Prototypical Procedure for Reductions with Diisobutylaluminum Hydride. To a solution of 100 mg (0.633 mmol) of **2c** in 10 ml of dry ether under nitrogen at 0 °C was added dropwise a 1.43 ml hexane solution of diisobutylaluminum hydride (2.50 mmol). After being stirred for 30 min at 0 °C, the mixture was treated with 2 ml of ethanol and 8 ml of aqueous hydrochloric acid (2 M). The separated ether layer was washed with brine and dried over magnesium sulfate. GLC analysis of the mixture gave the ratio of **3c** : **4c**=43 : 57. The products were separated with preparative TLC to give 35 mg (0.22 mmol) of **3c** and 47 mg (0.29 mmol) of **4c** in total yield of 81%. Yields for other derivatives were 86% for **2a**, 83% for **2b**, 76% for **2d**, 92% for **2e**, and 80% for **2f**.

Prototypical Procedure for Reductions with Lithium Tri-

***t*-butoxyaluminum Hydride.** To a suspension of 640 mg (2.52 mmol) of lithium tri-*t*-butoxyaluminum hydride in 5 ml of dry ether under nitrogen at 0 °C was added a solution of 100 mg (0.633 mmol) of **2c** in 5 ml of dry ether. After 30 min of stirring at 0 °C, the mixture was treated with 3 ml of ethanol and 8 ml of aqueous hydrochloric acid (2 M). The separated ether layer was washed with brine, dried over magnesium sulfate, and subjected to GLC analysis (**3c**:**4c**=93:7). The products were purified with preparative TLC to give 92 mg (0.58 mmol) of **3c** and 7 mg (0.04 mmol) of **4c** in total yield of 98%. The yields for other derivatives were 99% for **2a**, 79% for **2b**, 97% for **2d**, 99% for **2e**, and 97% for **2f**.

Prototypical Procedure for Reductions with Sodium Borohydride. To a solution of 26 mg (0.69 mmol) of sodium borohydride in 5 ml of dry ethanol at 0 °C was added a solution of 100 mg (0.633 mmol) of **2c** in 8 ml of dry ethanol. After being stirred for 30 min at 0 °C, the mixture was treated with 30 ml of water and extracted with 20 ml of ether twice. The ether layer was washed with brine and dried over magnesium sulfate. GLC analysis afforded the anti/syn ratio (**3c**:**4c**=81:19). Separation with preparative TLC gave 76 mg (0.48 mmol) of **3c** and 19 mg (0.12 mmol) of **4c** in 94% total yield. The yields for other derivatives were 99% for **2a**, 77% for **2b**, 94% for **2d**, 89% for **2e**, and 88% for **2f**.

Prototypical Procedure for Reductions with Diborane. To a suspension of 48 mg (1.3 mmol) of sodium borohydride in 10 ml of anhydrous THF under nitrogen at 15—18 °C was added dropwise 0.21 ml (1.7 mmol) of boron trifluoride etherate. After being stirred for 30 min, a solution of 100 mg (0.633 mmol) of **2c** in 5 ml of THF was added to the mixture at 0 °C. After 30 min, the mixture was treated with 3 ml of ethanol and 8 ml of aqueous hydrochloric acid (2 M) and extracted with 15 ml of ether twice. The organic layer was washed with brine and dried over magnesium sulfate. GLC analysis provided the anti/syn ratio (**3c**:**4c**=75:25). The products were separated with preparative TLC to give 68 mg (0.43 mmol) of **3c** and 23 mg (0.14 mmol) of **4c** in total yield of 90%. The yields for other derivatives were 91% for **2a**, 81% for **2b**, 92% for **2d**, 96% for **2e**, and 82% for **2f**. For the reduction of **2b**, **2b** was added as solids.

Prototypical Procedure for Reductions with Disiamylborane. To a suspension of 48 mg (1.3 mmol) of sodium borohydride and 0.35 ml (3.3 mmol) of 2-methyl-2-butene in 10 ml of dry diglyme under nitrogen at 0 °C was added 0.21 ml (1.7 mmol) of boron trifluoride etherate. The mixture was stirred for 30 min at 0 °C. To this suspension was added a solution of 100 mg (0.633 mmol) of **2c** in diglyme (5 ml) at 0 °C. After 3 h, 13 ml of aqueous sodium hydroxide (3 M) and 10 ml of 30% aqueous hydrogen peroxide were added to the mixture. After being stirred for overnight at room temperature, the mixture was poured into ice-water and extracted with 25 ml of ether twice. The ether layer was washed with brine, dried over magnesium sulfate, and subjected to GLC analysis (**3c**:**4c**=57:43). Separation with preparative TLC gave 56 mg (0.35 mmol) of **3c** and 38 mg (0.24 mmol) of **4c** in total yield of 93%. The yields for other derivatives were 86% for **2a**, 92% for **2d**, 89% for **2e**, and 72% for **2f**. Under similar conditions, **2b** was inert, resulting in 70—95% of recovery.

Prototypical Procedure for Singlet Oxygen Reactions. A water cooled solution of 200 mg (0.820 mmol) of **8e** and rose bengal (10 mg) in 50 ml of methanol was irradiated with sodium lamp (55 W×4) while oxygen was bubbled through the solution. After 8 h, the solvent was concentrated under reduced pressure to ca. 10 ml. The mixture was treated with 310 mg (8.20 mmol) of sodium borohydride and stirred at room temperature for 12 h. After addition of 30 ml of water, the products was extracted with 30 ml of ether twice. The ether layer was washed with brine and dried over magnesium sulfate. The mixture was carefully separated with preparative TLC to give 7 mg (0.03 mmol) of the recovered **8e**, 176 mg (0.677 mmol) of **21e**, and 18 mg (0.069 mmol) of **22e**. The anti/syn ratio was 91/9. **21e**: Colorless prisms; mp 110—112 °C; IR (KBr) 3590, 2940, 1492, 1467, 1422, 1330, 1286, 1250, 1222, 1116, 1098, 1078, 1007, 901 cm^{-1}; ^1H NMR (100 MHz, $CDCl_3$) δ=1.19 (m, 2H), 1.71 (m, 4H), 2.30 (m, 2H), 3.19 (dd, 2H, J=1.8, 1.8 Hz), 3.82 (s, 6H), 4.75 (m, 1H), 4.88 (m, 1H), 6.71 (s, 2H). Found: C, 73.63; H, 7.76%. Calcd for $C_{16}H_{20}O_3$: C, 73.82; H, 7.74%. **22e**: colorless prisms from hexane; mp 112—115 °C; IR (KBr) 3540, 2950, 1490, 1465, 1328, 1285, 1248, 1222, 1167, 1120, 1099, 1062 cm^{-1}; ^1H NMR (100 MHz, $CDCl_3$) δ=1.09 (m, 2H), 1.65—2.11 (m, 6H), 3.27 (dd, 2H, J=1.8,1.8 Hz), 3.87 (s, 6H), 5.08 (m, 1H), 5.16 (m, 1H), 6.91 (s, 2H). Found: C, 73.54; H, 7.73%. Calcd for $C_{16}H_{20}O_3$: C, 73.82; H, 7.74%. Under similar conditions **21c** and **22c** were obtained from **8c** in total yield of 95% with the ratio of **21c**:**22c**=80:20. Similarly, **21f** and **22f** were produced in total yield of 85% with the ratio of **21f**:**22f**=72:28. **21f**: colorless prisms from hexane. mp 81—82 °C; IR (KBr) 3585, 2925, 1476, 1460, 1416, 1368, 1301, 1271, 1123, 1077, 1068, 1017, 1006, 900 cm^{-1}; ^1H NMR (100 MHz, $CDCl_3$) δ=1.27 (m, 2H), 1.67—1.81 (m, 4H), 2.34 (m, 2H), 3.46 (dd, 2H, J=1.8,1.8 Hz), 3.83 (s,6H), 3.86 (s, 6H), 4.76 (m, 1H), 4.93 (m, 1H). Found: C, 67.21; H, 7.58%. Calcd for $C_{18}H_{24}O_5$: C, 67.48; H, 7.55%.

NMR Shift Reagent Study. The $Eu(fod)_3$ used was taken directly from a fresh bottle of commercial product. The purified alcohols (**3a**—f, **4b**—f) were each dissolved in $CDCl_3$ (25—30 mg/0.3 ml) in a NMR tube. The shift reagent, $Eu(fod)_3$, was weighed out and added into the solution five times in about 5 mg portions, and ^1H NMR spectrum was measured each time. The plots of the observed relative shift of each proton of the alcohol vs. the amount of added $Eu(fod)_3$ gave fairly good straight lines. From the slope of each proton, the relative shift value was calculated.

(Received July 27, 1988)

A new bitter triterpene ester glucoside have been isolated along with known bitter triterpene glucoside pedunclosside and some minor triterpenes ulsolic acid, rotundic acid, and rotungenic acid from the unripe fruits of *Ilex rotunda*. The structure was characterized as β-D-glucopyranosyl 3β,19α,24-trihydroxyurs-12-en-28-oate by spectral data and chemical means.

Ilex rotunda Thunb. (Aquifoliaceae) yields red fruits in winter. Birds pick up the ripe fruits in early spring but don't the unripe ones. Some triterpenoids have been isolated from this plant, i.e. a triterpene rotundic acid (**1**) from the seeds[1] and a triterpene glucoside pedunclosside (**2**) from the leaves.[2] But there is no detailed study on the constituents of the fruits. Then we were interested in the difference of their constituents and first investigated on the ripe fruits to get new triterpenes rotungenic acid (**3**) and rotundioic acid (**4**).[3] We now studied the constituents of the unripe fruits and isolated a new bitter triterpene ester glucoside rotungenoside (**5**) as minor glucoside along with major pedunclosside (**2**) and minor triterpenes ulsolic acid, rotundic acid (**1**), and rotungenic acid (**3**). These bitter glucosides **1** and **2** exhibited a weak insect antifeedant activity against the larvae of *Spodoptera litura* Fab. with the leaf disk choice test.

Results and Discussion

The fresh unripe fruits of *Ilex rotunda* were extracted with methanol. After concentration to one-tenth of its original volume, the extract was suspended in water and then extracted with ethyl acetate. The extract was roughly divided into two groups by passing through LH-20 column, one of which was a mixture of triterpenes and the other contained some triterpene glycosides. Triterpenoids were detected by the red-violet colour given by the Liebermann-Burchard test. Crystallization of the glycoside fraction afforded a mixture of two compounds which were separated to a major known pedunclosside (**2**) (28-β-D-glucopyranosyl 3β,19α,23-trihydroxyurs-12-en-28-oate) and minor new rotungenoside (**5**) on a DCCC(droplet countercurrent chromatography) using chloroform–methanol–water solvent system in ascending mode. From the triterpene fraction, three known compounds ulsolic acid, rotundic acid (**1**) (3β,19α,23-trihydroxyurs-12-en-28-oic acid) and rotungenic acid (**3**) (3β,19α,24-trihydroxyurs-12-en-28-oic acid) were isolated.

Rotungenoside (**5**), an amorphous white powder, $[\alpha]_D^{25}$ +5° (MeOH), was assigned the molecular formula $C_{36}H_{58}O_{10}$ from SIMS (*m/z* 673[M+Na]$^+$). Its IR and UV spectra showed the presence of hydroxyl and ester groups (3450 and 1720 cm^{-1}) and double bond (209 nm: ε 3000). Its ^{13}C NMR spectrum revealed thirty-six carbon signals (CH_3-X6, -CH_2-X9, >CH-X4, -<u>C</u>-X5, -CH_2-OX2, >CH-OX5, -<u>C</u>-OX1, -CH<O,O> X1, >C=CH-X1, -CO-OX1). The SI mass spectrum showed a characteristic peak at *m/z* 489 denoting the loss of 1 mol of glucose and two peaks of 471 and 453 indicated further successive loses of 1 and 2 mol of water. The ^{13}C NMR experiment (Table 1) suggested that this glycoside **5** had the same sugar (β-D-glucopyranose) with pedunclosside (**2**) which was linked to the aglycone with ester linkage. The anomeric carbon of **5** was also found at a higher field (δ 95.7) owing to the esterification effect;[4] pedunclosside (**2**): δ 96.0. Careful examination of ^{13}C NMR spectra of these aglycone part, clarified that these compounds had very similar aglycone; the only difference is the substitution around C-3 and C-4 in 3,18-dihydroxyurs-12-en-18-oic skeleton. In particular, the exchange of

the signal at δ 13.2 to δ 23.7 led to the conclusion that the C-23 methyl was replaced with a hydroxymethyl group since the signal of the C-24 methyl in most ursene triterpenoids having 3β-OH group has been observed to about 10 ppm higher field than the C-23 methyl signal.[5,6]

The glucoside **5** was acetylated to give the hexaacetate **6**. Its ^{1}H NMR spectrum (Table 2) supported very well the ester linked β-anomeric configuration (δ 5.52, 1H, d, J= 8Hz; H-1′) including glucose moiety and showed the presence of an 3β-acetoxyl group (δ 4.58, 1H, dd, J=11 and 5.5 Hz; H-3α). A signal at δ 2.53 (1H, br s; H-18) suggested the presence of the 19-*O*-substituted urs-12-ene skeleton,[7] while the 4-acetoxylmethylene signals at δ 4.14 and 4.36 (each d, J=12 Hz) showed the large down-field shift of 0.25 and 0.67 ppm compared to those of **7** (hexaacetate of **2**), which also suggested the 4β-CH_2OH configuration in **5**.

The aglycone of **3** was obtained by alkaline hydrolysis and identified as **3** by means of ^{13}C NMR and mass spectroscopies. It follows that **5** can be formulated as 28-β-D-glucopyranosyl 3β,19α,24-trihydroxyurs-12-en-28-oate. In the ^{1}H NMR spectrum of the diacetate (**8**), a W-type long-range coupling was observed between the H-3α signal at δ 4.58 (dd, J=10.5 and 5 Hz) and higher one of the axial 4β-acetoxymethyl signals at δ 4.38 and 4.12 (each d, J=11.5 Hz) but not observed in the hexaacetate **6**, which suggested a conformation change in the glucoside **6**.

Acid hydrolysis of **5** with hydrochloric acid in methanol afforded glucose (identified by TLC and paper chromatography) and a mixture of conjugated and nonconjugated dienes **9** and **10**. The dehydration product **9** showed a hindered conjugated diene system at 229 nm (ε 3400) in its UV spectrum and the ^{1}H NMR spectrum showed the presence of one olefinic methyl group at δ 1.75. On the other hand, compound **10** had a nonconjugated UV absorption at 207.5 nm (ε 6500) and showed two olefinic methyl signals at δ 1.53 and 1.63 in its ^{1}H NMR spectrum. These compounds were also obtained from rotungenic acid (**3**) by the acid treatment. A similar dehydration has been observed in the reaction of 19-hydroxyurs-12-ene or 19-hydroxyolean-12-enes[8,9] and so the compounds from **3** and **5**

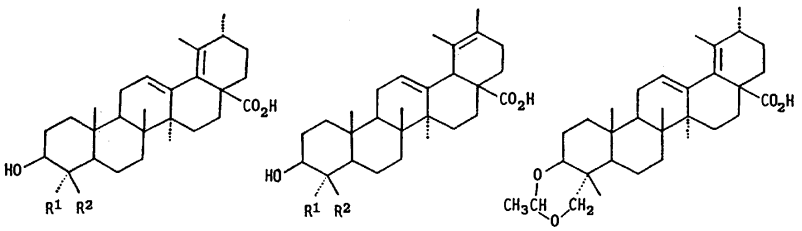
Measured in $CDCl_3$.



9: R^1= CH_3, R^2= CH_2OH 10: R^1= CH_3, R^2= CH_2OH 13

11: R^1= CH_2OH, R^2= CH_3 12: R^1= CH_2OH, R^2= CH_3

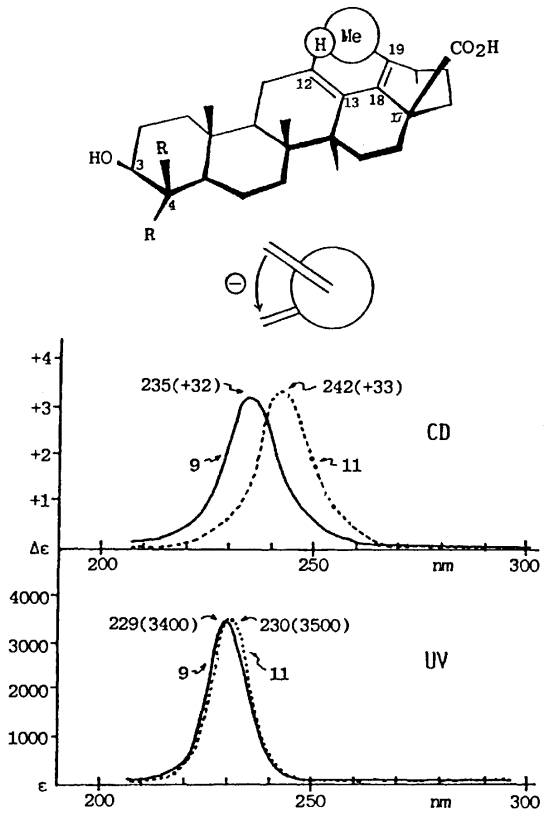


Fig. 1. UV and CD spectra of conjugated diene **9** and **11**.

were formulated as structures **9** and **10**. In the case of the reaction of **2** with dil sulfuric acid in ethanol, an acetal **13** was given in addition to dehydration products **11** and **12**.

The conjugated diene **9** exhibited a strong positive Cotton effect in the CD spectrum at 235 nm ($\Delta\varepsilon$ +32) like **11** (242 nm; $\Delta\varepsilon$ +33) due to π-π^* transition of conjugated diene (Fig. 1). The positive Cotton effect was well correlated with the chirarlity of chromophore, which is positive when the planes of the two double bonds are skewed in a right-handed helix. In the heteroannular cisoid diene, the sign of π-π^* cd is opposite to the chirality of the diene system.[10] Thus the positive effect expected for the negative chirality of the diene system in **9**, as predicted from its Dreiding model, was observed.

Among the compounds isolated in this work, pedunclosido and rotungenoside were active as an insect antifeedant against the larvae of *Spodoptera litura* Fab.

Experimental

Mps are uncorrected. Concentrations were performed under reduced pressure at bath temperatures not exceeding 50 °C. ^{1}H NMR spectra were obtained at 360 MHz and ^{13}C NMR spectra at 25.2 MHz. All the compounds were finally purified by HPLC on a C_{18} semiprep column using H_2O/MeOH solvent system. UV spectra were measured in methanol (MeOH).

Plant Material. Unripe fruits of the plant were collected at Kagoshima University in December 1983.

Extraction and Isolation. The unripe fruits (2 kg) were extracted with MeOH (3×10 l). After concn to 500 ml, H_2O (300 ml) was added and extracted with ethyl acetate (AcOEt) to give 18 g of an extract, which was passed through LH-20 column with MeOH to give two fractions. The first eluted fraction (7.2 g) was crystallized twice from AcOEt to give 2.1 g of a mixture of glucosides. The mixture (165 mg) was separated to a major component **2** (134 mg; 81.3%) and minor one **5** (14 mg; 8.4%) on a DCCC using $CHCl_3$-MeOH-H_2O (7 : 13 : 8 v/v) in ascending mode. The major component was eluted out at fractions 70—100 and the minor one at fractions 104—136. The elution of the compounds was monitored by TLC. Chromatography of the second fraction (3.4 g) on silica gel afforded ulsolic acid (25 mg) and a mixture of two triterpenes (1.2 g), which was separated to **1** (840 mg) and **3** (43 mg) by recrystallization from MeOH followed by HPLC (solvent; 20% H_2O/MeOH).

Rotungenoside (5). A white amorphous powder; $[\alpha]_D^{25}$ +5° (*c* 0.04, MeOH); UV 209 nm (ε 3000); IR (Nujol) 3500—3200, 1720 cm^{-1}; SIMS *m/z* 673 $(M+Na)^+$, 651 $(M+1)^+$, 581, 535, 489 $(651-C_6H_{11}O_5)^+$, 471 $(489-H_2O)^+$, 461, 453 $(471-H_2O)^+$, 435, 425, 407. Calcd for $C_{36}H_{59}O_{10}$: M+1, 651.

Pedunclosido (2). Prisms from AcOEt mp 213—214°C; $[\alpha]_D^{25}$ +22° (*c* 0.05, MeOH); SIMS *m/z* 673 $(M+Na)^+$, 489 $(M+1-C_6H_{11}O_5)^+$, 471 $(489-H_2O)^+$, 425, 407; IR (Nujol) 3500—3200, 1720 cm^{-1}; UV 210 nm (ε 4500). Found: C, 66.32; H, 8.83%. Calcd for $C_{36}H_{58}O_{10}$: C, 66.47; H, 8.92%.

Ursolic Acid. Mp 290 °C; EIMS *m/z* 456 $(M)^+$, 438, 410, 248, 207, 203, 189, which was identified by direct comparison (IR and MS) with an authentic sample.

Rotundic Acid (1). Prisms from MeOH, mp 272—274 °C (decomp); $[\alpha]_D^{25}$ +24° (*c* 0.1, MeOH); SIMS *m/z* 511 $(M+Na)^+$; EIMS *m/z* 488 $(M)^+$, 470, 452, 442, 264, 246, 223,

201, 175, 146; IR (Nujol) 3500—2600, 1690, 1640 cm^{-1}; UV 209 nm (ε4000); ^{13}C NMR (py-d_5) δ=13.1 (C-24), 16.0 (C-30), 16.8 (C-26), 17.3 (C-25), 18.8 (C-6), 24.1 (C-11), 24.7 (C-27), 26.5 (C-16), 27.0 (C-21), 27.2 (C-29), 27.7 (C-2), 29.4 (C-15), 33.4 (C-7), 37.3 (C-10), 38.5 (C-22), 38.9 (C-1), 40.4 (C-8), 42.2 (C-14), 42.4 (C-20), 42.9 (C-4), 47.9 (C-9), 48.3 (C-17), 48.8 (C-5), 54.7 (C-18), 68.2 (C-23), 72.7 (C-19), 73.7 (C-3), 128.1 (C-12), 140.0 (C-13), 180.7 (C-28). HRMS Found: m/z 488.3503. Calcd for $C_{30}H_{48}O_5$: M, 488.3502.

Rotungenic Acid (3). Column from H_2O-MeOH, mp 295—298 °C (decomp); $[\alpha]_D^{24}$ +50° (c 0.07, MeOH); SIMS m/z 489 $(M+1)^+$; EIMS m/z 488 $(M)^+$, 470, 452, 442, 264, 246, 223, 219, 205, 201, 175, 146; IR (Nujol) 3500—2600, 1690, 1640 cm^{-1}; UV 209 nm (ε 4000): ^{13}C NMR (py-d_5) δ=16.1 (C-30), 16.8 (C-26), 17.2 (C-25), 19.3 (C-6), 23.7 (C-23), 24.3 (C-11), 24.7 (C-27), 26.5 (C-16), 27.0 (C-21), 27.2 (C-29), 28.5 (C-2), 29.4 (C-15), 34.0 (C-7), 37.2 (C-10), 38.6 (C-22), 38.8 (C-1), 40.4 (C-8), 42.1 (C-14), 42.4 (C-20), 43.2 (C-4), 47.9 (C-9), 48.4 (C-17), 54.7 (C-18), 56.6 (C-5), 64.6 (C-24), 72.8 (C-19), 80.3 (C-3), 127.9 (C-12), 140.0 (C-13), 180.8 (C-28). HRMS Found: m/z 488.3504. Calcd for $C_{30}H_{48}O_5$: M, 488.3502.

Hexaacetylrotungenoside (6). Rotungenoside (**5**) (4 mg) was treated with acetic anhydride (Ac_2O) in py at 60 °C for 24 h to give the hexaacetate **6** (4 mg), mp 141—142.5 °C; $[\alpha]_D^{25}$ +15° (c 0.1, MeOH); IR (Nujol) 3450, 1740, 1720 cm^{-1}; UV 208 nm (ε 3700). Found: C, 63.77; H, 7.95%. Calcd for $C_{48}H_{70}O_{16}$: C, 63.84; H, 7.81%.

Hexaacetylpeduncloside (7). Peduncloside (**2**) (17 mg) was treated with Ac_2O in py at 60 °C for 24 h to give the hexaacetate **7** (15 mg), mp 160—161 °C; $[\alpha]_D^{25}$ +47° (c 0.1, MeOH); IR (Nujol) 3500, 1745, 1720 cm^{-1}; UV 209 nm (ε 3800). Found: C, 63.89; H, 7.92%. Calcd for $C_{48}H_{70}O_{16}$: C, 63.84; H, 7.81%.

3,24-Diacetylrotungenic Acid (8). Compound **3** (4.5 mg) was acetylated with Ac_2O in py to give the diacetate **8** (3 mg), mp 164—167 °C; EIMS m/z 554 $(M-H_2O)^+$, 526, 512, 264, 246.

Alkaline Hydrolysis of Rotungenoside (5). Rotungenoside (**5**) (11 mg) was treated with 10% aq potassium carbonate (K_2CO_3) (400 mg) in MeOH (10 ml) under reflux for 3 h. The crude product gave **3** (7 mg) as plates from MeOH, mp 295—298 °C (decomp).

Alkaline Hydrolysis of Peduncloside (2). Compound **2** (11 mg) was treated with 10% aq K_2CO_3 in MeOH under reflux for 10 h. Work-up as usual gave **1** (6.5 mg) as plates from H_2O-MeOH, mp 272—275 °C (decomp).

Acid Hydrolysis of Rotungenoside (5). Compound **5** (10 mg) was treated with 2M hydrochloric acid (HCl; 1M=1 mol dm^{-3}) (2 ml) in MeOH (10 ml) under reflux for 4 h. The product was extracted with ether and the extract was purified by HPLC (17.5% H_2O/MeOH) to give **9** (3 mg) and **10** (1 mg). Compound **9**, mp 198—199 °C as plates from MeOH; IR (Nujol) 3500—2500, 1690, 1650 cm^{-1}; UV 229 nm (ε 3400); CD (MeOH) 235 nm ($\Delta\varepsilon$ +32); EIMS m/z 470 $(M)^+$, 424 $(M-HCO_2H)^+$, 246, 223, 205, 201, 69 (base peak); ^1H NMR ($CDCl_3$) δ=0.88, 0.92, 0.97 (each 3H, s), 1.09 (3H, d, J=7.1 Hz), 1.25 (3H, s), 1.75 (3H, s) 3.34 (1H, br d, J=11.4 and 3.7 Hz), 3.45 (1H, br dd, J=11.5 and 5.0 Hz), 4.21 (1H, d, J=11.2 Hz), 5.44 (1H, dd, J=4.2 and 3.7 Hz). HRMS Found: m/z 470.3387. Calcd for $C_{30}H_{46}O_4$: M, 470.3395. Compound **10**; UV 207.5 nm (ε 6500); CD (MeOH) 210 nm ($\Delta\varepsilon$ −5.2); EIMS m/z 470 $(M)^+$, 472 $(M-H_2O)^+$, 426 $(M-CO_2)^+$, 424, 313, 246, 223, 205, 201, 149, 75 (base peak); ^1H NMR ($CDCl_3$) δ= 0.81, 0.90, 0.96, 1.24, 1.53, 1.63 (each 3H, s), 3.16 (1H, br s), 3.34 (1H, br d, J=11.4 Hz), 3.44 (1H, br dd, J=12 and 4 Hz), 4.21 (1H, d, J=11.2 Hz), 5.48 (1H, t, J=3.7 Hz). HRMS Found: m/z 470.3335. Calcd for $C_{30}H_{46}O_4$: M, 470.3395.

Methyl Ester of 9. Compound **9** was methylated with diazomethane (CH_2N_2) in MeOH to give the methyl ester **14**, a white amorphous powder; EIMS m/z 484 $(M)^+$, 260, 247, 201; ^1H NMR ($CDCl_3$) δ=0.84 (3H, s; 9-Me), 0.92 (3H, s; 4α-Me), 0.96 (3H, s; 11-Me), 1.07 (3H, d, J=7Hz; 20-Me), 1.25 (3H, s; 14-Me), 1.72 (3H, s; 19-Me), 3.34 (1H, m; 3-H), 3.45 (1H, br dd, J=11.5 and 4 Hz; 24-H), 4.21 (1H, d, J=11.5 Hz; 24-H), 5.35 (1H, dd, J=4 and 3.5 Hz; 12-H).

Methyl Ester of 10. Compound **10** was methylated with CH_2N_2 in MeOH to give the methyl ester **15**, mp 264—267 °C; EIMS m/z 484 $(M)^+$, 260, 248, 247, 215, 201 187; ^1H NMR ($CDCl_3$) δ=0.79 (3H, s; 9-Me), 0.90 (3H, s; 4α-Me), 0.95 (3H, s; 11-Me), 1.25 (3H, s; 14-Me), 1.53 (3H, s; 20-Me), 1.63 (3H, s; 19-Me), 3.20 (1H, br, s; 18-H), 3.33 (1H, br d, J=11 Hz; 3-H), 3.44 (1H, br dd, J=11.5 and 4 Hz; 24-H), 4.20 (1H, d, J=11.5 Hz; 24-H), 5.47 (1H, t, J=3.5 Hz; 12-H).

Acid Hydrolysis of Peduncloside (2). (i) Compound **2** (95 mg) was refluxed with 2 M HCl in MeOH for 3 h. HPLC separation of the crude product gave **11** (42 mg) and **12** (8 mg). Compound **11**, mp 145—146 °C; IR (Nujol) 3500—2500, 1690, 1650 cm^{-1}; UV 230 nm (ε 3500); CD (MeOH) 242 nm ($\Delta\varepsilon$ +33); SIMS m/z 493 $(M+Na)^+$, 471 $(M+1)^+$; ^1H NMR ($CDCl_3$) δ=0.87, 0.98, 1.03, 1.08 (each 3H, s), 1.09 (3H, d, J=7 Hz), 1.74 (1H, s), 3.45 (1H, d, J=10.5 Hz), 3.67 (1H, dd, J=9 and 7 Hz), 3.74 (1H, d, J=10.5 Hz), 5.46 (1H, t, J=4 Hz). HRMS Found: m/z 470.3391. Calcd for $C_{30}H_{46}O_4$: M, 470.3395. Compound **12**, mp 165—167 °C; IR (Nujol) 3500—2500, 1680, 1650 cm^{-1}; UV 207 nm (ε 4000); ^1H NMR ($CDCl_3$) δ=0.86, 0.89, 0.97, 1.01, 1.54, 1.61 (each 3H, s), 3.17 (1H, br s), 3.43 (1H, d, J=10.5 Hz), 3.64 (1H, dd, J=9 and 7 Hz), 3.73 (1H, d, J=10.5 Hz), 5.49 (1H, t, J=3.8 Hz). HRMS Found: m/z 470.3319. Calcd for $C_{30}H_{46}O_4$: M, 470.3395. (ii) Compound **2** (97 mg) was refluxed with 1 M sulfuric acid (15 ml) in ethanol (20 ml) for 5 h. Chromatography of the crude product on silica gel afforded an acetal **13** (8 mg) in addition to a mixture of **11** and **12**. Compound **13**, mp 215—216 °C; IR ($CHCl_3$) 3200—2500, 1690,1600 cm^{-1}; UV 247 nm (ε 4500); SIMS m/z 497 $(M+1)^+$, 451 $(497-HCO_2H)^+$, 404 $(451-CH_3CHO)^+$; ^1H NMR ($CDCl_3$) δ=0.87, 0.98, 1.03, 1.08 (each 3H, s), 1.09 (3H, d, J=7 Hz), 1.35 (3H, d, J=5.3 Hz; $C\underline{H}_3CH\begin{matrix}O\\O\end{matrix}$), 3.24 (1H, d, J=10.4 Hz; 23-H), 3.55 (1H, dd, J=10 and 4.5 Hz; 3-H), 3.77 (1H, d, J=10.4 Hz; 23-H), 4.74 (1H, q, J=5.3 Hz; $CH_3C\underline{H}\begin{matrix}O\\O\end{matrix}$), 5.42 (1H, t, J=3.5 Hz). SIMS Found: m/z 497. Calcd for $C_{32}H_{49}O_4$: M+1, 497.

Reaction of Rotungenic Acid (3) with Acid. Compound **3** (7 mg) was refluxed with 2 M HCl in MeOH for 3 h. Work-up as usual gave **9** (3 mg) and **10** (1 mg).

Reaction of Rotundic Acid (1) with Acid. Compound **1** was treated with 2 M HCl in a manner similar to **3**. The crude product gave **11** and **12**.

Insect Antifeedant Activity. The triterpenoids **1**, **2**, **3**, and **5** were tested against the larvae of the pest insect *Spodoptera litura* Fab. with the leaf disk method.[11] Peduncloside (**2**) and rotungenoside (**5**) showed the antifeedant activity at 2000 ppm concn.

We are grateful to Dr. Hideo Naoki and Takashi Iwashita (Suntory Institute for Bioorganic Research) for MS and NMR spectra and to Mr. Mitsuo Tahara (Sankei Chemical Co., Ltd.) for the supply of the insect.

The Synthesis of 1,3-Dithiolan-2-ones on the Reaction of Oxiranes with Carbon Disulfide under High Pressure

Yoichi TAGUCHI,* Masahiko YASUMOTO, Isao SHIBUYA, and Yasuo SUHARA
National Chemical Laboratory for Industry, Higashi, Tsukuba, Ibaraki 305
(Received July 27, 1988)

An equimolar reaction of 2-hexyloxirane with carbon disulfide in hexane was run in the presence of triethylamine under 800 MPa at 100 °C for 20 h, and gave 63% of 4-hexyl-1,3-dithiolan-2-one (**3a**), 21% of 4-hexyl-1,3-dithiolane-2-thione (**1a**) and 5% of 5-hexyl-1,3-oxathiolan-2-one (**4a**). Hexane, benzene, and diisopropyl ether were good solvents for the reaction. The reaction of a variety of oxiranes with carbon disulfide produced 1,3-dithiolan-2-ones as the main products under 500 MPa at 100 °C for 20 h. Upon a reaction of 2-hexyloxirane with carbon disulfide, 5-hexyl-1,3-oxathiolane-2-thione (**2a**), and 2-hexylthiirane (**5a**) were produced during the first stage of reaction. The formation of **1a** and **4a** began immediately, whereas, the formation of **3a** required a long induced period. A feasible mechanism for the formation of **3a** is proposed to be a rearrangement of **2a** in the presence of triethylamine, free from carbon disulfide.

Many organic reactions are accelerated by compression.[1,2] It has recently been reported that the reactions of many thiiranes with carbon disulfide in the presence of triethylamine under high pressure give 1,3-dithiolane-2-thiones nearly quantitatively.[3] The reactions of many oxiranes with carbon disulfide are also accelerated by compression to give 1,3-dithiolane-2-thiones (**1**) as a main product.[4] **1** is considered to be formed via 1,3-oxathiolane-2-thiones (**2**),[4] and the relative ratio of **2** to the total yield is high during the early period of the reaction. Therefore, it is expected that **2** is formed with high yield and selectivity by the choice of suitable reaction conditions. The equimolar reaction of oxiranes and carbon disulfide in a solvent was investigated under high pressure for this purpose. As a result, an interesting rearrangement was found to occur without yielding **2**.

In this paper, we report on reactions in which no **2** was obtained and 1,3-dithiolan-2-ones (**3**) were newly formed as the main products upon the reaction of oxiranes with carbon disulfide. When excess carbon disulfide was used, **3** was not found.[4] The formation of **3** is considered to include some rearrangement, since **3** can not be formed by a simple addition reaction. There have been no reports on a similar rearrangement under high pressure. The effects of the pressure, temperature, reaction time, molar ratio of reactants, the amount and kind of catalysts, and the kind of solvents have been investigated in detail with regard to the reaction of 2-hexyloxirane with carbon disulfide. The mechanism for the formation of the products is also discussed.

Results and Discussion

A reaction of 2-hexyloxirane with excess carbon disulfide at 100 °C for 20 h under 800 MPa gave 71% of 4-hexyl-1,3-dithiolane-2-thione (**1a**), 5% of 5-hexyl-1,3-oxathiolane-2-thione (**2a**) and 12% of 5-hexyl-1,3-oxathiolan-2-one (**4a**).[4] However, an equimolar reaction in hexane under the same reaction conditions gave 63% of 4-hexyl-1,3-dithiolan-2-one (**3a**), 21% of **1a** and 5% of **4a**; no **2a** was produced.

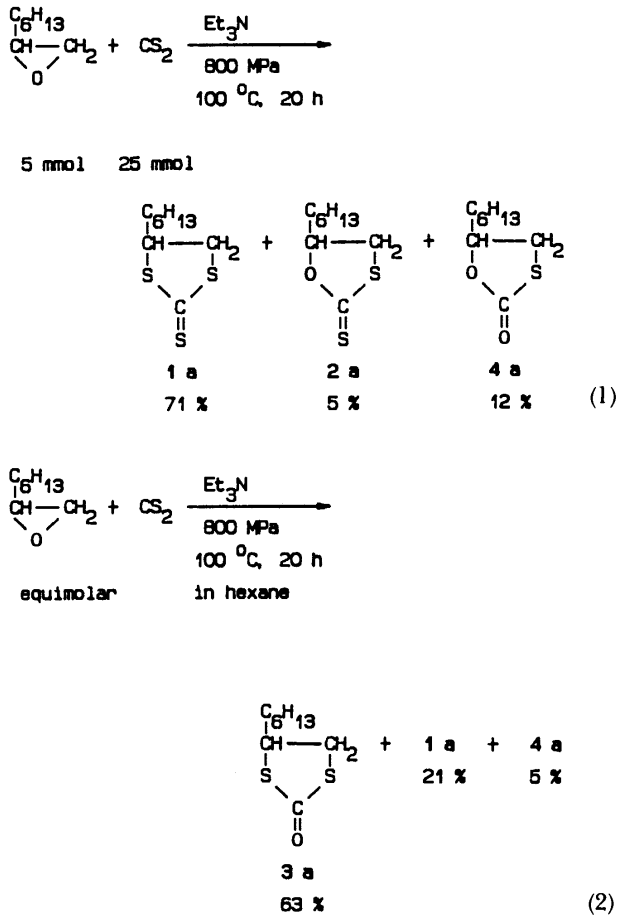

Table 1 shows the effects of pressure, temperature, and reaction time on the reaction. The reaction under ordinary pressure gave no products (Run 1); this fact shows that this reaction can be remarkably accelerated by compression. At a pressure higher than 500 MPa, **3a** was the main product and none of **2a** was produced unexpectedly (Runs 3—7). Under 200 MPa, both products **2a** and **3a** were obtained and 29% of 2-

hexylthiirane (**5a**) was also formed (Run 2).

Table 2 shows the effect of solvents. **3a** was formed in high yields in hexane, benzene, and diisopropyl ether (IPE); however, in polar solvents, such as acetone and *N*,*N*-dimethylformamide (DMF), the yield of **3a** decreased.

Table 3 shows the effect of catalysts. When *N*-methylmorpholine was used as a catalyst under 800 MPa at 100 °C, **3a** was obtained as the main product (Run 4), but under lower pressure or at a lower

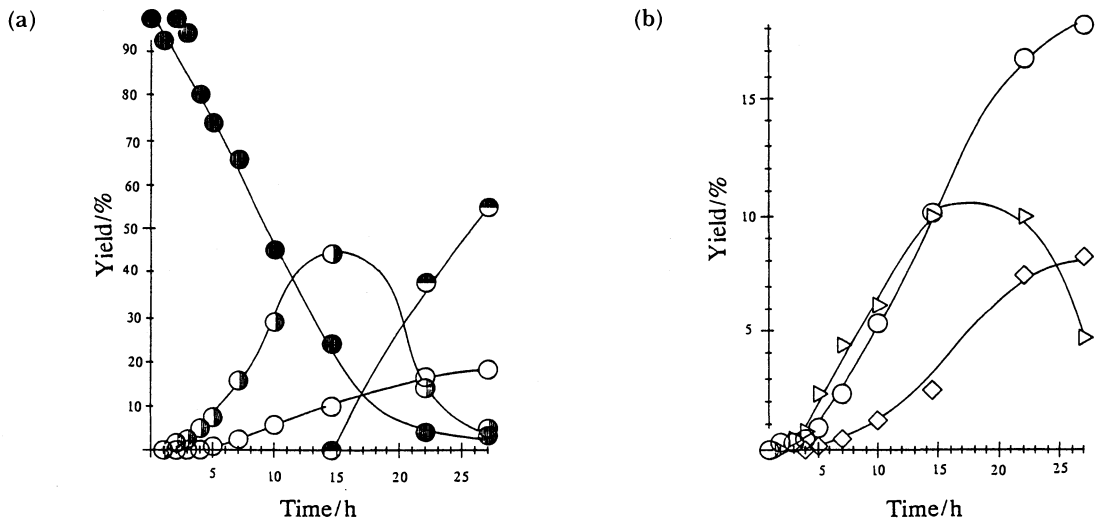

Fig. 1. Relation of the yields of products and reaction time on the reaction of 2-hexyloxirane with CS_2. Reaction temperature: 70 °C, pressure: 300 MPa, 2-hexyloxirane: 50 mmol, CS_2: 50 mmol, Et_3N: 5 mmol, heptane: 30 ml, tetradecane: 0.50 g.
—●—: 2-hexyloxirane, —○—: **1a**, —◑—: **2a**, —◒—: **3a**, —◇—: **4a**, —▷—: **5a**.

temperature **3a** was not formed (Runs 1—3).

Table 4 shows the relation between the yields of the products and the amount of triethylamine used as a catalyst on the reaction. Since the rate of the reaction of thiiranes with carbon disulfide is proportional to the amount of triethylamine catalyst,[3] it is considered that the rate of the reaction of 2-hexyloxirane is proportional to the amount of triethylamine in the range of 0.05—0.50 mmol. When 0.05 mmol of triethylamine was used, **2a** was formed as the main product and **3a** was not formed (Run 1); also, none of **2a** was detected and **3a** was given as the main product when 0.50 mmol of triethylamine was used (Run 5). As a result, it is suggested that **3a** is formed by the conversion of **2a**. When a slight excess of carbon disulfide was used, **1a** was obtained as the main product and the yield of **3a** decreased (Run 8). This shows that the ratio of products depends upon the molar ratios of oxiranes and carbon disulfide; but when the ratio of carbon disulfide was reduced, the polymerization of 2-hexyloxirane proceeded preferentially (Run 9).

Figure 1 shows the relation between the yields of the products and the reaction time on the reaction in heptane under 300 MPa at 70 °C. During the initial stage, **2a** was formed as the main product, and no **3a** was formed. **3a** was first detected at 22 h after starting ; **2a**

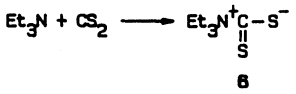
a) Oxirane 5 mmol; CS_2 5 mmol; Et_3N 0.5 mmol; pressure 500 MPa; reaction temperature 100 °C; reaction time 20 h.

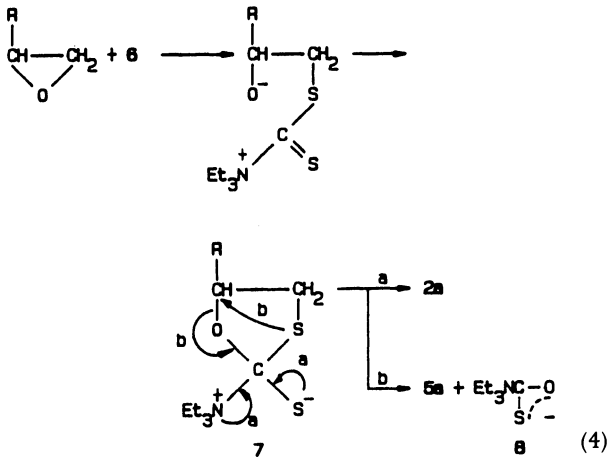
was reduced greatly. These phenomena verify that **2a** changes to **3a**, and that the formation of **3a** has a long induced period. In contrast to the production of **3a**, **1a** and **4a** were already detected at an early time, and increased as the reaction proceeded. The formation mechanisms of **1a** and **4a** are considered to be the same mechanisms as mentioned previously.[4]

Table 5 shows the products and yields for the reactions of various oxiranes with carbon disulfide. 2-Phenyloxirane and 2-methyloxirane which produce **1** easily upon reacting with excess carbon disulfide,[4] produced **3** as the main product under suitable reaction conditions (Runs 2 and 7). 2,2-Dimethyloxirane, which gave **2** as the main product on the reaction with excess carbon disulfide, also gave **2** as the main product, though **3** was obtained with 30% yield (Run 4).

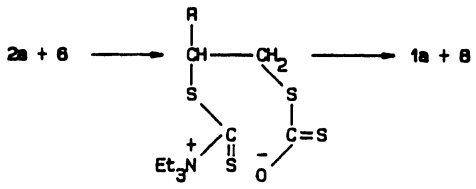
An equimolar reaction of 2-hexyloxirane with carbon disulfide in the presence of triethylamine seems to proceed as follows:



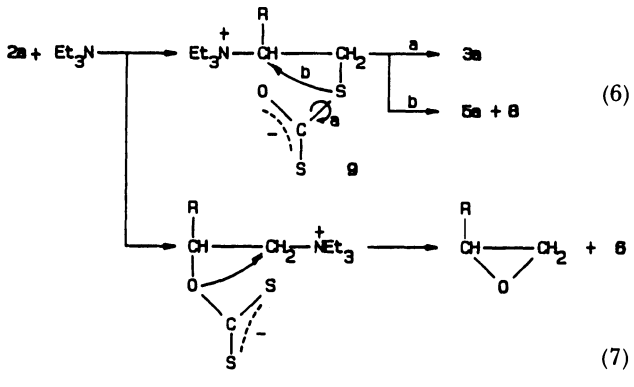
(3)



(4)



(5)



(6)

(7)

Adduct **6** attacks 2-hexyloxirane to give **2a** and **5a** (Eq. 4). **1a** is obtained through a reaction of **2a** with **6**, as mentioned previously (Eq. 5). When carbon disulfide is almost consumed and free triethylamine is present without producing **6** with carbon disulfide, **2a** reacts with triethylamine to give adduct **9**. **3a** is formed by a rotation of the C-S bond of **9**. A similar rotation has been reported regarding the isomerization of *N*-phenyl-1,3-dioxolan-2-imine.[5] To confirm this mechanism, **2a** in hexane was heated at 100 °C in the presence of triethylamine under 800 MPa for 20 h to form **3a** as the main product (Eq. 8). In contrast, a similar reaction in carbon disulfide gave **1a** as the main product; **3a** was not obtained (Eq. 9). It is considered that the reaction of Eq. 7 is also achieved, because the formations of **1a** and **4a** in Eq. 8 need 2-hexyloxirane and **6**.

$$\mathbf{2a} \xrightarrow[800\ \text{MPa, 100 °C}]{\text{Et}_3\text{N, Hexane}} \underset{9\%}{\mathbf{1a}} + \underset{18\%}{\mathbf{2a}} + \underset{52\%}{\mathbf{3a}} + \underset{6\%}{\mathbf{4a}} + \underset{15\%}{\mathbf{5a}} \quad (8)$$

$$\mathbf{2a} + CS_2 \xrightarrow[800\ \text{MPa, 100 °C}]{\text{Et}_3\text{N}} \underset{73\%}{\mathbf{1a}} + \underset{7\%}{\mathbf{2a}} + \underset{9\%}{\mathbf{4a}} + \underset{2\%}{\mathbf{5a}} \quad (9)$$

Of Eqs. 3—7, it has been reported[3,4] that the compression have an accelerating effect on reactions in Eqs. 3—5. The reactions of Eqs. 6 and 7 seem to also be accelerated by compression since a rearrangement of **2a** did not occur under ordinary pressure under similar reaction conditions to Eq. 8.

Some products[6-9] which are derived from **3** are known to be accricides, fungicides, or insecticides. Though various synthetic methods of 1,3-dithiolan-2-one have been reported,[10-14] the materials used for its derivatives are rather inaccessible. Synthesis of its derivatives by reactions of oxirane with carbon disulfide under high pressure have the advantage since many kinds of oxiranes may be obtained commercially.

Experimental

Apparatus. The apparatus used for the reaction under high pressure was the same as that described previously.[15]

Measurement. GLC was carried out using a JEOL 20KF chromatograph with 20% SE-30 columns. ^{1}H NMR spectra were measured with a Hitachi R-40 spectrometer. Mass spectra were measured with a JEOL D-300 GC-MS spectrometer by the CI (chemical ion) method with isobutane. IR spectra were obtained with a JASCO A-302 spectrophotometer.

Reaction of Oxiranes with Carbon Disulfide. A typical procedure is as follows: A homogeneous mixture of 2-hexyloxirane (5 mmol), carbon disulfide (5 mmol), and triethylamine (0.5 mmol) in a sealed Teflon tube was compressed to 800 MPa, heated at 100 °C, and maintained for 20 h in a high-pressure apparatus. The resulting mixture was subjected to evaporation and the residue was distilled with a Kugelrohr. The distillate was separated by column chromatography on silica gel using a mixture of hexane and chloroform (7 : 3 v/v) as an eluent. The spectral data of **1a** and **4a** agreed with the known data.[3,4] The structure of **3a** was identified by a comparison of ^{1}H NMR and IR spectra of **3a** with

those of **1a**, **2a**, **4a**, and 1,3-dithiolan-2-one.[10] **3a**: IR 1642 cm^{-1} ; ^1H NMR δ=0.89 (t, 3H, CH_3), 1.31 (s, 8H, $\{CH_2\}_4$), 1.65—2.10 (m, 2H, CH_2), 3.24—3.86 (m, 2H, CH_2), and 3.91—4.37 (m, 1H, CH); QM^+ 205.

2-Methyloxirane, 2-ethyloxirane, 2,2-dimethyloxirane, 2,3-tetramethyleneoxirane, and 2-phenyloxirane were treated with carbon disulfide similarly to 2-hexyloxirane. The spectral data of **1**, **2**, and **4** from these reactions agreed with the known data.[3,4] The spectral data of the other products of these reactions are as follows:

4-Methyl-1,3-dithiolan-2-one: IR 1642 cm^{-1}; ^1H NMR δ=1.60 (d, J=6.3 Hz, 3H, CH_3), 3.22—3.53 (dd, J=7.2 and 11.7 Hz, 1H, one proton of CH_2), 3.58—3.85 (dd, J=4.5 and 11.7 Hz, 1H, one proton of CH_2), and 4.00—4.42 (m, 1H, CH); QM^+ 135.

4-Ethyl-1,3-dithiolan-2-one: IR 1642 cm^{-1}; ^1H NMR δ= 1.06 (t, 3H, CH_3), 1.93 (quin, 2H, CH_2), 3.30—3.56 (dd, J=7.2 and 11.7 Hz, 1H, one proton of CH_2), 3.60—3.87 (dd, J=5.4 and 11.7 Hz, 1H, one proton of CH_2), and 3.89—4.22 (m, 1H, CH); QM^+ 149.

4,4-Dimethyl-1,3-dithiolan-2-one: IR 1643 cm^{-1}; ^1H NMR δ=1.70 (s, 6H, $2CH_3$), and 3.47 (s, 2H, CH_2); QM^+ 149.

4,5-Tetramethylene-1,3-dithiolan-2-one: IR 1624 cm^{-1}; ^1H NMR δ=1.2—2.3 (m, 8H, $4CH_2$), and 3.70—3.95 (m, 2H, 2CH); QM^+ 175.

4-Phenyl-1,3-dithiolan-2-one: IR 1651 cm^{-1}; ^1H NMR δ=3.71 (d, J=9 Hz, 2H, CH_2), 5.23 (t, 1H, CH), and 7.10—7.70 (m, 5H, C_6H_5); QM^+ 197.

Rearrangement of 2a in Hexane. A homogeneous mixture of **2a** (43.1 mg), triethylamine (4.0 mg), tetradecane (7.3 mg), and hexane (0.3 ml) in a sealed Teflon tube was compressed to 800 MPa, heated at 100 °C, and maintained for 20 h in a high-pressure equipment. The GLC analysis using tetradecane as a standard showed that 52% of **3a** was obtained.

Reaction of 2a with Carbon Disulfide. A homogeneous mixture of **2a** (43.3 mg), carbon disulfide (200 mg), triethylamine (3.8 mg), and tetradecane (5.9 mg) in a sealed tube was compressed to 800 MPa, heated at 100 °C, and maintained for 20 h in a high-pressure apparatus. A GLC analysis using tetradecane as a standard showed that 71% of **1a** was obtained.

(Received August 15, 1988)

The existence of ring transformation equilibrium (bond switch) in 5-(1-aminoethylideneamino)-3-methyl-1,2,4-thiadiazole (**5a**) was confirmed by nitrogen-15 labeling experiment. Kinetic studies were carried out under neutral or acidic conditions. Kinetic parameters of the intramolecular equilibration of the monoprotonated **5a** (**5a**-H^+) were obtained by line shape analyses of the ^1H NMR, i.e., $\Delta G^{\ddagger}_{273}=14.8\pm0.2$, $\Delta H^{\ddagger}=11.6\pm1.0$ kcal·mol^{-1} $\Delta S^{\ddagger}=-12\pm3$ eu, $k_{273}=9$ s^{-1}. Position of protonation was determined at the nitrogen of the ethylideneamino part of the amidino group. It was concluded that the central sulfur atom moves back and forth in the range of 0.38 Å nine times a second at 0 °C, that is, bond switching.

Labile and polarizable nature of three-center four-electron bond in hypervalent molecules has been amply demonstrated by X-ray analyses of organic molecules of main group elements and sulfuranes are typical examples among them. Sulfurane **1** was synthesized by Martin,[1a] and two S-O bond lengths are longer than usual covalent bond and differ by 0.25 Å. The S-S bond length in 1,6,6a-trithiapentalene system (**2**) lies close to 2.36 Å but fluctuates within the range of 0.4 Å according to substituents.[2] The lability of bond length is one of the characteristics of hypervalent bond. The apparent bond switch in the 1,3-dipolar cycloaddition of five-membered sulfur containing heterocycles with activated acetylenes and so on have been considered to proceed through unsymmetrical trithiapentalene type intermediates.[3] Large difference of reactivity with activated acetylenes was noticed between isoelectronic 3(2*H*)- and 5(2*H*)-isothiazolethiones (**3** and **4**), that is, the latter was much more reactive than the former, because the central sulfur atom could participate in the 1,3-dipolar cycloaddition.[3f] Reid and co-workers reported the bond switch in the trithiapentalene-tungsten complexes.[4]

We have communicated a facile bond switch in some 1,2,4-thiadiazol-5(4*H*)-imine system by methylation or protonation,[5] and simplified the system in order to observe reversible bond switch via symmetrical sulfurane as an intermediate. In this system the sulfur-nitrogen bond was switched by prototropy, and the facility of the equilibration would suggest that the stability of the intermediate **A** reduced the activation energy (Eq. 1).[6] This type of equilibration does not take place at all when an oxygen is substituted for the sulfur.

In this paper the observed phenomenon was confirmed to be bond switching by introducing ^{15}N to the amidino group and kinetic studies on equilibration were carried out under neutral and acidic conditions.[7]

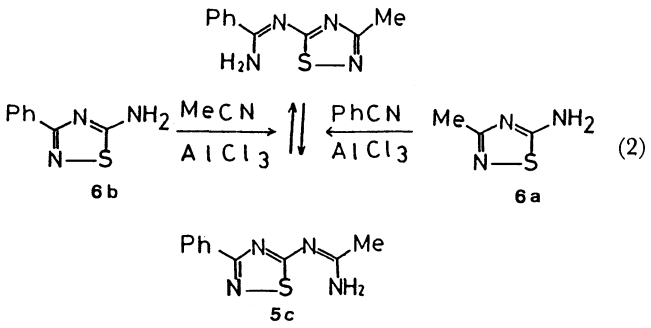
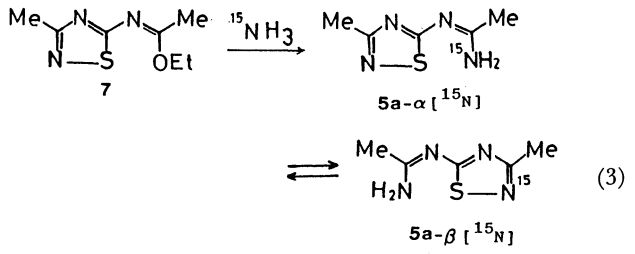
Results and Discussion

Confirmation of Bond Switch by ^{15}N Labeling Experiment and Estimation of the Rate under Neutral Conditions. As described before 5-(1-substituted 1-aminomethyleneamino)-3-methyl-1,2,4-thiadiazole (**5α**) was considered to be in equilibrium with the bond-switched **5β**. The conclusion was drawn by the following facts: (i) in the ^1H NMR spectra of unsymmetrical **5b** and so on signals due to the methyl and the substituent (R) appeared as a pair, respectively, but those of symmetrical **5a** (R=Me) showed only two peaks due to two different methyl groups; (ii) relative intensity of the methyl corresponded exactly to that of the other substituent (R). In order to present an unambiguous evidence for bond switch, **5c** was synthesized also from 5-amino-3-phenyl-1,2,4-thiadiazole (**6b**)[8] and acetonitrile in the presence of aluminum trichloride to give an identical compound with previously prepared one from 5-amino-3-methyl-1,2,4-thiadiazole (**6a**) and benzonitrile[6] (Eq. 2). Further



(2)

conclusive evidence came from the ^{15}N labeling experiment. Thus an imidate **7** was prepared from **6a** and triethyl orthoacetate in 95% yield. The imidate **7** was converted with ammonia at room temperature to give **5a**, which was identical with the compound synthesized previously. This method was mild and efficient thus it was applied to the synthesis of ^{15}N labeled **5a** in 60% yield using $^{15}NH_3$ (in situ prepared from [^{15}N]ammonium chloride (^{15}N 99% enriched) and 1 equiv of potassium hydroxide). In the proton



(3)

decoupled ^{15}N NMR spectrum of **5a**[^{15}N] two peaks with almost equal height were observed. The chemical shifts of these nitrogens were obtained from that of nitromethane as an external reference and were calculated into the values from liquid ammonia.[9a] The peak at δ 104.1 was observed as a triplet (J_{NH}=91 Hz) in nondecoupled conditions, thus it is assigned to the nitrogen of the amino group in the amidino group. It is reasonable that the other peak at δ 240.7 (singlet in nondecoupled conditions) is assigned to the N(2) of the thiadiazole ring by comparison with reported chemical shift data.[9b] Off-resonance ^{15}N NMR spectrum of **5a**[^{15}N] is shown in Fig. 1. Therefore bond switch was evidently confirmed to take place.

It is interesting that ^{15}N NMR chemical shift of the amino nitrogen is in somewhat lower field than usual and that of the N(2) of the thiadiazole is in higher field.[9b] This tendency can be understood by contribution of intramolecular electron shift from the electron-rich amidino group into the electron-deficient five-membered thiadiazole ring.[9c] The explanation can also be applied to the electronic effects of the subsituents on the equilibrium ratio (β/α), that is, 2.14 in **5b** (R=CH_2Cl), 5.99 in **5d** (R=*p*-MeC_6H_4), 14.5 in **5c** (R=C_6H_5), and ca. 50 in **5e** (R=*p*-ClC_6H_4) (all values in $CDCl_3$ at 34 °C). Thus β-forms are further stabilized in polar solvents (**5b**: 2.14 in $CDCl_3$, 6.46 in CD_3CN). Measurements of the equilibrium ratios of **5b** in several solvents at various temperatures were carried out to give thermodynamic parameters of the bond switch. The results are shown in Table 1. It was found that ΔS was about zero and ΔH was almost responsible for the equilibrium ratio.

The rather large difference between the equilibrium ratio in $CDCl_3$ and CD_3OD (2.9 and 10.7 at −26 °C) was tried to use for the determination of the rate of the equilibration. Thus, to a $CDCl_3$ solution of **5b** (β/α=3) at −50 °C precooled CD_3OD (−50 °C) was added and ^1H NMR spectrum of the mixture was measured quickly at that temperature. In the first measurement which was done during 2—3 min after mixing, the ratio (β/α) was determined to be ca. 7 and in

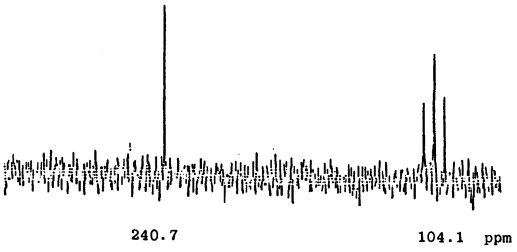


Fig. 1. Off-resonance ^{15}N NMR of **5a**[^{15}N] in neutral solution ($CDCl_3$).

Table 1. Solvent Effect on the Thermodynamic Parameters between **5bα** and **5bβ**

Solvent	Polarity E_T	β/α (34 °C)	ΔG_{307} kcal mol^{-1}	ΔH kcal mol^{-1}	ΔS eu
$CDCl_3$	39.1	2.14	−0.48	−0.75	−0.9

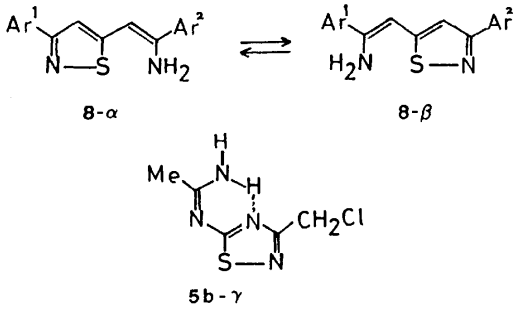
the next measurement (4—5 min after mixing) a new equilibrium ratio (β/α=8) was observed. Therefore it was concluded that the exchange process between α- and β-forms was fairly fast even at −50 °C. Although the ratios thus obtained contain large experimental error, the rate of equilibration ($\alpha \rightarrow \beta$) was roughly estimated to be ca. 10^{-2} s^{-1} at −50 °C by reversible first order approximations and $\Delta G^{\ddagger}_{223}$ was estimated to be about 14—15 kcal mol^{-1}(1 cal=4.184 J). Therefore the coalescence method was employed to determine the rate. A solution of **5b** in *o*-dichlorobenzene and DMSO-d_6 was heated until 170 °C in an NMR probe, but coalescence between two signals of the methyl (or chloromethyl) group was not observed. Free energy of activation ($\Delta G^{\ddagger}_{443}$) of the bond switch is calculated to be over 23 kcal mol^{-1} at 170 °C.

Accurate and detailed kinetic studies were carried out for a similar system **8** under neutral conditions



and kinetic parameters were obtained as $\Delta H^{\ddagger}$=12.2 kcal mol^{-1}, $\Delta S^{\ddagger}$=−41 eu, and $\Delta G^{\ddagger}$=24.4 kcal mol^{-1} (R^1=R^2=*p*-ClC_6H_4) (Eq. 4).[10a] The large negative value of activation entropy is characteristic and a much larger value is expected for **5**, because **5b**-γ is hydrogen-bonded intramolecularly in the ground state.[10b] Detailed discussion on the mechanism of the bond switch under neutral conditions was carried out for **8**.

Bond Switch under Acidic Conditions. When an acid was added to a solution of **5**, rate of bond switching was greatly accelerated and only one methyl signal could be observed at room temperature. Figure 2 shows that downfield shift of the methyl protons in **5a** takes place according to the amount of trifluoroacetic acid (TFA). Good linear relationship was observed until the added acid reached to one equiv to **5a**. When it exceeded one equiv, chemical shift of the methyl signal became constant even with large excess of TFA (6 equiv) or trifluoromethanesulfonic acid (13 equiv), indicating that only monoprotonation occurred and di- or polyprotonation did not. pK_a of **5a** was measured to be 4.87±0.02 by potentiometry, therefore the acidity of TFA (pK_a 0.23)[11] is high enough to protonate **5** stoichiometrically. The position of protonation will be discussed in a later section.

In order to determine the rate of equilibration under acidic conditions ^{1}H NMR of **5b** was measured in $CDCl_3$-DMSO-d_6 at low temperatures. By lowering the temperature two pairs of two singlets appeared again when a limited amount of TFA was added (Table 2). The fact that the signal split into two pairs indicates the bond switch between monoprotonated species [(**5b**-α-H^++**5b**-α)⇄(**5b**-β-H^++**5b**-β)] was to be observed. But in excess of TFA it was impossible to observe split because β/α ratio became large (> 15) according to the amount of TFA. Therefore in order to observe this exchange equilibration between protonated α- and β-forms, ^{1}H NMR of **5a** was measured. In the case of **5a**, protonated forms (**5a**-α-H^+⇄**5a**-β-H^+) are identical before and after the bond switch, therefore only two singlets were observed. After comparison of the experimental spectra with computer simulated ones,[12] the obtained rate constants were applied to the Eyring equation. In every case the spectra used to obtain one rate constant were measured at six to eight temperatures and the statistical errors of $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$ were rendered very small by deliberate experiments. The activation free energy ($\Delta G^{\ddagger}$) and the rate were calculated from $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$, and the $\Delta G^{\ddagger}$ was consistent with the value calculated from coalescence temperature (T_c) within 0.2 kcal mol^{-1}. In Table 3-A the effect of concentration of TFA is shown while that of **5a** is kept almost constant. Solubility of **5a** was much larger in CD_3OD and CD_3CN in comparison

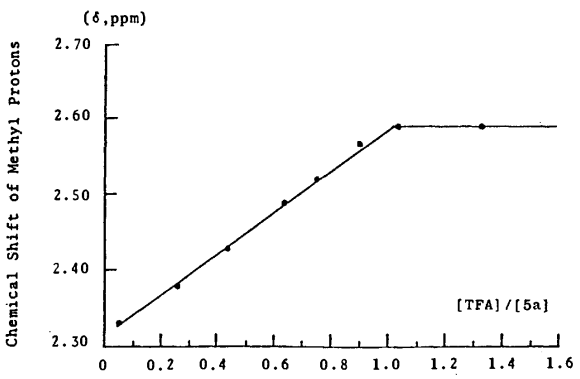


Fig. 2. Relation of chemical shift of methyl protons in **5a** and the amount of added TFA (CD_2Cl_2). [**5a**]=0.3—0.4 M.

Table 2. Low Temperature ^{1}H NMR Data of **5b** in the Presence of TFA[a,b]

TFA (equiv)	Temp °C	δ/ppm β	δ/ppm α	β/α
0	9	2.17, 4.61	2.49, 4.23	6
0.06	9	2.18, 4.63	2.48, 4.25	8
0.13	−17	2.21, 4.66	2.51, 4.27	9

a) $CDCl_3$-DMSO-d_6 as a solvent. b) The upfield signals are due to the methyl group and the downfield ones are assigned to methylene protons of the chloromethyl group.

with CD_2Cl_2 and so on, and in addition split widths ($\Delta\nu$) in polar solvents were larger than those in non-polar ones, therefore only CD_3OD and CD_3CN were used in the presence of more than one equiv of TFA. A remarkable point in Table 3-A was that the kinetic parameters in 1.23 equiv of TFA were considerably different from those in other cases. For example, free energy of activation ($\Delta G^{\ddagger}_{273}$) became larger from 13.5 (0.66 equiv) to 14.7 (1.23 equiv) kcal mol^{-1}, hence the rate (k_{273}) decreased considerably. So the effect of concentration of **5a** was studied with less than one equiv of TFA (Table 3-B) and it was clear that $\Delta G^{\ddagger}$ and the rate were dependent on the concentration. These facts imply that intermolecular process (ex. **5a**-α+**5a**-β-$H^+ \rightleftarrows$**5a**-α-H^++**5a**-β) played an important role for the bond switching in the presence of less than one equiv of TFA (Eq. 5). This intermolecular process cannot take part in the bond switching in the presence of more than one equiv of TFA. In fact both effects of concentration of **5a** and the ratio of the acid were not observed (Table 3-C). That is, $\Delta G^{\ddagger}_{273}$ was almost constant although split width ($\Delta\nu$) and coalescence temperature (T_c) changed with polarity of the solvent system. Evidently intramolecular reversible bond switching was observed under these conditions. Even when trifluoromethanesulfonic acid was used instead of TFA almost no change of kinetic parameters was observed. Therefore, the possibility that the equilibration proceeded through small amount of diprotonated intermediates can be ruled out. In CD_3CN different values of $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$ were obtained probably due to the effect of solvation but $\Delta G^{\ddagger}$ was nealy equal to that in CD_3OD.

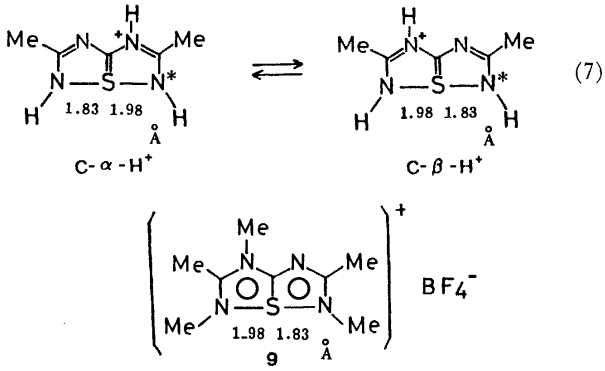
a) TFA was used throughout Run 1 to 14 (60 MHz), 16 (90 MHz) and trifluoromethanesulfonic acid was used for Run 15 (90 MHz).

tonated species, we conclude the structure of monoprotonated species observed in solution is **5a**-α-H^+-i (≡**5a**-β-H^+-i) among them. ^{15}N NMR peaks in the presence of 1.42 equiv of TFA at −20 °C ($CDCl_3$-CD_3CN=3 : 1) appeared at δ 129.3 and 242.5 under complete proton decoupled conditions and the latter was observed as a singlet and the former as a triplet (J_{NH}=92 Hz) under nondecoupled conditions, respectively. This indicates that the protonation took place at the nitrogen of the amino group in the amidino group which is *not* labeled by ^{15}N. Basicity of both N(2) and N(4) of the thiadiazole ring is very much smaller than that of **5**,[13] thus monoprotonation at those cannot be the case. Thus the possibility of Eq. 7



(7)

can be ruled out. But it is unlikely that **5a**-α-H^+-i is an appropriate precursor of the bond switch because of the much lowered nucleophilicity of the amidino group than **5a**. In contrast, **5a**-α-H^+-ii should be the precursor in the point that S-N bond in the thiadiazole ring is weakened by protonation at N(2) and the sulfur atom becomes highly susceptible to nucleophilic attack by the amino group. Kinetic data for the bond switching in Eq. 6 (Table 3-C) are summarized as $\Delta G^{\ddagger}_{273}$=14.8±0.2, $\Delta H^{\ddagger}$=11.6±1.0 kcal mol^{-1}, $\Delta S^{\ddagger}$=−12±3 eu, k_{273}=9 s^{-1}. The equilibrium ratio of (**5a**-α-H^+-i/**5a**-α-H^+-ii) is very difficult to estimate. It is not so unreasonable to assume that the ratio can be estimated by the difference between pK_a values in **5a** (4.87) and isothiazole (−0.51)[14] or 5-amino-3-phenyl-1,2,4-thiadiazole (1.4).[15] Thus the equilibrium ratio is estimated to be in the range of $10^{4.9-1.4}$ to $10^{4.9-(-0.5)}$. Then the real rate of the ring transformation should be in the range of $9\times10^{3.5}$ to $9\times10^{5.4}$ s^{-1} at 0 °C and the activation free energy ($\Delta G^{\ddagger}_{273}$) from **5a**-$\alpha$-$H^+$-ii to **5a**-$\beta$-$H^+$-ii is calculated to be from 8.0 to 10.3 kcal mol^{-1}. Such a low barrier of the bond switch can be attributed to the stability of the intermediate thiapentalenium salt **B** and also to the essential weakness of the hypervalent N-S^{IV}-N bond.

Total N-S^{IV}-N bond length of the intermediate (or transition state) **B** can be estimated based on the structure of thiapentalenium salt **9**, which was synthesized by us and the structure was determined by X-ray diffraction.[5,16] The N-S bond length in **5a**-α-H^+-ii can be estimated by the data for an isothiazolium salt to be 1.72 Å[17] then S-N bond length becomes 2.10 Å. It can be visualized that the central sulfur atom moves back and forth as a pendulum in the range of 0.38 Å nine times a second at 0 °C, that is, bond switching. This can be regarded as a model of reversible S_N2 reaction at the central sulfur (Eq. 6) and really is the first experimental evidence to show the presence of double minimum in energy in trithiapentalene analogous system, i.e., so called no-bond resonance compound.

Experimental

IR spectra were recorded on Hitachi EPI-G2 spectrometer. ^1H NMR spectra were obtained with Hitachi R-20B or R-24B spectrometer, and kinetic measurements were done mainly with JEOL FX-60 spectrometer. Partial measurement of kinetics in ^1H NMR and all work for ^{15}N NMR were carried out with JEOL FX-90Q and Hitachi R-90H spectrometer. All melting points were uncorrected.

Alternative Synthesis of 5-(1-Aminoethylideneamino)-3-phenyl-1,2,4-thiadiazole (5c). A mixture of 5-amino-3-phenyl-1,2,4-thiadiazole (**6b**) (480 mg, 2.7 mmol), anhydrous aluminum trichloride (414 mg, 3.1 mmol), and acetonitrile (0.18 ml, 3.5 mmol) was heated at 100 °C for 1 h, and it was poured into ca. 20 ml of aq HCl (0.5 M; 1 M=1 mol dm^{-3}) and the product was extracted with chloroform (50 ml×3). After drying ($MgSO_4$) and evaporation of the solvent, the residue was subjected to dry column chromatography to give 18% yield of **5c**, which was identical with the previously prepared compound from 5-amino-3-methyl-1,2,4-thiadiazole (**6a**) and benzonitrile by mp (148.0—148.7 °C), NMR and IR spectroscopy.[6]

5-(1-[^{15}N]Aminoethylideneamino)-3-methyl-1,2,4-thiadiazole (5a[^{15}N]). A mixture of 5-amino-3-methyl-1,2,4-thiadiazole (1.96 g, 17.0 mmol) and triethyl orthoacetate (8.01 g, 49.4 mmol) was heated at 110 °C for 16 h. After removal of the excess orthoacetate, the residue was distilled under reduced pressure to give 5-(1-ethoxyethylideneamino)-3-methyl-1,2,4-thiadiazole (**7**) as colorless liquid. Yield 3.00 g (95%); bp 70—71 °C/1 mmHg (1 mmHg≈133.322 Pa); ^1H NMR (CCl_4) δ=1.31 (t, 3 H, J=7 Hz), 2.11 (s, 3 H), 2.40 (s, 3 H), 4.20 (q, 2 H, J=7 Hz).

Aqueous ammonia (28%) (1.5 ml, 22.5 mmol) was added to a solution of **7** (1.02 g, 5.51 mmol) in 10 ml of ethanol at 0 °C, and the mixture was stirred for 3 h. After the solvent was evaporated the residue was recrystallized from benzene-hexane to give 701 mg (82%) of **5a**, which was identical with the previously synthesized compound by mp (109.5—111.5 °C), NMR and IR spectroscopy.[6]

To a solution of ammonium chloride (^{15}N 99% enriched, 105 mg, 1.93 mmol) in 5 ml of methanol a solution of potassium hydroxide (85%, 130 mg, 1.97 mmol) in 2 ml of methanol was added at 0 °C, and then **7** (346 mg, 1.87 mmol) was added to the mixture. After it was stirred for 5 h at room temperature, the solvent was evaporated and the residue was recrystallized from benzene-hexane to give 176 mg (60%) of **5a**[^{15}N]. Mp 108—110.5 °C. ^1H NMR ($CDCl_3$) δ=2.19 (s, 3H), 2.50 (s, 3H), 6.5 (bm, 2H). ^{15}N NMR ($CDCl_3$) δ=104.1 (t, J=91 Hz), 240.7 (s).

The Measurement of Bond Switching Equilibrium between 5b-α and 5b-β. About 10 to 15 mg of **5b** was dissolved in several solvents in an NMR sample tube (concen-

trations were kept almost the same (ca. 0.2 M)). The sample tube was cooled and the equilibrium ratio of the α- and β-isomers was measured from the peak area of both signals of the methyl protons and that of the methylene protons of the chloromethyl group. Integral ratios were measured four to six times for each condition and the average ratio was obtained. Thermodynamic parameters were calculated using the average ratios at five to six temperatures between 34 and −26 °C.

Low-Temperature ^{1}H NMR Measurement of 5b in the Presence of TFA. 34—38 mg of **5b** in $CDCl_3$ (510—600 mg) and DMSO-d_6 (199—234 mg) in the presence of the various amounts of TFA (0.06—3.26 equiv) were cooled to 9, −17, and −47 °C in an NMR tube and ^{1}H NMR were measured. Separation of peaks of methyl and chloromethyl groups could not be observed in the presence of more than 0.68 equiv of TFA.

Low-Temperature ^{1}H NMR Measurement of 5a in the Presence of TFA and Trifluoromethanesulfonic Acid. The chemical shift difference of the separated signals of the two methyl groups became constant at low temperatures (ca. −50—−60 °C) for each run in CD_3OD and CD_3CN and this constant value was employed as the line separation width without exchange ($\Delta\nu$). Computer calculation of all data were carried out using DNMR-3 program with Hitac 8700/8800 or Hitac M-200H computer in the University of Tokyo. The rate of exchange was determined by superimposing the simulated spectra on the observed ones.

This work was supported in part by a Grant-in-Aid for Scientific Research (No. 57430006) from the Ministry of Education, Science and Culture. We thank Prof. Naoki Inamoto for his helpful discussion and also wish to thank prof. Michinori Ōki for his kind permission to use the DNMR 3 program.

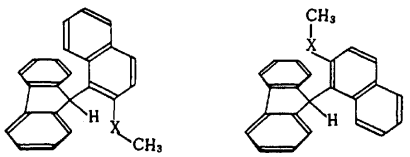
Reactivities of Stable Rotamers. XXV. Deprotonation at the 9-Position of 9-(2-Substituted 1-naphthyl)fluorene Rotamers with Butyllithium[1,2]

Kazuhiro MORIYAMA, Mikio NAKAMURA, Nobuo NAKAMURA, and Michinori ŌKI*,†
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received August 15, 1988)

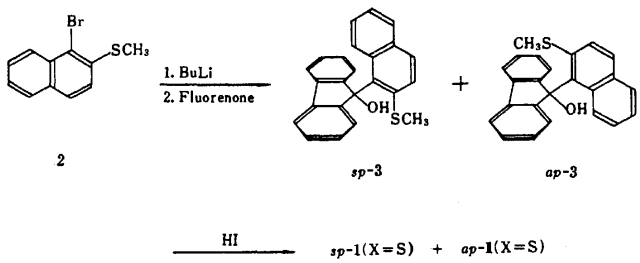
Deprotonation of 9-(2-substituted 1-naphthyl)fluorene rotamers, where the substituent is a dimethylamino, a methoxy, or a methylthio, has been carried out with butyllithium in hexane-benzene. While the reactions of the *ap*-isomers were generally slower than those of the *sp*-isomers, the difference in the methoxy compounds was the greatest among the compounds examined. The results are discussed on the basis of the ease of ligation of the substituent and the steric effects that prevail in the *ap*-isomers, together with the distance between 9-position and the ligation site in the subsituent.

Since the successful isolation of stable rotamers at room temperature,[3] we have been interested in reactivities of rotamers and have been able to show some interesting differences in their reactivities.[4] Among those examined so far, the difference in the rates of deprotonation of 9-(2-methoxy-1-naphthyl)fluorene rotamers (**1**: X=O) was one of the greatest.[2] We have thus been interested to explore further to understand the reactivity differences of these rotamers and have carried out the similar reactions of 9-(2-substituted 1-naphthyl)fluorene (**1**) rotamers where X is NCH_3, O, or S. This paper is to report the results and to discuss the interesting differences observed in the investigation.



sp-1 *ap*-1

The syntheses of the dimethylamino compound (**1**: X=CH_3N) and the methoxy compound (**1**: X=O) were already reported.[5,6] The methylthio compound (**1**: X=S) was synthesized in the following way. 1-Bromo-2-methylthionaphthalene (**2**) was lithiated with butyllithium and was treated with 9-fluorenone to afford a mixture of *ap*- and *sp*-9-(2-methylthio-1-naphthyl)-9-fluorenol (**3**) which was reduced with hydriodic acid to give the desired compound (**1**: X=S). The rotamers were separated by chromatography on silica gel.



2 *sp*-3 *ap*-3

† Present address: Department of Chemistry, Faculty of Science, Okayama University of Science, Ridaicho, Okayama 700.

The barriers to isomerization of the dimethylamino and the methoxy compounds have been reported.[5,6] The barrier to rotation of the methylthio compound was determined. It was 29.6 kcal mol^{-1} (1 cal=4.184 J) for the *ap*→*sp* process and 31.0 kcal mol^{-1} for the reverse process at 101 °C. The equilibrium constant, *sp*/*ap*, was 7.31 at the same temperature. Calculation of the rate constants of isomerization was carried out by assuming that the entropy of activation was zero[6,7] to find that the rates of deprotonation described below were larger than the rates of isomerization by a factor of more than 100 if the deprotonation was carried out at 34 °C in the cases of the dimethylamino and the methylthio compounds. However, the rates of deprotonation of the methoxy compound were only 5 times faster than those of isomerization from the *ap*-form to the *sp* at the same temperature.

We had to compromise, between the isomerization and the deprotonation, and decided to run the reaction with butyllithium in hexane-benzene at low temperatures where the contamination by the other rotamer, that might be formed by rotation under the reaction conditions, was minimal and the reaction rates were large enough for the conventional measurements. Because of the technical reasons, the reactions of the *ap*-forms were generally carried out only at 34 °C and the rates of the reactions were followed by the NMR integration, whereas those of the *sp*-forms below 40 °C and followed by mass spectra after decomposition of the lithiated product with trifluoroacetic acid-*d*. Therefore the rates of the reaction were compared by calculation of those of the *sp*-isomers with the use of kinetic parameters obtained from the results at low temperatures. The kinetics apparently followed the pseudo-first-order rate law in the substrate for both rotamers of **1**. The results are shown in Table 1, in which the second-order rate constants were compared with those of 9-(2-methyl-1-naphthyl)fluorene rotamers[8] that do not carry heteroatoms in the substituent.

The results indicate that the reaction rates are enhanced when a heteroatom is introduced to the 1-substituent of the naphthalene nucleus. It is well known that butyllithium forms a hexamer in hydro-

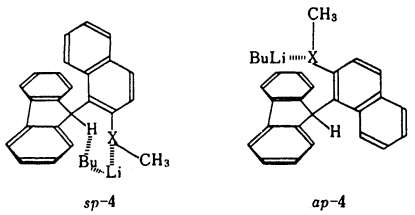
Table 1. Second-Order Rate Consants ($\times 10^5/s^{-1}$ mol^{-1} L) of Lithiation of **1** at 34.0 °C

2-Substituent	$N(CH_3)_2$	OCH_3	SCH_3	CH_3[a]
sp	34.2	1090	13.1	0.14
ap	27.8	2.73	4.68	1.0

a) At 42 °C.[8] Due to the change in precedence of the substituent in the sequence rule, that shown in the line of *sp* is actually the *ap* form and vice versa. This arrangement is taken for the convenience of the comparison.

carbon solvents.[9] Therefore, butyllithium is a very bulky reagent under the reaction conditions unless some assistance for deaggregation by the substrate is not available. We conclude therefore that the heteroatom in the substituent acts to deaggregate butyllithium in this instance as in the cases of solvents with heteroatoms.[10]

The enhancement is larger in the *sp* forms than in the *ap* forms. This might be attributed to the fact that in the ligated form of the *ap* (oversimplified as *ap*-**4**) the distance between the butyllithium and the 9-H is too far for the deprotonation to occur directly, whereas the direct deprotonation from the ligated form of *sp*, which is also shown by an oversimplified form (*sp*-**4**), is possible.



sp-4 *ap*-4

However, the enhancement is not very remarkable for both *ap* and *sp* forms of the compounds examined here, an only exception being *sp*-**1** (X=O). When one compares the rates of the reactions of *ap*-forms, the largest enhancement is seen in the nitrogen compound (*ap*-**1**: X=NCH_3) but the enhancement in the oxygen and the sulfur compounds is only a factor of ca. 5 relative to the compound which carries no heteroatoms, *sp*-9-(2-methyl-1-naphthyl)fluorene. This will mean that the deaggregation due to ligation of the heteroatom in the substituent in the *ap*-form is not efficient in the enhancement of the reaction rates.

To make a sharp contrast, the enhancement of the rates was distinct in the *sp*-isomers, the smallest case, sulfur, giving the enhancement of a factor of ca. 100, when one compares the rates with that of the methyl compound. Especially large is the enhancement by the oxygen-substituent, the factor being ca. 10^4.

We should like to attribute the results both to the steric effects that become operative on ligation of the heteroatom to the lithium cation and the ability of the heteroatom to ligate to the lithium. Although the amino-nitrogen is known to be the best ligating heteroatom to the lithium cation,[11] if the ligation takes place to the amino-nitrogen in compound **1** (X=NCH_3) the steric effects will be great even in the *sp*-form (*sp*-**4**): since alkyllithium is known to be largely covalent,[12] the butyl group will accompany the lithium atom in every case and the situation will not change to a large extent even when the ligation of the heteroatom takes place.[13] We believe that the stable conformation of the dimethylamino group in *sp*-**1** (X=NCH_3) is such that the lone-pair electrons of the nitrogen atom directs to the 9-H to minimize the steric effects and probably due to the presence of a weak hydrogen bond between the 9-CH of the fluorene and the heteroatom in the 2-substituent of the naphthalene.[15] However this conformation is no longer stable if the amino-nitrogen ligates to the lithium cation because of the accompanying steric effects.

By contrast, the oxygen and the sulfur atom have two pairs of unshared electrons, one of which can be used to ligate to the lithium cation without causing too much steric hindrance in these cases. The largest enhancement by the oxygen-substituent in the *sp* must be attributed to this effect. The sulfur atom is known to be a weakly ligating atom to the lithium cation.[16] The results observed here are derived by this nature together with the factor that the sulfur atom has two pairs of the unshared electrons.

Coming back to the data of *ap*-isomers, we still see the effect of the ligating atom: the amino compound gives the largest rate constant for the lithiation. It is also interesting to note that, while the *ap*-rotamers of 9-(2-dimethylaminomethyl-, methoxymethyl-, or methylthiomethyl-1-naphthyl)fluorene, which has one extra methylene group inserted between the 1-naphthyl-carbon and the heteroatom of **1**, exhibit reaction rates that obey second-order rate law,[14] the *ap*-forms of **1** all exhibit practically pseudo-first-order rates. The difference in the reaction conditions between the present case and that reported is the concentrations of the substrates: in the earlier paper, concentrations were higher than those used in this work by ca. 10. These suggest that the rates of the reactions we observe might involve both the second-order and the first-order ones. Thus we carried out the study on the effects of concentration of the substrate on the methoxy compound (*ap*-**1**: X=O).

The results shown in Table 2 indicate that there is indeed the effects of concentration observed: the higher concentration enhances the lithiation rates. However,

Table 2. The Effect of Concentration on the Apparent Pseudo-First-Order Rate Constants of Lithiation of *ap*-**1** (X=O) at 34 °C

Concentration/10^{-3} mol L^{-1}	Rate const/10^{-5} s^{-1}
6.34	2.48
12.7	2.62
31.3	3.11

there is one thing we have to take into account before discussing the data in Table 2. That is, the rates of rotation of the methoxy compound (**1** : X=O) are large enough, so that we cannot neglect the contribution of isomerization by rotation, especially at 40 °C.

We assumed that the rates of rotation under the reaction conditions were equal to those without the added butyllithium. Then the rates of isomerization can be calculated by the activation parameters reported previously.[6] Fortunately the rates of reaction of the *sp*-form, which was formed by isomerization, was large enough to assume that it reacted instantaneously to form the lithiated compound under the conditions. Then we can write the following equation for the decrease in the amount of the *ap*-form.

$$k_{obs} = k_{ap} + k_{iso} \quad (1)$$

where k_{ap} is the rate constant of lithiation of *ap*-**1** (X=O) and k_{iso} the rate of isomerization. Using these assumptions, we obtain the rates of lithiation of *ap*-**1** (X=O) as shown in Table 3. This kind of consideration will not be necessary for the compounds, in which X=$N(CH_3)_2$ or S, because their barrier to rotation is higher than the oxygen compound.

$$k_{obs} = k_1 + k_{iso} + k_2[ap\text{-}\mathbf{1}] \quad (2)$$

Then using the data in Tables 2 and 3 together with Eq. 2, we obtain k_2 as 2.55×10^{-4} s^{-1} $L\,mol^{-1}$. Thus, whereas the contribution of the second-order reaction at the concentration of 6.34×10^{-3} mol L^{-1} is only 6.5%, that at the concentration of 31.3×10^{-3} mol L^{-1} is 26%. It is clear that at the concentration reported previously (0.31 mol L^{-1}) the contribution of the first-order reaction is very minor.

Although detailed discussion of the reaction rates of the *ap* forms is precluded because of various unknown factors, we believe the first-order rate constant of the methoxy compound is significantly larger than that of the hydrocarbon. Probably this is caused by the fact that the methoxyl group is smaller than the methyl group to make the access of the deprotonation reagent to the 9-H easier by rotation of the naphthyl group.

The largest rates of the reaction of the dimethylamino compound in the *ap* series may involve factors of the most favorable ligation of the amino-nitrogen, the steric effects on ligation, and unassisted deprotonation. The detailed discussion of the factors is not possible at present.

Table 3. Observed Rate Constants, Calculated Isomerization Rate Constants, and True Rates of Lithiation of Compound **1** (X=O) at 34 °C

Temp/°C	$k_{obs}/s^{-1}(\times10^5)$	k_{iso}/s^{-1} $(\times10^5)$	$k_1/s^{-1}(\times10^5)$

Table 5. Activation Parameters for the Lithiation of **1**

Form	Substituent	ΔH^*/kcal mol^{-1}	ΔS^*/cal mol^{-1} K^{-1}
sp	$N(CH_3)_2$	10.8±0.5	−39.3±1.8
sp	OCH_3	14.9±1.7	−18.9±6.4
ap	OCH_3	13.3±1.9	−37.7±6.2
sp	SCH_3	12.7±1.2	−35.2±3.9

The products obtained after protonation of the lithiated compounds were *sp*-**1** in all the cases examined. We believe this is caused by the fact that the lithium compound obtained from the *sp* form is stabilized by ligation of the heteroatom in the substituent. The protonation of organolithium compounds is known to proceed with retention of stereochemistry,[17] there must be reasons for the isomerization of *ap*-**1** to *sp*-**1**. We believe that, in the *ap*-form, the initially formed lithium compound may be *ap* as well but, due to the fact that a larger substituent in the 9-position of the 9-arylfluorenes reduces the barrier height,[18] the rotation about the C_9(fluorene)-to-C_1(naphthalene) bond becomes easier and thermodynamically stable form is taken.

Experimental

Materials. 9-(2-Methoxy-1-naphthyl)fluorene rotamers were prepared according to the method described previously[6] with a minor modification. Since the method described earlier gives *ap*-isomer as a minor product which isomerizes easily at room temperature, the purification of this form is rather tedious. We thus prepared *ap*-**1** (X=O) by treating the corresponding phenol as described below. 9-(2-Dimethylamino-1-naphthyl)fluorene rotamers (**1**: X=NCH_3) were prepared by the method described in the literature.[5]

***ap*-9-(2-Methoxy-1-naphthyl)fluorene [*ap*-1 (X=O)].** To a solution of 2.0 g (6.5 mmol) of *ap*-1-(9-fluorenyl)-2-naphthol[6] in 100 mL of ether was added 4.3 mL (6.5 mmol) of a ca. 15% solution of butyllithium in hexane at −78 °C under a nitrogen atmosphere. After addition of 1.0 mL (8.8 mmol) of methyl trifluoromethanesulfonate, the mixture was warmed up to room temperature, and was stirred for 30 min. The mixture was poured into water. The ether layer was separated and the aqueous layer was extracted with ether. The combined ether solution was dried over magnesium sulfate. Evaporation of the solvent gave a crude product of which recrystallization from hexane-dichloromethane afforded 1.5

g (72%) of the desired product.[6] ^{1}H NMR ($CDCl_3$) δ=3.00 (3H, s), 5.81 (1H, s), 6.9—7.9 (13H, m), 8.3—8.5 (1H, m).

9-(2-Methylthio-1-naphthyl)fluoren-9-ol (3). To a solution of 10 g (40 mmol) of 1-bromo-2-methylthionaphthalene[19] in 300 mL of dry benzene was added 27 mL (41 mmol) of a ca. 15% hexane solution of butyllithium at ca. 0 °C under a nitrogen atmosphere. After stirring for 4 h at room temperature, 7.2 g (40 mmol) of 9-fluorenone was added rapidly. The mixture was refluxed for 4 h, cooled to room temperature, and treated with ca. 5% hydrochloric acid. The ether layer was separated and the aqueous layer was extracted with ether. The combined ether solution was dried over magnesium sulfate and filtered. After evaporation of the solvent from the filtrate, the residue was chromatographed on silica gel with 4 : 1 hexane-dichloromethane eluent to give 13 g (93%) of the desired product which consisted of the *sp* and the *ap* rotamers in 10 : 1 ratio. This product was used directly for the next reaction. The following ^{1}H NMR data ($CDCl_3$, δ) were collected: *sp* 2.72 (3H, s), 6.7—8.8 (14H, m); *ap* 1.89 (3H, s), 9.5—9.7 (1H, m).

9-(2-Methylthio-1-naphthyl)fluorene (1: X=S). A mixture of 10 g (28 mmol) of the product obtained above in 1 L of acetic acid and 100 mL of ca. 57% hydriodic acid was stirred for 30 min at room temperature and then poured into water. The mixture was extracted with ether and the combined ether solution was washed with aqueous sodium hydrogensulfite and then with aqueous sodium hydrogencarbonate. After drying over magnesium sulfate, the solvent was evaporated and the residue was submitted to chromatography on silica gel. Elution with hexane afforded 2.7 g (28%) of the *sp* rotamer which was purified by recrystallization from acetonitrile and then that with 10 : 1 hexane-dichloromethane did 4.0 g (42%) of the *ap* rotamer which was also purified by recrystallization from acetonitrile.

ap-**1** (X=S), mp 158.5—159.5 °C. Found: C, 85.47; H, 5.43; S, 9.60%. Calcd for $C_{24}H_{18}S$: C, 85.17; H, 5.36; S, 9.47%. ^{1}H NMR ($CDCl_3$) δ=1.91 (3H, s), 6.06 (1H, s), 7.0—7.9 (13H, m), 8.3—8.5 (1H, m).

sp-**1** (X=S), mp 145.5—146.0 °C. Found: 84.99; H, 5.36; S, 9.54%. Calcd for $C_{24}H_{18}S$: C, 85.17; H, 5.36; S, 9.47%. ^{1}H NMR ($CDCl_3$) δ=2.70 (3H, s), 6.52 (1H, s), 6.3—8.0 (14H, m).

Determination of Barriers to Rotation. *ap*-**1** (X=S) which was the unfavorable rotamer at equilibrium was dissolved in toluene-d_8 (30 mg of the sample in 0.4 mL of the solvent) and the solution was placed in an NMR sample tube. The tube was heated in a boiling water bath and the decrease in the starting material and the increase in *sp*-**1** (X=S) were determined by integration of the respective NMR signals with a Varian EM 390 spectrometer. The equilibrium constant was obtained after 96 h heating. The rate constant was obtained by assuming reversible unimolecular reactions.

Kinetic Study of Lithiation. A solution of ca. 0.03 mmol of an *sp*-rotamer in 2.0 mL of benzene was prepared as a stock solution. Eight portions of 0.2 mL each of the stock solution were placed in small tubes and frozen at −78 °C under a nitrogen atmosphere. To the sample solutions, 0.3 mL each of ca. 15% hexane solution of butyllithium was added. The mixture was immersed in a thermostatted bath and the rates of the reaction were determined by quenching the sample solution at an appropriate time interval with 0.1 mL of trifluoroacetic acid-*d* in 1 mL of toluene at −78 °C. The ratios of the 9-deuterio compound to the 9-protio compound were determined by the intensities of the molecular ion peaks in the mass spectra. Correction for the natural abundance of isotopes that give [M^+ +1] peaks was made according to the literature.[20] The results are shown in Table 4. *ap*-**1** (X=O) was treated similarly.

Table 4 shows the calculated activation parameters from the second-order rate constants. Entropies of activation are very large negative in every case to indicate that the reaction has the nature that the freedom of the substrates is restricted in the transition state.

For the determination of the rates of lithiation of the *ap* isomers, intensities of the proton signals in NMR spectra were used. A solution of 44 mmol (0.13 mmol) of the sample in 0.2 mL of benzene-d_6 was placed in an NMR sample tube and frozen at −78 °C under a nitrogen atmosphere. After addition of 0.3 mL of ca. 15% solution of butyllithium in hexane, the mixture was warmed with stirring to make a homogeneous solution and kept at 34 °C. It is known that, when lithiation takes place, the proton signals due to 4-H and 5-H of the fluorene ring appears at δ 8.0—8.3 and that at δ 8.2—8.5 due to 8-H of the naphthalene ring in the *ap* series disappears.[14] The intensities of these signals as well as those due to the 9-H of the fluorene ring could be directly used for the determination of the rates in the cases of the *sp*-isomers. For the *ap*-isomers, initial concentration of the substrate was calculated by dividing the sum of intensities of signals at δ 8.0—8.5 and at δ ca. 6 by 2. The amount of the lithiated compound was calculated by subtracting the intensity of the signal at δ ca. 6 from that at δ 8.0—8.5 and dividing the difference by 2. The results are shown in Table 1.

The quantity of the butyllithium in the solution was calculated from the signal intensity due to the α-protons of butyllithium. It was ca. 0.9 mol L^{-1}. This confirms that the pseudo-first-order conditions are satisfied.

The ^{1}H NMR spectra were obtained with a Varian EM 390 spectrophotometer and the mass spectra on a JEOL D300.

This work was supported by a Grant-in-Aid for Fundamental Scientific Research (62124035) of the Ministry of Education, Science and Culture.

15) We have noticed that in various rotational isomers of the 9-arylfluorene series those (*sp*) which carry a heteroatom in proximity of the 9-H of the fluorene ring very easily discolor on standing, whereas such phenomenon is not observed in the *ap*. This phenomenon is most easily explained if one assumes the presence of the hydrogen bond between the 9-CH, which is acidic, and the heteroatom in the substituent of the aryl group, because the interaction will facilitate the oxidation at the 9-position of the fluorene ring.

Stereoselective Syntheses of 2-Deoxy-β-*C*-arabino- and ribopyranosides: 2-Deoxy-β-arabino- and ribopyranosyl Cyanides

Kuniaki TATSUTA,* Jun HAYAKAWA, and Yukio TATSUZAWA
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Kohoku, Yokohama 223
(Received August 17, 1988)

2-Deoxy-β-arabino- and ribopyranosyl cyanides, which should be suitable for the syntheses of biologically active products, were stereoselectively prepared from the reaction of the enones, 1,5-anhydro-2-deoxy-*erythro*-hex-1-en-3-ulose derivatives, with acetone cyanohydrin, followed by the stereoselective reduction of the producing ketones with $NaBH_4$-$CeCl_3 \cdot 7H_2O$ and L-Selectride, respectively.

The C-C bond formation at the anomeric center of carbohydrates has become an increasingly important area in synthetic oraganic chemistry. In particular, a wide variety of medicinally imporatant *C*-nucleosides[1] have been discovered as well as several *C*-glycosyl flavonoids[2] and other structurally diverse *C*-glycosides.[3] Although a lot of stereoselective routes exist for *C*-glycopyranosides,[4] little synthetic strategies have been reported for 2-deoxy-*C*-glycosides.[5] Efficient and stereocontrolled methods for the 2-deoxy-*C*-glycosidation remain an imporatant synthetic objective, not only for the preparation of biologically active 2-deoxy-*C*-glycosides including antiviral[6] *C*-nucleosides but also for the homologation of carbohydrates to serve as chiral sources for other synthetic targets.

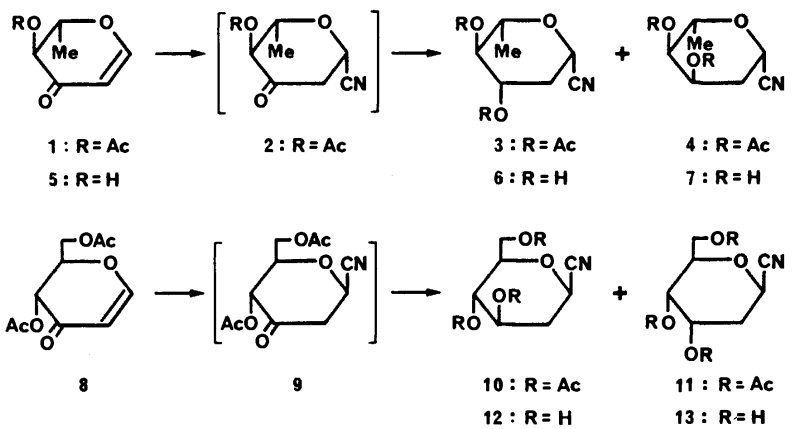
As part of an ongoing program in these and related areas, we wish to report the stereoselective syntheses of 2-deoxy-β-*C*-glycopyranosides: 2-deoxy-β-*C*-arabino- and ribopyranosyl cyanides by using acetone cyanohydrin, which is a tractable and inexpensive reagent.

Our strategy is based on the following considerations: i) the 1,4-addition of the cyanide ion[7] to the anomeric position of such enones as **1** and **8** in basic conditions to give thermodynamically the β-glycosyl cyanides; ii) the stereoselective reduction of the producing ketones such as **2** and **9** by $NaBH_4$-$CeCl_3 \cdot 7H_2O$[8] and bulky L-Selectride to give predominantly the arabino- and ribopyranosides, respectively, because of the significant influence of the C-4 substituent and the ring oxygen atom.[9]

Thus, reaction of acetone cyanohydrin[7] with the conjugated enone, 4-*O*-acetyl-1,5-anhydro-2,6-dideoxy-L-*erythro*-hex-1-en-3-ulose[10] (**1**) was best realized by using *N*,*N*-diisopropylethylamine as a catalytic base in acetonitrile to afford the intermediary 1,4-adduct **2**, which in turn was exclusively converted into the 2-deoxy-β-*C*-glycosides **3** and **4**. The 1,4-addition was also done by use of Na_2CO_3 as a catalyst in aqueous acetonitrile, but in a lower yield.

The keto cyanide **2** was submitted to the hydride reduction with $NaBH_4$ in the presence of $CeCl_3 \cdot 7H_2O$ in methanol, followed by acetylation to give predominantly 3,4-di-*O*-acetyl-2,6-dideoxy-β-L-arabinopyranosyl cyanide (**3**) in a 64% yield with the corresponding β-L-ribopyranosyl cyanide (**4**) in a 15% yield. The borohydride reduction without $CeCl_3$ gave a mixture of **3** and **4** in 23% and 22% yields without stereoselectivity. These selectivities suggested that $CeCl_3$ decreased the participation of the ring oxygen atom[9] and, relatively, $NaBH_4$ could approach to the C-3 carbonyl group from the same site of the C-4 acetoxyl group by the interaction.

In the transformation, other hydride reagents [$LiBH_4$, $Zn(BH_4)_2$, $LiBHEt_3$, $NaBH_3CN$, Bu_4NBH_4, Me_4NBH_4, $Me_4NBH(OAc)_3$, Red-Al, DIBAL, and $LiAlH_4$] were assayed in several solvents (MeOH, ether, THF, and dichloromethane), but they gave **3** and **4** in lower yields.



However, remarkably, the L-Selectride reduction in THF resulted the predominant formation of the ribopyranoside **4** in a 59% yield with only a 6% yield of the arabinopyranoside **3**. This result was reasonably supported by the consideration that the approach of the bulky hydride reagent to the C-3 carbonyl group would be restricted to the opposite site of the C-4 acetoxyl group by the steric hindrance as well as the aid of the ring oxygen atom[9] to give exclusively the cis-3,4-diol **4**.

The corresponding α-glycosyl cyanides were not recognized as detectable amounts in the aforesaid reactions.

The de-*O*-acetylated enone **5** was treated with the similar manner through borohydride reductions, but it gave **3** and **4** only in very low yields after acetylation.

The compounds **3** and **4** were de-*O*-acetylated by 7% methanolic ammonia solution to 2,6-dideoxy-β-L-arabino- and ribopyranosyl cyanides (**6** and **7**) in 95% and 87% yields, respectively, while the deacetylation with MeONa occurred in moderate yields.

When 4,6-di-*O*-acetyl-1,5-anhydro-2-deoxy-D-*erythro*-hex-1-en-3-ulose[10] (**8**) was used for the aforesaid addition, the corresponding products, 3,4,6-tri-*O*-acetyl-2-deoxy-β-D-arabino-and β-D-ribopyranosyl cyanides (**10** and **11**) were provided in almost same yields as described above, after borohydride reduction and acetylation. Namely, through the $NaBH_4$-$CeCl_3$ reduction, **10** and **11** were produced in 60% and 20% yields, while, through the L-Selectride reduction, **10** and **11** were in 4% and 60% yields.

Both compounds **10** and **11** were similarly de-*O*-acetylated to **12** and **13** in high yields, respectively. The latter compound **13** was slightly labile even on keeping in a refrigerator.

In conclusion, an efficient and stereoselective preparation of 2-deoxy-β-*C*-glycosides: 2-deoxy-β-arabino- and ribopyranosyl cyanides has been developed, starting from 1,5-anhydro-2-deoxy-*erythro*-hex-1-en-3-ulose derivatives (**1** and **8**) by using the addition of acetone cyanohydrin followed by borohydride reduction.

Experimental

Melting points were determined on a micro hot-stage Yanaco MP-S3 and were uncorrected. Optical rotations were measured with a JASCO DIP-360 photoelectric polarimeter in chloroform and methanol. IR spectra were recorded on a Hitachi Perkin-Elmer 225 spectrometer, and ^{1}H NMR spectra on a JEOL GX-400 spectrometer in $CDCl_3$ and CD_3OD using TMS as internal standard. Mass spectra were measured with a Hitachi M-80 mass spectrometer. TLC was carried out on Merck TLC plates (60F-254, 0.25 mm). Column chromatography was performed on silica gel, Merck Kieselgel 60. In general, organic solvents were purified and dried by the appropriate procedures, and evaporation was carried out under reduced pressure below 35 °C.

The starting materials, 4-*O*-acetyl-1,5-anhydro-2,6-dideoxy-L-*erythro*-hex-1-en-3-ulose (**1**), 1,5-anhydro-2,6-dideoxy-L-*erythro*-hex-1-en-3-ulose (**5**), and 4,6-di-*O*-acetyl-1,5-anhydro-2-deoxy-D-*erythro*-hex-1-en-3-ulose (**8**), were prepared according to the Czernecki's procedures.[10]

3,4-Di-*O*-acetyl-2,6-dideoxy-β-L-arabinopyranosyl Cyanide (3) and 3,4-Di-*O*-acetyl-2,6-dideoxy-β-L-ribopyranosyl Cyanide (4). A) By $NaBH_4$-$CeCl_3$: A mixture of **1** (1.74 g), acetone cyanohydrin (2.8 ml) and *N*,*N*-diisopropylethylamine (0.36 ml) in acetonitrile (17 ml) was stirred at 70 °C for 3 days, and then evaporated to a residue (approximately 3.5 g) containing **2**. A solution of the residue in methanol (100 ml) was stirred with $CeCl_3 \cdot 7H_2O$ (4.18 g) at 5 °C for 20 min, and $NaBH_4$ (1.0 g) was added. The mixture was stirred at the same temperature for 1.5 h and then at room temperature for 18 h. The reaction mixture was neutralized with Amberlite CG-50 (H type), filtered and evaporated to a residue, which was stirred with acetic anhydride (10 ml) in pyridine (30 ml) at room temperature for 24 h. After addition of ethanol, the mixture was evaporated and co-evaporated with toluene to a residue, which was chromatographed on silica gel (100 g) with 15:1 chloroform-ethyl acetate to give **3** (1.58 g, 64%) and **4** (0.37 g, 15%) having the R_f-values 0.45 and 0.37 (10:1 chloroform-ethyl acetate).

3: Needles from ethyl acetate-hexane; mp 102 °C; $[\alpha]_D^{31}$ −100° (*c* 1.1, $CHCl_3$); IR (KBr): 1720, 1240, and 1220 cm^{-1} (OAc); ^{1}H NMR (400 MHz, $CDCl_3$); δ=1.25 (3H, d, Me-5, *J*=6.2 Hz), 2.03 (1H, m, H-2ax), 2.04 and 2.08 (each 3H, s, OAc), 2.40 (1H, ddd, H-2eq, *J*=13.2, 5.1, and 1.5 Hz), 3.94 (1H, dq, H-5, *J*=9.6 and 6.2 Hz), 4.76 (1H, t, H-4, *J*=9.6 and 9.5 Hz), 4.86 (1H, dd, H-1, *J*=5.8 and 1.5 Hz), and 5.22 (1H, ddd, H-3, *J*=11.7, 9.5 and 5.1 Hz); MS *m/z* 242 (M^++1).

Found: C, 54.89; H, 6.11%. Calcd for $C_{11}H_{15}NO_5$: C, 54.77; H, 6.27%.

4: Syrup; $[\alpha]_D^{31}$ −157° (*c* 1.1, $CHCl_3$); IR (neat): 1740, 1245, and 1220 cm^{-1} (OAc); ^{1}H NMR (400 MHz, $CDCl_3$): δ=1.24 (3H, d, Me-5, *J*=6.1 Hz), 2.07 and 2.19 (each 3H, s, OAc), 2.26 (2H, m, H-2ax and 2eq), 4.31 (1H, dq, H-5, *J*=9.6 and 6.1 Hz), 4.61 (1H, dd, H-4, *J*=9.6 and 3.0 Hz), 4.77 (1H, dd, H-1, *J*=5.6 and 2.7 Hz), and 5.37 (1H, dd, H-3, *J*=6.3, 3.0 and 0 Hz); MS *m/z* 242 (M^++1).

Found: C, 54.64; H, 6.34%. Calcd for $C_{11}H_{15}NO_5$: C, 54.77; H, 6.27%.

B) By L-Selectride: A sample of **1** (1.70 g) was treated by the same procedure as described in the Section A. To a stirred solution of the residue (approximately 3.5 g) containing the adduct **2** in THF (100 ml) was added dropwise a 1 M L-Selectride solution in THF (25 ml) at −78 °C, and then stirring was continued for 1 h at the same temperature. After addition of 50% acetic acid, the mixture was partitioned between ethyl acetate and water. The combined organic layers were dried and evaporated to a residue, which was acetylated as described in the Section A. After silica-gel column chromatography, **3** (0.14 g, 6%) and **4** (1.42 g, 59%) were obtained.

2,6-Dideoxy-β-L-arabinopyranosyl Cyanide (6). A sample of **3** (335 mg) was stirred in 7% methanolic ammonia solution (3.4 ml) at 5 °C for 3 h. The reaction mixture was evaporated to a residue, which was chromatographed on silica gel (10 g) with 1:2 benzene-ethyl acetate to give a syrup of **6** (207 mg, 95%): R_f 0.33 (2:1 chloroform-acetone); $[\alpha]_D^{29}$ −66° (*c* 1.0, MeOH); IR (neat): 2230 cm^{-1} (CN); ^{1}H NMR (400 MHz, CD_3OD): δ=1.29 (3H, d, Me-5, *J*=6.0 Hz), 1.85 (1H, ddd, H-2ax, *J*=14, 11.5, and 6.0 Hz), 2.15 (1H, ddd, H-2eq, *J*=14, 4.8, and 1.6 Hz), 2.93 (1H, t, H-4, *J*=9.2 and 9.0

Hz), 3.59 (1H, dq, H-5, J=9.2 and 6.0 Hz), 3.71 (1H, ddd, H-3, J=11.5, 9.0 and 4.8 Hz), and 4.96 (1H, dd, H-1, J=6.0 and 1.6 Hz); MS m/z 157 (M^+).

Found: C, 53.01; H, 6.91%. Calcd for $C_7H_{11}NO_3$: C, 53.49; H, 7.05%.

2,6-Dideoxy-β-L-ribopyranosyl Cyanide (7). A sample of **4** (359 mg) was deacetylated by the procedure described in the preparation of **6**, and then worked up to give needles of **7** (203 mg, 87%) after recrystallization from ethyl acetate-hexane: R_f 0.32 (2:1 chloroform-acetone); mp 162 °C; $[\alpha]_D^{29}$: −107° (c 0.87, MeOH); IR (KBr): 2230 cm^{-1} (CN); ^1H NMR (400 MHz, CD_3OD): δ=1.25 (3H, d, Me-5, J=6.1 Hz), 2.1 (2H, m, H-2ax and 2eq), 3.17 (1H, dd, H-4, J=9.4 and 4.0 Hz), 4.03 (1H, dd, H-1, J=6.3 and 2.9 Hz), 4.04 (1H, dq, H-5, J=9.4 and 6.1 Hz), and 4.79 (1H, t, H-3, J=4.0 and 0 Hz); MS m/z 157 (M^+).

Found: C, 53.42; H, 7.11%. Calcd for $C_7H_{11}NO_3$: C, 53.49; H, 7.05%.

3,4,6-Tri-*O*-acetyl-2-deoxy-β-D-arabinopyranosyl Cyanide (10) and 3,4,6-Tri-*O*-acetyl-2-deoxy-β-D-ribopyranosyl Cyanide (11). A) By $NaBH_4$-$CeCl_3$: A mixture of **8** (1.02 g), acetone cyanohydrin (1.85 ml) and *N,N*-diisopropylethylamine (0.16 ml) in acetonitrile (10 ml) was stirred at room temperature for 3 days, and then evaporated to a residue containing **9**. The residue was treated with $NaBH_4$ and $CeCl_3 \cdot 7H_2O$ followed by acetylation as described in the preparation (Section A) of **3** and **4**, and then worked up to give **10** (0.80 g, 60%) and **11** (0.26 g, 20%) having the R_f-values 0.37 and 0.32 (8:1 chloroform-ethyl acetate).

10: Needles from ethyl acetate-hexane; mp 156 °C; $[\alpha]_D^{26}$ +63° (c 0.93, $CHCl_3$); IR (KBr): 1730 and 1220 cm^{-1} (OAc); ^1H NMR (400 MHz, $CDCl_3$): δ=2.05, 2.07 and 2.10 (each 3H, s, OAc), 2.11 (1H, ddd, H-2ax, J=13.8, 11.7 and 5.9 Hz), 2.42 (1H, ddd, H-2eq, J=13.8, 5.0 and 1.5 Hz), 4.05 (1H, ddd, H-5, J=9.6, 4.8 and 1.8 Hz), 4.12 (1H, dd, H-6, J=12.8 and 1.8 Hz), 4.35 (1H, dd, H-6′, J=12.8 and 4.8 Hz), 4.94 (1H, dd, H-1′, J=5.9 and 1.5 Hz), 5.02 (1H, dd, H-4, J=9.6 and 9.2 Hz), and 5.27 (1H, ddd, H-3, J=11.7, 9.2, and 5.0 Hz); MS m/z 300 (M^++1).

Found: C, 52.13; H, 5.54%. Calcd for $C_{13}H_{17}NO_7$: C, 52.17; H, 5.73%.

11: Needles from ethyl acetate-hexane; mp 92 °C; $[\alpha]_D^{26}$ +102° (c 1.0, $CHCl_3$); IR (KBr): 1730 and 1220 cm^{-1} (OAc); ^1H NMR (400 MHz, $CDCl_3$): δ=2.05, 2.09, and 2.21 (each 3H, s, OAc), 2.28 (2H, m, H-2ax and 2eq), 4.20 (1H, dd, H-6, J=12.7 and 1.9 Hz), 4.35 (1H, dd, H-6′, J=12.7 and 4.6 Hz), 4.42 (1H, ddd, H-5, J=9.8, 4.6, and 1.9 Hz), 4.85 (1H, dd, H-1, J=4.3 and 3.2 Hz), 4.89 (1H, dd, H-4, J=9.8 and 2.8 Hz), and 5.43 (1H, dd, H-3, J=6.0, 2.8 and 0 Hz); MS m/z 300 (M^++1).

Found: C, 51.90; H, 5.51%. Calcd for $C_{13}H_{17}NO_7$: C, 52.17; H, 5.73%.

B) By L-Selectride: A mixture of **8** (1.14 g), acetone cyanohydrin (2.05 ml), and *N,N*-diisopropylethylamine (0.17 ml) in acetonitrile (11 ml) was stirred at room temperature for 3 days, and then evaporated to a residue. The residue was treated with L-Selectride followed by acetylation as described in the preparation (Section B) of **3** and **4** to give **10** (0.060 g, 4%) and **11** (0.89 g, 60%).

2-Deoxy-β-D-arabinopyranosyl Cyanide (12). A sample of **10** (550 mg) was de-*O*-acetylated by the procedure described in the preparation of **6**, and then worked up to give needles of **12** (282 mg, 89%) after recrystallization from ethyl acetate-hexane: R_f 0.37 (6:1 chloroform-methanol); mp 129 °C; $[\alpha]_D^{29}$ +90° (c 1.0, MeOH); IR (KBr): 2340 cm^{-1} (CN); ^1H NMR (400 MHz, CD_3OD): δ=1.86 (1H, ddd, H-2ax, J=13.6, 11.6, and 5.3 Hz), 2.16 (1H, ddd, H-2eq, J=13.6, 4.8, and 1.4 Hz), 3.27 (1H, t, H-4, J=9.2 Hz), 3.55 (1H, ddd, H-5, J=9.20, 5.0 and 2.0 Hz), 3.71 (1H, dd, H-6, J=12 and 5.0 Hz), 3.77 (1H, ddd, H-3, J=11.6, 9.20, and 4.8 Hz), 3.85 (1H, dd, H-6′, J=12 and 2.0 Hz), and 5.04 (1H, dd, H-1, J=5.3 and 1.4 Hz); MS m/z 173 (M^+).

Found: C, 48.32; H, 6.39%. Calcd for $C_7H_{11}NO_4$: C, 48.55; H, 6.40%.

2-Deoxy-β-D-ribopyranosyl Cyanide (13). A sample of **11** (510 mg) was de-*O*-acetylated by the procedure described in the preparation of **6**, and then worked up to give a syrup of **13** (236 mg, 80%): R_f 0.34 (6:1 chloroform-methanol); $[\alpha]_D^{29}$ +83° (c 0.56, MeOH); IR (neat): 2330 cm^{-1} (CN); ^1H NMR (400 MHz, CD_3OD): δ=2.10 (2H, m, H-2ax and 2eq), 3.50 (1H, dd, H-4, J=9.6 and 3.2 Hz), 3.70 (1H, dd, H-6, J=12.2 and 5.3 Hz), 3.84 (1H, dd, H-6′, J=12.2 and 2.3 Hz), 3.98 (1H, ddd, H-5, J=9.6, 5.3, and 2.3 Hz), 4.07 (1H, dd, H-3, J=6.1, 3.2, and 0 Hz), and 4.85 (1H, d, H-1, J=4.3 and 0 Hz); MS m/z 174 (M^++1).

Found: C, 48.74; H, 6.42%. Calcd for $C_7H_{11}NO_4$: C, 48.55; H, 6.40%.

We are grateful to the Institute of Microbial Chemistry for the generous support of our program. Financial support by the Ministry of Education, Science and Culture (Grant-in-Aid for Scientific Research) is gratefully acknowledged.

Hongo, Bunkyo-ku, Tokyo, 113
(Received August 19, 1988)

Pd/TiO_2 catalysts prepared by different methods showed quite different catalytic activities in the hydrogenation of CO and other unsaturated compounds. The catalyst prepared by coprecipitation of Pd acetate and titanium tetraisopropoxide contained smaller Pd particles than those in catalysts prepared by impregnation methods. In the hydrogenation of CO, activities of the catalysts increased with increase in the Pd dispersion. The coprecipitated catalyst was much more active for this reaction than the other catalysts and showed high activity for methanol formation under normal pressure. In the hydrogenation of propionaldehyde to 1-propanol, the catalysts showed similar behavior to that in the CO/H_2 reaction. However, in hydrogenation of C=C double bonds, the activity order of the catalysts was reverse. Higher activity was obtained on the impregnated catalysts with larger Pd particle size and this trend was stronger in hydrogenation of the conjugated butadiene and C=C bond in acrylaldehyde than in the hydrogenation of ethylene.

Pd is widely used as a catalyst for the hydrogenation of various compounds. In some cases, supported Pd exhibits catalytic behavior much different from that of the bulk metal, and its activity and selectivity are quite sensitive to the nature of the supporting materials or other factors in preparation. Much research has been done concerning this problem. However, there is currently no agreement about a reliable way of describing the changes observed in the catalytic properties of a supported metal. In the case of Pd, hydrogenation of carbon monoxide is often studied for this purpose. Catalysts of Pd supported on various oxides were found to have very different activity and selectivity to this reaction.[1,2] Based on information obtained from the CO/H_2 reaction, there are mainly two ways of interpreting such variations in catalytic activity. One concerns the changes in the supported state of Pd caused by the interaction between Pd and the support, as suggested in the researches by Driessen[3] or by Fleisch.[4] On the other hand, some authors[5] have explained the support effect by the concept of ensemble effect wherein the support provides specific sites directly involved in the reaction rather than by considering changes in Pd. In the present work, we approach this problem from an alternate point of view. Titania-supported Pd catalysts with different Pd dispersions were prepared by coprecipitation and impregnation methods. The catalytic properties of these catalysts were investigated in hydrogenation of carbon monoxide, acrylaldehyde, propionaldehyde, 1,4-butadiene, and ethylene. The effect of Pd dispersion over titania was discussed on the basis of the activity order of the catalysts observed in the various reactions.

Experimental

Catalyst. The Pd/TiO_2 catalysts were prepared by three methods. (The resulting catalysts are denoted as A, B, and C respectively.) Catalyst A was prepared by coprecipitation by hydrolysis of $Ti(O\text{-}Pr^i)_4$ in its ether solution with $Pd(OAc)_2$. Diethyl ether was found to be a suitable solvent for the preparation, since alcoholic solvents such as methanol, ethanol, and propanols reduced the Pd salts and made it difficult to obtain a stable solution prior to the hydrolysis step. As soon as water was added to the solution hydrolysis took place. The yellow-brown color of $Pd(OAc)_2$ rapidly faded away from the solution along with the solid formation, indicating that the Pd salt had been adsorbed rapidly by the solid produced. Catalyst B was prepared by impregnating a commercial TiO_2 support (FA-50, 10 $m^2\ g^{-1}$, anatase, from Kogakogyo Corp.) with an ether solution of $Pd(OAc)_2$. Excess liquid was removed by evaporation. Catalyst C was prepared by impregnating the same FA-50 TiO_2 with a solution of $PdCl_2$ (0.25 ml/g-TiO_2), using the aqueous incipient wetness technique suggested by Tauster et al.[6] After coprecipitation or impregnation, the catalysts were dried in air at about 150 °C and then treated at assigned temperatures for use in the reactions.

Reaction Procedure. Reactions were carried out in conventional flow reactors and the products were analyzed by gas chromatography. For the hydrogenation of CO, a VZ-10 column was used to analyze hydrocarbons and a PEG-6000 column to analyze methanol and other oxygenates. For reactions of alkenes the products were also determined by a VZ-10 column, and for reactions of aldehydes a PEG-1000 column was used.

Other Measurements. Surface areas of catalysts were measured by N_2 adsorption. The irreversible adsorption of CO and H_2 was measured at room temperature using a pulse flow technique. Dispersion calculated from the adsorption amount of hydrogen (the atomic ratio H_{ad}/Pd) was used as the criterion to evaluate the specific activity of the catalysts. Measurements by X-ray diffraction and electron microscopy were also performed for characterization of the catalysts.

Results

Characterization of Catalysts. The different preparation methods resulted in catalysts with remarkably different Pd dispersions. Average Pd particle size calculated from the line broadening of the X-ray diffraction peak of Pd(111) are shown in Table 1. The measured surface area and the adsorption properties of the catalysts are also given in that table. Catalyst A, pre-

Table 1. Properties of Catalysts

Catalysts	Surf. area/ $m^2 g^{-1}$	Pd particle size from XRD/Å	Dispersion (H/Pd)

a) $Pd(OAc)_2$ was impregnated on the untreated solid obtained from hydrolysis of $Ti(O\text{-}Pr^i)_4$.

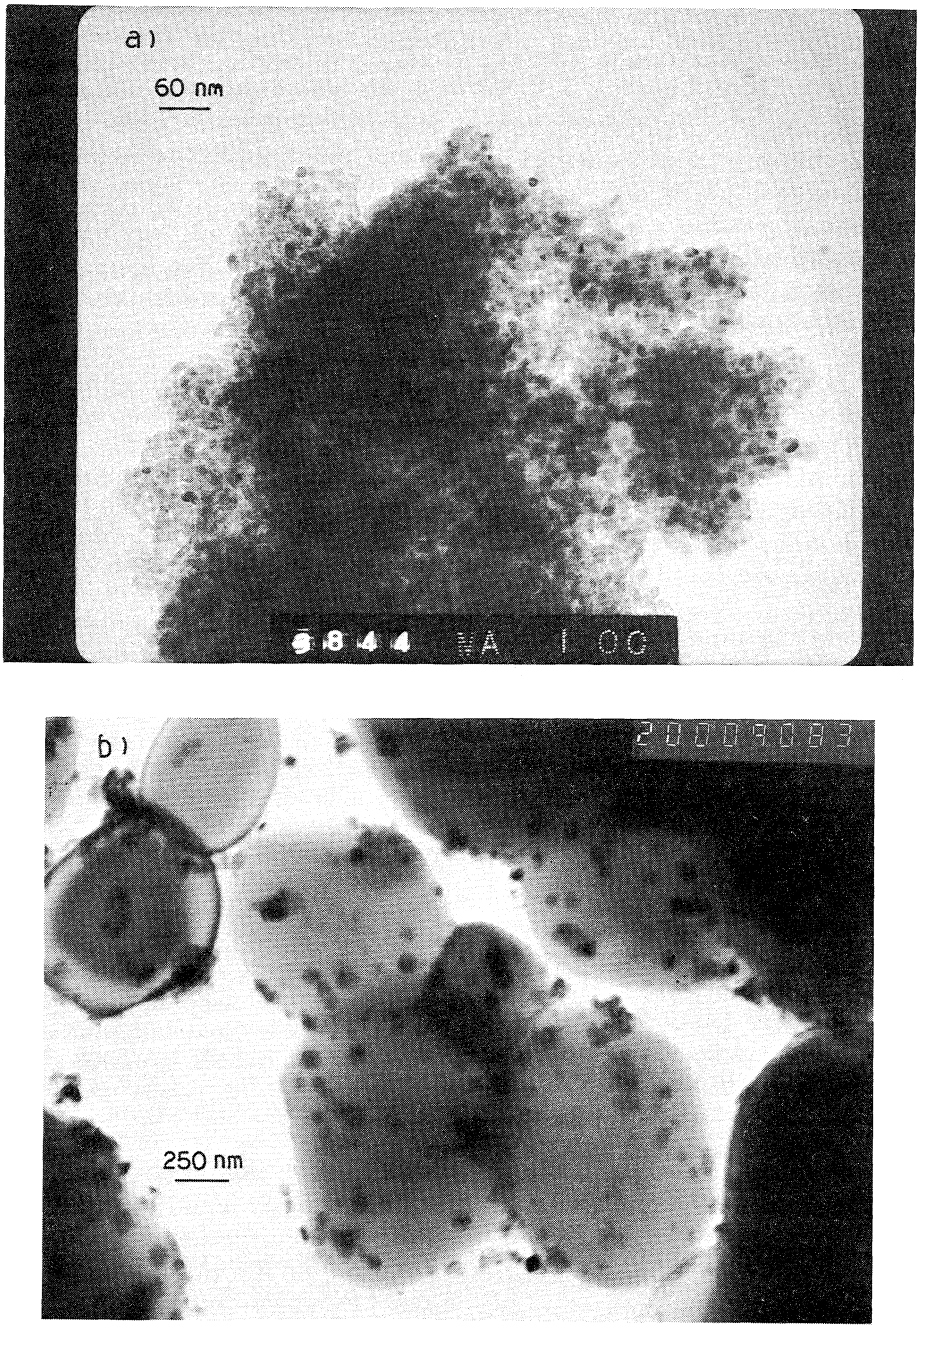

Fig. 1. TEM for a) coprecipitated catalyst A and b) impregnated catalyst B.

pared by coprecipitation of $Pd(OAc)_2$ and $Ti(O\text{-}Pr^i)_4$, achieved the highest surface area and the finest Pd particles among the three catalysts. Figure 1 shows TEM photographs for catalysts A and B. The distinction between the coprecipitated catalyst and the impregnated one is clearly seen. In the former, as a result of the preparation procedure, both Pd and the support were very fine particles and the two components were in such a well-mixed state that it is difficult to distinguish one from the other.

As shown in Table 1, a number of samples were prepared for each of the three catalysts with some variations in the conditions of heat treatment or in the preparation procedure to ensure reappearance by the preparation methods and the effects of the preparation conditions. Similar properties were generally achieved in the same group. For catalyst A, the amount of hydrogen adsorption apparently decreased after air treatment but no significant increase was seen in Pd particle size, as indicated by XRD.

The amount of hydrogen adsorption is presented as the ratio H_{ad}/Pd. Figure 2 gives a plot of H_{ad}/Pd vs. the reciprocal of average Pd particle size from XRD. The correlation between these two variables is approximately linear. The two air-treated samples of catalyst A deviated somewhat from the line. This is probably because during the air treatment the support crystal developed from its initial amorphous state and in that process some of the Pd might be wrapped inside the support. As a result, the adsorption capacity of the catalyst decreased without actual increase in Pd particle size. Though the proportional constant between the two amounts was not the same as that in the calculated equation[7] shown in the figure, the linear relationship shows that either of them can be used as a criterion to measure the relative difference of the catalysts. Here the value of H_{ad}/Pd is used to evaluate the specific activity of the catalysts.

Hydrogenation of CO. The main products of this reaction were methane and methanol. Under the pre-

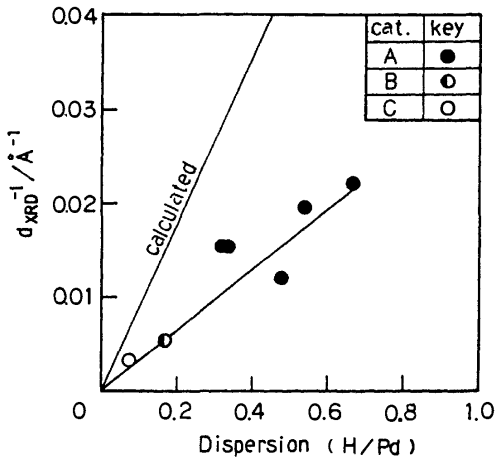

Fig. 2. Reciprocal of Pd particle diameter from XRD vs. Pd dispersion from hydrogen adsorption.

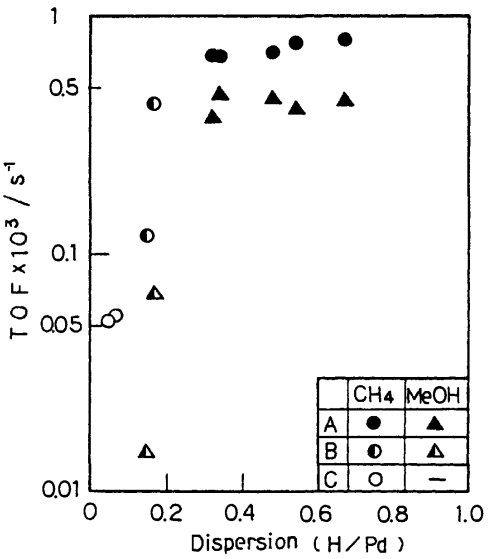

Fig. 3. Specific activity for formation of methane and methanol in the hydrogenation of CO: 1 atm, 230 °C, $CO:H_2=1:4$.

sent experimental conditions, the rate of methanol formation was affected significantly by equilibrium limitation as temperature increased beyond about 260 °C. Reactions were carried out mainly at 230 °C. Methanol production increased in the initial period of about two or three hours and then maintained a constant rate. Methane production deviated only slightly with time. Specific activities after reaching steady state are shown in Fig. 3 in terms of TOF (Turnover Frequency) based on hydrogen adsorption. Specific activity of the catalysts increased in the order C<B<A and this trend was especially remarkable for methanol formation. All the samples of catalyst A exhibited very similar activity and selectivity to each other and the production rate for methanol reached about 9 mmol/(g-Pd·h), which is quite high in comparison with the reported values for methanol synthesis on Pd catalysts at normal pressure.[1,8] However, catalyst C produced almost no methanol under the same conditions.

Hydrogenation of Acrylaldehyde (CH_2=CH-CHO) and Propionaldehyde (CH_3CH_2CHO). Acrylaldehyde is the simplest unsaturated aldehyde containing two kinds of double bonds—a C=C bond and a C=O bond. When hydrogenation of this compound was carried out at increasing temperature, at first the C=C bond was hydrogenated at comparatively low temperature and formed propionaldehyde. Then the second step of hydrogenating the formyl group took place at elevated temperature to produce 1-propanol. Catalyst A was found to be the only one on which the second step for 1-propanol formation occurred without completion of the first step. However, in the same temperature regime, though the hydrogenation of acrylaldehyde to propionaldehyde proceeded quite rapidly on catalysts B and C the resulting saturated aldehyde was not hydrogenated in spite of the completion of the first step.

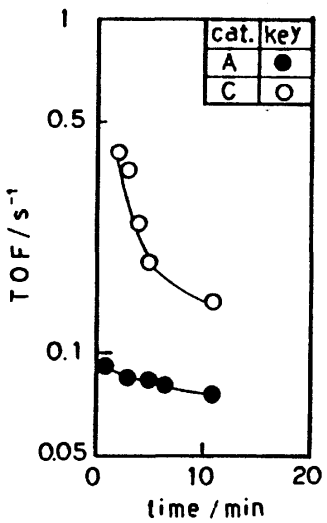

Fig. 4. Time dependence of activity for propionaldehyde formation in the hydrogenation of acrylaldehyde: acrylaldehyde 0.42%, H_2 33%, He 66.5%, 80°C.

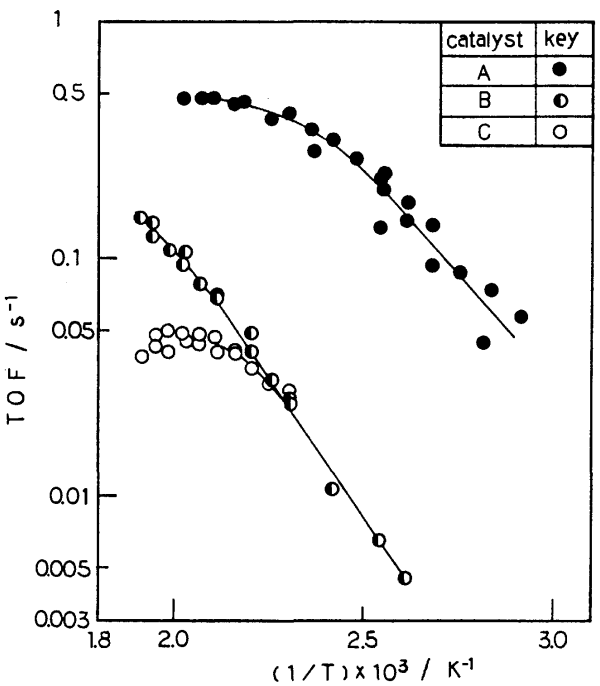

Fig. 5. Specific activity for 1-propanol formation in the hydrogenation of propionaldehyde: propionaldehyde 0.015%, H_2 33%, He 67%, 80°C.

Figure 4 shows the time dependence of the turnover frequency obtained at 80°C for catalysts A and C. In these experiments the total conversion was kept less than 10%. Under these conditions only propionaldehyde was produced and no 1-propanol was detected. The initial activity of catalyst C was about four times higher than that of catalyst A, when compared in terms of TOF.

However, in contrast to the C=C bond in acrylaldehyde, hydrogenation of the C=O bond in the formyl group was found to be quite different. In this case the relative activity of the catalysts showed a similar trend to that in the CO hydrogenation, with catalyst A being the most active one. Figure 5 shows the results from the reaction using propionaldehyde as the reactant. The figure is plotted as the temperature dependence of the production rate of 1-propanol. The activity of catalyst A was about one magnitude higher than that of the other two impregnated catalysts. The apparent slowness in increase of production rate observed in the high temperature region was due to the decomposition of the alcohol formed.

Hydrogenation of 1,4-Butadiene and Ethylene. Products of the hydrogenation of 1,4-butadiene included 1-butene, *trans*- and *cis*-2-butene and butane. Selectivities for the products are shown in Fig. 6, corresponding to the total conversion. All the catalysts had nearly the same selectivity and the general features of the product distribution were also consistent with those previously reported for Pd catalyst.[9] Among the products, *cis*-2-butene was produced only in a small amount. The fraction of butane was very low at small conversion but increased with the conversion, indicating that this product was a secondary product from successive hydrogenation of the butenes formed.

Remarkable differences in catalytic activity among the three catalysts were also observed in this reaction.

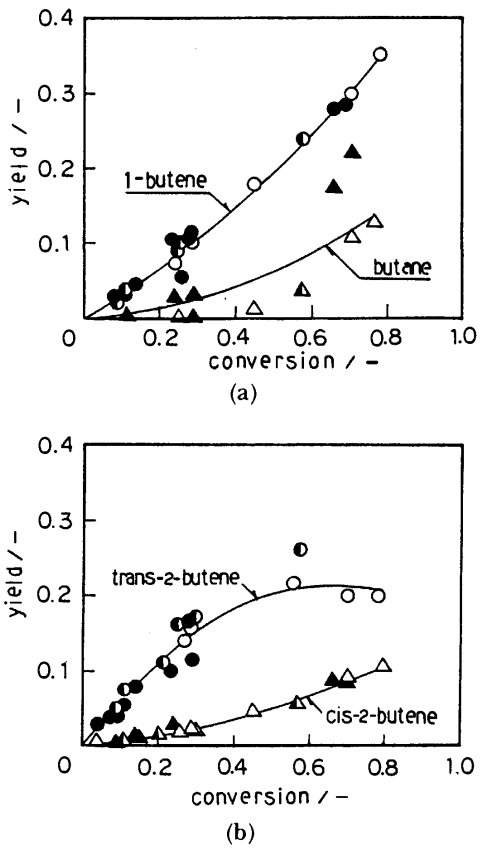

Fig. 6. Product distribution in the hydrogenation of 1,4-butadiene. ●▲ catalyst A, ◐◭ catalyst B, ○△ catalyst C.

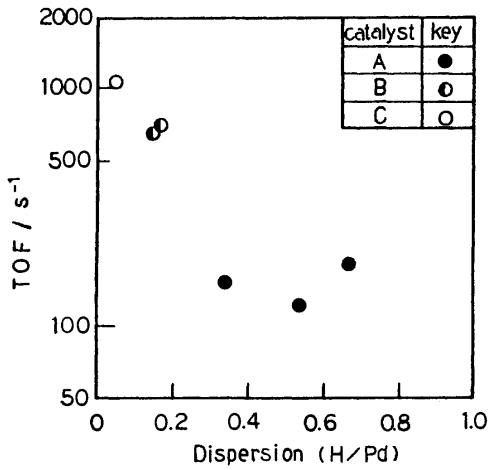

Fig. 7. Specific activity of catalysts in the hydrogenation of 1,4-butadiene: 1,4-C_4H_6 5%, H_2 95%, 80°C.

Figure 7 gives a comparison of the initial activity of the catalysts, which was in the order C>B>A, with the most poorly dispersed catalyst being the most active one. This trend is similar to the results for hydrogenation of acrylaldehyde to propionaldehyde but contrary to those for hydrogenation of CO and propionaldehyde.

Hydrogenation of ethylene was carried out in a similar way. In this reaction, catalyst C seemed to be the most active one but the difference among the catalysts was not so strong as was observed in the other reactions. Average values of TOF for each catalyst are given in Table 2, together with the results obtained in the other reactions.

Discussion

The preparation methods used in this study gave Pd/TiO_2 catalysts showing quite different catalytic behavior from one another. Table 2 gives a summary of the reaction results. Activities were compared in terms of TOF based on hydrogen adsorption capacity. In the hydrogenation of CO, both the total activity and the individual activities for formation of CH_4 and CH_3OH were in the order of A>B>C. The well-dispersed catalyst A in particular was much more active than the other two. The same trend was observed in the hydrogenation of the C=O double bond in an formyl group. However, with the C=C double bonds the activity order of the catalysts was reversed. For the hydrogenation of ethylene, the simplest olefin, the difference in TOF among the three catalysts was not very remarkable. But in the hydrogenation of a C=C bond which was conjugated with another C=C or C=O bond, as in butadiene or in acrylaldehyde, a catalyst with higher dispersion showed lower activity.

In interpreting the difference in the activity of the catalysts, the concept of ensemble effect as having been mentioned above does not seem to be applicable to our case. This concept places stress on the differences in support properties, but in the present study, the two catalysts B and C, for which the same particles of TiO_2 were used as support, also showed quite different activities in the reactions. Here, it might be more useful to study the reaction results in relation to the nature of the different reactants.

In the five reactions examined, as listed in Table 2, the activity order of the catalysts observed in the hydrogenation of CO and propionaldehyde showed a contrary trend to that observed in the other reactions. By looking at the reactants, one can find some significantly different features between the first two and the other three. In carbon monoxide and a formyl group, the oxygen atom inclines to draw the electron because of its large electronegativity and thereby makes the molecule of CO or the CO bond of the aldehyde less electron-donative. In the case of an olefin, however, the C=C bond is usually electronically rich with its π-electron and has a tendency toward electron donation. This electron-rich state becomes stronger in a conjugated compound, where overlapping of the π-electron orbitals causes higher electron density on the molecule. Such different properties of the reactants are expected to bring about different patterns in their ways of interactions with the catalyst. Changes in the work-function of a metal when a compound is adsorbed on it provides one way of indicating the electronic interaction between the adsorbent and the metal. According to previous reports, adsorption of CO on Pd surface causes a positive shift in the work-function of Pd of 0.82 eV[10] while with adsorption of ethylene the work-function of Pd shifts about 0.8 eV negatively.[11] Thus with adsorption of CO, the electron transfers from Pd to CO, but with ethylene the electron transfer occurs in the opposite direction. It has been found for

Table 2. Average Activities of Catalysts A, B, and C

Reactions		T/°C	TOF/s^{-1}		
			A	B	C
Hydrogenation of CO	methane	230	7.3×10^{-4}	2.8×10^{-4}	5.5×10^{-5}
	methanol		4.3×10^{-4}	4.0×10^{-5}	0
Hydrogenation of propionaldehyde		80	1.6×10^{-1}	4.5×10^{-3}	4.5×10^{-3}
Hydrogenation of ethylene		80	380	500	580
Hydrogenation of C=C bond in acrylaldehyde		80	0.09		0.4
Hydrogenation of 1,4-butadiene		80	150	680	1050

Pt, one of the metals which show very similar properties to those of Pd, that the work-function of a Pt surface shifted 0.2 eV positively with adsorption of CO in contrast to the negative shifts of 0.8 eV and 1.6 eV with adsorption of ethylene and butadiene, respectively.[12] This further indicates that donation of π-electron to the metal occurs to a larger extent on the conjugated diene than on ethylene. In corresponding to the relative extent of charge transfer on CO, ethylene and butadiene, our results showed that dependence of catalytic activity on Pd dispersion varied in reactions of these compounds. Activity for the hydrogenation of CO increased with increase in Pd dispersion. For the hydrogenation of ethylene, activity decreased slightly with the increase in Pd dispersion and in the reaction of 1,4-butadiene this decrease was much more obvious. As for the other two reactions of propionaldehyde and acrylaldehyde, the former behaved similarly to carbon monoxide while the latter was rather near to 1,4-butadiene as expected from the conjugating system composed of the C=C double bond and the aldehyde group in this molecule.

Pd with higher dispersion showed higher activity in the hydrogenation of electron-attractive compounds while in the hydrogenation of the electronically donative olefin bonds, Pd with lower dispersion was more active. These facts inversely suggest some changes in the electronic state of Pd, depending on its dispersed state on the support. According to the many studies of the hydrogenation of CO on Pd catalysts, it is known that bulk Pd metal is rather inactive in spite of its CO adsorption capacity.[7,13] Previous study[14] of a Pd alloy catalyst has shown that its catalytic activity was effectively increased after the alloy catalyst was treated in air to produce an oxidative state of Pd. These results indicated that the reaction of CO is favored by the oxidative state of Pd. In relation to these reported facts, the coprecipitated catalysts prepared in the present work are thought to be in a more oxidative state than Pd on the other catalysts.

The catalytic properties of supported metal catalysts may be affected by various factors and the situations are usually very complicated, making it difficult to determine the true state of the metal-support interaction. In this paper the experimental results obtained in the present work were discussed in relation to knowledge from past research and an interpretation of the different behavior observed for catalysts prepared by different methods was suggested by considering the electronic properties of the reactants and their interaction with Pd. The most plausible reason for the differences among the catalysts is thought to be the strength of the interaction between Pd and the TiO_2 support. Stronger interaction is expected on a catalyst prepared by coprecipitation which possesses a very large interface between Pd and the support.

The authors wish to express their thanks to Mr. Koji Adachi, the Engineering Research Institute of University of Tokyo, and Mr. Mineya Kuno, Sumitomo Electric Industries, Ltd., for orbtaining the measurement results of TEM.

(Received April 26, 1988)

A tailor-made catalyst design was attempted for a required substrate specificity by the authors' footprint imprinting method. Two silica(alumina) footprint catalysts were prepared by imprinting with *N*-benzoylbenzenesulfonamide (**1**) and *N*-(*p*-toluoyl)-*p*-toluenesulfonamide (**2**) from the same aluminum ion-doped silica gel. Their catalytic effects upon 2,4-dinitrophenolysis of benzoic anhydride, *p*-, *m*-, and *o*-toluic anhydrides were compared in order to find any difference in substrate specificities. The catalyst prepared by imprinting with **1** showed the largest specificity(k_{cat}/K_m) toward benzoic anhydride, whereas the catalyst prepared with **2** showed the largest specificity toward *p*-toluic anhydride. This finding evidently demonstrated that the substrate specificities of footprint catalytic sites are alterable, as required through selecting appropriate transition state analogs as template molecules for footprint marking.

Previous papers[1,2] of this series reported that unusual catalytic sites of Lewis acid could be marked by imprinting on a silica gel surface like the footprints of the template molecules with a complementary structure to them, and that these "footprint" catalytic sites possessed an exact molecular recognition capability toward the template molecules used in the imprinting process, a capability which was revealed as being an abnormally strong competitive inhibition in a catalysis. This molecular recognition of footprint catalytic sites should also be revealed in their substrate specificity, which would lead to a catalyst design for a required substrate specificity in demand.

During the course of previous studies,[1,2] butanolysis[3] of benzoic anhydride using a potentiometric titration[4] was employed as a catalytic activity assay system. However, several kinds of technical problems were encountered in which the butanolyses of benzoic anhydride proceeded very slowly, accompanying the uncatalyzed reaction in significant quantities. Also, potentiometric titration[4] was rather troublesome, lacking sensitivity, and less reliable for an accurate assay. Accordingly, an improved assay system has been necessarily required for the further investigation of substrate specificities upon the footprint catalytic sites.

The present report deals with two matters. The first is with regard to a new photometric assay system for catalytic activity using 2,4-dinitrophenolysis of benzoic anhydride, and its application to a method for catalytic sites titration with the aid of pyridine poisoning of the catalysts. The second regards an attempt to alter the substrate specificities of silica(alumina) catalysts by selecting appropriate transition state analogs for the reaction of the substrate as template molecules. The kinetic parameters in 2,4-dinitrophenolysis of two footprint catalysts and of a control silica(alumina) catalyst were measured upon four anhydride substrates, i.e., benzoic anhydride and *p*-, *m*-, *o*-toluic anhydrides; induced alterations of substrate specificities were clearly demonstrated.

Experimental

Materials. All chemicals were of the guaranteed grade of Nacalai Tesque Co., Ltd., if not specified.

Templates and Inhibitors: *N*-Benzoylbenzenesulfonamide (Ph-SO_2-NH-Bz, **1**) and *N*-(*p*-toluoyl)-*p*-toluenesulfonamide (CH_3-C_6H_4-SO_2-NH-CO-C_6H_4-CH_3, **2**), and dibenzamide (Ph-CO-NH-CO-Ph, **3**) were of the same preparations as those previously reported.[1,2] Pyridine and 2,6-dimethylpyridine were of guaranteed grade reagents and were used without further purification.

Silica Gel: Merck Kieselgel 60, art. no. 7754, particle size 0.06—0.20 mm, mesh 70—230, was used.

Substrate: Benzoic anhydride was recrystallized from benzene-petroleum benzine, mp 42 °C (lit,[5] 42 °C). Three toluic anhydrides were prepared according to a procedure described in the literature.[6] *p*-Toluic anhydride was recrystallized from ethanol, mp 95—95.5 °C (lit,[7] 95 °C). IR (Perkin-Elmer 1740) (KBr) 3050 (arom.), 1775, 1715 (C=O, anhydride), 1609 (arom.), 1449, 1376 (methyl), 840, 824 cm^{-1} (*p*-, arom.). *m*-Toluic anhydride was recrystallized from ether-petroleum ether, mp 67.0—68.5 °C (lit,[8] 71 °C). IR (KBr) 3070, 3036 (arom.), 1784, 1718 (C=O), 1591 (arom.), 1487, 1378 (methyl), 803, 743, 724 cm^{-1} (*m*-, arom.). *o*-Toluic anhydride was recrystallized from ether-petroleum benzine, mp 36.5—38.0 °C (lit,[9] 36—38 °C, 39 °C). IR (KBr) 3074 (arom.), 1784, 1719 (C=O), 1456, 1381 (methyl), 733 cm^{-1} (*o*-, arom.).

Nucleophile: Potassium 2,4-dinitrophenolate was prepared through the neutralization of 2,4-dinitrophenol in a minimum amount of methanol with concd aqueous potassium hydroxide; the salt was recrystallized from hot water, and dried at 130 °C in vacuo.

Solvent: Acetonitrile, previously dehydrated with calcium chloride, was dried over phosphorus pentoxide overnight, and distilled using a Hempel fractionating column, bp 81—82 °C. To the distillate was added calcium hydride and distillation was repeated to remove perfectly any trace of water or acidic impurities.

Catalysts: Three footprint catalysts were prepared according to an imprinting method which was previously described in detail,[1] using **1**, **2**, **3**, as templates, respectively, (they are referred hereafter as catalyst {**1**}, {**2**}, and {**3**} in text.) as follows.

Kieselgel (100 g) was refluxed for 6 h with concd hydrochloric acid (300 cm^3), and washed thoroughly (by decantation) with water (5 dm^3) and dil aqueous ammonia (pH 7.0—8.0). The gel sludge was immediately treated with an aluminium chloride aqueous solution (0.2 M†, 50 cm^3 per the gel sludge equivalent to 10 g of dry weitht) for two days for aluminium ion doping. The pH of the supernatant of the mixture was kept at 7.0—8.0 by occasional adjustments with aqueous ammonia. The aluminium ion-doped gel sludge, isolated by decantation from the supernatant and precipitated aluminium hydroxide and washed with dil hydrochloric acid (pH 4.0), was divided into parts for imprinted (gel) catalysts and a control (gel) catalyst. A part of the doped gel was added to an acetone solution of a template (2×10^{-3} M of **1**, **2**, or **3**, 30 cm^3 per the gel sludge equivalent to 10 g of dry weight) and the pH of the supernatant of the mixture was adjusted to 4.0 with dil hydrochloric acid (pH 1.0). The mixture was allowed to stand for 2—5 days. For the control (gel) catalyst preparation, a template was omitted, other procedure being the same those as above mentioned. The gel, washed with dil hydrochloric acid (pH 4.0) and collected by filtration, was dried in a desiccator over calcium chloride for one day at room temperature and atmospheric pressure, and for further two days at reduced pressure of 25 mmHg.†† Finally, it was dried at 120—140 °C and the pressure of 3 mmHg, to give an "imprinted" (gel) catalyst. In the study on substrate specificity alteration, the two imprinted catalysts {**1**} and {**2**}, and one control catalyst without the imprinting were prepared in particular from the same origin of aluminium ion-doped silica gel preparation for exact comparison of the imprinting effects on the substrate specificity.

Acidic properties characterizations were carried out by methods of Benesi[10] with Hammett indicators for acid strength determination, and of Pines and Haag[11] with phenolphthalein for Lewis acid sites detection.[1]

Apparatus. The spectrophotometers used were the Hitachi 124 and Shimadzu UV-160. Triple-wavelength measurements were carried out with the latter using its internal data-processing program.

Kinetic Measurement. An appropriate amount of stock benzoic anhydride solution freshly prepared (1.5×10^{-2} M in acetonitrile) was diluted to 29 cm^3 with acetonitrile (final substrate concentration, 1—5 $\times10^{-3}$ M) in a glass-stoppered flask. To this solution was added 30 mg of a catalyst; the mixture was equilibrated at 30 °C for 10 min under gentle stirring. One cm^3 of stock 2,4-dinitrophenolate solution (5.0×10^{-3} M, prepared by dissolving 27.8 mg of potassium 2,4-dinitrophenolate and equivalent molar of 18-crown-6 in 25 cm^3 acetonitrile) was added in order to initiate the reaction under vigorous stirring. An aliquot, 3 cm^3, was taken out at proper intervals (2—3 min) and was filtered to remove off catalyst gel particles as quickly as possible, and the O.D. at 430 nm was recorded. When a triple-wavelength photometer was available, this filtration procedure was omissible by selecting wavelengths at 400, 430, and 500 nm; thereby, a more reliable determination was achieved than by the filtration procedure. First-order rate constants, k_{obs}, were calculated from the decrease in O.D. at 430 nm. In inhibition studies, the catalyst was equilibrated with an inhibitor in acetonitrile for 1 h at 30 °C; after the addition of the substrate solution, equilibration was continued for a further 5—10 min. The following procedures were the same as those mentioned before. Kinetic parameters, K_m and $k_{obs.max}$ (V_{max} in Michaelis-Menten kinetics) were obtained from Lineweaver-Burk plots using a least-squares method, and k_{cat} s were calculated from the $k_{obs.max}$ divided by the catalytic sites molarities obtained from a catalytic sites titration (see text).

Results and Discussion

Photometric Assay of 2,4-Dinitrophenolysis. As can be seen in Fig. 1, the absorption spectra of 2,4-dinitrophenolate changed rapidly in the visible region (376, 430 nm) with the progress of the reaction; changes were evidently caused only by the catalytic 2,4-dinitrophenolysis, since no change was detected without a catalyst or substrate under the same reaction conditions.

Since no absorption of benzoic anhydride (substrate) or authentic 2,4-dinitrophenyl benzoate (product) was found in the region over 400 nm, the reaction rates could be simply determined through the O.D. decrease at 430 nm. After an initial slight curvature (within 8 min), linear semi-log plots of O.D. vs. time were usually observed over at least 1 half life, demonstrating that the reactions obey first-order kinetics with respect to the 2,4-dinitrophenolate concentration; the rate constants, $k_{obs.}$ s, were determined in the usual manner.

As a nucleophile, 2,4-dinitrophenolate was preferred to *p*-nitrophenolate, since the latter caused a too rapid *p*-nitrophenolysis of benzoic anhydride to determine the reaction rate, accompanying an uncatalyzed reaction in considerable quantities. The reverse reactions of the above-mentioned phenolyses, in which *p*-nitrophenyl benzoate or 2,4-dinitrophenyl benzoate were substrates and benzoate anion serves as a nucleophile[12] also caused a problem in that the release of phenolate anions was hindered by their adsorption on the gel surface.

As shown in Figs. 2 and 3 ([I])=0), the k_{obs} s obey Michaelis-Menten kinetics with respect to the anhydride substrates concentration. This fact suggests that

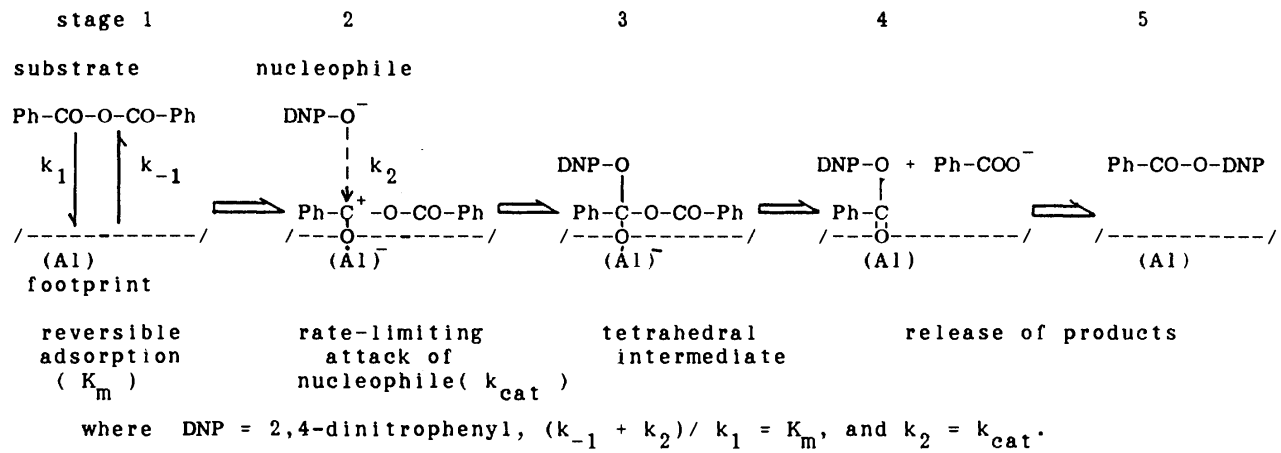

Scheme 1. Catalytic process of dinitrophenolysis of benzoic anhydride.

the reactions proceed through a Rideal-Eley mechanism with a rate-limiting nucleophilic attack (Scheme 1) similar to the butanolysis of benzoic anhydride previously reported.[1] The rate law is also expressed as follows.

$$\text{rate} = \frac{k_{cat}[\text{catalyst}][\text{benzoic anhydride}][\text{2,4-dinitrophenolate}]}{K_m + [\text{benzoic anhydride}]}$$

All of the imprinted catalysts under investigation were confirmed to possess footprint catalytic sites by the criterion that they showed typical competitive inhibition by the original template molecules with huge K_m/K_i values (K_i is the dissociation constant of the inhibitor bound on a catalytic site), as shown in Figs. 2, 3, and 4. Additionally to note, conjugate bases of the template molecules were used as inhibitors in the latter two cases (Figs. 2 and 3) and were found to be more (10-fold) effective than the free bases. This fact demonstrates that conjugate bases are probably the intrinsic footprint marking species in the imprinting process.

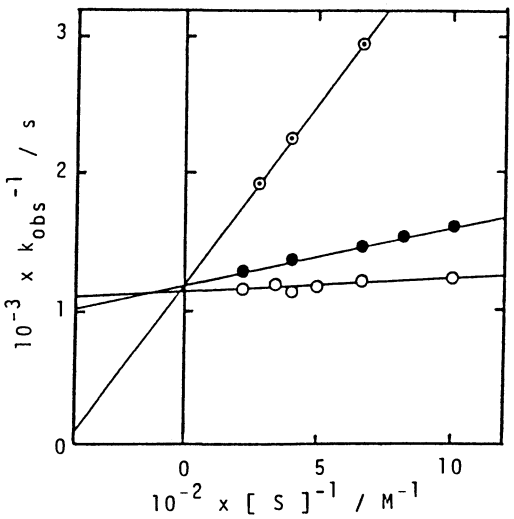

Fig. 4. Lineweaver-Burk plots of footprint cataltst {2}.

Inhibitor: 2-(CH_3-C_6H_4-SO_2-N^--CO-C_6H_4-CH_3).
○: [I]=0, ●: [I]=1.35×10^{-7} M, ◉: [I]=4.41×10^{-7} M.
K_m=7.85×10^{-5} M, K_i=2.45×10^{-8} M, K_m/K_i=3.2×10^3.

Regarding the acidic properties of the catalysts, all of the catalysts were positive to some Hammett indicators (Neutral Red, pK_a +6.8; Methyl Red, pK_a +4.8; 4-(phenylazo)diphenylamine, pK_a +1.5) and to phenolphthalein for Lewis acid (purple), which were the same as those reported previously.[1]

The kinetic parameters are summarized in Table 1, in which data of the butanolysis[1] analyzed by the potentiometric titration are also cited for a comparison. As can be seen, remarkable differences, 3 orders of magnitude, can be observed in the binding steps (K_m s, K_i s) between the 2,4-dinitrophenolysis and the butanolysis, These differences are presumably caused by the poor solvating ability of aprotic acetonitrile,[13] as compared with that of protic 1-butanol, i.e., all the substrate, inhibitors and footprint catalytic sites[14] might be less solvated or more "naked" in acetonitrile than in 1-butanol. The binding steps, thereby, would be strikingly enhanced. The huge rate enhancements observed in catalytic steps (k_{cat} s) (5 order of magnitude), are also explainable by the strengthened nucleophilicity of "naked" 2,4-dinitrophenolate anions solublized into dipolar acetonitrile with the aid of a crown ether.[15-17] The two effects mentioned above result in an enormous rate enhancement for the overall reaction (k_{cat}/K_m), 7 orders of magnitude.

By the application of this enhanced reaction in acetonitrile to an assay of a catalysis, a photometric method is successfully established as required, i.e., the butanolysis method needs 2.26 g of the substrate, 700 mg of a catalyst, and 120 min of reaction time at 55 °C per a measurement, whereas the new dinitrophenolysis method requires only 6.8 mg of the substrate, 30—50 mg of a catalyst, and 25 min at 30 °C per measurement.

Catalytic Sites Titration by Pyridine Poisoning. Figure 5 demonstrates typical Lineweaver-Burk plots for an irreversible poisoning of the catalytic sites of {3} with pyridine. Similar plots for the poisoning have also been observed with the catalysts, {1}, {2} and control (plots are not shown). This poisoning by pyridine was applied to a titration method for a molarity of catalytic sites which is a requisite for k_{cat} calculation. As shown for the example in Fig.6, the amounts of catalytic sites of {3} could be determined from extrapolations of the linear k_{obs} vs. pyridine concentration plots to intercept on abscissa, since pyridine showed no other effect on 2,4-dinitrophenolysis. The titration was so accurate that the amounts of catalytic sites per g of a catalyst {3} (0.99—1.03×10^{-5} mol) obtained from 30 and 40 mg of the samples were practically identical within the experimental error. Similar titration by pyridine poisoning for the butanolysis of benzoic anhydride was rather difficult because the excess pyridine induced a general base catalysis which promoted butanolysis. As can be seen in Fig. 7,[18] where k_{obs} vs. pyridine plots had a break, the number of catalytic sites (6.92×10^{-5} mol per g) calculated from the ambiguous break point was not so reliable in accuracy as that from the dinitrophenolysis method. However, the finding that estimates of the same orders of the catalytic sites per g have been found from both butanolysis and dinitrophenolysis supports the hypothesis that these two reactions are catalyzed by the same catalytic sites, though remarkable differences have been observed in the kinetic parameters.

[S]=benzoic anhydride concentration. [I]=pyridine concentration. ○: [I]=0. ●: [I] 1.28×10^{-6} M. ◉: [I]=2.56×10^{-6} M.

It is worth mentioning here that the magnitude of the molarity of footprint catalytic sites, e.g., 2.0×10^{-5} mol per g for a catalyst {1}, is so large that the footprints cover about 2—3 percent of the surface of Kieselgel, assuming that the surface area of the gel is 500 m^2 per g and that of the template **1** is about 100 Å^2 per molecule. This larfge coverage by footprints would be effectively applicable to the design of specific adsorbents for a kind of affinity chromatography.

Effect of 2,6-Dimethylpyridine (Noninhibition). Figure 6 also shows that the addition of 2,6-dimethylpyridine gives rise to a noninhibitory effect on catalytic sites. This finding evidently confirms the idea that the footprint catalytic sites possess Lewis acid

sites, as previously discussed, since if the catalytic sites are Brønsted acid sites, they should lose their catalytic activities by neutralization with 2,6-dimethylpyridine. However, Lewis acid sites were still active because they cannot form acid-base complexes with 2,6-dimethylpyridine through steric hindrance to two methyl groups. It should be noted that a footprint catalyst and 2,6-dimethylpyridine forms an unusual reaction medium in which an acid and a base cannot act on each other like the case of "wolf and lamb" reaction,[19] and its potential utility as a concerted acid-base catalysis might be promising.

Alteration of Substrate Specificities. In order to distinguish the footprint effects of different catalytic sites on the substrate specificities, phthalic anhydride is not adequate, though it has been used once as a substrate in a previous study.[1] This is because its much higher reactivity than benzoic anhydride has covered (by leveling off) the difference in the catalytic effects, which had been observed in the catalysis for benzoic anhydride, between the imprinted catalytic sites (of {1} and {2}) and the native Lewis acid sites of the control catalyst. Consequently, benzoic anhydride and its *p*-, *o*-, *m*-methyl derivatives are selected here as a set of substrates to be used to compare the catalytic activities, since they have similar original reactivities, and also have similar binding capabilities due to their weak hydrophobic interactions with a silicate surface of the catalyst.

The four anhydride substrates were subjected to catalyzed reactions by the three catalysts, {1}, {2} and the control catalyst, to give twelve Lineweaver-Burk plots. They showed fairly good plots (see correlation coefficients r in Table 2) except one (r=0.6362) for *m*-toluic anhydride by catalyst {1} for uncertain reasons. Some typical plots are shown in Figs. 8 and 9.

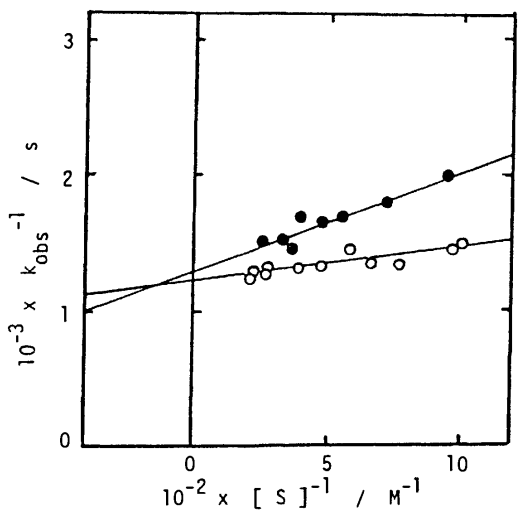

Fig. 8. Catalytic effects of footprint catalyst {1} upon benzoic anhydride and *o*-toluic anhydride.

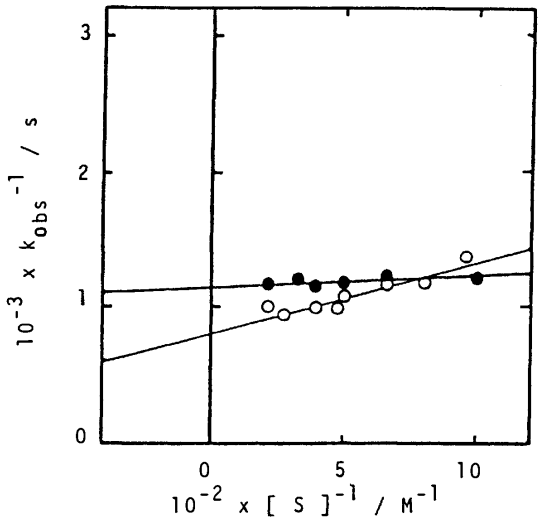

Fig. 9. Catalytic effects of footprint catalyst {2} upon benzoic anhydride and *p*-toluic anhydride.
○: benzoic anhydride. ●: *p*-toluic anhydride.

In Table 2 are summarized the kinetic parameters for the catalyzed reactions. Since the four anhydride substrates have still different reactivities in Lewis acid catalyzed reactions, the kinetic parameters have been normalized by dividing by the corresponding values of the control catalyst. With the aid of these normalized values, the characteristic catalytic effects of the footprint catalytic sites can be revealed separately from the original specificities of the control catalyst. The values of k_{cat}/K_m are reasonable to express and compare the substrate specificities of catalysts, as often used in enzyme kinetics.[20] The normalized k_{cat}/K_m values, otherwise, may represent "substrate specificity enhancement," a factor of alteration of the original specificity of "native" catalytic sites of the control catalyst by imprinting.

As can be seen in Table 2, remarkable differences in specificities exist between catalysts {1} and {2}. Though they have originated from the same aluminum ion-doped silica gel preparation, the former prefers benzoic anhydride (normalized k_{cat}/K_m=2.49) to other anhydrides (0.55—0.82), whereas the latter prefers *p*-toluic anhydride (3.97) to other anhydrides (1.04—1.26). These significant alterations in specificities are not brought about by changes in k_{cat} values (normalized values of 0.89—1.25 for catalyst {1}, 1.05—1.15 for {2}), but mainly come from changes in K_m values, owing to the exact molecular recognition of footprint catalytic sites.[2] Consequently, catalyst {1} shows the largest affinity (normalized K_m=0.36) to benzoic anhydride, possibly due to an inclusion effect of footprint sites through a best fitting with maximal interactions, and less affinities (1.46—1.79) to others due to exclusion effects of footprints through a steric hindrance to the methyl group of the substrates. However, catalyst {2} displays the largest affinity (0.31) to

p-toluic anhydride and also less affinity (1.0) to benzoic anhydride, though the latter can be bound onto the footprints of catalyst {**2**} without any steric hindrance. This fact suggests that the catalyst {**2**} can differentiate not only an inert methyl group in the *p*-, *m*-, or *o*-psition through the inclusion or exclusion effects, but also can recognize even a lack of the methyl group through a slight difference in their weak hydrophobic interactions.

Thus, the exact "complementarity" of the footprints to a template is clearly demonstrated to act effectively on substrate specificities in a catalytic reaction.

Conclusion

Substrate specificities of silica(alumina) catalysts can be inductively altered by the authors' imprinting method with a choice of appropriate template molecules, which would be the fundamental base of a practical tailor-made catalyst design.

(Received June 23, 1988)

Photocycloaddition of *exo,endo*-2,7-bis(methoxycarbonyl)-11,12-dioxatetracyclo[6.2.1.1^{3,6}.0^{2,7}]dodeca-4,9-diene with conjugated enones and *p*-quinones occurred exclusively at the exo-addition moiety to give [2+2]-cycloadducts. From cyclohexenone, all four possible photoadducts were obtained. A single photoadduct from cyclopentenone was a cis-transoid-cis isomer. Upon thermolysis, cyclobutene derivatives were formed from these photoadducts. An acid treatment of oxetane derivatives derived from photoadducts of *p*-quinones afforded Michael adducts instead of dienone-phenol rearrangement products.

Recently, we have shown that the thermal cycloaddition of 2,3-bis(methoxycarbonyl)-7-oxabicyclo[2.2.1]-heptadiene (**1**) and tropones,[2] cyclohepta[*b*]furan-2-ones,[3] and anthracenes[4] gave Diels-Alder adducts. Subsequent thermolysis of the adducts yielded homobarrelenones and dibenzobarrelenes. Therefore, **1** should be a useful "transfer reagent"[5,6] for acetylene. If **1** were applicable as an acetylene substitute in a photochemical version to form cyclobutenes, the utility of **1** should be extended to a great extent, since photoreactions of acetylenes with olefins were known to be contaminated by the formation of bicyclopropyl derivatives.[7] An irradiation of **1** with methyl 2,4-dioxopentanoate (**2**), however, solely gave a photoisomer of **1**, 7-oxaquadricyclane derivative (**3**),[8] but no intermolecular adduct. Instead of **1**, the reaction with *exo,endo*-2,7-bis(methoxycarbonyl)-11,12-dioxatetracyclo[6.2.1.1^{3,6}.0^{2,7}]dodeca-4,9-diene (**4**),[9] a 1 : 2-adduct of dimethyl butynedioate to furan, was investigated because the intramolecular process was prohibited. Herein, we describe our findings.

Photoadditions with *p*-Quinones. The UV-irradiation of **4** and *p*-benzoquinone (**5**) by means of a high-pressure mercury lamp gave a single photoadduct (**6**) in 78% yield. The ^{1}H NMR spectrum of **6** showed it to be a 1 : 1-adduct having an oxetane structure. The reactive double bond of **4** was identified as depicted in the structure, since the exo,exo-isomer (**7**) was photochemically inactive toward **5** under the conditions used. In addition, an iodolactonization[10] of **6** gave two isomeric iodo lactones (**8** and **9**), in 32 and 31% yields, respectively. Although the structures of **8** and **9** could not be differentiated at this stage, it is certain that the reaction occurred at the anti C=C bond in **4**.[11] The oxetane ring was deduced to have an exo-stereochemistry from the coupling constants (J_{ab}=J_{cd}= 0 Hz).

The UV-irradiation of **4** and 1,4-naphthoquinone (**10**) similarly gave a single product (**11**) in 44% yield. Again, the reaction occurred at the exo-C=C bond from the chemical shift of the remaining C=C carbons at δ=137.0 and 138.5 and the formation of two isomeric iodo lactones (**12** and **13**). The oxetane ring of **11** had an exo-stereochemistry according to the coupling constants (J_{ab}=J_{cd}=0 Hz). Its 1,4-dihydronaphthalene ring was exo from the observation of a high-field-shifted H$_c$ signal (δ=4.47), than the H$_c$ signal (δ=4.94 or 5.01) of **6**. An exclusive oxetane formation in *p*-quinones is a well-known reaction mode.[12,13]

It is interesting that in the ^{13}C NMR spectra the olefinic carbon signals of both photoadducts (**6** and **11**) appeared at nearly the same positions; in **6**, they were at 136.9 and 138.5, while those in **11** were at 137.0 and 138.5. These were also the case for photoadducts from the cycloalkanones and **2** (vide infra) and could be employed to deduce the structures of the products.

Photoadditions with Cyclic Enones. Similar UV-irradiation of **4** with 2-cyclohexenone (**14**) afforded four 1 : 1-adducts (**15—18**). The olefinic carbon signals of **15—18** appeared around 138 ppm, showing the occurrence of a reaction at the same C=C bond of **4**. The ^{1}H NMR spectra of **15—18** indicated that **14** attacked the exo site of **4**, but no further stereochemical information could be obtained at this stage. However, with potassium fluoride on Florisil,[14] **15** and **18** were converted to **17** and **16**, respectively; the newly-generated ring junctures of **16** and **17** were, thus, established to be cis.

Further chemical transformations clarified the remaining stereochemistry: When **16** was refluxed in xylene for 60 h, thermolysates (**19—21**) were obtained together with 3,4-bis(methoxycarbonyl)furan (**22**). Another cis-isomer **17** gave the thermolysate (**23**). Products **20** and **21** were identical with bicyclo[4.2.0]oct-7-en-2-one[15,16] and cyclooctadienone.[17] Since the ^{1}H NMR spectra of **19** and **23** were not informative to elucidate stereochemistries, an oxidation with *m*-chloroperbenzoic acid (MCPBA) was carried out; **19** gave a lactone (**24**), whereas **23** gave no oxidation product. The ^{1}H NMR spectrum of **24** showed a proton on the carbon bearing a lactonic oxygen atom at 4.39 (H$_a$, dd, J=6.6, 2.6 Hz). The nuclear Overhauser effect (NOE) experiments of **24** showed that the satura-

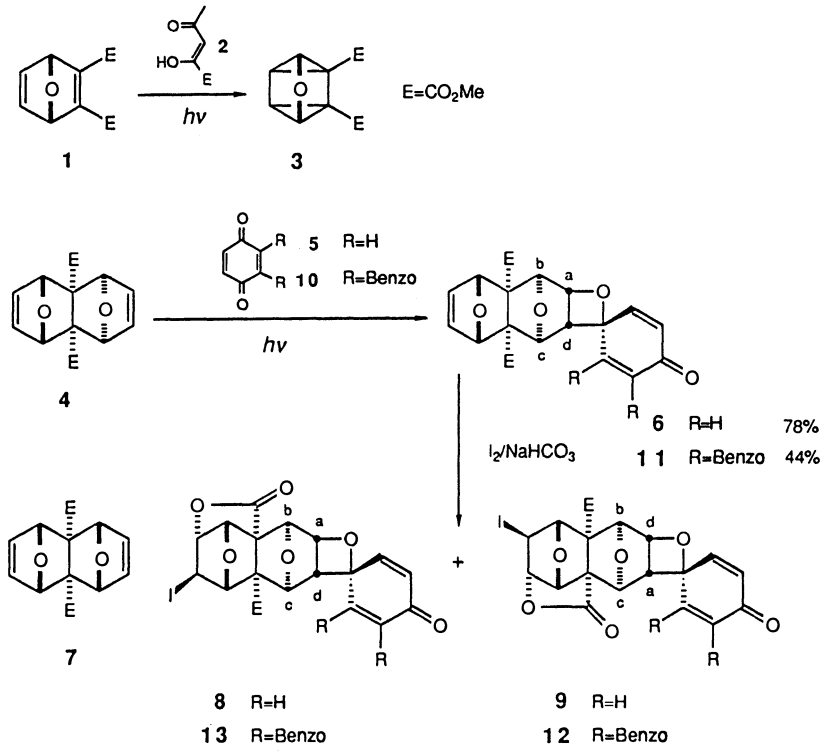
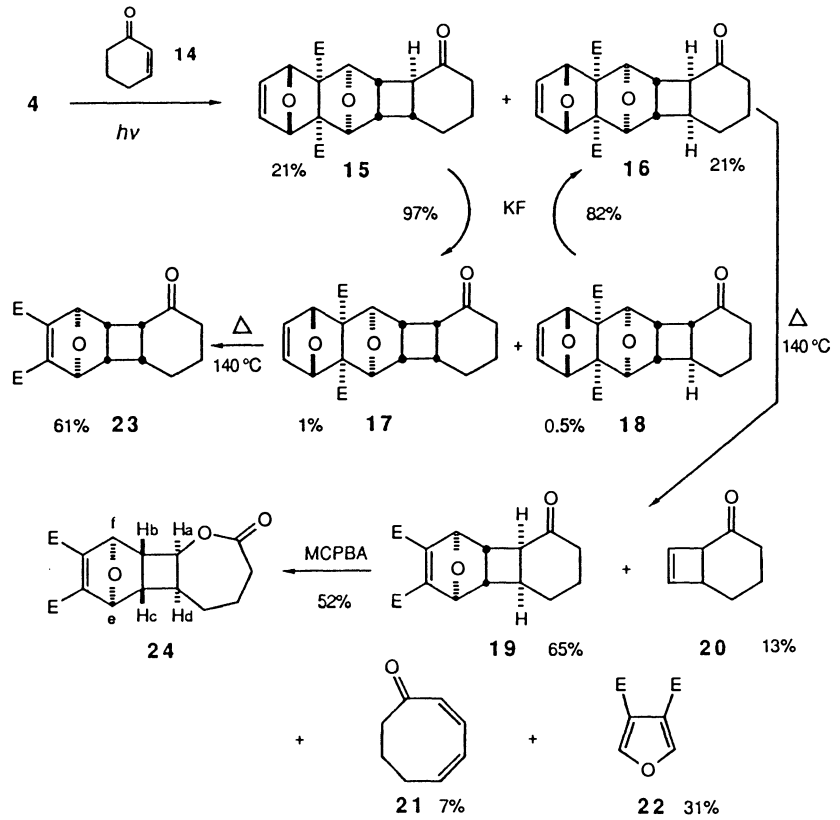


Scheme 1.



Scheme 2.

tion of the lower methine signal (H_f) resulted in an enhancement of both signals of H_a and H_b at 2.73 (1H, ddd, J=6.9, 2.6, 1.0 Hz), and the stereochemistry of **24** must be cis-transoid-cis. From these observations and the epimerization experiments, **16** and **17** were determined to be cis-transoid-cis and cis-cisoid-cis, respectively, and **15** and **18** were the corresponding trans epimers, as shown in Scheme 2.

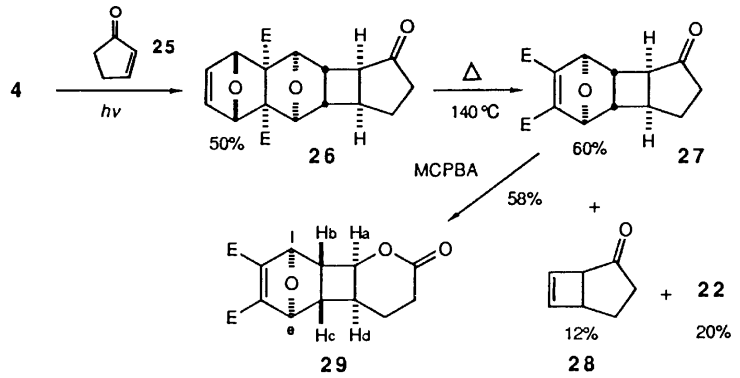
On the other hand, the irradiation of **4** with 2-cyclopentenone (**25**) gave a single product (**26**) in 50% yield. The stereochemistry of **26** was shown to be parallel to that of **16**: its thermolysis gave **27** and **28** in 60 and 12% yields, by refluxing in a xylene solution. The ^{1}H NMR spectrum of **28** was identical with that of the reported bicyclo[3.2.0]hept-6-en-2-one.[18,19] An MCPBA-oxidation of **27** did indeed occur to form a single lactone (**29**), whose ^{1}H NMR spectrum showed a proton signal on the lactonic carbon at δ=4.53 (H_a, dd, J=7.7, 2.9 Hz), which coupled to two signals (H_b and H_d) around 2.4 and 2.6, but not to a signal (H_c) at 2.32, being confirmed from the COSY spectrum. An irradiation of the lower methine signal (H_f) enhanced the signal of H_a.

The difference in the product distributions in reactions with **14** and **25** should be due to, at least in part, a large strain energy for *trans*-bicyclo[3.2.0]heptanone framework, which should have arisen from the latter (**25**).

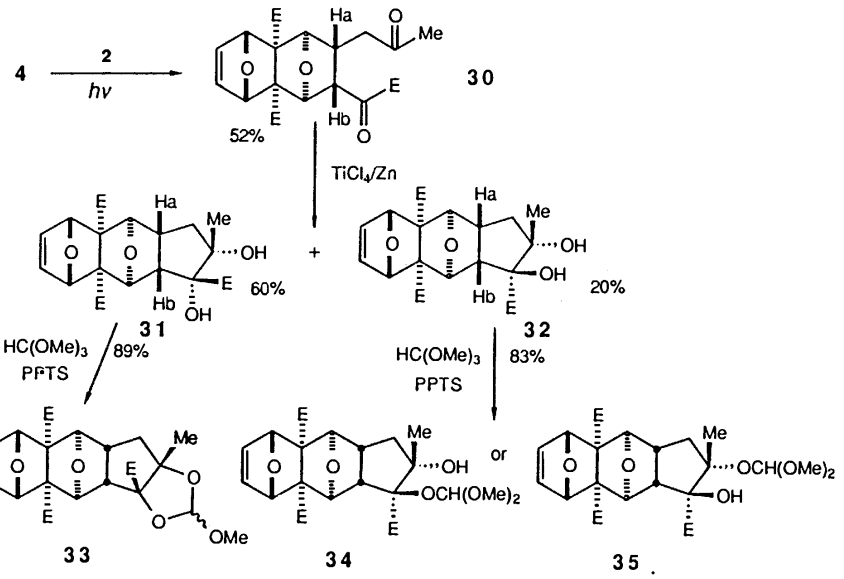
Photoaddition with Methyl 2,4-Dioxopentanoate (2). An irradiation of **4** with **2** gave a single product (**30**) via a [2+2] addition and a retro-aldol process.[20] The stereochemistry of **30** was determined to be as shown in Scheme 4 from the appearance of H_b as a doublet (J=8.4 Hz). A reductive cyclization of **30** with titanium(II) chloride[21] gave two 1,2-diols (**31** and **32**) in 60 and 20% yields. The NOE experiments of **31** and **32** established the cis relationship between the methyl group and protons H_a and H_b. Acetal formations of **31** to dioxolanes (**33**) and **32** to an uncyclized orthoformate (**34** or **35**) determined the *cis*- and *trans*-glycols, respectively.

All of the photoadducts from **4** with enones and *p*-quinones were derived by reactions at the anti C=C bond to the methoxycarbonyl groups. The inertness of the syn C=C bond toward photocycloaddition has been established without exception. The marked difference in the photochemical reactivity of these double bonds is interesting.

Thermal Cycloreversions of Photoadducts. As mentioned in the preparations of **19** and **27**, further cycloreversed products, **20** and **28**, were formed in 13 and 12% yields, respectively. Heating photoadduct **15** at 140 °C gave two products (**23** and **36**) in 44 and 38% yields, respectively. The latter **36** was quantitatively



Scheme 3.

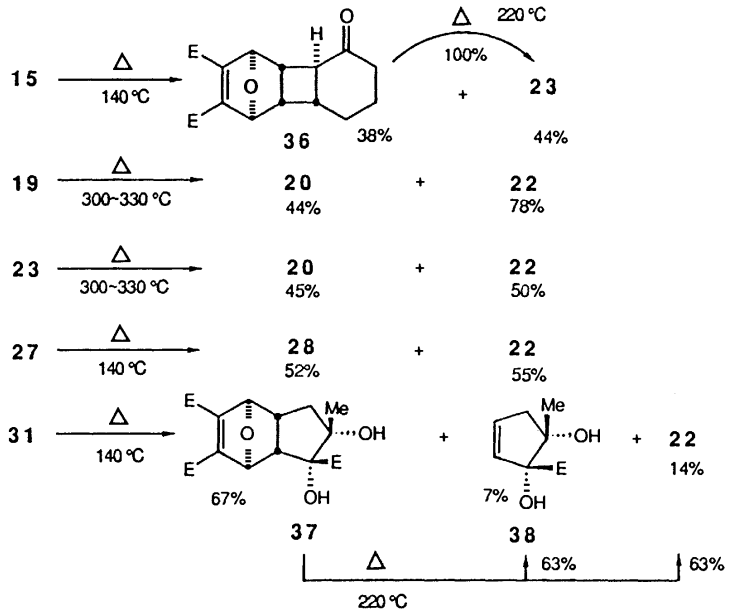


Scheme 4.

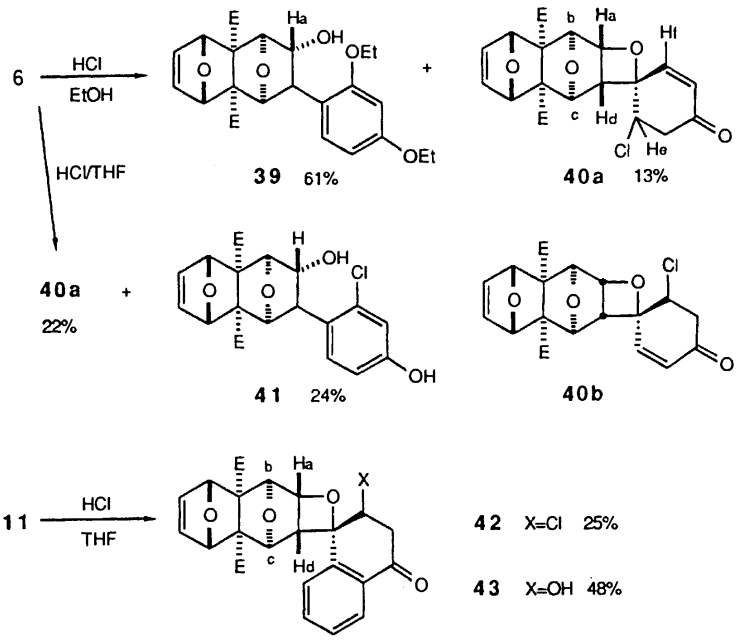
epimerized to **23** at 220 °C and the former **23** was obtained in 61% from the cis-cisoid-cis photoadduct **17**. Thermolysis of **19** and **23** at 330 °C gave **20** in 44 and 45% yields. While **27** was heated at 140 °C for 48 h, **28** was obtained in 52% yield together with **22**.

Subsequently, when **31** was thermolysed at 140 °C, thermolysates (**37** and **38**) were obtained in 67 and 7% yields. The former was converted to the latter in 63% yield at 220 °C.

Acid Treatments of Photoadducts from *p*-Quinones. Since photoadducts from *p*-quinones have a 2,5-cyclohexadienone chromophore, a dienone-phenol rearrangement would be expected.[12,13] When **6** was heated with hydrochloric acid in ethanol, two products (**39** and **40**) were formed in 61 and 13% yields. The major **39** had an aromatic ring with two ethoxyl groups, which were located at C-2 and C-4. The stereochemistry of the hydroxyl group was exo, from the coupling constant of H_a signal. The minor **40** had an enone chromophore and an oxetane ring. From the mass spectrum and an elemental analysis, **40** was shown to be a Michael adduct of hydrochloric acid. Two singlet signals of H_b and H_c appeared at 4.94 and 5.01 in **6**, whereas corresponding signals at 4.97 and 5.35 in **40**. One of them moved to the lower field upon the introduction of a chlorine atom. Therefore, the



Scheme 5.



Scheme 6.

structure **40a** should be as depicted. The stereochemistry of the chlorine atom was quasi-axial due to an observation of a long-range coupling between H_e and H_f. To minimize the Michael adduct formation, the reaction was carried out in tetrahydrofuran; a new chlorophenol derivative (**41**) was obtained along with **40a**. Similarly, **11** gave two Michael adducts (**42** and **43**) as shown in Scheme 6. A chlorine atom of **42** was quasi-equatorial because a methylene signal appeared as two doublets of doublets at 3.02 (J=18.7, 12.8 Hz) and 3.28 (J=18.7, 5.5 Hz), while the hydroxyl group of **43** was quasi-axial from the splittings of the methylene signals at 2.89 (dm, J=18.9 Hz) and 2.98 (dd, J=18.9, 2.7 Hz). The chemical shifts of H_b and H_c (5.10 and 4.24) of **42** were similar to those (5.19 and 4.47) of **11**.

Thus, a dienone-phenol rearrangement did not occur in these particular photoadducts from *p*-quinones.

Conclusion

As has been described, **4** was photochemically reactive with cyclic enones and a further thermal cycloreversion of the photoadducts afforded 1,2-unsubstituted cyclobutene derivatives. Photochemical additions of **4** were regioselective. The cis-transoid-cis isomer formed exclusively from **25** and predominantly from **14**. Ready thermolyses to cyclobutene and cyclopentene derivatives indicate that **4** is useful as cycloaddend in alicyclic synthesis.

Experimental

Elemental analyses were performed by Miss S. Hirashima, of Institute of Advanced Material Study, Kyushu University. NMR spectra were measured by a JEOL 270H spectrometer in $CDCl_3$ solution (unless otherwise specified): chemical shifts are expressed in the unit δ. Mass spectra were measured with a JEOL OISG-2 spectrometer. IR spectra were taken as KBr disks or as a $CHCl_3$ solution using a Jasco IR-A 102 spectrometer. UV spectra were measured by a Hitachi U-3200 spectrophotometer.

Photoreaction of 1 and Methyl 2,4-Dioxopentanoate (2). Formation of 7-Oxaquadricyclane Derivative (3). A $CDCl_3$ solution (0.5 cm^3) of **1** (40 mg) and **2** (16.2 mg) was irradiated with a 400-W high-pressure mercury lamp and the reaction was monitored by ^1H NMR spectroscopy. After 1 h, new signals [2.83(2H, d, J=3 Hz), 3.70 (6H, s), and 4.93 (2H, d, J=3 Hz)] of **3** appeared, which was identical with the spectrum of the authentic **3**.[8]

Photoreaction of 4 and *p*-Benzoquinone (5). a) A $CDCl_3$ solution (0.5 cm^3) of **4** (35 mg) and **5** (14.5 mg) was irradiated. After 20 min, the solvent was evaporated and the residue was chromatographed on a silica-gel column to isolate **6** [colorless crystals, mp 191—192 °C, 12.6 mg; 78%. Found: C, 62.19; H, 4.64%. Calcd for $C_{20}H_{18}O_8$: C, 62.18; H, 4.70%. ^1H NMR δ=3.26 (1H, d, J=5.1 Hz, H_d), 3.70 (3H, s), 3.74 (3H, s), 4.71 (1H, d, J=1.8 Hz), 4.84 (1H, d, J=1.8 Hz), 4.94 (1H, s, H_b or H_c), 5.01 (1H, s, H_c or H_b), 5.21 (1H, d, J=5.1 Hz, H_a), 6.14 (1H, dd, J=10.3, 2.2 Hz), 6.21 (1H, dd, J=10.3, 2.2 Hz), 6.54 (1H, dd, J=5.9, 1.8 Hz), 6.67 (1H, dd, J=5.9, 1.8 Hz), 7.28 (1H, dd, J=10.3, 2.9 Hz), and 7.69 (1H, dd, J=10.3, 2.9 Hz). ^{13}C NMR δ=49.1, 52.8, 72.0, 72.8, 79.3, 80.0, 80.2, 80.3, 81.2, 84.0, 127.1, 128.3, 130.5, 136.9, 138.5, 144.7, 148.7, 170.4, 170.5, and 185.2. IR ν: 1715, 1665, 1625, 1260, and 1220 cm^{-1}. UV (MeOH): 237.6 nm (ε=12450)] together with **5** [10 mg] and **4** [12 mg]. **b)** A $CDCl_3$ solution (0.8 cm^3) of **5** (138 mg) and a 3 : 1-mixture (476 mg) of **4** and **7** was reacted by similar manner. Product **6** [193 mg, 54%] was obtained together with recovered **5** [10 mg] and a mixture [204 mg] of **4** and **7**.

Photoreaction of 4 and 1,4-Naphthoquinone (10). A $CHCl_3$ solution (1 cm^3) of **4** (341 mg) and **10** (156 mg) was irradiated to give **11** [colorless crystals, mp 179—181 °C, 150 mg; 44%. Found: C, 65.81; H, 4.58%. Calcd for $C_{24}H_{20}O_8$: C, 66.05; H, 4.62%. ^1H NMR δ=3.24 (1H, d, J=4.8 Hz, H_d), 3.60 (3H, s), 3.75 (3H, s), 4.47 (1H, s, H_c), 4.66 (1H, br s), 4.87 (1H, br s), 5.19 (1H, s, H_b), 5.36 (1H, d, J=4.8 Hz, H_a), 6.29 (1H, d, J=10.3 Hz), 6.53 (1H, dd, J=5.9, 1.8 Hz), 6.64 (1H, dd, J=5.9, 1.8 Hz), 7.47 (1H, ddd, J=7.7, 7.0, 1.5 Hz), 7.64 (1H, ddd, J=7.7, 7.0, 1.5 Hz), 7.68 (1H, d, J=10.3 Hz), 8.06 (1H, dd, J=7.0, 1.5 Hz), and 8.52 (1H, dd, J=7.0, 1.5 Hz). ^{13}C NMR δ=51.7, 52.7, 52.9, 72.5, 73.6, 79.2, 80.0, 80.2, 81.4, 83.3, 83.7, 126.3, 126.5, 128.6, 129.9, 130.7, 132.3, 137.0, 138.5, 138.7, 153.0, 170.4 (2C), and 184.6. IR ν: 1720, 1670, 1597, and 1260 cm^{-1}. UV (MeOH): 244.2 (ε=11600), 278.8 (5000), and 312.0 nm (2200)] and recovered **4** [211 mg] and **10** [33 mg].

Photoreaction of 4 and Cyclohexenone (14). A $CHCl_3$ solution (2 cm^3) of **4** (824 mg) and **14** (2.03 g) was irradiated for 60 h to give **15** [colorless crystals, mp 126—127 °C, 221 mg: 21%. Epimerization of 36 to 23. Compound **36** (19 mg) was placed in a sealed tube and pyrolyzed at 220 °C to give **23** [19 mg; 100%].

Thermolysis of 19. The compound **19** (70 mg) was passed through a glass tube heated at 300—330 °C under an

N_2 stream to give **20** [8 mg; 44%], **22** [21.5 mg; 78%], and recovered **19** [24 mg].

Thermolysis of 23. Similarly, compound **23** (70 mg) was pyrolyzed at 300—330 °C under an N_2 stream to give **20** [6 mg; 45%], **22** [10 mg, 50%], and recovered **23** [36.6 mg].

Thermolysis of 26. A xylene solution (1 cm^3) of **26** (150 mg) was refluxed for 2 d to give **27** [a colorless oil, 48 mg, 60%. Found: *m/z* 292.0948 (M^+). Calcd for $C_{15}H_{16}O_6$: 292.0946. ^1H NMR δ=2.0—2.4 (6H, m), 2.55—2.7 (2H, m), 3.79 (3H, s), 3.81 (3H, s), 5.17 (1H, s), and 5.19 (1H, s). ^{13}C NMR δ=27.3, 36.4, 36.6, 39.3, 42.7, 45.4, 52.4 (2C), 82.7, 83.0, 142.0, 142.3, 162.4, 162.8, and 219.8. IR ν: 1730, 1630, 1260, and 1210 cm^{-1}. UV (MeOH): 227.8 nm (ε=5400)], **28**[18,19] [a colorless oil, 3.5 mg, 12%], **22** [10 mg, 20%], and recovered **26** [51 mg].

Thermolysis of 27. A xylene solution (1 cm^3) of **27** (58 mg) was refluxed for 2 d to give **28** [5 mg, 52%], **22** [9 mg, 55%], and recovered **27** [32.2 mg].

MCPBA-Oxidation of 19. A $CHCl_3$ solution (1.5 cm^3) of **19** (33 mg) and MCPBA (50 mg) was kept in a refrigerator for 10 h. The mixture was washed with aqueous $NaHSO_3$ and $NaHCO_3$ solutions and a $CHCl_3$ layer was dried on Na_2SO_4 and evaporated. The residue was chromatographed on a silica-gel column to give **24** [colorless crystals, mp 107—109 °C, 18 mg, 52%. Found: C, 59.80; H, 5.74%. Calcd for $C_{16}H_{18}O_7$: C, 59.62; H, 5.63%. ^1H NMR δ=1.6—1.8 (1H, m), 1.8—1.95 (3H, m), 2.1—2.2 (1H, m), 2.22 (1H, dd, *J*=7.0, 4.0 Hz), 2.4—2.5 (2H, m, H_c and H_d), 2.73 (1H, ddd, *J*=6.9, 2.6, 1.0 Hz, H_b), 3.80 (3H, s), 3.82 (3H, s), 4.39 (1H, dd, *J*=6.6, 2.6 Hz, H_a), 5.08 (1H, s, H_e), and 5.12 (1H, s, H_f). ^{13}C NMR δ=20.5, 24.8, 31.9, 36.8, 40.5, 43.1, 52.4, 52.5, 73.6, 81.4, 82.1, 141.8, 143.3, 162.2. 162.6, and 172.8. IR ν: 1737, 1690, 1615, and 1290 cm^{-1}. UV (MeOH): 232.2 nm (ε=6000)].

MCPBA-Oxidation of 23. A $CHCl_3$ solution (3 cm^3) of **23** (63 mg) and MCPBA (60 mg) was refluxed for 10 h. Same work-up gave no product.

MCPBA-Oxidation of 27. A $CHCl_3$ solution (3 cm^3) of **27** (97 mg) and MCPBA (80 mg) was kept for 1 d in a refrigerator. Same work-up gave **29** [colorless crystals. mp 144—145 °C, 59 mg, 58%. Found: C, 58.52; H, 5.34%. Calcd for $C_{15}H_{16}O_7$: C, 58.44; H, 5.23%. ^1H NMR δ=1.9—2.0 (1H, m), 2.15—2.2 (1H, m), 2.32 (1H, dd, *J*=7.0, 3.3 Hz, H_c), 2.35—2.5 (2H, m), 2.5—2.6 (2H, m, H_b and H_d), 3.81 (3H, s), 3.82 (3H, s), 4.53 (1H, dd, *J*=7.7, 2.9 Hz, H_a), 5.14 (1H, s, H_e), and 5.22 (1H, s, H_f). ^{13}C NMR δ=22.8, 28.6, 31.3, 40.6, 46.1, 52.5 (2C), 74.0, 81.5, 82.0, 141.7, 143.6, 162.2, 162.7, and 171.2. IR ν: 1720, 1630, and 1230 cm^{-1}. UV (MeOH): 231.8 nm (ε=5900)].

$TiCl_2$-Mediated Cyclization of 30. To an anhydrous THF solution (20 cm^3) of $TiCl_4$ (0.1 cm^3), Zn (0.1 g) was added at −60 °C under stirring. After warming to room temperature, pyridine (0.1 cm^3) was added. To the resultant suspension, a THF solution (10 cm^3) of **30** (102 mg) was added drop by drop. After stirring overnight, the mixture was quenched with aqueous K_2CO_3 and extracted with $CHCl_3$. The organic layer was dried on Na_2SO_4 and evaporated. The residue was chromatographed on silica-gel to give **31** [colorless crystals, mp 200—202 °C, 63 mg; 60%. Found: C, 56.55; H, 5.74%. Calcd for $C_{20}H_{24}O_{10}$: C, 56.60; H, 5.70%. ^1H NMR δ=1.13 (3H, s), 1.75 (1H, dd, *J*=14.3, 4.0 Hz), 2.31 (1H, dd, *J*=14.3, 9.6 Hz), 2.88 (1H, ddd, *J*=9.6, 7.3, 4.0 Hz), 3.15 (1H, d, *J*=7.3 Hz), 3.69 (6H, s), 3.79 (3H, s), 3.80 (1H, s, OH), 4.44 (1H, s, OH), 4.69 (1H, s), 4.77 (1H, s), 4.80 (1H, s), 5.12 (1H, s), and 6.64 (2H, s). ^{13}C NMR δ=22.2, 43.0, 43.7, 52.0, 52.3, 52.6 (2C), 71.6, 72.1, 79.5 (2C), 81.0, 82.6, 85.0, 87.0, 138.2, 138.3, 171.1, 171.2, and 173.9. IR ν: 3370, 1720, 1260, 1235, and 1215 cm^{-1}] and **32** [colorless crystals, mp 199—201 °C, 21 mg; 20%. Found: C, 56.62; H, 5.65%. Calcd for $C_{20}H_{24}O_{10}$: C, 56.60; H, 5.70%. ^1H NMR δ=1.26 (3H, s), 1.46 (1H, dd, *J*=13.2, 9.5 Hz), 2.00 (1H, dd, *J*=13.2, 8.1 Hz), 3.11 (1H, dt, *J*=9.5, 8.1 Hz), 3.21 (1H, d, *J*=8.1 Hz), 3.34 (1H, s, OH), 3.69 (3H, s), 3.71 (3H, s), 3.77 (1H, s, OH), 3.86 (3H, s), 4.64 (1H, s), 4.77 (1H, d, *J*=1.1 Hz), 4.82 (1H, d, *J*=1.1 Hz), 5.08 (1H, s), 6.60 (1H, d, *J*=4.0 Hz), and 6.67 (1H, d, *J*=4.0 Hz). ^{13}C NMR δ=20.4, 41.7, 44.4, 52.3, 52.5, 52.6, 52.9, 71.5, 72.3, 79.5, 80.0, 82.5, 84.3, 84.9, 85.3, 137.8, 138.6, 171.3, 171.4, and 173.7. IR ν: 3500, 1725, 1260, and 1215 cm^{-1}].

Dioxolane Formation of 31. A trimethyl orthoformate solution (2 cm^3) of **31** (37 mg) and PPTS (10 mg) was stirred overnight. The mixture was washed with aqueous Na_2CO_3 and extracted with $CHCl_3$. The solvent was evaporated to give **33** [colorless crystals, a 1 : 2.5-mixture of isomers, mp 161—168 °C, 36 mg, 89%. Found: C, 56.73; H, 5.68%. Calcd for $C_{22}H_{26}O_{11}$: C, 56.65; H, 5.62%. ^1H NMR of a major isomer δ=1.35 (3H, s), 1.95 (1H, dd, *J*=14.3, 7.3 Hz), 2.17 (1H, dd, *J*=14.3, 9.9 Hz), 2.93 (1H, ddd, *J*=9.9, 8.1, 7.3 Hz), 3.41 (1H, d, *J*=8.1 Hz), 3.46 (3H, s), 3.68 (6H, s), 3.80 (3H, s), 4.60 (1H, s), 4.75 (2H, s), 4.76 (1H, s), 5.95 (1H, s), and 6.6—6.7 (2H, m) and a minor isomer δ=1.26 (3H, s), 2.00 (1H, dd, *J*=14.3, 7.3 Hz), 2.37 (1H, dd, *J*=14.3, 9.2 Hz), 2.85 (1H, ddd, *J*=9.2, 8.1, 7.3 Hz), 3.43 (3H, s), 3.62 (1H, d, *J*=8.1 Hz), 3.66 (6H, s), 3.78 (3H, s), 4.57 (1H, s), 4.74 (1H, s), 4.78 (1H, s), 5.00 (1H, s), 6.04 (1H, s), and 6.6—6.7 (2H, m)].

Orthoformate Formation of 32. A trimethyl orthoformate solution (2 cm^3) of **32** (22.5 mg) and PPTS (10 mg) gave **34** or **35** [a colorless oil, 22 mg, 83%. ^1H NMR δ=1.42 (1H, dd, *J*=14.4, 9.6 Hz), 1.46 (3H, s), 2.50 (1H, dd, *J*=14.4, 8.0 Hz), 2.96 (1H, ddd, *J*=9.6, 8.0, 5.6 Hz), 3.21 (3H, s), 3.27 (3H, s), 3.66 (1H, d, *J*=5.6 Hz), 3.69 (6H, s), 3.80 (3H, s), 4.59 (1H, s), 4.82 (1H, s), 4.87 (1H, s), 5.03 (1H, s), 5.19 (1H, s), and 6.65 (2H, s)].

Thermolysis of 31. A xylene solution (1.5 cm^3) of **31** (93 mg) was refluxed for 1.5 d to give **37** [a colorless oil, 40 mg; 67%. Found: C, 54.06; H, 5.94%. Calcd for $C_{16}H_{20}O_9$:C, 53.93; H, 5.66%. ^1H NMR δ=1.14 (3H, s), 1.86 (1H, dd, *J*=14.3, 2.9 Hz), 2.38 (1H, dd, *J*=14.3, 9.5 Hz), 2.62 (1H, ddd, *J*=9.5, 7.7, 2.9 Hz), 2.84 (1H, d, *J*=7.7 Hz), 3.8 (1H, s, OH), 3.80 (3H, s), 3.82 (3H, s), 3.88 (3H, s), 4.39 (1H, s, OH), 5.02 (1H, s), and 5.42 (1H, s). ^{13}C NMR δ=22.4, 41.5, 42.4, 51.7, 52.2, 52.5, 52.8, 81.4, 81.9, 83.0, 85.1, 143.5, 144.1, 162.2, 162.4, and 174.1. IR ν: 3475, 3400, 1725, 1640, 1260, and 1220 cm^{-1}. UV (MeOH): 226.6 nm (ε=6200)], **38** [a colorless oil, 2 mg, 7%. Found: *m/z* 172.0736 (M^+). Calcd for $C_8H_{12}O_4$: 172.0736. ^1H NMR δ=1.24 (3H, s), 2.5—2.65 (2H, m), 3.80 (3H, s), 5.63 (1H, dt, *J*=6.2, 1.8 Hz), and 6.13 (1H, dt, *J*=6.2, 2.2 Hz). ^{13}C NMR δ=23.2, 46.4, 53.3, 80.4, 87.7, 130.8, 136.4, and 174.8. IR ν: 3500, 1725, 1250, and 1207 cm^{-1}], and **22** [4.4 mg, 14%], and recovered **32** [23 mg].

Thermolysis of 37. Compound **37** (36 mg) was placed in a tube equipped with a Dry-Ice cold finger and pyrolyzed at 220 °C under reduced pressure (1300 Pa) to give **38** [9.3 mg, 63%], **22** [10 mg: 63%], and recovered **37** [5.4 mg].

HCl-Catalyzed Reaction of 6. a) An EtOH solution (6 cm^3) of **6** (70 mg) and concd HCl (1 drop) was stirred for 30 min at room temperature. The solvent was evaporated and the residue was chromatoraphed on a silica-gel column to give **39** [colorless crystals, mp 139—141 °C, 51 mg; 61%.

Found: C, 62.62; H, 6.40%. Calcd for $C_{24}H_{28}O_9$: C, 62.60; H, 6.13%. ^{1}H NMR δ=1.37 (1H, d, J=9.2 Hz, OH), 1.40 (3H, t, J=7.0 Hz), 1.41 (3H, t, J=7.0 Hz), 3.68 (3H, s), 3.73 (3H, s), 4.02 (4H, q, J=7.0 Hz), 4.23 (1H, d, J=7.0 Hz), 4.50 (1H, dd, J=9.2, 7.0 Hz, H_a), 4.77 (1H, d, J=1.5 Hz), 4.87 (1H, d, J=1.8 Hz), 4.93 (1H, d, J=1.1 Hz), 5.02 (1H, d, J=1.8 Hz), 6.45 (1H, d, J=2.6 Hz), 6.47 (1H, dd, J=8.1, 2.6 Hz), 6.60 (1H, dd, J=5.9, 1.8 Hz), 6.75 (1H, dd, J=5.9, 1.8 Hz), and 7.40 (1H, d, J=8.1 Hz). ^{13}C NMR δ=14.8 (2C), 43.9, 52.5, 52.9, 63.5, 63.9, 71.4, 72.7, 73.3, 79.2, 80.1, 86.3, 88.5, 100.2, 105.0, 117.7, 128.6, 137.0, 139.2, 158.5, 159.4, 171.4, and 171.5. IR ν: 3530, 1740, 1717, 1607, 1575, 1500, 1280, 1255, 1217, 1175, 1115, and 1035 cm^{-1}. UV (MeOH): 208.8 (ε=17200), 228.6 (10100), and 279.2 nm (3000)] and **40a** [colorless crystals, mp 202—203 °C, 10 mg; 13%. Found: C, 57.07; H, 4.56%. Calcd for $C_{20}H_{19}O_8Cl$: C, 56.81; H, 4.53%. ^{1}H NMR δ=2.70 (1H, dd, J=20.4, 2.9 Hz), 2.78 (1H, dd, J=20.4, 2.9 Hz), 2.95 (1H, d, J=5.5 Hz, H_d), 3.70 (3H, s), 3.72 (3H, s), 4.62 (1H, d, J=5.5 Hz, H_a), 4.77 (1H, q, J=2.9 Hz, H_e), 4.80 (1H, d, J=1.8 Hz), 4.84 (1H, s), 4.97 (1H, d, J=1.5 Hz, H_b), 5.35 (1H, d, J=1.5 Hz, H_c), 5.93 (1H, d, J=9.9 Hz), 6.52 (1H, dd, J=9.9, 2.9 Hz, H_f), 6.60 (1H, dd, J=5.9, 1.8 Hz), and 6.67 (1H, dd, J=5.9, 1.8 Hz). ^{13}C NMR δ=37.3, 52.7, 52.8, 55.4, 65.4, 71.4, 72.6, 79.1, 79.8, 82.3, 83.1, 83.8, 88.1, 126.9, 136.9, 138.5, 145.9, 170.6, 170.8, and 194.9. IR ν: 1720, 1685, 1260, and 1225 cm^{-1}. UV (MeOH): 204.6 (ε=11500) and 219.6 nm (12200)].

b) A THF solution (6 cm^3) of **6** (51 mg) and concd HCl (1 drop) was stirred for 3 h at room temperature to give **40a** [12 mg; 22%] and **41** [colorless crystals, mp 158—159 °C, 13.3 mg; 24%. Found: C, 56.97; H, 4.71%. Calcd for $C_{20}H_{19}O_8Cl$: C, 56.81; H, 4.53%. ^{1}H NMR δ=1.38 (1H, d, J=9.2 Hz, OH), 3.68 (3H, s), 3.72 (1H, d, J=7.0 Hz), 3.73 (3H, s), 4.52 (1H, dd, J=9.2, 7.0 Hz), 4.80 (1H, d, J=1.8 Hz), 4.86 (1H, s), 4.92 (1H, s), 4.95 (1H, d, J=1.8 Hz), 5.64 (1H, s), 6.60 (1H, dd, J=5.9, 1.8 Hz), 6.74 (1H, dd, J=5.9, 1.8 Hz), 6.97 (1H, d, J=8.4 Hz), 7.20 (1H, dd, J=8.4, 2.2 Hz), and 7.44 (1H, d, J=2.2 Hz). ^{13}C NMR δ=51.0, 52.7 (2C), 71.4, 72.5, 74.0, 79.3, 80.0, 87.3, 88.2, 116.5, 120.4, 129.6, 129.7, 130.7, 137.0, 139.0, 150.7, 171.0, and 171.1. IR ν: 3600—2800, 1720, 1495, 1430, 1270, and 1220 cm^{-1}. UV (MeOH): 220.6 (ε=9500), 230.6 (7800), and 281.2 nm (2200)].

HCl-Catalyzed Reaction of 11. A THF solution (10 cm^3) of **11** (85 mg) and concd HCl (1 drop) was stirred for 2 h at room temperature to give **42** [colorless crystals, mp 190 °C (decomp), 8 mg, 25%. Found: C, 61.04; H, 4.68%. Calcd for $C_{24}H_{21}O_8Cl$: C, 60.96; H, 4.48%. ^{1}H NMR δ=3.02 (1H, dd, J=18.7, 12.8 Hz), 3.28 (1H, dd, J=18.7, 5.5 Hz), 3.57 (3H, s), 3.60 (1H, d, J=5.1 Hz, H_d), 3.72 (3H, s), 4.24 (1H, s, H_c), 4.48 (1H, dd, J=12.8, 5.5 Hz), 4.77 (1H, d, J=1.8 Hz), 4.89 (1H, d, J=1.8 Hz), 5.10 (1H, s, H_b), 5.34 (1H, d, J=5.1 Hz, H_a), 6.54 (1H, dd, J=5.5, 1.8 Hz), 6.66 (1H, dd, J=5.5, 1.8 Hz), 7.46 (1H, td, J=7.7, 1.1 Hz), 7.68 (1H, ddd, J=7.7, 7.3, 1.5 Hz), 7.91 (1H, dd, J=7.7, 1.5 Hz), and 8.16 (1H, dd, J=7.3, 1.1 Hz). ^{13}C NMR δ=44.0, 45.4, 52.6, 52.8, 61.5, 72.2, 73.0, 79.4, 80.2, 80.7, 82.1, 82.9, 87.9, 126.6, 128.9, 129.9, 130.7, 134.2, 136.9, 138.7, 140.3, 170.5, 170.6, and 193.6. IR ν: 1720, 1690, 1590, 1280, and 1265 cm^{-1}. UV (MeOH): 204.6 (ε=27300), 250.6 (6400), and 293.0 nm (1300)], **43** [colorless crystals, mp 201—202 °C, 15 mg; 48%. Found: C, 63.44; H, 5.13%. Protease-Catalyzed Peptide Formation under High Pressure

Shigeru KUNUGI,* Kazuo TANABE, Kouji YAMASHITA, Yoshio MORIKAWA, Takanobu ITO, Toshihiro KONDOH, Kouichirou HIRATA, and Akihiko NOMURA
Department of Applied Chemistry, Fukui University, Bunkyou 3-9-1, Fukui 910
(Received July 11, 1988)

The effect of high pressure on peptide formation by the catalysis of carboxypeptidase Y (substitution of ester or peptide by amino acid derivative) or by thermolysin (condensation of *N*-acylamino acid and amino acid amide) was studied. The carboxypeptidase Y-catalyzed substitution reaction of *N*-[3-(2-furyl)acryloyl]-phenylalanine ethyl ester with glycinamide or phenylalaninamide showed a six-fold higher total peptide yield at 200 MPa than at atmospheric pressure. In the case of the reaction of *N*-acyldipeptide and amino acid amide, both the peptide yield and substitution efficiency were improved at elevated pressure and the wasteful hydrolysis of the substrate was highly depressed by increasing pressure. The pressure was also effective to get rid of the substrate inhibition by the amino acid ester in the reaction between the *N*-acylamino acid ester and the amino acid ester and to yield much dipeptide ester at high pressure. An improvement of the peptide yield by pressure for the reaction of thermolysin was observed in a combination of less specific substrates, *N*-benzyloxycarbonyl-L-aspartic acid and phenylalanine methyl ester, since the high catalytic activity of this enzyme under elevated pressure was significant only in the case that the peptide yield was kinetic-controlled.

During the course of our studies on the reaction mechanisms of several proteases by examining the influence of hydrostatic pressure on the reactions,[1-3] we found that the pressure affected one type of activity of some enzymes in a considerably different manner from the other, depending on the nature of the scissile bond of the substrate. Also, a certain enzyme show a considerable apparent pressure-activation. One example of the former is carboxypeptidase from yeast (CPase Y),[2] which is grouped into serine carboxypeptidase.[4] The intrinsic carboxypeptidase activity of this enzyme (Eq. 1, where AA_i and R denote amino acid residue and alkyl group, respectively) was highly depressed by increasing the pressure, while an esterase (Eq. 2) or amidase (Eq. 3) reaction was less influenced by pressure; e.g., at 100 MPa the rate of hydrolysis of *N*-[3-(2-furyl)acryloyl]phenylalanine ethyl ester and amide was 85 and 75%, respectively, of that at atmospheric circumstance, while that of *N*-[3-(2-furyl)-acryloyl]glycylphenylalanine was decreased to less than 15% by the same pressure increase (pH 6, 25 °C). This resulted mainly from the difference in the ionic nature of the substrate and the discouraged electrostatic interaction at the elevated pressure to avoid any increase in the molar volume due to liberated hydration water around ionic groups.

$$---AA_1\text{-}AA_2 \longrightarrow ---AA_1 + AA_2 \quad (1)$$
$$---AA_1\text{-}OR \longrightarrow ---AA_1 + ROH \quad (2)$$
$$---AA_1\text{-}NH_2 \longrightarrow ---AA_1 + NH_3 \quad (3)$$

An example of the apparent pressure-activation was seen in the case of thermolysin, a zinc-containing

AA_i, amino acid residue; R, alkyl group.

endoprotease from *B. thermoproteolyticus*. A pressure increase of up to 100 MPa gave about a 15-fold higher second-order rate for the hydrolysis of *N*-acyldipeptide amide catalyzed by this enzyme.[3] This could be explained in terms of a change of the structure and a subsequent change in the hydration state of the protein coupled with the progress of the reaction. These findings led us to inspect the pressure effect on the protease-catalyzed peptide formation reactions, since both of these enzymes are known to catalyze such kinds of reactions.[5] Actually, in a preliminary study we found a strong influence of pressure on a peptide formation reaction by CPase Y.[6]

In this report we describe the pressure effect on various types of peptide formation reactions catalyzed by CPase Y and thermolysin. With CPase Y, peptides can be formed by a nucleophilic attack by an amino acid derivative on the acylated intermediate[7] (Scheme 1), which is derived from either an ester substrate[8] or a peptide substrate.[9] Nucleophile can be either an amino acid amide (X=NH_2) or an amino acid ester (X=OR). The reverse reaction of the hydrolysis, starting from e.g. *N*-acylamino acid and amino acid (Eq. 4), might also give peptides.[10] With thermolysin, peptide can be formed only by a reaction of this type and the carboxyl part of AA_2 should be capped (-X).

$$---AA_1 + AA_2(-X) \longrightarrow ---AA_1\text{-}AA_2(-X) \quad (4)$$

Experimental

Materials. CPase Y was kindly donated by Oriental Yeast Co. (Osaka, Japan) (Lot 21003001) and thermolysin was obtained from Daiwa Kasei Co. (Osaka, Japan) (Lot T4KB31,32). *N*-[3-(2-Furyl)acryloyl]amino acids (Fua-amino acids) and *N*-[3-(2-furyl)acryloyl]dipeptides including the standard samples for the chromatographic analysis were prepared by the *N*-hydroxysuccinimide method,[11] as previously reported.[1-3] This chromophoric acyl group was chosen since it facilitates product detection and since we had made some kinetic studies on the proteases by using this type of substrate. The principle obtained from the present results may be applicable to substrates with other acyl groups. Buffer reagents were purchased from Dojindo Laboratories (Kumamoto, Japan) and other amino acid derivatives were of commercial reagent grade. The authentic sample of *N*-benzyloxycarbonyl-Asp-Phe methyl ester (Cbz-Asp-Phe-OMe) was a kind gift from Prof. Y. Okahata, Tokyo Institute of Technology, Japan.

Methods. The reaction solution contained an appropriate amount of organic solvent (depending on the reaction species; dimethyl sulfoxide [DMSO], *N*,*N*-dimethylformamide [DMFA], or acetonitrile [MeCN]), enzyme and substrates, buffered at described pH with 2-morpholinoethanesulfonic acid, 2-[4-(2-hydroxyethyl)-1-piperazinyl]ethanesulfonic acid, 2-amino-2-hydroxy-methyl-1,3-propanediol, 3-[[2-hydroxy-1,1-bis(hydroxymethyl)ethyl]amino]-1-propanesulfonic acid, or 3-cyclohexylamino-1-propanesulfonic acid.

It was divided into two parts; one part was sealed in a small polypropylene-made bottle, placed in a stainless-steel pressure vessel located in a thermostated bath, while the other part was incubated under atmospheric pressure at a controlled temperature. Kerosene was used as the pressure medium.

After a prescribed period the reaction mixture was taken out from each part of the solution and quenched by adding 5 volumes of a mixture of acetonitrile and 5 mM-aqueous phosphoric acid (1M=1 mol dm^{-3}). Portions were then analyzed by liquid chromatography (Shimadzu LC6A-Cosmosil 5C18-P). The eluent was a 40—60% mixture of acetonitrile with 5 mM of aqueous phosphate (pH 2.5—3) containing 50 mM Na_2SO_4 or triethylamine. The amount of each species was calculated from the integration of the eluent curve (Shimadzu Chromatopak C-R6A) after corrections with the extinction coefficient measured on a spectrophotometer (Uvidec 610-B) independently.

Results and Discussion

Carboxypeptidase Y. Table 1 shows the product distribution of the CPase Y-catalyzed reaction of Fua-Phe-OEt with Gly-NH_2 or Phe-NH_2 at atmospheric pressure and at 200 MPa. With Gly-NH_2, Fua-Phe, and Fua-Phe-Gly-NH_2 were detected as the products and the yield of the dipeptide amide was larger at high pressure. As reported before,[12] this enzyme shows carboxamidopeptidase activity towards Fua-Phe-Gly-NH_2 and, therefore, the primarily produced dipeptide amide can be directly hydrolyzed to Fua-Phe and Gly-NH_2. With Phe-NH_2, a dipeptide having free carboxylate (Fua-Phe-Phe), was also detected in the reaction mixture. This *N*-acyldipeptide was produced by the amidase activity on the primary product, Fua-Phe-Phe-NH_2. Thus, Fua-Phe was produced by the hydrolysis of either Fua-Phe-OEt or Fua-Phe-Phe (Eq. 5). (For Fua-Phe-Phe-NH_2 CPase Y shows no carboxamidopeptidase activity.[1])

Table 1. Effect of Pressure on CPase Y-Catalyzed Formation of Dipeptide Amide from Fua-Phe-OEt and Amino Acid Amide[a]

Nucleophile	Pressure	Yield (%)		
	MPa	Fua-Phe	Fua-Phe-Xxx-NH_2	Fua-Phe-Xxx

$$\text{NH}_3 \qquad\qquad \text{Phe}$$

At 200 MPa, the total peptide yield was increased approximately six-fold. This result could be explained by considering the effect of pressure on the hydrolysis of Fua-dipeptide amides by this enzyme (Table 2). By increasing the pressure, the carboxypeptidase activity was retarded more rigorously than the amidase or the carboxamidopeptidase activity and, as a result, a dipeptide with a carboxylate end was obtained in higher yield.

An acyl-enzyme can be also produced from an *N*-acyldipeptide substrate which is attacked by amino acid amide to form an *N*-acyldipeptide amide. A time course of such a reaction under atmospheric pressure is shown in Fig. 1. After 3 h the reaction was completed. Table 3 shows the effect of pressure on such a peptide formation reaction: namely, the product distribution of a combination of Fua-Gly-Phe+Leu-NH_2 after 3 h reaction at 0.1 and 100 MPa. At elevated pressure the yield of Fua-Gly-Leu-NH_2 increased. At the same time the amount of remaining unreacted substrate, Fua-Gly-Phe, also increased, which was brought about by a strong retardation of the peptidase activity by pressure. This means that the pressure depressed the wasteful hydrolysis of the substrate.

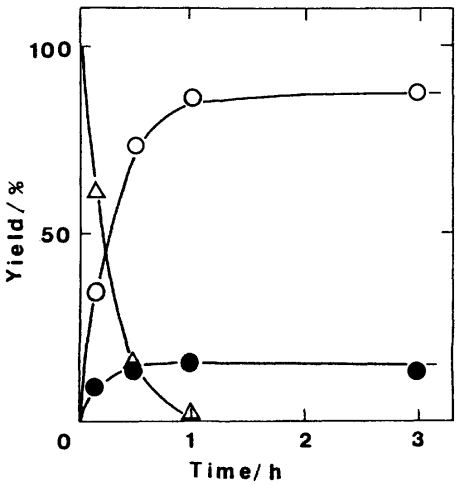

Fig. 1. Time course of CPase Y-catalyzed peptide formation from Fua-Gly-Phe and Leu-NH_2. Relative amounts of Fua-Gly (○), Fua-Gly-Phe (△), and Fua-Gly-Leu-NH_2 (●) are shown. [Fua-Gly-Phe]= 0.25 mM, [Leu-NH_2·HCl]=0.1 M, [enzyme]=1.0 μM, pH 6.5 (0.1 M Hepes), 2.5%(v/v) DMFA, 35 °C.

Relative amounts of Fua-Phe (○), Fua-Phe-OEt (△), Fua-Phe-Phe (●), Fua-Phe-Phe-OEt (▲), and Fua-Phe-Phe-Phe (◐) are shown. [Fua-Phe-OEt]=1.0 mM, [Phe-OEt·HCl]=0.05 M, [enzyme]=10 nM, pH 9.5, 7.0%(v/v) MeCN, 30 °C, 0.1 M NaCl.

acyldipeptide (Fua-Gly-Leu) appeared in the product, due to the amidase activity of this enzyme on the once produced dipeptide amide coupled with the highly depressed carboxypeptidase activity at elevated pressure. With this carboxypeptide used as an acyl donor, however, the peptide yield was relatively low, at most around 30%, even at elevated pressure.

Next, the reaction between *N*-acylamino acid ester and amino acid ester was examined. In this case the peptide ester once produced can further act as a substrate[8)] and the peptide chain can be extended, as shown in Fig. 2. Table 4 shows an example of the effect of pressure on such a reaction; Fua-Phe-OEt+Phe-OEt. At low Phe-OEt concentration the effect was practically negligible, since the esterase activity was affected by pressure to a smaller extent. Most of the product was *N*-acyldipeptide and small portions were dipeptide ester and tripeptide ester.

When the nucleophile (Phe-OEt) concentration was increased in order to increase the substitution efficiency, the amount of unreacted substrate increased, since this component also acted as a kind of inhibitor, of which the inhibition constant was estimated to be about 10 mM from the reported data.[4)] The pressure was highly effective to get rid of such a substrate inhibition and the yield of the dipeptide ester product was increased under high pressure.

Table 5. Effect of Pressure on Thermolysin-Catalyzed Peptide Formation Reaction

Reaction	pH	Pressure	Product yield
		MPa	%
Fua-Gly+Leu-NH_2[a)]	7.0	0.1	83.0
		200	52.1

		150	55.8[c)]
	7.0	0.1	15.3
		150	33.6

a) [Fua-Gly]=1 mM, [Leu-NH_2·HCl]=50 mM, [TLN]=1.1 μM, 30 °C, 5 (v/v)% DMSO. Incubation time 6 h. b) [Cbz-Asp]=5 mM, [Phe-OMe·HCl]=100 mM, [TLN]=5 μM, 30 °C, 5 (v/v)% DMSO 50 (v/v)% MeCN. Incubation time 4 h. c) [TLN]=7.5 μM, 35 °C. Other conditions are as above.

Thermolysin. This enzyme effectively catalyzes the condensation reaction of *N*-acylamino acid and amino acid amide. Table 5 shows the result on the effect of pressure on thermolysin-catalyzed peptide condensation.

For a reaction to form a specific dipeptide substrate, such as Fua-Gly+Leu-NH_2→Fua-Gly-Leu-NH_2 (the second-order rate constant of the hydrolysis of this substrate by thermolysin is about 2×10^4 $M^{-1}s^{-1}$ at pH 6.5, 25 °C), the condensation efficiency is very high, much higher than other proteases when we compare their hydrolytic activities.[13)] Though the condensed product did not precipitate under the present experimental conditions (the concentration of the acyl substrate was set well below the solubility of the product; monophasic system), the reaction proceeded fast (as shown in Fig. 3-a) and the product yield was deter-

●, at 0.1MPa; ○, at 150 MPa.

mined mostly by the equilibrium of the reaction (thermodynamic-controlled). At increased pressure the electrostriction of the water around the carboxylate and ammonium ions of the *N*-acylamino acid and amino acid amide, respectively, is favored in order to decrease the partial volumes in the system which in turn forces the reaction to proceed towards the dissociated (hydrolyzed) side and results in a lower yield of the peptide formation. At such a pressure as discussed in the present study the volume change contribution of enzyme protein structure is far less significant and that of the hydration change of the substrate (or protein) plays dominant roles.[14]

On the contrary the combination of Cbz-Asp and Phe-OMe (which is known as a reaction to produce a precursor of a sweetener[15]) is 'non-specific' to this enzyme and the reaction proceeded slowly (Fig. 3-b). Thus, the yield is determined rather "kinetically." In such a case the higher catalytic activity performed by the increased pressure is sufficient to exceed the negative factor given by the substrate hydration and, hence, a nearly six-fold increase in the peptide formation was observed under the present conditions.

These results indicate that pressure can be an important parameter in improving the peptide yield in a reaction catalyzed by proteolytic enzymes; this principle will be applied to other systems with different types of the substrate and enzyme. Though the pressure had been used to influence and improve various organic (or inorganic) syntheses,[16] the present example shows that the effect of pressure is exerted through molecular recognition and a reaction by a macromolecular catalyst which can amplify the effect to enable the control of reactions at relatively low pressure.

Cr(III) or Ce(IV) Impregnated Perfluorinated Resin-Sulfonic Acid Catalyst for the Oxidation of Alcohols

Shigekazu KANEMOTO,† Hiroyuki SAIMOTO,†† Koichiro OSHIMA,* Kiitiro UTIMOTO, and Hitosi NOZAKI†††
Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Yoshida, Kyoto 606
(Received July 26, 1988)

Several polymer supported catalysts are prepared by treatment of Nafion®551 (abbreviated NAFK below) with metal salts. Cr/NAFK and Ce/NAFK are found to be effective catalysts for the dehydrogenative oxidation of alcohols to the corresponding ketones by means of *t*-butyl hydroperoxide. Selective oxidation of secondary alcohols in the presence of primary ones was performed using a Ce/NAFK-$NaBrO_3$ system.

Polymer supported reagents are receiving considerable attention. The advantages of the use of polymeric reagents in organic synthesis have been described in a number of papers which are summarized in a monograph.[1] Major advantages of this approach are (1) the ease of purification of the final product and (2) the effective recycling use.

Two kinds of polymer reagents for the oxidation of alcohols to the corresponding aldehydes and ketones are described in literature. One is a reagent generated from poly(*p*-methylthiostyrene) and chlorine,[2] and the other is a polymeric analogue of pyridinium chlorochromate[3] or pyridinium dichromate.[4-6] The oxidation reactions using such stoichiometric reagents is easy to perform, but suffers from a couple of disadvantages including the requirement of a large amount of the reagent and a large volume of the solvent, because the exchange capacity of the polymer oxidant is usually low. Furthermore recycling of the reagents requires troublesome step of workup which prohibits the practical use. It is anticipated that the use of a catalytic amount of a polymer reagent in the presence of suitable co-oxidant such as *t*-BuOOH and $NaBrO_3$ could solve these disadvantages.[7] Here we wish to report convenient oxidation of alcohols with *t*-butyl hydroperoxide using a new type of polymer supported catalysts, i.e. Cr(III) and Ce(IV) impregnated perfluorinated resin-sulfonic acids.[8]

The structure of NAFK[9] is shown in Fig. 1. The perfluorinated resin has high stabilities thermally, chemically, and physically. NAFH (Nafion-H) has been widely used as a solid-state superacid reagent in several reactions.[10] Exchange of the counter metal on the polymer sulfonate was easily performed by treatment of the polymer potassium salt (NAFK) with the desired metal salts in deionized water. For instance, stirring of a mixture of NAFK and chromium(III) acetate for 36 h at 25 °C provided chromium impregnated catalyst (Cr/NAFK). Titrations of the generated catalyst indicated a capacity of 0.68 mmol of Cr(III) per gram which corresponds to 75% of the theoretical capacity of a fully loaded resin. Several kinds of metal impregnated perfluorinated resin-sulfonic acid catalysts were prepared and examined in the oxidation of 1-phenylethanol to acetophenone with anhydrous *t*-butyl hydroperoxide.[11] Among them, chromium(III) and cerium(IV) salts proved to efficiently catalyze the oxidation of alcohols. In contrast, polymer-supported catalysts carrying metals such as Cu(II), Ni(II), and Mn(II) were found less effective. The alcohols were only partly (at most 30%) converted into ketones with latter catalysts under the same reaction conditions.

Oxidation of secondary alcohols into ketones was studied using Cr/NAFK-*t*-BuOOH system in a

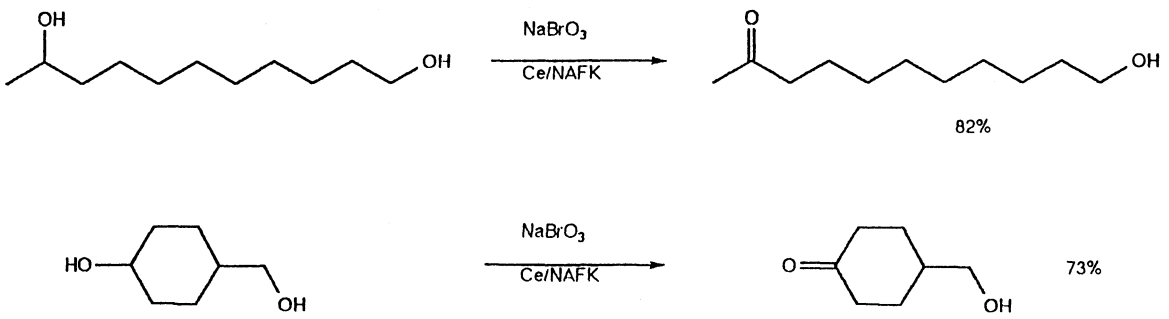
a) The hydroxy compounds (1.0 mmol), *t*-BuOOH (1.5 ml, 4.0 mmol), and Ce/NAFK (50 mg, 0.027 mmol) were combined in benzene and the mixture was stirred for 6 h at 80°C. b) Isolated and purified yields.

number of solvents under heating. Among them, chlorobenzene gave the best result. Reaction in benzene required a longer reaction time which caused contamination by undesired products. Toluene, which has similar boiling point to chlorobenzene, was not suitable for the oxidation of alcohols, because it was oxidized into benzaldehyde under the reaction conditions. The reaction proceeded upon heating a mixture of a substrate, an oxidant, and the resin catalyst suspended in chlorobenzene at 85 °C for several hours. The resin catalyst was filtered off and washed with ethyl acetate. Workup and purification of crude product gave the desired ketone effectively. Typical examples with Cr/NAFK-*t*-BuOOH chlorobenzene are summarized in Table 1. Secondary alcohols were converted into the corresponding ketones in good yields. Meanwhile, oxidation of primary alcohols generally gave complex mixtures of the unchanged substrates, the desired aldehydes, and the overoxidized carboxylic acids under the same reaction conditions. Ratios of these products were dependent on the reaction conditions (time, temperature). Prolonged reaction time or higher temperature naturally increased the formation of the carboxylic acids.

Recycling of the catalyst could be accomplished by simple filtration, washing with ethyl acetate, and drying. Titration of the recovered catalyst showed that more than 95% of chromium remained on the resin. Thus, 1-phenylethanol was oxidized to acetophenone in 92% (the second run) and 90% (the third run) yields by utilizing the recovered catalyst.

The resin cerium salt (Ce/NAFK) also has proved to be an efficient catalyst for the oxidation of alcohol by means of *t*-butyl hydroperoxide or sodium bromate. The catalyst, Ce/NAFK was prepared by stirring of a mixture of NAFK and $(NH_4)_2Ce(NO_3)_6$ for 36 h at 25 °C. In this catalytic system, the reaction proceeded at lower temperatures than Cr/NAFK-*t*-BuOOH system, so that benzene was found to be the preferred solvent. Table 2 shows the results of the oxidation of secondary alcohols. In contrast to the previously reported $(NH_4)_2Ce(NO_3)_6$-$NaBrO_3$ system,[12] the present system was not interfered with olefinic moiety in the substrates. Thus, 2-cyclododecen-1-ol and 11-dodecen-2-ol as well as carveol gave the corresponding olefinic ketones in good yields upon treatment with Ce/NAFK-*t*-BuOOH. Noteworthy is the fact that the cerium catalytic system does not oxidize primary alcohols into aldehydes. For example, 1-dodecanol was recovered practically unchanged under the general reaction conditions.

Reagents which are sufficiently selective to distinguish between functional groups of the same class are exceedingly valuable in syntheses. Recently several methods have been reported that permit the oxidation of secondary alcohols in the presence of primary ones.[13] It was anticipated that the treatment of primary, secondary diols with our new system would provide another method for selective formation of hydroxy ketones. This was indeed the case and selective oxidation of secondary hydroxyls in the presence of primary ones has been achieved as shown in Scheme



Scheme 1.

1, where choice of solvent and oxidant was critical. Oxidation in benzene with Ce/NAFK-*t*-BuOOH proceeded sluggishly and the desired products were contaminated by some unidentified by-products. For instance, oxidation of 1,10-undecanediol gave only 30% yield of 11-hydroxy-2-undecanone. The optimum yield of 82% was obtained with $NaBrO_3$ as a co-oxidant in AcOH at 55 °C. In similar fashion, 4-hydroxymethyl-1-cyclohexanol was converted into 4-hydroxymethyl-1-cyclohexanone in 73% yield with Ce/NAFK-$NaBrO_3$.

The Cr(III) and Ce(IV) catalysts prepared from Nafion-H (NAFH) also were effective for the transformation of alcohol into carbonyl compounds, but the products were contaminated by the di-*t*-butyl acetals which were generated by the NAFH catalyzed acetalization of the ketones.[14]

Experimental

Infrared spectra of neat liquid film samples were determined on a Hitachi grating infrared spectrometer 215, or JASCO IR 810, mass spectra and exact mass on a Hitachi M-80. NMR spectra were recorded on a Varian EM-390, or Varian XL-200 spectrometer using TMS as an internal standard unless otherwise noted. Multiplicity is designated as s, singlet; d, doublet; t, triplet, q, quartet; m, multiplet. Preparative TLC plates were prepared with Merck Kieselgel PF_{254}. Column chromatography was carried out with silica gel (Wakogel C-200) at atmospheric pressure.

Preparation of Metal/NAFK Catalyst. Preparation of Cr/NAFK is representative. Anhydrous chromium(III) acetate (0.69 g, 3.0 mmol) was dissolved in deionized water (30 ml). NAFK (1.1 g, 1.0 mmol of sulfonate) was added and the suspension was stirred for 36 h at 25 °C. The polymer catalyst was filtered off and washed with deionized water (10 ml×5) until the washings became practically colorless. The recovered polymer catalyst was dried in vacuo to constant weight, and used.

Capacity of thus prepared resin catalyst was confirmed as follows. Dried resin catalyst (500 mg) was suspended in aqueous hydrochloric acid (6 M; 1 M=1 mol dm^{-3} prepared with deionized water, 3 ml), and stirred for 5 h. The polymer was filtered off and washed with hydrochloric acid (5 ml×2). The recovered polymer catalyst was suspended again in hydrochloric acid (6 M, 3 ml) and the washing processes were repeated twice. Whole washings were collected and chromium(III) dissolved was titrated with ethylenediaminetetraacetic acid according to a described method.[15] Titration showed that 0.68 mmol of Cr(III) per gram was supported on the resin catalyst.

Preparation of Ce/NAFK. To a solution of $(NH_4)_2Ce(NO_3)_6$ (1.75 g, 3.0 mmol) in deionized water (30 ml) was added NAFK (1.1 g, 1.0 mmol of sulfonate), and the whole was stirred for 36 h at 25 °C. Titration of the dried resin indicated that 0.54 mmol of Ce(IV) per gram was loaded on the resin catalyst.

Other metal/NAFK catalysts prepared were Cu(II) (from $CuSO_4$ or $Cu(OAc)_2$), Ni(II) ($Ni(OAc)_2$), and Mn(II) ($Mn(OAc)_2$). Titration indicated that each metal/NAFK had capacity of more than 70% of theoretical one of fully loaded resin.

General Procedure for the Oxidation of Secondary Alcohols with *t*-Butyl Hydroperoxide Using Cr/NAFK as Catalyst. A solution of 1-phenylethanol (0.12 g, 1.0 mmol) in chlorobenzene (2.0 ml) was added to a suspension of Cr/NAFK (50 mg. 0.034 mmol as chromium(III) salt) in chlorobenzene (1.0 ml). A solution of *t*-butyl hydroperoxide in benzene (2.64 M, 1.5 ml, 4.0 mmol) was added and the whole was heated at 85 °C for 6 h. The solid catalyst was filtered off and washed with ethyl acetate. The filtrate and washings were combined and washed with aqueous sodium hydrogensulfite and brine successively. Purification of the concentrated crude product by silica gel column chromatography gave acetophenone (0.11 g) in 95% yield.

Oxidation of 1-Dodecanol with *t*-Butyl Hydroperoxide Using Cr/NAFK as Catalyst. To a suspension of Cr/NAFK (50 mg, 0.034 mmol of chromiun(III) salt) in chlorobenzene (2.0 ml) was added 1-dodecanol (0.18 g, 1.0 mmol) and *t*-butyl hydroperoxide in benzene (2.64 M, 1.5 ml. 4.0 mmol). The whole mixture was heated at 80 °C and stirred for 12 h. The resin catalyst was filtered off and the filtrate was treated with aqueous sodium hydrogensulfite. The water layer was acidified with aqueous hydrochloric acid (6 M, 2.0 ml) and extracted with ethyl acetate. Concentration of combined organic layer followed by separation by silica gel column chromatography gave dodecanal (0.07 g. 39%) and dodecanoic acid (0.03 g, 15%). Unchanged 1-dodecanol was also recovered (0.04 g, 24%).

General Procedure for the Oxidation of Secondary Alcohols with *t*-Butyl Hydroperoxide Using Ce/NAFK as Catalyst. Oxidation of carveol to carvone was representative. Carveol (0.15 g, 1.0 mmol) and *t*-butyl hydroperoxide (2.64 M benzene solution, 1.5 ml, 4.0 mmol) were added to a suspension of Ce/NAFK (50 mg, 0.027 mmol of cerium(IV) salt) in benzene (2.0 ml). The mixture was stirred for 2 h at 80 °C.

The resulting mixture was diluted with ethyl acetate, then Ce/NAFK catalyst was filtered off and washed with ethyl acetate on a glass filter. The organic layer was washed with aqueous sodium hydrogensulfite and brine, and dried over anhydrous sodium sulfate. Concentration gave a residual oil which was submitted to silica-gel column chromatography to give carvone (0.15 g) in 98% yield.

11-Hydroxy-2-undecanone: To a suspension of sodium bromate (0.15 g, 1.0 mmol) and Ce/NAFK (0.1 g, 0.054 mmol) in acetic acid (2.0 ml) was added a solution of 1,10-undecanediol (0.19 g, 1.0 mmol) in the same solvent (1.0 ml). The resulting mixture was stirred at 55 °C for 3 h. The resin catalyst was filtered off and washed with ethyl acetate. The filtrate and washings were combined and treated with aqueous sodium hydrogencarbonate, sodium hydrogensulfite, and brine. Concentration and purification by silica-gel column chromatography (hexane:ethyl acetate=2:1) gave the title compound (0.16 g) in 82% yield. Mp 42—43 °C; IR (neat) 3424, 1709, 1358, 1042 cm^{-1}; ^1H NMR (CCl_4) δ=1.1—1.8 (m, 14H), 2.09 (s, 3H), 2.36 (t, J= 6.6 Hz, 2H), 3.58 (t. J=6.8 Hz, 2H), 3.78 (b, 1H). Found: C, 70.65; H, 11.90%. Calcd for $C_{11}H_{22}O_2$: C, 70.92; H, 11.90%.

