The above argument in terms of the anion and esters of 3-benzoylpropanoic acid is equally applicable to explaining the observation of uncompetitive inhibition by the anion of benzoxyacetic acid but the lack of substrate inhibition with esters of this acid. A similar argument can also formally be made for the anion and esters of hippurylglycine, although in this case the NH unit which was suggested above to be related to substrate inhibition is present. On the other hand, esters of this acid are considerably longer than the other ester substrates considered above, and it is possible that this increased size of the ester substrate may critically influence the postulated sensitive conformational change in the E.S complex.

We have previously suggested (4) in the light of our studies of substrate inhibition that the presence of a CONH unit, as in hippuric acid, is essential for binding to occur at the substrate inhibitory site. On the other hand, the data in Table 1 suggest that the replacement of the hippuric acid NH by O or CH_2 actually slightly strengthens the binding of these uncompetitive inhibitors. If, as suggested above, the binding sites for uncompetitive inhibitors and inhibitory substrate molecules are the same, it then becomes clear that the apparent essentiality of a CONH unit for substrate inhibition is actually an artifact of the requirement for the NH unit in the E.S complex to allow the conformational change which is postulated to be a prerequisite for substrate inhibition. In view of the data in Table 1, the only specificity feature that is certain for binding at the inhibitory site is the requirement for a relatively large (*e.g.* phenyl) terminal group. Aceturate anion which lacks such a group does not show uncompetitive inhibition but instead is a poor competitive inhibitor (Table 3). The requirement for the carbonyl unit of the amide moiety is uncertain at the present time, since the only inhibitor that we have studied that could illuminate this point is the 4-phenylbutanoate ion which is such a strong competitive inhibitor (K_i = 0.58 m*M* (1)) that contributions from uncompetitive inhibition similar to that for the hippurate anion would not be observable.

If, as suggested above, uncompetitive inhibitors do bind at the same site as inhibitory substrate molecules, one might also expect that the resultant E.S.I species might show the same low catalytic activity as $E.S_2$ species which are approximately 25 times less reactive than E.S for hippurate ester substrates (5). Although we have not investigated this point in detail, it should be noted that in all cases the Lineweaver–Burk plots in the presence of inhibitor are of slightly different slope than, although approximately parallel to, the uninhibited line. Such a phenomenon is consistent with the E.S.I species having a low residual activity.

The predominant noncompetitive inhibition of the hydrolysis of *O*-hippuryl-L-3-phenyllactic acid by cbz-gly-gly-L-phe is consistent with recent conclusions (26–28) of quite different productive binding sites for ester and peptide substrates. The value of K_i = 1.2 m*M* observed in the present study (at ionic strength 0.2) for cbz-gly-gly-L-phe is somewhat larger than the value of K_m = 0.25 m*M* obtained (at ionic strength 1.0) (12) for this peptide as a substrate for carboxypeptidase A. Ionic strength effects, which are known (29) to be important for this enzyme, and the slight deviation from noncompetitive inhibition apparent in Fig. 7*A* are probably responsible for this difference between K_i and K_m.

The simple amide substrate *N*-chloroacetyl-L-phenylalanine is also a noncompetitive inhibitor of specific esterase activity. The value of K_i = 0.5 m*M* for this inhibitor (ionic strength 0.2, 25°) is in reasonable agreement with K_m = 0.24 m*M* (ionic strength 0.1, 20°) (30) reported for the hydrolysis of this amide by carboxypeptidase A. Auld and Vallee (13) have established that the p*H* profiles for the enzymic hydrolysis of *N*-chloroacetyl-L-phenylalanine and cbz-gly-gly-L-phe are similar.

We have previously noted (5) that one of the manifestations of different binding modes for ester and peptide substrates is the difference in preference shown by the enzyme for aliphatic and aromatic side chains in peptide and ester substrates. Thus, although K_m for cbz-gly-gly-L-phe is about 10-fold smaller than for cbz-gly-gly-L-leu (12), comparison of corresponding hippurate esters (5) and simple carboxylate ion competitive inhibitors for hippurate esters (1) containing benzyl (*cf.* phenylalanine) and isobutyl (*cf.* leucine) groups indicates that K_m and K_i values are, respectively, eight and four times smaller for the isobutyl group than for the benzyl group. We have explored this phe-

nomenon further in the present study by comparison of the inhibition of esterase activity by several derivatives of phenylalanine and leucine and the relevant K_i values are in Tables 2 and 3. It will be noted that the phenylalanine derivatives are considerably stronger inhibitors than the corresponding leucine derivatives for the D-amino acids (competitive inhibitors), the glycyldipeptides (competitive inhibitors) and *N*-chloroacetyl-L-amino acids (noncompetitive inhibitors). This preference for a benzyl rather than an isobutyl side chain is the same as that observed in the K_m values for peptide substrates (12).

The preference for aromatic over aliphatic side chains in the D-amino acids and glycyl dipeptides which are competitive inhibitors for *O*-hippuryl-L-3-phenyllactic acid contrasts with the reverse preference expressed in mono- and dicarboxylate anions (*e.g.* $(CH_3)_2\,CHCH_2CO_2^-$, $K_i = 0.12$ m*M* and $C_6H_5CH_2CO_2^-$, $K_i = 0.52$ m*M*) (1, 2) which are also competitive inhibitors of this same ester. This difference strongly suggests that the hydrophobic side chains of these amino acid derived competitive inhibitors are not bound in the same site as similar hydrophobic groups of simple carboxylic and dicarboxylic acid competitive inhibitors. This conclusion is further strengthened by the observation that, whereas phenylacetate ion is a competitive inhibitor for ester hydrolysis but a noncompetitive inhibitor for peptide hydrolysis (26), on the other hand glycyl-L-tyrosine (and presumably also gly-L-phe and gly-L-leu) is a competitive inhibitor for *both* peptide (12) and ester hydrolyses. Since it is shown above that peptide substrates are noncompetitive inhibitors for ester substrates, it is quite reasonable that competitive inhibitors of ester hydrolysis should be noncompetitive inhibitors of peptide hydrolysis. On this same basis, it is quite unexpected that glycyl-L-tyrosine should be a competitive inhibitor for both ester and peptide hydrolyses. The K_i value for glycyl-L-tyrosine observed in the present study for inhibition of ester hydrolysis (0.085 m*M*) agrees closely with the value reported by Auld and Vallee (12) for inhibition of peptide hydrolysis (0.1 m*M*) and there can then be little doubt that the same binding mode for this inhibitor is under observation in both studies. This competitive inhibition of both ester and peptide hydrolysis by glycyl-L-tyrosine may be interpreted in one of two ways. Thus, the glycyl-L-tyrosine may bind in such a way that it bridges the peptide and ester binding sites; this in turn requires that the ester and peptide binding sites should be close together, although nonoverlapping since peptides are noncompetitive inhibitors of ester binding. Alternatively, binding of glycyl-L-tyrosine may cause an enzymic conformational change which makes inaccessible either or both of the ester and peptide binding sites. Such an "indirect" competitive inhibition is kinetically equivalent to the more usually considered competitive inhibition due to overlapping substrate and inhibitor binding sites. It should be noted that there is a large conformational change in the crystalline enzyme upon glycyl-L-tyrosine binding (19, 20) and it has recently been suggested that even larger conformational changes may occur in solution (31); the influence of glycyl-L-tyrosine on the conformational mobility of carboxypeptidase A in solution has been directly shown by temperature-jump relaxation studies (24). In view of the close relationship discussed above between the binding of glycyl dipeptide inhibitors and peptide substrates it seems reasonable to propose that competitive inhibition of peptide hydrolysis by these dipeptides results from true competition for overlapping binding sites. The competitive inhibition of ester hydrolysis would then be associated with the conformational change in the enzyme that is referred to above.

D-Phenylalanine, a competitive inhibitor of ester hydrolysis in the present study, has several times been reported (15, 16, 21) to be also a competitive inhibitor for peptide hydrolysis. However, K_i values for inhibition of peptidase activity are in the range 1.0–2.0 m*M*, which is an order of magnitude larger than we find (0.15 m*M*) for inhibition of ester hydrolysis. It is therefore not clear whether the competitive inhibitions by D-phenylalanine of ester and peptide hydrolyses arise from the same binding mode for this inhibitor. Since it seems that the productive ester and peptide binding sites are quite separate, it is clearly possible for an inhibitor to independently competitively inhibit esterase and peptidase activities provided it can bind at more than one site. Our recent studies seem to indicate that a variety of binding sites for carboxylate ion inhibitors are available in this enzyme (1–3).

Finally, we note that the presence of a *para* substituent (OH or NO_2) in the phenylalanine ring has relatively little effect on K_i in Tables

2 and 3. This contrasts with the influence of these two substituents on inhibition by benzoate ions (3). Thus *p*-hydroxybenzoate ion is a threefold weaker inhibitor than the parent benzoate ion (competitive inhibitor) for the enzymic hydrolysis of *O*-hippuryl-L-3-phenyllactic acid, whereas the *p*-nitrobenzoate ion is such a poor competitive inhibitor that noncompetitive inhibition intervenes (3). Such differences in substituent effects tend to further support more than one mode of binding for carboxylate ions which act as competitive inhibitors for the enzymic hydrolysis of *O*-hippuryl-L-3-phenyllactic acid.

We appreciate the continued support of this work by the National Research Council of Canada, and by the award of a Walter C. Sumner Memorial Fellowship to C.D.M. We thank Dr. J. Murphy and Mr. S. S-T. Chu for samples of many of the inhibitors studied.

Lithium Aluminum Hydride Reductive Rearrangement of Allylic Acetals to Vinyl Ethers: A Synthesis of 3-Deoxy Glycals[1]

BERT FRASER-REID, STEVE Y-K. TAM,[2] AND BRUNO RADATUS[2]
Chemistry Department, University of Waterloo, Waterloo, Ontario
Received May 16, 1974[3]

BERT FRASER-REID, STEVE Y-K. TAM, and BRUNO RADATUS. Can. J. Chem. **53**, 2005 (1975).

Carbohydrate allylic acetals (hex-2-enopyranosides) are reductively rearranged to vinyl ethers (3-deoxy glycals) by treatment with lithium aluminium hydride in refluxing ethereal solvents. Under similar conditions, some allylic alcohols are also reductively rearranged to olefins, although the reaction appears to be confined to carbohydrate substrates since the reaction fails with typical carbocyclic allylic alcohols.

The results are rationalized by postulating the intermediacy of an oxygen–alane complex, this being formed more readily in the case of an hydroxyl (or ester) rather than an ethereal oxygen. An axial oxygen permits easier achievement of the reactive transition state than an equatorial oxygen. The complex normally leads to an S_N2' reductive rearrangement in which the entering hydride and departing oxygen are *syn*-related. Alternatively, and particularly when the double bond is flanked by an hydroxyl group at one allylic position and a leaving group at the other, an abnormal S_N2' process may occur so that the hydride ion is delivered vicinal and *cis* to the hydroxyl group, with ejection of the leaving group. The process is at all times stereospecific but not always regiospecific.

BERT FRASER-REID, STEVE Y-K. TAM et BRUNO RADATUS. Can. J. Chem. **53**, 2005 (1975).

Le traitement, par $LiAlH_4$ dans des solvants éthérés à reflux, permet de réduire des acétals allyliques de carbohydrates (hexèno-2 pyrannosides) avec réarrangement en éthers vinyliques (déoxy-3 glycals). Soumis à des conditions semblables, quelques alcools allyliques peuvent aussi être transformés en oléfines; il semble toutefois que la réaction ne s'applique qu'aux carbohydrates puisque la réaction ne se produit pas avec des alcools allyliques carbocycliques typiques.

On rationalise les résultats en faisant l'hypothèse qu'il y a formation d'un complexe intermédiaire oxygène–alane; ce complexe se formerait plus facilement avec un groupe hydroxyle (ou un ester) qu'avec l'oxygène d'un éther. Un oxygène axial permet plus facilement d'atteindre l'état de transition réactif qu'un oxygène équatorial. Le complexe conduit normalement à une réduction avec réarrangement impliquant un mécanisme S_N2' dans lequel l'hydrure qui approche et l'oxygène qui s'en va occupent une relation *syn*. Une alternative qui se présente, particulièrement quand la double liaison est flanquée par un groupe hydroxyle dans une position allylique et un groupe nucléofuge dans l'autre, implique un processus S_N2' anormal au cours duquel un ion hydrure s'approche en position vicinale et *cis* par rapport au groupe hydroxyle amenant l'expulsion du groupe nucléofuge. Le processus est toujours stéréospécifique mais il n'est pas toujours régiospécifique. [Traduit par le journal]

The vinyl ethers known in carbohydrate chemistry as glycals, are versatile synthons for a diverse array of saccharide derivatives (1). In a recent report from this laboratory, we reported the ready synthesis of the hitherto unknown 3-deoxy glycals (2) and, in subsequent publications, we demonstrated their synthetic utility (3) and examined some mechanistic aspects of the reaction by which they are produced (4). The present article reports in greater depth upon synthetic and mechanistic details of this reductive rearrangement.

Results

Reductive Rearrangements of Compounds 1–3.

In our first publication (2) we reported that use of high boiling ethereal solvent (dioxan > tetrahydrofuran > ether) caused remarkable improvement in the rate of the reductive rearrangements (*e.g.* **1** → **9**). The use of lithium aluminium deuteride (LAD) instead of lithium aluminium hydride (LAH) was also shown to be advantageous since it facilitated mechanistic interpreta-

tion via analysis of the n.m.r. spectra of the deuterated products. For these reasons, LAD in refluxing dioxan has been adopted for use in most of these studies. In this connection, it should be noted that reactions with LAD are usually much slower than with LAH, presumably because of isotope effects not presently understood (5).

Characterization of Products (see Table 1)

The progress of the reaction is readily followed on thin-layer chromatograms sprayed with sulfuric acid, whereupon the starting materials (*e.g.* **1–3**) char immediately in the cold to a black deposit, while the products (*e.g.* **9–11**) require heating in an oven before charring occurs. On the other hand, the products, but not the starting materials, are readily visualized by iodine vapor and the acyclic vinyl ethers such as **19** and **20** run much more slowly because of the free hydroxyl group. Hence a product running slower than the starting material, and which is visualized by iodine, is very likely to be an acyclic enol ether.

For the deuterated products **9**(D) and **11**(D) i.r. absorptions at 1645, 1233, and 1080 cm^{-1} and n.m.r. data (Table 2) provide standards for determining structural features of the other cyclic products shown in Table 1. Thus multiplets centered at τ 3.67 and 3.69, respectively, were appropriately located for H-1 of these glycals (6).

The definitive criteria for assigning the orientation of deuterium in **9**(D) and **11**(D) are the four-bond (J_{13}) and the three-bond (J_{23}) vinyl–allylic couplings. The former $|J_{13}|$ is larger and the latter $|J_{23}|$ smaller when the allylic proton is pseudoaxial than when it is pseudoequatorial. These criteria originally recognized by Garbisch (7) have been frequently supported, recently by ourselves, in a computer assisted study of a number of 3-substituted 3-deoxy glycals (8). The J_{13} values for **9**(D) and **11**(D) are -1.0 and -2.7 Hz, while the J_{23} values are 5.5 and 2.0 Hz, respectively. These are in agreement with the expected values and further support for the assigned structures is provided by the values for for J_{34} (9.5 and 6.0 Hz, respectively) which indicate diaxial and equatorial–axial relationships between the protons concerned.

Compounds **19** and **20** were also evidently vinyl ethers in view of the i.r. absorption at $\sim$1645 cm^{-1} and the presence of exchangeable protons in the n.m.r. suggested the free hydroxyl group. In the case of **19**, H-1 and H-2 were observed at τ 4.00 and 5.43, respectively, with a common coupling of 6.0 Hz indicative of *Z* arrangement. In **20**, H-1 and H-2 were at τ 3.57 and 5.10 with a common coupling of 13.0 Hz indicating *E* arrangement.

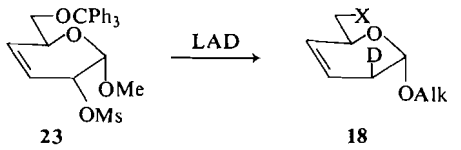
Reductive Rearrangements of Compounds 4–7

The α-D-diol **4***a* (Alk = Et) or its diacetate **4***b* (Alk = Et) gave only one product **12***a*, no trace of acyclic material being obtained. The acetylated product **12***b* was characterized by mass spectrometry and n.m.r. The anomeric β-D-olefin **5***b* gave the same cyclic ether **12***a* as well as the *trans*-triol **21***a*. The formation of **12***a* from **5***b* meant that the deuterium had added to the side of the molecule opposite to that vacated by the aglycon. Since this result was in contrast to that in substrates **1–4**, it was decided to examine other substrates having a *trans*-1,4-arrangement.

Compound **6***a* (Alk = Et) gave three cyclic products **14***a*, **16***a*, and **18***a* (Alk = Et) in 2:2:1 ratio, as well as the *trans*-triol **22**a. The products were separated by column chromatography except for the epimers **14***a* and **16***a* which travelled together. The H-1 signal in the n.m.r. spectrum of the mixture **14***a* and **16***a* was a deceptively simple doublet of doublets. H-2 was more complicated than "normal" but the prime indication of a mixture was the presence of two signals at τ 7.98 and 7.64 in the region appropriate for H-3. Confirmation was forthcoming from double irradiation of each signal which caused perturbations in the multiplets for H-1 and H-2. The signal to lower field is ascribed to the equatorial H-3 in **14***a*, in accordance with the expectation that the axial H-3 (in **16***a*) should resonate at higher field (9). The result is also in keeping with the studies of Hall and Manville (10) which show that an equatorial proton is deshielded, relative to its axial counterpart, by a vicinal hydroxyl group.

The structure of **18***a* (Alk = Et) was deduced by comparison with the analog prepared by deuterolysis of the methanesulfonate, **23** (11) followed by detritylation of the product **18***d* (Scheme 1). The alcohol so obtained, **18***a* (Alk = Me), gave superimposable n.m.r. spectra with that from the LAD reaction on **6***a* (Alk = Et) with the exception of the aglycon resonances.

The products from the benzylidenated derivative, **7**, were the previously encountered olefin **18***a* (Alk = Et) and compound **15** in a ratio of



23 **18**

7:1. Benzyl alcohol-d_1 was isolated from the reaction products and identified by comparison of the n.m.r. spectrum of its acetate with that of benzyl acetate.

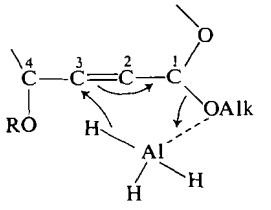
Discussion

Cyclic Products

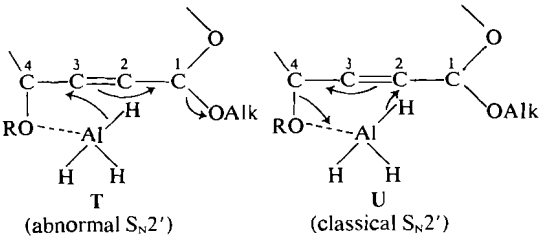
The anomers **1** and **3** each gave only one cyclic product, **9** and **11**, respectively, results which seemed to suggest a classical S_N2' mechanism (12) operating through a transition state such as that depicted in **S** (2).[4] However, shortly after our preliminary report (2), Achmatowicz and Szechner (17) reported the interesting observation that with LAD in ether at room temperature, the *cis*-1,4-analogs **4***c* and **8** were readily rearranged to glycals **12***e* and **17**, respectively, whereas the *trans*-1,4-analogs **5***c* and **6***c* were unrearranged after 7 days at *room* temperature.

In view of the equatorial orientation of the methoxy group in their substrate **5***c*, failure to observe rearrangement in ether at *room temperature*[5], did not seem surprising in view of our earlier observation on the low reactivity of **3** in *boiling* diethyl ether (2). Low reactivity of these β-D-derivatives (**3**, **5**, and **8**) seemed entirely consistent with the S_N2' transition state **S**, since with these substrates the equatorial methoxy – AlH_3 complex is poorly poised for delivering the deuteride to carbon-3, an energy-demanding conformational change being required to bring the complex into axial orientation before optimal geometry is achieved. The improved reactivity of **3** in the higher boiling solvents, as reported earlier (2), is in keeping with this concept. We were therefore prompted to test the response of some *trans*-1,4-derivatives (diequatorial as well as diaxial) in boiling dioxan.

Added impetus for this study was given by the suggestion of Achmatowicz and Szechner (17) that the site for coordination of the aluminium was not the aglycon, as we had originally proposed, but the carbon-4 oxygen. In fact, this principle could not have been tested in their experiments, since the carbon-1 and carbon-4 oxygens in their reactive substrates (**4***c* and **8**) are in *cis* relationship! Clearly only with a *trans*-1,4-substrate is it possible to tell, from the orientation as well as the position of the deuterium in the product, whether the intermediate oxygen–aluminium complex had been formed at carbon-1 or carbon-4.



S
(classical S_N2')



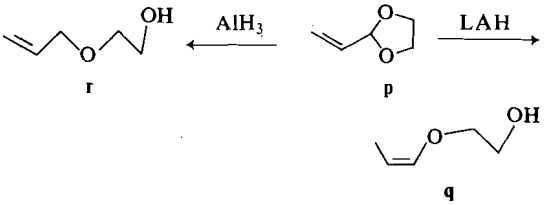
T (abnormal S_N2') U (classical S_N2')

Some observations relating the *cyclic* vinyl ethers obtained from reactions with LAD in boiling dioxan are summarized here.

(*i*) The olefinic acetals react whether the geometry of the oxygens is *cis*-1,4 or *trans*-1,4. Thus compounds **1**–**8** were all reductively rearranged (Table 1).

(*ii*) If the carbon-4 oxygen is an alcohol or ester which would be immediately converted to alkoxide by LAD, the abnormal S_N2' transition state T may be brought into operation.

[4]We have not done any experiments to determine the nature of the aluminium species in the intermediate complex. In our preliminary report (2) we suggested a pentacoordinate complex such as that favored by Eliel *et al.* (13). However, we are indebted to Professor W. Kraus (14) of the University of Tubingen, for suggesting in a private communication, that the tetracoordinate complex (*e.g.* **S**) would be more appropriate. This follows from the fact that the alane which is present in appreciable amounts in boiling solvents (15) is expected to be a better Lewis acid than AlH_4^- (15). Nevertheless it should be noted that a rearrangement (*p* to *q*) reported by Davis and Brown which is similar to those under discussion here, gives a different product (*r*) when pure alane is used as the reagent (16). *In any event, our mechanistic arguments remain the same whether the complex is pentacoordinate (with AlH_4^-) or tetracoordinate (with AlH_3).*



r p q

[5]In our hands, even the *cis*-1,4-derivatives **1**, **4***a*, or **4***b* do not rearrange in ether at *room temperature*, a period of heating being required to induce reaction.

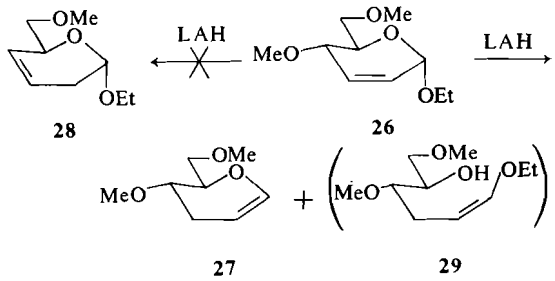
For personal use only.

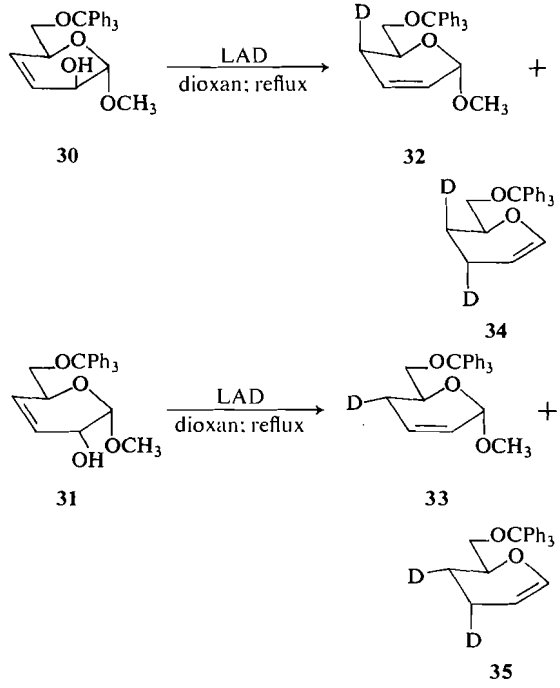
(*iii*) If the carbon-4 oxygen is etherified the abnormal transition state **T** is apparently rendered inoperative. We have no explanation for this effect but two entries in Table 1 support this conclusion. Substrate **5***b* gave **12***a* but the related benzylidenated substrate **3** gave none of the corresponding product **9**. Similarly **6***a* gave **16***a* but upon benzylidenation **7** did not give any **24**.

(*iv*) An axial allylic oxygen permits easier attainment of the S_N2' transition state than does its equatorial counterpart. This conclusion follows from (*a*) the greater reactivity of substrates **1** and **2** as compared with **3** and (*b*) from the appreciable formation of **18** in the reactions of **6***a* and **7** as compared for example, with the absence of compound **25** in the reaction of **4***b*. Further support for observation *iv* is found in the course of reaction of **26** in which an axial oxygen is pitted against an equatorial oxygen (2). (Scheme 2) The reduction produces **27** via complexation at the axial oxygen (transition state **S**) but no **28** which would have arisen by complexation at the equatorial oxygen (transition state **U**).[6,7]



SCHEME 2

(*v*) The formation of **18***a* from **6***b* or **7** indicates that the allylic oxygen lost in the reductive rearrangement may be a simple allylic alcohol and not necessarily a member of an acetal functionality. Further support for observation *v* is found in the formation of **32** and **33** from substrates **30** and **31** respectively (Scheme 3). Under the



SCHEME 3

reaction conditions, the primary products react further giving dideuterated products **34** and **35**, respectively. However, neither 1- nor 4-cholesten-3-ol reacted with LAD in refluxing dioxan.

(*vi*) Considered in relation to the operative transition state, the reactions are always stereospecific, since there is a definite and exclusive correlation between the configuration of substrates and products (19). However, the reactions are not always regiospecific (20).

The transformations **1** → **9** and **3** → **11** are clearly both stereo- and regiospecific and this conclusion suggests that there is only one transition state (**S**) in operation. In the case of **6**, two of the products (**14** and **16**) are epimers which at first sight might suggest a nonstereospecific process. However, in view of the weight of evidence from the other entries in the Scheme, formation of the epimers **14** and **16** may be rationalized as occurring stereospecifically through different transition states **S** and **T**, respectively. The carbon-4 complex decomposes in a nonregiospecific manner thereby producing both **16** and **18**.

[6]This result could, however, be influenced by other forces; thus, it has been proposed that the course of hydrogenolysis of acetals is dependent on a stabilized oxocarbonium ion intermediate (18). If so, the ring-oxygen will clearly favor the development of transition state "**S**" It will be of interest in the future to pit axial against equatorial oxygens, in less equivocal circumstances.

[7]Compound **12** could be formed from **4** via either transition state **S** or T. Our present results do not allow for any distinction between the two.

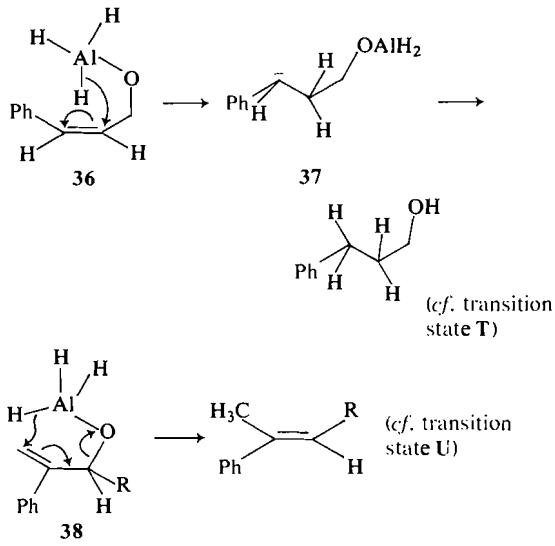
Acyclic Products

With regard to the acyclic products **19–22** and **29** correlation between their geometry and those of their progenitors, is very straightforward. If the 1,4-oxygens in the substrate are *cis*-related, the acyclic enol ether produced is itself *cis*; if *trans* in the substrate, the product is *trans*. The reasons for this regularity are not currently understood and experiments are underway to determine the basis for this correlation.

The transition state **T**, whereby products **12**, **16**, and **17** are formed, is reminiscent of that (**36**) operating in the hydrogenation of phenylallyl alcohols by LAH in refluxing tetrahydrofuran (21). These rearrangements all proceed via abnormal S_N2' five-center transition states, which are successful because of the intermediacy of a resonance-stabilized benzylic carbanion **37** in one case and because of the presence of a good leaving group in the other (see **T**) (Scheme 4).



SCHEME 4

In **36**, the hydride ion is donated to the proximate end of the double bond with the formation of the benzylic carbanion which is quenched subsequently by a proton. In the case of **5*b***, **6*a***, and **8**, the double bond moves over, ejecting the aglycon.

The "normal" S_N2 transition state **38** corresponding to **U** is observed with the formation of olefins from 2-phenylallyl alcohols.

In summary reductive rearrangement of hex-2-enopyranosides by LAH or LAD in ethereal solvents is a stereospecific reaction giving rise to cyclic and/or acyclic vinyl ethers. With hex-3-enopyranosides, reductive rearrangement of the allylic alcohol also takes place. The geometry of the acyclic vinyl ether products is strictly correlated with the relative configuration of the 1,4-allylic oxygens; *i.e.* *trans*-substrate giving *trans*-enol ether and *cis* giving *cis*.

The presence of an axial substituent at C-1 or C-4 greatly facilitates the achievement of an S_N2' transition state **S** or **U**, which leads to the 1,2- or 3,4-olefin, respectively. Appropriate with this principle, equatorial oxygens at these sites either retard or inhibit completely the formation of the related transition states, as judged by slow formation or absence, of the congruent products.

An allylic alkoxide generated *in situ* from an alcohol or an acetate is a prime site for complexation with the aluminium species[4] and delivers the hydride ion in a *cis* manner to the proximate end of the double bond, via transition state "**T**".

Experimental

General

Melting points were determined on a Fischer-Johns heating stage or a Mel-Temp apparatus and are uncorrected. The n.m.r. spectra whose analyses are given in Tables 2 and 3 were recorded using a Varian T-60, a Varian HA 100, or a Varian HR 220 spectrometer and unless otherwise specified, the solvent was deuteriochloroform containing 1% tetramethylsilane as internal standard. Coupling constants (in Hz) were obtained by measuring spacings of spectra judged to be first order. All geminal and allylic (through four bonds) couplings were assigned negative signs as predicted for these systems (7, 8, 23).

Infrared spectra were determined on a Beckman model IR 5 spectrometer using 0.1 mm sodium chloride solution cells (chloroform as solvent) and silver chloride plates for smears. Mass spectra were determined on a Hitachi Mass Spectrometer model RMU-6E.

Thin-layer chromatography was performed on glass plates coated with silica gel (HF-254, E. Merck) to a thickness of 0.3 mm. The solvent systems used were (*A*) ethyl acetate and (*B*) petroleum ether (35–60 °C) – ethyl acetate (4:1). The chromatograms were first viewed under u.v. light, then exposed to iodine vapor, and finally sprayed with concentrated sulfuric acid. With the latter the starting materials char instantly in the cold to a black deposit but the products either fail to char or char very faintly to a brown residue. Heating in an oven is required for complete visualization. On the other hand, the glycal products, but not the starting materials, are rapidly visualized by iodine vapor.

For column chromatography, E. Merck Silica Gel (0.05–0.20 mm, 70–325 mesh A.S.T.M.) was used. Dioxan, diethyl ether, and tetrahydrofuran were dried with benzophenone ketyl (24).

General Experimental Procedure

The general procedure below is described for reactions

TABLE 3. Proton magnetic resonance parameters of some unsaturated sugars*

*Determined at 100 MHz in $CDCl_3$ (TMS).

using lithium aluminium deuteride (LAD) in refluxing dioxan. However LAH, ether, or tetrahydrofuran can be substituted, without changing the product composition. In general, reactions with LAH go faster than those with LAD; on the other hand, the lower boiling solvents cause the reaction to be much slower than with dioxan.

In a typical experiment, the substrate (3 mmol) was dissolved in dry dioxan (25 ml) and LAD (0.38 g, 9 mmol) was added with efficient stirring with a magnetic stirrer – hot plate. The mixture was brought to gentle reflux and the progress of the reaction was followed by t.l.c. (see General). Upon completion, the method of work up *a* or *b*, depended upon the substrate. *a*) For the benzylidenated materials the excess LAD was destroyed by addition of a minimum amount of water and the aluminium hydroxide was removed by filtration through a bed of Celite. The filtrate was dried and evaporated under reduced pressure whereupon most of the compound usually crystallized. The products were recovered by recrystallization and/or silica column chromatography as described for the individual cases below. (*b*) If the substrate was an acetate or alcohol, the excess LAD was destroyed by dropwise addition of ethyl acetate. The salts were removed by filtration through Celite and the residue washed generously with ethyl acetate. (The product sometimes adheres strongly to the aluminium salts, in which case, the filter cake was stirred overnight with ethyl acetate.) The ethyl acetate filtrate was evaporated and the residue which still contains aluminium salts, was acetylated with acetic anhydride and pyridine. The ether soluble acetylated product is then recovered in the usual way and treated as described for the individual cases below.

Reactions of Methyl 4,6-O-Benzylidene-2,3-dideoxy α-D-erythrohex-2-enopyranoside, 1

4,6-O-Benzylidene-1,2,3-trideoxy-D-erythro-hex-1-enopyranose, 9(H)

Compound **1** (2.48 g, 0 01 mol) was treated with LAH (0.15 g) in refluxing dioxan for 0.5 h. The product isolated by procedure *a* was crystalline and its t.l.c. indicated two components (R_f 0.63 (major) and 0.31 (minor)) in solvent system *B*. Upon recrystallization from ethanol, the minor component remained in the mother liquor. The mother liquor was put on a short silica column (10 cm × 1.8 cm), eluted with solvent system *B*, and both components were separated to give a total 2.08 g (95% of cyclic compound 9(H)).

Compound **9**(H) was recrystallized from ethanol, m.p. 113–114 °C; $[\alpha]_D^{23}$ + 65.9° (*c*, 10.7 in $CHCl_3$); *m/e* = 218.

Anal. Calcd. for $C_{13}H_{14}O_3$: C, 71.54; H, 6.47. Found: C, 71.74; H, 6.43.

The 220 MHz n.m.r. data for compound 9(H) are: τ 2.60 (m, 5, Ph), 4.38 (5, 1, PhC*H*), 3.65 (dt, 1, $J_{12} = 6.0$, $J_{13} = -2.7$, $J_{13'} = -1.0$, H-1), 5.27 (m, 1, $J_{23} = 2.5$, $J_{23'} = 5.5$, H-2), 7.75 (calcd.) (m, 1, $J_{34} = 9.5$, $J_{33'} = -16.0$, H-3), 7.66 (calcd.) (m, 1, $J_{3'4} = 6.0$, H-3′), 6.11 (m, 1, $J_{45} = 9.0$, H-4), 6.16–6.31 (m, 2, $J_{56a} = 10.0$, $J_{56e} = 4.5$ (assumed), H-5, −6*a*), 5.63 (m, 1, $J_{6a6e} = -10.5$, H-6*e*); $\nu_{max}(CHCl_3)$ 1645, 1233, 1080 cm^{-1}.

4,6-O-Benzylidene-2,3-dideoxy-1-O-methyl-D-erythro-cis-hex-1-enose, 19(H)

The chromatogram described above afforded 0.98 g

(3.9%) of the minor product **19**(H). The structure was assigned on the basis of its molecular ion (*m/e* = 250); i.r.: ν_{max}(CHCl$_3$) 1645 cm^{-1}; n.m.r.: τ 2.60 (m, 5, Ph), 4.57 (s, 1, PhC*H*), 6.47 (s, 3, OCH$_3$), 4.00 (bd, 1, J_{12} = 6.0, H-1), 5.43 (td, 1, J_{23} = $J_{23'}$ = 7.0, H-2), 7.47 (m, 2, H-3, −3′), 6.53–6.80 (m, 5, H-4, -5, -6, -6′, OH).

Satisfactory microanalytical data could not be obtained for compound **19**(H).

*4,6-O-Benzylidene-1,2,3-trideoxy-3-deuterio-*D*-ribo-hex-1-enopyranose, 9(D)*

When compound **1** was treated as above with LAD instead of LAH, the reaction required 5 h for completion. The product, **9**(D), was isolated as above and recrystallized from ethanol, m.p. 113–114 °C; $[\alpha]_D^{23}$ +42.5° (*c*, 7.70 in CHCl$_3$); *m/e* = 219. The n.m.r. data for **9**(D) are shown in Table 1. The i.r. shows ν_{max}(CHCl$_3$) 2153 and 1645 cm^{-1}.

*Reactions of Methyl 4,6-O-Benzylidene-2,3-dideoxy-3-C-hydroxymethyl-α-*D*-erythro-hex-2-enopyranoside, 2*

*4,6-O-Benzylidene-1,2,3-trideoxy-3-C-hydroxymethyl-*D*-arabino-hex-1-enopyranose, 10(H)*

Compound **2** (0.262 g, 0.94 mmol) was dissolved in dry ether (60 ml) and LAH (0.1 g) added. The mixture was refluxed with constant stirring for 1 h when t.l.c. indicated completion. Upon isolation by process *a* (see General), compound **10**(H) was obtained (0.204 g, 87% yield) as a crystalline substance. After recrystallization from carbon tetrachloride, m.p. 138–140 °C; $[\alpha]_D^{23}$ −57.2° (*c*, 8.6 in CHCl$_3$); n.m.r.: τ 2.60 (m, 5, Ph), 4.68 (s, 1, PhC*H*), 8.02 (bs 1, exchangeable, OH), 3.73 (q, 1, J_{12} = 7.0, J_{13} = −2.5, H-1), 5.37 (q, 1, J_{23} = 2.0, H-2), 7.35 (m, 1, J_{37} = $J_{37'}$ = 5.5, H-3), 6.03–6.23 (m, 3, H-4, -5, -6*a*), 5.58 (q, 1, J_{6a6e} = −10.5, H-6*e*), 6.26 (m, 2, H-7, -7′); i.r.: ν_{max}(CHCl$_3$) 1645 cm^{-1}.

Anal. Calcd. for $C_{14}H_{16}O_4$: C, 67.72; H, 6.50. Found: C, 67.62; H, 6.21.

*Reactions of Methyl 4,6-O-Benzylidene-2,3-dideoxy-β-*D*-erythro-hex-2-enopyranoside, 3*

*4,6-O-Benzylidene-1,2,3-trideoxy-*D*-erythro-hex-1-enopyranose, 11(H)*

Compound **3** (2.48 g, 0.01 mol) was treated with LAH (0.15 g) in dry dioxan (30 ml) under reflux for 20 h. The t.l.c. (solvent system *B*) and n.m.r. of the isolated crystalline material indicated two components. The n.m.r. indicated that compound **11**(H) (*vide supra*) accounted for 82% of the reaction product. Most of the material was recovered by fractional crystallization and the mother liquors were chromatographed using the solvent system *B*.

*4,6-O-Benzylidene-2,3-dideoxy-1-O-methyl-*D*-erythro-trans-hex-1-enose, 20(H)*

The above chromatogram afforded (410 mg) of compound **20**(H) which was recrystallized from methanol, m.p. 76–78 °C; $[\alpha]_D^{23}$ −36.2° (*c*, 3.6 in CHCl$_3$). The 220 MHz n.m.r. spectrum of compound **20**(H) afforded the following data: τ 2.60 (m, 5, Ph), 4.58 (s, 1, PhC*H*), 6.45 (s, 3, OCH$_3$), 8.03 (bs, 1, exchangeable OH), 3.57 (d, 1, J_{12} = 13.0, J_{13} = $J_{13'}$ < −0.5 H-1), 5.10 (dt, 1, J_{23} = $J_{23'}$ = 7.5, H-2), 7.64 (m, 1, J_{34} = 7.5, $J_{33'}$ = −15.0, H-3), 7.48 (m, 1, $J_{3'4}$ = 4.0, H-3′), 6.20–6.49 (m, 3, H-4, -5, -6), 5.72 (q, 1, $J_{56'}$ = 4.5, $J_{66'}$ = −10.5, H-6′).

Anal. Calcd. for $C_{14}H_{18}O_3$: C, 67.18; H, 7.25. Found: C, 67.02; H, 6.71.

*4,6-O-Benzylidene-1,2,3-trideoxy-3-deuterio-*D*-arabino-hex-1-enopyranose, 11(D)*

Compound **3** (0.250 g, 0.001 mol) was treated with LAD (0.015 g) in dry dioxan (10 ml) under reflux for 2 days. The product was isolated by procedure *a*. The n.m.r. indicated that compound **11**(D) (*vide supra*) accounted for 86% of the reaction product. Most of the material was recovered by fractional crystallization and the mother liquors were chromatographed using the solvent system *B*.

Compound **11**(D) was recrystallized from ethanol, m.p. 117–119 °C; $[\alpha]_D^{23}$ +43.5° (*c* 6.6 in CHCl$_3$); *m/e* = 219. Its n.m.r. parameters are shown in Table 2; the i.r. spectrum shows ν_{max}(CHCl$_3$) 2153, 1645 cm^{-1}.

Anal. Calcd. for $C_{13}H_{13}DO_3$: C, 71.21; H and D, 6.90. Found: C, 71.15; H and D, 6.65.

*4,6-O-Benzylidene-2,3-dideoxy-3-deuterio-*D*-arabino-hex-1-enopyranose, 20(D)*

The chromatogram described above afforded 315 mg of **20**(D) which decomposed readily. The n.m.r. parameters were: τ 2.60 (m, 5, Ph), 4.55 (s, 1, PhC*H*), 6.50 (s, 3, OCH$_3$), 3.60 (d, 1, J_{12} = 13.0, J_{13} = −1.0, H-1), 5.13 (q, 1, J_{23} = 7.0, H-2), 7.70 (m, 1, H-3), 7.60 (bs, 1, exchangeable, OH), 5.73–6.70 (m, 4, H-4, -5, -6, -6′).

*Reaction of Ethyl 2,3-Dideoxy-α-*D*-erythro-hex-2-enopyranoside, 4a, or its Diacetate, 4b*

*1,2,3-Trideoxy-3-deuterio-*D*-ribo-hex-1-enopyranose, 12a, and its Diacetate, 12b*

Compound **4***a* (1.74 g, 0.01 mol) or **4***b* (2.58 g, 0.01 mol) was treated with LAD (1.20 g) in dry dioxan (50 ml) under reflux for 24 h when t.l.c. indicated the complete absence of starting material and the presence of a single new substance. The product, **12***a*, was isolated by procedure *b* (see General) and esterified with acetic anhydride (1 ml) and pyridine (5 ml) overnight. After customary work-up the ester was purified by passage down a silica column (10 cm × 1.9 cm). The product was a syrup: $[\alpha]_D^{23}$ +115.6° (*c*, 4.05 in CHCl$_3$); *m/e* = 215. The n.m.r. data for compounds **12***a* and **12***b* are shown in Table 2. The i.r. spectrum shows ν_{max}(CHCl$_3$) 2153, 1645 cm^{-1}.

*Methyl 4,6-Di-O-acetyl-2,3-di-O-methanesulfonyl-β-*D*-glucopyranoside*

The di-*O*-methanesulfonate (11.0 g, 0.025 mol) of methyl 4,6-*O*-benzylidene-β-D-glucopyranoside (25) was stirred with a mixture of water (240 ml), dioxan (360 ml), and concentrated sulfuric acid (30 g) at 60 °C for 1.5 h. Barium sulfate was then added to neutralize the acid and after filtering the insoluble material, the filtrate was extracted with petroleum ether (30–60 °C) twice to remove benzaldehyde. Evaporation of the water afforded a thick syrup which crystallized upon trituration with methanol. A portion (5.0 g) of the product was treated with acetic anhydride (30 ml) and pyridine (30 ml) at 0 °C for 5 h. Upon customary work-up, the title compound was obtained (5.7 g, 93% yield) as a crystalline substance. After recrystallization from chloroform – petroleum ether (30–60 °C), m.p. 144 °C; $[\alpha]_D^{23}$ − 31.9° (*c*, 1.0 in CHCl$_3$); *m/e* = 434.

Anal. Calcd. for $C_{13}H_{22}O_{12}S_2$: C, 35.96; H, 5.07; S, 14.77. Found: C, 36.25; H, 5.06; S, 14.79.

Methyl 4,6-Di-O-acetyl-2,3-dideoxy-β-D-erythro-hex-2-enopyranoside, 5b

Methyl 4,6-di-*O*-acetyl-2,3-di-*O*-methanesulfonyl-β-D-glucopyranoside, (5.7 g, 0.013 mol) was added to an efficiently stirred mixture of potassium iodide (1.1 g, 0.066 mol) and zinc–copper couple (4.16 g) in 40 ml of dimethylformamide. After 1 h the product, isolated in the previously described manner (26), afforded 2.5 g of material which on thin-layer chromatography (ethyl acetate–petroleum ether (30–60 °C) (1:1) as solvent) revealed two components of R_f 0.34 (**A**) and 0.52 (**B**), the latter being the major one. Treatment of the mixture with acetic anhydride and pyridine in the usual way gave **B** as the sole component. Silica column chromatography of the acetylation products afforded 2.5 g (78% yield) of **5b** (*m/e* 244). For the corresponding di-*O*-*p*-nitrobenzoate, m.p. 132.5 °C.

Anal. Calcd. for $C_{21}H_{18}O_{10}N_2$: C, 55.03; H, 3.96; N, 6.11. Found: C, 55.33; H, 4.01; N, 6.28.

Reaction of Methyl 4,6-Di-O-acetyl-2,3-dideoxy-β-D-erythro-hex-2-enopyranoside, 5b

1,2,3-Trideoxy-3-deuterio-D-ribo-hex-1-enopyranose, 12a, and its Di-O-acetate, 12b

Compound **5b** (1 g, 0.004 mol) was treated with LAD (425 mg, 0.010 mol) in dry dioxan (20 ml) under reflux for 30 h. The reaction was then worked-up by procedure *b* and esterified with acetic anhydride (3 ml) and pyridine (6 ml) overnight. After usual work-up the mixture showed two components (R_f 0.32 and 0.25) on t.l.c. in solvent system *B*. The mixture was easily separated on a silica column to give 305 mg (35%) of the previously encountered diacetate, **12b**.

4,5,6-Tri-O-acetyl-2,3-dideoxy-1-O-methyl-D-erythro-trans-hex-1-enose, 21b

The second compound from the chromatogram described above was the acyclic product **21b** (247 mg, 21%). The structure was assigned on the basis of its peaks in the mass spectrum at 229, 169, 127 for $M^+ - (HOAc)$, $M^+ - (HOAc)_2$, and $M^+ - ((HOAc)_2 + CH_2CO)$, respectively; i.r.: $\nu_{max}(CHCl_3)$ 1645 cm^{-1}, n.m.r.: τ 6.47 (s, 3, OCH_3), 3.63 (bd, 1, $J_{12} = 13.0$, $J_{13} = -1.0$, H-1) 5.20 (dd, 1, $J_{23} = 8.0$, H-2) 7.80 (m, 1, H-3), 4.65–5.10 (m, 2, H-4 and H-5) 5.66–6.05 (m, 2, H-6 and -6′) 7.90 (3s, 9, 3-OAc).

Ethyl 2,3-Dideoxy-α-D-threo-hex-2-enopyranoside, 6a

The title compound **6a** was obtained from diol **4a** by a modification of Ferrier's procedure (27). Methanesulfonyl chloride (6.6 ml, 0.086 mol) was added slowly to a cold (0 °C) and efficiently stirred solution of the diol **4a** (5 g, 0.029 mol) in dry pyridine (60 ml). After 5 h at 0 °C, the solution was poured slowly into about 200 ml ice water with vigorous stirring. The precipitated product **4g** was filtered and washed repeatedly with water until the washings were neutral and then dried overnight in a vacuum oven at ~35 °C. The dried material weighed 6.9 g (73% yield); m.p. 68.5–69.5 °C; $[\alpha]_D^{23}$ +71.9° (*c*, 1 in $CHCl_3$); R_f 0.53 in 50% EtOAc – petroleum ether (30–60°C); n.m.r.: τ 6.90, 6.92 (2 singlets, 6, 2 × OSO_2CH_3) 4.92 (bs, 1, $J_{12} = 2.0$, H-1) 4.08 (td, 1, $J_{23} = 10.0$, $J_{24} = -2.0$, H-2) 3.88 (dd, 1, $J_{34} = 1.5$, H-3), 4.75 (m, 1, $J_{45} = 9.0$, H-4), 5.77 (m, 1, H-5) 5.52 (with satellites, 2, $J_{66'} = -9.5$, H-6, -6′).

To a warm (~80 °C) mechanically stirred solution of the dimesylate **4g** (6.9 g, 0.021 mol) in dimethylformamide (900 ml), was added slowly, sodium benzoate (14.4 g, 0.1 mol). The mixture was then heated using a heating mantle up to 115 °C. After 12 h at that temperature the reaction mixture was allowed to cool and then filtered through a bed of Celite. The filtrate was washed with methylene chloride (~400 ml). Evaporation of the filtrate and washings afforded a thick syrup, which on t.l.c. (50% EtOAc – petroleum ether), showed four spots (R_f 0.71 (**6h**) 0.49 (**6i**) 0.38 (**6j**), and 0.30 (**6f**)). However, if the reaction was kept at 80 °C for 37 h only **6h** and **6i** in a ratio 5:9, were the products. In any case, the product mixture was easily separated on a silica column using petroleum ether (30–60 °C) – ethyl acetate (1:1) as eluent. Compounds **6h** and *f* and **6i** and *j* were separately combined, weighing 3.0 and 2.7 g, respectively. The mixture of **6i** and *j* was then treated with sodium benzoate (5.2 g) in dimethylformamide (450 ml) in the same manner as described above. From this reaction, 2 g of mixture of **6h** and *f* was isolated.

The mixture (5 g) of compounds **6h** and *f* obtained from above, was treated with methanol (150 ml), triethylamine (40 ml), and water (120 ml). After stirring at room temperature for 28 h, the solvents were evaporated off leaving a solid residue (4 g). Recrystallization from ethyl acetate – petroleum ether afforded 1 g of pure **6a**, m.p. 76–77 °C; $[\alpha]_D^{23}$ −77.3 (*c*, 1.0 in $CHCl_3$). The mother liquid was mainly **6a** as judged from its n.m.r.; the data are shown in Table 3.

Anal. Calcd. for $C_8H_{14}O_4$: C, 55.16; H, 8.10. Found: C, 55.04; H, 8.27.

Reaction of Ethyl 2,3-Dideoxy-α-D-threo-hex-2-enopyranoside, 6a, or its monobenzoate, 6f

1,2,3-Trideoxy-3-deuterio-D-arabino-hex-1-enopyranose, 14a, 1,2,3-Trideoxy-3-deuterio-D-ribo-hex-1-enopyranose, 16a, and their Acetates, 14b and 16b

Compound **6a** (400 mg, 0.0023 mol) or **6f** (640 mg, 0.0023 mol) was treated with LAD (240 mg, 0.0057 mol) in refluxing dioxan for 4 h. The reaction was worked-up by procedure *b*. The product mixture showed three components (R_f 0.45, 0.20, and 0.14) on t.l.c. in solvent system *A*. After silica column chromatography with ethyl acetate as solvent, the material of R_f 0.20 was found to be a mixture of epimers **14a** and **16a** (see Discussion on reductive rearrangement of compounds **4**–**7**). Acetylation of the mixture afforded **14b**, **16b** (both have R_f 0.31 in solvent system *B*) with a total weight of 201 mg (43.5% yield).

The n.m.r. data for compounds **14a**, **16a** and their acetates, **14b** and **16b**, obtained from the analysis of the

220 MHz n.m.r. spectrum of the two mixtures, are shown in Table 2; the i.r. shows $\nu_{max}(CHCl_3)$ 1645 cm^{-1}.

*Ethyl 2,3,4-Trideoxy-2-deuterio-α-D-threo-hex-3-enopyranoside, **18a**, and its acetate, **18b***

The chromatogram described above afforded 40 mg (10.5%) of the substance of R_f 0.45. The structure **18a**, was first assigned on the basis of the similarity of its n.m.r. spectrum to that of other 3,4-unsaturated glycosides. Later it was confirmed by comparison with the methyl analog **18a** (Alk = Me) synthesised as described below. Acetylation of **18a** with acetic anhydride and pyridine gave **18b** (R_f 0.38 in solvent system *B*). The n.m.r. data for compounds **18a** and **18b** are shown in Table 3.

*2,3-Dideoxy-1-O-methyl-D-threo-trans-hex-1-enose, **22a** and its triacetate, **22b***

The slowest-running compound **22a** (R_f 0.14) from the chromatogram described above after acetylation weighed 63 mg (9.1%) **22b** (R_f 0.24 in solvent system *B*); i.r. $\nu_{max}(CHCl_3)$ 1645 cm^{-1}; n.m.r.: τ 3.73 (d, 1, J_{12} = 13.0, H-1), 5.37 (dd, 1, J_{23} = 8.0, H-2), 7.80 (m, 1, H-3), 4.98 (dd, 1, J_{34} = 7.0, J_{45} = 4.0, H-4) 4.73 (m, 1, H-5) 5.95 (dd, J_{56} = 6.5, $J_{66'}$ = −12.2, H-6) 5.70 (dd, $J_{56'}$ = 6.5 H-6′). The material was not crystalline.

*Methyl 2,3,4-Trideoxy-6-O-trityl-2-deuterio-α-D-threo-hex-3-enopyranoside, **18d***

Methyl 3,4-dideoxy-2-*O*-methanesulfonyl-6-*O*-trityl-α-D-*erythro*-hex-3-enopyranoside, **23** (11) (1 g, 2 mmol) was treated with LAD (160 mg) in refluxing dioxan (25 ml) for 7 h. The product, **18d**, isolated by procedure *a* (see General), was purified on a silica column with solvent system *B* as eluent. After recrystallization from ethanol, m.p. 102–103 °C; *m/e* 387; $[\alpha]_D^{23}$ +8.9° (*c*, 1 in $CHCl_3$). The n.m.r. data are shown in Table 3.

Anal. Calcd. for $C_{26}H_{27}O_3$: C, 80.59; H, 7.00. Found: C, 80.48; H, 6.99.

*Methyl 2,3,4-Trideoxy-2-deuterio-α-D-threo-hex-3-enopyranoside, **18a***

Chloroform (10 ml) was cooled down to about −5 °C and hydrogen chloride gas slowly bubbled through for 10 s. The cold HCl–$CHCl_3$ solution (5 ml) was then added to a solution of the compound **18d** (250 mg) in 10 ml of cold chloroform, and the resulting solution stirred at −10 °C for half an hour. After quenching with solid sodium bicarbonate and filtration, the solution was evaporated to dryness and the residue purified on a silica column with ethyl acetate – petroleum ether (30–60 °C) (1:1) as eluent. The product **18a** (Alk = Me) isolated has a superimposable n.m.r. spectrum with that of the ethyl analog **18a** (Alk = Et) except for the aglycon resonances. The n.m.r. parameters are shown in Table 3.

*Ethyl 4,6-O-Benzylidene-2,3-dideoxy-α-D-threo-hex-2-enopyranoside, **7***

Crude **6a** (3 g) was treated with α,α-dimethoxytoluene (10 ml) and dimethylformamide (75 ml). Toluenesulfonic acid was then added to the stirred solution to achieve ~p*H* 2. After 25 min, saturated sodium bicarbonate solution was added to quench the reaction. The mixture was then extracted with chloroform and the extract was washed with water and dried with anhydrous sodium sulfate. Evaporation of the solvent with a high vacuum pump left a thick syrupy residue, which was purified on a silica column with solvent system *B* to give 780 mg of pure **7** and 2 g of mixture of **7** and an unidentified side product.

Compound **7** was recrystallized from ether, m.p. 145–146. 5 °C; *m/e* 262.

Anal. Calcd. for $C_{15}H_{18}O_4$: C, 68.69; H, 6.92. Found: C, 68.57; H, 6.78.

*Reaction of Ethyl 4,6-O-Benzylidene-2,3-dideoxy-α-D-threo-hex-2-enopyranoside, **7***

*4,6-O-Benzylidene-1,2,3-trideoxy-3-deuterio-D-xylo-hex-1-enopyranose, **15***

Compound **7** (780 mg, 0.003 mol) was treated with LAD (400 mg, 0.0095 mol) in refluxing dioxan (25 ml) for 8 h. The reaction was worked-up by procedure *a* and esterified with acetic anhydride (5 ml) and pyridine (5 ml) overnight. After customary work-up, the residue was tested on t.l.c. and shown to contain two components (R_f 0.42 and 0.20 with $CHCl_3$ as solvent). Purification on a silica column with chloroform as eluent afforded 11 mg pure **15**, 350 mg of a mixture of **15** and **18a**, and 200 mg of pure **18a**. The ratio of **15** to **18a** in the total mixture was about 1:7. The n.m.r. parameters for **15** shown in Table 2, support the assigned structure (see Discussion).

Compound **15** was recrystallized from hexane, m.p. 98–99 °C; $[\alpha]_D^{23}$ +162.3° (*c*, 2 in $CHCl_3$).

Anal. Calcd. for $C_{13}H_{13}DO_3$: C, 71.21; H, 6.90. Found: C, 71.30; H, 6.87.

In addition to compounds **15** and **18a** benzyl alcohol-d_1 was isolated. It was acetylated and identified by comparison of its n.m.r. spectrum with that of benzyl acetate.

*Reaction of Methyl 2,3-Dideoxy-4,6-di-O-methyl-α-D-erythro-hex-2-enopyranoside, **26***

*4,6-Di-O-methyl-1,2,3-trideoxy-D-erythro-hex-1-enopyranose, **27***

Compound **26** was prepared from compound **4a** by methylation, (28). Compound **26** (0.20 g, 0.001 mol) was treated with LAH (0.015 g) in dry dioxan (10 ml) under reflux for 5 h. The isolated product was a syrup and the n.m.r. spectrum showed two vinyl ethers present in equal amounts, which were obtained as syrups by silica column chromatography (EtOAc – petroleum ether (35–60 °C) 1:1) and identified as **27** and **29**.

For **27** (which was also obtained by methylation of **12a**(H)); $[\alpha]_D^{23}$ +93.3 (*c*, 9.6 in $CHCl_3$); *m/e* 158; $\nu_{max}(CHCl_3)$ 1645 cm^{-1}; n.m.r. data: τ 6.60 (s, 6, 2 × OCH_3), 3.20 (dt, 1, J_{12} = 6.0, J_{13} = $J_{13'}$ = −1.5, H-1), 5.40 (m, 1, H-2), 7.57–8.03 (m, 2, H-3, -3′), 6.00–6.50 (m, 4, H-4, -5, -6, -6′).

*2,3-Dideoxy-1-O-ethyl-4,6-di-O-methyl-D-erythro-cis-hex-1-enopyranose, **29***

Compound **29** was a syrup, *m/e* 204; $\nu_{max}(CHCl_3)$ 1645 cm^{-1}; n.m.r.: τ 6.63 (s, 6, 2 × OCH_3), 8.77 (t, 3, $J_{CH_2CH_3}$ = 7.0 Hz, OCH_2CH_3), 7.0 (bs, 1, exchangeable, OH), 3.92 (dt, 1, J_{12} = 6.0, J_{13} = $J_{13'}$ = −1.5, H-1), 5.53 (m, 1, J_{23} = $J_{23'}$ = 8.5, H-2), 7.60 (m, 2, J_{34} = $J_{3'4}$ = 6.0, H-3, -3′), 6.43–6.93 (m, 4, H-4, -5, -6, -6′).

*Reaction of Methyl 3,4-Dideoxy-6-O-trityl-α-D-threo-hex-3-enopyranoside, **30***

*Methyl 2,3,4-Trideoxy-4-deuterio-6-O-trityl-α-D-threo-hex-2-enopyranoside, **32***

Compound **30** (11) (3.50 g, 8.7 mmol) was treated with LAD (910 mg, 21.8 mmol) in refluxing dioxan (100 ml)

for 19 h. The reaction was worked up in the usual way, and the product mixture showed two components (R_f 0.70 and 0.57) on t.l.c. in chloroform as solvent. After silica column chromatography, the material of R_f 0.57 was found to be crystalline **32** (909 mg, 27% yield). The n.m.r. data are shown in Table 3.

Compound **32** was recrystallized from hexane, m.p. 81.5–82.5 °C; $[\alpha]_D^{23}$ −38.4° (*c*, 1 in $CHCl_3$).

Anal. Calcd. for $C_{26}H_{27}O_3$: C, 80.57; H, 7.02. Found: C, 80.85; H, 7.03.

*1,2,3,4-Tetradeoxy-3,4-dideuterio-6-O-trityl-*D*-xylo-hex-1-enopyranose, 34*

The chromatogram described above afforded 500 mg of the substance of R_f 0.7 (16% yield). The structure **34** was assigned on the basis of n.m.r. evidence (Table 3) which showed that the material was a glycal and the expected course of reductive rearrangement of the primary product, **32**. Satisfactory elemental analysis of **34** could not be obtained.

*Reaction of Methyl 3,4-Dideoxy-6-O-trityl-*α*-*D*-erythro-hex-3-enopyranoside, 31*

Compound **31** (11) (3.0 g, 7.45 mmol) was treated with LAD (1.6 g, 38 mmol) in refluxing dioxan (200 ml) for 1 week. The reaction was worked-up by procedure *a* and the products, **33** (554 mg) and **35** (210 mg), were isolated by column chromatography as described above (R_f 0.57 and 0.70). The structures of **33** and **35** were assigned on the basis of n.m.r. evidence (Table 3).

Compound **33** was recrystallized from hexane m.p. 75–77 °C; $[\alpha]_D^{23}$ +15.5° (*c*, 0.5 in $CHCl_3$).

Anal. Calcd. for $C_{26}H_{27}O_3$: C, 80.57; H, 7.02. Found: C, 80.60; H, 7.00.

*1,2,3,4-Tetradeoxy-3,4-dideuterio-6-O-trityl-*D*-ribo-hex-1-enopyranose, 35*

The structure of **35** is assigned on the n.m.r. evidence (Table 3) which shows it to be a glycal and the expected course of reductive rearrangement of the primary product **33**. Satisfactory elemental analysis of **35** could not be obtained.

The 2- and 3-*C*-Methyl Derivatives of Methyl 2,3-Dideoxy-α-D-*erythro*-hex-2-enopyranosid-4-ulose

DAVID ROY HICKS AND BERT FRASER-REID

Department of Chemistry, University of Waterloo, Waterloo, Ontario N2L 3G1

Received December 24, 1974

DAVID ROY HICKS and BERT FRASER-REID. Can. J. Chem. **53**, 2017 (1975).

The oxirane rings of carbohydrate 2,3-anhydro sugars are opened stereospecifically by lithium dimethyl cuprate. These reactions go in high yields, without the formation of abberant side products encountered with other organometallic reagents. The alcohols produced are converted via their xanthate esters to olefins in good overall yields. The latter on hydrolysis and oxidation give the title enones.

DAVID ROY HICKS et BERT FRASER-REID. Can. J. Chem. **53**, 2017 (1975).

Les cycles oxirannes des anhydro-2,3 carbohydrates sont ouverts d'une façon stéréospecifique par le diméthyl cuprate de lithium. Ces réactions se produisent avec des rendements élevés et sans la formation des produits secondaires aberrants rencontrés avec d'autres réactifs organométalliques. Les alcools formés peuvent être transformés en oléfines par l'intermédiaire de leur xantogénate; le rendement global de ces réactions est bon. Les oléfines soumises à une hydrolyse puis une oxydation conduisent aux énones mentionnées dans le titre.

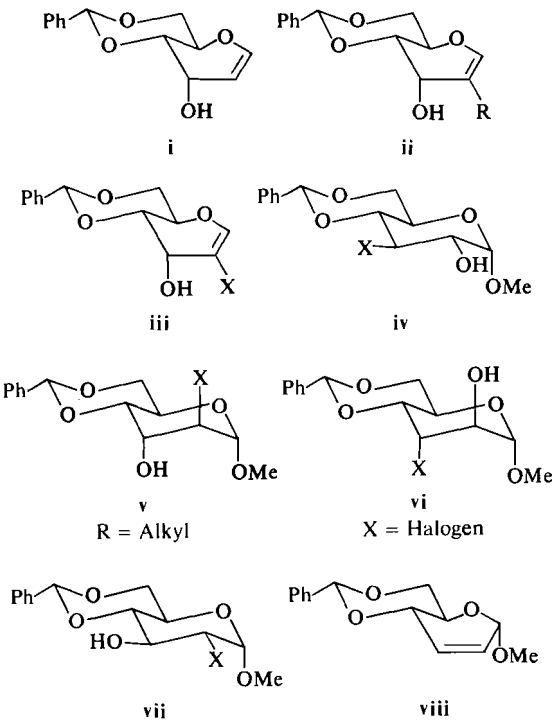
In connection with synthetic projects underway in this laboratory, we need to have ready access to the conjugated enones **7** and **16**, simpler congeners of which have proved to be versatile intermediates in the synthesis of deoxy (1), amino (2), and branched-chain (3) sugars. With regard to the last category, the alkyl substituents in **7** and **16** are of particular interest since they provide an additional branching point on the saccharide annulus. We therefore report herein syntheses of these enones via intermediates which are themselves of interest as precursors to highly modified sugars.

Conceptually, an appealing method for attaching an alkyl chain to carbons-2 and -3 of the sugar ring would be by reaction of the readily available oxiranes **1** (4) and **8** (5), respectively, with an organometallic reagent. This follows from the preferred geometry of ring opening which would be expected to give the alcohols **2***a* (*7b*) and **9** (*6a*). However, the reactions of carbohydrate epoxides with organometallic reagents have been shown to yield a great variety of unwanted products such as **i**–**viii** with the desired alcohols present in unsatisfactory yields (6, 7). The formation of the unsaturated compounds **i**, **ii**, and **iii** is probably due in part to the basicity of the organometallic reagent. Johnson has recently demonstrated the virtues of lithium dimethyl cuprate (8) in oxirane cleavage (9). Hence it occurred to us that this difficulty might



be overcome by use of this reagent which although a good nucleophile, is less prone to cause elimination than methyl lithium (see for example ref. 10).

With this in mind, reaction of the *allo*-epoxide **1** (4) with lithium dimethyl cuprate in ether at

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

0 °C, afforded a 1:8.5 mixture (n.m.r. estimate) of the glycal **3***a* and the desired alcohol **2***a* (*7b*). The latter could be crystallized from the mixture in about 65% yield using cold ethanol. The yield of **2***a* was increased to 75% by taking advantage of the reluctance of **2***a* to undergo esterification (*7b*). Thus treatment of the mixture (**2***a* and **3***a*) with acetic anhydride and pyridine for 5 h at 0 °C gave **2***a* and **3***b*, which were now readily separated on a silica gel column.

A method for the *cis*-elimination of the elements of water from the alcohol **2***a* to give the olefin **5** was now required. Burgess *et al.* (11) have reported the preparation and use of methyl (carboxysulfamoyl) triethylammonium hydroxide inner salt [$CH_3OCO\bar{N}SO_2\overset{+}{N}(C_2H_5)_3$] as a useful reagent for the dehydration of simple alcohols. Crabbé (12) has since extended this reaction to the preparation of steroidal olefins from the corresponding alcohols. However, when this method was applied to compound **2***a* extensive decomposition resulted due, no doubt, to the sensitive nature of the carbohydrate molecule which could not tolerate the sulfur trioxide liberated during the course of the reaction. Attempts to dehydrate **2***a* by heating with hexamethylphosphoric triamide (HMPT) (13) also failed.

Unsaturated carbohydrate derivatives have been obtained by Ferrier by application of the Chugaev elimination reaction sequence (14). Consequently the xanthate ester **4** was prepared by treatment of the alcohol **2***a* with sodium hydride, carbon disulfide, and methyl iodide in refluxing diethyl ether (14, 15). Compound **4** obtained as a light yellow syrup and used without further purification, yielded the desired olefin **5** upon pyrolysis in an equal amount of biphenyl at 235 °C for 1 h. Column chromatography of the pyrolysate mixture on silica gel using benzene as eluant afforded compound **5** in pure crystalline form.

Brief treatment of the olefin **5** with *p*-toluenesulfonic acid in dry methanol led to debenzylidenation and formation of the diol **6***a* a colorless syrup. This facile reaction made it necessary to isolate compound **5** chromatographically. Thus the crude pyrolysate was treated with methanol and *p*-toluenesulfonic acid and after neutralization and concentration the residue was partitioned between ether and water. The aqueous phase yielded **6***a* which was then oxidized using active manganese dioxide in chloroform (16) to give the desired ketone **7**.

Conceptually, conversion of the diastereomeric oxirane **8** (5) to the analogous ketone **16** should have been achieved by application of the same series of reactions employed in Scheme 1. However, several difficulties encountered when this was attempted, required several modifications (Scheme 2). First of all the *manno*-epoxide did not react with lithium dimethyl cuprate in diethyl ether at 0 °C and at room temperature three compounds were formed. Benzene or tetrahydrofuran as solvent gave equally discouraging results. However, if the reagent was prepared in dry hexane at 0 °C, the oxirane added and the reaction mixture allowed to warm to and stand at room temperature for 4 h a 70% yield of the desired alcohol **9** (*6a*) could be obtained. Unfortunately this reaction could not be adapted for large scale preparations of **9**. When the amount of **8** was greater than 0.008 mol, appreciable quantities of the iodohydrin **10** (*6c*) were formed.[1] However, the latter could be removed chromatographically using a silica gel column.

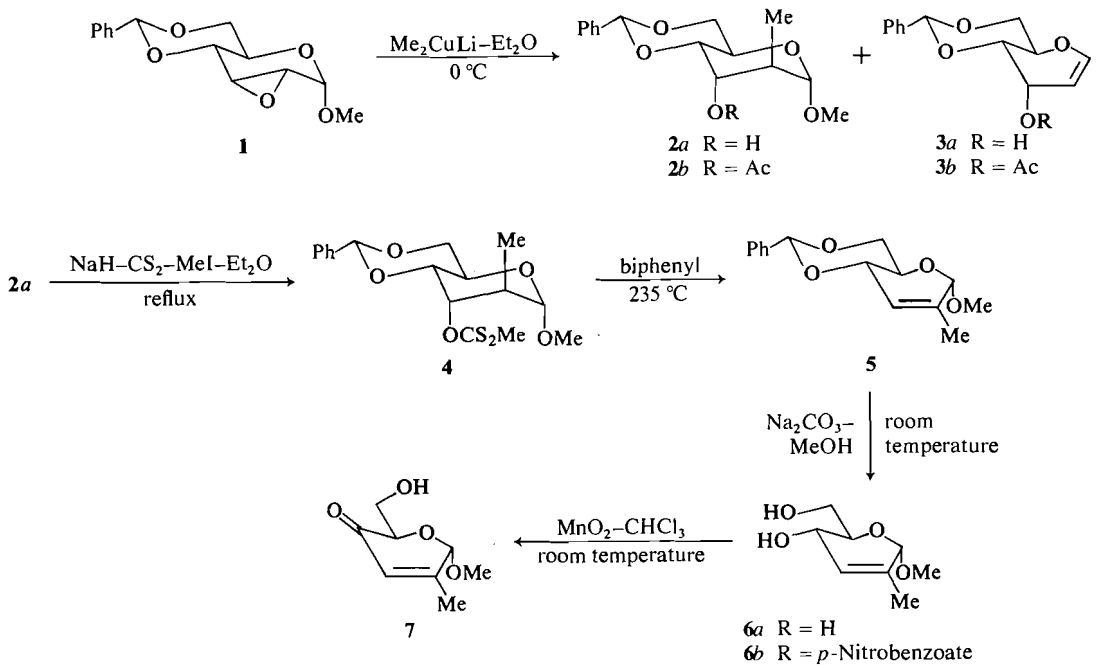
The xanthate ester **11** could be prepared in a similar manner to that used for the preparation of **4**. However, pyrolysis of **11** under identical conditions to those used for the formation of **5** did not yield the expected olefin **12** (17) but the diene **13** (18) as the only isolable product. Upon careful monitoring of the reaction on t.l.c., it was discovered that compound **13** was formed at the expense of a slower-moving material which had been formed initially. This material proved to be the desired olefin **12** which undergoes pyrolytic 1,4-elimination of methanol to form the diene **13**.[2] Optimum conditions for the formation of **12** were achieved by raising the pyrolysis temperature to 265 °C and shortening the reaction time to 15 min.

