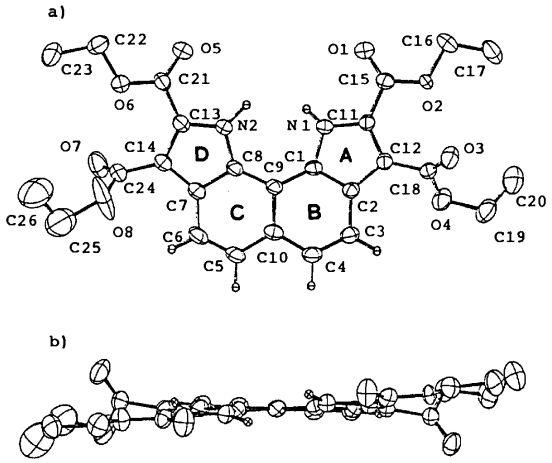

Fig. 1. Molecular structures of **2a**.
Non-hydrogen atoms are expressed as thermal ellipsoids with 40% probability level. Hydrogen atoms in ester groups are omitted for clarity.

Table 2.[10]

The molecule has an approximate twofold rotational symmetry with respect to the C(9)-C(10) bond. The fused angle C(1)-C(9)-C(8), 128.3 (4)°, is fairly large compared with the corresponding angle in naphthalene itself, 121.5°.[11] In a four-ring helicene, benzo[*c*]phenanthrene (**6**), the angle is 124.6°, which is smaller than that in **2a**.[12] These results reflect the

(6)

remarkable steric overcrowding in **2a**.

The dihedral angles between the four rings of **2a** defined in Fig. 1 are listed in Table 3 together with the corresponding data in **6**. The twistings are observed at same intervals from the ring A to the ring D in **2a**. Thus, the dihedral angle of the two pyrrole rings A and D is 9.8 (2)°, while the angle of the corresponding two benzene rings in **6** is 26.5°.[12] These results indicate that the molecule **2a** relieves the steric hindrance by enlargement of the angle C(1)-C(9)-C(8) and by rather small twists in the fused four rings, while the molecule **6** twists largely in order to relieve the steric hindrance. Although the two N-H bonds twist away from each other, the distance between the N-H hydrogen atoms is nearly equal to the sum of the van der Waals radii. The carbonyl groups bonded at the C(11) and C(13) atoms are almost coplanar to the pyrrole rings A and D, respectively, but the carbonyl groups at the C(12) and C(14) twist from the pyrrole ring planes by 55—60°.

The packing modes of molecules in the crystal is shown in Fig. 2. The crystal packing mainly results from intermolecular hydrogen bonds; the shortest

intermolecular distance is 3.005(6) Å for N(1)-O(3^{i}) (i=1−x,−y,1−z).

Experimental

Instruments. All melting points were determined on a Mettler FP61 instrument and were uncorrected. ^{1}H NMR spectra were obtained by a JEOL GX-400 spectrometer (399.65 MHz for ^{1}H nuclei) using TMS as an internal standard. IR and UV spectra were measured on a JASCO 5MP and a Shimadzu MPS-2000 spectrometer, respectively. MS spectra were measured with a JEOL JMS-01SG-2 spectrometer at 75 eV of ionization energy. Elemental analyses were performed on a YANACO MT-3 CHN analyzer.

Materials. Compounds **1** and **3** were prepared from 1,8-diazidonaphthalene and 1-azidonaphthalene, respectively, by 1,3-dipolar cycloaddition with acetylene dicarboxylate as previously reported.[2]

Photolyses of 1 and 3. A solution of **1a** (120 mg, 0.22 mmol) in 400 ml of methanol under nitrogen atmosphere was irradiated with a Ushio 450 W high-pressure mercury lamp through a quartz well at 30—35 °C for 15 minutes. Then, the solvent was evaporated, and the residue was chromatographed over silica gel (diethyl ether-hexane as eluent) to give pure **2a**.

2a: pale yellow needles, mp 209—210 °C, 76 mg (70%). Found: C, 63.08; H, 5.39; N, 5.62%. Calcd for $C_{26}H_{26}N_2O_8$: C, 63.15; H, 5.30; N, 5.66%.

Similarly, the photoreactions of **1b**, **3a**, and **3b** (0.22 mmol) in methanol gave **2b**, **4a**, and **4b**, respectively.

2b: pale yellow needles, mp 168—169°C, 72%. Found: C, 65.47; H, 6.16; N, 5.04%. Calcd for $C_{30}H_{34}N_2O_8$: C, 65.44; H, 6.22; N, 5.09%.

4a: colorless needles, mp 133—134 °C, 95%. Found: C, 69.52; H, 5.58; N, 4.53%. Calcd for $C_{18}H_{17}NO_4$: C, 69.44; H, 5.50; N, 4.50%.

4b: colorless needles, mp 116—117 °C, 94%. Found: C, 70.63; H, 6.31; N, 4.19%. Calcd for $C_{20}H_{21}NO_4$: C, 70.78; H, 6.24; N, 4.13%.

Irradiation of **1** for 2 min gave **5** together with the starting material (**1**) and indoloindole, and they were separated with silica-gel chromatography as in case of **2**.

5a: colorless needles, mp 93—94°C, 25%. Found: C, 59.65; H, 4.97; N, 10.65%. Calcd for $C_{26}H_{26}N_4O_8$: C, 59.77; H, 5.02; N, 10.72%.

5b: colorless needles, mp 67—68 °C, 30%. Found: C, 62.33; H, 5.95; N, 9.59%. Calcd for $C_{30}H_{34}N_4O_8$: C, 62.27; H, 5.92; N, 9.68%.

X-Ray Analysis of Compound 2a. Pale yellow needle-like crystals of **2a** were obtained by a slow evaporation of hexane-diethyl ether solution at room temperature. The crystal, approximate dimension of 0.75×0.25×0.10 mm, was used for intensity data measurements.

Crystal data of **2a**; $C_{26}H_{26}N_2O_8$, M=494.5, triclinic, space group $P\bar{1}$, a=9.366(1), b=10.330(1), c=13.052(2) Å, α=101.85(2), β=90.76(2), γ=104.35(4)°, V=1194.6(1) Å^3, D_m=1.39 Mg m^{-3} (by floatation in carbon tetrachloride and hexane), D_c=1.38 Mg m^{-3} for Z=2, μ(Mo$K\alpha$)=0.111 mm^{-1}. The cell dimension and diffraction intensity were measured on a Rigaku AFC-4 four-circle diffractometer with graphite monochromated Mo$K\alpha$ radiation (λ=0.71069 Å) at room temperature. Unit cell dimensions were determined by least-squares fits using 25 reflections in the range $20°<2\theta<30°$. Intensity data were collected by the ω-2θ scan mode at a rate of 2° (2θ)min^{-1}. The scan range was from 2° to 55°. Three standard reflections (202, 022, and 2—20) were measured after every 50 reflections, showing no significant intensity decay throughout the data collection. Totals of 5532 reflections were measured, of which 3111 with $|F_o|>3\sigma|F_o|$ were used. The usual Lorentz and polarization corrections were applied, but no absorption corrections were made. The structure was solved by the direct method using MULTAN78.[13] An E-map using 244 ($|E|>1.2$) revealed all non-hydrogen atoms. Hydrogen atoms in the rings were found from a difference electron density map and those in the ester groups were placed at the calculated positions. The structure was refined by a full-matrix least-squares method, using the UNICS III system.[14] Anisotropic thermal parameters were assumed for the non-hydrogen atoms, and isotropic parameters, for the hydrogen atoms. The final refinement, employing a weighting scheme of $w=(0.011\,|F_o|^2-0.161|F_o|+1.245)^{-1}$, led to R and R_w values of 0.085 and 0.090, respectively. The final atomic parameters are listed in Table 4. Atomic scattering factors were taken from International Tables for X-Ray Crystallog-

Lipid-Protein Interaction in Mixed Monolayers from Phospholipids and Proteins

Tomoyoshi MITA
Department of Natural Science, Osaka Women's University, Daisen-cho, Sakai, Osaka 590
(Received March 29, 1989)

The thermotropic behavior of different proteins with phospholipids in monolayers was investigated by measuring the surface pressure and the surface viscosity. When phospholipids, such as dipalmitoylphosphatidylcholine (DPPC) and dimyristoylphosphatidylcholine (DMPC), were mixed with the hydrophobic proteins, such as hemoglobin and β-casein, below their phase transition temperatures (T_c), a considerable expansion of monolayers was observed. On the other hand, when phospholipids were mixed with the hydrophilic proteins, such as bovine serum albumin (BSA) and lysozyme below T_c, no expansion was observed. When DMPC was mixed with different proteins at T_c or above, all mixtures formed slightly deviated monolayers from ideal mixing, independent of a variety of proteins. This type of behavior suggests that the hydrophobic proteins perturb the structure of boundary lipids near the protein molecule below T_c, while the hydrophobic proteins do not perturb the phospholipid structure below T_c because of their low hydrophobicities. At T_c or above the membrane properties are independent of a variety of proteins, because all lipid hydrocarbon chains cause a disordering, even without proteins. In addition, when DPPC was mixed with a hydrophobic protein, such as hemoglobin, the fluidity of monolayer increased significantly.

The importance of studying mixtures of lipids and proteins in membranes is obvious when one considers the currently accepted fluid mosaic model of membranes.[1] Good knowledge concerning lipid-protein interaction is a key to understanding the structure and function of biological membranes. Intimately related to the above subject is the question how different proteins affect the physical properties of biological membranes, such as membrane fluidity.

From this viewpoint, various theoretical models have been proposed to study the lipid-protein interaction and its effect on the properties of biological membranes.[2-6] A large body of experimental data on the lipid-protein interaction in membranes has also been accumulated during the last two decades by using different experimental techniques; e.g., differential scanning calorimetry (DSC), electron spin resonance (ESR), Raman spectroscopy, deuterium magnetic resonance (^{2}H NMR), fluorescence anisotropy (FA). Chapman et al.[7] have investigated the effect of proteins on the phase behavior of membranes by using DSC and noted that cytochrome C decreases the phase-transition temperature (T_c) of a lipid membrane. On the contrary, Verkleij et al.[8] have reported that the basic myelin protein increases the T_c of a membrane. Papahadjopoulos et al.[9] have reported that a variety of proteins has very different effects on the lipid phase transition from gel to liquid crystalline. In addition, the effect of proteins on lipid order in membranes has been intensively investigated by means of the above-mentioned techniques. That is, the results based on ESR, FA, and Raman spectroscopy indicate that proteins increase the lipid order.[10] On the other hand, ^{2}H NMR indicates that proteins decrease the lipid order.[11] In this way, no consensus has been attained as to whether proteins in biological membranes change the T_c of lipids or not and cause an ordering or disordering of the lipids.

According to the criteria of Papahadjopoulos et al.[9] the physical properties of biological membranes, are characteristic of a hydrophobic interaction between protein and lipid molecules. In addition, Jähnig[12] has demonstrated that the hydrophobic effect of proteins provides the main driving force for insertion into the membrane. Then, many investigators have attempted to define the hydrophobicity of proteins. A fluorescence probe method has been proposed for the evaluation of protein hydrophobicity.[13] However, the above-mentioned hydrophobicity is susceptible to change by the unfolding of proteins, since it reflects the surface hydrophobicity of native proteins. On the other hand, Bigelow[14] has proposed the average hydrophobicity, $H\phi_{ave}$, based on Tanford's Gibbs energy of the transfer of amino acid side chains from an organic environment to an aqueous environment. This index is not influenced by any conformational changes of proteins. In a similar manner, Kyte and Doolittle[15] have proposed the hydropathy index, based upon the probability of being exposed to water from the hydrophobic parts of proteins as well as the Gibbs energy of transfer from water to an organic solvent. The former method for protein hydrophobicity is considerably simpler than the latter. Proteins with high hydrophobicity exhibit higher values of $H\phi_{ave}$ (over 4.6 kJ·res.$^{-1}$).

Previously, the author reported on the thermotropic behavior of different proteins in monolayers.[16] It was observed that the temperature-dependences on the π-A isotherms of hydrophobic proteins, such as hemoglobin ($H\phi_{ave}$=4.65 kJ·res.$^{-1}$) and β-casein ($H\phi_{ave}$= 5.57 kJ·res.$^{-1}$), were fairly different from those of hydrophilic proteins, such as lysozyme ($H\phi_{ave}$=4.06 kJ·res.$^{-1}$) and bovine serum albumin (BSA, $H\phi_{ave}$= 4.35 kJ·res.$^{-1}$), and that hydrophobicity of proteins was an important factor related to the thermal stability of proteins in membranes. Thus, the above-

mentioned confusion may be attributed to differences in the hydrophobicity of proteins.

In order to study the lipid-protein interaction in membranes, the spread monolayer technique is useful, since the orientation of lipid and protein molecules at the air-water interface can be precisely understood by using this technique and the area occupied by each molecule can be determined over a wide limit by careful compression of the monolayers. Then, the interaction of proteins with lipids at the air-water interface has been studied by many workers,[17-21] usually by the technique of injecting protein under preformed lipid monolayers and by measuring the increment of surface pressure during the interaction. However, the above injection technique has serious limitations in that the surface concentration of proteins is not known. Recently, the interaction of lipids with proteins at the air-water interface by spreading the components from a common solvent has been investigated.[22-24]

In this paper, we examined the hydrophobic effect of proteins on the thermotropic behavior of phospholipids, as measured by the miscibility in the mixed monolayers which are obtained by spreading the mixtures dissolved in a common solvent. These results were then discussed concerning the phase behavior of phospholipids. Although the proteins used were not membrane bound but, rather, water soluble, they were chosen because of their well-known amino acid sequences and their three-dimensional structures. The present work also investigated the rheological properties of mixed monolayers from phospholipids and proteins by using a surface viscometer.

Experimental

Reagents. All chemicals were of the highest purity available, used without further purification. Water was distilled once, passed through a mixed ion bed exchanger and redistilled.

Materials. The following high-purity proteins were used in this study from the suppliers: BSA (fatty acid free), bovine hemoglobin (2×crystallized), and bovine β-casein were from Sigma Chemical Co., and lysozyme (6×crystallized) was product of Seikagaku Kogyo Co. The phospholipids dipalmitoylphosphatidylcholine (DPPC) and dimyristoylphosphatidylcholine (DMPC) (Sigma Chemical Co.) used were specified to be 99% pure and were used without further purification.

Surface Pressure. The film balance used for measuring the surface pressure has been described in detail elsewhere.[16] The trough was coated with Teflon and the entire balance was surrounded by a water jacket, providing temperature control within 1 °C. A 50% 1-propanol containing 0.5 mol·dm^{-3} sodium acetate was employed as a spreading solvent for proteins and phospholipids. After the respective proteins and phospholipids were dissolved in the solvent at a concentration of 0.05%, these solutions were stored in a refrigerator and used after about 24 h. For mixed monolayers, the mixtures of lipids and proteins were obtained by an appropriate volumetric mixing of solutions containing each component before application. In the experiments reported below, no buffer was used, in order to prepare a very simple subphase. The water was poured in the trough to a height of 1—2 mm above the rim. The surface of the subphase was cleaned by moving a Teflon barrier from one side of the trough to the other. The cleaning of the surface was repeated until the surface pressure of the subphase did not exceed 0.2 mN·m^{-1}. For the surface pressure-area (π-A) isotherm, these solutions (0.1 cm^3) were then spread onto an area of 897 cm^2. Monolayer spreading was made by a direct application of numerous small drops (≈0.0006 cm^3) of the solution to the surface of the subphase by using a microsyringe (Hamilton Co.), introduced by Ställberg and Teorell.[25] A time interval of 30 min was allowed for the equilibration of the monolayers before it was compressed. The π-A isotherms were obtained by using a compression velocity of 0.0567 m^2·mg^{-1}·min^{-1}.

Surface Viscosity. A Kyowa's surface viscometer (type SVR, Kyowa Surface Science Co.) was used. This apparatus was a rotational torsion surface viscometer of the type described by Karam.[26] The viscometer consisted of a knife-edged bob which hung freely from a torsion wire. A removable dish was placed on a turntable beneath the bob. The radii of the bob and dish were 2.5 and 7.5 cm, respectively. After the knife edge of the bob was placed on the surface of substrate, the monolayer spreading, based upon the recipe for measuring the surface pressure, was made. From the period and damping of the oscillation, the surface viscosity η_s expressed in mN·s·m^{-1} was calculated as follows:

$$\eta_s=\frac{2.303\,I}{2}\left(\frac{\lambda}{T}-\frac{\lambda_w}{T_w}\right)\left(\frac{1}{r_1^2}-\frac{1}{r_2^2}\right), \quad (1)$$

where I is the moment of interia, r_1 and r_2 the respective radii of the bob and dish, λ the (decadic) logarithmic decrement of the oscillation, and T their periodic time when the surface is covered by the monolayers; λ_w and T_w are the respective values for the clean surface.

Each part of all experiments was repeated at least three times and then averaged.

Results

Characteristics of Mixed Monolayers from DPPC and Proteins at an Air-Water Interface. Treatment of data involved adapting the theory of mixing in bulk to a two-dimensional situation. For ideal mixing, monolayers obey the following equation:[27]

$$A_{1,2}=n_1A_1+n_2A_2, \quad (2)$$

where $A_{1,2}$ is the average molecular area in the two-component film, n_1 and n_2 are the respective mole fractions, and A_1 and A_2 are the molecular areas in the two single-component films at the same surface pressure. In case the interaction between two components is detected, Eq. 2 is obeyed.

However, most biological membranes are composed of approximately 50% lipids and 50% proteins by weight,[28] and the molecular weights of proteins are extremely different from those of lipids. Then, Eq. 2

is modified as follows:

$$A_{l,p} = w_l A_l + w_p A_p, \quad (3)$$

where $A_{l,p}$ is the occupied area, expressed in $m^2 \cdot mg^{-1}$, in the mixed monolayer of lipid and protein, w_l and w_p are the respective weight fractions of lipid and protein, and A_l and A_p are the areas ($m^2 \cdot mg^{-1}$) in the lipid and protein monolayers at the same surface pressure.

Figure 1 shows typical π-A isotherms obtained at 25 °C for monolayers of hemoglobin, DPPC, and a mixture (1/1 in weight ratio) of the two spread on water, respectively. The calculated curve shown in Fig. 1 represents the behavior found when the additivity rule in Eq. 3 is obeyed. The result indicates that when DPPC is mixed with hemoglobin below its T_c (T_c=41 °C)[29] an expansion from the calculated curve occurs. Similar measurements were made with DPPC-β-casein, DPPC-BSA, and DPPC-lysozyme mixtures in various weight ratios. Although the deviation from ideal in the area of a mixed monolayer is observed by direct inspection of Fig. 1, a more convenient way of presenting the results of a number of runs on monolayers of the mixtures of different compositions is shown in Figs. 2 and 3. Here, the occupied area of the mixed monolayer at constant surface pressures is plotted as a function of the weight fraction of DPPC in the monolayers. The broken line on these plots represents the behavior found when the additivity rule is obeyed. When DPPC was mixed with such hydrophobic proteins as hemoglobin and β-casein[16] below T_c, an expansion or positive deviation from the additivity line occured. On the other hand, when DPPC was mixed with such hydrophilic proteins as BSA and lysozyme[16] below T_c, little deviation from the additivity line occured.

Phospholipids form a condensed monolayer or a gel phase below T_c and form an expanded monolayer or liquid crystalline phase above T_c.[27] Accordingly, the temperature-dependence upon the lipid-protein interaction in membranes must be investigated. However, the T_c of DPPC is fairly higher than room temperature, and it is difficult to measure the surface pressure near T_c or above, since the surface evaporation of water from subphase occurs appreciably. Then, additional experiments were made by using DMPC (T_c=24 °C[29]).

Temperature-Dependence of Mixed Monolayers from DMPC and Proteins at an Air-Water Interface. Figures 4 and 5 show plots of the area of mixed monolayers composed of DMPC-hemoglobin and DMPC-β-casein at constant surface pressures as a function of the weight fractions of DMPC in their monolayers at different temperatures, respectively. When DMPC was mixed with hemoglobin below T_c (15 °C), a positive deviation from the additivity rule occured as well as DPPC. On the contrary, when DMPC was mixed with hemoglobin at T_c (24 °C) or

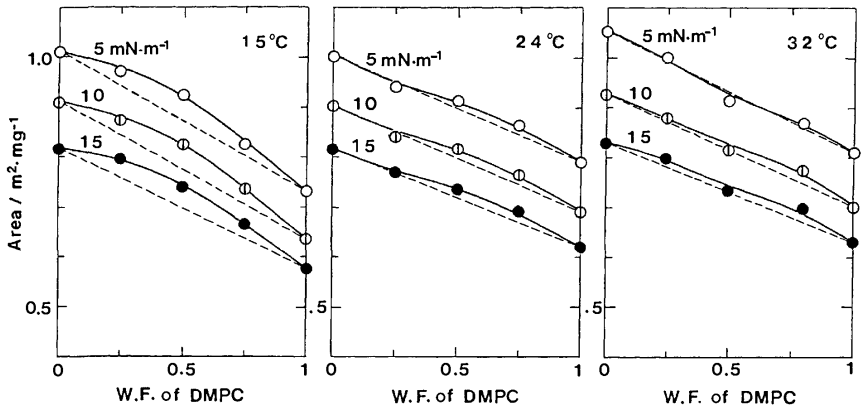

Fig. 4. Plots of mean area of DMPC-hemoglobin monolayer as a function of weight fractions of DMPC at different temperatures.

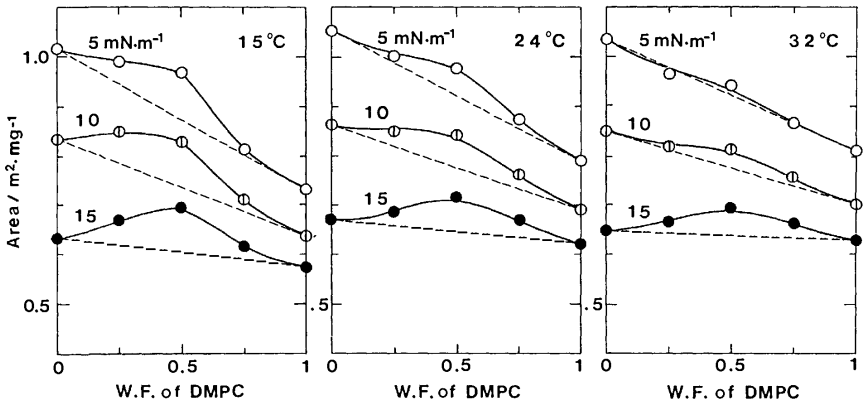

Fig. 5. Plots of mean area of DMPC-β-casein monolayer as a function of weight fractions of DMPC at different temperatures.

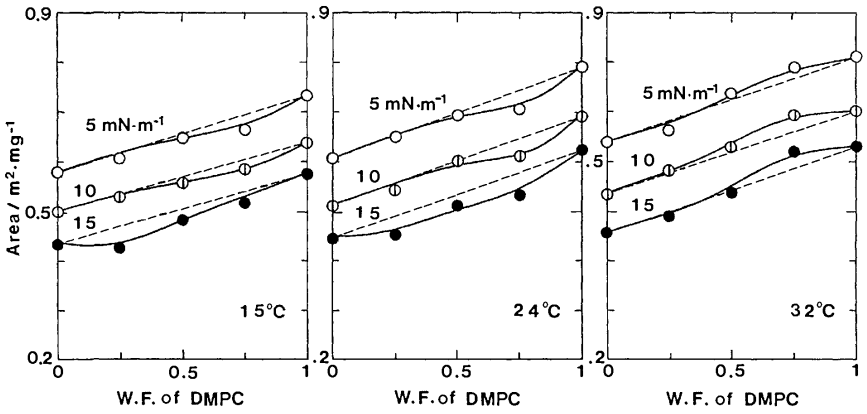

Fig. 6. Plots of mean area of DMPC-lysozyme monolayer as a function of weight fractions of DMPC at different temperatures.

above (32 °C), where DMPC was in a liquid crystalline state, little deviation from the additivity rule occured. When DMPC was mixed with β-casein below T_c, a large expansion from the additivity rule was observed. On the other hand, for the mixed monolayer of DMPC and β-casein, the magnitude of expansion decreased significantly at T_c or above. Figure 6 shows plots of area of the DMPC-lysozyme monolayer at constant surface pressures as a function of the weight fractions of DMPC at different temperatures. Strictly speaking, the DMPC-lysozyme mixture formed a slightly condensed monolayer from the ideal mixing at T_c or below, while the mixture formed a slightly deviated monolayer from the ideal mixing above T_c.

Surface Viscosity of Mixed Monolayers from DPPC and Proteins at an Air-Water Interface. The viscos-

ity, $\eta(c_A,c_B)$, of a solution containing two components, A and B, at concentrations c_A and c_B, is expressed by

$$\eta(c_A,c_B)=\eta_0\{1+([\eta_A]w_A+[\eta_B]w_B)c+s_mc^2+\cdots\}, \quad (4)$$

where $c=c_A+c_B$, $w_A=c_A/c$, $w_B=c_B/c$. η_0 is the solvent viscosity, $[\eta_A]$ and $[\eta_B]$ are the respective intrinsic viscosities of both components in a pure solvent, and s_m is the interaction parameter.[30] If there is no interaction between the two components, the third and following terms in the brace of the right-hand side of Eq. 4 may be ignored. Then, Eq. 4 can be approximated by

$$[\eta_{A,B}]=[\eta_A]w_A+[\eta_B]w_B, \quad (5)$$

where $[\eta_{A,B}]$ is the intrinsic viscosity of the solution containing two components. Accordingly, for ideal mixing without interaction between two components, the surface viscosity of monolayers may obey the additivity rule, as described in Eq. 3, although there are some problems in adapting the theory of mixing in bulk to the two-dimensional situation.

Figure 7 shows the surface viscosity-area (η_s-A) isotherms obtained at 25 °C for monolayers of hemoglobin, DPPC, and the mixtures of the two spread on water. The calculated curve for a mixture (1/1 in weight ratio) shown in Fig. 7 represents the behavior found when the additivity rule is obeyed. For the hemoglobin monolayer, η_s steeply appeared at a higher area than that where π was detectable. On the other hand, for the DPPC monolayer, η_s suddenly appeared at a slightly lower area than which corresponded to the limiting area (0.46 $m^2 \cdot mg^{-1}$). When DPPC was mixed with hemoglobin, a negative deviation from the additivity rule was observed, in contrast to the behavior of π-A isotherm. For example, when DPPC was mixed with hemoglobin at 1/1 in weight ratio, a considerable condensation from the calculated curve was observed. The above-mentioned result indicates that, when DPPC is mixed with hemoglobin below its T_c, η_s of the monolayer decreases by a fair amount. In addition, by using the mixture of DMPC and hemoglobin a measurement of η_s was attempted above T_c. Unfortunately, the measurement was unsuccessful because η_s of pure DMPC in a monolayer was very low.

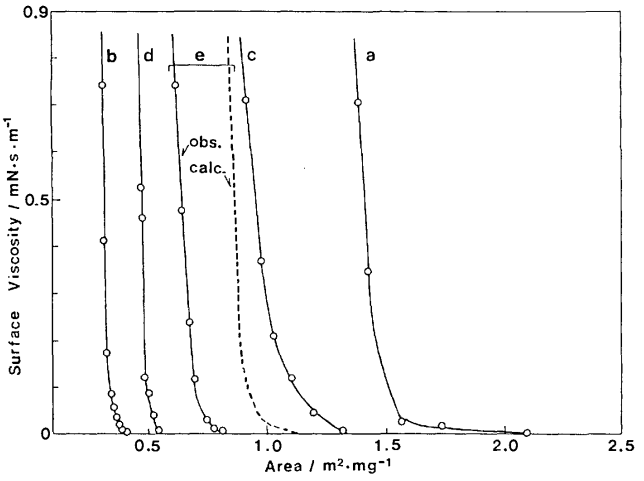

Fig. 7. η_s-A isotherms for monolayers of hemoglobin, DPPC, and mixtures of the two at 25 °C. a) hemoglobin, b) DPPC, c) DPPC-hemoglobin (1/3 in weight ratio), d) DPPC-hemoglobin (3/1), e) DPPC-hemoglobin (1/1); ——, experimental; ----, calculated from Eqs. 3 and 5.

Discussion

Because of the amphipathic nature of protein, the change to an extended conformation in which the protein molecule lowers the Gibbs energy of the system by maximizing contact of nonpolar side chains with the nonpolar phase is understandable. One must, therefore, consider whether the proteins denature irreversibly at the air-water interface or not. When the protein solutions are shaken, the insoluble protein due to the surface denaturation is occasionally seen to separate out. A comparison between the ease of coagulation (irreversible denaturation) by shaking a number of proteins has been carried out by Henson et al.[31] There is a significant difference in the ease of coagulation between the different proteins. Ovalbumin is especially susceptible, and β-lactoglobulin and γ-globulin also coagulate readily at the air-water interface. However, the β-casein, hemoglobin, BSA, and lysozyme, used in this study, are hardly influenced. According to MacRitchie,[32] every protein has a critical surface pressure, π_c, at the air-water interface, and will precipitate once this is exceeded. The coagulation may be observed, therefore, when the spread protein monolayers are compressed above π_c. However, our compression experiment was π_c. In addition, the view that the secondary structure of such proteins as the α-helix is stable at the air-water interface has been reported.[33] Accordingly, it is considered that surface denaturation did not occur during this study.

Biological membranes are sensitive to variation in the environment; for example, temperature essentially modifies such membrane characteristics as the permeability and excitability. Then, most lipids of biological membranes are normally in the liquid crystalline state at physiological temperatures and the lipids have the structure of a bilayer with low viscosity, deformability, and the ability to self-seal.[34] From this viewpoint, the effect of cholesterol on the membrane fluidity has been studied by a number of methods. The picture that emerges from these studies, summarized by Oldfield and Chapman,[35] is that cholesterol somehow fluidizes a lipid that is below the T_c, but rigidifies a lipid above T_c. This effect is called "dual effect."[36] Protein may also exhibit such a behavior as well as cholesterol in biological membranes. It has been found that boundary lipids near a

protein molecule have considerable differences in fluidity and conformation from those of the bulk lipids in the protein-free region and that the boundary lipids of many proteins are more fluid or have more gauche bonds in their hydrocarbon chains than the bulk lipids in the gel phase of the membranes, while the boundary lipids are more rigid or have more trans bonds than the bulk lipids in the liquid crystalline phase.[37-40]

When such phospholipids as DPPC and DMPC were mixed with such hydrophobic proteins as hemoglobin and β-casein below their T_c, a considerable expansion was observed (Figs. 2, 4, and 5), showing the lipid-protein interaction in membranes. On the other hand, when phospholipids were mixed with such hydrophilic proteins as BSA and lysozyme below T_c, no expansion was generally detected (Figs. 3 and 6), showing no interaction between lipids and proteins. Especially, the DMPC-lysozyme mixture formed a slightly condensed monolayer from the ideal mixing below T_c.

Papahajopoulos et al.[9] have extensively studied the effects of different proteins on the thermotropic phase transitions of phospholipid membranes, as detected by DSC and have indicated that ribonuclease leads to an increase in the enthalpy of the transition (ΔH) without any change in T_c, while hemoglobin and gramicidin induce a drastic decrease in ΔH accompanied by either a decrease or no change in T_c. Then, it is considered that a very hydrophilic protein, such as ribonuclease,[16] causes an ordering of the lipid hydrocarbon chains below the T_c of lipids, leading to an increase in ΔH, while such hydrophobic proteins as hemoglobin and gramicidin[14] cause a disordering of the chains below T_c, leading to a decrease in ΔH. In addition, O'Leary[41] has reported that proteins always weaken the intensity of the first-order lipid phase transition (pre-transition), and that they may cause it to broaden, and may induce other continuous transitions above or below it in temperature, depending on the system.

Accordingly, we consider that the hydrophobic proteins lead to an increase in the configurational freedom of lipid hydrocarbon chains, such as trans-gauche conversion,[6,42] due to a hydrophobic effect of proteins with lipid chains, resulting in an expansion of the monolayers composed of lipids and proteins, while that the hydrophilic proteins do not lead any configurational changes because of their low hydrophobicities, exhibiting ideal mixing. Very hydrophilic proteins, such as lysozyme, lead to an increase in the configurational restriction of lipid hydrocarbon chains, due to the electrostatic interaction of the polar head groups with the proteins, inducing the condensation of monolayers. On the other hand, when the phospholipid DMPC was mixed with different proteins near its T_c or above, all mixtures of DMPC-proteins formed little deviated monolayers from the ideal mixing, independent of a variety of proteins (Figs. 4—6). This suggests that the expansion behavior due to the hydrophobic effect does not occur, because all lipids are in the liquid crystalline state near T_c, or above.

The thermotropic behavior of phospholipid molecules in reconstituted glycophorin-containing vesicles has been investigated by means of DSC.[43] Each glycophorin molecule is able to perturb the properties of 80—100 phospholipid molecules, independent of the protein-to-lipid ratio in the membranes, in such a way that these lipid molecules no longer participate in the cooperative gel-to-liquid crystalline phase transition. A value of 15 lipid molecules per protein molecule has also been reported for lipophilin,[44] ten for melittin,[45] and six for gramicidin.[37]

The structural change of proteins owing to lipid-protein interaction in monolayers may be negligibly smaller than that of lipids. Then, the perturbed-to-unperturbed lipid ratios in the mixed monolayers are derived from Eq. 3,

$$A_{l,p} = w_l\{A'_l x + (1-x)A_l\} + w_p A_p, \quad (6)$$

where x is the mole fractions of the perturbed lipids in whole lipids, A'_l and A_l are the respective areas ($m^2 \cdot mg^{-1}$) in the perturbed and unperturbed lipid monolayers, A_p and $A_{l,p}$ are the respective areas in the protein and lipid-protein monolayers at the same surface pressure, and w_l and w_p are the respective weight fractions of lipid and protein. When the phospholipid DPPC is dispersed in excess water, the area per molecule in bilayers is about 4.8 nm^2 below T_c and about 7.0 nm^2 above T_c.[46] A fully-expanded DPPC monolayer above T_c occupies 7.0 $nm^2 \cdot molecule^{-1}$ when π is approximately 20 $mN \cdot m^{-1}$.[27] Since the value of the molecular weight of DPPC is 734, the areas expressed in 4.8 and 7.0 $nm^2 \cdot molecule^{-1}$ correspond to areas of 0.39 and 0.57 $m^2 \cdot mg^{-1}$, respectively. In Fig. 1, when π is 20 $mN \cdot m^{-1}$, hemoglobin and mixture (1/1 in weight ratio) occupy 0.70 and 0.60 $m^2 \cdot mg^{-1}$, respectively. This indicates that about 60% of all lipid molecules are perturbed in the mixed monolayer below T_c (25 °C). Then, it is understandable by the application of the molecular weight (64500) of hemoglobin that each hemoglobin molecule perturbs the properties of 50—60 phospholipid molecules.

Since the molecular weight of hemoglobin is about twice that of glycophorin,[47] and extremely larger than those of lipophilin, melittin, and gramicidin, the value of perturbed lipid molecules per hemoglobin molecule is slightly smaller than those of the integral proteins. This may be attributed not only to a difference in the hydrophobicity between the proteins, but also to a difference in the membrane properties between the monolayer and bilayer. When one considers a two-dimensional lattice of lipid molecules surrounding the protein, each hemoglobin molecule complexes 40—50 phospholipid molecules, independ-

ent of the protein-to-lipid ratio in the monolayer. However, this will be greatly diminished by the phase separation into the protein-rich and protein-free domain below T_c.[21] Then, the perturbation of the phospholipid structure near the hemoglobin molecule, while most pronounced within the annulus of the first neighbor molecules, will extend at least two layers beyond the annulus, coinciding with the result of Marčelja.[2]

Speth and Wunderlich[48] have shown by freeze-etch electron microscopy that, after chilling the cells of protozoan *Tetrahymena pyriformis*, the particles, which are randomly distributed on the outer faces of the fractured alveolar membranes, are largely aggregated, showing a clustering of membrane proteins. This indicates that, when the cells are rapidly cooled, the fluidity of biological membranes is regulated by the phase separation of membrane proteins.[49] The η_s-A isotherms for phospholipid-hemoglobin mixtures showed a considerable condensation below T_c, in contrast to the behavior of π-A isotherms (Fig. 7). Such behavior suggests that, when the phospholipids are mixed with the hydrophobic proteins such as hemoglobin below T_c, the fluidity of the monolayer increases significantly, depending on both the perturbation of lipid hydrocarbon chains and the phase separation of proteins in the monolayers. It is also related to the above-mentioned behavior that hemoglobin drastically increases the permeability of phospholipid vesicles.[50,51]

Finally, we consider the protein distribution is the mixed monolayers from phospholipids and proteins. According to Heckl et al.,[21] the high packing densities in the condensed lipid phases below T_c do not allow for a distribution due to protein penetration, while the low packing densities in the expanded lipid phases above T_c permit a homogeneous distribution of proteins in the monolayers. Accordingly, based on the lattice model of a phospholipid bilayer containing integral protein constructed by Lookman et al.,[52] the model shown in Fig. 8 is being proposed for monolayers composed of phospholipids and different proteins as a function of temperature. The black, open hexagons represent such hydrophobic proteins as hemoglobin and β-casein and such hydrophilic proteins as BSA and lysozyme, respectively. The dots represent perturbed lipids, and the blank areas represent unperturbed lipids. Below T_c the proteins are highly clustered, while at T_c or above they are more uniformly distributed. The hydrophobic proteins perturb the hydrocarbon chains of boundary lipids near the protein molecule below T_c. This perturbation, caused by the protein, extends at least to the second neighbor, leading to an expansion of the monolayers. On the other hand, the hydrophilic proteins do not perturb the phospholipid structure below T_c because of their low hydrophobicities, showing ideal mixing in monolayers. At T_c or above, the membrane properties are independent of a variety of proteins, since all lipid hydrocarbon chains cause a disordering, which results in ideal mixing.

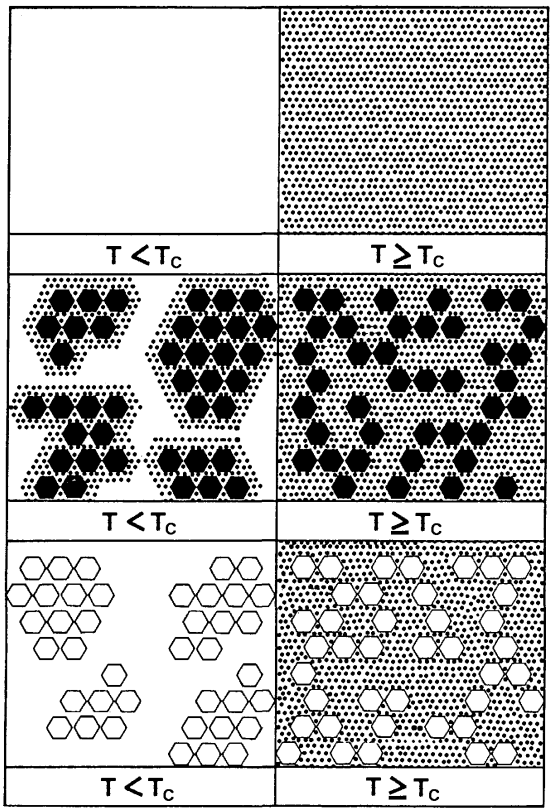

Fig. 8. A model of monolayers composed of phospholipids and different proteins as a function of temperatures, based on the lattice model of proteins and lipids in computer simulation by Lookman et al.[52] The black and open hexagons are the respective hydrophobic and hydrophilic proteins, the dots are perturbed lipids, and the blank areas are unperturbed lipids.

(Received March 31, 1989)

Polychlorobenzenes, polybromobenzenes, and polychloropolybromobenzenes ($C_6H_{6-n}X_n$) were photolyzed in benzene solutions; the products were analyzed by the GC/MS method. Both dehalogenation and phenylation were shown to take place competitively, producing (poly)halobenzenes bearing one less halogen atom ($C_6H_{7-n}X_{n-1}$) and (poly)halobiphenyls ($C_6H_{6-n}X_{n-1}$-C_6H_5) as the major products. Besides these products, terphenyl was produced by a consecutive phenylation of the halobiphenyl formed. Polychlorobenzenes were shown to form the corresponding terphenyls only when a pathway via 2-chlorobiphenyl is possible; however, polybromobenzenes can produce terphenyls through any of the isomeric bromobiphenyls intermediarily formed. Isomerization through *m*-migration of a chlorine atom was also shown to occur to a considerably lesser extent.

In connection with the photochemical degradation of toxic polyhalobenzenes, several photo-dehalogenation procedures of polyhaloaromatic compounds have been reported.[1-4] Pinhey and Rigby,[5] as well as Ichimura and Mori,[6,7] have independently studied the mechanism of dehalogenation of simple halobenzenes, showing that the initial photochemical process is the fission of the carbon-halogen bond proceeding via a pi-pi* triplet state, of this reaction involved. In contrast to the initial photophysical and photochemical processes involved, the subsequent reactions of the aryl free radicals generated from monohalobenzenes have been extensively studied.[8] The aryl free radical generated by this initial process is assumed to induce several subsequent reactions, such as the abstraction of a hydrogen atom from the solvent, substitution of a hydrogen atom in the solvent molecule, etc. However, relatively few investigations have been reported on the photolytic behavior of polyhalobenzens.[3,4]

We previously examined the photoreactions of polyhalobenzenes in both hexane[9] and acetonitrile,[10] showing that the reactivities of halogen atom in the substrate depend both on its chemical environment and on the nature and number of substituent halogen atoms. It was also shown that a more crowded halogen atom leaves more easily. The photolyses were also dependent on the nature of the solvent, giving isomerized products in solvents which resist hydrogen abstraction.

In this paper, we discuss the photochemical behavior of polyhalobenzenes in benzene solutions, where both dehalogenation and phenylation take place competitively. Special attention is paid to the formation of terphenyls by the consecutive phenylation of the halobiphenyls primarily formed.

Experimental

Materials. The polyhalobenzenes and chlorobiphenyls employed in this research are all known compounds. They were either purchased commercially or prepared by the known methods[11,12] and used after purification by distillation or by column chromatography.

Photoreactions. The photoreactions were carried out using a 32-W (or 20-W) low-pressure mercury arc lamp placed at the center of a concentrically surrounding quartz vessel containing the solution of the reactant polyhalobenzene. They were carried out under a nitrogen atmosphere, unless otherwise noted.

Spectral and Gas Chromatographic Measurements. Gas chromatography/mass spectrometry measurements were carried out on a Hitachi RMU-6L, a Shimadzu LKB-9000-B, or a Shimadzu QP1000 mass spectrometer. Routine gas chromatographic analyses of the products were carried out on a Shimadzu GC-6A or a GC-4B-PTF apparatus equipped with a Silicone SE 30 or an Apiezon L column (3 mm×2 m).