4-Hydroxymethyl-1-cyclohexanone: The product was identical with the authentic sample.[16]

Oxidation of 4-*t*-Butylcyclohexanol with *t*-Butyl Hydroperoxide Using Ce/NAFH as Catalyst. Ce/NAFH catalyst was generated in the same manner as the preparation of Ce/NAFK. Titration indicated the capacity of 0.60 mmol of Ce(IV) per one gram of resin. To a suspension of Ce/NAFH (50 mg, 0.03 mmol of Ce(IV) salt) in benzene (4.0 ml) was added 4-*t*-butylcyclohexanol (0.16 g, 1.0 mmol) and *t*-butyl hydroperoxide (2.64 M in benzene, 1.5 ml, 4.0 mmol) and the resulting mixture was stirred at 80 °C. The starting alcohol was consumed within 1.5 h and the resulting mixture was diluted with ethyl acetate. The resin catalyst was separated and washed with ethyl acetate. The filtrate and washings were treated with aqueous sodium hydrogensulfite and brine, dried over anhydrous sodium sulfate and concentrated. Purification of crude oil by silica-gel column chromatography (hexane:ethyl acetate=10:1) gave 4-*t*-butylcyclohexanone (0.05 g, 30%) and 4-*t*-butylcyclohexanone di-*t*-butyl acetal (0.15 g, 50%).

Buffering the reaction mixture by adding sodium hydrogencarbonate improved the yield of 4-*t*-butylcyclohexanone and suppressed the formation of acetal. Treatment of a mixture of Ce/NAFH (50 mg, 0.03 mmol of cerium(IV) salt), 4-*t*-butylcyclohexanol (0.16 g, 1.0 mmol) and sodium hydrogencarbonate (0.04 g, 0.5 mmol) in benzene (4.0 ml) with *t*-butyl hydroperoxide (2.64 M in benzene, 1.5 ml, 4.0 mmol) gave 4-*t*-butylcyclohexanone (0.11 g, 68%) which was contaminated by small amount of acetal (7%). Oxidation proceeded somewhat slower than the reaction without sodium hydrogencarbonate (80 °C, 3 h).

Development of a Facile Method for Polypeptide Synthesis. Synthesis of Bovine Pancreatic Trypsin Inhibitor (BPTI)

Saburo AIMOTO,* Noriko MIZOGUCHI, Hironobu HOJO, and Shoko YOSHIMURA
Institute for Protein Research, Osaka University, Yamakaoda, Suita, Osaka 565
(Received July 27, 1988)

A new method for the preparation of pure polypeptides based on the minimun-protection strategy is described. Its effectiveness was demonstrated by a synthesis of bovine pancreatic trypsin inhibitor (BPTI). Protected peptide segments of Z-[Arg(Tos)^{1}, Asp(O*c*Hex)^{3}, Cys(Acm)^{5}, Glu(O*c*Hex)^{7}]-BPTI(1—13), Boc-[Cys(Acm)^{14,30}, Lys(Z)^{15,26}]-BPTI(14—36), and [Cys(Acm)^{38,51,55}, Lys(Z)^{41,46}]-BPTI(37—58) were prepared by modifying the products obtained by solid-phase peptide syntheses. The protected peptides corresponding to BPTI(14—36) and BPTI(37—58) were coupled by an active ester method to give protected BPTI(14—58). Next, protected BPTI(1—13) was coupled to the BPTI(14—58) by an active ester method after removing the Boc group from the protected BPTI(14—58). All of the protecting groups on BPTI(1—58) were removed, and the resulting peptide was oxidized to give the native form of BPTI in a very pure form. The synthetic BPTI was shown to be identical with the native BPTI in an elution experiment on ion-exchange chromatography and in its inhibitory activity. The new method proved to be very effective for a rapid preparation of pure polypeptide.

Solid-phase peptide synthesis permits effective peptide-chain elongation on a solid support within a short time.[1] However, purification of the final product becomes more difficult with increasing peptide size. On the other hand, a liquid-phase synthesis of a polypeptide is extremely tedious, even for an experienced peptide chemist. To overcome these problems, several approaches have been proposed.[2-5]

We have reported a facile method[6] for the preparation of a cyclic peptide using a protected peptide derived from the product obtained by a solid-phase method. The results suggested that the method could be applied to the preparation of polypeptides.

In this paper, we describe a novel method for the preparation of polypeptide. Its effectiveness was demonstrated by the synthesis of a well-studied small protein, BPTI. This method should be applicable to the syntheses of other peptides of this size.

Results and Discussion

Preparation of Protected Peptide Segments. As shown in Fig. 1, BPTI was divided into three peptide segments: BPTI (1—13), BPTI (14—36), and BPTI (37—58). To avoid racemization during segment coupling, their carboxyl-terminal amino-acid residues were designed to be a glycine or proline residue.

Since BPTI (1—13) contains aspartyl and glutamyl residues, selective protection of α- and ω-carboxyl groups of this peptide segment was realized by the solid-phase method involving N^{α}-(3-nitro-2-pyridinesulfenyl) amino acids (Npys-amino acid) and N^{α}-(9-fluorenylmethyloxycarbonyl) amino acids (Fmoc-amino acid) as shown in Fig. 2. Preparation of the Npys-prolyl resin **6** and chain elongation by using Npys-amino acid were carried out by Matsueda's method.[7] Fmoc-Cys(Acm) was introduced according

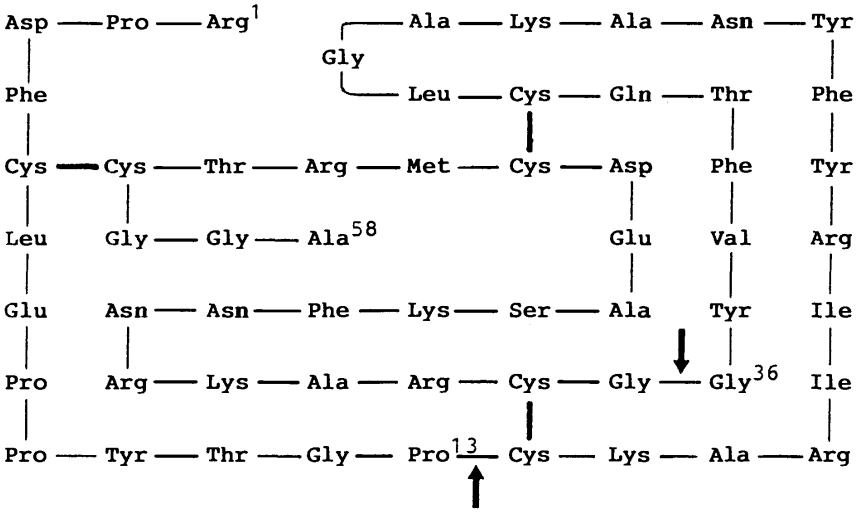

Fig. 1. Primary sequence of bovine pancreatic trypsin inhibitor (BPTI). Arrows indicate the sites where segment coupling was carried out.

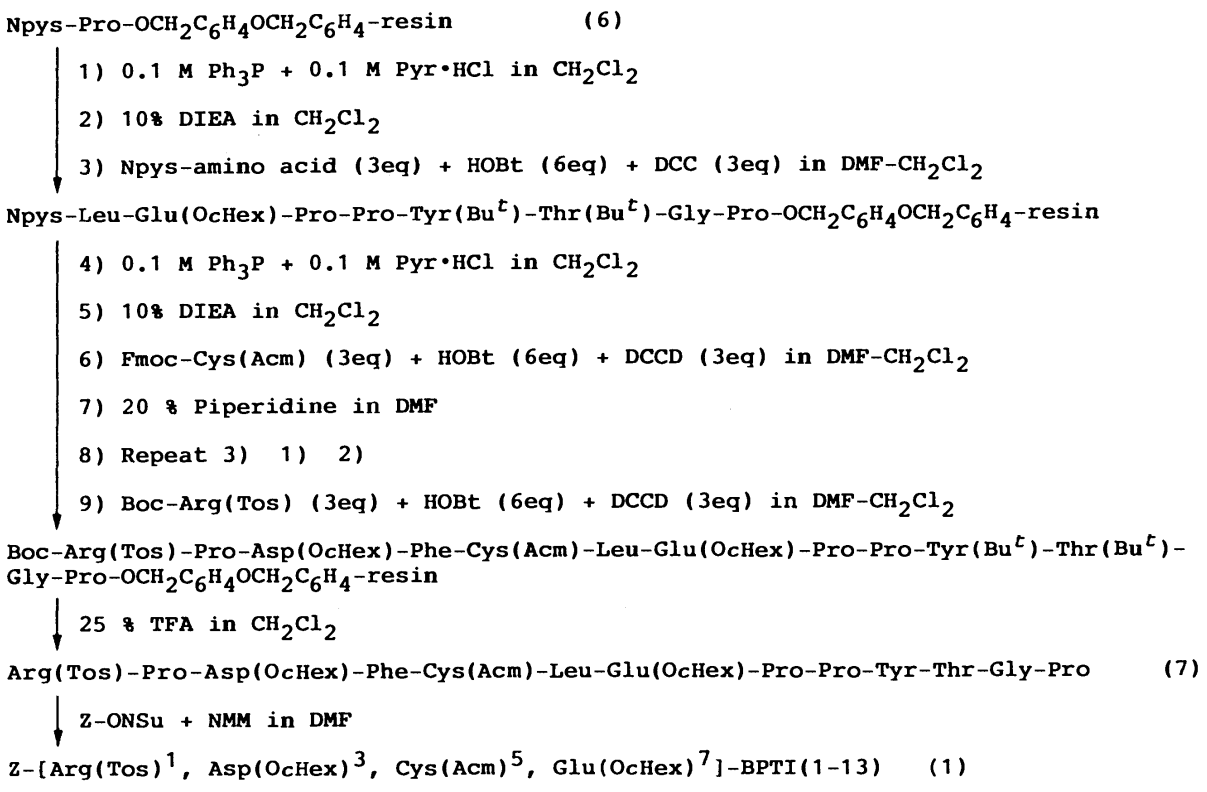

Fig. 2. Synthetic scheme of partially protected BPTI(1—13) **1**

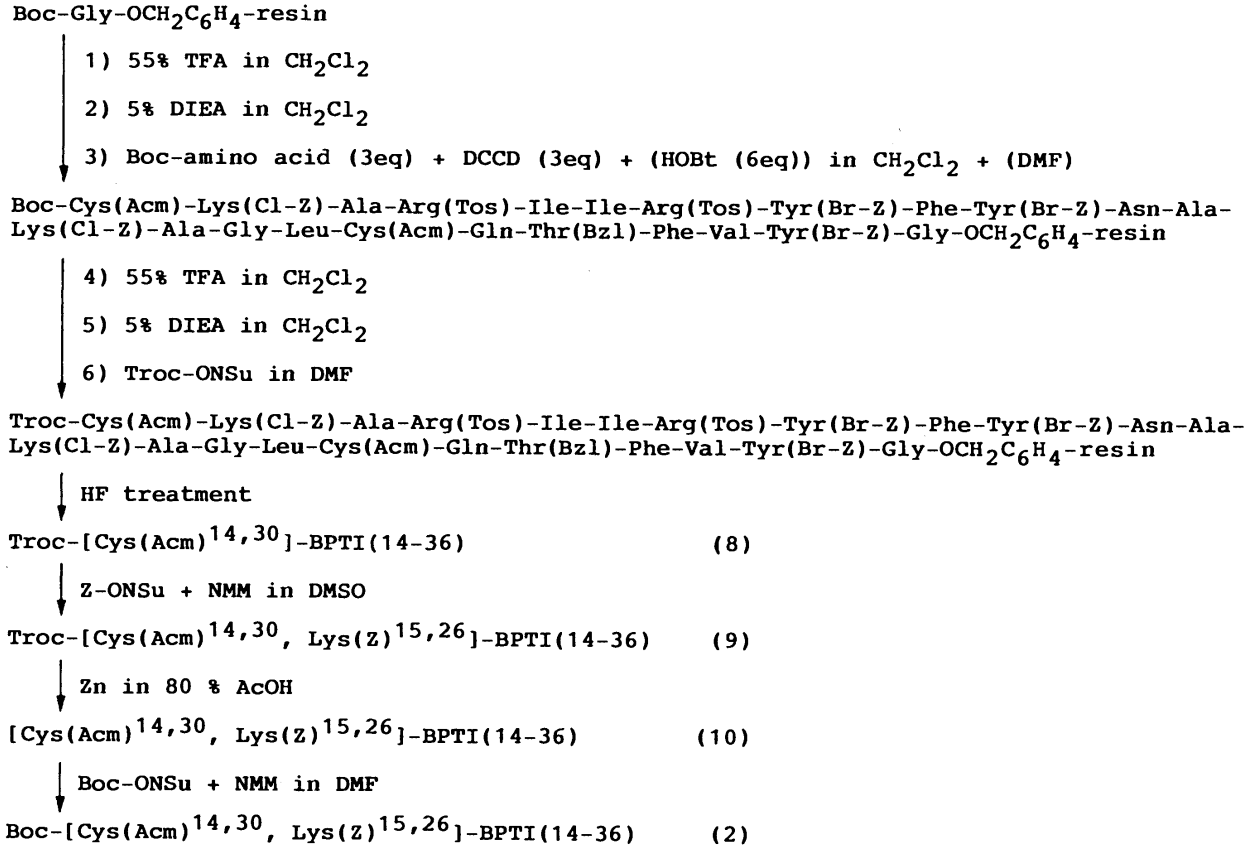

Fig. 3. Synthetic scheme of partially protected BPTI(14—36) **2**

to Chan et al. with slight modifications.[8] After completion of the peptide chain assembly, the protected peptide resin was treated with 25% trifluoroacetic acid (TFA) in CH_2Cl_2 to obtain protected peptide **7**. This peptide was hydrophobic, but very soluble in aqueous acetonitrile and easily purified by reversed-phase high-pressure liquid chromatography (HPLC). To the amino terminal of the purified peptide, the benzyloxycarbonyl (Z) group was introduced using *N*-(benzyloxycarbonyloxy)succinimide (Z-ONSu) in the presence of 4-methylmorpholine (NMM) as a base to give partially protected BPTI(1—13) **1** in a yield of about 30% based on crude peptide **7**. Confirmations of the protected peptides were carried out by a combination of amino acid analysis and fast atom bombardment (FAB) mass spectrometry.

Since BPTI(14—36) contains no side-chain carboxyl group, the protected BPTI (14—36) **2** was prepared by a solid-phase method involving N^{α}-(*t*-butoxycarbonyl) amino acids (Boc-amino acid). To the Boc-glycyl resin, which was prepared by Gisin's method,[9] Boc-amino acids were successively introduced by the standard Merrifield method,[1] in which the completion of each coupling reaction was checked by a Kaiser test.[10] After completion of the chain elongation, the terminal amino group was blocked by an acid-stable 2,2,2-trichloroethoxycarbonyl (Troc) group[6,11-13] to realize the selective protection of α- and ω-amino groups (Fig. 3). Treatment of the protected peptide resin with anhydrous hydrogen fluoride gave Troc-peptide **8**, which was converted to peptide **9** by a treatment with Z-ONSu in the presence of NMM. Treatment of peptide **9** with zinc dust in aqueous acetic acid gave peptide **10**, which was purified on HPLC. To the generated α-amino group of peptide **10**, a Boc group was introduced by a treatment with *N*-(*t*-butoxycarbonyloxy)succinimide (Boc-ONSu) in the presence of NMM to obtain partially protected BPTI (14—36) **2**. The yield of peptide **2** was as low as 3%, based on crude peptide **8**. Peptides **9**, **10**, and **2** tended to form gels in aqueous acetonitrile. This seemed to be responsible for the low recovery yield of the peptide after purification on HPLC.

Partially protected BPTI (37—58) **3** was prepared using the same strategy adopted for the synthesis of protected peptide **2** (Fig. 4). The yield of peptide **3** was about 30%, based on crude peptide **11**.

Segment Coupling of Partially Protected Peptides. Protected BPTI (1—58) **5** was prepared according to the scheme shown in Fig. 5. Peptide **2** was converted to the corresponding active ester in the presence of sevenfold molar excess of *N*-hydroxysuccinimide (HONSu) with a fivefold molar excess of 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide hydrochloride (WSCI·HCl). The ester-formation reaction was monitored by HPLC and FAB mass measurements. The ester was precipitated with the aid of ether, then washed successively with ethyl acetate, dioxane, and water and dried. The obtained powder was dissolved in dimethyl sulfoxide (DMSO) and peptide **3** and NMM were added. The resulting solution was stirred overnight at room temperature. The product, isolated by HPLC, was

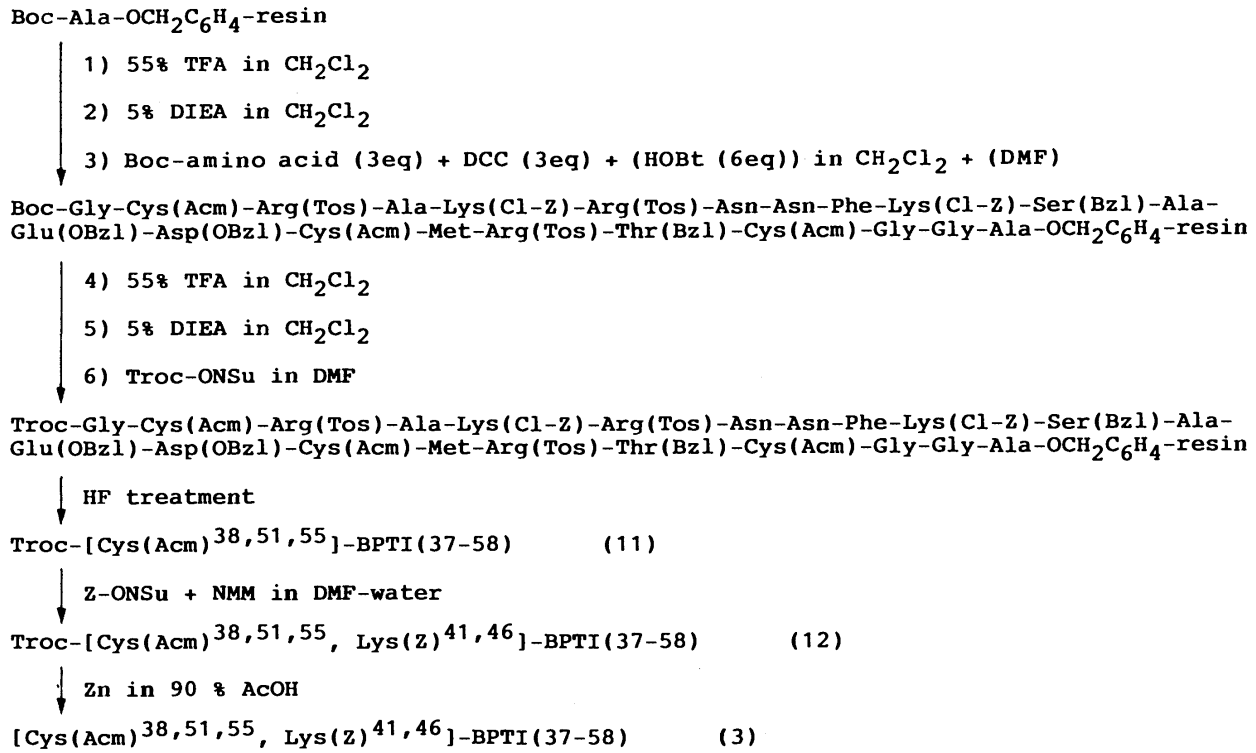

Fig. 4. Synthetic scheme of partially protected BPTI(37—58) **3**.

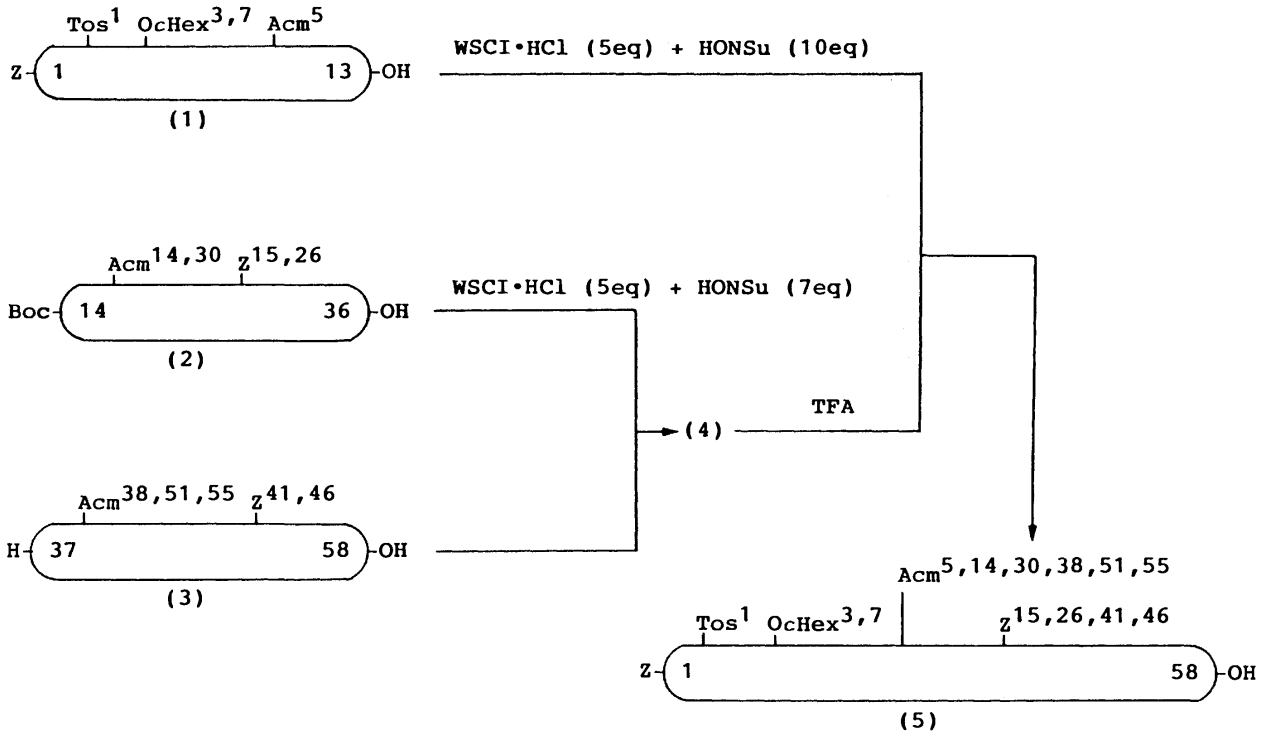

Fig. 5. Synthetic route leading to protected BPTI(1—58) **5** by segment coupling.

confirmed by amino acid analysis to be the desired product **4**, in a yield of about 50%. The active ester of peptide **1**, which was prepared as described above, and the amino-component peptide, which was obtained by TFA treatment of peptide **4**, were mixed in a 2 to 1 molar ratio in DMSO containing 5% NMM, and stirred overnight. Judging from the HPLC profile of the reaction mixture, the amino component reacted almost completely with the active ester to give a product. The amino acid analysis data of the product agreed with the theoretical values expected of protected BPTI (1—58) **5**. Though the segment coupling proceeded almost completely, the yield of the purified peptide **5** was about 30%. The low recovery yield seems to be due to the adsorption of the product on a reversed-phase column during the isolation process.

Generation of the Native Form of BPTI from Peptide 5 and Its Characterization. Protected BPTI (1—58) **5** was treated successively with anhydrous hydrogen fluoride, $Hg(AcO)_2$, and dithiothreitol (DTT) according to the procedure shown in Fig. 6. The reduced form of synthetic BPTI was oxidized in the presence of 1,2-dithiane-4,5-diol (the oxidized form of DTT) according to the method described by Creighton.[14] The native form of synthetic BPTI, thus generated, was adsorbed on TSK gel CM-5PW and eluted with a $AcONH_4$ (pH 8.6) linear gradient (0.01—1 M† $AcONH_4$), as shown in Fig. 7. The main product was eluted at the same position as that of native BPTI. The amino acid analysis data of the product agreed

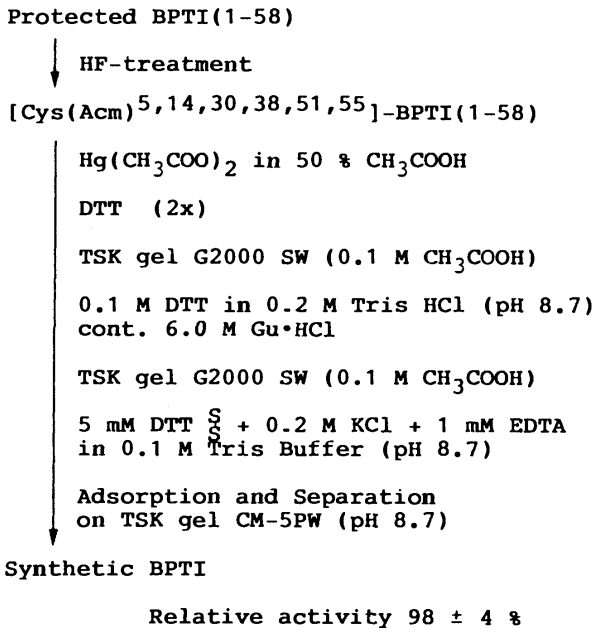

Fig. 6. Operation procedure leading to the native form of synthetic BPTI from protected BPTI(1—58) **5**. DTT^{S}_{S} indicates the oxidized form of DTT.

well with that of native BPTI (Table 1). Furthermore, the product had practically the same inhibitory activity (98±4%) against trypsin as native BPTI. These data show that highly pure BPTI was successfully synthesized.

Evaluation of the Newly Developed Method. Each of the protected peptide segments **1**, **2**, and **3** could be

†1 M=1 mol dm^{-3}.

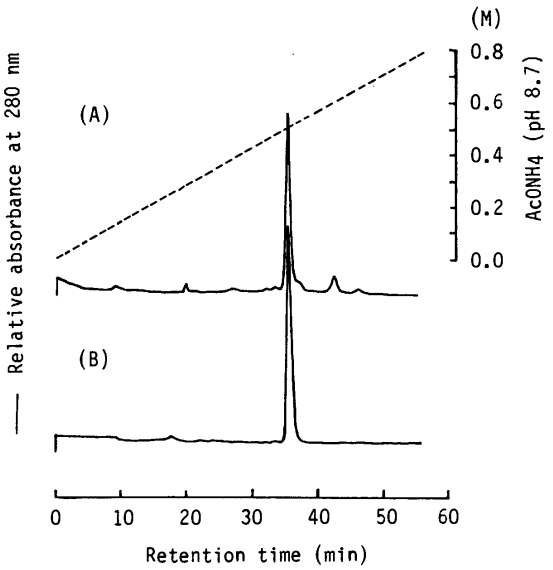

Fig. 7. Ion-exchange chromatogram of synthetic BPTI on TSK gel CM-5PW. (A) The elution profile of crude synthetic BPTI obtained by oxidation with DTT^{S}_{S}. (B) The elution profile of native BPTI. Broken line indicates the concentration of $AcONH_4$ in the buffer.

Table 1. Amino Acid Composition of Synthetic BPTI

	Synthetic BPTI	Native BPTI	Expected
Asp	5.33	5.18	5
Thr	2.98	2.94	3
Ser	1.19	1.03	1
Glu	3.29	3.22	3
Pro	4.02	4.08	4
Gly	6.16	6.14	6
Ala	6	6	6
1/2·Cys	5.11	5.26	6
Val	1.10	1.07	1
Met	0.94	0.96	1
Ile	1.24	1.28	2
Leu	2.07	2.07	2
Tyr	3.96	4.06	4
Phe	4.00	4.06	4
Lys	3.82	3.99	4
Arg	5.84	5.88	6

easily prepared within 2 to 3 weeks starting from the corresponding amino-acyl resins, and the total synthesis of BPTI was accomplished within 2 months. Therefore, the newly developed method enabled a very rapid polypeptide synthesis, which has a very important practical advantage. The minimum-protection strategy worked well on segment coupling. When NMM was used as a base, undesirable side reactions, such as acylation of alcoholic or phenolic hydroxyl groups, were not observed during segment coupling. Furthermore, the elution profile of the native form of BPTI (Fig. 7) revealed that a main product was eluted at the same retention time as native BPTI, and that the peak width of the main product was the same as that of the native one. These facts suggest that all the procedures involved in the synthesis of BPTI proceeded almost perfectly to give highly pure protected BPTI (1—58). Consequently, the pure final product, the native form of synthetic BPTI, could be obtained without employing affinity chromatography. One problem which did arise was the low recovery yield of peptide after HPLC purification. Other than this, we found our method to be useful for the preparation of pure polypeptides of this size.

Materials and Methods

All the amino acids used were of the L-configuration, except for glycine. Boc-amino acids and Bz-Arg-*p*NA·HCl were purchased from Peptide Institute Inc. (Minoh, Japan). Npys-amino acids except for Npys-Glu(O*c*Hex) and Npys-Asp(O*c*Hex), Npys-Cl, Fmoc-Cys(Acm), and *p*-alkoxybenzyl alcohol resin were purchased from Kokusan chemical Works, Ltd. (Tokyo, Japan). Trypsin (bovine pancreas) and bovine pancreatic trypsin inhibitor were purchased from Sigma Chemical Co. Troc-Cl and *trans*-1,2-dithiane-4,5-diol were purchased from Aldrich Chem. Co. *p*-Guanidinobenzoic acid *p*-nitrophenyl ester was purchased from Nacalai Tesque, Ltd. (Kyoto, Japan). All solvents used were of guaranteed grade. High-performance liquid chromatography (HPLC) was carried out on a handmade column of the YMC-Gel ODS S5 100 Å A-type (8×300 mm) (Yamamura Chemical Laboratory Co., Ltd., Kyoto, Japan). Amino acid analysis was carried out using a Jasco amino acid analysis system after acid hydrolysis of a peptide with 4 M methanesulfonic acid (Pierce Chemical Co.) at 110 °C for 24 h. Mass measurement was carried out using a Jeol double-focusing mass spectrometer JMS-HX100, equipped with a fast atom bombardment ion source. Sonication was carried out using a Branson Model B-220. The melting points were determined by the capillary method and are given as uncorrected values. Optical rotations were determined with a Perkin-Elmer Model 241 polarimeter. Abbreviations used are those recommended by IUPAC-IUB: *J. Biol. Chem.*, **247**, 977 (1972). Additional abbreviations: Acm, acetamidomethyl; Cl-Z, 2-chlorobenzyloxycarbonyl; Bzl, benzyl; Br-Z, 2-bromobenzyloxycarbonyl; O*c*Hex, cyclohexyl ester; DCHA, dicyclohexylamine.

Synthesis

Troc-ONSu. Troc-Cl (2.12 g, 10 mmol) and HONSu (1.27 g, 11 mmol) were mixed in dioxane (20 ml) in the presence of triethylamine (TEA) (1.82 ml, 13 mmol) at room temperature for 2 h. The solution was dried, and the product was dissolved in ethyl acetate, washed successively with diluted hydrochloric acid and water, and crystallized from a mixture of ethyl acetate and hexane to obtain Troc-ONSu (2.21 g, 76.0%), mp 105.5—106.0 °C. Found: C, 29.00; H, 2.00; N, 4.79; Cl, 36.48%. Calcd for $C_7H_6O_5NCl_3$: C, 28.94; H, 2.08; N, 4.82; Cl, 36.62%.

Npys-Glu(O*c*Hex)·DCHA. This compound was prepared from Npys-Cl and Glu(O*c*Hex) in the presence of TEA according to a method of Matsueda and Walter.[15] Npys-Glu(O*c*Hex)·DCHA; mp 150—151 °C, $[\alpha]_D^{23}$ +42.7° (*c* 1, ethanol). Found: C, 59.32; H, 7.92; N, 9.94%. Calcd for $C_{28}H_{44}O_6N_4S$: C, 59.55; H, 7.85; N, 9.92%.

Npys-Asp(OcHex)·DCHA. This compound was prepared from Npys-Cl and Asp(OcHex) in the presence of TEA according to a method of Matsueda and Walter.[14] Npys-Asp(OcHex)·DCHA; mp 157—158 °C, $[\alpha]_D^{23}$ +18.9° (*c* 1, ethanol). Found: C, 58.62; H, 7.77; N, 10.13%. Calcd for $C_{27}H_{42}O_6N_4S$: C, 58.87; H, 7.69; N, 10.18%.

Npys-Pro-OCH$_2$C$_6$H$_4$-O-CH$_2$C$_6$H$_4$-Resin (6). Npys-Pro (3.61 g, 13.4 mmol) was coupled to *p*-alkoxybenzyl alcohol resin (5 g, 0.67 meq OH/g) in the presence of 4-dimethylaminopyridine (DMAP) (1.64 g, 13.4 mmol) and dicyclohexylcarbodiimide (DCC) (2.76 g, 13.4 mmol) in *N*,*N*-dimethylformamide (DMF) (30 ml) at room temperature for 14 h. The resin, thus obtained, was treated twice with acetic anhydride (4 ml) in pyridine (20 ml) at room temperature for 30 min and gave 6.3 g of resin **6**. The proline content in the resin was determined to be 0.58 mmol g^{-1} by measuring the absorbance of the solution at 338 nm (ε=6330) after treatment of the resin with a dichloromethane solution containing 0.1 M triphenylphosphine in the presence of 0.1 M pyridine hydrochloride.[7]

Arg(Tos)-Pro-Asp(OcHex)-Phe-Cys(Acm)-Leu-Glu(OcHex)-Pro-Pro-Tyr-Thr-Gly-Pro (7). Npys-Pro resin (**6**) (0.86 g, 0.5 mmol) was placed in a reaction vessel, and the synthesis was carried out manually according to the following protocol by using Npys derivatives of Gly, Thr(Bu^t), Tyr(Bu^t), Pro, Glu(OcHex), Leu, Phe, and Asp(OcHex): (1) washing, CH_2Cl_2 (3×1 min); (2) deprotection, 0.1 M triphenylphosphine and 0.1 M pyridine hydrochloride/CH_2Cl_2 (1×1 min, 2×30 min); (3) washing, CH_2Cl_2 (3×1 min); (4) washing, 2-propanol (2×1 min); (5) washing, CH_2Cl_2 (3×1 min); (6) neutralization, 10% DIEA/CH_2Cl_2 (v/v) (3×1.5 min); (7) washing, CH_2Cl_2 (3×1.5 min) (8) coupling, Npys-amino acid (1.5 mmol) and 1-hydroxybenzotriazole (HOBt) (3 mmol)/DMF(5 ml) and DCC (1.5 mmol)/CH_2Cl_2 (5 ml) (1×1 h); (9) washing, DMF (3×1 min); (10) washing, CH_2Cl_2 (3×1 min); (11) washing, 2-propanol (3×1 min). Cys(Acm) was introduced to the peptide by using an Fmoc derivative under the coupling conditions used for Npys-amino acid; then, a peptide resin was washed successively with DMF, 2-propanol, and CH_2Cl_2. After that, the resin was treated as follows: (1) washing, CH_2Cl_2 (2×1 min); (2) washing, DMF (2×1 min); (3) deprotection, 20% piperidine/DMF (v/v) (1×1 min, 1×20 min); (4) washing, DMF (3×1 min); (5) washing, CH_2Cl_2 (3×1.5 min). The resin was coupled with Npys-Phe. Arg(Tos) was introduced by using its Boc derivative, and washed with DMF, CH_2Cl_2, and 2-propanol. The weight of the peptide resin, thus obtained, was 1.59 g. The whole resin was treated with 25 ml of 25% TFA/CH_2Cl_2 (v/v) for 30 min at room temperature. The resin was removed by filtration, and the filtrate was concentrated to dryness under reduced pressure, leaving a powder (720 mg). This crude product was purified on HPLC with the acetonitrile concentration increasing from 30% to 80% in 0.05% aq TFA at a flow rate of 2 ml min^{-1} and, gave 217.7 mg of compound **7**. Amino acid analysis: $Asp_{0.97}Thr_{1.01}Glu_{0.89}$ $Gly_{1.00}$ 1/2$Cys_{0.14}$ $Leu_{0.92}$ $Tyr_{0.93}Phe_{0.97}Arg_{0.27}Pro_{3.98}$. Found: *m*/*z* 1881.0 $(M+H)^+$ Calcd for $C_{90}H_{130}N_{17}O_{23}S_2$: 1881.0.

Z-[Arg(Tos)^1, Asp(OcHex)^3, Cys(Acm)^5, Glu(OcHex)^7]-BPTI(1—13) (1). Peptide **7** (23.4 mg, 12.4 μmol) and Z-ONSu (8 mg, 32.2 μmol) were dissolved in DMF (1 ml) containing NMM (10 μl), and the solution was stirred for 2 h. A product was precipitated by the addition of ether to the solution, and washed successively with ethyl acetate and dioxane. The product was further purified on HPLC under the same conditions as compound **7** and gave 14.0 mg of compound **1**. Amino acid analysis: $Asp_{0.98}Thr_{0.95}Glu_{0.97}Pro_{3.77}$ $Gly_{1.00}$ 1/2$Cys_{0.29}Leu_{0.99}Tyr_{1.00}Phe_{0.98}Arg_{0.36}$. Found: *m*/*z* 2014.9 $(M+H)^+$. Calcd for $C_{98}H_{136}N_{17}O_{25}S_2$: 2015.1.

Troc-Cys(Acm)-Lys-Ala-Arg-Ile-Ile-Arg-Tyr-Phe-Tyr-Asn-Ala-Lys-Ala-Gly-Leu-Cys(Acm)-Gln-Thr-Phe-Val-Tyr-Gly (Troc-[Cys(Acm)^{14,30}]-BPTI(14—36)) (8). Boc-Gly-OCH$_2$C$_6$H$_4$-resin (Gly 0.66 mmol g^{-1}, 2 g) was placed in a reaction vessel, and the synthesis was carried out manually using the Boc derivatives of Tyr(Br-Z), Val, Phe, Thr(Bzl), Gln, Cys(Acm), Leu, Gly, Ala, Lys(Cl-Z), Asn, Arg(Tos), and Ile. The schedule was as follows: (1) washing, CH_2Cl_2 (2×1 min); (2) deprotection, 55% TFA/CH_2Cl_2 (1×5 min, 1×15 min); (3) washing, CH_2Cl_2 (2×1 min); (4) washing, 33% dioxane/CH_2Cl_2 (1×2 min); (5) washing, CH_2Cl_2 (1×1 min); (6) washing, 33% dioxane (2×1 min); (7) washing, CH_2Cl_2 (3×1 min); (8) neutralization, 5% DIEA/CH_2Cl_2 (2×5 min); (9) washing, CH_2Cl_2 (3×1 min); (10) coupling, 3 equiv of Boc-amino acid/CH_2Cl_2 and 3 equiv of DCC/CH_2Cl_2 (1×120 min) except for Boc derivatives of Gln, Asn and Arg(Tos). For the coupling of Boc-Gln, Boc-Asn, or Boc-Arg(Tos), 3 equiv of Boc-amino acid and 6 equiv of HOBt/DMF, and 3 equiv of DCC/CH_2Cl_2 (1×120 min); (11) washing, CH_2Cl_2 (1×1 min); (12) washing, 2-propanol (1×2 min); (13) washing, CH_2Cl_2 (1×1 min); (14) washing, 2-propanol (1×2 min); (15) washing, CH_2Cl_2 (1×1 min); (16) Kaiser test.[10] When an unreacted amino group was detected at step 16, steps 9 to 16 were repeated. The terminal Troc group was introduced by adding 3 equiv of Troc-ONSu/DMF (2×150 min) after step 9. The weight of the protected-peptide resin, thus obtained, was 5.46 g. An aliquot of the resin (754 mg) was treated with anhydrous HF containing 10% anisole (v/v) at 0 °C for 70 min to give 374 mg of crude product **8** after lyophilization. This crude peptide was used for the preparation of compound **9** without further purification. An aliquot of the product was purified on HPLC, giving peptide **8**, which was confirmed as follows. Found: *m*/*z* 3002.0 $(M+H)^+$. Calcd for $C_{133}H_{201}N_{35}O_{34}S_2Cl_3$: 3001.6. Amino acid analysis: $Asp_{0.93}Thr_{0.90}Glu_{0.97}Gly_{1.89}Ala_{3.00}$1/2$Cys_{0.00}Val_{0.85}Ile_{0.89}$ $Leu_{0.91}Tyr_{2.74}Phe_{1.84}Lys_{1.86}$ $Arg_{1.78}$.

Troc-[Cys(Acm)^{14,30}, Lys(Z)^{15,26}]-BPTI(14—36) (9). Crude compound **8** (255 mg, ca. 85 μmol) was dissolved in DMSO (4 ml) containing NMM (0.4 ml). Z-ONSu (106 mg, 425 μmol) was added to the solution which was allowed to react for 3 h with stirring. Ether was added to the solution to precipitate a peptide, and the precipitate was washed with ethyl acetate and then dioxane. The product was purified on HPLC with the acetonitrile concentration increasing from 20% to 80% in 0.05% aq TFA at a flow rate of 2 ml min^{-1} and gave 43 mg of compound **9**. Found: *m*/*z* 3270.2 $(M+H)^+$. Calcd for $C_{149}H_{213}N_{35}O_{38}S_2Cl_3$: 3269.7. Amino acid analysis: $Asp_{0.98}$ $Thr_{0.96}Glu_{1.01}Gly_{1.92}Ala_{3.00}$1/2$Cys_{0.00}Val_{0.89}Ile_{0.87}Leu_{0.97}$ $Tyr_{2.73}Phe_{1.93}Lys_{1.89}Arg_{1.82}$.

[Cys(Acm)^{14,30}, Lys(Z)^{15,26}]-BPTI(14—36) (10). Compound **9** (40 mg) was dissolved in 80% aq acetic acid (6 ml) and zinc dust (100 mg) was added under mild sonication over 4 h at room temperature. The remaining zinc dust was removed by centrifugation. Water was added to the supernatant and the precipitate which formed was washed with water and dried, leaving a powder (35 mg). This powder was purified by HPLC under the conditions used for compound **9** to obtain compound **10** (24 mg); Found: *m*/*z* 3096.1 $(M+H)^+$. Calcd

for $C_{146}H_{212}N_{35}O_{36}S_2$: 3095.7. Amino acid analysis: $Asp_{0.98}Thr_{0.97}Glu_{0.98}Gly_{1.98}Ala_{3.00}l/2Cys_{0.81}Val_{0.84}Ile_{0.77}Leu_{0.97}Tyr_{2.76}Phe_{1.90}Lys_{1.86}Arg_{1.80}$.

Boc-[Cys(Acm)^{14,30}, Lys(Z)^{15,26}]-BPTI(14—36) (2). Compound **10** (21.7 mg) was dissolved in DMSO (0.5 ml) containing NMM (10 μl), and Boc-ONSu (20 mg) was added to the solution which was then stirred for 3 h at room temperature. Ethyl acetate was added to the solution to form a precipitate, which when washed with dioxane and freeze-dried gave a powder (19.0 mg). This was purified by HPLC under the conditions used for compound **7** and 8.2 mg of compound **2** was obtained. Found: m/z 3196.0 $(M+H)^+$. Calcd for $C_{151}H_{220}N_{35}O_{38}S_2$: 3195.8. Amino acid analysis: $Asp_{0.98}Thr_{0.95}Glu_{0.96}Gly_{1.97}Ala_{3.00}l/2Cys_{0.60}Val_{0.86}Ile_{0.80}Leu_{0.96}Tyr_{2.73}Phe_{1.90}Lys_{1.87}Arg_{1.83}$.

Troc-Gly-Cys(Acm)-Arg-Ala-Lys-Arg-Asn-Asn-Phe-Lys-Ser-Ala-Glu-Asp-Cys(Acm)-Met-Arg-Thr-Cys(Acm)-Gly-Gly-Ala (Troc-[Cys(Acm)^{38,51,55}]-BPTI(37—58)) (11). Boc-Ala-$OCH_2C_6H_4$-resin (Ala 0.53 mmol g^{-1}, 4.2 g) was placed in a reaction vessel, and peptide-chain elongation and introduction of a Troc group were carried out according to the schedule used for compound **8**, using Boc derivatives of Gly, Cys(Acm), Thr(Bzl), Arg(Tos), Met, Asp(OBzl), Glu(OBzl), Ser(Bzl), Lys(Cl-Z), Phe, and Asn. The weight of the protected peptide resin was 10.4 g. This resin (4.0 g) was treated with anhydrous HF (40 ml) containing anisole (4 ml) at 0 °C for 70 min and gave 1.16 g of crude peptide **11**, which was purified by HPLC with the acetonitrile concentration increasing from 10 to 45% in 0.05% aq TFA at a flow rate of 2 ml min^{-1}. Freeze-drying of the main fraction gave 414 mg of compound **11**. Found: m/z 2761.6 $(M+H)^+$. Calcd for $C_{104}H_{172}N_{38}O_{36}S_4Cl_3$: 2762.3. Amino acid analysis: $Asp_{2.95}Thr_{0.70}Ser_{0.92}Glu_{0.96}Gly_{2.82}Ala_{3.00}l/2Cys_{0.47}Met_{0.93}Phe_{0.94}Lys_{1.95}Arg_{2.95}$.

Troc-[Cys(Acm)^{38,51,55}, Lys(Z)^{41,46}]-BPTI(37—58) (12). Compound **11** (400 mg, 145 μmol) was dissolved in a mixture of DMF (5 ml) and water (2.5 ml). Z-ONSu (361 mg, 1.45 mmol) and NMM (500 μl) were then added, and the solution was stirred for 2 h at room temperature. Methanol (10 ml) was added to the solution to form a precipitate, which was washed with methanol (4×) and then with water (1×); it was then dried to give compound **12** (318 mg). Found: m/z 3031.0 $(M+H)^+$. Calcd for $C_{120}H_{184}N_{38}O_{40}S_4Cl_3$: 3030.4. Amino acid analysis: $Asp_{3.02}Thr_{0.74}Ser_{0.95}Glu_{1.00}Gly_{2.82}Ala_{3.00}l/2Cys_{0.24}Met_{0.94}Phe_{0.98}Lys_{1.92}Arg_{2.92}$.

[Cys(Acm)^{38,51,55}, Lys(Z)^{41,46}]-BPTI(37—58) (3). Compound **12** (318 mg, 105 μmol) was dissolved in 90% aq acetic acid (12 ml). Zinc dust (300 mg) was added with mild sonication under a nitrogen atmosphere over 3 h at room temperature. A product was isolated by HPLC with the acetonitrile concentration increasing from 25 to 50% in 0.05% aq TFA at a flow rate of 2 ml min^{-1}; 212 mg of compound **3** was obtained. Found: m/z 2856.6 $(M+H)^+$. Calcd for $C_{117}H_{138}N_{38}O_{38}S_4$: 2856.5. Amino acid analysis: $Asp_{3.04}Thr_{0.74}Ser_{0.95}Glu_{0.96}Gly_{3.07}Ala_{3.00}l/2Cys_{0.15}Met_{0.96}Phe_{0.97}Lys_{1.95}Arg_{2.99}$.

Z-[Cys(Acm)^{14,30,38,51,55}, Lys(Z)^{15,26,41,46}]-BPTI(14—58) (4). Compound **2** (7.4 mg, ca 2.2 μmol) was dissolved in DMSO (200 μl). HONSu (1.7 mg, 15 μmol) and WSCI·HCl (1.9 mg, 10 μmol) were added and the solution was stirred for 2 h at room temperature. Ether was added to the solution to form a precipitate, which was washed successively with ethyl acetate (1×), dioxane (1×), and water (2×) and dried. The obtained powder and compound **3** (12 mg, ca. 4.2 μmol) were dissolved in DMSO (100 μl) containing NMM (10 μl), and stirred overnight at room temperature. A product was isolated by HPLC with the acetonitrile concentration rising from 20 to 80% in 0.05% aq TFA to give 6.0 mg of compound **4**. Amino acid analysis of compound **4**: $Asp_{3.92}Thr_{1.61}Ser_{0.92}Glu_{1.98}Gly_{4.99}Ala_{6.00}l/2Cys_{0.57}Val_{0.83}Met_{0.83}Ile_{0.73}Leu_{0.98}Tyr_{2.42}Phe_{2.69}Lys_{3.70}Arg_{4.53}$.

Z-[Arg(Tos)^1, Asp(O*c*Hex)^3, Glu(O*c*Hex)^7, Cys(Acm)^{5,14,30,38,51,55}, Lys(Z)^{15,26,41,46}]-BPTI(1—58) (5). Compound **1** (4.35 mg, ca. 2.2 μmol), WSCI·HCl (0.42 mg, 2.2 μmol) and HONSu (1.1 mg, 10 μmol) were dissolved in DMSO (50 μl), and allowed to react for 3 h at room temperature. Ether was added to the solution and a precipitate of an active ester of compound **1** was formed. Compound **4** (6.0 mg, ca. 1 μmol) was treated with TFA (200 μl) at room temperature for 30 min. Freeze-drying of the solution in a test tube gave a solid mass. To the test tube, the active ester dissolved in DMSO (100 μl) and NMM (5 μl) were added. The resulting solution was stirred overnight at room temperature. A product was isolated from the reaction mixture by HPLC under the conditions used for compound **4** and 2.35 mg of compound **5** was obtained. Amino acid analysis: $Asp_{5.56}Thr_{3.35}Ser_{0.90}Glu_{3.67}Pro_{4.40}Gly_{6.51}Ala_{6.00}l/2Cys_{0.00}Val_{0.83}Met_{0.88}Ile_{0.77}Leu_{2.69}Tyr_{4.28}Phe_{4.50}Lys_{3.63}Arg_{5.36}$.

Generation of the Native Form of a Synthetic BPTI. Compound **5** (1.70 mg, 0.21 μmol) was treated with anhydrous HF (1 ml) containing anisole (0.1 ml) for 70 min at 0 °C. After evaporation of HF and anisole, the peptide was dissolved in 50% aq acetic acid (200 μl), and treated with $Hg(CH_3COO)_2$ (3 mg, 10 μmol) for 3 h at room temperature. DTT (5 mg, 32 μmol) in water (200 μl) was added and the precipitate that formed was removed by centrifugation after 30 min. To the supernatant, DTT (5 mg) was added. The solution was left for 2 h at room temperature, and then peptide was isolated by gel filtration on TSK-gel G2000 SW (7.5×600 mm), using 0.1 M aq acetic acid as a buffer. Fractions containing peptide were freeze-dried to obtain a powder, which was treated with DTT (2 mg, 13 μmol) in 0.2 M Tris·HCl (pH 8.7, 200 μl) containing 6.0 M guanidine hydrochloride under a nitrogen atmosphere for 5 h at room temperature. The solution was acidified by acetic acid, and the peptide was isolated by passing through TSK-gel G2000 SW (0.1 M acetic acid). Peptide-containing fractions were collected, and the peptide was oxidized in a buffer (13.44 ml) containing 0.2 M KCl, 1 mM EDTA, and 5 mM of the oxidized form of DTT after adjusting the pH of the buffer to 8.7 with solid tris(hydroxylmethyl)aminomethane at room temperature for 2 h. The solution was diluted to 150 ml with water. At each time, 50 ml of the solution was adsorbed on TSK-gel CM-5PW (7.5×75 mm) and eluted with a buffer (pH 8.7), increasing the ammonium acetate concentration from 0.01 M to 1 M over 70 min at a flow rate of 1 ml min^{-1}. This procedure was repeated three times. The total amount of the peptide in the main fractions was determined to be 27.6 nmol (13.1%) by amino acid analysis.

As a control experiment, native BPTI (76.9 nmol) was reduced and oxidized under the same conditions. The regenerated BPTI was isolated under the same procedure to obtain the native form of BPTI (11 nmol, 14%).

Inhibitory Activity of Synthetic BPTI. Active trypsin concentration was determined according to Chase and Shaw.[16] The trypsin inhibitor concentration was deter-

mined by amino acid analysis after acid hydrolysis of BPTI by 4 M methanesulfonic acid at 110 °C for 24 h. The remaining tryptic activity was measured according to Kassell by employing N^{α}-benzoyl-L-arginine *p*-nitroanilide (BAPNA).[17] Trypsin (1.69×10^{-5} M, 100 μl) and an appropriate amount of synthetic or native BPTI were added into 3 ml of 0.1 M tris buffer (pH 7.8) containing 0.02 M $CaCl_2$. The resultant solution was incubated for 3 min at 25 °C and then 100 μl of BAPNA solution (10 mg ml^{-1} of DMF) was added. The Δ OD_{405} per min was measured with a Hitachi 124 spectrophotometer. The activity of synthetic BPTI was measured at four different concentrations of synthetic BPTI. The specific activity of synthetic BPTI toward the native one was calculated to be 98±4%.

The authors wish to express their thanks to Professor Yasutsugu Shimonishi and Dr. Toshifumi Takao of the Institute for Protein Research, Osaka University for allowing use of the facilities for mass spectra measurement.

(Received August 9, 1988)

The structures of 1 : 1 complexes (**3b**, **4b**, and **5b**) of 1.4,7,10,13-pentaoxa-, 1,13-dioxa-4,7,10-trithia[13]- and 1,4,7,10,13,16-hexaoxa[16](1,1′)ruthenocenophanes (**3a**, **4a**, and **5a**) with $HgCl_2$, and **3a** have been determined by the single-crystal X-ray diffraction method. The complexing forms of the three complexes are quite similar to each other. Crystal data: **3b**, triclinic, space group $P\bar{1}$, a=12.043(3), b=10.759(2), c=8.529(2) Å, α=98.76(2), β=101.22(2), γ=77.03(2)°, U=1049.5 Å^3, Z=2, D_c=2.19 g cm^{-3}, μ(Mo $K\alpha$)=84 cm^{-1}. **4b**, triclinic, space group $P\bar{1}$ a=17.100(3), b=8.986(1), c=8.618(2) Å, α=105.17(1), β=62.24(1), γ=100.54(1)°, U=1128.1 Å^3, Z=2, D_c=2.18 g cm^{-3}, μ(Mo $K\alpha$)=81 cm^{-1}. **5b**, monoclinic, a space group $P2_1/a$, a=26.881(7), b=10.344(3), c=8.414(2), β=96.97(2)°, U=2322.2 Å^3, Z=4, D_c=2.11 g cm^{-3}, μ(Mo $K\alpha$)=76 cm^{-1}. **3a**, triclinic, space group $P\bar{1}$, a=11.107(1), b=8.816(1), c=9.788(1) Å, α=70.48(1), β=99.76(1), γ=101.31(1)°, U=877.6(2) Å^3, Z=2, D_c=1.59 g cm^{-3}, μ(Mo $K\alpha$)=9 cm^{-1}. Only the Ru atom of the ruthenocene nucleus of these complexes was coordinated to $HgCl_2$ with a slightly distorted trigonal-planar configuration. The distances between the Ru and the Hg atoms are 2.683(3), 2.704(1), and 2.696(2) Å, respectively.

Many research groups have recently attempted to investigate modified crown ethers in order to develop a new functionality for them.[1] For example, the syntheses of many kinds of macrocyclic compounds containing aza, thia, phosphorus, arsenic, and/or other coordinatable atoms have been reported. In this connection, several research groups have reported new-type crown ethers, thiacrown ethers, and oxathiacrown ethers which contain a ferrocene unit as an integral part of a ring member.[2] However, the complexes of crown ethers,[3] thiacrown ethers[4] and azacrown ethers[5] with $HgCl_2$ are rare, although a number of the complexes of crown ethers including ferrocenocrown ethers have already been reported.[2] In connection with this viewpoint, we have studied the preparation and structures of the complexes of metallocenocrown ethers with an interest in the electron-transfer interaction between the complexed cation and the metal atom of the metallocene nucleus.[6] In a previous paper,[7] we reported on the molecular structure of a 1 : 1 complex (**1b**) of 4,7,10,13-tetraoxa-1,16-dithia[16](1,1′)ruthenocenophane (**1a**) with $HgCl_2$, in which the linear Cl–Hg–Cl moiety was found to be held perpendicularly in the central cavity of the macrocyclic moiety. The distance between the Ru atom and the Hg atom is longer than 3.6 Å, which is too long for a direct Ru–Hg interaction. We have also previously reported[8] on the complexes (**2b**—**4b**) of polyoxa- and 1,n-dioxathia[n]ruthenocenophanes (**2a**—**4a**) with $HgCl_2$ (or $AgNO_3$) (**2**—**4**) and the presence of a strong electron-transfer interaction between the Ru atom and the Hg atom in **3a** and **4a** from the ^{1}H NMR and UV spectral data. The Ru–Hg interaction may be explained by two possible complexing manners: i) the Hg atom incorporated into the crown ether moiety interacts with the Ru atom; ii) the Hg atom is directly coordinated to the Ru atom from the opposite side of the macrocyclic ring. The result is very different from that of the 1:1 silver complex **2b** in which the Ag atom incorporated in the crown ether cavity of the host molecule does not interact with the Ru atom of the ruthenocene. In this paper,[9] we report on the molecular structures of **3b**, **4b** and the 1 : 1 complex **5b** of 1,4,7,10,13,16-hexaoxa[16](1,1′)ruthenocenophane (**5a**) in order to clarify the nature of the Ru–Hg interaction. An X-ray analysis of ruthenocenophane (**3a**) was also carried out in order to compare the structural change of the organic moiety by complexing.

Complexes **3b**, **4b**, and **5b** were prepared by the same method as mentioned in a previous paper.[8]

The molecular structures of **3a** and its $HgCl_2$ complex **3b** are illustrated in Fig. 1. Also, the molecular structures of **4b** and **5b** are also illustrated in Fig. 2. The final atomic parameters for **3b**, **4b**, **5b**, and **3a** are listed in Tables 1—4, and the bond lengths as well as the bond and torsion angles are given in Tables 5—8 for **3b**, **4b**, **5b**, and **3a**, respectively. In the complexes (**3b**—**5b**) the Hg atom is coordinated directly to the Ru atom of the ruthenocene nucleus from the opposite side of the crown ether moiety, with a slightly distorted trigonal-planar configuration. The Ru–Hg interatomic distances in **3b**, **4b**, and **5b** are 2.683(3), 2.704(1), and 2.696(2) Å, respectively, which essentially equal the sum (2.68 Å) of the covalent radii of Ru and Hg atoms.[10] The results differ completely from that of **1b** in which the Hg atom incorporated in the central cavity of the macrocyclic moiety forms a distorted hexagonal-bipyramidal geometry with the two chlo-

rine atoms coordinated axially and the Cl-Hg-Cl skelton is almost linear with an angle of 172.7(2)°.[7] The complexing manner is very similar to that of the 1 : 1 complex[3] of dibenzo-18-crown-6 with $HgCl_2$.

In the ^1H NMR spectra of the ruthenocenophanes (**3a** and **4a**), the chemical shift differences between α- and β-protons of the Cp rings are only 0.41 and 0.38 ppm, respectively.[8] The results suggest that the two Cp rings are nearly parallel[11] to each other. Furthermore, CPK model inspections suggest that cavity sizes of **3a** and **4a** are sufficient to encapsule the Hg atom. Also, if the Hg atom is incorporated into the crown ether part of **3b** and **4b**, the Hg atom has to take a distorted pentagonal-bipyramidal geometry with two Cl atoms coordinated axially. However, interestingly, the Hg atom in **3b** and **4b** is directly bonded to the Ru atom of the ruthenocene nucleus from the opposite side of the crown ether moiety. The result suggests that, in the complexes **3b** and **4b**, the pentagonal-bipyramidal geometry of the Hg atom is unstable compared with its hexagonal-bipyramidal geometry in **1b**, although some other factors can not be ruled out. It is noteworthy that the Hg atom in **5b**, which has the same ring number of the crown ether moiety as **1b**, is directly bonded to the Ru atom from the opposite site of the crown ether moiety with a slightly distorted trigonal-planar configuration, although the Hg atom in **1b** is incorporated into the macrocyclic moiety with a distorted hexagonal-bipyramidal geometry (as described above). The difference in the complexing mode of **5b** and **1b** is attributed to the presence of the two sulfur atoms in the crown ether moiety in **1b**, since the sulfur atom coordinates more strongly with the Hg atom than does the oxygen atom. In the complexes (**3b**, **4b**, and **5b**), the sums of the three bond angles about each Hg atom are 358.1, 354.7, and 345.7°, and

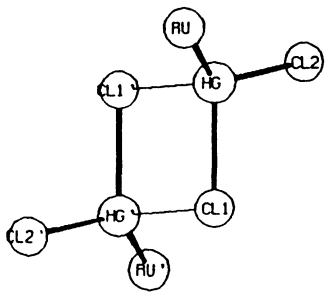

Fig. 3.

the deviations of the Hg atom from the Cl(1)-Ru-Cl(2) plane are 0.201, 0.340, and 0.562 Å, respectively. The deviation of the Hg atom from the Cl(1)-Ru-Cl(2) plane in **5b** is larger than those found in **3b** and **4b**. These values mean that the coordination of the Hg atom found in the present complexes is very close to trigonal, and that most probably those bonds are formed by sp^2 hybridization. This configuration of the Hg atom is very similar to those of $N(CH_3)_4HBr_3$[12] and $[(C_5H_5)_2Ru]_2 3HgCl_2$.[13] A slight distortion from sp^2 hybridization which would require an exactly planar configuration is due to the interaction with the adjacent molecule as described below. Furthermore, one Cl atom of the complex, which is the atom with the longer distance in the two Hg-Cl bonds, is linked by a weak bond to the Hg atom of the adjacent complex, as shown in Fig. 3. The bond length between Hg-Cl(2) (1−x, 1−y, 1−z) in **5b** which is responsible for the dimer formation is 2.697(6) Å, and the value is shorter than those (2.943 and 2.885 Å) for **3b** and **4b**, respectively. These distances for **3b**, **4b**, and **5b** are about 0.35—0.6 Å shorter than the sum of the van der Waals radii[10] of Hg and Cl atoms. These results indicate that the complexes (**3b**, **4b**, and **5b**) consist of a dimer of the Hg-Cl′ bond in crystals. Therefore, the total coordination sphere of the Hg atom can be described as a trigonal pyramid with the chlorine of the adjacent molecule in the apex.

The deviations of the dihedral angle between the plane of Cl(1)-Ru-Cl(2) and the average plane of the Cp rings in **5b**, 69.4(6) and 75.2(7)°, respectively, were also smaller than those (90.2 and 89.0°, 84.5 and 91.4°) for **3b** and **4b**, respectively. These results are thought to be due to differences in the ring numbers of the crown ether moieties in **3b**, **4b**, and **5b**.

^{13}C NMR Spectra. The ^{13}C NMR spectra of complex **5b** and the ruthenocenophane (**5a**) in DMSO-d_6 were obtained. The bridge-head carbon signal of **5b** is shifted up-field (10.40 ppm) and the α- and β-ring carbon signals down-field (1.0 and 1.1 ppm) compared with those of the ruthenocenophane (**5a**), although the methylene carbon signals are slightly shifted up-field (0.2 ppm). In the ^{13}C NMR spectra of **3b** and **4b**, however, the signals of the bridge-head carbon are shifted only 2.0 and 1.9 ppm up-field compared with those in the corresponding metal free ligands. Seyferth et al.[14] reported that the signal of the bridge-head carbon in (1,1′-ferrocenediyl)phenylphosphine, in which the Cp rings are highly tilted, is shifted up-field about 58 ppm compared with that of the corresponding acyclic compound (diphenylphosphinoferrocene). Also Osborne et al.[15] observed similar results in [1]ferrocenophanes. As shown in Fig. 2, the Cp rings of **5b** are tilted back to allow an interaction of the Hg atom to the ruthenium atom. The angles between the Cp ring planes in **5b** (22.1(9)°), **3b** (23.1(4)°), and **4b** (22.5(7)°) are larger than those found in **3a** (3.8(7)°) and **5a** (2.5°).[16] The angles of **5b** are comparable to those obtained for **3b** (23.1(4)°) and **4b** (22.5(7)°), and the differences in the tilt angles between **3a** and **3b**, **5a** and **5b** are nearly the same. However, the main conformational change in **5b** is reflected in the overlapping pattern between the two Cp rings compared with **3b** and **4b**. The torsion angle C(1)-Cp(1)-Cp(2)-C(22) (Cp1 and Cp2 are centroids of the Cp rings) in **5b** is 53.4°, although those of **3b** and **4b** are 69.3 and 75.9°, respectively. Therefore, the large shift of the bridge-head carbon in **5b** is not attributed only to the tilting of the Cp rings. The distances between the bridge-head carbon atom and C(22) and/or C(23) carbon atoms in the opposite Cp ring in **5b** are also nearly equal to those in **3b** and **4b**. Therefore, the large shift of the bridge-head carbon in **5b** is also not attributed to a steric compression.[17]

At present the reason is not clear.

Experimental

^{13}C NMR spectra were obtained on a JEOL FX-90Q spectrometer with TMS as internal standard.

Materials. 1,4,7,10,13-Pentaoxa[13](1,1′)ruthenocenophane (**3a**), 1,13-dioxa-4,7,10-trithia[13](1,1′)ruthenocenophane (**4a**), dichloro(1,4,7,10,13-pentaoxa[13](1,1′)ruthenocenophane)mercury(II) (**3b**), dichloro(1,13-dioxa-4,7,10-trithia[13](1,1′)ruthenocenophane)mercury(II) (**4b**), and dichloro(1,4,7,10,13,16-hexaoxa[16](1,1′)ruthenocenophane)-mercury(II) (**5b**) were prepared by the same manner as in described in the previous paper. Mercury(II) chloride used was reagent grade. Solvents were dried in appropriate methods and then purified by distillation under nitrogen.

^{13}C NMR Spectra (in DMSO-d_6). **3a**, 128.3(Cb), 60.2(C_β), 64.8(C_α), 71.2, 70.4, 69.8, 69.1(CH_2). **3b**, 130.3(Cb), 64.4(C_α), 61.5(C_β), 72.0, 66.5(CH_2). **4a**, 128.1(Cb), 60.2(C_β), 65.2(C_α), 72.5, 33.7, 32.5, 31.6(CH_2). **4b**, 130.0(Cb), 66.0(C_α), 61.4(C_β), 71.2, 70.3, 69.8, 69.0(CH_2). **5a**, 128.2(Cb), 60.1(C_β), 64.9(C_α), 71.0, 70.3, 70.0, 69.9, 69.1(CH_2). **5b**, 117.8(Cb), 65.9(C_α), 61.2(C_β), 71.0, 70.3, 69.9, 69.1(CH_2).

X-Ray Crystallography. Crystals of dimensions 0.5×0.5×0.2 mm, 0.5×0.2×0.1 mm, 0.4×0.2×0.2 mm, and 0.5×0.2×0.05 mm for the metal free ligand **3a**, complexes **3b**, **4b**, and **5b** were used for X-ray crystallography. Crystal data are as follows: **3a**, $C_{18}H_{24}O_5Ru$, Mw=421.5, triclinic, space group $P\bar{1}$, a=11.107(1), b=8.816(1), c=9.788(1) Å, α=70.48(1), β=99.76(1), γ=101.31(1)°, U=877.6(2) Å^3, Z=2, D_x=1.59 g cm^{-3}, μ(Mo $K\alpha$)=9 cm^{-1}. **3b**, $C_{18}H_{24}O_5RuHgCl_2$, Mw=693.0, triclinic, space group $P\bar{1}$, a=12.043(3), b=10.759(2), c=8.529(2) Å, α=98.76(2), β=101.22(2), γ=77.03(2)°, U=1049.5 Å^3, Z=2, D_x=2.19 g cm^{-3}, μ(Mo $K\alpha$)=84 cm^{-1}. **4b**, $C_{18}H_{24}O_2S_3RuHgCl_2$, Mw=741.2, triclinic, space group $P\bar{1}$, a=17.100(3), b=8.986(1), c=8.618(2) Å, α=105.17(1), β=62.24(1), γ=100.54(1)°, U=1128.1 Å^3, Z=2, D_x=2.18 g cm^{-3}, μ(Mo $K\alpha$)=81 cm^{-1}. **5b**, $C_{20}H_{28}O_6RuHgCl_2$, Mw=737.04, monoclinic, space group $P2_1/a$, a=26.881(7), b=10.334(3), c=8.414(2) Å, β=96.97(2)°, U=2322.2 Å^3, Z=4, D_x=2.11 g cm^{-3}, μ(Mo $K\alpha$)=76 cm^{-1}.

Intensity data for $2\theta \leq 50°$ were recorded on a Rigaku AF C-5R with graphite-monochromatized Mo $K\alpha$ radiation. Among totals of 3084 (**3a**), 3689 (**3b**), 3946 (**4b**), and 4070 (**5b**) independent reflections collected, 2996, 3244, 3394, and 3142 were considered to be observed at the 2.0σ (F_o) level and were corrected for Lorentz and polarization factors, but not for absorption. The structures of **3a**, **3b**, **4b**, and **5b** were solved by the heavy-atom method, and refined by a block-diagonal least-squares method. The positions of the hydrogen atoms could be estimated by using standard geometry. The final refinements with anisotropic temperature factors for the nonhydrogen atoms and isotropic temperature factors for the hydrogen atoms lowered the R values to 0.097 (R_w=0.123, $w=1/\sigma^2(F_o)$), 0.107 (R_w=0.128, w=1.0), 0.055 (R_w=0.057, $w=1/\sigma(F_o)$), and 0.067 (R_w=0.056, $w=1/\sigma^2(F_o)$) for **3a**, **3b**, **4b**, and **5b**, respectively. But, for **3b** the isotropic temperature factors were used for the O and C atoms because of the negative values of several atoms on the anisotropic refinements for the nonhydrogen atoms. Anomalous dispersion corrections were applied to the scattering factors of Hg, Ru, Cl, and S.[18]

Lists of structural factors, anisotropic thermal parameters, and H-atom coordination are being kept at the Chemical Society of Japan (Document No. 8853).

3,3′-Carbonylbis[5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione]: A Novel, Reactive, and Versatile Condensing Agent for Amide, Ester, Thiol Ester, Urea, Carbonate, Polyamide, and Polyurea Syntheses

Yasuo SAEGUSA,* Tatsushi WATANABE, and Shigeo NAKAMURA
Department of Applied Chemistry, Faculty of Engineering, Kanagawa University, Kanagawa-ku, Yokohama 221
(Received August 30, 1988)

A novel condensing agent, 3,3′-carbonylbis[5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione] (**3**), was readily prepared by the reaction of 5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione with trichloromethyl chloroformate in benzene. The reagent **3** was found to be very useful for the one-pot or direct preparation of amide, ester, thiol ester, urea, and carbonate under mild conditions. The one-pot or direct polycondensation of several dicarboxylic acids with aromatic diamines and of aromatic diamines using **3** proceeded smoothly at ambient temperature to produce high-molecular-weight polyamides and polyureas, respectively.

Heterocyclic amides, such as imidazolides,[1-5] pyrazolide,[6] triazolide,[7] and oxadiazolides,[8] are very useful and popular condensing agents for the preparation of amides, esters, ureas, carbonates, and particularly peptides by a one-pot or direct procedure. The acylation or coupling reaction by the use of these reagents, however, takes a relatively long period. They also are generally very sensitive even to atmospheric moisture and must be handled with special cautions. The studies on the more reactive and even hydrolytically stable condensing agents have been successfully progressed.[9-18]

In the preceding article, we demonstrated that *N*- and *S*-acyl derivatives of 5-aryl-1,3,4-oxadiazole-2(3*H*)-thiones are novel highly reactive acylating agents for the synthesis of amide and polyamides under mild conditions.[19,20] This finding prompted us to develop further a novel condensing agent, 3,3′-carbonylbis[5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione] (**3**), for the synthesis of amide and polyamides from carboxylic acids via *N*-acyl derivatives of 5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione (**1**) as an active intermediate. This reagent might be also expected to be highly reactive for nucleophiles such as amines and alcohols.

We now report that amide, ester, thiol ester, urea, carbonate, and polyamides and polyureas with moderate to high molecular weights can be easily obtained from carboxylic acids and/or the corresponding nucleophiles by a one-pot or direct procedure using **3** under mild conditions.

Results and Discussion

Preparation of 3,3′-Carbonylbis[5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione] (3). A novel and versatile condensing agent, 3,3′-carbonylbis[5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione] (**3**), was conveniently prepared by the reaction of 5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione (**1**) with trichloromethyl chloroformate (**2**) in a 1 : 1 molar ratio in benzene under reflux conditions (Scheme 1).

The reagent **3** is a pale yellow crystalline solid melting at 202 °C and has excellent hydrolytic stability compared with conventional condensing agents. Hence, this can be easily handled. The condensing agent **3** may be kept for a long period of time under atmospheric pressure.

The structure of **3** was assigned on the basis of infrared (IR) spectroscopy and elemental analysis. The IR spectrum exhibited a strong carbonyl absorption at 1760 cm^{-1} and a thiocarbonyl stretching absorption at 1355 cm^{-1}.

Reaction of 3 with Benzoic Acid (4), Isophthalic Acid (7a), and Adipic Acid (7b). In order to clarify the reactivity of **3** for carboxylic acids and the reaction pathway for the synthesis of amide, ester, thiol ester, and polyamides, the reaction of **3** with benzoic acid (**4**) was carried out in a variety of solvents including chloroform, tetrahydrofuran (THF), *N*,*N*-dimethylacetamide (DMA), *N*,*N*-dimethylformamide (DMF), and *N*-methyl-2-pyrrolidone (NMP) at room temperature (ca. 15°C) for 2 h in the presence or absence of pyridine as a tertiary base to form benzoate ion.

The condensing agent **3** reacted rapidly with **4** with the liberation of carbon dioxide and gave active amide intermediate, 5-phenyl-3-benzoyl-1,3,4-oxadiazole-2(3*H*)-thione[19] (**5**), in good yields (Table 1, Scheme 2). The use of pyridine was somewhat effective for the

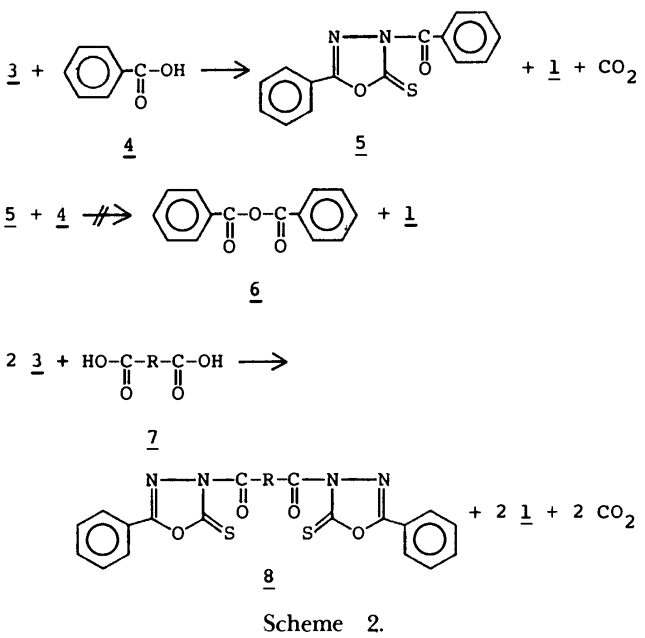
7b	NMP(4)	Py(2)	4	**8b**	97

a) Reaction was carried out with 1 mmol of **4**, **7a**, or **7b** using 1 and 2 mmol of **3** for **4** and for **7a** and **7b**, respectively, at room temperature. b) CF: chloroform. c) Py: pyridine. d) TEA: triethylamine.



Scheme 2.

formation of **5**. No definite effect of medium on the reaction was, however, observed. Probable active intermediate benzoic anhydride (**6**) was not detected nor isolated entirely from the reaction mixtures. The use of triethylamine was attempted in place of pyridine, but was found less suitable as a base.

Similarly, active bisamide intermediates, 3,3′-isophthaloylbis[5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione][19] (**8a**) and 3,3′-adipoylbis[5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione][19] (**8b**), were both isolated in quantitatively from the condensation of **3** with isophthalic acid (**7a**) and adipic acid (**7b**), respectively (Table 1, Scheme 2).

Active amide intermediates **5**, **8a**, and **8b** obtained here were identified by melting point and IR spectroscopy. They, the actual acylating agents, have been characterized by high reactivity toward aminolysis.

Preparation of Benzanilide (10), Phenyl Benzoate (12a), and *S*-Phenyl Benzothioate (12b). Based on these results, we first studied the preparation of benzanilide (**10**), phenyl benzoate (**12a**), and *S*-phenyl benzothioate (**12b**) from benzoic acid (**4**) and aniline (**9**), phenol (**11a**), and thiophenol (**11b**), respectively, by a one-pot procedure using **3**. This efficient procedure consists of reacting **3** with **4** in chloroform, THF, DMA, DMF, or NMP at ambient temperature for 2 h in the presence or absence of pyridine affording **5** as an active intermediate (step 1) and subsequently with the respective nucleophiles at that temperature for a prescribed period (step 2).

The reaction with **9** as a nucleophile proceeded smoothly even without pyridine to furnish amide **10** in high yields (Table 2, Scheme 3). NMP as a solvent was somewhat more favorable than the others in the preparation of **10**. Both the reactions with **11a** and **11b** progressed much more slowly, but almost quantitative conversions to ester **12a** and thiol ester **12b** could be achieved in 2 and 8 d, respectively (Table 2, Scheme 3). An increase in the reaction temperature above 50 °C in step 2, however, accelerated dramatically the alcoholysis of **5**. Esterification at room temperature required an equimolar quantity of pyridine and above to nucleophiles **11a** and **11b**.

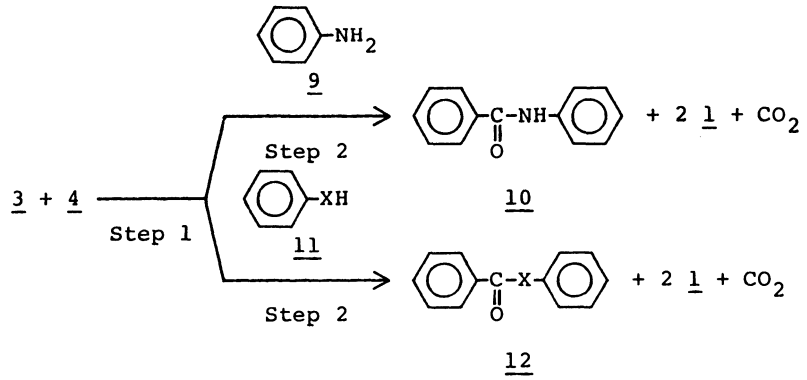
a) Reaction was carried out with 1 mmol of **3** and **4** for 2 h at room temperature. b) Reaction was carried out with 1 mmol of **9**, **11a**, or **11b** at room temperature unless otherwise noted. c) A trace amount of **5** was contained. d) Reaction was carried out at 50°C.



Scheme 3.

Preparation of *N,N'*-Diphenylurea (14) and Diphenyl Carbonate (16). The direct aminolysis and alcoholysis of **3** were next investigated to demonstrate the feasibility of the reactions for urea and carbonate formations, respectively. The reactions of **3** with twice-molar amounts of **9** and **11a** were conducted using chloroform, THF, DMA, DMF, and NMP as media at ambient temperature for a predetermined duration in the presence or absence of pyridine.

As shown in Table 3, **3** underwent aminolysis within a short time in the solvents to provide excellent yields of *N,N'*-diphenylurea (**14**) (Scheme 4). The use of NMP significantly affected the reaction rate of the aminolysis. Thus, the direct aminolysis of **3** is a facile, high-yield reaction which can be used for the synthesis of polyureas. The direct alcoholysis of **3** leading to diphenyl carbonate (**16**) took place relatively slow and required prolonged reaction time (much more than 8 d) for its completion (Table 3, Scheme 4). Raising the reaction temperature favored markedly the alcoholysis. Alcoholysis at room temperature required an equimolar quantity of pyridine to **11a**.

It is interesting to note that the treatments of **3** with an equimolar amounts of **9** and **11a** also afford high yields of **14** and **16**, respectively. This points to the following pathway (Scheme 4). A half-molar amount of **3** reacts first with **9** and **11a** to form 5-phenyl-3-anilinocarbonyl-1,3,4-oxadiazole-2(3*H*)-thione (**13**) and 5-phenyl-3-phenoxycarbonyl-1,3,4-oxadiazole-2(3*H*)-thione (**15**), respectively. The products **13** and **15** are more reactive than **5** as activated acylating agents and are less stable, and their enhanced reactivities cause them to react more rapidly with unreacted **9** and **11a**, respectively. Therefore, the formation of **13** and **15** is the rate-determining step in the proposed sequence of reactions.

Synthesis of Polyamides (18a—d). Facile one-pot amide preparation using the novel condensing agent **3** provides a promising route to polyamides. The polycondensation of dicarboxylic acids **7a** and **7b** with aromatic diamines including 4,4'-oxydianiline (**17a**) and 4,4'-methylenedianiline (**17b**) using **3** was therefore investigated by a one-pot procedure. Thus, the

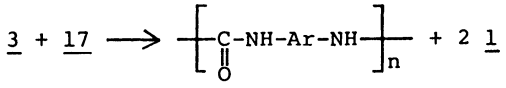
18

Scheme 5.

activation of the dicarboxylic acids was carried out by the addition of **3** to the respective NMP solutions of **7a** and **7b** at room temperature in the presence or absence of pyridine. After 5 h of stirring the diamine **17a** or **17b** was added, and the mixture was further stirred at that temperature for 1 or 3 d. The polyamides were isolated in the ordinary manner.

As can be seen from the reduced viscosities in Table 4, the corresponding polyamides (**18a—d**) with moderate molecular weights were easily synthesized in quantitative yields with pyridine (Scheme 5). Remarkable effect of pyridine on the polycondensations was observed.

Synthesis of Polyureas 19a and 19b. In order to further demonstrate the synthetic utility and versatility of the novel condensing agent **3**, it was applied to the synthesis of aromatic polyureas. The direct polycondensation leading to polyureas **19a** and **19b** was conducted in solution at ambient temperature for 1 h or 1 d in the presence of **3** using **17a** and **17b** as aromatic diamines. Equimolar amounts of the condensing agent and diamines were used. Polar aprotic solvent NMP was employed as a selected polymerization medium.



19

Scheme 6.

Although the polyureas were isolated in excellent yields, the molecular weights remained low, presumably due to the formation of a quasi-gel of polymers (Table 5, Scheme 6). High molecular weights were successfully attained by the addition of inorganic salts

such as lithium hydroxide and lithium chloride to the system in which the polymers remained dissolved.

In conclusion, these experimental results indicate that the novel condensing agent **3** is very useful for the preparation of amide, ester, thiol ester, urea, and carbonate and moderate- to high-molecular-weight polyamides and polyureas under mild conditions. Furthermore, **3** is a crystalline solid and is handled more easily than the conventional condensing agents.

Experimental

Melting points (mp) were uncorrected. Infrared (IR) spectra were recorded in potassium bromide on a JASCO IR-810 spectrophotometer. 5-Phenyl-1,3,4-oxadiazole-2(3*H*)-thione (**1**) was prepared as reported previously.[21] Trichloromethyl chloroformate (**2**), supplied by Hodogaya Chemical Industries Ltd., was used without further purification. The other reagents and solvents were obtained commercially and were used after purification by the usual manner. The products obtained were identified by spectral comparison and/or mp and mixed mp with the corresponding authentic samples unless otherwise noted.

3,3′-Carbonylbis[5-phenyl-1,3,4-oxadiazole-2(3*H*)-thione] (3). A mixture of **1** (17.8 g, 0.1 mol) and **2** (12 mL, 0.1 mol) in benzene (300 mL) was refluxed with stirring for 1 d. The solvent was removed in vacuo and the residue was recrystallized twice from benzene to give pale yellow granular crystals. Yield: 14.9 g (78%). Mp 202 °C (by differential thermal analysis); IR (KBr), 1760 (C=O), 1610 (C=N), and 1355 cm^{-1} (C=S).

Found: C, 53.52; H, 2.62; N, 14.76%. Calcd for $C_{17}H_{10}N_4O_3S_2$: C, 53.39; H, 2.64; N, 14.65%.

Reaction of 3 with Benzoic Acid (4). To a solution of **4** (0.122 g, 1 mmol) and/or pyridine (0.079 g, 1 mmol) in a solvent (2 or 4 mL) was added **3** (0.382 g, 1 mmol) followed by stirring at room temperature for 2 h. The reaction mixture was poured into 1% aqueous sodium hydrogencarbonate (50 mL). The resulting precipitate was collected, washed several times with water, and dried.

Reaction of 3 with Isophthalic Acid (7a) or Adipic Acid (7b). The condensing agent **3** (0.764 g, 2 mmol) was added to a solution of **7a** or **7b** (1 mmol) and/or pyridine (0.158 g, 2 mmol) in a solvent (4 or 8 mL). The solution was stirred at ambient temperature for 2 or 4 h, and then poured into 1% aqueous sodium hydrogencarbonate (100 mL). The solid, so formed, was filtered off, rinsed repeatedly with water, and dried.

Benzanilide (10). To a stirred solution of **4** (0.122 g, 1 mmol) and/or pyridine (0.079 g, 1 mmol), **3** (0.382 g, 1 mmol) at room temperature was added. After 2 h of the reaction aniline (**9**) (0.093 g, 1 mmol) was added, and the solution was stirred at that temperature for an additional 2 h. The product was isolated by pouring the solution into 1% aqueous sodium hydrogencarbonate (100 mL). It was gathered, washed thoroughly with water, and dried.

Phenyl Benzoate (12a) and *S*-Phenyl Benzothioate (12b). A mixture of **3** (0.382 g, 1 mmol), **4** (0.122 g, 1 mmol), and/or pyridine (1 or 2 mmol) in a solvent (2 or 4 mL) was stirred at ambient temperature for 2 h and phenol (**11a**) or thiophenol (**11b**) (1 mmol) was added. Stirring was further continued at that temperature or 50 °C for 12 h, 1, 2, 4, or 8 d. The reaction mixture was worked up as reported for **10**.

***N,N′*-Diphenylurea (14).** The condensing agent **3** (0.382 g, 1 mmol) was added to a solution of **9** (1 or 2 mmol) in a solvent (2 or 4 mL). This solution was stirred at room temperature for 1 or 2 h followed by treating as described.

Diphenyl Carbonate (16). A solution of **3** (0.382 g, 1 mmol), **11a** (1 or 2 mmol), and/or pyridine (1 or 2 mmol) in a solvent (2 or 4 mL) was reacted with stirring at ambient temperature or 60 °C for 1, 4, or 8 d. The work-up of the product was as usual.

Judging from IR and ^1H NMR spectra and the mp, all the products were virtually pure without any purifications.

Polyamides 18a—d. The condensing agent **3** (0.764 g, 2 mmol) was allowed to react with **7a** or **7b** (1 mmol) in *N*-methyl-2-pyrrolidone (NMP) (4 mL) in the presence or absence of pyridine (0.158 g, 2 mmol) and stirred at ambient temperature for 5 h. Diamine 4,4′-oxydianiline (**17a**) or 4,4′-methylenedianiline (**17b**) (1 mmol) was then added to this mixture. After 1 or 3 d of stirring at this temperature the polymer was separated by reprecipitation with 1% aqueous sodium hydrogencarbonate (300 mL). It was isolated, rinsed well with hot methanol, and dried. The reduced viscosity was measured at a concentration of 0.5 $g dL^{-1}$ in concentrated sulfuric acid at 30 °C.

Polyureas 19a and 19b. A mixture of **3** (0.382 g, 1 mmol) and **17a** or **17b** (1 mmol) in NMP or NMP (2 mL) containing 5 wt% of lithium hydroxide or lithium chloride reacted with stirring at room temperature for 1 h or 1 d. The polymerization solution was treated as described for **18**. The reduced viscosity was measured in NMP.

Manganese(III)-Mediated Formylation of Aromatic Compounds in the Presence of Malonic Acid

Hiroshi NISHINO,* Katsunori TSUNODA, and Kazu KUROSAWA
Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami 2-39-1, Kumamoto 860
(Received August 31, 1988)

The reaction of naphthalenes with malonic acid in the presence of manganese(III) acetate gives naphthalenecarbaldehydes and naphthalenecarboxylic acids. Similar reactions of anthracene, pyrene, and methoxybenzenes also yield formylated and carboxylated products. It was found that the formyl group introduced to the aromatic ring was not derived from carboxymethyl radical generated directly by the thermolysis of manganese(III) acetate, but from a dicarboxymethyl radical formed by the interaction of malonic acid and manganese(III) acetate. In addition, it was also found that the dicarboxymethyl radicals attacked the position of the highest electron density on the aromatic ring and that this formylation was effective when the ionization potential of the aromatic compound was lower than 7.8 eV.

It is known that the reaction of aromatic compounds with manganese(III) acetate, $[Mn_3O(OAc)_6(OAc)(HOAc)]\cdot 5H_2O$ (which is usually abbreviated to $[Mn_3O]$),[1] gives mainly acetoxymethylated products together with small amounts of carboxymethyl, diacetoxymethyl or formyl, and carboxyl derivatives.[2] This reaction is caused by carboxymethyl radicals, $\cdot CH_2CO_2H$, which are formed by the pyrolysis of manganese(III) acetate.[3] Kurosawa and McOmie have obtained a propellane, 7-oxa-10,11-benzotricyclo[4.3.2.0]undeca-2,4,10-trien-8-one, by the use of a similar oxidation of biphenylene.[4] On the other hand, Kurz and Chen have reported on the nitromethylation of aromatic hydrocarbons promoted by manganese(III) acetate.[5] A key of this nitromethylation is the formation of nitromethyl radicals, $\cdot CH_2NO_2$, formed by the

interaction of manganese(III) acetate and nitromethane. Recently, we have found the spiroannulation of alkenes by the use of a malonic acid-manganese(III) acetate system.[6] Fristad and Hershberger suggested that dicarboxymethyl radicals, $\cdot CH(CO_2H)_2$, produced in the oxidation system participated in this spiroannulation.[7] In connection with these manganese(III) acetate oxidations, we tried to apply a malonic acid-manganese(III) acetate system to aromatic hydrocarbons in order to obtain aromatic lactone annulation, such as the formation of propellane[4] or di-γ-lactone.[8] When aromatic compounds were oxidized with manganese(III) acetate in the presence of malonic acid, a reaction involving dicarboxymethyl radicals actually occurred. However, no aromatic lactone annulation was observed and the dicarboxymethyl group was introduced in the aromatic ring, followed by decarboxylation to give the corresponding aldehydes or further by oxidation to yield carboxylic acids. This paper now describes the results of our investigation into this reaction as regards synthetic utility, scope, limitations, and mechanistic pathway.

Results and Discussion

2,7-Dimethoxynaphthalene (**1a**) was selected as an aromatic substrate for the reason that the reaction products were readily separated from **1a** by TLC and could be easily characterized by spectrometry. When **1a** was oxidized with manganese(III) acetate in the presence of malonic acid under various reaction conditions (Table 1), 2,7-dimethoxy-1-naphthalenecarbaldehyde (**2a**) was obtained in moderate yield (Entries 1—7). Especially, the oxidation at a molar ratio of **1a**: malonic acid: $[Mn_3O]$=1 : 8 : 8 at reflux temperature gave **2a** in the best yield (Entry 6). Then, methoxynaphthalenes (**1b—f**) were oxidized at a molar ratio of 1 : 8 : 8 at reflux temperature, giving the corresponding naphthalenecarbaldehydes (**2b—f**) in moderate yields together with a small amount of naphthalenecarboxylic acids (**3b** and **3c**) as a by-product (Entries 8—14). The reaction of **1g** gave dicarbaldehyde (**4**) in addition to two kinds of carbaldehydes (**2g** and **2g'**) (Entry 15). In a similar oxidation of **1h**, 6,7-dimethoxy-1-naphthalenecarboxylic acid (**3h**) was mainly produced in 39% yield (Entry 16). When methylnaphthalenes (**1i—k**) and naphthalene (**1l**) were oxidized under similar reaction conditions, naphthalenecarboxylic acids (**3i—l**) were formed in 22—43% yields along with a small amount of carbaldehydes (**2i** and **2j**) and 1-(diacetoxymethyl)naphthalene (**5**) (Entries 17—20).

Anthracene (**6**) was oxidized with the manganese(III) acetate-malonic acid system to give four products: 9-acetoxyanthracene (**7**), 9-anthracenecarbaldehyde (**8**), 9-(diacetoxymethyl)anthracene (**9**), and 9-anthracenecarboxylic acid (**10**) (Entries 21, 22). Pyrene (**11**) also yielded an aldehyde (**12**), a diacetoxymethyl derivative (**13**), and a carboxylic acid (**14**)

under the similar reaction conditions (Entry 23).

On the contrary, anisole (**15a**), 1,3-dimethoxybenzene (**15b**), and 1,2,3-trimethoxybenzene (**15c**) were rather inactive under these oxidation conditions to afford only a small amount of benzaldehydes (**16b** and **16c**) and benzoic acids (**17a—c**) (Entries 24—26).

It is well-known that carboxymethyl radicals react with aromatic compounds and eventually give acetoxymethyl derivatives.[3] The acetoxymethylated products can be further oxidized with manganese(III) acetate to form diacetoxymethyl and/or formyl derivatives.[9] Aratani and Dewar have briefly reported that the oxidations of 1- and 2-methoxynaphthalene with manganese(III) acetate at 100 °C gave acetoxynaphthalenes and naphthoquinones.[10] When we repeated the oxidation of 2,7-dimethoxynaphthalene (**1a**) at a reflux temperature in which the carboxymethyl radicals could be formed more readily,[3] naphthalenecarbaldehyde, however, was not detected and the results were similar to those described in the literature (Scheme 1). Heiba and co-workers reported that a radical reaction preferentially occurred by the addition of acetic anhydride in a manganese(III) oxidation system.[3] The oxidation of **1a** was then carried out at reflux temperature under anhydrous conditions, but only acetoxymethylated product (**20**) was obtained, which was not further oxidized to give aldehyde under these reaction conditions (Scheme 2). It follows, therefore, that the formylation of aromatic compounds in the reaction of manganese(III) acetate–malonic acid system could not be caused by an attack of carboxymethyl radicals on the aromatic ring, but that malonic acid played an important role in this system. In order to clarify the source of formyl carbon, the reaction of **1a** was run by the use of malonic acid-d_4 in anhydrous benzene. As a result, a mixture of **2a** and 1-(formyl-*d*)naphthalene (**21**) was obtained in 24% yield (Scheme 3). Xanthene (**22**) was oxidized in a manganese(III) acetate–malonic acid system to give 9-(carboxymethyl)-xanthene (**23**) (Scheme 4). These facts indicate that dicarboxymethyl radicals directly attack the aromatic ring. The formation of **2a** in the reaction of **1a** with malonic acid-d_4 is probably due to a deuterium–hydrogen exchange between malonic acid-d_4 and acetic acid ligands of manganese(III) acetate. Accordingly, the mechanism for the manganese(III)-mediated formylation was depicted by the evidence mentioned above, as shown in Scheme 5, which involves double

decarboxylation. The isolation of diacetoxymethyl derivatives (**5**, **9**, and **13**) (Table 1) would also support this mechanism. As can be seen in Fig. 1, a substituent group, such as formyl, diacetoxymethyl, or carboxyl group, is introduced at the position of the highest electron density on the aromatic ring, except for the case of 2,3-dimethoxynaphthalene (**1h**). This fact corroborates that the dicarboxymethyl radical has an electrophilic nature. Perhaps, in the case of **1h**, the attack of a bulky dicarboxymethyl radical was inhibited by a steric hindrance of the vicinal methoxyl groups. The manganese(III)-mediated formylation in the presence of malonic acid occurs preferentially to aromatic compounds which have an ionization potential in the range 7.36 to 7.82 eV (Table 2). Aromatic hydrocarbons having an ionization potential higher than these levels tend to be oxidized up to carboxylic acids, though they come to be less reactive to manganese(III) oxidation. This has been shown in cases of **1h**—**l** in which the corresponding aldehydes or diacetoxymethyl derivatives may be more readily oxidized with manganese(III) than the parent compounds. Aromatic substrates having an ionization potential over 8.4 eV could not react in this oxidation system. This aptness is similar to the direct diacetylmethylation of aromatic compounds with tris(2,4-pentanedionato)manganese(III), which is pyrolyzed in acetic acid to generate diacetylmethyl radicals.[11] The formylation of anthracene (**6**) was restrained, since a direct reaction between **6** and manganese(III) acetate via an electron-transfer mechanism took place and 9-acetoxyanthracene (**7**) was formed.[12] At this point, the behavior of **6** is seen to be different from that of **6** in direct diacetylmethylation with tris(2,4-pentanedionato)manganese(III) (only radical reaction including diacetylmethyl radicals occurs in the reaction of **6** with tris(2,4-pentanedionato)-manganese(III)).[11]

In conclusion, this manganese(III)-mediated formylation could be applied to the aromatic compounds having a relatively lower ionization potential (≦7.82 eV), although the formylation of aromatic compounds is known as Vilsmeier, Gattermann, Gattermann-Koch, Reimer-Tiemann reaction, and etc. It should be emphasized that the reaction time is extremely short (within 1 min).

Experimental

Measurements. The ^{1}H NMR spectra were measured in deuteriochloroform on a JEOL JNM-PMX60SI spectrometer at room temperature. Chemical shifts are recorded in the δ scale, relative to TMS as an internal standard. The IR spectra were taken in chloroform on a JASCO A-102 infrared spectrophotometer, and the IR spectral data are expressed in cm^{-1}. The mass spectra were obtained with a JEOL JMS-DX300 mass spectrometer at 70 eV of ionization energy. All melting points were determined with a Yanagimoto micro-melting point apparatus and were uncorrected. Thin-layer chromatography was carried out on silica gel (Wakogel B-10) with chloroform as a developing solvent.

Materials. Methoxynaphthalenes and polymethoxybenzenes were synthesized by the methylation of the corresponding naphthols and phenols with dimethyl sulfate. Naphthalene, anthracene, pyrene, and anisole were commercially available. Manganese(III) acetate was prepared by the method described in the literature.[3]

Oxidation of Aromatic Compounds with Manganese(III) Acetate in the Presence of Malonic Acid. The typical procedure for the oxidation of aromatic compounds with manganese(III) acetate in the presence of malonic acid was as follows. To a heated solution of aromatic compound (1 mmol) and malonic acid (8 mmol) in acetic acid (25 cm^3), manganese(III) acetate (1.98 g, 8 mmol for Mn(III)) was added. The mixture was heated under reflux until its dark-brown color turned opaque white. The solvent was removed in vacuo, and the residue was triturated with 2 M (1 M=1 mol dm^{-3}) HCl (25 cm^3), followed by extraction with chloroform. The chloroform extract was washed with an aqueous sodium hydrogencarbonate solution and concentrated. The aqueous solution was acidified with concentrated hydrochloric acid and subsequently extracted with ethyl acetate.

The solvent was removed in vacuo and the residue was treated with diazomethane in methanol. The neutral and esterified products, respectively, were separated on TLC. The yields are summarized in Table 1.

Oxidation Products. 2,7-Dimethoxy-1-naphthalenecarbaldehyde (2a): Mp 97.7—98.7 °C (from ethanol) (lit,[13] mp 98 °C); IR 1665 (CHO); ^{1}H NMR δ=3.86 (3H, s, OCH_3), 3.90 (3H, s, OCH_3), 6.86 (1H, d, J=9.0 Hz, H-3), 6.95 (1H, dd, J=9.0, 2.4 Hz, H-6), 7.51 (1H, d, J=9.0 Hz, H-4 or H-5), 7.78 (1H, d, J=9.0 Hz, H-5 or H-4), 8.73 (1H, d, J=2.4 Hz, H-8), and 10.75 (1H, s, CHO); MS m/z (rel intensity), 216 (100, M^+), 187 (25), 159 (53), 144 (20), 115 (31), and 102 (20). Found: C, 71.99; H, 5.59%. Calcd for $C_{13}H_{12}O_3$: C, 72.21; H, 5.59%.

6,7-Dimethoxy-1-naphthalenecarbaldehyde (2h): Mp 108—109 °C (from ethanol); IR 1682 (CHO); ^{1}H NMR δ=3.98 (3H, s, OCH_3), 4.05 (3H, s, OCH_3), 7.07 (1H, s, H-5), 7.35—8.18 (3H, m, arom. H), 8.70 (1H, s, H-8), and 10.21 (1H, s, CHO); MS m/z (rel intensity), 216 (100, M^+), 188 (37), 173 (26), and 145 (54). Found: m/z 216.0770. Calcd for $C_{13}H_{12}O_3$: M, 216.0786.

Methyl Ester of 6,7-Dimethoxy-1-naphthalenecarboxylic Acid (3h): Mp 189—190 °C (from ethanol); IR 1709 (C=O) and 1254 (C-O-C); ^{1}H NMR δ=3.96 (6H, s, 2×OCH_3), 4.00 (3H, s, OCH_3), 6.99 (1H, s, H-5), 7.20 (1H, t, J=8.0 Hz, H-3), 7.74 (1H, dd, J=8.0 and 2.4 Hz, H-4), 8.06 (1H, dd, J=8.0 and 2.4 Hz, H-2), and 8.47 (1H, s, H-8); MS m/z (rel intensity), 246 (100, M^+), 215 (41), 187 (15), 173 (20), and 145 (14). Found: m/z 246.0895. Calcd for $C_{12}H_{14}O_4$: M, 246.0891.

4,6-Dimethoxy-1,5-naphthalenedicarbaldehyde (4): Mp 185—186 °C (from ethanol); IR 1680 and 1703 (CHO); ^{1}H NMR δ=3.93 (1H, s, OCH_3), 4.00 (1H, s, OCH_3), 6.88 (1H, d, J=8.0 Hz, H-3), 7.40 (1H, d, J=9.0 Hz, H-7), 7.76 (1H, d, J=8.0 Hz, H-2), 9.41 (1H, d, J=9.0 Hz, H-8), 10.09 (1H, s, CHO), and 10.61 (1H, s, CHO); MS m/z (rel intensity), 244 (100, M^+), 229 (20), 213 (30), 199 (15), 115 (55), and 102 (40). Found: C,68.57; H, 5.02%. Calcd for $C_{14}H_{12}O_4$: C, 68.84; H, 4.95%.

1-Diacetoxymethyl-4,5-dimethylnaphthalene (5): Mp 130.4—131.4 °C (from light petroleum); IR 1240 (O-CO), 1760 (OAc); ^{1}H NMR δ=2.10 (6H, s, 2×OAc), 2.90 (6H, s, 2×CH_3), 7.1—7.5 (3H, m), 7.52 (1H, d, J=8.0 Hz), 8.09 (1H, dd, H-8), and 8.16 (1H, s, -CH<). Found: C, 71.43; H, 6.42%. Calcd for $C_{17}H_{18}O_4$: C, 71.31; H, 6.34%.

4-Methoxy-1-naphthalenecarbaldehyde (2b) (lit,[14] mp 34 °C); **2-methoxy-1-naphthalenecarbaldehyde (2c)**, mp 82.2—83.1 °C (lit,[15] mp 82.0—83.5 °C); **4,8-dimethoxy-1-naphthalenecarbaldehyde (2d)**, mp 126.8—127.6 °C (lit,[16] mp 126 °C); **2,4-dimethoxy-1-naphthalenecarbaldehyde (2e)**, mp 161.8—162.3 °C (lit,[17] mp 161—162 °C); **2,6-dimethoxy-1-naphthalenecarbaldehyde (2f)**, mp 90.3—90.8 °C (lit,[13] mp 90 °C); **4,6-dimethoxy-1-naphthalenecarbaldehyde (2g)**, mp 103.5—104.4 °C (lit,[18] mp 104 °C); **2,8-dimethoxy-1-naphthalenecarbaldehyde (2g')** (lit,[18] mp 90 °C); **4-methyl-1-naphthalenecarbaldehyde (2i)**, liquid (lit,[19] bp 160—165 °C/1.3×10^3 Pa); **2-methyl-1-naphthalenecarbaldehyde (2j)**, mp 50—51 °C (lit,[20] mp 51.5—52 °C); **methyl esters of 4-methoxy-1-naphthalenecarboxylic acid (3b);**[21] **2-methoxy-1-naphthalenecarboxylic acid (3c)** (lit,[22] mp 52—53 °C); **4-methyl-1-naphthalenecarboxylic acid (3i)** (lit,[23] bp 192—194 °C/1.6×10^3 Pa); **2-methyl-1-naphthalenecarboxylic acid (3j)** (lit,[23] bp 168—170 °C/2×10^3 Pa); **4,5-dimethyl-1-naphthalenecarboxylic acid (3k)**[24] and **1-naphthalenecarboxylic acid (3l)** (lit,[25] bp 100—102 °C/5.3 Pa) were characterized by its ^{1}H NMR, IR spectrum, and by comparison of the melting point or the boiling point with those of literatures.

1-Acetoxyanthracene (7): Pale yellow needles (from ethanol), mp 132—133 °C (lit,[26] mp 134—135 °C); IR 1765 (OAc); ^{1}H NMR δ=2.59 (3H, s, OAc), 7.2—8.1 (8H, m, arom. H), and 8.31 (1H, s, H-10).

9-Anthracenecarbaldehyde (8): Mp 103.5—104.5 °C (from ethanol) (lit,[27] mp 104—105 °C).

9-Diacetoxymethylanthracene (9): Mp 138—139 °C (from ethanol); IR 1760 (OAc); ^{1}H NMR δ=2.08 (6H, s, 2×OAc), 7.18—8.80 (8H, m, arom. H), 8.48 (1H, s, H-10), and 9.25 (1H, s, -CH<); MS m/z (rel intensity), 308 (14, M^+), 206 (100), 178 (95), and 151 (29). Found: m/z 308.0955. Calcd for $C_{19}H_{16}O_4$: M, 308.1048.

1-Pyrenecarbaldehyde (12): Mp 125.5—126.5 °C (from ethanol) (lit,[28] mp 127 °C).

1-Diacetoxymethylpyrene (13): Mp 151—152 °C (from ethanol); IR 1761 (OAc); ^{1}H NMR δ=2.10 (6H, s, 2×OAc), 7.27—8.76 (9H, m, arom. H), and 9.21 (1H, s, -CH<); MS m/z (rel intensity), 332 (17, M^+), 230 (35), 201 (36), and 181 (100). Found: m/z 332.1048. Calcd for $C_{21}H_{16}O_4$: M, 332.1048.

Methyl Ester of 1-Pyrenecarboxylic Acid (14): Mp 100—101 °C (from ethanol) (lit,[29] mp 101—102 °C).

The structures for the benzaldehydes (**16b, c**) and the methyl esters of 9-anthracenecarboxylic acid (**10**) (lit,[30] mp 297—298 °C), benzoic acids (**17a, a', b, c**) were determined by the analyses of their IR and ^{1}H NMR spectral data.

Oxidation of 2,7-Dimethoxynaphthalene (1a) with Manganese(III) Acetate. A modified procedure of Aratani and Dewar[10] was used for the oxidation of **1a** with manganese(III) acetate. A mixture of **1a** (1 mmol) and manganese(III) acetate (4 mmol for Mn(III)) was heated under reflux for 13 min in acetic acid (25 cm^3). The solvent was removed in vacuo and the residue was triturated with 2 M HCl (30 cm^3). The aqueous solution was extracted with chloroform and the obtained products were purified on TLC to give 1-acetoxy-2,7-dimethoxynaphthalene (**18**, 25%) and 2,7-dimethoxy-1,4-naphthoquinone (**19**, 39%). These compounds have the same spectral properties as those in the literature.[10]

Oxidation of 2,7-Dimethoxynaphthalene (1a) with Manganese (III) Acetate in the Presence of Acetic Anhydride. A mixture of **1a** (1 mmol), manganese(III) acetate (4 mmol for Mn(III)), and acetic anhydride (40 mmol) was heated under reflux for 4 min in acetic acid (25 cm^3). The reaction mixture was treated with the method described above to yield 1-(acetoxymethyl)-2,7-dimethoxynaphthalene (**20**, 54%).[3]

Reaction of 2,7-Dimethoxynaphthalene (1a) with Manganese(III) Acetate in the Presence of Malonic Acide-d_4. A mixture of **1a** (1 mmol), malonic acid (4 mmol), and manganese(III) acetate (4 mmol for Mn(III)) was heated under reflux for 12 h in dry benzene (25 cm^3) instead of acetic acid. After the work-up, **2a** was obtained in a 23% yield. Then, a similar reaction was carried out in the presence of malonic acid-d_4 instead of malonic acid to afford a mixture of **2a** (12%) and 1-(formyl-d)-2,7-dimethoxynaphthalene (**21**, 12%).

Oxidation of Xanthene (22) with Manganese(III) Acetate in the Presence of Malonic Acid. To a heated solution of xanthene (**22**, 1 mmol) and malonic acid (4 mmol) in acetic acid (25 cm^3), manganese(III) acetate (4 mmol for Mn(III)) was added. The mixture was heated under reflux for 1 min. The solvent was removed off and the residue was treated with

2 M HCl (25 cm^3). The aqueous solution was extracted with chloroform, which was subsequently washed with aqueous sodium hydrogencarbonate solution. The aqueous solution was acidified with concentated hydrochloric acid and then extracted with ethyl acetate. The acidic products obtained was methylated with diazomethane in methanol. The neutral and esterified products were separated on TLC to give a dimethyl ester of 9-dicarboxymethylxanthene (**23**, 20%) and 9-xanthenone (**24**, 6%).

Dimethyl Ester of 23: IR 1735, 1755 (OAc); ^{1}H NMR δ=3.53 (6H, s, 2×OCH_3), 3.54 (1H, d, J=8.4 Hz, -CH<), 4.83 (1H, d, J=8.4 Hz, -CH<), 6.89—7.43 (8H, m, arom.H); MS m/z (rel intensity), 312 (8, M^+), 196 (33), 181 (98), 168 (29), 139 (20), and 82 (100). Found: m/z 312.0988. Calcd for $C_{18}H_{16}O_5$: M, 312.0997.

The authors wish to thank Associate Professor Akira Mori of the Research Institute of Industrial Science, Kyushu University, and Dr. Teruyoshi Marunaka of the Taiho Pharmaceutical Co., Ltd., Tokushima, for their arrangement for the measurements of the mass spectra. The present work was supported by a Grant-in-Aid for Encouragement of Young Scientists No. 62740301 from the Ministry of Education, Science and Culture (1987).

Study on Conjugated Redox Membranes Containing an Intercellular Component of Wool as an Electron Carrier

Yoshiharu NAKAMURA,* Noriaki KAMON, and Teruo HORI
Department of Applied Chemistry, Faculty of Engineering, Fukui University, Bunkyo 3-9-1, Fukui 910
(Received June 2, 1988)

To realize artificially such a conjugated redox reaction as that which is drived across the biological cell membrane, two enzymic redox reactions were conjugated across a hydrogel membrane prepared with urethane prepolymer holding stabilized isocyanate groups. As redox couples, glucose 6-phosphate (G6P)/glucose 6-phosphate dehydrogenase (G6PD)/gluconolactone 6-phosphate (GL6P) and glutathione oxidized form (GSSG)/glutathione reductase (GRD)/glutathione reduced form (GSH) were chosen together with their common coenzyme, $NADP^+$/NADPH. The driving of a system consisting of two redox couples separated with the hydrogel membrane containing the coenzyme $NADP^+$ was intiated by the reduction of $NADP^+$ on the membrane surface in contact with the G6PD/G6P solution. The conjugated redox reaction proceeded by electron exchange between coenzymes in the membrane and the reproducing of $NADP^+$, which was accompanied with the GRD/GSSG solution. The rate of electron transfer across the urethane membrane was markedly accelerated by incorporating a nonkeratinous intercellular cement compound extracted from wool into the membrane. From cyclic voltammograms of a methyl viologen mediator, using a bare electrode and an intercellular compound modified carbon electrode, it was confirmed that the intercellular component could surely act as a good electron carrier.

In a previous paper[1] it was shown that methylene blue (MB) can be reduced to its leuco-form in an aqueous bath containing untreated wool fibers. However, no reduction occurred in the presence of wool fibers lacking an intercuticular cement material (δ_L component) by extraction with formic acid. In order to clarify this phenomenon a model experiment was contrived using thioglycolic acid (TGA) as a simple model compound having an -SH group like wool. According to expectations, the decolorization rate of MB was accelerated markedly by the addition of the δ_L component, indicating that the reduction of MB by -SH groups of wool could be mediated by the δ_L component.

Such a consideration was also made by Koga et al.;[2] they had observed a reverse oxidation reaction of leuconaphthazarin to naphthazarin on wool fibers in an aqueous bath and explained it by considering the reduction of disulfide (-SS-) groups of wool mediated by the δ_L component.

These two experimental facts described above suggest such a possibility that the δ_L component can work as an electron carrier for a redox system.

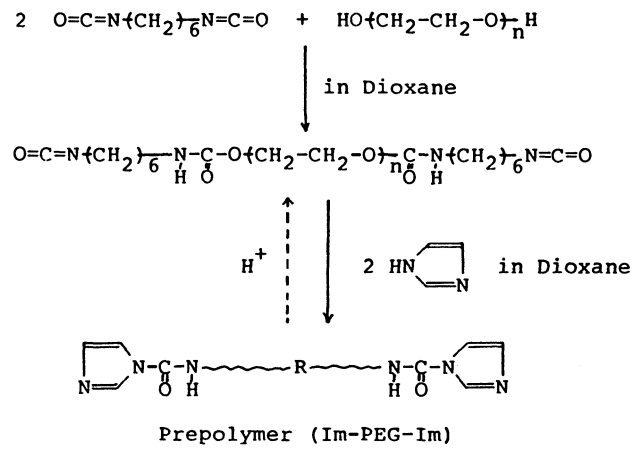
On the other hand, in connection with cell membranes there were a number of redox systems across membrane models such as micelles,[3] bilayer membranes,[4] and liquid membranes.[5] Such redox systems are, however, not suitable for practical uses because of such disadvantages as leakage of carrier or solvents from these membranes. To overcome such disadvantages, Endo et al., have devised some new systems for electron transfer across a synthetic solid membrane with a covalently bound electron mediator[6-8] and demonstrated redox reactions across the membrane. However, in the above-mentioned investigations enzymes were not used at all, which surely participate for driving the redox in real biological cell membranes.

In this study, we purposed to construct a new conjugated redox membrane system in which dehydrogenase and reductase separately adhere to both sides of a positively-charged polyurethane membrane containing $NADP^+$/NADPH as an electron mediator, and to demonstrate the driving of a redox reaction across the membrane. The intended purpose of this investigation involved improving a hitherto known conjugated redox system,[9] in which both enzymes are mixed together with their substrates and, hence, both products are also obtained in the mixture. In addition, the effect of incorporating the δ_L component into the membrane on the driving rate was investigated. It is worth noting that the δ_L component extracted from wool can truly work as an electron carrier. Except for cytochrome C, this is a unique example regarding the use of a natural electron carrier, although a large number of synthetic ones have been used.[10]

Experimental

Materials. Glucose 6-phosphate dehydrogenase (from yeast) G6PD and glutathione reductase (from yeast) GRD, nicotinamide-adenine dinucleotide phosphate $NADP^+$ and its reduced form NADPH were purchased from Oriental Yeast Co., Ltd. Glutathione, oxidized form GSSG, its reduced form GSH and glucose 6-phosphate **G6P** were all obtained commercially (Sigma) and were not further purified. The other reagents were analytical grade and used without further purifications.

Membrane. The requisites of a membrane for a conjugated redox system are as follows: the membrane should be hydrophilic because of use in aqueous system, it is charged positively to hold the negative charged coenzyme $NADP^+$/NADPH in it, and the pore size in the swollen membrane should be so adequate as to permit the thermal motion of the δ_L component in the membrane so as to diminish the leakage of enzymes, substrates, and products through the membrane.



Scheme 1. Synthesis of urethane prepolymer.

For this purpose the recently developed method to prepare an enzyme-fixed hydrophilic urethane gel membrane[11] was modified to make the membrane at lower temperature. The preparation process of the prepolymer is shown in Scheme 1.

Polyethylene glycol (PEG) (#600, Nakarai Chemicals Co., Ltd.,) (46.7 g) and hexamethylene diisocyanate (HMDI) (Tokyo Chem. Ind. Co., Ltd.,) (26.2 g) were dissolved in dioxane and heated with stirring up to 80—90 °C. The reaction was continued until the amount of an isocyanate (-NCO) group in the reaction mixture was reduced to one-half its initial value to prevent any further reaction, allophanation. The -NCO content was determined by the Sigga-Hanna method.[12] To protect the end -NCO group of produced poly(oxyethylene) bis(6-isocyanatehexylcarbamate), it was reacted with 2 molar imidazole in dioxane at 40 °C for 24 h. The prepared prepolymer (Im-PEG-Im) was stable for at least 6 months under dry conditions. Considerably strong and thin hydrogel membranes could be prepared by casting the mixture of the prepolymer Im-PEG-Im and 20% excess of aqueous solution of diethylenetriamine (DETA 0.5 mol dm^{-3}) as a cross-linking agent on a glass plate framed by a circled silicone rubber at room temperature for 2 days. The membrane was immersed in water for 1 to 2 weeks to remove dioxane and released imidazole.

Electron Carrier. The extraction of the nonkeratinous δ_L component was carried out by the usual method, described by Bradbury et al.[13] The Cu^{2+} content in the δ_L component was determined to be 1.65 mmol g^{-1} by using the Bathocuproin method.[14] From the amino acid analysis it became clear that the δ_L contained a relatively large amount of histidine, compared with the other fractions of wool.[1]

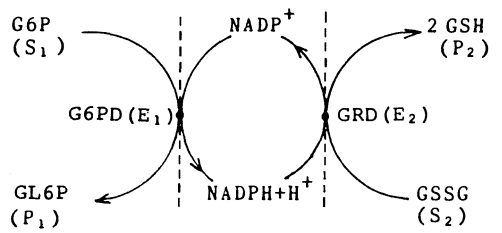
The incorporation of the δ_L component into the membrane was carried out as follows: the δ_L component (10 mg) dissolved in an aqueous solution of DETA (0.5 mol dm^{-3}, 1 ml) was mixed with Im-PEG-Im (1 g); the mixture was then cast on a glass plate to form a membrane.

Measurements. Cyclic Voltammetry: In order to confirm that the δ_L component can act as an electron carrier, cyclic voltammetry was employed. A Yanaco Voltammetric Analyzer P-1000/Function Generator FG-121B was used with an X-Y recorder for cyclic voltammetry. The electrode assembly consisted of a carbon electrode GC-P2, Yanaco P_{010} (not-modified or δ_L-modified) as a working electrode, a sodium chloride saturated calomel electrode (SSCE) as a reference electrode and a platinum spiral as a counter electrode. 1.0-M $NaClO_4$ solutions (1 M=1 mol dm^{-3}) adjusted to pH 7.0 with 0.02-M phosphate buffer, was used as the supporting electrolytic solution. The δ_L modified carbon electrode was prepared by casting a formic acid solution of the δ_L component (10 mg/g) on the electrode surface and drying it in air. The concentration of MV was 0.25-mM. As a model of δ_L, a 1-mM aqueous solution of Cu^{2+}-histidine (mixture of $CuSO_4$ and aqueous histidine solution in a molar ratio of 1 : 10) was also measured using a bare carbon electrode as the working electrode.

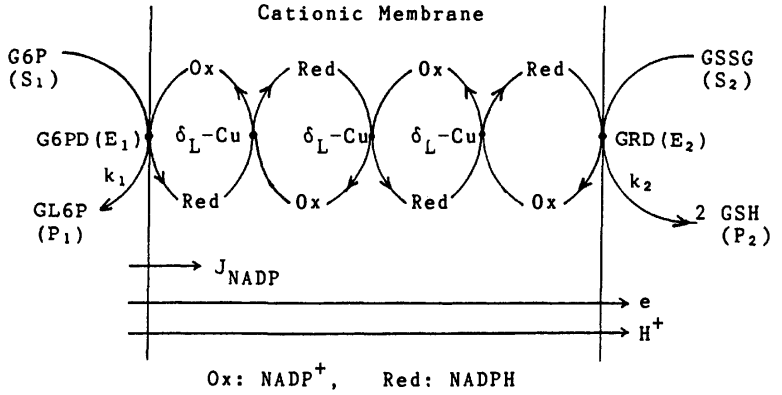
Differential Pulse Polarograhy: The reaction kinetics was followed by measuring the concentration of GSH and GSSG in the reaction system by means of a differential pulse polarographic method (DPP method), which is based on the fact that the reduction peak for GSSG in the DPP chart is shifted to a larger negative potential upon adding $NADP^+$; however, that for GSH it is not shifted.[15] The instrument used was a Yanaco Voltammetric Analyzer P-1000 with a Watanabe X-Y recorder WX4401. A stock solution of 4-M $NaNO_3$ containing a 0.08-M phosphate buffer was mixed with a sample solution of GSSG, GSH or both mixture and NADPH in appropriate ratio; the solution was then transferred to an electrochemical cell. The differential pulse polarograms of the sample solutions were measured at the scan rate 5 mV s^{-1}. From the corresponding peaks the amounts of GSSG, GSH, and NADPH were determined.

Membrane Potential: The membrane potential was determined in a cell that consists of two compartments as shown previously.[16] The potential was measured by means of a Digital Multimeter TR6843 (Takeda Riken Co., Ltd.) with pin-hole type of Ag/AgCl/sat. KCl electrodes (Horiba Co., Ltd. #2010). The mean value of two measurements obtained by exchanging the electrodes in both compartments was taken as a reliable membrane potential. The concentration of the KCl solution was kept constant in one compartment at $1{,}0 \times 10^{-3}$ M and in the other compartment at 1.0×10^{-4} M. The temperature was controlled at 25±0.2 °C.

Driving of Conjugated Redox Reaction: A conjugated redox reaction was performed by using a two-compartment cell, as shown in Scheme 2. Both compartments **I** and **II** were filled with a 35.0 ml phosphate buffer solution of pH 7.8, an optimum pH for activating both enzymes. To support the driving of the conjugated reaction a coenzyme, NADPH or $NADP^+$ was added to compartment **I** and adsorbed in the membrane. At the same time, the diffusion flux $J_{NADP(H)}$ of NADP(H) through the membrane was measured. The NADP(H) concentration was determined spectrophotometrically (molar extinction: 6.20×10^3 l mol^{-1} cm^{-1} at 340 nm). After this measurement, the solutions were taken away and a 0.25-mM $NADP^+$ aqueous buffer solution was again freshly filled in both compartments and the 1 mmol



Scheme 2. A conjugated redox-enzyme system.



Scheme 3. Effect of δ_L-Cu as electron carrier on the conjugated redox system.

G6P and 0.6 mmol GSSG in compartments **I** and **II**, respectively. The reaction was started by adding 0.3 mg of G6PD to compartment **I** and 0.35 mg GRD to the compartment **II** at same time, respectively. The concentration change of GSSG and GSH in both compartments with time was followed by the method described above. Before the measurements it was confirmed that both the enzymes G6PD and GRD could not permeate through the membrane, perhaps because of their large molecular sizes and their high affinity against positively charged membranes.

The cyclic voltammetry, the differential pulse polarography and the conjugated redox reaction were performed in the O_2-free solutions.

Results and Discussion

Some characteristics of the membranes prepared are summarized in Table 1. Membrane Code 0 was prepared without the incorporation of the δ_L component, while Membrane Code δ was obtained by mixing the δ_L component. The thickness of these membranes was almost the same (ca. 120 μm). However, the pore sizes of the membranes were considerably different from each other: 0.22 and 0.12 μm for Membrane Code 01 and δ2, respectively. It is clear from the large negative membrane potential that both membranes were charged positively. This means that negative charges in the δ_L component, appearing at the adjusted pH of the test solution, could not overcome positive charge in the urethane membrane.

Figure 1 shows cyclic voltammograms of MV using (a) a bare carbon electrode and (b) a δ_L-modified carbon electrode. The electrode reaction proceeds as

Table 1. Properties of Prepared Urethane Membranes

Membrane code	Thickness	Pore size	Membrane potential
	μm	μm	mV
01	120	0.22	−54.8
02	148	0.18	−51.0
δ1	106	0.14	−52.6
δ2	123	0.12	−49.6

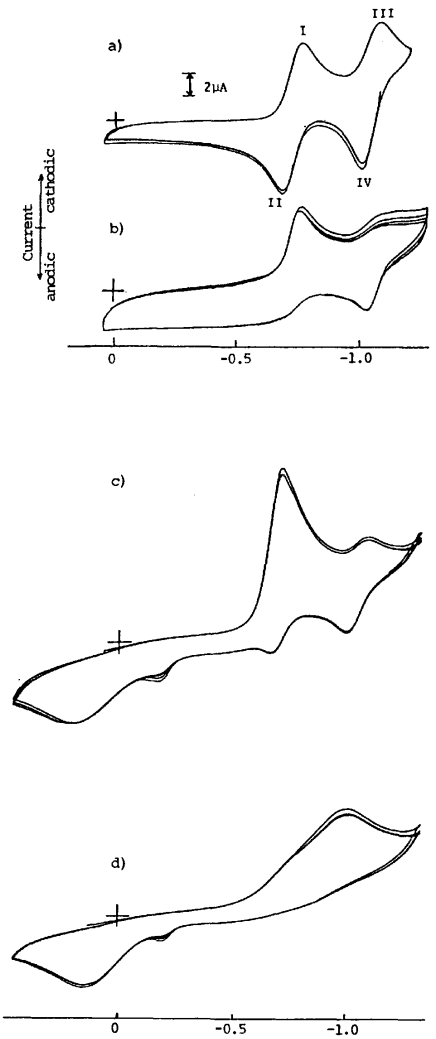


Fig. 1. Cyclic voltammograms of methyl viologen, supporting electrolyte: 1 M $NaClO_4$, pH 7.0 (0.02 M phosphate buffer), sweep rate: 150 mV s^{-1}.

follows:[17,18]

$$MV^{2+} + e \underset{II}{\overset{I}{\rightleftharpoons}} MV^{+\cdot} \quad (1)$$

$$MV^{+\cdot} + e \underset{IV}{\overset{III}{\rightleftharpoons}} MV^{\circ} \quad (2)$$

The numbers in **I—IV** correspond to those on the peaks of the curves in Fig. 1. The second reduction peak and the second oxidation peak were found to be smaller for the electrode (a), probably because the $MV^{+\cdot}$ produced in the first reduction step could be consumed by Cu^{2+} ions contained in the δ_L component. This could be confirmed from the fact that the same decrease in the peaks of CV was observed for a measurement of an aqueous MV solution containing a Cu^{2+}-histidine complex (Fig. 1c).

A typical feature of the conjugated redox reaction is shown in Fig. 2 for the case of a membrane containing δ_L. In this figure the concentrations of GSSG and GSH in components II are plotted against time. From the fact that the concentration of GSSG decreased and that of GSH increased after elapsed time, and the latter approached nearly double the initial concentration of GSSG, it is suggested that the recycle reaction between $NADP^+$ and NADPH occurs in the membrane, even if only small amounts of $NADP^+$ or NADPH (much fewer than one equibalent of the substrate) were added to the system. It should be noted that two GSH molecules are produced from one GSSG molecule. In this figure, the total concentration of glutathione in GSSG-form in both compartments was also plotted. This concentration decreases after a certain time, increases again and approaches a constant value equal to the initial concentration. This could be considered to be caused by the interaction of GSSG with the coenzyme adhering in the membrane (the interaction of GSSG with $NADP^+$ observed in DPP measurement).

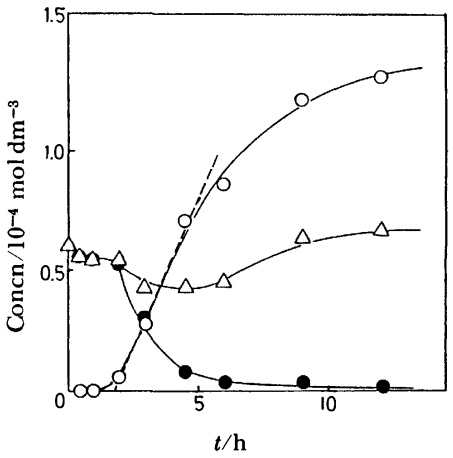

Fig. 2. Reduction of GSSG(●) and production of GSH(○) in compartment II in a conjugated redox reaction across the membrane containing δ_L component.
Membrane thickness; 90 mm(sustained Cu-treatment). △ shows the sum of GSSG and GSH (reduced to GSSG form).

For cases of membranes without δ_L, similar results were obtained, except that the concentration change of GSSG and GSH were much slower. The maximum production rate of GSH and the permeation time-lag were obtained from the slope and the intercept on the time-axis of the asymptote of the GSH-production curve (see Fig. 2), respectively. The effect of the electron carrier was estimated using the electron-transfer efficiency (ETE value),

$$ETE = J_{NADP(H)\leftarrow GSH} / J_{NADP(H)}, \quad (3)$$

where $J_{NADP(H)\leftarrow GSH}$ is an imaginary diffusion flux of NADP(H) reduced under the assumption that the production of GSH proceeds stoichiometrically according to the amount of NADPH diffused out through the membrane ($GSSG+NADPH+H^+ \rightarrow 2\ GSH+NADP^+$).

Kinetic data on the driving of the conjugated redox reaction through the membrane under various conditions are summarized in Table 2. Experiments No. 1 to 3 were made using membranes without the electron carrier δ_L component. No. 1 was driven without a prepermeation of the coenzyme, while Nos. 2 and 3 were driven after prepermeations of $NADP^+$ and NADPH, respectively. All of the values, d[GSH]/dt,

a) Calculated by using J_{NADPH}.

time-lag, $J_{NADP(H)\leftarrow GSH}$ and ETE-values were found to be almost same for both experiments. Of interest is the fact that the ETE-value is larger than 1. This means that the production of GSH in component II does not proceed based only on a simple diffusion of NADPH. Considering the fact that the time-lag of No. 3, in which NADPH was prepermeated, was not shorter than that of No. 2, an ETE-value larger than 1 can be explained considering either: that the electron exchange in the membrane took place between $NADP^+$ and NADPH, if they are ordered side by side in the membrane; or that not only the substrate, but the enzyme also could be condensed in the membrane because of the positive charge of the membrane. The latter should be meaningless, considering the following additional experiment: i.e. GSH was produced only in the compartment in contact with the membrane surface, on which GRD was previously adsorbed, when GSSG and NADPH were added to both compartments.

Of special interest are the results of experiments Nos. 4, 5, and 6 in the driving through the membrane entrapping the δ_L component. In these cases, the diffusion flux of $NADP^+$ is rather smaller and the time-lag are larger, compared with those in the cases of membranes without the δ_L component, perhaps because of a slightly smaller pore size, owing to the incorporation of the δ_L component in the membrane.

Experiment No. 5 was carried out by using the δ_L incorporated membrane after it was dipped in an aqueous $CuSO_4$ solution (1.6×10^{-6} mol dm^{-3}) for 24 h and slightly rinsed. In this case, GSH was not produced. An additional experiment showed that free copper ions inhibit the enzymic reaction in this system. Thus, the membrane was rinsed in water for 1 week and then used for driving experiment No. 5. A very interesting result was obtained wherein the rate of GSH-production was much larger, compared with those through the other membrane, although the diffusion flux J_{NADP} was considerably lower (1.6×10^{-12} mol cm^{-2} s^{-1}). Consequently, the ETE-value went up to over 300. In the case of the δ_L-incorporated membrane, the association of the substrates and coenzyme in the membrane could also be one of the causes of the extremely high ETE-value, though it does not seem likely considering the relatively small intake of coenzyme, and the considerably large time-lag. Therefore, it can be concluded that the large ETE-value for experiment No. 6 is achieved by the aid of the membrane-incorporated δ_L component catalyzing the electron-transfer reaction between the coenzymes. This consideration is shown schematically in Scheme 3. It is presumed that the electron can be transferred advantageously through the coenzymes probably adsorbed on the δ_L-component, a complex of Cu^{2+} with basic amino residues of polypeptides. However, further details of this electron-transfer mechanism have not yet been clarified.

Conclusion

Modeled on a biological cell membrane, an artificial conjugated redox membrane was constructed which incorporated dehydrogenase and reductase separately on both membrane surfaces. The conjugated redox reaction across the membrane was successfully demonstrated. The driving of redox reactions owes much to electron exchanges between $NADP^+$ and NADPH in the membrane. The electron-transfer efficiency (ETE value) could be improved by two orders of magnitude by incorporating the δ_L component extracted from wool fibers, compared with the fact that the ETE value was changed with the Cu^{2+} content in the δ_L component. The Cu^{2+} complex ions were regarded as being a cooperator for the electron transfer: they accelerate the electron-exchange reaction between coenzymes in the membrane.

The authors wish to express their hearty thanks to Professor Mitsugi Senda of the Kyoto University for valuable advice regarding CV measurements and to Associate Professor Shigeru Kunugi of Fukui University for useful discussions. Thanks are also due to Mrs. Yoshitaka Saito, Toshie Kobayashi, and Tomohiko Sugawara for their assistance in the experimental work.

The present work was supported by a Grant-in-Aid for Scientific Research No. 61550655 from the Ministry of Education, Science and Culture.

A part of this study was presented in the 3rd Membrane Symposium held by the Society of Fiber Science and Technology, Japan in 1987.

(Received July 16, 1988)

The mechanism of the desulfurization of the polynuclear thiophene compounds with a Raney nickel was studied in ethanol at atmospheric pressure and from 0 to 78.3 °C. The desulfurization rate was initially fast but reached zero in about 30 minutes. The major products were biphenyl in the desulfurization of dibenzothiophene (**1**), 1-phenylnaphthalene in the desulfurization of benzo[*b*]naphtho[1,2-*d*]thiophene (**2**), and 2-phenylnaphthalene in the reaction of benzo[*b*]naphtho[2,3-*d*]thiophene (**3**) and benzo[*b*]naphtho[2,1-*d*]thiophene (**4**). The desulfurization extent for the four compounds decreased in this sequence: **3**>**1**>**2**>**4**. The extent of the desulfurization of the polynuclear thiophene compound was not related to the reaction indices, Fr(E), Fr(N), and Fr(R), of the sulfur atom of the compounds, which were calculated by using a simple Hückel theory; rather, it was related to both the free valence and the π-electron density. Therefore, the polynuclear thiophene compounds were considered to adsorb on a Raney nickel through the free-electron pair of the sulfur atom; consequently, the adsorption led to the C-S bond scission.

The hydrodesulfurization of heavy petroleum feedstocks and coal-derived liquids requires the conversion of high-molecular-weight compounds like dibenzothiophene and benzonaphthothiophenes.[1,2] There are several studies in the literature which deal with the mechanism of the hydrodesulfurization of polynuclear thiophene compounds on cobalt or nickel molybdenum catalysts at high pressures and high temperatures.[3-5] However, there are only a few studies which relate the chemical reactivity of polynuclear thiophene compounds to their electronic structure,[6] although the adsorption and hydrodesulfurization of simple sulfur compounds, e.g., thiophene, have been studied recently using Hückel theory.[7,8]

There is competition between the different processes (hydrogenation and desulfurization) during the reaction. The hydrodesulfurization occurs through the extrusion of a sulfur atom to give the corresponding hydrocarbon, with some hydrogenation of the aromatic ring occurring either prior to or following the removal of the sulfur. It is difficult to understand the relationship between desulfurization and the electronic properties of the compounds under reaction conditions. However, a Raney nickel extrudes a sulfur atom from the molecule to form hydrocarbons without hydrogenation at a low temperature in a solvent. In the present investigation, the desulfurization studies are performed in a batch reactor over a Raney nickel. The sulfur compounds used here are dibenzothiophene, benzo[*b*]naphtho[1,2-*d*]thiophene, benzo[*b*]naphtho[2,3-*d*]thiophene, and benzo[*b*]naphtho[2,1-*d*]thiophene (Fig. 1). The dependence of the desulfurization extent on the electronic structure of the compounds was considered using simple Hückel molecular orbital calculations. The mechanism of the adsorption and desulfurization of benzonaphthothiophenes and dibenzothiophene is also discussed.

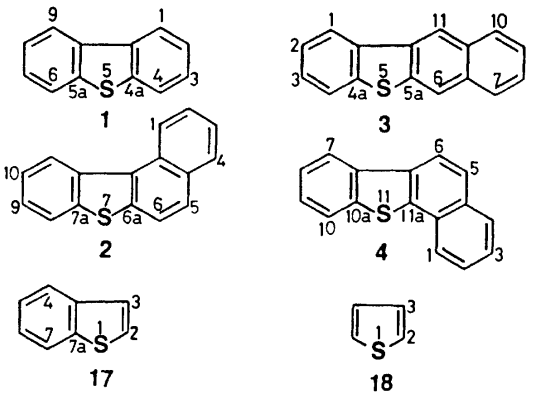

Fig. 1. Various thiophene compounds.

Experimental

Raney Nickel. The procedure was similar to that used in the preparation of W-7 Raney nickel described by Adkins et al.[9] A solution of 100 g of sodium hydroxide in 500 ml of H_2O at 50 °C was carefully added to 100 g of the Raney nickel alloy (41% Ni; Koso Chemical Co.). The addition was completed in approximately four and a half hours. The residue was washed by decantation with water and then by stirring with three successive portions of ethanol. The procedure was repeated three times using equal amounts of diethyl ether. The Raney nickel was used after it had then been stored in diethyl ether at 0 °C for more than one month.

Reactants. Dibenzothiophene (1): Compound **1** was synthesized according to the method of Gilman and Jacoby.[10] Mp 100.5—101 °C (lit, 99 °C[10])); Found: C, 78.29; H, 4.40; S, 17.31%. (Calcd: C, 78.22; H, 4.38; S, 17.40%).

Benzo[*b*]naphtho[1,2-*d*]thiophene (2): **2** was synthesized by dehydrogenating 5,6-dihydrobenzo[*b*]naphtho[1,2-*d*]-

†† Present address: Fukube Pharmaceutical Co., Ohatano, Kanagawa 257.

thiophene (**8**) in the presence of a Pd-C catalyst by the method of Campaigne and Osborn.[11] Compound **8** was obtained by the cyclization of 2-phenylthio-1-tetralone (**9**) in the presence of phosphorus pentaoxide. Compound **9** was prepared by reacting thiophenol with 2-bromo-1-tetralone. Mp 100.5—102 °C (lit, 102—102.5 °C,[10] 101.5—102 °C[11]); Found: C, 82.17; H 4.39% (Calcd: C, 82.01; H, 4.30%).

Benzo[*b*]naphtho[2,3-*d*]thiophene (3): **3** was synthesized in five stages from **1** and succinic anhydride as the starting compounds. Using 4-(dibenzothiophen-2-yl)-4-oxobutanoic acid, prepared by the Friedel Craft's reaction from the two starting compounds,[10] 4-(dibenzothiophen-2-yl)butanoic acid (**10**) was synthesized by the Huang-Minlon modification of the Wolff-Kishner reduction.[11] 9,10-dihydrobenzo[*b*]-naphtho[2,3-*d*]thiophen-7(8*H*)one (**11**) was synthesized by the cyclization of **10**.[12] Compound **3** was prepared by the dehydrogenation of the tetrahydrobenzo[*b*]naphtho[2,3-*d*]thiophene (**12**) with amorphous selenium. Compound **12** was synthesized by the reduction of **11** using the Wolff-Kishner procedure by the method of Campaigne and Osborn.[11] Mp 158.5—160 °C (lit, 160.5—161 °C,[11] 159—160 °C[13]).

Benzo[*b*]naphtho[2,1-*d*]thiophene (4): **4** was synthesized by a three stage reaction using 2-bromocyclohexanone (**13**) and 1-naphthalenethiol (**14**) as the starting compounds, while 2-(1-naphtylthio)cyclohexanone (**15**) was prepared by condensing **13** and **14**, which had been synthesized according to the method of Rabindran and Tilak.[12] Compound **4** was synthesized by the dehydrogenation of 7,8,9,10-tetrahydrobenzo[*b*]naphtho[2,1-*d*]thiophene (**16**) using amorphous selenium powder.[12] **16** was prepared by heating a mixture of **15** and phosphorus pentaoxide.[9] Mp 184—185 °C (lit, 182—184 °C,[11] 184—185 °C,[12] 186—187 °C[13]).

Apparatus and Procedure. Ten ml of abs. ethanol was placed in a pear-shaped flask equipped with a thermometer, a Dimroth condenser, and an electric stirrer. The Raney nickel (ca. 0.2 g) was weighted into the flask. An amount of the sample (0.2—1.47 mmol) was added to a certain solvent with the Raney nickel. The flask was then immediately placed in a glycerol bath at room temperature. After the solution had quickly been raised to the desired temperature, the stirrer was started and the initiation time was recorded. After the reaction, the flask was removed from the glycerol bath and cooled to room temperature. The catalyst was removed by filtration and washed with ethanol. The reaction mixture was then concentrated by evaporation to remove the solvent.

Analysis. The reaction products were analyzed by the use of conventional gas chromatography (Column packing: Apiezon Greese 20% Chromosorb W or Silicone OV-17 5% Uniport HP), using acenaphthene as the internal standard. The reaction products were identified by comparing the retention times with those obtained for known samples. No H_2S was observed during the reaction. Hydrogen sulfide was not trapped as zinc sulfide when an aqueous solution of zinc acetate was used for trapping. The extent of desulfurization, R, (mmol/g-Raney nickel), was calculated by the use of the following equation: $R=(A_0-A)/W$. A_0 is the initial number of moles of the reactant, while A is the number of moles of the reactant which have not reacted. W is the weight of the Raney nickel.

The simple Hückel theory (NEC microcomputer, Model PC-9801VM2) was used to calculate the π-electron density of a sulfur atom in addition to such other reaction indices as the π-bond order, free valence, and Fr(E), Fr(N), and Fr(R) introduced from the highest occupied, lowest unfilled, and singly occupied orbital (HOMO, LUMO, and SOMO) coefficients. In addition, benzothiophene (**17**) and thiophene (**18**) were studied in order to compare their behavior with that of the above compounds.

Results

Desulfurization of Dibenzothiophene. The extent of the desulfurization of dibenzothiophene with the Raney nickel in the ethanol solvent is shown in Fig. 2. Biphenyl was the principal product, with other compounds being formed only in trace amounts. The rate of desulfurization was fast initially, but reached zero in each case following a reaction time of about 30 minutes. This observation suggested that the activity of the Raney nickel was extremely high initially and that it then gradually diminished with the reaction. Therefore, for the time being, we shall assume that the desulfurization activity of the Raney nickel can be estimated by means of the initial rate of the desulfurization, v_0, at the starting time. The initial rates are 2.1, 1.5, 1.2, and 0.23 mmol/g-cat·h at 78.3, 48.8, 20.0, and 0 °C respectively.

A plot of log v_0 vs. $1/T$ gives an activation energy of 18.4 kJ mol^{-1} for the desulfurization of dibenzothiophene. This result is in good agreement with those obtained by Bartsch and Tanilian,[14] who studied the hydrodesulfurization of benzothiophene and dibenzothiophene, in dodecane as a solvent, over a sulfided $CoMo/Al_2O_3$ catalyst under atmospheric pressure and at 300—400 °C. These authors reported activation energies of 20.5 (for benzothiophene) and 22.5 kJ mol^{-1} (for dibenzothiophene). Moreover, a value of 15.5 kJ mol^{-1} was observed by Satterfield and Robert[15] for the

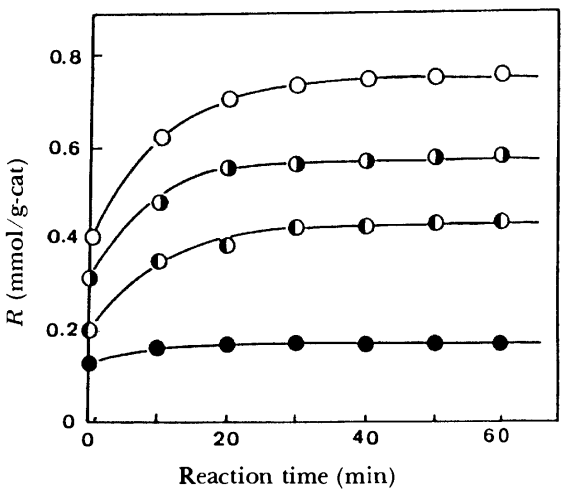

Fig. 2. The extent of desulfurization of dibenzothiophene with the Raney nickel in the ethanol solvent. The initial amount of the sample was 0.294 mmol and the catalyst weight was 0.2 g, ○: 78.3; ◑: 48.8; ◐: 20.0; ●: 0 °C.

hydrodesulfurization of thiophene over a sulfided $CoMo/Al_2O_3$ catalyst at 234—265 °C and at atmospheric pressure using a continuous-flow, stirred-tank reactor. On the other hand, in a previous gas phase study carried out in a fixed-bed microreactor,[16] an activation energy of 102 kJ mol^{-1} for the hydrodesulfurization of dibenzothiophene over a sulfided $NiMo/Al_2O_3$ catalyst was obtained. This is significantly higher than the 18.4 kJ mol^{-1} reported in the present study, which was performed in ethanol at low temperatures. These different results appear to be attributable to differences in the diffusion limitation for reactions carried out in the gas phase as opposed to the liquid phase.

The Initial Rate vs. the Extent of Desulfurization at 60 min. The Raney nickel initially exhibited a very high activity with dibenzothiophene, even though the reaction occurred before the reaction temperature reached the desired temperature. It is difficult to measure accurately the high initial rate of dibenzothiophene in the solvent of hydrocarbons, and there is a poor reproducibility in estimating the values of the desulfurization of benzonaphthothiophenes in small amounts. The Raney nickel gradually became less active during the reaction, though the extent of desulfurization was constant 60 min after the reaction had started. The extent of desulfurization at 60 min showed the total activity of the Raney nickel over the reaction time. Figure 3 shows that the extent of desulfurization at 60 min was proportional to the initial rate of desulfurization. Therefore, the extent of desulfurization at 60 min will be applied to further measurements of the desulfurization of dibenzothiophene and benzonaphthothiophenes with the Raney nickel.

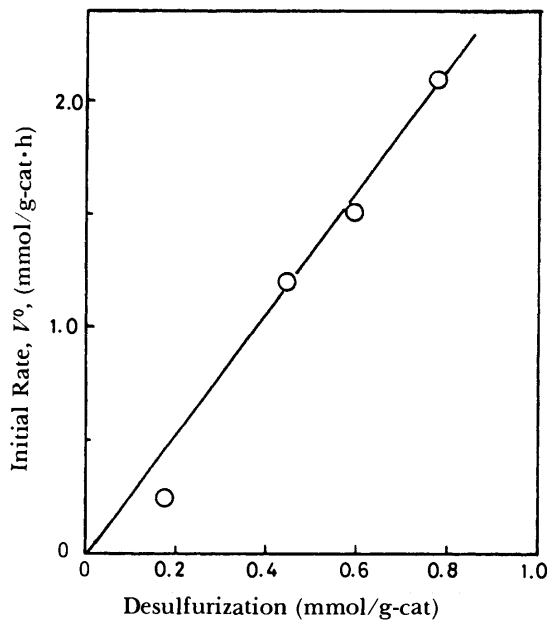

Fig. 3. The extent of desulfurization of dibenzothiophene at 60 min was proportional to the initial rate of desulfurization at 78.3 °C.

Effects of Solvents on the Desulfurization of Dibenzothiophene. The effects of the solvents on the desulfurization of dibenzothiophene by the Raney nickel at 78.3 °C for 60 min are shown in Table 1. The solvents exhibited a strong effect on the desulfurization activity of the Raney nickel. A high extent of desulfurization was observed when nonpolar solvents such as benzene or xylenes were used as solvents. This observation suggests that the nonpolar solvent blocks the Raney-nickel surface to a smaller extent than do other solvents. On the other hand, protic solvents, such as acetic acid and formic acid, depress the desulfurization. The extent of the desulfurization of dibenzothiophene in the presence of formic acid, acetic acid, and ethanol decreases with a decrease in the Y values of formic acid (Y value, +2.05), acetic acid (−1.64), and ethanol (−2.03). Since the Y value represents the ability of ionization of a solvent to the Raney nickel,[17] the protic solvents appear to decrease the activity of the Raney nickel because of the ionization of the nickel atom of the Raney nickel. Furthermore, formic acid poisons the surface of the Raney nickel by its carbonyl group.

Raney nickel contains hydrogen.[18,19,20] The carbon-sulfur bond of dibenzothiophene is split, and biphenyl formation occurs after the hydrogen has been used up. The solvent also reacted with this hydrogen of the Raney nickel. Methyl ethyl ketone was hydrogenated by the hydrogen. Therefore, the desulfurization of dibenzothiophene on the Raney nickel was depressed by the solvents because of the decrease in the amount of hydrogen in the Raney nickel, as well as because of the poisoning effect of the solvents and because of the ionization of the nickel atom of the Raney nickel.

Reactivity of Dibenzothiophene and Benzonaphthothiophenes. The desulfurization of dibenzothiophene and benzonaphthothiophenes over a Raney nickel in the ethanol solvent was performed at 78.3 °C for a period of 60 min. The major products (biphenyl **5** in the desulfurization of **1**, 1-phenylnaphthalene (**6**) in the desulfurization of **2**, and 2-phenylnaphthalene (**7**)

in the desulfurization of **3** and **4**) are shown in Fig. 4. Observation of these products shows that the reaction occurs through the extrusion of a sulfur atom to give the corresponding hydrocarbon, without any hydrogenation of the aromatic ring occurring either prior to or following the removal of sulfur. This indicates that the perpendicular adsorption of these compounds to the nickel atom is preferred during the reaction.

The results of the desulfurization of the four compounds with the Raney nickel in the ethanol solvent at 78.3 °C for 60 min are shown in Table 2. The extent of desulfurization for the four compounds decreased in this sequence: **3>1>2>4**. These results show that the tricyclic thiophene compound is not always more reactive than the tetracyclic compounds, since the reactivity of dibenzothiophene is lower than that of compound **3**. This last result is consistent with that obtained by Sapre et al.,[3] who found **3** more reactive than **1** on a sulfided $CoMo/Al_2O_3$ catalyst. This suggests that the reactivity of polynuclear thiophene compounds is not governed solely by the size of the molecule, but also by other elements which are related to the molecular structure.

Electronic-Structure Calculations. Parameters appropriate for the thiophene molecule are given in review articles by Zahradník[21,22] and Zdražil et al.[23] In this parameterization, $\alpha(S)=\alpha(C)+\beta(CC)$, $\alpha(C_\alpha)=\alpha(C)+0.1\beta(CC)$, and $\alpha(C_\alpha S)=0.8\beta(CC)$. Duben[24] studied thiophene using the simple Hückel molecular theory. He reported that, after a few trials had been made with other parameters, the only differences noted

Table 3. π-Electron Density and π-Bond Order of the Thiophene Compounds as Determined by a Simple Hückel Molecular Orbital Theory

Compound	q_s[a]	q_s-q_c[b]	πBond order of C-C bond	π-Bond order of C-S bond
			(2-3)	(4a-5) (5-5a)

a) $2(C_{HOMO,S})^2$. b) $2(C_{LUMO,S})^2$. c) $(C_{HOMO,S})^2+(C_{LUMO,S})^2$.

were some small changes in the orbital coefficients. For this reason, it was decided that the parameters specified in Zahradinik's article[21] could be used. Using these parameters, the Hückel molecular orbitals of polynuclear thiophenic compounds which are not adsorbed on the catalyst surface were calculated. The π-electron density of the sulfur atom and the π-bond order of the C-S bond are shown in Table 3, while the reaction indices, Fr(E), Fr(N), and Fr(R), of the sulfur atoms are presented in Table 4. Fr(E), Fr(N), and Fr(R) represent the ease of electrophilic, nucleophilic, and radical reactions at the sulfur atom of the compounds respectively. The π-electron density of the four compounds decreased in the following order: **3>1>2>4**. This order is in agreement with that of the desulfurization, but not with those of the reaction indices, Fr(E), Fr(N), and Fr(R).

Discussion

Relation between Desulfurization and Electron Structure. It was shown that the extents of desulfurization of the four compounds in ethanol at 78.3 °C for 60 min were 0.86, 0.78, 0.63, and 0.58 mmol/g-Raney nickel respectively. The correlation between the π-electron density of the sulfur atom of the polynuclear thiophene compounds and the extent of desulfurization is shown in Fig. 5. These data demonstrate that the desulfurization extent is proportional to the π-electron density of the sulfur atom. It appears, there-

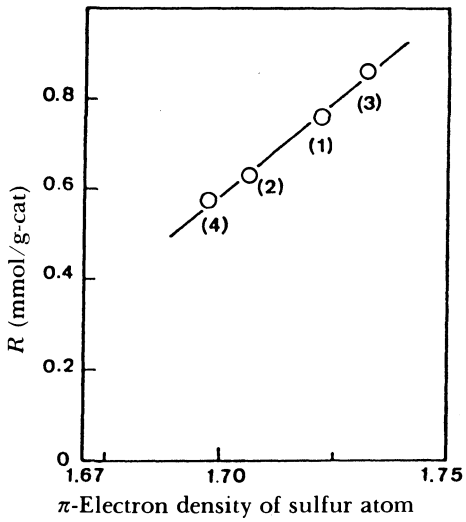

Fig. 5. Relationship between the extent of desulfurization of the polynuclear sulfur compounds and the π-electron density of their sulfur atom. The initial amount of sample was 0.2 mmol and the weight of the Raney nickel was 0.2 g.

fore, that the desulfurization which occurs on a Raney nickel depends on the π-electron density of the sulfur atom. This, in turn, is related to the strength of the adsorption of sulfur to a surface nickel atom of the Raney nickel. Hauptmann and Wladislaw[25] have also reported that the desulfurization was responsible for the first step of the reaction, that is, the adsorption of the organic compound on the metallic surface. This interaction with the Raney nickel is accomplished through the free-electron pair of sulfur. The sulfur can then readily split off from the ring without saturation occurring.

4 might be expected to exist a steric hindrance on the desulfurization, since it has the benzene ring in the compound on the side of the sulfur atom. Table 3 shows, however, that the π-bond order of C_{11a}-S_{11} of **4** is greater than that of C_{10a}-S_{11} of **4** which is similar to that of C_{7a}-S_7 of **2** and that, therefore, **4** is more easily desulfurized than expected, even though it has a steric hindrance. Thus, the preferential fission of the C-S bond can offset the effect of steric hindrance. Therefore, the interaction of the π electrons of the sulfur atom with the Raney nickel surface is more important than the molecular size for the desulfurization of polynuclear thiophene compounds over a Raney nickel.

Desulfrization Mechanism. Eisch and his coworkers[26] have undertaken a mechanistic study of the desulfurization of dibenzothiophene by the (2,2′-bipyridyl)nickel (0) complex and reported that a radical anion of the thiophene nucleus was formed and that this subsequently underwent C-S bond cleavage into S^- and aromatic radicals. However, it is obvious that there is no correlation between the desulfurization rate and the reaction indices, Fr(E), Fr(N), and Fr(R), as is shown in Table 4. These results suggest that there is no evidence in this study for either electron transfer or nucleophilic attack. Moreover, the radical reaction is not the rate-determining step in the desulfurization of the thiophene compounds on the Raney nickel, although the mechanism of desulfurization over a Raney nickel is most generally a free-radical mechanism.[25,27,28] Therefore, the rate-determining step in this reaction is not a C-S bond breaking, but the adsorption of the sulfur compound to a nickel atom of the Raney-nickel surface, with a competitive adsorption of the solvent. This adsorption leads to the removal of the sulfur from the thiophene compound. The sulfur reacts with the nickel atom of the Raney nickel to form nickel sulfide, but not hydrogen sulfide.

In the first step, the unshared electron pair of the sulfur is attracted to a low-valent nickel atom of the Raney-nickel surface. The compound is adsorbed on the surface through the unshared electron pair of sulfur, which acts as an electron donor. The carbon-sulfur bond is, therefore, weakened, and a free radical is formed. The hydrogen present on the Raney-nickel surface[18,19,20] then reduces the radical to the corresponding hydrocarbon.

On the other hand, for the monocyclic and bicyclic thiophene compounds, the hydrogenation of the C_2-C_3 bonds of **17** and **18** appears to take place competitively with the fission of the C-S bond. The difference (q_s—q_c) between the π-electron density of the sulfur atom and that of the carbon atom (C_3) (the carbon atom with the highest π-electron density) is small, although the charge density index refers to the nature of the molecule before allowance is made for perturbing effects due to the approaching reactant. Furthermore, the bond order of the C_2-C_3 bonds of **17** and **18** is larger than that of the others. For this reason, these two molecules must chemisorb by a multi-point mechanism.[29] According to the multi-point mechanism, thiophene molecules are chemisorbed in such a way that the C_2-C_3 bond is coordinated to an anion vacancy at the surface, with the adjacent sulfur center interacting with a contiguous sulfur atom on the surface. The mechanism by which the tricyclic and tetracyclic thiophene compounds are desulfurized is, therefore, quite different from that of the monocyclic and bicyclic compounds, **17** and **18**.

The Adsorption and Desorption of Nitrogen Oxide by the Aqueous Dispersion of the Chelate Resin-Immobilized Iron(II) Complex

Naoki TOSHIMA,* Hiroyuki ASANUMA, Kazuaki YAMAGUCHI,† and Hidefumi HIRAI††
Department of Industrial Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received August 19, 1988)

Aqueous dispersions of the chelate resin-iron(II) complex were prepared by ion-exchange in water from iron(II) sulfate and a chelate resin containing iminodiacetic acid moieties. The resulting dispersions in water (50 cm^3) can adsorb 78% of the nitrogen oxide (NO) from 6 dm^3 of nitrogen gas containing 1000 ppm of nitrogen oxide at 25 °C. The adsorption rate of NO by the dispersions depends greatly on both the particle size of the chelate resin used and the concentration of iron(II) in the supernatant. A fast adsorption of nitrogen oxide can be achieved by using small particles of the chelate resin and by dissolving a large amount of iron(II) ions in the aqueous part of the dispersions. The adsorption and desorption of nitrogen oxide can be understood in terms of a 1 : 1 reversible coordination of NO to the iron(II) ion immobilized on the chelate resin. The equilibrium constant, enthalpy change, and entropy change for the above adsorbing reaction were 3.11×10^4 $dm^3\,mol^{-1}$, −45.6 $kJ\,mol^{-1}$, and −68.2 $J\,K^{-1}\,mol^{-1}$ respectively. Since the adsorbing reaction of NO in this system is reversible, the adsorbed NO can be released by heating the dispersions which have already adsorbed NO. The amount of the released NO can be predicted from the equilibrium constant at the releasing temperature. Moreover, a concentrated recovery of the NO can be achieved by the present aqueous dispersions system.

The concentration of NO in the atmosphere has never decreased in the past decade in spite of many efforts. Since NO is toxic for the human body and causes photochemical smog through nitrogen dioxide, advanced technology for the removal of NO is strongly desired. At the present time, the catalytic reduction of NO into innoxious nitrogen by using a gaseous reducing agent like ammonia or hydrogen is a well-known practical method for the removal of NO.[1-4] This method has, however, some disadvantages, such as a rapid deactivation of the catalyst by the contaminated gases (sulfur dioxide) or dust. On the other hand, aqueous absorbents for NO have been studied because of the relatively high durability against these contaminants. The typical solution systems involve: 1) an aqueous solution of sodium hydroxide, where NO is absorbed by the aqueous solution after the oxidation of NO to NO_2 by contact with O_3,[5] and 2) an aqeous solution of iron(II)-ethylenediaminetetraacetic acid (Fe(II)-EDTA), where NO can form a complex with Fe(II)-EDTA.[6-9] Among these methods, the aqueous solution of Fe(II)-EDTA is noteworthy for its high capability for the absorption of NO and its possible application for the simultaneous removal of NO and sulfur dioxide.[9] This solution, however, has disadvantages in the recovery of the Fe(II)-EDTA complex for the recyclic usage, since the complex is easily dissolved in water and the Fe(II) ions are easily oxidized into inactive Fe(III) ions.

In the present investigation, the immobilization of Fe(II) ions on the chelate resin involving iminodiacetic acid moieties (Fig. 1) instead of EDTA and the dispersion of the resulting Fe(II)-chelate resin complex (CR-Fe(II)) into water were examined for the purpose of establishing a method of ensuring easy handling, a concentrated recovery of NO, and an improvement in the durability against oxygen. In general, the immobilization of metal ions on the polymer resin gives rise to the following advantages:[10] 1) Easy recovery and repeated use of the metal complex; 2) the stabilization of the complex or protection of the active species by the polymer matrix against oxygen or water, and 3) an improvement in the activity by the polymer field. Many successful results supporting these advantages have been reported in the macromolecular metal complex catalyst system.[11] In the present paper, the preparation and characterization of aqueous dispersions of the chelate resin-immobilized Fe(II) complex, and its properties for the adsorption and desorption of NO will be described in detail.[12,13]

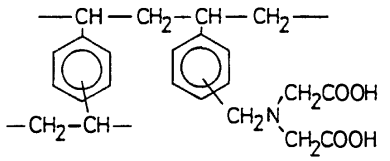

Fig. 1. Structure of the chelate resin.

Experimental

Materials. The chelate resin (Diaion CR-10; mean diameter of the particles, 0.5 mm), purchased from Mitsubishi Chemical Industries, Ltd., was used without further purification. The commercial resin was swollen with water. One gram of the swollen substance was determined by the pH-titration method to contain 0.98 mmol of iminodiacetic acid moieties. One gram of the resin dried in vacuo, on the other hand, had 2.78 mmol of the moieties. A mass of the chelate resin in a dry or a swollen state containing 21.0 mmol of iminodiacetic acid moieties was used at one time for the preparation of each aqueous dispersion.

† Present address: Applied Research Laboratory 1, Lion Co., Hirai, Edogawa-ku, Tokyo 132.
†† Present address: Department of Industrial Chemistry, Faculty of Engineering, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162.

The iron(II) sulfate 7 hydrate, iron(II) perchlorate 6 hydrate, and iron(II) chloride *n* hydrate (*n* was determined to be 4.59 by the 1,10-phenanthroline method[14]) were used without further purification.

Mixed gases of NO and nitrogen of the designed NO concentration were purchased from Takachiho Shoji, Ltd., and were used without further purification.

The chelate resin in a small size was prepared by grinding the commercial chelate resin with an agate mortar and a pestle. Its mean particle size was proved to be 10 μm by measurement with an optical microscope. In order to avoid any differences in the particle size in the experimental lots, the chelate resin was previously ground on a large scale, and all the dispersion systems were prepared by using samples of the same lot.

Preparation of Absorbents or Adsorbents. (1) Aqueous Dispersions of the Chelate Resin-Immobilized Iron(II) Complex: Chelate resin containing 21.0 mmol of iminodiacetic acid moieties (21.4 g in the swollen state, or 7.53 g in the dry state) was added to 15 cm^3 of water in which a desired amount of Fe(II) sulfate had been dissolved under nitrogen. The resulting mixtures were shaken for 48 h with a mechanical shaker or magnetic stirrer to immobilize the Fe(II) ions on the chelate resin.

(2) An Aqueous Solution of the Iron(II)-EDTA Complex: An aqueous solution of the Fe(II)-EDTA complex, used as a conventional absorbent of NO, was prepared by dissolving 0.139 g (0.50 mmol) of $FeSO_4$ $7H_2O$ and 0.187 g (0.50 mmol) of EDTA 2Na $2H_2O$ in 50 cm^3 of water under oxygen-free conditions.

(3) An Aqueous Solution of Iron(II) Salt: Various kinds of Fe(II) solutions were prepared by dissolving 31.4 mmol of various Fe(II) salts in water under oxygen-free conditions, adjusting the total volume of the solution to 50 cm^3.

(4) Dispersions of the Chelate Resin-Immobilized Iron(II) Complex in an Aqueous Iron(II) Solution at a Designed Concentration: After the preparation of aqueous dispersions of the immobilized complex from 7.53 g of the ground chelate resin and 8.72 g (31.4 mmol) of $Fe(II)SO_4$ $7H_2O$, the supernatant of the dispersions was removed by use of a centrifuge. Adding 15 cm^3 of a fresh aqueous solution of $FeSO_4$ $7H_2O$ at a desired concentration provided dispersions of the immobilized Fe(II) complex in a Fe(II) solution. The exact concentration of the Fe(II) ions in the supernatant was determined by the 1,10-phenanthroline method.[14]

Characterization of Aqueous Dispersions of the Chelate Resin-Iron(II) Complex. (1) Electronic Spectra of the Complexes: The electronic spectra of the aqueous solutions of the complexes were measured with a Hitachi model 340 spectrophotometer. The electronic spectrum of the dry or wet chelate resin-immobilized Fe(II) complex was measured at room temperature with the same spectrophotometer equipped with an integrated reflection apparatus.

(2) Measurement of the Amount of the Iron(II) Ions Immobilized on the Chelate Resin: The amount of immobilized Fe(II) ions was measured by the following method. Fifty cm^3 of an aqueous solution of $FeSO_4$ with an exact, desired amount was added to 7.53 g of the dry chelate resin (containing 21.0 mmol of iminodiacetic acid moieties), after which the mixture was stirred for 48 h. After the immobilization of the Fe(II) ions on the chelate resin, the concentration of the Fe(II) ions in the supernatant was measured by the 1,10-phenanthroline method,[14] while the amount of immobilized Fe(II) ions was calculated from the decrease in the concentration of Fe(II) ions in the aqueous phase.

Adsorption and Desorption Experiment on NO. (1) Adsorption of NO: Adsorption experiments on NO were carried out by using the closed-circulation system illustrated in Fig. 2. After removing the remaining gas in the system with a vacuum pump, 6 dm^3 of nitrogen containing 1000 ppm (or 980 ppm) of NO (the total amount of NO was 0.246 mmol) was introduced into this apparatus at room temperature and then circulated inside the apparatus, bubbling the aqueous dispersions through by means of a gas pump at the rate of 1.6 $dm^3\,min^{-1}$. The adsorbent was kept at the desired temperature in a water bath with a thermostat.

Changes in the NO concentration in nitrogen were traced by sampling 23.8 cm^3 of the mixed gas in a 100 mm-cell and by measuring the absorbance at 226.5 nm.

(2) Dependence of the Amount of Adsorbed NO at Equilibrium on the Partial Pressure of NO: After placing the dispersions in contact with 6 dm^3 of nitrogen containing 980 ppm of NO until the equilibrium had been reached, the gas remaining in the system was removed and another 6 dm^3 of nitrogen with NO was introduced; the gas was then circulated again for the further adsorption of NO with the same dispersions. The amount of adsorbed NO was obtained from the sum of those NO values from the first and second runs. The concentration of NO in the second run corresponded to the partial pressure of NO at equilibrium. By repeating the above operation, the relationship between the amount of NO adsorbed and the partial pressure of NO was measured.

(3) Desorption of NO: The desorption of NO was carried out by the following two methods of heating and purging with pure nitrogen.

Heating: After the dispersions had been equilibrated with the mixed NO gas at 25 °C, the gas circulation was stopped and the system was left as it was. Then the temperature of the dispersions was raised to 80 °C, below which temperature the resin was known to be stable enough; the gas was then circulated again at the rate of 1.6 $dm^3\,min^{-1}$. Repeated adsorption-desorption cycles were carried out by raising and dropping the temperature of the dispersions without exchanging the initially introduced mixed gas.

Purging with Pure Nitrogen: After the dispersions had been equilibrated with the mixed NO gas at 25 °C, the gas remaining in the circulation system was removed by the use

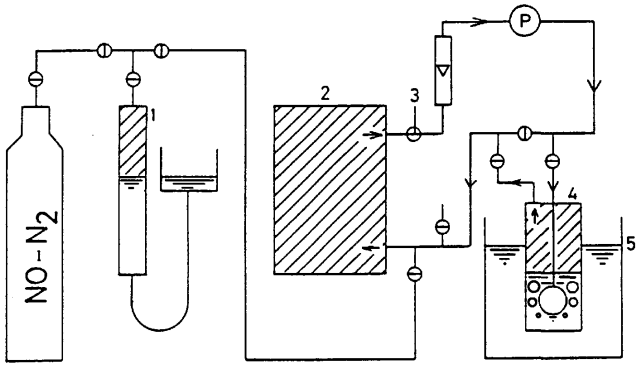

Fig. 2. Schematic diagram of gas adsorption apparatus.
1. Gas burette. 2. Gas holder. 3. Sampling outlet. 4. Adsorbing vessel. 5. Constant temperature water bath.

of a vacuum pump and 6 dm^3 of a pure nitrogen gas was freshly introduced into the system (except for the adsorbing vessel containing the dispersions). The nitrogen was then circulated through the dispersions at 25 °C. The error caused by the gas remaining in the adsorbing vessel was corrected in each run.

Results

Preparation and Characterization of an Aqueous Dispersion of the Chelate Resin-Immobilized Iron(II) Complex. The immobilization of Fe(II) ions on the chelate resin proceeds rapidly when the solution of Fe(II) ions is mixed with the chelate resin. The light green color of the solution gradually fades because of the decrease in the concentration of the Fe(II) ions in the supernatant. The immobilization was also observed in the electronic spectra. The chelate resin before the immobilization of the Fe(II) ions is white and has a peak at 280 nm in its electronic spectrum due to benzene chromophores in the matrices, as is shown by broken line in Fig. 3. The color of the resin changes from white to light green upon the immobilization of the Fe(II) ions, and a new peak appears at around 320 nm which does not exist in the electronic spectrum of an aqueous solution of $FeSO_4$ and the chelate resin. The exposure to NO gives new shoulder peaks around 450 and 600 nm, as is shown by the solid line in Fig. 3. A similar change has also been observed in the case of the adsorption by an aqueous solution of the Fe(II)-EDTA complex.[7,8] The release of NO by the heating of the adsorbed resin led to the disappearance of the two shoulder peaks and gave the same electronic spectrum as that of the original chelate resin-Fe(II) complex before the adsorption of NO.

Adsorption of NO by the Aqueous Dispersions of the Iron(II)-Chelate Resin Complex. Figure 4 shows the adsorption curves of various absorbents and adsorbents. An aqueous solution of Fe(II)-EDTA, a typical absorbent of NO, rapidly absorbs NO, even at a low concentration of NO. The absorption capacity, however, gradually decreases, probably because of the deterioration of the adsorbent by the trace amount of oxygen being contaminated by the leakage in air at the circulating pump. An aqueous solution of $FeSO_4$, the starting material of the dispersion system, absorbs only 3% of the initially charged amount of NO, as is shown by the open circles in Fig. 4. The mixture (the dispersions) prepared by adding the above aqueous solution of $FeSO_4$ to the chelate resin can adsorb enough NO, though its adsorption rate is not very fast. When these dispersions were separated into an aqueous part (the supernatant) and a solid part, however the aqueous part did not absorb NO, but the solid part did. This fact clearly indicates that Fe(II) ions immobilized on the chelate resin are the active species for the adsorption of NO.

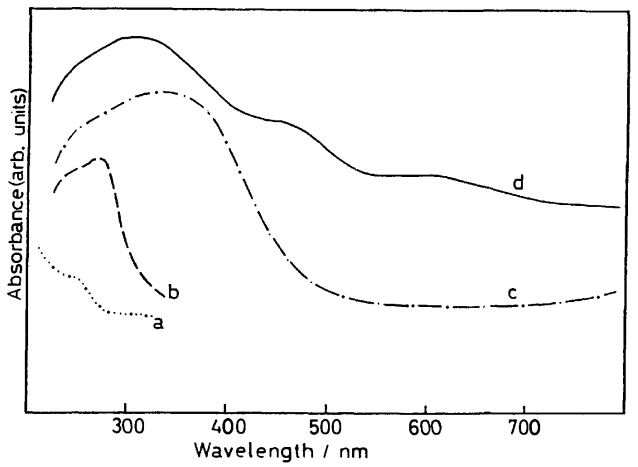

Fig. 3. Electronic spectra of the NO adsorbent and the related materials. a(·····): $FeSO_4$ solution in water, b(— —): chelate resin, c(·–·–): NO adsorbent before adsorption of NO, d(——): NO adsorbent after adsorption of NO.

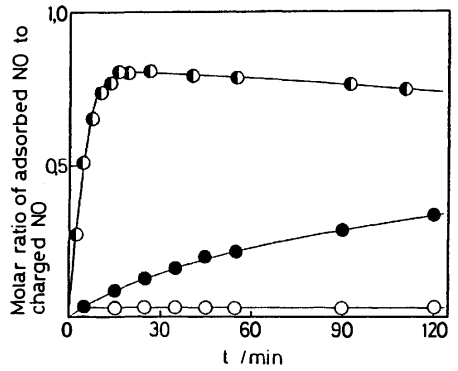

Fig. 4. Adsorption of NO at 25°C by Fe(II)-EDTA solution (◐, 0.01 mol dm^{-3}), Fe(II)-SO_4 solution (○, 0.36 mol dm^{-3}), and resin-immobilized adsorbent dispersion prepared by mixing 18 mmol of Fe(II)SO_4 and 21.4 g of the chelate resin in water by using a shaker (●). The adsorbents were contacted with 6 dm^3 of nitrogen containing 1000 ppm of NO.

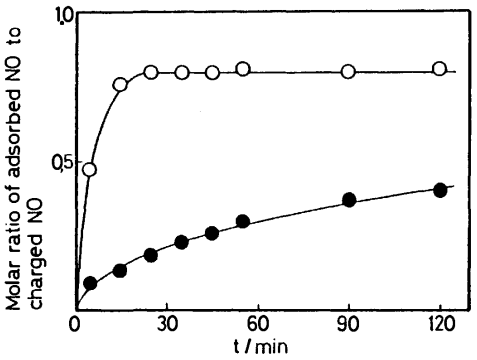

Fig. 5. Adsorption of NO at 25°C by the resin-immobilized Fe(II) adsorbents prepared from commercial beads (●) and from fine beads ground with agate mortar and pestle (○). Adsorption of NO was carried out by the contact with 6 dm^3 of nitrogen containing 980 ppm of NO at the rate of 1.6 dm^3 min^{-1}.

Figure 5 shows the NO adsorption curves of the dispersions of the adsorbents prepared by using the resin in a small size (10 μm) as well as in a commercial size (0.5 mm). The equilibrium is achieved within 25 min in the case of the small size resin by adsorbing 78% of NO at 25 °C, as Fig. 5 shows. Moreover, no deterioration by the contaminated oxygen as is seen in the case of an aqueous solution of Fe(II)-EDTA is observed in this system.

Figure 6 shows the dependence of the amount of adsorbed NO at equilibrium on the charged amount of Fe(II). The capital letter R in the figure shows the molar ratio of the initially charged amount of Fe(II) ions to the IDA moieties in the resin. The amount of NO adsorbed at equilibrium increases with the increase in the amount of charged Fe(II) ions and reaches saturation at the point where the amount of Fe(II) is half as much as the molar amount of IDA moieties in the resin by adsorbing 68% of the NO at 30 °C. The amount of immobilized Fe(II) ions, which are the active species for the adsorption of NO, reaches saturation over R=0.7, no further immobilization of the Fe(II) ions on the chelate resin was observed beyond this point.

The aqueous dispersions prepared from various Fe(II) salts with the different counter anions listed in Table 1 have almost the same activity for the adsorption of NO, while the aqueous solution of each Fe(II) salt absorbs only 6% of the NO. Thus, no significant difference in the adsorbing capability caused by the Fe(II) salts used was observed.

The adsorption rate of NO increased with the increase in the amount of charged Fe(II), as is shown in Fig. 7. The increase in the rate was observed after the saturation of Fe(II) immobilization, while the amount of adsorbed NO was at the saturation point.

The amount of NO adsorbed at equilibrium depends strongly on both the partial pressure of NO and the temperature. Figure 8 shows the relationship between the partial pressure of NO at equilibrium and the amount of NO adsorbed. As this figure shows, the

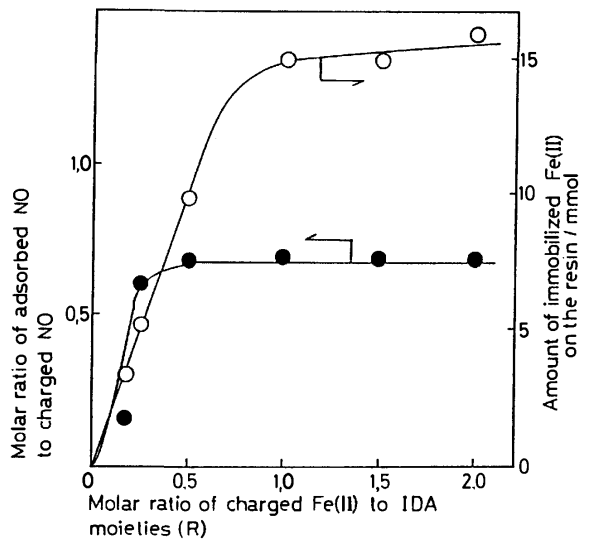

Fig. 6. Relationship between the amount of adsorbed NO at equilibrium (●) and the amount of immobilized Fe(II) on the resin (○) at various amount of Fe(II) charged. Initially charged amount of chelate resin was 7.53 g containing 21.0 mmol of IDA moieties.

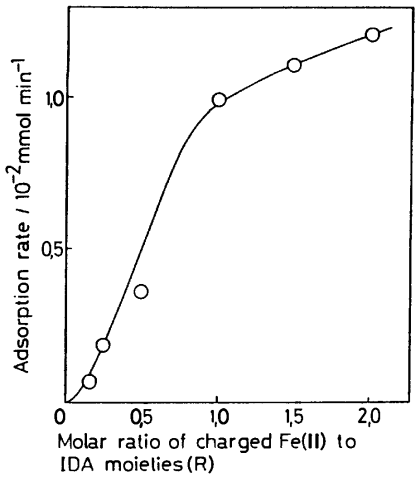

Fig. 7. Dependence of initial adsorption rate of NO on molar ratio (R) of the charged amount of Fe(II) to the amount of iminodiacetic acid moieties in the chelate resin by the contact with 6 dm^3 of nitrogen containing 980 ppm of NO at the rate of 1.6 dm^3 min^{-1} with the adsorbent dispersions prepared from 7.53 g of chelate resin containing 21.0 mmol of IDA moieties and designed amount of $FeSO_4$.

Table 1. Adsorption of NO with Fe(II) Complexes from Various Salts[a)]

Fe(II) complex		IDA[b)] of chelate resin/mmol	Molar ratio of adsorbed NO to charged NO
Fe(II) salt			
Formula	Amount/mmol		
$FeSO_4$	18	0	0.033
$FeSO_4$	31	21	0.776
$Fe(ClO_4)_2$	31	0	0.061
$Fe(ClO_4)_2$	31	21	0.700
$FeCl_2$	30	0	0.067
$FeCl_2$	30	21	0.767

a) Initial amount of NO=0.246 mmol. b) 21.0 mmol of the iminodiacetic acid (IDA) moieties were included by 21.4 g of the chelate resin.

amount of adsorbed NO increases linearly with the increase in the partial pressure of NO. As for the temperature-dependence, the increase in the temperature decreases the amount of NO adsorbed. Thus, the dispersions adsorbed 78% of NO at 25 °C; this figure decreased to 11% at 80 °C.

Desorption and Recyclic Use. Figure 9 shows the adsorption and desorption cycles of NO upon treatment with heat. The concentration of NO rapidly decreases to 220 ppm in 90 min when it is in contact with the dispersions at 25 °C. By elevating the temperature of the dispersions to 80 °C, the NO is smoothly released from the dispersions and the concentration of NO recovers to 876 ppm. In other words, 85% of the NO adsorbed is released, while only 12% of the NO charged remains in the dispersions at 80 °C. The adsorption-desorption cycles were repeated for 5 times without any deterioration.

The desorption of NO is also possible by letting pure nitrogen flow through the dispersions. Twenty-three percent (0.041 mmol) of the adsorbed NO was recovered at the concentration of 167 ppm by circulating 6 dm^3 of bubbling pure nitrogen through the dispersions, which had previously adsorbed NO (0.18 mmol) from 6 dm^3 of the mixed gas at 25 °C.

From the viewpoint of the recovery of NO as chemical resources, the recovery of NO at a higher concentra-

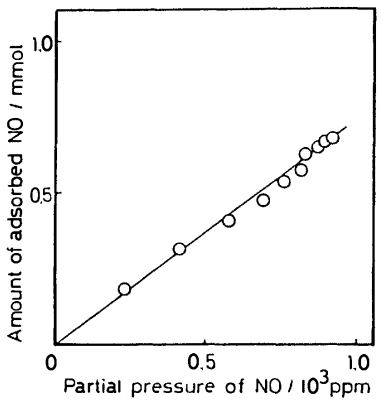

Fig. 8. Dependence of the amount of adsorbed NO at equilibrium on the concentration of NO. Adsorption experiment was carried out by the contact with 6 dm^3 of nitrogen containing 980 ppm of NO at 30 °C by the adsorbent dispersions prepared from 7.53 g of chelate resin containing 21.0 mmol of IDA moieties and 8.72 g of $FeSO_4$.

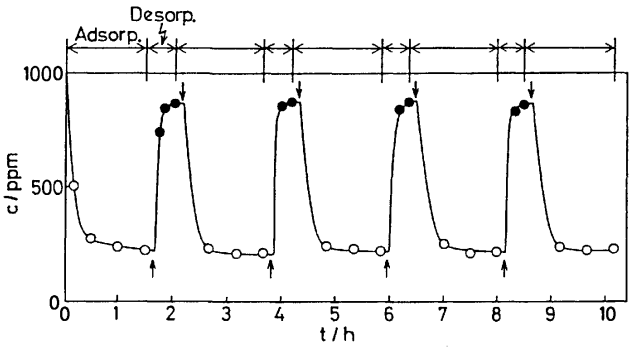

Fig. 9. Changes of the concentration (c) of NO in the gas phase with time (t) during the adsorption (○) of NO at 25 °C by Fe(II)-chelate resin adsorbent and desorption (●) of NO at 80 °C from the adsorbent. To adjust the temperature to a desired value, adsorbent was kept in the thermostat for 10 min without circulating the gas after adsorption (↑) or desorption (↓) of NO.

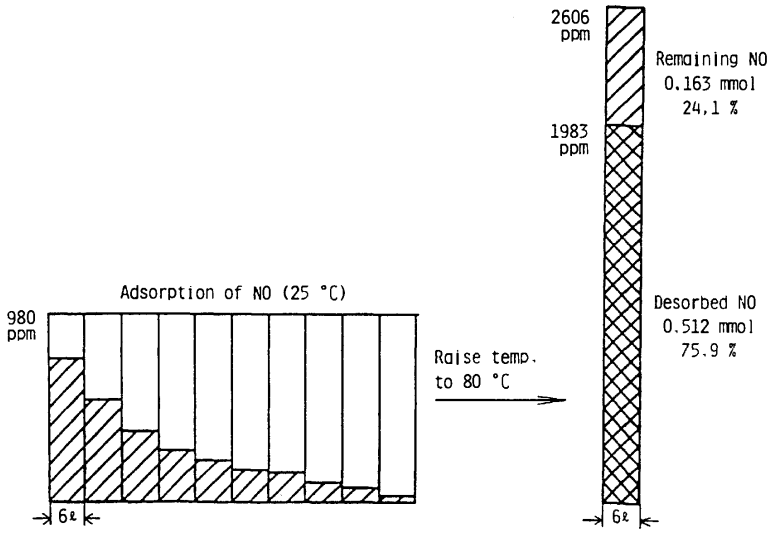

Fig. 10. The schematic presentation of the release of the cumulatively adsorbed NO from the adsorbent. Desorption of NO was carried out by circulating 6 dm^3 of pure nitrogen through the dispersions at the rate of 1.6 dm^3 min^{-1} till the equilibrium was attained after the dispersion was saturated with 980 ppm of NO by the contact with 6 dm^3 of nitrogen containing 980 ppm of NO for 10 times at 25 °C.

tion than that of the original gas is important. In order to test this possibility, the accumulated adsorption of NO was examined. After the first 6-dm^3 bag of the mixed gas had been circulated at 25 °C through the adsorbent until the equilibrium was reached, the remaining gas in the gas phase of the system was replaced by another 6 dm^3 of the fresh mixed gas, followed by a second circulation through the adsorbent. Ten repetitions of this procedure caused the adsorbent to be equilibrated with 980 ppm of NO. The total amount of NO adsorbed on the dispersions was 0.675 mmol. Then, 6 dm^3 of pure nitrogen was newly introduced into the system and circulated at 80 °C through the aqueous dispersions already saturated with 980 ppm of NO. This treatment released 0.512 mmol of NO, which corresponded to 76% of the total amount of that adsorbed , at the concentration of 1983 ppm. The above results are schematically illustrated in Fig. 10. These facts indicate that the concentrated NO can be obtained from the dilute one; that is, the concentrated recovery of NO is possible by using the present dispersion system.

Discussion

Complex Formation and Determination of the Equilibrium Constant. The appearance of a new peak at 320 nm upon the immobilization of the Fe(II) ions on the resin suggests the complex formation of Fe(II) with IDA moieties in the resin, as this peak does not exist in the separate spectra of Fe(II) and chelate resin. The new shoulder peaks at 450 nm and 600 nm appearing in the immobilized resin upon the contact with NO correspond to the charge-transfer band caused by the complex formation between NO and Fe(II). The appearance of such a charge-transfer band is observed in the case of an aqueous solution of an $Fe(II)SO_4$ or a monomeric Fe(II)-polyamine-*N*-carboxylic acid complex such as Fe(II)-EDTA.[15] These facts indicate that the adsorption of NO by the present aqueous dispersions proceeds through the complex formation between Fe(II) and NO, as in the case of the homogeneous aqueous solution of Fe(II)-EDTA or Fe(II).[16]

The above adsorbing reaction is considered to start from the dissolution of gaseous NO into water and to proceed according to Eqs. 1 and 2. Assuming the first-order reaction for the NO adsorption, i.e.:

$$NO_{gas} \rightleftharpoons NO_{aq} \quad (1)$$

$$n(NO_{aq}) + \text{CR-Fe(II)} \overset{K}{\rightleftharpoons} \text{CR-Fe(II)-(NO)}_n \quad (2)$$

$$K = [\text{CR-Fe(II)-NO}]/([\text{CR-Fe(II)}] \times [NO_{aq}])$$
$$= [\text{CR-Fe(II)-NO}] \times H/([\text{CR-Fe(II)}] \times p_{NO}) \quad (3)$$

$$K = n_{NO} \times H/([\text{CR-Fe(II)}]_0 \times p_{NO})$$
$$K \times p_{NO}/H = n_{NO}/[\text{CR-Fe(II)}]_0 \quad (4)$$

the 1 : 1 complex formation of NO with the Fe(II) ion (n=1 in Eq. 2), Eq. 3 can be obtained from Eq. 2, where p_{NO} and H are the partial pressure of NO (atm) and Henry's constant respectively. The amount of Fe(II) ions immobilized on the chelate resin, [CR-Fe(II)] in mmol, can have a linear relation with the amount of adsorbed NO n_{NO}; the uncoordinated amount is obtained by substracting the n_{NO} from the amount of the initially immobilized Fe(II) ions, $[\text{CR-Fe(II)}]_0$. As the CR-Fe(II) exists in a large excess to the adsorbed NO ($[\text{CR-Fe(II)}]/n_{NO}$=22 in the present case), however, the amount of unreacted CR-Fe(II), [CR-Fe(II)], can be regarded as the amount of the initially immobilized Fe(II) ions, $[\text{CR-Fe(II)}]_0$. Thus, Eq. 3 is transformed into Eq. 4. Equation 4 indicates that the partial pressure of NO at equilibrium should be in proportion to the amount of NO adsorbed when the 1 : 1 complex formation proceeds. In fact, the amount of NO adsorbed is in good proportion to the partial pressure of NO, as is shown in Fig. 8, which also indicates that the equilibrium constant, K, of the adsorbing reaction can be calculated according to Eq. 3.

Table 2 shows the equilibrium constant at each temperature obtained according to Eq. 3. The equilibrium constant decreases with the increase in the temperature because of the fall in the amount of NO adsorbed. The van't Hoff plots form a straight line, as is shown in Fig. 11, and the equilibrium constants K_c can be expressed as follows by using the temperature T as a parameter:

$$K_c = 3.32 \times 10^{-4} \times \exp(45.6 \times 10^3/RT) \quad (5)$$

where R=8.314 J K^{-1} mol^{-1}.

The enthalpy (ΔH) and entropy (ΔS) changes were obtained as −45.6 kJ mol^{-1} and −68.2 J K^{-1} mol^{-1} respectively. The enthalpy change in the absorbing reaction of NO with an aqueous solution of Fe(II)-EDTA was reported to be −66.1 kJ mol^{-1} [18] (−15.8 kcal mol^{-1}), which is lower by 20.5 kJ mol^{-1}

Table 2. Adsorption of NO by the Chelate Resin-Immobilized Fe(II) Complex at Various Temperatures

Temp/°C	Adsorbed NO[a]/mmol	Apparent equilibrium constant	
		$K_c H^{-1}$/atm^{-1}	K_c/dm^3 mol^{-1}
25.0	0.191(0.78)[b]	60.1	31.1 ×10^3
39.5	0.134(0.58)	23.2	14.8 ×10^3
59.8	0.069(0.29)	7.00	5.35×10^3
80.0	0.025(0.11)	2.02	1.67×10^3

a) Initial amount of NO=0.246 mmol. b) Molar ratio of adsorbed NO to charged NO.

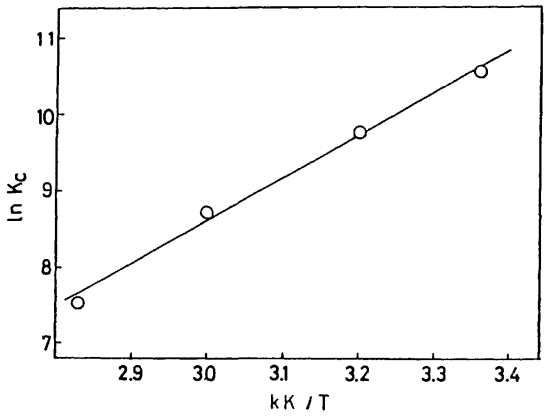

Fig. 11. The van't Hoff's plots for the adsorption of NO. The equilibrium constant at different temperature was calculated from the amount of adsorbed NO and partial pressure of NO at equilibrium according to the eq. 4. Adsorption experiment was carried out by circulating 6 dm^3 of nitrogen containing 980 ppm of NO at the rate of 1.6 dm^3 min^{-1}.

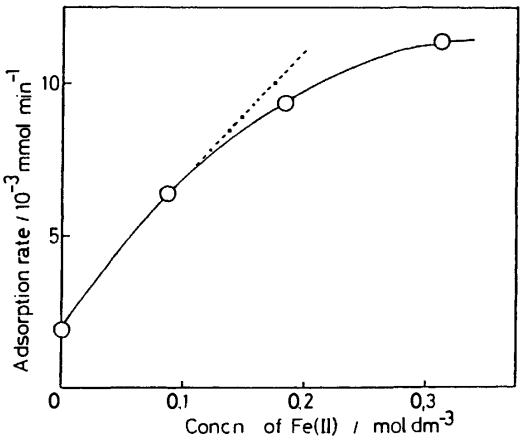

Fig. 12. Dependence of adsorption rate of NO on the concentration of $FeSO_4$ in the supernatant. In this system, amount of Fe(II) ion immobilized was kept constant (saturated) with 14.7 mmol. Adsorption experiment was carried out by circulating 6 dm^3 of nitrogen containing 1000 ppm of NO.

than that of CR-Fe(II). The strong NO-adsorbing capability of Fe(II)-EDTA is considered to be derived from the strong back-donation from Fe(II) to the NO molecule due to the increase in the electron density of the iron atom. In the case of the CR-Fe(II) complex, however, the coordination of NO to the Fe(II) ion is relatively weak due to the electron-releasing effect of the benzyl group compared with the case of the EDTA ligand.

Adsorption Rate. The increase in the rate of NO adsorption with small particles of the chelate resin suggests that the rate-determining step is the diffusion of the NO dissolved in the water into the resin inside. The adsorbing reaction is considered to occur by means of the following two steps: 1) the dissolution of NO into the supernatant of the dispersions, and 2) the adsorption of the NO dissolved by the CR-Fe(II) complex in the resin. The dissolution of the NO into the supernatant, the first step of the adsorption, is rapid and can always be brought to saturation by vigorous bubbling. The adsorption of the NO dissolved by the CR-Fe(II) complexes, the second step, occurs first on the surface of the resin, and then the NO adsorbed diffuses from the surface to the inside of the resin. This NO diffusion from the surface to the inside of the resin proceeds along with the diffusion of the aqueous solution in the resin. Therefore, the diffusion will be rather slow because of the low mobility of the solution in the resin. Thus, the adsorption of NO will proceed smoothly when large parts of the CR-Fe(II) complex exist near the surface of the resin. The fact that the CR-Fe(II) complex prepared from the ground resin adsorbs NO more rapidly than that prepared from the original resin can be explained by the 50-fold increase in the surface area of the resin by grinding the particles to from 0.5 mm to 10 μm in diameter.

The adsorption rate also increases with the increase in the charged amount of Fe(II) ions as is shown in Fig. 7. The increase in the rate is thought to be attributable to the increase in the amount of the CR-Fe(II) complex in the resin when the ratio (R) of the charged Fe(II) ions to the IDA moieties lies below 0.7. When R is over 0.7, the adsorption rate still increases, even though the immobilization of the Fe(II) ions is saturated in this region. This fact strongly suggests that the Fe(II) ions in the supernatant are closely connected with the adsorption rate of NO. Figure 12 shows the effect of the concentration of Fe(II) ions in the supernatant on the NO-adsorption rate. In this experiment, the amount of the CR-Fe(II) complexes was kept at saturation. In this case, no diffusion of the Fe(II) ions into the supernatant from the resin was observed because of the strong chelating interaction of the Fe(II) with the IDA moieties. Therefore, these experiments were performed under the same conditions except for the concentration of Fe(II) ions in the supernatant. Moreover, the amount of NO adsorbed at equilibrium was kept constant in each run. Even under these conditions, the adsorption rate depended greatly on the concentration of Fe(II) in the supernatant. The increase in the concentration of Fe(II) in the supernatant brought about the increase in the adsorption rate. On the contrary, the rate was extremely diminished by the exchange of the supernatant with distilled water. It is proposed from these facts that the Fe(II) ions in the supernatant work as accelerators, not as active species, of NO adsorption.

The concentration of NO in the supernatant is calculated to be 1.93×10^{-6} mol dm^{-3} by means of Henry's law when the supernatant is displaced by distilled water and is equilibrated with 1000 ppm of NO in the gas phase at 25 °C. In contrast, if the concentration of Fe(II) ions in the supernatant is 0.2 mol dm^{-3}, the concentration of Fe(II)-NO in the supernatant is calcu-

lated to be 1.27×10^{-4} mol dm^{-3} under the same conditions from the equilibrium constant of Eq. 6 (K_1=0.634 atm^{-1}).[16] Thus, when the supernatant contains Fe(II) ions, the concentration of NO in the supernatant 66 times higher than that in the case of the supernatant of pure water. Therefore, the Fe(II) ions work as carriers of NO molecules:

$$NO_{aq} + Fe(II) \overset{K_1}{\rightleftharpoons} Fe(II)\text{-}NO \quad (6)$$

$$K_1 = [Fe(II)\text{-}NO]/([NO]_{aq} \times [Fe(II)]) \quad (7)$$

$$Fe(II)\text{-}NO + CR\text{-}Fe(II) \overset{K_2}{\rightleftharpoons} CR\text{-}Fe(II)\text{-}NO + Fe(II) \quad (8)$$

$$NO_{aq} + CR\text{-}Fe(II) \rightleftharpoons CR\text{-}Fe(II)\text{-}NO \quad (9)$$

$$d[CR\text{-}Fe(II)\text{-}NO]/dt = k_1[Fe(II)\text{-}NO] \times [CR\text{-}Fe(II)] + k_2[NO]_{aq} \times [CR\text{-}Fe(II)] \quad (10)$$

$$d[CR\text{-}Fe(II)\text{-}NO]/dt = k_1K_1[NO]_{aq} \times [Fe(II)] \times [CR\text{-}Fe(II)] + k_2[NO]_{aq} \times [CR\text{-}Fe(II)] \quad (11)$$

These considerations suggest the following adsorption mechanism and equations. First, the dissolved NO reacts not only directly with CR-Fe(II) complexes, but also with Fe(II) ions in the solution, thus forming Fe(II)-NO complexes. The Fe(II)-NO complexes can transfer the NO molecules to the CR-Fe(II) complexes according to Eq. 8. The above reaction of Eq. 6 is rapidly equilibrated by the vigorous bubbling of NO, and the equilibrium constant K_1 is expressed as Eq. 7. The aqueous solution of NO resulting from Eq. 1 reacts directly with the CR-Fe(II) complexes to form CR-Fe(II)-NO complexes according to Eq. 9 as well as through the Fe(II)-NO complexes according to Eqs. 6 and 8. Under these conditions, the initial adsorption rate is expressed as Eq. 10 from Eqs. 8 and 9 by neglecting the diffusion of NO into the resin. Consequently, Eq. 11 is obtained by substituting [Fe(II)-NO] by using Eq. 7. This equation theoretically predicts that the adsorption rate will increase with the concentration of Fe(II) ions in the supernatant. In fact, the adsorption rate first increases linearly with the increase in the concentration of Fe(II). When the concentration of Fe(II) is zero, the adsorption proceeds according to Eqs. 1 and 9. At a high concentration of Fe(II) ions, the plots deviated from the line, probably due to the limitation of transferring the NO molecule of the Fe(II)-NO complex to CR-Fe(II).

The equilibrium constant K_2 of Eq. 8 is expressed as Eq. 12. The product of K_1 and K_2 corresponds to an equilibrium constant of the total reaction K, which should coincide with the K of Eq. 3. This means that the quantity of adsorbed NO is determined from the quantity of CR-Fe(II) and the concentration of NO, and that the concentration of Fe(II) ions does not affect the quantity of NO adsorbed at equilibrium:

$$K_2 = [CR\text{-}Fe(II)\text{-}NO] \times [Fe(II)]/([Fe(II)\text{-}NO] \times [CR\text{-}Fe(II)]) \quad (12)$$

$$K_1 \times K_2 = K$$

Desorption of NO. The adsorbed NO is easily desorbed by heating the dispersions or by bubbling in pure nitrogen. The latter is an operation equivalent to the lowering of the partial pressure of NO. The NO adsorbed at 25 °C can be released by elevating the temperature to 80 °C, leaving 12% of NO in the dispersions; this amount corresponds to the amount of NO adsorbed at 80 °C. This means that the quantity of NO released can be estimated from the difference between the quantities of NO equilibrated at the temperatures of adsorption and desorption. Moreover, no deterioration was observed after five repetitions; this clearly indicates that the adsorbing reaction of NO by the present dispersions proceeds reversibly according to Eq. 2 and that no side reaction, such as the reduction of NO by the Fe(II) ions into N_2O, occurs under these conditions. The reversible adsorption can clearly be understood by the desorption experiment using bubbling pure nitrogen. The amount of desorbed NO coincides again with the amount of NO (0.040 mmol) predicted from the equilibrium constant.

The present work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry Education, Science and Culture.

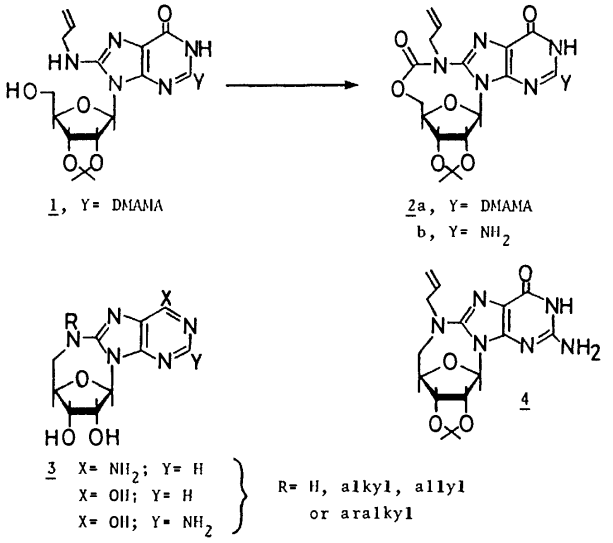
Synopsis. The crystal structure of 8,5′-[(allylimino)-carbonyloxy]-2-*N*-dimethylaminomethylene-9-(2′,3′-*O*-isopropylidene-β-D-ribofuranosyl)guanine (**2a**) methanol solvate was determined by X-ray analysis. Its base-sugar torsion angle conforms to the CD spectral behavior of the partially deprotected compound **2b** in the sense of anti-conformation.

A recent report from this laboratory has described the direct cyclization of 8-allylamino-2-*N*-dimethylaminomethylene-2′,3′-*O*-isopropylideneguanosine (**1**) to 8,5′-[(allylimino)carbonyloxy]-2-*N*-dimethylaminomethylene-9-(2′,3′-*O*-isopropylidene-β-D-ribofuranosyl)guanine (**2a**) with the use of diphenyl carbonate or *N*,*N*′-carbonyldiimidazole (CDI) in an attempt to realize a general synthesis of purine 8,5′-imino- and substituted imino cyclonucleosides (**3**) (Scheme 1).[1] Compound **2a** was deblocked to 8,5′-[(allylimino)-carbonyloxy]-9-(2′,3′-*O*-isopropylidene-β-D-ribofuranosyl)guanine (**2b**) (the allyl group was used as a *N*-protective group[2]). The facile formation of **2a** was interesting in view of our recent efforts to synthesize long-bridged cyclonucleosides for expanding the range of model base-sugar conformations[3] and hence we decided to determine the base-sugar torsion angle (Φ_{CN}) of the cyclized system **2** by X-ray analysis. Although the crystals of both **2a** and **2b** more or less had a propensity to effloresce in open atmosphere, the former proved to be more amenable to manipulation, and accordingly the results of its X-ray analysis are described herein.



Scheme 1.

Experimental

Compound **2a** (100 mg) was dissolved in methanol (1.5 ml) at 40 °C and left at room temperature. Small hexahedral crystals appeared after 24 h and were allowed to grow for 2 weeks. Since these crystals (mono-methanolate) proved to have a tendency to effloresce with releasing methanol of crystallization,[4] a crystal was quickly sealed inside a glass capillary containing a tiny volume of the saturated mother liquor at the tip. D_m was measured by flotation in a mixture of acetone and chloroform. All subsequent X-ray measurements were conducted using a Rigaku automated four-circles diffractometer, AFC-5, employing graphite monochromatized Cu $K\alpha$ radiation (λ=1.5418 Å). $C_{20}H_{25}N_7O_6 \cdot CH_3OH$, M_r=491.51, triclinic, $P\bar{1}$, a=9.556 (1), b=11.171 (1), c=5.987(1) Å; α=106.28(1), β=83.70(1), γ=106.16(1)°; V=588.9(1) Å^3, D_x=1.386 g cm^{-3}, D_m=1.381 g cm^{-3}; Z=1; crystal size, 0.32×0.20×0.80 mm; 2156 measured reflections, $2\theta_{max}$=126.0°, $-11 \leqq h \leqq 10$, $-11 \leqq k \leqq 12$, $-4 \leqq l \leqq 0$, R_{int}=0.007. Three standard reflections after every 100 reflections (decay less than 18%). The structure was solved by the Monte-Carlo direct method[5] with the aid of MULTAN 78 program[6] using 1880 non-zero unique reflections, and refined by the full-matrix least-squares procedure with the analytical absorption correction.[7] Non-H atoms assigned anisotropic temperature factors. All the H atoms (except for some H atoms of **2a**) could be located on a difference Fourier map and refined with the equivalent isotropic temperature factors to that for the bonded carbon or nitrogen atoms.

$R=0.063$, $S=[\sum W(|F_o|^2-|F_c|^2)^2/(m-n)]^{1/2}=2.9$, $W=1/\sigma^2(F^2)$, $\Delta\rho_{max}$=1.0 e Å^{-3}.

Atomic scattering factors from International Tables for X-Ray Crystallography.[8] ORTEP employed for drawing the molecular structure. All the calculations were done on a FACOM M-382 computer at the Computation Center of Nagoya University.[9]

Discussion

Figures 1 and 2 show the selected bond lengths and bond angles of **2a**, respectively. When compared with the normal ribo-, deoxyribonucleosides or guanosine itself, it is seen from these figures that (a) the N9-C10-O18 (=N^9-$C_{1'}$-$O_{1'}$)[10] bond angle in **2a**, 113.9°, is significantly larger than 108—109° commonly shown by natural ribonucleosides[11] and the angle C13-C14-O15 ($C_{4'}$-$C_{5'}$-$O_{5'}$), 107.7°, is significantly smaller than normal 111—112°,[11] (b) the C13-C14 (=$C_{4'}$-$C_{5'}$) as well as C14-O15 (=$C_{5'}$-$O_{5'}$) bond length, 1.527 and 1.447 Å, respectively, is longer than corresponding values 1.507—1.514 and 1.42—1.43 Å for the normal nucleosides,[11] and (c) the N7-C8 (=N^7-C_8) bond length of the base, 1.298 Å, is shorter but the C8-N9 (=C_8-N^9) bond length, 1.414 Å, is significantly longer than the corresponding values, 1.306

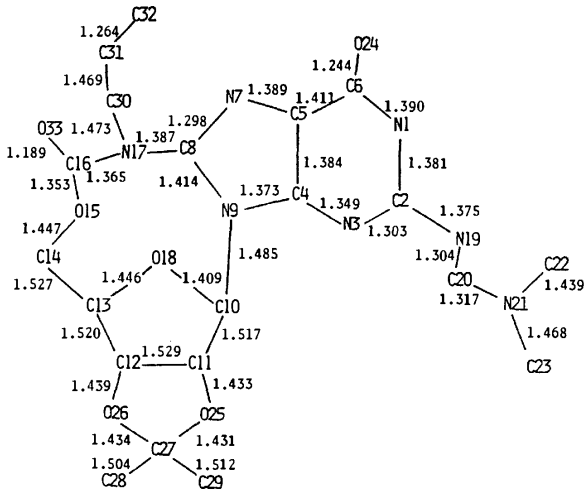


Fig. 1. Bond lengths of **2a** (l/Å).

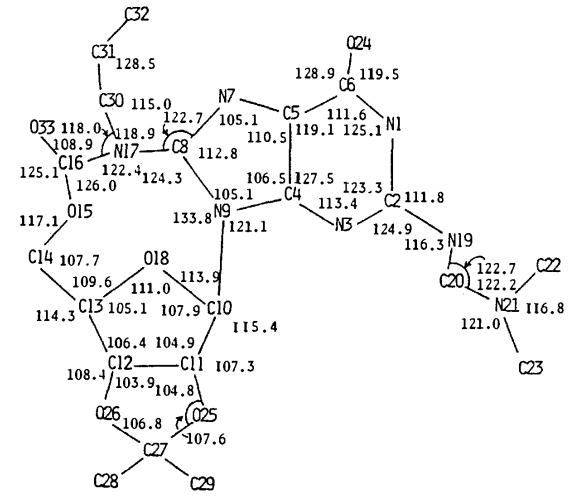

Fig. 2. Bond angles of **2a** (ϕ/°).

and 1.369 Å, shown by guanosine. These differences of the bond parameters seem to suggest the presence of some steric tension in the tricyclo[6.2.1] system including the bridge, which is probably reflected in our unsuccessful attempts to safely deisopropylidenate this type of compounds.

Figure 3 shows ORTEP drawing of the molecule as seen from over the base plane. It is recognized from this figure that the $O_{5'}$-CO-N^8(allyl)-bridge is located over the front side (2′,3′-side) of the nearly flat sugar ring. The base-sugar torsion angle (Φ_{CN}) defined as an angle from the $C_{1'}$-$O_{1'}$ bond was calculated as −90.20°, using the bond lengths and angles in Figs. 1 and 2. Here, the torsion angle was approximated by the dihedral angle between the plane C8-N9-C10 (=C_8-N^9-$C_{1'}$) and the plane O18-C10-N9 (=$O_{1'}$-$C_{1'}$-N^9). Similarly, the dihedral angle between the plane O18-C10-N9 (=$O_{1'}$-$C_{1'}$-N^9) and the plane C12-C10-N9 (=$C_{3'}$-$C_{1'}$-N^9) was calculated as −83.10° using appropriate bond parameters. Thus, the base-sugar torsion angle of **2a** has proved to reside between the two directions, $C_{1'}$-$C_{2'}$ and $C_{1'}$-$C_{3'}$, and quite near the $C_{1'}$-$C_{3'}$ line.

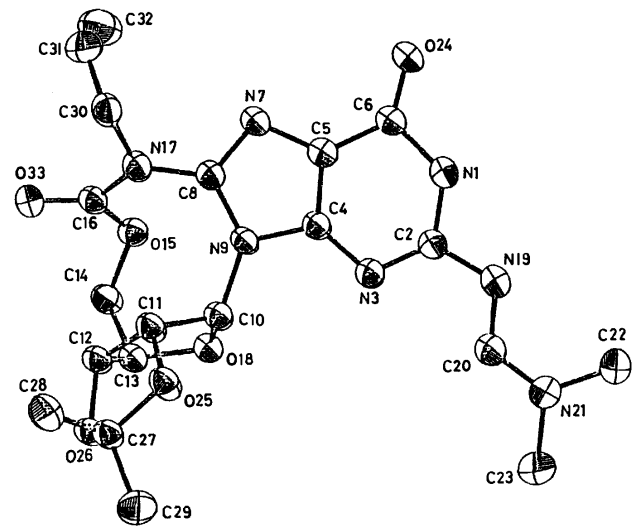

Fig. 3. An ORTEP drawing of **2a** as seen from the upside of the base plane. The H atoms and methanol of crystallization have been omitted for clarity (Thermal ellipsoids 30% probability level).

Table 1. UV and CD Spectra of **2b** and **4** in Methanol

CD spectra[13] of **2b** and 8,5′-allylimino-9-(5′-deoxy-2′,3′-*O*-isopropylidene-β-D-ribofuranosyl)guanine (**4**)[1] as an extreme anti conformer model are given in Table 1 together with their UV absorptions cited from Ref. 1. Although direct comparison between **2a** having an 8-iminocarbonyloxy group and **4** having an 8-amino group is rather inadequate, the strong positive Cotton effects of both compounds are in accord with the notion of the anti conformations of purine nucleosides.[14] It is anticipated that this type of long-bridged purine nucleosides in completely deprotected form would afford a different torsion angle or/and a different stereochemistry of the sugar part with releasing steric strain and further studies along this line are under way.

The Relationship between the Acoustic Property and the Hydration of Saccharides

Hisashi UEDAIRA* and Miyuki ISHIMURA
Department of Polymer Science, Faculty of Science, Hokkaido University, Sapporo 060
(Received May 18, 1988)

Synopsis. Values of the relative increment of the sound velocity, A, in aqueous solutions of sugars were calculated from the experimental sound velocities. The values of A correlated well with the mean number of equatorial OH groups in a sugar molecule.

Recently, it was found that the limiting diffusion coefficients[1] and the partial molar heat capacities[2] for saccharides in water correlate well with the mean number of equatorial OH groups, $n(e\text{-OH})$, in a sugar molecule. These properties, which are affected by hydration, depend sensitively on the conformation of saccharides in aqueous solution. The accoustic properties of aqueous solutions of saccharides are also thought to depend on the degree of their hydration. Høiland and Holvik,[3] however, showed that the isoentropic partial molar compressibilities of saccharides do not correlate with the number of e-OH groups. Sarvazyan and his co-workers[4,5] theoretically indicated that the relative increment of the sound velocity, $A=(U-U_0)/(U_0m)$, sensitively reflects the solute-water interactions, where U and U_0 are the sound velocity in solutions and pure water respectively, and m is the concentration. In this paper, we report on the values of A calculated from the densities and compressibilities of aqueous saccharides solutions and discuss the relation between the values of A and the conformations of saccharides.

Results and Discussion

Høiland and Holvik obtained the following equations for the densitites, d, and compressibilities, β_s, of the saccharides solutions at 25 °C:

$$d=d_0+\sum_{i=1}^{3} a_i m^i \tag{1}$$

and

$$\beta_s=\beta_s^0+\sum_{i=1}^{3} b_i m^i, \tag{2}$$

where d_0 and β_s^0 are the density and compressibility of pure water, respectively. We obtained the following relation for A in the low concentration range; this relation was calculated from Eqs. 1 and 2 by means of the Laplace relation for the sound velocity:

$$A=-(a_1/d_0+b_1/\beta_s^0), \tag{3}$$

where a_1 and b_1 are the coefficients of the terms proportional to m in Eqs. 1 and 2, respectively.

We calcualted the values of A from Eq. 3 by the use of Høiland and Holvik's data.[3] The values obtained are plotted against $n(e\text{-OH})$ for saccharides in Fig. 1. We used the values of $n(e\text{-OH})$ which were previously calculated.[1,2] The straight line in Fig. 1 was determined by the method of least squares and is represented by

$$A\times10^2=1.297+0.780\,n(e\text{-OH}), \tag{4}$$

with a very high correlation coefficient of 0.965.

The change of sound velocity in solution is ascribed to two effects: (1) an increase in the sound velocity by the introduction of incompressible solute molecule, and (2) a change in the water structure around the molecule.[6,7] If the solute molecule stabilizes the water structure, the sound velocity in the solution is hastened. We found that the sound velocity in aqueous solutions of alkali chlorides increases with increasing the degree of structure making of an ion, but in a cessium chloride solution, which is the strong structure-breaking ion, it is smaller than that in pure water.[7]

In Eq. 3, the value of a_1 depends on the total number of OH groups in a sugar molecule and the intrinsic volume.[3,8] The value of b_1 depends only on the sugar OH group-water interactions, which differ in different orientation of the OH group. The values of a_1 are positive, but those of b_1 are negative for all the saccharides in Fig. 1.[3] Since $A>0$ for all the saccharides in Fig. 1, the absolute values of a_1/d_0 are smaller than those of b_1/β_s^0. Thus, the value of A mainly reflects the second effect between the above two, and increases with an increase in the degree of hydration.

The e-OH groups in a sugar molecule may be effectively substituted for a water molecule within the water structure; therefore, the hydration of sugar hydroxyl groups has a stereospecific nature. Thus, a

1. Ribose, 2. arabinose, 3. mannose, 4. xylose, 5. galactose, 6. glucose, 7. sucrose, 8. maltose, 9. raffinose.

sugar molecule which has a larger number of *e*-OH groups in the molecule has a stronger stabilizing effect on the water structure.[1,9] We showed that ribose, which has only 2.1 *e*-OH groups, hardly affects the water structure.[1] The result of Fig. 1, therefore, is explained by the effect of *e*-OH groups on the water structure. The relative increments of the sound velocities in aqueous solutions of saccharides clearly show the conformation dependence of their molecules.

We wish to thank Dr. Hatsuho Uedaira for her helpful discussions.

Gamma-X Ray Coincidence Mössbauer Study with $FeSO_4 \cdot 7H_2O(^{57}Co)$

Takayuki KOBAYASHI
Department of Physics, Shiga University of Medical Science, Otsu, Shiga 520-21
(Received May 24, 1988)

Synopsis. The anomalous charge states formed after the EC decay of ^{57}Co in $FeSO_4 \cdot 7H_2O$ doped with ^{57}Co are investigated in detail using the gamma-X ray coincidence Mössbauer spectroscopy. The mechanism to form these states is explained in terms of the H_2O and SO_4^{2-} coordination shells around the decaying atom.

Anomalous states formed after a nuclear decay in insulating materials (aftereffects) have been usually investigated using the emission Mössbauer spectroscopy.[1-4] In hydrated divalent metallic compounds doped with ^{57}Co, anomalous Fe^{3+} states are usually formed and are considered to be due to the oxidation of Fe^{2+} by free OH radicals produced through radiolysis of the H_2O ligands.[5] This mechanism was examined in detail with cobalt chloride hydrates using the gamma-X ray coincidence Mössbauer spectroscopy,[6] and a determinant role of the nearest and the next nearest H_2O coordination shells according to the densities of H_2O molecules was noticed. In the recent study with metallic sulfate hydrates,[7] the influence of both H_2O and SO_4^{2-} ligands to the aftereffects has been suggested, but its detailed mechanism remains unknown. In the present work, a further investigation of the aftereffects in $FeSO_4 \cdot 7H_2O$ is therefore given using the gamma-X ray coincidence Mössbauer spectroscopy.

The principle of the experiment is based on the fact that the influence of low-energy electrons emitted during the Auger cascade after the EC decay of ^{57}Co on the surroundings of the decaying atom in the K-Auger process is approximately two times larger than that in the case of the K-X ray emission. A Mössbauer spectrum observed by using the coincidence technique only when K-X rays are emitted is, therefore, expected to give new information for the mechanism of the aftereffects on careful comparison with a conventional emission Mössbauer spectrum. More detailed explanations of the principle are described elsewhere.[6,8,9]

A sample of $FeSO_4 \cdot 7H_2O$ doped with ^{57}Co was prepared at room temperature from a very small amount of 0.25 $mol \cdot dm^{-3}$ H_2SO_4 solution of iron(II) sulfate including few μCi of ^{57}Co. The detectors used for 6.5 keV X-rays and 14.4 keV γ-rays were NaI(Tl) crystals with 1-inch diameter and 1-mm thickness. The coincidence spectrum was recorded by the conventional slow coincidence technique. The other experimental details including the block diagram of the measuring system has been given in our previous paper.[6]

The Mössbauer spectra observed and parameters obtained are shown in Fig. 1 and Table 1, respectively. The normal state in $FeSO_4 \cdot 7H_2O$ is represented by $Fe^{2+}(1)$ in Table 1, and the others are anomalous states. Figure 2 shows graphically the relative intensities of the components. The reason why the intensity of $Fe^{2+}(1)$ in the coincidence spectrum is large compared with that in the conventional spectrum can be explained obviously from the experimental principle.

The densities of the H_2O and SO_4^{2-} molecules in $FeSO_4 \cdot 7H_2O$ as a function of distance from the iron atom to the oxygen atom is shown in Fig. 3, which were calculated by considering the structure of the compound.[10] Two distinct coordination shells of H_2O and SO_4^{2-} are noticed at approximately 2 Å and 4 Å, respectively, from the iron atom. The component Fe^{3+} is considered to arise from a free OH radical pro-

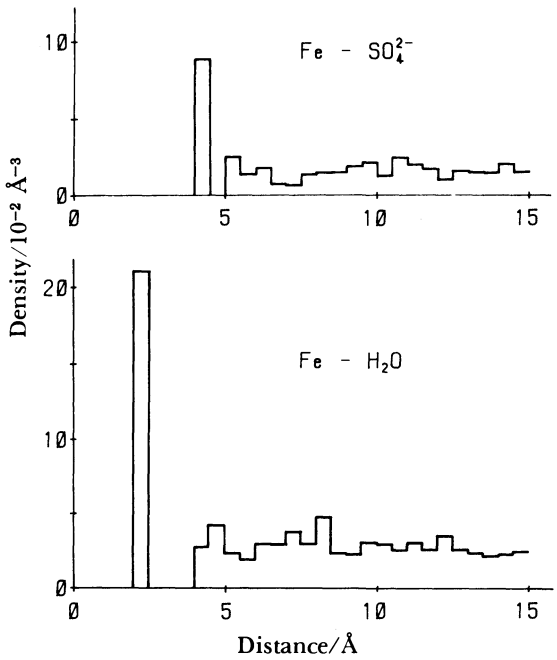

Fig. 3. Densities of H_2O or SO_4^{2-} molecules as a function of distance from a Fe atom in $FeSO_4 \cdot 7H_2O$.

duced through radiolysis of a H_2O ligand in the shell being nearest to the decaying atom, because its intensity in the coincidence spectrum is much smaller than that in the conventional spectrum. The species of Fe* having the unusual value of its isomer shift (I.S.) is unknown, but is probably a high-charged state.

The formation of the $Fe^{2+}(2)$ state can be attributed to the effect of radiolysis of SO_4^{2-} lingands. Owing to a relatively long distance between the decaying atom and a SO_3^- radical produced through radiolysis of a SO_4^{2-} ligand, this radical can hardly oxidize the iron ion which is produced after the decay of ^{57}Co. When this radical recombines with O^-, which is also produced through radiolysis, or remains in its state for a while, the local symmetry around the iron ion becomes lower and this results in a large Q.S. value. It is not easy to show the mechanism of the formation of the $Fe^{2+}(3)$ state, which has a smaller Q.S. value than the other divalent states and a similar I.S. value to the $Fe^{2+}(2)$ component. As in the case of $CoCl_2 \cdot 2H_2O$, where an equivalent component appears,[6] the ligands being further than those in the two H_2O and SO_4^{2-} shells may be involved in the formation of the $Fe^{2+}(3)$ state. The decreased $Fe^{2+}(3)$ intensity in the coincidence spectrum in comparison with that in the conventional spectrum supports this explanation. Owing to the reduction of the flux of low-energy electrons under the coincidence conditions, the number of electrons passing through the H_2O and SO_4^{2-} shells then decreases, which results in a low intensity of the component. The cause of the small Q.S. value of $Fe^{2+}(3)$ compared with that of the other divalent components is unknown.

The results obtained in the present work matches collectively with those of $CoCl_2 \cdot nH_2O$ (n=2,6).[6]

Miss Kazuko Fukumura should be acknowledged for her cooperation in preparing the sample material and in measuring the spectra.

The Thermodynamics of the Micelle Formation of Sodium α,ω-Alkanediyl Disulfate

Kenji IKEDA,* Tomoko NAKASIMA, Kunio ESUMI, and Kenjiro MEGURO
Department of Applied Chemistry, Institute of Colloid and Interface Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
(Received July 14, 1988)

Synopsis. The critical micelle concentrations of a α,ω-type surfactant: (sodium α,ω-alkanediyl disulfate: n=12, 14, 16) in an aqueous solution have been determined by studying the electrical conductivity, and the free energies of the micelle formation have then been estimated from these data. The free energy of micelle formation of a α,ω-type surfactant was smaller than that of a normal-type surfactant with the same alkyl chain length as the α,ω-type one. The free-energy changes per -(CH_2)- segment was also calculated from these data. It is found that the free-energy change per -(CH_2)- segment of the α,ω-type surfactant is −11.1 [kJ mol^{-1}].

A α,ω-type (bola form) surfactant has two head groups, are at each end of the hydrocarbon chain.[1-14] Interest in this surfactant has increased steadily in recent years from the standpoint of fundamental studies and applications. Studies of α,ω-type surfactant in aqueous solutions can be made from three points of view. First is how the α,ω-type surfactants are built up at the air-water interface. Second is how the micelle of the α,ω-type surfactants is formed in aqueous solutions and what kind of conformation the α,ω-type surfactants form in the micelle. Third is how the liquid crystalline phase of the α,ω-type surfactants is made up in a surfactant-water system. The critical micelle concentration and molecular areas have been determined by measuring the surface tension as a step in studying the carbon chain conformation in the air-water interface.[6,8] It has been suggested that the α,ω-type surfactant forms vertical "wicket-like" loops at the air-water interface. With regard to the micelle formation of α,ω-type surfactants, Zana et al.[10] have investigated the micelle properties of C_nMe_6 (N,N'-polymethylenebis(triethylammonium) dibromide: n= 12, 16, 22) by means of the P-jump and the ultrasonic absorption; they have concluded that the $C_{22}Me_6$ alkyl chain is probably folded in micelles, as the properties of $C_{22}Me_6$ are the same as those of normal alkyl-chain surfactant whose chain length is half that of $C_{22}Me_6$. We ourselves have investigated the micelle properties of $C_{20}Et_6$ in aqueous solutions by means of the ^{1}H NMR (FT PGSE technique)[12] and ^{13}C, ^{14}N NMR relaxation methods.[13] From the water, surfactant, and micelle self-diffusion coefficients, the length of alkyl carbon chain is obtained to be close to the micelle diameter. ^{13}C and ^{14}N NMR relaxation and NOE measurements indicate that the alkyl-carbon chain of $C_{20}Et_6$ is stretched out rather than folded.

The determination of the thermodynamic parameter of micelle formation has been studied by measuring the cmc at various temperatures. This kind of study is important in discussing the micelle property. In this study, several α,ω-type surfactants such as sodium α,ω-alkanediyl disulfate (n=12, 14, 16) were synthesized, and the cmc values at different temperatures were compared with that of a normal type surfactant, sodium alkyl sulfate.[16,17]

Experimental

Materials. The $C_{12}Na_2$ (sodium α,ω-dodecane disulfate) was prepared as has been described previously.[8] The $C_{14}Na_2$ and $C_{16}Na_2$ were synthesized via α,ω-alkanediol by using α,ω-alkanedioic acid (n=14, 16) (Tokyo Kasei Co.) as the starting material via α,ω-alkanediol. Normal alkanedioic acids were reduced to α,ω-alkanediol by using the borane-THF complex (Aldrich Chem. Co.). After the product has been recrystallized twice with benzene, the complete reduction to α,ω-alkanediol was confirmed by measuring the IR spectrum. The diol thus prepared was reacted with chlorosulfuric acid to give α,ω-alkane disulfate. Then, this disulfate was neutralized with sodium hydroxide. After the product has been recrystallized three times with an acetone-ethanol mixture and three times with an ethyl acetate-ethanol mixture, it was washed twice with diethyl ether and then dried more than 72 h under a vacuum. The purity of the white crystalline product was confirmed to be above 99% by means of elemental analysis, isotachophoresis (IP-3A: Shimadzu Co., Ltd.), NMR, and the surface tension.

Measurement. The electroconductivity of the solution was measured by means of a conductivity meter (Model CM-30ET Toa Denpa Co.) at 20, 25, 30, 40, 50, and 60 ±0.1 °C.

Results and Discussion

The cmc values were determined from plots of the specific conductance, κ, against the molar concentration, C, at several temperatures. These values are tabulated in Table 1. The cmc values decreased with the increase in the carbon chain lengths of the surfactant, while the cmc values of each surfactant increased with the increasing the temperature. Some cmc data taken from the literature[16] for hydrocarbon surfactants, sodium alkyl sulfates, are also shown in Fig. 1 for comparison with those for the α,ω-type surfactants. As the change in the cmc is small between 25 °C and 40 °C, the data for monoalkyl sulfate are used at 40 °C.[20] The C_nNa_2's cmc change against the carbon-chain length was smaller than that of the normal-type surfactant. From these results, it can be said that the

a) This value is taken from Ref. 7.

chain length of a α,ω-type surfactant is smaller than half the length of a normal-type surfactant.[19] Zana et al. reported that the C_nMe_6's cmc's change against the carbon-chain length was smaller than those of the C_nMe_3. This also suggests that the α,ω-type surfactant may be regarded as shorter than half the length of the normal-type surfactant. The micelle formation free energies of sodium α,ω-alkanediyl disulfate were calculated[15] from cmc measurements at different temperatures. These free energy values are shown in Table 2. A phase separation model was used for these calculations.[16] The following equation was used for the calculation of the micelle formation free energy:

$$\Delta G^\circ = (3-2\alpha)\, RT \ln \text{cmc} \qquad (1)$$

where α is the counterion binding of the micelle, R, the gas constant, and T, the absolute temperature. Each α value was also obtained by conductivity measurement. The micelle-formation free energies of C_nNa_2 were slightly decreased with increase in the temperature. The micelle-formation entropy changes in C_nNa_2 were also calculated from the cmc's at different temperatures, but the entropy changes of C_nNa_2 (n=12, 14) were negligibly small. These results show that the entropy change is not very important in forming the micelle in the case of n=12 or 14. In other words, the "iceberg" structure of water is not much destroyed when the C_nNa_2 (n=12, 14) micelle forms.[18] However, any further discussion of entropy change would be meaningless because these calculations of entropy changes contain many errors. Figure 2 shows the micelle formation free energy changes against the alkyl chain length at 60 °C. The free energy decreases with the increase in the alkyl carbon chain length. Increasing the alkyl carbon chain serves to increase in the hydrophobic effect and further to make micelle formation easier. The free energy change against the $-(CH_2)-$ segment of C_nNa_2 was -11.1 [kJ mol^{-1}].

Single Crystals Coimaged with the Gigantic Rod-Like Micelles in Viscoelastic Cationic Surfactant-Aromatic Additive Systems

Hirotaka HIRATA* and Yuko SAKAIGUCHI

(Received July 22, 1988)

Synopsis. In a system of hexadecyltrimethylammonium bromide (HTAB)-salicylic acid (SA) in which a remarkable viscoelasticity is induced, we noticed the existence of single crystals coimaged with the infinitely elongated rod-like micelles. The single crystal implied the formation of a new species, a complex which resulted from the interaction of HTAB and aromatic additives.

Previously, we reported the clear detection, under an electron microscope, of gigantic rod-like micelle images in a solution of several cationic surfactants, such as HTAB and hexadecylpyridinium bromide, with some aromatic substances added.[1] These solutions were always accompanied by a remarkable viscoelasticity.[2] The gigantic rod-like micelles showed an infinite length, and they were heavily entangled with each other, like cobwebs, in the electron micrographs.[3,4] It seemed that those aspects provided a sufficient explanation of the solution behavior in all senses.

In the course of carrying out the image observation of the elongated gigantic micelles under an electron microscope, we recently became aware of the existence of a few single crystals always together with the rod-like micelles in almost all of the surfactant and aromatic additive systems. The images of these single crystals are exhibited in Fig. 1.

The crystals in a system of HTAB-SA typically have a well grown shape in electron micrography. The image contrast to the background suggests that the crystal thickness is nearly the same as the rod-like micelle diameter or at least of the same order.

It is obvious that the crystals found in these photos are different from those of each component, CTAB or SA, for there is a clear difference in the apparent shapes of the component crystals, excluding such cases of a plausible coming out of the crystalline materials of each component from the solutions, especially of the precipitation of the surfactants below their Krafft points.

The analysis of the sharp spots caused by the electron diffraction from these single crystals are being successfully carried out in many gigantic rod-like micelle-producing systems. The spot patterns were also clearly different from those of each component crystal. The results will be reported in another place.[5]

In this context, it is worthwhile mentioning that in one of the most remarkable viscoelastic solutions, the HTAB-*o*-iodophenol system, we obtained crystalline materials which were unambiguously indicated through the elementary analysis to be composed of HTAB and *o*-iodophenol in a one-to-one molar ratio.[6] This fact distinctly reveals that a certain kind of interaction between HTAB, a quaternary ammonium, and aromatic additives acts to provide a complex.[7]

Commercially available HTAB was used after one recrystallization from an acetone-methanol mixture

(b)

Fig. 1. Single crystals coimaged in the transmission electron micrograph of CTAB-SA system in the magnification of 97,500. Specimens were prepared from 1×10^{-3} mol l^{-1} CTAB solution at mixing molar ratio of SA/CTAB=0.8. As for the details see Ref. 3.
a) Rhombus shaped single crystals are seen with a definite angle between edges.
b) Apparent hexagonal shaped single crystals are seen. The angles between edges are equal to each other as well.

while SA in a special pure grade was used as purchased. Transmission electron microscopy was carried out upon a JEOL 100CX apparatus operated at 80 kV. All the images were obtained by negative staining techniques with uranyl acetate.

We are very grateful for having received many suggestive comments on this subject from Mr. Atsuo Koreeda in the Institute of Scientific and Industrial Research of Osaka University and also for the ardent encouragement of Dr. Yoshie Kitayama of the Engineering Chemistry Department of Niigata University.

Synopsis. Catalytic activity of Y zeolites containing copper ions (CuY) for decomposition of nitrogen monoxide was enhanced through additional exchange of other metal ions or evacuation treatment around 923—973 K. In the first case, Co^{3+} or Ni^{2+} ions increase the catalytic activity while Ca^{2+}, Mn^{2+}, Fe^{2+}, and Zn^{2+} diminish the catalytic activity of CuY. In the second case, the catalytic activity of CuY evacuated at 973 K was twice that of CuY without the evacuation treatment, which is discussed in connection with the increment of Cu ions active for the decomposition.

Decomposition of nitrogen monoxide (NO) has been reported to be catalyzed over partially copper(II) ion-exchanged Y zeolites (CuY).[1] This process is the simplest method for the removal of harmful NO because any reducing agents or absorbents are not necessary.[2] Very recently we have also reported that copper ion-exchanged ZSM-5 zeolites are more active than the CuY.[3] However, much more metal ions can be exchanged into Y-type zeolite lattice than into ZSM-5, and Y zeolite can be synthesized more easily and more cheaply. From the viewpoint of practical use of the zeolite catalyst, therefore, it would be very desirable to enhance the catalytic activity of the CuY. In the present work, we have found two possible ways; an additional exchange of other metal ions or evacuation treatments at higher temperatures caused an increase in the catalytic activity of the decomposition.

Experimental

Experimental apparatus and procedures were similar to those reported previously.[1,3] The reactant gas containing 5 vol% of NO and 95% helium was passed through the catalyst bed at 773 or 823 K and the extents of conversion of NO and to N_2 and O_2 were measured by gas chromatography. The total flow rate of feed gases was 30 cm^3 min^{-1}, catalyst weight being 2.0 g. Zeolite samples prepared by the conventional ion exchange of a NaY zeolite (Linde SK-40). In the two-component zeolites (containing copper ion and additional metal ion), zeolites were ion-exchanged first with copper ion and then with the other metal ion, or in the reverse order. Exchange levels of copper and other metal ions in the two component systems were each ca. 30%.

Results and Discussion

The decomposition activities of the two-component zeolites at 773 K are summarized in Table 1. The reaction products at this temperature were N_2, O_2, and NO_2. The formation of N_2O was not observed. In the table it should be noted that the extent of converted NO was approximately twice as much as that of produced N_2. This is due to the oxidative reaction of NO with generated O_2 to yield NO_2, $2NO+O_2 \rightarrow 2NO_2$ as discussed in the previous paper.[1]

Two interesting observations should be pointed out concerning Table 1. First the activity was increased by the coexistence of Co^{3+} or Ni^{2+}, while Ca^{2+}, Mn^{2+}, Fe^{2+}, and Zn^{2+} ions diminished the decomposition ability of CuY. Secondly, the catalytic activities of the two-component zeolites were little dependent on the order of ion exchange, as shown in the table. This fact suggests that the locations of metal ions over various exchangeable sites are decided by the difference between preferences of two kinds of metal ions toward the sites and not by the order of ion exchange.

It was confirmed in separate experiments that Co^{3+} or Ni^{2+} exchanged zeolites (without Cu^{2+} ions) showed no catalytic activity for the NO decomposition, while these ions had an effect for enhancement of the catalytic activity of the CuY. This suggests that the Co^{3+} or Ni^{2+} ions presumably occupy preferentially inner sites S_I and/or $S_{I'}$ which are generally inert for the catalytic reactions, and more Cu^{2+} ions would locate on the super cage-sites. However, one can not deny the possibility that some interaction of Cu^{2+} with Co^{3+} (or Ni^{2+}) resulted in the enhancement of the activity.

Next, pretreatments for the activation of a CuY zeolite (exchange level=70%) were examined. In a pretreatment, the zeolite sample was heated to 773 K in a dynamic vacuum, exposed to oxygen for 30 min, and then reevacuated for 30 min at the same temperature to remove such impurities on the zeolite surface as water, carbon dioxide, and possibly hydrocarbons. Subsequently, the sample was again heated to a desired temperature in a dynamic vacuum and evacuated at this temperature for 1 h. The catalytic run was carried out at 823 K and the results are shown in Fig. 1. It is

Table 1. Catalytic Activities of Various Two Components Zeolites Containing Copper(II) Ions for the Decomposition of Nitrogen Monoxide at 773 K

Exchanged metal ion	CuMY[a]		MCuY[a]	
	Conversion(%)[b] of NO	to N_2	Conversion(%)[b] of NO	to N_2
Cu	10.5	6.4	—	—
Ca-Cu	4.4	2.9	7.4	3.6
Mn-Cu	6.1	3.7	10.6	4.1
Fe-Cu	6.7	3.0	5.9	5.3
Co-Cu	13.5	7.1	12.2	6.1
Ni-Cu	15.5	8.4	16.6	11.4
Zn-Cu	9.2	5.0	6.7	3.0
Ag-Cu	7.5	7.1	8.9	6.4

a) CuMY indicates the order of ion-exchange first with copper ion and then with another metal ion, while MCuY was ion-exchanged in the reverse order. b) These values were calculated on the basis of the amount of NO fed.

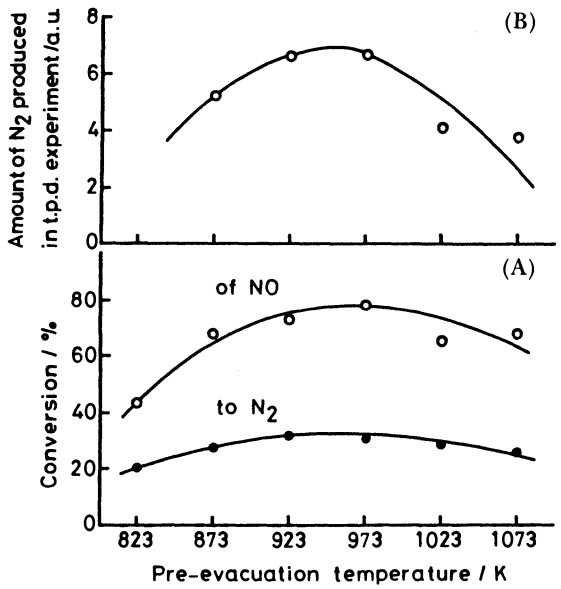

Fig. 1. Effect of the pre-evacuation temperature of the CuY zeolite (70%) on the catalytic activity for the NO decomposition at 823 K (A) and on the amounts of N_2 generated in TPD experiments (B).

evident that the evacuation at higher temperatures caused an increase in decomposition activity of the CuY, though too high evacuation temperatures resulted in a decrease in catalytic activity. The activity of the CuY evacuated at 973 K attained a level of two times as great as that of CuY without the evacuation treatment. The best temperature for evacuation were in the range 923—973 K. No deterioration of the effectiveness of the catalyst was found even after 10 h of continuous service.

To gather more evidence for the activity change of CuY catalysts, temperature programmed desorption (TPD) profiles of NO absorbed on the respective catalysts were investigated by means of the experimental method similar to that of Ref. 4. The amounts and temperatures of NO and N_2O desorbed remained roughly unchanged irrespective of the evacuation treatment. By contrast, the amounts of N_2 desorbed during the TPD procedures were dependent on the evacuation temperatures, though the desorption temperature did not change with the treatment. The amounts of N_2 are plotted in Fig. 1(B) as a function of the evacuation temperatures, indicating a bell-shaped dependence. It is noteworthy that the dependences of catalytic activities in flow system on the evacuation temperature is almost the same as that of N_2 formation in the TPD experiments. It was further confirmed in a separate TPD experiment that N_2 molecules did not chemically adsorb on the CuY surface at room temperature, indicating that the desorption of N_2 in the TPD experiments of adsorbed NO is due to the decomposition or reaction of some surface intermediates. Therefore, it follows that the increase in catalytic activity due to the evacuation around 923—973 K results from the increment of the number of active sites for the decomposition and not from the increment of turnover frequency per active site.

We have recently suggested that the active sites for the decomposition reaction would be copper(I) ions on zeolites.[3] In addition, it has also been reported that an evacuation treatment at higher temperatures above 873 K resulted in the desorption of oxygen molecules.[5,6] The desorption of oxygen would cause formation of copper(I) ions from copper(II) ions owing to charge transfer from anionic oxygen species to metal ions, which would result in the increase in the activity. The decrease in activity of CuY evacuated above 1023 K might be due to partial destruction of the zeolite lattice,[7] though we could not observe it by X-ray analysis.

In conclusion, the additional ion exchange of Co^{3+} or Ni^{2+} or the evacuation treatment around 923—973 K have been shown to enhance the catalytic activity of the CuY for the NO-decomposition.

This work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

The Formation and Stereochemistry of $[Co^{III}_3(L\text{-cys-}N,S)_n(aet)_{6-n}]^{3-n}$ Type *S*-Bridged Complexes (n=0—6, L-cys=L-cysteinate, and aet=2-aminoethanethiolate)

Takumi KONNO,* Sen-ichi AIZAWA, and Jinsai HIDAKA
Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305
(Received June 27, 1988)

Synopsis. Three kinds of *S*-bridged trinuclear complexes, $\Delta_{LLL}\Delta_{LLL}$-$[Co_3(L\text{-cys-}N,S)_6]^{3-}$, $\Delta_{LLL}\Delta$- and $\Delta_{LLL}\Lambda$-$[Co_3(L\text{-cys-}N,S)_3(aet)_3]^0$, and $[Co_3(aet)_6]^{3+}$,[1] were formed by the reaction of a mixture of Δ_{LLL}-*fac*-$[Co(L\text{-cys-}N,S)_3]^{3-}$ (L-cys=L-cysteinate) and *fac*-$[Co(aet)_3]$ (aet=2-aminoethanethiolate) with $[CoCl(NH_3)_5]^{2+}$. The reaction with an excess amount of Co^{2+} led to the formation of seven kinds of *S*-bridged complexes, $[Co_3(L\text{-cys-}N,S)_n(aet)_{6-n}]^{3-n}$($n$=0—6).

Several *S*-bridged trinuclear metal complexes with L-cysteinate (L-cys) or 2-aminoethanethiolate (aet) have been investigated because of their stereochemical and spectrochemical interest.[2-12] Recently, it was found that the formation of $[M^{III}\{Co^{III}(L\text{-cys-}N,S)_3\}_2]^{3-}$ (M=Co, Fe) by the reaction of Δ_{LLL}-*fac*-$[Co^{III}(L\text{-cys-}N,S)_3]^{3-}$ with an excess amount of Co(II) or Fe(II) was accompanied by the inversion of the starting Δ_{LLL} complex and that only the $\Delta_{LLL}\Delta_{LLL}$ isomer was formed.[9-11] On the other hand, the reaction with Co(III) or Fe(III) proceeded with a retention of the Δ_{LLL} configuration, and the $\Delta_{LLL}\Delta_{LLL}$ isomer was selectively formed.[9-11] However the mechanism of this inversion is still unknown. In order to elucidate the stereoselectivity and the mechanism of the inversion for the *S*-bridged trinuclear complexes with L-cysteinate, an attempt was made to investigate the mixed-type trinuclear complexes containing L-cysteinate and 2-aminoethanethiolate. In this paper, we report the reactions of a mixture of Δ_{LLL}-*fac*-$[Co^{III}(L\text{-cys-}N,S)_3]^{3-}$ and *fac*-$[Co^{III}(aet)_3]$ with Co(III) and with Co(II). The reaction products were characterized on the basis of the absorption and CD spectra and their column chromatographic behavior in comparison with that of $[Co_3(L\text{-cys-}N,S)_6]^{3-}$ and $[Co_3(aet)_6]^{3+}$.

Experimental

1a) Reaction with Co(III). To a solution of $[CoCl(NH_3)_5]Cl_2$ (0.18 g, 0.72 mmol) in 15 cm^3 of water was added *fac*-$[Co(aet)_3]$[3] (0.20 g, 0.70 mmol), followed by the dropwise addition of a solution containing Δ_{LLL}-*fac*-$K_3[Co(L\text{-cys-}N,S)_3]9H_2O \cdot 0.5KCl$[11] (0.51 g, 0.70 mmol) in 5 cm^3 of water. The mixture was stirred at room temperature for 30 min and then filtered to remove any insoluble materials. The dark brown filtrate was poured onto a cation-exchange column (SP-Sephadex C-25 Na^+ form, 3.5 cm×90 cm). The negative-charged band (green) containing $\Delta_{LLL}\Delta_{LLL}$-$[Co_3(L\text{-cys-}N,S)_6]^{3-}$ [10,11,13] was eluted quickly with water, and then the neutral band was eluted slowly with water and finally separated into two bands, F-1 (brown) and F-2 (green), in this order. The formation ratio of the two isomers was about 1:1. Each eluate was concentrated to dryness with a rotary evaporator. The crude F-2 isomer was recrystallized from water and the F-1 isomer from water by adding a large amount of ethanol. Found for F-1: C, 22.83; H, 5.24; N, 9.86%. Calcd for $[Co_3(L\text{-cys-}N,S)_3(aet)_3] \cdot 4H_2O \cdot 0.5C_2H_5OH = C_{16}H_{44}N_6O_{10.5}S_6Co_3$: C, 22.41; H, 5.17; N, 9.80%. Found for F-2: C, 20.01; H, 5.52; N, 9.31%. Calcd for $[Co_3(L\text{-cys-}N,S)_3(aet)_3] \cdot 8H_2O = C_{15}H_{49}N_6O_{14}S_6Co_3$: C, 19.87; H, 5.45; N, 9.27%. ^{13}C NMR for F-1: δ 19.50 (CH_3 of ethanol), 34.89 (CH_2S of aet), 38.36 (CH_2S of L-cys), 49.79 (CH_2NH_2 of aet), 60.13 (CH_2 of ethanol), 66.36 (CH of L-cys), 177.96 (COO of L-cys). The ^{13}C NMR spectrum of the F-2 isomer could not be measured because of its low solubility in water. The remaining band, adsorbed on the top of the column, contained only $[Co_3(aet)_6]^{3+}$, which was eluted with a 0.2 mol dm^{-3} aqueous NaCl solution and separated into two bands, meso ($\Delta\Lambda$, brown) and racemic ($\Delta\Delta$ and $\Lambda\Lambda$, green) isomers[4,13,14] in this order.