Unlike compound **4**, which is an unambiguous case, the xanthate ester **11** contained two available *cis*-hydrogens (19) and could conceivably have led to the formation of the olefin **17** on

---

[1]The formation of the iodohydrin **10** must arise from oxirane cleavage by iodide ion. However, we are unable to account for the formation of **10** since in control experiments lithium iodide was found to be insoluble in hexane at room temperature and oxirane **8** did not react with cuprous iodide in hexane at room temperature.

[2]This and other routes leading to **13** will be described in detail in a forthcoming issue of this journal.



SCHEME 1

pyrolysis. The fact that none of this material was isolated supported our faith in precedents which have indicated that the hydrogen α to the two oxygens at carbon-1 would be less readily removed in the olefin forming step (14, 20).

Another difference with Scheme 1 was encountered when the acid-catalyzed debenzylidenation of **12** proved to be unworkable since the molecule appeared to be too sensitive to acid. If correct, this problem would be circumvented by using base-labile blocking groups. Therefore, with this in mind, the benzylidene group of the xanthate ester **11** was removed and the resulting diol **15***a* was converted to the diacetate **15***b*. Pyrolysis of this compound in a manner similar to that used for the analogous benzylidene derivative **11** afforded the olefin diacetate **14***b*. The diol **14***a* was then obtained upon deacetylation of the diester **14***b* with sodium carbonate and dry methanol and easily oxidized (16) as before to the required ketone **16**.

Experimental

Melting points were determined in capillary tubes in a Mel-Temp block and are uncorrected. Elemental analyses were performed by Microanalyses Laboratory, Toronto, Ontario. The n.m.r. spectra ($CDCl_3$, TMS) were determined on a Varian T-60 or a Varian HR-220 spectrometer the J values quoted being the spacing measured directly from the spectra. Infrared spectra were determined on a Beckman model IR-10 spectrometer using 0.1 mm sodium chloride solution cells (chloroform as solvent). Optical rotations were determined on a Carl Zeiss model LEP nür 370740 Lichtelektrishes Präzision polarimeter at 23 °C.

Thin-layer chromatography was performed on glass plates coated with silica gel (HF-254, E. Merck) to a thickness of 0.3 mm. The following solvent systems were used to develop the plates. (*A*) ethyl acetate – petroleum ether (30–60 °C) (1:4); (*B*) ethyl acetate – petroleum ether (30–60 °C) (1:1); (*C*) ethyl acetate; (*D*) benzene. For column chromatography E. Merck silica gel (0.063–0.20 mm 70–230 mesh A.S.T.M.) was used.

Methyl 4,6-O-Benzylidene-2-deoxy-2-C-methyl-α-D-altropyranoside (2) and 4,6-O-Benzylidene-1,2-dideoxy-D-ribo-hex-1-enopyranose (3)

Cuprous iodide (15.2 g, 0.08 mol), in anhydrous ether (90 ml), was stirred under dry nitrogen at 0 °C in a three-necked round bottom flask. A stock solution of methyl lithium (2 *M* in ether) was added to this suspension until a colorless solution was obtained, approximately 80 ml being required. Compound **1** (10.56 g, 0.04 mol) was added to this reagent and the reaction was allowed to stir at 0 °C.

After 4 h the starting material had disappeared and two new spots (R_f 0.46 and 0.38 solvent *B*) had appeared. At this time the contents of the reaction flask were transferred to a separatory funnel and the flask was washed with ether. The combined ether solutions were washed with a saturated ammonium chloride solution (2 × 20 ml) and saturated sodium bicarbonate solution (20 ml)

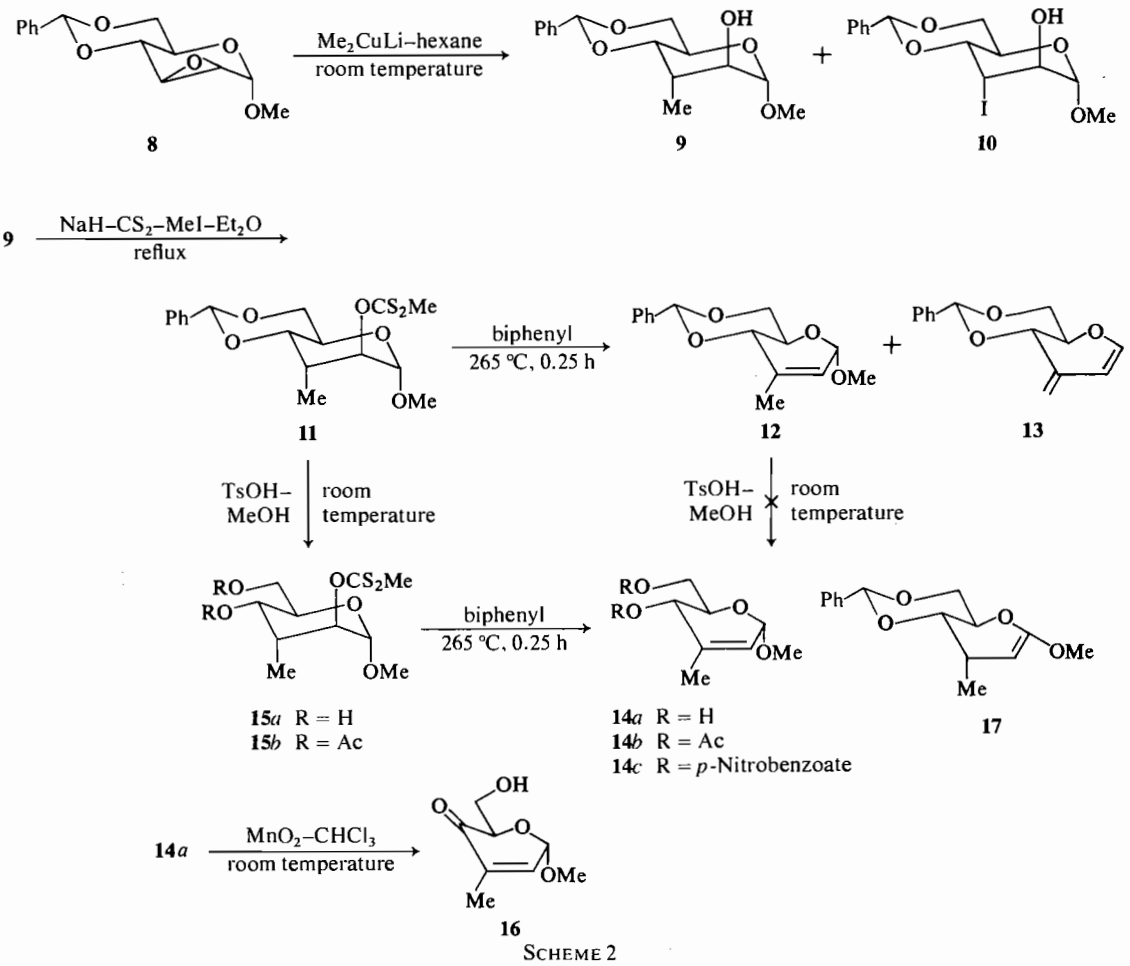

SCHEME 2

and then dried over sodium sulfate and evaporated: yield 9.7 g, 89%.

The alcohol **2** (6.9 g) was recovered when the crude product was crystallized from ethanol. A further amount of **2***a* (1.5 g) was obtained when the mother liquors were acetylated and chromatographed (see below). Compound **2***a* was recrystallized from ether–*n*-hexane, m.p. 111–113 °C; $[\alpha]_D^{23}$ +122.5° (*c*, 1 in $CHCl_3$) (lit. (7*b*) 110–111 °C; $[\alpha]_D^{23}$ +120.8° (*c*, 1 in $CHCl_3$)).

*3-O-Acetyl-4,6-O-benzylidene-1-2-dideoxy-*D*-ribo-hex-1-enopyranose (3b)*

The residue (1.0 g) obtained upon evaporation of the mother liquors from above was dissolved in dry pyridine (5 ml) and cooled in an ice bath. Acetic anhydride (3 ml) was added and the reaction stirred for 5 h at 0 °C. At this time methanol (10 ml) was added to the reaction mixture and the solution was allowed to warm up to and remain at room temperature for 1 h. The solvents were then removed on a rotary evaporator and the residue dissolved in chloroform (20 ml) washed with a 5% HCl solution (20 ml) and a saturated sodium bicarbonate solution (20 ml), dried over sodium sulfate, and evaporated. The resulting syrup was then chromatographed on a silica column using solvent *A* to yield compound **2***a* (0.55 g) and compound **3***b* (0.49 g). Compound **3***b* was recrystallized from ethanol, m.p. 120–121 °C; $[\alpha]_D^{23}$ +237° (*c*, 0.17 in ethanol) (lit. (7*c*) m.p. 121–121.5 °C; $[\alpha]_D$ +253° (*c*, 0.17 in ethanol)).

*Methyl 3-O-Acetyl-4,6-O-benzylidene-2-deoxy-2-C-methyl-*α*-*D*-altropyranoside (2b)*

Compound **2***a* (0.50 g, 1.79 mmol) was dissolved in dry pyridine (5 ml) and cooled in an ice bath to 0 °C while acetic anhydride (3 ml) was added to the stirred solution. The reaction mixture was allowed to warm to room temperature. After 24 h, t.l.c. indicated that the starting material had disappeared and a new faster-running compound (R_f 0.29, solvent *A*) had been formed. The reaction mixture was worked-up as above to yield **2***b* (5.02 g, 87%) recrystallized from hexane, m.p. 65–65.5 °C; $[\alpha]_D^{23}$ +81.2° (*c*, 1 in $CHCl_3$) (lit. (7*b*) m.p. 65–66 °C; $[\alpha]_D^{25}$ +86.5° (*c*, 1 in $CHCl_3$)).

*Methyl 4,6-O-Benzylidene-2-deoxy-2-C-methyl-3-O-((thiomethyl)thiocarbonyl)-*α*-*D*-altropyranoside (4)*

Sodium hydride (2.54 g, 0.053 mol) (50% oil dispersion) was placed in a dry 250-ml round-bottom flask fitted

For personal use only.

with a magnetic stirrer, reflux condenser, and drying tube. The sodium hydride was then washed free of oil with pentane by stirring and decantation. Compound **2***a* (12.0 g, 0.043 mol) dissolved in dry diethyl ether (100 ml) was added to the flask and the reaction mixture was refluxed for 3 h. Carbon disulfide (5.3 ml) and methyl iodide (5.4 ml) were added dropwise to the solution after 3 and 6 h, respectively. After a total reflux period of 9 h t.l.c. indicated that the starting material had disappeared and a new faster-running material (R_f 0.60, solvent *B*) had been formed. The excess sodium hydride was destroyed by the cautious addition of water to the cooled solution. The ether layer was washed with water (3 × 50 ml), dried over sodium sulfate, and evaporated to give the xanthate ester **4** (14.82 g, 89%). Significant n.m.r. features were: δ 1.20 (d,3,J = 8.0 Hz, C—CH_3), 2.58 (s,3,S—CH_3), 3.37 (s,3,OCH_3), 3.98 (bs,1,H-1), 5.63 (s,1,H-7), 5.87 (m,1,H-3).

Methyl 4,6-O-Benzylidene-2,3-dideoxy-2-C-methyl-α-D-erythro-hex-2-enopyranoside (5)

The xanthate ester **4** (10 g, 0.057 mol) unpurified was mixed with biphenyl (10 g) in a 50-ml round-bottom flask fitted with a magnetic stirrer and an air condenser. A stream of nitrogen was passed over the reaction mixture by means of a capillary tube extending into the flask through the condenser. A preheated (240 °C) Wood's metal bath was then raised around the flask and the temperature of the bath was maintained at 235 °C for 1 h. At this time no starting material was apparent on t.l.c. only a faster running spot (R_f 0.50, solvent *A*) now remained. The crude pyrolysate was then chromatographed on a silica column using solvent *D* to yield the olefin **5** (4.45 g, 67%). The material after recrystallization from ether–hexane had m.p. 141.5–142.5 °C; $[\alpha]_D^{23}$ +105.7 (*c*, 4.72 in $CHCl_3$); n.m.r., δ 1.77 (m,3, C—CH_3), 3.50 (s, 3, OCH_3), 3.76–4.40 (m, 4, H-4, 5, 6, 6′), 4.73 (bs, 1, H-1), 5.63 (s, 1, H-7), 5.83 (m, 1, H-2).

Anal. Calcd. for $C_{15}H_{18}O_4$: C, 68.69; H, 6.92. Found: C, 68.87; H, 6.92.

Methyl 2,3-Dideoxy-2-C-methyl-α-D-erythro-hex-2-enopyranoside (6a)

Method A

The benzylidene olefin **5** (3.95 g, 0.015 mol) was placed in a round-bottom flask equipped with a magnetic stirring bar. Dry methanol (100 ml) and *p*-toluenesulfonic acid (0.100 g) were added and the reaction mixture was allowed to stir at room temperature until the reaction was complete (~20 min). The solution was neutralized by the addition of solid sodium bicarbonate and filtered. The methanol was removed on a rotary evaporator and the residue partitioned between water (50 ml) and ether (20 ml). The ether layer was extracted with water (50 ml) and the combined aqueous layers were evaporated to dryness. The resulting residue was extracted with ethyl acetate and filtered. Upon evaporation of the ethyl acetate the diol **6***a* was obtained as a light yellow syrup: yield 2.15 g, 79%.

The diol **6***a* was characterized as the di-*p*-nitrobenzoate **6***b* which after recrystallization from ethanol had m.p. 138–139 °C; $[\alpha]_D^{23}$ +158.5° (*c*, 1.18 in $CHCl_3$); n.m.r. δ 1.81 (m,3,C—CH_3), 3.53 (s,3,O—CH_3), 4.15–4.75 (m,3,H-5,6,6′), 4.83 (bs,1,H-1), 5.6–5.9 (m,2,H-3,4), 8.28 (bs,8, phenyl).

Anal. Calcd. for $C_{22}H_{20}N_2O_{10}$: C, 55.94; H, 4.27; N, 5.93. Found: C, 56.06; H, 4.22; N, 6.01.

Method B

When the total crude pyrolysis mixture was treated with methanol and *p*-toluenesulfonic acid as described above, the diol **6***a* was isolated in 47% yield from **4**.

Methyl 2,3-Dideoxy-2-C-methyl-α-D-glycero-hex-2-enopyranosid-4-ulose (7)

The olefinic diol **6***a* (2.15 g, 12.3 mmol) was dissolved in chloroform (500 ml) and active manganese dioxide (27 g) was added. The reaction mixture was stirred at room temperature and the progress of the reaction was followed on t.l.c. After 5½ h the starting material had disappeared and been replaced by a faster-moving material (R_f 0.30, solvent *B*). The reaction mixture was then filtered through Celite to remove the manganese dioxide and the filterate was evaporated to dryness. The crystalline product was recrystallized from ether–hexane to give the ketone **7**: yield 1.44 g, 68%; m.p. 94–95 °C; $[\alpha]_D^{23}$ −2.17° (*c*, 3.65 in $CHCl_3$); n.m.r. δ 2.02 (m,3,C—CH_3), 2.75 (bs,1,OH), 3.57 (s,3,OCH_3), 3.8–4.1 (m,2,H-6,6′), 4.38 (t,l,J_{56} = $J_{5'6'}$ = 5.0 Hz, H-5), 4.98 (s,1,H-1), 5.93 (m,1,H-3), i.r. ν_{max} ($CHCl_3$) 3600, 1680, 1645 cm^{-1}.

Anal. Calcd. for $C_8H_{12}O_4$; C, 55.81; H, 7.02. Found: C, 55.82; H, 7.21.

Methyl 4,6-O-Benzylidene-3-deoxy-3-C-methyl-α-D-altropyranoside (9)

Cuprous iodide (3.04 g, 0.016 mol) and dry hexane (60 ml) were placed in a dry three-necked flask equipped with nitrogen inlet, condenser, drying tube, and rubber septum. The reaction mixture was stirred at 0 °C under dry nitrogen while a stock solution of methyl lithium (2 *M* in ether) was added. After the addition of 2 equiv. of methyl lithium, the yellow precipitate formed initially had been replaced by a white precipitate of lithium dimethyl cuprate and lithium iodide. The reagent was stirred for 30 min at 0 °C and then compound **8** (2.11 g, 0.008 mol) was added and the reaction allowed to warm to room temperature. After 4 h the reaction mixture was poured into a separatory funnel and the flask was rinsed with diethyl ether (100 ml). The combined organic solutions were washed with a saturated solution of ammonium chloride (2 × 50 ml), saturated sodium bicarbonate solution (50 ml), and water (50 ml) and then dried over sodium sulfate. After evaporation of the solvents a light yellow oil was obtained which crystallized on standing to yield **9** (1.56 g, 70%). The material after recrystallization from ether–hexane had m.p. 116–117.5 °C; $[\alpha]_D^{23}$ +104.1° (*c*, 0.28 in ethanol) (lit. (*6a*) m.p. 114–115 °C; $[\alpha]_D^{24}$ +115.9° (*c*, 0.28 in ethanol)).

If the reaction was attempted on larger amounts of **8** appreciable quantities of the iodohydrin **10** were formed. This compound, when isolated by means of column chromatography (solvent *B*) and recrystallized from ethyl acetate, gave the following physical constants: m.p. 163–164.5 °C; $[\alpha]_D^{23}$ +117.0° (*c*, 4 in $CHCl_3$) (lit. (*5c*) m.p. 163–163.5 °C; $[\alpha]_D^{24}$ +111° (*c*, 4 in $CHCl_3$)).

Methyl 4,6-O-Benzylidene-3-deoxy-3-C-methyl-2-O-((thiomethyl)thiocarbonyl)-α-D-altropyranoside (11)

Sodium hydride (2.84 g, 0.06 mol) (a 50% oil dispersion) was placed in a dry round-bottom flask fitted with

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

a magnetic stirrer, a reflux condenser, and a calcium chloride drying tube. The sodium hydride was washed free of oil with pentane (3 × 20 ml) by stirring and decantation. Dry diethyl ether (100 ml) and the alcohol **9** (4.90 g, 0.0175 mol) were then placed in the flask and the reaction mixture was stirred and refluxed for 24 h. Carbon disulfide (4.5 ml) and methyl iodide (4.5 ml) were added to the reaction mixture after 12 and 18 h, respectively. The solution was cooled to room temperature and water was added dropwise to destroy the excess sodium hydride. The ether layer was then washed with water (3 × 50 ml) and dried over sodium sulfate. The light yellow syrup which remained upon evaporation of the solvent weighed 5.60 g (82%) and showed as one spot on t.l.c. (R_f 0.62, solvent *B*). Significant n.m.r. features were: δ 1.28 (d,3,J = 7.0 Hz, C—CH_3), 2.60 (s,3,S—CH_3), 3.40 (s,3,O—CH_3), 4.75 (bs, 1, H-1), 5.62 (bs, 2, H-2,7).

*Methyl 4,6-O-Benzylidene-2,3-dideoxy-3-C-methyl-α-D-erythro-hex-2-enopyranoside (**12**)*

The xanthate ester **11** (0.50 g, 1.28 mmol) and biphenyl (1.0 g) were placed in a 5 ml round-bottom flask fitted with a magnetic stirrer and an air condenser. The system was flushed with nitrogen by means of a capillary tube extending through the condenser. The flask was then placed in a preheated Wood's metal bath (270 °C). The temperature of the reaction mixture was maintained at 265–270 °C for 15 min. At this time t.l.c. indicated all of the starting material had been converted to a new compound (R_f 0.49, solvent *B*). The olefin **12** (16) was isolated as a crystalline solid (0.204 g, 61%) when the crude pyrolysate was chromatographed on a silica column using benzene as the eluant. The material when recrystallized from ethanol gave the following data: m.p. 138.5–139.5 °C; $[\alpha]_D^{23}$ +62.7° (*c*, 4.15 in $CHCl_3$) (lit. (16) m.p. 139–140 °C; $[\alpha]_D^{27}$ +60.6° (*c*, 4.15 in $CHCl_3$)).

*4,6-O-Benzylidene-1,2,3-trideoxy-3-C-methylene-D-erythro-hex-1-enopyranose (**13**)*

The xanthate ester **11** (0.50 g, 1.28 mmol) and biphenyl (1.0 g) were pyrolyzed in the same manner as above. After 30 min at 265 °C a t.l.c. of the reaction mixture indicated that all of the xanthate ester **11** had been converted to a faster-running compound (R_f 0.62, solvent *A*). When the crude pyrolysate was chromatographed on a silica column using benzene as eluant a compound whose n.m.r. spectrum was identical to the known diene **13** (16) was obtained (0.074 g, 25%). The compound was recrystallized from ethanol, m.p. 95–96 °C; $[\alpha]_D^{23}$ +97.7° (*c*, 3.6 in $CHCl_3$) (lit. (16) m.p. 98–100 °C; $[\alpha]_D^{23}$ +98.4° (*c*, 3.6 in $CHCl_3$)).

*Methyl 3-Deoxy-3-C-methyl-2-O-((thiomethyl)-thiocarbonyl)-α-D-altropyranoside (**15a**)*

The xanthate ester **11** (1.4 g, 3.6 mmol) was dissolved in dry methanol (60 ml) and *p*-toluenesulfonic acid (0.07 g, 0.4 mmol) was added. The reaction mixture was stirred at room temperature for 5 h. At this time t.l.c. indicated that the starting material had been consumed and a new lower-running compound (R_f 0.21, solvent *B*) had been formed. The solution was then neutralized with solid sodium bicarbonate, filtered through Celite, and evaporated to dryness. The residue was then extracted with chloroform and filtered. Compound **15a** (1.0 g, 92%) was obtained as a light yellow syrup upon evaporation of the filtrate. Significant n.m.r. features were: δ 1.21 (d, 3, J = 7.0 Hz, C—CH_3), 2.60 (s, 3, S—CH_3), 3.42 (s, 3, O—CH_3), 4.78 (bs, 1, H-1), 5.62 (m, 1, H-2).

*Methyl 4,6-Di-O-acetyl-3-deoxy-C-methyl-2-O-((thiomethyl)thiocarbonyl)-α-D-altropyranoside (**15b**)*

The diol **15a** (1.0 g, 3.32 mmol) was dissolved in dry pyridine (10 ml) and cooled to 0 °C in an ice bath. Acetic anhydride (3 ml) was added and the reaction mixture was left at 0 °C for 10 h. At this time methanol (5 ml) was added and the solution allowed to warm to room temperature. After evaporation of the solvents the residue was dissolved in chloroform (20 ml) washed with a 5% hydrochloric acid solution (20 ml), a saturated sodium bicarbonate solution (20 ml) and water (20 ml). The chloroform layer was then dried over sodium sulfate and evaporated to give **15b** as a light yellow syrup (1.06 g, 83%). Compound **15b** was homogeneous on t.l.c. (R_f 0.55, solvent *B*) and exhibited the following n.m.r. features: δ 1.18 (d, 3, J = 7.0 Hz, C—CH_3), 2.07 and 2.10 (pair of singlets, 6, —$OCOCH_3$), 2.60 (s, 3, S—CH_3), 3.43 (s, 3H, OCH_3), 4.85 (bs, 1, H-1), 5.10–5.40 (m, 1, H-4), 5.7 (m, 1, H-2).

*Methyl 4,6-Di-O-acetyl-2,3-dideoxy-3-C-methyl-α-D-erythro-hex-2-enopyranoside (**14b**)*

The diacetate **15b** (0.880 g, 2.28 mmol) and biphenyl (1.5 g) were placed in a 5 ml round-bottom flask and pyrolyzed as above at 265 °C. After 15 min a t.l.c. of the reaction mixture indicated a new compound (R_f 0.47, solvent *B*) and none of the starting xanthate. Column chromatography on the crude pyrolysate using benzene as solvent yielded the diacetate olefin **14b** (0.391 g, 66%). Significant n.m.r. features were: δ 1.63 (m, 3, C—CH_3), 2.02 and 2.07 (pair of singlets, 6, —$OCOCH_3$), 3.37 (s, 3, OCH_3), 4.78 (d, 1, J_{12}=4 Hz, H-1), 5.2–5.6 (m, 1, H-2).

*Methyl 2,3-Dideoxy-3-C-methyl-α-D-erythro-hex-2-enopyranoside (**14a**)*

The diacetate olefin (2.42 g, 11.2 mmol) was dissolved in dry methanol (175 ml) and sodium carbonate (2.68 g) was added. After 9 h at room temperature t.l.c. indicated that the reaction was complete and a new compound (R_f 0.10, solvent *B*) had been formed. The residue obtained when the reaction mixture was filtered and evaporated to dryness, was extracted with ethyl acetate, and filtered to remove residual inorganic salts. Concentration of the filtrate yielded compound **14a** (1.70 g, 87%) as a colorless syrup. The diol **14a** was characterized as the di-*p*-nitrobenzoate **14c** which after recrystallization from ethanol gave the following data: m.p. 147–148 °C; $[\alpha]_D^{23}$ +162.1° (*c*, 0.63 in $CHCl_3$); n.m.r. δ 1.75 (m, 3, C—CH_3), 3.48 (s, 3, OCH_3), 4.3–4.7 (m, 3, H-5, 6.6′), 5.0 (m, 1, H-1), 5.65–6.0 (m, 2, H-2,4), 8.3 (bs, 8, phenyl).

Anal. Calcd. for $C_{22}H_{20}N_2O_{10}$: C, 55.94; H, 4.27; N, 5.93. Found: C, 56.05; H, 4.19; N, 5.96.

*Methyl 2,3-Dideoxy-3-C-methyl-α-D-glycero-hex-2-enopyranosid-4-ulose (**16**)*

The olefinic diol **14a** (1.25 g, 7.2 mmol) was dissolved in chloroform (575 ml) and active manganese dioxide (12.5 g) was added and the mixture stirred at room temperature. After 6 h t.l.c. indicated that the starting material had disappeared and a new compound (R_f 0.24,

solvent *B*) had been formed. The manganese dioxide was removed by filtration through Celite and evaporation of the filtrate yielded a crystalline solid which was recrystallized from ether–hexane to give the ketone **16** (0.95 g, 77%), m.p. 104–105 °C; $[\alpha]_D^{23}$ +56.47° (*c*, 3.17 in $CHCl_3$); n.m.r. δ 1.83 (m, 3, C—CH_3), 2.33 (bs, 1, OH), 3.53 (s, 3, OCH_3), 4.0 (m, 2, H-6, 6′), 4.5 (t, 1, $J_{56}=J_{56'}$ = 4.0 Hz, H-5), 5.16 (d, 1, J_{12}=4.0 Hz, H-1), 6.70 (m, 1, H-2); i.r. ν_{max} ($CHCl_3$) 3600, 1685, 1650 cm^{-1}.

Anal. Calcd. for $C_8H_{12}O_4$: C, 55.81; H, 7.02. Found: C, 55.68; H, 7.14.

Electric Dipole Moment Investigation of Buttressing in Alkyl Duryl Ketones

A. George Pinkus and Herman C. Custard, Jr.[1]
Department of Chemistry, Baylor University, Waco, Texas 76703

Received April 9, 1974[2]

A. George Pinkus and Herman C. Custard, Jr. Can. J. Chem. **53**, 2024 (1975).

Dipole moments (D) determined for the following alkyl duryl ketones in benzene at 30° were: Me, 2.83; Et, 2.80; *i*-Pr, 2.74; *t*-Bu, 2.65. The decrease in the series is explained by increasing rotational restriction about the carbonyl group due to an increasing interference by the *ortho* methyl groups with the alkyl group. This results in a greater twist from coplanarity between the ring and carbonyl and less π-electron delocalization and consequently a lower dipole moment as the size of the alkyl increases. The increase observed for the duryl ketone moments over those of corresponding mesityl ketones is tentatively explained as due to a higher duryl group moment relative to the mesityl moment. The interplanar angles (angles of twist) for the duryl ketones calculated with the Braude–Sondheimer equation were slightly larger than those calculated for the mesityl ketones, the magnitude depending on the method of calculation. It is tentatively concluded that evidence from dipole moment data indicates that a small buttressing effect exists in the duryl ketone system.

A. George Pinkus et Herman C. Custard, Jr. Can. J. Chem. **53**, 2024 (1975).

Les moments dipolaires (D) des alkyl duryl-cétones suivantes, tels que déterminés dans le benzène à 30°, sont: Me, 2.83; Et, 2.80; *i*-Pr, 2.74; *t*-Bu, 2.65. On explique l'abaissement des valeurs au fur et à mesure que l'on progresse dans la série en faisant l'hypothèse qu'il y a augmentation de l'empêchement à la rotation autour du groupe carbonyle dû à une augmentation de l'interférence des groupes méthyles en *ortho* avec le groupe alkyle. Cette interférence provoque un éloignement plus grand de la planéité du cycle et du groupe carbonyle et une délocalisation plus faible des électrons π; ceci amène un moment dipolaire plus faible à mesure que la grosseur du groupe alkyle augmente. On attribue l'augmentation du moment dipolaire lorsque l'on passe des mésityl-cétones aux duryl-cétones correspondantes au fait que le groupe duryle à un moment dipolaire plus élevé que celui du groupe mésityle. On a calculé les angles interplanaires (angles de torsion) des duryl-cétones à l'aide de l'équation de Braude–Sondheimer; ces valeurs sont légèrement supérieures à celles calculées pour les mésityl-cétones mais l'amplitude des différences dépend du modèle de calcul. On en conclut que les moments dipolaires suggère qu'un petit effet de compression existe dans les duryl-cétones.
[Traduit par le journal]

Introduction

The dipole moments of a series of alkyl mesityl ketones (**1**) were found (1) to decrease from methyl (2.81 D) to *t*-butyl (2.50 D). This decrease was attributed to decreasing π–π conjugation of the aromatic ring with the carbonyl group due to increasing steric interference between the alkyl group from methyl to *t*-butyl with *ortho* methyls thus increasing the angle between the aromatic ring and the C—CO—C plane. As an extension of the study on mesityl ketones, dipole moments of a corresponding series of alkyl duryl ketones (**2**) were determined to investigate whether "buttressing" of *ortho* methyl groups by adjacent methyl groups in the *meta* positions would be detectable via dipole moment data.

Experimental

Determination of Dielectric Constants

The apparatus, procedure, and method of calculation of dipole moments were described previously (1). Linear plots were obtained on extrapolation to infinite dilution.[3]

[1]Present address: Mobil Research & Development Corp., Dallas, Texas.

[2]Revision received April 3, 1975.

[3]The equation of Halverstadt and Kumler (2) which was used to calculate solute polarization ($_\infty P_2$) at infinite dilution was misprinted previously (1) and is reproduced here to correct this error:

$$_\infty P_2 = \frac{3\alpha_0 v_1 M_2}{(\varepsilon_1 + 2)^2} + M_2(v_1 + \beta)\frac{\varepsilon_1 - 1}{\varepsilon_1 + 2}$$

Preparation and Purification of Compounds and Solvents

Thiophene-free benzene was purified as described previously (1). The duryl ketones were prepared by the general method given for isopropyl duryl ketone. The compounds were checked for the presence of impurities by v.p.c.

Isopropyl Duryl Ketone

Anhydrous aluminum chloride (60 g, 0.45 mol) in a flask was cooled in an ice–salt bath. Methylene chloride (100 ml) previously cooled to 0° was added. A solution of durene (26.8 g, 0.200 mol) and isobutyryl chloride (25 g, 0.23 mol) in methylene chloride (400 ml) was added dropwise at such a rate that the temperature of the reaction mixture did not rise above 10°. The reaction mixture was poured slowly into a mixture of cracked ice and hydrochloric acid. The methylene chloride layer was washed twice with 10% sodium bicarbonate, twice with water, and dried with anhydrous sodium sulfate. On removing the solvent, a white powder was obtained which was recrystallized once from methanol and twice from cyclohexane; 25% yield; m.p. 49.8–50.0° (lit. (3) 40–41°).

Anal. Calcd. for $C_{14}H_{20}O$: C, 82.30; H, 9.80. Found:[4] C, 82.28; H, 10.01.

t-Butyl Duryl Ketone

Reagents: pivaloyl chloride; same relative amounts of other reagents. After three recrystallizations from methanol and two from cyclohexane, 20% yield; m.p. 102.8–103.2°.

Anal. Calcd. for $C_{15}H_{22}O$: C, 82.51; H, 10.16. Found:[4] C, 82.93; H, 10.28.

Methyl Duryl Ketone

Prepared in 61% yield; recrystallized from methanol, m.p. 73–74° (lit. (4) 73°; (5) 75°; (6) 74–75°).

Ethyl Duryl Ketone

Prepared in 79% yield; recrystallized from methanol, m.p. 78.0–78.5° (lit. (7) 79°; (3) 78–79°).

Results and Discussion

Weight fractions (w_2), dielectric constants (ε_{12}), and specific volumes (v_{12}) for solutions are in Table 1; molar refractions ($m.r._D$), solute polarizations at infinite dilution ($_\infty P_2$), values of α_0 and β, and dipole moments (μ) are in Table 2.

On the basis of our experience,[5] it is felt that the differences between dipole moments of the ketones reported in the present paper are significant. Thus, for example, when the dipole moment was determined for different samples of the same pure reference compound by five different workers in our laboratory at different periods of time using the same apparatus, the deviations in the dipole moment between the extreme results differed by only 0.02 D. For the same worker, the variation would be expected to be less than this. The differences in the present paper are well within this limit of error.

The dipole moment of 2.83 obtained for methyl duryl ketone in benzene at 30° checks with the value of 2.81 D in carbon tetrachloride at 25° reported by Aroney *et al.* (8) but is higher than the value of 2.63 in benzene at 25° reported by Kadesch and Weller (9). Dipole moments for the other three ketones have not previously been reported.

The decrease in dipole moments in the series from methyl to *t*-butyl is analogous to that found previously for alkyl mesityl ketones and is explicable in terms of increasing rotational restriction about the carbonyl group with size of alkyl due to its interference with *ortho* methyl groups. Since the carbonyl group is twisted more from coplanarity with the aromatic ring the larger the alkyl group, the less π–π electron delocalization between the carbonyl group and aromatic ring and consequently the lower the dipole moment. However, the dipole moments of alkyl duryl ketones are higher than those for each of the corresponding mesityl ketones listed in Table 2 for comparison. *A priori*, on the basis that buttressing would result in enhanced restriction of rotation of

the carbonyl group, it might have been expected that lower moments would be obtained for the corresponding members of the duryl series. This apparent anomaly can be rationalized as follows. As was pointed out previously (1) in comparing dipole moments from one series of compounds to another, the relative group moments must be taken into account. Estimates of differences in mesityl and duryl group moments can be made from published dipole moment data for corresponding monosubstituted mesityl and duryl derivatives where the substituent exerts little or no steric influence on *ortho* methyl groups and in itself has no complicating rotational isomerism. For substituents fulfilling this criterion, data are available for only bromo, hydroxy, and amino compounds. The available data are collected in Table 3. Although some minor variations in the data may exist because of differences in temperatures and methods of calculation, the duryl values for the bromo and hydroxy derivatives are higher from 0.03 for Br to 0.32 D for OH, these being in the range of the increases for the ketone data of the present paper. On this basis, it is reasonable to attribute an appreciable component of the higher moments for the duryl ketones to a higher duryl group moment. More data on monosubstituted mesityl and duryl compounds would be desirable to decide this question more conclusively. At the present time, no other alternative explanation seems evident.

Another approach to the question as to whether buttressing is detectable from dipole moments is in a comparison of interplanar angles (angles of twist) (θ) for the duryl and mesityl ketones. These can be calculated from dipole moment data on duryl ketones using the Braude–Sondheimer equation (13)

$$\cos^2\theta = (\mu_{obs} - \mu_{90})/(\mu_0 - \mu_{90})$$

where μ_{obs} is the observed dipole moment, μ_{90} is the moment for a "completely deconjugated system" (where plane of the ring and the carbonyl group to alkyl-carbon plane are at right angles), and μ_0 is the moment for a coplanar configuration. As was pointed out in the calculations on mesityl ketones (1) the moment for a saturated ketone cannot be used for μ_{90} as suggested by Braude and Sondheimer (13). As a better standard for μ_{90}, *t*-butyl mesityl ketone was used (1) since it was assumed that maximum restriction of rotation would be present and the angle of the carbonyl group with the ring would be 90° as indicated in molecular models. This assumption is justified on the basis of a recent X-ray study (14) on 2,4,6-trimethyl-3-pivaloylbenzoic acid (15) where the mean plane through the keto group was found to make an angle of 89.9° with the mean plane of the six-membered ring. Analogously, the moment of *t*-butyl duryl ketone can be used as the standard for μ_{90} in the present calculations.

As was done for the calculations on mesityl ketones, a corrected value of 3.09 D was used for μ_0 to correct the observed dipole moment of acetophenone for influences of the methyl groups by adding 0.04 D to the value. This value is obtained by applying a correction of +0.04 D to the experimental value of 3.05 D obtained (1) for acetophenone. The correction is based on reported moments (9) of 2.96 D for mesitylaldehyde (2,4,6-trimethylbenzaldehyde) and 2.92 D for benzaldehyde (measured under the same conditions) which reflect an increase of 0.04 D for mesitylaldehyde in a comparison of mesityl and phenyl systems where the same type of carbonyl group is not sterically prevented from conjugation with the ring since there is no steric interference between the *ortho*-methyls and hydrogen and little, if any, interference with the carbonyl oxygen. A better value for μ_0 for the duryl ketones could be similarly derived;

however, although the corresponding duryl aldehyde (2,3,5,6-tetramethylbenzaldehyde) has recently been prepared (16) the dipole moment has not been reported. Thus, the same value of 3.09 D for μ_0 was used for the duryl series although a slight increase would be anticipated which would result in slightly larger values for the interplanar angles. The values calculated on this basis are in Table 4.

In the Braude–Sondheimer procedure of correcting for methyl substituent effects, μ_0 is calculated on the following basis. The μ_0 moment is compounded of the group moment of C=O taken as the experimental value for acetophenone or 3.05 D as previously determined (1) and C_6H_4—Me (taken as 0.40 D, the value for toluene for *o*- and *m*-methyl substituents, and as 0.54, the observed vector component in 4-methylacetophenone for *p*-methyl substituents). The vector addition is carried out assuming the carbon–carbon and carbon–oxygen bond angles to be 120°. The value for μ_0 for the mesityl ketones on this basis is 3.12 D. For the duryl ketones, since the moments of the two opposing pairs of methyl groups cancel each other, μ_0 is taken as equal to acetophenone, or 3.05 D in the present case. The interplanar angles for the mesityl and duryl ketones as calculated[6] on this basis are also listed in Table 4 for comparison.

In comparing the results by the above two methods, it can be seen that the calculated values for the interplanar angles are nearly the same in all cases. The increases in the interplanar angles for each alkyl group ($\Delta\theta$ = θ(duryl) − θ(mesityl)) are listed in Table 5 for the two methods A and B described above. For comparison the values determined by Dhami and Stothers (3, 6) using carbonyl ^{13}C n.m.r. data[7] are also listed in Tables 4 and 5. The values check very well except for the isopropyl derivative in both the mesityl and duryl series, the angles being slightly lower for the ^{13}C method. The correlation between the

*Calculations with Braude–Sondheimer equation using μ_0 = 3.09 D.
†Calculations with Braude–Sondheimer equation using μ_0 = 3.12 D for mesityl ketones and μ_0 = 3.05 D for duryl ketones.
‡Calculations from ^{13}C n.m.r. data (3, 6).

^{13}C and present dipole moment methods is much better than with the values for methyl mesityl ketone of 62° calculated by Braude and Sondheimer (13) from the dipole moment determined by Bentley *et al.* (17), 63° determined by Braude and Sondheimer (13) from ultraviolet data, and 90° determined by Aroney *et al.* (8) from Kerr constants and 90° for methyl duryl ketone also by the latter workers (8).

Dhami and Stothers (3, 6) concluded that the increases ($\Delta\theta$) of 1 to 6° in interplanar angles on going from the mesityl to the corresponding duryl ketones were evidence for the operation of a buttressing effect by the additional *meta* methyl groups in the duryl ketones. In the present investigation, increases of 1 to 5° as calculated by method A and values to 3° using method B were obtained. Since the amount of increase depends on the validity of the method of calculation, it is concluded that evidence for buttressing from dipole moment data in the duryl ketone system is tentative at the present time.

The authors express appreciation to the Robert A. Welch Foundation of Houston, Texas for partial support of the work reported and to Professor J. Trotter, University of British Columbia for a copy of his paper (14) before publication.

[6]These were calculated by a referee and rechecked during the revision of the paper. The authors express appreciation to the referee for constructive comments on this and other points.

[7]The values listed are "corrected" values which are derived from "corrected" ^{13}C shielding data which were applied to correct for an *ortho* effect ascribed to a non-steric origin as observed in a significant variation in chemical shifts between *ortho* derivatives compared with *meta*- and *para*-substituted ones.

Received November 4, 1974

JEAN-CLAUDE RICHER et CLAUDE LAMARRE. Can. J. Chem. 53, 2033 (1975).

On examine la stéréochimie de la réaction d'hydroboration du *tert*-butyl-4 diméthyl-2,2 méthylène-1 cyclohexane et du triméthyl-3,3,5 méthylène-1 cyclohexane. Pour fins de comparaison, la stéréochimie de la réaction d'hydroboration du *tert*-butyl-4 méthylène-1 cyclohexane a aussi été examinée. Les *tert*-butyl-4 hydroxyméthyl-1 diméthyl-2,2 cyclohexanes *cis* et *trans* ainsi que les hydroxyméthyl-1 triméthyl-3,3,5 cyclohexanes *cis* et *trans* ont été obtenus à l'état pur et leur stéréochimie respective prouvée par l'intermédiaire des acides et des esters correspondants.

JEAN-CLAUDE RICHER and CLAUDE LAMARRE. Can. J. Chem. 53, 2033 (1975).

The stereochemistry of the hydroborations of 4-*tert*-butyl-2,2-dimethyl-1-methylenecyclohexane and of 3,3,5-trimethyl-1-methylenecyclohexane has been studied for comparison with that of the hydroboration of 4-*tert*-butyl-1-methylenecyclohexane which also was examined. *cis*- and *trans*-4-*tert*-butyl-1-hydroxymethyl-2,2-dimethylcyclohexane as well as *cis*- and *trans*-1-hydroxymethyl-3,3,5-trimethylcyclohexane were obtained in a pure state and their configurations proved by means of the corresponding acids and esters. [Journal translation]

Introduction

Dans le cadre de nos travaux sur la stéréochimie des réactions d'addition sur des cyclohexanones (1) et du méthylène cyclohexane **1***a* (2) et dans le but de préparer les hydroxyméthyl-1 cyclohexanes correspondants, nous avons été amenés à examiner la stéréochimie des réactions d'hydroboration des méthylènes cyclohexanes **1***a*, **1***b* et **2**. Ce sont les résultats obtenus au cours de cette étude qui font l'objet du présent mémoire. La stéréochimie de la réaction d'hydroboration du *tert*-butyl-4 méthylène-1 cyclohexane (**1***b*) a été rapportée (3) depuis que ce travail a été complété; nous comparons les résultats obtenus avec ceux rapportés antérieurement.

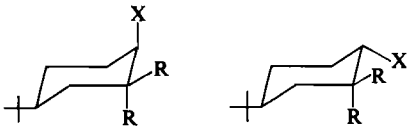
Résultats

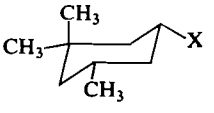
Hydroboration du tert-butyl-4 diméthyl-2,2 méthylène-1 cyclohexane (1a)

L'hydroboration de l'alcène **1***a* dans le diglyme, selon la méthode décrite par Brown et Zweifel (4), fournit les organoboranes **3***a* et **4***a* qui, par oxydation par l'eau oxygénée alcaline, conduisent aux alcools primaires **3***b* et **4***b* accompagnés du *bis*(*tert*-butyl-4 diméthyl-2,2 cyclohexyl)-1,2 éthane (**5**). Les quantités relatives des alcools **3***b* et **4***b* ont été déterminées par chromatographie en phase gazeuse à l'aide des

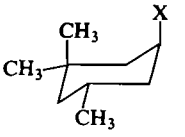


3 R = CH_3
9 R = H

4 R = CH_3
10 R = H



6



7

a X = CH_2—B<
b X = CH_2OH
c X = $CH_2OSi(CH_3)_3$
d X = COOH
e X = COOEt
f X = Br
g X = OH
h X = MgBr

éthers silylés **3***c* et **4***c* préparés selon la méthode de Sweeley *et al.* (5). On note alors la présence de 42.5% d'éther *cis* **3***c* par rapport à 57.5% d'éther *trans* **4***c*. L'oxydation du mélange des alcools **3***b* et **4***b* par de l'acide chromique selon le procédé de Brown et Garg (6) conduit avec un rendement de 50% aux acides correspondants **3***d* et **4***d*. L'estérification de ces acides en milieu acide par l'éthanol selon la méthode de Mori (7) fournit les esters éthyliques correspondants **3***e* et **4***e*. L'analyse par chromatographie en phase gazeuse de ces esters indique la présence de 22% d'ester éthylique *cis* **3***e* et 78% d'ester éthylique *trans* **4***e*. Ce résultat analytique indique qu'une épimérisation se produit au cours de la transformation des alcools primaires en esters. Les esters éthyliques **3***e* et **4***e* ont été séparés par chromatographie en phase gazeuse préparative.

TABLEAU 1. Les résultats de l'épimerisation des esters **3***e* et **4***e*

Esters	δ C*H* (COOEt) (p.p.m.)	% à l'équilibre
3*e*	2.20	9
4*e*	1.65	91

Les configurations relatives *cis* et *trans* des esters éthyliques **3***e* et **4***e* furent établies en se basant sur les deux critères suivants.

(*a*) Le déplacement chimique en r.m.n. du méthine en α du carboéthoxy: Lemieux *et al.* (8) et Eliel et Gianni (9) ont démontré que les méthines axiaux apparaissent dans la r.m.n. à des champs plus forts que les méthines équatoriaux pour les dérivés *cis* et *trans* dans le système *tert*-butyl-4 cyclohexyle du type 4-$(CH_3)_3$—C—CH—$(CH_2)_4$—CHX. Si l'on fait l'hypothèse que les groupes *tert*-butyle et *gem*-diméthyle n'affectent pas le déplacement chimique du méthine en α du groupement carboéthoxy; il est raisonnable de supposer que l'ester dont le méthine apparait au champ le plus fort possède la configuration relative *trans*. L'examen du tableau 1 permet d'attribuer la configuration relative *cis* à l'ester éthylique **3***e* et la configuration relative *trans* à l'ester éthylique **4***e*.

(*b*) La position de l'équilibre lors de l'épimérisation des esters éthyliques en présence d'une quantité catalytique de *tert*-butylate de potassium dans du DMSO à 25°: Les résultats obtenus lors de l'épimérisation de chacun des esters éthyliques **3***e* et **4***e* par une quantité catalytique de *tert*-butylate de potassium dans le DMSO à 25° sont résumés dans le tableau 1. Ils mettent en évidence la présence d'une quantité prépondérante de l'ester équatorial **4***e*. La différence d'énergie libre entre les deux esters serait de 1.39 kcal/mol et cette valeur est en accord avec la différence d'énergie libre que l'on peut calculer en faisant appel aux valeurs préconisées d'une part par Tichy et Sicher (10) pour les interactions *gauches* vicinales entre le couple CH_3 . . . COOMe et d'autre part par divers auteurs (11) pour les interactions 1,3 diaxiales entre le substituant COOEt et les hydrogènes axiaux en position 3 et 5. Cette conclusion suppose que l'on fait l'hypothèse que les valeurs de l'énergie d'interaction *gauche* vicinale du couple CH_3 . . . COOEt sont du même ordre de grandeur que celles du couple CH_3 . . . COOMe.

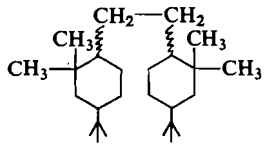
La connaissance des configurations relatives

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

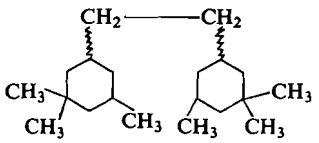
des esters éthyliques **3***e* et **4***e* permet également, par réduction par l'hydrure de lithium et d'aluminium des esters obtenus à l'état pur, d'attribuer les configurations relatives *cis* et *trans* aux alcools primaires **3***b* et **4***b*.

Hydroboration du triméthyl-3,3,5 méthylène-1 cyclohexane (2)

L'hydroboration de l'alcène **2**, préparé à partir de la triméthyl-3,3,5 cyclohexanone (**12**) de la manière de Cross et Whitham (12), conduit par oxydation directe des organoboranes intermédiaires **6***a* et **7***a* aux alcools primaires **6***b* et **7***b* en plus d'un produit auquel on a attribué la structure du *bis*(triméthyl-3,3,5 cyclohexyl)-1,2 éthane (**8**) par extrapolation des résultats obtenus lors



5



8

de l'hydroboration de l'alcène **1***a*. Le rapport *cis*/*trans* des alcools primaires **6***b* et **7***b* est de 12:88. L'alcool primaire *trans* **7***b* a été isolé de ce mélange par chromatographie en phase gazeuse préparative; on peut aussi l'obtenir par la suite des réactions décrites ci-dessous. L'oxydation du mélange des alcools primaires **6***b* et **7***b* par l'acide chromique conduit aux acides correspondants **6***d* et **7***d*. L'estérification de ce mélange avec de l'éthanol en milieu acide conduit aux esters **6***e* et **7***e*. Le triméthyl-3,3,5 cyclohexane carboxylate d'éthyle *trans* (**7***e*) a été isolé de ce mélange réactionnel par chromatographie en phase gazeuse préparative et sa réduction par l'hydrure de lithium et d'aluminium conduit au même alcool **7***b* qui a été isolé du milieu réactionnel d'hydroboration. La chromatographie en phase gazeuse préparative n'a pas permis d'isoler l'alcool primaire *cis* **6***b* formé lors de la réaction d'hydroboration. Cet alcool a été synthétisé et obtenu à l'état pur en faisant appel à la procédure expérimentale qui suit. Le dérivé bromé **7***f* est préparé par l'action du tribromure de phosphore sur le triméthyl-3,3,5 cyclohexanol-1 *cis* (**6***g*) selon les indications de Braude et Evans (13). La carbonation de l'organomagnesien (**6***h* ou **7***h*) permet d'obtenir l'acide carboxylique **6***d* et l'estérification de cet acide avec de l'éthanol en milieu acide conduit à l'ester éthylique *cis* **6***e*. La réduction de **6***e* par l'hydrure de lithium et d'aluminium permet d'obtenir l'alcool primaire *cis* **6***b* pur et son temps de rétention en c.p.g. correspond à l'alcool primaire non isolé de la réaction d'hydroboration. La détermination des configurations relatives des esters éthyliques **6***e* et **7***e* sur laquelle repose l'attribution des configurations relatives des alcools primaires **6***b* et **7***b* dépend: (*i*) de la position de l'équilibre lors de l'épimérisation des esters éthyliques **6***e* et **7***e* à l'état pur, (*ii*) des vitesses relatives de saponification de ces esters et (*iii*) du déplacement chimique des protons $\rangle CH$—COOEt tel que décrit précédemment. Les résultats consignés dans le tableau 2 montrent que l'ester équatorial *cis* **6***e* est présent en quantité prépondérante (95%) dans le mélange à l'équilibre. Ce pourcentage correspond à une différence d'énergie libre entre les deux esters de 2.06 kcal/mol. Par ailleurs la plus grande vitesse de saponification de l'ester équatorial *cis* **6***e* est en accord avec les résultats rapportés antérieurement par Eliel *et al.* (11*c*) pour l'hydrolyse des *tert*-butyl-4 cyclohexane carboxylates d'éthyle (**9***e* et **10***e*).

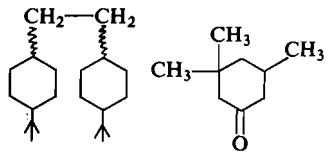
Hydroboration du tert-butyl-4 méthylène-1 cyclohexane (1b)

L'hydroboration de l'alcène **1***b* dans le diglyme selon la technique habituelle (4) conduit après oxydation des organoboranes intermé-

TABLEAU 2. Les résultats de l'épimerisation des esters **6***e* et **7***e*

Esters	δ *CH* (COOEt) (p.p.m.)	% à l'équilibre	Vitesse de saponification ($l\ mol^{-1}\ s^{-1}$)
6*e*	2.44	95	29.02×10^{-4}
7*e*	2.61	5	6.30×10^{-4}

diaires **9***a* et **10***a* aux alcools primaires correspondants **9***b* et **10***b* accompagnés d'un composé auquel on a attribué la structure *bis*(*tert*-butyl-4 cyclohexyl)-1,2 éthane de configuration non déterminée (**11**) par comparaison avec les résultats



11 **12**

obtenus lors de l'hydroboration de l'alcène **1***a*. Les quantités relatives d'alcools **9***b* et **10***b* présents dans le milieu réactionnel ont été déterminées par chromatographie en phase gazeuse par l'intermédiaire de leurs éthers silylés **9***c* et **10***c*, préparés d'après la méthode de Sweeley *et al.* (5). Le produit *cis* **9***b* et le produit *trans* **10***b* seraient présents dans les proportions de 52 et de 48%. L'oxydation du mélange d'alcools par l'acide chromique selon la méthode de Brown et Garg (6) conduit aux acides correspondants **9***d* et **10***d* et leur estérification conduit aux esters éthyliques **9***e* et **10***e*; d'après la chromatographie en phase gazeuse, ils sont présents dans les proportions de 52% de **9***e* et 48% de **10***e*. Ces résultats confirmeraient ceux obtenus à l'aide des éthers silylés et indiqueraient bien que les alcools primaires **9***b* et **10***b* sont formés en quantités pratiquement égales. L'épimérisation du mélange des esters **9***e* et **10***e* a été effectuée dans les conditions classiqués, c'est à dire, dans l'éthanol absolu en présence d'éthylate de sodium à la température de 80°. Le pourcentage des différents isomères à l'équilibre a été déterminé par chromatographie en phase gazeuse et il est de 14.4% d'ester *cis* **9***e* et de 85.6% d'ester *trans* **10***e*. Ce résultat concorde avec celui d'Eliel *et al.* (11*c*) qui ont obtenu 84.7 ± 0.6% d'ester éthylique *trans* **10***e*. La réduction par $LiAlH_4$ du mélange d'esters **9***e* et **10***e* (14.4:85.6) de configuration relative connue permet d'obtenir le mélange des alcools primaires **9***b* et **10***b*. L'analyse par chromatographie en phase gazeuse, après le traitement par les réactifs de silylation, indique la présence de 15.5% d'éther silylé *cis* **9***c* et 84.5% d'éther silylé *trans* **10***c* et permet ainsi d'attribuer les configurations relatives *cis* et *trans* aux alcools primaires **9***b* et **10***b*. Ces résultats sont différents de ceux rapportés, depuis que ce travail a été terminé, par Klein et Litchtenberg (3) qui ont observé que le diborane dans le tétrahydrofuranne s'additionne à l'alcène **1***b* pour conduire à un mélange d'alcools primaires *cis* **9***b* et *trans* **10***b* dans les proportions de 68 et 32%, respectivement.

Discussion

Les résultats obtenus lors de la réaction d'hydroboration des alcènes **1***a*, **1***b* et **2** sont rapportés dans le tableau 3. Pour fins de comparaison, les résultats de l'époxydation des al-

cènes **1***a*, **1***b* et **2**, de l'addition de l'organomagnésien CH_3MgI, de l'addition de l'hydrure de lithium et d'aluminium et de la méthylénation par l'action du méthylure de diméthylsulfonium sur les cétones correspondantes sont aussi rapportés.

On peut déduire de ces résultats que la stéréochimie de la réaction d'hydroboration sur l'alcène **2** est dirigée principalement par la présence du méthyle axial en position 3 par rapport au centre réactionnel qui provoque une réaction par la face opposée de la molécule conduisant principalement à l'alcool primaire **7***b* du type *trans*. La comparaison des résultats obtenus lors de l'hydroboration des alcènes **1***a* et **1***b* met de nouveau en évidence l'influence du groupe méthyle axial en position 2 qui empêche une attaque par cette face de la molécule et provoque l'entrée par la face axiale opposée réduisant ainsi le pourcentage d'entrée équatoriale.

La correspondance entre les résultats rapportés dans le tableau 3 pour les réactions d'hydroboration, d'époxydation, de Grignard, d'addition d'hydrure et de méthylénation montre la similitude des facteurs influençant le cours stéréochimique de ces réactions.

Partie expérimentale

Les instruments utilisés pour déterminer les propriétés physiques des produits obtenus au cours de cette étude ont été décrits dans une publication précédente (21). Les propriétés physiques sont consignées dans le tableau 4. Les poids moléculaires ont été déterminés au moyen d'un osmomètre à pression de vapeur de la compagnie Perkin-Elmer modèle 115 en utilisant le chloroforme comme solvant. La précision est de $\pm 2\%$.

Les séparations par chromatographie en phase gazeuse (c.p.g.) préparative ont été effectuées à l'aide d'un appareil Varian modèle 705 dans les conditions suivantes: (*a*) Colonne en aluminium de 20 pieds par 3/8 de pouce de diamètre remplie de Chromport XXX (80–90 mesh) supportant 20% de son poids de silicone SE-52. La colonne est maintenue à une température de 185°; le collecteur à 115°; le détecteur à 250°; l'injection est faite à 225°. Le gaz porteur est l'azote; son débit est de 165 ml/min. (*b*) Colonne en aluminium de 20 pieds par 3/8 de pouce de diamètre remplie de Chromosorb P (30–60 mesh) supportant 20% de son poids d'hyprose. La colonne est maintenue à une température de 160°; le collecteur à 135°; le détecteur à 255°; et l'injecteur à 225°. Le gaz porteur est l'azote; son débit est de 165 ml/min.

Dans le but de vérifier si tous les pourcentages relatifs d'épimères qui sont rapportés au cours de ce travail sont exacts, des mélanges connus d'épimères ont été préparés par pesée et analysée par c.p.g. Dans chaque cas, le pourcentage obtenu par c.p.g. s'est avéré exact.

Synthèse des tert-butyl-4 hydroxyméthyl-1 diméthyl-2,2 cyclohexanes cis (3b) et trans (4b)

L'hydroboration oxydative de 3 g (16 mmol) d'alcène **1***a* en solution dans le diglyme en suivant la méthode décrite par Brown et Zweifel (4) conduit à 3.6 g d'un liquide visqueux. La chromatographie de 2.83 g de ce mélange sur 200 g d'alumine Woëlm (activité 1) fournit 756 mg du dimère **5** et 1.73 g du mélange des alcools primaires **3***b* et **4***b*. L'analyse de ces alcools, sous forme d'éthers silylés (5), indique la présence de 42.5% d'éther *cis* (**3***c*) et 57.5% d'éther *trans* (**4***c*); une analyse semblable effectuée sur le produit brut de l'hydroboration montre que les composés **5**, **3***c* et **4***c* sont respectivement présents dans les proportions 20:34:46 soit un rapport 42.5:57.5 pour les alcools primaires **3***b*/**4***b*.

L'oxydation de 12 g (61 mmol) du mélange des alcools **3***b* et **4***b* (débarrassé de l'hydrocarbure **5**) selon la technique de Brown et Garg (6) conduit à 6.3 g (50% de rendement) du mélange des acides **3***d* et **4***d* se présentant sous forme de solide de p.f. 115° après recristallisation dans un mélange acide acétique - eau.

L'estérification de 14.6 g (69 mmol) du mélange des acides carboxyliques **3***d* et **4***d* en suivant la technique de Mori (7) permet d'obtenir les esters éthyliques **3***e* et **4***e* correspondants avec un rendement de 50%. Les deux esters **3***e* et **4***e* ont été obtenus à l'état pur par c.p.g. préparative sur la colonne de SE-52; leurs propriétés respectives sont résumées au tableau 4.

La réduction de chacun de ces esters **3***e* et **4***e* par le $LiAlH_4$ dans le THF conduit aux alcools correspondants **3***b* et **4***b* à l'état pur. Les propriétés de ces alcools sont aussi résumées au tableau 4.

L'épimérisation de chacun des esters **3***e* et **4***e* (45 mg, 0.18 mmol) a été effectuée à l'aide de 3.2 ml (0.22 mmol) d'une solution (0.072 *N*) de *tert*-butylate de potassium dans le DMSO; la réaction, sous atmosphère d'azote, dure 18 h.

Synthèse des hydroxyméthyl-1 triméthyl-3,3,5 cyclohexanes 6b et 7b

L'alcène **2** est obtenu avec un rendement de 70% (35 g) à partir de la cétone correspondante **12** (50 g, 0.38 mol) et du méthylène triphénylphosphine, préparé à partir de 185 g (0.5 mol) de bromure de méthyltriphénylphosphonium et de 32 g (0.5 mol) de butyllithium, selon le mode opératoire décrit par Cross et Whitham (12).

L'hydroboration oxydative de 15 g (0.11 mol) de l'alcène **2** selon la technique de Brown et Zweifel (4) conduit à un mélange réactionnel formé de 10% de l'alcool **6***b*, 75% de l'alcool **7***b* et 15% de l'hydrocarbure **8**.

L'hydroxyméthyl-1 triméthyl-3,3,5 cyclohexane *trans* (**7***b*) a été isolé par c.p.g. préparative sur la colonne d'hyprose et purifié par distillation. Ses caractéristiques sont résumées dans le tableau 4.

L'oxydation de 6.5 g du mélange des alcools **6***b* et **7***b* en suivant la procédure de Brown et Garg (6) conduit à 2.1 g (30% de rendement) des acides carboxyliques **6***d* et **7***d* correspondants; l'estérification de 1.6 g de ces acides en opérant selon la technique de Mori (7) conduit aux esters éthyliques **6***e* et **7***e* avec un rendement de 96%.

La c.p.g. préparative permet d'isoler l'ester éthylique *trans* **7***e* à l'état pur; ses caractéristiques sont résumées au

[a]A moins d'indication contraire, les spectres i.r. et r.m.n. ont été déterminés dans le CCl_4.
[b]Les analyses par chromatographie en phase gazeuse (c.p.g.) ont été effectuées à l'aide des appareils suivants: colonne A: F et M (modèle 700) à ionisation de flamme: SE-30 10% – Chromport XXX 80–90, 12 pieds, diamètre 1/4 pouce (3*c*, 4*c* et 5, *T*: 200°, He: 40 ml/min et **11**, *T*: 180°, He: 30 ml/min); colonne B: "Microtek" à détection thermique: SE-52 5% – Chromport XXX 80–90, 15 pieds, diamètre 1/4 pouce (3*e* et 4*e*, *T*: 200°, He: 75 ml/min et 6*e* et 7*e*, *T*: 150°, He: 60 ml/min); colonne C: F et M (modèle 810) à ionisation de flamme: Ucon Polar 20% Chromosorb W 30–60, 15 pieds, diamètre 1/4 pouce, *T*: 160°, He: 30 ml/min; colonne D: "Microtek" à détection thermique: hyprose 15% – Chromosorb P 30–60, 10 pieds, diamètre 1/4 pouce, *T*: 150°, He: 75 ml/min.
[c]La partie AB du système ABX pour le signal du —CH_2OH est obtenue par calcul du premier ordre. Les constantes de couplage de spin, *J*, sont exprimés en Hz. Le centre de symétrie est rapporté pour le signal d'un multiplet ou d'un massif.
[d]Les temps de retention des éthers silylés 3*c* et 4*c* sont respectivement de 21 et 33 min (colonne A).
[e]Spectres r.m.n. déterminés dans $CDCl_3$.

tableau 4. Sa réduction par $LiAlH_4$ conduit à un alcool primaire *trans* **7***b* identique à celui isolé précédemment.

L'acide triméthyl-3,3,5 cyclohexane carboxylique *cis* (**6***d*) est préparé selon la technique de Braude et Evans (13); ses propriétés, identiques à celles rapportées par ces auteurs, sont résumées au tableau 4. Son estérification selon la technique de Mori (7) fournit l'ester éthylique **6***e* avec un rendement de 90%; les propriétés de cet ester sont résumées au tableau 4. Sa réduction par $LiAlH_4$–éther conduit à l'alcool primaire **6***b* à l'état pur; les propriétés de cet alcool sont aussi résumées au tableau 4.

L'épimérisation des esters **6***e* et **7***e* se fait en chauffant 2 mmol d'ester, sous atmosphère d'azote pendant 72 h, en présence de 33 mmol d'éthylate de sodium dans l'éthanol.

Les vitesses de saponification sont obtenues par mesure de conductivité dans une cellule Radiometer du type CDC 104 reliée à un conductomètre Radiometer du type CDC 2d. La cellule est immergée durant toute l'expérience dans un bain maintenu à la température constante de 35.2°. Les mesures sont effectuées en utilisant une solution aqueuse de soude et une solution éthanolique d'ester à saponifier dans des proportions équimoléculaires et les constantes de vitesse sont calculées d'après la méthode du temps infini (22) et sont analysées comme réaction du deuxième ordre. Les résultats de ces cinétiques sont rapportés dans le tableau 2.

Hydroboration du tert-butyl-4 méthylène-1 cyclohexane (1b)

L'hydroboration oxydative de 8.5 g d'alcène **1***b* en solution dans le diglyme en suivant la technique de Brown et Zweifel (4), fournit 10 g de produits réactionnels qui par chromatographie sur 400 g d'alumine Woëlm (activité 1) permet de recueillir 2.6 g du dimère **11** et 7.2 g du mélange des alcools primaires **9***b* et **10***b*. La silylation de cette dernière fraction et son analyse par c.p.g. met en évidence que les quantités relatives des éthers **9***c* et **10***c* sont 52 et 48%.

L'oxydation des alcools **9***b* et **10***b* et l'estérification des acides **9***d* et **10***d*, dont les propriétés sont discutées dans la littérature (7, 23) ont été effectuées de la façon décrite précédemment. L'épimérisation des esters éthyliques **9***e* et **10***e* a été effectuée dans les mêmes conditions que celles décrites par Eliel *et al.* (11*c*).

Les auteurs remercient vivement le Conseil national de recherches du Canada et le Ministère de l'Education de la Province de Québec pour l'aide financière apporté sous forme d'octrois de recherche (A-1295) et de bourses d'étude (C.L.).

The Mechanism of the Microbial Hydroxylation of Steroids. Part 2. Hydroxylation of a Δ^4-3-Ketosteroid Analog by *Rhizopus arrhizus* ATCC 11145

HERBERT L. HOLLAND AND BARBARA J. AURET

Department of Chemistry, The Queen's University of Belfast, Belfast, Northern Ireland BT9 5AG

Received February 7, 1975

HERBERT L. HOLLAND and BARBARA J. AURET. Can. J. Chem. **53**, 2041 (1975).

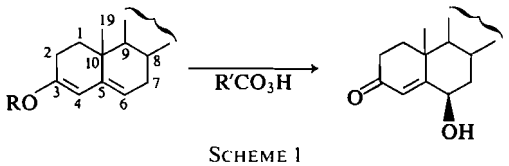
The Δ^4-3-ketosteroid analog (±)-4a-methyl-4,4a,5,6,7,8-hexahydro-2(3*H*)-naphthalenone (**1**) is hydroxylated at both C-8α and C-8β by *Rhizopus arrhizus* ATCC 11145. The ratio of C-8α to C-8β hydroxylation is compared with that obtained from the peracid oxidation of 2-ethoxy-4a-methyl-3,4,4a,5,6,7-hexahydronaphthalene (**4**) and a mechanism is proposed for both microbial and chemical hydroxylation in which the stereochemistry of the product is transition state controlled. The significance of this to the mechanism of microbial C-6β hydroxylation of Δ^4-3-ketosteroids is discussed.

HERBERT L. HOLLAND et BARBARA J. AURET. Can. J. Chem. **53**, 2041 (1975).

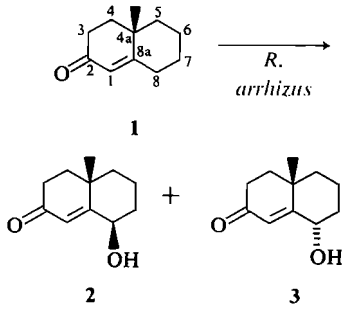
Sous l'action du *Rhizopus arrhizus* ATCC 11145, la (±)-méthyl-4a hexahydro-4,4a,5,6,7,8-(3*H*)naphtalènone-2, qui est un analogue des Δ^4 céto-3 stéroides, est hydroxylée aux positions C-8α et C-8β. On compare les quantités relatives d'hydroxylation en C-8α et en C-8β avec les résultats obtenus lors de l'époxydation de l'éthoxy-2 méthyl-4a hexahydro-3,4,4a,5,6,7 naphtalène; on propose des mécanismes pour les hydroxylations microbiologiques et chimiques indiquant que le produit est contrôlé par l'état de transition. On discute de la signification de ce mécanisme par rapport à celui de l'hydroxylation microbiologique en C-6β des Δ^4 céto-3 stéroides. [Traduit par le journal]

It has long been known (1, 2) that microbial hydroxylations at the enolizable C-2 and C-6 of Δ^4-3-ketosteroids give only axial (β) products: the corresponding equatorial (α) hydroxyketones are not available by microbial methods. Analogously, treatment of steroid enols with electrophiles leads to exclusive axial substitution (3), exemplified by the reaction of $\Delta^{3,5}$ enols with peracids to give only 6β-hydroxy-Δ^4-3-ketones (4) (Scheme 1) and controlled by a stereoelectronic effect arising from preferred interaction of reagent orbitals in the transition state leading to axial substitution (5, 6). It has been proposed (1, 2) that microbial hydroxylations of ketosteroids at enolizable positions involve enolic intermediates and that oxygenation occurs under chemical rather than enzymic control.

We have found a significant lack of stereospecificity in both microbial and chemical hydroxylation at C-8 of the Δ^4-3-ketosteroid analog (±)-4a-methyl-4,4a,5,6,7,8-hexahydro-2(3*H*)-naphthalenone (**1**). Hydroxylation of **1** at C-8 is analogous to C-6β hydroxylation of Δ^4-3-ketosteroids, a reaction performed by *Rhizopus arrhizus* ATCC 11145 (7).



SCHEME 1



1 **2** **3**

SCHEME 2

Incubation of **1** with *R. arrhizus* gave two products, 8β-hydroxy-4a-methyl-4,4a,5,6,7,8-hexahydro-2(3*H*)-naphthalenone (**2**)[1] and 8α-hydroxy-4a-methyl-4,4a,5,6,7,8-hexahydro-2(3*H*)-naphthalenone (**3**) (Scheme 2). Their structures follow from p.m.r. data (Table 1). The position of the C-4a-methyl signal of **2** is characteristic of the presence of 1,3 diaxially disposed hydroxyl

[1]The terms α and β are used with the same connotation as that applicable to the steroid molecule.

TABLE 1. Proton magnetic resonance spectral data of compounds **1–4**

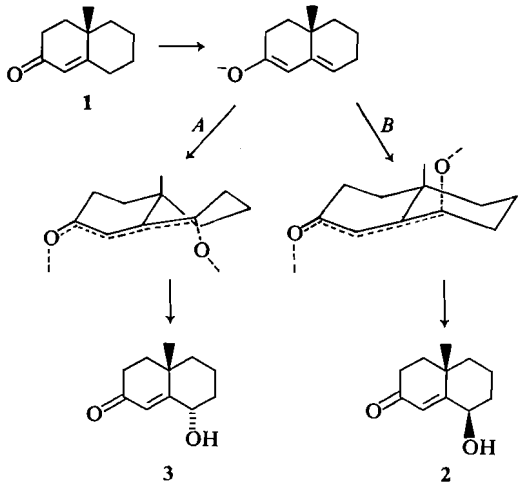
Compound	δ value		
	C-4a methyl	C-1 H	C-8 H
1	1.24	5.74	—
2	1.46	5.80	4.34
3	1.24	6.22	4.10–4.40
4	1.02	5.18–5.30	

(8) and confirmation of structure is provided by the width of the C-1 proton signal ($\omega_{1/2}$ = 1.3 Hz). The C-1 proton of **1** is, by analogy with corresponding steroids (9) coupled to the C-8β proton and appears as a broad singlet ($\omega_{1/2}$ = 3.8 Hz). The C-4a-methyl and methine proton geminal to hydroxyl of **3** show signals consistent with substitution at C-8α. Confirmation of structure comes from the C-1 proton signal at δ 6.22 (d, J = 2.0 Hz). A similar downfield shift and multiplicity is observed for the C-4 proton of C-6α substituted Δ^4-3-ketosteroids (10). The conversion of **2** to **3** has been achieved by acid catalysis.