Results and Discussion

General Trends of the Photoreactions. As described in our previous papers,[9,10] the photoreactions were pursued by quantitative GC analyses of the products and the unreacted starting halobenzene. Since our interests were focused on the products in various solvents, only the relative reactivity is presented and discussed. The reaction mixture was sampled at regular intervals and the products were analyzed. The products at halfway conversions of various polyhalobenzenes are given in Table 1.[13]

The reactions in benzene solutions proceeded far more slowly than those in hexane. They are even slower than those in acetonitrile, which is assumed to be a less reactive solvent towards hydrogen abstraction. For example, *o*-dichlorobenzene was photolyzed 26.5-times faster in hexane and 17.6-times faster in acetonitrile when compared with a similar reaction in benzene. The retardation by benzene is quite general in the photolyses in Table 1; it might be ascribable to light absorption by the solvent.

As foreseen from the previous results,[8,14] both dehalogenation and phenylation reactions proceed com-

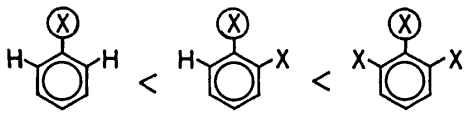
a) Reactions were carried out by using a 32-W low pressure mercury arc lamp under nitrogen atmosphere at ambient temperature (ca. 25 °C). The concentrations of the reactants were 0.10 mol l^{-1} except the runs otherwise remarked. Following abbreviations were used: C=conversion of the reactant, B=benzene, BP=biphenyl, and TP=terphenyl. Yields were calculated with respect to the reactant. b) The overlap of other weaker GC peak(s) is suspected. c) 20-W Lamp was employed for the irradiation. d) 0.04 mol l^{-1}.

petitively. In all runs in Table 1, the phenylation proceeds more predominantly than the dehalogenation when compared with the products of the primary photolysis of the starting polyhalobenzenes. This trend is shown illustratively in the time-conversion curves of Fig. 1. The preference of phenylation becomes more significant in the cases of chlorinated benzenes than in the cases of brominated benzenes. Dihydrobiphenyl derivatives can also be expected to be generated by the disproportionation of the arylcyclohexadienyl radical intermediate (**1**).[15,16)] Actually, they were detected in neither case.

The orientation of the photochemical dechlorination and phenylation in benzene is similar to those observed previously with the reactions in hexane;[9)] i.e., the C-Cl bond scissored by two adjacent(ortho) halogen atoms is cleaved most easily and the one scissored by two hydrogen atoms most difficultly. Thus, the reactivity of the encircled halogen atom increases in the following order:



Scheme 1.

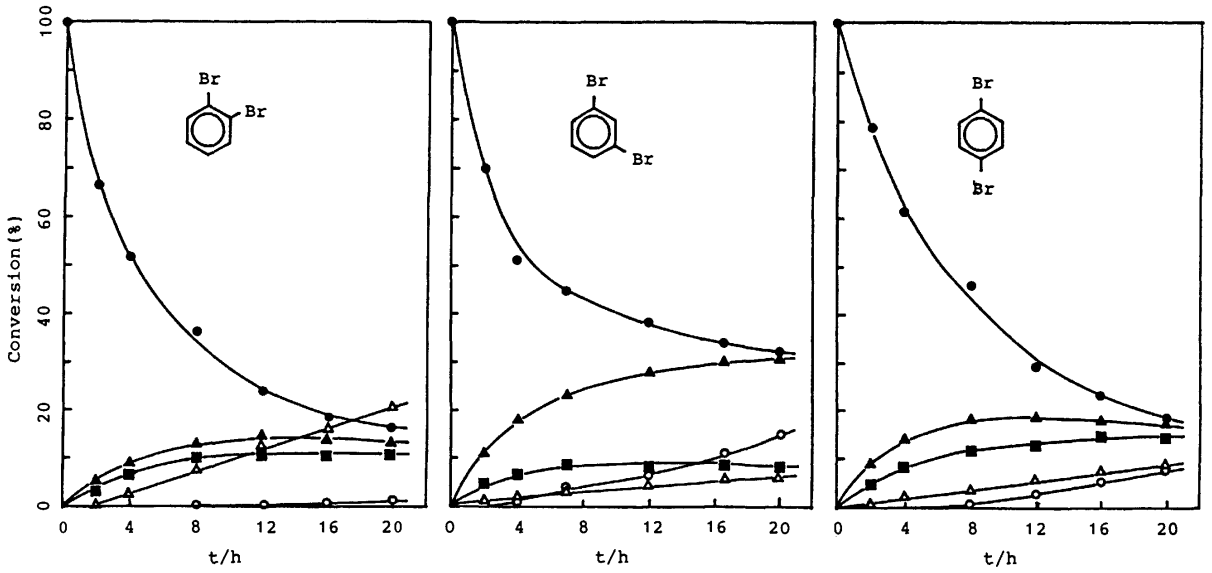


Fig. 1. Time conversion curves for the photolyses of dibromobenzenes (—●—, dibromobenzene (reactant); —▲—, bromobiphenyl; —■—, bromobenzene; —○—, terphenyl; —△—, biphenyl),

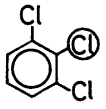
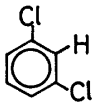
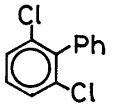
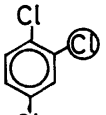
This trend is more significant with the photolyses of polychlorobenzenes in benzene solution; the reaction occurs far more preferably on the most crowded C-Cl bond in benzene. Thus, 2,6-dichloro-, 2,5-dichloro-, 2,3,6-trichloro-, and 2,4,6-trichlorobiphenyls were obtained almost exclusively as the phenylated products of the photolyses in benzene of 1,2,3-trichloro-, 1,2,4-trichloro-, 1,2,3,4-tetrachloro-, and 1,2,3,5-tetrachlorobenzenes, respectively.

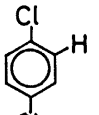
Corresponding dechlorination products (H in place of C_6H_5) were also found, except for the runs on dichlorobenzenes. These are known as the major products of photolyses in hexane.[9] This fact suggests that the reactions in both solvents proceed via a common haloaryl free-radical intermediate generated by a photolytic cleavage of the encircled chlorine atom in Scheme 2.

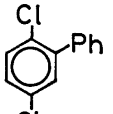
Reactant	Major Products	
	in Hexane	in Benzene
								


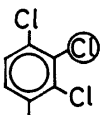


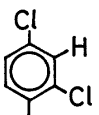


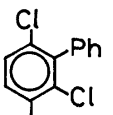


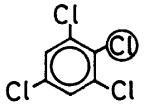


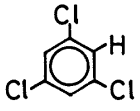


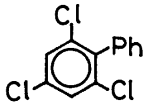












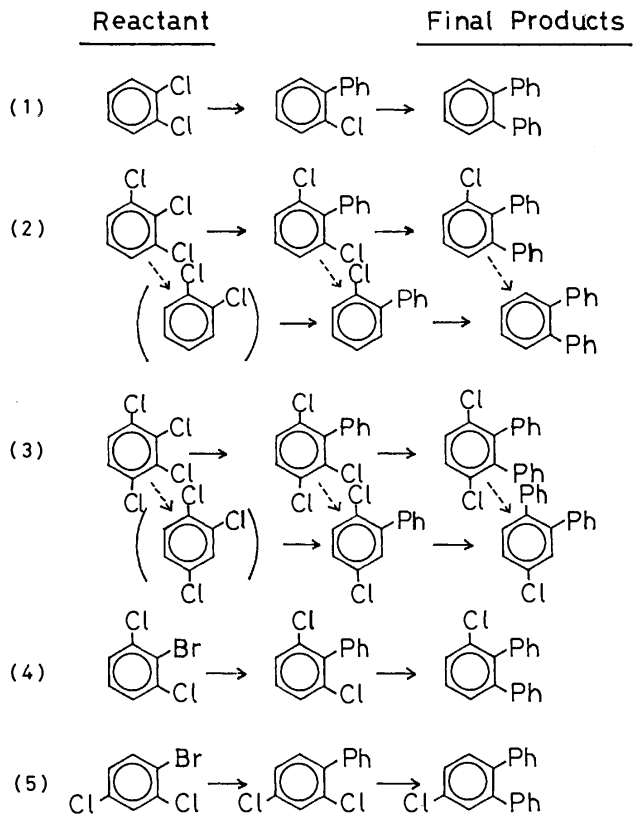
Scheme 2.

In the cases of polybromobenzenes, the reactions proceed less selectively, giving most of the possible phenylated and debrominated products. The distribution of products is not so selective as in the reactions of polychlorobenzenes, on the whole becoming more similar to the reactions in hexane. For example, the photolysis of 1,2,3-tribromobenzene gave comparable amounts of 2,6-dibromobiphenyl (14.0%, a phenylation product), 2,3-dibromobiphenyl (12.0%, the other phenylation product), and *m*-bromobenzene (9.5%, a dehalogenation product). This illustrated that the phenylation does not proceed so regioselectively and is not so overwhelming, as in the photolysis of 1,2,3-trichlorobenzene, which gave 28.3% of 2,6-dichlorobiphenyl and its descents and only 1.0% of *m*-chlorobenzene (all could be derived by the replacement of 2-chlorine atom) without giving detectable amounts of products derived by the replacement of the 1-chlorine atom. Similarly, considerable amounts of *m*-dibromo-, *p*-dibromo-, 1,2,4-tribromo-, 1,3,5-tribromo-, and 1,2,4,5-tetrabromobenzenes were produced as debromination products during the photolyses of 1,2,3-tribromo-, 1,2,4-tribromo-, 1,2,3,4-tetrabromo-, 1,2,3,5-tetrabromo-, and pentabromobenzenes, respectively, in benzene.

In a series of (poly)bromochlorobenzenes, $C_6H_{6-n-m}Br_nCl_m$, bromine is always easier to leave, giving a product formed by the replacement of bromine.

When two different bromine atoms in the same molecule are compared, the reactivity is still governed by the same rule (that the replacement of the most crowded halogen atom takes place most favorably), as is the cases for other polyhalobenzenes. For example, 2-chloro-4-bromobiphenyl, which is produced by the replacement of more crowded bromine atom, is the major photo-product from 2,5-dibromochlorobenzene.

Consecutive Phenylation Forming Terphenyls. As could easily be deduced from the fact that terphenyls were found as the products of the photolyses of dihalobenzenes (Table 1), the primarily produced halobiphenyls were further subjected to subsequent photoreactions producing terphenyl (phenylation) and biphenyl (dehalogenation). Judging from the products of the photolyses of dihalobenzenes, which contain lesser amounts of terphenyls than biphenyl, phenylation should proceed less predominantly than dehalogenation during the photolyses of halobiphenyls. The arylation by the photochemically generated biphenylyl radicals seemed to be dependent both on the nature and the location of the leaving halogen atom. 2-Chlorobiphenyls tend to produce the corresponding *o*-terphenyls far more favorably than 3- and 4-chlorobiphenyls. This trend is considerably different from the photolyses of polyhalobenzenes, which produce phenylated product far more predominantly. As given in Scheme 3, all terphenyls from polychlorobenzenes could be explained by a series of ortho-phenylation (solid arrows) and dehalogenation (broken arrows) reactions. In contrast, the C-Br bonds were shown to behave quite differently from the C-Cl bond. Thus, 3- and 4-bromobiphenyls are inclined to form the corresponding terphenyls more favorably than 2-bromobiphenyls.



Scheme 3.

In order to confirm the fact that the produced halobiphenyls are subjected to the consecutive photolyses producing terphenyls and biphenyl, the photolyses of chlorobiphenyls were examined in benzene solutions. The photolyses of chlorinated biphenyls had been shown to give dehalogenated products when carried out in solvents susceptible to hydrogen abstraction (alkanes and alcohols).[17,18] Photolysis in benzene has never been reported, however. The reactions of the three isomeric chlorobiphenyls were carrid out under exactly the same conditions as the reactions of dichlorobenzenes in benzene solutions, except for the duration of the reaction. The products and their yields are given in Table 2.

As expected from the results on dichlorobenzenes, 2-chlorobiphenyl photolyzes far faster than the other two isomers, giving biphenyl, *o*-terphenyl, and 4-chlorobiphenyl. *m*- and *p*- Terphenyls were not detected as the products of runs starting from 3- and 4-chlorobiphenyls. In the latter two runs, dechlorination also proceeded much more slowly than the *o*-isomer. The three runs on isomeric chlorobiphenyls (in Table 2) agreed with the assumption that *o*-terphenyl was formed by the successive photolysis of 2-chlorobiphenyl, which is a primary product of the photolysis of *o*-dichlorobenzene. Therefore, the above pathway of the reaction was supported by experiments. In line with the expectation from the results in Table 1, the dechlorination predominates over the phenylation in this series of compound.

The formation of terphenyls from dibromobenzenes can also be assumed to proceed via the concecutive phenylation of bromobiphenyl, which is a primary photoproduct, since the amount of formed terphenyls could be accounted for almost quantitatively from the amounts of bromobiphenyls present in the reaction mixture. To be more concrete, the time-conversion curve (Fig. 1) shows that the amount of the newly produced terphenyl is approximately proportional to the amount of the bromobiphenyl present in the reaction system at the time of measurement.

Isomerization of *o*-Dichlorobenzene and 2-Chlorobiphenyl. We have recently reported the novel

photo-rearrangement of a chlorine atom in polychlorobenzenes bearing two or more contiguous halogen atoms on the ring. The meta-migration of the chlorine atom has been shown to take place exclusively, giving, for example, *p*-dichlorobenzene from *o*-dichlorobenzene in acetonitrile.[10] This reaction is very specific; products from ortho- and para-migrations were detected in neither case. The rearrangement seems to compete with the hydrogen abstraction reaction and becomes observable with the photoreactions in solvents resistive to hydrogen-abstraction. The C-H bond of benzene can be expected to be a little less susceptible to hydrogen-abstraction than acetonitrile, since its bond dissociation energy (469 kJ mol^{-1}) is slightly higher than that of acetonitrile (429 kJ mol^{-1}).[20] Thus, the photoproducts from *o*-dichlorobenzene and 2-chlorobiphenyl in benzene were carefully examined in search of the rearranged products.

A small amount (0.7%) of 4-chlorobiphenyl was found in the photoproduct from 2-chlorobiphenyl. Although routine GC analyses gave no evidence of its presence, a trace amount of 4-chlorobiphenyl was also detected by a careful GC/MS examination of the products from the photolysis of *o*-dichlorobenzene. Its yield was estimated to be 0.2%. Rearranged products could not be detected with the runs starting from *m*- and *p*-dichlorobenzenes, even if the products were analyzed by exactly the same conditions using GC/MS.

The authors thank Professor Sachio Fukushi for his advice and encouragement throughout this work. This research was supported partly by the Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture to which we are grateful.

(Received April 4, 1989)

Benzotris- (**3**) and benzobis[1,2,5]thiadiazole (**4**) were prepared in a moderate yield, respectively, by the reaction of tetrasulfur tetranitride (**5**) with halocatechols (**6**) and -resorcinols (**7**). The reduction of **3** and **4** with Sn powder in a mixture of concentrated hydrochloric acid and dioxane gave benzenehexamine (**1**) and 1,2,3,4-benzenetetramine (**2a**) and its 5-methyl derivative (**2b**) in good yields, as a stable tri- (**1**·**3HCl**) and dihydrochloride (**2**·**2HCl**), respectively.

Synthesis of benzenehexamine (**1**) was first reported in 1929[2] and some of its derivatives in 1937.[3] It attracted little attention until recently when it has been recognized as a building block for materials having interesting physical properties.[4-8] As to 1,2,3,4-benzenetetramines (**2**), literature survey revealed that 1,2,3,4-benzenetetramine (**2a**)[9] and its 5-methyl derivative (**2b**)[10] were already prepared in 1889 and 1890, respectively. To our best knowledge, subsequently, **2** has not been mentioned, except for LCAO-MO calculations on **2a**.[11]

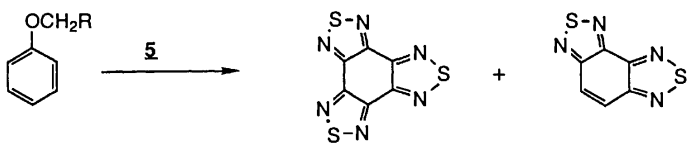
Previously, it was found[12] that benzotris- (**3**) and benzobis[1,2,5]thiadiazole (**4a**), which are synthetic equivalents of **1** and **2a**, respectively, were obtained by the reaction of tetrasulfur tetranitride N_4S_4 (**5**) with alkyl phenyl ether but only in poor yield (Scheme 1). We recently reported[13,14] the reaction of **5** with alkyl- and alkylhalophenols, giving 2,1,3-benzothiadiazoles and the conversion of 4,6-di-*t*-butyl-2,1,3-benzothiadiazole into *o*-phenylenediamine (Scheme 2).

The present paper deals with the convenient preparation of **3** and **4** by the reaction of **5** with benzenediols and benzenetriols such as catechols (**6**), resorcinols (**7**), phloroglucinol (**8a**), and pyrogallol (**8b**) and their reduction to give benzenehexamine (**1**) and 1,2,3,4-benzenetetramine (**2a**) and its 5-methyl derivative (**2b**), respectively.

Results and Discussion

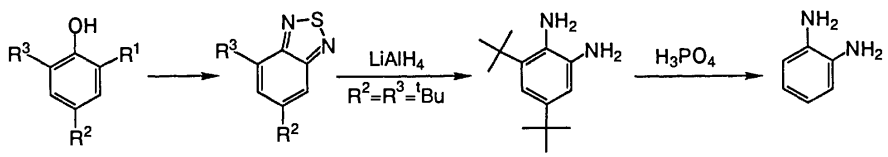
Preparation of 3 and 4. Reactions of **5** with **6**, **7**, and **8** were carried out in refluxing toluene (Schemes 3 and 4). The results are summarized in Tables 1 and 2.

It was found[14,15] that, in the reaction of **5** with phenols, *t*-butyl groups and halogen atoms worked well as a leaving group. In the formation of *t*-butylbenzobis[1,2,5]thiadiazole (**4b**), however, the *t*-butyl group was not effective but bromine atom worked well, giving **4b** in 45% yield. The methyl derivative (**4c**) was prepared in 23% yield from 4-



3 **4a**

Scheme 1.



Scheme 2.

bromo-5-methylcatechol (**6e**). Tribromocatechol (**6f**) gave **4d** in a poor yield (8%). Isopropylcatechol (**6g**) gave the expected **4e** in only 6% yield. In reactions with **6e—6g**, a small amount of benzotris[1,2,5]-thiadiazole (**3**) was obtained as a by-product. Interestingly, **3** was the sole product in 32% yield in the reaction with **6h**. Compound **3** is now easily accessible, starting from catechol in only two steps.

In the reactions of **5** with *t*-butylresorcinols, **7a** and **7b**, **4b** was obtained in low yields. Dibromoethylresorcinol (**7c**) gave the expected **4f** in 11% yield, accompanied with 4-(1,2,5-thiadiazol-3-yl)benzobis-[1,2,5]thiadiazole (**4g**). Though **4g** was considered to be formed via **4f**, the reaction of **5** with **4f** did not proceed in refluxing toluene and unchanged **4f** was recovered. The reaction of **5** with polyhaloresorcinols, **7d**, **7e**, **7h**, **7i**, and **7k**, provides a convenient preparative method for halobenzobis[1,2,5]thiadiazoles, **4h** and **4i**. Benzotris[1,2,5]thiadiazole (**3**) was obtained as a by-product in 10—15% yield in these reactions. Only a bromine atom was removed in the reactions with **7h**, **7i**, and **7k**, giving **4i**. Both **4h** and **4i** are inert towards **5** in refluxing toluene. This indicates that **3** was not formed via **4h** and **4i**. The bromo derivative (**4d**) was obtained in a better yield (40%) in the reaction with tribromoresorcinol (**71**) than with tribromocatechol (**6f**) (8%). The reaction with benzenetriols (**8**) gave unsatisfactory results.

Reduction of 3 and 4. The reduction of benzotris-(**3**) and benzobis[1,2,5]thiadiazole (**4**) to benzenehexamine (**1**) and 1,2,3,4-benzenetetramine (**2**) were investigated.

$LiAlH_4$-reduction of **3** and **4** proceeded as evolution of H_2S was observed, but, isolation of unstable **1** and **2** was unsuccessful and tarry materials were formed.

We expected that reduction under acidic conditions might give **1** and **2** as a stable salt. Treatment of **3** with Sn powder in a hot mixture of concentrated hydrochloric acid and dioxane brought about the precipitation of **1-HCl-dioxane** (1/3/0.5) as a white solid during the reaction. This compound gave benzotripyrazine (**9**)[6] in the reaction with benzil (**10**) in 60% yield from **3** (Scheme 5).

When **4b** was treated under the conditions described above, **4b** was consumed, but precipitation of the expected 5-*t*-butyl-1,2,3,4-benzenetetramine dihydrochloride did not occur. Neutralization of the reaction mixture with $NaHCO_3$ afforded dark violet resinous materials. On the other hand, the expected **2b·2HCl** was obtained as white solid in the reduction of **4c**. A bromine atom was eliminated in the reduction of **4d**, and **2b·2HCl** was obtained. A halogen atom was also reductively removed in the reduction of **4h** and **4i**, and both of the compounds gave **2a·2HCl**. Reaction of **2a·2HCl** and **2b·2HCl** with **10** in acetic acid afforded the expected benzodipyrazine **11a** and **11b** (Scheme 6).

In conclusion, benzenehexamine (**1**) and 1,2,3,4-benzenetetramines, (**2a**) and (**2b**), are readily accessible, as stable salts, via the reduction of benzotris- (**3**)

and benzobis[1,2,5]thiadiazole (**4**), which are obtainable by the reaction of tetrasulfur tetranitride (**5**) with halobenzenediols, **6** and **7**.

Experimental

General. All melting points were determined on a Yanagimoto micro melting point apparatus and Mitamura-riken MELT-THERMO and are uncorrected. IR spectra were measured on a Nippon-bunko A-102 spectrophotometer as potassium bromide pellets. NMR spectra were recorded on a Nippon Denshi JEOL FT-100 and GSX-270 using TMS as an internal standard in $CDCl_3$. Mass spectra were obtained on a Nippon Denshi JMS-01SG-2 mass spectrometer at 75

eV using a direct inlet system.

Materials. Compounds, **6a**, **6b**, **6d**, **6g**, **7a**, **7g**, **7j**, **7n**, and **8b**, are commercially available and **6f**,[15] **6h**,[16] and **8a**[17] were prepared according to the reported methods. Compounds, **6c**, **6e**, **7b**, **7c**,[18] **7d**,[19] **7e**,[20] **7f**,[21] **7h**,[22] **7i**, **7k**,[22] **7l**,[20] and **7m**, were prepared by the bromination of the corresponding benzenediols with benzyltrimethylammonium tribromide according to Kajigaeshi-Kakinami's procedure[23,24] in the yields as follows. Physical and spectral properties of newly prepared compounds in this study are also given below.

3-Bromo-5-*t*-butylcatechol (6c): Yield 49%; colorless needles (hexane); mp 86—87 °C; IR 3350 cm^{-1}; ^1H NMR δ=1.24 (9H, s), 5.30 (1H, s, D_2O-exchanged), 5.37 (1H, s, D_2O-exchanged), 6.90 (1H, d, J=2.0 Hz), and 6.98 (1H, d, J=2.0 Hz); MS m/z 246 (M^+) and 244 (M^+).

Found: C, 49.04; H, 5.41%. Calcd for $C_{10}H_{13}BrO_2$: C, 49.00; H, 5.35%.

4-Bromo-5-methylcatechol (6e): Yield 68%; colorless needles (cyclohexane); mp 96—98 °C (decomp); IR 3375 cm^{-1}; ^1H NMR δ=2.26 (3H, s), 4.91 (2H, br s, D_2O-exchanged), 6.76 (1H, s), and 7.04 (1H, s); MS m/z 204 (M^+) and 202 (M^+).

Found: C, 41.33; H, 3.69%. Calcd for $C_7H_7BrO_2$:C, 41.41; H, 3.47%.

2-Bromo-4,6-di-*t*-butylresorcinol (7b): Yield 71%; pale yellow prisms (light petroleum); mp 109—111 °C; IR 3540 cm^{-1}; ^1H NMR δ=1.36 (18H, s), 5.35 (2H, s, D_2O-exchanged), and 7.14 (1H, s); MS m/z 302 (M^+) and 300 (M^+).

Found: C, 55.55; H, 7.11%. Calcd for $C_{14}H_{21}BrO_2$: C, 55.82; H, 7.03%.

2,4-Dibromo-6-ethylresorcinol (7c): Yield 76%; mp 69—70 °C (lit,[18] 74 °C).

4,6-Dibromoresorcinol (7d): Yield 71%; mp 112—114 °C (lit,[19] 110—112 °C).

3,4,6-Tribromoresorcinol (7e): Yield 77%; mp 112.5—113.5 °C (lit,[20] 111 °C).

4,6-Dibromo-2-methylresorcinol (7f): Yield 70%; mp 97—99 °C (lit,[21] 102 °C).

4-Bromo-6-chlororesorcinol (7h): Yield 73%; mp 108.5—111 °C (lit,[22] 108.5 °C).

2,4-Dibromo-6-chlororesorcinol (7i): Yield 75%; pale yellow needles (hexane); mp 104—105 °C; IR 3475 cm^{-1}; ^1H NMR δ=5.88 (1H, s, D_2O-exchanged), 5.92 (1H, s, D_2O-exchanged), and 7.45 (1H, s); MS m/z 306 (M^+), 304 (M^+), 302 (M^+), and 300 (M^+).

Found: C, 23.91; H, 1.01%. Calcd for $C_6H_3Br_2ClO_2$: C, 23.84; H, 1.00%.

2-Bromo-4,6-dichlororesorcinol (7k): Yield 75%; mp 101.5—102 °C (lit,[22] 101 °C).

5-Methyl-2,4,6-tribromoresorcinol (7l): Yield 74%; mp 97—99 °C (lit,[20] 98 °C).

2,4-Dibromo-6-formylresorcinol (7m): Yield 76%; colorless needles (chloroform); mp 185—203 °C (decomp); IR 3275 and 1635 cm^{-1}; MS m/z 298 (M^+), 296 (M^+), and 294 (M^+).

Found: C, 28.40; H, 1.50%. Calcd for $C_7H_4Br_2O_3$: C, 28.41; H, 1.36%.

Reaction of N_4S_4 (5) with Benzenediols, 6 and 7, and Benzenetriol 8. Typical procedure. A mixture of **6**, **7**, or **8** (5 mmol) and an appropriate amount of **5** in toluene (40 cm^3) was refluxed for the time shown in Tables 1 and 2. After it was cooled to room temperature, insoluble materials were filtered and extracted with hot CH_2Cl_2. The filtrate and the extract were combined, condensed in vacuo, and chromatographed on silica gel (Wako gel, C-300). After sulfur was eluted with hexane, **4b**, **4d**, **4e**, and **4h** were eluted with benzene, **4c** with $CHCl_3$, and **3**, **4f**, **4g**, and **4i** with CH_2Cl_2. Physical and spectral properties of **4** are as follows.

4-*t*-Butylbenzo[1,2-*c*:3,4-*c'*]bis[1,2,5]thiadiazole (4b): Colorless needles (hexane); mp 128—129.5 °C; ^1H NMR δ=1.63 (9H, s) and 7.86 (1H, s): ^{13}C NMR δ=29.70, 36.57, 118.64, 146.58, 147.58, 148.95, 155.94, and 156.81; MS m/z 250 (M^+).

Found: C, 48.13; H, 4.18; N, 22.14%. Calcd for $C_{10}H_{10}N_4S_2$: C, 47.93; H, 4.03; N, 22.38%.

4-Methylbenzo[1,2-*c*:3,4-*c'*]bis[1,2,5]thiadiazole (4c): Colorless needles (hexane); mp 172—174 °C; ^1H NMR δ=2.78 (3H, d, J=1.5 Hz) and 7.78 (1H, d, J=1.5 Hz); MS m/z 208 (M^+).

Found: C, 40.13; H, 2.11; N, 27.02%. Calcd for $C_7H_4N_4S_2$: C, 40.37; H, 1.93; N, 26.90%.

4-Bromo-5-methylbenzo[1,2-*c*:3,4-*c'*]bis[1,2,5]thiadiazole (4d): Pale yellow prisms (cyclohexane); mp 203—204.5 °C; ^1H NMR δ=2.90 (s, 3H); ^{13}C NMR δ=18.87, 118.71, 134.53, 145.46, 146.80. 154.99, and 157.04; MS m/z 288 (M^+) and 286 (M^+).

Found: C, 29.31; H, 1.35; N, 19.26%. Calcd for $C_7H_3N_4BrS_2$: C, 29.28; H, 1.05; N, 19.51%.

4-Isopropylbenzo[1,2-*c*:3,4-*c'*]bis[1,2,5]thiadiazole (4e): Pale violet needles (methanol-water); mp 95—97 °C; ^1H NMR δ=1.48 (6H, d, J=7.0 Hz), 3.78 (1H, d sept, J=7.0 and 0.8 Hz), and 7.80 (1H, d, J=0.8 Hz); MS m/z 236 (M^+).

Found: C, 45.51; H, 3.54; N, 23.28%. Calcd for $C_9H_8N_4S_2$: C, 45.74; H, 3.40; N, 23.66%.

4-Ethylbenzo[1,2-*c*:3,4-*c'*]bis[1,2,5]thiadiazole (4f): Colorless prisms (methanol); mp 135—136 °C; ^1H NMR δ=1.48 (3H, t, J=7.5 Hz), 3.22 (2H, d, q, J=1.3 and 7.5 Hz), and 7.80 (1H, d, J=1.3 Hz): ^{13}C NMR δ=12.89, 25.42, 119.85, 140.19, 147.54, 148.02, 156.88, and 157.01; MS m/z 222 (M^+).

Found: C, 42.99; H, 2.60; N, 24.98%. Calcd for $C_8H_6N_4S_2$: C, 43.22; H, 2.72; N, 25.21%.

4-(1,2,5-Thiadiazol-3-yl)benzo[1,2-*c*:3,4-*c'*]bis[1,2,5]-thiadiazole (4g): Colorless prisms (carbon tetrachloride); mp 206—208 °C; ^1H NMR δ=8.92 (1H, s), and 9.92 (1H, s); MS m/z 278 (M^+).

Found: C, 34.36; H, 0.60; N, 30.07%. Calcd for $C_8H_2N_6S_3$: C, 34.52; H, 0.72; N, 30.19%.

4-Bromobenzo[1,2-*c*:3,4-*c'*]bis[1,2,5]thiadiazole (4h): Pale orange needles (cyclohexane); mp 177—180 °C; ^1H NMR δ=8.32 (1H, s); ^{13}C NMR δ=118.91, 126.17, 146.54, 147.55, 154.40, and 156.02; MS m/z 274 (M^+) and 272 (M^+).

Found: C, 26.39; H, 0.37; N, 20.51%. Calcd for $C_6HN_4BrS_2$: C, 26.59; H, 0.41; N, 20.44%.

4-Chlorobenzo[1,2-*c*:3,4-*c'*]bis[1,2,5]thiadiazole (4i): Colorless prisms (cyclohexane); mp 167—167.5 °C; ^1H NMR δ=8.15 (1H, s); ^{13}C NMR δ=122.54, 130.33, 147.19, 147.26, 153.60, and 155.56; MS m/z 230 (M^+) and 228 (M^+).

Found: C, 31.61; H, 0.40; N, 24.56%. Calcd for $C_6HN_4ClS_2$: C, 31.51; H, 0.44; N, 24.50%.

Reduction of 3. To a stirred mixture of **3** (252 mg, 1 mmol) and Sn powder (1.54 g, 13 mmol) in degassed dioxane (12 cm^3) at reflux, concentrated hydrochloric acid (6 cm^3) was added dropwise for 6 h. After it was cooled to room temperature, the precipitated solid was filtered, washed with ethanol, and dried at 90 °C under reduced pressure overnight, giving **benzenehexamine trihydrochloride [1-HCl-**

dioxane (1/3/0.5)] (230 mg, 70%) as grey powder: mp 140—165 °C (decomp); MS *m/z* 168 (M^+).

Found: C, 30.22; H, 6.29; N, 26.42%. Calcd for ($C_6H_{15}N_6Cl_3$+C_2H_4O): C, 29.87; H, 5.95; N, 26.13%.

Reduction of 4c. To a mixture of **4c** (208 mg, 1 mmol) and Sn powder (1.19 g, 10 mmol) in degassed dioxane (10 cm^3) under reflux, concentrated hydrochloric acid (4 cm^3) was added dropwise under a nitrogen stream for 3 h. After it was cooled to room temperature, the precipitated solid was filtered. The crude product was dissolved in hot methanol and to the solution, a 5 : 1-mixture of hexane and ethanol was added dropwise to give **5-methyl-1,2,3,4-benzenetetramine dihydrochloride (2b·2HCl)** as white powder (134 mg, 60%): mp 160—170 °C (decomp); MS *m/z* 152 (M^+).

Found: C, 37.05; H, 6.62; N, 24.41%. Calcd for $C_7H_{14}N_4Cl_2$: C, 37.35; H, 6.27; N, 24.89%.

Reduction of 4h. A stirred mixture of **4h** (819 mg, 3 mmol) and Sn powder (3.65 g, 30 mmol) in degassed dioxane (30 cm^3) was treated with concentrated hydrochloric acid (12 cm^3) and worked up as described in the reduction of **4c**, giving **1,2,3,4-benzenetetramine dihydrochloride (2a·2HCl)** (410 mg, 65%) as white powder: mp 170—195 °C (decomp); MS *m/z* 138 (M^+).

Found: C, 34.26; H, 5.70; N, 26.38%. Calcd for $C_6H_{12}N_4Cl_2$: C, 34.14; H, 5.73; N, 26.54%.

Preparation of 9. A mixture of **1·3HCl** [prepared from **3** (252 mg, 1 mmol)] and **10** (1.26 g, 6 mmol) in a 3 : 1-mixture (20 cm^3) of degassed ethanol and degassed acetic acid was refluxed for 11 h under a nitrogen atmosphere. After it was cooled to room temperature, the precipitated solid was filtered and washed with ethanol, giving **1,2,5,6,9,10-hexaphenylbenzo[1,2-*b*:3,4-*b'*:5,6-*b''*]tripyrazine (9)** (417 mg, 60% from **3**): mp 360—361.5 °C (lit,[5] 358 °C).

Preparation of 11a. Crude **2a·2HCl** [obtained from **4h** (550 mg, 2 mmol)] was reacted with **10** (840 mg, 4 mmol) in a mixture of degassed ethanol (15 cm^3) and degassed acetic acid (5 cm^3) at reflux under nitrogen atmosphere for 3 h. The precipitated solid was filtered and recrystallized from a mixture of hexane and chloroform, giving **2,3,6,7-tetraphenylbenzo[1,2-*b*:3,4-*b'*]dipyrazine (11a)** (395 mg, 41% from **4h**) as colorless needles; mp 260—262 °C; ^{1}H NMR δ=7.28—7.40 (12H, m), 7.56—7.74 (8H, m), and 8.34 (2H, s); MS *m/z* 486 (M^+).

Found: C, 84.00; H, 4.53; N, 11.46%. Calcd for $C_{34}H_{22}N_4$: C, 83.93; H, 4.56; N, 11.51%.

From **4i** (460 mg, 2 mmol), **11a** was similarly obtained in 39% overall yield (379 mg).

Preparation of 11b. Crude **2b·2HCl** [obtained by the reduction of **4c** (208 mg, 1 mmol)] was treated with **10** (840 mg, 4 mmol) as described in the preparation of **11a**, giving **5-methyl-2,3,8,9-tetraphenylbenzo[1,2-*b*:3,4-*b'*]dipyrazine (11b)** (114 mg, 23% from **4c**) as colorless prisms (cyclohexane); mp 234—237 °C (lit,[10] 222—225 °C); ^{1}H NMR δ=3.00 (3H, d, *J*=2.5 Hz), 7.32—7.44 (12H, m), 7.57—7.80 (8H, m), and 8.20 (1H, d, *J*=2.5 Hz); MS *m/z* 500 (M^+); (Found: C, 83.86; H, 4.90; N, 10.94%).

Compound **11b** (253 mg) was obtained from **4d** (574 mg, 2 mmol) in total 25% yield.

We are grateful to Professor K. Präfcke of Technische Universität Berlin for providing sample of **9**.

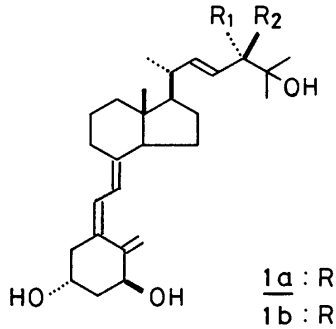
A New and Convenient Synthesis of 1α,25-Dihydroxyvitamin D_2 and Its 24*R*-Epimer

Masahiro Tsuji,* Shinji Yokoyama, and Yoji Tachibana
Research Center, Nisshin Flour Milling, Co., Ltd., Ooimachi, Iruma-gun, Saitama 354
(Received April 8, 1989)

1α, 25-Dihydroxyvitamin D_2 (**1a**) was synthesized by irradiation and subsequent thermal isomerization of (22*E*)-5,7,22-ergostatriene-1α,3β,25-triol (**16a**). The triol **16a** was obtained via 22-oxo-5α,8α-(4-phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-23,24-dinor-6-cholene-1α,3β-diyl diacetate (**12**) starting from (22*E*)-5,7,22-ergostatriene-1α,3β-diyl diacetate (**10**), a precursor of 1α-hydroxyvitamin D_2. Introduction of the new side chain with the desired stereochemistry was carried out selectively by the reductive elimination of the β-hydroxy sulfone derived from the C-22 aldehyde (**12**) and an optically active sulfone, prepared via (*S*)-2,3-dimethyl-1,3-butanediol from methyl (*S*)-3-hydroxy-2-methylpropionate. Similarly a C-24 epimer of **1a** was synthesized.

Although the metabolism of vitamin D_2 (ercalciol) has not been extensively investigated as in the case of vitamin D_3 (calciol), it has been shown that vitamin D_2 is hydroxylated at C-25 position in the liver to 25-hydroxyvitamin D_2 (ercalcidiol) and subsequently at the C-1α position in the kidney to 1α,25-dihydroxyvitamin D_2 (ercalcitriol) (**1a**), a most potent metabolite.[1,2] Because it has been reported that 1α-hydroxyvitamin D_2 ((1*S*)-hydroxyercalciol)[3,4] is less toxic than the corresponding 1α-hydroxyvitamin D_3 ((1*S*)-hydroxycalciol), in spite of the almost equal potency of vitamin D activity,[5-7] much attention has been paid to the 1α-hydroxylated vitamin D_2. However, 1α,25-dihydroxyvitamin D_2 (**1a**), an "active form" of vitamin D_2, seems to be more potent than 1α-hydroxyvitamin D_2 for vitamin D activity, because **1a** is thought to elicit its physiological activity after being hydroxylated at C-25 position as described above. These observations prompted us to investigate the synthesis of **1a** and its 24*R*-epimer (**1b**).

DeLuca et al. reported the synthesis of **1a** and/or **1b**[8,9] by the selective hydroxylation at C-1α position of cyclovitamin D derivatives. However, this method



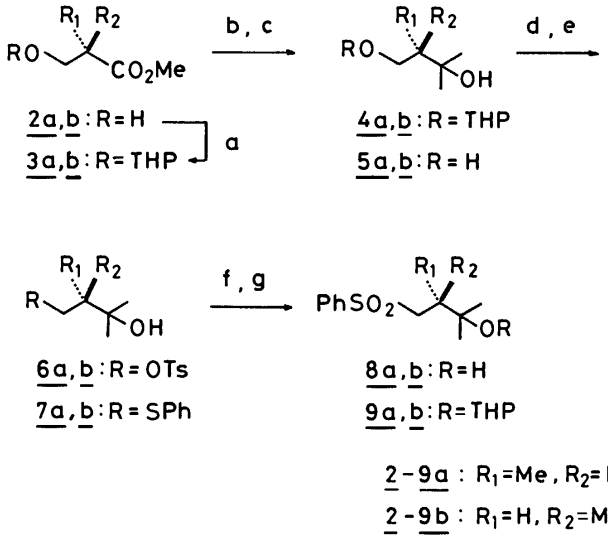
1a : R_1 = Me, R_2 = H
1b : R_1 = H, R_2 = Me

gave 1β-hydroxylated and transvitamin D derivatives as by-products, which were difficult to separate from the 1α-hydroxylated compound. Although Baggiolini et al. reported the synthesis of **1a**,[10] their procedure is complicated.

It is advantageous to use the steroidal block as an intermediate for the preparation of 1α-hydroxylated vitamin D derivatives, because 1α-hydroxylated provitamin D derivatives are easily and selectively converted to the corresponding 1α-hydroxylated vitamin D derivatives.

Previously, we reported the convenient synthesis of (22*E*)-5,7,22-ergostatriene-1α,3β-diyl diacetate (**10**),[11] a precursor of 1α-hydroxyvitamin D_2. To our best knowledge, no one has used this **10** in the synthesis of **1a** and **1b**. The C-22 aldehyde (**12**), available readily from **10**, seemed to be a good key-intermediate for the preparation of **1a** and **1b**. In the present paper we wish to describe a new and convenient synthesis of **1a** and **1b** using **10** as the starting material.

The side-chain fragments, namely optically active sulfones **9a**[12] for **1a** and **9b**[9] for **1b**, were synthesized respectively starting from methyl (*S*)- and (*R*)-3-hydroxy-2-methylpropionate (**2a** and **2b**) as follows (Scheme 1). Although it would be possible to convert **2a** directly to the diol (**5a**) by the Grignard reaction, this method gave a poor yield of **5a** due to its solubility in water. Thus, the hydroxyl group of **2a** was protected as a tetrahydropyranyl (THP) ether[13] to give **3a**.