1b) Reaction with Co(II). To a solution of $CoCl_2 \cdot 6H_2O$ (1.0 g, 4.2 mmol) in 15 cm^3 of water was added *fac*-$[Co(aet)_3]$[3] (0.2 g, 0.70 mmol), followed by the dropwise addition of a solution containing Δ_{LLL}-*fac*-$K_3[Co(L\text{-cys-}N,S)_3] \cdot 9H_2O \cdot 0.5KCl$[11] (0.51 g, 0.70 mmol) in 5 cm^3 of water. The mixture was stirred at room temperature for 30 min and then filtered to remove any insoluble materials. The dark brown filtrate was poured onto a cation-exchange column (SP-Sephadex C-25, Na^+ form, 3.5 cm×90 cm). The negative-charged NC band was quickly eluted with water, and then the neutral A band was slowly eluted with water and finally separated into four bands, A-1 (brown), A-2 (green), A-3 (brown), and A-4 (green), in this order. After the neutral A band had been eluted with water, the positive-charged band adsorbed on the top of the column was eluted with a 0.2 mol dm^{-3} aqueous NaCl solution. The first-eluted B band was separated into four bands; B-1 (brown), B-2 (green), B-3 (brown), and B-4 (green), the secondly eluted C band into three bands; C-a (pink), C-1 (brown), and C-2 (green), and the last-eluted D band containing $[Co_3(aet)_6]^{3+}$ into two bands; meso (D-1, brown) and racemic (D-2, green) isomers.[4,13,14] The NC eluate was poured onto an anion-exchange column (QAE-Sephadex A-25, Cl^- form, 3.5 cm×90 cm). No band was eluted with water. After the column had been swept with water, the negative-charged band adsorbed on the top of the column was eluted with a 0.2 mol dm^{-3} aqueous NaCl solution. The first-eluted B′ band was separated into three bands; B′-1 (green), B′-2 (brown), and B′-3 (green), and the secondly eluted C′ band into two bands; C′-1 (brown) and C′-2 (green). Finally, the green D′ band containing $\Delta_{LLL}\Delta_{LLL}$-$[Co_3(L\text{-cys-}N,S)_6]^{3-}$ [10,11,13] was eluted. The pink C-a band was found to be an unreacted Co^{2+} species from its absorption spectrum. In this reaction, the complex could not be isolated from each eluate because of its quite small amount. Accordingly, the concentration of each eluate was estimated on the basis of the extinction coefficients of $[Co_3(aet)_6]^{3+}$ [14] and $[Co_3(L\text{-cys-}N,S)_6]^{3-}$.[11]

2) Measurements. The electronic absorption specta were recorded with JASCO UVIDEC-1 and UVIDEC-610 spectrometers, and the CD spectra with a JASCO J-20 spectropolarimeter. The ^{13}C NMR spectrum was recorded with a JEOL JNM-FX-90Q NMR spectrometer in a D_2O solvent at the probe temperature. Sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS) was used as the internal reference.

Results and Discusston

Three configurations, $\Delta\Delta$, $\Lambda\Lambda$, and $\Delta\Lambda$, with respect to the absolute configuration of the two terminal *fac*-[Co(bidentate-*N*,*S*)$_3$] moieties are possible for each of the *S*-bridged trinuclear complexes, [Co$_3$(L-cys-*N*,*S*)$_n$(aet)$_{6-n}$]$^{3-n}$ (n=0—6) (Fig. 1). In addition, another type of isomers arising from the arrangement of the L-cys-*N*,*S* and aet ligands are possible for each of the [Co$_3$(L-cys-*N*,*S*)$_n$(aet)$_{6-n}$]$^{3-n}$ (n=0—6) complexes (Table 1). The reaction of a mixture containing Δ_{LLL}-*fac*-[Co(L-cys-*N*,*S*)$_3$]$^{3-}$ and *fac*-[Co(aet)$_3$] with [CoCl(NH$_3$)$_5$]$^{2+}$ produced the F-1 (brown) and F-2 (green) neutral isomers besides $\Delta_{LLL}\Delta_{LLL}$-[Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$ and [Co$_3$(aet)$_6$]$^{3+}$. Figure 2 illustrates the absorption and CD spectra of the F-1 and F-2 isomers. The absorption spectra of the F-1 and F-2 isomers coincide well with those of [Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$ [10-12] and [Co$_3$(aet)$_6$]$^{3+}$. [4,14]

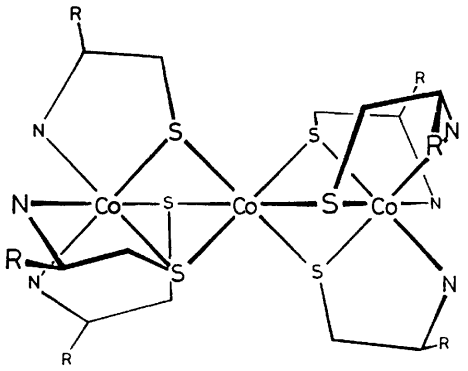

Fig. 1. Structure of [Co$_3$(L-cys-*N*,*S*)$_n$(aet)$_{6-n}$]$^{3-n}$ having the $\Delta\Lambda$ configuration. (R=H for aet, R=COO$^-$ for L-cys)

The CD spectra of the F-1 and F-2 isomers are in good agreement with those of $\Delta_{LLL}\Lambda_{LLL}$-[Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$ [12] and $\Delta_{LLL}\Delta_{LLL}$-[Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$ [10,11] respectively. These facts suggest that the green isomer is $\Delta_{LLL}\Lambda$-[Co$_3$(L-cys-*N*,*S*)$_3$(aet)$_3$], while the brown isomer is the $\Delta_{LLL}\Lambda$ one. Thus, for the reaction with [CoCl(NH$_3$)$_5$]$^{2+}$ the starting Δ_{LLL}-*fac*-[Co(L-cys-*N*,*S*)$_3$]$^{3-}$ and/or *fac*-[Co(aet)$_3$] complexes bridge to the Co(III) ion through the facial thiolato donor atoms, forming three types of trinuclear complexes; $\Delta_{LLL}\Delta_{LLL}$-[Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$, $\Delta_{LLL}\Delta$- and $\Delta_{LLL}\Lambda$-[Co$_3$(L-cys-*N*,*S*)$_3$(aet)$_3$]^0, and [Co$_3$(aet)$_6$]$^{3+}$. This formation mechanism is consistent with the fact that the reaction of Δ_{LLL}-*fac*-[Co(L-cys-*N*,*S*)$_3$]$^{3-}$ with [CoCl(NH$_3$)$_5$]$^{2+}$ produced only $\Delta_{LLL}\Delta_{LLL}$-[Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$, retaining the absolute configuration of the starting Δ_{LLL} complex. [10,11] The overall absorption spectra of the $\Delta_{LLL}\Lambda$ (green) and $\Delta_{LLL}\Lambda$ (brown) isomers are similar to each other, but a notable difference is observed in the lowest energy region; the $\Delta_{LLL}\Lambda$ (green) isomer has an absorption peak at 18.18×10^3 cm^{-1}, while the corresponding absorption component for the $\Delta_{LLL}\Lambda$ (brown) isomer appears as a shoulder at 18.9×10^3 cm^{-1} (Fig. 2). A similar difference in the absorption spectra between the $\Delta\Delta$ or $\Lambda\Lambda$ isomer (green) and the $\Delta\Lambda$ isomer (brown) was also observed for [Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$ [10-12] and [Co$_3$(aet)$_6$]$^{3+}$. [4,14]

In contrast with the reaction with [CoCl(NH$_3$)$_5$]$^{2+}$, the reaction with an excess amount of Co^{2+} gave a number of trinuclear complexes, of which absorption and CD spectral behavior agrees well with that of [Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$ and [Co$_3$(aet)$_6$]$^{3+}$. The last-eluted D band of a cation-exchange column and the last-eluted D′ band of an anion-exchange column contained [Co$_3$(aet)$_6$]$^{3+}$ and $\Lambda_{LLL}\Lambda_{LLL}$-[Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$

Table 1. Possible Isomers and Formation Ratio of Isomers for [Co$_3$(L-cys-*N*,*S*)$_n$(aet)$_{6-n}$]$^{3-n}$(n=0—6)

Complexes	Possible Isomers	Eluates	Assignments	Formation Ratio (%)	Δ:Λ

[Co$_3$(L-cys-*N*,*S*)$_6$]$^{3-}$	$\Delta_{LLL}\Delta_{LLL}$, $\Lambda_{LLL}\Lambda_{LLL}$ $\Delta_{LLL}\Lambda_{LLL}$	D′(green)	$\Lambda\Lambda$	11.4	0:100

The number of the subscript L for Δ or Λ denotes the number of the L-cys-*N*,*S* ligand in the terminal moiety.

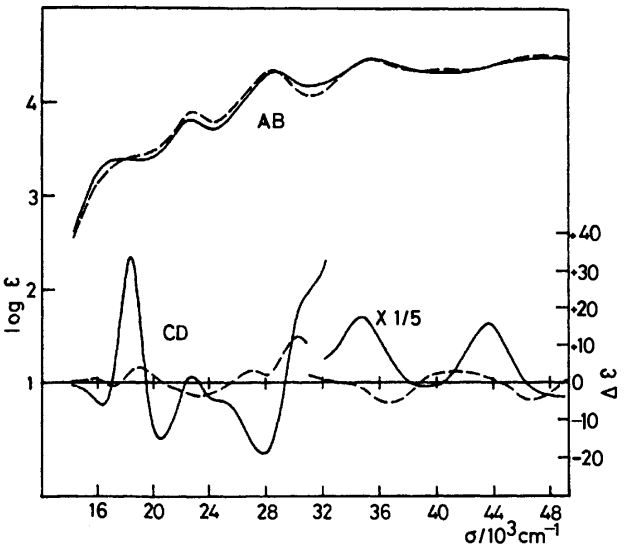

Fig. 2. Absorption and CD spectra of the $\Delta_{LLL}\Delta$ (——) and $\Delta_{LLL}\Lambda$ (----) isomers of $[Co_3(L\text{-cys-}N,S)_3(aet)_3]$.

respectively. Taking these absorption and CD spectral and column chromatographic behavior into consideration, it is probable that the C, B, A, B′, and C′ adsorbed bands contained the *S*-bridged trinuclear complexes, $[Co_3(L\text{-cys-}N,S)(aet)_5]^{2+}$, $[Co_3(L\text{-cys-}N,S)_2(aet)_4]^{+}$, $[Co_3(L\text{-cys-}N,S)_3(aet)_3]^{0}$, $[Co_3(L\text{-cys-}N,S)_4(aet)_2]^{-}$, and $[Co_3(L\text{-cys-}N,S)_5(aet)]^{2-}$ respectively. The formation of all seven kinds of complexes, $[Co_3(L\text{-cys-}N,S)_n(aet)_{6-n})]^{3-n}$ (n=0—6), indicates that the L-cys-*N*,*S* and aet ligands dissociate from the starting Δ_{LLL}-*fac*-$[Co(L\text{-cys-}N,S)_3]^{3-}$ and *fac*-$[Co(aet)_3]$ complexes through the reaction with Co^{2+}, followed by the rearrangement of these ligands to form a trinuclear structure. The green isomers showing an absorption peak at ca. 18×10^3 cm^{-1} are assignable to take the $\Delta\Delta$ or $\Lambda\Lambda$ configuration, while the brown isomers showing a shoulder at ca. 19×10^3 cm^{-1} take the $\Delta\Lambda$ configuration (vide supra). Moreover, the CD spectra of the isomers are classified into the three CD patterns of $\Delta_{LLL}\Delta_{LLL}$-, $\Delta_{LLL}\Lambda_{LLL}$-, and $\Lambda_{LLL}\Lambda_{LLL}$-$[Co_3(L\text{-cys-}N,S)_6]^{3-}$.[10-12] Accordingly, the absolute configuration ($\Delta\Delta$, $\Delta\Lambda$, or $\Lambda\Lambda$) for each trinuclear isomer can be assigned on the basis of the absorption and CD spectra as given in Table 1, although it is difficult to determine the arrangement of the L-cys-*N*,*S* and aet ligands. The formation ratios of the isomers obtained by the reaction with an excess amount of Co^{2+} are summarized in Table 1. The ratio of the Δ and Λ terminals in each trinuclear complex ($\Delta:\Lambda$) was evaluated from the values of the formation ratio of the $\Delta\Delta$, $\Delta\Lambda$, and $\Lambda\Lambda$ configurations (Table 1). No $\Delta\Delta$ isomer was formed for $[Co_3(L\text{-cys-}N,S)_6]^{3-}$, $[Co_3(L\text{-cys-}N,S)_5(aet)]^{2-}$, $[Co_3(L\text{-cys-}N,S)_4(aet)_2]^{-}$, and $[Co_3(L\text{-cys-}N,S)_3(aet)_3]$, which contain the $[Co(L\text{-cys-}N,S)_3]^{3-}$ and/or $[Co(L\text{-cys-}N,S)_2(aet)]^{-}$ terminals. Of these complexes, $[Co_3(L\text{-cys-}N,S)_6]^{3-}$ gave only the $\Lambda_{LLL}\Lambda_{LLL}$ isomer (D′), as in the case of the reaction of Δ_{LLL}-*fac*-$[Co(L\text{-cys-}N,S)_3]^{3-}$ with an excess amount of Co^{2+}[10,11] and the two isomers of $[Co_3(L\text{-cys-}N,S)_5(aet)]^{2-}$, $\Lambda_{LLL}\Delta_{LL}$ (C′-1) and $\Lambda_{LLL}\Lambda_{LL}$ (C′-2), were formed in a ratio of about 1:8. This behavior indicates that the $[Co(L\text{-cys-}N,S)_3]^{3-}$ and $[Co(L\text{-cys-}N,S)_2(aet)]^{-}$ terminals prefer strongly the Λ configuration to the Δ one. The Λ configurational preference is observed even for the $[Co(L\text{-cys-}N,S)(aet)_2]^{+}$ terminal; the C-2 eluate containing $\Delta_L\Delta$- and $\Delta_L\Lambda$-$[Co_3(L\text{-cys-}N,S)(aet)_5]^{2+}$ showed the same CD spectral pattern as did $\Lambda_{LLL}\Lambda_{LLL}$-$[Co_3(L\text{-cys-}N,S)_6]^{3-}$,[10,11] suggesting that the $\Delta_L\Lambda$ isomer is dominant in the C-2 eluate.[15] Thus, the L-cys-*N*,*S* ligand exerts a significant influence on the Λ configurational selectivity for the trinuclear structure, and the influence for each trinuclear complex can be estimated from the ratios of $\Delta:\Lambda$. That is, the values of the Λ terminal increase almost in proportion to the number of the L-cys-*N*,*S* ligand in the trinuclear complex (Table 1). This result is in contrast with the fact that mononuclear complexes with the L-cys-*N*,*S* ligand prefer the Δ configuration.[16-18]

Cis to Trans Photoisomerization of $[CoCl_2\{(CH_3)_2PCH_2CH_2CH_2P(CH_3)_2\}_2]^+$, $[CoCl(H_2O)\{(CH_3)_2PCH_2CH_2P(CH_3)_2\}_2]^{2+}$ and Related Complexes

(Received August 22, 1988)

Synopsis. Ligand field irradiation of *cis*-$[CoCl_2\{(CH_3)_2PCH_2CH_2CH_2P(CH_3)_2\}_2]^+$ in methanol and *cis*-$[CoCl(H_2O)\{(CH_3)_2PCH_2CH_2P(CH_3)_2\}_2]^{2+}$ in acetonitrile at 5 °C led to isomerization to the trans isomer with quantum yields of 0.010 and 0.070, respectively. The same cis to trans photoisomerization of $[CoCl_2(R_2PCH_2CH_2PR_2)_2]^+$ (R=CH_3, C_4H_9) occurred with much smaller quantum yields (ca. 1×10^{-4}) and *cis*-$[CoCl_2\{(C_6H_5)_2PCHCHP(C_6H_5)_2\}_2]^+$ was reduced to cobalt(II) species on irradiation.

Although photochemistry of cobalt(III) complexes has been studied extensively, reactions with a high quantum yield are limited to a few complexes.[1] Recently, Houlding and Miskowski[2] have reported the photoaquation of $[Co\{(CH_3O)_2PCH_2CH_2P(OCH_3)_2\}_3]^{3+}$ with a high quantum yield of 0.26. In this paper we report photoisomerizations of several *cis*-bis(diphosphine)cobalt(III) complexes to trans isomers in methanol or aceotnitrile solutions. The phosphine ligands are $(CH_3)_2PCH_2CH_2P(CH_3)_2$=dmpe, $(CH_3)_2PCH_2CH_2CH_2P(CH_3)_2$=dmpp, $(C_4H_9)_2PCH_2CH_2P(C_4H_9)_2$=dbpe, and *cis*-$(C_6H_5)_2PCHCHP(C_6H_5)_2$=dpee.

Experimental

Materials. The complexes were prepared as described peviously.[3] Methanol and acetonitrile used for solvents were purified and dried by standard methods, and purged with dry nitrogen for 10 min prior to use.

Quantum Yield Determinations. Photolyses were carried out with solutions (3.0 cm^3, ca. 3.0×10^{-4} to 3.0×10^{-3} mol dm^{-3}) in a 1.0 cm length spectrophotometer cell which was thermostated at 5±0.5 °C. Solutions in the cell were stirred during irradiation. The light source was a 150 W Xenon short arc lamp of Ushio Co., Ltd. with a mirror to enhance the light intensity on the cell window. Irradiation light was made monochromatic by use of a JASCO CT-10 monochrometer. The incident photon flux on the cell window as measured by trioxalatoferrate(III)[4] and reineckate actinometry[5] ranged from 6.4×10^{-9} to 3.2×10^{-8} einstein cm^{-2} s^{-1}. Absorption spectral changes of a solution were recorded on a JASCO UVIDEC 650 or a HITACHI U-3400 spectrophotometer at appropriate intervals during irradiation. Quantum yields were determined from the spectral data for less than 20% reactions according to the method of Adamson et al.[6] The values were corrected for thermal reactions (isomerization) in the dark, which were, however, negligibly slow under the experimental conditions (5 °C).[3]

Results and Discussion

Figures 1 and 2 show absorption spectra of *cis*- and *trans*-$[CoCl_2(dmpp)_2]^+$ and *cis*- and *trans*-$[CoCl(H_2O)(dmpe)_2]^{2+}$, respectively. In a previous paper,[3] we assigned the band at 16700 cm^{-1} of *trans*-$[CoCl_2(dmpp)_2]^+$ to the split component (Ia) of the first d-d band ($^1T_{1g}\leftarrow{}^1A_{1g}(O_h)$), and the broad band (17000—22000 cm^{-1}) and the shoulder around 25000 cm^{-1} of *cis*-$[CoCl_2(dmpp)_2]^+$ to the first and the second

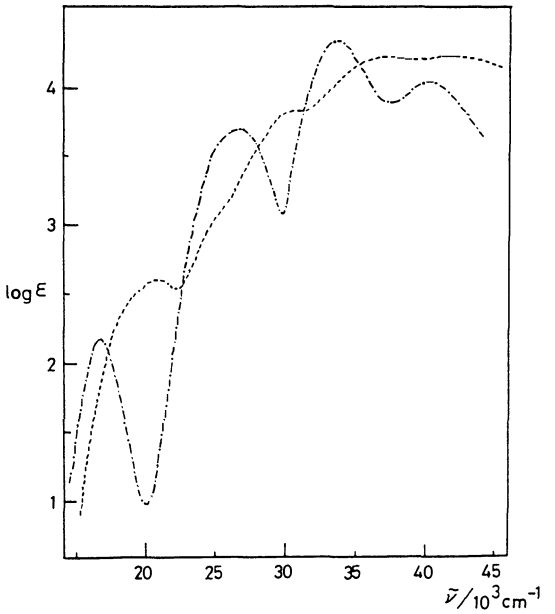

Fig. 1. Absorption spectra of *cis*- and *trans*-$[CoCl_2(dmpp)_2]^+$, (——) and (–·–·–).

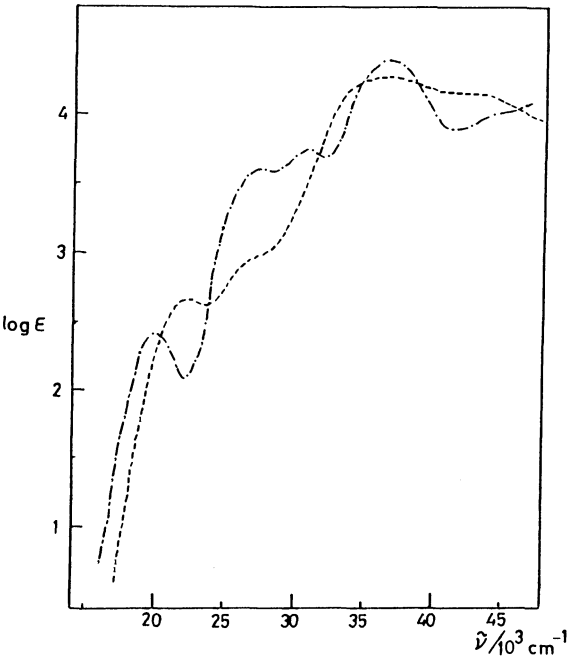

Fig. 2. Absorption spectra of *cis*- and *trans*-$[CoCl(H_2O)(dmpe)_2]^{2+}$, (——) and (–·–·–).

† Present address: Hitachi Research Laboratory, Hitachi Ltd., Hitachi, Ibaraki 319-12.

($^1T_{2g} \leftarrow {}^1A_{1g}(O_h)$) d-d bands, respectively. The ligand field spectra of other $[CoCl_2L_2]^+$ (L=dmpe, dbpe, dpee) are very similar to those of the corresponding isomers of the dmpp complex except that the absorption maxima are slightly shifted to higher energy in the order L=dpee<dbpe<dmpp<dmpe. For $[CoCl(H_2O)(dmpe)_2]^{2+}$, the trans isomer shows the first band at 20100 cm^{-1}, and the cis isomer gives the first band at 22400 cm^{-1} and the second one around 27000 cm^{-1} as a shoulder. Other strong bands in the higher energy region are all attributable to charge-transfer transitions from ligands to cobalt(III).

Figure 3 shows the changes in absorption spectrum at 5 min intervals that occur upon 480 nm irradiation of *cis*-$[CoCl_2(dmpp)_2]^+$ in methanol at 5 °C. Two clear isosbestic points were found at 442 nm and 571 nm. After 3 h irradiation the spectrum almost coincided with that of *trans*-$[CoCl_2(dmpp)_2]^+$. The *trans*-$[CoCl_2(dmpp)_2]^+$ isomer showed no spectral change by the same irradiation even for more than 10 h. Thus the photolysis of *cis*-$[CoCl_2(dmpp)_2]^+$ is concluded to afford only the trans isomer. Photolyses with 545 and 452 nm lights gave similar results. The quantum yields were determined according to the method of Adamson et al.,[6] and are listed in Table 1.

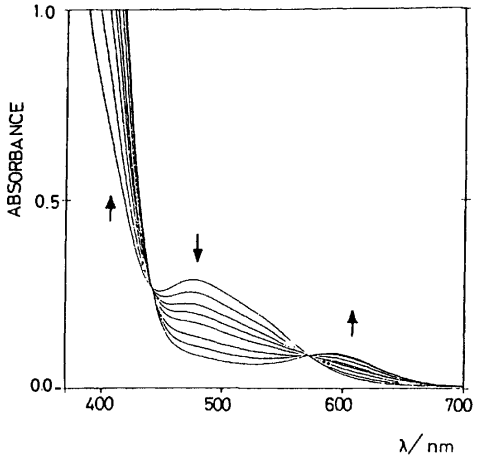

Fig. 3. Sequence of absorption spectra on 480 nm irradiation of *cis*-$[CoCl_2(dmpp)_2]^+$ in methanol at 5°C (5 min intervals).

a) Solvent; methanol. b) Reductions to Co(II) species. c) Solvent; acetonitrile.

Ligand field irradiation of *cis*-$[CoCl_2(L)_2]^+$ (L=dmpe and dbpe) caused very small changes in the absorption spectra. The changes have isosbestic points and also indicate the isomerization to the trans isomers. However, the quantum yields were about 1×10^{-4}. In the case of the dpee complex, the spectrum changed with no isosbestic points and the intensity decreased. The changes indicate that the reduction of cobalt(III) to cobalt(II) took place by irradiation, although the photolysis products were not characterized. Thus the *cis*-dichloro complexes of 1,2-diphosphines exhibited different photochemical behavior from that of the 1,3-diphosphine, dmpp complex.

In contrast to rather photoinert *cis*-$[CoCl_2(dmpe)_2]^+$, *cis*-$[CoCl(H_2O)(dmpe)_2]^{2+}$ in acetonitrile yielded the trans isomer on irradiation at 452 nm with a quantum yield of 0.070. This value is about 700 times as large as that of *cis*-$[CoCl_2(dmpe)_2]^+$. The trans isomer was photoinert under the same conditions. Sheridan and Adamson[6] reported similar photoisomerization for an ethylenediamine (en) analog, *cis*-$[CoCl(H_2O)(en)_2]^{2+}$ in 0.2 mol dm^{-3} HCl; the complex undergoes cis to trans isomerization on 488 nm irradiation with a quantum yield of 0.0042, while the trans isomer is photoinert. Thus both chloroaqua complexes of en and dmpe exhibit similar photoreactivity, but the quantum yield of the former is smaller than that of the latter by a factor of about 10.

On irradiation with ultraviolet light (254 and 334 nm) *cis*-$[CoCl_2(L)_2]^+$ (L=dmpe and dmpp) and *cis*-$[CoCl(H_2O)(dmpe)_2]^{2+}$ isomerized to the trans isomers. In the spectral changes, isosbestic points were almost kept until about 45, 50, and 80% reactions of the dichloro complexes of dmpe and dmpp, and the chloroaqua complex of dmpe, respectively. Further photolyses led to apparent deviation from the isosbestic points. The deviations will be attributable to photoreaction of the reaction products, trans isomers, since all of these trans isomers undergo photolyses on 254 nm irradiation at moderate rates. These reactions are supposed to be reduction of cobalt(III) to cobalt(II), since ligand field bands characteristic of cobalt(III) complexes disappear. The quantum yields were obtained from the spectral data for less than 20% reactions. The value of *cis*-$[CoCl_2(dmpp)_2]^+$ was nearly the same as those obtained by ligand field irradiation. The independence on the wavelength of irradiation light suggests a reaction from a low energy excited state, although the mechanism is not clear at present. For most photoreactions of cobalt(III) complexes with strong ligands such as CN^- a ligand field triplet pathway has been postulated.[1] However, the value of *cis*-$[CoCl_2(dmpe)_2]^+$ obtained by 254 nm irradiation is about fifty times as large as that by 452 nm irradiation. No explanation can be given to the difference between the dmpp and dmpe complexes at present. The dbpe and dpee complexes were more susceptible to photoreduction on irradiation at 254 nm and the quantum

yields were not determined.

A Mild Selective Monobromination Reagent System for Alkoxybenzenes; *N*-Bromosuccinimide-Silica Gel

Hisatoshi KONISHI,* Katsutomo ARITOMI, Tamon OKANO, and Jitsuo KIJI
Department of Environmental Chemistry & Technology, Tottori University, Koyama-minami, Tottori 680
(Received May 2, 1988)

Synopsis. The monobromination of alkoxybenzenes with *N*-bromosuccinimide catalyzed by silica gel in carbon tetrachloride occurred preferentially at the para-position. *m*-*t*-Butylmethoxybenzene yielded 4-bromo-3-*t*-butyl-1-methoxybenzene with a selectivity of 74% even in the presence of a bulky substituent at the meta-position.

A variety of methods for the selective nuclear bromination of activated aromatic compounds has been developed in view of the importance of the brominated compound in organic syntheses. The monobromination of 1,3-dimethoxybenzenes was conducted using a dioxane-bromine complex.[1] The reagent is somewhat troublesome to use due to its hygroscopic property and thermal instability at room temperature.

Silica-gel-catalyzed chlorination of aromatic compounds has attracted much interest owing to its simplicity and selectivity.[2-5] Various types of chlorinating agents may be used. These studies prompted us to examine the silica-gel-catalyzed nuclear bromination of activated aromatic compounds with *N*-bromosuccinimide (NBS). Recently, the bromination of indoles and benzimidazoles with NBS-silica gel has been reported.[6] Here, we would like to describe a facile method for the selective monobromination of reactive alkoxybenzenes and to briefly discuss the role of silica gel in the reaction.

Results and Discussion

The results of bromination are summarized in Table 1. The reaction of *m*-dimethoxybenzene with a slight excess of NBS in carbon tetrachloride containing silica gel at 30 °C for 2 h gave 1-bromo-2,4-dimethoxybenzene in quantitative yield. No trace of the dibromo compound was detected. In the absence of silica gel, no bromination was observed. The rate of the reaction was largely dependent upon the amount of silica gel and the stirring speed. This was due to the heterogeneity of the reaction. A variety of silica gels showed the catalytic activity of bromination; an acidic silica gel (Microbead 3A, chromatographic material, Fuji-Davison) is very effective.

A similar treatment of *o*-dimethoxybenzene and 1-methoxynaphthalene gave monobrominated products in excellent yields. Methoxybenzene and ethoxybenzene required a longer time. The bromination is highly para-selective. Methoxybenzene gave a para-isomer of >98.5% purity. In the cases of substrates with a para-substituent, such as *p*-dimethoxybenzene and 2-methoxynaphthalene, ortho bromination occurred in moderate yields.

The reaction of *m*-dimethoxybenzene with 2.2 equivalent of NBS for 45 h gave 1,5-dibromo-2,4-dimethoxybenzene in 80% yield. In other cases, dibromination is of no practical value, due to the slow reaction.

In order to obtain some insight into the mechanism of bromination, the reaction of a series of *m*-alkylmethoxybenzenes was carried out. Electrophilic bromination with NBS in polar solvents has been reported,[7,8] and it was considered that NBS was activated on the polar silica-gel surface. It was expected that the regioselectivity of the bromination by a bulky electrophile is affected by a substituent at the meta position. However, the bromination of *m*-methyl-, *m*-ethyl-, and *m*-isopropylmethoxybenzenes occurred exclusively at the para-position to the methoxyl group. It was particularly noteworthy that *m*-*t*-butylmethoxybenzene yielded 4- and 6-bromo-3-*t*-butyl-1-methoxybenzene in a ratio of 74:26. These

Table 1. Bromination of Alkoxybenzenes with *N*-Bromosuccinimide/Silica Gel in Carbon Tetrachloride[a]

Alkoxybenzene	Time / h	Product	Yield / %
m-Dimethoxybenzene	2	1-Bromo-2,4-dimethoxybenzene	99
o-Dimethoxybenzene	4	4-Bromo-1,2-dimethoxybenzene	98
p-Dimethoxybenzene	24	2-Bromo-1,4-dimethoxybenzene	58
1-Methoxynaphthalene	4	4-Bromo-1-methoxynaphthalene	99

m-Isopropylmethoxybenzene	20	4-Bromo-3-isopropyl-1-methoxybenzene	78
m-*t*-Butylmethoxybenzene	20	4- and 6-Bromo-3-*t*-butyl-1-methoxybenzene	85[b]

a) Substrate (2 mmol), NBS (2.1 mmol), Silica gel (Microbead 3A, 1g), CCl_4 (20 ml), 30°C.
b) Product distribution (4-/6-=74/26).

results were entirely unexpected, since electrophilic aromatic substitution at the ortho-position to a *t*-butyl group is highly suppressed due to its bulkiness.[9] Indeed, the iron-catalyzed bromination of *m*-*t*-butylmethoxybenzene yielded only 6-bromo-3-*t*-butyl-1-methoxybenzene. These findings imply that the steric repulsion between a *m*-alkyl substituent and a brominating species is not a dominant factor for controlling the isomer distribution.

Thallium(III)-induced bromination of meta-alkylmethoxybenzenes has been reported to be para selective.[10] The formation of 4-bromo-3-*t*-butyl-1-methoxybenzene with ca. 40% selectivity was attributed to the electronic control. In the present system, NBS is slightly polarized on the silica-gel surface; it can, therefore, be presumed that the brominating species has a considerable soft character. The regioselectivity in the electrophilic aromatic substitution by soft electrophiles is determined by the frontier electron density,[11] the reaction is expected to occur preferentially at the para-position for the methoxybenzene.

The regioselectivity is affected by the nature of the silica gels. Neutral and basic silica gels gave somewhat better selectivity, though the conversion was lower than that catalyzed by Microbead 3A. The silica gel, conversion/% at 10 h, and the selectivity for the 4-bromo-3-*t*-butyl-1-methoxybenzene were follows: Microbead 3A, 97, 74; Microbead 4B (neutral, Fuji-Davison), 62, 79; Microbead 5D (basic, Fuji-Davison), 51, 86; Wakogel C-300 (Wako Chemicals), 38, 84; Kieselgel 60 (Merck), 51, 82.

The commercial availability of the reagent, simple reaction conditions, no evolution of hydrogen bromide and excellent yields of the monobrominated products make our method valuable from a preparative point of view.

Experimental

N-Bromosuccinimide was recrystallized from water and dried over phosphorus pentaoxide. Silica gels were used as received. The bromination was conducted in the dark. ^{1}H NMR and ^{13}C NMR spectra were recorded on a JEOL GX-270 spectrometer in $CDCl_3$ operating at 270 and 67.9 MHz with tetramethylsilane as an internal standard. IR spectra were obtained with a JASCO IRA-1 spectrophotometer. GC-MS measurements were carried out on a Hitachi M-52 mass spectrometer. The IR and mass spectral properties of the products were in accord with the assigned structure. Analytical gas chromatography was performed on a Yanagimoto G-180 with a flame ionization detector using 3 m×3 mm Silicone OV-17(2%)/Chromosorb W, Silicone DC-560 (10%)/Chromosorb W, and PEG 20M(25%)/Shimalite columns. The GLPC analyses of the isolated products indicated the purity of >98%.

Silica-Gel-Catalyzed Bromination of *m*-Dimethoxybenzene with NBS: A Typical Procedure: To a solution of *m*-dimethoxybenzene (276 mg, 2 mmol) in carbon tetrachloride (20 ml) were added *N*-bromosuccinimide (374 mg, 2.1 mmol) and Microbead 3A (1.00 g). The mixture was vigorously stirred at 30 °C for 2 h. The insoluble material was removed by filtration, washed with aqueous sodium thiosulfate, and dried over anhydrous sodium sulfate. Filtration, removal of the solvent, and Kugelrohr distillation (bath temperature 133 °C, 2.7 kPa) yielded 433 mg (99%) of 1-bromo-2,4-dimethoxybenzene. ^{1}H NMR ($CDCl_3$); δ=3.862 (MeO), 3.897 (MeO), 6.393 (H-5, dd, J_{35}, 2.4 Hz, J_{56}, 8.7 Hz), 6.482 (H-3, d), 7.398 (H-6, d).

4-Bromo-1,2-dimethoxybenzene (135 °C, 2.7 kPa). ^{1}H NMR ($CDCl_3$); δ=3.834 (MeO), 3.867 (MeO), 6.732 (H-6, d, J_{56}, 8.6 Hz), 6.976 (H-3, d, J_{35}, 2.3 Hz), 7.029 (H-5, dd).

2-Bromo-1,4-dimethoxybenzene (133 °C, 2.7 kPa). ^{1}H NMR ($CDCl_3$); δ=3.758 (MeO), 3.842 (MeO), 6.81 (H-5 and H-6, m), 7.116 (d, J_{45}, 2.6 Hz).

4-Bromo-1-methoxynaphthalene (105 °C, 25 Pa). ^{1}H NMR ($CDCl_3$); δ=3.920 (MeO), 6.617 (H-2, d, J_{23}, 8.0 Hz), 7.50 (H-7, m), 7.59 (H-6, m), 7.628 (H-3, d), 8.148 (H-5, d, J_{56}, 8.0 Hz), 8.250 (H-8, d, J_{78}, 8.0 Hz).

1-Bromo-2-methoxynaphthalene (110 °C, 30 Pa). ^{1}H NMR ($CDCl_3$); δ=4.008 (MeO), 7.250 (H-3, d, J_{34}, 9.0 Hz), 7.38 (H-6, m), 7.55 (H-7, m), 7.757 (H-5, d, J_{56}, 8.0 Hz), 7.788 (H-4, d), 8.216 (H-8, d, J_{78} 8.7 Hz).

***p*-Bromomethoxybenzene** (120 °C, 3.3 kPa). ^{1}H NMR ($CDCl_3$); δ=3.756 (MeO), 6.76 and 7.36 (AA'BB').

***p*-Bromoethoxybenzene** (123 °C, 3.0 kPa). ^{1}H NMR ($CDCl_3$); δ=1.399 (CH_3, t, *J* 6.9 Hz), 3.990 (CH_2, q) 6.75 and 7.34 (AA'BB').

4-Bromo-3-methyl-1-methoxybenzene (123 °C, 3.3 kPa). ^{1}H NMR ($CDCl_3$); δ=2.360 (CH_3), 3.765 (MeO), 6.607 (H-6, dd, J_{56}, 8.6 Hz, J_{26}, 3.0 Hz), 6.781 (H-2, d), 7.391 (H-5, d).

4-Bromo-3-ethyl-1-methoxybenzene (112 °C, 1.9 kPa). ^{1}H NMR ($CDCl_3$); δ=1.212 (CH_3, t, *J*, 7.5 Hz), 2.713 (CH_2, q), 3.781 (MeO), 6.615 (H-6, dd, J_{56}, 8.6 Hz, J_{26}, 3.0 Hz), 6.786 (H-2, d), 7.269 (H-5, d).

4-Bromo-3-isopropyl-1-methoxybenzene (116 °C, 2.1 kPa). ^{1}H NMR ($CDCl_3$); δ=1.228 (CH_3, d, *J*, 6.9 Hz), 3.310 (CH, sep), 3.788 (MeO), 6.606 (H-6, dd, J_{26} 2.9 Hz, J_{56} 8.7 Hz), 6.826 (H-2, d), 7.411 (H-5, d).

6-Bromo-3-*t*-butyl-1-methoxybenzene: To a mixture of *m*-*t*-butylmethoxybenzene (20 mmol) and a trace amount of iron powder was added a solution of bromine (20 mmol) in carbon tetrachloride (20 ml). The mixture was stirred for 2 h, and poured into water (50 ml). After the conventional work-up, 6-bromo-3-*t*-butyl-1-methoxybenzene was obtained by Kugelrohr distillation (125 °C, 2.0 kPa) in 85% yield. ^{1}H NMR ($CDCl_3$); δ=1.314 (*t*Bu), 3.900 (MeO), 6.857 (H-4, dd, J_{24}, 2.2 Hz, J_{45}, 8.3 Hz), 6.918 (H-2, d), 7.425 (H-5, d). ^{13}C NMR ($CDCl_3$); δ=31.1 (q), 34.7 (s), 55.9 (q), 108.3 (C-6, s), 109.5 (C-2, d), 118.8 (C-4, d), 132.4 (C-5, d), 152.0 (C-3, s), 155.2 (C-1. s).

Bromination of *m*-*t*-Butylmethoxybenzene with NBS–Silica Gel: Silica-gel-catalyzed bromination was carried out in a similar manner as described above for 20 h. ^{1}H and ^{13}C NMR analysis of the distillate indicated that it consisted of two components in a ratio of 74:26. The NMR spectral data of the minor component was identical with those of 6-bromo-3-*t*-butyl-1-methoxybenzene. On the basis of the ^{1}H and ^{13}C NMR data, the major component was assigned to 4-bromo-3-*t*-butyl-1-methoxybenzene: ^{1}H NMR ($CDCl_3$) δ= 1.492 (*t*Bu), 3.781 (MeO), 6.577 (H-6, dd, J_{26}, 3.2 Hz, J_{56}, 8.7 Hz), 6.997 (H-2, d), 7.465 (H-5, d). ^{13}C NMR ($CDCl_3$); δ=29.6 (q), 36.6 (s), 55.3 (q), 111.5 (C-6, d), 113.0 (C-4, s), 115.3 (C-2, d), 136.1 (C-5, d), 148.9 (C-3, s), 158.6 (C-1, s).

(Received July 13, 1988)

Synopsis. Four pentapeptide *N*-hydroxysuccinimide esters [X-Orn(Z)-Leu-Y-Pro-ONSu (X=Val or D-Val, and Y=Phe or D-Phe)] related to gramicidin S were allowed to cyclize in pyridine. The peptides with a L-Phe residue preceding Pro tend to form various cyclic polymers, while ones with a D-Phe residue exclusively yielded a cyclic monomer or cyclic dimer. Peptides with a D-Val residue at the N-terminal produced monomerization products. The observed tendencies were similar for cyclization of four hexapeptide *N*-hydroxysuccinimide esters [X-Val-Orn(Z)-Leu-Y-Pro-ONSu (X=Tyr(Bzl) or D-Tyr($BzlCl_2$), and Y= Phe or D-Phe)] related to gratisin.

An antibiotic peptide, gramicidin S (GS),[1] is a cyclic decapeptide consisting of two identical pentapeptide sequences of -Val-Orn-Leu-D-Phe-Pro- (Fig. 1).[2] In 1957, Schwyzer and Sieber reported that the cyclization of the H-Val-Orn(Tos)-Leu-D-Phe-Pro *p*-nitrophenyl ester produced cyclic decapeptide (the ditosyl derivative of GS) instead of cyclic pentapeptide.[3] Since then, various analogs of GS have been synthesized by this cyclic dimerization method.[4] In an investigation of the influence of substitution of each amino acid residue in the H-$\overset{1}{\text{Val}}$-$\overset{2}{\text{Orn}}$(Z)-$\overset{3}{\text{Leu}}$-D-$\overset{4}{\text{Phe}}$-$\overset{5}{\text{Pro}}$ *p*-nitrophenyl ester to the cyclization, Izumiya et al. reported that the steric hindrance of the side chains of amino acid residues at the N-terminal and at position 4 in the active esters greatly affects the reaction.[4] However, the effects of an alteration of the configurations of the constituent amino acid have been little studied.

In present studies, four pentapeptide *N*-hydroxysuccinimide esters related to GS, X-Orn(Z)-Leu-Y-Pro-ONSu (X= Val or D-Val, and Y=Phe or D-Phe) (Fig. 2), were cyclized in order to examine the influence of the configurations of amino acid residues at the N-terminal and position 4. In addition, a similar investigation was carried out concerning four hexapeptide *N*-hydroxysuccinimide esters related to gratisin (GR) (Fig. 1),[5,6] X-Val-Orn(Z)-Leu-Y-Pro-ONSu [X=Tyr(Bzl) or D-Tyr($BzlCl_2$), and Y=Phe or D-Phe] (Fig. 2).

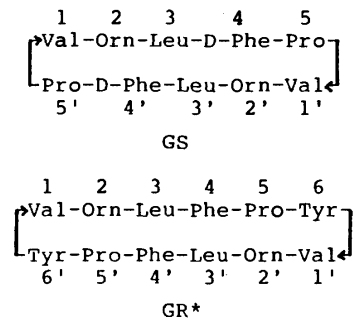

Fig. 1. Primary structures of GS and GR.
*The configuration of each amino acid residue has not been established yet.

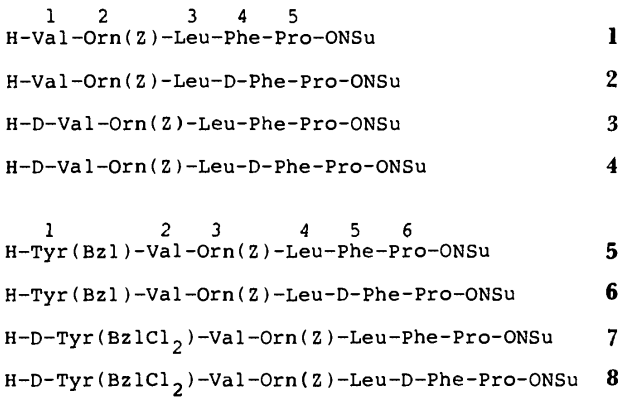

Fig. 2. Primary structures of penta- and hexapeptide active esters.

Boc-penta- and -hexapeptides were prepared by a conventional method.[6,7] Boc-penta- and -hexapeptides were converted into the penta- and hexapeptide-ONSu trifluoroacetates, which were cyclized in pyridine for 1 d at 25 °C (concentration of peptides in pyridine: 3×10^{-3} M). The ratio of the cyclic products was determined by high-performance liquid chromatography (HPLC) analysis. The molecular weight of each cyclic product isolated by semipreparative HPLC was determined by fast atom bombardment (FAB) or secondary ion mass spectrometry.

HPLC profiles of crude cyclic products are shown in Figs. 3 and 4. Cyclic peptides were eluted in order of the ring sizes.

Data of the cyclization are summarized in Table 1. Compounds **1** and **3**, both of which contain a L-Phe residue preceding Pro, gave cyclic products with widely distributed molecular weights. The former yielded the cyclic dimer, trimer, tetramer, and pentamer (roughly evenly), but not the cyclic monomer. The latter produced the cyclic monomer, dimer, trimer, and tetramer. Compound **2** yielded exclusively the cyclic dimer, diZ-GS, while Izumiya et al. reported that compound **2** gave a considerable amount of the cyclic monomer under similar conditions.[4,8] Compound **4** gave the cyclic monomer as a sole product. In the cases of the hexapeptide esters (**5**—**8**), each gave its cyclic monomer and dimer regardless of the configurations of the constituent amino acids. The ester con-

Table 1. Products of Cyclization of Penta- and Hexapeptide Active Esters[a]

Starting compounds	Yield(%)[b] of cyclic product	Ratios of cyclic peptides				
		Monomer	Dimer	Trimer	Tetramer	Pentamer
1	30	0	34[1409]	32[2115]	24[2820]	10[3524]
2	57	0	100[1409]	0	0	0
3	40	30[704]	46[1409]	21[2115]	3[2819]	0[3523][c]
4	48	100[704]	0	0	0	0
5	26	43[958]	57[1916]	0[2875][c]	0	0
6	38	45[958]	55[1916]	0	0	0
7	53	78[1027]	22[2053]	0	0	0
8	70	67[1027]	33[2053]	0	0	0

a) Numbers in brackets are mass numbers observed as the molecular ion peaks. b) The yield based on cyclic peptides separated from reaction mixture by HPLC. c) Small amount of the corresponding cyclic trimer or pentamer was separated using HPLC.

taining a L-Phe residue preceding Pro (**5**) yielded some cyclic products with higher molecular weights, though their amounts were negligible. The data indicated that the configurations of the constituent amino acids in the active esters and the lengths of the esters affect the course of cyclic polymerization. In both cases, the penta- and hexapeptide active esters, the configuration of the N-terminal amino acids affects cyclization. Esters with D-amino acids (**3**, **4**, **7**, **8**) clearly produce products of cyclic monomerization or cyclization at lower molecular weights.

Experimental

Synthesis of Boc-penta- and -hexapeptides was performed as manner described in our previous papers.[6,7]

Boc-Tyr(Bzl)-Val-Orn(Z)-Leu-D-Phe-Pro-OH. Yield, 79% from the corresponding benzyl ester: mp 181—184 °C; $[\alpha]_D^{20}$, −29.3° (*c* 1.0, DMF): Found: C, 64.80; H, 7.24: N, 8.95%. Calcd for $C_{59}H_{77}N_7O_{12}\cdot H_2O$: C, 64.76; H, 7.27; N, 8.96%.

Boc-D-Tyr(BzlCl$_2$)-Val-Orn(Z)-Leu-D-Phe-Pro-OH. Yield, 90% from the corresponding benzyl ester; mp 164—165 °C; $[\alpha]_D^{20}$, −14.5 (*c* 1.1, DMF); Found: C, 60.71; H, 6.63; N, 8.04%. Calcd for $C_{59}H_{75}N_7O_{12}Cl_2\cdot H_2O$: C, 60.92; H, 6.67; N, 8.43%. Cyclization via an active ester was performed in a similar manner to that described in our previous paper.[7] HPLC analysis was carried out using a Twincle system (Jasco) consisting of a Twincle pump, a VL-611 injector and a UVIDEC 100-III detector. A Finepak SIL C18 column (10 μm, 250×4.6 mm I.D., or 250×6.7 mm I.D., Jasco) was used: flow rate, 1 ml min^{-1}; solvent, methanol-water (9:1); monitoring wavelength, 220 nm. The peak area was recorded using a Chromatopac C-R3A integrator (Shimadzu Co.). Molecular weights of the cyclic products were determined by FAB mass spectrometry using a JEOL JMS-D300 mass spectrometer (in Toyo Jozo Co., Ltd.) and a JEOL JMS-HX110 mass spectrometer (in JEOL Ltd.), and/or secondary ion mass spectrometry using a Hitachi M-80 mass spectrometer (in Meijo Univ.).

We are grateful to Professor Makoto Suzuki and Associate Professor Ken-ichi Harada, Meijo University, for measurements of secondary ion mass spectrometry.

Regioselective Reaction of Oxiranes with *S*-Phenyl Thioesters Catalyzed by Quaternary Onium Salts or Crown Ether-Metal Salt Complexes

Takashi IIZAWA,* Akira GOTO, and Tadatomi NISHIKUBO
Department of Applied Chemistry, Faculty of Engineering, Kanagawa University, Rokkakubashi, Kanagawa-ku, Yokohama 221
(Received June 16, 1988)

Synopsis. Regioselective addition reactions of 2-substituted oxiranes with *S*-phenyl thioesters gave 2-aceyloxy-1-phenylthio derivatives in high yield using some 18-crown-6-metal complexes as well as tetrabutylammonium salts as a catalyst under relatively mild conditions.

The addition reaction of oxiranes with esters has attracted much attention in the field of polymer chemistry since two distinct functional groups are introduced into their molecules at the same time.[1] Since these substrates do not show a high reactivity, it is very important to select suitable catalysts for the reaction. Funahashi[2] previously undertook the reaction of oxiranes with esters using such bases as tertiary amines or potassium *t*-butoxide as a catalyst at high reaction temperatures. Recently, we found[3] that the reaction of a pendant epoxy group in a polymer with an active ester and thioester proceeded smoothly upon the addition of onium salts, which had much higher catalytic activities than the bases as a catalyst, under relatively mild conditions; crown ether-metal complexes were also available catalysts for this reaction.

We wish to report herein the identification of the addition products of 2-substituted oxiranes with *S*-phenyl thioesters, and to discuss the catalytic effect of crown ether-metal salt complexes on this reaction in comparison with that of tetrabutylammonium salt.

The addition reaction of 2-(phenoxymethyl)oxirane and 2-(methoxymethyl)oxirane with *S*-phenyl thiobenzoate and *S*-phenyl thioacetate was carried out in DMF using Bu_4NBr as a catalyst. The reactions did not occur without a catalyst; however, the addition of Bu_4NBr caused the reaction to proceed with high conversion, as shown in Table 1. The reaction could be expected to give two products, the corresponding 2-acyloxy-1-phenylthic derivatives (**1**) and 1-acyloxy-2-phenylthio derivatives (**2**), as shown in Scheme 1. However, the reaction of oxirane with *S*-phenyl thioester yielded only one product other than a very small amount of 2-hydroxy-3-(phenylthio) propyl ether (**3**). The reaction product agreed with **1** obtained from an acylation of **3**. **3** was also prepared from an addition reaction of the oxirane with thiophenol. Furthermore, it is easy to distinguish between **1** and **2**, which show very different ^1H NMR spectra.[4] The addition products of oxirane with *S*-phenyl thioester showed similar chemical shifts of methine and methylene protons to those of the known compounds **1**.[4a] These results strongly substantiated that the reaction of oxirane with *S*-phenyl ester proceeded regioselectively to give **1**.

Scheme 1

The catalytic effect of crown ether-metal salt complexes on the addition reaction of 2-(phenoxymethyl) oxirane with *S*-phenyl thiobenzoate was investigated at 90 °C in diglyme, as shown in Table 2. Tertiary amines have been used as catalysts in the reaction of oxirane with ester;[2] however, tertiary amines, such as tributylamine and triethylamine, hardly showed any catalytic activity under these conditions. The reaction took place upon the addition of a mixture of 18-crown-

a) 18-C-6: 18-crown-6.

6 and potassium salts as well as quaternary ammonium salt. Since neither 18-crown-6 nor potassium salt individually showed any catalytic activity, the 18-crown-6-metal salt complexes produced from the mixture worked as catalysts. The catalytic activity was markedly affected by the counter ions in the catalysts. The effect of a counter ion in tetrabutylammonium salt and 18-crown-6-potassium salt complex changed in the order; $HSO_4^- = ClO_4^- < I^- < Br^- < Cl^-$ and $AcO^- > Br^- > F^- > I^- > Cl^- > HSO_4^- = ClO_4^-$, respectively. The counter-ion effect was much different between the tetrabutylammonium salt and 18-crown-6-potassium salt complex. On the other hand, 18-crown-6-potassium acetate showed almost the highest catalytic activity of tetrabutylammonium salts and the crown ether-potassium salt complexes. These results suggest that 18-crown-6-potassium salt complexes are also suitable catalysts for an addition reaction of oxiranes with thioesters.

Experimental

General Procedure for Synthesis of 2-Acyloxy-3-(phenylthio)propyl Ethers (Table 1). 2-Benzoyloxy-3-(phenylthio)propyl Phenyl Ether (1a): The mixture of 2-(phenoxymethyl)oxirane (7.51 g, 50 mmol), *S*-phenyl thiobenzoate (10.70 g, 50 mmol), Bu_4NBr (1.61 g, 5 mmol), and dry DMF (50 ml) was stirred at 110 °C for 25 h. The conversion was 82.4%, measured by GLC. Ether (150 ml) was added to the reaction mixture, and the etheral solution was washed with water (50 ml×3), dried with $MgSO_4$, and evaporated in vacuo. The residue was recrystallized from hexane to afford **1a** (12.90 g, 71.0%); mp 39—40 °C; IR (KBr) 1720 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=3.35 (d, 2H, S-CH_2), 4.32 (d, 2h, O-CH_2), 5.36—5.70 (m, 1H), 6.80—8.10 (m, 15H). Found: C, 72.55; H, 5.80%. Calcd for $C_{22}H_{20}O_3S$: C, 72.50; H, 5.53%.

2-Acetoxy-3-(phenylthio)propyl Phenyl Ether (1b): Bp 190—195 °C/0.05 mmHg (1 mmHg≈133.322 Pa); IR (neat) 1740 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=1.98 (s, 3H), 3.28 (d, 2H, S-CH_2), 4.14 (d, 2H, O-CH_2), 5.10—5.40 (m, 1H), 6.76—7.56 (m, 10H). Found: C, 67.56; H, 6.27%. Calcd for $C_{17}H_{18}O_3S$: C, 67.52; H, 6.00%.

2-Benzoyloxy-3-(phenylthio)propyl Methyl Ether (1c): Viscous oil; IR (neat) 1720 cm^{-1} (C=O). ^1H NMR ($CDCl_3$) δ=3.34 (d, 2H, S-CH_2), 3.38 (s, 3H), 3.76 (d, 2H, O-CH_2), 5.24—5.56 (m, 1H), 7.10—8.20 (m, 10 H). Found: C, 67.82; H, 6.25%. Calcd for $C_{17}H_{18}O_3S$: C, 67.52; H, 6.00%.

2-Acetoxy-3-(phenylthio)propyl Methyl Ether (1d): Bp 96—100 °C/0.03 mmHg; IR (neat) 1740 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ= 2.00 (s, 3H), 3.18 (d, 2H, S-CH_2), 3.34 (s, 3H), 3.60 (d, 2H, O-CH_2), 5.00—5.24 (m, 1H), 7.10—7.52 (m, 5H). Found: C, 60.02; H, 6.81%. Calcd for $C_{12}H_{16}O_3S$: C, 59.97; H, 6.71%.

3-Hydroxy-3-(phenylthio)propyl Phenyl Ether (3a): The mixture of 2-(phenoxymethyl)oxirane (15.02 g, 0.10 mol), thiophenol (11.02 g, 0.10 mol), Bu_4NBr (1.61 g, 5 mmol), and dry diglyme (50 ml) was stirred at 90 °C for 5 h. After the usual work-up, the residue was distilled under reduced pressure to give **3a** (20.32 g, 78.1%); bp 179—180 °C/0.03 mmHg; IR (neat) 3450 cm^{-1} (OH); ^1H NMR ($CDCl_3$) δ=2.76 (d, 1H, O-H), 3.16 (d, 2H, S-CH_2), 3.90—4.30 (m, 1H, CH), 4.02 (d, 2H, O-CH_2), 6.20—7.60 (m, 10H). Found: C, 69.20; H, 6.19%. Calcd for $C_{15}H_{16}OS$: C, 69.61; 6.20%.

3-Hydroxy-3-(phenylthio)propyl Methyl Ether (3b): Yield 67.2%; bp 110—112 °C/0.02 mmHg (lit,[5)] 103—104 °C/0.03 mmHg); IR (neat) 3450 cm^{-1} (OH); ^1H NMR ($CDCl_3$) δ=2.80 (d, 1H, O-H), 3.00 (d, 2H, S-CH_2), 3.08 (s, 3H, CH_3), 3.40 (d, 2H, O-CH_2), 3.70—4.10 (m, 1H, CH), 7.00—7.50 (m, 5H).

Synthesis of 1b from 3a: To a solution of **3a** (0.200 g, 73 mmol) in pyridine (5 ml) was added acetyl chloride (0.576 g, 73 mmol) at 5 °C. After allowing the mixture to stand at room temperature for 1 h, the mixture was poured into water, and extracted with ether. The etheral extract was washed with a dilute hydrochloric solution, dried, and evaporated in vacuo. The residue was chromatographed on silica gel, using benzene-ethyl acetate (10:1), to give **1b** (0.245 g, 95%) as a colorless viscous oil.

Synthesis of 1d from 3b: Yield 85.0%, after purification from chromatography on silica gel using hexane-ethyl acetate (7:3).

Reaction of 2-(Phenoxymethyl)oxirane with *S*-Phenyl Thiobenzoate (Table 2): A mixture of 2-(phenoxymethyl)-oxirane (10 mmol), *S*-phenyl thiobenzoate (10 mmol), catalyst (quaternary onium salt or potassium salt and 18-crown-6, 0.5 mmol), and dried diglyme (5 ml) was stirred at 90 °C under nitrogen flow. The amount of **1a** was monitored by GLC.

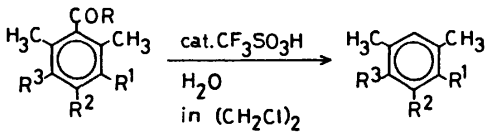
The Triflic Acid-Catalysed Deacylation and Decarboxylation of Polymethylbenzenecarbonyl Derivatives under Mild Conditions

Takashi KEUMI,* Toshio MORITA, Yoshihiro OZAWA, and Hidehiko KITAJIMA
Department of Applied Chemistry, Faculty of Engineering, Fukui University, Bunkyo, Fukui 910
(Received June 27, 1988)

Synopsis. Sterically hindered acylarenes are deacylated to arenes in good yields on heating in boiling 1,2-dichloroethane containing a catalytic amount of triflic acid and water. Hindered arenecarboxylic acids undergo decarboxylation under the same conditions to give arenes in high yields.

It is known that sterically hindered aromatic ketones and carboxylic acids can undergo protodeacylation or decarboxylation in the presence of concd sulfuric acid,[1] polyphosphoric acid,[2] or Friedel-Crafts catalysts.[3] However, the reaction of acylpolymethylbenzenes with these catalysts is accompanied by some side reactions, such as the sulfonation,[4,5] disproportionation,[6] or isomerization of alkyl groups in the substrates or products.[7,8] Olah and his co-workers reported that perfluororesin sulfonic acid, "Nafion-H," is an efficient catalyst for the deacylation of hindered aromatic ketones in hot toluene or anisole.[9] However, this procedure involves the problem of isolating the products from excess toluene or anisole. In addition, polymerized products result from the ketene formed during the deacetylation. We have previously reported on the transacylation between acylpolymethylbenzenes and some arenes in boiling trifluoroacetic acid (TFA).[10] In that paper, we described how the presence of a nucleophile in TFA accelerates the protodeacetylation rate of acetylpentamethylbenzene (AcPMB).

We wish to report now that the addition of a small amount of water to TFA increases the protodeacetylation rate of AcPMB and that, therefore, the deacylation of a variety of acylarenes to arenes can be selectively performed with a catalytic amount of triflic acid (TFSA) in boiling 1,2-dichloroethane (DCE) containing a small amount of water. The decarboxylation of arenecarboxylic acids with this system will be described.



Scheme 1.

Results and Discussion

When AcPMB is heated in TFA under reflux, deacetylation proceeds to afford pentamethylbenzene (PMB). The apparent rate constant for the formation of PMB was determined in the presence of water. The rate

constant obeys pseudo-first-order kinetics with respect to AcPMB in a solution with a large excess of TFA (more than a 50-fold excess) (Table 1). The results indicate that the addition of water into TFA promotes the deacetylation rate. The rate constant increased with the increase in the molar ratio of the added water. The effect of water was also confirmed in a preparative experiment. It can be seen from the results shown in Table 2 that the yield of PMB increases with the increase in the amount of water added. We found that TFA with a water content of ca. 15% works efficiently in the deacetylation of AcPMB. In order to save some of the TFA, the deacetylation was attempted in a DCE solution containing a small amount of water. The reaction with two equivalents of TFA in DCE did not occur at all, and the yield of PMB was only 8%, even with five equivalents of TFA. In contrast, the reaction using TFSA as an acid proceeded smoothly to give PMB in a quantitative yield. The deacetylation product can be obtained in a good yield even with a catalytic amount of TFSA. In the absence of water, though, the reaction was accompanied by some side reactions to result in a low yield of PMB and a low recovery of AcPMB.

A variety of pentamethylbenzenecarbonyl derivatives were subjected to deacylation or decarboxylation with TFSA in a DCE solution. The results are summarized in Table 3. Pentamethylbenzenecarbonyl derivatives, having not only alkanoyl but aroyl moieties, were deacylated to give PMB in satisfactory yields. The decarboxylation of pentamethylbenzoic acid was also efficiently performed under these conditions. However, in the case of ethyl pentamethylbenzoate, the yield of PMB was low and the starting ester was recovered.

Furthermore, various polymethylbenzenecarbonyl derivatives were reacted with catalytic amounts of TFSA in boiling DCE (Table 4).

As can be seen from the results listed in Table 4, the method works satisfactorily for sterically hindered alkyl aryl ketones, benzophenones, and benzoic acids, which have methyl groups at both the 2- and 6-positions. No side reactions have been observed.

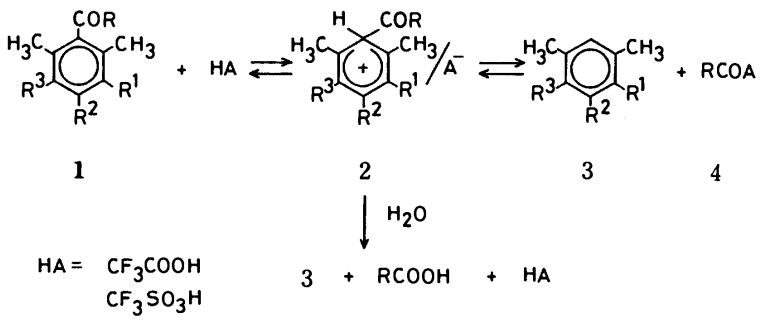
a) Carried out with 0.5 equivalent of TFSA in boiling 1,2-dichloroethane containing ca. one equivalent of water. b) Determined by GLC.



Scheme 2.

As regards the mechanism of the deacylation reaction, an ipso-protonated intermediate (**2**) at the ring C-atom attached to the acyl group may be assumed as has been reported before (Scheme 2).[10] In the absence of water, a conjugate base of the acids works as a nucleophile for the removal of the acyl group to give the hydrocarbon (**3**) and the mixed anhydride (**4**). The latter is known to acylate arenes in a TFA solution.[11,12] Thus in the deacetylation of AcPMB in boiling TFA, an equilibrium is reached with the formation of 40% of PMB.[10] When water is present in the solution, it works as a nucleophile to remove the acetyl group, thus giving PMB, TFA, and acetic acid. In the case of a stronger acid TFSA relative to TFA, the TFSA regenerated from a reaction of the intermediate **2** with water will work again for the ipso-protonation so that it may be enough in catalytic amount. Ethyl pentamethylbenzoate might be protonated at the alkoxyl oxygen to resist ipso-protonation to the ring carbon for the deethoxycarbonylation.

Experimental

Materials and Measurements: The acylpolymethylbenzenes were prepared from polymethylbenzenes and acyl chloride following the usual Friedel-Crafts reaction procedure. Commercial TFA (Peptide Institute) was used after distilling in the presence of a small amount of trifluoroacetic anhydride. The TFSA used was a commercial one (Aldrich). The GLC analyses were carried out on a Hitachi GC 163 Model gas chromatograph equipped with a hydrogen flame ionization detector and a stainless steel column (length 3 m, i.d., 3 mm) packed with 3% Dexil 300 GC on Chromosorb W. The product yields were calculated from the relative peak area with respect to the internal standard (dibenzofuran) on a System Instruments Chromatocorder 11 after calibration for each authentic compound.

Kinetic Studies: AcPMB (0.125 g, 0.657 mmol) was dissolved in TFA (5 ml) containing a given amount of water in a 10 ml flask. The mixture was immediately brought to reflux by immersing the reaction flask in an oil-bath maintained at 110 °C . After refluxing for a given period, the reaction mixture was quenched by pouring it into an excess of a cold 5% aqueous sodium carbonate solution; the resulting oily product was extracted with ether containing dibenzofuran (0.100 g) (as the internal standard for GLC analysis). The organic layer was washed with water and dried over anhydrous sodium sulfate. After the evaporation of the solvent, the residue was dissolved in benzene and then analyzed by means of GLC.

General Procedure for the Deacylation: The typical procedure described is for the reaction of AcPMB with TFSA: To a solution of AcPMB (0.114 g, 0.600 mmol) in 1,2-dichloroethane (3 ml) containing water (20 μl, 1.2 mmol) placed in a 30 ml flask, was added TFSA (0.045 g, 0.300 mmol) in DCE (2 ml) and the mixture was heated under reflux for 5 h. After that, the reaction mixture was poured into an excess of a cold 5% aqueous sodium carbonate solution and then extracted with ether (50 ml) containing dibenzofuran (0.100 g). The organic layer was washed with water and dried over anhydrous sodium sulfate. After the subsequent evaporation of the solvent under reduced pressure, the residue was analyzed by means of GLC.

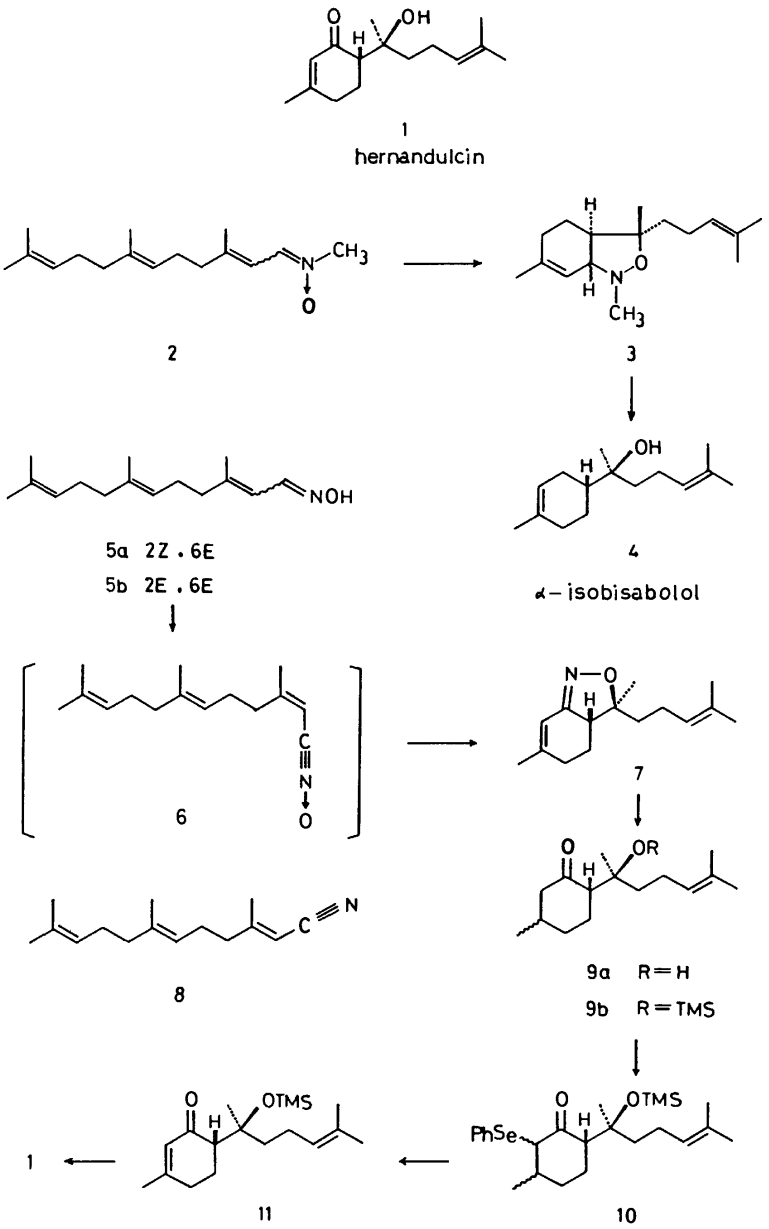
Synthesis of (±)-Hernandulcin by an Intramolecular Nitrile Oxide Cycloaddition Route from Farnesol

Guo-Chi ZHENG and Hiroshi KAKISAWA*
Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305
(Received June 28, 1988)

Synopsis. An intramolecular addition reaction of the nitrile oxide derived from (2*Z*, 6*E*)-farnesal oxime afforded an isoxazoline derivative, which was converted into hernandulcin, a sweet sesquiterpene of Verbenaceae plant.

Hernandulcin was found as a strongly sweet sesquiterpene from the Mexican plant *Lippia dulcis* Trev. (Verbenaceae) by Kinghorn[1] according to a classic book written in 1570—1576 by a Spanish physician, F. Hernandez, about natural history of ancient Mexico. Hernandez described a remarkably sweet plant known to the Aztec people by the name *Tzonpelic xihuitl* (literally 'sweet herb').[2] The structure and relative stereochemistry of this sesquiterpene **1** were proposed by Kinghorn[1] and the absolute configuration was determined by Mori et al. by a synthesis.[3] This report describes a convenient synthesis of (±)-hernandulcin from farnesol via an intramolecular nitrile oxide cycloaddition route.

Previously, the author reported that a nitrone **2** derived from (6*E*)-farnesal afforded a cycloaddition product **3** which was convertible into α-isobisabolol



(**4**).[4] Although the relative stereochemistry of isoxazoline intermediate **3** was the same as that of hernandulcin, several attempts failed in converting the intermediate into hernandulcin. An isoxazoline derivative **7** was then made from farnesal oxime.[5] The reaction of (2*Z*,6*E*)-farnesal with hydroxylamine in pyridine afforded a mixture of (*E*)- and (*Z*)-oximes **5a** in a ratio of 4:1. Exposure of the mixture to aqueous sodium hypochlorite in dichloromethane with triethylamine as a catalyst at 0 °C resulted in the formation of a corresponding nitrile oxide (**6**), which was simultaneously cyclized by an intramolecular 1,3-dipolar cycloaddition to give an isoxazoline **7** in 83% yield. By means of the same reactions (2*E*, 6*E*)-farnesal oxime (**5b**) afforded the same isoxazoline **7** in poor yield (28%), besides 55% of nitrile derivative **8**. The stereochemistry of the isoxazoline **7** was assigned from the stereoselectivity of the cycloaddition of nitrile oxide. A catalytic hydrogenation of the isoxazoline in the presence of a deactivated Raney nickel afforded dihydrohernandulcin (**9a**) as a diastereomeric mixture.[6,7] The mixture of dihydro compounds was converted into a phenylseleno compound **10** after protecting the hydroxyl group with trimethyl silyl ether.[8] An oxidative elimination of the selenyl group by hydrogen peroxide[9] gave trimethylsilylhernandulcin in an overall yield 62% from the isoxazoline **7**. Removing the protecting group with dilute hydrogen fluoride[10] yielded hernandulcin (**1**) in quantitative yield.

Experimental

Proton magnetic resonance (^{1}H NMR) spectra were recorded on either a JEOL FX90Q spectrometer or a Bruker AM500 spectrometer with chemical shifts given in parts per million (δ) downfield from tetramethylsilane as an internal standard. Carbon magnetic resonance (^{13}C NMR) spectra were recorded at either 22.5 MHz on a JEOL EX 90 Q or 125 MHz on a Bruker AM 500 instrument. Infrared (IR) spectra were measured on a Hitachi 215 or a JASCO FT/IR-3 spectrophotometer. Mass spectra (MS) were obtained on a Hitachi RMU-6H GC/MS system using electrons of 70 eV ionization energy. Ultraviolet (UV) spectra were recorded on a Hitachi EPS-3T spectrophotometer. Elemental analyses were performed by the University of Tsukuba chemical analysis center. Gas chromatography data were obtained with a 063 Hitachi gas chromatograph by using a 1.7 m/3 mm i.d. glass column packed with 5% SE-30. Wako C-300 silica gel was used for flash column chromatography. Merck Kiesel gel 60 F-254 were used for analytical (0.25 mm) and preparative (0.5 mm) thin-layer chromatography.

(2*Z*,6*E*)-3,7,11-Trimethyl-2,6,10-dodecatrienal Oxime (5a). The (2*Z*,6*E*)-farnesal (2.61 g, 11.9 mmol, prepared by the procedure of Iwashita)[11] was dissolved in 100 ml pyridine and a recrystallized hydroxylamine hydrochloride (1.08 g, 15.5 mmol) was added. The reaction mixture was stirred for 10 min and the resulting mixture was poured into 200 ml of ether, washed with a saturated $CuSO_4$ solution and water, dried (Na_2SO_4), and concentrated to an odorous oil. The residue was purified by flash chromatography (SiO_2, hexane/ethyl acetate 9:1) to give **5a** (2.77 g, 99%). Though initially a mixture of the (*E*)-(80%) and (*Z*)-(20%) oximes, it gradually isomerized to only the (*E*)-form. The physical data of the (*E*)-oxime isomer are as follows: IR($CHCl_3$) 3560, 3250, 2900, 1635, and 1430 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ= 1.60 (6H, s, CH_3×2), 1.68 (3H, s, CH_3), 1.86 (3H, br, s, CH_3), 1.86—2.19 (8H, m, CH_2CH_2, CH_2CH_2), 5.08 (2H, br, t), 5.90 (1H, d, J=10 Hz), 8.00 (1H, d, J=10 Hz), and 8.05 (1H, br, s); ^{13}C NMR ($CDCl_3$) δ=16.1 (q), 17.7 (q), 24.2 (q), 25.7 (q), 26.8 (t), 32.0 (t), 32.8 (t), 39.7 (t), 118.9 (d), 123.0 (d), 124.3 (d), 131.4 (s), 136.4 (s), 147.8 (s), and 148.7 (d); MS *m/z* (rel intensity %) 235 (M^+, 13), 217 (83), 202 (12), 135 (85), 120 (66), 110 (92), and 82 (100). The physical data of (*Z*)-isomer are as follows: ^{1}H NMR ($CDCl_3$) δ=1.60 (6H, s), 1.68 (6H, s), 1.86—2.19 (8H, m), 5.08 (2H, br, t), 6.50 (1H, br, d), and 7.26 (1H, br, d). Found: C, 76.70; H, 10.82; N, 6.01%. Calcd for $C_{15}H_{25}ON$: C, 76.54; H, 10.71; N, 5.95%.

(2*E*,6*E*)-3,7,11-Trimethyl-2,6,10-dodecatrienal Oxime (5b). The (2*E*,6*E*)-farnesal (4.71 g, 21.4 mmol, prepared by a procedure of Iwashita)[11] was dissolved in 150 ml of pyridine and a hydroxylamine hydrochloride(1.93 g, 27.8 mmol) was added. The reaction mixture was stirred for 10 min and then worked up, as described for (2*Z*, 6*E*)-farnesal oxime. Chromatography (SiO_2, hexane/ethyl acetate 8:2) provided a mixture of (*E*)-(80%) and (*Z*)-(20%) oximes (4.93 g, 98%), which gradually isomerized to only the (*E*)-form. The physical data of (*E*)-oxime are as follows: ^{1}H NMR ($CDCl_3$) δ=1.61 (6H, s, CH_3×2), 1.68 (3H, s, CH_3), 1.86 (3H, br, d, CH_3), 1.82—2.15 (8H, m, CH_2CH_2, CH_2CH_2), 5.10 (2H, br, t), 5.93 (1H, d, J=10 Hz), 8.07 (1H, d, J=10 Hz), and 8.42 (1H, br, s); ^{13}C NMR ($CDCl_3$) δ=16.0 (q), 17.2 (q), 17.6 (q), 25.7 (q), 26.3 (t), 26.8 (t), 39.8 (t), 40.1 (t), 118.0 (d), 123.4 (d), 124.4 (d), 130.2 (s), 134.1 (s), 147.7 (s), and 149.1 (d). The data of (*Z*)-oxime are as follows: ^{1}H NMR ($CDCl_3$) δ=1.61 (9H, s, CH_3×3), 1.68 (3H, s, CH_3), 1.82—2.15 (8H, m, CH_2CH_2, CH_2CH_2), 5.10 (2H, br, t), 6.52 (1H, d, J=9.5 Hz), and 7.35 (1H, d, J=9.5 Hz).

3,6-Dimethyl-1,3,3a,4,5,7a-hexahydro-3-(4-methyl-3-pentenyl)-2,1-benzisoxazole (7). To a vigorously stirred solution of the (2*Z*, 6*E*)-farnesal oxime (**5a**) (0.183 g, 0.78 mmol) in 30 ml of dichloromethane cooled to 0 °C was added 1 ml of commercial 11% aqueous sodium hypochlorite dropwise. After 1 h, TLC analysis revealed that the oxime had been consumed; stirring was stopped, the ice bath was removed, and the reaction mixture was allowed to stand overnight. The organic phase was separated and the aqueous phase was extracted with dichloromethane. The combined organic layers were dried over Na_2SO_4 and the solvent removed under reduced pressure. The resulting crude oil was chromatographed (Wakogel C-300, hexane/ethyl acetate 5:1) to provide 0.15 g (83%) of the isoxazoline as an oil. IR (film) 2971, 2929, 2858, 1718, 1650, 1447, 1378, 1110, 894, and 866 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.11 (3H, s), 1.61 (3H, s), 1.67 (3H, s), 1.85 (3H, s), 1.64—2.23 (8H, m), 2.85 (1H, dd, J=4.6, 13 Hz), 5.09 (1H, br, t), and 6.18 (1H, s); ^{13}C NMR ($CDCl_3$) δ=17.7 (q), 19.9 (q), 22.7 (t), 23.2 (t), 23.8 (q), 25.6 (q), 31.3 (t), 39.9 (t), 51.9 (d), 87.4 (s), 114.3 (d), 123.9 (d), 131.9 (s), 158.2 (s), and 158.4 (s); MS *m/z* 235, 234, 233 (M^+), 218, 217, 215, 203, 200, 192, 191, 188, 135, 133 (base), 105, and 101; Found: C, 77.32; H, 9.90; N, 6.09%. Calcd for $C_{15}H_{23}ON$: C, 77.20; H, 9.94; N, 6.00%.

The same reaction was repeated with oxime (**5b**). To a stirred solution of the (2*E*, 6*E*)-farnesal oxime (**5b**) (1.2 g, 5.1 mmol) in dichloromethane (200 ml) was added 11% aqueous sodium hypochlorite (8 ml) dropwise at 0 °C. After 1 h, chromatography of the reaction mixture on a Wakogel C-300 (CH_2Cl_2/CH_3OH 20:1) gave the less polar nitrile (**8**) (0.61 g, 55%) as an oil. IR ($CHCl_3$) 2950, 2900, 2840, 2270, 1615, 1428, 1375, 1344, 1290, and 1100 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.85 (6H, s), 1.67 (3H, s), 1.98 (3H, br, s), 2.00—2.30 (8H, m), 5.05 (2H, br, s), and 5.12 (1H, s); ^{13}C NMR ($CDCl_3$) δ=16.13 (q), 17.76 (q), 20.82 (q), 25.75 (q), 25.81 (t), 26.67 (t), 38.44 (t), 39.69 (t), 95.0 (d), 95.0 (s), 122.4 (d), 124.2 (d), 131.6 (s), 136.8 (s), and 160.6 (s); MS *m/z* 217 (M^+), 202, 175, 148, 146, 123, 122, 121, 108, 107, 106, 93, 91, 80 (base), 69, and 53. The more

polar compound (0.33 g, 28%) was identified as same isoxazoline as **7**.

2-(1-Hydroxy-1,5-dimethyl-4-hexenyl)-5-methylcyclohexanone (9a). A mixture of W-2 Raney nickel (0.4 g), which was deactivated prior to use by refluxing for 3 h with acetone, the isoxazoline **7** (0.4 g, 1.72 mmol), an acid solution made from 0.001 mol BCl_3 and 1 ml of methanol, and 100 ml of 5:1 MeOH/H_2O, was stirred under a hydrogen-filled balloon for 30 min. The reaction mixture was filtered and the filter was washed with MeOH. The combined filtrates were concentrated under reduced pressure. The residue was partitioned between ether and water. The organic phase was dried over Na_2SO_4 and concentrated to afford a crude oil (0.35 g, 85%), which was used without further purification for the next silylation step. An analytical sample was separated by preparative TLC. Spectral data were obtained with a mixture of two diastereomers (**9a**) in a ratio of 55:45. IR (film) 3600—3300, 2956, 2928, 2871, 1699, 1458, and 1420 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.02 and 1.20 (totally 3H, d, J=7.5 Hz), 1.18 (3H, s), 1.59 (3H, s), 1.67 (3H, s), 1.41—2.30 (11H, m), 2.38 (1H, dd), 3.95 (1H, s), and 5.08 (1H, br, t). ^{13}C NMR ($CDCl_3$) δ=17.7 (q), 22.1 (q), 22.3 (q), 23.8 (q), 25.7 (t), 28.5 (t), 34.1 (t), 35.4 (t), 40.6 (t), 51.6 (d), 56.9 (d), 73.0 (s), 124.6 (d), 131.5 (s), and 215.4 (s); MS m/z 238 (M^+), 223, 222, 221, 220 (base), 192, 191, 190, 189, 179, 178, 177, 162, 154, and 138. Found: C, 75.73; H, 10.89%. Calcd for $C_{15}H_{26}O_2$: C, 75.58; H, 11.00%.

2-(1-Trimethylsilyloxy-1,5-dimethyl-4-hexenyl)-5-methylcyclohexanone (9b). To a mixture of dry triethylamine (0.76 g, 7.56 mmol), crude tertiary alcohol **9a** (1.2 g, 5.04 mmol), 0.1 ml of DMSO and dry ether (40 ml) was added trimethylsilyl chloride (0.65 g, 6 mmol) in 10 min with stirring. After 30 min the reaction mixture was poured into ice water (50 ml). After being washed with water, the ethereal solution was dried over Na_2SO_4 and then concentrated under reduced pressure. The crude product was chromatographed on silica gel with hexane/ether 5:1 as eluent to yield 1.31 g (84%) of the title compound as a colorless oily diastereomeric mixture. IR (film) 2957, 2927, 2869, 1703, 1457, 1376, 1250, 1042, 840, and 754 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.10 and 0.11 (totally 9H, s), 0.92, 1.00 (totally 3H, d, J=7.5 Hz), 1.24 and 1.32 (totally 3H, s), 1.59 (3H, s), 1.69 (3H, s), 1.40—2.20 (11H, m), 2.28 (1H, m), and 5.08 (1H, br, s); MS m/z 295 (M^+−15), 285, 226, 220, 219, 203, 183, 175, 106 (base), 91, 79, and 78; Found: C, 69.84; H, 11.13%. Calcd for $C_{18}H_{34}O_2Si$: C, 69.61; H, 11.04%.

6-(1-Trimethylsilyloxy-1,5-dimethyl-4-hexenyl)-3-methyl-2-(phenylseleno)cyclohexanone (10). To a solution of diisopropylamine (0.043 g, 0.42 mmol) in 5 ml of dry THF, was added 0.35 ml of 1.36 M n-BuLi (1M=1mol dm^{-3}) in hexane under an argon atmosphere at −78 °C. After being stirred for 30 min at 0 °C, the LDA solution was chilled to −78 °C; then, a solution of **9b** (0.11 g, 0.35 mmol) in 5 ml of THF was added dropwise and the mixture was stirred for 30 min. A solution of benzeneselenenyl chloride (0.08 g, 0.42 mmol) in 3 ml of THF was added rapidly to the enolate solution. After 1.5 h, the reaction mixture was warmed to 0 °C and poured into a saturated $NaHCO_3$ solution (10 ml) and dichloromethane (20 ml). The organic layer was washed with water and saturated NaCl solution. After solvent removal, chromatography on SiO_2 (benzene) gave 0.127 g (78%) of **10** as a mixture of two diastereomers. ^1H NMR ($CDCl_3$) δ=0.11 and 0.12 (totally 9H, s), 1.15 (3H, d), 1.22 and 1.23 (totally 3H, s), 1.54 (3H, s), 1.58 (3H, s), 1.50—2.35 (10H, m), 3.17—3.80 (1H, m), 5.08 (1H, m), and 7.26—7.49 (5H, m); MS m/z 465 (M^+), 463, 450, 448, 376, 375, 373, 327, 326, 325 (base), 323, 310, 268, 252, 239, 226, 184, 165, 156, and 137. Found: C, 61.77; H, 8.40%. Calcd for $C_{24}H_{38}O_2SeSi$: C, 61.91; H, 8.23%.

6-(1-Trimethylsilyloxy-1,5-dimethyl-4-hexenyl)-3-methyl-2-cyclohexen-1-one (11). To a solution of 0.16 g (0.344 mmol) of a seleno compound **10** in 3 ml of dichloromethane containing 0.06 ml of pyridine was gradually added 0.1 g of 30% H_2O_2 and 0.1 ml of water at 0 °C. The reaction mixture was stirred vigorously at 25 °C for an additional 15 min and then poured into 40 ml of dichloromethane and 10 ml of a 20% $NaHCO_3$ solution. The aqueous layer was extrated with dichloromethane and the combined organic layers were washed with a 10% HCl solution, saturated NaCl and dried over Na_2SO_4. The organic phase was concentrated in vacuo to afford a residue, which was chromatographed on Wakogel C-300 (hexane/ether 4.5:1) to provide 0.1 g of **11** (95%). ^1H NMR ($CDCl_3$) δ=0.10 (9H, s), 1.47 (3H, s), 1.60 (3H, s), 1.65 (3H, s), 1.88 (3H, s), 1.60—2.50 (9H, m), 5.07 (1H, br, t), and 5.76 (1H, s); IR (film) 2965, 2930, 1652, 1210, 1124 cm^{-1}. Found: C, 70.18; H, 10.44%. Calcd for $C_{18}H_{32}O_2Si$: C, 70.07; H, 10.45%.

6-(1-Hydroxy-1,5-dimethyl-4-hexenyl)-3-methyl-2-cyclohexenone (1) (Hernandulcin). To a solution of acetonitrile (3 ml) containing 5% of 40% aqueous HF was added 0.079 g (0.26 mmol) of the silyl ether **11**. After 15 min dichloromethane and water were added. The organic phase was separated and evaporated to give pure hernandulcin (**1**) 0.061 g (100%). An analytical sample was obtained by chromatography on SiO_2 (hexane/ether 2:1). IR (film) 3470, 2969, 2935, 2870, 1650, 1215, 1126 and 1022 cm^{-1}. UV (c 0.0399, EtOH) λ_{max} 236 nm (13300); ^1H NMR ($CDCl_3$) δ=1.17 (3H, s), 1.47 (2H, ddd, J=8.4, 8.4, and 1.2 Hz), 1.62 (3H, s), 1.675 (1H, m), 1.677 (3H, s), 1.96 (3H, s), 2.02 (1H, m), 2.05 and 2.16 (2H, ddt, J=14.6, 7.2, and 8.4 Hz), 2.31 (1H, ddd, J=18.5, 5.0, and 2.5 Hz), 2.37 (1H, dm, J=13.0 Hz), 2.41 (1H, dd, J=14.1 and 14.5 Hz), 5.11 (1H, tm, J=7.2 Hz), 5.24 (1H, s), and 5.87 (1H, s); ^{13}C NMR ($CDCl_3$) δ= 17.7, 21.7, 23.7, 24.2, 25.2, 25.8, 31.4, 40.3, 52.3, 74.0, 124.6, 127.7, 131.6, 163.5, and 204.1; MS m/z 236 (M^+), 218, 110, 95, and 82 (base).

The authors are grateful to Kuraray Co., Ltd. for the kind provision of (2*E*,6*E*)-farnesol.

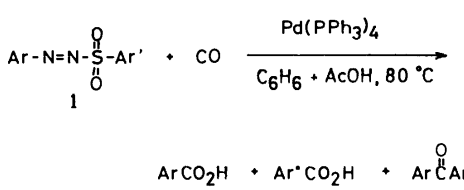
The Reaction of Arylazo Aryl Sulfones with Carbon Monoxide and Nucleophiles Catalyzed by the Palladium(0) Complex[1)]

Nobumasa KAMIGATA,* Akira SATOH, Masato YOSHIDA, and Masayuki KAMEYAMA
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received June 29, 1988)

Synopsis. The reaction of arylazo aryl sulfone (**1**) with carbon monoxide in the presence of the palladium(0) catalyst affords substituted benzoic acid in a good yield, together with minor yields of diaryl ketone and biaryl. The reactions of **1** with carbon monoxide and such nucleophiles as alcohols and amines under similar conditions give esters and amides, respectively.

Arylpalladium reagents obtained from aryl halides or arylmercurials have been utilized extensively for the arylation of olefins.[2)] Kikukawa et al. reported that arylpalladium species was also formed from arenediazonium salts[3)] or *N*-nitrosoacetanilide[4)] catalyzed by palladium complexes to arylate olefins in high yields. Recently, we reported the reaction of arylazo aryl sulfones with olefins catalyzed by the palladium(0) complex to give aryl olefins in a high yield, and a diarylpalladium(II) species was proposed as an intermediate.[5)] If such an intermediate participates in this reaction, the insertion of carbon monoxide into the carbon-metal σ-bond and the resulting carbonylated products can be expected, since a number of reactions of organometallics with carbon monoxide have been reported.[6)] We studied the reactions of arylazo aryl sulfone with carbon monoxide and nucleophiles catalyzed by the palladium(0) complex in order to clarify the formation of a diarylpalladium(II) intermediate by obtaining carbonylated products, and the results are described herein.

When carbon monoxide was passed through, with bubbling, into a solution of phenylazo *p*-tolyl sulfone (**1a**) in benzene and acetic acid, benzoic acid (35%), *p*-methylbenzoic acid (37%), *p*-methylbenzophenone (1%), and *p*-methylbiphenyl (6%) were obtained. Similarly, *p*-tolylazo phenyl sulfone (**1b**) afforded benzoic acid (42%), *p*-methylbenzoic acid (34%), 4-methylbenzophenone (1%), and *p*-methylbiphenyl (3%) under similar reaction conditions. When the two aryl groups of **1** are the same (**1c**: Ar=Ar′=Ph, **1d**: Ar=Ar′=*p*-Tol, and **1e**: Ar=Ar′=*p*-$MeOC_6H_4$), sole benzoic acid or substituted benzoic acid was formed in a good yield. The results are summarized in Table 1. It is of interest that almost equal amounts of benzoic acid and *p*-methylbenzoic acid were obtained, respectively, from the reactions of the azosulfone **1a** and **1b** with carbon monoxide catalyzed by the palladium(0) complex; these results suggest the formation of an intermediate, such as diarylpalladium(II), having an equal reactivity toward carbon monoxide, as we proposed previously.[5)]



At first, we expected that diaryl ketone (ArCOAr′) would be formed as a major product; however, such a compound was obtained in a yield of only a few percent, and instead, carboxylic acid was formed in a good yield. The formation of benzoic acids may be attributed by the reaction of diarylpalladium(II) species with a carbon dioxide contaminated impurity in the carbon monoxide gas, similar to the reaction of a Grignard reagent and carbon dioxide. The reaction of **1c** with carbon dioxide was carried out in the presence of the palladium(0) complex under similar conditions. However no benzoic acid was detected in the reaction mixtures. Thus, the possibility of the formation of benzoic acids by the reaction of diarylpalladium(II) species with carbon dioxide can be excluded.

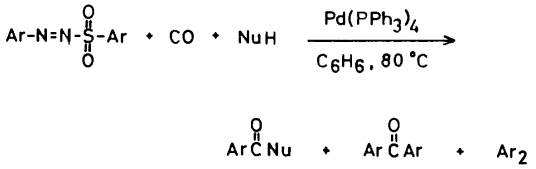
Then, we considered that the carboxylic acid was formed by the nucleophilic reaction of water, a contaminated impurity in carbon monoxide gas, and unremovable moisture in the reaction equipment, with the (arylcarbonyl)arylpalladium(II) species which had been formed by the insertion of carbon monoxide into the diarylpalladium(II) species. If this reaction path is real, the formation of esters or amides can be expected when the palladium(0)-catalyzed reaction of **1**

Table 1. Reaction of Arylazo Aryl Sulfone (**1**) with Carbon Monoxide Catalyzed by Tetrakis(triphenylphosphine)palladium(0)

	Ar and Ar′ in **1**		Products, Yield[a)]/%			
	Ar	Ar′	$ArCO_2H$	$Ar'CO_2H$	ArCOAr′	ArAr′
1a	Ph	*p*-Tol	35	37	1	6
1b	*p*-Tol	Ph	34	42	1	3
1c	Ph	Ph	76[b)]	—	2	5
1d	*p*-Tol	*p*-Tol	78[b)]	—	1	4
1e	*p*-$CH_3OC_6H_4$	*p*-$CH_3OC_6H_4$	72[b)]	—	1	5

a) The yields were determined by means of GC. b) This value includes the yield of $Ar'CO_2H$, since the products, $ArCO_2H$ and $Ar'CO_2H$, are identical when the Ar and Ar′ groups in **1** are the same.

is carried out in the presence of such nucleophiles as alcohols or amines. The reaction of **1c** catalyzed by the palladium(0) complex was carried out in benzene–methanol at 80 °C. As we expected, methyl benzoate was formed, although the yield was not so high; no benzoic acid was detected in this case. Similarly, the reaction of azosulfone **1** with such nucleophiles as ethanol, sodium methoxide, and amines under similar conditions gave the corresponding esters and amides in moderate yields. However, the reaction of **1c** with sodium acetate did not give acetylbenzoate or phenylbenzoate. The acetate ion may not have enough nucleophilicity to react with (arylcarbonyl)arylpalladium(II) species. The results are summarized in Table 2. These findings support our consideration of the formation of the diarylpalladium(II) species which is carbonylated by carbon monoxide to form arylcarbonyl aryl palladium(II) species and a subsequent reaction with nucleophiles to give the final product.



The palladium(II)-catalyzed reaction of arylazo aryl sulfones with carbon monoxide and nucleophiles is accounted for by Scheme 1, involving the oxidative addition of **1** to the palladium(0) catalyst to give the adduct **2**, which then extrudes nitrogen and sulfur dioxide to give the diarylpalladium(II) species (**3**). Carbon monoxide inserts into the palladium–carbon bond of the intermediate **3** to give (arylcarbonyl)arylpalladium(II) (**4**), which degrades to the corrsponding carboxylic acid derivatives and arylhydridopalladium(II) (**5**) upon the reaction with the nucleophiles. The reductive elimination of arene from **5** gives palladium(0), and thus the catalytic cycle is achieved.

The reason why the formation of benzophenone derivatives is minor may be attributed to the reaction of the (arylcarbonyl)arylpalladium(II) species with the nucleophiles to give benzoic acids or their esters and amides is faster than the reductive elimination of benzophenone derivatives from **4**,[7] (Eq. 1). The formation

Table 2. Reaction of Azosulfone (**1**) with Carbon Monoxide and Nucleophiles Catalyzed by Tetrakis(triphenylphosphine)-plladium(0)[a]

Azosulfone	Nucleophile	Product, Yield[b]/%	
1c	MeOH	$PhCO_2Me$	28

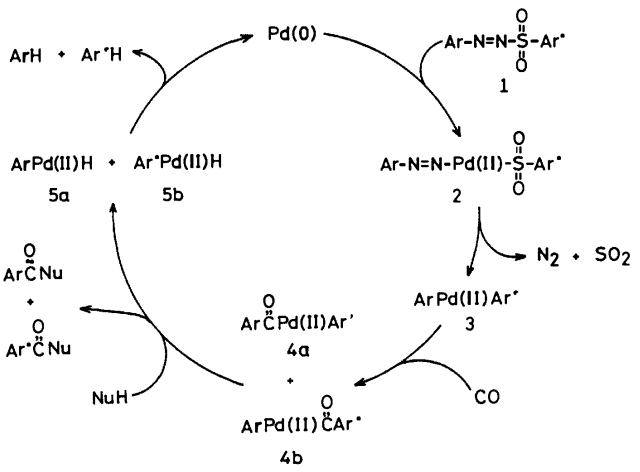
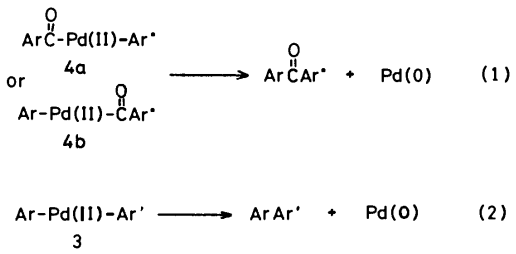
1c	AcONa	$PhCO_2Ac$	0

a) Diaryl ketone (Ar_2CO; 1—2%) and biaryl (Ar_2; 4—10%) were formed in all cases. b) The yields were determined by means of GC.



Scheme 1.

of biaryl may be accounted for by the reductive elimination from diarylpalladium(II) before which is carbonylated by carbon monoxide (Eq. 2).



Experimental

Measurement. The melting points and boiling points are uncorrected. The infrared absorption spectra were determined on a Hitachi Model 260-10 spectrophotometer, using samples as either neat liquid or in KBr disks. The ^1H NMR spectra were recorded at 60 MHz by using a JNM-PMX 60 SI spectrometer, with tetramethylsilane as the internal standard in $CDCl_3$. The mass spectra were determined with a JEOL JMS-DX 300 mass spectrometer with the JEOL JMA-5000 Mass Data System at an ionizing voltage of 20—70 eV. The gas chromatography was carried out with Hitachi Models 163 and 263-30 gas chromatographs using a 1 m column packed with 10% SE-30. The gel-permeation chromatography was performed by using a JAI LC-08 liquid chromatograph with a JAIGEL column (20ϕ×600 mm×2, with chloroform as an eluent).

Materials. All the solvents were distilled and stored under nitrogen. Palladium chloride of Wako Chemicals was used without further purification. Tetrakis(triphenylphosphine)palladium(0) was prepared by the method described in the literature.[8] Phenylazo p-tolyl sulfone (**1a**) (mp 90—91 °C (90—91 °C)), p-tolylazo phenyl sulfone (**1b**) (mp 82—83 °C), phenylazo phenyl sulfone (**1c**) (mp 75—76 °C (76—77 °C)), p-tolylazo p-tolyl sulfone (**1d**) (mp 96—97 °C (96—97 °C)), and p-methoxyphenylazo p-methoxyphenyl sulfone (**1e**) (mp 111—112 °C) were prepared by the published procedures.[9]

General Procedure for the Reaction of Arylazo Aryl Sulfone with Carbon Monoxide Catalyzed by Tetrakis(triphenylphosphine)palladium(0). To a stirred solution containing arylazo aryl sulfone (2.0 mmol) and tetrakis(triphenylphosphine)palladium(0) (0.2 mmol) in 10.0 cm^3 of benzene–acetic acid (1 : 1) at 80 °C, carbon monoxide was introduced by bubbling for 2 h. The crude reaction mixture was then

concentrated and chromatographed on silica gel, using ethyl acetate as the eluent. The products were identified by comparing their retention times of GC and the IR, ^{1}H NMR, and mass spectra with those of authentic samples.

General Procedure for the Reaction of Arylazo Aryl Sulfone with Carbon Monoxide and Nucleophiles Catalyzed by the Palladium(0) Complex. a) To a stirred solution containing arylazo aryl sulfone (2.0 mmol), nucleophile (alcohol or amine, 2.0 cm^3), and tetrakis(triphenylphosphine)palladium(0) (0.2 mmol) in 10.0 cm^3 of benzene at 80 °C, carbon monoxide was introduced by bubbling for 2 h. b) To a stirred suspension containing arylazo aryl sulfone (2.0 mmol), nucleophile (sodium methoxide or sodium acetate, 10.0 mmol), and tetrakis(triphenylphosphine)palladium(0) (0.2 mmol) in 10.0 cm^3 of benzene at 80 °C, carbon monoxide was introduced by bubbling for 2 h. The crude reaction mixture was then concentrated and chromatographed on silica gel, using ethyl acetate as the eluent. The products were identified by comparing their retention times of GC and the IR, ^{1}H NMR, and mass spectra with those of authentic samples.

(Received July 19, 1988)

Synopsis. Highly optically pure (*R*)- and (*S*)-phoracantholide I were synthesized in relatively short steps starting from diethyl 3-oxoglutarate by means of a microbial asymmetric reduction of the intermediate keto acid with immobilized baker's yeast entrapped in gels of κ-carrageenan.

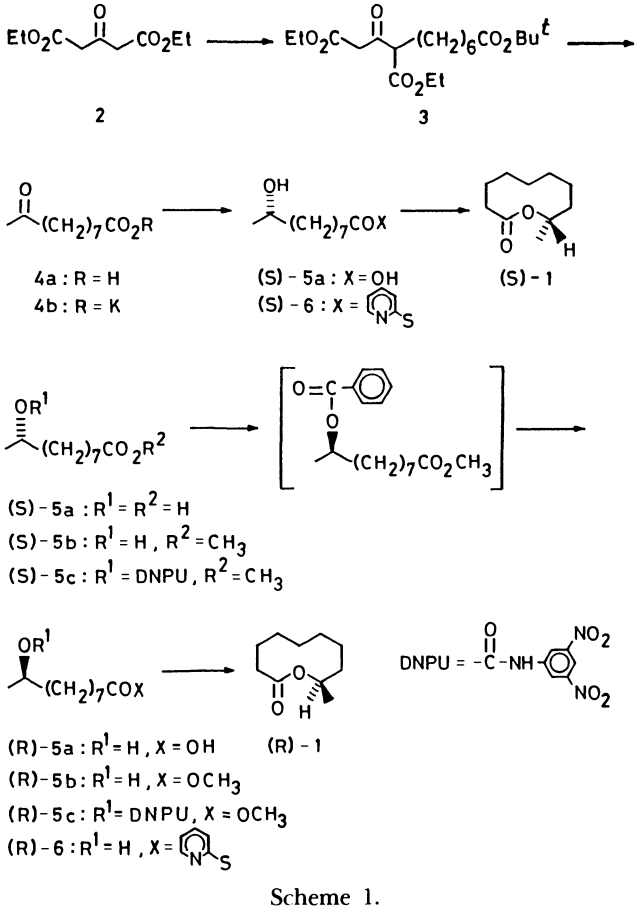
Since phoracantholide I (**1**), possessing a ten-membered lactone ring, has been isolated as a defensive secretion from the metasternal gland of the eucarypt longicorn, *Phoracantha synonyma*,[2)] several synthetic methods were reported for racemic **1**.[3)] The first synthesis of optically active **1** has recently been achieved by Kitahara et al. and the (*R*)-enantiomer was announced as the natural form of a defensive secretion of the insect.[4)] However, the method required multiple steps and the optical purity of synthesized enantiomers based on their GLC analyses with a chiral stationary phase was 89% e.e.

Recently we synthesized each enantiomer of 5-hexadecanolide and 4-dodecanolide with high optical purities via asymmetric reduction with immobilized baker's yeast (IBY).[5)] These are the pheromone of the oriental hornet and a defensive secretion of rove beetles. IBY, compared with free baker's yeast, has been found to have advantages in terms of the separation of products from the catalyst and of the reuse of the catalyst.[5,6)] In the expansion of the horizons of IBY in organic synthesis, we report herein a facile and short-step synthesis of the two enantiomers of **1** with highly optically pure forms.

Results and Discussion

First, diethyl 3-oxoglutarate (**2**) was alkylated regioselectively with *t*-butyl 7-bromoheptanoate and $Mg(OEt)_2$ to give the monoalkylated 3-oxoglutarate **3**, which was converted by a decarboxylative hydrolysis to the keto acid **4a** with a 78% yield from **2**. Compound **4a**, after treatment with an aqueous solution of KOH, was subjected to a microbial asymmetric reduction in an aqueous solution of KCl with the IBY entrapped by κ-carrageenan[5)] to give an optically pure alcohol (*S*)-**5a**. The optical purity of (*S*)-**5a** was determined to be 96% e.e. by HPLC analysis of the corresponding 3,5-dinitrophenylurethane (DNPU) derivative (*S*)-**5c**. Finally, (*S*)-**5a** was lactonized via the corresponding pyridinethiol ester (*S*)-**6** in the presence of $AgClO_4$ to give (*S*)-**1** with a 44% yield. For the synthesis of (*R*)-**1** reported as the natural form of **1**, the methyl ester (*S*)-**5b** was converted via a Mitsunobu inversion to (*R*)-**5a** with about 95% e.e. This was based on the HPLC analysis of a DNPU derivative (*R*)-**5c**. Lactonization of (*R*)-**5a**, as described above, gave the desired (*R*)-**1**. Thus highly optically pure (*R*)- and (*S*)-**1** were synthesized in seven and four steps, respectively, starting from **2**. The optical purity of the two enantiomers should be at least 95% e.e., because it was assumed that no apparent racemization at the chiral center of (*R*)- and (*S*)-**5a** occurred during their lactonization.

As shown in Table 1 the reuse of the IBY was achieved in two solvent systems, one of which is an aqueous KCl solution and the other an aqueous KCl solution containing ethyl acetate (EA). The reproducibility of both the chemical and optical yields was examined in each system. For the aqueous KCl solution system the first use of IBY catalyst gave a low chemical yield of (*S*)-**5a**, but after the 3rd use the yield was raised to 41%, a maximum yield of 46% being obtained after the 4th use. It is of interest that the



Scheme 1.

Table 1. Reuse of Immobilized Baker's Yeast in the Asymmetric Reduction of 9-Oxodecanoic Acid (**4a**)

Recycle number	Yieid of **5a** (%)		Optical purity of (*S*)-**5a** (% e.e.)	
	AK[a]	AKEA[b]	AK[a]	AKEA[b]
1	23	22	96	96
2	28	26	96	95
3	41	31	96	96
4	46	38	96	96
5	32	21	96	94
6	30	—	96	—
7	15	—	96	—

a) AK: 2% aqueous KCl solution. b) AKEA: 2% aqueous KCl solution containing ethyl acetate.

optical purity of the product (*S*)-**5a** remained almost constant, 96% e.e., throughout all the repetitive use of the catalyst. An EA-containing aqueous solution system with a carboxylic acid **4a** as the substrate also produced (*S*)-**5a**, and the optical purity was about the same as that observed for the aqueous solution system employing a potassium salt **4b**. Further, the trend of the chemical yield for EA-containing aqueous solution system was comparable with that obtained for aqueous solution system, the yield of **5a** attaining a maximum of 38% after the 4 th use.

It is noteworthy that (1) the IBY catalyst entrapped with κ-carrageenan can be stored in a 2% aqueous solution of KCl for six or more months at 0—5 °C, (2) the catalyst is reusable many times during the period, (3) the optical purity of the product is reproducible throughout all of the use of the catalyst, (4) the catalyst can be recovered and separated easily from the reaction mixture by simple filtration.

Experimental

General. IR spectra were determined on a Hitachi 260-10 spectrometer and on a Perkin Elmer 1720 Fourier transform IR spectrometer. ^{1}H and ^{13}C NMR spectra were obtained on a Hitachi R-24B spectrometer and on a Hitachi R-90H Fourier transform NMR spectrometer, respectively, in $CDCl_3$ solutions with tetramethylsilane as an internal standard. EI and CI mass spectra were recorded on a JEOL JMS-D300 mass spectrometer at 70 eV and 200 eV (isobutane), respectively, using a direct insertion probe. Optical rotations were measured on a Horiba SEPA-200 high sensitivity polarimeter. Column chromatography was carried out with 70—230 mesh silica gel (Merck Kieselgel 60 Art 7734).

Determination of the Optical Purities of (*R*)- and (*S*)-5a. (*R*)- and (*S*)-**5a** were converted via their methyl esters to (*R*)- and (*S*)-**5c** by treating with 3,5-dinitrophenyl isocyanate. HPLC analyses were carried out on a Gasukuro Kogyo model 576 liquid chromatograph equipped with a UV detector (254 nm). A Sumipax 2100 4X250 mm column (Sumitomo Chemical Co., Ltd., Osaka) was used with hexane: 1,2-dichloroethane:ethanol=100:20:1 (v/v, flow rate, 1 mL min^{-1}) as solvent. (*R*)- and (*S*)-**5c** were separable under these conditions and each showed two peaks. (*R*)-**5c**: R_t 12.4 min (2.5%) and 13.7 min (97.5%). (*S*)-**5c**: R_t 12.4 min (98%) and 13.7 min (2%). The optical purities of (*R*)- and (*S*)-**5a** were therefore 95% e.e. and 96% e.e.

9-*t*-Butyl Diethyl 2-Oxo-1,3,9-nonanetricarboxylate (3). Compound **3** was synthesized by alkylating diethyl 3-oxoglutarate (**2**, 20.2 g, 100 mmol) with *t*-butyl 7-bromoheptanoate (29.2 g, 110 mmol) in the presence of $Mg(OEt)_2$ according to the procedures described previously.[7] Purification by column chromatography on silica gel (hexane: ethyl acetate=3:1, v/v) gave **3** as a pale yellow viscous liquid (33.9 g, 88%). IR (neat) 1730, 1715 cm^{-1}. ^{1}H NMR δ=1.12—1.50 (21H, s at 1.43), 3.43 (2H, s), 3.55 (1H, t, *J*=7.2 Hz), 4.15 (4H, q, *J*=7 Hz). ^{13}C NMR δ=197.33, 172.82, 169.01, 166.44, 79.79. EIMS *m/z* (%) 330 (M^+ −56, 1), 313 (M^+ −73, 13), 202 (41), 156 (73), 57 (100). CIMS *m/z* (%) 387 [$(M+H)^+$, 41], 331 [$(M+H-56)^+$, 100].

9-Oxodecanoic Acid (4a). Monoalkylated 3-oxoglutarate **3** (19.3 g, 50 mmol) was heated in a 15% aqueous solution of NaOH (360 mL) under reflux for 15 h. The hydrolyzed mixture was acidified with concd HCl, saturated with NaCl and extracted with ether. Work-up of the ethereal solution gave a crude solid, which was recrystallized from petroleum ether to give **4a** as needles (8.28 g, 89%), mp 41—42 °C. IR (KBr) 3100, 1700 cm^{-1}. ^{1}H NMR δ=1.14—1.88 (10H, m), 2.15 (3H, s), 8.96 (1H, s). ^{13}C NMR δ=208.89, 179.09, 43.57. EIMS *m/z* (%) 186 (M^+, 2), 168 (M^+ −18, 6), 111 (20), 58 (70), 43 (100). CIMS *m/z* (%) 187 [$(M+H)^+$, 100]. Found: C, 64.38; H, 9.89%. Calcd for $C_{10}H_{18}O_3$: C, 64.69; H, 9.74%.

(*S*)-(+)-9-Hydroxydecanoic Acid [(*S*)-5a]. Use of Aqueous Solution System: According to the procedures described previously,[1,5] a mixture of the potassium salt **4b** derived from **4a** (1 g), baker's yeast (50 g) immobilized in carrageenan beads, and D-glucose (40 g) in a 2% aqueous solution of KCl (1000 mL) was shaken at 30 °C. Work-up of the reaction mixture gave crude (*S*)-**5a**, which was purified by column chromatography on silica gel (hexane:ethyl acetate=1:1, v/v) to give (*S*)-**5a** as a colorless liquid (465 mg, 46%), $[\alpha]_D^{22}$ +8.14° (*c* 0.41, chloroform). IR (neat) 3500, 1710 cm^{-1}. ^{1}H NMR δ=1.18 (3H, d, *J*=6 Hz), 1.12—1.86 (12H, m), 2.25 (4H, m), 3.72 (1H, m), 7.08 (2H, s). ^{13}C NMR δ=178.85, 68.08. EIMS *m/z* (%) 170 (M^+ −18, 1), 115 (17), 101 (41), 45 (100). CIMS *m/z* (%) 189 [$(M+H)^+$, 24], 171 [$(M+H-18)^+$, 100]. Found: C, 63.72; H, 10.91%. Calcd for $C_{10}H_{20}O_3$: C, 63.79; H, 10.71%.

Use of EA-Containing Aqueous Solution System: The same procedure was followed as described above except for using a 2% aqueous solution of KCl (1000 mL) containing ethyl acetate (10 mL) as solvent and the keto acid **4a** (1 g) itself as substrate.

(*S*)-(+)-Phoracantholide I [(*S*)-1]. To a solution of (*S*)-**5a** (160 mg, 0.85 mmol) in dry benzene (1 mL) were added triphenylphosphine (320 mg, 1.22 mmol) and dipyridyl disulfide (270 mg 1.22 mmol) under argon and the mixture was stirred for one hour at room temperature. The resulting pyridinethiol ester (*S*)-**6** was dissolved in dry benzene (50 mL) and the solution was added dropwise to a stirred suspension of $AgClO_4$ (1.13 g) in refluxing benzene (120 mL) under argon over period of 8 h with a motor-drive syringe (Micro Feeder JP-V, Furue Science, Tokyo). After the addition had been completed, the mixture was refluxed for an additional 15 min and cooled to room temperature. The precipitate was filtered off and washed with ether. The filtrate and washings were combined and concentrated in vacuo. The residue was purified by column chromatography on silica gel (hexane: ethyl acetate=10:1, v/v) followed by fractional distillation to give (*S*)-**1** (63 mg, 44%) with a characteristic odor, bp 65 °C (bath temperature)/3 mmHg (1 mmHg=133.32 Pa), $[\alpha]_D^{22}$ +38.38° (*c* 0.06, chloroform) [lit,[4] $[\alpha]_D^{22}$ +38.8° (*c* 0.68, chloroform)]. IR (neat) 1725 cm^{-1}. ^{1}H NMR δ=1.25 (3H, d, *J*=6 Hz), 4.72—5.51 (1H, m). EIMS *m/z* (%) 170 (M^+, 3), 152 (M^+ −18, 17), 126 (12), 111 (11), 98 (100), 84 (50), 69 (30), 54 (64), 40 (55). CIMS *m/z* (%) 171 [$(M+H)^+$, 100]. Found: C, 70.32; H, 10.63%. Calcd for $C_{10}H_{18}O_2$: C, 70.54; H, 10.66%.

(*R*)-(−)-9-Hydroxydecanoic Acid [(*R*)-5a]. Methyl ester (*S*)-**5b** (220 mg, 1.1 mmol) prepared from (*S*)-**5a** was dissolved in dry THF (15 mL) and the solution was stirred under ni-

trogen while triphenylphosphine (600 mg, 2.2 mmol) and benzoic acid (300 mg, 1.6 mmol) were added. To the stirred solution was slowly added diethyl azodicarboxylate (400 mg, 2.2 mmol) and the mixture was allowed to stir at room temperature overnight. After evaporation of the solvent in vacuo, the residue was chromatographed on silica-gel column. Elution with benzene gave a benzoate ester, a solution of which in THF (2 mL) was added dropwise over a 10-min period to a stirred and ice-cooled 1 mol dm^{-3} aqueous solution of KOH (2 mL) containing methanol (1.5 mL). After being stirred for 30 min at room temperature, the mixture was acidified with concd HCl to pH 1—2 under ice-cooling and extracted with dichloromethane. Work-up of the organic layer gave a crude product, which was purified by column chromatography on silica gel (hexane : ethyl acetate=2 : 1, v/v) followed by preparative TLC (hexane : ethyl acetate=1 : 1, v/v) to give (*R*)-**5a** as a colorless liquid (112 mg, 54% from (*S*)-**5a**), $[\alpha]_D^{22}$ −8.13° (*c* 0.11, chloroform). The IR, NMR, and CI mass spectra were identical with those of (*S*)-**5a**. Found: C, 63.66; H, 10.78%. Calcd for $C_{10}H_{20}O_3$: C, 63.79; H, 10.71%.

(*R*)-(−)-Phoracantholide I [(*R*)-1]. Lactonization of (*R*)-**5a** (94 mg, 0.5 mmol), as described for (*S*)-**5a**, gave (*R*)-**1** (28 mg, 33%), $[\alpha]_D^{22}$ −37.4° (*c* 0.02, chloroform) [lit,[4] $[\alpha]_D^{22}$ −35.1° (*c* 1.15, chloroform)]. (*R*)-**1** was identical in its spectral data with (*S*)-**1**. Found: C, 70.29; H, 10.81%. Calcd for $C_{10}H_{18}O_2$: C, 70.54; H, 10.66%.

We wish to thank Dr. Seiichiro Kawabe, Department of Fundamental Natural Science, Okayama University of Science, for his advice concerning the immobilization of baker's yeast. The present work was partially supported by the Agricultural Chemical Research Foundation and by a Grant-in-Aid for Scientific Research No. 63560135 from the Ministry of Education, Science and Culture.

Synthesis of 10-(8-Aminooctyl)flavin and Its Use in Affinity Chromatography

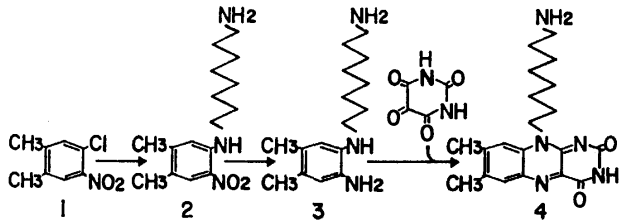
Sabu KASAI,* Hideko NAKANO, Kazuya MAEDA,† and Kunio MATSUI††
Research Institute for Atomic Energy, Osaka City University, Sugimoto, Sumiyoshi-ku, Osaka 558
†General Education Course, Osaka City University, Sugimoto, Sumiyoshi-ku, Osaka 558
(Received July 23, 1988)

Synopsis. 7,8-Dimethyl-10-(8-aminooctyl)isoalloxazine was synthesized by coupling *N*-(8-aminooctyl)-4,5-dimethyl-1,2-benzenediamine with alloxan. The flavin was immobilized to epoxy activated gel to use for affinity chromatography. The gel was effective for purification of riboflavin-binding protein from egg white and flavokinase from rat liver.

10-(ω-Aminoalkyl)flavins (7,8-dimethylisoalloxazines) are readily bound covalently to many kinds of solid supports, for example, epoxy-, CNBr-, or *N*-hydroxysuccinimide-activated ones, with the alkylamino group. The immobilized flavin would be useful for affinity chromatography, technology using flavin-flavin binding protein complexes, study on flavoenzyme mechanism, preparation of flavoenzyme functioned materials, and others. The only example of such a flavin to be reported is 7,8-dimethyl-10-(2-aminoethyl)isoalloxazine. This was synthesized by reductive amination of 10-(formylmethyl)flavin, a periodate oxidation product of riboflavin, with sodium cyanotrihydroborate and ammonium chloride.[1] This synthetic route, however, is an unusual one for an (ω-aminoalkyl)flavin. In this report, we describe a more convenient synthetic method for this kind of flavin, as is shown in Scheme 1.

1-Chloro-2-nitro-4,5-dimethylbenzene (**1**) was coupled with 1,8-octanediamine to give 1-(8-aminooctylamino)-2-nitro-4,5-dimethylbenzene (**2**), which was catalytically hydrogenated with Raney's catalyst. Addition of strong acid was necessary to complete the reduction. The reduced compound **3** was coupled with alloxan in the usual way to give 7,8-dimethyl-10-(8-aminooctyl)isoalloxazine (**4**).

The epoxy-activated Cellulofine, a cellulose gel, was prepared and was bound with **4** as described by Sundberg and Porath.[2] The flavin content of the gel so prepared was approximately 17 μmol of the flavin/mL of the hydrated gel, and was relatively high compared with many kinds of flavin immobilized gel prepared by Merrill and McCormick (16.4—1.4 μmol mL^{-1}).[3]



Scheme 1.

The flavin immobilized gel so obtained was used for affinity chromatography to show the high efficiency of the gel. Many kinds of flavin affinity chromatographic materials have already been prepared which have various features including ease or difficulty of preparation, high or low flavin content, high or low efficiency, etc.[4] An important factor is the position of immobilization of the flavin; for example, only gels immobilized at position 10 of flavin were effective for the purification of flavokinase from rat liver; gels immobilized at position 3 and 8 were negative.[3] Consequently, two proteins were chosen for purification; riboflavin-binding protein (RBP) from egg white, since this protein has been used for many studies and is easy to obtain, and flavokinase from rat liver, since the gel seems to be suitable for the purification of this protein as described above.

RBP, partially purified as described in the experimental section, was subjected to affinity chromatography and the elution pattern was shown in Fig. 1. RBP was bound to the gel and selectively eluted with a buffer containing 20 μM (M=mol dm^{-3}) riboflavin.

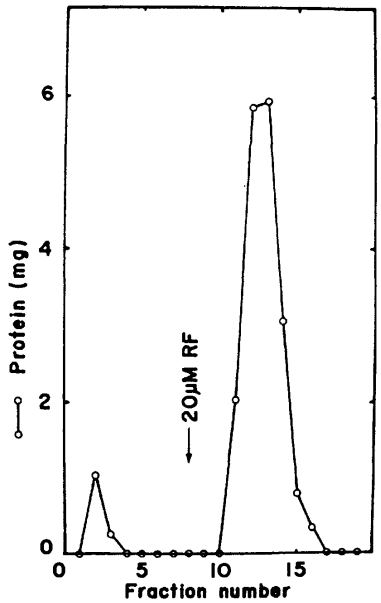


Fig. 1. Elution pattern for affinity chromatography of riboflavin-binding protein. Partially purified RBP was applied on a flavin-immobilized column and the column was washed. The bound RBP was eluted from the column with a phosphate buffer containing 20 μM riboflavin. The amount of protein in each fraction was determined according to Lowry et al.[7] and plotted.

†† Present address: Teikoku Women's University, Department of Home Economics, 6-173 Touda-cho, Moriguchi-shi, Osaka 570.

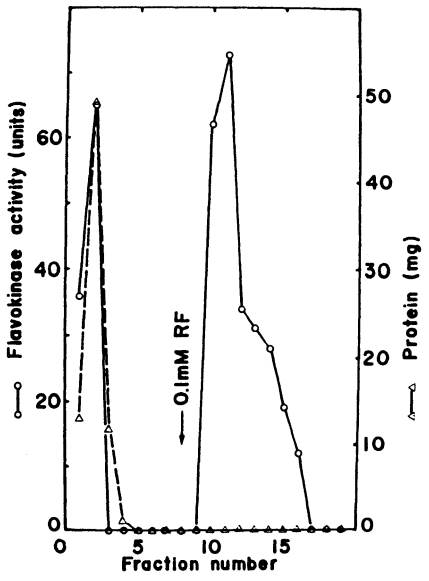

Fig. 2. Elution pattern for affinity chromatography of flavokinase from rat liver. A pooled sample from Sephadex G-75 chromatography was applied on an affinity chromatography and the column was washed. The bound flavokinase was eluted from the column with 100 μM riboflavin solution. The amount of protein (△) and flavokinase activity (○) in each fraction were plotted. Protein concentrations were determined according to Smith et al.[8]

The purified sample was analyzed by sodium dodecyl sulfate (SDS)-polyacrylamide gel electrophoresis and gave a single band (data not shown).

A crude extract of rat liver was fractionated with ammonium sulfate, and a 55 to 75% saturation fraction was chromatographed on a Sephadex G-75 column. Fractions containing flavokinase activity were collected and applied on the affinity column. Flavokinase with high specific activity was eluted with 0.1 mM riboflavin solution as shown in Fig. 2, though approximately 30% of the total eluted activity were found in the washings similarly to the affinity column reported by Merrill and McCormick.[5] Flavokinase binds irreversibly to fresh gel, so that a better yield was obtained after using several times.

These results indicate that the affinity column so prepared is effective for the purification of many proteins such as riboflavin carrier protein and flavokinase from many different origins.

Experimental

UV spectra were recorded on a Hitachi 320 recording spectrophotometer; 400 MHz ^{1}H NMR spectra were taken with a JEOL NMR spectrometer model JMM GX 400. Melting points were measured with a Yanaco MP micro melting point apparatus.

1-(8-Aminooctylamino)-2-nitro-4,5-dimethylbenzene (2). 1-Chloro-2-nitro-4,5-dimethylbenzene (**1**) was synthesized according to the procedure of Adams et al.[6] from 4,5-dimethyl-2-nitroaniline (Aldrich). A mixture consisting of 5.0 g of **1** and 25.0 g of 1,8-octanediamine was heated at 100 °C for 2 h and cooled to room temperature. The brown syrup obtained was then dissolved in 250 mL CH_2Cl_2 and washed five times with water. Anhydrous $MgSO_4$ was added to the organic phase and filtered off. The filtrate and washings were combined and evaporated in vacuo. The residue, dissolved in CH_2Cl_2, was applied on a silica-gel column (Wakogel C-200, 3 ×25 cm) and developed with a mixture of CH_2Cl_2 and methanol (8 : 2). Fractions from the second large red band were collected and evaporated. The syrupy residue was dissolved in a minimum amount of toluene and **2** was crystallized by gradually adding hexane. Fine orange crystals were filtered off, washed with hexane and dried over $CaCl_2$ in vacuo. Yield 7.0 g (88%): mp 68—70 °C; ^{1}H NMR ($CDCl_3$) (*exchangeable H) δ=1.34 (6H, m, CH_2), 1.44 (2H, m, CH_2), 1.51 (2H, m, CH_2), 1.71 (2H, m, CH_2), 2.17 (3H, s, CH_3), 2.27 (3H, s, CH_3), 2.62* (2H, s(broad), NH_2), 2.74 (2H, t, J=7 Hz, 8′CH_2), 3.26 (2H, td, J=5 and 7 Hz, 1′CH_2), 6.61 (1H, s, φ-H), 7.91 (1H, s, φ-H), 7.97* (1H, s(broad), NH). Found: C, 65.60; H, 9.20; N, 14.04%. Calcd for $C_{16}H_{27}N_3O_2$: C, 65.49; H, 9.28; N, 14.32%.

7,8-Dimethyl-10-(8-aminooctyl)isoalloxazine (4). 1.0 g of **2** was dissolved in 30 mL acetic acid and hydrogenated over 5% palladium on carbon (400 mg) at 100 °C under atmospheric pressure. When the color of the solution changed from orange-red to colorless (approximately 1 h later), 3 mL concentrated hydrochloric acid was added to the reaction mixture and hydrogenation was continued for a further 1 h. The catalyst was filtered off and washed with acetic acid. The combined filtrate and washings were evaporated and 30 mL water was added to the residue. The solution was evaporated to dryness to remove acetic acid. This procedure was repeated twice. The residue was dissolved in 30 mL water and DEAE-cellulose (OH^- form, suction dried weight, 20 g) was added to the solution and the suspension stirred gently for 10 min. The cellulose was filtered off and washed with water. The combined filtrate and washings were evaporated. Because the triamine so obtained was readily oxidized, it was subjected to the next reaction without isolation. The residue, dissolved in 30 mL methanol, was added to a hot solution of 0.5 g alloxan monohydrate and 10 g boric acid in 20 mL methanol. The solution was heated at 60 °C for 2 h and evaporated. The syrupy residue was crystallized from a solution of 2 g boric acid in 20 mL ethanol to yield 1.0 g (43%) of **4** as pentaborate. The crystals were dried over P_2O_5 at 150 °C overnight for elemental analysis: mp over 300 °C; ^{1}H NMR (DMSO-d_6) δ=1.32 (6H, m, CH_2), 1.47 (2H, m, CH_2), 1.57 (2H, m, CH_2), 1.71 (2H, m, CH_2), 2.40 (3H, s, CH_3), 2.52 (3H, s, CH_3), 2.75 (2H, m, 8′CH_2), 4.58 (2H, t, J=8 Hz, 1′CH_2), 7.81 (1H, s, φ -H), 7.90 (1H, s, φ-H), 8.06* (2H, s(broad), NH_2), 11.31* (1H, s, 3NH). UV (50 mM phosphate buffer pH 7.0) 223 nm (ε_{mM} 27.3), 266 (31.5), 368 (8.86), 443 (10.7); (6 M HCl) 265 (28.9), 392 (18.0), (0.1 M NaOH) 270 (36.3), 352 (10.3), 447 (10.8); Found: C, 41.71; H, 4.97; N, 12.43%. Calcd for $C_{20}H_{27}N_5O_2 \cdot 1.3H_2B_4O_7$: C, 41.86; H, 5.19; N, 12.20%.

Preparation of Flavin Immobilized Gel. Cellulose gel (Cellulofine, Chisso) was epoxy-activated using 1,4-butanediol diglycidyl ether according to Sundberg and Porath,[2] and allowed to react with **4**. 2.7 g of **4** was dissolved in a mixture of 50 mL of dioxane and 50 mL of 0.2 M carbonate buffer, pH 10.5, and 120 mL epoxy-activated Cellulofine gel (hydrated) was added to the solution. The slurry was stirred gently at 60 °C for 24 h. The yellow stained gel was filtered off and washed with hot water, dioxane, acetic acid and 20% NaCl solution repeatedly until greenish yellow fluorescence was not observed in the washings. Finally, the gel was washed with buffer for affinity chromatography. The nitrogen contents in the dried samples of modified and unmodified Cellulofine were 0.66 and 0.06% respectively. It was calculated from these data that the dry and hydrated gel contained approximately 86 μmol of flavin/g and 17 μmol of

flavin/mL respectively.

Affinity Chromatography. RBP from Egg White. RBP was partially purified from two eggs according to Nishina[9] before affinity chromatography; RBP was bound to 20 g DEAE-cellulose at pH 4.3 and then eluted with 0.1 M acetate buffer, pH 3.6. The collected fractions were rechromatographed on a Sephadex G-25 column (90×2.6 cm) using a glycine-HCl buffer (pH 3.15) to remove riboflavin. Protein was precipitated from the eluate by adding ammonium sulfate to 85% saturation. The precipitate was dialyzed against a 50 mM phosphate buffer (pH 7.0). The dialyzed sample (3 mL) was applied on a column of the flavin immobilized gel (15×1.0 cm), and the column was washed with the same buffer. RBP was eluted from the column with the phosphate buffer containing 20 μM riboflavin.

Flavokinase from Rat Liver. A buffer containing 0.1 M 3-morpholino-1-propanesulfonic acid (MOPS) and 0.1 mM $ZnSO_4$, pH 7.0 was used throughout. Flavokinase activity was determined as follows; each assay mixture was prepared adding 100 μL sample to 300 μL of a buffer containing 100 μM riboflavin, 1 mM ATP, 0.1 mM $ZnSO_4$, and 0.1 M MOPS, pH 8.0. After 30 min incubation at 37 °C, 50 μL of the mixture was assayed using HPLC; a Cosmosil 10C18 packed column (4.6×150 mm, Nacalai Tesque) and 50 mM phosphate buffer, pH 6.25, containing 0.5% pyridine, 9% ethanol, were used for separation. FMN synthesis was expressed in units of flavokinase activity; one unit produces 1 nmol FMN/h under the conditions described above.

Three rat livers (approximately 25 g) were homogenized in 75 mL buffer and the supernatant was fractionated by adding ammonium sulfate. A 55 to 75% saturation precipitate was dissolved in a small amount of buffer and applied on a Sephadex G-75 column (30×2.6 cm). After development, the fractions containing flavokinase activity were pooled and approximately one third of the volume was applied on the flavin affinity column (10×1.0 cm) again and the column was washed with the buffer. Fractions with high flavokinase activity were obtained by elution with the buffer containing 100 μM riboflavin.

The authors thank Mr. Junichi Goda for the elemental analyses.

Synthetic Photochemistry. XLVII.[1] Formation and Degenerate Cope Rearrangement of 9-Dicyanomethylenebarbaralane

Guan Rong TIAN,† Shigeru SUGIYAMA, Akira MORI, and Hitoshi TAKESHITA*
Institute of Advanced Material Study, 86, Kyushu University, Kasuga-koen, Kasuga, Fukuoka 816
(Received August 3, 1988)

Synopsis. Photolysis of 2-dicyanomethylenehomobarrelene gave 9-dicyanomethylenebarbaralane, 5-dicyanomethylenetricyclo[4.3.0.0^{2,9}]nonadiene, and 1-dicyanomethyleneindan. Dicyanomethylenebarbaralane showed time-averaged NMR signals.

Recently, we synthesized several barbaralane derivatives[2] by a photolysis of 2-methylenehomobarrelenes[3] prepared from 1*H*-cyclohepta[*b*]furan-2-one derivatives and 2,3-bis(methoxycarbonyl)-7-oxanorbornadiene. In this paper we describe the synthesis of 9-dicyanomethylenebarbaralane (**1**)[4] from 2-dicyanomethylenehomobarrelene (**2**) and the time-averaged NMR spectrum of this internal Cope-rearrangement system.

Results and Discussion

When a chloroform solution of **2**, prepared by high-pressure cycloaddition-thermal cycloreversion procedure from 8,8-dicyanoheptafulvene (**3**) and 2,3-bis(methoxycarbonyl)-7-oxanorbornadiene (**4**),[3] was irradiated, three products (**1**,[4] **5**, and **6**[5]) were obtained in 18, 29, and 24% yields, respectively. These structures were determined by comparisons with the spectral data of the related compounds prepared previously.[3] The barbaralane derivative, **1**, revealed a time-averaged NMR spectra, as expected. A kinetic analysis of this intramolecular Cope rearrangement was carried out by measuring the half-height widths of NMR signals.[6] The kinetic parameters obtained are summarized in Table 1 together with those of related compounds, barbaralone (**7**)[4,7] and barbaralane (**8**).[4] In both toluene-d_8 and acetone-d_6, the rates of exchange were nearly equal and insensitive to the polarity of the solvent. This is consistent, together with other thermodynamic parameters, as the concerted rearrangement.[7-11]

The activation energy (E_a) of **1** was similar to that reported by Nakanishi for **7**.[7] A retardation of the

IR ν: 2210, 1595, and 1540 cm^{-1}. UV (MeOH): 242.0 (ε 5200 sh), 279.8 (7500), and 339.2 nm (10900). MS (%) 180 (M^+, 26), 153 (51), and 115 (base)], **6** [colorless crystals, mp 146—147 °C, 43 mg, 24%. Found: C, 79.77; H, 4.14; N, 15.37%. Calcd for $C_{12}H_8N_2$: C, 79.88; H, 4.47; N, 15.54%. ^{1}H NMR δ=3.1—3.4 (4H, m), 7.3—7.7 (3H, m), and 8.20 (1H, dm, J=7.5 Hz). ^{13}C NMR δ=29.6, 34.6, 78.0, 112.9, 113.5, 126.1, 126.2, 128.1, 135.1, 135.7, 154.0, and 179.2. IR ν: 2240 and 1575 cm^{-1}. UV (MeOH): 230.0 (ε 8300), 236.0 (7450), 255.4 (1850), 290.0 (11800 sh), 306.4 (15500), and 331.8 nm (17800). MS m/z (%) 180 (M^+, 63), 153 (47), 115 (base), 43 (68), and 39 (38)], and unreacted **2** (142.2 mg). **b**) An acetone-d_6 solution (1 cm^3) of **2** (143 mg) was irradiated to give **1** [16.9 mg, 15%], **5** [30.6 mg, 28%], **6** [26.7 mg, 24%], and unreacted **2** [32.8 mg].

Kinetics Measurements. A kinetic analysis was carried out by variable-temperature ^{13}C NMR measurements at 67.5 MHz (JEOL 270) in acetone-d_6 and toluene-d_8. The rate constants of the chemical exchange process were determined by broadened line widths of the exchangeable signals at the half height. Natural line widths were obtained from the signals of C-3 and C-7 around δ 121 in toluene and δ 122 in acetone. The temperature range was between −80 and 60 °C in toluene and between −80 and 50 °C in acetone.

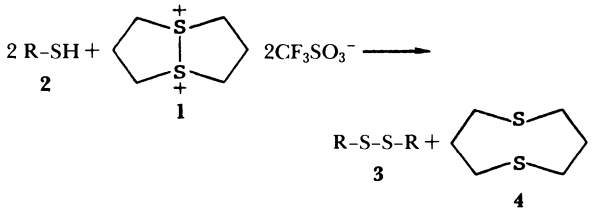
A Mild, High-Yield Conversion of Thiols into Disulfides Using Disulfide Dication Salt: A New Redox System

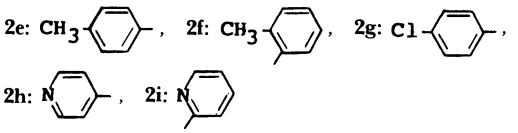
Hisashi FUJIHARA, Ryouichi AKAISHI, and Naomichi FURUKAWA*
Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305
(Received August 3, 1988)

Synopsis. A new redox reaction of thiols with disulfide dication salt, 1,5-dithioniabicyclo[3.3.0]octane bis(trifluoromethanesulfonate), under mild conditions gave the corresponding disulfides in good yields together with 1,5-dithiacyclooctane.

The conversion of thiols into disulfides is an important phenomenon in chemical and biological redox reactions.[1,2] Numerous procedures are available for the oxidation of thiols to disulfides.[1] Meanwhile, the formation and the isolation of a few disulfide dications have been reported.[3,4] However, reactions using disulfide dication have not been well explored because of difficulties to obtain stable compounds. Recently, we succeeded in the preparation of the disulfide dication, 1,5-dithioniabicyclo[3.3.0]octane bis(trifluoromethanesulfonate) (**1**), as a remarkably stable crystalline salt which was first characterized by X-ray diffraction.[5] We found that the disulfide dication **1** acts both as an oxidizing agent and as an electrophile toward aromatics.[6] No synthetic application of this attractive organosulfur compound has been reported. We present here a new type of redox reaction of thiols with the disulfide dication salt **1** under mild conditions.



2a: n-C_4H_9, **2b**: *cyclo*-C_6H_{11}, **2c**: t-C_4H_9, **2d**: C_6H_5,



The disulfide dication salt **1** is a remarkably stable compound under dry conditions and can be easily prepared by the reaction of 1,5-dithiacyclooctane 1-oxide with trifluoromethanesulfonic anhydride. A redox reaction was carried out simply by stirring anhydrous acetonitrile solution of thiols (**2a—i**) and dication salt **1** under an Ar atmosphere at room temperature. Disulfides were completely consumed within a few hours, as determined by GLC or TLC. After the usual work-up procedure, the residue was purified by column chromatography to give the corresponding symmetrical disulfides (**3a—i**) in good yields, together with 1,5-dithiacyclooctane (**4**) as a reduction product. The results are summarized in Table 1. This method can be applied to the oxidation of a variety of alkane- (**2a—c**), arene- (**2d—g**), and heteroarenethiols (**2h** and **2i**).

Table 1. Oxidation of Thiols with Dication **1**[a]

R-SH	Yield/%		Mp or Bp/°C/mmHg[b] (lit)

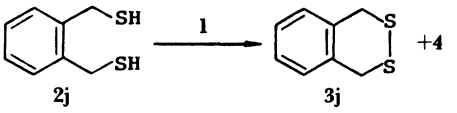
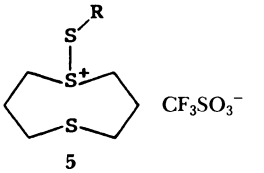
2e	78	60	46(44—46)[10]
2f	73	83	36(36—38)[11]
2g	80	86	72(72—73)[12]
2h	86	80	d)
2i	83	84	57—58(57)[13]
2j	44	77	80(80—81)[14]

a) Time, 5 h. b) 1 mmHg≈133.322 Pa. c) At 0 °C. d) Determined by NMR with authentic compound.

2-Methyl-2-propanethiol (**2c**) can be oxidized to the corresponding disulfide in comparatively low yield, though in general the oxidation of **2c** is difficult. The oxidative cyclization of 1,2-bis(mercaptomethyl)benzene (**2j**) was performed using a high-dilution method and gave the corresponding cyclic disulfide **3j** and **4** (see Table 1). These were obtained together with polymeric products, due to an intermolecular oxidation of **2j**.



These results demonstrate that the disulfide dication **1** employed acts as an oxidant toward thiols. This redox reaction may proceed through an electron-transfer process between thiols and the dication **1**, since the oxidation potential of thiols is relatively lower than that of **4** as a precursor of **1**.[6] Another possibility, that involves the thiasulfonium cation intermediate, such as **5**, is also conceivable in the present reaction.



Thus, a new organosulfur compound, disulfide dication **1**, can be used for the oxidation of several thiols under mild conditions.

Experimental

The IR spectra were obtained on a JASCO A-3 spectrometer. ^{1}H NMR spectra were measured on a Hitachi R-600 FT-NMR spectrometer. All of the reactions were monitored by

gas chromatography (GLC) [Hitachi 163, using a 2% Silicon OV-1 Chromosorb W on SiO_2 (80—100 mesh) column] or thin-layer chromatography (TLC) [Wakogel B-5F].

Thiols, as shown in Table 1, were obtained from Wako Pure Chemicals. 1,2-Bis(mercaptomethyl)benzene was prepared from 1,2-bis(bromomethyl)benzene by a standard procedure.[7] 1,5-Dithiacyclooctane 1-oxide was prepared by a method given in the literature.[4] Other chemicals were of reagent grade.

Preparation of Disulfide Dication 1. To a stirred solution of 1,5-dithiacyclooctane 1-oxide (3.2 g, 19.5 mmol) in anhydrous dichloromethane (160 mL) was added dropwise a solution of trifluoromethanesulfonic anhydride (5.5 g, 19.5 mmol) in anhydrous dichloromethane (160 mL) at −20 °C. After the addition was complete, the mixture was stirred for 3 h, and the white precipitates were filtered and washed with anhydrous dichloromethane, giving salts **1** in 80% yield: mp 100—102 °C; ^{1}H NMR (CD_3CN) δ=2.2—2.7 (br s, 4H, CH_2) and 2.9—3.6 (br s, 8H, $^+SCH_2$). Calcd for $C_8H_{12}F_6O_6S_4$: C, 21.52; H, 2.70%. Found: C, 21.42; H, 2.71%.

Oxidation of Thiols with Dication 1. In a typical run, to a stirred solution of disulfide dication **1** (240 mg, 0.54 mmol) in anhydrous acetonitrile (5 mL) was added a solution of benzenethiol (118 mg, 1.08 mmol) in anhydrous acetonitrile (3 mL) under an Ar atmosphere at room temperature. The mixture was stirred at room temperature and the reaction was monitored by GLC. After the reaction was complete, the reaction mixture was treated with aqueous sodium hydrogencarbonate solution. The mixture was extracted with dichloromethane (5×20 mL). The extracts were dried with magnesium sulfate, and the solvent was evaporated under reduced pressure. The residue was purified with column chromatography on silica gel (eluent: hexane) to afford diphenyl disulfide. The oxidations of the other thiols were confirmed by the similar procedure. The yields of disulfides obtained are listed in Table 1. The purity of the isolated product was confirmed by GLC analysis: the IR and NMR spectra, and bp or mp, were in satisfactory agreement with values found in the literature.

Oxidation of 1,2-Bis(mercaptomethyl)benzene (2j). A solution of dication **1** (240 mg, 1.54 mmol) in anhydrous acetonitrile (20 mL) and 1,2-bis(mercaptomethyl)benzene (**2j**) (92 mg, 1.54 mmol) in anhydrous acetonitrile (20 mL) was added separately and simultaneously over 2 h to a vigorously stirred solution of anhydrous acetonitrile (10 mL). The mixture was stirred at room temperature for 8 h under an Ar atmosphere. The mixture was then treated as described above. Cyclic disulfide **3j** was obtained in 44% yield.

Formation and Reaction of Oxazoles. Synthesis of *N*-Substituted 2-(Aminomethyl)oxazoles

Toshikazu IBATA* and Yasushi ISOGAMI
Institute of Chemistry, College of General Education, Osaka University, Toyonaka, Osaka 560
(Received August 13, 1988)

Synopsis. The BF_3-catalyzed reaction of substituted α-diazoacetophenones with chloroacetonitrile gave 5-aryl-2-chloromethyloxazoles (**3**) in high yields. Methyl *p*-nitrophenyldiazoacetate also yielded 2-(chloromethyl)-5-methoxy-4-(*p*-nitrophenyl)oxazole. The nucleophilic substitution of **3** with primary, secondary, and tertiary amines afforded the corresponding secondary amines, tertiary amines, and quaternary ammonium salts bearing a 2-oxazolylmethyl group.

The chemistry of oxazoles has strongly been interested in these two decades in connection with the synthesis of biologically active natural products containing oxazole ring system.[1] And also, the oxazoles having an (alkylamino)methyl group or an (dialkylamino)methyl group on C-2 have been paid attention because of their pharmaceutical properties.[2]

The authors have reported the general method of the synthesis of oxazoles through the BF_3-catalyzed reaction of α-diazo carbonyl compounds with nitrile.[3,4] We wish to report here the synthesis of *N*-alkyl-substituted 2-(aminomethyl)oxazole derivatives by the combination of the following two reactions: (i) the BF_3-catalyzed reaction of α-diazo carbonyl compounds with chloroacetonitrile to give 2-(chloromethyl)-oxazoles (**3**), (ii) the nucleophilic substitution reaction of **3** with amines.

Results and Discussion

Synthesis of 2-(Chloromethyl)oxazoles. The BF_3-catalyzed decomposition of substituted α-diazoacetophenones (**1**) in a chloroacetonitrile solution at −5 °C gave BF_3 salts of the corresponding 5-aryl-2-(chloromethyl)oxazoles (**3**) with evolution of nitrogen gas. The free 5-aryl-2-(chloromethyl)oxazoles (**3**) were obtained in high yields after neutralization with sodium hydrogencarbonate (Table 1). Structure of 3 was characterized on the basis of their spectroscopic data: The ^1H NMR signals of CH_2Cl and methine proton of oxazole-C-4 were observed at δ 4.65—4.72 and 7.3—7.5, respectively (Table 1). The yields of **3** are relatively lower than those of reactions of α-diazoacetophenones with acetonitrile.[3] This seems to be attributed to the low electron density on nitrogen atom of chloroacetonitrile.

The reaction of methyl *p*-nitrophenyldiazoacetate with chloroacetonitrile also gave 2-chloromethyl-5-methoxy-4-(*p*-nitrophenyl)oxazole (**3d**; R_1=CH_3O, R_2=*p*-$NO_2C_6H_4$) in moderate yield.

Nucleophilic Substitution Reaction of 2-(Chloromethyl)oxazoles with Amines. The 2-(chloromethyl)-oxazoles (**3**) are expected to have high reactivity toward nucleophilic reagents because they have structures similar to benzyl chloride. The reaction of 2-chloromethyl-5-(*p*-nitrophenyl)oxazole (**3a**: R_1=*p*-$NO_2C_6H_4$, R_2=H) with various primary, secondary, and tertiary amines was studied. The reactions were carried out in a benzene or an alcohol solution at room temperature or 40 °C using five molar equivalents of amines. Primary and secondary amines gave the corresponding secondary and tertiary amines (**4**), having a 2-oxazolylmethyl group in high yields. Aliphatic primary amines gave products **4a**—**4f** in quite high yields even in the case of bulky *t*-butylamine (Table 2). The ^1H NMR signals of CH_2-N group of these products were observed at δ 3.99—4.02.

2-Aminoethanol gave 2-[(2-hydroxyethylamino)-

methyl]-5-(*p*-nitrophenyl)oxazole (**4g**) as a sole product, which was confirmed on the basis of its ^{1}H NMR spectrum. Chemical shift (δ 4.05) of CH_2-N group attached to oxazole ring of **4g** is quite similar to those of reaction products (δ 3.99—4.02) of other primary amines (Table 2). This indicates that the reaction site of 2-aminoethanol is not the hydroxyl group but the amino group as is predicted from the difference in nucleophilicities of amino and hydroxyl groups. Similarly, *N*,*N*-dimethylethylenediamine clarified not to react at the tertiary amine but to react at the primary amine to give secondary amine (**4h**).

Secondary amines also react with **3a** to yield the tertiary amines (**4**) in high yields (Table 2, Runs i—o). Diethylamine is shown to be less reactive than most primary amines listed in Table 2. However, cyclic secondary amines such as pyrrolidine, piperidine, morpholine, and piperazine are indicated to have higher reactivity than the usual primary amines. *N*-Methylpiperazine reacted with **3a** at the site of secondary amine to give tertiary amine (**4n**) which was characterized on the basis of ^{1}H NMR data. The chemical

Table 4. Results of the Elemental Anlysis of **3** and **4**

shifts of N-CH_3 of **4n** (δ 2.30) is quite similar to that of the starting *N*-methylpiperazine (δ 2.26), and CH_2 group attached to oxazole-C-2 of **4n** (δ 3.79) shows a signal in the same region as those of other cyclic secondary amines products (δ 3.76—3.89). 2-(Methylamino)ethanol also reacts at the nitrogen atom to give *N*-methyl-*N*-[[5-(*p*-nitrophenyl)-2-oxazolyl]-methyl]-2-hydroxyethylamine (**4o**) in 95% yield.

Tertiary amines such as triethylamine, 1,4-dimethylpiperazine, and 1,4-diazabicyclo[2.2.2]octane (DABCO) gave the corresponding quaternary ammonium chlorides (**5**) in high yields (Table 3). The reaction with triethylamine was very slow at room temperature. Although 1,4-dimethylpiperazine and DABCO have two reaction sites in each molecule, they afforded a 1 : 1-adduct even when half equivalent amount of amine was used.

Experimental

Melting points were measured with Yanagimoto Melting Point Apparatus and described without correction. The IR spectra were recorded on Hitachi Perkin Elmer Infrared Spectrometer model 983 in KBr mull. The ^1H NMR spectra were recorded in $CDCl_3$ solution at 90 MHz on a Varian Spectrometer model EM390 using TMS as an internal standard.

Materials. α-Diazoacetophenones were synthesized by the reaction of the corresponding acid chlorides with excess of diazomethane in the presence of triethylamine according to Newman's method.[5] Methyl *p*-nitrophenyldiazoacetate was synthesized by the diazo group transfer reaction reported by Regitz.[6] Chloroacetonitrile and amines were purified by distillation just before use.

General Procedure of the BF_3-Catalyzed Reaction of Diazo Carbonyl Compounds with Chloroacetonitrile. Diazo carbonyl compound (**1**; 5 mmol) was added in small portions to 20 ml of chloroacetonitrile containing BF_3 etherate (1.0 ml) at −5 °C or 0 °C under magnetic stirring. The reaction proceeded with vigorous evolution of nitrogen gas and gave a gray precipitate. After the N_2 evolution ceased, the reaction mixture was cooled to −15 °C to complete the precipitate formation. The precipitate (BF_3 salt of **3**) was separated by filtration, and was neutralized with saturated aqueous solution of $NaHCO_3$. Free 2-(chloromethyl)oxazole (**3**)[7] was extracted with ether (50 ml) twice. The oxazoles (**3**) were obtained from ether layer, after drying over anhydrous Na_2SO_4, evaporation of solvent. Analitical data of **3** were shown in Table 4.

General Procedure of the Nucleophilic Substitution of 3 with Amines. A benzene or an ethanol solution (only for methylamine and ethylamine) of 2.0 mmol of 2-chloromethyloxazole (**3a**) was treated with 10 mmol of amine at room temperature or 40 °C. The end point of the reaction was determined by the disappearance of the spot of **3a** in TLC. In the case of primary and secondary amine, solvent and excess amine were evaporated, and the residue was purified by recrystallization from benzene-hexane. The reaction products of tertiary amines were separated by filtration from benzene solution, washed with benzene, and recrystallized from dichloromethane.

Reactivities of Stable Rotamers. XXVI. Some Bimolecular Elimination Reactions of 9-(2-Substituted 1-naphthyl)fluorene Rotamers[1]

Yoriko SONODA, Jiro TSUKAHARA, Nobuo NAKAMURA, and Michinori ŌKI*,†
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received August 15, 1988)

Synopsis. Various elimination reactions which are believed to proceed with E_2-type mechanisms have been examined on 9-[2-(1,2-dibromoethyl)-1-naphthyl]fluorene and 9-[2-(1-hydroxy-2-trimethylsilylethyl)-1-naphthyl]fluorene rotamers. Generally, the reaction of the *sp* rotamers was faster than that of the *ap* by a factor of 2—9. The results are attributed to the steric effects that are operative in the *ap* form.

In the course of comparative study of the reactivities of rotational isomers of 9-arylfluorene series (1), we have noticed that S_N2 type reactions that occur over the fluorene ring (namely in *ap*-**1**) is much slower than the same type of reactions that occur in the other rotamer (*sp*-**1**) which does not suffer from steric hindrance at the reaction site.[2] The same was true for chromium(VI) oxide oxidation of alcohols and an aldehyde[3] due to the fact that the rate-limiting step in these reactions is the formation of bulky transition states.[4] Summarizing these results, we have concluded that a reaction that occurs over the fluorene ring (*ap*) with the space-demanding transition state is much slower than the counterpart (*sp*) in which the formation of the same transition state is less energy-requiring.

In contrast to these findings, addition reactions to a carbon-to-carbon[5] and a carbon-to-oxygen[3] double bonds did not show large differences in reactivities of the rotamers and we have explained the results by assuming that the least space-demanding hydrogen atom in the formyl or the vinyl group directs toward the fluorene ring in the transition states of the reactions.[5]

The transition state of the E_2-type elimination is assumed to be synchronous elongation, with assistance of a nucleophile and an electrophile, of the two bonds which connect the leaving groups to the two carbon frame, as well as the shortening of the carbon-to-carbon bond.[6] Thus the E_2-type eliminations will be candidates of demonstrating of a larger differences in the reactivities of rotamers than a mere addition reaction, because either a nucleophile or an electrophile must approach the group to be eliminated which is located over the fluorene ring in the *ap*-isomer whereas the steric effect will be small in the *sp*-isomer. Thus we have explored some E_2-type elimination reactions of the rotamers of the 9-arylfluorene series and wish to report the results in this paper.

There are varieties of elimination reactions reported in a paper which gives rise to *cis*-stilbene from *dl*-1,2-dibromo-1,2-diphenylethane with high stereospecificity.[7] These reactions may be assumed to proceed with the E_2 reaction mechanisms. We have examined these reactions, namely debromination from *ap*- and *sp*-rotamers (**2**) of 9-[2-(1,2-dibromoethyl)-1-naphthyl]-fluorene and compared the relative rates, k_{sp}/k_{ap}, with that in the reaction of which mechanism is thought to be different. The results are given in Table 1.

Debromination of **2** with zinc dust[8] proceeded smoothly at room temperature but the selectivity was very low as was expected from the behavior in the elimination from *dl*-1,2-dibromo-1,2-diphenylethane. The reaction must proceed via electron transfer from the metal as was discussed in the literature and is different from the bimolecular elimination.[7] Although sodium iodide is often used for debromination from 1,2-dibromoethane derivatives,[9] the reaction did not occur for the compounds in question below 50 °C, the temperature which is low enough to assure nonexistence of internal rotation of the compound.

Among the reagents that eliminate bromine from the dibromide listed in the literature, lithium tetrahydridoaluminate is one of those which give the highest stereoselectivity in the reaction.[7] Indeed, this reagent gave the highest k_{sp}/k_{ap} values of the reagents examined here, as are shown in Table 1. Interestingly, the selectivity was insensitive to the temperature of the reaction.

† Present address: Department of Chemistry, Faculty of Science, Okayama University of Science, Ridaicho, Okayama 700.

Recently, Suzuki and Inouye described that sodium telluride gave the high stereospecificity in the elimination reactions of 1,2-dibromides.[10] Examination of this reagent with our rotamers revealed that, though the elimination in the *sp*-dibromo compound (**2**: X=Y=Br) was indeed faster than in the *ap*, the selectivity was not so high as that observed with the tetrahydridoaluminate reagent.

Another example of stereospecific elimination is Peterson reactions,[11] of which stereoselectivity was studied by Hudrlik and Peterson.[12] It is known that, if acid is used for the elimination from β-hydroxyalkylsilanes, the elimination takes place in the trans-fashion and, if the base is used, the reaction is cis-elimination. Since the compounds we examine, 9-arylfluorenes, carry acidic hydrogen at the 9-position, the strong base can cause isomerization.[2,3] We therefore concentrated our effort to the acidic trans-elimination, which should be compared with the debromination described in this paper. The results in Table **1** indicate that the Peterson reaction is modestly selective.

Summarizing the results, we notice that the steric effects in the *ap*-form of the 9-arylfluorene series are operative in various elimination reactions, relative to the *sp*-series. The results will mean that a nucleophile or an electrophile, which is larger than a hydrogen atom, must approach a leaving group at the α-position of the substituent of the naphthalene ring, which is over the fluorene ring, to make the reaction of the *ap*-form slower than that of the *sp*. The enhancement of the selectivity, though small, relative to the addition to the olefinic bond,[5] should be attributed to the fact that the nucleophile or the electrophile is larger than the hydrogen atom which is the main cause of steric interaction with the fluorene moiety in the case of addition reactions in the olefin and the aldehyde. Yet, the selectivity in the elimination reactions studied here is inferior to that of the S_N2 type reactions. We believe this is due to the fact that, while in the S_N2 reactions two bulky groups, a leaving group and a incoming group, approach the α-position of the substituent over the fluorene ring in the *ap* form, there is only one bulky group, the nucleophile or the electrophile, approaching the α-position of the substituent over the fluorene ring in the case of E_2-type reactions. Thus the steric effects in the E_2-reactions are less demanding than the S_N2 reactions.

Experimental

9-[2-(1,2-Dibromoethyl)-1-naphthyl]fluorene rotamers (**2**: X=Y=Br) were prepared according to the method described in the literature.[5]

9-[2-(1-Hydroxy-2-trimethylsilylethyl)-1-naphthyl]fluorene (2: X=OH, Y=Si(CH$_3$)$_3$). To a solution of 100.0 mg (0.313 mmol) of *ap*-9-(2-formyl-1-naphthyl)fluorene[3] in 10.0 mL of ether, was added 0.34 mL (0.34 mmol) of 1.0 mol L^{-1} solution of trimethylsilylmagnesium chloride in ether which was available from Aldrich Chemical Co. under a nitrogen atmosphere at once. The mixture was stirred for 80 min with vigorous refluxing and then decomposed with aqueous ammomium chloride. The ether layer was washed with aqueous sodium hydrogencarbonate and dried over magnesium sulfate. After evaporation of the solvent, the product was purified by preparative TLC on silica gel with a 5:7 hexane-dichloromethane eluent and then recrystallized from hexane to give the *ap* form of the desired product in 74% yield. The amount of the magnesium compound was crucial in obtaining the product in a good yield because the excess caused contamination with unidentified materials and the less caused recovery of the unreacted aldehyde. It was recrystallized from acetonitrile, mp 120.0—121.0 °C. Found: C, 81.87; H, 6.94%. Calcd for $C_{28}H_{28}OSi$: C, 82.30; H, 6.91%. ^{1}H NMR ($CDCl_3$) δ=−0.40 (9H, s), −0.05 (1H, app d, *J*=14.7 Hz), 0.76—0.91 (2H, m), 3.80 (1H, app d, *J*=11.5 Hz), 6.13 (1H, s), 7.14—7.95 (13H, m), 8.49—8.53 (1H, m).

The *sp*-form, mp 110.0—111.0 °C, was obtained much more easily than the *ap*-form: the usage of 1.0 mol of trimethylsilylmethylmsgnesium chloride per 1 mol of the aldehyde sufficed to give 93% yield of the product. It was recrystallized from methanol. Found: C, 82.29; H, 6.85%. Calcd for $C_{28}H_{28}OSi$: C, 82.30; H, 6.91%. ^{1}H NMR ($CDCl_3$) δ=0.08 (9H, s), 1.40—1.60 (2H, m), 1.97 (1H, br d, *J*=2.9 Hz), 5.70—5.80 (1H, m), 5.97 (1H, s), 6.38—8.00 (14H, m).

Elimination Reactions. Elimination reactions of **2** were carried out under the same conditions described for the competitive reactions below except that a single rotational isomer was submitted to the reaction conditions. It was confirmed that *ap*- or *sp*-9-(2-vinyl-1-naphthyl)fluorene (**3**)[5] was the exclusive product, the yield being over 95% in every case.

Competitive Debrominations. a) Debromination with Zinc. To a solution of 10.0 mg each of *sp*- and *ap*-**2** (X=Y=Br) in 30 mL of ether were added 3.0 mL of acetic acid and 30 mg of zinc dust and the whole was stirred for ca. 10 min at room temperature. The solid material was removed by filtration and the filtrate was washed with water and then with aqueous sodium hydrogencarbonate. After drying over magnesium sulfate, the solvent was evaporated and the residue was submitted to analysis.

b) Debromination with Lithium Tetrahydridoaluminate. To a solution of 10.0 mg each of *sp*- and *ap*-**2** (X=Y=Br) in 50 mL of tetrahydrofuran was added the specified amount of lithium tetrahydridoaluminate and the mixture was allowed to react for the time interval shown below. The reaction was quenched by cooling the mixture at −78 °C, water was added to the mixture at this temperature, and the temperature was allowed to rise to 0 °C. It was confirmed that the reaction was negligibly slow at −78 °C. Then dilute hydrochloric acid was added to the mixture which was extracted with ether. The ether extract was treated as above. The reaction temperature, the amount of the lithium tetrahydridoaluminate used, and the reaction period are given below.

Temperature/°C	Amount of $LiAlH_4$/mg	Period/min
ca. −15	30	30
0	25	30
40	20	4

c) Debromination with Telluride. A sodium telluride solution was prepared in the following way.[9,13] Tellurium (18 mg or 0.14 mmol) and 240 mg (1.56 mmol) of sodium hydroxymethanesulfinate dihydrate were added to 2 mL of 1 mol L^{-1} aqueous sodium hydroxide and 5 mL of dioxane and the mixture was stirred for ca. 10 min at 70 °C to give a dark red to purple solution. To this solution was added a solution of 10.0 mg each of *ap*- and *sp*-**2** (X=Y=Br) in 3.0 mL of dioxane and the mixture was stirred for 5—6 min at room temperature under a nitrogen atmosphere. The reaction was quenched by introducing air or adding water and ether to the reaction mixture. The formed tellurium was removed by decantation and the product was extracted with ether. The product was treated similarly as above.

Since debromination from 1,2-dibromoethane derivatives with a sulfinate was reported,[14] the dibromide was treated

with a sodium hydroxymethanesulfinate solution under the same conditions. However, no sign of formation of the olefin was detected.

Competitive Peterson Reaction. To a solution of 10.0 mg each of *sp*- and *ap*-rotamer of **2** (X=OH, Y=$Si(CH_3)_3$) in 30 mL of tetrahydrofuran was added 4 drops of concentrated sulfuric acid and the mixture was stirred for 15 min at 15 °C or for 30 min at 0 °C. The reaction was quenched by adding aqueous sodium hydrogencarbonate. The treatment of the mixture hereafter was the same with that described above.

Acquisition and Treatment of Data in Competitive Reactions. The reactions were quenched at less than 50% completion of the reaction, if both the isomers were counted, and the unreacted compounds were analyzed by ^1H NMR with the use of a JEOL GX270 NMR spectrometer. The relative rates (k_{rel}) were obtained by the following equation. The results shown in Table 1 are the averages of two to three runs.

$$k_{rel} = \frac{k_{ap}}{k_{sp}} = \frac{[\ln(a_0 - a)/a_0]_{sp}}{[\ln(a_0 - a)/a_0]_{ap}}$$

A Total Synthesis of (−)-Sacculatal

Hisahiro HAGIWARA* and Hisashi UDA
Chemical Research Institute of Non-aqueous Solutions, Tohoku University, Katahira, Sendai 980
(Received August 20, 1987)

Synopsis. The total synthesis of a tumor promoter, (−)-sacculatal (**1**), has been completed.

According to the recent study in chemical carcinogenesis, there are two successive stages, initiation and promotion, that are induced by chemical substances, initiater and promoter, respectively. Among them, control of the latter stage is much more important to prevent cancer because of its reversibility. (−)-Sacculatal (**1**), a diterpene dialdehyde isolated from the liverworts *Trichocoleopsis sacculata* and *Pellia endiviifolia* by Asakawa and his co-workers, was at first known as a constituent of pungent taste of liverworts.[1a] Later on, in connection with skin irritant property of these plants, (−)-sacculatal (**1**) was found to have tumor promoting activity by testing ornithine decarboxylase (ODC) activity, which was estimated as 1/100 active as 12-*O*-tetradecanoylphorbol 13-acetate.[1b] As a part of our program directed toward total syntheses of biologically active sacculatane type natural products,[3] we disclose herein our synthesis of natural (−)-sacculatal (**1**) starting from (4a*S*,5*S*,8a*S*)-(−)-5β,8aβ-dimethyl-5α-(4-methyl-3-pentenyl)-3,4,4a,-5,6,7,8,8a-octahydro-1(2*H*)-naphthalenone (**3**), an advanced common intermediate for sacculatane synthesis.[3b]

Results and Discussion

The (−)-ketone **3** {[α]$_D$ −8.2° (*c* 3.0 in MeOH); 80% enantiomeric excess} was formylated with ethyl formate in the presence of sodium hydride in benzene to give the keto aldehyde **4**, which was oxidized with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) in dioxane to introduce an unsaturation furnishing the enone **5**. The formyl carbonyl group was selectively protected as an ethylene acetal to afford the acetal **6**. Although two intermediary aldehydes, **4** and **5**, were used without purification because of their instability, the overall yield of **6** from the ketone **3** was 69%. Finally, a protocol of Magnus[4] was employed in order to introduce a formyl group at the electronically less reactive and sterically congested C-1 position. Addition of methoxy(trimethylsilyl)methyllithium afforded in almost quantitatively the fragile single adduct **7** whose stereochemistry has not yet been determined. After extensive efforts to eliminate trimethylsilanol,

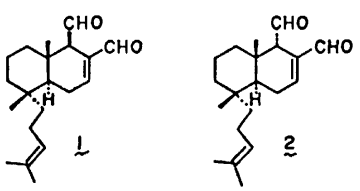

Fig. 1.

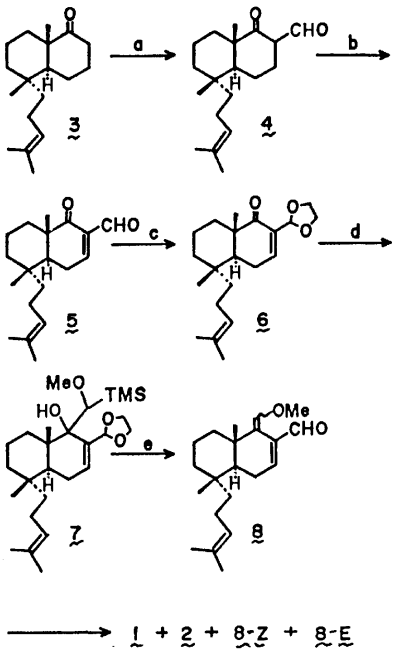

Scheme 1. Total synthesis of (−)-sacculatal (**1**). (a): HCO_2Et, NaH, benzene, (b): DDQ, dioxane, (c): Ethylene glycol, cat. *p*-TsOH, benzene, (d): $TMSCH_2OMe$, *s*-BuLi, THF, (e): Et_2O saturated with 46% aqueous HF.

treatment of the adduct **7** in ether saturated with 46% hydrogen fluoride[5] underwent facile deprotection of acetal and subsequent elimination of trimethylsilanol followed by slow hydrolysis of the resulting enol ethers **8** to afford (−)-sacculatal (**1**) (26%), isosacculatal (**2**) (16%), and the precursory enol ethers **8-Z** and **8-E** (20%). Attempts to eliminate trimethylsilanol with KH simply gave decomposition products. Isomerization of sacculatal (**1**) to isosacculatal (**2**) was unavoidable because of A$^{(1,2)}$ strain of formyl group at C-1β in addition to peri repulsion between proton at C-8β. The product which exhibited a singlet proton at δ 7.36 in ^{1}H NMR spectrum was assigned to be the (*E*)-enol ether **8-E**. The spectral data of synthetic (−)-sacculatal (**1**) (^{1}H NMR and IR), as well as the optical rotation and mp values {[α]$_D$ −30° (*c* 0.48, $CHCl_3$) (lit,[1a] [α]$_D$ −31.4° (*c* 3.5, $CHCl_3$)}; mp 65—66 °C (lit,[1a] mp 65—66 °C)], are identical with those of the natural sample.

In summary, we have completed the total synthesis of a tumor promoter, (−)-sacculatal (**1**).

Experimental

General. Melting point is uncorrected. Anhydrous solvents were distilled from sodium (benzene) or lithium aluminum hydride (tetrahydrofuran). All infrared spectra were obtained with a JASCO A-3 spectrophotometer for solutions

in carbon tetrachloride. ^{1}H NMR spectra were recorded with a JEOL PMX-60 SI (60 MHz) or FX-90Q (90 MHz) instrument. Chemical shifts were reported δ values relative to tetramethylsilane. Mass spectra were obtained with a JEOL JMS DX-300 mass spectrometer at 70 eV and relative intensities were reported. Optical rotations were recorded on a JASCO DIP-4S polarimeter for solutions in chloroform unless otherwise specified. Preparative medium-pressure liquid chromatographies (MPLC) were carried out on a JASCO PRC-50 system.

(4a*S*,5*S*,8a*S*)-(+)-5β,8aβ-Dimethyl-2-formyl-5α-(4-methyl-3-pentenyl)-3,4,4aα,5,6,7,8,8a-octahydro-1(2*H*)-naphthalenone (4). To a stirred slurry of sodium hydride (60%, 54 mg, 1.35 mmol) in anhydrous benzene (1 mL) were added a solution of the ketone **3** (51.8 mg, 0.198 mmol) in benzene (2 mL) and then ethyl formate (80 μL, 0.99 mmol). After stirring at room temperature for overnight under nitrogen, the resulting solution was poured into dil. HCl, and extracted with ether (30 mL×2). The combined extracts were washed with water and brine and dried. Evaporation of the solvents afforded the keto aldehyde **4** (67.4 mg), which was used soon for the next reaction without purification. The sample purified by MPLC exhibited $[\alpha]_D$ +22.3° (*c* 0.546, methanol); IR ν 1700, 1640, 1590, 1455 cm^{-1}; ^{1}H NMR (60 MHz) δ=0.88 (s, 3H), 1.23 (s, 3H), 1.6 (s, 3H), 1.7 (s, 3H), 1.0—2.5 (m, 16H), 5.09 (br t, 1H), 8.43 (d, *J*=4 Hz, 1H); MS *m/z* 290 (M^+, 9), 138 (19), 58 (41), 43 (100); Calcd for $C_{19}H_{30}O_2$: M, 290.22449. Found: *m/z* 290.22419.

(4a*S*,5*S*,8a*S*)-(+)-5β,8aβ-Dimethyl-2-formyl-5α-(4-methyl-3-pentenyl)-4a,5,6,7,8,8a-hexahydro-1(4*H*)-naphthalenone (5). To a solution of the crude keto aldehyde **4** (67.4 mg) in dioxane (3 mL) was added DDQ (freshly recrystallized from dichloromethane, 134 mg, 0.59 mmol) in one portion. The resulting solution was stirred for 1 h, and extracted with ether (30 mL×2). The combined organic layer was washed with water and brine. After evaporation of the solvents, the residue was passed through silica-gel short column with the aid of hexane/ethyl acetate. Evaporation of the solvents gave the enone **5** (162 mg), which was used without purification for the next reaction. The pure enone **5** after MPLC purification exhibited $[\alpha]_D$ +75.5° (*c* 0.249); IR ν 1705, 1680, 1620, 1450, 1380 cm^{-1}; ^{1}H NMR (90 MHz) δ=1.02 (s, 3H), 1.12 (s, 3H), 1.57 (s, 3H), 1.68 (s, 3H), 1.0—2.5 (m, 13H), 5.0 (br t, 1H), 7.92 (m, 1H), 10.0 (s, 1H); MS *m/z* 288 (M^+, 12), 273 (29), 245 (31), 189 (17), 175 (18), 162 (19), 150 (23), 137 (22), 109 (37), 69 (52), 58 (74), 43 (100); Calcd for $C_{19}H_{28}O_2$: M, 288.20891. Found: *m/z* 288.20891.

(4a*S*,5*S*,8a*S*)-(−)-5β,8aβ-Dimethyl-2-(1,3-dioxolan-2-yl)-5α-(4-methyl-3-pentenyl)-4aα,5,6,7,8,8a-hexahydro-1(4*H*)-naphthalenone (6). A solution of the crude enone **5** (162 mg) in anhydrous benzene (5 mL) in the presence of ethylene glycol (0.3 mL) and a catalytic amount of *p*-toluenesulfonic acid was refluxed for 30 min using a Dean-Stark water separator. After cooling to room temperature, the resulting solution was poured into aqueous $NaHCO_3$, and the product was extracted with ether (30 mL×2). Evaporation of the solvent followed by MPLC separation (silica gel, 4:1 hexane/ethyl acetate) afforded the enone acetal **6** (45 mg, 69% in overall 3 steps), which exhibited $[\alpha]_D$ −4.76° (*c* 0.315); IR ν 1680, 1620 cm^{-1}; ^{1}H NMR (60 MHz) δ=1.0 (s, 3H), 1.1 (s, 3H), 1.6 (s, 3H), 1.68 (s, 3H), 1.0—2.5 (m, 13H), 3.98 (br s, 4H), 5.02 (br t, 1H), 5.57 (s, 1H), 7.1 (t, *J*=4 Hz, 1H); MS *m/z* 332 (M^+, 64), 317 (56), 243 (33), 203 (30), 180 (37), 154 (37), 109 (68), 73 (100), 69 (70), 55 (34), 45 (45), 41 (66); Calcd for $C_{21}H_{32}O_3$: M, 332.23502. Found: *m/z* 332.23442.

(4a*S*,5*S*,8a*S*)-5β,8aβ-Dimethyl-2-(1,3-dioxolan-2-yl)-1-[methoxy(trimethylsilyl)methyl]-1,4,4aα,5,6,7,8,8a-octahydro-1-naphthalenol (7). To a stirred solution of methoxytrimethylsilylmethane (106 μL, 0.68 mmol) in anhydrous THF (1 mL) was added a hexane solution of *s*-BuLi (1.02 M†, 0.66 mL, 0.67 mmol) at −65 °C under nitrogen. After stirring for 30 min at −30 to −25 °C, a solution of the enone acetal **6** (45 mg, 0.136 mmol) in anhydrous THF (4 mL) was added. The resulting solution was stirred at −25 to 0 °C for 30 min and then at 0 °C for further 30 min. The reaction was quenched by addition of aqueous NH_4Cl and the product was extracted with ether (30 mL×2). Evaporation of the solvent left the trimethylsilyl alcohol **7**, an oil (77 mg), which was used without purification. IR ν 3500, 1385, 1250 cm^{-1}; ^{1}H NMR (60 MHz) δ=0.12 (s, 9H), 0.92 (s, 6H), 1.6 (s, 3H), 1.68 (s, 3H), 1.0—2.5 (m, 14H), 3.35 (s, 3H), 3.4 (s, 1H), 3.95 (m, 4H), 5.05 (br t, 1H), 5.37 (s, 1H), 6.67 (t, *J*=3 Hz, 1H).

(1*R*,4a*S*,5*S*,8a*R*)-(−)-5β,8aβ-Dimethyl-1β,2-diformyl-5α-(4-methyl-3-pentenyl)-1,4,4aα,5,6,7,8,8a-octahydronaphthalene [(−)-Sacculatal] (1), (1*S*,4a*S*,5*S*,8a*S*)-5β,8aβ-Dimethyl-1α,2-diformyl-5α-(4-methyl-3-pentenyl)-1,4,4aα,5,6,7,8,8a-octahydronaphthalene (Isosacculatal) (2), (4a*S*,5*S*,8a*S*)-5β,8aβ-Dimethyl-2-formyl-1*Z*-methoxymethylene-5α-(4-methyl-3-pentenyl)-1,4,4aα,5,6,7,8,8a-octahydronaphthalene (8-Z), and (4a*S*,5*S*,8a*S*)-5β,8aβ-Dimethyl-2-formyl-1*E*-methoxymethylene-5α-(4-methyl-3-pentenyl)-1,4,4aα,5,6,7,8,8a-octahydronaphthalene (8-E). A solution of the crude trimethylsilyl alcohol **7** (77 mg) in ether saturated with 46% aqueous hydrogen fluoride (5 mL) was stirred at room temperature for 6 h. The resulting solution was poured into cold aqueous $NaHCO_3$ and extracted with ether (30 mL×2). Evaporation of the solvent followed by MPLC separation of the residue (silica gel, 1:4 hexane/ethyl acetate) afforded (−)-sacculatal (**1**) (2.7 mg, 26.3%), isosacculatal (**2**) (1.6 mg, 15.6%) and a mixture of the enol ethers (**8-Z**) and (**8-E**) (2.1 mg, 19.6%) which were separated by repeated MPLC. (−)-Sacculatal (**1**) which crystallized spontaneously at −20 °C, exhibited mp 65—66 °C (lit,[1] mp 65—66 °C); $[\alpha]_D$ −30.1° (*c* 0.478) (lit,[1] −31.4°, *c* 3.5); IR ν 2700, 1725, 1685, 1640, 1385, 1240 cm^{-1}; ^{1}H NMR (90 MHz) δ=0.96 (s, 3H), 0.98 (s, 3H), 1.59 (s, 3H) 1.67 (s, 3H), 2.41 (m, 2H), 2.84 (br s, 1H), 1.0—2.0 (m, 11H), 5.05 (t, *J*=5 Hz, 1H), 7.11 (m, 1H), 9.46 (s, 1H), 9.49 (d, *J*=4.4 Hz, 1H); MS *m/z* 302 (M^+, 3), 274 (50), 259 (91), 231 (49), 121 (53), 91 (47), 69 (100), 55 (55), 41 (99); Calcd for $C_{20}H_{30}O_2$: M, 302.22453. Found: *m/z* 302.22263. Isosacculatal (**2**) exhibited IR ν 2700, 1685, 1650, 1450, 1380 cm^{-1}; ^{1}H NMR (90 MHz) δ=0.93 (s, 3H), 0.99 (s, 3H), 1.59 (s, 3H), 1.67 (s, 3H), 1.0—2.5 (m, 13H), 3.28 (br s, 1H), 5.04 (br t, 1H), 7.1 (m, 1H), 9.41 (s, 1H), 9.85 (d, *J*=2.6 Hz, 1H); MS *m/z* 302 (M^+, 18), 259 (34), 201 (38), 105 (47), 74 (64), 69 (70), 59 (100), 55 (51), 45 (58), 43 (54), 41 (94); Calcd for $C_{20}H_{30}O_2$: M, 302.22463. A Facile Reductive Removal of Bromine Atom(s) of 6,6-Dibromo- and 6-Bromopenicillanate Derivatives in a Pb/Al Bimetal System

Hideo TANAKA, Motoaki TANAKA, Akira NAKAI, Yasumi KATAYAMA, and Sigeru TORII*
Department of Applied Chemistry, Faculty of Engineering, Okayama University, Tushima-naka, Okayama 700
(Received September 1, 1988)

Synopsis. Reductive removal of the bromine atom(s) of 6,6-dibromo- and 6-bromopenicillanate 1-oxides has been performed successfully on treatment with aluminum metal in the presence of a catalytic amount of lead(II) bromide in methanol containing 1% aqueous hydrobromic acid. In a similar manner, 6,6-dibromopenicillanates and their 1,1-dioxides can be converted to the corresponding debromination products, respectively.

Since the discovery of the β-lactamase inhibitory properties of penicillanic acid 1,1-dioxide (sulbactam) **1a**,[1] its homologues, bearing the proper substituents at the β-C(2)-methyl group, have received much attention as potential β-lactamase inhibitors. Namely, the chloro, triazolyl, and tetrazolylthio substituted derivatives **1b** (BRL-2013),[2] **1c** (YTR-830),[3] and **1d**[4] have been proven to exhibit potent β-lactamase inhibitory activities. The syntheses of the penicillanic acid 1,1-dioxides **1** have been performed by the transformation of commercially accessible 6-aminopenicillanic acid (**2**). An inevitable task in the transformation (**2**→**1**) is the removal of the C(6)-amino moiety of **2**. The procedures available for this purpose have generally relied on the catalytic hydrogenation of 6-bromo- or 6,6-dibromopenicillanic acid derivatives **3**—**6**,[1c,5,6] derived from 6-aminopenicillanic acid **2**. Reductive debromination reactions with tributyltin hydride[7] or zinc[8] have also been utilized. However, most of these procedures suffer from one or more drawbacks: unsatisfactory yields of the hydrogenation products **7**—**10**, instability of protecting groups of C(3)-carboxylic acid (e.g., benzhydryl and allyl) under hydrogenolysis conditions and difficulty in removing the metal complexes generated in the zinc and tributyltin hydride reductions. Consequently, continuing efforts have been made to look for a new method for the reductive removal of the C(6)-bromine atom(s).

We have recently developed a new Pb/Al bimetal system, involving aluminum and a catalytic amount of lead salts, which acts as a powerful reductant for various synthetic purposes.[9] A new application of the Pb/Al bimetal system for the reductive debromination of the 6-bromo- and 6,6-dibromopenicillanates **3**—**6**, providing a simple and efficient route to the corresponding hydrogenation products **7**—**10**, respectively (Scheme 1), is described herein.

Reduction of 6,6-dibromopenicillanate 1-oxide **3a** (X^1=X^2=Br, Y=H, R=PMB) with aluminum and a catalytic amount of lead(II) bromide (0.1 equiv) was carried out at 30 °C in various media. Some of the examples are shown in Table 1. In aqueous media (Entries 3 and 4), the reduction of **3a** was completed in 1—2 h to afford 60—86% yields of the hydrogenation product **7a**, while in nonaqueous media, e.g., methanol and acetone, (Entries 1 and 2), only less than 24% yield of **7a** was obtained. Notably, addition of a small amount of 1% hydrobromic acid facilitates the hydrogenation of **3a**, affording up to 92% yield of **7a** (Entries 5—7). The reduction (**3a**—**7a**) can similarly be performed in a mixed solvent, e.g., MeOH/THF/aq HBr and MeOH/CH_2Cl_2/aq HBr (Entries 8 and 9).

9	MeOH/THF/aq 1% HBr(9/5/1)	3	87

a) Carried out with $PbBr_2$ (0.1 equiv) and Al(2.2 equiv) at 30°C. b) Isolated Yield. c) Recovered **3a**.

The presence of lead(II) bromide is essential for this purpose, since, in the absence of lead(II) bromide, most of the starting material **3a** is recovered intact (Table 2, Entry 2). This fact can be well understood by assuming that lead(0) generated by two-electron reduction of lead(II) on the aluminum surface[9] acts as a reductant in the reductive removal of the bromine atoms and thus generated lead(II) is again submitted to reduction with aluminum (Scheme 1). Satisfactory results were also obtained by use of lead(II) chloride or lead powder in combination with aluminum (Entries 3 and 4), while bismuth(III) chloride is less effective (Entry 5) and tin(II) bromide, titanium(IV) chloride, manganese(III) chloride, and chromium(III) chloride are not effective at all (Entries 6—9).

The Pb/Al bimetal system was successfully applied to the reduction of various halopenicillanate derivatives **3—6**. The conditions and results are summarized in Table 3. The reductive removal of bromine atoms of 6,6-dibromopenicillanate 1α-oxides **3** was performed in a methanolic mixed-solvent containing aqueous 1% hydrobromic acid to afford the penicillanate 1α-oxides **7** in 77—93% yields (Entries 1—3). Similarly, 6α-bromopenicillanate 1β-oxides **4**, 6,6-dibromopenicillanate **5**, and 6,6-dibromopenicillanate 1,1-dioxides **6** underwent the reductive debromination affording the hydrogenation products **8**, **9**, and **10**, respectively (Entries 4, 5, 7—12), in which, the substituents on the 2β-methyl group, e.g., chlorine and 1,2,3-triazolyl moiety, were retained intact. However, 6α-chloropenicillanate 1-oxide (**4c**) gave no appreciable amount of hydrogenation product **8c** (Entry 6).

The proper choice of the solvent for each compound **4—6** is significant. For example, when 6,6-dibromopenicillanate (**5a**) was treated with the aluminum and lead(II) bromide combination in methanol and aqueous 1% hydrobromic acid (9/1), the reaction was quite slow and, even after 15 h, afforded only 52% yield of penicillanate **9a** along with monobromo derivatives **5** (X^1=H; X^2=Br; and X^1=Br; X^2=H, 24%) (Entry 8). In contrast, when a small amount of acetone was added to this medium, the reaction was significantly accelerated and completed in 5 h to give **9** in 72% (Entry 7).

Another interesting observation is that the *p*-methoxybenzyl (PMB), benzhydryl, methyl, and allyl esters of 6-bromo- and 6,6-dibromopenicillanates **3—6** are successfully reduced to the corresponding penicillanates **7—10** without affecting the ester moieties, while the *p*-nitrobenzyl ester **6e** is completely resistant to the reductive debromination (Entry 13). The latter failure is probably ascribable to the fact that the nitrobenzyl moiety is susceptible to reduction to form a stable anion radical.[8b,c]

Table 2. Reduction of 6,6-Dibromopenicillanate 1α-Oxide **3a** with MX_n/Al[a]

Entry	Mx_n	Time	Yield/%[b]

silane as an internal standard. Mass spectra were obtained on a JEOL JMS-DX303 spectrometer. Microanalyses were performed in our laboratory. 6-Bromo- and 6,6-dibromopenicillanates **3—6** were prepared from 6-aminopenicillanic acid **2** according to the procedures reported in the literatures.[1c,2,5,9]

Reductive Removal of Bromine Atom(s) of 6,6-Dibromo- and 6-Bromopenicillanates with $PbBr_2$-Al: To a stirred mixture of *p*-methoxybenzyl 6,6-dibromopenicillanate 1α-oxide **3a** (2 mmol), $PbBr_2$ (0.2 mmol) and finely cut aluminum foil (4.4 mmol) in methanol (4 ml) and dichloromethane (5 ml) was added aqueous 1% hydrobromic acid (1 ml). The stirring was continued at 30 °C until most of **3a** was consumed (3 h). The reaction mixture was diluted with EtOAc, washed with aqueous 5% hydrochloric acid followed by brine, dried, and concentrated to give penicillanate 1α-oxide **7a** (95%) as a light yellow foam. The analytical sample was obtained by a short silica-gel column with benzene-EtOAc (5 : 1) as an eluant: mp 103—103.5 °C; IR ($CHCl_3$) 1780 and 1745 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.25 (s, 3H, CH_3), 1.53 (s, 3H, CH_3), 3.10—3.70 (m, 2H, 6-H), 3.82 (s, 3H, OCH_3), 4.38 (s, 1H, 3-H), 4.50—4.65 (m, 1H, 5-H), 5.17 (s, 2H, OCH_2), 6.88 (d, J=9 Hz, 2H, aromatic H), and 7.33 (d, J=9 Hz, 2H, aromatic H); Found: C, 56.83; H, 5.70; N, 4.11%. Calcd for $C_{16}H_{19}NO_5S$: C, 56.96; H, 5.68; N, 4.15%.

In a similar manner, the following compounds were obtained.

Benzhydryl Penicillanate 1α-Oxide (7b): IR ($CHCl_3$) 1785 and 1745 cm^{-1}; ^1H NMR δ=1.09 (s, 3H, CH_3), 1.53 (s, 3H, CH_3), 3.27, 3.51 (AB-X, J_{AB}=14, J_{AX}= 2, J_{BX}=4 Hz, 2H, 6-H), 4.40 (s, 1H, 3-H), 4.48 (dd, J=2, 4 Hz, 1H, 5-H), 6.82 (s, 1H, $CHPh_2$), and 7.22 (s, 10H, aromatic H); HRMS, Found: m/z 406.1107. Calcd for $C_{21}H_{21}NO_4SNa$: M+Na, 406.1089.

Methyl Penicillanate 1α-Oxide (7c):[8b] IR (neat) 1770 and 1745 cm^{-1}; ^1H NMR δ=1.34 (s, 3H, CH_3), 1.58 (s, 3H, CH_3), 3.34, 3.58 (AB-X, J_{AB}=14, J_{AX}=2, J_{BX}=4 Hz, 2H, 6-H), 3.77 (s, 3H, CH_3), 4.36 (s, 1H, 3-H), and 5.07 (dd, J=2, 4 Hz, 5-H).

***p*-Methoxybenzyl Penicillanate 1β-Oxide (8a):** Mp 144—145 °C; IR ($CHCl_3$) 1780, 1735 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.07 (s, 3H, CH_3), 1.62 (s, 3H, CH_3), 3.30 (d, J=4 Hz, 2H, 6-H), 3.80 (s, 3H, OCH_3), 4.49 (s, 1H, 3-H), 4.89 (t, J=4 Hz, 1H, 5-H), 5.06, 5.21 (AB-q, J=11 Hz, 2H, OCH_2), 6.84 (d, J=8 Hz, 2H, aromatic H), and 7.27 (d, J=8 Hz, aromatic H); Found: C, 56.71; H, 5.76; N, 4.15%. Calcd for $C_{16}H_{19}NO_5S$: C, 56.96; H, 5.68; N, 4.04%.

Benzhydryl Penicillanate 1β-Oxide (8b): Mp 150—151.5 °C (lit,[8a] mp 145—148 °C); IR ($CHCl_3$) 1780 and 1740 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.94 (s, 3H, CH_3), 1.66 (s, 3H, CH_3), 3.30 (d, J=3 Hz, 2H, 6-H), 4.59 (s, 1H, 3-H), 4.86 (t, J=3 Hz, 1H, 5-H), 6.92 (s, 1H, $CHPh_2$), and 7.29 (s, 10H, aromatic H).

***p*-Methoxybenzyl Penicillanate (9a):** IR ($CHCl_3$) 1765 and 1740 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.36 (s, 3H, CH_3), 1.61 (s, 3H, CH_3), 3.04, 3.54 (AB-X, J_{AB}=14, J_{AX}=2, J_{BX}=4 Hz, 2H, 6-H), 3.80 (s, 3H, OCH_3), 4.46 (s, 1H, 3-H), 5.12 (s, 2H, OCH_2), 5.27 (dd, J=2, 4 Hz, 1H, 5-H), 6.94 (d, J=8 Hz, 2H, aromatic H), and 7.30 (d, 2H, J=8 Hz, aromatic H); HRMS, Found: m/z 344.0851. Catalytic Hydrogenation and Cracking of Anthracene over $MoCl_3$-LiCl-KCl and $NiCl_2$-LiCl-KCl Salts

Chunshan SONG, Tomohiro ONO, and Masakatsu NOMURA*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamada-oka 2-1, Suita, Osaka 565
(Received August 13, 1988)

Synopsis. The $MoCl_3$- and $NiCl_2$-LiCl-KCl salts, which are effective coal liquefaction catalysts, promoted the hydrogenation of anthracene (at 400 °C for 1 h with 9.8 MPa H_2) and afforded tetrahydro- and octahydro- as well as dihydroanthracene as major products. However, these catalysts did not remarkably enhance the ring-opening cracking reactions. A comparative examination suggested that the addition of LiCl-KCl to $MoCl_3$ and $NiCl_2$ suppressed their cracking ability and improved their hydrogenation selectivity.

Because of the complexity of coal structures and catalytic coal liquefaction reaction systems, hydrogenation and cracking reactions of polycyclic aromatic compounds have been taken as model test reactions for clarifying the effects of various catalysts for coal hydroliquefaction and upgrading of coal-derived products.[1-4] Recently, $MoCl_3$-LiCl-KCl and $NiCl_2$-LiCl-KCl salts have been found to be effective catalysts for the hydroliquefaction of brown, subbituminous and bituminous coals.[5,6] The most interesting features of these new catalysts are that they significantly promote oil production but do not remarkably enhance gas formation. This work was undertaken in order to develop a better understanding of their catalytic effects in promoting the hydrogenation and cracking of polycyclic aromatics.

Experimental

The synthesized and purified $MoCl_3$[5] and reagent grade $NiCl_2$, LiCl, and KCl were used in preparing $MoCl_3$-LiCl-KCl (molar composition, 12:51:37) and $NiCl_2$-LiCl-KCl (14:50:36) ternary salts and LiCl-KCl (58:42) binary salt.[5,6] The amounts of the salt catalysts used in the reactions, MCl_n-LiCl-KCl and MCl_n (MCl_n=$MoCl_3$, $NiCl_2$), were maintained at MCl_n/anthracene (3 g, 16.85 mmol)=0.3 (molar ratio). Hydrogenation was carried out in a 60-ml SUS-316 rocking autoclave at 400 °C for 1 h with an initial H_2 pressure of 9.8 MPa. The gaseous products were analyzed by GC. The liquid and solid products were analyzed quantitatively by GLC (Shimadzu GC-4C), with the aid of GC-MS (Hitachi RMU-6MG) analyses for product identification. The experimental and analytical procedures used in this work are similar to those described elsewhere.[2]

Results and Discussion

Hydrogenation and cracking of anthracene at 400 °C for 1 h produced various hydrocarbons. These prod-

a, b) Molar contents of $MoCl_3$ (a) and $NiCl_2$ (b) are 12% and 14%, respectively. c) R, R_1 and R_2 mean alkyl groups or hydrogen. d) *unsym*-Octahydroanthracene. e) *sym*-Octahydroanthracene. f) *sym*-Octahydrophenanthrene.

ucts were grouped into 1) C_1—C_4 gases; 2) C_5—C_9 paraffins and cycloparaffins; 3) alkylbenzenes; 4) alkyltetralins and indans; 5) alkylnaphthalenes; 6) *unsym*-octahydro-, 7) *sym*-octahydro-, 8) tetrahydro-, and 9) dihydroanthracene; 10) anthracene; 11) isomerized tricyclic hydroaromatics (*sym*-octahydrophenanthrene). The results are given in Table 1. Among the 3-ring aromatics, anthracene is known to show a relatively high reactivity.[2,3] About 86% of anthracene was converted, even in a noncatalytic run. The run with LiCl-KCl (Run 2) alone, gave very similar results to those of a noncatalytic run. However, the major product in these runs was dihydroanthracene. The use of $MoCl_3$-LiCl-KCl (Run 3) and $NiCl_2$-LiCl-KCl (Run 4) considerably promoted the hydrogenation of anthracene and/or dihydroanthracene and increased the yield of tetrahydroanthracene. Moreover, the formation of *sym*- and *unsym*-octahydroanthracene was also enhanced by these catalysts; the yields of these products were somewhat higher with $MoCl_3$-LiCl-KCl (Run 3) than those with $NiCl_2$-LiCl-KCl (Run 4). The appearance of small amounts of bicyclic and monocyclic products in these runs (Runs 3, 4) indicates that ring-opening cracking reactions occurred, but only to a very limited degree, as can be seen from Table 1.

To examine the influence of the content of $MoCl_3$ and $NiCl_2$, runs with an increased content of MCl_n (25 mol%) in MCl_n-LiCl-KCl (MCl_n=$MoCl_3$, $NiCl_2$) at a constant mol ratio of MCl_n/anthracene (0.3) were also carried out. The results shown in Fig. 1 indicate that an increase in the molar content of $MoCl_3$ (from 12 to 25%, Fig. 1A) and $NiCl_2$ (from 14 to 25%, Fig. 1B) decreased the yield of tetrahydroanthracene and increased the yields of octahydroanthracene, without any remarkable increase of cracking products. These results suggest that increasing the content of $MoCl_3$ and $NiCl_2$ in $MoCl_3$- and $NiCl_2$-LiCl-KCl ternary salts could increase their hydrogenation activity without a remarkable change in the cracking ability. On the other hand, the runs with $MoCl_3$ and $NiCl_2$ alone converted more than 92% of the reactant, and produced more octahydroanthracene and hydrocracked products than their corresponding ternary salts (Table 1, Fig. 1). Especially in a run with $MoCl_3$, alone, dihydroanthracene disappeared and only a small amount of tetrahydroanthracene remained, whereas large quantities of products derived from extensive hydrogenation and cracking, such as *sym*- and *unsym*-octahydroanthracenes, bicyclic and monocyclic compounds and paraffins were formed (Table 1). It is worth while noting that in the catalytic runs of anthracene, *sym*-octahydrophenanthrene was also produced, as can be seen from Table 1. This is considered to be due to the isomerization of *sym*-octahydroanthracene, which is known to occur in the presence of Lewis acids, such as $ZnCl_2$ and $AlCl_3$.[2,3] The isomerization extent could be indicative of the relative Lewis acidity of the salt catalysts. As shown in Fig. 2, the yield of *sym*-octahydrophenanthrene increased as the molar content of MCl_n of MCl_n-LiCl-KCl increased, which appeared to be more remarkable with the $MoCl_3$-containing salts than with the $NiCl_2$-containing salts.

A comparison of the runs using $MoCl_3$- or $NiCl_2$-LiCl-KCl with runs using $MoCl_3$ or $NiCl_2$ (Table 1) indicates that the former promoted hydrogenation reactions and suppressed cracking reactions. This difference was most remarkable between $MoCl_3$-LiCl-KCl and $MoCl_3$ (Table 1, Fig. 1). Since the reactions were carried out at a constant MCl_n/anthracene ratio for both MCl_n-LiCl-KCl and MCl_n salt catalysts and LiCl-KCl showed essentially no catalytic effect, the comparative examination revealed that $MoCl_3$-LiCl-KCl and $NiCl_2$-LiCl-KCl have a lower cracking ability and a higher hydrogenation selectivity than their corresponding $MoCl_3$ and $NiCl_2$ single salts. This suggests that the addition of LiCl- KCl to $MoCl_3$ and $NiCl_2$ suppressed their cracking ability and improved

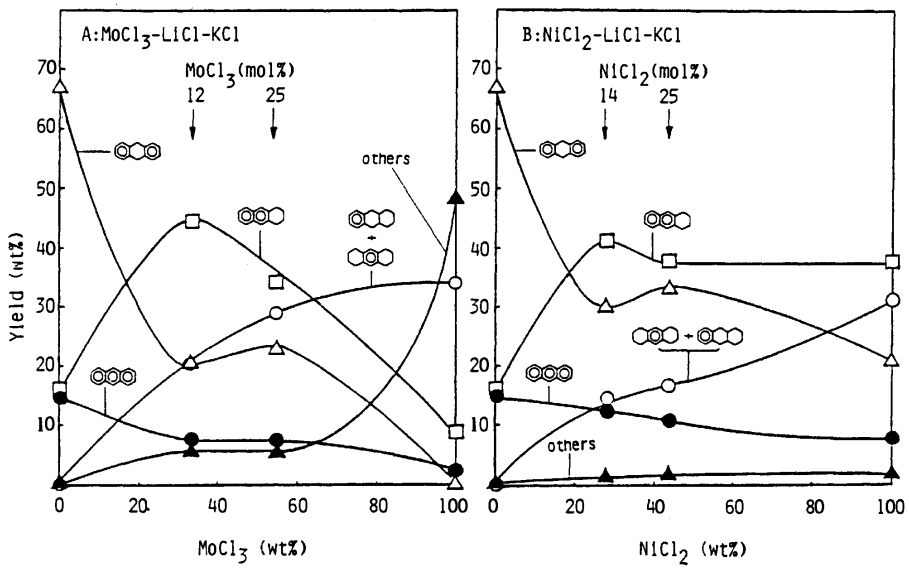

Fig. 1. The influence of MCl_n content in MCl_n-LiCl-KCl on hydrogenation of anthracene. Yields of octahydroanthracenes (○) include those of the isomerized octahydroanthracenes.

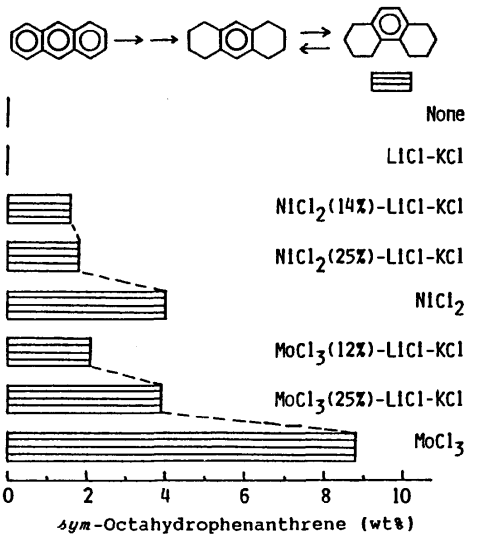

Fig. 2. Yield of *sym*-octahydrophenanthrene formed from hydrogenation of anthracene over MCl_n-LiCl-KCl. The number in the parenthesis indicates the molar content of MCl_n.

their hydrogenation selectivity.[7] This was probably because addition of LiCl-KCl to $MoCl_3$ or $NiCl_2$ led to the formation of some complex species[8] such as MCl_m^{n-} (M=Mo or Ni), which decreased the Lewis acidity of the catalyst. In addition, the hydrogenation of phenanthrene was also performed. Although it showed a lower reactivity, as is well-known,[2,3] the trend for difference between MCl_n-LiCl-KCl and MCl_n (MCl_n=$MoCl_3$, $NiCl_2$) appeared to be similar to that observed in the runs involving anthracene.

In our previous papers[5,6] we demonstrated that $MoCl_3$- and $NiCl_2$-LiCl-KCl salt catalysts greatly enhanced coal conversion with relatively low hydrogen consumption, and significantly increased yield of oil products, without any remarkable increase of C_1—C_4 gas yields. ^{1}H NMR analysis of the oil products revealed that the use of these catalysts increased the content of α- and β-methylene hydrogens present in hydroaromatic structures.[6] The present results show that these catalysts remarkably enhanced the production of partially hydrogenated aromatics without extensive cracking reactions, being consistent with the above-mentioned ^{1}H NMR analyses. Therefore, the results of this study provided a basis for assessing the extent of hydrogenation and cracking of polyaromatics occurring during coal hydroliquefaction using $MoCl_3$- and $NiCl_2$-based salt catalysts.

Ab Initio Calculation for the Interaction Energy of He-He$^+$

Akira ICHIHARA* and Reikichi ITOH

(Received July 22, 1988)

Synopsis. Using an ab initio calculation with a configuration interaction (CI) treatment, the interaction energy of a He-He$^+$ system in the ground ($X^2\Sigma_u^+$) electronic state was calculated. For $X^2\Sigma_u^+He_2^+$ calculations, the Gaussian-type [6s3pld] basis set of Khan and Jordan was employed, and the effect of the basis set superposition error was estimated.

From a theoretical point of view, He_2^+ is a comparatively simple homonuclear ion, and there have been a number of reports in which the interaction energy of He_2^+ in the ground ($X^2\Sigma_u^+$) state has been calculated by the use of an ab initio MO method.[1-6] Recently Khan and Jordan utilized the multi-configuration self-consistent field (MC SCF) procedure to calculate the potential energy curve of $X^2\Sigma_u^+He_2^+$.[5] A contracted Gaussian-type [6s3pld] basis set was employed for their MC-SCF calculation. They determined the vibrational and rotational energy levels from the potential energy curve; the resulting spectroscopic constants were in excellent agreement with the experimental values. This result indicates that the [6s3pld] Gaussian set can give a significantly improved description of the potential energy curve of $X^2\Sigma_u^+He_2^+$.

On the other hand, we have calculated the interaction energies for the He-He[7] and He-H[8] systems in the ground and several electronic excited states. For these simple systems, the full CI treatment could be performed, and the basis set superposition error[9,10] was eliminated correctly from the interaction energies. Thus, it appears to be of interest to investigate the effect of the basis set superposition error on the interaction energy of $X^2\Sigma_u^+He_2^+$, itself calculated with the basis set of Khan and Jordan. In this paper we will report the results of full CI calculations of the interaction energy of $X^2\Sigma_u^+He_2^+$, and the basis set superposition error for these energies will be discussed. Our results concerning the vibrational and rotational energy levels will then be compared with the experimental and theoretical values.

Computational Details

In the CI treatment, $X^2\Sigma_u^+He_2^+$ is mainly described by a single configuration ($1\sigma_g^2 1\sigma_u$) for the whole range of internuclear distances calculated here; it has a dissociation limit, He($1s^2$) +He$^+$(1s), at an infinite separation. The results of full CI calculations for the interaction energy of $X^2\Sigma_u^+He_2^+$ were corrected in order to eliminate the basis set superposition error. We employed the function counterpoise method of Boys and Bernardi[9] to avoid this error. In this method, the He-He$^+$ interaction energy (E_{int}) is calculated using the difference between the full CI energy of $X^2\Sigma_u^+He_2^+$ ($E_{He_2^+}$) and an appropriate refference energy (E_{ref}):

$$E_{int}(R) = E_{He_2^+}(R) - E_{ref}(R), \quad (1)$$

where R is the internuclear distance of He-He$^+$. The reference energy is defined as the sum of the full CI energies of the He($1s^2$) and He$^+$(1s), with ghost orbitals at the expected location of the other atom:

$$E_{ref}(R) = E_{ghost}^{He(1s^2)}(R) + E_{ghost}^{He^+(1s)}(R) \quad (2)$$

The term "ghost" represents an atom with a zero nuclear charge and without any electrons.

Then the calculated interaction energy curve was interpolated in order to determine the vibrational and rotational energy levels of $X^2\Sigma_u^+He_2^+$. The vibrational analysis was given by the Störmer-Levy difference method, while the vibrational eigen functions were utilized to determine the rotational constants. The detailed procedure has been described elsewhere.[11,12] This method gives an accurate solution in a numerical form with a great number of mesh points and with the proper selection of position to make an initial guess from outside of the potential well.

In the present work, the spatial symmetry considered in the CI treatment of the $X^2\Sigma_u^+He_2^+$ is $D_{\infty h}$. The CI calculations contain 4562 configurations for the $^2\Sigma_u^+$ symmetry. The number of calculated interaction energy values was 18 points in the range of internuclear distances from 0.7 to 5.0 Å; the interpolated mesh width was taken to be 0.001 Å. The MO calculations were performed by using the graphical unitary group approach (GUGA) program of our group[7] and the HITAC M680 system of the Computer Center of the Institute for Molecular Science (IMS).

Results and Discussion

Table 1 indicates the interaction energies of $X^2\Sigma_u^+He_2^+$. The full CI energies of He($1s^2$) and He$^+$(1s) (E_{He}, E_{He^+}), without ghost orbitals, are −2.9016276 and −1.9998712 a.u. respectively. These energies are equal to $E_{ghost}^{He(1s^2)}$ and $E_{ghost}^{He^+(1s)}$ at the internuclear distance of R=5.0 Å. The basis set superposition error is evaluated by the use of $E_{ref}-E_{He}-E_{He^+}$ in Table 1. It can be seen from Table 1 that the basis set superposition error is less than 2.0×10^{-4} a.u. for the whole range of R values calculated and that it decreases rapidly as the internuclear separation is increased. In the present CI calculations, the interaction energy minimum was found to be −0.0902342 a.u. at R=1.080 Å. (The resulting dissociation energy (D_e) is 56.585 kcal mol^{-1}, while the D_e value calculated by Khan and Jordan is 56.52 kcal mol^{-1}.[5]) The basis set superposition error changes the energy well depth by only 0.06 percent. From these results, the basis set superposition error can be said to be negligible for $X^2\Sigma_u^+He_2^+$ in the range from 0.7 to 5.0 Å. On the other hand, it seems that the basis set superposition error can not be neglected in the strongly repulsive region.

Table 2 indicates the vibrational energy levels ($G(v)$[13]) of $X^2\Sigma_u^+He_2^+$ with the vibrational quantum number v. The difference in successive $G(v)$ values ($\Delta G(v+1/2)$[13]) and the mean values of R ($\langle R\rangle$) are also indicated in Table 2. In the present calculation, we obtained a $G(21)$ value about 41 cm^{-1} higher than the result calculated by Khan and Jordan.[5] The first four $G(v)$ values in Table 2 were then used in order to determine the vibrational constants ω_e and $\omega_e\chi_e$.[13] The resulting ω_e and $\omega_e\chi_e$ values are 1697.85 and 35.97 cm^{-1} respectively. These ω_e and $\omega_e\chi_e$ values are in significantly better agreement with both the experimental values (1698.5, 35.3 cm^{-1})[14] and the values calculated by Khan and Jordan (1697.4, 35.35 cm^{-1}).[5]

Table 3 indicates the rotational constants B_v[13] at each vibrational energy level, where the mean values of $1/R^2$ ($\langle 1/R^2\rangle$) are also indicated. It can be seen from Tables 2, 3 that the calculated $\langle 1/R^2\rangle$ values are always larger than the corresponding $1/\langle R\rangle^2$ values. The rotational constant, α_e[13]=0.2580 cm^{-1}, was obtained from the first four B_v values and from the equilibrium distance, R_e=1.080 Å (B_e=7.22214 cm^{-1}). Our α_e value is different from both the experimental value (0.224 cm^{-1})[14] and the value calculated by Khan and Jordan (0.224 cm^{-1}).[5] This discrepancy is mainly due to our smaller B_o value, i.e., to the smaller

$\langle 1/R^2 \rangle_{v=0}$ value.

It may be concluded from the results of this investigation that the basis set superposition error of the $X^2\Sigma_u^+ He_2^+$ system calculated by the use of [6s3pld] basis of Khan and Jordan is almost negligible in the range from 0.7 to 5.0 Å. The present interaction energy curve can give the vibrational energy levels. On the other hand, a rotational constant α_e larger than the experimental value was obtained.

We wish to thank Dr. Toshikazu Saitoh, Kazuhide Mori, and Kohtoku Sasagane for making their program code avaiable to us.

(Received August 3, 1988)

Synopsis. Measurements and calculations of ignition delay times were performed in a mixture of CH_4-CH_3I-O_2-Ar in order to understand the characteristics of compouds including iodine during ignition. CH_3I accelerated the ignition of CH_4 more than CH_3Cl did, but less than CH_3Br did. The remarkably small bond-dissociation energies of CH_3I and HI, in comparison to these of other halomethanes, were the major cause of the characteristic behavior.

It is well-known that CH_4 is very difficult to ignite in relatively simple hydrocarbons and that all additives but permanent gases, which act only as diluents, promote the ignition.[1-8] The addition effects of CH_3Br and CH_3Cl[8] on the ignition of CH_4 have already been analyzed in experiments using shock tubes and by simulations based on an assumed reaction mechanism. CH_3Br was more effective as an ignition-promotor than CH_3Cl, although both of them promoted the ignition; the differences were accounted for by chemical kinetic reasons.

In this study, the addition effect of CH_3I on the ignition of CH_4 is investigated by the same method, and the action due to the difference in halogens is discussed.

Experimental

The ignition-delay times were measured in a mixture of CH_4 (2.0 mol%)-O_2 (4.0 mol%)-CH_3I (0.1 mol%)-Ar (93.9 mol%) at temperatures between 1500 and 2000 K and at pressures between 2.3 and 3.3 atm behind the shock wave. Analytical studies were performed by using the mechanism shown in Table 1, in addition to that of the CH_4-oxidation.[8] The details of the experiments and calculation are given in Ref.8. The measurements included an error of only a few %; the error due to the procedure of estimating the ignition-delay times was below 1 μs at 1800 K.

Results and Discussion

The measured ignition-delay times agree well with the calculated values (Fig.1). The promotion effect of CH_3I is larger than that of CH_3Cl, but somewhat smaller than that of CH_3Br. Table 1 includes ignition-delay times which calculated by simultaneously decreasing both forward and reverse rate constants concerning halogen species, one by one, to zero or to one-tenth of their both values at 1800 K. The time calculated by means of normal rate constants was 124 μs. The results indicate that the reactions which have large effects on the ignition are $R1_I$, $R4_I$, $R5_I$, and $R8_I$ (hereafter, a subscript will express the kind of halogen

a) Reaction in which both forward and reverse rate constants are changed. The ignition-delay time calculated by the normal rate constants is 124 μs. b) Forward rate constants in the form $A\times T^n\exp(-E/RT)$, in cm^{-3}, mol, s, kcal, and K units.

in the corresponding reaction).

Although the thermal-decomposition reaction, $R1_I$, contributes most to the acceleration of an ignition like those of CH_3Cl and CH_3Br, each situation is different. When the forward and reverse rate constants of thermal decomposition, $R1_{Br}$ or $R1_{Cl}$, are changed by 10% in systems including CH_3Br or CH_3Cl, the ignition -delay time changes a small percentage, but it does not change at all in this case, and it only decreases about 1% with one-tenth of the $R1_I$. On the other hand, when both rate constants of thermal decomposition (R1) are zero, the ignition delay times are similar (about 220 μs) in the three halomethanes. The forward rate constant of $R1_I$ is two orders of magnitude larger than those of $R1_{Br}$ and $R1_{Cl}$, so the greater part of the CH_3I is decomposed in the early stage of the induction period, as is shown in Figs. 2 and 3. This means that the decomposition rate of CH_3I is very fast and that a small change in the decomposition rate does not affect the ignition-delay time.

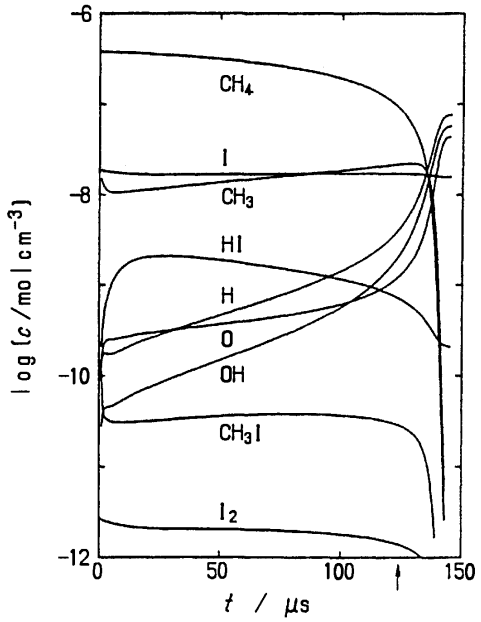

Fig. 2. Calculated concentration profiles at 1800 K. t is time after the arrival of shock wave. Arrow indicates the ignition-delay time.

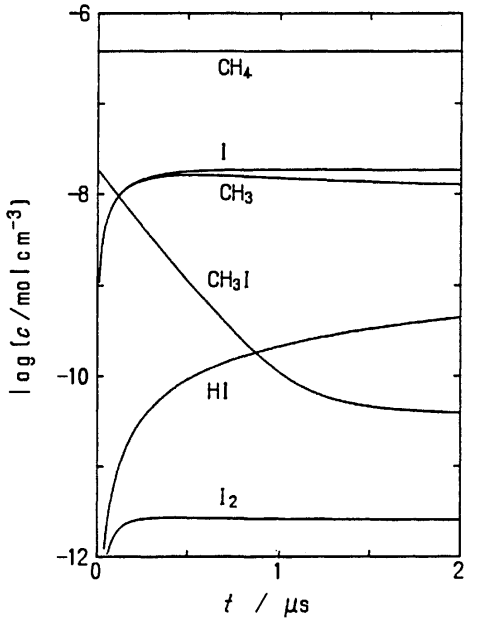

Fig. 3. Calculated concentration profiles at 1800 K in early stage of induction period.

The concentration profiles (Fig. 3) in the early stages of the induction period indicate that CH_3, which is importatnt in ignition, is generated from CH_3I, but not from CH_4. The concentration of iodine atoms reaches its maximum value 0.5 μs after the arrival of a shock wave and is the same as the decomposition value of CH_3I. The net reaction rate of $R1_I$ is very fast in the early stage of the induction period, but it is about 10^{-5} mol cm^{-3} s^{-1} during most of the induction period; this value is smaller by one or two orders than those of $R1_{Br}$ and $R1_{Cl}$. Therefore, $R1_I$ contributes significantly to the ignition only in the early stage. Since $R4_I$ proceeds in the forward direction and promotes the ignition, $R4_I$ has the possibility of making a chain with $R1_I$, in which the forward reaction is fast, and with $R2_I$, in which the reverse reaction is fast, just as in the case of CH_3Br addition.[8] However, the change of the forward and reverse rate constants of $R2_I$ has no effect on the calculated ignition-delay time (Table 1), and the net rate of $R1_I$ is slow through the greater part of the induction period. Therefore, the chain of $R1_I$, $R2_I$, and $R4_I$ is impossible. On the other hand, $R8_I$ proceeds in the reverse diretion and promotes the ignition. As a result, $R4_I$ forms a chain with $R8_I$, and their net reaction corresponds to the production of one H radical and one CH_3 radical from CH_4 in each chain. This net reaction is equivalent to that which is formed by $R1_{Br}$,

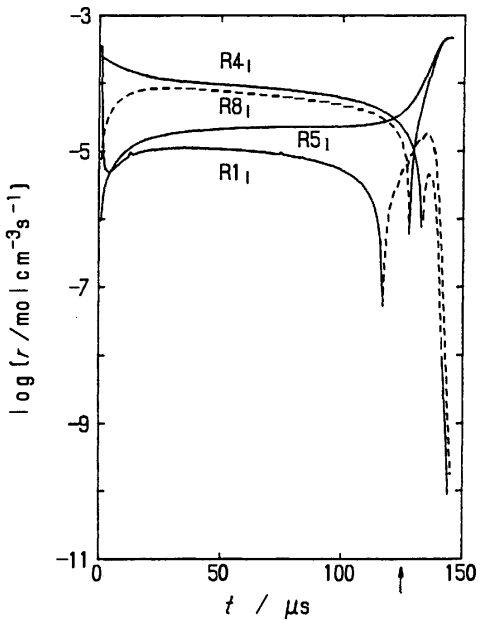

Fig. 4. Net reaction rates. t is time after the arrival of shock wave. Solid and dotted lines indicate that net reaction proceeds in the forward direction and in the reverse direction, respectively. Arrow indicates the ignition-delay time.

$R2_{Br}$, and $R4_{Br}$ when CH_3Br is used. However, the promotion effect of CH_3I is weaker than that of CH_3Br. As is apparent from Fig. 4, the net rate of $R4_I$ is nearly equal to the rate of $R8_I$ except for the early stage of the induction period, and the net rates of $R1_{Br}$, $R2_{Br}$, and $R4_{Br}$ previously reported are also equal to each other. However the net rate of $R2_{Br}$ controlling the rate of the chain formed in the CH_4-CH_3Br system is two times faster than that of $R8_I$ controlling the rate of chain formed when CH_3I is used; consequently, we infer that CH_3Br promotes the ignition better than CH_3I does.

Only $R5_I$ inhibits the ignition in the system involving CH_3I. When $R5_I$ or $R5_{Br}$ is deleted from the reaction mechanism in a system including CH_3I or CH_3Br, the calculated ignition-delay time becomes too short by 2 μs or 5 μs respectively. Although the forward reaction of $R5_I$ is fast and should greatly inhibit ignition, its reverse reaction is also fast, in spite of the low reverse rate constant, because iodine above 90% exists as iodine atoms, as is shown in Fig. 2. Therefore, the net rate of $R5_I$ is lower than that of $R2_I$ and $R8_I$ and has only a little effect on the inhibition of the ignition. In the system involving CH_3Br, the concentration of HBr is about three times that of Br atoms, and the rate constant of $R5_{Br}$ in the reverse direction is smaller by 2 orders than that in the forward direction, so the net rate of $R5_{Br}$ also becomes slow compared with those of other reactions which have a large effect on the ignition.

(Received August 8, 1988)

Synopsis. The structure of cumulene bearing bulky substituents, 1,1,4,4-tetrakis(trimethylsilyl)butatriene, has been determined by an X-ray diffraction method. The molecule is centrosymmetric, and the variation in carbon-carbon double bonds has been observed. The distance of the central C=C bond is 1.276(8) Å, whereas that of the terminal C=C bond is 1.319(6) Å. These bond lengths are very similar to the unsubstituted butatrienes and the influence of bulky trimethylsilyl groups is not recognized in this context. Some distortions have been observed in the bond angles concerning the trimethylsilyl groups; the overcrowded environment of the central C=C bond seems to make this less reactive.

Cumulene is a very reactive molecule and it is important to know more details about the molecular structure in order to correlate its reactivety with structure. The trimethylsilyl group is an important substituent in synthetic chemistry because it gives an overcrowded environment to unsaturated compounds. Differences in the reactivity between 1,1,4,4-tetrakis(trimethylsilyl)butatriene (**1**) and other butatrienes have been reported. The hydrogenation of **1** with Rh-C or Pd-C gives $(Me_3Si)_2CH\text{-}CH{=}CH\text{-}CH(SiMe_3)_2$ and the hydrogenation of 1,4-diphenylbutatriene provides 1,4-diphenyl-1,3-butadiene.[1] Here, we wish to describe the molecular structure of 1,1,4,4-tetrakis(trimethylsilyl)butatriene and to discuss the effect of bulky substituents on the cumulene structure.

Experimental

A tetrahydrofuran solution of bis(trimethylsilyl)butadiyne (1.0 mmol) was added to a solution of $(Me_3Si)_3MnMgMe$ (2.0 mmol) at 0 °C.[2] The resulting mixture was stirred at 0 °C for 1 h, then 30 min at 25 °C. A workup and purification by preparative thin-layer chromatography on silica gel gave 1,1,4,4-tetrakis(trimethylsilyl)butatriene (0.11 g)[3] in 33% yield and was subjected to X-ray structure analysis. Pale-yellow crystals were obtained from a benzene solution. The specimen was sealed by immersion in collodion to prevent any sublimation. The unit cell parameters were determined from 25 Bragg angles, carefully measured on a Rigaku four-circle diffractometer. Graphite monochromatized Cu$K\alpha$ radiation was used. Crystal data: $C_{16}H_{36}Si_4$, FW=340.78, crystal size 0.2×0.15×0.15 mm^3, triclinic, space group $P\bar{1}$; Z=1; a=11.075(2), b=12.035(2), c=6.501(1) Å, α=97.67(2), β=94.38(2), and γ=134.37(1)°. D_c=0.95 g cm^{-3}. μ(Cu$K\alpha$)=21.41 cm^{-1}. The intensity data were collected by a θ-2θ scan method at 24 °C. A total of 1727 reflections were obtained up to sin θ/λ<0.56 Å^{-1}, of which 1613 reflections were non-zero and used for the subsequent structure analysis. No absorption correction was performed. The structure was solved by the direct method with use of the computer program MULTAN,[4] and refined by block-diagonl least-squares method. Each weighting factor was assigned to twenty levels of the observed structure factors, divided according to their magnitude, in order to minimize any residuals in each region. Hydrogen atoms were located on a difference map and were included in the refinement. the final discrepancy indices, R and R_w, for 1613 non-zero reflections were 0.042 and 0.043, respectively. The calculation was carried out by a NEC PC-9801 computer using the UNICS computer program system[5] modified by Profs. Y. Katsube and N. Tanaka. The atomic scattering factors were taken from Ref. 6. The final atomic parameters are listed in Table 1, whereas the anisotropic thermal parameters and complete tables of the observed and calculated structure factors are kept as Document No. 8855 by the Editor of the Bulletin of the Chemical Society of Japan.

Results and Discussion

The molecular structure is shown in Fig. 1. A linear molecule lies on the center of symmetry in the crystal, and four trimethylsilyl groups are located in a staggered form. The effect of the bulkiness of the trimeth-

ylsilyl groups is reflected on the bond angles around the C(1) atom. As can be seen from Table 2, which summarizes the interatomic distances and the angles in the molecule, the angle of C(2)-C(1)-Si(1) is larger than that of C(2)-C(1)-Si(2). This is due to the repulsion of C(2) and C(3), the latter being forced to lie on the plane through C(2), C(1), and Si(1) because of the overcrowded trimethylsilyl groups. The C(1)-C(2) double bond is seemingly buried by these groups and should be less reactive. The structure of tetrakis(trimethylsilyl)ethylene at −70 °C was reported by Sakurai and his co-workers.[7] The effect of bulky substituents has been observed on the molecular structure. The C=C bond length is 1.368(3) Å, significantly longer than the usual double bond. Furthermore, substituted ethylene is no longer planar, the dihedral angle between two Si-C-Si plane being 29.5°. It is reasonable that the effect of bulky trimethylsilyl groups on the present molecule is less remarkable than the tetrakis(trimethylsilyl)ethylene, because two bis(trimethylsilyl) groups are located at a greater distance in the former molecule than in the latter. In fact, a treatment of **1** with 1M HCl (1M=1 mol dm^{-3}) in THF at 25 °C provides $Me_3SiC{\equiv}C{-}CH{=}C(SiMe_3)_2$ quantitatively. Meanwhile, tetrakis(trimethylsilyl)ethylene was quite stable and was recovered unchanged under the same conditions.

The varieties observed in the C=C bond lengths in substituted cumelenes have been discussed by Irngartinger and his co-workers.[8] They recognized that a clear difference exists between cumulenes with

Table 3. The Variation in C=C Bond Lengths in Butatriene

	1.318(5)	1.283(5)	Electron diffraction	12

an even number and those with an odd number of double bonds: that is, the terminal double bonds in the former are somewhat shorter than those in the latter. We summarize in Table 3 the C=C bond lentgths observed in substituted butatrienes. The longer terminal double bond in tetraphenylbutatriene may be attributed to conjugation with the phenyl group, whereas the bond lengths observed in the present molecule is very similar to those in unsubstituted butatriene.

The authors wish to thank to Professors Yukiteru Katsube and Nobuo Tanaka for their kind permission to use their computer programs. They are also indebted to Dr. Yukio Morimoto for his invaluable assistance in performing computations.

Activation of Dinitrogen over Various Raney Type Metal Catalysts

Yoichi OGATA, Ken-ichi AIKA,* and Takaharu ONISHI
Research Laboratory of Resources Utilization, Tokyo Institute of Technology, 4259 Nagatsuta, Midori-ku, Yokohama 227
(Received August 26, 1988)

Synopsis. Raney Ni, Rh, Re, and Ir adsorbed molecular nitrogen which was stable up to about 300 K. Raney Fe, Co, Ni, Ru, Rh, Ir, and Pt adsorbed atomic nitrogen which was desorbed around 700 or 800 K. The XPS spectra of atomically adsorbed nitrogen was observed on Co, Ni, and Ru samples. While the per-weight activity of Raney Ru for isotopic equilibration of N_2 is much higher than that of 5% Ru-K/AC, those of other Raney metals are lower than those of 5% metal-K/AC.

Supported Ru catalysts are known to be promoted with metallic potassium,[1,2] however, Raney Ru, which has no potassium promoter, was found to be as active as potassium-promoted Ru catalysts.[3] Thus, other transition metals of Raney-type catalysts might be active without a potassium promoter. The adsorption characteristics and the activity of isotopic equilibration (IE) reaction of the N_2 are compared for various Raney catalysts.

Experimental

Raney catalysts were prepared by leaching metal-Al alloys (weight ratio; 1/1) with a 5 M of KOH solution at 373 K for 2 h.[4] The weight of the leached sample was estimated to be that of the starting transition metal (normally 1 g), thereby neglecting the weight of remaining Al (ca. 10%). After the sealing water was evacuated in the reactor at room temperature for 10 h the sample was dryed under circulating He at 523 K with a liquid-nitrogen trap for 5 h, and then evacuated at 523 K for 2 h. After the BET surface area was measured by N_2 at 77 K, the sample was stabilized under a N_2 atmosphere at 623 K for 40 to 50 h. This treatment caused N_2 adsorption and sintering of the sample. After evacuation at 623 K (here, ca. one third of N_2 was still irreversibly adsorbed in the case of Ru sample) H_2 chemisorption (273 K) and the BET area (77 K) were again measured. The rate of the IE reaction of N_2 was measured this time at 473 to 773 K. Another series of samples were sealed in glass tubes after N_2 adsorption at 623 K, and were then transfered into the XPS spectrometer.

Results

Characterization of Various Raney Metal. Most of the metal-Al alloys were leached smoothly, except for the Fe sample (10 h for the leaching). The resultant solution of the Fe sample was dark greenish, which suggested that a part of the Fe was dissolved. The leached Raney Fe was treated exceptionally with H_2 at 723 K for 100 h since the surface might have been oxidized. The BET surface area of all the samples measured before N_2 uptake are shown in Table 1. The leached samples have a high surface area (27 to 142 m^2g^{-1}), except for Pd (5 m^2g^{-1}) and Fe (14 m^2g^{-1}), compared to the starting alloy (ca. 1 m^2g^{-1}). The surface area (Table 1) was decreased by sintering during the N_2 treatment at 623 K, except for the Fe sample, in which case nitride formation was suggested.[1]

The metallic atom percentage on the surface was calculated by assuming the relation: (number of H chemisorbed)/(number of surface metal estimated by BET area)[5] (Table 1). The metallic atom percentage on the surface was also measured by XPS, assuming the molar ratio Me/(Me+Al); see Table 1. The XPS results show that Al remained on the surface, except for Raney Re. The surface metallic atom percentage measured by H_2 chemisorption is generally lower than that measured by XPS. Several reasons have been suggested: 1) The surface dencity of Al atoms is lower than that of Ru, because oxidized Al requires a wider space for the counter anion (oxygen); 2) irreversibly adsorbed nitrogen might partly remain; and 3) a part of the surface transition metal, such as Fe or Re, is oxidized. An XPS study showed that about 20% of Re and 70% of Fe were oxidized; however, other samples were all metallic. The residual Al was metallic (Al_{2s}=117.5 eV) over Rh, Pt, and Ir samples, though, it was almost oxidized (Al_{2s}=119.0 eV) over other sam-

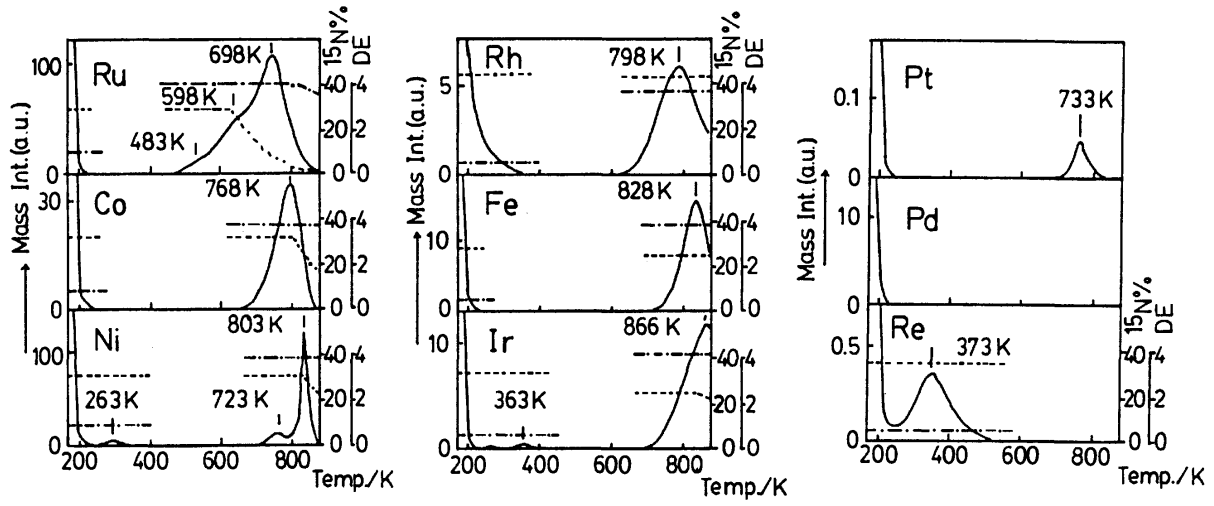

Fig. 1. TPD spectra of adsorbed nitrogen after some extent of isotopic randomization over various Raney type metals. The kind of metal is shown in the figures. ——; total nitrogen ($^{28}N_2+^{29}N_2+^{30}N_2$), ·····; $^{15}N\%$ ($^{29}N_2/2+^{30}N_2$), -·-·-; DE in the text.

ples (Co, Ni, Ru, and Pd).

TPD Study Using ^{15}N Isotope. About one half of the gas-phase nitrogen ($^{28}N_2$) was replaced with $^{30}N_2$ at 573 K. At this point the IE reaction was carried out at 573 K in order to supply an isotopic mixture of surface nitrogen until the degree of equilibration (D.E.) reached approximately unity.

$$\text{D.E.} = (^{29}N_2)^2(^{28}N_2)^{-1}(^{30}N_2)^{-1} \quad (1)$$

An adequate value of D.E. could not be obtained for Pd, Re, and Pt, because of the low activity. The adsorbed nitrogen was quenched and the gas-phase nitrogen was evacuated at 77 K for 3 h; then, a TPD run was carried out to 873 K at a rate of 4 K min^{-1}.

In Fig. 1, the solid lines indicate the total amount of all isotopes of nitrogen during TPD, and the dots and lines show the value of D.E. If no isotopic randomization in N_2 molecule occurs during the desorption (i.e., molecular adsorption), the value of D.E. of the desorbing gas should be kept unchanged from the initial D.E. (ca. 1.0). If isotopic randomization occurs (i.e., atomic adsorption), the value of D.E. should reach about 4.0. Therefore, peaks below 195 K were all assigned to the molecular species (γ-type) because of the low D.E. value (ca. 1.0). Molecular species which were stable at around room temperature (α-type) were observed on Ni, Re, Ir, and probably on Rh catalyst. Peaks above 500 K were all assigned to atomic species since the D.E. values were near 4. It is interesting that Pt, Ir, and Rh samples have β-type, despite the fact that these metals are known to be poor catalysts for N_2 activation, and that there has been no report concerning atomic adsorbed nitrogen from N_2.[1]

The $^{15}N\%$ of the desorbing gas is also shown as dotted lines in Fig. 1. If pre-adsorbed nitrogen (containing ^{14}N) is completely mixed during the IE reaction at 573 K, the $^{15}N\%$ should be constant during a TPD run. However, the value becomes lower at high temperature for Ru, Co, and Ni samples. This means that some pre-adsorbed nitrogen did not take part in the IE reaction at 573 K, and that the atomic nitrogen was adsorbed at various heats of adsorption (surface heterogeneity).

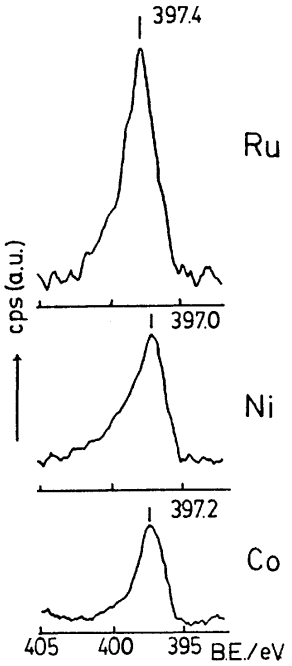

Fig. 2. XPS spectra of N_{1s} region of adsorbed nitrogen on Raney Ru, Ni, and Co.

XPS Spectra of Adsorbed Nitrogen. Only Ru, Ni, and Co samples showed XPS spectra of nitrogen (Fig. 2). The binding energies are 397.4 for Ru, 397.0 for Ni, and 397.2 eV for Co sample, respectively. Since the binding energy of AlN is 396.7 eV, these spectra have been identified to be adsorbed nitrogen on transition metals. Since molecularlly adsorbed nitrogen was evacuated in the XPS chamber at room temperature, the observed XPS spectra should correspond to atomic nitrogen (β-type) for Ru, Ni,[6] and Co catalysts. The relative XPS intensities of nitrogen against metal are 0.07 for Ru, 0.05 for Ni, 0.04 for Co sample, respec-

tively. These values are lower than the surface metallic atom percentages listed in Table 1, probably because of an overestimation of the bulk metal by XPS.

Isotopic Equilibration Reaction of Dinitrogen. The rates of the IE reaction were observable at a temperature where the β-type started to be desorbed. Kinetic data of the reaction are shown on Table 2. The activities are rearranged as TOF in which the number of sites is based on H_2 chemisorption. The activities of all the catalysts were stable during runs for several days at 473 to 773 K.

Discussion

TPD of Adsorbed Nitrogen and TOF of IE Reaction. Molecularly adsorbed nitrogen (α-type) was found at around room temperature on Raney Ni, Re, Ir, and probably on Rh catalysts. Molecularly adsorbed nitrogen has been also observed by ir on Ni-SiO_2 (2202 cm^{-1}), Rh-SiO_2 (2236 cm^{-1}), and Ir (2185 cm^{-1}).[1]

Atomically adsorbed nitrogen should be related with an IE reaction. The desorption peak temperature of the β-type nitrogen is compared with the TOF of an IE reaction at 588 K in Table 2. Raney Ru, which has the lowest desorption temperature, is extraordinarily active. Since the desorption process is one of the steps in the IE reaction, the above two data should be related to each other. The surprizing thing is the activity difference among the catalysts. Only Raney Ni and Ru have multiple TPD peaks for atomic nitrogen. All of the other samples give sharp and single TPD spectra of the β-type. Raney Ni and Ru seem to have multiple active sites. The β-type species must be the intermediate for the IE reaction. The activation energy of IE reaction is equal to that of the adsorption step when the coverage is low and is equal to that of desorption step when the coverage is high. Among Fe, Co, Ni, and Ru on which nitrogen coverage seems to be high (see the mass intensity in Fig. 1), Ru gives the lowest activation energy (Table 2). Rh and Ir give low activation energies, probably, because the coverages are low. Of course, the activation energy data is not decisive in explaining the extraordinal activeness of Raney Ru. It is suggested that a relatively high concentration of the special active site is formed.[3]

Comparison of the Activity of Raney Metal with That of Potassium Promoted Metals. Activity data of potassium promoted metals on AC (Me-K/AC) are only available for comparing the activity of various metal catalysts.[2] The activity is, however, described on the bases of catalyst weight, shown in Table 2. The per-weight activity over Raney Ru is quite high (17000×10^{16} molec. min^{-1} g^{-1}), compared to that (503×10^{16} molec. min^{-1} g^{-1}) over 5%Ru-K/AC.[2,4] The major reason is that Raney Ru has 6% dispersion, i.e., (0.06 g-surface Ru) (g-catalyst)$^{-1}$, and that the 5%Ru/AC has only 12.7% dispersion i.e., (0.0064 g-surface Ru) (g-catalyst)$^{-1}$. Thus, if the two catalysts have the same TOF, the per-weight activity of Raney catalyst must be about ten-times higher than that of 5% Me-K/AC. In this respect, the TOFs of Raney Co, Ni, Rh, and Ir seem to be less than one tenth of those of 5% Me-K/AC. This is because these Raney catalysts have an even lower per-weight activity than Me-K/AC catalysts (Table 2).

Inactiveness of Fe and Re. Fe and Re single crystals have been reported to be quite active for ammonia synthesis.[7] XPS results showed that our Fe and Re samples were partly oxidized because the Raney-type catalyst is prepared in water. This must be the reason why the activities of these samples are low.

Acid-Catalyzed Oxidation of Oxiranes with Dimethyl Sulfoxide Giving α-Hydroxy Ketones

Tadakazu TSUJI
Department of Chemistry, Japan Women's University, Mejirodai, Bunkyo-ku, Tokyo 112
(Received June 14, 1988)

Synopsis. The reaction of various oxiranes with dimethyl sulfoxide in the presence of Molecular Sieve 4A and acid afforded the corresponding α-hydroxy ketones. The molecular sieve was found to accelerate the reaction.

It has previously been reported that the boron trifluoride induced dimethyl sulfoxide (DMSO) oxidation of some oxiranes gave α-hydroxy ketones.[1] Subsequently, the proposed intermediacy of (2-hydroxyalkoxy)sulfonium salts has been prepared by Swern and co-workers as a stable form by the treatment of oxiranes with excess DMSO in the presence of an equimolar amount of acid (i.e., CF_3CO_2H, HBF_4, and CH_3SO_3H).[2,3] However, they reported that the thermolysis of the intermediate alkoxysulfonium salt from 1,2-epoxycyclohexane gave a complex mixture without giving any predominant products.[3] They also described that the reaction of the salts from 2-phenyloxirane and 2,3-dimethyloxirane in DMSO-d_6 at 100 °C for 1 h resulted in an exclusive formation of phenylethanal and 2-butanone, respectively.[2,3] We found that the treatment of a DMSO solution of 2-phenyloxirane (**1a**) at 100 °C in the presence of a catalytic amount of alkoxysulfonium salt (**2a**), which was generated in situ from DMSO, **1a** and CF_3CO_2H, gave the expected 2-hydroxy-1-phenylethanone (**3a**). This finding led us to investigate the reactions of oxiranes with DMSO and acid giving α-hydroxy ketones via the alkoxysulfonium salts. The present paper deals with reactions of the various types of oxiranes with DMSO in the presence of an appropriate acid as catalyst.

Results and Discussion

The acid-catalyzed DMSO oxidation of 2-phenyloxirane (**1a**) in the presence of molecular sieve was examined in a ^1H NMR sealed tube. The solution of **1a** (0.5 mmol) in DMSO or DMSO-d_6 (2.5 mmol) showed the NMR signals which are assignable to the starting material. Upon the addition of CF_3CO_2H (0.025 mmol) and Molecular Sieve 4A (20 mg) at room temperature, three signal sets appeared: a methylene doublet at δ 3.90 and a methine triplet at δ 5.70 along with a pair of singlet of two nonequivalent *S*-methyl groups at δ 3.35 and 3.50. The new spectral sets observed are consistent with those of the reported (2-hydroxyalkoxy)sulfonium salt **2a**.[3] The molar ratio of **1a** : **2a** was calculated to be about 25 : 1, by a comparison of the signal magnitude of methylene protons of **1a** (δ 2.80 and 3.15) with that of *S*-methyl protons of **2a**. Upon heating the mixture at 100 °C, the signals of oxirane ring protons gradually disappeared and were replaced by three sets of signals: a singlet at δ 4.98 and two multiplets at δ 7.33—7.75 and 7.91—8.71. By a comparison with the spectrum of authentic sample **3a**,[1] the singlet and two multiplets could be assigned to the methylene and aromatic protons of **3a**. The simultaneous appearance of the other additional sets of signals, two multiplets at δ 3.0—3.8 and 4.4—4.8, and a singlet at δ 7.1, were observed. These are assigned to the methylene, methine, and aromatic proton signals[4] of the polymer of **1a** (**4**), which was isolated from the mixture after work-up. In addition, the formation of dimethyl sulfide was found in the NMR spectra (δ 2.00, singlet). No formation of 1,2-diol nor aldehyde was observed in a reaction mixture by NMR and GC-MS analysis, but a trace amount of the dimer of **1a** was detected by GC-MS. The dimer was assumed to be in a mixture of 2,5-diphenyl-1,4-dioxane and 2-benzyl-4-phenyl-1,3-dioxolane by NMR.[5] The relation between the used amount of CF_3CO_2H and the yields of **3a** and **4** in this reaction (100 °C, 7 and 14 h with molecular sieve) was examined, and the results are shown in Table 1. The yields of both compounds were calculated by an integration of their methylene signals using the aromatic proton signals as an internal standard. As shown in the table, the yield of **3a** reached its maximum value, 68.5% in a concentration of 0.05 equimolar amount of acid (Run 3). The yield of polymer **4** was 28.3% in this run. The use of a large amount of acid resulted in a decrease in the formation of **3a**. However, a longer time was required for completion at a lower content of CF_3CO_2H amount. In one run using 0.05 equivalent of CF_3CO_2H without a molecular sieve (Run 4), the reaction rate was slower than that in the presence of a molecular sieve (Run 3).