The use of replacement culture (see Experimental) implies that the hydroxylation of **1** is performed by an enzyme which is noninduced and therefore a normal constituent of the fungus. Incubation of **1** with autoclaved *R. arrhizus* did not give transformation products and control experiments confirm that **2** is stable under the incubation conditions, excluding formation of **3** from **2**. We therefore feel that **2** and **3** are produced by the steroid C-6β hydroxylase but rigid proof of this is presently lacking.

The epimers **2** and **3** were obtained in the ratio 13 to 1. The microbial hydroxylation of **1** thus shows no stereoselectivity such as that observed for Δ^4-3-ketosteroids, where concomittant C-6α and C-6β hydroxylation has not been observed (1). Incubation of Δ^4-3-ketosteroids under conditions identical with those used for the hydroxylation of **1** does not give C-6α hydroxylated products (1, 7).[2]

The results may be rationalized by a consideration of the conformational mobility of **1** and the postulate that hydroxylation proceeds via the $\Delta^{2,8a}$ enol. Malhotra and Ringold have shown (5) that the transition state for electrophilic addition to a $\Delta^{3,5}$ enolic steroid resembles the keto form. The C-6—O bond is almost complete and the C-5—C-6 bond has lost most of its π electron density. Ring B is close to a chair conformation with the C-6β bond axial. During electrophilic addition to the bicyclic system, however, the C-8α bond may become pseudoaxial in a transition state with a twist-boat conformation of ring B. Attack of oxygen under stereoelectronic control will, favoring axial addition, form the C-8α substituted product **3** (Scheme 3, route *A*). Proceeding via a transition state with ring B in the chair conformation, the C-8β substituted product **2** will result. For the more rigid steroid molecule, only a transition state with ring B in the chair form is feasible and only C-6β substitution is observed. The proportion of **2** to **3** may therefore reflect the relative stabilities of the transition states (Scheme 3) from which C-8α or C-8β becomes axial.



SCHEME 3

If the concurrent microbial formation of **2** and **3** is a consequence of the stereoelectronic control of oxygen addition to the enol, a parallel should exist in the chemical reaction of that enol with electrophilic oxygen. Accordingly, the enol ether **4** was prepared and its oxidation studied. The structure of **4** follows from u.v. spectral data (11) and p.m.r. analysis (Table 1) (8).

A close parallel with the microbial reaction was observed on oxidation of **4** with *m*-chloroperbenzoic acid (Scheme 4), when **2** and **3** were obtained in the ratio 4 to 1. Control experiments have shown that **2** is stable under the

SCHEME 4

reaction conditions and so the formation of **3** from **2** may be discounted. The formation of both **2** and **3** indicates that, if normal stereoelectronically controlled axial addition is operative, then two reaction pathways such as those discussed above must be present. The greater degree of selectivity observed in the enzymic process may be due to some enzyme control of oxygen addition, but the microbial formation of **3** indicates that such control, if present, is not rigid.

The parallel between the peracid oxidation of **4** and the microbial hydroxylation of **1** thus suggests that prior enolization of **1** occurs in the microbial reaction but this cannot be definitively stated without further investigation.

Experimental

Apparatus, Materials, and Methods

Melting points were determined on a Kofler heating stage and are uncorrected. Infrared spectra were recorded with a Perkin-Elmer 137 and ultraviolet spectra in methanol solution with a Perkin-Elmer 402. Extinction coefficients were measured on a Unicam SP500. Proton magnetic resonance spectra were obtained at 100 MHz with a Varian HA100 or at 60 MHz on a Varian A60, using deuteriochloroform as solvent and tetramethylsilane as internal standard. Mass spectra were obtained with an AEI MS902 at an ionizing voltage of 70 eV. Accurate mass measurements were made by reference to appropriate ions of the perfluorokerosene spectrum.

Column chromatography was performed on silica gel (Woelm activity 1) and thin-layer chromatography on Merck silica $PF_{254+366}$.

Rhizopus arrhizus ATCC 11145 was obtained from the American Type Culture Collection, Washington D.C. and was maintained on 2% malt agar slopes.

Incubations with R. arrhizus

The fungus was grown in a medium consisting of a solution of glucose (250 g), peptone (100 g), and corn steep liquor (Dista Products Ltd., 15 ml) in water (5 l). One-litre Erlenmeyer flasks, each containing 150 ml of medium, were sterilized at 15 p.s.i. for 20 min and allowed to cool. A spore suspension obtained from an agar slope of the fungus by shaking with sterile glass beads in water was transferred to each flask using a sterile syringe and the flasks incubated on a rotary shaker (180 r.p.m.) at 28° for 60 h. The mycelium was then separated by centrifugation, washed by maceration with water, and resuspended in aliquots of distilled water (150 ml) in 1-l Erlenmeyer flasks. A solution of **1** (50 mg) in ethanol (3 ml) was added to each flask and shaking continued at 28° for a further 24 h; the p*H* of the suspension during this time remained constant at 5.0–5.3. The mycelium and water were separated by centrifugation and both extracted with dichloromethane. The combined organic extract was dried and evaporated to give a residue which was subjected to chromatography.

Incubation with autoclaved *R. arrhizus* was performed as follows. The washed mycelium, obtained as above, was resuspended in distilled water in 1-l Erlenmeyer flasks (150 ml per flask) and then autoclaved at 15 p.s.i. for 20 min. After cooling the suspension, the substrate was added and subsequent operations performed as above. The p*H* of the suspension of autoclaved mycelium was 5.0–5.3.

Incubation of 4a-Methyl-4,4a,5,6,7,8-hexahydro-2(3H)-naphthalene (1) (12)

Incubation of **1** (2 g) gave a residue (1.79 g) which was chromatographed by 5% stepwise elution from chloroform to dioxan to give **1** (0.32 g), b.p. 110–112°/2.5 mm, 2,4-DNP m.p. 166–169° (lit (12) b.p. 102–110°/2.5 mm, 2,4-DNP m.p. 169°).

8β-Hydroxy-4a-methyl-4,4a,5,6,7,8-hexahydro-2(3H)-naphthalenone (**2**) (0.43 g), b.p. 124–126°/0.15 mm; n^{22} 1.5362; i.r.: ν_{max} (film) 3440, 1680, 1640 cm^{-1}, u.v.: λ_{max} 234 nm (log ε 4.18), p.m.r.: included signals at δ 1.46 (3H, s, C-4a methyl), 4.34 (1H, t, J = 3, 3 Hz, C-8 H), 5.80 (1H, s, $\omega_{1/2}$ = 1.3 Hz, C-1 H); 2,4-DNP m.p. 155–157° (EtOH).

Anal. Calcd. for $C_{11}H_{16}O_2$: C, 73.29; H, 8.94. Found: C, 72.98; H, 8.82.

8α-Hydroxy-4a-methyl-4,4a,5,6,7,8-hexahydro-2(3H)-naphthalenone (**3**) (0.032 g), b.p. 100–110°/0.1 mm; M^+ 180.1158 ($C_{11}H_{16}O_2$ requires 180.1150); i.r.: ν_{max} (film) 3440, 1680, 1640 cm^{-1}; u.v.: λ_{max} 238 nm (log ε 4.20); p.m.r.: included signals at δ 1.24 (3H, s, C-4a methyl), 4.10–4.40 (1H, m, C-8 H), 6.22 (1H, d, J = 2.0 Hz, C-1 H); 2,4-DNP m.p. 234–236° (dec.) (EtOH).

Anal. Calcd. for $C_{11}H_{16}O_2$: C, 73.29; H, 8.98. Found: C, 73.12; H, 8.90.

Incubation of **2** with *R. arrhizus* resulted in the recovery on an oil which was shown by chromatographic and spectral analysis to consist of unchanged **2** only.

Epimerization of the Alcohol 2

A solution of **2** (0.4 g) in methanol (5 ml) and hydrochloric acid (37%, 0.3 ml) was stirred at room temperature for 12 h and then poured onto water (25 ml) and extracted with ether (3 × 10 ml). The extract was washed with 2 *M* sodium bicarbonate and water, and then dried and evaporated to give a residue which, on purification by passage through a short column of silica in ether, afforded an oil (0.37 g), identical in all respects with **3**.

2-Ethoxy-4a-methyl-3,4,4a,5,6,7-hexahydronaphthalene (4)

This was prepared from **1** (5 g) and ethylorthoformate (5 ml) by the method described (13). Distillation gave the title compound (3.2 g, 61%), b.p. 68–72°/0.35 mm; n^{21} 1.5190; i.r.: ν_{max} (film) 1650, 1625 cm^{-1}; u.v.: λ_{max} 240 nm (log ε 4.14); p.m.r.: included signals at δ 1.02 (3H, s, C-4a methyl), 1.30 (3H, t, J = 7, 7 Hz, $—CH_2CH_3$), 3.79 (2H, q, J = 7, 7, 7 Hz, $—CH_2CH_3$), 5.18–5.30 (2H, m, C-1 and C-8 H's).

Anal. Calcd. for $C_{13}H_{20}O$: C, 81.20; H, 10.48. Found: C, 81.29; H, 10.55.

Oxidation of 4 by m-Chloroperbenzoic Acid

A solution of m-chloroperbenzoic acid (2.59 g, 80%, 0.012 mol) and sodium hydroxide (0.24 g, 0.006 mol) in 50% aqueous dioxan (200 ml) was added over a period of 1 h to a stirred solution of **4** (1.96 g, 0.01 mol) in 50% aqueous dioxan (200 ml) at room temperature. Stirring was continued at room temperature for 12 h and then water (500 ml) was added and the mixture extracted with dichloromethane (4 × 100 ml). The extract was washed with 2 *M* sodium sulfite, 2 *M* sodium bicarbonate and water, and then dried and evaporated to give an oil which was chromatographed to give 4a-methyl-4,4a,5,6,7,8-hexahydro-2(3*H*)-naphthalenone (**1**) (0.2 g, 12%), identified by spectral and t.l.c. comparison with an authentic sample, *8β-hydroxy-4a-methyl-4,4a,5,6,7,8-hexahydro-2(3H)-naphthalenone* (**2**) (1.24 g, 64%), b.p. 120–125°/0.15 mm, 2,4-DNP m.p. 156–158° (EtOH), identical in spectral and t.l.c. comparison with a sample of **2** obtained from the incubation of **1** with *R. arrhizus*, and *8α-hydroxy-4a-methyl-4,4a,5,6,7,8-hexahydro-2(3H)-naphthalenone* (**3**) (0.3 g, 16%), b.p. 100–110°/0.1 mm, 2,4-DNP m.p. 234–236° (dec.) (EtOH), identical in spectral and chromatographic properties with a sample of **3** produced by the incubation of **1** with *R. arrhizus*.

The alcohol **2** was recovered unchanged following treatment with *m*-chloroperbenzoic acid by the above procedure.

The award of a demonstratorship (to HLH) from the Queen's University of Belfast is gratefully acknowledged, as also is the able technical assistance of Miss H. Reid with the microbiological work.

Thanks are also due to Dr. D. B. MacLean of McMaster University, Hamilton, Ontario, who read the manuscript and offered many helpful suggestions.

Bridged Xanthenes. I. An Intermolecular Cycloaddition Route

PETER YATES AND D. J. BICHAN

Lash Miller Chemical Laboratories, University of Toronto, Toronto, Ontario M5S 1A1

Received January 22, 1975

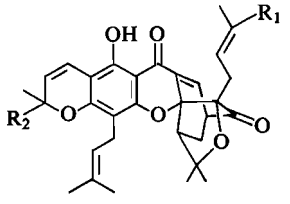
PETER YATES and D. J. BICHAN. Can. J. Chem. **53**, 2045 (1975).

Condensation of *o*-hydroxybenzyl alcohol (**4**) with 1,3-cyclohexanedione (**7**) in hexamethylphosphoramide gives 3,4-dihydro-1(2*H*)-xanthenone (**9**). Treatment of the tosylhydrazone of **9** with methyllithium gives 3,4-dihydroxanthene (**12**), which undergoes Diels–Alder reactions with dimethyl acetylenedicarboxylate and propiolonitrile to give the bridged xanthenes **15** and **17**, respectively. Condensation of *o*-hydroxybenzyl alcohol (**4**) with 4-carboxamido-1,3-cyclohexanedione (**29**) and 4-carbomethoxy-1,3-cyclohexanedione (**38**) gives 2-carboxamido- (**30**) and 2-carbomethoxy-3,4-dihydro-1(2*H*)-xanthenone (**39**), respectively.

PETER YATES et D. J. BICHAN. Can. J. Chem. **53**, 2045 (1975).

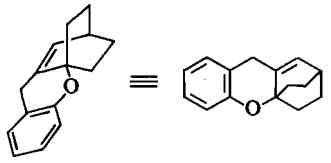
La condensation de l'alcool *o*-hydroxybenzylique (**4**) avec la cyclohexanedione-1,3 (**7**) dans l'hexaméthylphosphoramide conduit à la dihydro-3,4 (2*H*)-xanthènone-1 (**9**). Une réaction entre la tosylhydrazone de **9** et le méthyllithium fournit le dihydro-3,4 xanthène (**12**) qui peut subir des réactions de Diels–Alder avec l'acétylènedicarboxylate de méthyle et le propiolonitrile pour conduire respectivement aux xanthènes pontés **15** et **17**. La condensation de l'alcool *o*-hydroxybenzylique (**4**) avec la carboxamido-4 cyclohexanedione-1,3 (**29**) et la carbométhoxy-4 cyclohexanedione-1,3 (**38**) conduit respectivement aux carboxamido-2 (**30**) et carbométhoxy-2 dihydro-3,4 (2*H*)-xanthènone-1. [Traduit par le journal]

The naturally occurring coloring matters morellin (**1**) (1) and gambogic acid (**2**) (2) and their congeners have a nucleus consisting of the 2,4a-ethano-2,3,4,4a-tetrahydroxanthene system (**3**). In this and the following paper (3) we



1 $R_1 = CHO; R_2 = CH_3$
2 $R_1 = CO_2H; R_2 = CH_2CH_2CH{=}C(CH_3)_2$

discuss two methods that we have developed for the synthesis of this bridged xanthene system.[1] While this work was in progress Quillinan and Scheinmann (5) reported a third route to this system.



3

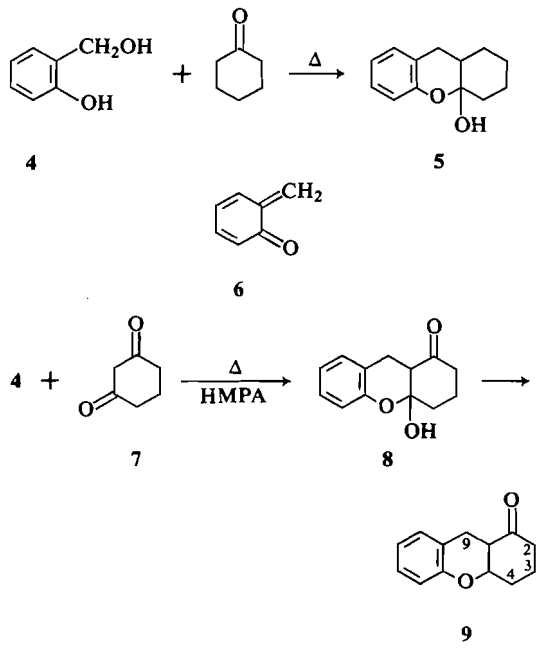
[1]For preliminary accounts of this work, see ref. 4.

The approach to be described here is based on the synthesis of the bicyclo[2.2.2]octene system of **3** via a Diels–Alder reaction of the corresponding 1,3-diene with an external dienophile; our other approach (3) involves an intramolecular cycloaddition reaction. The 1,3-dienes required for the intermolecular cycloadditions are 3,4-dihydroxanthenes, a class of compounds that had not been described hitherto. We therefore first addressed ourselves to developing a method for the synthesis of such compounds.

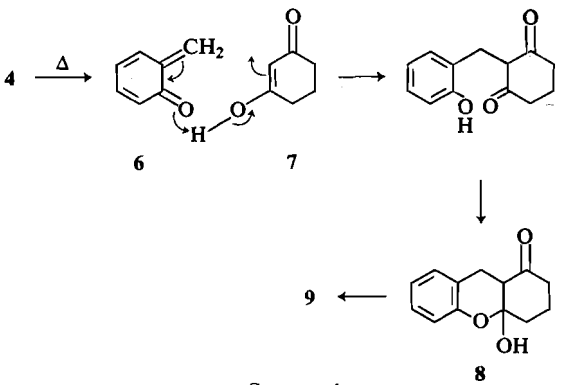
Quagliaro *et al.* (6) have shown that when *o*-hydroxybenzyl alcohol (**4**) and cyclohexanone are heated together to 200° the alcohol **5** is formed; the yield is increased by amine catalysis and *o*-quinonemethide (**6**) is considered to be an intermediate (*cf.* ref. 7). This suggested to us that the reaction of **4** with 1,3-cyclohexanedione (**7**) might provide a ready route to 3,4-dihydro-1(2*H*)-xanthenone (**9**) via dehydration of an intermediate of type **8**, analogous to **5**.

In the event, when **4** was heated with **7** in hexamethylphosphoramide (HMPA) at 195°, a crystalline product was obtained in 43% yield whose elemental composition and spectral characteristics are in accord with its formulation as **9**. Bands at 6.00 (shoulder) and 6.05 μ in its i.r. spectrum and maxima at 221 nm (ε 11 100) and 286 nm (ε 6100) in its u.v. spectrum

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

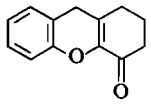


are in good accord with the presence of a β-aryloxy-α,β-enone chromophore. A broad two-proton singlet in its p.m.r. spectrum at δ 3.50 can be assigned to the methylene protons at C.9; multiplets at δ 2.03 (2 H), 2.45 (4 H), and 7.14 (4 H) are attributable to the C.3 protons, the C.2 and C.4 protons, and the aromatic protons, respectively. These data do not rigorously exclude the alternative formulation **10** for this product; however, structure **7** is much more likely on mechanistic grounds (Scheme 1) and was confirmed by subsequent transformations.[2]



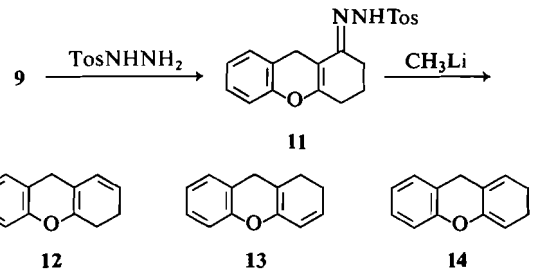
SCHEME 1

[2]For another route to 3,4-dihydro-1(2*H*)-xanthenones, see ref. 8.



10

Compound **9** was converted via its tosylhydrazone **11** to 3,4-dihydroxanthene (**12**) by the method of Dauben *et al.* (9). The diene **12** was obtained in 76% overall yield from **9**; its elemental composition and spectral characteristics are in accord with the structural assignment but do not distinguish it from **13**, the product that would be anticipated from **10**.[3] Bands at 5.92 (m) and 6.03 (w) μ in its i.r. spectrum and maxima in its u.v. spectrum at 290 (ε 6400), 298 (sh, ε 6000), and 314 nm (sh, ε 3700) are in accord with the presence of an aryloxy-1,3-cyclohexadiene chromophore. Two one-proton signals in its p.m.r spectrum at δ 5.56 (m) and 5.68 (d, J = 9 Hz) can be assigned to the vinylic protons at C.2 and C.1, respec-



tively; a two-proton singlet at δ 3.29 and a four-proton multiplet centered at δ 6.96 are attributable to the C.9 methylene protons and the aromatic protons, respectively; the remaining protons at C.3 and C.4 give rise to a "deceptively simple" doublet at δ 2.29.

Treatment of **12** with dimethyl acetylenedicarboxylate at room temperature gave a 1:1 adduct in 95% yield. This is assigned the bridged xanthene structure **15**. Its i.r. spectrum shows the presence of two nonequivalent ester groups with carbonyl-stretching bands at 5.70 and 5.78 μ as does its p.m.r. spectrum with two three-proton singlets at δ 3.69 and 3.73. The latter spectrum shows a two-proton broad

[3]Another possible structure, **14**, may be considered to be unlikely, since diene formation from the tosylhydrazones of α,β-enones has previously been observed to occur exclusively via removal of the α′- rather than the δ-hydrogen (9).

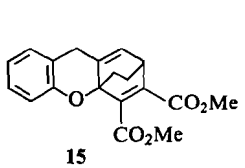
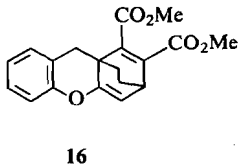
singlet at δ 3.48 assigned to the benzylic allylic protons, broadened by slight nonequivalence and by allylic coupling with the olefinic proton. This gives rise to a doublet of triplets at δ 6.11 (1 H), owing to vicinal coupling with the bridgehead proton (J = 6 Hz) in addition to allylic coupling with the two benzylic allylic protons (J = 2 Hz). The doubly allylic bridgehead proton gives a signal at δ 4.17 (1 H), which is a doublet of triplets, attributable to coupling with the vinyl proton (J = 6 Hz) and with each of the methylene protons adjacent to it (J = 3 Hz). Examination of a molecular model indicated that the dihedral angles in this latter situation are each *ca* 60°, in accord with the magnitude of the coupling observed. The u.v. spectrum of the adduct shows absorption comparable with that of chroman (*cf.* ref. 10).



15



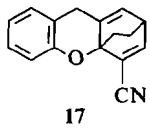
16

The formation of the adduct **15** not only confirms the presence of the 1,3-diene system in **12** but also provides evidence against the alternative diene structure **13**. The adduct of the latter with dimethyl acetylenedicarboxylate would have structure **16**, which is contraindicated by the splitting pattern of the vinylic proton signal in the p.m.r. spectrum of the adduct.[4]

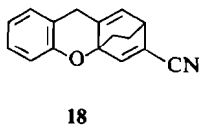
A second bridged xanthene, **17**, was obtained in 93% yield by treating **12** with boiling propiolonitrile (b.p. 42.5°). A choice of structure **17** rather than its regioisomer **18** can be made on the basis of p.m.r. spectroscopy. A one-proton complex multiplet at δ 3.71 is assigned to the bridgehead proton; when double irradiation was carried out at the frequency corresponding to the signal of the adjacent methylene protons, the bridgehead proton signal collapsed to a triplet (J = 6 Hz). This is in accord with equal coupling between the bridgehead proton and the two vicinal vinylic protons of **17**; such equal coupling would not be possible in **18**, where one of the vinyl protons is vicinal and the other allylic with respect to the bridgehead proton.

[4]This spectrum excludes structure **14** for the diene.

In contrast to the case of **15**, the benzylic allylic methylene protons of **17** show a distinct difference in chemical shift, giving rise to a pair of one-proton doublets of doublets at δ 3.40



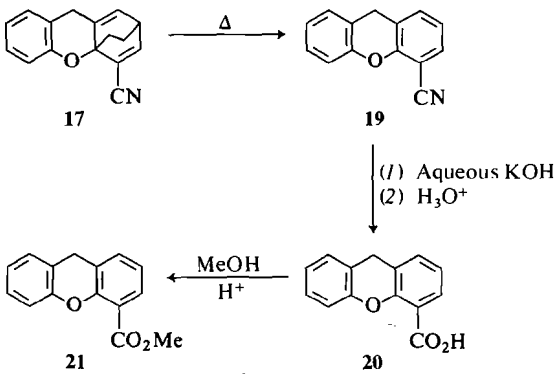
17



18

and 3.51. The coupling constants are 17 and 2 Hz; the former is attributable to geminal coupling between the methylene protons and the latter to coupling of each with the allylic proton. The presence of an α,β-unsaturated nitrile group in **17** was confirmed by a band at 4.54 μ in its i.r. spectrum; its u.v. spectrum resembles that of chroman (10).

Full confirmation of the foregoing assignments was accomplished by a simple degradation of **17**. When **17** was treated at 163° for 5 min, a retro-Diels–Alder reaction occurred with elimination of ethylene to give 4-cyanoxanthene (**19**). The structure of the latter was established by its hydrolysis to 4-xanthenecarboxylic acid (**20**) and the esterification of this to methyl 4-xanthenecarboxylate (**21**) (Scheme 2). The



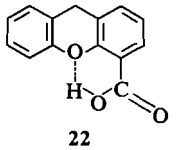
17 19 21 20

SCHEME 2

methylene proton signal in the p.m.r. spectrum of **19** occurs at δ 4.04 (*cf.* xanthene, δ 4.01) but the seven aromatic protons were not differentiable and thus the position of attachment of the nitrile group was not immediately apparent, although its presence was demonstrated by a band at 4.49 μ in the i.r. spectrum of the pyrolysis product. However, the carboxylic acid **20** is a known compound (11) and is reported to have a similar m.p. and u.v. spectrum

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

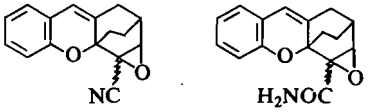
to that of the hydrolysis product obtained here (see Experimental). Furthermore, the carbonyl-stretching band in the i.r. spectrum of this product occurs at 5.76 μ; this is at unusually low wavelength for an aromatic carboxylic acid but is explicable in terms of strong intramolecular hydrogen bonding in the 4-xanthenecarboxylic acid (*cf.* **22**), which disrupts the dimeric structure normally assumed by carboxylic acids in solution. Related phenomena have been thoroughly documented in the i.r. spectra of other *o*-phenoxybenzoic acids (12). Finally, in accord with these structural assignments, the p.m.r. spectrum of the methyl ester **21** shows a one-proton signal at *ca* 0.6 p.p.m. downfield from the signals of the other six aromatic protons; this signal is a doublet of doublets (J = 7 and 2 Hz) and can be assigned to the C.3 proton of **21**.



22

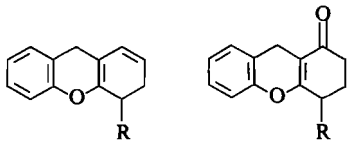
The determination of **19** as the structure of the pyrolysis product from **17** not only establishes the structure of the latter, but also establishes the structure of the diene **12** and, in turn, of the ketone **9**.

Some preliminary experiments were carried out on the further transformation of **17** to a compound with functionality more closely related to **1** and **2**. Epoxidation with *t*-butyl hydroperoxide and potassium *t*-butoxide in dimethyl sulfoxide (*cf.* ref. 13) gave a mixture of products that are considered to be the epimers **23** (see Experimental). These products could not be separated and were not fully characterized; treatment with aqueous alkali gave a mixture considered to consist of the epimeric amides **24**.



23 **24**

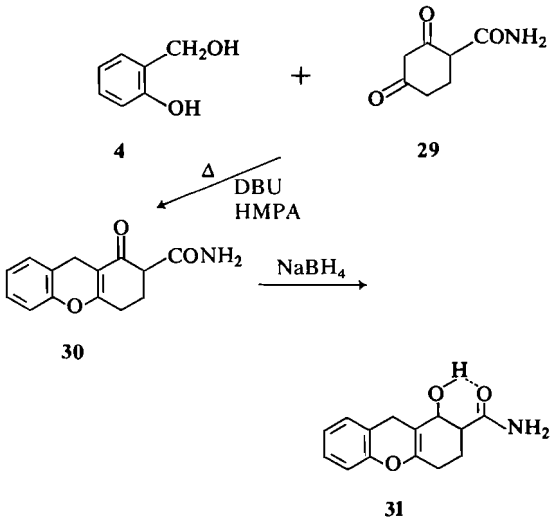
Since any closer approach to **1** and **2** via compounds of type **17** would require the presence of a functional group on the ethano bridge, modifications of the route to **17** were



25 R = $CONH_2$ **27** R = $CONH_2$
26 R = CO_2Me **28** R = CO_2Me

undertaken in attempts to prepare compounds **25** and **26**. This required the preparation of the ketones **27** and **28**. When *o*-hydroxybenzyl alcohol (**4**) and 4-carboxamido-1,3-cyclohexanedione (**29**) (14) were heated at 185° in a mixture of HMPA and 1,5-diazabicyclo[5.4.0]undec-5-ene (DBU), one major product was formed in 67% yield. The elemental composition and spectra of this product were in accord with its formulation as either **27** or **30**, as was the fact that on treatment with boiling hydrochloric acid it gave compound **9**.

Evidence suggesting that this product is **30** rather than **27** was obtained by its reduction with sodium borohydride, which gave a dihydro compound arising from reduction of the ketonic



4 **29**

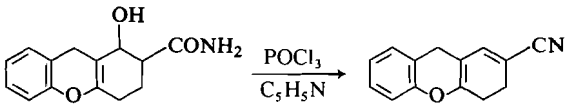
30

31

group. The position of the amide carbonyl-stretching band in the i.r. spectrum of this product at 6.02 μ indicates that the amide carbonyl group is hydrogen bonded with the hydroxyl group as in **31** and that the original product is **30**. This conclusion is buttressed by the observation that bisdehydration of the dihydro compound with phosphorus oxychloride and pyridine gave a product whose spectra

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

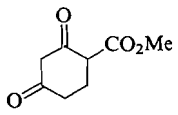
are in accord with its formulation as 2-cyano-3,4-dihydroxanthene (**32**). Thus its i.r. spectrum shows a band at 4.55 μ attributable to an extensively conjugated nitrile group; a high intensity maximum at 336 nm (ε 12 100) also suggests extensive conjugation. Its p.m.r. spectrum shows a single vinyl proton signal at δ 6.53 that appears as a slightly broadened singlet. These data exclude structures **33** and **34** for this product, one or both of which would have been expected to have arisen from the keto amide had it had structure **27**.



31 **32**

33 **34**

Full confirmation of these conclusions was obtained by dehydrogenation of **32** with 5% palladium-on-carbon, which afforded 2-cyanoxanthene (**35**); this in turn was hydrolyzed to the corresponding carboxylic acid **36**, which was esterified to give the methyl ester **37** (Scheme 3). Although **35** and **36** were not fully characterized, it was demonstrated that their i.r. spectra were different from those of the corresponding 4-substituted xanthenes, **19** and **20**, respectively. The ester **37** was fully characterized and shown to be different from methyl 4-xanthenecarboxylate (**21**). Furthermore, as expected in terms of the earlier considerations relating to the 4-substituted xanthene series, the carbonyl-stretching band in the i.r. spectrum of **36** occurs at 5.91 μ and the p.m.r. spectrum of **37** shows the presence of two low field aromatic proton signals. Thus structure **27** can be excluded for the keto amide and structure **30** must be assigned to it.

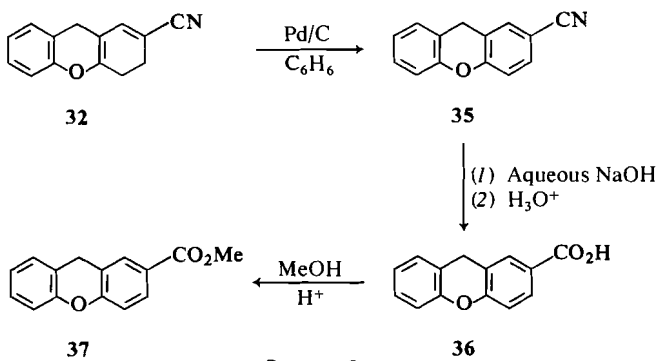


38

Attention was next turned to the case of an ester rather than an amide substituent. When *o*-hydroxybenzyl alcohol (**4**) and 4-carbomethoxy-1,3-cyclohexanedione (**38**) were heated together at 100° without solvent under reduced pressure (15 mm), one major product was formed in 51% yield. The elemental composition and spectra of this product were in accord with its formulation as either the 4-carbomethoxy derivative **28** or the 2-carbomethoxy compound **39**. Reduction, dehydration, and dehydrogenation of this product gave via **40** and **41** a compound that was identical with the ester **37** obtained from **30**; again the undesired regioisomer had been formed and the original keto ester must be **39** (Scheme 4).

Thus, although the generality of the method for the synthesis of 3,4-dihydro-1(2*H*)-xanthenones has been demonstrated[5] and the conversion of the parent compound to bridged xanthenes has been effected, a close approach to the more ramified systems of compounds **1** and **2** by this route has encountered obstacles.

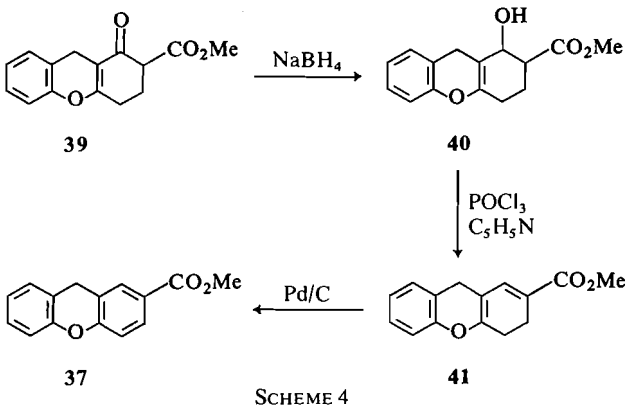
[5]For other examples, see ref. 4*a*.



32 **35**

37 **36**

SCHEME 3



39 40 37 41

SCHEME 4

Although these may well not be insuperable, the successful outcome of an alternative approach that leads to a bridged xanthene incorporating several of the additional features of **1** and **2** (3) led us to place the present approach in abeyance.

Experimental

Melting points were determined with a Thomas Hoover Uni-Melt apparatus and are uncorrected. Infrared spectra were recorded in chloroform solution, ultraviolet spectra in methanol solution, and proton magnetic resonance spectra in deuteriochloroform, unless otherwise indicated. Solutions in organic solvents were dried over anhydrous magnesium sulfate.

3,4-Dihydro-1(2H)-xanthenone (9)

o-Hydroxybenzyl alcohol (**4**) (12.40 g, 100 mmol), 1,3-cyclohexanedione (7) (11.20 g, 100 mmol), and hexamethylphosphoramide (15 ml) were heated together to 195° for 30 min. The cooled solution was taken up in benzene (500 ml) and washed with 5% hydrochloric acid (2 × 400 ml), aqueous 10% sodium hydroxide (3 × 300 ml), and water (400 ml), dried, and evaporated to yield 8.52 g (43%) of **9**, m.p. 79–89°, which after two recrystallizations from methanol had m.p. 90.3–91.3°; $\lambda_{max}(CCl_4)$ 6.00 (sh), 6.05, 7.22 μ; λ_{max}(EtOH) (ε) 221 (11 100), 286 (6100) nm; δ 2.03 (m, 2 H), 2.45 (m, 4 H), 3.50 (br s, 2 H), 7.14 (m, 4 H); *m/e* 200.

3,4-Dihydro-1(2H)-xanthenone Tosylhydrazone (11)

3,4-Dihydro-1(2*H*)-xanthenone (**9**) (4.42 g, 22.1 mmol) and *p*-toluenesulfonylhydrazine (4.11 g, 22.1 mmol) were dissolved in 95% ethanol (125 ml) and the solution was stirred for 17 h at room temperature in the presence of 10% hydrochloric acid (10 drops). Filtration yielded 6.59 g (82%) of **11**, m.p. 215–216° (dec.). The filtrate was evaporated to 25 ml and allowed to crystallize to yield a further 670 mg (8%) of **11**, m.p. 212–215° (dec.). Three recrystallizations of the first crop from acetone gave material with m.p. 219–220° (dec.); λ_{max} 3.08 (w), 3.17 (w), 6.00 μ; λ_{max} (ε) 288 (16 400) nm; δ 1.86 (m, 2 H), 2.34 (m, 4 H), 2.40 (s, 3 H), 3.45 (br s, 2 H), 7.18 (m, 6 H), 7.97 (d, J = 8 Hz, 2 H); *m/e* 368.

3,4-Dihydroxanthene (12)

A slurry of 3,4-dihydro-1(2*H*)-xanthenone tosylhydrazone (**11**) (1.73 g, 4.70 mmol) in anhydrous ether (15 ml) was stirred in an ice bath. Ethereal 2.43 *M* methyllithium (10 ml, 24.3 mmol) was added dropwise over 20 min. Stirring was continued for 1 h until gas evolution ceased. The mixture was poured into pentane (200 ml) and water was very carefully added dropwise with stirring until two clear layers separated. The pentane layer was decanted and the aqueous layer was extracted again with pentane (150 ml). The combined extracts were dried and evaporated to yield 800 mg (93%) of **12** as an oil that after sublimation (65°, 0.1 mm) had m.p. 33–35°; $\lambda_{max}(CCl_4)$ 5.92 (m), 6.03 (w) μ; λ_{max} (ε) 290 (6400), 298 (sh, 6000), 314 (sh, 3700) nm; δ 2.29 (d, J = 2 Hz, 4 H), 3.29 (s, 2 H), 5.56 (m, 1 H), 5.68 (d, J = 9 Hz, 1 H), 6.96 (m, 4 H); *m/e* 184.

Reaction of 12 with Dimethyl Acetylenedicarboxylate: Diester 15

3,4-Dihydroxanthene (**12**) (122 mg, 0.66 mmol) and dimethyl acetylenedicarboxylate (94 mg, 0.85 mmol) were mixed and the mixture was allowed to stand at room temperature for 16 h. Deuteriochloroform (0.5 ml) was added and the solution was allowed to stand at room temperature for 33 h. The deuteriochloroform was evaporated and the residue was placed under vacuum (0.03 mm) for 19 h to yield 205 mg (95%) of **15** as a gum that solidified at −20°. Three recrystallizations from methanol gave material with m.p. 92–96°; $\lambda_{max}(CCl_4)$ 5.70, 5.78, 5.97 (w), 6.09 (w) μ; λ_{max} (ε) 269 (2100), 278 (1700), 305 (650) nm; δ 1.70 (m, 4 H), 3.48 (br s, 2 H), 3.69 (s, 3 H), 3.73 (s, 3 H), 4.17 (dt, J = 6, 3 Hz, 1 H), 6.11 (dt, J = 6, 2 Hz, 1 H), 7.04 (m, 4 H); *m/e* 326.

Anal. Calcd. for $C_{19}H_{18}O_5$: C, 69.92; H, 5.56. Found: C, 70.10; H, 5.58.

Reaction of 12 with Propiolonitrile: Nitrile 17

3,4-Dihydroxanthene (**12**) (500 mg, 2.72 mmol) was dissolved in propiolonitrile (1.0 g, 20 mmol) and the solution was boiled under reflux for 10 h. The excess propiolonitrile was distilled and the residue was taken

up in benzene and placed on a column of silica gel (12 g). Elution with benzene yielded 600 mg (93%) of **17** as an oil. Crystallization and recrystallization from methanol yielded material with m.p. 75–78°; $\lambda_{max}(CCl_4)$ 4.54 (m) μ; λ_{max} (ε) 270 (1600), 276 (1400) nm; δ 1.62 (m, 4 H), 3.40 (dd, J = 17, 2 Hz, 1 H), 3.51 (dd, J = 17, 2 Hz, 1 H), 3.71 (m, 1 H), 5.95 (dt, J = 6, 2 Hz, 1 H), 7.14 (m, 5 H); *m/e* 235.

4-Cyanoxanthene (19)

Nitrile **17** (282 mg, 1.20 mmol) was heated to 163° for 5 min while a colorless gas was evolved. The residue solidified on cooling to give 248 mg (100%) of **19**. Two recrystallizations from ethanol–acetone gave material with m.p. 91–93°; $\lambda_{max}(CCl_4)$ 4.49 (w) μ; λ_{max} (ε) 252 (7000), 279 (2100), 307 (4200) nm; δ 4.04 (s, 2 H), 7.29 (m, 7 H); *m/e* 207.

Anal. Calcd. for $C_{14}H_9NO$: C, 81.14; H, 4.38; N, 6.76. Found: C, 81.24; H, 4.40; N, 6.76.

Xanthene-4-carboxylic Acid (20)

4-Cyanoxanthene (**19**) (30 mg, 0.15 mmol) and aqueous 10% potassium hydroxide (5 ml) were heated together under reflux for 1 h. The resulting solution was cooled, diluted with water (95 ml), and acidified to pH 2 with concentrated hydrochloric acid (~1.5 ml). The resulting precipitate was collected and dried to give 33 mg (100%) of **20**. One recrystallization from boiling benzene–acetone gave material with m.p. 185–186° (dec.); λ_{max} 3.04 (m), 5.76, 5.86 (sh) μ; λ_{max} (ε) 248 (8200), 279 (2400), 303 (2800) nm; *m/e* 226.

Anal. Calcd. for $C_{14}H_{10}O_3$: C, 74.33; H, 4.46. Found: C, 74.10; H, 4.36.

Methyl Xanthene-4-carboxylate (21)

Xanthene-4-carboxylic acid (**20**) (189 mg, 0.84 mmol) was dissolved in methanol (25 ml). Concentrated sulfuric acid (1 ml) was added with stirring and stirring was continued at room temperature for 21 h; the solution was poured into ether (150 ml). The ethereal solution was washed with water (2 × 100 ml) and saturated aqueous sodium bicarbonate (100 ml), dried, and evaporated to yield 176 mg (87%) of **21**, which was purified by elution with benzene from a column of silica gel (8 g) followed by crystallization from ethanol to give material with m.p. 48–49°; λ_{max} 5.82 μ; λ_{max} (ε) 248 (8200), 278 (2300), 305 (3200) nm; δ 3.94 (s, 3 H), 3.99 (s, 2 H), 7.11 (m, 6 H), 7.72 (dd, J = 7, 2 Hz, 1 H); *m/e* 240.

Epoxidation of 17: Cyano Epoxides 23

Nitrile **17** (472 mg, 2.01 mmol) and *t*-butyl hydroperoxide (dried by azeotropic distillation of water with benzene followed by distillation; 181 mg, 2.01 mmol) were dissolved in anhydrous dimethyl sulfoxide (5 ml). Potassium *t*-butoxide (20 mg, 0.18 mmol) was added; the solution was swirled, allowed to stand at room temperature for 5 min, and poured into ether (300 ml). The ethereal solution was washed with water (5 × 50 ml), dried, and evaporated to yield 471 mg (93%) of **23** as a gum. Partial separation of the two diastereomers was achieved by elution from a silica gel column with carbon tetrachloride – 25% methylene chloride. The mixture had $\lambda_{max}(CCl_4)$ 4.45 (w) μ; δ 1.3–2.6 (m, 7 H), 3.88 (d, J = 4 Hz, 1 H), 6.08 (t, J = 1.5 Hz, 1/2 H), 6.25 (t, J = 1.5 Hz, 1/2 H), 6.89 (m, 4 H); *m/e* 251.

Base Hydrolysis of 23: Epoxy Amides 24

Cyano epoxides **23** (91 mg, 0.36 mmol) and sodium hydroxide (92 mg, 2.30 mmol) were dissolved in aqueous 60% methanol (5 ml) and the solution was stirred at room temperature for 19 h and poured into ether (100 ml). The ethereal solution was washed with water (2 × 75 ml), dried, and evaporated to yield 45 mg (46%) of **24** as a gum, λ_{max} 2.94 (m), 3.04 (m), 5.90 μ; δ 3.88 (d, J = 4 Hz).

2-Carboxamido-3,4-dihydro-1(2H)-xanthenone (30)

o-Hydroxybenzyl alcohol (**4**) (1.24 g, 10 mmol), 4-carboxamido-1,3-cyclohexanedione (**29**) (**14**) (1.55 g, 10 mmol), 1,5-diazabicyclo[5.4.0]undec-5-ene (1.5 ml), and hexamethylphosphoramide (3 ml) were heated together in an oil bath at 190° under reflux under a vacuum of 100 mm for 30 min. The mixture was cooled briefly and poured into water (300 ml) with vigorous stirring. The solution was acidified to pH 2 with concentrated hydrochloric acid and stirred for 17 h at room temperature. The precipitate was collected and dried to yield 1.62 g (67%) of **30**, which after three recrystallizations from methanol had m.p. 217–218°; λ_{max} 2.96 (m), 3.05 (m), 5.91, 6.12, 7.20 μ; λ_{max} (ε) 221 (12 100), 291 (6800) nm; δ 2.42 (m, 4 H), 3.25 (m, 1 H), 3.52 (br s, 2 H), 5.42 (v br s, 1 H), 7.16 (m, 4 H); *m/e* 243.

Anal. Calcd. for $C_{14}H_{13}NO_3$: C, 69.12; H, 5.39; N, 5.76. Found: C, 68.98; H, 5.46; N, 5.72.

Conversion of 30 to 9

2-Carboxamido-3,4-dihydro-1(2*H*)-xanthenone (**30**) (349 mg, 1.44 mmol) and concentrated hydrochloric acid (15 ml) were heated under reflux for 20 h. The mixture was cooled, diluted with water to 200 ml, and extracted with ether (200 ml); the extract was dried and evaporated to yield 139 mg (48%) of a solid, which was recrystallized from methanol and shown (by i.r., m.p., and mixture m.p.) to be identical with **9** prepared from 1,3-cyclohexanedione.

Reduction of 30: Hydroxy Amide 31

A slurry of 2-carboxamido-3,4-dihydro-1(2*H*)-xanthenone (**30**) (538 mg, 2.21 mmol) in 2-propanol (75 ml) was stirred at room temperature. Sodium borohydride (252 mg, 6.63 mmol) was added in three equal portions at t = 0, 45, and 300 min. Ethanol (10 ml) was added after 120 min. After 9 h the solution was poured into water (250 ml) and extracted with chloroform (2 × 250 ml) and ether (2 × 200 ml). The combined extracts were dried and evaporated to yield 511 mg (94%) of **31** which after three recrystallizations from acetone–ethanol had m.p. 188–192°; λ_{max}(KBr) 6.02, 6.08 (m) μ; λ_{max} (ε) 248 (3700), 279 (1900) nm; *m/e* 245.

Anal. Calcd. for $C_{14}H_{15}NO_3$: C, 68.55; H, 6.16; N, 5.71. Found: C, 68.52; H, 6.21; N, 5.61.

2-Cyano-3,4-dihydroxanthene (32)

Hydroxy amide **31** (441 mg, 1.80 mmol) was dissolved in anhydrous pyridine (10 ml) and phosphorus oxychloride (225 mg, 1.47 mmol) was added with stirring, which was continued for 4 h at room temperature. The solution was poured into ether (150 ml) and the

For personal use only.

ethereal extract was washed with 4% hydrochloric acid (2 × 75 ml) and water (75 ml), dried, and evaporated to yield 210 mg of a gum, which was placed on a silica gel t.l.c. plate (20 × 20 × 0.05 cm) in chloroform. Elution with ether yielded 79 mg (21%) of **32** ($R_f \simeq 0.85$), which after one recrystallization from methanol had m.p. 112–114°; λ_{max} 4.55 (m), 5.97 (m), 6.38 μ; λ_{max} (ε) 232 (4730), 245 (sh, 3500), 279 (sh, 3500), 289 (2700), 336 (12 100) nm; δ 2.52 (br s, 4 H), 3.43 (br s, 2 H), 6.53 (br s, 1 H), 7.02 (m, 4 H); *m/e* 209.

Anal. Calcd. for $C_{14}H_{11}NO$: C, 80.36; H, 5.30; N, 6.69. Found: C, 80.25; H, 5.30; N, 6.52.

Methyl Xanthene-2-carboxylate (37) (from 32)

2-Cyano-3,4-dihydroxanthene (**32**) (197 mg, 0.94 mmol) was dissolved in benzene (25 ml) and 5% palladium-on-carbon (201 mg) was added. The mixture was stirred and boiled under reflux for 16 h, cooled, filtered, and evaporated to yield 2-cyanoxanthene (**35**) ($\lambda_{max}(CHCl_3)$ 4.48 (w) μ), which was dissolved in methanol (3 ml). Water (2 ml) and sodium hydroxide (185 mg, 4.63 mmol) were added and the solution was boiled under reflux for 21 h, diluted to a volume of 50 ml with water, acidified to p*H* 2 with 4% hydrochloric acid, and extracted with ether (2 × 100 ml). The combined extracts were dried and evaporated to yield xanthene-2-carboxylic acid (**36**) (λ_{max} 3–4 (m), 5.91 μ), which was dissolved in methanol (25 ml). Concentrated sulfuric acid (951 mg) was added and the solution was stirred for 19 h at room temperature, poured into ether (125 ml), and washed with water (2 × 75 ml) and saturated aqueous sodium bicarbonate (75 ml). The organic layer was dried and evaporated to yield 43 mg (19%, from **32**) of **37**, which after crystallization from methanol had m.p. 129–130° and was shown (by i.r. and mixture m.p.) to be identical with **37** prepared from **39**.

4-Carbomethoxy-1,3-cyclohexanedione (38)[6]

Sodium hydroxide (60 g, 1.5 mol) was dissolved in water (600 ml) in a 2-l beaker. The solution was heated to 90° and the heat source was turned off. Nickel–aluminum alloy (1:1, 20 g) was added in small amounts with stirring at a rate sufficient to maintain a temperature of 90–95°. Stirring was continued for a further 30 min at 90° and during subsequent cooling to room temperature. The aqueous layer was decanted and aqueous 10% sodium hydroxide (400 ml) was added; the mixture was stirred for 10 min and the aqueous layer was decanted. This procedure was repeated three times with water. The slurry was transferred to a 500-ml roundbottomed flask (*Caution*: Raney nickel of this activity spontaneously bursts into flame in the presence of oxygen if allowed to become dry), the aqueous layer was decanted, and benzene (250 ml) was added. Azeotropic distillation of the residual water was carried out to completion. Most of the benzene was decanted and dry methanol was added. The mixture was swirled several times, the nickel was allowed to settle, and most of the methanol–benzene solution was decanted. More methanol was used to transfer the nickel to a 500 ml hydrogenation bottle where it was allowed to settle and most of the methanol was decanted. Methyl 2,4-dihydroxybenzoate (32.5 g, 193 mmol) and methanolic sodium methoxide prepared by the reaction of sodium (4.89 g, 213 mmol) with methanol (300 ml) were added to the hydrogenation bottle which was subjected to a pressure of 80 p.s.i. of hydrogen at 55° with shaking for 5 days. The mixture was cooled and filtered and the methanol was evaporated. Water (200 ml) was added followed by concentrated hydrochloric acid to p*H* 8. Saturated aqueous sodium bicarbonate (200 ml) was added and the solution was extracted with ether (400 ml) and chloroform (400 ml). The aqueous layer was acidified with concentrated hydrochloric acid to p*H* 2 and extracted with ether (400 ml) and chloroform (400 ml). The latter extracts were combined, dried, and evaporated to yield 11.5 g (35%) of **38** which after crystallization and recrystallization from boiling benzene had m.p. 81–82°; λ_{max} 2.7–4.3 (m), 5.77, 5.82, 6.21 μ; λ_{max} (ε) 257 (14 500), 286 (sh, 5730) nm; δ 2.55 (m), 3.17 (s), 2.39 (m), 3.74 (s), 3.81 (s), 5.54 (s), 8.47 (br s); *m/e* 170.

2-Carbomethoxy-3,4-dihydro-1(2H)-xanthenone (39)

o-Hydroxybenzyl alcohol (**4**) (2.17 g, 17.5 mmol) and 4-carbomethoxy-1,3-cyclohexanedione (**38**) (2.94 g, 17.5 mmol) were heated together to 100° at 15 mm for 42 h. The mixture was dissolved in hot methanol (30 ml), cooled, and poured into ether (150 ml). The ethereal solution was washed with aqueous 1% sodium hydroxide (2 × 100 ml), dried, and evaporated to yield 2.30 g (51%) of **39**, which after elution from silica gel (95 g) in benzene – 1% ether and two recrystallizations from methanol had m.p. 126–127.5°; λ_{max} 5.77, 6.00 (sh), 6.10, 7.22 μ; λ_{max} (ε) 222 (13 400), 291 (8200) nm; δ 2.35 (m, 2 H), 2.64 (m, 2 H), 3.48 (m, 1 H), 3.55 (br s, 2 H), 3.79 (s, 3 H), 7.19 (m, 4 H); *m/e* 258.

Anal. Calcd. for $C_{15}H_{14}O_4$: C, 69.75; H, 5.46. Found: C, 69.72; H, 5.55.

Methyl Xanthene-2-carboxylate (37) (from 39)

4-Carbomethoxy-3,4-dihydro-1(2*H*)-xanthenone (**39**) (463 mg, 1.80 mmol) was dissolved in methanol and cooled to 0° with stirring. Sodium borohydride (284 mg, 7.5 mmol) was added in four equal portions at 30 min intervals. Stirring was continued for 1 h after the last addition and the solution was poured into ether (125 ml). The ethereal solution was washed with water (2 × 75 ml), dried, and evaporated to yield 460 mg of a gum, which was placed on four silica gel t.l.c. plates (20 × 20 × 0.05 cm). Elution with benzene – 50% ether yielded 308 mg (66%) of the hydroxy ester **40** ($R_f \simeq 0.4$); $\lambda_{max}(CHCl_3)$ 2.87–3.20 (m), 5.78, 5.89 (sh) μ.

Hydroxy ester **40** (75 mg, 0.29 mmol) was dissolved in anhydrous pyridine (3 ml) and phosphorus oxychloride (44 mg, 0.29 mmol) was added with swirling. The solution was allowed to stand at room temperature for 19 h under a drying tube and then poured into ether (125 ml). The ethereal solution was washed with 4% hydrochloric acid (75 ml) and water (2 × 75 ml), dried, and evaporated to yield 39 mg (56%) of the diene ester **41**; λ_{max} 5.88, 6.00 (m) μ. This was dissolved in methanol (15 ml) and 5% palladium-on-carbon (103 mg) was added. The mixture was boiled under reflux for 19 h, cooled, filtered, and evaporated to yield 25 mg of a gum, which was placed on a silica gel t.l.c. plate (20 × 5 × 0.05 cm) in

[6]This procedure is a modification of that of Tomino (14).

chloroform. Elution with benzene afforded 10 mg (26%) of **37** ($R_f \simeq 0.4$); λ_{max} 5.82 μ; λ_{max} (ε) 275 (11 800), 300 (sh, 4600) nm; δ 3.98 (s, 3 H), 4.13 (s, 2 H), 7.22 (m, 5 H), 7.98 (m, 2 H); *m/e* 240.

Anal. Calcd. for $C_{15}H_{12}O_3$: C, 74.99; H, 5.03. Found: C, 74.60; H, 5.03.

Bridged Xanthenes. II. An Intramolecular Cycloaddition Route

D. J. BICHAN AND PETER YATES

Lash Miller Chemical Laboratories, University of Toronto, Toronto, Ontario M5S 1A1

Received January 22, 1975.

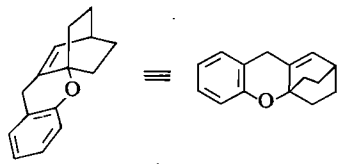
D. J. BICHAN and PETER YATES. Can. J. Chem. **53**, 2054 (1975).

Oxidation of mesitol (**8**) with lead tetraacetate in acrylic acid followed by gentle heating gives 6-hydroxy-4,6,7-trimethyl-5-oxobicyclo[2.2.2]oct-7-ene-2-carboxylic acid lactone (**13**), which is considered to be formed via intramolecular cycloaddition of 6-acryloxy-2,4,6-trimethyl-2,4-cyclohexadienone (**11**). Similar treatment of 4-methylxanthen-3-ol (**7**) gives the corresponding bridged xanthene keto lactone **5**. Ketalization of this with ethylene glycol, followed by treatment with methylmagnesium iodide, hydrolysis, and pyrolysis gives the bridged xanthene keto ether **4**, which possesses many of the structural features of the nucleus of the naturally occurring coloring matters morellin and gambogic acid.

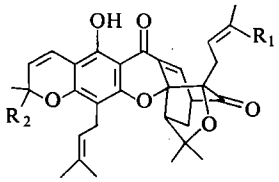
D. J. BICHAN et PETER YATES. Can. J. Chem. **53**, 2054 (1975).

L'oxydation du mésitol (**8**) par le tétraacétate de plomb dans l'acide acrylique suivie par un léger chauffage conduit à la lactone de l'acide hydroxy-6 oxo-5 triméthyl-4,6,7 bicyclo-[2.2.2]octène-2 carboxylique; on croit que ce composé se forme par une cycloaddition intramoléculaire de l'acryloxy-6 triméthyl-2,4,6 cyclohexadiène-2,4 one (**11**). Dans des conditions similaires, le méthyl-4 xanthénol-3 conduit au xanthène céto-lactonique **5**. La cétalisation de ce composé par de l'éthylène glycol, suivie successivement par une réaction avec de l'iodure de méthylmagnésium, par une hydrolyse puis par une pyrolyse, conduit au xanthène céto-éther **4** qui possède déjà plusieurs caractéristiques importantes des noyaux de la morelline et de l'acide gambogique, deux colorants naturels. [Traduit par le journal]

In the preceding paper (1) we have adumbrated the reasons for our interest in devising methods for the synthesis of bridged xanthene systems of type **1** and have reported on the successful development of a method based on Diels–Alder reactions of 3,4-dihydroxanthene with external dienophiles. Difficulties were experienced, however, when we sought to extend this method to bridged xanthenes incorporating additional functionality related to the naturally occurring compounds morellin (**2**) and gambogic acid (**3**) that had originally stimulated these synthetic studies. We now report on an alternative route based on an intramolecular cycloaddition reaction that leads to bridged xanthenes more closely related to **2** and **3**.[1]



1



2 $R_1 = CHO$, $R_2 = CH_3$
3 $R_1 = CO_2H$; $R_2 = CH_2CH_2CH{=}C(CH_3)_2$

The goal we set ourselves was the synthesis of compound **4**, which incorporates into the bridged xanthene system **1** several of the functional features of **2** and **3**. This is clearly closely related to the keto lactone **5**, which we conceived might be formed by an intramolecular cycloaddition reaction of **6**. Compound **6** was reminiscent of the 6-acetoxy-2,4-cyclohexadienones formed by Wessely oxidation of *o*-alkylphenols with lead tetraacetate (4) and we entertained the possibility that it might be accessible via a modified Wessely oxidation of **7** with lead tetraacrylate as the effective oxidizing agent.

An investigation of this route was first undertaken in a model series. Mesitol (**8**) was chosen for this purpose since its oxidation with lead tetraacetate in acetic acid gives the 6-acetoxy-2,4-cyclohexadienone **9** in good yield; further, its oxidation with lead tetraacetate in propionic

[1]For a preliminary account of this work, see ref. 2; for another route, see ref. 3.

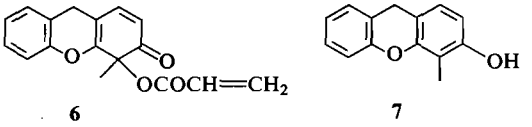
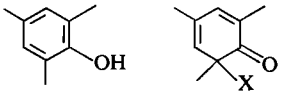
4 5



6 7

acid has been shown to give the 6-propionoxy-2,4-cyclohexadienone **10** (5). This latter observation suggested that lead tetraacetate in acrylic acid might serve our purpose, thus avoiding the necessity for the preparation of lead tetraacrylate.

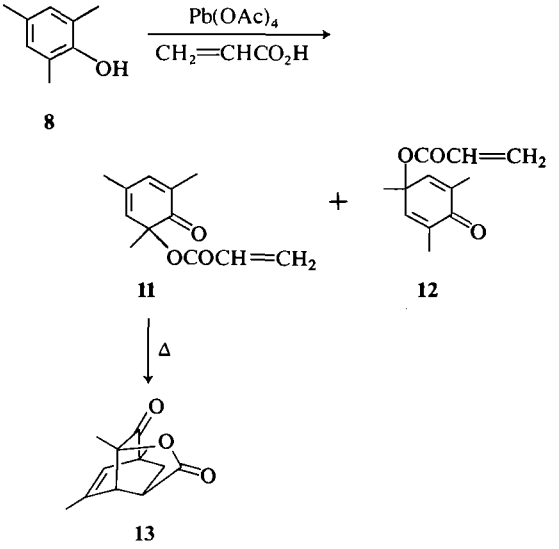


8 **9** X = $OCOCH_3$
10 X = $OCOCH_2CH_3$

In the event, when **8** was added to a stirred solution of lead tetraacetate in acrylic acid at room temperature and stirring was continued for a few minutes, a slightly exothermic reaction occurred, and work-up gave in essentially quantitative yield a mixture of two products, which are considered to be the 6-acryloxy-2,4- and 4-acryloxy-2,5-dienones **11** and **12** (Scheme 1). The i.r. spectrum of the mixture shows carbonyl-stretching bands at 5.80, 5.96, and 6.02 μ; the first is attributable to the acrylate ester groups of both **11** and **12**, while the others are assigned to the ketonic groups of **11** and **12**, respectively. The p.m.r. spectrum of the mixture shows a complex set of signals in the region δ 5.6–6.6 attributable to the vinyl protons of **11** and **12**; it also shows singlets at δ 1.4 and 1.9 that can be assigned to methyl protons on sp^3 carbon bearing oxygen and to vinyl methyl protons, respectively.

Attempts to separate the product mixture by chromatography led to decomposition. Accordingly, a solution of the mixture in hexane was boiled under reflux overnight; on cooling the solution deposited a crystalline product that is considered to be the desired keto lactone **13**, formed by an intramolecular Diels–Alder reaction of **11** (Scheme 1). The yield from **8** was 41%.

The structural assignment **13** is based on the elemental composition and spectral characteristics of the product. Its i.r. spectrum shows carbonyl-stretching bands at 5.74 and 5.58 μ, assigned to the ketone and lactone groups, respectively. Each band appears at shorter wavelength than that normally associated with the group concerned; this can be attributed to increased strain in **13** and dipole–dipole interaction between the carbonyl groups (6). As expected for a bicyclo[2.2.2]oct-5-enone (7), **13** shows enhanced $n \rightarrow \pi^*$ absorption in its u.v. spectrum (λ_{max} 312 nm (ε 184)). Its p.m.r. spectrum can readily be interpreted in terms of the assigned structure (Table 1); the observed coupling constants are in accord with dihedral angle measurements made on a molecular model.



SCHEME 1

The structural assignment was corroborated by the degradation shown in Scheme 2. Treatment of **13** with aqueous base followed by acidification effected hydrolysis of the lactone and gave the corresponding hydroxy acid **14**, which is unstable and rapidly reverts to the lactone. Addition of periodic acid to the basic solution followed by acidification to p*H* 2 resulted in oxidative cleavage of the α-ketol system, accompanied by some reclosure to **13**. The resulting keto acid **15***a* exists, at least in solution, mainly as the lactol acid **15***b*, since its i.r. spectrum shows in addition to typical carboxylic acid absorption a strong peak at 5.71 μ

attributable to the lactol carbonyl group. That **15***b* exists in equilibrium with **15***a* was shown by treatment with diazomethane to give a product, which, although not fully characterized, shows i.r. and p.m.r. spectra in accord with the keto diester structure **16** (see Experimental). Reaction of **15***b* with lead tetraacetate and pyridine gave a product that is assigned structure **17**, which can be envisaged as arising by oxidative decarboxylation to give the allylic cation **19**, followed

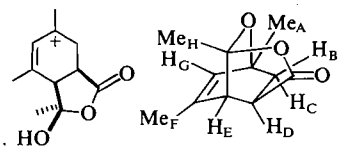
by ether formation by attack of the lactol hydroxyl group at one terminus of the cation. Its i.r. spectrum shows a carbonyl-stretching band at 5.64 μ. Its p.m.r. spectrum shows



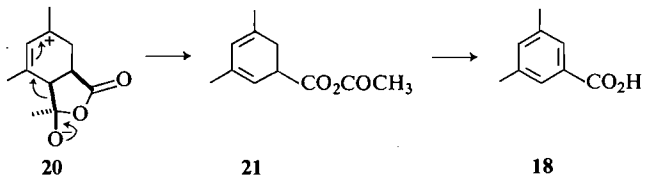
19 17

several similarities to that of **13**; although the signals attributable to H_B, H_C, and H_D overlap in the δ 2.0–2.6 region, the H_E (δ 3.19, dd, J_{DE} = 4 Hz, J_{EG} = 2 Hz), H_G (δ 6.12, br s) and Me_F (δ 1.90, d, J_{FG} = 2 Hz) signals are clearly analogous to the signals of the corresponding protons in **13**; the Me_A and Me_H signals (δ 1.40 s, 1.42 s) appear close together in the case of **17**, since each is now attached to an sp^3 carbon bearing one or more oxygen atoms.

When **17** was heated in boiling ethylene glycol monomethyl ether (b.p. 125°) with palladium-on-carbon, 3,5-dimethylbenzoic acid (**18**) was formed and identified by comparison with an authentic sample. It seems probable that the transformation involves thermal conversion of **17** to the anhydride **21** by a retro-Diels–Alder reaction or a stepwise process via **20** followed by dehydrogenation and solvolysis (Scheme 3).

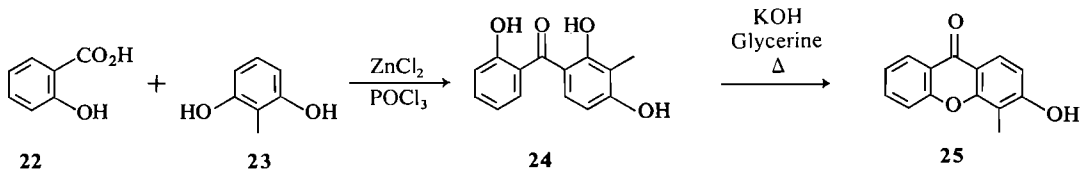
Having established the practicability of the intramolecular cycloaddition route in the case of mesitol (**8**), we proceeded to apply it to the xanthene system. 3-Hydroxy-4-methylxanthone (**25**), which had previously been obtained by another method (8), was prepared by a modification of the general xanthone synthesis of Grover *et al.* (9) (Scheme 4). Treatment of salicylic acid (**22**) and 2-methylresorcinol (**23**) with zinc chloride and phosphorus oxychloride gave the benzophenone **24**. The structure of this product was corroborated by the occurrence of the carbonyl-stretching band at 6.20 μ in its i.r. spectrum as a result of hydrogen bonding with two *o*-hydroxyl groups (*cf.* 2,4-dihydroxybenzophenone: 6.13 μ (10)). The p.m.r. spectrum of **24** shows three hydroxyl proton signals at δ 5.82, 10.27, and 11.83; the last two can be assigned to the two hydroxyl groups that are intramolecularly hydrogen bonded to the carbonyl group; their chemical shifts may be compared with those recorded for the hydroxylated benzophenones **26** (δ 10.4), **27** (δ 10.2, 11.5), and **28** (δ 12.6) (11). The remainder of the p.m.r. spectrum is in good accord with the assigned structure (see Experimental). Nevertheless, a discrepancy was encountered on comparison of the u.v. spectrum of **24** (λ_{max} (MeOH) (ε) 297(12 700), 332(9600) nm) with that reported (12) for the unmethylated analog **29** (λ_{max} (MeOH) (ε) 288(25 100), 329(24 000) nm); although the small differences in band positions are not unexpected, the large differences in band intensities appear to be anomalous. However, there is reason to question the intensity values reported for **29**, since its monomethyl ether is reported to have a long wavelength maximum at 327 nm (ε 10 100) in its u.v. spectrum (13).

The general procedure (9) referred to above called for heating of **24** to 200–220° to convert



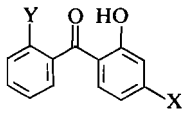
20 21 18

SCHEME 3

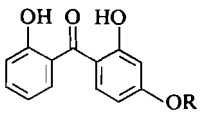


22 23 24 25

SCHEME 4



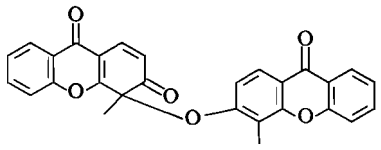
26 X = H; Y = OH
27 X = OMe; Y = OH
28 X = OMe; Y = H



29 R = H
30 R = Me

it to the xanthone **25**. This led to low yields of very impure xanthone; however, heating **24** with a trace of potassium hydroxide in glycerol at 210–215° cleanly afforded **25** in high yield. The melting point of this product (271–272°) is close to that originally reported (8) for **25** (268°) and its i.r. spectrum is reasonably related to that reported (14) for its nonmethylated analog, 3-hydroxyxanthone. A discrepancy was encountered again when the u.v. spectrum of **25** (λ_{max} (ε) 237(40 600), 266(6300), 276(5700), 313(12 500), 332(9800) nm) was compared with that reported (15) for 3-hydroxyxanthone (λ_{max} (ε) 235(25 600), 261(5750), 270(5310), 307(9630), 333(6530) nm). As before, the discrepancy concerns the intensities rather than the positions of the maxima. However, there is again reason to question the reported intensity values since xanthone itself has λ_{max} (ε) 239(42 800), 260(12 500), 288(4400), 336(7000) nm (16).

The xanthone **25** was treated with lead tetraacetate in acrylic acid in the hope that a product analogous to **11** would be formed. One main product was obtained in high yield but this was not the desired compound as was immediately apparent from its p.m.r. spectrum. It was not fully characterized but is considered to have structure **31** on the basis of its spectra (see Experimental).



31

It appeared possible that one or both of two factors might account for the difference in the course of the reactions of the xanthone **25** and mesitol (**8**) with lead tetraacetate in acrylic acid. First, in the case of **25** but not of **8** there is a ketonic carbonyl group attached to the ring undergoing oxidation, and second, the reaction mixture with **25** did not become homogeneous until after several hours of stirring at room temperature, whereas with **8** the reaction mixture became homogeneous very rapidly and was worked-up after a few minutes. We therefore converted **25** to 4-methylxanthen-3-ol (**7**), which lacked the carbonyl group of **25** and was also expected to be more soluble (see Scheme 5).

The conversion was carried out with lithium aluminum hydride under vigorous conditions (*cf.* ref. 17). The xanthene **7** was an unstable compound, whose spectra were in accord with anticipation (see Experimental). Treatment with lead tetraacetate in acrylic acid gave a product that is considered to be a mixture of the desired cyclohexadienone **6** with the cyclohexadienones **32** and **33**. Its p.m.r. spectrum includes extensive acrylate proton absorption and three singlets in the region δ 1.5–2; the most intense of these (δ 1.62) is assigned to the methyl protons of **6**, while the others (δ 1.95, 2.05) are tentatively assigned to the vinyl methyl protons of **32** and **33**.

As in the case of mesitol, an attempt to separate the Wessely oxidation product mixture by chromatography led to decomposition. The mixture was therefore heated in boiling benzene to effect intramolecular cycloaddition of **6**. Chromatography of the resulting mixture gave the keto lactone **5** in an overall yield from **7** of 23%. Its i.r. spectrum in the carbonyl-stretching region resembled that of the keto lactone **13** with bands at 5.58 and 5.72 μ, and its u.v. spectrum showed similarly enhanced $n \rightarrow \pi^*$ absorption (λ_{max} 310 nm (ε 204)); the latter showed in addition bands attributable to a chroman-type system (λ_{max} (ε) 271(1410), 275(1380) nm) (*cf.* ref. 18). Its p.m.r. spectrum is in complete accord with the assigned structure (Table 2) and shows the expected relationship to the p.m.r. spectrum of **13** (Table 1); the observed coupling constants are in accord with dihedral angle measurements made on a molecular model.

With the structure of **5** secure, we turned to the final stage in attaining our goal, the conversion of **5** to the keto ether **4** (Scheme 6). The ketonic group of **5** was first protected by conversion of the latter to the ketal **34**. Treatment of this with a large excess of methylmagnesium iodide in boiling benzene–ether for 2 days gave the ketal diol **35**, which on treatment with dilute aqueous acid afforded the keto diol **36**. This was heated at 200° (100 mm) in a sublimation apparatus to effect dehydration; these conditions were designed to maximize dehydration and sublima-

to the spectra of **13** and **5**. Its i.r. spectrum shows a single carbonyl-stretching band at 5.75 μ, and its u.v. spectrum (λ_{max} (ε) 271(1600), 275(1600), 312(580) nm) shows both chroman-type and enhanced n → π* absorption. The intensity of the latter is much greater than in the case of **5** (λ_{max} 310 (204) nm). This is considered to result from a change in the geometry of the bridged ring system arising from steric repulsion between the Me_L group and H_B, which examination of a molecular model shows are in very close proximity. The p.m.r. spectrum of **4** is given in Table 3. Some departure from first order coupling patterns and uncertainties regarding some assignments prevented full analysis of this spectrum. However, its relationship to that of **5** corroborates the structural assignment **4**, with changes in coupling constants interpretable in terms of the geometrical change to which reference has been made above.