2-**9a** : R_1 = Me, R_2 = H
2-**9b** : R_1 = H, R_2 = Me

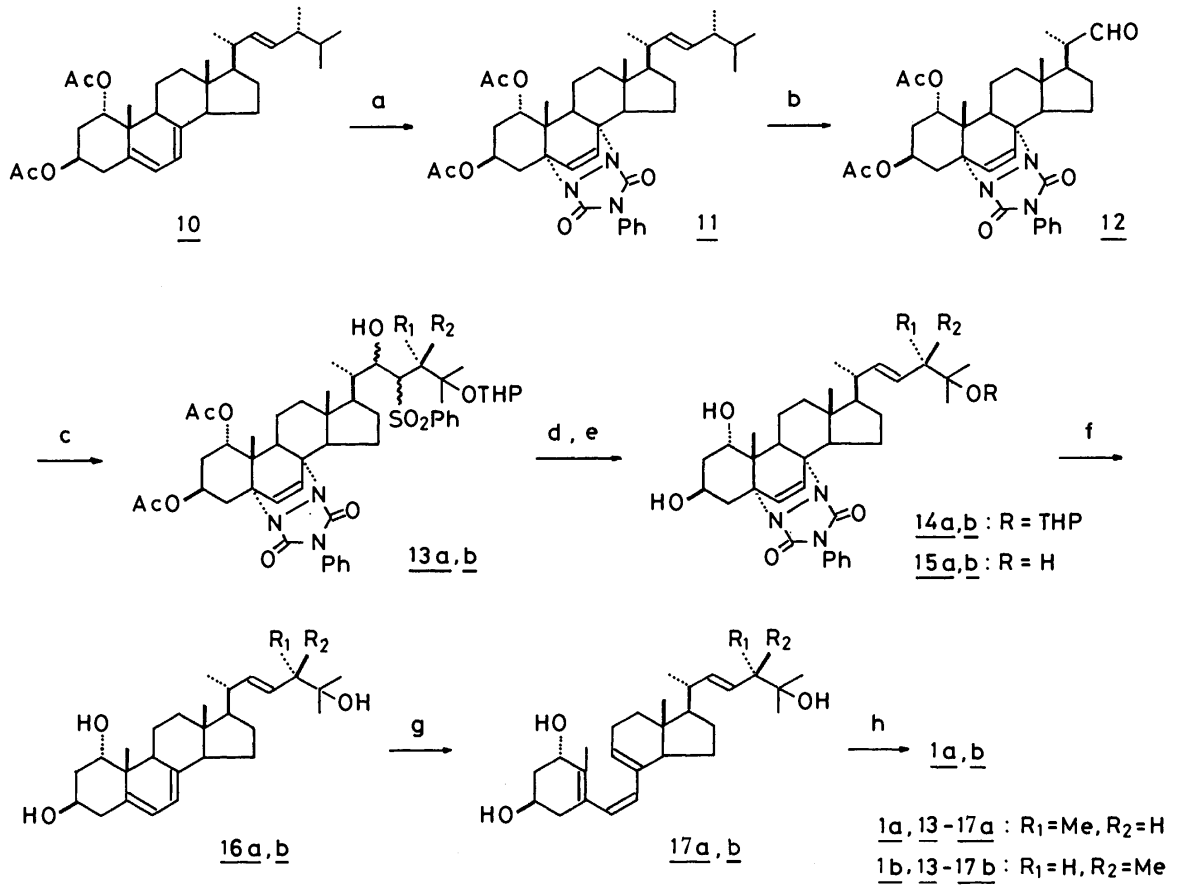
Scheme 1. a) DHP, *p*-TsOH; b) MeMgI/Et_2O; c) *p*-TsOH/MeOH; d) *p*-TsCl, Py; e) PhSH, *t*-BuOK/DMF; f) Na_2WO_4-H_2O_2; g) DHP, PPTS.

The Grignard reaction of **3a** using methylmagnesium iodide in ether afforded **4a**, which was subsequently subjected to deprotection of the THP group to provide the diol (**5a**) after distillation in 84% yield from **2a**. Tosylation of the primary hydroxyl group of **5a** in the usual manner afforded the tosylate (**6a**), which was reacted with benzenethiol in the presence of potassium *t*-butoxide in DMF to give the phenyl sulfide (**7a**). Oxidation of **7a** with Na_2WO_4-H_2O_2 yielded the crystalline hydroxy sulfone (**8a**) in 92% yield. Conventional protection of the hydroxyl group of **8a** as a THP ether gave **9a** in 92% yield. Similarly, **2b** was converted to the corresponding sulfone (**9b**) via the hydroxy sulfone (**8b**).

The next task was to construct the (22*E*)-olefin moiety leading to **1a** and **1b** (Scheme 2). The 5,7-diene of (22*E*)-5,7,22-ergostatriene-1α,3β-diyl diacetate (**10**), our starting material, was protected as a Diels-Alder adduct with 4-phenyl-3*H*-1,2,4-triazole-3,5(4*H*)-dione (PTAD)[14] to give **11** in 87% yield. Selective cleavage of the side-chain double bond of **11** was achieved by ozonolysis at −65 °C in 1% pyridine-CH_2Cl_2 solution and successive reductive workup of the resulting ozonide with dimethyl sulfide[14,15] to give the C-22 aldehyde (**12**) after recrystallization in 49% yield. The ^1H NMR spectrum of **12** exhibited only a doublet at δ 9.55 for the aldehyde proton (22-H), while the ^1H NMR spectrum of C(20) epimeric mixture, obtained by treatment of **12** with alumina (grade II—III) in $CHCl_3$,[14] showed a pair of doublets at δ 9.55 and 9.48. This indicates that the aldehyde obtained (**12**) was a single isomer.

Addition of the aldehyde (**12**) to the carbanion generated from the sulfone (**9a**) by butyllithium in THF[16-18] gave the β-hydroxy sulfone (**13a**), which was used in the next step without further purification. Reductive elimination of the β-hydroxy sulfone (**13a**) with sodium amalgam in buffered MeOH (Na_2HPO_4)[16-18] afforded the olefinic product (**14a**) in 32% yield from **12**. This olefination reaction is known to give predominantly or exclusively an (*E*)-olefin.[16-19] Removal of the THP group of **14a** by pyridinium *p*-toluenesulfonate (PPTS) in EtOH afforded the triol (**15a**), which was treated with $LiAlH_4$ in refluxing THF for removal of the triazoledione protective group[14] to give (22*E*)-5,7,22-ergostatriene-1α,3β,25-triol (**16a**) in 54% yield from **14a**.

Irradiation[3,4] of the 5,7-diene-1α,3β,25-triol (**16a**) with a high-pressure mercury lamp using aq. 1.5% KNO_3 solution as a filter gave the previtamin D (**17a**). Thermal-isomerization[3,4] of **17a** in refluxing EtOH and purification by preparative HPLC furnished



Scheme 2. a) 4-Phenyl-3*H*-1,2,4-triazole-3,5(4*H*)-dione; b) O_3/1% Py-CH_2Cl_2, then Me_2S; c) **9a** or **9b**, *n*-BuLi/THF; d) Na-Hg/MeOH (Na_2HPO_4); e) PPTS/EtOH; f) $LiAlH_4$/THF; g) *hν*; h) reflux/EtOH.

1α,25-dihydroxyvitamin D_2 (**1a**) in 22% yield from **16a**. The physical and spectral data of **1a** were in accord with those reported earlier.[8,10]

Similarly, (24*R*,22*E*)-5,7,22-ergostatriene-1α,3β, 25-triol (**16b**) was prepared from the aldehyde (**12**) and the sulfone (**9b**) in place of **9a** in four steps in 15% yield from **12**. Irradiation of **16b** and purification by preparative HPLC gave the previtamin D (**17b**), which was thermally isomerized to afford the crystalline (24*R*)-1α,25-dihydroxyvitamin D_2 (**1b**) in 12% yield from **16b** after purification by preparative HPLC.

Since (22*E*)-5,7,22-ergostatriene-1α,3β,25-triol is obtainable readily from (22*E*)-5,7,22-ergostatriene-1α,3β-diyl diacetate (**10**), the present study provides an efficient method for the preparation of 1α,25-dihydroxyvitamin D_2. The synthetic method described here will be applicable to other 1α-hydroxylated vitamin D_2 or D_3 derivatives.

Experimental

All the melting points and boiling points are uncorrected. IR spectra were measured on a Jasco IR-810 spectrometer. ^{1}H NMR spectra were recorded with TMS as an internal standard and $CDCl_3$ as a solvent at 200 MHz on a JEOL JNM-FX 200 spectrometer unless otherwise stated. Optical rotations were measured with $CHCl_3$ as a solvent on a Jasco DIP-4 polarimeter or a Jasco DIP-370 polarimeter unless otherwise stated. Mass spectra were recorded on a Hitachi M-80 spectrometer at 70 eV. UV spectra were measured on a Hitachi 320 spectrometer. Merck Kieselgel 60 (Art 7734, 70—230 mesh) or Merck Kieselgel 60 (Art 9385, 230—400 mesh) were used for SiO_2 column chromatography. TLC analyses were performed on a Merck Kieselgel 60 F-254 (Art 5715, 0.25 mm).

(*S*)-2,3-Dimethyl-1,3-butanediol (5a). A solution of methyl (*S*)-3-hydroxy-2-methylpropionate (**2a**) (8.09 g, 68.6 mmol; Sigma Chemical Co.), dihydropyran (8.63 g, 0.10 mol), and *p*-TsOH·H_2O (0.10 g) in dry ether (50 ml) was stirred for 1 h. The mixture was washed with sat. $NaHCO_3$ solution and brine, dried ($MgSO_4$), and concentrated in vacuo to give 13.8 g of crude **3a**. Its IR spectrum was identical with that reported previously.[13] This was employed in the next step without further purification.

A Grignard reagent was prepared from methyl iodide (29.2 g, 0.21 mol) and magnesium (5.00 g, 0.21 mol) in dry ether (30 ml). To this Grignard solution, a solution of crude **3a** (13.8 g) in dry ether (30 ml) was added dropwise for 1 h at a rate sufficient to maintain a gentle reflux. The mixture was stirred for 2 h at reflux temperature. Then to the ice-cooled reaction mixture was carefully added dropwise a cold sat. NH_4Cl solution. The ether layer was separated and the aq. layer was extracted with ether. The combined ether solution was washed with brine, dried ($MgSO_4$), and concentrated in vacuo to give 13.5 g of crude **4a**: IR (film) 3460, 1460, 1390, 1205, 1180, 1125, 1080, 1060, 980 cm^{-1}. This was employed in the next step without further purification.

A solution of crude **4a** (13.5 g) and *p*-TsOH·H_2O (0.65 g, 3.4 mmol) in MeOH (150 ml) was stirred for 1 h at room temperature. The mixture was neutralized with K_2CO_3 and filtered through Celite. After removal of MeOH in vacuo from the filtrate, the residue was dissolved in ether. The ether solution was dried ($MgSO_4$), and concentrated in vacuo. The residue was distilled to give 6.28 g (84% from **2a**) of **5a**: bp 83—85 °C/0.22 mmHg (1 mmHg≈133.322 Pa); n_D^{23} 1.4439; $[\alpha]_D^{23}$+1.7° (*c* 5.12)[lit,[12] $[\alpha]_D^{22}$−2.5° (0.18%, $CHCl_3$)]; IR (film) 3350, 1470, 1385, 1370, 1175, 1160, 1030 cm^{-1}; ^{1}H NMR δ=0.84 (3H, d, *J*=7.1 Hz), 1.18 (3H, s), 1.25 (3H, s), 1.81 (3H, m), 3.70 (1H, m), 3.91 (1H, s), 4.17 (1H, t, *J*=4.6 Hz). Found: *m/z* 118.1000. Calcd for $C_6H_{14}O_2$: M, 118.0994.

(*S*)-3-Hydroxy-2,3-dimethylbutyl *p*-Toluenesulfonate (6a). To a stirred and ice-cooled solution of **5a** (6.00 g, 50.8 mmol) in dry pyridine (24 ml) was added *p*-toluenesulfonyl chloride (11.64 g, 61.1 mmol) and the mixture was stirred for 2 h at that temperature. The mixture was poured into ice water and extracted with ether. The ether solution was washed with water, sat. $CuSO_4$ solution, sat. $NaHCO_3$ solution and brine, dried ($MgSO_4$), and concentrated in vacuo to give 13.5 g of crude **6a**: IR (film) 3450, 1600, 1500, 1470, 1360, 1190, 1175, 1100, 965 cm^{-1}; ^{1}H NMR δ=0.96 (3H, d, *J*=7.1 Hz), 1.12 (3H, s), 1.19 (3H, s), 1.54 (1H, s), 1.80 (1H, m), 2.45 (3H, s), 3.92 (1H, dd, *J*=9.5 and 9.8 Hz), 4.23 (1H, dd, *J*=9.5 and 4.4 Hz), 7.35 (2H, d, *J*=8.3 Hz), 7.80 (2H, d, *J*=8.3 Hz). This was employed in the next step without further purification.

(*R*)-2,3-Dimethyl-4-phenylthio-2-butanol (7a). To a stirred solution of potassium *t*-butoxide (5.89 g, 53.4 mmol) and benzenethiol (5.87 g, 53.4 mmol) in dry DMF (60 ml) was added crude **6a** (13.5 g) and the mixture was stirred for 4 h at room temperature under N_2. The mixture was poured into water and extracted with benzene. The benzene solution was washed with water and brine, dried ($MgSO_4$), and concentrated in vacuo. The residue was chromatographed over SiO_2 (100 g) eluting with hexane-EtOAc (9:1) to give 10.13 g of **7a**: IR (film) 3420, 3060, 1590, 1485, 1440, 1375, 1140, 1095, 1030 cm^{-1}; ^{1}H NMR δ=0.96 (3H, d, *J*=6.8 Hz), 1.18 (3H, s), 1.23 (3H, s), 1.54 (1H, s), 1.80 (1H, m), 2.55 (1H, dd, *J*=10.1 and 12.7 Hz), 3.40 (1H, dd, *J*=10.1 and 2.9 Hz), 7.15—7.48 (5H, m). This was employed in the next step without further purification.

(*R*)-2,3-Dimethyl-4-phenylsulfonyl-2-butanol (8a). WO_3 (55 mg) in water (18 ml) was dissolved by adding 50% NaOH solution to pH 11, the solution was then adjusted to pH 5.6 by adding AcOH. To this solution was added **7a** (10.13 g) in EtOH (10 ml) and then 30% H_2O_2 (3.4 ml). The mixture was stirred for 10 min at 60°C. To the mixture was added 30% H_2O_2 (3.4 ml) and the mixture was stirred for a further 30 min at 75°C. After cooling, $Na_2S_2O_3$ was added to the reaction mixture. The mixture was next extracted with benzene. The benzene solution was washed with water and brine, dried ($MgSO_4$), and concentrated in vacuo. The residue was chromatographed over SiO_2 (200 g) eluting with hexane-EtOAc (9:1—4:1) to give 11.32 g (92% from **5a**) of **8a**, which crystallized on standing. Recrystallization from ether gave **8a** as prisms: mp 68.4—69.1 °C; $[\alpha]_D^{25}$−33.7° (*c* 1.26) [lit,[12] $[\alpha]_D^{22}$−22.4° (0.6%, $CHCl_3$)]; IR (KBr) 3500, 3070, 1585, 1450, 1370, 1300, 1155, 1140, 1110, 1085 cm^{-1}; ^{1}H NMR δ=1.03 (3H, s), 1.12 (3H, d, *J*=6.8 Hz), 1.22 (3H, s), 1.88 (1H, s), 2.15 (1H, m), 2.82 (1H, dd, *J*=13.9 and 9.3 Hz), 3.60 (1H, dd, *J*=13.9 and 2 Hz), 7.53—7.95 (5H, m). Found: C, 59.49; H, 7.48; S, 13.25%. Calcd for $C_{12}H_{18}O_3S$: C, 59.48; H, 7.49; S, 13.23%.

(3*R*)-2,3-Dimethyl-4-phenylsulfonyl-2-butanol THP Ether

(**9a**). A solution of **8a** (5.31 g, 21.9 mmol), dihydropyran (2.76 g, 32.9 mmol) and PPTS (0.55 g, 2.2 mmol) in dry CH_2Cl_2 (60 ml) was stirred for 4 h at room temperature. The mixture was washed with water and brine, dried ($MgSO_4$), and concentrated in vacuo. The residue was chromatographed over SiO_2 (150 g) eluting with hexane-EtOAc (4 : 1) to give 6.58 g (92%) of **9a**: IR (film) 3060, 1585, 1450, 1395, 1305, 1200, 1150, 1110, 1090, 1085, 1025 cm^{-1}; ^1H NMR δ=1.04 and 1.06 (3H, pair of s), 1.13 (3H, m), 1.18 and 1.19 (3H, pair of s), 1.3—1.8 (6H, m), 2.19 (1H, m), 2.88 (1H, m), 3.42 (1H, m), 3.65 (1H, m), 3.82 (1H, m), 4.73 (1H, m), 7.51—7.94 (5H, m).

(*R*)-2,3-Dimethyl-1,3-butanediol (5b). In the same manner as described for **5a**, methyl (*R*)-3-hydroxy-2-methylpropionate (**2b**) (9.28 g, 78.6 mmol; Sigma Chemical Co.) was converted in three steps to 7.61 g (82%) of **5b**: bp 83—84°C/0.25 mmHg; n_D^{23} 1.4437; $[\alpha]_D^{23}$—1.6° (*c* 5.29). Its IR and ^1H NMR spectra were identical with those of **5a**.

(*S*)-2,3-Dimethyl-4-phenylsulfonyl-2-butanol (8b). In the same manner as described for **8a**, **5b** (6.58 g, 55.8 mmol) was converted in three steps to 12.10 g (90%) of **8b**: mp 68.2—69.0°C (from ether, prisms); $[\alpha]_D^{23}$+34.1° (*c* 1.09) [lit,[9]) a thick, colorless oil; $[\alpha]_D^{22}$+27.9° (*c* 1.3, $CHCl_3$)]. Its IR and ^1H NMR spectra were identical with those of **8a**. Found: C, 59.35; H, 7.48; S, 13.29%. Calcd for $C_{12}H_{18}O_3S$: C, 59.48; H, 7.49; S, 13.23%.

(3*S*)-2,3-Dimethyl-4-phenylsulfonyl-2-butanol THP Ether (9b). In the same manner as described for **9a**, **8b** (6.23 g, 25.7 mmol) was converted to 7.89 g (94%) of **9b**. Its IR and ^1H NMR spectra were identical with those of **9a**.

(22*E*)-5α,8α-(4-Phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-6,22-ergostadiene-1α,3β-diyl Diacetate (11). To a stirred solution of (22*E*)-5,7,22-ergostatriene-1α,3β-diyl diacetate (**10**) (5.62 g, 11.3 mmol) in $CHCl_3$ (70 ml) was added dropwise a solution of 4-phenyl-3*H*-1,2,4-triazole-3,5(4*H*)-dione (PTAD) (2.26 g, 13 mmol) in acetone (40 ml) at room temperature until a faint pink coloration persisted, and the mixture was concentrated in vacuo. The residue was chromatographed over SiO_2 (80 g) eluting with hexane-EtOAc (2 : 1) to give 6.61 g (87%) of **11** as a foam: $[\alpha]_D^{25}$—139° (*c* 1.09); IR (KBr) 1750, 1700, 1600, 1505, 1395, 1240, 1030 cm^{-1}; ^1H NMR δ=0.79 and 0.82 (6H, each d, *J*=3.7 Hz, 26-H_3 and 27-H_3), 0.84 (3H, s, 18-H_3), 0.89 (3H, d, *J*=6.8 Hz, 28-H_3), 1.02 (3H, d, *J*=6.6 Hz, 21-H_3), 1.06 (3H, s, 19-H_3), 2.01 (3H, s, Ac), 2.03(3H, s, Ac), 3.25 (1H, dd, *J*=13.7 and 5.6 Hz, 9-H), 5.11 (1H, m, 1-H), 5.20 (2H, m, 22-H and 23-H), 5.89 (1H, m, 3-H), 6.33 and 6.45 (2H, ABq, *J*=8.3 Hz, 6-H and 7-H), 7.24—7.51 (5H, m, Ph); MS *m/z* (rel intensity) 671(M^+; 0.3), 496(0.4), 436(8), 376(100), 251(28), 209(23), 155(34).

22-Oxo-5α,8α-(4-phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-23,24-dinor-6-cholene-1α,3β-diyl Diacetate (12). Ozone (flow rate 0.07 mmol min^{-1}) was bubbled into a solution of **11** (10.00 g, 14.9 mmol) in 1% pyridine-CH_2Cl_2 (400 ml) with stirring for 4.5 h at −65°C. After the excess ozone was driven out by bubbling Ar, dimethyl sulfide (20 ml) was added dropwise to the mixture at −65°C, and the mixture was stirred for 1 h at −65°C. After the cooling bath was removed, stirring was continued for a further 1 h. The mixture was washed with 2% HCl and brine, dried ($MgSO_4$), and concentrated in vacuo. The residue was chromatographed over SiO_2 (130 g) eluting with hexane-EtOAc (1 : 1) to give 5.99 g of **12.** This was recrystallized from benzene to give 4.40 g (49%) of **12** as needles: mp 191—193°C; $[\alpha]_D^{25}$—131° (*c* 1.06); IR (KBr) 2720, 1740, 1685, 1605, 1505, 1405, 1370, 1250, 1230, 1035 cm^{-1}; ^1H NMR δ=0.87 (3H, s, 18-H_3), 1.07 (3H, s, 19-H_3), 1.14 (3H, d, *J*=6.8 Hz, 21-H_3), 2.01 (3H, s, Ac), 2.04 (3H, s, Ac), 3.26 (1H, dd, *J*=14.2 and 5.4 Hz, 9-H), 5.12 (1H, m, 1-H), 5.88 (1H, m, 3-H), 6.36 and 6.44 (2H, ABq, *J*=8.3 Hz, 6-H and 7-H), 7.26—7.51 (5H, m, Ph), 9.55 (1H, d, *J*=3.4 Hz, 22-H); MS *m/z* (rel intensity) 603(M^+; 0.3), 428(0.3), 368(11), 308(100), 235(20), 177(20), 141(57). Found: C, 67.57; H, 6.84; N, 6.99%. Calcd for $C_{34}H_{41}N_3O_7$: C, 67.64; H, 6.84; N, 6.96%.

(22*E*)-5α,8α-(4-Phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-25-tetrahydropyranyloxy-6,22-ergostadiene-1α, 3β-diol (14a). Butyllithium (1.5 mol dm^{-3} in hexane, 3.5 ml, 5.2 mmol) was added to a stirred solution of **9a** (1.70 g, 5.2 mmol) in dry THF (60 ml) at −60—−70°C under Ar. After stirring for 30 min, a solution of **12** (2.40 g, 4.0 mmol) in dry THF (25 ml) was added and the mixture was stirred for 30 min at −60—−70°C. Sat. NH_4Cl solution (1 ml) was added dropwise to the mixture at that temperature, and the mixture was allowed to rise to room temperature. The mixture was poured into sat. NH_4Cl solution and extracted with EtOAc. The EtOAc solution was washed with brine, dried ($MgSO_4$), and concentrated in vacuo to give crude **13a.** This was employed in the next step without further purification.

To a solution of crude **13a** in MeOH saturated with Na_2HPO_4 (330 ml) sodium amalgam (5%, 18.3 g) was added and the mixture was stirred for 15 h at 0°C, followed by a further 3 h at room temperature. The supernatant was concentrated in vacuo, and the residue was poured into water and extracted with EtOAc. The EtOAc solution was washed with brine, dried ($MgSO_4$), and concentrated in vacuo. The residue was chromatographed over SiO_2 (65 g) eluting with hexane-EtOAc (1 : 4) to give 0.87 g (32% from **12**) of **14a** as a crystalline material: IR (KBr) 3420, 1745, 1685, 1600, 1505, 1405, 1315, 1130, 1025, 980 cm^{-1}; ^1H NMR δ=3.48 (1H, m, 6′-H), 3.69 (1H, m, 1-H), 3.95 (1H, m, 6′-H), 4.78 (1H, m, 2′-H), 4.85 (1H, m, 3-H), 5.15—5.42 (2H, m, 22-H and 23-H), 6.18 and 6.34 (2H, ABq, *J*=8.3 Hz, 6-H and 7-H), 7.2—7.4 (5H, m, Ph); MS *m/z* (rel intensity) 512 (M^+—PTAD; 0.3), 428(3), 410(22), 324(3), 251(5), 177(22), 119(28), 85(100), 59(94). This was employed in the next step without further purification.

(22*E*)-5,7,22-Ergostatriene-1α,3β,25-triol (16a). A solution of **14a** (0.84 g, 1.2 mmol) and PPTS (15 mg, 0.06 mmol) in 95% EtOH (6 ml) was stirred for 1 h at 50°C. After removal of EtOH in vacuo from the mixture, the residue was extracted with EtOAc. The EtOAc solution was washed with brine, dried ($MgSO_4$), and concentrated in vacuo to give crude **15a.** This was employed in the next step without further purification. An analytical sample was prepared by recrystallization from ether-EtOH to give **15a** as needles: mp 209—212°C; $[\alpha]_D^{25}$—86.4° (*c* 0.22); IR (KBr) 3530, 3470, 1745, 1680, 1505, 1415, 1150, 1035 cm^{-1}; ^1H NMR δ=0.84 (3H, s, 18-H_3), 0.93 (3H, s, 19-H_3), 0.98 (3H, d, *J*=7.1 Hz, 28-H_3), 1.05 (3H, d, *J*=6.6 Hz, 21-H_3), 1.13 and 1.16 (6H, each s, 26-H_3 and 27-H_3), 1.21 (t, *J*=7.1 Hz, Et_2O), 3.15 (1H, dd, *J*=14 and 7.1 Hz, 9-H), 3.48 (q, *J*=7.1 Hz, Et_2O), 3.85 (1H, m, 1-H), 4.90 (1H, m, 3-H), 6.26 and 6.41 (2H, ABq, *J*=8.3 Hz, 6-H and 7-H), 7.30—7.45 (5H, m, Ph); MS *m/z* (rel intensity) 428(M^+—PTAD; 18), 350(15), 324(25), 251(15), 177(90), 119(100). Found: C, 71.06; H, 8.28; N, 6.81%. Calcd for $C_{36}H_{49}N_3O_5 \cdot 1/4\ Et_2O$: C, 71.41; H, 8.34; N, 6.75%.

A mixture of crude **15a** and $LiAlH_4$ (0.73 g) in dry THF (80 ml) was stirred for 1.5 h at reflux temperature. The excess $LiAlH_4$ was destroyed by the successive addition of water (0.7 ml), 10% NaOH solution (0.7 ml), water (2.1 ml) to the stirred and ice-cooled mixture. The mixture was stirred for a further 30 min at room temperature, dried ($MgSO_4$), and filtered through Celite. The filtrate was concentrated in vacuo to give crude crystalline **16a**. This was recrystallized from EtOH to give 0.28 g (54% from **14a**) of **16a** as needles: mp 222—224 °C; $[\alpha]_D^{25}$−55° (*c* 0.12, MeOH); IR (KBr) 3520, 3350, 1655, 1610, 1465, 1370, 1135, 1070, 975 cm^{-1}; ^1H NMR δ=0.64 (3H, s, 18-H_3), 0.95 (3H, s, 19-H_3), 1.00 (3H, d, *J*=7.1 Hz, 28-H_3), 1.05 (3H, d, *J*=6.8 Hz, 21-H_3), 1.13 and 1.17 (6H, each s, 26-H_3 and 27-H_3), 3.77 (1H, m, 1-H), 4.04 (1H, m, 3-H), 5.35 (3H, m, 7-H, 22-H and 23-H), 5.73 (1H, m, 6-H); MS *m/z* (rel intensity) 428(M^+; 4), 353(2), 312(2), 251(5), 225(5), 145(8), 81(15), 59(100); UV (EtOH) 282nm (ε 11900). Found: C, 77.97; H, 10.40%. Calcd for $C_{28}H_{44}O_3$: C, 78.48; H, 10.35%.

1α,25-Dihydroxyvitamin D_2 (1a). A solution of **16a** (100 mg, 0.23 mmol) in ether–THF (19:1, 1000 ml) was irradiated for 3 min under Ar at water-cooled temperature with a high-pressure mercury lamp (Ushio, UM-452) using 1.5% KNO_3 solution as a filter. The mixture was next concentrated in vacuo. A solution of the residue containing the previtamin D (**17a**) in EtOH (30 ml) was stirred for 1 h at reflux temperature under Ar. The mixture was concentrated in vacuo. The residue was chromatographed on HPLC (Merck, LiChrosorb® Si60 (7 μm), 25×250 mm) eluting with 4% MeOH–CH_2Cl_2 (8.0 ml min^{-1}) to give 22 mg (22% from **16a**) of crystalline **1a**. This was recrystallized from hexane–ether to give **1a** as needles: mp 168—170 °C; $[\alpha]_D^{25}$+48° (*c* 0.07, EtOH) [lit,[10] mp 169—170 °C; $[\alpha]_D^{25}$+47.2° (*c* 0.2, EtOH)]; IR (KBr) 3400, 1640, 1460, 1380, 1370, 1350, 1300, 1265, 1220, 1140, 1055, 975 cm^{-1}; ^1H NMR δ=0.56 (3H, s, 18-H_3), 1.00 (3H, d, *J*=6.8 Hz, 28-H_3), 1.04 (3H, d, *J*=6.8 Hz, 21-H_3), 1.13 and 1.17 (6H, each s, 26-H_3 and 27-H_3), 4.23 (1H, m, 3-H), 4.42 (1H, m, 1-H), 5.00 (1H, narrow m, 19-H), 5.32 (3H, m, 19-H, 22-H and 23-H), 6.01 (1H, d, *J*=10.6 Hz, 7-H), 6.38 (1H, d, *J*=10.6 Hz, 6-H); MS *m/z* (rel intensity) 428(M^+; 5) 410(9), 392(12), 352(6), 269(10), 197(15), 152(23), 134(100); UV (EtOH) 265 nm (ε 16400). Found: *m/z* 428.3271. Calcd for $C_{28}H_{44}O_3$: M, 428.3292.

(24*R*,22*E*)-5α,8α-(4-Phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-25-tetrahydropyranyloxy-6,22-ergostadiene-1α,3β-diol (14b). In the same manner as described for **14a**, **12** (1.50 g, 2.5 mmol) and **9b** (1.62 g, 5.0 mmol) was converted in two steps to 0.46 g (27%) of **14b**: IR (KBr) 3430, 1750, 1690, 1605, 1505, 1410, 1310, 1135, 1030, 985 cm^{-1}; ^1H NMR δ=3.50 (1H, m, 6′-H), 3.71 (1H, m, 1-H), 3.90 (1H, m, 6′-H), 4.75 (1H, m, 2′-H), 4.85 (1H, m, 3-H), 5.15—5.40 (2H, m, 22-H and 23-H), 6.19 and 6.35 (2H, ABq, *J*=8.3 Hz, 6-H and 7-H), 7.2—7.4 (5H, m, Ph); MS *m/z* (rel intensity) 428 (M^+−PTAD−DHP; 10), 410 (7), 350 (12), 177 (40), 119 (100).

(24*R*,22*E*)-5α,8α-(4-Phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-6,22-ergostadiene-1α,3β,25-triol (15b). This was prepared in the same manner as described for **15a**, and recrystallization from ether–EtOH gave an analytical sample as needles: mp 212—215 °C; $[\alpha]_D^{23}$−95.6° (*c* 0.25); IR (KBr) 3530, 3450, 1745, 1680, 1505, 1420, 1155, 1035 cm^{-1}; ^1H NMR δ=0.83 (3H, s, 18-H_3), 0.92 (3H, s, 19-H_3), 0.98 (3H, d, *J*=7.1 Hz, 28-H_3), 1.04 (3H, d, *J*=6.4 Hz, 21-H_3), 1.12 and 1.15 (6H, each s, 26-H_3 and 27-H_3), 1.21 (t, *J*=7.1 Hz, Et_2O), 3.14 (1H, dd, *J*=13.7 and 4.4 Hz, 9-H), 3.48 (q, *J*=7.1 Hz, Et_2O), 3.83 (1H, m, 1-H), 4.90 (1H, m, 3-H), 5.32 (2H, m, 22-H and 23-H), 6.25 and 6.40 (2H, ABq, *J*=8.1 Hz, 6-H and 7-H), 7.30—7.45 (5H, m, Ph); MS *m/z* (rel intensity) 428 (M^+−PTAD; 22), 350 (16), 324 (48), 251 (20), 177 (75), 119 (100). Found: C, 70.63; H, 8.34; N, 6.62%. Calcd for $C_{36}H_{49}N_3O_5 \cdot 1/4\ Et_2O$: C, 71.41; H, 8.34; N, 6.75%.

(24*R*,22*E*)-5,7,22-Ergostatriene-1α,3β,25-triol (16b). In the same manner as described for **16a**, **14b** (0.87 g, 1.3 mmol) was converted in two steps to 0.31 g (57%) of **16b**: mp 214—217 °C (from EtOH, needles); $[\alpha]_D^{24}$−16.2° (*c* 0.14, MeOH); IR (KBr) 3510, 3360, 1660, 1610, 1465, 1385, 1145, 1075, 970 cm^{-1}; ^1H NMR δ=0.65 (3H, s, 18-H_3), 0.95 (3H, s, 19-H_3), 0.99 (3H, d, *J*=6.8 Hz, 28-H_3), 1.05 (3H, d, *J*=6.8 Hz, 21-H_3), 1.13 and 1.17 (6H, each s, 26-H_3 and 27-H_3), 3.77 (1H, m, 1-H), 4.08 (1H, m, 3-H), 5.35 (3H, m, 7-H, 22-H and 23-H), 5.74 (1H, m, 6-H); MS *m/z* (rel intensity) 428 (M^+; 42), 251 (60), 225 (62), 157 (100), 145 (80); UV (EtOH) 282 nm (ε 11700). Found: C, 78.24; H, 10.37%. Cacld for $C_{28}H_{44}O_3$: C, 78.48; H, 10.35%.

(24*R*)-1α,25-Dihydroxyvitamin D_2 (1b). A solution of **16b** (100 mg, 0.23 mmol) in ether–THF (19:1, 1000 ml) was irradiated for 3 min under Ar at water-cooled temperature with a high pressure mercury lamp (Ushio, UM-452) using 1.5% KNO_3 solution as a filter. The mixture was next concentrated in vacuo. The residue was chromatographed over HPLC (Merck, LiChrosorb® Si60 (7 μm), 25×250 mm) eluting with 5% MeOH–CH_2Cl_2 (8.0 ml min^{-1}) to give 28 mg (28%) of the previtamin D (**17b**): ^1H NMR δ=0.72 (3H, s, 18-H_3), 0.99 (3H, d, *J*=6.8 Hz, 28-H_3), 1.05 (3H, d, *J*=6.6 Hz, 21-H_3), 1.13 and 1.17 (6H, each s, 26-H_3 and 27-H_3), 1.76 (3H, s, 19-H_3), 4.05 (1H, m, 3-H), 4.19 (1H, m, 1-H), 5.31 (2H, m, 22-H and 23-H), 5.51 (1H, m, 9-H), 5.76 and 5.92 (2H, ABq, *J*=12.9 Hz, 6-H and 7-H).

A solution of **17b** (28 mg) in EtOH (15 ml) was stirred for 1 h at reflux temperature. The mixture was concentrated in vacuo. The residue was chromatographed on HPLC (Merck, LiChrosorb® Si60 (7 μm), 25×250 mm) eluting with 5% MeOH–CH_2Cl_2 (7.0 ml min^{-1}) to give 11.8 mg (42%: 12% from **16b**) of **1b**. This was recrystallized from hexane–CH_2Cl_2 to give **1b** as rods: mp 150—152 °C [lit,[9] a colorless oil]; $[\alpha]_D^{23}$+74° (*c* 0.16, EtOH); ^1H NMR δ=0.56 (3H, s, 18-H_3), 0.99 (3H, d, *J*=6.8 Hz, 28-H_3), 1.03 (3H, d, *J*=6.6 Hz, 21-H_3), 1.12 and 1.17 (6H, each s, 26-H_3 and 27-H_3), 4.22 (1H, m, 3-H), 4.42 (1H, m, 1-H), 4.99 (1H, narrow m, 19-H), 5.32 (3H, m, 19-H, 22-H and 23-H), 6.01 (1H, d, *J*=11.2 Hz, 7-H), 6.37 (1H, d, *J*=11.2 Hz, 6-H); MS *m/z* (rel intensity) 428 (M^+; 6), 410 (7), 392 (10), 352 (5), 334 (16), 269 (9), 251 (10), 134 (100), 105 (46); UV (EtOH) 265 nm (ε 16900).

(Received April 12, 1989)

The preparation of hydroxy amides from a wide variety of lactones and amines has been achieved at 9 kbar and 30 or 65 °C. The yields of hydroxy amides were moderate to excellent. Some limitations were encountered in the reaction of 6-hexanolide; for example, diethylamine gave only a 15% yield of the corresponding amide at 8 kbar and 60 °C. 4-Pentanolide did react with extremely unreactive amines such as 4-nitroaniline and diphenylamine, and the product was a mixture of the hydroxy amide and 3-aminobutyric acid.

Particular attention has been directed to certain hydroxy amides that can serve as novel types of surfactants,[1a] (metal) chelating agents,[1b] liquid crystals,[1c] and protecting groups,[1d] as well as important intermediates for the synthesis of pharmacologically intriguing substances.[1e] Although one of the most convenient and simplest methods for preparing hydroxy amides would consist in the direct nucleophilic ring opening of lactones with amines, this conversion is generally limited either to strained three-membered lactones such as 3-propanolide[2] and 3-butanolide[3] or to relatively highly nucleophilic amines.[4] Specifically, the reactions of 4-substituted 4-butanolides with amines were reported to be sluggish,[5] and 3-butanolide did not react with 4-nitroaniline in refluxing acetonitrile.[3] Since we have previously demonstrated that secondary amines reacted in high yields at moderate temperatures with a variety of nonactivated esters to produce the corresponding acid amides if the reactions were performed under a few kbar,§[6] the same technique was expected to effect aminolysis of lactones by nucleophilic displacement at the carbonyl group.[7,8]

In this paper we wish to report in full detail the preparation of hydroxy amides by the aminolysis of lactones under high pressure.[9] The representative results are summarized in Table 1.

The structures of the amides **3** were confirmed on the basis of their analytical and ^{1}H and ^{13}C NMR spectroscopic data (see Experimental). Neither an inert atmosphere nor dry solvents were required. Alkyl-, aryl-, and aralkylamines **2** react with a wide variety of lactones **1** in moderate to excellent yields at 9 kbar and at room temperature to 65 °C affording the corresponding hydroxy amides **3**. For example, 4-butanolide (**1a**), 4-pentanolide (**1b**), and 5-pentanolide (**1d**) underwent aminolysis with piperidine (**2a**) at 30 °C to give the corresponding hydroxy amides **3aa**, **3ba**, and **3da** in 99, 95, and 96% yields, respectively, whereas no appreciable reaction was observed in refluxing acetonitrile at 1 bar. Similarly, diethylamine (**2b**) reacted smoothly with **1a**, **1b**, and **1d** at 9 kbar and

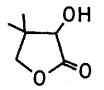
a) At 5 kbar for 12 h, **10** (oil) was obtained in 13% yield. b) A 3% yield of **10**. c) The yield of **11e**. d) In THF. e) The yield of **11f**. f) In toluene.

Present address: Ibaraki Research Laboratory, Hitachi Chemical Co., Ltd., Hitachi, Ibaraki 317.

§ 1 bar=10^5 Pa.

30 °C to produce **3ab**, **3bb**, and **3db** in 100, 95, and 94% yield, respectively, while at 5 kbar and 30 °C only a 36% yield of **3bb** was obtained, thus demonstrating a considerable pressure effect in this reaction. It is rather surprising that the reaction of 4-pentanolide (**1b**) with benzylamine (**2c**) took place quantitatively at 9 kbar since some of the original lactone was always recovered even under the vigorous conditions at 1 bar and 190 °C for several days that resulted in much decomposition.[4] Furthermore, **1a** and **1b** did react with aniline (**2d**) at 9 kbar and 65 °C affording **3ad** and **3bd** albeit in moderate yields (47 and 39%). Aniline, with a pK_a of 4.69, is one million times less basic than a typical primary alkylamine and is therefore reported to be inert to **1b** upon heating to 180 °C.[4] 5-Pentanolide (**1d**) was more reactive than 4-butanolide (**1a**), thus 94% yield of the hydroxy amide **3dd** was obtained at 9 kbar and 55 °C.

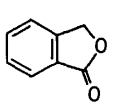
Other examples of five membered lactones include 4-decanolide (**1c**) and 4,5-dihydro-3-hydroxy-4,4-dimethyl-2(3*H*)-furanone (**4**) that reacted with **2a** and **2b** under similar conditions giving the hydroxy amides **3ca**, **3cb**, **5a**, and **5b**, respectively. The most versatile reagents for the mild aminolysis of esters[10] and lactones[11] are the dialkylaluminum amides. However, the hydrolysis procedure employed in this method often leads to recyclization to the original lactones as exemplified in the reaction of 1(3*H*)-isobenzofuranone (**6**) with diethylaluminum dimethyl amide.[11] This is not the case in the present method;



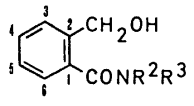
4

$HOCH_2C(CH_3)_2CH(OH)CONR^2R^3$

5a, b



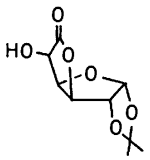
6



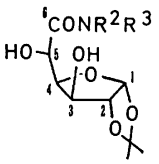
7a, b

for instance, **6** with **2a** at 9 kbar and 30 °C produced the hydroxy amide **7a** in 77% yield.

In contrast to **1a** and **1b**, a bicyclic lactone, 1,2-*O*-isopropylidene-α-D-glucofuranurono-6,3-lactone (**8**) underwent facile aminolysis with **2a** and **2c** at 1 bar and room temperature to give the corresponding amides **9a** and **9c** in 87 and 100% yields, respectively.



8



9a, c

This is presumably because of the bicyclic ring strain or the more constrained *cis*-ester structure.[12]

The reaction of 6-hexanolide (**1e**) with the amines was more complicated. For example, **1e** with **2a** at 9

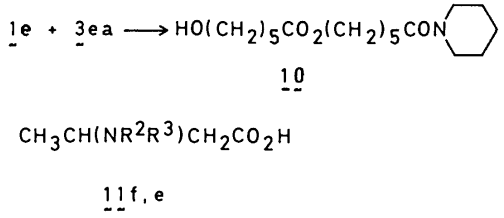
a) In this column are shown eluents of a column chromatography on silica gel to isolate the product: E=ethyl acetate, A=acetone, B=benzene, T=toluene; and in the parentheses the solvent ratio or g=gradient fashion.

kbar and 30 °C gave an 86% yield of **3ea** along with 6-oxo-6-piperidinohexyl 6-hydroxyhexanoate (**10**, 3%), the formation of which can be explained in terms of acyl-oxygen fission of **1e** with **3ea**. At the lower pressure (5 kbar) and employing the shorter reaction time (12 h), the yield of **10** increased to 13% while that of **3ea** decreased to 40%. Under higher pressure and a longer reaction time, **10** apparently undergoes further aminolysis to give **3ea**. Diethylamine (**2b**) was almost inert to **1e** at 8 kbar and 30 °C. However, the reaction took place at 8 kbar and 60 °C, producing a complex mixture of products from which the amide **3eb** was isolated only in 15% yield.



Three-membered lactones, like 3-propanolide and 3-butanolide, readily undergo aminolysis, but presumably because of the effect of ring strain, alkyl-oxygen fission is also observed. The course of the

a) In DMSO-d_6.

observed and only 0.8% of the amino acid **11f** was formed in the reaction of **1f** with **2f** upon heating at 180—190 °C.[3a] The desired amides **3fe** and **3ff** were obtained in 40 and 35% yields, along with 3-(4-nitrophenylamino)- and 3-(diphenylamino)butyric acids **11e**(60%) and **11f**(28%), respectively. A slight improvement in the yield of **11e** was obtained using tetrahydrofuran as a solvent, whereas the use of more nonpolar solvents, like toluene, in the reaction of **1f** with **2f** retarded the reaction, the product ratio being little improved.