Meanwhile, the correlation between the amount of DMSO (2—9 equivalents) and the yield of **3a** was examined in the presence of a molecular sieve and 0.05 equivalent of CF_3CO_2H at 100 °C for 7 h. As a result, it was found that the use of a 5 equivalent amount of DMSO is optimum to yield **3a**.

Subsequently, the catalytic efficacy of other acids

a) Detected by GC-MS.[6] b) A mixture of monomer and dimer.[1]

were examined by the NMR technique. A reaction of **1a** with DMSO in the presence of either $HBF_4 \cdot Me_2O$ (0.05 equivalent) or CH_3SO_3H (0.1 equivalent) at 100 °C for 10 h gave **3a** in modest yield, 30.1 and 25.2%, respectively.

The preparative experiment was carried out by the reaction of oxiranes with 5 equivalent DMSO in the presence of Molecular Sieve 4A and a catalytic amount of acid at 100 °C. The reaction conditions and results are given in Table 2. When Runs 2 and 3 were compared, it seemed likely that the use of a molecular sieve promotes the reaction of *trans*-2,3-diphenyloxirane (**1b**). The similar effect of a molecular sieve is demonstrated in Table 1, in a reaction of 2-phenyloxirane (**1a**). Thus, the other runs in Table 2 were performed in the presence of a molecular sieve. Compounds **3a** and **3b** were synthesized by the use of CF_3CO_2H as acid, while the preparation of other α-hydroxy ketones, **3c—3g**, were accomplished by the use of 0.04—0.05 equivalents of $HBF_4 \cdot Me_2O$, but not by CF_3CO_2H and CH_3SO_3H. No formation of isomeric 2-hydroxy aldehyde was observed in the oxidation of **1c** or **1d**. The reaction of 1,2-epoxycyclododecane (**1g**) gave a mixture of 2-hydroxycyclododecanone (**3g**) and cyclododecanone in yields of 19.9 and 50%, respectively. The modest yield of **3g** may be due to the steric hindrance of a bulky cycloalkyl group against the attack of DMSO on the oxonium salt of **1g**. 2-Methyl-2-phenyloxirane (**1h**) afforded 2-phenylpropanal exclusively in 44% yield. The GC-MS analysis of the crude product suggested the presence of a trace amount of 2-hydroxy aldehyde.

Swern and co-workers have reported that a treatment of the intermediate salt **2a** from 2-phenyloxirane **1a** with a base gave **3a**, but other salts prepared from other oxiranes decomposed by the action of base to a mixture of simple ketones, 1,2-diols or other products without giving α-hydroxy ketones.[3] In contrast, various α-hydroxy ketones were now obtained by the acid-catalyzed oxidation of oxiranes via salts **2**.

The present method for the preparation of α-hydroxy ketones has synthetic utility. The reaction pathway involving the formation of (2-hydroxyalkoxy)sulfonium salts **2** and the elimination of dimethyl sulfide from **2** giving **3** are under way.

Experimental

^1H NMR spectra were obtained using a JEOL JNM-PMX 60 spectrometer (60 MHz). TMS was used as an internal

standard. GC-MS was performed on a JEOL JMX-DX 300 spectrometer at 70 eV.

NMR Monitoring Experiment for Oxidation of 2-Phenyloxirane (1a) with DMSO. Compound **1a** (0.5 mmol), DMSO-d_6 or DMSO (2.5 mmol) containing DSS as an NMR internal standard, Molecular Sieve 4A (20 mg) and CF_3CO_2H (0.025 mmol) were introduced into NMR tube in this order. The tube was sealed after the atmosphere was displaced by CO_2, and the NMR spectrum was then measured. The molar ratios of the reactants and yields of the products were calculated by integrating the NMR signals using the aromatic signals as an internal standard.

General Procedure for Preparation of α-Hydroxy Ketones by DMSO Oxidation of Oxiranes. Oxirane, anhydrous DMSO, Molecular Sieve 4A (beads size) and acid were placed in a sealed tube, and a stream of dry CO_2 was passed through the apparatus in order to displace the air. The vessel was sealed and the reaction mixture was heated at 100 °C. After completion of the reaction, the reaction mixture was poured into ice water and extracted with CH_2Cl_2. The CH_2Cl_2 solution and the aqueous solution were separately evaporated in vacuum. The residues were purified by recrystallization or distillation in vacuo. The products were identified by comparisons with authentic samples (mp, IR and /or ^{1}H NMR spectra).

2-Hydroxy-1-phenylethanone (3a): Bp 105—110 °C/7 mmHg (1 mmHg≈133.322 Pa); mp 74—75 °C (lit,[2] 75 °C); IR (KBr) 3400 (OH) and 1690 cm^{-1} (C=O); ^{1}H NMR (DMSO-d_6) δ=4.98 (2H, s, CH_2), 7.33—7.75 (2H, m, arom) and 7.91—8.71 (3H, m, arom).

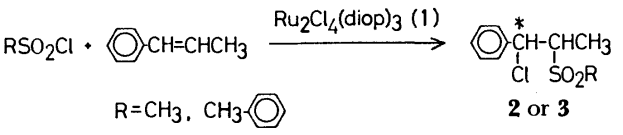
Asymmetric Radical Reaction in the Coordination Sphere. IV.[1] Ruthenium(II)-Catalyzed Asymmetric Addition of Sulfonyl Chloride to 1-Phenylpropene

Masayuki KAMEYAMA and Nobumasa KAMIGATA*
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received June 23, 1988)

Synopsis. The asymmetric addition of methane- and *p*-toluenesulfonyl chloride to 1-phenylpropene catalyzed by $Ru_2Cl_4[(-)\text{-diop}]_3$ affords optically active 1 : 1 adducts, (+)-(1*R*,2*RS*)-1-chloro-2-methylsulfonyl-1-phenylpropane (**2**) and (+)-(1*R*,2*RS*)-1-chloro-1-phenyl-2-tosylpropane (**3**), with about 13—19%ee. Similarly, (−)-(1*S*,2*RS*)-**2** and (−)-(1*S*,2*RS*)-**3** were obtained when $Ru_2Cl_4[(+)\text{-diop}]_3$ was employed. A enantiolace differentiation is considered to occur in the chlorine atom transferring step from the ruthenium(III) species to the carbon radical in the coordination sphere.

Polyhaloalkanes and sulfonyl chlorides reacted with olefins in the presence of transition metal complexes such as $RuCl_2(PPh_3)_3$ to give 1 : 1 adducts in high yields.[2,3] It is considered that these reactions proceed by a radical redox mechanism and the intermediate radicals are restricted in the coordination sphere of the metal complexes. We assume that the resulting radical complexes closely resemble carbene-metal complexes. The asymmetric addition of alkyl diazoacetates to olefins catalyzed by copper-chiral ligands complexes is known to form optically active cyclopropanes and in which reaction involves a carbenoid intermediate.[4] An asymmetric addition of bromotrichloromethane to styrene catalyzed by a rhodium complex with a chiral ligand has also been reported.[5] Thus, an asymmetric induction is expected in the reaction of sulfonyl chlorides with olefins which proceeds by a radical intermediate in the coordination sphere. We recently found that alkane- and arenesulfonyl chlorides,[6] trichloromethanesulfonyl chloride, and carbon tetrachloride[1] reacted with olefins in the presence of a catalytic amount of ruthenium(II) complex with chiral ligand, $Ru_2Cl_4[(+)\text{-diop}]_3$ ((+)-**1**) or $Ru_2Cl_4[(-)\text{-diop}]_3$ ((−)-**1**), to give optically active adducts with about 10—40% ee. However, we have only observed an asymmetric induction to a benzylic carbon bonding to a chlorine atom since terminal olefins, such as styrene, were used in these addition reactions. An asymmetric induction to the β-position of olefins, bonding to the sulfonyl group, may also be possible by using internal olefins. Here, we report on the asymmetric addition of methane- and *p*-toluenesulfonyl chloride to *trans*- and *cis*-1-phenylpropene catalyzed by the ruthenium(II) complex with chiral ligand **1**.

The addition of methanesulfonyl chloride with 1-phenylpropene was carried out in the presence of the ruthenium(II)-DIOP complex **1** as a catalyst. When $Ru_2Cl_4[(-)\text{-diop}]_3$ ((−)-**1**) was used as a catalyst, the reaction of methanesulfonyl chloride with *trans*-1-phenylpropene at 100 °C for 24 h in a degassed sealed tube gave a 1 : 1 adduct (**2**) in 47% yield. Adduct **2** showed a specific rotation $[\alpha]_D$ +4.7° (*c* 5.3, $CHCl_3$). In



a similar manner, the reaction of methanesulfonyl chloride with *trans*-1-phenylpropene catalyzed by $Ru_2Cl_4[(+)\text{-diop}]_3$ ((+)-**1**) was carried out; 1 : 1 adduct (**2**) was formed in 47% yield and showed $[\alpha]_D$ −4.9° (*c* 6.0, $CHCl_3$). Methanesulfonyl chloride reacted with *cis*-1-phenylpropene by using (−)-**1** as a catalyst to give adduct **2**, which showed $[\alpha]_D$ +4.2° (*c* 11, $CHCl_3$). Adduct **2** showed the same positive optical rotation as product **2**, which formed in the reaction of *trans*-1-phenylpropene.

In order to examine an asymmetric induction to a β-carbon of 1-phenylpropene bonding to the methanesulfonyl group, the adduct (+)-**2** ($[\alpha]_D$ +4.7° (*c* 5.3, $CHCl_3$)) was reduced by lithium aluminum hydride to afford 2-methylsulfonyl-1-phenylpropane, which was an optically inactive compound.[7] This means that an asymmetric induction did not occur in the β-position. In other words, the methanesulfonyl radical, generated by an interaction of the ruthenium(II)-DIOP complex **1**, was not interacted with effectively by the chiral ligands in the addition step to the olefin.

The reaction of *p*-toluenesulfonyl chloride with *trans*- and *cis*-1-phenylpropene was also carried out with (+)-**1** or (−)-**1** as a chiral catalyst, in a similar way, to give 1 : 1 adducts (**3**). The results are summarized in Table 1.

The enantiomeric excess and absolute configuration of products **2** and **3** in the present reactions were estimated by making comparison with optically pure compounds, which were prepared by a similar procedure to that mentioned in our previous report.[5] Starting from commercially available, optically pure (+)-(*S*)- and (−)-(*R*)-mandelic acid, (+)-(*R*)-**2** or (+)-(*R*)-**3** and (−)-(*S*)-**2** or (−)-(*S*)-**3** were synthesized with retention, respectively.

The ruthenium(II)-catalyzed asymmetric addition can be explained by the following process involving a radical redox mechanism in the coordination sphere of the ruthenium(II) complexes[8] (Scheme 1). Methanesulfonyl chloride is activated by the ruthenium(II) complex **1** to give a methanesulfonyl radical confined in the coordination sphere of the ruthenium(III) complex (**4**). Then, the confined sulfonyl radical intermediate **4** reacts with 1-phenylpropene without any effect of the chiral ligands to form a 1-phenyl-2-(methylsulfonyl)propyl radical confined in the ruthenium(III) species (**5**). The carbon radical in **5** abstracts the chlo-

Table 1. Reaction of Sulfonyl Chloride with 1-Phenylpropene

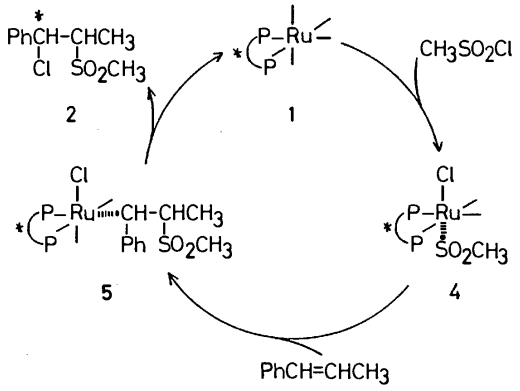

Scheme 1.

rine atom from the ruthenium(III) species containing chiral ligands to give adduct **2** and regenerates the ruthenium(II) complex, **1**. Since 1-phenylpropene is not coordinated as strongly as the sulfonyl radical coordinated to the ruthenium(III) complex (such as **4**), an asymmetric induction does not occur in the intermolecular addition of **4** to the olefin. However, an asymmetric induction occurs in the chlorine atom abstracting step by a carbon radical effected by the chiral ligand, since the carbon radical is coordinated with the ruthenium complex as **5**. The same products were formed in both reactions of *trans*- and *cis*-1-phenylpropene. This means that the sulfonyl radical, generated by a homolytic cleavage of sulfonyl chloride with the ruthenium complex, added to the olefin and a free rotation took place around the carbon-carbon bond in intermediate **5**.

Experimental

Measurement. The infrared absorption spectra were determined on a Hitachi Model 260-10 spectrophotometer with samples as neat liquids. The proton magnetic resonance spectra were recorded at 60 MHz by using a JNM-PMX 60 SI spectrometer with Me_4Si as an internal standard in $CDCl_3$. Optical rotations were measured with a JASCO DIP-140 polarimeter. The gel-permeation liquid chromatography was performed by using a JAI LC-08 liquid chromatograph with a JAIGEL-1H column (20ϕ×600 mm×2, chloroform as an eluent). Mass spectra were determined with a JEOL JMX-DX 300 mass spectrometer with JEOL JMX 5000 Mass Data System at ionizing voltages of 20—70 eV.

Materials. The ruthenium(II) complexes, such as Ru_2Cl_4-[(−)-diop]$_3$ ((−)-**1**) and Ru_2Cl_4[(+)-diop]$_3$ ((+)-**1**), were prepared by methods described in the literature.[9] Methanesulfonyl chloride, *trans*-1-phenylpropene (Wako Chemicals), and *cis*-1-phenylpropene (ICN Pharmaceuticals) were purified by distillation under nitrogen prior to use. *p*-Toluenesulfonyl chloride (Nacalai Tesque) was purified by recrystallization from hexane prior to use.

General Procedure for the Reaction of Sulfonyl Chloride with Olefin. A solution containing 1.0 mmol of sulfonyl chloride, 1.5 mmol of 1-phenylpropene, and 0.01mmol of **1** in 2.0 cm^3 of benzene was degassed and heated in a sealed tube at 100 °C for 24 h. The reaction mixture was chromatographed on Florisil (4:1 (v/v) hexane-ethyl acetate as an eluent) to remove any ruthenium complexes. Purification by gel-permeation liquid chromatography using chloroform as an eluent gave 1:1 adducts (**2** and **3**). The products were identified by their infrared absorption spectra, proton magnetic resonance spectra, mass spectra, and high-resolution mass spectra. The physical and spectral data of the compounds (**2** and **3**) are as follows.

(+)-(1*R*,2*RS*)-1-Chloro-1-phenyl-2-tosylpropane (3): $[\alpha]_D$ +48° (*c* 4.5, $CHCl_3$); IR (neat) 1320, 1300, and 1150 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.40 (3H, d, *J*=7.2 Hz), 2.41 (3H, s), 3.41 and 3.46 (1H, qd, *J*=7.2 and 3.0 Hz), 5.63 (1H, d, *J*=3.0 Hz), 7.20 (5H, s), and 7.22 and 7.68 (4H, ABq, *J*=8.4 Hz); MS *m/z* (rel intensity) 308 (M^+; 1), 272 (5), 271 (15), 233 (14), 209 (29), 158 (15), and 157 (100); HRMS, Found: *m/z* 308.0658. Calcd for $C_{16}H_{17}O_2SCl$: M, 308.0638.

(−)-(1*S*,2*RS*)-1-Chloro-1-phenyl-2-tosylpropane (3): $[\alpha]_D$ −50° (*c* 1.4, $CHCl_3$); IR (neat) 1320, 1300, and 1150 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.25 (1.5H, d, *J*=7.2 Hz), 1.42 (1.5H, d, *J*=7.2 Hz), 2.44 (3H, s), 3.30—3.90 (1H, m), 5.50—7.70 (1H, m), 7.36 (5H, s), and 7.34 and 7.74 (4H, ABq, *J*=8.4 Hz); MS *m/z* (rel intensity) 308 (M^+; 1), 273 (1), 272 (4), 209 (9), 158 (14), and 157 (100); HRMS, Found: *m/z* 308.0641. Calcd for $C_{16}H_{17}O_2SCl$: M, 308.0638.

Reduction of (−)-(1*S*,2*RS*)-2 by Lithium Aluminum Hydride. To a stirred suspension of 210 mg (5.5 mmol) of lithium aluminum hydride in 5 cm^3 of dry tetrahydrofuran was added dropwise 250 mg (1.1 mmol) of (−)-(1*S*,2*RS*)-**2** in 10 cm^3 of dry tetrahydrofuran at room temperature under nitrogen. After the addition was completed, the mixture was refluxed for an additional 12 h, then cooled in an ice bath, and treated with water and then with 5% sulfuric acid. Ether was added to the mixture and the ethereal layer was separated and dried over magnesium sulfate. The solvent was evaporated to give 132 mg (61%) of 2-methylsulfonyl-1-phenylpropane; $[\alpha]_D$ 0° (*c* 6.6, $CHCl_3$); IR (neat) 1300 and 1140 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.31 (3H, d, *J*=6.0 Hz), 2.76 (3H, s), 2.90—3.60 (3H, m), and 7.22 (5H, s); MS *m/z* 198 (M^+).

(Received August 2, 1988)

Synopsis. A new 1,3-dimethylurea-formaldehyde condensate like a crown compound with two rings, 5,5′-carbonylbis[1,3-dimethyl-3,4,5,6-tetrahydro-1,3,5-triazin-2(1*H*)-one], was prepared. The molecular structure of the complex with the condensate and copper(II) chloride (1 : 1) was determined by means of X-ray analysis. The copper(II) ion was coordinated intermolecularly between two oxygen atoms (O(2) and O(2)′ in the adjacent molecule).

The previous papers[1,2] reported that the addition of 1,3-dimethylurea-formaldehyde condensates, such as 1,3,5,7-tetramethyltetrahydro-1,3,5,7-tetrazocine-2,6-(1*H*,3*H*)-dione and bis(1,3-dimethylureido)methane, changed the absorption spectrum of a solution of the metal salts of phenol into that of free phenol. An apparent specific interaction between these condensates and the metal ions was suggested.

A new 1,3-dimethylurea-formaldehyde condensate like a crown compound with two rings, 5,5′-carbonylbis[1,3-dimethyl-3,4,5,6-tetrahydro-1,3,5-triazin-2(1*H*)-one] (CDTTO), was prepared, and the molecular structure of the complex with CDTTO and copper(II) chloride (1 : 1) was determined by means of X-ray analysis in order to elucidate the coordination between the CDTTO and copper(II) chloride.

Experimental

Preparation of a Complex with 5,5′-Carbonylbis[1,3-dimethyl-3,4,5,6-tetrahydro-1,3,5-triazin-2(1*H*)-one] and Copper(II) Chloride. One mole of 1,3-bis(methoxymethyl)-urea, two moles of 1-methoxymethyl-1,3-dimethylurea, and a small amount of *p*-toluenesulfonic acid as an acid catalyst were dissolved in DMF. The solution was then heated at 110 °C in an oil bath for 30 min. After the DMF has distilled away, the crystals deposited (CDTTO) were recrystallized from EtOH (Yield, 76%). Elemental analysis: Found, C, 46.45; H, 7.11; N, 29.47%; Calcd for $C_{11}H_{20}N_6O_3$, C, 46.47; H, 7.09; N, 29.56%. ^{1}H NMR (DMSO-d_6): δ=4.58 (8H, s, -C$\underline{H}_2$-), 2.74 (12H, s, -C$\underline{H}_3$): ^{13}C NMR (DMSO-d_6): δ=160.43 (O=$\underline{C}$<), 150.79 (O=$\underline{C}$<), 61.74 (-$\underline{C}$H$_2$-), 31.98 (-$\underline{C}$H$_3$). MS (FD): m/z=284 (M^+).

Equimolecular quantities of CDTTO and copper(II) chloride were dissolved in distilled water, after which the solution was stirred for 30 min at room tempersture. After the evaporation of the solvent, the deposited crystals were recrystallized from EtOH. The copper content in the complex with CDTTO and copper(II) chloride was determined by atomic absorption analysis. CDTTO : Cu=1.01 : 1.

X-Ray Analysis. A brown, transparent crystal with dimensions of ca. 0.2×0.2×0.2 mm^3 was mounted on a Rigaku AFC-6S automated diffractometer. The systematic absences of (h00) reflections for h odd and (0k0) for k odd led to the space group of $P2_12_12$. The intensity data were measured by means of the ω-2θ scan mode (scan speed 4° min^{-1} in ω) up to 2θ of 60° by using graphite-monochromated Mo $K\alpha$ radiation (λ=0.7107 Å). Lorentz and polarization corrections were made, but no correction for absorption. Among the 1495 reflections measured, 1351 reflections with $|F_o|>3\sigma(|F_o|)$ were used for the structure determination.

Crystal Data. $C_{11}H_{20}N_6O_3\cdot CuCl_2$. F.W.=418.77, orthorhombic, space group $P2_12_12$, a=12.772(2), b=10.850(4), c=6.004(1) Å, V=832.1 Å^3, Z=2, D_c=1.67 g·cm^{-3} μ (Mo $K\alpha$)=16.6 cm^{-1}.

The structure was solved by the direct method (MULTAN78[3]). The positions of the H atoms were determined from a difference Fourier map. The structure was refined anisotropically for non-H atoms and isotropically for H atoms by a block-diagonal least-squares method. The final discrepancy factors were R=0.056 and R_w=0.085 (w=unit wt), and $(\Delta/\sigma)_{max}$ in the final refinement cycle was 0.110 for non-H atoms. The scattering factors were taken from Ref. 4. The calculations were carried out on a HITAC M-680H computer at the Computer Center of The University of Tokyo, using the local version of UNICS III.[5]

Results and Discussion

The final atomic and equivalent isotropic thermal parameters, as defined by Hamilton,[6] are listed in Table 1.[7] The selected bond lengths and bond angles, and also some interatomic distances, are shown in Table 2. A perspective view of the complex along the b-axis, with atomic numbering, is shown in Fig. 1. The carbonyl group of C(1)-O(1) and Cu^{2+} are on the two-fold rotation axis. The four atoms of C(1), O(1), N(1), and N(1)′ lie on the same plane. The least-squares plane formed by the seven atoms of O(2), C(2), C(3), C(4), N(1), N(2), and N(3) intercepts another least-squares plane formed by seven symmetric atoms (O(2)′, C(2)′, C(3)′, C(4)′, N(1)′, N(2)′, and N(3)′) at

Cu-Cl	2.211(3)	C(4)-N(3)-C(6)	121.8(7)
Cu-O(2)	1.948(6)	N(2)-C(4)-O(2)	120.0(8)
		N(3)-C(4)-O(2)	120.7(8)
		N(2)-C(4)-N(3)	119.3(7)
		N(1)-C(1)-N(1)′	114.8(8)
		Cl-Cu-Cl′	143.0(1)
		Cl-Cu-O(2)	98.3(2)
		Cl-Cu-O(2)″[a]	95.9(2)
		O(2)-Cu-O(2)″[a]	134.1(3)

a) O(2)″ is the O(2)′ atom in the adjacent molecule.

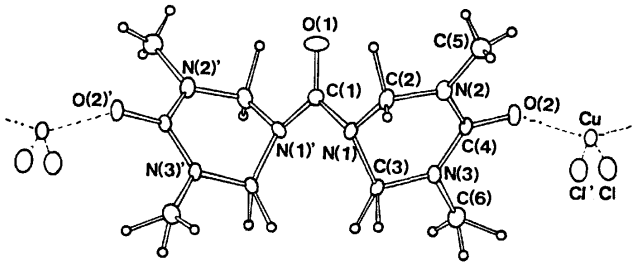

Fig. 1. A view of the molecular structure of the complex with 5,5′-carbonylbis[1,3-dimethyl-3,4,5,6-tetrahydro-1,3,5-triazin-2(1*H*)-one] and copper(II) chloride with the numbering scheme.

the angle of 148°. The Cu^{2+} ion is not located between the two ring structures of 1,3-dimethyl-3,4,5,6-tetrahydro-1,3,5-triazin-2(1*H*)-one in the same molecule; it coordinates intermolecularly to two oxygen atoms (O(2) and O(2)′ in the adjacent molecule).

The observed interatomic distance of Cu-O(2) (1.948 Å) was shorter than that of 2.71—2.75 Å of Cu-O in the complex with 1,4,10,13-tetraoxa-7,16-diazacyclooctadecane and copper(II) chloride.[8] Furthermore, it was shorter than the value of 2.12 Å which was estimated by considering the van der Waals radius of the oxygen atom and the ionic radius of Cu^{2+}. These results suggest a strong interaction between Cu^{2+} and O(2).

The bond lengths for the carbonyl groups of C(1)-O(1) and C(4)-O(2) were 1.213 and 1.216 Å respectively. While C(1)-O(1) has a strong double-bond character, C(4)-O(2) is intermediate between single and double bonds. The resonated structures of $N\text{-}\overset{\displaystyle O^-}{\overset{|}{C}}\text{=}N^+$ and $N^+\text{=}\overset{\displaystyle O^-}{\overset{|}{C}}\text{-}N$ make a larger contribution to N(2)-C(4)O(2)-N(3) than to N(1)′-C(1)O(1)-N(1), partly because of the effect of the two methyl groups and partly because of the stabilization of the anionic structure of O(2) by the coordination to Cu^{2+}.

We wish to thank Professor Hayao Kobayashi for his kind support in the data collection on the Rigaku AFC-6S diffractometer at Toho University and in the computation and Dr. Minoru Takada for his atomic absorption analyses.

The High-Temperature Reaction of Iron with Sulfur Dioxide

Ken-ichiro OTA,* Hiroyuki SUGIMOTO,†,†† and Kazuo FUEKI†,†††
Department of Energy Engineering, Faculty of Engineering, Yokohama National University, Tokiwadai, Hodogaya-ku, Yokohama-shi 240

(Received July 11, 1988)

The reaction of Fe with SO_2 has been studied in the temperature range from 923 K to 1123 K and in the pressure range from 1.3 kPa to 101 kPa. The reaction obeyed the parabolic law except for the initial period, and the rate constant was equal to that in O_2. In the scale, Fe_3O_4, FeO, and FeS were found as the reaction products. Among them, FeS was formed only in the initial period of the reaction and stayed at the scale/metal interface. The constant amount of sulfide in the scale became larger at higher temperatures or at lower SO_2 pressures. The sulfide formation in the initial period of the reaction might cause the increase in the corrosion of Fe at low pressures of SO_2 and cause the difference from the corrosion by O_2.

The corrosion of metals by SO_2 gas causes severe problems in the combustion processes of fossil fuels containing sulfur and also in thermochemical hydrogen production, where high-concentration SO_2 is utilized at high temperatures.

Several reports on the high temperature corrosion of Fe in SO_2 have been published.[1-5] Baukloh and Valena[1] studied the corrosion of Fe in 101 kPa SO_2 and found that the reaction started at 473 K and obeyed the parabolic law between 673—1273 K. Chretien and Broglin,[2] however, observed a deviation from the parabolic law in the initial period between 773 and 1073 K. Flatley and Birks[3] studied the reaction in the temperature range of 773—1273 K and the SO_2 pressure range of 0.25—20 kPa. The reaction obeyed the linear law in the initial period and the parabolic law in the latter period. The same tendency was reported by Kurokawa[5] at 1073 K. According to Flatley and Birks,[3] the parabolic rate constant reached a maximum value at a SO_2 pressure of 2 kPa at 1073 K. When the SO_2 pressure was increased beyond 2 kPa, however, the parabolic rate constant decreased until it reached that in pure oxygen.

Three kinds of iron compounds, FeS, FeO, and Fe_3O_4, were found in the scale.[3-5] FeS always appeared at the metal/scale interface, and its existence promoted the falling of the scale during thermal cycles. Therefore, it is important to elucidate the mechanism of FeS formation in a scale. According to Rahmel,[6] FeS is formed as a result of the inward penetration of SO_2 through micropores in the scale as well as by the diffusion of sulfur from the gas/scale interface to the scale/metal interface. Ross et al.[7,8] studied the reaction between mild steel and sulfur and speculated that FeS is formed in the initial period of the reaction where the reaction rate is high. However, they presented no supporting experimental result. Gilewicz-Wolter[9] studied the corrosion of Fe in SO_2 of 101 kPa at 1073 K using a radio-isotope ^{35}S and found that FeS was formed along the cracks in the scale, mostly in the initial stage of the reaction.

These works carried out previously have thus not yielded a clear interpretation of the mechanism of FeS formation in SO_2. The present paper aims to evaluate the formation of FeS during the reaction between Fe and SO_2 by means of a chemical analysis in order to elucidate the mechanism of the formation of FeS around 1073 K.

Experimental

(1) Specimen. A pure iron sheet supplied by the Nippon Steel Corp. was used as the sample. Table 1 shows the result of the chemical analysis of the impurities. The sheet was cut into rectangular specimens 10×10×0.8 mm; they were polished with No. 1000 SiC polishing paper, washed with soap and water, rinsed in alcohol, and dried.

(2) Reaction-Rate Measurement. A finished and weighed specimen was suspended in the room-temperature region of a mulite reaction tube; then the entire system was evacuated, and SO_2 gas was introduced. The specimen was lowered to the reaction zone, the temperature of which was controlled to within 2 K. In order to react the iron specimen with SO_2, SO_2 gas was circulated by means of a magnetic piston pump. After the predetermined time of reaction, the specimen was taken out of the reaction tube and the weight change was determined.

(3) Analysis of Scale. The reaction products were examined by the X-ray diffraction methods. The cross-sections of the reacted specimens were studied by EPMA as well as with an optical microscope.

Table 1. Results of Chemical Analysis of Iron

Component	wt%	Component	wt%

In order to know the sulfide growth, the total amount of sulfur in the scale was chemically analyzed by the following method. A reacted specimen was dissolved in a HCl (1 M§)–Br_2 (0.01 M) solution in order to oxidize the sulfide ions to sulfate ions. After the filtation, the solution was passed through cation-exchange resin (Dow Chemical 50W-X8) and the Fe ions were removed. Then $BaSO_4$ was precipitated by adding a $BaCl_2$ solution to the solution. The amounts of sulfur were calculated from the weight of the $BaSO_4$ precipitate.

Results and Discussion

Figure 1 shows a parabolic plot of the weight increase in Fe at the SO_2 pressure of 101 kPa. The temperature range was from 923 K to 1123 K. Clearly, the reaction obeys the parabolic rate law except for the very initial period. In order to compare with the oxidation reaction, the oxidation of Fe in 101 kPa O_2 was carried out at 1073 K. The oxidation reaction obeyed the parabolic rate law from the initial period. The parabolic rate constants for oxidations in SO_2 and in O_2 were the same (6.6×10^{-8} g^2 cm^{-4} s^{-1}); the only difference appeared in the initial period. These results agree well with those of Baukloh[1] and Flatley.[3]

By the observations of the cross-sections of specimens reacted with SO_2 in 101 kPa at 1073 K utilizing a optical microscope, the scale was found to be composed of a monolayer at the very initial period of the reaction and to become double layers after a 1-h reaction. The inner layer or the layer at the metal/scale interface showed a lamellar structure, as has been shown in previous papers.[3–5]

After Fe was oxidized in 101 kPa SO_2 at 1073 K for 16 h, the products were examined by the X-ray diffraction methods. X-Ray diffraction obtained by gradual sectioning from the surface revealed that the scale had a layer structure of Fe_3O_4/FeO/FeO–FeS. When the scale was peeled off from the base metal and ground to a powder, however, only FeO was detected. This result indicates that FeO is the major oxide for this sample and that Fe_3O_4 exists only on the surface of the scale.

Figure 2 shows the Arrhenius plots of the parabolic rate constants for Fe in 101 kPa SO_2. The parabolic rate constants for oxidation in pure O_2[10,11] (B, C) and in S_2[12] (A) are also shown for the sake of comparison. A linear relation is observed for SO_2 reaction. The rates are very close to the oxidation rate in O_2.

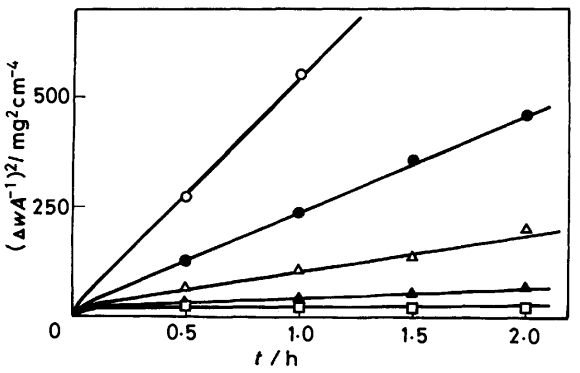

Fig. 1. Parabolic plot of reaction of Fe in SO_2 (101 kPa).
○: 1123 K, ●: 1073 K, △: 1023 K, ▲: 973 K, □: 923 K.

§ 1 M=1 mol dm^{-3}.

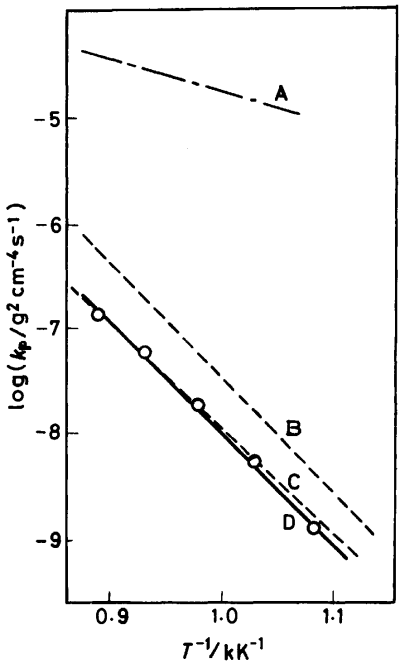

Fig. 2. Arrhenius plot of parabolic rate constant.
A: Sulfidation in S_2.[12] B: Oxidation in O_2.[10] C: Oxidation in O_2.[11] D: This work.

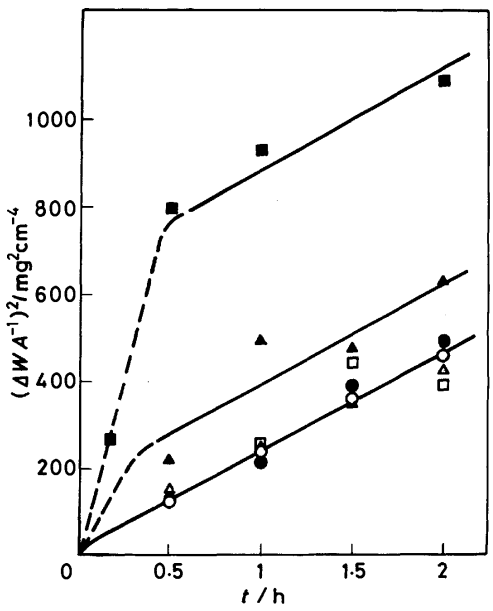

Fig. 3. Parabolic plot of reaction of Fe in SO_2 at 1073 K.
■: 1.3 kPa, ▲: 2.1 kPa, △: 13 kPa, □: 25 kPa, ●: 51 kPa, ○: 101 kPa.

Compared to the sulfidation rate (A), the absolute value and the slope of line are both different. This shows that the reaction of Fe in 101 kPa SO_2 might be fundamentally the same as that in pure O_2, including the rate determining step.

Figure 3 shows the parabolic plot of the weight increase in Fe in SO_2 gas at 1073 K. The SO_2 pressures are 1.3, 2.1, 13, 25, 51, and 101 kPa respectively. The low SO_2 pressure was controlled by the temperature of the cold spot in the reaction system utilizing a Dry Ice–ethanol mixture. The reacted amounts are almost the same when the SO_2 pressure is between 13 and 101 kPa. At lower SO_2 pressures, the reacted amounts increase. However, the difference appears only at the initial period (less than 0.5 h). After a 1-h reaction the parabolic rate constants do not depend on the SO_2 pressure; that is, the rate is equal to that in O_2. The corrosion reaction that is characteristic of SO_2 gas might take place only in the initial period of the reaction.

Figure 4 shows the results of EPMA analysis for the cross-sections of specimens reacted in 101 kPa SO_2 at 1073 K for 10 min, 1.5 h, and 8 h respectively. In this figure, l denotes the scale thickness, and 0, the metal/scale interface. The scale/gas interface is the point where the oxygen concentration diminishes to zero. The sulfide is formed near the metal/scale interface. It appears from these results that the oxide thickness increased during the reaction, while sulfide did not grow.

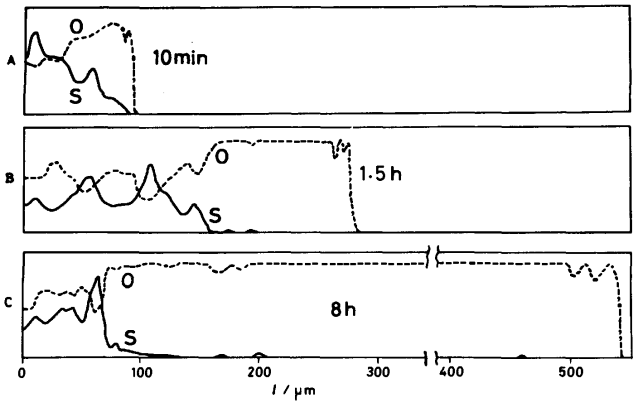

Fig. 4. Distribution of sulfur and oxygen in the scales reacted 10 min, 1.5 h and 8 h in SO_2 (101 kPa) at 1073 K.

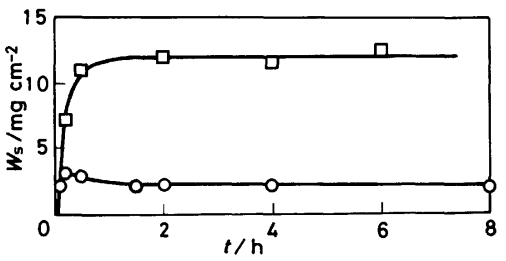

Fig. 5. Change of the total sulfur weight in the scale during the reaction of Fe in SO_2 at 1073 K.
□: 1.3 kPa, ○: 101 kPa.

Figure 5 shows the amounts of sulfur (W_s) in a scale, as obtained by chemical analysis. The total amounts of sulfur are constant after the reaction times of 5 min and 1 h under SO_2 pressures of 101 and 1.3 kPa respectively. These results indicate that the sulfide is formed only in the initial period of the reaction. The constant amount of sulfur in 101 kPa SO_2 was smaller than that in 1.3 kPa SO_2. The difference in the reactions in the initial period shown in Fig. 3 might be explained by the sulfide formation. At low SO_2 pressures a large amount of sulfide formation takes place during the initial period, thus leading to the increase in the total amount reacted. However, once the formation of sulfide ceases, only the oxidation reaction proceeds. At this stage there is no significant difference in the reaction rates (parabolic rate constants).

Figure 6 shows the dependence of the constant

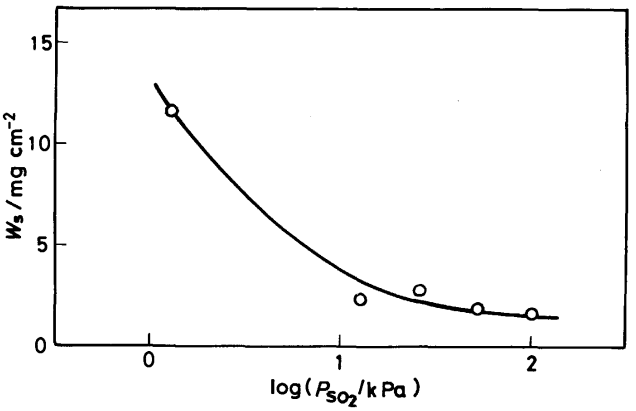

Fig. 6. Dependence of the constant sulfur amount in the scale on SO_2 pressure during the reaction of Fe in SO_2 at 1073 K.

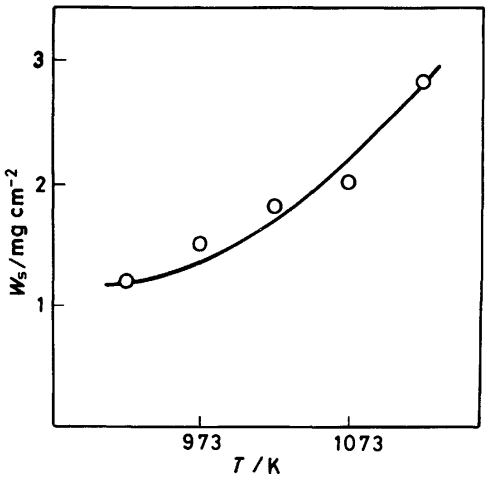

Fig. 7. Dependence of the constant sulfur amount in the scale on temperature during the reaction of Fe in SO_2 (101 kPa).

sulfur amount in the scale on the SO_2 pressure. The amount of sulfur increases at lower SO_2 pressures. Figure 7 shows the dependence of the constant sulfur amount in the scale on the temperature. The sulfur amount increases with the rise in the reaction temperature.

FeS is thermochemically unstable in a SO_2 atmosphere.[5] In order to study the reaction of FeS on Fe with SO_2 and confirm a stable phase, Fe was sulfided for 20 min in pure H_2S at 1073 K and then reacted with SO_2 of 101 kPa for 20 h at 1073 K. It was found that, after the reaction, the sulfide scale was covered with the oxides, FeO and Fe_3O_4. Another experiment was carried out using a single crystal of FeS. It was reacted with SO_2 of 101 kPa at 1073 K. By means of an X-ray diffraction study, only Fe_3O_4 was found as the reaction product. From this result, Fe_3O_4 was found to be a stable compound in 101 kPa SO_2 at 1073 K.

In order to know whether sulfur diffuses inward through the oxide scale, Fe was oxidized for 10 and 30 min in pure O_2 at 1073 K and then reacted with SO_2 of 101 kPa for 20 h. In both cases, no sulfide was detected by the chemical analysis. The sulfide formed after oxidation might be less than 1/20 of that without preoxidation, considering the limits of the analysis. According to Gilewicz-Wolter,[9] sulfur does not diffuse through the scale after Fe is reacted with SO_2 for 3 h at 1073 K. Watanabe and Ohira[13] reported that sulfide was not formed at 1023 K during the reaction of SO_2 and Fe, which was covered with a thick oxide film formed by the preoxidation for 4 h in pure O_2 at 1023 K. The present study has shown that a thin oxide film formed by only a 10-min preoxidation is able to suppress the sulfur diffusion throughout the scale. From these results it is concluded that sulfur cannot diffuse easily through a dense oxide scale. Thus, the FeS at the scale/metal interface is not formed as a result of the penetration of sulfur through the oxide layer. FeS might, however, be formed by the direct reaction between Fe and sulfur in the initial period of the reaction, as has been proposed by Chattergie[4] and Kurokawa.[5]

The Meaning of the Equilibrium Spreading Pressure of Fatty Acid Being Relatively Soluble in an Underlying Subphase

Makio IWAHASHI,* Kimiyo IIDUKA,†,†† Takashi WATANABE,†,††† and Tsutomu SEIMIYA†
Department of Chemistry, School of Hygienic Sciences, Kitasato University, Sagamihara, Kanagawa-ken 228
†Department of Chemistry, Faculty of Sciences, Tokyo Metropolitan University, Setagaya-ku, Tokyo 158
(Received July 15, 1988)

The spreading pressure of a lipid monolayer in equilibrium with its crystal placed at the air/water interface is a thermodynamical property—i.e., the equilibrium spreading pressure (ESP). It is, however, quite likely that the apparently constant spreading pressure of a lipid with a relatively large desorption rate into the underlying subphase is not a thermodynamical property but merely a steady-state one. Mutual comparisons were, therefore, carried out for the rate constants of the six possible processes associated with the spreading pressure of tetradecanoic acid, whose monolayer has a relatively large desorption rate into the underlying subphase; it was found that monolayer formation from its crystal was predominant and that the desorption from the monolayer little affected the spreading pressure, even at high temperatures. Consequently, the apparently constant spreading pressure for the tetradecanoic acid can be regarded as the ESP even at high temperatures, in which the dissolution of the monolayer into the subphase occurs very rapidly.

Many lipids spread spontaneously when placed in a solid or liquid form at the air/water interface, thus giving monolayers in apparent equilibrium with the excess bulk lipid phase. The corresponding surface pressure (Π) of the monolayer is generally known as the equilibrium spreading pressure (ESP). The ESP is, in principle, useful for obtaining thermodynamic information on the crystal-monolayer transition; monolayer experiments carried out beyond the pressure of ESP are thought to be thermodynamically invalid. However, it appears to be doubtful that the apparently constant spreading pressure for the lipid, which has a relatively large desorption rate into the underlying subphase, is a true equilibrium property; that is, it seems quite likely that the apparent constancy of the spreading pressure is attributable not to the genuine ESP, but to a steady-state caused by the monolayer material being lost from the interface by desorption.

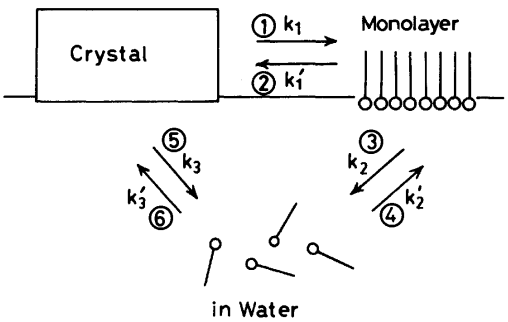

Fig. 1. General mode for the monolayer spreading process.

Six processes (see Fig. 1) are, in general, possible in accounting for the spreading of a relatively soluble and nonvolatile lipid crystal: (1) a monolayer formation by the spreading of the lipid from its crystal; (2) the re-binding of the molecule in the monolayer to the crystal; (3) the dissolving of the monolayer into the underlying subphase; (4) the adsorption from the subphase to the monolayer; (5) the dissolution of lipid molecules from its crystal into the subphase; and (6) the adsorption from the subphase to the crystal.

In the present study we investigated the above processes for tetradecanoic acid, which has a relatively large desorption rate into the underlying water, and discussed kinetically the meaning of the ESP by comparing the rate constants for the above processes with one another.

Experimental

The sample of tetradecanoic acid (purity: 99.7%; Applied Science Co., Ltd.) was further purified by repeated slow crystallizations overnight from hexane. Needle-like (small) and plate-like (large) crystals formed from the hexane solution were both freed of the solvent by being pumped out for a week on a vacuum line. The crystallographic forms were determined for the two types of crystals with a X-ray diffraction instrument (Rigaku Denki Model Geigerflex RAD-1A). The needle-like and plate-like crystals were A-super-type and C-type forms respectively.[1] The purest grade hexane from the Wako Co., Ltd. (Tokyo), was redistilled two times before being used for the preparation of the above crystal samples and as the spreading solvent in the monolayer-desorption experiment. The subphase solution consisted of triply distilled water whose pH has been adjusted to 2 with twice-distilled HCl.

The spreading pressure of the crystal was measured by the Wilhelmy plate method, using the apparatus shown in Fig. 2 and under temperatures (constant to ±0.01 K) over the range of 290—318 K and at almost a 100% humidity. A Wilhelmy

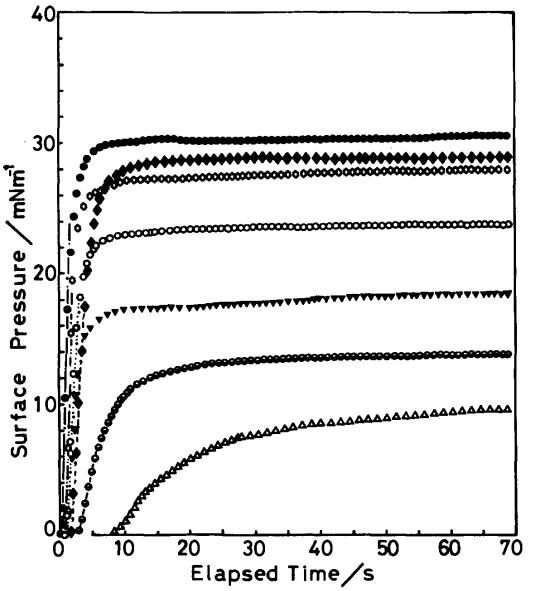

Fig. 3. Time dependences of spreading pressure of tetradecanoic acid crystal on the water surface at various temperatures. Diamond denotes plate-like crystal and other symbols needle-like crystal. △: T=292.1 K, ○: 296.1 K, ▽: 303.1 K, ○: 308.1 K, □: 313.1 K, ● and ◆: 318.1 K.

plate was connected to an electrobalance (Shimadzu Model TGA-31), whose output was in turn connected to a digital multimeter (Hewlett-Packard Model 3478A) and a personal computer (NEC Model PC-8001MKII). Needle-like crystals (or a single crystal of a plate-like form) were introduced onto the clean surface through the hole A (shown in Fig. 2); the surface pressure was recorded every half-second. The sensitivity of the balance was ±0.01 mN m^{-1}, and the reproducibility was ±0.1 mN m^{-1}. A constant surface pressure was obtained 5—10 min after the crystal has been placed onto the water surface; the constancy of the pressure for the plate-like crystal did not change for 120 h, while that for the needle-like crystals varied somewhat with the time. The constant values thus obtained were taken as the apparent ESP (see Table 1).

For desorption experiments on the monolayer at constant surface pressures, we used a Langmuir glass trough (600 mm× 109 mm×57 mm) whose surface has been treated with dimethyldichlorosilane in order to make it hydrophobic. Two glass pipes were set on the bottom of the trough for temperature control (±0.1 K). The surface pressure was also observed by the Wilhelmy plate method. After spreading a monolayer and evaporating the spreading solvent, compression was carried out to a surface pressure below about 0.3 mN m^{-1} of the apparent ESP so as to avoid spontaneous monolayer collapse. This pressure was maintained constant within 0.1 mN m^{-1} by further manually decreasing the area. This area decrease was measured as a function of the time.

Scanning electron micrographic observation (SEM) for the plate-like crystals used in the spreading-pressure experiments was carried out with a JOEL JXA-840 scanning electron microscope.

Results and Discussion

Figure 3 shows the time dependence of the spreading pressure of the tetradecanoic acid crystal introduced at the air/water interface. After a retardation time, the surface pressure Π increased rapidly for a few seconds, followed by a gradual increase before it reached a constant value. The yield point was dependent on the crystal type or on the temperature. In the case of the needle-like crystal at a higher temperature (318.1 K), we could not recognize the retardation time. The yield point was defined as time zero for the spreading process of the molecules from the crystal.

In the six processes illustrated in Fig. 1, the contributions of Processes (4) and (6), i.e., the k_2' and k_3' terms, to the whole system appear to be negligibly small because of the extremely small concentration of the tetradecanoic acid in the water,[2] especially at the initial stage. Furthermore, the k_3 (the desorption constant from the crystal into water) in Process (5) is thought to be smaller than the k_2 (the desorption constant from monolayer into water) in Process (3), for the molecules in the crystal are more ordered and are combined more tightly with one another than the molecules in the monolayer.

Spreading Process. Assuming the first-order mode for every process, the rate equation for the monolayer formation (spreading) is given by:

$$d\Gamma/dt = k_1C - (k_1' + k_2)\Gamma \quad (1)$$

where Γ is the amount of molecules in the monolayer; t, the elapsed time after the yield point of the spreading pressure; C, the amount of crystal directly in contact with the water; k_1, the rate constant for the spreading process of the molecules from the crystal to form the monolayer (Process (1)), and k_1', the rate constant for the re-binding of the molecules to the crystal (Process (2)).

In the initial stage of the spreading from the crystal, the molecular density in the monolayer is so small that Γ can be almost zero. Consequently, Eq. 1 is expressed as:

$$d\Gamma/dt = k_1C \quad (2)$$

In the temperature range of 290—318 K in our experiment, the monolayer of tetradecanoic acid is in the liquid-expanded state.[3,4] For the liquid-expanded film, Langmuir proposed the following equation:[3]

$$(\Pi - \Pi_0)(A - A_0) = RT \quad (3)$$

where Π is the surface pressure (mN m^{-1}): Π_0, the characteristic surface pressure of the film material ($\Pi_0 = -11.2$ mN m^{-1} for tetradecanoic acid[5]); A, the occupied area per mole (m^2 mol^{-1}) of the film material; A_0, the excluded area per mole (m^2 mol^{-1}); R, the gas constant and T, the absolute temperature.

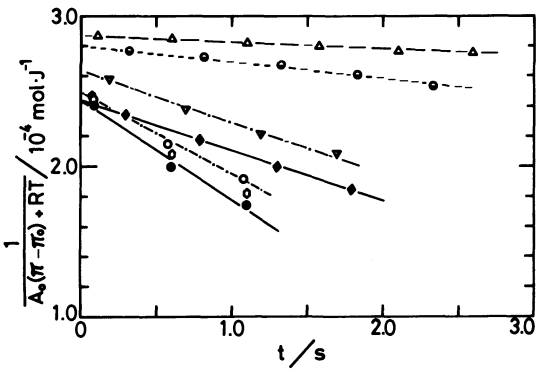

Fig. 4. $1/[A(\Pi-\Pi_0)+RT]$-t relationships for tetradecanoic acid monolayers on 0.01 M HCl at various temperatures. Diamond denotes plate-like crystal and other symbols needle-like crystal. △: T=292.1 K, ○: 296.1 K, ▽: 303.1 K, ○: 308.1 K, □: 313.1 K, ● and ◆: 318.1 K.

Many theoretical equations[6-9] of the state for liquid-expanded monolayers have been proposed; Smith[9] compared the equations with the experimental data for fatty acids and concluded that Langmuir's equation described the experimental data better than any other equation in spite of the variation in Π_0. Consequently, by using Langmuir's equation and by defining $\Gamma = A_T/A$, where A_T is the area of the trough (m^2) containing the subphase solution, we obtain:

$$\Gamma = A_T(\Pi - \Pi_0)/[A_0(\Pi - \Pi_0) + RT] \quad (4)$$

wherefrom we obtain:

$$d\Gamma/dt = (d\Gamma/d\Pi)(d\Pi/dt) = \{A_TRT/[A_0(\Pi - \Pi_0)+RT]^2\}(d\Pi/dt). \quad (5)$$

The substitution of Eq. 2 in Eq. 5 and subsequent integration yield:

$$\{1/[A_0(\Pi - \Pi_0) + RT]\} = -(A_0k_1C/A_TRT)t + 1/(RT - A_0\Pi_0). \quad (6)$$

Figure 4 shows the relationship between $\{1/[A_0(\Pi - \Pi_0) + RT]\}$ and t at various constant temperatures. Good linearities are observed. The slopes for these lines give us k_1C values by the use of A_T=59.17×10^{-4} m^2 and A_0=6022×[12.0+0.178(T−273.15)] m^2 mol^{-1} for the tetradecanoic acid monolayer.[5] The k_1C values thus obtained are listed in Table 1.

The surface pressure, especially at the initial spreading process of the film, is thought to be associated with the number of acid molecules, which are directly in contact with the water, in the crystal. Consequently, we can evaluate the k_1 value only if we know the actual amount of molecules, C.

Figure 5 shows the relationship between the k_1C and the amount of crystal placed on the water surface at 318.1 K. The k_1C value for the needle-like crystals (circle) is always larger than that for the plate-like crystal (square). This may be attributable to the fact that the needle-like crystals have many sharp points[10] at the ends of the crystal, as is shown in the SEM

Table 1. ESP, k_1, k_2, and k_1' Values for the Needle-Like Crystal at Various Temperatures

T	ESP	k_1C	k_1	k_2	k_1'
K	mN m^{-1}	mol·s^{-1}	s^{-1}	s^{-1}	s^{-1}
292.1	14.0	9.96×10^{-10}	13.8	1.2×10^{-5}	2.0×10^{-2}
296.1	16.7	1.81×10^{-9}	25.1	1.8×10^{-5}	5.6×10^{-2}
303.1	20.4	6.15×10^{-9}	85.2	2.8×10^{-5}	19.2×10^{-2}
308.1	24.3	8.08×10^{-9}	112	5.9×10^{-5}	25.3×10^{-2}
313.1	27.0	8.45×10^{-9}	117	33.8×10^{-5}	26.3×10^{-2}
318.1	30.9	8.88×10^{-9}	123	74.0×10^{-5}	27.7×10^{-2}
		5.25×10^{-9}[a]	72.8[a]		

a) These values are for a plate-like crystal.

photograph **A** in Fig. 6, rather than to the difference in the crystallographic forms. The k_1C for the plate-like crystal is independent of the crystal size, while that for the needle-like crystals is also independent of their amounts. Consequently, the number of molecules which are directly in contact with the water seems to be restricted and to be almost constant, regardless of the size or amount of the crystal placed onto the water surface: there is never a time when all the crystal is in contact with the water. In fact, as is shown in the SEM photograph **B** in Fig. 6, the surface of the plate-like crystal used for the spreading-pressure experiment was found to be corroded only partially, even after the crystal has stood on the water surface for 7 days at 318.1 K.

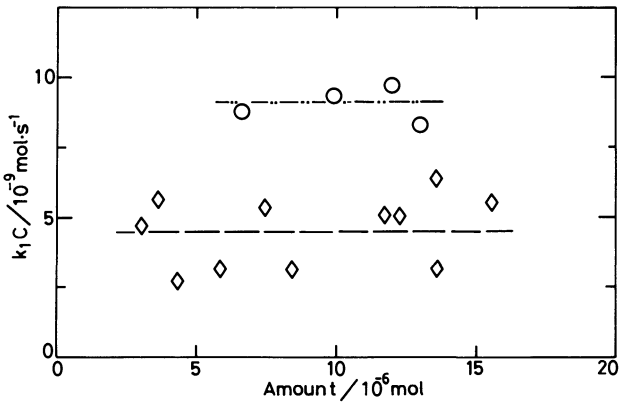

Fig. 5. Relationship between k_1C and amount of crystals placed on water surface at 318.1 K. Circles denote needle-like crystals; diamonds, plate-like crystals.

Although it is essential to know the amount of the molecules, C, directly in contact with the water in the initial stage of the spreading process, the estimation of the genuine amount is impracticable at the present time. Accordingly, a rough approximation was carried out as follows.

C is assumed to be the amount of the molecules in the outermost molecular layer of the crystal facing the underlying water, disregarding the fact that only a part of the crystal surface is directly in contact with the water. The area of the plate-like crystal used in our experiment was determined to be in the range of 7.83—26.7 mm^2 by means of photographic observations. The amount of C for the 7.83 mm^2-sized crystal was estimated to be 7.22×10^{-11} mol by using the cross-section of the 18 Å^2/molecule for the fatty-acid molecule. The k_1 values thus obtained from this C amount at various temperatures are listed in Table 1. Although the ESP increases linearly with the temperature, the k_1 increases in an S-shape. The rapid increase in the k_1 value between 296 and 308 K seems to due not only to the increase in its genuine value, but also to the increase in the wettability of the crystal to water-that is, the increase in the amount of C which is directly in contact with the water. The k_1 value at low temperatures is, therefore, probably smaller than the genuine value because water has a low wettability against the crystal surface because of the higher surface tension of water at low temperatures. The magnitude of k_1 is, however, sufficiently large in comparison with the other rate constants which will be mentioned below.

Desorption Process. In order to estimate the rate constant k_2 in the process of dissolving tetradecanoic acid from its monolayer (Process (3)), desorption

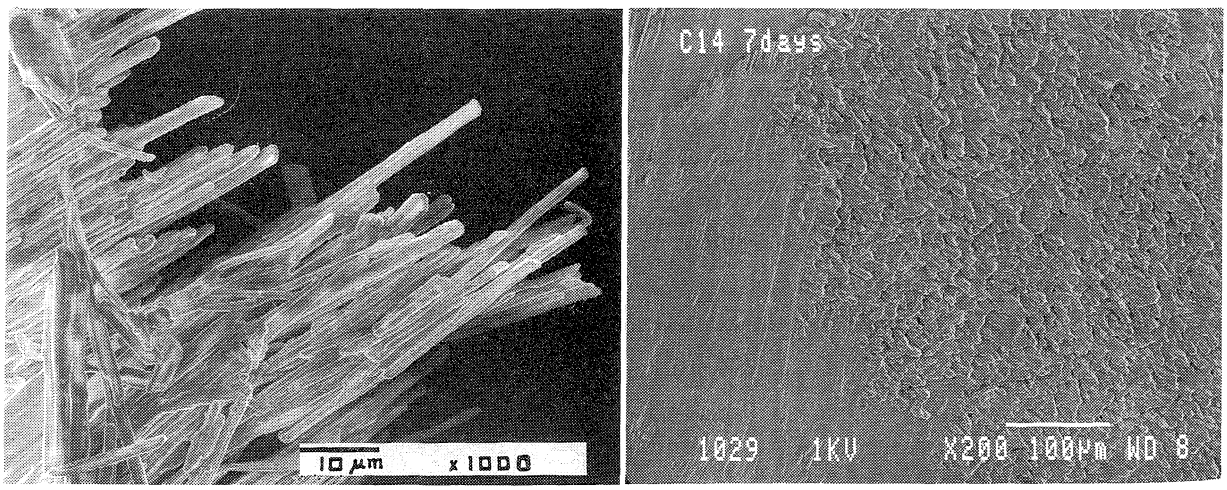

Fig. 6. Photograph **A** represents the needle-like crystals which have sharp ends. Photograph **B** represents a plate-like crystal which was kept for standing on water surface for 7 days at 318.1 K. Only right side of the crystal is corroded.

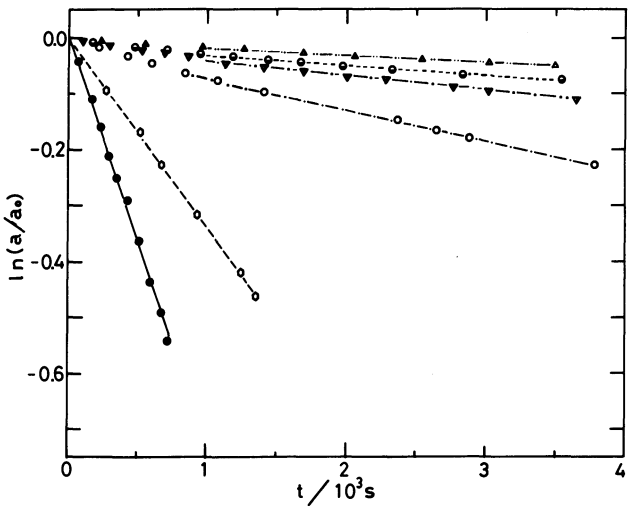

Fig. 7. Desorption performance of tetradecanoic acid from its monolayer into subphase of 0.01 M HCl under 0.3 mN m^{-1} below ESP values at various temperatures. △: T=292.1 K, ◒: 296.1 K, ▼: 303.1 K, ○: 308.1 K, ⬡: 313.1 K, and ●: 318.1 K.

experiments on the tetradecanoic acid monolayer were carried out under the conditions of constant surface pressures and at various temperatures. In Fig. 7, the logarithm of the relative area, $\ln(a/a_0)$, is plotted against t, in which a_0 is the initial area of the monolayer immediately after the monolayer had been compressed to a desired surface pressure, and a, the area of the monolayer at time t. The desorption curve for an experiment at a low temperature has two parts: a curved part at the beginning and a linear one for a higher value of t, as has also been reported by Ter Minassian-Saraga.[10] That is to say, the first desorption stage (shown as a curved part) is diffusion-controlled, while the second one (shown as a linear part) is steady-state. At lower temperatures the steady-state commences at t=ca. 15 min, while at higher temperatures it appears to begin immediately. The rate constant k_2 of the dissolving process was consequently obtained from the $\ln(a/a_0)$ vs. t relationship in the steady-state; it also is listed in Table 1. The k_2 value is found to increase very rapidly with the temperature above 308 K.

Re-binding Process. Next we must consider the re-binding process of the film molecule to the crystal (Process (2)). The variation in the surface concentration of the acid molecules, $d\Gamma/dt$, expressed by Eq. 1, is zero after the spreading pressure becomes constant:

$$d\Gamma/dt = k_1C - (k_1' + k_2)\Gamma_s = 0 \quad (7)$$

where Γ_s is the saturated amount of molecules in the monolayer possessing the area of A_T. Consequently, k_1' is expressed as:

$$k_1' = (k_1C/\Gamma_s) - k_2. \quad (8)$$

The Γ_s value for an insoluble monolayer is, in general, obtainable as the inverse of the molar area of the monolayer at the ESP in its Π–A relationship. The Γ_s for the tetradecanoic acid monolayer at 318.1 K could not be, however, obtained from its Π–A relationship because of the rapid dissolving of the monolayer into the underlying subphase solution. Therefore, by substituting the values of A_t, A_0, Π (ESP), and Π_0 into Eq. 4, the Γ_s value was obtained. For example, the Γ_s value thus obtained at 318.1 K was 3.19×10^{-8} mol, the molecular area being 30.8 Å^2/molecule. This value is reasonable for the acid monolayer at that temperature. On the other hand, the value of C, 7.22×10^{-11} moles, used for the evaluation of the k_1 value seems to be too small compared with this Γ_s value. The C value is, however, the molar amount of the acid in the outermost molecular layer of its crystal directly in contact with the water surface. Even if the outermost layer is desorbed from the crystal into the monolayer, the next layer will appear continuously.

The k_1' value obtained from k_1C, k_2, and Γ_s is also listed in Table 1. When comparing these rate constants with one another, the k_1 is found to be much larger than k_2 at various temperatures. Therefore, the constant spreading pressure, even at high temperatures, at which the monolayer dissolves into the subphase very rapidly, can be regarded as a property in the equilibrium state, namely, the ESP.

The authors wish to express their thanks to Professor Koichi Kobayashi and Mr. Akira Yoshida of Musashi Institute of Technology for their technical help in performing the SEM observations. The present work was supported by a Grant-in-Aid for Scientific Research from the Ministry of Education.

Formulation and Enumeration of Five-Center Organic Reactions

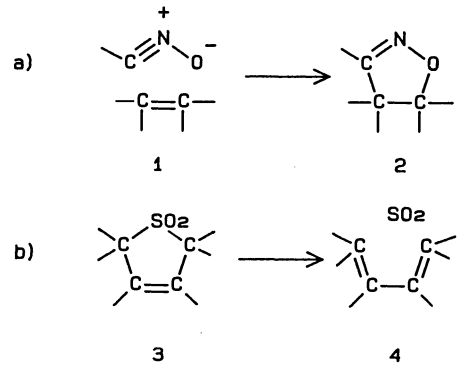
Shinsaku FUJITA
Research Laboratories, Ashigara, Fuji Photo Film Co., Ltd.,
Minami-Ashigara, Kanagawa-ken 250-01
(Received July 30, 1988)

Five-center organic reactions are formulated in the form of pentagonal reaction-center graphs (RCC's) that are subgraphs of imaginary transition structures. This formulation is based on the concept of a charge space that affords rational representations of coordinate bonds. Pólya's theorem is applied to the enumeration of these RCG's, in which the obligatory minimum valencies of vertices restrict the mode of substitution.

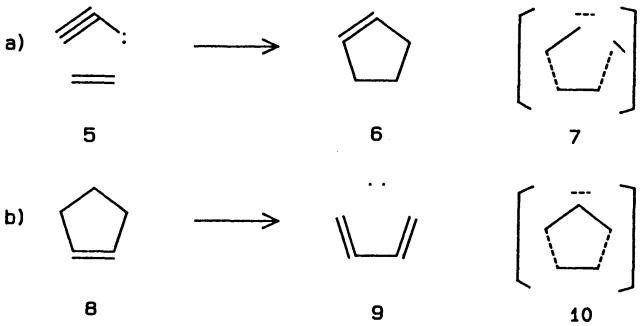
The enumeration of reaction types is important for any computer manipulation of organic reactions. In previous papers,[1] we have reported on the enumeration of generic reaction types in the form of the counting of reaction graphs (RG's) that are defined as subgraphs of imaginary transition structures (ITS's).[1b,c] Thus, we have enumerated pentagonal RG's, which represent five-center organic reactions, such as 1,3-dipolar additions and cheletropic reactions.[1c] However, the enumeration of RG's has disregarded the variation of atoms that occupy the vertices of the RG's and has, thus, been limited within the counting of modes of bond-switchings. For an effective manipulation of organic reactions, it is necessary to count more specific reaction types that define the variation of the atoms as well as the modes of bond-switching. This can be accomplished by counting the reaction-center graphs (RCG's) of the pentagonal class. In a continuation of the enumeration of hexagonal RCG's,[1n] this paper will discuss that of pentagonal RCG's.

A Charge Space for Representing Coordinate Bonds in the Imaginary Transition Structure Approach. In an enumeration of such five-center organic reactions, one of the most troublesome problems is in the treatment of coordinate bonds (Scheme 1). Although many approaches have been devoted to this problem, none of them have ever resulted in a comprehensive solution. For example, Ugi et al.[2] have expressed reactions (1a) and (1b) with graphs (**7** and **10**, respectively) in the most abstract fashion (Scheme 2). They have ascribed the two graphs (**7** and **10**) to irreducible reaction matrices (R-matrices) that are presumed to represent five-membered cyclic processes. However, expression (**7**) disregards the presence of a coordinate bond, which is in turn replaced by lone pairs on the terminal atoms. In other words, graph (**7**) and the corresponding R-matrix indicate an acyclic process in their strict sense. Although they had intended to classify **7** and **10** into the same class, this classification requires the presupposition of an implicit invariant bond. If the implicit invariant bond is neglected, just as the graph (**7**) indicates, there would be no good reason to classify reactions **7** and **10** into the same class.

Hendrickson's representations for five-center reactions[3] are equivalent to the formulas (**7** and **10**) in an abstract fashion. Hence, his method has the same drawback as that mentioned as above, although it claims that both of the two formulas represent pericyclic five-center reactions. Vladutz[4] has presented a participating charge with a special symbol placed on an atom. Zefirov et al.[5] have treated a charge as an independent node (vertex). These methods permit an ionic representation as well as the covalent one, where both of the two representations are legitimately alternative forms and, in other words, are not integrated. Brandt el al.[6] have adopted Ugi's R matirices along with the same representation of charges as Vladutz's one. Although these approaches have described the appearance and disappearance of charges, they have paid little attention to the difficulty concerned with coordinate bonds and the dual character of a bond (i.e. the covalent vs. ionic character). Dubois et al.[7] have reported the concept of chromatic transfographs,



Scheme 1.



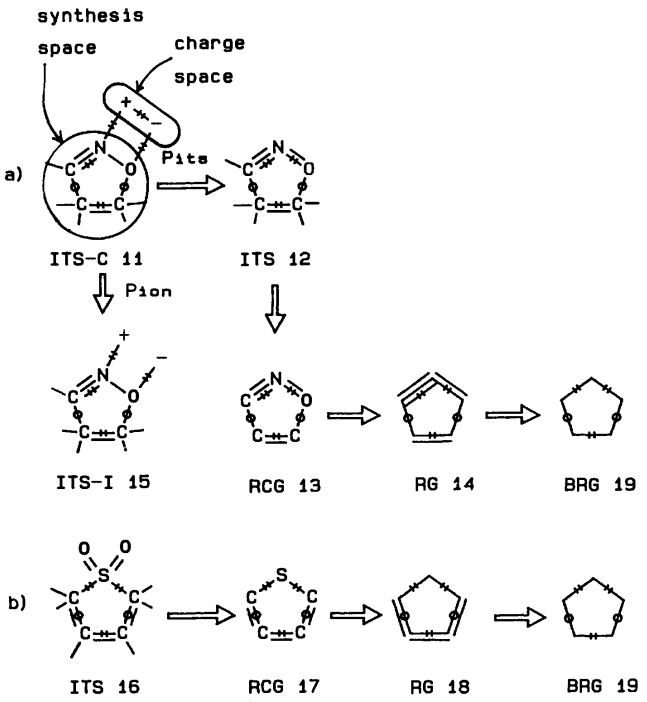
Scheme 2.

which also pays no attention to charges and abnormal valencies.

In order to settle the problem, the ITS approach has introduced a charge space that is attached to a synthesis space (Scheme 3).[1h] The synthesis space contains all nodes that represent atoms or groups participating in a reaction. The charge space consists of charges that are regarded as independent nodes. These nodes (atoms and charges) are linked by par-bonds (——), in-bonds (-⊖-), and out-bonds (-⊣⊢-) in accord with any structural changes during a reaction. The resulting structural formula is called a *full ITS* or an *ITS with charges.* The concept of charge space thus allows us to described a 1,3-dipolar reaction (Scheme 1a) in light of a full ITS (**11**). This type of representation is an integrated representation of covalent and ionic characters (Scheme 3). Thus, the ionic representation (e.g. N^+–O^-) of a coordinate bond and the covalent counterpart (e.g. N=O) are interconvertible to one another via the full ITS (e.g. **11**).

The corresponding ITS (**12**) is obtained by projecting to an ITS (P_{its}), which is a deletion of interspace bonds[8] and of charges and a simultaneous attachment of the intraspace bonds[9] to the respective edges. A corresponding ionic representation (**15**) can be generated by projecting to an ionic ITS (P_{ion}) that deletes the bonds of a charge space.

The graphic representations collected in Scheme 3 may be unfamiliar to organic chemists who used to discuss organic reactions in terms of the usual reaction diagrams. To convert an ITS representation into a reaction diagram, projections to the starting stage and to the product stage (PS and PP) are introduced. The PS operation represents a deletion of all in-bonds. This operation regenerates the starting stage. The PP operation, on the other hand, represents a deletion of all out-bonds, the operation of which creates the product stage.



Scheme 3.

In the enumeration procedures of the ITS approach, the covalent representation of a bond is preferred rather than the ionic one.[1c] This methodology can be rationalized by the indroduction of a charge space and by the defining of the P_{its} and P_{ion} operations.[1h] The preference of the covalent character has an advantage in that this overcomes an apparent difference provided by the dual representation of the bond character. Note, for example, that though the ionic repesentation ($N^+(=O)$–O^-) of a nitro group indicates the unequality of the two oxygen atoms in the literal sense, the covalent representation ($N(=O)_2$) equalifies them.

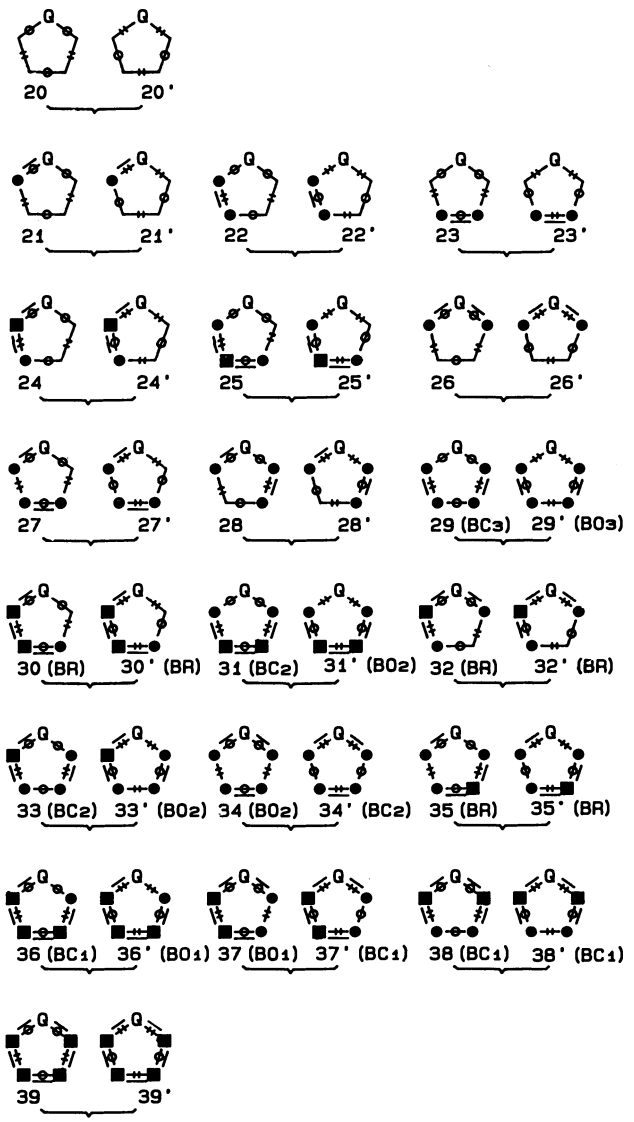
In light of the ITS's extended in this section, a general treatment of five-center reactions is available. As shown in Scheme 3, reaction (1b) is represented by an ITS (**16**) in the usual fashion, since it contains no charge space. Reactions (1a) and (1b) (Scheme 1) produce the corresponding RCG's (**13** and **17**) and RG's (**14** and **18**). The latter pair affords a common basic reaction graph (BRG **19**), which logically indicates that the two reactions belong to the same category of pentagonal class.[10]

Enumeration of Pentagonal RCG's. The present method that enumerates RCG's consists of the following steps:[11,12] (1) finding the permutation group of a parent RG, (2) considering the obligatory minimum valency (OMV) of each vertex (node), (3) obtaining the corresponding cycle index, and (4) substituting the variables of the cycle index by appropriate atom-figure inventories to afford an RCG-counting polynomial as a generating function.

Table 1 lists parent RG's of the pentagonal class.[1c] There are no self-reaction pairs[13] in this series. Each of the RG's has one vertex to which two out-bonds (or two in-bonds) are incident. We call this a valency-changed position (or vertex) because of its chemical meaning. For simplicity of discussions, we suppose that an atom Q always occupies the valency-changed position of each parent RG (Table 1). Several examples for atoms Q are collected in Table 2. The expressions of expanded valencies listed in Table 2 have a sound basis by means of a charge space. The present approach is capable of producing both the covalent representation and the ionic one with the appropriate projections (Scheme 3). The ITS approach permits a quinquivalent nitrogen, a quadrivalent oxygen and so on in the level of ITS's projected from full ITS's.

Positions other than a valency-changed atom undergo ordinary interconversions in which one in-bond and one out-bond are attached to each of the positions.

Table 1. Parent Reaction Graphs of Pentagonal Class That Have 0 to 5 Single Par-Bonds and Are Occupied by an Atom Q[a-c]



a) The positions marked by ■, ●, and none have minimum valencies of v=3, 2, and 1, respectively. b) Each couple linked with a brace is a reaction pair (an RG pair). There are no self-reaction pairs. c) BO_p is a bridge of ring opening of order p. BC_q is a bridge of ring closure of order q. BR is a bridge of rearrangement.

Their obligtory minimum valencies (OMV) are v=1 (unmarked), v=2 (marked with ●), or v=3 (marked with ■) in accord with the substitution of par-bonds. The unmarked positions are substituted by any atoms that have a valency of larger than 1. We choose carbon, hydrogen, oxygen, and nitrogen atoms as substituents in order to simplify the following discussions. Any position marked with ● (v=2) is capable of taking C, N, or O, but incapable of taking a hydrogen atom. Each position of v=3 (■) is capable of having C or N as a substituent.

a) The parent RG's are collected in Table 1. b) G: a cycle index for counting RCG's.

The OMV requires an extension of Pólya's theorem, in which positions of different OMV's take different atom-figure inventories.[1n] Table 3 summarizes the cycle indices corresponding to the parent RG's of Table 1, where variables a_r, b_r, and c_r are assigned to the vertices marked by ■, ●, and none, respectively.[14]

If the variables of the cycle indices (Table 3) are substituted by atom-figure inventories (Eqs. 21 to 23), RCG-counting polynomials are obtained as generating functions:[15]

$$a_r = 1 + u^r, \tag{21}$$

$$b_r = 1 + u^r + v^r, \tag{22}$$

and

$$c_r = 1 + u^r + v^r + w^r. \tag{23}$$

Table 5. RCG Isomers with N_2O Based on **36**, **37**, and **38**

Parent RG	RCG with N_2O
36	37	38	
Equation 21 is an atom-figure inventory for counting the modes of C and N substitution, where a variable for C is not expressed explicitly. Equation 22 enumerates the modes of C, N, and O substitution. The modes of C, N, O, and H substitution are counted by Eq. 23. The coefficients of the RCG-counting polynomial series are collected in Table 4, in which each column is in accord with a given parent RG, each line indicates the powers (i, j, and k) and their intersection is the coefficient of the $u^i v^j w^k$. This value is the number of RCG isomers with i nitrogens, j oxygens, and k hydrogens ($N_iO_jH_k$).

Table 5 shows RCG isomers derived form parent RG's (**36**, **37**, and **38**) by N_2O substitution. The number of RCG isomers from **36** is 3, which is found at column **36** and line i=2, j=1, and k=0 in Table 4. The number of RCG isomers derived from **37** and **38** are also listed in Table 4.

Table 6 collects parent RG's in which a pentagonal basic reaction graph (BRG **19**) has one double par-bond and two single par-bonds. One Q atom preoc-

cupies the valency-changed position of each of the RG's. The other positions are discriminated by their OMV's (i.e. ▲ for v=4, ■ for v=3, ● for v=2, and none for v=1).

Table 7 summarizes the cycle indices corresponding to the respective RG's of Table 6. Each of the cycle indices contains variables selected from a_r (for v=3), b_r (for v=2), and c_r (for v=1). The position marked by ▲ can be substituted only by a carbon atom and, hence, takes no variables in the present treatment. If the

Table 8. RCG Isomers with One Oxygen on **34′**, **50′**, and **52′**

34′	50′	
52′	
variables (a_r, b_r, and c_r) of each cycle index (Table 7) are substituted by the atom figure inventories (Eqs. 21 to 23), the corresponding RCG-counting polynomial is obtained as a generating function for each case. The coefficient of the term $u^iw^jw^w$ in the RCG-counting polynomial indicates the number of RCG isomers having $N_iO_jH_k$.

Table 8 compares the RG's (**34′**, **50′**, and **52′**) substituted by one oxygen. The number of isomeric RCG's based on each of the RG's emerges as the coefficient of term v in an RCG-counting polynomial derived from Eq. 15, 34, or 36.

Conclusion

Five-center organic reactions are formulated in the form of pentagonal reaction-center graphs (RCG's). These RCG's are enumerated by extending Pólya's theorem, so that different variables are assigened to the vertices of each parent reaction graph (RG) in accord with the obligatory minimum valencies of the vertices.

Study of Conformers of 2,2′-, 3,3′-, and 4,4′-Dimethylbiphenyls in the Phosphorescent Triplet States by Electron Spin Resonance and Phosphorescence

Katsumi TANIGAKI,† Noriyuki TAGUCHI, Mikio YAGI, and Jiro HIGUCHI*
Department of Physical Chemistry, Faculty of Engineering, Yokohama National University, Tokiwadai, Hodogaya-ku, Yokohama 240
(Received August 13, 1988)

For the phosphorescent triplet (T_1) states of symmetrically-substituted dimethylbiphenyls, the relationship between the twisting angle of the two aromatic rings and the zero-field splitting parameters is discussed in terms of the ESR spectra. Two sets of ESR spectra observed for 2,2′- and 3,3′-dimethylbiphenyls (2DMBP and 3DMBP) are precisely assigned to the corresponding s-cis or s-trans conformer. The results clarify the inadequate assignment of the spectra of these molecular species in the previous literature. The lifetime obtained for the s-cis conformer is different from that of the s-trans one for both 2DMBP and 3DMBP. Examining the T_1–T_1 energy transfer from one conformer to the other, the relative locations for the T_1 states of s-cis and s-trans conformers are obtained, even if phosphorescence measurements do not provide each isolated spectrum: E_T (*s-cis*-3DMBP)<E_T(*s-trans*-3DMBP) and E_T(*s-cis*-2DMBP)>E_T(*s-trans*-2DMBP).

The geometry of biphenyl (BP) has been discussed under different conditions. In the ground (G) state BP is a nonplanar molecule and its twisting angle between the two phenyl rings is 20—40° in the vapor phase and in solutions,[1,2] while it is zero (or nearly zero) in a crystal.[3,4] In the lowest excited triplet (T_1) state, however, BP has been clarified to be planar[5,6] by the phosphorescence and T_n←G absorption measurements[7] as well as photochemical quenching data.[6] Several theoretical calculations[8–10] have supported the coplanar structure between two phenyl rings of BP in its T_1 state.

In the T_1 states, s-cis and s-trans conformers have been detected by ESR for some of biphenyl derivatives and their related molecules. For the ESR spectra of 2,2′-bipyridine (BPY), the s-cis and s-trans conformers are detectable.[11–13] However, their twisting angles (θ's) between the two aromatic rings are nearly zero, and one of the zero-field splitting (ZFS) parameters, D, is almost the same for both conformers.[11–13] As a result, the influence of any deviation from a coplanar structure upon the ZFS parameters could not be experimentally obtained. On the other hand, the dimethylbiphenyls (DMBP's)†† are actually suitable examples in examining such an influence, since θ is expected to be changed without any large affection of the electronic structures upon the positions of the methyl substituents. Fourteen years ago, Scheve and Wagner[14] studied the ESR of the T_1 states of methyl-substituted biphenyls and found two sets of conformers for some of the DMBP's, although their assignment to the conformation is still uncertain. Their result is distinctly contradictory to the theoretical prediction that the D value decreases with increasing θ. Under these circumstances, we tried to reexamine the ESR of the symmetrically-substituted DMBP's.

In the present paper, we report on the ESR and phosphorescence of symmetrically-substituted DMBP's. For 2DMBP and 3DMBP, two sets of observed ESR spectra have been assigned to the corresponding s-cis and s-trans conformers using a stretched poly(vinyl alcohol) (PVA) film as a host. The spectra obtained for 2DMBP are remarkably different from those reported by Scheve and Wagner.[14] The relationship between the ZFS parameters and θ of the conformers will be discussed.

The ESR spectra observed in the T_1 states of DMBP's are interpreted by the following spin Hamiltonian:

$$\begin{aligned}\mathscr{H} &= g\mu_B \boldsymbol{B}\cdot\boldsymbol{S} + \boldsymbol{S}\cdot\boldsymbol{D}\cdot\boldsymbol{S} \\ &= g\mu_B \boldsymbol{B}\cdot\boldsymbol{S} - XS_x^2 - YS_y^2 - ZS_z^2 \quad (S=1) \\ &= g\mu_B \boldsymbol{B}\cdot\boldsymbol{S} + D[S_z^2 - (1/3)S^2] + E[S_x^2 - S_y^2]:\end{aligned}$$

where $\boldsymbol{D}(x,y,z)$ is the ZFS tensor with principal values ($-X$, $-Y$, and $-Z$) and principal axes (x,y,z). D and E denote the ZFS parameters and are related to ($-X$,$-Y$,

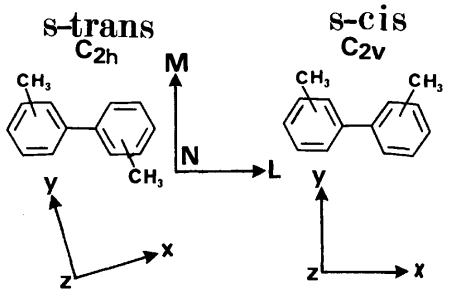

Fig. 1. Molecular structures and coordinate systems for DMBP's: Molecular axes (L,M,N), $\boldsymbol{D}$ tensor axes (x,y,z).

† Permanent address: Fundamental Research Laboratories, NEC Corporation, 1-1, Miyazaki 4-chome, Miyamae-ku, Kawasaki 213.

†† In the present paper, 2,2′-, 3,3′- and 4,4′-dimethylbiphenyls are abbreviated as 2DMBP, 3DMBP, and 4DMBP, respectively.

$-Z$) by $D=(-3/2)Z$ and $E=(-1/2)(X-Y)$. The other symbols have their usual meanings. The anisotropy of the g tensor is neglected since the observed ESR spectra could be reasonably analyzed with the isotropic g_e for free electrons.

For the planar conformation of DMBP's in their T_1 states, the principal axes of $\boldsymbol{D}(x,y,z)$ and the molecular axes (L,M,N) are taken to be as shown in Fig. 1. For $\boldsymbol{D}(x,y,z)$, the x-axis is relatively close to the longest direction of the molecule, the y-axis is perpendicular to it in the molecular plane and the z-axis is normal to the molecular plane. For the molecules treated here, L is parallel to the central C–C bond that connects two of the same aromatic rings, M is perpendicular to it in the molecular plane, and N is normal to the molecular plane. For a stretched PVA film, s is the stretched direction, c is perpendicular to it in the film plane, and n is normal to the film plane.

Experimental

4,4′-Dimethylbiphenyl (Tokyo Kasei) was purified two times by recrystallization from its ethanol solution. 3DMBP (Tokyo Kasei) was distilled under reduced pressure (bp=114—115 °C/400 Pa). 2DMBP (Tokyo Kasei) was distilled under reduced pressure (bp=90 °C/153 Pa) and was further purified with a silicagel (Kanto Chemicals C-200) column using hexane as an elutant (more than five times). Three unremovable impurities still remained after only distillation. Two of them could be easily removed by column purification, though the other was very difficult to remove. At least four column purifications were required in order to obtain pure 2DMBP, which is sufficient for ESR and phosphorescence measurements. Hexane was the best elutant among the solvents studied. The solvents suitable for a rigid glass medium, ethanol (Wako S.S.G.) and methylcyclohexane (Dotite Spectrosol), were used without further purification after being carefully checked for the absence of an extraneous ESR and phosphorescence signals prior to use.

The purity of 2DMBP and 3DMBP was checked by gas chromatography (GC) with a Shimadzu GC-4A apparatus using a Shimadzu SE-30 column. They exhibited a single peak after purification (more than 99.95%). No impurities were spectroscopically detected for 4DMBP and BP by phosphorescence and ESR measurements.

The PVA films containing 2DMBP, 3DMBP, or 4DMBP were prepared following the same method as described previously.[15] The PVA sample films were prepared by the diffusion method using methanol solutions.[16] The standard concentrations of the 4DMBP, 3DMBP, and 2DMBP solutions used were 1.0×10^{-3}, 8.9×10^{-4}, and 8.3×10^{-3} mol dm^{-3}, respectively. The concentrations of the sample solutions for 3DMBP and 2DMBP were chosen in order to obtain the nearly equal intensities of spectra between s-cis and s-trans conformers. The PVA films obtained were stretched at 80 °C with Shibayama SS-60 film stretcher. The films, thus obtained, have about 200% of stretch in the stretched direction s.

Sample-cooling was controlled by the penetration rate of a quartz tube (5 mm o.d.) into liquid nitrogen from rapid cooling to 0.042 mm s^{-1}. For the magnetophotoselection experiments, a Glan-Thompson polarizer was placed between the Xe-Hg lamp and the sample cavity.

The ESR and phosphorescence spectra were measured at 77 K in the same way as reported previously.[13]

Results

The ESR spectrum of $\Delta M_S=\pm1$ transitions for the T_1 state of 4DMBP was measured in an ethanol glass, as shown in Fig. 2a. For the assignment of the observed signals to the corresponding magnetic principal axes of $\boldsymbol{D}(x,y,z)$, we measured the ESR spectra using a stretched PVA film as a host. According to the general relationships concerning the orientation of planar guest molecules in the stretched PVA films,[15,16] the assignment of the observed signals is straightforward, as shown in Figs. 2b ($\boldsymbol{B}//\boldsymbol{s}$) and 2c ($\boldsymbol{B}//\boldsymbol{n}$). As a result, we can reasonably assign all of the observed signals, as indicated in Fig. 2a.

For 3DMBP, the ESR of $\Delta M_S=\pm1$ transitions was measured in an ethanol glass. As shown in Fig. 2d, we clearly observed two sets of spectra, which are ascribed

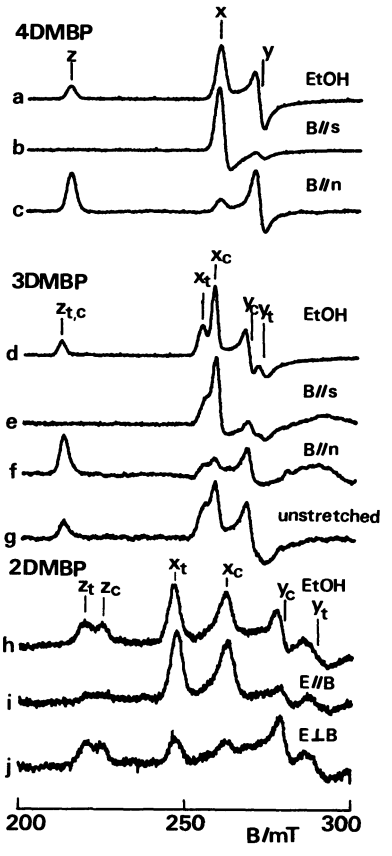

Fig. 2. ESR spectra of the low field $\Delta M_S=\pm1$ transitions for the T_1 state of 4DMBP in ethanol (a) and in PVA films [$\boldsymbol{B}//\boldsymbol{s}$ (b) and $\boldsymbol{B}//\boldsymbol{n}$ (c)], 3DMBP in ethanol (d) and in PVA films [$\boldsymbol{B}//\boldsymbol{s}$ (e), $\boldsymbol{B}//\boldsymbol{n}$ (f) and unstretched (g)], and 2DMBP in ethanol with no polarization (h) and in ethanol with $\boldsymbol{E}//\boldsymbol{B}$ (i) and $\boldsymbol{E}\perp\boldsymbol{B}$ (j).

to the s-cis and s-trans conformers. The spectra resembled those reported by Scheve and Wagner.[14] As in the case of 4DMBP, the observed signals were reasonably assigned to the corresponding magnetic principal axes of $\boldsymbol{D}(x,y,z)$ using a stretched PVA film as a host,[15,16] as shown in Figs. 2e and 2f.

In a randomly oriented rigid glass, the assignment of two sets of spectra to the corresponding s-cis and s-trans conformers is generally impossible. Here, we tried to assign the observed two sets of spectra to the corresponding conformers with the help of the orientation of guest molecules in stretched PVA films.[11] For the s-cis conformer with symmetry C_{2v}, the principal x-axis is parallel to L ($x//L$), while that of the s-trans one with symmetry C_{2h} should deviate from L to some extents. When $\boldsymbol{B}$ is applied parallel to s ($\boldsymbol{B}//s$), the intensity of the x-signal for the s-cis conformer would be more enhanced than that for the s-trans one. For 3DMBP, the relative intensity of the x-signal at 260 mT to that at 256 mT was enhanced in stretched PVA films with $\boldsymbol{B}//s$ [Fig. 2e], compared with that in unstretched PVA films [Fig. 2g]. As a result, a set of signals belonging to the x-signal at 260 mT was assigned to the s-cis conformer, and the other set of signals belonging to the x-signal at 256 mT was assigned to the s-trans one. The assignment carried out in this work disagrees with that by Scheve and Wagner,[14] possibly because of their unreasonable postulation that the larger anisotropic electron distribution in the molecular plane is for the s-cis conformer.

For 2DMBP, two sets of ESR spectra were also observed in an ethanol glass as shown in Fig. 2h. However, these obtained spectra were markedly different from those reported by Scheve and Wagner.[14] Furthermore, no dependence of cooling rate on the relative intensity between the two sets of spectra was found in our experiments (see, Experimental section), which is also contradictory to their report.[14] ^{1}H NMR and GC measurements supported that 2DMBP used here is extremely pure (more than 99.95%). In their ESR measurements, therefore, some impurities might be incorporated and their assignment on the basis of the cooling rate dependence seems to be meaningless.

We tried to assign the two sets of spectra to the corresponding s-cis or s-trans conformer, and each signal to the principal axes of $\boldsymbol{D}(x,y,z)$ using the stretched PVA film method. However, 2DMBP was tremendously difficult to incorporate into PVA films to obtain an ESR spectrum with sufficient intensity, even if a high concentration of 1.0×10^{-2} mol dm^{-3} was adopted. For the assignment of the principal axes of $\mathbf{D}(x,y,z)$, therefore, we used the magnetophotoselection method.[17] The main excitation path for 2DMBP is associated with the absorption of a strong band centered at around 250 nm, which shows mainly a long-axis polarization.[18] Therefore, the transition moment of 2DMBP at the wavelength of the exciting light used in this experiment is considered to be parallel (or nearly parallel) to L. If the electric vector of the exciting light ($\boldsymbol{E}$) is parallel to $\boldsymbol{B}$ ($\boldsymbol{E}//\boldsymbol{B}$), the x-signals would be more enhanced than the other signals and be easily distinguishable from the others. As shown in Figs. 2i and 2j, the signals at 249 mT and 264 mT were more enhanced than the others with $\boldsymbol{E}//\boldsymbol{B}$, indicating that these two signals are x-signals. The two sets of outer signals are assigned to the z-signals, since the character of the T_1 states of 2DMBP should not be largely different from that of BP because of the D values of ca. 0.1 cm^{-1} and the lifetimes of 2—4 s. The assignment of these two sets of spectra to the s-cis and s-trans conformers will be described in the following paragraph.

The ZFS parameters and the lifetimes obtained in the present work are listed in Table 1, including the D^* values obtained from the B_{min} signals. The D values are considered to be closely related to the twisting angle between two aromatic rings. From this table, the $|D|$ values for the s-cis and s-trans conformers of 3DMBP are almost identical within the resolution of our experiments and are close to that of 4DMBP. This

implies that the twisting angle of the T_1 state of 3DMBP is nearly the same and possibly zero for both s-cis and s-trans conformers. On the other hand, one of the $|D|$ values observed for 2DMBP was especially small among those for the other DMBP's and BP, while the $|D|$ value of the other species is slightly smaller than those for the other DMBP's and BP. The twisting angle of the *s-cis*-2DMBP is considered to deviate substantially from zero due to the large repulsion between the two methyl substituents, though its deviation of *s-trans*-2DMBP would be small. From this consideration, the different features of one ESR spectrum from that of the others lead us to its assignment to the s-cis conformer.

The $|E|$ values for the s-cis conformers were smaller than those for the s-trans ones for both 3DMBP and 2DMBP. For a planar conformation, if the coordinate system is chosen to be in the same direction of the molecular axes (*L,M,N*), the nonzero off-diagonal elements of the ***D*** tensor appear only for the s-trans conformers with C_{2h}, while all of the off-diagonal elements are zero for the s-cis ones with C_{2v} from the viewpoint of their symmetries.[11] From this consideration, the $|E|$ value for the s-cis conformers should be smaller than that for the s-trans ones if the electron spin distribution is not much different from each other. The tendency of the $|E|$ values observed for 3DMBP would be simply explained by this analysis. For a discussion concerning 2DMBP with a nonplanar conformation in the T_1 state, a similar relationship is also valid, although further studies of other 2,2′-disubstituted biphenyls are required.

The lifetimes in the T_1 states of DMBP's were obtained from the decay of the low-field *x*-signals of the ESR spectra. All decay's were exponential over at least three times the lifetimes (within experimental error). For 3DMBP, the lifetime of the s-cis conformer (4.2 s) was different from that of the s-trans one (4.5 s). Although the difference was very small, it was beyond the experimental error. For 2DMBP, the lifetime of the s-cis conformer (2.2 s) was almost half of that of the s-trans one (4.6 s). The difference was quite large. Considering that the T_1 lifetimes of DMBP's except *s-cis*-2DMBP are very close to that of BP, the twisting angle of only *s-cis*-2DMBP would deviate to a great extent from zero, due to a steric hindrance between the two methyl groups.

The phosphorescence spectra for DMBP's were measured in ethanol at 77 K, as shown in Fig. 3. Especially for 2DMBP, the phosphorescence spectrum was very broad and did not show any vibronic structure. We could not isolate the phosphorescene of s-cis and s-trans conformers for both 2DMBP and 3DMBP. From the edge of the high-energy region, as well as the 0-0 bands of the phosphorescence, we estimated the locations of the T_1 states (E_T) for DMBP's and BP in the order of E_T(2DMBP)>E_T(BP)>E_T(3DMBP)~E_T(4DMBP).

The lifetimes for DMBP's in the T_1 states were also measured from the decay of phosphorescence. BP and 4DMBP showed the same lifetimes as those obtained by ESR (within experimental error). The decay of 3DMBP was almost single exponential at any wavelength monitored; however, it could not be discussed in detail because of the overlapping of the two types of phosphorescence with very close lifetimes of s-cis and s-trans conformers. On the other hand, 2DMBP showed a nonexponential decay because of the coexistence of the conformers with appreciably different lifetimes.

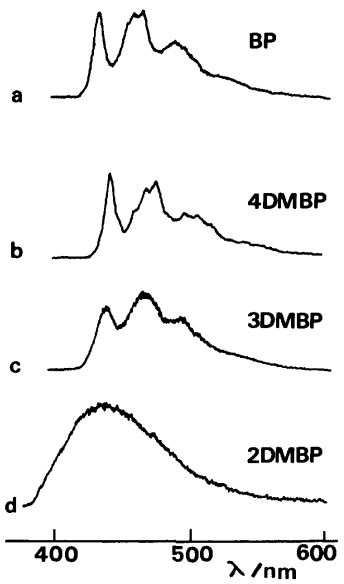

Fig. 3. Phosphorescence spectra of BP (a), 4DMBP (b), 3DMBP (c), and 2DMBP (e) in ethanol at 77 K.

Discussion

An important question to be argued concerns the state, from which the s-cis and s-trans conformers detected in the T_1 states are formed. There are two possibilities: one is that these conformers are formed from the two species in the G states trapped in a rigid medium prior to excitation; the other is that they are formed in the excited states, S_1 and/or T_1, through the conformational change after excitation, even if a species with only one conformation is trapped in a rigid medium. Information related to this problem is provided by the dependence of the excitation wavelength and the kind of rigid media upon the ESR signal intensity ratio between the s-cis and s-trans conformers.

For 3DMBP the ESR spectra were measured in ethanol with various filter combinations. The results are shown in Figs. 4a—4c. The intensity of the ESR signal for the s-trans conformer relative to that for the s-cis one decreased under lower energy excitation. This indicates that two kinds of species with different

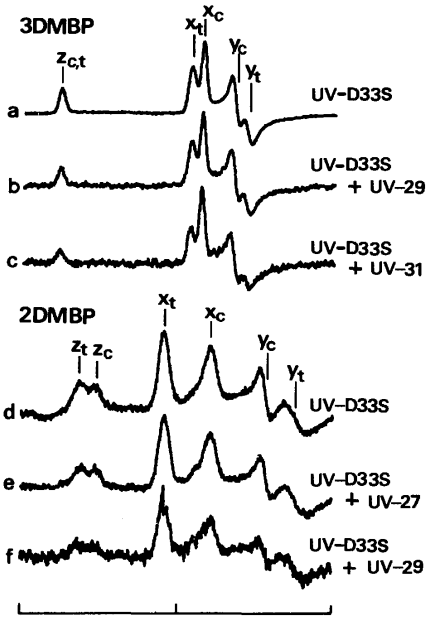

Fig. 4. ESR spectra of the low field $\Delta M_S=\pm 1$ transitions for the T_1 state of 3DMBP in ethanol with UV-D33S (a), UV-D33S+UV-29 (b) and UV-D33S+UV-31 (c) excitation, and for 2DMBP in ethanol with UV-D33S (d), UV-D33S+UV-27 (e) and UV-D33S+UV-29 (f) excitation. The filters used, UV-D33S, UV-27, UV-29, and UV-31, cut off the shorter wavelength region and have transmittances of 50% at $\lambda\approx 255$, 270, 290, and 310 nm, respectively. The UV-D33S filter also cuts off the longer wavelength region and has a transmittance of 50% at $\lambda=$ 385 nm.

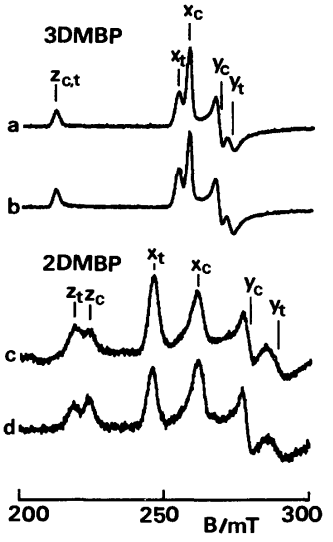

Fig. 5. ESR spectra of the low field $\Delta M_S=\pm 1$ transitions for the T_1 state of 3DMBP in ethanol (a) and methylyclohexane (b), and 2DMBP in ethanol (c) and methylcyclohexane (d).

absorption characteristics exist in the frozen media prior to excitation. The s-cis conformer arises from a species with longer wavelength absorption than the other, from which the s-trans conformer arises. The ESR spectra observed for 3DMBP were independent of the kind of frozen media, ethanol or methylcyclohexane, as shown in Figs. 5a and 5b, although two kinds of species with different conformations exist.

For 2DMBP, the dependence of the ESR spectra on the kind of frozen media was also studied using ethanol and methylcyclohexane, as shown in Figs. 5c and 5d. The intensity ratio of the ESR signal of the s-cis conformer to that of the s-trans one was distinctly influenced by the rigid media. This phenomenon shows the existence of two kinds of species trapped in the frozen media: that is, the s-cis and s-trans conformers are independently formed from the two kinds of species in their G states. No excitation wavelength dependence on the signal intensity ratio between the s-cis and s-trans conformers was observed, as shown in Figs. 4d—4f. This shows that the two species trapped in the frozen media are scarcely different from each other in their absorption characteristics.

The phosphorescence spectra measured in this study did not give any information on the relative locations for the T_1 levels of the s-cis and s-trans conformers. The relative locations of the T_1 levels could be compared using the T_1–T_1 energy transfer from one conformer to the other, as has widely been admitted.[19–22] Regarding the ESR signal intensity ratio, the contribution of the energy transfer from the lowest singlet state of one conformer to that of the other is considered to be small owing to the relatively shorter lifetimes of the S_1 states than those of the T_1 states.

Figures 6a—6c show the ESR spectra of the low-field $\Delta M_S=\pm 1$ transitions for 3DMBP in ethanol with concentrations of 5.4×10^{-2} to 8.9×10^{-5} mol dm^{-3}. The signal intensity ratio of the s-cis conformer to that of the s-trans one increased as the concentration of the samples increased. This indicates that the absorbed energy transfers from the T_1 level of the *s-trans*-3DMBP to that of *s-cis*-3DMBP. Thus, we can conclude that E_T(*s-trans*-3DMBP) locates higher in energy than E_T(*s-cis*-3DMBP).

For 2DMBP, the ESR spectra of the low-field $\Delta M_S=\pm 1$ transitions were measured in ethanol, changing the concentration of 2DMBP from 8.3×10^{-2} to 8.3×10^{-5} mol dm^{-3}, as shown in Figs. 6d—6f. In this case the opposite trend to that for 3DMBP was obtained. As a result, we concluded that E_T(*s-trans*-2DMBP) locates lower in energy than E_T(*s-cis*-2DMBP).

Ortho methyl substituents were found to impede a coplanar conformation of the two aromatic rings, even in the T_1 state (especially for the s-cis conformer). D values and lifetimes were closely related to the twisting angle between the two phenyl rings. The results indicated that the $|D|$ value decreases with increasing the deviation of the twisting angles between the two

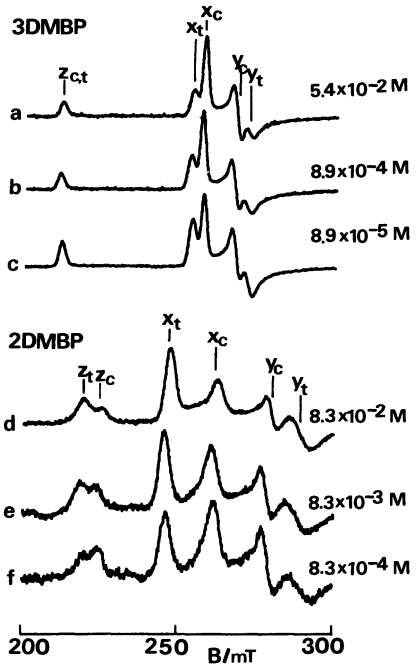

Fig. 6. ESR spectra of the low field $\Delta M_S=\pm 1$ transitions for T_1 state of 3DMBP in ethanol of 5.4×10^{-2} mol dm^{-3} (a), 8.9×10^{-4} mol dm^{-3} (b), and 8.9×10^{-5} mol dm^{-3} (c), and for 2DMBP in ethanol of 8.3×10^{-2} mol dm^{-3} (d), 8.3×10^{-3} mol dm^{-3} (e), and 8.3×10^{-4} mol dm^{-3} (f). 1 M=1 mol dm^{-3}.

aromatic rings from zero, as was seen for *s-trans*-3,3′-dimethyl-2,2′-bipyridine.[11] This is quite the same conclusion as that deduced from a theoretical consideration on the spin delocalization in a biphenyl molecule. It should be noted here that in ESR spectroscopy the influence of methyl substitution in BP appears only for a change in the twisting angle. Further studies of other substituted biphenyls would systematically clarify the relationship between ZFS parameters and conformation, especially for the twisting angle.

γ-Radiolysis of 1-Substituted 5-Fluorouracil Derivatives

Tokuyuki KURODA,* Koji HISAMURA, Ikuo MATSUKUMA, Hiroshi NISHIKAWA, and Nobuhiro NAKAMIZO
Pharmaceutical Research Laboratories, Kyowa Hakko Kogyo Co. Ltd., Shimotogari, Nagaizumi-cho, Sunto-gun, Shizuoka 411
(Received August 26, 1988)

A new concept, "Radiation-Induced Drug (RID)", was proposed as a novel type of drugs for cancer therapy. To test the usefulness of this concept, 5-fluorouracil (5-FU) derivatives having various types of substituents at the 1-position were prepared and the γ-radiolyses of their aqueous solutions were studied. The compounds having sulfonyl and thioureido groups as the substituents produced efficiently 5-FU with high G values upon γ-irradiation. The medium effects on the radiolyses revealed that the above two substituents were removed mainly with HO· and hydrated electrons e^-_{eq}.

It has long been recognized that a serious problem in cancer chemotherapy is the lack of site-selectivity in drug action for tumor cells.[1-3] The drugs usually manifest severe side effects on normal cells.[1-3] In the radiotherapy, tumor cells often resist against γ-radiation, and also most of solid tumors are known to have a low sensitivity to γ-radiation.[3-6] However, there is the possibility that these defects in the cancer therapies may be removed by developing a novel type of drugs which we call "Radiation-Induced Drug (RID)". We define the RID as that the drug itself is pharmaceutically inactive both for cancer and normal cells, but it produces an active drug specifically for cancer cells upon γ-irradiation. Since γ-ray can be irradiated selectively on cancer cells, the RID is supposed to become an anticancer drug with minimal toxicity for normal cells. We have thought that the RID may be prepared by the chemical modification of a drug which is known to be active for cancer cells. This approach consists in the conversion of the active drug to its functionalized derivative from which the functional group can be removed by γ-radiolysis to reproduce the active drug.

The previous work has shown that the chemically active species in the radiotherapy are the species generated by the γ-radiolysis of water.[7] Such species are shown in Eq. 1 with the G values of their formation.

$$\underset{\text{G value}}{H_2O} \xrightarrow{\gamma\text{-ray}} \underset{2.6}{e^-_{aq}}, \quad \underset{2.6}{HO\cdot}, \quad \underset{0.7}{H\cdot}, \quad \underset{0.65}{H_2O_2}, \quad \underset{0.4}{H_2} \qquad (1)$$

With this background we have initiated to search candidate compounds for the RID. In this investigation, we chose 5-fluorouracil (5-FU, 5-fluoro-2,4(1*H*, 3*H*)-pyrimidinedione) as a base active drug of the RID and synthesized its derivatives having various substituents at the 1-position. We then studied the γ-radiolysis of aqueous solutions of these compounds. A special attention was focused on what kinds of the reactive species play an important role in the γ-ray radiolysis of the aqueous solutions of the RID candidate compounds. The results are described in this paper.

Results and Discussion

Synthesis of 5-FU Derivatives. Twenty-five 5-FU derivatives (Table 1) which have various substituents at the 1-position were synthesized according to the routes outlined in Scheme 1. The detailed synthetic procedures and the structure confirmation of the compounds are described in the Experimental section.

Chemically Reactive Species Generated by the γ-Radiolysis of Water. The reactive species generated by the γ-radiolyses of water (Eq. 1) may be classified into two types: the reductive species such as hydrated electron (e^-_{aq}), H· and H_2, and the oxidative species such as HO· and H_2O_2. In this investigation, we confined our attention specifically to the reactivities of three reactive species, e^-_{aq}, HO· and H·, toward the RID candidate compounds because of the large G values of the formation of these reactive species. We then attempted to examine the way to discriminate the predominant reactive species from other species.

The rate constants for the reactions of these reactive species with molecules closely related to this investiga-

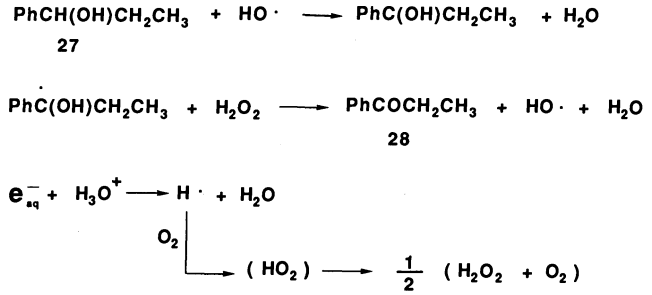
a) γ-Irradiations were carried out in 1 vol% methanol-water solutions. b) γ-Irradiations were carried out in 1 vol% methanol-water solutions containing 0.05 M H_2SO_4. c) γ-Irradiations were carried out in 1 vol% acetonitrile-water solutions saturated with N_2O gas.

tion have already been reported. The typical data are shown in Eqs. 2—7.[7,8] The other data have shown that the rate constants for the reactions of e^-_{aq} and HO· with organic compounds lie in the region of 10^8—10^{11}.[9-12]



Scheme 2.

$$k(CH_3OH + HO\cdot \longrightarrow \dot{C}H_2OH + H_2O) = 4.8\times10^8 \quad (2)$$

$$k(CH_3OH + e^-_{aq}) < 10^4 \quad (3)$$

$$k(CH_3CN + HO\cdot \longrightarrow \cdot CH_2CN + H_2O) = 5.5\times10^6 \quad (4)$$

$$k(CH_3CN + e^-_{aq}) = 2.5\times10^7 \quad (5)$$

$$k(e^-_{aq} + H_3O^+ \longrightarrow H\cdot + H_2O) = 2.4\times10^{10} \quad (6)$$

$$k(e^-_{aq} + N_2O \longrightarrow HO\cdot + HO^- + N_2) = 8.7\times10^9 \quad (7)$$

These data indicate that methanol reacts with HO· much faster than with e^-_{aq}. Therefore, it is reasonable to assume that in the γ-radiolysis of an aqueous solution, the HO· species can be quenched effectively by adding methanol to the reaction mixture. On the other hand, acetonitrile reacts rather slowly and at comparable rates with both HO· and e^-_{aq}. Hence, even if acetonitrile is added to the reaction mixture, no selective quenching of both the reactive species can be expected. This presumption was confirmed by the following experiments.

Previously, Yamamoto et al. have reported that the γ-ray radiolysis of an aqueous solution of 1-phenyl-1-propanol (**27**) gives 1-phenyl-1-propanone (**28**) via the pathways shown in Scheme 2.[13]

By examining the solvent effects on this reaction, we found that the *G* value for the formation of **28** was affected to a small extent by adding acetonitrile, but to a great extent by adding methanol to the reaction system. The results are shown in Fig. 1. The addition of 1 vol% methanol caused the significant decrease in the *G* value for the formation of **28**; the *G* value decreased from 1.17 to 0.24. However, the addition of 1 vol% of acetonitrile caused no appreciable change in the *G* value; the *G* value changed from 1.17 to 1.14. These results strongly suggest that the reactive species would be quenched in accord with the pathways indicated in Eqs. 2—7.

From these quenching experiments, we made the following assumption about the reactive species in the γ-radiolysis: (1) e^-_{aq} is the principal reactive species in the reactions in 1 vol% methanol aqueous solution, (2) H· is that in the reaction in 0.05 M (M=mol dm^{-3}) H_2SO_4 solution in 1 vol% methanol aqueous solution,

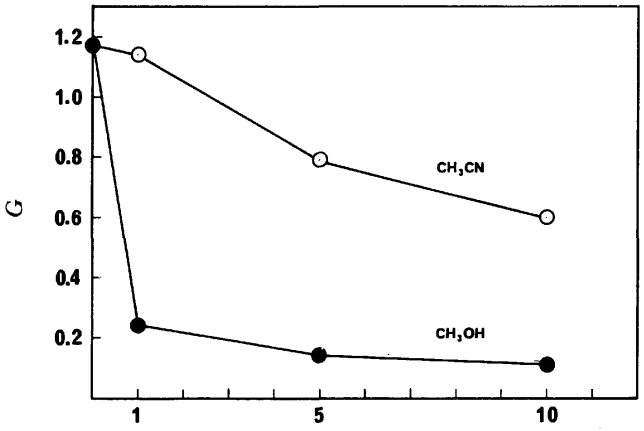


Fig. 1. Effects of added organic solvents on the G values for the formation of **28** in the γ-radiolysis of the aqueous solution of **27**.

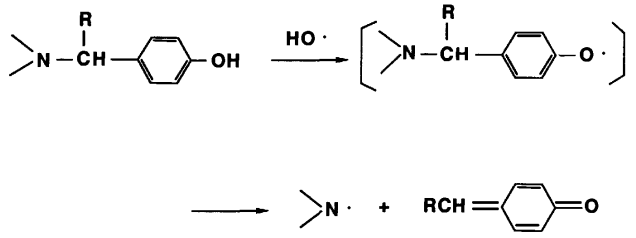


Scheme 3.

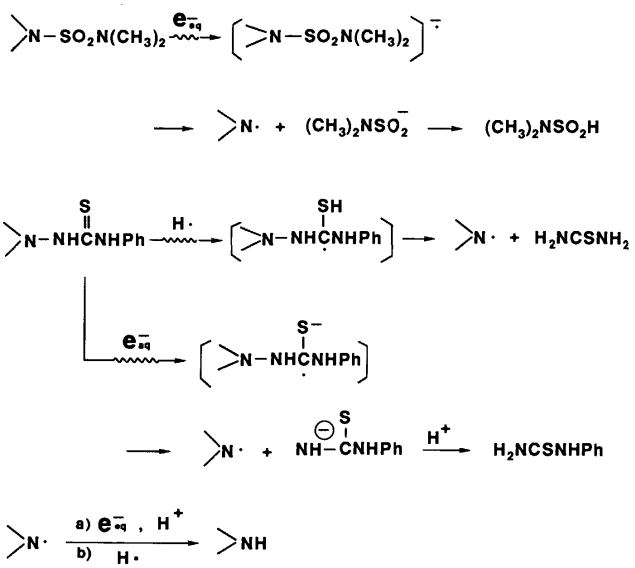
(3) HO· is that in the reaction in N_2O saturated 1 vol% acetonitrile aqueous solution.

γ-Radiolyses of 5-FU Derivatives. The γ-radiolyses of 5-FU derivatives were carried out under the conditions described in the preceding section and the G values for the formation of 5-FU were measured. The results are summarized in Table 1. The efficiency of the γ-radiolyses of the compounds are discussed separately according to types of bonds that are cleaved.

(1) N-C Bond Cleavage: We expected at the outset of this study that **20** and **21** may be cleaved to 5-FU via the routes shown in Scheme 3 (N represents the nitrogen at the 1-position of 5-FU). But, this type of the reaction was found not to occur appreciably. We also found that **22**, which has no hydrogen at the α carbon of the substituent, was unstable under the reaction conditions and gave 5-FU along with 2-(4-hydroxyphenyl)-2-propanol by sponthaneous hydrolysis.

For the γ-radiolysis of compound **3**, we expected that the reaction with e^-_{aq} may occur to produce 5-FU. However, this compound was also unstable under the reaction conditions and gave 5-FU by spontaneous hydrolysis.

(2) N-O Bond Cleavage: Compounds **24**, **25**, and **26** produced 5-FU mainly by the reaction with e^-_{aq} upon γ-irradiation, but the efficiency of this reaction



Scheme 4.

was low.

(3) N-S Bond Cleavage: The *N*-sulfonyl compounds, **1** and **2**, were cleaved efficiently to produce 5-FU upon γ-irradiation. The medium effects on this reaction showed that the radiolysis was promoted mainly with e^-_{aq} and partly with HO·.

(4) N-N Bond Cleavage: The *N*-imido compounds, **7** and *N*-diacylamino compounds **8**, **9** were cleaved relatively efficiently to produce 5-FU mainly with e^-_{aq} upon γ-irradiation. However, we found that among all the compounds examined, the compounds having thioureido substituents such as **13—16** were efficiently cleaved to produce 5-FU upon γ-irradiation, although ureido substituents were insensitive to the γ-radiolysis. The high sensitivity of the thioureido substituents to the γ-radiolysis is due to the fact that these substituents are highly reactive toward two reductive species e^-_{aq} and H· as well as the oxidative species HO·. It should be pointed out here that the results for compounds **1** and **19** show that the N-S bond is much more sensitive than the N-N bond to the γ-radiolysis.

Mechanistic Implication. The results so far obtained indicate that 5-FU derivatives having sulfonyl or thioureido groups at the 1-position efficiently produce 5-FU upon γ-irradiation of their aqueous solutions, and they would become good candidates for the RID. The results also indicate that the sulfonyl and thioureido substituents of 5-FU derivatives are eliminated mainly with reductive species such as e^-_{aq} and H·. The plausible mechanisms for the γ-radiolysis of these sulfur-containing compounds are presented in Scheme 4.

The sulfonyl and thioureido groups have a relatively high electron-accepting ability. In addition, the radical anions of these group produced by electron

transfer become good leaving groups as their anions, and hence these groups are cleaved efficiently upon γ-irradiation.

The usefulness of the concept of RID and the mechanistic details of their γ-radiolysis are now under investigation, and will be reported in subsequent papers.

Experimental

Melting points were determined with a Büchi 510 capillary melting point apparatus and are uncorrected. ^{1}H NMR spectra were recorded on a JEOL JNM-PMX 60 spectrometer using Me_4Si as an internal standard. IR spectra were obtained on a Shimadzu IR-400 spectrometer. Mass spectra were recorded on a JEOL JMS-D300 mass spectrometer. Column chromatography was performed on silica gel (silica gel 60, Merck). The purity of compounds was checked by TLC on silica-gel plates (silica gel 60, F_{254}, Merck). Elementary analyses were performed by an Yanagimoto CHN Corder MT-3, and the errors were within ±0.4% of calculated values. γ-Irradiations were carried out by ^{137}Cs source at the National Institute of Genetics. HPLC analyses were performed on a Shimadzu LC-3A, using a 25 cm×4 mm i.d. stainless steel column packed with RP-18 chemically bonded silica gel (Lichrosorb, 10 μm, Merck).

Preparation of Materials. 1-(Dimethylaminosulfonyl)-5-fluorouracil (1). To a solution of 5-FU (200 mg, 1.54 mmol) in 2 cm^3 of *N,N*-dimethylacetamide were added *N,N*-dimethylsulfamoyl chloride (342 mg, 2.38 mmol) and triethylamine (0.5 cm^3). The mixture was stirred at room temperature for 6 h, acidified to pH 3.0 with 1 M HCl, and filtered. The filtrate was concentrated, and the residue was chromatographed on silica gel with $CHCl_3$–acetone (15:1) to give 280 mg (77%) of **1**; mp 211—212 °C. IR (KBr) 1700, 1670, 1330, 1170 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=3.16 (6H, s), 8.42 (1H, d, *J*=6.0 Hz), 12.46 (1H, bs); MS *m/z* 237 (M$^+$). Found: C, 30.61; H, 3.35; N, 17.49%. Calcd for $C_6H_8N_3O_4FS$: C, 30.38; H, 3.40; N, 17.72%.

5-Fluoro-1-(2-phenylethenesulfonyl)uracil (2). A mixture of 5-FU (200 mg, 1.54 mmol), 2-phenylethenesulfonyl chloride (467 mg, 2.31 mmol) and triethylamine (2 cm^3) in *N,N*-dimethylacetamide (2 cm^3) was stirred at room temperature for 2.5 h. Water (8 cm^3) and 1 M HCl (2 cm^3) were added and then the mixture was extracted three times with 20 cm^3 portions of $CHCl_3$. The organic layer was washed with water, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–acetone (30:1) to give **2** (270 mg, 59%) as colorless crystals; mp 180—182 °C. IR (KBr) 1700, 1670, 1330, 1170 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=7.26—8.08 (7H, m), 8.19 (1H, d, *J*=6.6 Hz), 12.24 (1H, bs); MS *m/z* 296 (M$^+$). Found: C, 48.48; H, 3.11; N, 9.51%. Calcd for $C_{12}H_9N_2O_4FS$: C, 48.65; H, 3.06; N, 9.46%.

5-Fluoro-1-(2,2,2-trichloroethoxycarbonyl)uracil (3). To a solution of 5-FU (156 mg, 1.20 mmol) in 2.2 cm^3 of DMF were added 1,1,1-trichloroethoxycarbonyl chloride (386 mg, 1.82 mmol) and triethylamine (170 mg, 1.68 mmol). The mixture was stirred under ice-cooling for 1.5 h and filtered. The filtrate was concentrated. The residue was dissolved in a small amount of DMF and poured into water to give **3** (176 mg, 48%) as white crystals; mp 164—166 °C. IR (KBr) 1800 and 1680 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=5.14 (2H, s), 8.22 (1H, d, *J*=7.2 Hz), 11.22 (1H, bs); MS *m/z* 304 (M$^+$). Found: C, 27.37; H, 1.39; N, 9.34%. Calcd for $C_7H_4N_2O_4Cl_3F$: C, 27.52; H, 1.32; N, 9.17%.

5-Fluoro-1-(4-methoxybenzyloxycarbonyl)uracil (4). A mixture of trichloromethyl chloroformate (0.3 cm^3) and active carbon (200 mg) in $ClCH_2CH_2Cl$ (10 cm^3) was stirred at room temperature for 30 min, and cooled to 5 °C. A solution of 4-methoxybenzyl alcohol (350 mg, 4 mmol) and triethylamine (610 mg, 6 mmol) in 2 cm^3 of $ClCH_2CH_2Cl$ was then added dropwise, and stirred at room temperature for 3.5 h. The precipitate was filtered off and the filtrate was concentrated. The residue was dissolved in a small amount of DMF, and then 5-FU (260 mg, 2 mmol) and triethylamine (0.4 cm^3) were added to this solution. After stirring for 6 h, the mixture was poured into water and extracted with $CHCl_3$. The organic layer was washed with aqueous NaCl solution, dried (Na_2SO_4) and concentrated to give crystals, which were recrystallized from $CHCl_3$–hexane to afford pure **4** (120 mg, 20%); mp 162.5—163.5 °C. IR (KBr) 1700, 1680 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=3.76 (3H, s), 4.76 (2H, s), 6.94—7.34 (4H, m), 8.18 (1H, d, *J*=6.8 Hz), 11.84 (1H, bs); MS *m/z* 294 (M$^+$). Found: C, 52.83; H, 3.91; N, 9.47%. Calcd for $C_{13}H_{11}N_2O_5F$: C, 53.07; H, 3.77; N, 9.52%.

5-Fluoro-1-[(4-methoxybenzylthio)carbonyl]uracil (5). A mixture of trichloromethyl chloroformate (0.3 cm^3) and active carbon (200 mg) in dioxane (12 cm^3) was stirred at room temperature for 30 min and cooled to 5 °C. A solution of 4-methoxyphenylmethanethiol (460 mg, 3 mmol) and triethylamine (610 mg, 6 mmol) in dioxane (2 cm^3) was added dropwise and stirred at room temperature for 3 h. The precipitate was filtered off and the filtrate was evaporated. The residue was dissolved in a small amount of DMF and then 5-FU (260 mg, 2 mmol) and triethylamine (0.4 cm^3) were added. After stirring for 1.75 h, the mixture was poured into water. The deposited solid was recrystallized from AcOEt–acetone to give **5** (430 mg, 74%); mp 197—198 °C. IR (KBr) 1735, 1700 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=3.68 (3H, s), 4.12 (2H, s), 6.86—7.30 (4H, m), 8.36 (1H, d, *J*=7.2 Hz), 12.30 (1H, bs); MS *m/z* 310 (M$^+$). Found: C, 50.20; H, 3.44; N, 9.26%. Calcd for $C_{13}H_{11}N_2O_4FS$; C, 50.32; H, 3.57; N, 9.03%.

1-(Benzylideneamino)-5-fluorouracil. To a solution of 5-FU (50 g, 0.38 mol) and KOH (112 g, 1.71 mol) in water (600 cm^3) was added an aqueous solution (200 cm^3) containing hydroxylamine-*O*-sulfonic acid (6.44 g, 1.16 mol) below 10 °C. The mixture was stirred for 4 h at room temperature and acidified to pH 3 with 5 M HCl. A solution of benzaldehyde (40 g, 0.38 mol) in ether (300 cm^3) was then added, and the resulting mixture was stirred at room temperature for 4 h. The precipitated solid was filtered, washed with water and dried to give 74.7 g of crude product which was then stirred in 750 cm^3 of dioxane at 60 °C for 30 min and cooled. The precipated white crystals were filtered to give 47.5 g (64%) of 1-(benzylideneamino)-5-fluorouracil; mp 229—231 °C. TLC (AcOEt) R_f 0.60; IR (KBr) 1722, 1650, 1605, 1565 cm^{-1}; ^{1}H NMR (DMSO-d_6) δ=7.39—8.04 (6H, m), 8.67 (1H, s), 11.31 (1H, bs).

1-Amino-5-fluorouracil Hydrochloride (6). Hydrogen gas was bubbled into a solution of 1-benzylideneamino-5-fluorouracil (20 g, 0.086 mol) in CH_3OH (200 cm^3) containing 0.5 M HCl (200 cm^3) and 10% Pd–C (2.0 g) with stirring at room temperature for 9 h. The mixture was filtered, and the filtrate was concentrated to dryness and triturated with

ether to give amorphous **6** (15.1 g, 97%). IR (KBr) 1735, 1660 cm^{-1}; ^1H NMR (DMSO-d_6) δ=5.47 (2H, bs), 7.76 (1H, d, J=5.6 Hz); MS m/z 181 (M^+). Found: C, 26.21; H, 2.71; N, 23.02%. Calcd for $C_4H_5N_3O_2ClF$: C, 26.46; H, 2.78; N, 23.15%.

5-Fluoro-1-succinimidouracil (7). To a solution of **6** (1.0 g, 5.5 mmol) in 20 cm^3 of DMF were added succinyl dichloride (0.67 cm^3, 6.1 mmol) and triethylamine (3.1 cm^3, 22 mmol) under ice-cooling. The mixture was stirred at room temperature for 15 h, and filtered. The filtrate was concentrated, poured into water, and extracted with AcOEt. The organic layer was washed with aqueous NaCl solution, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with AcOEt–hexane (1:1) to give **7** (500 mg, 42.5%); mp 204—206.5 °C. IR (KBr) 1755, 1735, 1700 cm^{-1}; ^1H NMR (DMSO-d_6) δ=2.97 (4H, s), 7.40 (1H, d, J=5.4 Hz), 11.44 (1H, bs); MS m/z 227 (M^+). Found: C, 42.48; H, 2.69; N, 18.73%. Calcd for $C_8H_6N_3O_4F$: C, 42.30; H, 2.66; N, 18.50%.

1-(Diacetylamino)-5-fluorouracil (8). Acetyl chloride (1.73 g, 22 mmol) was added to a solution of **6** (1.0 g, 5.5 mmol) in DMF (10 cm^3) and pyridine (20 cm^3) under ice-bath cooling. The mixture was stirred at room temperature for 3 h and filtered. The filtrate was concentrated, poured into water (40 cm^3) and then extracted with AcOEt. The extract was washed with water, dried (Na_2SO_4) and evaporated. The residue was recrystallized from AcOEt to give **8** (420 mg, 33%); mp 154.5—156.0 °C. TLC (AcOEt) R_f 0.58; IR (KBr) 1760, 1745, 1700, 1680 cm^{-1}; ^1H NMR (DMSO-d_6) δ=2.29 (6H, s), 8.06 (1H, d, J=6.2 Hz), 11.33 (1H, bs); MS m/z 229 (M^+). Found: C, 41.79; H, 3.65; N, 18.46%. Calcd for $C_8H_8N_3O_4F$: C, 41.93; H, 3.52; N, 18.34%.

1-(Dibenzoylamino)-5-fluorouracil (9). Benzoyl chloride (1.15 g, 8.22 mmol) was added to a solution of **6** (500 mg, 2.75 mmol) in 10 cm^3 of pyridine under ice-cooling. The mixture was stirred at room temperature overnight and filtered. The filtrate was concentrated, poured into water (200 cm^3), and extracted with AcOEt. The extracts was washed with water, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with AcOEt–hexane (1:1) to give **9** (535 mg, 55%); mp 168.5—170 °C. TLC (AcOEt–hexane (1:2) R_f 0.35; IR (KBr) 1760, 1700 cm^{-1}; ^1H NMR (DMSO-d_6) δ=6.79—7.85 (11H, m), 9.24 (1H, bs); MS m/z 353 (M^+). Found: C, 60.92; H, 3.38; N, 11.63%. Calcd for $C_{18}H_{12}N_3O_4F$; C, 61.19; H, 3.42; N, 11.89%.

5-Fluoro-1-phthalimidouracil (10). Phthaloyl dichloride (1.40 g, 6.9 mmol) was added to a solution of **6** (1.0 g, 5.5 mmol) in *N,N*-dimethylacetamide (20 cm^3) and pyridine (20 cm^3) under ice-bath cooling. The mixture was stirred at room temperature for 1 h, concentrated to dryness, poured into water (50 cm^3), and then extracted with AcOEt. The extracts was washed with water, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–MeOH (20:1). Recrystallization of the crude product from AcOEt–hexane gave pure **10** (300 mg, 20%) as white crystals; mp 248.0—249.5 °C. TLC (AcOEt) R_f 0.65; IR (KBr) 1760, 1740, 1700 cm^{-1}; ^1H NMR (DMSO-d_6) δ=7.79—8.36 (4H, m), 8.23 (1H, d, J=6.0 Hz), 10.57 (1H, bs); MS m/z 275 (M^+). Found: C, 52.51; H, 2.28; N, 15.34%. Calcd for $C_{12}H_6N_3O_4F$: C, 52.37; H, 2.20; N, 15.27%.

1-(4-Chlorobenzenesulfonamide)-5-fluorouracil (11). To a solution of **6** (2.0 g, 11.0 mmol) in 20 cm^3 of pyridine and 40 cm^3 of *N,N*-dimethylacetamide was added 4-chlorobenzenesulfonyl chloride (2.79 g, 13.2 mmol). The mixture was stirred at room temperature for 3.5 h, concentrated to dryness, poured into water (50 cm^3), and then extracted with AcOEt. The extract was washed with water, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–MeOH (9:1) to give **11** (1.31 g, 37%); mp 254—255.5 °C. TLC (AcOEt) R_f 0.57; IR (KBr) 1745, 1700, 1680, 1370, 1170 cm^{-1}; ^1H NMR (DMSO-d_6) δ=7.55—8.25 (5H, m), 11.02 (1H, br), 11.81 (1H, br); MS m/z 319 (M^+). Found: C, 37.39; H, 2.10; N, 13.36%. Calcd for $C_{10}H_7N_3O_4ClFS$: C, 37.57; H, 2.21; N, 13.14%.

5-Fluoro-1-(2,2,2-trichloroethoxycarbonylamino)uracil (12). 2,2,2-Trichloroethyl chloroformate (2.90 g, 13.7 mmol) was added to a solution of **6** (1.0 g, 5.5 mmol) in *N,N*-dimethylacetamide (20 cm^3) and pyridine (20 cm^3) under ice-bath cooling. The mixture was stirred at room temperature overnight, concentrated to dryness, poured into water (50 cm^3), and then extracted with AcOEt. The extract was washed with water, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–MeOH (20:1) to give **12** (1.06 g, 60.3%); mp 226.5—227.0 °C. TLC (AcOEt) R_f 0.80; IR (KBr) 1735, 1680 cm^{-1}; ^1H NMR (DMSO-d_6) δ=4.73—5.02 (2H, m), 7.73—8.13 (1H, m), 9.39 (2H, bs); MS m/z 319 (M^+). Found: C, 26.51; H, 1.58; N, 13.27%. Calcd for $C_7H_5N_3O_4Cl_3F$: C, 26.24; H, 1.57; N, 13.11%.

1-[*N'*-(Ethoxycarbonyl)thioureido]-5-fluorouracil (13). To a solution of **6** (500 mg, 2.75 mmol) in 20 cm^3 of pyridine was added ethoxycarbonyl isothiocyanate (397 mg, 3.03 mmol). The mixture was stirred at room temperature for 4 h, concentrated, poured into water (50 cm^3) and then extracted with AcOEt. The extract was washed with aqueous NaCl solution, dried (Na_2SO_4) and concentrated to give **13** (547 mg, 72%) as white crystals; mp 188—189 °C. IR (KBr) 1735, 1695, 1520 cm^{-1}; ^1H NMR (DMSO-d_6) δ=1.25 (3H, t, J=7.3 Hz), 4.21 (2H, q, J=7.2 Hz), 7.90 (1H, d, J=5.8 Hz), 11.31 (3H, bs); MS m/z 276 (M^+). Found: C, 34.51; H, 3.02; N, 20.49%. Calcd for $C_8H_9N_4O_4FS$: C, 34.78; H, 3.28; N, 20.28%.

5-Fluoro-1-[*N'*-(phenyl)thioureido]uracil (14). From **6** (2.75 mmol) and phenyl isothiocyanate (3.03 mmol), **14** was obtained in a 98% yield in a similar manner as described for **13**; mp 188—189 °C. TLC ($CHCl_3$–MeOH (4:1)) R_f 0.50; IR (KBr) 1740, 1690, 1540 cm^{-1}; ^1H NMR (DMSO-d_6) δ=7.02—7.66 (5H, m), 7.89 (1H, d, J=5.2 Hz), 10.12 (2H, br), 11.12 (1H, bs); MS m/z 280 (M^+). Found: C, 47.29; H, 3.08; N, 20.24%. Calcd for $C_{11}H_9N_4O_2FS$: C, 47.14; H, 3.24; N, 19.99%.

1-[*N'*-(*t*-Butyl)thioureido]-5-fluorouracil (15). From **6** (2.75 mmol) and *t*-butyl isothiocyanate (3.03 mmol), **15** was obtained in a 79% yield in a similar manner as described for **13**; mp 201—202 °C. TLC ($CHCl_3$–MeOH (4:1)) R_f 0.52; IR (KBr) 1720, 1680, 1525 cm^{-1}; ^1H NMR (DMSO-d_6) δ=1.44 (9H, s), 7.79 (1H, bs), 7.84 (1H, d, J=5.8 Hz), 9.14 (1H, bs), 11.06 (1H, bs). MS m/z 260 (M^+). Found: C, 41.70; H, 5.31; N, 21.38%. Calcd for $C_9H_{13}N_4O_2FS$: C, 41.53; H, 5.03; N, 21.53%.

1-[*N'*-(Benzyl)thioureido]-5-fluorouracil (16). From **6** (2.75 mmol) and benzyl isothiocyanate (3.03 mmol), **16** was obtained in a 84% yield in a similar manner as above; mp 163—165 °C. TLC ($CHCl_3$–MeOH (4:1)) R_f 0.48; IR (KBr) 1740, 1680, 1555 cm^{-1}; ^1H NMR (DMSO-d_6) δ=4.68 (2H, d, J=5.4 Hz), 7.00—7.42 (3H, m), 7.82 (1H, d, J=5.2 Hz), 8.72

(1H, t, J=5.7 Hz), 9.69 (1H, bs); MS m/z 294 (M^+). Found: C, 49.18; H, 3.93; N, 19.17%. Calcd for $C_{12}H_{11}N_4O_2FS$: C, 48.97; H, 3.77; N, 19.04%.

5-Fluoro-1-(*N'*-phenylureido)uracil (17). From **6** (2.75 mmol) and phenyl isocyanate (3.02 mmol), **17** was obtained in a 22% yield; mp 258—260 °C. IR (KBr) 1740, 1680 cm^{-1}; ^1H NMR (DMSO-d_6) δ=6.78—7.63 (5H, m), 7.90 (1H, d, J=5.8 Hz), 8.62 (1H, bs), 9.12 (1H, bs), 11.27 (1H, bs); MS m/z 264 (M^+). Found: C, 49.79; H, 3.21; N, 21.13%. Calcd for $C_{11}H_9N_4O_3F$: C, 50.00; H, 3.43; N, 21.21%.

1-(*N'*-*t*-Butylureido)-5-fluorouracil (18). To a solution of **6** (1.0 g, 5.51 mmol) in pyridine (40 cm^3) was added *t*-butyl isocyanate (600 mg, 6.06 mmol) and the mixture was stirred at room temperature for 10 h. Work-up of the reaction mixture in the similar manner as above gave **18** in a 45% yield as white crystals; mp 238 °C. TLC (AcOEt) R_f 0.20; IR (KBr) 1740, 1690 cm^{-1}; ^1H NMR (DMSO-d_6) δ=1.25 (9H, s), 6.33 (1H, bs), 7.71 and 7.80 (1H, d, J=6.0 Hz, 5.2 Hz), 7.96 (1H, bs), 11.09 (1H, bs); MS m/z 244 (M^+). Found: C, 44.44; H, 5.48; N, 22.84%. Calcd for $C_9H_{13}N_4O_3F$: C, 44.26; H, 5.37; N, 22.94%.

1-(*N,N*-Dimethylsulfamoylamino)-5-fluorouracil (19). To a solution of **6** (1.0 g, 5.51 mmol) and triethylamine (5 cm^3) in DMF (25 cm^3) was added *N,N*-dimethylsulfamoyl chloride (1.22 g, 8.50 mmol). The mixture was stirred at room temperature for 5 h, and filtered. The filtrate was concentrated, poured into water and extracted with AcOEt. The extract was washed with aqueous NaCl solution, dried (Na_2SO_4), and concentrated. The residue was recrystallized from acetone to give **19** (690 mg, 50%); mp 187—189 °C. TLC (AcOEt) R_f 0.60; IR (KBr) 1710, 1680, 1380, 1180 cm^{-1}; ^1H NMR (DMSO-d_6) δ=3.40 (6H, s), 8.00 (1H, d, J=6.0 Hz), 11.01 (1H, br), 11.47 (1H, br); MS m/z 252 (M^+). Found: C, 28.35; H, 3.57; N, 21.93%. Calcd for $C_6H_9N_4O_4FS$: C, 28.57; H, 3.60; N, 22.21%.

1-[4-(Tetrahydropyranyloxy)phenyl]ethanol. A mixture of *p*-hydroxylbenzaldehyde (2.4 g), 3,4-dihydro-2*H*-pyran (20 cm^3) and pyridine *p*-toluenesulfonate (0.7 g) was stirred at room temperature for 15 h, concentrated and poured into water (200 cm^3), and then extracted with $CHCl_3$. The chloroform layer was washed with aqueous NaCl solution, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–acetone (40:1) to give 2.2 g (54.3%) of 4-(tetrahydro-2-pyranyloxy)benzaldehyde; TLC ($CHCl_3$–acetone (20:1)) R_f 0.80. The protected aldehyde thus obtained was dissolved into ether (10 cm^3), and the ether solution was added to a solution of CH_3Li (2.12 mmol) in ether over 5 min. The resulting mixture was refluxed for 1 h, cooled, and poured into water (100 cm^3). The ether layer was separated, washed with an aqueous NaCl solution, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–acetone (40:1) to give 1.28 g (54%) of 1-[4-(tetrahydropyranyloxy)phenyl]ethanol. IR (KBr) 3410, 2950, 1620, 1520 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.39 (3H, d, J=6.4 Hz), 1.10—2.24 (6H, m), 2.71 (1H, bs), 3.26—4.15 (2H, m), 4.74 (1H, q, J=6.4 Hz), 5.22—5.46 (1H, m), 6.94 and 7.18 (4H, ABq, J=8.8 Hz).

5-Fluoro-1-[1-(4-hydroxyphenyl)ethyl]uracil (20). To a solution of 1-[4-(tetrahydropyranyloxy)phenyl]ethanol (435 mg) in $ClCH_2CH_2Cl$ (30 cm^3) was added thionyl chloride (1 cm^3). The mixture was stirred at room temperature for 30 min and concentrated. The residue was dissolved into acetonitrile (10 cm^3), and 2,4-*O*-bis(trimethylsilyl)-5-fluorouracil (1.5 g) and $SnCl_4$ (0.06 cm^3) was then added to the solution. The mixture was stirred at room temperature for 1 h, and 5% aqueous $NaHCO_3$ solution (20 cm^3) was added and the reacting mixture was extracted with AcOEt. The organic layer was washed with an aqueous NaCl solution, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–acetone (30:1) to give 330 mg (67%) of amorphous **20**. TLC ($CHCl_3$–acetone (4:1)) R_f 0.20; IR (KBr) 1700, 1680 cm^{-1}; ^1H NMR (DMSO-d_6) δ=1.61 (3H, d, J=7.0 Hz), 5.68 (1H, q, J=7.5 Hz), 6.76—7.18 (4H, m), 7.88 (1H, d, J=6.1 Hz), 9.46 (1H, bs), 11.78 (1H, bs); MS m/z 250 (M^+). Found: C, 57.43; H, 4.29; N, 11.02%. Calcd for $C_{12}H_{11}N_2O_3F$: C, 57.60; H, 4.43; N, 11.20%.

Bis(4-acetoxyphenyl)methyl Bromide. Acetic anhydride (6 cm^3) was added to a solution of bis(4-hydroxyphenyl)methanol (1.0 g, 5 mmol) in pyridine (20 cm^3) and stirred at room temperature for 15 h. The mixture was concentrated, poured into water, and extracted with AcOEt. The organic layer was washed successively with 5% aqueous $NaHCO_3$ and aqueous NaCl solution, dried (Na_2SO_4), and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–MeOH (20:1) to give 1.22 g (26%) of bis(4-acetoxyphenyl)-methane; mp 66—68 °C. IR (KBr) 1745, 1200 cm^{-1}; ^1H NMR (DMSO-d_6) δ=2.19 (6H, s), 3.88 (2H, s), 6.94 and 7.16 (8H, ABq, J=8.4 Hz). To a solution of bis(4-acetoxyphenyl)-methane (90 mg, 3.16 mmol) in CCl_4 (30 cm^3) was added *N*-bromosuccinimide (0.63 g) and catalytic amount of AIBN. After refluxing for 1 h, the reaction mixture was concentrated. The residue was chromatographed on silica gel with $CHCl_3$–acetone (40:1) to give 0.73 g (64%) of bis(4-acetoxyphenyl)methyl bromide. TLC ($CHCl_3$–actone (20:1)) R_f 0.7; ^1H NMR ($CDCl_3$) δ=2.27 (6H, s), 5.36 (1H, s), 7.06 and 7.35 (8H, ABq, J=8.8 Hz).

1-[Bis(4-hydroxyphenyl)methyl]-5-fluorouracil (21). To a solution of bis(4-acetoxyphenyl)methyl bromide (0.63 g, 1.74 mmol) and 2,4-*O*-bis(trimethylsilyl)-5-fluorouracil (0.98 g) in acetonitrile (20 cm^3) was added $SnCl_4$ (0.2 cm^3) and the mixture was stirred for 1.2 h. After adding 5% aqueous $NaHCO_3$ solution (20 cm^3), the reaction mixture was extracted with AcOEt. The AcOEt layer was washed with aqueous NaCl solution, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–acetone (30:1) to give 0.5 g of 1-[bis(4-acetoxyphenyl)methyl]-5-fluorouracil. IR (KBr) 1760, 1705, 1670, 1380, 1245, 1205 cm^{-1}; ^1H NMR (DMSO-d_6) δ=2.25 (6H, s), 6.92 (1H, bs), 7.16 and 7.25 (4H, ABq, J=9.0 Hz), 7.63 (1H, d, J=6.8 Hz), 11.93 (1H, bs). 1-[Bis(4-acetoxyphenyl)methyl]-5-fluorouracil (0.32 g, 0.78 mmol) in ethanol was dissolved in aqueous 1 M NaOH solution. The solution was acidified to pH 3.8 with dil HCl and extracted with AcOEt. The organic layer was washed with aqueous NaCl solution, dried (Na_2SO_4), and concentrated to give solids. The solids was triturated with ether to afford 250 mg (68%) of amorphous **23**. TLC ($CHCl_3$–acetone (4:1)) R_f 0.10; IR (KBr) 1700, 1680 cm^{-1}; ^1H NMR (DMSO-d_6) δ=6.53—7.20 (9H, m), 7.45 (1H, d, J=6.8 Hz), 9.68 (2H, bs), 11.69 (1H, bs); MS m/z 328 (M^+). Found: C, 62.45; H, 4.18; N, 8.38%. Calcd for $C_{17}H_{13}N_2O_4F$: C, 62.20; H, 3.99; N, 8.53%.

2-[4-(Tetrahydropyranyloxy)phenyl]-2-propanol. Pyridine *p*-toluenesulfonate (10.7 g) was added to a solution of methyl *p*-hydroxybenzoate (2.13 g) and 3,4-dihydro-2*H*-pyran (20 cm^3) in acetone (20 cm^3). The mixture was stirred

at room temperature for 15 h, concentrated, poured into water, and then extracted with $CHCl_3$. The organic layer was washed with aqueous NaCl solution, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with hexane–AcOEt (15:1) to give 3.34 g (100%) of methyl 4-(tetrahydropyranyloxy)benzoate, which was dissolved in ether (30 cm^3). To this ether solution was added CH_3Li (60 mmol) in ether over 10 min. The reaction mixture was refluxed for 1 h, diluted with water (10 cm^3) and then extracted with AcOEt. The organic layer was washed with aqueous NaCl solution, dried (Na_2SO_4) and concentrated to afford 2.64 g of 2-[4-(tetrahydropyranyloxy)phenyl]-2-propanol. TLC ($CHCl_3$–acetone (4:1)) R_f 0.80; ^1H NMR ($CDCl_3+D_2O$) δ=1.50 (6H, s), 1.16—2.10 (6H, m), 3.27—4.08 (2H, m), 5.24—5.43 (1H, m), 6.92 and 7.31 (4H, ABq, J=8.7 Hz).

5-Fluoro-1-[1-(4-hydroxyphenyl)-1-methylethyl]uracil (22). To a solution of 2-[4-(tetrahydropyranyloxy)phenyl]-2-propanol (2.1 g) and 2,4-*O*-bis(trimethylsilyl)-5-fluorouracil (10.0 g) in acetonitrile (50 cm^3) was added $SnCl_4$ (1 cm^3) at −20 °C. The mixture was stirred at the same temperature for 30 min, and then 5% aqueous $NaHCO_3$ (20 cm^3) was added and was extracted with AcOEt. The organic layer was washed with aqueous NaCl solution, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–acetone (30:1) to give 330 mg (14%) of **22**; mp 270—272 °C. TLC ($CHCl_3$–acetone (4:1) R_f 0.12; IR (KBr) 1710, 1660 cm^{-1}; ^1H NMR (DMSO-d_6) δ=1.74 (6H, s), 6.67—7.03 (4H, m), 8.07 (1H, d, J=8.4 Hz), 9.23 (1H, bs), 11.43 (1H, d, J=5.0 Hz); MS m/z 264 (M^+). Found: C, 58.88; H, 4.86; N, 10.83%. Calcd for $C_{13}H_{13}N_2O_3F$: C, 59.09; H, 4.96; N, 10.60%.

5-Fluoro-1-hydroxyuracil (23). Hydrogen gas was introduced at room temperature into a solution of **24** (500 mg, 2.1 mmol) in ethanol–water (8:2) containing 10% Pd–C (50 mg) for 1.3 h and the catalyst was filtered off. The filtrate was concentrated and the residue was triturated with ether to give 220 mg (72%) of **23**; mp 208 °C (decomp). TLC ($CHCl_3$–MeOH–AcOH (40:5:1)) R_f 0.22; IR (KBr) 3450, 1710, 1670 cm^{-1}; ^1H NMR (DMSO-d_6) δ=8.33 (1H, d, J=7.0 Hz), 11.28 (2H, bs); MS m/z 146 (M^+). Found: C, 32.61; H, 2.21; N, 18.93%. Calcd for $C_4H_3N_2O_3F$: C, 32.85; H, 2.07; N, 19.15%.

1-Benzyloxy-5-fluorouracil (24). A mixture of 3-benzyloxyamino-2-fluoroacrylamide (5.3 g, 25 mmol) and oxalyl dichloride (7.2 g, 57 mmol) in CH_2Cl_2 (220 cm^3) was refluxed for 27 h and then concentrated. The residue was chromatographed on silica gel with $CHCl_3$–MeOH (100:1) to give 1.55 g (26%) of **24**; mp 184—185 °C. IR (KBr) 1725, 1695 cm^{-1}; ^1H NMR (DMSO-d_6) δ=5.10 (2H, s), 6.98—7.79 (6H, m), 11.91 (1H, bs); MS m/z 236 (M^+). Found: C, 55.77; H, 3.60; N, 11.72%. Calcd for $C_{11}H_9N_2O_3F$: C, 55.94; H, 3.84; N, 11.86%.

1-(4-Chlorophenylsulfonyloxy)-5-fluorouracil (25). To a solution of **23** (300 mg, 2.05 mmol) in pyridine (5 cm^3) was added 4-chlorobenzenesulfonyl chloride. The mixture was stirred at room temperature for 15 min, concentrated, diluted with water, and then extracted with AcOEt. The organic layer was successively washed with 0.1 M NaOH and aqueous NaCl solution, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–MeOH (4:1) to give 220 mg (33%) of **25**; mp>300 °C. TLC ($CHCl_3$–MeOH (4:1)) R_f 0.63; IR (KBr) 1720, 1640 cm^{-1}, ^1H NMR (DMSO-d_6) δ=7.72—7.98 (4H, m), 8.47 (1H, d, J=6.0 Hz), 11.07 (1H, bs); MS m/z 320 (M^+). Found: C, 37.63; H, 1.71; N, 8.53%. Calcd for $C_{10}H_6N_2O_5ClFS$: C, 37.45; H, 1.89; N, 8.74%.

1-(4-Chlorobenzyloxy)-5-fluorouracil (26). To a solution of **23** (500 mg, 3.42 mmol) in pyridine (10 cm^3) was added 4-chlorobenzoyl chloride (0.46 cm^3, 3.60 mmol). The mixture was stirred at room temperature for 30 min, concentrated, diluted with water (70 cm^3) and then extracted with AcOEt. The organic layer was washed with aqueous NaCl solution, dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel with $CHCl_3$–MeOH (4:1). The crude product obtained by evaporation of the solvent was diluted with tetrahydrofuran, and then the insoluble matter was filtered off. The filtrate was concentrated and the residue was triturated with ether to give 350 mg (36%) of **26**; mp 201—203 °C. TLC ($CHCl_3$–MeOH (4:1)) R_f 0.68; IR (KBr) 1780, 1710 cm^{-1}; ^1H NMR (DMSO-d_6) δ=7.69—8.09 (4H, m), 8.67 (1H, d, J=6.0 Hz), 10.68 (1H, bs); MS m/z 284 (M^+). Found: C, 46.27; H, 2.30; N, 9.89%. Calcd for $C_{11}H_6N_2O_4ClF$: C, 46.42; H, 2.12; N, 9.84%.

γ-Radiolysis of 1-Phenyl-1-propanol (27). Stock solutions of **27** were prepared by dissolving it in deionized distilled water or in 1%, 5%, and 10% (v/v) aqueous acetonitrile or methanol in concentration of 200 μg cm^{-3}. The each solution was deaerated with N_2 bubbling for 20 min. An approximately 2 cm^3 of the solution was put into a 5 mmϕ Pyrex glass tube under N_2 and irradiated for 100 Gy (3.15 Gy min^{-1}) with the γ-ray of ^{137}Cs at room temperature (ca. 20 °C). The irradiated mixture was subjected to HPLC to analyze **28**. The conditions of the HPLC analyses were as follows: Column; Lichrosorb RP-18, Mobile phase; aqueous 30% (v/v) methanol solution, Detection; UV, 254 nm.

General Procedure for γ-Radiolysis of 5-Fluorouracil Derivatives. Three kinds of sample solutions of 5-fluorouracil derivatives were prepared by dissolving them in the following three deaerated solvents in concentration of 50 μg cm^{-3}; (a) deaerated aqueous 1% methanol (v/v) solution, (b) 0.1 M H_2SO_4 deaerated solution in aqueous 1% methanol (v/v), (c) deaerated aqueous 1% acetonitrile (v/v) solution saturated with N_2O gas.

Each sample solution was irradiated with γ-ray in the same manner as the γ-radiolysis of **27**. After irradiation, the amount of 5-FU produced by the radiolysis was analyzed by HPLC. The conditions of the HPLC were as follows: Column; Lichrosorb RP-18, Mobile phase; 0.02 M KH_2PO_4–0.02 M K_2HPO_4–2% CH_3CN, Detection; UV, 270 nm.

The authors wish to express their thanks to Professor Yoshio Otsuji of University of Osaka Prefecture for his useful comments and helpful discussions.

Proton and Carbon-13 NMR Study of 1,1,4,4-Tetraphenyl- and 1,4-Diphenyl-1,3-butadiene Dianions in Solution. The Charge Distributions, Structural Features and Rotational Barriers of Phenyl Groups

Yukihiro YOKOYAMA, Yutaka TAKAKURA, Takeshi SAWASAKI, and Kensuke TAKAHASHI*

(Received September 1, 1988)

The dicarbanions (**1** and **2**) produced from 1,1,4,4-tetraphenyl- and 1,4-diphenylbutadienes (**1a** and **2a**) were investigated by means of the ^1H and ^{13}C NMR techniques. Large upfield shifts of the proton and carbon signals caused by the conversion of the hydrocarbons into the dianions were observed. Such shifts were used for evaluating the excess charge distributions in the dianions. From the coupling constants obtained it is concluded that the configuration of the central bond of the anion is the trans one for **1** but the cis one for **2**. Thermodynamical parameters were obtained for the restricted rotation of the phenyl group of the lithium salt of **2**.

Butadiene is the simplest hydrocarbon among the acyclic unsaturated conjugate ones. The dianions derived from the butadienes are, therefore, one of the interesting objectives from their electronic and structural view points. There have been many NMR studies concerning carbanions with odd carbon skeletons, such as allyl, pentadienyl, or heptatrienyl carbanions.[1] Little work, however, has been reported on the NMR parameters of the acyclic carbanions with even carbon skeletons. A ^1H NMR study of 1,1,4,4-tetraphenylbutadiene dianion (**1**) was reported in our previous paper.[2] Recently, we have observed the NMR spectra of the dianions (**2**) produced from 1,4-diphenylbutadiene.[3] We therefore wish to report on the structures and behaviors of these dianions, evaluated from their ^1H and ^{13}C NMR data.

Experimental

The starting materials, **1a** and **2a**, were commercially available and were used without further purification. The solvents used for the preparation of the anionic sample solutions, THF, THF-d_8, and DME, were refluxed upon sodium metal, distilled, degassed, and finally kept on a sodium-potassium alloy. The starting hydrocarbon, **1a** or **2a**, was sublimed, degassed under vacuum, and then dissolved in dried and degassed solvents. The solution was in contact with freshly cut alkali metal flakes (lithium, sodium, or potassium) at room temperature in a hand-made reaction container under vacuum. Immediately after contact, the solution showed a deep-purple color. This colored solution sometimes did not give any narrow ^1H NMR signals, except for very broad ones which were ascribed to a contamination of some anionic radical species. Consequently, the solution was kept in its vessel with stirring for a day or two longer at room temperature so that the reaction would come to completion. Then, the resulting solution was filtered and sealed in an NMR tube and a glass ampule with a breakable seal. All NMR samples were prepared to be 0.1—0.3 mol dm^{-3} solutions sealed in 5 or 10 mm o.d. NMR tubes.

All of the NMR spectra were measured on a Varian XL-200 Fourier transform NMR spectrometer. Variable-temperature spectra were measured in the range from +50 to −95 °C. The proton and carbon-13 NMR chemical shifts were evaluated from the solvent peak used as an internal reference and then converted to δ_H and δ_C values from TMS, by taking δ_H 1.79 (1.75) and δ_C 26.4 (25.4) for THF (THF-d_8), and δ_H 3.28 and δ_C 58.8 for DME.

In order to obtain chemical evidence that the anionic species are dicarbanions, the sodium salt of **2** in THF was quenched by deuterium oxide. The quenched products consist of two isomers. A major component was shown to have a structure consistent with *cis*-1,4-dideutero-1,4-diphenyl-2-butene, C_6H_5-CHD-CH=CH-CHD-C_6H_5; yield ca. 80%; its NMR data were δ_C(CHD)=33.2, $^1J_{CD}$=19.5, δ_H(CHD)=3.48 broad, δ_H(CH)=5.70, doublet (J=5.1 and $J_{\beta\beta'}$=11.4). Another minor component was shown to have a structure consistent with *trans*-3,4-dideutero-1,4-diphenyl-1-butene, C_6H_5-CH=CH-CHD-CHD-C_6H_5: yield ca. 20%; its NMR data were δ_H(C_1H)=6.41, doublet (J=15.9); δ_H(C_2H)=6.23, d-d (J=15.9, 6.6); δ_H(C_3HD)=2.49, d-d (J=6.6, 8) broad; δ_H(C_4HD)=2.75, doublet (J=8 broad).

Results and Discussion

NMR Chemical Shifts and Excess Charge Distributions. The NMR parameters obtained for the anionic species and their precursors are summarized in Tables 1 and 2. Typical examples of the ^{13}C NMR spectra are also shown in Figs. 1 and 2.

All of the ^1H chemical shifts of the dianions are shielded by about 0.2 to 3.4 ppm, as compared with those of the corresponding precursors. This tendency of the upfield shift changes is consistent with the general trend observed in other carbanions.[1] However, it should be pointed out here that the β-proton-chemical-shift change of **2** is significantly large and characteristic. For example, the upfield shift changes of the lithium salt of **2** are about 3.4 and 1.7 ppm for α- and β-protons. While those of pentadienyllithium (as a typical odd-carbon carbanion) are about 2.0, 0.0, and 1.9 ppm for α-, β-, and γ-protons respectively.[4] The upfield shift changes are clearly alternative for the example of odd-carbon carbanions. **2** (as an example of even-carbon

Table 1. Proton NMR Data of The Carbanions and Their Precursors at 200 MHz and 23 °C

Compd/metal/solvent	Chemical shifts δ/ppm					Couplings/Hz

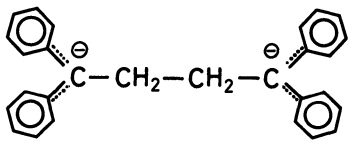
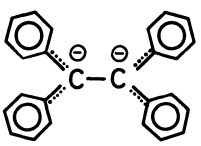
carbanions), however, cannot have such alternation of the shift changes because of its symmetrical even-carbon skeleton. It is also noted that the aromatic proton shifts of **2** are in order of meta, ortho, and para positions from low to high field in the same manner as phenylmethanide ion,[5] while those of **1** are in the order of ortho, meta, and para positions as well as those of 1,1,4,4-tetraphenylbutane-1,4-diide (**3**) and 1,1,2,2-tetraphenylethanediide ions (**4**).[6] This distinc-



3



4

tion between the two casses can be explained in terms of several reasons. One is due to the number of phenyl groups available to delocalization of excess charge, as is pointed out before.[6c] This is because the former dianion has one phenyl group, but the latter has two phenyl groups on the α-carbon, which is an anionic center.

The large upfield shifts of the carbon signals caused by the conversion of hydrocarbons into dianions as well as those of the proton signals are transpired from the data given in Table 2. It is well-known that for delocalized carbanions, carbon-13 shift changes have been used as empirical guides to the distribution of electron densities within the carbanions.[1,7] Because the change are much larger in magnitude than those observed in the ^1H chemical shifts and are less sensitive to other effects than to changes in the electron density. The excess charges on carbons in the carbanions are obtained from a comparison of the chemical shifts between the carbanions and their neutral precursors. The differences of the chemical shifts are extremely large, for example 58—64 ppm at α-carbon, 17—36 ppm at β-carbon, and 30—47 ppm at the total sum of the phenyl carbons, as shown in Table 2. An estimation of the charges on the carbon atoms is made by using an empirical equation proposed by Fraenkel et al.[8] and a factor (160 ppm/electron) presented by Spiesecke and Schneider.[9] The experimentally evaluated values are presented in Table 3. As for the dianion **2**, in comparison with the total excess charges on a phenyl ring, the value of the lithium salt (0.265) is smaller than the values of the sodium and potassium salts (0.283 and 0.296 respectively). However, the excess charge of **1** is estimated to be 0.189 per phenyl ring. This value is smaller than even the smallest one of **2** (0.265). On the other hand, the excess charges on the α- and β-carbon atoms increase from potassium to lithium salts. Furthermore, excess charge on the β-carbon is estimated to be 0.207—0.227 for **2**, though for **1** it is almost one half of **2**. These facts can be explained on the basis of the following: the relative decrease of the charge on the α- of β-carbon atom is consistent with a large delocalization of the charge into phenyl rings. Therefore, the total excess charges on the carbon atoms of dianions **1** and **2** are evaluated to be about 1.7—1.8e from Table 3. It must be pointed out here that the excess charges on the β-carbon of **2** is the second largest next to the α-carbon of **2**. This is one of the characteristic points of the dianion of **2**. This situation will be related to the structural features described later.

Structural Features of the Dianions in Solution. As shown in Table 1, the values of $J_{\alpha\beta}$ and $J_{\beta\beta'}$ of the neutral precursor (**2a**) agree with the previous data reported by Bothner-By and Harris.[10] Consequently, this confirms that **2a** has a certain configuration of trans, trans geometry. Further, the values of $J_{\beta\beta'}$ of **1a** and **2a** have an approximately average value between the typical magnitudes of the s-trans geometries with respect to the rotation about the central bond. In the dianions, on the other hand, $J_{\beta\beta'}$ of **1** and **2** were about 15 and 8 Hz, respectively. These values suggest that the configuration around the central bond of the anion is trans for **1**, but cis for **2**. The situations are quite different for the two carbanions, **1** and **2**. This can be explained as follows: Two phenyl groups attached to the C_α of **1** will have a greater repulsion than the α-carbon moiety of **2** due to steric effects. Another fact must be noted, that the $J_{\beta\beta'}$ value of the sodium salt of **2** is almost similar to that of the lithium salt. Therefore, the cis configuration of **2** is one of its characteristic structural features. The results obtained here regarding the THF solution are consistent with a theoretical prediction[11] and an X-ray analysis of the dianion in the solid state.[12] The *cis*-butene-like skeleton of **2**, thus determined, can surround the counter-cations. This situation is related to the fact that the excess charge is concentrated, especially on both the α- and β-carbons in the dianion **2**, as stated in the former section. From the large excess charge on C_α and C_β it is considered that the two carbons are expected to be in the proximity of the counter cations. As described in the experimental section, the main quenched product of **2** has the cis configuration in the central bond, which is assigned from its coupling constant of 11.4 Hz, as compared with the value of 2-butene.[13] Therefore, it is concluded that the configuration of **2** is held as it is when it is quenched by D_2O.

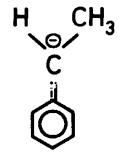
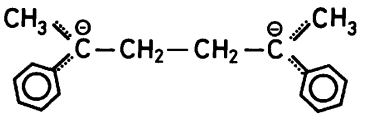
a) Average values of two positions. b) Not available.

Equivalency or Nonequivalency of Ortho or Meta Positions in the Phenyl Groups of the Dianions. The chemical shifts of two ortho or meta carbons in a phenyl ring of **1** are equivalent, but those of **2** are nonequivalent, as is shown in Figs. 1a and 2b. Additionally, coalescence of meta carbon lines and broadening of ortho carbon resonances were observed for the lithium salt of **2** at room temperature, as shown in Fig. 2a. The appearance of the nonequivalency in the sodium and potassium salts was attributed to the higher rotational barrier about the C_α and C_i bond, as compared with the case of lithium salt (Figs. 2a and 2b). This fact can be interpreted on the basis of the effect of the counter cations.[14] The nonequivalency was caused by a conjugative interaction between C_i and C_α. This situation is similar to the nonequivalency observed in 1-phenylethanide (**5**) and 2,5-diphenylhexane 2,5-diide (**6**) ions.[6c,14,15] This is due to the fact



5



6

that both a phenyl ring and a butadiene skeleton prefer to take their positions on a plane because of a strong $p\pi$–$p\pi$ interaction. However, in the neutral molecule **2a** there is a free rotation around the bond between the phenyl ring and its adjacent carbon; however, in the case of **2** the rotation is restricted in its NMR time scale. On the other hand, the two phenyl rings connected to the α-carbon of **1** cannot be coplanar due to their steric hindrance as well as those of the neutral precursor **1a**.[15] As is shown in Fig. 1, however, the ^{13}C spectra of **1** showed an equivalency of the four ortho or meta carbons in the two geminal phenyl rings, while there are two C_i, C_o, C_m, and C_p signals in **1a**. These facts suggest that there is a free rotation about the C_i and C_α bond in **1** and **1a**, while the rotation around the bond between the C_α and C_β atoms is forbidden in **1a** but allowded in **1** at room temperature.

Temperature Dependency of the Chemical Shifts of 2. It was pointed out before that in the ^{13}C NMR spectrum of the lithium salt of **2** (Fig. 2a) coalescence of the C_m signals and broadening of the C_o signals were observed at room temperature. These phenomena can be explained by the restricted rotation of the phenyl group around the C_i–C_α bond. The temperature-dependent ^{13}C chemical shifts are shown in Figs. 3a and 3b. As shown in the figures the C_m and C_β shifts are almost constant in the temperature range studied, while the C_i, C_o, and C_p shifts move towards a lower field by about 1—2 ppm in magnitude when the temperature is raised; the C_α shift, however, moves towards a higher field by about 2 ppm. This tendency

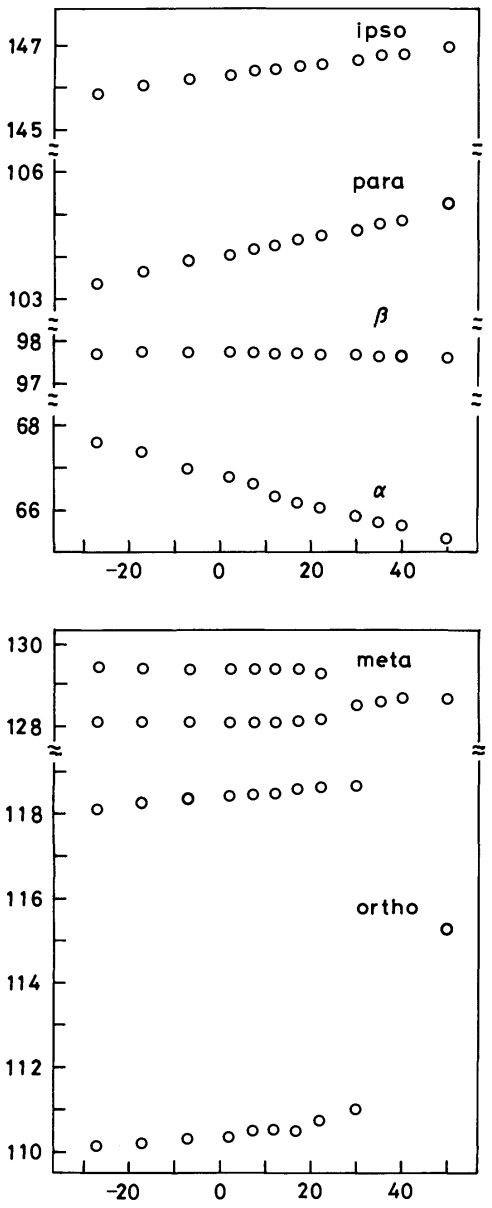


Fig. 3. ^{13}C chemical shifts (ordinate in ppm) of **2** in THF-d_8 as a function of temperature (abscissa in °C) at 50.3 MHz.

can be explained by an excess charge on the C_α which increases with increasing temperature. This means that the $p\pi$–$p\pi$ interaction between the C_α and C_i decreases with increasing temperature. This is consistent with the fact that the phenyl ring can rotate at higher temperature, faster than that of the NMR time scale. In the sodium salt of **2**, on the other hand, the spectrum does not change its line shape in the temperature range from −70 to 60 °C. Therefore, the activation free-energy change will be larger than 68 kJ mol^{-1} by using an equation given by Sandström[16] and the chemical-shift difference of 78.5 Hz. Therefore, it must be said that the barrier of phenyl rotation of **2** is strongly affected by a counterion whose tendency is similar to that stated by Worsfold and Brownstein.[14]

Table 4. Thermodynamical Parameters for the Hindered Rotation of the Phenyl Group of the Lithium Salt of **2**

Site	E_a/kJ mol^{-1}	log A	ΔH^*/kJ mol^{-1}	ΔS^*/J K^{-1} mol^{-1}
Ortho	62.7±1.2	13.0±0.3	60.3±1.1	−3.0±4.0
Meta	61.6±1.4	12.7±0.3	59.2±1.4	−10.0±5.0

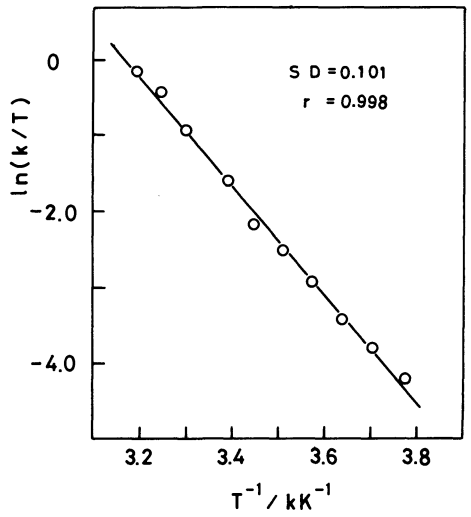

Fig. 4. An Eyring plot for the rotation of phenyl groups of the lithium salt of **2** in THF-d_8.

In the lithium salt of **2**, ^{13}C NMR analyses were carried out for both the ortho and meta carbon signals as an AX-spin system. The parameters used for the DNMR analyses are $\Delta\delta$ (ortho)=405; $\Delta\delta$ (meta)=64.3 Hz; T_2*=0.134 s. The kinetic parameters have been determined by visual fittings of the calculated line shapes with the experimental ones. The thermodynamic parameters were obtained by the Arrhenius and Eyring plots of the rate constants with inverse temperatures, one of which is shown in Fig. 4. The parameters, thus determined, are given in Table 4. The parameters independently obtained for both the ortho and meta carbons are consistent with each other within the experimental errors. The values are compared with those reported for similar substituted phenylmethanide ions.[14,17-20] The barrier of the phenyl rotation of **2** is larger than those observed for diphenylmethanide ions.[21,22]

The authors wish to thank Messrs. Katsuhiko Kushida and Hajime Katoh (Varian Instruments Ltd.) for their kindness in measuring several ^{1}H spectra at 300 MHz. This work was partly supported by a Grant-in-Aid for Scientific Research (1988), No. 63540336, from the Ministry of Education, Science and Culture.

(Received September 5, 1988)

The single crystals of $NiPc(SbF_6)_{0.5}$ and $NiPc(AsF_6)_{0.5}$ were prepared by means of an electrochemical method. The electrical, magnetic, optical, and structural properties of these crystals were examined. These crystals are isostructural to each other, and exhibit a metallic behavior at least above 200 K. The g-values of the ESR signals remarkably depend upon temperature. By the aid of the low temperature experiments of XANES and reflectance spectrum, the temperature dependence is explained by the model based on the interaction between the small amount of local spins on the Ni atoms and the conduction electrons on the ligand chain. In addition, a sample dependence was found on the ESR properties of the crystals of $NiPc(AsF_6)_{0.5}$. This is attributed to the sample dependence of the concentration of the local spins on Ni atoms. From these considerations, we concluded that the ligand part is mainly oxidized in these partially oxidized salts, in other words the conduction electrons are located on the ligand chain. The bandwidth of the conduction band was estimated to be about 1 eV.

The one-dimensional metals based on the metal phthalocyanine (MPc) or metal tetrabenzoporphyrin (MTBP) are unique materials which may be able to involve two conduction pathways in the same metal macrocycle column.[1] These pathways are possibly composed of the π-orbital of the ligand and the d_{z^2}-orbital of the central metal, first because the molecules are stacking with the overlapping mode of a metal-over-metal type,[2] secondly because the highest occupied molecular orbital (HOME) of a phth alocyanine (Pc) does not mix with the d_{z^2}-orbital of the central metal due to the symmetry restriction, thirdly because their orbital energies are quite close.[3-5] The excitonic superconducting mechanism is theoretically proposed in the materials which involve this kind of composite energy bands that are weakely coupled and proximately located to each other.[6] Therefore, it is of great importance to elucidate which orbitals are contributing to make the conduction bands. The research group at Northwestern University extensively studied the partially oxidized salts of metal phthalocyanine (MPc) and metal tetrabenzoporphyrin (MTBP).[1,2,7-14] As for the iodine complex (NiPcI) of NiPc, the conduction band is formed from the highest occupied molecular orbital (HOMO, a_{1u}) of the Pc ligand, and the d-orbital is not involved in the conduction band.[2] On the other hand, the conduction electrons of CoPcI are located on the metal chain in the Pc column.[10] Furthermore, the unpaired electrons of the iodine complex (NiTBPI) of NiTBP exhibit that they are located partly at the ligand site and partly at the Ni site.[1] Martinsen et al. interpreted this phenomenon by considering that the conduction band is composed of $a_{1g}(3d_{z^2})$-band along the metal chain and the $a_{1u}(\pi)$-band along the ligand chain.[1] We prepared the analogous complexes, $NiPc(SbF_6)_{0.5}$ and $NiPc(AsF_6)_{0.5}$, by the use of the electrochemical oxidation of NiPc, and found that the ESR behavior of $NiPc(SbF_6)_{0.5}$ is quite similar to that of NiTBPI.[15,16] Later on, we found a strong sample dependence on the ESR property of $NiPc(AsF_6)_{0.5}$. Lookig at this phenomenon through the eyes of ESR, some crystals of $NiPc(AsF_6)_{0.5}$ behave like NiPcI, someone like CoPcI, and the others like NiTBPI. We are interested in whether the conduction band of $NiPc(SbF_6)_{0.5}$ is really composed of the π-and d_{z^2}-orbitals, and whether the sample dependence of $NiPc(AsF_6)_{0.5}$ is the intrinsic property. In this paper, we present the experimental results on the temperature dependence of the ESR property, XANES and reflectance spectrum of $NiPc(SbF_6)_{0.5}$, and characterize the magnetically different $NiPc(AsF_6)_{0.5}$ by means of EPMA, X-ray diffraction, and reflectance spectrum.

Experimental

The finely powdered NiPc was refluxed in the pyridine solution and was filtrated to remove CoPc. This procedure was repeated over ten times and then the filtrated NiPc powder was sublimed in vacuum for four times. The contamination by the magnetic impurity was less than 10^{-4} spins per a NiPc molecule which was estimated with the aid of ESR at low temperature. The ESR signal of this impurity, probably Co^{2+} species, was not attributed to CoPc, since the ESR pattern due to the hyperfine splitting was entirely different from that of CoPc.[17] $(n\text{-}Bu)_4NSbF_6$ and $(n\text{-}Bu)_4NAsF_6$ which were used as electrolytes for the electrochemical oxidation were prepared by mixing the equimolar aqueous solutions of $(n\text{-}Bu)_4NBr$ and $NaSbF_6$ or $KAsF_6$. The precipitated $(n\text{-}Bu)_4NSbF_6$ and $(n\text{-}Bu)_4NAsF_6$ were recrystallized from the methanol solution for three times. 1-chloronaphthalene was refluxed with CaH_2 and purified by vacuum distillation. The radical salts of NiPc were prepared by the method of electrochemical crystallization at 120±2 °C under the Ar

† Present address: Institute for Molecular Science, Myodaiji-cho, Okazaki, Aichi 444.

atmosphere. The concentrations of the electrolyte and NiPc were 2.5×10^{-3} and 3×10^{-4} mol l^{-1}, respectively. The crystals were grown for about two weeks with a galvanostatic mode of 2 μA.

The chemical analysis of Ni, Sb, and As were conducted with the aid of ICP atomic emission spectroscopy. Several single crystals (ca. 10 μg) were dissolved in concd H_2SO_4, then decomposed in concd HNO_3 and diluted with pure water. The emission lines, 231.6, 206.8, and 193.6 nm were used for the detection of Ni, Sb, and As. The intensities of these emission lines were measured simultaneously by using Jarrel-Ash, Model Plasma Atomcomp MK-II. The atomic ratios were Sb/Ni=0.48±0.04 for NiPc-SbF_6 and As/Ni=0.50±0.02 for NiPc-AsF_6. The sample dependence of the atomic ratio between Ni and As of the single crystal was measured by means of EPMA using JEOL superprobe 733. The Ni foil and the single crystal of GaAs were used as the standard materials of Ni and As atoms. EPMA were performed at seven points on each crystal of 0.03 mm×0.03 mm×0.3 mm by the use of the electron beam of 1 μm diameter.

ESR was measured on a needle-like single crystal or a bundle of single crystals using JEOL JES-FE1XG combined with an Air Products LTR-3-110 continuous flow type liquid He cryostat. The needle-like crystals over 10 were aligned in the Pyrex capillary. Li-TCNQ was used as the standard sample to determine the g-value. The intensity of the ESR signal was calculated by the numerical double integration, and this intensity was transformed to the spin susceptibility by the comparison with the intensity of the ESR signal of violanthrone for which the static susceptibility had been measured.

For the experiment of X-ray diffraction, we used the needle-like crystal of $NiPc(AsF_6)_{0.5}$ developing along the c-axis, the typical dimension of which was 0.05 mm×0.05 mm×0.5 mm. The 2296 reflections were collected using Rigaku four-circle automated diffractometer. The X-ray source was the Cu $K\alpha$ radiation monochromatized with a graphite plate. We selected 1940 reflections which are three times larger than the standard deviations estimated from the counting errors. The absorption correction was made with a program ACACA written by Prewitt. The structure was solved by the heavy atom method and was refined by the block-diagonal least-squares method with the anisotropic temperature factors for Ni, N, C, As, and F atoms and the isotropic temperature factors for H atoms. The possible space group was *Pncm* or *Pnc*2 from the systematic absence. At first the structure was analyzed assuming the space group, *Pncm*. However, the final R-value was 0.12, and the temperature factors of F atoms were too large. This means that F atoms are neither located on the mirror plane nor two-fold axis. Thus, the structure was analyzed in the non-centrosymmetric space group, *Pnc*2. The final R-value was 0.065.

The X-ray absorption spectrum near the Ni K-edge was measured using the EXAFS facilities at the beam line 10B of the Photon Factory in the National Laboratory for High Energy Physics (KEK-PF).[18] The single crystal of the dimension, 0.15 mm×0.15 mm×2 mm, was used for measuring the transmission spectrum. This crystal was fixed with vacuum grease onto the round mask which was made from stainless steel with the thickness of 0.1 mm, and had a rectangular diaphragm of 0.1 mm×1 mm. Polarized spectra were measured with the X-ray polarization parallel, 45°, and perpendicular to the long axis of the crystal. The CTi cryocooler, Model 20, was used for cooling the sample crystal.

The polarized reflectance spectra of single crystals were measured at room temperature and 80 K using the micro-spectro-reflectometer which was designed and constructed in our laboratory (Chemistry Department, the University of Tokyo).[19]

Temperature dependence of the electrical resistivity was measured by the low-frequency AC four-probe method. The electrical contact to the 10 μm gold wires was made with carbon paint. The cooling rate of the crystal was about 0.5 K min^{-1}.

Results and Discussion

$NiPc(SbF_6)_{0.5}$. The chemical ratio between NiPc and SbF_6 is consistent with the crystal structure which we have published in the previous paper.[15] The crystal belongs to the orthorhombic system, the space group being *Pnc*2. The lattice constants are a=14.113(1) Å, b=28.710(2) Å, c=6.441(2) Å, and Z=2. The crystal structure is essentially the same as that of $NiPc(AsF_6)_{0.5}$, the structural details of which will be described in the next section. NiPc is stacking metal-over-metal with the planes of molecules normal to the stacking axis. Successive molecules are staggered by 41.0°. The unit cell contains two molecular columns. The counter anions, SbF_6^-, are located on the same plane of NiPc, so that NiPc is pushed away by 0.2 Å from the stacking axis. Therefore, the metal chain of NiPc is aligned zigzag along the c-axis. Unlike the disordered arrangement of I_3^- in the NiPcI crystal,[2] SbF_6^- is three dimensionally ordered in this material. However, they are probably thermally fluctuating since the temperature factors of anion is larger by a factor of 5—10 than those of NiPc.[15]

The electrical conductivity is 10—200 S cm^{-1} at room temperature and gradually increases on lowering temperature down to 250 K. At lower temperature, however, the resistivity jumps take place at various temperatures, which are not reproducible in the heating or cooling processes. Therefore, the intrinsic behavior of the electrical resistivity in the low temperature region is unidentified at present. Since these resistivity jumps are sometimes observed in the one-dimensional materials, this phenomenon indicates the one-dimensional electric conduction in this material.

The angle dependence of the g-value at room temperature was showm in Fig. 1. The principal values are $g_{/\!/}$=1.994 and $g_{\perp}$=2.030, where // and ⊥ denote the geometrical relation between the c-axis of the crystal and the static magnetic field. These axes just coincide with the principal axes of the NiPc molecule. The principal values of NiPc molecule are

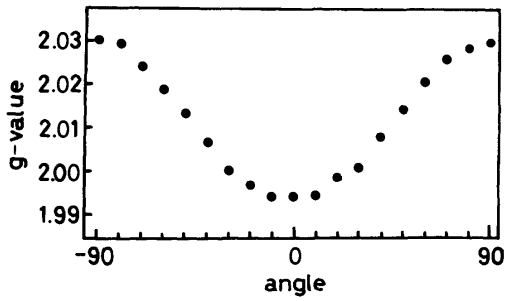

Fig. 1. Angular dependence of the g-value of $NiPc(SbF_6)_{0.5}$. The c-axis is parallel to the static magnetic field when the angle is 0°.

$g_{/\!/}$=2.113 and $g_\perp$=2.292 for metal-oxidized species, $Ni^{3+}Pc^{2-}$, and $g_{/\!/} \sim g_\perp$=2.003 for ligand-oxidized species, $Ni^{2+}Pc^{-}$.[20] Therefore the unpaired electrons of $NiPc(SbF_6)_{0.5}$ has an intermediate character between the metal-oxidized $Ni^{3+}Pc^{2-}$ and the ligand-oxidized $Ni^{2+}Pc^{-}$. This character of the unpaired electrons show a contrast to the π-character of NiPcI, in which the principal values are $g_{/\!/}$=2.0075, $g_\perp$=2.0007.[2] Martinsen et al. found the intermediate g-values ($g_{/\!/}$=2.060 and $g_\perp$=2.018) in NiTBPI, and attributed them to the rapid transfer of the unpaired electron between a ligand and a central metal.[1] Therefore, a similar situation is possibly realized in $NiPc(SbF_6)_{0.5}$. The relation, $g_{/\!/} > g_\perp$, which is reverse to the usual square planar d^7 complex with a low spin configuration, was explained on the basis of the back charge transfer from triiodide ion. In this sense, the contrary relation, $g_{/\!/} < g_\perp$, in this crystal is consistent with their interpretation, because this material does not contain triiodide ions. At the same time, the angular dependence of the g-value indicates that the ESR signal is originated from the $Ni^{3+}Pc^{2-}$ species in the crystal, and suggests that the d-hole configuration of $Ni^{3+}Pc^{2-}$ is $(d_{x^2-y^2})^2(d_{z^2})^1$.[21]

The temperature dependence of ESR were conducted on ca. 20 single crystals aligned in the glass capillary so that the needle axes (//c) were perpendicular to the static magnetic field. The temperature dependence of $g_\perp$, a linewidth, and a doubly integrated intensity were displayed in Figs. 2b—2d. With the decrease of temperature,the linewidth and $g_\perp$ remarkably increase and the intensity slightly decreases. The increase of the linewidth is closely related to the increase of $g_\perp$ which is the measure of the contribution of d-orbital which brings about the fast relaxation due to the large spin-orbit coupling constant. The temperature-dependent spin susceptibility was divided into two components, one of which comes from the metal chain and the other from the ligand chain using the following equation.[22]

$$\chi_{Ni}(T) = [(g_{obs} - g_{Pc})/(g_{Ni} - g_{Pc})]\chi_{obs}(T)$$
$$\chi_{Pc}(T) = [(g_{Ni} - g_{obs})/(g_{Ni} - g_{Pc})]\chi_{obs}(T)$$

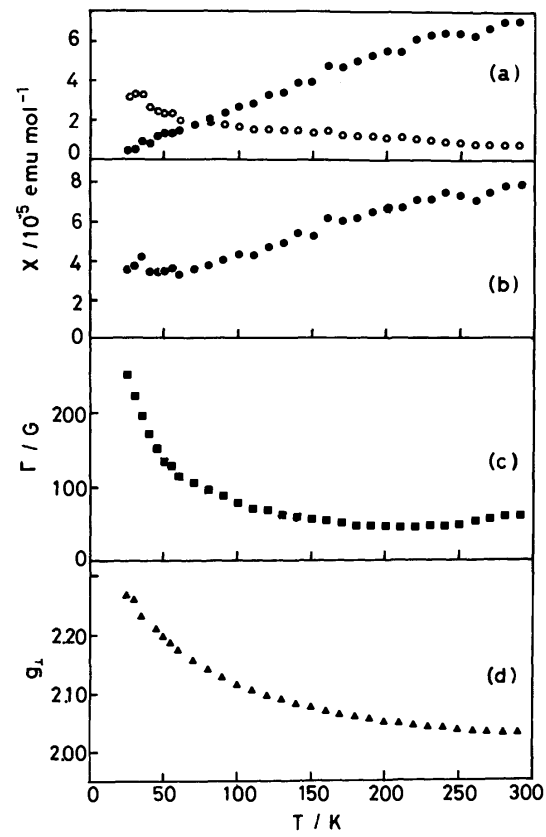

Fig. 2. Temperature dependence of the ESR signal (H⊥c) of $NiPc(SbF_6)_{0.5}$. (a) Spin susceptibilities of the Ni chain (open circle) and the Pc chain (solid circle), (b) observed spin susceptibility, (c) linewidth, and (d) g-value.

These results are drawn by solid and open circles in Fig. 2a. In this process, we tentatively used g_{Ni}=2.292 and g_{Pc}=2.003 which were reported by Bobrovskii and Sidorov in the oleum solution of NiPc.[20] The $g_\perp$ of $NiPc(SbF_6)_{0.5}$ is in-between those of $Ni^{3+}Pc^{2-}$ and $Ni^{2+}Pc^{-}$, but the $g_{/\!/}$ is smaller than both of them. It is well-known that the g-values of the transition metal atoms coordinated with a square planar mode are very sensitive to the axial coordination by the solvent molecule. In fact as we will mention in the next section, the $g_\perp$-value of some crystals of $NiPc(AsF_6)_{0.5}$ is larger than $g_\perp$=2.292 of $Ni^{3+}Pc^{2-}$. Therefore, the larger values than 2.292 should be taken as the standard g-value of a metal-oxidized species. Taking this situation into account, the contribution of $\chi_{Ni}(T)$ is overestimated in this analysis, but we believe that the qualitative trend on temperature dependence is reliable. At low temperature, $\chi_{Ni}(T)$ increases and overwhelms $\chi_{Pc}(T)$ which is dominant at room temperature.

Martinsen et al. studied the structure and properties of NiTBPI, which exhibits quite similar ESR properties to that of $NiPc(SbF_6)_{0.5}$.[2] They qualitatively interpreted the d-character of the unpaired electrons using the

band model composed of the two conduction bands, one of which derived from the HOMO of the ligand (a_{1u}-band) and the other from the $3d_{z^2}$ orbital of a Ni atom (a_{1g}-band). They regarded the a_{1g}-band as the origin of the d-character. The conduction electrons in the a_{1u} and a_{1g} bands exchange with each other faster than the microwave frequency. In this model a considerable amount of charge carriers are located on the conducting Ni chain as well as on the conducting Pc chain. However, it is not easy to explain the temperature dependence of the g-value by this model. For example, the contribution of $\chi_{Pc}(T)$ is dominant at room temperature, but it is reverse at low temperature as shown in Fig. 2a. To explain this behavior based on the Pauli paramagnetism of the two tight-binding bands, we have to shift the relative position of these band centers depending upon the temperature so as to adjust the density of state at the Fermi level of each band. This requires the temperature dependent band filling factor, namely the degrees of oxidation at the Ni and ligand sites. Another possible interpretation is based on the model in which the conduction electrons are located mainly on the ligands and they exchange rapidly with a small amount of localized electrons on the Ni sites. This is the extreme case where the bandwidth of the d-band is much narrower than that of π-band. In this model, the increase of $\chi_{Ni}(T)$ is attributed to the Curie law, and the decrease of $\chi_{Pc}(T)$ is related to a narrow energy gap in the conduction band, which will be discussed again in the next section. Assuming the Curie law as to $\chi_{Ni}(T)$, the spin concentration at the Ni site with $S=1/2$ was estimated to be 4×10^{-3} spins per a NiPc. Therefore, the ligand site is predominantly oxidized, so that the temperature dependent degree of oxidation at the ligand site is not necessary in this model. These two models can be distinguished from the temperature dependence of the numbers of charge carriers on each chain. If the degree of oxidation on each chain does change at low temperature, we have to adopt the former model, while the latter model will be appropriate if not. The temperature dependence of the d-holes at the Ni site is examined with the X-ray absorption spectrum of 1s→3d transition, and the change of the degree of oxidation at Pc site at low temperature is checked by the intensity of the Q-band.

The X-ray absorption spectrum of the electron quadrupole transition, 1s→3d, provides the information on the bulk property of the vacant d-orbitals. The spectra (1) and (2) shown in Fig. 3 are the X-ray absorption spectra near the K-edge on the powdered samples of $NiPc(SbF_6)_{0.5}$ and NiPc, respectively. As for the 1s→3d transition at 8321.5 eV, no significant difference was found between them. The spectra (3), (4), and (5) in Fig. 3 are the polarized absortion spectra of the 1s→3d quadrupole transition of the single crystal of $NiPc(SbF_6)_{0.5}$. The selection rule of the

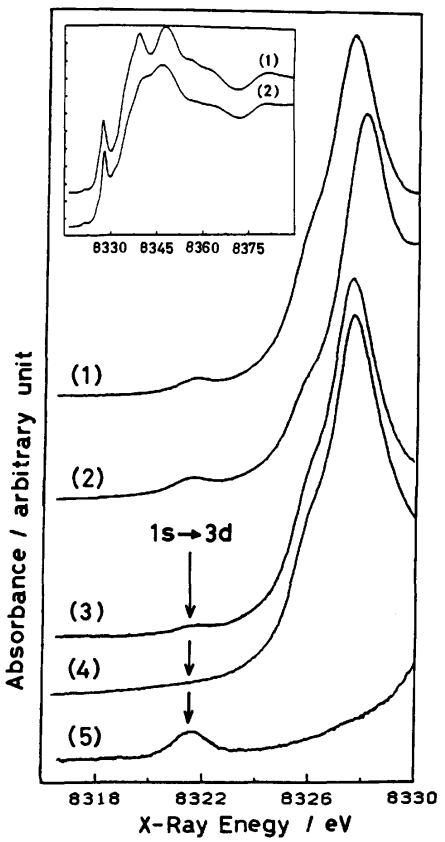

Fig. 3. X-Ray absorption spectra of the powdered samples of (1) $(NiPc)_2SbF_6$ and (2) NiPc, and (3—5) the single crystals of $NiPc(SbF_6)_{0.5}$. A weak absorption band at about 8321.5 eV is the 1s→3d electric quadrupole transition, and the absorption band at about 8328 eV is the electric dipole 1s→π^* transition. (3) The electric vector makes an angle of 45° with the c-axis in the polarization plane. (4) The electric vector of the incident light is parallel to the c-axis. (5) The polarization plane of the incident light is perpendicular to the c-axis.

quadrupole transition is determined by the relative direction between the one-dimensional Ni chain and the polarization plane (the plane of vibration of electric field).[23] The selection rule of the 1s to 3d transition is listed in Table 1. If this absorption band is a single component, this transition is assigned to the 1s→$3d_{x^2-y^2}$ from the selection rule and the theoretical study of the NiPc free molecule.[5] This experimental result apparently indicates that the d-orbitals except $3d_{x^2-y^2}$ is fully occupied as expected in the second model. However, the interpretation of this spectrum is not simple, because CoPc and FePc also exhibited a single absorption band for the 1s→3d transition,[24] although they have respectively the electronic configurations of $(3d)^7$ and $(3d)^6$. Therefore, we cannot preclude the possibility that 1s→3d band of $NiPc(SbF_6)_{0.5}$ is attributed to the superposition of the 1s→$3d_{x^2-y^2}$ transition and the other 1s→3d transition. This case is consistent with the first model (two-band model). If

Table 1. Selection Rule of Quadrupole Transition

(1) E⊥c: When the c-axis of the crystal is perpendicular to the polarization plane, a quadrupole transition is allowed only from 1s to $3d_{x^2-y^2}$ and to $3d_{xy}$. (2) E//c: When the electric vector is parallel to the c-axis, quadrupole transition is allowed from 1s to $3d_{xy}$ and $3d_{yz}$. (3) $\angle(E,c)=45°$: When the c-axis makes an angle of 45° against the electric field vector in the polarization plane, the transition from 1s to $3d_{z^2}$ and $3d_{x^2-y^2}$ is allowed.

this is the case, the candidate of this vacant d-orbital is $3d_{z^2}$ or $3d_{xy}$ from the selection rule shown in Table 1, and then the $1s\rightarrow 3d_{z^2}$ or $1s\rightarrow 3d_{xy}$ transition should change significantly at low temperature accompanying the change of the degree of oxidation at the Ni site. However, no significant change was detected in the 50 K spectra of the powdered sample and the single crystal. This result supports the second model, that is, the majority of carriers are located on the ligand chain and a small amount of unpaired electrons are localized at the Ni site. The d-character of the ESR signal is attributable to the rapid exchange between these local spins at the Ni site and the migrating spins on the ligand chain. Figure 4 shows the polarized reflectance spectrum of the single crystal of $NiPc(SbF_6)_{0.5}$. In the ⊥c spectrum, the intramolecular transition (Q-band) of a neutral NiPc was observed at 15400 cm^{-1}. Figure 5 shows the comparison of the ⊥c spectra at room temperature and 80 K. In this spectrum, weak shoulders showed up around 13000 and 23000 cm^{-1}. These weak dispersions are tentatively assigned to the intramolecular transitions of $Ni^{2+}Pc^-$ cation radical

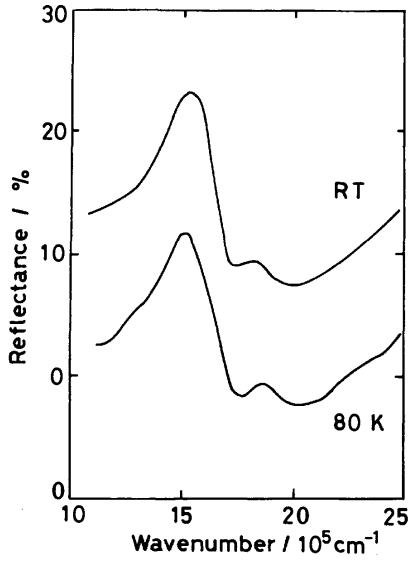

Fig. 5. Reflectance spectrum of the Q-band measured at 80 K and room temperature.

from the comparison of the solution spectra of Li^+Pc^-[25] and $Co^{2+}Pc^-$,[26] the ligands of which are oxidized. Since the transition probability of the intramolecular transitions of NiPc cation radicals are small, we consider that these shoulders are faded away at room temperature. The reflectivity of the Q-band of $NiPc(SbF_6)_{0.5}$ is considerably smaller than that of NiPcI.[8] This result is reasonable, since the degree of oxidation $NiPc(SbF_6)_{0.5}$ is larger than that of NiPcI. Thus, the intensity of the Q-band reflects the degree of oxidation at the ligand site. Although a considerable increase of the d-character is expected at 80 K from the g-value of the ESR signal, the reflectivity of the Q-band does not change significantly. This result supports again the second case that the majority of carriers are located on the π-band in the whole temperature range.

We analyzed the reflectance curve of the //c spectrum using the Drude model, and obtained the plasma frequency and the relaxation time. The plasma frequency, $\hbar\omega_P$, was estimated to be 0.86 eV, the relaxation time, $(0.8—1.2)\times10^{-14}$ s, and dielectric constant, 2.1. The bandwidth, $4t$, was calculated using the following equation,

$$4t = \{V_m(\hbar\omega_P)^2\}/\{4e^2c^2\sin(k_fc)\}$$

where V_m is the volume of $(NiPc)(SbF_6)_{0.5}$, c the interplanar distance between the adjacent phthalocyanines, e the unit charge of an electron, and k_f the Fermi wavevector. Since the majority of carrier is located on the ligand chain, the width of the π-band, 4t is estimated to be 1.1 eV from the values, $V_m=6.524\times10^{-22}$ cm^3, $\hbar\omega_p=0.86$ eV, $c=3.22\times10^{-8}$ cm, and $k_fc=3\pi/4$. In the analogous materials like H_2PcI, NiPcI, and CuPcI, the conduction bands are made up of π-orbitals

of ligands. The bandwidth of these materials are 0.84,[2] 1.3,[12] and 1.4 eV[14] for NiPcI, H_2PcI, and CuPcI, respectively. The bandwidth, 1.1 eV, of $NiPc(SbF_6)_{0.5}$ falls in the range of these materials with π-conduction bands. We briefly comment on the relaxation time of conduction electrons which is the measure of the strength of the electron-phonon interaction. Although the ambiguity of the relaxation time is much larger than that of plasma frequency in the curve-fitting analysis, the following discussion is qualitatively reliable. The relaxation time is comparable with the corresponding values, 0.7×10^{-14} s for NiPcI and 0.9×10^{-14} s for H_2PcI, and 1.4×10^{-14} s for CuPcI[14] but significantly longer than the room-temperature values of other organic metals, 0.4×10^{-14} s for TTF-TCNQ,[27] 0.2×10^{-14} s for $TTF\text{-}I_{0.71}$,[28] 0.3×10^{-14} s for $(TMTSF)_2PF_6$,[29] 0.4×10^{-14} s for $(TMTSF)_2ClO_4$,[30] 0.3×10^{-14} s for $(DMtTSF)_2ReO_4$.[31] These results suggest that the conduction electron on the phthalocyanine ring is interacting weakly with the lattice phonon.

$NiPc(AsF_6)_{0.5}$. In contrast to $NiPc(SbF_6)_{0.5}$, we found a strong sample dependence on the magnetic property of $NiPc(AsF_6)_{0.5}$. To characterize these magnetically different crystals, we selected 90 crystals which were larger than 0.05 mm×0.05 mm×6 mm, and measured the ESR signal on each crystal under the condition that the needle axis is perpendicular to the static magnetic field. Figure 6 shows the distribution of the ESR patterns which was classified by the linewidth. The ESR signal is sometimes composed of two or three components with different linewidths. These mixtures are indicated by the dotted histograms. As shown in this figure, the linewidth of the ESR signal is almost continuously distributed from about 1 G to over 100 G (1 G=10^{-4} T). F denotes the sample which is ESR silent probably due to the too broad linewidth. The typical examples of the ESR pattern is shown in Fig. 7. The different types of crystals, i.e. types A and D, were usually found in the same batch. We consider that the sample dependence is not attributed to the contamination of the magnetic impurities because the samples are prepared from the same starting materials as what was used for the preparation of $NiPc(SbF_6)_{0.5}$ which does not show such a sample dependence. The temperature dependence of the magnetic susceptibility, linewidth and g-value of the typical types of crystals were measured on the single crystals of the types A and B and the aligned crystals of the types D and E. The results are shown in Fig. 8.

It is well-known that the electrochemical oxidation of BEDT-TTF (bis(ethylenedithio)tetrathiafulvalene) produces the crystals which have many chemical compositions and a variety of polymorphs with the same composition.[32] In these crystals of BEDT-TTF, the physical properties are quite different from each other. In order to examine whether these ESR patterns

comes from the different chemical compositions or the polymorphism, we conducted the elementary analysis on each crystals with the aid of EPMA. The results shown in Table 2 indicates that all these crystals have essentially the same chemical composition, 2:1 for Ni:As within the experimental error.

The oscillation and Weissenberg photographs indicated that these crystals belonged to the same orthorhombic system with the space group, *Pncm* or *Pnc*2. The lattice constants of the types A, B, D, and E

were determined using a four-circle diffractometer on the crystals of $NiPc(AsF_6)_{0.5}$. The results are shown in Table 3 together with that of $NiPc(SbF_6)_{0.5}$. The lattice constants agreed with each other except that of the type B crystal. We consider that this small difference comes from the poor quality of the crystal B, which is reflected on the 10 times larger standard deviations. The crystal structure analysis was conducted on the type A crystal which exhibits most different magnetic behavior from that of $NiPc(SbF_6)_{0.5}$. The final atomic coordinates are shown in Table 4. Figure 9 illustrates the molecular arrangement in the crystal of $NiPc(AsF_6)_{0.5}$. The NiPc molecules are slightly zigzag stacking along the c-axis. The shift of the central Ni atom from the axis (0.5, 0.25, z) is 0.21 Å, which is the same value as that of $NiPc(SbF_6)_{0.5}$. The neighboring NiPc is staggered by 40.4° around the stacking axis. The crystal structure is almost exactly the same as that of $NiPc(SbF_6)_{0.5}$.[33] The temperature factors of AsF_6^- is considerably larger than those of NiPc. The root-mean-square displacement of the As atom is 0.23, 0.19, and 0.45Å along the a-, b-, and c-axes, respectively. Since the c-component of the temperature factor of As is also large, AsF_6^- is not only orientationally disordered, but also positionally fluctuated along the c-axis. Therefore, the molecular structure of AsF_6^- is determined to be heavily distorted as shown in Fig. 9a. This kind of distortion was also observed on SbF_6^- in the crystal of $NiPc(SbF_6)_{0.5}$.[15] Incidentally the equivalent isotropic temperature factors of SbF_6^- were 7.8 for Sb and 14.9, 15.2, and 25.9 for F atoms. No significant difference was found in the molecular structure of NiPc between this complex and $NiPc(SbF_6)_{0.5}$. We consider that the structure of the type A crystal is essentially the same as

those of the other types of crystals and of $NiPc(SbF_6)_{0.5}$. The anisotropic temperature factors and F_o-F_c data are deposited as Document No. 8856 at the office of the Editor of Bull. Chem. Soc. Jpn.

The electrical conductivities of the crystals of types C and F exhibited metallic behavior at least down to 200 K. The temperature dependence of the resistivity of these crystals was exactly the same with each other. Due to the resistivity jumps, the intrinsic electrical properties in the low temperature region could not be revealed.

The reflectance spectra of the crystals, C and F, were measured at room temperature. The spectrum of the type C crystal was shown in Fig. 10. These crystals exhibited a typical metallic reflection spectrum with a one-dimensional nature along the c-axis. The reflectivity curve around the plasma edge was analyzed by the use of Drude model. The plasma frequencies and the relaxation times were obtained to be 0.89 eV and 1×10^{-14} s for the type C crystal and 0.91 eV and 0.9×10^{-14} s for the type F crystal. The bandwidth of the tight binding band of these crystals were estimated to be 1.2 eV for both types. The $\perp c$ spectrum was drawn by a dotted line. The dispersions around 15000 cm^{-1} are the Q-band of the neutral NiPc. No significant difference was found between the spectra of the types C and F in the Q-band region. If we use the two-band model, the degree of oxidation at the Ni site of the type F is different from that of the type C. However, the plasma edge and the Q-band of the type C were almost exactly the same as those of the type F. This result is quite similar to the temperature independent property on the Q-band of $NiPc(SbF_6)_{0.5}$.

The crystal structure, electrical conductivity, and reflectance spectrum of $NiPc(AsF_6)_{0.5}$ are essentially the same as those of $NiPc(SbF_6)_{0.5}$. The temperature dependence of g-values and the linewidths of some $NiPc(AsF_6)_{0.5}$ quite resemble those of $NiPc(SbF_6)_{0.5}$, and $NiPc(SbF_6)_{0.5}$ is situated between the types D and E comparing the ESR property of $NiPc(SbF_6)_{0.5}$ with those of $NiPc(AsF_6)_{0.5}$ shown in Fig. 8. Thus, the magnetic

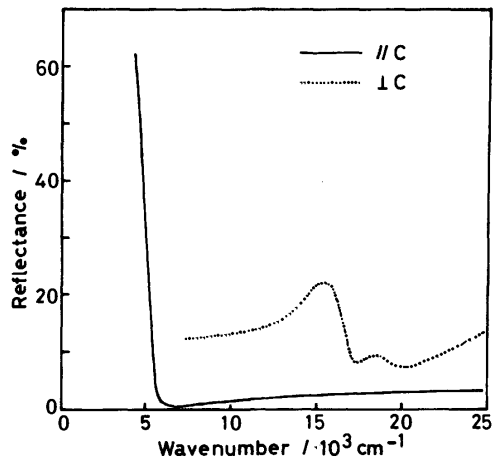

Fig. 10. Polarized reflectance spectrum of the single crystal of $NiPc(AsF_6)_{0.5}$.

properties of $NiPc(AsF_6)_{0.5}$ should be explained on the same basis as $NiPc(SbF_6)_{0.5}$. The spin susceptibilities of these types were divided into the contribution from the Ni chain, $\chi_{Ni}(T)$, and that from the Pc chain, $\chi_{Pc}(T)$, applying the same method as described before. The results are shown in the top panels od Fig. 8. As shown in these figures, $\chi_{Ni}(T)$ increases upon cooling like Curie law. Analyzing the temperature dependence of $\chi_{Ni}(T)$ by the use of the Curie law, the spin concentrations at the Ni site were estimated to be 2×10^{-4}, 3×10^{-3}, 4×10^{-3} spins per a NiPc for the types B, D, and E. These concentrations are reasonable for the localized spins at i.e. the defect sites. Furthermore, the chemical compositions, lattice parameters, electrical conductivities, and reflectance spectra of $NiPc(AsF_6)_{0.5}$ are sample independent. Therefore, these results support that the oxidation takes place mainly at the ligand site so that the conduction electrons are located on the ligand chain, from the same reason as the temperature independent bulk properties of $NiPc(SbF_6)_{0.5}$. Thus the sample dependence of the ESR properties of $NiPc(AsF_6)_{0.5}$ is understandable from the sample dependent concentration of the local spins at the Ni site. That is to say, the concentration of the local spins at the Ni site increases in order of A, B, C, D, E, and F, and the ESR property of the sample A is mostly reflecting the conduction electrons in the Pc chain. This interpretation is consistent with the fact that the behavior of $\chi(T)$ in the crystal A is qualitatively the same as those of $\chi_{Pc}(T)$ of other crystals, B, D, E, of $NiPc(AsF_6)_{0.5}$, and the concentration of the local spins increases from B to E. Unfortunately, the absolute value of the spin susceptibility of the type A crystal could not be obtained, since the number of crystals in this class was very small. The local spins on the lattice defect seem to be located not only at the Ni site but also at the ligand site. The local spins with narrow linewidth are characterized from the sharp rise at low temperature, and they are found in the crystals of types A and B as shown in the top panels of Figs. 8a and 8b. The broader linewidth of the type B crystal is probably attributed to the exchange interaction with the local spins at the Ni sites. We consider that the rise-up of the ESR intensity below 20 K in the crystals of the types A and B is probably related to the low concentration of the local spins at Ni site. When the concentration of the local spins at Ni sites becomes higher like the crystals of the types D and E, the ESR signal of the local spins at the ligand sites are probably hidden by the exchange interaction with the local spins at Ni sites through the conduction electrons on the ligand chain.

The magnetic properties of $NiPc(AsF_6)_{0.5}$ and $NiPc(SbF_6)_{0.5}$ are different from those of NiPcI, although the one-dimensional structure of the NiPc column is the same among them. This different property is connected with the higher degree of oxidation in $NiPc(AsF_6)_{0.5}$ and $NiPc(SbF_6)_{0.5}$ than in NiPcI, and also with the near orbital energy between the $3d_{z^2}$ orbital of the Ni atom and the HOMO (a_{1u}) of the ligand.[5] However, it is not clear at present why such a heavy sample dependence takes place only in the crystals of $NiPc(AsF_6)_{0.5}$, since the different point between $NiPc(AsF_6)_{0.5}$ and $NiPc(SbF_6)_{0.5}$ is only the anion size. If we adopt the model that the conduction electrons are located mainly on the Pc chain, the spin susceptibility on the Pc chain, $\chi_{Pc}(T)$, cannot be the Pauli paramagnetism, since $\chi_{Pc}(T)$ decreases upon the decrease of temperature. We consider that the number of conduction electrons decreases on lowering temperature due to the existence or growing-up of a narrow energy gap. The origin of this narrow gap is either the Peierls instability or the strong electron-electron Coulomb interaction. In the organic metals, the electron-electron Coulomb interaction is estimated from the enhancement of the spin susceptibility as compared with the Pauli paramagnetic susceptibility calculated from the transfer integrals which is obtained from the optical spectrum.[34] The spin susceptibility, $\chi_{Pc}(T)$, was roughly estimated from the flat region of $\chi_{Pc}(T)$. They are 8×10^{-5} emu mol^{-1} at room temperature for $NiPc(SbF_6)_{0.5}$ and $(5-7)\times10^{-5}$ emu mol^{-1} at room temperature for the crystals of types B, D, and E. The Pauli paramagnetic susceptibility (χ_{Pauli}) was calculated to be 5×10^{-5} emu mol^{-1} for all the crystals of $NiPc(AsF_6)_{0.5}$ and $NiPc(SbF_6)_{0.5}$. Therefore, the enhancement factor, $\chi_{s,obs}/\chi_{Pauli}$, is significantly smaller than the corresponding values, 3.0 for TTF-TCNQ and 3.3 for $TMTSF(PF_6)_{0.5}$.[34] Therefore, the Coulomb interaction on the Pc chain is considered to be weak, so that Peierls distortion may be one of the candidates for the energy gap.

The crystals of $NiPc(SbF_6)_{0.5}$ and $NiPc(AsF_6)_{0.5}$ belong to the orthorhombic system, wheres the crystals of NiPcI and $NiPc(ClO_4)_{0.39-0.47}$ to the tetragonal

system. This structural difference comes from the shape and the position of the counter anions. In the case of the NiPcI crystal, the periodicity of the linear I_3^- does not coincide with that of NiPc, so that the I_3^- is only ordered one-dimentionally along the stacking axis. The tetrahedral ClO_4^- is located at the interstitial position of the molecular layers of NiPc with the site occupancy of about 0.5. Therefore, in both crystals the counter anions are positionally disordered. On the other hand, the SbF_6^- and AsF_6^- are located at the same plane as the molecular layer of NiPc. This location of the anion brings about the two zigzag chains in the unit cell. Thus the unit cell contains two channels for accommodating the counter anions, so that these anions are three-dimensionally ordered. The difference of the periodic potential may affect the electronic conduction along the one-dimensional NiPc column at low temperature. According to Martinsen et al., the electrical conductivity of NiPcI exhibits an extrinsic peak around 20—30 K, and the Peierls instability is suppressed by the random potential.[8] From this viewpoint, it is interesting to examine the low temperature behavior of the electrical resistivity of $NiPc(SbF_6)_{0.5}$ and $NiPc(AsF_6)_{0.5}$. Unfortunately, the electrical conductivity of these material in the low temperature region is unidentified at present because of the occurrence of frequent resistivity jumps.

The State of Polarization of Light Scattered by Anisotropic Spheroids

Yoh SANO
National Institute of Agrobiological Resources, Tsukuba Science City, Ibaraki 305
(Received September 12, 1988)

Using the light scattering theory of Rayleigh-Gans, theoretical expressions were derived for the state of polarization of light scattered by anisotropic spheroids in the case of linearly polarized incident light whose electric vector is inclined by ψ to the scattering plane. The azimuth of the ellipse of the light scattered is a function of the two scattering angles, θ and ψ, only and the scattered light is linearly polarized for linearly polarized incident light. The degree of polarization of the scattered light, which is defined as the ratio of the polarized component to the intensity of the scattered light, depends on the intrinsic anisotropy, p_m; the relative refractive index of the spheroid to the solvent, m, and θ, together with the ψ angle. The degree of polarization varies from 1.0 to 0, depending strongly on p_m, p, and m. It has been suggested that the determination of the degree of polarization as a function of ψ and θ provides good information about the optically intrinsic anisotropy of the spheroid.

For most proteins and nucleoproteins in water or dilute salt solutions, the anisotropy is too small to affect the angular distribution of light scattering. Only in the case of positively birefringent and anisometric particles is there likely to be any influence of the anisotropy on the angular distribution of light scattering.[1,2] Bovine serum albumin in a native state is known to be somewhat asymmetrical and to possess an intrinsic anisotropy.[3,4] The appreciable intrinsic anisotropy parameter of bovine serum albumin has been experimentally determined.[3]

The light scattered by optically anisotropic scatterers is partially polarized and contains some unpolarized component. In the cases of optically isotropic and anisometric particles[5,6] and also optically anisotropic spheres,[7] the state of polarization of scattered light has already been calculated on the basis of the Rayleigh[8]–Gans[9] theory, which will henceforth be referred to as the Rayleigh–Gans theory of spheroids (RGS theory) in order to avoid confusion with the well-known Rayleigh–Gans (RG) theory of scattering, which involves the restrictive assumption that the refractive index of the particle is close to that of the surrounding medium. However, to the author's knowledge, no theory exists for taking into consideration the optically anisotropic effect on the light scattered by spheroids.

In the present paper, the effect of the intrinsic optical anisotropy on the state of polarization of light scattered by spheroids such as bovine serum albumin is discussed on the basis of the RGS theory by examining a set of parameters: the degree of polarization, ellipticity, azimuth, and handedness of the ellipse of the polarized component of the scattered light.

Theory

General Consideration. Let us consider the light scattered by a small, optically anisotropic and spheroidal particle whose symmetrical center is situated in the center of the scattering cell. We will consider the effect of the anisotropy on the optical polarizability, that is, the intrinsic (structural) anisotropy. The intrinsic anisotropy occurs when the dispersed phase (the material composing the particle) itself has optical anisotropy.[10] If the dispersed spheroid is optically uniaxial, the excess polarizability, which is the difference between the polarizabilities of the particle and the medium, can be expressed by a spheroid, i.e., $(\alpha_a,\alpha_b,\alpha_b)$, while the optical anisotropy is given by this ratio:

$$p_g = \alpha_a/\alpha_b. \tag{1}$$

In the following discussion, it is reasonable to assume that the direction of the principal polarizability of the spheroid is in agreement with that of the symmetry a-axis of the spheroid.

If the principal refractive indices divided by the refractive index of the solvent n_0 are (m_a,m_b,m_b), the intrinsic (structural) anisotropy p_m is defined by:

$$p_m = (m_a^2 - 1)/(m_b^2 - 1), \tag{2}$$

and the mean relative refractive index m is defined by reference to the equation of the index ellipsoid:

$$1/(m^2 - 1) = [1/(m_a^2 - 1) + 2/(m_b^2 - 1)]/3. \tag{3}$$

Scattering Matrix. All possible states of scattered light can easily be analyzed by using the Stokes parameters and the Mueller or scattering matrix, which depends only on the characteristics of the scattering medium.

If the particle is sufficiently small compared to the wavelength of light, the scattering matrix $\boldsymbol{M}$ for a randomly oriented spheroid is given by the RGS theory with the help of the matrix element:[11]

$$\boldsymbol{M} = \begin{vmatrix} S_{11} & S_{12} & 0 & 0 \\ S_{12} & S_{22} & 0 & 0 \\ 0 & 0 & S_{33} & 0 \\ 0 & 0 & 0 & S_{44} \end{vmatrix}, \tag{4}$$

where the matrix elements, S_{11}, S_{12}, S_{22}, S_{33}, and S_{44}, are given for the optically anisotropic spheroid

$$\begin{aligned} S_{11} &= F_1(1 + \cos^2\theta) + F_2, \\ S_{12} &= F_1(\cos^2\theta - 1), \\ S_{22} &= F_1(\cos^2\theta + 1), \\ S_{33} &= 2F_1\cos\theta, \\ S_{44} &= 2(F_1 - F_2)\cos\theta, \end{aligned} \tag{5}$$

where:

$$\begin{aligned} F_1 &= F_0(p_g^2 + 3p_g + 7/2), \\ F_2 &= F_0(p_g - 1)^2, \\ F_0 &= (x^6/135p^4)\{(m^2 - 1)(1 + 2p_m)/ \\ &\quad [3p_m + (m^2 - 1)(1 + 2p_m)L_b]\}^2. \end{aligned} \tag{6}$$

The x is the size parameter defined by:

$$x = 2\pi a/\lambda, \tag{7}$$

where λ is the wavelength of light in the medium. The anisometry, i.e., the form anisotropy, is expressed by the axial ratio of the spheroid:

$$p = a/b, \tag{8}$$

while the shape parameter L_b in the b-direction is only a function of axial ratio p, as has been shown in a previous paper.[10]

A particle of isotropic material has the same relative refractive index m in all directions of an electric vector of light, independent of the particle form. Therefore, in the case of the anisometric particle made of the isotropic phase (p_m=1), we obtain:

$$\begin{aligned} F_1 &= (A^2 + 2AB/3 + 2B^2/15)/2, \\ F_2 &= 2B^2/15, \\ p_g &= 1 + B/A. \end{aligned} \tag{9}$$

These results agree with those obtained in a previous paper.[5] Here, A and B are functions of m, and the axial ratio p as defined by Eq. 15 in Ref. 5.

State of Polarization of the Scattered Light. The scattered light is, in general, partially polarized, and behaves as an incoherent sum of the polarized, I_p, and the unpolarized, I_u, components, which are defined in terms of time averages of the electric-field components of an electromagnetic wave. To give a complete description of a partially elliptically polarized beam of scattered light, we should state the intensities associated with both polarized and unpolarized components, and also give the full specifications of the polarization ellipse.

If we consider a linearly polarized incident light whose electric vector makes an angle ψ with the scattering plane, we can calculate each parameter of partially polarized scattered light with the help of the Stokes parameters and the scattering matrix as follows:

$$\begin{aligned} I_p &= I_p^\circ(1 - \cos^2\psi\sin^2\theta), \\ I &= I_p^\circ(1 - \cos^2\psi\sin^2\theta) + I_u, \\ I_p^\circ &= 2F_1,\ I_u = 2F_2, \\ \eta &= 0. \end{aligned} \tag{10}$$

The I_u term is contributed only by the F_2 term, showing the optical anisotropy analogously to the cases of an optically isotropic spheroid and an optically anisotropic sphere.

The ellipticity η of the polarized component of scattered light is always equal to 0, which means that the polarized component for an anisotropic spheroid is linearly polarized in the case of linearly polarized incident light.

The azimuth, ζ, of the linearly polarized component of the scattered light is given by:

$$\tan\zeta = \tan\psi/\cos\theta, \tag{11}$$

and is only a function of ψ and θ, it is independent of m, p, x, and p_m in the case of an anisotropic spheroid. The ζ has the same sign as ψ for the forward scattering ($0<\theta<90°$), while it has the opposite sign for the backward scatterig($90°<\theta<180°$).

The degree of polarization, P, defined as the ratio of the intensity of the polarized portion to the intensity, is given by Eq. 10:

$$\begin{aligned} P_\psi(\theta) &= (1 - \sin^2\theta\cos^2\psi)/[(1 - \sin^2\theta\cos^2\psi) + (F_2/F_1)], \\ F_2/F_1 &= (p_g - 1)^2/(p_g^2 + 3p_g + 7/2), \end{aligned} \tag{12}$$

and depends on p, p_m, m, θ, and ψ. In the case of isotropic spherical particles (p_m=1), the $P_\psi(\theta)$ is always equal to 1 over the entire range of θ. For an anisotropic sphere ($p_m \neq 1$, p=1) and an optically isotropic (p_m=1, $p \neq 1$) or anisotropic ($p_m \neq 1$, $p \neq 1$) spheroid, the $P_\psi(\theta)$ is smaller than 1.0, but it is independent of x, as far as RGS theory holds.

Numerical Results and Discussion

Variation of the Intensity of the Scattered Light. The numerical calculations were made with an ACOS 850/20 Computer at the Computer Center of the Ministry of Agriculture and Forestry. Figure 1 shows the variation in the intensities of the scattered light for the unpolarized component I_u and the maximum of the polarized component I_p° as a function of the intrinsic anisotropy p_m for m=1.20. The I_u depends strongly on the p_m value. Here, the quantity I is called the "intensity" of the scattered light, but it is a dimensionless quantity which is equal to the Rayleigh ratio

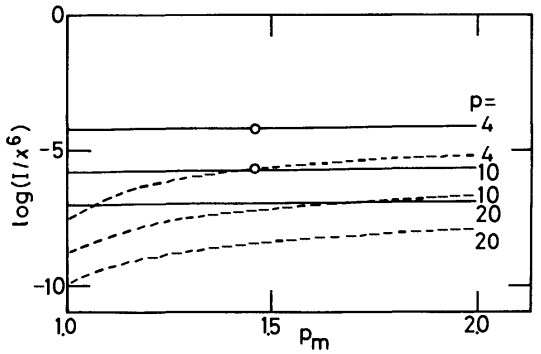

Fig. 1. Variation of $\log(I_u/x^6)$ (dotted lines) and $\log(I_p{}^\circ/x^6)$ (solid lines) with the intrinsic anisotropy $p_m>1$ for $m=1.20$. Open circles show bovine serum albumin molecule.

per particle multiplied by k^2 (where $k=2\pi/\lambda$) and is usually expressed by i.

Bovine serum albumin in a native state is a globular protein, and its overall molecular shape may be represented as a prolate spheroid whose major semiaxis and minor semiaxis are 7.1 and 1.7 nm respectively.[4] The intrinsic anisotropy parameter of bovine serum albumin is calculated to be $p_m=1.46$ with the refractive index increment and the scattering ratio at a scattering angle of 90°.[3] For such a spheroidal particle, it is reasonable to assume that the direction of the principal polarizability of the spheroid is in agreement with that of the symmetry a-axis of the spheroid; therefore, it is satisfactory to think of the case of $m_a>m_b$, i.e., the values of $p_m>1$, and also to think about the values of $p_m<2.0$.

Variation in the Degree of Polarization. The degree of polarization at $\theta=90°$, as given by Eq. 12, is:

$$P_\psi(90) = \sin^2\psi/(\sin^2\psi + F_2/F_1). \quad (13)$$

Figure 2 shows the variation in $P_\psi(90)$ with the intrinsic anisotropy p_m and ψ, especially in cases in which the ψ is from 1° to 20°.

Figure 3 shows the variation in $P_\psi(90)$ with $\pm\psi$. The $P_\psi(90)$ increases monotonously from 0 to almost 1 with the increase in $|\psi|$, its value becomes smaller, however, as the p_m deviates from the isotropic materials ($p_m=1$).

Determination of Parameter Values. The scattering ratio is defined by the ratio of the intensity scattered at $\theta=90°$ for the incident light vibrating perpendicular to and parallel to the plane of observation. The scattering ratio is of the same numerical value as the depolarization ratio, which is defined by the ratio of the intensity of the parallel component to the perpendicular component of the scattered light for an unpolarized incident beam, when the orientation of the particle is assumed to be completely random. However, the latter has an experimental disadvantage, for perfectly unpolarized incident light is rather difficult to obtain.

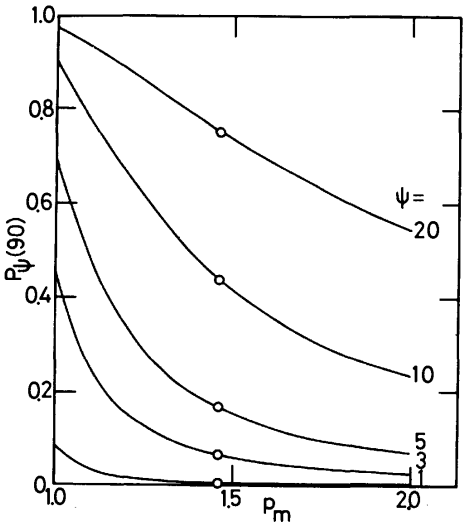

Fig. 2. Variation of the degree of polarization at $\theta=90°$, $P_\psi(90)$, with the intrinsic anisotropy $p_m>1$ and $m=1.20$ and $p=4$ for various values of ψ(degree). Open circles show bovine serum albumin molecule.

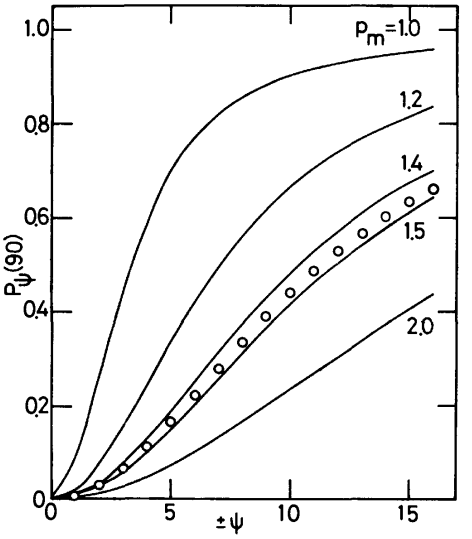

Fig. 3. Variation of the degree of polarization at $\theta=90°$, $P_\psi(90)$, with ψ(degree) and $m=1.20$ and $p=4$ for various values of $p_m>1$. Open circles show bovine serum albumin molecule.

The degree of polarization can also be measured by rotating the polarizer, similar to the case of the scattering ratio. Although only the two special cases of parallel to ($\psi=0$) and perpendicular to ($\psi=90°$) the scatterring plane are discussed in the case of the scattering ratio, the degree of polarization can be mainly used for small ψ values, as is shown in Figs. 2 and 3. The degree of polarization depends strongly on the intrinsic anisotropy p_m, and it is independent of x. If we measure the $P_\psi(90)$ value, the intrinsic (structual) anisotropy can be determined directly from the curvefitting method to the theoretical values.

Knowledge about p_m and m gives information regarding the refractive index of both the a- and b-axes of the spheroid if the refractive index of the solvent is known.

In conjunction with the knowledge of the intrinsic anisotropy p_m, the value of x is obtained from the intensities, I, I_p, and I_u, and the knowledge of x immediately gives information on the molecular weight if the partial specific volume is known.

The theory presented in this paper can be efficiently applied to relatively small p_m values, as is shown in Fig. 3.

This work was supported in part by a Grant-in-Aid (Bio Media Program) from the Ministry of Agriculture, Forestry, and Fisheries (BMP 89-IV-1-1).

Parametrized Equations-of-Motion Method at the (1p-1h)+(2h-2p) Level and Its Application to Linear Polyenes

Tai-ichi SHIBUYA,* Tadashi FUNADA,# and Susumu NARITA
Department of Chemistry, Faculty of Textile Science and Technology,
Shinshu University, Ueda, Nagano-ken 386
(Received September 24, 1988)

The previously proposed idea of parametrizing the equations-of-motion method [*Int. J. Quantum Chem.*, **18**, 205 (1980)] has been worked out for the $\pi\rightarrow\pi^*$ transitions of linear polyenes. The excitation operator consists of not only 1p-1h creation and annihilation operators but also 2p-2h creation and annihilation operators. [*Bull. Chem. Soc. Jpn.*, **61**, 1103 (1988)]. The proposed scheme accounts for the effect of $\sigma\rightarrow\sigma^*$ mixings in contrast with the traditional pi-electron theories. In the present work, the two-center Coulomb integrals are evaluated by $1/R$, and all the one-center integrals on the C atom are assumed to be the same. Values of the three parameters (a, b, ζ) introduced in the scheme are so determined that the computed excitation energies of ethylene and *s-trans*-butadiene fit the observed values. The scheme has been applied to a series of all-s-trans linear polyenes through dodecahexaene. Some notable results are: (1) The $\sigma\rightarrow\sigma^*$ mixings play a significant role in lowering the excitation energies of the allowed transition to 1^1Bu; (2) the 2^1Ag state is of Ag^- type and almost free from this effect; (3) double excitations (2p-2h states) are dominant in the 2^1Ag state but practically negligible in the 1^1Bu state.

The basic idea of the equations-of-motion (EOM) method employed here is to find an excitation operator $O_\lambda^\dagger$ which creates an excited state $|\lambda>$ by its action on the ground state $|0>$:

$$|\lambda> = O_\lambda^\dagger |0> \qquad (\text{and } O_\lambda|0> = 0). \tag{1}$$

The operater $O_\lambda^\dagger$ is constructed as a linear combination of creation and annihilation operators of particle-hole pairs and their products. The coefficients of the linear combination are determined in such a way that the excitation operator $O_\lambda^\dagger$ satisfies an equation which is formally the same as the equation of motion for a boson creation operator:

$$[H, O_\lambda^\dagger]\,|0> = \omega_\lambda O_\lambda^\dagger|0>. \tag{2}$$

Certain molecular integrals appearing in the traditional configuration interaction (CI) calculations for the ground and excited states are eliminated in the EOM calculations because Eq. 2 is set up directly for the difference between the two states.[1]

In a previous publication,[2] we proposed a way to parametrize the EOM for the $\pi\rightarrow\pi^*$ transition in conjugated molecules. Emphasis was then laid on the treatment of the effect of $\sigma\rightarrow\sigma^*$ mixings. This effect, called the sigma-dynamical screening,[3] was expected to make a significant contribution to lowering of the singlet transition energies.[2-4] The traditional pi-electron theories like the PPP method do not explicitly account for this type fo sigma-electron screenings. In the PPP calculations on conjugated hydrocarbons, the one-center integral γ_{00} is set equal to 11 eV instead of 17 eV as evaluated by the Slater 2p orbital with the effective nuclear charge Z^*=3.18.[5] The discrepancy was analyzed by Orloff and Sinanoglu[6] from the view point of sigma-pi electron correlations.

The proposed semiempirical scheme is constructed on the EOM initially written for the STO-basis "Hartree-Fock" orbitals. In the final form of the scheme, however, the SCF orbitals are computed only for pi-orbitals; sigma-electrons are assumed to be localized in separate bonds (C-C and C-H). Excitation energies for $\sigma\rightarrow\sigma^*$ are all set equal to an adjustable parameter a which is expected to be around 1. Hereafter, Hartree's atomic units are employed unless otherwise specified. The one-center integrals needed in this scheme are all for the 2p orbitals of the C atom and set equal to one parameter $\gamma_{00}=(93/256)\zeta$ whose value is expected to be around 0.6 (i.e. 17 eV) (or ζ=1.6) as evaluated from the Slater orbitals. The two-center integrals γ_{pq} are all set equal to $1/R_{pq}$ which is the leading term in the expansion of γ_{pq} when the Slater orbitals are used. The resonance integrals β_{pq} are set to be $-bS_{pq}/R_{pq}$, where S_{pq} are the overlap integrals evaluated with the Slater orbitals, and b is an adjustable parameter which is expected to be around 1. Values of these parameters (a, b, ζ) are determined in such a way that the calculated transition energies fit the observed values for the N→T, V transitions of ethylene and butadiene.

Low-lying excited states of conjugated molecules are usually well described as linear combinations of singly excited configurations. However, the 2^1Ag state of linear polyenes is the well-known exception where doubly excited configurations are thought to be more important.[7] Thus, in the present study, we employ the (1p-1h) plus (2p-2h) EOM[8] which may also be termed as the 2nd higher RPA.[1b] The proposed scheme is applied to all-trans linear polyenes through dodecahexaene.

The EOM method employed in the present work is closely related to the propagator methods. A recent review article[9] gives ample references on these methods.

Present address: Yashiro High School, Koshoku, Nagano-ken 387.

1. Summary of the (1p-1h)+(2p-2h) EOM[8]

The following form is assumed for the excitation operator:

$$O^{\dagger}(\lambda SM) = \sum_{m\gamma}\{Y_{m\gamma}(\lambda S)C_{m\gamma}^{\dagger}(SM) - Z_{m\gamma}(\lambda S)C_{m\gamma}(\overline{SM})\} + \sum_{(m\gamma,n\delta)}\{Y^{(2)}_{(m\gamma,n\delta)}(\lambda S)\Gamma_{(m\gamma,n\delta)}^{\dagger}(SM) - Z^{(2)}_{(m\gamma,n\delta)}(\lambda S)\Gamma_{(m\gamma,n\delta)}(\overline{SM})\}. \quad (3)$$

In this expression, $C_{m\gamma}^{\dagger}(SM)$ and $C_{m\gamma}(\overline{SM})$ are the creation and annihilation operator of particle-hole (1p-1h) pairs (m, γ),[1a] and $\Gamma_{(m\gamma,n\delta)}^{\dagger}(SM)$ and $\Gamma_{(m\gamma,n\delta)}(\overline{SM})$ are the creation and annihilation operators of 2p-2h states $(m\gamma, n\delta)$.[1b,8] They produce excited states with spin symmetry (S, M) by their action on the closed-shell ground state $|0\rangle$. Hereafter, m and n refer to unoccupied (particle state) orbitals, and γ and δ to occupied (hole state) orbitals. They are assumed to be the Hartree-Fock (HF) orbitals. The $\Gamma_{(m\gamma,n\delta)}^{\dagger}$ listed in Table 1 are "orthonormal" in a sense that the 2p-2h states created by these operators acting on the Hartree-Fock ground state $|HF\rangle$ are orthonormal.