In addition to its application to the synthesis of bridged xanthenes herein described, the reaction sequence of Wessely oxidation of phenols with lead tetraacetate in acrylic acid followed by intramolecular cycloaddition clearly has wider potentialities for the synthesis of bicyclo[2.2.2]octane derivatives and has been successfully applied with α,β-unsaturated carboxylic acids other than acrylic acid (19).

Experimental

Melting points were determined with a Thomas Hoover Uni-Melt apparatus and are uncorrected. Infrared spectra were recorded in chloroform solution, ultraviolet spectra in methanol solution, and proton magnetic resonance spectra in deuteriochloroform, unless otherwise indicated. Solutions in organic solvents were dried over anhydrous magnesium sulfate.

*Lead Tetraacetate Oxidation of Mesitol (**8**) in Acrylic Acid and Subsequent Intramolecular Cycloadditions: Keto Lactone **13***

Lead tetraacetate (20.1 g, 45.4 mmol) was dissolved with stirring in acrylic acid (150 ml) and the solution was stirred for 5 min at room temperature. Mesitol (**8**) (4.13 g, 30.4 mmol) was added and stirring was continued for 10 min. Ethylene glycol (25 ml) was added and the solution was stirred for 2 min and poured into hexane (400 ml). The hexane extract was washed with water (5 × 400 ml) and dried. Evaporation of a small aliquot yielded a gum with λ_{max} 5.80, 5.96, 6.02 (m) μ; δ 1.4 (s), 1.9 (s), 5.6–6.6 (m). The remainder of the solution was evaporated to a volume of 70 ml, and boiled under reflux for 21 h. The solution was evaporated to a volume of 20 ml, when crystallization yielded 2.56 g (41%) of **13** which after two recrystallizations from boiling hexane had m.p. 111–112°; λ_{max} (CCl_4) 5.58, 5.74 μ; λ_{max} (ε) 312 (184) nm; *m/e* 206.[2]

Anal. Calcd. for $C_{12}H_{14}O_3$: C, 69.88; H, 6.84. Found: C, 69.90; H, 6.85.

*Hydrolysis of **13** and Subsequent Periodic Acid Cleavage: Lactol Acids **15b***

Keto lactone **13** (1.06 g, 5.15 mmol), sodium hydroxide (450 mg, 11.3 mmol), and aqueous 50% tetrahydrofuran (63 ml) were stirred together for 23 h at room temperature. The solution was filtered and periodic acid (1.20 g, 5.26 mmol) was added. The p*H* was brought to 2 by slow dropwise addition of 4% hydrochloric acid with stirring, and stirring was continued for 20 h; the solution was poured into saturated aqueous sodium bicarbonate (60 ml) and extracted with chloroform (70 ml). The chloroform layer was dried and evaporated to give 201 mg (19%) of **13**. The aqueous layer was acidified to p*H* 2 with 4% hydrochloric acid and extracted with ether (2 × 125 ml). The extracts were dried and evaporated to yield 915 mg (74%) of **15***b*, which after crystallization from chloroform had m.p. 178–181°; λ_{max} 3–4 (m), 5.71, 5.85 μ; δ (C_5H_5N) 1.50 (s, 3 H), 1.82 (s, 3 H), 2.23 (br s, 3 H), 2.45 (m, 1 H), 3.15 (m, 2 H), 3.53 (m, 1 H), 6.07 (br s, 1 H).

Anal. Calcd. for $C_{12}H_{16}O_5 \cdot \frac{1}{4} H_2O$: C, 58.89; H, 6.75. Found: C, 58.82; H, 6.43.

*Esterification of **15**: Keto Diester **16***

Lactol acids **15***b* (64 mg, 0.27 mmol) were dissolved in ether (15 ml). Ethereal diazomethane was added slowly dropwise with stirring to the solution until a pale yellow color persisted and 4% hydrochloric acid (5 drops) was added. The solution was poured into chloroform (85 ml), washed with water (100 ml), dried, and evaporated to yield 67 mg (71%) of **16** as a gum; λ_{max} 5.79 μ; δ 1.28 (s, 3 H), 1.83 (br s, 3 H), 2–3 (m, 3 H), 2.25 (s, 3 H), 3.43 (br d, J = 4 Hz, 1 H), 3.72 (s, 6 H), 5.70 (br s, 1 H).

*Lead Tetraacetate Oxidation of **15b**: Lactone Ether **17***

Lactol acids **15***b* (217 mg, 0.90 mmol) were added to a solution of lead tetraacetate (845 mg, 1.91 mmol) in dry benzene (15 ml) and dry pyridine (158 mg, 12 drops) (*cf.* ref. 21). The solution was refluxed for 3 h under a drying tube and cooled. Ethylene glycol (1 ml) was added, and the mixture was stirred for 2 min and poured into benzene (100 ml). The benzene extract was washed with water (2 × 100 ml), dried, and evaporated to yield 156 mg (89%) of **17**, which after sublimation (55°, 0.1 mm) had m.p. 56–57.5°; λ_{max} 5.64 μ; δ 1.40 (s, 3 H), 1.42 (s, 3 H), 1.90 (d, J = 2 Hz, 3 H), 2.0–2.6 (m, 3 H), 3.19 (dd, J = 4, 2 Hz, 1 H), 6.12 (br s, 1 H); *m/e* 194.

Anal. Calcd. for $C_{11}H_{14}O_3$: C, 68.02; H, 7.27. Found: C, 68.13; H, 7.48.

*3,5-Dimethylbenzoic Acid (**18**) from Degradation of Lactone Ether **17***

Lactone ether **17** (61 mg, 0.31 mmol) was dissolved in 2-methoxyethanol (15 ml) and 5% palladium-on-carbon (106 mg) was added. The mixture was boiled under reflux for 16 h, cooled, and filtered. The filtrate was evaporated to give 42 mg of a gum, which was placed on a silica gel t.l.c. plate (20 × 10 × 0.05 cm) in chloroform. Elution with chloroform yielded 11 mg (23%) of

[2]For p.m.r. spectrum, see Table 1.

For personal use only.

18 ($R_f \simeq 0.3$), which after recrystallization from boiling cyclohexane had m.p. 166–169° (lit. (22) m.p. 170°), which was undepressed upon admixture with authentic material. Identity was also established by comparison of i.r., n.m.r., u.v., and mass spectra.

2,2′,4-Trihydroxy-3-methylbenzophenone (24)

Salicyclic acid (**22**) (13.8 g, 100 mmol), 2-methylresorcinol (**23**) (12.4 g, 100 mmol), anhydrous zinc chloride (42 g, 310 mmol), and phosphorus oxychloride (100 ml) were heated together with stirring in an oil bath at 60–65° under dry nitrogen for 4 h. The mixture was allowed to cool for 5 min and poured into a 1500-ml beaker full of ice. The resulting mixture was stirred for several hours until it had cooled to room temperature. The aqueous layer was decanted, saturated aqueous sodium bicarbonate (1 l) was added, and the mixture was stirred at room temperature for 17 h. The aqueous layer was decanted and benzene (600 ml) was added to the residue. The mixture was boiled with stirring until the volume was reduced to 500 ml. The solution was decanted, charcoal (10 g) was added, and the mixture was boiled gently with stirring until the volume was reduced to 400 ml and filtered. The filtrate was concentrated by evaporation to a volume of 50 ml and allowed to crystallize to yield 12.3 g of **24** as a yellow solid. A second crop (1.13 g) brought the total yield to 55%. Two recrystallizations of the first crop from benzene yielded material with m.p. 145.5–147°; λ_{max} 2.88 (m), 3.0–3.4 (m), 6.20 μ; λ_{max} (ε) 241 (sh, 7300), 297 (12 700), 332 (sh, 9600) nm; δ 2.17 (s, 3 H), 5.82 (v br s, 1 H), 6.38 (d, J = 9 Hz, 1 H), 6.91 (td, J = 8, 1.5 Hz, 1 H), 7.07 (dd, J = 8, 1.5 Hz, 1 H), 7.41 (m, 3 H), 10.27 (br s, 1 H), 11.83 (s, 1 H); *m/e* 244.

Anal. Calcd. for $C_{14}H_{12}O_4$: C, 68.84; H, 4.95. Found: C, 68.55; H, 5.05.

3-Hydroxy-4-methylxanthone (25)

2,2′,4-Trihydroxy-3-methylbenzophenone (**24**) (13.9 g, 52 mmol), glycerine (100 ml), and sodium hydroxide (118 mg, 2.95 mmol) were heated together under nitrogen to 210–215° with stirring for 2 h. The solution was cooled to *ca.* 130° and poured slowly into water (400 ml) with stirring. The precipitate was collected, washed with water, and dried to give 11.5 g (89%) of **25**, which after recrystallization from boiling benzene–ethanol had m.p. 271–272° (lit. (8) m.p. 268°); λ_{max} (KBr) 6.06 (m), 6.19, 6.23 μ; λ_{max} (ε) 237 (40 600), 266 (6300), 276 (5700), 313 (12 500), 332 (sh, 9800) nm.

Lead Tetraacetate Oxidation of 25 in Acrylic Acid

3-Hydroxy-4-methylxanthone (**25**) (1.39 g, 6.15 mmol), lead tetraacetate (4.64 g, 10.5 mmol), and acrylic acid (60 ml) were stirred together at room temperature under a drying tube for 2.5 h while the mixture became homogeneous. Ethylene glycol (1.5 ml) was added and the solution was stirred for 1 min and poured into benzene (200 ml). The benzene solution was washed with water (7 × 200 ml), dried, and evaporated to yield 1.56 g of a yellow solid, which was triturated in ethanol – 17% chloroform to yield 1.31 g (95%) of **31**, m.p. 170° (dec.); λ_{max} 5.90 (m), 6.04, 6.21 μ; δ 2.00 (s, 3 H), 2.65 (s, 3 H), 6.12 (d, J = 8 Hz, 1 H), 6.48 (d, J = 10 Hz, 1 H), 7.2–8.4 (m, 10 H).

4-Methylxanthen-3-ol (7)

3-Hydroxy-4-methylxanthone (**25**) (1.01 g, 4.47 mmol), lithium aluminum hydride (700 mg, 18.4 mmol), anhydrous ether (50 ml), and anhydrous benzene (30 ml) were stirred together and heated for 3 h under reflux with protection from atmospheric moisture with a drying tube. The mixture was then stirred for 20 h at room temperature. Aqueous 10% ammonium chloride was added carefully until no further hydrogen evolution was observed. Ether (50 ml) was added followed by water (125 ml) and 3% hydrochloric acid until the aqueous layer became homogeneous. Ether (75 ml) and water (75 ml) were added, and the mixture was shaken. The organic layer was separated, dried, and evaporated to yield 835 mg (88%) of **7**, which after sublimation (90°, 0.1 mm) had m.p. 120–121°; λ_{max} 2.86 (m), 3.08 (w) μ; λ_{max} (ε) 250 (5740), 277 (3070) nm; δ 2.25 (s, 3 H), 3.94 (s, 2 H), 4.59 (br s, 1 H), 6.52 (d, J = 8.5 Hz, 1 H), 7.25 (m, 5 H); *m/e* 212.

Anal. Calcd. for $C_{14}H_{12}O_2$: C, 79.22; H, 5.70. Found: C, 78.76; H, 5.67.

Lead Tetraacetate Oxidation of 7 in Acrylic Acid and Subsequent Intramolecular Cycloaddition: Keto Lactone 5

Lead tetraacetate (15.8 g, 36.7 mmol) was dissolved in acrylic acid (100 ml) and the solution was stirred at room temperature for 5 min and placed in an ice bath. Immediately 3-hydroxy-4-methylxanthene (**7**) (5.01 g, 23.6 mmol) in acrylic acid (75 ml) was added dropwise over 2 min. The ice bath was removed and stirring was continued for 8 min more. Ethylene glycol (10 ml) was added and stirring was continued for 2 min. The solution was poured into benzene (400 ml) and the benzene extract was washed with water (4 × 400 ml) and aqueous 1% potassium bicarbonate (400 ml) and dried. Evaporation of a small aliquot gave a gum with λ_{max} ($CHCl_3$) 5.79, 5.91 (m), 5.98–6.02 μ; δ 1.62 (s), 1.95 (s), 2.05 (s), 3.62 (m), 5.6–6.6 (m). Hydroquinone (87 mg, 0.79 mmol) was added and the solution was heated under reflux for 20 h under nitrogen. Evaporation of the solvent yielded 6.13 g of a red gum, which was placed on silica gel (375 g) in benzene and eluted with benzene – 1% ether; 200-ml fractions were collected. Fractions 16–35 contained 1.51 g (23%) of **5**, which after three recrystallizations from methanol had m.p. 116–118°; λ_{max} 5.58; 5.72 μ; λ_{max} (ε) 271 (1410), 275 (1380), 310 (204) nm; *m/e* 282.[3]

Anal. Calcd. for $C_{17}H_{14}O_4$: C, 72.33; H, 5.00. Found: C, 72.15; H, 5.16.

Ketalization of 5: Lactone Ketal 34

Keto lactone **5** (219 mg, 0.78 mmol), ethylene glycol (1.5 ml), *p*-toluenesulfonic acid monohydrate (1.22 g, 6.4 mmol), and benzene (50 ml) were heated under reflux in a nitrogen atmosphere for 21 h with azeotropic removal of water. The solution was cooled and poured into ether (75 ml). The ethereal solution was washed with saturated aqueous sodium bicarbonate (70 ml), dried, and evaporated to yield 492 mg of a yellow gum, which was placed on Florisil (25 g) and eluted with benzene to yield 240 mg (95%) of **34**, which after two recrystallizations from boiling cyclohexane–benzene had m.p.

Keto Ether 4

Methyl iodide (1.51 g, 10.6 mmol), magnesium (270 mg, 11.3 mol), and anhydrous ether (25 ml) were stirred in a flame-dried apparatus under dry nitrogen to form methylmagnesium iodide. Anhydrous ether (35 ml) was added with stirring followed by lactone ketal **34** (295 mg, 0.91 mmol) in anhydrous benzene (5 ml). The mixture was stirred and heated under reflux for 42 h while the volume of ether was maintained by intermittent addition from a dropping funnel. The solution was cooled, 4% hydrochloric acid (10 ml) was added very carefully, and stirring was continued until both phases were clear. The solution was poured into a separatory funnel and the volume of each phase was made up to 150 ml by addition of ether and water. The organic layer was separated and washed with aqueous 1% sodium bicarbonate (125 ml), dried, and evaporated to yield 331 mg of a gum. This was placed on two silica gel t.l.c. plates (20 × 20 × 0.05 cm) in chloroform and eluted with ether to yield 286 mg (88%) of the ketal diol **35** ($R_f \simeq 0.2$); λ_{max} 2.9–3.3 (m) μ; δ 1.15 (s, 3 H), 1.25 (s, 3 H), 1.4–2.2 (m, 3 H), 1.68 (s, 3 H), 2.48 (m, 1 H), 3.49 (d, J = 2 Hz, 2 H), 3.98 (m, 4 H), 4.34 (br s, 2 H), 5.89 (dt, J = 7, 2 Hz, 1 H), 7.04 (m, 4 H).

Ketal diol **35** (286 mg, 0.80 mmol) and *p*-toluenesulfonic acid monohydrate (450 mg, 2.37 mmol) were dissolved in aqueous 80% tetrahydrofuran (15 ml) and the solution was refluxed gently for 17 h under nitrogen and poured into ether (150 ml). The ethereal extract was washed with water (50 ml) and saturated aqueous sodium bicarbonate (50 ml), dried, and evaporated to yield 228 mg (91%) of the keto diol **36** as a gum; λ_{max} 2.9–3.3 (m), 5.75 μ; δ 1.17 (s, 3 H), 1.33 (s, 3 H), 1.6–2.3 (m, 3 H), 1.73 (s, 3 H), 3.14 (m, 1 H), 3.50 (d, J = 2 Hz, 2 H), 4.34 (br s, 2 H), 5.93 (dt, J = 7, 2 Hz, 1 H), 7.10 (m, 4 H).

Keto diol **36** (51 mg, 0.17 mmol) was placed in a sublimation apparatus with a cold water cold finger and the pressure was reduced to 160 mm. The apparatus was placed in an oil bath at 200°. After 5 min the pressure was reduced to 100 mm over 5 min and sublimation was allowed to continue for 45 min. The sublimate consisted of a gum (38 mg), which was placed on a silica gel t.l.c. plate (20 × 10 × 0.05 cm) in chloroform. Elution with chloroform yielded 14 mg (27%) of starting material **36** ($R_f \simeq 0.1$) and 15 mg (31%) of the keto ether **4** ($R_f \simeq 0.6$), which after crystallization from hexane had m.p. 110–113°; λ_{max} (CCl_4) 5.75 μ; λ_{max} (ε) 271 (1600), 275 (1600), 312 (580) nm; *m/e* 296.[4]

Refinement of the Crystal Structure of the Low-quartz Modification of Ferric Phosphate

HOK NAM NG AND CRISPIN CALVO

Institute for Materials Research, McMaster University, Hamilton, Ontario L8S 4M1

Received February 5, 1975

HOK NAM NG and CRISPIN CALVO. Can. J. Chem. **53**, 2064 (1975).

The structure of ferric phosphate at room temperature was refined on a Dauphiné-twinned crystal using full-matrix least-squares methods. The final R value was 0.078 for 487 symmetry-independent reflections whose intensities were corrected for twinning. The structure was found to be isotypic with $AlPO_4$ (berlinite) with the space group $P3_121$ and four formula units in a unit cell defined by $a = 5.036(2)$ and $c = 11.255(4)$ Å. The structure is also closely related to that of α-quartz with a nearly doubled c-axis because of the ordering of Fe and P atoms. The PO_4 tetrahedron is almost regular with a mean P—O distance of 1.526 Å. The Fe^{3+} ion is tetrahedrally coordinated with an average Fe—O distance of 1.853 Å.

HOK NAM NG et CRISPIN CALVO. Can. J. Chem. **53**, 2064 (1975).

On a raffiné la structure du phosphate ferrique tel qu'il existe à la température de la pièce en appliquant la méthode des moindres carrés (matrice complète) à un cristal Dauphiné mâclé. La valeur finale R est de 0.078 pour 487 réflexions de symétrie indépendantes dont l'intensité a été corrigée pour le mâclage. On a trouvé que la structure est isostructurale avec celle de $AlPO_4$ (berlinite) avec un groupe d'espace $P3_121$ et quatre molécules par maille définie par $a = 5.036(2)$ et $c = 11.255(4)$ Å. Cette structure ressemble beaucoup à celle de quartz α; l'axe c est toutefois le double à cause de l'alignement des atomes de Fe et de P. Le tétraèdre PO_4 est pratiquement régulier avec une distance P—O de 1.526 Å. L'ion Fe^{3+} est coordonné tétraédriquement avec une distance moyenne de 1.853 Å. [Traduit par le journal]

Introduction

Ferric phosphate ($FePO_4$) has long been known to have a structure isotypic with the berlinite structure of aluminum phosphate ($AlPO_4$). Both, in turn, are related to the α-quartz structure (1). The structures of both berlinite (2, 3) and quartz (4) have been accurately refined. They belong to the space group $P3_121$ or its enantiomorph $P3_221$, and may be considered as a three-dimensional network of corner sharing tetrahedra. The arrangements of P and Al are completely ordered in berlinite with alternate sheets of PO_4 and AlO_4 tetrahedra stacked up the c-axis. The c-axis and therefore the unit cell volume is double that of quartz to accommodate the inequivalence of P and Al. All three compounds have a characteristic "α–β" transformation and these are found at 573, 586, and 707 °C for quartz, $AlPO_4$, and $FePO_4$, respectively. In the present study we refined the room temperature structure of $FePO_4$ and compared it with those of quartz and $AlPO_4$. Accurate positional and thermal parameters for the atoms are needed in order to assess the distortions resulting from the substitution of Al^{3+} by Fe^{3+} in the electron paramagnetic resonance study of the α–β phase transformation of Fe^{3+}-doped $AlPO_4$ (5).

Experiments

$FePO_4$ was prepared by the method of Royen and Korinth (6) from an aqueous solution of $Fe(NO_3)_3 \cdot 9H_2O$ and $(NH_4)_2HPO_4$ in stoichiometric amounts. The warm solution was neutralized with 2 M ammonia solution and a pale yellow precipitate was obtained. The precipitate was filtered, washed with distilled water, and then dried at 200 °C. This material (possibly strengite $FePO_4 \cdot 2H_2O$) was heated at 600 °C for 6 h, transforming into a white crystalline powder identified as $FePO_4$ by a Debye–Scherrer pattern. This powder was melted in a platinum crucible at 1300 °C and cooled at 6°/h to 600 °C and then quenched to room temperature. Clear yellowish crystals of $FePO_4$ were obtained.

Precession photographs showed that $FePO_4$ has a primitive unit cell very similar to that of $AlPO_4$ with $00l$ reflections absent unless $l = 3n$, thus verifying the space group as $P3_121$ or $P3_221$. Lattice parameters were obtained by a least-squares fit of 15 2θ values measured with the Syntex $P\bar{1}$ automatic diffractometer ($\lambda\alpha_1 = 0.70926$ Å). The crystal data are as follows:

trigonal f.w. = 150.85

$a = 5.036(2)$, $c = 11.255(4)$ Å, $V = 247.20$ Å^3, $Z = 3$, $\rho_{calc} = 3.054$ g/cm^3, space group $P3_121$, $T = 22$ °C, $\mu = 50.18$ cm^{-1} (MoKα).

A good quality crystal was selected by using a petrographic microscope and then ground into a sphere, with a radius of 0.012 cm, for subsequent measurements of the diffracted intensity with a Syntex $P\bar{1}$ automatic diffractometer. θ/2θ scan at variable rate was employed with graphite monochromatized MoKα radiation. Reflections were labelled unobserved when the measured

intensity corrected for background was less than three times the standard deviation. A total of 828 reflections, some of which are symmetry equivalent, were collected within a sphere with $2\theta \leqslant 60°$. Lorentz, polarization, and absorption corrections were applied to the intensity data.

Refinement of the Structure

Refinement of the structure was performed on a CDC 6400 computer by using a least-squares program that minimizes the function $\Sigma\omega(|F_o| - |F_c|)^2$. The coefficients of the weighting function $\omega = (a + bF_o + cF_o^2)^{-1}$ were chosen such that the square of the difference between the observed and calculated structure factors $\omega(\Delta F)^2$ would be independent of the local average value of F_o. Unobserved reflections were given zero weight if the calculated structure factor was less than the local minimum observable value. Atomic scattering curves for Fe^{3+}, P, and O were taken from Cromer and Waber (7) and that for Fe^{3+} was corrected for anomalous scattering (8).

The final positional and thermal parameters of $AlPO_4$ (3) in the space group $P3_121$ were used as initial parameters for the refinement. After three cycles the R value was 0.28. The crystal appeared to show Dauphiné-twinning as in quartz, since the observed and calculated structure factors of $hk0$ and hhl reflections were in better agreement than the others. The Dauphiné twins are related by a 180° rotation about the c-axis. Thus reflection hkl from one component of the twin will superimpose on reflection $\bar{h}\bar{k}l$ from the other, so that the observed intensity $I(hkl)$ is a weighted sum of the intensity $I'(hkl)$ from part of the crystal and the intensity $I''(\bar{h}\bar{k}l)$ from its twin. Assuming that Friedel's law holds, we may write

$$[1] \quad |F(hkl)|^2 = f \cdot |F'(hkl)|^2 + (1 - f) \cdot |F''(hk\bar{l})|^2$$

and

$$[2] \quad |F(hk\bar{l})|^2 = f \cdot |F'(hk\bar{l})|^2 + (1 - f) \cdot |F''(hkl)|^2$$

where f is the volume fraction of the unrotated crystal. It has been shown by Young (4) that for special reflections of the type $hk0$ and hhl

$$|F'(hk0)| = |F''(\bar{h}\bar{k}0)|$$

and

$$|F'(hhl)| = |F''(\bar{h}\bar{h}l)|$$

Therefore, the intensities of these reflections are unaffected by Dauphiné-twinning.

The volume fraction is difficult to determine directly from experiment. Since all the reflections are overlapped as a result of Dauphiné-twinning, the volume fraction was treated as a parameter to be determined by an iterative method. The best structure was first obtained by using $hk0$ and hhl type data only since their intensities are independent of the volume fraction f. The R value converged to 0.033 for these 81 reflections. This structural model was then used to calculate $F_c(hkl)$ and $F_c(hk\bar{l})$. By putting these values of the F_c's on the right-hand side of eqs. 1 and 2 and the corresponding observed structure factors on the left, an initial value of f was determined as the average value over all the reflections. Equations 1 and 2 could be rewritten as

$$|F_o(hkl)|^2 = f \cdot |\bar{F}_o(hkl)|^2 + (1 - f) \cdot |\bar{F}_o(hk\bar{l})|^2$$

$$|F_o(hk\bar{l})|^2 = f \cdot |\bar{F}_o(hk\bar{l})|^2 + (1 - f) \cdot |\bar{F}_o(hkl)|^2$$

and solved for $|\bar{F}_o(hkl)|$ and $|\bar{F}_o(hk\bar{l})|$ by using the average value of f and the actually observed $|F_o(hkl)|$ and $|F_o(hk\bar{l})|$. These $|\bar{F}_o|$'s are the structure factors that would have been observed for an untwinned crystal of the same total volume as the one being studied. For a small number of reflections (10), all weak or unobserved, the $|\bar{F}_o(hkl)|^2$ values were calculated to be negative. These reflections were removed from further consideration. This set of corrected observed structure factors was used for a few more cycles of least-squares refinement of the atomic parameters. When the R value converged this second model was used to obtain a new average value of f and the process was repeated until the value of f converged to 0.64(1) and the unweighted R factor converged to 0.061. Symmetry equivalent reflections were averaged at this stage. A parameter g, for correcting the effects of secondary extinction following Larson (9), was also refined and was found to be 0.50×10^{-5}. The final weighted R value

$$R_\omega = \left[\frac{\Sigma\omega(|F_o| - |F_c|)^2}{\Sigma\omega|F_o|^2}\right]^{1/2}$$

was 0.078 for 487 symmetry independent reflections among which 445 were classified as observed. The weighting function was $\omega = [3.0 - 0.008F_o + 0.0015F_o^2]^{-1}$ with coefficients chosen so that $\omega|F_o - F_c| \sim 1$. The structure was also refined in the enantiomorphic space group $P3_221$, and the values of R and R_ω converged to 0.064 and 0.081 respectively. The space group $P3_221$, same as $AlPO_4$ (2), was then chosen for $FePO_4$. The final positional and thermal parameters are listed in Table 1. The calculated and hypothetical observed structure factors are listed in Table 2. Table 3 lists the actually observed structure factors and the structure factors calculated from eqs. 1 and 2 for $f = 0.64$.[1]

Discussion

$AlPO_4$ and $FePO_4$ are isostructural. The molecular geometries of these compounds are compared with that of quartz in Table 4. The berlinite structure has been discussed in detail by Schwarzenbach (2). These structures consist of helices of alternate FeO_4 or AlO_4 and PO_4 tetrahedra running parallel to the c-axis. In quartz, of course, the two tetrahedra are identical. Each oxygen atom is bonded to a P and a Fe in the present structure. The average Fe—O distance of 1.853 Å compares well with the value of the sum of the effective ionic radii for tetrahedrally coordinated Fe^{3+} and two-coordinated oxygen (10). The average P—O distance is 1.526 Å, as compared with 1.522 Å for P—O in $AlPO_4$. However, this difference is within one standard deviation and hardly significant. The O—P—O bond angles and O—O distances in the PO_4 group appear to be signi-

ficantly more uniform in $FePO_4$. In contrast, the O—M—O bond angles (M = Fe, Al) have a higher dispersion in $FePO_4$ than in $AlPO_4$. Both groups are angularly more irregular than the SiO_4 groups in quartz although in all cases the M—O(1) distance is about 0.01 Å larger than the M—O(2) distance. The angular distortion of the SiO_4 tetrahedron is a result of twisting the O(1)—O(1)6 edge about the twofold axis relative to the O(2)—O(2)5 edge. In $FePO_4$ the distortion is equivalent to a compression of the FeO_4 tetrahedron along the twofold axis at both ends, which leads to O(1)—Fe—O(1)6 and O(2)—Fe—O(2)5 angles both larger than the ideal tetrahedral angle. In $AlPO_4$ only the O(1)—Al—O(1)6 end is compressed. The angular distortion of the MO_4 tetrahedron can be related to the reduction in the M—O—P angle in $FePO_4$ compared with $AlPO_4$ and quartz. This reduction in the M—O—P angle results in a stronger metal–phosphorus repulsion, which in turn leads to larger tetrahedral angles in FeO_4. However, the Al—O—P angles are only slightly smaller than the Si—O—Si angle in quartz and yet the AlO_4 tetrahedron displays considerably greater angular distortion than the SiO_4. This suggests that other factors are also playing a role, *e.g.*, the difference in covalency of the bonds of the cations with oxygen.

The question of the immediate environment of the Fe^{3+} ion substituted in $AlPO_4$ is an open one. Although the M—O(1) distance is characteristically shorter than the M—O(2) distance by about 0.01 Å for both AlO_4 and FeO_4 tetrahedra, it is uncertain what the angular distortion will be for such a substitution. We calculated

the spin Hamiltonian parameter D for Fe^{3+} in $AlPO_4$ from a point-charge model, assuming no distortion of the environment due to substitution, *vs.* FeO_4 type tetrahedron for the substituent site. The difference in the values of D is a nontrivial 400%. Thus it appears that this distortion is important and can perhaps be measured by an examination of the diffuse scattering in highly doped $AlPO_4$ crystals.

The Two-step Synthesis and Crystal and Molecular Structure of Tetracyclo[6.4.0.0^{2,11}.0^{4,9}]dodec-6-ene-3,10-dione

YUEN-MUI NGAN, STEVEN J. RETTIG, JOHN R. SCHEFFER, AND JAMES TROTTER

Department of Chemistry, University of British Columbia, Vancouver, British Columbia V6T 1W5

Received January 27, 1975

YUEN-MUI NGAN, STEVEN J. RETTIG, JOHN R. SCHEFFER, and JAMES TROTTER. Can. J. Chem. **53**, 2068 (1975).

The photochemistry of the *trans*-1,3,5-hexatriene-*p*-benzoquinone Diels–Alder adduct has been investigated. Irradiation of this material in its long wavelength n → π* absorption band leads to a single photoproduct in high yield. A single crystal X-ray structure determination shows this product to be tetracyclo[6.4.0.0^{2,11}.0^{4,9}]dodec-6-ene-3,10-dione, the result of a novel regiospecific intramolecular 2+2 photoaddition between the side chain vinyl group and the ene-dione double bond. Crystals of tetracyclo[6.4.0.0^{2,11}.0^{4,9}]dodec-6-ene-3,10-dione are monoclinic, a = 7.5290(7), b = 19.072(1), c = 6.7237(4) Å, β = 107.918(6)°, Z = 4, space group $P2_1/n$. The structure was solved by direct methods and was refined by full-matrix least-squares procedures to a final R of 0.041 for 1603 reflections with $I \geq 3\sigma(I)$. The structure consists of well-separated molecular units. Bond distances are: C=O, 1.216 and 1.219(2), C=C, 1.318(2), mean C(sp^3)—C(sp^2), 1.508, mean C(sp^3)—C(sp^3), 1.560 in the four-membered ring and 1.544 elsewhere, mean C(sp^3)—H, 0.99, and mean C(sp^2)—H, 0.95 Å. Bond distances between nonhydrogen atoms have been corrected for thermal motion. A possible rationalization for the observed photoprocess is discussed in terms of conformational and radical stability effects.

YUEN-MUI NGAN, STEVEN J. RETTIG, JOHN R. SCHEFFER et JAMES TROTTER. Can. J. Chem. **53**, 2068 (1975).

On a étudié la photochimie du produit provenant de la réaction de Diels–Alder entre l'hexatriène-1,3,5 *trans* et la *p*-benzoquinone. L'irradiation de ce produit, a une longueur d'onde correspondant à la bande d'absorption n → π*, conduit à un seul produit avec un excellent rendement. La structure de ce produit a été établie par diffraction de rayons-X sur un cristal unique; il s'agit de la tétracyclo[6.4.0.0^{2,11}.0^{4,9}]dodécène-6 dione-3,10 qui provient d'une nouvelle réaction de photoaddition 2+2 intramoléculaire et régiospécifique impliquant le groupe vinyle de la chaine latérale et la double liaison de la portion ènedione. Les cristaux de cette dicétone sont monocliniques, a = 7.5290(7), b = 19.072(1), c = 6.7237(4) Å, β = 107.918(6)°, Z = 4, groupe d'espace $P2_1/n$. On a résolu sa structure par des méthodes directes et on l'a affinée par la méthode des moindres carrés (matrice complète) jusqu'à une valeur finale de R de 0.041 pour 1603 réflexions avec $I \geq 3\sigma(I)$. La structure comprend des unités moléculaires bien définies. Les longueurs des liaisons sont: C=O, 1.216 et 1.219(2); C=C, 1.318(2); valeur moyenne des C(sp^3)—C(sp^2), 1.508; valeur moyenne des C(sp^3)—C(sp^3), 1.560 dans le cycle à quatre chainons et 1.544 ailleurs; valeur moyenne C(sp^3)—H, 0.99 et valeur moyenne C(sp^2)—H, 0.95 Å. On a corrigé les longueurs des liaisons entre atomes autres que l'hydrogène afin de tenir compte des mouvements thermiques. On discute d'une rationalisation possible du photoprocessus observé en termes d'effets conformationnels et de stabilité du radical. [Traduit par le journal]

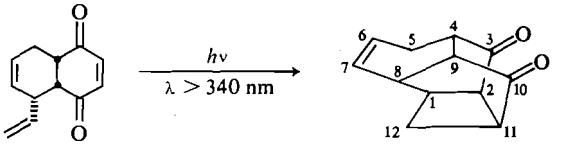
Introduction

The photochemistry of Diels–Alder adducts of *p*-benzoquinone with 1,3-dienes has proven to be a remarkably rich source of interesting and unusual polycyclic ring systems. Among the ring systems so produced are derivatives of tricyclo[4.4.0.0^{2,8}]decane (1–4), tricyclo[4.4.0.0^{2,9}]decane (3, 4), tricyclo[4.4.0.0^{3,9}]decane (1–3), and tricyclo[5.3.1.0^{2,7}]undecane (2, 3) as well as "cage" photoproducts possessing the basic tetracyclo[4.4.0.0^{3,9}.0^{4,8}]decane ring system[1] and their 7,10-bridged analogs (5).

In this paper we report a derivative of another novel ring system which may easily be obtained in this way in good yield, namely tetracyclo-[6.4.0.0^{2,11}.0^{4,9}]dodec-6-ene-3,10-dione (2) via intramolecular 2+2 cycloaddition in the benzoquinone-*trans*-1,3,5-hexatriene Diels–Alder adduct **1**.

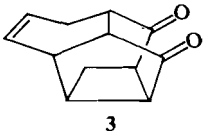
[1]J. R. Scheffer and B. Jennings. Unpublished results.

Diels–Alder adduct **1** is unreported in the literature, although two substituted derivatives are known (6). Adduct **1** may be prepared as a light yellow solid, m.p. 58–60°, in 40–50% yield simply by warming *p*-benzoquinone with a threefold molar excess of *trans*-1,3,5-hexatriene. The stereochemistry of **1** shown is that expected from concerted *cis-endo* addition and is the only configuration capable of giving the observed photoproduct **2**. The n → π* u.v. spectrum of **1** (λ_{max} (EtOH) 355 nm, ε 75) is essentially identical to that of the parent butadiene–benzoquinone Diels–Alder adduct (1) thus indicating no ground state interaction between the side chain vinyl group and the ene–dione double bond.



1 **2**

Diels–Alder adduct **1** (200 mg in 200 ml of benzene or *tert*-butyl alcohol) was irradiated in its n → π* absorption band with light of λ > 340 nm (Corning 7380 glass filter) and the reaction followed by t.l.c. This showed the formation of essentially only one photoproduct which could be isolated in 60–70% yield by column chromatography on alumina. The recrystallized photoproduct (50% yield) was a colorless solid, m.p. 91.5–92.5°, whose spectra (see Experimental section) indicated that it had been formed by intramolecular vinyl–ene-dione 2+2 cycloaddition. However these data were incapable of distinguishing between structure **2** and its alternative, **3**, shown below. For example, the i.r. data, which were expected to be of help in distinguishing between structures **2** and **3**, were equivocal, showing carbonyl stretching frequencies of 1715 and 1735 cm^{-1} in KBr and 1725 cm^{-1} in carbon tetrachloride. For this reason, and because the photoproduct promised to have an interesting and unusual strained polycyclic ring skeleton, an X-ray crystal structure investigation was undertaken.



3

X-Ray Crystal Structure Determination

The crystal chosen for study was mounted with *b* parallel to the goniostat axis and had dimensions of *ca.* 0.8 × 0.5 × 1.0 mm. Unit-cell and space group data were obtained from film and diffractometer measurements. The unit-cell parameters were refined by a least-squares treatment of $\sin^2\theta$ values for 24 reflections measured on a diffractometer with CuK_α radiation. Crystal data are:

$C_{12}H_{12}O_2$ f.w. = 188.2

Monoclinic, a = 7.5290(7), b = 19.072(1), c = 6.7237(4) Å, β = 107.918(6)°, V = 918.6(1) $Å^3$, ρ_m = 1.359 (flotation in aqueous KI), Z = 4, ρ_c = 1.3609(2) g cm^{-3}, $F(000)$ = 400 (22 °C, CuK_α, λ = 1.5418 Å, μ = 7.5 cm^{-1}). Absent reflections: $0k0$, $k \neq 2n$, and $h0l$, $h + l \neq 2n$ define uniquely the space group $P2_1/n$ (C_{2h}^5, No. 14).

Intensities were measured on a Datex-automated General Electric XRD 6 diffractometer, with a scintillation counter, CuK_α (nickel filter and pulse height analyzer), and a θ–2θ scan at 2 deg min^{-1} over a range of (1.80 + 0.86 tan θ)° in 2θ, with 10 s background counts being measured at each end of the scan. Data were measured to 2θ = 146° (minimum interplanar spacing 0.81 Å). The intensity of the check reflection remained constant to within ±1.5% of its initial value throughout the data collection. Lorentz and polarization

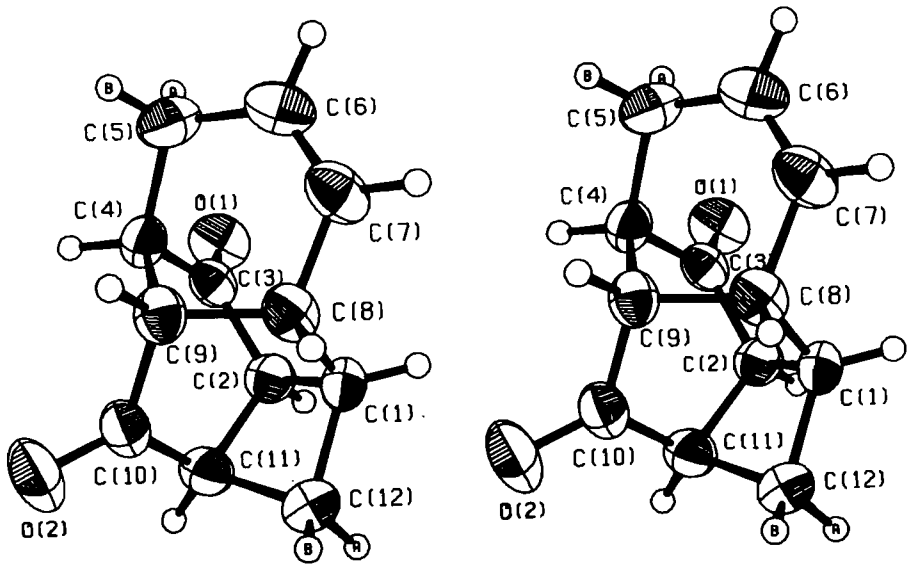

FIG. 1. Stereoscopic view of the tetracyclo[6.4.0.0^{2,11}.0^{4,9}]dodec-6-ene-3,10-dione molecule showing the atom numbering scheme and 50% probability thermal ellipsoids for the nonhydrogen atoms.

corrections and check reflection scaling were applied, and the structure amplitudes were derived. No absorption correction was made in view of the low value of μ. Of the 1856 independent reflections measured, 230 had intensities less than $3\sigma(I)$ above background where $\sigma^2(I) = S + B + (0.06S)^2$ with S = scan count and B = time averaged background count. These reflections were given zero weight in the refinement but were included in the structure factor calculations.

Structure Analysis

The structure was solved by direct methods. Sixteen sets of signs for 236 reflections with $|E| \geq 1.50$ were determined by a computer program which uses Sayre relationships in an iterative procedure (7). One set of signs was outstanding in that it converged in 6 cycles to a set having the highest consistency index (7), 0.80, with 126 positive and 110 negative signs. The 14 nonhydrogen atoms accounted for the 14 highest peaks on the E-map computed from the 236 signed values of E from this set.

Three cycles of isotropic followed by two cycles of anisotropic full-matrix least-squares refinement of the overall scale factor and the O and C atoms gave R 0.091. A difference map at this point clearly gave the positions of the 12 hydrogen atoms which were included in all subsequent cycles of refinement with isotropic thermal parameters. The entire structure was refined for six cycles giving a final R of 0.041 and R_w 0.056 for 1603 reflections with $I \geq 3\sigma(I)$ (23 reflections which had $|F_o - F_c| > 3\sigma(F)$ were removed from the data set in the final stages of refinement).

The least-squares refinement was based on the minimization of $\Sigma w |F_o| - |F_c/(1 + gI)|]^2$ where g is the extinction parameter and I the uncorrected intensity. The final value of g was 1.89×10^{-7}. The scattering factors of ref. 8 were used for the nonhydrogen atoms and those of ref. 9 for the hydrogen atoms. Anomalous scattering factors from ref. 10 were used for the oxygen and carbon atoms. The anisotropic thermal parameters employed in the refinement are U_{ij} in the expression

$$f = f^0 \exp[-2\pi^2(U_{11}h^2a^{*2} + U_{22}k^2b^{*2} + U_{33}l^2c^{*2} + 2U_{12}hka^*b^* + 2U_{13}hla^*c^* + 2U_{23}klb^*c^*)]$$

where f^0 is the tabulated scattering factor and f is that corrected for thermal motion. The weighting scheme: $w = 1$ if $|F_o| < 6.0$ and $w = (6.0/|F_o|)^2$ if $|F_o| \geq 6.0$ gave uniform average values of $w(|F_o| - |F_c|)^2$ over ranges of $|F_o|$ and was employed in the final stages of refinement.

On the final cycle of refinement the greatest parameter shift was 0.31 σ and the mean parameter shift was 0.06 σ. A final difference map showed maximum fluctuations of ±0.27 e Å^{-3}. The final positional and thermal parameters appear in Tables 1 and 2 respectively. Measured and calculated structure factors have been placed in the Depository of Unpublished Data.[2]

[2]The structure factor table is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

Thermal Motion and Correction of Molecular Geometry

The ellipsoids of thermal motion for the nonhydrogen atoms are shown in Fig. 1. The thermal motion has been analyzed in terms of the rigid-body modes of translation (**T**), libration (**L**), and screw (**S**) motion (11) using the computer program MGTLS. The r.m.s. standard deviation in the temperature factors U_{ij} is 0.00074 Å^2 indicating that the thermal motion of the 14 nonhydrogen atoms of the molecule is reasonably described by the rigid-body thermal parameters in Table 3 (r.m.s. ΔU_{ij} = 0.0021 Å^2). The unique origin lies close to the center of gravity. The orientation of the principal axes

of **L** is as expected: L_1 lies roughly along the long axis of the molecule, L_2 is 6° from the C(1)—C(2) vector, and L_3 is 11° from the C(11)—C(10) vector.

The appropriate bond distances and angles have been corrected for libration (12, 13), using shape parameters q^2 of 0.08 for all atoms involved. Independent motion corrections based on the ΔU_{ij} (14, 15) have also been applied. Both corrected and uncorrected bond distances appear in Table 4. The changes in the bond angles were insignificant, thus only the uncorrected values appear in Table 5.

Discussion

Figure 1 shows a general view of the molecule and the atom numbering scheme. Dihedral angles are given in Table 6 and selected intra- and intermolecular nonbonded distances are listed in Table 7.

The structure analysis has shown that the major product, which has the structure **2**, is formed from **1** by the formation of the C(1)—C(2) and C(11)—C(12) bonds and has provided accurate details of the geometry of this unusual tetracyclic system. The cage structure may be thought of as being derived from bicyclo[2.2.2]octa-2,5-diene by addition of a one atom bridge between C(1) and C(11) and a three atom bridge from C(4) to C(8) (numbering of Fig. 1).

Both carbonyl groups are slightly, but significantly, nonplanar. C(3) and C(10) are displaced 0.008 (6σ) and 0.017 Å (23σ) from the O(1)C(2)C(4) and O(2)C(9)C(11) planes. The grouping about the C(6)—C(7) double bond is also nonplanar, the dihedral angle C(5)[C(6)—C(7)]C(8) being 2.7(1)°. The nonplanarity of these groups is presumably a result of strain in the polycyclic system.

There are five six-membered rings in the structure. Those three which form the bicyclo[2.2.2]octadiene subgroup have distorted conformations which are best described as intermediate between the boat and twist-boat conformations. The fourth six-membered ring, C(1) and C(8)—C(12), has a distorted chair conformation. These distortions are hardly surprising since each of the four rings mentioned above has 2 or 3 atoms in common with a four-membered ring. The last six-membered ring, which contains the double bond, shows only a small amount of strain. The conformation of this ring is close to the average of those calculated for the minimum energy conformations of 4,5- and 3,4-disubstituted cyclohexenes (16), also shown in Table 6. Dihedral angles in the eight membered ring, C(1)—C(8), are also given, but understandably do not correspond to any of the usual minimum energy conformations (17, 18).

The four-membered ring [C(1),C(2),C(11), C(12)] is nonplanar, the dihedral angles in the

ring having a mean magnitude of 26.0°. The bond lengths in the ring are divided into two groups, those involving the "free" C(12) atom (C(1)—C(12), 1.544(2), and C(11)—C(12), 1.554(2) Å) being significantly shorter than the other two bonds (C(1)—C(2), 1.569(2), and C(2)—C(11), 1.572(2) Å). Bond distances in gaseous cyclobutane (19) and in the four-membered ring of bicyclo[3.1.1]heptane (20) are 1.548 and 1.553 Å respectively. Mean C—C distances in the four-membered rings of gaseous bicyclo[2.2.0]hexane (21) and gaseous *anti*- and *syn*-tricyclo[4.2.0.$0^{2,5}$]octane (22) are 1.556, 1.557, and 1.566 Å compared to a mean bond length of 1.560 Å in the four-membered ring of the present structure. Bond angles in the four-membered ring range from 85.7(1)° at C(2) to 87.7(1)° at C(1). These values are similar to those in related molecules, *e.g.* 84.9 and 87.1° in bicyclo[3.1.1]heptane (20).

Bond distances and angles in the remainder of the molecule are normal. The C=C distance of 1.318(2) Å is the same as that in the related molecule tricyclo[4.4.0.$0^{2,8}$]dec-3-ene-7,10-dione (1, 23). Other mean bond distances are C=O, 1.218, C(sp^2)—C(sp^3), 1.508, C(sp^3)—C(sp^3), (not in the four-membered ring), 1.544, C(sp^3)—H, 0.99, and C(sp^2)—H, 0.95 Å.

The crystal structure consists of well-separated molecular units. The shortest intermolecular contacts, listed in Table 7, correspond to normal van der Waals contacts.

The observation that the photocyclization of **1** leads exclusively to **2** is interesting particularly in view of the fact that **2** undoubtedly incorporates more ring strain than **3**. One possible

rationalization for this regiospecificity can be made in terms of arguments based on conformational analysis and radical stability. Mono-C_5-substituted 4a,5,8,8a-tetrahydro-1,4-naphthoquinones (*e.g.*, **1**) possess six well-defined conformations only two of which, in the case of **1**, are capable of vinyl–ene-dione cycloaddition. These are the conformations **1***a* and **1***b* shown below. If, as seems likely (24), the cycloaddition is a two-step process, then initial bonding in the case of **1** should occur preferentially between C_2 or C_3 and the terminal carbon of the vinyl group so as to give the more stable (presumably diradical) intermediate. In both **1***a* and **1***b* however, the terminal carbon of the vinyl group can approach C_3 much more closely than C_2 without serious nonbonded interactions; hence photoproduct **2** is eventually formed in preference to **3**. This argument, ignoring as it does the likely intermediacy of twisted ene–dione excited states and/or intramolecular exciplex intermediates, should be regarded as tentative.

Experimental

Preparation of the trans-1,3,5-Hexatriene-p-benzoquinone Diels–Alder Adduct **1**

A mixture of 4.0 g (0.05 mol) of 1,3,5-hexatriene (prepared by the method of Hwa and Sims (25)) and 1.6 g (0.014 mol) of freshly recrystallized *p*-benzoquinone was stirred at 60° for 2 h during which time the benzoquinone slowly dissolved. The solution was then stirred for 4 h at room temperature and the hexatriene removed *in vacuo* to leave a yellow solid. Two recrystallizations of this material from petroleum ether afforded 1.2 g (43%) of light yellow crystals, m.p. 58–60°; i.r. ($CHCl_3$) 1695 (C=O) and 1610 (weak, C=C) cm^{-1}; n.m.r. ($CDCl_3$) τ 3.3 (d, 2, AB quartet, J = 10 Hz, C_2 and C_3 vinyls), 4.1–4.6 (m, 3), 4.9–5.1 (m, 2, methylene vinyls), and 6.5–8.0 (m, 5); n → π* u.v. max (EtOH) 355 nm, ε 75; mass spectrum parent (70 eV) *m/e* 188.

Anal. Calcd. for $C_{12}H_{12}O_2$: C, 76.59; H, 6.39. Found: C, 76.51; H, 6.30.

Photolysis of Diels–Alder Adduct **1**

Numerous photolyses were carried out in either benzene or *tert*-butyl alcohol with identical results; the following description is typical. A solution of 200 mg of adduct **1** in 200 ml of anhydrous distilled benzene was situated external (6 in.) to a standard immersion well

Metastable Ion Studies. V. The Identification of $C_2H_4O^{+\cdot}$ Ion Structures from their Characteristic Kinetic Energy Releases

JOHN L. HOLMES AND JOHAN K. TERLOUW[1]

Chemistry Department, University of Ottawa, Ottawa, Canada K1N 6N5

Received March 6, 1975

JOHN L. HOLMES and JOHAN K. TERLOUW. Can. J. Chem. **53**, 2076 (1975).

Metastable ion peaks for the fragmentation $C_2H_4O^{+\cdot} \rightarrow C_2H_3O^+ + H^\cdot$ have been studied in the first field-free region of a double focussing mass spectrometer under conditions of good energy resolution. Three isomeric $C_2H_4O^{+\cdot}$ ions were generated, (a) $CH_2—CH_2^{+\cdot}$ (O), (b) $CH_3CHO^{+\cdot}$, and (c) $CH_2{=}CHOH^{+\cdot}$ from ethylene oxide, acetaldehyde, and ethyl vinyl ether respectively, each fragment producing a different $^1m^*$ peak having a characteristic shape and kinetic energy release. The above ions do not therefore interconvert prior to fragmentation and their characteristic $^1m^*$ peaks permit their unequivocal identification, thus providing a powerful method for ion structure determination.

In agreement with some recent collisional activation data it was found that the unbranched aldehydes, cyclic alcohols, and 2-haloethanols investigated generated (c) type $C_2H_4O^{+\cdot}$ ions. These are also produced by glycidol and α-furfuryl alcohol. Some compounds generated composite $^1m^*$ peaks, *e.g.* 1,3-dioxolane produces (a) and (c) ions, while compounds which produce prominent $C_2H_5O^+$ ions having the protonated acetaldehyde structure, generate *m/e* 44 ions of structures (b) and (c). In isopropanol these components were separated by a deuterium labelling experiment. Contrary to earlier proposals, pyruvic acid does not generate (b) type ions but produces predominantly ions of structure (c).

JOHN L. HOLMES et JOHAN K. TERLOUW. Can. J. Chem. **53**, 2076 (1975).

On a étudié les pics des métastables de la fragmentation $C_2H_3O^{+\cdot} \rightarrow C_2H_3O^+ + H^\cdot$ dans la première région libre de champ d'un spectromètre de masse à double focalisation dans des conditions où l'on peut observer une bonne résolution des énergies. On a produit respectivement les trois ions isomères $C_2H_4O^{+\cdot}$ suivants (a) $CH_2—CH_2^{+\cdot}$ (O), (b) $CH_3CHO^{+\cdot}$ et (c) $CH_2{=}CHOH^{+\cdot}$ à partir de l'oxyde d'éthylène, de l'acétaldehyde et de l'éther vinylique. Chaque ion se fragmente pour conduire à un pic $^1m^*$ différent tant par sa forme que par l'émission d'énergie cinétique. Les ions mentionnés plus haut ne se transforment donc pas les uns dans les autres avant leur fragmentation et leurs pics $^1m^*$ caractéristiques permet donc de les identifier sans ambiguïté; cette propriété fournit donc une méthode puissante pour déterminer la structure des ions.

On a trouvé, en accord avec des données récentes sur l'activation collisionnelle, que les aldéhydes en chaîne droite, que les alcools cycliques et que les halogéno-2 éthanols étudiés fournissent tous des ions $C_2H_4O^{+\cdot}$ du type (c). Ces ions se forment aussi à partir du glycidol et de l'alcool α-furfurylique. Quelques composés conduisent à des pics $^1m^*$ composés; par exemple le dioxolanne-1,3 fournit des ions du type (a) et du type (c) alors que des composés qui produisent pour $C_2H_5O^+$ des ions importants de structure acétaldehyde protoné, donnent naissance à des ions de $m/e = 44$ ayant les structures (b) et (c). Dans l'isopropanol, on a séparé ces constituants à l'aide d'expériences impliquant un marquage au deutérium. Contrairement à ce qui a été proposé antérieurement, l'acide pyruvique ne conduit pas à des ions du type (b) mais principalement à des ions de structure (c). [Traduit par le journal]

Introduction

Three methods have been widely used in recent years to try to establish ion structures and fragmentation mechanisms. These are (*i*) the metastable ion peak abundance ratio test (for competing fragmentations of a given ion) originally proposed by Shannon and McLafferty (1). This well-known approach is a comparative method and applies to *ions fragmenting in the microsecond time frame* and having a range of internal energies of several eV; (*ii*) ion cyclotron

[1]Permanent address: Analytical Chemistry Laboratory, University of Utrecht, Croesestraat 77A, Utrecht, The Netherlands.

resonance (i.c.r.) spectroscopy, which identifies *ions having insufficient energy to fragment in the millisecond time frame*, by examining their reaction with various neutral substrate molecules; (*iii*) collisional activation spectrometry (c.a.) identifies *ions which have insufficient energy to dissociate within the microsecond time frame* (the first field-free region of a reversed geometry double-focussing mass spectrometer) by inducing their dissociation with a neutral collision gas and then examining the ion kinetic energy spectrum of the products.

Application of these methods to small heteroatom containing ions such as $C_2H_5O^+$ (1–4), $C_2H_6N^+$ (5–7), $C_3H_8N^+$ (5–7), $C_3H_7O^+$ (8, 9), and small hydrocarbon ions $C_3H_6^{+\cdot}$ (10, 11) has certainly advanced our knowledge of these systems. These methods are however not unambiguous and because of the wide range of ion internal energies and lifetimes involved they should be considered as complementary. Moreover the abundance ratio test and c.a. approaches are most useful for ion identification by comparison with selected reference ions of known or assumed structure.

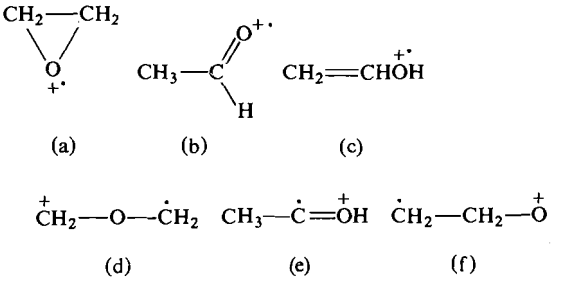
Another method, which has mainly been pioneered by Beynon and co-workers (12), is based upon measurement of the kinetic energy released in the dissociation of metastable ions. This technique, which relies on the recording of ^{1}m* peaks under conditions of good energy resolution, has not been widely practised, possibly because of the level of electronic stability required for reproducible ^{1}m* measurements with a very narrow β-slit setting. Without additional measurements this too is only a comparative technique, but when combined with appropriate accurate thermochemical measurements, unequivocal precursor and daughter ion structures may confidently be assigned (13, 14).

We have undertaken a study of ^{1}m* peaks for $C_2H_4O^{+\cdot}$ fragmentations under conditions of high energy resolution. This ion, *m/e* 44, which is a prominent fragment ion in the mass spectra of many organic oxycompounds has been studied by both the metastable peak abundance method (15) and by c.a. (16). In the present work the chosen probe reaction was H atom loss because the associated ^{1}m* peak was found clearly to be characteristic of the $C_2H_4O^{+\cdot}$ ion structure. A discussion of the energetics of this fragmentation as a function of $C_2H_4O^{+\cdot}$ structure and their relationship with ^{1}m* observations will be described in a future publication (17).

Results and Discussion

Choice of Reference Ions and the Probe Reaction

The following structures can be envisaged for $C_2H_4O^{+\cdot}$ ions



(a) (b) (c)

(d) (e) (f)

(a) and (b) are directly related to stable neutral species, whereas (c), ionized vinyl alcohol, has no known neutral counterpart. The remaining three ions may not be stable observable entities although (e) has been postulated as an intermediate in the formation of $C_2H_4O^{+\cdot}$ ions from pyruvic acid (18). Ion (d) might be generated by loss of H_2 from the molecular ion of dimethyl ether and (f) is a ring opened form of (a). These will be discussed later.

In their c.a. study of $C_2H_4O^{+\cdot}$, Van de Sande and McLafferty (16) only considered (a), (b), and (c) as possible structures.[2] They selected ethylene oxide, acetaldehyde, and a series of unbranched aldehydes as reference compounds for the generation of (a), (b), and (c) respectively, and found that their c.a. spectra were markedly different. They concluded therefore that (a), (b), and (c) represent stable species with lifetimes of $>10^{-5}$ s. With the above as reference spectra they compared the behavior of a number of *m/e* 44 ions derived from a variety of oxygen containing molecules and were able in every case to identify the ions as being either of class (a) or (b) or (c) or in a few instances as a mixture thereof.

In order to classify $C_2H_4O^{+\cdot}$ ions by examination of their ^{1}m* energy release characteristics, a suitable probe reaction is required which produces a metastable ion peak of good abundance from each isomeric structure. Accordingly the 70 eV metastable ion spectra of ethylene

[2]Our notation (a), (b), and (c) is the same as that of Van de Sande and McLafferty (16).

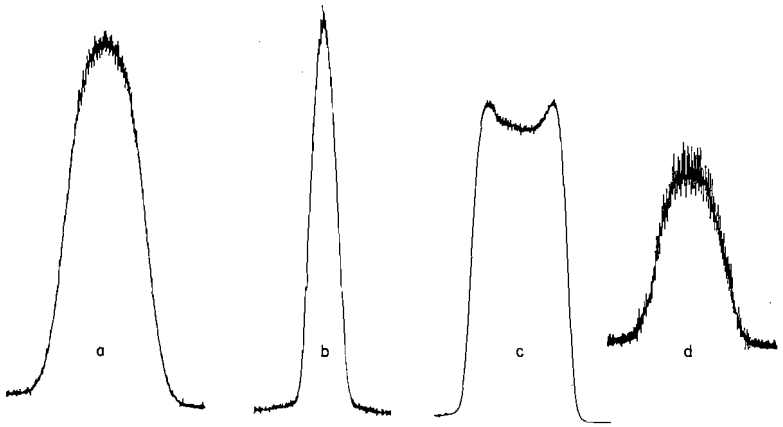


FIG. 1. $^1m^*$ peaks for $C_2H_4O^{+\cdot} \rightarrow C_2H_3O^+ + H^\cdot$, precursor molecule (*a*) ethylene oxide; (*b*) acetaldehyde; (*c*) ethyl vinyl ether; (*d*) dimethyl ether.

oxide (a), acetaldehyde (b), and (c) which is very probably generated from ethyl vinyl ether (16, 19), were examined first by use of a scintillation photomultiplier detector (see Experimental) and then by separation from the main ion beam by the acceleration potential scan method. Of the four possible primary fragmentations of interest, namely loss of $H^\cdot$, H_2, $CHO^\cdot$, and $CH_3^\cdot$ only H atom loss was accompanied by an intense $^1m^*$ in each case. For H_2 elimination only a weak $^1m^*$ is generated, loss of $HCO^\cdot$ is absent in (a) and of only moderate intensity (partly collision induced) in (b) and (c). Formation of HCO^+ from ethylene oxide produced a strong $^1m^*$, for (b) it was weak and it was barely detectable in (c). Pritchard (15) compared the $^2m^*$ for the latter reaction with that for the dissociation which generates CH_3^+ in the mass spectra of (a) and (b) and acetaldehyde-d_4. His intent was to use the $^2m^*$ abundances to characterize the fragmenting ions; however the results for acetaldehyde (d_0 and d_4) were difficult to interpret and we have not been able to repeat his observations (see below). In any case, the presence of only one metastable ion peak of appreciable intensity makes structure identification by comparing peak abundances a hazardous undertaking. Because of its good intensity in (a), (b), and (c) we chose H atom loss as the probe reaction and the corresponding $^1m^*$ peaks are shown in Fig. 1, together with that derived from *m/e* 44 in the mass spectrum of dimethyl ether (d). As can be seen, these $^1m^*$ are markedly different in appearance under the energy resolution conditions employed (see Experimental). The $T_{0.5}$ values are (a) 430 meV, (b) 43 meV, (d) 320 meV, and for (c) 580 meV; the latter is a dished flat-top peak and $T_h = 300$ meV represents all or a fraction of the reverse activation energy of this fragmentation.[3] It could be argued that the $^1m^*$ for (a) is either made up of a mixture of (b) and (c) or that it represents (b) ions having a different range of internal energy contents. The former is certainly not the case, it proving impossible to reproduce the shape of (a) by summing (b) and (c) in various proportions. The latter possibility is effectively ruled out by thermochemical data (17) and in any case differences in kinetic energy release in noncomposite $^1m^*$ peaks due to internal energy content effects are usually found to be small (20, 21). Furthermore, as will be shown below, $T_{0.5}$ values for this fragmentation produced from a wide range of precursor molecules vary very little from those of the "model" compounds.

The shape of the ethylene oxide peak deserves comment; it is neither a dished flat-top peak (as would normally be expected for a fragmentation having so large a $T_{0.5}$ and such steep sides (14)) nor does it have the Gaussian profile so commonly observed. Note the similarity of (a) to (d); the latter has a *smaller* $T_{0.5}$ than (a); it is possible that they are both composite peaks in which different proportions of two (or more) isomeric daughter ions are generated; this and related matters will be discussed elsewhere (17).

[3] T_h is the energy release calculated from the peak width at its upper extremities or "horns" (14).

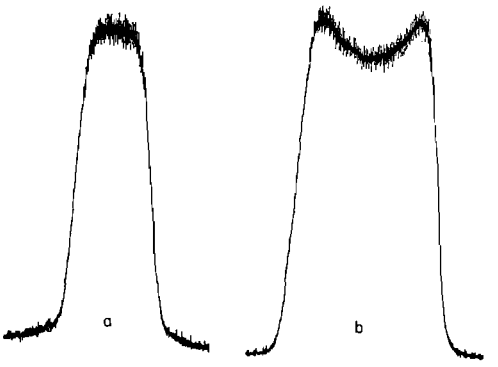

FIG. 2. (*a*) ^{1}m* peak for $CH_3CDO^{+\cdot} \rightarrow CH_3CO^+ + D^\cdot$; (*b*) ^{1}m* peak for $C_2H_3DO^{+\cdot} \rightarrow C_2H_3O^+ + D^\cdot$ generated from cyclobutanol-OD.

The observations described thus far parallel those of the recent c.a. study (16) and these ^{1}m* peaks should permit a clear distinction to be made between fragmenting *m/e* 44 daughter ions.

It is evident from these results and the c.a. data (16) that (b) and (c) are easily differentiated both as fragmenting and nonfragmenting ions. This is contrary to the proposal of Pritchard (15) that (b) and (c) undergo a facile tautomerization. This suggestion arose from the observation that whereas generation of CDO^+ from CD_3CDO yielded a weak ^{2}m*, the unlabelled compound produced no detectable metastable ion peak. In order to explain this observation a large kinetic isotope effect was invoked and it was proposed that methyl loss was preceded by a tautomeric hydrogen shift. We have reexamined the ^{2}m* spectra of CH_3CHO, CD_3CDO, and CH_3CDO, and were unable to observe any significant difference in the intensities of the weak ^{2}m* for the CHO^+, CDO^+ generating fragmentations. Furthermore CH_3CDO yielded only CDO^+ daughter ions both in the normal mass spectrum (fragmentations in the ion source) and in the ^{2}m*. These observations rule out the tautomeric change proposed by Pritchard.

The H loss (probe reaction) provides further evidence that (b) ions do not rearrange prior to fragmentation either in the ion source or field-free regions. $CH_3CDO^{+\cdot}$ loses exclusively the D atom and the ^{1}m* peak is shown as Fig. 2*a*. It is noteworthy that $T_{0.5} = 104$ meV[4] is appreciably larger than in unlabelled (b), thus $T_H/T_D = 0.4$. This result, $T_H/T_D < 1$, is an uncommon observation (22) and its significance will be discussed elsewhere (17).

The H atom lost from (c) is exclusively the hydroxyl hydrogen. This is borne out by observations on cyclobutanol partially exchanged with D_2O in the mass spectrometer's inlet system. This molecule yields (c) without mechanistic complexity by a simple elimination of C_2H_4 from the molecular ion (23); this too is in accord with the c.a. results (16). In the mass spectrum of the partially labelled compound, ions of *m/e* 45 $C_2H_3DO^{+\cdot}$, lost exclusively D and the ^{1}m* peak is shown in Fig. 2*b*. $T_{0.5}$ for this dissociation was 640 meV, close to that for the unlabelled counterpart, $T_{0.5}^H = 609$ meV.

Structure Assignments of $C_2H_4O^{+\cdot}$ Fragment Ions (Table 1)

Compounds Producing (c) Type Ions ($CH_2{=}\overset{+\cdot}{C}HOH$)

In order to compare our method with the c.a. investigation (16) we have examined molecules representative of four of the classes of compounds reported therein (see Table 1, **4–9**). Results from the two experimental methods agree and thus for these compounds both the fragmenting and nonfragmenting $C_2H_4O^{+\cdot}$ ions retain their structural identity in the microsecond time frame.

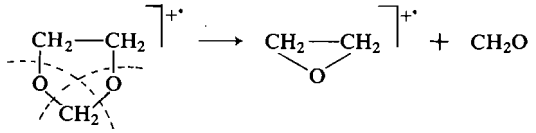
$C_2H_4O^{+\cdot}$ ions of structure (c) were also found to be generated from α-furfuryl alcohol (**10** in Table 1) and glycidol (**11**). Partial deuterium exchange in these compounds produced the same observations as obtained with cyclobutanol. The potential scope of this method of ion identification is well exemplified by the glycidol result; this molecule contains an ethylene oxide ring in addition to a $-CH_2OH$ moiety and the generation of two *m/e* 44 ion structures could well be envisaged. The present method easily and clearly establishes ion structure, a result not achieved by conventional e.i. labelling experiments.

1,3-Dioxolane

This compound is of special interest because in the c.a. study it was shown to generate a mixture of (a) and (c) the proportions of which varied with ionizing electron energy (16) (5:1 at 70 eV and 2:1 at 20 eV respectively). It was proposed that (a) was generated directly from

[4]The same value was found for D$^\cdot$ loss from $C_2D_4O^{+\cdot}$ ions.

the molecular ion as shown below



The generation of (c) type ions is difficult to envisage but they may arise by H loss from *m/e* 45, $C_2H_5O^+$, a fragmentation accompanied by a ^{1}m*. $C_2H_5O^+$ is generated from the $[M—H]^+$ ion with an intense ^{2}m*. The elucidation of the route for the formation of these ions awaits a deuterium labelling experiment. It is worth noting that the mass spectrum of this compound also contains an intense ^{2}m* for *m/e* 44 → *m/e* 29, again supporting the (a) structure for the $C_2H_4O^{+\cdot}$ ions. The ^{1}m* peak for the probe reaction in 1,3-dioxolane is shown as item (a) in Fig. 3*a*. Superficially it indeed closely resembles that shown in Fig. 1*a*, however the $T_{0.5}$ value, 480 meV, is significantly higher than that observed in the ethylene oxide fragmentation. Following the c.a. results, the extra broadening can be attributed to a contribution from (c) type ions. Trial and error summations of peaks 1*a* and 1*c* allowed duplication of peak 3*a* using relative abundances of 2(a):1(c). This ratio is different from that reported in the c.a. experiments but it must be remembered that the two methods deal with ions having different initial internal energy contents. Furthermore, the accuracy with which relative contributions of metastable peaks in a composite signal can be assigned, decreases with decrease in the difference between their $T_{0.5}$ values. A more accurate assessment can be made by an overall peak-shape analysis rather than by using a single parameter (*e.g.* the half-height width).

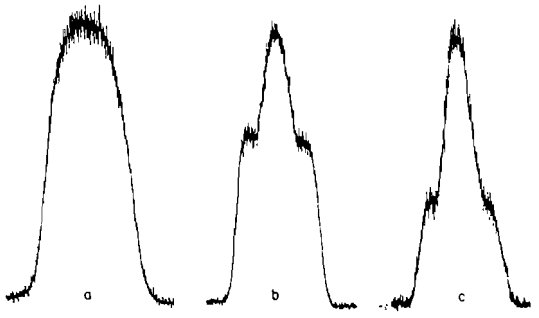


FIG. 3. ^{1}m* ion peaks for $C_2H_4O^{+\cdot} \rightarrow C_2H_3O^+ + H^\cdot$ generated from (*a*) 1,3-dioxolane; (*b*) isopropanol; and (*c*) diisopropyl ether.

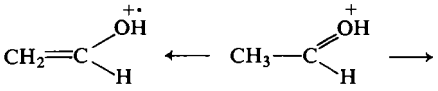
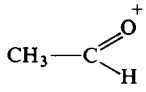
Composite ^{1}m Peaks of (b) plus (c) Type*

From the i.c.r. experiments of Beauchamp and Dunbar (4) it was concluded that $C_2H_5O^{+\cdot}$ ions generated from ethanol, isopropanol, diethyl ether, and diisopropyl ether had either the protonated acetaldehyde or protonated ethylene oxide structure. A later c.a. study (2) showed that protonated acetaldehyde was the more probable structure for the above compounds and acetal. The $C_2H_5O^+$ ions in the mass spectra of the above five compounds are prominent and are accompanied by relatively weak *m/e* 44, $C_2H_4O^{+\cdot}$ ions. The latter are largely (but not exclusively) generated by H loss from the former and so we investigated the corresponding ^{1}m*'s for $C_2H_4O^{+\cdot} \rightarrow C_2H_3O^+$. In every case a (b) plus (c) composite peak was observed (see Table 1 and Figs. 3*b* and 3*c*). This is in keeping with the proposed protonated acetaldehyde structure for $C_2H_5O^+$ ions, which can lose H in two ways



(c)



(b)

to yield (c) and (b) as shown. (The oxirane type of $C_2H_5O^+$ ion might be expected to generate (a).) This suggestion is further supported by observations on isopropanol-OD. The *m/e* 46 ions of proposed structure[5]  lose both H$^\cdot$ and D$^\cdot$ with accompanying ^{1}m* peaks. The label retaining ion *m/e* 45, of proposed structure (c) *exclusively* lost D$^\cdot$ with a $T_{0.5}$ of 635 meV, and the peak shape was closely similar to that observed for cyclobutanol (see Fig. 4*b*). The ion generated by D loss from *m/e* 46, generated a ^{1}m* peak with a shape and $T_{0.5}$ characteristic of acetaldehyde. This result is shown in Fig. 4*a*. Note that there is a residual (c) (vinyl alcohol) component in the *m/e* 44 → *m/e* 43 ^{1}m*, Fig.