Experimental

General. Melting points are uncorrected. ^{1}H NMR spectra were measured either on a Hitachi R40(90 MHz) or JEOL FX-90Q(90 MHz) or Varian VRX-200(200 MHz) and ^{13}C NMR on a JEOL FX-90Q. The high-pressure instrument employed has been described elsewhere.[7]

High-Pressure Reaction of Lactones 1 with Amines 2. A General Procedure. A mixture of **1** (5 mmol) and **2** (10 mmol) was diluted with acetonitrile in a PTFE (8 cm^3) capsule, which was then stored for a stated time (Table 1) at 9 kbar. After evaporation of the solvent and amine (if volatile), the residue was chromatographed on silica gel, in general using ethyl acetate–acetone (or toluene or benzene) as an eluent in gradient fashion (Table 2). The results of analytical and ^{1}H and ^{13}C NMR spectroscopic data were collected in Tables 2—4.

Reaction of 1,2-*O*-Isopropylidene-α-D-glucofuranurono-6,3-lactone (8) with Piperidine (2a). A mixture of **8** (1 mmol) and **2a** (2 mmol) was stirred in acetonitrile (1 cm^3) at room temperature for 5 h. After evaporation of the solvent and amine, the residue was chromatographed on silica gel. Elution with benzene–ethyl acetate (1:3) gave *N*,*N*-pentamethylene-1,2-*O*-isopropylidene-α-D-glucofuranuronamide (**9a**) in 87% yield: mp 148—149 °C (see Tables 3 and 4). Found: C, 55.84; H, 7.71; N, 4.61%. Calcd for $C_{14}H_{23}NO_6$: C, 55.79; H, 7.71; N, 4.65%.

***N*-Benzyl-1,2-*O*-isopropylidene-α-D-glucofuranuronamide (9c).** The procedure was the same as described above for **9a**. **9c** was obtained quantitatively: mp 130—131 °C (see Tables 3 and 4). Found: C, 59.48; H, 6.47; N, 4.13%. Calcd for $C_{16}H_{21}NO_6$: C, 59.42, H, 6.56; N, 4.33%.

The Ullmann Condensation Reaction of Haloanthraquinone Derivatives with Amines in Aprotic Solvents. VI.[1] The Combination of Cu(I) and Hydroxo or Alkoxo Cu(II) as Effective Catalyst System

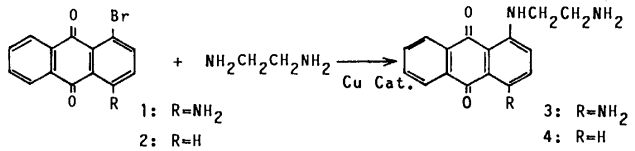
Sadao Arai, Yoshio Hashimoto, Takamichi Yamagishi, and Mitsuhiko Hida*
Department of Industrial Chemistry, Faculty of Technology, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received April 14, 1989)

The reaction rate of the Ullmann condensation reaction of haloanthraquinone with ethylenediamine (EN) by copper(I) halide catalyst decreased along with the formation of inactive Cu(II) species [$Cu(EN)_2X_2$] by one-electron transfer from Cu(I) to haloanthraquinone. However, the combination of Cu(I) and Cu(II) salts, having an OH, OCH_3, or OCOR group, enhanced the reaction rate in the following order: CuCl<CuCl-CuCl(OCH_3)<CuCl-Cu(OCH_3)$_2$<CuCl-Cu(OH)$_2$. In condensation using Cu(OR)$_2$ or CuCl(OCH_3) alone, the Cu(II) species was reduced to Cu(I) to form an active catalyst system [Cu(I)+Cu(II)]. On the other hand, $CuBr_2$ or $CuCl_2$ was not reduced and was ineffective for the reaction. These were confirmed by ESR measurements and the presence of a dehalogenation product. Mixed valence species bridged by the alkoxo or hydroxo group was proposed as an active species.

A wide variety of copper species, such as copper powder, copper(I) oxide, copper(I) halides, and copper(II) salts, has been used for the catalyst of nucleophilic substitution of aryl halides (the Ullmann condensation).[2,3] The choice of the catalyst depends on the structure of aryl halides, nucleophiles, and solvents; however, it is often found that a catalyst that is effective for a certain reaction is ineffective for another reaction system.[3] The mechanism of the Ullmann condensation is further complicated by the fact that a copper species changes its oxidation state during a reaction. For example, a Cu(0) catalyst was changed to the effective Cu(I) species by oxidation with molecular oxygen or some other oxidants.[4] In the case of a Cu(II) catalyst, the reduction of Cu(II) to Cu(I) accelerated the reaction.[4,5]

Although Cu(I) salts were more effective catalysts than Cu(II) salts in the homogeneous Ullmann condensation of haloanthraquinones with amines in aprotic solvents,[6] Cu(II) species formed by a one-electron transfer from Cu(I) to haloanthraquinone under a nitrogen atmosphere played a very important role. The catalytic activity of Cu(I) was enhanced by Cu(II) species produced in condensation with 2-aminoethanol,[6-8] whereas with ethylenediamine (EN)[9] only Cu(I) was active and the reaction rate decreased along with the formation of an ineffective Cu(II) species. On the other hand, the alkoxocopper(II) species enhanced the rate of condensation with EN by a cooperative interaction with the Cu(I) species.[1]

These results prompted us to study a combination of Cu(I) and Cu(II) species in order to explore the more active catalyst system in the Ullmann condensation reaction. In this paper we will report on the results for the catalytic behavior of alkoxo or hydroxo copper(II) as a promoter in the Ullmann condensation reaction of haloanthraquinones with ethylenediamine.



Experimental

Materials. 1-Amino-4-bromoanthraquinone (**1**) and 1-bromoanthraquinone (**2**) were prepared by desulfonation of sodium 1-amino-4-bromoanthraquinone-2-sulfonate with 80% sulfuric acid and by Sandmeyer's bromination of 1-aminoanthraquinone, respectively, as reported previously.[6] Copper(I) bromide and copper(I) chloride were prepared and purified as described in the literature.[10] Commercially available copper(II) bromide and copper(II) chloride (Kanto Chemical Co. Inc., GR grade) were purified according to methods described in the literature.[11] Chloromethoxycopper(II)[12] was prepared by the reaction of copper(I) chloride with molecular oxygen in methanol (Found: Cu. 49.0%). Dimethoxycopper(II)[13] was obtained by the reaction of anhydrous copper(II) chloride with lithium methoxide in methanol (Found: Cu, 50.7%). All other copper salts were commercial materials (Kanto Chemical Co. Inc., GR grade) and used without further purification. All solvents and ethylenediamine were dried and purified by the standard procedure, and stored under a nitrogen atmosphere.

Reaction Procedure. The condensation was initiated by the addition of a solution of copper salt and ethylenediamine in ethanol to the haloanthraquinone solution in THF-ethanol at a regulated temperature. The reaction was carried out under a dry, oxygen-free nitrogen atmosphere. The yield was determined spectrophotometrically as described in our previous papers.[1,6] The debromination product was analyzed by the use of a Shimadzu LC-3A HPLC (column: Unisil C18; mobile phase: methanol-water 4:1) with 1-amino-2-bromoanthraquinone as an internal standard.

Instruments. UV and visible spectra were measured with

a Shimadzu UV-210 spectrometer. ESR spectra were obtained by the use of a JEOL-PE-3X spectrometer, equipped with a 100-kHz field modulation unit.

Results and Discussion

The reaction rate of the condensation of 1-amino-4-bromoanthraquinone (**1**) or 1-bromoanthraquinone (**2**) with ethylenediamine (EN) catalyzed by Cu(I) salt (CuCl or CuBr) decreases along with the formation of an inactive Cu(II) species $[Cu(EN)_2X_2]$ by a one-electron transfer from Cu(I) to haloanthraquinone.[9] However, upon the addition of hydroxo or alkoxo Cu(II) salt the condensation catalyzed by Cu(I) salt was accelerated. As a typical example, Fig. 1 indicates the results of the condensation of **1** with EN using a CuCl-$Cu(OH)_2$ catalyst system. The yield of 1-amino-4-(2-aminoethylamino)anthraquinone (**3**) depended on the molar fraction of $Cu(OH)_2$ to the total copper ([CuCl]+[$Cu(OH)_2$]). An induction period was observed when the copper species was $Cu(OH)_2$ alone.

Copper(II) Species as a Promoter. Figure 2 illustrates plots of the initial rate (V_0) vs. the fraction of Cu(II) to the total copper. In condensation using a CuBr-$CuBr_2$ catalyst system, the initial rate decreased linearly with an increase in the fraction.[1] On the other hand, in catalyst systems containing alkoxo or hydroxo Cu(II) species, the maximum initial rate was observed at a fraction of around 0.3 and the catalytic activity increased in the following order: CuCl-$CuCl(OCH_3)$<CuCl-$Cu(OCH_3)_2$<CuCl-$Cu(OH)_2$. These results clearly show that in condensation using a CuBr-$CuBr_2$ catalyst system, only Cu(I) is effective and the Cu(II) species containing two halide ligands is ineffective. This contrasts to other catalyst systems where the Cu(II) species acts as a promoter.

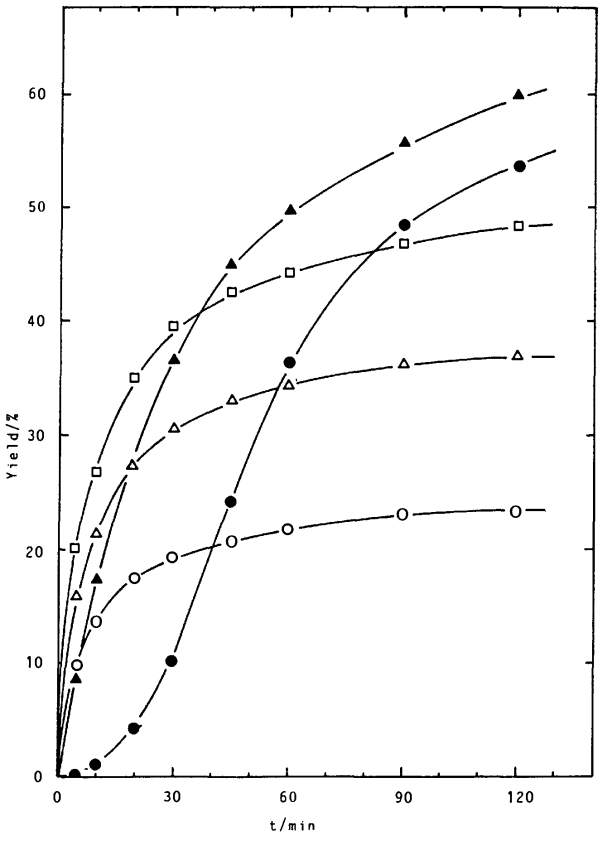


Fig. 1. Time course of the reaction of **1** with EN by CuCl-$Cu(OH)_2$ catalyst system.
$[\mathbf{1}]_0=5.0\times10^{-3}$ mol dm^{-3}, $[EN]_0=0.5$ mol dm^{-3}, $[CuCl+Cu(OH)_2]_0=2.1\times10^{-3}$ mol dm^{-3}, temp 50 °C, solvent THF-EtOH 1 : 1.
○: r ($[Cu(OH)_2]_0/[CuCl+Cu(OH)_2]_0$)=0, △: r=0.164, □: r=0.288, ▲: r=0.755, ●: r=1.0.

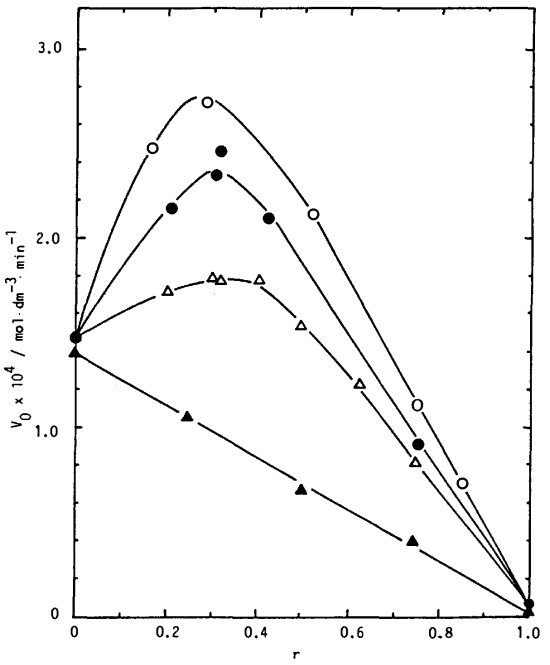

Fig. 2. The dependence of the initial rates, (V_0) on the ratio r ($[Cu(II)]_0/[Cu(I)+Cu(II)]_0$) in the reaction of **1** with EN.
$[\mathbf{1}]_0=5.0\times10^{-3}$ mol dm^{-3}, $[EN]_0=0.5$ mol dm^{-3}, $[Cu(I)+Cu(II)]_0=2.1\times10^{-3}$ mol dm^{-3}, temp 50 °C, solvent THF-EtOH 1 : 1.
○: CuCl-$Cu(OH)_2$, ●: CuCl-$Cu(OMe)_2$, △: CuCl-CuCl(OMe), ▲: CuBr-$CuBr_2$.

The initial rates of the condensation by various kinds of Cu(II) species were compared at a molar ratio of about 0.3 (Table 1). Cu(II) species having an OH, OCH_3, or OCOR group increased the catalytic activity of Cu(I), whereas a Cu(II) species having NO_3, ClO_4, or S, deactivated the condensation. The hyperfine coupling constants (A)[13] of $CuBr_2$ or $CuCl_2$ in a THF-EtOH (1 : 1) solution containing EN were around 80 G, whereas those of the Cu(II) species coordinated by an OY-type ligand (Y=H, R, COR) were around 70 G.

Consequently, the initial rate (V_0) can be expressed as

$$V_0 = k_1[Cu(I)] + k_2[Cu(I)]^m[Cu(II)]^n. \quad (1)$$

Table 1. Initial Rates (V_0)[a] for the Condensation of **1** with EN by Cu catalyst and the Coupling Constants (A) of Cu(II) Species

Catalyst system			V_0	A
Cu(II)	+	Cu(I)	mol·dm^{-3}·min^{-1}	G
$Cu(OH)_2$		CuCl	2.70	69.6
$Cu(OMe)_2$		CuCl	2.33	70.5

a) $[\mathbf{1}]_0=5.0\times10^{-3}$ mol·dm^{-3}, $[EN]_0=0.5$ mol·dm^{-3}, $[Cu(I)+Cu(II)]_0=2.1\times10^{-3}$ mol·dm^{-3}, $[Cu(II)]_0/[Cu(I)+Cu(II)]_0=0.3$, temp 50 °C, solvent THF-EtOH 1 : 1.

If f and v_0 denote the fraction of Cu(I) to the total copper ([Cu(I)]+[Cu(II)]) and the initial rate catalyzed by Cu(I) alone, respectively, Eq. 1 becomes

$$V_0 - fv_0 = k_2[Cu(I)]^m[Cu(II)]^n. \quad (2)$$

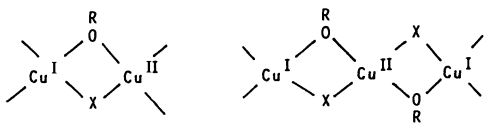
Figure 3 shows a plot of V_0-fv_0, which indicates the rate catalyzed by a Cu(I) and Cu(II) couple, against fraction (r) of Cu(II) to total copper. In the CuCl-CuCl(OMe) system, the maximum rate was observed at $r=0.5$, whereas in the CuCl-$Cu(OMe)_2$ and CuCl-$Cu(OH)_2$ systems it appeared at $r=0.3$. Therefore, in a CuCl-CuCl(OMe) catalyst system the ratio of m to n is 1 : 1, whereas in CuCl-$Cu(OH)_2$ and CuCl-$Cu(OMe)_2$ catalyst systems the ratio is 2 : 1. These results suggest that the active species (alkoxo or hydroxo Cu(I)) is formed by the following ligand-exchange reactions:

$$CuCl + CuCl(OMe) \rightarrow CuOMe + CuCl_2$$

and

$$2CuCl + Cu(OR)_2 \rightarrow 2CuOR + CuCl_2.$$

However, the coupling constant (A) of CuCl-$Cu(OH)_2$ (2 : 1) in a THF-EtOH (1 : 1) solution was not 80 G but, rather, 70 G and the ESR spectrum of this system was the same as that of $Cu(OH)_2$-EN. These results exclude the possibility of alkoxo or hydroxo Cu(I) formation by a ligand-exchange reaction. The above results can be explained in terms of the idea that a Cu(II) species having OH or OCH_3 interact with the Cu(I) species to form an oxygen-bridged multi copper species as follows:



Although we failed to detect the presence of these oxygen-bridged species by ESR measurement, many

examples of alkoxo- or hydroxo-bridged copper species have been reported.[14] On the other hand $CuBr_2$ or $CuCl_2$, which does not form an oxygen-bridged species, is ineffective as a promoter. No reasonable explanation is possible for the deactivation by $Cu(NO_3)_2$, $Cu(ClO_4)_2$.

Change of Oxidation States of Copper Species during the Condensation. Figure 4 shows the results of an ESR measurement of the condensation system (**1**-EN-CuCl). The Cu(II) signal height[15] increased as the condensation proceeded and the coupling constant A remained unchanged at 80 G during the condensation. The ESR spectra of this condensation system were the same as that of a violet solution[16] of $CuBr_2$-EN or $CuCl_2$-EN in THF-EtOH (1 : 1) (A=80 G; Table 1). Therefore, the ineffective Cu(II) species formed during the condensation is considered to be a mononuclear Cu(II) complex: $Cu(EN)_2X_2$.

On the other hand, in the case of CuCl-$Cu(OH)_2$ (2 : 1) catalyst system, which is the most effective one, the formation of the Cu(II) species was much depressed compared to that using the CuCl catalyst system (Fig. 4). However, the coupling constant (70 G) was gradually increased and went up to 77 G after 90 min. This would be due to the coordination of bromide ions accumulated in the solution. These results suggest that a Cu(I)-Cu(II) couple containing an OH group was relatively stable or that a concurrent reduction of Cu(II) to Cu(I) occurred with the oxidation of Cu(I).

In condensation using CuCl-$Cu(OCH_3)_2$ (2 : 1) and CuCl-CuCl(OCH_3) (2 : 1) catalyst systems the time

$[\mathbf{1}]_0=5.0\times10^{-3}$ mol dm^{-3}, $[EN]_0=0.5$ mol dm^{-3}, $[Cu]_0=2.1\times10^{-3}$ mol dm^{-3}, temp 50 °C, solvent THF-EtOH 1 : 1.
△: Yield of **3** by CuCl-CuCl(OMe) catalyst (r=0.309), ○: yield of **3** by CuCl-Cu(OMe)$_2$ catalyst (r=0.306), ▲: Cu(II) signal height of the reaction system by CuCl-CuCl(OMe) catalyst (r=0.309), ●: Cu(II) signal height of the reaction system by CuCl-Cu(OMe)$_2$ catalyst (r=0.306).

course of the yield of **3** and the coupling constant of Cu(II) (see Fig. 5) lies between those of the CuCl system and CuCl-Cu(OH)$_2$ system.

In condensation using Cu(OH)$_2$, Cu(OMe)$_2$, or CuCl(OMe) alone, which has an induction period, the Cu(II) signal height decreased and then slightly increased as the condensation proceeded (Figs. 6 and 7). It was also observed that the reaction rate tended to decrease along with an increase in the coupling constant. These results show that a part of the Cu(II) species was reduced to the Cu(I) species to form an active catalyst system [Cu(I) + Cu(II)]; then, Cu(I) was oxidized to ineffective Cu(II) by one-electron transfer from Cu(I) to haloanthraquinone and the coupling constant (A) of Cu(II) increased from 70 G to 80 G along with an increase of halide ions in the solution.

The reduction of Cu(II) to the Cu(I) species was also supported by the debromination of **1**. We previously reported that the debromination was caused through a radical anion intermediate, as follows:[8]

$$AQBr + Cu(I) \rightarrow AQBr^{\cdot-} + Cu(II)$$

$$AQBr^{\cdot-} \rightarrow AQH.$$

In fact, Fig. 6 shows that in the case of the **1**-EN-Cu(OH)$_2$ system 1-aminoanthraquinone was formed with an decrease in the Cu(II) signal height. The yields of the aminated product, [1-(2-aminoethylamino)anthraquinone: **4**], and the debrominated product, (anthraquinone) in **2**-EN-Cu(OH)$_2$, were larger than those in **1**-EN-Cu(OH)$_2$. This result corresponds to the fact that the decrease in the Cu(II) signal height was larger in the system of **2**-EN-Cu(OH)$_2$ than in that of **1**-EN-Cu(OH)$_2$ (Fig. 7).

Reduction of Cu(II) to the Cu(I) Species. As described above, the reduction of Cu(II) to the Cu(I) species was clearly observed in a condensation system using Cu(OH)$_2$, Cu(OMe)$_2$, or CuCl(OMe). Figure 6 also shows that in the absence of haloanthraquinone, the Cu(II) signal height was slightly decreased. The catalyst solution [Cu(OH)$_2$-EN] was heated at 50 °C for 110 min and then added to a solution of **1**. In this case the induction period was slightly shortened. These results also indicated that Cu(OH)$_2$ was slightly reduced to the Cu(I) species, even in the absence of haloanthraquinone. Contrary to haloanthraquinones, 1-aminoanthraquinone or anthraquinone did not facilitate a reduction of the Cu(II) species in the system of Cu(OH)$_2$-EN. These results suggest that the Cu(II) species is coordinated by the halogen moiety of haloanthraquinone, and reduced to Cu(I) by a one-electron transfer from EN. This was also sup-

ported by the fact that the addition of 1-aminoanthraquinone equimolar to **2** little affected Cu(II) reduction in the system of **2**-EN-$Cu(OH)_2$.

The coupling constants of the catalyst systems containing alkoxo or hydroxo Cu(II) were smaller than that of the $CuCl$-$CuCl_2$ or $CuBr$-$CuBr_2$ system (Table 1). This suggests that the former Cu(II) species has a stronger covalent bond character than that of the latter.[17] On the basis of the reduction potentials of various Cu(II) complexes obtained by polarography, Patterson and Holm[18] reported that mononuclear Cu(II) complexes with a nonplanar structure (e.g., distorted tetrahedron and trigonal bipyramid) were readily reduced to Cu(I), compared with their planar analogs. It has also been reported that binuclear Cu(II) complexes with a planar structure and Cu(II) complexes with a distorted tetrahedral structure were readily reduced to Cu(I) by ascorbic acid, while planar mononuclear Cu(II) complexes were not reduced.[19] Consequently, copper(II) species having a promoter-character in our case has an alkoxo- or hydroxo-bridged structure and would be reduced to Cu(I) by EN. On the other hand, no reduction of Cu(II) to

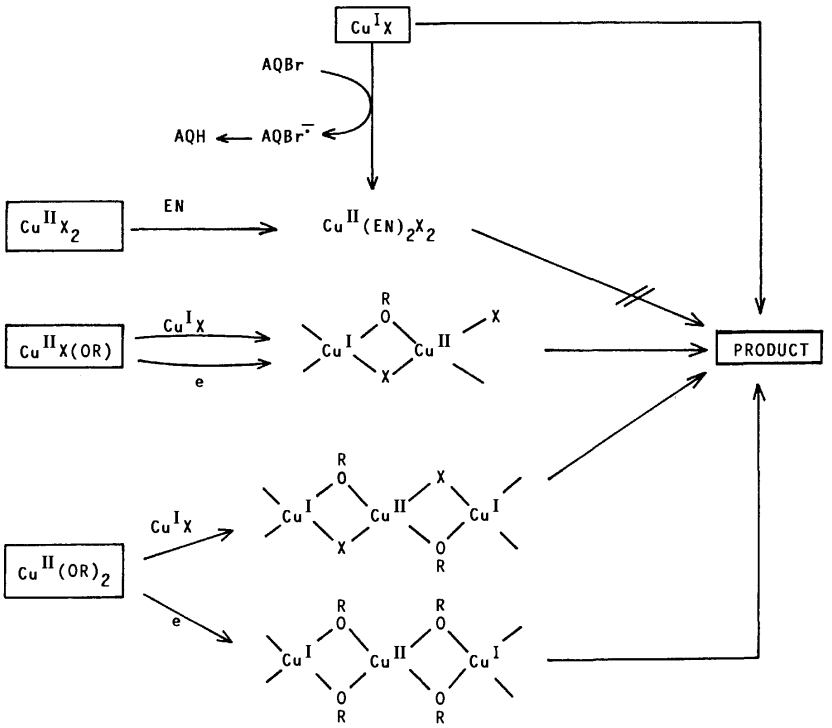

Fig. 9. Reaction pathways.

Cu(I) was observed in the systems using ineffective $Cu(EN)_2X_2$ with a planar structure (A= 80 G).

As Fig. 8 shows, upon the addition of glucose to the condensation system (**1**-EN-$Cu(OH)_2$), little induction period was observed and the Cu(II) signal height decreased very little. Since the coupling constant was observed to be 75 G, even at 4 min, it was concluded that during the first stage of the reaction the Cu(II) species was reduced to active Cu(I) by glucose and then reoxidized to an inactive Cu(II) species. The yield of **3** in **1**-EN-CuCl was decreased upon the addition of glucose. These results suggest that the coordination of glucose to the Cu(I) species interrupts the coordination of haloanthraquinone.

Reaction Pathways. The reaction pathways of the Ullmann condensation using $Cu(OR)_2$ or CuX(OR) are shown in Fig. 9.[20] As discussed above, all of the observed results support the reaction pathways including a Cu(I)···Cu(II) mixed valence complex. Although Cu(I) halide is an active catalyst, the reaction rate decreases along with the formation of inactive $Cu(EN)_2X_2$. The alkoxo- or hydroxo-bridged mixed valence complex would be formed by the reaction between the Cu(I)X and the alkoxo or hydroxo Cu(II) species, or by the reduction of the alkoxo- or hydroxo-bridged Cu(II) species.

(Received May 11, 1989)

Specifically modified linear oligosaccharides were prepared by enzymatic hydrolysis of 6- or 2-*O*-substituted γ-cyclodextrin by Taka amylase A. These results suggest that the importance of the interactions between hydroxyl groups and the subsites (P—V) of Taka amylase A decreases in the following order; for C-6-OH, S>R>T>Q,U and for C-2-OH, R,S>T>Q, U.

Substrate specificity of Taka amylase A[2-8)] has been successfully studied by use of partially *O*-methylated amylose and specifically modified phenyl maltosides in order to obtain information about interaction between the subsites (Fig. 1)[6-8)] of Taka amylase A and substrates.[9-14)] We have reported a novel synthetic method for the preparation of specifically modified linear oligosaccharides by Taka amylase A degradation of α-cyclodextrin (α-CD) or β-cyclodextrin (β-CD) derivatives.[15-21)] This also provided new information about interactions between substrates and the subsites of Taka amylase A. The Taka amylase A-catalyzed hydrolysis of 6-*O*-substituted cyclodextrins (CDs)[16,17,22)] and $6^A,6^X$-*O*-disubstituted (X=B, C, or D) CDs[15-17)] revealed that interaction between subsite S and the C-6-OH was important. Also, the Taka amylase A-catalyzed hydrolysis of 2-*O*-substituted CDs disclosed the importance of interaction between the C-2-OH and subsites R and S.[21)] However, these experiments using the α- or β-CD derivatives can not tell us about the importance of other subsites. The reason is that the slow rate of cleavage of the CD macrocyclic ring does not allow accumulation of intermediate linear oligosaccharides in enough amount to be isolated. However, since γ-cyclodextrin (γ-CD) is hydrolyzed much faster than α- or β-CD by Taka amylase A,[23)] the hydrolysis of γ-CD derivatives can reasonably be expected to give new specifically modified linear oligosaccharides (new intermediates in the enzymatic hydrolysis) which can not be isolated in the hydrolysis of α- or β-CD. Also, this result will provide novel information concerning the importance of the subsites. We describe here Taka amylase A-catalyzed hydrolysis of 6-*O*-tosyl-γ-cyclodextrin (**1**), 6-*O*-(1-naphthylsulfonyl)-γ-cyclodextrin (**2**), 6-*O*-(2-naphthylsulfonyl)-γ-cyclodextrin (**3**), 2-*O*-(1-naphthylsulfonyl)-γ-cyclodextrin (**4**), and 2-*O*-(2-naphthylsulfonyl)-γ-cyclodextrin (**5**).

Results and Discussion

Preparation of Modified γ-Cyclodextrins. Sulfonates (**1**—**3**) were prepared by the reaction of γ-CD with the corresponding arenesulfonyl chloride in pyridine. Sulfonates **4** and **5** were synthesized by the reaction of γ-CD with the corresponding arenesulfonyl chloride using dibutyltin oxide in DMF.[24)] The sulfonates could be also more coveniently, however in lower yield, synthesized by the reaction of γ-CD with the corresponding arenesulfonyl chloride in water (see Experimental).

Taka Amylase A-Catalyzed Hydrolysis of the Modified γ-Cyclodextrins. The γ-CD derivatives were hydrolyzed by Taka amylase A to give specifically modified linear oligosaccharides. The reaction conditions, products, and yields are summarized in Table 1.

The modified maltose (**12**) or the modified maltotriose (**17** or **18**) was identified by comparing its high-performance liquid chromatography (HPLC) retention time and its fast atom bombardment mass (FAB MS) spectrum with those of the corresponding authentic compound.[21,22] The other 6′-*O*-(arylsulfonyl)maltoses (**13** and **14**) were converted to *S*-phenyl-6′-thiomaltose[16,17] and then identified similarly. Structures of other linear oligosaccharides were determined as follows. All compounds showed FAB MS spectra and ^{13}C NMR spectra consistent with their structures, whereas the position of sulfonylation in the chain of oligosaccharide was not determined by the spectral data. Sulfonates **6** and **9** were reduced with $NaBH_4$ to give **19** and **20**, respectively, followed by complete acetylation with acetic anhydride in pyridine. The resultant acetates (**21** and **22**) were analyzed by electron impact mass (EI MS) spectra in order to determine the sulfonylation position. The results are shown in Fig. 2. The sulfonate, **10**, or **11**, was converted to the 6″-phenylthio derivative (**23**) which was identified by comparing its HPLC retention time and its FAB MS spectrum to those of an authentic sample prepared from the reaction of **9** with thiophenol.

The sulfonate, **7** or **8**, was converted to the 3,6-anhydro derivative (**24**) by treatment with $Ba(OH)_2$ in water and identified by comparing its HPLC retention time and its FAB MS spectrum to those of the authentic compound which was prepared by the reaction of **6** with aqueous $Ba(OH)_2$. Authentic 3″,6″-anhydromaltotetraose (**24**) was also prepared by Taka-amylolysis of 3,6-anhydro-γ-cyclodextrin.[25,26]

25

its FAB MS spectrum to those of the authentic sample.[21]

α- or β-CD analogues of **1**, **2** or **3** and **4** or **5** gave only G′-G and G′-G-G, respectively, upon Taka amylase A-catalyzed hydrolysis at 40 °C[21] (Hereafter, the following abbreviations are used: G, glucose unit; G′, modified glucose unit.). In an attempt to obtain intermediate linear oligosaccharides, reactions at lower temperature (10 °C or 0 °C) were carried out. However, the reaction rates were too slow to allow accumulation of stable linear oligosaccharide intermediates. The derivatives of γ-CD (**1**—**5**) were enzymatically hydrolyzed much more rapidly than the α- and β-CD analogues at 40 °C, although **1**—**3**, and **4** or **5** gave G′-G and G′-G-G, respectively, at this temperature similarly to the α- and β-CD analogues (Table 1). This suggests the accumulation of intermediates at lower temperature in the case of γ-CD derivatives.

The enzymatic hydrolysis of **1**—**3** at 10 °C afforded a mixture of G′-G-G and G-G′-G-G. Amylolyses of **1**—**3** at 40 °C or at 10 °C for longer reaction period (2 days) gave G′-G exclusively, demonstrating that G′-G-G and G-G′-G-G were the intermediates and that G-G′-G-G was a precursor of G′-G-G which led to G′-G. The enzymatic hydrolysis of **4** and **5** at 10 °C afforded a mixture of G′-G-G and G-G′-G-G. The reactions of **4** and **5** at 40 °C or 10 °C for 1 day gave G′-G-G, showing that G-G′-G-G was an intermediate leading to G′-G-G. Taka amylase A has seven subsites (P—V) in the active site and an oligosaccharide is cleaved between S and T subsites as shown in Fig. 1. The results with **1**—**3** demonstrate that interaction of the C-6-OH with the subsites R and T is important, but that interaction with T is less important than that with R and much less important than that with S. The results with **4** and **5** demonstrate that interaction of the C-2-OH with T is less important than those with R and S. Thus, the order of importance of the subsites is as follows. For C-6-OH, S>R>T>Q,U and for C-2-OH, R, S>T>Q, U. Unfortunately, estimation of importance of the subsites Q, U, P, and V was not possible because the higher oligosaccharides did not accumulate in enough amount to be isolated in this reaction system. It is interesting to note that difference in kind of modification (Ts, 1-Ns or 2-Ns) on the hydroxyl group of saccharide did not influence the kind of product (G′-G, G-G′-G-G, etc.) and that only the position of the modification (2-O or 6-O) determined the kind of product.

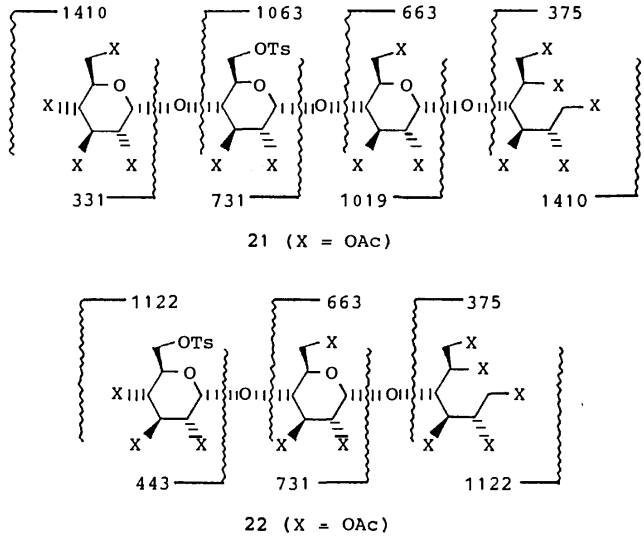

Fig. 2. EI MS spectral fragmentation patterns of **21** and **22**, which also showed correct molecular ions in FD MS spectra.

As mentioned before, the specifically activated (sulfonylated) oligosaccharides **6**—**11**, **15**, and **16** descibed in the present study can not be isolated from the enzymatic hydrolysis of 6- and 2-*O*-arylsulfonyl-α- or β-CDs, even when Taka amylase A was used in an amount equal to that of the CD derivative and/or the reaction was carried out at 5 °C or 10 °C. On the other hand, purely chemical methods for the preparation of these compounds from smaller sugars will need troublesome repeats of activation, protection, and deprotection of hydroxyl groups of the sugars. One-step chemical synthesis of specifically modified linear oligosaccharides from the corresponding linear oligosaccharides is also impossible. This method will require tedious separation of many regioisomeric monosulfonylated oligosaccharides.

Since there does not exist any regiochemical isomer, 2- and 6-*O*-arylsulfonyl-γ-CDs can be easily prepared and easily isolated as a pure material. As shown above, they can be smoothly hydrolyzed to give one or two modified oligosaccharide(s) at 10 °C. Furthermore, the products can be effectively separated by reversed-phase column chromatography. Therefore, the selective chemical modification of γ-CD followed by the Taka amylase A-catalyzed hydrolysis has several advantages for preparation of specifically modified oligosaccharides.

Experimental

General. ^{13}C NMR spectra were determined with a

JEOL FX-90Q spectrometer (22.5 MHz) and a JEOL FX-100 spectrometer (25 MHz). Fast atom bombardment mass spectra (FAB MS), field desorption mass spectra (FD MS), and electron impact mass spectra (EI MS) were recorded with a JEOL JMX DX-300 or DX-303/JMA 5000 data system. Thin-layer chromatography (TLC) was run with precoated silica-gel plates (Merck, Art 5554). Spot detection was carried out by UV light and/or staining with 0.1% 1,3-naphthalenediol in EtOH-H_2O-H_2SO_4 (200:157:43 v/v/v). The solvent for TLC development was n-C_3H_7OH-AcOH-H_2O(7:7:5 v/v/v). A Merck Lobar prepeaked column (LiChroprep RP18 column, 25 mm×310 mm) and/or a Kusano prepacked column ODS (CPO-HS-221-20, 22 mm×100 mm) was used for reversed-phase column chromatography. High-performance liquid chromatography (HPLC) was performed on a Shimadzu LC3A with a Zorbax ODS column (4.6 mm×150 mm, 5 μm, DuPont) or with a TSKgel ODS-120T (4.6 mm×250 mm, 5 μm, TOSOH).

6-*O*-Arylsulfonyl-γ-cyclodextrins (1—3). *p*-Toluenesulfonyl chloride (12 g) was added to a solution of γ-CD (10 g) in pyridine (800 cm^3) and the mixture was stirred for 1 h. After addition of water (10 cm^3), the mixture was concentrated in vacuo and chromatographed on a reversed-phase column with gradient elution from water (1 dm^3) to 50% aqueous ethanol (1 dm^3) to give the monotosylate **1** (3.5 g, 31%). The other arylsulfonates **2** and **3** were similarly prepared and isolated in similar yields.

2-*O*-Arylsulfonyl-γ-cyclodextrins (4 and 5). The titled compound was synthesized by the reaction of γ-CD with the corresponding arenesulfonyl chloride using dibutyltin oxide in DMF following the method of Murakami et al.[24] The compounds **4** and **5** can be more coveniently, however in lower yields, prepared as follows. Powdered arenesulfonyl chloride (3.0 g) was added in one portion to 10 cm^3 of aqueous solution (pH 12.0, adjusted by addition of aqueous NaOH) of γ-CD (2.0 g). The suspension was vigorously stirred at room temperature and the pH of the suspension was allowed to decrease. After the mixture became neutral, it was filtered and chromatographed on a reversed-phase column with gradient elution from water (1 dm^3) to 30% aqueous CH_3CN (1 dm^3) to give **4** (117.0 mg) or **5** (235.2 mg).

4: ^{13}C NMR (25 MHz, Me_2SO-d_6, characteristic nonaromatic absorptions) δ=59.9, 69.0, 72.1, 72.4, 77.2, 80.4, 80.9, 81.1, 96.7, 101.6; FAB MS m/z 1487 ($M+H^+$).

5: ^{13}C NMR (25 MHz, Me_2SO-d_6, characteristic nonaromatic absorptions) δ=59.9, 69.0, 72.2, 72.4, 72.6, 72.8, 77.9, 79.9, 80.0, 80.3, 80.6, 80.9, 97.1, 101.5, 101.7; FAB MS m/z 1487 ($M+H^+$).

Taka Amylase A-Catalyzed Hydrolysis. Commercially available Taka amylase A (α-amylase from Aspergillus oryzae, Type X-A, Sigma) was used. A solution of Taka amylase A and a modified γ-CD (**1—5**) in acetate buffer solution (pH 5.5, 0.2 mol dm^{-3}) containing calcium chloride (0.01 mol dm^{-3}) was kept at 40 °C or 10 °C to give a limited mixture of oligosaccharides as main products. The enzymatic reaction was monitored by silica-gel TLC. Although the reaction at 40 °C gave mainly a single product (**12**, **13**, **14**, **17**, or **18**), a similar reaction for a shorter reaction period at 10 °C afforded mainly two products. After 1% aqueous HCl was added to make the solution acid (pH 2—3) for denaturation of the enzyme, the supernatant obtained by centrifugation of the mixture was filtered, and applied on a reversed-phase column. After elution with water to remove inorganic salts, gradient elution, changing from water to methanol or acetonitrile, was used to give pure products. The reaction conditions and the yields are shown in Table 1.

6: ^{13}C NMR (25 MHz, D_2O, characteristic nonaromatic absorptions) δ=23.5, 62.7, 63.1, 94.8, 98.4, 102.2, 102.6; FAB MS m/z 843 ($M+Na^+$).

7: ^{13}C NMR (25 MHz, D_2O, characteristic nonaromatic absorptions) δ=62.7, 63.1, 98.4, 101.7, 102.0, 102.4; FAB MS m/z 857 ($M+H^+$), 879 ($M+Na^+$).

8: ^{13}C NMR (25 MHz, D_2O, characteristic nonaromatic absorptions) δ=62.7, 63.2, 94.5, 98.4, 102.2, 102.6; FAB MS m/z 857 ($M+H^+$).

9: ^{13}C NMR (25 MHz, D_2O, characteristic nonaromatic absorptions) δ=23.5, 63.2, 94.5, 98.4, 102.2, 102.5; FAB MS m/z 659 ($M+H^+$).

10: ^{13}C NMR (25 MHz, D_2O, characteristic nonaromatic absorptions) δ=63.1, 94.5, 98.4, 102.2, 102.5; FAB MS m/z 695 ($M+H^+$).

11: ^{13}C NMR (25 MHz, D_2O, characteristic nonaromatic absorptions) δ=63.2, 98.4, 102.2, 102.5; FAB MS m/z 695 ($M+H^+$), 717 ($M+Na^+$).

12: ^{13}C NMR (25 MHz, D_2O, characteristic nonaromatic absorptions) δ=23.5, 63.4, 71.6, 72.4, 72.5, 72.9, 73.9, 74.0, 75.3, 75.8, 76.6, 77.2, 78.8, 80.0, 80.2, 94.5, 98.4, 102.2; FAB MS m/z 519 ($M+Na^+$).

13: FAB MS m/z 533 ($M+H^+$).

14: FAB MS m/z 533 ($M+H^+$).

15: ^{13}C NMR (25 MHz, D_2O, characteristic nonaromatic absorptions) δ=62.9, 81.0, 81.3, 81.8, 82.7, 94.7, 96.3, 98.5, 103.0, 103.3; FAB MS m/z 857 ($M+H^+$).

16: ^{13}C NMR (22.5 MHz, D_2O, characteristic nonaromatic absorptions) δ=63.0, 80.6, 80.9, 82.1, 94.5, 97.7, 98.4, 102.9; FAB MS m/z 857 ($M+H^+$).

Treatment of 6″-*O*-(Arylsulfonyl)maltotrioses (9—11) and 6′-*O*-(Arylsulfonyl)maltoses (12—14) with Thiophenol. A mixture of 6″-O-(arylsulfonyl)maltotriose (**9**) (10 mg), thiophenol (0.1 cm^3), and $CsCO_3$ (33 mg) in dry DMF (1 cm^3) was heated at 60 °C for 17 h under nitrogen. After addition of water, the solution was neutralized by addition of dilute HCl, and washed with ether. The mixture was chromatographed on a reversed-phase column with gradient elution of water-CH_3CN to give 7.7 mg (85.0%) of *S*-phenyl-6″-thiomaltotriose (**23**). Similarly, **10** (20 mg) or **11** (20 mg) gave **23** (10.3 mg, 59.9% or 8.1 mg, 47.1%, respectively). Following the procedure described above, **12—14** were converted to the known compound, *S*-phenyl-6′-thiomaltose.

23: FAB MS m/z 597 ($M+H^+$).