With this excitation operator $O^{\dagger}(\lambda)$, Eq. 2 approximately leads[8] to

$$\begin{bmatrix} \mathscr{A} & \mathscr{B} & \mathscr{A}^{\circ(1,2)} & 0 \\ -\mathscr{B} & -\mathscr{A} & 0 & -\mathscr{A}^{\circ(1,2)} \\ \mathscr{A}^{\circ(2,1)} & 0 & A^{\circ(2,2)} & 0 \\ 0 & -\mathscr{A}^{\circ(2,1)} & 0 & -A^{\circ(2,2)} \end{bmatrix} \begin{bmatrix} \mathscr{Y} \\ \mathscr{Z} \\ Y^{(2)} \\ Z^{(2)} \end{bmatrix} = \omega \begin{bmatrix} \mathscr{Y} \\ \mathscr{Z} \\ Y^{(2)} \\ Z^{(2)} \end{bmatrix}. \quad (4)$$

In this matrix equation,

$$\mathscr{Y}_{m\gamma} = g_{m\gamma}Y_{m\gamma};\ \mathscr{Z}_{m\gamma} = g_{m\gamma}Z_{m\gamma}, \quad (5)$$

$$g_{m\gamma} = (1 + \rho_{\gamma\gamma} - \rho_{mm})^{1/2}, \quad (6)$$

$$\mathscr{A}_{m\gamma,n\delta}(S) = \delta_{mn}\delta_{\gamma\delta}(\varepsilon_m - \varepsilon_\gamma) + \{-[(mn\,|\,\gamma\delta) + \delta_{mn}T_{\gamma\delta} - \delta_{\gamma\delta}T_{mn}] + (\delta_{S0})2(m\gamma\,|\,n\delta)\}/(g_{m\gamma}g_{n\delta}), \quad (7a)$$

$$\mathscr{B}_{m\gamma,n\delta}(S) = \{-(-1)^S[(m\delta\,|\,n\gamma) - S_{m\gamma,n\delta}] + (\delta_{S0})2(m\gamma\,|\,n\delta)\}/(g_{m\gamma}g_{n\delta}), \quad (7b)$$

$$S_{m\gamma,n\delta} = -\sum_{p\mu}[(m\delta\,|\,p\mu)C_{p\mu,n\gamma}(0) + (n\gamma\,|\,p\mu)C_{p\mu,m\delta}(0)], \quad (8a)$$

$$T_{mn} = (1/2)\sum_{\nu}S_{m\nu,n\nu};\ T_{\gamma\delta} = -(1/2)\sum_{p}S_{p\gamma,p\delta}, \quad (8b)$$

$$\rho_{mn} = (1/2)\sum_{p\mu\nu}\sum_{S=0,1}C'_{mv,p\mu}(S)C_{nv,p\mu}(S), \quad (9a)$$

$$\rho_{\gamma\delta} = -(1/2)\sum_{pq\mu}\sum_{S=0,1}C'_{q\gamma,p\mu}(S)C_{q\delta,p\mu}(S), \quad (9b)$$

where

$$C'(0) = [3C(0) + C(1)]/4;\ C'(1) = [C(0) + 3C(1)]/4 \quad (10)$$

and

$$C_{m\gamma,n\delta}(S) = -[-(-1)^S(m\delta\,|\,n\gamma) + (\delta_{S0})2(m\gamma\,|\,n\delta)]/(\varepsilon_m + \varepsilon_n - \varepsilon_\gamma - \varepsilon_\delta). \quad (11)$$

Hereafter, p and q refer to unoccupied orbitals and μ and ν to occupied orbitals. In these expressions, ε_k is the HF orbital energy and $(ij|kl)$ is the two-electron molecular integral:

$$(ij\,|\,kl) = \int[i(1)j(1)](1/r_{12})[k(2)l(2)]\,d\upsilon_1 d\upsilon_2. \quad (12)$$

In Eq. 4,

$$\mathscr{A}^{\circ(2,1)} = \tilde{\mathscr{A}}^{\circ(1,2)}, \quad (13a)$$

$$\mathscr{A}^{\circ(1,2)}{}_{m'\gamma':(m\gamma,n\delta)}(S) = A^{\circ(1,2)}{}_{m'\gamma':(m\gamma,n\delta)}(S)/g_{m'\gamma'}, \quad (13b)$$

Table 1. The "Orthonormal" 2p-2h Creation Operators $\Gamma_{(m\gamma,n\delta)}^{\dagger}(SM)$

$S=M=0$	
$\Gamma_{(m\gamma,m\gamma)}^{\dagger} = C_{m\gamma}^{\dagger}(00)C_{m\gamma}^{\dagger}(00)$	
$\Gamma_{(m\gamma,n\gamma)}^{\dagger} = \sqrt{2}C_{m\gamma}^{\dagger}(00)C_{n\gamma}^{\dagger}(00)$	$(m\neq n)$
$\Gamma_{(m\gamma,m\delta)}^{\dagger} = \sqrt{2}C_{m\gamma}^{\dagger}(00)C_{m\delta}^{\dagger}(00)$	$(\gamma\neq\delta)$
$\Gamma_{(m\gamma,n\delta)_1}^{\dagger} = C_{m\gamma}^{\dagger}(00)C_{n\delta}^{\dagger}(00) + C_{m\delta}^{\dagger}(00)C_{n\gamma}^{\dagger}(00)$	$(m\neq n, \gamma\neq\delta)$
$\Gamma_{(m\gamma,n\delta)_2}^{\dagger} = (1/\sqrt{3})[C_{m\gamma}^{\dagger}(00)C_{n\delta}^{\dagger}(00) - C_{m\delta}^{\dagger}(00)C_{n\gamma}^{\dagger}(00)]$	$(m\neq n, \gamma\neq\delta)$
$S=1, M=0$	
$\Gamma_{(m\gamma,n\gamma)}^{\dagger} = (1/\sqrt{2})[C_{m\gamma}^{\dagger}(10)C_{n\gamma}^{\dagger}(00) - C_{n\gamma}^{\dagger}(10)C_{m\gamma}^{\dagger}(00)]$	$(m\neq n)$
$\Gamma_{(m\gamma,m\delta)}^{\dagger} = (1/\sqrt{2})[C_{m\gamma}^{\dagger}(10)C_{m\delta}^{\dagger}(00) - C_{m\delta}^{\dagger}(10)C_{m\gamma}^{\dagger}(00)]$	$(\gamma\neq\delta)$
$\Gamma_{(m\gamma,n\delta)_1}^{\dagger} = (1/2)[C_{m\gamma}^{\dagger}(10)C_{n\delta}^{\dagger}(00) - C_{n\delta}^{\dagger}(10)C_{m\gamma}^{\dagger}(00)] + [C_{m\delta}^{\dagger}(10)C_{n\gamma}^{\dagger}(00) - C_{n\gamma}^{\dagger}(10)C_{m\delta}^{\dagger}(00)]$	$(m\neq n, \gamma\neq\delta)$
$\Gamma_{(m\gamma,n\delta)_2}^{\dagger} = (1/2)[C_{m\gamma}^{\dagger}(10)C_{n\delta}^{\dagger}(00) - C_{n\delta}^{\dagger}(10)C_{m\gamma}^{\dagger}(00) - C_{m\delta}^{\dagger}(10)C_{n\gamma}^{\dagger}(00) + C_{n\gamma}^{\dagger}(10)C_{m\delta}^{\dagger}(00)]$	$(m\neq n, \gamma\neq\delta)$
$\Gamma_{(m\gamma,n\delta)_3}^{\dagger} = (1/\sqrt{2})[C_{m\gamma}^{\dagger}(10)C_{n\delta}^{\dagger}(00) + C_{n\delta}^{\dagger}(10)C_{m\gamma}^{\dagger}(00)]$	$(m\neq n, \gamma\neq\delta)$

and $A^{\circ(1,2)}$ and $A^{\circ(2,2)}$ are defined by

$$A^{\circ(1,2)}{}_{m'\gamma':(m\gamma,n\delta)}(S) \equiv <HF|[C_{m'\gamma'}(S0), H, \Gamma_{(m\gamma,n\delta)}{}^{\dagger}(S0)]|HF>, \tag{14a}$$

$$A^{\circ(2,2)}{}_{(m'\gamma',n'\delta'):(m\gamma,n\delta)}(S) \equiv <HF|[\Gamma_{(m'\gamma',n'\delta')}(S0), H, \Gamma_{(m\gamma,n\delta)}{}^{\dagger}(S0)]|HF>, \tag{14b}$$

where $|HF>$ is the HF ground state (i.e. the noncorrelated part of $|0>$.) Referring to Table 1, we can readily obtain these elements from their primitive ones

$$\begin{aligned} A^{\circ(1,2)}{}_{m'\gamma':m\gamma,n\delta}(S) &\equiv <HF|[C_{m'\gamma'}(S0), H, C_{m\gamma}{}^{+}(S0)C_{n\delta}{}^{+}(00)]|HF> \\ &= \sqrt{2}\{\delta_{\gamma\gamma'}[(mm'|n\delta) - (nm'|m\delta)/2] \\ &+ \delta_{\delta\gamma'}[\delta_{s0}(nm'|m\gamma) - (mm'|n\gamma)/2] \\ &- \delta_{mm'}[(\gamma\gamma'|n\delta) - (\delta\gamma'|n\gamma)/2] \\ &-\delta_{nm'}[\delta_{s0}(\delta\gamma'|m\gamma) - (\gamma\gamma'|m\delta)/2]\}; \end{aligned} \tag{15}$$

$$\begin{aligned} A^{\circ(2,2)}{}_{m'\gamma',n'\delta':m\gamma,n\delta}(S) &\equiv <HF|[(C_{m'\gamma'}{}^{+}(S0)C_{n'\delta'}{}^{+}(00))^{\dagger}, \\ &\qquad H, C_{m\gamma}{}^{+}(S0)C_{n\delta}{}^{+}(00)]|HF> \\ &= \{(\varepsilon_m + \varepsilon_n - \varepsilon_\gamma - \varepsilon_\delta)[(\delta_{mm'}\delta_{nn'}\delta_{\gamma\gamma'}\delta_{\delta\delta'} \\ &- \delta_{mm'}\delta_{nn'}\delta_{\delta\gamma'}\delta_{\gamma\delta'}/2 - \delta_{nm'}\delta_{mn'}\delta_{\gamma\gamma'}\delta_{\delta\delta'}/2) \\ &+ (\delta_{s0})\delta_{nm'}\delta_{mn'}\delta_{\delta\gamma'}\delta_{\gamma\delta'}] \\ &+ (\delta_{mm'}\delta_{nn'} - \delta_{nm'}\delta_{mn'}/2)(\gamma\gamma'|\delta\delta') \\ &+ ((\delta_{s0})\delta_{nm'}\delta_{mn'} - \delta_{mm'}\delta_{nn'}/2)(\delta\gamma'|\gamma\delta') \\ &+ (\delta_{\gamma\gamma'}\delta_{\delta\delta'} - \delta_{\delta\gamma'}\delta_{\gamma\delta'}/2)(mm'|nn') \\ &+ ((\delta_{s0})\delta_{\delta\gamma'}\delta_{\gamma\delta'} - \delta_{\gamma\gamma'}\delta_{\delta\delta'}/2)(mn'|nm')\} \\ &+ \{[\delta_{mm'}\delta_{\gamma\gamma'}2(n'\delta'|n\delta) - (\delta_{mm'}\delta_{\gamma\delta'}(n'\gamma'|n\delta) \\ &+ \delta_{mn'}\delta_{\gamma\gamma'}(m'\delta'|n\delta) + \delta_{nm'}\delta_{\gamma\gamma'}(n'\delta'|m\delta) \\ &+ \delta_{mm'}\delta_{\delta\gamma'}(n'\delta'|n\gamma)) + (1/2)(\delta_{mm'}\delta_{\delta\delta'}(n'\gamma'|n\gamma) \\ &+ \delta_{nn'}\delta_{\delta\gamma'}(m'\delta'|m\delta) + \delta_{nm'}\delta_{\gamma\delta'}(n'\gamma'|m\delta) \\ &+ \delta_{mn'}\delta_{\delta\gamma'}(m'\delta'|n\gamma))] + (\delta_{s0})[2(\delta_{nm'}\delta_{\delta\gamma'}(n'\delta'|m\gamma) \\ &+ \delta_{mn'}\delta_{\gamma\delta'}(m'\gamma'|n\delta) + \delta_{nn'}\delta_{\delta\delta'}(m'\gamma'|m\gamma)) \\ &- (\delta_{nn'}\delta_{\delta\gamma'}(m'\delta'|m\gamma) + \delta_{nm'}\delta_{\delta\delta'}(n'\gamma'|m\gamma) \\ &+ \delta_{mn'}\delta_{\delta\delta'}(m'\gamma'|n\gamma) + \delta_{nn'}\delta_{\gamma\delta'}(m'\gamma'|m\delta))]\} \\ &+ \{[- (\delta_{mm'}\delta_{\delta\delta'}(nn'|\gamma\gamma') + \delta_{nn'}\delta_{\gamma\gamma'}(mm'|\delta\delta') \\ &+ \delta_{mm'}\delta_{\gamma\gamma'}(nn'|\delta\delta') + \delta_{nn'}\delta_{\delta\delta'}(mm'|\gamma\gamma')) \\ &+ (1/2)(\delta_{mm'}\delta_{\gamma\delta'}(nn'|\delta\gamma') + (\delta_{mn'}\delta_{\gamma\gamma'}(nm'|\delta\delta') \\ &+ \delta_{nm'}\delta_{\gamma\gamma'}(mn'|\delta\delta') + \delta_{mm'}\delta_{\delta\gamma'}(nn'|\gamma\delta') \\ &+ \delta_{nn'}\delta_{\delta\gamma'}(mm'|\gamma\delta') + \delta_{nm'}\delta_{\delta\delta'}(mn'|\gamma\gamma') \\ &+ \delta_{mn'}\delta_{\delta\delta'}(nm'|\gamma\gamma') + \delta_{nn'}\delta_{\gamma\delta'}(mm'|\delta\gamma'))] \\ &+ (\delta_{s0})[- (\delta_{nm'}\delta_{\gamma\delta'}(mn'|\delta\gamma') + \delta_{mn'}\delta_{\delta\gamma'}(nm'|\gamma\delta') \\ &+ \delta_{nm'}\delta_{\delta\gamma'}(mn'|\gamma\delta') + \delta_{mn'}\delta_{\gamma\delta'}(nm'|\delta\gamma'))]\}. \end{aligned} \tag{16}$$

In solving Eq. 4, we split it into two equations. By doing so, the order of the matrix to be diagonalized is reduced to half. They are written as follows:

$$\begin{bmatrix} \mathscr{A} - \mathscr{B} & \mathscr{A}^{\circ(1,2)} \\ \mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)} \end{bmatrix} \begin{bmatrix} \mathscr{A} + \mathscr{B} & \mathscr{A}^{\circ(1,2)} \\ \mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)} \end{bmatrix} \begin{bmatrix} \mathscr{Y} + \mathscr{X} \\ Y^{(2)} + Z^{(2)} \end{bmatrix} = \omega^2 \begin{bmatrix} \mathscr{Y} + \mathscr{X} \\ Y^{(2)} + Z^{(2)} \end{bmatrix}; \tag{17a}$$

$$\begin{bmatrix} \mathscr{A} + \mathscr{B} & A^{\circ(1,2)} \\ \mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)} \end{bmatrix} \begin{bmatrix} \mathscr{A} - \mathscr{B} & A^{\circ(1,2)} \\ \mathscr{A}^{\circ(2,1)} & A^{\circ(2,2)} \end{bmatrix} \begin{bmatrix} \mathscr{Y} - \mathscr{X} \\ Y^{(2)} - Z^{(2)} \end{bmatrix} = \omega^2 \begin{bmatrix} \mathscr{Y} - \mathscr{X} \\ Y^{(2)} - Z^{(2)} \end{bmatrix}. \tag{17b}$$

Note that the eigenvalues in these equations are ω^2.

The transition dipole moment is given by

$$\boldsymbol{D}_\lambda \equiv - <0|(\boldsymbol{r})_{op}|\lambda> = (\delta_{s0})\sqrt{2}\Sigma_{m\gamma}\{\mathscr{Y}_{m\gamma}(\lambda 0) + \mathscr{X}_{m\gamma}(\lambda 0)\}(g_{m\gamma}\boldsymbol{d}^{\circ}{}_{m\gamma}), \tag{18}$$

where

$$\boldsymbol{d}^{\circ}{}_{m\gamma} \equiv \int m(r)\boldsymbol{r}\gamma(r)\mathrm{d}^3r. \tag{19}$$

Note that terms of $Y^{(2)}$ and $Z^{(2)}$ vanish in deriving the last expression of Eq. 18.[8] The oscillator strength is written

$$f_\lambda = (2/3)\omega_\lambda|\boldsymbol{D}_\lambda|^2. \tag{20}$$

It is important to note that the result in Eq. 18 has been derived on the assumption of the normalization condition $<\lambda|\lambda>=1$ or equivalently

$$\Sigma_{m\gamma}\{|\mathscr{Y}_{m\gamma}(\lambda S)|^2 - |\mathscr{X}_{m\gamma}(\lambda S)|^2\} + \Sigma_{(m\gamma,n\delta)}\{|Y^{(2)}{}_{(m\gamma,n\delta)}(\lambda S)|^2 - |Z^{(2)}{}_{(m\gamma,n\delta)}(\lambda S)|^2\} = 1. \tag{21}$$

Thus, $\boldsymbol{D}_\lambda$ is indirectly affected by $Y^{(2)}$ and $Z^{(2)}$ through this normalization condition. Normalization of the eigenvectors of the reduced Eqs. 17a,b must be handled with great care so that they satisfy Eq. 21.[10]

2. Effective EOM for the $\pi \rightarrow \pi^*$ Transitions

Previously[2,3] an effective EOM for the $\pi \rightarrow \pi^*$ transitions was derived by partitioning the (1p-1h) EOM into the $\Pi \equiv (\pi^*, \pi)$ and $\Sigma \equiv (\sigma^*, \sigma)$ parts. The assumption of the zero differential overlaps between pi- and sigma-orbitals leads[4] to

$$\mathscr{A}_{\sigma^*\sigma,\pi^*\pi}(S) = \mathscr{B}_{\sigma^*\sigma,\pi^*\pi}(S) = (\delta_{s0})2(\sigma^*\sigma|\pi^*\pi)/(g_{\sigma^*\sigma}g_{\pi^*\pi}). \tag{22}$$

We shall later let $g_{\sigma^*\sigma}=1$. It was then shown[2] that the effect of the Σ part on the EOM for the Π part was to reduce the integral $(m\gamma|n\delta)$ in $\mathscr{A}$ and $\mathscr{B}$, Eq. 7, as follows:

$$(m\gamma|n\delta) \rightarrow (m\gamma|n\delta)'' = (m\gamma|n\delta) - \frac{a}{a^2 - \omega_\lambda{}^2} G_{m\gamma,n\delta}, \tag{23}$$

where

$$G_{m\gamma,n\delta} = 4\Sigma_{\sigma^*\sigma}(m\gamma|\sigma^*\sigma)(n\delta|\sigma^*\sigma). \tag{24}$$

Henceforth, m and n refer to the π^*-orbitals, and γ and

δ to the π-orbitals. In deriving Eq. 23, we have set all the diagonal elements $\mathscr{A}_{\sigma^*\sigma,\sigma^*\sigma}$ equal to one adjustable parameter a which is expected to be around 1 (in Hartree a.u.). In order to calculate G in Eq. 24, we construct sigma-orbitals by linear combinations of sp^2 hybrids for carbon and 1s orbitals for hydrogen. Employing the approximation of complete neglect of differential overlaps between sigma-AO's and the approximation that all the charge densities of sigma-AO's be 1 and the bond orders be 1 for bonded sigma-AO's and 0 otherwise, we have

$$G_{m\gamma,n\delta} = \sum_{\eta}^{\text{sigma-bonds}} [m\gamma|\eta][n\delta|\eta], \tag{25}$$

where, for a sigma-bond (η) formed by sigma-AO's u and v,

$$[m\gamma|\eta][n\delta|\eta] \equiv [(m\gamma|uu) - (m\gamma|vv)][(n\delta|uu) - (n\delta|vv)]. \tag{26}$$

In dealing with the 2p-2h states, we shall consider only those of pi-electrons and ignore any 2p-2h states in which sigma-electrons are involved. Then, our effective EOM for pi-electrons takes the same form as Eq. 4 or 17 with m and n referring to the π^*-orbitals and γ and δ to the π-orbitals. Only the difference is that the integral $(m\gamma|n\delta)$ in Eq. 7 should be replaced by $(m\gamma|n\delta)''$ given in Eq. 23. In computing the S, T, and ρ in Eqs. 8a—9b, however, note that the summations of p and q run over both π^* and σ^*, and the summations of μ and ν run over both π and σ. Therefore, if these summations are restricted to running over only π- and π^*-orbitals in the effective EOM for the $\pi\rightarrow\pi^*$ transitions, one must add to these S, T, and ρ the following correction terms S', T', and ρ', respectively, due to correlations with sigma-electrons. As is shown in Appendix A, they are written as

$$S'_{m\gamma,n\delta} = (1/2)[(a + \varepsilon_m - \varepsilon_\delta)^{-1} + (a + \varepsilon_n - \varepsilon_\gamma)^{-1}]G_{m\delta,n\gamma}, \tag{27}$$

$$T'_{mn} = (1/2)\sum_{\pi} S'_{m\pi,n\pi}; T'_{\gamma\delta} = -(1/2)\sum_{\pi^*} S'_{\pi^*\gamma,\pi^*\delta}, \tag{28}$$

$$\rho'_{mm} = (1/2)\sum_{\pi} G_{m\pi,m\pi}/(a + \varepsilon_m - \varepsilon_\pi)^2; \tag{29a}$$

$$\rho'_{\gamma\gamma} = -(1/2)\sum_{\pi^*} G_{\pi^*\gamma,\pi^*\gamma}/(a + \varepsilon_{\pi^*} - \varepsilon_\gamma)^2. \tag{29b}$$

When Eq. 4 or 17, with the replacement of Eq. 23, is solved for pi-electrons, the normalization condition in Eq. 21 is satisfied for the amplitudes of pi-electrons. Then, the norm $\langle\lambda|\lambda\rangle$ becomes greater than 1 due to contributions from the amplitudes of sigma-electrons. As is shown in Appendix B, we have

$$N_\lambda^2 \equiv \langle\lambda|\lambda\rangle \cong 1 + (\delta_{s0})\frac{4a\omega_\lambda}{(a^2 - \omega_\lambda^2)^2}\sum_{\pi_1^*\pi_1}\sum_{\pi_2^*\pi_2}(G_{\pi_1^*\pi_1,\pi_2^*\pi_2}/[g_{\pi_1^*\pi_1}g_{\pi_2^*\pi_2}]) \times \{\mathscr{Y}_{\pi_1^*\pi_1}(\lambda) + \mathscr{X}_{\pi_1^*\pi_1}(\lambda)\}\{\mathscr{Y}_{\pi_2^*\pi_2}(\lambda) + \mathscr{X}_{\pi_2^*\pi_2}(\lambda)\}. \tag{30}$$

Thus, the transition dipole moment in Eq. 18 should be written as

$$\boldsymbol{D}_\lambda = (\delta_{s0})N_\lambda^{-1}\sqrt{2}\sum_{m\gamma}\{\mathscr{Y}_{m\gamma}(\lambda 0) + \mathscr{X}_{m\gamma}(\lambda 0)\}(g_{m\gamma}\boldsymbol{d}^{\circ}_{m\gamma}). \tag{31}$$

3. Parametrization

A parameter a has been already introduced as an averaged energy for the $\sigma\rightarrow\sigma^*$ excitations. In evaluating the two-electron integrals, we have been employing the zero-differential overlap (ZDO) approximation. For these integrals, we only have the following types:

$$(ij|kl) = \sum_p C^{(i)}{}_p C^{(j)}{}_p C^{(k)}{}_p C^{(l)}{}_p \gamma_{pp} + \sum_p \sum_{(q\neq p)} \sum_q C^{(i)}{}_p C^{(j)}{}_p C^{(k)}{}_q C^{(l)}{}_q \gamma_{pq}; \tag{32a}$$

$$(ij|u_q u_q) = C^{(i)}{}_q C^{(j)}{}_q \gamma'_{qu_q} + \sum_{p(\neq q)} C^{(i)}{}_p C^{(j)}{}_p \gamma'_{pu_q}, \tag{32b}$$

where i, j, k, and l refer to π and/or π^* MO's and u_q is a sigma-AO at atom q. The coefficients $C^{(k)}{}_p$ are of the SCF pi-MO k. We set

$$\gamma_{pp} = \gamma'_{pu_p} = \gamma_{00} \equiv (93/256)\zeta; \tag{33a}$$

$$\gamma_{pq} = \gamma'_{pu_q} = 1/R_{pq} \quad (p \neq q), \tag{33b}$$

where R_{pq} is the distance between atoms p and q.

Now, the SCF-MO's for pi-electrons are obtained according to the usual procedure.[11] The coefficients of the LCAO-MO's and the orbital energies satisfy the equations

$$\sum_s F_{rs} C^{(i)}{}_s = \varepsilon_i C^{(i)}{}_r, \tag{34}$$

where the Fock matrix elements are, in the ZDO approximation,

$$F_{rr} = H_{rr} + (1/2)P_{rr}\gamma_{rr} + \sum_{s(\neq r)} P_{ss}\gamma_{rs}; \tag{35a}$$

$$F_{rs} = H_{rs} - (1/2)P_{rs}\gamma_{rs} \quad (r \neq s), \tag{35b}$$

and

$$P_{rs} \equiv 2\sum_i^{occ} C^{(i)}{}_r C^{(i)}{}_s. \tag{36}$$

The diagonal elements H_{rr} of the core Hamiltonian operator are approximated as

$$H_{rr} = U_{rr} - \sum_{s(\neq r)} \gamma_{rs}, \tag{37}$$

where the one-center terms U_{rr} are all the same (U_0) for carbon atoms. We set

$$U_{rr} = U_0 = -0.4101 \text{ (the negative of I.P. for C(2p))}, \tag{38}$$

although any other value of U_0 suffices for the present purpose as we need only the orbital coefficients and

the orbital energy differences rather than the absolute values of ε_k. The off-diagonal core matrix elements H_{rs} are approximated to be the resonance integrals. Here we employ Ohno's proposal[12] that

$$\beta_{rs} = (\gamma_{rs} - 2/R_{rs})S_{rs}. \tag{39}$$

We therefore set

$$H_{rs} = \beta_{rs} = -bS_{rs}/R_{rs}, \tag{40}$$

where b is an adjustable parameter whose value is expected to be around 1 and S_{rs} is the overlap integral

$$S_{rs} = [1 + \rho + (2/5)\rho^2 + (1/15)\rho^3]\exp(-\rho); \quad \rho \equiv \zeta R_{rs}. \tag{41}$$

Note that the simple replacement of γ_{rs} by $1/R_{rs}$ in Ohno's formula corresponds to letting b=1 in Eq. 40.

4. Application to Linear Polyenes

The effective EOM with adjustable parameters described in the preceding sections is now applied to the $\pi \rightarrow \pi^*$ transitions of all-*s*-trans linear polyenes.

(i) Determination of the Values of a, b, and ζ. Values of the parameters a, b, and ζ are determined in such a way that the computed transition energies fit the observed values for the N→T, V transitions of ethylene and butadience. The assignment of 4.6 eV to the N→T and 7.6 eV to the N→V of ethylene is well established.[13] On the other hand, the ordering of the lowest excited states of *s-trans*-butadiene has been a subject of considerable controversy.[7,13-21] In the present work, we employ the assignment proposed by Doering in his electron impact study,[20a] i.e., 5.9 eV for the optically allowed ^{1}Bu state and 5.8 eV for the 2^1Ag state. The value for the ^{1}Bu state seems well established both in UV spectral[19] and electron impact[20] studies.

These four values are used to determine values of the three parameters a, b, and ζ in the vicinity of a=1, b=1, and ζ=1.6. An optimized set of values has been obtained as a=1.10, b=1.05, and ζ=1.65. With these parameter values, we obtain 4.21 eV, 6.65 eV for the T, V states of ethylene, and 5.72 eV, 5.83 eV for the ^{1}Bu, 2^1Ag states of butadiene, respectively.

(ii) Computational Details. Input data of molecular geometries are as follows. The planar shape with the C_{2h} symmetry (D_{2h} for ethylene) is assumed for all the polyene molecules. For ethylene, *s-trans*-butadiene, and *s-trans*-hexatriene, the following experimental data[22] are used: R(C=C)=1.337 Å, R(C–H)=1.103 Å, and ∠HCH=116.2° for ethylene, R(C=C)=1.3405 Å, R(C–C)=1.463 Å, R(C–H)=1.090 Å (averaged), and ∠CCC=123.3° for butadiene, and R(C=C)=1.337 Å at both ends and 1.367 Å at center, R(C–C)=1.457 Å, ∠CCC=121.7° (outer), and 124.4° (inner) for hexatriene. The angular conformation of the CH_2 group at both ends of butadiene and hexatriene is assumed to be the same as that of ethylene. All the ∠CCH's, except at both ends, are assumed to be the same, and R(C–H)= 1.09 Å is assumed for all the C–H bonds. For longer polyenes, we set R(C=C)=1.367 Å (but 1.337 Å at both ends), R(C–C)=1.457 Å, R(C–H)=1.09 Å and ∠HCH= ∠CCH=∠CCC=120°.

With these molecular geometries and a given set of parameters a, b, and ζ, the SCF-MO's for pi-electrons are obtained by solving the secular equations of Eq. 34. Then, the matrices $\mathscr{A}$, $\mathscr{B}$, $\mathscr{A}^{\circ(1,2)}$, and $A^{\circ(2,2)}$ are constructed including the S', T', and ρ' described in Section 2, and Eq. 17a or 17b is solved for ω. For each singlet transition, the molecular integrals $(m\gamma|n\delta)$ of $\mathscr{A}$ and $\mathscr{B}$ are replaced by the reduced quantities $(m\gamma|n\delta)''$ with the previously obtained eigenvalue of ω, and Eq. 17a or 17b with these new $\mathscr{A}$ and $\mathscr{B}$ is solved to give final results for the singlet transition. As mentioned above, great care is needed in normalization of the eigenvectors in this case.[10]

(iii) Results. The transition energies computed with the parameter values (a=1.10, b=1.05, and ζ=1.65) are listed in Table 2. The weight of (2p-2h) components, i.e. the value of the second term in Eq. 21, is also given in parentheses for each transition. For the allowed transitions, 1^1Ag→1^1Bu, the oscillator strengths are given in square brackets. Due to the correction of Eq. 23, i.e. the sigma-dynamical screening effect, the transition energy for the 1^1Bu state was reduced by 1.56 eV for ethylene, 1.16 eV for butadiene, 1.05 eV for hexatriene, 1.03 eV for octatetraene, 1.00 eV for decapentaene, and 1.00 eV for dodecahexaene. Such reduction was negligibly small for the 2^1Ag states: 0.02 eV for butadiene, 0.01 eV for hexatriene, 0.003 eV for octatetraene, and so forth. All of these 2^1Ag states were of A_g^- type. The observed values for ^{1}Bu listed in Table 2 are all taken from Table 2 of Ref. 7. They agree very well with those more recently given by Leopold et al.,[23] i.e., 5.74 eV for butadiene, 4.93 eV for hexatriene, and 4.41 eV for octatetraene. Ramasesha and Soos[24a] gave values of the oscillator strength per site by their "exact" PPP calculations. They are 0.169 for hexatriene, 0.164 for octatetraene, and 0.159 for decapentaene, which may be compared with our values 0.193, 0.184, and 0.180, respectively. The oscillator strength f is plotted against the number of double bonds in Fig. 1. The f value of the s-trans linear polyene with 11 double bonds is that of β-carotene which was deduced from its absorption intensities in various organic solvents[25] using the dielectric theory proposed by Shibuya.[26] The transition energies for 1^3Bu, 1^3Ag, 1^1Bu, and 2^1Ag are plotted in Fig. 2.

5. Discussion

The numerical results presented in the preceding Section appear fairly reasonable as a whole. As is seen

Table 2. Computed Transition Energies (in eV) to the Low-Lying Valence States of All-s-Trans Linear Polyenes

	^{3}Bu	(obsd)	^{3}Ag	(obsd)	^{1}Bu	(obsd)[a]	2^1Ag	(obsd)[a]
Butadiene	3.44 (0.05)	3.2[b]	4.61 (0.01)	4.95[b]	5.72 (0.007) [0.85]	5.91	5.83 (0.73)	
Hexatriene	2.88 (0.08)	2.7[c]	4.04 (0.06)	4.2[c]	4.93 (0.02) [1.16]	4.93	4.89 (0.77)	
Octatetraene	2.58 (0.11)	2.1[d]	3.48 (0.08)	3.6[d]	4.42 (0.02) [1.47]	4.40	4.21 (0.79)	3.97
Decapentaene	2.41 (0.13)		3.11 (0.10)		4.08 (0.03) [1.80]	4.02	3.86 (0.81)	3.48
Dodecahexaene	2.32 (0.14)		2.85 (0.12)		3.83 (0.029) [2.137]	3.65	3.67 (0.82)	2.91

Values in parentheses are the weights of (2p–2h) components, and values in square brackets are the oscillator strengths. a) All taken from the review article of Hudson et al.[7] b) From Doering.[20a] c) R. McDiarmid, A. Sabljic, and J. P. Doering, *J. Am. Chem. Soc.*, **107**, 826 (1985). d) M. Allan, L. Neuhaus, and E. Haselbach, *Helv. Chim. Acta*, **67**, 1776 (1984).

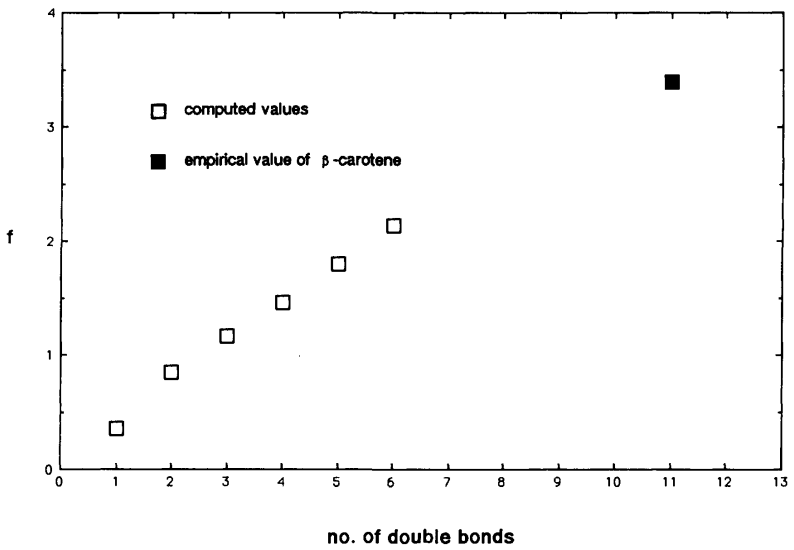

Fig. 1. The oscillator strength (f) of the 1^1Bu transition of all-s-trans linear polyenes against the number of double bonds. The empirical value of β-carotene was deduced from its absorption intensities in various organic solvents[25] using the dielectric theory.[26]

in Fig. 1, the plot of the calculated oscillator strengths well extrapolates to the "empirical" value of β-carotene. The computed transition energies of the allowed ^{1}Bu states are all in excellent agreement with experiment. The 2^1Ag states, which mostly lie below the allowed ^{1}Bu states, were found to be essentially dominated by the 2p-2h states. This agrees with the widely accepted notion.[7] Figure 2 indicates that these transition energies converge to certain finite values as the number of double bonds increases.

We have tried to see whether a pure pi-electron EOM scheme is possibly constructed. This means that not only the sigma-dynamical screening Eq. 23 is omitted but also the correction terms S', T', and ρ' are ignored. In this case we would have only two parameters b and ζ. This, however, was not successful: The EOM became instable for the triplet transitions. The inclusion of the correction terms S' and T' was

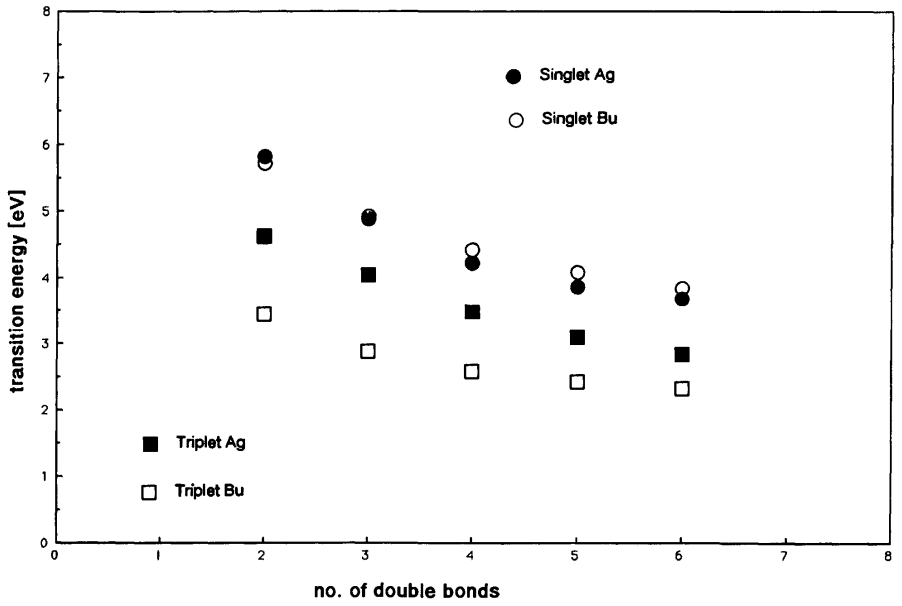

Fig. 2. Calculated transition energies for the four lowest excited valence states (1^3Bu, 1^3Ag, 1^1Bu, 2^1Ag) of all-s-trans linear polyenes against the number of double bonds.

essential. Parametrization at the RPA level would also fail, as the RPA fails for the triplet transitions already in its non-empirical treatment.[1)]

Great interest in polyacetylene $(CH)_x$ as an electronic material has stimulated some recent investigations of the low-lying excitations in linear polyenes.[24,27-29)] Gutsev et al.[27)] employed the Discrete Variational Xα method, but all the other investigators[24,28-29)] employed schemes in the framework of the PPP approximation. Hemley et al.[30)] employed an extended PPP-CI theory to analyze the absorption spectra of the $1A_g \rightarrow 1^1B_u$ transition of jet-cooled hexatriene.[23b)]

Application of the present scheme to nonlinear conjugated hydrocarbons is straightforward,and such a study is currently in progress.

Appendix A: The Correction Terms S', T', and ρ'

From Eq. 8a, we have

$$S'_{m\gamma,n\delta} = -\sum_{\sigma^*\sigma}[(m\delta|\sigma^*\sigma)C_{\sigma^*\sigma,n\gamma}(0) + (n\gamma|\sigma^*\sigma)C_{\sigma^*\sigma,m\delta}(0)], \quad (A\cdot1)$$

where m and n refer to the π^*-orbitals and γ and δ to the π-orbitals. Note that in the summation of Eq. 8a, the terms for $(p,\mu)=(\pi^*, \sigma)$ and (σ^*, π) vanish due to the symmetry or to the ZDO approximation between the pi- and sigma-orbitals. Using Eq. 11, we have

$$C_{\sigma^*\sigma,n\gamma}(0) = -2(\sigma^*\sigma|n\gamma)/(\varepsilon_n - \varepsilon_\gamma + a), \quad (A\cdot2)$$

and a similar expression for $C_{\sigma^*\sigma,m\delta}(0)$. In deriving Eq. A. 2, we have let all the $\varepsilon_{\sigma^*}-\varepsilon_\sigma=a$ according to the approximation introduced in Section 2, and $(\sigma^*\gamma|n\sigma)=0$ due to the ZDO approximation. Substituting these expressions in Eq. A. 1 and using the G defined by Eq. 24, we obtain

$$S'_{m\gamma,n\delta} = (1/2)[(\varepsilon_m - \varepsilon_\delta + a)^{-1} + (\varepsilon_n - \varepsilon_\gamma + a)^{-1}]G_{m\delta,n\gamma}. \quad (A\cdot3)$$

To derive T', first note that $S_{m\sigma,n\sigma}=S_{\sigma^*\gamma,\sigma^*\delta}=0$ due to the ZDO approximation. Then, from Eq. 8b together with the result Eq. A. 3, we have

$$T'_{mn} = (1/2)\sum_\pi S'_{m\pi,n\pi};\ T'_{\gamma\delta} = -(1/2)\sum_{\pi^*} S'_{\pi^*\gamma,\pi^*\delta}. \quad (A\cdot4)$$

The derivation of ρ' is more complicated. Substituting Eq. 10 together with Eq. 11 into Eq. 9a, we obtain

$$\rho_{mm} = (1/2)\sum_{p\mu\nu}[3(p\mu|m\nu)^2 - 2(p\mu|m\nu)(p\nu|m\mu) + (p\nu|m\mu)^2]/(\varepsilon_p + \varepsilon_m - \varepsilon_\mu - \varepsilon_\nu)^2 \quad (A\cdot5)$$

where m refers to the π^*-orbitals, but p to both π^* and σ^*, and μ and ν to both π and σ. We note that the terms in the summation of Eq. A. 5 vanish due to the ZDO approximation if both μ and ν are σ. Similarly, the terms with $\mu\nu=\sigma\pi$ or $\pi\sigma$ are nonvanishing only if $p=\sigma^*$. Therefore,

$$\rho'_{mm} = (1/2)\sum_\pi\sum_{\sigma^*\sigma} 4(\sigma^*\sigma|m\pi)^2/(\varepsilon_m - \varepsilon_\pi + \varepsilon_{\sigma^*} - \varepsilon_\sigma)^2. \quad (A\cdot6)$$

Letting all the $\varepsilon_{\sigma^*}-\varepsilon_\sigma=a$, we obtain Eq. 29a. The expression of $\rho'_{\gamma\gamma}$ in Eq. 29b is derived in a similar manner.

Appendix B: The Normalization Constant N_λ^{-1} in Eq. 30

Originally the normalization condition $\langle\lambda|\lambda\rangle=1$ was assumed as in Eq. 21. For the effective EOM for pi-electrons, however, the summations in Eq. 21 run over the 1p-1h and 2p-2h states of pi-electrons only. Thus, $N_\lambda^2=\langle\lambda|\lambda\rangle$ differs from 1 and becomes greater than 1 due to the contribution

from the terms of sigma-electrons. In our model, the mixing of $\sigma \rightarrow \sigma^*$ is considered only at the level of 1p-1h states. Therefore,

$$N_\lambda^2 - 1 = \sum_{\sigma^*\sigma} \{ |\mathcal{Y}_{\sigma^*\sigma}(\lambda)|^2 - |\mathcal{X}_{\sigma^*\sigma}(\lambda)|^2 \}$$
$$\equiv [\mathcal{Y}_\Sigma(\lambda) \; -\mathcal{X}_\Sigma(\lambda)] \begin{bmatrix} \mathcal{Y}_\Sigma(\lambda) \\ \mathcal{X}_\Sigma(\lambda) \end{bmatrix}. \quad \text{(B.1)}$$

As was shown earlier,[3]

$$\begin{bmatrix} \mathcal{Y}_\Sigma(\lambda) \\ \mathcal{X}_\Sigma(\lambda) \end{bmatrix} =$$
$$- \begin{bmatrix} (\mathcal{A}_{\Sigma\Sigma} - \omega_\lambda) & \mathcal{B}_{\Sigma\Sigma} \\ -\mathcal{B}_{\Sigma\Sigma} & -(\mathcal{A}_{\Sigma\Sigma} + \omega_\lambda) \end{bmatrix}^{-1} \begin{bmatrix} \mathcal{B}_{\Sigma\Pi} & \mathcal{A}_{\Sigma\Pi} \\ -\mathcal{A}_{\Sigma\Pi} & -\mathcal{B}_{\Sigma\Pi} \end{bmatrix} \begin{bmatrix} \mathcal{Y}_\Pi(\lambda) \\ \mathcal{X}_\Pi(\lambda) \end{bmatrix}. \quad \text{(B.2)}$$

Letting $\mathcal{B}_{\Sigma\Sigma}=0$ and using Eq. 22, we have

$$\begin{bmatrix} \mathcal{Y}_\Sigma(\lambda) \\ \mathcal{X}_\Sigma(\lambda) \end{bmatrix} = \begin{bmatrix} -(\mathcal{A}_{\Sigma\Sigma} - \omega_\lambda)^{-1} \mathcal{A}_{\Sigma\Pi} \{\mathcal{Y}_\Pi(\lambda) + \mathcal{X}_\Pi(\lambda)\} \\ (\mathcal{A}_{\Sigma\Sigma} + \omega_\lambda)^{-1} \mathcal{A}_{\Sigma\Pi} \{\mathcal{Y}_\Pi(\lambda) + \mathcal{X}_\Pi(\lambda)\} \end{bmatrix}. \quad \text{(B.3)}$$

So that,

$$N_\lambda^2 - 1 = |(\mathcal{A}_{\Sigma\Sigma} - \omega_\lambda)^{-1} \mathcal{A}_{\Sigma\Pi} \{\mathcal{Y}_\Pi(\lambda) + \mathcal{X}_\Pi(\lambda)\}|^2$$
$$- |(\mathcal{A}_{\Sigma\Sigma} + \omega_\lambda)^{-1} \mathcal{A}_{\Sigma\Pi} \{\mathcal{Y}_\Pi(\lambda) + \mathcal{X}_\Pi(\lambda)\}|^2$$
$$= \left[\frac{1}{(a - \omega_\lambda)^2} - \frac{1}{(a + \omega_\lambda)^2} \right] \sum_{\pi_1^*\pi_1} \sum_{\pi_2^*\pi_2} \sum_{\sigma^*\sigma}$$
$$\{\mathcal{Y}_{\pi_1^*\pi_1}(\lambda) + \mathcal{X}_{\pi_1^*\pi_1}(\lambda)\} \mathcal{A}_{\pi_1^*\pi_1, \sigma^*\sigma}(S)$$
$$\times \mathcal{A}_{\sigma^*\sigma, \pi_2^*\pi_2}(S) \{\mathcal{Y}_{\pi_2^*\pi_2}(\lambda) + \mathcal{X}_{\pi_2^*\pi_2}(\lambda)\} \quad \text{(B·4)}$$

In deriving the last expression, we have let $\mathcal{A}_{\sigma^*\sigma,\sigma^*\sigma}=a$ and all the off-diagonal elements of $\mathcal{A}_{\Sigma\Sigma}$ be 0. Now, referring to Eqs. 22 and 24 and letting $g_{\sigma^*\sigma}=1$, we obtain

$$N_\lambda^2 - 1 = (\delta_{s0}) \frac{4a\omega_\lambda}{(a^2 - \omega_\lambda^2)^2} \sum_{\pi_1^*\pi_1} \sum_{\pi_2^*\pi_2}$$
$$(G_{\pi_1^*\pi_1, \pi_2^*\pi_2} / [g_{\pi_1^*\pi_1} g_{\pi_2^*\pi_2}]) \{\mathcal{Y}_{\pi_1^*\pi_1}(\lambda) + \mathcal{X}_{\pi_1^*\pi_1}(\lambda)\}$$
$$\times \{\mathcal{Y}_{\pi_2^*\pi_2}(\lambda) + \mathcal{X}_{\pi_2^*\pi_2}(\lambda)\}. \quad \text{(B·5)}$$

Computations were carried out using facilities of the Computer Centers both at Shinshu University and the University of Tokyo. This work was supported by a Grant-in-Aid for Scientific Research from the Ministry of Education.

Electrochemistry of Tris(β-diketonato)ruthenium(III) Complexes at Platinum Electrodes in Nonaqueous Solutions and Substituent Effects on Their Reversible Half-Wave Potentials[1,2]

Akira ENDO, Yoshimasa HOSHINO, Keigo HIRAKATA, Yasushi TAKEUCHI, Kunio SHIMIZU, Yuriko FURUSHIMA, Haruko IKEUCHI, and Gen P. SATÔ*

(Received September 10, 1988)

The one-electron oxidation and reduction processes at platinum electrodes of a series of β-substituted and γ-substituted tris(β-diketonato)ruthenium(III) complexes are studied in acetonitrile, *N*,*N*-dimethylformamide, and nitromethane solutions, each containing 0.1 mol dm^{-3} $(C_2H_5)_4NClO_4$ at 25 °C. Syntheses of three new γ-substituted derivatives are described. Attempts to isolate the immediate product of the one-electron oxidation of [Ru(acac)$_3$] in acetonitrile failed; bis(acetonitrile)bis(acetylacetonato)ruthenium(III) was obtained instead. Diffusion coefficients of the complexes in the acetonitrile medium are presented. The reversible half-wave potentials for the oxidation and the reduction in the acetonitrile medium depended linearly on the sum of the Hammett constants of the substituents (σ_p for the β-substituents and σ_m for the γ-substituents). Analysis of the dependence of the half-wave potentials on several kinds of substituent parameters suggests that the inductive effect is operative at both the β-positions and the γ-position, while the resonance effect is operative only at the β-positions.

Electrochemical properties of tris(β-diketonato)complexes involving many kinds of metals (e.g., cobalt(III),[3-7] chromium(III),[4,5,8,9] europium(III),[5] cerium(III),[5,6] iron(III),[4-6,9-12] manganese(III),[4-6,13] ruthenium(III),[14-18] and osmium(III)[15]) have been studied in various solvents. Most of these complexes undergo simple one-electron reduction and/or one-electron oxidation. In some cases, the reversible half-wave potentials for the reduction have been found to be linearly correlated with σ_p, σ_m, and σ^*, where σ_p and σ_m are the Hammett constants for para and meta positions, respectively, and σ^* is Taft's polar substituent constant.

Reduction processes of some tris(β-diketonato)ruthenium(III) complexes to the corresponding ruthenium(II) complexes have been studied in acetonitrile (AN)[14-18] and in *N*,*N*-dimethylformamide (DMF).[15] Linear relationships between the half-wave potentials and the sum of the Hammett constants were also reported.[15,18] These complexes, however, were all β-substituted complexes with one exception, and only a few quantitative analyses of oxidation processes to the ruthenium(IV) state have been reported.[14,16,19-21]

This paper deals with the electrochemical reduction and oxidation processes at platinum electrodes of a series of both β-substituted and γ-substituted tris(β-diketonato)ruthenium(III) complexes in AN, DMF, and nitromethane (NM). The electrochemistry in AN is studied in detail, since the potential window of AN, particularly its anodic limit for platinum electrodes, is wider than those of the other solvents. Substituent effects on the half-wave potentials for both the oxidation and the reduction are examined in terms of σ_p and σ_m. The diffusion coefficients of the complexes in AN are presented together with the partial molar volumes of a few related complexes.

Experimental

Preparation of the Ruthenium(III) Complexes.** All the tris(β-diketonato)ruthenium(III) complexes except **12**, **13**, and **14** were synthesized according to the "ruthenium blue solution" method.[22,23] The three halogenated complexes were prepared by the direct substitution at the γ-positions of the ligands of **9**. In the cases of **12** and **13**, a chloroform solution of *N*-bromosuccinimide (Wako Pure Chemical Ltd.) or *N*-chlorosuccinimide (Aldrich Chemical Company Inc.) was added to **9** dissolved in chloroform. In the case of **14**, a benzene solution of *N*-iodosuccinimide (Fluka AG) was added to a benzene solution of **9**, because preliminary experiments indicated that extended refluxing in chloroform led to complete decomposition of all the complex species. The amount-of-substance ratio of the *N*-halosuccinimide to **9** was 4.5 for **12**, 3.0 for **13**, and 9.0 for **14**. Too large an excess of the succinimide resulted in the decomposition of the product in the cases of **12** and **13**. *N*-Bromosuccinimide immediately reacted with **9** to give **13**. However, **12** was obtained by allowing the mixture to stand overnight, and **14** was obtained by refluxing the mixture for ca. 2 h. The solution containing the product was passed through a column of Merck Aluminiumoxid 90 (in the case of **12**, it was necessary to evaporate off the solvent and to extract the residue with benzene before the chromatographic separation). The eluent was evaporated to dryness. The residue was recrystallized from ethanol, and the crystals were dried under a vacuum. Interestingly, when the benzene solution of iodine monochloride was introduced to the benzene solution of **9**, the γ-chloro complex, not the γ-iodo complex, was produced immediately with ca. 100% yield, although this

** The ligand symbols are given in Table 1; the complexes are numbered as indicated there.

Table 1. Ligand Symbols[a] and Numbers for the Complexes

Number	Complex	[O=CR-CR′-CR″=O]⁻ R	R′	R″
β-Substituted complexes				
1	[Ru(fhfa)$_3$]	CF_3	H	CF_3

Mixed-ligand complexes				
18	[Ru(acac)$_2$(bhfa)][20,35]			
19	[Ru(acac)$_2$(fhfa)][20]			
20	[Ru(acac)$_2$(mClma)]			

a) These provisional symbols (except the usual "acac") are constructed as follows: the first and the penultimate letters represent R and R″; the middle R′; the last "a" means a derivative of acetylacetone; "b" stands for phenyl, "e" for ethyl, "f" for trifluoromethyl, "h" for hydrogen, "m" for methyl, "o" for 2-furyl, "p" for *t*-butyl, and "s" for 2-thienyl.

compound is known to be an iodination reagent in chloroform or in acetate buffer.[24] When a small amount of chloro-, bromo-, or iodosuccinimide was added to **9**, a mixture of the mixed-ligand complexes [Ru(acac)$_n$(mXma)$_{3-n}$] (X=Cl, Br, I) was formed. These mixed-ligand complexes may be separated by column chromatography. Actually, **20** was obtained in this way.

The three γ-halogenated complexes are new compounds. They are readily soluble in benzene and chloroform giving reddish blue solutions; they are sparingly soluble in acetonitrile and acetone. Their elemental analyses and other characteristics are as follows. **12** Found: Ru, 20.1; C, 37.1; H, 3.6%. Calcd for $RuC_{15}H_{18}O_6Cl_3$: Ru, 20.1; C, 35.9; H, 3.6%. **13** Found: Ru, 14.9; C, 27.3; H, 2.7%. Calcd for $RuC_{15}H_{18}O_6Br_3$: Ru, 15.9; C, 28.4; H, 2.9%. **14** Found: Ru, 12.0; C, 23.5; H, 2.3%. Calcd for $RuC_{15}H_{18}O_6I_3$: Ru, 13.0; C, 23.3; H, 2.3%. UV (AN; λ_{max}/nm with log [ε/mol^{-1} dm^3 cm^{-1}] in the parentheses): **12** 563 (3.36), 362 (3.95), 287 (4.15); **13** 556 (3.39), 363 (3.94). 291 (4.09); **14** 563 (3.44), 367 (3.92), 291 (4.08). ^{1}H NMR (C_6D_6): **12** δ=−8.31; **13**, δ=−7.79; **14**, δ=−7.16. Magneton number (μ_{eff}/μ_B): **12** 1.79; **13** 1.76; **14** 1.73.

All the complexes have optical isomers, and those complexes with three asymmetrical ligands have geometrical isomers. The samples used in the present experiment were mixtures of the isomers as prepared. No differences in the electrochemical behavior of the geometrical isomers were discernible.

Other Chemicals. Tris(acetylacetonato)iron(III) and tris-(acetylacetonato)cobalt(III) were purified by sublimating the samples purchased from Dojindo Laboratories under a reduced pressure at ca. 180 °C and ca. 200 °C, respectively. The sample of [Fe(phpa)$_3$] was prepared according to Hammond et al.[25] and purified by sublimation at ca. 200 °C; the same procedure was used for preparing [Fe(mbma)$_3$], except that the ligand was dissolved in ethanol instead of methanol and the sample was purified by recrystallization from benzene–petroleum ether.

Tetraethylammonium perchlorate (TEAP), tetrabutylammonium perchlorate (TBAP), and tetrabutylammonium tetrafluoroborate ((TBA)BF_4) used as supporting electrolytes were of special polarographic grade purchased from Nakarai Chemicals, Ltd. Silver perchlorate was prepared by dissolving silver oxide in perchloric acid (this silver oxide was obtained by adding a sodium hydroxide solution to a silver nitrate solution). The mixture was evaporated to dryness. The anhydrous salt was obtained by drying the residue under vacuum at room temperature for ca. 24 h, and then at 50 °C for a few days. The purification method of acetonitrile[26] was slightly modified: the third distillation with calcium hydride was carried out under argon atmosphere by means of a Widmer-type distilling column (ca. 100 cm long). *N*,*N*-Dimethylformamide was spectral reagent grade (Dojindo Laboratories, Dotite Spectrosol). Nitromethane was purified according to the literature method.[27] The other chemicals were of guaranteed reagent grade.

Measurement. Two kinds of platinum test electrodes were used in the voltammetric experiments. One was a platinum disk electrode (PtDE) of 1.99 mm diameter embedded in glass, which was used for the cyclic and normal pulse voltammetry. The other was a rotating platinum disk electrode (RPtDE) of 1.96 mm diameter embedded in poly(tetrafluoroethylene). Both electrodes were polished with aluminium oxide (particle size, ca. 0.03 μm).

A platinum gauze electrode was used as the working electrode for controlled potential electrolysis. An MCI AS01 hanging mercury electrode (Mitsubishi Chemical Industries, Ltd.) was used for the chronoamperometric determination of diffusion coefficients. In all the experiments, a spiral of platinum wire or a sheet of platinum was used as an auxiliary electrode.

Silver–silver ion reference electrodes were used for all the solvents: a spiral of silver wire was immersed in the respective solvent containing 0.1 mol dm^{-3} $AgClO_4$. The $AgClO_4$ solution was freshly prepared at each experiment. The reference electrode was placed in a compartment of an H-type cell with a G4 glass frit plug. It was connected to the test solution through a bridge filled with 0.1 mol dm^{-3} TEAP, TBAP, or (TBA)BF_4 solution of the needed solvent. All the potential values in this report are referred to these electrodes.

The concentration of the supporting electrolyte was 0.1 mol dm^{-3}. All the electrochemical measurements were carried out at (25.0±0.1) °C. Deoxygenation of the solutions was carried out with argon gas which had been passed through a series of two washing bottles containing the needed solvent kept at 25 °C. A Fuso Polarograph Model 312 was used for normal pulse voltammetry. For cyclic voltammetry, a Fuso Potential Scanning Unit Model 321 was attached to this instrument. When the voltammetry was performed with RPtDE, a Nikko Keisoku Motor Speed Controller SC-5 was used.

The reversible half-wave potentials ($E^{1}_{1/2}$) were determined from the normal pulse or hydrodynamic voltammograms by means of the conventional logarithmic plot method (natural logarithm was used) in Nernstian cases. In quasi-reversible cases, the reversible half-wave potentials were obtained by extrapolating the plots of $E+(RT/nF)\ln(I/(I_d-I))$ against E.[28]

Controlled potential electrolysis was carried out by using either the Polarograph Model 312 with a Fuso Coulometer Model 343 or a controlled potential electrolyzer with digital coulometer[29] constructed in this laboratory. The computerized data acquisition-processing system used for the chronoamperometric determination of diffusion coefficients was described elsewhere.[30]

The partial molar volumes were determined as follows. The densities (d) of acetonitrile solutions containing the complex to be studied at different molalities (m) were measured by means of a digital density meter (Anton Paar, DMA 60 with a DMA 602 cell). The cell temperature was controlled within ±0.003 °C. The density meter was calibrated with nitrogen and ultrapure deionized water at the beginning and the end of each day's measurements. When $(1+mM)/d$, where M is the molar mass of the complex, is plotted against m, the slope of the tangent of this curve at m gives the partial molar volume at m. In the present experiment, the plot was linear in every case, and the partial molar volume at infinite dilution was determined as the slope of the linear least squares regression.

Results and Discussion

The Reduction Process in AN. Each ruthenium(III) complex gave a well-defined reduction step on the normal pulse polarogram and a pair of cathodic and anodic peaks on the cyclic voltammogram in 0.1 mol dm^{-3} TEAP–acetonitrile solution. In some cases, the reduction step was followed by a second step, which was partly covered by the final discharge of the base solution. Only the first steps will be discussed.

In every case, the limiting current of the first reduction step of the normal pulse voltammogram was diffusion controlled as indicated by the inversely proportional dependence of the limiting current on the square root of the sampling time. The logarithmic plot of the step was a straight line with a reciprocal slope near the Nernstian value for a one-electron step (RT/F=25.7 mV at 25 °C), except in the cases of **10**, **11**, **16**, and **17**, which had the most negative half-wave potentials. The logarithmic plots of these four complexes were curved, indicating that their reduction processes were quasi-reversible at the platinum electrode, whereas their reduction processes were Nernstian at mercury electrodes. The peak separations of the cyclic voltammograms (ΔE_p) reflected this situation. These data are presented in Table 2. The reversible half-wave potentials of the reduction at PtDE for all the complexes were in good agreement with those observed at a dropping mercury electrode.

At RPtDE, all the complexes except the above-mentioned four complexes showed Nernstian steps over the rotation frequency range between 400 min^{-1} and 3600 min^{-1}. The limiting currents were convective-diffusion-controlled. The voltammograms of **10** and **11** showed Nernstian steps only at lower rotation frequencies. The reduction steps of **16** and **17** were poorly reproducible even at lower rotation frequencies.

The Reduction Processes in DMF and NM. The following five complexes were examined: **1**, **5**, **8**, **9**, and **11**. In 0.1 mol dm^{-3} TEAP–DMF solution, **5** and **8** gave Nernstian reduction steps at PtDE, as indicated by the ΔE_p values (Table 3) and the reciprocal slopes of the logarithmic plots of the normal pulse voltammograms (not listed). However, the reduction processes of **9** and **11** were quasi-reversible at PtDE, although Patterson and Holm[15] reported that the reductions at a platinum electrode were Nernstian in DMF. The data for **1** in DMF were obtained from the quasi-reversible oxidation step observed with a test solution containing K[Ru(fhfa)$_3$], because **1** was quickly reduced to the ruthenate(II).

In 0.1 mol dm^{-3} TEAP–NM solution, **1**, **5**, and **8** showed quasi-reversible reduction steps at PtDE, while no reduction steps of **9** and **11** were observed within the potential window of this medium.

The reversibility of the reduction processes of the tris(β-diketonato)ruthenium(III) complexes depended on both the kind of solvent and the electrode material. Nevertheless, the relative values of $E^{1}_{1/2}$ in each solvent (the values referred to **8** are given in Table 4) were almost independent of the kind of solvent. The

solvent effects on the reversible half-wave potential for the reduction appear to be small, in spite of the difference in the donor numbers of these solvents.

Oxidation Process in AN. A well-defined oxidation step was observed at both PtDE and RPtDE, and the cyclic voltammogram at PtDE exhibited a corresponding pair of anodic and cathodic peaks for each complex, except in the case of **1**, which showed no oxidation step within the potential window. In most cases, this step was followed by an ill-defined, irreversible second oxidation step, which will not be discussed.

The first steps were diffusion controlled. Comparison of their diffusion currents to those of the first reduction steps indicated that they were one-electron steps. These steps were Nernstian, except for the three complexes with the most positive half-wave potentials, i.e., **3**, **5**, and **6**. The oxidation steps of these three complexes were quasi-reversible. The $E^{I}_{1/2}$ values and the reciprocal slopes are presented in Table 2 together with the cyclic voltammetric ΔE_p values.

The constant potential coulometry of **8**, **9**, **11**, and **15** in AN confirmed that the steps were of the one-electron oxidation process to the corresponding ruthenium(IV) species and that the ruthenium(IV) complexes were stable and could be electrolytically reduced to the original ruthenium(III) species in a quantitative way.

In some other cases, however, the oxidation process was accompanied by slow subsequent reactions. When **3** was electrolyzed at +1.5 V in 0.1 mol dm^{-3} TEAP–AN, the anodic diffusion current decreased only slightly with the progress of the electrolysis, and the reduction step of $[Ru^{IV}(bhfa)_3]^+$ did not appear. Instead, new steps appeared at more negative potentials. Similar phenomena were observed when the supporting electrolyte was (TBA)BF_4 or TBAP. These facts show that the most part of $[Ru^{IV}(bhfa)_3]^+$ was reduced back to **3** by some species, whose oxidation product(s) produced the new reduction steps. Such regenerative reduction of the ruthenium(IV) species was observed also in the cases of **2**, **5**, and **6**. The oxidized forms of the complexes with $E^{I}_{1/2}(Ru^{IV}/Ru^{III})$ values more positive than +1.2 V catalyzed the oxidation of some unidentified species. These catalytic oxidation processes were fast enough to be observed in the controlled potential electrolysis, but they were too slow to affect the voltammetric current–voltage curves.

Since the oxidized forms of those complexes with less positive half-wave potentials (**9**, **11**, **15**, etc.) were stable in the acetonitrile solution, as mentioned above, attempts were made to isolate the ruthenium(IV) species. A blue solution which was obtained by the electrolytic oxidation of **9** in the $NaClO_4$–AN solution was evaporated under a reduced pressure. The residue was extracted with benzene. A blue solid was obtained when the benzene extract was evaporated. These operations were carried out under an argon atmosphere, and care was taken to exclude moisture as far as possible.

This blue solid was $[Ru^{III}(acac)_2(CH_3CN)_2](ClO_4)$ as indicated by the elemental analyses: Found: C,33.5; H, 4.0; N, 5.7% (Calcd for $RuC_{14}H_{20}N_2O_8Cl$: C, 35.0; H, 4.2; N, 5.7%), although the UV-vis spectrum of its $NaClO_4$–AN solution (λ_{max}/nm=285, 322, 580) was almost the same as that of the original solution from which it had been separated (λ_{max}/nm=280, 323, 560). This compound in the AN medium showed a reversible reduction step with $E^{I}_{1/2}$=−0.24 V, which agreed well with the half-wave potential of the oxidation step of $[Ru^{II}(acac)_2(CH_3CN)_2]$.[31] Its other characteristics are as follows: IR (KBr) 1095 cm^{-1} (ClO_4^-), 2300 cm^{-1} (CH_3CN). Magneton number, 1.75.

In this way, $[Ru^{IV}(acac)_3]^+$ was converted to the bis(acetonitrile) complex in the course of isolation. Attempts at isolating the oxidized products of **11** and **15**, which were also found to be stable in the acetonitrile solution, have so far led to recovering the original ruthenium(III) complexes. It appears that these tris(β-diketonato)ruthenium(IV) species were stable only in the presence of acetonitrile, and that their isolation would be very difficult, if not impossible, although a number of mononuclear ruthenium(IV) species with O^{2-}, halide ions, pyridine, or other organic ligands have been isolated.[19,32]

Oxidation Processes in DMF and NM. Five complexes, **1**, **5**, **8**, **9**, and **11**, were examined in these media. Among them, **8**, **9**, and **11** showed quasi-reversible one-electron oxidation steps (Table 3). The oxidation steps of the complexes with trifluoromethyl substituents lay beyond the positive ends of the potential windows of these media. Here again, the relative values of $E^{I}_{1/2}$ were roughly the same in the three solvents (Table 4).

Diffusion Coefficients and Partial Molar Volumes. The values of the diffusion coefficients of the tris(β-diketonato)ruthenium(III) complexes were evaluated approximately on the basis of the Levich equation from both the oxidation and the reduction limiting currents at the RPtDE, with the following values for 0.1 mol dm^{-3} TEAP–AN solution at 25 °C: density, 0.7901 g cm^{-3} and viscosity, 3.627×10^{-3} g cm^{-1} s^{-1}. For each complex, the value of the diffusion coefficient calculated from the oxidation limiting current agreed well with that calculated from the reduction limiting current. These values are listed in Table 2.

In order to establish the validity of these values, a more accurate value of the diffusion coefficient of **9** was determined by means of the chronoamperometric method with hanging mercury drop electrode[33] at several potentials in the cathodic diffusion current region. The average value obtained from four independent data sets (each consisting of at least six

b) Molar volume of crystal/cm³ mol⁻¹.

chronoamperograms) was (14.4±0.3)×10⁻¹⁰ m² s⁻¹ at 95% confidence level. The agreement between this value and the value in Table 2 is satisfactory.

The complexes with more bulky ligands seem to have smaller diffusion coefficients. Table 2 includes the Stokes radii calculated from the D values on the basis of the Einstein-Stokes relation. The partial molar volume (V_m) of **9** in AN (not containing the supporting electrolyte) was determined and is presented in Table 5 together with the values for some other tris(β-diketonato) complexes. The averages were calculated by pooling the data over all the temperatures, because the variations of V_m with temperature were within the experimental errors. It is seen that the V_m values are slightly larger than the molar volumes of the crystals.

The radius of a sphere having the same volume as the V_m/L value (L is the Avogadro constant) of **9** is 0.471 nm, and the radius calculated on the basis of the molar volume of the crystal is 0.463 nm. The Stokes radius of **9** is smaller than these values. Such a "negative effect" is reported in the cases of tetraalkylammonium perchlorate, and other bulky polyatomic ions.[34]

Substituent Effect on $E^r_{1/2}$. The values of $E^r_{1/2}$(Ru^{III}/Ru^{II}) and $E^r_{1/2}$(Ru^{IV}/Ru^{III}) in AN are listed in Table 2; the data for some mixed ligand complexes are also included. The values depended on the substituents of the ligands: with the increase in the number and/or the strength of electron-withdrawing substituents, both $E^r_{1/2}$(Ru^{III}/Ru^{II}) and $E^r_{1/2}$(Ru^{IV}/Ru^{III}) became more positive. Patterson and Holm[15] investigated the substituent effect on $E^r_{1/2}$(Ru^{III}/Ru^{II}) at platinum electrode in DMF of a series of β-substituted tris(β-diketonato)ruthenium(III) complexes, which included eight of the present ones. They found linear relationships between $E^r_{1/2}$(Ru^{III}/Ru^{II}) and the sums of Hammett constants or Taft constants. We have also reported a similar linear relationship for the reduction at mercury electrodes in AN.[18]

A more detailed study of the substituent effect is feasible now that quite a number of the β-substituted and γ-substituted derivatives have become available. Here, the effect of the substituents at the β- and γ-positions on the reversible half-wave potentials for the reduction and the oxidation is examined in terms of the following combinations of σ_m, and σ_p, where σ_m and σ_p are the Hammett constants for the meta and the para positions of the specified substituents.

$$\Sigma\sigma_{mmm} = 3[\sigma_m(R) + \sigma_m(R') + \sigma_m(R'')] \quad (1)$$

$$\Sigma\sigma_{mpm} = 3[\sigma_m(R) + \sigma_p(R') + \sigma_m(R'')] \quad (2)$$

$$\Sigma\sigma_{pmp} = 3[\sigma_p(R) + \sigma_m(R') + \sigma_p(R'')] \quad (3)$$

$$\Sigma\sigma_{ppp} = 3[\sigma_p(R) + \sigma_p(R') + \sigma_p(R'')] \quad (4)$$

Linear regression lines are drawn through the plots of $E^r_{1/2}$(Ru^{III}/Ru^{II}) and $E^r_{1/2}$(Ru^{IV}/Ru^{III}) against these parameters (the plots against $\Sigma\sigma_{pmp}$ are presented in Fig. 1). The plots against $\Sigma\sigma_{mpm}$ and $\Sigma\sigma_{pmp}$ fit to straight lines better than the others, mainly because the points for the γ-substituted complexes tend to deviate from the regression line for the β-subsituted complexes if $\Sigma\sigma_{mmm}$ or $\Sigma\sigma_{ppp}$ is taken as the parameter.

Whether $\Sigma\sigma_{mpm}$ or $\Sigma\sigma_{pmp}$ is more reasonable, however, cannot be decided by the fitness of the regressions. A more detailed piece of information is obtained when the relationships of $E^r_{1/2}$ with Taft's inductive substituent constant σ_I and the resonance substituent constant σ_R^0 are examined, because σ_p is a parameter which pertains to both the inductive and resonance effects.

When the $E^r_{1/2}$ values are plotted against $\Sigma\sigma_I$, two pairs of straight lines can be drawn: one for the β-substituted complexes and the other for the γ-substituted complexes (Fig. 2). This fact indicates that the inductive effect of the substituent strongly affects $E^r_{1/2}$ both at the β-position and at the γ-position. But, the slopes of the lines for the γ-substituents is smaller than those for the β-substituents, probably reflecting the γ-position's remoteness from the ruthenium atom.

When $E^r_{1/2}$ is plotted against $\Sigma\sigma_R^0$ (Fig. 3), an evident linear correlation is found only for the β-substituted complexes, while the points for the γ-substituted complexes are scattered. This fact

indicates that the resonance effect plays a less decisive role when the substituent is at the γ-position. In other words, the effect of the substituent at the γ-position is predominantly inductive, whereas the substituents at the β-positions exert both inductive and resoance effects. It is, therefore, $\Sigma\sigma_{pmp}$ that describes the substituent effects more reasonably than the other combinations of σ_p and σ_m. The same tendency has been observed in chromium(III) and cobalt(III) systems. In the case of tris(β-diketonato)chromium(III) complexes, Handy and Lindvedt[8] and Tsiamis et al.[9] established linear dependence of $E^{I}_{1/2}(Cr^{III}/Cr^{II})$ on $\Sigma\sigma_{pmp}$. With β-substituted tris(β-diketonato)cobalt-(III) complexes, the regression of the half-wave potential on $\Sigma\sigma_p$ was better than that on $\Sigma\sigma_m$.[3]

The substituent effects in β-diketonato ruthenium-(III) complexes have been explained qualitatively in terms of the influence of the substituents on the electron densities in the dπ orbitals.[15] The above-mentioned tendency has been accounted for by the idea that the β-substituents perturb the electron density on the ligating oxygen atoms rather than on the central atom.[8] Quantitative explanation is difficult, however, in the case of β-diketonato ruthenium-(III) complexes, which are paramagnetic, since no information about the electronic state is available directly from the UV-vis spectra, and the molecular orbital calculations are not easy.

The authors thank Makiko Ikai, Shinji Arai, and Noriko Mihara for their experimental assistance and

Dr. Yuichi Satsu for his helpful discussions. Dr. Kazuko Tanaka, The Institute of Physical and Chemical Research, kindly permitted the use of the digital density meter of her laboratory. Mrs. Nakako Tokita's assistance in the elemental analyses is gratefully acknowledged. Thanks are also due to Dr. F. Scott Howell, Sophia University, for correcting the manuscript. This work was partially supported by Grants-in-Aid for Scientific Research Nos. 547045 and 58740287 from the Ministry of Education, Science and Culture.

Catalysis by Heteropoly Compounds. XII.[1] Absorption Properties of 12-Tungstophosphoric Acid and Its Salts

Toshio OKUHARA,* Shin TATEMATSU,† Kwan Young LEE, and Makoto MISONO*
Department of Synthetic Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received September 19, 1988)

The absorption of organic molecules into the bulk of $H_3PW_{12}O_{40}$ and its salts was studied. Polar (or basic) molecules, such as alcohols and amines, were readily absorbed into $H_3PW_{12}O_{40}$, but nonpolar hydrocarbons were not absorbed. The absorption depended not only on the polarity but also on the molecular size. The diffusion coefficients of the absorption of C_1—C_4 alcohols were of similar magnitudes, and were much smaller than that of the intracrystalline diffusion of methanol in ZSM-5. The amounts of absorbed molecules in $H_3PW_{12}O_{40}$ tended to be in discrete values: that is, integral multiples of the number of protons (3, 6, etc.). This fact indicates that these polar molecules are protonated and form stable secondary structures throughout the bulk. It was confirmed in the case of methanol or ethanol that the transition between the states of 6 and 9 molecules/anion took place through the pressure changes. The absorptivity was greatly suppressed by the substitution of Cs^+ for more than two H^+, while the Na salts showed an absorptivity similar to that of $H_3PW_{12}O_{40}$.

We previously reported that the important characteristic of solid heteropoly acids, such as $H_3PW_{12}O_{40}$, is that these compounds absorb readily polar molecules, such as alcohols and amines, but not nonpolar hydrocarbons.[2-4] This property discriminates molecules by the difference in the polarity. This is different from zeolites which recognize molecular size.

Due to the absorptivity, some reactions proceed very rapidly in the bulk. This state has been called the "pseudoliquid phase".[3-6] The pseudoliquid phase brings about peculiar activity patterns[6,7] and selectivities in the reactions of alcohols and ethers.[8-11] We recently reported unusual pressure dependencies of the rate and selectivity of ethanol dehydration over $H_3PW_{12}O_{40}$, and explained the phenomenon in terms of changes in the number of ethanol molecules absorbed in the pseudoliquid phase.[12] Thus, the pseudoliquid phase behavior is essential for understanding the catalysis of heteropoly compounds.

The absorption of alcohols has already been studied by us,[2] Niiyama et al.,[13] and Moffat et al.[14] However, the factors determining the absorption rate, the amount, and the diffusion coefficient in the pseudoliquid phase have not been fully elucidated and the transition process between two pseudoliquid phases[15] has not been examined in detail. In this study, the rates of absorption as well as the amounts were systematically measured for various molecules over $H_3PW_{12}O_{40}$ under controlled conditions. It was also attempted to control the absorptivity of $H_3PW_{12}O_{40}$ by the substitution of Na^+ or Cs^+ for H^+.

Experimental

Catalysts and Materials. $H_3PW_{12}O_{40}$ (Nippon Inorganic Colour and Chemical Co., Ltd.) was recrystallized from water after purification by extraction with diethyl ether.[6] The salts of Na and Cs were prepared from Na_2CO_3 and Cs_2CO_3 by a previously described method.[6,10] The amount of water of crystallization was measured with a thermogravimeter (Shimadzu TG-30) which was connected to a vacuum system. The surface area was measured by the BET method using N_2-gas adsorption after the samples were pretreated at 130 °C in He. Pyridine, alcohols (C_1—C_4), and amines (C_3—C_4) were degassed by a freeze-thaw cycle; water contained as an impurity was removed by Molecular Sieve 3A. Ethers (C_2—C_6) were used after being degassed by a freeze-thaw cycle.

Apparatus and Procedure. Absorption and desorption of molecules were followed by a quartz spring balance (sensitivity; 14 mg mm^{-1}) which was connected to a vacuum system. The heteropoly compounds (about 1.0 g) were exposed to the vapor of the molecules at 28 °C and at a desired pressure after being evacuated at 130 °C for 1 h. We call the saturated amount of absorption obtained in the presence of the vapor the "amount of saturated absorption". The number of molecules held in heteropoly compounds after evacuation at 28 °C is called the "amount of irreversible absorption".

If absorption occurs into a particle with a radius, r, Eq. 1 can be used for large t,[16,17] where Q_t and Q_∞ are the amounts of absorption at time t and at equilibrium, respectively:

$$Q_t/Q_\infty = 1 - (6/\pi^2)\exp(-D\pi^2 t/r^2). \quad (1)$$

Here, D is the diffusion coefficient in a particle of $H_3PW_{12}O_{40}$. The concentration of molecule at the surface of the $H_3PW_{12}O_{40}$ particle is assumed to be constant during the absorption. We estimated r to be about 1000 Å from the surface area (5.0 m$^2\cdot$g^{-1}) and the density (5.8 g$\cdot$cm^{-3}) of $H_3PW_{12}O_{40}$.[18] From Eq. 1, the slope of a straight line in a plot of $\ln(1-Q_t/Q_\infty)$ against t gives D. This plot was compared with another one, $Q_t/Q_\infty=6(D/\pi r^2)^{1/2}t^{1/2}$, which is suitable for small t.[17] As a result, the former was confirmed to be adequate for our data.

In order to follow rapid changes in the amounts of absorption by the pressure jump of methanol or ethanol, a

† Present address: Asahi Glass Co., Ltd., Hazawa-cho, Kanagawa-ku, Yokohama 221.

thermogravimeter connected to the vacuum system was used. About 50 mg of $H_3PW_{12}O_{40}$ was pretreated in vacuo at 130 °C for 1 h. Methanol and ethanol were introduced at 45 and 60 °C, respectively. The pressures were changed by controlling the temperature of the liquid of the alcohols in a Pyrex tube container connected to the system. It was confirmed that no reaction took place under these conditions.

Results

Rate of Absorption into $H_3PW_{12}O_{40}$. Typical time courses of the absorption of methanol and diethyl ether are shown in Fig. 1. The ordinate is the amount of absorption in the unit of the number of molecules per polyanion, $PW_{12}O_{40}^{3-}$ (averaged over whole bulk). In the case of methanol, the initial rate of absorption, which is defined as the amount absorbed in the initial 10 min, appeared to be slightly dependent on the pressure; however, the amount of saturated absorption showed two discrete values: about 6 molecules/anion at the pressure of 15—30 Torr (1 Torr=133.3 Pa) and about 12 molecules/anion at 60—100 Torr. As discussed previously,[2] these amounts correspond to more than 50 surface layers. Therefore, it is obvious that the uptake is not the adsorption but the absorption. In accordance with this idea, the expansion of the sample volume was observed.

The absorption of diethyl ether was slow at a pressure lower than 70 Torr (Fig. 1b). However, at higher pressures (160—350 Torr), the absorption reached very rapidly about 6 molecules/anion. The presence of a similar critical pressure has previously been observed for acetone.[2]

In Table 1, the initial rates of absorption as well as the amounts of absorption are summarized. In spite of the great difference in the pressure introduced, the variation of the initial rates was within an order of magnitude for alcohols and amines. As for the alcohols, the rates in the pressure range of 20—30 Torr were in the following order: methanol≈ethanol >1-propanol>2-propanol.

Figure 2 shows a plot of $\ln(1-Q_t/Q_\infty)$ against t for

a) Amount of saturated absorption; number of molecule·anion⁻¹.

alcohols and amines (see Eq. 1). All of the curves could be fitted by straight lines. The diffusion coefficients, D, which were calculated from the slopes of the curves, are summarized in Table 2. In the case of the alcohols, the D in the pressure range from 20 to 30 Torr was in the following order: methanol> ethanol>1-propanol>2-propanol. For a comparison, the data reported for the intracrystalline diffusion of various molecules for zeolites are given in Table 3.[19-24]

In Fig. 3, the pressure dependencies of the initial absorption rates and the diffusion coefficients are shown for methanol and 1-propanamine, where the abscissa is the relative pressure, which is the ratio of the pressure introduced to the saturated vapor pressure at 28°C multiplied by 100. It was found that the pressure dependence of the absorption rate was different in these molecules; when the relative pressure increased from 10 to 60%, the absorption rate of 1-propanamine increased by a factor of about 3. However, the increase in the rate for methanol was small. The initial absorption rate tended to be nearly constant for each molecule at higher relative pressures (>40%).

Amounts of Absorption. The influence of the pressure on the amounts of absorption is shown in

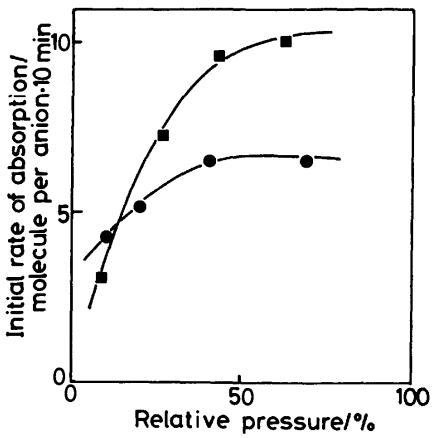

Fig. 3. Changes of the initial absorption rates as a function of the relative pressure.
●: Methanol, ■: 1-propanamine.

Table 3. Diffusion Coefficients of Molecules into Zeolites

Molecules/Zeolite	Temperature / °C	D / cm²·s⁻¹	Ref.
CH_3OH/H-ZSM-5	30	2.6×10^{-11}	19
$(CH_3)_2O$/H-ZSM-5	30	7.5×10^{-11}	19
C_2H_5OH/Zeolite-T	150	1.0×10^{-11}	20
C_2H_6/H-ZSM-5	25	7.0×10^{-11}	21
C_3H_8/H-ZSM-5	25	1.3×10^{-11}	22
n-C_4H_{10}/Ca-A	75	6.0×10^{-14}	22
C_6H_6/H-ZSM-5	20	8.6×10^{-11}	19
C_6H_{12}/H-ZSM-5	73	5.2×10^{-14}	23
C_6H_{12}/H-ZSM-5	80	2.2×10^{-14}	24
p-C_8H_{10}/H-ZSM-5	80	2.2×10^{-12}	24

Fig. 4. For methanol, the amounts of saturated absorption were about 6 and 12 molecules in the relative pressure of 10—80%. The amount of irreversible absorption was 3 molecules/anion in this pressure range. On the other hand, the amount of irreversible absorption of ethanol and diethyl ether was about 6 molecules/anion. As summarized in Table 1, the amounts of irreversible absorption of alcohols and ethers often showed values close to 3 and 6 molecules per anion, respectively. The ratios of the amount of irreversible absorption to that of monolayer adsorption are shown in parentheses in Table 1. Hereafter, this ratio is called the "number of surface layers".

The transition between the different absorption states can be seen in Figs. 5 and 6. The state of 6 molecules of methanol per anion, which was obtained at a pressure of 20 Torr, did not change upon the pressure increase to 55 Torr (Fig. 5). By a further increase to 70 Torr, the number of molecules increased to 9 molecules/anion. This state (9 molecules/anion) remained unchanged until the pressure was decreased to 20 Torr, inducing a change of the state to 6 molecules/anion. Figure 6 shows a similar behavior for ethanol. The transition between 6 and 9 molecules/anion took place reversibly through a pressure change from 45 to 3.5 Torr.

The absorption properties of acidic salts of Na and Cs were measured by using ethanol as a probe molecule; they are summarized in Table 4. The uptakes of ethanol for Na and Cs salts are shown in Fig. 7 in units of "number of surface layer" as a function of the cation content. The "number of surface layer" was estimated from the cross section of ethanol (25 Å^2) and the surface area of these salts.[25] As can be seen in Fig. 7, the numbers of surface layers for Na salts were about 60

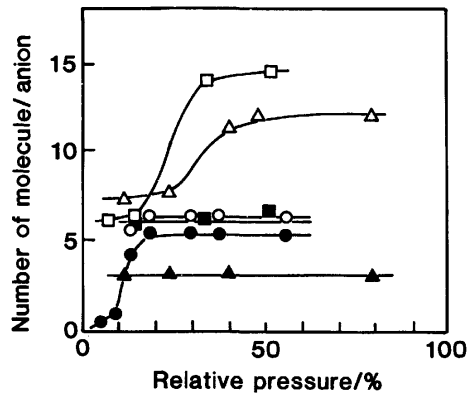

Fig. 4. Pressure dependence of the amounts of absorption into $H_3PW_{12}O_{40}$ at 28°C.
Saturated amount: (□) ethanol, (△) methanol, (○) diethyl ether.

and 143 in $0 \leq x \leq 2$ and at $x=3$, respectively. On the other hand, this number changed greatly from 322 to 0.5 as x varied from 1 to 3 for Cs salts.

Discussion

Factors Determining the Absorption. The uptakes of benzene, ethylene (Table 1), and other hydrocarbons were nearly equal to or less than the amount of monolayer;[2] the numbers of surface layers were less than 1. This shows that these hydrocarbons are not absorbed. On the other hand, the numbers of surface layers for alcohols, ethers, and amines were greater than 26, indicating that these polar molecules are absorbed into the bulk of $H_3PW_{12}O_{40}$. Due to a large uptake, an increase in the sample temperature was always observed. Since $H_3PW_{12}O_{40}$ is a strong acid, an acid–base interaction must be the driving force of the absorption of basic (or polar) molecules.

The basicity may be expressed by pK_a of the protonated molecules (conjugate acid), where K_a is the dissociation constant of protonated molecules; $BH^+ + H_2O \rightleftarrows B + H_3^+O$ (B; base). Then, the molecules can be classified into three groups by their pK_a values. The first group consists of alcohols and ethers, of which the pK_a values are between −2.0 and −4.3. The molecules in the second group are amines having pK_a's of about 10, which are much more strongly basic. The third is the group of hydrocarbons. While the values of pK_a of hydrocarbons are not clear, these molecules must be much less basic than alcohols and ethers. In the gas phase, oxygenated compounds like alcohol and ether are generally more basic than olefins.[26]

The polarity of molecule also appears to be relevant to the absorption. The polarity may be represented by the dipole moment. As shown in Table 1, alcohol, ether, and amine have large dipole moments (e.g., about 1.7 (alcohols), 1.2 (ethers), 1.3 (amines), and 2.2 (C_5H_5N) in the unit of Debye),[27] but it is zero for ethylene and benzene. Generally, hydrocarbons have very small dipole moments. Therefore, it is concluded that either the basicity or polarity of molecules is important regarding absorption. Since these molecules tend to form hydrogen bonding, whether the hydrogen bonding is formed with $H_3PW_{12}O_{40}$ or not may be a key factor for absorption.

Rate of Absorption. As shown in Fig. 3, the initial absorption rate had a nearly constant value at the relative pressure higher than about 40%. When the initial rates measured at the relative pressure higher than 40% were plotted against the molecular size, correlations for polar molecules were obtained as shown in Fig. 8. The initial rates of alcohols greatly decreased as the molecular size increased (20 Å^2 (methanol)—35 Å^2 (1-butanol)). However, the initial rates for propanamines and 1-butanamine were distinctly higher than those of alcohols in spite of their greater molecular size. This difference is probably due to the large difference in the pK_a values of alcohols ($-2 \leq pK_a \leq -3.8$) and amines ($pK_a \approx 10$). It may therefore be stated that the rate is primarily determined by the basicity (or polarity) and secondarily by the molecular size.

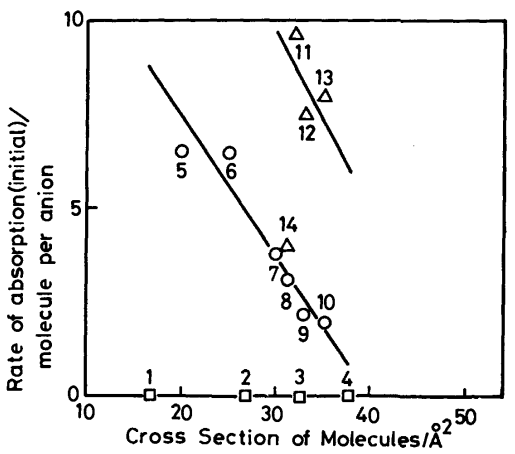

Fig. 8. Initial rates of absorption of various molecules by $H_3PW_{12}O_{40}$ vs. molecular size.
1. Ethylene (0.13), 2. dichloromethane (27), 3. benzene (43), 4. toluene (91), 5. methanol (68), 6. ethanol (71), 7. 1-propanol (80), 8. 2-propanol (57), 9. 1,4-dioxane (76), 10. 1-butanol (50), 11. 1-propanamine (43), 12. 2-propanamine (46), 13. 1-butanamine (47), 14. pyridine (62).
The figures in parentheses are the relative pressure.

As shown in Table 2, the diffusion coefficients for alcohols tended to become lower as the molecular size increased (from methanol to 2-propanol). This trend is the same as the initial rates. Since the diffusion coefficient is regarded as being the rate constant of absorption, the rate of absorption would be proportional to the product of the diffusion coefficient and the concentration of the molecule at the surface. There-

fore, the difference in the initial rate for alcohols may mainly be ascribable to a difference in the diffusion coefficient. Although the diffusion coefficients of the amines were not so great (Table 2), the initial rates were high (Fig. 8). The higher initial rates for the amines are probably brought about by the higher concentrations of amines on the surface as compared with those of alcohols, while the concentration at the surface during the absorption is not yet known.

The diffusion coefficient for the hydrocarbons into the pore of ZSM-5 zeolite varied from 10^{-11} to 10^{-14} $cm^2 \cdot s^{-1}$ depending on the molecules (Table 3). This great difference in D is called the molecular sieve effect.[17] In the case of $H_3PW_{12}O_{40}$, the difference between hydrocarbons and polar molecules was very large. But, the diffusion coefficients of alcohols and amines into the bulk of $H_3PW_{12}O_{40}$ showed similar values, about $0.42—1.80\times10^{-14}$ $cm^2 \cdot s^{-1}$ (at 30 Torr). The uptake of $H_3PW_{12}O_{40}$ is not diffusion into pores,[3] but absorption into the bulk between the polyanions. Therefore, it may meet a much greater resistance than the diffusion of molecules into the micropores of zeolite.

It is clear that the absorptivity of $H_3PW_{12}O_{40}$ was greatly suppressed by the substitution of Cs^+ for H^+, while the absorptivity varied little upon substitution of Na^+ for H^+ (Fig. 7). Since the acidity decreased upon substitution of Na^+ for H^+,[6] the decrease in the rate of ethanol absorption as the content of Na^+ increased (Table 4) also suggests the importance of the acidity of heteropoly compounds (basicity of molecules).

Transition between Pseudoliquid Phases. As for the absorption of polar molecules, there are at least two states which differ in the number of absorbed molecules. The states of 6 and 9 molecules/anion existed (Figs. 5 and 6) and each state was stable within a certain range of pressure. We reported for the dehydration of 2-propanol over $H_3PW_{12}O_{40}$ that there were at least two pseudoliquid phases differing in the catalytic activity.[15] At 80 °C, the number of 2-propanol absorbed was 3 molecules/anion for the high-activity state and 8—9 molecules/anion for the low-activity states. Their transitions brought about unusual pressure dependencies of the activity.[15]

It is noted that the amounts of alcohol, ether, and pyridine were nearly integral multiples (1, 2, and 3) of the number of protons present in the bulk of $H_3PW_{12}O_{40}$. These numbers indicate that these molecules are homogeneously absorbed and that the stable forms are probably, e.g., $CH_3OH_2^+$, $(C_2H_5OH)_2H^+$, and $(Py)_2H^+$. IR and gravimetric measurements have previously suggested that pyridinium ion in dimer species, $(Py)_2H^+$ existed.[2] Recently, ^1H and ^{13}C solid-state NMR of ethanol absorbed on $H_3PW_{12}O_{40}$ have been measured.[28] ^1H NMR spectra of $H_3PW_{12}O_{40}\cdot6C_2H_5OH$ resembled those of protonated ethanol in superacid,[29] suggesting that this species is $(C_2H_5OH)_2H^+$.[28] Furthermore, the infrared spectra of $H_3PW_{12}O_{40}\cdot6C_2H_5OH$ also supported the presence of $(C_2H_5OH)_2H^+$ in the bulk.[30] Although the exact structure of a compound having 6 molecules/anion is unknown yet, for example, the structure of $H_3PW_{12}O_{40}\cdot6C_2H_5OH$ may be similar to that of $H_3PW_{12}O_{40}\cdot6H_2O$, of which the structure was determined by X-ray diffraction,[31] since the XRD patterns were similar.

Summary

1. For absorption, the basicity or polarity of molecules was important. The rate of absorption depended on the molecular size as well as basicity.

2. In the absorption state (i.e., pseudoliquid phase), the numbers of molecules were integral multiples of the number of protons; the amount of irreversible absorption of methanol was equal to the number of H^+; those of ethanol, diethyl ether, and propanols were twice the number.

3. In the presence of gas-phase methanol or ethanol, the transition between different pseudoliquid phases takes place reversibly, depending on the pressure ranges.

4. The absorptivity of $H_3PW_{12}O_{40}$ can be controlled by the formation of acidic salts of Cs.

The present work was supported in part by a Grant-in-Aid for Scientific Research No. 62470070 from the Ministry of Education, Science and Culture and by Asahi Glass Foundation.

Cobalt(III) Complexes with Quadridentate Ligands. VIII.[1] The Preparation and Properties of Cis-β_1 and β_2-Isomers of the Thiosalicylato-(quadridentate amine)cobalt(III) Complexes

Yoshihisa YAMAMOTO,* Kayoko YOSHII, Eiko TOYOTA, and Kazuko KONNO
Faculty of Pharmaceutical Sciences, Higashi Nippon Gakuen University,
Ishikari-Tobetsu, Hokkaido 061-02
(Received May 2, 1988)

cis-β_1 and β_2-Thiosalicylato(quadridentate amine)cobalt(III) complexes, *cis*-β_1, β_2-[Co(thiosal)L]X·nH$_2$O (L: trien (2,2,2-tet), 3,2,3-tet; X: Cl, NO_3), have been prepared from a reaction mixture of [$CoCl_2$L]Cl·nH$_2$O (L: trien, 3,2,3-tet), Ag_2O, thiosalicylic acid (*o*-mercaptobenzoic acid), and 28% aqueous ammonia. Two geometrical isomers (cis-β_1 and β_2) of their complexes were separated by Dowex 50W-X2 column chromatography. The isomerization between the cis-β_1 and β_2-isomers is reversible in water at 40 °C. The IR spectra of these complexes showed four or five absorption bands in the 990—1100 cm^{-1} region and four absorption bands in the 3000—3300 cm^{-1} region. This indicates that these complexes assume the cis-β-form. Their cis-β_1 and β_2 configurations have been established by their absorption and NMR spectra. The *cis*-β_1 and β_2-thiosalicylato(trien)cobalt(III) complexes have been tentatively assigned to the *RR,SS* diastereoisomer by their ^{1}H NMR spectra. The color of solid state materials, solubilities in alcohols, isomerization at 40 °C, reaction in 60% nitric acid, absorption spectra, and chemical shift of Co–S–C carbon of the coordinated thiosalicylato ligand for the title complexes are different from those of the corresponding *cis*-β_1 and β_2-salicylato(quadridentate amine)cobalt(III) complexes, *cis*-β_1, β_2-[Co(sal)L]Cl·nH$_2$O (L: trien, 2,3,2-tet, 3,2,3-tet, 3,3,3-tet), reported previously.

Previous papers[2,3] have been concerned with the preparation, properties, and NMR spectra of *cis*-β_1 and β_2-salicylato(quadridentate amine)cobalt(III) chloride hydrates, *cis*-β_1, β_2-[Co(sal)L]Cl·nH$_2$O (L: trien, 2,3,2-tet, 3,2,3-tet, 3,3,3-tet).

Many investigations[4–10] of the metal complexes with thiosalicylato (*o*-mercaptobenzoato) ligand have been concerned with the stability, formation constants, and potentiometric studies. However, the preparation of thiosalicylato metal complexes has not yet been described, except for Rh(thiosal)$_2$,[11] Ni(thiosal)$_2$,[12] [Pt(bpy)(thiosal)],[13] and (PPh_4)[Mn(thiosal)$_2$(HIm)][14] (HIm: imidazole). Little is known of the preparation and physical and general properties for octahedral thiosalicylato metal complexes, in contrast with those of octahedral salicylato cobalt complexes and the related complexes.[1–3,15–18] The present paper deals with the preparation and properties of *cis*-β_1 and β_2-thiosalicylato(quadridentate amine)cobalt(III) complexes, *cis*-β_1, β_2-[Co(thiosal)L]Cl·nH$_2$O (L: trien, 3,2,3-tet), and deals with the assignments of the configuration of cis-β_1 and β_2-isomers on their IR, NMR, and absorption spectra.

Experimental

Measurements. The electric conductivities in aqueous solutions were determined by the use of a conductometric meter, CM-30 (Shimadzu), at room temperature. The magnetic susceptibilities were measured by Faraday's method using a magnetic balance (Shimadzu) at room temperature. The IR spectra were recorded in potassium bromide disks with a 270—30 spectrophotometer (Hitachi). The visible absorption spectra were recorded with a Shimadzu UV-210 recording spectrophotometer. The NMR spectra were recorded with an FX90Q apparatus (JEOL) for ^{1}H NMR and an FX-60 apparatus (JEOL) for ^{13}C NMR. The melting points were measured on a MP-500D apparatus (Yanako).

Preparation of Complexes. *cis*-α-Dichloro(triethylenetetramine)cobalt(III) Chloride (1) and *trans*-Dichloro(4,7-diazadecane-1,10-diamine)cobalt(III) Chloride Hydrate (2): These complexes were prepared by the methods of Sargeson[19] and Bosnich.[20]

***cis*-β_1-Thiosalicylato(triethylenetetramine)cobalt(III) Chloride Hydrate (3) and β_2-Thiosalicylato(triethylenetetramine)-cobalt(III) Chloride Trihydrate (4):** Complex **1** (5.0 g, 16.05 mmol) was added to moistend fresh Ag_2O, which was made from silver nitrate (5.5 g, 32.10 mmol) and potassium hydroxide (1.80 g, 32.10 mmol). The mixture was stirred for several minutes at room temperature; to the mixture was added 20 cm^3 of water and kept for about 30 min at 60 °C. The precipitated silver chloride was filtered off. Then, thiosalicylic acid (2.5 g, 16.2 mmol) and 3 cm^3 of 28% aqueous ammonia were added to the solution. From the reaction mixture, complexes **3** and **4** were obtained according to the following methods 1—3.

Method 1: The reaction mixture was stirred at 50 °C for 6 h; it was then concentrated on a rotary evaporator and dried. Yield: 6.38 g for *cis*-β-[Co(thiosal)trien]Cl·nH$_2$O. *cis*-β-[Co(thiosal)trien]Cl·nH$_2$O of 0.8 g was dissolved in 2 cm^3 of water, and the solution was injected onto a column of ion-exchange resin (Dowex 50W-X2, ϕ2.5×30 cm). Upon elution with 0.1 mol dm^{-3} NaCl, the effluent of the first russet band of complex **4** and that of the second russet band of complex **3** was collected and concentrated, respectively. The separated NaCl was removed. The purification for complexes **3** and **4** was recrystallized from water–acetone. Yields: 2.61 g (39.5%) for **3**, 2.30 g (32.0%) for **4**.

Method 2: The reaction mixture was stirred at 40 °C for 3 h, and allowed to remain one night in an icebox; then the precipitated complex **3** was filtered and recrystallized. To the filtrate was added ethanol; the mixture was allowed to remain one night. The precipitated complex **4** was filtered

and recrystallized from water-acetone. Yields: 1.0 g (15.2%) for **3**, 2.6 g (36.1%) for **4**.

Method 3: The reaction mixture was stirred at 60 °C for 6 h, and concentrated on a rotary evaporator. A little water was added to the reaction mixture, and the separated complex **3** filtered and recrystallized from water-acetone. To the filtrate was added ethanol. The separated complex **4** was filtered, and recrystallized from water-acetone. Yields: 3.2 g (48.5 %) for **3**, 0.9 g (13.6%) for **4**. Color: dark russet for **3** and violet russet for **4**. Found **3**: C, 38.30; H, 6.07; N, 13.43; Cl, 9.12%. Calcd for $CoC_{13}H_{24}N_4O_3SCl$ (MW 410.81) C, 38.01; H, 5.89; N, 13.64; Cl, 8.63%. Found **4**: C, 34.93; H, 6.43; N, 12.89; Cl, 8.53%. Calcd for $CoC_{13}H_{28}N_4O_5SCl$ (MW 446.84) C, 34.94; H, 6.32; N, 12.54; Cl, 7.93%. Mp: 241 °C for **3**, 233 °C for **4**. Λ=130 for **3** and 118 S cm^2 mol^{-1} for **4** in water. IR spectra: 994, 1034, 1054, 1078, 1094 cm^{-1}, and 3040, 3112, 3204, 3272 cm^{-1} for **3**, 1000, 1034, 1056, 1066, 1080 cm^{-1}, and 3070, 3116, 3200, 3280 cm^{-1} for **4**.

Complexes **3** and **4** did not isomerize to **4** and **3**, respectively, in water or aqueous ammonia (pH≒10) at 20 °C after for 24 h, though **3** and **4** did isomerize to **4** and **3**, respectively, in water at 40 °C after for 24 h.

***cis*-β_1 and β_2-Thiosalicylato(4,7-diazadecane-1,10-diamine)-cobalt(III) Chloride Hydrate (cis-β_1 (5), β_2 (6)):** Complex **2** (5.8 g, 16.2 mmol) was added to moistend fresh Ag_2O, which was made from silver nitrate (5.5 g, 32.1 mmol) and potassium hydroxide (1.8 g, 32.1 mmol). The mixture was stirred for several minutes at room temperature before adding 20 cm^3 of water. The mixture was left for about 30 min at 60 °C. The precipitated silver chloride was filtered off. Then, thiosalicylic acid (2.5 g, 16.2 mmol) and 3 cm^3 of 28% aqueous ammonia were added to the solution. From the reaction mixtures, complexes **5** and **6** were obtained according to the methods described in 1—2.

Method 1: The reaction mixture was stirred at 40 °C for 6 h, and concentrated on a rotary evaporator. The concentrated solution was injected on a column chromatograph on alumina. Upon elution with ethanol, the first green band was collected and concentrated on a rotary evaporator. The solution was cooled in an icebox; separated complex **5** was filtered and recrystallized. The filtrate was concentrated and dried. The dried product (0.8 g) was dissolved in 2 cm^3 of water. This solution was injected onto a column of ion-exchange resin (Dowex 50W-X2, ϕ2.5× 30 cm). On elution with 0.1 mol dm^{-3} NaCl, the effluent of the first green band of complex **6** and that of the second green band of complex **5** was collected and concentrated, respectively. The separated NaCl was removed. Complex **5** was recrystallized from water-methanol (1 : 7) and complex **6** was recrystallized from ethanol. Yields: 3.3 g (46.5%) for **5**, 0.8 g (11.3%) for **6**.

Method 2: The reaction mixture was stirred at 50 °C at 6 h and then concentrated on a rotary evaporator. The concentrated solution was injected onto a column chromatograph on alumina on elution with ethanol; the green band was collected and concentrated on a rotary evaporator. The solution was allowed to remain one night in an icebox. The precipitated complex **5** was filtered. From the filtrate of **5**, separation of **5** and **6** was achieved by a column of ion-exchange resin of the method 1. Yields: 3.45 g (48.5%) for **5**, 0.21 g (3.0%) for **6**. Color: greenish gray for **5** and **6**. Found **5**: C, 41.18; H, 6.67; N, 12.82; Cl, 8.11%. Found **6**: C, 41.15; H, 6.63; N, 13.01; Cl, 8.36%. Calcd for $CoC_{15}H_{28}N_4O_3SCl$ (MW 438.86) C, 41.05; H, 6.43; N, 12.77; Cl, 8.08%. Mp: 234 °C for **5** and **6**. Λ=105 for **5** and 110 S cm^2 mol^{-1} for **6** in water. IR spectra: 1018, 1036, 1052, 1067 cm^{-1}, and 3060, 3120, 3200, 3276 cm^{-1} for **5**, 1014, 1038, 1056, 1088 cm^{-1}, and 3084, 3160, 3192, 3260 cm^{-1} for **6**. Complexes **5** and **6** isomerize to **6** and **5**, respectively in water at 40 °C after for 24 h.

***cis*-β_1-Thiosalicylato(triethylenetetramine)cobalt(III) Nitrate Hydrate (7) and *cis*-β_2-Thiosalicylato(triethylenetetramine)cobalt(III) Nitrate Dihydrate (8):** Complexes **7** and **8** were prepared from the reaction mixture of silver nitrate (0.20 g, 1.20 mmol) and **3** (0.49 g, 1.19 mmol) or **4** (0.53 g, 1.19 mmol) in water, respectively. They were recrystallized from water-acetone and were unstable in 1.8 mol dm^{-3} and 3.6 mol dm^{-3} D_2SO_4 solution. Yields: 0.22 g (42.3%) for **7**, 0.25 g (46.3%) for **8**. Color: grayish russet for **7** and **8**. Found **7**: C, 35.87; H, 5.72; N, 16.27%. Calcd for $CoC_{13}H_{24}N_5O_6S$ (MW 437.37) C, 35.70; H, 5.53; N, 16.01%. Found **8**: C, 34.49; H, 6.02; N, 15.32%. Calcd for $CoC_{13}H_{26}N_5O_7S$ (MW 455.38) C, 34.29; H, 5.76; N, 15.38%. Mp: 230 °C for **7**, 227 °C for **8**. Λ=107 for **7** and 103 S cm^2 mol^{-1} for **8** in water. IR spectra: 999, 1035, 1068, 1088 cm^{-1}, and 3115, 3145, 3210, 3255 cm^{-1} for **7**, 990, 1035, 1065, 1077 cm^{-1}, and 3105, 3160, 3190, 3240 cm^{-1} for **8**. Absorption spectra: 294 nm (ε=12000),415 sh, 533 (250), and 580 (235) for **7**, 295 nm (ε=12500) and 570 (315) for **8** in water.

Results and Discussion

***cis*-β_1 and β_2-Thiosalicylato(quadridentate amine)-cobalt(III) Chloride Hydrates:** Abbreviations of the thiosalicylato(quadridentate amine)cobalt(III) complexes studied in this paper are listed in Table 1. Octahedral thiosalicylato(quadridentate amine)cobalt-(III) complexes exist in three isomeric forms of cis-α, cis-β_1, and cis-β_2, as shown in Fig. 1. A mixture of *cis*-β_1 and β_2-thiosalicylato(quadridentate amine)cobalt-(III) chloride hydrates has been obtained from a reaction mixture of complex **1** or **2**, Ag_2O, thiosalicylic acid and 28% aqueous ammonia. Two geometrical isomers (cis-β_1 (**3** and **5**) and cis-β_2 (**4** and **6**)) of their complexes were separated by Dowex 50W-X2 column chromatography. The *cis*-β_1 and β_2-thiosalicylato(trien)-cobalt(III) nitrate hydrate (**7** and **8**) have been prepared from the reaction mixture of silver nitrate and the

corresponding chloride complexes (**3** and **4**). Complex **3** is soluble in water, and complexes **4**—**6** are very soluble in water. Complexes **3**—**6** are very soluble in methanol and DMSO, and soluble in ethanol but insoluble in the other common organic solvents, such as acetone and ether. The isomerization between **3** and **4** or **5** and **6** was reversible in water at 40 °C. Complexes **3** and **4** were diamagnetic, indicated by the magnetic susceptibility. The electric conductivities for **3**—**6** in aqueous solutions were 103—130 S cm^2 mol^{-1}.

The absorption spectra of **3**—**6** were measured in water, as shown in Fig. 2. The absorption bands at around 300 nm of **3**—**6** were assigned to the charge transfer band for the S–Co(III) bond.[21–23] The absorption bands at the 570—590 nm region for **4** and **6** are assigned to the first absorption band,[23] and those at 530—560 and 580—600 nm regions for **3** and **5** can be assigned to the split first absorption band.[24–26]

The ^{1}H NMR spectra of **3**—**6** were measured in 1.8 mol dm^{-3} D_2SO_4, as shown in Fig. 3. The signals at δ 2.1—3.8 and 3.6—6.8 of **3**—**6** were assigned to the methylene protons and amine protons of the coordinated quadridentate amine ligand respectively, and the lowest field signals at δ 7.0—8.1 were assigned to the coordinated thiosalicylato protons.[13] The signals of

the center, NH_2- side, and NH- side methylene protons and of the primary and secondary amine protons of **3**—**6** have been assigned by comparisons with those of *cis*-β_1- and β_2-salicylato(quadridentate amine)cobalt(III) chloride hydrate, *cis*-β_1, β_2-[Co(sal)L]Cl·nH_2O (L: trien (β_1:**9**, β_2:**10**); 3,2,3-tet (β_2:**11**)),[2,3] and collected in Table 2. The signals of the primary and secondary amine protons of **3** and **4** disappeared in heavy water.

The ^{13}C NMR spectra of **3**—**6** were measured in D_2O, as shown in Fig. 4 and Table 2. There have been observed 6—8 signals for the quadridentate amine ligands and 5—7 signals for the thiosalicylato ligand. The chemical shifts of the coordinated thiosalicylato ligand in **3**—**6** and of thiosalicylic acid have been assigned by comparisons with those of the coordinated salicylato ligand in **9**—**11**[2,3] and salicylic acid,[17] respectively. On the other hand, the chemical shifts of the coordinated quadridentate amine ligands are difficult to assign to the individual carbon atoms; however, regions of the chemical shifts of the center, NH_2- side, and NH- side methylene carbons are around δ 21—28, 37—48, and 49—57, respectively, and their regions are close to those of **9**—**11**,[2,3] as shown in Table 2.

A distinction between **3** and **4** or **5** and **6** was found in the IR, NMR, and absorption spectra. The IR spectra of **3**—**6** showed four absorption bands in the NH stretching region (3000—3300 cm^{-1}) and four or five absorption bands in the NH_2 twisting region (990—1100 cm^{-1}), as shown in Experimental section. The ^{13}C NMR spectra of **3**—**6** showed 6—8 signals for the quadridentate amine ligands. They indicate that these complexes assume the cis-β-form.[2,27] In the ^1H NMR spectra, the methylene proton signals for the trien ligand in **4** can be divided into two groups of the NH_2- side methylene protons at δ 2.1—2.7 and NH- side methylene protons at δ 2.7—3.5 regions, as shown in Fig. 3. However, those of **3** could not be divided into two groups. One proton in the NH_2- side methylene protons for **4** overlapps to the NH- side methylene protons, since the intensity ratio of both methylene proton signals is 3:9. Also, the chemical shift (δ 3.45—4.0) of the proton signal of the N(1)H_2 group of **4** is at a higher field than that (δ 4.28) of **3**, i.e., the N(1)H_2 group of **4** is considered to be at a position trans[2] to the carboxyl oxygen of the coordinated thiosalicylato ligand, which is more electronegative than the thiolato sulfur. In addition, the spectrum of **4** showed five peaks with an intensity ratio of 2:1:1:1:1 for the amine protons, while that of **3** showed five peaks with an intensity ratio of 1:1:2:1:1, as shown in Fig. 2 and Table 2. These properties of **4** and **3** are similar to those of **10** and **9**,[2] respectively, as shown in Table 2. Thus, complexes **4** and **3** have been assigned to the cis-β_2 and β_1-isomers, respectively. On the other hand, complexes **5** and **6** could not be assigned from the ^1H NMR spectra, but they can be assigned from results of the absorption spectra. For instance, complexes **3**—**6** give the first absorption band at nearly the same position, but the first absorption band of **5** differs remarkably from that of **6**, and the absorption bands of **5** and **6** are very close to those of **3** and **4**, respectively, as shown in Fig. 2. Also, the elution order of **5** and **6** is similar to that of **3** and **4**, respectively. Then, complexes **5** and **6** are assigned to the cis-β_1 and β_2-isomers, respectively.

Buckingham and Sargeson have been concerned with the ^1H NMR, absorption spectra, and X-ray diffraction of the diastereoisomers of *cis*-β_1 and β_2-glycinato(trien)cobalt(III) complexes,[28,29] *cis*-β_1, β_2-[Co(gly)trien]$^{2+}$ ions, (β_1-*RR,SS*: **12a**, β_1-*RS,SR*: **12b**; β_2-*RR,SS*: **13a**, β_2-*RS,SR*: **13b**). The difference ($\Delta\delta$:0.5) of the chemical shifts for the N(1)H_2 protons in the ^1H NMR spectra of β_1 (**12**) and β_2 (**13**) is bigger than that ($\Delta\delta$:0) of **12a** and **12b** or of **13a** and **13b**. The first absorption bands of **12a** and **13a** are close to those of **12b** and **13b**, respectively. If the same relation holds in **3** and **4**, the difference ($\Delta\delta$:0.7) of the chemical shift for the N(1)H_2 protons of **3** and **4** is close to that of cis-β_1 (**12**) and β_2 (**13**). The first absorption band of **3** differs remarkably from that of **4**, i.e., complexes **3** and **4** could not be assigned to the diastereoisomers, and have been assigned to the cis-β_1 and β_2-isomers, respectively. Next, the differences of the chemical shifts of the both N(2)H and N(3)H protons of **12a** and **12b** which are in positions trans of O atom and N atom

Solvent and standard: ^{1}H NMR: 1) 1.8 mol dm^{-3} D_2SO_4, 2) 3.6 mol dm^{-3} D_2SO_4, 3) D_2O, internal DSS (δ=0); ^{13}C NMR: **3**—**6**, **9**—**11**: D_2O, internal dioxane (δ=67.4): L′: thiosalicylic acid, L″: salicylic acid: MeOH-d_4 (δ=49.8). a) This signal overlapped with each solvent. b) Very week shoulder. c) Ref. 2. d) Ref. 3. e) This spectrum has small spectrum of **5**, because of isomerism in the measurement. f) Ref. 17.

are 0.8 and 0 ppm, respectively, while those of **13a** and **13b** which are in positions trans of N atom and N atom are 0.15 and 0.25 ppm, respectively. In the case of **3** and **4**, the differences of the chemical shifts of both the NH protons of **3** and **4** which are in positions trans S atom and N atom are 0.8 and 1.0 ppm, respectively. They are very close to that of **12a**. Thus, complexes **3** and **4** are tentatively assigned to the *cis*-β_1-*RR,SS*- and *cis*-β_2-*RR,SS*-[Co(thiosal)trien]Cl·nH$_2$O, respectively.

In the complexes **3—6**, the melting point and solubility of **3** and **4** are almost similar to those of **5** and **6**. However, the color of the solid state, formation ratio, and first absorption band of **3** and **4** are different from those of **5** and **6**, i.e., the formation ratio of **3** and **4** is ca. 4:3 at 50 °C but that of **5** and **6** is ca. 16:1 at 50 °C. The ε of the first absorption band of **3** and **4** is larger than that of **5** and **6**, respectively and their first absorption band shifts from 530—580 nm to 550—600 nm. These results are similar to those of **9—11**, and the related complexes, *cis*-β_1, β_2-[Co(sal)L]Cl·nH$_2$O (L: 2,3,2-tet (β_1: **14**, β_2: **15**), 3,3,3-tet (β_2:**16**)), i.e., it is attributable to the center methylenes of the quadridentate ligands.[3]

***cis*-β_1 and β_2-Thiosalicylato(trien)cobalt(III) Complexes (3 and 4) and *cis*-β_1 and β_2-Salicylato(trien)-cobalt(III) Complexes (9 and 10):** The color of the solid state, solubilities in alcohols, formation ratio, isomerization, absorption and ^{13}C NMR spectra, and reaction in 60% nitric acid for **3** and **4** are different from those for **9** and **10**.[2] The color of **3** and **4** is dark russet and violet russet, respectively, but that of **9** and **10** is russet. The formation ratios of **3** and **4** are ca. 3:7 at 40 °C, ca. 4:3 at 50 °C and ca. 4:1 at 60 °C, i.e., the yield for **3** increases with a rise in reaction temperature. The formation ratio of **9** and **10** is ca. 1:20 at 50 °C. The isomerization between **3** and **4** is reversible in water at 40 °C, but isomerization between **9** and **10** is irreversible in water, i.e., complex **10** does not isomerize to **9** at 40 °C after for 24 h. The first absorption band of **3** showed at 533 and 580 nm, but that of **9** showed at 530 nm. The chemical shift (δ ca. 143) of C-2 carbon of the coordinated thiosalicylato ligand in **3** and **4** differs remarkably from that (δ ca. 168) of **9** and **10**. It can be affected by the electronic effect of the S atom of the coordinated thiosalicylato ligand. The paramagnetic 5-nitrothiosalicylato(trien)-cobalt(III) complexes could not be prepared from a reaction mixture of **3** or **4** and 60% nitric acid, while the paramagnetic *cis*-β_1 and β_2-5-nitrosalicylato(trien)-cobalt(III) complexes, *cis*-β_1,β_2-[Co(5-NO$_2$sal)trien]Cl·NO$_3$·2H$_2$O, were obtained from the reaction mixture of **9** or **10** and 60% nitric acid, reported previously.[18] These properties can be attributed to differences of the electronic effect and atomic radius of S and O atoms, and of the stability between the Co–S and Co–O bonds of coordinated ligands.

Some properties for complexes **3—6** and **9—11** are listed in Table 2 and Experimental section.

Photochemical Generation of Sn(III) in Hydrochloric Acid Solutions

Nobuyoshi SHINOHARA* and Makoto INOUE
Department of Chemistry, Yokohama City University, Seto, Kanazawa-ku, Yokohama 236
(Received June 7, 1988)

In the flash photolysis of Sn(II) in a deaerated hydrochloric acid solution, Sn(III) was produced. Sn(III) has an absorption maximum at 280 nm in a 1 mol dm^{-3} hydrochloric acid solution. In the flash photolysis of a deaerated Sn(IV) solution, intermediates of Sn(III) and Cl_2^- were produced. Transient absorption spectra of intermediates generated by the flashed Sn(IV) solutions were measured under various concentrations of dissolved oxygen. Since Sn(III) reacts with oxygen very rapidly, only Cl_2^- was confirmed in the oxygen-saturated Sn(IV) solution. In the flash photolysis of Sn(IV) solutions containing Sn(II), the yield of Sn(III) increased with an increase of the added Sn(II), due to the generation of Sn(III) by the reaction of Cl_2^- with Sn(II). It was found that only Sn(III) was produced in the irradiation of 5.0×10^{-4} mol dm^{-3} Sn(IV) solution containing Sn(II) at concentrations of more than ca. 7×10^{-5} mol dm^{-3}. The reaction rate constant for the reaction of Sn(II) with Cl_2^- was estimated to be 8.9×10^8 mol^{-1} dm^3 s^{-1}. The mechanisms for the photochemical generation of Sn(III) are discussed.

Flash photolysis and pulse radiolysis have proved to be very useful in the generation and characterization of metal ions in unusual valency states. The species formed include the metal ions known to be formed as intermediates in thermal reactions. However, they are poorly characterized beause of their instability and difficulty to form novel valency states in other ways. Though the chemical properties and behavior of these species have been investigated, much still remains to be studied.[1,2]

The stable oxidation states of non-transition elements usually differ by two units in their mononuclear compounds. Most oxidation-reduction reactions of such elements involve either a two-equivalent change with the direct formation of a stable oxidation state or successive one-equivalent steps. In the latter case, an unstable intermediate oxidation state of non-transition metal is produced, which may show some of the characteristics of a free radical. In Sn(II)-Sn(IV) redox chemistry, unstable Sn(III) is assumed to be an intermediate.[3-6] Only a few studies of the intermediate oxidation state, Sn(III), have been carried out briefly regarding radiation chemistry.[7-9] In a previous paper, we reported on the photochemical generation of Sn(III) from tin ions in deaerated aqueous hydrochloric acid solutions.[10] In the present paper we give more details regarding Sn(III) generated upon the irradiation of tin ions in hydrochloric acid solutions.

Experimental

Sn(II) solutions used for flash photolysis were obtained by adding $SnCl_2$ to a deaerated solution of hydrochloric acid. The deaerations were carried out by bubbling with oxygen-free nitrogen obtained through a tube containing heated cupper metal pieces. All preparations of Sn(II) solutions should be carried out with adequate safety precautions. Mixed gases were prepared by mixing pure oxygen and nitrogen. The oxygen content in the mixture was determined gas chromatographically. Sn(IV) solutions containing dissolved oxygen at the desired concentration were obtained by bubbling with the mixed gas. Sn(IV) solutions were prepared by the oxidation of Sn(II) with oxygen. All of the chemicals were of chemically pure grade. Pure water obtained from a Millipore Super-Q system was used for the preparation of samples. A flash photolysis apparatus was the same as that used previously.[10] The main flash lamps dissipated 450 J max. at 15 kV with a flash duration of 10 μs. Solutions for flash photolysis were taken in a quartz cell with a 10-cm path length. Transient absorption changes were recorded on a Textronix 7633 oscilloscope.

Results and Discussion

Photolysis of Sn(II) Solutions. In our previous paper we reported on the absorption spectrum of Sn(III) obtained by using a flash photolysis technique.[10] The spectrum is shown in Fig. 1 together with the absorption spectra of Sn(II) and Sn(IV), measured in a 1 mol dm^{-3} hydrochloric acid solution.

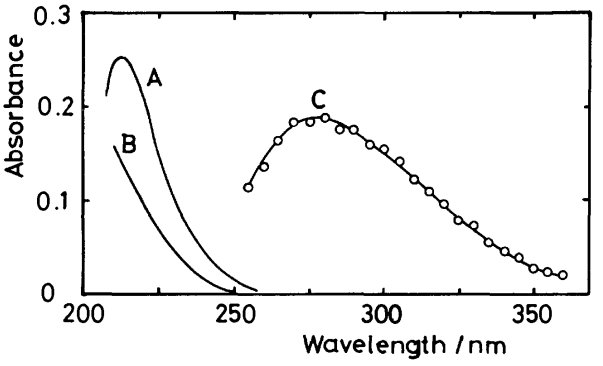

Fig. 1. Absorption spectra of Sn(II), Sn(III), and Sn(IV) in 1 mol dm^{-3} hydrochloric acid solutions. A: 1.0×10^{-5} mol dm^{-3} Sn(II), B: 4.0×10^{-5} mol dm^{-3} Sn(IV), C: Sn(III) obtained in the flash photolysis of 1.0×10^{-4} mol dm^{-3} Sn(II) in the deaerated solution.

Under our experimental conditions, these tin ions exist in chloro complex forms.[11-13] The Sn(II) hydrochloric acid solution, subjected to a flash, showed a transient absorption maximum at 280 nm, which was attributed to the generation of Sn(III), as shown in Reaction (1).

$$Sn(II) + H^+ \xrightarrow{h\nu} Sn(III) + H \quad (1)$$

The resulting H atoms produced H_2 by Reaction (2). However, since Sn(II) can be oxidized by oxygen very easily, the Sn(II) solution usually contains a small amount of Sn(IV) as an impurity. Therefore, some of H atoms react with Sn(IV) very rapidly, according to Reaction (3).[14]

$$H + H \rightarrow H_2 \quad (2)$$
$$Sn(IV) + H \rightarrow Sn(III) + H^+ \quad (3)$$

Photolysis of Sn(IV) solutions. Typical oscillograms obtained by flashing oxygenated Sn(IV) solutions are given in Fig. 2. When the Sn(IV) solution containing a small amount of dissolved oxygen was flashed, there was a fast decay after a rapid increase (within the flash) in absorbance (oscillogram A in Fig. 2). However, the fast decay step could not be observed in the flash photolysis of the oxygen-saturated Sn(IV) solution ($[O_2]=1.38\times10^{-3}$ mol dm^{-3}) (oscillogram B in Fig. 2). Oxygen has a large effect upon the reaction course. Then, flash photolysis was carried out in Sn(IV) solutions under various concentrations of dissolved oxygen, and the obtained absorption spectra are given in Fig. 3. The transient absorption spectrum obtained in the deaerated Sn(IV) solution shows a discernible shoulder at the shorter-wavelength side of the main absorption band at 340 nm. The absorbance near 280 nm decreased with increasing the concentration of dissolved oxygen. The absorption spectrum in an aerated solution is close to that in an oxygen-saturated solution. This fact shows that the amount of oxygen in an aerated solution is sufficient to scavenge the Sn(III) formed by photolysis. The spectrum obtained in the oxygen-saturated solution has an absorption maximum at 340 nm which is attributed to Cl_2^-.[15-18] The difference between the spectrum obtained in the oxygen-free solution and the spectrum obtained in the oxygen-saturated solution (Fig. 3) is similar to the spectrum of Sn(III) in Fig. 1. This suggests that Sn(III) are produced in a flashed Sn(IV) solution. Thus, the reactions in the flashed Sn(IV) solution can be explained by Eqs. 4 and 5, where Sn(IV)-Cl denotes chloro complexes.

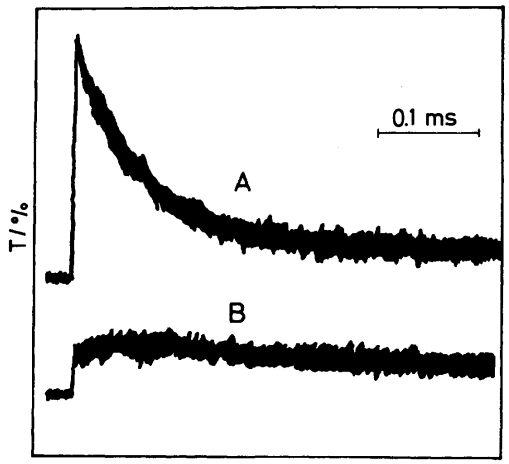

Fig. 2. Oscilloscope traces showing changes in absorption measured at 280 nm after the flash of 5.0×10^{-4} mol dm^{-3} Sn(IV) in 1 mol dm^{-3} hydrochloric acid solutions in the presence of dissolved oxygen.
Concentrations of dissolved oxgen A: 8.83×10^{-5} mol dm^{-3}, B: 1.38×10^{-3} mol dm^{-3}.

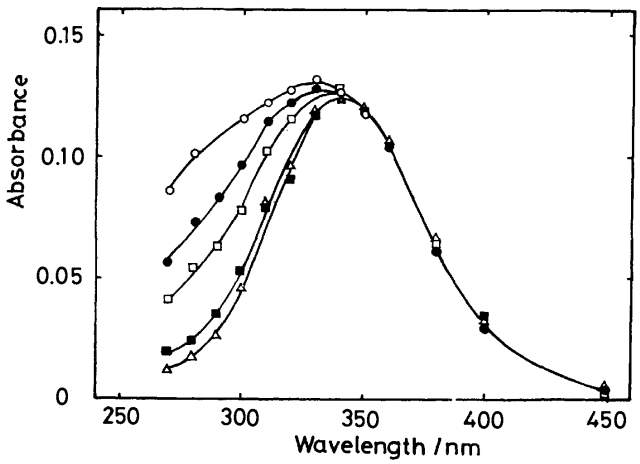

Fig. 3. Transient absorption spectra obtained in the flash photolysis of Sn((IV) solutions in the presence of various concentration of oxygen at 30 μs after the flash.
Concentrations of oxygen; ○: 0, ●: 8.83×10^{-5}, □: 1.60×10^{-4}, ■: 2.84×10^{-4} (aerated), △ 1.38×10^{-3} mol dm^{-3} (oxygen-saturated).

$$Sn(IV)\text{-}Cl \xrightarrow{h\nu} Sn(III) + Cl \quad (4)$$
$$Cl + Cl^- \longrightarrow Cl_2^- \quad (5)$$

The resulting Cl_2^- disappears by Reaction (6), where the rate constant was estimated to be $2k_6=9.7\times10^9$ mol^{-1} dm^3 s^{-1}, as shown in our previous paper.[10]

$$Cl_2^- + Cl_2^- \rightarrow Cl_3^- + Cl^- \quad (6)$$

Sn(III) reacts very rapidly with oxygen; the rate constant k_7 was obtained to be 1.7×10^8 mol dm^3 s^{-1}.

$$Sn(III) + O_2 + H^+ \rightarrow Sn(IV) + HO_2 \quad (7)$$

Photolysis of Sn(IV) Solutions Containing Sn(II). The effect of Sn(II) on the generation of Sn(III) in

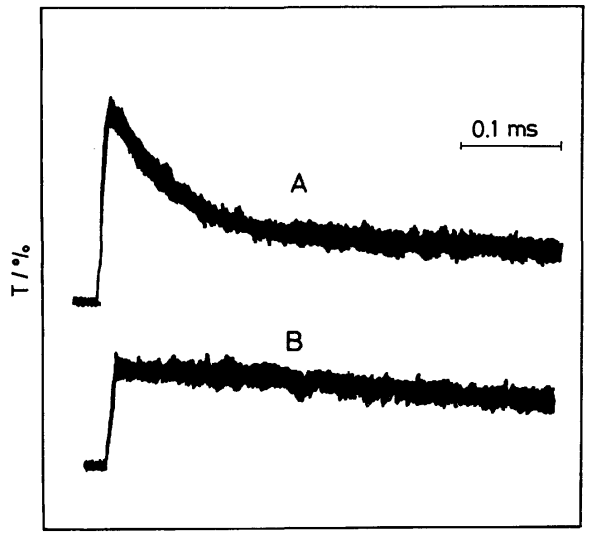

Fig. 4. Oscilloscope traces showing changes in absortion measurd at 350 nm after the flash of 5.0×10^{-4} mol dm^{-3} Sn(IV) containing Sn(II) in the deaerated 1 mol dm^{-3} hydrochloric acid solutions. Concentration of Sn(II); A: 1.7×10^{-5} mol dm^{-3}, B: 8.9×10^{-5} mol dm^{-3}.

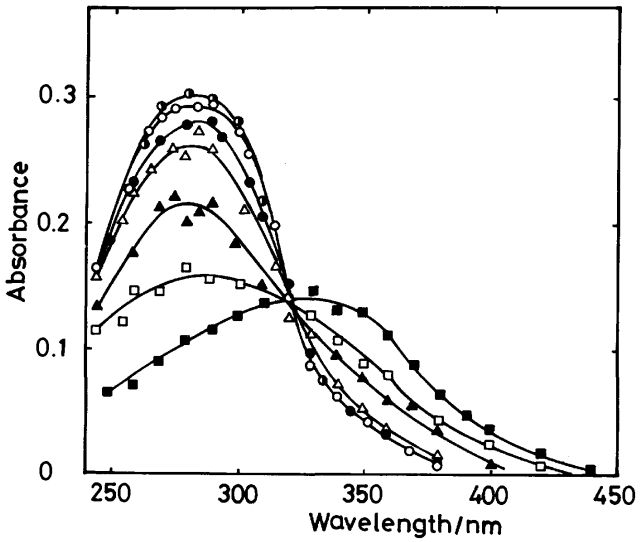

Fig. 5. Transient absorption spectra obtained in the flash photolysis of 5.0×10^{-4} mol dm^{-3} Sn(IV) solutions with various concentration of Sn(II) in deaerated 1 mol dm^{-3} hydrochloric acid solutions. Absorbance were measured 30 μs after the flash. Concentrations of Sn(II); ■: 0, □: 1.7×10^{-5}, ▲: 3.0×10^{-5}, △: 5.0×10^{-5}, ●: 6.9×10^{-5}, ○: 8.9×10^{-5}, ◑: 1.3×10^{-4} mol dm^{-3}.

flash photolysis of a deaerated Sn(IV) solution was studied. Figure 4 shows typical oscillograms obtained in the flash photolysis of Sn(IV) solutions containing Sn(II). Oscillogram A had a fast decay species which did not appear in oscillogram B, measured in a solution containing Sn(II) at a higher concentration. The fast decay is attributed to the reaction of Cl_2^- with

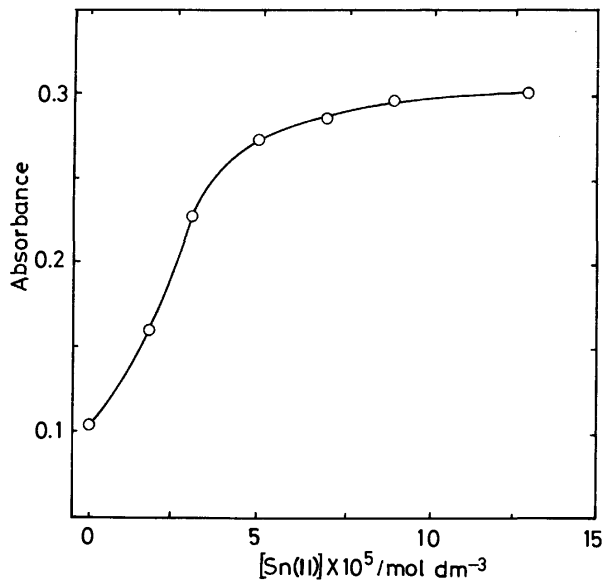

Fig. 6. The dependence of the yields of Sn(III) as a function of the Sn(II) concentration in the deaerated 1 mol dm^{-3} hydrochloric acid solution. The yields are expressed as the absorbances measured at 280 nm 30 μs after the flash. The concentration of Sn(IV) was kept at constant, 5.0×10^{-4} mol dm^{-3}.

Sn(II). The transient absorption spectra obtained in the flash photolysis of Sn(IV) with Sn(II) at various concentrations are shown in Fig. 5. An increase in Sn(II) caused a decrease in the absorbance at 340 nm, followed by an increase in the absorbance at 280 nm. The dependence of the yields of Sn(III) is shown as a function of the Sn(II) concentration in Fig. 6. The yield increases rapidly with an increase in the concentration of the Sn(II), but gradually at higher Sn(II) concentration (> ca. 7×10^{-5} mol dm^{-3}). A pronounced effect on the transient absorption spectrum is caused by the presence of the added Sn(II).

The obtained results can be explained in terms of the following reaction sequence:

$$Sn(II) + H^+ \xrightarrow{h\nu} Sn(III) + H \quad (1)$$

$$Sn(IV) + H \rightarrow Sn(III) + H^+ \quad (3)$$

$$Sn(IV)\text{-}Cl \xrightarrow{h\nu} Sn(III) + Cl \quad (4)$$

$$Cl + Cl^- \rightarrow Cl_2^- \quad (5)$$

$$Sn(II) + Cl_2^- \rightarrow Sn(III) + 2Cl^- \quad (8)$$

An H atom can react rapidly with Sn(IV) to give Sn(III), as already described. The reaction is completed very fast within the flash. The lack of an absorption maximum at 340 nm in the flashed Sn(IV) solution containing Sn(II) at a higher concentration (Fig. 5) can be attributed to the reaction of Cl_2^- with the added Sn(II) (Eq. 8). The rate constant k_8 was estimated to be 8.9×10^8 mol^{-1} dm^3 s^{-1} from a kinetic plot of the curve A in Fig. 4. The Sn(III) yield increases rapidly with increasing Sn(II) concentration,

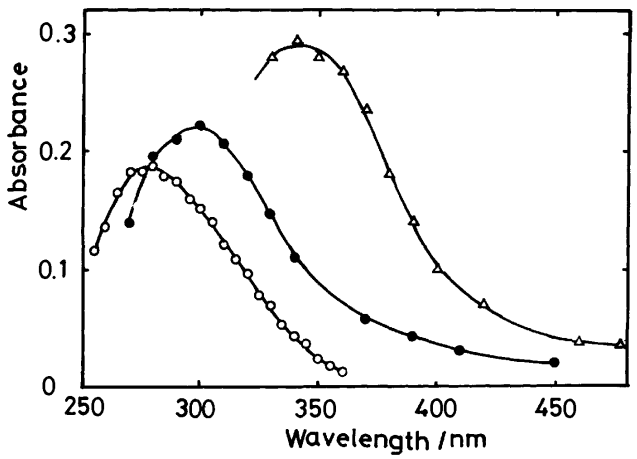

Fig. 7. Transient absorption spectra of Sn(III) obtained in the flash photolysis of 1.0×10^{-4} mol dm^{-3} Sn(II) in 1 mol dm^{-3} acidic solutions.
O: Hydrochloric acid, ●: hydrobromic acid, △: hydroiodic acid.

as shown in Fig. 6. The rapid increase is attributed to the Sn(III) formed by Reactions (1) and (8). Since the Sn(IV) concentration is held constant at 5.0×10^{-4}mol dm^{-3}, the Cl_2^- yield from Reactions (4) and (5) is kept constant. Therefore, the Sn(III) yield from Reaction (8) is also kept constant in the high Sn(II) concentration region (> ca. 7×10^{-5} mol dm^{-3}), in which all the Cl_2^- react with Sn(II). For this reason, a slight increase in the Sn(III) yield in such a concentration region is attributed to the only contribution arising from Reaction (1). Thus, the Sn(III) species can be produced efficiently in the photolysis of an Sn(II)–Sn(IV) mixture.

The transient absorption spectra obtained in the flash photolysis of Sn(II) in hydrobromic and hydroiodic acid solutions are shown in Fig. 7. The spectrum of Sn(III) obtained in a hydrochloric acid solution is also shown for comparison. The spectrum might be attributed to bromo and iodo complex formations of Sn(III), which have the absorption maxima at 300 and 340 nm, respectively.

Photochemical Reactions of the Oxoperoxovanadium(V) Complex in an Acidic Aqueous Solution

Nobuyoshi SHINOHARA* and Yayoi NAKAMURA
Department of Chemistry, Yokohama City University, Seto, Kanazawa-ku, Yokohama 236
(Received July 5, 1988)

The photochemical decomposition of oxoperoxovanadium(V), $VO(O_2)^+$, was studied in perchloric acid media. It was found that the irradiation of $VO(O_2)^+$ solutions with 313, 365, and 436 nm exciting light resulted in the photoreduction of the complex, and gave VO^{2+}, with an evolution of oxygen. The overall reaction is: $4VO(O_2)^+ + 4H^+ \longrightarrow 4VO^{2+} + 3O_2 + 2H_2O$. The photochemical reaction mechanism is also discussed.

A large number of papers have been published on various aspects of the solution chemistry of peroxovanadium(V) complexes. There have been a large number of interesting kinetic studies of the formation,[1-8] decomposition,[9,10] and substrate reactions[11-15] of peroxo vanadium complexes. Further, vanadium compounds have been used as catalysts for the oxidation of olefins by H_2O_2 or ROOH.[16,17] The mechanisms of the redox reactions of peroxo vanadium compounds are generally complicated and cannot be interpreted by simple redox reactions between $VO(O_2)^+$, VO_2^+, VO^{2+}, and H_2O_2. Short-lived transients must often be assumed, particularly radical species arising from the reduction or oxidation of H_2O_2.

Information about the photochemical reactions of vanadium compounds is relatively scanty. The present study of the photolysis of the oxoperoxovanadium(V) complex in an acidic aqueous solution is an attempt to elucidate the mechanism of the photochemical reaction of the peroxo complex.

Experimental

All the chemicals used were of an analytical grade. Pure water obtained from a Millipore Super-Q system was used for the preparation of the samples. Sodium metavanadate (Soekawa Chemicals, >99% in purity) was used as the source of VO_2^+. Solutions of $VO(O_2)^+$ were prepared by adding the required amount of a standardized solution of hydrogen peroxide to a VO_2^+ solution. The equilibrium ($VO_2^+ + H_2O_2 \rightleftarrows VO(O_2)^+ + H_2O$) was thoroughly investigated.[1,9,12] The rate of the decomposition of $VO(O_2)^+$ is sufficiently slow so that photochemical reactions can be studied. The changes in the concentrations of $VO(O_2)^+$ and VO^{2+} were followed by means of absorption spectrophotometry using a Shimadzu MPS-2000 spectrophotometer. The $VO(O_2)^+$ solution was irradiated with a high- or ultrahigh-pressure mercury lamp. The monochromatic light (313, 365, and 436 nm) was obtained by the combination of solution and glass filters. The incident-light intensities were measured by the use of the tris(oxalato)ferrate(III) ion as the actinometer.[18] The oxygen evolution was measured polarographically with a Clarke-type electrode attached to a Yellow Springs Instruments Oxygen Monitor. A cell equipped with the oxygen electrode was used as the reaction vessel. The cell was thermostated at 25±0.1 °C. The reactant solution was deaerated in the reaction vessel with pure nitrogen gas in order to keep the evolved oxygen in solution as completely as possible. The oxygen dissolved initially had no influence on the photochemical reactions of $VO(O_2)^+$.

Results

Figure 1 shows the absorption spectra of oxoperoxovanadium(V), bisoxovanadium(V), and oxovanadium(IV) in 1 mol dm^{-3} perchloric acid solutions: These substances exist as $VO(O_2)^+$, VO_2^+, and VO^{2+} respectively. The absorption maxima of these vanadium compounds are as follows: $VO(O_2)^+$: absorption maxima at 285 nm (ε=486 mol^{-1} dm^3 cm^{-1}) and 456 nm (ε=281 mol^{-1} dm^3 cm^{-1}); VO_2^+: two shoulders at 260 and 330 nm; VO^{2+}: two shoulders at 240 and 640 nm and absorption maximum at 764 nm (ε=17.4 mol^{-1} dm^3 cm^{-1}).

The acidic solutions of $VO(O_2)^+$ underwent the spectral changes upon irradiation (Fig. 2). The absorbance at 456 nm decreased with an increase in the irradiation time, and a new absorption appeared at 764 nm, with an isosbestic point at about 660 nm which was due to the formation of VO^{2+}. In Fig. 3, the amounts of the decomposed $VO(O_2)^+$ and of the generated VO^{2+} upon irradiation with 366 nm light are plotted against the irradiation time. The changes in the concentration of $VO(O_2)^+$ and VO^{2+} were measured spectrophotometrically at 456 and 764 nm respectively. The amount of VO^{2+} generated increased

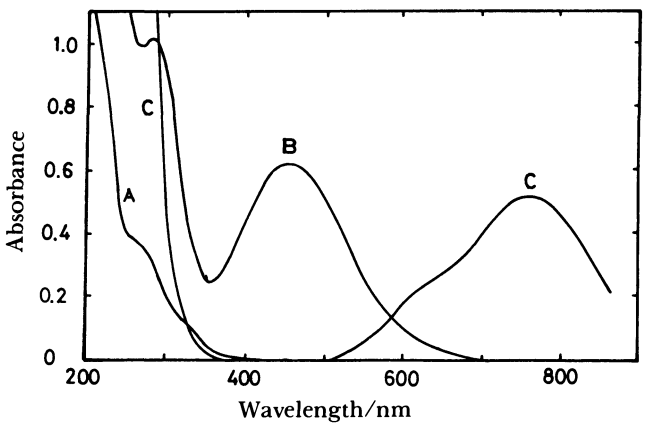

Fig. 1. Absorption spectra of VO_2^+, $VO(O_2)^+$, and VO^{2+} in 1 mol dm^{-3} perchloric acid solutions: A: 4.50×10^{-4} mol dm^{-3} VO_2^+, B: 2.20×10^{-3} mol dm^{-3} $VO(O_2)^+$, C: 3.00×10^{-2} mol dm^{-3} VO^{2+}.

Table 1. Yields of Decomposed $VO(O_2)^+$ and Produced VO^{2+} and Oxygen[a]

	$-[VO(O_2)^+]$[b]	$[VO^{2+}]$	$[O_2]$
	10^4/mol dm^{-3}	10^4/mol dm^{-3}	10^4/mol dm^{-3}
$VO(O_2)^+$[c]	2.20	2.07	1.41
$VO(O_2)^+$[c] + 2-PrOH[d]	2.12	2.10	0.93

a) Irradiation time: 20 min, wavelength for irradiation: 366 nm. $-[VO(O_2)^+]$ and $[VO^{2+}]$ were obtained with the same irradiated solutions as were used for the determination of the evolved oxygen. A 5-cm cell was used for the spectrometrical determination of VO^{2+}, the extinction coefficient of which was small. b) Determined for the disappearance of $[VO(O_2)]^+$. c) $[VO(O_2)^+]=1.8\times10^{-3}$ mol dm^{-3}. d) [2-PrOH]=0.25 mol dm^{-3}.

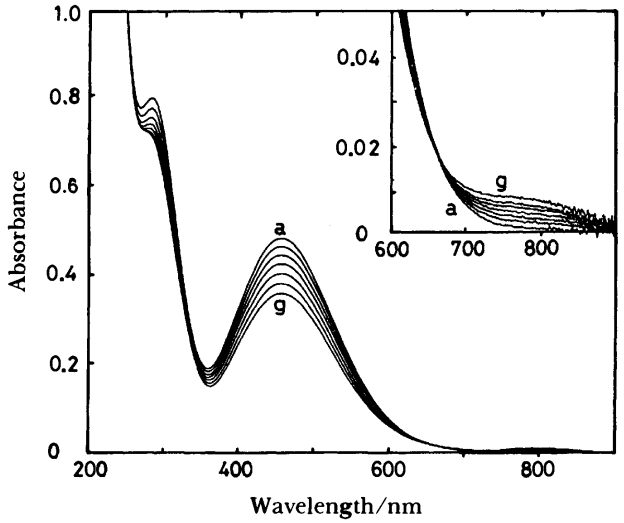

Fig. 2. Absorption spectra changes induced by 366 nm photolysis of $VO(O_2)^+$: Photolysis times for curves a—g respectively are 0, 10, 20, 30, 40, 50, and 60 min. The insert shows the enlarged spectra.

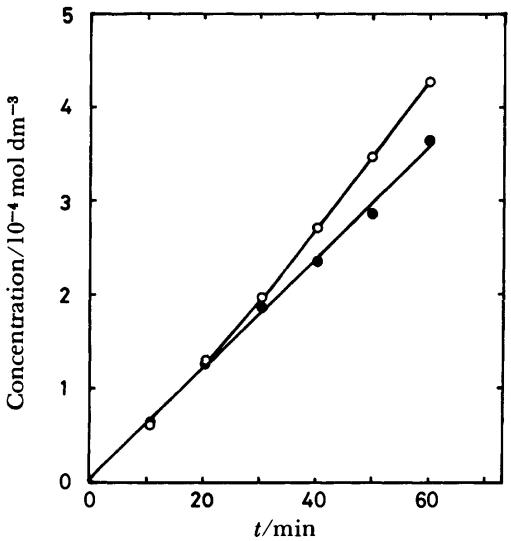

Fig. 3. Decomposition of $VO(O_2)^+$ (○) and generation of VO^{2+} (●) as a function of time upon 366 nm irradiation of 1.8×10^{-3} mol dm^{-3} $VO(O_2)^+$ in 1 mol dm^{-3} perchloric acid solution.

linearly with the increase in the irradiation time. The amount of $VO(O_2)^+$ decomposed was initially equal to that of the generated VO^{2+}. However, the former

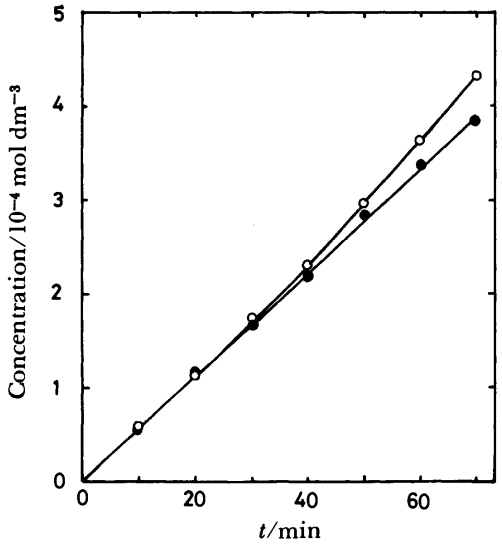

Fig. 4. Decomposed $VO(O_2)^+$ (○) and generated VO^{2+} (●) as a function of time upon 366 nm irradiation of 1.8×10^{-3} mol dm^{-3} containing 0.25 mol dm^{-3} 2-propanol in perchloric acid solution.

became larger than the latter with the increase in the irradiation time. The decomposition of $VO(O_2)^+$ was accompanied by the evolution of oxygen. The photolysis of $VO(O_2)^+$ gave 4 mol of VO^{2+} and 3 mol of O_2 per 4 mol of the complex decomposed at the initial stage. The quantum yields for the decomposition of the complex at 313, 366, and 436 nm were 0.010, 0.0038, and 0.0015 respectively.

$VO(O_2)^+$ solutions containing 2-propanol were irradiated in a 1 mol dm^{-3} percloric acid solution. The amount of $VO(O_2)^+$ decomposed by irradiation with a 366 nm light is plotted against the irradiation time in Fig. 4. The quantity of VO^{2+} resulting increased linearly with the irradiation period. The yields of VO^{2+} were the same in both the presence and absence of 2-propanol, within the limits of experimental error. The photolysis of $VO(O_2)^+$ in the presence of 2-propanol gave 2 mol of VO^{2+} and 1 mol of O_2 per 2 mol of the decomposed $VO(O_2)^+$, as is shown in Table 1.

Discussion

Photolysis of $VO(O_2)^+$. The quantum yields for the photochemical disappearance of $VO(O_2)^+$ in 1 mol dm^{-3} perchloric acid solutions increased with the in-

crease in the energy of the exciting light; this suggests that the photodecomposition occurs into the tail of the ultraviolet band. The irradiation of an acidic solution of $VO(O_2)^+$ gave rise to complicated reactions which eventually led to 4 mol of VO^{2+} for 4 mol of $VO(O_2)^+$ decomposed, with the evolution of 3 mol of oxygen. These results suggest the following overall reaction:

$$4VO(O_2)^+ + 4H^+ \xrightarrow{h\nu} 4VO^{2+} + 3O_2 + 2H_2O \quad (2)$$

We propose the following scheme to explain our results:

$$VO(O_2)^+ \xrightarrow{h\nu} [O=V^{IV}-O-O\cdot^+]^* \quad (3)$$

$$[O=V^{IV}-O-O\cdot^+]^* + H^+ \longrightarrow VO^{2+} + HO_2 \quad (4)$$

$$VO(O_2)^+ + HO_2 + H^+ \longrightarrow VO^{2+} + O_2 + H_2O_2 \quad (5)$$

$$VO^{2+} + H_2O_2 \longrightarrow VO_2^+ + OH + H^+ \quad (6)$$

$$VO(O_2)^+ + OH \longrightarrow VO_2^+ + HO_2 \quad (7)$$

$$VO_2^+ + H_2O_2 \longrightarrow VO(O_2)^+ + H_2O \quad (8)$$

It seems reasonable to conclude that the primary photochemistry responsible for Reaction (2) is electron transfer from O_2^{2-} to V^V (Eq. 3). This conclusion is reached for the following reasons: (1) the products of the photolysis of $VO(O_2)^+$ were VO^{2+} and O_2; the electron transfer from O_2^{2-} to V^V occured later to give VO^{2+} and O_2; (2) vanadium(IV) compounds were obtained in the photolysis of VO_2^+,[19] alkoxy vanadium(V) chelates,[20] and $VO(acac)_2Cl$[21]; (3) vanadium(IV) is the most stable oxidation state of vanadium under ordinary conditions. This intermediate $O=V^{IV}-O-O\cdot^+$ may be presumed to be very unstable. Thus, we assume that the first step is a cleavage of a V-O bond, affording formally the hyperoxovanadium(IV) complex (Eq. 3) in a manner similar to that previously reported in the photolysis of the diperoxo(porphyrinato)molybdenum(VI) complex.[22] The next step will be the departure of HO_2, providing VO^{2+} (Eq. 4). The resulting HO_2 will react with $VO(O_2)^+$ to generate H_2O_2, as is shown in Eq. 5. Rush and Bielki[23] have investigated the kinetics of the reaction of HO_2 with $VO(O_2)^+$ using a pulse radiolysis technique; they showed that HO_2 reduces $VO(O_2)^+$ to VO^{2+} according to Eq. 5 ($k_5=2.8\times10^5$ mol^{-1} dm^3 s^{-1}). The resulting H_2O_2 in Eq. 5 will react with VO^{2+} ($k_6=6.3$ mol^{-1} dm^3 s^{-1} [2]) as well as Fe(II) (Fenton's reagent) to give VO_2^+ and OH radicals. Samuni et al.[2] have reported that the oxidation of VO^{2+} to VO_2^+ by H_2O_2 is accompanied by a generation of $VO(O_2)^+$, even in the absence of an excess of H_2O_2 (Eq. 8). Working at $[H_2O_2]<[VO^{2+}]$ results in the appearance of $VO(O_2)^+$ even before all the VO^{2+} has been oxidized to VO_2^+.[1] That is, Reaction (6) is rapidly followed by Reaction (8) ($k_6=6.3$ mol^{-1} dm^3 s^{-1},[2] $k_8=2.96\times10^4$ mol^{-1} dm^{3}s^{-1} [10]). $VO(O_2)^+$ and VO^{2+} compete for the OH radicals formed by Eq. 6 (Eqs. 7 and 9):

$$VO^{2+} + OH \longrightarrow VO_2^+ + H^+ \quad (9)$$

Since $VO(O_2)^+$ is in excess relative to VO^{2+} under our present experimental conditions, the OH radicals react predominantly through Reaction (7) ($k_7=2.1\times10^{10}$ mol^{-1} dm^3 s^{-1}, $k_9=6.4\times10^8$ mol^{-1} dm^3 s^{-1} [2]). The HO_2 generated by Reaction (7) goes to Reaction (5). Thus, the overall reaction (2) can be explained by assuming Reactions (3)—(8).

As is shown in Fig. 3, the amount of the decomposed $VO(O_2)^+$ was equal to that of the VO^{2+} generated at the initial stage. However, the former became larger than the latter during a prolonged irradiation time. The difference was attributed to the thermal decomposition catalyzed with VO^{2+}. The thermal decomposition was investigated by Gardes-Alberyt et et al.[10]; they found the decomposition products to be VO_2^+ and O_2. At the initial stage, the thermal decomposition can be neglected. The amount of the decrease in the absorption at 285 nm in Fig. 2 became smaller with the increase in the irradiation time; this phenomenon is attributed to the generation of VO_2^+ by the thermal decomposition for the larger extinction coefficient of VO_2^+ ($\varepsilon=697$ mol^{-1} dm^3 cm^{-1}) compared to that of $VO(O_2)^+$ ($\varepsilon=468$ mol^{-1} dm^3 cm^{-1}). However, the amount of VO_2^+ generated at the initial stage is negligibly small.

Effect of 2-Propanol on the Photolysis of $VO(O_2)^+$. The assumption stated above was checked by the addition of an excess of 2-propanol to the reaction mixture. In such a case, OH radicals will react with 2-propanol ($k_{10}=2.0\times10^9$ mol^{-1} dm^3 s^{-1} [26]) to yield 2-propanol radicals, according to:

$$(CH_3)_2CHOH + OH \longrightarrow (CH_3)_2COH + H_2O \quad (10)$$

The 2-propanol radicals react with a number of metal ions and complex ions very rapidly; their rate constants were also measured.[27] The resulting 2-propanol radicals react thus with VO_2^+:

$$(CH_3)_2COH + VO_2^+ + H^+ \longrightarrow VO^{2+} + (CH_3)_2CO + H_2O \quad (11)$$

or

$$(CH_3)_2COH + O_2 \longrightarrow (CH_3)_2C(OH)O_2\cdot \quad (12)$$

$$VO_2^+ + (CH_3)_2C(OH)O_2\cdot + H^+ \longrightarrow VO^{2+} + (CH_3)_2CO + O_2 + H_2O \quad (13)$$

Reaction (11) (or Reactions (12) ($k_{12}=4.5\times10^9$ mol^{-1} dm^3 s^{-1} [28]) and (13)) can be supported by the facts that VO_2^+ was not detected at the initial stage of the photolysis and that ketone (acetone) as an oxidation product was detected in the irradiated solutions.[29] Thus, when Reactions (3)—(6), (10), and (11) (or (12)

and (13) instead of (11)) are assumed as the photochemical reaction mechanism in the presence of 2-propanol, the overall reaction can be written as follows:

$$2VO(O_2)^+ + (CH_3)_2CHOH + 2H^+ \xrightarrow{h\nu} 2VO^{2+} + (CH_3)_2CO + O_2 + 2H_2O \quad (14)$$

The results given in Table 1 can be explained satisfactorily in terms of Reaction (14).

It may be concluded that the photochemical decomposition reactions of $VO(O_2)^+$ in acidic aqueous solution occur according to the scheme presented above.

Preparation of μ-Cyano Dinuclear Chromium(III) Complexes $M^I[F(en \text{ or } tn)_2Cr(NC)Cr(CN)_5]$ from the Doubly Complexed Salts of the Form $M^I[CrF(H_2O)(en \text{ or } tn)_2][Cr(Cn)_6]$

Makoto JOHDA, Masatatsu SUZUKI, and Akira UEHARA*
Department of Chemistry, Faculty of Science, Kanazawa University, Kanazawa 920
(Received July 30, 1988)

Preparation of the μ-cyano dinuclear complexes $M^I[F(en \text{ or } tn)_2Cr(NC)Cr(CN)_5]\cdot nH_2O$ from the double complexes $M^I[CrF(H_2O)(en \text{ or } tn)_2][Cr(CN)_6]\cdot nH_2O$ was carried out both in the solid state and in solution, where M^I is Li^+, Na^+, K^+, or Rb^+ ion; en and tn stand for 1,2-ethanediamine and 1,3-propanediamine, respectively. The desired μ-cyano dinuclear complexes were successfully obtained in solution, but the mixture of di- and trinuclear complexes was formed along with unknown polymeric species in the solid state. The electronic spectra of the dinuclear complexes exhibited a small but clear band due to spin-forbidden transition ($^4A_{2g}\rightarrow{}^2E_g$). Magnetic moments of the dinuclear complexes were 3.4—3.5 μ_B at ambient temperatures and 2.2—2.4 μ_B at 80 K, which are substantially smaller than the spin-only value (3.87 B.M.). The J values for the dinuclear complexes were estimated to be −19—−20 cm^{-1}, indicating that an antiferromagnetic superexchange interaction is exerted between two chromium(III) ions through μ-CN group, but the magnitude of the interaction is smaller than that of the μ-oxo complexes (J=−450 cm^{-1}) and comparable to that of the μ-hydroxo complexes (J=−23 cm^{-1}) reported previously.

Several magnetic studies have declared that a superexchange interaction is exerted in the dinuclear chromium(III) complexes containing μ-hydroxo,[1-10] μ-oxo,[1,11-15] and μ-alkoxo[16,17] groups: e.g., $[(NH_3)_5Cr(OH)Cr(NH_3)_5]Br_5$[5,6] and $[(NH_3)_5Cr(O)Cr(NH_3)_5]Br_4$[11] give the magnetic moments of 3.44 (294.5 K) and 1.29 μ_B (294.7 K) respectively, which are considerably lower magnetic moments than that expected from the spin-only value for the chromium(III) ion. The J values for the μ-hydroxo[5,6] and μ-oxo[11] complexes have been evaluated as −23 and −450 cm^{-1}, respectively. Earnshaw and Lewis[1] have pointed out from magnetic studies on the analogues of the above dinuclear complexes that the degree of metal–metal interaction depends upon the nature of the bridging group and markedly upon the M–L–M′ bond angle: The greater the bonding ability of the bridging groups and the larger the M–L–M′ bond angle is, the stronger the metal–metal interaction becomes (M and M′ are the same or different metal ions, and L is the bridging ligand). From this point of view, the dinuclear chromium(III) complexes containing a single μ-cyano group are another interesting candidates for examining magnetic interaction between two metal ions because Cr(III)–CN–Cr(III) is linear. Unfortunately, although polymeric μ-cyano complexes have been reported,[18,19] any dinuclear chromium(III) complex with a single μ-cyano group has not been known except for $K[F(en)_2Cr(NC)Cr(CN)_5]$ reported by Ribas et al.[20,21] Very recently, we derived the same complex from $K[CrF(H_2O)(en)_2][Cr(CN)_6]$ in solution, and found that our complex exhibits astonishingly different physicochemical properties from that reported previously.[20,21] For example, the magnetic moments of our complex were 3.40 μ_B at 300 K and 2.22 μ_B at 80 K, whereas those of the previous complex were 3.79 μ_B at 293.5 K and 3.51 μ_B at 77 K.[20] Thus, we suspected that the previous complex is not a dinuclear complex, but simply a doubly complexed salt $K[CrF(H_2O)(en)_2][Cr(CN)_6]$.

Therefore, the present paper was undertaken (1) to prepare a series of the dinuclear chromium(III) complexes with a single μ-cyano group $M^I[F(en \text{ or } tn)_2Cr(NC)Cr(CN)_5]$ from the double complexes $M^I[CrF(H_2O)(en \text{ or } tn)_2][Cr(CN)_6]$, where M^I is Li^+, Na^+, K^+, or Rb^+; en and tn stand for 1,2-ethanediamine and 1,3-propanediamine, respectively, and (2) to examine physicochemical properties of the complexes especially from the view point of a superexchange interaction exerted between two chromium(III) ions through a μ-cyano group.

Experimental

Preparation of the Starting Materials for Obtaining Double Complexes. $K_3[Cr(CN)_6]$[22] and *trans*-$[CrF(H_2O)(en)_2](ClO_4)_2$[23a] were prepared by the same methods as those described in the literature.

trans-$[CrF(H_2O)(tn)_2](ClO_4)_2$ was obtained from *trans*-$[CrF_2(py)_4]ClO_4$ (py: pyridine)[24] as follows: *trans*-$[CrF_2(py)_4]ClO_4$ (20 mmol) and 1,3-propanediamine (40 mmol) were dissolved in 2-methoxyethanol (80 cm^3). The solution was refluxed for 1 h and cooled to room temperature. Products thus obtained were collected by filtration, washed with ethanol and ether, and air-dried. Purification of the products was carried out by dissolving them in water and adding a mixture of ethanol and ether (1:1) to the solution.

Preparation of Double Complexes. ***trans*-$K[CrF(H_2O)(en \text{ or } tn)_2][Cr(CN)_6]\cdot H_2O$.** *trans*-$[CrF(H_2O)(en \text{ or } tn)_2](ClO_4)_2$ (25 mmol) was dissolved in ice-cooled water (100 cm^3), to which $K_3[Cr(CN)_6]$ (25 mmol) was added with stirring. After several minutes, the $KClO_4$ which formed was removed by filtration. To the filtrate was added ethanol (100 cm^3) to give products, which were collected by filtration, washed with ethanol and ether, and air-dried. The products were purified by dissolving them in a minimum amount of ice-cooled

water and adding ethanol to the solution.

***trans*-Li[CrF(H_2O)(en)$_2$][Cr(CN)$_6$]·2H_2O and *trans*-Na[CrF(H_2O)(en)$_2$][Cr(CN)$_6$]·H_2O.** K_3[Cr(CN)$_6$] (25 mmol) was dissolved in a minimum amount of water (100 cm^3) and thereto excess $LiClO_4$ or $NaClO_4$ (125 mmol) was added. The solution was stirred for 5 min. The $KClO_4$ thus formed was filtered off. To the filtrate, *trans*-[CrF(H_2O)(en)$_2$](ClO_4)$_2$ (25 mmol) was added. The solution was once filtered and thereto ethanol (100 cm^3) was added with stirring to produce precipitates. The precipitates were collected by filtration, washed with ethanol and acetone, and air-dried. Purification was carried out in a manner similar to that of *trans*-K[CrF(H_2O)(en)$_2$][Cr(CN)$_6$]·H_2O.

***trans*-Rb[CrF(H_2O)en$_2$][Cr(CN)$_6$]·H_2O.** K_3[Cr(CN)$_6$] (25 mmol) was added to a solution of *trans*-[CrF(H_2O)(en)$_2$](ClO_4)$_2$ (25 mmol) in ice-cooled water (100 cm^3). The solution was allowed to stand for several minutes to precipitate $KClO_4$. After the $KClO_4$ was removed out by filtration, RbCl (50 mmol) was added to the filtrate. To the resulting solution, ethanol (100 cm^3) was added with stirring to produce precipitates. The precipitates were collected by filtration, washed with ethanol and acetone, and air-dried. Purfication was carried out by the same method as that of *trans*-K[CrF(H_2O)(en)$_2$][Cr(CN)$_6$]·H_2O.

Preparation of Dinuclear Complexes from Double Complexes in Water. The double complexes *trans*-M^I[CrF(H_2O)(en)$_2$][Cr(CN)$_6$]·*n*H_2O (M^I: Li^+, Na^+, K^+, or Rb^+) (5.0 g) were dissolved in a minimum amount of water (10 cm^3) and the resulting solution was warmed for 30 min at 45—50 °C. The solution was once filtered and the filtrate was cooled at 0 °C to produce crude dinuclear complexes. The crude complexes were recrystallized from water. K[F(tn)$_2$Cr(NC)Cr(CN)$_5$]·1.5 H_2O was similarly prepared except that *trans*-K[CrF(H_2O)(tn)$_2$][Cr(CN)$_6$]·H_2O was used in place of M[CrF(H_2O)(en)$_2$][Cr(CN)$_6$]·*n*H_2O.

The double complexes are in general pink in color, while the dinuclear complexes are orange. The analytical data of the complexes obtained are summarized in Table 1 together with the molar conductivities measured in water of the complexes.

Spectral Measurements. The IR spectra of samples were measured by a KBr-disk method with a Jasco Model A-3 infrared spectrophotometer. Visible and UV spectra in water were measured with a Jasco UVIDEC-505 UV/VIS recording digital spectrophotometer. The spectra in the solid state were measured by a diffuse reflectance methed with a Jasco UVIDEC-410 UV/VIS spectrophotometer equipped with a Jasco Model TIS-241 reflectance attachment.

Molar Conductivity Measurements. Molar conductivities of the complexes were measured in water at 25 °C on a Toa CM-20S conductivity meter at a concentration of 10^{-3} mol dm^{-3}.

Magnetic Measurements. The effective magnetic moments of samples were evaluated from magnetic susceptibilities measured by Gouy method at room temperature. Hg[Co(NCS)$_4$] was employed as a susceptibility standard in all cases. Variable-temperature(78—300 K) magnetic susceptibilities were monitored on a Shimadzu torsion magnetometer MB-2 which was calibrated with Hg[Co(NCS)$_4$]. Diamagnetic correction was made by using Pascal's constants.

TG and DTA Measurements. The TG and DTA measurements for samples were carried out with a Seiko TA Station SSC 5000 system under a constant flow of nitrogen (100 cm^3 min^{-1}), sample weight being in the range of 10—20 mg. Heating rate was 2.0 °C min^{-1}. Heating processes were also observed by using a Chyo 100-L thermobalance.

Results

For clarification of the following discussion, the double complexes *trans*-M^I[CrF(H_2O)(en or tn)$_2$][Cr(CN)$_6$] and the dinuclear complexes M^I[F(en or tn)$_2$Cr(NC)Cr(CN)$_5$]will be simply abbreviated as M(en or tn)[Cr][Cr] and M(en or tn)[Cr–Cr]. The first and second products stand for the products formed at the temperature of the first and second plateaus during the thermal reactions of the double complexes, respectively.

Molar Conductivities. The values for molar conductivities of the complexes are given in the last column of Table 1. The values of the double and the dinuclear comlexes are in the range of 272—341 and 95—130 Ω^{-1}cm^2 mol^{-1}, indicating that the double and the dinuclear complexes are 2:1 and 1:1 electrolytes, respectively.[25]

Thermal Reactions of the Double Complexes in the Solid State. The thermal reactions of the double complexes were observed in the solid state by means of TG and DTA methods. As an example, Fig.1 shows the TG and DTA curves of *trans*-K[CrF(H_2O)(en)$_2$]-[Cr(CN)$_6$]·H_2O and *trans*-K[CrF(H_2O)(tn)$_2$][Cr(CN)$_6$]·H_2O. The TG curve of the complex K(en)[Cr][Cr] shows two steps of the mass losses at 25—162 °C. The first mass loss starts at about 25 °C endothermically. Then, a break point appears at about 52 °C, after which a smooth plateau is obtained at 52—110 °C. The second mass loss takes place at 110—162 °C, the second plateau being obtained at 162—210 °C. The first and second mass losses correspond to the losses of one mole of lattice water (Found: 3.8%; Calcd: 3.8%), and one mole of coordinated water (Found: 3.7%; Calcd: 3.8%). The original pink color remained unchanged at the first plateau and changed to orange at the second plateau. Similar TG and DTA patterns can be seen for the complex K(tn)[Cr][Cr]. The complex turned in color from the original pink to orange at the second plateau. The color change is due to the formation of the dinuclear complex K(en or tn)[Cr–Cr] along with minor polynuclear species as mentioned later. Table 2 lists up the temperatures and enthalpy changes (ΔH) for the evolution of lattice and coordinated waters of the double complexes. The ΔH's for the evolution of coordinated waters are greater than those for those of lattice water for all the double complexes.

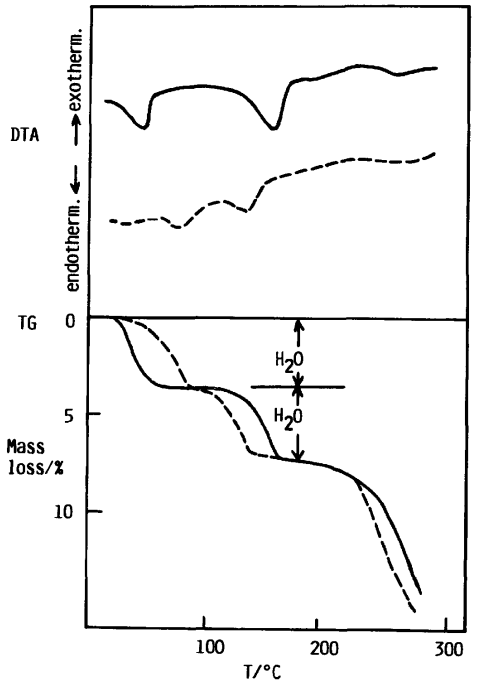

Fig. 1. TG and DTA curves of *trans*-K[CrF(H_2O)-(en)$_2$][Cr(CN)$_6$]·H_2O (——) and *trans*-K[CrF(H_2O)-(tn)$_2$][Cr(CN)$_6$]·H_2O (------).

IR Spectra. Table 3 summarizes the IR data due to CN stretching vibration. As seen from the table, all the double complexes give a single peak at 2130—2138 cm^{-1}, which is assignable to the terminal CN stretching vibration of $[Cr(CN)_6]^{3-}$ (2135 cm^{-1}). On the other hand, the dinuclear complexes indicate two peaks at 2130—2138 and 2160—2170 cm^{-1}; the former is due to the terminal CN stretching and the latter is attributable to the bridging CN stretching vibration.[26] The first products show only terminal-CN stretching band, whereas the second products, both terminal- and bridging-CN stretching bands.

Electronic Spectra. The electronic spectral data of the double and the dinuclear complexes in water are listed in Table 4 together with those of the reference complexes *trans*-[CrF(H_2O)(en or tn)$_2$](ClO_4)$_2$ and K_3[Cr(CN)$_6$]. On the other hand, the electronic spectral data in the solid state are summarized in Table 5 which also includes the data of the second products obtained by heating the double complexes M(en or tn)[Cr][Cr]. Figure 2 shows the electronic spectra in water of *trans*-[CrF(H_2O)(en)$_2$](ClO_4)$_2$, K_3[Cr(CN)$_6$], the double complex K(en)[Cr][Cr] and the dinuclear complex K(en)[Cr–Cr]. The spectrum of the double complex K(en)[Cr][Cr] exhibits four bands at 505, 451, 376, and 307 nm. The bands at 505 and 451 nm are due to the components of the first band of the cationic moiety *trans*-[CrF(H_2O)-(en)$_2$]$^{2+}$. The band at 376 nm may be the mixture of the second band (370 nm) of *trans*-[CrF(H_2O)(en)$_2$]$^{2+}$ and the first band (377 nm) of $[Cr(CN)_6]^{3-}$. The last band at 307 nm is assignable to the second band of $[Cr(CN)_6]^{3-}$. On the other hand, in the spectrum of the dinuclear complex K(en)[Cr–Cr], three bands can be seen at 677, 492, and 372 nm; the small but clear band at 677 nm (ε=≈5) comes from spin-forbidden transition ($^4A_{2g}\rightarrow$

Figure 3 illustrates the electronic spectra in the solid state of the double complex K(en)[Cr][Cr], of the dinuclear complex K(en)[Cr–Cr], and of the second product obtained by heating the double complex K(en)[Cr][Cr]. The spectrum of the double complex gives five bands at 665, 520, 460 (sh), 380, and 307 nm (Table 5). The bands at 520 and 460 nm are due to the components of the first band of *trans*-$[CrF(H_2O)(en)_2]^{2+}$; the band at 380 nm is assignable to the mixture of the second band of *trans*-$[CrF(H_2O)(en)_2]^{2+}$ plus the first band of $[Cr(CN)_6]^{3-}$; and the band at 307 nm is the second band of $[Cr(CN)_6]^{3-}$. A tiny band can be seen at 665 nm, which may be due to spin-forbidden transition. The spectrum of the second product obtained by heating the double complex

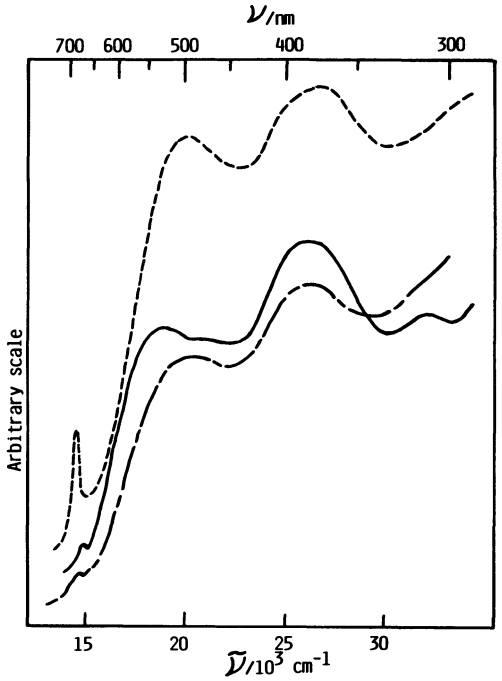

Fig. 3. Electronic spectra in the solid state of *trans*-K[CrF(H_2O)(en)$_2$][Cr(CN)$_6$]·H_2O (———), the product obtained by heating the double complex (———), and K[F(en)$_2$Cr(CN)Cr(CN)$_5$]·1.5H_2) (-----).

K(en)[Cr][Cr] is very similar to that of the dinuclear complex, but the spin-forbidden band at 677 nm is much smaller than that of the dinuclear complex. This implies that the product contains some species other than the dinuclear species (vide infra).

Magnetic Properties. Table 6 summarizes the effective magnetic moments (μ_{eff}) of the double complexes, of the second products obtained by heating the double complexes, and of the dinuclear complexes. As seen from the table, the μ_{eff}'s per a Cr(III) ion of all the double complexes are 3.81—3.89 B.M. at ambient temperatures, whereas those of the second products obtained by heating the double complexes are 3.40—3.67 B.M., and those of the dinuclear complexes are 3.31—3.47 B.M. In both cases of the second products and of the dinuclear complexes, the μ_{eff}'s are obviously reduced from the spin-only value and so it is

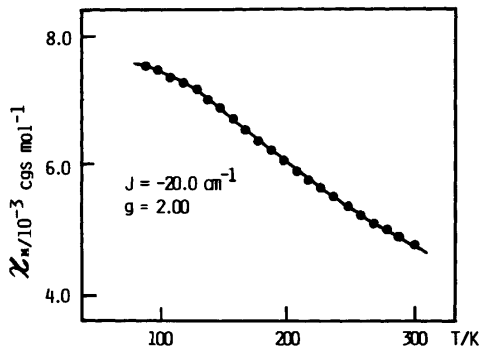

Fig. 4. Temperature dependence of magnetic susceptibilities of K[F(en)$_2$Cr(CN)Cr(CN)$_5$]·1.5H_2O.

conceivable that certain metal–metal interaction is exerted through the CN bridge.

The measurements of the magnetic susceptibilities in the temperature range of 80—300 K, however, indicated different results between the second product and the dinuclear complexes. The results were analyzed with the spin–spin interaction Hamiltonian, $H=-2JS_1\cdot S_2$. The molar susceptibility (χ_M) of an $S_1=S_2=3/2$ exchange coupling dimer is given by the following equation:

$$\chi_M = \frac{N\beta^2 g^2}{3\kappa T}\cdot\frac{3x^{10}+15x^6+42}{x^{12}+3x^{10}+5x^6+7}$$

where $x=\exp(-J/\kappa T)$ and the symbols have their usual meanings. The experimental values are well-interpreted in terms of the above equation as can be seen in Fig. 4. The solid line is a calculated curve by using the following parameters, $J=-20.0$ cm^{-1} and $g=2.00$ for K(en)[Cr–Cr], indicating that an antiferromagnetic interaction is effected in the dinuclear complex. Such antiferromagnetic interaction was also observed in another dinuclear complex: $J=-19.0$ cm^{-1} and $g=2.00$ for Rb(en)[Cr–Cr].

On the other hand, the magnetic properties of second product obtained by heating the double complex K(en)[Cr][Cr] were not explained by the above equation. This may be due to the presence of impure species (vide infra).

Discussion

Preparation of Dinuclear Complexes. Ribas et al. reported that the dinuclear complex K[F(en)$_2$Cr(NC)-Cr(CN)$_5$]·2H_2O is obtained by mixing *trans*-[CrF-(H_2O)(en)$_2$](ClO_4)$_2$ with K_3[Cr(CN)$_6$] in water-ice bath.[20,21] Our reexamination of the procedures always gave the pink double complex K[CrF(H_2O)-(en)$_2$][Cr(CN)$_6$]·H_2O. On the other hand, we obtained the dinuclear complexes M(en or tn)[Cr–Cr] by heating the corresponding double complexes in water at 45—50 °C for about 30 min. Our dinuclear complexes are orange in color and have magnetic moments of 3.4—3.7 μ_B at room temperatures and 2.2—2.4 μ_B at 80 K, whereas the previously reported complex is pink in color and has magnetic moments of 3.79 μ_B at 293.5 K and 3.51 μ_B at 77.0 K. It seems reasonable to consider that the previous complex is not a dinuclear complex, but the double complex K[CrF-(H_2O)(en)$_2$][Cr(CN)$_6$]·H_2O.

Products Obtained by Heating the Double Complexes in the Solid State. The pinkish double complexes M(en or tn)[Cr][Cr], upon heating, evolved first lattice waters and then coordinated waters to convert into orange products (second products). From the results of TG and DTA analyses, the second products are seemingly conceivable to be dinuclear complexes. However, minute examination of the orange products revealed that the products are the mixture of di- and trinuclear complexes along with unknown polymeric species. This suggests that the thermal deaquation-anation of the double complexes in the solid state does not give pure dinuclear complexes.

Configuration of the Dinuclear Complexes. Two geometrical isomers (cis and trans) are possible for the dinuclear complexes $K[CrF(en \text{ or } tn)_2Cr(NC)Cr(CN)_5]$ with respect to the positions of F^- ion and $-(NC)Cr(CN)_5$ moiety. It is difficult to accurately decide the geometrical configurations from electronic spectral data because both isomers are expected to give a similar spectrum to each other. In fact, it has been reported that both *cis*- and *trans*-$[CrF(NH_3)(en)_2]^{2+}$ exhibit close band maxima except for ε values because they have the same core ($CrFN_5$) and hence the same symmetry (C_{4v}).[30,31] However, we tentatively conclude that the dinuclear complexes in the present study are trans-configuration provided that trans-to-cis isomerization were not involved in the preparative procedures. Possibility of the isomerization can be completely discarded in the case of the tn complex because $[CrX_2(tn)_2]^+$ has been found to undergo cis-to-trans isomerization, but not trans-to-cis isomerization.[32] Comparison of the λ_{max}'s and ε's in Table 4 implies that both en and tn dinuclear complexes give essentially similar spectra except that the λ_{max}'s of the tn complex appear at longer wavelengths than those of the en complexes, which arises from the difference in ligand field strength of en and tn. Therefore, it seems reasonable to consider that the en dinuclear complexes also have trans-configuration.

(Received August 5, 1988)

Several new mixed nickel(II) nitrate complexes with 1,2-dipiperidinoethane (dipe) and β-diketonate ions (dike), [Ni(NO_3)(dike)(dipe)], have been obtained and characterized. The crystal structure of one of them, [Ni(NO_3)(acac)(dipe)], was determined by X-ray crystallography. The crystal is monoclinic with the space group *Cc*, $Z=4$, $a=9.0517(4)$, $b=21.932(1)$, $c=9.8814(6)$ Å, $\beta=88.151°$. Block-diagonal least-squares refinements have led to a final R value of 0.036 for 2471 reflections. It was confirmed that the nitrate ion in the octahedral complex acts as a bidentate ligand and that the conformation of the piperidine ring in dipe is a chair form. The spectral behaviors of these complexes in various organic solvents are discussed in comparison with those of similar complexes with other *N,N'*-alkylated ethylenediamine ligands (diam). It was concluded that, in a solvent with low polarity, the complexes are dissolved unchanged; in a more polar solvent, however, dissociation of NO_3^- takes place, producing solvated or unsolvated cationic species ([Ni(dike)(diam)(Solvent)$_2$]$^+$ (Oh) or [Ni(dike)(diam)]$^+$ (Square Planar)) according to the donor and acceptor properties of the solvent.

1,2-Dipiperidinoethane ($(CH_2)_5N(CH_2)_2N(CH_2)_5$;dipe) is a potential bidentate ligand which has not been thoroughly studied so far.[1] The chelate ring structure of dipe is similar to that of *N,N,N',N'*-tetramethylethylenediamine (tmen), but the bulky groups $-(CH_2)_5-$ on the N-donor atoms hinder the coordination of this ligand to the central metal ion, and also that of other ligands in the coordination sphere. Therefore, dipe is expected to be a weaker ligand than tmen.

We have reported the mixed nickel(II) complexes with various kinds of *N,N'*-alkylated ethylenediamines (diam) and β-diketonate ions (dike), many of which show remarkable chromotropic behaviors in the solid state or solutions.[2] While continuing this series of studies, we recently obtained several kinds of Ni(II) nitrates containing both dipe and dike, in which the nitrate ion acts as a bidentate ligand. In addition to the results regarding their IR and electronic spectra, as well as their electric conductivities in organic solvents, we have determined the crystal structure of [Ni(NO_3)(acac)(dipe)] in order to understand the mode of the nitrate coordination and the conformation of the dipe ligand. The structural results and a spectral comparison of the dipe complexes with similar mixed ligand complexes containing tmen and related ligands are discussed in this paper.[3–9]

Experimental

Materials. Nickel(II) nitrate hexahydrate, tmen, *N,N,N'*-triethylethylenediamine (Et3en), and *N,N,N',N'*-tetraethylethylenediamine (teen) (Wako Pure Chemical Co.), dipe (Aldrich), and all of dikeH (Dojindo Laboratory) were purchased and used without further purification. All solvents used for physical measurements were Guaranteed Reagent or Spectro grade; hygroscopic solvents were dried by conventional methods.[10]

General Preparation of Solid Complexes: [Ni(NO_3)(dike)(diam)] (dike:acetylacetonate (acac), benzoylacetonate (bzac), dibenzoylmethanate (dibm), dipivaloylmethanate (dipm), trifluoroacetylacetonate (tfac), and hexafluoroacetylacetonate (hfac) ions; diam:teen, Et3en, tmen, and dipe). To an ethanolic solution of $Ni(NO_3)_2\cdot 6H_2O$ (10 mmol in 30 ml of ethanol (EtOH)) a mixture of an appropriate β-diketone and KOH (10 mmol each) dissolved in 20 ml of EtOH is added; then, diam (10 mmol in 10 ml of EtOH) is dropped into it with vigorous stirring. After completing the reaction, the deep-green solution is filtered (to separate the precipitate of KNO_3) and dried up in a rotary evaporator. The crude crystals obtained are dissolved in hot 1,2-dichloroethane (DCE) and filtered; the solution is kept in a freezer for several days. The obtained complex is recrystallized again from hot DCE. [Ni(NO_3)(hfac)(dipe)] could not be obtained in this way, but a non-charged chelate [Ni(hfac)$_2$(dipe)] was formed instead. The dipm mixed complex was obtained as a hydrate, [Ni(NO_3)(dipm)(dipe)-(H_2O)], in a small quantity, though it was rather unstable in solution and decomposed gradually to a mixture of the noncharged chelate [Ni(dipm)$_2$(dipe)] and an unknown green paste.[9]

Physical Measurements. The methods used in the measurements of IR and electronic spectra (solid and solution), magnetic susceptibilities, TG-DTA curves, and electric conductivities in solution are the same as those reported before.[11]

Determination of the Crystal Structure of [Ni(NO_3)(acac)(dipe)]. The crystal used for X-ray work was grown from a DCE solution. Crystal data are as follows: $NiC_{17}H_{31}N_3O_5$; M. W. 416.2; monoclinic; $a=9.0517(4)$, $b=21.932(1)$, $c=9.8814(6)$ Å, $\beta=88.151(4)°$; $U=1960.6(2)$ Å^3; $D_x=1.41$ g cm^{-3}; $Z=4$; space group *Cc*; μ (Mo $K\alpha$) $=1.02$ mm^{-1}. The intensity data were collected on a Rigaku automated four-circle diffractometer AFC-5 with the θ–2θ scan technique, scan range $(1.1+(1/2)\tan\theta)°$ and scan speed 3° min^{-1} in θ. Dimensions of the crystal used for the data collection were 0.38×0.34×0.21 mm. A total of 3036 independent reflections

were measured ($2°<2\theta<60°$), using graphite monochromated Mo $K\alpha$ radiation, of which 2471 reflections were $|F_o|>3\sigma(|F_o|)$. Corrections for Lorentz and polarization factors were made, but not for absorption. The structure was solved by the heavy-atom method using the UNICS-III program system.[12] A refinement was carried out by block-diagonal least-squares. Atomic scattering factors were taken from "International Tables for X-ray Crystallography".[13] The R and R_w values converged to 0.036 and 0.036, respectively. Computations were performed on FACOM M-360R and M-360 computers at the Computer Center of Josai University.

Results and Discussion

Solid Complexes. In Table 1, analytical data and some properties of the solid complexes obtained in this study, [Ni(NO3)(dike)(dipe)], are listed. The complexes containing hfac or dipm seem to have a tendency to be converted into the non-charged octahedral complexes, [Ni(dike)2(dipe)]. We could thus obtain only a small amount of a monohydrate, [Ni(NO3)(dipm)(dipe)(H2O)], and two noncharged complexes, [Ni(dipm)2(dipe)] and [Ni(hfac)2(dipe)], for these ligands. In the same table, the data on another nitrate complex with Et3en are also given, which is similar in appearance and properties to those of the complexes of tmen and teen reported earlier.[3-5] From the colors and magnetic moments of the complexes, it can be seen that all these complexes have an octahedral geometry. There is a simple and very useful criterion for the coordination mode of NO_3 from the IR spectra, devised by Lever et al.[14] The key region is 1700—1800 cm^{-1}, where a weak combination band of the NO_3^- ion in a complex compound appears. This band is often split in two; when the splitting is small ($\Delta\tilde{\nu}_{NO_3}$=20—25 cm^{-1}), the NO_3^- ion is a monodentate ligand, but when it is larger, the ion is a bidentate ligand.[15,16] The IR data of the anhydrous complexes in this region are given in Table 2. All of the anhydrous nitrate complexes obtained here have a rather large splitting of this band ($\Delta\tilde{\nu}_{NO_3}$=45—50 cm^{-1}), showing that the NO_3^- ions in these anhydrous complexes act as bidentate ligands.[17] There is only one exception; the monohydrate [Ni(NO3)(dipm)(dipe)(H2O)] shows a small splitting ($\Delta\tilde{\nu}_{NO_3}$=18 cm^{-1}), which indicates that NO_3^- in it is a monodentate ligand.[18]

The difference between the C=O and C=C stretching frequencies of dike ($\Delta\tilde{\nu}_{dike}=\tilde{\nu}_{C=O}-\tilde{\nu}_{C=C}$) is also a characteristic value. As reported earlier,[3,4] this difference notably decreases in going from as octahedral (high-spin) Ni(II) complex to a square planar (low-spin) 4-coordinate one, indicating that, as the Ni-O(dike) bonds become stronger, the C=O bonds become weaker, and the C=C bonds become stronger.[20] This view is also supported by the bond distances of C=O and C=C of acac in its complexes with different coordination numbers.[21,22] The IR data are consistent with this view; the values of $\Delta\tilde{\nu}_{dike}$ observed in the range of 1600—1500 cm^{-1} ($\Delta\tilde{\nu}_{dike}$=78—115 cm^{-1}; cf. Table 2) are similer to those of the octahedral complexes studied before, confirming the octahedral structure of the new complexes.

Structure of [Ni(NO3)(acac)(dipe)]. As stated above, evidences for the bidentate coordination of NO_3^- in the complexes studied can be obtained form IR spectra, and electronic spectral data and conductivity data in solution (vide infra) are also consistent with this view. We have now determined the crystal structure of [Ni(NO3)(acac)(dipe)] to understand how such coordination takes place. The final atomic

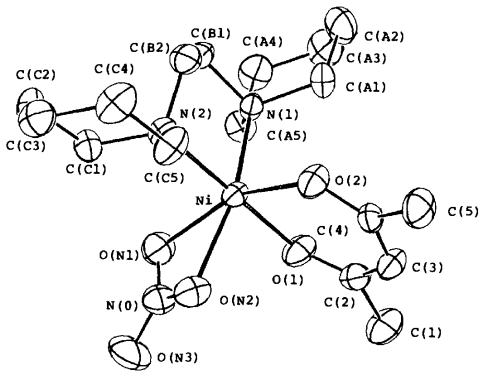

Fig. 1. Molecular structure of the complex $[Ni(NO_3)(acac)(dipe)]$ with atom numbering projected on the O(N1)-O(1)-N(1) plane.

parameters and their estimated standard deviations are listed in Table 3, and the bond distances and angles are shown in Table 4 (numbering scheme indicated in Fig. 1). Figure 2 shows the crystal structure projected on (10$\bar{1}$) plane.

From the X-ray results, it is noted that (1) the NO_3^- is really a bidentate ligand, which is coordinated to the Ni(II) ion with the two bonds, Ni-O(N1) and Ni-O(N2) of nearly the same length. The bite angle, ($\angle$O(N1)-Ni-O(N2)=60.13°), is rather narrow; such a value is not so rare among the data on the bidentate nitrates.[23] The Ni-O(NO_3) bonds are remarkably longer than Ni-O(acac), explaining the easy cleavage of Ni-O(NO_3) bonds in some solvents (DMSO or CH_3NO_2; vide infra). The terminal N(O)-O(N3) bond length is shorter than the other two N-O bonds because both of the O atoms of the latter bonds are coordinated to the central metal ion. It is now quite obvious that this complex and also the nitrate complexes $[Ni(NO_3)(dike)(diam)]$ of other diam and dike with similar properties are octahedral complexes with the bidentate NO_3^- ligand, in agreement with the expectation from Lever's criterion. The crystallographic data of this compound are the first evidence for a bidentate coordination mode of NO_3^- in Ni(II) complexes. (2) The bond distances between Ni(II) and the acac ligand, and those in this ligand itself, are nearly the same as those reported for another octahedral Ni(II) complex, $[Ni(acac)_2(py)_2]$ (py=pyridine).[24] Although there is no crystal data for the planar $[Ni(acac)(dipe)]^+$ (vide infra), the preliminary X-ray data for the dinuclear Ni(II) complex, $[(tmen)Ni(1)(tetraketonate)Ni(2)(tmen)(H_2O)_2]^{2+}$, in which the coordination sphere of Ni(1) is square planar and that of Ni(2) is octahedral, indicate that the coordinate bonds in the square planar arrangement are much shorter than those in the octahedral species.[25] (3) Both piperidine rings in dipe are in the chair conformation, and the three bidentate ligands, i.e. dipe, acac, and NO_3^-, are placed so as to minimize the interligand

repulsions. The chelate bite angles, ∠O(1)–Ni–O(2) (for acac) and ∠N(1)–Ni–N(2) (for dipe), are 89.48° and 85.87°, respectively.

Three tables for atomic coordinates of the H atoms (Table A), mean square displacement tensors of atoms (Table B), and structure factors (Table C) are deposited at the Chemical Society of Japan, Document No. 8858.

Electronic Spectra in Solution. Figure 3 shows the electronic spectra of [Ni(NO_3)(acac)(dipe)] in four kinds of organic solvents, i.e., DCE, CH_3NO_2, acetone, and DMSO. In Table 5, the spectral data for similar complexes are summarized. From these data, it can be seen that two kinds of spectral changes take place with changes in solvent polarity.

[I] The spectra in DCE, acetone and EtOH are nearly of the same pattern, showing two bands ($\tilde{\nu}_1$ and $\tilde{\nu}_2$; $\tilde{\nu}_1 < \tilde{\nu}_2$) which correspond to the octahedral structure of the complexes. The spectral shape is, however, somewhat anomalous, i.e., the values of the intensity ratio of the two bands ($R=\varepsilon(\tilde{\nu}_2)/\varepsilon(\tilde{\nu}_1)$) are nearly the same in these solvents and are about 2, whereas the same ratio for a typical octahedral complex (e.g., [Ni en_3]$^{2+}$) is nearly 1.[26] The same type of anomaly is also observed in the spectra of the solid nitrate complexes. This anomaly is probably related to the existence of a highly strained 4-membered chelate ring of NO_3^- in the coordination sphere (vide supra). On the other hand, in the case of DMSO solutions, the values of R are close to unity, so that the spectra look quite normal. The electric conductivity

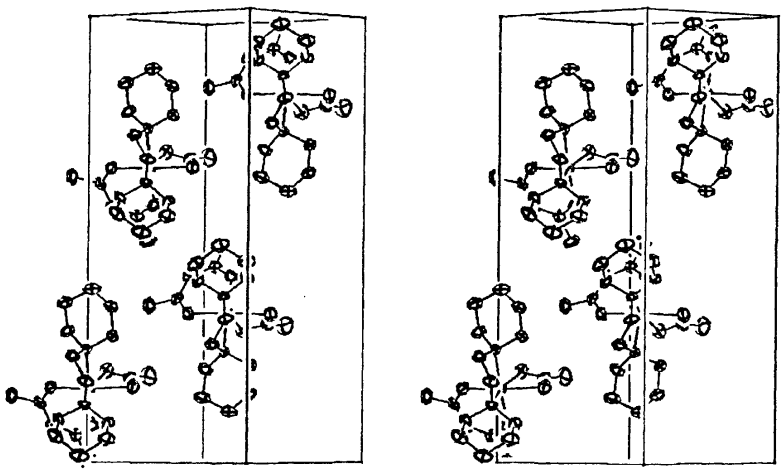

Fig. 2. Stereoscopic view of a unit cell projected on the (101) plane; horizontal [10$\bar{1}$], vertical b.

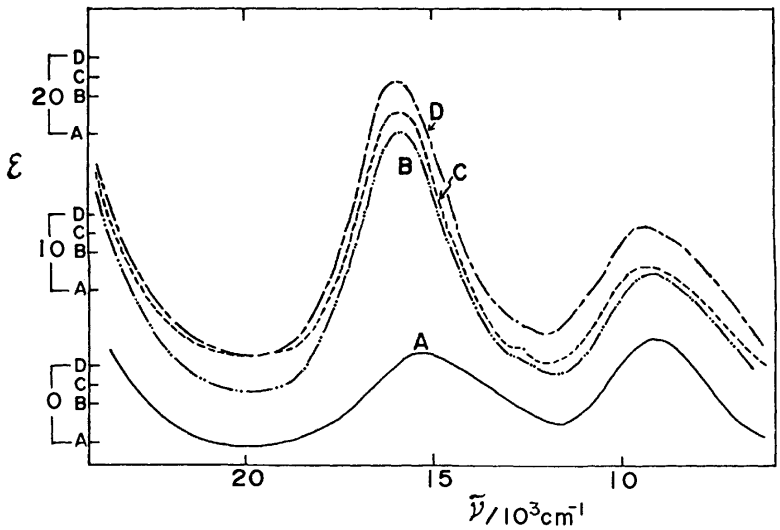

Fig. 3. Absorption spectra of [Ni(NO_3)(acac)(dipe)] in various solvents. Concn: 4×10^{-2} mol dm^{-3}, temp: ca. 20°C. A=DMSO, B=acetone, C=CH_3NO_2, D=DCE.

data shown in Table 6 indicate now that the complex species in DCE or acetone are non-charged ones, while those in DMSO are 1:1 electrolytes.

These results lead to the conclusion that, in a solvent such as DCE (DN=0, AN=16.7)[28] or acetone (DN=17.0, AN=12.5) which have a relatively low polarity, the complex structure in the solid state remains unchanged, i.e., the species in the solution is the non-charged complex [Ni(NO_3)(acac)(diam)]:

[Ni(NO_3)(acac)(diam)]⟶[Ni(NO_3)(acac)(diam)]
(Solid) Blue/Green, Oh ($R\approx2$)

When the complex is dissolved in DMSO (DN=29.8, AN=19.3) which is a more polar solvent, however, it dissociates the NO_3^- ion to form the solvated cations [Ni(acac)(diam)(Solvent)$_2$]$^+$:

[Ni(NO_3)(acac)(diam)] ⟷ [Ni(acac)(diam)(Solvent)$_2$]$^+$ + NO_3^-
Blue/Green, Oh ($R\approx2$) Blue, Oh ($R\approx1$) (1)

This equilibrium is strongly shifted to the right hand side in DMSO; the strain in the coordination sphere is thereby lost, and the spectrum of the solution looks quite normal.

[II] Although the occurrence of the spectral change (I) was already indicated in our former studies,[2-5] there is another kind of spectral change (II) which we have overlooked hitherto. This change occurs in CH_3NO_2 solutions where, according to the conductivity data (Table 6), partial dissociation of the complexes occurs, which increases in the following order of diam:

Table 5. Absorption Spectra of the Complexes [Ni(NO_3)(dike)(diam)] in Solid State and in Various Solvents ($\tilde{\nu}_{max}/10^3$ cm^{-1}, ε_{max} in Parentheses, Concn: 4×10^{-2} mol dm^{-3}, Temp: ca. 20 °C)

Table 6. Molar Conductivity Data of the Complexes [Ni(NO_3)(dike)(diam)] in Various Organic Solutions (Λ_M/S cm^2 mol^{-1}, Concn: 2×10^{-2} mol dm^{-3}, Temp: 25±0.1 °C)

[A] [Ni(NO_3)(dike)(dipe)]				
dike	DCE	CH_3NO_2	Acetone	DMSO
tfac	0.02	6.80	1.65	32.97
bzac	0.03	3.77	0.91	41.06
acac	0.05	5.06	0.93	30.46

[B] [Ni(NO_3)(acac)(diam)]				
diam	DCE	CH_3NO_2	Acetone	DMSO
dipe	0.05	5.06	0.93	30.46
teen	0.30	33.77	2.01	33.84
tmen	0.04	4.73	1.29	36.99
Et_3en	0.06	6.26	1.45	34.31
Ref.[a]	20.89	100.6	137.8	39.10
	(10—24)	(75—95)	(100—140)	(ca. 35)

a) The values for [Ni(acac)(tmen)]ClO_4, i.e., a typical 1:1 electrolyte, in the respective solvents, and standard values for an 1:1 electrolyte in parentheses.[27]

teen ≫ Et_3en > dipe ~ tmen.

The values of R in these solutions do not change so much from 2; however, a new band appears at ca. 20×10^3 cm^{-1}, which can be assigned to the unsolvated square planar chelate cation [Ni(dike)(diam)]$^+$.[2-5] This change can, thus, be ascribed to the change:

$$[Ni(NO_3)(acac)(diam)] \rightleftarrows [Ni(acac)(diam)]^+ + NO_3^- \quad (2)$$

Blue/Green, Oh ($R\approx2$) Red, square planar

In this case, the solvent (CH_3NO_2) is a very weak donor, but a relatively strong acceptor (DN=2.7, AN=20.5). Since the coordination of NO_3^- in the complex is weak (vide supra), a part of the NO_3^- ions can be solvated and dissociated from the complex by interaction with this acceptor solvent. On the other hand, the solvent molecules will not coordinate effectively to Ni(II) to form an octahedral species, as those in Eq. 1, owing to their poor donor ability, so that the "naked"square planar cation newly appears in solution.

Figure 4 shows the absorption spectra of four kinds of [Ni(NO_3)(acac)(diam)] in CH_3NO_2. It can be seen that the relative intensity of the band at ca. 20×10^3 cm^{-1}, which is an approximate measure for the formation of the square planar species in this solvent, decreases in the order of diam

$$\text{teen} \gg Et_3\text{en} > \text{tmen} \gtrsim \text{dipe}^{29)} \quad (3)$$

for this series of complexes, which is nearly in parallel with the expectation from the conductivity data. It is easy to understand that the free movements of the ethyl groups on the N-donor atoms of teen will strongly destabilize the octahedral chelate by their steric hindrance, so that the equilibrium in Eq. 2 will be shifted strongly to the right-hand side. This destabilizing effect will decrease in the order teen>Et_3en> tmen, with the decrease in size and number of the alkyl groups. The piperidino groups of dipe are very bulky, but their free movements (and especially those toward the axial sites) are strongly restricted by their rigid ring structure.[1] Therefore, the complex [Ni(NO_3)(acac)-(dipe)] will be much more stable than the corresponding complexes with teen or Et_3en, and comparable to that of tmen (or even more than that, if the decreased ligand field strength (l.f.s.) of dipe (vide infra) is taken into account), with respect to the equilibrium of Eq. 2. The above-mentioned ligand order will, thus, come about.

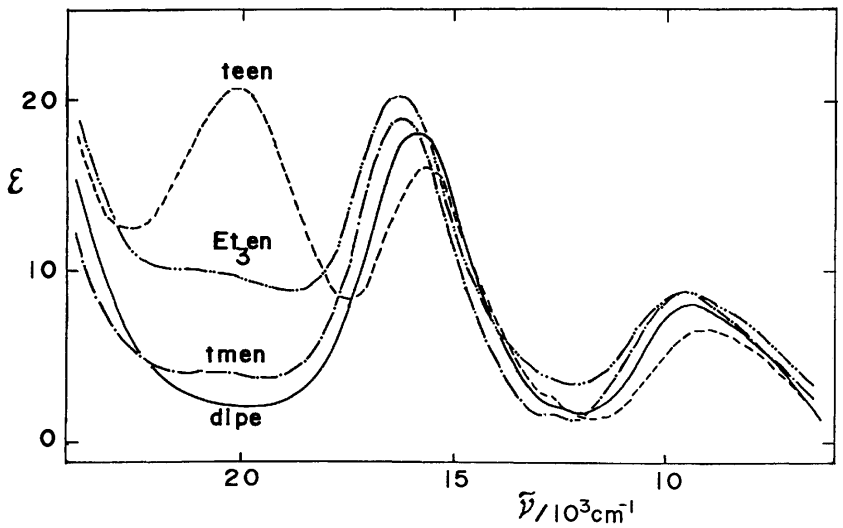

Fig. 4. Absorption spectra of [Ni(NO_3)(acac)(diam)] (diam=teen, Et_3en, dipe, and tmen) in CH_3NO_2. Concn: 4×10^{-2} mol dm^{-3}, temp: ca. 20 °C.

The spectra of these nitrate complexes in CH_3NO_2 show concentration and temperature dependence, especially in the vicinity of the band of the square planar species. In each case, a gradual increase of the square planar species takes place at lower concentrations and at higher temperatures, showing that the nitrate dissociation is favored by dilution and heating, and confirming the existence of the equilibrium shown in Eq. 2. Quantitative aspects of this equilibrium, and also those of the equilibria observed in EtOH solutions,[30] are now under study.

Finally, it may be pointed out that the differences among the l.f.s. of the diamines used in this study can be estimated from the values of $\tilde{\nu}_1$ of the octahedral nitrate complexes in DCE. Although such differences are not large, the data in Table 5 indicate that the order of decreasing l.f.s. of the diamines is:

$$\text{tmen} > \text{Et}_3\text{en} > \text{dipe} > \text{teen}. \quad (4)$$

It is generally conceivable that a ligand with a strong donor property will tend to form a square planar complex with Ni(II), and to shift the solution equilibrium between a square planar complex and an octahedral one to the side of the former. The order of Eq. 4, however, dose not coincide with that of Eq. 3, indicating that the steric hindrance of the bulky substituent groups on the N-donor atoms is important in determining the equilibrium.

28) DN and AN are donor number and acceptor number of the solvent, respectively; cf. Ref. 20.

29) In the case of the acac-dipe complex, this band is nearly imperceptible on the curve in Fig. 4. However, an analysis of the absorption curve indicates its existence. Upon heating the solution to ca. 40 °C, or upon diluting it to 4×10^{-3} mol dm^{-3}, it appears as a clear hump, with an intensity which is apparently comparable to that of the tmen complex under the same conditions. Therefore, the positions of tmen and dipe in this order are quite near, as indicated by the conductivity data (cf. Table 6).

30) In EtOH solutions of the complex, it seems that the equilibria of (Eq. 1) and (Eq. 2) take place at the same time, i.e., there is a partial ionization of NO_3^- (cf. Table 6), but the cations formed are an equilibrium mixture of $[Ni(dike)(diam)(EtOH)_2]^+$ and $[Ni(dike)(diam)]^+$. The proportion of the latter ion in this mixture decreases again in the order of teen $\gg$ Et_3en $>$ tmen $\approx$ dipe.

Base-Catalyzed Isomerization and Racemization Reactions of $[Co(L_1)(L_2)]^+$-Type Complexes (L_1=Iminodiacetato or *N*-Methyliminodiacetato and L_2=3-Azapentane-1,5-diamine or 3-Methyl-3-azapentane-1,5-diamine)

Hiroshi KAWAGUCHI,* Masato SHIMIZU, Tomoharu AMA, and Takaji YASUI
Department of Chemistry, Faculty of Science, Kochi University, Akebono-cho, Kochi 780
(Received August 12, 1988)

The isomerization and racemization reactions of the $[Co(ida)(dien)]^+$ and $[Co(ida)(mdien)]^+$ systems were studied in an aqueous solution. The main isomerization path of the $[Co(ida)(dien)]^+$ system was *u-fac*⇌*mer*⇌*s-fac* and the rate law for each of the processes could be described as $R=k[\text{complex}][OH^-]$. In the $[Co(ida)(mdien)]^+$ system, there was an additional isomerization path of *u-fac*⟶*s-fac*. The equilibrium mole ratio of three isomers was *u-fac*:*mer*:*s-fac*=25:19:56% for $[Co(ida)(dien)]^+$ and *u-fac*:*mer*:*s-fac*=3:3:94% for $[Co(ida)(mdien)]^+$. In the isomerization of $(+)^{CD}_{564}$-*u-fac*-$[Co(mida)(mdien)]^+$, $(+)^{CD}_{582}$-*mer* isomer was stereoselectively produced. The racemization mechanisms of *mer*-$[Co(ida)(dien)]^+$ and *mer*-$[Co(mida)(dien)]^+$ are also discussed.

As part of a study of the structure-reactivity pattern in octahedral complexes, our attention was drawn to cobalt(III) complexes containing two terdentate ligands such as dien, ida, and their analogs.[1] This type complex provides three possible geometrical isomers; *s-fac*, *u-fac*, and *mer* (Fig. 1). Each isomer of $[Co(dien)_2]^{3+}$ isomerized in water at high temperature (82 °C), giving a mixture of all three isomers. The isomerization reaction was thought to proceed through three intramolecular paths; *u-fac*⇌*mer*, *mer*⇌*s-fac*, and *s-fac*⇌*u-fac*.[2] We previously studied the isomerization reactions of the $[Co(ida)_2]^-$ and $[Co(ida)(mida)]^-$ systems and found that the reactions proceeded through two intramolecular paths, as shown in Scheme 1. All of the reactions are base-catalyzed and probably involve conjugate base intermediates.[3] The isomers of $[Co(mida)_2]^-$, which have no N–H proton to deprotonate, did not isomerize under the same conditions as those for the isomers of $[Co(ida)_2]^-$.[4] The isomers of $[Co(edma)_2]^+$ also isomerized to other ones in a basic aqueous solution; however, the main reaction paths are quite different from those of the $[Co(ida)_2]^-$ system.[5]

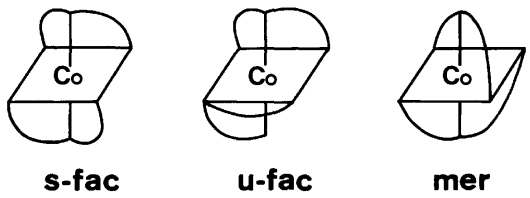

Fig. 1. Three geometrical isomers of the [Co(L)(L′)] type complex, where L and L′ are symmetrical terdentate ligands.

u-fac ⇌ mer ⇌ s-fac

Scheme 1.

Recently, we presented preliminary results concerning the reactivities of the $[Co(ida)(dien)]^+$, $[Co(ida)(mdien)]^+$, $[Co(mida)(dien)]^+$, and $[Co(mida)(mdien)]^+$ complexes.[6] In this paper, we describe a detailed study of the isomerization reaction of those complexes. In addition, we also report on rate data regarding racemization for the *mer* isomers of $[Co(ida)(dien)]^+$ and $[Co(mida)(dien)]^+$.

Experimental

Complexes and Reagents. The complexes examined here were prepared according to the methods described in previous papers.[7] They are *u-fac*-$[Co(ida)(dien)]Cl\cdot 0.5H_2O$, *mer*-$[Co(ida)(dien)]Cl\cdot H_2O$, *s-fac*-$[Co(ida)(dien)]Cl\cdot 0.5H_2O$, *u-fac*-$[Co(ida)(mdien)]Cl\cdot 1.5H_2O$, *mer*-$[Co(ida)(mdien)]Cl\cdot 2H_2O$, *u-fac*-$[Co(mida)(dien)]Cl\cdot 1.5H_2O$, *mer*-$[Co(mida)(dien)]Cl\cdot 1.5H_2O$, *u-fac*-$[Co(mida)(mdien)]Cl\cdot 3H_2O$, *mer*-$[Co(mida)(mdien)]Cl\cdot 2H_2O$, $(+)^{CD}_{538}$-*u-fac*-$[Co(ida)(dien)]Cl\cdot 2H_2O$ ($\Delta\varepsilon_{538}$=+2.014), $(-)^{CD}_{550}$-*u-fac*-$[Co(ida)(mdien)]Cl\cdot 1.5H_2O$ ($\Delta\varepsilon_{550}$=−1.804), $(+)^{CD}_{544}$-*u-fac*-$[Co(mida)(dien)]Cl\cdot 0.5H_2O$ ($\Delta\varepsilon_{544}$=+2.441), $(+)^{CD}_{564}$-*u-fac*-$[Co(mida)(mdien)]Cl\cdot 3H_2O$ ($\Delta\varepsilon_{564}$=+1.658), $(+)^{CD}_{560}$-*mer*-$[Co(ida)(dien)]Cl\cdot 1.5H_2O$ ($\Delta\varepsilon_{560}$=+0.214), and $(-)^{CD}_{570}$-*mer*-$[Co(mida)(dien)]Cl\cdot 1.5H_2O$ ($\Delta\varepsilon_{570}$=−0.205).

All the chemicals used were of reagent grade, and the deionized water was degassed before use.

Isomerization. ***u-fac*-$[Co(ida)(dien)]^+$:** The following reaction conditions were set: complex concentration, 4.0×10^{-3} M (M=mol dm^{-3}); pH, 10.00±0.03, 10.30±0.03, and 10.60±0.03 (Na_2CO_3–$NaHCO_3$ buffer); ionic strength (*I*), 0.1 M ($NaClO_4$); temperature, 40.0±0.1 °C. The isomerization reaction was started by dissolving the isomer (540.20 mg) in 400 cm^3 of the buffer solution in a reaction vessel kept in a thermostated bath. The temperature and pH of the reaction solution were checked with a thermistor thermometer (TAKARA D221) and a pH meter (TOA TSC-10A), respectively. At prescribed time intervals, a constant volume (30.0 cm^3) of the reaction solution was taken out and acidified to pH 6 in order to stop the reaction, and then applied to a column (3.0 cm×60 cm) of SP-Sephadex C-25 (K^+ form) cation exchanger. On elution with 0.2 M KCl, two bands, el. 1 (*mer*) and el. 2 (*s-fac* and *u-fac*), were separated.

The two eluates were collected separately and concentrated to constant volumes (10 or 20 cm^3) and the amounts of the isomers were spectrophotometrically determined with a JASCO UVIDEC-670 spectrophotometer. The amounts of *u-fac* and *s-fac* were calculated from binary-curve analyses of the absorption spectrum of the concentrated el. 2 eluate. (In this curve analysis, the spectral data at 25 points in the visible region were used.) The analysis calculations were carried out on an NEC PC-9801F computer using the least-squares method. The isomerization reactions of *s-fac*- and *mer*-$[Co(ida)(dien)]^+$ were carried out by a procedure similar to that used for *u-fac* isomer.

The isomerization reactions for the $[Co(ida)(mdien)]^+$, $[Co(mida)(dien)]^+$, and $[Co(mida)(mdien)]^+$ systems were also conducted according to a similar method as described above.

CD Decrease of *u-fac* Isomers and Racemization of *mer* Isomers. The rates of CD decrease of optically active *u-fac* isomers were measured with a JASCO J-22 spectropolarimeter. A reaction vessel with a jacket and a water-jacket cell mounted in the cell compartment of the spectropolarimeter were thermostated at 40.0 °C with circulating water. The reaction was started by dissolving the complex in 20.0 cm^3 of a buffered solution in the reaction vessel. About 3 cm^3 of this solution was quickly transferred into the cell in order to record the decrease of the CD intensity. The reaction conditions were as follows: complex concentration, 5.0×10^{-3} M; pH, 10.30±0.05 (Na_2CO_3-$NaHCO_3$ buffer); *I*, 0.1 M ($NaClO_4$); temperature, 40.0±0.1 °C.

The racemization reactions of *mer*-$[Co(ida)(dien)]^+$ and *mer*-$[Co(mida)(dien)]^+$ were carried out by a procedure similar to that described above. The following reaction conditions were set: complex concentration, 5.02×10^{-3} M; pH, 4.2—6.0 (CH_3COOH-CH_3COONa buffer); *I*, 1.0 M ($NaNO_3$); temperature, 30—40 °C. The ionic product of water at the appropriate temperature was obtained from the literature[8] and the appropriate activity coefficient corrections for ionic strength were made using the same source. The hydroxide concentration could then be calculated. Plots of ln[CD intensity] vs. time gave a straight line over three half-lives, from which the pseudo-first-order rate constant k_{obsd} (s^{-1}) was obtained. Analyses of the kinetic data were carried out using the least-squares method. In each of the kinetic data analyses, the value of the standard deviation was within ±1% of the rate constant.

Results and Discussion

Isomerization of the $[Co(ida)(dien)]^+$ System. The isomerization reaction of *u-fac*-$[Co(ida)(dien)]^+$ was carried out under the conditions of pH 10.30 and I=0.1 M at 40.0 °C. Figure 2-a shows the concentration changes of the starting material and reaction products. A part of the numerical data are listed in Table 1.[9] In this reaction, *mer* was first formed and *s-fac* was subsequently formed. After about 25 h, the amount of *mer* began to decrease. The *s-fac* isomer gradually increased in its amount, and was a major product at the final stage of the reaction. Isomerization reactions using *mer* and *s-fac* as the starting materials were also carried out under the same conditions as used for *u-fac*. The results are shown in Figs. 2-b and 2-c and a part of the numerical data are listed in Table 1. The isomerization of *mer* proceeded rapidly, and *u-fac* and *s-fac* were formed simultaneously. The amount of *u-fac* formed was maximal about 30 h after the start of the reaction; it then gradually decreased. However, the isomerization of

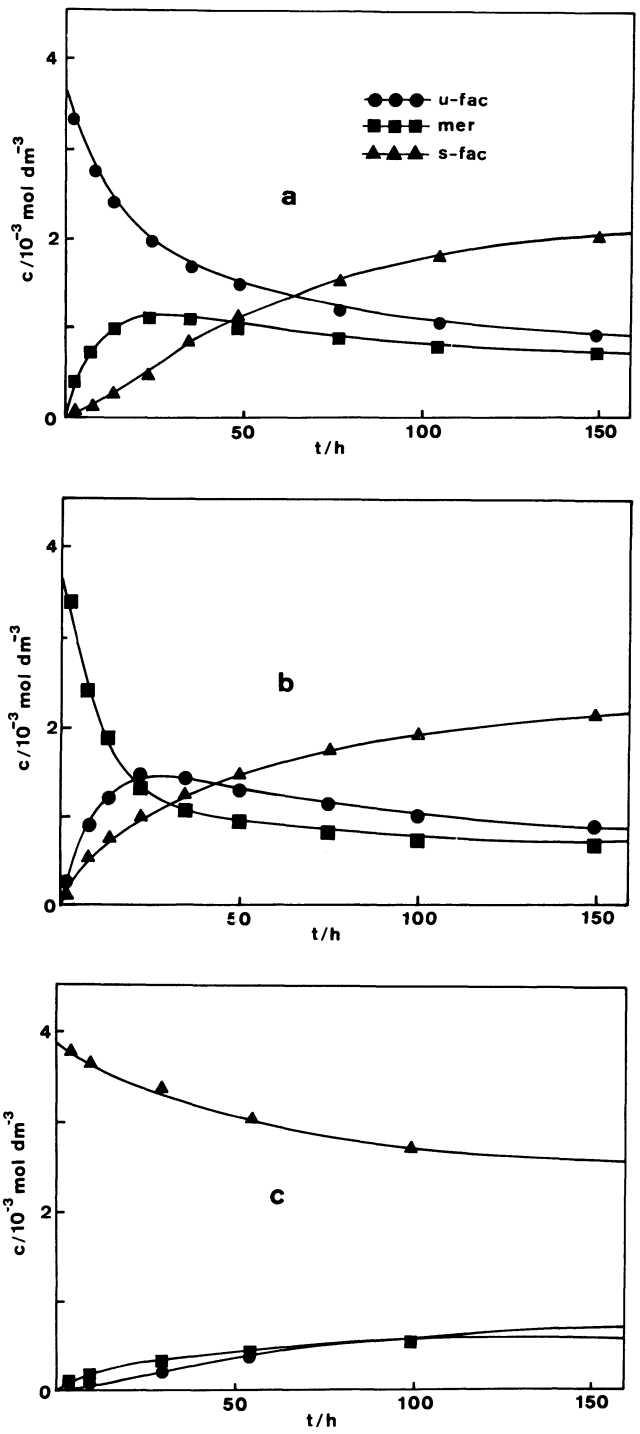

Fig. 2. The isomerization reaction of $[Co(ida)(dien)]^+$ in a basic aqueous solution (pH 10.30) at 40.0 °C. Starting isomers are *u-fac* (a), *mer* (b), and *s-fac* (c). Each of the lines is the curve calculated from the data at Table 2 by using Runge-Kutta method.

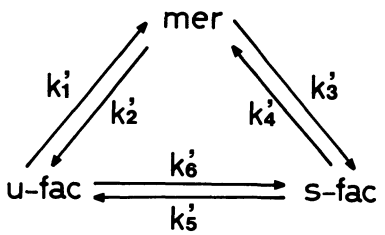
s-fac (Fig. 2-c), of which the rate was very slow, produced *mer* at first and then *u-fac*. The amount of *u-fac* exceeded that of *mer* after about 70 h. The equilibrium mole ratio of the three isomers was *u-fac*:*mer*:*s-fac*=25:19:56%.

In the isomerization of the [Co(ida)(dien)]+ system, the reaction paths are described as Scheme 2. The rate constants (k_1'—k_6') were obtained on the basis of the following procedure. Tentative values of the rate constants, k_1'—k_6', were estimated from the initial rates and the equilibrium mole ratio of the three isomers. Curves of the concentration change of each isomer was obtained by Runge-Kutta method[10] using these tentative rate constants. The calculation of Runge-Kutta method was repeated using the modified



Scheme 2.

values of the rate constants until the difference between the calculated curves and the observed ones was minimized. The results are listed in Table 2 and the best-fit curves are shown in Fig. 2. The *u-fac*⇌*s-fac* change hardly occurs (Table 2). Thus, the main

isomerization paths of [Co(ida)(dien)]$^+$ system can be described as in Scheme 1, which is found in the isomerization reaction of the [Co(ida)$_2$]$^-$ system.

The isomerization reaction of the [Co(ida)(dien)]$^+$ system was also carried out under the conditions of pH 10.00 and 10.60 at 40.0 °C, and analyzed by the same method as described above. The pseudo-first-order rate constants (k_n') and second-order rate constants (k_n=k_n'/[OH$^-$]) are listed in Table 2. Judging from the constancy of k_n, the rate law for each isomerization path can be described as R=k_n[complex][OH$^-$]. It is probable that the isomerization of the [Co(ida)(dien)]$^+$ system proceeds through the conjugate base intermediate. In the isomerization reaction of the [Co(ida)-(dien)]$^+$ system, other species except for three geometrical isomers were little detected. This fact suggests that the ligand dissociation is not involved in the reaction; if such dissociation was involved, the reaction should provide hydrolysis products. Thus, the isomerization must involve only the intramolecular paths. We can consider two possibilities for the intramolecular rearrangement; twist proceeding through the trigonal prismatic transition state and bond rupture forming a five-coordinate intermediate and followed by rearrangement within the intermediate by a subsequent recoordination of the COO$^-$ group. The *mer*⇌*s-fac* change (in Scheme 2) can be sufficiently explained in terms of only the bond-rupture mechanism, whereas the *u-fac*⇌*mer* (and also *u-fac*⇌*s-fac*) change may be described by the mechanisms of both bond rupture and twist.

Isomerization of the [Co(ida)(mdien)]$^+$ System. The isomerization reactions using *u-fac*- and *mer*-[Co(ida)(mdien)]$^+$ as the starting materials were carried out under the conditions of pH 10.30 and I=0.1 M at 40.0 °C. The reaction rate was relatively faster in the [Co(ida)(mdien)]$^+$ system than in the [Co(ida)(dien)]$^+$ system. The concentration changes in the starting materials and products are shown in Figs. 3-a and 3-b. A part of the numerical data (five data points) are listed in Table 1.[9] In the isomerization reactions of both *u-fac* and *mer*, a small amount of pink by-product was formed together with the other isomers in the initial stage of the reactions. The pink by-product

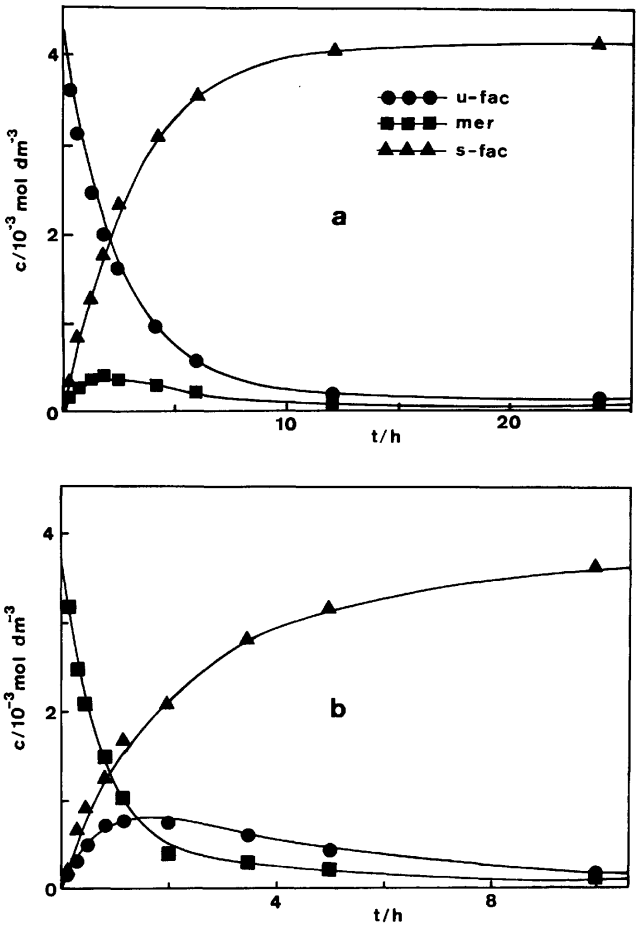

Fig. 3. The isomerization reaction of [Co(ida)(mdien)]$^+$ in a basic aqueous solution (pH 10.30) at 40.0 °C. Starting isomers are *u-fac* (a) and *mer* (b). Each of the lines is the curve calculated from the data in Table 2 by using Runge-Kutta method.

was eluted prior to the mixture of *u-fac* and *s-fac* but posterior to *mer* on SP-Sephadex column chromatograph. Therefore, the pink by-product must be +1 charged one. The pink by-product could not be isolated, because it was unstable and was formed only in a small amount. During the concentration of a solution containing the pink by-product under reduced pressure at 35—40 °C, the pink by-product changed to *s-fac*. The amount of the pink by-product was esti-

mated on the basis of the absorption spectrum of the *s-fac* formed from the pink by-product. The amount of the pink by-product was maximal about 30 min after the start of the reaction. It is likely that the pink by-product was a monoaqua species whose formation competes with isomerization in a bond-rupture process. No other species, except for three geometrical isomers and pink by-product, were detected in the isomerization reaction of the [Co(ida)(mdien)]+ system. At the final stage of the reaction, *s-fac* was the main product.

The base-catalyzed isomerization reaction of the [Co(ida)(mdien)]+ system was also analyzed by the Runge–Kutta method assuming Scheme 2. In this calculation, the formation of the pink by-product was neglected. The results are listed in Table 2, indicating that the reactions proceed through three intramolecular paths. The calculated curves of the concentration changes by Runge-Kutta method are shown in Fig. 3. It is worth noting that the *u-fac*⟶*s-fac* change occurs very easy in the [Co(ida)(mdien)]+ system but hardly in the [Co(ida)(dien)]+ system.

The *u-fac*⇌*mer* change can be explained in terms of both bond rupture and twist. However, the fact that the isomerization rate is faster in the mdien complex than in the dien complex (Tables 1 and 2) is not favorable to the twist mechanism, judging from the view point of the intramolecular steric factor. The equilibrium mole ratio of three isomers of [Co(ida)(mdien)]+ were *u-fac*:*mer*:*s-fac*=3:3:94%. The equilibrium further shifts to *s-fac* side compared with that of the [Co(ida)(dien)]+ system. Similarly, the equilibriums of [Co(ida)(mida)]− and [Co(dien)(mdien)]3+ systems shift more to *s-fac* side compared with those of the $[Co(ida)_2]^-$ and $[Co(dien)_2]^{3+}$ systems respectively.[2,3] These tendencies may be explained by the intramolecular steric repulsion.

Isomerization of the [Co(mida)(dien)]+ and [Co(mida)(mdien)]+ Systems. The isomerization reactions of the [Co(mida)(dien)]+ and [Co(mida)(mdien)]+ systems were studied under the conditions of pH 10.30 at 40.0 °C. A part of the numerical data are listed in Table 1. The *s-fac* isomer of [Co(mida)(dien)]+ was stable under the reaction conditions; other species, such as isomerization and/or hydrolysis products, were scarcely detected throughout a reaction of over 80 h. As shown in Table 1, the *u-fac*- and *mer*-[Co(mida)(dien)]+ interconverted each other accompanying the formation of unknown by-products with more than 2+ charge in a considerable amount. The *s-fac* isomer was scarcely formed in the isomerization reactions of *u-fac* and *mer*. In the isomerization of *mer*-[Co(mida)(mdien)]+, *u-fac* and *s-fac* were formed simultaneously, while in the isomerization of *u-fac*-[Co(mida)(mdien)]+, *mer* was mainly formed. The isomerization of *s-fac* was very slow. In these isomerization reactions, considerable amounts of unknown by-products with more than 2+ charge were formed. The isomerization reactions of the [Co(mida)(dien)]+ and [Co(mida)(mdien)]+ systems were complicated, so that the reaction processes could not be analyzed.

The CD Decrease of Optically Active *u-fac* Isomers. The rates of CD decrease of optically active *u-fac* isomers were measured under the conditions of pH 10.30 at 40.0 °C. In each case of [Co(ida)(dien)]+, [Co(ida)(mdien)]+, and [Co(mida)(dien)]+, the intensities of CD at two arbitrary wavelengths decreased in the same ratio, and the isocircular dichroism points lay on the base line. This fact indicates that no optically active products are formed. The rate constants of the CD decrease, k_{CD} (s^{-1}), for $(+)^{CD}_{538}$-*u-fac*-[Co(ida)(dien)]+ is $24\times10^{-6}\ s^{-1}$, which is larger than the sum of values of k_1' and k_6' (Table 2), probably indicating that racemization of *u-fac* itself occurs. The value of k_{CD} for $(-)^{CD}_{550}$-*u-fac*-[Co(ida)(mdien)]+ is $128\times10^{-6}\ s^{-1}$, which is nearly equal to the sum of the values of k_1' and k_6'. Therefore, the CD decrease of *u-fac*-[Co(ida)(mdien)]+ is attributed to the isomerization reaction. The rate of CD decrease for $(+)^{CD}_{544}$-*u-fac*-[Co(mida)(dien)]+ ($k_{CD}=84\times10^{-6}\ s^{-1}$) was also close to the rate of the decrease of the *u-fac* due to isomerization and decomposition.

For each of [Co(ida)(dien)]+, [Co(ida)(mdien)]+, and [Co(mida)(dien)]+, no optically active *mer* isomer was obtained from the isomerization reaction of optically active *u-fac* (as described above). However, this fact does not imply that the path of the *u-fac*⇌*mer* change is not stereoselective, because the racemizations of these *mer* are very fast under the present reaction conditions (vide post).

Figure 4 shows the CD spectral change of $(+)^{CD}_{564}$-*u-fac*-[Co(mida)(mdien)]+ with the passage of time under the conditions of pH 10.30 at 40.0 °C. The isocircular

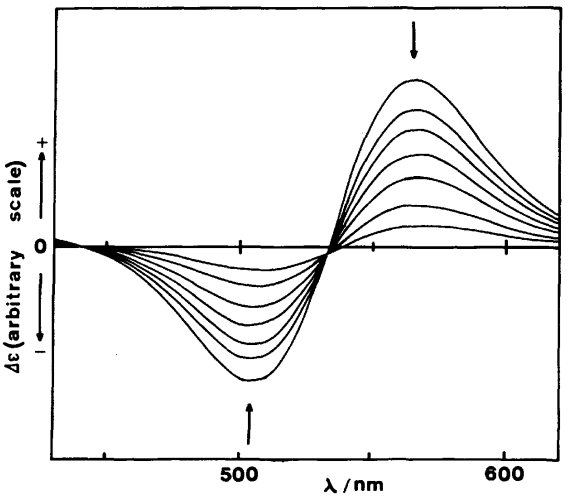

Fig. 4. The CD spectral change of $(+)^{CD}_{564}$-*u-fac*-[Co(mida)(mdien)]+ in a basic aqueous solution (pH 10.30) at 40.0 °C. Each of the curves was recorded at 2, 12, 19, 28, 39, 60, and 101 min, respectively.

dichroism points do not lie on the base line. This observation indicates the formation of an optically active product (*mer*). The reaction solution was acidified in order to stop the reaction 30 min after its start; then, optically active *mer* in the reaction solution was isolated by SP-Sephadex column chromatography. As shown in Fig. 5, the *mer* formed from $(+)^{CD}_{564}$-*u-fac* isomer is $(+)^{CD}_{582}$ form, and its optical purity is presumed to be considerably high, because its CD strength is comparable to that of pure $(-)^{CD}_{570}$-*mer*-[Co(mida)(dien)]$^+$. The absolute configuration of $(+)^{CD}_{564}$-*u-fac* has been determined to *ΛΔΛ*.[7a] The absolute configuration of $(+)^{CD}_{582}$-*mer* can be assigned to *λ*-spiral by a comparison of the CD spectral pattern with that of $(-)^{CD}_{570}$-*mer*-[Co(mida)(dien)]$^+$, the absolute configuration of which has been determined to be *δ*-spiral by the X-ray diffraction method.[12] The stereoselectivity in the *u-fac*⟶*mer* change (Scheme 3) may be attributed to the steric repulsion of two CH_3 groups in the isomerization process.

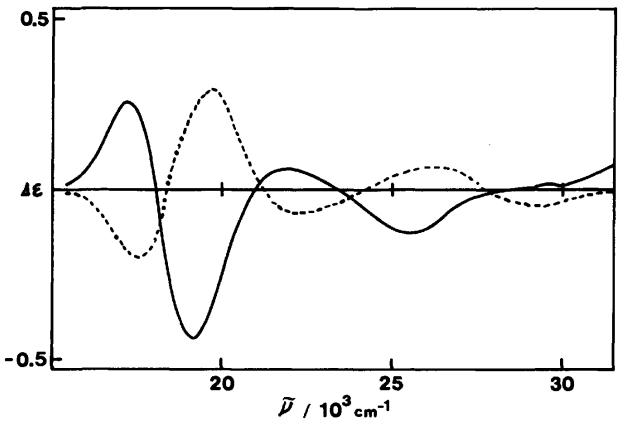

Fig. 5. CD spectral measured in 0.1 M HCl: $(-)^{CD}_{570}$-*mer*-[Co(mida)(dien)]$^+$ (·····) and $(+)^{CD}_{582}$-*mer*-[Co(mida))(mdien)]$^+$ (——) formed from $(+)^{CD}_{564}$-*u-fac* isomer.

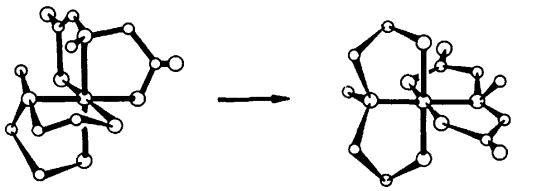
Racemization of *mer*-[Co(ida)(dien)]$^+$ and *mer*-[Co(mida)(dien)]$^+$. Two *mer* isomers, *mer*-[Co(ida)(dien)]$^+$ and *mer*-[Co(mida)(dien)]$^+$, have been resolved into optically active ones; however, we have not yet been successful with *mer*-[Co(ida)(mdien)]$^+$. The enantiomer of these *mer* are designated by the *δ*- or *λ*-spiral configuration, due to the arrangement of the two trans N-H groups in *mer*-[Co(ida)(dien)]$^+$ or due to the arrangement of the trans N-H and N-CH_3 groups in *mer*-[Co(mida)(dien)]$^+$; the absolute configurations of $(-)^{CD}_{570}$-*mer*-[Co(mida)(dien)]$^+$ and $(-)^{CD}_{560}$-*mer*-[Co(ida)-(dien)]$^+$ are assigned to the *δ*-spiral configuration.[12] The CD spectra of $(+)^{CD}_{560}$-*mer*-[Co(ida)(dien)]$^+$ and $(-)^{CD}_{570}$-*mer*-[Co(mida)(dien)]$^+$ changed with time in an acetate buffer solution (pH 4.20—6.00 at 30—40 °C). The isocircular dichroism points lay on the base line and the values of the CD intensities at various wavelengths decreased in the same ratio. The absorption spectra did not change during a CD measurement, indicating that no isomerization and/or hydrolysis oc-



Scheme 3.

Table 3. Rate Constants and Activation Parameters for Racemization of $(+)^{CD}_{560}$-*mer*-[Co(ida)(dien)]$^+$ and $(-)^{CD}_{570}$-*mer*-[Co(mida)(dien)]$^+$ Ions (I=1.0 M)

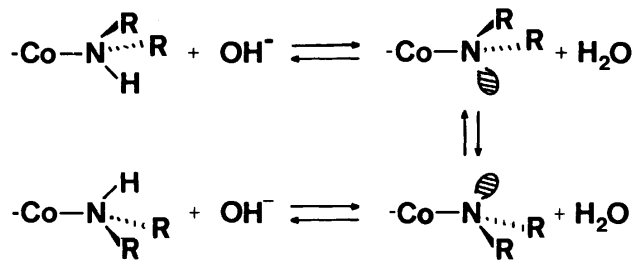

Scheme 4.

curred. Therefore, the CD decreases can be due to racemizations of *mer*, themselves. The progress of the racemization was followed by monitoring the decrease of the CD intensity at 560 nm for *mer*-[Co(ida)(dien)]+ and at 570 nm for *mer*-[Co(mida)(dien)]+. Kinetic data are summarized in Table 3. The values of the racemization rate constant k_{rac} ($=k_{rac}'/[OH^-]$) for *mer*-[Co(ida)-(dien)]+ at 30.0 °C are essentially constant, so that the rate law is described as $R=k_{rac}$[complex][OH^-]. Activation energies E_a were calculated by a least-squares method of the Arrhenius plots of k_{rac}. The activation parameters calculated for the two complexes are given in Table 3. The racemization rate of *mer*-[Co(mida)-(dien)]+ is about one order faster than that of *mer*-[Co(ida)(dien)]+, and the activation enthalpy of the former is smaller than that of the latter. It seemes likely that the electron-donative CH_3 group exerts a trans effect in *mer*-[Co(mida)(dien)]+, enhancing the racemization rate. A similar trans effect (enhancing of the racemization rate) was observed in the racemization of *mer*-[Co(edma)(mdien)]2+.[13]

All of the racemization data for the present complexes can be explained according to the mechanism shown in Scheme 4, proposed for the racemizations of *mer*-[Co(dien)$_2$]3+ [14] and *mer*-[Co(edma)(dien)]2+.[13] This proposal can be supported by the fact that optically active *mer*-[Co(mida)(mdien)]+ did not racemize, even in a weakly basic aqueous solution.

The racemization rates for *mer*-type complexes increase in the order of [Co(dien)$_2$]3+<[Co(edma)-(dien)]2+<[Co(ida)(dien)]+. The difference in the racemization rates may be attributed to the electronic property of the chelates. The electronegative carbonyl group decreases the electron density on the secondary amine nitrogen center, in which inversion occurs. Consequently, the pre-equilibrium of Scheme 4 displaces to the deprotonated form and the racemization rate increases.

(Received October 24, 1988)

A reddish brown oxovanadium(V) complex, [V^{V}O(sal-L-ala)(OCH$_3$)(CH$_3$OH)] (**2a**, sal-L-ala=*N*-salicylidene-L-alaninate) was formed by dissolving [V^{IV}O(sal-L-ala)(H$_2$O)] (**1a**) in methanol. Treatment of **2a** with wet dichloromethane yielded deep blue crystals of {[V^{V}O(sal-L-ala)]$_2$O}$_2$·2CH$_2$Cl$_2$ (**3a**). The structures of **2a** and **3a** have been determined by X-ray analyses. Crystal data are: [VO(sal-L-ala)(OCH$_3$)(CH$_3$OH)] (**2a**), monoclinic, *C*2, *a*=19.621(6), *b*=6.734(1), *c*=12.059(4) Å, *β*=117.72(2)° and *Z*=4. {[VO(sal-L-ala)]$_2$O}$_2$·2CH$_2$Cl$_2$ (**3a**), orthorhombic, $P2_12_12_1$, *a*=19.938(4), *b*=23.854(5), *c*=11.526(2) Å, and *Z*=4. In **2a**, the tridentate sal-L-ala ligand and a methoxide ion occupy the basal positions, and form distorted octahedral geometry around the vanadium(V) ion together with one methanol molecule (V–O distance: 2.384(4) Å) and the oxide ion of oxovanadium(V). The tetranuclear complex (**3a**) consists of two *μ*-oxo dinuclear vanadium(V) complexes, and each vanadium(V) ion has a distorted octahedral coordination. The Schiff base coordinates equatorially to each vanadium(V) ion, of which one axial site is occupied by O^{2-} and the other is weakly linked to the carboxylate O atom of a nearby Schiff base (V–O distance: 2.34—2.56 Å). Octahedral coordination on each vanadium(V) is achieved by sharing an equatorial O^{2-} ligand. The brown complexes, [VO(sal-L-aa)(OCH$_3$)(CH$_3$OH)] (**2**, sal-L-aa=*N*-salicylidene L-amino carboxylate) catalyze the oxidation of methyl phenyl sulfide with *t*-butyl hydroperoxide in dichloromethane at 4 °C to give (*R*)-methyl phenyl sulfoxide with optical yields (e.e.) of 8—14%.

In a previous paper,[1] we reported that optically active tetradentate Schiff base–oxovanadium(IV) complexes catalyze asymmetric oxidation of sulfides into the corresponding sulfoxides with organic hydroperoxides. However, neither the mechanism nor the characterization of useful precursors was discussed in detail. Recently, we found that the oxovanadium(V) complex with a tridentate $^{-}$O–N–O^{-}-type ligand, [V^{V}O(dipic)(OOBu^{t})(H$_2$O)] (H$_2$dipic=2,6-pyridinedicarboxylic acid, HOOBu^{t}=*t*-butyl hydroperoxide)[2] catalyzes a similar reaction very efficiently.[3] Thus, it seems interesting to examine catalytic activity of oxovanadium(V) complexes with optically active, tridentate $^{-}$O–N–O^{-}-type Schiff base ligands.

This paper deals with the preparation and characterization of oxovanadium(V) complexes with *N*-salicylidene L-amino carboxylates, X-ray crystal structure analysis of the L-alanine derivatives, and their catalytic activity on asymmetric oxidation of methyl phenyl sulfide with *t*-butyl hydroperoxide.

Experimental

Synthesis. [V^{V}O(sal-L-aa)(OCH$_3$)(CH$_3$OH)] (2) (L-aa=L-ala, L-phe, L-val, and L-leu). These complexes were prepared by a method similar to that of Gillard et al.[4] The procedure is described for the L-ala derivative. The other three complexes were prepared by similar procedures. [V^{IV}O(sal-L-ala)(H$_2$O)][5] (**1a**) (2.11 g, 7.65 mmol) was dissolved in methanol (50 cm^3) to give a reddish brown solution. The solvent was evaporated slowly in a refrigerator to yield brown crystals of [V^{V}O(sal-L-ala)(OCH$_3$)(CH$_3$OH)] (**2a**), which were collected by filtration and air dried. Yield: 1.4 g (57%). Found: C, 44.67; H, 5.02; N, 4.36%. Calcd for C$_{12}$H$_{16}$NO$_6$V: C, 44.87; H, 5.02; N, 4.36%. Found: C, 54.12; H, 4.62; N, 3.72%. Calcd for [VO(sal-L-phe)(OCH$_3$)(CH$_3$OH)]=C$_{18}$H$_{20}$NO$_6$V (**2b**): C, 54.41; H, 5.07; N, 3.52%. Found: C, 47.89; H, 5.21; N, 4.27%. Calcd for [VO(sal-L-val)(OCH$_3$)(CH$_3$OH)]=C$_{14}$H$_{20}$NO$_6$V (**2c**): C, 48.14; H, 5.77; N, 4.01%. Found: C, 49.13; H, 5.60; N, 4.06%. Calcd for [VO(sal-L-leu)(OCH$_3$)(CH$_3$OH)]=C$_{15}$H$_{22}$NO$_6$V (**2d**): C, 49.59; H, 6.10; N, 3.86%.

{[VO(sal-L-ala)]$_2$O}$_2$·2CH$_2$Cl$_2$ (3a). Complex **2a** (1.4 g, 4.4 mmol) was dissolved in wet dichloromethane (30 cm^3), and the dark blue solution was evaporated to ca. 5 cm^3. The concentrate was allowed to stand in a refrigerator to yield dark blue crystals of **3a**. Yield: 0.9 g (66%).

Crystal Structure Analysis of 2a and 3a. Crystals of [V^{V}O(sal-L-ala)(OCH$_3$)(CH$_3$OH)] (**2a**) and {[V^{V}O(sal-L-ala)]$_2$O}$_2$·2CH$_2$Cl$_2$ (**3a**) were grown by slow evaporation, respectively, from methanol and dichloromethane solutions at room temperature. Crystal data and experimental details are listed in Table 1. A reddish brown prism of **2a** was coated first with paraffin and then with epoxy resin to avoid intensity changes during the data collection. The crystals of **3a** deteriorated when removed from the mother liquor, presumably owing to loss of the solvent of crystallization. A dark blue prism of **3a** was coated with epoxy resin. Intensity data for **2a** and **3a** were collected on a Rigaku AFC-5 and a Rigaku AFC-5R four-circle diffractometer, respectively, by use of graphite monochromatized Mo *Kα* radiation (*λ*= 0.71073 Å). Lattice constants were determined by least-squares calculations based on 2*θ* values ($22<2\theta<32°$) of 36 reflections for **2a**, and 30 2*θ* values ($20<2\theta<26°$) for **3a**. The

structures were solved by the direct method (MULTAN 78)[6] and refined by the block-diagonal least-squares method for **2a**, and by the full-matrix least-squares method for **3a**. The absolute configuration of the structures was assigned on the basis of the known configuration of the L-alanine moiety. The reason for the rather high R-value of **3a** (R=0.088, R_w=0.111) will be discussed later. Atomic scattering factors and anomalous scattering corrections were taken from Ref. 7. The final atomic parameters are listed in Table 2. All the calculations were carried out on a HITAC M-680 computer at the Computer Center of Institute for Molecular Science using the Universal Crystallographic Computation Program System UNICS-III[8] for **2a** and RADIEL[9] for **3a**. Lists of observed and calculated structure factors, anisotropic thermal parameters for nonhydrogen atoms, and the coordinates of hydrogen atoms, and the ORTEP drawings of crystal structures are deposited at the office of the Chemical Society of Japan (Document No. 8861).

Reactions. Reaction of 3a with Organic Hydroperoxide. To a dichloromethane solution of **3a** was added ten times molar quantity of 1-methyl-1-phenylethyl hydroperoxide (73%). The color of the solution changed immediately from deep blue to reddish brown. Hexane was added to this solution slowly, and the mixture was allowed to stand in a refrigerator to yield brown crystals (**4a**). Complex **4a** is unstable both in solution and in the solid state. When *t*-butyl hydroperoxide was used instead of 1-methyl-1-phenylethyl hydroperoxide, a similar color change occurred but the product was not isolated because of its high solubility in common organic solvents.

Oxidation of Methyl Phenyl Sulfide by *t*-Butyl Hydroperoxide with a Catalytic Amount of 2. To a dichloromethane solution (10 cm^3) of **2** (0.1 mmol) were added methyl phenyl sulfide (1.0 mmol) and *t*-butyl hydroperoxide (80%, 1.0 mmol), and the mixture was kept at 4 °C. After 5.5—8 h, the solvent was removed under reduced pressure, and the residue was extracted with diethyl ether. The solvent was evaporated off, and methyl phenyl sulfoxide was isolated from the resulting oil. It was purified by column chromatography on silica gel (ϕ 1.0 cm×10 cm, eluent: ethyl acetate–cyclohexane (1:1 (v/v)). The enantiomeric excess (e.e.) was determined on the basis of the reported optical rotation of the pure enantiomer.[10]

Spectroscopic Measurements. ^{1}H NMR spectra were recorded on a JEOL GX-400 spectrometer using TMS as an internal reference. Optical rotations were measured with a JASCO DIP 4 polarimeter. Absorption spectra were recorded on a Hitachi U-3400 spectrophotometer.

Results and Discussion

Characterization and X-Ray Analysis of the Complexes. [V^{V}O(sal-L-ala)(OCH$_3$)(CH$_3$OH)]: The bluish-gray oxovanadium(IV) complexes (**1**) with the general formula of VO(sal-aa)(H_2O) were prepared by Theriot et al. and characterized as a square pyramidal complex with an aqua ligand at the basal site.[5] Recently, this structure was confirmed by X-ray analysis on the L-alanine derivative.[11] Gillard et al.[4] obtained brown complexes (**2**) from methanol solutions of the bluish-gray complexes (**1**) (Scheme 1). They assigned **2** to monomeric oxovanadium(V) species with the formula [V^{V}O(sal-aa)(OCH$_3$)(CH$_3$OH)], the oxidizing agent being suggested to be atmospheric oxygen. The assignment was confirmed by the present X-ray structure determination on [V^{V}O(sal-L-ala)(OCH$_3$)(CH$_3$OH)] (**2a**). Complex **2a** was prepared from [V^{IV}O(sal-L-ala)-(H_2O)] by a method similar to that of Gillard et al.[4] without any particular oxidizing agent.

Figure 1 shows a perspective view of **2a**. Selected bond distances and angles are listed in Tables 3 and 4.

a) Equivalent isotropic temperature factors ($B_{eq}=4/3\{\sum_i\sum_j B_{ij}a_ia_j\}$) for noncarbon atoms, and isotropic temperature factors for carbon atoms.

The complex has a distorted octahedral coordination. The tridentate Schiff base ligand and a methoxide ion occupy the basal positions, and one methanol molecule (V–O distance: 2.384(4) Å) coordinates at the position trans to the oxo group. Thus the complex has a V^vO^{3+} core and the oxidizing agent should be atmospheric oxygen. Since oxidation of $V^{IV}O^{2+}$ is reported to form a *cis*-$V^vO_2^+$ core preferentially,[12] the present result is quite characteristic. The vanadyl V^v=O distance (1.579(3) Å) is almost the same as that (1.578(3) Å) in [V^{IV}O(sal-L-ala)(H_2O)] (**1a**).[11] The V=O bond length seems to be scarcely influenced by the oxidation of the vanadium ion. The vanadium(V) ion of **2a** deviates by 0.306 Å from the best least-squares equatorial plane towards the vanadyl O atom. In [V^vO(salen)ClO_4] (H_2salen=*N*,*N*′-disalicylideneethylenediamine), the

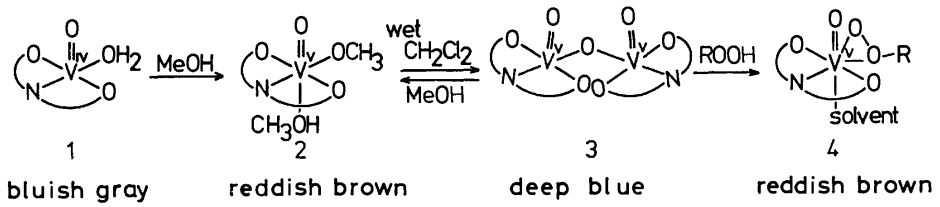

Scheme 1.