[5]In completely deuterated isopropanol-OD, *m/e* 45 (unlabelled compound) is completely shifted to *m/e* 46 (3).

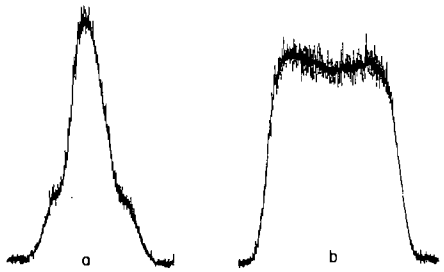


FIG. 4. (*a*) ^{1}m* peak for $C_2H_4O^{+\cdot} \rightarrow C_2H_3O^+ + H^\cdot$ generated from $CH_3CH(OD)CH_3$; (*b*) ^{1}m* peak for $C_2H_3DO^{+\cdot} \rightarrow C_2H_3O^+ + D^\cdot$ generated from $CH_3CH(OD)CH_3$.

4*a*, but that is entirely due to the presence of unlabelled material. The unlabelled compound also accounts for the markedly reduced dish in the $C_2H_3OD^+ \rightarrow C_2H_3O^+ + D^\cdot$ ^{1}m* (Fig. 4*b*); here the dish is partly filled by the weak flat-topped ^{1}m* corresponding to the fragmentation $C_2H_5O^+ \rightarrow C_2H_3O^+ + H_2$. Closely similar results were obtained with ethanol. As can be seen in Table 1, the relative proportions of the (b) and (c) components depend upon the precursor molecules but the $T_{0.5}$ values are essentially precursor independent. These differences arise from the possibility of additional routes for the generation of *m/e* 44 and/or the production of *m/e* 44 ions having different internal energy distributions.

Tetrahydrofuran provided a surprising result in that (b) and (c) type *m/e* 44 ions were generated therefrom. This result negates the earlier proposal (24), that they have an ethylene oxide (a) structure. Although some deuterium labelled tetrahydrofurans have been examined (25, 26), it is still not possible to propose sound mechanisms for the formation of $C_2H_4O^{+\cdot}$ daughter ions.

Ethylene Glycol Dimethyl Ether, a Composite of (a)/(d), (b) Type

Ion cyclotron resonance, c.a., and thermochemical evidence indicate that there is another stable $C_2H_5O^+$ ion, of structure $CH_3—\overset{+}{O}=CH_2$, which can be generated for example, from ethylene glycol dimethyl ether, $CH_3—O—CH_2—CH_2—O—CH_3$. This compound displays a prominent *m/e* 45 peak in its mass spectrum but only a very weak *m/e* 44. However there is a weak ^{1}m* for the fragmentation *m/e* 45 → *m/e* 44 and since this may herald the production of $C_2H_4O^{+\cdot}$ ions of structure (d), the probe reaction for this compound was duly measured. The ^{1}m* is shown in Fig. 5*a*. It contains at least two components, one of which can be identified as ion (b) (generated by an unknown pathway) while the broad component arises from either or both of (a) and (d) ions. Unfortunately, the weak signal renders difficult an accurate analysis of the peak shape. However the broad component certainly is not ion (c) because the estimated $T_{0.5}(= 410$ meV) is too small and also because under the optimum energy resolution conditions employed no clearly defined shoulder can be seen.

For example in Fig. 3*b* the isopropanol (b) and (c) composite peak shows clearly defined shoulders under optimum resolution conditions (these are only poorly seen when moderate resolution is employed, Fig. 5*b*). In the present case *no* shoulder was apparent even under the best experimental conditions; such a peak can be produced by summation of (a) with (b) or (d).

1,4-Dioxane and Pyruvic Acid

Both of these precursor molecules generated *m/e* 44 ions consisting mainly of ion (c) and the ^{1}m* peaks are shown in Fig. 5. For 1,4-dioxane, the dish in (c) (Fig. 5*c*) appears to be filled in presumably by an (a) and a (b) component. The $C_2H_4O^{+\cdot}$ ions are formed by at least two different routes, directly from the molecular ion and via the intense *m/e* 45 ions, since both fragmentations exhibit the appropriate ^{1}m* peaks. Additional experiments with labelled compounds would probably provide the answers.

The pyruvic acid fragmentation has been discussed previously by Turro *et al.* (18) who used the gas-phase photolytic behavior of this com-

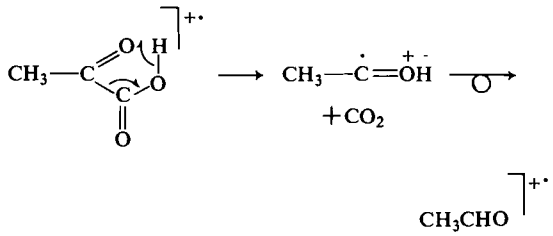
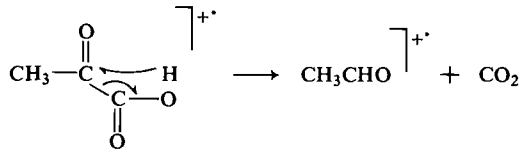
FIG. 5. 10 α-Furfuryl alcohol	c*	615	**20** 1,4-Dioxane	c†	580 (c)
11 Glycidol	c	618	**21** Pyruvic acid	c*†	500

In compounds 7, 9, 10, 13, 14, and 21 the hydroxylic hydrogen atom was partially exchanged with D_2O in the inlet system of the mass spectrometer. In all cases a similar flat-topped ^{1}m peak associated with an energy release $T_{0.5} = 637 \pm 10$ meV, was observed for the transition $45 \rightarrow 43 + 2(C_2H_3OD^{+\cdot} \rightarrow C_2H_3O^+ + D\cdot)$.
†See text for discussion.

pound to provide an analogy for the fragmentation mechanism. They proposed that an ion of structure (e), $CH_3\dot{C}{=}\overset{+}{O}H$, was formed via a five-centered intermediate. This ion was then supposed to isomerize to an acetaldehyde



structure. Bentley and Johnstone (27) suggested an alternative four-centered mechanism



The ^{1}m* for *m/e* 44 → *m/e* 43 in pyruvic acid was of shape type (c) but the $T_{0.5}$ value, 500 meV, was significantly less than that found for all other (c) producing species (see Table 1). However, it was found that in pyruvic acid-OD,[6] the $C_2H_3DO^{+\cdot}$ ions lost D with a pure (c)-type ^{1}m*, $T_{0.5} = 640$ meV. In addition, and unlike all the other $C_2H_3DO^{+\cdot}$ ions discussed above, there was a small ^{1}m* corresponding to H loss therefrom. This was a flat-topped peak with $T_{0.5} = 460$ meV, an energy release appreciably smaller than that found in unlabelled (c) ions. Possibly this result indicates the generation of a hitherto unobserved isomeric form of $C_2H_4O^{+\cdot}$ ions. It is quite clear however that acetaldehyde (b)-type ions are *not* involved in the fragmentation of pyruvic acid and the photochemical analogy remains uncertain. The five-centered mechanism however provides the simplest route to ion (c) possibly via ion (e) as intermediate. As will be described elsewhere (17), the vinyl alcohol molecular ion is the most stable form of $C_2H_4O^{+\cdot}$ and this may explain the nonrearrangement of (e) to (b).

This last example particularly clearly illustrates how metastable ion studies of this kind can readily provide detailed information concerning ion structures of fragmenting ions of relatively low internal energy content. These experiments can be performed with a double-focussing mass spectrometer provided that it is equipped with an energy resolving β-slit. For $C_2H_4O^{+\cdot}$ ions the method is at least the equal of the c.a. technique which examines ions with insufficient internal energy to dissociate in the microsecond time frame. It seems possible however that the present method may prove less successful when applied to larger ions where the greater variety of isomeric species are less likely to be noninterconverting in the energy ranges appropriate for generating ^{1}m* peaks.

[6]The compound was deuterated by exchange with D_2O in the mass spectrometer. There was some small uptake of a *second* D atom presumably by enol exchange.

Experimental

All metastable ion peak measurements were performed with an A.E.I.-G.E.C. MS902S instrument. The peaks were separated from the main ion beam by the acceleration sweep method. Instrument parameters were: source slit 0.002 in.; β-slit 0.005 in. (for lower energy resolution 0.025 in.); collector slit *ca.* 90% transmission; acceleration potential for transmitted ions *ca.* 6200 V; electron energy 70 V. Compounds were admitted to the ion source via a Granville–Phillips variable leak; sample pressures *ca.* 5×10^{-7} Torr. Second field-free region metastable ion peaks were examined using a scintillator photomultiplier detector of the type described by Daly *et al.* (28). Energy release values were calculated in the usual way having first corrected the half-height widths for the main beam energy spread by subtracting the limiting main beam width (as the β-slit is narrowed a point is reached at which the main beam width no longer changes; this width corresponds to *ca.* 1.3 acceleration volts at *ca.* 6 kV). For most of the measurements recorded here this represents *ca.* 5% of the $^1m^*$ peak width.

Compounds were obtained commercially and purified where necessary.

We wish to thank Dr. F. P. Lossing for many valuable discussions. We also thank Prof. F. W. McLafferty for permission to quote his results (16) prior to publication. This work was financially supported by the National Research Council of Canada. One of us (J.K.T.) thanks the Netherlands Organisation for the Advancement of Pure Research (Z.W.O.) for a Fellowship during the tenure of which this work was completed.

The structure of 2-(4′-carbomethoxy-2′-nitrophenoxy)-1,3,5-trimethylbenzene, $C_{17}H_{17}NO_5$, has been determined by X-ray diffraction. The crystals are monoclinic, $a = 8.352(4)$, $b = 17.892(10)$, $c = 10.966(6)$ Å, $\beta = 100.59(3)°$, $P2_1/c$ with $Z = 4$. The intensities of 3877 independent reflections were measured on a four circle diffractometer; 2272 of these reflections were used to obtain a final least-squares residual of 0.053 and traditional R factor of 0.054. The general conformation is similar to that found earlier for differently substituted diphenyl ethers. Comparison of this structure with those previously determined indicates that distortions in ring angles are primarily a result of electronic rather than steric effects.

SIMON P. N. VAN DER HEIJDEN, ELIZABETH A. H. GRIFFITH, W. DAVID CHANDLER et BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2084 (1975).

On a déterminé la structure cristalline du (carbométhoxy-4′ nitro-2′ phénylate)-2 triméthyl-1,3,5 benzène, $C_{17}H_{17}NO_5$, par diffraction de rayons-X. Les cristaux sont monocliniques, $a = 8.352(4)$, $b = 17.892(10)$, $c = 10.966(6)$ Å, $\beta = 100.59(3)°$, $P2_1/c$ avec $Z = 4$. On a mesuré les intensités de 3877 réflexions indépendantes à l'aide d'un diffractomètre à quatre cercles. On a utilisé 2272 de ces réflexions pour affiner la structure jusqu'à une valeur de R pondérée de 0.053 et une valeur de R conventionnelle de 0.054. La conformation générale de cette molécule se rapproche de celle observée antérieurement pour des diphényléthers substitués dans diverses positions. Une comparaison de cette structure avec d'autres déterminées antérieurement indique que les distorsions dans les angles du cycle sont dues principalement à des effets électroniques plutôt que stériques. [Traduit par le journal]

Introduction

The structures determined previously in this series (2-(3′-methyl-4′-nitrophenoxy)-1,3-diisopropylbenzene (1), 2-(2′,4′-dinitrophenoxy)-1,3,5-tri-*t*-butylbenzene (2), 2-(2′-carbomethoxy-4′-nitrophenoxy)-1,3,5-trichlorobenzene(3)) show a common general conformation which appears to be related both to the presence of two *ortho* substituents on one ring and the electronic character of the substituents. The compound whose structure is reported here is one of a series of structures of substituted diphenyl ethers with no more than one *ortho* substituent on the phenyl ring containing electron-withdrawing substituents. It is also one of a series of studies of bridged diphenyls identically substituted but with variation in the nature of the bridging group.

Previously determined structures in this series have shown deviations from the ideal value of 120° in the internal ring angles at the substituted carbon atoms, which may be related to either the electronic or steric character of the substituents. If the decrease in internal ring angles at the carbon atoms bonded to alkyl groups in the previously reported structures of 2-(3′-methyl-4′-nitrophenoxy)-1,3-diisopropylbenzene (1) and 2-(2′,4′-dinitrophenoxy)-1,3,5-tri-*t*-butylbenzene (2) as opposed to the increase in similar angles at ring carbon atoms bonded to chlorine atoms in 2-(2′-carbomethoxy-4′-nitrophenoxy)-1,3,5-trichlorobenzene (3), from the expected 120° for a hexagonally symmetric ring, is due to electronic rather than steric (substituent size) effects, one would expect a similar decrease in the case of a trimethyl-substituted ring. As has been discussed previously (4), ring distortions limit the accuracy with which conformational parameters can be determined from ring-current shielding measurements. Hope (5) made the observation that in aromatic chlorine compounds the internal ring angle at the carbon atom carrying the chlorine group is greater than 120°. This effect has also been observed by

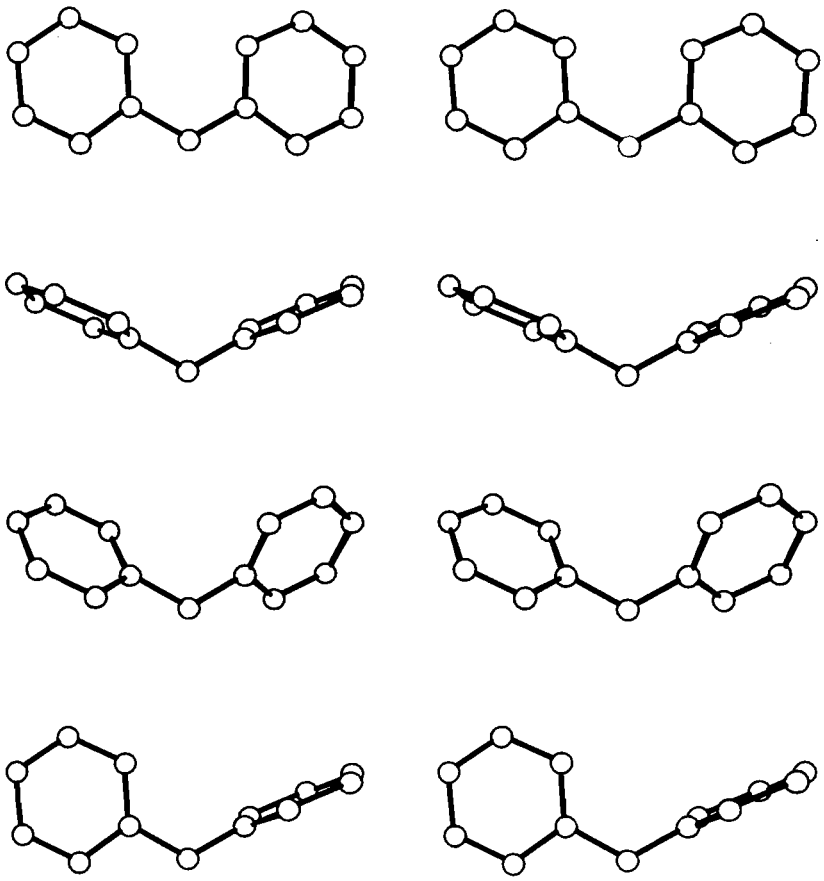

FIG. 1. Stereoscopic view of the four basic conformations for bridged diphenyl compounds. From top to bottom; planar, butterfly, twist, and skew.

Carter *et al.* (6) in aromatic nitro compounds and has been linked to the electron-withdrawing ability of these substituents. The van der Waals radius of CH_3 (2.00 Å) is similar to that of Cl (1.80 Å) (7) and therefore would be expected to show a similar effect if it is determined by steric factors.

Nomenclature

Several systems of nomenclature are currently being used to describe the conformation of bridged diphenyl compounds. We attempt here to establish a uniform nomenclature based upon those currently in use and further we will suggest guidelines for assigning this nomenclature. The basic conformations were first discussed by Higgasi and Smyth (8).

The conformations of bridged diphenyls may be divided conveniently into four general categories, idealized examples of which are shown in Fig. 1. The names assigned to these by most authors (some exceptions exist) are respectively planar, butterfly, twist, and skew.

As a result of the various orientations of the phenyl rings, caused by rotation around their bonds to the bridging group, intermediate conformations are possible. The conformations which deviate only slightly from the basic ones are usually assigned the same name as the basic conformation. However, no limits have been set on the conformational parameters which are associated with a given conformational type. The suggested classification scheme is illustrated in Fig. 2. The horizontal axis represents the largest of the two dihedral angles which the phenyl rings make with the central plane. The vertical axis represents the dihedral angle between the other ring and the central plane.

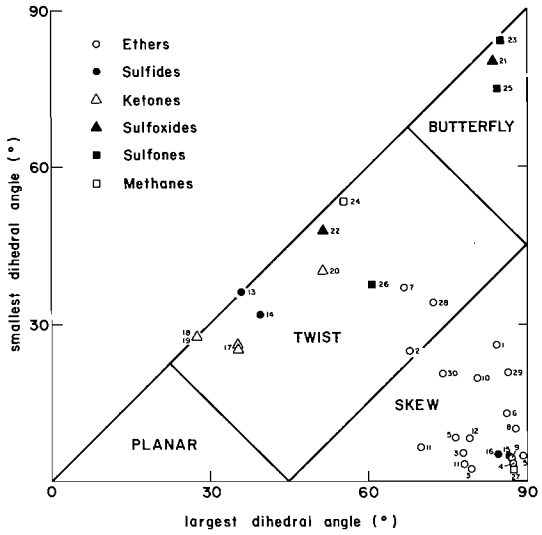

FIG. 2. Density plot of the conformations of bridged diphenyl compounds as determined by X-ray diffraction. The numbers refer to those in Table 1.

Both dihedral angles are taken between 0° and 90°. The lines within the triangle in Fig. 2 define the four basic conformations. The diagram indicates that, for example, a conformation is still considered to be planar when one ring is coplanar with the central plane and the other is allowed to deviate up to 45°. However, if the first ring is allowed to deviate from coplanarity, the allowable range for the second ring decreases. Other conformations have similar constraints. Points representing the conformations of structures reported in this series and others related to them are also shown in Fig. 2.

In a molecule which is not distorted from idealized geometry the dihedral angle between the bridging plane and the plane of the phenyl ring corresponds to the torsional angle about the bond to the bridging group. A number of choices are possible for the definitions of these angles. In order to avoid the establishment of a convention to choose the end of the molecule from which the torsional angles will be viewed, we will define each angle as viewed from the opposite ring. Since the sense of rotation is not dependent on this choice, the signs given for the angles may be compared directly with those given for thyroid hormones where the angles are both viewed from the end of the molecule bearing the amino acid group.

We will choose, in our definition of the torsional angle, the ring atom adjacent to the atom bonded to the bridging atom so that the magnitude of the torsional angle is less than 90°. This implies that when both torsional angles are zero one of the two *ortho* positions is *distal* and the other is *proximal*. The configuration of the planar molecule, corresponding to both torsional angles being placed at their zero values, will be specified by labeling unsymmetrically substituted *ortho* or *meta* substituents as *distal* or *proximal*. We shall use in determining the magnitudes of the torsional angles the least-squares planes fitted to the entire ring in question because this is a more accurate indicator of the relative orientation of the parts of the molecule than the torsional angles based on planes formed by only three atoms.

All of the structures studied to date in this series contain a center of symmetry, Thus the torsional angles must appear in either the pairs (+ +),(− −) or (+ −),(− +). In cases of the butterfly and twist conformations, the combinations of signs (+ −),(− +) would lead to steric problems even in unsubstituted molecules, and no such combination of signs is known to exist. No planar bridged diphenyl compounds have been identified but steric interactions would clearly favor the (+ +),(− −) combinations of signs. In the case of the skew conformation, a rotation of the *proximal ortho* hydrogen atom or a *proximal ortho* substituent towards one of the *ortho* hydrogen atoms or substituents on the other ring clearly favors a rotation of the other ring which moves that *ortho* position away from the *proximal* hydrogen atom or substituent. This leads again to the (+ +),(− −) combination of signs.

In summary then, the conformations of all bridged diphenyl compounds would be expected to show a (+ +) or (− −) conformation of signs, and in the case of centrosymmetric structures both of these combinations would be present. The only observed exception to this prediction is the conformation of the second molecule in the asymmetric unit of 2-(2′-carbomethoxy-4′-nitrophenoxy)-1,3,5-trichlorobenzene (3) where the angles are −89.7° and 4.6°; *i.e.*, a decrease in the former angle greater than 0.3° would lead to a change in the choice of torsional angle such that the prediction would be followed.

Figure 3 shows two of the four possible conformations for a substituted bridged diphenyl compound with a substituent R on the right

phenyl ring and a substituent X on the left phenyl ring. Both molecules have the (− −) combination of torsional angles. The conformation of the upper molecule in Fig. 3 would then be a twist-2-R-*distal*-1′-X-*proximal* conformation, while that of the lower would be a twist-2-R-*proximal*-1′-X-*proximal* conformation.

Experimental

The synthesis of 2-(4′-carbomethoxy-2′-nitrophenoxy)-1,3,5-trimethylbenzene, $C_{17}H_{17}NO_5$, has been reported earlier (33). It was recrystallized from 95% ethanol, m.p. 104–106 °C. A sample with dimensions of 0.6 × 0.4 × 0.5 mm was used for data collection. The systematic absences ($h0l$, $l = 2n + 1$; $0k0$, $k = 2n = 1$) and the Laue symmetry as determined by film methods, gave the space group $P2_1/c$. The crystal was then mounted on a Picker FACS I four circle automatic diffractometer equipped with a graphite monochromator. Twenty-four reflections with 2θ values between 35 and 45°, where the MoKα_1 and Kα_2 diffraction peaks were resolved, were used to calculate the cell constants by least squares. The cell constants are given below with the estimated errors calculated as three times the estimated standard deviations given by the least-squares procedure.

The crystal data are as follows:

$C_{17}H_{17}NO_5$ f.w. = 315.33

Monoclinic, $P2_1/c$: $a = 8.352(4)$, $b = 17.892(10)$, $c = 10.966(6)$ Å, $\beta = 100.59(3)°$, $\rho_o = 1.28$ g cm^{-3} (flotation), $\rho_c = 1.32$ g cm^{-3}, $Z = 4$, $F(000) = 664e$, λ(MoKα_1) = 0.70926 Å, μ(MoKα) = 1.05 cm^{-1}, $T = 22 \pm 2$ °C. The angle settings of 12 of the centered reflections were used to determine the orientation of the crystal on the diffractometer. The integrated intensities of 3877 independent reflections with 2θ values between 3.5 and 55° were collected with MoKα radiation. The θ–2θ scan mode was used with a 1 deg min^{-1} scan rate, a minimum base width of 3.2°, and 40 s background counts at each limit of the scan. The intensities of three standard reflections were measured every 100 reflections, and were not found to vary significantly. The data were reduced to observed structure factors using standard procedures. No corrections were made for absorption or extinction effects. A Wilson statistical calculation gave an overall temperature factor of 4.4 Å^2. The scattering factors for oxygen, nitrogen, and carbon were taken from the series coefficients given by Cromer and Mann (34). The scattering factors for the hydrogen atoms were those given by Stewart *et al.* (35). The 397 reflections with $|E| > 1.62$ were used to solve the structure by the logical symbolic addition method.[2] The solution with the highest figures of merit gave an *E*-map showing all 23 nonhydrogen atom positions. Full-matrix least-squares refinement with unit weights and individual anisotropic temperature factors reduced the weighted residual R_w, defined as $R_w = \{\Sigma w(|F_o| - |F_c|)^2 / \Sigma w|F_o|^2\}^{1/2}$; $w = \sigma^{-2}$, to 0.114 A difference map at this point revealed all 17 hygrogen atoms. The final least-squares weights were calculated from $w^{-1/2} = 0.5962 - 0.02640|F_o| + 0.000848|F_o|^2$. The 2272 reflections for which $|F_o| > 2.0w^{-1/2}$ were used in the final cycles of refinement. The final values of R_w and the conventional R factor were 0.053 and 0.054 respectively. The observed and calculated structure factors have been placed in the Depository of Unpublished Data.[3] The final positional and thermal parameters are listed in Table 2. The estimated errors are the estimated standard deviations from the least-squares analysis. The bond lengths and angles and the atomic numbering are given in Figs. 4 and 5. The numbering of the atoms is based upon standard crystallographic practice; *i.e.*, atoms of the same chemical species will be differentiated by arabic numbers enclosed in parentheses. This implies that the crystallographic designation will be quite different from the chemical designation of the same atom. Primes will be used to differentiate between equivalent atoms belonging to separate molecules within the asymmetric unit.

Past practice in this series has been to report errors as three times the estimated standard deviations determined by the least-squares refinement. The errors in the bond lengths and angles have also been multiplied by the factor 3. The degree of consistency between equivalent bond lengths and angles in related structures in the series suggests that this method of reporting errors is unnecessarily conservative. Therefore in this and succeeding papers, the errors in least-squares determined structural parameters and in parameters derived from them will be given as the estimated standard deviations with no modifications.

In the case of the errors in lattice constants, our experience indicates that significant differences often occur between lattice constants obtained by least-squares refinements of the positions of different sets of reflections from the same crystal, even when the zero settings of the angle encoders are not fixed and are included as least-squares variables. We assume that these differences arise from imperfections in alignment settings such as those associated with the positioning of the crystal, the geometry of the rotation axes of the goniostat, or the positioning of the X-ray source. Errors in lattice constants will therefore be multiplied by three as before.

Discussion

The molecular packing diagram is shown in Fig. 6.

The crystal structure shows no unusual intermolecular contacts. Bond lengths to hydrogen atoms range from 0.86(4) to 1.00(5) Å and the isotropic hydrogen temperature factors, B, range from 5 to 15 Å^2.

[2]The direct methods program LSAM, written by Germain and Woolfson (36) was used for structure solution. Fourier calculations were carried out with the Zalkin program FORDAP (37). Least-squares refinement was done with the Busing *et al.* program ORFLS (38). The molecular geometry and associated e.s.d's were determined with the Busing and Levy program ORFFE (39). Stereograms were prepared with the aid of the Johnson Program ORTEP (40).

[3]Complete set of tabular data is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

The C(9)—O(5) bond length is 0.053(5) Å longer than the C(1)—O(5) bond length. A comparison of this value for the difference in lengths to the ether oxygen atom with those found earlier shows that the difference in these bond lengths increases as the difference in total electron-withdrawing ability of the substituents on the two rings increases.

The deviation from coplanarity of the electron-withdrawing ring (the ring containing the nitro group) with the central C—O—C′ plane in the tri-*ortho*-substituted compounds ranges from 8.8° to 2.1° (1–3), with the present value being 8.7°.

The trimethyl-substituted ring is nearly perpendicular to the central plane, the general

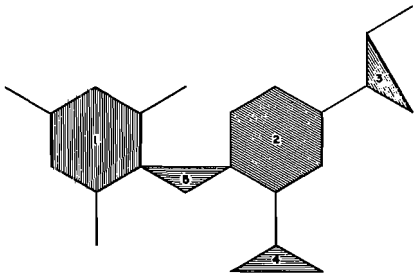

FIG. 7. Labeling of the least-squares planes.

conformation being skew-nitro-*distal* as suggested by p.m.r. data for the same compound (41). The dihedral angles between the normals to the molecular planes, which are labeled in Fig. 7, are given in Table 3. The torsional angles ϕ[C(9)—O(5)—C(1)—C(6)] and ψ[C(1)—O(5)—C(9)—C(14)], corresponding to the dihedral angles between the planes 2,5 and 1,5, occur in (+ +) and (− −) pairs as expected. In 2-(4′-carbomethoxy-2′-nitrophenoxy)-1,3,5-trimethylbenzene the O(5)—C(1)—C(6) angle is 6.1° larger than the O(5)—C(1)—C(2) angle, because of a bending of the nitro-substituted ring away from the mesityl ring by 3.05(15)°. A stereoscopic view of the molecule is given in Fig. 8. This type of distortion has also been observed in other nitro-substituted compounds and varies from 4.2° in 2-(3′-methyl-4′-nitrophenoxy)-1,3-diisopropylbenzene to 2.5° in 2-(2′,4′-dinitrophenoxy)-1,3,5-tri-*t*-butylbenzene. The bending at the bridgehead carbon atom is probably a result of steric interaction between the H(6) hydrogen atom and the mesityl ring.

TABLE 3. Least-squares planes

(*b*) Dihedral angles

Planes	Angle (deg)
1,2	79.9
1,5	79.0
2,3	11.9
2,4	36.2
2,5	8.7

The nitro group is bent away from the ether oxygen atom by 1.5(2)°. A similar bending (3)° is observed for the *ortho*-nitro group of 2-(2′,4′-dinitrophenoxy)-1,3,5-tri-*t*-butylbenzene.

In the present study the nitro group is rotated by 36.2° from the plane of the phenyl ring, which is greater than any of the values found previously. Holden and Dickenson (16) observed a rotation of 75° and 37° for the 2- and 4,6-nitro groups respectively of 1,3-dichloro-2,4,6-trinitrobenzene. This suggests that the twist of the nitro groups is due to repulsive interaction of the ether oxygen and one of the nitro group oxygen atoms. The intramolecular nitro oxygen,

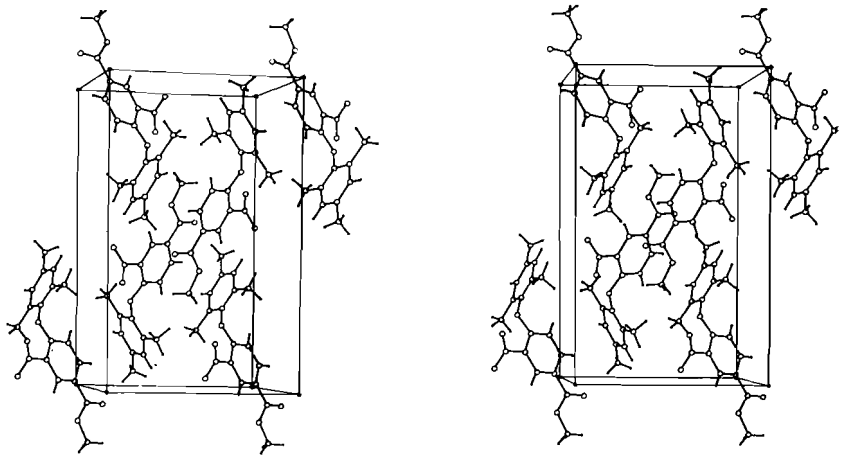

FIG. 8. Stereoscopic view of the molecular packing.

O(1), to ether oxygen distance is 2.659 Å, which is similar to the ether oxygen distance of 2.570 Å in 2-(2′,4′-dinitrophenoxy)-1,3,5-tri-*t*-butylbenzene (2) and the average carbonyl oxygen to ether oxygen distance of 2.703 Å in 2-(2′-carbomethoxy-4′-nitrophenoxy)-1,3,5-trichlorobenzene (3).

The internal ring angles at the carbon atoms bonded to the methyl group are decreased from the 120° expected for a hexagonally symmetric ring. This deviation is the same as for the isopropyl and *t*-butyl groups but opposite in sign to that of the chlorine-substituted benzene ring in 2-(2′-carbomethoxy-4′-nitrophenoxy)-1,3,5-trichlorobenzene. We therefore conclude that the distortions in the internal ring angles are primarily a result of electronic rather than steric effects.

The research was supported by grants from the National Research Council of Canada.

Conformations of Bridged Diphenyls. VIII. Crystal Structure of 2-(2′,6′-Dinitrophenoxy)-*t*-butylbenzene

KAPIL GURTU, W. DAVID CHANDLER, AND BEVERLY E. ROBERTSON[1]

Faculty of Science, University of Regina, Regina, Saskatchewan S4S 0A2

Received November 22, 1974

KAPIL GURTU, W. DAVID CHANDLER, and BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2093 (1975).

The crystal structure of 2-(2′,6′-dinitrophenoxy)-*t*-butylbenzene, $C_{16}H_{15}N_2O_5$, has been determined by X-ray diffraction. The crystals are monoclinic, space group $P2_1/c$: a = 13.949(9), b = 9.652(6), c = 23.806(12) Å, β = 93.82(5), Z = 8. The integrated intensities of 6811 reflections were recorded with a four circle automated diffractometer at 20 °C; 3334 of these reflections were used in the refinement of the structure to a least-squares weighted residual of 0.057 and a traditional R factor of 0.057.

The two crystallographically independent molecules both have the skew-*t*-butyl-*distal* conformation, suggesting that the steric effects of the two *ortho*-nitro groups play a greater role in determining the conformation than does conjugation with the bridging oxygen atom.

KAPIL GURTU, W. DAVID CHANDLER et BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2093 (1975).

On a déterminé la structure cristalline du (dinitro-2′,6′-phénylate)-2 *t*-butyl benzène, $C_{16}H_{15}N_2O_5$, par diffraction de rayons-X. Les cristaux sont monocliniques, groupe d'espace $P2_1/c$: a = 13.949(9), b = 9.652(6), c = 23.806(12) Å, β = 93.82(5)°, Z = 8. On a mesuré, à 20 °C, les intensités de 6811 réflexions indépendantes à l'aide d'un diffractomètre à quatre cercles. On a utilisè 3334 de ces réflexions pour affiner la structure jusqu'à une valeur de R pondérée de 0.057 et une valeur de R conventionnelle de 0.057.

Les deux molécules cristallographiquement indépendantes adoptent chacune une conformation *t*-butyl-*gauche distal* impliquant que les effets stériques des deux groupes nitro en *ortho* jouent, par opposition à la conjugaison avec l'atome d'oxygène du pont, un rôle plus grand dans la détermination de la conformation. [Traduit par le journal]

Introduction

In the *ortho*-substituted diphenyl ethers whose structures have been reported previously in this series (1–4) one benzene ring has been di-*ortho*-substituted with halogen atoms or electron-donating groups. Each of these compounds was found to adopt the skew-H-*proximal* conformation. This conformation has also been predicted on the basis of p.m.r. studies of the same compounds. (5). The notation used here to indicate the conformation was introduced previously in this series of papers (4).

The skew conformation for molecules of this sort allows the steric repulsion between the *ortho* substituents on the di-*ortho*-substituted ring and the rest of the molecule to be minimized while keeping the more electron-withdrawing ring in the C—O—C plane. Montaudo *et al.* (6) have discussed the conformational effect of double bond character arising out of the overlap of π electrons in the phenyl rings and the unshared electrons on the bridging oxygen atom. This effect tends to favor a conformation which is planar. Steric interactions appear, however, to discourage the planar conformation. Then the ring which contains the more electron-withdrawing substituents would be expected to be more nearly coplanar with the central C—O—C plane than the other ring, as has been observed to be the case (1–4).

In all compounds reported previously in this series, both the *ortho* substituent steric effect and the conjugation effect have favored the same conformation, and it has not been possible to estimate the relative importance of these two effects in determining the conformation of diphenyl ethers. In the compound whose structure is reported here, the electron-withdrawing phenyl ring is di-*ortho*-substituted. If steric effects are overriding, the molecular conformation will be skew-*t*-butyl-*distal*; if mesomeric effects predominate, a skew-NO_2-*distal* (or *proximal*) conformation will result; if the two effects are of nearly equal weight one would

[1]Author to whom correspondence should be addressed.

expect a twist-*t*-butyl-*distal* conformation. Lehmann (7) and Lehmann and McEachern (8) have used dipole moment studies and p.m.r. to investigate the conformation of di-*ortho*-nitro-substituted compounds and have concluded that the conjugation between the electron-withdrawing ring and the ether oxygen atom will lead either to a skew- or twist-nitro-*proximal* conformation with the *proximal* nitro group rotated to near coplanarity with the adjacent ring. For the sake of clarity it should be pointed out here that the above conformations could equally be labeled skew-nitro-*distal* or twist-nitro-*distal* because of the presence of identical *ortho*-nitro substituents.

Experimental

The method of Wright and Jorgensen (9), as modified by Bergman (10), was used to synthesize 2-(2′,6′-dinitrophenoxy)-*t*-butylbenzene, ($C_{16}H_{16}N_2O_5$). The ether was recrystallized from methanol as small light yellow crystals, m.p. 115–118 °C. Another recrystallization from a petroleum ether – acetone (1:1) mixture aided by slow evaporation yielded monoclinic crystals suitable for diffraction studies. A crystal of approximate dimensions 0.3 × 0.5 × 0.7 mm was first examined by film methods. The Laue symmetry and systematic extinctions ($h0l$, $l = 2n \pm 1$, $0k0$, $k = 2n + 1$) indicated the space group $P2_1/c$.

The crystal was mounted on a Picker FACS I diffractometer. The crystal orientation was determined by a least-squares fit to the positions of 12 strong reflections centered with MoKα_1 radiation. Accurate cell parameters were determined later by fitting to the positions of 30 reflections.

Crystal data are as follows:

$C_{16}H_{16}N_2O_5$ f.w. = 326.34

Monoclinic, $P2_1/c$: $a = 13.949(3)$, $b = 9.652(2)$, $c = 23.806(4)$ Å, $\beta = 93.82(4)°$, $Z = 8$, $\rho_o = 1.32$ g cm^{-3}, $\rho_c = 1.34$ g cm^{-3}, $F(000) = 1328e$, μ(MoKα) = 1.35 cm^{-1}, λ(MoKα_1) = 0.70926 Å, $T = 20$ °C.

The integrated intensities of 6811 reflections were recorded using the θ–2θ scan mode for 2θ values between 3° and 50° with a scan rate of 1 deg min^{-1}. The background was counted for 20 s at each limit of the scan. The intensities of three standard reflections were recorded after every 50 reflections and their intensities were not observed to change significantly. The data were reduced to observed structure factors using standard procedures. A Wilson statistical calculation gave an overall temperature factor of 4.8 Å^2.

The scattering factors for nonhydrogen atoms were taken from Cromer and Mann (11). The scattering factors for the hydrogen atoms were from Stewart *et al.* (12). The structure was solved by direct methods using the logical symbolic addition method.[2] An *E*-map calculated with the set of nontrivial signs with the highest figure of merit revealed 50 peaks. Forty-three of these were used to construct two independent molecules. The structure was then refined through one cycle of least squares. All reflections were initially assigned equal weighting. Most of the hydrogen atoms and the three missing nonhydrogen atoms were located using a difference map. The structure was further refined to a least-squares residual, defined by $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$, of 0.12.

It was observed at this point that one of the four NO_2 substituents showed irregular geometry. A new difference map was calculated and it indicated that both NO_2 groups on one of the two independent molecules were disordered by rotation about the C—N bond. Four additional oxygen atoms were then introduced into the structure, and each of the eight NO_2 oxygen atoms were assigned an occupation number of $\frac{1}{2}$. The occupation numbers and positions of the eight disordered oxygen atoms were allowed to vary in the least-squares refinement and the occupation numbers refined to values which did not differ significantly from $\frac{1}{2}$. They were therefore fixed at $\frac{1}{2}$. The positions of four of the hydrogen atoms were still undetermined at this point. Peaks for these atoms were found in the difference maps but attempts to refine their positions led to unreasonable molecular geometry. Their positional parameters were therefore not varied in the final least-squares process. The temperature factors for these atoms were set equal to the isotropic temperature factor of the carbon atoms to which they were bonded, as determined by averaging over the three axes of the thermal ellipsoid of the carbon atoms.

In the final stages of full-matrix least squares the weights were calculated as $w = \sigma^{-2}$ where $\sigma = 1.0313 - 0.00914|F_o| + 0.00015|F_o|^2$. The 3334 reflections for which $|F_o| > 2.3\sigma$ were used in the final cycles of least squares. The final value of the least-squares residual and the conventional *R* factor were both 0.057.

The observed and calculated structure factors have been placed in the Depository of Unpublished Data.[3] The final positional and thermal parameters are listed in Table 1. The estimated errors are the estimated standard deviations given by the least-squares analysis. The bond lengths and angles, and the atom numbering for both of the two independent molecules in the asymmetric unit of the structure are given in Figs. 1 and 2. In the case of oxygen or hydrogen atoms labeled with a double subscript, the first subscript refers to the atom to which it is bonded. In the disordered molecule, indicated as molecule **2** in Table 1 and in Fig. 1*b*, the subscripts 3 and 4 on oxygen or nitrogen atoms refer to the disordered nitro groups associated with the nitro groups labeled 1 and 2 respectively. The atoms N′(3) and N′(4) are assumed to be identical with N′(1) and N′(2).

Discussion

All of the hydrogen atoms except four of those belonging to the *t*-butyl substituents on molecule **2** are in reasonable positions with bond

[2]The Germain and Woolfson program LSAM (13) was used for structure solution. The Busing *et al.* program ORFLS (14) was used for least-squares refinement. The Johnson program ORTEP (15) was used to prepare the stereograms.

[3]Complete set of tabular data is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

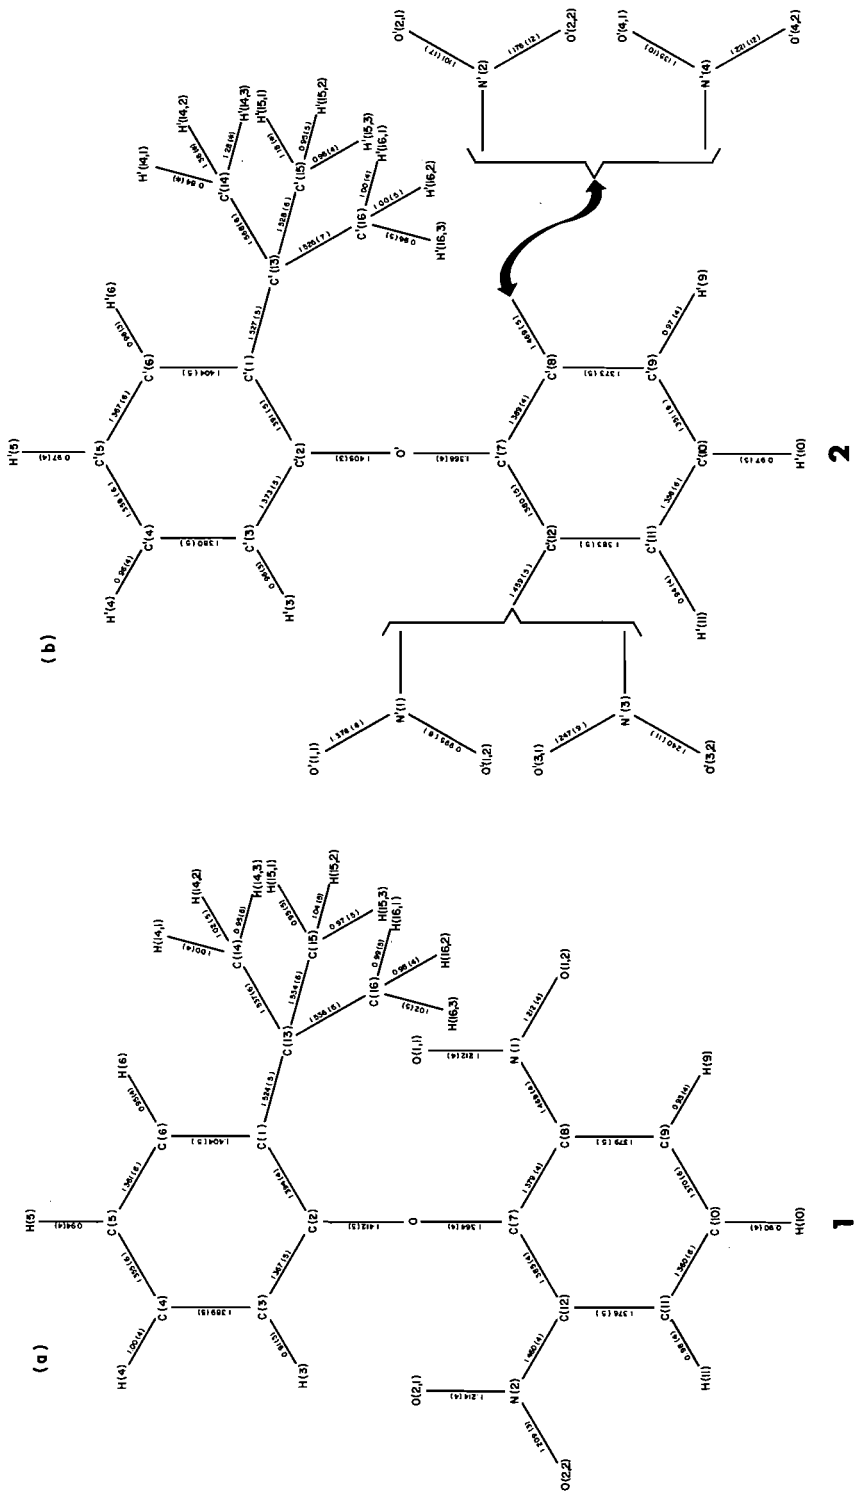

FIG. 1. (*a*) Bond lengths (Å) and atom labeling in molecule **1**. (*b*) Bond lengths (Å) and atom labeling in molecule **2**. The numbers in parentheses are the estimated standard deviations in the bond lengths. The asterisks indicate that the estimated standard deviation of the bond length was not determined.

distances varying from 0.90 to 1.05 Å. The four hydrogen atoms in question, H′(14,1), H′(14,2), H′(14,3), and H′(15,1), are those whose coordinates were not refined by least squares. The difficulty in placing these hydrogen atoms and the abnormal C—H bond lengths, marked by an asterisk in Fig. 2, are presumably related to the high values of the anisotropic thermal parameters for those carbon atoms as shown in Table 1.

A stereoscopic view of the molecular packing is shown in Fig. 3. The packing diagram suggests that the molecules pack in loosely associated pairs, with the *t*-butyl-substituted ring of molecule **2** lying roughly parallel and relatively close to the dinitro-substituted ring of molecule **1**.

Stereoscopic views of the conformation of molecule **1** and molecule **2** are shown in Figs. 4 and 5 respectively. The large ellipsoids of the terminal *t*-butyl carbon atoms are evident in the stereograms. Also the thermal ellipsoids of the nitro oxygen atoms on molecule **2** clearly suggest that those nitro substituents may be undergoing hindered rotation about the C—N bonds.

Table 2 shows the dihedral angles between

the planes of the two molecules. The planes are labeled in Fig. 6. The dihedral angles 1,2 and 2,3 and the conformations as shown in Figs. 4 and 5 clearly indicate that the conformation is skew-*t*-butyl-*distal*, in contrast to the predictions made by other workers (7, 8). These latter conclusions were based in part on the observation of a large chemical shift for the H(6) hydrogen atom. It seems quite clear that this shielding arises from its proximity to the *other* ring rather than a *proximal* nitro group as has been suggested by Lehmann (7). It also seems quite clear that the dipole moment method of predicting conformations of bridged diphenyls is somewhat unreliable since this was the method used originally to assess the conformation (7, 8).

The conformation determined for both molecules indicates that the steric effects of the *ortho* substituents are more important than mesomeric electronic effects in determining the conformations of bridged diphenyls. However, Fig. 1 shows that the O—C bond lengths to the dinitro-substituted ring are 0.048(7) and 0.039(7) Å shorter than the O—C bond length to the *t*-butyl-substituted ring on molecules **1** and **2** respectively. These values are approximately one-half those observed for rings containing two electron-withdrawing substituents where steric factors allow the electron-withdrawing ring to be coplanar with the central plane. The angles of 70.1° and 78.6° between the normals to planes 2 and 3 in the two molecules hardly allow for any significant conjugation effects even if the unshared electron pair on the oxygen atom is in a nonpure p orbital. In both of the two independent molecules the angles ϕ[C(7)—O—C(2)—C(3)] and ψ[C(2)—O—C(7)—C(8)] occur in (+ +) pairs in one enantiomer and (− −) pairs in the other, as would be expected.

The structures of the two independent mole-

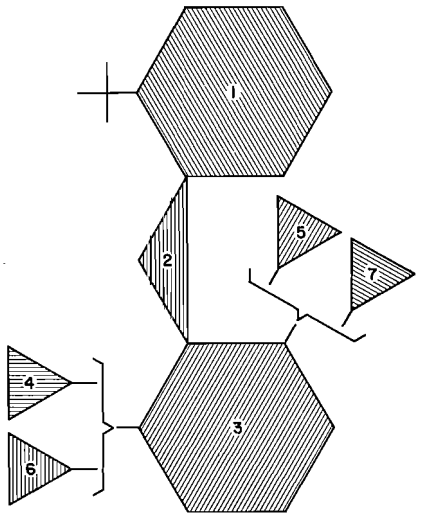

FIG. 6. Numbering of the molecular planes. The planes labeled 6 and 7 appear only in molecule **2**.

cules show deviations from idealized geometry which are consistent with observations made earlier. The internal ring angles at the carbon atoms bonded to the electron-donating *t*-butyl group are 113.4(4)° and 114.0(4)°. The internal ring angles at the carbon atoms bonded to the electron-withdrawing nitro groups average 122°. The internal ring angles at C(2) are *ca.* 3.5° greater than 120° and *ca.* 3.5° less than 120° at C(7). The *t*-butyl-substituted ring is bent 1.6° and 2.2° away from the dinitro-substituted ring. The *t*-butyl terminal carbon atom lying closest to the plane of the phenyl ring bearing the *t*-butyl substituent is rotated through a torsional angle of 3.5° about the C(1)—C(13) bond towards the *proximal* nitro group from the plane of the phenyl ring in molecule **1** and 2.0° away from the *proximal* nitro group in molecule **2**.

Conformations of Bridged Diphenyls. IX. Crystal Structure of 2-(4′-Carbomethoxy-2′-nitrothiophenyl)-1,3,5-trimethylbenzene

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, AND BEVERLY E. ROBERTSON[1]

Faculty of Science, University of Regina, Regina, Saskatchewan S4S 0A2

Received November 22, 1974

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, and BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2102 (1975).

The structure of 2-(4′-carbomethoxy-2′-nitrothiophenyl)-1,3,5-trimethylbenzene, $C_{17}H_{17}NO_4S$, has been determined by X-ray diffraction. The crystals are monoclinic, $a = 18.616(15)$, $b = 5.739(8)$, $c = 15.712(14)$ Å, $\beta = 101.97(3)°$, $P2_1/c$ with $Z = 4$. The intensities of 3820 independent reflections were measured on a four circle diffractometer; 2825 reflections were used in the refinement of the structure to give a final least-squares weighted residual of 0.059 and a traditional R factor of 0.054. The presence of electron-withdrawing groups on one of the phenyl rings increases the conjugation between the ring and the sulfur atom in a similar manner as that observed in diphenyl ethers. The mesityl ring is nearly orthogonal to the C—S—C plane.

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER et BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2102 (1975).

On a déterminé la structure cristalline du (carbométhoxy-4′ nitro-2′ thiophényl)-2 triméthyl-1,3,5 benzène, $C_{17}H_{17}NO_4S$, par diffraction de rayons-X. Les cristaux sont monocliniques, $a = 18.616(15)$, $b = 5.739(8)$, $c = 15.712(14)$ Å, $\beta = 101.97(3)°$, $P2_1/c$ avec $Z = 4$. On a mésure les intensités de 3820 réflexions indépendantes à l'aide d'un diffractomètre à quatre cercles. On a utilisé 2825 de ces réflexions pour affiner la structure jusqu'à une valeur de R pondérée de 0.059 et une valeur de R conventionnelle de 0.054. La présence de groupes électroaffinitaires sur un des groupes phényle augmente, d'une façon similaire à celle observée dans les diphényl éthers, la conjugaison entre le cycle et l'atome de soufre. Le cycle mésityle est presque perpendiculaire au plan C—S—C. [Traduit par le journal]

Introduction

This is the first study in this series of a compound having an atom other than oxygen as a bridging atom. From previous studies on diphenyl ethers it has been shown that the conformation for this type of compound is in general determined by steric rather than electronic effects (1–5). In order to be able to describe changes in conformation due to changes in the bridging group the compound chosen is identically substituted to one of the diphenyl ethers (4) studied previously.

Few crystallographic studies of diphenyl sulfides are reported in the literature (6–8) and none of these carried any *ortho* substituents. Both di-*p*-tolyl sulfide (6) and di-*p*-bromophenyl sulfide (7) show a twist conformation, while 4-dimethylaminodiphenyl sulfide (8) is a skew conformation with the *ortho* hydrogen of the substituted ring *proximal, i.e.* the unsubstituted ring is coplanar with the central C—S—C plane and almost perpendicular to the substituted ring. The nomenclature used here has been defined earlier (4).

Experimental

The synthesis of 2-(4′-carbomethoxy-2′-nitrothiophenyl)-1,3,5-trimethylbenzene, $C_{17}H_{17}NO_4S$, has been reported earlier (9). It was recrystallized from 95% ethanol, m.p. 125–126 °C. A sample with well-defined faces and approximate dimensions of $0.6 \times 0.4 \times 0.5$ mm (mounted with the long axis parallel to the fiber axis) was used for data collection. The systematic absences ($h0l$, $l = 2n + 1$; $0k0$, $k = 2n + 1$) and the Laue symmetry ($2/m$) as determined by film methods gave the space group $P2_1/c$.

The intensity data were collected on a Picker FACS I automated diffractometer using monochromatic MoKα radiation (graphite monochromator). The θ–2θ scan mode was used with a scan rate of 1 deg min^{-1}, covering a minimum scan width of 3°, in 2θ. Background counts (40 s) were measured at each limit of the scan. The centered positions of 24 reflections with 2θ values between 35 and 45° as determined using MoKα_1 radiation were used to calculate the cell parameters. Twelve of these reflections were used to determine the orientation of the crystal on the diffractometer. The errors in the lattice constants are given as three times the estimated standard deviations

given by the least-squares procedures. Errors in atomic coordinates and derived quantities will be presented as unmodified estimated standard deviations. The rationale for this convention has been presented earlier (4).

Crystal data are as follows:

$C_{17}H_{17}NO_4S$ f.w. = 331.39

Monoclinic, $P2_1/c$; $a = 18.616(15)$, $b = 5.739(8)$, $c = 15.712(14)$ Å, $\beta = 101.97(3)°$, $\rho_o = 1.36$ g cm^{-3} (flotation), $\rho_c = 1.34$ g cm^{-3}, $Z = 4$, $F(000) = 696e$, $\lambda(MoK\alpha_1) = 0.70926$ Å, $\mu(MoK\alpha) = 2.17$ cm^{-1}, $T = 22 \pm 2$ °C. The integrated intensities of 3820 independent reflections between 3.5 and 55° in 2θ were collected with MoKα radiation. The data were reduced to the observed structure factors using standard procedures. No corrections were made for the effects of extinction or absorption. The scattering factors for the nonhydrogen atoms were taken from Cromer and Mann (10). The scattering factors for the hydrogen atoms were taken from Stewart *et al.* (11). A Wilson statistical calculation gave an overall temperature factor of 3.52 Å^2. The 447 reflections with $|E| > 1.58$ were used to solve the structure by the logical symbolic addition method.[2] An *E*-map calculated from the solution with the highest figures of merit, yielded all nonhydrogen positions. The weighted residual, R_w, of the full-matrix least squares was lowered to 0.109, using individual anisotropic temperature factors and unit weights. The weighted residual is defined as: $R_w = \{\Sigma w(|F_o| - |F_c|)^2 / \Sigma w|F_o|^2\}^{1/2}$. The least-squares process minimizes R_w^2. A difference Fourier map at this point revealed all hydrogen atom positions; 2825 reflections, for which $|F_o| > 1.0w^{-1/2}$, were used in the final refinement cycles using full-matrix least squares and weights calculated from $w^{-1/2} = 0.7042 - 0.01168|F_o| + 0.000360|F_o|^2$. The final values of R_w and the conventional R factor were 0.059 and 0.054 respectively. The final observed and calculated structure factors have been placed in the Depository of Unpublished Data.[3] The final positional and thermal parameters are given in Table 1 with estimated standard deviations. The bond lengths and angles and the atomic numbering are given in Figs. 1 and 2.

Discussion

The dihedral angles between the planes labeled in Fig. 3 are given in Table 2. The sulfide, 2-(4′-carbomethoxy-2′-nitrothiophenyl)-1,3,5-trimethylbenzene has a skew-nitro-*distal* conformation similar to that observed for the corresponding ether (4), in agreement with p.m.r. studies of the same compound (9). The notation used here has been introduced earlier (4). The conformation is also similar to that of 4-dimethylaminodiphenyl sulfide (8) where the dimethylamine-substituted ring is 7.8° from being orthogonal to the C—S—C plane compared with an angle of 3.6° here for the mesityl ring. The unsubstituted ring in the former is 4.9° from being coplanar with the C—S—C plane compared with 4.2° here for the nitro-substituted ring.

In both cases the ring bearing the electron-donating substituents is nearly perpendicular to the C—S—C plane. We have shown that in the case of diphenyl ethers, steric factors associated with the *ortho* substituents may make this conformation (*i.e.* coplanarity of the C—O—C plane with the plane of the electron-withdrawing side of the molecule) unfavorable. The conformation of diphenyl ethers and sulfides suggests, however, that in the absence of steric hindrances, the conjugation effect leads to this particular skew conformation, despite the tendency to the twist conformation for unsubstituted or symmetrically substituted compounds. The torsional angles φ[C(9)—S—C(1)—C(6)] and ψ[C(1)—S—C(9)—C(10)] occur in (+ +) pairs in one enantiomer and (− −) pairs in the other, as would be expected.

The structures of both 2-(4′-carbomethoxy-2′-nitrothiophenyl)-1,3,5-trimethylbenzene and 4-dimethylaminodiphenyl sulfide show C—S bonds from the electron-withdrawing ring shorter (0.026(4) and 0.017(11) Å) than C—S bonds from the other ring. This effect was also observed for the diphenyl ethers but the differences are smaller in the sulfides. The average C—S bond length, 1.772 Å, is shorter than the sum of Pauling single bond covalent radii of 1.812 Å (16). The C—S—C bond angle of 102.9(1)° is slightly smaller than the values observed for other diphenyl sulfides (6, 8) but is within the range observed for C—S—C bonds.

The nitro-substituted ring appears to be bent 0.6(2)° towards the mesityl ring. The value of the bending is calculated from [∠(S—C(1)—C(2)) − ∠(S—C(1)—C(6))]/2. The direction of the bending is opposite from that observed in the corresponding ether (4). However, because of the fact that the C—S bonds are *ca.* 0.40 Å longer than the C—O bonds, the *proximal* hydrogen atom, H(6), remains 2.38 Å from the plane of the mesityl ring which is not significantly different from 2.43 Å in the ether despite the op-

[2]The structure was solved using the Germain and Woolfson program LSAM (12). All Fourier calculations were carried out with the Zalkin program FORDAP (13). The Busing *et al.* program ORFLS (14) was used for least-squares refinement. Stereograms were prepared with the aid of the Johnson program ORTEP (15).

has also been observed for the skew conformation of 2-(3′-methyl-4′-nitrophenoxy)-1,3-diisopropylbenzene (1) which also lacks a bulky *ortho* substituent in the *distal ortho* position.

The longer C—S bonds also require the *ortho*-nitro group to twist only through 11.7° from coplanarity with the ring to which it is bonded in order to accommodate steric repulsion between the nitro oxygen atom and the sulfur atom. The O(1)—S distance is 2.64 Å which is similar to the O(1)—O distance of 2.66 Å in the identically substituted ether where the twist about the C—N bond is 36.7°.

All of the hydrogen atoms appear to be in reasonable positions. The bonds to hydrogen atoms range in length from 0.92(2) to 0.97(3) Å for the phenyl hydrogen atoms and from 0.86(5) to 0.96(6) Å for the methyl hydrogen atoms on the methyl group. The isotropic temperature factors range from 4(1) to 5(1) $Å^2$ for the phenyl hydrogen atoms and 7(1) to 13(2) $Å^2$ for the methyl hydrogen atoms. A stereoscopic view of the packing of the molecules is shown in Fig. 4. The packing of the molecules produces no unusually short intermolecular contacts.

A stereogram of details of the molecular con-

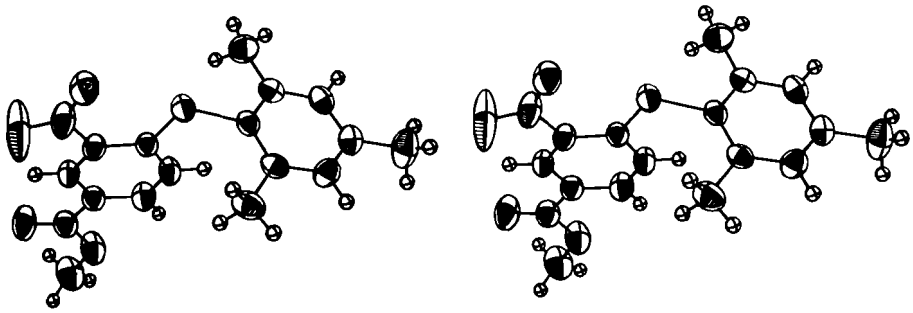

FIG. 5. Stereoscopic view of 2-(4′-carbomethoxy-2′-nitrothiophenyl)-1,3,5-trimethylbenzene. The thermal ellipsoids for the nonhydrogen atoms are drawn at the 50% probability level. The hydrogen atoms are given arbitrary temperature factors.

formation is shown in Fig. 5. The nitro oxygen atom further from the sulfur atom shows an anomalous thermal ellipsoid suggesting either large motion normal to the phenyl plane or disorder. Similar anomalous thermal ellipsoids have been observed previously in these compounds (1) but have not been satisfactorily explained.

Conformations of Bridged Diphenyls. X. Crystal Structure of 2-(4′-Carbomethoxy-2′-nitrophenylsulfinyl)-1,3,5-trimethylbenzene

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, AND BEVERLY E. ROBERTSON[1]

Faculty of Science, University of Regina, Regina, Saskatchewan S4S 0A2

Received November 22, 1974

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, and BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2108 (1975).

The crystal structure of 2′-(4′-carbomethoxy-2′-nitrophenylsulfinyl)-1,3,5-trimethylbenzene, $C_{17}H_{17}NO_5S$, has been determined by X-ray diffraction. The crystals are triclinic, $a = 9.848(11)$, $b = 7.654(10)$, $c = 12.513(15)$ Å, $\alpha = 107.33(8)$, $\beta = 100.73(8)$, $\gamma = 106.53(8)°$, $P\bar{1}$ with $Z = 2$. The intensities of 3850 independent reflections were measured on a four circle diffractometer; 2985 reflections were used in the refinement to give a final least-squares residual of 0.053 and a traditional R factor of 0.052.

Repulsion between the sulfoxide oxygen atom and the nitro oxygen atoms forces the molecule into the twist-nitro-*proximal* conformation as opposed to the nitro-*distal* conformation which has been observed for other bridged diphenyls in this series.

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER et BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2108 (1975).

On a déterminé la structure cristalline du (carbométhoxy-4′ nitro-2′ phénylsulfinyl)-2 triméthyl-1,3,5 benzène, $C_{17}H_{17}NO_5S$, par diffraction de rayons-X. Les cristaux sont tricliniques: $a = 9.848(11)$, $b = 7.654(10)$, $c = 12.513(15)$ Å, $\alpha = 107.33(8)$, $\beta = 100.73(8)$, $\gamma = 106.53(8)°$, $P\bar{1}$ avec $Z = 2$. On a mesuré les intensités de 3850 réflexions indépendantes à l'aide d'un diffractomètre à quatre cercles. On a utilisé 2985 de ces réflexions pour affiner la structure jusqu'à une valeur de R pondérée de 0.053 et une valeur de R conventionnelle de 0.052.

La répulsion entre l'atome d'oxygène du sulfoxyde et les atomes d'oxygène du groupe nitro force la molécule à adopter une conformation nitro-croisé "*proximal*" et ceci par opposition avec la conformation nitro-*distal* qui est observée pour d'autres diphényles pontés de cette série.

[Traduit par le journal]

Introduction

This is the third report in this series of studies by X-ray diffraction of the conformations of similarly substituted bridged diphenyl compounds, each with a different bridging group (1, 2). It is also the first structure reported in this series of a compound in which the bridging group is not a single atom (1–6). Based on p.m.r. studies of the shielding of ring currents within the molecule, the conformation of this compound has been predicted to be in the twist-nitro-*proximal* conformation (7). The nomenclature used here has been discussed earlier (1). This method for predicting conformations and also its validity have been discussed previously (8, 9). The conformation of diphenyl sulfoxide itself is reported to be butterfly (10).

Experimental

The synthesis of 2-(4′-carbomethoxy-2′-nitrophenylsulfinyl)-1,3,5-trimethylbenzene, $C_{17}H_{17}NO_5S$, has been reported earlier (7). It was recrystallized from absolute ethanol, m.p. 168–169 °C. A sample of approximate dimensions 0.41 × 0.32 × 0.36 mm was chosen for data collection.

The crystal was mounted on a Picker FACS 1 four circle automated diffractometer, equipped with a graphite monochromator. Twenty-four reflections with 2θ values between 35 and 45°, where the MoKα_1 and Kα_2 diffraction peaks were resolved, were used to calculate the cell constants by least squares. The estimated errors shown below are calculated as three times the estimated standard deviations given by the least-squares procedure. Errors in atomic coordinates and derived quantities will be presented as unmodified estimated standard deviations. The rationale for the convention has been presented earlier (1).

The crystal data are as follows:

$C_{17}H_{17}NO_5S$ f.w. = 347.39

Triclinic $P\bar{1}$; $a = 9.848(11)$, $b = 7.654(10)$, $c = 12.513(15)$ Å, $\alpha = 107.33(8)$, $\beta = 100.73(8)$, $\gamma = 106.53(8)°$, $\rho_o = 1.43$ g cm^{-3} (flotation), $\rho_c = 1.40$ g cm^{-3}, $Z = 2$, $F(000) = 364$e, $\lambda(\text{MoK}\alpha_1) = 0.70926$ Å, $\mu(\text{MoK}\alpha) = 2.24$ cm^{-1}, $T = 22 \pm 2$ °C. The angle settings of 12 reflections were used to determine the orientation of the crystal on the diffractometer. The integrated intensities of 3850 independent reflections with 2θ values between 3.5 and 55° were collected with MoKα radiation. The θ–2θ scan mode was used with a 1 deg min^{-1} scan rate, a base

width of 3.2° and 40 s background counts at each limit of the scan.

The intensities of three standard reflections were measured every 100 reflections and were not found to vary significantly. The data were reduced to the observed structure factors using standard procedures. No corrections were made for absorption or extinction effects. The standard deviation of each reflection was calculated as $\sigma = 1.0 + 0.01|F_o| + \sigma'$ where σ' is based entirely on counting statistics. A Wilson statistical calculation gave an overall temperature factor of 3.02 Å^2. The scattering factors for the sulfur, oxygen, nitrogen, and carbon atoms were taken from the series coefficients of Cromer and Mann (11). The scattering factors for the hydrogen atoms were those given by Stewart *et al.* (12). The average values of $|E|$ and $|E^2 - 1|$ were determined to be 0.788 and 0.981 respectively, indicating the centrosymmetric triclinic space group. The lattice parameters for the sulfoxide were similar to those observed for 2-(4′-carbomethoxy-2′-nitrobenzoyl)-1,3,5-trimethylbenzene (13), the structure of which has been determined previously but will appear later in this series. An examination of the larger normalized structure factors of the ketone and the sulfoxide showed a considerable degree of similarity in their values. It was therefore apparent that crystals of the two compounds were isostructural. The coordinates of all the nonhydrogen atoms except the sulfoxide oxygen atom were taken directly from those of the equivalent atom in the refined structure of 2-(4′-carbomethoxy-2′-nitrobenzoyl)-1,3,5-trimethylbenzene (13). The isotropic temperature factors were set at 3.0 Å^2. An electron density Fourier map calculated with the phases from these atoms revealed all the nonhydrogen atoms, including the sulfoxide oxygen atom.

The structure was refined by full-matrix least squares to a weighted residual R_w of 0.083 using individual anisotropic temperature factors and weights calculated from $w^{-1/2} = \sigma$. The least-squares refinement, in effect, minimizes R_w^2 where R_w is defined by $R_w = (\Sigma w(|F_o| - |F_c|)^2 / \Sigma w|F_o|^2)^{1/2}$. A difference Fourier map revealed all 17 hydrogen atoms.[2] The strongest peak in the difference map was located 1.2 Å from the sulfur atom on the side of the C—S—C plane opposite to the oxygen atom. The 2985 reflections for which $|F_o| > 2.5w^{-1/2}$ were used in the final cycles. The weights in the final cycles of refinement were calculated from $w^{-1/2} = 0.6406 - 0.0368|F_o| + 0.00113|F_o|^2$. The final values of the conventional R factor and R_w were 0.052 and 0.053 respectively.

The observed and calculated structure factors have been placed in the Depository of Unpublished Data.[3] The final positional and thermal parameters are listed in Table 1. The estimated standard deviations are given in parentheses and are taken directly from the least-squares refinement. The bond lengths, bond angles, and the atom numbering are given in Figs. 1 and 2.

[2]The program FORDAP written by Zalkin (14) was used for all Fourier calculations. The program ORFLS written by Busing *et al.* (15) was used for least-squares refinement. The program ORTEP written by Johnson (16) was used to prepare the stereographic drawings.

[3]Complete set of tabular data is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

Discussion

The angles between the planes of 2-(4′-carbomethoxy-2′-nitrophenylsulfinyl)-1,3,5-trimethylbenzene, as labeled in Fig. 3, are given in Table 2. The angles between the planes of the two phenyl rings and the central C—S—C plane are 51.6° and 48.1°. The stereogram of the molecule as shown in Fig. 4 shows that the *ortho*-nitro substituent is pointed towards the other ring. The conformation is then twist-nitro-*proximal* in agreement with the p.m.r. studies (7). The angle between the mesityl ring and the C—S—C plane is only slightly outside the range of values predicted for that angle (7). The torsional angles ϕ[C(9)—S—C(1)—C(2)] and ψ[C(1)—S—C(9)—C(10)] occur in (+ +) pairs in one enantiomer and in (− −) pairs in the other as is implied by the definition of the twist conformation (1).

The *proximal* conformation observed here is in marked contrast to the *distal* conformations observed previously in this series. The only other *proximal* conformation observed for a bridged diphenyl is that of 3,5,3′-triiodothyronine where the *proximal* iodine substituent is in the *meta* position (17). Although this conformation may be affected by the solvent used to crystallize the compound (17), we would assume that the *proximal* conformation is related to the interactions between the nitro oxygen atoms and the sulfoxide oxygen atom that would result if the molecule adopted the *distal* conformation. It would appear, however, upon examination of Fig. 4, that by suitable adjustment of the dihedral angles between the nitro-substituted ring and the C—S—C plane and the plane of the NO_2 group, a twist-nitro-*distal* conformation could be accommodated sterically. The coulombic interaction between the oxygen atoms therefore plays an important role in determining the conformation.

The nitro-*proximal* conformation leads to a number of distortions within the molecule. A survey of the C—S—C angles in sulfoxides (18) gives an average C—S—C angle of 97.1°, which is 4.3° less than the value observed here. The nitro-substituted ring is bent 6.1(2)° away from the mesityl ring at the bridging carbon atom C(1′). The nitro group is rotated through 41.4° from coplanarity with the phenyl ring to which it is bonded leaving it 35.5° from coplanarity with the mesityl ring. All of these factors accommodate the steric interactions between the nitro group and the mesityl ring. The nearest nitro

1,4	35.5

oxygen atom, O(1), is 2.64 Å from the plane of the mesityl ring.