Treatment of 6″-*O*-(Arylsulfonyl)maltotetraoses (6—8) with Aqueous Ba(OH)$_2$. A solution of **6** (11.8 mg) in 0.05 mol dm^{-3} $Ba(OH)_2$ (1.2 cm^3) was stirred at room temperature for 5 h, neutralized with 0.05 mol dm^{-3} H_2SO_4 and filtered. The filtrate was chromatographed on a reversed-phase column with eluting with water to give 8.7 mg (93.5%) of 3″,6″-anhydromaltotetraose (**24**) which was identified by comparing its HPLC retention time and its FAB MS spectrum with those of the authentic compound.[25,26] Similarly, **7** (9 mg) or **8** (45.0 mg) gave **24** (4.2 mg, 61.8% or 24.5 mg, 71.8%, respectively).

Treatment of 2″-*O*-(Arylsulfonyl)maltotetraoses (15—16) with Aqueous Ba(OH)$_2$. A solution of **16** (40.6 mg) in 0.05 mol dm^{-3} $Ba(OH)_2$ (4.06 cm^3) was stirred at room temperature for 1 h and neutralized with 0.05 mol dm^{-3} H_2SO_4. After filtration, the filtrate was chromatographed on a

reversed-phase column with elution of water to give 21.3 mg (69.4%) of (2″*S*,3″*S*)-2″,3″-anhydromaltotetraose (**25**) which was identified by comparing its HPLC retention time and its FAB MS spectra with those of the authentic compound.[21] Similarly, **15** (7.6 mg) gave **25** (3.3 mg, 56.9%).

Reduction of 6″-*O*-Tosylmaltotetraose (6) or 6″-*O*-Tosylmaltotriose (9) with $NaBH_4$. A solution of **9** (50 mg) in 1% aqueous $NaBH_4$ (5 cm^3) was kept at 2 °C for 1 h. After neutralization of the solution by addition of dilute HCl, the mixture was chromatographed on a reversed-phase column with gradient elution of aqueous methanol to give **20** (49.9 mg, 99.5%). Similarly, **6** (50 mg) give **19** (44.5 mg, 88.8%).

19: ^{13}C NMR (22.5 MHz, D_2O, characteristic nonaromatic absorptions) δ=23.5, 62.7, 63.1, 64.9, 65.4, 79.4, 80.1, 84.5, 102.2, 102.6, 102.9; FAB MS *m/z* 823 ($M+H^+$), 845 ($M+Na^+$).

20: ^{13}C NMR (22.5 MHz, D_2O, characteristic nonaromatic absorptions) δ=23.6, 63.2, 65.0, 65.5, 80.1, 84.6, 102.5, 103.0; FAB MS *m/z* 661 ($M+H^+$).

Acetylation of 19 or 20. A solution of **20** (10 mg) and acetic anhydride (1 cm^3) in pyridine (1 cm^3) was allowed to stand at room temperature for 48 h and concentrated by evaporation of all volatile materials with a stream of nitrogen. After dry chloroform (1 cm^3) was added to the residue, evaporation was repeated. This procedure was carried out two more times. The crude product was purified by reversed-phase HPLC to give **22** (10.5 mg, 61.8%). Similarly, **19** (10 mg) gave **21** (6.8 mg, 39.5%).

21: MS *m/z* 1433 ($M+Na^+$).

22: FD MS *m/z* 1145 ($M+Na^+$).

We are indebted to Japan Maize Products Co. Ltd. for a generous gift of γ-CD.

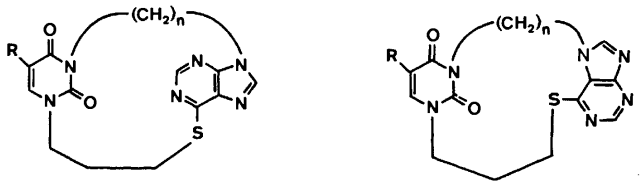
Unusual Reactivity of Purinophanes Due to Stereoelectronic Effect[1)]

Yoshiteru SAKATA,* Hiroyuki HIGUCHI, Kazuo DOYAMA, Takayuki HIGASHII, Miho MITSUOKA, and Soichi MISUMI
The Institute of Scientific and Industrial Research, Osaka University, Ibaraki, Osaka 567
(Received May 12, 1989)

Four types of purinophanes (**1**, **2**, **7**, and **10**) where a 6-thiopurine ring is bridged between S^6- and 9-positions or between S^6- and 7-positions were synthesized. Among them (6,9)purinophanes (**1**, **7**, and **10**) showed unusual high reactivity toward nucleophiles ($MeNH_2$, Me_2NH, OH^-) at 6-position to give acyclic compounds. The increased rate constants of these compounds against (6,7)purinophanes **2** and 9-methyl-6-(methylthio)purine could not be explained by molecular strain, neighboring group participation, or some electronic effect due to faced π-systems, but successfully explained by the stereoelectronic effect proposed by Deslongchamps. The rate of the reactions in **1**, **7**, and **10** was increased with an increase in rigidity of the tetrahedral intermediate where lone pairs of two adjacent heteroatoms orient antiperiplanar to the departing group.

The stereoelectronic effect[2)] is recognized as having a major influence on the reactivity of various molecules such as cyclic acetals, esters, amides, and related compounds, all of which contain geminal heteroatoms with nonbonded electron lone pair. The effect, however, has not so far been observed in biologically important nucleic acid bases in spite of their satisfying the structural requirement. Recently, we prepared a series of purinophanes[3)] and pyrimidinopurinophanes[4)] for studying the relationship between hypochromism and stacking geometry of two nucleic acid bases. In the course of the study we observed that **1a**, **b** react with nucleophiles such as alkylamines and hydroxide anion at room temperature to give acyclic compounds such as **3a**, while the isomeric compounds **2a**, **b** did not show such reactivity under



1 **2**

a: R=H, n=3
b: R=H, n=4
c: R=CH_3, n=3
d: R=OCH_3, n=3
e: R=NO_2, n=3

the same conditions. To understand the anomalous behavior of **1a**,**b**, we have prepared various kinds of related compounds and concluded that the stereoelectronic theory provides the best explanation for the unusual reactivity of **1a**,**b**. Here we report the first observation of the stereoelectronic effect in nucleic acid bases.

Results and Discussion

When the electronic spectra of **1a**,**b** were measured in 0.1 M NaOH (1 M=1 mol dm^{-3}), methylamine/H_2O, and dimethylamine/H_2O at room temperature, the spectra changed with time having one or two isosbestic points. A typical example is shown in Fig. 1. Similar behavior was observed for nucleophiles such as RS^-, RNH_2, and R_2NH in ethanol, but not observed for CN^-, I^-, R_3N, and R_4N^+. Figure 1 shows clearly that **1b** underwent some reaction to give single product, which is assumed to be an acyclic compound **3a**. The structure of **3b**, which was derived from **3a**, was determined by the alternative synthesis as summarized in Scheme 1. Thus, the spectral data of the reaction product of **1b** with methylamine, followed with dimethyl sulfate are consistent with those of the coupling product between **4** and **5** (see the Experimental part). Therefore, it is apparent that nucleophiles attack at 6-position of **1a**,**b** to give the product. On the other hand, isomeric pyrimidinopurinophanes **2a**,**b** did not show any spectral change at all under the same conditions as those for **1a**,**b**. First, we assumed that the unusual reactivity originates from strain in the molecules, because cyclophanes frequently show such behavior.[5)] In order to

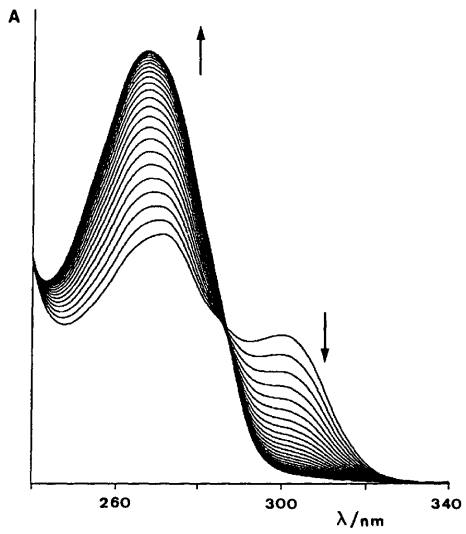


Fig. 1. Spectral change of **1b** at the interval of 30 minutes in the presence of methylamine in ethanol at 25 °C.

a) Values in parentheses are standard deviations.

confirm this point, X-ray analysis[6)] was carried out for **1b** and **2a**. Bond lengths and bond angles of purine and pyrimidine rings in **1b** and **2a** are summarized in Table 1 and the deviations of the ring atoms from the least-squares planes of the two rings are shown in Table 2. From Table 1 it is apparent that there are not so large differences in bond lengths and bond angles between **1b** and **2a**. This is also true when these values are compared with those of 6-(methylthio)purine[9)] and 1,3-dimethyluracil.[10)] The extents of the planality of the purine and pyrimidine rings in **1b** and **2a** are quite similar as shown in Table 2. All of these data clearly show that the reactivity of **1a,b** can not be explained by molecular strain.

The second possible reason for the abnormal reactivity is considered to be the neighboring group participation. As seen from Fig. 2, the carbonyl group at C2′ position in **1b** is located closely to the reaction center: namely, the nonbonded distances in **1b** are

Scheme 2.

4.229 Å between C5 and O2′ and 4.058 Å between C5 and C2′. Assuming the C5 participation to C2′, the reaction will proceed via transition state or intermediate **6** as shown in Scheme 2. In order to determine whether such mechanism is correct or not, we prepared **1c—1e**,[4] where an electron-donating or an electron-withdrawing substituent is introduced into the pyrimidine ring so that the reaction rate will more or less be influenced. We also prepared **7**,[4] where the

S6 atom is linked not to N3′ as in the case for **1**, but to C5′. Based on molecular model considerations, **7** has a structure, where the carbonyl group in question is located far apart from the reaction center. On the basis of spectrophotometry, the rate constants of **1**, **7**, and reference compound **8** toward methylamine in ethanol were obtained at 25±1 °C by analyzing the reaction as pseudo-first-order and the results are summarized in Table 3. One can see from the table that there is no essential change among the rate constants of **1b—1e** and **7**. Therefore, it is concluded that the carbonyl group at 2′ position in **1** is not responsible for the unusual reactivity.

The third possibility for the elucidation of the abnormality is some electronic effect due to the transannularly located π-system, that is, pyrimidine ring. To make this point clear, we synthesized **10**, where 6-thiopurine is bridged with a polymethylene chain at the same positions as **1** and **7** and hence there is no possibility of the electoinc effect due to the faced pyrimidine ring. Synthesis of **10a—c** was carried out by the intramolecular cyclization reaction of **9a—c**, which was prepared by the reaction of 6-mercaptopurine and α,ω-dibromoalkane with sodium hydride. The crude product was purified by column chromatography on silica gel and then, recrystallized from chloroform. In ^{1}H NMR spectra methylene protons adjacent to the sulfur atom in **10a—c** show complex multiplets, while the corresponding protons of acyclic compounds **9a—c** appear with the first-order splitting. The other bridge protons of **10a—c** also show complex signals. The result indicates that the purinophanes **10a—c** have more or less rigid structure in solution. The rate constants of **10a—c** thus prepared were determined for the reaction with methylamine in a manner similar to those for **1** and the results are summarized in Table 3. The fact that the values for **10a—c** are similar to those for **1** clearly indicates that the reactivity of **1** is not attributable to the faced pyrimidine ring. Molecular model considerations on **10a—c** revealed that there exists no strain even in **10a** having the shortest bridge among them. This leads to the same conclusion as for **1** that molecular strain does not play an important role for the reactivity of **10a—c**.

The only reasonable explanation for the increased rate constants of **1**, **7**, **10** is, at the present stage, given by the stereoelectronic theory[2] by Deslongchamps. The theory states that in tetrahedral intermediate **11** such reactions are favored for conformations where lone-pair orbitals on two adjacent heteroatoms lie

Table 3. Reaction Rate Constants of **1a—e**, **7**, **8**, and **10a—c** with Monomethylamine in Ethanol at 25±1 °C

antiperiplanar to the bond to the leaving group (X). Theoretical justification for the concept has been given by lowering the energy of transition state by mixing of lone-pair orbitals with the antibonding orbital of the C-X bond. When we apply the theory to the present molecules, the reaction scheme is written as shown in Fig. 3. The tetrahedral intermediate **13a**, which will easily be obtained from **12a**, is expected to give smoothly **14a**, because of its antiperiplanar orientation of the two lone-pair orbitals on the nitrogen atoms and the C-S bond. In the case of (6,7)purinophanes, however, the steric hindrance among R^1, R^2, and R^3 would prevent the formation of tetrahedral intermediate **13b** from **12b** and hence the C-S bond is not cleaved easily. This must be the reason for the higher reactivity of (6,9)-purinophanes than (6,7)-isomers. For the enhancement in reaction rate by the stereoelectronic effect it is requested that the corresponding antiperiplanar conformations have rigid structures.[2c] This is reflected in the order of the rate constants of **10a—c** in Table 1. Thus, the value increases with a decrease of the length of the bridging chain, i.e., **10a>10b>10c**. The quite low reactivity of the reference compound **8** might be also explained by the conformational flexibility of the antiperiplanar structure of the tetrahedral intermediate.

In the present study the unusual reactivity of **1**, **7**, and **10** is well-explained by the stereoelectronic effect and this is the first example for the concept to be successfully applied in the field of purine ring. This suggests that the theory is widely applicable to the elucidation of the reaction course of nucleophilic substitution reactions which occur at various heteroaromatic rings including nucleic acid bases.

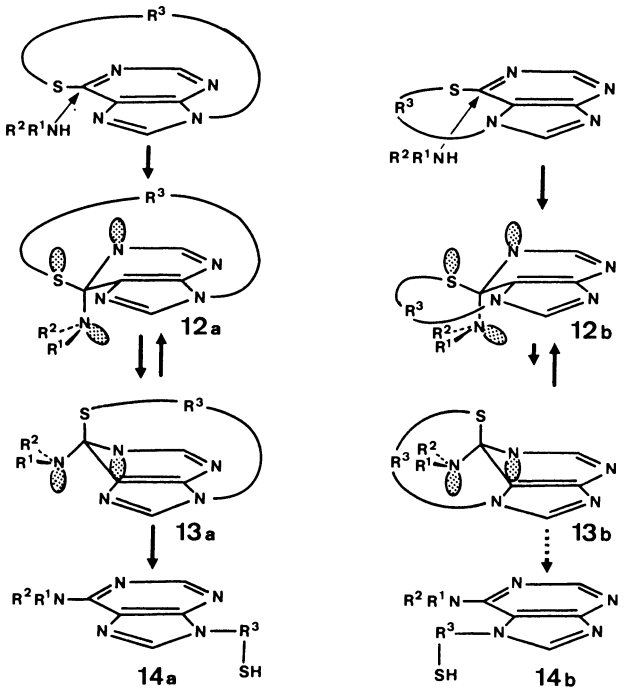

Fig. 3. Reaction course of (6,9)- and (6,7)-purinophanes with alkylamines.

Experimental

Melting points were recorded on a Yanagimoto apparatus and are not corrected. NMR spectra were measured on a JNM PMX-60SI (60 MHz), a JNM FX-100 (100 MHz), and a Brucker WH-360 (360 MHz). Mass spectra were obtained on a Hitachi RMU-7 and UV spectra were measured on a Hitachi 330 and a Hitachi U-3210.

6-(10-Bromodecylthio)purine (9b). To a stirred suspension of 60% NaH (0.17 g, 4.33 mmol) in dry DMSO (5 ml) was added a solution of 6-mercaptopurine[11](0.57 g, 3.78 mmol) and 1,10-dibromodecane (5.17 g, 17.23 mmol) in DMSO (35 ml) at 55 °C in a period of 45 min. Additional stirring was continued for 5 h at 55 °C. After cooling, the mixture was poured onto water and it was extracted with chloroform. The organic layer was washed with sat aq solution of NaCl and dried ($MgSO_4$). The solvent was removed under reduced pressure and the crude product was chromatographed on silica gel with chloroform-acetone (5 : 1) to give 0.22 g (15.7% yield) of **9b**. Recrystallization from chloroform gave pure **9b** as colorless plates, mp 123.0—125.0 °C. ^{1}H NMR ($CDCl_3$, 360 MHz) δ=1.30—1.50 (m, 12, CH_2), 1.76—1.89 (m, 4, CH_2), 3.39—3.44 (m, 5, NH+SCH_2+CH_2Br), 8.32 (s, 1, H8), 8.79 (s, 1, H^2).

Found: C, 48.56; H, 6.11; N, 15.10; S, 8.39; Br, 21.38%. Calcd for $C_{15}H_{23}N_4SBr$: C,48.52; H,6.24; N,15.09; S,8.63; Br,21.52%.

The synthesis of **9a** and **9c** was carried out by the similar method described for **9b**.

9a: 32% yield, mp 96—100 °C. ^{1}H NMR ($CDCl_3$, 360 MHz) δ=1.32—1.48 (m, 10, CH_2), 1.75—1.86 (m, 4, CH_2), 3.38—3.43 (m, 5, NH+SCH_2+CH_2Br), 8.50 (s, 1, H8), 8.80 (s, 1, H2).

9c: 28% yield, mp 101—103 °C. ^{1}H NMR ($CDCl_3$, 360 MHz) δ=1.28—1.52 (m, 14, CH_2), 1.77—1.88 (m, 4, CH_2), 3.35—3.45 (m, 5, NH+SCH_2+CH_2Br), 8.44 (s, 1, H8), 8.83 (s, 1, H2).

1-Thia[11](6,9)purinophane (10b). To a stirred suspension of 60% NaH (0.04 g, 1.02 mmol) in dry DMSO (15 ml) was added dropwise a solution of **9b** (0.37 g, 0.79 mmol) in dry DMSO (25 ml) at 55 °C in a period of 3 h. Additional stirring was continued for 5 h at the same temperature. After cooling, the mixture was poured on cold water and it was extracted with chloroform. The extracts were washed successively with water and sat aq solution of NaCl and dried ($MgSO_4$). Crude product was chromatographed on silica gel with ether to give 18 mg (7.7% yield) of **10b**. Recrystallization from hexane gave pure **10b** as colorless prisms, mp 105.0—107.0 °C. **10b:** MS m/z 290 (M^+). ^{1}H NMR ($CDCl_3$, 360 MHz) δ=0.33—1.22 (m, 12, CH_2), 1.53—2.07 (m, 4, CH_2), 3.28—3.56 (m, 1, SCH_2), 4.02—4.10 (m, 2, SCH_2+NCH_2), 4.59—4.66 (m, 1, NCH_2), 8.06 (s, 1, H8), 8.79 (s, 1, H2).

The synthesis of **10a** and **10c** was carried out in a manner similar to the above.

10a: 8.6% yield, colorless prisms from chloroform, mp 103—104 °C; MS m/z 276 (M^+); ^{1}H NMR ($CDCl_3$, 360 MHz) δ=0.27—1.23 (m, 10, CH_2), 1.49—2.14 (m, 4, CH_2), 3.14—3.49 (m, 1, CH_2), 4.00—4.09 (m, 2, SCH_2+NCH_2), 4.61—4.70 (m, 1, NCH_2), 8.11 (s, 1, H8), 8.73 (s, 1, H2).

10c: 13% yield; colorless prisms from chloroform, mp 99—102 °C; MS *m/z* 304 (M^+); ^{1}H NMR ($CDCl_3$, 360 MHz) δ=0.36—1.35 (m, 14, CH_2), 1.59—2.11 (m, 4, CH_2), 3.26—3.61 (m, 1, SCH_2), 4.06—4.19 (m, 2, SCH_2+NCH_2), 4.60—4.71 (m, 1, NCH_2), 8.09 (s, 1, H8), 8.82 (s, 1, H2).

9-(14-Bromobutyl)-6-(methylamino)purine (4). In a Pyrex ampule were placed 6-(methylthio)purine·$3H_2O$ (1.0 g, 4.2 mmol), H_2O (1 ml), and 40% aq solution of methylamine and the mixture was heated at 130—140 °C for 18 h in the sealed tube. After cooling, the mixture was concentrated to half of its original volume and the residue was kept at 0 °C for 1 h. Yielded precipitates were collected and washed well with water. Crude product was dried by azeotropic distillation with benzene to give 6-(methylamino)-purine·$2H_2O$[11] (590 mg, 81%). Without further purification it was used for the following reaction.

To a stirred suspension of 1,4-dibromobutane (2.0 ml, 16.3 mmol) and K_2CO_3 (1.0 g, 9.0 mmol) in dry DMSO (50 ml) was added dropwise a solution of 6-(methylamino)-purine·$2H_2O$ (590 mg) in dry DMSO (30 ml) in a period of 7.5 h under nitrogen atmosphere. After addition was over, stirring was continued for 11 h. Salts were filtered off and the solvent was removed under reduced pressure. Water (50 ml) was added to the residue and it was extracted with chloroform. The organic layer was washed well with sat aq solution of NaCl and water and dried ($MgSO_4$). Removal of the solvent gave **4** (290 mg, 30% yield) as colorless oil. MS *m/z* 285, 283 (M^+), 204 (M^+−Br); ^{1}H NMR ($CDCl_3$, 60 MHz) δ=2.0 (m, 4, CCH_2CH_2C), 3.2 (d, J=5 Hz, 3, NCH_3), 3.4 (t, 2, CH_2Br), 4.2 (t, 2, CH_2N), 7.0 (br s,. 1,NH), 7.7 (s, 1, H8), 8.4 (s, 1, H2).

1-(3-Methylthiopropyl)uracil (5). A solution of 1-(3-bromopropyl)uracil[12] (300 mg, 1.3 mmol) and thiourea (105 mg, 1.35 mmol) in ethanol (10 ml) was refluxed for 12 h. After removal of ethanol, water (5 ml) was added to the residue and the atmosphere was replaced with N_2. To the mixture was added NaOH (104 mg, 2.6 mmol) and it was heated at 90—100 °C. After cooling, methyl iodide (0.08 ml, 1.3 mmol) was added to the mixture and additional stirring was continued for 1.5 h. To the mixture was added dil HCl and the medium was adjusted to pH around 5 and then, it was extracted with chloroform. The extract was washed with sat aq solution of NaCl and water and dried ($MgSO_4$). After removal of the solvent, the crude product was recrystallized from benzene-hexane to give **5** (50 mg, 19% yield). **5**: colorless crystals, mp 78—79 °C. MS *m/z* 200 (M^+), 186 (M^+−CH_3), 153 (M^+−SMe). ^{1}H NMR ($CDCl_3$, 60 MHz) δ=2.0 (m, 2, CCH_2C), 2.1 (s, 3, SCH_3), 2.2 (m, 2, SCH_2), 3.8 (t, 2, NCH_2), 5.7 (d, 1, H5), 7.2 (d, 1, H6).

6-Methylamino-9-[4-[1,2,3,6-tetrahydro-3-(3-methylthiopropyl)-2,6-dioxo-1-pyrimidinyl]butyl]purine (3b). A suspension of **4** (73 mg, 0.26 mmol), **5** (50 mg, 0.25 mmol), and K_2CO_3 (69 mg, 0.5 mmol) in DMSO (10 ml) was stirred for 12 h at room temperature under nitrogen atmosphere. After usual workup, crude product was purified by preparative-layer chromatography on silica gel with methanol-chloroform (1:15) to give **3b** (54 mg, 54% yield). **3b:** colorless solid from chloroform-ether, mp 53.5—56.0 °C. MS *m/z* 403 (M^+) 388, 357, 356, 342. ^{1}H NMR ($CDCl_3$, 100 MHz) δ=1.40—2.10 (m, 6, CCH_2C), 2.10 (s, 3, SCH_3), 2.52 (t, 2, SCH_2), 3.21 (d, J=5.1 Hz, 3, NCH_3), 3.85 (t, 2, NCH_2), 5.70 (d, J=6.8 Hz 1, H5′), 6.01 (br s, 1, NH), 7.18 (d, J=6.8 Hz, 1, H6′), 7.79 (s, 1, H8), 8.39 (s, 1, H2).

Found: C, 52.96; H, 6.25; N, 24.30%. Calcd for $C_{18}H_{27}N_7SO_2$: C, 53.58; H, 6.25; N, 24.30%.

Synthesis of 3b by the Reaction of 1b with Methylamine Followed by Dimethyl Sulfate. To an ampule was placed **1b** (25 mg, 0.067 mmol) and water (0.5 ml). After replacement of the atmosphere with nitrogen, 40% aq solution of methylamine (0.1 ml, 1.3 mmol) was added to the mixture and it was heated for 1.5 h at 120 °C in the sealed tube. After reaction was over, the ampule was opened and excess methylamine was removed by vigorous bubbling of nitrogen. To the mixture was added NaOH (20 mg, 0.5 mmol) at 0 °C and it was stirred for 10 min at the temperature. To the solution was added dropwise dimethyl sulfate (0.1 mmol) diluted with dioxane. Additional stirring was continued for 2 h at room temperature. After reaction was over, the mixture was extracted with chloroform. The extract was washed well with water and dried ($MgSO_4$). Removal of the solvent gave oily product, which was purified by preparative-layer chromatography on silica gel to give colorless oil (12 mg, 43% yield). **3b:** colorless solid from chloroform-ether, mp 54—56 °C. Spectroscopic data were identical with those of the specimen described above.

Kinetic Studies. Kinetic measurements were carried out on a UV-visible spectrophotometer. The cells were maintained at a constant temperature (25±1 °C) by means of a thermostated cuvette holder. The pseudo-first-order rate constants were determined from the slopes of a $[A_s(t)+A_p(t)-A_\infty]$ vs. time plot, where $A_s(t)$, $A_p(t)$, and A_∞ are absorbance of substrate, product, and final, respectively. Reactions were followed by measuring the rate of decreasing of the 6-(methylthio)purine chromophore at its absorbance maximum (around 304 nm).

This work was supported by Grants-in-Aid for General Scientific Research (Nos. 56470018 and 59470018) from the Ministry of Education, Science and Culture, to Yoshiteru Sakata. He also thanks to Prof. Deslongchamps for helpful discussion.

Intramolecular [2+2] Photocycloaddition. 5.[1] Synthetic Methods toward [2.*n*]-, [3.*n*]-, and [4.*n*]Naphthalenophane Skeletons by Using α,ω-Bis(vinylnaphthyl)alkanes

(Received May 15, 1989)

[2+2] Photocycloaddition, cationic cyclocodimerization, and reductive ring enlargement were developed for the syntheses of [2.*n*]-, [3.*n*]-, and [4.*n*]naphthalenophanes, respectively, from α,ω-bis(vinylnaphthyl)-alkanes as a single starting material. Using the exclusive syn selectivity of the former two methods, the room required for the intraannular naphthalene-ring rotation in the ring system is determined.

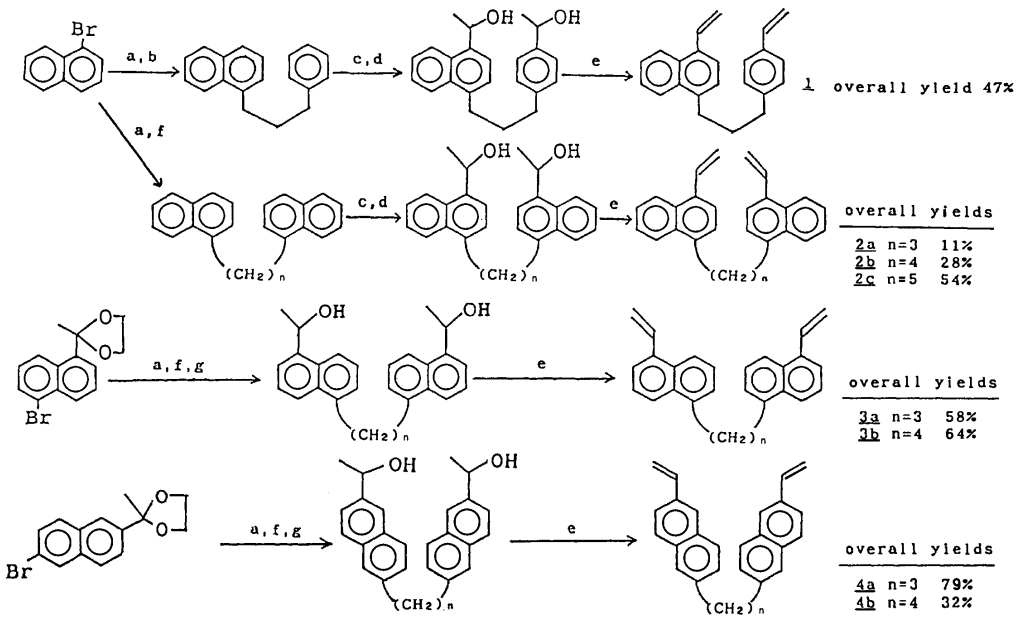
Several naphthalenophanes were already made by 1,6-Hoffman degradation,[2] by solvolysis of appropriate tosylate,[3] by malonate synthesis[4] and tosmic synthesis,[5] and by using dithia intermediates as the most general precursor.[6] Until now *syn*- and *anti*-[2.2](1,4)naphthalenophane,[2] chiral and achiral [2.2](2,6)napthalenophane,[6] [2.2](2,7)naphthalenophane,[7] [2.2](2,6)(2,7)naphthalenophane,[8] [2.2]paracyclo-(1,4)- and (2,6)naphthalenophane,[9] *syn*- and *anti*-[3.3](1,4)naphthalenophane,[4] and chiral and achiral [3.3](2,6)naphthalenophane[10] were reported.

We developed some new methods toward these structurally, physicochemically interesting naphthalenophanes.[11] Here in this paper, we report a photochemical route toward [2.*n*]naphthalenophanes from vinylnaphthalene derivatives and their Birch reduction to [4.*n*] ones together with some application of cationic cyclocodimerization[12] to [3.*n*] skeletons. Moreover we determined the room required for the naphthalene ring rotation after Birch reduction of the conformationally unstable *syn*-naphthalenophane derivatives.

Results

Preparation of Vinylnaphthalenes. Synthetic methods of starting materials are depicted in Chart 1. The standard conditions were already reported for several vinylarene derivatives.[13]

Only the preparation of 2-acetyl-6-bromonaphthalene did not record satisfactory yields. For a large scale preparation, the material should be obtained by other routes than this method which is based on the equilibrium attained in the Friedel-Crafts acylation of 2-bromonaphthalene.[14]



a) Mg/THF. b) Br(CH2)3Ph, CuBr-HMPA. c) CH3COCl, AlCl3/CH2ClCH2Cl.
d) LiAlH4/ether. e) KHSO4/DMSO. f) Br(CH2)nBr, CuBr-HMPA.
g) HCl/DOX-H2O.

Chart 1. Preparation of vinylnaphthalenes.

Synthesis of [2.*n*]Naphthalenophane Derivatives. Intramolecular [2+2] photocycloaddition of vinylnaphthalene derivatives **1—4** successfully gave corresponding naphthalenophanes **5—8** as reported briefly.[11] By this method *syn*-[2.*n*]paracyclo(1,4)-, *syn*-[2.*n*](1,4)-, *syn*-[2.*n*](1,5)-, and [2.*n*](2,6)-naphthalenophanes were prepared. The reaction gives exclusively syn isomer, because the vinyl group has only exo conformation (conformational rigidity of vinyl group[15]) and never attains an endo, exo-divinyl combination for the formation of anti isomer. This selectivity is quite important, because previously reported synthetic methods listed above generally give conformationally stable *anti*-naphthalenophanes exclusively.

Reactions together with their yields are shown in Chart 2. Physical, analytical, and spectroscopic data of products are listed in Tables 1 and 2.

The reaction mixture of olefin **4** showed two HPLC peaks (Cosmosil-C18, MeOH) in the range where naphthalenophanes of this sort should be eluted. These two compounds were isolated from a small portion of the mixture by HPLC for the structural determination, and the major portion was treated by Birch reduction as described below.

a) Melting points of new olefins are as follows: **2b**, 139—140; **2c**, 103—104; **3a**, 79—80; **3b**, 104—105; **4a**, 174—175 ; **4b**, 167—168. b) IR absorption of three substituted olefin appears at 813 cm^{-1}. c) IR absorption at 813 cm^{-1}. d) IR absorption at 817 cm^{-1}. e) IR absorption at 815 cm^{-1}. f) Not determined. g) This is a conformationally fluxional compound, so that it contains **22b** as a conformational isomer (see text for details).

Synthesis of [3.*n*]Naphthalenophane Derivatives. One of the synthetic methods for [3.*n*]naphthalenophanes is the cationic cyclocodimerization, although the structures of naphthalenophanes produced are intricate with two substituents at one of their linkages.[12,15] The detailed feature of the reaction has been already discussed with some naphthalenophane derivatives.[15] In this work this cationic cyclization was employed for the synthesis of [3.*n*](1,5)- and [3.*n*](2,6)-skeletons.

Because of the conformational rigidity of the α-vinyl group, only one isomer of 1-methyl-3-(β-methylstyryl)[3.3](1,5)naphthalenophane **15a** was obtained in a reasonable yield from olefin **3a**. The structure was determined by NOESY spectroscopy. A large NOE enhancement (12%) is observed between a peri-hydrogen and allylic hydrogen (H-3).[16] The results clearly indicate that naphthalenophane **15a** is an exo, cis-isomer (See Ref. 16 for the definition of exo, endo-configuration). Syn conformation of **15a** is assigned unequivocally by comparison of the chemical shifts of aromatic proton resonances with those of [3.3](1,4)naphthalenophane derivatives. Accordingly the structure of **15a** is determined as depicted in Chart 3. Since an anti-oriented cation of the reaction

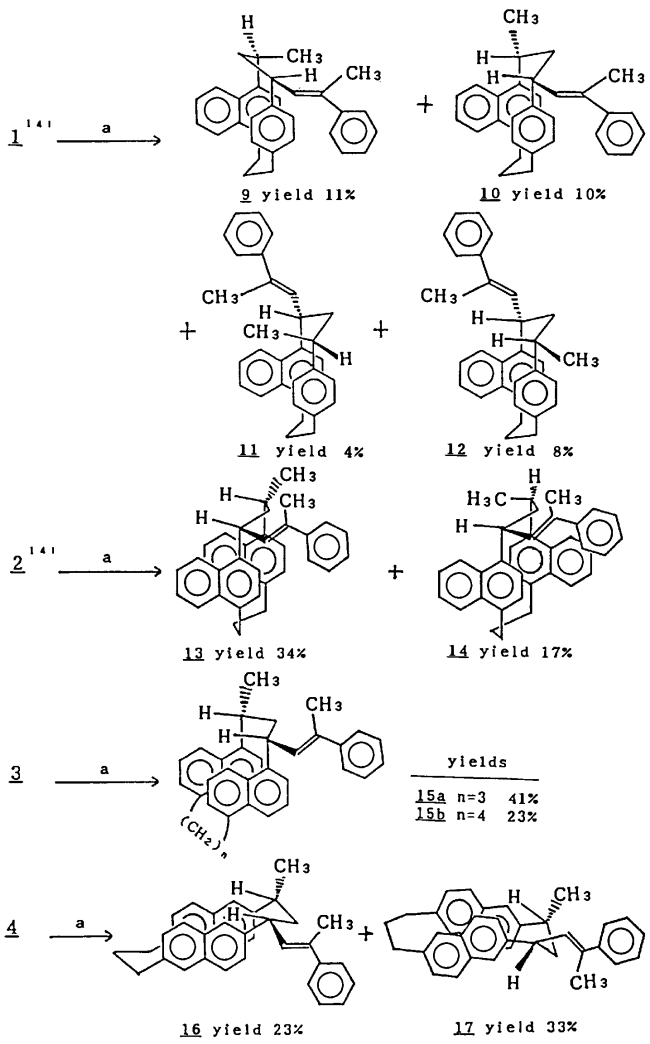
a) Taken in $CDCl_3$. b) In nitrobenzene-d_5. c) NMR data of achiral **21b** and chiral [4.4](2,6)naphthalenophane **22b** were read from the spectrum of the conformer mixture.



a) 2-phenylpropene, CF_3SO_3H/C_6H_6, 50 °C, 30 min.

Chart 3. Cationic cyclocodimerization toward [3.*n*]-naphthalenophanes.

is sterically unfavorable,[5] only one possible syn-oriented cation with exo-vinyl group affords exo, cis, syn-isomer **15a**, as observed. The structure of **15b** was determined by the same method as above.[16]

From the reaction mixture of olefin **4a** two isomers of 1-methyl-3-(β-methylstyryl)[3.3](2,6)naphthalenophanes (a 1.0:1.4 ratio and total 56% yield) were isolated by HPLC (Develosil-PYE, MeOH). Compared with reported NMR data of chiral and achiral [3.3](2,6)naphthalenophanes,[10] especially underlined chemical shift(s) for peri-hydrogens in Table 2, compound **16** can be concluded as a derivative of the achiral isomer. An NOE experiment indicates that H-1 and one of the peri-hydrogens (22% NOE enhancement), and also H-3 and another peri-hydrogen (14% NOE enhancement), are in vicinity, so that the disubstituted three-carbon bridge is of cis, exo-configuration. Thus the exo, cis, achiral-structure of **16** is concluded as indicated in Chart 3. Compound **17** can be easily concluded to be a derivative of the chiral isomer, as mentioned above.[10] VT-NMR spectra taken in acetone-d_6 from 20 to −90 °C show considerable change at the region of aromatic proton resonance. This change should be the attribute of two conformationally unstable three-carbon linkages, compared with the small change of the aromatic proton peaks of cis-isomer **16**. The fact suggests that **17** has the trans-configuration. The NOE experiment indicates that H-1 and one of the peri-hydrogens are in vicinity (15% NOE enhancement), so that the disubstituted three-carbon bridge must be of exo-configuration. Thus **17** is assigned to the structure depicted in Chart 3. It is interesting that the reaction gave mainly **16** and **17** in an almost equal amount, although eight diastereomers are possible at a random cyclization. This selectivity must be due to the predominant exo-conformation of starting 2-vinylnaphthalene moiety which had already been deduced from the consideration on the chemical shift of methine hydrogen of the 2-vinyl group.[17]

Synthesis of [4.*n*]Naphthalenophane Derivatives. Cyclobutane ring is known to be cleaved regioselectively by electron-transfer reduction like Birch one.[18] The ring cleavage of naphthalenophanes **5—8** becomes ultimately a general synthetic method of [4.*n*]naphthalenophanes which are prepaced only in low yields by other ones reported previously.

Treated under the usual Birch reduction conditions, naphthalenophanes **5—8** gave several over-reduced products. ^{1}H NMR spectroscopic analysis of the products showed olefinic hydrogens which were generated by the reduction of naphthalene rings. In order to obtain desired naphthalenophanes from them, the reduced material were oxidized in decalin with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) at 170 °C. Yields are shown in Chart 4.

The sequence of reactions is depicted in Chart 4. The products were easily isolated by column chromatography (SiO_2, benzene/cyclohexane), purified by recrystallization from hexane, and characterized mainly by ^{1}H NMR spectroscopy. Analytical and spectroscopic data are listed in Tables 1 and 2.

From naphthalenophanes **7**, products **20** were obtained without conformational alteration of naphthalene nuclei, whereas **6** gave conformationally stable *anti*-naphthalenophanes **19** exclusively. Compound **8a** (the chiral/achiral isomer ratio=4.2) gave two isomeric [3.4](2,6)naphthalenophanes **21a** and **22a** (chiral **22a**/achiral **21a** isomer ratio=4.2), which were isolated by HPLC (SiO_2, hexane). These structures were determined by ^{1}H NMR spectroscopy, just as done for compounds **16** and **17**.

Compound **19a** did not change the chemical shift of intraannular hydrogens even at 200 °C. Therefore it is concluded that the naphthalene ring rotation in the ring system needs very high activation energy. On the other hand, compound **19b** showed the coalescence

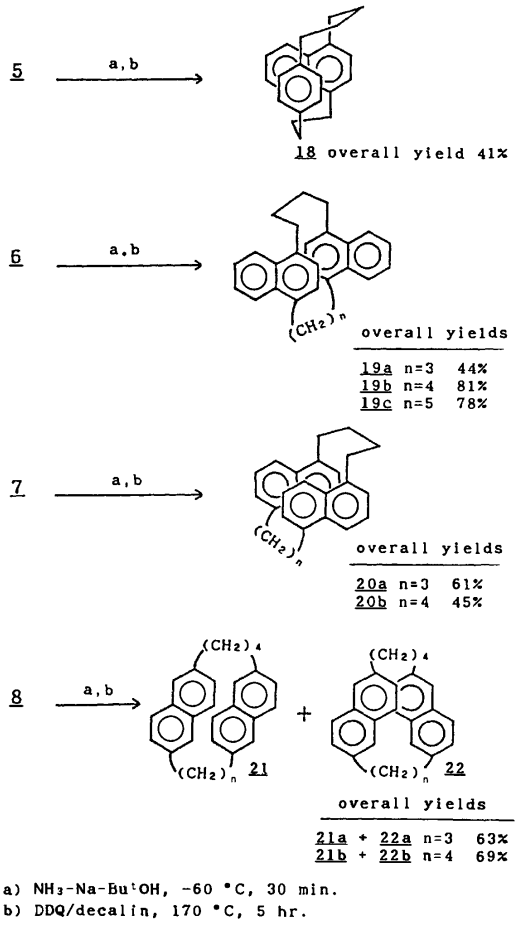


Chart 4. Birch reduction toward [4.*n*]naphthalenophanes.

of intraannular aromatic hydrogens of its syn and anti conformers at 10±5 °C. The rotation barrier at the coalescence temperature is calculated 13 kcal mol^{-1}. Chiral naphthalenophane **22a** was heated at 200 °C for 12 h, but there occurred no isomerization to achiral **21a** by the ring rotation, according to the HPLC analysis. On the other hand, naphthalenophanes **8b** gave conformationally fluxional [4.4](2,6)naphthalenophanes **21b** and **22b**. The conformer ratio (chiral/achiral) at r.t. was 2.4:1. Naphthalenophanes **21b** and **22b** showed the coalescences of aromatic and aliphatic hydrogens at 175±5 °C, and the rotation barrier is calculated 22 kcal mol^{-1}.

Discussion

Among several synthetic methods for structurally interesting naphthalenophanes, the present methods have an advantage; i.e., a single starting material for [2.*n*]-, [3.*n*]-, and [4.*n*]naphthalenophane skeletons. When one needs a large amount of naphthalenophanes, the methods using vinylnaphthalene derivatives will be an unignorable one.

The syn selectivity of the methods mentioned here has a great advantage, because syn isomers are generally conformationally unstable and given as minor products by ordinary methods. By using this advantage of the syn selectivity the room required for the intraannular rotation of naphthalene nuclei was determined. By the enlargement of the ring system from [2.3] to [4.4] one, the (1,5)naphthalenophanes always kept syn conformation under the experimental conditions of −60 °C to 180 °C, because quite a large volume is necessary if the nucleus rotates around the axe through C1 and C5 of naphthalene ring.

Interestingly the (1,4)naphthalenophanes showed the point for the nuclei to start the rotation within [2.3] to [4.5] system. Namely [3.4](1,4)naphthalenophane takes only anti-conformation after the transformation of *cis,exo*-1,2-ethano-*syn*-[2.3]naphthalenophane **6a**, whereas *syn*-[3.3] and [2.4]naphthalenophane take only syn-conformation upto their melting points. The room requirement for the rotation of naphthalene rings is just similar to that previously reported for [*n.m*]paracyclophanes:[19] i.e., activation free energies for [3.4]- and [4.4]paracyclophanes are reported 33 kcal mol^{-1} at 160 °C and 15 kcal mol^{-1} at ca. 15 °C, respectively. From the coalescence temperatures, activation free energies for **19a** and **b** were calculated ≥25 kcal mol^{-1} (≥200 °C) and 13 kcal mol^{-1} (10 °C), respectively.