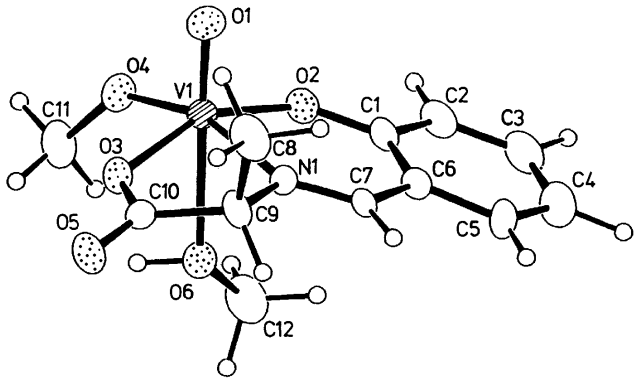

Fig. 1. ORTEP drawing and atom-numbering scheme for [V^{V}O(sal-L-ala)(OCH_3)(CH_3OH)] (**2a**). Vanadium and oxygen atoms are shown as shaded and dotted circles, respectively.

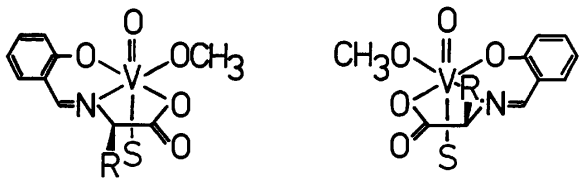

Fig. 2. Two possible geometrical isomers of [V^{V}O-(sal-L-aa)(OMe)(MeOH)], and S denotes a methanol molecule.

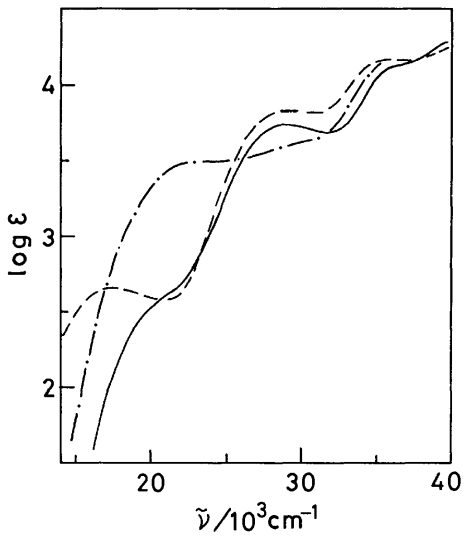

Fig. 3. Absorption spectra of [V^{V}O(sal-Lala)(OCH_3)-(CH_3OH)] (**2a**, ca. 1×10^{-3} mol dm^{-3} in the visible region and ca. 1×10^{-4} mol dm^{-3} in the UV region) in methanol (——), in wet dichloromethane (— — —) to form [VO(sal-L-ala)]$_2$O, and in wet dichloromethane in the presence of a large excess of *t*-butyl hydroperoxide (—·—) to form **4**.

vanadium atom is displaced towards the vanadyl O atom by 0.318 Å from the best salen N_2O_2 least-squares plane, and the V–O (perchlorate) length is relatively long (2.456(3) Å).[13] The vanadyl V^{V}=O distance of 1.576(3) Å in this complex is nearly the same as that of **2a**, but is shorter by 0.012 Å than the V^{IV}=O distance of [V^{IV}O(salen)].[14]

For the [VO(sal-L-aa)(OCH_3)(CH_3OH)] (**2**) complexes, two geometrical isomers are possible with respect to the mutual disposition of the substituent on L-aa and the V=O group (Fig. 2). The crystal of **2a** subjected to the present analysis contains the endo isomer. However, the ^{1}H NMR spectrum of complex **2a** in CD_3OD gives two doublet methyl signals due to the L-ala moiety at δ 1.60 and 1.73 in a relative ratio of 3:4, indicating the existence of two isomers. Since rapid isomerization between the two isomers is very unlikely, the complex obtained by the present synthesis will be a mixture of the two isomers. Attempts to separate the isomers by fractional crystallization were unsuccessful. Other methanolato complexes **2b—2d** were assigned to the same structure as **2a**, since the absorption spectra of these complexes are very similar to that of **2a** shown in Fig. 3.

[V^{V}O(sal-L-ala)]$_2$O·CH_2Cl_2: When the brown complex, **2a** was dissolved in wet dichloromethane, the color of the solution changed immediately from reddish brown to dark blue (Fig. 3), from which the dark blue crystals, **3a** were obtained (Scheme 1). Theriot et al.[15] obtained a green complex by a similar reaction and assigned it as a dimeric vanadium(IV) complex with the formula [V^{IV}O(sal-L-ala)(H_2O)]$_2$ on the basis of the data of magnetic susceptibility and molecular weight measurements, the carboxylate oxygen atoms being suggested to bridge the vanadium atoms. However, compound **3a** has the chemical composition of [VO(sal-L-ala)]$_2$O·CH_2Cl_2 and is ESR inactive both in the solid state and in frozen

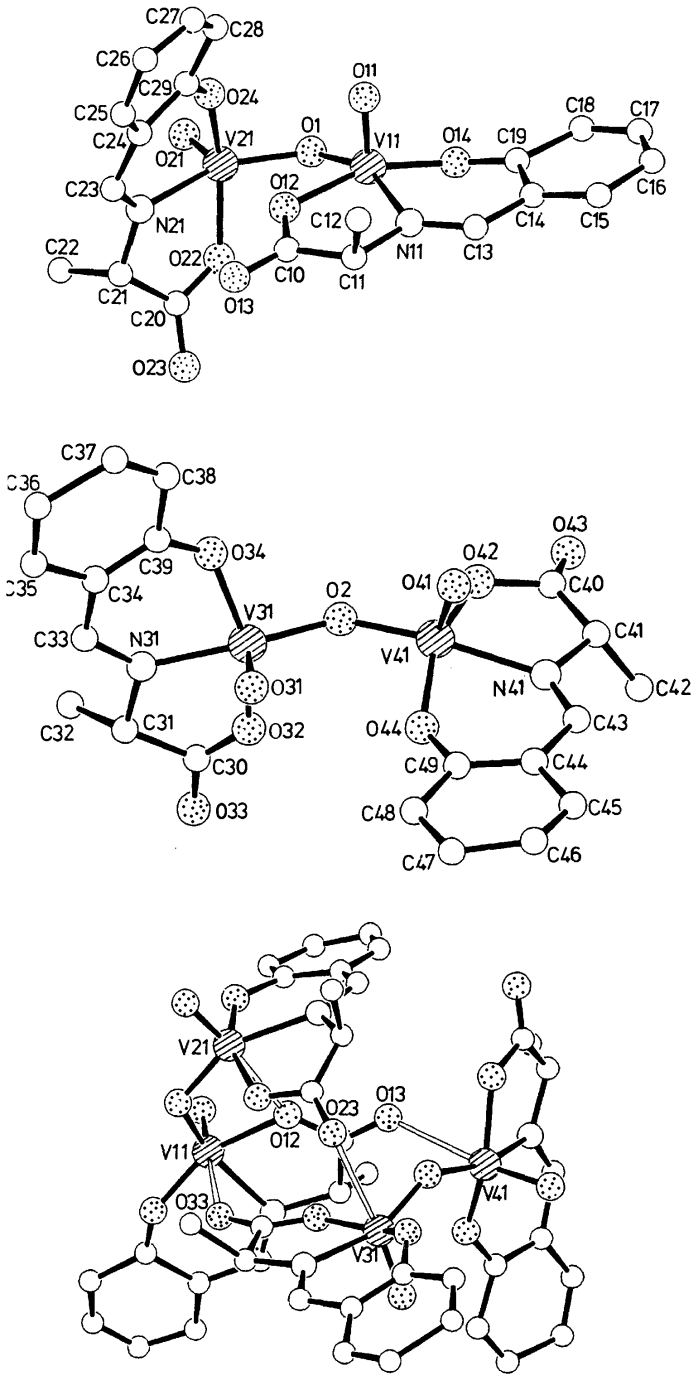

Fig. 4. ORTEP drawings and atom-numbering schemes for **3a-1** (endo form) (a), **3a-2** (exo form) (b), and the tetranuclear unit (**3a**) consisting of **3a-1** and **3a-2** (c). Vanadium and oxygen atoms are shown as shaded and dotted circles, respectively. Open rods indicate weak V–O bonds.

dichloromethane. These facts indicate that the oxidation state of vanadium is +5. The ^{1}H NMR spectrum of **3a** in CD_2Cl_2 exhibits two methyl doublets at δ 1.49 and 1.55 with the same intensity.

The X-ray analysis of **3a** disclosed that two isomeric dimers, **3a-1** and **3a-2** exist in a unit cell together with dichloromethane molecules (Fig. 4). Dimers **3a-1** and **3a-2** are close to each other to form a tetranuclear unit (Fig. 4(c)) and linked by weak bonds between vanadium atoms and carboxylate oxygen atoms of nearby Schiff bases with V–O distances of 2.344(17)—2.562(16) Å (Fig. 4(c)). The geometry around each vanadium atom can be described as a distorted octahedron. The tridentate Schiff base ligand coordinates in the basal plane. The vanadyl O atom occupies an axial site, and the carboxylate O atom of a nearby Schiff base ligand weakly coordinates at the site trans to the oxide ion. The octahedral coordination is completed by sharing an equatorial O^{2-} ligand. The two halves of each dimeric unit have the same geometrical configuration with respect to the disposition of the methyl and V=O groups; **3a-1** consists of two endo isomers while **3a-2** two exo isomers. Each V atom is displaced toward the vanadyl O atom by 0.291—0.363 Å from the equatorial plane. Close contact between O(31) and O(44) in **3a-2** is avoided by the large V(31)–O(2)–V(41) angle (141.4(10)°). In **3a-1**, there is no such close contact around the bridging group, and the V(11)–O(1)–V(21) angle is 116.2(8)°.

The dichloromethane molecules are highly disordered and are continuously distributed along the c-axis in a tunnel structure of the crystal. This structure should be responsible for the loss of solvent of crystallization and also for the large thermal parameters. Thus enough numbers of reflection data were not obtained to determine more accurate structure. An attempt of low temperature measurement was not effective.

Complex **3a** was formed by the treatment of **2a** with wet dichloromethane, but regenerated **2a** on treatment with methanol (Scheme 1). It is to be noted that **3a** is not formed when **2a** is dissolved in anhydrous dichloromethane. Thus the bridging oxygen atom seems to come from water in wet dichloromethane. Brown complex **4a** was obtained by the reaction of **3a** with 1-methyl-1-phenylethyl hydroperoxide in dichloromethane. The complex was unstable both in solution and in the solid state. When *t*-butyl hydroperoxide was used instead of 1-methyl-1-phenylethyl hydroperoxide, a similar color change occurred but the product was not isolated. Figure 3 shows the absorption spectrum of **3a** in the presence of a large excess of *t*-butyl hydroperoxide. Structure determination of **4a** was not achieved because of its instability. Organic peroxide complexes of vanadium(V) with dipic have been prepared and the structure of $[VO(dipic)(OOBu^t)(H_2O)]$ has been determined by the X-ray method.[2] This complex takes a pentagonal bipyramidal structure, the basal positions of which are occupied by two oxygen atoms of the peroxo group, and one nitrogen and two oxygen atoms of the dipic ligand. The peroxide ligand in the complex was

Table 5. Asymmetric Oxidation of Methyl Phenyl Sulfide to the Sulfoxide with *t*-Butyl Hydroperoxide by Complex Catalyst **2** (4°C)[a]

Entry	Complex catalyst	Time/h	Yield/%[b]	e.e./%[c]	Sulfoxide configuration
1	**2a**	8	50	4	*R*
2	**2b**	8	80	11	*R*
3	**2c**	6	78	14	*R*
4	**2d**	5.5	84	9	*R*

a) All reactions were performed as described in detail in Experimental. Molar ratio of complex catalyst: *t*-butyl hydroperoxide: methyl phenyl sulfide=1:10:10. b) Isolated yields, based on the sulfide. c) Based on the optical rotation of the pure enantiomer reported in Ref. 10.

reported to dissociate partially in a $(CD_3)_2CO$ solution by the NMR spectrum. Complex **4a** gives a reddish brown solution when dissolved in dichloromethane, but the color changed to violet brown within a few minutes at room temperature. The ^1H NMR spectrum of **4a** in CD_2Cl_2 shows a singlet methyl signal at δ 1.58 (6H) and multiplet phenyl signals at δ 7.25—7.56 (5H). These signals are identical with those of free 1-methyl-1-phenylethyl hydroperoxide in the same solvent. No signal attributable to the coordinated hydroperoxide was observed in the spectrum. The structure of complex **4a** remains unknown, but the complex seems to contain the peroxide coordinated to the vanadium(V) ion in a similar manner to the above dipic complex, and seems to release the peroxide rapidly on dissolution in dichloromethane. The peroxide complex will be formed only in the presence of a large excess of the peroxide.

The ^1H NMR spectrum of **4a** in CD_2Cl_2 changes within a few days at room temperature. Intensity of the methyl signal due to free 1-methyl-1-phenylethyl hydroperoxide at δ 1.58 becomes weaker and new signals grow gradually at δ 1.55, 2.12, and 2.58, which were assigned to the methyl groups of 2-phenyl-2-propanol, acetone, and acetophenone, respectively. In the absence of complex, such reductive decomposition of the hydroperoxide proceeds much more slowly.

Catalytic Activity of the Complexes. Table 5 shows the results of asymmetric oxidation of methyl phenyl sulfide with *t*-butyl hydroperoxide catalyzed by **2a—2d** in CH_2Cl_2. Dissolving **2** in wet dichloromethane yields a deep blue solution of **3**, and the color of the solution changes immediately to reddish brown on the addition of excess *t*-butyl hydroperoxide to form the peroxo complex **4** (Scheme 1 and Fig. 3). The activated peroxide in **4** will oxidize sulfides. For example, methyl phenyl sulfide is oxidized to the sulfoxide in CH_2Cl_2 with *t*-butyl hydroperoxide almost completely in 20 min at room temperature in the presence of a catalytic amount of **2a**. It was found that $[V^VO(dipic)(OOBu^t)(H_2O)]$ is also an excellent catalyst for the same oxidation in acetonitrile; the oxidation was completed in 10 min at room temperature.[3] On the other hand, the same reaction proceeds very slowly in dichloromethane with the oxovanadium(V) complexes containing tetradentate Schiff bases such as $[V^VO(sal\text{-}(RR)\text{-}chxn)X]$ ($H_2sal\text{-}(RR)$-chxn=(1*R*,2*R*)-*N*,*N*′-disalicylidene-1,2-cyclohexanediamine, X=ClO_4, Cl, NO_3), where the Schiff base occupies the four basal coordination sites.[16] Thus, sulfides seem to be oxidized easily only when the vanadium(V) ion can provide a basal coordination site for an organic peroxide. Since the ligand at the site trans to the vanadyl O atom is known to be replaced rapidly by another ligand, a sulfide (substrate) may coordinate at this apical site and be oxidized to the sulfoxide by the activated peroxide.

Recently, Colonna et al.[17] reported that oxidation of sulfides with *t*-butyl hydroperoxide in the presence of a catalytic amount of an oxovanadium complex containing sal-L-val led to racemic products, the characterization of the complex being not described. When **2** was used as the catalyst, however, (*R*)-methyl phenyl sulfoxide was obtained with an enantiomeric excess (e.e.) of 4—14% (Table 5). The e.e. seems to increase with a decrease in temperature. For example, at −30 °C the e.e. was 8% (*R*) for the same reaction with complex catalyst **2a**.

The Effect of pH and Counter Ion of Oxalate Ion on Photoreduction of Methylviologen

Hideyuki TAGAYA,* Hiroaki SAITO, Susumu SUDA, and Koji CHIBA*
Department of Applied Chemistry, Faculty of Engineering,
Yamagata University, Jonan, Yonezawa 992
(Received May 12,1988)

A higher formation of the methylviologen radical cation was observed at higher pH and when the counter ion of an oxalate ion was large in the continuous photolysis of deaerated solutions of methylviologen (MV^{2+})-oxalate ion ($C_2O_4^{2-}$). A dissociation of oxalic acid to the ion depended upon the pH at pH<7 and the dissociation constant of a MV^{2+}-$C_2O_4^{2-}$ complex depended on the pH at pH>10. The calculated absorbance of the MV^{2+}-$C_2O_4^{2-}$ complex at 350 nm, by using the dissociation constants of oxalic acid and the complex, agreed well with the observed absorbance. It was considered that the pH depedence of the MV^{+} formation resulted from the pH dependence of the concentration of the MV^{2+}-$C_2O_4^{2-}$ complex. The effect of a counter ion on the photoinduced electron transfer was explained in terms of the difference in the stability of the complex ion, in which smaller ions (Li^+, Na^+) tended to form more stable complexes than larger ions (NH_4^+, K^+).

Methylviologen (1,1′-dimethyl-4,4′-bipyridinum ion, MV^{2+}) has received considerable attention in recent years as being an efficient electron relay in the photocatalyzed reduction of water to hydrogen.[1] Therefore, reductions of MV^{2+} by various donors were carried out by many researchers.[2] On the other hand, an oxalate ion ($C_2O_4^{2-}$) has been used as a sacrificial electron donor.[3] The oxidation of the oxalate ion leads to the formation of $C_2O_4^{-}$, which undergoes rapid decomposition to CO_2 and CO_2^{-}. CO_2^{-} is well-known as a strong donor and gives CO_2 by donating an electron. Such a photoinduced irreversible electron transfer of carboxylic acid is known as the photo-Kolbe reaction.[4] In an electron acceptor–oxalate ion system it is expected that an electron-accepted molecule is stable for a long time because a back electron transfer from the electron-accepted molecule to $C_2O_4^{-}$ is minimized. Certainly it was reported that the continuous photolysis of a deaerated solution of MV^{2+}-$C_2O_4^{2-}$ generated MV^{+} which was stable for a long time.[5]

However, the study was carried out in an aqueous solution at neutral pH; no distinct discussion of the effect of the pH was presented. By elucidating the effect of the pH on the reaction, information on a reaction mechanism and most suitable conditions for a photoinduced electron transfer are given. Furthermore, the effect of a counter ion on a photoinduced electron transfer from an oxalate ion was scarcely mentioned. The photoinduced electron transfer from organic anions have been studied in relation to ion-pair phenomena.[6]

We undertook to investigate photoinduced electron transfer from anions.[7] In this work we carried out a continuous photolysis of the MV^{2+}-$C_2O_4^{2-}$ system and clarified the effects of the pH and counter ions of an oxalate ion on the yield of MV^{+} formation.

Experimental

Materials. Methylviologen dichloride (Nakarai) was used as received. $Li_2C_2O_4$, $Na_2C_2O_4$, $K_2C_2O_4$, and $(NH_4)_2C_2O_4$ were used without further purification. Aqueous solutions were prepared from distilled and deionized water and the pH was adjusted by the addition of KOH or NaOH to a $H_2C_2O_4$ solution.

Method. Aqueous solutions of MV^{2+} including oxalate ion were introduced into a 10 cm-long quarz cell jointed to a 2 mm quarz spectrophotometer cell. The concentrations of MV^{2+} and $C_2O_4^{2-}$ determined the concentration of the MV^{2+}-$C_2O_4^{2-}$ complex. In this study oxalate ions (0.1 M; 1 M=1 mol dm^{-3}) were in large excess to MV^{2+} (0.0025 M), in which about 70% of MV^{2+} formed a complex with the oxalate ions. Solutions for irradiation were thoroughly purged with Ar gas before irradiation, since MV^{+} reactions with O_2 to give MV^{2+} was well-known.[8] Irradiation was performed with a 500 W Xe lamp using an IRA-25S filter in which light longer than 300 nm was passed. Absorbance at 605 nm (extinction coefficient=1.37×10^4 M^{-1} cm^{-1})[9] due to the MV^{+} formed was monitored at determined time intervals.

Results and Discussion

The Effect of pH on the Yield of MV^{+}. The pH of MV^{2+}-$H_2C_2O_4$ solutions were adjusted by the addition of KOH (pH; 2.3—12.70); aqueous solutions of MV^{2+}-$H_2C_2O_4$ were irradiated for 5 h. The formation of MV^{+} depended upon the pH, as shown in Fig. 1. The production mechanism of the MV^{+} was complex because two MV^{2+} were reduced by one oxalate ion, despite one MV^{2+} formed complex with one oxalate ion (as described later). To avoid complexity we chose mild reaction conditions in which a small amount of MV^{2+} was reduced. It was expected in such conditions that MV^{2+} would be reduced linearly with the reaction time. However, the production rate of MV^{+} decreased with the reaction time over 2 h (Fig. 1). We must note here that the oxidation of an oxalate ion leads to the formation of two CO_2 which act as acid in an aqueous solution. Since the formation of MV^{+} was slow at low pH, lowering the pH might suppress the formation of MV^{+}. The concentration of CO_2 was calculated from the concentration of MV^{+} on the reaction at pH 7.2 for 5 h irradiation. The proton concentration, calculated

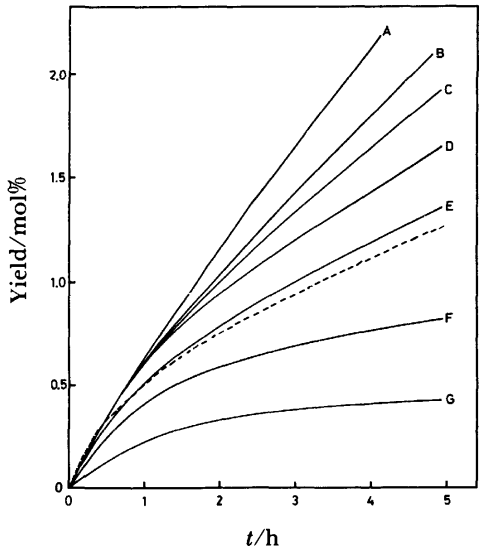

Fig. 1. The effect of pH on the yield of MV^+ in the irradiation of MV^{2+}-$K_2C_2O_4$ solutions. A; pH 12.70, B; 12.18, C; 10.61, D; 7.17, E; 5.60, F; 4.39, G; 3.0. The dotted line is the simulated curve.

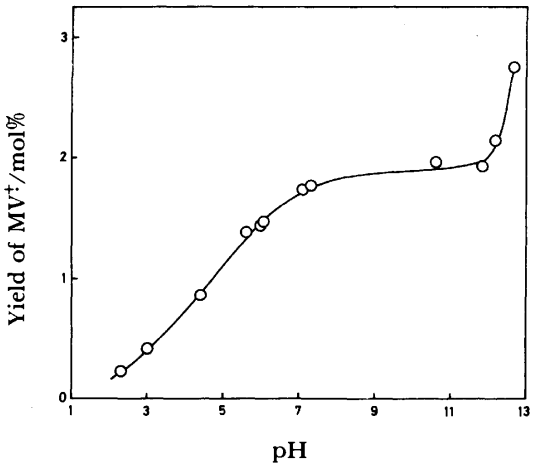

Fig. 2. The effect of pH on the yield of MV^+ in the irradiation of MV^{2+}-$K_2C_2O_4$ solutions for 5 h.

from the concentration of CO_2, reached 3×10^{-6} M, which could reduce the pH of the solution from 7.2 to 5.5 if all of the CO_2 was dissolved into the aqueous solution. The Ostwald solubility coefficient of CO_2 was 0.8280 at 25 °C, larger than 0.0341 of Argon gas.[10] However, The quantity of Argon present in the reaction vessel was larger by a factor of 10^4 than that of CO_2. This meant that a large amount of CO_2 was present as gas, indicating that the contribution of CO_2 to pH reduction was small. Certainly, the decrease of the production rate was observed not only at pH ca. 7, but also at low pH ca. 3, in which the proton concentration was an order of 10^{-3} M and CO_2, which evolved from an oxalate ion, could not change the pH of the solution. The decrease in the production rate with the reaction time could be explained in terms of the accumulation of MV^+. MV^+ possesses a strong absorption peak around 390 nm (extinction coefficient=4.2×10^4 M^{-1} cm^{-1} (1 M=1 mol dm^{-3}))[9] the extinction coefficient at 350 nm was 6000—7000 M^{-1} cm^{-1}. This value was fairly larger than 8.2 M^{-1} cm^{-1} of the MV^{2+}-$C_2O_4^{2-}$ complex at 350 nm (shown later). If the light intensity was reduced by the absorption of MV^+ which did not further react, a photoinduced electron transfer should be simply proportional to the absorption ratio of 8.2 [MV^{2+}-$C_2O_4^{2-}$] and 6500 [MV^+]+8.2 [MV^{2+}-$C_2O_4^{2-}$], in which the extinction coefficient of MV^+ was assumed to be 6500 M^{-1} cm^{-1} and the absorption by uncomplexed MV^{2+} was ignored. The dotted curve in Fig. 1 represents the calculated relationship between the reaction time and the yield of MV^+, considering the change of light intensity with the concentration of MV^+. The decrease in the production rate of MV^+ with the reaction time was well simulated. It was considered that the accumulation of MV^+ might suppress the photoinduced reaction, since MV^+ absorbed the light which was effective for the photoinduced reaction. Namely, MV^+ acted as a filter to reduce the light.

Higher yields of MV^+ were observed at higher pH's, as shown in Fig. 2, along with the yield of MV^+ for 5 h irradiation. An increase of the MV^+ yield at pH 2—5 and at above pH 11 was steep. It had already been reported that MV^{2+} was reduced to MV^+ in an alkaline aqueous solution in the absence of air without irradiation,[8b] and that the rate of MV^+ formation (R_i) obeyed the following rate law: $R_i=k_{obsd}[MV^{2+}]^2[OH^-]^2$: $k_{obsd}=0.12$ M^{-3} min^{-1} at 25 °C. We applied this rate law to our reaction conditions. The production of MV^+ was calculated as 0.02 mol% in the conditions at pH 12.7 for 5 h irradiation. The value was fairly small. We could not deny the possibility of the participation of OH^- in the high-pH region on the MV^{2+} reduction; however, the contribution of the reaction to MV^+ formation must be small.

The Effect of pH on the Absorption of MV^{2+}-Oxalate Solutions. It is well-known that MV^{2+} forms a complex with ionic and neutral species, such as $C_2O_4^{2-}$.[11] The absorption of a MV^{2+}-$C_2O_4^{2-}$ solution at $\lambda>300$ nm is larger than the absorption of MV^{2+} alone, despite the fact that $C_2O_4^{2-}$ possesses little absorption at wavelengths greater than 300 nm. This is because MV^{2+} forms a complex with $C_2O_4^{2-}$ and absorbs light when $\lambda>300$ nm.[5] To form the complex with an oxalate ion is one important ability of MV^{2+} on a photochemical reaction, since the complex has been believed to be a photoactive species.[5] The pH dependence of the absorption at 350 nm is shown in Fig. 3. The small change of the spectra in the pH range 7.0—10.0 is the same as which was reported.[5] However, at each oxalate ion concentration (0.02—0.1 M), the increase of the absorbance at pH 2—5 and at above pH 11 was steep. The pH dependence of absorption at

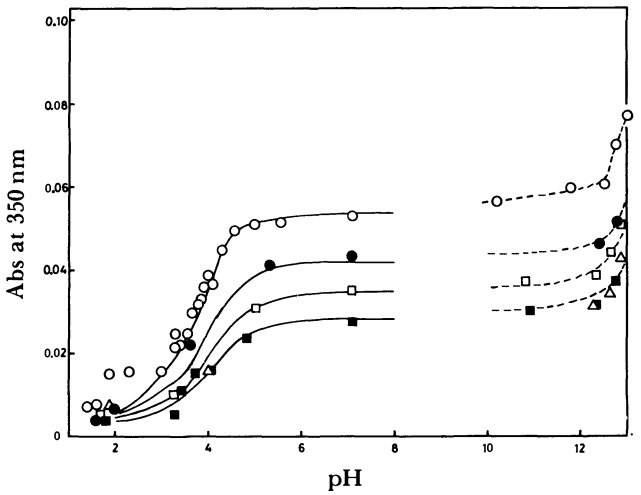

Fig. 3. The absorbance at 350 nm of MV^{2+}-$H_2C_2O_4$ solution whose pH was adjusted by the addition of KOH. Concentration of $H_2C_2O_4$ was 0.1 (○), 0.05 (●), 0.035 (□), 0.025 (■), and 0.02 (△) M and MV^{2+} was 0.01 M. The calculated absorbance by using the concentration of the MV^{2+}-$C_2O_4^{2-}$ complex and its ε_{350} was shown as the solid line.

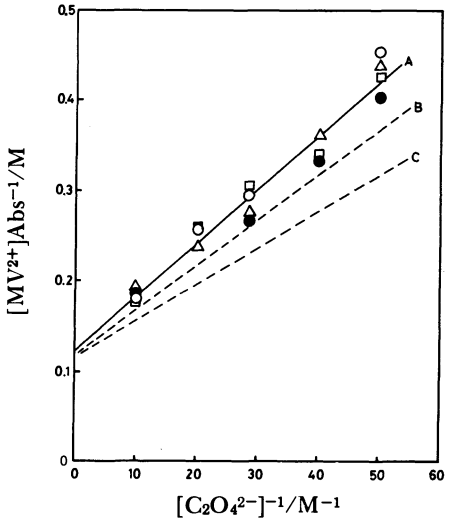

Fig. 4. The Benesi-Hildebrand analysis at 350 nm for the MV^{2+}-Li^+ (○), Na^+ (●), K^+ (△), or NH_4^+ (□) oxalate ion solutions. The pH was 7.1 (A), 12.35 (B), and 12.65 (C).

350 nm was similar with that of the $MV^{+\cdot}$ yield for 5 h irradiation. Since a complex with a 1:1 stoichiometry had already been clarified by a Job's plot,[5,12] the Benesi-Hildebrand analysis for a 1:1 donor-acceptor complex[13] was carried out for the absorbance of MV^{2+}-$M_2C_2O_4$ ($M=Li^+$, Na^+, K^+, or NH_4^+) solutions at 350 nm. Although Fig. 4 shows some scatter, an almost linear relation was observed and the effect of the counter ion on the spectra was small. Little effect of the counter ion on the spectra indicated that $M_2C_2O_4$ was completely dissociated into $C_2O_4^{2-}$ and 2 M^+ (Eq. 1 in the Scheme 1). A Benesi-Hildebrand analysis

$$M_2C_2O_4 \longrightarrow 2M^+ + C_2O_4^{2-} \quad (1)$$

$$C_2O_4^{2-} + H^+ \rightleftharpoons HC_2O_4^- \quad (2)$$

$$HC_2O_4^- + H^+ \rightleftharpoons H_2C_2O_4 \quad (3)$$

$$C_2O_4^{-} \longrightarrow CO_2^{-\cdot} + CO_2 \quad (8)$$

$$MV^{2+} + CO_2^{-\cdot} \longrightarrow MV^{+\cdot} + CO_2 \quad (9)$$

$$MV^{+\cdot} + C_2O_4^{-} \longrightarrow MV^{2+} + C_2O_4^{2-} \quad (10)$$

$$MV^{2+} + Cl^- \longrightarrow MV^{2+}Cl^- \quad (11)$$

$$MV^{2+}Cl^- + Cl^- \rightleftharpoons MV^{2+}(Cl^-)_2 \quad (12)$$

Scheme 1.

yielded K_3=20.4 M^{-1} and ε_{350}=8.2 $M^{-1}\,cm^{-1}$, which were almost identical to the reported values for K^+, 21 M^{-1} and 7.2 $M^{-1}\,cm^{-1}$, respectively.[5] The dissociation equilibrium constants of Eqs. 2 and 3 were reported as being 14500 and 17.5 $M^{-1}\,cm^{-1}$.[14] These values enabled us to calculate the concentration of $C_2O_4^{2-}$ in the reaction solution. The absorbance at 350 nm was calculated from the concentration of $C_2O_4^{2-}$, the values of K_3, ε_{350} of the complex and ε_{350} of uncomplexed MV^{2+} (ca. 0.9 $M^{-1}\,cm^{-1}$). The calculated absorbance (as shown in the solid line in Fig. 3) agreed very well with the observed value. This indicated that MV^{2+} could form the complex with only $C_2O_4^{2-}$ and that K_3 did not change in the pH range 2—8. Above pH 10, oxalate dissociates completely. This means that an increase in the amount of the oxalate ion was not the reason. And another reason was present for the increase in the absorbance at 350 nm and the yield of $MV^{+\cdot}$ with a pH in the high pH range. The Benesi-Hildebrand analysis was further applied for the absorbance at 350 nm in the high pH range as shown in Fig. 4. Here, lines B and C are best fit lines at pHs 12.35 and 12.65, respectively. Higher K_3s 23.3 and 28.5 M^{-1} than that in the lower pH range were obtained. This indicated that the increase of the formation of MV^+ with pH at above pH 10 might have resulted from an increase in the MV^{2+}-$C_2O_4^{2-}$ complex concentration, since the concentration of the MV^{2+}-$C_2O_4^{2-}$ complex increased with K_3.

The Effect of Ionic Strength and a Counter Cation on the Yield of $MV^{+\cdot}$. It was reported that modest concentrations (<0.5 M) of ions had a negligible effect on the yield of $MV^{+\cdot}$.[2c] However, in this study a

Table 1. The Effect of a Counter Ion of Oxalate Ion on the Yield of MV^+ after the Irradiation for 5 h

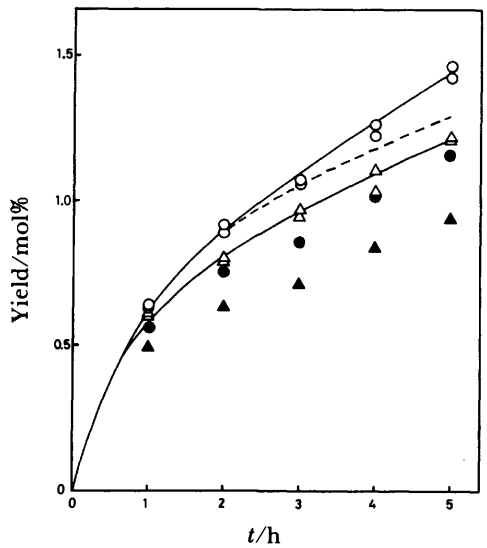

Fig. 5. The yields of MV^+ in the irradiation of the MV^{2+}–oxalate solutions. The pH was adjusted by using KOH (○, ●) or NaOH (△, ▲) with KCl (●, ▲) or without KCl (○, △). The dotted line was the results in which pH was adjusted by using the 1 : 1 mixture of NaOH and KOH solutions.

detrimental effect of an ionic strength on the yield MV^+ was observed, even at low ionic strength, upon the addition of KCl. The ion strength increased from 0.1 to 0.3, as shown in Fig. 5. The dissociation equilibrium constant of Eq. 12 in the scheme had been estimated from conductance measurements as being 0.1 M.[2b,15] The dissociation equilibrium constant of Eq. 11 was not reported; however, it was reported that the value was fairly larger than that of Eq. 12. If MV^{2+} existed as $MV^{2+}Cl^-$ initially, 3.4% of $MV^{2+}Cl^-$ could associate with Cl^- since initial concentration of MV^{2+} of our conditions was 0.0025 M. However, addition of KCl (0.2 M) increased the concentration of dichloride complex as large as 66.8%. The detrimental effect of anionic species, such as Cl^- on the yield of MV^+ might have resulted from the complex formation of MV^{2+} with Cl^-, which reduced the concentration of the photo active MV^{2+}–$C_2O_4^{2-}$ complex.

The yields of MV^+ in the solutions in which pH was adjusted by KOH were larger than that in the solutions in which pH was adjusted by NaOH as shown in Fig. 5. The yield of MV^+, in which a mixture of the KOH and NaOH solution was used as a pH moderator, was between them. MV^{2+}–$C_2O_4^{2-}$ solutions with other counter ions, Li^+ and NH_4^+ were also irradiated. The yield of MV^+ for 5 h irradiation increased with the ion radius of the counter ion (Table 1).

The effect of cationic species on photoinduced and electroinduced electron transfer from anions had been already discussed from the standpoint of a contact and loose ion pair.[6] For example, the rate constant of electron transfer from free biphenylide radical ions (B^-) to pyrene was $4.8\times10^{10}\ M^{-1}\ s^{-1}$; however, the rate constant from sodium biphenylide radical ions (B^-, Na^+) was $0.6\times10^{10}\ M^{-1}\ s^{-1}$.[6a] We have already reported that in electron transfer from the 9*H*-thioxanthene-9-one 10,10-dioxide (TO-SO_2) radical anion to diaryl disulfides, the order of the rate constant of electron transfer is as follows.[7a] $(TO\text{-}SO_2)^-$ is free radical anion.

$$(TO\text{-}SO_2)^- > (TO\text{-}SO_2)^-, K^+ > (TO\text{-}SO_2)^-, Na^+.$$

Smaller ions tended to form more stabilized ion pairs (contact ion pairs) since their charge densities were larger than those of larger ions. It was considered that a contact ion pair stabilized ion species and electron transfer from a cation contacted anion became slow compared to that from a solvent-separated ion or free ion. In the contact ion pair system, the ion contact was known to cause a blue shift in the absorption maximum;[16] however, we could not clarify the shift from the absorption of the MV^{2+}–$C_2O_4^{2-}$ complex since the absorption of uncomplexed MV^{2+} overlapped with that of the complex. The effect of a solvent-separated ion pair on a photoinduced electron transfer from a donor to MV^{2+} was reported by Mandell and Hoffman in the photo reduction of MV^{2+} using EDTA as the donor.[2c] They reported that EDTA formed ion pairs not only with MV^{2+} but also with $[Ru(bpy)_3]^{2+}$ and that electron transfer proceeded more easily than under conditions in which SO_4^{2-} was used instead of EDTA because SO_4^{2-} could not form any ion pairs.

$$[Ru(bpy)_3^{2+}\cdots EDTA\cdots MV^{2+}] \rightarrow$$

$$[Ru(bpy)_3^{3+}\cdots EDTA\cdots MV^{+}] \rightarrow [Ru(bpy)_3^{2+}\cdots EDTA_{ox}\cdots MV^{+}]$$

It was also reported that at high concentrations of MV^{2+} (>1 mM), MV^{2+} existed as an aggregate surrounded by $C_2O_4^{2-}$. In such aggregates, a participation of counter cation (M^+) with a MV^{2+}–$C_2O_4^{2-}$ aggregate was probable, although the spectroscopic effect of M^+ on the absorbance at 350 nm was not observed, as shown in Fig. 4. A possible sketch of the aggregate (dimer) of MV^{2+}–$C_2O_4^{2-}$ and participation of M^+ with the aggregate is as follows.

$$M^+$$
$$[C_2O_4^{2-}, MV^{2+}, C_2O_4^{2-}, MV^{2+}]$$
$$M^+$$

It was considered that smaller ions (Li^+, Na^+) tended to form more stable complexes with the MV^{2+}–$C_2O_4^{2-}$ aggregate than larger ions (K^+, NH_4^+) if the participation of M^+ with the aggregate occurred. It was also considered that a photoinduced electron transfer from the oxalate ion to MV^{2+} was more likely to occur in less stabilized complexes, such as the NH_4^+ or K^+ oxalate–MV^{2+} complex, than in a stabilized complex by the small ions, such as Li^+ or Na^+.

Individuality of Amino Acid Residues in Protected Peptides.[1] Conformational and β-Sheet Structure-Disrupted Behaviors of Resin-Bound Peptides

(Received July 18, 1988)

The conformational behavior of cross-linked polystyrene resin-bound peptides swollen in CH_2Cl_2 was analyzed using IR absorption spectroscopy. All of the resin-bound peptides easily aggregated with each other through intermolecular hydrogen bonding to form a β-sheet structure. The disruption of the β-sheet structure was further investigated by a solvent titration method in order to clarify the individuality of amino acid residues. At a pentapeptide level, the β-sheet structure was easily disrupted by the addition of a small amount of HFIP. On the other hand, at a larger peptide level, the disrupted behavior of the β-sheet structure was different from each other according to the amino acid composition. Based on the view that the secondary structure of globular proteins reflects the individuality of the 20 kinds of amino acid residues in proteins, we attempted to evaluate how easily the β-sheet structure of peptides is disrupted by HFIP using the average conformation values: $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$. As a result, the β-sheet structure-disruption of peptides having a low potential for a β-sheet→helix transformation as well as for the randomness was difficult by adding increasing amounts of HFIP. On the other hand, that of the peptides having a $\langle P_c \rangle$ value larger than 0.85 and/or a high potential for the β-sheet→helix transformation proceeded smoothly upon adding increasing amounts of HFIP.

The 20 kinds of amino acid residues in proteins must reflect their individuality to form native three-dimensional structures of proteins. In order to predict the secondary structure of native globular proteins, Chou and Fasman determined the conformational parameters (P_α, P_β, and P_c) for the 20 kinds of amino acid residues on the basis of the three-dimensional structures of 15 kinds of proteins which were resolved by X-ray crystallography.[2] Thus, we have the view that parameters P_α, P_β, and P_c reflect the individuality of the 20 kinds of amino acid residues in proteins. In fact, in previous studies[3-6] we successfully applied the coil conformational parameters P_c to solubility predictions for protected peptides. The solubility-prediction method is based on the assumption that the larger P_c values of hydrophilic amino acid residues than those of hydrophobic ones reflect the tendency that the polar side-chain groups interact with their neighboring peptide bonds through hydrogen bonds, resulting in a disruption of helix and β-sheet structures.

In the solubility prediction, we also showed the usefulness of the average coil conformation value, $\langle P_c \rangle$, for estimating the potential of protected peptides for a β-sheet formation.[4,7,8] Furthermore, in a conformational transformation of protected peptides with an application of strong shear stress or with an increasing peptide chain length, we showed the usefulness of their average helix and β-sheet conformation values, $\langle P_\alpha \rangle$ and $\langle P_\beta \rangle$, for estimating their potential for the β-sheet→helix transformation.[8-10]

On the other hand, we found that the β-sheet structure of Boc–Val–Gly–Phe–Gly–Leu–Ile–Leu_2–OBzl in CH_2Cl_2 solution is easily disrupted by the addition of HFIP, a strong electron-acceptor solvent.[11]

In this paper, we demonstrate the usefulness of the $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$ values for estimating the conformation of resin-bound peptides and the stability of their β-sheet structure, and discuss the individuality of amino acid residues included in protected peptides. The resin-bound peptides used in this study are shown in Fig. 1.

Table 1. Solid-Phase Peptide Synthesis Cycle for the Addition of One Oligopeptide[a]

Function	Solvent and/or reagent (amount)	Time/min	Number of application
1. Swelling	NMP[b] (30 ml)	10	1
2. Peptide	Tetra- or octapeptide (3.0 or 2.0 equiv) HOBt (3.0 or 2.0 equiv)	30	1
3. Coupling	DCC (3.0 or 2.0 equiv) in NMP[b] (5 ml)	3 days	1
4. Washing[c]	NMP, EtOH and CH_2Cl_2	5	3
5. Termination	Pyridine–acetic anhydride (Vol. ratio 1:1, 30 ml)	2 h	1
6. Washing[c]	CH_2Cl_2, EtOH, and CH_2Cl_2	5	3
7. Deprotection	TFA/CH_2Cl_2 (Vol. ratio 2:3, 30 ml)	2 h	1
8. Washing[c]	CH_2Cl_2, EtOH, and NMP	5	3
9. Neutralization	TEA (20 equiv) in NMP (20 ml)	10	2
10. Washing[c]	NMP, EtOH, CH_2Cl_2	5	3
11. Drying			

a) The resins used were 2.0 g, respectively. b) For assembly of the octapeptide (resin-bound peptides C_1—C_3), a mixture of NMP and CH_2Cl_2 (1:1, v/v) was used. c) Washing was carried out using each solvent.

Table 2. The Peptide Contents and Graft Ratios of the Resin-Bound Peptides

Resin-bound peptide	Peptide content[a]	Graft ratio[b]
A_1	133	1.4
A_2	89	1.0
A_3	66	0.77
B_1	116	1.3
B_2	50	0.58
B_3	34	0.40
C_1	83	0.95
C_2	56	0.68
C_3	48	0.61
D_1	106	1.2
D_2	97	1.1
D_3	79	1.0

a) $\mu mol\ g^{-1}$ of resin. The content does not include the terminated peptides. b) The ratio of grafted peptide to 100 styrene unit.

Experimental

Materials. Copoly(styrene/1% divinylbenzene) beads of 200—400 mesh, Bio-beads S-X1, were purchased from Bio-Rad Laboratories and used as polymer supports. Resin-bound peptides D_1, D_2, and D_3 were prepared before.[9] Other resin-bound peptides were prepared virtually using the cycle summarized in Table 1. The acid hydrolyses of resin-bound peptides A_1, A_2, A_3, B_1, B_2, and B_3 were carried out with propionic acid/12 M HCl (2:1, v/v; 1 M=1 mol dm^{-3})[12] for 10 days at 115 °C in evacuated and sealed tubes; those of resin-bound peptides C_1, C_2, and C_3, were carried out for 2 days at 115 °C. The amino acid composition of acid hydrolysates was determined using a Shimadzu HPLC LC-3A all amino acid analysis system. The peptide contents and graft ratios of the resin-bound peptides are shown in Table 2.

IR Measurements. The IR absorption spectra of resin-bound peptides were recorded at room temperature with a JEOL Model JIR-100 FT-IR spectrometer. IR measurements in the swollen state were performed by holding the samples between potassium bromide windows after resin-bound peptides were swollen overnight in CH_2Cl_2 or a mixture of HFIP and CH_2Cl_2.

Results

The Conformation of the Resin-Bound Peptides Swollen in CH_2Cl_2. The IR absorption spectra of the resin-bound peptides, except for D_1, D_2, and D_3, swollen in CH_2Cl_2 are presented in Figs. 2 and 3. They show significant spectral regions for conformational assignments (3500—3200 cm^{-1}, amide A; 1750—1600 cm^{-1}, amide I). All of the resin-bound peptides show strong bands around 3280 cm^{-1} in the amide A region and around 1630 cm^{-1} in the amide I region, assigned to a β-sheet structure.[10,13] This result is essentially the same as that of resin-bound peptides D_1, D_2, and D_3. Since the initial peptide contents of the resin-bound peptides were selected in order to obtain rational information for peptide chain interactions in solid-phase peptide synthesis, these results indicate that hydrogen bonding between pendant peptide chains do commonly occur in solid-phase peptide synthesis, as reported before.[9,10]

The Disruption of the β-Sheet Structure of the Resin-Bound Peptides by HFIP. The disruption of the β-sheet structure by HFIP was investigated using a solvent titration method.[14] It was monitored by a successive decrease in the intensity of the band around 1630 cm^{-1}, together with a successive addition of HFIP. Figure 4 shows the typical IR absorption spectra of resin-bound peptides A_1, A_3, B_1, and B_3 in a mixture of HFIP and CH_2Cl_2. Figures 5 and 6 illustrate the solvent-titration curves of resin-bound peptides A_1—A_3 and B_1—B_3, respectively, in CH_2Cl_2 using HFIP as a titrating solvent. The relative intensities shown in Figs. 5 and 6 as well as Figs. 7 and 8 were obtained using the band at 1603 cm^{-1} due to the aromatic ring of the resin support as a standard and were normalized to be 1.0 for each relative intensity in the absence of HFIP. In the case of resin-bound peptides A_1—A_3 and B_1, a successive addition of HFIP to CH_2Cl_2 induces a dramatic decrease in the strong band around 1630 cm^{-1} and an increase in the broad

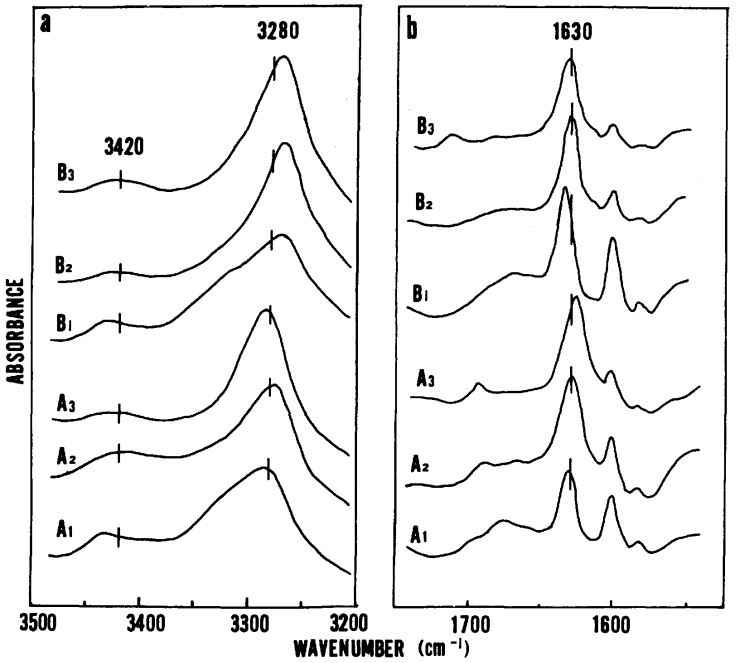

Fig. 2. IR absorption spectra (a) in the amide A and (b) in the amide I regions of the resin-bound peptides A_1—A_3 and B_1—B_3 swollen in CH_2Cl_2. The absorption band at 1603 cm^{-1} is due to aromatic rings of the polystyrene supports.

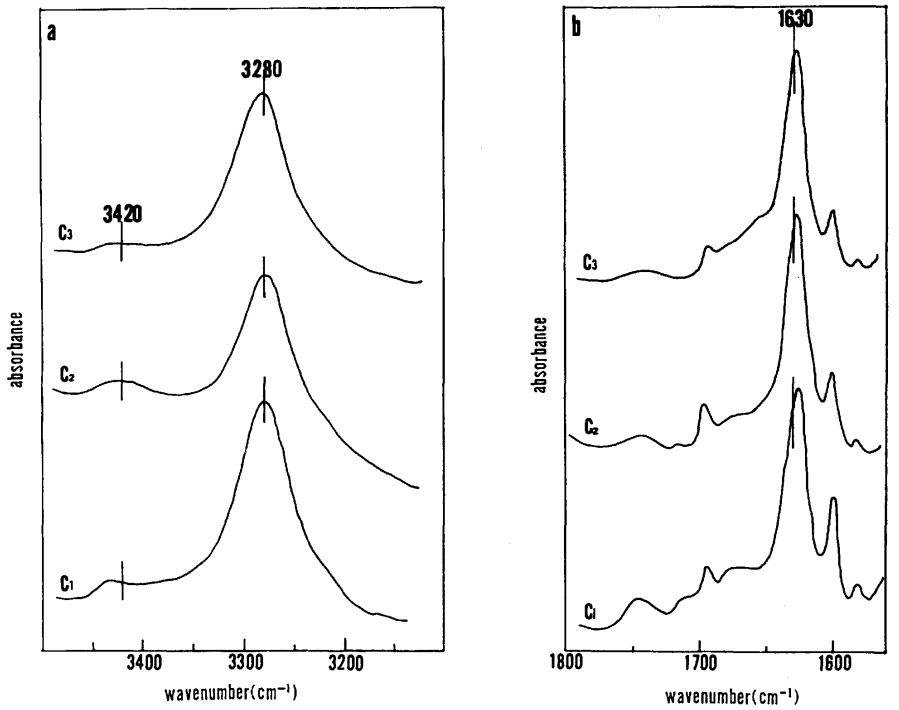

Fig. 3. IR absorption spectra (a) in the amide A and (b) in the amide I regions of the resin-bound peptides C_1—C_3 swollen in CH_2Cl_2.

band around 1655 cm^{-1}, indicating that the β-sheet aggregation of resin-bound peptides A_1—A_3 and B_1 is easily disrupted by increasing the amounts of HFIP. On the other hand, in the case of resin-bound peptides B_2 and B_3, the amide I carbonyl stretching band at 1632 cm^{-1} only shifts at 1637 cm^{-1} with broadening

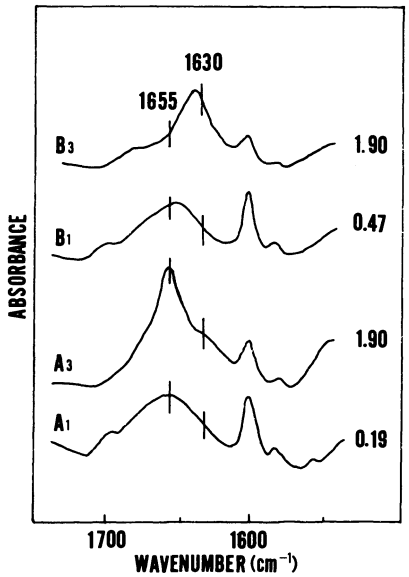

Fig. 4. Typical IR absorption spectra in the amide I region of the resin-bound peptides A_1, A_3, B_1, and B_3 swollen in HFIP–CH_2Cl_2. The numerals in Fig. 4 indicate concentrations of HFIP (M).

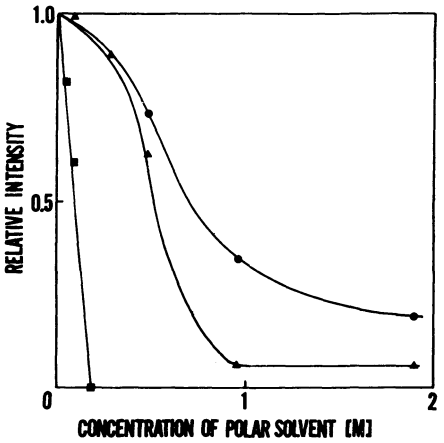

Fig. 5. The solvent-titration curves of the peptides A_1—A_3 in CH_2Cl_2 using HFIP as a titrating solvent. The peptide A_1, —■—; the peptide A_2, —▲—; the peptide A_3, —●—.

and a slight decrease in the intensity. This result strongly suggests that the β-sheet structure of the sequence of $(Val\text{-}Ile\text{-}Val\text{-}Ile)_n$ (n=2 and 3) is stable even in the presence of HFIP, although it is not clear why the band at 1632 cm^{-1} shifts at 1637 cm^{-1}. Figures 7 and 8 also present the solvent-titration curves of resin-bound peptides C_1—C_3 and D_1—D_3, respectively, in CH_2Cl_2 using HFIP as a titrating solvent. The result indicates that, regardless of an increasing peptide chain length, the β-sheet aggregation of resin-bound peptides C_1—C_3 and D_1—D_3 is easily disrupted by increasing the amounts of HFIP.

Discussion

The conformational behaviors of protected peptides must reflect the individuality of amino acid residues included in the peptides. We have the view that the conformational parameters, P_α, P_β, and P_c, for amino acid residues determined by Chou and Fasman[2] reflect the individuality of the 20 kinds of amino acid residues in proteins because the prediction method for the secondary structure of globular proteins using their $<P_\alpha>$ and $<P_\beta>$ values, proposed by Chou and Fasman,[15] is based on the three-dimensional structures of 15 kinds of proteins which are determined by X-ray crystallography.

In fact, the individuality of each amino acid residue reflected in the P_α, P_β, and P_c values is as follows. (1) The P_β values of the C^β-branched amino acid residues, that is, 1.60 of Ile, 1.20 of Thr, and 1.65 of Val are significantly larger than their P_α values, 1.00 of Ile, 0.82 of Thr, and 1.14 of Val, respectively. These values reflect the fact that the C^β-branched amino acid residues resist being included in a helical structure. (2) The values of P_α (0.53) and P_β (0.81) of the Gly residue are low and the P_c (1.50) value is extremely high. These values have been explained by the great freedom of the backbone dihedral angles, ϕ and ψ, of the Gly residue.[16] (3) The values of P_α (0.59) and P_β (0.62) of the Pro residue are low and P_c (1.59) is extremely high. These values clearly reflect the absence of an N–H bond of the Pro residue in the peptide bond.[17] (4) The P_c values of the hydrophilic amino acid residues (Arg, 1.04; Asn, 1.35; Asp, 1.20; Cys, 1.18; Gln, 0.86; Glu, 0.83; His, 1.06; Lys, 0.98; Ser, 1.32; Thr, 1.07; Tyr, 1.06) are larger than those of hydrophobic amino acid residues, except for the Pro residue, (Ala, 0.70; Ile, 0.66; Leu, 0.68; Met, 0.58; Phe, 0.71; Trp, 0.75; Val, 0.62) since the polar side-chain groups have a tendency to form hydrogen bonds with their neighboring peptide bonds, resulting in a disruption of the helical and β-sheet structures. (5) The P_c values of the hydrophilic amino acid residues having polar groups at their C^β atoms (Asn, 1.35; Asp, 1.20; Cys, 1.18; Ser, 1.32; Thr, 1.07) are larger than those of the other hydrophilic amino acid residues (Arg, 1.04; Gln, 0.86; Glu, 0.83; His, 1.06; Lys, 0.98; Tyr, 1.06). These values probably reflect the tendency that the former interacts more easily with the neighboring peptide bonds than the latter. (6) In the P_c values of the hydrophilic amino acid residues having polar groups at their C^β atoms, the P_c value of the Thr residue is the lowest due to the low freedom of the hydroxyl group. With respect to the P_c parameters for the 20 kinds of amino acid residues, our P_c parameters[3] used in this study are different from those obtained by Chou and Fasman.[2] Chou and Fasman determined them on the basis of data concerning 15 kinds of globular proteins, while we determined them on the basis of data concerning 29 kinds of globular proteins.

Table 3. The Average Conformation Values, $<P_\alpha>$, $<P_\beta>$, and $<P_c>$, of the Resin-Bound Peptides

Resin-bound peptide	$<P_\alpha>$	$<P_\beta>$	$<P_c>$
A_1—A_3	1.30	1.31	0.66
B_1—B_3	1.07	1.63	0.64
C_1—C_3	1.04	1.23	0.88
D_1	1.14	1.03	0.90
D_2	1.07	1.11	0.93
D_3	1.18	0.95	0.90

The $<P_\alpha>$, $<P_\beta>$, and $<P_c>$ values of the peptides A_1—A_3, B_1—B_3, and C_1—C_3 do not include their C-terminal amino acid residues.

Thus, the $<P_\alpha>$ and $<P_\beta>$ values of protected peptides must reflect their potential for helix and β-sheet formations, respectively, as much as their $<P_c>$ values reflect their potential for randomness. In Table 3, the average conformation $<P_\alpha>$, $<P_\beta>$, and $<P_c>$ values of the resin-bound peptides are summarized. The values of $<P_\alpha>$, $<P_\beta>$, and $<P_c>$ are necessarily determined, regardless of the amino acid sequence of the peptides.[15] They are only dependent on their amino acid composition.

With respect to the conformational behavior of resin-bound peptides, the fact that the resin-bound heptadecapeptide C_2 and pentacosapeptide C_3 swollen in CH_2Cl_2 have a β-sheet structure is quite different from that of H-Leu_n-Phe-resins (n=15 and 20), showing a helical structure in the swollen state in CH_2Cl_2.[10] Regardless of the increase in the peptide chain length, the amino acid sequence of peptides C_2 and C_3 has a high potential for a β-sheet formation, though a low potential for a helix formation, corresponding to the fact that their $<P_\alpha>$ and $<P_\beta>$ values are 1.04 and 1.23, respectively. In a conformational study of human hemoglobin α-chain fragments in the solid state,[8] we have shown that the potential of protected peptides for the β-sheet→helix transformation is clearly estimated using their $<P_\alpha>$ and $<P_\beta>$ values when the β-sheet→helix transformation occurs in the solid state under the application of shear stress. The conformational behavior of the resin-bound peptides C_1—C_3 indicates that the retention of the high potential for a β-sheet formation, regardless of an increase in the peptide chain length, can also be estimated using their $<P_\alpha>$ and $<P_\beta>$ values. Nevertheless, we should continuously make efforts to determine key sequences which dominate the peptide conformations, since the conformation of peptides is estimated to be essentially dependent on the key sequence. Concerning the sequence of peptides A_2 and A_3, its helical structure may be unstable due to repulsion between C^β-branched Ile and Val residues in the sequence of -Ile-Leu-Leu-Val-, as previously discussed in the sequence of

-Val-Ser-Thr-Val-,[8] as well as the great freedom of the backbone dihedral angles ϕ and ψ of two Gly residues.[15] Although $\langle R_\alpha \rangle$ and $\langle P_\beta \rangle$ values of protected peptides are necessarily determined regardless of the amino acid sequences of peptides and are only dependent on their amino acid compositions, they are still effective for estimating the potential for the β-sheet→helix transformation of peptides with increasing peptide chain length as well as with the application of shear stress.[8]

With regard to the β-sheet structure-disruption, Figs. 5—8 clearly show that, at a pentapeptide level, the β-sheet structure of resin-bound peptides is easily disrupted, regardless of their $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$ values. This corresponds to the fact that protected peptides of a pentapeptide level have high solubility in highly polar solvents, regardless of their $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$ values. In the case of peptides as long as or larger than an octapeptide, the β-sheet structure-disruption by HFIP is dependent on their $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$ values. The $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$ values of peptides A_2 and A_3 containing the Val and Ala residues are 1.30, 1.31, and 0.66, respectively, and their β-sheet structure is disrupted together with increasing amounts of HFIP (Fig. 5). On the other hand, the values of $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$ of peptides B_2 and B_3 containing the Val and Ile residues are 1.07, 1.63, and 0.64, respectively, and their β-sheet structure-disruption is difficult, even with increasing amounts of HFIP (Fig. 6). As reflected in the $\langle P_\alpha \rangle$ and $\langle P_\beta \rangle$ values, peptides B_2 and B_3 have the sequence -(Val-Ile-Val-Ile)$_n$-, which can not form a helical structure due to the steric hindrance of side chains; however, peptides A_2 and A_3 have the sequence of -(Val-Ala-Val-Ala)$_n$- which can form a helical structure. Furthermore, the $\langle P_c \rangle$ values of both series of peptides are low, indicating that these peptides have a low potential for randomness. The result of the conformational behaviors of peptides A_2, A_3, B_2, and B_3 indicates that the β-sheet structure of a peptide having a high potential for a β-sheet→helix transformation, which is estimated from the $\langle P_\alpha \rangle$ and $\langle P_\beta \rangle$ values, can be disrupted by adding increasing amounts of HFIP. On the other hand, the β-sheet structure disruption of peptides is difficult when they have a low potential for a β-sheet→helix transformation, as well as for randomness. The $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$ values of peptides C_1—C_3 are 1.04, 1.23, and 0.88, indicating a low potential for the β-sheet→helix transformation and a high potential for randomness; their β-sheet structure is disrupted regardless of an increase in peptide chain length (Fig. 7). The $\langle P_c \rangle$ values of peptides D_2 and D_3 are 0.93 and 0.90, respectively, and their β-sheet structure is also disrupted, regardless of any increase in the peptide chain length (Fig. 8). Peptide D_3 has been estimated to have a high potential for the β-sheet→helix transformation, while peptide D_2 has not been. Peptides D_2 and D_3 contain protected Asp and Glu residues and the use of the P_α, P_β, and P_c parameters of unprotected Asp and Glu residues for an evaluation of the $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$ values of peptides D_2 and D_3 causes trouble. This is because side-chain protection clearly reduces the interaction of side chains with neighboring peptide bonds. Nevertheless, the $\langle P_\alpha \rangle$, $\langle P_\beta \rangle$, and $\langle P_c \rangle$ values of resin-bound peptides D_2 and D_3 are also useful for estimating the potential for their β-sheet structure-disruption.

The results in this paper strongly suggest the adequacy of the solubility prediction method for protected peptides using their $\langle P_c \rangle$ values, previously proposed by us.[3]

The authors wish to thank Central Glass Co., Ltd., Mitsubishi Kasei Co., Ltd., and Ajinomoto Co., Ltd., for the generous gift of reagents.

The Electron Donor-Acceptor Interaction between Mixed Solvents and Its Influence on Their β-Sheet Structure-Disrupting Potential[1)]

Mitsuaki NARITA,* Hiroshi UMEYAMA, Shizuko ISOKAWA, Shinya HONDA, Chie SASAKI, and Hideaki KAKEI
Department of Industrial Chemistry, Faculty of Technology, Tokyo University of Agriculture and Technology, Koganei 184
(Received August 9, 1988)

Cross-linked polystyrene resin-bound peptides were useful for the investigation of the β-sheet structure-disrupting potential of mixed solvents although their β-sheet structure-disrupted behavior by mixed solvents was different from that of peptides free from a macromolecular protecting group due to the concentrating efficacy of a cross-linked resin. In mixed solvents, the electron-acceptor and -donor numbers (AN and DN) of organic solvents were one of the most important factors to estimate their β-sheet structure-disrupting potential. In a mixture of electron-acceptor solvents themselves or -donor solvents, the electron donor-acceptor interaction between solvents did not occur and electron-accepting or -donating property of each solvent was kept to disrupt the β-sheet aggregation in mixed solvents. On the other hand, in a mixture of electron-acceptor solvent and -donor solvent, the electron donor-acceptor interaction between solvents occurred predominantly to decrease the β-sheet structure-disrupting potential of mixed solvents. The present results clarify the criteria of the search for effective solvents in peptide and protein synthesis.

The β-sheet aggregation of peptides bound to a cross-linked polystyrene resin in the swollen state is one of the most serious obstacles in solid phase peptide synthesis.[2–6)] To elucidate the hydrogen-bonding behavior of resin-bound oligopeptides, we have investigated the conformational properties of oligo(Leu)s,[2)] human proinsulin C-peptide fragments,[3)] and a few of hydrophobic peptides[6)] which were bound to cross-linked polystyrene resins.

The β-sheet aggregation of peptides free from a macromolecular protecting group is also one of the most serious obstacles in classical peptide and protein synthesis since it causes the insolubility of peptide intermediates, protected peptides.[7–12)] In the study of the β-sheet structure-disruption of Boc–Val–Gly–Phe–Gly–Leu–Ile–Leu_2–OBzl in mixed solvents,[13)] we found that, in a mixture of organic solvents, their electron-acceptor and -donor numbers (AN and DN)[14)] were useful for estimating their solvating potential for peptide main chains, that is, their β-sheet structure-disrupting potential. As AN and DN of solvents were larger, their β-sheet structure-disrupting potential became higher. Moreover, on the basis of the results of the β-sheet structure-disruption of Boc–Val–Gly–Phe–Gly–Leu–Ile–Leu_2–OBzl in a three component solvent system, it could be concluded that the combination of electron-donor solvents themselves or -acceptor solvents was suitable in peptide and protein synthesis, but that of electron-donor solvent and -acceptor solvent was not effective due to the electron donor–acceptor interaction between them. The conclusion was obtained using Boc–Val–Gly–Phe–Gly–Leu–Ile–Leu_2–OBzl as a model peptide, which was a novel octapeptide to be soluble as a β-sheet structure in CH_2Cl_2. Thus, it is important to establish that the conclusion is generally available.

In this paper, we first demonstrate that the β-sheet structure-disruption of cross-linked polystyrene resin-bound peptides is more difficult than that of peptides free from a macromolecular protecting group due to the concentrating efficacy of a cross-linked resin. We next demonstrate the generality of the results of Boc–Val–Gly–Phe–Gly–Leu–Ile–Leu_2–OBzl and discussed the validity of AN and DN for the estimation of the electron donor-acceptor interaction between solvents as well as the hydrogen bonding interaction between a peptide and a solvent. The resin-bound peptides **1**—**5** used in this study are shown in Fig. 1.

Experimental

Materials. Copoly(styrene/1% divinylbenzene) beads of 200—400 mesh, Bio-Beads S-Xl, were purchased from Bio-Rad Laboratories. The resin-bound peptides except for **1b** and **1c** were prepared in previous papers,[3,6)] and the peptides **1b** and **1c** were also prepared by the method described previously.[6)] The graft ratios (grafted peptides per 100 styrene

Boc-ValGlyPheGlyLeuIleLeuLeu-Ala-OCH_2Pam-resin-a **1a**
Boc-ValGlyPheGlyLeuIleLeuLeu-Ala-OCH_2Pam-resin-b **1b**
Boc-ValGlyPheGlyLeuIleLeuLeu-Ala-OCH_2Pam-resin-c **1c**
Boc-ValAlaValAlaGly-OCH_2Pam-resin **2**
Boc-GlnValGlu(OBzl)LeuGly-$NHCH_2$-resin **3**
Boc-GlnValGlyGlnValGlu(OBzl)LeuGly-$NHCH_2$-resin **4**
Boc-Glu(OBzl)AlaGlu(OBzl)Asp(OBzl)LeuGlnValGlyGlnValGlu(OBzl)LeuGly-$NHCH_2$-resin **5**

Fig. 1. The resin-bound peptides **1**—**5** used in this study.

units) of the resin-bound peptides **1a—1c** are different with each other to be 0.95, 2.5, and 5.7%, respectively. Those of the resin-bound peptides **2—5** are 1.4, 1.2, 1.1, and 1.0%, respectively.

IR Measurements. The IR absorption spectra of resin-bound peptides were recorded at room temperature with a JEOL Model JIR-100 FT-IR spectrometer. IR measurements in the swollen state were performed by holding the samples between potassium bromide windows after resin-bound peptides were swollen overnight in various molar ratios of mixed solvents. The conformational analysis of the resin-bound peptides **1—5** was carried out using IR absorption spectroscopy as described in the previous papers.[3,6]

Results

The β-Sheet Structure-Disruption of Cross-Linked Polystyrene Resin-Bound Peptides by a Titrating Solvent. The β-sheet structure-disruption was investigated by a solvent-titration method.[15] It was monitored by the successive decrease in the intensity of the band around 1630 cm^{-1} due to the β-sheet structure together with the successive addition of a titrating solvent. Figure 2 shows the typical IR absorption spectra of the resin-bound peptide **1a** in a mixture of HFIP and CH_2Cl_2 at 0.19 M (1 M=1 mol dm^{-3}) and 0.38 M of HFIP. Figure 3 illustrates the solvent-titration curves of the resin-bound peptides **1a—1c**, which are different from each other in a peptide content, using HFIP and TFE as titrating solvents. Relative intensities in Fig. 3 as well as Figs. 4—10 were obtained using the band at 1603 cm^{-1} due to the aromatic ring of the resin support as a standard and were normalized to be 1.0 for each relative intensity in the absence of a titrating solvent. Figure 3 indicates that the more the loading amount of peptide chains on the matrices is, the more difficult the disruption of the β-sheet structure is. HFIP, a strong electron-acceptor solvent, has the high potential for the β-sheet structure disruption[13,16] and the β-sheet structure of the resin-bound peptides **1a—1c** swollen in CH_2Cl_2 is easily disrupted by adding increasing amounts of HFIP. However, in contrast with the fact that the β-sheet structure of Boc-Val-Gly-Phe-Gly-Leu-Ile-Leu_2-OBzl, which is free from a macromolecular protecting group, is completely disrupted at 0.19 M of HFIP,[13,16] that of the resin-bound peptides **1a—1c** is barely disrupted at the same concentration of HFIP. Moreover, the solvent-titration curves of the resin-bound peptides **1a—1c** with TFE show that the β-sheet structure of the resin-bound peptides **1a—1c** is incompletely disrupted even at 1.0 M of TFE, being in contrast with the fact that of Boc-Val-Gly-Phe-Gly-Leu-Ile-Leu_2-OBzl is completely disrupted below 1.0 M of TFE. The solvent-titration curves of the resin-bound peptide **1a** in CH_2Cl_2 using HMPA, DMSO, MeOH, and EtOH as titrating solvents (Fig. 4) are also quite different from those of Boc-Val-Gly-Phe-Gly-Leu-Ile-Leu_2-OBzl. The β-sheet structure of Boc-Val-Gly-Phe-Gly-Leu-Ile-Leu_2-OBzl in CH_2Cl_2, an electron-acceptor solvent, was easily disrupted by adding increasing amounts of strong electron-donor

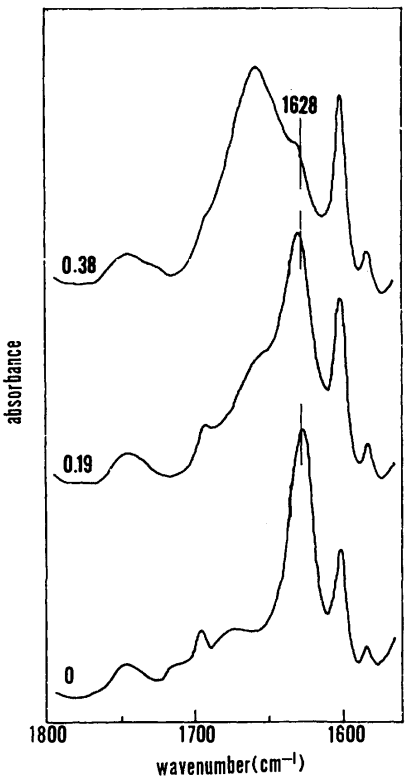

Fig. 2. Typical IR absorption spectra in the amide I region of the resin-bound peptides **1a** swollen in HFIP-CH_2Cl_2. The numerals in Fig. 2 indicate concentrations of HFIP (M).

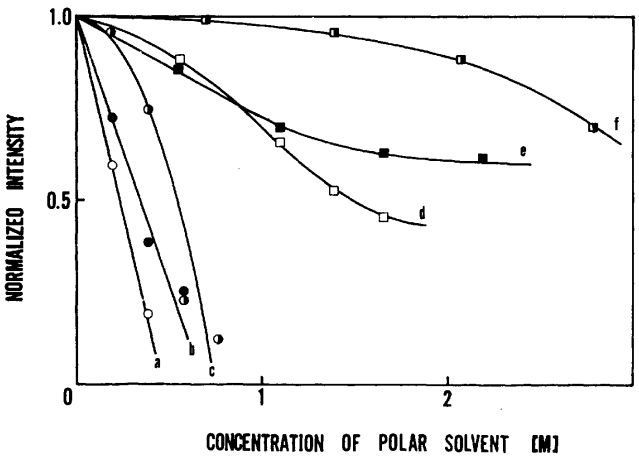

Fig. 3. The solvent-titration curves of the peptides **1a—1c** in CH_2Cl_2 using HFIP (a—c) and TFE (d—f) as titrating solvents. (a) and (d), the peptide **1a**; (b) and (e), the peptide **1b**; (c) and (f), the peptide **1c**. Relative intensities in Fig. 3 as well as Figs. 4—10 were obtained using the band at 1603 cm^{-1} due to the aromatic ring of the resin support as a standard and were normalized to be 1.0 for each relative intensity in the absence of a titrating solvent.

solvents, HMPA and DMSO, and -acceptor solvents, MeOH and EtOH, [13,17] while that of the resin-bound peptide **1a** could not be disrupted by the addition of these solvents. The solvent-titration curves in CH_2Cl_2 show that the larger the AN of titrating solvents is, the greater the β-sheet structure-disruption is, suggesting that AN of titrating solvents is the important factor to estimate their β-sheet structure-disrupting potential in CH_2Cl_2.

The Electron Donor-Acceptor Interaction between Mixed Solvents. Although the β-sheet structure-disruption of resin-bound peptides is more difficult than that of peptides free from a macromolecular protecting group, the fact that the β-sheet structure of resin-bound peptides is not disrupted in a mixture of electron-donor solvent and -acceptor solvent (Fig. 4) suggests that the electron donor-acceptor interaction occurs between mixed solvents. Thus, to certain the generality of the electron donor-acceptor interaction between electron-donor solvent and -acceptor solvent, the β-sheet structure-disruption of resin-bound peptides was examined using the peptides **2**—**5** having a variety of amino acid

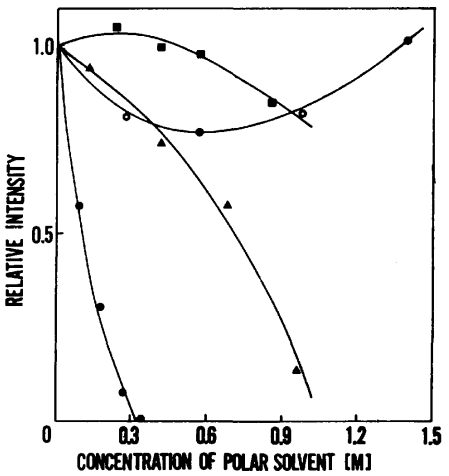

Fig. 7. The solvent-titration curves of the resin-bound peptide **4** in CH_2Cl_2 using HFIP (●), TFE (▲), HMPA (■), and DMSO (O) as titrating solvents.

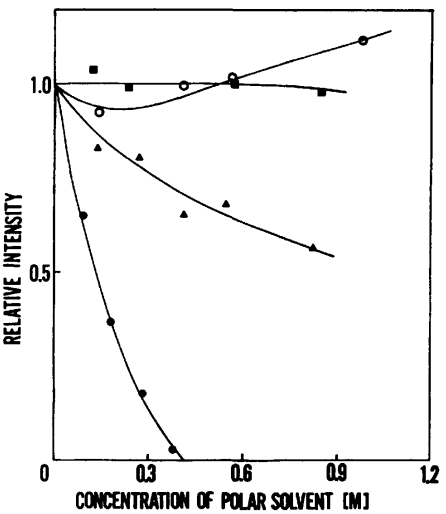

Fig. 8. The solvent-titration curves of the resin-bound peptide **5** in CH_2Cl_2 using HFIP (●), TFE (▲), HMPA (■), and DMSO (O) as titrating solvents.

sequences. It was monitored by the successive decrease in the intensity of the bands at 1632, 1630, 1628, and 1626 cm^{-1}, respectively. Figures 5—8 illustrate the solvent-titration curves of the resin-bound peptides **2—5** in CH_2Cl_2, an electron-acceptor solvent, using HFIP and TFE, electron-acceptor solvents, or DMSO and HMPA, electron-donor solvents, as, titrating solvents. The solvent titration curves in Figs. 5—8 also indicated that the combination of electron-acceptor solvents themselves effectively kept their β-sheet structure-disrupting potential and that of electron-donor solvent and -acceptor solvent did not, suggesting the electron donor-acceptor interaction between them. Furthermore, Figs. 5—8 exhibit that the β-sheet structure-disruption of peptides is strongly dependent on amino acid compositions and peptide chain lengths as discussed in the previous paper.[6]

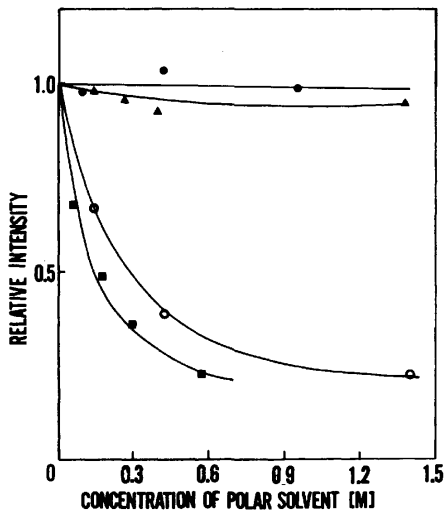

Fig. 9. The solvent-titration curves of the resin-bound peptide **2** in THF using HFIP (●), TFE (▲), HMPA (■), and DMSO (○) as titrating solvents.

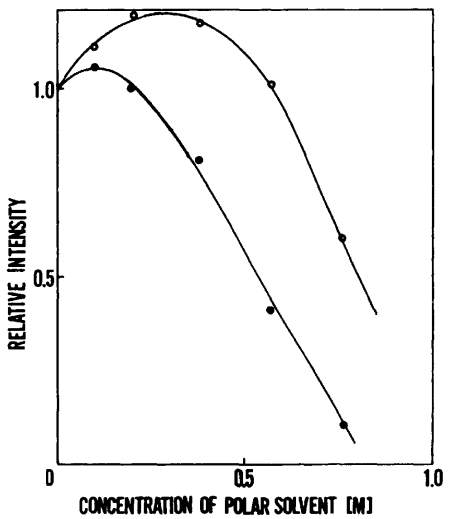

Fig. 10. The solvent-titration curves of the resin-bound peptide **4** in a mixture of CH_2Cl_2 and HMPA (●) and in that of CH_2Cl_2 and DMSO (○) using HFIP as a titrating solvent. Molar concentrations of HMPA and DMSO in CH_2Cl_2 were 0.17 M and 0.42 M, respectively.

Contrary to the results in an electron-acceptor solvent (Figs. 5—8), Fig. 9 illustrates the solvent titration curves of the resin-bound peptide **2** in an electron-donor solvent, THF. The results in Fig. 9 also indicate that the addition of heterogeneous electron-acceptor solvents (HFIP and TFE) decreases in their β-sheet structure-disrupting potential for peptides in THF, while that of homogeneous electron-donor solvents (HMPA and DMSO) does not influence on their β-sheet structure-disrupting potential. However, the β-sheet structure of Boc-(Val-Ala-Val-Ala)$_n$-Ile-OCH_2 Pam-resins (n=2 and 3)[6] in THF could little be disrupted by the successive addition of HMPA due to the low potential of HMPA for the β-sheet structure-disruption of the resin-bound nona- and tridecapeptides (not shown). The solvent titration curves in Fig. 10 illustrates the β-sheet structure-disruption of the peptide **4** in the three component solvent system. In a mixture of CH_2Cl_2 and HMPA or DMSO, the successive addition of HFIP changes the conformation of the resin-bound peptide **4**. The little increase in relative intensity together with the initial addition of HFIP denotes the increase in the β-sheet structure, also indicating the electron donor-acceptor interaction between HFIP and HMPA or HFIP and DMSO.

Discussion

Although peptides having a β-sheet structure in organic solvents usually could not be analyzed their conformation in solution due to their insolubility, anchoring of peptides to a cross-linked polystyrene-resin enabled their conformational analysis in various organic solvents in the swollen state. The solvent-titration curves of the resin-bound peptides **1a—1c** (Figs. 3 and 4) showed that their β-sheet-structure-disrupted behavior was quite different from that of Boc-Val-Gly-Phe-Gly-Leu-Ile-Leu_2-OBzl, which was free from a macromolecular protecting group, and strongly dependent on the loading amount of peptide chains on the matrices. The dependence on the loading amount clearly indicates that anchoring of a peptide to a cross-linked resin has a concentrating efficacy as pointed out before,[2,3] being contrary to the assumption that the high dilution principle would be achieved in solid-phase organic synthesis.[17]

The solvent-titration curves of the resin-bound peptides **1—5** (Figs. 3—10) also indicate that a mixture of heterogeneous solvents (combination of electron-acceptor solvent and -donor solvent) decreases in their β-sheet structure-disrupting potential due to the electron donor-acceptor interaction between them, while that of homogeneous solvents (Combination of electron-acceptor solvents themselves or -donor solvents) keeps electron-accepting or -donating property

Table 1. AN and DN of Organic Solvents Used in This Study[13,14]

Solvent	AN	DN
CH_2Cl_2	20.4	—
THF	8.0	20.0
HMPA	10.6	38.8
DMSO	19.3	29.8
HFIP	88	—
TFE	70	—
MeOH	41.3	19
EtOH	37.1	20

AN and DN of a peptide bond are not reported, but DN of *N*,*N*-dimethylacetamide is 27.8 and AN of formamide is 39.8.

of each solvent. Especially, the solvent-titration curves in Fig. 10 clearly show the electron donor–acceptor interaction between HFIP and HMPA or HFIP and DMSO. In the absence of HFIP, a small amount of HMPA or DMSO contributes solvation of peptide bonds and, by the initial addition of HFIP, the strong electron donor–acceptor interaction between HFIP and HMPA or HFIP and DMSO brings about to help the β-sheet formation of the resin-bound peptide **4**. By the further addition of HFIP, HFIP effectively solvates peptide bonds to disrupt the β-sheet aggregation. These conformational behaviors just correspond to those of Boc–Val–Gly–Phe–Gly–Leu–Ile–Leu_2–OBzl in a three component solvent system.[13] As discussed for the β-sheet structure-disruption of Boc–Val–Gly–Phe–Gly–Leu–Ile–Leu_2–OBzl in the three component solvent system,[13] the electron-accepting and -donating property of solvents indicated by AN and DN is one of the important factors to estimate their β-sheet structure-disrupting potential.

AN and DN of organic solvents used in this study were summarized in Table 1. AN of CH_2Cl_2 is 20.4, indicating that CH_2Cl_2 is a medium electron-acceptor solvent. DN of CH_2Cl_2 is not obtained, but is thought to be near zero since 1,2-dichloroethane is used as a standard for evaluation of DN of organic solvents.[14] In the medium electron-acceptor solvent, CH_2Cl_2, strong electron-acceptor solvents, HFIP and TFE, have a high potential for the β-sheet structure-disruption of the resin-bound peptides **1**—**5** having a variety of amino acid sequences (Figs. 3 and 5—8). On the other hand, strong electron-donor solvents, HMPA and DMSO, have no or little potential for their β-sheet structure-disruption (Figs. 4—8). These results clearly indicate that, in a mixture of homogeneous electron-acceptor solvents, electron donor–acceptor interaction does not occur and electron-accepting property of HFIP and TFE is kept to disrupt the β-sheet aggregation in CH_2Cl_2, while, in a mixture of heterogeneous solvents, electron donor–acceptor interaction occurs predominantly to lose electron-donating property of HMPA and DMSO for peptide N–H bonds.

Contrary to CH_2Cl_2, THF is a medium electron-donor solvent (DN, 20.0) and a weak electron-acceptor solvent (AN, 8.0). In THF, strong electron-donor solvents, HMPA and DMSO, have a high potential for the β-sheet structure-disruption of the resin-bound peptide **2**, while strong electron-acceptor solvents, HFIP and TFE, lose it. Namely, the electron donor–acceptor interaction does not occur in a mixture of homogeneous electron-donor solvents, and electron-donating property of HMPA and DMSO is kept to disrupt the β-sheet aggregation in THF, while, in a mixture of heterogeneous solvents, the electron donor–acceptor interaction occurs predominantly to lose electron-accepting property of HFIP and TFE for peptide C=O bonds. AN and DN of HMPA are 10.6 and 38.8, and those of DMSO, 19.3 and 29.8, respectively. These AN values suggest that the electron-donating property of HMPA and DMSO does not reduce in THF because the electron-accepting property of THF is smaller than that of HMPA and DMSO. HFIP has AN of 88 and strongly interacts with HMPA and DMSO through electron transfer, showing the solvent-titration curves presented in Fig. 10.

Conclusion

Cross-linked polystyrene resin-bound peptides were useful for the investigation of the β-sheet structure-disrupting potential of mixed solvents although their β-sheet structure-disruption by solvents was more difficult than that of peptides free from a macromolecular protecting group due to the concentrating efficacy of a cross-linked resin. As a results, the concentrating efficacy helped the observation of the electron donor–acceptor interaction between heterogeneous solvents which could not be observed for Boc–Val–Gly–Phe–Gly–Leu–Ile–Leu_2–OBzl. The β-sheet structure-disruption of resin-bound peptides having a variety of amino acid sequences indicates that the β-sheet structure disrupting potential of mixed solvents decreases in the case of the combination of heterogeneous solvents due to the electron donor–acceptor interaction. In peptide and protein synthesis, mixed solvents are commonly used in coupling reactions[18] since mixed solvents have a high solubilizing potential for large peptide intermediates probably due to the enhancement of solvation to peptide side chains by mixing. The results in this study clarify the criteria of the search for effective solvents in peptide and protein synthesis. The combination of homogeneous solvents should be selected in the direction that each solvent plays an important role in solvation of various kinds of peptide side-chains.

The Zinc(II)-Catalyzed Henkel Reaction of Dipotassium 1,8-Naphthalenedicarboxylate in a Dispersion Medium

Koichi FUJISHIRO and Shuichi MITAMURA*
Chemicals Research Laboratory, R & D Laboratories-1,
Nippon Steel Co. 1618 Ida, Nakahara-ku, Kawasaki 211
(Received July 21, 1988)

The Henkel reaction of dipotassium 1,8-naphthalenedicarboxylate in naphthalene as a dispersion medium gave dipotassium 2,6-naphthalenedicarboxylate (**1**) in a higher yield and with a better reproducibility than the reaction without a dispersion medium . Catalysts, particularly zinc catalysts, were examined in detail. The anion moiety of zinc catalysts affected the reaction, and the halide anion was effective for the selective formation of **1**. The addition of potassium halide to the zinc catalysts also increased the yield of **1**. The catalytic activity of the halide anion increased in the order; $Cl^- < Br^- < I^-$. The activity of the zinc catalysts was also compared with that of cadmium catalysts.

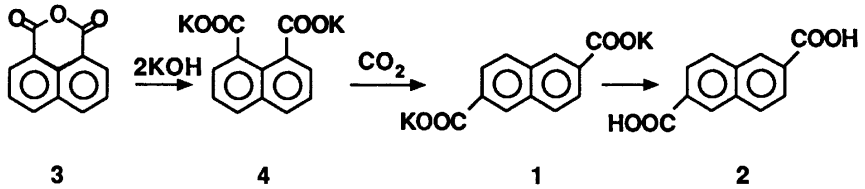
2,6-Naphthalenedicarboxylic acid (**2**) has attracted attention because it is often used as a component of high-performance polymers. For example, poly(ethylene naphthalenedicarboxylate) is known for its heat resistance and high modulus.[1] We have been studying the preparation of **2** from 1,8-naphthalenedicarboxylic anhydride (**3**) (Scheme 1). The transformation of dipotassium 1,8-naphthalenedicarboxylate (**4**) into the 2,6-isomer (**1**) is well-known as the Henkel reaction, which is usually carried out by heating **4** under a pressure of carbon dioxide at 350—450 °C in the presence of a catalytic amount of cadmium salts or sometimes zinc salts.[2-7] The activity of the cadmium catalysts is much higher than that of the zinc catalysts. In order to produce **1** industrially, however, some practical problems must be overcome: (1) It is difficult to transport the starting material **4** and the reaction mixture because both of them are in the solid state during this process. (2) The powders of the reaction mixture stick together during the reaction, which leads to inefficient mixing and local superheating, resulting in a poor reproducibility of the reaction along with a low yield of **1**. (3) Cadmium salts are very toxic, though their catalytic activity is very high. We have focused our efforts on overcoming these problems. We have found that the addition of a dispersion medium such as naphthalene to the starting material obviates the problems, and improves both the reproducibility of the reaction and the yield of **1**. We have also found that the cadmium catalysts can be replaced by a combination of zinc(II) and the halide anion X^-, whose activity is as same as that of the cadmium catalysts. The roles of zinc(II) and X^- during the reaction are discussed on the basis of the effects of the anionic moiety of the zinc catalyst on the reaction and on the basis of thermal gravimetric analyses.

Experimental

All high-performance liquid chromatographies (HPLC) were taken on a Shimadzu LC-4A apparatus. All melting-points were measured with a Yanagimoto micro melting point apparatus and are uncorrected. The ^1H NMR spectra were taken on a JEOL JMN-FX90 spectrometer. The thermal gravimetric analyses were done with a Rigaku Denki TG-DTA apparatus.

Preparation of 4. According to the reported procedure,[2] **4** was prepared from 1,8-naphthalenedicarboxylic anhydride (**3**) and potassium hydroxide.

Henkel Reaction in a Dispersion Medium (General Procedure). The dipotassium salt **4** and the catalyst (1—12 mol% based on **4**) were mixed intimately in a glass ball mill. After drying in vacuo at 150 °C, 10 g of the mixed powder was put into a 200 cm^3 autoclave, which had been preheated at 100 °C, along with 30 g of a dispersion medium such as naphthalene. The autoclave was then filled with carbon dioxide to a pressure of 4.1 MPa. While the mixture in the autoclave was stirred at 100 °C, carbon dioxide was occasionally introduced into the autoclave until there was no pressure drop. The mixture was thereafter heated to 450 °C at the heating rate of 6 °C min^{-1} while being stirred; it was then maintained at 450 °C for 1 h. The pressure increased to 7.1 MPa. After the autoclave had been cooled, toluene (200 cm^3) and water (200 cm^3) was successively added to the reaction mixture; the mixture was then stirred at 60 °C for 0.5 h. The insoluble materials, which mainly consisted of carbonized materials, were separated by filtration. After the organic layer had been removed, the aqueous layer was washed with toluene (100 cm^3×2), and then subjected to the



3 4 1 2

Scheme 1. Henkel process.

following product analysis.

Analysis of Products. Ten isomers of dipotassium naphthalenedicarboxylates can be obtained. Nine of them, potassium 2-naphthoate and tripotassium 2,3,6-naphthalenetricarboxylate were determined by HPLC using 1-naphthoic acid as the internal standard (column: Shimadzu Co.; Shimpack CLC ODS, and/or Japan Spectroscopic Co.; Finepak SIL C18S, eluent: a mixture of methanol and 0.2 wt% aqueous phosphoric acid solution). The yield of **1** is given by Eq. 1 (Eq. 2 is used in the case of a reaction using zinc naphthalate as the catalyst);

$$\text{Yield of } \mathbf{1}\,(\%) = 100\,A/R \quad (1)$$

$$\text{Yield of } \mathbf{1}\,(\%) = 100\,A/(R + C) \quad (2)$$

A/mol: Molar amount of **1** in the reaction mixture was determined by HPLC.

R/mol: Molar amount of **4**.

C/mol: Molar amount of zinc naphthalate.

Authentic Specimens. In order to analyze the products in the reaction mixture, a wide variety of naphthalenecarboxylic acids was prepared as follows. The 2,6-naphthalenedicarboxylic acid, 2,3-naphthalenedicarboxylic acid, 1,8-naphthalenedicarboxylic anhydride, 1-naphthoic acid, and 2-naphthoic acid were commercially available. Other dicarboxylic acids, such as the 1,2-, 1,3-, 1,4-, 1,5-, 1,6-, and 2,7-isomers, were prepared by the oxidation of the corresponding dimethylnaphthalenes with aqueous sodium dichromate.[9] The acid values were measured by titration in aqueous methanol with 0.1 mol dm^{-3} aqueous potassium hydroxide using 3,3-bis(4-hydroxyphenyl)phthalide as an indicator. The diacids prepared from dimethylnaphthalenes were esterified into the corresponding dimethyl esters by a usual procedure (catalyst: concd sulfuric acid) and were identified as follows.

1,2-Naphthalenedicarboxylic Acid: Acid value: 517.2. (Calcd for naphthalenedicarboxylic acid: 519.1). Dimethyl ester. Mp 83.5—84.8 °C (lit,[9] mp 84.0—85.0°C). ^{1}H NMR ($CDCl_3$) δ=3.96 (3H, s), 4.08 (3H, s), 7.5—7.7 (2H, m), 7.8—8.1 (4H, m).

1,3-Naphthalenedicarboxylic Acid: Acid value: 518.2. Dimethyl ester. Mp 101.5—102.5 °C (lit,[9] mp 104.5—105.0 °C. ^{1}H NMR ($CDCl_3$) δ=3.99 (3H, s), 4.08 (3H, s), 7.5—7.8 (2H, m), 7.9—8.0 (1H, m), 8.72 (2H, s), 8.93 (1H, d, J=8 Hz).

1,4-Naphthalenedicarboxylic Acid: Acid value: 517.5. Dimethyl ester. Mp 63.4—64.8 °C (lit,[9] mp 65.0—66.0 °C). ^{1}H NMR ($CDCl_3$) δ=4.00 (6H, s), 7.61 (2H, dd, J=10 Hz, 3 Hz), 8.05 (2H, s), 8.80 (2H, dd, J=10 Hz, 3 Hz).

1,5-Naphthalenedicarboxylic Acid: Acid value: 518.0. Dimethyl ester. Mp 119.0—119.5 °C (lit,[9] mp 119.0—120.0 °C). ^{1}H NMR ($CDCl_3$) δ=4.00 (6H, s), 7.61 (2H, t, J=8 Hz), 8.19 (2H, d, J=9 Hz), 9.11 (2H, d, J=9 Hz).

1,6-Naphthalenedicarboxylic Acid: Acid value: 518.4. Dimethyl ester. Mp 98.6—99.5 °C (lit,[9] mp 98.0—99.0 °C). ^{1}H NMR ($CDCl_3$) δ=3.98 (3H, s), 4.01 (3H, s), 7.54 (1H, dd, J=8 Hz, 8 Hz), 8.0—8.4 (3H, m), 8.61 (1H, d, J=2 Hz), 8.98 (1H, d, J=9 Hz).

2,7-Naphthalenedicarboxylic Acid: Acid value: 519.0. Dimethyl ester. Mp 136.5—137.3 °C (lit,[9] mp 136.5—137.0 °C). ^{1}H NMR ($CDCl_3$) δ=3.90 (6H, s), 7.7—8.2 (4H, m), 8.60 (2H, s).

2,3,6-Naphthalenetricarboxylic acid was isolated by sublimation from the reaction mixture as follows. The aqueous layer, which had been obtained from the reaction mixture as described in the general procedure, was concentrated in vacuo to give a slurry. The subsequent filtration of the slurry yielded **1** as colorless crystals. The filtrate was treated with active charcoal and acidified (pH less than 1) with concd hydrochloric acid to give precipitates of a mixture of naphthalenecarboxylic acids. The precipitates were filtered, washed with water, and dried. The esterification of the mixture of naphthalenecarboxylic acids with methanol was carried out in a usual procedure (catalyst; concd sulfuric acid, 130 °C, 0.61 MPa, 2 h). The esters were recrystalyzed from methanol to afford colorless crystals. The crystals were hydrolyzed with aqueous alkali, and then acidified with concd hydrochloric acid to give the corresponding acids. HPLC revealed that these acids were an isomeric mixture of naphthalenetricarboxylic acids and consisted mainly of the 2,3,6-isomer. The sublimation of the acids at 230 °C/133 Pa gave 2,3,6-naphthalenetricarboxylic acid 2,3-anhydride as colorless crystals. Found: C, 64.40; H, 2.41%. Calcd for $C_{13}H_6O_5$: C, 64.47; H, 2.50%. Trimethyl ester. Mp 123.0—125.0 °C (lit,[9] mp 125.0—126.0 °C). ^{1}H NMR ($CDCl_3$) δ=3.97 (6H, s), 4.00 (3H, s), 7.9—8.4 (4H, m), 8.64 (1H, s).

Thermal Gravimetric Analysis (TGA). A mixture (15 mg) of **4** and the catalyst was put into a platinum cell, and then heated to 520 °C at the rate of 10 °C min^{-1} in a stream of carbon dioxide.

Results and Discussion

Dispersion Mediums. The results of the Henkel reaction with and without a dispersion medium are summarized in Table 1. A mixture of zinc chloride and potassium iodide (8 mol% based on **4**, respectively) was used as the catalyst. Without a dispersion medium, the composition of the reaction mixture varied depending on the site in the autoclave. It was also found that **1** was obtained in a low yield and that the reproducibility of the reaction was very poor (Runs 1—3). On the other hand, the reaction in naphthalene as a dispersion medium gave **1** in a good yield (70 mol%), and the reproducibility was improved (Runs 4, 5). Using a specially designed autoclave equipped two windows in its wall, we were able to observe the reaction process and found that black powders of the crude products were dispersed uniformly in the liquid naphthalene. It should be also noted that the reaction gave almost the same products irrespective of whether or not **4** and the catalyst had been premixed before they were charged into liquid naphthalene. These results indicate that the liquid naphthalene promotes both heat and mass transfer in the reaction, so that the reproducibility of the reaction is improved along with the yield of **1**.

When biphenyl, a mixture of diphenyl ether and biphenyl, or phenanthrene was used as the dispersion medium, the yield of **1** was also improved (Runs 6—8).[10] On the other hand, the addition of methylnaphthalene or ethylbipenyl decreased the yield of **1** and gave more tarry materials (Runs 9, 10). Aromatic compounds with acidic hydrogens of the alkyl groups,

Table 1. Henkel Reaction in Various Dispersion Mediums

Run No.	Dispersion medium	Yields of products/mol%[a]			
		1	5	6	7
1	None	53.8	12.0	10.6	4.3
2	None	45.7	17.2	19.6	4.5
3	None	48.1	15.2	18.0	4.5
4	Naphthalene	69.1	2.5	3.0	2.4
5	Naphthalene	69.2	2.7	3.1	2.5
6	Biphenyl	62.6	3.3	2.5	2.5
7	Diphenyl ether+biphenyl[b]	60.4	2.8	2.5	3.3
8	Phenanthrene	61.3	4.8	9.0	3.3
9	Methylnaphthalene	44.6	1.1	10.5	0.4
10	Ethylbiphenyl[c]	21.3	21.3	34.0	0.8

4 was heated at 45 °C (c; 410 °C) for 1 h in the presence of $ZnCl_2$ (8 mol%) and KI (8 mol%). The initial pressure of CO_2 was 4.1 MPa at 100 °C. Thirty grams of the dispersion medium were used for each 10 g of the starting materials (**4** and the catalyst). a) **1**: dipotassium 2,6-naphthalenedicarboxylate, **5**: dipotassium naphthalenedicarboxylate except for **1**, **6**: potassium 2-naphthoate, **7**: tripotassium 2,3,6-naphthalenetricarboxylate. b) The molar ratio of diphenyl ether to biphenyl was 74/26.

Table 2. Zinc(II)-Catalyzed Henkel Reaction

Run No.	Catalyst	Yields of products/mol%[a]			
		1	5	6	7
11	ZnO	41.1	17.5	22.4	5.7
12	$ZnCO_3$	55.1	7.8	11.5	2.6
13	Zinc naphthalate[b]	57.1	4.6	8.2	4.5
14	$ZnCl_2$	62.3	4.0	7.7	4.7
15	ZnI_2	69.6	2.6	4.1	2.7
16	$ZnCl_2$+KCl	62.5	4.2	8.2	4.5
17	$ZnCl_2$+KBr	64.8	3.7	6.1	4.4
4	$ZnCl_2$+KI	69.1	2.5	3.0	2.4
18	Zinc naphthalate+KI[b]	70.3	2.4	5.1	2.4
19	ZnO+KI	45.8	20.7	16.1	3.7
20	$ZnCO_3$+KI	58.1	4.9	9.6	1.3

The reactions were carried out at 45 °C for 1 h in the presence of 8 mol% (b) 8.7 mol%) of the catalyst. The initial pressure of CO_2 was 4.1 MPa. Thirty grams of naphthalene were used for each 10 g of the starting materials (**4** and the catalyst). a) **1**: dipotassium 2,6-naphthalenedicarboxylate, **5**: dipotassium naphthalenedicarboxylate except for **1**, **6**: potassium 2-naphthoate, **7**: tripotassium 2,3,6-naphthalenetricarboxylate.

such as methylnaphthalene and ethylbiphenyl, seem to bring about the decarboxylation of both the starting material **4** and the products to lower the yield of **1**.

Catalysts. Zinc catalysts have rarely been used for the Henkel reaction because their catalytic activity was lower than that of cadmium catalysts.[2-6] From the standpoint of industrial production, however, it is desired to replace cadmium catalysts with zinc catalysts because of their toxicity and high price. Therefore, a wide variety of zinc compounds was examined as catalysts on this Henkel reaction.

Effects of the Anionic Moiety of the Zinc Catalysts: The results of the reactions with a wide variety of zinc compounds are shown in Table 2. The influence of the anionic moiety of the zinc catalysts on the yields of products was unexpecctedly large. Zinc halides were the most effective catalysts to yield **1** predominantly (Runs 14, 15), while zinc oxide (Run 11) or zinc carbonate (Run 12) gave **1** in a low yield. The addition of potassium halides to zinc chloride or zinc naphthalate catalyst (Runs 16—18, 4) was also effective in increasing the yield of **1**. The catalytic activity increased in the order;

$$Cl^- < Br^- < I^-$$

On the other hand, the addition of potassium iodide to zinc oxide (Run 19) or zinc carbonate (Run 20) hardly improved the yield of **1** at all.

Effects of the Amount of the Catalyst: The effects of the amounts of zinc naphthalate and potassium iodide are summarized in Table 3. It was found that the yield of **1** depended on both the amount of the zinc naphthalate and the molar ratio of the potassium iodide to the zinc naphthalate. When the amount of the zinc naphthalate was 1 mol%, regardless of the amount of potassium iodide, the reaction gave **1** in a low yield (Runs 21, 22). When the amount of the zinc naphthalate was over 4 mol%, the yield of **1** increased, whereas the yields of the isomers of **1** (**5**) and potas-

Table 3. Effects of the Amount of the Catalyst

Run No.	Amount of catalyst/mol%[a]		Yields of products/mol%[b]			
	Zinc naphthalate	KI	**1**	**5**	**6**	**7**
21	1.0	1.0	55.7	10.1	15.1	5.5
22	1.0	8.0	56.9	12.7	12.5	3.2
23	4.3	4.3	67.5	3.8	7.3	3.6
24	8.7	4.3	64.5	4.5	6.1	4.3
18	8.7	8.7	70.3	2.4	5.1	2.4
25	8.7	12.0	69.5	2.5	5.2	3.1

The reactions were carried out at 45 °C for 1 h. The initial pressure of CO_2 was 4.1 MPa. Thirty grams of naphthalene were used for each 10 g of the starting materals (**4** and the catalyst). a) The amounts of the catalyst were based on **4**. b) **1**: dipotassium 2,6-naphthalenedicarboxylate, **5**: dipotassium naphthalenedicarboxylate except for **1**, **6**: potassium 2-naphthoate, **7**: tripotassium 2,3,6-naphthalenetricarboxylate.

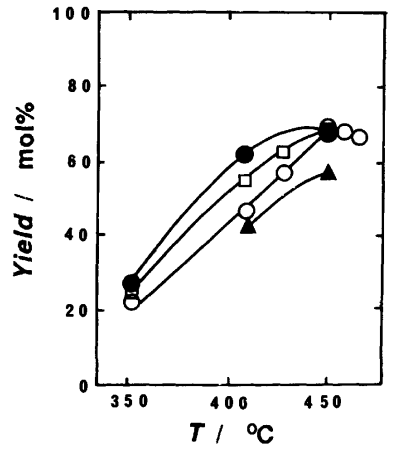


Fig. 1. Yields of **1** at different temperatures: **4** was heated at different temperatures for 1 h. The initial pressure of CO_2 was 4.1 MPa at 100 °C. Thirty grams of naphthalene were used for each 10 g of the starting materials (**4** and the catalyst). ○: zinc naphthalate (8.7 mol%)+KI (8.7 mol%), □: $ZnCl_2$ (8 mol%)+KI (8 mol%), ●: CdI_2 (8 mol%), ▲: CdO (8 mol%).

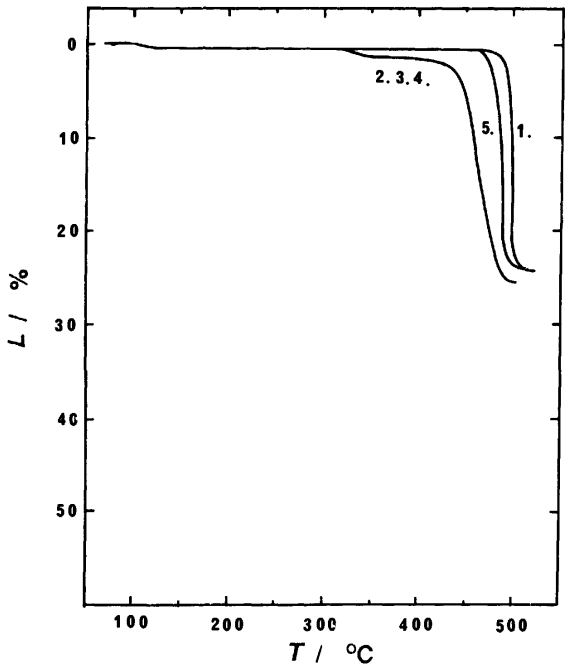

Fig. 2. Thermal gravimetric analyses for the starting materials in carbon dioxide stream: *L* is the weight loss of the starting material. 1: **4**, 2: **4**+$ZnCl_2$ (8 mol%)+KI (8 mol%), 3: **4**+zinc naphthalate (8.7 mol%)+KI (8.7 mol%), 4: **4**+zinc naphthalate (8.7 mol%), 5: **4**+ZnO (8 mol%)+KI (8 mol%).

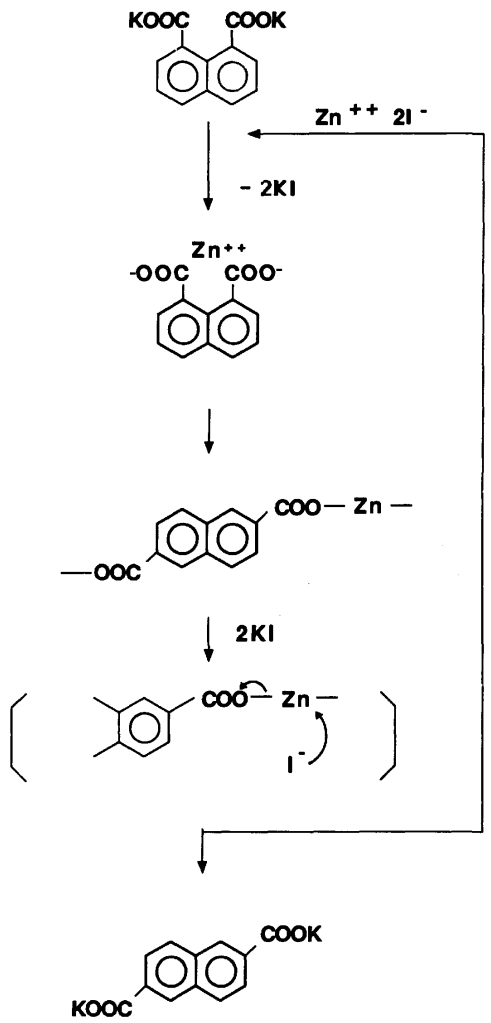
sium 2-naphthoate (**6**) decreased. When the amount of the potassium iodide was used more than that of the zinc naphthalate, **1** was obtained in a satisfactory yield, i.e., 67—70 mol% (Runs 18, 23, and 25).

Comparison between Zinc and Cadmium Catalyst: The reaction using the zinc catalyst was carried out at different temperatures in order to compare the activity with that of the cadmium catalyst. The results are shown in Fig. 1. The activities of zinc catalysts having iodide anion (plots ○, □) were lower than that of the cadmium iodide (plot ●) below of the reaction temperature 430 °C, but almost the same as that at 450 °C.

The activity of the cadmium oxide (plot ▲) was lower than that of the cadmium iodide (plot ●), so the anionic moiety of the cadmium catalyst seems to play the same role as that of the zinc catalyst. Ogata et al. reported a similar observation that the increasing order of the catalytic activity was $CdCl_2 < CdBr_2 < CdI_2$ in the preparation of dipotassium terephthalate from dipotassium phthalate.[11]

We found that the cadmium catalyst could be replaced by a combination of zinc(II) and I^- catalyst whose activity was the same as that of the cadmium catalyst.

Thermal Gravimetric Analyses (TGA). TGA of **4** in the presence of various catalysts were carried out in order to examine the thermal behavior of **4** in its dependence on the kinds of the zinc catalysts. The results of TGA in a steam of carbon dioxide at an atmospheric pressure are shown in Fig. 2. In the presence of a catalytic amount of zinc chloride or zinc naphthalate (Line 2—4), **4** started to lose weight from 320 °C with foaming. The weight loss observed from 320 °C in TGA may be due to the decarboxylation of **4**.



Scheme 2. Roles of the catalysts.

It should be noted that the Henkel reaction began to proceed at almost the same temperature. On the other hand, **4** without the catalyst (Line 1) or **4** with the catalytic amount of zinc oxide and potassium iodide (Line 5) started to lose weight over 450 °C. These results indicate that the zinc cation of zinc halide or zinc naphthalate can react with **4** and bring about the cleavage of the C–C bond between the carboxyl group and the naphthalene nucleus of **4**. In the case of zinc oxide, however, the affinity of the oxygen to the zinc is so strong that a little zinc oxide reacts with **4**.

Role of Catalysts: On the basis of our experimental findings, we propose the roles of the catalysts as shown in Scheme 2. The potassium cation of **4** is replaced by the zinc cation to form a zinc compound such as zinc naphthalate. The zinc cation of the zinc naphthalate loosens the C–C bond between the carboxyl group and the naphthalene nucleus and allows **4** to rearrange to give 2,6-isomer; then, the zinc cation is exchanged for the potassium cation. In this exchange reaction, the halide anion promotes the exchange rate.

(Received July 29, 1988)

A methodology to improve lipid microspheres (LM) as a carrier for lipophilic drugs and their physicochemical properties are described. The LM were prepared from glycerides, glycerol, and phospholipids. The method involves coating of the surface of the LM with a naturally occurring or chemically modified polysaccharide. Special emphasis will be made on cholesterol-bearing pullulan and amylopectin. This is the same approach as that adopted for the stabilization of liposomes. Turbidity measurement revealed that the coating effectively depressed the Ca^{2+}-induced aggregation of the LM. From fluorescence polarization measurements, it was concluded that the fluidity of the LM surface decreased with the polysaccharide coating. Furthermore, the coating effect was investigated by zeta-potential measurements. The coating reduced the negative zeta-potential of the LM to an apparently neutral value.

Lecithin emulsions, so-called lipid microspheres (LM) or microdroplets, have recently gained wide interest as a carrier for lipophilic drugs.[1-4] Liposomes are complementary to LM as a drug carrier system (DDS), especially for hydrophilic drugs. However, there are several advantages of LM over liposomes, such as a high colloidal stability, which makes it possible to store the emulsions for a long period (several months) at room temperature without any noticeable change in their physicochemical properties. Furthermore, they can be produced on an industrial scale, and maybe most importantly, LM can incorporate a relatively large amount of lipophilic substances. LM are oil-in-water emulsions where phospholipids are used as the emulsifying agent.[1] The oil phase can entirely consist of a substance with medicinal potency, such as methoxyflurane used as local anesthesia.[2] Alternatively, a neutral fat is used, e.g. soybean oil, in which lipophilic drugs are dissolved. Steroids[3] and prostaglandins[4] are examples of drugs which have been incorporated in LM and successfully employed in treatments of several diseases.

The methodology for using liposomes in DDS has been relatively well established, and their physicochemical properties and fate in biological systems also have been rather well characterized.[5,6] For liposomes, in addition, much effort have been made to improve their stability and cell-recognizability.[7] However, relatively few significant investigations have been made on LM.

Therefore, we investigated the colloidal stability of LM in the presence of salts and polysaccharides by turbidity measurements. The zeta-potential of the LM was determined by microelectrophoretic measurements in the presence and absence of the polysaccharides. Furthermore, an extensive fluorescence spectroscopic investigation was carried out. The spectral behavior and the fluorescence polarization of two different fluorophores encapsulated in the LM were monitored. The amphiphilic *N*-dansylhexadecylamine (DSHA) and the hydrophobic 1,6-diphenylhexatriene (DPH) were used as the fluorescent probes.

The employed polysaccharides were the same as those previously used for the stabilization of liposomes, namely cholesterol-bearing amylopectin and pullulan.[7] As a comparison, we also investigated the effects of unmodified dextran, amylopectin, and pullulan, respectively. In addition, we used ethyl(2-hydroxyethyl)cellulose (EHEC) which is a nonionic cellulose ether. EHEC is widely used, inter alia, as an emulsifier in foodstuffs and pharmaceutical formulations.[8]

Experimental

Materials. Lipid microspheres (LM) were kindly prepared by Dr. Kiyoshi Iwamoto, Eisai Co., Tsukuba, Japan.[9] One ml of an aqueous LM emulsion contained 100 mg of soybean oil, 12 mg of egg yolk phospholipids, and 25 mg of glycerol which makes the system isoosmotic in normal saline solution. The phospholipids employed (Asahi Chemical Industry Co., Japan) contained 67.0 mol% phosphatidylcholine, 18.6 mol% phosphatidylethanolamine, and 0.8 mol% lysolecithin. In addition, the phospholipids consisted of an unspecified amount of negatively charged lipids, such as phosphatidic acid and phosphatidylserine. The acid value was 17.1 mg/kg. The LM were sealed in glass ampoules under N_2 atmosphere and stored at 5 °C prior to use. All measurements were performed on LM diluted 1000 times (by volume) with water.

Pullulan-50 (M.W. 50000) and amylopectin-112 (M.W. 112000) were kind gifts from Hayashibara Biochemical Laboratories, Inc., Okayama, Japan. Dextran-40 (M.W. 40000) was purchased from Tokyo Kasei Co., Tokyo, and dextran-176 (M.W. 176000) from Nakarai Chemicals Ltd., Kyoto. Ethyl(2-hydroxyethyl)cellulose-146 (EHEC-146; M.W.

† On leave from Physical Chemistry 1, Chemical Center, Lund University, P.O.B. 124, S-221 00, Lund, Sweden.

146000 with 2,12-hydroxyethyl groups and 0.9 ethyl group per glucose unit) was kindly presented by Berol Kemi AB, Stenungsund, Sweden. Cholesterylpullulan (CHP) and cholesterylamylopectin (CHAp) were prepared according to the procedure described elsewhere.[10] CHP was synthesized from pullulan-61 (M.W. 61000) in Dojindo Laboratories, Kumamoto, Japan. This sample contained 1.0 cholesteryl group per 100 glucose units (analyzed by ^{1}H NMR) and is coded as CHP-61-1.0. Another CHP sample was synthesized in this laboratory (by the courtesy of K. Sakai) from pullulan-50 and contained 1.9 cholesteryl groups per 100 anhydroglucose units. This is coded as CHP-50-1.9. CHAp was synthesized from amylopectin-112 and it contained 1.8 cholesteryl groups per 100 glucose units and is coded as CHAp-112-1.8.

Both *N*-dansylhexadecylamine (DSHA) and 1,6-diphenyl-1,3,5-hexatriene (DPH) were the same as those used in previous studies.[11,12] All other reagents were of analytical grade and used without further purification. Membrane-filtrated water (Milli-Q, Millipore Corp., Bedford, USA) was used in all experiments and all glass wares were washed in dichromate-sulfuric acid and rinsed carefully with pure water.

Turbidity Measurements. An appropriate amount of electrolyte solution was added to a cuvette cell containing the LM emulsion diluted 1 : 1000 and preincubated at a given temperature (adjusted within ±0.5 °C). The turbidity (the optical density increase) was recorded at 600 nm as a function of time on a Hitachi 200-10 recording spectrophotometer, equipped with a thermoregulated cell compartment as previously described.[13] No stirring of the emulsion was performed. The results are presented as turbidity change $\Delta\tau$, calculated from $\tau_t-\tau_0$, where τ_t is the turbidity at time t and τ_0 is the turbidity of the LM emulsion at time zero without salt (τ_0 was typically 0.2 absorbance unit at λ=600 nm).

Zeta-Potential Measurements. Microelectrophoretic measurements were carried out on a Laser Zee Meter model 501 (PenKem, Inc., New York). In general, for charged particles, the zeta-potential ζ (V) is related to the electrophoretic mobility v ($m^2V^{-1}s^{-1}$) by the following equation:[14,15]

$$\zeta = v\eta/\{\varepsilon_r\varepsilon_0 f(\kappa, R)\} \quad (1)$$

where η is the viscosity of the medium, ε_r is the relative permittivity of the medium, ε_0 is the permittivity of free space, κ is the Debye-Hückel parameter, and R is the particle radius. For spherical particles at relatively low ionic strength, $f(\kappa, R)$=2/3 and thus Eq. 1 becomes the following:

$$\zeta = 3v\eta/(2\varepsilon_r\varepsilon_0) \quad (2)$$

In an aqueous solution at 20 °C Eq. 2 reduces to

$$\zeta = 2.126 \times 10^6 v \quad (3)$$

Actually, the instrument reads out ζ directly as calculated automatically from ζ=1.417×10^6 v, assuming that the measurement is carried out in an aqueous solution at 20 °C and that $f(\kappa, R)$ is unity. However, the latter assumption is only valid at relatively high ionic strength. In fact, we performed most of the measurements without salt or at low ionic strength (e.g. 5 mM $CaCl_2$). This means a transformation is necessary.[15]

The measurements of ζ were made on LM diluted 1 : 1000 over a temperature range of 20—24 °C. Since both ε_r and η are temperature dependent, the ζ-potential was corrected to 20 °C by the relation: $\zeta_{corr.}=\zeta_{meas.}[1-0.02(t-20)]$, where t (°C) is the actual temperature at which the measurement was made.

When polymer was added, the system was sonicated with a probe-type sonicator for 1 min (20 W) at 0 °C. The final polymer concentration in the cuvette cell was 0.1 wt%. This means that one can discard the effect of added polymer on the viscosity of the sample emulsion (cf. Eqs. 1 and 2). When salt was added, normally 3-4 measurements were made on a freshly prepared LM-salt sample and the whole procedure (from the addition of salt to the recording of ζ) was completed within 4 min.

Fluorescence and Fluorescence Polarization Measurements. The procedures were essentially the same as those previously adopted for the characterization of liposomes.[11-13,16,17] A small amount of the fluorescent probe dissolved in THF was added to the LM emulsion (diluted 1 : 1000), which also contained appropriate amounts of salt and/or polymer. The resulting mixture was then sonified on a Tomy UR-200P probe-type sonicator (20 W, duty 40 on the meter of the instrument) for 2 min at 60—70 °C under N_2 atmosphere. The final concentrations of DSHA and DPH in the LM were 1×10^{-6} M (M=mol dm^{-3}) and 2.5×10^{-8} M, respectively. The molar ratio of the fluorescent probe to the phospholipid was 1/15 for DSHA and 1/615 for DPH, respectively.

Spectral measurements were performed on a Hitachi 650-10S fluorescence spectrophotometer equipped with a thermoregulated cell compartment. Fluorescence polarizations were measured out on a Union Giken FS-501S fluorescence polarization spectrophotometer equipped with a thermoregulated cell compartment and a magnetic stirrer. A Sord Microcomputer M 200 Mark II system was combined with the instrument to control the measurement conditions and collect the data. DSHA was excited at 340 nm and its fluorescence was detected using a sharp cut-off filter Y-46 (Hoya Glass Works, Tokyo) to shut out the light of wavelengths less than 440 nm. DPH was excited at 360 nm and an L-39 filter was employed to cut the light below 370 nm. The degree of fluorescence polarization p was calculated by the following equation:[18]

$$p = (I_{VV} - C_f I_{VH})/(I_{VV} + C_f I_{VH}) \quad (4)$$

where I is the fluorescence intensity and subscripts V and H refer to the vertical and horizontal orientations of the excitation (first subscript) and analyzer (second) polarizers, respectively. The factor C_f ($=I_{HV}/I_{HH}$) corrects for artifacts arising from mismatched detectors.[19] All the I-values were taken as an average of at least 20 runs, with a gate time of 1 second. Before the computation of p, the intensity data were corrected by subtracting the intensity from a conventional LM emulsion. This was done in order to avoid artifacts arising from light scattering and fluorescent impurities which otherwise would yield a too high p-value.[19]

Table 1. Zeta-Potentials for LM at 20.0°C and Different Ca^{2+}- and Na^{+}-Ion Concentrations

	C_{salt}/mM	ζ/mV[a]
Without salt		−62.9±4.2

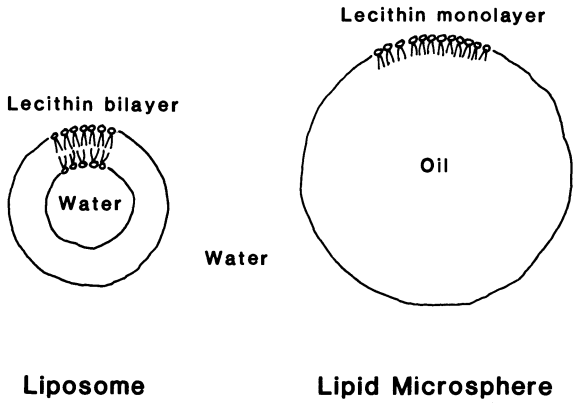

Fig. 1. Schematic representation of the structures of liposome and lipid microsphere.

Results and Discussion

As reported so far by Sunamoto and his co-workers,[7] liposomes can be effectively stabilized by coating the surface with a naturally occurring polysaccharide which bears cholesteryl groups in part. As we mentioned under Experimental the LM contain anionic lipids. Therefore, the surface of the LM employed in this work is negatively charged (Table 1), and the LM easily aggregate and are salted-out upon the addition of small amounts of electrolytes (Fig. 2). If one realizes the structural similarity of the LM surface, which is considered to be covered by a lipid monolayer, to that of liposomes as schematically represented in Fig. 1, it seems possible to also coat the LM with polymers in order to improve their structural stability. Therefore we investigated the colloidal stability of LM after coating the surface with different polysaccharides, particularly focusing on the effect of salt addition.

Due to the large particle size of the oil droplets and the difference in the refractive index between water and oil, the LM emulsion scatters light when irradiated. This feature was utilized to monitor the aggregation of LM in the presence of salt and different water-soluble polymers. Electrolytes were added up to the concentration corresponding to that under the physiological conditions. (In general, for mammalian the extra cellular fluid contains 145 mM Na^{+}, 5 mM K^{+}, 2.5—5 mM Ca^{2+}, and 1—2 mM Mg^{2+}.) The polymer concentration was arbitrarely chosen to be approximately

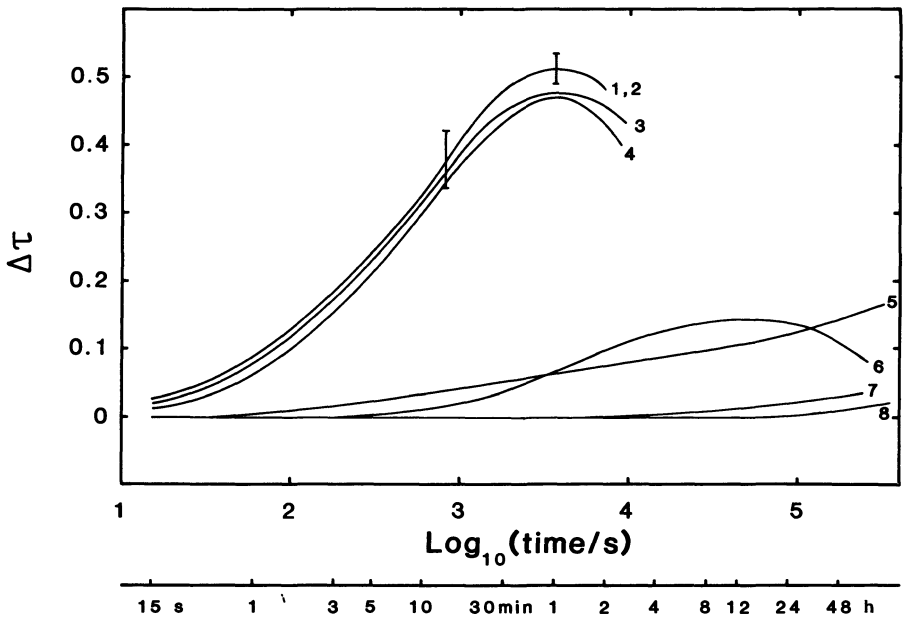

Fig. 2. Turbidity change ($\Delta\tau$) vs. time for LM (diluted 1:1000) after addition of 5 mM aqueous $CaCl_2$ at 37.0°C. 1: Without polysaccharide; 2: dextran-40 (0.96 mg ml^{-1}); 3: amylopectin-112 (0.95 mg ml^{-1}); 4: dextran-176 (0.95 mg ml^{-1}); 5: EHEC-146 (0.92 mg ml^{-1}); 6: pullulan-50 (0.95 mg ml^{-1}); 7: CHP-50-1.9 (0.87 mg ml^{-1}); 8: CHAp-112-1.8 (0.95 mg ml^{-1}).

0.9 mg per ml of LM emulsion (diluted 1:1000).

Presented in Fig. 2 are the turbidity measurements for LM in 5 mM aqueous $CaCl_2$ at 37 °C as a function of time. In the polymer-free system, a relatively rapid increase in the turbidity was observed, and after about 1 h $\Delta\tau$ reached its maximum. Due to precipitation of the LM aggregates, no further measurements were made after $\Delta\tau_{max}$. The same turbidity increase was recorded also at 25 °C. An almost clear solution was obtained if the samples were kept for 1—2 days in the presence of salts. Though not presented here, the effect of 150 mM Na^+-ion was less than that of 5 mM Ca^{2+}-ion. This was reflected through a slower increase in $\Delta\tau$ and a lower $\Delta\tau_{max}$. Even the addition of Na^+-ion caused a precipitation of the LM aggregates and led to a cleared supernatant. However, this was not observed until one week later. In the absence of salts, no significant change in turbidity was observed even after several months. These results suggest to us that we have to seriously consider the colloidal stability of LM in the blood stream when LM are employed as a carrier for lipophilic drugs, especially at higher concentrations.

However, if either CHAP-112-1.8, CHP-50-1.9, EHEC-146, or pullulan-50 was added to the LM before the addition of Ca^{2+}-ion, the aggregation behavior was dramatically altered (Fig. 2). This was reflected on the almost invariant $\Delta\tau$ values. Especially, the cholesterol-bearing polymers were superior in supressing the Ca^{2+}-induced aggregation, For example, the CHAP-112-1.8-coated LM showed no significant turbidity change even after 48 h. This means that these polysaccharides adsorb to the LM and effectively coat the surface, thereby largely preventing the salt-induced aggregation through steric stabilization.[20,21] The effect of pullulan-50 was noteworthy compared to the other three unmodified polysaccharides (amylopectin-112, dextran-40, and dextran-176). The three latter polymers completely lacked the ability to prevent LM aggregation. Even a three-fold increase in the concentration of amylopectin-112 did not significantly affect the result. Pullulan is a rather linear polymer and adsorbs more effectively to the LM surface than the other branched polymers.[13] The bulkyness of a branched polymer leads to a less surface coverage than that of a linear one.

Presented in Table 1 are the zeta-potential data for LM diluted 1:1000 at 20 °C as a function of the Ca^{2+}- and the Na^+-ion concentrations. The zeta-potential of the conventional LM employed in this work was approximately −63 mV. As expected, the addition of Na^+- or Ca^{2+}-ion led to a significant reduction in ζ, with the divalent cation substantially more effective than the monovalent,[22] as seen from the effective salt concentrations for to become zero. Thus, when the electrostatic double-layer repulsion is diminished, the colloidal particles can easily aggregate. No measurements were performed on systems in which both Ca^{2+}- and Na^+-ions were simultaneously present at the physiological concentration. If the Ca^{2+}-ion concentration is greater than 3% of the Na^+-ion concentration, the surface potential is solely determined by the Ca^{2+} ions.[22] Here, it should be pointed out that the obtained ζ-values probably are overestimated at the highest salt concentrations since $f(\kappa, R)$ in Eq. 1 appproaches unity at high ionic strength.[15] However, the measurements gave a qualitative picture of the changes of the surface potential upon the salt addition, and no efforts were made to correct the data.

Table 2. Zeta-Potentials for LM–Polysaccharide Systems[a] at 20.0 °C

Polymer	Concentration/mg ml^{-1}	ζ/mV
Dextran-40	1.00	−47.5
Dextran-176	1.01	−45.2
Pullulan-50	0.98	−32.6
EHEC-146	0.97	−13.5
CHP-61-1.0	0.98	−25.3
CHP-50-1.9	0.87	−18.8
CHAp-112-1.8	0.95	−11.3

a) The LM were diluted by water 1000 times (by vol.) prior to the addition of polysaccharide solution.

Table 2 presents the zeta-potentials of LM when various polysaccharide were added to the LM. The addition of all polymers caused a decrease in the zeta-potential. When a polymer adsorbs to the LM surface the charge density remains the same. However, due to the adsorbed polymer layer, the slipping plane is now moved to a point further out from the surface and therefore a lower ζ-potential is recorded. The effect of the two dextran derivatives was considerably less than that of the others. The results suggest that the coating efficiency by dextran is relatively low. In all cases in which the polymers were added, the addition of Ca^{2-}-ion to a concentration of 5 mM completely abolished the surface potential of the LM.

Clearly from the results the stability of the LM was largely affected by salts. The LM were especially sensitive to a divalent cation even at low concentration such as 5 mM Ca^{2+} (which is approximately the physiological concentration of the ion). The aggregation of the LM and the subsequent precipitation were directly observed as changes in the turbidity of the LM emulsions (Fig. 2).

The fluorescence polarization technique has frequently been used for the determination of the microviscosity of a molecular assembly, such as lipid bilayer membranes.[23] An important advantage of this technique is that the polarization data in terms of fluidity can be interpreted without further mathematical treatment. Presented in Fig. 3 are the p-values (as defined from Eq. 4) of DPH (top) and DSHA (bottom) in LM diluted 1:1000 as a function of temperature. Irrespective of the temperature, the p-

values of DPH in the hydrophobic core[23] of the LM were lower than those obtained in liposomal membranes.[12,16] This indicates that the fluidity of the interior core of the LM is higher compared to that of the lipid bilayers. Lipid bilayer membranes provide a more confined hydrophobic domain which leads to a more restricted motion of the fluorescent probe. The p-value of DPH in the LM decreased with an increase in the temperature, which indicates an increase in the fluidity of the interior core of the LM at higher temperatures. The fluorescence emission maximum (E_{max}) of DPH in the LM was 429 nm and constant over the range of 15—50 °C. The same emission maximum has been obtained when DPH was dissolved in both benzene and liposomes.[16,23] This indicates that DPH is locating in a very hydrophobic domain of the LM.

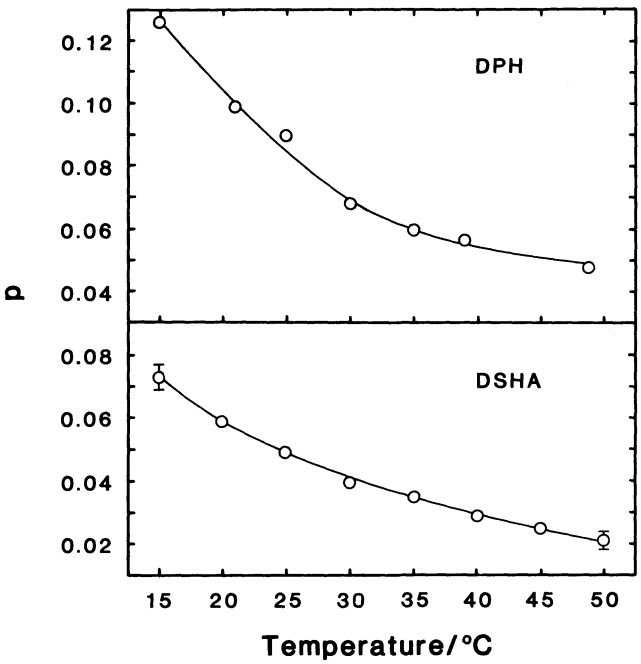

Fig. 3. Fluorescence polarization (p) of DPH (top) and DHSA (bottom) in LM (diluted 1:1000) as a function of temperature. The concentrations of DPH and DSHA in the LM were 2.5×10^{-8} M and 1×10^{-6} M, respectively.

The p-values of DSHA in LM (diluted 1:1000) as a function of temperature are given in Fig. 3 (bottom). DSHA is relatively amphiphilic and the dansyl moiety of DSHA is believed to locate in polar region close to the membrane surface in liposomal membranes.[11] Consequently, it is assumed that when DSHA is added to LM the polar dansyl group is in the region close to the microsphere-water interface and is surrounded by phospholipids. As for DPH, the p-value of DSHA also decreased on heating. This reflects that the fluidity of the phospholipid monolayer of the LM is also temperature dependent. The present data suggest either that the LM surface is more fluid compared with that of a liposomal surface, or that the probe is locating in a more fluid region close to the oil phase. For example, we obtained a p-value of 0.03 at 37 °C, while for egg L single-walled liposomes the p-value was 0.06 at the same temperature.[11] Over the temperature range studied, the emission maximum of DSHA was constant at 483 nm. This is 30—35 nm lower than that in single-walled liposomes,[11,12] and 7 nm lower than the value in water, where DSHA molecules self-aggregate.[11] This blue shift in E_{max} of DSHA in LM indicates that the probe is in a less polar environment compared with that in bilayer membranes of liposomes.

Emission maxima and p-values of DSHA at 37 °C are summarized in Table 3. The addition of Ca^{2+}- and Na^{+}-ions to concentrations of 5 and 150 mM, respectively, did not lead to any significant change in the p-value of DSHA. On the basis of this result, we did not investigate the salt effect on the DPH polarization.

Table 3. Fluorescence Emission Maxima and p-Values of DSHA (1×10^{-6} M) in LM (diluted 1:1000) at 37.0 °C

	Concentration		E_{max}/nm	p
	Salt/mM	Polymer/mg ml^{-1}		
No additives			483	0.031
Ca^{2+}	1		480	0.034
	5		479	0.029
	50		477	0.030
Na^{+}	150		480	0.029
Dextran-40		0.99		0.036
Dextran-176		1.00		0.032
Dextran-176+Ca^{2+}	5	1.00		0.030
Pullulan-50		1.01	482	0.038
Pullulan-50+Ca^{2+}	5	1.01	478	0.030
EHEC-146		1.0	478	0.041
EHEC-146+Ca^{2+}	5	1.0	478	0.038
CHP-61-1.0		1.00	482	0.046
CHP-61-1.0+Ca^{2+}	5	1.00	480	0.043
CHAp-112-1.8		1.00	478	0.057
CHAp-112-1.8+Ca^{2+}	5	1.00		0.061

However, a slight blue shift in E_{max} (3—6 nm) was observed when salts were present, probably because of the movement of the probe into a more hydrophobic domain upon the dehydration around the polar head group. The shift was more pronounced by adding 50 mM Ca^{2+}-ion. The addition of dextran-40 and -176, pullulan-50, and EHEC-146 showed no or little effect on the p-value of DSHA. However, the cholesterol-bearing polysaccharides (CHP-61-1.0 and CHAp-112-1.8) considerably increased the polarization of DSHA. Especially the addition of the latter one led to a two-fold increase in the p-value. This suggests that when these two polymers adsorb onto the LM surface, the cholesteryl group behaves as a hydrophobic anchor in the surface lipid layer. This would result in a lower fluidity of the surface of the LM. Though data are not shown, the difference in the p-values between the two groups of polymers was more pronounced at lower temperatures (15—30 °C). Even the addition of Ca^{2+} to a concentration of 5 mM to the LM-polymer samples did not significantly change the p-value.

After the addition of DSHA, the LM-EHEC-146 sample was sonicated under milder conditions (3 short flashes at 40 °C under N_2 atmosphere) in order to avoid phase separation during this procedure. Of the polymers employed in this work, EHEC-146 is the most hydrophobic one. This is evident from a lower critical solution temperature of an aqueous EHEC solution.[24] The change in the procedure for encapsulating the probe did not significantly alter the p-value of DSHA in a polymer-free LM sample (Fig. 3).

Judging from the results through the present investigation, we could conclude that the LM can effectively be coated by cholesterol-bearing polysaccharides similarly to liposomes. The coating of the LM surface with the polysaccharide derivatives led to a reduction of the divalent metal ion-induced aggregation of the LM. This is very promising for LM to be utilized as an improved carrier for lipophilic drug.

The stay of A. Carlsson in Japan was supported by a grant from the Swedish National Board for Technical Development. Comments on this work from Prof. Björn Lindman and Dr. Björn Bergenståhl are gratefully acknowledged. The instrument for microelectrophoretic measurements was kindly put at our disposal by Tsukuba Research Laboratories, Eisai Co. This research was financially supported by a Grant-in-Aid (No. 62850151) from the Ministry of Education, Science and Culture.

Facile Synthesis of (2*S*,3*R*,4*R*)-2-Hydroxymethyl-3,4-pyrrolidinediol and 4-Acetamido-1,2,3-tri-*O*-acetyl-4-deoxy-L-xylopyranose from the Photoproduct of D-Mannose

Akira HOSAKA, Shuji ICHIKAWA, Hiroko SHINDO, and Tadashi SATO*

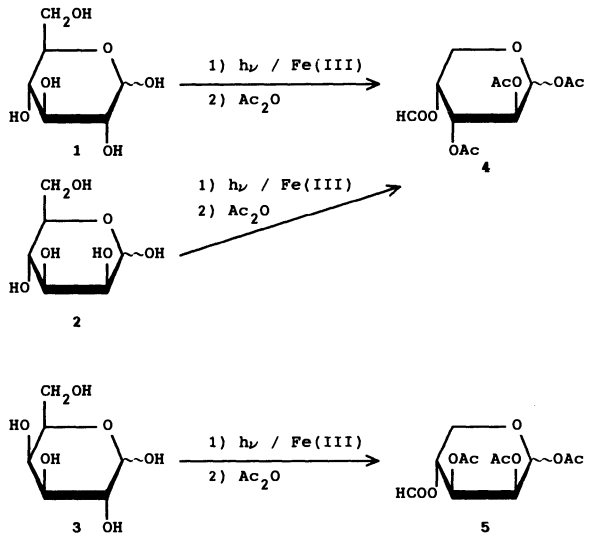
(Received July 30, 1988)

Synthesis of (2*S*,3*R*,4*R*)-2-hydroxymethyl-3,4-pyrrolidinediol and 4-acetamido-1,2,3-tri-*O*-acetyl-4-deoxy-L-xylopyranose were attained in four steps from D-mannose, using iron(III)-catalyzed photoreaction as a key reaction.

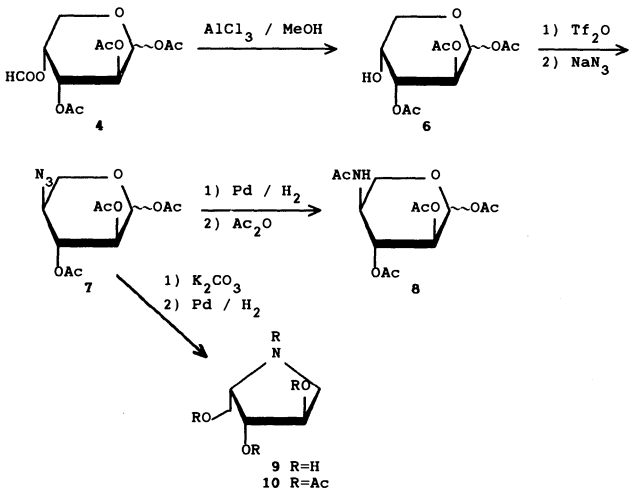
In our previous papers,[1] we reported that UV irradiation of D-glucose (**1**) or D-mannose (**2**) in the presence of iron(III) chloride followed by acetylation gave 1,2,3-tri-*O*-acetyl-4-*O*-formyl-D-arabinopyranose (**4**), while D-galactose (**3**) gave 1,2,3-tri-*O*-acetyl-4-*O*-formyl-D-lyxopyranose (**5**) under the same conditions. The most characteristic point of the reaction is that the aldohexoses produce aldopentoses in which only C4 hydroxyl group is protected by formyl group.



In order to explore the applicability of the photoproducts for synthetic purpose, we chose a pyrrolidine derivative and an amino sugar as the target compounds.

Some hydroxylated pyrrolidine derivatives have been known to possess glycosidase inhibition or immunoregulative activities.[2,3] In order to clarify the structure–bioactivity relationship, it is biologically important to prepare epimers of the bioactive molecules. Several stereoisomers of 2-hydroxymethyl-3,4-pyrrolidinediol have been synthesized.[2–6] We envisioned that (2*S*,3*R*,4*R*)-2-hydroxymethyl-3,4-pyrrolidinediol (**9**) could be synthesized quite easily by starting from our photoproduct.

In this paper we describe the facile synthesis of 4-acetamido-1,2,3-tri-*O*-acetyl-4-deoxy-L-xylopyranose (**8**) as well as **9**, using the photoproduct **4** as a key intermediate. The compounds **8** and **9** have been synthesized from 2-amino-2-deoxy-D-glucose in nine steps.[5]



Although we have utilized iron(III) chloride as the catalyst for the selective photocleavage at C1–C2 bond of the carbohydrates, the reaction was accompanied by the formation of brown material, which adhered to the inside of the vessel, causing inconvenience for the large-scale preparation. We found that iron(III) trifluoromethanesulfonate (triflate) is superior to the chloride as shown below.

A pyridine solution of D-mannose (**2**) containing iron(III) triflate or iron(III) chloride was irradiated with a high-pressure mercury lamp in a Pyrex vessel while oxygen gas was bubbled through. After the irradiation for 8 h or 24 h, the products were isolated as acetates by treating the irradiated pyridine solution with acetic anhydride. The major product was an anomeric mixture of an aldopentose derivative **4**, along with the starting material as pentaacetate. The results are shown in Table 1. Evidently iron(III) triflate catalyzed the reaction more effectively than iron(III) chloride, and no solid material separated out during the irradiation under these conditions. In view of these results, we used 1/100 equiv of iron(III) triflate

Table 1. Catalytic Activities of Iron(III) Chloride and Iron(III) Triflate

Carbohydrate	Iron salt	Mole ratio to carbohydrate	Reaction time	Relative yield/%	
			h	Product	Starting material
D-Glucose	$FeCl_3$	1	24	**4** 45	55
	$Fe(OTf)_3$	1/100	8	**4** 44	56
D-Mannose	$FeCl_3$	1	24	**4** 17	83
	$Fe(OTf)_3$	1/100	8	**4** 57	43
D-Galactose	$FeCl_3$	1	24	**5** 40	60
	$Fe(OTf)_3$	1/100	8	**5** 56	44

for the large-scale preparation.

Treatment of the crude material, obtained from **2** through the irradiation and succeeding acetylation, with aluminium chloride in aqueous methanol[1] gave 1,2,3-tri-*O*-acetyl-D-arabinopyranose (**6**) in 24% overall yield from **2** after the purification on a silica-gel chromatography. Triflation of **6** with trifluoromethanesulfonic anhydride followed by treatment with sodium azide gave 1,2,3-tri-*O*-acetyl-4-azido-4-deoxy-L-xylopyranose (**7**) in 55% yield. It has been reported that no side reactions occur under these conditions.[7]

Catalytic hydrogenation of **7** followed by acetylation gave **8** in 27% yield. Deacetylation of **7** with potassium carbonate in methanol followed by catalytic hydrogenation gave **9** in 77% yield, after purification on an ion-exchange chromatography. Acetylation of **9** gave tetraacetate **10** in 55% yield. Treatment of the acetate with hydrochloric acid afforded the corresponding hydrochloride in 83% yield. The ^{13}C NMR spectrum of the hydrochloride was identical with that reported for its enantiomer.[6]

Experimental

General. Column chromatography was performed on Wakogel C-200 (Wako), and TLC was performed on Kieselgel 60 GF_{254} (Merck). ^1H NMR spectra (60 MHz) were recorded on a Hitachi R-24 spectrometer. ^1H NMR (90 MHz) and ^{13}C NMR spectra were measured on a Hitachi R-90H spectrometer, high-resolution mass spectra on a JEOL DX-300 mass spectrometer, IR spectra on a Shimadzu IR-400 spectrometer, and optical rotations on a JASCO DIP-4 polarimeter.

The irradiations were carried out using a high-pressure mercury lamp [Sen SL-2000 (2 kW)] at the temperature of running water.

1,2,3-Tri-*O*-acetyl-D-arabinopyranose (6). A pyridine solution (900 cm^3) of D-mannose (9 g, 50.0 mmol) and iron(III) triflate (252 mg, 5.01×10^{-1} mmol) was irradiated in a Pyrex vessel for 8 h while oxygen gas was bubbled through. Acetic anhydride (70 cm^3, 0.742 mmol) was added to the solution, and the solution was stirred for 14 h at room temp. The solution was concentrated under reduced pressure (35 °C) and the residue was partitioned between diethyl ether (100 cm^3) and brine (100 cm^3). After extraction of the aqueous layer with diethyl ether (100 $cm^3\times2$), the combined ether solution was dried over $MgSO_4$. The solvent was removed in vacuo, and the residue was dissolved in methanol (500 cm^3) containing aluminium chloride (410 mg, 3.07 mmol) and water (25 cm^3). After stirred for 36 h at room temp, the solution was concentrated in vacuo, and water (50 cm^3) was added. The mixture was shaken with dichloromethane, the extract was dried over $MgSO_4$, and the solvent was removed in vacuo. The residue was chromatographed (silica gel/Et_2O) to afford **6** (3.26 g, 24%) as a syrup (R_f=0.30, Et_2O).[1]

1,2,3-Tri-*O*-acetyl-4-azido-4-deoxy-L-xylopyranose (7). To a stirred solution of **6** (1.85 g, 6.70 mmol) in a mixture of dry dichloromethane (160 cm^3) and dry pyridine (0.81 cm^3) was added trifluoromethanesulfonic anhydride (1.24 cm^3, 7.37 mmol) dropwise at 0 °C under an atmosphere of nitrogen. After stirring for 1 h at 0 °C, the solution was poured into 100 cm^3 of ice-water. The organic layer was separated, and the aqueous layer was extracted with two 50 cm^3 portions of dichloromethane. The combined extract was dried over $MgSO_4$ and the solvent was removed to give a brown syrup. The crude triflate was dissolved in *N,N'*-dimethylformamide (80 cm^3), and sodium azide (435 mg, 6.70 mmol) and 15-crown-5 (1.33 cm^3, 6.70 mmol) were added to the solution. After stirred for 24 h at room temp, the solution was concentrated and the residue was partitioned between diethyl ether (30 cm^3) and water (30 cm^3). After extraction of the aqueous layer with diethyl ether (30 $cm^3\times2$), the combined extract was dried over $MgSO_4$. The solvent was evaporated and the residue was chromatographed (silica gel/Et_2O) to afford **7** (1.11 g, 55%, α/β=1/2) as a colorless syrup (R_f=0.74, Et_2O). IR (neat) ν_{max} 2110, 1750 cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.00, 2.03, 2.08, 2.09, 2.11, 2.16 (9H, singlets, Ac), 3.39—4.14 (3H, m, H_4, H_5, $H_{5'}$), 4.88—5.45 (2H, m, H_2, H_3), 5.61 (1/3H, d, J=7.4 Hz, α-H_1), 6.19 (2/3H, d, J=3.5 Hz, β-H_1). ^{13}C NMR ($CDCl_3$), for α anomer, δ=58.48 (C_4), 63.94 (C_5), 70.10 (C_3), 72.93 (C_2), 92.14 (C_1); for β anomer, δ=59.09 (C_4), 61.56 (C_5), 69.49 (C_3), 70.43 (C_2), 89.34 (C_1).

4-Acetamido-1,2,3-tri-*O*-acetyl-4-deoxy-L-xylopyranose (8). A solution of **7** (660 mg, 2.19 mmol) in acetic acid (25 cm^3) was hydrogenated in the presence of 10% Pd-C (900 mg) under hydrogen (1 atm) for 2 h. The catalyst was filtered and the solvent was evaporated. To the residue dissolved in pyridine (30 cm^3) was added acetic anhydride (1.5 cm^3, 15.9 mol) and the mixture was stirred for 18 h at room temp. The solution was concentrated and the residue was partitioned between dichloromethane (15 cm^3) and brine (15 cm^3). After extraction of the aqueous layer with dichloromethane (15 $cm^3\times2$), the combined extract was dried over $MgSO_4$. The solvent was removed and the residue was chromatographed on silica gel (MeOH). A fraction corresponding to R_f 0.65 (MeOH) was β-8 (187 mg, 27%), a syrup, $[\alpha]_D^{23}$ −69° (*c* 3.56, MeOH). IR (neat) ν_{max}=3280, 2964, 1750, 1640, 1520 cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.93 (3H, s, NAc), 2.01, 2.07, 2.13 (9H,

singlets, 3×OAc), 3.53—4.03 (3H, m, H_4, H_5, $H_{5'}$), 4.94—5.20 (2H, m, H_2, H_3), 5.96 (1H, bs, NHAc), 6.23 (1H, d, J=3.0 Hz, H_1). ^{13}C NMR ($CDCl_3$) δ=20.43, 20.73 (OAc-Me), 23.05 (NAc-Me), 49.88 (C_4), 62.11 (C_5), 69.27, 69.67 (C_2, C_3), 89.55 (C_1), 168.70, 169.31, 170.04 (OAc-CO), 171.69 (NAc-CO). HRMS, Found: m/z 318.1193. Calcd for $C_{13}H_{20}NO_8$: M+H, 318.1189.

(2*S*,3*R*,4*R*)-2-Hydroxymethyl-3,4-pyrrolidinediol (9). To a stirred solution of **7** (1.00 g, 3.32 mmol) in 10% aqueous methanol (10 cm^3) was added aqueous saturated potassium carbonate solution (0.5 cm^3) at 0 °C. After the solution was stirred for 15 min at 0 °C, acetic acid (25 cm^3) was added. The mixture was stirred under hydrogen (1 atm) with 10% Pd-C (1 g) for 3 days. After removal of the catalyst, the filtrate was concentrated to a volume of 1 cm^3. This solution was loaded onto an acid ion exchange column (Dowex 50X8-100, H^+ form). Acetic acid and inorganic substances were washed away with water and then the basic material was eluted from the column with 2.8% aqueous ammonium hydroxide. The solvent was removed from the eluate to give **9** (342 mg, 77%) as a syrup, ^{13}C NMR (D_2O with dioxane reference) δ=53.57 (C_5), 62.26 (CH_2OH), 64.06 (C_2), 69.30 (dioxane), 79.06, 79.33 (C_3, C_4). HRMS, Found: m/z 102.0568. Calcd for $C_4H_8NO_2$: M−CH_2OH, 102.0555.

Acetylation of **9** with pyridine-acetic anhydride gave acetate **10** in 55% yield as a syrup (R_f=0.50, MeOH: $CHCl_3$=1:15) after purification by column chromatography (silica gel/MeOH:$CHCl_3$=1:15). $[\alpha]_D^{24}$ −19° (c 4.37, MeOH). ^{1}H NMR ($CDCl_3$) δ=2.02—2.06 (12H, singlets), 3.24—3.45 (1H, m), 3.86—4.26 (4H, m), 5.18—5.30 (2H, m). ^{13}C NMR ($CDCl_3$) δ=20.52, 20.64, 20.82 (OAc-Me), 22.17 (NAc-Me), 50.25 (C_5), 55.28 (CH_2OH), 60.10 (C_2), 73.57, 74.12 (C_3, C_4), 169.46, 169.61, 169.77, 169.95 (CO). HRMS, Found: m/z 302.1231. Calcd for $C_{13}H_{20}NO_7$: M+H, 302.1240.

The hydrochloride of **9** was prepared by refluxing a solution of **10** (98 mg, 0.326 mmol) in methanol (2 cm^3) and aqueous HCl (4 mol dm^{-3}, 2 cm^3) for 16 h followed by concentration and purification through a column (Florigil/MeOH). The hydrochloride was obtained as powder (46 mg, 83%). ^{13}C NMR (D_2O with dioxane reference)[6] δ=53.32 (C_5), 60.09 (CH_2OH), 65.67 (C_2), 69.30 (dioxane), 77.14 (C_3, C_4).

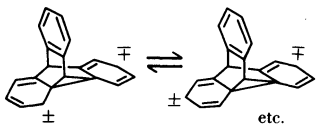
Effects of Substituents and Solvents on the Electronic Spectra of 9,10-Dihydro-9,10-*o*-benzenoanthracene-1,4-diones: Intramolecular Charge Transfer

Nobuya KITAGUCHI†
Department of Chemistry, Faculty of Science, Kyoto University,
Kitashirakawa, Sakyo-ku, Kyoto 606
(Received August 2, 1988)

Electronic spectra of substituted 9,10-dihydro-9,10-*o*-benzenoanthracene-1,4-diones (triptycenequinones) in various solvents and that of benzo- and dibenzotriptycenequinones were investigated in this paper. Intramolecular charge-transfer (CT) bands ware observed in triptycenequinone system as a result of intramolecular interaction between benzene ring and benzoquinone moiety. Substituents on the benzene rings strongly affected the CT bands. Electron-donating groups gave absorption maxima at long wavelength. Naphthalene ring gave similar but stronger CT bands than benzene ring. Hammett σ^+ value of substituents gave good linear relationship with the energy of the CT bands. Calculations of reduced charge matrix of triptycenequinones by extended Hückel theory showed that the charge of aromatic ring(s) were transferred to benzoquinone moiety accompanying HOMO–LUMO excitation. Especially, absorption maxima of the methyl-substituted triptycenequinones gave good correlation with the amounts of charge transferred from benzene ring to benzoquinone moiety. These analysis confirmed clearly CT character of the absorption maxima of triptycenequinones. However, solvent effect of these CT bands maxima is not so clear as the substituent effect.

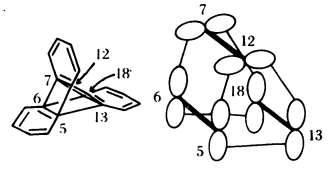
The problem of transannular π–π interaction among neighboring benzene rings in triptycene system is of increasing interest in organic chemistry.[1–10]

On the electronic state of triptycene, Bartlett explained its absorption spectrum by the cross-ring interaction as follows.[1,2]



Structure **A**

Wit[3] prepared a variety of heterocyclic triptycenes and reported that the energy of their absorption maxima correlated to the energy calculated by Hückel MO including "through-space resonance" as follows. This fact suggests that "through-space" interactions may exist in triptycene system.



Structure **B**

Investigation of the intramolecular orbital interactions was reported to reveal differences in the nature of the interactions between the three benzene rings of triptycene based on electronic transmission spectroscopy.[4] It was also reported that the LUMO of triptycene is expected to have the significant contribution of the through-bond interaction, on the contrary to the HOMO which include the dominant through-space interaction.[5,6] 9,10-*o*-Benzenoanthracene-1,4,5,8-tetrone and 5,18:7,16:9,14-tri(*o*-benzeno)heptacen-1,4,6,8,10,13,15,17-octone derivatives were examined as electron acceptors in the intermolecular CT complex formation with 2-(1,3-dithiol-2-ylidene)-1,3-dithiole.[7] The properties of radical anions of triptycene bis- and tris-quinones have also been investigated.[8]

Furthermore, Murata observed charge-transfer (CT) transition for symmetry-forbidden CT interaction in methyl- or methoxy- substituted 9,10-*o*-benzenoanthracene-1,4-diones (triptycenequinones) (**1e—i**) using CH_2Cl_2 as a solvent.[9,10]

Thus, according to these previous results above, triptycene system itself has intramolecular through-space interaction between three benzene rings. It is interesting to investigate the change of such intramolecular interaction caused by introducing benzoquinone moiety into triptycene system and a variety of substituents into benzene rings.

In this paper, effect of substituents, (methyl, acetylamino, dichloro) on the absorption spectra of triptycenequinones (**1a—d**) as well as benzotriptycenequinone (**3**), dibenzotriptycenequinone (**4**) and non-aromatic analogue (**2**) will be reported together with solvent effect on substituted triptycenequinones **1a—d**. Some results of those quinones were discussed in view of charge flow induced by HOMO–LUMO excitation calculated with Extended Hückel Theory (EHT).

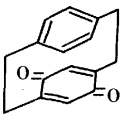
dichloro (**1d**), gave shorter absorption maximum than unsubstituted triptycenequinone (**1a**). So, these maxima can be regarded as the result of CT interaction between benzene ring and benzoquinone moiety (further analysis is given in the part of Discussion). Such maxima could not be observed by intermolecular interaction between **2** and benzene (Fig. 1). Intermolecular CT band of **2** and benzene appeared in the region of 280—300 nm (Fig. 2), far shorter wavelength than that of triptycenequinones. The 280—300 nm band of **2** in benzene is compatible to the reported CT band between 1,4-benzoquinone and benzene.[15] Furthermore, the absorption maxima of triptycenequinones are completely different from those observed in the electronic spectrum of cyclophanequinone **5**. The latter showed the CT band at 340 nm arising from interaction between benzene and 1,4-benzoquinone moieties.[16]



5

Result

1. Absorption Spectra of the Substituted Triptycenequinones. Figure 1 shows the absorption spectra (λ; wavelength, ε; absorptivity) of triptycenequinones **1a—d** in $CHCl_3$ and that of non aromatic derivative **2** in C_6H_6. The triptycenequinones have characteristic absorption maxima (ε; 190—360) in the region of 390—430 nm. Substitution with electron-donating groups, methyl (**1b**) or acetylamino (**1c**) group, gave absorption maxima at longer wavelength. To the contrary, substitution with electron-withdrawing group,

Consequently, it can be concluded that these absorption maxima of **1a—d** observed in the region of 390—430 nm are of characteristic in the triptycenequinone system, and that these bands are due to intramolecular CT interaction.

2. Solvent Dependency of the Absorption Maxima in Triptycenequinones 1a—d. To make clear CT character of the absorption maxima in triptycenequinone system, solvent dependency of absorption band of **1a** was examined in 14 solvents. Three solvents were used in the case of **1b—d**. The results are summarized in Tables 1 (**1a**) and 2 (**1b—d**). As a

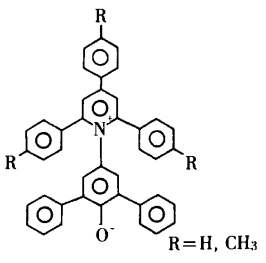
parameter of solvent polarity, Dimroth's E_T values[17,18] were adopted instead of Kosower's Z values by two reasons. Main reason is that Z values of some solvents have not been reported yet. The other reason is that E_T values are determined from intramolecular CT transition of diphenyl betaines **6**. Meanwhile, Z values are determined from closely-contacted interionic CT interaction between iodide anions and pyridium cations. Good linear correlation was obtained between E_T value and Z value (Z=1.259E_T+13.76).[18] In the case of the solvents whose E_T- and Z-values were both reported, analysis with Z values gave similar results as E_T values.

No clear solvent dependency can be recognized as given in Tables 1 and 2. However, among the solvents shown in Table 1, acetone, DMF, and acetonitrile are classified as "dissociating solvents" and acetic acid is classified as "associating solvent",[19-21] because these solvents affect excitation of compounds in a little different way from other solvents. When those dissociating and associating solvents are excluded, the energy of the absorption maximum (E) somehow tends to decrease with increase of solvent polarity E_T as given in Fig. 3. This tendency may support the CT character of the absorption maxima in triptycenequinone system.

Standing on another viewpoint, unclear solvent dependency of the absorption maxima can be speculated to be due to the following two reasons. One is that the charge separation of excited state in triptycenequinones is not so large as that in the compound (**6**) used for determination of E_T values. The other reason is that the character of n-π* transition of carbonyl group (blue shift when solvent polarity increases) might complex with the CT character (red shift when solvent polarity increases).



6

3. Absorption Spectra of Benzotriptycenequinone 3 and Dibenzotriptycenequinone 4. Naphthalene-ring-incorporated triptycenequinone analogues, benzotri-

ptycenequinone **3** and dibenzotriptycenequinone **4**, showed quite different spectra from that of a 1:1 mixture of **2** and naphthalene (Fig. 4) as in the case of benzene derivatives **1a—d**. The λ_{max}'s were 411—412 nm (ε= 468) in **3** and 400.5 nm (708) in **4**. The ε of the absorption maximum of **4** were larger than that of **3**, so it can be said that additional naphthalene ring may raise degree of intramolecular interaction. These absorption maxima in the region of 400—420 nm were very similar to those of **1a—d**, but had a little larger ε.

However, in the region of 470—550 nm, the quinones **3** and **4** have fairly strong absorption bands (ε's at 500 nm were ca. 100 and 160, respectively) compared with **1a—d**. The ε_A's—apparent absorptivity—of these absorption maxima of **3** and **4** did not depend on the concentration of these compounds. So, these 470—550 nm bands can be considered to come from *intramolecular* process.

Although a 1:1 mixture of **2** and naphthalene at low concentration showed no band arising from the intermolecular interaction between these two molecules ([**2**]=4.83×10^{-3} mol dm^{-3}, [naphthalene]=5.13×10^{-3} mol dm^{-3}), a highly concentrated 1:100 mixture of **2** and naphthalene ([**2**]=1.02×10^{-2} mol dm^{-3}, [naphthalene]=1.4 mol dm^{-3}) showed a weak band at 450 nm (Fig. 5). Based on these observations and the results of triptycenequinones described above, the strong and large absorption maxima of **3** and **4** in the region around 400—550 nm can be assigned to the intramolecular CT transition between naphthalene ring and benzoquinone moiety.

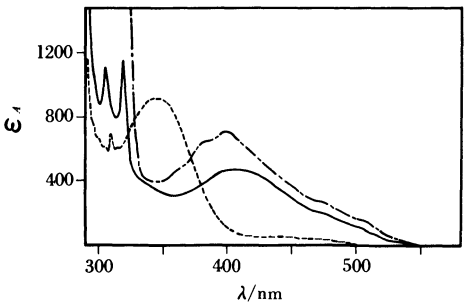


Fig. 4. Absorption spectra of **3** (——), **4** (— — — —), and 1:1 mixture of **2** and naphthalene (----) in $CHCl_3$. In the region of longer wavelength than 400 nm, [**2**]=4.83×10^{-3} mol dm^{-3}, and [naphthalene]=5.13×10^{-3} mol dm^{-3}. In the region of shorter wavelength than 400 nm, 4.83×10^{-4} mol dm^{-3} and 5.13×10^{-4} mol dm^{-3}, respectively.

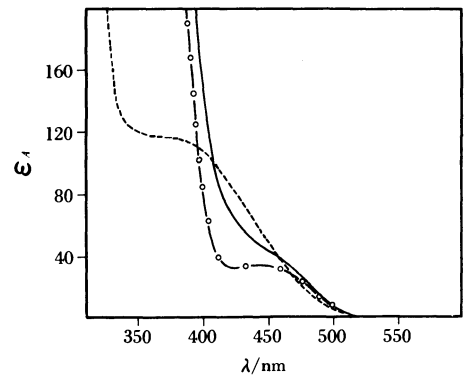

Fig. 5. Absorption spectra of 1:100 mixture of **2** (1.02×10^{-2} mol dm^{-3}) and naphthalene (1.4 mol dm^{-3}) (——), 1:100 mixture of 1,4-benzoquinone (1.02×10^{-2} mol dm^{-3}) and naphthalene (9.99×10^{-1} mol dm^{-3} (--------), and **2** itself (—O—O—). Solvent; $CHCl_3$.

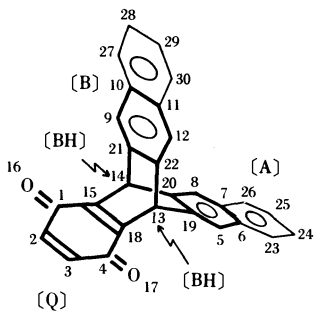
4. Reduced Charge Calculations by EHT.[22,23] The calculation of the charges of each atom (reduced charge matrix, molecular orbital-atom) was carried out in HOMO and in LUMO of triptycenequinones **1a—d** by EHT in order to investigate more details on the absorption maxima.

The probable conformations of the triptycenequinones were calculated by molecular mechanics theory (see Experimental section), then reduced charge matrix were obtained by EHT calculation. As a result of these calculations, the overlap integrals and overlap populations between homoconjugative atoms (carbon atoms vicinal to bridgehead carbons) were found to be significant in these triptycenequinones. Reduced charge matrix in HOMO and in LUMO (one electron in each MO) and differences between these two MOs (Δ_{L-M}: LUMO minus HOMO, considered as S_0–S_1 excitation) are given in Table 3 in the case of unsubstituted triptycenequinone **1a**. In the case of other triptycenequinones (**1b—i**, **3**, **4**), only the summations of Δ_{L-M} in each moiety [$\sum$(moiety Δ_{L-H})] are tabulated in Table 4. Numbering of atoms are shown in the following structure. Here, [A] represents mainly-substituted aromatic ring, [B]; another aromatic ring, [Q]; benzoquinone moiety, and [BH]; bridgehead carbon atom.



Structure **C**

As shown in Tables 3 and 4, $\sum(\Delta_{L-M})$ in each moiety are all negative in ring A and in sum of A and B (A+B), but all positive in ring Q, suggesting that HOMO-LUMO excitation in triptycenequinone system involves charge transfer from aromatic ring (ring A and/or B) to benzoquinone moiety (ring Q). That is, rings A and B can be considered as electron donor,

Table 3. Reduced Charge Matrix and Population Change Δ_{L-H} in **1a** Calculated by EHT

a) Reduced net AO population was normalized to one electron occupation. b) Two of asymmetrical triptycenequinone derivatives (6-Me, **1b** and 6-NHCOCH$_3$, **1c**) were calculated as 7-Me and 7-NHCOCH$_3$ derivatives, respectively, for convenience sake.

and ring Q as electron acceptor, so charge is calculated to be transferred from mainly ring Q accompanying HOMO–LUMO excitation.

For comparison, reduced charge matrix of 9,10-dihydro-1,4-anthracenedione **7a** and its 6-methyl derivative **7b** were calculated by the same method as in the case of triptycenequinones. The results are summarized in Table 5. In both cases, sums of population change are all positive in ring A and "Bridge Head", and all negative in ring Q, as opposed to sterically rigid triptycenequinone system. So charge flow in

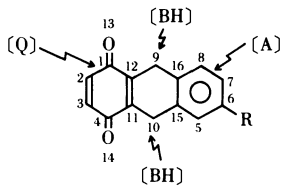
Table 5. Summation of Population Change in Each Moiety Σ(moiety Δ_{L-H})[a] of **7a, b**

Quinone	Σ(moiety Δ_{L-H})		
	A	BH	Q
7a	0.2804	0.2237	−0.5830
7b	0.3113	0.1808	−0.5651

a) Reduced net AO population was normalized to one electron occupation.

1a—i, **3**, and **4** can be considered as characteristic of these triptycenequinones.

More details are described in the part of "Discussion".



7a R=H
b R=CH_3

Discussion

Substituent effects and the CT character of absorption maxima in triptycenequinone system are analyzed using Hammett σ^+ constant and population change calculated by EHT as parameters.

The absorption maxima in triptycenequinone system could be analyzed quantitatively by the linear free energy relationship. When the positions 6, 7, 10, 11 of **1a—d** are assumed to be *p*-position and the positions 5,8,9,12 are *m*-position, the energy of these bands in three solvents (CH_3CN, $CHCl_3$, and C_6H_6) gave straight lines in Hammett plot using σ^+ values[24,25] (Fig. 6). Furthermore the absorption maxima of other triptycenequinones **1e—i**, obtained in CH_2Cl_2 previously by Murata et al.,[8,9] were analyzed with similar Hammett plot as shown in Table 6 and Fig. 7.

As shown in Figs. 6 and 7, clear linear correlation was obtained between energy of absorption maximum and σ^+, not σ. It suggests that benzene ring has a little cationic (electron-donating) character in the course of S_0–S_1 excitation, and then that these absorption maxima in triptycenequinones may reflect the presence of the charge-transfer electron transition from neighboring aromatic rings to 1,4-benzoquinone moiety.

This interpretation was also supported by EHT calculations of reduced charge. Sum of population change $\Sigma(\Delta_{L-H})$ in each moiety, benzene rings A and B, bridge head BH, and benzoquinone Q, are compared with energy of the absorption maxima in substituted triptycenequinones **1a—i**, **3**, and **4**. Population changes

Table 6. Energy of the Characteristic Bands[8,9] of Triptycenequinones **1a**, **b**, and **1e—i** in CH_2Cl_2 with Hammett Constant[a]

Quinone	E/kJ mol^{-1}	σ^+	σ
1a	288.3	0	0
1b	282.4	−0.26	−0.17
1e	287.9	−0.065	−0.069
1f	289.5	−0.13[b]	−0.138[b]
1g	273.2	−0.622[b]	−0.34[b]
1h	287.0	0.10[b]	0.23[b]
1i	253.6	−1.30[b]	0.536[b]

a) σ^+ values of **1c** and **1d** is −0.25 and 0.80, respectively.
b) Calculated as summation of σ or σ^+ values of single substituent.

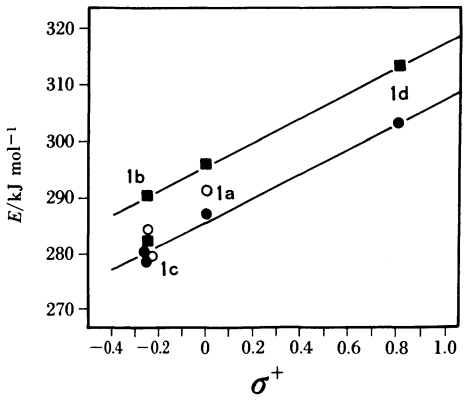


Fig. 6. Hammett plot: the energies of the absorption maxima in **1a—d** vs. σ^+ values. Closed circle; in $CHCl_3$. Closed square; in CH_3CN. Open circle; in C_6H_6.

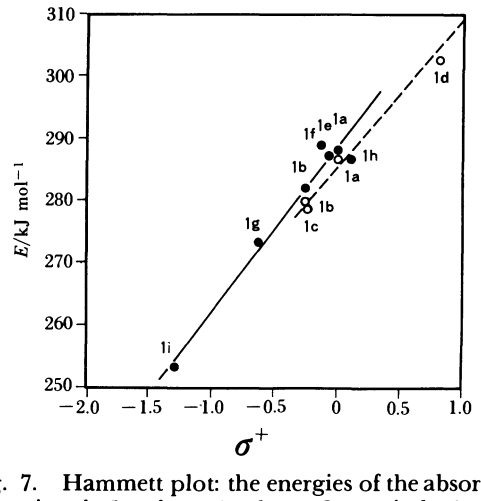

Fig. 7. Hammett plot: the energies of the absorption maxima in **1a—i** vs. σ^+ values. Open circle; **1a—d** in $CHCl_3$. Closed circle; **1a**, **1b**, and **1e—i** in CH_2Cl_2.[8,9]

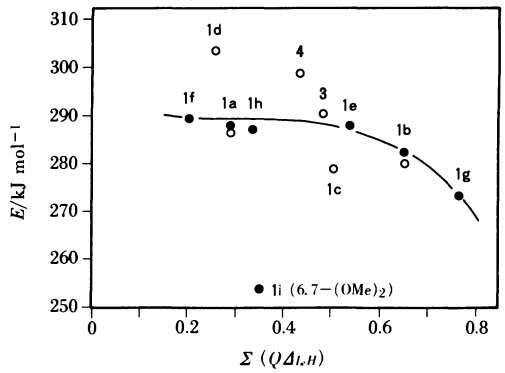

Fig. 8. A plot of sum of population change in moiety Q against absorption maximum energy. Open circle; **1a—d**, **3**, and **4** in $CHCl_3$. Closed circle; **1a**, **1b**, and **1e—i** in CH_2Cl_2.

in moiety Q[$\Sigma(Q\Delta_{L-H})$] are plotted against energy of the absorption maxima (Fig. 8). $\Sigma(Q\Delta_{L-H})$ shows good correlation to absorption maxima, especially in the case of methyl substituted triptycenequinones. Population change in moiety A and B [$\Sigma((A+B)\Delta_{L-H})$] gave similar results as $\Sigma(Q\Delta_{L-H})$.

Thus, analysis of S_0–S_1 transition by MO calculation strongly suggests that absorption maxima of triptycenequinones can be attributed to the charge transfer from benzene ring to quinone moiety, as well as analysis by Hammett plots. This charge transfer may be occurred mainly "through-space" because the quite different results were obtained by the calculation of **7a,b**, which can be considered to include much less "through-space" interaction than triptycenequinones because of their planar conformation.

The quite different population change of **7a,b** compared to triptycenequinones may result mainly from the difference of overlap integrals. The overlap populations between atomic orbitals of the carbon atoms adjacent to bridgehead carbons were much larger in triptycenequinones than in **7a,b**. Those in **7a,b** were almost zero. So, triptycenequinones may have much stronger through-space interaction than **7a,b**. Such difference was explicitly shown by the population change in bridgehead carbon atoms, which can interact with the benzoquinone moiety mainly by through-bond interaction. **7a,b** gave much larger $\Sigma(BH\Delta_{L-H})$ than triptycenequinones (Tables 4 and 5).

The summation of reduced charge of all atoms in benzoquinone moiety Q changed from 0.5809 to 0.8677 in **1a** and from 0.8603 to 0.2773 in **7a** through S_0–S_1 excitation. In the course of that excitation, population change of carbonyl groups was calculated to be 0.2131 for carbon atom and 0.0010 for oxygen atom in **1a**, and −0.2431 for C and −0.0436 for O in **7a**. So, the difference of population change $\Sigma(Q\Delta_{L-H})$ mainly came from the difference of the population change of carbonyl carbons. In the case of **7a,b**, the electron in S_0 state may exist mainly on the benzoquinone moiety, especially on carbonyl carbon atoms, and may diffuse into whole molecule by through-bond interaction in the course of excitation to S_1 state. Further, according to population change of carbonyl oxygen atoms described above, S_0–S_1 excitation of triptycenequinones might have somewhat π–π^* character, on the other hand, that of **7a,b** might have less π–π^* and more n–π^* character, because more electron on carbonyl oxygen atoms may diffuse in S_1 state in **7a,b** than in triptycenequinones. The cause of the different population change is still unclear and more investigation is required for exact explanation.

Based on good linear correlation between absorption maximum and σ^+ constant, the absorption maximum can be expected by Hammett plot such as Fig. 7. Furthermore, as far as methyl-substituted triptycenequinones, the absorption maximum may be expected also by such simple EHT calculation. However, neither $\Sigma(A\Delta_{L-H})$ nor $\Sigma(Q\Delta_{L-H})$ of 6,7-dimethoxy (**1i**), acetylamino (**1c**), chloro (**1d**), and dibenzo (**4**) derivatives gave clear correlation to the absorption maximum, compared with Hammett σ^+ constants. It is speculated as due to the effect of lone-pair electrons which is not perhaps involved sufficiently within this EHT calculation.

Experimental

Apparatus for Measurements. Electronic spectra were taken with a Shimadzu UV-200 spectrometer. ^{1}H NMR spectra were taken with a JEOL PS-100MHz spectrometer in suitable solvents using TMS as the internal standard.

Solvents. For absorption spectra measurements, solvents were dried with appropriate desiccant, and distilled.

Quinones. 1a—d, 3, 4 were prepared according to the previously reported method[1,10] with some modification. Corresponding anthracenes were synthesized (for **1b—d**) or purchased (for **1a**). Naphthacene (for **3**) and pentacene (for **4**) were synthesized as described later. All polyacenes were purified by recrystallization. Triptycenequinones were synthesized as follows. After Diels-Alder reaction of 1,4-benzoquinone and a polyacene, the adduct was precipitated with cooling to room temperature. The precipitate was recrystallized from benzene and then treated with HBr in acetic acid to give the corresponding hydroquinone. The hydroquinone was then oxidized to the corresponding triptycenequinone with potassium bromate in acetic acid. Detail conditions of Diels-Alder reaction were as follows [given as target compound, polyacene used (g), 1,4-benzoquinone used (g), solvent (ml), refluxing period, yield (g)]: **1a**, 10.8, 7.3, xylene 65, 3 h, 13.8; **1b**, 5.3, 3.6, xylene 65, 3 h, 5.9; **1c**, 2.1, 1.6, toluene 25, 3 h, 3.0; **1d**, 4.5, 2.1, xylene 30, 3.5 h, 2.8; **3**, 3.0, 1.4, xylene 25 (under N_2), 30 min, 2.1, 3.8; **4**, 1.9, 0.8, xylene 14 (under N_2), 20 min, 0.5.

The physical properties of **1a—d, 3, 4** were as follows.

1a: Yellow prisms recrystallized from $CHCl_3$, mp 289—294 °C (decomp) (lit, 292—296 °C). ^{1}H NMR ($CDCl_3$): δ=5.76 (s, 2H), 6.56 (s, 2H), 6.96—7.20 (m, 4H), 7.30—7.56 (m, 4H). IR (KBr): ν_{CO}=1655 cm^{-1}. UV ($CHCl_3$): λ_{max}= 416 nm (ε=357), 311 (513), 244 (16500).

1b: Yellow crystals from benzene, mp 165.2—168.4 °C (slightly decomp)(sealed tube). ^{1}H NMR ($CDCl_3$): δ=2.57 (s, 3H), 6.51 (s, 2H), 7.40 (s, 2H), 7.66 (m like d, 1H), 7.80—8.00 (m, 2H), 8.14 (s, 1H), 8.16—8.38 (m, 3H). IR (KBr): ν_{CO}=1660 cm^{-1}, $\nu_{C=C}$=1598 cm^{-1}. MS m/z=298 (M^+), 280 (M−CO). UV ($CHCl_3$): λ_{max}=427 nm (ε=316), 320 (526), 279 (3060), 261 (sh, 15100), 255 (15700). Found: C, 84.40; H, 4.81%. Calcd for $C_{21}H_{14}O_2$: C, 84.54; H, 4.73%.

1c: Orange yellow needles, mp 180.0—181.0 °C (decomp). ^{1}H NMR ($CDCl_3$): δ=2.10 (s, 3H), 5.66 (s, 2H), 6.50 (s, 2H), 6.87—7.03 (m, 3H), 7.1—7.4 (m, 4H, including NH), 7.60 (brs, 1H). IR (KBr): ν_{CO}=1652 cm^{-1} (broad), 1590, 1532, 1303. MS m/z=341 (M^+), 298 (M−Ac). UV ($CHCl_3$): λ_{max}=428.5 nm (ε=192), 321 (398), 257 (18400). Found: C, 77.28; H, 4.39; N, 3.88%. Calcd for $C_{22}H_{15}NO_3$: C, 77.41; H, 4.43; N, 4.10%.

1d: Yellow crystals from $CHCl_3$, mp at >240 °C slightly red and at 303—305 °C melted with decomposition (sealed tube). ^{1}H NMR ($CDCl_3$): δ=6.38 (s, 2H), 6.75 (s, 2H), 6.9—

7.3 (m, 4H), 7.3—7.6 (m like dd, 2H). IR (KBr): ν_{CO}= 1665 cm^{-1}, $\nu_{C=C}$=1590, 1570 cm^{-1}. MS m/z=354, 352 (M^+). UV ($CHCl_3$): λ_{max}=395.5 nm (ε=348), 298 (sh, 469), 278 (sh, 1000), 254.3 (14300). Found: C, 67.92; H, 2.79; Cl, 20.39%. Calcd for $C_{20}H_{10}O_2Cl_2$: C, 68.01; H, 2.85; Cl, 20.08%.

3: Orange yellow crystals, mp 210.5—211.0 °C (decomp) (sealed tube). ^{1}H NMR ($CDCl_3$): δ=5.86 (s, 2H), 6.58 (s, 2H), 7.0—7.2 (m, 2H), 7.4—7.6 (m, 4H), 7.6—7.8 (m, 2H), 7.78 (s, 2H). IR (KBr): ν_{CO}=1650 cm^{-1}, $\nu_{C=C}$=1585 cm^{-1}, ν=1305 cm^{-1}. MS m/z=335 (M+1), 334 (M^+). UV ($CHCl_3$) λ_{max}=411.5 nm (ε=460), 320.6 (1170), 306.8 (1120), 287.6 (4840), 262.5 (sh, 18900), 260 (19400), 243 (65600). Found: C, 86.13; H, 4.18%. Calcd for $C_{24}H_{14}O_2$: C, 86.21; H, 4.22%.

4: Orange crystals, mp 242—243 °C (sealed tube). ^{1}H NMR ($CDCl_3$): δ=5.92 (brs, 2H), 6.52 (s, 2H), 7.3—7.5 (m, 4H), 7.5—7.7 (m, 4H), 7.79 (s, 4H). IR (KBr): ν_{CO}=1655 cm^{-1}, $\nu_{C=C}$=1592 cm^{-1}, ν=1305 cm^{-1}. MS m/z=385 (M+1), 384 (M^+), 356, 355. UV ($CHCl_3$): λ_{max}=400.5 nm (ε=708). Found: C, 87.38; H, 4.22%. Calcd for $C_{28}H_{16}O_2$: C, 87.48; H, 4.20%.

2-Methylanthracene[11] and 1,5-Dichloroanthracene. 2-Methyl-9,10-anthraquinone and 1,5-dichloro-9,10-anthraquinone were reduced to the corresponding anthracenes with diborane in situ prepared by $NaBH_4$ and BF_3-etherate in diglyme. Crude substituted anthracene was purified by column chromatography on silica gel to give the mixture of the substituted anthracene and its 9,10-dihydro derivative. This mixture was oxidized with 1,4-benzoquinone (in the case of 2-methylanthracene) or chloranil (in the case of 1,5-dichloroanthracene) to give pure substituted anthracene.

2-Acethylaminoanthracene. 2-Amino-9,10-anthraquinone was reduced to 2-aminoanthracene in a similar manner as 6-methyl derivative. 2-Aminoanthracene obtained was acetylated with refluxing acetic anhydride to give 2-acetylaminoanthracene.

Naphthacene and Pentacene. 5,12-Naphthacenedione[12] and 6,13-pentacenedione[12] were prepared by condensation of $\alpha,\alpha,\alpha',\alpha'$-tetrabromo-*o*-xylene[13] and 1,4-naphthoquinone with NaI in dry *N,N*-dimethylformamide, and then reduced in a similar manner as in the case of substituted anthracenes.

5,6,7,8-Tetrahydro-5,8-ethano-1,4-naphthoquinone (2). Cyclohexadiene and 1,4-benzoquinone were condensed by Diels-Alder reaction. The adduct was rearranged to the corresponding hydroquinone, and then reduced with H_2/Pd-C. The hydroquinone was oxidized by $FeCl_3$. **2** was obtained as yellow crystals from hexane-benzene, mp 85.7—87.0 °C (sealed tube). ^{1}H NMR ($CDCl_3$): δ=1.2—1.6 (m, 4H), 1.6—1.9 (m, 4H), 3.34 (d, J=1 Hz, 2H), 6.71 (s, 2H). IR (KBr): ν_{CO}=1640 cm^{-1}, $\nu_{C=C}$=1585 cm^{-1}, ν=1303 cm^{-1}. MS m/z=188 (M^+), 186, 160 ($M-CH_2=CH_2$). UV ($CHCl_3$): λ_{max}=445 nm (ε=33), 348 (936), 254 (18000). Found: C, 76.41; H, 6.55%. Calcd for $C_{12}H_{12}O_2$: C, 76.57; H, 6.43%.

Purification of Quinones. In order to avoid the contamination with polyacenes, triptycenequinones **1a—d**, **3**, **4**, and nonaromatic quinone **2** were purified by column chromatography on silica gel twice and by recrystallization in a dark room.

EHT Calculations. A packaged soft for chemical calculations "CHEMLAB-II" supplied by MDL Inc. (U.S.A.) was used on VAX11/780, Digital Equipment Company. Molecular coordinates were calculated by "PRXBLD", one of suboptions in CHEMLAB-II, based on molecular mechanics. Extended Hückel calculations were carried out by "EHT" suboption.

The author wishes to express his grateful thanks to Professor Kazuhiro Maruyama for his guidance and invaluable discussions in this work. He is grateful to Dr. Yasuo Kubo for his helpful suggestions. He also thanks Dr. Tetsuo Otsuki, Dr. Yoshinori Naruta and Dr. Tatsuhisa Kato for fruitful discussion. The author wishes to thank Mr. Kazunori Toma for assistance of EHT calculations.

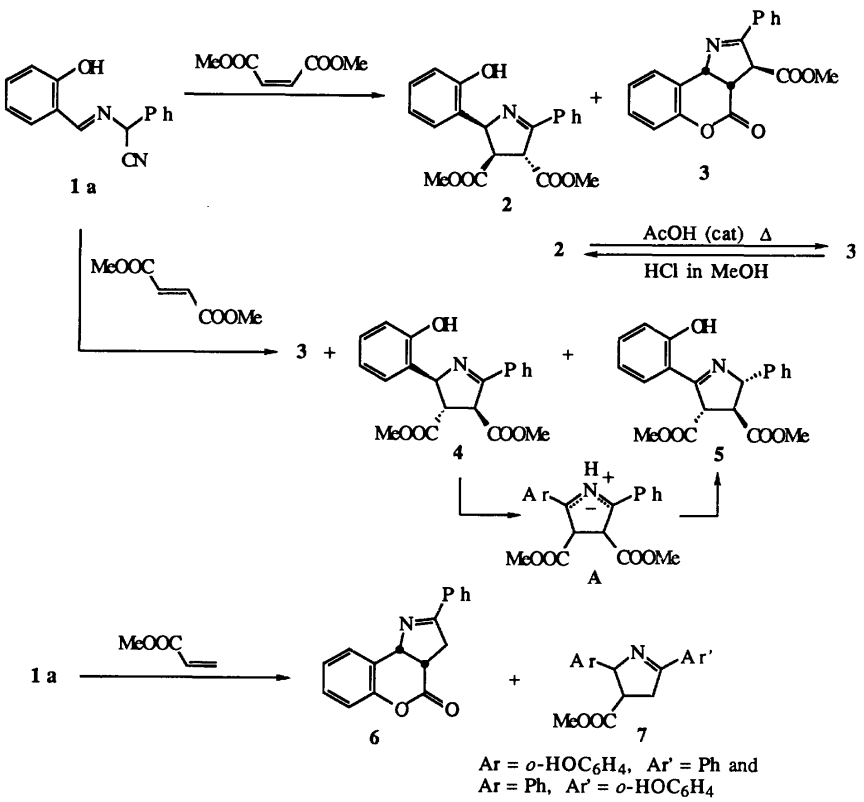
(Received August 3, 1988)

Cycloadditions of azomethine ylides generated from α-benzylideneamino nitriles bearing a hydroxyl or its *O*-protected moiety with α,β-unsaturated esters such as dimethyl maleate, fumarate, methyl acrylate, crotonate, methacrylate, and cinnamate lead stereoselectively to 3,3a-*trans*-3a,9b-*cis*-3a,9b-dihydro[1]benzopyrano[4,3-*b*]pyrrole-4(3*H*)-ones after subsequent lactonization.

The imines, bearing an electron-withdrawing substituent at the sp^3 carbon adjacent to the imine nitrogen, undergo a thermal imine–azomethine ylide tautomerism.[1] Since this tautomerism is catalyzed by a weak acid,[2] an intramolecular hydrogen bond to the nitrogen would accelerate such ylide generation. The replacement of the benzylidene moiety of α-benzylideneamino nitriles with a 2-hydroxybenzylideneamino group offers model compounds with which catalysis by an intramolecular hydrogen bond could be conveniently tested.

N-Unsubstituted azomethine ylides generated by the thermal tautomerism of *C*-aryl imines undergo stereo- and regioselective cycloadditions with α,β-unsaturated esters to produce cycloadducts, pyrrolidines or pyrrolines, in which the aryl and the ester groups are cis to each other. Therefore, the use of α-(2-hydroxybenzylideneamino) nitriles would lead to [1]benzopyrano[4,3-*b*]pyrrol-4(3*H*)-ones, which could be useful compounds for the synthesis of the hetero analogs of cannabinoids.[3]

The present article describes the generation of azomethine ylides from α-(arylmethyleneamino) nitriles bearing a hydroxy moiety or their *O*-protected derivatives. The ylides were utilized in stereoselective cycloadditions with α,β-unsaturated esters, followed by lactonization to give pyrrole ring-fused [1]benzopyrans.



Scheme 1.

Results and Discussion

Among the *N*-unsubstituted azomethine ylides generated by a thermal tautomerism of α-benzylideneamino nitriles, the compounds bearing an aryl group on C_2 of the nitrile is one of the most reactive ylides toward α,β-unsaturated esters.[4] 2-(2-Hydroxybenzylidenamino)-2-phenylacetonitrile (**1a**) underwent a smooth and stereoselective cycloaddition with dimethyl maleate under reflux in toluene to give 4,5-*cis*-1-pyrroline **2** and its lactonized product **3** in a combined yield of 96% (Scheme 1).

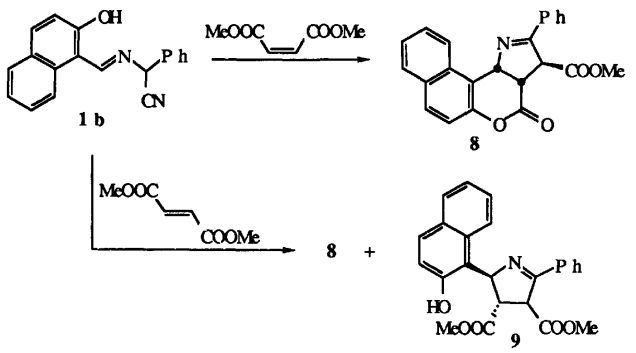
The 3,4-trans geometry of **2** is due to epimerization through an imine–enamine tautomerism.[4] The 4,5-cis configuration of **2** was assigned on the basis of the strong shielding of the ester methyl protons on C_4 by the adjacent phenyl ring. The structures of **2** and **3** were confirmed by the facts that **2** could be quantitatively converted into **3** on heating with a catalytic amount of acetic acid, and that **3** underwent methanolysis giving **2** in 85% yield.

With dimethyl fumarate under similar conditions, the lactone **3** (31%) and an inseparable mixture of two isomeric 1-pyrrolines **4** and **5** (2:1, 62%) were obtained. The latter 1-pyrroline **5** must have been derived from **4**, presumably through a double-bond migration via an *N*-protonated azomethine ylide intermediate **A**. On the other hand the 4,5-cis stereoisomer **2** did not isomerize at all under comparable conditions.

The exclusive cis-selectivity achieved in the cycloaddition of **1a** with dimethyl maleate and the poor trans/cis ratio (2/1) observed in that with dimethyl fumarate correspond to the results previously observed in reactions of 2-(benzylideneamino)-2-phenylacetonitrile with both esters.[4]

In a reaction of **1a** with methyl acrylate, the expected lactone **8** was produced in 67% yield, together with an inseparable mixture (26%, 2:1) of two regioisomeric 1-pyrrolines **9**.

Similar stereoselectivities were observed in the reactions of 2-[(2-hydroxy-1-naphthyl)methylenamino]-2-phenylacetonitrile (**1b**) with dimethyl maleate and fumarate. Thus, lactone **6** was the sole product (91%) from the maleate, whereas a mixture of **6** (50%) and 1-pyrroline **7** (41%) was obtained from the fumarate (Scheme 2).



Scheme 2.

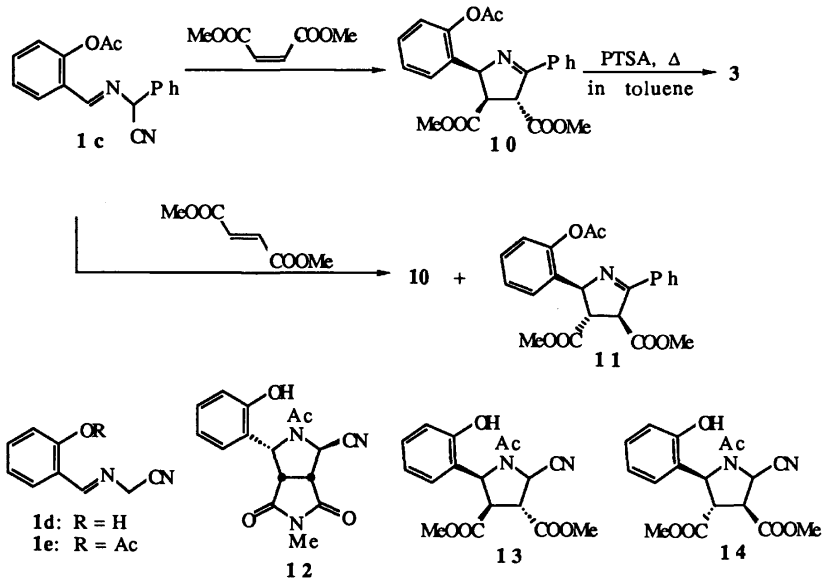
Thus, imines **1a** and **1b** can thermally generate, without *O*-protection, the corresponding *N*-unsubstituted azomethine ylides. These ylides undergo cycloadditions to several α,β-unsaturated esters producing 4,5-cis cycloadducts as exclusive or major isomers, which give lactones after spontaneous or acid-catalyzed lactonization. However, catalysis for ylide generation by an intramolecular hydrogen bond was unexpectedly insufficient, no remarkable rate acceleration of the ylide generation being observed. Accordingly, *O*-protected imines were employed in the following reactions.

O-Acetylation of **1a** gave imine **1c**. 4,5-*cis*-1-Pyrroline **10** (91%) or a mixture of **10** and 4,5-*trans*-1-pyrroline **11** (70% and 26%) was yielded from **1c** and dimethyl maleate or fumarate, respectively. The isomer ratio agrees with that obtained from 2-(benzylideneamino)-2-phenylacetonitrile and the fumarate.[4] The cis isomer **10** was converted into lactone **3** upon heating in toluene in the presence of a catalytic amount of *p*-toluenesulfonic acid (PTSA) in a moderate yield (60%).

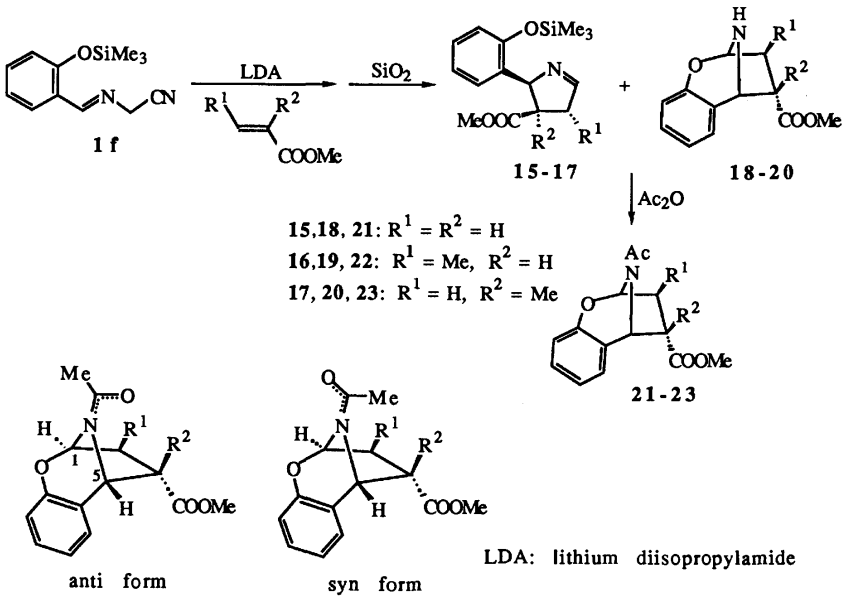
(2-Hydroxybenzylideneamino)acetonitrile (**1d**) was found to be much less reactive than expected. Thus, the reactions of **1e** with *N*-methylmaleimide and dimethyl fumarate, under reflux in toluene for 14 h, gave unsatisfactory yields of the *N*-acetylated 6,6a-cis cycloadduct **12** (35%) and a mixture of two stereoisomeric cycloadducts, **13** (34%) and **14** (9%). The acetyl group migration from the phenolic oxygen atom to the pyrrolidine nitrogen atom occurred presumably through intramolecular aminolysis, since it is already known that the formation of 1-pyrrolines by the elimination of HCN is extremely slow in these systems.[4,5]

As *N*-unsubstituted (or *N*-protonated) azomethine ylides show only a limited reactivity toward the unsaturated esters, a higher degree of activation of ylides is needed. *N*-Lithiated azomethine ylides are our choice. A highly enhanced reactivity as well as an exclusive cis-selectivity in their cycloadditions was recently reported.[6,7]

The *O*-silyl derivative **1f**, readily prepared by the silylation of **1d** with chlorotrimethylsilane and triethylamine, generated the *N*-lithiated azomethine ylide upon a treatment with LDA in THF at −78 °C. The ylide smoothly underwent stereoselective cycloadditions to methyl acrylate, crotonate, and methacrylate at −78 °C. Though the unpurified reaction mixtures were shown to consist mostly of the *O*-silylated 4,5-*cis*-1-pyrrolines **15**—**17** by ^{1}H NMR, their purification by silica-gel chromatography brought about desilylation to give bicyclic *N*,*O*-acetals **18**—**20** as single stereo-



Scheme 3.



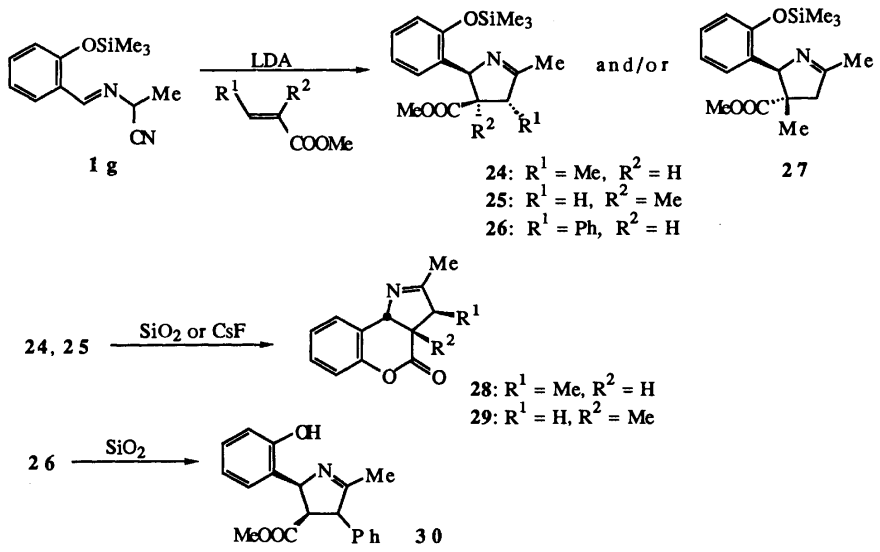
Scheme 4.

isomers in all cases (Scheme 4). Since they were too unstable to be further purified, their acetylation was carried out, leading to **21—23**.

Interestingly, these *N*-acetylated bicyclic *N,O*-acetals **21—23** exist as two isomeric forms in deuteriochloroform in 2:3 to 1:2 ratios. The major isomers, which show lower acetyl methyl protons, lower 5-Hs, and higher 1-Hs in their ^{1}H NMR spectra, were assigned as anti forms and, hence, the minor ones as syn forms. Ready formation of the bicyclic *N,O*-acetals **18—20** occurred probably because of the absence of substituents at C_2 of 1-pyrrolines **15—17**. Accordingly, methyl-substituted imine **1g** was employed in similar cycloadditions (Scheme 5).

With methyl crotonate and cinnamate, 4,5-*cis*-1-pyrrolines **24** and **26** were exclusively formed, however, the reaction with methyl methacrylate was rather nonstereoselective; a 3.5:1 mixture of 4,5-*cis*- **25** and 4,5-*trans*-1-pyrroline **27** was obtained.

Desilylation of **24** occurred easily on its chromatography over silica gel to give lactone **28** in 84% yield based on **1g**. The more stable **25** was only partly desilylated by a similar treatment, but was cleanly converted into **29** (78%) when **25** (as a mixture with **27**) was treated with cesium fluoride in THF. The desilylated derivative of the minor cycloadduct **27** was



Scheme 5.

also separated.

A chromatographic treatment of the cinnamate adduct **26** resulted in a rather slow desilylation, giving a mixture of **26** and the desilylated product, 4,5-*cis*-1-pyrroline **30**. Smooth lactonization of **30** was not observed under various conditions since it was decomposed in all cases.

Experimental

General. Melting points were determined on a Yanagimoto melting-point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-40 (90 MHz), a JEOL FX-100 (100 MHz), or a JEOL GSX-270 (270 MHz) instruments, and ^{13}C NMR on a JEOL FX-100 (25.05 MHz) or a JEOL GSX-270 spectrometer (67.94 MHz). Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra were measured with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. High-resolution mass spectra (HRMS) were obtained on the same instrument. Elemental analyses were performed on a Hitachi 026 CHN analyzer. Thin-layer chromatography (TLC) was accomplished on 0.2 mm precoated plates of silica gel 60 F-254 (Merck). Visualization was made with ultraviolet light (254 and 365 nm), iodine, molybdophosphoric acid (5% in ethanol), or *p*-anisaldehyde (5% in ethanol containing 5% of sulfuric acid). For preparative column chromatography, Wakogel C-200, C-300 (Wako), and Silicagel 60 (Merck) were employed. Flash chromatography was carried out on an Eyela EF-10 apparatus using a column (20×180 mm) packed with Silicagel 60 (Merck, size: 0.04—0.063 mm). Gas liquid chromatography (GLC) was accomplished on a Yanaco G-2800 gas chromatograph (Yanagimoto) with an ionization flame detector using a glass column (SE-30, 3×2000 mm) or a glass capillary column (Silicone GE, SE-30, 0.25×50000 mm). Micro vacuum distillation was carried out on a Sibata GTO-250R Kugelrohr distilling apparatus. Solvents were evaporated with a Tokyo Rikakikai rotary evaporator type-V at about 50 °C unless otherwise stated.

Materials and Solvents. 2-(2-Hydroxybenzylideneamino)-2-phenylacetonitrile (**1a**), 2-[(2-hydroxy-1-naphthyl)methyleneamino]-2-phenylacetonitrile (**1b**), 2-(2-acetoxybenzylideneamino)-2-phenylacetonitrile (**1c**), (2-hydroxybenzylideneamino)acetonitrile (**1d**), and (2-acetoxybenzylideneamino)-acetonitrile (**1e**) were prepared by condensations of the corresponding aldehydes with amino nitriles by an application of the reported methods.[4] **1a:** Colorless prisms (diethyl ether–hexane); mp 59—60 °C; IR (KBr) 3200—2400, 2240, and 1630 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=5.53 (1H, d, J=1.0 Hz, CH), 6.7—7.4 (9H, m, Ar), 8.47 (1H, d, J=1.0 Hz, CH=N), and 11.86 (1H, br s, OH); MS *m/z* (rel intensity, %) 236 (M^+, 2), 116 (base peak), and 89 (58). Found: C, 76.20; H, 5.12; N, 11.71%. Calcd for $C_{15}H_{12}N_2O$: C, 76.25; H, 5.12; N, 11.86%. **1b:** Colorless prisms (diethyl ether–hexane); mp 116—117 °C; IR (KBr) 3350, 2230, and 1630 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.84 (1H, s, CH), 7.0—8.3 (12H, m, Ar and CH=N), and 10.65 (1H, s, OH). Found: C, 79.66; H, 5.06; N, 9.58%. Calcd for $C_{19}H_{14}N_2O$: C, 79.70; H, 4.93; N, 9.78%. **1c:** Colorless liquid; IR (KBr) 2240, 1740, and 1630 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.20 (3H, s, Ac), 5.66 (1H, d, J=1.0 Hz, CH), 7.0—7.5 (8H, m, Ar), 7.82 (1H, m, Ar), and 8.55 (1H, d, J=1.0 Hz, CH=N). **1e:** Colorless liquid; IR (neat) 2250, 1765, and 1640 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.30 (3H, s, Ac), 4.52 (2H, t, J=1.5 Hz, CH_2), 6.7—7.8 (4H, Ar), and 8.43 (1H, t, J=1.5 Hz, CH=N). 2-[2-(Trimethylsilyloxy)benzylideneamino]-acetonitrile (**1f**) was prepared as follows: A solution of chlorotrimethylsilane (0.48 g, 4.1 mmol) in dry benzene (3 ml) was slowly added to a mixture of **1a** (0.56 g, 4 mmol) and triethylamine (0.45 g, 4.5 mmol) in benzene (10 ml). After stirring at room temperature for 1 h, the precipitate was removed off by filtration and the filtrate was subjected to vacuum distillation to give **1f** (0.66 g, 71%): Yellow liquid; bp 150 °C/133 Pa (bulb-to-bulb), IR (neat) 2220, 1640, 920, 840, and 760 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.30 (9H, s, $SiMe_3$), 4.63 (2H, d, J=2.0 Hz, CH_2) 6.8—7.9 (4H, m, Ar), and 8.90 (1H, t, J=2.0 Hz, CH=N); MS *m/z* (rel intensity, %) 232 (M^+, 8), 218

(17), 217 (base peak), 135 (38), 120 (25), 91 (23), and 77 (15). HRMS Found: *m/z* 232.1055. Calcd for $C_{12}H_{16}N_2OSi$: M, 232.1057. 2-[2-(Trimethylsilyloxy)benzylideneamino]propanenitrile (**1g**) was synthesized according to the following procedure: To a solution of freshly prepared LDA (10 mmol in THF (15 ml)) was added dropwise a solution of **1f** (1.6 g, 6.9 mmol) in THF (10 ml) at −78 °C. After 5 min, methyl iodide (1.56 g, 7.6 mmol) in THF (5 ml) was added. Stirring was continued at −78 °C for 3 h. The mixture was poured into saturated ammonium chloride and extracted with diethyl ether (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was assigned as 2-(2-hydroxybenzylideneamino)-propanenitrile: Pale yellow liquid; IR (neat) 3200—2400, 2250, and 1630 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.75 (3H, d, J=7.0 Hz, Me), 4.73 (1H, dq, J=7.0 and 2.0 Hz, CH), 6.9—7.5 (4H, m, Ar), 8.60 (1H, d, J=2.0 Hz, CH=N), and 12.20 (1H, br s, OH); MS *m/z* (rel intensity, %) 174 (M^+, 78), 173 (13), 160 (11), 159 (16), 120 (base peak), 106 (13), 102 (16), 91 (13), and 77 (23). HRMS Found: *m/z* 174.0790. Calcd for $C_{10}H_{10}N_2O$: M, 174.0790. To a mixture of this imine (2.25 g, 12.9 mmol) and chlorotrimethylsilane (1.72 g, 15.8 mmol) in dry benzene (35 ml) was added triethylamine (1.6 g, 15.8 mmol) in benzene (5 ml). After stirring at room temperature for 1 h, the precipitate was filtered off and the filtrate was distilled under reduced pressure to give **1g** (2.7 g, 85%): Yellow liquid; bp 180 °C/133 Pa (bulb-to-bulb); IR (neat) 2215, 1640, 920, 850, and 760 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.30 (9H, s, $SiMe_3$), 1.67 (3H, d, J=7.0 Hz, Me), 4.66 (1H, dq, J=7.0 and 1.5 Hz, CH), 6.8—7.9 (4H, m, Ar), and 8.90 (1H, d, J=1.5 Hz, CH=N).

Reaction of 1a with Dimethyl Maleate Leading to 2 and 3. A mixture of **1a** (0.146 g, 0.6 mmol) and dimethyl maleate (0.09 g, 0.6 mmol) in dry toluene (3 ml) was heated under reflux for 20 h. The toluene was evaporated in vacuo and the residue was chromatographed over silica gel by using chloroform as an eluent to give **3** (0.1 g, 50%) and then **2** (0.1 g, 46%). **2**: Colorless liquid; IR (neat) 3500—3050, 1740, and 1640 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.12 (3H, s, COOMe), 3.63 (3H, s, Me), 3.95 (1H, dd, J_{4-5}=7.0 and J_{4-3}=2.0 Hz, 4-H), 4.64 (1H, t, J_{3-4}=J_{3-5}=2.0 Hz, 3-H), 5.97 (1H, dd, J_{5-4}=7.0 and J_{5-3}=2.0 Hz, 5-H), 6.6—7.5 (7H, m, Ar), 7.85 (2H, m, Ar), and 8.40 (1H, br, OH); ^{13}C NMR ($CDCl_3$) δ=30.83 (d, 4-C), 53.00, 53.30 (each q, COOMe), 56.83 (d, 3-C), 75.12 (d, 5-C), 116.60, 119.71, 123.07, 128.25, 128.72, 128.91 (each d, Ar), 132.01 (s, Ar), 155.40 (s, Ar), 170.19 (s, 2-C), 170.30, and 171.78 (each s, COOMe); MS *m/z* (rel intensity, %) 353 (M^+, 40), 295 (15), 294 (78), 263 (20), 262 (base peak), 235 (35), 234 (11), 209 (31), 208 (15), 206 (13), 148 (24), 131 (21), 115 (24), 106 (11), 105 (21), 104 (15), 103 (18), 102 (9), 91 (10), 78 (30), and 77 (44). Found: C, 68.23; H, 5.32; N, 4.20%. Calcd for $C_{20}H_{19}NO_5$: C, 67.98; H, 5.42; N, 3.96%. **3**: Colorless liquid; IR (neat) 1750, 1735, 1610, 1490, and 1460 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.64 (3H, s, COOMe), 3.85 (1H, dd, J_{3a-9b}=7.0 and J_{3a-3}=2.0 Hz, 3a-H), 5.00 (1H, t, J_{3-3a}=J_{3-9b}=2.0 Hz, 3-H), 5.49 (1H, dd, J_{9b-3a}=7.0 and J_{9b-3}=2.0 Hz, 9b-H), and 6.9—7.9 (9H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=46.47 (d, 3a-C), 53.00 (q, COOMe), 58.71 (d, 3-C), 70.12 (d, 9b-C), 117.23, 125.42, 128.83, 129.13, 130.25, 130.72 (each d, Ar), 131.83, 132.13 (each s, Ar), 150.72 (s, Ar), 167.54 (s, 2-C), 168.78, and 169.66 (each s, COO and COOMe); MS *m/z* (rel intensity, %) 321 (M^+, 21), 320 (base peak), 262 (13), 260 (36), 209 (39), and 105 (21). Found: C, 71.05; H, 4.74; N, 4.38%. Calcd for $C_{19}H_{15}NO_4$: C, 71.02; H, 4.71; N, 4.36%.

Acid-Catalyzed Cyclization of 2 Leading to 3 and Acid-Catalyzed Methanolysis of 3 into 2. Cyclization: A solution of **2** (0.1 g, 0.28 mmol) in toluene (3 ml) containing a catalytic amount of acetic acid was heated under reflux for 24 h. The mixture was evaporated to dryness in vacuo to give **3** (0.88 g, 98%). Methanolysis: A solution of **3** (0.084 g, 0.2 mmol) in methanol (10 ml) containing a catalytic amount of hydrochloric acid was heated under reflux for 1 h. The mixture was poured into ice water and extracted with chloroform (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo to afford almost pure **2** (0.06 g, 85%).

Reaction of 1a with Dimethyl Fumarate Leading to 3—5. A mixture of **1a** (0.236 g, 1 mmol) and dimethyl fumarate (0.144 g, 1 mmol) in dry toluene (3 ml) was heated under reflux for 3.5 h. The solvent was evaporated in vacuo and the residue was chromatographed over silica gel by using chloroform to give **3** (0.1 g, 31%) and, then, an inseparable mixture of **4** and **5** (0.237 g, 62%). **4** and **5** (a 2:1 mixture (^1H NMR)): Colorless liquid; IR (neat) 3400—3100, 1740, 1640, 1495, and 1455 cm^{-1}; ^1H NMR ($CDCl_3$) one isomer: δ=3.53, 3.70 (each 3H, s, COOMe), 3.70 (1H, t, J_{4-3}=J_{4-5}=7.0 Hz, 4-H), 4.65 (1H, dd, J_{3-4}=7.0 and J_{3-5}=2.0 Hz, 3-H), 5.68 (1H, dd, J_{5-4}=7.0 and J_{5-3}=2.0 Hz, 5-H), 6.7—7.4 (7H, m, Ar), 7.70 (2H, m, Ar), and 9.00 (1H, br, OH); the other isomer: δ=3.58, 3.68 (each 3H, s, COOMe), 3.65 (1H, dd, J_{4-3}=7.5 and J_{4-5}=7.0 Hz, 4-H), 4.60 (1H, dd, J_{3-4}=7.5 and J_{3-5}=2.0 Hz, 3-H), 5.87 (1H, dd, J_{5-4}=7.0 and J_{5-3}=2.0 Hz, 5-H), 6.7—7.4 (7H, m, Ar), 7.70 (2H, m, Ar), and 8.20 (1H, m, OH); MS *m/z* (rel intensity, %) 353 (M^+, 50), 295 (15), 294 (71), 263 (20), 262 (base peak), 261 (13), 235 (41), 234 (13), 209 (30), 206 (18), 131 (31), 115 (28), 106 (13), 105 (20), 104 (20), 103 (20), 78 (32), and 77 (43). Found: C, 67.87; H, 5.46; N, 3.84%. Calcd for $C_{20}H_{19}NO_5$: C, 67.98; H, 5.42; N, 3.96%.

Reaction of 1a with Methyl Acrylate Leading to 6 and 7. A mixture of **1a** (0.4 g, 1.69 mmol) and methyl acrylate (0.36 g, 4.29 mmol) was heated under reflux in toluene (10 ml) for 28 h. The residue obtained by the evaporation of all the volatile materials in vacuo, was triturated with diethyl ether–hexane to give **6** (0.32 , 67%) as a colorless solid. The filtrate was evaporated and the residue chromatographed over silica gel with chloroform to afford **7** (0.14 g, 26%) as a 2:1 mixture of two isomers (^1H NMR). **6**: Colorless needles (benzene–hexane); mp 183—184 °C; IR (KBr) 1755, 1610, 1490, 1455, 1220, and 1195 cm^{-1}; ^1H NMR ($CDCl_3$) δ= 3.3—3.9 (3H, m, 3- and 3a-H), 5.36 (1H, dt, J_{9b-3a}=5.0 and J_{9b-3}= 3.0 Hz, 9b-H), and 7.0—7.9 (9H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=40.94 (t and d, 3- and 3a-C), 70.12 (d, 9b-C), 117.24, 120.13, 125.24, 128.07, 128.77, 129.83, 130.25 (each d, Ar), 131.48, 133.24, 150.54 (each s, Ar), 169.12 (s, 2-C), and 172.60 (s, 4-C); MS *m/z* (rel intensity, %) 263 (M^+, 24), 209 (17), 208 (base peak), 160 (14), 132 (18), 131 (30), 115 (25), 105 (26), 104 (16), 103 (22), 102 (11), 89 (13), 77 (75), and 76 (19). Found: C, 77.48; H, 4.98; N, 5.43%. Calcd for $C_{17}H_{13}NO_2$: C, 77.55; H, 4.98; N, 5.32%. **7** (an inseparable 2:1 mixture of two regioisomers (^1H NMR)): Colorless liquid; IR (neat) 3400—2800, 1740, 1615, 1580, 1495, 1450, 1340, and 1250 cm^{-1}; ^1H NMR ($CDCl_3$) major isomer: δ=2.2—2.6 (1H, m, one of 4-H), 2.8—3.1 (1H, m, the other of 4-H), 3.63 (3H, s, COOMe), 4.27 (1H, dt, J_{3-4}=10.0 and J_{3-5}=2.0 Hz, 3-H), 5.60 (1H, dt, J_{5-4}=8.0 Hz and J_{5-3}=2.0 Hz, 5-H), 6.8—7.9 (9H, m, Ar), and 8.5—9.5 (1H, br, OH); minor isomer: δ=2.2—2.6

(1H, m, one of 4-H), 2.8—3.1 (3H, m, the other of 4-H), 3.53 (3H, s, COOMe), 4.16 (1H, m, 3-H), 5.36 (1H, dt, J_{5-4}=10.0 and J_{5-3}=2.0 Hz, 5-H), 6.8—7.9 (9H, m, Ar), and 8.5—9.5 (1H, br, OH); ^{13}C NMR ($CDCl_3$) major isomer: δ=35.71 (t, 3-C), 53.47 (q and d, COOMe and 4-C), 73.12 (d, 5-C), 169.42 (s, 2-C), 171.54 (s, COOMe); minor isomer: δ=36.12 (t, 3-C), 52.65 (q, COOMe), 53.47 (d, 4-C), 72.36 (d, 5-C), 169.95 (s, 2-C), 172.36 (s, COOMe); the other signals: δ=117.07, 119.71, 126.48, 127.89, 128.59, 128.89, 131.53, 131.54, 136.12, 156.25.

Reaction of 1b with Dimethyl Maleate Leading to 8. A solution of **1b** (0.278 g, 1 mmol) and dimethyl maleate (0.144 g, 1 mmol) in dry toluene (3 ml) was heated under reflux for 14 h. The mixture was evaporated in vacuo and the residue was chromatographed over silica gel by using chloroform to give **8** (0.36 g, 91%): Colorless needles (benzene-hexane); mp 203—204 °C; IR (KBr) 1755, 1730, 1625, 1510, 1430, 1305, 1270, 1220, and 1160 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.67 (3H, s, COOMe), 3.90 (1H, dd, J_{3a-11c}=8.0 and J_{3a-3}=1.5 Hz, 3a-H), 5.10 (1H, dd, J_{3-11a}=2.0 and J_{3-3a}=1.5 Hz, 3-H), 6.00 (1H, dd, J_{11c-3a}=8.0 and J_{11c-3}= 2.0 Hz, 11c-H), 7.0—8.0 (10H, m, Ar), and 8.25 (1H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=46.03 (d, 3a-C), 52.89 (q, Me), 58.12 (d, 3-C), 67.34 (d, 11c-C), 112.19, 117.00, 124.05, 125.46, 127.58, 128.19, 128.40, 128.63, 130.92 (each d), 131.04, 131.51, 131.92, 148.19 (each d, Ar), 167.26 (s, 2-C), 168.62, and 169.43 (each s, COOMe and 4-C); MS *m/z* (rel intensity, %) 371 (M^+, 38), 312 (34), 284 (13), 258 (86), and 152 (base peak). Found: C, 74.45; H, 4.83; N, 3.77%. Calcd for $C_{23}H_{17}NO_4$: C, 74.38; H, 4.61; N, 3.77%.

Reaction of 1b with Dimethyl Fumarate Leading to 8 and 9. By a similar procedure, using **1b** (0.43 g, 1.5 mmol) and dimethyl fumarate (0.216 g, 1.5 mmol) in toluene (6 ml), after heating under reflux for 20 h and chromatography over silica gel with chloroform-ethyl acetate (49:1 v/v), **8** (0.28 g, 50%) and then **9** (0.28 g, 41%) were obtained, **9**: Colorless prisms (benzene-hexane); mp 188—189 °C; IR (KBr) 3500—2900, 1740, 1620, 1575, 1515, 1440, 1270, and 1210 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.60 (3H, s, COOMe), 3.80 (1H, dd, J_{4-5}=5.0 and J_{4-3}=2.0 Hz, 4-H), 4.70 (1H, dd, J_{3-4}=J_{3-5}= 2.0 Hz, 3-H), 6.32 (1H, dd, J_{5-4}=5.0 and J_{5-3}=2.0 Hz, 5-H), 7.0—8.0 (11H, m, Ar), and 10.00 (1H, br s, OH); MS *m/z* (rel intensity, %) 403 (M^+, 23), 344 (15), 313 (23), 312 (base peak), 285 (25), 284 (15), 259 (37), 258 (19), 256 (16), 228 (15), 181 (17), 153 (21), 128 (45), 127 (30), 115 (38), 105 (10), 104 (15), and 77 (27). Found: C, 71.71; H, 5.18; N, 3.72%. Calcd for $C_{24}H_{21}NO_5$: C, 71.45; H, 5.25; N, 3.47%.

Reaction of 1c with Dimethyl Maleate Leading to 10. A mixture of **1c** (0.278 g, 1 mmol) and dimethyl maleate (0.144 g, 1 mmol) was heated under reflux in toluene (1 ml) for 14 h. The mixture was evaporated in vacuo and the residue was chromatographed over silica gel by using chloroform-ethyl acetate (9:1 v/v) to give **10** (0.36 g, 91%): Colorless prisms (benzene-hexane); mp 96—97 °C; IR (KBr) 1765, 1730, 1620, 1570, 1430, 1200, and 1160 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.24 (3H, s, OAc), 3.06 (3H, s, 4-COOMe), 3.58 (3H, s, 3-COOMe), 3.86 (1H, dd, J_{4-5}=9.0 and J_{4-3}=3.0 Hz, 4-H), 4.80 (1H, dd, J_{3-4}=3.0 and J_{3-5}=1.5 Hz, 3-H), 5.95 (1H, dd, J_{5-4}=9.0 and J_{5-3}=1.5 Hz, 5-H), 7.0—7.4 (7H, m, ArH), and 7.90 (2H, m, Ar); MS *m/z* (rel intensity, %) 395 (M^+, 18), 294 (26), 262 (30), 261 (10), 208 (19), 131 (14), 115 (16), 105 (14), 77 (12), 76 (30), 51 (14), and 42 (base peak). Found: C, 67.11; H, 5.34; N, 3.75%. Calcd for $C_{22}H_{21}NO_6$: C, 66.87; H, 5.35; N, 3.54%.

refluxing for 8.5 h and the subsequent column chromatography over silica gel by using chloroform-ethyl acetate (9:1

This compound **10** (0.395 g, 1 mmol) and a catalytic amount of *p*-toluenesulfonic acid were heated under reflux in toluene (5 ml) for 13 h. The mixture was poured into water and extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel with chloroform to give **3** (0.193 g, 60%).

Reaction of 1c with Dimethyl Fumarate Leading to 10 and 11. By a similar procedure, using **1c** (0.278 g, 1 mmol) and dimethyl fumarate (0.144 g, 1 mmol) in toluene (1 ml), after v/v), a mixture of **10** and **11** (1:1 (^{1}H NMR), 0.208 g) and then **10** (0.17 g, 43%) were obtained. The yield of **10** was 69% and that of **11** was 26%. The latter product **11** could not be isolated in its pure form. **11**: ^{1}H NMR ($CDCl_3$): δ=2.20 (3H, s, OAc), 3.43 (1H, t, J_{4-3}=6.0 Hz, 4-H), 3.53 (3H, s, 3-COOMe), 3.65 (3H, s, 4-COOMe), 4.50 (1H, dd, J_{3-4}=6.0 and J_{3-5}=1.5 Hz, 3-H), 5.67 (1H, dd, J_{5-4}=6.0 and J_{5-3}=1.5 Hz, 5-H).

Reaction of 1e with *N*-Methylmaleimide Leading to 12. A solution of **1e** (0.404 g, 2 mmol) and *N*-methylmaleimide (0.222 g, 2 mmol) in dry toluene (15 ml) was heated under reflux for 14 h. The solvent was evaporated in vacuo and the residue was triturated with diethyl ether to give a colorless solid of **12** (0.057 g). The ether filtrate was evaporated and the residue was chromatographed over silica gel with chloroform-ethyl acetate (3:2 v/v) to afford another portion of **12** (0.16 g, total yield: 35%): **12**: Colorless prisms (acetonitrile): mp 239—240 °C; IR (KBr) 3100, 2225, 1790, 1710, and 1620 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.70 (3H, s, OAc), 2.65 (3H, s, NMe), 4.00 (1H, dd, J_{3a-6a}=10.0 and J_{3a-4}=2.0 Hz, 3a-H), 4.24 (1H, t, J_{6a-3a}=J_{6a-6}=10.0 Hz, 6a-H), 5.14 (1H, d, J_{4-3a}=2.0 Hz, 4-H), 5.38 (1H, d, J_{6-6a}=10.0 Hz, 6-H), 6.6—7.2 (4H, m, Ar), and 9.78 (1H, br s, OH); ^{13}C NMR ($CDCl_3$) δ=22.35 (q, NAc), 24.59 (NMe), 48.77 (d, 3a-C), 50.24 (d, 6a-C), 57.00 (d, 4-C), 63.24 (d, 6-C), 116.13 (d, Ar), 118.18 (s, CN), 119.42, 122.60 (each d, Ar), 130.18 (s, Ar), 131.60 (d, Ar), 154.19 (s, Ar), 169.48 (s, NAc), 173.54, and 175.60 (each s, CON); MS *m/z* (rel intensity, %) 313 (M^+, 19), 286 (8), 270 (38), and 160 (base peak). Found: C, 61.23; H, 4.90; N, 13.39%. Calcd for $C_{16}H_{15}N_3O_4$: C, 61.33, H, 4.83; N, 13.41%.

Reaction of 1e with Dimethyl Fumarate Leading to 13 and 14. A solution of **1e** (0.404 g, 2 mmol) and dimethyl fumarate (0.288 g, 2 mmol) in dry toluene (10 ml) was heated under reflux. When the mixture was cooled down to room temperature, a colorless solid of **13** (0.252 g, 34%) was precipitated. The filtrate was evaporated in vacuo and the residue was chromatographed over silica gel by using chloroform-ethyl acetate (3:1 v/v) to give **14** (0.06 g, 9%). **13**: Colorless prisms (acetonitrile); mp 222—223 °C; IR (KBr) 3600—3000, 2250, 1740, and 1620 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.64 (3H, s, NAc), 3.36 (3H, s, 4-COOMe), 3.70 (3H, s, 3-COOMe), 3.93 (2H, m, 3- and 4-H), 5.46 (1H, d, J_{2-3}=7.6 Hz, 2-H), 5.75 (1H, d, J_{5-4}=7.6 Hz, 5-H), 6.6—7.1 (4H, m, Ar), and 9.76 (1H, br s, OH); ^{13}C NMR ($CDCl_3$) δ=21.47 (q, NAc), 45.42 (d, 3-C), 47.83 (d, 4-C), 49.36 (d, 2-C), 51.77, 52.83 (each q, COOMe), 57.47 (d, 5-C), 115.42 (d, Ar), 116.48 (s, CN), 119.24 (d, Ar), 123.48 (s, Ar), 128.42, 129.54 (each d, Ar), 154.66 (s, Ar), 168.54, 168.83, and 169.19 (each s, COOMe and NAc); MS *m/z* (rel intensity, %) 346 (M^+, 51), 303 (42), 271 (28), 160 (73), and 42 (base peak); Found: C, 58.88; H, 5.29; N, 8.15%. Calcd for $C_{17}H_{18}N_2O_6$: C, 58.95; H,

5.24; N, 8.09%. **14**: Colorless prisms (acetonitrile); mp 194—195 °C; IR (KBr) 3270, 1750, 1730, 1635, and 1600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.27 (3H, s, NAc), 3.46 (1H, dd, J_{3-4}=12.0 and J_{3-2}=9.0 Hz, 3-H), 3.62, 3.68 (each 3H, s, COOMe), 3.88 (1H, dd, J_{4-3}=12.0 and J_{4-5}=9.0 Hz, 4-H), 5.30 (1H, d, J_{2-3}=9.0 Hz, 2-H), 5.40 (1H, d, J_{5-4}=9.0 Hz, 5-H), 6.8—7.3 (4H, m, Ar), and 9.63 (1H, br s, OH); ^{13}C NMR ($CDCl_3$) δ=21.94 (q, NAc), 48.47 (d, 3-C), 50.12 (d, 4-C), 53.42 (d, 2-C), 53.71, 54.89 (each q, COOMe), 61.24 (d, 5-C), 116.83 (d, Ar), 117.89 (s, CN), 122.24 (d, Ar), 127.18 (s, Ar), 128.01, 130.83 (each d, Ar), 155.31 (s, Ar), 169.36, 170.00, and 171.66 (each s, COOMe and NAc); MS *m/z* (rel intensity, %) 346 (M^+, 26), 303 (11), 271 (12), 245 (10), 218 (12), 193 (31), 186 (21), 185 (17), 176 (27), 161 (18), 160 (30), 159 (13), 133 (17), 132 (13), 131 (22), 77 (18), and 43 (base peak). Found: C, 58.74; H, 5.20; N, 7.91%. Calcd for $C_{17}H_{18}N_2O_6$: C, 58.95; H, 5.24; N, 8.09%.

General Procedure for the Reaction of 1f with Olefins in the Presence of LDA Leading to 15—17 and 18—20. To a freshly prepared solution of LDA (1.6 mmol) in dry THF (5 ml) was slowly added a solution of **1f** (1.5 mmol) in THF (5 ml) at −78 °C. After 5 min, an olefin (1.5 mmol) in THF (5 ml) was added. The mixture was stirred at −78 °C for 5 h, poured into saturated aqueous ammonium chloride, and extracted with diethyl ether (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using chloroform to give an inseparable mixture of **15** and **18** or **17** and **20**. However **16** and **19** could be separated from each other.

15 and **18** (a 3:2 mixture (^1H NMR)): Yield 94%; ^1H NMR ($CDCl_3$) **15**: δ=0.30 (9H, s, $SiMe_3$), 2.3—2.6 (2H, m, 3-H), 3.15 (1H, m, 3-H), 5.75 (1H, d, J_{5-4}=9.0 Hz, 5-H), 6.6—7.2 (4H, m, Ar), and 7.80 (1H, br s, 2-H); **18**: δ=2.3—2.6 (3H, m, CH_2 and CH), 3.50 (3H, s, COOMe), 4.40 (1H, d, J=6.0 Hz, NCH), 5.50 (1H, d, J=4.0 Hz, OCHN), and 6.6—7.2 (4H, m, Ar).

16 (50%) and **19** (20%): **16**: Pale yellow liquid; IR (neat) 1730, 1635, 1595, 1450, 910, 840, 750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.30 (9H, s, $SiMe_3$), 1.25 (3H, d, J_{Me-3}=7.5 Hz, 3-Me), 2.16 (3H, d, J=6.5 Hz, Me), 3.13 (3H, s, COOMe), 3.6—3.8 (2H, m, 3- and 4-H), 5.75 (1H, dd, J_{5-4}=8.0 Hz, J_{5-3}=2.0 Hz, 5-H), and 6.6—7.2 (4H, m, Ar); MS *m/z* (rel intensity, %) 319 (M^+, 23), 304 (19), 260 (33), 219 (31), 186 (29), 146 (19), 128 (50), 86 (13), 77 (10), 73 (30), and 44 (20). HRMS Found: *m/z* 319.1619. Calcd for $C_{17}H_{25}NO_3$: M, 319.1617. **19**: Colorless liquid; IR (neat) 3350, 2980, 1730, 1610, 1585, 1490, 1460, 1025, 910, and 760 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.16 (3H, d, J=7.0 Hz, Me), 2.1—2.7 (1H, br NH), 2.8—3.3 (2H, m, CH), 3.56 (3H, s, COOMe), 4.41 (1H, d, J=6.0 Hz, NCH), 5.10 (1H, s, OCHN), and 6.6—7.4 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=19.38 (Me), 42.08 (CHMe), 51.72 (COOMe), 58.64 (CHCOOMe), 60.44 (NCH), 93.90 (OCHN), 116.38, 119.36, 125.19, 126.45, 129.25, 151.41 (each Ar), and 171.37 (COOMe); MS *m/z* (rel intensity, %) 233 (M^+, 38), 175 (25), 174 (21), 85 (61), 83 (base peak), and 47 (29). HRMS Found: *m/z* 233.1049. Calcd for $C_{13}H_{15}NO_3$: M, 233.1047.

17 and **20** (**17**: 62%; **20**: 16% (^1H NMR)). Only **20** was isolated in a pure form): **17**: ^1H NMR ($CDCl_3$) δ=0.30 (9H, s, $SiMe_3$), 3.14 (3H, s, COOMe), and 7.70 (1H, d, J=2.0 Hz, 2-H). Other signals were overlapped with those of **20**. **20**: Colorless liquid; IR (neat) 3320, 2950, 1720, 1590, 1450, 1250, and 750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.52 (3H, s, Me), 1.90 (1H, dd, J_{gem}=15.0 and J=4.0 Hz, one of CH_2), 2.95 (1H, d, J_{gem}=15.0 Hz, the other of CH_2), 3.0—3.3 (1H, br, NH), 3.46 (3H, s, COOMe), 3.95 (1H, s, NCH), 5.47 (1H, d, J=4.0 Hz, OCHN), and 6.6—7.3 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=25.80 (q, Me), 42.48 (t, CH_2), 51.79 (q, COOMe), 58.10 (s, *q*-C), 63.51 (d, NCH), 88.52 (OCHN), 116.35, 119.13, 125.45, 126.83, 129.08 (each d, Ar), 151.51 (s, Ar), and 174.77 (s, COOMe); MS *m/z* (rel intensity, %) 233 (M^+, 35), 175 (15), 174 (base peak), 172 (10), 133 (29), 132 (17), 131 (13), 112 (21), 105 (22), 104 (14), 91 (29), 84 (18), 82 (29), and 77 (21). HRMS Found: *m/z* 233.1049. Calcd for $C_{13}H_{15}NO_3$: M, 233.1049.

Acetylation of 18 Leading to 21. A mixture of **15** and **18** (2:1, 0.23 g) in acetic acid (1 ml) containing acetic anhydride (1 ml) was stirred at room temperature for 1 h. After the reaction was complete, ethanol (30 ml) was added. The mixture was evaporated in vacuo and the residue was triturated with diethyl ether to give a colorless solid of **21** (0.16 g, 71%): Colorless prisms (benzene-hexane); mp 129—130 °C; IR (KBr) 1725, 1640, 1475, 1400, 1200, 1170, 1020, 930, 890, and 745 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.13 (1/3×3H, s, Ac (syn)), 2.23 (2/3×3H s, Ac (anti)), 2.3—3.0 (2H, m, CH_2), 3.2—3.6 (1H, m, CH), 3.56 (3H, s, COOMe), 4.98 (1/3H, d, J=7.0 Hz, NCH (syn)), 5.49 (2/3H, d, J=6.5 Hz, NCH (anti)), 5.91 (2/3H, d, J=5.5 Hz, OCHN (anti)), 6.35 (1/3H, d, J=5.5 Hz, OCHN (syn)), and 6.6—7.3 (3H, m, Ar); MS *m/z* (rel intensity, %) 261 (M^+, 26), 202 (20), 160 (base peak), 132 (16), 131 (11), and 76 (13). Found: C, 64.64; H, 5.90; N, 5.31%. Calcd for $C_{14}H_{15}NO_4$:C, 64.36; H, 5.79; N, 5.36%.

Acetylation of 19 Leading to 22. A similar procedure using a mixture of **16** and **19** (3:1, 0.3 g) gave **22** (0.21 g, 73%): Colorless needles (benzene-hexane); IR (KBr) 1735, 1650, 1420, 1360, 1310, 1250, 1200, and 750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.22 (3H, d, J=7.6 Hz, Me), 2.09 (2/5×3H, s, Ac (syn)), 2.20 (3/5×3H, s, Ac (anti)), 2.8—3.3 (2H, m, CH), 4.96 (2/5H, d, J=6.0 Hz, NCH (syn)), 5.44 (3/5H, br s, OCHN (anti)), 5.49 (3/5H, d, J=6.0 Hz, NCH (anti)), 5.94 (2/5H, br s, OCHN (syn)), and 6.7—7.2 (4H, m, Ar); MS *m/z* (rel intensity, %) 275 (M^+, 33), 216 (26), 175 (14), 174 (base peak), 132 (16), and 77 (15). Found: C, 65.44; H, 6.26; N, 4.90%. Calcd for $C_{15}H_{17}NO_4$: C, 65.44; H, 6.22; N, 5.09%.

Acetylation of 20 Leading to 23. A similar procedure using a mixture of **17** and **20** (4:1, 0.24 g) gave **23** (0.165 g, 73%): Colorless prisms (benzene-hexane); mp 137—138 °C; IR (KBr) 1725, 1650, 1410, 1290, 1200, 1160, 1120, and 750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.44 (2/3×3H, s, Me (anti)), 1.50 (1/3×3H, s, Me (syn)), 2.10 (1/3×3H, s, Ac (syn)), 2.23 (2/3×3H, s, Ac (anti)), 2.8—3.3 (2H, m, CH_2), 3.50 (3H, s, COOMe), 4.50 (1/3H, s, NCH (syn)), 5.06 (2/3H, s, NCH (anti)), 5.92 (2/3H, d, J=6.0 Hz, OCHN (anti)), 6.35 (1/3H, d, J=6.0 Hz, OCHN (syn)), and 6.6—7.2 (4H, m, Ar); MS *m/z* (rel intensity, %) 275 (M^+, 20), 216 (30), 175 (10), 174 (66), 172 (16), 133 (17), 132 (25), 131 (14), 78 (13), and 77 (26). Found: C, 65.56; H, 6.47; N, 5.09%. Calcd for $C_{15}H_{17}NO_4$: C, 65.44; H, 6.22; N, 5.09%.

Reaction of 1g with Methyl Crotonate Leading to 24 and 28. To a solution of freshly prepared LDA (1.6 mmol) in THF (5 ml) was added at −78 °C a solution of **1g** (0.369 g, 1.5 mmol) in THF (5 ml). After the addition of methyl crotonate (0.16 g, 1.6 mmol in THF (5 ml)), the mixture was stirred at −78 °C for 1.5 h, poured into saturated aqueous ammonium chloride, and then extracted with diethyl ether (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was assigned as

24 on the basis of the following ^{1}H NMR spectrum ($CDCl_3$): δ=0.30 (9H, s, $SiMe_3$), 2.15 (3H, d, J_{Me-3}=6.5 Hz, 3-Me), 3.13 (3H, s, COOMe), 3.1—3.4 (1H, m, 3-H), 3.6—3.7 (1H, m, 4-H), 5.75 (1H, d, J_{5-4}=9.0 Hz, 5-H), and 6.7—7.2 (4H, m, Ar). It was chromatographed over silica gel by using chloroform as an eluent to give **28** (0.271 g, 84%): Colorless liquid; IR (neat) 2960, 1750, 1730, 1630, 1580, 1490, 1450, 1375, and 760 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.38 (3H, d, J_{Me-3}=7.0 Hz, 3-Me), 2.05 (3H, d, J=1.0 Hz, 2-Me), 3.08 (1H, dq, J_{3-Me}=7.0 and J_{3-Me}=1.0 Hz, 3-H), 3.73 (1H, d, J_{3a-9b}=8.0 Hz, 3a-H), 5.30 (1H, br d, J_{9b-3a}=8.0 Hz, 9b-H), and 6.7—7.7 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=15.98 (3-Me), 17.55 (2-Me), 48.64 (3a-C), 51.86 (3-C), 67.10 (9b-C), 116.93, 117.48, 125.09, 129.40, 129.56, 149.46, 168.59, and 178.28 (COO); MS *m/z* (rel intensity, %) 215 (M^+, 28), 174 (19), 146 (base peak), 131 (16), and 43 (21). HRMS Found: *m/z* 215.0933. Calcd for $C_{13}H_{13}NO_2$: M, 215.0933.

Reaction of 1g with Methyl Methacrylate Leading to 25, 27, and 29. A similar procedure using LDA (1.6 mmol) in THF (5 ml), **1g** (0.369 g, 1.5 mmol) in THF (5 ml), and methyl methacrylate (0.16 g, 1.6 mmol) in THF (5 ml), after column chromatography over silica gel with chloroform, gave **29** (0.16 g, 50%), and then an inseparable mixture of **25** and **27** (1:1 (^{1}H NMR), 0.17 g, 36%). The mixture of **25** and **27** (1:1, 0.17 g, 0.53 mmol) was stirred at room temperature for 1 h in the presence of cesium fluoride (10 mg) in THF (2 ml). After the reaction was completed, the mixture was poured into ice water and extracted with diethyl ether (20 ml). The extract was dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using chloroform to give **29** (0.045 g, 79%) and **27** (0.06 g, 91%). **27**: Colorless prisms (benzene-hexane); mp 143—144 °C; IR (KBr) 3200—2800, 1730, 1640, 1590, 1450, 1370, 1110, and 750 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.43 (3H, s, 4-Me), 2.05 (3H, d, J_{Me-5}=2.0 Hz, 2-Me), 2.5—2.7 (2H, m, 3-H), 3.71 (3H, s, COOMe), 5.22 (1H, q, J=2.0 Hz, 5-H), and 6.8—7.2 (4H, m, Ar). Found: C, 69.39; H, 6.62; N, 5.32%. Calcd for $C_{14}H_{17}NO_3$: C, 69.48; H, 6.61; N, 5.40%. **29**: Colorless liquid; IR (neat) 1760, 1630, 1495, 1460, 1430, 1380, 1250, 1220, 1190, 1140, 1090, and 760 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.50 (3H, s, 3a-Me), 2.06 (3H, d, J_{Me-9b}=1.0 Hz, 2-Me), 2.70 (1H, d, J_{gem}=16.0 Hz, one of 3-H), 3.45 (1H, d, J_{gem}=16.0 Hz, the other of 3-H), 4.76 (1H, br s, 9b-H), and 6.7—7.7 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=20.23 (3a-Me), 22.54 (3-C), 48.94 (4-C), 51.84 (COOMe), 76.44 (9b-C), 117.11, 120.03, 129.94, 130.50, 150.42 (each Ar), and 175.73 (2C, COOMe and 4-C); MS *m/z* (rel intensity, %) 215 (M^+, 2), 213 (11), 146 (10), 100 (12), 94 (89), 85 (11), 83 (14), and 75 (base peak). HRMS Found: *m/z* 215.0934. Calcd for $C_{13}H_{13}NO_2$: M, 215.0933.