The length of the C(9)—S and C(1)—S bonds are 1.798(3) and 1.819(2) Å respectively. The difference of 0.021(4) Å is opposite to that observed in the corresponding ether (1) and sulfide (2), where the bond to the nitro-substituted ring was the shorter. This shortening effect has been explained in terms of conjugation between the electron-withdrawing ring and the unshared electrons on the bridging atom. The effect persists even when the plane of the electron-withdrawing ring is nearly orthogonal to the C—X—C plane where X is the bridging atom (4).

The reverse of the effect here is related to the fact that the sulfoxide group is itself slightly electron-withdrawing, which results in a shortening of the bond to the electron-donating mesityl ring rather than the electron-withdrawing nitro-substituted ring.

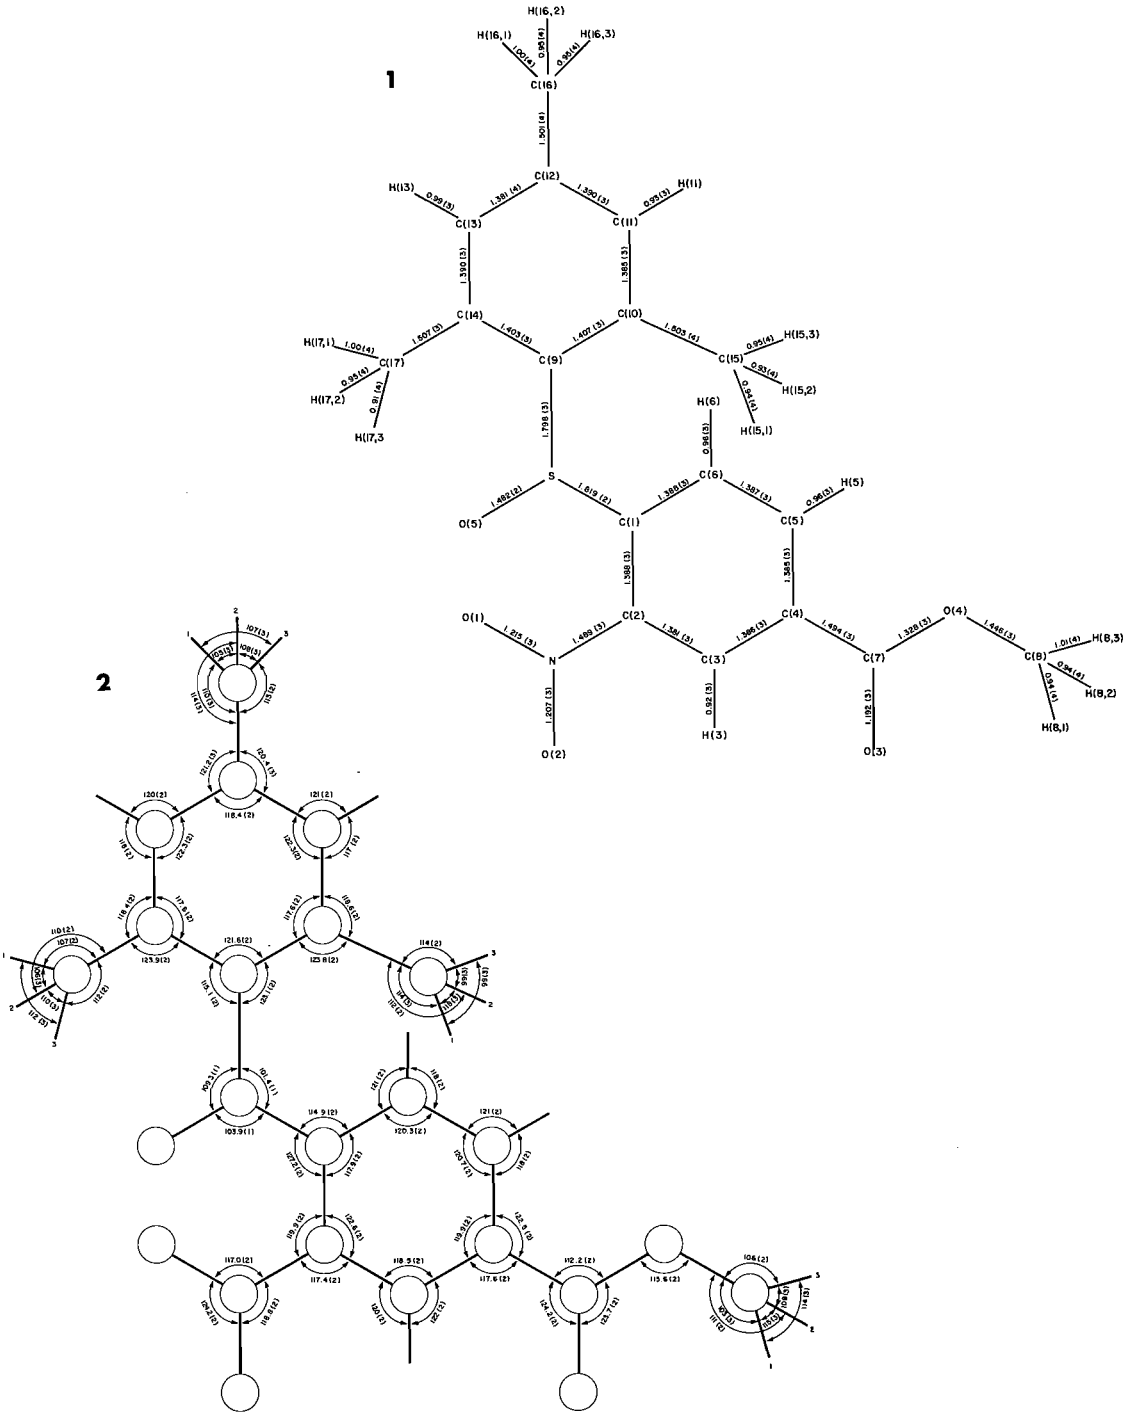

FIG. 1. Bond lengths and atom labeling for 2-(4′-carbomethoxy-2′-nitrophenylsulfinyl)-1,3,5-trimethylbenzene. Numbers in parentheses are the estimated errors based on the errors in Table 1 for the atom positions and the errors in the lattice constants.

FIG. 2. Bond angles. The numbers in parentheses are the estimated errors.

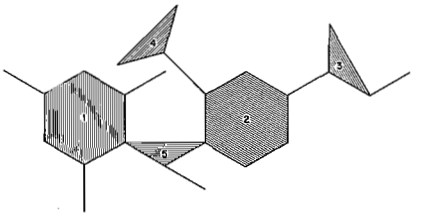

FIG. 3. Labeling of the planes of the molecule.

The sulfoxide oxygen atom does not lie in the C—S—C plane but is removed 1.32 Å from it. The second strongest density peak (0.52 electrons $Å^{-3}$) observed in the difference Fourier map used to locate the hydrogen atoms was located 1.2 Å from the sulfur atom on the opposite side of the C—S—C plane to the oxygen atom. The average density corresponding to the five ring hydrogen atoms was 0.45 electrons $Å^{-3}$. The angle between the plane formed by this peak, the oxygen and sulfur atoms, and the C—S—C plane, is 87°. This peak then corresponds to the lone pair electrons on the sulfur atom.

The bonds to hydrogen atoms range from 0.91 to 1.01 Å in length. The isotropic temperature factors for the hydrogen atoms attached to the phenyl ring range from 3 to 4 $Å^2$ and for methyl hydrogen atoms the temperature factors range from 7 to 9 $Å^2$. There are no unusual intermolecular contacts in the structure. The molecular packing is shown in Fig. 5.

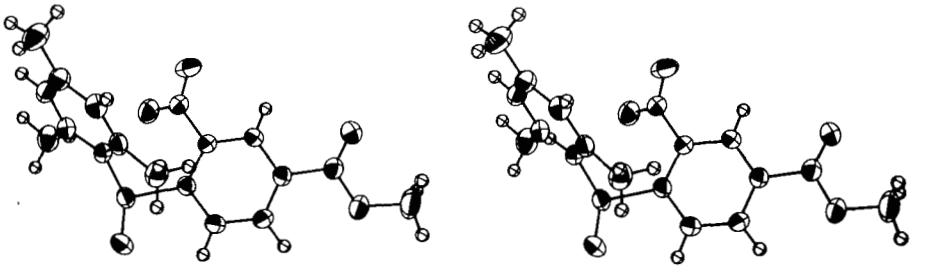

FIG. 4. Stereoscopic view of 2-(4′-carbomethoxy-2′-nitrophenylsulfinyl)-1,3,5-trimethylbenzene. The thermal ellipsoids for the nonhydrogen atoms are drawn at the 50% probability level. The hydrogen atoms are given arbitrary temperature factors.

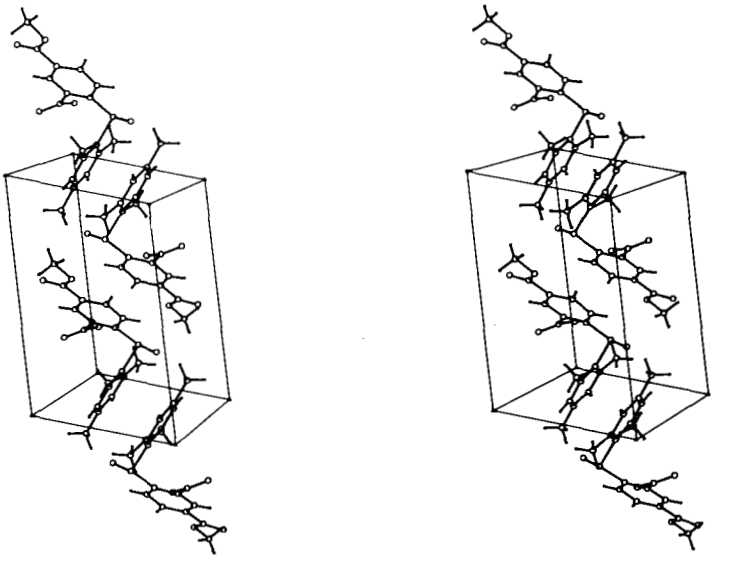

FIG. 5. Stereoscopic view of the packing.

Conformations of Bridged Diphenyls. XI. Crystal Structure of 2-(4′-Carbomethoxy-2′-nitrophenylsulfonyl)-1,3,5-trimethylbenzene

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, AND BEVERLY E. ROBERTSON[1]

Faculty of Science, University of Regina, Regina, Saskatchewan S4S 0A2

Received December 20, 1974

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, and BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2115 (1975).

The crystal structure of 2-(4′-carbomethoxy-2′-nitrophenylsulfonyl)-1,3,5-trimethylbenzene, $C_{17}H_{17}NO_6S$, has been determined by X-ray diffraction. The crystals are triclinic, a = 12.907(13), b = 7.577(5), c = 9.1808(9) Å, α = 105.82(3), β = 112.81(5), γ = 93.97(4)°, $P\bar{1}$ with Z = 2. The integrated intensities of 3792 independent reflections were measured on a four circle diffractometer and 2985 reflections were used in the refinement to give a least-squares residual of 0.046 and a conventional R factor of 0.057.

The molecule shows a twist-nitro-*proximal* conformation. However, the dihedral angles made by the mesityl ring and the nitro-substituted ring with the central C—S—C plane are dissimilar in contrast to the nearly equal angles found for the similarly substituted sulfinyl compound.

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER et BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2115 (1975).

On a déterminé la structure cristalline du (carbométhoxy-4′ nitro-2′ phenylsulfonyl)-2 triméthyl-1,3,5 benzène, $C_{17}H_{17}NO_6S$, par diffraction de rayons-X. Les cristaux sont tricliniques, a = 12.907(13), b = 7.577(5), c = 9.1808(9) Å, α = 105.82(3), β = 112.81(5), γ = 93.97(4)°, $P\bar{1}$ avec Z = 2. On a mesuré les intensités de 3792 réflexions indépendantes à l'aide d'un diffractomètre à quatre cercles. On a utilisé 2985 de ces réflexions pour affiner la structure jusqu'à une valeur de R pondérée de 0.046 et une valeur de R conventionnelle de 0.057.

La molécule existe dans une conformation nitro croisé "*proximal*". Toutefois, par opposition avec les résultats obtenus avec des composés sulfinyles substitués d'une manière similaire, les angles dièdres des noyaux mésityle et nitrobenzène avec le plan C—S—C central ne sont pas semblables. [Traduit par le journal]

Introduction

This is the fourth in a series of reports of the structures of similarly substituted bridged diphenyls with variation in the bridging group (1–3). The present compound represents an increase in the bulkiness of the bridging group over those in the structures reported previously.

In 1951 Koch and Moffit observed that in diphenyl sulfones the sulfur 3d and 3p orbitals may overlap with the π orbitals of the phenyl rings if the dihedral angles between the rings and the C—S—C plane are both 90°, thus making the butterfly conformation favorable (4). The structures of 4,4′-dichlorodiphenyl sulfone (5) and 4,4′-diaminodiphenyl sulfone (6) are consistent with the predictions made by Koch and Moffit. However, in 2,2′,4,4′,6,6′-hexamethyldiphenyl sulfone (7) steric hindrances between the four *ortho* substituents lead to a twist conformation with dihedral angles near 55°. The present study involves a compound which is tri-*ortho*-substituted. The notation used here has been discussed in detail previously (1).

Benjamins and Chandler (8) have studied this compound using ring-current shielding effects and have concluded that the conformation is near butterfly although this conformation brings the NO_2 group and a CH_3 group into close proximity.

Experimental

The synthesis of 2-(4′-carbomethoxy-2′-nitrophenylsulfonyl)-1,3,5-trimethylbenzene, $C_{17}H_{17}NO_6S$, has been reported earlier (8). The sample was recrystallized from 95% ethanol, m.p. 169–170 °C. A crystal with dimensions 0.59 × 0.32 × 0.28 mm was prepared for data collection with the long axis parallel to the axis of the fiber with which it was mounted on a Picker FACS I four circle automated diffractometer equipped with a graphite monochromator. The orientation of 23 reflections with 2θ values between 30° and 40° was determined using MoKα_1 radiation. These were used to obtain accurate lattice constants by least squares. Twelve of these reflections were used to orient the crystal on the diffractometer.

The crystal data are as follows:

$C_{17}H_{17}NO_6S$ f.w. = 363.38

Triclinic $P\bar{1}$, a = 12.907(13), b = 7.577(5), c = 9.808(9) Å, α = 105.82(3), β = 112.81(5), γ = 93.97(4)°, ρ_o = 1.40 g cm^{-3} (flotation), ρ_c = 1.44 g cm^{-3}, Z = 2, $F(000)$ = 380e, $\lambda(MoK\alpha_1)$ = 0.70926 Å, $\mu(MoK\alpha)$ = 2.29 cm^{-1}, T = 20 ± 1 °C.

The integrated intensities of 3792 independent reflections between the 2θ values of 3.5° and 55° were collected using the θ–2θ scan mode with a scan rate of 1 deg min^{-1}, a minimum base width of 3.2° in 2θ, MoKα radiation, and background times of 40 s. Three standard reflections were used to monitor changes in the apparatus or crystal. Two of the standard reflections did not change in intensity during the period of the data collection but

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

the intensity of the third decreased by 10%. The data were reduced to observed structure factors using standard procedures. No corrections were made for extinction or absorption. The scattering factors for the sulfur, oxygen, nitrogen, and carbon atoms were taken from Cromer and Mann (9). The scattering factors for the hydrogen atoms were taken from Stewart *et al.* (10). Reflections below background were assigned zero intensity.

A Wilson statistical calculation gave an overall temperature factor of 2.51 Å^2. The average values of $|E^2 - 1|$ and $|E|$ were 1.022 and 0.768 indicating the centrosymmetric space group $P\bar{1}$. The 429 reflections with $|E| > 1.62$ were used to solve the structure using the logical symbolic addition method.[2] An *E*-map generated from the nontrivial set having the highest figures of merit yielded all nonhydrogen atom positions.[3]

A difference Fourier map calculated at this point revealed all 17 hydrogen positions and refinement was completed with anisotropic temperature factors assigned to the nonhydrogen atoms and isotropic temperature factors assigned to the hydrogen atoms.

The least-squares weights were calculated from $w^{-1/2} = 0.4013 - 0.01237|F| + 0.000676|F|^2$. The 2985 reflections for which $|F_o| > 2.6w^{-1/2}$ were used in the final cycles of refinement. The final values of R_w and the conventional R factor were 0.046 and 0.057. The observed and calculated structure factors have been placed in the Depository of Unpublished Data.[4] The final positional and thermal parameters are listed in Table 1. The estimated errors are taken directly from the least-squares analysis. The bond lengths with estimated standard deviations and the atomic numbering are given in Fig. 1. The bond angles are given in Fig. 2.

[2]The direct methods program LSAM written by Germain and Woolfson (11) was used for structure solution. The program FORDAP written by Zalkin (12) was used for all Fourier calculations. The Busing *et al.* program ORFLS (13) was used for least-squares refinement. Stereoscopic drawings were prepared with the aid of the program ORTEP written by Johnson (14).

[3]The least-squares refinement revealed that the accuracy of the data collected last (that with $2\theta < 40°$) was less accurate than that collected at the beginning of the data collection, indicating some loss of alignment precision had occurred during the data collection. The original crystal was therefore placed on the diffractometer and realigned. The data between $2\theta > 3.5°$ and $2\theta > 42°$ were collected again. The agreement between the two sets of data in the region $40° < 2\theta < 42°$ was within the counting statistics. The final cycles of refinement used the first set of data for $2\theta > 42°$ and the second set of data for $2\theta < 42°$. We are obliged to point out that the final parameters therefore suffer from any systematic errors which may arise from the use of two sets of alignment parameters. However, a comparison of the bond lengths in all identically substituted bridged diphenyls in this series, including this one, shows that the r.m.s. deviation of equivalent bonds not affected by the bridging group is less than (or equal to) the average e.s.d.'s of those bond lengths.

[4]Complete set of tabular data is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

Discussion

The angles between the planes of 2-(4′-carbomethoxy-2′-nitrophenylsulfonyl)-1,3,5-trimethylbenzene, as labeled in Fig. 3, are given in Table 2. The molecule shows the twist-nitro-*proximal* conformation as does the identically substituted sulfoxide compound (3). However the angles made by the mesityl ring and the nitro-substituted ring with the central C—S—C plane in the present compound are dissimilar at 60.6° and 38.2°, while in the sulfinyl compound they are nearly identical at 51.7° and 48.3° respectively. The torsional angles ϕ[C(9)—S—C(1)—C(2)] and ψ[C(1)—S—C(9)—C(10)] occur in (+ +) pairs in one enantiomer and in (− −) pairs in the other, as is implied by the twist conformation. A stereogram of the molecule is shown in Fig. 4.

The conformation observed here is not the one predicted on the basis of p.m.r. studies of the ring-current shielding of phenyl hydrogen atoms (8). In view of the rigidity of the molecule it does not seem likely that the conformation in solution and in the solid state are markedly different. We conclude that because of the small values of the "other ring" shielding parameters and thus the lack of sensitivity of the p.m.r. method in the case of the diphenyl sulfones, the conformation predicted by that method may have been erroneous.

FIG. 2. Bond angles. The numbers in parentheses are the estimated errors.

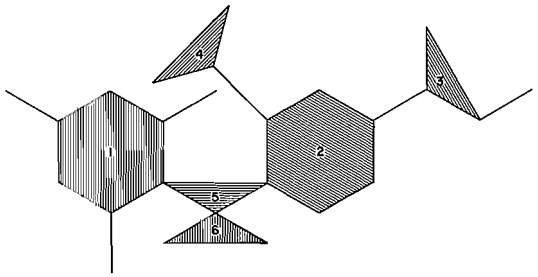

FIG. 3. Labeling of the least-squares planes.

The molecule shows deviations from idealized geometry similar to those which have been observed previously. The nitro-substituted ring is bent 6.1(2)° away from the mesityl ring at C(1) as it was in the sulfoxide. The mesityl ring is bent 1.8(2)° away from the nitro-substituted ring compared to a bending 4.0(2)° in the sulfoxide. The larger value for the bending of the mesityl ring in the sulfoxide may be related to the asymmetric nature of the sulfinyl bridging group. The C(9)—S bond length is 0.032(5) Å shorter than the C(1)—S bond length. The difference is opposite in sign to that observed for ethers and in 2-(4′-carbomethoxy-2′-nitrothiophenyl)-1,3,5-trimethylbenzene and is of the same sign as in the corresponding sulfoxide but it is slightly greater because of the greater electron-withdrawing character of the sulfonyl over the sulfinyl moiety.

The S—O bond lengths in the sulfone are 0.051 Å shorter than is the S—O bond length in the sulfoxide, and are in agreement with

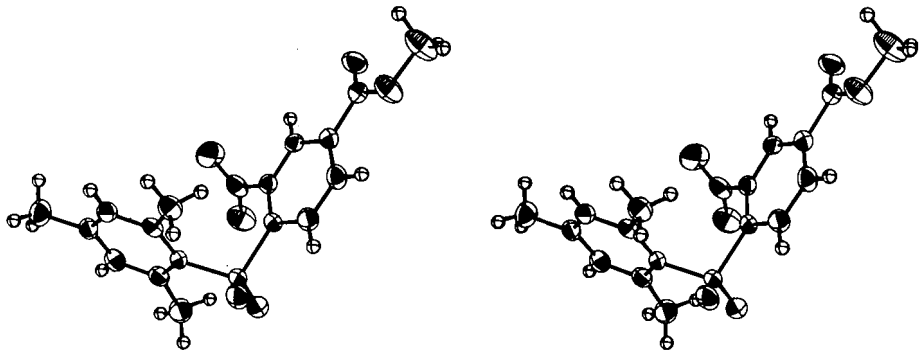

FIG. 4. Stereoscopic view of 2-(4′-carbomethoxy-2′-nitrophenylsulfonyl-1,3,5-trimethylbenzene. The thermal ellipsoids for the nonhydrogen atoms are drawn at the 50% probability level. The hydrogen atoms are given arbitrary temperature factors.

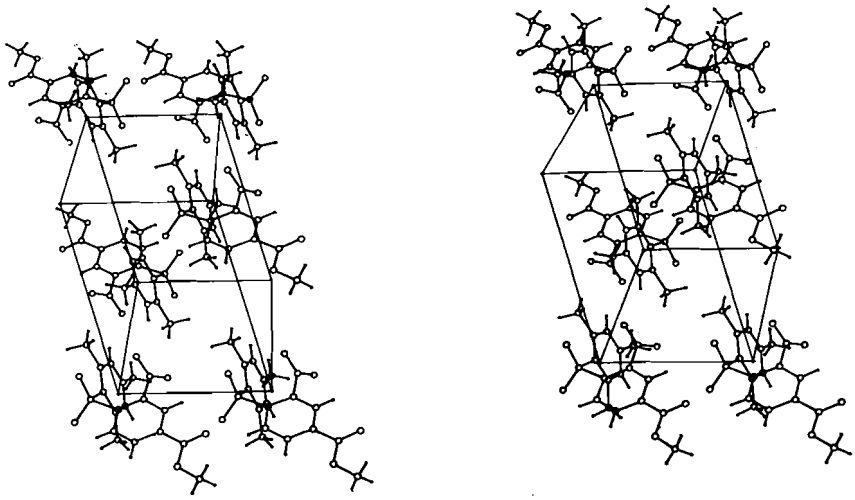

FIG. 5. Stereoscopic view of the molecular packing.

values observed in other sulfones (15). Bent (16) has predicted a value of 1.43 Å with a deviation of up to 0.03 Å depending on the electronegativity of the substituents of the sulfur. The O—S—O angle of 117.4(2)° is typical of other sulfones.

The packing of the molecules is shown in Fig. 5. The structure shows no unusual intermolecular contacts. Bond lengths to phenyl hydrogen atoms range from 0.91(3) to 0.95(2) Å with isotropic temperature factors from 3(1) to 4(1) Å^2. The bond lengths to methyl hydrogen atoms range from 0.88(5) to 1.03(5) Å with isotropic temperature factors from 5(2) to 10(3) Å^2.

Conformations of Bridged Diphenyls. XII. Crystal Structure of 2-(4′-Carbomethoxy-2′-nitrobenzyl)-1,3,5-trimethylbenzene

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, AND BEVERLY E. ROBERTSON[1]

Faculty of Science, University of Regina, Regina, Saskatchewan S4S 0A2

Received December 20, 1974

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, and BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2121 (1975).

The crystal structure of 2-(4′-carbomethoxy-2′-nitrobenzyl)-1,3,5-trimethylbenzene, $C_{18}H_{19}NO_4$, has been determined by X-ray diffraction. The crystals are triclinic, $a = 9.534(5)$, $b = 11.887(7)$, $c = 7.431(6)$ Å, $\alpha = 101.62(3)$, $\beta = 97.25(3)$, $\gamma = 88.61(3)°$, $P\bar{1}$ with $Z = 2$. The integrated intensities of 3789 independent reflections were measured on a four circle diffractometer; 2448 reflections were used in a full-matrix refinement to a least-squares residual of 0.067 and a conventional R factor of 0.055.

The molecule is in the skew-nitro-*distal* conformation. The angle between the di-*ortho*-substituted ring and the central C—CH_2—C plane is 87.6° and the angle between the nitro-substituted ring and the C—CH_2—C plane is 2.2°.

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER et BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2121 (1975).

On a déterminé la structure cristalline du (carbométhoxy-4′ nitro-2′ benzyl)-2 triméthyl-1,3,5 benzène, $C_{18}H_{19}NO_4$, par diffraction de rayons-X. Les cristaux sont tricliniques, $a = 9.534(5)$, $b = 11.887(7)$, $c = 7.431(6)$ Å, $\alpha = 101.62(3)$, $\beta = 97.25(3)$, $\gamma = 88.61(3)°$, $P\bar{1}$ avec $Z = 2$. On a mesuré les intensités de 3789 réflexions indépendantes à l'aide d'un diffractomètre à quatre cercles. On a utilisé 2448 de ces réflexions pour affiner la structure par la méthode des moindres carrés (matrice complète) jusqu'à une valeur de R pondérée de 0.067 et une valeur de R conventionnelle de 0.055.

La molécule existe dans une conformation avec le nitro-*gauche* "*distal*". L'angle entre le cycle *ortho*-disubstitué et le plan du C—CH_2—C central est de 87.6°; l'angle entre le cycle substitué par le groupe nitro et le plan C—CH_2—C est de 2.2°.

[Traduit par le journal]

Introduction

In diphenylmethanes one would expect little overlap, if any, between the π orbitals of the phenyl rings and the orbitals of the bridging carbon atom. The methylene group can carry only a small charge and there are no unshared electrons present. Therefore coulombic repulsion would not be expected to be an important factor in determining the conformation of diphenylmethanes. The factors that remain then, are the steric interactions associated with the *ortho* substituents, both among themselves and with the bridging group. In the nitro *distal* conformation the nitro group must be accommodated between the methylene hydrogen atoms and an adjacent hydrogen atom on the ring. Other structures determined in this series would indicate that in the *proximal* conformation the nitro group would be rotated out of coplanarity with the ring on which it is substituted through contact with the π electrons of the mesityl ring (1, 2). The notation used here has been discussed in detail previously (13).

The conformation of the compound reported here, 2-(4′-carbomethoxy-2′-nitrobenzyl)-1,3,5-trimethylbenzene, has been studied by n.m.r. and was predicted to have a skew-nitro-*distal* conformation (3) similar to the ether and sulfide analogs. The structure of 3,3′-dichloro-4,4′-dihydroxydiphenylmethane has been studied by X-ray diffraction and has the twist conformation with both chlorine substituents *proximal* (4).

Experimental

The syntheses of 2-(4′-carbomethoxy-2′-nitrobenzyl)-1,3,5-trimethylbenzene, $C_{18}H_{19}NO_4$, has been reported earlier (3). It was recrystallized from absolute ethanol, m.p. 104–105 °C. A sample with dimensions 0.42 × 0.28 × 0.34 mm was chosen for data collection. It was mounted on a Picker FACS I four circle diffractometer equipped with a graphite monochromator. The centered positions of 27 reflections with 2θ values between 35° and

45° were determined using MoKα_1 radiation. These reflections were used to determine accurate cell parameters by a least-squares calculation. Twelve of these reflections were used to determine the orientation of the crystal on the diffractometer.

The crystal data are as follows:

$C_{18}H_{19}NO_4$ f.w. = 313.35

Triclinic $P\bar{1}$, $a = 9.534(5)$, $b = 11.887(7)$, $c = 7.431(6)$ Å, $\alpha = 101.62(3)$, $\beta = 97.25(3)$, $\gamma = 88.6(3)°$, $\rho_o = 1.30$ g cm^{-3} (flotation), $\rho_c = 1.27$ g cm^{-3}, $Z = 2$, $F(000) = 332e$, $\lambda(\text{MoK}\alpha_1) = 0.70926$ Å, $\mu(\text{MoK}\alpha) = 0.97$ cm^{-1}, $T = 20 \pm 1$ °C.

The integrated intensity of 3789 independent reflections with 2θ values between 3.5° and 55° were collected using the θ–2θ scan mode with a scan rate of 1 deg min^{-1}, a minimum base width of 2.7°, and 40 s background counts at each limit of the scan. The intensities of three standard reflections were measured after every 30 reflections and were not found to vary significantly. The data were reduced to observed structure factors using standard procedures. Corrections were not made for absorption or extinction effects. The scattering factors for the carbon, nitrogen, and oxygen atoms were taken from Cromer and Mann (5). The scattering factors for the hydrogen atoms were taken from Stewart *et al.* (6). A Wilson statistical calculation gave an overall temperature factor of 4.38 Å^2. The average values of $|E|$ and $|E^2 - 1|$ were 0.741 and 1.075 respectively, indicating the centrosymmetric space group $P\bar{1}$.

The 369 reflections with normalized structure factors, $|E|$, greater than 1.63 were used to solve the structure using the logical symbolic addition method.[2] The solution of the structure proved to be other than straightforward. Attempts were made to solve the structure by using Patterson methods directly but the lowest least-squares residual, R_w, that could be obtained with any model was 0.44. Unsuccessful attempts to solve the structure were also made using noncentrosymmetric programs.

The normalized structure factors were modified to provide proper scaling for subsets of the data and a new electron density map was obtained. This yielded a 15 atom solution which could be fitted to a model of the molecule. However, it was too close to a center of symmetry and the space group symmetry was therefore lowered to $P1$. The complete structure was found in this space group and a true center of symmetry was then identified between similar molecules. The structure was now easily refined in the space group $P\bar{1}$ and the hydrogen atoms were found from difference Fourier maps. The least-squares weights were calculated from $w^{-1/2} = 0.3106 - 0.00926|F_o| + 0.000912|F_o|^2$; 2448 reflections with $|F_o| > 2.6w^{-1/2}$ were used in the final cycles of refinement. The final values of the least-squares residual and the conventional R factor were 0.067 and 0.055 respectively.

The observed and calculated structure factors have been placed in the Depository of Unpublished Data.[3] The final positional and thermal parameters are listed in Table 1 with estimated standard deviations taken from the least-squares analysis. The bond lengths, bond angles, and the atom labeling are given in Figs. 1 and 2.

Discussion

The compound 2-(4′-carbomethoxy-2′-nitrobenzyl)-1,3,5-trimethylbenzene adopts the skew-nitro-*distal* conformation. The dihedral angles between the planes labeled in Fig. 3 are given in Table 2. They show that the conformation has very small deviations from the idealized skew conformation. The result is consistent with predictions based on n.m.r. ring shielding measurements (3). Since conjugation effects and coulombic repulsion are not important here, the skew conformation is clearly determined by the steric interactions of the *ortho* substituents. The nitro-substituted ring adopts the *distal* conformation to avoid contact between the nitro oxygen atoms and the π electrons of the mesityl ring. The mesityl ring is forced to be orthogonal to the nitro-substituted ring to avoid contact between its *ortho* substituents and the nitro substituent. The torsional angles ϕ[C(9)—C(18)—C(1)—C(6)] and ψ[C(1)—C(18)—C(9)—C(10)] occur in (+ +) pairs in one enantiomer and (− −) pairs in the other. The observed C—CH_2 bond lengths to the bridging methane group are nearly equal at 1.514(3) and 1.522(3) Å and are slightly shorter than the length of single C—C bonds. The C—CH_2—C bond angle at 114.3(2)° is larger than the tetrahedral angle as is the case for 3,3′-dichloro-4,4′-dihydroxydiphenylmethane where the reported value is 119(6)° (4).

The NO_2 group is rotated through 16.8° from coplanarity with the phenyl ring on which it is substituted. This rotation brings the nitro oxygen to methane hydrogen contact distance, H(18,1)—O(1), to 2.38(3) Å in comparison with an H(18,2)—O(1) contact distance of 2.55(2) Å. The contact distance between the other nitro

[2]The direct methods programs LSAM written by Germain and Woolfson (7) and MULTAN written by Germain *et al.* (8), were used for structure solution in centrosymmetric and noncentrosymmetric space groups respectively. The program FORDAP, written by Zalkin (9), was used for all Fourier calculations. The program ORFLS, written by Busing *et al.* (10), was used for least-squares refinement. The stereograms were prepared with the aid of the Johnson program ORTEP (11).

[3]Complete set of tabular data is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

oxygen atom and the adjacent hydrogen atom H(3) is 2.33(2) Å. It would appear that the nitro group is wedged between the methane hydrogen atoms and the adjacent hydrogen atom H(3) on the ring and rotates out of plane in order to fit between them. A similar situation was shown to arise in 2-(3′-methyl-4′-nitrophenoxy)-1,3,5-diisopropylbenzene and there the nitro groups

towards the mesityl ring. The similarly substituted ether and thioether and other ethers reported in this series which have a similar conformation to that of the methane are bent in the opposite sense. The difference here is caused by the contacts between the methylene hydrogen atoms and the atom O(1). This bending brings the atom H(6) closer to the π electrons of the mesityl ring but, because the C—CH_2 bond lengths here are longer than the C—O bond lengths in the ethers, the distance from the mesityl plane to the atom H(6) is not unusually short at 2.43 Å. Figure 4 shows a stereoscopic view of the molecule and Fig. 5 shows the molecular packing.

Conformations of Bridged Diphenyls. XIII. Crystal Structure of 2-(4′-Carbomethoxy-2′-nitrobenzoyl)-1,3,5-trimethylbenzene

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, AND BEVERLY E. ROBERTSON[1]

Faculty of Science, University of Regina, Regina, Saskatchewan S4S 0A2

Received December 20, 1974

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER, and BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2127 (1975).

The structure of 2-(4′-carbomethoxy-2′-nitrobenzoyl)-1,3,5-trimethylbenzene, $C_{18}H_{17}NO_5$, has been determined by X-ray diffraction. The crystals are triclinic, $a = 10.266(5)$, $b = 7.672(5)$, $c = 11.975(8)$ Å, $\alpha = 105.11(3)$, $\beta = 100.08(3)$, $\gamma = 111.50(3)°$, $P\bar{1}$ with $Z = 2$. The integrated intensities of 3732 independent reflections were measured on a four circle diffractometer; 2784 of these reflections were used in the refinement to give a final least-squares weighted residual of 0.046 and a conventional R factor of 0.053.

The molecule adopts the twist-nitro-*proximal* conformation similar to the conformation in the corresponding sulfoxide and sulfone. The angle subtended at the bridging carbon atom is 118.5(2)° and its bond lengths to phenyl carbon atoms are 1.502(2) and 1.503(2) Å.

SIMON P. N. VAN DER HEIJDEN, W. DAVID CHANDLER et BEVERLY E. ROBERTSON. Can. J. Chem. **53**, 2127 (1975).

On a déterminé la structure du (carbométhoxy-4′ nitro-2′ benzoyl)-2 triméthyl-1,3,5 benzène, $C_{18}H_{17}NO_5$, par diffraction de rayons-X. Les cristaux sont tricliniques, $a = 10.266(5)$, $b = 7.672(5)$, $c = 11.975(8)$ Å, $\alpha = 105.11(3)$, $\beta = 100.08(3)$, $\gamma = 111.50(3)°$, $P\bar{1}$ avec $Z = 2$. On a mesuré les intensités de 3732 réflexions indépendantes à l'aide d'un diffractomètre à quatre cercles. On a utilisé 2784 de cas réflexions pour affiner la structure jusqu'à une valeur de R pondérée de 0.046 et une valeur de R conventionnelle de 0.053.

Les molécules existent dans une conformation nitro-croisé "*proximal*" semblable à celle des sulfoxydes et des sulfones correspondantes. L'angle sous-tendu à l'atome de carbone de pont est de 118.5(2)° et les longueurs de liaisons avec les atomes de carbone des groupes phényles sont de 1.502(2) et 1.503(2) Å. [Traduit par le journal]

Introduction

This is the sixth and final detailed report of the structures of a series of similarly substituted bridged diphenyls in which the bridging group is varied (1–5). The conformation of this structure also has been studied by p.m.r., using the effect of ring-current shielding (6). The results of that study were not conclusive because of complications produced by the magnetic anisotropy of the carbonyl functional group. By comparison of the results with those obtained for the corresponding sulfoxide it was inferred, however, that the conformation was probably twist-nitro-*proximal*.

The results of the X-ray diffraction study of the sulfoxide and sulfone suggest that the coulombic repulsion between the nitro oxygen atoms and the carbonyl oxygen atom would promote a nitro-*proximal* conformation for this compound. The effect of possible conjugation between the bridging group and π electrons on either of the two rings is not important here and both the skew and twist conformation would seem possible based on this consideration. The notation used here has been discussed in detail previously (1).

The structures of three benzophenones have been determined previously by X-ray diffraction. Benzophenone and 3,3′-dibromobenzophenone both adopt the twist conformation (7, 8). The dihedral angles made by both phenyl rings and the central C—CO—C plane being *ca.* 27.5° in each case. 4,4′-Dimethoxybenzophenone (9) has two molecules per asymmetric unit with dihedral angles ranging from 24.2° to 35.4°. This conformation is presumably influenced by the steric interaction between the *ortho* hydrogen atoms and the carbonyl oxygen atom. The twist conformations thus seem to be preferred in diphenyl ketones.

Experimental

The synthesis of 2′-(4′-carbomethoxy-2′-nitrobenzoyl)-1,3,5-trimethylbenzene, $C_{18}H_{17}NO_5$, has been reported earlier (6). It was recrystallized from absolute ethanol, m.p. 121–122 °C. A sample with approximate dimensions 0.60 × 0.28 × 0.24 mm was examined by film techniques.

The crystal orientation and cell constants were deter-

mined on a Picker FACS 1 automated four circle diffractometer, equipped with a graphite monochromator. The cell constants were determined by least squares. The errors in the cell constants are calculated as three times the estimated standard deviations obtained from the least-squares analysis. Twenty-three reflections centered at 2θ values between 35 and 45° were used in the calculation.

The crystal data are as follows:

$C_{18}H_{17}NO_5$ f.w. = 327.34

Triclinic, $P\bar{1}$, $a = 10.226(5)$, $b = 7.672(5)$, $c = 11.975$ (8) Å, $\alpha = 105.11(3)$, $\beta = 100.08(3)$, $\gamma = 111.50(3)°$, $\rho_o = 1.39$ g cm^{-3} (flotation), $\rho_c = 1.35$ g cm^{-3}, $Z = 2$, $F(000) = 344e$, $\mu(MoK\alpha) = 1.06$ cm^{-1}, $\lambda(MoK\alpha_1) = 0.70926$ Å, $T = 22 \pm 2$ °C.

The integrated intensities of 3732 independent reflections with 2θ values between 3.5 and 55° were collected with MoKα radiation using the θ–2θ scan mode, a minimum base width of 3.0° in 2θ, and 20 s background counts at each limit of the scan. The data were reduced to structure factors using standard procedures. No corrections were made for extinction or absorption.

A Wilson statistical calculation gave an overall temperature factor of 3.32 Å^2. The scattering factors for carbon, oxygen, and nitrogen atoms were taken from those given by Cromer and Mann (10). The scattering factors for the hydrogen atoms were taken from Stewart *et al.* (11). The average values of $|E|$ and $|E^2 - 1|$ were 0.767 and 1.044 indicating the centrosymmetric space group $P\bar{1}$. The 411 reflections with $|E| > 1.58$ were used to solve the structure using the logical symbolic addition method.[2] The *E*-map calculated from the solution with the second highest figures of merit yielded all 24 non-hydrogen atom positions. Using individual anisotropic temperature factors and unit weights, the weighted residual, R_w, of the full-matrix least squares was lowered to 0.116.[3]

The hydrogen atoms were found by difference Fourier calculations. The 2784 reflections for which $|F_o| > 1.0w^{-1/2}$ were used in the final cycles of refinement with the least-squares weights now calculated from $w^{-1/2} = 0.3907 - 0.05003|F_o| + 0.002630|F_o|^2$.

The final values of R_w and the conventional R factor were 0.046 and 0.053 respectively. The observed and calculated structure factors have been placed in the Depository of Unpublished Data.[4] The final positional and thermal parameters are listed in Table 1, with errors taken directly from the least-squares analysis. The bond lengths, bond angles, and atomic numbering are given in Figs. 1 and 2.

Discussion

The angles between the planes of 2-(4′-carbomethoxy-2′-nitrobenzoyl)-1,3,5-trimethylbenzene, as defined in Fig. 3, are given in Table 2. The molecule has the twist-nitro-*proximal* conformation as predicted. The larger dihedral angles made by the phenyl rings with the central plane than in the case of other reported benzophenones are caused, at least in part, by the larger van der Waals radius of the methyl groups as compared with hydrogen atoms in the benzophenone structures reported previously (7–9). The dihedral angles found here are in fact similar to those of the identically substituted sulfoxide and sulfone (3, 4). The torsional angles φ[C(9)—C(18)—C(1)—C(2)] and ψ[C(1)—C(18)—C(9)—(C10)] occur in (+ +) pairs in one enantiomer and in (− −) pairs in the other as is inferred by the twist conformation.

Buchanan *et al.* (16) have used ^{13}C n.m.r. as a tool in studying the conformations of benzophenones. They are able, however, to predict only the value of $\cos^2 \phi + \cos^2 \psi$. The only tri-*ortho*-substituted benzophenone which they considered contained three methyl groups. They concluded that the di-*ortho*-substituted ring is perpendicular to the central plane and the other is rotated through 30°. Although no predictions were made for compounds of the type reported here, it seems reasonable that the charges on the oxygen atoms of the nitro group might lead to a different conformation for 2-(4′-carbomethoxy-2′-nitrobenzoyl)-1,3,5-trimethylbenzene. A stereogram of the molecule is shown in Fig. 4.

The molecule shows no unusual intermolecular contacts and the hydrogen atoms show bond lengths ranging from 0.87(3) to 1.03(3) Å. The

[2]The direct methods program LSAM, written by Germain and Woolfson (12), was used for structure solution. The program FORDAP written by Zalkin (13) was used for all Fourier calculations. The program ORFLS, written by Busing *et al.* (14), was used for least-squares refinement. Stereograms were prepared with the aid of the program ORTEP, written by Johnson (15).

[3]During the data collection the angular setting of one of the Teflon coated arcs of the gonimeter head changed causing a drop in the intensity of the standard reflections. The crystal was realigned and data collection was resumed at a point such that all the data affected by the arc slippage were assumed to have been collected again. However, during the structure refinement it became apparent that this assumption was not correct and that some of the data not recollected were inaccurate. Therefore all of the data (approximately 400 reflections) in the shell of data including the inaccurate data were excluded from the final stages of refinement. We are obliged to point out, then, that the results of this analysis suffer from any systematic errors associated with either the use of two sets of alignment parameters for data collection or the exclusion of a shell of data from the least-squares refinement. However, a comparison of the bond lengths in all identically substituted bridged diphenyls in this series, including this one, shows that the r.m.s. deviation in the bonds not affected by the bridging group is less than (or equal to) the average e.s.d.'s of that bond length.

[4]Complete set of tabular data is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

packing of the molecules is shown in Fig. 5, and is the same as for the similarly substituted sulfoxide. The packing scheme assumed by both compounds shows an association of phenyl rings of adjacent molecules as was the case for 2-(2′,6′-dinitrophenoxy)-*t*-butylbenzene (17), although the actual packing in the latter case was not the same as that reported here.

The bond lengths to the central carbon atom are virtually identical at 1.503(2) and 1.502(2) Å. They are slightly shorter than in the identically substituted diphenylmethane (1.514(3) and 1.522(3) Å for the mesityl and nitro-substituted ring respectively) (5). The angle subtended at the bridging carbon atom is 118.5(2)°, which is smaller than in the reported structures of other

Phosphorescence Lifetime of SO_2 in the $\tilde{a}^3B_1$ State at Low Pressure

J. PHILIP BRIGGS,[1] ROBERT B. CATON,[2] AND MICHAEL J. SMITH[3]

Department of Chemistry and Scarborough College, University of Toronto, West Hill, Ontario M1C 1A4

Received December 11, 1974

J. PHILIP BRIGGS, ROBERT B. CATON, and MICHAEL J. SMITH. Can. J. Chem. **53**, 2133 (1975).

The emission decay rate (inverse lifetime) of the optically-excited $\tilde{a}^3B_1$ electronic state of SO_2 vapor at approximately 25 °C has been measured in a 35 cm diameter spherical container over the pressure range $1 < P < 500$ mTorr in pure SO_2 and in mixtures of SO_2 with He, Ar, or Xe. The Stern–Volmer rate constant for quenching by SO_2 ($\tilde{X}^1A_1$) was determined to be $(4.46 \pm 0.11) \times 10^8$ l mol^{-1} s^{-1}, and the extrapolated, zero-pressure decay rate was calculated to be $(3.75 \pm 0.58) \times 10^2$ s^{-1}. The latter quantity implies a considerably greater proportionate contribution by radiative, as opposed to nonradiative, relaxation of this state than has been reported previously.

J. PHILIP BRIGGS, ROBERT B. CATON et MICHAEL J. SMITH. Can. J. Chem. **53**, 2133 (1975).

On a mesuré le taux d'émission de dégénérescence (inverse du temps de vie) de l'état électronique $\tilde{a}^3B_1$ du SO_2 sous forme vapeur excité optiquement; ces mesures ont été effectuées à environ 25 °C, dans un récipient sphérique de 35 cm de diamètre, à des pressions allant de 1 à 500 mTorr de SO_2 pur et dans des mélanges de SO_2 avec He, Ar ou Xe. On a déterminé que la constante de vitesse de Stern–Volmer pour le piégage du SO_2 ($\tilde{X}^1A_1$) est $(4.46 \pm 0.11) \times 10^8$ l mol^{-1} s^{-1} et on a calculé, par extrapolation, que le taux de dégénérescence à pression zéro est $3.75 \pm 0.58 \times 10^2$ s^{-1}. Contrairement à ce qui avait été rapporté antérieurement, cette dernière valeur suggère que la relaxation de cet état evolue relativement plus par des processus radiatifs que par des processus non-radiatifs. [Traduit par le journal]

Introduction

Recent theories of radiationless transitions (1) predict that for small molecules, which possess relatively few vibrational degrees of freedom, the experimental phenomenon of nonradiative relaxation should be absent in an isolated molecule. The variety of attempts which have been made both to measure and to calculate the zero-pressure, or collision-free lifetime of the $\tilde{a}^3B_1$ electronic state of sulfur dioxide vapor have not demonstrated convincingly whether this system behaves as predicted by theory.

Recent experimental measurements of the decay rate of SO_2 phosphorescence by flash lamp excitation (2), by pulsed laser excitation (3), and by a Becquerrel phosphoroscope technique (4) have led to the conclusion that there is a dominant nonradiative contribution to the relaxation rate. This conclusion, however, is based, in part, on a long extrapolation of the linear portion of τ^{-1} *vs.* P plots from a minimum 70 mTorr to obtain the value of the intercept, τ_0^{-1}, the collision-free relaxation rate constant.

Such behavior is, of course, at odds with theory (1) and with the fact that the discrete rotational structure of the transitions to the first few levels of the $\tilde{a}^3B_1$ state, whose lifetime was measured in these studies, can be assigned line-by-line and shows no major perturbations (5). If these levels decay by primarily nonradiative channels, the lines should be severely inhomogeneously broadened (1) or should exhibit severe perturbations (6), neither of which is observed.

We felt it worthwhile to reinvestigate the transient decay characteristics of optically-excited SO_2 in its $\tilde{a}^3B_1$ state, specifically to measure the $^3SO_2$ lifetime at considerably lower pressures than had been reached previously. The SO_2 triplets in our study, as in refs. 2 and 4, were produced by intersystem crossing from the electronically-excited singlet manifold of the 290 nm absorption system. We have also examined the effect of rare gas collision partner on the lifetime of $^3SO_2$.

*NOTE: Emission detected at 415 nm.

Experimental

SO_2 gas (Anhydrous Grade, 99.995%) and the rare gases He, Ar, and Xe (Research Grade, 99.995 to 99.9995%) were supplied by Matheson of Canada and were used without further purification.

SO_2 at about 25 °C in a spherical, 35 cm diameter cell was excited by the 289, 297, or 313 nm pressure-broadened lines of a 200 W Hg/Xe compact arc lamp, which were selected by a ½ m monochromator having a bandpass of about 2.4 nm. The number density of $^3SO_2$ in the cell and the collection of the emission were enhanced by means of a multi-pass optical system described by Parmenter and Schuyler (7).

The detector, an EMI 6256S PMT, was interfaced with the cell either directly via a Jena WG-1 cutoff filter (1% transmission at 350 nm) or via a Spex ¾ m spectrometer. The latter arrangement allowed the decay characteristics of individual vibronic features of the emission spectrum to be monitored.

Modulation of the exciting light was achieved mechanically by means of a sectored disk rotated at 1750 r.p.m. The time-dependent $^3SO_2$ (or in some cases $^1SO_2$) emission was measured as follows. A phototransitor mounted behind the entrance slit of the ½ m monochromator was part of a Schmitt trigger circuit whose output fed a Tektronix 2101 pulse generator. The delayed trigger from this pulse generator activated the coincidence gate of an Ortec photon-counting unit for a time period equal to the width of the pulse. The output signals from both the phototransitor and the pulse generator were displayed on a Tektronix 547 dual-trace oscilloscope. The counting period (normally 20 μs) and delay time, which were set with the 2101 pulse generator, could be observed and measured with the oscilloscope. The time bases of the oscilloscope and pulse generator were recently calibrated.

The pressure of SO_2 (or of gas mixtures) over the entire pressure range was measured with an M.K.S. Baratron capacitance manometer which was attached directly to the cell. The accuracy of this instrument was checked between 1 and 500 mTorr by calibrating it against an H.S. Martin and Son McLeod gauge. Helium was used as the calibrating gas to prevent error due to pumping by the stream of mercury vapor flowing from the gauge to the isolating cold trap (8). The M.K.S. specification of 1% accuracy was found to be satisfactory above 30 mTorr, whereas, the agreement was within 5% below this pressure.

Photon counts were normally accumulated for 200 s on a digital scaler, and the emission intensity as a function of the gate delay time was recorded manually. Inverse lifetimes were computed from the exponential

decay curves according to the usual relationship: $\ln (I_0/I) = \tau^{-1}t$ by a linear least-squares method. Ten to twelve data points, corrected for background, were used for each inverse lifetime calculation.

The graph of these τ^{-1} values plotted *vs.* pressure was in turn fitted by an unweighted linear least-squares method to obtain its slope and intercept, the desired Stern–Volmer bimolecular quenching rate constant and inverse collision-free lifetime, respectively. The calculation assumed no error in the independent variable, namely pressure at a given time. The validity of this assumption was established by the calibration procedures described above.

Results

The measured emission decay pseudo-first-order rate constants at each pressure are presented for pure SO_2 in Table 1, and for SO_2/rare gas mixtures in Table 2, along with the excitation wavelengths.

These data show that the $^3SO_2$ decay rate was insensitive to variations in the exciting wavelength at a given pressure, which suggests that the observed rate is characteristic of $^3SO_2$ and not of the rate process which populates $^3SO_2$ from $^1SO_2$. Decay rates measured for the $\tilde{a}^3B_1$ (000)–$\tilde{X}^1A_1$ (110) vibronic band at 415 nm were indistinguishable from those for the integrated $^3SO_2$ emission passed by the cutoff filter. Because of low signal, the 415 nm band could be monitored only at pressures greater than about 30 mTorr; thus, the low-pressure rates refer only to integrated emission passed by the WG-1 filter.

The least-squares equation for τ^{-1} as a function of pressure for the linear portion of this

*NOTE: Partial pressure of SO_2 = 2 mTorr in all experiments.

TABLE 3. Summary of decay rate constants for optically excited $^3SO_2$ in pure SO_2 compared with literature values

k_q (l mol^{-1} s^{-1} × 10^{-8})*	$k_p + k_{nr}$ (s^{-1} × 10^{-3})*	Reference
4.46 ± 0.11	0.375 ± 0.058	This work
4.52 ± 0.18	1.12 ± 0.20	4
	2.0 ± 0.8	4
3.9 ± 0.1	0.98 ± 0.68	2
3.9 ± 0.7	1.13 ± 0.18	3

*NOTE: Errors quoted are 2 standard deviations in most cases.

function, that is, for the 43 points in the pressure range 10 to 480 mTorr, is

$$[1]\quad \tau^{-1} = (3.75 \pm 0.58) \times 10^2 + (23.8 \pm 0.6) \times P_{SO_2}\ \text{mTorr s}^{-1}$$

Thus, the rate constants for processes 2, 3, and 4 in the usual Stern–Volmer quenching scheme:

$$[2]\quad {}^3SO_2 + SO_2 \xrightarrow{k_q} 2SO_2$$

$$[3]\quad {}^3SO_2 \xrightarrow{k_p} SO_2 + h\nu_p$$

$$[4]\quad {}^3SO_2 \xrightarrow{k_{nr}} SO_2$$

may be computed to be

$$[5]\quad k_q = (4.46 \pm 0.11) \times 10^8\ \text{l mol}^{-1}\ \text{s}^{-1}$$

and

$$[6]\quad (k_p + k_{nr}) = (3.75 \pm 0.58) \times 10^2\ \text{s}^{-1}$$

The errors noted are two standard deviations.

These values of k_q and $(k_p + k_{nr})$ are compared with literature values in Table 3. The zero-pressure rate constant [6] is barely within the uncertainty limits of the pulsed laser experiments of Calvert and co-workers (3) and is nearly a factor of three smaller than that of Otsuka and Calvert (2) and Strickler *et al.* (4).

There is no noticeable curvature of the τ^{-1} *vs.* P plot at low pressure which might have led to this considerable disagreement. The 17 values of τ^{-1} for pressures greater than 35 mTorr give essentially the same slope and intercept (23.7 mTorr^{-1} s^{-1} and 400 s^{-1}, respectively) as the 26 values corresponding to pressures between 10 and 35 mTorr (24.8 mTorr^{-1} s^{-1} and 357 s^{-1}, respectively). Thus, vibrational relaxation effects which were observed by Caton and Gangadharan (9) at pressures less than approximately 35 mTorr did not influence the present results appreciably.

The heterogeneous quenching reaction

$$[7]\quad {}^3SO_2 + \text{wall} \rightarrow SO_2 + \text{wall}$$

has prevented previous investigators from making accurate measurements of inverse lifetime below 100 mTorr pressure. Both Calvert and co-workers (2, 3) and Strickler *et al.* (4) have used containers of small diameter (~5 cm) to make $^3SO_2$ lifetime measurements below 100 mTorr, which may have influenced their results.

The slope of the τ^{-1} *vs.* P plot, k_q, is essentially identical to the values reported by Calvert (2, 3) and Strickler (4). The disagreement between the present and previous results concerns only the intercept, which is, of course, extremely sensitive to small deviations in the slope and to extrapolation. The smallest measured value of τ^{-1} for pure SO_2 in this work, 580 s^{-1} at 10.1 mTorr, is already a factor of two smaller than Strickler's intercept, and the minimum value of τ^{-1} measured in an SO_2/Xe mixture was about 330 s^{-1}. These facts suggest that our extrapolated value of τ^{-1} is more significant than that of Calvert and co-workers (2, 3) and of Strickler *et al.* (4).

The analogs of eq. 1 for SO_2 (2 mTorr partial pressure) in the presence of the added gases He, Ar, or Xe are

$$[8]\quad \tau^{-1}(\text{He}) = (304 \pm 28) + (2.70 \pm 0.18) \times P_{\text{total}}\ \text{mTorr s}^{-1},\ P > 60\ \text{mTorr}$$

$$[9]\quad \tau^{-1}(\text{Ar}) = (301 \pm 17) + (1.78 \pm 0.14) \times P_{\text{total}}\ \text{mTorr s}^{-1},\ P > 24\ \text{mTorr}$$

$$[10]\quad \tau^{-1}(\text{Xe}) = (262 \pm 11) + (3.88 \pm 0.10) \times P_{\text{total}}\ \text{mTorr s}^{-1},\ P > 17\ \text{mTorr}$$

The quenching rate constants for these three gases with respect to reaction 11:

$$[11]\quad {}^3SO_2 + M \xrightarrow{k_q'} SO_2 + M$$

are then

$$k_q'(\text{He}) = (5.06 \pm 0.34) \times 10^7\ \text{l mol}^{-1}\ \text{s}^{-1}$$

$$k_q'(\text{Ar}) = (3.34 \pm 0.26) \times 10^7\ \text{l mol}^{-1}\ \text{s}^{-1}$$

$$k_q'(\text{Xe}) = (7.27 \pm 0.19) \times 10^7\ \text{l mol}^{-1}\ \text{s}^{-1}$$

For comparison, Sidebottom *et al.* (10) measured k_q' for He, Ar, and Xe, respectively, to be $(6.8 \pm 0.7) \times 10^7$, $(5.2 \pm 0.5) \times 10^7$, and $(7.1 \pm 1.1) \times 10^7$ l mol^{-1} s^{-1} for direct laser excitation of the $\tilde{a}^3B_1$ state. Wampler *et al.* (11)

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

found $k_q'(Ar)$ to be $(4.75 \pm 0.96) \times 10^7$ l mol^{-1} s^{-1} for broadband excitation of the singlet manifold or $(5.58 \pm 0.56) \times 10^7$ l mol^{-1} s^{-1} for direct laser excitation of the triplet state. These data were obtained at much higher pressure than the present results.

As a check on the instrumentation, the long-lived $^1SO_2$ emission discovered by Brus and McDonald (12) was monitored at 351 nm at pressures between 0.5 and 5 mTorr in pure SO_2. For excitation at 297 nm, τ_0 was 140 μs, and at 313 nm, 200 μs. The Stern–Volmer quenching rate constants were 1.6×10^{-10} and 2.0×10^{-10} cm^3 s^{-1}, respectively. These values are to be compared with Brus and McDonald's values (12) for τ_0 of 184 μs (296 nm excitation) and 308 or 532 μs (304 or 320 nm excitation, respectively). Brus and McDonald's quenching constants were 1.09×10^{-10} and 1.47×10^{-10} or 1.53×10^{-10} cm^3 s^{-1}, respectively. The agreement is satisfactory, considering the severe wavelength and bandwidth dependence of the $^1SO_2$ lifetime.

Discussion and Conclusions

The Effect of Container Diameter on the Measured Decay Rate of $^3SO_2$

The data reported in Table 1 are represented in Fig. 1 along with the analogous results of Otsuka and Calvert (2) and Strickler *et al.* (4). Comparison of these data reveals the effect of container size on the measured decay rates. Otsuka and Calvert (2), as well as Strickler *et al.* (4), attributed the curvature in their $^3SO_2$ τ^{-1} *vs.* P graphs to the boundary process [7]. Our data support this explanation of the earlier investigators. Detection geometry may also influence the measured decay rates (13), and deviation from the linear Stern–Volmer relation at low pressure can occur if $^3SO_2$ diffuses from the monitored volume element (2). Such diffusion apparently explains the decrease in $^3SO_2$ lifetime below 10 mTorr in pure SO_2. If the decay rates for pressures of pure SO_2 less than 10 mTorr are plotted as $(\tau_{obs}^{-1} - \tau_{calc}^{-1})$ *vs.* P^{-1}, where τ_{calc}^{-1} is calculated from eq. 1, by analogy with Fig. 3 of ref. 2, a linear relationship is found. Such a linear relationship is to be expected if either diffusion-controlled wall deactivation or diffusion from the field of view of the detector is important (2). Analysis of our data indicates that diffusion alters the measured decay rates by less than 10% above 10 mTorr

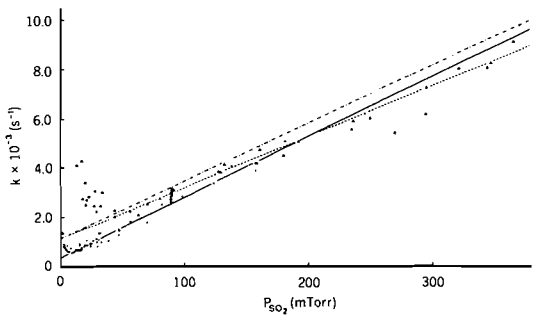

FIG. 1. Plot of τ^{-1} *vs.* P for pure SO_2: ● and —, present work; ▲ and ---, data from Table 1 of ref. 2; △ and –·–, data reconstructed from Fig. 1 of ref. 4.

in pure SO_2 and by only 20% at 10 mTorr, the lowest pressure which was used in obtaining eq. 1.

Caton and Gangadharan (9) have demonstrated the influence of vibrational relaxation on the population of $^3SO_2$ from $^1SO_2$ at pressures less than 5 mTorr. Vibrational relaxation (cascade) effects, such as emission from possibly shorter-lived vibrationally-excited levels of $^3SO_2$, might be indistinguishable from diffusion-loss effects. This point is discussed further in ref. 9.

In any case, the emission collection geometry and the large cell which were employed in the present work have clearly extended, by an order of magnitude, the pressure range over which diffusion-free decay constants could be measured.

The Effect of He, Ar, and Xe on the Measured Decay Rates of $^3SO_2$

The diffusion coefficient of SO_2, in mixtures with the rare gases at a given total pressure should decrease monotonically from He to Xe, as predicted by the usual gas kinetic formulae. Deviations from Stern–Volmer behavior are thus to be expected at higher pressures in SO_2/He mixtures than in SO_2/Ar and SO_2/Xe mixtures, respectively. Figure 2, in which the data of Table 2 are plotted for pressures less than 50 mTorr, shows clearly that at low pressures the inverse lifetimes do in fact increase in the order $\tau^{-1}(Xe) < \tau^{-1}(Ar) < \tau^{-1}(He)$ at a given pressure. Furthermore, curvature in the Stern–Volmer plot appears at a much higher pressure in He mixtures (about 50 mTorr) than in Xe mixtures (about 15 mTorr), as expected if diffusional loss is responsible.

The slopes of eqs. 8, 9, and 10 are also expected to increase monotonically in the order

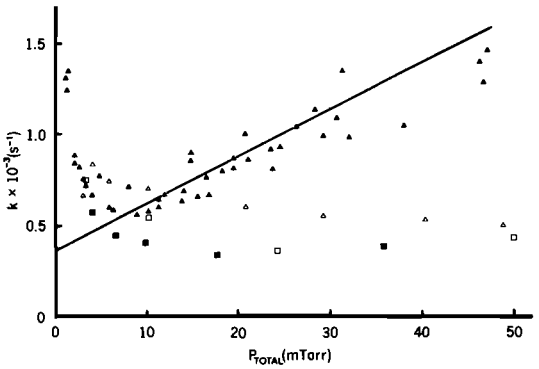

FIG. 2. Plot of τ^{-1} *vs.* P for pure SO_2 and for mixtures of SO_2 with He, Ar, or Xe in the low pressure region. Partial pressure of SO_2 in each mixture = 2 mTorr. △, He; □, Ar; ■, Xe; ▲, SO_2. The solid line is the least-squares fit to the pure SO_2 data between 10 and 480 mTorr, eq. 1.

$k_q'(\text{He}) < k_q'(\text{Ar}) < k_q'(\text{Xe})$, since both the polarizability (14) and spin–orbit coupling (external heavy atom effect) increase in this order. On the basis of the present data, Xe is clearly somewhat more effective than Ar and He, but a more quantitative theoretical treatment on the basis of these three isolated data does not seem justifiable. Our values of k_q' for He, Ar, and Xe agree reasonably well with the values reported in refs. 10 and 11. The fact that $k_q'(\text{He})$ and $k_q'(\text{Ar})$ are slightly smaller for initial excitation into the singlet manifold than for direct triplet excitation may be a real effect of intersystem crossing and vibrational relaxation.

The intercepts of eqs. 8, 9, and 10 should not be taken very seriously because of the uncertainty of extrapolating graphs with such shallow slopes, but they are nearly within the error limits of the pure SO_2 (eq. 1) intercept and serve to support our contention that τ_0^{-1} is considerably less than the value reported by other investigators.

Calculated Values of the Zero-pressure Decay Rate of $^3SO_2$

The purely radiative rate constant for reaction 3 has been calculated from absorption spectroscopic data (4) and found to be (79 ± 5) s^{-1}.

In calculating this value Strickler *et al.* made use of the formula

$$A_{u\to l} = 2.880 \times 10^{-9} n^2 \langle \bar{\nu}_e^{-3} \rangle_{Av}^{-1} g_l/g_u \times \frac{\langle M^2 \rangle_u}{\langle M^2 \rangle_l} \int \varepsilon \, d \ln \bar{\nu}$$

for the radiative transition probability, where the ratio of the degeneracies of the lower and upper states ($\tilde{X}^1A_1$ and $\tilde{a}^3B_1$, respectively) was taken as $g_l/g_u = 1/3$. Strickler and Berg (15) pointed out in their development of the above equation that a triplet state should be given a degeneracy of three only if all possible transitions between the spin components of the triplet state and the ground singlet state are equally allowed or if "... there is a rapid equilibrium established between molecules in the different component states of each degenerate level." Brand *et al.* (5) have shown that 80 to 90% of the intensity in the $\tilde{a}^3B_1$–$\tilde{X}^1A_1$ transition of SO_2 is carried by the z-spin component (b-axis polarization), which does not satisfy the first criterion of Strickler and Berg and implies that g_u should be near unity.

If the rapid equilibrium hypothesis is valid at pressures greater than about 10 mTorr (70 mTorr in previous studies), then the linearly-extrapolated, zero-pressure value of τ^{-1} would correspond to $g_u = 3$ as claimed by Strickler *et al.* (4). Since Strickler and Berg (15) intended this criterion to be applied to the condensed phase, the existence of a rapid equilibrium amongst the three spin levels, under conditions of low pressure in the gas-phase, is only hypothetical in the absence of an experimental test. A rough calculation indicates that a $^3SO_2$ molecule undergoes about 150 collisions during its measured lifetime at 10 mTorr in pure SO_2 and about 100 collisions during that time in the 1:5 SO_2/Xe mixture at 10 mTorr. These collision numbers are probably sufficient to bring about equilibration of the spin level populations, since the available data for polyatomic molecules suggest that only a few collisions are necessary to bring about randomization of rotational angular momentum from an initially nonequilibrium distribution. This fact, combined with the fact that the spin–spin and spin–rotation coupling constants are of the same magnitude as the spin–orbit splitting in the $\tilde{a}^3B_1$ state (5), argues in favor of the rapid equilibration model.

If the value of (79 ± 5) s^{-1} is to be used for k_p ($g_u = 3$), $\tilde{a}^3B_1$ relaxation is about 20% radiative, rather than 6% as found by Calvert *et al.* (2, 3) and Strickler *et al.* (4).

If the rapid equilibration model is incorrect, the calculated value of k_p should be multiplied by a factor of 3, such that the predicted zero-pressure intercept of τ^{-1} *vs.* P would be (237 ±

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

For personal use only.

15) s^{-1}. Comparing this revised calculated value with the present experimental value of (375 ± 58) s^{-1}, it appears that $\tilde{a}^3B_1$ would be predominantly radiative, rather than predominantly nonradiative as suggested in refs. 2–4.

Several arguments can be put which support the reliability of the present results. The reasonable agreement between our values for the lifetimes and quenching constants of long-lived $^1SO_2$ and those of Brus and McDonald (12) and the fact that we measured our pressures with a single, reliable gauge over the entire pressure range (which had not been the case previously) imply that a systematic error should not be invoked to explain the large difference in intercept between our Stern–Volmer plots and those of previous investigators. The loss of precision associated with our use of 10 or 12 manually-set scaler channels as compared with 100 electronically scanned channels of Strickler *et al.* should not be critical, since the statistical significance is related to the square root of the sample size.

General Discussion

All of the results of experiments in which optical excitation was used (this work and refs. 2–4) should be compared with those of the only other study in which the emission decay characteristics of SO_2 were monitored to a pressure of 1 mTorr (16). Caton and Duncan (16) reported the parameters $\tau(^3SO_2)$, $k_q(SO_2)$, and $k_q'(He)$ as derived from an analysis of transient decay traces produced by a pulsed electrodeless electrical discharge. Their values of $\tau_0^{-1} = (1.4 \pm 0.2) \times 10^2\ s^{-1}$ and of both $k_q(SO_2)$ and $k_q'(He) \approx 0$ are far outside the experimental uncertainty of those from the optical studies. One can conclude with some caution that the electrically-excited emission processes are not the same as those processes described in this paper and in the other reports on optical experiments. A source of the vast difference between these two sets of results may be the significant degree of dissociation of the SO_2, which occurred in the discharge and the consequent uncertainty of the nature of the emitting species. It is possible of course, that these results refer to sublevels of $^3SO_2$ which are not populated by optical processes.

In summary, the present study demonstrates that electronic relaxation of optically-excited $^3SO_2$ has a significantly greater radiative contribution than has been reported earlier. The data suggest that radiative decay occurs with between 20 and 60% efficiency, depending upon the argument outlined in the previous section of this Discussion. This conclusion, which remains unexplained on theoretical grounds, should be tested further, perhaps by molecular beam magnetic resonance techniques. Some attempt, as well, should be made to elucidate the differences between the characteristics of optically-excited and electrically-excited emission processes in SO_2.

We thank Professor S. J. Strickler for helpful discussions and correspondence.

Introduction

About a year ago we have completed (1) the synthesis of the delphinine-type alkaloid talatisamine **V** by a route which proceeded via the main stages **I**, **II**, **III**, and **V** and included the "biogenetic" rearrangement (*cf.* ref. 2) of the substituted atisine derivative **II** (Scheme 1). In spite of this success it became quite clear that this route has two built-in fundamental disadvantages which cannot be remedied by development work.

(*i*) In the rearrangement of the atisine derivative **II** the desired product **III** is accompanied by an equal quantity of the useless compound **IV**.

(*ii*) The formation of the last carbon ring, the ring B bridge, in the final stages of the synthesis is a poor yield reaction (40%).

It is obvious that a modification of the approach which would introduce the ring B bridge at the very beginning of the synthesis might be completely free of both these defects. Consequently, we have projected a synthesis of a delphinine-type alkaloid[1] which would proceed via the main stages **VI** through **IX** (Scheme 2).

The relatively simple and stereospecific synthesis of the starting material **VI** may be accomplished by the use of our aziridine rearrangement method (5).[2]

The crucial step of the synthesis is the rearrangement of the polysubstituted denudatine derivative **VII**. It is expected to produce compound **VIII** as the only product and to proceed with greater ease than the similar rearrangement **II** → **III**. The bicyclooctane C/D ring system in compound **VII** (unlike the same system in compound **II**) is twisted and strained. The relief of this strain should provide additional driving force for the rearrangement **VII** → **VIII**.

In spite of the efficiency which we have now developed in the synthesis of compounds of the type **VI**, it would be quite expensive to produce a quantity of this material large enough to try out experimentally all the conceivable variations of the process **VI** → **VII** → **VIII** → **IX**. For this reason we have worked out a simple and efficient conversion of the model starting material **1** to the product **26** (Scheme 3).

We believe that the experience obtained in this model work will be applicable without any major changes to compound **VI**. This last material while structurally complex is operationally as simple as the model compound **1**. The entire system of **VI** is saturated and very stable and it is expected to survive easily all the reaction conditions which we have employed in the conversion **1** → **26**.

Discussion

The model starting material **1** (6) was first converted to the α,β-unsaturated ketone **2** by Birch reduction followed by treatment with dilute aqueous hydrochloric acid at room temperature. The ketone **2** was oily but homogeneous in thin-layer (t.l.c.) and gas–liquid (g.l.c.) chromatog-

[1]The formula **IX** represents the alkaloid chasmanine. It has been shown recently (3) that the ring A methoxyl configuration in this compound originally assigned (4) anti to the nitrogen was incorrect and has to be reversed.

[2]We have already prepared and characterized the ring A methoxy epimer of compound **VI**. This product is now useless as a starting material for chasmanine. The synthesis of compound **VI** by the same method is in progress.