This is the first report on the naphthalene ring rotation in the skeletons of the (2,6)naphthalenophanes. The ring rotation barrier for [4.4](2,6)naphthalenophane exceeds that of [4.4](1,4)naphthalenophane by 9 kcal mol^{-1}.

Experimental

General. Elemental analyses were done at the Microanalysis Center of Kyoto university. Melting points are not corrected. NMR spectra were recorded on a Varian XL200 FT-NMR spectrometer. IR spectra were taken on a JASCO IR-810 infrared spectrophotometer. Mass spectra were recorded on a Hitachi M-80A mass spectrometer. High performance liquid chromatographic analyses (HPLC) were carried out by using Altex Model 100A and Knauer 64 pumps with a Hitachi wavelength tunable effluent monitor and a Shimadzu SPD-6A UV spectrophotometric detector.

Solvents like benzene, THF, and ether were distilled over sodium diphenylketyl after prolonged reflux. Other commercially available highest-grade reagents were used without further purification. Monomers were prepared conveniently by our methods depicted in Chart 1.[12]

Synthesis of 1,2-Ethano[2.4](1,5)naphthalenophane 7b (General Procedure). A 1-l Pyrex flask equipped with a magnetic stirrer, reflux condenser, and N_2 inlet was placed 4.28 g (11.8 mmol) of 1,4-bis(5-vinyl-1-naphthyl)butane **3b** dissolved in 900 ml of dry benzene under N_2. It was irradiated by a high-pressure mercury lamp (400 W) for 17 h. Then benzene was removed by evaporation. Reaction mixture dissolved in 20 ml of dry THF was transferred to 50-ml two-necked flask equipped with a magnetic stirrer, dropping funnel, and N_2 inlet. A 10 ml of B_2H_6-THF complex (0.1 M) was added to it slowly at r.t. After stirred for 12 h at r.t., THF was removed and products were isolated by column chromatography (SiO_2, hexane). Recrystallization

from benzene–methanol gave 1.41 g (33%) of *cis,exo*-1,2-ethano-*syn*-[2.4](1,5)naphthalenophane.

Synthesis of *cis,exo*-1-Methyl-3-(β-methylstyryl)[3.3](1,5)-naphthalenophane 15a (General Procedure). A 1-l, four-necked round-bottomed flask was equipped with a magnetic stirrer, thermometer, and N_2 inlet was placed 2.36 g (6.78 mmol) of 1,3-bis(5-vinyl-1-naphthyl)propane **3a** and 3.9 ml (36.2 mmol) of 2-phenylpropene which were dissolved in 566 ml of dry benzene under N_2 at 50 °C. Trifluoromethanesulfonic acid (0.01 g, 0.068 mmol) was dissolved in 1 ml of dry benzene and added at once to initiate the reaction under vigorous stirring. After stirred for 30 min, 200 ml of 10% aqueous NaOH was added to stop the reaction. The reaction mixture was washed with 200 ml of water 3 times and dried anhydrous Na_2SO_4. After the reaction mixture was filtered and benzene was removed, products were isolated by column chromatography (SiO_2, benzene–hexane). Recrystallization from benzene–methanol gave 0.73 g (41%) of the title compound as the sole naphthalenophane derivative.

Compound **15** can be isolated by crystallization after the column chromatography. The purity of so-crystallized **15** was usually 95%. Compound **16** and **17** can be separated from each other by MeOH extraction. From the MeOH solution **17** was crystallized and purified up to 90%. From the MeOH-insoluble part **16** was purified up to 95% by recrystallization from EtOH.

Synthesis of *syn*-[4.4](1,5)Naphthalenophane 20b (General Procedure). A 200 ml, three-necked round-bottomed flask equipped with a magnetic stirrer, N_2 inlet, and gas inlet was cooled by Dry Ice–methanol bath at ca. −50 °C. Ammonia gas was introduced into the system. When ca. 100 ml of liquid ammonia was condensed, the gas inlet tube was replaced with a glass stopper. About 1 g of Na was added carefully piece by piece into liquid ammonia and stirred for 10 min. *cis,exo*-1,2-Ethano-*syn*-[2.4](1,5)-naphthalenophane **7b** (500 mg, 1.38 mmol) and 2 ml of *t*-butyl alcohol dissolved in 20 ml of dry THF were added slowly in it, and the mixture was stirred for 30 min. Then the excess Na was consumed by cautious addition of 10 ml of water. The ammonia was allowed to evaporate itself slowly in a hood. Then products were extracted by 20 ml of benzene. The benzene extract was washed with 20 ml of water three times and dried over anhydrous Na_2SO_4. After filtration, benzene was removed, products were isolated by column chromatography (SiO_2, benzene–hexane). The yield was 350 mg. A 50 ml flask equipped with a magnetic stirrer, reflux condenser, and N_2 inlet was placed 200 mg of the Birch reduction products and 300 mg (1.32 mmol) of DDQ were dissolved in 30 ml of decalin under N_2. The reaction mixture was heated with stirring at ca. 180 °C for 12 hours. After removed the decalin, products were isolated by column chromatography on SiO_2 (benzene–hexane). Recrystallization from benzene gave 130 mg (0.036 mmol, a 45% yield) of *syn*-[4.4](1,5)naphthalenophane.

The support of this work through grants from the Ministry of Education, Science and Culture, from Gunma University Foundation for Science and Technology, and from Toray Science Foundation is gratefully acknowledged.

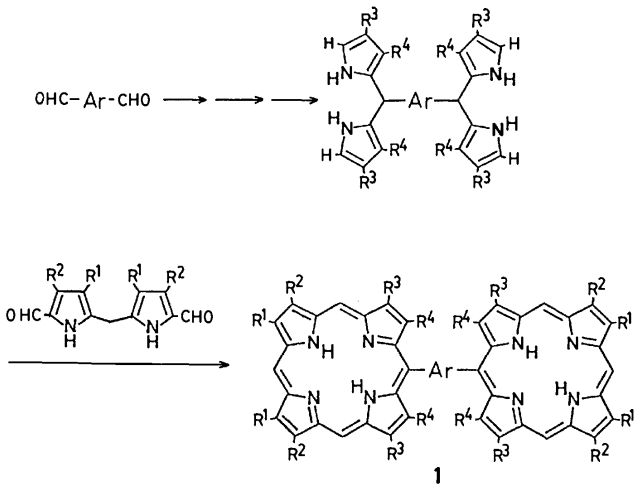
A Synthesis of Unsymmetric Porphyrin Dimers

Kazuhiro MARUYAMA,* Toshi NAGATA, Noboru ONO, and Atsuhiro OSUKA
Department of Chemistry, Faculty of Science, Kyoto University, Kyoto 606
(Received May 18, 1989)

A new synthetic method of porphyrins via bis(hydroxymethyl)dipyrromethanes is described. This new method can be utilized for preparation of several unsymmetric porphyrin dimers.

In recent years, much interest has been focussed on development of conformationally restricted porphyrin dimers as models for photosynthetic reaction center[1] and metalloenzymes such as cytochrome oxidase.[2] Among these, octaalkylporphyrin dimer (**1**) bridged by an aromatic spacer has been shown to be a useful model. The relative geometry of the two porphyrin rings in these compounds is rather restricted because of the steric hindrance between the aromatic spacer and the flanking peripheral alkyl groups.

Symmetric porphyrin dimer **1** is generally prepared by the synthetic routes shown in Scheme 1.[3] However, synthesis of unsymmetric dimers, such as **10a** and **10b**, is not so straightforward as **1**.

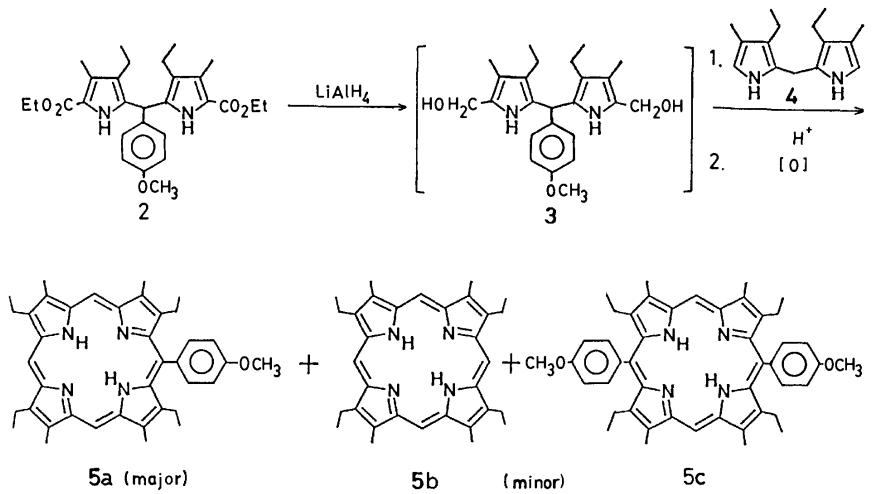


Scheme 1.

We wish to report here a new synthetic method of porphyrins by acid-catalyzed condensation of 5,5′-bis(hydroxymethyl)dipyrromethane and 5,5′-unsubstituted dipyrromethane. Since the conditions are mild enough, this method can be applied for a stepwise synthesis of non-symmetric dimers. It should be noted that this method is an application of the synthesis of octaalkyl- and octaarylporphyrins reported by Ono and Maruyama, in which $LiAlH_4$ treatment of 5-unsubstituted 2-ethoxycarbonylpyrrole followed by acid catalyzed self-condensation is utilized.[4]

Results and Discussion

Dipyrromethane diester **2** was treated with lithium aluminum hydride to give the corresponding diol **3**, which was immediately allowed to react with the 5,5′-unsubstituted dipyrromethane **4** in the presence of acid catalyst. After standing for 1—2 days at room temperature, the reaction mixture was worked up and separated by column chromatography. The desired product **5a** was obtained in a moderate yield. Generally two other porphyrins, **5b** and **5c**, were obtained together with **5a**. These by-products were formed through self-coupling of each dipyrromethane unit. Several cyclization conditions were employed, and the results are summarized in Table 1.



Scheme 2.

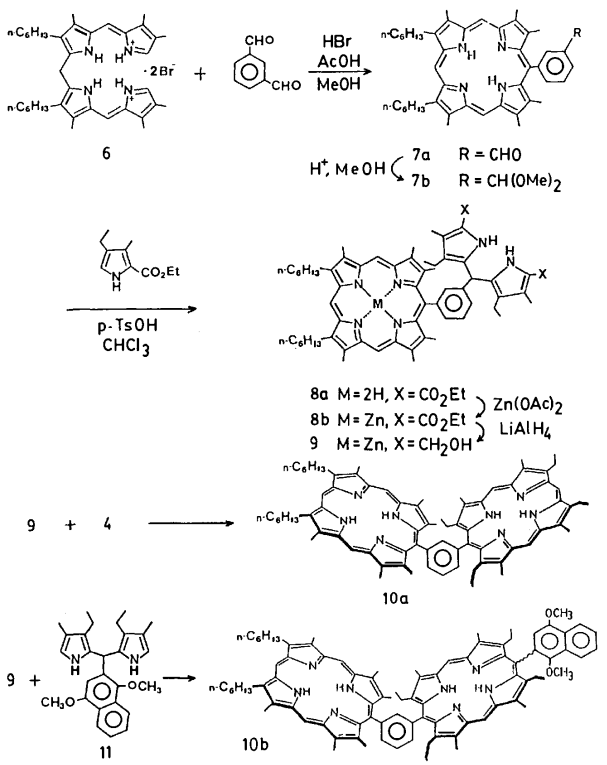
In several cases (Runs 1, 2, and 4), "scrambling" of the peripheral alkyl substituents took place during cyclization. This is probably due to acid-catalyzed redistribution reactions of the porphyrinogens (the saturated precursor of porphyrins).[5] When more weakly acidic conditions were employed, no scrambling was observed (Runs 3, 5, and 6). Thus, it was concluded that acetic acid in methanol or silica gel in dichloromethane was the reagent of choice in the reaction of **3** and **4**.

The present method of porphyrin formation was applied for synthesis of unsymmetric porphyrin dimers. Condensation of 1,19-dideoxybiladiene-ac dihydrobromide **6** with isophthalaldehyde gave a porphyrin bearing a formyl group (**7**),[6] which was allowed to react with ethyl 4-ethyl-3-methyl-2-pyrrolecarboxylate to give **8a**. The porphyrin-dipyrromethane **8a** was converted to the zinc complex **8b**, and treated with $LiAlH_4$ to give the corresponding diol **9**, which was allowed to react with **4** in methanol/dichloromethane (pure methanol did not dissolve the porphyrin) in the presence of silica gel. The dimer **10a** was obtained in a moderate yield (9%).

Table 1. Coupling Reaction of **3** and **4**

Run	Catalyst	Solvent	Yield (%) of **5a**[a]
1	$HClO_4$	MeOH	6[b]
2	pTsOH	MeOH	18[b]
3	AcOH	MeOH	15
4	AcOH	CH_2Cl_2	14[c]
5	C-200[d]	CH_2Cl_2	9
6	AcOH	$MeOH/CH_2Cl_2$(1/1)	13

a) Including scrambled products. b) Scrambling. c) Slight scrambling. d) Silica gel (Wako Pure Chemicals).



Scheme 3.

Coupling of **9** with dipyrromethane **11** similarly gave an unsymmetric porphyrin dimer **10b** in 0.5% yield. The dimer **10b** can be transformed into a quinone-linked porphyrin dimer, which is a very important model compound in the studies of plant- and bacterial photosynthesis. We are currently preparing other quinone-linked porphyrin dimers with restricted conformation by a similar method as described here, and the photophysical properties of these photosynthetic model systems will be presented in the near future.

Experimental

The instruments were as previously reported.[7] Mass spectra were recorded on a JEOL DX-300 spectrometer using the FAB method; the FAB matrix was $CHCl_3$+trifluoroacetic acid/*m*-nitrobenzyl alcohol (NBA)/glycerol unless otherwise stated. High-resolution mass spectrum was recorded on a JEOL JMS-SX102 spectrometer.

5-(4-Methoxyphenyl)-3,7,13,17-tetraethyl-2,8,12,18-tetramethylporphine (5a). Various conditions were employed (see Table 1), and one typical experiment is described here.

To a suspension of $LiAlH_4$ (40 mg) in 2 ml of anhydrous tetrahydrofuran, a solution of dipyrromethane **2**[8] (100 mg, 0.21 mmol) in tetrahydrofuran (10 ml) was dropwise added (under nitrogen, at room temperature). After 40 minutes, water was carefully added, and the mixture was extracted with dichloromethane (quickly!). The extract was washed with water and dried over sodium sulfate.

The resultant solution (**3**) was diluted with 70 ml of methanol, and bis(3-ethyl-4-methyl-2-pyrrolyl)methane[10] (**4**, 48 mg=0.21 mmol) was added. Acetic acid (15 drops) was added, and the mixture was stirred in the dark under nitrogen for 38 hours (room temperature). Chloranil (50mg) was added, and stirring was continued for 24 hours.

Solvent was evaporated from the reaction mixture, 10% aqueous NaOH was added and the mixture was extracted with dichloromethane. The extract was washed with aqueous NaOH and water, dried (Na_2SO_4), and treated with saturated solution of zinc acetate in methanol (1 ml) for 2 hours at refluxing temperature. The reaction mixture was washed with water, dried, evaporated, and separated by flash column chromatography (CH_2Cl_2). The fractions containing zinc porphyrin were collected, shaken twice with 4M HCl (1 M=1 mol dm^{-3}), neutralized, dried, and evaporated. Separation by flash column chromatography (CH_2Cl_2) gave three porphyrinic fractions. The first fraction was porphyrin **5b**, the second was the desired product **5a**, and the third was bis(*p*-methoxyphenyl)porphyrin **5c**. Yield of **5a**: 19 mg (0.032 mmol, 15%). Mp 290—295 °C. ^{1}H NMR ($CDCl_3$): δ=10.17 (s, 2H, 10,20-H), 9.92 (s, 1H, 15-H), 8.08+7.20 (d+d, 2H+2H, aromatic-H), 4.11 (s, OMe), 4.06 (q, 13,17-Et), 3.64+3.57 (s+s, 6H+6H, Me), 2.82 (q, 4H, 3,7-Et), 1.18+1.17(t+t, 6H+6H, Et), −3.0+−3.2 (br, 1H+1H, NH). UV-vis (CH_2Cl_2): 404, 503, 537, 574 and 624 nm. MS (FAB): *m*/*z* 585 ($M+H^+$).

5-[3-(Dimethoxymethyl)phenyl]-13,17-dihexyl-2,3,7,8,12,18-hexamethylporphine (7b). HBr-catalyzed condensa-

tion[6] of the 1,19-dideoxybiladiene-ac dihydrobromide **6**[11] (286 mg, 0.40 mmol) and isophthalaldehyde (536 mg, 4.0 mmol) gave 5-(3-formylphenyl)-13,17-dihexyl-2,3,7,8,12,18-hexamethylporphine **7a** in 68% yield (185 mg, 0.27 mmol). **7a:** mp 298—301 °C, IR (KBr): 1700 cm^{-1} (C=O). The formylporphyrin **7a** (73mg, 0.11 mmol) was dissolved in chloroform (40 ml). Methanol (10 ml) and *p*-toluenesulfonic acid monohydrate (60 mg) were added, and the resultant mixture was heated under reflux for 5.5 hours. The reaction mixture was cooled, washed with aqueous $NaHCO_3$ and brine, dried, and evaporated. The dimethyl acetal **7b** was obtained in quantitative yield. Mp 271—283 °C. ^1H NMR ($CDCl_3$): δ=10.15 (s, 2H, 10,20-H), 9.95 (s, 1H, 15-H), 5.68 (s, 1H, C<u>H</u>$(OMe)_2$), 4.04 (t, 4H, hex-1), 3.63+3.52+3.49 (s+s+s, 6H+6H+6H, Me and OMe), 2.45 (s, 6H, 3,7-Me), 2.30 (quint, 4H, hex-2), 1.76 (quint, 4H, hex-3), 1.51 (m, hex-4), 1.39 (sext, 4H, hex-5), 0.92 (t, hex-6), −3.15 +−3.30 (s+s, NH); phenyl: 8.18 (s, 1H), 8.01+7.91 (d+d, 1H+1H), 7.75 (t, 1H). UV-vis (CH_2Cl_2): 403, 502, 536, 570, and 623 nm. MS (FAB): *m/z* 713 ($M+H^+$). IR (KBr): no carbonyl. Found: C, 79.28; H, 8.59; N, 7.78%. Calcd for $C_{65}H_{82}O_4N_6$: C, 79.17; H, 8.48; N, 7.76%.

5-(3-[Bis(5-ethoxycarbonyl-3-ethyl-4-methyl-2-pyrrolyl)-methyl]phenyl)-13,17-dihexyl-2,3,7,8,12,18-hexamethylporphine Zinc Complex (8b). The porphyrin dimethyl acetal **7b** (183 mg, 0.26 mmol) and ethyl 4-ethyl-3-methyl-2-pyrrolecarboxylate (183 mg, 1.01 mmol) was dissolved in chloroform (100 ml), *p*-toluenesulfonic acid monohydrate (180 mg, 0.95 mmol) was added, and the resultant mixture was refluxed for 12 hours. The reaction mixture was then cooled, washed with aqueous $NaHCO_3$, and dried over Na_2SO_4. The resultant solution was treated with 10 ml of $Zn(OAc)_2$/MeOH solution (reflux, 2 hours). The reaction mixture was separated by flash column chromatography (benzene). After the unreacted pyrrole and non-porphyrinic by-products were eluted, the porphyrin zinc complex **8b** was eluted by benzene/diethyl ether (v/v=95/5). Yield 246 mg (0.23 mmol, 89%). Mp 140—148 °C. ^1H NMR ($CDCl_3$): δ=10.14 (s, 2H, 10,20-H), 10.03 (s, 1H, 15-H), 4.04 (t, 4H, hex-1), 3.62+3.52 (s+s, 6H+6H, Me), 2.3 (m, 4H, hex-2), 2.46 (s, 6H, 3,7-Me), 1.79 (quint, 4H, hex-3), 1.6 (m, hex-4), 1.41 (m, 4H, hex-5), 0.93 (t, 6H, hex-6); phenyl: 7.99 (d, 1H), 7.95 (s, 1H), 7.73 (t, 1H), 7.50 (d, 1H); pyrrole: 8.44 (s, 2H, NH), 5.83 (s, 1H, $(pyrrolyl)_2C$<u>H</u>-), 4.34 (q, 4H, OC<u>H_2</u>CH_3), 2.41 (m, 4H, C<u>H_2</u>CH_3), 2.31 (s, 6H, Me), 1.39 (t, 6H, OCH_2C<u>H_3</u>), 0.99 (t, 6H, CH_2C<u>H_3</u>). UV-vis (CH_2Cl_2): 407, 537, and 572 nm.

5-[3-(3,7,13,17-Tetraethyl-2,8,12,18-tetramethyl-5-porphinyl)-phenyl]-13,17-dihexyl-2,3,7,8,12,18-hexamethylporphine (10a). The dipyrromethane-porphyrin zinc complex **8b** (66 mg, 0.061 mmol) was treated with $LiAlH_4$ (26 mg) in tetrahydrofuran (10 ml) at 4 °C for 1 hour. The reaction mixture was quenched with aqueous NH_4Cl, and extracted with CH_2Cl_2. The extract was washed with water, dried, and evaporated. The resultant solids were dissolved in 2 ml of CH_2Cl_2, which was added to the solution of dipyrromethane **4** (30 mg) in 10 ml of methanol. Silica gel (C-100, Wako Pure Chemicals) was added (1.0 g), and the mixture was stirred for 3 days (dark, under nitrogen, room temperature). Chloranil (20 mg) was added and the mixture was stirred for 2 hours.

The silica gel was removed by filtration, and the resultant mixture was treated in the similar manner as in the case of **5a**. The dimer **10a** was obtained. Yield 6 mg (0.005 mmol, 9%). Mp>300 °C. ^1H NMR ($CDCl_3$): δ=10.12+10.01 (s+s, 2H+2H, meso), 9.81+9.80 (s+s, 1H+1H, meso), 3.98+3.95 (q+t, 8H, 13,17-Et+hex-1), 3.62+3.57+3.53+3.46+3.6 (4s+m, 28H, 4Me+3,7-C<u>H_2</u>CH_3), 2.97 (s, 6H, Me), 2.20 (quint, 4H, hex-2), 1.80 (t, 6H, Et), 1.67 (quint, hex-3), 1.60 (t, Et), 1.43 (quint, hex-4), 1.31 (sext, hex-5), 0.85 (t, 6H, hex-6), −2.5 to −3.3 (br, 4H, NH); phenyl: 9.38 (d, 1H), 8.58 (d, 1H), 8.23 (t, 1H), 7.83 (s, 1H). UV-vis (CH_2Cl_2): 407, 505, 538, 574, and 626 nm. MS (FAB): *m/z* 1116 ($M+H^+$).

5-(1,4-Dimethoxy-2-naphthyl)-15-[3-(13,17-dihexyl-2,3,7,8,12,18-hexamethyl-5-porphinyl)phenyl]-3,7,13,17-tetraethyl-2,8,12,18-tetramethylporphine (10b). The porphyrin dimer **10b** was prepared by the same method as **10a**, starting from **8b** and 2-[bis(3-ethyl-4-methyl-2-pyrrolyl)methyl]-1,4-dimethoxynaphthalene **11**[1c] (0.5% yield). ^1H NMR ($CDCl_3$):[12] δ=10.14 (s, 2H, meso), 9.97 (s, 2H, meso), 9.75 (s, 1H, meso), 3.97—3.86 (m, 7H, hex-1 and OMe), 3.57—3.42 (5s, 27H, Me and OMe), 2.93 (s, 6H, Me), 2.93—2.50 (4m, 4H, Et), 2.3—2.13 (2m, 4H, hex-2), 1.7—1.6 (2m, hex-3), 1.5—1.2 (m, hex-4 and hex-5), 1.08 (t, Et), 0.81 (t, hex-6), −1.8 (br, NH), −3.1 and −3.2 (br, NH); naphthyl: 8.46+8.1 (m+br, 1H+1H, 6- and 7-H), 7.6 (m, 2H, 5- and 8-H), 7.5 (br, 1H, 3-H); phenyl: 9.3+8.55 (br+br, 1H+1H, 4- and 6-H), 8.17 (t, 1H, 5-H), 7.9 (br, 1H, 2-H). UV-vis (CH_2Cl_2): 404, 505, 537, 575, 624 and 654nm. High resolution mass (FAB, $CHCl_3$+NBA). Found: 1301.806 ($M+H^+$). Calcd for $C_{88}H_{101}O_2N_8$: 1301.805.

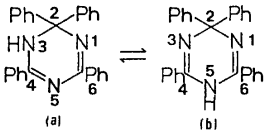
Crystal Structure and Photochemical Behavior of 2,2,4,6-Tetraphenyldihydro-1,3,5-triazine and Its Inclusion Compounds

Yukie MORI, Yuji OHASHI, and Koko MAEDA*
Department of Chemistry, Faculty of Science, Ochanomizu University, Bunkyo-ku, Tokyo 112
(Received February 14, 1989)

Crystal structures of 2,2,4,6-tetraphenyldihydro-1,3,5-triazine (**1**), which shows photocoloration, and its photostable propylamine solvate (**2**) have been determined. The molecular structure of the dihydrotriazine in **1** and **2** showed that it exists in 2,3-dihydro form in the crystals, but the bond distance of N(3)-C(4) was shorter than a normal C-N single bond, indicating that lone-pair electrons on N(3) interact with the π system of C(4)=N(5)-C(6)=N(1). Comparison of crystal structures of **1**, **2**, and other inclusion compounds previously determined revealed that the difference in the photochemical behavior of the crystals is attributable to different hydrogen bonding schemes. Photolysis of **1** in the solid state, which was carried out in connection with the structural investigation of the photocolored species, gave 2,4,6-triphenyl-1,3,5-triazine as a main product.

2,2,4,6-Tetraphenyldihydro-1,3,5-triazine (abbreviated as TPDT) was reported to exhibit photochromism in the solid state by Lottermoser in 1896,[1] but the structure of the colored species is still undetermined. The photochromism is not observed in solutions around room temperature. In 1985 one of the authors revealed that TPDT exists in an equilibrium mixture



of 2,3-dihydro (a) and 2,5-dihydro (b) forms and the preferred tautomeric form is 2,3-dihydro (a) form both in solutions and in the solid state.[2] Recently we found that TPDT forms 1 : 1 inclusion compounds with various solvent molecules on recrystallization and the inclusion compounds can be classified into two types in terms of their photochemical coloration, that is, photolabile and photostable crystals. In the previous papers[3,4] the crystal structures of photostable ethanol solvate (**3**), 2-propanol solvate (**4**), and photolabile acetone solvate (**5**) were determined and the hydrogen bond between the hydroxyl hydrogen in the solvent molecules and ring nitrogen in TPDT was shown to inhibit the photocoloration. These facts suggested that hydrogen-donating solvents in the inclusion compounds of TPDT inhibit the photocoloration and hydrogen-accepting solvents do not affect the photocoloration. In order to confirm this assumption we have determined the crystal structures of TPDT with no inclusion solvent (**1**), which was recrystallized from toluene-hexane, and its propylamine solvate (**2**) including a different kind of hydrogen-donating solvent from **3** and **4**. Although the red color obtained after irradiation of colorless crystals of **1** gradually faded apparently in the dark, after repeated irradiations and fading processes, TPDT was found to undergo photochemical reactions.

Experimental

Apparatus. Absorption spectra were obtained on a Shimadzu UV-240 spectrophotometer. IR spectra were recorded on a JASCO A-302 IR spectrometer and difference IR spectra were obtained by using a JASCO DP-A330 IR data processor. FT-IR spectra for the reflection method were obtained by a JASCO FT-IR 7000 spectrophotometer. The PA spectrum was measured by Professor Sugitani, University of Tsukuba. The light source was a 500 W xenon lamp (WACOM XD501S), and the light beam was modulated at a frequency of 18 Hz by a chopper. A Nicon P250 spectrometer was used. The output of the microphone was amplified by means of a lock-in amplifier (NF LI-574) and the data were treated with a HP 9816 computer. The correction was carried out by using a PA spectrum of carbon black.

Photolysis of TPDT in the Solid State. The photolysis of **1** or **3** in the solid state was carried out in a KBr pellet [2%(w/w)]. A 100 W high-pressure mercury lamp (Ushio UI-100) was used for the irradiation at room temperature. The progress of the reaction was monitored by difference IR spectra.

General Procedure of Photolysis for Isolation of the Photoproducts in Solutions. All the reactions were performed on solutions (150 cm^3) irradiated by a 400 W high-pressure mercury lamp from outside of a vessel at room temperature under nitrogen. The reactions were monitored by TLC to

control the irradiation time. After irradiation was stopped, the solvent was removed under reduced pressure and the resulted residue was chromatographed on a silica gel column with benzene-ethanol as eluent.

Crystal Structure Determination. Colorless plate-like crystals of **1** and **2** were obtained by recrystallization of TPDT from toluene-hexane and propylamine-hexane, respectively. A crystal of **2**, which easily lost the solvent molecule, was sealed in a glass capillary. Cell parameters were refined by least-squares on the basis of 21 and 20 independent 2θ values for **1** and **2**, respectively. Crystal data and some experimental conditions are listed in Table 1. Intensities were measured on a Rigaku AFC-4 diffractometer with graphite-monochromated Cu$K\alpha$ radiation up to $2\theta=125°$, using the ω-2θ scan technique. Background counts were accumulated for 5s before and after each scan. Three standard reflections were monitored for every 50 reflections and no significant variations in intensities were observed. Corrections for the Lorentz and polarization factors were made, but no correction for absorption was applied.

The structure of **1** was solved by the direct method with the program MULTAN 78[5] and refined by the full-matrix least squares with the program SHELX 76.[6] All the hydrogen atoms were found on the difference map. The final refinement was made with the anisotropic temperature factors for non-hydrogen atoms and the isotropic ones for hydrogen atoms. The quantity minimized was $\sum w(|F_o|-|F_c|)^2$ and $w=[\sigma^2(|F_o|)+0.00654\,|F_o|^2]^{-1}$. The final R and R_w values became 0.063 and 0.080 for 2731 observed reflections. No peaks higher than 0.2 e Å^{-3} were found on the final difference map.

The procedure of the structure determination for **2** was similar to that for **1**. The intense reflections with a low 2θ angle (110, 120, and 111) were removed since their F_o values seemed to suffer from extinction. Some of hydrogen atoms were found on the difference map. The others were calculated geometrically and included in further refinements. The atoms of propylamine molecule were disordered between three sets of positions and were refined under the constrained conditions with the usual geometry (C-N 1.47, C-C 1.54 Å, N-C-C 110, C-C-C 109°). The occupancy factors were fixed to 0.33333 for each set, considering from the temperature factors of the disordered atoms. The final refinement was made with the anisotropic temperature factors for non-hydrogen atoms of TPDT molecule and the isotropic ones for hydrogen atoms and the atoms of propylamine. The weighting scheme was $w=[\sigma^2(|F_o|)+0.0097\,|F_o|^2]^{-1}$. The final R and R_w values became 0.095 and 0.117 for 2957 observed reflections. Considerably high R values may be due to the disordered structure of the solvent molecule. No peaks higher than 0.25 e Å^{-3} were found on the final difference map. The atomic scattering factors were taken from the International Tables for X-ray Crystallography.[7] The computation was carried out on HITAC M-680 computer at the Computer Center of the University of Tokyo.

Results and Discussion

Absorption and Photoacoustic (PA) Spectra of the Colored Species of 1. The crystals of **1** and its inclusion compounds showed no absorption longer than 430 nm in the dark. After irradiation for a few minutes, the color of **1**, **5**, and chloroform solvate turned red. The absorption spectrum of **1** obtained by an opal-glass transmission method after irradiation is shown in Fig. 1(a). The absorption spectrum of the crystals of **5** obtained by irradiation in a KBr pellet is shown in Fig. 1(b). Irradiation of the chloroform solvate gave a spectrum similar to that of **5**. The absorption maxima around 510 and 730 nm for the colored species from **1** are considered to be shifted to slightly longer and shorter wavelengths, respectively, by inclusion of solvent molecules.

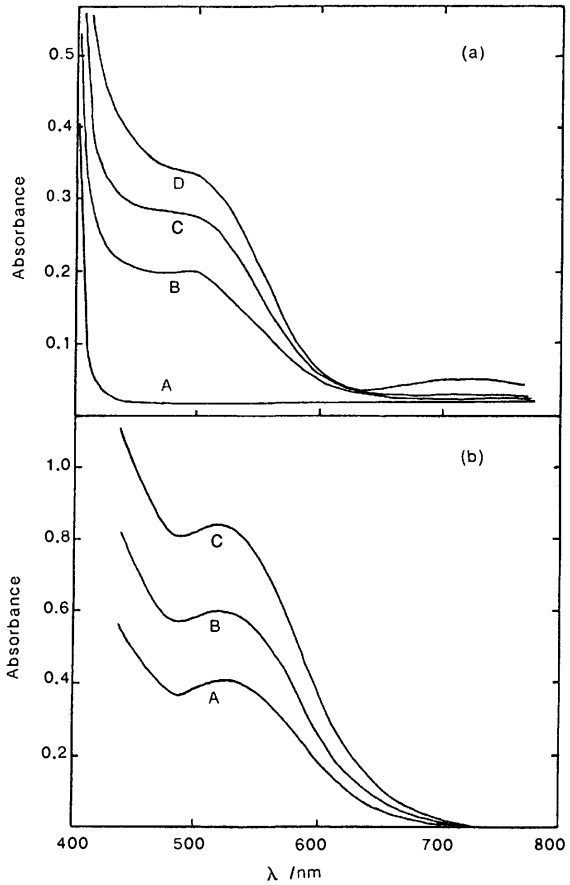

Fig. 1. Variation of absorption spectrum after repeated irradiations. (a) crystal of **1** measured by an opal-glass transmission method (A: before irradiation, B: 1 min, C: 3 min, D: 20 min) (b) acetone solvate (**5**) in a KBr pellet (A: 1 min, B: 4 min, C: 20 min).

The PA spectrum of **1** after 20 min irradiation showed a broad band around 510 nm and a weaker band around 690 nm. The PA spectrum was similar to the absorption spectrum of **1** obtained after 20 min irradiation shown in Fig. 1(a).

Photochemical Reactions of TPDT. Any recognizable differences between IR spectra of colorless and colored crystals of **1** were not obtained under short-time irradiation. After 2 h irradiation, although the red color still remained, a difference IR spectrum showed a number of new bands indicating occurrence

of photochemical reactions. In order to identify the photoproducts, preparative photolysis of **1** was carried out in solutions of benzene or chloroform. On the photolysis of **1** (150 mg) in benzene, the irradiation was stopped after 5 h even **1** still remained, because much longer irradiation afforded dark oily products. In the reaction mixture six products were detected by TLC besides unreacted **1**. Chromatographically two products, 2,4,6-triphenyl-1,3,5-triazine **6** (3 mg) and 2,4,5-triphenylimidazole **7** (5 mg) were isolated and 69 mg of **1** was recovered. Irradiation of **1** in chloroform gave a similar result. After **1** was almost consumed **6** and **7** were isolated in very low yields with a larger amount of dark oily products.

The bands appeared at 1520, 1370, 759, and 690 cm^{-1} in the difference IR spectrum between before and after irradiation of **1** were compared with both of the IR spectrum of the photoproducts **6** and **7**. The bands coinciding with that of **6** indicated the formation of **6** under the solid state photolysis. Although bands assignable to **7** were not found in the difference IR spectrum, after the extraction of the irradiated pellet with benzene **7** was detected by TLC.

In order to obtain the relationship between photocoloration and photoreaction products in the solid state, photolysis of **3** was also carried out. Neither photocoloration nor recognizable differences between IR spectra before and after irradiation (5 h) were found. By extraction of the irradiated pellet with benzene, however, **7** was detected by TLC. The facts indicated that the two types of hydrogen bonds[3] in **3** inhibit both of photocoloration and photoformation of **6**. In connection with the photolysis in the solid state an ethanol solution of **1** (56 mg) was irradiated until **1** was almost consumed. Only one product **7** was detected by TLC and 8 mg of **7** was isolated.

Previously one of the authors reported that irradiation of 2,4,4,6-tetraphenyl-1,4-dihydropyridine (**8**) exhibits photocoloration in deaerated solutions or in the solid state and after a long-time irradiation in solutions 2,3,4,6-tetraphenylpyridine (**10**) was produced. As is shown in Scheme 1 a di-π-methane rearrangement to give 1,3,5,6-tetraphenyl-2-azabicyclo-[3.1.0]hex-3-ene (**9**) has been suggested as the unisolable intermediate.[8]

TPDT has aza-di-π-methane moiety in the molecule, and on the photolysis of **1** occurrence of an aza-di-π-methane rearrangement to give a bicyclic intermediate, 1,3,5,6-tetraphenyl-2,4,6-triazabicyclo[3.1.0]hex-3-ene (**13**), similar to **9** is assumed. Presently carbonyl

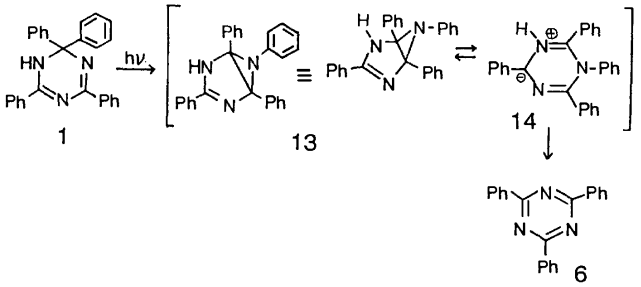

Scheme 3.

ylides and azomethine ylides which are the ring-opening products of oxetane and aziridine, respectively, are attracting considerable interest.[9] Furthermore the 1,5-electrocyclic ring-opening reactions of the bicyclic heterocycles such as homofuran, homopyrrole, and homothiophene are shown to lead to ylide intermediates **12**[10] as is shown in Scheme 2. Photochromic reactions involving these types of ylides or zwitter ions as the colored species have been also reported.[11] As is shown in Scheme 3 as one of the possible candidates of the photocolored species an azomethine ylide type intermediate **14** is postulated, which is formed from **13** by cleavage of the central bond C^1-C^5 in aziridine, as required for the electrocyclic process. IR spectrum of TPDT exhibits two C=N stretching bands at 1610 and 1680 cm^{-1} assignable to 2,3-dihydro- and 2,5-dihydro forms of the dihydrotriazine ring respectively.[2] As the bicyclic intermediate **13** containing an imidazoline ring is produced successfully, appearance of another C=N stretching band around 1650 cm^{-1} is postulated.[12] The difference FT-IR spectrum obtained by the reflection method between before and after irradiation of fine crystals of **1** exhibited a weak band at 1655 cm^{-1}, as it was expected, besides the two characteristic C=N stretching bands in TPDT. This observation supports partially the reaction course shown in Scheme 3. Furthermore, broad bands appeared in the FT-IR spectrum on the range of 2400—3300 cm^{-1} obtained after irradiation suggested involvement of **14** in the photocoloration. It is reasonable to consider that the back reaction from **13** to **1** is not possible and the photochemical color change of **1** is not reversible. Conversion of the colored intermediate **14** into **6** stabilized by its resonance energy is postulated (Scheme 3). The formation of trace amount of **7** can be explained by cleavage of one of the peripheral aziridine bonds C^1-N^6 or C^5-N^6 in **13** followed by intramolecular nucleophilic addition of the nitrogen lone pair to the heterodiene system as is shown in Scheme 4.

a) $B_{eq}=\frac{4}{3}\sum_i\sum_j B_{ij}a_ia_j$.

On the photolysis of **3**, in which TPDT molecule connected with solvent molecules alternatively to form a helix structure by two types of hydrogen bonds at N(3)-H and N(5),[3] even if the aza-di-π-methane rearrangement should give the bicyclic intermediate **13** successfully, the following ring-opening process to give **14** should be prohibited by the helical structure. Only small amount of **13** probably transforms into **7** in the same fashion shown in Scheme 4.

Molecular and Crystal Structures. The final atomic coordinates and equivalent isotropic temperature factors for non-hydrogen atoms in **1** and **2** are given in Tables 2 and 3 respectively.** Selected bond distan-

** The lists of the anisotropic temperature factors for non-hydrogen atoms, atomic coordinates and temperature factors for hydrogen atoms, and the observed and calculated structure factors are kept in the Office of the Chemical Society of Japan (Document No. 8899).

a) Ref. 3. b) Ref. 4.

ces and angles of **1** and **2** are listed in Table 4, together with those of **3**, **4**, and **5**, and some torsion angles and dihedral angles are in Table 5. Figure 2 shows the molecular structure of TPDT with the atom numbering in the crystal of **1**. For **2** the same numbering scheme is used. The molecular structure of TPDT in **1** and **2** is similar to that in **3**, **4**, or **5**. During the refinements the difference maps showed that a hydrogen atom is bound to N(3), not N(5), that is, TPDT exists in 2,3-dihydro (a) form in both **1** and **2**, as it does in **3**, **4**, or **5**. However, the differences between N(3)-C(4) and C(4)-N(5) were found to be rather small in both **1** and **2**, as was reported for the other three inclusion compounds.[3,4] The bond distance of N(3)-C(4) for the five crystals **1**—**5** (1.323—1.346 Å) is similar to a typical C-N distance of six-membered N-containing aromatic rings. The sums of bond angles around N(3) are 359 and 360° for **1** and **2** respectively, that is, N(3) is planar rather than pyramidal. These results suggest that lone pair electrons on N(3) is effectively conjugated with the π system of C(4)=N(5)-C(6)=N(1). Further inspection of Table 4 reveals that

Table 5. Some Torsion Angles (ϕ/°) and Dihedral Angles (ϕ/°)[a] for **1** and **2**

	1	**2**
N(3)-C(4)-C(13)-C(14)	6.4(4)	−30.2(7)
N(5)-C(6)-C(7)-C(8)	19.8(4)	11.9(6)
N(3)-C(4)-N(5)-C(6)	13.0(3)	−8.0(6)
C(4)-N(5)-C(6)-N(1)	−18.0(4)	11.3(6)
N(5)-C(6)-N(1)-C(2)	−7.8(4)	7.9(6)
[1][a]	53.7(1)	77.4(2)
[2][a]	86.5(1)	78.9(2)
[3][a]	32.2(3)	24.8(4)
[4][a]	12.7(3)	7.7(4)

a) [1]: the dihedral angle between the least-squares plane of N(1), N(3), C(4), and N(6) (plane A) and the least-squares plane of C(19)-C(24). [2]: the dihedral angle between plane A and the least-squares plane of C(25)-C(30). [3]: the dihedral angle between plane A and the plane of N(1), C(2), and N(3). [4]: the dihedral angle between plane A and the plane of C(4), N(5), and C(6).

the bond distance of N(3)-C(4) in **2** is shorter than that in **1**. The corresponding bond distance in **3**, **4**, or **5** is also slightly shorter than that in **1**, suggesting that the hydrogen bond involving N(3) has an effect on N(3)-C(4) bond. The shortening of N(3)-C(4) tends to enlarge N(3)-C(4)-N(5) bond angle in **2**—**5**. The bond distance of C(4)-C(13) in **2** is larger than that in **1**, which may also result from the shortening of N(3)-C(4). No other significant differences in bond distances or angles were observed for the five crystals **1**—**5**. The dihydrotriazine ring in **1** and **2** was found to exist in the boat conformation with the apexes of C(2) and N(5) as was reported in **3**, **4**, or **5**. The torsion angles of N(3)-C(4)-N(5)-C(6) and C(4)-N(5)-C(6)-N(1) in **2** are smaller than the corresponding angles in **1** respectively, indicating that the N(3)-C(4)-N(5)-C(6)-N(1) system in **2** is more planar than that in **1**. The torsion angles of N(5)-C(6)-C(7)-C(8) and N(3)-C(4)-C(13)-C(14) and the dihedral angles between the plane composed of N(1), N(3), C(4), and C(6) and that composed of the phenyl ring C(19)-C(24) or that composed of the ring C(25)-C(30) in **1** and **2** are similar to the corresponding angles in **3**, **4**, or **5**: the two phenyl rings at 4- and 6-positions are nearly coplanar with the dihydrotriazine ring, while the two at 2-position are almost perpendicular to it.