Reaction of 1g with Methyl Cinnamate Leading to 26 and 30. A similar procedure using LDA (1 mmol) in THF (3 ml), **1g** (0.246 g, 1 mmol) in THF (3 ml), and methyl cinnamate (0.162 g, 1 mmol) in THF (3 ml) gave **26** as a single product (by ^{1}H NMR). This crude product was chromatographed over silica gel with chloroform to give **26** (35%) and **30** (32%): **26**: Pale yellow liquid; IR (neat) 1735, 1650, 920, and 850 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.30 (9H, s, $SiMe_3$), 2.05 (3H, d, J_{Me-5}=2.0 Hz, 2-Me), 3.12 (3H, s, COOMe), 3.53 (1H, dd, J_{4-5}=9.0 and J_{4-3}=5.0 Hz, 4-H), 4.50 (1H, d, J_{3-4}=5.0 Hz, 3-H), 6.00 (1H, dd, J_{5-4}=9.0 and J_{5-Me}=2.0 Hz, 5-H), and 6.7—7.4 (9H, m, Ar); MS *m/z* (rel intensity, %) 381 (M^+, 10), 366 (3), 219 (15), 121 (13), and 86 (69). HRMS Found: *m/z* 381.1765. Calcd for $C_{22}H_{27}NO_3Si$: M, 381.1760. **30**: Pale yellow liquid; IR (neat) 3400—2800, 1730, and 1650 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.10 (3H, s, Me), 3.23 (3H, s, COOMe), 3.60 (1H, dd, J_{4-5}=9.0 and J_{4-3}=4.0 Hz, 4-H), 4.40 (1H, br s, 3-H), 5.90 (1H, br d, J_{5-4}=9.0 Hz, 5-H), and 6.7—7.5 (9H, m, Ar); MS *m/z* (rel intensity, %) 309 (M^+, 42), 251 (23), 250 (base peak), 236 (25), 147 (24), 84 (55), and 47 (18). HRMS Found: *m/z* 309.1347. Calcd for $C_{19}H_{19}NO_3$: M, 309.1363.

Allylation of Quinones via Photoinduced Electron-Transfer Reactions from Allylstannanes

Kazuhiro MARUYAMA* and Hiroshi IMAHORI
Department of Chemistry, Faculty of Science, Kyoto University, Kyoto 606
(Received August 5, 1988)

Photochemical reactions of quinones with allylstannanes provided four types of products: adducts of allyl group to the carbonyl oxygens of quinones, adducts of allyl group to the olefinic carbons, adducts of allyl group to the carbonyl carbons, and hydroquinones. An electron-transfer mechanism was confirmed by ^{1}H-CIDNP (Chemically Induced Dynamic Nuclear Polarization) method. This study suggests that a) photoinduced electron transfer from allylstannanes to quinones produces the corresponding quinone anion radicals and tin cation radicals, b) the tin cation radicals cleave to give allyl radicals as well as tin cation, and c) the allyl radicals attack the quinone anion radicals resulting in the formation of final products, allylated quinones.

During the last decade the photostimulated electron-transfer reactions have been a topic in organic photochemistry.[1] One-electron transfer from donor to acceptor results in the formation of ion radical pair followed by the secondary reactions to produce final products. Efficacy of the secondary reactions, however, is controlled by the rate of back electron transfer. Many efforts to reduce the back electron transfer have been done so far. One of the way to solve this problem is the use of stabilized radical species generated by fragmentation of the cation radicals (Scheme 1). This process has been realized in the photooxidation of acid,[2] alcohol,[3] ether,[3] amine,[4] olefin,[5] silane,[6,7] stannane,[8-11] and so on[12] accompanied with the subsequent loss of a cation or a proton.

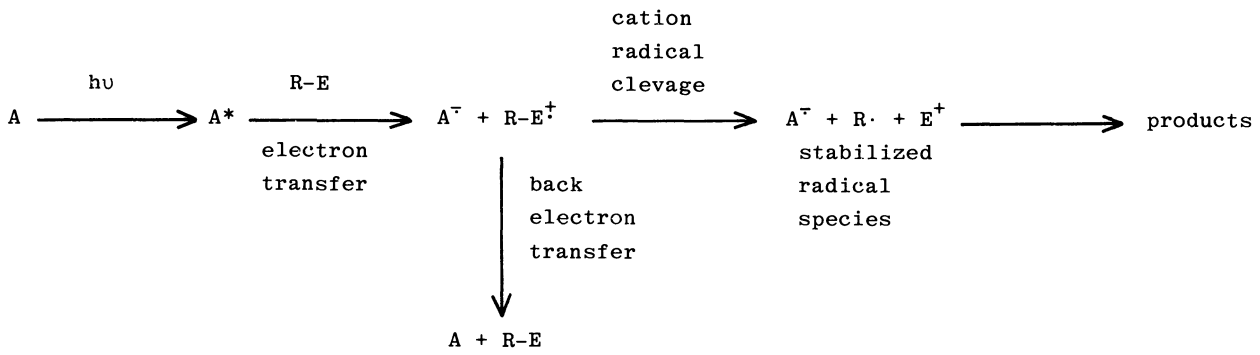
Mariano[6] and Mizuno[7] reported photoaddition reactions related to the allylsilane-iminium salt and allylsilane-cyano aromatics which were initiated by one-electron transfer and subsequent cleavage of silane cation radical to allyl radical and silane cation. However, only a few photochemical reactions of allyltin reagents have been reported.[8-11]

Allylation of quinones[13-15] is a major route for preparing isoprenoid quinones,[16] which play an important role in several metabolic sequences as well as being a key step in synthesis of antitumor-antibiotic quinonoid compounds.[17] It has been proved that allyl 4B metal compounds, allylsilane[14] and allylstannane,[15] are excellent reagents for direct introduction of allyl group to quinonoid nucleus. Thermal reactions of quinones with allylstannanes in the presence of a Lewis acid, especially BF_3, was of the most effective for allylation of quinones.[15] There have been a lot of reports on these thermal allylation of quinones, while by our knowledge one communication has appeared on photoallylation of quinones with allylsilane,[18] and no report on photoallylation of quinones with allylstannanes.

To explore the synthetic utility of the photochemistry of quinones with allylstannanes and to clarify the difference between thermal and photochemical reactions including the difference of reactivities between allylsilane and allylstannane, we have attempted to study the photochemistry of allylstannane-quinone systems. Now we will discuss the photochemistry of quinones with allylstannanes in this paper.

Results

Photochemical Reactions between Quinones and Allyltributylstannane. Photochemical reactions of a variety of quinones with allyltributylstannane were investigated. Irradiation of a benzene solution (25 ml) containing chloranil **1a** (1 mmol) and allyltributylstannane **2a** (2 mmol) with a high-pressure mercury lamp through an aqueous $CuSO_4$ filter ($h\nu$>315 nm) for 3 h under argon afforded a mixture of 4-allyloxy-



Scheme 1.

2,3,5,6-tetrachlorophenol **3a** (20%), 4-allyl-2,3,5,6-tetrachloro-4-hydroxy-2,5-cyclohexadien-1-one **7a** (20%), and 2,3,5,6-tetrachloro-1,4-benzenediol **8a** (50%). The yields of the respective products were based on the consumed quinone **1**. Likewise, **3a** (28%), **7a** (14%), and **8a** (12%) were obtained in acetonitrile (Run 2), but with different product distribution compared to the reaction in benzene. Structures of the products were readily assigned from the ^{1}H NMR, IR, mass spectroscopy, elemental analyses, suitable chemical transformations, and comparisons with those of structually related substances.[15] The IR spectrum of **3a** showed characteristic band due to hydroxyl group at 3430 cm^{-1}, while that of **7a** showed characteristic bands due to carbonyl and hydroxyl group at 1665 and 3400 cm^{-1}, respectively. In the mass spectrum of **3a** parent peaks appeared at *m/z* 286, 288, 290, 292, 294, indicating that one propene moiety had been incorporated into **1a**. In its ^{1}H NMR spectrum the α proton signal of allyl group in **3a** appeared at 4.53 as a doublet, while that of **7a** was at 2.97 as a doublet. Compound **3a** was compared with the authentic sample obtained by independent synthesis (see Experimental section). The results of photochemical reactions of quinones **1a—h** with allylstannane **2a** are summarized in Table 1. In the case of benzoquinone **1b** (Run 3), hydroquinone **8b** (52%) was major product besides yielding 4-(allyloxy)phenol **3b** (26%) and 2-allylhydroquinone **4b** (6%). On the other hand, naphthoquinone derivatives gave no 1,4-naphthalenediol (Runs 5—16). In the case of 2,3-dibromo-1,4-naphthoquinone **1c**, 2-allyl-3-bromo-1,4-naphthoquinone **5c** (29%) and 4-allyl-4-hydroxy-1(4*H*)-naphthalenone (designated to allyl quinol, hereafter) **7c** (28%) were obtained. The IR spectrum of **5c** showed characteristic bands due to carbonyl group at 1665 cm^{-1}, while that of **7c** showed those due to carbonyl and hydroxyl group at 1650 and 3360 cm^{-1}, respectively. In the mass

a) Irradiated for 3 h except Run 8 (35 h). b) Isolated yield based on a starting quinone consumed.

spectrum of **5c** parent peaks appeared at *m/z* 276, 278, indicating incorporation of one allyl group into **1c** and lose of one bromine atom from **1c**. In its ^{1}H NMR spectrum the α proton signal of allyl group in **5c** appeared at 3.66 as a doublet, while that of **7c** showed diastereotopic methylene at 2.70 (1H, dd, J=6, 13 Hz), 3.02 (1H, dd, J=6, 13 Hz). Similarly, 2,3-dichloro-1,4-naphthoquinone **1d** gave allyl quinone **5d** (35%) and allyl quinol **7d** (15%) (Run 7). 2-Bromo-1,4-naphthoquinone **1e**, however, gave no allyl quinol, but allyl quinones **5c** (9%) and **5e** (20%) were the products. Naphthoquinone **1f** gave all possible products, allyl ether **3f** (21%), allyl quinone **5e** (14%), and allyl quinol **7f** (29%). Reactions of unsymmetrical quinones, 2-methyl-1,4-naphthoquinone **1g** or 2-methoxy-1,4-naphthoquinone **1h**, gave allyl quinone **5g** (38%), 2-allyl-2,3-dihydro-1,4-naphthalenedione (abbreviated to allyl dione, hereafter) **6g** (28%), and allyl quinol **7g** (26%) (Run 13), or allyl quinone **5h** (53%) and allyl quinol **7h** (37%), respectively (Run 15). The ^{1}H NMR of allyl dione **6g** showed two pairs of diastereotopic methylene at δ 2.29 (1H, dd, J=7, 14 Hz), 2.61 (1H, dd, J=7, 14 Hz), 2.85 (1H, d, J=17 Hz), 3.10 (1H, d, J=17 Hz), and the ^{13}C NMR of **6g** showed carbonyl carbons at δ 196.0, 200.1. Surprisingly, in the cases of **1g** and **1h**, the corresponding allyl quinols **7g** and **7h**, were formed regioselectively.[19] Assignment of the regiochemistry was as follows. Since the ^{13}C NMR shift of β carbon in α,β-unsaturated ketone is characteristic, the signals appeared at δ 135.8 and 145.5 due to C2 and C3 may be assigned to 2-methyl-2-cyclohexen-1-one, while those appeared at δ 126.5 and 162.2 due to C2 and C3 to 3-methyl-2-cyclohexen-1-one, respectively. The ^{13}C NMR signals of **7g** due to C2 and C3 appeared at δ 129.9 and 147.1, respectively, which were determined by off-resonance decoupling of ^{13}C NMR spectroscopy and two dimensional ^{13}C–^{1}H shift correlation NMR spectroscopy. The structure of **7h** was assigned by comparison with the previously reported data.[15] Some of allyl quinols and allyl ethers were fairly unstable, and then after the hydroxyl group of them were acetylated the structure were confirmed (see Experimental section). In all cases, product distributions were quite dependent on solvents; benzene or acetonitrile, but there was no consistent inclinations.

Photochemical Reactions of 2,3-Dichloro-1,4-naphthoquinone with Prenyl (or Benzyl) Tin Reagents. The photochemical reactions of **1d** (1 mmol) with (3-methyl-2-butenyl)tributylstannane **2b** or benzyltributylstannane **2c** (2 mmol) were carried out in benzene (25 ml). As expected, three classes of products were obtained in both cases; compounds **9**, **10**, and **11**, which were also assigned by spectroscopic data and chemical transformation (see Experimental section). In the reaction of prenylstannane **2b**, prenyl ether **9b** (27%), prenyl quinone **10b** (27%), and prenyl quinol **11b** (19%) having α adduct structures were obtained exclusively[20] (Scheme 3). This method will provide a feasible route of isoprenoid quinones, which play an important role in biological electron transfer. Similarly, the photochemical reaction of **1d** with benzylstannane **2c** gave benzyl ether **9c** (26%), benzyl quinone **10c** (36%), and benzyl quinol **11c** (23%).

Mechanistic Aspects of the Reactions. To clarify the reaction mechanism, we have applied ^{1}H-CIDNP method to the photochemical reactions.[10] When a benzene-d_6 solution of **1d** ($\approx 10^{-2}$ mol dm^{-3}) and **2a** ($\approx 10^{-2}$ mol dm^{-3}) was irradiated (>330 nm) under argon, strong ^{1}H-CIDNP signals due to the allyl quinone **5d** and the by-product, 1,5-hexadiene **12a**, which were assigned by comparison with the authentic samples, were observed (Fig. 1). In acetonitrile-d_3 similar but weaker polarizations were observed. These polarizations are explained reasonably by the Kaptein's rule (See Ref. 21 for the polarization signals due to **5d** and **12a**). In the reaction of **1c** with **2a**, similar polarizations of allyl quinone **5c** and diene **12a** were observed in benzene-d_6, and furthermore in that of **1e** with **2a**, polarization signals due to allyl quinones **5c**,

Scheme 3.

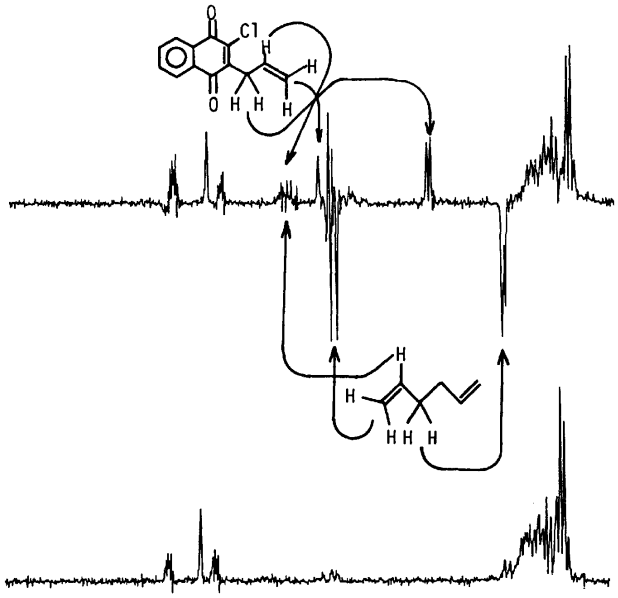

Fig. 1. ^{1}H NMR spectra (100 MHz) of a benzene-d_6 solution containing **1d** and **2a** in the dark (bottom) and during irradiation (top).

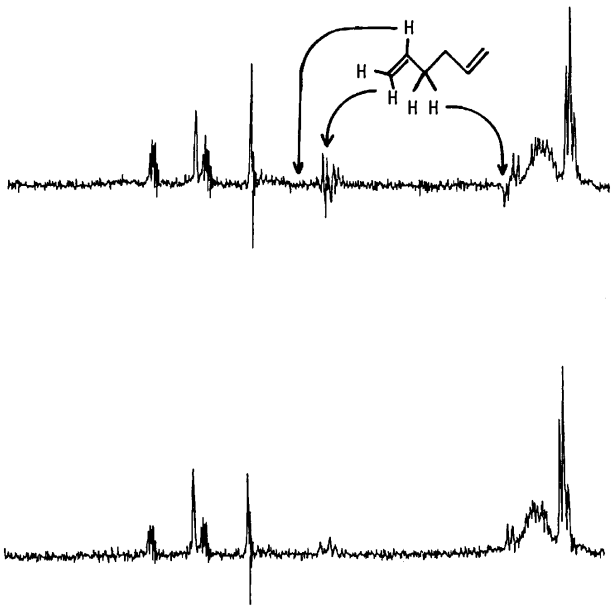

Fig. 2. ^{1}H NMR spectra (100 MHz) of a benzene-d_6 solution containing **1f** and **2a** in the dark (bottom) and during irradiation (top).

5e and diene **12a** were observed. But in the reactions of **1f** or **1g** with **2a**, only polarization signals due to **12a** were observed in benzene-d_6 (Fig. 2). None of the polarizations were observed in the reactions of **1b** or **1h** with **2a** in benzene-d_6. On the other hand in the reaction of **1a** with **2a**, the strongest polarizations due to both an adduct and diene **12a**, were observed in benzene-d_6, but the polarization due to the adduct could not be assigned to the final products, **3a**, **7a**, and

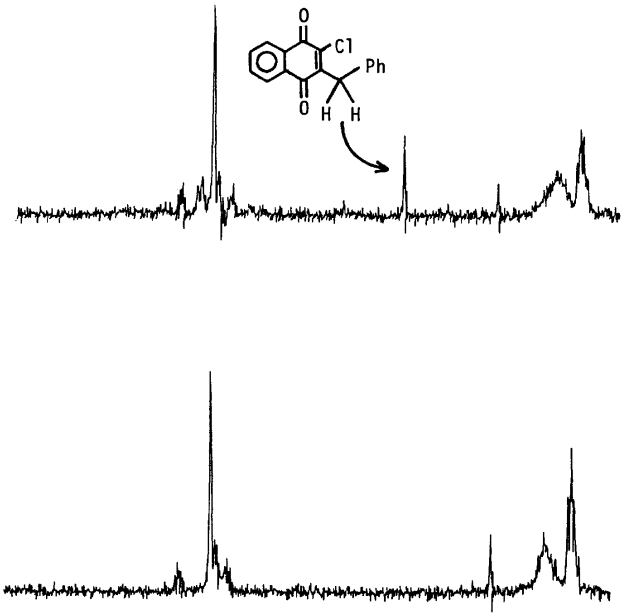

Fig. 3. ^{1}H NMR spectra (100 MHz) of a benzene-d_6 solution containing **1d** and **2c** in the dark (bottom) and during irradiation (top).

8a. In the reaction of **1d** with **2b**, ^{1}H NMR polarizations of allyl quinone **10b** were observed in benzene-d_6,[22] but polarizations based on other by-products; i.e, 2,7-dimethyl-2,6-octadiene, were not verified because of the complex signal derived from -SnBu$_3$ group. In the reaction of **1d** with **2c**, the polarization signals due to benzyl quinone **10c** were observed in benzene-d_6[23] (Fig. 3). In all of the CIDNP experiments, same pattern of polarization signals were observed in the reactions of both benzene-d_6 and acetonitrile-d_3 solution, but, in general, polarizations in benzene were stronger than that in acetonitrile.

Discussion

The free energy changes in electron-transfer process from a tin reagent to excited triplet quinone can be estimated by Rehm-Weller equation[24] (Eq. 1), where $E_{1/2}{}^{ox}$ and $E_{1/2_{red}}$ are redox potential of the electron donors and acceptors, respectively. $\Delta E_{0,0}$ is the excita-

$$\Delta G(\text{kcal mol}^{-1}) = 23.06(E_{1/2}^{ox} - E_{1/2}^{red} + C) - \Delta E_{0,0} \quad (1)$$

(1 cal = 4.184 J)

tion energy of **1**, and C represents the Coulomb term. We assume that the Coulomb term is too small to influence the present reactions. The reported or measured values of $E_{1/2}^{ox}$,[7] $E_{1/2}^{red}$,[25,26] and $\Delta E_{0,0}$[16b,27] were used for calculating the values of ΔG (see Table 2). The calculated values of ΔG were all negative, indicating that the electron transfer was possible.

Direct unambiguous evidences for electron-transfer

processes were obtained by CIDNP method. It is noteworthy that with some exceptions polarizations in the forward reaction path, but not in the reverse one, were observed. That is, polarizations due to both allyl quinone **5** and dimerization product of allyl radical **12a** were observed simultaneously in the reactions of **1c—e** with **2a**, whereas in many other photoinduced electron-transfer processes such as the reactions between quinones and 1,1-diarylethylenes[25] polarizations due to starting reactants based on the back electron transfer used to be observed. On the contrary, in the reactions of quinones **1f** or **1g**, only polarizations due to **12a** were observed, and in addition, no polarizations were observed in the reactions of quinones **1b** or **1h**. These quinones, i.e., **1b**, **1f—h**, have relatively low reduction potential. Therefore, an appreciable amount of polarizations would not be observed, because of the insufficient electron transfer in an unit time. This correlation between CIDNP polarizations and reduction potentials of quinones is another support of the electron-transfer processes in this system. Result of CIDNP in the reaction of **1a** with **2a** is interesting, polarizations of unstable adduct are quite strong and similar to those due to allyl quinones, but the adduct could not be isolated.[29]

In the reaction of **1d** with **2b**, polarizations due to prenyl quinone and possibly dimerization product of prenyl radical were observed similar to the reaction of **1d** with **2a**, but in the reaction of **1d** with **2c** only corresponding polarizations due to adduct **10c** were observed. But trace amount of 1,2-diphenylethane, dimerization product of benzyl radical, (GLC<1%) was detected in the photoproduct. Thus, the photochemical reactions of quinones with benzyltrialkylstannane as well as allyltrialkylstannane could proceed by electron-transfer mechanism.

On the basis of these findings, we propose an electron-transfer mechanism[30] shown in Scheme 4. This is analogous to the well-established mechanism for the iminium salt-allylsilane photochemical reaction.[6] Because of the strong oxidizing power of quinones and lower oxidation potential of allyl or benzylstannanes as compared to allylsilane, electron transfer easily occurs from tin reagent to excited triplet quinone,[31] producing the ion radical pair ($1^{\cdot-}$, $2^{\cdot+}$), but in nonpolar solvent the corresponding intermediate may be an exciplex.[32] Owing to the instability of $2^{\cdot+}$,[33] allyl or benzyl radical may cleave from the tin cation radical, forming triplet ion radical pair ($1^{\cdot-}$, R·, $SnBu_3^+$)^T subsequently. Attack of allyl or benzyl radical toward quinone anion radical $1^{\cdot-}$ followed by bonding with tin cation could give the corresponding intermediates, which lead to formation of the adducts **3—7**, **9—11** (Scheme 5). Quinone anion radical and allyl radical escaped from the solvent cage would give reduction product, hydroquinone **8**,[34] and the dimerization product **12** of allyl or benzyl radical.[35]

In the reactions of **1** with **2a**, conversion of reactions decreased as decrease of the reduction potential of quinones, suggesting the electron-transfer processes in the reactions. There is a tendency that allylations occur at almost all positions of quinones,[36] because spin densities of quinone anion radical are rather similar at all positions.[37,38] It is noteworthy, however, that allyl quinols **7g** and **7h** were formed regioselectively. Probably both steric hindrance of alkyl tin moiety against methyl group in **1g** and coordination of tin to the methoxyl group in **1h** affect the regioselective formation of **7g** and **7h**. In the reaction of **1d** with **2b**, it gave α adducts exclusively. The regioselectivity of the addition (α or γ addition) of allylic moiety may be influenced by steric hindrance between methyl groups in prenyl radical and func-

tional group in quinone.

Comparison of Other Related Reactions. In the thermal reactions allylation of quinones requires Lewis acids, e.g., BF_3, as catalyst, but in the photochemical reactions none of Lewis acids, of course, is required except with electronic activation of quinones. As the result of the mechanistic study of the thermal reaction between quinone and allyltin reagent in the presence of a Lewis acid, it was established that allylation of quinones proceeds via 1,2-addition followed by allyl rearrangement[15] (Scheme 6). Allyl quinol **7** obtained in the photoreaction of quinones with allylstannane is fairly stable once purified but gradually rearranges to give allyl quinone **5**. In fact, photoproduct **7d** could be transformed to **5d** in refluxing benzene for 2 days (75%), as reported previously.[15] On the contrary, **7d** underwent no photochemical reaction for 4 h, indicating that the same mechanism for the thermal allylation does not occur in the photoreaction.

Fujita et al.[18] reported that in the photochemical reactions of quinones with allylsilane **13**, [2π+2π] cyclobutane adducts were obtained as sole photoproduct (Scheme 7). To compare the difference in their reactivity between allylsilane and allylstannane, photo-CIDNP examination of quinone–allylsilane systems was carried out, but no polarizations were observed in the photochemical reactions of **1f** with **13** and even in the reaction of **1d** with **13**. This phenomena suggests that efficient electron transfer from **13** to quinones does not occur. Equation 1 allows us to estimate ΔG for photoinduced electron transfer from **13** to quinones **1** (Table 2). Much larger values of ΔG compared with the allylstannane–quinone systems, reflecting the higher oxidation potential of allylsilane, also support the inefficient electron-transfer process in the latter systems. Thus, in the reported photochemical reactions of allylsilane, only [2+2] cyclobutane adduct would be formed, while in those of allylstannane a variety of allylation

products of quinones could be produced via electron transfer including radical processes.

Experimental

General Procedures. All melting points were determined with a Yanagimoto micro melting point apparatus and uncorrected. Mass spectra were taken on a JEOL JMS-DX300 mass spectrometer. The electronic spectra were obtained by Shimadzu UV-200 spectrometer. ^{1}H NMR spectra were taken by using a JEOL JNM-PS-100 spectrometer or JEOL JNM-GX-400 spectrometer and chemical shifts were recorded in parts per million (ppm) on the δ scale from tetramethylsilane as an internal standard, while ^{13}C NMR spectra were taken by using JEOL JNM-GX-400 spectrometer. IR spectra were obtained by using a JASCO IRA-1 spectrometer on KBr pellets or liquid film on NaCl. Gas chromatography analyses were carried out by using JEOL-1100. Fluorescence and phosphorescence spectra were taken by using a Shimadzu RF-502A spectrometer. Elemental analyses were performed at the Micro Analytical Center of Kyoto University. Cyclic voltammetry was performed with a PAR Model 174. The working electrode was platinum wire. A Ag/Ag+ (0.1 M; 1 M=1 mol dm^{-3}) electrode was used as a reference electrode and 0.1 M tetraethylammonium perchlorate as supporting electrolyte.

In general, irradiation of a benzene or an acetonitrile solution (25 ml) containing quinone (1 mmol) and tin reagent (2 mmol) through an aqueous $CuSO_4$ and a Pyrex filter under argon are carried out at room temperature. After irradiation the reaction mixture is concentrated and separated by flash column chromatography on silica gel (Merck kiesel gel 60H), developing with hexane–benzene, benzene subsequently, and chloroform finally. The first band contains allylstannanes **2**, the second one contains allyl ether **3**, the third one contains allyl quinones **5** (**4**, **6**), the fourth one contains quinone **1**, the fifth one contains allyl quinol **7**, and the final one contains hydroquinone **8**.

Starting Materials. Chloranil **1a** benzoquinone **1b**, 2,3-dichloro-1,4-naphthoquinone **1d**, 1,4-naphthoquinone **1f**, and 2-methyl-1,4-naphthoquinone **1g** were commercially available and were purified by column chromatography, recrystallization, and sublimation. 2,3-Dibromo-1,4-naphthoquinone **1c**[39] and 2-bromo-1,4-naphthoquinone **1e**,[40] and 2-methoxy-1,4-naphthoquinone **1h**[41] were synthesized by the previous reported methods. Allyl and benzylstannanes **2a**—**c** were prepared by our previously reported method[42] and allyltrimethylsilane **13** was commercially available. Acetonitrile and benzene were used after distillation. Acetonitrile-d_3 and benzene-d_6 were commercially available and were used without further purification.

Physical Properties of the Products. 4-Allyloxy-2,3,5,6-tetrachlorophenol (**3a**): White plates from hexane–chloroform; mp 86.5—88.5 °C. MS; m/z 286, 288, 290, 292, 294 (M+). Found: C, 37.73; H, 1.99; Cl, 48.98%. Calcd for $C_9H_6O_2Cl_4$: C, 37.54; H, 2.10; Cl, 49.25%. IR (KBr); 3430 (OH) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=4.53 (2H, d, J=6 Hz), 5.3—5.6 (2H, m), 5.9—6.4 (2H, m). Compound **3a** was synthesized independently by the thermal allylation of the corresponding hydroquinone **8a** with K_2CO_3 and allyl bromide and the structure was confirmed.

4-(Allyloxy)phenol (3b): Colorless oil. High-resolution mass spectrum. Found: m/z 150.0685. Calcd for $C_9H_{10}O_2$: M, 150.0680. IR (NaCl); 3360 (OH) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=4.46 (2H, d, J=5 Hz), 5.1—5.5 (2H, m), 5.56 (1H, br-s),

5.8—6.2 (1H, m), 6.72 (4H, s).

4-Allyloxy-1-naphthol (3f): White needles from hexane–chloroform; mp 100—102 °C. MS; *m/z* 200 (M^+). Found: C, 77.94; H, 5.95%. Calcd for $C_{13}H_{12}O_2$: C, 77.98; H, 6.04%. IR (KBr); 3230 (OH) cm^{-1}. ^1H NMR ($CDCl_3$) δ=4.52 (2H, d, *J*=5 Hz), 5.2—5.6 (2H, m), 5.9—6.4 (1H, m), 6.46 (1H, d, *J*=8 Hz), 6.67 (1H, d, *J*=8 Hz), 7.01 (1H, br-s), 7.3—8.3 (4H, m).

2-Allyl-3-bromo-1,4-naphthoquinone (5c): Yellow crystals from hexane–chloroform; mp 46—49 °C. High-resolution mass spectrum. Found: *m/z* 275.9787. Calcd for $C_{13}H_9O_2{}^{79}Br$: M, 275.9786. Found: *m/z* 277.9765. Calcd for $C_{13}H_9O_2{}^{81}Br$: M, 277.9767. IR (KBr); 1665 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=3.66 (2H, d, *J*=6 Hz), 5.1—5.5 (2H, m), 5.7—6.2 (1H, m), 7.84 (2H, m), 8.20 (2H, m).

2-Allyl-3-chloro-1,4-naphthoquinone (5d): Yellow needles from hexane–chloroform; mp 54—57 °C. High-resolution mass spectrum. Found: *m/z* 232.0293. Calcd for $C_{13}H_9O_2{}^{35}Cl$: M, 232.0291. Found: *m/z* 234.0256. Calcd for $C_{13}H_9O_2{}^{37}Cl$: M, 234.0261. IR (KBr); 1675 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=3.62 (2H, d, *J*=6 Hz), 5.0—5.5 (2H, m), 5.7—6.3 (1H, m), 7.87 (2H, m), 8.23 (2H, m).

2-Allyl-3-methyl-1,4-naphthoquinone (5g): Yellow oil. High-resolution mass spectrum. Found: *m/z* 212.0838. Calcd for $C_{14}H_{12}O_2$: M, 212.0837. IR (NaCl); 1660 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.17 (3H, s), 3.40 (2H, d, *J*=8 Hz), 5.0—5.1 (2H, m), 6.7—6.9 (1H, m), 7.6—7.8 (2H, m), 8.0—8.1 (2H, m).

2-Allyl-3-methoxy-1,4-naphthoquinone (5h): Yellow oil. High-resolution mass spectrum. Found: *m/z* 228.0784. Calcd for $C_{14}H_{12}O_3$: M, 228.0783. IR (NaCl); 1660 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=3.33 (2H, d, *J*=7 Hz), 4.11 (3H, s), 4.9—5.3 (2H, m), 5.6—6.1 (1H, m), 7.5—7.7 (2H, m), 7.9—8.1 (2H, m).

2-Allyl-2,3-dihydro-2-methyl-1,4-naphthalenedione (6g): Yellow oil. High-resolution mass spectrum. Found: *m/z* 214.0989. Calcd for $C_{14}H_{14}O_2$: M, 214.0994. IR (NaCl); 1680 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.30 (3H, s), 2.29 (1H, dd, *J*=7, 14 Hz), 2.61 (1H, dd, *J*=7, 14 Hz), 2.85 (1H, d, *J*=17 Hz), 3.10 (1H, d, *J*=17 Hz), 4.9—5.3 (2H, m), 5.6—6.1 (1H, m), 7.7—7.9 (2H, m), 8.0—8.2 (2H, m). ^{13}C NMR ($CDCl_3$) δ=23.5, 42.6, 48.4, 49.2, 119.2, 125.8, 127.2, 132.4, 133.5, 133.7, 134.1, 134.6, 196.0, 200.1.

4-Allyl-2,3,5,6-tetrachloro-4-hydroxy-2,5-cyclohexadien-1-one (7a): White needles from hexane–chloroform; mp 88—90.5 °C. MS; *m/z* 286, 288, 290, 292, 294 (M^+). Found: C, 37.56; H, 2.11; Cl, 49.03%. Calcd for $C_9H_6O_2Cl_4$: C, 37.54; H, 2.10; Cl, 49.25%. IR (KBr); 3400 (OH), 1665 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.97 (2H, d, *J*=6 Hz), 4.41 (1H, br-s), 5.0—5.5 (3H, m).

4-Allyl-2,3-dibromo-4-hydroxy-1(4*H*)-naphthalenone (7c): White crystals from hexane–chloroform; mp 88—91 °C. MS; *m/z* 356, 358, 360 (M^+). IR (KBr); 3360 (OH), 1650 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.70 (1H, dd, *J*=6, 13 Hz), 3.02 (1H, dd, *J*=6, 13 Hz), 3.60 (1H, br-s), 4.7—5.4 (3H, m), 7.4—8.2 (4H, m). The hydroxyl group of compound **7c** was acetylated by acetic anhydride and *N,N*-dimethylaniline and the structure was confirmed.

4-Acetoxy-4-allyl-2,3-dibromo-1(4*H*)-naphthalenone (14c): White crystals from hexane–chloroform; mp 90—92 °C. MS; *m/z* 398, 400, 402 (M^+). Found: C, 45.24; H, 3.10; Br, 39.80%. Calcd for $C_{15}H_{12}O_3Br_2$: C, 45.03; H, 3.02; Br, 39.95%. IR (KBr); 1730 (C=O), 1640 (C=O) cm^{-1}. ^1H NMR (CCl_4) δ=2.10 (3H, s), 2.68 (1H, dd, *J*=6, 13 Hz), 3.05 (1H, dd, *J*=6, 13 Hz), 4.8—5.2 (3H, m), 7.3—7.7 (3H, m), 8.18 (1H, m).

4-Allyl-2,3-dichloro-4-hydroxy-1(4*H*)-naphthalenone (7d): White crystals from hexane–chloroform; mp 86—88 °C. MS; *m/z* 269, 271, 273 ($M+1^+$). Found: C, 58.02; H, 3.66; Cl, 26.14%. Calcd for $C_{13}H_{10}O_2Cl_2$: C, 58.02; H, 3.75; Cl, 26.35%. IR (KBr); 3440 (OH), 1640 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.78 (1H, dd, *J*=6, 14 Hz), 3.04 (1H, dd, *J*=6, 14 Hz), 3.48 (1H, br-s), 4.7—5.4 (3H, m), 7.4—8.2 (4H, m).

4-Allyl-4-hydroxy-1(4*H*)-naphthalenone (7f): Pale green oil. High-resolution mass spectrum. Found: *m/z* 200.0832. Calcd for $C_{13}H_{12}O_2$: M, 200.0837. IR (NaCl); 3400 (OH), 1660 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.61 (2H, d, *J*=8 Hz), 4.25 (1H, br-s), 4.7—5.6 (3H, m), 6.21 (1H, d, *J*=10 Hz), 6.91 (1H, d, *J*=10 Hz), 7.2—8.3 (4H, m).

4-Allyl-4-hydroxy-2-methyl-1(4*H*)-naphthalenone (7g): Colorless oil. High-resolution mass spectrum. Found: *m/z* 214.0990. Calcd for $C_{14}H_{14}O_2$: M, 214.0994. IR (NaCl); 3440 (OH), 1680 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.92 (3H, s), 2.62 (2H, m), 2.82 (1H, br-s), 4.94 (2H, m), 5.37 (1H, m), 6.70 (1H, s), 7.3—8.0 (4H, m). ^{13}C NMR ($CDCl_3$) δ=15.7, 47.9, 70.2, 119.6, 126.0, 126.3, 127.8, 129.9 (C_2), 131.3, 132.6, 134.6, 146.0, 147.1 (C_3), 185.0.

4-Allyl-4-hydroxy-3-methoxy-1(4*H*)-naphthalenone (7h): ^{13}C NMR ($CDCl_3$) δ=47.8 (t), 55.9 (q), 72.6 (s), 101.8 (d), 119.1 (t), 125.3 (d), 125.5 (d), 127.7 (d), 129.8 (s), 130.6 (d), 132.5 (d), 143.0 (s), 174.4 (s), 185.0 (s).

2,3-Dichloro-4-(3-methyl-2-butenyloxy)-1-naphthol (9b): Colorless oil. MS; *m/z* 296, 298, 300 (M^+). IR (NaCl); 3400 (OH , 1660 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.70 (3H, s), 1.80 (3H, s), 5.60 (1H, m), 5.86 (1H, s), 7.3—7.6 (2H, m), 7.9—8.2 (2H, m). The hydroxyl group of compound **9b** was acetylated as in the case of **7c** and the structure was confirmed.

1-Acetoxy-2,3-dichloro-4-(3-methyl-2-butenyloxy)naphthalene (15b): Yellow crystals from hexane–chloroform; mp 70—72 °C. MS; *m/z* 338, 340, 342 (M^+). Found: C, 59.90; H, 4.66; Cl, 20.63%. Calcd for $C_{17}H_{16}O_3Cl_2$: C, 60.19; H, 4.75; Cl, 20.90%. IR (KBr); 1740 (C=O) cm^{-1}. ^1H NMR (CCl_4) δ=1.70 (3H, s), 1.80 (3H, s), 2.45 (3H, s), 4.64 (2H, d, *J*=7 Hz), 5.67 (1H, t, *J*=7 Hz), 7.4—7.8 (3H, m), 8.0—8.2 (1H, m).

4-Benzyloxy-2,3-dichloro-1-naphthol (9c): White crystals from hexane–chloroform; mp 142—144 °C. MS; *m/z* 318, 320, 322 (M^+). Found: C, 63.97; H, 3.79; Cl, 22.21%. Calcd for $C_{17}H_{12}O_2Cl_2$: C, 64.26; H, 4.02; Cl, 22.01%. IR (KBr); 3370 (OH) cm^{-1}. ^1H NMR ($CDCl_3$) δ=5.15 (2H, s), 6.15 (1H, br-s), 7.3—8.4 (9H, m).

2-Chloro-3-(3-methyl-2-butenyl)-1,4-naphthoquinone (10b): Yellow plates from hexane–chloroform; mp 81—83 °C. MS; *m/z* 260, 262 (M^+). Found: C, 68.98; H, 4.93; Cl, 13.78%. Calcd for $C_{15}H_{13}O_2Cl$: C, 69.10; H, 5.03; Cl, 13.60%. IR (KBr); 1660 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.67 (3H, s), 1.80 (3H, s), 3.49 (2H, d, *J*=8 Hz), 5.09 (1H, m), 7.5—7.8 (2H, m), 7.9—8.2 (2H, m).

2-Benzyloxy-3-chloro-1,4-naphthoquinone (10c): Yellow crystals from hexane–chloroform; mp 120—122 °C. High-resolution mass spectrum. Found: *m/z* 282.0442. Calcd for $C_{17}H_{11}O_2{}^{35}Cl$: M, 282.0447. Found: *m/z* 284.0414. Calcd for $C_{17}H_{11}O_2{}^{37}Cl$: M, 284.0417. IR (KBr); 1670 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=4.15 (2H, s), 6.9—8.3 (9H, m).

2,3-Dichloro-4-hydroxy-4-(3-methyl-2-butenyl)-1(4*H*)-naph-

thalenone (11b): Colorless oil. MS; *m/z* 296, 298, 300 (M^+). IR (NaCl); 3420 (OH), 1650 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=1.21 (3H, s), 1.43 (3H, s), 2.60 (1H, dd, *J*=7, 12 Hz), 2.93 (1H, dd, *J*=7, 12 Hz), 3.87 (1H, br-s), 4.32 (1H, m), 7.2—8.1 (4H, m). The hydroxyl group of compound **11b** was acetylated as in the case of **7c** and the structure was confirmed.

4-Acetoxy-2,3-dichloro-4-(3-methyl-2-butenyl)-1(4*H*)-naphthalenone (16b): Colorless oil. MS; *m/z* 338, 340, 342 (M^+). Found: C, 60.06; H, 5.04; Cl, 20.61%. Calcd for $C_{17}H_{16}O_3Cl_2$: C, 60.19; H, 4.75; Cl, 20.90%. IR (NaCl); 1730 (C=O), 1650 (C=O) cm^{-1}. ^1H NMR (CCl_4) δ=1.23 (3H, s), 1.49 (3H, s), 2.08 (3H, s), 2.65 (1H, dd, *J*=14, 8 Hz), 2.99 (1H, dd, *J*=14, 8 Hz), 4.33 (1H, t, *J*=8 Hz), 7.3—7.7 (3H, m), 8.13 (1H, d, *J*=6 Hz).

4-Benzyl-2,3-dichloro-4-hydroxy-1(4*H*)-naphthalenone (11c): Colorless oil. MS; *m/z* 318, 320, 322 (M^+). IR (NaCl); 3420 (OH), 1670 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$) δ=3.12 (1H, d, *J*=13 Hz), 3.43 (1H, d, *J*=13 Hz), 3.96 (1H, br-s), 6.3—6.5 (2H, m), 6.9—8.0 (7H, m). The hydroxyl group of compound **11c** was acetylated as in the case of **7c** and the structure was confirmed.

4-Acetoxy-4-benzyl-2,3-dichloro-1(4*H*)-naphthalenone (16c): Colorless oil. MS; *m/z* 360, 362, 364 (M^+). Found: C, 63.17; H, 3.61; Cl, 19.55%. Calcd for $C_{19}H_{14}O_3Cl_2$: C, 63.18; H, 3.91; Cl, 19.63%. IR (NaCl); 1740 (C=O), 1650 (C=O) cm^{-1}. ^1H NMR (CCl_4) δ=2.11 (3H, s), 3.22 (1H, d, *J*=12 Hz), 3.52 (1H, d, *J*=12 Hz), 6.3—6.5 (2H, m), 6.8—7.7 (6H, m), 7.91 (1H, d, *J*=6 Hz).

CIDNP Examinations. A typical CIDNP examination of the photochemical reaction was undertaken as follows: suitable amounts ($\approx 10^{-2}$ mol dm^{-3}) of quinone **1** and tin reagent **2** or silane reagent **13** were dissolved in benzene-d_6 or in acetonitrile-d_3 in a Pyrex NMR sample tube. The sample purged with argon for 2 min was irradiated at room temperature by a high-pressure Hg lamp through a glass filter (Toshiba UV-35) and the ^1H NMR signals were observed before, during, and after irradiation.

19) Regioselective formation of allyl quinol **7h** was also observed in the thermal reaction of allylstannane in the presence of BF_3,[15] while reverse regioselective formation for **7g** was observed in the thermal reaction of allylsilane in the presence of $TiCl_4$.[14]

20) Similar exclusive formation of α adducts in the thermal reaction of **1h** with **2b** in the presence of BF_3 was observed.[15]

21) Electron transfer from **2a** to triplet quinone **1d** generates an ion pair in the triplet state (μ>0). *g*-Factor of allyl radical (*g*=2.0026) is lower than that of the quinone anion radical ($g \approx 2.004$-5; Δg<0). The products are generated by recombination of the radical ion (ε>0) or escape (ε<0). The sign of hyperfine coupling constant are calculated by McLachlan-Hückel MO and McConnell relationship. For example, Γne(-$\underline{CH_2}$-CH=CH_2)=$\mu \cdot \Delta g \cdot \varepsilon \cdot a$=+·−·+·−=+ for **5d** and Γne(-$\underline{CH_2}$-CH=CH_2)=+·−·−·−=− for **12a**. See, R. Kaptein, *J. Chem. Soc., Chem. Commun.*, **1971**, 732.

22) Γne(-$\underline{CH_2}$-CH=CMe_2)=+·−·+·−=+ for **10b**.

23) Γne(-$\underline{CH_2}$-Ph)=+·−·+·−=+ *for* **10c**.

29) Seemingly, the adduct could have structure (shown in Fig. 4), which would convert to give **3a** or **7a**.

30) Similar electron-transfer mechanism was proposed in the photochemical reactions between quinones and organotin compounds by ESR and CIDEP methods. S. Emori, D. Weri, and J. K. S. Wan, *Chem. Phys. Lett.*, **84**, 512 (1981); K. S. Chen, J. K. S. Wan, and J. K. Kochi, *J. Phys. Chem.*, **85**, 1726

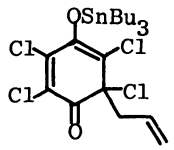

Fig. 4.

(1981).

31) It is said that $S_1 \rightarrow T_1$ process of quinones occurs with high efficiency (0.8—1.0),[16b] and no fluorescence spectra of quinones **1** were observed. Thus, this reaction proceeds via triplet state.

32) A mixture of **1d** and **2a** showed no charge-transfer (CT) band in the ground state. Accordingly, these reactions could not proceed via CT complex.

33) J. K. Kochi, "Organometallic Mechanisms and Catalysis," Academic Press, New York (1978); B. W. Walther, F. Williams, W. Lau, and J. K. Kochi, *Organometallics*, **2**, 688 (1983).

34) Quinone anion radical escaped from the solvent cage might be coordinated by tin cation.[30]

35) Eaton[8] and Mizuno[11] were reported that 1,2-diphenylethane and 1,5-hexadiene as by-product were produced from the corresponding tin reagents.

36) Productions of allyl ethers **3** which were not obtained in the thermal reactions (Scheme 6) support the involvement of radical processes.

Synthesis of Pyranoisoflavones from Pyronochalcones: Synthesis of Elongatin and Its Angular Isomer

Masao TSUKAYAMA,* Yasuhiko KAWAMURA, Hiroto TAMAKI, Tomoya KUBO, and Tokunaru HORIE
Department of Chemical Science and Technology, Faculty of Engineering,
The University of Tokushima, Minamijosanjima-cho, Tokushima 770
(Received August 6, 1988)

Elongatin (4′,5-dihydroxy-2′,5′-dimethoxy-2″,2″-dimethylpyrano[5″,6″-*g*]isoflavone) was synthesized by an oxidative rearrangement of the corresponding pyronochalcone [6-(1-oxo-3-phenyl-2-propenyl)-4-chromanone] with thallium(III) nitrate and a regioselective reduction of 7-(4-benzoyloxy-2,5-dimethoxyphenyl)-2,3-dihydro-2,2-dimethyl-5-tosyloxy-4*H*,6*H*-benzo[1,2-*b*:5,4-*b*′]dipyran-4,6-dione with sodium borohydride–palladium chloride, followed by dehydration of the resultant alcohol and hydrolysis. Its angular isomer (4′,5-dihydroxy-2′,5′-dimethoxy-2″,2″-dimethylpyrano[6″,5″-*h*]isoflavone) was also synthesized from the corresponding pyronochalcone in a similar manner.

A lot of natural isoflavones were synthesized by oxidative rearrangements of chalcones with thallium(III) nitrate (TTN).[1,2] Pyranoisoflavones (jamaicin and leiocarpin) containing an acid-labile group, such as a dimethylchromene ring, were directly synthesized from the corresponding pyranochalcones by this method.[3] We have also reported that pyranoisoflavones (elongatin and toxicarol isoflavone) of linear and angular phloroglucinol-types can be prepared by an oxidative rearrangement of the corresponding dihydropyranochalcones with TTN, followed by a dehydrogenation of the resultant dihydropyranoisoflavones.[4] Thus, the oxidative rearrangement of 2′-hydroxychalcones with TTN seems at present to be a more useful method for synthesizing natural linear and angular pyranoisoflavones (7-phenyl-2*H*,6*H*-benzo[1,2-*b*:5,4-*b*′]dipyran-6-ones and -4*H*,8*H*-benzo[1,2-*b*:3,4-*b*′]dipyran-4-ones). However, this method has not been applied hitherto to the synthesis of linear and angular pyronoisoflavones (2,3-dihydro-7-phenyl-4*H*,6*H*-benzo[1,2-*b*:5,4-*b*′]dipyran-4,6-diones and 8,9-dihydro-3-phenyl-4*H*,10*H*-benzo[1,2-*b*:3,4-*b*′]dipyran-4,10-diones) from the corresponding pyronochalcones [6-(1-oxo-3-phenyl-2-propenyl)-4-chromanones].

It is of much interest as a new pathway to extend this methodology to the synthesis of pyranoisoflavones from pyronochalcones with TTN; the subsequent regioselective reduction of the pyronoisoflavones, followed by dehydration of the resultant alcohols leads to the corresponding pyranoisoflavones. We report here on the synthesis of a linear pyranoisoflavone, elongatin (4′,5-dihydroxy-2′,5′-dimethoxy-2″,2″-dimethylpyrano[5″,6″-*g*]isoflavone)[5] (**1**) and its angular isomer (4′,5-dihydroxy-2′,5′-dimethoxy-2″,2″-dimethylpyrano[6″,5″-*h*]isoflavone)[4] (**2**)—systematic name 5-hydroxy-7-(4-hydroxy-2,5-dimethoxyphenyl)-2,2-dimethyl-2*H*,6*H*-benzo[1,2-*b*:5,4-*b*′]dipyran-6-one and 5-hydroxy-3-(4-hydroxy-2,5-dimethoxyphenyl)-8,8-dimethyl-4*H*,8*H*-benzo[1,2-*b*:3,4-*b*′]dipyran-4-one—by this method.

The condensation of 2,4,6-trihydroxyacetophenone with 3-methyl-2-butenoic acid in the presence of polyphosphoric acid (PPA) in dioxane afforded 8-acetylchromanone[6] (**3**) as a major product and 6-

acetylchromanone (**4**) as a minor product. It was first found that chromanone (**3**) was easily isomerized to chromanone (**4**) with potassium carbonate in acetone; this method offers an efficient synthesis of the 6-acetylchromanone (**4**). Tosylation of **4**, and a successive methylation of the tosylate (**5**), followed by hydrolysis of the resultant methyl ether (**6**) afforded 7-hydroxy-5-methoxychromanone (**7**). Condensation of **7** with 4-benzyloxy-2,5-dimethoxybenzaldehyde[4] (**8**) in the presence of piperidine and pyridine in ethanol afforded chalcone (**9**), which was subsequently converted into acetate (**10**). The oxidative rearrangement of **10** with TTN in methanol, followed by cyclization of the resultant compound with diluted hydrochloric acid under reflux afforded a linear pyronoisoflavone (**11**) and a small amount of aurone (**12**). The ^1H NMR spectrum of **11** showed the presence of C_8-proton as a singlet at δ 7.67. A signal at δ 6.45 in the ^1H NMR spectrum of **12** is due to the benzylidene proton and is characteristic of an aurone system. Hydrogenolysis of **11** with palladium on charcoal afforded a mixture of the corresponding 4′-hydroxyisoflavone and 4′-hydroxyisoflavanone. However, the 5-hydroxypyronoisoflavone (**13**), which was prepared by demethylation of **11** with aluminum bromide in acetonitrile, was hydrogenolyzed with palladium on charcoal to give 4′,5-dihydroxypyronoisoflavone (**14**) in good yield. Compound **14** was easily converted into the ditosylate (**15**) with *p*-toluenesulfonyl chloride in acetone. We have reported that the carbonyl group in the chromanone ring of acetylchromanones is selectively reduced with sodium borohydride–palladium chloride to give the alcohols and that the subsequent dehydration affords the corresponding chromenes.[6] This method was applied to the synthesis of pyranoisoflavones from pyronoisoflavones. Compound **15** was reduced with sodium borohydride in the presence of palladium chloride in tetrahydrofuran–water to give the desired monoalcohol (**16**) and dialcohol (**17**). The monoalcohol (**16**) was easily dehydrated in the presence of *p*-toluenesulfonic acid to give linear pyranoisoflavone (**18**). Hydrolysis of **18** by a potassium hydroxide solution in boiling ethanol afforded linear pyranoisoflavone (elongatin) (**1**) and its isomeric angular pyranoisoflavone (**2**). This result shows that the tosyl group is not suitable for the protection of the hydroxyl group, since the hydrolysis of **18** is accompanied by a ring isomerization to its angular isomer (**2**). Therefore, a benzoyl group was tested for the protection of the hydroxyl group. Benzoylation of **14** with benzoyl chloride in acetone easily afforded 4′-benzoate (**19**), but did not yield 4′,5-dibenzoate. The 5-tosylate (**20**) of a 5-hydroxy compound (**19**) was selectively reduced with sodium borohydride in the presence of palladium chloride to give monoalcohol (**21**). Dehydration of compound **21** led to pyranoisoflavone (**22**), which was easily hydrolyzed with a potassium hydroxide solution without ring isomerization to give the desired linear pyranoisoflavone (elongatin) (**1**) in good yield. The physical properties of **1**, the diacetate (**23**), and the dimethyl ether (**24**) were identical with those of their authentic samples, prepared by a method described before,[4] respectively.

The partial benzylation of 2,4,6-trihydroxyacetophenone with benzyl chloride in the presence of potassium carbonate in hexamethylphosphoric triamide (HMPA) afforded 2,4-bis(benzyloxy)-6-hydroxyacetophenone (**25**) in good yield. This benzylation is superior to that in acetone[7] or *N*,*N*-dimethylformamide[8] since no *C*-benzylated compound is formed. Debenzylation of the methyl ether (**26**) of the 6-hydroxyacetophenone (**25**) with palladium on charcoal afforded 2,4-dihydroxy-6-methoxyacetophenone[9] (**27**). Condensation of **27** with 3-methyl-2-butenoyl chloride by a Friedel–Crafts reaction afforded 1-(3-acetyl-2,6-dihydroxy-4-methoxyphenyl)-3-methyl-2-buten-1-one (**28**) in good yield. The structure of **28** was determined by nuclear Overhauser effect (NOE) experiments at the C_5-proton: The integrated intensity of the signal at δ 5.85 for **28** increased up to 25% when the methoxyl

37

protons were saturated by double irradiation. The diketone (**28**) was easily converted into the 5-hydroxy-7-methoxychromanone (**29**) with a potassium hydroxide solution in methanol. Condensation of **29** with **8** afforded the chalcone (**30**), which was converted into acetate (**31**). An oxidative rearrangement of **31** with TTN under similar conditions to that of **11** afforded angular pyronoisoflavone (**32**), while the corresponding aurone was not obtained in this case. Demethylation of **32** and a subsequent debenzylation of the resultant 5-hydroxypyronoisoflavone (**33**) afforded 4′,5-dihydroxypyronoisoflavone (**34**). The partial benzoylation of **34** and tosylation of the resultant 4′-benzoate (**35**), followed by a reduction of the 5-tosylate (**36**) with sodium borohydride–palladium chloride, yielded quantitatively monoalcohol (**37**). Dehydration of **37** led to the pyranoisoflavone (**38**), which was easily hydrolyzed to give the desired angular pyranoisoflavone (**2**) in good yield. The physical properties of **2**, the diacetate (**39**), the 4′-methyl ether (toxicarol isoflavone) (**40**), and the dimethyl ether (**41**) were identical with those of their authentic samples prepared by the method described before,[4] respectively.

From the results described above, the selective reduction of the carbonyl group in the pyronoisoflavones and the subsequent dehydration are easier than the dehydrogenation of dihydropyranoisoflavones,[4] and therefore, this method is a facile synthesis of pyranoisoflavones.

Experimental

All the melting points are uncorrected. The UV spectra were taken in ethanol on a Hitachi 124 spectrophotometer. The ^1H NMR spectra were measured with a Hitachi R-20 spectrometer (60 MHz), using tetramethylsilane as an internal standard (δ, ppm). Column chromatography and thin-layer chromatography were carried out on Kieselgel 60 (70—230 mesh) and with Kieselgel 60 F-254 (Merck).

8-Acetyl-5,7-dihydroxy-2,2-dimethyl-4-chromanone (3) and 6-Acetyl-5,7-dihydroxy-2,2-dimethyl-4-chromanone (4). A mixture of 2,4,6-trihydroxyacetophenone (35.5 g) and 3-methyl-2-butenoic acid (28.7 g) in anhydrous dioxane (127 ml) was stirred in the presence of PPA (100 g) at 60 °C for 3 h. The reaction mixture was poured into ice-cold water and neutralized with a saturated K_2CO_3 solution to give precipitates. The resulting precipitates were recrystallized from MeOH–Me_2CO to give **3** (41 g, 77%) as colorless needles (R_f=0.38; hexane–EtOAc (4:1) on a silica-gel TLC plate): mp 158—160 °C; ^1H NMR ($CDCl_3$) δ=1.58 (6H, s, CH_3×2), 2.64 (3H, s, $COCH_3$), 2.79 (2H, s, $COCH_2$), 5.91 (1H, s, C_8–H), 12.65 and 14.30 (each 1H, s, OH).

Found: C, 62.26; H, 5.79%. Calcd for $C_{13}H_{14}O_5$: C, 62.39;

H, 5.64%.

The mother liquor was chromatographed over a silica-gel column with $CHCl_3$ to give **4** (2.11 g, 4%) as colorless needles (R_f=0.62): mp 148—150 °C; ^{1}H NMR ($CDCl_3$) δ=1.43 (6H, s, CH_3×2), 2.67 (3H, s, $COCH_3$), 2.70 (2H, s, $COCH_2$), 5.83 (1H, s, C_8–H), 14.10 and 14.40 (each 1H, s, OH).

Found: C, 62.41; H, 5.66%. Calcd for $C_{13}H_{14}O_5$: C, 62.39; H, 5.64%.

6-Acetyl-5,7-dihydroxy-2,2-dimethyl-4-chromanone (4). A mixture (14.9 g) of **3** and **4** was refluxed with stirring in the presence of K_2CO_3 (70 g) in anhydrous Me_2CO (500 ml) for 50 h. After removal of K_2CO_3 and the solvent, the residue was dissolved in EtOAc, washed with dil. HCl and water, and dried (Na_2SO_4). The resulting compound was recrystallized from MeOH–$CHCl_3$ to give **4** (13 g, 87%) as colorless needles; mp 148—150 °C.

6-Acetyl-5-hydroxy-2,2-dimethyl-7-tosyloxy-4-chromanone (5). A mixture of **4** (16.5 g), TsCl (14.1 g), and K_2CO_3 (46 g) in Me_2CO (450 ml) was refluxed with stirring for 1.5 h. After removal of K_2CO_3 and the solvent, the residue was dissolved in EtOAc, washed with dil. HCl and water, and dried (Na_2SO_4). The resulting compound was chromatographed over a silica-gel flash column with hexane–EtOAc (3:2) to give **5** (17 g, 64%) as colorless prisms: mp 105—106 °C (MeOH); ^{1}H NMR ($CDCl_3$) δ=1.46 (6H, s, CH_3×2), 2.38 (3H, s, $C_6H_4CH_3$), 2.45 (3H, s, $COCH_3$), 2.74 (2H, s, $COCH_2$), 6.38 (1H, s, C_8–H), 7.30 and 7.77 (each 2H, d, J=8.8 Hz, $C_6H_4CH_3$), 12.46 (1H, s, OH).

Found: C, 59.50; H, 5.00%. Calcd for $C_{20}H_{20}O_7S$: C, 59.39; H, 4.99%.

6-Acetyl-5-methoxy-2,2-dimethyl-7-tosyloxy-4-chromanone (6). A mixture of **5** (19.2 g), $(MeO)_2SO_2$ (11.4 ml), and K_2CO_3 (34 g) in Me_2CO (450 ml) was refluxed with stirring for 3.5 h. The reaction mixture was treated in the usual way, and the resulting compound was recrystallized from MeOH to give **6** (17.6 g, 88%) as colorless prisms: mp 110—111 °C; ^{1}H NMR ($CDCl_3$) δ=1.46 (6H, s, CH_3×2), 2.36 (3H, s, $C_6H_4CH_3$), 2.47 (3H, s, $COCH_3$), 2.69 (2H, s, $COCH_2$), 3.79 (3H, s, OCH_3), 6.72 (1H, s, C_8–H), 7.36 and 7.78 (each 2H, d, J=8.8 Hz, $C_6H_4CH_3$).

Found: C, 60.10; H, 5.26%. Calcd for $C_{21}H_{22}O_7S$: C, 60.28; H, 5.30%.

6-Acetyl-7-hydroxy-5-methoxy-2,2-dimethyl-4-chromanone (7). Compound **6** (11.0 g) was refluxed in the presence of K_2CO_3 (25 g) in MeOH (200 ml) with stirring for 1.5 h. The reaction mixture was poured into ice-cold water and acidified with HCl, and extracted with EtOAc, and dried (Na_2SO_4). The resulting compound was recrystallized from MeOH to give **7** (6.6 g, 95%) as colorless needles: mp 83—85 °C; ^{1}H NMR ($CDCl_3$) δ=1.46 (6H, s, CH_3×2), 2.66 (2H, s, $COCH_2$), 2.69 (3H, s, $COCH_3$), 3.92 (3H, s, OCH_3), 6.18 (1H, s, C_8–H), 13.70 (1H, s, OH).

Found: C, 63.61; H, 6.14%. Calcd for $C_{14}H_{16}O_5$: C, 63.63; H, 6.10%.

7-Hydroxy-5-methoxy-2,2-dimethyl-6-[1-oxo-3-(4-benzyloxy-2,5-dimethoxyphenyl)-2-propenyl]-4-chromanone (9). A mixture of **7** (2.64 g) and 4-benzyloxy-2,5-dimethoxybenzaldehyde[4] (**8**) (2.72 g) was refluxed with stirring in the presence of piperidine (2.8 ml) and pyridine (3.2 ml) in EtOH (150 ml) for 14 h. The reaction mixture was poured into ice-cold water and acidified with HCl. The resulting compound was recrystallized from MeOH to give **9** (1.62 g, 60%) as yellow needles: mp 167—169 °C; ^{1}H NMR ($CDCl_3$) δ=1.45 (6H, s, CH_3×2), 2.66 (2H, s, $COCH_2$), 3.78, 3.83, and 3.86 (each 3H, s, OCH_3), 5.19 (2H, s, $C_6H_5CH_2$), 6.22 (1H, s, C_8–H), 6.50 and 7.12 (each 1H, s, Arom-H), 7.36 (5H, s, C_6H_5), 7.77 and 8.20 (each 1H, d, J=16 Hz, CH=), 13.88 (1H, s, OH).

Found: C, 69.19; H, 5.74%. Calcd for $C_{30}H_{30}O_8$: C, 69.48; H, 5.83%.

Acetate 10. Compound **9** was converted into the acetate **10** as yellow needles by an acetic anhydride–sodium acetate method: mp 145—147 °C (MeOH); ^{1}H NMR ($CDCl_3$) δ=1.46 (6H, s, CH_3×2), 2.14 (3H, s, $COCH_3$), 2.68 (2H, s, $COCH_2$), 3.68, 3.79, and 3.82 (each 3H, s, OCH_3), 5.16 (2H, s, $C_6H_5CH_2$), 6.44 (1H, s, C_8–H), 6.53 and 7.00 (each 1H, s, Arom-H), 6.90 and 7.69 (each 1H, d, J=16 Hz, CH=), 7.33 (5H, s, $C_6H_5CH_2$).

Found: C, 68.40; H, 5.68%. Calcd for $C_{32}H_{32}O_9$: C, 68.55; H, 5.76%.

7-(4-Benzyloxy-2,5-dimethoxyphenyl)-2,3-dihydro-5-methoxy-2,2-dimethyl-4*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-4,6-dione (11) and 2-[(4-Benzyloxy-2,5-dimethoxyphenyl)methylene]-6,7-dihydro-4-methoxy-7,7-dimethyl-5*H*-furo[3,2-*g*][1]benzopyran-3(2*H*),5-dione (12). A mixture of **10** (3.55 g) and TTN (4.2 g) was stirred in MeOH (1.3 l) at 36—38 °C for 10 h, and then 10% HCl (70 ml) was added, and the mixture was refluxed for a further 3 h. After removal of the precipitates by filtration, the filtrate was concentrated to ca. 600 ml under reduced pressure and poured into a large amount of ice-cold water. The mixture was allowed to stand overnight at room temperature to give precipitates. The precipitates were recrystallized from MeOH to give **11** (2.30 g, 70%) as colorless needles: mp 164—165 °C; ^{1}H NMR ($CDCl_3$) δ=1.47 (6H, s, CH_3×2), 2.71 (2H, s, $COCH_2$), 3.62, 3.82, and 3.98 (each 3H, s, OCH_3), 5.14 (2H, s, $C_6H_5CH_2$), 6.57 (1H, s, C_{10}–H), 6.64 and 6.85 (each 1H, s, Arom-H), 7.35 (5H, bs, $C_6H_5CH_2$), 7.67 (1H, s, C_8–H).

Found: C, 69.89; H, 5.49%. Calcd for $C_{30}H_{28}O_8$: C, 69.75; H, 5.46%.

The mother liquor was chromatographed over a silica-gel column with $CHCl_3$–Me_2CO (50:1) to give the aurone **12** (40 mg, 1%) as pale yellow needles: mp 216—218 °C (MeOH); ^{1}H NMR ($CDCl_3$) δ=1.45 (6H, s, CH_3×2), 2.67 (2H, s, $COCH_2$), 3.72, 3.88, and 4.32 (each 3H, s, OCH_3), 5.16 (2H, s, $C_6H_5CH_2$), 6.37 (1H, s, C_9–H), 7.20 and 7.71 (each 1H, s, Arom-H), 6.45 (1H, s, C=CH), 7.34 (5H, s, $C_6H_5CH_2$).

Found: C, 69.63; H, 5.31%. Calcd for $C_{30}H_{28}O_8$: C, 69.75; H, 5.46%.

7-(4-Benzyloxy-2,5-dimethoxyphenyl)-2,3-dihydro-5-hydroxy-2,2-dimethyl-4*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-4,6-dione (13). A solution of anhydrous $AlBr_3$ (14.5 g) in MeCN (50 ml) was added to a solution of **11** (5.46 g) in MeCN (250 ml), and the mixture was stirred at 40 °C for 25 min. The reaction mixture was poured into a mixture of HCl and ice-cold water and then stirred at 55—60 °C for 20 min to give precipitates. The precipitates were recrystallized from MeOH–Me_2CO to give **13** (4.85 g, 91%) as pale-yellow needles: mp 173—174 °C; ^{1}H NMR ($CDCl_3$) δ=1.48 (6H, s, CH_3×2), 2.73 (2H, s, $COCH_2$), 3.63 and 3.82 (each 3H, s, OCH_3), 5.12 (2H, s, $C_6H_5CH_2$), 6.30 (1H, s, C_{10}–H), 6.57 and 6.84 (each 1H, s, Arom-H), 7.35 (5H, br, $C_6H_5CH_2$), 7.76 (1H, s, C_8–H), 14.62 (1H, s, OH).

Found: C, 69.56; H, 5.22%. Calcd for $C_{29}H_{26}O_8$: C, 69.31;

H, 5.22%.

2,3-Dihydro-5-hydroxy-7-(4-hydroxy-2,5-dimethoxyphenyl)-2,2-dimethyl-4*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-4,6-dione (14). Compound **13** (4.67 g) was hydrogenolyzed over 10% palladium on charcoal (2 g) in MeOH (350 ml) and EtOAc (350 ml). The resulting compound was recrystallized from MeOH to give **14** (3.51 g, 92%) as colorless needles: mp 192—194 °C; ^{1}H NMR ($CDCl_3$) δ=1.47 (6H, s, CH_3×2), 2.73 (2H, s, $COCH_2$), 3.70 and 3.82 (each 3H, s, OCH_3), 6.15 (1H, s, $C_{4'}$–OH), 6.31 (1H, s, C_{10}–H), 6.60 and 6.82 (each 1H, s, Arom-H), 7.81 (1H, s, C_8–H), 14.65 (1H, s, C_5–OH).

Found: C, 64.20; H, 4.97%. Calcd for $C_{22}H_{20}O_8$: C, 64.07; H, 4.90%.

2,3-Dihydro-7-[2,5-dimethoxy-4-(tosyloxy)phenyl]-2,2-dimethyl-5-tosyloxy-4*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-4,6-dione (15). A mixture of **14** (1.24 g), TsCl (2.0 g), and K_2CO_3 (4.2 g) was refluxed with stirring in Me_2CO (150 ml) for 6 h. The resulting compound was recrystallized from MeOH to give **15** (1.73 g, 80%) as colorless prisms: mp 152—154 °C; ^{1}H NMR ($CDCl_3$) δ=1.44 (6H, s, CH_3×2), 2.34 and 2.41 (each 3H, s, $C_6H_4CH_3$), 2.61 (2H, s, CH_2CO), 3.47 and 3.65 (each 3H, s, OCH_3), 6.73 (1H, s, Arom-H), 6.80 (2H, s, Arom-H×2), 7.1—7.9 (9H, m, $C_6H_4CH_3$×2 and C_8–H).

Found: C, 61.17; H, 4.40%. Calcd for $C_{36}H_{32}O_{12}S_2$: C, 61.36; H, 4.58%.

3,4-Dihydro-4-hydroxy-7-[2,5-dimethoxy-4-(tosyloxy)phenyl]-2,2-dimethyl-5-tosyloxy-2*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-6-one (16) and 3,4-Dihydro-4,6-dihydroxy-7-[2,5-dimethoxy-4-(tosyloxy)phenyl]-2,2-dimethyl-5-tosyloxy-2*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran (17). A mixture of **15** (650 mg) and $PdCl_2$ (230 mg) was stirred in THF (70 ml) and water (14 ml), adding 180 mg each of $NaBH_4$ (360 mg) for two times, at 14—17 °C for 40 min, and then Me_2CO (5 ml) was added to the reaction mixture. After removal of the catalyst by filtration, water was added to the filtrate, and the solvent was removed under reduced pressure below 40 °C. The residue was extracted with EtOAc, washed with dil. HCl and brine, and dried (Na_2SO_4). The resulting compound was chromatographed over a silica-gel column with 1,2-dichloroethane–EtOAc–petroleum ether (50:2:1) to give the monoalcohol **16** (300 mg, 46%) as colorless needles (mp 204—206 °C; from Et_2O) and the dialcohol **17** (280 mg, 43%) as colorless needles (mp 194—196 °C; from Et_2O): ^{1}H NMR spectrum of **16**, ($CDCl_3$) δ=1.38 and 1.51 (each 3H, s, CH_3), 1.95—2.15 (2H, m, CH_2CHOH), 2.40 (6H, s, $C_6H_4CH_3$×2), 3.47 and 3.64 (each 3H, s, OCH_3), 5.07 (1H, t, J=5 Hz, CH_2CHOH), 6.74 (2H, s, Arom-H×2), 6.85 (1H, s, Arom-H), 7.1—8.0 (9H, m, $C_6H_4CH_3$×2 and C_8–H).

Found: C, 59.59; H, 4.51%. Calcd for $C_{36}H_{34}O_{12}S_2$: C, 59.83; H, 4.74%.

^{1}H NMR spectrum of **17**, ($CDCl_3$) δ=1.32 (6H, s, CH_3×2), 2.43 (8H, s, CH_2CHOH and $C_6H_4CH_3$×2), 3.35 and 3.57 (each 3H, s, OCH_3), 5.18 (1H, s, $CHOH$), 5.45 (1H, m, CH_2CHOH), 6.26, 6.45, and 6.47 (each 1H, s, Arom-H), 7.2—7.9 (8H, m, $C_6H_4CH_3$×2), 8.69 (1H, s, C_8–H).

7-[2,5-Dimethoxy-4-(tosyloxy)phenyl]-2,2-dimethyl-5-tosyloxy-2*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-6-one (18). Compound **16** (160 mg) was refluxed in toluene (30 ml) in the presence of TsOH·H_2O (20 mg) for 20 min. The resulting compound was recrystallized from MeOH–Me_2CO to give **18** (140 mg, 92%) as colorless prisms: mp 206—208 °C; ^{1}H NMR ($CDCl_3$) δ=1.42 (6H, s, CH_3×2), 2.40 and 2.43 (each 3H, s, $C_6H_4CH_3$), 3.49 and 3.67 (each 3H, s, OCH_3), 5.51 (1H, d, J=10 Hz, C_3–H), 6.31 (1H, d, J=10 Hz, C_4–H), 6.71, 6.77, and 6.90 (each 1H, s, Arom-H), 7.1—7.9 (9H, m, $C_6H_4CH_3$×2 and C_8–H).

Found: C, 61.17; H, 4.40%. Calcd for $C_{36}H_{32}O_{11}S_2$: C, 61.36; H, 4.58%.

Hydrolysis of 18. Compound **18** (143 mg) was refluxed in EtOH (150 ml) with a 20% KOH solution (12 ml) for 40 min. The resulting compound was separated by preparative TLC on silica gel with 1,2-dichloroethane–EtOAc–petroleum ether (50:2:3) to give linear pyranoisoflavone (elongatin) (**1**) and its angular isomer **2**.

7-(4-Benzoyloxy-2,5-dimethoxyphenyl)-2,3-dihydro-5-hydroxy-2,2-dimethyl-4*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-4,6-dione (19). A mixture of **14** (3.31 g), PhCOCl (1.2 ml), and K_2CO_3 (11.2 g) in Me_2CO (350 ml) was refluxed with stirring under an atmosphere of N_2 for 1 h. The resulting compound was recrystallized from MeOH to give **19** (3.53 g, 85%) as colorless needles: mp 240—242 °C; ^{1}H NMR ($CDCl_3$) δ=1.49 (6H, s, CH_3×2), 2.74 (2H, s, CH_2CO), 3.75 and 3.78 (each 3H, s, OCH_3), 6.36 (1H, s, C_{10}–H), 6.84 and 7.01 (each 1H, s, Arom-H), 7.4—8.3 (5H, m, C_6H_5CO), 7.87 (1H, s, C_8–H), 14.60 (1H, s, C_5–OH).

Found: C, 67.29; H, 4.74%. Calcd for $C_{29}H_{24}O_9$: C, 67.44; H, 4.68%.

7-(4-Benzoyloxy-2,5-dimethoxyphenyl)-2,3-dihydro-2,2-dimethyl-5-tosyloxy-4*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-4,6-dione (20). Tosylation of **19** (2.92 g) with TsCl (1.40 g) in Me_2CO (250 ml) and dioxane (150 ml) gave **20** (3.20 g, 84%) as colorless needles: mp 213—215 °C ($MeOH–Me_2CO$); ^{1}H NMR ($CDCl_3$) δ=1.46 (6H, s, CH_3×2), 2.38 (3H, s, $C_6H_4CH_3$), 2.67 (2H, s, CH_2CO), 3.73 and 3.76 (each 3H, s, OCH_3), 6.80 (1H, s, C_{10}–H), 6.87 and 7.00 (each 1H, s, Arom-H), 7.2—8.3 (9H, m, $C_6H_4CH_3$ and C_6H_5CO), 7.78 (1H, s, C_8–H).

Found: C, 64.21; H, 4.47%. Calcd for $C_{36}H_{30}O_{11}S$: C, 64.47; H, 4.52%.

7-(4-Benzoyloxy-2,5-dimethoxyphenyl)-3,4-dihydro-4-hydroxy-2,2-dimethyl-5-tosyloxy-2*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-6-one (21). A mixture of **20** (680 mg) and $PdCl_2$ (270 mg) in THF (200 ml) and water (40 ml) was stirred with adding $NaBH_4$ (380 mg) at 5—9 °C for 1 h. The reaction mixture was worked up by a method similar to that used for the preparation of **16** to give **21** (464 mg, 68%) as colorless needles: mp 174—176 °C (MeOH); ^{1}H NMR ($CDCl_3$) δ=1.42 and 1.55 (each 3H, s, CH_3), 2.07 (2H, m, CH_2CHOH), 2.42 (3H, s, $C_6H_4CH_3$), 3.74 and 3.76 (each 3H, s, OCH_3), 3.60 (1H, br, CH_2CHOH), 5.12 (1H, m, CH_2CHOH), 6.81 (2H, s, $C_{3'}$–H and C_{10}–H), 7.06 (1H, s, $C_{6'}$–H), 7.1—8.3 (9H, s, $C_6H_4CH_3$ and C_6H_5CO), 7.82 (1H, s, C_8–H).

Found: C, 63.98; H, 4.93%. Calcd for $C_{36}H_{32}O_{11}S$: C, 64.27; H, 4.80%.

7-(4-Benzoyloxy-2,5-dimethoxyphenyl)-2,2-dimethyl-5-tosyloxy-2*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-6-one (22). Dehydration of **21** (320 mg) with TsOH·H_2O (20 mg) gave **22** (280 mg, 90%) as colorless needles: mp 226—227 °C ($MeOH–Me_2CO$); UV λ_{max} nm (log ε) (EtOH) 263 (4.49), 294sh (4.32), 338sh (3.92); ^{1}H NMR ($CDCl_3$) δ=1.44 (6H, s, CH_3×2), 2.42 (3H, s, $C_6H_4CH_3$), 3.76 and 3.78 (each 3H, s, OCH_3), 5.59 (1H, d, J=10 Hz, C_3–H), 6.46 (1H, d, J=10 Hz, C_4–H), 6.76 (1H, s, C_{10}–H), 6.83 and 7.06 (each 1H, s, Arom-H), 7.1—8.3

(9H, m, $C_6\underline{H}_4CH_3$ and C_6H_5CO), 7.81 (1H, s, C_8–H).

Found: C, 65.97; H, 4.58%. Calcd for $C_{36}H_{30}O_{10}S$: C, 66.04; H, 4.63%.

5-Hydroxy-7-(4-hydroxy-2,5-dimethoxyphenyl)-2,2-dimethyl-2*H*,6*H*-benzo[1,2-*b*:5,4-*b'*]dipyran-6-one (Elongatin) (1). Hydrolysis of **22** (300 mg) with a 5% KOH solution in MeOH and dioxane gave **1** (151 mg, 83%) as colorless needles: mp 181—183 °C (MeOH) (lit,[4] mp 181—182 °C). Compound **1** was converted into the diacetate **23** (227—228 °C; lit,[4] mp 227—228 °C) and the dimethyl ether **24** (mp 132—134 °C; lit,[4] mp 132—134 °C), respectively.

2,4-Bis(benzyloxy)-6-hydroxyacetophenone (25). A mixture of 2,4,6-trihydroxyacetophenone (40 g), $PhCH_2Cl$ (58 ml), and K_2CO_3 (100 g) in HMPA (340 ml) was stirred under an atmosphere of N_2 at 90—93 °C for 70 min [monitered by silica-gel TLC with petroleum ether–1,2-dichloroethane (2:1), R_f=0.39]. After removal of K_2CO_3, the filtrate was poured into ice-cold water and acidified to pH 4 with dil. HCl, and then heated at 60—70 °C for 1 h to give white precipitates. The precipitates were recrystallized from MeOH–Me_2CO to give **25** (66.3 g, 80%): mp 100—102 °C (lit,[7] mp 98—100 °C, lit,[8] mp 96—98 °C).

Found: C, 75.68; H, 5.79%. Calcd for $C_{22}H_{20}O_7$: C, 75.84; H, 5.79%.

2,4-Bis(benzyloxy)-6-methoxyacetophenone (26). Methylation of **25** (30 g) with $(MeO)_2SO_2$ (20.4 g) gave **26** (28.4g, 91%) as colorless needles: mp 64—65 °C (MeOH–Me_2CO); ^{1}H NMR ($CDCl_3$) δ=2.43 (3H, s, $COCH_3$), 3.72 (3H, s, OCH_3), 4.99 (4H, s, $C_6H_5C\underline{H}_2$×2), 6.28 (2H, s, C_3–H and C_5–H), 7.30 and 7.33 (each 5H, s, $C_6\underline{H}_5CH_2$).

Found: C, 76.14; H, 5.97%. Calcd for $C_{23}H_{22}O_4$: C, 76.22; H, 6.12%.

2,4-Dihydroxy-6-methoxyacetophenone (27). Debenzylation of **26** (21.65g) with 10% palladium on charcoal (3 g) gave **27** (9.65 g, 89%) as colorless needles: mp 201—202 °C (MeOH) (lit,[9] mp 203—204 °C).

Found: C, 59.45; H, 5.30%. Calcd for $C_9H_{10}O_4$: C, 59.33; H, 5.53%.

1-(3-Acetyl-2,6-dihydroxy-4-methoxyphenyl)-3-methyl-2-buten-1-one (28). 3-Methyl-2-butenoyl chloride (7.8 g) in Et_2O (50 ml) was added, with stirring and cooling at 0 °C, to a solution of **27** (9.6 g) and $AlCl_3$ (4.9 g) in Et_2O (150 ml); the reaction mixture was then stirred for an additional 15 h. After removal of the ethereal layer, the residue was poured into a mixture of ice and HCl, and then warmed at 40 °C to give precipitates. The precipitates were recrystallized from EtOH to give **28** (12.4 g, 89%) as yellow needles: mp 117—119 °C; ^{1}H NMR ($CDCl_3$) δ=2.00 and 2.17 (each 3H, s, CH_3), 2.57 (3H, s, $COCH_3$), 3.86 (3H, s, OCH_3), 5.85 (1H, s, Arom-H), 7.12 (1H, m, CH=), 15.25 and 16.35 (each 1H, s, OH).

Found: C, 63.55; H, 5.96%. Calcd for $C_{14}H_{16}O_5$: C, 63.62; H, 6.10%.

6-Acetyl-5-hydroxy-7-methoxy-2,2-dimethyl-4-chromanone (29). A mixture of the diketone **28** (12.27 g) and 10% KOH solution (150 ml) in MeOH (350 ml) was stirred at room temperature for 3 h. The resulting compound was recrystallized from MeOH–H_2O to give **29** (11.43 g, 93%) as colorless needles: mp 116—117 °C; ^{1}H NMR ($CDCl_3$) δ=1.44 (6H, s, CH_3×2), 2.50 (3H, s, $COCH_3$), 2.70 (2H, s, $COCH_2$), 3.85 (3H, s, OCH_3), 5.95 (1H, s, Arom-H), 13.04 (1H, s, OH).

Found: C, 63.81; H, 6.11%. Calcd for $C_{14}H_{16}O_5$: C, 63.62; H, 6.10%.

5-Hydroxy-7-methoxy-2,2-dimethyl-6-[1-oxo-3-(4-benzyloxy-2,5-dimethoxyphenyl)-2-propenyl]-4-chromanone (30). Condensation of **29** (9.25 g) with **8** (9.53 g) gave **30** (9.80 g, 55%) as yellow needles: mp 148—150 °C (MeOH); ^{1}H NMR ($CDCl_3$) δ=1.47 (6H, s, CH_3×2), 2.70 (2H, s, $COCH_2$), 3.69, 3.80, and 3.85 (each 3H, s, OCH_3), 5.16 (2H, s, $C_6H_5C\underline{H}_2$), 6.00 (1H, s, C_8–H), 6.47 and 7.06 (each 1H, s, Arom-H), 6.94 and 7.76 (each 1H, d, J=16 Hz, CH=), 7.36 (5H, s, $C_6\underline{H}_5CH_2$), 12.35 (1H, s, OH).

Found: C, 69.25; H, 6.01%. Calcd for $C_{30}H_{30}O_8$: C, 69.48; H, 5.83%.

Acetate 31. Acetylation of 5-hydroxy compound **30** gave the acetate **31** as yellow needles: mp 167—169 °C (EtOH); ^{1}H NMR ($CDCl_3$) δ=1.47 (6H, s, CH_3×2), 2.20 (3H, s, $COCH_3$), 2.63 (2H, s, $COCH_2$), 3.70, 3.78, and 3.83 (each 3H, s, OCH_3), 5.15 (2H, s, $C_6H_5C\underline{H}_2$), 6.33 (1H, s, C_8–H), 6.47 and 6.98 (each 1H, s, Arom-H), 6.85 and 7.66 (each 1H, d, J=16 Hz, CH=), 7.35 (5H, s, $C_6\underline{H}_5CH_2$).

Found: C, 68.42; H, 5.69%. Calcd for $C_{32}H_{32}O_9$: C, 68.56; H, 5.75%.

3-(4-Benzyloxy-2,5-dimethoxyphenyl)-8,9-dihydro-5-methoxy-8,8-dimethyl-4*H*,10*H*-benzo[1,2-*b*:3,4-*b'*]dipyran-4,10-dione (32). The oxidative rearrangement of **31** (7.0 g) with TTN (6.4 g) and the subsequent cyclization gave **32** (4.91 g, 76%) as colorless needles: mp 204—206 °C (EtOAc); ^{1}H NMR ($CDCl_3$) δ=1.48 (6H, s, CH_3×2), 2.73 (2H, s, $COCH_2$), 3.59, 3.82, and 3.94 (each 3H, s, OCH_3), 5.16 (2H, s, $C_6H_5C\underline{H}_2$), 6.29 (1H, s, C_6–H), 6.56 and 6.97 (each 1H, s, Arom-H), 7.35 (5H, s, $C_6\underline{H}_5CH_2$), 7.92 (1H, s, C_2–H).

Found: C, 69.54; H, 5.29%. Calcd for $C_{30}H_{28}O_8$: C, 69.75; H, 5.47%.

3-(4-Benzyloxy-2,5-dimethoxyphenyl)-8,9-dihydro-5-hydroxy-8,8-dimethyl-4*H*,10*H*-benzo[1,2-*b*:3,4-*b'*]dipyran-4,10-dione (33). Demethylation of **32** (4.90 g) with $AlBr_3$ (15.2 g) gave **33** (4.65 g, 97%) as colorless needles: mp 186—188 °C (MeOH–EtOAc); ^{1}H NMR ($CDCl_3$) δ=1.46 (6H, s, CH_3×2), 2.71 (2H, s, $COCH_2$), 3.62 and 3.83 (each 3H, s, OCH_3), 5.15 (2H, s, $C_6H_5C\underline{H}_2$), 6.26 (1H, s, C_6–H), 6.57 and 6.90 (each 1H, s, Arom-H), 7.33 (5H, s, $C_6\underline{H}_5CH_2$), 8.06 (1H, s, C_2–H), 13.75 (1H, s, C_5–OH).

Found: C, 69.12; H, 5.40%. Calcd for $C_{29}H_{26}O_8$: C, 69.30; H, 5.23%.

8,9-Dihydro-5-hydroxy-3-(4-hydroxy-2,5-dimethoxyphenyl)-8,8-dimethyl-4*H*,10*H*-benzo[1,2-*b*:3,4-*b'*]dipyran-4,10-dione (34). Debenzylation of **33** (3.55 g) with 10% palladium on charcoal gave **34** (2.76 g, 95%) as colorless needles: mp 197—198 °C (MeOH–Me_2CO); ^{1}H NMR ($CDCl_3$) δ=1.50 (6H, s, CH_3×2), 2.72 (2H, s, $COCH_2$), 3.70 and 3.83 (each 3H, s, OCH_3), 5.95 (1H, s, $C_{4'}$–OH), 6.25 (1H, s, C_6–H), 6.60 and 6.86 (each 1H, s, Arom-H), 8.06 (1H, s, C_2–H), 10.93 (1H, s, C_5–OH).

Found: C, 64.05; H, 4.70%. Calcd for $C_{22}H_{20}O_8$: C, 64.07; H, 4.90%.

3-(4-Benzoyloxy-2,5-dimethoxyphenyl)-8,9-dihydro-5-hydroxy-8,8-dimethyl-4*H*,10*H*-benzo[1,2-*b*:3,4-*b'*]dipyran-4,10-dione (35). Benzoylation of **34** (310 mg) with PhCOCl (0.92 ml) gave **35** (380 mg, 97%) as colorless needles: mp 253—255 °C (MeOH–Me_2CO); ^{1}H NMR ($CDCl_3$) δ=1.50 (6H, s, CH_3×2), 2.70 (2H, s, $COCH_2$), 3.70 and 3.73 (each 3H, s, OCH_3), 6.23 (1H, s, C_6–H), 6.77 and 6.97 (each 1H, s, Arom-H), 7.3—8.2 (5H, m, C_6H_5CO), 8.06 (1H, s, C_2–H), 13.58 (1H, s, C_5–OH).

Found: C, 67.33; H, 4.51%. Calcd for $C_{29}H_{24}O_9$: C, 67.44;

H, 4.68%.

3-(4-Benzoyloxy-2,5-dimethoxyphenyl)-8,9-dihydro-8,8-dimethyl-5-tosyloxy-4*H*,10*H*-benzo[1,2-*b*:3,4-*b'*]dipyran-4,10-dione (36). Tosylation of **35** (710 mg) with TsCl gave **36** (820 mg, 89%) as colorless needles: mp 183—185 °C (Me_2CO); ^1H NMR ($CDCl_3$) δ=1.50 (6H, s, CH_3×2), 2.40 (3H, s, $C_6H_5C\underline{H}_3$), 2.76 (2H, s, $COCH_2$), 3.68 and 3.73 (each 3H, s, OCH_3), 6.75 (1H, s, C_6–H), 6.88 and 6.96 (each 1H, s, Arom-H), 7.1—8.2 (9H, m, C_6H_5CO and $C_6\underline{H}_4CH_3$), 7.91 (1H, s, C_2–H).

Found: C, 64.29; H, 4.49%. Calcd for $C_{36}H_{30}O_{11}S$: C, 64.47; H, 4.52%.

3-(4-Benzoyloxy-2,5-dimethoxyphenyl)-9,10-dihydro-10-hydroxy-8,8-dimethyl-5-tosyloxy-4*H*,8*H*-benzo[1,2-*b*:3,4-*b'*]dipyran-4-one (37). The selective reduction of **36** (780 mg) with $NaBH_4$ (460 mg) and $PdCl_2$ (310 mg) at 35—38 °C for 30 min gave **37** (712 mg, 91%) as colorless needles: mp 233—234 °C (Me_2CO–petroleum ether); ^1H NMR ($CDCl_3$) δ=1.41 and 1.46 (each 3H, s, CH_3), 2.08 (2H, d, J=4 Hz, $C\underline{H}_2$-CHOH), 2.38 (3H, s, $C_6H_4C\underline{H}_3$), 2.85 (1H, d, J=4 Hz, C_{10}–OH), 3.67 and 3.72 (each 3H, s, OCH_3), 5.07 (1H, t, J=4 Hz, $CH_2C\underline{H}OH$), 6.67, 6.75, and 6.96 (each 1H, s, Arom-H), 7.1—8.2 (9H, m, C_6H_5CO and $C_6\underline{H}_4CH_3$), 7.80 (1H, s, C_2–H).

Found: C, 64.00; H, 4.53%. Calcd for $C_{36}H_{32}O_{11}S$: C, 64.28; H, 4.80%.

3-(4-Benzoyloxy-2,5-dimethoxyphenyl)-8,8-dimethyl-5-tosyloxy-4*H*,8*H*-benzo[1,2-*b*:3,4-*b'*]dipyran-4-one (38). Dehydration of crude **37** (900 mg) gave **38** (510 mg, 67% yield based on **36**) as colorless needles: mp 215—217 °C (MeOH–Me_2CO); UV λ_{max} nm (log ε) (EtOH) 258 (4.59), 263 (4.59), 301 (4.15); ^1H NMR ($CDCl_3$) δ=1.46 (6H, s, CH_3×2), 2.39 (3H, s, $C_6H_4C\underline{H}_3$), 3.70 and 3.75 (each 3H, s, OCH_3), 5.65 (1H, d, J=10 Hz, C_9–H), 6.70 (1H, d, J=10 Hz, C_{10}–H), 6.67, 6.78, and 6.99 (each 1H, s, Arom-H), 7.1—8.2 (9H, m, C_6H_5CO and $C_6\underline{H}_4CH_3$), 7.80 (1H, s, C_2–H).

Found: C, 65.82; H, 4.63%. Calcd for $C_{36}H_{30}O_{10}S$: C, 66.04; H, 4.63%.

5-Hydroxy-3-(4-hydroxy-2,5-dimethoxyphenyl)-8,8-dimethyl-4*H*,8*H*-benzo[1,2-*b*:3,4-*b'*]dipyran-4-one (2). Hydrolysis of **38** (400 mg) gave **2** (180 mg, 74%) as yellow needles: mp 174—175 °C (MeOH–H_2O) (lit,[4] mp 173—175 °C). Diacetate **39** of **2**: mp 225—226 °C; lit,[4] mp 224—226 °C. 4′-Methyl ether (toxicarol isoflavone) (**40**): mp 219—220 °C; lit,[4] mp 219—220 °C. Dimethyl ether **41**: mp 178—180 °C; lit,[4] mp 179—180 °C.

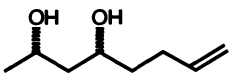
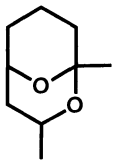
(Received September 5, 1988)

A short and stereoselective asymmetric synthesis of (2*S*,4*R*)-7-octene-2,4-diol (a key intermediate in the Bartlett synthesis of nonactic acid) and two stereoisomers of a biologically active substance isolated from Norway spruce infested by ambrosia beetle, *endo*-(1*S*,3*S*,5*R*)- and *exo*-(1*R*,3*S*,5*S*)-1,3-dimethyl-2,9-dioxabicyclo-[3.3.1]nonane, was effectively accomplished in three and four reaction steps, respectively, by starting with easily obtainable (*S*)-1-(1,3-dithian-2-yl)-2-propanol by baker's yeast asymmetric reduction. The main strategy was based on a facile construction of optically active β-hydroxy ketones via alkylation of the dianion of (*S*)-1-(1,3-dithian-2-yl)-2-propanol with alkyl halides, followed by their stereoselective reductions.

A 1,3-dihydroxylated structure is often found on the backbone of natural products or important key intermediates for natural products synthesis (e.g., polyoxo and polyether natural products). The compounds, (2*S*,4*R*)-7-octene-2,4-diol (**1**) and 1,3-dimethyl-2,9-dioxabicyclo[3.3.1]nonane (**2**) are typical



1

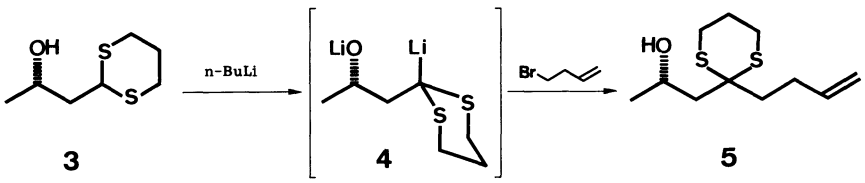


2

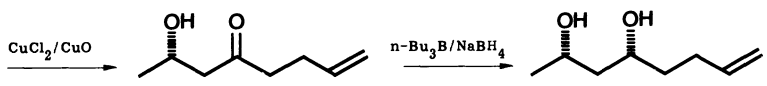
and simple examples. The former diol is known to be a key intermediate for the Bartlett synthesis of nonactic acid[1] and the latter bicyclic acetal, which is regarded to be potentially a 1,3-diol molecule, is a host-specific substance isolated from Norway spruce infested by the ambrosia beetle (*Trypodendron lineatum* Oliv.).[2] Although these compounds have already been synthesized in optically active forms by several groups,[3] some of these syntheses require lengthy reaction steps and are laborious in spite of their synthetic importances. In a preceding communication,[4] we showed the usefulness of (*S*)-1-(1,3-dithian-2-yl)-2-propanol (**3**) as a chiral building block for the synthesis of the Bartlett diol (**1**). In this paper, we would like to describe a short and efficient asymmetric synthesis of (2*S*,4*R*)-7-octene-2,4-diol (**1**) and two stereoisomers of **2**, *endo*-(1*S*,3*S*,5*R*)- and *exo*-(1*R*,3*S*,5*S*)-1,3-dimethyl-2,9-dioxabicyclo[3.3.1]nonane (**12** and **13**), which demonstrates the usefulness of **3** for the facile construction of this type of optically active 1,3-diols.

As outlined in Schemes 1 and 2, the present methodology comprises the alkylation of the dianion **4** with alkyl halides followed by the hydrolysis of the dithioacetal group and the subsequent 1,3-asymmetric induction by employing the stereoselective reduction of the resulting β-hydroxy ketones **6** and **9** leading to the corresponding 1,3-syn and 1,3-anti diols **1**, **10**, and **11**.

As shown in the previous communication[4] as well as in the literature,[5] optically active alcohol (*S*)-**3** was easily obtained by the baker's yeast asymmetric reduction of (1,3-dithian-2-yl)acetone in nearly quantitative yield with excellent optical purity (>99% ee). The transformation of (*S*)-**3** into the dianion **4** was

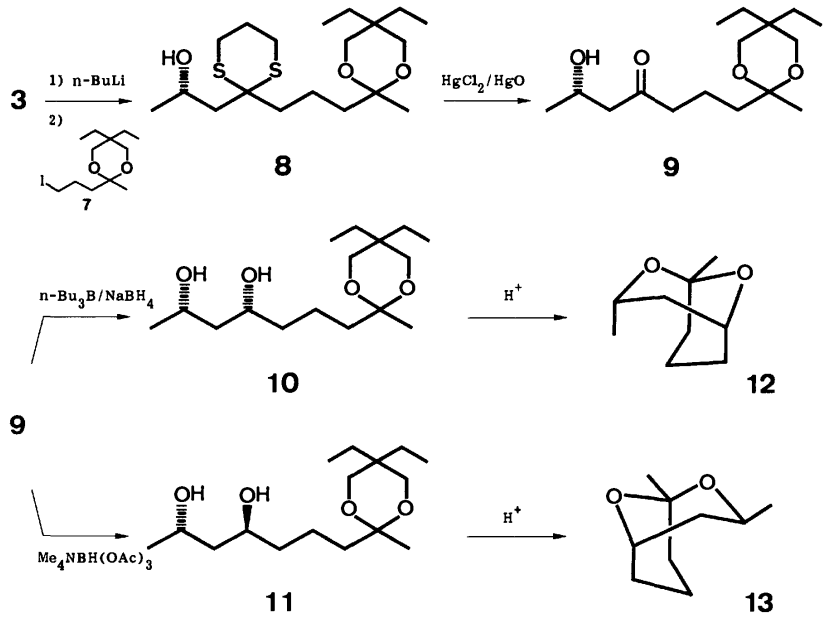


3 **4** **5**



6 **1**

Scheme 1.



Scheme 2.

achieved by the reaction with 2.2 equiv. of *n*-BuLi in THF at −30—0 °C. When dianion **4** was treated with 1.1 equiv. of 4-bromo-1-butene in THF at −30—0 °C, the *C*-alkylation product (*S*)-**5** was obtained in high yield. (*S*)-**5** was then hydrolyzed with $CuCl_2/CuO$ in aqueous acetone[6] to give the optically active β-hydroxy ketone (*S*)-**6** in good yield without any evidence of dehydration. The stereoselective reduction of (*S*)-**6** to the syn-diol **1** was effectively accomplished using n-$Bu_3B/NaBH_4$[7] which produced the mixture of the Bartlett diol **1** and its C-4 epimer with high selectivity (syn:anti=97:3). They were cleanly separated by column chromatography on silica gel to give pure **1**.

We next tried the synthesis of *endo*-(1*S*,3*S*,5*R*)-**12** and *exo*-(1*R*,3*S*,5*S*)-**13** starting with the (*S*)-alcohol **3**, according to the following sequence (Scheme 2). The reaction of the dianion **4** with 1.1 equiv. of 2-(3-iodopropyl)-2-methyl-5,5-diethyl-1,3-dioxane (**7**) at −30—0 °C proceeded selectively to give (*S*)-**8** in high yield without the concomitant of *O*-alkylation product. In contrast to the case of a similar ethylene acetal analogue reported very recently,[8] the selective hydrolysis of the dithioacetal group in **8** could be easily achieved without the hydrolysis of the 2,2-diethyl-1,3-propanediyl acetal protecting group by the standard procedure using $HgCl_2/HgO$ in aqueous acetonitrile[9] to give the desired β-hydroxy ketone (*S*)-**9** in good yield. The reduction of (*S*)-**9** with n-$Bu_3B/NaBH_4$ satisfactorily provided the syn-diol **10** in excellent yield with high stereoselectivity (syn:anti=94:6), although the syn selective reduction of a similar ethylene acetal analogue has been reported ($Zn(BH_4)_2$: 9:1,[8] $NaBH_4/Et_2BOMe$: >99:1[30]). On the other hand, the anti-isomer **11** could be quantitatively obtained with excellent stereoselectivity (syn:anti=6:94) by reducing (*S*)-**9** with $Me_4NBH(OAc)_3$ in acetonitrile–acetic acid[10] in sharp contrast to the poor selectivity (1:2) on the reduction of an ethylene acetal analogue by $NaBH(OAc)_3$ in acetic acid or $NaBH_4/CeCl_3$ in methanol.[8] Although the isomers of *syn*-**10** and *anti*-**11** could be separated by silica-gel column chromatography, the crude diol mixture in both cases was available for use in the final cyclization stage without separation of the minor isomer or further purification. Thus, the acid-catalyzed cyclization of the crude mixtures was performed by means of a two-layer method with hexane–2 M H_2SO_4 (1 M=1 mol dm^{-3}) to produce *endo*-**12** and *exo*-**13** in good yields, respectively. These isomers were cleanly separated by the separable-TLC technique to obtain them as pure form, respectively.

In summary, (2*S*,4*R*)-**1**, *endo*-(1*S*,3*S*,5*R*)-**12**, and *exo*-(1*R*,3*S*,5*S*)-**13** of high chemical and enantiomeric purity were obtained in 75%, 61%, and 70% overall yield, respectively. Spectroscopic data of these compounds were in good agreement with reported values. Because of the ready availability of the starting alcohol (*S*)-**3**, high overall yields of products, and simplicity of the procedure, the method can be regarded as a general and useful one for the facile construction of this type of optically active 1,3-diols.

Experimental

Optical rotations were determined with a Union Digital PM-101 polarimeter. IR spectra were obtained on a JASCO A-202 spectrophotometer. ^1H NMR spectra were measured with JEOL JNM-GX400 spectrophotometer at 400 MHz with tetramethylsilane as an internal reference. Silica gel (Merck silica gel 60, 230—400 mesh ASTM) was used for

medium-pressure liquid chromatography (MPLC). Analytical and preparative TLC were carried out on Merck precoated silica gel plates (Merck silica gel 60 F_{254}).

Materials. The solvents were purified by the usual methods and were freshly distilled before use. (1,3-Dithian-2-yl)acetone was prepared from 4,4-dimethoxy-2-butanone and 1,3-propanedithiol according to the method in the literature.[11] 5-Iodo-2-pentanone was prepared by the halogen-exchange reaction of the corresponding chloride with NaI according to the method of Findlay et al.[12] Fresh baker's yeast (Oriental Yeast Co.) used was commercially available. The other reagents were supplied as high-grade commercial products and used without further purification.

(*S*)-(+)-1-(1,3-Dithian-2-yl)-2-propanol (3). The following modified procedure gave optically pure (*S*)-**3** in excellent yield.[5] Baker's yeast (200 g) was dispersed into a solution of sucrose (40 g) and $Na_4P_2O_7$ (10 g) in distilled water (600 ml), and then stirred for 1 h at 25 °C. To the fermenting mixture was added (1,3-dithian-2-yl)acetone (8 g, 45.4 mmol) and stirred at the same temperature for 1 day. An additional baker's yeast (100 g), sucrose (20 g), $Na_4P_2O_7$ (5 g), and distilled water (300 ml) were supplied and the stirring was continued for an additional day. Ethyl acetate (500 ml) was added to the reaction mixture and the mixture was stirred for 16 h. After filtration through a Celite pad, the filtrate was extracted with ethyl acetate and the extract was dried with $MgSO_4$. The solvent was removed by evaporation under reduced pressure and the residue was diluted with CH_2Cl_2. The solution was filtered through a silica-gel pad (Wakogel C-300) and the concentration of the filtrate in vacuo gave the almost TLC-pure (*S*)-**3** in quantitative yield (>99% ee by ^1H NMR analysis of the alcohol with the chiral shift reagent (+)-Eu(hfc)$_3$ and of the corresponding (+)-MTPA ester[13]). Distillation of this product gave pure (*S*)-**3** as a colorless oil (7.63 g, 94%); bp 135 °C/0.1 mmHg (lit,[5] 105 °C/0.05 mmHg; 1 mmHg≈133.322 Pa); $[\alpha]_D^{25}$ +25.1° (*c* 2.0, $CHCl_3$) (lit,[5] $[\alpha]_D^{20}$ +24.7° (*c* 2.0, $CHCl_3$)); IR (neat film) 3400, 2900, 1420, 1370, 1270, 1240, 1180, 1120, 1070, 1020, 940, 900, 860, 840, and 760 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.23 (d, 3H, *J*=6.1 Hz), 1.81—1.95 (m, 3H), 1.98 (br, 1H), 2.13 (m, 1H), 2.81—2.96 (m, 4H), 4.13 (m, 1H), and 4.24 (dd, 1H, *J*=8.5, 5.9 Hz).

(*S*)-(+)-2-(3-Butenyl)-2-(2-hydroxypropyl)-1,3-dithiane (5). A stirred solution of (*S*)-**3** (1.0 g, 5.6 mmol) in dry THF (8 ml) under nitrogen was cooled to −30 °C and 1.6 M solution of *n*-BuLi in hexane (8.4 ml, 13.4 mmol) was added dropwise. The mixture was stirred for 30 min at −30 °C and then for 3 h at 0 °C. The mixture was again cooled to −30 °C. 4-Bromo-1-butene (0.62 ml, 6.2 mmol) was slowly added to the solution and stirred for 1 h at −30 °C. After allowing to warm to 0 °C, the reaction mixture was stirred for additional 4 days in a refrigerator and then quenched by the addition of water. The aqueous mixture was extracted with benzene and the extract was washed successively with water, 7% aqueous KOH solution, and water. After drying the extract with $MgSO_4$, the solution was concentrated in vacuo and the residual oil was purified by MPLC (benzene/ethyl acetate 3:1 v/v) to give pure (*S*)-**5** as a colorless oil (1.18 g, 91%); $[\alpha]_D^{24}$ +25.5° (*c* 3.84, $CHCl_3$); IR (neat film) 3400, 3050, 2900, 1630, 1440, 1410, 1360, 1260, 1230, 1120, 1050, 980, 900, 860, and 780 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.20 (d, 3H, *J*=6.3 Hz), 1.88—2.22 (m, 6H), 2.33 (m, 2H), 2.81 (m, 2H), 2.97 (m, 2H), 3.50 (s, 1H), 4.16 (m, 1H), 5.00 (dq, 1H, *J*=10.1, 1.7 Hz), 5.07 (dq, 1H, *J*=17.1, 1.7 Hz), and 5.82 (m, 1H).

(*S*)-(+)-2-Hydroxy-7-octen-4-one (6). To a solution of (*S*)-**5** (800 mg, 3.44 mmol) in 99% aqueous acetone (34 ml) was added $CuCl_2$ (925 mg, 6.88 mmol) and CuO (1.09 g, 13.76 mmol). The mixture was stirred for 3 h at room temperature. It was filtered through a Celite pad and the Celite was washed with ether. The combined filtrate and washings were concentrated under reduced pressure and the residue was diluted again with ether (30 ml). The solution was thoroughly washed with 5% aqueous $NaHCO_3$ solution and dried with $MgSO_4$. After concentration in vacuo, MPLC purification of the residue (benzene–ethyl acetate 4:1 v/v) gave pure (*S*)-**6** as a colorless heavy oil (441 mg, 90%); $[\alpha]_D^{30}$ +59.3° (*c* 2.0, $CHCl_3$) (lit,[3d] $[\alpha]_D^{22}$ −57.2° (*c* 2.27, $CHCl_3$) for (*R*)-**6**); IR (neat film) 3450, 3100, 2975, 2925, 1710, 1640, 1410, 1380, 1280, 1110, 1070, 1040, 1000, 940, 920, 840, and 740 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.19 (d, 3H, *J*=6.3 Hz), 2.33 (q, 2H, *J*=7.3 Hz), 2.52 (d, 1H, *J*=17.5 Hz), 2.54 (t, 2H, *J*=7.3 Hz), 2.61 (dd, 1H, *J*=17.5, 3.4 Hz), 3.19 (br, 1H), 4.23 (m, 1H), 5.02 (m, 2H), and 5.80 (m, 1H).

(2*S*,4*R*)-(+)-7-Octene-2,4-diol (1). To a solution of (*S*)-**6** (200 mg, 1.41 mmol) in dry THF (3.5 ml) was added tributylborane (1.55 ml, 1.55 mmol) and then air (4.2 ml) was slowly bubbled into the solution. The mixture was stirred for 2 h at room temperature under nitrogen. After the mixture was cooled to −78 °C, $NaBH_4$ (59 mg, 1.55 mmol) was added and then stirred for 3 h at the same temperature. The reaction mixture was allowed to warm to room temperature and the mixture of 30% H_2O_2 (7 ml), buffer solution (pH 7, 14 ml), and methanol (21 ml) was then added. The solvent was removed by evaporation under reduced pressure and the residue was extracted with CH_2Cl_2. The extract was dried with $MgSO_4$ and the solvent was removed in vacuo to yield the almost pure mixture of *syn*-**1** and its C-4 epimer in 98% yield (syn:anti=97:3 by ^1H NMR analysis). MPLC purification (benzene/ethyl acetate 1:2 v/v) of the mixture gave pure *syn*-**1** (187 mg, 92%); $[\alpha]_D^{26}$ +18.5° (*c* 1.13, CCl_4) (lit,[1] $[\alpha]_D^{20}$ −18.3° (*c* 0.75, CCl_4) for the enantiomer of **1**); IR (neat film) 3400, 3100, 3000, 2950, 1650, 1440, 1380, 1330, 1130, 1080, 1000, 920, and 840 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.21 (d, 3H, *J*=6.1 Hz), 1.46—1.64 (m, 4H), 2.16 (m, 2H), 3.11 (s, 2H), 3.88 (m, 1H), 4.05 (m, 1H), 4.98 (dq, iH, *J*=10.0, 0.5 Hz), 5.05 (dq, 1H, *J*=17.1, 0.5 Hz), and 5.84 (m, 1H).

5,5-Diethyl-2-(3-iodopropyl)-2-methyl-1,3-dioxane (7). A mixture of 5-iodo-2-pentanone (21.2 g, 100 mmol), 2,2-diethyl-1,3-propanediol (26.4 g, 200 mmol), and *p*-toluenesulfonic acid monohydrate (1.90 g, 10 mmol) in benzene (247 ml) was refluxed in an apparatus equipped with a Dean–Stark trap for 15 h. After cooling to room temperature, 5% aqueous $NaHCO_3$ solution was added to the reaction mixture and then extracted with ether. The extract was washed with 0.1 M aqueous $Na_2S_2O_3$ solution and dried with $MgSO_4$. The solvent was removed by evaporation under reduced pressure and the residual pale yellow oil was distilled to yield pure **7** (23.7 g, 73%); bp 135 °C/0.1 mmHg; IR (neat film) 2900, 2850, 1440, 1360, 1280, 1240, 1220, 1180, 1160, 1100, 1040, 990, 920, 850, 780, 760, and 740 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.79 (t, 3H, *J*=7.8 Hz), 0.81 (t, 3H, *J*=7.8 Hz), 1.29 (q, 2H, *J*=7.8 Hz), 1.36 (s, 3H), 1.47 (q, 2H, *J*=7.8 Hz), 1.78 (m, 2H), 1.97 (m, 2H), 3.23 (t, 2H, *J*=6.8 Hz),

and 3.52, 3.54, 3.56, 3.59 (each s, 4H).

(+)-5,5-Diethyl-2-[(*S*)-6-hydroxy-4,4-(trimethylenedithio)-heptyl]-2-methyl-1,3-dioxane (8). To a cooled and stirred solution of (*S*)-**3** (5.17 g, 29 mmol) in dry THF at −30 °C under nitrogen, was added dropwise 1.6 M hexane solution of *n*-BuLi (41 ml, 65 mmol). After stirring for 30 min at −30 °C, the mixture was allowed to slowly warm to 0 °C and then stirred for 3 h. Iodide **7** (10.5 g, 32 mmol) was added dropwise to the resulting dianion solution cooled again to −30 °C and then stirring was continued for 2 h. The reaction mixture was allowed to warm to 0 °C and stood for 2 days at 0 °C in refrigerator. The mixture was then quenched by the addition of water and the aqueous mixture was extracted with benzene. The extract was successively washed with water, 7% aqueous KOH solution, and water and then dried with $MgSO_4$. The solvent was removed in vacuo to yield almost pure (*S*)-**8** in quantitative yield; $[\alpha]_D^{30}$ +12.7° (*c* 2.18, $CHCl_3$); IR (neat film) 3450, 2950, 1720, 1460, 1420, 1380, 1280, 1250, 1220, 1190, 1100, 1060, 1000, 930, 910, 870, 790, 760, and 740 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.79 (t, 3H, *J*=7.6 Hz), 0.81 (t, 3H, *J*=7.6 Hz), 1.20 (d, 3H, *J*=6.3 Hz), 1.31 (q, 2H, *J*=7.6 Hz), 1.36 (s, 3H), 1.47 (q, 2H, *J*=7.6 Hz), 1.68 (m, 4H), 1.86—2.08 (m, 5H), 2.33 (dd, 1H, *J*=15.4, 9.5 Hz), 2.79 (m, 2H), 2.98 (m, 2H), 3.50, 3.53 (each d, 2H, *J*=2.2 Hz), 3.55, 3.58 (each s, 3H), and 4.14 (m, 1H).

(+)-5,5-Diethyl-2-[(*S*)-6-hydroxy-4-oxoheptyl]-2-methyl-1,3-dioxane (9). To a stirred suspension of $HgCl_2$ (14.3 g, 52.8 mmol) and HgO (11.4 g, 52.8 mmol) in acetonitrile-water (4:1 v/v, 38 ml), a solution of (*S*)-**8** (9.04 g, 24 mmol) in acetonitrile-water (4:1 v/v, 230 ml) was added dropwise under nitrogen and then stirred for 4 h at room temperature. The reaction mixture was filtered through Celite and the Celite was washed with hexane-CH_2Cl_2 (1:1 v/v). 5 M aqueous ammonium acetate solution was added to the combined filtrate and washings and filtered again through Celite. The filtrate was washed with water and saturated aqueous NaCl solution. After drying with $MgSO_4$, the solvent was removed by evaporation under reduced pressure. The residual oil was purified by MPLC (benzene/ethyl acetate 1:1 v/v) to give pure (*S*)-**9** as a colorless heavy oil (5.71 g, 83%); $[\alpha]_D^{25}$ +32.9° (*c* 2.85, $CHCl_3$); IR (neat film) 3450, 3000, 1710, 1460, 1410, 1380, 1250, 1220, 1200, 1120, 1100, 1040, 1010, 940, 860, 790, 760, and 740 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.79 (t, 3H, *J*=7.6 Hz), 0.81 (t, 3H, *J*=7.6 Hz), 1.19 (d, 3H, *J*=6.3 Hz), 1.28 (q, 2H, *J*=7.6 Hz), 1.36 (s, 3H), 1.48 (q, 2H, *J*=7.6 Hz), 1.69 (m, 4H), 2.46 (t, 2H, *J*=7.1 Hz), 2.50 (dd, 1H, *J*=17.6, 9.0 Hz), 2.61 (dd, 1H, *J*=17.6, 2.9 Hz), 3.16 (d, 1H, *J*=3.2 Hz), 3.50, 3.53, 3.56, 3.59 (each s, 4H), and 4.22 (m, 1H).

(+)-5,5-Diethyl-2-[(4*R*,6*S*)-4,6-dihydroxyheptyl]-2-methyl-1,3-dioxane (10). To a solution of (*S*)-**9** (716 mg, 2.5 mmol) in dry THF (6.2 ml) was added tributylborane (2.75 ml, 2.75 mmol) and then air (7.5 ml) was slowly bubbled into the solution. The mixture was stirred for 3 h at room temperature under nitrogen. After cooling to −78 °C, $NaBH_4$ (104 mg, 2.75 mmol) was added and then stirred for 3 h at the same temperature. The reaction mixture was allowed to warm to room temperature and a mixture of 30% H_2O_2 (13 ml), buffer solution (pH 7, 23 ml), and methanol (38 ml) was then added. The solvent was removed by evaporation under reduced pressure and the residue was extracted with CH_2Cl_2. The extract was dried with $MgSO_4$ and the solvent was removed in vacuo to yield an almost pure diastereomeric mixture of **10** and **11** (707 mg, 98%, **10**:**11**=94:6 by ^1H NMR analysis). This mixture was used for the next cyclization without further purification. TLC purification (benzene/ethyl acetate 1:1 v/v) of a part of the mixture gave pure sample of *syn*-**10**; $[\alpha]_D^{26}$ +4.1° (*c*1.02, $CHCl_3$); IR (neat film) 3400, 2950, 1460, 1380, 1360, 1330, 1240, 1200, 1150, 1130, 1100, 1080, 1060, 1030, 970, 940, 870, 840, 800, 760, and 740 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.79 (t, 3H, *J*=7.6 Hz), 0.81 (t, 3H, *J*=7.6 Hz), 1.21 (d, 3H, *J*=6.1 Hz), 1.28 (q, 2H, *J*=7.6 Hz), 1.36 (s, 3H), 1.49 (m, 7H), 1.59 (dt, 1H, *J*=14.4, 2.6 Hz), 1.69 (m, 2H), 3.03 (bs, 1H), and 3.18 (bs, 1H), 3.51, 3.54, 3.57, 3.60 (each s, 4H), 3.88 (m, 1H), and 4.05 (m, 1H).

(1*S*,3*S*,5*R*)-(+)-1,3-Dimethyl-2,9-dioxabicyclo[3.3.1]nonane (12). The two-layer mixture of a solution of crude *syn*-**10** (515 mg, 1.79 mmol) in hexane (6.3 ml) and 2 M H_2SO_4 (1.5 ml) was vigorously stirred for 4 days at room temperature. Saturated aqueous $NaHCO_3$ solution was carefully added to the reaction mixture and the mixture was extracted with ethyl acetate. The organic layer was washed with saturated NaCl solution and dried with $MgSO_4$. After removal of the solvent by evaporation under reduced pressure, the pure *endo*-**12** was isolated from the residue by preparative TLC (CH_2Cl_2); 209 mg, 75%; $[\alpha]_D^{26}$ +31.1° (*c* 0.405, pentane) (lit,[3c] $[\alpha]_D^{20}$ +37.5° (*c* 5.4, pentane)); IR (neat film) 3450, 2950, 2850, 1460, 1380, 1280, 1240, 1200, 1160, 1120, 1080, 1050, 1020, 970, and 940 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.20 (d, 3H, *J*=6.3 Hz), 1.27 (s, 3H), 1.30—1.81 (m, 6H), 2.04—2.17 (m, 2H), 3.94 (m, 1H), and 4.27 (brm, 1H).

(+)-5,5-Diethyl-2-[(4*S*,6*S*)-4,6-dihydroxyheptyl]-2-methyl-1,3-dioxane (11). To a cooled and stirred solution of tetramethylammonium triacetoxyborohydride (4.62 g, 17.5 mmol) in a mixture of dry acetonitrile (14 ml) and acetic acid (14 ml) at −40 °C was added dropwise a solution of (*S*)-**9** (1.00 g, 3.5 mmol) in dry acetonitrile (3.5 ml) under nitrogen. After the mixture was stirred for 5 h at −20 °C, it was quenched by the addition of 0.5 M aqueous sodium potassium tartarate (Rochelle salt) (52 ml) with vigorous stirring and then stirred for further 30 min. The mixture was diluted with CH_2Cl_2 and washed with saturated aqueous $NaHCO_3$ solution. The organic layer was dried with Na_2SO_4 and concentrated in vacuo to yield an almost pure diastereomeric mixture of **11** and **10** in quantitative yield (**11**:**10**=94:6 by ^1H NMR analysis). This mixture was used for the next cyclization without further purification. TLC purification (benzene/ethyl acetate 1:1 v/v) of a part of the mixture gave pure sample of *anti*-**11**; $[\alpha]_D^{23}$ +8.7° (*c* 1.43, $CHCl_3$); IR (neat film) 3400, 3000, 1470, 1380, 1260, 1220, 1200, 1140, 1100, 1040, 1010, 940, 870, 840, 800, and 760 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.79 (t, 3H, *J*=7.6 Hz), 0.81 (t, 3H, *J*=7.6 Hz), 1.25 (m, 5H), 1.36 (s, 3H), 1.49—1.70 (m, 10H), 2.33 (bs, 1H), 2.40 (bs, 1H), 3.51, 3.54, 3.57, 3.60 (each s, 4H), 3.98 (m, 1H), and 4.17 (m, 1H).

(1*R*,3*S*,5*S*)-(−)-1,3-Dimethyl-2,9-dioxabicyclo[3.3.1]nonane (13). The two-layer mixture of a solution of crude *anti*-**11** (675 mg, 2.34 mmol) in hexane (8.2 ml) and 2 M H_2SO_4 (2 ml) was stirred for 3 days at room temperature. After a similar workup for *endo*-**12**, pure *exo*-**13** was isolated by preparative TLC (CH_2Cl_2); 307 mg, 84%; $[\alpha]_D^{24}$ −6.1° (*c* 0.212, pentane) (lit,[3c] $[\alpha]_D^{20}$ +4.7° (*c* 3.2, pentane) for the enantiomer of **13**); IR (neat film) 3500, 1470, 1460, 1420, 1380, 1260, 1160,

1100, 1020, 860, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.16 (d, 3H, J=6.1 Hz), 1.32 (s, 3H), 1.53—2.20 (m, 8H), 4.21 (brm, 1H), and 4.60 (m, 1H).

Synthesis and Reductive Desulfurization of Crown Ethers Containing Thiophene Subunit[1)]

Tyo SONE,* Kazuaki SATO, and Yoshihiro OHBA
Department of Applied Chemistry, Faculty of Engineering,
Yamagata University, Yonezawa 992
(Received September 13, 1988)

Crown ethers containing 3,4-thiophenediyl and 3,4-thiophenediylbis(methylene) subunits as a ring constituent were prepared starting from 2,5-bis(ethoxycarbonyl)-3,4-thiophenediol and 2,5-dichloro-3,4-bis(chloromethyl)thiophene, respectively. A Raney nickel desulfurization of the thiophene-containing crown ethers afforded crown ethers having two adjacent side chains, such as a methyl or ethoxycarbonylmethyl group. The extraction ability of these crown ethers towards alkali metal cations was also examined by the solvent extraction method.

In spite of much work, only a few crown ethers containing a thiophene subunit as part of the macrocyclic ring have appeared in the literature. The crown ethers so far prepared are restricted to those[2)] containing a 2,5-dimethyl-3,4-thiophenediylbis-(methylene) unit, thiacrown ethers[3)] containing a 2,5-thiophenediylbis(methylene) unit, crown esters[4)] derived from 2,5-thiophenedicarboxylic acid, and azacrown ethers[5)] derived from 2,5-thiophenedicarbaldehyde. None of the thiophene analogues (thienocrown ether) of benzocrown ether, in which thiophene nucleus is directly incorporated into the crown ether ring, has been synthesized. We report here on the syntheses of crown ethers **7** and **8** (3,4-thienocrown ether) containing a 3,4-thiophenediyl subunit and those (**12**, **13**) containing a 3,4-thiophenediylbis(methylene) subunit and their extraction ability towards alkali metal cations.

Recently, functionalized and substituted crown ethers received attention in view of the immobilization[6)] and modification of the properties of crown ethers.[7)] In this connection, we also report on the transformation of the thiophene-containing crown ethers into novel crown ethers having two adjacent methyl or ethoxycarbonylmethyl groups by a reductive desulfurization of the thiophene ring.

Results and Discussion

Synthesis. Thiophenediols, potential starting substances for the preparation of the thienocrown ethers, are unstable and easily decompose in air, although the corresponding dialkoxythiophenes are rather stable. This seems to be the principal reason for the lack of thienocrown ethers. It has been reported that 2,5-bis(ethoxycarbonyl)-3,4-thiophenediol (**1**), almost the only stable thiophenediol derivative available, reacts with 1,2-dibromoethane and bromochloromethane in the presence of a base to give 2,5-bis(ethoxycarbonyl)-

a) Isolated yield based on **1** used.

3,4-ethylenedioxythiophene,[8] 2,5-bis(ethoxycarbonyl)-3,4-methylenedioxythiophene, and 6,8,14,16-tetrakis(ethoxycarbonyl)-2,4,10,12-tetraoxa-7,15-dithiatricyclo[11.3.0.0^{5,9}]hexadeca-1(16),5,8,13-tetraene,[9] respectively. The thienocrown ethers, **7** and **8**, were synthesized by the route outlined in Scheme 1. Namely, by the modification of the procedures described above, ethoxycarbonylthienocrown esters **3** (and, if any **4**) were first synthesized by the reaction of **1** and oligoethylene glycol ditosylates (**2**). The expected esters, **3** (and **4**), were obtained in relatively high yield, when **1** was reacted with **2** in refluxing MeCN for 25—30 h using CsF (KF for the synthesis of **3a**) as a base (Table 1). No satisfactory results were obtained by the use of other bases, such as NaH or EtONa, or a solvent, such as dioxane, even upon prolonged heating. Alkaline hydrolysis of **3** (or **4**) in 50% EtOH at 60 °C for 2 h gave the corresponding thienocrown acids, **5** (or **6**). It is interesting to note that the tetracarboxylic acid, **6a**, forms an adduct with four molecules of H_2O, which releases the H_2O upon heating under reduced pressure (130 °C/2 mmHg; 1 mmHg≈133.322 Pa) for 5 h. The thienocrown acids **5** (or **6**) underwent decarboxylation merely by heating at ca. 50 °C higher than their melting points under reduced pressure (20 mmHg) for 0.5—5 h to afford **7** and **8**.

The crown ethers, **12** and **13**, were synthesized as outlined in Scheme 2 in order to compare their physical properties with those of **7** and **8**. First, crown ethers **10** and/or **11**, containing a 2,5-dichloro-3,4-thiophenediylbis(methylene) unit, were prepared by the reaction of 2,5-dichloro-3,4-bis(chloromethyl)thiophene (**9**) with sodium or potassium oligoethylene glycolates according to Reinhoudt's method[2a] (Table 2). Early studies suggest that the chlorine atom(s) in chlorothiophene derivatives can be removed only with difficulty.[10] However, **10** and **11** were dechlorinated easily without any cleavage of the crown ether ring[11] by catalytic hydrogenation at room temperature in an atmospheric pressure hydrogenation apparatus; expected crown ethers **12** and **13** were obtained in good yields.

The structures of the new crown ethers were

established by their elemental analyses and spectral data (MS, ^{1}H NMR, and IR).

Reductive Desulfurization. Considering the fact that thiophene ring is desulfurized by the action of Raney nickel with a complete saturation of the thiophene ring, the thiophene-containing crown ethers are potentially useful intermediates for the synthesis of crown ethers having two adjacent substituents on the macrocyclic ring. From this view, crown ethers **3**, **12**, and **13** were subjected to reductive desulfurization with Raney nickel, and found to proceed smoothly as expected. Namely, being stirred in refluxing EtOH with excess Raney nickel for 2 h, **3** yielded novel crown ethers **15** having two adjacent ethoxycarbonylmethyl groups. Similarly, novel crown ethers, **16** and **17**, having two adjacent methyl groups were obtained from **12** and **13**.

17

An NMR spectral study suggests that the desulfurized crown ethers consist of pairs of cis and trans isomers. For example, the ^{1}H NMR spectrum (200 MHz, $CDCl_3$) of **16a** shows, together with the complex absorptions ascribable to the oxymethylene protons of the crown ring, two doublets due to methyl protons at δ 0.85 and 0.88 with the coupling constants of 6.1 and 7.2 Hz, and a multiplet at δ ca. 2 due to the adjacent methine protons. ^{13}C NMR spectrum is consistent with the assignment; two peaks for the methyl carbons at δ 13.1 and 13.8 and two peaks for the methine carbons at δ 34.3 and 35.7 together with the peaks (δ 70.2, 70.4, 70.8, 70.9, 74.5, and 74.7) due to the methylene carbons.[12]

a) Measured by Pedersen's method[13] at 25 °C: aqueous phase: [picric acid]=7×10^{-5} M (1 M=1 mol dm^{-3}), [MNO_3]=0.1 M; organic phase (CH_2Cl_2): [crown compd]=7×10^{-4} M. H_2O:CH_2Cl_2=1:1 (v/v). b) Figures in parentheses denote the values obtained for the corresponding benzo (or dibenzo) crown ethers which were prepared according to the literatures.[14] c) Prepared according to the literature.[2a]

It should be emphasized that the present results indicate the usefulness of the incorporation of a thiophene unit for the structural modification of a crown ring.

Extraction Ability. The extraction ability of the thiophene-containing crown ethers as well as the desulfurized crown ethers towards alkali metal cations was examined by Pedersen's extraction method.[13] Tables 3 and 4 summarize the results. The thienocrown ethers, **7** and **8**, and the corresponding benzocrown

17-C-5[b)]	1	11	10	5	4

a) Measured under similar conditions as described in the footnote in Table 3. b) Prepared according to the literature.[15)]

ethers are similar in selectivity, but the former shows a much higher K^+/Na^+ selectivity than the latter. On the other hand, the extraction ability of the thienocrown ethers are a little lower than that of benzocrown ethers; the thiophene unit with a sulfur atom in the position opposite to the crown ring weakens the coordination interaction between the crown oxygens and the metal cations.

Crown ethers **12** and **13**, having the 3,4-thiophenediylbis(methylene) unit(s), generally exhibit a lower extractability than that of the thienocrown ethers, **7** and **8**, with the same number of oxygens. This is probably due to the less symmetry arrangement of the donor oxygen[15)] and the non-coplanarity of the thiophene ring with the crown ether ring[2b)] in the molecules. Comparisons of a series of 17-crown-5 derivatives (the parent 17-crown-5,[15)] **10b**, **12b**, **14**, and **16a**) indicate that the extractability is not affected essentially by the incorporation of the thiophene unit in the crown ring, although the selectivity for Na^+ over K^+ somewhat increases. Crown ethers **7** and **12** exhibit a similar cation selectivity with a minor difference in that **12b** shows its highest extractability for Na^+, while **7b** for K^+.

Experimental

All the melting and boiling points are uncorrected. The ^1H NMR (90 MHz, TMS as an internal reference, $CDCl_3$ solution unless otherwise noted), MS (70 eV, unless otherwise noted), and UV spectra were obtained on Hitachi R-22, Hitachi R-90H, Hitachi RMU-6M, and Hitachi 228A spectrometers, respectively. TG/DTA curves were recorded with a Seiko Denshi Kogyo TG/DTA A30 Instrument with a heating rate of 10 °C min^{-1} under N_2 stream.

2,5-Bis(ethoxycarbonyl)-3,4-thiophenediol (**1**),[9)] 2,5-dichloro-3,4-bis(chloromethyl)thiophene (**9**),[16)] and oligoethylene glycol ditosylates (**2**)[15)] were prepared as described in the literature.

General Procedure for the Syntheses of 3 and 4 by the Reaction of 2,5-Bis(ethoxycarbonyl)-3,4-thiophenediol (1) with Oligoethylene Glycol Ditosylates (2). Under an N_2 atmosphere CsF (0.06 mol; KF for the synthesis of **3a**) was added to a solution of **1** (3.9 g, 0.015 mol) in dry MeCN (250 ml); the mixture was stirred for 1 h. To the resulting yellow suspension a solution of **2** (m=4—6; 0.015 mol) in dry MeCN (100 ml) was added and the mixture was refluxed with stirring for 25—30 h. The reaction mixture was filtered while hot and the precipitate was washed with MeCN (50 ml). Treatment of the precipitate with a dilute HCl solution yielded the recovered **1**. The filtrate and the washing were combined, the solvent evaporated to dryness, and the residual mass was extracted twice with $CHCl_3$ (100 ml, 50 ml). After removing the solvent from the $CHCl_3$ extracts, the residue was chromatographed (silica gel/AcOEt–hexane (2—4:1)) giving **3b—d** and, if any, **4** which were purified by recrystallization.

The crown ethers, **3a** and **4a**, were produced by the reaction of **1** with triethylene glycol ditosylate (**2**, m=3) using KF as a base. After removing the solvent from the $CHCl_3$ extracts, the residue was treated in hot MeOH (50 ml); **4a** was separated as a precipitate. The MeOH-soluble substances, after removing the MeOH, were chromatographed (silica gel/AcOEt–hexane (2:1), repeatedly to give **3a** and another crop of **4a**.

13,15-Bis(ethoxycarbonyl)-2,5,8,11-tetraoxa-14-thiabicyclo[10.3.0]pentadeca-1(15),12-diene (3a). White crystals (MeOH); ^1H NMR δ=1.37 (t, J=7.1 Hz, 6H, $CO_2CH_2\underline{CH_3}$), 3.7—4.4 (m, 12H, CH_2CH_2O), and 4.34 (q, J=7.1 Hz, 4H, $CO_2\underline{CH_2}CH_3$); MS m/z (rel intensity) 374 (M^+, 45). Found: C, 51.25; H, 6.03%. Calcd for $C_{16}H_{22}O_8S$: C, 51.33; H, 5.92%.

13,15,28,30-Tetrakis(ethoxycarbonyl)-2,5,8,11,17,20,23,26-octaoxa-14,29-dithiatricyclo[25.3.0.0^{12,16}]triaconta-1(30),12,15,27-tetraene (4a). White prisms (MeOH–$CHCl_3$); ^1H NMR δ=1.37 (t, J=7.1 Hz, 12H, $CO_2CH_2\underline{CH_3}$), 3.6—4.4 (m, 24H, CH_2CH_2O), and 4.33 (q, J=7.1 Hz, 8H, $CO_2\underline{CH_2}CH_3$); MS m/z 748 (M^+, 1). Found: C, 51.81; H, 5.93%. Calcd for $C_{32}H_{44}O_{16}S_2$: C, 51.33; H, 5.92%.

16,18-Bis(ethoxycarbonyl)-2,5,8,11,14-pentaoxa-17-thiabicyclo[13.3.0]octadeca-1(18),15-diene (3b). White plates (MeOH); ^1H NMR δ=1.37 (t, J=7.1 Hz, 6H, $CO_2CH_2\underline{CH_3}$), 3.7—4.4 (m, 16H, CH_2CH_2O), and 4.33 (q, J=7.1 Hz, 4H, $CO_2\underline{CH_2}CH_3$); MS m/z 418 (M^+, 56). Found: C, 51.60; H, 6.38%. Calcd for $C_{18}H_{26}O_9S$: C, 51.66; H, 6.26%.

16,18,34,36-Tetrakis(ethoxycarbonyl)-2,5,8,11,14,20,23,26,29,32-decaoxa-17,35-dithiatricyclo[31.3.0.0^{15,19}]hexatriaconta-1(36),15,18,33-tetraene (4b). White crystals (AcOEt); ^1H NMR δ=1.37 (t, J=7.1 Hz, 12H, $CO_2CH_2\underline{CH_3}$), 3.6—4.4 (m, 32H, CH_2CH_2O), and 4.33 (q, J=7.1 Hz, 8H, $CO_2\underline{CH_2}CH_3$); MS m/z 836 (M^+, 3). Found: C, 51.76; H, 6.38%. Calcd for $C_{36}H_{52}O_{18}S_2$: C, 51.66; H, 6.26%.

19,21-Bis(ethoxycarbonyl)-2,5,8,11,14,17-hexaoxa-20-thiabicyclo[16.3.0]heneicosa-1(21),18-diene (3c). White needles (MeOH); ^1H NMR δ=1.37 (t, J=7.1 Hz, 6H, $CO_2CH_2\underline{CH_3}$), 3.6—4.4 (m, 20H, CH_2CH_2O), and 4.33 (q, 4H, J=7.1 Hz, $CO_2\underline{CH_2}CH_3$); MS (20 eV) m/z 462 (M^+, 100). Found: C, 51.91; H, 6.62%. Calcd for $C_{20}H_{30}O_{10}S$: C, 51.94; H, 6.54%.

22,24-Bis(ethoxycarbonyl)-2,5,8,11,14,17,20-heptaoxa-23-thiabicyclo[19.3.0]tetracosa-1(24),21-diene (3d). White prisms (petroleum ether–AcOEt); ^1H NMR δ=1.37 (t, J=7.1 Hz, 6H, $CO_2CH_2\underline{CH_3}$), 3.6—4.4 (m, 24H, $CH_2\underline{CH_2}O$), and 4.33 (q, J=7.1 Hz, 4H, $CO_2\underline{CH_2}CH_3$); MS (20 eV) m/z 506 (M^+, 72). Found: C, 52.05; H, 6.88%. Calcd for $C_{22}H_{34}O_{11}S$: C, 52.16; H, 6.77%.

General Procedure for the Hydrolysis of 3 and 4. To a

solution of **3** (0.003 mol) in EtOH (15 ml) was added 5% NaOH solution (15 ml); the mixture was stirred at 60 °C for 2 h. After cooling the reaction mixture was acidified with HCl and stirred for ca. 30 min; then most of the EtOH was distilled off. Except for **3d**, the crystalline mass separated out upon ice-cooling, which was collected by filtration. It was dissolved in a minimum amount of hot H_2O; to the hot solution a few ml of 10% HCl solution was added. The contents were cooled and the white precipitate was collected by filtration and washed with a small amount of cold H_2O to afford pure dicarboxylic acid, **5**. By this procedure **4a** yielded the tetracarboxylic acid (**6a**), as the adduct with $4H_2O$, which, in turn, converted into the free acid upon heating at 130 °C under reduced pressure (2 mmHg) for 5 h. In the case of **3d**, the mixture was extracted with $CHCl_3$ after evaporating the EtOH. The extract was washed with H_2O and dried. Evaporation of the solvent gave **5d**.

2,5,8,11-Tetraoxa-14-thiabicyclo[10.3.0]pentadeca-1(15),12-diene-13,15-dicarboxylic Acid (5a). Yield, 76%. Colorless needles; mp 263—264 °C; MS (20 eV) *m/z* 318 (M^+, 10). Found: C, 45.01; H, 4.47%. Calcd for $C_{12}H_{14}O_8S$: C, 45.28; H, 4.43%.

2,5,8,11,14-Pentaoxa-17-thiabicyclo[13.3.0]octadeca-1(18),15-diene-16,18-dicarboxylic Acid (5b). Yield, 73%. Colorless needles, mp 244—245 °C; MS (20 eV) *m/z* 362 (M^+, 10). Found: C, 46.35; H, 5.18%. Calcd for $C_{14}H_{18}O_9S$: C, 46.41; H, 5.01%.

2,5,8,11,14,17-Hexaoxa-20-thiabicyclo[16.3.0]heneicosa-1(21),18-diene-19,21-dicarboxylic Acid (5c). Yield, 67%. Colorless needles, mp 191—192 °C; MS (20 eV) *m/z* 406 (M^+, 4). Found: C, 47.07; H, 5.51%. Calcd for $C_{16}H_{22}O_{10}S$: C, 47.29; H, 5.46%.

2,5,8,11,14,17,20-Heptaoxa-23-thiabicyclo[19.3.0]tetracosa-1(24),21-diene-22,24-dicarboxylic Acid (5d). Yield, 89%. White crystals (AcOEt), mp 146—147 °C; MS (20 eV) *m/z* 450 (M^+, 1). Found: C, 47.74; H, 5.90%. Calcd for $C_{18}H_{26}O_{11}S$: C, 47.99; H, 5.82%.

Attempted recrystallization of **5d** from H_2O yielded colorless needles, mp 81—83 °C, containing H_2O in the ratio **5d**:H_2O=1:1.6 (TG and ^1H NMR), which gradually released the H_2O on being left standing at room temperature for a few days.

2,5,8,11,17,20,23,26-Octaoxa-14,29-dithiatricyclo[25.3.0.$0^{12,16}$]triaconta-1(30),12,15,27-tetraene-13,15,28,30-tetracarboxylic Acid (6a). Yield, 74%. White powder, mp 250—251.5 °C; MS (20 eV) *m/z* 546 (M^+−90, 8). Found: C, 45.46; H, 4.39%. Calcd for $C_{24}H_{28}O_{16}S_2$: C, 45.28; H, 4.43%.

6a·4H₂O: Colorless needles, mp 257—258 °C. Found: C, 40.71; H, 5.02%. Calcd for $C_{24}H_{28}O_{16}S_2$ $4H_2O$: C, 40.68; H, 5.12%. TG/DTA data were given in the text.

General Procedure for the Syntheses of 7 and 8 by the Decarboxylation of 5 and 6. Crown ether **5** or **6** (0.003 mol) was placed in a small equipment for vacuum sublimation and heated at ca. 50 °C higher than its melting point under a pressure of 20 mmHg for 0.5 (for **5a** and **6a**), 3 (for **5b**—**c**), or 5 h (for **5d**). A dark-brown color developed concomitantly with the evolution of CO_2 gas. The residual mass was chromatographed (alumina/AcOEt) to give the desired crown ether, which was purified by recrystallization.

2,5,8,11-Tetraoxa-14-thiabicyclo[10.3.0]pentadeca-1(15),12-diene (7a). Yield, 69%. Colorless crystals (petroleum ether), mp 40—41.5 °C; ^1H NMR δ=3.6—4.3 (m, 12H, CH_2CH_2O) and 6.44 (s, 2H, Th-H); MS (20 eV) *m/z* 230 (M^+, 100). Found: C, 51.99; H, 6.25%. Calcd for $C_{10}H_{14}O_4S$: C, 52.16; H, 6.13%.

2,5,8,11,14-Pentaoxa-17-thiabicyclo[13.3.0]octadeca-1(18),15-diene (7b). Yield, 58%. Colorless needles (hexane–AcOEt), mp 71—72 °C; ^1H NMR δ=3.6—4.3 (m, 16H, CH_2CH_2O) and 6.26 (s, 2H, Th-H); MS (20 eV) *m/z* 274 (M^+, 95). Found: C, 52.45; H, 6.72%. Calcd for $C_{12}H_{18}O_5S$: C, 52.54; H, 6.61%.

2,5,8,11,14,17-Hexaoxa-20-thiabicyclo[16.3.0]heneicosa-1(21),18-diene (7c). Yield, 63%. Colorless needles (hexane–AcOEt), mp 89—90 °C; ^1H NMR δ=3.6—4.3 (m, 20H, CH_2CH_2O) and 6.19 (s, 2H, Th-H); MS (20 eV) *m/z* 318 (M^+, 66). Found: C, 52.67; H, 7.11%. Calcd for $C_{14}H_{22}O_6S$: C, 52.81; H, 6.97%.

2,5,8,11,14,17,20-Heptaoxa-23-thiabicyclo[19.3.0]tetracosa-1(24),21-diene (7d). Yield, 83%. Colorless crystals (hexane–AcOEt), mp 62—63 °C; ^1H NMR δ=3.5—4.3 (m, 24H, CH_2CH_2O) and 6.20 (s, 2H, Th-H); MS (20 eV) *m/z* 362 (M^+, 57). Found: C, 52.96 H, 7.46% Calcd for $C_{16}H_{26}O_7S$: C, 53.02; H, 7.23%.

2,5,8,11,17,20,23,26-Octaoxa-14,29-dithiatricyclo[25.3.0.$0^{12,16}$]triaconta-1(30),12,15,27-tetraene (8a). Yield, 51%. Colorless needles ($CHCl_3$–AcOEt), mp 140—141 °C; ^1H NMR δ=3.6—4.3 (24H, m, CH_2CH_2O) and 6.19 (s, 4H, Th-H); MS (20 eV) *m/z* 460 (M^+, 100). Found: C, 52.00; H, 6.17%. Calcd for $C_{20}H_{28}O_8S_2$: C, 52.16; H, 6.13%.

General Procedure for the Syntheses of 10 and 11 by the Reaction of 2,5-Dichloro-3,4-bis(chloromethyl)thiophene (9) and Oligoethylene Glycolate. Under an N_2 atmosphere NaH (for **2′**, *m*=3—5) or *t*-BuOK (for **2′**, *m*=6) (0.04 mol) was added to a solution of oligoethylene glycol (**2′**; 0.02 mol) in dry toluene (120 ml); the mixture was stirred at 60°C for 1 h. The mixture was then cooled to room temperature and a solution of **9** (5.0 g, 0.02 mol) in dry toluene (50 ml) was added at once to the mixture, which was then heated to reflux for 6 h. The precipitate formed was filtered and washed with a small amount of $CHCl_3$. The filtrate and washing were combined and evaporated. The residue was dissolved in $CHCl_3$ (50 ml), washed with H_2O, and dried. After removing the solvent, the crude products were chromatographed (alumina/hexane–dioxane (4:1)) to give **10**, together with **11**, which were purified by recrystallization.

15,17-Dichloro-3,6,9,12-tetraoxa-16-thiabiscyclo[12.3.0]heptadeca-1(17),14-diene (10a). White needles (hexane); ^1H NMR δ=3.66 (s, 4H, CH_2CH_2O), 3.72 (s, 8H, CH_2CH_2O), and 4.62 (s, 4H, $ThCH_2O$); MS (20 eV) *m/z* 326 (M^+, 32) and 328 (M^++2, 27). Found: C, 44.12; H, 5.04%. Calcd for $C_{12}H_{16}Cl_2O_4S$: C, 44.05; H, 4.93%.

15,17,32,34-Tetrachloro-3,6,9,12,20,23,26,29-octaoxa-16,33-dithiatricyclo[29.3.0.$0^{14,18}$]tetratriaconta-1(34),14,17,31-tetraene (11a). White needles (hexane); ^1H NMR δ=3.66 (s, 24H, CH_2CH_2O), and 4.59 (s, 8H, $ThCH_2O$); MS (20 eV) *m/z* 652 (M^+, 17) and 654 (M^++2, 20). Found: C, 44.07; H, 4.98%. Calcd for $C_{24}H_{32}Cl_4O_8S_2$: C, 44.05; H, 4.93%.

18,20-Dichloro-3,6,9,12,15-pentaoxa-19-thiabicyclo[15.3.0]-eicosa-1(20),17-diene (10b). White crystals (hexane); ^1H NMR (C_6D_6) δ=3.36, 3.50 (s, 8H each, CH_2CH_2O), and 4.53 (s, 4H, $ThCH_2O$); MS *m/z* 370 (M^+, 22) and 372 (M^++2, 12). Found: C, 45.30; H, 5.58%. Calcd for $C_{14}H_{20}Cl_2O_5S$: C, 45.29; H, 5.43%.

18,20,38,40-Tetrachloro-3,6,9,12,15,23,26,29,32,35-decaoxa-19,39-dithiatricyclo[35.3.0.$0^{17,21}$]tetraconta-1(40),17,20,37-tetraene (11b). White prisms (hexane); ^1H NMR (C_6D_6) δ=3.49 (s, 32H, CH_2CH_2O) and 4.56 (s, 8H, $ThCH_3O$); MS (20 eV) *m/z*

740 (M^+, 6) and 742 (M^++2, 8). Found: C, 45.20; H, 5.49%. Calcd for $C_{28}H_{40}Cl_4O_{10}S_2$: C, 45.29; H, 5.43%.

21,23-Dichloro-3,6,9,12,15,18-hexaoxa-22-thiabicyclo[18.3.0]-tricosa-1(23),20-diene (10c). Colorless plates (petroleum ether); ^{1}H NMR (C_6D_6) δ=3.3—3.6 (m, 20H, CH_2CH_2O) and 4.61 (4H, s, $ThCH_2O$); MS (20 eV) m/z 414 (M^+, 63) and 416 (M^++2, 48). Found: C, 46.23; H, 5.92%. Calcd for $C_{16}H_{24}Cl_2O_6S$: C, 46.27; H, 5.82%.

21,23,44,46-Tetrachloro-3,6,9,12,15,18,26,29,32,35,38,41-dodecaoxa-22,45-dithiatricyclo[41.3.0.0^{20,24}]hexatetraconta-1(46),20,23,43-tetraene (11c). Colorless needles (hexane); ^{1}H NMR δ=3.64 (br s, 40H, CH_2CH_2O) and 4.59 (s, 8H, $ThCH_2O$); MS (20 eV) δ= 828 (M^+, 3) and 830 (M^++2, 4). Found: C, 46.35; H, 5.98%. Calcd for $C_{32}H_{48}Cl_4O_{12}S_2$: C, 46.27; H, 5.82%.

24,26-Dichloro-3,6,9,12,15,18,21-heptaoxa-25-thiabicyclo-[21.3.0]hexacosa-1(26),23-diene (10d). Colorless viscous oil; ^{1}H NMR (C_6D_6) δ=3.4—3.7 (m, 24H, CH_2CH_2O) and 4.60 (s, 4H, $ThCH_2O$); MS (20 eV) m/z 458 (M^+, 22) and 460 (M^++2, 16). Found: C, 46.88; H, 6.29%. Calcd for $C_{18}H_{28}Cl_2O_7S$: C, 47.06; H, 6.14%.

24,26,50,52-Tetrachloro-3,6,9,12,15,18,21,29,32,35,38,41,44,47-tetradecaoxa-25,51-dithiatricyclo[47.3.0.0^{23,27}]dopentaconta-1(52),23,26,49-tetraene (11d). White crystals (hexane); ^{1}H NMR δ=3.65 (br s, 48H, CH_2CH_2O) and 4.59 (s, 8H, $ThCH_2O$); MS (20 eV) m/z 916 (M^+, 1) and 918 (M^++2, 2). Found: C, 47.04; H, 6.24%. Calcd for $C_{36}H_{56}Cl_4O_{14}S_2$: C, 47.06; H, 6.14%.

General Procedure for the Preparation of 12a—d and 13 by the Catalytic Dechlorination of 10a—d and 11. The reaction was conducted at room temperature by stirring a mixture of **10** or **11** (0.005 mol), KOH (1.5 g), 10% Pd-C (0.7 g), and MeOH (100 ml) in an atmospheric pressure hydrogenation apparatus. Within 1—2 h the calculated amounts of H_2 were consumed. The catalyst was filtered off and washed with $CHCl_3$ (50 ml). The filtrate was concentrated and water added to the residue. The products were extracted with the $CHCl_3$ washing. The extract was washed with H_2O, 5% HCl solution, and then H_2O, and dried. Evaporation of the solvent gave **12a—d** or **13** as an oil.

3,6,9,12-Tetraoxa-16-thiabicyclo[12,3,0]heptadeca-1(17),14-diene (12a). Yield, 83%. Colorless viscous oil; ^{1}H NMR (200 MHz) δ=3.67 (s, 4H, CH_2CH_2O), 3.74 (s, 8H, CH_2CH_2O), 4.74 (s, 4H, $ThCH_2O$), and 7.24 (s, 2H, Th-H); MS (20 eV) m/z 258 (M^+, 60). Found: C, 55.24; H, 7.11%. Calcd for $C_{12}H_{18}O_4S$: C, 55.79; H, 7.02%.

3,6,9,12,15-Pentaoxa-19-thiabicyclo[15.3.0]eicosa-1(20),17-diene (12b). Yield, 88%. Colorless viscous oil, bp 160 °C (bath)/5×10^{-3} mmHg. ^{1}H NMR (C_6D_6) δ=3.38, 3.52 (s each, 16H, CH_2CH_2O), 4.63 (s, 4H, $ThCH_2O$), and 7.07 (s, 2H, Th-H); MS (20 eV) m/z 302 (M^+ 100). Found: C, 55.39; H, 7.49%. Calcd for $C_{14}H_{22}O_5S$: C, 55.61; H, 7.33%.

3,6,9,12,15,18-Hexaoxa-22-thiabicyclo[18.3.0]tricosa-1(23),20-diene (12c). Yield, 81%. Colorless viscous oil, bp 160 °C (bath)/10^{-3} mmHg; ^{1}H NMR (C_6D_6) δ=3.49, 3.52 (s each, 20H, CH_2CH_2O), 4.58 (s, 4H, $ThCH_2O$), and 7.00 (2H, s, Th-H); MS (20 eV) m/z 346 (M^+, 94). Found: C, 54.78; H, 7.71%. Calcd for $C_{16}H_{26}O_6S$: C, 55.47; H, 7.56%.

3,6,9,12,15,18,21-Heptaoxa-25-thiabicyclo[21.3.0]hexacosa-1(26),23-diene (12d). Yield, 83%. Colorless viscous oil, bp 170—190 °C (bath)/10^{-3} mmHg; ^{1}H NMR (C_6D_6) δ=3.4—3.7 (m, 24H, CH_2CH_2O), 4.57 (s, 4H, $ThCH_2O$), and 7.03 (s, 2H, Th-H); MS (20 eV) m/z 390 (M^+, 90). Found: C, 54.98; H, 7.96%. Calcd for $C_{18}H_{30}O_7S$: C, 55.79; H, 7.02%.

3,6,9,12,20,23,26,29-Octaoxa-16,33-dithiatricyclo[29.3.0.0^{14,18}]tetratriaconta-1(34),14,17,31-tetraene (13a). Yield, 85%. Colorless viscous oil, bp 230 °C (bath)/10^{-3} mmHg; ^{1}H NMR (C_6D_6) δ=3.51, 3.47 (s each, 24H, CH_2CH_2O), 4.54 (s, 8H, $ThCH_2O$), and 7.02 (s, 4H, Th-H); MS (20 eV) m/z 516 (M^+, 20). Found: C, 55.59; H, 7.11%. Calcd for $C_{24}H_{36}O_8S_2$: C, 55.79; H, 7.02%.

Reductive Desulfurization of the Thiophene-Containing Crown Ethers (3a—d, 12b—d, and 13) with Raney Nickel. W-7 Raney nickel prepared from 15 g of the alloy was added to the solution of the crown ether (0.005 mol) in EtOH (50 ml); the mixture was stirred at the reflux temperature for 2 h. The reaction mixture was filtered and the nickel was washed with EtOH (10 ml). The filtrate and the washing were combined and evaporated. The residual oil was chromatographed (silica gel/hexane–dioxane (4:1) for **16** and **17**, silica gel/AcOEt–hexane (2—4:1) for **15**) giving the desulfurized crown ether.

2,3-Bis(ethoxycarbonylmethyl)-1,4,7,10-tetraoxacyclododecane (2,3-Bis(ethoxycarbonylmethyl)-12-crown-4) (15a). Yield, 53%. Colorless oil, bp 110 °C (bath)/10^{-3} mmHg; ^{1}H NMR δ=1.26 (t, J=7.1 Hz, 6H, $CH_2\underline{CH_3}$), 2.40 (d, J=5.3 Hz, 2H, $\underline{CH_2}CH$), 2.55 (d, J=8.1 Hz, 2H, $\underline{CH_2}CH$), 3.66, 3.71 (br s each, 12H, CH_2CH_2O), and 4.15 (q, J=7.1 Hz, $\underline{CH_2}CH_3$, overlapped with the $CH_2\underline{CH}$ peaks, 6H); MS (50 eV) m/z 348 (M^+, 41). Found: C, 54.41; H, 8.08%. Calcd for $C_{16}H_{28}O_8$: C, 55.16; H, 8.10%.

2,3-Bis(ethoxycarbonylmethyl)-1,4,7,10,13-pentaoxacyclopentadecane (2,3-Bis(ethoxycarbonylmethyl)-15-crown-5) (15b). Yield, 51%. Colorless oil, bp 125 °C (bath)/10^{-3} mmHg; ^{1}H NMR δ=1.26 (t, J=7.1 Hz, 6H, $CH_2\underline{CH_3}$), 2.37 (d, J=5.1 Hz, 2H, $\underline{CH_2}CH$), 2.51 (d, J=8.1 Hz, 2H, $\underline{CH_2}CH$), and 3.55—4.3 (m, 22H, CH_2CH_2O, $CH_2\underline{CH}$, and $\underline{CH_2}CH_3$ (4.15, q, J=7.1 Hz)); MS (50 eV) m/z 392 (M^+, 30). Found: C, 54.92; H, 8.41%. Calcd for $C_{18}H_{32}O_9$: C, 55.09; H, 8.22%.

2,3-Bis(ethoxycarbonylmethyl)-1,4,7,10,13,16-hexaoxacyclooctadecane (2,3-Bis(ethoxycarbonylmethyl)-18-crown-6) (15c). Yield, 55%. Colorless oil, bp 140 °C (bath)/10^{-3} mmHg; ^{1}H NMR δ=1.26 (t, J=7.1 Hz, 6H, $CH_2\underline{CH_3}$), 2.49 (d, J=4.5 Hz, 2H, $\underline{CH_2}CH$), 2.55 (d, J=6.1 Hz, 2H, $\underline{CH_2}CH$), and 3.45—4.3 (m, 26H, CH_2CH_2O, $CH_2\underline{CH}$, and $\underline{CH_2}CH_3$ (4.15, q, J=7.1 Hz)); MS (50 eV) m/z 436 (M^+, 60). Found: C, 54.67; H, 8.55%. Calcd for $C_{20}H_{36}O_{10}$: C, 55.03; H, 8.31%.

2,3-Bis(ethoxycarbonylmethyl)-1,4,7,10,13,16,19-heptaoxacycloheneicosane (2,3-Bis(ethoxycarbonylmethyl)-21-crown-7) (15d). Yield, 56%. Colorless oil, bp 150 °C (bath)/10^{-3} mmHg; ^{1}H NMR δ=1.26 (t, J=7.1 Hz, 6H, $CH_2\underline{CH_3}$), 2.49 (d, J=3.8 Hz, 2H, $\underline{CH_2}CH$), 2.55 (d, J=5.9 Hz, 2H, $\underline{CH_2}CH$), and 3.45—4.3 (m, 30H, CH_2CH_2O, $CH_2\underline{CH}$, and $\underline{CH_2}CH_3$ (4.15, q, J=7.1 Hz)); MS (50 eV) m/z 480 (M^+, 5). Found: C, 54.14; H, 8.53%. Calcd for $C_{22}H_{40}O_{11}$: C, 54.99; H, 8.39%.

15,16-Dimethyl-1,4,7,10,13-pentaoxacycloheptadecane (16a). Yield, 49%. Colorless oil, bp 100 °C (bath)/10^{-3} mmHg; ^{1}H NMR (200 MHz) δ=0.85, 0.88 (d, J=6.1 Hz, 7.2 Hz each, 6H, CH_3), 1.85—2.1 (m, 2H, $\underline{CH}CH_2O$), and 3.3—3.8 (m, 20H, CH_2CH_2O); MS (20 eV) m/z 276 (M^+, 8). Found: C, 60.13; H, 10.42%. Calcd for $C_{14}H_{28}O_5$: C, 60.84; H, 10.21%.

18,19-Dimethyl-1,4,7,10,13,16-hexaoxacycloeicosane (16b). Yield, 52%. Colorless oil, bp 120 °C (bath)/10^{-3} mmHg; ^{1}H NMR (200 MHz) δ=0.79, 0.89 (d, J=6.7 Hz, 6.8 Hz each, 6H, CH_3), 1.85—2.15 (m, 2H, $\underline{CH}CH_2O$), and 3.25—3.8 (m, 24H, CH_2CH_2O); MS (20 eV) m/z 320 (M^+, 1). Found: C, 59.33; H, 10.21%. Calcd for $C_{16}H_{32}O_6$: C, 59.98; H, 10.07%.

21,22-Dimethyl-1,4,7,10,13,16,19-heptaoxacyclotricosane (16c).

Yield, 52%. Colorless oil, bp 140—150 °C (bath)/10^{-3} mmHg; ^{1}H NMR (200 MHz) δ=0.80, 0.90 (d, J=6.8 Hz each, 6H, CH_3), 1.8—2.15 (m, 2H, $\underline{CH}CH_2O$), and 3.2—3.9 (m, 28H, CH_2CH_2O); MS (20 eV) m/z 364 (M^+, 1). Found: C, 58.37; H, 10.05%. Calcd for $C_{18}H_{36}O_7$: C, 59.32; H, 9.96%.

12,13,26,27-Tetramethyl-1,4,7,10,15,18,21,24-octaoxacyclooctacosane (17). Yield, 43%. Colorless oil, bp 170 °C (bath)/10^{-3} mmHg; ^{1}H NMR (200 MHz) δ=0.79, 0.89 (d, J=6.7 Hz, 6.8 Hz each, 12H, CH_3), 1.8—2.15 (m, 4H, $\underline{CH}CH_2O$), and 3.25—3.8 (m, 32H, CH_2CH_2O); MS (20 eV) m/z 464 (M^+, 1). Found: C, 61.23; H, 10.96%. Calcd for $C_{24}H_{48}O_8$: C, 62.04; H, 10.41%.

Solvent Extraction. Solvent extraction was carried out according to Pedersen's method.[13] The CH_2Cl_2 solution (5 ml) containing the crown ether (7×10^{-4} mol) and the aqueous solution (5 ml) containing the metal nitrate (1×10^{-1} mol) and picric acid (7×10^{-5} mol) were mixed and shaken for 10 min at 25 °C. The solution was equilibrated. Extraction of the picrate was followed by monitoring the absorbance of the aqueous solution at 354 nm.

The authors wish to thank Professor Kensuke Takahashi of Nagoya Institute of Technology for the ^{1}H (200 MHz) and ^{13}C NMR spectral measurements, and Messrs. Kohki Chiba, Shigeki Watanabe, Hideaki Kobayashi, Koichi Takahashi, Yoshikazu Inao, and Masahiro Wada for their assistance with some of experiments.

Stereoselective β-*C*- and β-*S*-Glycosylation of 2-Deoxyribofuranose Derivatives Controlled by the 3-Hydroxy Protective Group

Yuh-ichiro ICHIKAWA, Hideki KUBOTA, Ken'ichi FUJITA, Tatsuo OKAUCHI, and Koichi NARASAKA*

(Received September 29, 1988)

β-*C*-2-Deoxyribofuranosides and β-*S*-2-deoxyribofuranosides are prepared stereoselectively from 1-*O*-acetyl-5-*O*-benzyl-3-*O*-[2-(methylsulfinyl)ethyl]-2-deoxy-D-*erythro*-pentofuranose or the corresponding 3-*O*-(2-pyridylmethyl)pentofuranose *N*-oxide by the reaction with silyl enol ethers or trimethlsilyl sulfides in the presence of a Lewis acid.

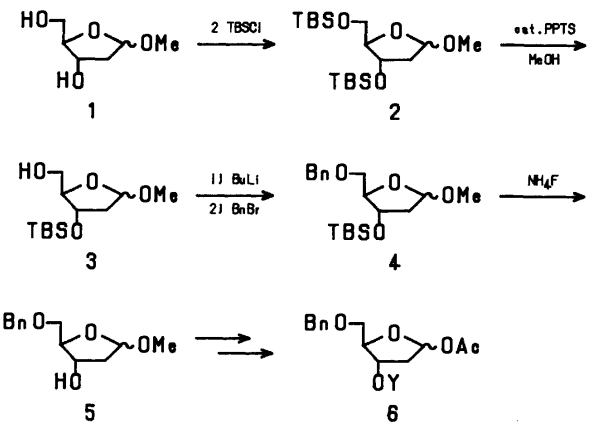
Because of the potential utility in chemotherapeutic studies and in biochemical investigation of specific enzyme-catalyzed reactions, much effort has been devoted to preparing various types of glycoside derivatives.[1] One of the problems in the synthesis of glycoside derivatives is the stereoselective formation of β-glycoside linkages.

In the synthesis of ribofuranosides and xylo-type furanosides which have 2-α-hydroxyl group, the formation of β-glycoside linkage is generally controlled by using neighboring group participation of the adjacent 2-α-*O*-acyl group (so called the Baker's 1,2-trans rule).[2] On the other hand, there is no generally applicable method to obtain β-isomers stereoselectively in the case of the preparation of glycosides which possess no 2-α-hydroxyl group such as 2-deoxy-, 2-fluoro-, and 2-arabino-type glycosides.[1-3] The exceptional high β-selectivity has been reported only in the S_N2 type displacement of 2-deoxy-α-D-*erythro*-pentofuranosyl halide by purine derivatives or cyanide under basic conditions[4] and by silylated pyrimidine[5] and 5-(acetyl)thiouracil[6] derivatives under the modified Hilbert–Johnson conditions.[5]

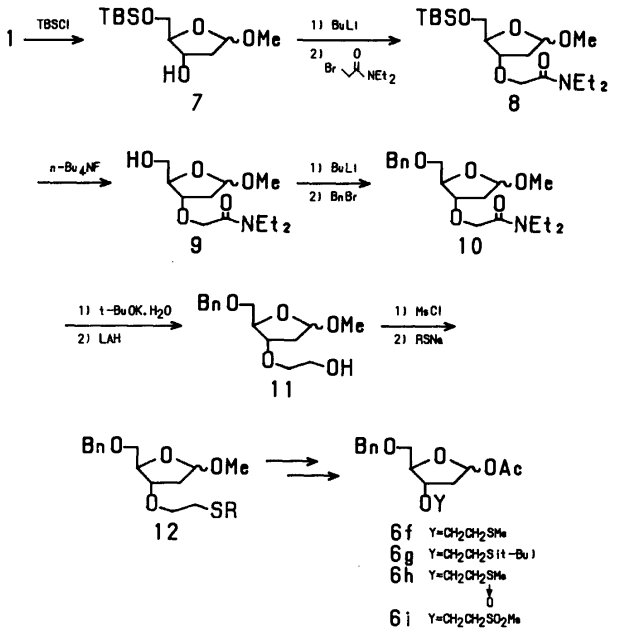
In this paper, we wish to report the results on the stereocontrol in glycosylation reaction by neighboring group participation of a 3-α-*O*-substituent of 2-deoxy-D-*erythro*-pentofuranose (2-deoxyribofuranose) derivatives.[7] It was considered that when a suitable 3-*O*-subtituent was introduced instead of an acyl group for stabilizing the 1-cationic center in acid catalyzed glycosylation reactions, the stereoselection of the glycosylation would be controlled to give β-glycosides selectively. We, therefore, investigated *C*-glycosylation of 2-deoxyribofuranose derivatives with silyl enol ethers in the presence of a Lewis acid employing 1-*O*-acetyl-5-*O*-benzyl-2-deoxyribofuranoses which have various substituents on the 3-hydroxyl group.

Various 3-*O*-substituted 2-deoxyribofuranoses such as 3-*O*-substituted 1-*O*-acetyl-5-*O*-benzyl-2-deoxyribofuranoses **6a—e** and 1-*O*-acetyl-5-*O*-benzyl-3-*O*-[2-(alkylthio)ethyl]-2-deoxyribofuranose **6f—i** are prepared from methyl 2-deoxy-D-ribofuranoside, and the synthetic pathways are outlined in Schemes 1 and 2, respectively.

In these courses of the synthses, alkylation reaction reaction of the 3- or 5-hydroxy intermediates containing a silyl protective group (**3** and **7**) met some troubles in the conventional reaction conditions (NaH/DMF),



Scheme 1.



Scheme 2.

because of the migration of the silyl group and a low yield of the desired alkylated product. However, the alkylation was found to proceed even at room temperature affording the alkylated products in excellent yield, when the lithium alkoxides of **3** and **7** generated by treatment with *n*-BuLi or *t*-BuOLi were treated with bromides in the presence of sodium iodide and hexamethylphosphoric triamide (HMPA) in tetrahydrofuran (THF). This procedure appears to be of general utility in alkylation of other hydroxy compounds **5** and **9**.

At first, the reaction of 3-*O*-benzyl derivative **6a** with 1-trimethylsilyloxy-1-phenylethylene **13a** was examined at −78 °C in dichloromethane in the presence of $SnCl_4$,[8] and the α-*C*-glycoside **14a** was found to be produced in good selectivity (α-**14a**:β-**14a**=82:18). This result means that the introduction of such a group like benzyl group which would not tightly interact with the 1-cationic center results in the highly preferential formation of the α-glycoside.

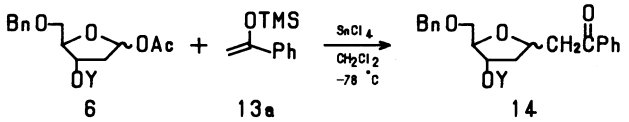


Table 1. Stereoselectivity of the Reaction of **6** and **13a**

6	Y	Yield of **14**/%	α : β
6a	CH_2Ph	92	82 : 18
6b	$CH_2OCH_2CH_2OMe$	83	75 : 25
6c	CH_2SMe	56	82 : 18
6d	$CH_2S(O)Me$	53	52 : 48
6e		87	49 : 51
6f	CH_2CH_2SMe	46	42 : 58
6g	$CH_2CH_2SBu^t$	44	68 : 32
6h	$CH_2CH_2S(O)Me$	92	32 : 68
6i	$CH_2CH_2SO_2Me$	54	50 : 50

In order to find out the suitable substituent for the selective preparation of the β-isomer, effects of the 3-*O*-substituents on the stereoselectivity were examined using various 3-*O*-derivatives and the results are listed in Table 1. Among a variety of 3-substituents such as ethers, esters, and sulfides, 2-(alkylthio)ethyl group was found to afford slight excess amounts of the β-isomer. That is, by employing **6f** which has 2-(methylthio)-ethyl group, the corresponding *C*-glycosides **14f** were obtained in 46% yield in the ratio of α:β=42:58.

It was also noted that the reaction in a solvent which has little donor ability[9] such as dichloromethane or toluene exhibited higher selectivity as compared with a solvent having large donar property (for example, α:β=89:11 in acetonitrile). The ratio of the α-isomer to the β-isomer was not influenced by the kind of Lewis acids, namely $SnCl_4$,[8] trityl perchlorate,[10] and trimethylsilyl trifluoromethanesulfonate (TMSOTf).[11]

Then, 2-(methylthio)ethyl derivative **6f** was converted to the corresponding sulfoxide **6h** by considering that the participation by the sulfinyl group should be more efficient with respect to the electronic and steric effects. The sulfoxide **6h** actually reacted with the silyl enol ether **13a**, giving the β-*C*-glycoside β-**14h** predominantly (α-**14h**:β-**14h**=32:68) in an excellent yield. Reaction of an analogous *N*-oxide derivative **6e** having 2-pyridylmethyl group *N*-oxide as a 3-*O*-functionality, however, afforded almost equal amount of α- and β-isomers.

As the introduction of 3-*O*-methylsulfinyl group revealed to realize a good β-selectivity, the reactions of

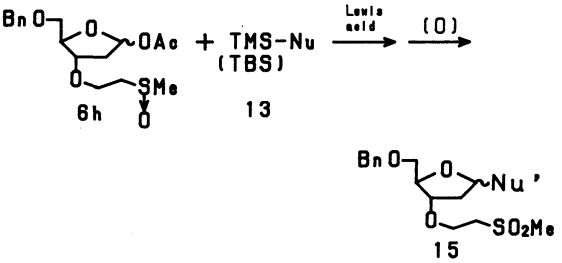

Table 2. Reaction of **6h** with Silyl Nucleophiles **13**

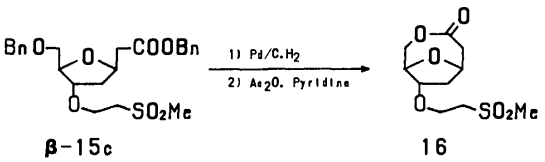
	Nucleophile	Lewis acid	**15**, Nu′	Yield **15**/%	α : β
13a		$SnCl_4$	CH_2COPh	92	32 : 68
13b		$SnCl_4$	CH_2COMe	82	22 : 78
13c		TMSOTf	CH_2COOCH_2Ph	86	9 : 91
13d		TMSOTf	CH(OH)COOMe	91	11 : 89
13e		TMSOTf	$C(OMe)_2COOMe$	73	33 : 67
13f		$SnCl_4$	$CH_2CH=CH_2$	50	87 : 13

6h with several silyl nucleophiles were examined using $SnCl_4$ or TMSOTf as a Lewis acid, and the results are summarized in Table 2.

The stereochemistry and the isomer ratio of these products are determined after conversion of the products to the corresponding sulfones **15**. The configuration of the major isomer of the *C*-glycosides **15c** was determined as the β-configuration by the transformation of **15c** into a lactone **16** by hydrogenolysis and successive treatment with acetic anhydride–pyridine.



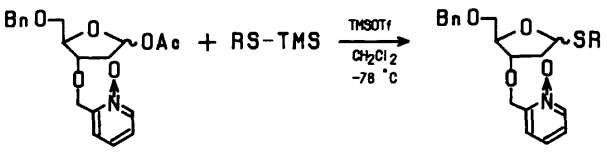
β-15c 16

Stereochemistry and isomer ratio of other products were determined by HPLC and by the comparison of their 400 MHz or 270 MHz ^1H NMR spectra with that of the above glycosides **15c**, in which the characteristic pattern of C-2 proton(s) appears as shown in Table 3.

The results in Table 2 clearly show that the stereoselectivity largely depends on the nucleophilicity of silyl nucleophiles. For example, allyltrimethylsilane, a weak nucleophile as compared with silyl enol ethers, affords the corresponding α-isomer predominantly. On the other hand, reaction with ketene silyl acetals **13c** and **13d**, gave the corresponding β-isomers **β-15c** and **β-15d** in about 90% selectivity.

Consequently, useful synthetic intermediates such as **15c** and **15d** for the synthesis of various *C*-nucleosides[12] were prepared in a highly β-selective manner by using the neighboring group participation of methylsulfinylethyl group on the 3-hydroxyl group. The 2-(methylsulfinyl)ethyl group was found to be easily removed after conversion to 2-(methylsulfonyl)-ethyl group by treatment with potassium *t*-butoxide in 1,2-dimethoxyethane at 0 °C.

Next, we applied this stereocontrol to prepare *S*-glycosides from 2-deoxyribofuranose. In the synthesis of *S*-glycosides, 2-(methylsulfinyl)ethyl group is not considered to be suitable because thioglycoside bond would be cleaved in the deprotecting process of the 2-(methylsulfinyl)ethyl group (oxidation followed by base treatment). 2-Pyridylmethyl group *N*-oxide was therefore chosen as a 3-*O*-protective group, and the reaction of **6e** with trimethlysilyl sulfides was tried in the presence of TMSOTf at −78 °C in dichloromethane, and the corresponding β-*S*-glycosides **β-17** were prepared predominantly as shown in the following table.



6e 17

Table 4. Reaction of **6e** with Trimethylsilyl Sulfides

17	R	Yield/%	α : β
17a	Et	83	16 : 84
17b	$PhCH_2$	77	25 : 75
17c	*i*-Pr	75	21 : 79
17d	t-Bu-	82	35 : 65

In these reactions, better selectivity was also observed by employing silyl sulfide having better nucleophilicity such as ethyl trimethylsilyl sulfide. The produced β-ethylthioglycoside **β-17a** isomerized by treatment with $SnCl_4$ at 0 °C, and quenching the reaction after cooling to −78 °C afforded an α-major mixture (α:β=75:25). Consequently, the β-selectivity of the above *S*-glycosylation reaction at −78 °C is indicated to be controlled kinetically.

Furthermore, when 3-*O*-benzyl derivative **6a** was

a) Overlapped with other signals(s). b) Poorly resolved.

employed in the reaction with ethyl trimethylsilyl sulfide under the same reaction conditions, the product was isolated as a 1:1 mixture of the α- and β-isomers, These results apparently show that the neighboring group participation from 3-*O*-functionality plays the efficient role to control the stereochemistry in acid catalyzed glycosylation reactions.

Experimental

General. The IR spectra were determined on a Hitachi Model 260-30 spectrometer. The ^{1}H NMR spectra were recorded with Hitachi R-24B, JEOL GX-270, and/or JEOL GX-400 spectrometers in $CDCl_3$ with tetramethylsilane as an internal standard, unless otherwise noted. The optical rotations were carried out on a JMN DIP-181 polarimeter. HPLC analyses were performed on μPorasil P/N 27477 S/N or Resolve 5μ-silica with Shimadzu LC-6A system. All reactions except for hydrolysis were carried out under an anhydrous argon atmosphere. The reaction mixtures and combined extracts were dried over Na_2SO_4, if necessary, and concentrated in vacuo by an evaporator at 30—40 °C. Purification of products was performed by column chromatography on silica gel (Wakogel C-200 or Merck, Art. 9385 Kieselgel 60, 230—400 mesh). Acetonitrile, dichloromethane, HMPA, and *N,N*-dimethylformamide (DMF) were distilled from CaH_2 and stored over Molecular Sieves. Tetrahydrofuran (THF) was freshly distilled from sodium benzophenone ketyl. Methanol was distilled with $Mg(OMe)_2$ and stored over Molecular Sieves. The 3-*O*-substituted 1-*O*-acetyl-5-*O*-benzyl-2-deoxy-D-ribofuranoses were prepared as their anomeric mixtures throughout the synthetic course, and the elemental analyses were carried out when samples were purified as each single isomer.

Methyl 5-*O*-*t*-Butyldimethylsilyl-2-deoxy-D-*erythro*-pentofuranoside (7). To a solution of methyl 2-deoxy-D-*erythro*-pentofuranoside[13] (**1**) (7.41 g, 50 mmol), triethylamine (6.37 g, 63 mmol), and 4-(dimethylamino)pyridine (DMAP) (cat. amount) in dichloromethane–DMF (10/1, v/v) (110 ml) was added *t*-butyldimethylsilyl chloride (7.91 g, 52 mmol) at 0 °C. After stirring at ambient temperature overnight, the mixture was quenched with pH 7 phosphate buffer and the organic layer was extracted with dichloromethane. The extract was washed with water and aqueous NaCl and dried. The dichloromethane solution was evaporated and the residue was purified by column chromatography (ethyl acetate:hexane=1:3, v/v) to give methyl 5-*O*-*t*-butyldimethylsilyl-2-deoxy-D-ribofuranoside (**7**) (10.81 g, 82%): α-isomer; $[\alpha]_D^{25}$ −87.1° (*c* 0.982, $CHCl_3$); IR(neat) 3400, 2920, 1100, 835, 780 cm^{-1}; ^{1}H NMR δ=0.05 (6H, s), 0.89 (9H, s), 1.73—2.43 (2H, m), 2.93 (1H, d, *J*=10.5 Hz), 3.40 (3H, s), 3.47—3.93 (2H, m), 3.93—4.43 (2H, m), 5.07 (1H, dd, *J*=1.5, 4.0 Hz); Found: C, 54.76; H, 10.13%. Calcd for $C_{12}H_{26}O_4Si$: C, 54.92; H, 9.99%. β-Isomer; $[\alpha]_D^{24.7}$ +85.8 (*c* 1.053, $CHCl_3$); IR(neat) 3400, 2920, 1100, 835, 780 cm^{-1}; ^{1}H NMR δ=0.08 (6H, s), 0.91 (9H, s), 1.83—2.37 (2H, m), 2.50 (1H, brs), 3.35 (3H, s), 3.47—4.37 (3H, m), 4.43 (1H, m), 5.07 (1H, dd, *J*=3.5, 5.5 Hz); Found: C, 54.66; H, 10.07%. Calcd for $C_{12}H_{26}O_4Si$: C, 54.92; H, 9.99%.

Alkylation of Hydroxy Compounds via Lithium Alkoxides: Methyl 5-*O*-*t*-Butyldimethylsilyl-2-deoxy-3-*O*-(diethylcarbamoyl)methyl-D-*erythro*-pentofuranoside (8). To a solution of monosilylated methyl furanoside (**7**) (17.92 g, 68.3 mmol) and NaI (10.2 g, 68 mmol) in THF (200 ml) was added slowly the solution of *n*-BuLi in hexane (45 ml, 68.2 mmol) at −78 °C, and the mixture was stirred at the same temperature for 30 min. After addition of HMPA (23.8 ml, 136 mmol) and freshly distilled *N,N*-diethy-l-bromoacetamide (11.6 ml, 81.9 mmol), the mixture was stirred at room temperature overnight. After addition of diethylamine (5 ml) and stirring for 1 h, pH 7 phosphate buffer was added, and the mixture was extracted with ether. The ether extract was washed with water and aqueous NaCl and dried. The ether solution was concentrated and the residue was purified by column chromatography (ethyl acetate:hexane=1:3—2:1, v/v) to give the alkylated silyl compound **8** (23.22 g, 91%): α-isomer; $[\alpha]_D^{26}$ +73.6° (*c* 1.09, $CHCl_3$); IR(neat) 2930, 1650, 1460, 1260, 1100, 840, 780 cm^{-1}; ^{1}H NMR δ=0.05 (6H, s), 0.88 (9H, s), 1.13 (6H, brt, *J*=7.0 Hz), 2.00—2.20 (2H, m), 3.32 (4H, q, *J*=7.0 Hz), 3.33 (3H, s), 3.53—3.75 (2H, m), 3.90—4.23 (2H, m), 4.10 (2H, s), 4.97 (1H, dd, *J*=2.8, 4.0 Hz); Found: C, 57.31; H, 10.01; N, 3.73%. Calcd for $C_{18}H_{37}NO_5Si$: C, 57.56; H, 9.93; N, 3.73%. β-Isomer; $[\alpha]_D^{22.6}$ −58.6° (*c* 0.517, $CHCl_3$); IR(neat) 2930, 1650, 1460, 1260, 1110, 840, 780 cm^{-1}; ^{1}H NMR δ=0.09 (6H, s), 0.90 (9H, s), 1.16 (6H, brt, *J*=7.0 Hz), 2.05—2.33 (2H, m), 3.05—3.80 (6H, m), 3.26 (3H, s), 3.80—4.28 (2H, m), 4.09 (2H, s), 5.03 (1H, t, *J*=4.2 Hz); Found: C, 57.32; H, 9.78; N, 3.76%. Calcd for $C_{18}H_{37}NO_5Si$: C, 57.56; H, 9.93; N, 3.73%.

Methyl 2-Deoxy-3-*O*-(diethylcarbamoyl)methyl-D-*erythro*-pentofuranoside (9). An 1 M-solution (1 M=1 mol dm^{-3}) of tetrabutylammonium fluoride in THF (6 ml, 6 mmol) was added to a solution of the above silyl compound **8** (1.88 g, 5.0 mmol) in THF (5 ml) at 0 °C and the mixture was stirred for 5 h at room temperature. Then the mixture was concentrated and purified by column chromatography (ethyl acetate:methanol=30:1—20:1, v/v) to give the hydroxy compound **9** (1.26 g, 96%): α-isomer; $[\alpha]_D^{26}$ +161.9° (*c* 1.461, $CHCl_3$); IR(neat) 3400, 2920, 1630, 1100 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.95—1.40 (6H, m), 1.80—2.40 (2H, m), 3.10—4.15 (9H, m), 3.30 (3H, s), 4.07 (2H, s) 4.90 (1H, dd, *J*=2.0, 5.2 Hz). β-Isomer; $[\alpha]_D^{26}$ −33.9° (*c* 0.577, $CHCl_3$); IR(neat) 3400, 2920, 1630, 1100 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.17 (6H, brt, *J*=7.0 Hz), 1.90—2.23 (2H, m), 2.70 (1H, br), 3.10—3.80 (6H, m), 3.25 (3H, s), 3.80—4.30 (2H, m), 4.07 (2H, s), 4.93 (1H, dd, *J*=2.5, 4.7 Hz).

Methyl 5-*O*-Benzyl-2-deoxy-3-*O*-(diethylcarbamoyl)methyl-D-*erythro*-pentofuranoside (10). Alkylation of methyl 2-deoxy-3-*O*-(diethylcarbamoyl)methyl-D-*erythro*-pentofuranoside (**9**) (1.20 g, 4.6 mmol) with benzyl bromide (0.94 g, 5.5 mmol) in the same manner as mentioned before gave the benzylated compound **10** (1.40 g, 87%): α-isomer; $[\alpha]_D^{24.5}$ + 90.6° (*c* 0.980, $CHCl_3$); IR(neat) 2940, 1650, 1370, 1210, 1110, 740, 700 cm^{-1}; ^{1}H NMR δ=1.10 (6H, t, *J*=7.0 Hz), 1.80—2.70 (2H, m), 3.05—3.70 (4H, m), 3.37 (3H, s), 3.60 (2H, d, *J*=6.0 Hz), 3.87—4.43 (2H, m), 4.10 (2H, s), 4.54 (2H, s), 5.03 (1H, dd, *J*=2.2, 4.7 Hz), 7.26 (5H, s); Found: C, 64.65; H, 8.50; N, 3.90%. Calcd for $C_{19}H_{29}NO_5$: C, 64.94; H, 8.32; N, 3.99% β-Isomer; $[\alpha]_D^{26}$ −57.0° (*c* 0.965, $CHCl_3$); IR(neat) 2940, 1650, 1370, 1210, 1110, 740, 700 cm^{-1}; ^{1}H NMR δ=1.10 (6H, t, *J*=7.0 Hz), 2.00—2.35 (2H, m), 2.90—3.60 (6H, m), 3.28 (3H, s), 4.07 (2H, s), 3.96—4.40 (2H, m), 4.52 (2H, s), 5.02 (1H, t, *J*=3.8 Hz), 7.26 (5H, s); Found: C, 64.78; H, 8.55; N, 3.76%. Calcd for $C_{19}H_{29}NO_5$: C, 64.94; H, 8.32; N, 3.99%.

Methyl 5-*O*-Benzyl-2-deoxy-3-*O*-(2-hydroxy)ethyl-D-*ery*-

thro-**pentofuranoside (11).** A slurry of the amide **10** (6.06 g 17.2 mmol), *t*-BuOK (12.76 g, 114 mmol), and water (0.62 ml, 34 mmol) in THF (170 ml) was stirred vigorously at room temperature overnight.[14] After addition of ice and water, the mixture was washed with ether. Aqueous layer was acidified with aqueous 2 M $KHSO_4$ and extracted with ether for five times. The ether extract was dried over $MgSO_4$ and evaporated to give the crude carboxylic acid.

To a suspension of lithium aluminum hydride (653 mg, 17.2 mmol) in THF (52 ml) was added dropwise a solution of the above carboxylic acid in THF (10 ml) at 0 °C, and the mixture was stirred at room temperature overnight. To this mixture was added carefully ethyl acetate followed by aqueous 30%-Rochelle salt, and the mixture was extracted with ether. The ether extract was dried and evaporated. Purification of the residue by column chromatography (ethyl acetate:hexane=2:1—1:0, v/v) gave the 2-hydroxyethyl compund **11** (4.15 g, 85%): α-isomer; $[\alpha]_D^{22.5}$ +94.6° (*c* 2.16, $CHCl_3$); IR(neat) 3450, 2900, 1450, 1360, 1200, 1100, 730, 690 cm^{-1}; ^1H NMR δ=1.90—2.25 (2H, m), 2.53 (1H, br), 3.20—4.40 (8H, m), 3.36 (3H, s), 4.52 (2H, s), 5.03 (1H, m), 7.25 (5H, s). β-Isomer; $[\alpha]_D^{22}$ −49.8° (*c* 0.765, $CHCl_3$); IR(neat) 3450, 2900, 1450, 1360, 1200, 1100, 730, 690 cm^{-1}; ^1H NMR δ=2.00—2.30 (2H, m), 2.55 (1H, br), 3.26 (3H, s), 3.30—3.80 (6H, m), 3.80—4.30 (2H, m), 4.52 (2H, s), 5.02 (1H, dd, *J*=2.6, 4.6 Hz), 7.27 (5H, s).

Methyl 5-*O*-Benzyl-2-deoxy-3-*O*-[(2-methylthio)ethyl]-D-*erythro*-pentofuranoside (12f). To a solution of the hydroxyethyl compound **11** (2.30 g, 8.2 mmol) and triethylamine (1.5 g, 14.7 mmol) in dichloromethane (30 ml) was added slowly methanesulfonyl chloride (1.4 g, 12.2 mmol) at 0 °C, and stirred at the same temperature for 30 min. After addition of pH 7 phosphate buffer, the mixture was extracted with ether. The ether extract was dried and evaporated to give the corresponding mesylate.

To a solution of dimethyl disulfide (1.62 ml, 18 mmol) in ethanol (10 ml) was added sodium borohydride (680 mg, 18 mmol) at 0 °C, and the above mesylate was added to the mixture and the resulting mixture was stirred at room temperature overnight. After evaporation of the solvent, followed by addition of water, the mixture was extracted with dichloromethane. The extract was dried and evaporated. The residue was purified by column chromatography (ethyl acetate:hexane=1:3, v/v) to afford 2-(methylthio)ethyl compound **12f** (1.71 g, 91%): α-isomer; $[\alpha]_D^{29}$ +106.7° (*c* 0.588, $CHCl_3$); IR(neat) 2900, 1445, 1360, 1200, 1100, 730, 690 cm^{-1}; ^1H NMR δ=1.95 (3H, s), 1.60—2.10 (2H, m), 2.48 (2H, t, *J*=7.0 Hz), 3.23 (3H, s), 3.30—4.16 (6H, m), 4.45 (2H, s), 4.91 (1H, dd, *J*=2.0, 5.6 Hz), 7.27 (5H, s); Found: C, 61.41; H, 7.84%. Calcd for $C_{16}H_{24}O_4S$: C, 61.51; H, 7.74%. β-Isomer; $[\alpha]_D^{29}$ −43.9° (*c* 1.154, $CHCl_3$); IR(neat) 2900, 1445, 1360, 1200, 1100, 730, 690 cm^{-1}; ^1H NMR δ=2.07 (3H, s), 1.70—2.30 (2H, m), 2.60 (2H, t, *J*=7.0 Hz), 3.26 (3H, s), 3.35—3.73 (4H, m), 3.80—4.30 (2H, m), 4.52 (2H, s), 5.00 (1H, dd, *J*=2.4, 4.4 Hz), 7.25 (5H, s); Found: C, 61.51; H, 7.78%. Calcd for $C_{16}H_{24}O_4S$: C, 61.51; H, 7.74%.

Methyl 5-*O*-Benzyl-2-deoxy-3-*O*-[(2-methylsulfinyl)ethyl]-D-*erythro*-pentofuranoside. To a solution of the methylthio compound **12f** (367 mg, 1.17 mmol) in methanol was added a solution of sodium periodate (265 mg, 1.23 mmol) in water (0.5 ml), and stirred at room temperature overnight. After separation of inorganic precipitates, the filtrate was diluted with dichloromethane and dried. Evaporation of the solution and purification by column chromatography (ethyl acetate:hexane:methanol=5:3:1, v/v/v) gave the methylsulfinyl compound (384 mg, 100%): α-isomer; IR(neat) 2900, 1450, 1360, 1100, 1050, 740, 700 cm^{-1}; ^1H NMR δ=2.00—2.50 (2H, m), 2.55 (3H, s), 2.80—3.10 (2H, m), 3.40 (3H, s), 3.50—3.70 (2H, m), 3.86 (2H, t, *J*=7.4 Hz), 3.95—4.40 (2H, m), 4.60 (2H, s), 5.05 (1H, dd, *J*=2.0, 5.0 Hz), 7.30 (5H, s). β-Isomer; IR(neat) 2900, 1450, 1360, 1100, 1050, 740, 700 cm^{-1}; ^1H NMR δ=1.90—2.40 (2H, m), 2.55 (3H, s), 2.70—3.10 (2H, m), 3.36 (3H, s), 3.40—3.70 (2H, m), 3.80 (2H, t, *J*=7.6 Hz), 3.97—4.35 (2H, m), 4.53 (2H, s), 5.01 (1H, dd, *J*=3.0, 4.6 Hz), 7.26 (5H, s).

1-*O*-Acetyl5-*O*-benzyl-2-deoxy-3-*O*-[(2-methylsulfinyl)-ethyl]-D-*erythro*-pentofuranose (6h). A vigorously stirred mixture of methyl 5-*O*-benzyl-2-deoxy-3-*O*-[(2-methylsulfinyl)ethyl]-D-*erythro*-pentofuranoside (**12f**) (1.47 g, 4.5 mmol) and Dowex 50-X8 (10 ml) in THF-water (2/1, v/v, 12 ml) was maintained at 45 °C for 5 h. After separation of the resin, the filtrate was extracted with dichloromethane. The extract was dried and evaporated to give a residue. To a solution of this residue, pyridine (0.36 ml, 4.5 mmol), and DMAP (67 mg 0.5 mmol) in dichloromethane (10 ml) was added acetic anhydride (0.64 ml, 6.8 mmol) at 0 °C. After stirring the mixture for 1 h at room temperature, the mixture was evaporated and purified by column chromatography (ethyl acetate:hexane:methanol=5:3:1, v/v/v) to give the desired acetate **6h** (1.30 g, 81%): IR(neat) 2900, 1735, 1370, 1240, 1100, 1050, 740, 700 cm^{-1}; ^1H NMR δ=1.93 (2/3×3H, s), 2.02 (1/3×3H, s), 2.10—2.45 (2H. m), 2.55 (2/3×3H, s), 2.58 (1/3×3H, s), 2.70—3.00 (2H, m), 3.51 (2H, d, *J*=5.0 Hz), 3.82 (2H, t, *J*=5.5 Hz), 3.93—4.37 (2H, m), 4.47 (1/3×2H, s), 4.52 (2/3×2H, m), 6.23 (1H, m), 7.26 (5H, s).

Methyl 3,5-Bis[*O*-(*t*-butyldimethylsilyl)]-2-deoxy-D-*erythro*-pentofuranoside (2). This compound was prepared from 2-deoxy-D-ribose by the same procedure used for the compound **7** except for using 2.6 equiv of *t*-butyldimethylsilyl chloride and 3.0 equiv of triethylamine in 87% yield. IR(neat) 2950, 1480, 1260, 1120, 840, 780 cm^{-1}; ^1H NMR δ=0.08 (12H, s), 0.88 (18H, s), 1.53—2.65 (2H, m), 3.33 (1/3×3H, s), 3.36 (2/3×3H, s), 3.50—4.10 (3H, m), 4.10—4.62 (1H, m), 4.85—5.18 (1H, m).

Methyl 3-*O*-*t*-Butyldimethylsilyl-2-deoxy-D-*erythro*-pentofuranoside (3). A solution of the disilyl compound **2** (25.6 g, 68 mmol) and pyridinium *p*-toluenesulfonate (1.58 g, 6.3 mmol) in methanol (80 ml) was stirred at room temperature for 1 d. After addition of aqueous Na_2CO_3, the reaction mixture was concentrated followed by extraction with dichloromethane. The extract was washed with water and then aqueous NaCl, dried, and evaporated. Separation of the residue by column chromatography (ethyl acetate:hexane=1:5—1:1, v/v) gave the recovered starting disilyl compound **2** (8.5 g, 33% recovered) and the desired 3-*O*-monosilylated compound **3** (9.75 g, 55%): α-isomer; IR(neat) 3400, 2930, 1460, 1250, 1100, 840, 790 cm^{-1}; ^1H NMR δ=0.05 (6H, s), 0.89 (9H, s), 1.73(1H, ddd, *J*=3.0, 6.0, 13.5 Hz), 2.27 (1H, ddd, *J*=5.5, 8.0, 13.5 Hz), 2.37 (1H, s), 3.27 (3H, s), 3.33—3.87 (3H, m), 4.13 (1H, dt, J_d=8.0 Hz, J_t=6.0 Hz), 4.83 (1H, dd, *J*=3.0, 5.5 Hz). β-Isomer; IR(neat) 3400, 2930, 1250, 1100, 840 cm^{-1}; ^1H NMR δ=0.07 (6H, s), 0.87 (9H, s), 1.67—2.23 (2H, m), 2.30 (1H, t, *J*=6.0 Hz), 3.28 (3H, s), 3.33—3.67 (2H, m), 3.80 (1H, m), 4.38 (1H, dt, J_d=4.0 Hz, J_t=6.0 Hz), 4.92 (1H, dd, *J*=2.5, 4.5 Hz).

Methyl 5-*O*-Benzyl-3-*O*-*t*-butyldimethylsilyl-2-deoxy-D-*ery*-

thro-pentofuranoside (**4**). According to the method for alkylation, the 3-*O*-monosilylated compound **3** was alkylated by benzyl bromide to the 5-*O*-benzyl-3-*O*-silyl derivative **4** in 92% yield: IR(neat) 2900, 1470, 1360, 1260, 1100, 840, 780, 700 cm^{-1}; ^1H NMR δ=0.05 (6H, s), 0.83 (9H, s), 1.50—2.62 (2H, m), 3.27 (1/2×3H, s), 3.33 (1/2×3H, s), 3.40—3.66 (2H, m), 3.70—4.45 (2H, m), 4.51 (2H, s), 4.80—5.10 (1H, m), 7.22 (5H, s).

Methyl 5-*O*-Benzyl-2-deoxy-D-*erythro*-pentofuranoside (5). Compound **5** was prepared from the above 5-*O*-benzyl-3-*O*-silyl compound **4** by the same procedure used for the compound **9** in 98% yield: IR(neat) 3450, 2900, 1100, 740, 700 cm^{-1}; ^1H NMR δ=1.80—2.14 (2H, m), 2.45—3.00 (1H, m), 3.27 (2/5×3H, s), 3.35 (3/5×3H, s), 3.30—3.60 (2H, m), 3.60—4.30 (2H, m), 4.44 (2H, brs), 4.75—4.98 (1H, m), 7.26 (5H, s).

Methyl 5-*O*-Benzyl-2-deoxy-3-*O*-(2-pyridylmethyl)-D-*erythro*-pentofuranoside *N*-Oxide. To a mixture of the methyl 5-*O*-benzyl-2-deoxyriboside **5** (480 mg, 2 mmol), sodium iodide (750 mg, 5 mmol), and *t*-butyl alcohol (296 mg, 4 mmol) in THF (7 ml) was added 60% sodium hydride (240 mg, 6 mmol), and the mixture was stirred for 1 h at room temperature. Then 2-(chloromethyl)pyridine *N*-oxide hydrochloride (558 mg, 3 mmol) was added to the mixture are the resulting mixture was stirred for 12 h at room temperature. After addition of pH 7 phosphate buffer, the organic compounds were extracted with the combined solvent (ether:ethanol=20:1, v/v). The extract was dried and evaporated. Purification of the residue by column chromatography (ethyl acetate:hexane:methanol=5:3:1, v/v/v) gave the titled compound (624 mg, 90%): IR(neat) 2920, 1500, 1435, 1360, 1250, 1100, 1050, 860, 770, 740, 700 cm^{-1}; ^1H NMR δ=2.00—2.33 (2H, m), 3.25 (2/5×3H, s), 3.33 (3/5×3H, s), 3.40—3.70 (2H, m), 3.90—4.45 (2H, m), 4.50 (2H, s), 4.69 (2H, s), 4.90—5.15 (1H, m), 6.95—7.70 (8H, m), 7.90—8.22 (1H, m).

1-*O*-Acetyl-5-*O*-benzyl-2-deoxy-3-*O*-(2-pyridylmethyl)-D-*erythro*-pentofuranose *N*-Oxide (6e). According to the procedure used for the compound **6h**, methyl 5-*O*-benzyl-2-deoxy-3-*O*-(2-pyridylmethyl)-D-*erythro*-pentofuranoside *N*-oxide was hydrolyzed then acetylated to give the 1-*O*-acetyl compound **6e** in 85% yield: IR(neat) 2900, 1730, 1480, 1420, 1360, 1230, 1100, 1000, 840, 760, 730, 690 cm^{-1}; ^1H NMR δ=1.93 (2/3×3H, s), 2.00 (1/3×3H, s), 2.10—2.50 (2H, m), 3.40—3.70 (2H, m), 4.10—4.60 (2H, m), 4.53 (2H, s), 4.73 (2H, s), 6.22—6.40 (1H, m), 6.90—7.60 (8H, m), 8.05—8.30 (1H, m).

Other 3-*O*-substituted 5-*O*-benzyl-2-deoxy-D-*erythro*-pentofuranosides listed in Table 1 were prepared by the essentially same procedure described above.

***C*-Glycosylation Reaction: Benzyl 5-*O*-Benzyl-2-deoxy-3-*O*-[(2-methylsulfonyl)ethyl]-D-*erythro*-pentofuranosylacetate (15c).** To a solution of methylsulfinyl compound (**6h**) (188 mg, 0.53 mmol) and 1-benzyloxy-1-(*t*-butyldimethylsilyloxy)ethylene (**13c**) (177 mg, 0.67 mmol) in dichloromethane (10 ml) was added a solution of TMSOTf (178 mg, 0.80 mmol) in dichloromethane (2 ml) slowly at −78 °C, and the mixture was stirred for 12 h at this temperature. The reaction mixture was quenched by addition of pH 7 phosphate buffer and the mixture was extracted with dichloromethane. The dichloromethane extract was dried and evaporated. After purification of the residue by column chromatography (ethyl acetate:hexane:methanol=5:3:1, v/v/v), the products were dissolved in methanol (10 ml) and oxidized by 10% H_2O_2 (10 ml) at room temperature in the presence of ammonium molybdate (VI) tetrahydrate (100 mg, 0.08 mmol) at room temperature. The reaction mixture was extracted with dichloromethane and dried, then followed by evaporation of the solvent. Purification of the residue by column chromatography (ethyl acetate:hexane=2:1, v/v) gave the mixture of the isomers of the *C*-glycoside **15c** (220 mg, 86%) (α:β=9:91): IR(neat) 2900, 1730, 1450, 1300, 1100, 740, 690 cm^{-1}; ^1H NMR δ=1.72 (9/10×1H, ddd, J=6.4, 10.1, 13.4 Hz), 1.78 (1/10×1H, m), 2.13 (9/10×1H, dd, J=5.2, 13.4 Hz), 2.39 (1/10×1H, td, J_t=6.8 Hz, J_d=13.4 Hz), 2.57 (1H, dd, J=6.5, 15.8 Hz), 2.72 (1H, dd, J=6.5, 15.8 Hz), 2.88 (1/10×3H, s), 2.92 (9/10×3H, s), 3.17 (2H, t, J=5.6 Hz), 3.38 (1H, dd, J=6.2, 10.2 Hz), 3.53 (1H, dd, J=4.3, 10.2 Hz), 3.82 (1H, dd, J=6.5, 11.7 Hz), 3.86 (1H, dd, J=5.6, 11.7 Hz), 3.96—4.01 (1H, m), 4.01—4.07 (1H, m), 4.37—4.48 (1H, m), 4.52 (2H, s), 5.13 (2H, s), 7.25—7.38 (10H, m).

The characteristic patterns of C-2 protons in NMR spectrum were summerized in Table 3 together with those of the other *C*-glycosides.

2-[5-*O*-Benzyl-2-deoxy-3-*O*-[(2-methylsulfonyl)ethyl]-D-*erythro*-pentofuranosyl]-1-phenylethanone (15a): IR(neat) 2920, 1680, 1600, 1450, 1310, 1130, 740, 695 cm^{-1}; ^1H NMR δ=1.50—2.50 (2H, m), 2.89 (1/3×3H, s), 2.96 (2/3× 3H, s), 3.00—3.26 (4H, m), 3.40—3.58 (2H, m), 3.77—4.44 (4H, m), 4.53 (2H, s), 4.55—4.85 (1H, m), 7.25—7.65 (8H, m), 7.90—8.10 (2H, m).

1-[5-*O*-Benzyl-2-deoxy-3-*O*-[(2-methylsulfonyl)ethyl]-D-*erythro*-pentofuranosyl]-2-propanone (15b): IR(neat) 2900, 1710, 1310, 1290, 1130, 1100, 740, 700 cm^{-1}; ^1H NMR δ=1.40—2.40 (2H, m), 2.16 (3H, s), 2.50—2.90 (1H, m), 2.92 (3H, s), 3.00—3.60 (4H, m), 3.70—4.10 (4H, m), 4.10—4.50 (1H, m), 4.51 (2H, s), 7.30 (5H, s).

Methyl 2-[5-*O*-Benzyl-2-deoxy-3-*O*-[(2-methylsulfonyl)-ethyl]-D-*erythro*-pentofuranosyl]glycolate (15d): IR(neat) 3470, 2900, 1735, 1120, 740, 700 cm^{-1}; ^1H NMR δ=1.60—2.45 (2H, m), 2.90 (3H, s), 3.00—3.65 (5H, m), 3.70—4.60 (9H, m), 4.50 (2H, s), 7.26 (5H, s).

Methyl 5-*O*-Benzyl-2-deoxy-3-*O*-[(2-methylsulfonyl)ethyl]-D-*erythro*-pentofuranosylacetate (15d'). To a solution of methyl 2-[5-*O*-benzyl-2-deoxy-3-*O*-[(2-methylsulfonyl)ethyl]-D-*erythro*-pentofuranosyl]glycolate (**15d**) (78 mg, 0.19 mmol), triethylamine (50 mg, 0.35 mmol), and DMAP (cat. amount) in anhydrous acetonitrile (3 ml) was added phenyl carbonochloridothioate (60 mg, 0.35 mmol) at 0°C and the solution was stirred at room temperature for 1 d. After addition of pH 7 phosphate buffer, the mixture was extracted with dichloromethane. The extract was dried and evaporated. The residue was purified by column chromatography (ethyl acetate:hexane=2:1, v/v) to give corresponding thiocarbonate (74 mg, 77%): ^1H NMR δ=1.75—2.40 (2H, m), 2.90 (3H, s), 3.00—3.60 (4H, m), 3.65—4.30 (6H, m), 4.48 (2H, s), 4.30—4.80 (1H, m), 5.56 (1H, dd, J=3.6 Hz, 8.0 Hz), 6.90—7.60 (5H, m), 7.25 (5H, s).

A solution of the thiocarbonate obtained above (74 mg, 0.146 mmol), tributyltin hydride (47 mg., 0.162 mmol), and azobisisobutyronitrile (cat. amount) in dry toluene (5 ml) was heated under reflux for 2 h. Evaporation of the mixture and purification of the residue by column chromatography (ethyl acetate:hexane=1:2, v/v) gave the deoxygenated compound (**15d'**) (42 mg, 75%): IR(neat) 2900, 1735, 1100, 745, 705 cm^{-1}; ^1H NMR δ=1.72 (9/10×1H, ddd, J=6.7, 11.0,

13.4 Hz), 1.82 (1/10×1H, m), 2.16 (9/10×1H, ddd, J=1.2, 5.1, 13.4 Hz), 2.40 (1/10×1H, td, J_t=6.4 Hz, J_d=13.3 Hz), 2.53 (1H, dd, J=6.1, 15.6 Hz), 2.67 (1H, dd, J=6.9, 15.6 Hz), 2.94 (1/10×3H, s), 2.96 (9/10×3H, s), 3.19 (2H, t, J=5.5 Hz), 3.41 (1H, dd, J=5.8, 10.0 Hz), 3.55 (1H, dd, J=4.6, 10.0 Hz), 3.68 (3H, s), 3.78—3.93 (2H, m), 3.97—4.18 (2H, m), 4.53 (2H, s), 7.27—7.42 (5H, m).

Methyl 2-[5-*O*-Benzyl-2-deoxy-3-*O*-[(2-methylsulfonyl)-ethyl]-D-*erythro*-pentofuranosyl]-2,2-dimethoxyacetate (15e): IR(neat) 2900, 1740, 1300, 1100, 735, 700 cm^{-1}; ^{1}H NMR δ=1.60—2.40 (2H, m), 2.85 (3H, s), 3.23 (2/5×6H, s), 3.33 (3/5×6H, s), 3.61 (3/5×3H, s), 3.71 (2/5×3H, s), 2.90—4.30 (9H, m), 4.43 (2H, s), 7.20 (5H, s).

3-[5-*O*-Benzyl-2-deoxy-3-*O*-[(2-methylsulfonyl)ethyl]-D-*erythro*-pentofuranosyl]-1-propene (15f): IR(neat) 2900, 1640, 1310, 1290, 1100, 740, 700 cm^{-1}; ^{1}H NMR δ=1.58—1.76 (1H, m), 1.96—2.50 (3H, m), 2.93 (3H, s), 3.18 (2H, t, J=5.4 Hz), 3.36—3.58 (2H, m), 3.77—3.92 (2H, m), 3.97—4.18 (3H, m), 4.55 (2H, s), 5.03—5.15 (2H, m), 5.72—5.88 (1H, m), 7.25—7.38 (5H, m).

(1*R*,6*R*,8*S*)-8-[(2-Methylsulfonyl)ethyl]-3,9-dioxabicyclo-[4.2.1]nonan-4-one (16). The dibenzyl *C*-glycoside **15c** (100 mg, 0.22 mmol) was hydrogenated with 10%-Pd/C (20 mg) in ethanol (1 ml) at 50 °C for 12 h. Separation of the catalyst and evaporation gave the corresponding hydroxy carboxylic acid **15c′** in quantitative yield: IR(neat) 3400, 2950, 1720, 1400, 1280, 1130, 1100, 960, 820, 740 cm^{-1}; ^{1}H NMR (CD_3OD) δ=1.71 (9/10×1H, ddd, J=6.2 10.3, 13.4 Hz), 1.83 (1/10×1H, m), 2.19 (9/10×1H, dd, J=5.6, 13.4 Hz), 2.39 (1/10×1H, m), 2.56 (2H, d, J=6.4 Hz), 3.02 (3H, s), 3.35 (2H, t, J=5.4 Hz), 3.51 (1H, dd, J=5.6, 11.5 Hz), 3.56 (1H, dd, J=5.1, 11.5 Hz), 3.82—3.94 (3H, m), 4.00—4.04 (1H, m), 4.42—4.57 (1H, m).

A solution of the above carboxylic acid **15c′** (33 mg, 0.12 mmol) and acetic anhydride (12 μl, 0.13 mmol) in anhydrous pyridine (12 ml) was heated under reflux for 12 h. The reaction mixture was condensed and purified by silica-gel preparative TLC (ethyl acetate) to give the lactone **16** (14 mg, 45%): IR (CH_2Cl_2) 1740, 1310, and 1100 cm^{-1}; ^{1}H NMR δ=2.15—2.30 (2H, m), 2.89 (1H, dd, J=5.1, 16.5 Hz), 2.98 (3H, s), 3.03 (1H, d, J=16.5 Hz), 3.19—3.24 (2H, m), 3.80—3.93 (2H, m), 4.28 (1H, dd, J=4.0, 13.6 Hz), 4.37 (1H, d, J=13.6 Hz), 4.40—4.45 (2H, m), 4.57—4.63 (1H, m).

S-Glycosilation reactions were performed with essentially the same procedure as the *C*-glycosylation reaction. The IR and NMR data of the *S*-glycosylation products listed in Table 3 are as follows:

Ethyl 5-*O*-Benzyl-2-deoxy-3-*O*-(2-pyridylmethyl)-1-thio-D-*erythro*-pentofuranoside *N*-Oxide (17a): IR(neat) 2850, 1500, 1440, 1360, 1230, 1100, 840, 760, 735, 690 cm^{-1}; ^{1}H NMR δ=1.30 (0.84×3H, t, J=7.5 Hz), 1.32 (0.16×3H, t, J=7.5 Hz), 2.07 (0.16×1H, m), 2.13 (0.84×1H, ddd, J=5.6, 8.6, 13.3 Hz), 2.43 (0.84×1H, ddd, J=3.4 6.0, 13.3 Hz), 2.60—2.80 (2.16H, m), 3.56 (1H, dd, J=6.0, 15.0 Hz), 3.66 (1H, dd, J=5.6, 15.0 Hz), 4.15—4.32 (2H, m), 4.57 (2H, s), 4.74 (1H, d, J=15.5 Hz), 4.82 (1H, d, J=15.5 Hz), 5.40 (0.84×1H, dd, J=6.0, 8.6 Hz), 5.53 (0.16×1H, dd, J=3.7, 7.6 Hz), 7.16—7.40 (7H, m), 7.49—7.63 (1H, m), 8.20 (1H, m).

Benzyl 5-*O*-Benzyl-2-deoxy-3-*O*-(2-pyridylmethyl)-1-thio-D-*erythro*-pentofuranoside *N*-Oxide (17b): IR(neat) 2870, 1485, 1425, 1240, 1085, 850, 760, 730, 690 cm^{-1}; ^{1}H NMR δ=2.02 (0.25×1H, td, J_t=3.0 Hz, J_d=14.2 Hz), 2.15 (0.75×1H, ddd, J=6.4, 7.8, 13.9 Hz), 2.37 (0.75×1H, ddd, J=2.9, 6.4, 13.9 Hz), 2.58 (0.25×1H, td, J_t=7.6 Hz, J_d=14.2 Hz), 3.59 (1H, dd, J=6.0, 13.5 Hz), 3.68 (1H, dd, J=5.0, 13.5 Hz), 3.82 (0.25×1H, d, J=13.5 Hz), 3.83 (0.75×1H, d, J=13.5 Hz), 3.93 (0.25×1H, d, J=13.5 Hz), 3.94 (0.75×1H, d, J=13.5 Hz), 4.13—4.47 (2H, m), 4.58 (2H, s), 4.75 (2H, s), 5.28 (0.75×1H, dd, J=6.4, 7.7 Hz), 5.37 (0.25×1H, dd, J=3.0, 7.6 Hz), 7.14—7.38 (12H, m), 7.45—7.63 (1H, m), 8.20 (1H, m).

Isopropyl 5-*O*-Benzyl-2-deoxy-3-*O*-(2-pyridylmethyl)-1-thio-D-*erythro*-pentofuranoside *N*-Oxide (17c): IR(neat) 2900, 1490, 1430, 1240, 1085, 850, 765, 740, 700 cm^{-1}; ^{1}H NMR δ=1.30 (6H, d, J=7.0 Hz), 1.95—2.18 (1H, m), 2.40—2.78 (1H, m), 3.18 (1H, m), 3.54 (1H, m), 3.66 (1H, m), 4.13—4.43 (2H, m), 4.58 (2H, s), 4.73 (1H, d, J=14.0 Hz), 4.82 (1H, d, J=14.0 Hz), 5.45 (0.79×1H, dd, J=6.2, 8.6 Hz), 5.58 (0.21×1H, dd, J=3.7, 8.1 Hz), 7.16—7.38 (7H, m), 7.48—7.55 (1H, m), 8.22 (1H, m).

4-*t*-Butylphenyl 5-*O*-Benzyl-2-deoxy-3-*O*-(2-pyridylmethyl)-1-thio-D-*erythro*-pentofuranoside *N*-Oxide (17d): IR(neat) 2950, 1420, 1240, 1100, 1080, 840, 760, 730, 690 cm^{-1}; ^{1}H NMR δ=1.29 (0.35×9H, s), 1.30 (0.65×9H, s), 2.10—2.32 (1H, m), 2.40—2.80 (1H, m), 3.56—3.68 (2H, m), 4.20—4.40 (2H, m), 4.48—4.65 (2H, m), 4.75—4.85 (2H, m), 5.58 (0.65×1H, dd, J=6.2, 9.0 Hz), 5.73 (0.35×1H, dd, J=3.1, 7.3 Hz), 7.15—7.35 (9H, m), 7.43—7.68 (3H, m), 8.18—8.33 (1H, m).

Formation of *N*-Tributylstannyl Heterocycle from Bis(tributyltin) Oxide and ω-Haloalkyl Isocyanate. One-Pot Convenient Synthesis of 2-Oxazolidinones and Tetrahydro-2*H*-1,3-oxazin-2-one

Ikuya SHIBATA,* Kenji NAKAMURA, Akio BABA, and Haruo MATSUDA

(Received September 30, 1988)

Novel types of compounds, *N*-tributylstannyl-2-oxazolidinone (**4a**) and tetrahydro-2*H*-1,3-oxazin-2-one (**4b**), are formed from the adduct of $(n\text{-Bu}_3\text{Sn})_2\text{O}$ (**1**) with ω-haloalkyl isocyanate (**2**), and the subsequent coupling reaction with alkyl halides gives a variety of *N*-substituted 2-oxazolidinones and tetrahydro-2-oxazinones in a one-pot procedure. Both the cyclization and the coupling reaction proceed quantitatively in the presence of HMPA which enhances the reactivity of the Sn–heteroatom bond by coordination.

Many organotin reagents have become widely used in organic synthesis.[1] Some important features of tin compounds are facile insertion of a heterocumulene such as an isocyanate toward a Sn–O bond,[2] and a great affinity toward a sulfur[3] or a halogen atom.[4]

We have reported the preparation of five- and six-membered heterocyclic compounds from the adduct of tributyltin ω-haloalkoxides ($n\text{-Bu}_3\text{SnO(CH}_2)_n\text{X}$) with a heterocumulene[5] (Scheme 1), in which a Lewis base plays an important role in the cyclization.

The coordination of a base toward the Sn atom increases the basicity of the adjacent heteroatom, which induces facile cyclization.

In connection with our interest in the use of this type of cyclization, we wish to report here a convenient method for the preparations of new compounds, *N*-tributylstannyl-2-oxazolidinone (**4a**) and tetrahydro-2*H*-1,3-oxazin-2-one (**4b**), by the cyclization of the adduct (**3**), generated from $(n\text{-Bu}_3\text{Sn})_2\text{O}$ (**1**) and ω-haloalkyl isocyanate (**2**). Furthermore, the preparation of a variety of *N*-substituted 2-oxazolidinones and tetrahydro-2-oxazinones by the subsequent coupling reaction could be achieved under mild and neutral conditions (Scheme 2).[6] 2-Oxazolidinones are an important class of heterocyclic compounds which have many biological uses.[7] In particular, the use of *N*-stannyl-2-oxazolidinones and tetrahydro-2-oxazinones in organic synthesis has never been reported, although the silylated analogue is widely known as a silylating agent.[8]

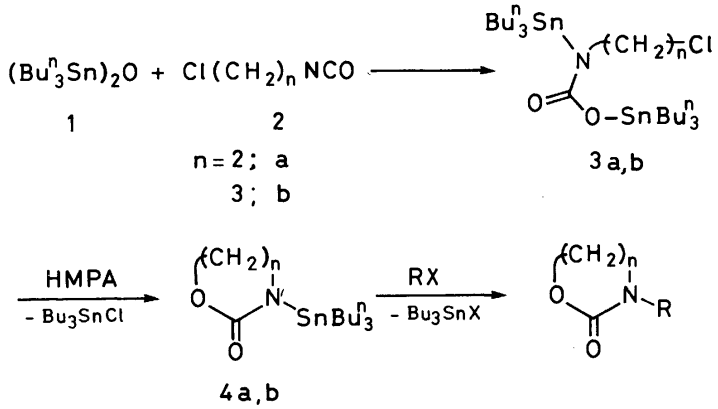
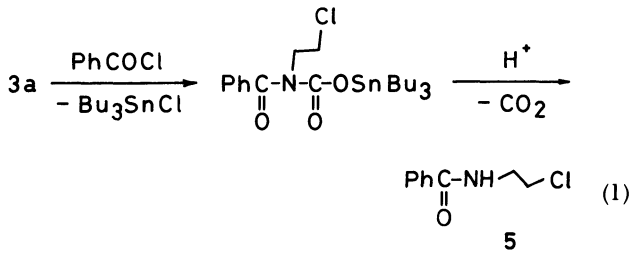


Scheme 2.

Results and Discussion

As shown in Scheme 2, *N*-tributylstannyl-2-oxazolidinone (**4a**) could be readily formed from the reaction of $(n\text{-Bu}_3\text{Sn})_2\text{O}$ (**1**) and 2-chloroethyl isocyanate (**2a**). At first, the isocyanate inserts into the Sn–O bond spontaneously to give *N*-stannylcarbamate (**3a**). This intermediate was indicated by the appearance of an IR absorption band at 1600 cm^{-1} in place of the NCO group (2280 cm^{-1}). ^1H NMR showed the multiplet peaks between δ 3.30 and 3.70 due to methylene groups adjacent the nitrogen and chloro atoms. To trap the intermediate **3a**, we tried the reaction with benzoyl chloride (Eq. 1). The *N*-acylation proceeded smoothly, and subsequent work-up gave the amide (**5**) in 98% yield, accompanied by decarboxylation.

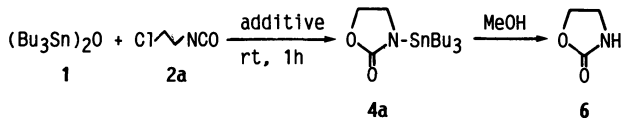


(1)

In the next stage, heating of **3a** induces the cyclization to give **4a**. IR band of the C=O group shifted to 1680 cm^{-1}, and ^1H NMR indicated the peaks of methylene groups adjacent to the nitrogen and chloro groups at δ 3.40—3.80 and 4.25—4.65, respectively. Moreover, GLC analysis showed the quantitative formation of the eliminated by-product, *n*-Bu_3SnCl.

The compound **4a** is so reactive that it was readily protonated to give 2-oxazolidinone (**6**) during work-up. Interestingly, the cyclization step is affected by additives (Table 1). Without any additives, the reaction hardly took place under the mild conditions (Entry 1), and elevated temperature (80 °C) was necessary to complete the cyclization (Entry 1, parentheses). Among the additives, the ones bearing a high coordinating ability toward a Sn atom are effective for the cyclization, and particularly, hexamethylphosphoric triamide (HMPA) was the most suitable one.[9] This coordination increases the basicity of the heteroatom adjacent to the Sn atom. Thus, the cyclization to form **4a** proceeded in high yield at room temperature in the presence of HMPA (Entry 6).

Table 1. Effect of Additive[a]



Entry	Additive	Yield of **6**/%[b]
1	—	tr (98)[c]
2	Et_3N	tr
3	Bu_3P	tr
4	DMF	73
5	Bu_3PO	62
6	HMPA	85

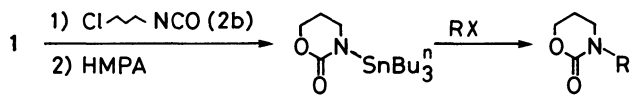
a) **1**; 5 mmol, **2a**; 5 mmol, additive 10 mmol. b) GLC yield. c) 80 °C, 1 h.

We next examined the coupling reactions of **4a** with organic halides. It is possible to carry out a one pot cyclization-coupling reaction by simply adding an acid chloride to the cyclization mixture. In this way, 3-benzoyl-2-oxazolidinone (**7**) was formed directly in 86% yield (Table 2, Entry 1). The acylation proceeded cleanly, affording the corresponding 3-acyl-2-oxazolidinones[10] (**7**—**13**). The yields are good or excellent, no side reactions were observed. Moreover, purification of the products was simple, and the by-product, *n*-Bu_3SnCl, could be removed completely by column chromatography using hexane as an eluent. With a half molar equivalent of oxalyl dichloride and adipoyl dichloride, bis(2-oxazolidinones) (**14**, **15**) were obtained, respectively (Entries 8 and 9).

Other organic halides also gave good yields. Similar to acid chlorides, the reactions with phosphoryl chlorides and a sulfonyl chloride proceeded spontaneously, and gave 3-phosphoryl- and 3-sulfonyl-2-oxazolidinones (**16**—**18**), respectively (Entries 10—12). With activated organic halides such as α-bromo carbonyl compounds, allyl and benzyl bromides, the coupling reactions proceeded at 80 °C to form **19**—**25** in high yields (Entries 13—19).

As in the cyclization reactions, HMPA was found to facilitate these coupling reactions, in contrast to the severe conditions previously reported for the alkylation of *N*-unsubstituted 2-oxazolidinone (**6**).[7a] For example, reaction of **4a** with cinnamyl bromide in the absence of HMPA at 80 °C for 1 h afforded only 31% of compound **22**; in the presence of HMPA, 73% yield was obtained (Entry 16). Apparently, HMPA enhances the reactivity of the Sn–N bond by coordination.

We next tried to prepare six-membered compounds, tetrahydro-2*H*-1,3-oxazin-2-one derivatives, by the analogous reactions using 3-chloropropyl isocyanate (**2b**) (Eq. 2).



(2)

These results are shown in Table 3. Compared to the case of five-membered ring formation, the cyclization to form **4b** required severe conditions (80 °C, 1 h) for completion. Subsequent reaction with organic halides gave a variety of tetrahydro-2-oxazinone derivatives (**26**—**30**) in good yields.

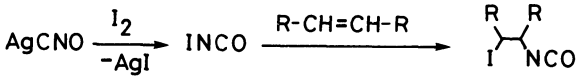
a) At the coupling reaction. b) Isolated yield. c) 0.5 equiv of RX was used.

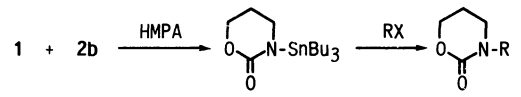
Next, the preparation of 4,5-disubstituted 2-oxazolidinones was accomplished as follows. It is reported that iodine isocyanate (INCO) derived from silver cyanate and iodine, adds to an olefin in a stereospecific manner to produce 2-iodoethyl isocyanates[11] (Eq. 3).



(3)

Employing these substrates, the preparation of 4,5-dialkyl-2-oxazolidinones could be achieved by the

Table 3. Synthesis of Tetrahydro-2-oxazinones



4b

Entry	RX	Condition[a]	Product	Yield/%[b]
1		rt, 10 min	 **26**	100
2		80 °C, 15 h	 **27**	72

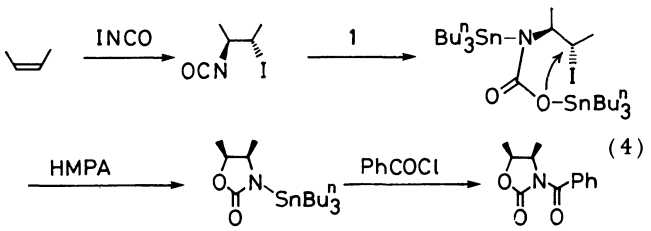
Table 4. Synthesis of 2-Oxazolidinones from Olefins

Entry	Olefin	Product	Yield/%[a]
1		 **31**	88
2		 **32**	98
3		 **33**	66
4		 **34**	50
5		 **35**	52

a) Isolated yield.

combination with our method (Table 4). For example, as shown in Eq. 4, *cis*-2-butene afforded *threo*-iodo isocyanate which reacted with **1** to give the adduct. Next, the cyclization to form *N*-stannyl-2-oxazolidinone proceeded via backside attack of the oxygen on the terminal alkyl iodide.[12] As a result, *cis*-4,5-dimethyl-2-oxazolidinone (**31**) was prepared in 88% overall yield (Entry 1).



(4)

Similarly, the diastereoisomer, *trans*-dimethyl-2-oxazolidinone (**32**), was obtained from *trans*-2-butene (Entry 2).[13] Thus, 4,5-disubstituted 2-oxazolidinones could be easily prepared from olefins in a stereospecific manner by a one-pot reaction. The additional results obtained using other olefins are shown in Table 4.

In summary, we have demonstrated an effective and direct method for the preparation of 2-oxazolidinones and tetrahydro-2*H*-1,3-oxazin-2-ones by using organotin reagents. Our method provides several advantages in terms of mild and neutral conditions, high yields of products and operational convenience.

Experimental

Melting points were obtained by using a Yanaco Micromelting point apparatus and are uncorrected. IR spectra were recorded on a Hitachi 260-30 spectrometer using KBr pelletes or KRS-5 cells. ^{1}H NMR and ^{13}C NMR spectra were performed on Hitachi R-90HS spectrometer. Mass spectra were recorded on a Hitachi RMU-6E instrument. Analytical GLC was performed on Shimadzu GC-3B with TCD using a 2 m×3 mm glass column packed with Silicone OV-1 on uniport HP (5%, 60—80 mesh). Silica-gel column chromatography was used (Wakogel C-200).

Benzoyl-2-chloroethylamide (5). Under dry nitrogen, 0.53 g (5 mmol) of 2-chloroethyl isocyanate (**2a**) was added to 2.98 g (5 mmol) of bis(tributyltin) oxide (**1**). This process to form **3a** proceeded spontaneously. Next, to this solution was added 1.40 g (10 mmol) of PhCOCl at room temperature. After stirring for 10 min, the reaction mixture was chromatographed by silica-gel column, where decarboxylation occurred. Elusion with benzene gave the compound **5** which was purified by recrystallization from benzene–hexane (1:1): Mp 86—87 °C; MS *m/z* 183.5 (M^+); IR 1630 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.50—4.00 (m, 4H, CH_2), 6.35—6.85 (br, 1H, NH), 7.20—7.90 (m, 5H, phenyl). Calcd for $C_9H_{10}NOCl$: C, 58.86; H, 5.45; H, 7.63%. Found: C, 58.55; H, 5.41; N, 7.97%.

3-Benzoyl-2-oxazolidinone (7) (General Procedure for the Preparation of 2-Oxazolidinones): To the liquid of **3a** formed in situ was added 1.80 g (10 mmol) of HMPA. This mixture was stirred at 40 °C for 1 h, giving *N*-stannyl-2-oxazolidinone (**4a**) which was converted to **6** upon MeOH. Without HMPA, the cyclization required severe conditions (80 °C, 1 h). To this mixture containing **4a** was added 0.70 g (5 mmol) of benzoyl chloride at room temperature. After

10 min, the reaction mixture was chromatographed, and purified by recrystallization from benzene–hexane (1 : 1): mp 166—168 °C (lit,[14] mp 168 °C); IR (KBr) 1670, 1770 cm^{-1}; MS *m/z* 191 (M^+); ^1H NMR ($CDCl_3$) δ=3.80—4.35 (m, 2H, $C\underline{H}_2O$), 4.35—4.90 (m, 2H, $C\underline{H}_2N$), 7.10—8.00 (m, 5H, phenyl). The following compounds **8—18** were obtained in a similar manner by using suitable organic halides.

3-Acetyl-2-oxazolidinone (8): Mp 85 °C (lit,[7a] mp 87—87.5 °C); IR (KBr) 1690, 1780 cm^{-1}; MS *m/z* 129 (M^+); ^1H NMR ($CDCl_3$) δ=2.55 (s, 3H, $C\underline{H}_3$), 4.05 (t, *J*=8 Hz, 2H, $C\underline{H}_2N$), 4.45 (t, *J*=8 Hz, 2H, $C\underline{H}_2O$).

3-Isopropionyl-2-oxazolidinone (9): Wax, purified by Kugelrohr distillation at 100 °C/10^{-3} mmHg (1 mmHg= 133.322 Pa); IR (neat) 1700, 1780 cm^{-1}; MS *m/z* 157 (M^+); ^1H NMR ($CDCl_3$) δ=1.20 (d, *J*=7 Hz, 6H, $C\underline{H}_3$), 3.60—3.90 (m, 1H, $Me_2C\underline{H}$), 4.05 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2N$), 4.45 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2O$); Calcd for $C_7H_{11}NO_3$: C, 53.50; H, 7.01; N, 8.92%. Found: C, 53.38; H, 6.98; N, 9.04%.

3-Phenylacetyl-2-oxazolidinone (10): Mp 55—56 °C; IR (KBr) 1690, 1760 cm^{-1}; MS *m/z* 205 (M^+); ^1H NMR ($CDCl_3$) δ=3.95 (t, *J*=8 Hz, 2H, $C\underline{H}_2N$), 4.10—4.60 (m, 4H, $C\underline{H}_2O$ and $PhC\underline{H}_2$), 6.90—7.60 (m, 5H, phenyl); Calcd for $C_{11}H_{11}NO_3$: C, 64.39; H, 5.37; N, 6.83%. Found: C, 64.18; H, 5.07; N, 6.88%.

3-Phenoxyacetyl-2-oxazolidinone (11): Mp 93—95 °C; IR (KBr) 1720, 1790 cm^{-1}; MS *m/z* 221 (M^+); ^1H NMR ($CDCl_3$) δ=4.05 (t, *J*=8 Hz, 2H, $C\underline{H}_2N$), 4.50 (t, *J*=8 Hz, 2H, $C\underline{H}_2O$), 5.25 (s, 2H, $PhOCH_2$), 6.80—7.50 (m, 5H, phenyl); Calcd for $C_{11}H_{11}O_4N$: C, 59.72; H, 4.98; N, 6.33%. Found: C, 59.66; H, 4.93; N, 6.32%.

3-Cinnamoyl-2-oxazolidinone (12): Mp 148—149 °C; IR (KBr) 1620, 1770 cm^{-1}; MS *m/z* 217 (M^+); ^1H NMR ($CDCl_3$) δ=4.00—4.30 (m, 2H, $C\underline{H}_2N$), 4.30—4.60 (m, 2H, $C\underline{H}_2O$), 7.20—8.00 (m, 7H, phenyl and $C\underline{H}_2$=CH-Ph); Calcd for $C_{12}H_{11}NO_3$: C, 66.36; H, 5.07; N, 6.45%. Found: C, 66.24; H, 4.95; N, 6.55%.

3-Benzyloxycarbonyl-2-oxazolidinone (13): Mp 98—100 °C (lit,[7a] mp 101—102 °C); IR (KBr) 1800 cm^{-1}; MS *m/z* 221 (M^+); ^1H NMR ($CDCl_3$) δ=3.80—4.20 (m, 2H, $C\underline{H}_2N$), 4.30—4.60 (m, 2H, $C\underline{H}_2O$), 5.30 (s, 2H, $PhC\underline{H}_2$), 7.20—7.70 (m, 5H, phenyl).

3,3′-Oxalylbis(2-oxazolidinone) (14). The compounds **14** and **15** were prepared by using 0.5 equiv of acyl chlorides: mp 234—236 °C (lit,[7a] mp 238 °C); IR (KBr) 1710, 1790 cm^{-1}; MS *m/z* 228 (M^+); ^1H NMR ($CDCl_3$) δ=4.00—4.50 (m, 4H, $C\underline{H}_2N$), 4.50—4.90 (m, 4H, $C\underline{H}_2O$).

3,3′-Adipoylbis(2-oxazolidinone) (15): Mp 138 °C (lit,[7a] mp 138 °C); IR (KBr) 1710, 1780 cm^{-1}; MS *m/z* 284 (M^+); ^1H NMR ($CDCl_3$) δ=1.70—2.00 (m, 4H, $COCH_2C\underline{H}_2$), 2.96 (t, *J*=7 Hz, 4H, $COC\underline{H}_2$), 4.01 (t, *J*=7 Hz, 4H, $C\underline{H}_2N$), 4.32 (t, *J*=7 Hz, 4H, $C\underline{H}_2O$).

3-Phenylsulfonyl-2-oxazolidinone (16): Mp 136—138 °C (lit,[15] mp 130—135 °C); IR (KBr) 1770 cm^{-1}; MS *m/z* 227 (M^+); ^1H NMR ($CDCl_3$) δ=3.90—4.30 (m, 2H, $C\underline{H}_2N$), 4.30—4.60 (m, 2H, $C\underline{H}_2O$), 7.40—8.20 (m, 5H, phenyl).

3-Diphenyloxyphosphinyl-2-oxazolidinone (17): Mp 94—95 °C; IR (KBr) 1770 cm^{-1}; MS *m/z* 319 (M^+); ^1H NMR ($CDCl_3$) δ=3.84 (t, *J*=8 Hz, 2H, $C\underline{H}_2N$), 4.33 (t, *J*=8 Hz, 2H, $C\underline{H}_2O$), 7.20—7.40 (m, 10H, phenyl); Calcd for $C_{15}H_{14}NO_5P$: C, 56.43; H, 4.39; N, 4.39%. Found: C, 56.57; H, 4.44; N, 4.49%.

3,3′-Phenoxyphosphinylidenebis(2-oxazolidinone) (18). This compound was prepared by using 0.5 equiv of phenyl phosphorodichloridate: mp 158 °C; IR (KBr) 1770 cm^{-1}; MS *m/z* 312 (M^+); ^1H NMR ($CDCl_3$) δ=4.00—4.30 (m, 4H, $C\underline{H}_2N$), 4.40—4.70 (m, 4H, $C\underline{H}_2O$), 7.20—7.50 (m, 5H, phenyl); Calcd for $C_{12}H_{13}N_2O_6P$: C, 46.15; H, 4.17; N, 8.97%. Found: C, 45.99; H, 4.20; N, 8.89%.

3-Phenacyl-2-oxazolidinone (19). The coupling reaction of **4a** formed in situ with phenacyl bromide was performed at 80 °C for 15 h. The following compounds **20—25** were obtained in a similar manner using suitable organic halides: mp 105—108 °C; IR (KBr) 1700, 1750 cm^{-1}; MS *m/z* 205 (M^+): ^1H NMR ($CDCl_3$) δ=3.73 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2N$), 4.45 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2O$), 4.70 (s, 2H, $PhCOC\underline{H}_2$), 7.20—8.30 (m, 5H, phenyl); Calcd for $C_{11}H_{11}NO_3$; C, 64.38; H, 5.40; N, 6.83%. Found: C, 64.54; H, 5.29; N, 6.66%.

3-Ethoxycarbonylmethyl-2-oxazolidinone (20): Wax, purified by Kugelrohr distillation at 100 °C/10^{-3} mmHg; IR (neat) 1740, 1760 cm^{-1}; MS *m/z* 173 (M^+); ^1H NMR ($CDCl_3$) δ=1.29 (t, *J*=7 Hz, 3H, $C\underline{H}_3$), 3.70 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2N$), 4.02 (s, 2H, $C\underline{H}_2COOEt$), 4.10—4.50 (m, 4H, $C\underline{H}_2Me$ and $C\underline{H}_2O$); Calcd for $C_7H_{11}NO_4$: C, 48.55; H, 6.36; N, 8.09%. Found: C, 48.75; H, 6.47; N, 7.99%.

3-Allyl-2-oxazolidinone (21): Wax, purified by Kugelrohr distillation at 100 °C/10^{-3} mmHg (lit,[16] bp 123—125 °C/0.7 mmHg); IR (neat) 1750 cm^{-1}; MS *m/z* 127 (M^+); ^1H NMR ($CDCl_3$) δ=3.51 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2N$), 3.90 (d, *J*=6 Hz, 2H, $NC\underline{H}_2CH$=CH_2), 4.34 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2O$), 5.10—6.10 (m, 3H, $C\underline{H}$=$C\underline{H}_2$).

3-Cinnamyl-2-oxazolidinone (22): Mp 69 °C; IR (KBr) 1740 cm^{-1}; MS *m/z* 203 (M^+); ^1H NMR ($CDCl_3$) δ=3.62 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2N$), 4.08 (d, *J*=7 Hz, 2H, $CH_2C\underline{H}$=CHPh), 4.38 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2O$), 6.00—6.70 (m, 2H, $C\underline{H}$=$C\underline{H}$Ph), 7.20—7.60 (m, 5H, phenyl); Calcd for $C_{12}H_{13}NO_2$: C, 70.94; H, 6.40; N, 6.90%. Found: C, 70.78; H, 6.46; N, 6.66%.

3-Benzyl-2-oxazolidinone (23): Mp 77—78 °C (lit,[7a] mp 79—80 °C); IR (KBr) 1750 cm^{-1}; MS *m/z* 177 (M^+); ^1H NMR ($CDCl_3$) δ=3.40 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2N$), 4.28 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2O$), 4.41 (s, 2H, $PhC\underline{H}_2$), 7.40—7.60 (m, 5H, phenyl).

3-Benzyloxymethyl-2-oxazolidinone (24): Wax, purified by Kugelrohr distillation at 150 °C/10^{-3} mmHg; IR (neat) 1760 cm^{-1}; MS *m/z* 207 (M^+); ^1H NMR ($CDCl_3$) δ=3.62 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2N$), 4.25 (dd, *J*=7 and 9 Hz, $C\underline{H}_2O$), 4.56 (s, 2H, $C\underline{H}_2Ph$), 4.83 (s, 2H, $NC\underline{H}_2O$), 7.30—7.50 (m, 5H, phenyl); Calcd for $C_{11}H_{13}NO_3$:C, 63.77; H, 6.28; N, 6.76%. Found: C, 63.37; H, 6.41; N, 6.86%.

3-Hexyl-2-oxazolidinone (25): Wax, purified by Kugelrohr distillation at 100 °C/10^{-3} mmHg (lit,[7a] bp 176 °C/1 mmHg); IR (neat) 1740 cm^{-1}; MS *m/z* 171 (M^+); ^1H NMR ($CDCl_3$) δ=0.80—1.90 (m, 11H, $NCH_2C_5H_{11}$), 3.28 (t, *J*=7 Hz, 2H, $C\underline{H}_2C_5H_{11}$), 3.58 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2N$), 4.33 (dd, *J*=7 and 9 Hz, 2H, $C\underline{H}_2O$).

3-Benzoyltetrahydro-2*H*-1,3-oxazin-2-one (26) (General Procedure for the Preparation of Tetrahydro-2*H*-1,3-oxazin-2-ones). To a neat liquid of 2.98 g (5 mmol) of **1** was added 0.60 g (5 mmol) of 3-chloropropyl isocyanate (**2b**). After 10 min, 1.80 g (10 mmol) of HMPA was added to this reaction mixture, and heated at 80 °C for 1 h, where *N*-stannyltetrahydro-2*H*-1,3-oxazin-2-one (**4b**) was formed. Next, 0.70 g (5 mmol) of benzoyl chloride was added to this solution, and stirred at room temperature for 10 min. The product **26** was obtained by column chromatography: mp

87 °C; IR (KBr) 1680, 1720 cm^{-1}; MS *m/z* 205 (M^+); ^{1}H NMR ($CDCl_3$) δ=2.00—2.40 (m, 2H, $C\underline{H}_2$), 3.91 (t, *J*=6 Hz, 2H, $C\underline{H}_2N$), 4.43 (t, *J*=5 Hz, 2H, $C\underline{H}_2O$), 7.20—8.20 (m, 5H, phenyl); Calcd for $C_{11}H_{11}NO_3$: C, 64.39; H, 5.37; N, 6.83%. Found: C, 64.11; H, 5.43; N, 6.84%.

3-Phenacyltetrahydro-2*H*-1,3-oxazin-2-one (27). The coupling reaction of **4b** with organic halides to form **27—30** was performed at 80 °C for 15 h: mp 93 °C; IR (KBr) 1680, 1700 cm^{-1}; MS *m/z* 219 (M^+); ^{1}H NMR ($CDCl_3$) δ=2.16 (m, 2H, $C\underline{H}_2$), 3.43 (t, *J*=6 Hz, 2H, $C\underline{H}_2N$), 4.41 (t, *J*=5 Hz, $C\underline{H}_2O$), 4.82 (s, 2H, $PhCOC\underline{H}_2$), 7.20—8.00 (m, 5H, phenyl); Calcd for $C_{12}H_{13}NO_3$: C, 65.75; H, 5.94; N, 6.39%. Found: C, 65.55; H, 5.91; N, 6.45%.

3-Cinnamyltetrahydro-2*H*-1,3-oxazin-2-one (28): Wax, purified by Kugelrohr distillation at 150 °C/10^{-3} mmHg; IR (neat) 1690 cm^{-1}; MS *m/z* 217 (M^+); ^{1}H NMR ($CDCl_3$) δ=1.90—2.00 (m, 2H, $C\underline{H}_2$), 3.32 (t, *J*=6 Hz, 2H, $C\underline{H}_2N$), 4.11 (d, *J*=6 Hz, 2H, $C\underline{H}_2CH$=CHPh), 4.26 (t, *J*=5 Hz, 2H, $C\underline{H}_2O$), 6.00—6.70 (m, 2H, $C\underline{H}$=$C\underline{H}$Ph), 7.10—7.60 (m, 5H, phenyl); Calcd for $C_{13}H_{15}NO_2$: C, 71.89; H, 6.91; N, 6.45%. Found: C, 71.65; H, 7.08; N, 6.34%.

3-Benzyltetrahydro-2*H*-1,3-oxazin-2-one (29): Mp 35 °C; IR (KBr) 1690 cm^{-1}; MS *m/z* 191 (M^+); ^{1}H NMR ($CDCl_3$) δ=2.03 (m, 2H, $C\underline{H}_2$), 3.21 (t, *J*=6 Hz, 2H, $C\underline{H}_2N$), 4.25 (t, *J*=5 Hz, 2H, $C\underline{H}_2O$), 4.55 (s, 2H, $PhC\underline{H}_2$), 7.20—7.30 (m, 5H, phenyl); Calcd for $C_{11}H_{13}NO_2$: C, 69.11; H, 6.81; N, 7.33%. Found: C, 68.93; H, 6.83; N, 7.34%.

3-Hexyltetrahydro-2*H*-1,3-oxazin-2-one (30): Wax, purified by Kugelrohr distillation at 100 °C/10^{-3} mmHg; IR (neat) 1690 cm^{-1}; MS *m/z* 185 (M^+); ^{1}H NMR ($CDCl_3$) δ=0.80—1.90 (m, 11H, $NCH_2C_5\underline{H}_{11}$), 1.90—2.20 (m, 2H, $C\underline{H}_2$), 3.30 (m, 4H, $C\underline{H}_2N$ and $NC\underline{H}_2C_5H_{11}$), 4.23 (t, *J*=5 Hz, 2H, $C\underline{H}_2O$); Calcd for $C_{10}H_{19}NO_2$: C, 64.86; H, 10.27; N, 7.57%. Found: C, 64.97; H, 9.96; N, 7.68%.

3-Benzoyl-*cis*-4,5-dimethyl-2-oxazolidinone (31). *cis*-2-Butene (0.56 g, 10 mmol) was added to AgNCO (1.50 g, 10 mmol) in 5 ml of ether at −10 °C. The mixture was stirred vigorously while I_2 (2.54 g, 10 mmol) was added. Stirring was continued for 3 h. The slurry was filtered, and concentration of the solution gave a mobile brown liquid. To this liquid was added **1** (5.96 g, 10 mmol) at room temperature. After 10 min, HMPA (3.60 g, 20 mmol) was added to this reaction mixture, and heated at 40 °C for 1 h. Moreover, the addition of benzoyl chloride (1.40 g, 10 mmol) at room temperature and stirring for 10 min gave **31**. Mp 78 °C; IR (KBr) 1670, 1780 cm^{-1}; MS *m/z* 219 (M^+); ^{1}H NMR ($CDCl_3$) δ=1.39 (d, *J*=6.5 Hz, 3H, $NCHC\underline{H}_3$), 1.46 (d, *J*=6.5 Hz, 3H, $OCHC\underline{H}_3$), 4.50—5.00 (m, homodecoupling *J*=8 Hz, 2H, $C\underline{H}$), 7.20—7.90 (m, 5H, phenyl); ^{13}C NMR ($CDCl_3$) δ=13.2, 14.8, 54.9, 74.7, 127.9, 128.8, 132.2, 133.6, 153.0, 169.9; Calcd for $C_{12}H_{13}NO_3$: C, 65.75; H, 5.94; N, 6.39%. Found: C, 65.46; H, 5.94; N, 6.42%.