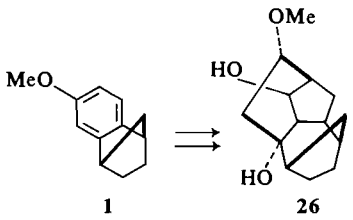

SCHEME 3

raphy in several systems. The nuclear magnetic resonance spectrum (n.m.r.)[3] of the product showed the allylic proton as a multiplet at 7.04 p.p.m.

In a kinetically controlled acid hydrolysis of the dihydrobenzenoid derivative obtained in the Birch reduction of **1** a stereoselective formation of **2** is expected, because of the well-known (7) preference of bicycloheptene derivatives for *exo* protonation. Compound **2** was now subjected to equilibration in methanolic hydrochloric acid – dioxane under reflux and the mixture was periodically examined by g.l.c. After 6 days the equilibrium was reached and the final ratio of compound **2** and the epimer **3** was 2.7:1. A similar equilibrium ratio (2.4:1) was obtained in *t*-butyl alcohol – potassium *t*-butoxide at 155 °C in a sealed tube.

The isomer **3** was separated in a preparative (acid-catalyzed) run by careful column chromatography on silica gel. The recovery of both products **2** and **3** was practically quantitative. Thus, the synthesis of compound **3** was somewhat laborious but it was accomplished in a very good yield.

The product **3** was an oil and its spectral data were very similar to those of compound **2**. The allylic hydrogen in the n.m.r. spectrum of **3** was shifted slightly upfield and appeared as a multiplet at 7.16 p.p.m. While it was not quite clear why the epimer **2** predominated in the equilibrium (the identical equilibrium ratio was also reached starting with **3**), the assignment of configuration to the two isomers seemed unambiguous.

The photoaddition of allene to the α,β-unsaturated ketone **3** was predicted to yield stereospecifically the adduct **5**. The stereochemistry of such additions (8, 9) is controlled by the stability of the excited state. The β-carbon of this (presumably n–π*) excited state is pyramidal and carries a σ orbital which can swing through the plane of the substituents and select the more stable configuration. If we assume that the β-carbon has an excess of negative charge with respect to the α-carbon, the excited state of the ketone **3** may be represented as **4**. It is clear that this stereoisomer with a *cisoid exo* ring junction is more stable than its *transoid* epimer.

Thus, it was possible to make the superficially unlikely prediction, that allene addition will take place from the distinctly more sterically hindered *endo* side. In fact, a single oily adduct homogeneous in t.l.c. and g.l.c. was obtained in a yield of 90%.

To prove that the configuration of this product corresponded indeed to the formula **5** the ketone was reduced by lithium aluminum hydride and the oily alcohol **6** was converted to the crystalline (m.p. 101 °C) *p*-bromobenzoate **7**. The structure of this ester was determined by Przybylska and Ahmed (10) by single crystal X-ray analysis and was found to agree with our expectations.

The conversion of the adduct **5** to the substituted "denudatine model" **16** proceeded in principle along the lines of our talatisamine synthesis (1). There were, however, differences between the two processes which originated (*a*) in the reversed configurations of the two allene adducts and (*b*) in the fact, that the strain of the denudatine system which is absent from the atisine system required special measures to be applied in the former case.

The adduct **5** was first converted to the ketal **8** and this compound gave by ozonolysis, sodium borohydride reduction and acid treatment the ketoaldehyde **9** in a yield of 92%. Analogous ketoaldehydes in the atisine series were never isolated since they underwent immediate ring closure of the 2.2.2-bicyclooctane system by aldol condensation. In the present case the equilibrium of the reversible internal aldol – retroaldol reaction favors the open keto aldehyde **9** and no amount of base or acid treatment can bring about ring closure.

However, the aldol condensation may be forced if it is performed under acetylating conditions (*cf.* ref. 11). Presumably the trace of the energetically unfavorable strained aldol condensation product, which is in equilibrium with the keto aldehyde **9** is removed by acetylation. In

[3]All spectra of all compounds were recorded and are given in the Experimental. In the Discussion only specially significant spectral results are mentioned to conserve space

For personal use only.

this manner the equilibrium is disturbed and new aldol is formed and acetylated until the entire amount of the starting material is converted to the product **10**. The acetoxy ketone **10** was a homogeneous sharply melting (m.p. 112 °C) compound and it was thus clear, that the condensation was stereospecific with respect to the new asymmetric center created in this process.

In order to prove the configuration of the acetoxy ketone **10**, this compound was reduced with sodium borohydride in absolute methanol. The oily but homogeneous acetoxy alcohol **11** was obtained in a quantitative yield. Saponification of this material yielded quantitatively the crystalline sharply melting (m.p. 99 °C) diol **12**. Finally treatment of compound **12** with phosgene and pyridine in absolute benzene gave a quantitative yield of the cyclic carbonate **13** (m.p. 185 °C; i.r.: 1740 cm^{-1} (carbonate carbonyl)).

The acetoxy alcohol **11** was now methylated with diazomethane and BF_3 etherate to the oily methoxy derivative **14**. The acetoxy group of this material was saponified and the resulting oily alcohol **15** was oxidized with chromium trioxide in pyridine to the oily ketone **16** in a quantitative yield. Finally, the ketone **16** was converted by heating under reflux with ethylene glycol and *p*-toluenesulfonic acid in benzene to the crystalline ketal **17** (m.p. 115 °C) in a quantitative yield.

The substitution of the model system may now be completed by the introduction of a β-oriented leaving group next to the ketal. Here we encounter a further advantage of the "denudatine route" as opposed to the "atisine route" utilized by us previously in the synthesis of talatisamine (1). Several steps were required in this last case to introduce the necessary β-tosyloxy function.

The greater ease of rearrangement of the denu-

For personal use only.

datine system makes it possible to use bromine as a leaving group and it can be introduced in a single step in the correct configuration.

The ketal **17** was brominated in tetrahydrofuran with pyridine hydrobromide perbromide. The oily but homogeneous bromo derivative **18** was isolated in a yield of 65% by chromatography on silica gel. The configuration of the bromine atom in compound **18** followed mainly from the clean and unique outcome of the subsequent rearrangement step, which requires antiplanarity of the leaving group and the migrating bond. The n.m.r. spectrum of compound **18** showed a narrow doublet at 5.72 p.p.m. for the proton deshielded by the bromine atom. This was consistent with the assigned configuration but of course did not prove it.

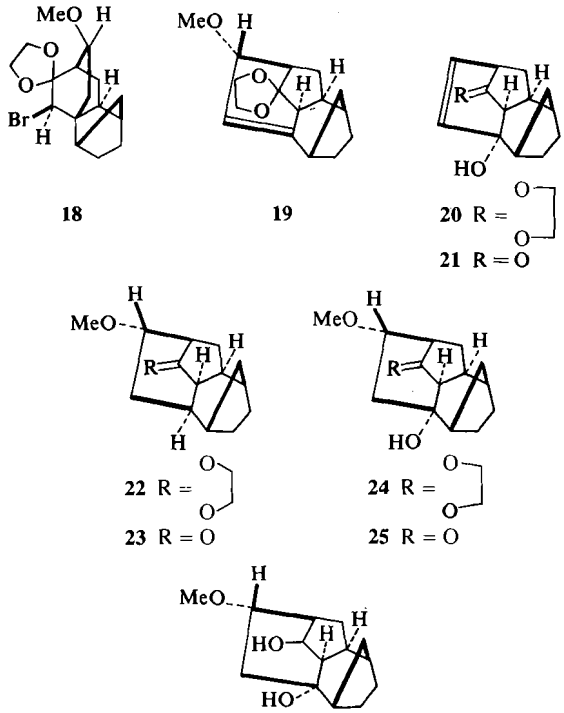
A number of methods were tried to bring about the crucial rearrangement of the bromo ketal **18**. It turned out that the most efficient one was heating under reflux in absolute benzene with 1,5-diazabicyclo[3.4.0]nonene (as base) for several days. Chromatography of the reaction mixture yielded 90% of the pure oily rearranged product **19**. The n.m.r. spectrum of this material showed the vinylic proton as a doublet at 4.53 p.p.m.

To prove the structure of compound **19** we have attempted to liberate the keto group under mild acidic conditions. However, treatment with dilute hydrochloric acid in tetrahydrofuran at room temperature yielded the allylic rearrangement product **20** with the ketal group still intact.

This compound was oily but homogeneous in t.l.c. and its n.m.r. spectrum showed clearly the loss of the methoxyl and the acquisition of two vinylic protons which appeared as a quartet at 4.01 and doublet at 4.49 p.p.m. Allylic rearrangements of so called "pyroderivatives" of delphinine type alkaloids, which have the same functional group system as **19**, have been recognized by us (12) many years ago and it is with some satisfaction that we have observed the same reactivity in our synthetic system.

Deketalization of compound **20** in 60% acetic acid at 70 °C yielded the corresponding crystalline (m.p. 115 °C) ketone **21**. The i.r. spectrum of this material showed a carbonyl peak at 1760 cm^{-1} in agreement with our expectation based on i.r. spectra of diterpene alkaloid derivatives with a keto group in the same position.

Hydrogenation of the rearrangement product



19 with palladium–charcoal in methanol gave a quantitative yield of the dihydro derivative **22**. This material was now deketalized with 60% acetic acid at 70 °C and the corresponding ketone **23** was obtained as an oil homogeneous in t.l.c. Compound **23** showed again in the i.r. spectrum the expected carbonyl maximum at 1760 cm^{-1}.

All these transformations left no doubt that the structure assigned to compound **19** is indeed correct. The stage was now set for the final modification of the functional groups.

Compound **19** was stirred at room temperature with mercuric acetate in 50% aqueous acetone. Chromatography of the reaction mixture yielded 70% of the oily oxymercuration product **24**. This material was deketalized to the crystalline (m.p. 104 °C) ketone **25** in a yield of 98% by heating with 50% acetic acid at 70 °C.

The i.r. spectrum of compound **25** showed hydroxyl peaks at 3600, 3475 cm^{-1} and a carbonyl peak at 1755 cm^{-1}. The n.m.r. spectrum showed a methoxyl peak at 6.63 p.p.m. A high resolution mass spectrum confirmed the precise molecular weight.

For further characterization crystals of the

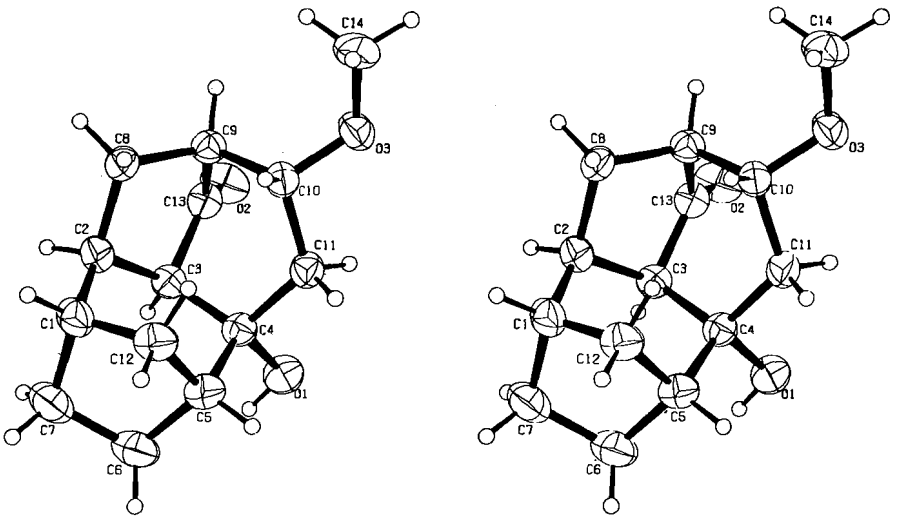


FIG. 1. Stereoscopic view of ketone **25**.

ketone **25** were submitted to Dr. John F. Blount, (Hoffmann–La Roche Inc, Nutley, New Jersey) who has kindly agreed to determine the structure of the material by single crystal X-ray crystallography. The structure derived by Dr. Blount in a remarkably short time is given in the Fig. 1 and fully confirms our expectations.

Reduction of the ketone **25** with sodium borohydride in methanol gave the alcohol **26** (m.p. 79 °C) in a yield of 80% after recrystallization. Diterpene alkaloid ketones analogous to **25** are known (1) to undergo stereospecific hydride reduction to yield alcohols with the hydroxy group in the "natural" configuration. Consequently we may safely assume that the reduction of our model ketone followed the same steric course.[4]

The present work clearly demonstrates that the synthesis of (say) chasmanine **IX** from the starting material **VI** is not only feasible but a practically solved problem. Whether or not it will be carried out depends on several nonchemical factors which are not under our control.

Experimental

Preparation of the α,β-Unsaturated Ketone 2

A solution of compound **1** (6) (32.7 g) in anhydrous tetrahydrofuran (190 ml) and *t*-butyl alcohol (190 ml) was added dropwise over a period of 30 min to a stirred solution and extracted with ether. The extract was washed with water, dried, and evaporated to dryness. The resulting residue was purified by chromatography on silica gel to give the oily α,β-unsaturated ketone **2** (23.8 g, 77%) homogeneous by t.l.c. in several solvent systems.

Mol. Wt. Calcd. for $C_{11}H_{14}O$: 162.1044. Found (high resolution mass spectroscopy): 162.1043.

Infrared (CCl_4): 1675 (conjugated six-membered ketone), 1655 cm^{-1} (double bond); u.v.: λ_{max}(EtOH) 245 nm (log ε 4.24); n.m.r. ($CDCl_3$): τ 4.30 (d, J = 1.5 Hz, 1H, vinylic proton), 7.04 p.p.m. (m, 1H, allylic proton).

Isomerization of 2 to 3

(*A*) The α,β-unsaturated ketone **2** (20.5 g) was dissolved in dioxane (600 ml) and saturated methanolic hytion of lithium metal (13.2 g) in distilled liquid ammonia (700 ml). The mixture was stirred at acetone – Dry Ice temperature for 2½ h. Absolute methanol was added until the blue color disappeared and the reaction mixture was allowed to stand to evaporate the ammonia. After workup by the standard procedure, the product (30 g) was treated with 5% aqueous hydrochloric acid (400 ml) and methanol (500 ml) at room temperature for 2 days. The mixture was neutralized with aqueous sodium bicarbonate drogen chloride (500 ml) was added. The mixture was heated under reflux in a nitrogen atmosphere. The reaction was examined by g.l.c. (15% Carbowax 20 M on Chromosorb W at 180 °C) and after 6 days it appeared that the equilibrium was reached (ratio of **2** to **3** about 2.7:1). The cooled reaction mixture was poured into a saturated sodium chloride solution and extracted with methylene dichloride. The extract was washed with water and dried over anhydrous magnesium sulfate. Evaporation of the solvent gave 20 g of an oily mixture of the ketones **2** and **3**. This mixture was separated by careful column chromatography on silica gel. Elution with 3% ethyl acetate in *n*-hexane resulted in the isolation of pure **3** (5.4 g) as an oil. Further elution yielded the starting material **2** (14.5 g).

[4]In the unlikely event that "natural" and model derivatives would be reduced with opposite stereospecificity our method would nevertheless yield the correct final product if applied to the synthesis of a natural alkaloid.

(*B*) The α,β-unsaturated ketone **2** (133 mg) was heated in a sealed tube at 155 °C with potassium *t*-butoxide (100 mg) in *t*-butyl alcohol (8 ml) in an inert atmosphere for 8 days. Under these conditions the final ratio of **2** to **3** was about 2.4:1.

Mol. Wt. Calcd. for $C_{11}H_{14}O$: 162.1044. Found (high resolution mass spectroscopy): 162.1041.

The entire mass spectra of **2** and **3** were practically identical; i.r. (CCl_4): 1675 (conjugated six-membered ketone), 1655 cm^{-1} (double bond); u.v.: λ_{max}(EtOH) 241 nm (log ε 4.12); n.m.r. ($CDCl_3$): τ 4.36 (broad s, 1H, vinylic proton), 7.16 p.p.m. (m, 1H, allylic proton).

Photoaddition of Allene to Compound 3

Compound **3** (5 g) was dissolved in anhydrous tetrahydrofuran (500 ml) and cooled to −70 °C. Allene was added in excess (60 g) and the reaction mixture was irradiated by a 200 W Hanovia Mercury lamp with a Pyrex filter for 8 h under nitrogen. After evaporation of the solvent and the excess allene, the photoadduct **5** was purified by chromatography on silica gel. The yield was 6.2 g (90%).

Mol. Wt. Calcd. for $C_{14}H_{18}O$: 202.1358. Found (high resolution mass spectroscopy): 202.1351.

Infrared (CCl_4): 1710 cm^{-1} (six-membered ketone); n.m.r. (CCl_4): τ 5.14 p.p.m. (sextet, 2H, vinylic protons).

Preparation of Bromo Compound 7 for X-Ray Analysis

A solution of the photoadduct **5** (23 mg) in anhydrous ether (5 ml) was added dropwise to a cold stirred suspension of $LiAlH_4$ (10 mg) in anhydrous ether (5 ml). The reaction mixture was stirred for 20 min at room temperature and work-up in the usual manner gave the alcohol **6** (22 mg, 96%) as a colorless oil homogeneous in t.l.c.

Mol. Wt. Calcd. for $C_{14}H_{20}O$: 204. Found (mass spectroscopy): 204.

Infrared (CCl_4): 3560, 3400 cm^{-1} (hydroxyl); n.m.r. (CCl_4): τ 5.07 (m, 2H, vinylic protons), 6.43 p.p.m. (m, 1H, proton unshielded by hydroxyl).

The alcohol **6** (80 mg) was dissolved in anhydrous benzene (10 ml) and *p*-bromobenzoyl chloride (150 mg) and anhydrous sodium carbonate (15 mg) were added. The mixture was heated under reflux for 3 days. After cooling the reaction mixture was diluted with ether (100 ml), washed with water, dried over anhydrous magnesium sulfate, and evaporated to dryness. Chromatography of the crude product by preparative t.l.c. on silica gel yielded the crystalline compound **7** (82 mg, 54%). A sample of **7** for X-ray analysis (m.p. 101 °C) was prepared by recrystallization from pentane.

Anal. Calcd. for $C_{21}H_{23}O_2Br$: C, 65.26; H, 5.97. Found: C, 65.24; H, 6.04.

Infrared (CCl_4): 1720 cm^{-1} (ester); n.m.r. ($CDCl_3$): τ 2.00, 2.34 (two d, J = 9 Hz, 4H, aromatic protons), 5.17 p.p.m. (m, 3H, vinylic protons and proton deshielded by benzoate).

Preparation of the Ketal 8

The photoadduct **5** (6 g) was dissolved in anhydrous benzene (500 ml) to which ethylene glycol (5 ml) and *p*-toluenesulfonic acid (600 mg) were added. The reaction mixture was heated under reflux for 3½ h with a water separator. The crude product was chromatographed on a column of basic alumina (grade II). The ketal **8** was eluted with 2% ether in *n*-hexane as an oil homogeneous in t.l.c. The yield was 5.15 g (72%).

Mol. Wt. Calcd. for $C_{16}H_{22}O_2$: 246.1620. Found (mass spectroscopy): 246.1615.

Nuclear magnetic resonance (CCl_4): τ 4.94 (q, 1H, vinylic proton), 5.20 (m, 1H, vinylic proton), 6.13 p.p.m. (broad s, 4H, dioxolane protons).

Preparation of the Keto Aldehyde 9

Compound **8** (3.5 g) was dissolved in methanol (150 ml) and cooled to −70 °C. A stream of ozone was slowly passed through the solution until it acquired a permanent blue color. Sodium borohydride (3 g) was then added in portions and the reaction mixture was stirred for an additional 20 min at 0 °C. The solution was acidified with 5% aqueous hydrochloric acid and stirred for 6 h at room temperature. The reaction mixture was then diluted with saturated aqueous sodium chloride (250 ml) and extracted with methylene dichloride. The extract was washed with water and dried over anhydrous magnesium sulfate. Removal of the solvent *in vacuo* gave the unstable oily keto aldehyde **9** (2.7 g, 92%) which had to be used immediately without purification.

Mol. Wt. Calcd. for $C_{13}H_{18}O_2$: 206. Found (mass spectroscopy): 206.

Infrared (CCl_4): 2840, 2730 (aldehyde), 1720 cm^{-1} (aldehyde and six-membered ketone); n.m.r. ($CDCl_3$): τ 0.32 p.p.m. (t, 1H, aldehyde).

Cyclization of Compound 9 to the Keto Acetate 10

A solution of the keto aldehyde **9** (4.7 g) in acetic acid (15 ml) was added dropwise under nitrogen at −10 °C to a stirred mixture of boron trifluoride etherate (50 ml), acetic anhydride (50 ml), and acetic acid (85 ml). The stirring was continued at room temperature under nitrogen for 5 days. The solvents were removed *in vacuo*, the dark residue was dissolved in ice water (300 ml), and the solution was extracted with methylene dichloride (3 × 150 ml). The combined extracts were washed with water, dilute aqueous sodium bicarbonate, then water again, dried over anhydrous sodium sulfate, and evaporated to dryness. Chromatography of the brown residue on silica gel and elution with 5% ether in *n*-hexane yielded the crystalline keto acetate **10**. The compound melted at 112 °C after one recrystallization from *n*-hexane (3.5 g, 62%).

Anal. Calcd. for $C_{15}H_{20}O_3$: C, 72.55; H, 8.12. Found: C, 72.30; H, 8.24.

Infrared (CCl_4): 1734 cm^{-1} (acetate and six-membered ketone); n.m.r. (CCl_4): τ 4.86 (heptet, J = 7, 5, and 2 Hz, 1H, proton unshielded by acetoxyl), 8.01 p.p.m. (s, 3H, acetoxy methyl).

Reduction of Compound 10 to the Alcohol 11

The keto acetate **10** (1.6 g) was dissolved in absolute methanol (60 ml) and sodium borohydride (600 mg) was added to the solution at 0 °C. The reaction mixture was maintained at this temperature for an additional 30 min. After this time the solution was neutralized with aqueous acetic acid and extracted with methylene dichloride. The extract was washed with water, dried over anhydrous magnesium sulfate, and evaporated to dryness. The alcohol **11** was obtained in a quantitative yield as a colorless oil, homogeneous in t.l.c.

Mol. Wt. Calcd. for $C_{15}H_{22}O_3$: 250.1575. Found (high resolution mass spectroscopy): 250.1569.

shielded by acetoxyl), 6.23 (m, 1H, proton unshielded by hydroxyl), 8.06 p.p.m. (s, 3H, acetoxy methyl).

Preparation of the Diol **12**

A solution of compound **11** (45 mg) in 1% methanolic potassium hydroxide (4 ml) was stirred at room temperature for 3½ h and worked-up in the usual manner. The product **12** was recrystallized from ether to a m.p. of 99 °C. The yield was quantitative.

Anal. Calcd. for $C_{13}H_{20}O_2$: C, 75.01; H, 9.61. Found: C, 75.08; H, 9.58.

Infrared (CCl_4): 3540, 3345 cm^{-1} (hydroxyl); n.m.r. (CCl_4): τ 5.84 p.p.m. (m, 2H, protons unshielded by hydroxyls).

Preparation of the Carbonate **13**

A solution of phosgene (10 drops) in anhydrous benzene was added to a stirred solution of the diol **12** (21 mg) and pyridine (15 drops) in the same solvent (3 ml). The resulting mixture was stirred at room temperature for 4 h. The solution diluted with benzene (50 ml) was washed with water, dried, and evaporated to dryness. The crude product was crystallized from ether and gave the pure carbonate **13** (m.p. 185 °C) in quantitative yield.

Anal. Calcd. for $C_{14}H_{18}O_3$: C, 71.77; H, 7.74. Found: C, 71.46; H, 7.64.

Infrared ($CHCl_3$): 1740 cm^{-1} (carbonate); n.m.r. ($CDCl_3$): τ 5.26 p.p.m. (m, 2H, protons deshielded by carbonate).

Preparation of the Methyl Ether **14**

An excess of diazomethane in ether was added dropwise to a stirred solution of the alcohol **11** (500 mg) and boron trifluoride etherate (40 mg) in methylene dichloride (30 ml) at 0 °C. The reaction mixture was stirred at this temperature for a further 30 min, after which time it was poured into 5% aqueous sodium bicarbonate and extracted with ether. The combined extracts were washed with water, dried and evaporated to dryness. The crude product was purified by chromatography in silica gel and yielded the pure oily methyl ether **14** (350 mg, 70%,) homogeneous in t.l.c.

Mol. Wt. Calcd. for $C_{16}H_{24}O_3$: 264.1726. Found (mass spectroscopy): 264.1734.

Infrared (CCl_4): 1730 cm^{-1} (acetate); n.m.r. (CCl_4): τ 5.03 (broad, t, 1H, proton unshielded by acetoxyl), 6.80 (s, 3H, methoxyl), 8.03 p.p.m. (s, 3H, acetoxy methyl).

Hydrolysis of Compound **14** *to the Alcohol* **15**

A solution of **14** (350 mg) in 2% methanolic potassium hydroxide (10 ml) was stirred at room temperature for 24 h and worked-up in the usual manner. The alcohol **15** (300 mg) was obtained as an oil homogeneous in t.l.c. The yield was quantitative.

Mol. Wt. Calcd. for $C_{14}H_{22}O_2$: 222. Found (mass spectroscopy): 222.

Infrared (CCl_4): 3545 cm^{-1} (hydroxyl); n.m.r. (CCl_4): τ 6.67 p.p.m. (s, 3H, methoxyl).

Preparation of the Ketone **16**

The alcohol **15** (206 mg) in methylene dichloride (5 ml) was added dropwise to a stirred solution of the chromium trioxide – pyridine complex (1.5 g) in methylene dichloride (30 ml). The mixture was stirred at room temperature for 1 h. It was then dissolved in ether (100 ml) and the brown precipitate was removed by filtration. The filtrate was washed with dilute hydrochloric acid, dilute aqueous sodium bicarbonate, and finally with water. The ether solution was dried over anhydrous magnesium sulfate and filtered through a short neutral alumina column (grade II). The pure ketone **16** was obtained as a thick oil in quantitative yield. It behaved homogeneously in t.l.c.

Mol. Wt. Calcd. for $C_{14}H_{20}O_2$: 220.1463. Found (high resolution mass spectroscopy): 220.1462.

Infrared (CCl_4): 1730 cm^{-1} (six-membered ketone); n.m.r. (CCl_4): τ 6.43 (q, 1H, proton unshielded by methoxyl), 6.83 p.p.m. (s, 3H, methoxyl).

Preparation of the Ketal **17**

The ketone **16** (330 mg) was dissolved in anhydrous benzene (60 ml) to which ethylene glycol (0.3 ml) and *p*-toluenesulfonic acid (30 mg) were added. The solution was heated under reflux with a water separator for 1½ h and worked-up by the usual procedure. The ketal **17** was crystallized from *n*-hexane and melted at 115 °C. The yield was quantitative.

Infrared (CCl_4): 1630 cm^{-1} (weak; double bond); n.m.r. ($CDCl_3$): τ 4.53 (d, J = 6 Hz, 1H, vinylic proton), 6.03 (broad s, 4H, dioxolane protons), 6.53 (q, J = 6 and 2 Hz, 1H, proton unshielded by methoxyl), 6.65 p.p.m. (s, 3H, methoxyl).

*Rearrangement of Compound **19** to the Tertiary Allylic Alcohol **20***

Compound **19** (30 mg) was dissolved in tetrahydrofuran (2 ml) to which 1 *N* aqueous hydrochloric acid (1 ml) was added. The mixture was stirred at room temperature for 30 min, after which time it was poured into water (50 ml) and extracted with ether. The extract was worked-up by the usual procedure. Evaporation of the solvent yielded quantitatively the oily product **20** which behaved homogeneously in t.l.c.

Mol. Wt. Calcd. for $C_{15}H_{20}O_3$: 248. Found (mass spectroscopy): 248.

Infrared (CCl_4): 3560 cm^{-1} (tertiary alcohol); n.m.r. ($CDCl_3$): τ 4.01 (q, J = 10 and 6 Hz, 1H, vinylic proton), 4.49 (d, J = 10 Hz, 1H, vinylic proton), 6.03 p.p.m. (broad s, 4H, dioxolane protons).

*Deketalization of **20** to **21***

Compound **20** (25 mg) was dissolved in 60% aqueous acetic acid (5 ml) and the solution was heated to 70 °C for 1 h. The solvent was removed *in vacuo*, ether (50 ml) was added, and the solution was washed, dried, and evaporated to dryness. The product **21** was crystallized from ether to a m.p. of 115 °C. The yield was quantitative.

Mol. Wt. Calcd. for $C_{13}H_{16}O_2$: 204.1150. Found (high resolution mass spectroscopy): 204.1140.

Infrared (CCl_4): 3600 (tertiary hydroxyl), 1760 cm^{-1} (five-membered ketone). n.m.r. ($CDCl_3$): τ 3.80 (q, J = 9 and 6 Hz, 1H, vinylic proton), 4.46 p.p.m. (d, J = 9 Hz, 1H, vinylic proton).

*Hydrogenation of Compound **19** to the Dihydro Derivative **22***

Compound **19** (17 mg) was hydrogenated in methanol (3 ml) with 10% palladium-on-charcoal (10 mg) overnight. The catalyst was filtered off and the methanolic solution was evaporated to dryness. The product **22** was obtained as a colorless oil in a quantitative yield. It was homogeneous in t.l.c.

Mol. Wt. Calcd. for $C_{16}H_{24}O_3$: 264. Found (mass spectroscopy): 264.

Nuclear magnetic resonance ($CDCl_3$): τ 6.07 (broad s, 4H, dioxolane protons), 6.53 (m, 1H, proton unshielded by methoxyl), 6.70 p.p.m. (s, 3H, methoxyl).

*Deketalization of Compound **22** to the Ketone **23***

A solution of compound **22** (17.5 mg) in 60% aqueous acetic acid (5 ml) was heated to 70 °C for 1½ h and worked-up in the usual manner. Purification of the crude product by preparative t.l.c. on silica gel yielded the pure ketone **23** (12 mg, 81%) as a thick oil, homogeneous in t.l.c.

Mol. Wt. Calcd. for $C_{14}H_{20}O_2$: 220.1462. Found (high resolution mass spectroscopy): 220.1463.

Infrared (CCl_4): 1760 cm^{-1} (five-membered ketone); n.m.r. ($CDCl_3$): τ 6.06 (broad t, J = 8 Hz, 1H, proton deshielded by methoxyl), 6.70 p.p.m. (s, 3H, methoxyl).

*Preparation of the Tertiary Alcohol **24***

A solution of the olefin **19** (130 mg) and mercuric acetate (acetic acid free) (320 mg) in 50% aqueous acetone (30 ml) was stirred at room temperature for 44 h. The reaction mixture was cooled in an ice bath and an excess of 0.5 *M* sodium borohydride in 3 *M* aqueous sodium hydroxide (10 ml) was added dropwise to it. The mixture was stirred for 30 min, poured into saturated aqueous sodium chloride (80 ml), and extracted with ether (4 × 50 ml). The combined extracts were washed with 2% aqueous hydrochloric acid, water, and dried over anhydrous magnesium sulfate. Evaporation of the solvent gave a yellow crude product. Purification by preparative t.l.c. (ether–hexane, 3 : 2) gave the pure alcohol **24** (88 mg, 70%) as a colorless oil homogeneous in t.l.c.

Mol. Wt. Calcd. for $C_{16}H_{24}O_4$: 280.1675. Found (high resolution mass spectroscopy): 280.1683.

Infrared (CCl_4): 3585 cm^{-1} (tertiary hydroxyl); n.m.r. ($CDCl_3$): τ 6.05 (broad s, 4H, dioxolane protons), 6.67 (s, 3H, methoxyl), 6.70 p.p.m. (broad t, 1H, proton unshielded by methoxyl).

*Deketalization of **24** to **25***

A solution of the hydroxy ketal **24** (34 mg) in 50% aqueous acetic acid (4 ml) was heated to 70 °C for 3 h. The reaction mixture was worked-up in the usual manner. The ketone **25** was crystallized from ether–chloroform and melted at 104 °C. The yield was quantitative.

Mol. Wt. Calcd. for $C_{14}H_{20}O_3$: 236.1412. Found (high resolution mass spectroscopy): 236.1402.

Infrared (CCl_4): 3600, 3475 (hydroxyl), 1755 cm^{-1} (five-membered ketone); n.m.r. ($CDCl_3$) : τ 6.24 (sextet, J = 7, 6, and 2 Hz, 1H, proton unshielded by methoxyl), 6.63 p.p.m. (s, 3H, methoxyl).

*Reduction of the Ketone **25** to the Alcohol **26***

The ketone **25** (30 mg) was dissolved in methanol (5 ml) and sodium borohydride (15 mg) was added in portions at room temperature. The reaction mixture was stirred at room temperature for 1 h and poured into saturated aqueous sodium chloride (10 ml). The product **26** was isolated by extraction with methylene dichloride, purified by preparative t.l.c. on silica gel and recrystallized from ether to a constant m.p. of 79 °C. The yield was 80%.

Anal. Calcd. for $C_{14}H_{22}O_3$: C, 70.58; H, 9.24. Found: C, 70.32; H, 9.33.

Mol. Wt. Calcd.: 238.1564. Found (high resolution mass spectroscopy): 238.1569.

Infrared (CCl_4): 3575, 3480 cm^{-1} (hydroxyls); n.m.r. ($CDCl_3$): τ 5.81 (t, 1H, proton unshielded by secondary hydroxyl), 6.63 (m, 1H, proton unshielded by methoxyl), 6.65 p.p.m. (s, 3H, methoxyl).

We wish to express our gratitude to Dr. M. Przybylska and F. R. Ahmed (the National Research Council of Canada, Ottawa) and Dr. John F. Blount, Hoffmann–La Roche, Inc., Nutley, New Jersey (U.S.A.) for the X-ray structure determination of our compounds.

We also thank the National Research Council of Canada, Ottawa, and the Hoffmann–La Roche Company, Vaudreuil, Quebec, for financial support of this study.

General Base Catalysis of β Elimination by a Steroidal Enzyme Model

J. PETER GUTHRIE AND STELLA O'LEARY
Department of Chemistry, University of Western Ontario, London, Ontario N6A 3K7
Received October 30, 1974

J. PETER GUTHRIE and STELLA O'LEARY. Can. J. Chem. **53**, 2150 (1975).

The water soluble steroid **1** acts as a catalyst for the enolization of the ketones **2***a–c*. The rate enhancement for **1**-catalyzed reaction relative to imidazole-catalyzed reaction (*R*), increases as the size of the aromatic ring system of the substrate increases; a plot of log *R vs.* π has a slope of 0.43. This is interpreted in terms of hydrophobic binding between steroid α-surface and aromatic ring system which lowers the free energy level of the transition state for steroid-catalyzed enolization.

J. PETER GUTHRIE et STELLA O'LEARY. Can. J. Chem. **53**, 2150 (1975).

Le stéroide **1** soluble dans l'eau agit comme catalyseur pour l'énolisation des cétones **2***a–c*. L'augmentation de la vitesse de la réaction catalysée par **1** par rapport à celle catalysée par l'imidazole (*R*) varie en fonction de l'augmentation de la grosseur du système cyclique aromatique du substrat; une courbe de log *R* en fonction de π a une pente de 0.43. On interprète ce résultat en fonction d'une liaison hydrophobe entre la face α du stéroide et le système cyclique aromatique; ceci à comme effet d'abaisser l'énergie libre de l'état de transition de l'énolisation catalysée par les stéroides. [Traduit par le journal]

Introduction

Numerous enzyme model systems showing rate enhancements due to noncovalent binding of substrate to catalyst have been reported in recent years (1–13). Almost invariably (1–9) these have involved hydrolytic reactions, normally of aryl esters, which are sensitive to nucleophilic catalysis. We have prepared a steroidal enzyme model **1** (14, 15) which is water soluble by virtue of its two ionic substituents and has a hydrophobic binding surface as well as a catalytic group, the 17β-imidazolyl substituent. This compound was shown to be a catalyst for the hydrolysis of active esters with hydrophobic substituents, with a marked specificity for phenanthrene derivatives (15). However, it became evident that nucleophilic attack by the steroidal imidazole upon ester carbonyl groups was subject to steric and conformational constraints which limited its catalytic potential (16). Therefore, we sought a reaction, subject to catalysis by imidazole, which would be less sterically and conformationally demanding, in hopes of seeing larger catalytic effects. We wish to report experiments demonstrating the activity of **1** as a general base catalyst for the enolization of suitable ketones. This reaction turns out to have some definite advantages for enzyme model studies and in particular can be considered a more "specific" reaction for the enzyme model **1**.

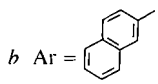
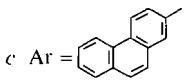
2 **3**





Results

Elimination of acetic acid from **2***a–c* is readily followed spectrophotometrically because of the strongly absorbing chromophore which develops. Our kinetics results for this elimination are found in Tables 1 and 2. Exploratory studies were conducted with **2***b*: the elimination reaction was shown to be subject to catalysis by hydroxide ion and by buffers. The buffer catalysis observed for carbonate–bicarbonate buffer is due to carbonate alone. This behavior

parallels that reported for other β-acetoxy ketones (17–18). A Brønsted plot of the data for simple buffers assuming that only general base catalysis occurs gives a β value of *ca.* 0.5; there is an indication that nitrogen bases are slightly more effective than oxygen bases but the overall pattern is of general base catalysis.

The products of the eliminations, **3***a–c*, are expected to be unstable to retroaldol cleavage; however, the rate constants for this process are such that it is much slower than the elimination: for **2***b* the rate constant for hydroxide-catalyzed decomposition is 8.2 $M^{-1}\ s^{-1}$; for **3***b* the corresponding rate constant is $2.1 \times 10^{-4}\ M^{-1}\ s^{-1}$ or 40 000-fold slower.

The rate constants for the imidazole-catalyzed elimination reaction of **2***a–c* show an increase in rate with increasing size of the aromatic ring. Since these rate constants are independent of amine or ketone concentration, they must reflect an electronic effect upon the rate by changing the size of the ring system. No value of σ* for phenanthryl appears to be available but from literature values of σ* for phenyl (19) and 2-naphthyl (19), one can calculate an approximate ρ* of 0.8 for the elimination reaction.

The rate constants for **1**-catalyzed elimination reaction of **2***a–c* are consistently larger than those for imidazole-catalyzed elimination and show a much more marked increase with increasing ring size. Since the imidazole group of **1** has a pK_a virtually identical to that of imidazole itself (16), this rate enhancement must result from a favorable interaction of steroid and substrate in the transition state. To isolate this effect we calculate relative rates, $k_{rel} = k_2^{steroid}/k_2^{imidazole}$. A plot of log k_{rel} *vs.* π (the Hansch hydrophobicity parameter (20)) is shown in Fig. 1. The plot gives a good straight line,

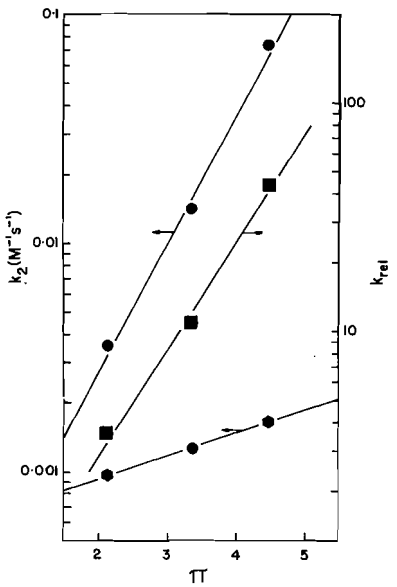

FIG. 1. Dependence upon π, the Hansch hydrophobicity parameter, of the logarithms of the second-order rate constants for imidazole- (●) and **1**- (●) catalyzed elimination reactions (left ordinate) and of the logarithms of the relative rate constants, $k_{rel} = k_2^{1}/k_2^{imidazole}$, (■) (right ordinate).

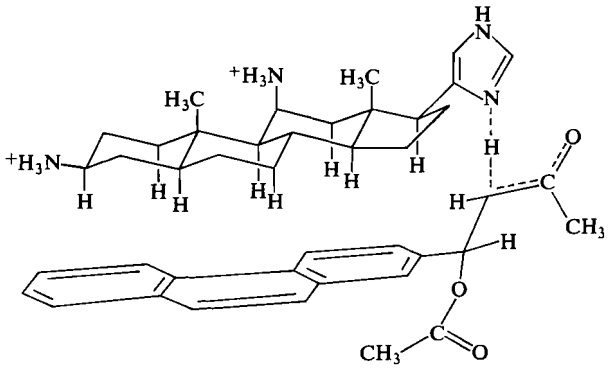
†Total catalyst concentration.

implying that the rate enhancement resulting from steroid–substrate interactions is dependent upon the hydrophobicity of the substrate. The slope is 0.43 ± 0.05, suggesting that rather less than half the hydrophobic surface of the aromatic ring systems is being removed from contact with water, which is consistent with the observed 1:1 stoichiometry of reaction. If the geometries of the transition states for **1**- and imidazole-catalyzed enolization were identical except for the presence of the steroid, then for $\pi = 0$, k_{rel} should be 1.0, since there would then be no stabilizing interaction to make the transition state for **1**-catalyzed reaction distinguishable from that for imidazole-catalyzed reaction. In fact the graph of log k_{rel} *vs.* π extrapolates to $k_{rel} = 0.4$; if the deviation from $k_{rel} = 1$ is real it suggests that in fact the geometry appropriate for hydrophobic interaction of the aryl group with the steroid is not quite optimal for the general base catalyzed reaction so that a small conformational destabilization must be introduced to gain the larger hydrophobic stabilization. Since the values of log k_{rel} increase

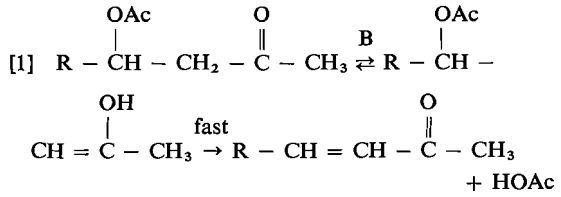
Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.



linearly with π, it appears reasonable to conclude that the transition state geometry is the same for all three substrates, with only the amount of contact changing. For $\pi = 0$, k_{rel} reflects the relative rate appropriate for this geometry. The magnitude of the hydrophobic rate enhancement should then be estimated as the rise from the intercept at $\pi = 0$ to the observed value for a given aryl group. Values so calculated are: phenyl, 9.0; naphthyl, 27; phenanthryl, 110.

Discussion

The mechanism of general base catalyzed elimination of acetic acid from β-acetoxy ketones is believed to be that of eq. 1 (17, 18).



[1] $R-CH(OAc)-CH_2-C(=O)-CH_3 \overset{B}{\rightleftarrows} R-CH(OAc)-CH(OH)=C(CH_3)-CH_3 \xrightarrow{\text{fast}} R-CH=CH-C(=O)-CH_3 + HOAc$

with the rate determining step being the enolization. It is difficult to rule out unequivocally the alternative one-step process where loss of acetate is simultaneous with loss of proton. For the present purposes the uncertainty as to detailed mechanism is not important, since in either case, the transition state geometry is quite suitable for contact of the 17β-imidazole with the enolizable hydrogen *and* of the α-surface of the steroid with the aryl substituent of the ketone. The enolization–elimination reaction is far more convenient for kinetics experiments than is simple enolization, since it can be followed spectrophotometrically at very low concentrations. The techniques which have been employed to study kinetics of enolization (hydrogen isotope exchange or halogenation)[1] would be difficult or impossible in the present case, where the concentration of substrate had to be extremely low.

The origin of the rate enhancement for **1**-(compared to imidazole) catalyzed eliminations must now be considered. The pK_a's of **1** (7.2, (16*a*)) and imidazole (7.1 (16*b*)) are essentially identical, so catalyst basicity is not responsible. The imidazole group in **1** has a bulky substituent which should if anything retard reaction of **1**. If the inherent reactivity of the catalytic group is not responsible for the rate of enhancements, then some favorable interaction of the rest of the steroid with the substrate must be involved. Since the imidazole of **1** is abstracting a proton from the substrate at the transition state and the substrates **2***a–c* show progressively greater rate enhancements, the conformation of the transition state must be such that the aromatic rings of the substrate interact with the steroid. The monotonic increase in rate enhancement as the size of the aromatic ring system increases suggests strongly that the conformation of the transition state is the same for all substrates. The environment of the reaction center in such a conformation will have rather less polar character than for the imidazole-catalyzed reaction because one side of the developing double bond will be shielded from water by the steroid but this solvent effect will be constant for **2***a–c*.[2] The only noncovalent interaction

[1]For a discussion of the experimental problems associated with these techniques, see ref. 21.

[2]A referee has suggested that a local solvent effect of this sort may be responsible for some of the rate effects which we observe. This appears quite possible but we feel that any such effect should be essentially constant for the series **2***a–c*.

between an aromatic hydrocarbon and an alicyclic system which would explain the observed rate effect is hydrophobic bonding (22). The magnitude of the interaction to be expected can be estimated after Némethy and Scheraga (23), although there is some uncertainty about the proper way to estimate the number of water molecules released from contact with hydrocarbon as the two molecules come together. Our estimate of the free energy of hydrophobic interaction for phenanthrene plus perhydrophenanthrene is -2.4 kcal mol^{-1} or a potential rate factor of 56-fold, which is relatively close to the observed value. (It should be noted that Némethy and Scheraga used unitary free energies, corresponding to a standard state of hypothetical unit mole fraction, while we use a standard state of hypothetical unit molarity, so that it is necessary to apply a suitable correction to the values derived from their equations.)

The elimination reaction of β-acetoxy ketones can clearly be used in enzyme model studies: it has the advantage of relatively small steric requirements but suffers from the disadvantages of being inherently rather slow and of having a rather small selectivity for imidazoles as catalysts, compared with nucleophilic reactions of aryl esters. The uncatalyzed enolization of **2***c* at p*H* 8 and 25° has a half-life of *ca.* 15 h; in the presence of 0.01 *M* imidazole, **2***c* has a half-life of *ca.* 6 h or twofold faster; in the presence of 0.01 *M* **1**, **2***c* would have a half life of *ca.* 15 min. By contrast, uncatalyzed hydrolysis of *p*-nitrophenyl acetate in aqueous solution at p*H* 8 and 25° has a half-life of *ca.* 14 h (24); in the presence of 0.01 *M* imidazole the half-life is *ca.* 3 min (24) or 280-fold faster.

Inherently slow reactions are more convenient for enzyme model studies *if* the enzyme model is an efficient catalyst but not if the catalysis is modest. We conclude that as enzyme model systems with stronger substrate binding abilities than **1** are developed, elimination reactions such as that reported above will become more suitable than hydrolysis of active esters, since large catalytic effects will not compel the use of stopped-flow techniques to measure the rates of reaction and uncatalyzed reactions will be negligibly slow.

The experiments reported above were conducted under second-order conditions, *i.e.* at low concentrations of both substrate and catalyst. The observed second-order rate constants were demonstrated to be independent of both substrate and catalyst concentrations. These values permit a discussion of the difference in free energy between isolated completely solvated reactions and the overall transition state, in which we believe that the hydrophobic groups of substrate and catalyst are in contact with each other, and partially desolvated. We believe that it is probable that this transition state is reached by a two-step process,

$$\text{Substrate} + \text{Catalyst} \overset{K}{\rightleftarrows} (\text{Substrate–catalyst}) \overset{k}{\rightarrow} \text{Product} + \text{Catalyst}$$

analogous to the Michaelis–Menton mechanism for enzymic catalysis. It would be of immense interest to evaluate the k and K parameters if this mechanism truly applies; however, this is unlikely to be attainable with the present system, since the equilibrium constant for substrate–catalyst binding which is useful for interpreting the kinetics is the one corresponding to formation of the reactive conformation, *i.e.* productive binding, whereas any measured equilibrium constant would include all possible modes of nonproductive binding.[3] Until an enzyme model with a more specific binding site, which would constrain the substrate to bind in only one mode can be prepared, it is better to use the second-order rate constants (specificity constants (25)) since these can be interpreted in a straightforward way.

Experimental

Materials

Imidazole and tris-hydroxymethylaminomethane were recrystallized before use. KCl, NaOH, $NaHCO_3$, and KH_2PO_4 were reagent grade chemicals, used without further purification. Compound **1** was prepared and purified as described previously (14). Acetonitrile (Eastman spectrograde) was passed through a column of grade I neutral alumina (Woelm) to remove nucleophilic impurities.

4-Acetoxy-4-(2-phenanthryl)-2-butanone, 2c

2-Acetylphenanthrene (Aldrich), m.p. 139–141° (lit. (26) m.p. 143°) was converted to 2-phenanthroic acid, m.p. 260–262° (lit. (26) m.p. 258–260°) by hypochlorite oxidation (26). 2-Phenanthroic acid (2.25 g in 22.5 ml

[3]For the simple scheme, involving one productive $(ES)_P$ and one nonproductive, $(ES)_{NP}$, complex:

$$(ES)_{NP} \overset{K_{NP}}{\rightleftarrows} E + S \overset{K_P}{\rightleftarrows} (ES)_P \overset{k_{cat}}{\rightarrow} E + P$$

it may readily be shown that Michaelis–Menton kinetics will be followed with $K_{m_{app}} = (1/K_P + 1/K_{NP})^{-1}$.

For personal use only.

dry THF) was added to $LiAlH_4$ (0.56 g in 22.5 ml dry THF); the mixture was refluxed for 2½ h, cooled, and treated with saturated aqueous sodium potassium tartarate. The mixture was acidified and extracted with ether. The combined extracts were washed with saturated aqueous NaCl, dried over $MgSO_4$, and evaporated. Crystallization of the residue (benzene – petroleum ether) gave 1.36 g of 2-phenanthryl carbinol, m.p. 123–127° (lit. (27) m.p. 125–125.5°). 2-Phenanthryl carbinol (1.36 g in 35 ml dry CH_2Cl_2) was added dropwise to a solution of 4.05 g CrO_3 and 5.4 ml pyridine in 100 ml dry CH_2Cl_2. After 40 min at room temperature, the solution was poured into water in a separatory funnel and the tarry residue was rinsed with CH_2Cl_2 and with ether. These rinsings were added to the separatory funnel and shaken well. The aqueous layer was washed with CH_2Cl_2; the combined organic layers were washed with aqueous HCl, water, and saturated aqueous NaCl. After drying the solution ($MgSO_4$) and removing the solvent a brown oil remained. This was partially purified by treating with methanol, centrifuging to remove insoluble material, and evaporating the supernatant. The aldehyde was at best a semicrystalline gum; (lit. (27) m.p. 59–59.5°); n.m.r. δ ($CDCl_3$): 7.3–9.05 (9 H, complex multiplet), 10.10 (0.74 s, 1H, Ar—C*H*O). Crude 2-phenanthraldehyde (0.55 g in acetone (1.92 ml)) was cooled in an ice bath and added to 0.055 *N* NaOH (27 ml, in 1.5:1 acetone–water) cooled in an ice bath. The solution was stirred (ice bath) for 1.5 h, neutralized (*N* HCl), and extracted three times with ether; the extracts were washed with saturated aqueous NaCl, dried ($MgSO_4$), and evaporated to give 0.62 g of a white solid. Crystallization (ethyl acetate – petroleum ether) gave 0.188 g of 4-hydroxy-4-(2-phenanthryl)-2-butanone, m.p. 82–87°; n.m.r. δ ($CDCl_3$): 2.2 (s, 3H, *C*H_3—CO—), 2.9 (multiplet, 2H, —CH_2—CO—), 5.3 (multiplet, 1H, —C*H*(OH)—), 7.2–8.9, (complex, aromatic H).

4-Hydroxy-4-(2-phenanthryl)-2-butanone (0.188 g, in 4:1 glacial acetic acid – acetic anhydride, 5.15 ml, containing 4 mg of *p*-toluenesulfonic acid) was stirred at room temperature for 2 h, neutralized by addition of sodium acetate, and partitioned between water and ether. The combined ether extracts were washed with saturated aqueous $NaHCO_3$ (five times), water, and saturated aqueous NaCl. Evaporation gave 0.214 g of a white solid which on crystallization from benzene–cyclohexane gave 0.046 g of 4-acetoxy-4-(2-phenanthryl)-2-butanone, m.p. 92–95°; n.m.r. δ ($CDCl_3$): 2.04 (s, *C*H_3—CO—O—), 2.12 (s, *C*H_3—CO—CH_2—), 3.02 (t, CO—*C*H_2—), 6.38 (multiplet, —C*H*(OAc)—), 7.4–8.8 (complex, aromatic H).

Anal. Calcd. for $C_{20}H_{10}O_3$: C, 78.66; H, 5.99. Found, C, 78.37; H, 5.92.

4-Acetoxy-4-(2-naphthyl)-2-butanone, 2b

By the same procedures, 2-naphthaldehyde (Aldrich) was converted into 4-hydroxy-4-(2-naphthyl)-2-butanone, m.p. 60–61° (benzene–cyclohexane); n.m.r. δ ($CDCl_3$): 2.1 (s, 3H, *C*H_3—CO—), 2.8 (m, 2H, CO—*C*H_2—), 2.8 (m, 2H, CO—*C*H_2—), 3.6 (br s, 1H, —CH(O*H*)—), 5.2 (m, 1H, —C*H*(OH)—), 7.0–7.8 (complex, 7H, aromatic H). Acetylation gave 4-acetoxy-4-(2-naphthyl)-2-butanone, m.p. 40–41° (absolute ethanol); n.m.r. δ ($CDCl_3$): 2.0_2 (s, *C*H_3—CO—O), 2.1_2 (s, *C*H_3—CO—CH_2), 3.0 (m, CO—*C*H_2—), 6.3 (m, —C*H*(OAc)—), 7.2–7.9 (complex, aromatic H).

Anal. Calcd. for $C_{16}H_{16}O_3$: C, 74.95; H, 6.29. Found: C, 74.89; H, 6.41.

4-Acetoxy-4-phenyl-2-butanone, 2a

By the same procedures, benzaldehyde was converted into 4-hydroxy-4-phenyl-2-butanone, m.p. 33–36° (lit. (29) m.p. 34–36°); n.m.r. δ ($CDCl_3$): 2.1 (s, 3H, *C*H_3—CO—), 2.8 (m, 2H, CO—*C*H_2—), 3.5 (s, 1H, —CH(O*H*)—), 5.1 (m, 1H, —C*H*(OH)—), 7.2 (s, 5H, aromatic H). Acetylation gave 4-acetoxy-4-phenyl-2-butanone as an oil which was purified by preparative-layer chromatography (Merck silica gel PF 254, eluting with 2:1 petroleum ether – ether). Analysis was performed by injecting a known amount into aqueous sodium hydroxide. Comparison of the absorbance at 295 nm (extrapolated to zero time to correct for slow retroaldol reaction) with that of an authentic sample of benzalacetone, m.p. 40° (lit. (28) m.p. 42°) showed that **2a** was 98% pure; n.m.r. δ ($CDCl_3$): 1.9_4 (s, 3H, *C*H_3—CO—O), 2.0_6 (s, 3H, *C*H_3—CO—CH_2), 2.9 (t, 2H, —CO—*C*H_2—), 6.1 (m, 1H, —C*H*(OAc)—), 7.2 (s, 5H, aromatic H).

Kinetic Procedures

Reactions were initiated by adding a small portion of a stock solution of substrate in purified acetonitrile to temperature equilibrated buffer in a spectrophotometer cell. Changes in absorbance were followed using a Gilford Model 240 spectrophotometer. p*H* values were measured at the end of the reaction using a Radiometer p*H* Meter 25SE with a GK 2301C combined electrode. For the slower reactions, secondary reactions became significant at long times, so that it was not possible to determine infinity points for the elimination reactions by following to 8 or 10 half-lives. In these cases, data to 4 or 5 half-lives were fitted to the equation

$$\text{Absorbance} = a + be^{-ct}$$

using a nonlinear least-squares (30, 31) program.

The Use of Magnesium and its Salts in the Reaction of α,β-Unsaturated Carbonyl Compounds with Sodium Acetylide

JOHN NICHOLSON GARDNER

Technical Development Department, Hoffmann-La Roche Inc., Nutley, New Jersey 07110

Received December 30, 1974

JOHN NICHOLSON GARDNER. Can. J. Chem. **53**, 2157 (1975).

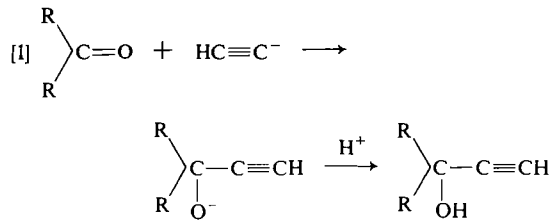
Conditions are described for the preparation in anhydrous ammonia of a magnesium–acetylene complex. In the presence of this complex, the addition of sodium acetylide to the carbonyl groups of some α,β-unsaturated aldehydes and ketones is shown to be a much more efficient reaction than when sodium acetylide alone is employed.

JOHN NICHOLSON GARDNER. Can. J. Chem. **53**, 2157 (1975).

On décrit les conditions permettant de préparer, dans l'ammoniac liquide, un complexe magnésium–acétylène. On démontre qu'en présence de ce complexe l'addition de l'acétylure de sodium sur les groupes carbonyles de certains aldéhydes et cétones α,β-non-saturés est une réaction beaucoup plus efficace que la réaction de l'acétylure de sodium seul.

[Traduit par le journal]

The addition of the monoanion of acetylene to the carbonyl functions of aldehydes and ketones, as shown in [1], is an important synthetic method. For example, the reaction in



liquid ammonia of sodium acetylide with such carbonyl groups plays a major role in syntheses of vitamin A and β-carotene (see for example ref. 1) and yields in excess of 90% are not uncommon when the substrate is a saturated ketone. However, with α,β-unsaturated aldehydes and ketones, the reaction with sodium acetylide takes a less felicitous course. Thus, Hennion and Lieb (2) reported yields of 20–27% for the ethynylcarbinols prepared from methyl vinyl ketone (MVK), ethylidenacetone, mesityl oxide, and benzalacetone by this reaction, whereas with crotonaldehyde the reaction went in only 46% yield. This last case was examined in detail by other workers (3) who concluded that, to obtain yields of 72–77%, it was necessary to use carefully purified reagents at a temperature of −80°. Without these precautions, they recorded yields as low as 55%. Yet another group (4) examined the reaction of MVK with sodium acetylide in liquid ammonia at reflux and found that the yield of the corresponding ethynylcarbinol could be raised to 40% if 4.5 g-at. of sodium was used per mole of MVK.

Because of the problems encountered in reacting sodium acetylide with α,β-unsaturated ketones, Oroshnik and Mebane (5) explored the use of the acetylides of potassium, lithium, and calcium. They reported that the first of these was no better than sodium but with lithium and calcium they obtained superior results. For example, with MVK, calcium acetylide gave the ethynylcarbinol in 71% yield and with lithium acetylide the figure was 68%. Thus, these acetylides provide a satisfactory method for the addition of acetylene to α,β-unsaturated carbonyl groups but the high costs of lithium and calcium have discouraged the use of these reactions on an industrial scale.

The fact that lithium and calcium acetylides react with α,β-unsaturated carbonyl groups in high yield led us to consider the possibility that magnesium, which is chemically somewhat similar but less expensive, might yield an acetylide which would react in the same way. A report in the literature (6) encouraged the belief that magnesium could be made to dissolve in liquid ammonia although it might be necessary to have another reactant present. It was quickly established that magnesium does not dissolve in liquid ammonia in the presence of acetylene but if magnesium metal is added

to a solution of sodium acetylide in ammonia which contains excess acetylene, dissolution of the magnesium occurs with concomitant formation of a white precipitate. A few trials demonstrated that the resultant suspension gave encouraging yields of the ethynylcarbinol from MVK and an investigation of the phenomena involved was undertaken.

When sodium and magnesium in a ratio of 1:9 by weight were stirred in anhydrous ammonia under reflux with acetylene passing through the mixture, dissolution of the magnesium was essentially complete in 15–18 h. The resultant white precipitate was isolated by centrifugation and proved to be sufficiently stable to air and moisture for these operations to be performed without the need for any special precautions. After drying over phosphorus pentoxide, the precipitate was analyzed for sodium, magnesium, ammonia, and acetylene. Small amounts of sodium and ammonia were detected but the analysis showed that the solid was essentially a complex of magnesium and acetylene with the approximate composition $Mg(C{\equiv}CH)_{1.2}$. This result is consistent with the observation that, when the complex was prepared in liquid ammonia as described and was reacted *in situ* with a large excess of 6-methyl-5-hepten-2-one, the amount of ketone converted to ethynylcarbinol was in agreement with each magnesium atom being associated with one molecule of acetylene available for reaction.

The reaction of the complex with MVK was then explored. Addition, to the acetylides in liquid ammonia, of the MVK as a solution in ether at $-20°$ gave the optimum yield. Ether proved to be the preferred solvent and better results were obtained with it than with diisopropyl ether or toluene. It was found that, up to a ratio of about 4.5:1 of sodium to magnesium, the ethynylcarbinol could be obtained in 67–70% yield but with more sodium present the yield fell.

Using the conditions which had been optimized for MVK, experiments were run with other α,β-unsaturated carbonyl compounds. These results, together with figures from the literature for reactions using sodium, lithium, and calcium, are set forth in Table 1. In most cases the results with sodium–magnesium mixtures compare favorably with those from the other methods.

When magnesium metal is added to a solution of sodium acetylide in liquid ammonia which contains no excess acetylene and the mixture is stirred for several hours, a white precipitate forms and the blue color characteristic of solutions of metals in liquid ammonia may be seen faintly. Addition of acetylene discharges the color but it will return on further stirring. These results suggest that an equilibrium such as

$$Mg + xNaC{\equiv}CH \rightleftharpoons Mg(C{\equiv}CH)_x + xNa^+ + xe^- \text{ (solvated)}$$

is involved and only when the sodium ions are converted to the acetylide is the equilibrium displaced in favor of $Mg(C{\equiv}CH)_x$. This hypothesis led to the supposition that sodamide might function in the same manner as sodium acetylide and it was found that, if sodamide is prepared in liquid ammonia, using iron as a catalyst, magnesium will dissolve in the suspension. The resultant suspension, of what is presumably sodium and magnesium amides, may be reacted with acetylene and then with MVK to give the ethynylcarbinol in as high yield as when sodium acetylide is used to attack the magnesium.

From the data already cited, it seems quite certain that it is the presence of $Mg(C{\equiv}CH)_x$ in the reaction mixture which results in improved yields in reactions with α,β-unsaturated ketones. Therefore, we sought to devise alternative methods for the formation of this species. In anhydrous ammonia, the equilibrium between sodium acetylide and a soluble magnesium salt on the one hand and insoluble $Mg(C{\equiv}CH)_x$ and a sodium salt on the other should favor the formation of $Mg(C{\equiv}CH)_x$ and thus yield an effective reagent for conversion of α,β-unsaturated ketones and aldehydes to the corresponding ethynylcarbinols. That this hypothesis is correct was shown by addition of ethyl magnesium bromide in ether to a solution of sodium acetylide in anhydrous ammonia. Reaction of this mixture with MVK yielded the ethynylcarbinol in 67% yield. The other salts shown in Table 2 were therefore screened for their influence upon the reaction. It will be noted that, in addition to ethyl magnesium bromide, magnesium chloride and sulfate gave yields of the carbinol close to those obtained with magnesium metal. Because of its vigorous reaction with

ammonia, magnesium chloride is less convenient to use than is magnesium sulfate.

Results obtained using magnesium sulfate are given in Table 1. Only the reaction with MVK was optimized, a yield of 70% being achieved. Our experiences with different grades of magnesium sulfate strongly suggest that its surface properties are important in the reaction, but a finely divided, reagent grade material usually works well. Magnesium sulfate has little, if any, solubility in anhydrous ammonia and so, in its case, the hypothesis of a metathetical reaction in solution with sodium acetylide is very likely an oversimplification. However, although the mechanism of the reaction is not understood, the procedure is a useful one and is attractive as it avoids the lengthy stirring period which is required when magnesium metal is used.

Experimental

Materials

Methyl vinyl ketone was fractionated at atmospheric pressure through a 12 in. Goodloe column. The distillate was stabilized by addition of 0.1% of acetic acid and 0.1% of hydroquinone. It assayed 96–98% by gas chromatography. The other α,β-unsaturated carbonyl compounds were flash distilled and assayed 92–100%. The structures of the alcohols obtained from the α,β-unsaturated carbonyl compounds were confirmed by n.m.r. spectroscopy. Anhydrous magnesium sulfate (reagent grade) was purchased from the J. T. Baker Chemical Company or made as described below. Yields were calculated on the basis of the assays of the starting materials and products.

Analysis of the Magnesium–Acetylene Complex

The acetylene content was determined gasometrically, the complex being decomposed with dilute acid because water gave incomplete decomposition. The gas evolved was identified as acetylene by i.r. spectroscopy. Magnesium was determined by titration with ethylenediamine tetraacetic acid and sodium by precipitation with zinc uranyl acetate. Ammonia, which was entrained with nitrogen from the surface of the solid and from a solution in alkali, was absorbed in dilute acid and determined by back titration.

Determination of Water in Magnesium Sulfate

A known amount of dry methanol was added to the weighed sample and the mixture was agitated in an ultrasonic bath for 3 h. The water content of the methanol was then determined gas chromatographically by comparison with mixtures of water and methanol of known composition.

Procedure for the Precipitation and Drying of Magnesium Sulfate

Magnesium sulfate (300 g, anhydrous) was dissolved in deionized water (1050 ml) and this solution, after filtration, was added with vigorous stirring to acetone (5000 ml). The precipitated solid was isolated by filtration and dried for 18 h at 60–80°. Drying was continued for 3.5 days, the temperature being raised to 140° over 1.5 days and maintained at this value for 1 day. The solid was then held at 400° for 1 day. The water content of the product was 0.28% and the particle size was *ca.* 200 mesh.[1] Drying at too high an initial temperature causes the magnesium sulfate to dissolve in its water of crystallization.

Procedure for Reaction of MVK with Acetylene using Sodium and Magnesium Metals

Sodium (60 g, 2.61 mol) and magnesium turnings (20 g, 0.83 mol) were added to anhydrous ammonia (1500 ml) and acetylene was passed rapidly through the solution until the blue color was discharged. The gas flow was reduced to a slow, steady rate and the mixture was stirred for 15–18 h, at the end of which almost all the magnesium had reacted and a white precipitate had formed. Ether (200 ml) was added and, while agitating as rapidly as possible, a solution of MVK (189 g, 97%, 2.62 mol) in ether (600 ml), precooled to −10 to −20°, was introduced over 20–30 min. The acetylene was shut off, the ammonia was evaporated by warming the reaction flask with steam, and when the temperature of the residue reached −15 to −20°, the contents of the flask were added over about 20 min to a solution of sulfuric acid (200 ml) in water (1200 ml) maintained at 0–15°. The aqueous phase, which had p*H ca.* 2, was separated and extracted with ether (2 × 200 ml). The combined organic phases were washed with a mixture of saturated sodium bicarbonate solution (20 ml) and saturated brine (80 ml), and dried over sodium sulfate. The ether was removed by distillation through a 12 in. Goodloe column and the residue (254 g) was distilled through a 12 in. Vigreux column to yield 3-methylpent-1-en-4-yn-3-ol (182 g, assay 93%, 1.76 mol), b.p. 46–57°/48 Torr. A forerun (12 g, assay 51%, 0.06 mol) was also obtained. The yield was thus 69%.

[1]When drying was stopped at a water content of 2.5%, the product resulted in reduced yields when used in the reaction of MVK with acetylene.

Procedure for the Reaction of MVK with Acetylene using Sodamide and Magnesium Metal

Anhydrous ferric chloride (0.2 g) was dissolved in anhydrous ammonia (1500 ml) and sodium (60 g) was added in pieces (1–2 g), each being allowed to react to form sodamide before the next was added. Magnesium turnings (20 g) were then introduced and the mixture was stirred for 15–18 h, at the end of which most of the magnesium had reacted and a pale grey precipitate had formed. Acetylene was passed through the mixture for 1 h and its color darkened until it was almost black. Ether and MVK were added in exactly the same manner as in the previous experiment and the product was isolated as before. The yield was the same within experimental error.

Procedure for Reaction of Crotonaldehyde with Acetylene using Sodium Metal and Magnesium Sulfate

Sodium (80 g, 3.48 mol) was added to anhydrous ammonia (1500 ml) and acetylene was passed rapidly through the solution until the blue color was discharged. While continuing slow passage of acetylene, anhydrous magnesium sulfate (100 g, 0.83 mol) was added and the mixture was stirred for 30 min.[2] Ether (200 ml) was added and then a solution, at −10 to −20°, of crotonaldehyde (170 g, 99%, 2.40 mol) in ether (600 ml) was introduced over 20 min. The ether was evaporated and the product isolated as described for the reaction using MVK. Hex-4-en-1-yn-3-ol (186 g, assay 92%, 1.78 mol), b.p. 58–65°/20 Torr, was obtained in 74% yield.

[2]Use of less magnesium sulfate resulted in lower yields, as did a shorter stirring time.

Isolation of the Magnesium–Acetylene Complex

Sodium (5 g) and magnesium turnings (45 g) were reacted with acetylene in anhydrous ammonia (1500 ml) as already described. The resultant white suspension was decanted from a little unreacted magnesium. The suspended solid was isolated by centrifugation, resuspended in anhydrous ammonia, and again centrifuged. After drying over phosphorus pentoxide under vacuum, it was analyzed.

Anal. Found: Mg, 37.9; Na, 1.3; C_2H_2, 49; NH_3, 6.7 (4.3% surface NH_3 and 2.4% combined NH_3).

The ratio of $Mg:C_2H_2$ corresponds to a complex of empirical formula $Mg(C{\equiv}CH)_{1.2}$.

The author wishes to thank Prof. George M. Whitesides for many helpful discussions during the course of this work. He is grateful to Dr. V. S. Venturella, Dr. A. V. Holmgren, and Mr. P. DePaolo for the analytical data and to Mr. F. E. Dyer and Miss O. Abril for much of the experimental work.

Linear Free Energy Relationships. IV.[1] Synthesis and Spectral Characterization of Some New Solvatochromics. *N*-(*p*-Substituted)benzyl-2′-hydroxy-4-stilbazolium Betaines

HARRY W. GIBSON AND F. C. BAILEY

Webster Research Center, Xerox Corporation, Webster, N.Y. 14580

Received November 20, 1974

HARRY W. GIBSON and F. C. BAILEY. Can. J. Chem. **53**, 2162 (1975).

The spectral data for the present series of compounds indicate that the long wavelength $\pi \rightarrow \pi^*$ transition in each case involves transfer of negative charge from the phenol–quinone moiety to the pyridyl ring. Two separate features bear on this point: the transition energy dependence on (*i*) substituent and (*ii*) solvent. The plots of transition energy *vs.* Hammett substituent constant for the salts and the betaines have negative slopes as expected for such a transition. The plots of transition energy for the betaines *vs.* the solvent polarity parameter have large positive slopes, which are evidence for a large decrease in dipole moment upon excitation, consistent with such a transition. Through study of the p*H* dependence of the spectrum, the pK_a of the parent compound was found to be 8.37 at 22°. From this pK_a the apparent σ_{ortho} for the *N*-benzylstilbazolium substituent was estimated to be 0.75.

HARRY W. GIBSON et F. C. BAILEY. Can. J. Chem. **53**, 2162 (1975).