Figure 3 shows the crystal structures of **1** and **2**. In **2** the nitrogen atom of the propylamine is involved in two types of hydrogen bond: N(3)-H(3)···N(31) and N(5)···H-N(31). The distances of N(3)···N(31), N(3)···N(31′), and N(3)···N(31″) are 2.92(1), 3.07(1), and 3.05(1) Å respectively. The distances of N(5)···N(31) [3.18(1) Å], N(5)···N(31′) [3.25(1) Å], and N(5)···N-(31″)[3.31(1) Å] are slightly longer. By these hydrogen bonds TPDT and the solvent molecules are alternately connected to form a ribbon-like structure along the two-fold screw axis, as is shown in Fig. 3(b). This hydrogen bonding scheme was also seen in **3** and **4**, where oxygen atoms of the solvent molecules were involved in the hydrogen bonds. No other short contacts were found between TPDT and the solvent molecules in **2**, which seemed to allow the solvent molecules to take a disordered structure. In **1** there are no unusually short contacts. Thus, comparison of crystal structures of **1**—**5** revealed that the hydrogen bonding scheme constructing the ribbon-like structure is characteristic of **2**, **3**, and **4**, which are photostable. On the other hand in **1** and **5**, which exhibit photocoloration, each TPDT molecule is isolated. It is, therefore, confirmed that the hydrogen bonds observed in **2**, **3**, and **4** inhibit the photocoloration of the crystals.

We thank Professor Yoshinori Sugutani, University of Tsukuba, for the measurement of PA spectrum. We thank Dr. Keiko Takano, Ochanomizu University, for her valuable discussion. This work was supported by a Grant-in-Aid for Scientific Research from Ministry of Education, Science and Culture (No. 63628505).

Preparation of Optically Active 1-Aminoalkylphosphonic Acids from Chiral Carbamates and Chiral Ureas

Tatsuo OSHIKAWA* and Mitsuji YAMASHITA
Department of Applied Chemistry, Faculty of Engineering, Shizuoka University, Hamamatsu 432
(Received February 15, 1989)

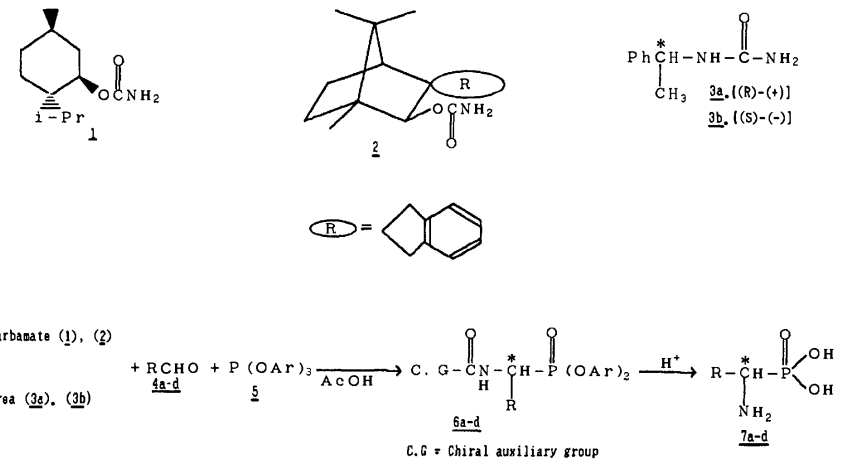
Optically active 1-aminoalkylphosphonic acids were successfully synthesized from chiral carbamate and urea derivatives which were prepared from such chiral substrates as (−)-menthol, (+)-camphor, and (*R*)-(+)- and (*S*)-(−)-(1-phenylethyl)ureas by the actions of aldehydes and triaryl phosphites. 1-Aminoalkylphosphonic acid derivatives, thus prepared, have an (*R*)-(+)- or (*S*)-(−)-configuration, depending on the chiral source via a retention of the configuration; i.e., (+)-products were prepared from chiral (+)-carbamate and (+)-urea derivatives, and (−)-products from chiral (−)-carbamate and (−)-urea derivatives.

Phosphonodipeptides and phosphonotripeptides possess inhibitory biological activities. Especially, 1-aminoethylphosphonic acid is a well-known substance which inhibits the growth of bacteria by interfering with the biosynthesis of peptidoglycan of the bacteria cell walls.[1]

In general, 1-aminoalkylphosphonic acids were derived by several synthetic methods; addition reactions of Schiff bases with dialkyl phosphonates,[2] Mitsunobu reactions of 1-hydroxyalkylphosphonates with phthalimides,[3] condensation of hydrazines with phosphonoacetic esters,[4] catalytic reduction of dimethylhydrazones of 1-oxoalkylphosphonates,[5] reduction of *t*-butyl diazo(diethoxyphosphoryl)acetate,[6] hydrolyses of diethyl 1-(formylamino)alkylphosphonates,[7] and alkylation of 1-(ethoxycarbonylamino)-1-(ethylthio)methylphosphonate.[8] However, only racemic products were afforded by these reported methods. Optically active 1-aminoalkylphosphonic acids have so far been obtained by the optical resolution of racemic 1-aminoalkylphosphonic acids prepared by peptide synthesis.[1] Successful methods known for the asymmetric syntheses of 1-aminoalkylphosphonic acids are enantioselective addition reactions of dialkyl phosphonates with chiral Shiff bases[9,10] and a reaction of chiral (1-phenylethyl)urea with aldehydes and triethyl phosphite.[11] We now wish to report on the useful application of (−)-menthyl carbamate (**1**), 1,7,7-trimethylspiro[bicyclo[2.2.1]heptane-3,2′-indan]-2-yl carbamate (**2**), and (*R*)-(+)- and (*S*)-(+)-(1-phenylethyl)ureas (**3a** and **3b**) to the asymmetric synthesis of 1-aminoalkylphosphonic acids (**7a—d**) according to Oleksyszyn's methods.[12,13] In a previously published paper[11] no definite reaction mechanism for the formation of optically active 1-aminoalkylphosphonic acids from chiral ureas was discussed; therefore, the present paper deals with the further investigation concerning the reaction mechanism for the formation of chiral 1-aminoalkylphosphonic acids starting from both chiral carbamates and ureas.

Results and Discussion

Chiral carbamates **1** and **2** were synthesized[14] from (−)-menthol and 1,7,7-trimethylspiro[bicyclo[2.2.1]-heptane-3,2′-indan]-2-ol,[15] respectively, in the presence of trifluoroacetic acid and sodium cyanate in benzene. Chiral ureas **3a** and **3b** were synthesized according to the reported method.[11] The reaction of aldehydes **4a—d** with (−)-menthyl carbamate **1** and triaryl phosphite **5** in acetic acid led to **6a—d**, which were hydrolyzed without isolation. Optically active 1-aminoalkylphosphonic acid derivatives **7a—d** given by this methods were levorotatory. (+)-Isomenthyl



carbamate was then used as the chiral source of this reaction so as to clarify the stereoselectivity. (+)-Isomenthyl carbamate gave phosphonic acid with low optical activity (Table 1).

On the other hand, the reaction with chiral carbamate **2** led to dextrotatory 1-aminoalkylphosphonic acids **7**. Levorotatory 1-aminoalkylphosphonic acids are known to be an (*S*)-configuration, while dextrotatory enantiomers are (*R*)-configuration.[1,16] Therefore, 1-aminoalkylphosphonic acids prepared from (−)-menthyl carbamate (**1**) by the present method must be the (*S*)-enantiomer with a retention of the configuration. The stereoselectivity of 1-aminoalkylphosphonic acid produced by the reaction of (*R*)-(+)- and (*S*)-(−)-(1-phenylethyl)urea (**3a** and **3b**, respectively) led to the same conclusion obtained by a method described in the literature[11] where (*R*)-(+)-urea **3a** produced (*R*)-(+)-1-aminoalkylphosphonic acids and (*S*)-(−)-urea **3b** did (*S*)-(−)-1-aminoalkylphosphonic acids (Table 2). Two plausible reaction mechanisms (routes A and B in Scheme 1) may be proposed, based on the stereoselectivity observed in the present reaction, where (*R*)-(+)-urea **3a** and (*S*)-(−)-urea **3b**, afforded 1-aminoalkylphosphonic acid derivatives having (*R*)-(+)- and (*S*)-(−)-configurations, respectively.

Route A: phosphite attacks intermediate **8** in a similar way as that generated [urylenebis(methylene)]-bisphosphonate.[17] Route B: phosphite attacks enantioselectively the iminium ion.[18] In both routes, triaryl phosphite **5** attacks the carbon atom of aldehydes **4** after formation of carbon-nitrogen bond. In route A, optically active (*R*)-(+)- and (*S*)-(−)-(1-phenylethyl)ureas could attack either the *re* or *si* plane of aldehydes, while (*R*)-(+)-urea **3a** predominantly attacks the *si* plane of the aldehyde, leading to intermediate **8**. The intermediate is expected to be thermodynamically stable owing to hydrogen bonding to form a six-membered ring between the oxygen atom of the carbonyl group and the hydrogen atom of the

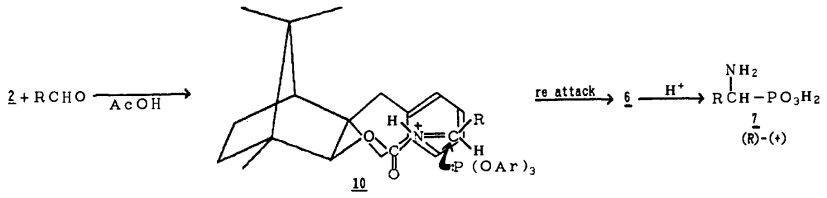
hydroxyl group (Scheme 1). An attack of triaryl phosphite on intermediary formed **8** should occur at the same side of the hydroxyl group, since the stereochemistry of the product was retained at the chiral center, i.e., dextrotatory 1-aminoalkylphosphonic acids were derived from (*R*)-(+)-urea **3a**, and levorotatory products from (*S*)-(−)-urea **3b**. Generally, it is known that chiral secondary alcohols add to the formed phosphonium salt at the rate-determining step in an Arbuzov reaction of triaryl phosphite with alkyl halide to produce inverted halides from the chiral alcohol.[19] Alternatively, in route B, the intermediate iminium ion **9** could exist as the syn and anti form, where the anti form **9a** is more stable than *syn*-**9b**. Therefore, triaryl phosphite may approach to *anti*-**9a** from the opposite side of the (*R*)-(+)-(1-phenylethyl) group, acting as the chiral source and, hence, the product should be optically active (*R*)-(+)-1-aminoalkylphosphonic acids. In fact, (*R*)-(+)-1-aminoalkylphosphonic acids were derived from (*R*)-(+)-urea **3a** and (*S*)-(−)-1-aminoalkylphosphonic acids from (*S*)-(−)-urea **3b**. Therefore, route B predominantly proceeds over route A in this reaction. The reaction mechanism via the iminium ion intermediate was further supported by the fact that the 1-aminoalkylphosphonic acids obtained from chiral carbamate **2** retained the (*R*)-configuration (see Table 3 and Scheme 2). If molecule **10** forms such an intermediate as **8**, forming a six-membered ring, **8** should offer such a severe steric hindrance that the chemical yield would be suppressed; however, no such low yield result was obtained. Furthermore, reaction of (−)-menthyl carbamate (**1**) afforded (*S*)-(−)-1-aminoalkylphosphonic acid by Cram's rule.

Tris(*o*-methylphenyl) phosphite showed little effect on the improvement of the optical yield in comparison with triphenyl phosphite, probably because of a remote chiral auxiliary from the reaction center. The optical yield was, nevertheless, improved by using tris(*o*-methylphenyl) phosphite in the case of 1-



Scheme 2.

aminoethylphosphonic acid (R=CH_3), which is a ubstance which inhibits the growth of bacteria (alafosfaline[1]).

Experimental

Measurements. Melting poits were measured on a Yanagimoto Seisakusho micro melting-point apparatus. ^1H NHR spectra were recorded on a Hitachi R-24B (60 MHz) spectrometer with TMS as an internal standard, and optical rotations were determined with a JASCO DIP-4 digital and Atago Polax polarimeters, and IR spectra on a JASCO A-3 infrared spectrophotometer.

Preparation of Menthyl Carbamate (1); General Procedure: To a stirred mixture of (−)-menthol 7.8 g (50 mmol) and sodium cyanate 6.5 g (100 mmol) in 30 ml of benzene was added slowly 8.0 ml of trifluoroacetic acid at room temperature; the reaction mixture turned cake immediately. The reaction mixture was heavily stirred for 3 h, and then filtrated. A white crystalline mass was washed with benzene (10 ml×3) and water (50 ml×2); obtained crystalline compound **1** was then dried in desiccator under reduced pressure on standing overnight; yield 67%; mp 156—157 °C; IR (cm^{-1}) 3400 (NH_2), 1720 (C=O); $[\alpha]_D^{17}$ −125° (*c* 0.60, $CHCl_3$).

(+)-Isomenthyl carbamate was synthesized by the same method; yield 57%; mp 61—63 °C; $[\alpha]_D^{19}$+23.7° (*c* 1.1, $CHCl_3$).

Preparation of 1,7,7-Trimethylspiro[bicyclo[2.2.1]heptane-3,2′-indan]-2-yl Carbamate (2). A mixture of camphor 4.4 g (28.7 mmol) and sodium amide 2.5 g (63.2 mmol) in anhydrous toluene (30 ml) was heated at 100—105 °C until evaporation of ammonia gas ceased; a mixture of α,α′-dichloro-*o*-xylene 5.0 g (28.7 mmol) and toluene (20 ml) was then slowly added to the solution. The reaction mixture was refluxed for 3 h, cooled to room temperature, and then added into water (20 ml). The product was extracted with benzene (20 ml×2), and the combined organic layer was dried over anhydrous sodium sulfate; the solvent was evaporated in vacuo. The resulting syrupy products were further subjected to reduced pressure in order to remove unreacted camphor. The separation of products by column chromatography on silica gel (eluent; benzene/hexane=4/1, v/v) afforded the syrupy product; 1,7,7-trimethylspiro[bicyclo-[2.2.1]heptane-3,2′-indan]-2-on in 39% yield, ^1H NMR ($CDCl_3$) δ=0.92 (s, 3H, CH_3), 0.96 (s, 3H, CH_3), 1.01 (s, 3H, CH_3), 1.55—2.01 (m, 8H, CH_2×4), 3.11 (t, *J*=6.0 Hz, 1H, CH), 7.04 (s, 4H, C_6H_4). To anhydrous tetrahydrofuran (10 ml) solution of 1,7,7-trimethylspiro[bicyclo[2.2.1]heptane-3,2′-indan]-2-on 1.3 g (5.1 mmol) was added slowly lithium aluminium hydride 0.20 g (5.3 mmol) at room temperature; and the mixture was stirred for 2 h. The reaction was quenched by the addition of diluted hydrochloric acid. The product was extracted with ether (30 ml×3), and the combined organic layer was dried over anhydrous magnesium sulfate; the solvent was then evaporated. The residue was separated by thin-layer chromatography on silica gel (eluent; benzene/hexane= 4/1, v/v) to give the syrupy product, 1,7,7-trimethylspiro[bicyclo[2.2.1]heptane-3,2′-indan]-2-ol,[15] in 95% yield; ^1H NMR ($CDCl_3$) δ=0.98 (s, 6H, CH_3×2), 1.31 (s, 3H, CH_3), 1.55—1.79 (m, 8H, CH_2×4), 2.80 (dd, *J*=15.0 Hz, 1H, CH), 3.38 (br s, 1H, OH), 3.52 (s, 1H, CH), 7.09 (s, 4H, C_6H_4). Carbamate **2** was synthesized by the same procedure as that for carbamate **1**. ^1H NMR ($CDCl_3$) δ=0.90 (s, 3H, CH_3), 0.98 (s, 3H, CH_3), 1.28 (s, 3H, CH_3), 1.61—1.82 (m, 8H, CH_2×4), 3.03—3.18 (m, 2H, CH×2), 4.55 (s, 2H, NH_2), 7.09 (s, 4H, C_6H_4); $[\alpha]_D^{22}$+21.9° (*c* 2.1, EtOH).

Preparation of 1-Aminoalkylphosphonic Acid 7; General Procedure: Mixing of triphenyl phosphite 3.1 g (10 mmol), benzaldehyde 1.6 g (15 mmol), (−)-menthyl carbamate (**1**) 2.0 g (10 mmol), and glacial acetic acid (15 ml) immediately caused a slightly exothermic reaction; the reaction mixture was then stirred for 0.5 h.

The mixture was heated for additional 1 h at 85 °C and hydrolyzed with concentrated hydrochloric acid (15 ml) for 7 h under reflux. The resulting solution was washed with benzene (20 ml×3) in order to remove phenol and menthol; then, the aqueous solution was evaporated in vacuo. The residue was dissolved in methanol (5 ml) and the solution was treated with propylene oxide until pH 6 was reached. The precipitated aminoalkylphosphonic acid **5** was recrystallized from ethanol-water.

Reactions of Alkenes with Iodine(III) Tris(trifluoroacetate)

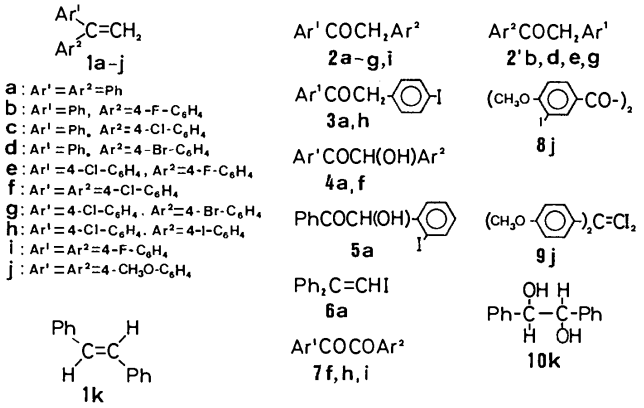
Yasuo FUTAMI, Hiroshi NISHINO, and Kazu KUROSAWA*
Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami 2-39-1, Kumamoto 860
(Received May 10, 1989)

The reactions of 1-arylethene, 1,1-diarylethenes, and 1,1-diarylpropenes with iodine(III) tris(trifluoroacetate) gave 1,2-diaryl-1-alkanones, 1-aryl-2-(4-iodophenyl)-1-alkanones, benzoins, benzils, and iodoethenes. A similar reaction of 1,1,4,4-tetraaryl-1,3-butadiene yielded 1,2,4,4-tetraaryl-3-buten-1-one. The reactions of 1,1,5,5-tetraaryl-1,4-pentadienes and 1,1,6,6-tetraaryl-1,5-hexadienes also gave dicarbonyl compounds. The reaction involves aryl migration. The mechanisms and the utility of the reaction for organic synthesis are discussed.

Among the hypervalent iodine compounds, iodine(III) tris(trifluoroacetate) (ITT) has not been well investigated. This is partly because the reagent is extremely unstable towards moisture, although it is readily prepared. However, several interesting reactions of this reagent with alkanes, alkenes, ethers, and ketones have been reported.[1] During our previous investigation of the reaction of aromatic ketones with ITT[2] we found that 1,2-diphenylethanone gave 2-hydroxy-2-(2-iodophenyl)-1-phenylethanone (**5a**) in fairly good yield. This may suggest that iodine could be incorporated into the aromatic ring via an intermediate involving enol form of **5a**. We therefore investigated the reactions of 1,1-diarylethenes, 1,1-diarylpropene, and 1,1,ω,ω-tetraarylalkadienes; however, these gave mainly 1,2-diaryl-1-alkanones and aryl-substituted diketones. It seems to us that such reactions may have a synthetic utility in the preparation of 1,2-diarylethanones and 1,2-diarylpropanones; thus, these reactions were examined by changing the molar ratios of the substrate versus ITT, the substituent in the aromatic ring as well as in olefinic double bond, the reaction temperature, the reaction time, and the solvents.

Results and Discussion

1,1- and 1,2-Diarylethenes. When the reactions of 1,1-diphenylethene (**1a**) with ITT were carried out in various molar ratios at 23 °C for 3 h (Table 1), the products were found to be 1,2-diphenylethanone (**2a**), 1-phenyl-2-(4-iodophenyl)ethanone (**3a**), 2-hydroxy-1,2-diphenylethanone (**4a**), and 2-hydroxy-2-(2-iodophenyl)-1-phenylethanone (**5a**). The best total yield for the products was attained at a molar ratio of 1 : 1 (Table 1, Entry 3). The yield also depended on the temperature: it gave a similar yield at lower temperature, though the major product was **3a** at the reflux temperature (Entry 4). The products distribution changed greatly, depending on the solvent used (Entries 7—12). The reaction in benzene yielded only two products, **2a** and 2-iodo-1,1-diphenylethene (**6a**). In dichloromethane and hexane the reaction gave almost the same products as in the reaction in CCl_4, but in poor yields. In tetrahydrofuran and acetonitrile **6a** was found to be the sole product in poor yield. The reaction was also examined by changing the reaction times (Entries 13—18). It was observed that the maximum yield of **2a** was attained after 1 h, and then the yield gradually decreased, while **3a** slightly increasd.



The reactions were examined for 1-(4-fluorophenyl)-1-phenylethene (**1b**), 1-(4-chlorophenyl)-1-phenylethene (**1c**), 1-(4-bromophenyl)-1-phenylethene (**1d**), 1-(4-chlorophenyl)-1-(4-fluorophenyl)ethene (**1e**), 1,1-bis(4-chlorophenyl)ethene (**1f**), 1-(4-bromophenyl)-1-(4-chlorophenyl)ethene (**1g**), 1-(4-chlorophenyl)-1-(4-iodophenyl)ethene (**1h**), 1,1-bis(4-fluorophenyl)ethene (**1i**), and 1,1-bis(4-methoxyphenyl)ethene (**1j**). The results are shown in Table 2.

1,2-Diarylethanone obtained from **1b** was a mixture of 2-(4-fluorophenyl)-1-phenylethanone (**2b**) and 1-(4-fluorophenyl)-2-phenylethanone (**2'b**) with an isomer ratio of 69 : 31, which was determined by measuring the intensities of the signals due to the methylene groups in their ^{1}H NMR spectra with the help of a shift reagent, Eu(fod)$_3$. 1,2-Diarylethanones from **1d**, **1e**, and **1g** were also found to be a mixture of two isomers, the ratios of which were determined in the same way as mentioned above (Table 2). Compounds **1h—j** gave an ethanone (**2i**), ethanediones (**7h**, **i**, **8j**), and a 1,1-diiodoethene (**9i**). The reaction of *trans*-stilbene (**1k**) yielded *erythro*-1,2-diphenyl-1,2-ethanediol (**10k**) (Entry 28).

Arylpropenes. Aryl migration was also observed in the reaction of arylpropenes as in that of 1,1-

diarylethenes. 2-Phenylpropene (**11a**) gave 1-phenyl-2-propanone (**12a**) and 1-(4-iodophenyl)-2-propanone (**13a**) (Entry 29). 1,1-Diphenylpropene (**11b**), 1-(4-chlorophenyl)-1-phenylpropene (**11c**), and 1,1-bis(4-chlorophenyl)propene (**11d**) yielded the corresponding 1,2-diaryl-1-propanones, (**12b**, **12c**, **12'c**, and **12d**), respectively (Entries 30—32). The isomer ratio was found to be 69 : 31 for **12c** and **12'c**.

1,1,ω,ω-Tetraarylalkadienes. We also studied the reactions of 1,1,ω,ω-tretraarylalkadienes. The reactions of 1,1,4,4-tetraphenyl-1,3-butadiene (**14a**) and 1,1,4,4-tetrakis(4-chlorophenyl)-1,3-butadiene (**14b**) with ITT gave allyl phenyl ketones, i.e. 1,2,4,4-tetraphenyl-3-buten-1-one (**15a**) and 1,2,4,4-tetrakis(4-chlorophenyl)-3-buten-1-one (**15b**). The reactions of 1,1,5,5-tetraphenyl-1,4-pentadiene (**14c**) and 1,1,5,5-tetrakis(4-chlorophenyl)-1,4-pentadiene (**14d**) yielded diketones, i.e. 1,2,4,5-tetraphenyl-1,5-pentanedione (**16c**) and 1,2,4,5-tetrakis(4-chlorophenyl)-1,5-pentanedione (**16d**). Similarly, the reaction of 1,1,6,6-tetraphenyl-1,5-hexadiene (**14e**) and 1,1,6,6-tetrakis(4-

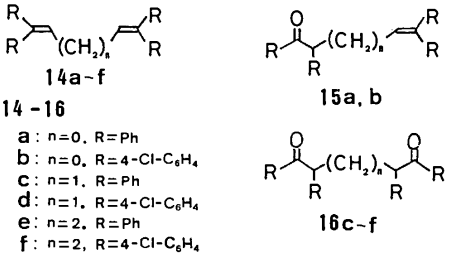
a) Yields are based on the substrate added. b) Substrate was recovered (60%).

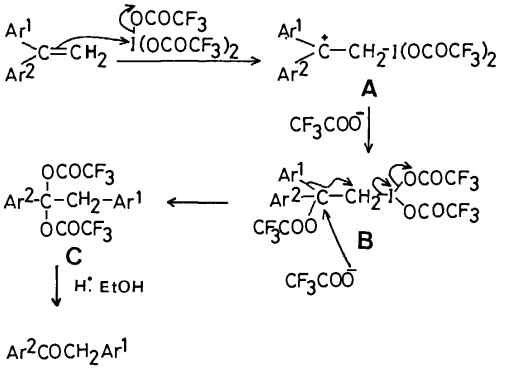
chlorophenyl)-1,5-hexadiene (**14f**) gave 1,2,5,6-tetraphenyl-1,6-hexanedione (**16e**) and 1,2,5,6-tetrakis(4-chlorophenyl)-1,6-hexanedione (**16f**), respectively (Table 3). These diketones (**16c**—**f**) can be a mixture



of two diastereoisomers; however, the ^{1}H NMR spectra of these compounds showed that only one of the isomers is produced. The reaction of 1,1,2-triphenylethene with ITT yielded a complex mixture, the products of which could not be characterized.

Reaction Mechanisms. The reaction of alkenes with ITT has been reported by Buddrus,[3] who described that trifluoroacetoxyl groups added to the double bond to form mainly 1,2-glycol bis(trifluoroacetate). The reaction of styrene was briefly mentioned as giving 1,1-bis(trifluoroacetate) as well as 1,2-bis(trifluoroacetate).[4] Our study revealed that 1,1-diaryl-1-alkenes always gives ketones. The reaction mechasnism could be depicted as involving 1,2-aryl shift (**B**→**C**) and the hydrolysis of the reaction intermediate (**C**) upon treatment with aqueous acid (Scheme 1). The ^{1}H NMR (CCl_4) spectrum of the reaction mixture after an hour of stirring showed a singlet at δ=3.83 corresponding to the methylene group in **C**. The IR spectrum (CCl_4) also exhibited a strong absorption at 1802 cm^{-1} due to a trifluoroacetoxyl group. Evidence for an intramolecular rearrangement was obtained when a mixed substrate, **1a** and **1f**, was subjected to a reaction with ITT. The only products that we could find were **2a**, **2f**, and **3a**; there was no crossover product, such as 2-(4-chlorophenyl)-1-phenylethanone and 1-(4-chlorophenyl)-2-phenylethanone.

The substituent in the aromatic ring has a significant effect on the migratory aptitude of the aryl group. As shown in the isomer ratio of **2b**:**2'b**, which is in



Scheme 1.

favor of **2b**, the 4-fluorophenyl group is more movable than the phenyl group. The phenyl group, on the other hand, is more readily transfered than the 4-bromophenyl and 4-chlorophenyl groups, the latter two being about the same in migratory aptitute. Thus, the order of migratory aptitude is as follows:

$$4\text{-F-}C_6H_4\text{-} > C_6H_5\text{-} > 4\text{-Br-}C_6H_4\text{-} \fallingdotseq 4\text{-Cl-}C_6H_4\text{-}$$

1-Aryl-2-(4-iodophenyl)ethanones (**3a** and **3h**) and 1-(4-iodophenyl)-2-propanone (**13a**) may be formed after a migration of the phenyl group in intermediate **A**. The formation of 2-hydroxyethanone (**5a**) and ethanediones (**7**) has already been discussed in a previous paper.[2]

The formation of iodoethenes, **6a** and **9j**, indicates the electron-donating nature of phenyl and 4-methoxyphenyl groups. These groups stabilize the carbonium ion **A** which is deprotonated and, eventually, affords the iodoethenes (**6a** and **9j**).

In conclusion, the reaction of ITT proved to be useful for the preparation of ethanones and 1,1,ω,ω-tetraarylalkanediones from 1,1-diarylethenes and 1,1,ω,ω-tetraarylalkadienes, respectively. The reaction involves intramolecular aryl migration, confirmed by the absence of the crossover products in the product mixture.

Experimental

Measurements. All ^{1}H NMR spectra were taken in deuteriochloroform or carbon tetrachloride solutions with tetramethylsilane as the internal standard on a JNM-PMX 60 SI spectrometer (60 MHz). The IR spectra were measured in chloroform solutions on a JASCO A-102 IR spectrometer. The mass spectra were obtained with JMS-OISG-2 and JMS-DX-303 HF instruments using a direct-insertion probe at an ionizing voltage of 70 eV. The melting points were determined with a Yanagimoto micromelting point apparatus and were not corrected.

Materials. Arylethenes (**1a**—**j**) arylpropenes (**11a**—**d**) and 1,1,ω,ω-tetraarylalkadienes (**14a**—**f**) were obtained by the dehydration of the corresponding alcohols, which were prepared by a Grignard reaction.[5] **1k** was commercially available from Katayama Chemical Industories. **1g**: Mp 71—72 °C (ethanol); IR ν (cm^{-1}) 1659 (C=C); ^{1}H NMR

($CDCl_3$) δ=5.51 (2H, s, $=CH_2$), 7.03—7.30 (6H, m, ar.H), and 7.34—7.59 (2H, m, H-2′, H-6′). Found: *m/z* 291.9653, Calcd for $C_{14}H_{10}{}^{79}Br^{35}Cl$: M, 291.9655. **1h**: Mp 67 °C (ethanol); IR ν (cm^{-1}) 1660 (C=C); ^1H NMR ($CDCl_3$) δ=5.41 (2H, s, $=CH_2$), 6.89—7.16 (2H, m, H-3′, H-5′), 7.19—7.46 (4H, m, ar.H), and 7.49—7.76 (2H, m, H-2′, H-6′). Found: *m/z* 339.9542, Calcd for $C_{14}H_{10}{}^{35}ClI$: M, 339.9516.

Reactions of Iodine(III) Tris(trifluoroacetate). The general procedure for the reaction of ITT was as follows. To a solution of a substrate (1 or 2 mmol) in a solvent (20 cm^3), iodine(III) tris(trifluoroacetate)[2] (0.5—2 mmol, as shown in Tables 1, 2, and 3), was added under a nitrogen atmosphere. The solution was stirred with undissolved ITT at 23 °C for 3 h. Water (30 cm^3) was added to the reaction mixture and the mixture was stirred again for 1 h. The reaction mixture was then extracted with chloroform and the organic layer was separated and washed with 5% aqueous sodium thiosulfonate solution, and water. The solvent was removed under reduced pressure and the residue was heated with a mixture of ethanol (30 cm^3) and concd hydrochloric acid (0.5 cm^3) at 100 °C for 1 h. The solvent was removed under reduced pressure. The products were separated on TLC with benzene as the developing solvent. The yields on reasonably pure products are summarized in Tables 1,2, and 3. Analytical samples were further purified by recrystallization. The known compounds were identified by comparisons of their spectral data and/or the melting points with those found in the literature.

Perkin-Markovnikov Type Reaction Initiated with Electrogenerated Superoxide Ion

Fumihiro OJIMA and Tetsuo OSA*
Pharmaceutical Institute, Tohoku University, Aobayama, Aoba-ku, Sendai 980
(Received May 12, 1989)

The cyclic condensation of active methylene compounds such as diethyl malonate, dimethyl malonate, ethyl acetoacetate, or acetylacetone and dibromoalkanes such as 1,2-dibromoethane, 1,3-dibromopropane, 1,4-dibromobutane, 1,5-dibromopentane, 1,6-dibromohexane, 1,3-dibromobutane, or 1,4-dibromopentane with electrogenerated superoxide ion was studied electrochemically in *N,N*-dimethylformamide (DMF) using cyclic voltammetry (CV) and controlled potential macro-electrolysis. The CV shows that electrogenerated superoxide ion reacts with both active methylene compounds and dibromoalkanes in the dissolved oxygen medium. Controlled potential macro-electrolysis of the above components generally yielded cycloalkanes as the main products. In comparison, the chemical method using sodium ethoxide was also carried out. Two reaction mechanisms via the proton abstraction of active methylene compounds with electrogenerated superoxide ion and via the nucleophilic attack of the superoxide ion on dibromoalkanes are presented.

Superoxide ion ($O_2^{\cdot-}$) is not only one of the most important activated forms of molecular oxygen in biological systems but also novel activating reagent for organic synthesis,[1-3] and has recently attracted a great deal of attention of biological and organic chemists. Superoxide ion is produced by the electrochemical reduction of oxygen dissolved in non-aqueous solvent such as pyridine, acetonitrile, or *N,N*-dimethylformamide (DMF) at −0.85 V vs. silver-silver chloride (Ag/AgCl) as shown in Eq. 1.

$$O_2 + e^- \rightarrow O_2^{\cdot-} \quad (1)$$

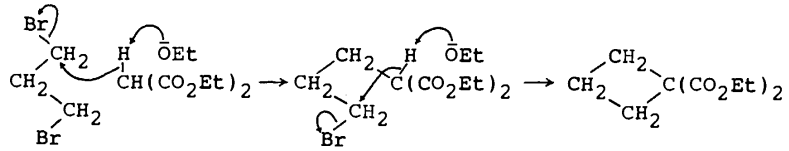
Superoxide ion possesses various reactivities, namely characteristics as a strong base, a nucleophile, an oxidant, a reductant, a free radical, and an electron-transfer agent.[4] In aprotic solvents, superoxide ion acts as an electrogenerated base (EGB),[5] and abstracts a proton of an active methylene group to form a carbanion (EWG-$\bar{C}$H-EWG, EWG: electron-withdrawing group). Electrogenerated superoxide ion has another feature, as a nucleophile;[6] it reacts with alkyl halides to form alkylperoxy radicals (R-OO·), which might be readily reduced further by electrogenerated superoxide ion or by an electron from the electrode to form alkylperoxide ions (R-OO$^-$).

Alkali metal superoxides of potassium and sodium salts are well-known, but their insolubility in the usual organic solvents makes them of little preparative use.[6] Therefore, the reaction of alkali metal superoxides with organic compounds in benzene has been reported by the use of crown ethers in order to solve the problem of their insolubility.[7] On the other hand, the electrochemical method is experimentally more convenient because superoxide ion is continuously generated on the electrode and its solubility is sufficiently high in the presence of the tetraethylammonium cation of supporting electrolyte.[8]

We have investigated the characteristics of the reactivity of electrogenerated superoxide ion toward active methylene compounds and dibromoalkanes, and have reported preliminary results on the reaction of the active methylene compound, such as diethyl malonate, dimethyl malonate, or ethyl acetoacetate and dibromoalkane with electrogenerated superoxide ion.[9] In this paper, we describe in detail the reaction of dibromoalkanes and active methylene compound of acetylacetone as well as malonates and ethyl acetoacetate with electrogenerated superoxide ion in DMF solutions, using cyclic voltammetry and controlled potential macroelectrolysis.

The reaction of this type is well known as Perkin-Markovnikov reaction (Scheme 1).[10,11] The reaction using sodium ethoxide as a base to form an aliphatic ring compound is widely used in organic syntheses. However, the reports on the reaction of this type using electrogenerated superoxide ion as a base, have not previously been published.

After detailed investigation using cyclic voltammetry and macro-electrolysis in DMF, we have concluded that the present reaction system should be considered in terms of the nucleophilic reaction of electrogenerated superoxide ion with dibromoalkanes as frequent as in terms of the proton abstraction of electrogenerated superoxide ion from active methylene compounds. We report here the reaction of active methylene compounds and dibromoalkanes using cyclic



Scheme 1.

voltammetry and macro-electrolysis in DMF, and discuss the results in terms of the basic properties and the nucleophilicity of electrogenerated superoxide ion.

Experimental

Materials. DMF (Guaranteed reagent, Tokyo Kasei) was stored over Molecular Sieves (4A 1/16) for 24 h and then distilled under reduced pressure. Further purification was achieved by passage through a column of activated alumina (ICN Alumina N-Akt. I). Tetraethylammonium perchlorate (TEAP) from Tokyo Kasei (Guaranteed reagent) was dried in vacuo and used as a supporting electrolyte in the electrochemical experiments. The substrates, diethyl malonate (Guaranteed reagent, Nakarai Chemicals), dimethyl malonate (Extra pure reagent, Tokyo Kasei), ethyl acetoacetate (Extra pure reagent, Wako Pure Chemical Industries), and acetylacetone (Guaranteed reagent, Nakarai Chemicals) were purchased commercially and were redistilled. 1,2-Dibromoethane (Extra pure reagent), 1,3-dibromopropane (Extra pure reagent), 1,4-dibromobutane (Guaranteed reagent), 1,5-dibromopentane (Guaranteed reagent), 1,6-dibromohexane (Extra pure reagent), 1,3-dibromobutane (Extra pure reagent), and 1,4-dibromopentane (Extra pure reagent) were also obtained commercially from Tokyo Kasei and were distilled under reduced pressure before use.

Cyclic Voltammety. Cyclic voltammetry was carried out in a DMF solution containing 0.2 M (1 M=1 mol dm^{-3}) TEAP as a supporting electrolyte. A glassy carbon (GC) disk (area ca. 0.71 cm^2) was employed as a working electrode, and a platinum wire was employed as a counter electrode for cyclic voltammetry. The working electrode was polished with a 0.05 μm alumina/water slurry on a felt surface, sonicated in distilled water, throughly washed with acetone, and dried before electrochemical measurements. The cathode potentials were referred to Ag/Ag^+ (0.05 M $AgNO_3$ and 0.1 M TEAP in acetonitrile). Cyclic potential sweeps were generated by a self-made function generator in conjunction with a Hokuto Denko Model HA-305 potentiostat/galvanostat. Cyclic voltammograms were recorded on a Graphtec Model WX1200 X-Y recorder. All electrochemical measurements were carried out at room temperature under a nitrogen atmosphere.

Controlled Potential Macro-Electrolysis. For controlled potential macro-electrolysis, a three compartment cell (H-type cell), in which cathodic and anodic chambers were separated by two fine-porosity sintered-glass frits, was employed with a magnetic stirrer and a reference electrode was put near the cathode. A glassy carbon plate with a surface area of ca. 12.5 cm^2 was used as the cathode, and a platinum plate was used as the anode. An electrolyte solution (0.2 M TEAP) of 60 cm^3 containing two substrates (0.1 M activated methylene compound and 0.1 M dibromoalkane) was placed in the cathodic chamber (25 cm^3), the anodic chamber (25 cm^3), and the middle chamber (10 cm^3). Dry oxygen was bubbled through the cathode. The cathode potential was controlled with a Hokuto Denko Model HA-305 potentiostat/galvanostat. The quantity of electricity passed was measured with a Hokuto Denko Model HF-201 coulomb/amperehour meter. These electrolyses were carried out at room temperature under a nitrogen atmosphere.

Identification of Products and Determination of the Yields. The products of the electrolyses were separated from the catholyte and identified by the following procedure. The catholyte was evaporated in vacuo to remove DMF. The residue was dissolved in water and extracted with diethyl ether. The ether layer was dried over anhydrous sodium sulfate and the ether was removed by distillation under reduced pressure. The resulting liquid was tried to be separated into its components by silica-gel column chromatography using several organic mixed eluents such as hexane–diethyl ether (20 : 1), but could not be well separated.

Authentic samples of the cycloalkanes were prepared by the ordinary chemical preparative method.[12] The procedure was as follows. In a 100-ml three-necked round bottomed flask, equipped with a reflux condenser capped with a calcium chloride tube, a magnetic stirrer, and a 50-ml pressure-equalizing dropping funnel for addition of prepared 0.02 g·atom sodium ethoxide–ethanol solution, were mixed 0.01 mol each of active methylene compound and dibromoalkane. The mixture was heated to 80 °C and vigorously stirred while the sodium ethoxide–ethanol solution was slowly added into the flask over a 1.5 h period. After the addition was finished, the mixture was refluxed, with continued stirring, for an additional 45 min, and then the ethanol was removed by distillation. The reaction mixture was cooled, and 5 ml of cold water was added. After the sodium halides were completely dissolved, the organic layer was separated and the aqueous layer was extracted with three 10 ml portions of diethyl ether. The combined ether extracts were shaken with 5 ml of saturated NaCl solution, dried over anhydrous sodium sulfate, filtered, and concentrated on a rotary evaporator. The identity of the electrochemically prepared cycloalkanes with the respective authentic samples was established by gas chromatography and GC-MS spectroscopy. The main products of electrolyses were detected by using a Shimadzu Model GC-4CM gas chromatograph equipped with 2 m×3 mmϕ column packed with Carbowax 20M, and identified by comparing their retention times with those of authentic samples. Yields of the products were also determined by gas chromatographic analysis. The by-products of electrolyses were identified by using a JEOL Model JMS-DX300 GC-MS spectrograph equipped with 2 m × 3 mmϕ column packed with Silicone OV-101.