3-Benzoyl-*trans*-4,5-dimethyl-2-oxazolidinone (32): Mp 47 °C; IR (KBr) 1680, 1780 cm^{-1}; MS *m/z* 219 (M^+); ^{1}H NMR ($CDCl_3$) δ=1.46 (d, *J*=6 Hz, 3H, $NCHC\underline{H}_3$), 1.53 (d, *J*=6 Hz, 3H, $OCHC\underline{H}_3$), 4.00—4.50 (m, homodecoupling *J*=6 Hz, 2H, $C\underline{H}$), 7.20—7.90 (m, 5H, phenyl); ^{13}C NMR ($CDCl_3$) δ=17.8, 19.3, 58.2, 77.9, 128.0, 128.4, 129.2, 132.5, 162.7, 186.1; Calcd for $C_{12}H_{13}NO_3$: C, 65.75; H, 5.94; N, 6.39%. (Received October 1, 1988)

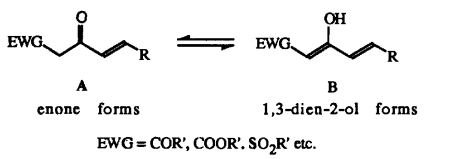
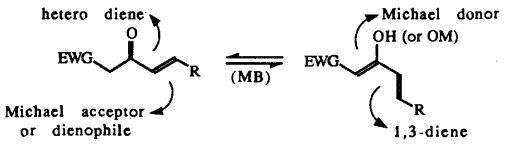
A new method of synthesizing phosphinyl-substituted enones, 2-oxo-3-alkenylphosphonates, is developed via the dianion of diethyl 2-oxopropylphosphonate. The enones serve as hetero dienes in thermal reactions with vinly ethers producing 2-alkoxy-6-(phosphinylmethyl)-3,4-dihydro-2*H*-pyrans. Acid-catalyzed cleavage of these cycloadducts is followed spontaneously by internal condensation furnishing 2-phosphinyl-2-cyclohexen-1-one derivatives.

It is well-known that a variety of α,β-unsaturated carbonyl compounds undergo thermal cycloadditions with electron-rich olefins such as vinyl ethers,[1] enamines,[2] or simple alkenes[3] producing dihydropyran skeletons. However no reaction example has been reported so far, to the best of our knowledge, of inverse electron-demand Diels–Alder cycloadditions[4] using readily enolizable hetero dienes such as 2-oxo-3-alkenyl ketones, 3-oxo-4-alkenoates, or 2-oxo-3-alkenyl sulfones.





These hetero dienes with a general structure **A** undergo ready enolization into 1,3-dien-2-ols **B**. For example, methyl 3-oxo-4-pentenoate (**A**, EWG=COOMe, R=H) known as the Nazarov reagent[5] exists as a 1:1 mixture (^{1}H NMR) with enol form **B** in deuteriochloroform, and 5-hexene-2,4-dione (**A**, EWG=COMe, R=H) 1:19 (**A**:**B**) in deuteriobenzene.[6] In polar or protic medium, relative contribution of 1,3-dien-2-ols **B** must be increased. Only two examples of Diels–Alder cycloadditions of such enolized dienes **B** are known as intramolecular versions with simple olefin dienophiles.[7]

We became interested in this class of compounds as reagents in the study on Diels–Alder cycloadditions. They can be utilized as highly functionalized unsaturated molecules such as hetero dienes (enone), 1,3-dienes (1,3-dien-2-ol), and dienophiles,[8] and also as annulation reagents for six-membered ring formation via Michael type cyclizations.

To open the versatility of enone reagents of type **A**, we picked up 2-oxo-3-alkenylphosphonates (**A**, EWG=$(EtO)_2PO$). Their new synthetic method was developed and their thermal Diels–Alder reactions with electron-rich vinyl ethers were investigated. The details are presented herein.

Rsults and Discussion

Syntheses of 2-Oxo-3-alkenylphosphonates 4a—f. The known syntheses of 2-oxo-3-alkenylphosphonates consist of hydrolysis of 2-alken-1-ynylphosphonates,[9] acylation of anions of methylphosphonates,[10] and dehydration of 4-hydroxy-2-oxoalkylphosphonates.[11] As parent diethyl 2-oxo-3-butenylphosphonate (**4a**) could not be prepared[12] according to the acylation procedure reported in the literature,[10a] we needed another synthetic method of **4a**.[13]

Several examples are known for alkylations using dianion of diethyl 2-oxopropylphosphonate (**1**)[14] which is readily prepared from commercially available diethyl methylphosphonate. Therefore, we planned to open to new synthetic route of 2-oxo-3-alkenylphosphonates via the dianion of **1**.

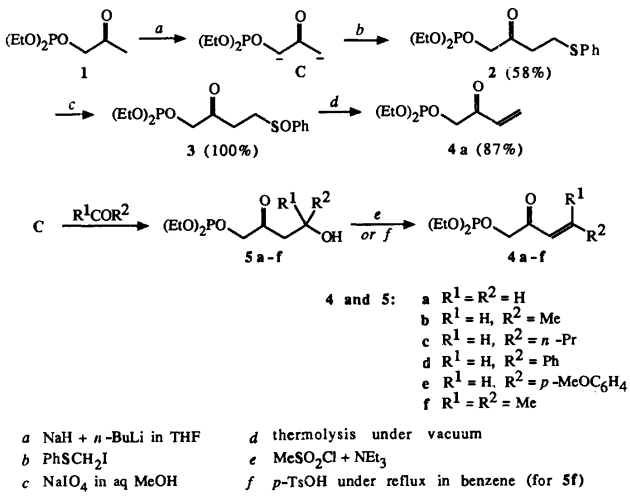
The dianion **C**, generated according to the Grieco's method by treating **1** with sodium hydride and then butyllithium (both 1.1 equiv), was reacted with phenylthiomethyl iodide to give diethyl 2-oxo-4-(phenylthio)butylphosphonate (**2**) in 58% yield (Scheme 1). Oxidation of **2** with sodium periodate led to a quantitative yield of sulfoxide **3**. The sulfoxide **3** was then subjected, without further purification, to vacuum thermolysis (at 145 °C/13 Pa) in a Kugelrohr distilling apparatus to provide **4a** as mixture with diphenyl disulfide. A repeated distillation is enough to remove the disulfide and pure **4a** was obtained in 87% yield.

Another route to **4a** is even more general. When dianion **C** was treated with paraformaldehyde in THF in the presence of a catalytic amount of hexamethylphosphoric triamide (HMPA, 1 mol%), diethyl 4-hydroxy-2-oxobutylphosphonate (**5a**) was produced.[15] Dehydration of **5a** leading to the enone **4a** was

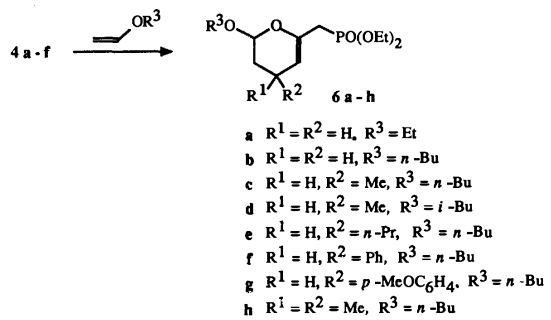
Table 1. Reactions of Dianion **C**[a] with Carbonyl Compounds Leading to 4-Hydroxy-2-oxoalkylphosphonates **5a—f** and 2-Oxo-3-alkenylphosphonates **4a—f**

Carbonyl compound	Condition[b]	Product (yield/%)[c]	Condition[d]	Product (yield/%)[c]
Paraformaldehyde	0 °C, 4 h[e]	**5a** (55)	0 °C, 20 min	**4a** (70)
MeCHO	−78 °C, 1 h	**5b** (72)	rt, 1 h	**4b** (89)
n-PrCHO	−78 °C, 30 min	**5c** (75)	0 °C, 1 h	**4c** (95)
PhCHO	−78 °C, 1 h	**5d** (83)	rt, 30 min	**4d** (88)[f]
p-MeOC$_6$H$_4$CHO	−78 °C, 30 min	**5e** (95)	rt, 1 h	**4e** (86)
MeCOMe	−78 °C, 1 h	**5f** (80)	80 °C, 2 h[g]	**4f** (91)

a) Dianion **C** was generated in THF by treating **1** with sodium hydride (1.1 equiv, rt, 30 min) and butyllithium (1.1 equiv, −30 to −40 °C, 30 min). b) 1.1 to 1.2 equivalent of a carbonyl compound was employed. c) Yields of isolated products. d) Triethylamine (3 equiv) was added at −30 to −50 °C to the mixture of **5** and methanesulfonyl chloride (1.2 equiv), and the mixture was stirred under conditions listed above. e) In the presence of HMPA (0.25 equiv). f) One-flask procedure without isolation of **5d** gave 80% yield of **4d** (based on **1**). g) Under reflux in benzene with *p*-TsOH (0.5 equiv).



Scheme 1.



Scheme 2.

successfully carried out by a one-flask sequence of *O*-mesylation and *β*-elimination.[11]

Carbonyl compounds other than formaldehyde, such as aliphatic and aromatic aldehydes and acetone, could be employed in the condensation route with dianion **C** to give *β*-substituted derivatives **4b—f** in excellent yields (Scheme 1 and Table 1). Acid-catalyzed dehydration with *p*-toluenesulfonic acid (*p*-TsOH) was more effective for **5f**→**4f**.

Hetero Diels–Alder Reactions of 2-Oxo-3-alkenylphosphonates 4a—f with Vinyl Ethers. Thermally quite stable 2-oxo-3-alkenylphosphonates **4a—f** can undergo Diels–Alder cycloadditions as hetero dienes with vinyl ethers. Since their reactivity was not satisfactorily high, inexpensive vinyl ethers were employed in a large excess. The mixture of an enone **4a—f** and a vinyl ether in benzene was heated in a sealed tube at 85 °C for *β*-unsubstituted diene **4a**, or above 130 °C for other *β*-substituted dienes **4b—f**. In order to inhibit polymerization of vinyl ethers, a catalytic amount of *N*,*N*-diisopropylethylamine was added as a base.[16] According to these procedures, satisfactory yields of 2-alkoxy-6-(phosphinylmethyl)-3,4-dihydro-2*H*-pyrans **6a—h** were obtained (Scheme 2 and Table 2), while sterically hindered diene **4f** showed relatively decreased reactivity.

All these Diels–Alder reactions were regioselective like the previously observed examples,[1] however stereoselectivity was poor. The isolated products **6a—h** were always the mixtures of 2,4-trans and 2,4-cis isomers in 7:3 to 6:4 ratios (^{1}H NMR). However, stereoisomeric purity at the 2-position is not important in the present work because 2-alkoxy-3,4-dihydro-2*H*-pyrans **6a—h** are to be hydrolyzed in the following step.

Reactivity of 2-oxo-3-alkenylphosphonate **4a** as a hetero diene was comparable to that of 3-buten-2-one[17] or even higher, indicating that ready enolization of enones does not affect their activity as hetero dienes. Even *β*-aryl-substituted enones **4d—e**, whose dienol forms should be more highly stabilized than others, underwent smooth cycloadditions.

Acid-Hydrolysis and Subsequent Cyclization of the Diels–Alder Cycloadducts 6a—h. The hemiacetal moiety of 2-ethoxy-6-(diethoxyphosphorylmethyl)-3,4-dihydro-2*H*-pyran (**6a**) was readily hydrolyzed in 5 min at room temperature when treated with 4 M hydrochloric acid (1 M=1 mol dm^{-3}) in THF. The unpurified product was assigned to be almost pure 6-(diethylphosphoryl)-5-oxohexanal **D** (R^1=R^2=H in Scheme 3) on the basis of ^{1}H NMR spectrum: δ=1.33 (6H, t, J=7.0 Hz, OEt), 1.90 (2H, quint, J=7.0 Hz, 3-H), 2.50, 2.70 (each t, J=7.0 Hz, 2- and 4-H), 3.10

Table 2. Hetero Diels-Alder Reactions of **4a**—f with Vinyl Ethers and Subsequent Acid-Catalyzed Hydrolysis of the Cycloadducts **6a**—**h** Leading to 2-Phosphinyl-2-cyclohexen-1-ones **7a**—f

Heterodiene	Vinyl ether[a]	Condition[b]	Cycloadduct (yield/%)[c]	Condition[d]	Product (yield/%)[c]

Scheme 3.

(2H, d J_{C-P}=22.5 Hz, 6-H), 4.20 (4H, dq J=7.0 and J_{C-P}=7.7 Hz, OEt), and 9.77 (1H, br s, CHO).

It was found that aldehyde **D** (R^1=R^2=H) underwent smooth cyclization leading to 2-(diethoxyphosphoryl)-2-cyclohexen-1-one (**7a**) in 87% yield on its attempted purification through column chromatography on silica gel. Presumably such a weak acid as silica gel is requisite in this facile cyclization since intermediate **D** (R^1=R^2=H) was found stable in 4 M hydrochloric acid as mentioned above. With a more diluted hydrochloric acid, the hydrolysis of **5a** becames slower and instead the acid-catalyzed cyclization of **D** is relatively accelerated, isolation of the intermediate aldehyde **D** in a pure form becoming more difficult.

Other 2-alkoxy-3,4-dihydro-2*H*-pyrans **4b**—**f** were hydrolyzed under similar conditions and crude reaction mixtures were subjected to silica-gel chromatoraphy to give 2-phosphinyl-2-cyclohexen-1-ones **7b**—**f** in satisfactory yields (Scheme 3 and Table 2).

Although acyclic vinylphosphonates bearing an acyl or ester moiety at the 1-position have been synthesized by the secondary amine-promoted condensation of phosphonates[18] or the β-elimination[19] of 1-sulfinyl phosphonates, synthetic example of 1-cycloalkenylphosphonates is quite limited.[20,21] The present reactions offer a high-yield and short step synthesis of 2-phosphinyl-2-cyclohexen-1-ones bearing a substituent at the 5-position.

Experimental

General. Melting points were determined on a Yanagimoto melting point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-40 (90 MHz), a JEOL FX-100 (100 MHz), or a JEOL GSX-270 instrument (270 MHz), and ^{13}C NMR on a JEOL FX-100 (25.05 MHz) or a JEOL GSX-270 spectrometer (67.94 MHz). Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra and high resolution mass spectra were measured with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. Elemental analyses were performed on a Hitachi 026 CHN analyzer. For preparative column chromatography, Wakogel C-200, C-300 (Wako), and Silicagel 60 (Merck) were employed. Flash chromatography was carried out on an EYELA EF-10 apparatus using a column (20×180 mm) packed with Silicagel 60 (Merck, size: 0.04—0.063 mm). Gas liquid chromatography (GLC) was accomplished on a Yanaco G-2800 gas chromatograph (Yanagimoto) with an ionization flame detector using a glass column (SE-30, 3×2000 mm) or a glass capillary column (Silicone GE, SE-30, 0.25×50000 mm). Micro vacuum distillation was carried out on a Sibata GTO-250R Kugelrohr distilling apparatus. Solvents were evaporated with a Tokyo Rikakikai rotary evaporator type-V at about 50 °C unless otherwise stated.

Materials. Compounds **4d** and **5d** were previously prepared and characterized.[3] Though compounds **4a**, **4b**, **4f** are all known,[10a] refractive indexes, ^{1}H NMR spectra without coupling constants, and boiling points are the only reported data. Accordingly full data of these compounds are presented below. Triethylamine and dichloromethane were purified by distillation on potassium hydroxide and calcium hydride, respectively. Tetrahydrofuran (THF) was distilled on lithium aluminum hydride under nitrogen prior to use.

Diethyl 2-Oxo-4-(phenylthio)butylphosphonate (2). To a suspension of sodium hydride (60% in mineral oil, 0.93 g, 22 mol) in dry THF (60 ml) was added diethyl 2-oxopropylphosphonate (**1**, 3.88 g, 20 mmol) under nitrogen. After 30 min at room temperature, butyllithium (in hexane, 13 ml, 23 mmol) was added at −5 °C. The mixture was stirred at room temperature for 30 min and phenylthiomethyl iodide

(4.5 g, 18 mmol) was added. After stirring was continued at −10 to −5 °C for 2 h, the mixture was poured into ice-cold 3 M hydrochloric acid and then extracted with diethyl ether (30 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane-ethyl acetate (1:2 v/v) to give **2** (3.32 g, 58%): Pale yellow liquid; IR (neat) 1710, 1580, 1475, 1440, 1250, 1050, 1015, 960, 800, 740, and 690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.31 (6H, t, J=7.0 Hz, EtO), 2,95 (2H, t, J_{3-4}=6.9 Hz, 3-H), 3.07 (2H, d, J_{H-P}=22.7 Hz, 1-H), 3.14 (2H, t, J_{4-3}=6.9 Hz, 4-H), 4.12 (4H, quint, J=J_{H-P}=7.0 Hz, EtO), and 7.2—7.4 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=16.28 (d, J_{C-P}=5.9 Hz, EtO), 27.36 (4-C), 42.59 (d, J_{C-P}=127.1 Hz, 1-C), 43.58 (3-C), 62.66 (d, J_{C-P}=5.9 Hz, EtO), 126.39, 129.03, 129.63, 135.58 (each Ph), and 200.11 (d, J_{C-P}=5.9 Hz, CO); MS m/z (rel intensity, %) 316 (M^+, 31), 207 (base peak), 179 (40), 152 (26), 151 (44), 125 (39), 123 (35), 110 (21), 109 (35), and 97 (10). HRMS Found: m/z 316.0754. Calcd for $C_{14}H_{21}O_4PS$:M, 316.0897.

Oxidation of 2 with Sodium Periodate and Subsequent Thermolysis of 3 Leading to 4a. To a solution of **2** (1.8 g 5.69 mmol) in methanol (35 ml) was added aqueous sodium periodate (1.95 g, 9.1 mmol in 13 ml of water) at −10 to 0 °C. The mixture was stirred at 0 °C for 4 h and extracted with chloroform (25 ml). The extract was dried over magnesium sulfate and evaporated in vacuo. The crude sulfoxide **3** (1.9 g, 100%) was heated at 145 °C under vacuum (27 Pa) in a Kugelrohr distilling apparatus. The distillate (1.4 g) was purified by vacuum distillation to give **4a** (bp 130 °C/13 Pa, 1.13 g, 87%). The data of **4a** are presented below.

General Procedure for the Preparation of Diethyl 4-Hydroxy-2-oxoalkylphosphonates 5a—f. As a typical example the preparation of **5a** is described as follows: To the THF solution of dianion **C** freshly prepared from **1** (3.88 g, 20 mmol) according to the method mentioned above were added at −78 °C paraformaldehyde (0.6 g, 20 mmol) and hexamethylphosphoric triamide (HMPA, 0.1 ml). After stirred at 0 °C for 4 h, the mixture was acidified with 1 M hydrochloric acid. The THF was removed in vacuo and the aqueous residue was extracted with dichloromethane (40 ml×4). The combined extracts were dried over magensium sulfate and evaporated in vacuo. The crude product (4.6 g) was chromatographed over silica gel with ethyl acetate-methanol (99.5:0.5 to 96:4 v/v) to give **5a** (2.45 g, 55%). No HMPA was needed in the preparation of other derivatives **5b**—f; the reaction conditions and the results are summarized in Table 1. Eluents used in the chromatographic purification are as follows: **5b**, **5c**, and **5e**: ethyl acetate-methanol (95:5 v/v); **5d**: ethyl acetate; **5f**: ethyl acetate-methanol (98:2 v/v).

Diethyl 4-Hydroxy-2-oxobutylphosphonate (5a): Colorless liquid; IR (neat) 3400, 1710, 1240, 1020, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 (6H, t, J=7.0 Hz, EtO), 2.83 (2H, t, J_{3-4}=6.0 Hz, 3-H), 3.14 (2H, d, J_{H-P}=23.0 Hz, 1-H), 3.48 (1H, br s, OH), 3.48 (2H, t, J_{4-3}=6.0 Hz, 4-H), and 4.12 (4H, dq, J=7.0 and J_{H-P}=8.0 Hz, EtO); ^{13}C NMR ($CDCl_3$) δ=16.32 (qd, J_{C-P}=7.4 Hz, EtO), 42.65 (td, J_{C-P}=126.5 Hz, 1-C), 46.77 (t, 3-C), 57.47 (t, 4-C), 62.83 (td, J_{C-P}=5.9 Hz, EtO), and 202.30 (d, J_{C-P}=5.9 Hz, CO); MS m/z (rel intensity, %) 224 (M^+, 5), 194 (base peak), 179 (45), 152 (44), 151 (42), 125 (67), 123 (57), 109 (32), 108 (20), 97 (41), 81 (28), and 43 (28). HRMS Found: m/z 224.0808. Calcd for $C_8H_{17}O_5P$: M, 224.0813.

Diethyl 4-Hydroxy-2-oxopentylphosphonate (5b): Colorless liquid; IR (neat) 3400, 1710, 1245, 1050, 1020, 960, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.24 (3H, d, J_{5-4}=6.7 Hz, 5-H), 1.35 (6H, t, J=7.0 Hz, EtO), 2.76 (1H, d, J_{3-4}=6.4 Hz, one of 3-H), 2.74 (1H, d, J_{3-4}=5.5 Hz, the other of 3-H), 3.17 (2H, d, J_{H-P}=22.9 Hz, 1-H), 3.66 (1H, br d, J=4.0 Hz, OH), 4.16 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO), and 4.0—4.3 (1H, m, 4-H); ^{13}C NMR ($CDCl_3$) δ=16.26 (dq, J_{C-P}=5.9 Hz, EtO), 22.76 (q, 5-C), 43.38 (dt, J_{C-P}=126.0 Hz, 1-C), 52.59 (t, 3-C), 62.60 (dt, J_{C-P}=5.9 Hz, EtO), 63.77 (d, 4-C), and 202.19 (d, J_{C-P}=5.9 Hz, CO); MS m/z (rel intensity, %) 238 (M^+, 3), 223 (25), 195 (27), 194 (base peak), 179 (31), 167 (21), 152 (34), 151 (22), 139 (20), 125 (44), 123 (33), 97 (25), 81 (21), and 43 (20). HRMS Found: m/z 238.0963. Calcd for $C_9H_{19}O_5P$: M, 238.0969.

Diethyl 4-Hydroxy-2-oxoheptylphosphonate (5c): Colorless liquid; IR (neat) 3400, 1710, 1395, 1250, 1050, 1020, 975, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.92 (3H, t, J_{7-6}=7.0 Hz, 7-H), 1.34 (6H, t, J=7.0 Hz, EtO), 1.3—1.6 (4H, m, 5- and 6-H), 2.70 (1H, dd, J_{gem}=17.2 and J_{3-4}=8.4 Hz, one of 3-H), 2.80 (1H, dd, J_{gem}=17.2 and J_{3-4}=3.7 Hz, the other of 3-H), 3.10 (1H, dd, J_{gem}=13.0 and J_{H-P}=22.7 Hz, one of 1-H), 3.19 (1H, dd, J_{gem}=13.0 and J_{H-P}=22.7 Hz, the other of 1-H), 3.35 (1H, br s, OH), 4.07 (1H, m, 4-H), and 4.15 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO); ^{13}C NMR ($CDCl_3$) δ=13.98 (7-C), 16.33 (d, J_{C-P}=5.9 Hz, EtO), 18.68 (6-C), 38.89 (5-C), 43.09 (d, J_{C-P}=127.2 Hz, 1-C), 51.16 (3-C), 62.76 (d, J_{C-P}=6.9 Hz, EtO), 67.38 (4-C), and 202.89 (d, J_{C-P}=5.9 Hz, CO); MS m/z (rel intensity, %) 266 (M^+, 5), 222 (base peak), 195 (34), 194 (43), 179 (20), 139 (20), 125 (23), 123 (20), and 97 (13). HRMS Found: m/z 266.1320. Calcd for $C_{11}H_{23}O_5P$: M, 266.1320.

Diethyl 4-Hydroxy-4-(*p*-methoxyphenyl)-2-oxobutylphosphonate (5e): Colorless liquid; IR (neat) 3350, 1705, 1610, 1580, 1505, 1300, 1250, 1175, 1025, 960, 825, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 (6H, t, J=6.6 Hz, EtO), 2.92 (1H, dd, J_{gem}=17.2 and J_{3-4}=3.7 Hz, one of 3-H), 3.05 (1H, dd, J_{gem}=17.2 and J_{3-4}=8.8 Hz, the other of 3-H), 3.07 (1H, dd, J_{gem}=13.5 and J_{H-P}=22.7 Hz, one of 1-H), 3.16 (1H, dd, J_{gem}=13.5 and J_{H-P}=22.7 Hz, the other of 1-H), 3.65 (1H, br, OH), 4.12 (4H, m, EtO), 5.11 (1H, dd, J_{4-3}=8.8 and 3.7 Hz, 4-H), 6.86 (2H, dt, J=8.4 and 1.8 Hz, Ar), and 7.28 (2H, dt, J=8.4 and 1.8 Hz, Ar); ^{13}C NMR ($CDCl_3$) δ=16.30 (d, J_{C-P}=5.9 Hz, EtO), 43.11 (d, J_{C-P}=127.0 Hz, 1-C), 52.87 (3-C), 55.28 (*p*-MeO), 62.73 (d, J_{C-P}=6.9 Hz, EtO), 69.50 (4-C), 113.86, 126.97, 135.17, 159.10 (each Ar), and 201.98 (d, J_{C-P}=5.9 Hz, CO); MS m/z (rel intensity, %) 330 (M^+, 19), 195 (32), 194 (85), 167 (29), 161 (44), 152 (47), 150 (20), 139 (26), 137 (37), 136 (25), 135 (base peak), 125 (63), 123 (28), 109 (31), 96 (42), 80 (31), 76 (31), and 43 (33). HRMS Found: m/z 330.1235. Calcd for $C_{15}H_{23}O_6P$: M, 330.1231.

Diethyl 4-Hydroxy-4-methyl-2-oxopentylphosphonate (5f): Colorless liquid; IR (neat) 3400, 1705, 1470, 1440, 1380, 1350, 1320, 1240, 1155, 1040, 1020, 970, and 780 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.27 (6H, s, 5-H and 4-Me), 1.35 (6H, t, J=7.0 Hz, EtO), 2.82 (2H, s, 3-H), 3.14 (2H, d, J_{H-P}=22.7 Hz, 1-H), 3.70 (1H, br, OH), and 4.15 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO); ^{13}C NMR ($CDCl_3$) δ=16.31 (d, J_{C-P}=5.9 Hz, EtO), 29.33 (5-and 4-Me), 43.83 (d, J_{C-P}=126.2 Hz, 1-C), 55.09 (3-C), 62.69 (d, J_{C-P}=5.9 Hz, EtO), 69.67 (4-C), and 203.55 (d, J_{C-P}=5.9 Hz, CO); MS m/z (rel intensity, %) 253 (M^++1, 5), 237 (91), 195 (25), 194 (94), 179 (47), 167 (49), 152 (49), 151 (36), 139 (77), 125 (81), 124 (22), 123 (77), 121 (41), 109 (37), 108 (20), 105

(22), 97 (63), 96 (43), 81 (61), 78 (24), 65 (33), 59 (73), 58 (21), and 43 (base peak). No analytical data was obtained because of the absence of parent ion peak and the hygroscopic nature.

General Procedure for the Dehydration of 5a—f Leading to 2-Oxo-3-alkenylphosphonates 4a—f. As a typical example the conversion of **5a** into **4a** is described as follows: To a solution of **5a** (5.15 g, 23 mmol) and methanesulfonyl chloride (3.16 g, 27.6 mmol) in dry dichloromethane (50 ml) was added dropwise triethylamine (6.91 g, 68.9 mmol) at −50 °C. After stirring at 0 °C for 20 min, the mixture was poured into ice water. The dichloromethane separated was washed with 1 M hydrochloric acid and water, dried over magnesium sulfate, and then evaporated in vacuo. The crude product (4.4 g) was subjected to vacuum distillation to give **4a** (3.3 g, 70%). Other compounds **5b—e** were similarly dehydrated under the reaction conditions listed in Table 1. Eluents used for the chromatographic purification of **4b—e** are as follows: **4b**: hexane–ethyl acetate (1:1 to 0:1 v/v); **4c**: ethyl acetate; **4d**: hexane–ethyl acetate (1:2 v/v); **4e**: hexane–ethyl acetate (1:4 to 0:1 v/v).

Diethyl 2-Oxo-3-butenylphosphonate (4a):[10a] Colorless liquid; bp 130 °C/13 Pa (bulb-to-bulb); IR (neat) 1670, 1610, 1240, 1020, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 (6H, t, J=7.0 Hz, EtO), 3.24 (2H, d, J_{H-P}=22.5 Hz, 1-H), 4.12 (4H, dd, J=7.0 and J_{H-P}=8.0 Hz, EtO), 5.90 (1H, dd, $J_{4-3(cis)}$=9.0 and J_{gem}=2.5 Hz, one of 4-H), 6.26 (1H, dd, $J_{4-3(trans)}$=17.5 and J_{gem}=2.5 Hz, the other of 4-H), and 6.50 (1H, dd, $J_{3-4(trans)}$=17.5 and $J_{4-3(cis)}$=9.0 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=16.35 (qd, J_{C-P}=5.9 Hz, EtO), 39.88 (td, J_{C-P}=129.4 Hz, 1-C), 62.71 (td, J_{C-P}=5.9 Hz, EtO), 130.60 (t, 4-C), 136.42 (d, 3-C), and 192.04 (s, 2-C); MS m/z (rel intensity, %) 206 (M^+, 79), 179 (35), 178 (35), 161 (34), 151 (70), 134 (33), 133 (34), 125 (60), 123 (73), 109 (48), 97 (52), 96 (22), 81 (34), 70 (31), and 55 (base peak). HRMS Found: m/z 206.0698. Calcd for $C_8H_{15}O_4P$: M, 206.0707.

Diethyl (*E*)-2-Oxo-3-pentenylphosphonate (4b):[10a] Colorless liquid; bp 145—150 °C/20 Pa (bulb-to-bulb); IR (neat) 1660, 1625, 1440, 1290, 1245, 1050, 1020, 960, and 940 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (6H, t, J=7.0 Hz, EtO), 1.94 (3H, br d, J_{5-4}=6.9 Hz, 5-H), 3.19 (2H, d, J_{H-P}=22.7 Hz, 1-H), 4.14 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO), 6.26 (1H, br d, J_{3-4}=15.8 Hz, 3-H), and 6.96 (1H, br dq, J_{4-3}=15.8 and J_{4-5}=6.9 Hz, 4-H); ^{13}C NMR ($CDCl_3$) δ=16.31 (d, J_{C-P}=5.9 Hz, EtO), 18.37 (5-C), 40.06 (d, J_{C-P}=123.3 Hz, 1-C), 62.56 (d, J_{C-P}=5.9 Hz, EtO), 131.72 (3-C), 145.58 (4-C), and 191.10 (d, J_{C-P}=6.9 Hz, CO); MS m/z (rel intensity, %) 220 (M^+, 22), 125 (35), 97 (30), 69 (base peak), and 41 (49). HRMS Found: m/z 220.0863. Calcd for $C_9H_{17}O_4P$: M, 220.0863.

Diethyl (*E*)-2-Oxo-3-heptenylphosphonate (4c): Colorless liquid; bp 150 °C/27 Pa (bulb-to-bulb); IR (neat) 1690, 1665, 1625, 1250, 1055, 1025, 975, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.95 (3H, t, J_{7-6}=7.4 Hz, 7-H), 1.33 (6H, t, J=7.0 Hz, EtO), 1.52 (2H, sex, J_{6-5}=J_{6-7}=7.4 Hz, 6-H), 2.24 (2H, br q, J_{5-4}=J_{5-6}=7.4 Hz, 5-H), 3.21 (2H, d, J_{H-P}=22.7 Hz, 1-H), 4.14 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO), 6.24 (1H, br d, J_{3-4}=15.8 Hz, 3-H), and 6.95 (1H, br dt, J_{4-3}=15.8 and J_{4-5}=7.4 Hz, 4-H); ^{13}C NMR ($CDCl_3$) δ=13.68 (7-C), 16.32 (d, J_{C-P}=6.8 Hz, EtO), 21.25 (6-C), 34.54 (5-C), 40.12 (d, J_{C-P}=128.1 Hz, 1-C), 62.52 (d, J_{C-P}=6.8 Hz, EtO), 130.22 (3-C), 150.25 (4-C), and 191.31 (d, J_{C-P}=5.9 Hz, CO); MS m/z (rel intensity, %) 248 (M^+, base peak), 220 (33), 179 (27), 152 (30), 151 (27), 125 (39), 123 (34), 110 (26), 97 (34), and 55 (33). HRMS Found: m/z 248.1191. Calcd for $C_{11}H_{21}O_4P$: M, 248.1176.

Diethyl (*E*)-4-(*p*-Methoxyphenyl)-2-oxo-3-butenylphosphonate (4e): Colorless prisms (diethyl ether–hexane); mp 53—54 °C; IR (KBr) 1675, 1640, 1595, 1295, 1250, 1175, 1075, 1050, 1025, 960, and 840 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (6H, t, J=7.0 Hz, EtO), 3.30 (2H, d, J_{H-P}=22.7 Hz, 1-H), 3.84 (3H, s, *p*-MeO), 4.17 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz EtO), 6.77 (1H, br d, J_{3-4}=16.1 Hz, 3-H), 6.91 (2H, br d, J=8.9 Hz, Ar), 7.53 (2H, br d, J=8.9 Hz, Ar), and 7.61 (1H, br d, J_{4-3}=16.1 Hz, 4-H); ^{13}C NMR ($CDCl_3$) δ=16.36 (d, J_{C-P}=5.9 Hz, EtO), 40.93 (d, J_{C-P}=128.1 Hz, 1-C), 55.42 (*p*-MeO), 62.58 (d, J_{C-P}=5.9 Hz, EtO), 114.50, 123.60, 126.88, 130.42, 144.60, 161.98 (Ar, 3- and 4-C), and 190.91 (d, J_{C-P}=5.9 Hz, CO); MS m/z (rel intensity, %) 312 (M^+, 24), 174 (56), 161 (base peak), and 133 (18). Found: C, 57.71; H, 7.01%. Calcd for $C_{15}H_{21}O_5P$: C, 57.69; H, 6.78%.

Diethyl 4-Methyl-2-oxo-3-pentenylphosphonate (4f).[10a] A solution of **5f** (1.008 g, 4 mmol) and *p*-toluenesulfonic acid monohydrate (0.38 g, 2 mmol) in benzene (30 ml) was heated under reflux for 2 h with continuous removal of water by the aid of a Dean-Stark trap. The mixture was evaporated in vacuo, the residue was washed with water, and extracted with dichloromethane (25 ml×2). The combined extracts were washed with saturated aqueous sodium hydrogencarbonate, dried over magnesium sulfate, and evaporated in vacuo. The residue was chromatographed over silica gel with dichloromethane–ethyl acetate (2:1 v/v) to give **4f** (0.85 g, 91%): Colorless liquid; bp 150 °C/27 Pa (bulb-to-bulb); IR (neat) 1680, 1620, 1445, 1390, 1250, 1025, 965, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (6H, t, J=7.0 Hz, EtO), 1.92, 2.16 (each 3H, s, 5-H and 4-Me), 3.07 (2H, d, J_{H-P}=22.7 Hz, 1-H), 4.14 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO), and 6.25 (1H, s, 3-H); ^{13}C NMR ($CDCl_3$) δ=16.32 (d, J_{C-P}=5.9 Hz, EtO), 21.02 (5-C), 27.79 (4-Me), 43.70 (d, J_{C-P}=127.2 Hz, 1-C), 62.42 (d, J_{C-P}=5.9 Hz, EtO), 123.93 (3-C), 158.04 (4-C), and 190.85 (d, J_{C-P}=5.9 Hz, 2-C); MS m/z (rel intensity, %) 234 (M^+, 17), 97 (23), 96 (61), 83 (base peak), 81 (34), 59 (66), and 58 (26).

Genral Procedure for the Hetero Diels-Alder Reaction of 4a—f Leading to 3,4-Dihydro-2*H*-pyrans 6a—h. As a typical procedure the reaction of **4a** with ethyl vinyl ether is described as follows: A mixture of **4a** (1.035 g, 5.02 mmol), ethyl vinyl ether (7.2 g, 100 mmol), and *N,N*-diisopropylethylamine (trace) in benzene (1 ml) was heated in a sealed tube at 85 °C for 18 h. The mixture was condensed in vacuo and the residue was chromatographed over silica gel by using ethyl acetate–methanol (1:0 to 98:2 v/v) to give **6a** (1.16 g, 83%). Other cycloadducts **6b—h** were similarly obtained under the reaction conditions listed in Table 2. Eluents used for the chromatographic purification are as follows: **6b**: hexane–ethyl acetate (1:2 to 0:1 v/v); **6c** and **6d**: dichloromethane–ethyl acetate (2:1 to 2:3 v/v); **6e** and **6h**: hexane–ethyl acetate (1:2 v/v); **6f**: hexane–ethyl acetate (2:3 v/v); **6g**: dichloromethane–ethyl acetate (3:1 v/v); No satisfactory analytical data were obtained because of the hygroscopic nature of **6a—h**. Analysis by HRMS was carried out for the stereochemically pure **6a, b**. The other compounds **6c—h** were characterized on the basis of spectral data and employed for the following reactions.

2-Ethoxy-6-[(diethoxyphosphoryl)methyl]-3,4-dihydro-2*H*-

pyran (6a): Colorless liquid; IR (neat) 1675, 1475, 1440, 1380, 1240, 1155, 1110, 1050, 1025, and 955 cm^{-1}; ^1H NMR (C_6D_6) δ=1.10 (6H, dt, J=7.0 and J_{H-P}=4.0 Hz EtO), 1.14 (3H, t, J=7.0 Hz, 2-EtO), 1.5—1.8 (3H, m, 3- and 4-H), 2.17 (1H, m, one of 3-H), 2.60 (2H, d, J_{H-P}=20.9 Hz, 6-CH_2P), 3.43 (1H, dq, J_{gem}=9.5 and J=7.0 Hz, 2-EtO), 3.9—4.1 (1H, m, 2-EtO), 4.13 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO), 4.73 (1H, br q, J_{5-4}=J_{H-P}=4.4 Hz, 5-H), and 4.88 (1H, t, J_{2-3}=3.3 Hz, 2-H); ^{13}C NMR (C_6D_6) δ=15.33 (2-EtO), 16.53, 16.56 (each d, J_{C-P}=5.9 Hz, EtO), 17.32 (4-C), 26.58 (3-C), 32.94 (d, J_{C-P}=139.9 Hz, 6-CH_2P), 61.61, 61.81 (each d, J_{C-P}=5.9 Hz, EtO), 63.79 (2-EtO), 97.71 (2-C), 99.88 (d, J_{C-P}=9.8 Hz, 5-C), and 143.14 (d, J_{C-P}=10.8 Hz, 6-C); MS m/z (rel intensity, %) 278 (M^+, 45), 233 (37), 232 (base peak), 231 (49), 207 (30), 203 (65), 151 (33), 140 (30), 123 (24), 95 (42), 94 (61), and 72 (42). HRMS Found: m/z 278.1284. Calcd for $C_{12}H_{23}O_5P$: M, 278.1282.

2-Butoxy-6-[(diethoxyphosphoryl)methyl]-3,4-dihydro-2*H*-pyran (6b): Colorless liquid; IR (neat) 1675, 1445, 1390, 1360, 1250, 1120, 1030, 965, 840, 805, and 790 cm^{-1}; ^1H NMR (C_6D_6) δ=0.87 (3H, t, J=7.0 Hz, *n*-BuO), 1.10 (6H, dt, J=7.0 and J_{H-P}=4.4 Hz, EtO), 1.38 (2H, m, *n*-BuO), 1.55 (2H, m, *n*-BuO), 1.5—1.8 (3H, m, 3- and 4-H), 2.15 (1H, m, one 3-H), 2.62 (2H, d, J_{H-P}=20.9 Hz, 6-CH_2P), 3.41 (1H, dt, J_{gem}=9.5 and J=6.5 Hz, *n*-BuO), 3.9—4.1 (5H, m, EtO and *n*-BuO), 4.74 (1H, q, J_{5-4}=J_{H-P}=4.0 Hz, 5-H), and 4.89 (1H, t, J_{2-3}=3.4 Hz, 2-H); ^{13}C NMR (C_6D_6), δ=14.10 (*n*-BuO), 16.54, 16.57 (each d, J_{C-P}=5.9 Hz, EtO), 17.35 (d, J_{C-P}=2.1 Hz, 4-C), 19.73 (*n*-BuO), 26.59 (3-C), 32.18 (*n*-BuO), 32.96 (d, J_{C-P}=140.9 Hz, 6-CH_2P), 61.58, 61.77 (each d, J_{C-P}=5.9 Hz, EtO), 68.17 (*n*-BuO), 97.92 (2-C), 99.85 (d, J_{C-P}=9.6 Hz, 5-C), and 143.18 (d, J_{C-P}=10.8 Hz, 6-C); MS m/z (rel intensity, %) 306 (M^+, 28), 233 (29), 232 (base peak), 231 (34), 207 (26), 203 (55), 179 (26), 151 (32), 123 (23), 95 (28), 94 (55), and 56 (23). HRMS Found: m/z 306.1635. Calcd for $C_{14}H_{27}O_5P$: 306.1595.

2-Butoxy-6-[(diethoxyphosphoryl)methyl]-4-methyl-3,4-dihydro-2*H*-pyran (6c): A 34:66 mixture of cis and trans isomers (^{13}C NMR); Colorless liquid; IR (neat) 1675, 1450, 1390, 1370, 1325, 1295, 1250, 1120, 1050, 1020, 960, 830, and 770 cm^{-1}; ^1H NMR (C_6D_6) cis: δ=0.87 (3H, t, J=7.3 Hz, *n*-BuO), 0.92 (3H, d, J=6.6 Hz, 4-Me), 1.11 (6H, dt, J=7.0 and J_{H-P}=1.5 Hz, EtO), 1.2—1.7 (5H, m, 3-H and *n*-BuO), 1.83 (1H, dddd, J_{gem}=13.2, J_{3-4}=6.0, J_{3-2}=2.2, and J_{3-5}=1.0 Hz, one of 3-H), 2.19 (1H, m, 4-H), 2.57 (1H, dd, J_{gem}=15.0 and J_{H-P}=21.0 Hz, one of 6-CH_2P), 2.65 (1H, dd, J_{gem}=15.0 and J_{H-P}=21.0 Hz, the other of 6-CH_2P), 3.42 (1H, dt, J_{gem}=9.5 and J=6.8 Hz, *n*-BuO), 4.01 (4H, quint, J=J_{H-P}=7.0 Hz, EtO), 4.01 (1H, dt, J_{gem}=9.5 and J=6.8 Hz, *n*-BuO), 4.57 (1H, m, 5-H), and 4.86 (1H, dd, J_{2-3}=8.1 and 2.2 Hz, 2-H); trans: δ=0.87 (3H, t, J=7.0 Hz, *n*-BuO), 0.87 (3H, d, J=6.6 Hz, 4-Me), 1.10 (6H, br d, J=7.0 Hz, EtO), 1.2—1.7 (5H, m, 3-H and *n*-BuO), 1.7—1.9 (1H, m, one of 3-H), 2.52 (1H, m, 4-H), 2.5—2.7 (2H, m, 6-CH_2P), 3.3—3.4 (1H, m, *n*-BuO), 3.9—4.1 (5H, m, *n*-BuO and EtO), 4.65 (1H, m, 5-H), and 4.93 (1H, t, J_{2-3}=3.0 Hz, 2-H); ^{13}C NMR (C_6D_6) cis: δ=14.05 (*n*-BuO), 16.56 (d, J_{C-P}=5.9 Hz, EtO), 19.70 (*n*-BuO), 21.58 (d, J_{C-P}=2.9 Hz, 4-Me), 26.69 (d, J_{C-P}=2.0 Hz, 4-C), 32.20 (*n*-BuO), 32.69 (d, J_{C-P}=139.9 Hz, 6-CH_2P), 36.30 (3-C), 61.77 (d, J_{C-P}=5.9 Hz, EtO), 68.67 (*n*-BuO), 100.40 (2-C), 105.93 (d, J_{C-P}=9.8 Hz, 5-C), and 143.29 (d, J_{C-P}=10.8 Hz, 6-C); trans: δ=14.13 (*n*-BuO), 16.59 (d, J_{C-P}=5.9 Hz, EtO), 19.76 (*n*-BuO), 21.40 (d, J_{C-P}=2.9 Hz, 4-Me), 22.68 (d, J_{C-P}=2.0 Hz, 4-C), 32.22 (*n*-BuO), 32.89 (d, J_{C-P}=139.9 Hz, 6-CH_2P), 35.19 (3-C), 61.57 (d, J_{C-P}=5.9 Hz, EtO), 68.19 (*n*-BuO), 97.51 (2-C), 106.68 (d, J_{C-P}=9.8 Hz, 5-C), and 142.23 (d, J_{C-P}=10.8 Hz, 6-C); MS m/z (rel intensity, %) 320 (M^+, 34), 247 (35), 246 (86), 245 (36), 231 (91), 221 (74), 217 (29), 123 (40), 110 (25), 108 (base peak), 58 (22), and 57 (28).

6-[(Diethoxyphosphoryl)methyl]-2-isobutoxy-4-methyl-3,4-dihydro-2*H*-pyran (6d): A 38:62 mixture of cis and trans isomers (^{13}C NMR); Colorless liquid; IR (neat) 1675, 1450, 1390, 1365, 1250, 1120, 1050, 1020, 975, 895, 830, and 775 cm^{-1}; ^1H NMR (C_6D_6) cis: δ=0.92 (6H, d, J=7.0 Hz, *i*-BuO), 0.93 (3H, t, J=7.0 Hz, 4-Me), 1.11 (6H, dt, J=7.0 and J_{H-P}=1.5 Hz, EtO), 1.49 (1H, ddd, J_{gem}=13.2, J_{3-4}=9.2, and J_{3-2}=8.1 Hz, one of 3-H), 1.82 (1H, m, the other of 3-H), 1.88 (1H, m, *i*-BuO), 2.20 (1H, m, 4-H), 2.57, 2.65 (each 1H, dd, J_{gem}=13.5 and J_{H-P}=21.0 Hz, 6-CH_2P), 3.18, 3.81 (each 1H, dd, J_{gem}=9.5 and J=7.0 Hz, *i*-BuO), 4.01 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO), 4.58 (1H, m, 5-H), and 4.85 (1H, dd, J_{2-3}=8.1 and 2.2 Hz, 2-H); trans: δ=0.88 (3H, d, J=7.0 Hz, 4-Me), 0.92, 0.94 (each 3H, d, J=7.0 Hz, (C_6D_6), 1.10 (6H, dt, J=7.0 and J_{H-P}=4.1 Hz, EtO), 1.26 (1H, ddd, J_{gem}=13.2, J_{3-4}=10.3, and J_{3-2}=2.9 Hz, one of 3-H), 1.76 (1H, m, the other of 3-H), 2.51 (1H, m, 4-H), 2.5—2.7 (2H, m, 6-CH_2P), 3.17, 3.84 (each 1H, dd, J_{gem}=9.5 and J=7.0 Hz, *i*-BuO), 4.65 (1H, m, 5-H), and 4.92 (1H, t, J_{2-3}=2.9 Hz, 2-H); ^{13}C NMR (C_6D_6) cis: δ=16.59 (d, J_{C-P}=5.9 Hz, EtO), 19.50, 19.54 (each *i*-BuO), 21.58 (d, J_{C-P}=2.9 Hz, 4-Me), 26.62 (d, J_{C-P}=2.0 Hz, 4-C), 28.91 (*i*-BuO), 32.83 (d, J_{C-P}=139.9 Hz, 6-CH_2P), 36.14 (3-C), 61.58 (d, J_{C-P}=5.9 Hz, EtO), 61.76 (d, J_{C-P}=6.9 Hz, EtO), 75.66 (*i*-BuO), 100.52 (2-C), 105.94 (d, J_{C-P}=9.8 Hz, 5-C), and 143.22 (d , J_{C-P}=9.8 Hz, 6-C); trans: δ=16.59 (d, J_{C-P}=5.9 Hz), 19.50, 19.54 (each *i*-BuO), 21.39 (d, J_{C-P}=2.9 Hz, 4-Me), 22.66 (d, J_{C-P}=2.0 Hz, 4-C), 28.91 (*i*-BuO), 32.83 (d, J_{C-P}=140.9 Hz, 6-CH_2P), 35.15 (3-C), 61.58 (d, J_{C-P}=5.9 Hz, EtO), 61.76 (d, J_{C-P}=6.9 Hz, EtO), 75.03 (*i*-BuO), 97.59 (2-C), 106.69 (d, J_{C-P}=9.8 Hz, 5-C), and 142.18 (d, J_{C-P}=9.8 Hz, 6-C).

2-Butoxy-6-[(diethoxyphosphoryl)methyl]-4-propyl-3,4-dihydro-2*H*-pyran (6e): A 35:65 mixture of cis and trans isomers (^{13}C NMR); Colorless liquid; IR (neat) 1670, 1250, 1120, 1055, 1020, and 965 cm^{-1}; ^1H NMR (C_6D_6) cis: δ=0.82 (3H, t, J=7.3 Hz, *n*-Pr), 0.88 (3H, t, J=7.3 Hz, *n*-BuO), 1.11 (6H, br t, J=7.0 Hz, EtO), 1.2—1.6 (9H, m, *n*-BuO, *n*-Pr, and 3-H), 1.88 (1H, dddd, J_{gem}=13.2, J_{3-4}=6.0, J_{3-2}=2.2, and J_{3-5}=1.0 Hz, one of 3-H), 2.14 (1H, m, 4-H), 2.59 (1H, dd, J_{gem}=13.5 and J_{H-P}=21.0 Hz, one of 6-CH_2P), 2.66 (1H, dd, J_{gem}=13.5 and J_{H-P}=21.0 Hz, the other of 6-CH_2P), 3.44 (1H, dt, J_{gem}=9.5 and J=7.2 Hz, *n*-BuO), 4.0—4.1 (5H, m, *n*-BuO, and EtO), 4.66 (1H, m, 3-H), and 4.88 (1H, dd, J_{2-3}=8.1 and 2.2 Hz, 2-H); trans: δ=0.82 (3H, t, J=7.3 Hz, *n*-Pr), 0.88 (3H, t, J=7.3 Hz, *n*-BuO), 1.10 (6H, br t, J=7.0 Hz, EtO), 1.8—1.9 (9H, m, *n*-BuO, *n*-Pr, and 3-H), 2.45 (1H, m, 4-H), 2.5—2.7 (2H, m, 6-CH_2P), 3.4—3.5 (1H, m, *n*-BuO), 3.9—4.1 (5H, m, *n*-BuO and EtO), 4.74 (1H, m, 5-H), and 4.97 (1H, dd, J_{2-3}=3.0 and 2.2 Hz, 2-H); ^{13}C NMR (C_6D_6) cis: δ=14.05 (*n*-BuO), 14.29 (*n*-Pr), 16.57 (d, J_{C-P}=5.9 Hz, EtO), 19.70 (*n*-BuO), 20.30, 31.68 (each *n*-Pr), 32.24 (*n*-BuO), 32.71 (d, J_{C-P}=139.9 Hz, 6-CH_2P), 34.50 (3-C), 38.54 (d, J_{C-P}=2.0 Hz, 4-C), 61.72 (d, J_{C-P}=6.9 Hz, EtO), 68.68 (*n*-BuO), 100.63 (2-C), 104.53 (d, J_{C-P}=9.8 Hz, 3-C), and 143.50 (d, J_{C-P}=10.8 Hz, 6-C); trans: δ=14.07 (*n*-BuO), 14.37 (*n*-Pr), 16.60 (d, J_{C-P}=5.9 Hz, EtO) , 19.77 (*n*-BuO), 20.10, 27.44 (each *n*-Pr),

2-Butoxy-4-phenyl-6-[(diethoxyphosphoryl)methyl]-3,4-dihydro-2*H*-pyran (6f): A 23:77 mixture of cis and trans isomers (^{13}C NMR); Colorless liquid; IR (neat) 1670, 1600, 1250, 1125, 1050, 1025, 960, 755, and 695 cm^{-1}; ^1H NMR (C_6D_6) cis: δ=0.87 (3H, t, J=7.3 Hz, *n*-BuO), 1.14 (6H, dt, J=7.0 and J_{H-P}=1.1 Hz, EtO) 1.38 (2H, sex, J=7.3 Hz, *n*-BuO), 1.57 (2H, quint, J=7.3 Hz, *n*-BuO), 1.92 (1H, ddd, J_{gem}=13.2, J_{3-4}=10.6, and J_{3-2}=9.2 Hz, one of 3-H), 2.10 (1H, dddd, J_{gem}=13.2, J_{3-4}=6.0, J_{3-2}=1.8, and J_{3-5}=1.0 Hz, the other of 3-H), 2.5—2.8 (2H, m, 6-CH_2P), 3.3—3.5 (2H, m, 4-H and *n*-BuO), 3.9—4.1 (5H, m, EtO and *n*-BuO), 4.76 (1H, m, 5-H), 4.93 (1H, dd, J_{2-3}=9.2 and 1.8 Hz, 2-H), and 7.0—7.3 (5H, m, Ph); trans: δ=0.88 (3H, t, J=7.3 Hz, *n*-BuO), 1.09 (6H, t, J=7.0 Hz, EtO), 1.38 (2H, sex, J=7.3, *n*-BuO), 1.57 (2H, quint, J=7.3 Hz, *n*-BuO), 1.73 (1H, ddd, J_{gem}=13.2, J_{3-4}=10.6, and J_{3-2}=2.7 Hz, one of 3-H), 2.0—2.2 (1H, m, the other of 3-H), 2.5—2.8 (2H, m, 6-CH_2P), 3.75 (2H, m, 4-H and *n*-BuO), 3.9—4.1 (5H, m, EtO and *n*-BuO), 4.88 (1H, m, 5-H), 4.93 (1H, t, J_{2-3}=3.2 Hz, 2-H), and 7.0—7.3 (5H, m, Ph); ^{13}C NMR (C_6D_6) cis: δ=13.64 (*n*-BuO), 16.16, 16.21 (each d, J_{C-P}=5.9 Hz, EtO), 19.24, 31.76 (each *n*-BuO), 32.32 (d, J_{C-P}=139.9 Hz, 6-CH_2P), 37.29 (3-C), 38.20 (d, J_{C-P}=2.0 Hz, 4-C), 61.32, 61.43 (each d, J_{C-P}=6.9 Hz, EtO), 68.28 (*n*-BuO), 100.27 (2-C), 103.32 (d, J_{C-P}=9.8 Hz, 5-C), 126.32, 127.28, 128.33 (each Ar), 144.87 (d, J_{C-P}=10.8 Hz, 6-C), and 145.29 (Ar); trans: δ=14.11 (*n*-BuO), 16.53, 16.59 (each d, J_{C-P}=5.9 Hz, EtO), 19.73, 32.15 (each *n*-BuO), 32.94 (d, J_{C-P}=139.9 Hz, 6-CH_2P), 34.60 (d, J_{C-P}=2.0 Hz, 4-C), 36.26 (3-C), 61.59, 61.86 (each d, J_{C-P}=6.9 Hz, EtO), 68.38 (*n*-BuO), 97.30 (2-C), 103.97 (d, J_{C-P}=9.8 Hz, 5-C), 126.66, 127.97, 128.79 (each Ar), 143.75 (d, J_{C-P}=10.8 Hz, 6-C), and 145.92 (Ar); MS *m/z* (rel intensity, %) 382 (M^+, 2), 170 (32), 144 (23), 131 (21), 129 (34), 128 (36), 123 (34), 116 (31), 110 (21), 103 (23), 81 (26), 77 (21), and 30 (base peak).

2-Butoxy-4-(*p*-methoxyphenyl)-6-[(diethoxyphosphoryl)-methyl]-3,4-dihydro-2*H*-pyran (6g): A 26:74 mixture of cis and trans isomers (^{13}C NMR); Colorless liquid; IR (neat) 1675, 1610, 1510, 1460, 1445, 1370, 1250, 1030, 960, and 830 cm^{-1}; ^1H NMR (C_6D_6) cis: δ=0.87 (3H, t, J=7.3 Hz, *n*-BuO), 1.11 (6H, dt, J=7.0 and J_{H-P}=1.8 Hz, EtO), 1.36 (2H, sex, J=7.3 Hz, *n*-BuO), 1.56 (2H, quint, J=7.3 Hz, *n*-BuO), 1.94 (1H, ddd, J_{gem}=13.2, J_{3-4}=10.6, and J_{3-2}=9.2 Hz one of 3-H), 2.13 (1H, ddd, J_{gem}=13.2, J_{3-4}=6.0, and J_{3-2}=1.8 Hz, the other of 3-H), 2.62, 2.71 (each 1H, dd, J_{gem}=13.5 and J_{H-P}=21.6 Hz, 6-CH_2P), 3.35 (3H, s, *p*-MeO), 3.45, 4.03 (each 1H, dt, J_{gem}=9.5 and J=7.3 Hz, *n*-BuO), 3.4—3.5 (1H, m, 4-H), 4.02 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO), 4.80 (1H, m, 5-H), 4.95 (1H, dd, J_{2-3}=9.2 and 1.8 Hz, 2-H), 6.81, and 7.14 (each 2H, dt, J=8.4 and 1.8 Hz, Ar); trans: δ=0.89 (3H, t, J=7.3 Hz, *n*-BuO), 1.11 (6H, dt, J=7.0 and J_{H-P}=1.8 Hz, EtO), 1.36 (2H, sex, J=7.3 Hz, *n*-BuO), 1.59 (2H, quint, J=7.3 Hz, *n*-BuO), 1.76 (1H, ddd, J_{gem}=13.2, J_{3-4}=10.6, and J_{3-2}=3.2 Hz, one of 3-H), 2.0—2.2 (1H, m, the other of 3-H), 2.5—2.8 (2H, m, 6-CH_2P), 3.4—4.5 (2H, m, 4-H and *n*-BuO), 3.78 (3H, s, *p*-MeO), 4.0—4.1 (5H, m, *n*-BuO, and EtO), 4.92 (1H, m, 5-H), 4.95 (1H, t, J_{2-3}=3.2 Hz, 2-H), 6.81, and 7.14 (each 2H, dt, J=8.4 and 1.8 Hz, Ar); ^{13}C NMR (C_6D_6) cis: δ=14.04 (*n*-BuO), 16.56, 16.59 (each d, J_{C-P}=5.9 Hz, EtO), 19.65, 32.18 (each *n*-BuO), 32.73 (d, J_{C-P}=138.9 Hz, 6-CH_2P), 37.88 (d, J_{C-P}=2.0 Hz, 4-C), 38.01 (3-C), 54.83 (*p*-MeO), 61.65, 61.82 (each d, J_{C-P}=6.9 Hz, EtO), 68.69 (*n*-BuO), 100.77 (2-C), 104.19 (d, J_{C-P}=10.8 Hz, 5-C), 114.27, 128.58 (each Ar), 137.20 (d, J_{C-P}=2.0 Hz, Ar), 145.07 (d, J_{C-P}=10.8 Hz, 6-C), and 158.93 (Ar); trans: δ=14.11 (*n*-BuO), 16.56, 16.62 (each d, J_{C-P}=5.9 Hz, EtO), 19.74, 32.20 (each *n*-BuO), 32.99 (d, J_{C-P}=139.9 Hz, 6-CH_2P), 33.89 (d, J_{C-P}=2.0 Hz, 4-C), 36.54 (3-C), 54.83 (*p*-MeO), 61.52, 61.76 (each d, J_{C-P}=5.9 Hz, EtO), 68.38 (*n*-BuO), 97.42 (2-C), 104.37 (d, J_{C-P}=9.8 Hz, 5-C), 114.34, 128.58 (each Ar), 137.89 (d, J_{C-P}=2.0 Hz, Ar), 143.66 (d, J_{C-P}=10.8 Hz, 6-C), and 158.93 (Ar); MS *m/z* (rel intensity, %) 412 (M^+, 8), 312 (34), 231 (88), 200 (36), 174 (28), 161 (41), 136 (21), 123 (27), 69 (54), and 30 (base peak).

2-Butoxy-4,4-dimethyl-6-[(diethoxyphosphoryl)methyl]-3,4-dihydro-2*H*-pyran (6h): Colorless liquid; IR (neat) 1670 1645, 1465, 1445, 1390, 1365, 1250, 1160, 1120, 1055, 1025, 960, and 795 cm^{-1}; ^1H NMR (C_6D_6) δ=0.85 (3H, t, J=7.0 Hz, *n*-BuO), 0.95, 1.03 (each 3H, s, 4-Me), 1.11 (6H, dt, J=7.0 and J_{H-P}=1.4 Hz, EtO), 1.2—1.8 (6H, m, *n*-BuO and 3-H), 2.56, 2.64 (each 1H, dd, J_{gem}=12.0 and J_{H-P}=20.0 Hz, 6-CH_2P), 3.43 (1H, dt, J_{gem}=9.5 and J=6.6 Hz, *n*-BuO), 4.02 (4H, dq, J=7.0 and J_{H-P}=8.1 Hz, EtO), 4.05 (1H, dt, J_{gem}=9.5 and J=6.6 Hz, *n*-BuO), 4.54 (1H, d, J_{H-P}=4.4 Hz, 5-H), and 4.94 (1H, dd, J_{2-3}=7.0 and 3.0 Hz, 2-H); ^{13}C NMR (C_6D_6) δ=14.07 (*n*-BuO), 16.59 (d, J_{C-P}=5.9 Hz, EtO), 19.71 (*n*-BuO), 29.88 (d, J_{C-P}=2.0 Hz, 4-C), 30.36 (d, J_{C-P}=2.9 Hz, 4-Me), 31.55 (d, J_{C-P}=3.9 Hz, 4-Me), 32.25 (*n*-BuO), 32.73 (d, J_{C-P}=139.9 Hz, 6-CH_2P), 41.83 (3-C), 61.63 (d, J_{C-P}=5.9 Hz, EtO), 68.78 (*n*-BuO), 98.93 (2-C), 110.64 (d, J_{C-P}=10.8 Hz, 5-C), and 141.79 (d, J_{C-P}=10.8 Hz, 6-C); MS *m/z* (rel intensity, %) 334 (M^+, 14), 245 (base peak), 235 (54), 123 (19), and 41 (23).

General Procedure for the Hydrolysis and Cyclization Sequence of 6a—h Leading to 2-Cyclohexen-1-ones 7a—f. As a typical procedure the conversion of **6a** into **7a** is described as follows: To a solution of **6a** (0.055 g, 0.198 mmol) in THF (4 ml) was added 4 M hydrochloric acid (2 ml). After stirring at room temperature for 5 min, the mixture was extracted with dichloromethane (15 ml×2). The combined extracts were dried over magesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using ethyl acetate-methanol (9:1 v/v) to give **7a** (0.04 g, 87%). Other compounds **6b—h** were similarly treated under the reaction conditions listed in Table 2. The purification of **7b—f** was carried out by silica-gel column chromatography using ethyl acetate-methanol: **7b**, **7c**, and **7e**: 9:1 v/v; **7d**: 98:2 v/v; **7f**: 19:1 v/v.

2-(Diethoxyphosphoryl)-2-cyclohexen-1-one (7a): Colorless liquid; IR (neat) 1675, 1600, 1345, 1245, 1160, 1060, 1025, and 965 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (6H, dt, J=7.0 and J_{H-P}=0.8 Hz, EtO), 2.06 (2H, quint, J_{5-4}=J_{5-6}=6.6 Hz, 5-H), 2.50 (2H, t, J_{6-5}=6.6 Hz, 6-H), 2.54 (2H, dt, J_{4-5}=6.6 and J_{4-3}=4.1 Hz, 4-H), 4.17 (4H, m, EtO), and 7.92 (1H, dt, J_{3-4}=4.1 and J_{H-P}=21.3 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=16.39 (d, J_{C-P}=5.9 Hz, EtO), 22.03 (5-C), 26.82 (d, J_{C-P}=14.7 Hz, 4-C), 38.48 (d, J_{C-P}=7.8 Hz, 6-C), 62.48 (d, J_{C-P}=5.9 Hz, EtO), 131.60 (d, J_{C-P}=181.9 Hz, 2-C), 163.37 (d, J_{C-P}=5.9 Hz, 3-C), and 196.05 (d, J_{C-P}=5.9 Hz, 1-C); MS *m/z* (rel intensity, %) 232 (M^+, 48), 204 (37), 177 (20), 176 (94), 159 (46), 149 (48), 148 (76), 132 (21), 127 (22), 123, (26), 121 (78), 120 (52), 106 (49), 95

(30), 94 (30), 91 (21), 81 (47), and 79 (26). HRMS Found: *m/z* 232.0859. Calcd for $C_{10}H_{17}O_4P$: M, 232.0863.

2-(Diethoxyphosphoryl)-5-methyl-2-cyclohexen-1-one (7b): Colorless liquid; IR (neat) 1675, 1600, 1360, 1340, 1240, 1155, 1095, 1050, 1020, 960, 790, 750, and 620 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.09 (3H, d, J=5.9 Hz, 5-Me), 1.32 (6H, dt, J=7.0 and J_{H-P}=0.7 Hz, EtO), 2.1—2.4 (3H, m, 4- and 5-H), 2.59 (2H, m, 6-H), 4.16 (4H, m, EtO), and 7.88 (1H, ddd, J_{3-4}=7.7, 2.2, and J_{H-P}=20.5 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=16.37 (d, J_{C-P}=5.9 Hz, EtO), 20.59 (5-Me), 29.70 (5-C), 34.98 (d, J_{C-P}=14.7 Hz, 4-C), 46.58 (d, J_{C-P}=7.8 Hz, 6-C), 62.42, 62.46 (each d, J_{C-P}=5.9 Hz, EtO), 131.28 (d, J_{C-P}=182.9 Hz, 2-C), 162.69 (d, J_{C-P}=5.9 Hz, 3-C), and 196.29 (d, J_{C-P}=5.9 Hz, 1-C); MS *m/z* (rel intensity, %) 246 (M^+, 50), 231 (27), 203 (26), 176 (39), 175 (21), 173 (21), 149 (35), 148 (41), 121 (45), 120 (34), 91 (26), 81 (27), 79 (27), and 29 (base peak). HRMS Found: *m/z* 246.1065. Calcd for $C_{11}H_{19}O_4P$: M, 246.1019.

2-(Diethoxyphosphoryl)-5-propyl-2-cyclohexen-1-one (7c): Colorless liquid; IR (neat) 1675, 1600, 1345, 1240, 1050, 1025, 970, 790, and 755 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (3H, t, J=6.2 Hz, *n*-Pr), 1.2—1.5 (4H, m, *n*-Pr), 1.27 (6H, dt, J=7.0 and J_{H-P}=0.7 Hz, EtO), 2.1—2.4 (3H, m, 4- and 5-H), 2.56 (2H, m, 6-H), 4.12 (4H, m, EtO), and 7.84 (1H, ddd, J_{3-4}=5.5, 2.2, and J_{H-P}=21.1 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=13.98 (*n*-Pr), 16.37 (d, J_{C-P}=5.9 Hz, EtO), 19.50 (*n*-Pr), 33.31 (d, J_{C-P}=14.7 Hz, 4-C), 34.27, 37.72 (each *n*-Pr), 44.87 (d, J_{C-P}=7.8 Hz, 6-C), 62.45 (d, J_{C-P}=4.9 Hz, EtO), 131.41 (d, J_{C-P}=182.9 Hz, 2-C), 162.83 (d, J_{C-P}=5.9 Hz, 3-C), and 196.42 (d, J_{C-P}=5.9 Hz, 1-C); MS *m/z* (rel intensity, %) 274 (M^+, 3), 222 (base peak), 195 (32), 194 (37), 179 (23), 167 (24), 152 (24), 151 (20), 139 (33), 125 (35), 123 (44), 121 (25), 109 (23), 97 (30), and 81 (35). HRMS Found: *m/z* 274.1423. Calcd for $C_{13}H_{23}O_4P$: M, 274.1333.

2-(Diethoxyphosphoryl)-5-phenyl-2-cyclohexen-1-one (7d): Colorless liquid; IR (neat) 1680, 1600, 1500, 1450, 1390, 1365, 1345, 1250, 1215, 1100, 1060, 1025, 970, 790, 760, and 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.34 (6H, dt, J=7.0 and J_{H-P}=4.8 Hz, EtO), 2.6—2.9 (4H, m, 4- and 6-H), 3.37 (2H, m, 5-H), 4.20 (4H, m, EtO), 7.2—7.4 (5H, m, Ph), and 7.96 (1H, ddd, J_{3-4}=5.5, 2.6, and J_{H-P}=19.5 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=16.39 (d, J_{C-P}=4.9 Hz, EtO), 34.58 (d, J_{C-P}=14.7 Hz, 4-C), 40.14 (5-C), 45.27 (d, J_{H-P}=7.8 Hz, 6-C), 62.54, 62.56 (each d, J_{C-P}=5.9 Hz, EtO), 126.59, 127.25, 128.89 (each Ph), 131.59 (d, J_{C-P}=18.4 Hz, 2-C), 142.23 (Ph), 162.18 (d, J_{C-P}=5.9 Hz, 3-C), and 195.57 (d, J_{C-P}=5.9 Hz, 1-C); MS *m/z* (rel intensity, %) 308 (M^+,7), 228 (82), 200 (51), 184 (22), 183 (base peak), 182 (29), 155 (31), and 67 (23). HRMS Found: *m/z* 308.1172. Calcd for $C_{16}H_{21}O_4P$: M, 308.1176.

2-(Diethoxyphosphoryl)-5-(*p*-methoxyphenyl)-2-cyclohexen-1-one (7e): Colorless liquid; IR (neat) 1675, 1610, 1510, 1250, 1180, 1060, 1025, 970, 835, 795, and 750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.35 (6H, dt, J=7.3 and J_{H-P}=4.4 Hz, EtO), 2.5—2.9 (4H, m, 4- and 6-H), 3.30 (1H, m, 5-H), 3.80 (3H, s, *p*-MeO), 4.19 (4H, m, EtO), 6.88 (2H, dt, J=8.8 and 2.2 Hz, Ar), 7.15 (2H, dt, J=8.8 and 2.2 Hz, Ar), and 7.95 (1H, ddd, J_{3-4}=5.5, 2.2, and J_{H-P}=20.2 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=16.40 (d, J_{C-P}=5.9 Hz, EtO), 34.88 (d, J_{C-P}=14.7 Hz, 4-C), 39.44 (5-C), 45.61 (d, J_{C-P}=7.9 Hz, 6-C), 55.30 (*p*-MeO), 62.53, 62.58 (each d, J_{C-P}=5.9 Hz, EtO), 114.24, 127.57 (each Ar), 131.55 (d, J_{C-P}=182.9 Hz, 2-C), 134.41, 158.71 (each Ar), 162.33 (d, J_{C-P}=5.9 Hz, 3-C), and 195.57 (d, J_{C-P}=5.9 Hz, 1-C); MS *m/z* (rel intensity, %) 338 (M^+, 79), 337 (21), 217 (27), 201 (28), 200 (45), 172 (22), 134 (base peak), 128 (26), 121 (54), 119 (30), 115 (28), 91 (37), 81 (34), and 77 (29). HRMS Found: *m/z* 338.1284. Calcd for $C_{17}H_{23}O_5P$: M, 338.1282.

2-(Diethoxyphosphoryl)-5,5-dimethyl-2-cyclohexen-1-one (7f): Colorless liquid; IR (neat) 1675, 1600, 1385, 1350, 1235, 1050, 1020, 965, 780, and 750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.06 (6H, s, 5-Me), 1.32 (6H, t, J=7.0 Hz, EtO), 2.35 (2H, d, J_{H-P}=1.1 Hz, 6-H), 2.42 (1H, t, J_{4-3}=J_{H-P}=4.0 Hz, 4-H), 4.16 (4H, m, EtO), and 7.81 (1H, dt, J_{3-4}=4.0 and J_{H-P}=20.5 Hz, 3-H); ^{13}C NMR ($CDCl_3$) δ=16.37 (d, J_{C-P}=5.9 Hz, EtO), 28.13 (5-Me), 33.74 (5-C), 40.91 (d, J_{C-P}=15.7 Hz, 4-C), 52.14 (d, J_{C-P}=7.8 Hz, 6-C), 62.45 (d, J_{C-P}=5.9 Hz, EtO), 130.56 (d, J_{C-P}=182.9 Hz, 2-C), 161.66 (d, J_{C-P}=5.9 Hz, 3-C), and 196.26 (d, J_{C-P}=5.9 Hz, 1-C). MS *m/z* (rel intensity, %) 260 (M^+, 3), 176 (12), 149 (14), 121 (18), 81 (27), 79 (20), and 30 (base peak). HRMS Found: *m/z* 260.1179. Calcd for $C_{12}H_{21}O_4P$: M, 260.1176.

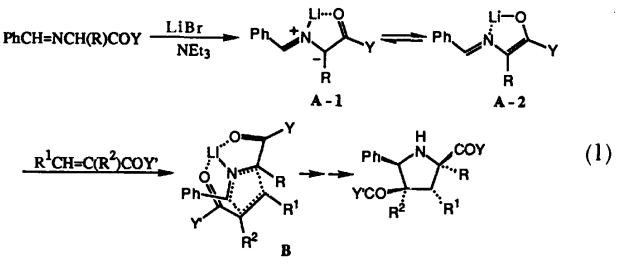
The lithiated intermediate derived from methyl 2-(benzylideneamino)propanoate and lithium bromide/triethylamine undergoes cycloaddition and Michael addition with methyl acrylate. 1,3-Dipole character of the intermediate is suggested on the basis of the product ratios obtained under a variety of conditions. The reaction mechanism via a four-centered transition state is proposed.

It was found that treatment of 2-(benzylideneamino)-alkanoates or -alkanamides PhCH=NCH(R)COY (Y= OMe, NHBu-*t*, or 1-pyrrolidinyl; R=H, Me, or *i*-Pr) with lithium bromide/triethylamine or 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) in tetrahydrofuran (THF) led to the generation of lithiated intermediates **A** (Eq. 1).[1] These species **A** showed high reactivity toward electron-deficient olefins and underwent highly stereo- and regioselective cycloadditions with α,β-unsaturated esters or ketones $R^1CH=C(R^2)COY'$ (Y'=COOMe, COOBu-*t*, COMe, or COAr) to produce stereochemically defined pyrrolidines.



(1)

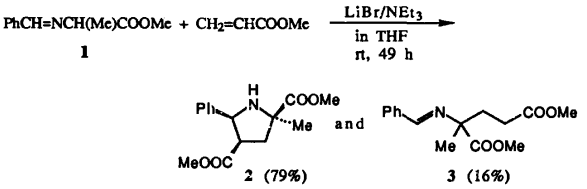
In the preceding paper,[1] we proposed two possible reaction mechanisms, concerted 1,3-dipolar cycloaddition of *N*-lithioazomethine ylide **A-1** and tandem Michael-imine addition of lithium enolate **A-2**. It was concluded that the high selectivity was due to the tight lithium chelation in the transition state, while specification of the reacting species was not made.

On the other hand, Michael additions with the imines of α-amino esters[2] or nitriles[3] are known. In some cases, metallic bases such as lithium diisopropylamide (LDA) and potassium *t*-butoxide were used as bases so that metalated intermediates like **A** must have been involved. Accordingly, metalated intermediates derived from the imines of α-amino esters can serve as both 1,3-dipoles and Michael donors, and probably the course of reactions depends upon the reaction conditions.

In the present article, the reaction of methyl 2-(benzylideneamino)propanoate with methyl acrylate has been investigated under various conditions employing metal halides/triethylamine or DBU. An alternative reaction mechanism leading to cycloaddition and Michael addition is presented.

Results and Discussion

An exception of the highly stereo- and regioselective cycloadditions of anions **A** depicted in Eq. 1 was the reaction of methyl 2-(benzylideneamino)propanoate (**1**) with methyl acrylate under identical conditions (with lithium bromide and triethylamine in THF at room temperature). A 5:1 mixture of cycloadduct **2** and Michael adduct **3** was produced (Scheme 1 and Entry 1 in Table 1). Therefore this reaction was investigated here under a variety of conditions. Analysis of the product ratio would help us to solve the factors which may be responsible for the determination of the reaction courses. The results are summarized in Table 1.



Scheme 1.

In most cases the reactions were carried out under the standard conditions using each 1.5 and 1.2 equivalent amounts of lithium bromide and triethylamine at room temperature in dry THF (5 ml for 1 mmol of imine **1**). The isomer ratio **2**:**3** remained unchanged (4—5:1) for several reaction times and temperatures (Entries 1—3 and 8). The comparable **2**:**3** ratio was observed even in the midst of reaction, indicating the kinetically controlled formation of both **2** and **3** (Entry 4). In fact compounds **2** and **3** were not interconverted with each other under these reaction conditions.[4]

A possible reaction mechanism was illustrated on the basis of the above results and the following observations (Fig. 1). Lithium bromide coordinates

with the imine nitrogen of **1** so that the α-hydrogen of **C** can be easily deprotonated with a weak base such as triethylamine to generate lithiated intermediate **D**.

As mentioned above, two intermediates **A-1** and **A-2** (R=Me, Y=OMe) were proposed in the preceding paper.[1] However the only structural difference between **A-1** and **A-2** comes from the relative covalency of the lithium–heteroatom bonds, indicating the existence of little, if any, energy barrier between them. We propose that anionic species **D** can be an intermediate which may exhibit properties both as *N*-lithiated azomethine ylide and as ester enolate.

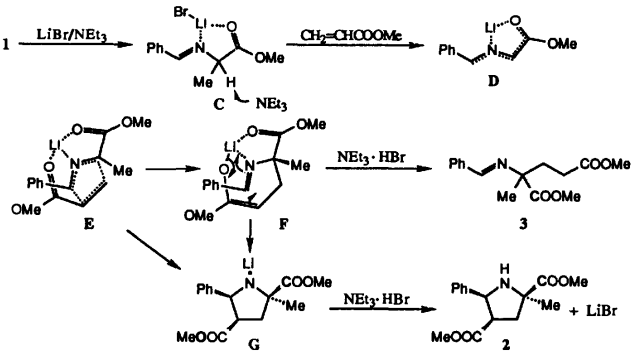


Fig. 1. Competitive formation of a cycloadduct **2** and a Michael adduct **3**.

Intermediate **D** would then be involved in the transition state **E** previously proposed for the lithium-chelated concerted cycloaddition.[1] Bond formation at the β-carbon of the acrylate precedes that at the α-carbon to give **F**. Quenching of **F** with a proton source, presumably triethylammonium bromide, leading to Michael adduct **3** competes with intramolecular cyclization producing cycloadduct lithium amide **G**.[5] Ready quenching of **G** with the ammonium salt produces cycloadduct **2**. The direct formation of **G** from **E** may also be involved.

In Entries 9—13, a catalytic amount of lithium bromide and/or triethylamine was employed. Both lithium bromide and triethylamine can be effectively recycled in the manner shown in Fig. 1. Since the step of deprotonation of **1** (**C**→**D**) is rate-determining as suggested by the rate acceleration upon using DBU (Entries 22—24), the catalyzed reactions were relatively decelerated. It is not surprising that no reaction took place in the absence of lithium bromide (Entry 13).

When either lithium bromide or triethylamine was used in moderate excess, the ratio of cycloaddition increased (Entries 14, 15). Presumably the excess lithium bromide or triethylamine reduces acidity of triethylammonium bromide by coordination.

Dilution with THF increased the amount of **2** (Entries 3 and 5—7). Since collapse of **F** into **3** is an

a) Unless otherwise stated, 5 ml of solvent was used for 1 mmol of **1**. The amount in parenthesis indicates the volume of THF used for 1 mmol of **1**. b) Yield of isolated mixtures. c) Based on the ^1H NMR of an isolated mixture of **2** and **3**. d) Lithium iodide was used instead of LiBr.

intermolecular reaction and the dilution procedure disfavors this process, the relative rate of intramolecular process **F**→**G** was increased as a result. The effect of only catalytic amounts of lithium bromide and triethylamine (Entry 12) is similar to that of dilution.

Addition of water results in an increase of proton source; the Michael adduct formation increased (Entries 16, 17). It should be emphasized, however, that both anions **D** and **F** are quite stable toward water. Most of them can survive upon addition of 0.7 equivalent of water which corresponds to a large excess against **D** and **G**.[6]

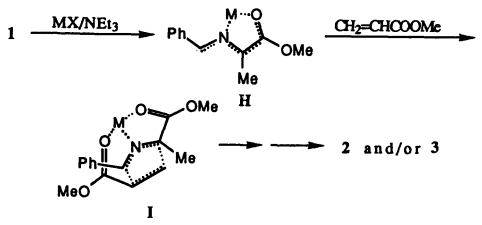
When lithium bromide (Entry 11) or triethylamine (Entries 9, 10) was used in a large excess (tweleve- or fifteen-fold equivalents) in some catalyzed reactions, the **2**:**3** ratio was unexpectedly decreased. The large excess lithium bromide and triethylamine presumably collapse the lithium chelation **E** which is essential for the formation of **G**.

Replacement of THF by acetonitrile, dichloromethane, or diethyl ether favored the Michael addition (Entries 18—20). However the effect of polarity of solvent on **2**:**3** ratio remains ambiguous because all the reactions except in THF were carried out as suspension.

When DBU was employed as a stronger base, reactions were completed within 1 min at room temperature, indicating high acceleration of the deprotonation step leading to **D**. The decreased 2:3 ratio (1.8:1, Entry 21) is due to a relatively high concentration of intermediate **D** compared with the case employing triethylamine. No change of the **2**:**3** ratio in the DBU-catalyzed reaction (Entry 23) and predominant formation of the cycloadduct **2** in the ten-fold dilution reaction (Entry 22) are both comparable to the above results, Entries 9—11 and Entries 5, 6, respectively.

Deprotonation of **1** with lithium bromide and DBU occurred even at −78 °C, but the reaction with methyl acrylate at −78 °C unfortunately gave a low **2**:**3** ratio (Entry 24). Addition of water provided a similar result (Entry 25).

As discussed above, the **2**:**3** ratio is mainly determined by the relative rate of cyclization of **F** into **G**. On the other hand, route **E**→**F** competes with the direct cyclization route **E**→**G**. Substitution of the electropositive lithium metal in the intermediate **D** with a less positive one such as aluminum or magnesium is expected to increase the relative contribution of route **E**→**G**.



Scheme 2.

With an expectation to open the entry for similar metalated intermediates **H**, other metal halides (MX) were employed in the deprotonation step of imine **1** (Scheme 2). Thus **1** was treated with a variety of metal halides and triethylamine in dry THF in the presence of methyl acrylate. Since the resulting intermediates **H** certainly undergo chelation-controlled reactions with the acrylate via **I**, cycloadduct **2** and/or Michael adduct **3** are to be formed.

The results are summarized in Table 2. Quantitative recovery of the starting imine **1** in Entries 3 and 5 is due to the extremely poor solubility of sodium bromide and potassium iodide in THF. Use of sodium iodide generated intermediate **H** (M=Na) which led to preferred formation of Michael adduct **3** (Entry 4). Magnesium bromide diethyl etherate, zinc chloride, and ethylaluminum dichloride are also effective; the cycloadduct **2** was the only identified product as expected in all cases (Entries 6—10).

Michael additions occur regioselectively at the β-carbon of the olefins bearing an anion-stabilizing substituent. On the other hand, the regioselectivity of 1,3-dipolar cycloadditions with azomethine ylides

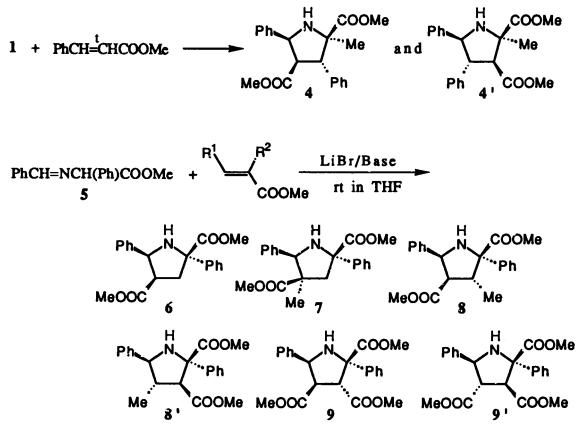
depends upon the orbital coefficients of frontier orbitals of both reagents.[7] Accordingly, examination of regioselectivity of the above reactions is an important clue by which the reaction mechanism is solved.

The lithium chelation-controlled cycloadditions of imines of α-amino esters and amides with electron-deficient olefins offer a few exceptional selectivities as shown below. Reaction of the lithium anion of **1** with methyl cinnamate gave two cycloadducts **4** and **4'** in a 2:1 ratio (Scheme 3 and Table 3). The major product **4** was assigned as a normal stereoisomer on the basis of the chemical shifts of 2-COOMe (δ=3.79), 4-COOMe (3.08), and 2-Me (1.19), while **4'** was its regioisomer (COOMe: 3.59 and 3.75; 2-Me: 1.74; 3-H: 3.31 as a doublet; 4-H: 3.75 as a doublet-doublet).



Scheme 3.

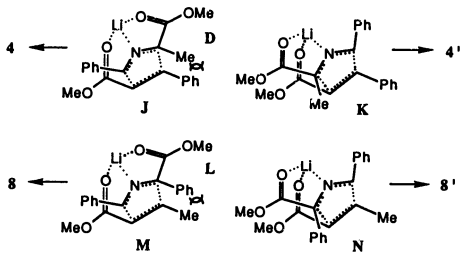


Fig. 2. Decreased regioselectivity by a steric repulsion.

Methyl 2-(benzylideneamino)phenylacetate (**5**) was reacted with several olefins in the presence of lithium bromide and triethylamine (Scheme 3 and Table 3). With methyl acrylate and methyl methacrylate normal regio- and stereoisomers **6** and **7** were obtained as single products. The reaction with methyl crotonate, however, gave two regioisomeric cycloadducts **8** and **8'** (1:6). It was quite surprising that abnormal regioisomer **8'** was the far major product. Structures of **8** and **8'** were also based on their ^{1}H NMR spectra: **8**: 4-COOMe: 3.21; 4-H: 3.02 as doublet-doublet; **8'**: 3-COOMe: 3.62; 3-H: 3.32 as a doublet.

In both approaches **J** and **M** leading to normal regioisomers **4** and **8**, respectively, serious steric repulsion exists between the methyl and phenyl substituents. Especially the repulsion in **M** should be more critical because the phenyl plane of **L** is forced out of the ylide triangle due to steric congestion caused by the adjacent methoxyl moiety.[8] Substitution by a phenyl moiety at the β-carbon of acrylate causes a decrease of the coefficient of the lowest unoccupied molecular orbital (LUMO) at this position. The reported atomic orbital coefficients (LUMO) are as follows:[9] methyl acrylate: C(C_α): 0.4286; C(C_β): −0.6194. Methyl cinnamate: C(C_α): 0.4717; C(C_β): −0.4248. This may be the reason why the regioisomeric approach **K** has participated in cycloaddition to give **4'**.

The unexpected regioselectivity giving **8'** as a far major regioisomer should be due to the serious steric repulsion in approach **M** which was already mentioned above. Predominant formation of **9'** in the reaction of **5** with dimethyl fumarate stems from a similar steric repulsion.

The above anomalous regiochemical consequences support the cycloaddition transition state, for example **E**, of anionic intermediate such as **D** or **H** first proposed in the present work.

Experimental

General. Melting points were determined on a Yanagimoto melting point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702

a) All reactions were carried out in dry THF at room temperature. b) Yield of the isolated product(s). Yield of unreacted **5** is in parenthesis. c) Both isomers were separated from each other. The ratio was determined by ^{1}H NMR of the unpurified product. d) As an inseparable mixture. e) Based on ^{1}H NMR of the unpurified mixture.

spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-40 (90 MHz), a JEOL FX-100 (100 MHz), or a JEOL GSX-270 instrument (270 MHz), and ^{13}C NMR on a JEOL FX-100 (25.05 MHz) or a JEOL GSX-270 spectrometer (67.94 MHz). Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra and high resolution mass spectra (HRMS) were measured with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. Elemental analyses were performed on a Hitachi 026 CHN analyzer. For preparative column chromatography, Wakogel C-200, C-300 (Wako), and Silica gel 60 (Merck) were employed. Flash chromatography was carried out on an EYELA EF-10 apparatus using a column (20×180 mm) packed with Silica gel 60 (Merck, size: 0.04—0.063 mm). Gas liquid chromatography (GLC) was accomplished on a Yanaco G-2800 gas chromatograph (Yanagimoto) with an ionization flame detector using a glass column (SE-30, 3×2000 nm) or a glass capillary column (Silicone GE, SE-30, 0.25×50000 mm). Micro vacuum distillation was carried out on a Sibata GTO-250R Kugelrohr distilling apparatus.

General Procedures for Metal Halide/Amine-Induced Reactions of Imine 1[1] or 5[10] with Electron-Deficient Olefins. To a solution of imine **1** or **5** in dry THF (or other solvent) was added a metal halide under nitrogen. Addition of an olefin was followed and then an amine, both with the aid of a syringe. If necessary, an additive was added and the resulting mixture was stirred under the reaction conditions listed in Tables 1—3. After the reaction was over, the mixture was treated with saturated ammonium chloride and extracted with diethyl ether. The extract was dried over magnesium sulfate and evaporated in vacuo. The residue was subjected to ^{1}H NMR measurement to know the purity of products as well as the isomer ratio.

Dimethyl 2-(Benzylideneamino)-2-methylglutarate (3): This compound **3** decomposed so readily when chromatographed on silica gel that its separation from the mixture with **2**[1] was unsuccessful. **3**: Colorless liquid; IR (neat) 1730 (C=O) and 1630 (C=N) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.49 (3H, s, Me), 1.9—2.6 (4H, m, CH_2), 3.60, 3.69 (each 3H, s, COOMe), 7.3—7.4 (3H, m, Ph), 7.7—7.8 (2H, m, Ph), and 8.24 (1H, s, CH=N); MS *m/z* (rel intensity, %) 278 (M^++1, 2), 219 (17), 218 (base peak), 158 (47), 131 (19), 130 (19), 104 (34), 98 (53), 90 (28), and 89 (19). No HRMS was obtainable due to the lack of M^+.

Dimethyl 2-Methyl-*t*-3,*c*-5-diphenylpyrrolidine-*r*-2,*c*-4-dicarboxylate (4): The mixture of **4** and **4′** was chromatographed on silica gel by using hexane–ethyl acetate (5:1 v/v) to give **4** and then **4′**. **4**: Colorless prisms (chloroform–hexane); mp 84—85 °C; IR (KBr) 3330 (NH), 1735, and 1720 (each C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.19 (3H, s, 2-Me), 3.06 (1H, br s, NH), 3.08 (3H, s, 4-COOMe), 3.79 (3H, s, 2-COOMe), 3.91 (1H, dd, J_{4-3}=10.6 and J_{4-5}=9.5 Hz, 4-H), 4.20 (1H, d, J_{3-4}=10.6 Hz, 3-H), 4.90 (1H, d, J_{5-4}=9.5 Hz, 5-H), 7.2—7.4 (8H, m, Ph), and 7.44 (2H, d, Ph); ^{13}C NMR ($CDCl_3$) δ=21.22 (2-Me), 51.32, 52.44 (each COOMe), 54.44, 54.98 (3- and 4-C), 62.81 (5-C), 68.87 (2-C), 127.30, 127.38, 127.77, 128.19, 128.28, 128.64, 137.22, 140.34 (each Ph), 171.69, and 175.50 (each COOMe); MS *m/z* (rel intensity, %) 353 (M^+, 1), 295 (18), 294 (83), 234 (31), 192 (16), 191 (base peak), 132 (13), 131 (92), 130 (17), 115 (18), 103 (11), 91 (17), 90 (16), and 77 (10). Found: C, 71.18; H, 6.55; N, 4.00%. Calcd for $C_{21}H_{23}NO_4$: C, 71.37; H, 6.56; N, 3.96%.

Dimethyl 2-Methyl-*t*-4,*c*-5-diphenylpyrrolidine-*r*-2,*c*-3-dicarboxylate (4′): Colorless needles (chloroform–hexane); mp 108—109 °C; IR (KBr) 3360 (NH), 1735, and 1717 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.74 (3H, s, 2-Me), 3.03 (1H, br s, NH), 3.31 (1H, d, J_{3-4}=12.1 Hz, 3-H), 3.59 (3H, s, 3-COOMe), 3.63 (1H, dd, J_{4-3}=12.1 and J_{4-5}=10.6 Hz, 4-H), 3.75 (3H, s, 2-COOMe), 4.31 (1H, d, J_{5-4}=10.6 Hz, 5-H), and 7.1—7.3 (10H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=27.37 (2-Me), 51.98, 52.76 (each COOMe), 57.33 (3-C), 63.18 (4-C), 67.87, 69.12 (2- and 5-C), 127.05, 127.27, 127.61, 127.71, 128.43, 128.51, 138.02, 140.13 (each Ph), 171.77, and 175.19 (each COOMe); MS *m/z* (rel intensity, %) 294 (M^+—COOMe, 28), 192 (11), 191 (87), 132 (13), 131 (base peak), 130 (23), 129 (17), 128 (10), 115 (16), 91 (17), 90 (17), and 77 (10). Found: C, 71.35; H, 6.61; N, 4.02%. Calcd for $C_{21}H_{23}NO_4$: C, 71.37; H, 6.56; N, 3.96%.

Dimethyl 2,*c*-5-Diphenylpyrrolidine-*r*-2,*c*-4-dicarboxylate (6): Colorless needles (chloroform–hexane); mp 104—105 °C; IR (KBr) 3360 (NH), 1735, and 1730 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.61 (1H, dd, J_{gem}=13.2 and J_{3-4}=7.0 Hz, one of 3-H), 3.15 (1H, dd, J_{gem}=13.2 and J_{3-4}=5.9 Hz, the other of 3-H), 3.22 (3H, s, 4-COOMe), 3.23 (1H, ddd, J_{4-5}=7.3 and J_{4-3}=7.0 and 5.9 Hz, 4-H), 3.48 (1H, br s, NH), 3.75 (3H, s, 2-COOMe), 4.57 (1H, d, J_{5-4}=7.3 Hz, 5-H), 7.3—7.4 (8H, m, Ph), and 7.74 (2H, d, Ph); ^{13}C NMR ($CDCl_3$) δ=40.99 (3-C), 50.32 (4-C), 51.16, 52.81 (each COOMe), 64.74 (5-C), 71.83 (2-C), 126.33, 126.75, 127.48, 127.64, 128.23, 128.33, 139.22, 143.08 (each Ph), 173.05, and 174.48 (each COOMe); MS *m/z* (rel intensity, %) 281 (20), 280 (M^+—COOMe, base peak), 220 (27), 193 (27), 115 (17), 104 (11), and 76 (11). Found: C, 70.86; H, 6.30; N, 4.02%. Calcd for $C_{20}H_{21}NO_4$: C, 70.78; H, 6.24; N, 4.13%.

Dimethyl *t*-4-Methyl-2,*c*-5-diphenylpyrrolidine-*r*-2,4-dicarboxylate (7): Colorless prisms (chloroform–hexane); mp 114—115 °C; IR (KBr) 3360 (NH), 1720, and 1710 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.24 (3H, s, 4-Me), 2.31 (1H, d, J_{gem}=13.6 Hz, one of 3-H), 3.31 (3H, s, 4-COOMe), 3.37 (1H, d, J_{gem}=13.6 Hz, the other of 3-H), 3.76 (3H, s, 2-COOMe), 3.82 (1H, br s, NH), 4.02 (1H, s, 5-H), 7.2—7.4 (8H, m, Ph), and 7.76 (2H, d, Ph); ^{13}C NMR ($CDCl_3$) δ=21.28 (4-Me), 50.83 (3-C), 51.33, 52.84 (each COOMe), 56.34 (4-C), 71.30 (2-C), 73.33 (5-C), 126.45, 126.48, 127.32, 128.07, 128.28, 128.35, 137.45, 144.59 (each Ph), 175.01, and 175.27 (each COOMe); MS *m/z* (rel intensity, %) 353 (M^+, 1), 294 (18), 293 (87), 252 (40), 233 (30), 194 (19), 193 (base peak), 129 (11), 115 (13), 104 (14), 91 (18), 90 (15), 89 (11), 77 (15), and 44 (10). Found: C, 71.52; H, 6.56; N, 4.08%. Calcd for $C_{21}H_{23}NO_4$: C, 71.37; H, 6.56; N, 4.08%.

Dimethyl *t*-3-Methyl-2,*c*-5-diphenylpyrrolidine-*r*-2,*c*-4-dicarboxylate (8) + Dimethyl *t*-4-Methyl-2,*c*-5-diphenylpyrrolidine-*r*-2,*c*-3-dicarboxylate (8′): An inseparable mixture of **8** and **8′** (1:6 by ^{1}H NMR) was obtained after column chromatographic purification of the crude reaction mixture on silica gel with chloroform. Spectral data were obtained as a mixture. **8**: ^{1}H NMR ($CDCl_3$) δ=0.82 (3H, d, J_{Me-3}=6.6 Hz, 3-Me), 3.02 (1H, dd, J_{4-3}=10.2 and J_{4-5}=9.2 Hz, 4-H), 3.21 (3H, s, 4-COOMe), 3.40 (2H, m, 3-H and NH), 3.78 (3H, s, 2-COOMe), 5.01 (1H, d, J_{5-4}=9.2 Hz, 5-H), and 7.3—7.5 (10H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=15.35 (3-Me), 41.11 (3-C), 51.14, 52.47 (each COOMe), 55.72 (4-C), 62.53 (5-C), 74.25 (2-C), 126.62, 127.17, 127.56, 128.07, 128.13, 128.69, 140.79, 142.00 (each Ph), 171.41, and 174.00 (each COOMe). **8′**:

^{1}H NMR ($CDCl_3$) δ=0.89 (3H, d, J_{Me-4}=6.6 Hz, 4-Me), 2.53 (1H, tq, J_{4-3}=J_{4-5}=9.5 and J_{4-Me}=6.6 Hz, 4-H), 3.32 (1H, d, J_{3-4}=9.5 Hz, 3-H), 3.40 (1H, br s, NH), 3.61 (1H, d, J_{5-4}=9.5 Hz, 5-H), 3.62 (3H, s, 4-COOMe), 3.78 (3H, s, 2-COOMe), 7.3—7.5 (8H, m, Ph), and 7.81 (2H, d, Ph); ^{13}C NMR ($CDCl_3$) δ=15.55 (4-Me), 49.00 (4-C), 52.18, 52.91 (each COOMe), 64.25 (3-C), 69.07 (5-C), 74.25 (2-C), 127.08, 127.34, 127.63. 127.87, 128.25, 128.69, 140.23, 142.93 (each Ph), 173.11, and 173.93 (each COOMe).

Trimethyl 2,*c*-5-Diphenylpyrrolidine-*r*-2,*t*-3,*c*-4-tricarboxylate (9) + Trimethyl 2,*c*-5-Diphenylpyrrolidine-*r*-2,*c*-3,*t*-4-tricarboxylate (9′): An inseparable mixture of **9** and **9′** (1 : 5 by ^{1}H NMR) was obtained after column chromatographic purification of the crude reaction mixture on silica gel with chloroform. Spectral data were obtained as a mixture. **9**: ^{1}H NMR ($CDCl_3$) δ=3.25, 3.34 (each 3H, s, 3- and 4-COOMe), 3.6—3.9 (2H, m, 4-H and NH), 3.80 (3H, s, 2-COOMe), 4.54 (1H, d, J_{3-4}=7.3 Hz, 3-H), 5.15 (1H, d, J_{5-4}=8.0 Hz, 5-H), 7.2—7.6 (8H, m, Ph), and 7.85 (2H, d, Ph); ^{13}C NMR ($CDCl_3$) δ=52.40, 52.67, 52.76 (each COOMe), 54.47 (4-C), 61.90 (3-C), 67.95 (5-C), 74.67 (2-C), 126.79, 126.88, 127.67, 127.83, 128.68, 129.00, 139.78, 139.89 (each Ph), 171.05, 171.36, and 173.30 (each COOMe). **9′**: ^{1}H NMR ($CDCl_3$) δ=3.47 (1H, dd, J_{4-5}=9.2 and J_{4-3}=8.4 Hz, 4-H), 3.51, 3.65 (each 3H, s, 3- and 4-COOMe), 3.73 (1H, br s, NH), 3.78 (3H, s, 2-COOMe), 4.09 (1H, d, J_{3-4}=8.4 Hz, 3-H), 4.31 (1H, d, J_{5-4}=9.2 Hz, 5-H), 7.3—7.5 (8H, m, Ph), and 7.80 (2H, d, Ph); ^{13}C NMR ($CDCl_3$) δ=52.11, 52.51, 53.03 (each COOMe), 57.18 (4-C), 59.60 (3-C), 64.98 (5-C), 74.97 (2-C), 127.11, 127.99, 128.07, 128.19, 128.38, 128.78, 139.54, 140.95 (each COOMe), 171.82, 172.33, and 173.08 (each COOMe).

The present work was financially supported by a Grant-in-Aid for Scientific Research (No. 63550652) from the Ministry of Education, Science and Culture.

Stereochemical Control in Microbial Reduction. 8. Stereochemical Control in Microbial Reduction of β-Keto Esters

Kaoru NAKAMURA,* Yasushi KAWAI,† Shinzaburo OKA,† and Atsuyoshi OHNO†

(Received October 7, 1988)

Stereochemistry of the reduction of β-keto esters with bakers' yeast is controlled by the addition of a certain α,β-unsaturated carbonyl compound (or its reduced form). Glucose also exerts the same effect. The additives tend to shift the stereochemistry of the reduction toward the production of D-hydroxy ester. Namely, methyl 3-oxopentanoate and ethyl 3-oxo-6-heptenoate were reduced to the corresponding D-hydroxy esters with excellent stereoselectivities and chemical yields. The enones are supposed to inhibit the enzymes that produce the L-hydroxy ester, whereas glucose plays a role to activate the enzymes that produce the D-hydroxy ester.

Since chiral alcohols are versatile and convenient building blocks in the syntheses of biologically important compounds, asymmetric reduction of ketones has been studied quite extensively.[1] Namely, the reduction mediated by a microbe has been a promising candidate to synthesize chiral alcohols in an excellent stereoselectivity and the research in this field has been expanded tremendously within recent one or two decade(s).[2] In most cases so far reported, the results are satisfactory with high chemical yields and high stereoselectivity. However, it should be emphasized that there was a lot of examples that afforded unsatisfactory results; low chemical yields and/or low stereoselectivities. Usually, almost all of these results are discarded unreported.

At the same time, a microbe does not necessarily afford the compound of desired configuration for further use in syntheses. In this case, we have to control or reverse the stereochemistry of the reduction. There are several methods to improve or control the stereoselectivity of the reduction. The first and most common method is to screen microbes to find a suitable one for a particular purpose.[3–5] This is a purely biological method and the result can not be predicted on the basis of chemistry. The second is the modification of the substrate.[6–8] In most cases in this category, steric bulk of two substituents on the carbonyl group is differentiated so that the enzyme (or enzymes) can recognize the *re*- and *si*-faces of the substrate easily, and the results are more or less chemically predictable. The third and brand-new method reported from our laboratory is to modify the reaction conditions.[9,10] Immobilization of a microbe into a hydrophobic network of a polymer is a typical example in this category. It has been reported that there is a relationship between the hydrophobicity of medium in the vicinity of microbe and the preferability to the configuration in the product hydroxy ester.[9,10]

In this paper, we would like to report the fourth method: the addition of a third reagent to the reaction system affects the stereochemical course of the reduction and the stereoselectivity can be improved up to satisfactory levels.[11]

Results and Discussion

There are two possibilities for an unsatisfactory stereoselectivity. One of them is the case in which only one dehydrogenase is responsible for the reduction of a substrate and the structure of the substrate is not suitable to exert its enantio- (or diastereo)-facial difference in the pocket of the enzyme. A low stereoselectivity seen in the reduction with an isolated dehydrogenase is the extreme of this category.[12,14] The other is the case in which two or more dehydrogenases are operating simultaneously but some enzymes produce the (*R*)-alcohol while others contribute to produce the (*S*)-alcohol, although each reduction proceeds with a high stereoselectivity.[15] There is a good chance to obtain a racemic mixture from a microbial reduction system. If the low stereoselectivity observed in a microbial reduction is due to the latter situation, there is a chance for a chemist to improve the stereoselectivity: inhibition or activation of an appropriate enzyme (or enzymes) will result in higher stereoselectivity. Based on the concept mentioned above, we looked for an inhibitor and an activator for particular enzymes responsible for the reduction of β-keto esters with bakers' yeast.

Two different states of bakers' yeast were employed as the microbe. One is the raw bakers' yeast (RBY) and the other is the dry bakers' yeast (DBY). Although the effect of the additive is much larger for RBY than for DBY, the activity of RBY changes from a lot to another and sometimes the stereoselectivity of reduction deviates up to 10% from a run to another when the specificity is relatively low. The activity of RBY also decreases on storage and it is difficult to confirm the reproducibility in stereoselectivity of the reduction with RBY. Therefore, we employed the result from DBY to discuss fundamental trends of the reduction, but RBY is recommended for practical purpose,

Table 1. Effect of the Amount of Bakers' Yeast on the Reduction of Methyl 3-Oxopentanoate[a]

Yeast/g	Configuration	e.e./%[b]	Chem. yield/%[c]
RBY (1)	*R* (D)	54	19
RBY (2)	*R*	51	37
RBY (3)	*R*	44	33
RBY (5)	*R*	33	35
DBY (1)	*R*	10	50
DBY (2)	*R*	7	41
DBY (4)	*R*	12	46

a) Substrate, 1 mmol; Water 20 ml. b) Reproducibility in the reaction with RBY and DBY are about 10% and 1%, respectively. c) Reproducibility in the reaction with RBY and DBY are about 5% and 1%, respectively.

because the latter affords a better stereoselectivity, an enantiomer excess (e.e.).

As listed in Table 1, the relative amount of DBY against the substrate does not affect the stereoselectivity of the reduction meaningfully, whereas that of RBY results in decreases in e.e. Thus, it seems probable that DBY and RBY are different in levels of various enzymes. In other words, plural enzymes are operating in the reduction system and the effect of an additive can be expected for this system.

The effect of α,β-unsaturated carbonyl and hydroxy compounds on the e.e. of product was studied in the reduction of methyl 3-oxopentanote with DBY and the results are summarized in Table 2. The bakers' yeast was preincubated for 30 min in the presence of an

4	0	*R*	12	46
4	1	*R*	31	61

a) Substrate, 1 mmol; water, 20 ml.

additive (or additives), then a substrate was added to the reduction system. It should be mentioned that e.e. of methyl 3-hydroxypentanoate obtained from the reduction without an additive is only 12%, which means that the enzyme(s) which affords the D-product (D-enzyme) and that (those) which affords the L-product (L-enzyme) are nearly equally active for this substrate. In contrast, the addition of methyl vinyl ketone or 2-cyclohexen-1-one improves the stereoselectivity up to 60—70% e.e. Allyl alcohol exerts the same effect, but the substitution of one methyl group on any carbon of allyl alcohol decreases the effect sharply as seen in the reductions in the presence of *trans*-2-buten-1-ol, 3-buten-1-ol, and 2-methyl-2-propen-1-ol. Propargyl alcohol is ineffective either. Thus, molecular shape plays a crucial role in exerting the effect on stereochemistry of the reduction. Acrylic acid and its methyl ester are also effective, though the effect is a little bit smaller than those of ketones. It is interesting to note that the specificity decreases in the presence of iodoacetamide, which indicates that this compound shifts the stereoselectivity toward the L-side. The results from the reduction with RBY is also listed in Table 2 for comparison.

In the presence of glucose, the energy-gaining and NAD(P)H-producing glycolysis system of yeast is stimulated. Consequently, the dehydrogenase-levels are distorted in yeast and the change in the stereoselectivity of the reduction can be expected. The results from the addition of glucose to the reduction system are summarized in Table 3. Indeed, it is recognized that the addition of glucose improves both the chemical yield and the stereoselectivity toward the D-side.

In order to elucidate the mechanism for the shift of stereochemistry on addition of an α,β-unsaturated carbonyl compound or its corresponding alcohol and of glucose, the kinetics of the reduction were followed in the presence or absence of these additives. The results plotted in Fig. 1 clearly show that glucose accelerates and methyl vinyl ketone retards the reduction in comparison to that without the additive. Since both glucose and methyl vinyl ketone are the additives that increase the yield of the *R* (D)-product, there is no doubt that the former *activates* the D-enzyme(s) (along the glycolysis cycle), whereas the latter *inhibits* the L-enzyme(s). The improvement of the specificity toward the D-side is not due to

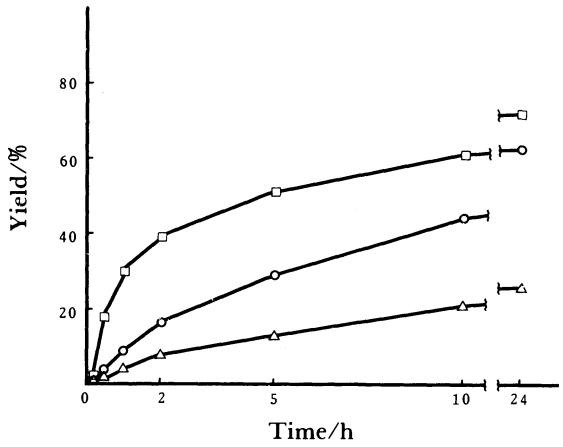

Fig. 1. Plots of the chemical yields of methyl 3-hydroxypentanoate against reaction time for the reduction of methyl 3-oxopentanoate with DBY in the presence of glucose (—□—□—) or methyl vinyl ketone (—△—△—), or absence of an additive (—○—○—).

decomposition of the *S* (L)-product.

We believe that the hydroxy compounds employed as inhibitors are once oxidized in yeast by the dehydrogenase system, than the resulted aldehyde is again trapped by an enzyme(s) in the reducing system. Since all the additives so far exerted the efficient inhibitory effect are good Michael acceptors, it is conceivable that the attack on the double bond in the α,β-unsaturated carbonyl compound by a nucleophile at the vicinity of the reaction center of dehydrogenase takes place faster than the process to reduce the substrate.[16)] It is not clear at present why these compounds do not inhibit the D-enzyme(s). Probably, the D- and L-enzymes locate in different sites in yeast so that the D-enzyme does not find a chance to encounter with these inhibitors. Another alkylating agent, 2-chloroethanol, did not work effectively.

For practical purpose, a composite use of glucose and an enone in the reduction with RBY will afford the most favorable result. This idea has been tested for various β-keto esters and the results are summarized in Table 4. It is obvious that the present method is quite useful in obtaining the D-hydroxy esters. Although the reduction of ethyl acetoacetate did not result in the reversion of configuration, it should be noted that, unlike other β-keto esters, the stereoselectivity of the

reduction of this substrate without additives is quite high in the L-side. The present method is not effective enough to shift the e.e. more than 40% toward the D-side. More effective device is awaited for a versatile reversion of configuration.

Experimental

Instruments. ^{1}H NMR spectra were recorded on a Varian VXR-200 spectrometer in $CDCl_3$ with Me_4Si as an internal standard. Gas chromatograms were recorded on a YANACO G-2800 gas chromatograph. HPLC was performed on a Hitachi 655 liquid chromatography with Wakosil 5SIL (4.6×150 mm) column and an IRICA 852-III spectrophotometer. Optical rotation was measured with a Perkin-Elmer 241 polarimeter.

Materials. Methyl 3-oxopentanoate, methyl and ethyl 4-chloro-3-oxobutanoates, and (*R*)-(+)-α-methoxy-α-(trifluoromethyl)phenylacetic acid (MTPA) were purchased from Aldrich Chemical Co. Ethyl 3-oxo-6-heptenoate was prepared according to the literature procedure.[17] Raw bakers' yeast (pressed bakers' yeast; RBY) and dry bakers' yeast DBY) were purchased from Oriental Yeast Co. and stored in a refrigerator. Other reagents were purchased from Nacalai Tesque Co.

Reduction of β-Keto Ester. In general, an appropriate amount of an additive was added to a suspension composed of 4 g of dry bakers' yeast and 20 ml of water. The whole mixture was stirred for 30 min at 30 °C. Then, 1 mmol of a substrate was added to the mixture and the stirring was continued at the same temperature. After 1 day, Hyflo-super cel and ethyl acetate was added to the suspension and the resulted mixture was filtered. The celite was washed with ethyl acetate and the combined filtrate was extracted with ethyl acetate. The organic portion was washed with water and brine, dried over anhydrous sodium sulfate, concentrated under reduced pressure, and the residue was subjected to preparative gas chromatography (PEG, 1.5 m, 130—170 °C), giving the corresponding hydroxy ester.

Determination of the Optical Purity. To a stirred mixture of 0.03 mmol of a β-hydroxy ester and 1 ml of benzene, were added 1.5 mmol of pyridine and 0.2 mmol of (*R*)−(+)−α-methoxy-α-(trifluoromethyl)phenylacetyl chloride in this order and the mixture was stirred overnight. Ethyl acetate and water were added to the mixture and the layers were separated. The organic portion was washed with 1 M hydrochloric acid (1 M=1 mol dm^{-3}), saturated aqueous sodium carbonate, and brine, then dried over anhydrous sodium sulfate and concentrated to give the corresponding (*R*)-MTPA ester in more than 90% yield.

The enantiomer excess in the hydroxy ester was determined by GLC (OV 1701, 25 m, 200 °C; ethyl 3-hydroxybutanoate and methyl 3-hydroxypentanoate) and HPLC (hexane/ethyl acetate=30/1; methyl and ethyl 4-chloro-3-hydroxybutanoate, and ethyl 3-hydroxy-6-heptenoate) analyses of the corresponding (*R*)-MTPA ester.

Kinetics of the Reduction. To a suspension containing 2 g of DBY in 20 ml of water 1 mmol of methyl 3-oxopentanoate was added and the whole suspension was stirred at room temperature. After appropriate time intervals, 2 ml aliquots were taken out from the suspension and poured into 5 ml of ethyl acetate containing ethyl succinate (an internal standard for GLC). The organic materials were extracted and subjected to GLC (PEG, 1 m, 100 °C). The experiment with glucose (2 g, 11 mmol) or methyl vinyl ketone (70 mg, 1 mmol) was also run in the same way as mentioned above by adding these additives to the suspension of DBY in water 30 min before the addition of

methyl vinyl ketone. The results are plotted in Fig. 1.

The authors wish to thank the Ministry of Education, Japan for financial support for this research by the Grants Nos. 62216011 and 63303002.

Isolation of Four 2,3,5,6,11,11b-Hexahydro-3-oxo-1*H*-indolizino[8,7-*b*]indole-5-carboxylic Acids from *Clerodendron Trichotomum* Thunb and Properties of Their Derivatives

Hajime IRIKAWA,* Yasuhiro TOYODA, Hiroaki KUMAGAI, and Yasuaki OKUMURA
Department of Chemistry, Faculty of Science, Shizuoka University, Ohya, Shizuoka 422
(Received October 12, 1988)

Four 2,3,5,6,11,11b-hexahydro-3-oxo-1*H*-indolizino[8,7-*b*]indole-5-carboxylic acids, plausible precursors of trichotomine, were isolated as the methyl esters from *Clerodendron trichotomum* Thunb, and the structures elucidated on the basis of their spectral and chemical evidences. The existence of two pairs of the C-11b epimers in the above plant were supported by the methoxide-catalyzed equilibrations of the compounds having the substituent on C-11b. Blue pigments were formed from the isolated compounds.

A blue pigment, trichotomine (**1**), was isolated from the fruits of *Clerodendron trichotomum* Thunb and the structure was elucidated by Iwadare et al.[1] The synthesis of **1** was reported by three groups.[2–4] Iwadare et al. prepared trichotomine dimethyl ester (**2**) by the autoxidation of **3**.[2] Kapadia and Rao synthesized **1** by one-pot reaction of L-tryptophan and 2-oxoglutaric acid, and suggested the intermediacy of **4**, formed from **5a** and/or **5b**, in the biosynthesis of **1**.[3] Since the skeleton of L-tryptophan with intact steric configuration is present in **1**, we attempted to search the extracts of the above plant for the substances supposed to be biosynthetic precursors of **1** in the lights of ultraviolet absorptions and color reactions with Ehrlich's reagent. Preliminary results of this study have been published in two communications.[5,6]

Isolation and Structure of 5a,b and 6a,b. The extracts were chromatographed on TSK gel G-3000s and then on Sephadex LH-20 to give four acidic compounds **5a,b** and **6a,b**, which showed characteristic blue sports on TLC with Ehrlich's reagent. On treatment with ethereal diazomethane, **5a,b** and **6a,b** afforded the dimethyl esters **7a,b** and the monomethyl esters **8a,b**, respectively.

The structures of **7a** and **7b** were deduced from the spectral data, and confirmed by the synthesis. Reaction of L-tryptophan methyl ester hydrochloride and dimethyl 2-oxoglutarate in methanol gave **7a** and **7b**, which were identical with the natural specimens of **7a** and **7b** by spectroscopic (IR, ^{1}H NMR, MS, and CD) and TLC comparisons, respectively. The diester **7b** was also prepared as follows. In a manner similar to that of Kapadia and Rao,[3] a mixture of L-tryptophan and 2-oxoglutaric acid in water was kept under nitrogen atmosphere at room temperature for two weeks to give **9a**, which was treated with ethereal diazomethane to afford the trimethyl ester **9b**. On treatment with 8 wt% hydrogen chloride–methanol, **9b** underwent cyclization to **7b**.

The stereochemical relationship of the two methoxycarbonyl groups in **7b** was determined in the following way. Reduction of **7b** with sodium borohydride in methanol–tetrahydrofuran gave the diol **10**, which afforded the ether **11** on treatment with *p*-toluenesulfonyl chloride in pyridine. Formation of **11** can be rationalized by tosylation of the hydroxymethyl group on C-5, followed by an intramolecular nucleophilic attack on the tosyloxymethyl carbon with the oxygen of the hydroxymethyl group on C-11b. Thus, formation of **11** indicates that the two methoxycarbonyl groups in **7b** bear 1,3-cis relationship to each other.

On treatment with sodium methoxide in methanol, the natural **7a** gave a mixture of **7a** and the antipode of **7b** in a ratio of 1:9, since the CD spectrum of the epimerization products was almost identical with that of the antipode of **7b** prepared from D-tryptophan methyl ester hydrochloride and dimethyl 2-oxoglutarate.

Accordingly, the structures of **7a** and **7b** were confirmed as shown in Fig. 1 including absolute configurations.

The structures of **8a** and **8b** were deduced from the spectral data, and confirmed by the synthesis.

Reaction of L-tryptophan methyl ester and 2-oxoglutaric acid in refluxing benzene afforded **8a** and **8b**[7] which were identical with the natural specimens of **8a** and **8b** in every respect of spectroscopic (IR, ^{1}H NMR, MS, and CD) and TLC comparisons, respectively. On treatment with sodium methoxide in methanol, **8a** underwent epimerization at C-5 to an epimer, which was identical with the antipode of **8b** prepared from D-tryptophan methyl ester and 2-oxoglutaric acid ($[\alpha]_D$, IR, ^{1}H NMR, and CD). The absolute configurations of the C-11b proton in **8a** and **8b** were supported by comparison of the CD spectra with those of yohimbane and pseudo-yohimbane, respectively.[8]

Accordingly, the structures of **8a** and **8b** were confirmed as shown in Fig. 1 including the absolute configurations.

Methoxide-Catalyzed Equilibrations. Tendency of epimerization at C-5 observed in **7a** and **8a** caused us to study on the methoxide-catalyzed equilibrations of the 11b-substituted derivatives of **8a** and **8b**.[6]

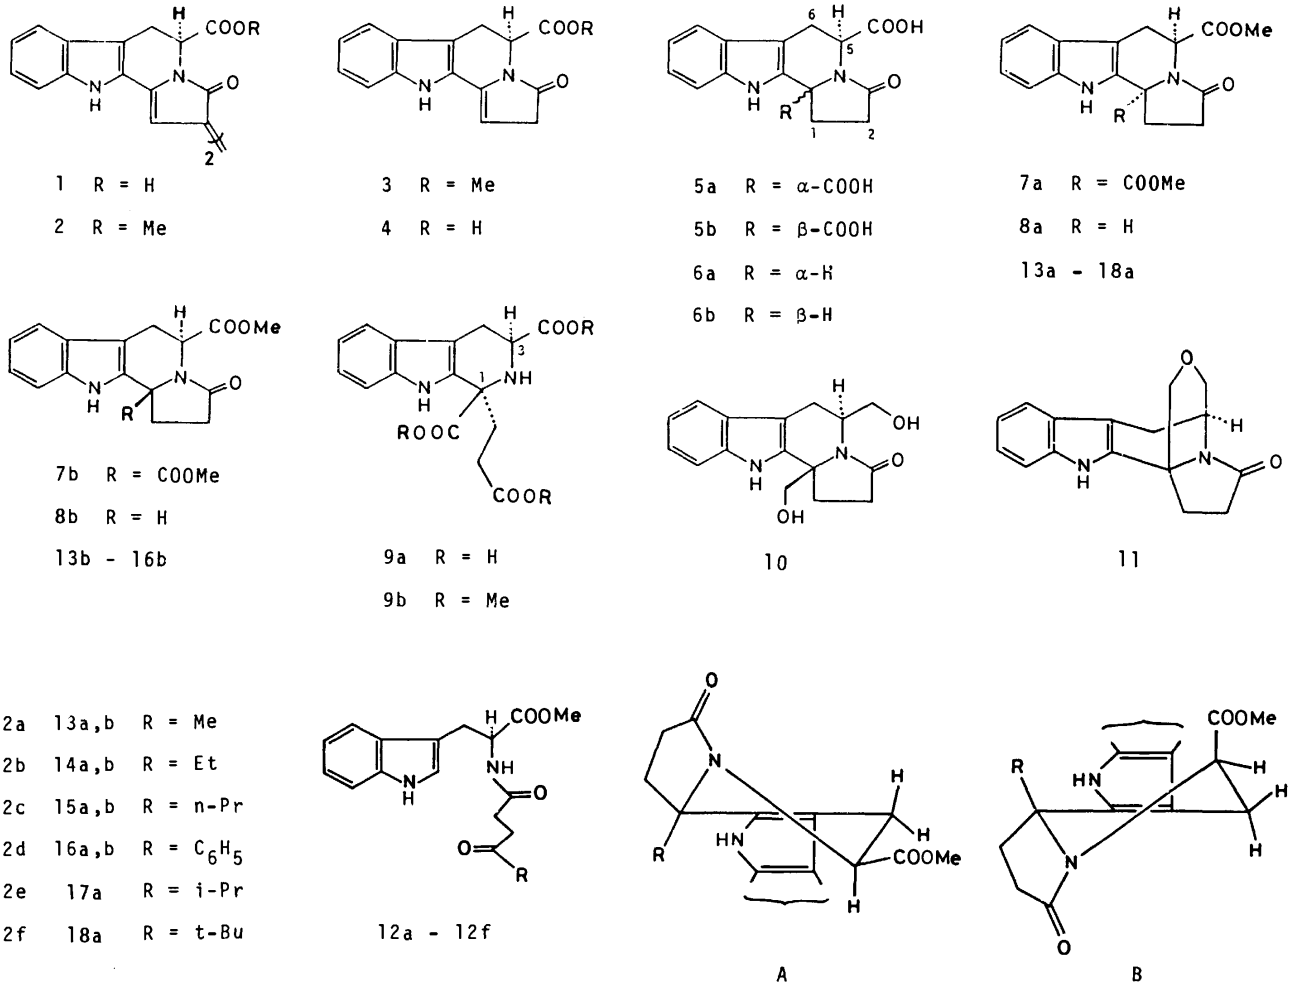

Fig. 1.

a) Equilibration ratios determined by HPLC. b) Double doublet, J=10.0—11.1 and 5.1—5.8 Hz. c) Double doublet, J=6.6—8.1 and 1.5—2.1 Hz. d) Assignment may by interchangeable with the singlet at δ=3.87.

The amides **12a—12f** were prepared from L-tryptophan methyl ester and the corresponding 4-oxo carboxylic acids. On treatment with 13 wt% hydrogen chloride–methanol, **12a—12d** afforded **13a** and **13b** (in a ratio of 1:2), **14a** and **14b** (2:1), **15a** and **15b** (2:1), **16a** and **16b** (>20:1), respectively.[9] Cyclization of **12e** and **12f** under similar conditions yielded predominantly **17a** and **18a**, respectively. The stereoselective formation of **17a** and **18a** seems to be due to the interaction between the methoxycarbonyl group and the bulky R group (R=*i*-Pr or *t*-Bu) in the cyclization intermediates, respectively.[10]

The conformations of the compounds described above were analyzed as follows. As shown in Table 1, the ^{1}H NMR spectra of **7a**, **8a**, and **13a—18a** showed the signals at δ=3.88—4.51 (dd, $J_{5\alpha,6\beta}$=10.0—11.1 and $J_{5\alpha,6\alpha}$=5.1—5.8 Hz), which suggested the axial orientations of the C-5 proton in these compounds. On the

other hand, the double doublet signals in **7b**, **8b**, and **13b—16b** were observed at δ=5.23—5.48 ($J_{5\alpha,6\alpha}$=6.6—8.1 and $J_{5\alpha,6\beta}$=1.5—2.1 Hz), indicating the equatorial orientations of the C-5 proton in these compounds.[11] The proton signals of the methoxycarbonyl group in **7b**, **8b**, and **13b—15b** were observed at δ=3.59—3.69, while that in **16b** appeared at δ=2.89 because of the magnetic anisotropic effect of the phenyl group on C-11b, being in line with the 1,3-cis relationship of the two substituents on C-5 and -11b in **16b**.[12]

As shown in Table 1, the ^{13}C NMR signals for C-5 and -11b in **7a**, **8a**, and **13a—16a** appeared at lower field than those in the corresponding **7b**, **8b**, and **13b—16b**. This trend is also in agreement with the above-mentioned orientations of the methoxycarbonyl group in these compounds.[13,14] The ^{1}H and ^{13}C NMR characteristics are similar to those of the 1,3-disubstituted 1,2,3,4-tetrahydro-β-carbolines (^{1}H NMR signals of C-3 and -4 protons and ^{13}C NMR signals of C-1 and -3).[12,14,15]

Therefore, assuming that the indolizinone ring is cis-fused,[16] the conformer **A** was assigned to **7a**, **8a**, and **13a—18a**, and the conformer **B** to **7b**, **8b**, and **13b—16b**.

The methoxide-catalyzed equilibrations of the above-mentioned compounds were examined as follows. Each of the compounds **7a,b**, **8a,b**, **13a,b—16a,b**, **17a**, and **18a** was dissolved in 0.1 mol dm^{-3} methanolic sodium methoxide, and let stand at room temperature for a few days until the equilibrium was reached. The ratios of a pair of epimers were determined by HPLC, and the results were shown in Table 1.[9]

The unsubstituted **8a** is thermodynamically more unstable than **8b**, and exists to the extent of less than 1%. Compound **8a** seems to be destabilized by the interaction between the amide carbonyl group and the methoxycarbonyl group on C-5 as shown in the conformer **A** (R=H). Epimerization at C-5 in **7b**, and **13b—16b** seems to be affected by another interaction between the substituent on C-11b and the methoxycarbonyl group on C-5 as shown in the conformer **B**. No epimerization isomers of **17a** and **18a** were detected either by ^{1}H NMR or HPLC. Similar epimerization trend was reported in tetrahydro-β-carboline derivatives.[15]

The equilibration experiments excluded the possibility of the epimerization at C-5 in **5a,b** and **6a,b** during the isolation procedure, and supported the existence of two pairs of **5a,b** and **6a,b** in the above plant.

Oxidative Dimerization. Autoxidation of indole compounds gave various products via 3*H*-indol-3-yl hydroperoxides.[17] The coloration of **8b** above its melting point resulted from the formation of **2**, which might proceed via the 3*H*-indol-3-yl hydroperoxide from **8b**.[18] Treatment of **8b** with *N*-bromosuccinimide in *t*-butyl alcohol gave **2** in one-pot reaction; **2** might be produced through **3** derived from **8b** via the corresponding 3-bromo-3*H*-indole. Trichotomine **1** was formed from **7b** by hydrolysis with potassium hydroxide in aqueous methanol, followed by autoxidation in aqueous acetic acid. These results suggested that **5a,b** and **6a,b** were plausible precursors of trichotomine **1**.

In general, indole compounds are stable against autoxidation when the indole nitrogen atom bears a protecting group. Therefore, we examined the oxidative dimerization of **19**, the acetate of **3**.

Acetylation of **8a** and **8b** with acetic anhydride and pyridine gave **20a** and **20b**, respectively. On electrolysis in methanol containing tetrabutylammonium tetrafluoroborate as a supporting electrolyte, both **20a** and **20b** afforded the methoxy lactam **21**, which was formed probably by addition of methanol to an intermediate **22**.[19] The ^{1}H NMR signals of the C-5 proton in **21** (δ=5.37, dd, J=7.2 and 0.9 Hz) indicated the β-orientation of the methoxyl group on C-11b. Treatment of **21** with formic acid yielded **19** after a loss of methanol. On aeration of a solution of **19** in butyl alcohol, **19** underwent oxidative dimerization to trichotomine dimethyl ester diacetate (**23**).[1]

Isolation of **5a** and **5b** shows the involvement of 2-oxo acid, 2-oxoglutaric acid, in the biosynthetic pathway of trichotomine **1** [L-tryptophan→**9a** and /or an epimer at C-1→**5a** and/or **5b**→(**6a** and/or **6b**)→**4**→**1**]; this indicates another example of G. Hahn's proposal.[3] The formation of **1** from **4** and of **23** from **19** might be another type of well-known oxidative dimerization of indoxyl to indigo.[20]

Fig. 2.

Experimental

All melting points were determined on a Yanagimoto micro melting point apparatus and are uncorrected. IR spectra were recorded on a Hitachi EPI-G$_3$. ^{1}H NMR spectra were obtained on a Varian EM-390 (90 MHz) or a JNM-GSX-400 (400 MHz), and ^{13}C NMR spectra on a JNM-PFT-60 (15 MHz) or a JNM-GSX-400 (100 MHz), using $CDCl_3$ as solvent, unless otherwise stated. UV spectra were measured on a JASCO UVIDEC-510 and CD spectra on a JASCO J-500A, using MeOH as solvent. Mass spectra were obtained on a Hitachi M-52 or M-80 at an ionization energy of 70 eV. Optical rotations were measured on a Union PM-101. Analytical TLC was carried out on silica-gel plates (Kieselgel 60 F_{254}, E. Merk). HPLC were performed on a JASCO Trirotor apparatus using a 4.6×250 mm Fine SIL-5 column with $CHCl_3$–hexane (3:2) at 1.3 ml min^{-1} flow rate.

Isolation. The blue fruits of the plant *Clerodendron trichotomum* Thunb (30 kg) were collected in October and immersed in EtOH (75 l) at room temperature for 2 weeks and then filtered. The combined filtrates were concentrated under reduced pressure to ca. 12 l. The remaining aqueous solution (3 l) was washed with AcOEt (3 l×3), and then roughly separated by column chromatography on TSK-gel G-3000s (900 g) using a gradient solution of H_2O–EtOH to give 4 fractions: fraction 1, H_2O 1 l; fraction 2, H_2O–EtOH (4:1) 1 l; fraction 3, H_2O–EtOH (3:2) 1 l; fraction 4, H_2O–EtOH (2:3) 1 l. In the same way, the remaining aqueous solution was separated to 4 fractions. The eluates of fraction 2, 3, and 4 were concentrated under reduced pressure, respectively. Analytical TLC of the residues of fraction 2, 3, and 4 (*n*-BuOH–AcOH–H_2O, 4:1:1) showed the blue spots of **5a** (R_f 0.40), **5b** (R_f 0.52), and **6a,b** (R_f 0.63) with Ehrlich's reagent, respectively. The residue of fraction 2 was further separated by column chromatography on Sephadex LH-20 using MeOH as eluent to give an acidic compound **5a**. To a solution of **5a** in MeOH was added an ethereal solution of CH_2N_2. The mixture was allowed to stand at room temperature overnight, and evaporated to leave an oil, which was purified by column chromatography on SiO_2 using MeOH–$CHCl_3$ (3:100) to give the diester **7a** as a colorless oil (8 mg): IR($CHCl_3$) 3450, 1740, and 1705 cm^{-1}; ^{1}H NMR δ=2.1—3.0 (4H, m, C_1-2H, C_2-2H), 2.99 (1H, dd, J=15.9 and 5.4 Hz, C_6-H), 3.34 (1H, dd, J=15.9 and 10.5 Hz, C_6-H), 3.83 (3H, s, OMe), 3.87 (3H, s OMe), 4.39 (1H, dd, J=10.5 and 5.4 Hz, C_5-H), 7.0—7.6 (4H, m, aromatic protons), and 8.25 (1H, br s, NH); MS *m/z* (rel intensity) 342 (M$^+$; 3), 283 (100), and 223 (29); CD $[\theta]_{295}$ −1600, $[\theta]_{291}$ −800, $[\theta]_{286}$ −3200, $[\theta]_{259}$ 0, $[\theta]_{236}$ +38000, $[\theta]_{225}$ 0, and $[\theta]_{218}$ −48000. Found: *m/z* 342.1234. Calcd for $C_{18}H_{18}N_2O_5$: M, 342.1214.

According to essentially the same procedure as described above, fraction 3 afforded **7b** as crystals (76 mg): mp 189—190 °C; IR($CHCl_3$) 3450, 1741, and 1696 cm^{-1}; ^{1}H NMR δ=1.9—3.0 (4H, m, C_1-2H, C_2-2H), 3.06 (1H, dd, J=16.2 and 6.6 Hz, C_6-H), 3.31 (1H, dd, J=16.2 and 1.8 Hz, C_6-H), 3.59 (3H, s, OMe), 3.81 (3H, s, OMe), 5.48 (1H, dd, J=6.6 and 1.8 Hz, C_5-H), 7.0—7.6 (4H, m, aromatic protons), and 8.53 (1H, br s, NH); MS *m/z* (rel intensity) 342 (M$^+$; 14), 283 (100), and 223 (31); CD $[\theta]_{295}$ +900, $[\theta]_{290}$ 0, $[\theta]_{270}$ +4000, $[\theta]_{259}$ 0, $[\theta]_{238}$ −19000, $[\theta]_{231}$ 0, and $[\theta]_{221}$ +81000.

According to essentially the same procedure as described above, fraction 4 gave a mixture of **8a** and **8b**, which was separated by column chromatography on SiO_2 (MeOH–$CHCl_3$, 3:100). **8a** (as an oil, 9 mg): IR(film) 3300, 1740, and 1677 cm^{-1}; ^{1}H NMR δ=2.0—2.7 (4H, m, C_1-2H, C_2-2H), 2.98 (1H, ddd, J=15.9, 5.1, and 1.8 Hz, C_6-H), 3.35 (1H, ddd, J=15.9, 10.2, and 2.1 Hz, C_6-H), 3.82 (3H, s, OMe), 4.12 (1H, dd, J=10.2 and 5.1 Hz, C_5-H), 5.05 (1H, m, C_{11b}-H), 7.0—7.6 (4H, m, aromatic protons), and 8.02 (1H, br s, NH); MS *m/z* (rel intersity) 284 (M$^+$; 90), 225 (100), and 223 (60). **8b** (as an oil, 29 mg): IR(film) 3260, 1740, and 1671 cm^{-1}; ^{1}H NMR δ=1.7—2.9 (4H, m, C_1-2H, C_2-2H), 3.10 (1H, ddd, J=15.9, 7.2 and 2.1 Hz, C_6-H), 3.44 (1H, dt, J=15.9 and 1.5 Hz, C_6-H), 3.63 (3H, s, OMe), 5.16 (1H, m, C_{11b}-H), 5.34 (1H, dd, J=7.2 and 1.5 Hz, C_5-H), 7.0—7.6 (4H, m, aromatic protons), and 8.31 (1H, br s, NH); MS *m/z* (rel intensity) 284 (M$^+$; 100), 225 (60), and 223 (62).

Synthesis of 7a and 7b. A mixture of L-tryptophan methyl ester hydrochloride (1.27 g, 5.0 mmol) and dimethyl 2-oxoglutarate (1.22 g, 7.0 mmol) in MeOH (15 ml) was refluxed for 24 h. The solution was concentrated under reduced pressure to ca. 4 ml,† and allowed to stand at 4 °C overnight to give the crystals of **7b** (0.52 g). The mother liquor was concentrated under reduced pressure to leave an oil, which was dissolved in $CHCl_3$. From the solution, the starting L-tryptophan methyl ester hydrochloride (0.12 g) was recovered by filtration. The filtrate was separated by column chromatography (SiO_2–$CHCl_3$) to give **7b** (0.45 g, total amount of **7b**, 0.97 g, 57%) and **7a** (as an oil, 0.15 g, 10%), which were identical with natural **7a** and **7b** by spectroscopic (IR, ^{1}H NMR, MS, and CD) and TLC comparisons, respectively. **7a**: $[\alpha]_D$ −37° (*c* 0.54, MeOH); UV 220 (ε 27400), 276 (7490), 282 (7810), and 291 nm (6380); ^{13}C NMR δ=22.6 (C-6), 29.4 (C-1*), 30.2 (C-2*), 52.5 (OMe), 53.3 (OMe), 53.7 (C-5), 66.7 (C-11b), 110.1 (C-6a), 111.5 (C-10), 118.7 (C-7), 120.1 (C-8), 123.1 (C-9), 126.1 (C-6b), 130.1 (C-11a), 136.8 (C-10a), 170.2 (-COO-), 171.3 (-COO-), and 175.2 (C-3). **7b**: $[\alpha]_D$ +110° (*c* 0.219, MeOH); UV 222 (ε 37600), 273 (8390), 280 (8350), and 290 nm (6550); ^{13}C NMR δ=24.0 (C-6), 30.8 (C-2), 34.0 (C-1), 49.2 (C-5), 52.3 (OMe), 52.8 (OMe), 63.9 (C-11b), 105.8 (C-6a), 111.4 (C-10), 118.5 (C-7), 119.7 (C-8), 122.6 (C-9), 126.0 (C-6b), 130.7 (C-11a), 137.0 (C-10a), 170.8 (-COO-), 172.2 (-COO-), and 174.9 (C-3). Anal. ($C_{18}H_{18}N_2O_5$) C, H, N.

Preparation of 9b. A mixture of L-tryptophan (4.0 g, 20 mmol) and 2-oxoglutaric acid (3.4 g, 23 mmol) in H_2O (250 ml) was allowed to stand at room temperature for 2 weeks under nitrogen atmosphere. The precipitate of the crude **9a** (1.4 g) was collected. To a solution of **9a** (0.80 g) in MeOH (30 ml) was added an ethereal solution of CH_2N_2. The solution was allowed to stand at room temperature for 4 h, and evaporated to leave an oil, which was crystallized from MeOH to give **9b** (0.49 g): mp 142.0—142.5 °C; $[\alpha]_D$ −41° (*c* 0.285, MeOH); UV 222 (ε 35300), 276 (sh, 8910), 283 (9580), and 291 nm (8090); IR(Nujol) 3420, 3330, 1753, and 1726 cm^{-1}; ^{1}H NMR δ=2.1—2.9 (4H, m), 2.74 (1H, dd, J=15.3 and 9.6 Hz), 3.11 (1H, dd, J=15.3 and 4.8 Hz), 3.60 (3H, s), 3.77 (3H, s,), 3.83 (3H, s), 3.6—3.8 (1H, m), 7.0—7.5 (4H, m), and 8.28 (1H, br s); ^{13}C NMR δ=25.8, 29.5, 34.3,

† HPLC analysis of this solution showed the presence of **7a** and **7b** in a ratio of 1:5. *Asterisks indicate that assignments are not unambiguous.

51.6, 52.3, 53.1, 61.4, 108.9, 111.2, 118.4, 119.6, 122.5, 126.5, 131,5, 136.1, 172.7, and 173.7; MS *m/z* 374 (M^+); CD $[\theta]_{298}$ +700, $[\theta]_{295}$ 0, $[\theta]_{291}$ −2600, $[\theta]_{288}$ −1200, $[\theta]_{283}$ −2600, $[\theta]_{267}$ −1300, $[\theta]_{235}$ −36600, $[\theta]_{227}$ 0, and $[\theta]_{219}$ +45200. Anal. ($C_{19}H_{22}N_2O_6$) C, H, N.

Cyclization of 9b to 7b. A solution of **9b** (43 mg) in 8 wt% HCl-MeOH (5 ml) was refluxed for 1 h. The solution was concentrated under reduced pressure to leave an oil, which was crystallized with $CHCl_3$-hexane to give **7b** (25 mg, 64%), which was identical with that obtained above by IR and TLC comparisons.

$NaBH_4$ Reduction of 7b. A mixture of **7b** (1.0 g, 2.9 mmol) and $NaBH_4$ (0.4 g, 11 mmol) in MeOH-THF (4—16 ml) was stirred at room temperature for 1 h, and then concentrated under reduced pressure. The residue was partitioned between H_2O and $CHCl_3$. The organic layer was dried over Na_2SO_4, and evaporated under reduced pressure to give **10** (0.58 g, 69%): mp 226—227 °C (from acetone-diisopropyl ether); $[\alpha]_D$ +138° (*c* 0.208, MeOH); UV 223 (ε 37400), 273 (7940), 278 (8090), 281 (8070), and 289 nm (6570); IR(Nujol) 3380, 3290, and 1664 cm^{-1}; ^1H NMR(CD_3OD) δ=1.9—3.1 (6H, m), 3.54 (1H, dd, *J*=10.8 and 8.4 Hz), 3.70 (1H, d, *J*=11.7 Hz), 3.72 (1H, dd, *J*=10.8 and 7.5 Hz), 3.92 (1H, d, *J*=11.7 Hz), 4.9 (1H, m), and 6.8—7.5 (4H, m); ^{13}C NMR (pyridine-d_5) δ=22.2, 31.5, 32.0, 49.7, 63.6, 64.1, 69.5, 104.9, 111.8, 118.8, 119.5, 121.9, 127.9, 135.9, 137.7, and 175.5; MS *m/z* 286 (M^+). Anal. ($C_{16}H_{18}N_2O_3$) C, H, N.

Formation of 11. A mixture of **10** (300 mg, 1.1 mmol) and *p*-toluenesulfonyl chloride (300 mg, 1.6 mmol) in pyridine (3 ml) was kept at 60 °C for 30 h. The solution was concentrated under reduced pressure to leave an oil, which was dissolved in $CHCl_3$. The solution was successively washed with dilute HCl, H_2O, and aqueous $NaHCO_3$, and then dried over Na_2SO_4. Evaporation of the solvent under reduced pressure gave an oil, which was crystallized from $CHCl_3$-hexane to yield **11** (96 mg, 34%): mp>300 °C (from EtOH); UV 224 (28800), 274 (sh 7210), 279 (sh 7430), 281 (7450), and 289 nm (6050); IR(Nujol) 3250, 1671, and 1649 cm^{-1}; ^1H NMR (pyridine-d_5) δ=1.7—2.8 (4H, m), 2.88 (1H, d, *J*=16.2 Hz), 3.39 (1H, ddd, *J*=16.2, 6.9, and 0.9 Hz), 3.48 (1H, d, *J*=10.5 Hz), 3.71 (1H, dd, *J*=11.4 and 2.7 Hz), 3.90 (1H, d, *J*=10.5 Hz), 3.99 (1H, dd, *J*=11.4 and 0.9 Hz), 4.60 (1H, dd, *J*=6.9 and 2.7 Hz), 7.2—7.7 (4H, m), and 8.70 (1H, br s); ^{13}C NMR (pyridine-d_5) δ=25.0, 25.6, 30.0, 46.1, 59.2, 72.2, 73.4, 110.5, 112.0, 118.5, 119.5, 121.7, 127.6, 135.1, 137.2, and 172.1; MS *m/z* 268 (M^+). Anal. ($C_{16}H_{16}N_2O_2$) C, H, N.

Epimerization of 7a. A solution of the natural **7a** (4 mg) in 0.1 mol dm^{-3} methanolic NaOMe (0.2 ml) was allowed to stand at room temperature overnight. After addition of AcOH (2 drops), the solution was concentrated under reduced pressure. The residue was partitioned between aqueous $NaHCO_3$ and $CHCl_3$. The organic layer was dried over Na_2SO_4, and concentrated under reduced pressure to give a mixture of **7a** and the antipode of **7b** in a ratio of 1:9 (by HPLC). CD of the reaction products $[\theta]_{238}$ +17000, $[\theta]_{231}$ 0, and $[\theta]_{221}$ −67000.

Antipode of 7b. According to essentially the same procedure as described above, the reaction of D-tryptophan methyl ester hydrochloride and dimethyl 2-oxoglutarate in MeOH yielded the antipode of **7b**: $[\alpha]_D$ −107° (*c* 0.205, MeOH); CD $[\theta]_{295}$ −1100, $[\theta]_{291}$ 0, $[\theta]_{286}$ −2200, $[\theta]_{284}$ −2000, $[\theta]_{270}$ −4300, $[\theta]_{259}$ 0, $[\theta]_{238}$ +18000, $[\theta]_{231}$ 0, and $[\theta]_{221}$ −78000.

Synthesis of 8a and 8b. According to the literature,[7] L-tryptophan methyl ester (4.36 g, 20 mmol) was dissolved in benzene (400 ml), and 2-oxoglutaric acid (3.5 g, 24 mmol) was added in small portions to the refluxing solution. After addition, reflux was continued for 19 h. The solution was washed with aqueous $NaHCO_3$, dried over Na_2SO_4, and then concentrated under reduced pressure to ca. 20 ml[††] to yield the crystals of **8b**[7] (2.94 g). The mother liquor was concentrated under reduced pressure to leave an oil, which was separated by column chromatography on SiO_2. Elution with $CHCl_3$ gave **8b** (0.62 g, total amount of **8b**, 3.56 g, 64%) and **8a** (0.94 g, 12%), which were identical with the natural **8b** and **8a** by spectroscopic (IR, ^1H NMR, MS, and CD), and TLC comparisons, respectively. **8a:** mp 109—111 °C (from $CHCl_3$); $[\alpha]_D$ −110° (*c* 0.218, MeOH); ^{13}C NMR δ=22.8 (C-6), 24.3 (C-1), 30.1 (C-2), 52.5 (OMe), 54.7 (C-5), 56.3 (C-11b), 108.0 (C-6a), 111.3, (C-10), 118.2 (C-7), 119.8 (C-8), 122.2 (C-9), 126.5 (C-6b), 133.3 (C-11a), 136.5 (C-10a), 170.2 (-COO-), and 175.9 (C-3); CD $[\theta]_{294}$ +2400, $[\theta]_{289}$ +100, $[\theta]_{285}$ +2700. $[\theta]_{282}$ +2400, $[\theta]_{269}$ +6100, $[\theta]_{246}$ +2700, $[\theta]_{231}$ +15700, $[\theta]_{226}$ 0, and $[\theta]_{218}$ −42300. Anal. ($C_{16}H_{16}N_2O_3 \cdot CHCl_3$) C, H, N. Found: *m/z* 284.1174. Calcd for $C_{16}H_{16}N_2O_3$: M, 284.1159. **8b:** mp 202—203 °C (from $CHCl_3$-hexane); $[\alpha]_D$ +187° (*c* 0.214, MeOH); ^{13}C NMR δ=23.7 (C-6), 26.3 (C-1), 31.6 (C-2), 49.5 (C-5), 52.5 (C-11b and OMe), 105.0 (C-6a), 111.1 (C-10), 118.3 (C-7), 119.7 (C-8), 122.1 (C-9), 126.6 (C-6b), 132.6 (C-11a), 136.5 (C-10a), 171.1 (-COO-), and 173.9 (C-3); CD $[\theta]_{295}$ −400, $[\theta]_{293}$ 0, $[\theta]_{289}$ +1600, $[\theta]_{286}$ 0, $[\theta]_{285}$ −200, $[\theta]_{284}$ 0, $[\theta]_{282}$ +400, $[\theta]_{280}$ 0, $[\theta]_{232}$ −22000, $[\theta]_{227}$ 0, and $[\theta]_{215}$ +61000.

Epimerization of 8a. A solution of **8a** (170 mg) in 0.1 mol dm^{-3} methanolic NaOMe (2 ml) was allowed to stand at room temperature for 2 h. After addition of AcOH (0.1 ml), the solution was worked up as described above to give an epimer almost quantitatively, which was identical with the antipode of **8b** prepared as described below ($[\alpha]_D$, IR, ^1H NMR, and CD).

Antipode of 8b. According to essentially the same procedure as described above, the reaction of D-tryptophan methyl ester and 2-oxoglutaric acid in benzene yielded the antipode of **8a** and the antipode of **8b**. Antipode of **8a:** $[\alpha]_D$ +112° (*c* 0.203, MeOH). Antipode of **8b:** $[\alpha]_D$ −186° (*c* 0.205, MeOH); CD $[\theta]_{295}$ +600, $[\theta]_{292}$ 0, $[\theta]_{289}$ −1700, $[\theta]_{285}$ −300, $[\theta]_{282}$ −800, $[\theta]_{278}$ 0, $[\theta]_{232}$ +23000, $[\theta]_{226}$ 0, and $[\theta]_{215}$ −61000.

Preparation of 12a. A solution of L-tryptophan methyl ester (2.18 g, 10 mmol) and 5-methyl-2(3*H*)-furanone (1.20 g, 12 mmol) in benzene (30 ml) was allowed to stand at room temperature for 22 h to give **12a** (2.86 g, 91%): mp 139—140 °C (from MeOH); IR(Nujol) 3360, 1753, 1701, and 1654 cm^{-1}; MS *m/z* 316 (M^+); Anal. ($C_{17}H_{20}N_2O_4$) C, H, N.

Preparation of the Amides 12b—12f. 1) A typical procedure is described for the preparation of **12b**. To a solution of L-tryptophan methyl ester (2.18 g, 10 mmol) and 4-oxohexanoic acid[21] (1.30 g, 10 mmol) in CH_2Cl_2 (60 ml) was added a solution of dicyclohexylcarbodiimide (2.06 g, 10 mmol) in CH_2Cl_2 (40 ml). The reaction mixture was stirred at room temperature for 7 h. AcOH (3 drops) was added to the reaction mixture, and the *N,N'*-dicyclohexylurea which precipitated was removed by filtration. The filtrate was concentrated under reduced pressure to leave an oil, which was crystallized from benzene to give the crude **12b**.

†† HPLC analysis of this solution showed the presence of **8a** and **8b** in a ratio of 1:3.

Recrystallization from MeOH afforded the colorless crystals of **12b** (2.70 g, 82%): mp 129—130 °C; IR(Nujol) 3280, 1753, 1708, and 1654 cm^{-1}; MS *m/z* 330 (M^+); Anal. ($C_{18}H_{22}N_2O_4$) C, H, N.

2) The amide **12c** was prepared using 4-oxoheptanoic acid.[22] **12c** (77%): mp 89—90 °C; IR(Nujol) 3390, 1739, 1720, and 1660 cm^{-1}; MS *m/z* 344 (M^+); Anal. ($C_{19}H_{24}N_2O_4$) C, H, N.

3) The amide **12d** was prepared using 3-benzoylpropanoic acid. **12d** (84%): mp 101—102 °C; IR(Nujol) 3310, 1739, and 1660 cm^{-1}; MS *m/z* 378 (M^+); Anal. ($C_{22}H_{22}N_2O_4$) C, H, N.

4) The amide **12e** was prepared using 5-methyl-4-oxohexanoic acid.[23] **12e** (88%): mp 128—129 °C; IR(Nujol) 3280, 1740, 1715, and 1660 cm^{-1}; MS *m/z* 344 (M^+); Anal. ($C_{19}H_{24}N_2O_4$) C, H, N.

5) The amide **12f** was prepared using 5,5-dimethyl-4-oxohexanoic acid.[23] **12f** (86%): mp 160—161 °C; IR(Nujol) 3270, 1740, 1709, and 1661 cm^{-1}; MS *m/z* 358 (M^+); Anal. ($C_{20}H_{26}N_2O_4$) C, H, N.

Cyclization of the Amides 12a—12f. 1) A typical procedure is described for the cyclization of the amide **12a**. A solution of **12a** (158 mg, 0.50 mmol) in 13 wt% hydrogen chloride-MeOH (10 ml) was allowed to stand at room temperature for 20 h. The solution was concentrated under reduced pressure. The residue was partitioned between aqueous $NaHCO_3$ and $CHCl_3$. The organic layer was dried over Na_2SO_4. Evaporation of the solvent under reduced pressure gave a mixture of **13a** and **13b** (ratio determined by HPLC, 1:2) almost quantitatively, which were separated after column chromatography (SiO_2-$CHCl_3$). **13a**: mp 247—248 °C (from MeOH); IR($CHCl_3$) 3460, 1740, and 1691 cm^{-1}; ^1H NMR δ=1.70 (3H, s), 2.1—2.8 (4H, m), 2.95 (1H, dd, *J*=15.9 and 5.1 Hz), 3.33 (1H, dd, *J*=15.9 and 10.8 Hz), 3.79 (3H, s), 4.09 (1H. dd, *J*=10.8 and 5.1 Hz), 7.0—7.6 (4H, m), and 8.33 (1H, br s); ^{13}C NMR δ=22.7, 27.0, 29.7, 32.1, 52.2, 52.4, 61.9, 107.1, 111.3, 118.3, 119.8, 122.2, 126.5, 136.4, 137.2, 170.7, and 176.6; MS *m/z* 298 (M^+) and 283; Anal. ($C_{17}H_{18}N_2O_3$) C, H, N. **13b**: mp 218—219 °C (from $CHCl_3$-hexane); IR($CHCl_3$) 3460, 1745, and 1683 cm^{-1}; ^1H NMR δ=1.58 (3H, s), 2.0—2.8 (4H, m), 2.98, (1H, dd, *J*=15.9 and 7.8 Hz), 3.57 (1H, dd, *J*=15.9 and 1.5 Hz), 3.66 (3H, s), 5.40 (1H, dd, *J*=7.8 and 1.5 Hz), 7.0—7.5 (4H, m), and 8.33 (1H, br s); ^{13}C NMR δ=21.8, 25.9, 30.6, 34.7, 48.7, 52.4, 59.8, 103.6, 111.1, 118.6, 119.6, 122.1, 126.5, 136.4, 136.7, 171.7, and 174.2; MS *m/z* 298 (M^+) and 283; Anal. ($C_{17}H_{18}N_2O_3$) C, H, N.

2) Cyclization of the amide **12b** gave a mixture of **14a** and **14b** (ratio, 2:1) almost quantitatively. **14a**: mp 246—247 °C (from MeOH); IR($CHCl_3$) 3460, 1748, and 1693 cm^{-1}; ^1H NMR δ=1.12 (3H, t, *J*=7.5 Hz), 1.98 (2H, q, *J*=7.5 Hz), 2.0—2.7 (4H, m), 2.96 (1H, dd, *J*=15.9 and 5.1 Hz), 3.34 (1H, dd, *J*=15.9 and 10.8 Hz), 3.83 (3H, s), 4.07 (1H, dd, *J*=10.8 and 5.1 Hz), 7.0—7.6 (4H, m), and 8.00 (1H, br s); ^{13}C NMR δ=8.1, 22.6, 28.2, 29.9, 31.9, 52.1, 52.4, 64.9, 106.9, 111.2, 118.2, 119.7, 122.1, 126.5, 136.4, 137.8, 170.6, and 176.6; MS *m/z* 312 (M^+) and 283; Anal. ($C_{18}H_{20}N_2O_3$) C, H, N. **14b**: mp 191—192 °C (from MeOH); IR($CHCl_3$) 3460, 1744, and 1681 cm^{-1}; ^1H NMR δ=1.08 (3H, t, *J*=7.2 Hz), 1.83, (2H, q, *J*=7.2 Hz), 2.0—2.9 (4H, m), 3.04 (1H, dd, *J*=16.2 and 8.1 Hz), 3.51 (1H, dd, *J*=16.2 and 2.1 Hz), 3.68 (3H, s), 5.39 (1H, dd *J*=8.1 and 2.1 Hz), 7.0—7.6 (4H, m), and 8.15 (1H, br s); ^{13}C NMR δ=8.5, 21.4, 30.3, 31.0, 33.7, 48.9, 52.3, 63.1, 104.1, 111.0, 118.6, 119.8, 122.2, 126.5, 136.2, 137.1, 171.8, and 174.7; MS *m/z* 312 (M^+) and 283; Anal. ($C_{18}H_{20}N_2O_3$) C, H, N.

3) Cyclization of the amide **12c** gave a mixture of **15a** and **15b** (ratio, 2:1). **15a** (54%): $[\alpha]_D$ −148° (*c* 0.119, MeOH): IR($CHCl_3$) 3450, 1742, and 1688 cm^{-1}; ^1H NMR δ=0.96 (3H, t, *J*=6.6 Hz), 1.3—2.0 (4H, m), 2.0—2.7 (4H, m), 2.96 (1H, dd, *J*=16.0 and 5.1 Hz), 3.34 (1H, dd, *J*=16.0 and 10.7 Hz), 3.82 (3H, s), 4.10 (1H, dd, *J*=10.7 and 5.1 Hz), 7.0—7.6 (4H, m), and 8.30 (1H, br s); ^{13}C NMR δ=14.3, 17.2, 22.6, 29.1, 29.9, 41.8, 52.2, 64.6, 107.0, 111.2, 118.2, 119.7, 122.1, 126.5, 136.3, 137.6, 170.6, and 176.5; MS *m/z* 326 and 283. Found: *m/z* 326.1612. Calcd for $C_{19}H_{22}N_2O_3$: M, 326.1628. **15b** (20%): mp 244—245°C (from $CHCl_3$-hexane); $[\alpha]_D$ +105° (*c* 0.124, MeOH); IR($CHCl_3$) 3450, 1740, and 1677 cm^{-1}; ^1H NMR δ=0.91 (3H, t, *J*=6.6 Hz), 1.2—2.0 (4H, m), 2.0—2.8 (4H, m), 3.03 (1H, dd, *J*=15.9 and 8.1 Hz), 3.51 (1H, dd, *J*=15.9 and 2.1 Hz), 3.69 (3H, s), 5.37 (1H, dd, *J*=8.1 and 2.1 Hz). 7.0—7.6 (4H, m), and 8.03 (1H, br s); ^{13}C NMR δ=14.3, 17.4, 21.4, 31.0, 43.3, 48.9, 52.4, 62.9, 103.8, 111.0, 118.5, 119.6, 122.1, 126.4, 136.2, 137.2, 171.7, and 174.7; MS *m/z* 326 (M^+) and 283; Anal. ($C_{19}H_{22}N_2O_3$) C, H, N.

4) Cyclization of the amide **12d** gave a mixture of **16a** and **16b** (ratio, >20:1). **16a** (82%): mp 236—237 °C (from MeOH); IR($CHCl_3$) 3450, 3270, 1735, and 1690 cm^{-1}; ^1H NMR δ=2.1—2.7 (4H, m), 2.87 (1H, dd, *J*=15.6 and 5.1 Hz), 3.42 (1H, dd, *J*=15.6 and 11.1 Hz), 3.74 (3H, s), 3.88 (1H, dd, *J*=11.1 and 5.1 Hz), 7.0—7.6 (9H, m), and 8.97 (1H, br s); ^{13}C NMR δ=22.2, 30.1, 34.1, 52.1, 52.4, 68.1, 109.6, 111.4, 118.5, 119.8, 122.6, 126.4, 126.5, 128.1, 128.7, 134.2, 136.5, 142.9, 170.4, and 177.0; MS *m/z* 360 (M^+) and 283; Anal. ($C_{22}H_{20}N_2O_3$) C, H, N. **16b** (3%): mp 265—266 °C (from $CHCl_3$-hexane); IR($CHCl_3$) 3450, 1745, and 1684 cm^{-1}; ^1H NMR δ=2.4—3.2 (4H, m), 2.89 (3H, s), 3.00 (1H, dd, *J*=15.6 and 7.8 Hz), 3.50 (1H, dd, *J*=15.6 and 1.8 Hz), 5.23 (1H, dd, *J*=7.8 and 1.8 Hz), 7.0—7.7 (9H, m), and 8.25 (1H, br s); ^{13}C NMR δ=20.7, 31.1, 34.3, 48.3, 51.7, 64.4, 107.5, 111.1, 118.9, 120.0, 122.6, 126.4, 127.1, 128.2, 128.7, 134.0, 136.4, 143.0, 170.4, and 173.8; MS *m/z* 360 (M^+) and 283; Anal. ($C_{22}H_{20}N_2O_3$) C, H, N.

5) Cyclization of the amide **12e** gave **17a** (80%): $[\alpha]_D$ −80° (*c* 0.201, MeOH); IR($CHCl_3$) 3460, 1742, and 1689 cm^{-1}; ^1H NMR δ=1.09 (3H, d, *J*=7.1 Hz), 1.17 (3H, d, *J*=7.1 Hz), 2.0—2.6 (5H, m), 2.96 (1H, dd, *J*=15.9 and 5.4 Hz), 3.37 (1H, dd, *J*=15.9 and 10.8 Hz), 3.81 (3H, s), 4.15 (1H, dd, *J*=10.8 and 5.4 Hz), 7.0—7.6 (4H, m), and 8.27 (1H, br s); ^{13}C NMR δ=17.2, 22.4, 24.5, 29.8, 35.5, 51.8, 52.4, 67.7, 108.0, 111.2, 118.3, 119.8, 122.3, 126.5, 136.2, 137.2, 170.6, and 176.8; MS *m/z* 326 and 283. Found: *m/z* 326.1642. Calcd for $C_{19}H_{22}N_2O_3$: M, 326.1629.

6) Cyclization of the amide **12f** gave **18a** (79%): mp 231—232 °C (from benzene); $[\alpha]_D$ −90° (*c* 0.201, MeOH); IR ($CHCl_3$) 3460, 1740, and 1685 cm^{-1}; ^1H NMR δ=1.16 (9H, s), 2.0—2.7 (4H, m), 2.98 (1H, dd, *J*=16.0 and 5.8 Hz), 3.31 (1H, dd, *J*=16.0 and 10.0 Hz), 3.78 (3H, s), 4.51 (1H, dd, *J*=10.0 and 5.8 Hz), 7.0—7.6 (4H, m), and 8.20 (1H, br s); ^{13}C NMR δ=22.2, 27.1, 28.0, 30.0, 39.6, 52.3, 53.9, 70.5, 109.0, 111.2, 118.2, 119.6, 122.2, 126.3, 135.5, 136.4, 171.1, and 177.9; MS *m/z* 283 (M^+ −57). Anal. ($C_{20}H_{24}N_2O_3$) C, H, N.

Methoxide-Catalyzed Equilibration. Each compound **7a,b**, **8a,b**, **13a,b**—**16a,b**, **17a**, and **18a** (0.1 mmol) was dissolved in 0.1 mol dm^{-3} methanolic NaOMe (3 ml). Each solution was kept at room temperature for a few days until the equilibrium was reached. After addition of AcOH (2 drops), each solution was worked up as described above to give a

residue, which was analyzed by HPLC. The results were summarized in Table 1.

***N*-Bromosuccinimide (NBS) Oxidation of 8b.** A mixture of **8b** (57 mg, 0.20 mmol) and NBS (53 mg, 0.30 mmol) in *t*-BuOH (30 ml) was stirred at 26—32 °C for 2 days. The resulting blue solution was concentrated under reduced pressure to give a residue, which was dissolved in AcOEt. The solution was washed with water, dried over Na_2SO_4, and evaporated under reduced pressure. Separation of the residue by column chromatography (SiO_2–$CHCl_3$) afforded **2** (6 mg, 11%), which was identical with that synthesized following the procedure of Iwadare et al.[2] (IR, ^1H NMR, CD, and TLC).

Conversion of 7b into 1. A solution of **7b** (103 mg, 0.30 mmol) and KOH (45 mg, 0.80 mmol) in H_2O–MeOH (0.8—8 ml) was allowed to stand at 26—30 °C for 22 h to give crystals of the potassium salt of **5b** (90 mg, 77%): IR(Nujol) 1676, 1640, and 1609 cm^{-1}; ^1H NMR (D_2O) δ=1.98 (1H, m), 2.44 (1H, m), 2.63 (1H, m), 2.84 (1H, dd, J=15.8 and 7.3 Hz), 2.98 (1H, m), 3.19 (1H, dd, J=15.8 and 1.5 Hz), 4.96 (1H, dd, J=7.3 and 1.5 Hz), 7.14 (1H, t, J=8.0 Hz), 7.22 (1H, t, J=8.0 Hz), 7.46 (1H, d, J=8.0 Hz), and 7.54 (1H, d, J=8.0 Hz); ^{13}C NMR (D_2O) δ=26.4, 34.4, 36.3, 55.5, 70.1, 107.5, 114.2, 121.1, 121.9, 124.4, 128.7, 137.6, 139.1, 179.3, 180.1, and 181.1.

A solution of the potassium salt of **5b** (30 mg) in H_2O–AcOH (3—0.2 ml) was stirred at 24—29 °C for 4 days to give a dark blue precipitate (13 mg). Analytical TLC of the precipitate (*n*-BuOH–AcOH–H_2O, 4:1:1) showed the presence of a blue spot (R_f 0.88) corresponding to trichotomine **1**. To a solution of the precipitate (13 mg) in MeOH (10 ml) was added an ethereal solution of CH_2N_2. The mixture was allowed to stand at 24 °C for 2 h, and evaporated. Separation of the blue residue by column chromatography (SiO_2–$CHCl_3$) gave **2** (0.3 mg), which was identical with the authentic sample[2] (^1H NMR and TLC).

Acetylation of 8a. A solution of **8a** (202 mg, 0.50 mmol) in acetic anhydride–pyridine (5—8 ml) was heated at 88—93 °C for 15 h. The solution was concentrated under reduced pressure to give an oil, which was purified by column chromatography (SiO_2–$CHCl_3$), and crystallized from MeOH to give **20a** (102 mg, 63%): mp 261—263 °C; $[\alpha]_D$ −314° (*c* 0.042, MeOH); UV 204 (ε 27900), 241 (18100), 264 (11700), 291 (6160), and 299 nm (6160); IR(Nujol) 1742, 1703, and 1682 cm^{-1}; ^1H NMR δ=1.8—2.9 (4H, m), 2.80, (3H, s), 2.91 (1H, ddd, J=16.8, 4.8 and 2.4 Hz), 3.28 (1H, ddd, J=16.8, 10.8, and 2.7 Hz), 3.88 (3H, s), 3.99 (1H, dd, J=10.8 and 4.8 Hz), 5.48 (1H, m), and 7,2—7.8 (4H, m); ^{13}C NMR δ=23.3, 25.3, 26.9, 29.8, 52.5, 53.9, 58.8, 114.0, 117.1, 119.2, 123.5, 124.9, 129.6, 135.3, 137.0, 168.7, 169.7, and 175.4; MS *m/z* 326 (M^+), 283, 225, and 223; CD $[\theta]_{288}$ −11300, $[\theta]_{282}$ −10800, $[\theta]_{252}$ −42700, $[\theta]_{242}$ 0, $[\theta]_{226}$ +55600, $[\theta]_{210}$ 0; Anal. ($C_{18}H_{18}N_2O_4$) C, H, N.

Acetylation of 8b. A solution of **8b** (284 mg) in acetic anhydride–pyridine (5—7 ml) was heated at 90 °C for 8 h, and work up as described above to give **20b** (257 mg, 79%): mp 183—184 °C (from MeOH); $[\alpha]_D$ +277° (*c* 0.205, MeOH); UV 204 (ε 24000), 241 (16100), 263 (10100), 290 (5090), and 299 nm (5020); IR(Nujol) 1745, 1716, and 1697 cm^{-1}; ^1H NMR δ=1.6—3.2 (5H, m), 2.79 (3H, s), 3.41 (1H, dt, J=16.5 and 1.5 Hz), 3.67 (3H, s), 5.39 (1H, dd, J=7.2 and 1.2 Hz), 5.50 (1H, m), and 7.2—7.8 (4H, m), ^{13}C NMR δ=23.7, 27.1, 31.0, 48.4, 52.6, 55.0, 114.0, 119.1, 123.2, 124.7, 129.5, 135.1, 135.5, 168.6, 170.6, and 173.9; MS *m/z* 326 (M^+), 283, 225, and 223; CD $[\theta]_{256}$ +28700, $[\theta]_{242}$ 0, and $[\theta]_{227}$ −36400; Anal. ($C_{18}H_{18}N_2O_4$) C, H, N.

Electrolysis of 20a and 20b. A mixture of **20a** (65 mg, 0.20 mmol), tetrabutylammonium tetrafluoroborate (330 mg) and MeOH (80 ml) was placed in a beaker-type undivided cell, and glassy carbon rods were used as an anode and a cathode, respectively.[24] After electrolysis at constant potential of 1.3 V vs. SCE (electricity: ca. 5.5 F mol^{-1} (1F=96480 C)), the electrolytic solution was concentrated under reduced pressure to give a residue, which was dissolved in benzene. The solution was washed with H_2O and with brine, and then dried over Na_2SO_4. Evaporation of the solvent under reduced pressure gave an oil, which was purified by column chromatography (SiO_2–$CHCl_3$) to afford **21** (as an oil, 47 mg, 66%): IR($CHCl_3$) 1744 and 1708 cm^{-1}; ^1H NMR δ=2.2—3.5 (4H, m), 2.80 (3H, s), 2.89 (1H, dd, J=16.2 and 7.2 Hz), 3.32 (3H, s), 3.53 (1H, dd, J=16.2 and 0.9 Hz), 3.70 (3H, s), 5.37 (1H, dd, J=7.2 and 0.9 Hz), and 7.2—7.8 (4H, m); MS *m/z* 356 (M^+), 325, 283, 282, and 223. Found: *m/z* 356.1387. Calcd for $C_{19}H_{20}N_2O_5$: M, 356.1371.

Under similar conditions to those described above, **20b** (65 mg, 0.20 mmol) was electrolyzed to give **21** (43 mg, 61%), which was identical with that obtained from **20a** by ^1H NMR and TLC comparisons.

Formation of 19. A solution of **21** (49 mg, 0.14 mmol) in 99% HCOOH–$CHCl_3$ (0.3—2.7 ml) was kept at 15 °C for 1 h. The solution was washed with aqueous $NaHCO_3$, and dried over Na_2SO_4. Evaporation of the solvent under reduced pressure gave an oil, which was purified by column chromatography (SiO_2–$CHCl_3$) to yield **19** (as an oil, 37 mg, 82%): IR($CHCl_3$) 1748, 1710, and 1641 cm^{-1}; ^1H NMR δ=2.77 (3H, s), 3.12 (1H, dd, J=16.8 and 6.9 Hz), 3.35 (2H, m), 3.66 (3H, s), 3.67 (1H, dd, J=16.8 and 1.2 Hz), 5.22 (1H, dd, J=6.9 and 1.2 Hz), 5.71 (1H, t, J=3.0 Hz), 7.2—7.8 (3H, m), and 7.90 (1H, m); MS *m/z* 324 (M^+), 282, and 223. Found: *m/z* 324.1105. Calcd for $C_{18}H_{16}N_2O_4$: M, 324.1109.

Air Oxidation of 19. According to Iwadare's method,[2] air was bublled with capillary tubing through a solution of **19** (37 mg) in *n*-BuOH (50 ml) kept at 66—76 °C for 19 h. The blue solution was concentrated under reduced pressure. The residue was separated by column chromatography (SiO_2–$CHCl_3$) to give **23** (8 mg, 22%), which was identical with that synthesized following the procedure of Iwadare et al.[1,2] (IR, ^1H NMR, and TLC). **23**: ^{13}C NMR δ=24.8, 27.0, 48.5, 53.0, 102.7, 115.1, 120.2, 123.2, 124.0, 126.8, 127.5, 128.0, 128.9, 136.2, 139.3, 168.1, 169.8, and 170.4; CD $[\theta]_{427}$ −12000, $[\theta]_{407}$ 0, $[\theta]_{364}$ +55000, $[\theta]_{345}$ 0, and $[\theta]_{326}$ −38400.

We would like to thank Dr. Hiroshi Sakurai of Meijo University for obtaining the mass spectra.

Synthesis of $Ba_2YCu_3O_{7-\delta}$ Superconductor through Organometallic Route

Shin-ichi HIRANO,* Takashi HAYASHI, Masashi MIURA, and Hiroyuki TOMONAGA
Department of Applied Chemistry, Faculty of Engineering, Nagoya University,
Furo-cho, Chikusa-ku, Nagoya 464
(Received June 30, 1988)

The chemical synthesis of a high-T_c $Ba_2YCu_3O_{7-\delta}$ superconductor was investigated through the organometallic route, using Ba metal, $Y(OPr^i)_3$, and Cu-alkoxides or Cu-acetylacetonate as starting materials. Chemically homogeneous submicron powders of single phase $Ba_2YCu_3O_{7-\delta}$ were successfully prepared at 750 °C by controlled partial hydrolysis of metal alkoxides. The utilization of ozone for favorable decomposition of $Ba_2YCu_3O_{7-\delta}$ precursors was found to have a remarkable effect on suppressing the formation of $BaCO_3$ and lowering the formation temperature of $Ba_2YCu_3O_{7-\delta}$ to about 650 °C. The single phase $Ba_2YCu_3O_{7-\delta}$ ceramics exhibited superconductivity at approximately 83 K (T_c end).

Recently, intensive studies on the preparation of high-T_c $Ba_2YCu_3O_{7-\delta}$ superconductor have been performed.[1] The superconducting $Ba_2YCu_3O_{7-\delta}$ compound has been usually prepared by the conventional solid-state reaction between Y_2O_3, $BaCO_3$, and CuO and sintering at 950 °C, followed by slow cooling in the range of 350—650 °C. It is, however, difficult to prepare chemically homogeneous, highly pure fine particles by the solid state reaction and to control the particle size and morphology suitable for the fabrication of dense ceramics on sintering. Therefore, the alternative chemical routes such as coprecipitation of nitrates with oxalate[2,3] and citrate,[4] pyrolysis of organic acid salts,[5,6] and spray pyrolysis of nitrate solution[7] have currently received particular attention. These procedures may allow the synthesis of more chemically homogeneous fine particles. Although the chemical route affords highly pure and homogeneous particles and more controllable processing, there are some difficulties: non-uniform and incomplete precipitation, contamination by precipitating agents, and heterogeneous segregation due to the difference in decomposition temperatures of organic acid salts. Furthermore, another unavoidable problem encountered in the chemical route is the formation of $BaCO_3$ during calcination of the powder precursors, resulting easily in heterogeneous phase separation and, thereby, the formation of secondary phases such as $BaCuO_2$, Y_2O_3, Y_2BaCuO_5, etc. In particular, pyrolytic process of organic acid salts involves easier formation of $BaCO_3$.

The sol-gel method using alkoxides generally offers possibility of formation of films and fibers by controlling the solution viscosity as well as of high homogeneity, high purity, and lower temperature processing.

In a preceding work,[8] we reported the preparation of $Ba_2YCu_3O_{7-\delta}$ superconductor through an organometallic route with metal alkoxides and acetylacetonates. The preliminary experiments were tried to select organometallic compound and metal alkoxide as starting materials and appropriate solvent to prepare homogeneous solution. However, the calcination conditions to prepare $Ba_2YCu_3O_{7-\delta}$ powders at temperatures as low as possible have not fully optimized and the influence of firing atmosphere on the formation of $Ba_2YCu_3O_{7-\delta}$ compound has not been clarified. The present paper describes the selection of Cu-compound and solvent, a newly developed preparation process of chemically homogeneous solution, and calcination conditions to prepare fine powders of orthorhombic $Ba_2YCu_3O_{7-\delta}$ compound at temperatures as low as possible.

Experimental

The use of cupric organometallic compounds as starting materials is limited due to low solubility in common organic solvents. In the present work, $Cu(OEt)_2$, $Cu(OC_2H_4OEt)_2$, $Cu(acac)_2$, and $Cu(C_{17}H_{35}COO)_2$ with chemical-pure grade were examined as the source of Cu-compounds. The solubility of each Cu-compound in various organic solvents is compared in Table 1. $Cu(OEt)_2$ was found to be insoluble in organic solvents except amine and acetylacetone which tend to form readily coordination compounds with Cu-compounds. $Cu(C_{17}H_{35}COO)_2$ was soluble in toluene, pyridine, and acetylacetone, while these solvents were not suitable for $Y(OPr^i)_3$ and $Ba(OPr^i)_2$. $Cu(acac)_2$ was soluble in 2-methoxy-and 2-ethoxyethanol. $Cu(OC_2H_4OEt)_2$ was soluble in 2-ethoxyethanol, THF, and amine solvents. Thus, $Cu(acac)_2$ and $Cu(OC_2H_4OEt)_2$ were selected as starting materials. 2-Methoxy- and 2-ethoxyethanol were the most suitable solvents among common organic solvents for these starting materials.

Figure 1 shows the flowchart for chemical processing of $Ba_2YCu_3O_{7-\delta}$ superconductors through the organometallic route. $Y(OPr^i)_3$ (purity 99.9%) and high-pure Ba metal (purity 99.99%), which are soluble in common organic solvents, were used as starting materials.

The starting materials were dissolved in absolute 2-ethoxyethanol in the stoichiometric composition of Ba:Y:Cu=2:1:3. The initial concentration of alkoxides was 0.005 mol l^{-1}. The solution was stirred in dry nitrogen and heated at 40 °C for 12 h. Then, the solution was hydrolyzed by slow addition of desired amount of water diluted with solvent (1:10 volume ratio). The molar ratio of water to the sum of Ba-, Y-, and Cu-alkoxides was 1/4 and 1 (the theoretically required amount). After stirring and heating for several hours, the solution was evaporated with stirring

under vacuum at about 40 °C to give an amorphous powder precursor. The powder was calcined in flowing O_2 or O_2/O_3 (3000 ppm O_3) mixture at the temperatures range between 650 and 950 °C for 24 h. The calcined powder was die-pressed and sintered in flowing O_2 at temperatures up to 920 °C, followed by annealing at temperatures between 450 and 550 °C. Thin film was also prepared on the substrates from concentrated solution with controlled viscosity by a dip-coating method.

The specimens were characterized by the X-ray powder diffraction method. DTA-TG analysis was performed at a heating rate of 10 °C min^{-1}. The dc resistivity of the specimens was measured by the four probe method with indium contact electrodes. The magnetization was measured by the vibrating sample magnetometry.

Results and Discussion

Figure 2 shows DTA-TG curves of as-prepared specimens by the hydrolysis of Y-, Ba-, and Cu-alkoxides. Two exothermic peaks with gradual weight loss were observed for all the specimens at 200—300 and 400—500°C; the second peak corresponds to thermal decomposition and oxidation of organic groups. In the specimens prepared by the hydrolysis of metal alkoxides, less-noticeable weight loss was observed above 600 °C, while a large weight loss was observed above 800 °C for the specimen prepared without water addition (no-hydrolysis). The large weight loss corresponds to the decomposition of $BaCO_3$ formed during heating by the reaction of barium compound with carbonaceous residue from organic groups.

Also, when $Cu(acac)_2$ was used as a starting material insterd of $Cu(OC_2H_4OEt)_2$, more remarkable exothermic peak associated with large weight loss was observed, which corresponds to the thermal decomposition and the oxidation of organic groups. The fact indicates the formation of coordination compounds between $Cu(acac)_2$ and 2-ethoxyethanol, and/or a partially exchange reaction of acac groups of $Cu(acac)_2$ with the solvent.

Figure 3 shows the X-ray powder diffraction patterns of the powders calcined at 850 °C for 12 h, 900 °C for 7 h, and 920 °C for 5 h, followed by the annealing at 450—550 °C in O_2 flow. In the powders prepared by the hydrolysis of metal alkoxides with the

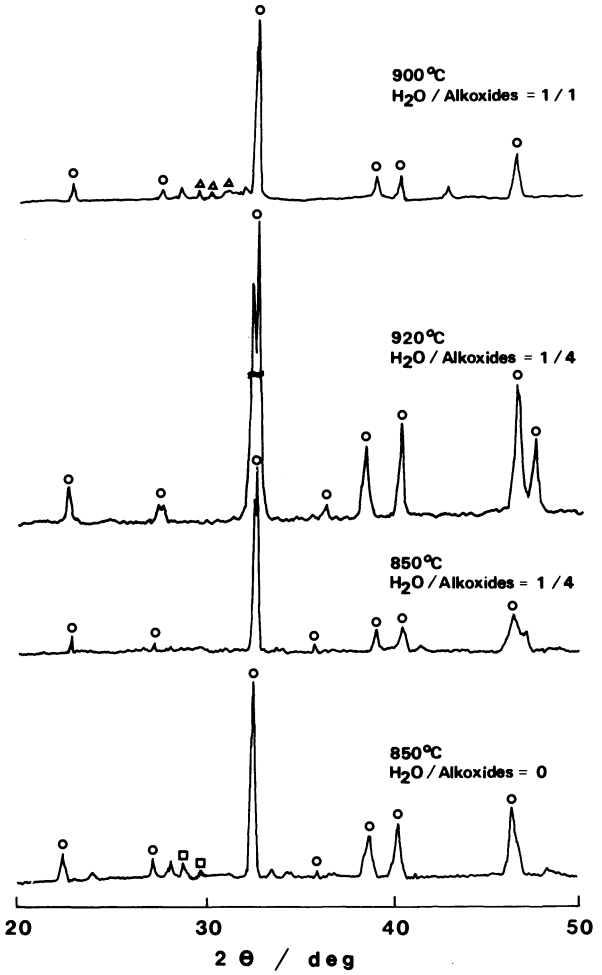

Fig. 3. X-Ray powder diffraction patterns of $Ba_2YCu_3O_{7-\delta}$ powders calcined at 850°C for 12 h, 900 °C for 7 h and 920°C for 5 h.
O: $Ba_2YCu_3O_{7-\delta}$ △: Y_2BaCuO_5, □: $BaCuO_2$.

equivalent amount of water, $BaCuO_2$ and Y_2BaCuO_5 were formed together with $Ba_2YCu_3O_{7-\delta}$. On the other hand, chemically homogeneous submicron powders of single phase $Ba_2YCu_3O_{7-\delta}$ were prepared at 850 °C by the controlled partial hydrolysis of metal alkoxides with addition of water less than the equivalent amount.

Figure 4 shows the X-ray powder diffraction patterns of the powders prepared by the calcination of partially hydrolyzed precursors at various temperatures for 12 h. The as-prepared powders were amorphous. $Ba_2YCu_3O_{7-\delta}$ compound formed at 750 °C was of single phase, and its crystallinity was further improved by heat treatment at 850 °C. Furthermore, by flowing O_2/O_3 mixture during the thermal decomposition of organic groups of the precursors, $Ba_2YCu_3O_{7-\delta}$ compound was prepared at the temperature as low as 650 °C. The importance of the utilization of O_3 gas was indicated by suppressed formation of $BaCO_3$. The addition of O_3 results in the direct formation of $Ba_2YCu_3O_{7-\delta}$ compound without any formation of intermediate phases such as $BaCuO_2$ and Y_2BaCuO_5. The carbon content in calcined powders, for example, in pure O_2 flow was 2.24%, which was drastically decreased to 0.94% by flowing O_2/O_3 mixture.

Figure 5 shows the SEM photograph of $Ba_2YCu_3O_{7-\delta}$ powders calcined at 850 °C. The resulting powders were chemically homogeneous, less agglomerated submicron particles, which can be ultrasonically dispersed homogeneously in organic solvents.

Figure 6 shows the dc resistivity of $Ba_2YCu_3O_{7-\delta}$ sintered at 920°C as a function of temperature. The superconducting transition starts at approximately 90 K and the resistance becomes zero at about 83 K. The superconducting-state magnetization, $Ms(H)$, of the fine powders determined by a magnetic balance, is shown at 85 K in Fig. 7. The hysteresis caused by the trap of magnetic flux exists in the $Ms(H)$ curves between the increase and the decrease of the magnetic field (H). The lower critical field H_{c1} was about 0.2 kOe at 85 K and the susceptibility was about −0.016 emu g^{-1}.

Figure 8 shows the fracture surface of the $Ba_2YCu_3O_{7-\delta}$ sintered body. The microstructure consisted of uniform grains of 2—3 μm, and no abnormal grain

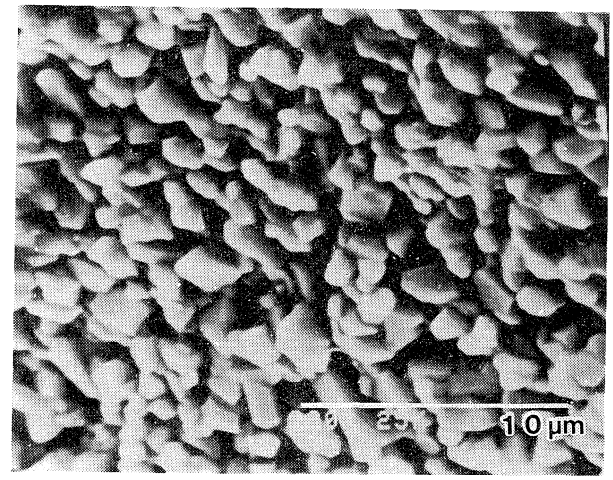

Fig. 8. Fracture surface of the $Ba_2YCu_3O_{7-\delta}$ sintered body.

growth was observed. No significant difference of properties was recognized for the powders or sintered bodies prepared from $Cu(OC_2H_4OEt)_2$ and $Cu(acac)_2$ in a flow of O_2/O_3 mixture.

The further research is in progress to synthesize the epitaxially grown films with c-axis orientation and the fibers of $Ba_2YCu_3O_{7-\delta}$ at lower temperature, on which

details will be reported elsewhere.

Conclusion

The synthesis of high-T_c $Ba_2YCu_3O_{7-\delta}$ superconductor in the relatively low temperature range was investigated through organometallic route, using Ba metal, $Y(OPr^i)_3$, and $Cu(OC_2H_4OEt)_2$ or Cu-acetylacetonate as starting materials by use of appropriate solvent.

1) Chemically homogeneous submicron powders of single phase $Ba_2YCu_3O_{7-\delta}$ was successfully prepared at 750 °C by controlled partial hydrolysis of alkoxides.

2) Utilization of O_2/O_3 mixture for the decomposition of the $Ba_2YCu_3O_{7-\delta}$ precursors showed a remarkable effect on suppressing the formation of $BaCO_3$ and lowering the formation temperature of $Ba_2YCu_3O_{7-\delta}$ to 650 °C.

3) It was confirmed by dc resistivity and magnetic susceptibility measurements that the single phase $Ba_2YCu_3O_{7-\delta}$ ceramics thus formed exhibit superconductivity at about 83 K (T_c end).

The Removal of Nitrogen Monoxide by the Dry Iron(II) Complex Immobilized on Chelate Resin. The Preparation and Characterization of the Complex

Naoki TOSHIMA,* Hiroyuki ASANUMA, and Hidefumi HIRAI†
Department of Industrial Chemistry, Faculty of Engineering,
The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received September 1, 1988)

A new dry-type adsorbent for nitrogen monoxide was successfully prepared from an iron(II) salt and a chelate resin containing iminodiacetic acid moieties. The capability of adsorbing nitrogen monoxide depended greatly on the method of preparation. The very active adsorbent was prepared by mixing 31.4 mmol of iron(II) sulfate and a commercial chelate resin containing 21.0 mmol of iminodiacetic acid moieties; the mixture was dried after the solid parts had been washed with methanol. The resulting solid adsorbent could adsorb more than 99% of the nitrogen monoxide from 6 dm^3 of nitrogen gas containing 1000 ppm of nitrogen monoxide within 25 min. This high capability for adsorbing nitrogen monoxide was derived from the increase in the surface area (43.1 $m^2 g^{-1}$) of the resin-immobilized iron(II) complex upon washing with methanol. The mechanism for the increase in the surface area is also discussed.

The atmosphere has been fairly well improved by the recent high technologies for protecting the environment. The concentration of nitrogen monoxide (NO), which is a source of pollution such as photochemical smog in the atmosphere has, however, not decreased in the past decade. Therefore, advanced technology for the removal of NO is strongly desired. At the present time, the catalytic reduction of NO into nitrogen by a gaseous reducing agent like ammonia is practically adopted, especially for such statistic sources as heavy oil and coal boilers.[1-3] Other methods under investigation involve the absorption of NO by molten salts, where the catalytic reduction proceeds partially,[4] and the absorption of NO by an aqueous solution of iron(II)–ethylenediaminetetraacetic acid (Fe(II)–EDTA), which can form a complex with NO.[5-8] Since an aqueous solution of Fe(II)–EDTA absorbs NO and desorbs it reversibly, this method has potential for use as an absorbent for recovering NO; i.e., the absorbed NO can be used again as a resource for nitrogen industries. However, this solution involves Fe(II) ions, which are easily oxidized into inactive Fe(III) ions by the contaminated oxygen. A reducing agent is necessary to avoid this deactivation of the complex in this system. Moreover, the recovery of the complex from the solution is difficult because of the homogeneity of the solution.

The immobilization of a metal complex, in general, offers the following advantages:[9] 1) the protection of the active site of the metal complex; 2) an increase in the activity by the polymer effect, and 3) easier handling because of the solidification of the complex by using a polymer support. Some polymer complexes have been investigated in order to apply them to catalysts and to the absorbents of carbon monoxide and ethylene.[10-13] Since, however, few studies have been reported on the application of a polymer complex for the removal of NO, it is significant to investigate an absorbent composed of the polymer complex with the above advantages. We have successfully prepared an aqueous dispersion by mixing an aqueous solution of Fe(II) ions with a chelate resin involving iminodiacetic acid moieties instead of EDTA in order to achieve easier handling and higher stability than the aqueous solution of Fe(II)–EDTA.[14,15] The resulting dispersions can absorb NO effectively, even at a low concentration, and can desorb NO reversibly upon heating at a higher concentration. The chelate resin-immobilized Fe(II) complex (CR–Fe(II)) can easily be recovered from the dispersions by filtration. Moreover, it has a higher durability against oxygen than Fe(II)–EDTA, the usual absorbent of NO, since the central atom of Fe(II) can be protected by polymer matrices.

We have examined the preparation of the dry-type, water-free chelate resin-immobilized Fe(II) complexes in order to develop more active and stable absorbents. Dry-type absorbents have been expected to have the following advantages: 1) contamination with the solvent vapor can be avoided in the recovery of NO; 2) much of the heat loss can be avoided when the adsorbed NO is recovered by heating, and 3) the handling of the adsorbent is easy enough to be applied to the moving sources of NO. To the best of our knowledge, nothing has yet been reported about the dry-type adsorbent of NO except for the active carbon[16] and the active carbon fiber-supported FeOOH.[17] Since the adsorption by these adsorbents is mainly based on a physical interaction between NO molecules and the adsorbents, they are not usually used for the removal of NO at extremely low concentrations. Now, we have successfully prepared a dry-type adsorbent of NO composed of the polymer complex.[18] In the present paper, the preparation and characterization of the

† Present address: Department of Industrial Chemistry, Faculty of Engineering, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162.

polymer complex and its capability of adsorbing NO are reported.

Experimental

Materials. A commercial chelate resin (Diaion CR-10; mean diameter of the particles, 0.5 mm) purchased from Mitsubishi Chemical Industry, Ltd., was used in a swollen state, as it was, or in a dry state by drying after washing with a large amount of methanol since the commercial resin is swollen with water. One gram of the swollen resin was determined by pH titration to contain 0.98 mmol of iminodiacetic acid moieties. One gram of the resin dried in vacuo, on the other hand, has 2.78 mmol of the moieties. A mass of the chelate resin in a dry or a swollen state containing 21.0 mmol of iminodiacetic acid moieties was used at one time for the preparation of each adsorbent.

The reagent-grade solvents were used without further purification.

The iron(II) sulfate 7 hydrate and the Fe(II) chloride n hydrate (the n was determined to be 4.59 by the 1,10-phenanthroline method[19]) were used without further purification.

The gases of NO and nitrogen mixed at designed NO concentration were purchased from Takachiho Shoji, Ltd., and were used without further purification.

Preparation of the Adsorbent. 1) Preparation of the Aqueous Dispersions of the Chelate Resin-Immobilized Iron(II) Complex: The chelate resin containing 21.0 mmol of iminodiacetic acid moieties (21.4 g in a swollen state or 7.53 g in a dry state) and 31.4 mmol of Fe(II) salts were stirred in 50 cm^3 of water under nitrogen for 24 h to immobilize any Fe(II) ions on the resin. We will hereafter call the resulting aqueous mixture the "aqueous dispersion."

2) Preparation of Dry Adsorbent by Washing: The supernatant of the aqueous dispersion prepared as above was removed by decantation. After the solid part of the aqueous dispersion had been washed with 50 cm^3 of another solvent (a washing solvent) 4 times, drying it at 50 °C in vacuo gave a dry-type solid adsorbent.

3) Preparation without Washing: A solid adsorbent was prepared only by evacuating water from the aqueous dispersion at 50 °C in vacuo.

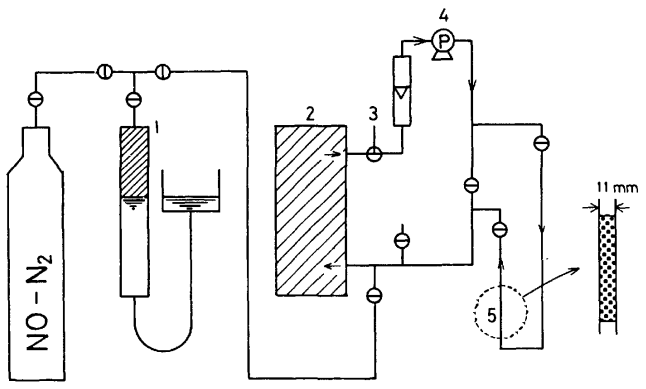

Fig. 1. Schematic diagram of gas adsorption apparatus. 1. Gas burette. 2. Gas holder. 3. Sampling outlet. 4. A gas-circulating pump. 5. An adsorbent column.

Adsorption of NO. The adsorption experiments of NO were carried out by using the closed circulation system illustrated in Fig. 1. After putting an adsorbent in a column of 1 l ϕ, 6 dm^3 of nitrogen containing 1000 ppm (or 980 ppm) of NO (the total amount of NO was 0.246 mmol) was introduced into this apparatus at room temperature, after which the sample gas was circulated through the column at the rate of 1.6 $dm^3\ min^{-1}$. Changes in the NO concentration in nitrogen were traced by sampling the mixed gas in a 100 mm-cell and measuring the absorbance at 226.5 nm.

Measurement of the Spectrum of the Adsorbent. The electronic spectra of the solid complexes were measured with a Hitachi model 340 spectrophotometer equipped with an integrated reflection apparatus. The ESR spectra were measured with a JEOL PE-1X ESR spectrometer. The chelate resin-Fe(II)-NO complex for the spectroscopic measurement was prepared by placing the solid adsorbent in contact with pure NO at 1 atm for 24 h.

Measurement of the Specific Surface Area. The BET surface area of the dry-type adsorbent was measured from the amount of adsorbed nitrogen at 77 K with a Micromeritics Instrument Co., Ltd., model 2200A rapid surface-area analyzer. The sample was completely dried by heating the sample at 90 °C for 40 min under a nitrogen stream before the measurement.

Electron Microscopy and X-Ray Microanalysis. Scanning electron microscopy (SEM) and X-ray microanalysis (EPMA) on the resin of the adsorbents were carried out by the use of a Hitachi model X-650 micro-scanning X-ray analyzer, the resolution of the X-ray image of which is around 100 Å. The sample beads were cut with a stainless steel cutter and then coated with gold so that cross-sections of the beads were irradiated by an electron beam. The distributions of Fe and S atoms were evaluated by the intensity of the characteristic X-ray.

Measurement of the Immobilized Iron(II) Ions on the Resin. The concentration of Fe(II) ions in the supernatant of the aqueous dispersion was measured by the 1,10-phenanthroline method.[19] The amount of immobilized Fe(II) ions was calculated from the discrepancy in the amount of initially charged Fe(II) ions and that of Fe(II) ions remaining in the supernatant after the immobilization. The amount of immobilized Fe(II) ions was 16.2 mmol when 7.53 g of the chelate resin containing 21.0 mmol of iminodiacetic acid moieties and 8.72 g of $FeSO_4$ was used.

Results

Preparation of the Adsorbent and Its Capability to Adsorb NO. The supernatant of the adsorbent dispersions prepared from Fe(II) sulfate and the chelate resin had a light green color due to the dissolution of Fe(II) sulfate. The light greenish color of the aqueous solution gradually diminished due to the immobilization of the dissolved Fe(II) ions onto the resin through ion-exchange. In contrast, the chelate resin (solid part) acquired a light green color by the immobilization. The immobilization completed within a few hours. The amount of immobilized Fe(II) ions was found to be 16.2 mmol. The solvent-free adsorbent prepared only by removing the water

from the aqueous dispersion in vacuo adsorbed any scarcely NO in spite of the immobilization of the Fe(II) ions on the resin, as is shown by open circles in Fig. 2. In contrast, the adsorbent prepared by drying after the immobilizing resin has been washed 4 times with 50 cm^3 of a "washing solvent" had the capability of adsorbing NO. Especially, the adsorbent prepared by washing with methanol shows so high a capability that almost all the NO in the system was adsorbed within 25 min, as is illustrated by the closed circles in Fig. 2.[20]

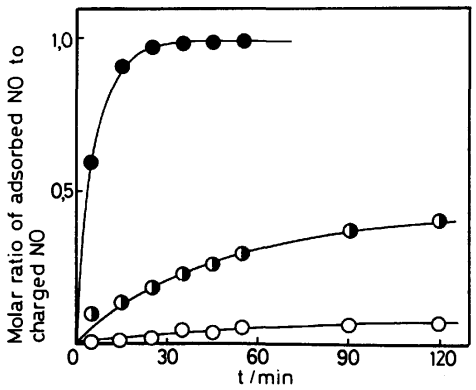

Fig. 2. Adsorption curves for NO by the chelate resin-immobilized adsorbent prepared by drying after washing with methanol (●), water (◑), and without washing (○). These adsorbents were prepared from 21.4 g of chelate resin and 8.72 g (31.4 mmol) of $FeSO_4 \cdot 7H_2O$. Adsorption experiment was carried out by circulating 6 dm^3 of nitrogen containing 1000 ppm of NO at room temperature at the rate of 1.6 $dm^3\ min^{-1}$.

Figure 3 reveals the adsorption curves of NO by the adsorbent prepared from Fe(II) chloride instead of sulfate according to the same method as was used with the sulfate. The adsorbent prepared from Fe(II) chloride by washing with methanol also shows as high a capability for the adsorption of NO as that of the adsorbent from the sulfate. The adsorbents obtained from chloride without washing or by washing with water, however, have a higher capability than the corresponding adsorbents prepared from the sulfate illustrated in Fig. 2.

A freeze-dried absorbent was also prepared by freeze-drying after the solid part of the aqueous dispersion had been washed with water. However, it has almost the same capability as the adsorbent dried at 50 °C in vacuo, as is shown in Fig. 4. Table 1 compares the amount of NO adsorbed by the dry-type adsorbent, the original chelate resin itself, the powder of the Fe(II) sulfate, and that of Fe(II) chloride. This table clearly

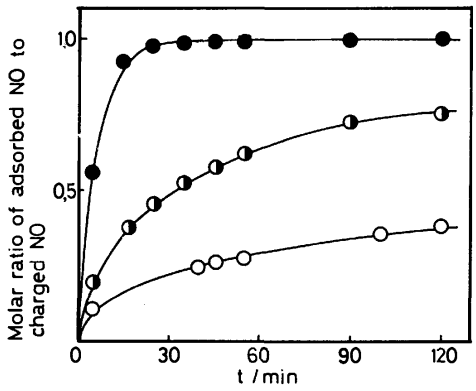

Fig. 3. Adsorption curves for NO by the CR-Fe(II) complex prepared from 31.4 mmol of $FeCl_2$ and 21.4 g of chelate resin by drying after washing with methanol (●), water (◑), and without washing (○). The adsorbent was contacted with 6 dm^3 of nitrogen containing 1000 ppm of NO at room temperature at the rate of 1.6 $dm^3\ min^{-1}$.

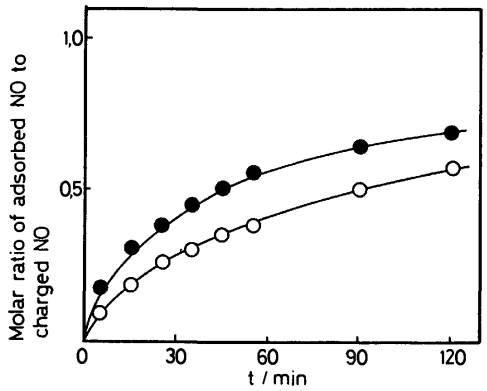

Fig. 4. Effect of the drying temperature on the adsorption of NO. The adsorbents were prepared by drying at 50 °C (○) and by freeze-drying (●) after washing the CR-Fe(II) complex with water. The adsorbent was contacted with 6 dm^3 of nitrogen containing 1000 ppm of NO at room temperature at the rate of 1.6 $dm^3\ min^{-1}$.

Table 1. Adsorption of NO by the Dry-Type CR-Fe(II) Adsorbent and Its Starting Materials

Material	Amount/g	Amount of adsorbed NO[a]/mmol
Chelate resin[b]	7.53	0.0
$FeCl_2 \cdot 4.59H_2O$	6.56 (31.4 mmol)	0.0
$FeSO_4 \cdot 7H_2O$	8.72 (31.4 mmol)	0.0
CR-Fe(II)[c]	9.02	0.246

a) Adsorption experiments were carried out by placing the material in contact with 6 dm^3 of nitrogen containing 1000 ppm of NO. The initially charged amount of NO was 0.246 mmol. b) The commercial chelate resin dried after having been washed with ethanol. c) A dry-type chelate resin-Fe(II) adsorbent prepared by drying after washing with methanol. See text for details.

Table 2. Effects of Solvents for the Immobilization of Iron(II) Ions on the Adsorbing Capability for NO[a]

Solvent	Molar ratio of adsorbed NO to charged NO	
	In 15 min	At equilibrium[b]
Water	0.170	>0.425
Methanol	0.173	>0.536
Ethanol	0.443	0.921
2-Propanol	0.263	>0.794
Acetone	0.139	>0.502
Acetonitrile	0.111	>0.464
Chloroform[c]	0.023	0.026

a) Adsorbents were prepared from 50 cm^3 of a solvent, 31.4 mmol of $FeCl_2$, and 21.4 g of the chelate resin swollen with water. b) When the equilibrium was not attained within 180 min, the ratio of the adsorbed NO at this time is shown in this column. c) The adsorbent was prepared from chloroform, $FeCl_2$, and dried chelate resin which had previously been washed with ethanol.

indicates that the adsorption of NO does not take place only by means of each starting material, but the adsorbent resulting from mixing the starting materials does.

The preparation of adsorbent dispersions was examined from 21.4 g of water-swollen chelate resin, 31.4 mmol of $FeCl_2$, and 50·cm^3 portions of various organic solvents. The color of the supernatant became light green in each system and then gradually faded through the immobilization of the Fe(II) on the resin, which showed the light green color in contrast. In this system, the supernatant is actually composed of the organic solvent and water derived from the water-swollen resin. The ratio of water to the organic solvent is calculated to be 0.27 (v/v), because 21.4 g of the chelate resin contains 13.4 g of water. The adsorbent was prepared by removing the solvent from the above dispersion in vacuo at 50 °C. The amounts of NO adsorbed by these adsorbents are listed in Table 2; the table shows not very high adsorbing capabilities in this method except for the adsorbent prepared with ethanol.

In order to avoid the effect of water in the solvent, the adsorbent dispersion was prepared from ethanol (the solvent used for immobilization), the dried chelate resin, and $FeCl_2$, which is soluble in ethanol. The ethanol solution of $FeCl_2$ offered a brownish color, although the aqueous solution was light green. The immobilization of Fe(II) scarcely proceeded, since, though the resin was colored a little brownish, no fading in the color of the supernatant was observed. The removal of the ethanol by the adsorbent dispersions gave the resin-immobilized Fe(II) complex and a large amount of $FeCl_2$ salts which were not immobilized on the resin. The adsorbing capability of the adsorbent prepared by the above method is illustrated with closed circles in Fig. 5; it is not so high as that given by the washing method. The adsorbent prepared by using chloroform as a solvent scarcely adsorbs any NO at all, as is shown by the open circles in the same figure. In this system, the Fe(II) ions could

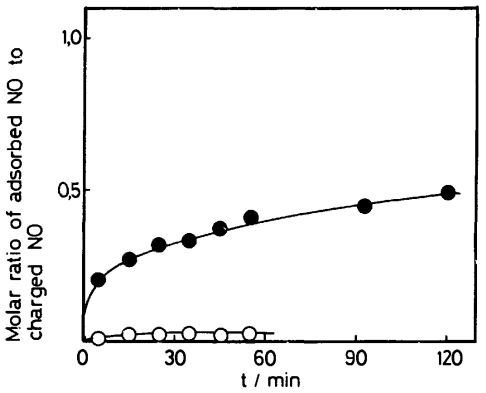

Fig. 5. Effect of the solvent used for immobilization of Fe(II) ions on the adsorbing capability for NO. The adsorbents were prepared from 7.53 g of the dried chelate resin, 31.4 mmol of $FeCl_2$, and ethanol (●) or chloroform (○) for immobilization of Fe(II) ions on the resin. See text for details.

not be immobilized on the resin because $FeCl_2$ does not dissolve in chloroform. These results indicate that chloroform is not an appropriate solvent for the immobilization of Fe(II) on the resin.

Among the methods examined, the method to prepare the most effective adsorbent has turned out to be the use of water as a solvent for the immobilization, followed by drying under a vacumm after washing the swollen CR–Fe(II) complex with methanol (vide infra).

Adsorbing Capability for NO and Specific Surface Area of the Dry-Type Chelate Resin-Iron(II) Complex Prepared by Washing with a Solvent. We have shown in the previous paragraph that the adsorbent prepared by drying after washing the swollen CR–Fe(II) complex with methanol has the highest adsorbing capability for NO among those examined. Table 3 indicates the effect of the washing solvent on the capability for adsorbing NO. An obvious difference in the adsorption rate of NO is observed in the solvent used for washing the swollen CR–Fe(II), but there is

no significant difference in its appearance. The adsorbent prepared by using methanol or ethanol adsorbs NO at the initial rate of 1.54×10^{-2} mmol min^{-1}. The adsorption rate, however, slightly decreases in the case of acetone. A significant decrease in the adsorption rate is observed in the case of water and chloroform, which is immiscible with water. Table 3 also shows the specific surface area ($A/m^2\,g^{-1}$) of each adsorbent, as measured by the BET method, which clearly demonstrates that the adsorption rate is in reasonable linear relationship with the specific surface area.

The above results show the best method of preparation to be as follows: 1) the immobilization of the Fe(II) ion on the resin has to be carried out in water, and 2) the drying of the CR-Fe(II) dispersion

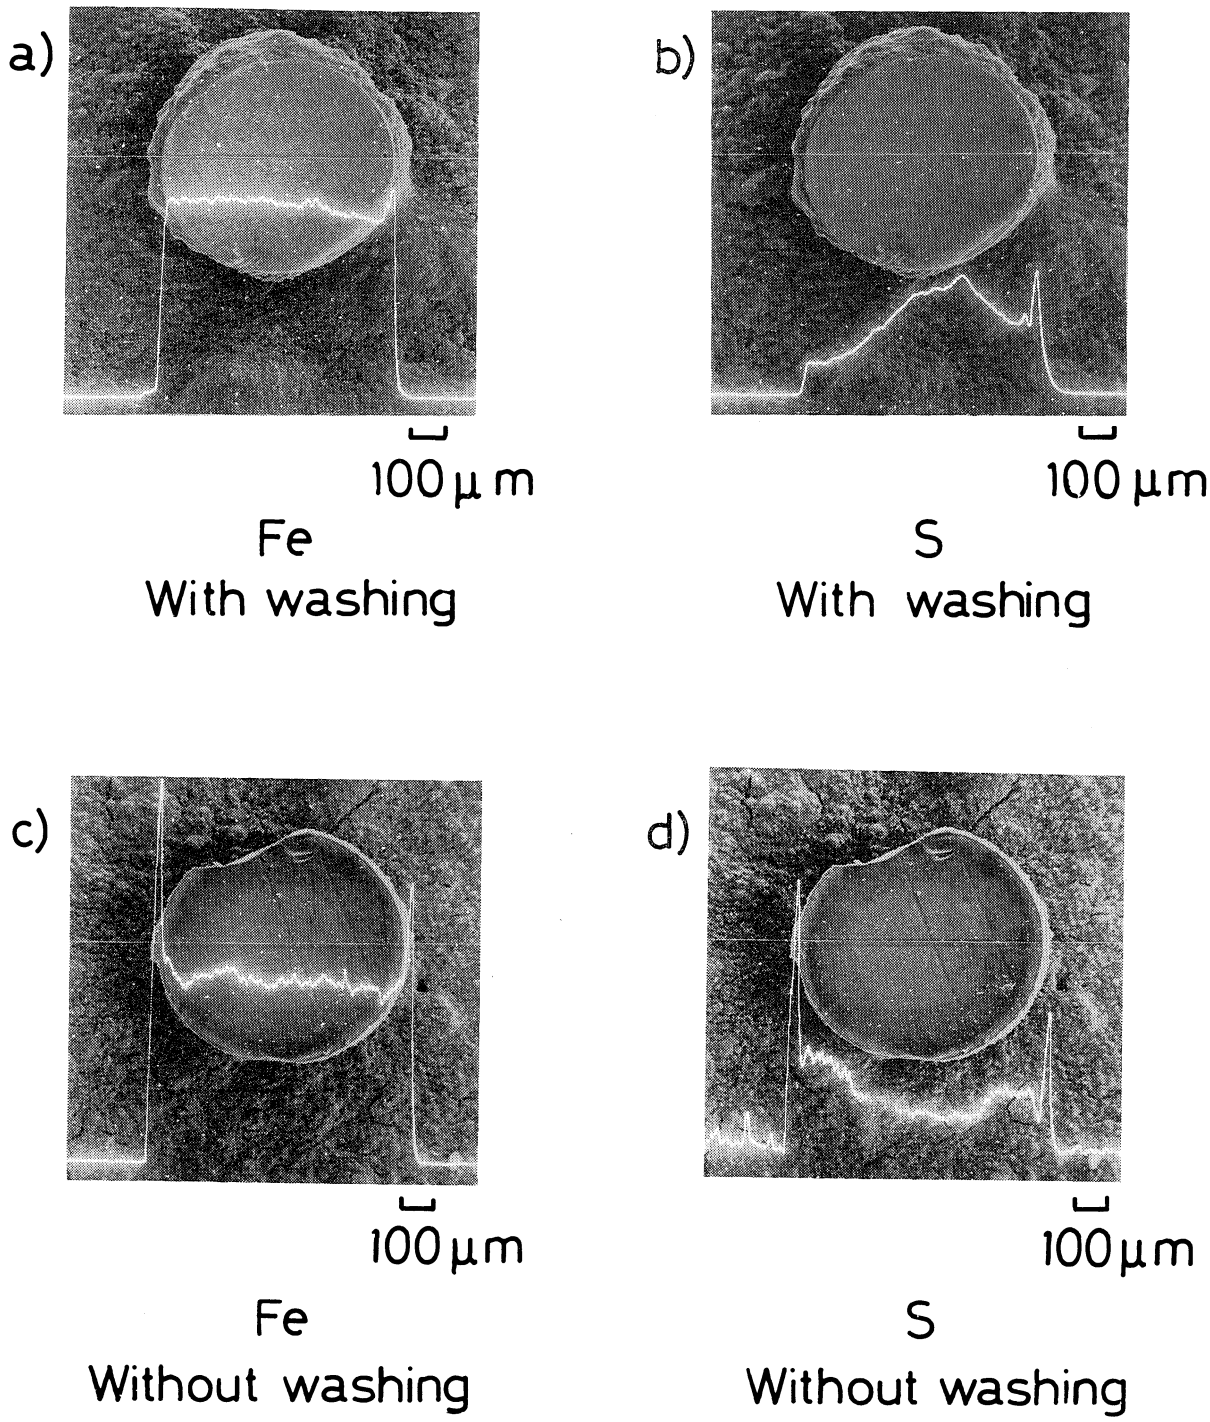

Fig. 6. SEM photographs and EPMA data of the cross-section of the dry adsorbents prepared from $FeSO_4$ and the chelate resin with washing with ethanol (a, b) or without washing (c, d).

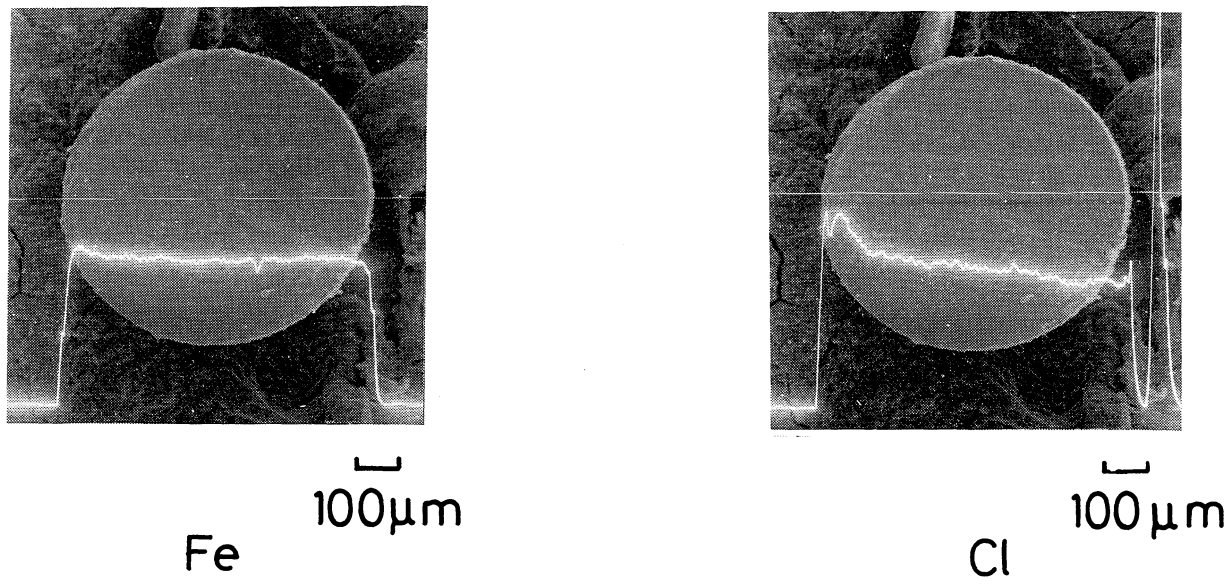

Fig. 7. SEM photograph of the cross section of the adsorbent prepared from $FeCl_2$ and the chelate resin without washing and its EPMA traces for Fe and Cl.

had better to be carried out after washing the resin with an organic solvent miscible with water, especially with methanol. Moreover, the effect of the washing has turned out to be an increase in the surface area of the adsorbent.

Analysis of the Adsorbent with Electron Microscopy and X-Ray Microanalysis. The distribution of the immobilized Fe(II) salts on the resin beads was analyzed by means of SEM and EPMA. Figure 6 shows SEM photographs of the dry-type adsorbent prepared by drying after washing with ethanol and by drying without washing. The waveline refers to the distributions of Fe and S atoms along the corresponding white straight lines on the cross-sections of the beads. The height of the waveline refers to the density of each atom. For both adsorbents, Fe atoms are homogeneously distributed inside the resin. For the adsorbent without washing, however, the density of Fe atoms is higher on the outer surface than inside the bead, while, for the adsorbent with washing, it is uniformly distributed not only inside the beads, but also on the surface. A low distribution of S atoms is observed both inside and on the surface of the bead. For the adsorbent without washing, however, many S atoms are located near the surface of the bead. These analyses indicate that the $FeSO_4$ is attached to the outer surface of the bead without washing. For the adsorbent prepared from $FeCl_2$, a homogeneous distribution of Fe atoms inside and on the outer surface was observed, as is depicted in Fig. 7.

The above facts clearly indicate that the residual powder of $FeSO_4$, which is not immobilized on the resin, is attached to the outer surface of the resin beads and that it suppresses the diffusion of NO molecules into the inside of the resin, resulting in a low capability for adsorbing NO. On the contrary, the adsorbent with $FeCl_2$ without washing has a sufficient adsorbing capability for NO. This fact also coincides with the results of the EPMA, which show the delocalized distribution of Fe atoms.

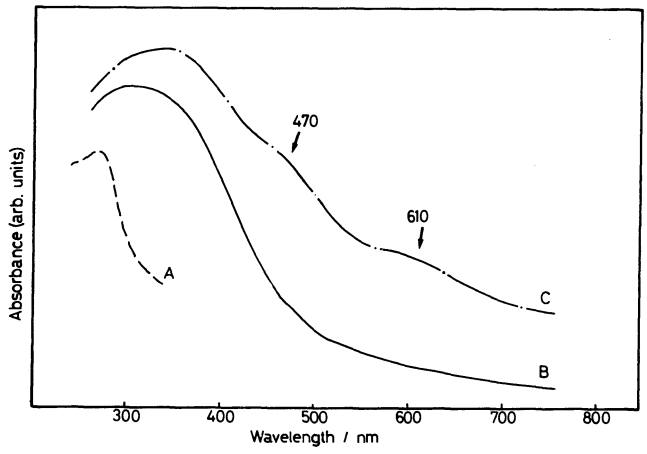

Fig. 8. Electronic spectra of the NO adsorbent and the related materials. A(——): chelate resin, B(—): CR-Fe(II), and C(—·—): CR-Fe(II)-NO.

Spectra of the Adsorbent. The water-swollen chelate resin before the immobilization of Fe(II) ions is white and has its maximum peak in its electronic spectrum at 280 nm due to the benzene chromophore of the matrices, as is shown by the broken line in Fig. 8. The color of the resin changes from white to light green upon the immobilization of the Fe(II) ions; also, a new peak appears around 300 nm. The exposure of the CR-Fe(II) complex to pure NO rapidly change its color from light green to brown, and new shoulder peaks appear in its electronic spectrum at 470 and

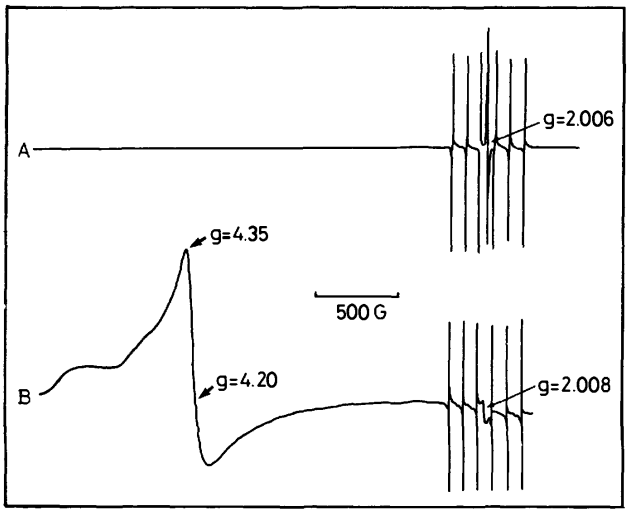

Fig. 9. ESR spectra of chelate resin (A) and CR-Fe(II) complex before the exposure with NO gas (B). Six signals in the same magnitude are derived from a Mn^{2+} marker.

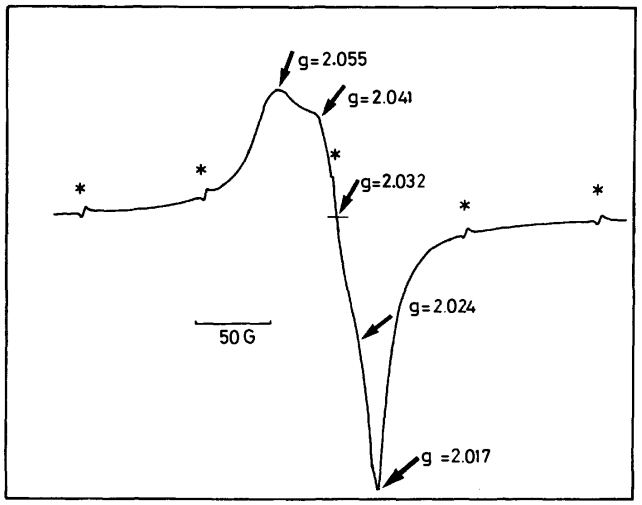

Fig. 10. ESR spectrum of CR-Fe(II)-NO complex at central magnetic field. Five weak signals with asterisks are derived from a Mn^{2+} marker.

610 nm. A similar change has been observed in the case of the absorption of NO by an aqueous solution of the Fe(II)-EDTA complex.[6]

In the ESR spectrum, the dried commercial resin before the immobilization of Fe(II) ions has a sharp signal at g=2.006 assigned to the organic radical, while no signals are observed at low magnetic fileds, as is illustrated in A of Fig. 9. The six sharp signals in Fig. 9 are derived from a manganese marker (S=5/2). By the immobilization of the Fe(II) ions on the resin, the sharp signal at g=2.006 disappears and broad new signals, probably due to the contaminated Fe(III), appear at g=4.20,[21] as is shown in B of Fig. 9. A new, unsymmetrical, strong, broad signal with unresolved shoulders appears upon the exposure to NO as is

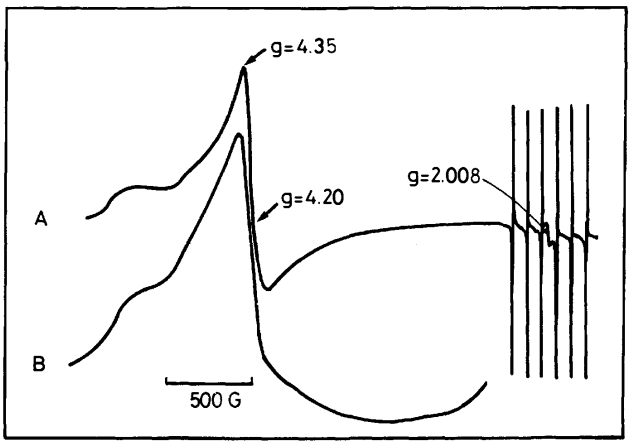

Fig. 11. ESR spectra of CR-Fe(II) (A) and CR-Fe(II)-NO (B) at low magnetic field. Six signals at central magnetic field are derived from a Mn^{2+} marker. The spectrum B in the central magnetic field region is shown in Fig. 10 and omitted in this Figure.

shown in Fig. 10. The g values at the maximum and minimum of the signal were 2.055 and 2.017 respectively. In this case, the signal at g=4.20 does not change, as is shown in Fig. 11.

Discussion

Coordination of Nitrogen Monoxide. The appearance of a new band in the electronic spectrum by the immobilization of Fe(II) ions indicates the coordination of Fe(II) ions to the IDA moieties in the chelate resin. Upon the adsorption of NO new shoulder peaks appear at 470 nm and 610 nm; this is similar to the change in the spectrum observed with an aqueous solution of Fe(II)-EDTA or Fe(II) salts.[6] This change is reported to be due to the coordination of an NO molecule on the Fe(II) ion.[6] Thus, the adsorption of NO by the present dry-type adsorbent proceeds by the coordination of an NO molecule with the Fe(II) ion in the resin complex.

The ESR signals around g=2.03 appearing upon the contact of the adsorbent with an NO gas are commonly observed in the case of Fe(II)-NO complexes derived from an NO molecule with a free electron.[22] This fact also strongly supports the idea that the adsorption of NO by the present adsorbent proceeds by means of the coordination of NO on the Fe(II) ion. Moreover, the appearance of the signal at around g=2.03, not in the lower magnetic field, indicates the formation of a low-spin (S=1/2) Fe(II)-NO complex.[22] In general, there are two types of Fe(II)-NO complexes. One is a low-spin state (S=1/2), and the other, a high-spin state (S=3/2). When a ligand field is strong enough, a low-spin complex is known to be formed. In the present system, since the IDA moieties in the chelate resin work as strong ligands, the low-spin complexes of Fe(II)-NO are thought to be produced.

Preparation of a Dry-Type Adsorbent with a High Capability for Adsorbing NO upon Washing. From the results of EPMA, the Fe atoms in the adsorbent prepared with washing seem to be distributed homogeneously both inside and on the surface of the resin beads. On the contrary, in the case of the adsorbent prepared without washing, more Fe atoms are distributed on the surface than on the inside of the resin. A similar result is also observed in the distribution of S atoms. These results indicate that the Fe(II) ions which cannot be immobilized on the resin are attached on the surface of the resin beads as $FeSO_4$. This $FeSO_4$ attached on the surface suppresses the diffusion of NO molecules into the resin inside.

The capability for adsorbing NO, especially the adsorption rate of the adsorbent prepared by washing, coincides well with the specific surface area, as is shown in the right column in Table 3. Figure 12 shows the plots of the adsorption rate of NO against the specific surface area. The adsorption rate linearly increases with an increase in the surface area until 24 $m^2 g^{-1}$. This fact clearly demonstrates that the increase in the surface area contributes directly to the increase in the adsorption rate. Over a surface area of 24 $m^2 g^{-1}$, the adsorption rate is so fast that the adsorption apparatus used in this experiment cannot follow the increase in the adsorption rate while keeping a constant rate at 1.54×10^{-2} mmol min^{-1}.

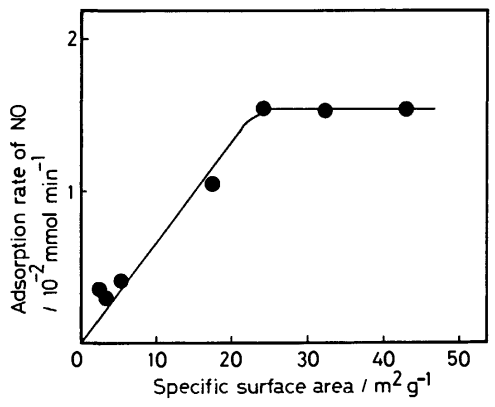

Fig. 12. Correlation of the specific surface area with the adsorption rate of NO by various CR-Fe(II) adsorbents.

The increase in the specific surface area upon washing with an organic solvent can be explained as follows. The chelate resin swells well in water and exists in a rubber state. When the solvent (water) in the resin in the rubber state is exchanged with an organic solvent miscible with water, many microgels will be generated through a phenomenon similar to the "reprecipitation" of the polymer by the addition of a poor solvent to the polymer solution, since the freeze-dried adsorbent from water has a low porosity. The resin is transformed from the rubber state into a glassy state during the exchange of the solvent because of the poor swelling in the organic solvent.[23,24] In this glassy state, the shrinkage of the resin during the drying of the resin is suppressed by the low mobility of the polymer. Consequently, the surface area increases due to the remaining of the pores produced by drying the resin after the exchange of the solvent. On the contrary, the resin swollen in water shrinks during the evacuation of the solvent in the resin, for the polymer chains have a high mobility in the rubber state. In

Table 3. Effects of the Washing Solvents on the Adsorption Rate of NO and the Specific Surface Area of the Adsorbent

Solvent	Adsorption rate[a]/ 10^{-2} mmol min^{-1}	Ratio of adsorbed NO[b]	Specific surface area[c]/$m^2 g^{-1}$
Chloroform	0.36	0.789	2.3
Water	0.30	>0.425	3.2
Acetone	1.04	0.933	17.1
Ethanol[d]	1.54	0.997	31.1
Methanol[d]	1.54	0.997	43.1

a) The adsorption rates were evaluated from the amount of NO adsorbed in 15 min. b) Molar ratio of adsorbed NO to charged NO at equilibrium. c) Measured by a BET method. d) No difference in the adsorption of NO between the two adsorbents could be observed because the adsorption occurred too fast.

Table 4. Effects of the Washing Solvents on the Specific Surface Area of the Chelate Resin-Immobilized Fe(II) Complex

Solvent	Solubility parameter $\delta^{a)}/10^3$ $(J m^3)^{1/2}$	Specific surface area[b]/$m^2 g^{-1}$
Chloroform	19.0	2.3
Water	47.9	3.2
Acetone	20.3	17.1
2-Propanol	23.5	31.7
Ethanol	26.0	31.1
Methanol	29.7	43.1

a) Quoted from Ref. 25. b) Measured by a BET method.

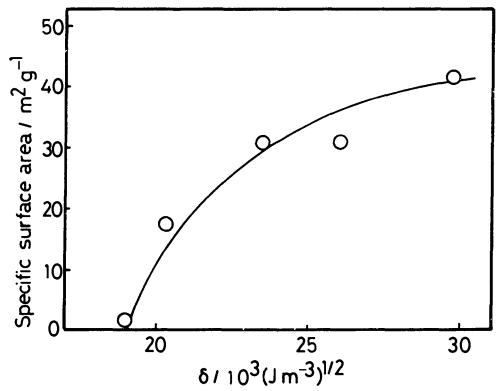

Fig. 13. Relationship between the specific surface area and the solubility parameter (δ) of the solvent used for washing the water-swollen CR-Fe(II) complex.

fact, the adsorbent prepared by washing with the organic solvent is lower in apparent density than that prepared by washing with water.

The surface area increases with the increase in the solubility parameter δ[25] in the order of: acetone, ethanol, and methanol, as is shown in Table 4. The date are plotted in Fig. 13. This parameter δ corresponds to the square root of the cohesive energy density ($(E/V)^{1/2}$).[25] If the solubility parameters δ of two solvents are close to each other, it indicates that their mutual miscibility is high.[25] The adsorbent prepared by chloroform, whose δ is apart from that of water, has a small surface area. On the contrary, the maximum porosity is obtained by the use of methanol, whose δ is close to that of water. These facts indicate that mutual miscibility with water contributes to the surface area (porosity) of the adsorbent. Probably, the solvent with a δ close to that of water, like methanol, will be able to penetrate into the inner portions of the resin and be exchanged with water to make pores through "reprecipitation."

The dry-type resin-immobilized Fe(II) complexes prepared from $FeSO_4$ without washing cannot adsorb NO, while those from $FeCl_2$ can adsorb NO even without washing. From the results of EPMA, $FeCl_2$ seemed not so much attached on the outer surface of the resin as was observed in the case of $FeSO_4$. This phenomenon is probably connected with the crystallinity of the Fe(II) salts. For $FeSO_4$, an excess amount of the salt can form crystals easily and can cause it to attach itself on the surface, resulting in a suppression of the adsorption of NO. On the contrary, since the excess amount of $FeCl_2$ is not attached on the surface, the adsorption of NO takes place.

Concerning the adsorbent prepared by using a hydrophilic organic solvent and a water-swollen resin without the washing treatment, though the immobilization of Fe(II) ions took place, its adsorbing capability for NO was as low as that when using water without washing, except when ethanol was used as the hydrophilic solvent. In these systems, since the solvents used has boiling points lower than that of water, the organic solvent was first removed from the water-mixed solvent by evaporation. Consequently, these adsorbents prepared from the water-mixed solvent were the same as that dried directly from water without an organic solvent. In the case of ethanol, however, the evaporation of an azeotropic mixture of ethanol and water actually proceeded resulting in an adsorbent different from that prepared from only water.

In the case of the adsorbent prepared by using ethanol and the dried chelate resin, the immobilization of Fe(II) ions does not proceed even for $FeCl_2$, which is soluble in ethanol. Since the immobilization of Fe(II) ions occurs by means an ion-exchange with sodium ions in water, the ion-exchange does not proceed smoothly in ethanol, which is not a good electrolyte.

Conclusion

1) The dry-type adsorbent was prepared from 21.4 g of chelate resin (containing 21.0 mmol of iminodiacetic acid moieties) and 31.4 mmol of $FeSO_4$ by drying after the water-swollen CR-Fe(II) complex had been washed with methanol. The resulting adsorbent adsorbed almost all the NO from 6 dm^3 of nitrogen containing 1000 ppm of NO within 25 min.

2) The high adsorbing capability for NO obtained by washing with an organic solvent is derived from the increase in the specific surface area. The surface area greatly depends on the kind of washing solvent used. The maximum porosity (43.1 $m^2 g^{-1}$) was obtained by using methanol, whose solubility parameter δ was close to that of water. On the contrary, no increase in the surface area was observed with chloroform, whose δ is far from that of water. Thus, it is clarified that the mutual miscibility with water greatly contributes to the increase in the surface area.

3) The adsorbent after the contact with an NO gas exhibits the two shoulder peaks at 470 nm and 610 nm in the electronic spectra. A similar appearance of the peaks is observed with an aqueous solution of a Fe(II)-NO complex. Thus, the adsorption of NO by the present dry adsorbent proceeds through the coordination of NO on Fe(II). Moreover, the CR-Fe(II) complex after the adsorption of NO has signals centered at g=2.03 in the ESR spectrum, which is characteristic of the low spin Fe(II)-NO complex. This fact also supports the idea that the adsorption proceeds through the coordination of the NO on the Fe(II) ion in the resin.

The authors wish to express their thanks to Dr. Eisuke Ogata of the Department of Reaction Chemistry, The University of Tokyo, for his technical advice on measuring the specific surface area.

(Received September 9, 1988)

Hydrogen molybdenum bronzes, H_xMoO_3, of Type-I (x=0.21), Type-III (x=1.55), and Type-IV (x=1.90) were prepared by the Glemser's method. Type-II (x=0.91) was obtained from Type-III by standing in air for 120 days. The bronzes with low hydrogen contents were stable, but those with high contents were not so stable. All these bronzes have been studied by X-ray diffraction, IR spectroscopy, and TG-DTA. Bronzes with high hydrogen contents were changed upon heating in air, successively, to those with low hydrogen contents by the evolution of H_2.

Hydrogen molybdenum bronzes, H_xMoO_3 ($0<x\leqq2$), are obtained from MoO_3 by reduction in an acidic media[1,2] and hydrogen spillover.[3] Recently, Birtill and Dickens[4] have confirmed four distinct phases in the range $0<x\leqq2$ and their ranges of homogeneity with the approximate limit: Type-I (blue, orthorhombic), $0.23<x<0.4$; Type-II (blue, monoclinic), $0.85<x<1.04$; Type-III (red, monoclinic), $1.55<x<1.72$ and Type-IV (green, monoclinic), $x=2$. Among these phases, Type-I has been characterized by many authors using X-ray diffraction,[4] neutron diffraction,[5] thermal decomposition,[6-8] IR,[9-11] and NMR.[12,13] The catalytic activity for 1-butene isomerization on Type-I was also studied and the effect of hydrogen atoms on catalytic activity has been confirmed.[9] On the other hand, there are several reports on Type-III studied by NMR.[12-14] Its catalytic activity for hydrogenation reaction has been reported.[15,16] However, Type-II and Type-IV have not been characterized completely because of instability.

The authors have studied[6-8] precisely the thermal decomposition of Type-I by vacuum heating and have discussed its decomposition mechanism. We also attempted to study other phases of bronzes. However, it was very difficult to prepare all types of bronze and to isolate them. The purpose of this work was to prepare all phases of hydrogen molybdenum bronzes and to characterize them by X-ray diffraction, IR spectroscopy, and TG-DTA.

Experimental

Preparation of Hydrogen Molybdenum Bronzes. All phases of hydrogen bronzes were obtained by the Glemser's method.[1]

Type-I. 30 g of MoO_3 was suspended in a 2—3 M (mol l^{-1}) HCl aqueous solution at 0—10 °C. 5 g of Zn powder was divided into several portions; about 1 g of Zn powder was introduced every after nascent hydrogen was stopped to generate. When all the Zn powder was consumed the sample was filtrated, and washed with 2—3 M HCl and then water. The sample was blue and the X-ray result was identical with that of Birtill and Dickens.[4] The hydrogen content was determined to be x=0.21 by chemical analysis.[17] Type-I was very stable, even after standing in air for more than six months.

Type-II. It was very difficult to isolate only one phase of Type-II by the Glemser's method.[1] Type-II was obtained from Type-III by standing in air for at least 120 days. The color was blue and the X-ray result was identical to that of Birtill and Dickens.[4] The hydrogen content was x=0.91. This was stable for more than two months.

Type-III. Type-III was prepared from MoO_3 or Type-I by repeating from three to five runs of the same method described above. The color was red and the X-ray result was identical to that of Birtill and Dickens.[4] The hydrogen content was x=1.55. This was stable for about 10 days (Fig. 1). According to X-ray results, Type-II appeared after Type-III had stood in air for at least 11 days; it increased gradually. Type-III was completely transformed to Type-II by 120 days.

Type-IV. Type-IV was prepared from Type-III by repeating one to two runs of the same method. The sample

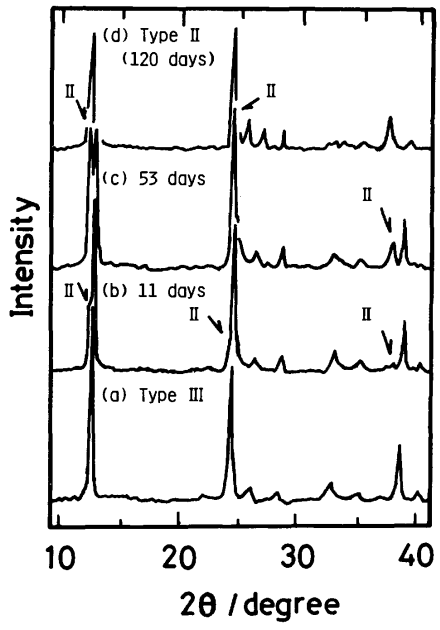

Fig. 1. Changes of X-ray diffraction patterns of Type III by standing in air. (a): Type III (immediately after filtration), (b): stood for 11 days, (c): stood for 53 days, and (d): Type II (stood for 120 days).

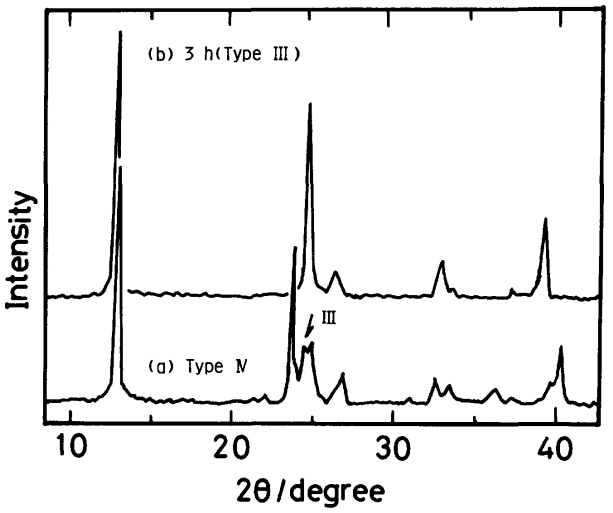

Fig. 2. Changes of X-ray diffraction patterns of Type IV by standing in air. (a): Type IV (immediately after filtration) and (b): stood for 3 h (Type III).

began to decompose immediately after being washed with water and completely transformed to Type-III within three hours (Fig. 2).* However, it kept the Type-IV phase when it was filtrated by a suction filter without washing. Type-IV was green in color and the X-ray result was identical to that of Birtill and Dickens.[4] The hydrogen content was x=1.90. When this sample was left standing in a 2—3 M HCl aqueous solution it kept its monoclinic structure and green color for about seven days.

Characterization of Hydrogen Molybdenum Bronzes. Samples were observed and identified by a powder X-ray diffraction method. IR spectra were obtained by using JASCO 701G and SIMADZU FTIR-4000 spectrophotometers. TG-DTA curves were carried out on a MAC SCIENCE TG-DTA 2000 with a heating rate of 10 K min^{-1}.

The hydrogen contents of hydrogen bronzes were determined chemically by the Choain and Marion's method.[17]

Results and Discussion

Figure 3 shows the IR absorption bands at 1001, 855, 677, 590, 436, and 370 cm^{-1} for Type-I, at 956 and 501 cm^{-1} for Type-II, and at 950, 615, and 450 cm^{-1} for Type-III. The spectrum of Type-IV is nearly the same to that of Type-III. MoO_3 shows bands at 992, 877, 819, 614, 375, and 304 cm^{-1}. By the insertion of hydrogen atoms into the MoO_3 layers, the band at 992 cm^{-1} in MoO_3 shifted to 1001 cm^{-1} in Type-I. The bands at 877 and 819 cm^{-1} decreased in intensity. A small band at 855 cm^{-1} in Type-I with x=0.21 remained, but Type-I with x=0.34 showed no detectable band in this region. The band in this region appeared and gradually increased,[10,11] when Type-I was heated in vacuo. This suggests that the band at 855 cm^{-1} may have been due to a residual MoO_3 framework which is not completely reduced to Type-I. This leads to the conclusion that the insertion of hydrogen atoms causes a rearrangement of octahedron

from the MoO_3 structure to the structure of Type-I (Fig. 4). Berrclough et al.[19] have assigned the band at 992 cm^{-1} to Mo=O(1), that at 877 cm^{-1} to Mo–O(3,3′)–Mo, and that at 819 cm^{-1} to Mo–O(2′)–Mo in MoO_3. On the other hand, Py and Maschke[20] have interpreted the experimental results of MoO_3 by using a modification of the intralayer force constants proposed by Beattie et al.[21] According to their calculation,[20] bands at 877 and 819 cm^{-1} in MoO_3 can be assigned to Mo–O(3,3′)–Mo and the band at 614 cm^{-1}, to Mo–O(2′)–Mo.

According to Kihlborg,[18] a schematic model of the oxygen atoms around a molybdenum atom is shown

in Fig. 4. The bond length in MoO_3 of Mo–O(2′), Mo–O(3), and Mo–O(3′) is 1.95, 2.25, and 1.73 Å, respectively. By insertion of atomic hydrogen into MoO_3, the bond length of Mo–O(3) is shortened to 1.96 Å and that of Mo–O(3′) is lengthened to 1.96 Å. The bond length of Mo–O(2′) and Mo–O(3,3′) become equal in Type-I. The bond length of Mo=O(1) is lengthened from 1.67 Å in MoO_3 to 1.69 Å in Type-I. The bond angle of O(1)–Mo–O(3) changes from 87° in MoO_3 to 97° in Type-I.

It has been reported[9,12,13] that a hydrogen atom connects with terminal oxygen (Mo=O(1)). This suggests that the bond strength of a doubly bonded terminal Mo=O(1) may be weakened; this may cause a shift to lower frequencies. In fact, a shift from 998 to 1001 cm^{-1} takes place. This result is not understandable in terms of the bond strength; other effects should possibly be considered. No large change in the bond length has been observed between MoO_3 and Type-I, while the bond angle of O(1)–Mo–O(3) changes upon the insertion of hydrogen atoms as mentioned above. The change of this bond angle may effect the stretching vibration of Mo=O(1). According to Py and Maschke,[20] the band at 614 cm^{-1} in MoO_3 has been assigned to Mo–O(2′)–Mo with a bond length of 1.95 Å. The bond length of Mo–O(2′,3,3′) in Type-I is 1.96 Å; this is very similar to that of Mo–O(2′)–Mo in MoO_3. Therefore, the band at 677 cm^{-1} in Type-I should be due to Mo–O(2′,3,3′)–Mo.

In the range of Mo–O stretching vibration, Type-II and Type-III(IV) show bands at 956 and 950 cm^{-1}, respectively. The band at 1001 cm^{-1} in Type-I shifts to lower frequencies. This is reasonable because Type-II and Type-III(IV) contain more hydrogen atoms than Type-I; a difference in the structure exists between Type-I (orthorhombic) and Type-II, Type-III, and Type-IV (monoclinic). These hydrogen atoms also attach to terminal oxygen and the bond strength of Mo=O(1) is weakened. The authors are studying by NMR the bahavior of hydrogen atoms in all phases. Considering the NMR results, a precise assignment of the band in Type-II and Type-III(IV) will be reported elsewhere.