Results and Discussion

Cyclic Voltammetry of Active Methylene Compounds and Dibromoalkanes. The cyclic voltammetry of diethyl malonate (**1**), dimethyl malonate (**2**), ethyl acetoacetate (**3**), acetylacetone (**4**), 1,2-dibromoethane (**a**), 1,3-dibromopropane (**b**), 1,4-dibromobutane (c), 1,5-dibromopentane (**d**), 1,6-dibromohexane (**e**), 1,3-dibromobutane (**f**), and 1,4-dibromopentane (**g**) was carried out in a 0.2 M TEAP/DMF solution under a nitrogen atmosphere. All the substrates were reduced at more negative potentials than −2.5 V vs. Ag/Ag^+ as shown in Table 1. The compounds **4**, **c**, **d**, **e**, and **g** exhibited prepeaks (E_p^1) at more positive potentials than the main peaks (E_p^2). The cyclic voltammograms of **1**, **a**, and c are demonstrated in Fig. 1. The reduction peak of **1** could not

be measured directly because of the deformed CV curve, but the peak potential is estimated to be −3.36 V.

Cyclic Voltammetry of Oxygen in the Presence of Active Methylene Compounds (1—4). As the first reduction potential of oxygen in a 0.2 M TEAP/DMF solution on glassy carbon electrode is −1.28 V, the dissolved oxygen is generally reduced more easily than active methylene compounds. Figure 2 indicates the cyclic voltammograms of saturated oxygen in the absence and presence of **1**. In the absence of **1**, the ratio of the anodic peak current (i_a°) to the cathodic peak current (i_c°) is almost 1.0; that is, the superoxide ion formed in this system is stable. In the presence of 2 mM **1**, the reductive peak current of oxygen at −1.28 V increased and the reoxidation peak current of the superoxide ion at −1.16 V decreased, in comparison with those in the absence of **1**. These results indicate that some of the superoxide ion are consumed by the reaction of **1**. The cathodic peak current of oxygen is linear to the square root of scan speed in the presence of **1** (Inset in Fig. 3). This means that the electrode reaction of oxygen is apparently diffusion-controlled, even if **1** is present in the system. The oxygen reduction behavior in the presence of other active methylene compounds **2**, **3**, and **4** gave similar to those of **1**. But the cyclic voltammograms of oxygen reduction in the case of **3** and **4** gave prepeaks. The prepeaks in the case of **3** is shown in Fig. 4.

The cyclic voltammetry of oxygen in the differrent concentrations of **1** is demonstrated in Fig. 5. Increasing the concentration of **1** resulted in a corresponding increase in the reduction peak current of oxygen. This increase of catalytic current did not continue

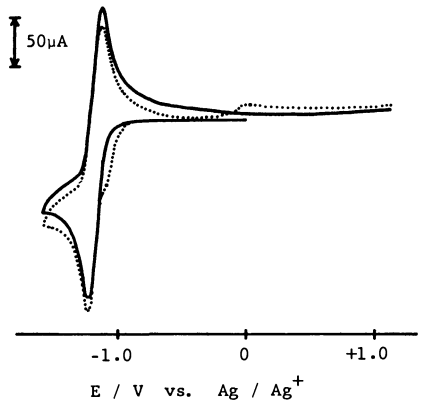

Fig. 4. Cyclic voltammograms of O_2 in the absence (——) and presence (·····) of 2 mM **3**.
Sweep rate: 0.1 V s^{-1}.

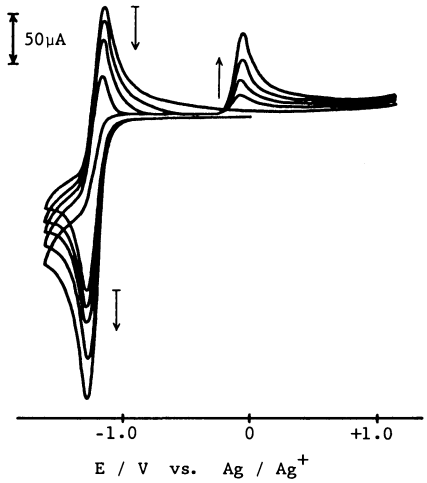

Fig. 5. Cyclic voltammograms of O_2 in the presence of different concentrations (0, 2, 4, 8, and 16 mM) of **1**.
Sweep rate: 0.1 V s^{-1}.

infinitely but reached a saturation at 18 mM **1**. The maximum value of the ratio, i_c/i_c°, is ca. 1.65, where i_c and i_c° are the reduction peak currents of oxygen in the presence and absence of **1**, respectively. These behavior is shown in Fig. 6. Increasing the concentration of **1** also resulted in a corresponding decrease in the reoxidation peak current of the superoxide ion. The peak current ratios, i_a/i_a° are getting smaller with increasing concentrations of **1**, where i_a and i_a° are the reoxidation peak currents of the superoxide ion in the presence and absence of **1**, respectively. These results also support that the electrogenerated superoxide ion is consumed by subsequent chemical reactions during cyclic voltammetry. The new anodic wave at −0.08 V (Fig. 5) is considered to be the oxidation peak characteristics of carbanion ($\overline{C}H(CO_2Et)_2$) at glassy carbon electrode, overlapped with the reoxidation wave of hydroperoxide ion (HO_2^-) formed by the following elementary reactions.

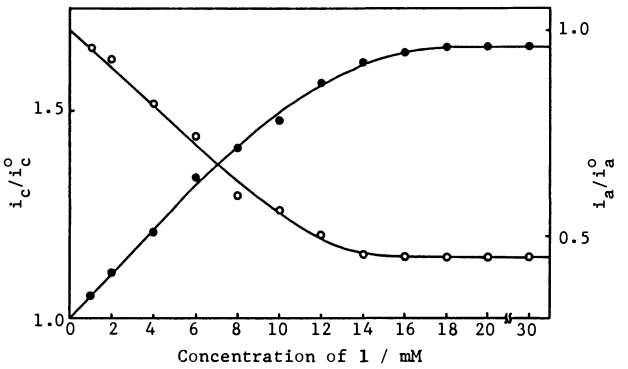

Fig. 6. Dependences of the peak current ratio for the concentration of **1**.
Sweep rate: 0.1 V s^{-1}, ●: i_c/i_c°, ○: i_a/i_a°.

$$O_2 + e^- \rightarrow O_2^{\cdot-} \quad (1)$$

$$\begin{matrix} R_1 \\ \diagdown \\ \quad CH_2 \\ \diagup \\ R_2 \end{matrix} + O_2^{\cdot-} \rightarrow \begin{matrix} R_1 \\ \diagdown \\ \quad \overline{C}H \\ \diagup \\ R_2 \end{matrix} + HO_2^{\cdot} \quad (2)$$

$$HO_2^{\cdot} + e^- \rightarrow HO_2^- \quad (3)$$

R_1, R_2: electron-withdrawing group (EWG)

The new anodic waves agreed with the oxidation peaks observed in the cyclic voltammogram of **1** by the addition of sodium ethoxide and in the cyclic voltammogram of H_2O_2 by the addition of tetraethylammonium hydroxide, respectively.

This oxidation peak current increased with the increasing concentrations of **1**. The increase did not continue infinitely, but reached a saturation in the presence of **1** of more than 18 mM. In the acetylacetone system, three new anodic peaks beside the oxidation peak of the superoxide ion formed appeared as shown in Fig. 7. The first anodic peak at −0.05 V and the second anodic peak at +0.10 V were assigned

Sweep rate: 0.1 V s^{-1}, ——: 0 mM, ----: 4 mM, —·—: 8 mM, ·····: 16 mM.

Table 2. Observed Peak Potentials in the CV of O_2 under **1**—**4**

	Reduction peak potential/V		Reoxidation peak potential/V			
	Prepeak	Oxygen	Superoxide ion	HO_2^-	Carbanion	Unknown
1	—	−1.28	−1.16	−0.08	−0.08	—
2	—	−1.28	−1.16	−0.06	−0.06	—
3	−1.20	−1.28	−1.17	−0.07	+0.00	+0.86
4	−1.18	−1.28	−1.16	−0.05	+0.10	+0.57

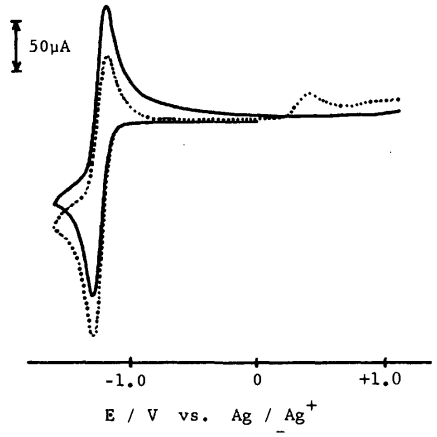

Fig. 8. Cyclic voltammograms of O_2 in the absence (——) and presence (·····) of 2 mM **a**.
Sweep rate: 0.1 V s^{-1}.

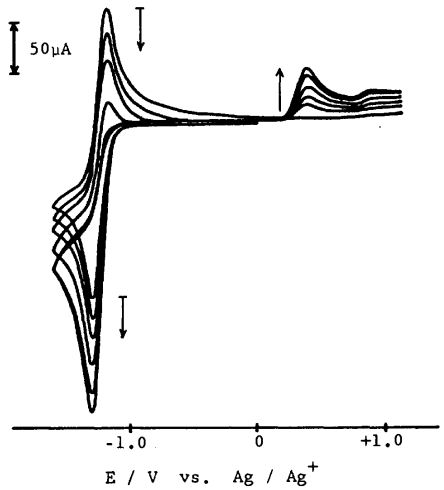

Fig. 9. Cyclic voltammograms of O_2 in the presence of different concentrations (0, 1, 2, 4, 8, and 16 mM) of **a**.
Sweep rate: 0.1 V s^{-1}.

to the oxidation peaks of HO_2^- and $\overline{C}H(COCH_3)_2$, respectively. The second peak was confirmed to appear by the addition of sodium ethoxide. The third anodic peak was not reasonably assigned. The cyclic voltammograms of oxygen in the presence of **2** were very similar to those of **1** and those of **3** were similar to those of **4**. These results are summarized in Table 2.

By comparing the ratio of anodic peak current to cathodic peak current for the oxygen redox system in the presence of 8 mM active methylene compounds, the superoxide ion is found to react with active methylene compounds in the order of **4**(pK_a=9.0)>**3** (10.2)>**2**=**1**(13.5). This order is the same as that of acidity (pK_a) of active methylene compounds as carbon acids.

Cyclic Voltammetry of Oxygen in the Presence of Dibromoalkanes (a—g). As a typical result, the cyclic voltammetry of oygen in the presence of **a** is shown in Fig. 8. This cyclic voltammogram is very similar to that in the presence of **1**. In the presence of 2 mM **2**, the first reduction peak current of oxygen at −1.30 V increased, and the reoxidation peak current of the superoxide ion at −1.18 V decreased, in comparison with those of the saturated oxygen alone. These results indicate a progress of the reaction of superoxide ion with **a**. The cyclic voltammetry of oxygen in the presence of other dibromoalkanes (**b**—**g**) gave similar results to that of **a**.†

† The electrode reaction of oxygen is also apparently diffusion-controlled in the presence of **a**—**g**.

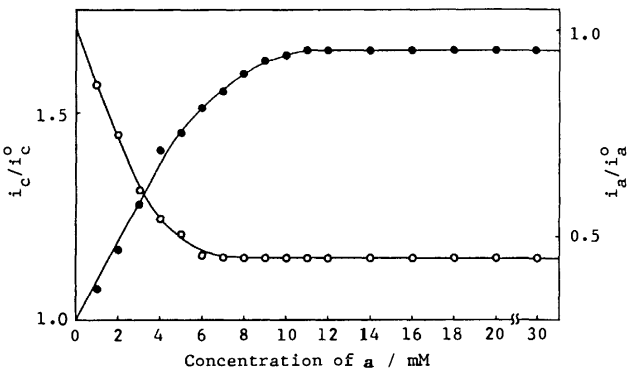

Fig. 10. Dependences of the peak current ratio for the concentration of **a**.
Sweep rate: 0.1 V s^{-1}, ●: i_c/i_c°, ○: i_a/i_a°.

When dichloroalkanes were used in place of dibromoalkanes, no change of cyclic voltammogram in the absence and presence of dichloroalkanes was observed. This means that the superoxide ion is hard to react with dichloroalkanes. On the other hand, when diiodoalkanes were used in place of dibromoalkanes, the superoxide ion reacted with diiodoalkanes to reach a saturation at lower concentrations than dibromoalkanes.

The cyclic voltammetry of oxygen was also carried out in the different concentrations of dibromoalkanes. A typical result containing **a** is shown in Fig. 9.

Table 3. Observed Peak Potentials in the CV of O_2 under a—g

	Reduction peak potential/V		Reoxidation peak potential/V		
	Prepeak	Oxygen	Superoxide ion	Bromide ion	Unknown
a	—	−1.30	−1.18	+0.38	+0.86
b	—	−1.30	−1.18	+0.33	+0.86
c	—	−1.29	−1.18	+0.33	+0.83
d	—	−1.29	−1.18	+0.35	+0.85
e	—	−1.29	−1.18	+0.40	+0.90
f	—	−1.30	−1.19	+0.32	+0.82
g	—	−1.30	−1.19	+0.32	+0.82

Increasing the concentration of **a** resulted in a corresponding increase in the reduction peak current and reached a saturation in the presence of 11 mM **a**. The maximum value of the ratio, i_c/i_c°, is ca. 1.65 and the same as in the presence of active methylene compounds. This behavior is demonstrated in Fig. 10. Two new anodic peaks at +0.38 V and +0.86 V observed in the presence of **a** can be ascribed to the oxidation of bromide ion which was produced by the nucleophilic substitution of the superoxide ion

$$Br(CH_2)_nBr + O_2^{\cdot-} \rightarrow Br(CH_2)_nOO\cdot + Br^- \quad (4)$$

with the dibromoalkane (Fig. 8). These oxidation peak currents also increased with the increasing concentrations of **a** and reached a saturation at the concentration of 11 mM. The cyclic voltammograms of oxygen in the presence of other dibromoalkanes (**b**—**g**) gave similar behavior to that of **a** and are summarized in terms of the potentials in Table 3.

Determination of Simple Rate Constants. In order to clarify each reaction rate of the electrogenerated superoxide ion with a variety of substrates, rate constants have been estimated based on a simple ECE reaction mechanism and the values determined by use of a digital simulation method are listed in Table 4. This is the method which simulates the ratio of enhancement of the cathodic peak current of oxygen reduction in the presence of substrate to that in the absence of substrate. The results indicate that the superoxide ion is more reactive with dibromoalkanes than with active methylene compounds. The rate constants for **3** and **4** could not be obtained accurately in the present simulation method, since the cyclic voltammograms of oxygen showed the prepeaks which might be a very rapid reaction between $O_2^{\cdot-}$ and **3** or **4**.

Table 4. Reaction of Electrogenerated $O_2^{\cdot-}$ with Substrates

Substrate	Rate constant $k^{a)}$/$M^{-1}s^{-1}$
Diethyl malonate (**1**)	1×10^2
Dimethyl malonate (**2**)	1×10^2
Ethyl acetoacetate (**3**)	1×10^2
Acetylacetone (**4**)	1×10^2
1,2-Dibromoethane (**a**)	6×10^2
1,3-Dibromopropane (**b**)	6×10^2
1,4-Dibromobutane (**c**)	5×10^2
1,5-Dibromopentane (**d**)	6×10^2
1,6-Dibromohexane (**e**)	6×10^2
1,3-Dibromobutane (**f**)	6×10^2
1,4-Dibromopentane (**g**)	5×10^2

a) Determined by digital simulation based on the following mechanisms.

(1) $O_2 + e^- \longrightarrow O_2^{\cdot-}$
$O_2^{\cdot-} + RH_2 \longrightarrow RH^- + HO_2^{\cdot}$
$O_2^{\cdot-} + e^- \longrightarrow HO_2^-$
$R = (EWG)_2C$

(2) $O_2 + e^- \longrightarrow O_2^{\cdot-}$
$O_2^{\cdot-} + RBr \longrightarrow ROO^{\cdot} + Br^-$
$ROO^{\cdot} + e^- \longrightarrow ROO^-$
$R = Br(CH_2)_n$

Controlled Potential Macro-Electrolysis. The controlled potential macro-electrolyses of oxygen in the presence of two kinds of substrates, active methylene compounds (**1**—**4**) and dibromoalkanes (**a**—**d**, **f**, and **g**) were carried out at −1.5 V in a 0.2 M TEAP/DMF solution. At −1.5 V, only oxygen was reduced to superoxide ion by one-electron transfer, while both

7a—d **7f, g**
8a—d **8f, g**

Scheme 2.

the substrates, active methylene compounds and dibromoalkanes, were not reduced.

The main products were aliphatic cyclic or annulated compounds of one carbon extension comparing to the starting dibromoalkanes (Scheme 2).

Diethyl cycloalkanedicarboxylates (**5a—d**, **f**, and **g**) were produced from diethyl malonate and dibromoalkanes in the presence of electrogenerated superoxide ion, dimethyl cycloalkanedicarboxylates (**6a—d**, **f**, and **g**) from dimethyl malonate and dibromoalkanes, ethyl 1-acetylcycloalkanecarboxylates (**7a—d**, **f**, and **g**) from ethyl acetoacetate and dibromoalkanes, and 1,1-diacetylcycloalkanes (**8a—d**, **f**, and **g**) from acetylacetone and dibromoalkanes, respectively.

The electrolysis results are summarized in Table 5. Numbers in parentheses show the yields of the corresponding products by the ordinary chemical preparative method using sodium ethoxide as a base. The total amount of charge passed was ca. 482.5 C (2 F mol^{-1}). The yields by the electrochemical method and the ordinary chemical method are based on the consumed amount of active methylene compounds. The highest yield of the annulated compounds by the electrochemical method was 90% of **6c**. The yields of **5**, **6**, and **8** by the electrochemical method were higher than those by the chemical method except the case of **5f**. However, the yields of **7** were of the inverse tendency. The yields of the annulated products depended markedly on the methylene length of α,ω-dibromoalkanes, and the yields of stable ring size such as five or six membered ring were generally high. The reason can be explained by the degree of strain, when the ring closure occurs.

In the case of **1** or **2** as active methylene compound, the yields of the annulated products by the electrochemical method decreased in the order of $C_5>C_6>C_4>C_3$, similarly to those observed in the ordinary chemical reaction. In the case of **3**, a somewhat different tendency was observed. For instance, the yields by the electrochemical method decreased in the order of $C_6>C_5>C_4\approx C_3$, whereas the yields by the chemical method was in the order of $C_5>C_4\approx C_6>C_3$.

Table 5. Yields of Annulated Products by Preparative Electrochemical Method

Substrate No.	Product No.	Dibromoalkane a	b	c	d	f	g
1	**5**	49% (28%)	51% (43%)	87% (66%)	82% (50%)	20% (48%)	83% (58%)[a]
2	**6**	52% (4%)	55% (19%)	90% (20%)	81% (21%)	17% (14%)	89% (36%)
3	**7**	28% (20%)	30% (58%)	35% (58%)	56% (67%)	27% (45%)	29% (61%)
4	**8**	19% (3%)	68% (16%)	72% (23%)	58% (25%)	36% (21%)	37% (22%)

a) Numbers in parentheses show the yields of the corresponding products by the chemical preparative method in which 0.01 mol each of active methylene compound and dibromoalkane was reacted with 0.02 g·atom sodium ethoxide in ethanol at 80 °C.

The use of branched dibromoalkanes such as 1,3-dibromobutane (**f**) and 1,4-dibromopentane (**g**) decreased the yields of the annulated products in comparison to those of the same membered ring products formed from α,ω-dibromoalkanes; the yields of **5—8f**, and **7g**, **8g** are lower than those of **5—8c** and **7d**, **8d**, respectively (excluding the cases of **5f**=**5d** and **6f**>**6d**). This trend may be caused by steric hindrance of methyl branch at the carbon substituted.

From the above mentioned results, the following electrochemical reaction mechanism for the system of malonic acid ester and α,ω-dibromoalkane can be presented:

Mechanism 1: Superoxide ion as an EGB

$$O_2 + e^- \rightarrow O_2^{\cdot-} \quad (1)$$

$$\begin{matrix} R_1 \\ \diagdown \\ CH_2 \\ \diagup \\ R_2 \end{matrix} + O_2^{\cdot-} \rightarrow \begin{matrix} R_1 \\ \diagdown \\ \bar{C}H \\ \diagup \\ R_2 \end{matrix} + HO_2^{\cdot} \quad (2)$$

$$HO_2^{\cdot} + e^-(O_2^{\cdot-}) \rightarrow HO_2^- \quad (3)$$

Mechanism 2: Superoxide ion as a nucleophile

$$O_2 + e^- \rightarrow O_2^{\cdot-} \quad (1)$$

$$Br(CH_2)_nBr + O_2^{\cdot-} \rightarrow Br(CH_2)_nOO^{\cdot} + Br^- \quad (4)$$

$$Br(CH_2)_nOO^{\cdot} + e^-(O_2^{\cdot-}) \rightarrow Br(CH_2)_nOO^- \quad (5)$$

$$\longrightarrow Br(CH_2)_nO^- \quad (6)$$

$$\begin{matrix} R_1 \\ \diagdown \\ CH_2 \\ \diagup \\ R_2 \end{matrix} + Br(CH_2)_nOO^- \rightarrow$$

$$\begin{matrix} R_1 \\ \diagdown \\ \bar{C}H \\ \diagup \\ R_2 \end{matrix} + Br(CH_2)_nOOH \quad (7)$$

$$\left(\begin{matrix} R_1 \\ \diagdown \\ CH_2 \\ \diagup \\ R_2 \end{matrix} + Br(CH_2)_nO^- \rightarrow \right.$$

$$\left. \begin{matrix} R_1 \\ \diagdown \\ \bar{C}H \\ \diagup \\ R_2 \end{matrix} + Br(CH_2)_nOH \right) \quad (8)$$

$$\begin{matrix} R_1 \\ \diagdown \\ \bar{C}H \\ \diagup \\ R_2 \end{matrix} + Br(CH_2)_nBr \rightarrow \begin{matrix} R_1 \\ \diagdown \\ C \\ \diagup \\ R_2 \end{matrix} \begin{matrix} H \\ \diagup \\ \\ \diagdown \\ (CH_2)_nBr \end{matrix} + Br^-$$

$$\rightarrow\rightarrow \begin{matrix} R_1 \\ \diagdown \\ C^- \\ \diagup \\ R_2 \end{matrix} \begin{matrix} \\ \diagup \\ \\ \diagdown \\ (CH_2)_nBr \end{matrix} \rightarrow\rightarrow \begin{matrix} R_1 \\ \diagdown \\ C \\ \diagup \\ R_2 \end{matrix} \overset{(CH_2)_n}{\frown} + Br^- \quad (9)$$

R_1, R_2: electron-withdrawing group (EWG)

In mechanism 1, superoxide ion, as an electrogenerated base (EGB), deprotonates an active methylene compound (Eq. 2), and the resulting carbanion reacts with α,ω-dibromoalkane to yield the aliphatic annulated compound (Eq. 9). In mechanism 2, superoxide ion, as a nucleophile, reacts with α,ω-dibromoalkane, and the produced bromoalkylperoxy radical (Eq. 4) is further reduced by superoxide ion or by an electron from the electrode to form bromoalkylperoxide ion

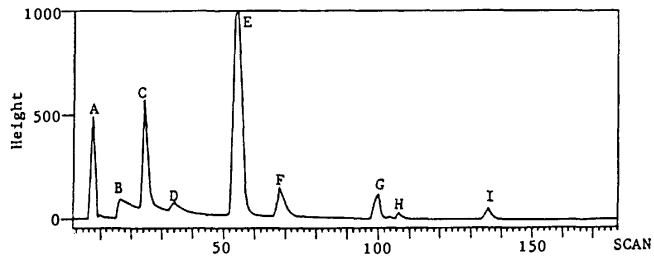

Fig. 11. Typical gas chromatogram of the reaction of $O_2^{\cdot-}$ with **1** and **c**.

F:  (M^+=231),

G:  (M^+=319),

H:  (M^+=333),

I:  (M^+=375).

(Eq. 5) or bromoalkyloxide ion (Eq. 6). The resulting anions deprotonate, as a base, the active methylene compound (Eqs. 7 and 8), and the produced carbanion reacts with α,ω-dibromoalkane to yield the aliphatic annulated compound as mechanism 1 (Eq. 9). The similar reaction mechanism can be presented in the other cases of branched dibromoalkanes.

In addition to the annulated compounds, cyclic ethers such as tetrahydrofuran and diols such as 1,4-butanediol from **c** were also detected as minor products by the careful gas chromatographic analysis at room temperature, and identified by comparing their retention times with those of authentic samples. Other by-products, mainly some dimers, were detected and assigned using GC-MS spectroscopy. The gas chromatogram in the case of the reaction of $O_2^{\cdot-}$ with **1** and **c** is demonstrated in Fig. 11, and each peak was assigned to the compound shown in the figure, respectively. Most of these by-products were not detected in the products by the ordinary chemical method.

These results indicate that the reaction mechanism for the present electrochemical reaction might be partly different from that for the ordinary chemical reaction. The main difference is that electrogenerated superoxide ion forms intermediates shown in Eqs. 4—6, whereas sodium ethoxide does not form such intermediates. Therefore, the carbanion formation via Eqs. 7 and 8 cannot proceed by the ordinary chemical method.

Conclusion

Perkin-Markovnikov type reaction initiated with electrogenerated superoxide ion was investigated electrochemically using cyclic voltammetry and controlled potential macro-electrolysis. By electrolyses, superoxide ion acted as a base and a nucleophile, and reacted with both the substrates, active methylene compounds and dibromoalkanes, to yield the end products, aliphatic cyclic compounds. This electrochemical method can be applied to synthesize one carbon-extended cyclic compounds from dibromoalkanes.

Besides these compounds as the main products, many by-products, such as dimers and cyclic ethers were detected using GC-MS spectroscopy. The formation reaction of the cyclic ethers is a novel reaction which has never been seen in the usual base-catalyzed reactions. All of these results are based on the dual nature of electrogenerated superoxide ion; i.e., basicity and nucleophilicity, which vary with substrates.

Studies of the Acidity and Ionic Conductivity of Silica-Supported Heteropoly Compounds. I. The Dehydration of *t*-Butyl Alcohol over Heteropoly Compound Catalysts

Reiji OHTSUKA,* Yoshio MORIOKA, and Jun-ichi KOBAYASHI
Department of Applied Chemistry, Faculty of Engineering, Shizuoka University, Johoku, Hamamatsu 432
(Received February 21, 1989)

The dehydration of *t*-butyl alcohol (TBA) using various heteropoly compound (HPC) catalysts has been studied. Taking the adsorption of water on the surface of the catalyst into consideration, it is presumed that the dehydration of liquid TBA is governed by a Langmuir-Hinshelwood-like mechanism. Also, the change in the catalytic activity with the amount of HPC supported on the silica suggests that TBA is dehydrated through a pseudo-liquid mechanism in which a few layers of the HPC supported take part in the catalytic reaction. The layer thickness, regarded as a pseudo-liquid phase, depends markedly on the kind of HPC supported. For the dehydration of gaseous TBA, on the contrary, the reaction is found to be of the zero-order; it proceeds through in outer-surface mechanism in which only the outer layer of HPC is effective.

Heteropoly compounds (HPC) e.g., 12-molybdophosphoric acid and its salts have been widely used as catalysts for various kinds of reactions since SOHIO catalysts were applied to the oxidation of α,β-unsaturated aldehydes.[1] As may be seen from the latest industrial applications of the hydration of propylene,[2] the selective oxidation of methacrylaldehyde[3] and the oxidative dehydrogenation of isobutyric acid,[4] it is apparent that heteropoly acid (HPA) catalysts are useful for the hydration, dehydration, and dehydrogenation of organic compounds.[5-9]

Some of the HPA catalysts not only behave as strong acids, but also play rôles as oxidizing agents.[10] Also, it has been reported that both surface and inner sites of solid HPC take part in some catalytic reactions, like liquid catalysts. Misono et al. have called this phenomenon the "pseudo-liquid mechanism."[11] For these reasons, there is still much controversy as to the catalytic rôle in the supported HPC for the respective reactions, despite the fact that they are widely used practically.[12] The present paper, therefore, deals with the dehydration of liquid and gaseous *t*-butyl alcohol (TBA):

$$(CH_3)_3C\text{-}OH \rightarrow (CH_3)_2C{=}CH_2 + H_2O \qquad (1)$$

in the presence of the supported HPA on the basis of the activity and the activation energy of the dehydration reaction obtained. HPC prepared by the substitution of other cations, such as sodium, potassium, and ammonium, for the hydrogen ions of HPA will be examined as well, since the control of acid and oxidizing properties is particularly important for catalytic reactions in order to get products with a high yield and selectivity.

Experimental

Preparation of Catalysts. As-received 12-molybdophosphoric acid and 12-tungstophosphoric acid from the Japan New Metals Co., Ltd., were used. The supports used AEROSIL-200, AEROSIL-OX50, AEROSIL-300, and AEROSIL-380 (Aerosil Nippon Co., Ltd.) has surface areas S of about 200, 50, 130, 300, and 380 m^2g^{-1} respectively. Solutions or emulsions of HPC were prepared as follows: Potassium salt emulsions of HPA were prepared by the slow addition of an aqueous potassium carbonate solution into a HPA solution. Sodium and ammonium salt solutions and cesium salt emulsions were obtained by the same procedures. Bismuth oxide salt solutions were prepared by using bismuth carbonate oxide in 0.10 mol dm^{-3} nitric acid. The degree of the substitution of other cations for the hydrogen ion of HPA was defined as the number of hydrogen-ion-substituted n.

The support-free catalysts were as-received HPA themselves or were prepared drying the HPC solutions or the emulsions at 383 K for 24 h, grinding them, and then calcining them at 573 K for 3 h. The supported catalysts were obtained by the following procedure. The support was calcined at 773 K for 3 h and then impregnated with a required amount of the HPC solution. The resulting solution was dried at 383 K for 24 h, ground, and then calcined at 573 K for 3 h. The supported amount of HPC was expressed as m, milimoles of HPC per gram of support; The m varied are the range of 0.05—1.50 mmol/g-supt. The IR spectra confirmed that the catalysts containing bismuth oxide ions were free from nitrate ions. The resulting support-free and supported catalysts will hereafter be abbreviated as H_3PMo-HPA and H_3PMo/SiO_2-200 respectively, where SiO_2-200 stands for AEROSIL-200.

Dehydration of *t*-Butyl Alcohol. The dehydration of liquid TBA in the heterogeneous system using supported catalyst was carried out in a batchwise reactor. The TBA of 0.212 mol (20 cm^3) was pipetted into a 300 cm^3 flask, after which the supported catalyst of 0.15 g was placed in an inner glass ampoule separated from the TBA. They were kept in a preheated oil bath. The TBA was refluxed for more than 1 h at 355.3 K. Afterwards, the ampoule was broken to cause the dehydration of TBA to start. The amount of isobutene (IB) generated as time passed was measured by the use of a gas burette.

The conversion X(liq) was determined as follows:

$$X(\text{liq}) = A/B_0 \times 100 \qquad (2)$$

where A and B_0 stand for the amount of IB generated (mol) and the initial amount of TBA (mol) respectively.

The eluted HPA was determined as follows. The HPA dissolved in the TBA solution was separated from the

dispersed HPA on the support by means of centrifugation. The TBA solution was dried at 383 K for 24 h and then calcined at 573 K for 3 h. The residue was dissolved in a certain volume of water for analysis. An appropriate volume of the sodium hydroxide solution was added to the solution, and then the excess amount of sodium hydroxide was titrated with hydrochloric acid.

The dehydration of TBA in the presence of a support-free H_3PMo solution, in which the H_3PMo has been dissolved in TBA of 20 cm^3, was also examined. The H_3PMo concentration was adjusted to 3.00 mmol dm^{-3}. The amount of H_3PMo present in the solution of 20 cm^3 corresponds to that in 0.40 mmol/g-supt H_3PMo/SiO_2-200 of 0.15 g.

Gas-phase dehydration was performed in a conventional cylindrical continuous-flow-type quartz-reactor, 16 mmϕ× 525 mm, in the temperature range between 413 and 513 K under atmospheric pressure. The catalyst (0.15 g) was mixed with glass beads (5 g) and then placed in the fixed-bed. TBA was fed continuously into the reactor through a preheated tube at the flow rate of 0.158, 0.211, 0.317, and 0.422 mol h^{-1} using a microfeeder. After passing through the reactor, the gas was cooled by a circulation device using circulated ice-cooled water in order to remove the TBA and water. Then the IB generated was assayed by measuring the time taken to obtain 10 cm^3 of IB by the use of a gas burette.

The conversion X(gas) was estimated as:

$$X(\text{gas}) = V/F \times 100 \tag{3}$$

where V is the velocity of IB generated (mol h^{-1}), and F, the velocity of TBA supplied (mol h^{-1}).

Results and Discussion

Kinetics of the Dehydration of Liquid *t*-Butyl Alcohol. Figure 1 shows the representative plots of the conversion X(liq) as a function of the time exiled. The conversion increases markedly with the amount of the supported H_3PMo at the low loadings (less than 0.6 mmol/g-supt), while it increases slightly at higher loadings (Fig. 1(a)). When the hydrogen ions of H_3PMo and H_3PW are replaced by a potassium ion, the catalytic activity decreases with the increase in the number of hydrogen ions substituted n from 1 to 3 (Fig. 1(b)). A similar trend was observed for the replacement of sodium and ammonium ions.

It seems probable that the water evolved during the dehydration of TBA is adsorbed on the surface of HPC. Assuming the formation of the TBA, HPC, TBA·HPC, and H_2O·HPC species, the following Langmuir-Hinshelwood mechanism is obtained:

$$\text{TBA} + \text{HPC} \overset{K_B}{\rightleftarrows} \text{TBA}\cdot\text{HPC} \tag{4}$$

moreover

$$H_2O + \text{HPC} \overset{K_W}{\rightleftarrows} H_2O\cdot\text{HPC} \tag{5}$$

$$\text{TBA}\cdot\text{HPC} \xrightarrow{k_1} \text{IB} + H_2O + \text{HPC} \tag{6}$$

where K_B, and K_W are the equilibrium constants for Eqs. 4 and 5 respectively, and k_1, the rate constant for

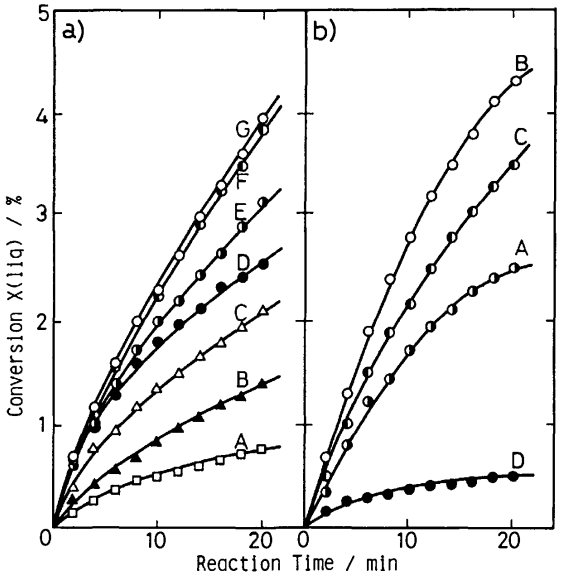

Fig. 1. Plots of the conversion vs. the exciled time for the dehydration of liquid TBA over a) H_3PMo/SiO_2-200 with various loadings of H_3PMo; A: m=0.05, B: m=0.10, C: m=0.20, D: m=0.30, E: m=0.45, F: m=0.60, G: m=0.90 mmol/g-supt H_3PMo/SiO_2-200 and b) 0.10 mmol/g-supt $K_nH_{3-n}PW/SiO_2$-200; A: n=0, B: n=1, C: n=2, D: n=3.

Reaction 6, which will be defined in detail in a later paragraph. Equilibria 4 and 5 lead to these relations:

$$K_B = \frac{[\text{TBA}\cdot\text{HPC}]_s}{[\text{TBA}]\cdot[\text{HPC}]_s} \tag{7}$$

and

$$K_W = \frac{[H_2O\cdot\text{HPC}]_s}{[H_2O]\cdot[\text{HPC}]_s} \tag{8}$$

respectively, where [TBA] and [H_2O] are the equilibrium concentrations of TBA and water (mol dm^{-3}) respectively and where [HPC]$_s$, [TBA·HPC]$_s$, and [H_2O·HPC]$_s$ are the concentrations of HPC, TBA·HPC, and H_2O·HPC at the surface of the catalyst per liter of the HPC-dispersed TBA solution (mol dm^{-3}). If K_B and K_W are big enough, the total concentration of the surface HPC, [HPC]$_{s,t}$ (mol dm^{-3}), should be expressed as:

$$[\text{HPC}]_{s,t} = [\text{TBA}\cdot\text{HPC}]_s + [H_2O\cdot\text{HPC}]_s \tag{9}$$

By combining Eqs. 7, 8, and 9, the following relation is derived:

$$\frac{[\text{TBA}\cdot\text{HPC}]_s}{[\text{HPC}]_{s,t}} = \frac{K_B\cdot[\text{TBA}]}{K_B\cdot[\text{TBA}]+K_W\cdot[H_2O]} \tag{10}$$

On the other hand, the rate of the reaction r (min^{-1}) for Eq. 6 is given by:

$$r = k_1\cdot[\text{TBA}\cdot\text{HPC}]_s, \tag{11}$$

and so the relation:

$$r=\frac{k_1\cdot K_B\cdot[TBA]\cdot[HPC]_{s,t}}{K_B\cdot[TBA]+K_W\cdot[H_2O]} \quad (12a)$$

or

$$\frac{1}{r}=\frac{K_W\cdot[H_2O]}{K_B\cdot k_1\cdot[HPC]_{s,t}\cdot[TBA]}+\frac{1}{k_1\cdot[HPC]_{s,t}} \quad (12b)$$

is worked out. Eq. 12b implies a linear relationship between $1/r$ and $[H_2O]/[TBA]$.

Figure 2 shows the plots of $1/r$ as a function of $[H_2O]/[TBA]$, in which the value of the rate of the reaction for each point was estimated from the data in Fig. 1. It can be seen that this does indeed give a linear relation, implying that the mechanism assumed above is reasonable for the dehydration of liquid TBA with the supported HPC. The same mechanism can also be deduced for the other supported HPCs examined. For this reason, the apparent rate constant k_1' ($=k_1\cdot[HPC]_{s,t}$) and the value of K_W/K_B for the dehydration of liquid TBA with the supported HPC are evaluated from the intercept and the slope of the lines in Fig. 2 respectively.

In the series of molybdophosphates examined, it was observed that the catalysts turned from yellow to blue during the dehydration of TBA, indicating that hexavalent molybdenum is reduced to a pentavalent one. However, the catalysts pre-reduced by hydrogen gas at 373 K did not show any particular catalytic activity. This proves that the dehydration of TBA proceeds via an acid catalytic reaction, not via a redox reaction.

Mechanism of the Dehydration of Liquid *t*-Butyl Alcohol. Figure 3 shows the plots of the apparent rate constant k_1' against the amount of HPC supported on AEROSIL-200. It is noteworthy that, for all the catalysts studied, the apparent rate constant k_1' increases linearly with the amount of HPC loaded, and that it then approaches a limiting value. Also, the activity is in this order: H_3PMo/SiO_2-200<H_3PW/SiO_2-200, while it decreases with the degree of substitution for the hydrogen ion of HPA. The limiting values of the apparent rate constant, k_L, for the respective catalysts are summarized in Table 1.

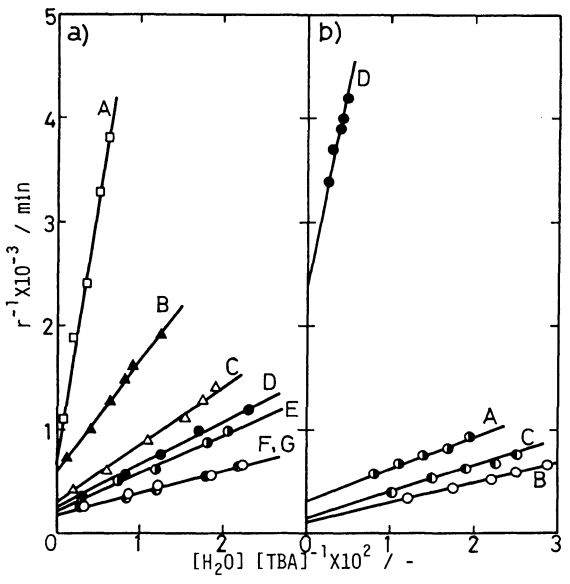

Fig. 2. Kinetics for the dehydration of liquid TBA over a) H_3PMo/SiO_2-200 with various loadings of H_3PMo; A: m=0.05, B: m=0.10, C: m=0.20, D: m=0.30, E: m=0.45, F: m=0.60, G: m=0.90 mmol/g-supt H_3PMo/SiO_2-200 and b) 0.10 mmol/g-supt $K_nH_{3-n}PW/SiO_2$-200; A: n=0, B: n=1, C: n=2, D: n=3.

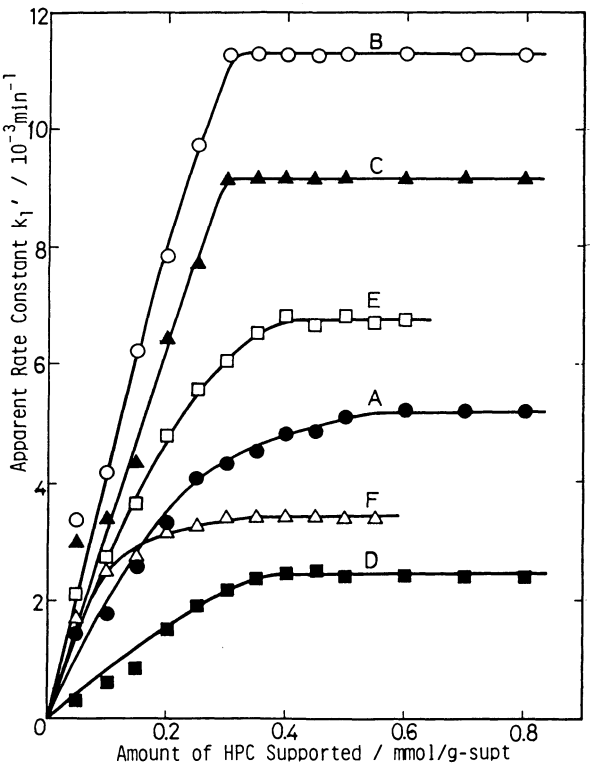

Fig. 3. The plots of the apparent rate constants for the dehydration of liquid TBA k_1' against the amount of HPC supported on silica m; A: H_3PMo/SiO_2-200, B: KH_2PMo/SiO_2-200, C: K_2HPMo/SiO_2-200, D: K_3PMo/SiO_2-200, E: H_3PW/SiO_2-200, F: H_3PMo/SiO_2-130.

Considering the effective cross section per molecule σ of HPC:

$$\sigma=1.09\,(M/L\cdot D)^{2/3} \quad (13)$$

the surface coverage θ is expressed as:

$$\theta=m\cdot\sigma\cdot(L/S)\times10^{-4} \quad (14)$$

where M and D are the molecular weight and the density of HPC respectively, and L, the Avogadro number.