Les données spectrales concernant la nouvelle série de composés indiquent que dans chaque cas la transition $\pi \rightarrow \pi^*$ observée à grande longueur d'onde implique un transfert d'une charge négative de la position phénol–quinone vers le cycle pyridyl. Il y a deux caractéristiques principales qui suggèrent cette conclusion: la dépendance de l'énergie de transition sur (*i*) les substituants et (*ii*) le solvant. Les courbes montrant l'énergie de transition en fonction des constantes de Hammett pour des substituants sous formes de sels ou de bétaines possèdent des pentes négatives telles que l'on pourrait les prédire pour de telles transitions. Les courbes de l'énergie de transition pour les bétaines en fonction du paramètre pour la polarité du solvant montrent de fortes pentes positives; ceci indique qu'il y a un fort abaissement du moment dipolaire lors de l'excitation et ceci est en accord avec une telle transition. A l'aide d'études sur l'influence du p*H* sur le spectre, on a pu évaluer que le pK_a du composé de base est 8.37 à 22°. En se basant sur ce pK_a, on a pu estimer que la valeur apparente du σ_{ortho} pour le substituant *N*-benzylstilbazolium est de 0.75. [Traduit par le journal]

Introduction

Solvatochromic compounds undergo changes in 'color' with changes in solvent (1). In valence bond terminology this is ascribed to the variation in relative contribution of two resonance forms to the hybridized structure and molecular orbital calculations support this picture (2). Compounds which show the largest solvatochromic effects are those possessing extreme resonance forms: a polarized or zwitterionic one and a delocalized or quinoidal one. Increasing polarity of the solvating medium thus shifts the electron distribution of the ground state continuously toward the polar resonance from while the structure of the excited state is affected negligibly (Franck–Condon principle); this results in a change in energy difference and absorption wavelength (3). Such compounds have, therefore, served as empirical solvent polarity indicators (1, 3, 4).

Our interest in solvatochromics arises from our work relating molecular orbital energy levels and structure by means of linear free energy relationships (5–7). In a previous report (6) the synthesis and absorption spectra of solvatochromic compounds **1** were described. In this series the energy of the longest wavelength band is linearly related to the substituent constant in all five solvents examined (6). This is in contrast to the generally limited success of such correlations in substituted benzenes (8). Part of this latter difficulty may arise from crossover of energy levels as substituents are changed and the resultant problem of proper assignment of transitions. However, such linear correlations of *hν* and substituent constant are observed in dyes (9–12),

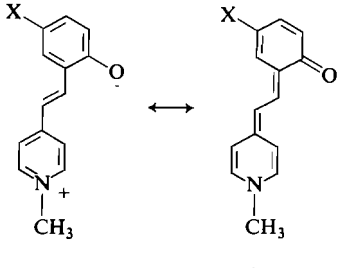
where the identity of the absorption is readily assigned to a given transition for the entire series due to its isolation in the visible portion of the spectrum, and in donor–acceptor complexes of both inter-(13–15) and intramolecular (14) types. In intermolecular charge transfer transitions, it also is known that to a good approximation $h\nu = I - A + C$ (16), where I is the ionization potential of the donor, A is the electron affinity of the acceptor, *i.e.*, the energy levels of the orbitals involved, and C is a constant containing solvation, polarization, and nonbonding terms. Thus, a linear relationship between I and σ, and A and σ may be inferred.

Although not generally thought of in these terms, intramolecular charge transfer transitions can be similarly considered. Thus, attachment of a substituent at a particular site causes a larger perturbation of the energy levels in that moiety than in the other portion of the charge transfer couple. Thus, the primary effect is to vary the highest occupied orbital (ionization potential) of the donor moiety or the lowest unoccupied orbital (electron affinity) of the acceptor portion. In series **1**, as X becomes more electron withdrawing, the long wavelength transition energy increases. On the basis of these substituent and solvent effects on the absorption spectra, it was concluded that the long wavelength absorption transition involves transfer of electron density from the phenol–quinone moiety to the pyridyl ring, *i.e.*, excitation involves conversion of a ground state resembling **1***a* to an excited state more like **1***b*. Thus, the effect of substituent is primarily to alter the energy of the highest occupied molecular orbital associated with the phenolate–quinone moiety. The fact that this energy is lowered (ionization potential raised) by electron withdrawing groups is consistent with substituent effects on ionization potentials in other aromatic systems (5, 7).[2]



a *b*

1

To corroborate this picture of the long wavelength transition of these compounds, we chose to examine *N*-(*p*-substituted)benzyl-2′-hydroxy-4-stilbazolium betaines (**2**). In this series of compounds, the substituent is attached to the pyridyl portion of the molecule. Since this is the acceptor portion of the molecule in the model deduced previously, the primary effect of the substituent is expected to be a result of alteration of the lowest unoccupied molecular orbital. By study of series **1** and **2**, substituent effects on the donor and acceptor portions can be discerned to some extent independently, in addition to the effects of solvent on the resultant electronic transitions.

2

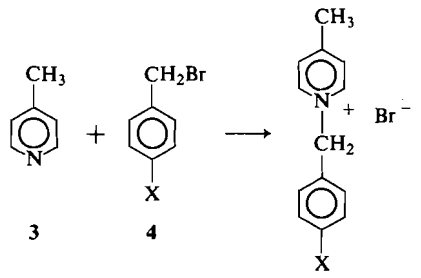
Discussion

Synthesis

The synthesis of this new solvatochromic series is analogous to our previous work (6). 4-Picoline (**3**) and the *p*-substituted-benzyl bromides (**4**) react in tetrahydrofuran(THF) to yield the quaternary salts (**5**) in ~90% yields. The yields, melting points, and elemental analyses are given in Table 1.

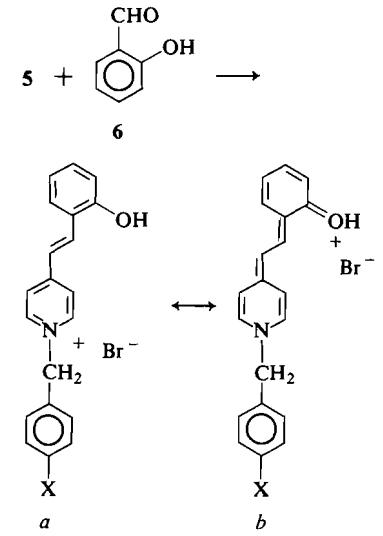
Condensation of the quaternary salts **5** with salicylaldehyde (**6**) in the presence of piperidine led to the (*p*-substituted)benzyl-2′-hydroxy-4-stilbazolium bromides (**7**) in variable yields. The synthesis and characterization data are summarized in Table 2. As expected all of these com-

[2]For example the first four ionization potentials of substituted pyridine-*N*-oxides (data of Maier and Muller (33)) are linearly correlated (correlation coefficients r = 0.994, 0.995, 0.945, 0.935, respectively) with positive slopes by sums of σ^+_{para} substituent constants.



3 4 5

pounds are more soluble in organic solvents than the corresponding methiodides of series **1**. Significantly, none of the 1 : 1 complexes of **2** and **7** was observed; these compounds differ in this respect from series **1**, which form such complexes with the corresponding hydriodide salts.



6

a b

7

In addition to the compounds listed in Table 2, the syntheses of **7**, X = CN, NO_2, were also pursued. Though these compounds were believed to have been prepared, they could not be isolated in pure form even by column chromatography.

Similarly attempts to isolate and purify the solvatochromic series **2** after their generation by base treatment of **7** were unsuccessful. Attempted recrystallization led to formation of intractable gums. These may be polymers arising from intermolecular electron transfer reactions. This proclivity for gum formation was also observed in the previously studied **1**, X = OCH_3.

Spectral Characterization

The ultraviolet–visible spectrum of the salt **7**, X = H, in water is shown in Fig. 1. Compounds **2** were generated *in situ* by addition of NaOH to solutions of the salts **7**. The spectra were then recorded within a few minutes time. The spectrum of **2**, X = H, in water is shown in Fig. 2. As can be seen by comparison of Figs. 1 and 2, the major spectral change is a shift of the long wavelength band from 372 to 458 nm. The spectra of other salts **7** and solvatochromics **2** were recorded in a

variety of other solvents as well and similar changes occur.

To demonstrate unequivocally that the solvatochromic species do have structure **2** and not that of the ylid **8** (and associated resonance forms) resulting from removal of a benzylic proton from **7**, the *O*-methyl derivative (**9**) of **2**, X = H, was synthesized and examined. The m.p., n.m.r. spectrum, and solution properties of **9** are very similar to those of **2**, X = H. The u.v.–visible spectrum of **9** in aqueous acid is shown in Fig. 3; its λ_{max}(362 nm) and ε (9.55×10^3) are very similar to those of **2**, X = H (Fig. 1; 372; 9.55×10^3). The spectrum is unchanged in solutions of p*H* up to 10.5 (Fig. 4). Thus, the benzylic protons of **9** are not sufficiently acidic to be removed at this p*H*. It is, therefore, concluded that the structure of the solvatochromic compounds under discussion is indeed **2**.

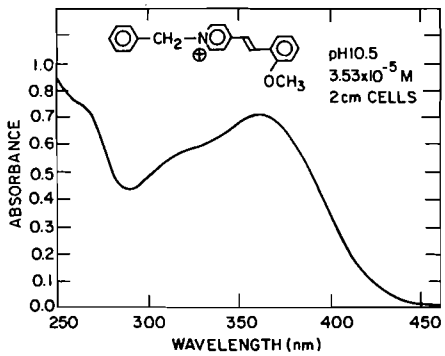

FIG. 4. Ultraviolet–visible spectrum of *N*-benzyl-2′-methoxy-4-stilbazolium bromide (**9**) in H_2O (sodium hydroxide, sodium bicarbonate buffer (32), p*H* 10.484).

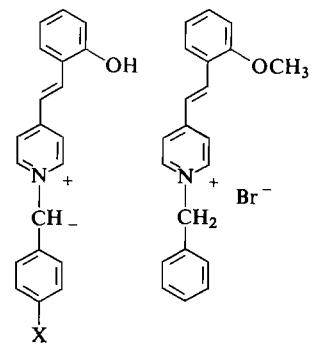
The long wavelength transition energies of salts **7** and the solvatochromics **2** are displayed as a function of substituent constant, σ_X, in Figs. 5 and 6, respectively. It is significant that



8 **9**

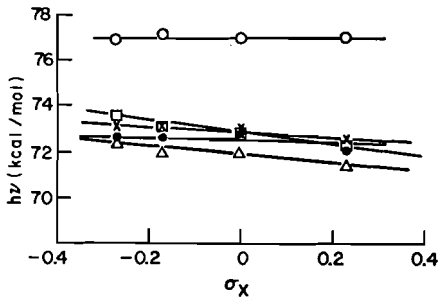

FIG. 5. Energy of longest wavelength transition *vs.* Hammett substituent constant for *N*-(*p*-substituted)-benzyl-2′-hydroxy-4-stilbazolium bromides (**7**): ○ H_2O: $h\nu = -0.164\sigma_X + 76.9$ ($r = 0.358$); □ 95% EtOH: $h\nu = -2.64\sigma_X + 72.8$ ($r = 0.986$); △ *i*-PrOH: $h\nu = -1.94\sigma_X + 71.8$ ($r = 0.942$); × *t*-BuOH: $h\nu = -1.33\sigma_X + 72.8$ ($r = 0.943$); ● $CHCl_3$: $h\nu = -0.955\sigma_X + 72.4$ ($r = 0.614$).

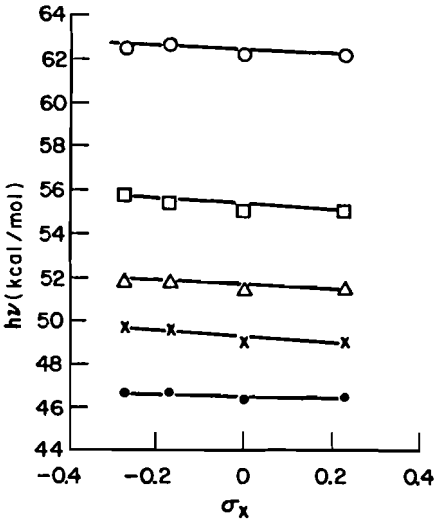

FIG. 6. Energy of longest wavelength transition *vs.* Hammett substituent constant for *N*-(*p*-substituted)-benzyl-2′-hydroxy-4-stilbazolium betaines (**2**): ○ H_2O: $h\nu = -0.708\sigma_X + 62.4$ ($r = 0.907$); □ 95% EtOH: $h\nu = -1.28\sigma_X + 55.3$ ($r = 0.968$); △ *i*-PrOH: $h\nu = -1.02\sigma_X + 51.6$ ($r = 0.938$); × *t*-BuOH: $h\nu = -1.40\sigma_X + 49.3$ ($r = 0.993$); ● $CHCl_3$: $h\nu = -0.466\sigma_X + 46.5$ ($r = 0.884$).

straight lines result and that the slopes are all negative, in contrast to the highly positive slopes for the series **1** and the corresponding hydriodide salts (6). Results for series **1** are shown in Fig. 7 for direct comparison.

As pointed out above the substituents in **2** and **7** are attached to the acceptor portion of the molecule and their effect is primarily a consequence of changes in the lowest unoccupied orbital. It has been demonstrated both by 'charge transfer' spectroscopy (13–15, 17) and electrochemistry (15, 18–20) that the electron affinity increases with σ_X in aromatic compounds; that is, the energy of the lowest unoccupied orbital level decreases. On this basis for both of the present series **2** and **7** then, increasing the electron withdrawing power should cause a decrease in transition energy. This is what is observed (Figs. 3 and 4).

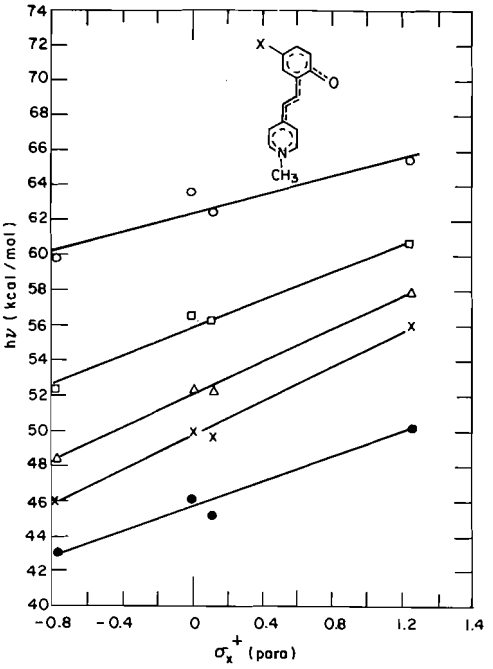

FIG. 7. Energy of longest wavelength transition *vs.* electrophilic substituent constant for *N*-methyl-5′-substituted-2′-hydroxy-4-stilbazolium betaines (**1**): ○ H_2O: $h\nu = +2.66\sigma^+ + 62.4$ ($r = 0.949$); □ 95% EtOH: $h\nu = +3.98\sigma^+ + 55.8$ ($r = 0.990$); △ *i*-PrOH: $h\nu = +4.70\sigma^+ + 52.0$ ($r = 0.998$); × *t*-BuOH: $h\nu = +4.96\sigma^+ + 49.7$ ($r = 0.995$); ● $CHCl_3$: $h\nu = +3.47\sigma^+ + 45.6$ ($r = 0.983$).

A further point is that while the results for series **1** were fit better by σ^+ (the electrophilic substituent constant) than by σ (the normal Hammett substituent constant), with the present compounds σ fits better than σ^+ as judged on the basis of the correlation coefficient, r (*e.g.*, **2** in H_2O, 0.907 *vs.* 0.696; **2** in 95% EtOH, 0.968 *vs.* 0.959; **2** in *i*-PrOH, 0.938 *vs.* 0.736). Again, this is consistent with the nature of the transition. In series **1** and the corresponding salts, σ^+ fits better since the substituent X is on the phenolate–

For personal use only.

quinone moiety which becomes positively (or less negatively) charged; in series **2** and **7** the substituent is nearer the pyridyl ring which becomes negatively (or less positively charged) and hence σ would be expected to describe the energetics better than σ^+.

A word should be said regarding the relative magnitudes of the slopes of *hν vs.* σ for series **1** and **2**. For series **1** slopes using σ (not σ^+ as reported (6)) range from +1.7 to +8.7, whereas in the present case (**2**) the range is −0.5 to −1.4, as shown in Fig. 6. The larger slopes in **1** are due to the fact that the substituents are directly attached to the chromophore, whereas in **2** they are not in conjugation with the chromophore because of the presence of the insulating methylene group.

Thus, the negative slopes of Figs. 5 and 6 and the better fit by σ support the previous conclusion regarding the nature of the electronic transitions in compounds **1** and **2** and the corresponding salts. The transition involves conversion from a ground state structure resembling **2***a* (and **7***a*) to an excited state structure more like **2***b* (and **7***b*). The transitions are most certainly of $\pi \rightarrow \pi^*$ type on the basis of recent molecular orbital calculations for compound **10** (2, 23) and the large extinction coefficients ($\sim 10^4$).

In Fig. 8 the transition energy of **7** is plotted as a function of the solvent polarity parameter, E_T (21). These plots are all nonlinear but the degree of solvatochromism is relatively small ($\Delta h\nu \sim 5$ kcal/mol). For comparison, nitrobenzene's ^1L_a band suffers a 2.5 kcal/mol decrease in energy when the solvent is changed from water to ethanol (22). The magnitudes are similar to those observed previously as are the shapes of the curves

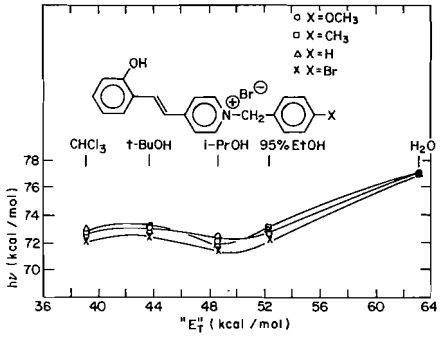

FIG. 8. Energy of longest wavelength transition *vs.* solvent polarity parameter for *N*-(*p*-substituted)benzyl-2′-hydroxy-4-stilbazolium bromides (**7**).

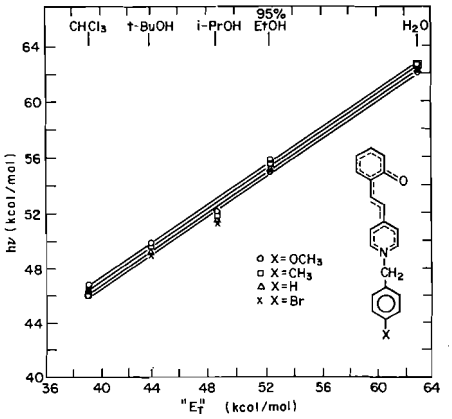

FIG. 9. Energy of longest wavelength transition *vs.* solvent polarity parameter for *N*-(*p*-substituted)benzyl-2′-hydroxy-4-stilbazolium betaines (**2**): X = OCH_3: $h\nu = 0.699E_T + 20.2$ ($r = 0.996$); X = CH_3: $h\nu = 0.687E_T + 19.2$ ($r = 0.998$); X = H: $h\nu = 0.673E_T + 19.8$ ($r = 0.997$); X = Br: $h\nu = 0.670E_T + 19.7$ ($r = 0.996$).

(6). The nonlinearity of these plots indicates that on a molecular level these salts are not solvated in the same manner as the reference compound used to evaluate E_T. This could be due to variations in the extent of ion pairing or degree of solvation because of the steric effect of the counter ion.

Figure 9 is a plot of the transition energy of **2** as a function of the solvent polarity parameter, E_T. As with **1**, large positive slopes are observed. The slopes of the lines are very similar to each other (0.67–0.69) and to those of **1**, X = OCH_3, H, Cl (0.71–0.73) (6). The range of solvatochromism ($\Delta h\nu$) in the present compounds **2** is about the same as observed in compounds **1** (6). Like the situation with **1**, the large positive slope of Fig. 9 is indicative of a large decrease in dipole moment (charge distribution) with excitation (1). This result corroborates the conclusion that light absorption converts a ground state resembling **1***a* or **2***a* to an excited state which resembles **1***b* or **2***b* to a greater extent.

Acidity

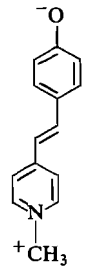
It was deemed of interest to ascertain the acidity of the stilbazolium salts **7** as a measure of the relative electron distribution in **7** and the corresponding 'anion' **2**. In view of the small spectral changes encountered in both of these series, the acidity of **7**, X = H, alone was determined in the belief that changes in acidity would also be small across the series.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

A series of aqueous buffer solutions comprised of sodium hydroxide, boric, phosphoric, and acetic acids covering a pH range from 3.2 to 10.5 was prepared (24). Solutions of **7**, X = H, at 10^{-5} M were prepared using these buffer solutions, so as to eliminate the possibility of associative phenomena. By comparison of the ratio of the long wavelength peak due to **2**, X = H, at 458 nm (see Fig. 2) to that at 372 nm due to **7**, X = H, (see Fig. 1) and taking into account the extinction coefficients measured at the extreme high and low pH's ,the pK_a of **7**, X = H, at 22° was determined to be 8.37 ($\pm$0.01 standard deviation, three different buffer solutions).

Recently, the pK_a of the conjugate acid of **10** (as the hydriodide salt) was similarly evaluated by spectroscopic means and found to be 8.57 at room temperature (23). Thus **7**, X = H, is somewhat more acidic than the salt of **10**. The increase in acidity must be due to the substitution of an *N*-benzyl group for an *N*-methyl group inasmuch as the conjugate acid of **10** and its 2′-hydroxyl analog (**1**, X = H) (6) have identical pK_a's within experimental error (25). The *N*-benzyl group is expected to be more electron withdrawing than the *N*-methyl substituent on the basis of the Hammett substituent constants of $CH_2C_6H_5$ and CH_3 (−0.09 and −0.16, respectively) as well as those of C_6H_5 and H (0.02 and 0.00, respectively) (26). Thus the benzyl group would cause a larger net positive charge on the pyridinium ring and the rest of the conjugated system and in this way enhance the acidity.

Furthermore, it is interesting to note that the pK_a of salicylaldehyde (**6**) is reported to be 8.37 (27) and 8.34 (28) at 25°, virtually identical to that of **7**, X = H. Salicylaldehyde is significantly less acidic than the isomeric *p*-hydroxybenzaldehyde (pK_a 7.62 (27, 28)); this difference is attributed to hydrogen bonding in the former in concert with the mesomeric effect in the latter (28). Nonetheless, the identity of the acidities of **6** and **7**, X = H, is very striking. The net effects of the *N*-benzylstilbazolium and formyl substituents on the acidity of *ortho* substituted phenol are identical. Thus, one can assign to the *N*-benzylstilbazolium substituent a value of +0.75 for the apparent *ortho* substituent constant (σ_{ortho}) based on that of the CHO group (29). In view of the known complexity in treatment of the effects of *ortho* substituents (30), detailed discussion of the observed results seems unwarranted at this time.



10

In conclusion, the spectral examination of a new series of *N*-(*p*-substituted)benzyl-2′-hydroxy-4-stilbazolium betaines (**2**) substantiates our previous conclusion based on the related *N*-methyl-5′-substituted-2′-hydroxy-4-stilbazolium betaines (**1**) (6). The conclusion was that the long wavelength transition in **1**, **2**, and their salts involves the $\pi \rightarrow \pi^*$ excitation of a predominantly zwitterionic ground state to a more delocalized or quinoidal excited state, *i.e.*, **1***a* → **1***b*, **2***a* → **2***b*, and **7***a* → **7***b* in valence bond terms. The experimental evidence in support of this is the dependence of the transition energy on (*i*) substituent and (*ii*) the polarity of the solvent. The first point bears on the effect of substituents on molecular orbital energy levels; in the present series the energy of the lowest unoccupied orbital was effectively varied while in the former that of the highest occupied orbital was effectively varied, both by substituent changes. The second point relates to the large changes in dipole moments (or electron distributions) upon excitation, which are negative in both systems. The solvatochromism of this new series **2** is similar in magnitude to that of the previous series (**1**), while the dependence of the transition energy on substituent is much less striking in the present series.

The pK_a of the parent salt **7**, X = H, at 22° is 8.37. This compound is slightly more acidic than the conjugate acid of **10** whose pK_a is 8.57 (23). This increase in acidity is attributed to the electron withdrawing effect of the *N*-benzyl group relative to the *N*-methyl group. From the pK_a a value for the apparent σ_{ortho} of the *N*-benzylstilbazolium substituent in phenols is found to be 0.75.

(p-Substituted)benzyl-4-picolinium Bromides (5)

To a solution of 18.6 g (0.200 mol) of 4-picoline (**3**) in 150 ml THF was added 0.205 mol of the *p*-substituted benzyl bromide (**4**). The mixture was refluxed for 2.5 h and filtered. The solid was washed with *n*-hexane and recrystallized from ethanol–benzene. The results are summarized in Table 1.

(p-Substituted)benzyl-2′-hydroxy-4-stilbazolium Bromides (7)

To a solution of 0.100 mol of the quaternary salt **5** in a minimum amount of methanol (50–100 ml) was added 15.3 g (0.125 mol) of salicylaldehyde (**6**) and 2.5 ml piperidine. After 3.5 h reflux the solution was concentrated, cooled, and filtered. The solid was recrystallized from methanol. Table 2 summarizes the results. The n.m.r. spectrum of **7**, X = H, in CD_3SOCD_3 was typical: δ 3.38 (s, 1H, O*H*), 5.78 (s, 2H, CH_2), 6.6–8.0 (m, 11H, aromatic *H*), 8.20 (d, 2H, H_3, H_5, J = 6 Hz), 9.05 (d, 2H, H_2, H_6, J = 6 Hz).

N-Benzyl-2′-methoxy-4-stilbazolium Bromide (9)

This was prepared by the above procedure using *o*-anisaldehyde and **5**, X = H. The desired product, isolated in about 30% yield by elution from acidic alumina with chloroform, was recrystallized three times from isopropanol: yellow plates, m.p. 187.0–187.5°.

Anal. Calcd. for $C_{21}H_{20}NBrO$: C, 65.97; H, 5.27; N, 3.66; Br, 20.90. Found: C, 65.11; H, 5.10; N, 3.72; Br, 21.44.

Its u.v.–visible spectra in aqueous acid and base are shown in Figs. 3 and 4: λ_{max} 362, ε 9.55 × 10^3 in base and 9.25 × 10^3 in acid; n.m.r. (CD_3SOCD_3): δ 3.88 (s, 3H, OCH_3), 5.84 (s, 2H, CH_2), 6.8–8.0 (m, 11H, aromatic), 8.21 (d, 2H, H_3, H_5, J = 6 Hz), 9.11 (d, 2H, H_2, H_6, J = 6 Hz). **9** was also prepared in 79% yield by reaction of benzyl bromide and 2′-methoxy-4-stilbazole, which was synthesized by condensation of 4-picoline and σ-anisaldehyde. 2′-Methoxy-4-stilbazole has b.p. 163°/0.5 mm; n.m.r. ($CDCl_3$) δ 3.71 (s, 3H, OCH_3), 6.7–7.8 (m, 4H, H_3, H_4, H_5, H_6), 7.29 (d of d, 2H, H_3, H_5, J = 2, 6 Hz), 8.51 (d of d, 2H, H_2, H_6, J = 2, 6 Hz).

Anal. Calcd. for $C_{14}H_{13}NO$: C, 79.59; H, 6.20; N, 6.63. Found: C, 79.00; H, 6.61; N, 6.39.

Ultraviolet–Visible Spectra

These were recorded on a Cary 15 instrument in quartz cells using matched reference cells containing solvent. Triply distilled water, commercial 95% ethanol (U.S. Industrial Chemicals), spectrophotometric grade 2-propanol (Baker), chloroform (Baker), and reagent grade *t*-butyl alcohol (Baker) were used.

The spectra of the salts **7** were determined first. Then a drop of 10% aqueous sodium hydroxide was added to 5 ml of the solution to generate the solvatochromic **2**. These stoppered solutions were stirred for a few minutes prior to spectral determination. Concentrations were 10^{-4}–10^{-5} *M*.

Determination of pK_a of 7, X = H

Buffer solutions were prepared from sodium hydroxide, boric acid, phosphoric acid, and acetic acid (24); these were not of constant ionic strength. The p*H* values were determined at 22° on a Beckman Research p*H* meter calibrated using standard buffer solutions. An aqueous 1.02 × 10^{-4} *M* solution of **7**, X = H, was then diluted to 1.02 × 10^{-5} *M* with each of the following buffer solutions: p*H* 3.243, 8.293, 8.629, 8.866, and 10.484. Spectra were determined at 22° as before in 2-cm cells using the appropriate buffer as reference. From the lowest p*H* solution the extinction coefficient of the 372 nm peak due to **7**, X = H, was found to be 9.55 × 10^3 while that of the 458 nm peak of **2**, X = H from the highest p*H* solution was 7.42 × 10^3. Due to the fact that there was absorption at 372 nm in **2**, X = H, the absorption at this wavelength at the intermediate p*H*'s was corrected in direct proportion to the 458 absorption. The pK_a of **7**, X = H, was then determined for these solutions by the equation:

$$pK_a = pH - \log\left[\frac{A_{458}\varepsilon_{372}}{A_{372}\varepsilon_{458}}\right]$$

which is derived from

$$K_a = \frac{[H^+][2, X = H]}{[7, X = H]}$$

The average pK_a value of the three intermediate buffer solutions was 8.37 with a standard deviation of 0.01.

The authors wish to acknowledge helpful discussion with Dr. James Kuder, the encouragement of Dr. Wolfgang Gunther, and the suggestions of a referee.

Received March 18, 1975

GERALD O. ASPINALL, THINNAYAM N. KRISHNAMURTHY, IVAN FURDA, and RIAZ KHAN. Can. J. Chem. **53**, 2171 (1975).

6-*O*-β-D-Glucopyranosyl-3-*O*-methyl-D-glucose (**4**) has been synthesized as a model compound for regions of branching in polysaccharides. Alkaline degradation of the disaccharide affords an epimeric pair of *O*-glycosyl metasaccharinic acids which have been characterized by reduction to 3-deoxy-6-*O*-β-D-glucopyranosyl-D-*ribo*-hexose (**6**) and 3-deoxy-6-*O*-β-D-glucopyranosyl-D-*arabino*-hexose (**7**). Alkaline degradation of the branched β-D-glucan from *Sclerotium rolfsii* followed by reduction of the derived metasaccharinic acids furnishes 3-deoxy-D-*ribo*-hexose (**8**), 3-deoxy-D-*arabino*-hexose (**9**), and the two disaccharides (**6** and **7**).

GERALD O. ASPINALL, THINNAYAM N. KRISHNAMURTHY, IVAN FURDA et RIAZ KHAN. Can. J. Chem. **53**, 2171 (1975).

On a synthétisé le 6-*O*-β-D-glucopyrannosyl-3-*O*-méthyl-D-glucose (**4**) comme produit de référence pour les positions de branchement dans les polysaccharides. La dégradation alcaline du disaccharide fournit une paire d'acides *O*-glycosyl métasaccharinques épimères, caractérisés par réduction en 3-déoxy-6-*O*-β-D-glucopyrannosyl-D-*ribo*-hexose (**6**) et en 3-déoxy-6-*O*-β-D-glucopyrannosyl-D-*arabino*-hexose (**7**). La dégradation alcaline du β-D-glucane ramifié provenant du *Sclerotium rolfsii* suivie d'une réduction des acides métasaccharinques dérivés, conduit au 3-déoxy-D-*ribo*-hexose (**8**), au 3-déoxy-D-*arabino*-hexose (**9**) et aux deux disaccharides (**6** et **7**).

3-*O*-Substituted reducing sugars are degraded by alkali with elimination of the 3-*O*-substituent and with the formation of an epimeric pair of metasaccharinic acids (3-deoxyhexonic acids) (1). In (1 → 3)-linked polysaccharides, stepwise degradation occurs from the reducing end by the 'peeling' mechanism (2) and branched glycans with (1 → 3)-linked interior chains carrying side chains at 0–6 would be expected to give *O*-glycosyl metasaccharinic acids. Some years ago (3) exploratory investigations were carried out on larch arabinogalactan (4) and the resulting saccharinic acids were treated with hypochlorite at p*H* 5 (5) to give the corresponding 2-deoxy-5-*O*-glycosylpentoses. The desired products, however, were formed in less than satisfactory yield and were accompanied by a parallel series of oligosaccharides lacking the reducing 2-deoxypentose residues. We have therefore reexamined the alkaline degradation giving an epimeric pair of *O*-glycosyl metasaccharinic acids using (*a*) the disaccharide 6-*O*-β-D-glucopyranosyl-3-*O*-methyl-D-glucose (**4**) as a model compound for regions of branching in polysaccharides and (*b*) the branched β-D-glucan from *Sclerotium rolfsii* (6, 7) in which a (1 → 3)-linked chain carries at 0–6 of every third residue a side chain of a single β-D-glucopyranosyl residue. Attempted degradations of the *O*-glycosyl saccharinic acids to give a single transformation product, namely the disaccharide 2-deoxy-5-*O*-β-D-glucopyranosyl-D-*erythro*-pentose (**5**), were again unsuccessful and the saccharinic acids have been characterized by reduction to neutral disaccharides.

1,2,4-Tri-*O*-acetyl-6-*O*-(2,3,4,6-tetra-*O*-acetyl-β-D-glucopyranosyl)-3-*O*-methyl-β-D-glucopyranose (**3**) was prepared (*a*) by the Koenigs–Knorr condensation of 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl bromide and 1,2,4-tri-*O*-acetyl-3-*O*-methyl-β-D-glucopyranose (**2**) or (*b*) by the Bredereck condensation (8) of the glycosyl halide

and 1,2,4-tri-*O*-acetyl-3-*O*-methyl-6-*O*-trityl-β-D-glucopyranose (**1**). De-*O*-acetylation of the hepta-*O*-acetyl derivative furnished the disaccharide, 6-*O*-β-D-glucopyranosyl-3-*O*-methyl-D-glucose (**4**), which afforded a crystalline hexa-*O*-acetyl-*N*-*p*-nitrophenylglycosylamine.

Degradation of disaccharide **4** with oxygen-free lime water gave a mixture of *O*-glycosyl saccharinic acids. Treatment of the saccharinic acids with hypochlorite at p*H* 5 (5) gave some of the desired disaccharide **5** but glucose was formed in a similar amount. A similar mixture of products was formed on Ruff degradation (9) of the saccharinic acids. In a later experiment the mixture of saccharinic acids from alkaline degradation of the β-D-glucan was converted into the corresponding saccharinamides which were treated with sodium hypochlorite at p*H* 13 (Hofmann rearrangement) (10). Whereas the unsubstituted metasaccharinic acids furnished 2-deoxy-D-*erythro*-pentose, the 6-*O*-glycosyl saccharinic acids gave only glucose and no disaccharide **5** was formed. In the following paper (11) other syntheses of 2-deoxy-5-*O*-β-D-glycopyranosyl-D-*erythro*-pentose (**5**) are reported and the observation that the disaccharide is readily degraded by base with the liberation of glucose provides an explanation for the present results.

The *O*-glycosyl saccharinic acids from disaccharide **4** were lactonized and then reduced with sodium borohydride at p*H* 3–4 (12) to give two epimeric disaccharides. The disaccharides were separated by chromatography on cellulose and g.l.c. – mass spectrometry of the derived methylated *O*-glycosylalditols (13) (Scheme 1) confirmed that both disaccharides were 3-deoxy-6-*O*-hexosylhexoses. One disaccharide gave glucose and 3-deoxy-*ribo*-hexose on hydrolysis and was characterized as 3-deoxy-6-*O*-β-D-glucopyranosyl-D-*ribo*-hexose (**6**) by conversion into the

For personal use only.

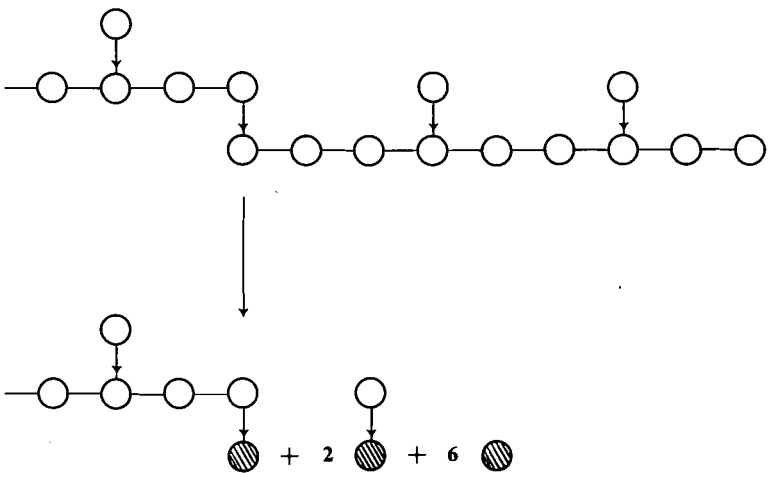
crystalline heptaacetate which was identical with a synthetic sample (11). The second disaccharide, which gave glucose and 3-deoxy-*arabino*-hexose on hydrolysis, yielded a crystalline hexa-*O*-acetyl-*N*-*p*-nitrophenylglycosylamine, and was assigned the structure 3-deoxy-6-*O*-β-D-glucopyranosyl-D-*arabino*-hexose (**7**).

The β-D-glucan from *Sclerotium rolfsii* was heated at 56° in oxygen-free sodium hydroxide until no further degradation took place. Degraded alkali-stable polysaccharide was separated by precipitation and the soluble metasaccharinic acids were lactonized and reduced with sodium borohydride at p*H* 3–4 to give a mixture of neutral sugars. Chromatographic fractionation afforded 3-deoxy-D-*ribo*-hexose (**8**), 3-deoxy-D-*arabino*-hexose (**9**), and the two above-mentioned disaccharides (**6** and **7**), each sugar being characterized by conversion into a crystalline derivative.

The alkaline degradations of 3,6-di-*O*-substituted hexoses described here result in metasaccharinic acid formation diagnostic for the 3-*O*-substituent and with retention of the 6-*O*-substituent. The formation of an epimeric pair of metasaccharinic acids and thence, after reduction, of the corresponding 3-deoxyhexoses, from the degradation of each type of 3-*O*-substituted structural unit would be an obvious disadvantage in the extension of this degradative procedure to more complex polysaccharides. Additional factors, however, must be taken into account when the degradation of a polysaccharide proceeds in stepwise manner from a single reducing group, as in the case of the β-D-glucan when degradation came to a halt before complete erosion of the (1 → 3)-linked chains had taken place. The isolation of an alkali-stable polysaccharide may have resulted from a number of causes, *e.g.* (*i*) from the presence in the polysaccharide preparation of two types of molecule, one of which contained natural nonreducing end groups, *cf.* the mannitol-terminated chains in laminaran (14), whilst alkaline degradation of the reducing chains proceeded to completion; (*ii*) by the exposure of an alkali-insensitive reducing group arising from some unrecognized minor structural feature; or (*iii*) by the interception of a 'stopping' reaction giving rise to a nonreducing end group. Methylation analyses of the β-D-glucan and the alkali-degraded β-D-glucan showed no detachable differences between the polysaccharides. The results were consistent with the previously proposed structure (6, 7) but also revealed the presence of *ca.* 2.4% of (1 → 6)-linkages at other than branch points. Since the native and degraded polysaccharides contained the same proportion of these structural units it is probable that they are distributed at regular intervals along the chain. The exposure of an unbranched 6-*O*-substituted unit after erosion of the (1 → 3)-linked chain would provide occasion for intervention by a 'stopping' reaction to give an alkali-stable metasaccharinic acid (3-deoxy-



SCHEME 2. Alkaline degradation of β-D-glucan: ○ = β-D-glucopyranose residue, ▨ = 3-deoxyhexonic acid (metasaccharinic acid) residue, — = (1→3)-linkage, → = (1 → 6)-linkage.

For personal use only.

hexonic acid) end group (Scheme 2) as shown by Burns and Somers (15) during the alkaline degradation of isomaltooligosaccharides.

We conclude that alkaline degradations of branched polysaccharides initiated at the single reducing groups are liable to provide only limited information on detailed structure since the stepwise 'peeling' reaction, like other chain reactions, is susceptible to premature termination with the consequent formation of saccharinic acids or other degradation products from only part of the polysaccharide structure. However, oligosaccharides of relatively low molecular weight will undergo degradation reactions diagnostic for substitution pattern in satisfactory yield with few detectable side reactions. Where *O*-glycosyl saccharinic acids are formed these may be separated by anion-exchange chromatography (15). A more generally satisfactory approach in polysaccharide studies would be to expose reducing groups by the selective cleavage of interior glycosidic linkages, *e.g.* by base-catalyzed β-elimination of 4-*O*-substituted hexuronate residues (16–18), and to submit the resulting oligosaccharides to alkaline degradation.

Experimental

Melting points are uncorrected. Optical rotations were measured with a Perkin–Elmer model 141 polarimeter at 20 ± 2°. The i.r. and u.v. spectra were measured on Unicam SP 200 and SP 800A spectrophotometers. The n.m.r. spectra were recorded on JEOL C-60H and Varian A-60 and HA-100 spectrophotometers, usually with tetramethylsilane as internal standard. Mass spectra were recorded on an Hitachi-Perkin-Elmer RMU-6 mass spectrometer with an ionization potential of 70 eV. The g.l.c. was performed with a Hewlett-Packard model 5750 chromatograph using columns of dichlorodimethylsilane-treated Celite coated with (*a*) 5% of neopentylglycol adipate polyester (operating temperature 160–185°), (*b*) 3% of silicone gum OV-225 (operating temperature 200–240°), and (*c*) 3% of silicone gum ECNSS-M (operating temperature 180°). Retention times (*T*) are quoted relative to methyl 2,3,4,6-tetra-*O*-methyl-β-D-glucopyranoside for methyl glycosides, to 2,3,4,6-tetra-*O*-methyl-D-glucitol diacetate for methylated alditol acetates, and to maltitol nonamethyl ether for methylated disaccharide alditols. For g.l.c. – mass spectrometry columns *b* and *c* were used in a Perkin–Elmer 990 chromatograph which was attached to the mass spectrometer via a Watson–Biemann separator.

The t.l.c. was performed with Kieselgel HF 254 as the adsorbent and the dried plates were sprayed with ethanol containing 5% of sulfuric acid and heated at about 150°. Solvent systems used for t.l.c. were chloroform–acetone (4:1), benzene–acetone (4:1), and light petroleum – acetone (5:1). Column chromatography was carried out on silica gel (Davison grade 950, 60–200 mesh) and microgranular cellulose powder (Whatman No. CC 31). Paper chromatography was carried out on Whatman filter paper No. 1 using the following solvent systems (v/v): (*A*) butanone–1-propanol–water (14:3:3), (*B*) ethyl acetate – acetic acid – formic acid – water (18:3:1:4). Light petroleum refers to the fraction of b.p. 30–60°. Solutions were concentrated below 50° under reduced pressure. Microanalyses were determined by A. B. Gygli, Toronto, Ontario, and by F. and E. Pascher, Bonn, West Germany.

1,2,4-Tri-O-acetyl-3-O-methyl-6-O-trityl-β-D-glucopyranose (1) and 1,2,4-Tri-O-acetyl-3-O-methyl-β-D-glucopyranose (2)

Reaction of 3-*O*-methyl-D-glucose (19) (10 g) with chlorotriphenylmethane in pyridine under standard conditions (20) followed by normal work-up and chromatography on silica gel furnished syrupy 3-*O*-methyl-6-*O*-trityl-D-glucose (16.7 g), $[\alpha]_D$ +32° (*c*. 1,2 in dichloromethane). The trityl ether (10 g) was acetylated with acetic anhydride and anhydrous sodium acetate, and normal work-up followed by crystallization from methanol furnished 1,2,4-tri-*O*-acetyl-3-*O*-methyl-6-*O*-trityl-β-D-glucopyranose (**1**) (8 g), m.p. 169–170°, $[\alpha]_D$ +27° (*c*, 1.0 in dichloromethane) (lit. (21) m.p. 173–175° $[\alpha]_D$ +18° (chloroform)). Concentration of the filtrate from the above crystallization afforded 1,2,4-tri-*O*-acetyl-3-*O*-methyl-6-*O*-trityl-α-D-glucopyranose (3.5 g), m.p. 143–144°, $[\alpha]_D$ +102° (*c*, 1.1 in dichloromethane) (lit. (21, 22) m.p. 145°, $[\alpha]_D$ +92.2° (chloroform)). As reported by Perlin (21, 22) acetylation with acetic anhydride and pyridine gave relatively more of the α-anomer.

The trityl ether (**1**) (5 g) was reacted with hydrogen bromide in acetic acid in the usual way and recrystallization of the product from ether afforded 1,2,4-tri-*O*-acetyl-3-*O*-methyl-β-D-glucopyranose (**2**) (2.4 g), m.p. 117–119°, $[\alpha]_D$ −2.5° (*c*, 1.1 in chloroform) (lit. (22) m.p. 121–122°, $[\alpha]_D$ +13.2° (chloroform)).

1,2,4-Tri-O-acetyl-6-O-(2,3,4,6-tetra-O-acetyl-β-D-glucopyranosyl)-3-O-methyl-β-D-glucopyranose (3)

(*a*) Iodine (450 mg) and 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl bromide (2.5 g) were added to 1,2,4-tri-*O*-acetyl-3-*O*-methyl-β-D-glucopyranose (1.5 g) in benzene (50 ml) in the presence of silver carbonate (2.5 g) and Drierite (7.5 g) and the mixture was stirred for 48 h at room temperature. The mixture was filtered and concentration of the filtrate afforded a crystalline residue which was recrystallized from methanol to give the acetylated disaccharide (**3**) (1.5 g), m.p. 174–175°, $[\alpha]_D$ −15.8° (*c* 1.3 in chloroform); n.m.r. data ($CDCl_3$): τ 6.45 (3-proton singlet, OCH_3), 7.8–8.05 (21 protons, 7 × $OCOCH_3$).

Anal. Calcd. for $C_{27}H_{38}O_{18}$: C, 49.84; H, 5.84. Found: C, 49.86; H, 6.08.

(*b*) Tetra-*O*-acetyl-α-D-glucopyranosyl bromide (4.11 g) and the trityl ether (**1**) (5.63 g) were condensed in nitromethane (20 ml) in the presence of Drierite (1.5 g) and silver perchlorate (2.2 g) and the mixture was heated at 80° for 10 min. The mixture was filtered, the filtrate was washed with cold saturated aqueous sodium hydrogen carbonate and filtered, and concentration of the filtrate furnished a syrup which crystallized in methanol and on recrystallization from ethanol gave the acetylated disaccharide (**3**) (3.9 g), m.p. 174–175°, $[\alpha]_D$ −15.1° (*c*, 1.2 in

chloroform), whose n.m.r. spectrum was identical to that of the previously prepared sample.

6-O-β-D-Glucopyranosyl-3-O-methyl-D-glucose (4)

The acetylated disaccharide (**3**) (2.5 g) was de-*O*-acetylated with sodium methoxide in methanol (23) and the product was chromatographed on cellulose in solvent *A* to give the disaccharide (**4**) (0.9 g) as a semicrystalline solid, m.p. 80°, $[\alpha]_D$ +1° (*c*, 1.5 in water).

Anal. Calcd. for $C_{13}H_{24}O_{11}$: C, 43.75; H, 6.79. Found: (after drying at 80°): C, 43.83; H, 7.08.

A sample (100 mg) of the disaccharide (**4**), glacial acetic acid (0.1 ml), and *p*-nitroaniline (50 mg) were heated under reflux in ethanol–water (4:1) (2 ml) for 1 h (24). After removal of solvent the residue was chromatographed on cellulose (20 × 2.5 cm) using solvent *A* to give syrupy glycosylamine (60 mg) which was reacted with acetic anhydride and pyridine. Recrystallization of the product from ethanol–chloroform (7:3) afforded 6-*O*-β-D-glucopyranosyl-3-*O*-methyl-*N*-*p*-nitrophenyl-D-glucosylamine hexaacetate (70 mg), m.p. 139–140°, $[\alpha]_D$ −105° (*c*, 2.0 in chloroform); ν_{max}(chloroform) 1470, 1310 (NO_2), 1720 (acetate C=O) 3500 cm^{-1} (NH); n.m.r.: τ 1.85, 3.34 (2 × 2-proton doublets, splitting 9 Hz, 4 aromatic H's) 4.32 (1-proton doublet, splitting 8 Hz, H-1), 6.51 (3-proton singlet, OCH_3), 7.8–8.1 (18 protons, 6 × $OCOCH_3$).

Anal. Calcd. for $C_{31}H_{40}N_2O_{18}$: C, 51.10; H, 5.34; N 3.84. Found: C, 51.23; H, 5.55; N, 3.78.

Alkaline Degradation of Disaccharide 4 and Reduction of Metasaccharinolactones

Disaccharide **4** (1.2 g) was kept in oxygen-free saturated lime-water (250 ml) at room temperature for 144 h, after which time paper chromatography showed complete disappearance of starting material. The solution was passed through a column of Amberlite resin IR-120(H) and freeze-dried to give a mixture of saccharinolactones (0.9 g); ν_{max} (film) 1708 cm^{-1} (lactone C=O). A solution of the lactones (0.9 g) in water (10 ml) at 0–3° was adjusted to p*H* 3–4 by dropwise addition of 0.5 *M* sulfuric acid, sodium borohydride (100 mg) in water (0.75 ml) was added dropwise during 15 min with maintenance of p*H* and temperature, and the solution was kept for 1 h (12). The solution was neutralized with barium carbonate, stirred with Amberlite resin IR-120(H), filtered, and repeatedly evaporated with methanol to remove boric acid. Paper chromatography of the resulting syrup (0.8 g) in solvent *A* showed two reducing disaccharides, $R_{glucose}$ 0.68 and 0.85, with smaller amounts of unchanged lactones and neutral alditols. The syrup was passed through a column of diethylaminoethyl-Sephadex A-25 (formate form), elution with water giving the neutral components (0.6 g). The neutral components were chromatographed on cellulose using solvent *A* to give disaccharides **6** (0.27 g), $R_{glucose}$ 0.68, $[\alpha]_D$ −8° (*c*, 1.1 in water) and **7** (0.16 g), $R_{glucose}$ 0.85, $[\alpha]_D$ −1° (*c*, 1.8 in water).

Hydrolysis of disaccharide **6** gave glucose and 3-deoxy-*ribo*-hexose. A sample (5 mg) of the disaccharide was reduced with sodium borohydride (5 mg) in water (1 ml) and the resulting disaccharide alditol was methylated with methyl iodide and sodium hydride in *N*,*N*-dimethylformamide (25). Gas–liquid chromatography of the methylated disaccharide alditol on column *b* at 240° showed a single peak, *T* 1.20, and g.l.c. – mass spectrometry showed characteristic fragment ions at *m/e* 219(10), 205(26), 147(23), 103(15), 89(95), 88(100), and 45(75). The disaccharide (40 mg) was characterized by reaction with acetic anhydride and sodium acetate to give 1,2,4-tri-*O*-acetyl-3-deoxy-6-*O*-(2,3,4,6-tetra-*O*-acetyl-β-D-glucopyranosyl)-D-*ribo*-hexopyranose (45 mg), m.p. and mixture m.p. 195–196°, $[\alpha]_D$ −14° (*c*, 1.0 in chloroform), whose n.m.r. spectrum was identical with that of a synthetic sample (11).

Hydrolysis of disaccharide **7** gave glucose and 3-deoxy-*arabino*-hexose. A sample of the disaccharide alditol was methylated as described above and g.l.c. of the methylated derivative on column *b* at 240° showed a single peak, *T* 1.12, and g.l.c. – mass spectrometry showed characteristic fragment ions at *m/e* 219(9), 205(24), 147(21), 103(14), 89(85), 88(100), and 45(70). The disaccharide was characterized by reaction with *p*-nitroaniline, followed by acetylation in acetic anhydride and pyridine, to give 2,4-di-*O*-acetyl-3-deoxy-6-*O*-(2,3,4,6-tetra-*O*-acetyl-β-D-glucopyranosyl)-*N*-*p*-nitrophenyl-D-*arabino*-hexopyranosylamine, m.p. 214–215°, $[\alpha]_D$ −47° (*c*, 0.6 in chloroform); ν_{max} (chloroform) 1340 (NO_2), 1720 (ester C=O), 3500 cm^{-1} (NH); n.m.r.: τ 1.85, 3.34 (2 × 2-proton doublets, splitting 9 Hz, 4 aromatic H's), 4.32 (1-proton doublet, splitting 8 Hz, H-1), 7.8–8.1 (18 protons, 6 × $OCOCH_3$).

Anal. Calcd. for $C_{30}H_{38}N_2O_{17}$: C, 51.57; H, 5.48; N, 4.01. Found: C, 51.87; H, 5.41; N, 3.98.

Alkaline Degradation of β-D-Glucan

An oxygen-free solution of β-D-glucan (5 g) in water (1 l) containing sodium hydroxide (4 g) was maintained in an atmosphere of nitrogen at 56°. Aliquot portions were withdrawn at intervals and analyzed for metasaccharinic acid by thiobarbituric acid assay of the periodate oxidation products (26) and for carbohydrate content by the phenol – sulfuric acid procedure (27). No further change (metasaccharinic acid, 56%; undegraded glucose residues, 44%) occurred after 10 days and the cooled solution was passed through a column of Amberlite resin IR-120(H), concentrated to 100 ml, and poured into acetone (750 ml). The precipitated polysaccharide was separated by centrifugation and the supernatant liquid was concentrated again, poured into acetone, centrifuged to remove further precipitate, and concentrated to a syrup (2.7 g) which contained saccharinic acid and nonreducing sugar residues in the proportions of 2.6:1. The combined degraded polysaccharide precipitates (2.0 g) contained saccharinic acid and nonreducing sugar residues in the proportions of 1:12.

A portion (1.8 g) of the above syrup (as saccharinolactones) was reduced with sodium borohydride at p*H* 3–4 as described previously and furnished a mixture of neutral sugars (1.2 g) after passing through a column of diethylaminoethyl-Sephadex A-25 (formate form). Paper chromatography in solvent *A* showed the presence of four reducing sugars and a nonreducing fraction ($R_{glucose}$ 0.31), and column chromatography on cellulose afforded homogeneous samples of the reducing sugars. Fraction 1 (0.25 g), $R_{glucose}$ 2.85, $[\alpha]_D$ −17.5° (*c*, 1.0 in water), was chromatographically indistinguishable from 3-deoxy-D-*arabino*-hexose (**9**) and was characterized by conversion into 3-deoxy-D-*arabino*-hexitol pentabenzoate, m.p. 102–104°, $[\alpha]_D$ −34° (*c*, 0.5 in chloroform) (lit. (28) m.p. 104–105°, $[\alpha]_D$ −33.6° (chloroform)). Fraction 2 (0.35 g), $R_{glucose}$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

2.45, $[\alpha]_D$ +32° (*c*, 1.0 in water), was chromatographically indistinguishable from 3-deoxy-D-*ribo*-hexose (**8**) and was characterized by conversion into the β-D-tetraacetate which was identical (m.p. and mixture m.p. 129–130°, $[\alpha]_D$ −16° (*c*, 1.0 in chloroform), and n.m.r. spectrum) to an authentic sample. Fraction 3 (0.16 g), $R_{glucose}$ 0.85, $[\alpha]_D$ −1° (*c*, 1.0 in water), was chromatographically indistinguishable from the previously characterized disaccharide **7**, and its identity was further established by g.l.c.–mass spectrometry of the methylated disaccharide alditol and by conversion into the *N*-*p*-nitrophenyl-glycosylamine hexaacetate which was identical (m.p. and mixture m.p., $[\alpha]_D$, i.r. and n.m.r. spectra) to the previous sample. Fraction 4 (0.12 g), $R_{glucose}$ 0.68, was chromatographically indistinguishable from disaccharide **6** and was characterized by g.l.c. – mass spectrometry of the methylated disaccharide alditol and by conversion into the β-D-heptaacetate which was identical (m.p. and mixture m.p., $[\alpha]_D$, i.r. and n.m.r. spectra) to previous samples.

Methylation of β-D-*Glucan and Alkali-degraded* β-D-*Glucan*

β-D-Glucan (200 mg) was methylated with methyl iodide and sodium hydride in dimethyl sulfoxide (29) to give methylated β-D-glucan (160 mg), $[\alpha]_D$ —30° (*c*, 1.5 in chloroform) (found: OMe, 45.1%). Similarly degraded polysaccharide (50 mg) isolated from the above alkaline degradation furnished methylated degraded β-D-glucan (40 mg), $[\alpha]_D$ −21° (*c*, 1.2 in chloroform) (found: OMe, 44.8%). Samples of both methylated polysaccharides were hydrolyzed, reduced with sodium borohydride, and acetylated to give mixtures of partially methylated alditol acetates which were estimated and identified by g.l.c. on column *c*. In both cases derivatives of the component sugars, 2,3,4,6-tetra-(*T* 1.00), 2,4,6-tri-(*T* 1.95), and 2,4-di-*O*-methylglucose (*T* 5.1) were present in the molar ratio of 1:2:1. In addition small amounts (~2.4%) of a 2,3,4-tri-*O*-methylglucose derivative (*T* 2.51) were present. This minor component was further identified by analysis of the methyl glycosides formed on methanolysis of the methylated glucan.

Degradations of Saccharinic Acids

(*a*) The mixture (0.6 g) of saccharinic acids from the alkaline degradation of β-D-glucan was kept in methanolic 5% hydrogen chloride for 20 min at room temperature to ensure complete esterification or lactonization. Removal of acid by repeated evaporation with methanol afforded a mixture of esters and lactones (0.6 g); ν_{max} (film) 1780 (γ-lactone) and 1750 cm^{-1} (ester C=O). The syrup was treated with saturated methanolic ammonia for 24 h and concentration furnished a mixture of amides (0.57 g); ν_{max} (film) 1650 cm^{-1} (amide C=O). Sodium hypochlorite solution (0.5 *M*, 20 ml) was added to the amides (0.5 g) in water at 0°, the solution was maintained at p*H* 13 for 1 h, and acetic acid was added to p*H* 5 and the solution was left overnight at room temperature. The solution was deionized by passage through columns of Amberlite resins IR-120(H) and IR-45(OH) and concentrated to a syrup. The syrup was chromatographed on charcoal–Celite (1:1) and elution with water and water containing 2% of butanone gave (*i*) D-glucose (0.10 g), identified by t.l.c. of the sugar and g.l.c. of glucitol hexaacetate, and (*ii*) 2-deoxy-D-*erythro*-pentose (0.15 g), identified by conversion into the *N*-phenyl glycosylamine, m.p. and mixture m.p. 172–173°. No 2-deoxy-5-*O*-β-D-glucopyranosyl-D-*erythro*-pentose (**5**) (11) could be detected.

(*b*) The mixture (50 mg) of *O*-glycosylsaccharinic acids from the alkaline degradation of disaccharide **4** was treated with sodium hypochlorite at p*H* 5 as described by Whistler and Schweiger (5) and the reaction mixture was worked-up to give a syrup which was examined by paper chromatography in solvents *A* and *B* and shown to contain approximately equal amounts of glucose, disaccharide **5** ($R_{glucose}$ 1.9 in solvent *A*), and unchanged saccharinic acids.

(*c*) The mixture (100 mg) of *O*-glycosyl saccharinic acids from the alkaline degradation of disaccharide **4** was submitted to a Ruff degradation by the modified procedure of Haga *et al.* (9). The reaction mixture was worked-up to give a syrup which was shown by paper chromatography to contain approximately equal amounts of glucose and disaccharide **5** together with some unchanged saccharinic acid.

The authors wish to acknowledge financial support from the National Research Council of Canada and a grant from the Institute of Paper Chemistry, Appleton, Wisconsin, under the Pioneering Research Program. We thank Dr. Milton H. Fischer of The Pillsbury Company, Minneapolis, for a generous supply of the β-D-glucan.

Received March 18, 1975

GERALD O. ASPINALL, THINNAYAM N. KRISHNAMURTHY, and IVAN FURDA. Can. J. Chem. **53**, 2178 (1975).

Acetylated derivatives (**3** and **10**) of the disaccharides 6-*O*-β-D-glucopyranosyl-3-*O*-mesyl-D-glucose and 3-deoxy-6-*O*-β-D-glucopyranosyl-D-*ribo*-hexose have been synthesized. The parent disaccharides have been degraded to give 2-deoxy-5-*O*-β-D-glucopyranosyl-D-*erythro*-pentose (**4**) which has been characterized as the methylated disaccharide alditol.

GERALD O. ASPINALL, THINNAYAM N. KRISHNAMURTHY et IVAN FURDA. Can. J. Chem. **53**, 2178 (1975).

On a synthétisé les dérivés acétylés (**3** et **10**) des disaccharides 6-*O*-β-D-glucopyrannosyl-3-*O*-mésyl-D-glucose et 3-déoxy-6-*O*-β-D-glucopyrannosyl-D-*ribo*-hexose. Les disaccharides mères ont été dégradés produisant ainsi le 2-déoxy-5-*O*-β-D-glucopyrannosyl-D-*érythro*-pentose (**4**) qui a été identifié comme le disaccharide méthylé de l'alditol.

In part VII (1) attempts to degrade an epimeric pair of 3-deoxy-6-*O*-β-D-glucopyranosylhexonic acids (*O*-glycosyl metasaccharinic acids) to a single transformation product, 2-deoxy-5-*O*-β-D-glucopyranosyl-D-*erythro*-pentose (**4**), were less than fully successful due to the susceptibility of the disaccharide (**4**) to further degradation. In addition to degradation of 3-deoxyhexonic acids (metasaccharinic acids), *e.g.* by the Ruff procedure (2), 2-deoxy-D-*erythro*-pentose is conveniently prepared by alkaline degradation of 3-*O*-methanesulfonyl (mesyl)- or 3-*O*-*p*-toluenesulfonyl (tosyl)-D-glucose (3) or by reaction of 3-deoxy-D-*ribo*-hexose with 1 mol of periodate (4). We describe here syntheses of the peracetates of 6-*O*-β-D-glucopyranosyl-3-*O*-mesyl-D-glucose and 3-deoxy-6-*O*-β-D-glucopyranosyl-D-*ribo*-hexose from which the parent disaccharides have been obtained for further degradation to disaccharide **4**.

Reaction of 3-*O*-mesyl-D-glucose (5) with chlorotriphenylmethane in pyridine furnished 3-*O*-mesyl-6-*O*-trityl-α-D-glucopyranose (**1**) as a crystalline pyridine complex which gave 1,2,4-tri-*O*-acetyl-3-*O*-mesyl-6-*O*-trityl-α-D-glucopyranose (**2**) on acetylation. Bredereck condensation (6,7) of 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl bromide with the trityl ether (**2**) afforded the β-heptaacetyl derivative (**3**) of 6-*O*-β-D-glucopyranosyl-3-*O*-mesyl-D-glucose. The parent disaccharide was formed on de-*O*-acetylation and was used directly for conversion into disaccharide **4**. Further treatment of the 3-*O*-mesyl disaccharide under controlled conditions gave 2-deoxy-5-*O*-β-D-glucopyranosyl-D-*erythro*-pentose (**4**) but in confirmation of previous observations (1) it was noted that the disaccharide **4** on prolonged contact with base underwent degradation with the liberation of glucose. Accordingly disaccharide **4** was not isolated but its formation was confirmed by reduction with sodium borohydride and conversion into 2-deoxy-5-*O*-(2,3,4,6-tetra-*O*-methyl-β-D-glucopyranosyl)-1,3,4-tri-*O*-methyl-D-*erythro*-pentitol (**5**). The methylated disaccharide alditol (**5**) showed characteristic fragment ions in the mass spectrum and methanolysis gave components with the retention times of 2-deoxy-1,3,4-tri-*O*-methyl-D-*erythro*-pentitol and the methyl glycosides of 2,3,4,6-tetra-*O*-methyl-D-glucose.

Acetylation of the 6-*O*-trityl derivative (**6**) of 3-deoxy-D-*ribo*-hexose (8) gave a mixture of 1,2,4-tri-*O*-acetyl-3-deoxy-6-*O*-trityl-β-D-*ribo*-hexopyranose (**7**) and 1,2,5-tri-*O*-acetyl-3-deoxy-6-*O*-D-*ribo*-hexofuranose (**8**). The formation of appreciable quantities of the furanose acetate is not surprising since n.m.r. studies (9) have shown

the presence of *ca.* 25% of furanose isomers in aqueous solutions of 3-deoxy-D-*ribo*-hexose. In like manner Zinner *et al.* (10) have shown that acetylation of 3-deoxy-D-*xylo*-hexose gives isolable quantities of the furanose acetate. The β-heptaacetyl derivative (**10**) of 3-deoxy-6-*O*-β-D-glucopyranosyl-D-*ribo*-hexose was prepared (*i*) by Bredereck condensation of trityl ether **7** with tetra-*O*-acetyl-α-D-glucopyranosyl bromide and (*ii*) by the de-*O*-tritylation of the trityl ether **7** to give 1,2,4-tri-*O*-acetyl-3-deoxy-β-D-*ribo*-hexopyranose (**9**) followed by Koenigs–Knorr condensation with tetra-*O*-acetyl-α-D-glucopyranosyl bromide. The parent disaccharide formed on de-*O*-acetylation of the heptaacetate **10** was oxidized with periodic acid and furnished 2-deoxy-5-*O*-β-D-glucopyranosyl-D-*erythro*-pentose (**4**). The disaccharide **4** was characterized by conversion into the methylated disaccharide alditol **5**, whose identity was established by g.l.c. – mass spectrometry.

No detailed explanation is yet available for the alkali lability of 2-deoxy-5-*O*-β-D-glucopyranosyl-D-*erythro*-pentose (**4**). The alkaline degradation of 2-deoxy-D-*erythro*-pentose is discussed in a recent review (11) and it is noteworthy that derivatives of this sugar which are also present in the furanose form in deoxyribonucleic acid derivatives are readily degraded by alkali (12).

Experimental

Unless otherwise stated experimental conditions were as described in part VII (1).

*3-O-Mesyl-6-O-trityl-*D*-glucose (1)*

Reaction of 3-*O*-mesyl-D-glucose (3) (25 g) with chlorotriphenylmethane in pyridine under standard conditions (13), followed by extraction with chloroform and concentration by repeated distillation with toluene to remove excess of pyridine, furnished 3-*O*-mesyl-6-*O*-trityl-D-glucose (**1**) as a crystalline pyridine complex (53 g), which after recrystallization from toluene had m.p. 112–118° (slow heating on the hot stage), 129–131° (rapid heating in a capillary), and $[\alpha]_D$ +38.6° (constant during 4 h) (*c*, 1.0 in chloroform); n.m.r. ($CDCl_3$): τ 2.55–2.62 (2 protons, α-H of pyridine residue, *cf.* τ 2.40 of pyridine), 2.40–3.00 (18 protons, trityl and β- and γ-H of pyridine residue), 4.79 (1-proton doublet, $J_{1,2}$ = 3.8 Hz, H-1), 6.93 (3-proton singlet, mesyl).

Anal. Calcd. for $C_{26}H_{28}O_8S \cdot C_5H_5N$: C, 64.10; H, 5.74; S, 5.51; N, 2.42. Found: C, 64.42; H, 5.69; S, 5.70; N, 2.45.

*1,2,4-Tri-O-acetyl-3-O-mesyl-6-O-trityl-*α*-*D*-glucopyranose (2)*

Reaction of the trityl ether **1** as the pyridine complex (24 g) with acetic anhydride (170 ml) containing anhydrous sodium acetate (12 g) at 125° for 3 h, followed by normal work-up and recrystallization from ethanol afforded the triacetate **2** (27 g), m.p. 120–122°, $[\alpha]_D$ +95° (*c*, 1.0 in chloroform); n.m.r. ($CDCl_3$): τ 4.67 (1-proton doublet, $J_{1,2}$ = 3.7 Hz, H-1), 7.08 (3-proton singlet, mesyl), 7.88, 7.95, 8.22 (3 × 3-proton singlets, 3 × $OCOCH_3$).

Anal. Calcd. for $C_{32}H_{34}O_{11}S$: C, 61.31; H, 5.47; S, 5.10. Found: C, 60.83; H, 5.36; S, 5.45.

*1,2,4-Tri-O-acetyl-6-O-(2,3,4,6-tetra-O-acetyl-*β*-*D*-glucopyranosyl)-3-O-mesyl-*α*-*D*-glucopyranose (3)*

2,3,4,6-Tetra-*O*-acetyl-α-D-glucopyranosyl bromide (8.22 g) and the trityl ether **2** (12.5 g) were condensed in nitromethane (20 ml) in the presence of Drierite (5 g) and silver perchlorate (4.5 g), and the mixture was kept at

For personal use only.

room temperature for 10 min. The reaction mixture was worked-up in the usual way (1), crystallization from methanol removed most of the tritanol, and further crystallization gave acetylated disaccharide **3** (4.7 g), m.p. 149–151°, $[\alpha]_D$ +46° (*c*, 1.0 in chloroform); n.m.r. ($CDCl_3$): τ 3.80 (1-proton doublet, $J_{1,2}$ = 4 Hz, H-1), 7.07 (3-proton singlet, mesyl), 7.87–8.30 (21 protons, 7 × $OCOCH_3$).

Anal. Calcd. for $C_{27}H_{38}O_{20}S$: C, 45.34; H, 5.35; S, 4.48. Found: C, 45.22; H, 5.36; S, 4.85.

Alkaline Degradation of 1,2,4-Tri-O-acetyl-6-O-(2,3,4,6-tetra-O-acetyl-β-D-glucopyranosyl)-3-O-mesyl-α-D-glucopyranose (3)

Methanolic sodium methoxide was added to the acetylated disaccharide **3** (500 mg) in methanol (25 ml) in order to maintain permanent alkalinity and the solution was stirred for 5 min in an atmosphere of nitrogen. The major product had $R_{glucose}$ 1.15 on paper chromatography in solvent *A*. Oxygen-free lime-water (250 ml) was added to the methanolic solution during 1 h and reaction was continued for 3 h in an atmosphere of nitrogen. At this point paper chromatography showed a major component, $R_{glucose}$ 1.9, which gave a positive staining reaction with the perchloric acid – acetone spray for 2-deoxy sugars (14), together with glucose as a minor component. Prolonged reaction resulted in the formation of increasing amounts of glucose. The reaction mixture was treated with cation and anion exchangers and concentrated to a syrup which was treated with sodium borohydride (250 mg) in water (5 ml) and worked-up in the usual way to give the corresponding mixtures of alditols (140 mg). The mixture of alditols was methylated with methyl iodide and sodium hydride in *N*,*N*-dimethylformamide (15) and g.l.c. on column *b* showed hexa-*O*-methylglucitol (*T* 0.24) as a minor component and a major component with *T* 0.48. Methanolysis of the methylated alditols and examination of the products by g.l.c. on column *a* at 150° showed components with the retention times of 2-deoxy-1,3,4-tri-*O*-methyl-D-*erythro*-pentitol (*T* 0.69; a reference sample was prepared from 2-deoxy-5-*O*-trityl-D-*erythro*-pentose (16) by reduction, methylation, and de-*O*-tritylation) and the methyl glycosides of 2,3,4,6-tetra-*O*-methyl-D-glucose (*T* 1.00 and 1.49). Examination of the major component by g.l.c. – mass spectrometry showed characteristic fragment ions at *m/e* 219(5), 161(30), 147(21), 103(53), 59(16), and 45(100). Preparative-layer chromatography of the mixture of methylated alditols on silica gel using chloroform–ethanol (9:1) afforded a sample of 2-deoxy-5-*O*-(2,3,4,6-tetra-*O*-methyl-β-D-glucopyranosyl)-1,3,4-tri-*O*-methyl-D-*erythro*-pentitol (**5**), $[\alpha]_D$ −18° (*c*, 0.4 in methanol).

Anal. Calcd. for $C_{18}H_{36}O_9$: OMe, 54.8. Found: OMe, 54.3.

3-Deoxy-6-O-trityl-D-ribo-hexose (6) and Acetylated Derivatives (7 and 8)

3-Deoxy-D-*ribo*-hexose (8) (2.65 g) was reacted with chlorotriphenylmethane in pyridine under standard conditions (13) and normal work-up followed by chromatography on silica gel furnished with syrupy trityl ether **6** (3.5 g).

Anal. Calcd. for $C_{25}H_{26}O_5$: C, 73.87; H, 6.45. Found: (after drying at 80°): C, 73.89; H, 6.56.

Reaction of the trityl ether **6** (3.5 g) with acetic anhydride (40 ml) containing anhydrous sodium acetate (2 g) at 130° for 3 h, followed by normal work-up and fractional crystallization from ethanol gave (*i*) 1,2,4-tri-*O*-acetyl-3-deoxy-6-*O*-trityl-β-D-*ribo*-hexopyranose (**7**) (1.4 g), m.p. 200°, $[\alpha]_D$ +14° (*c*, 3.0 in chloroform); n.m.r. ($CDCl_3$): τ 2.43–2.86 (15-proton multiplet, trityl), 4.28 (1-proton doublet, $J_{1,2}$ = 8 Hz, H-1), 7.90, 7.96, 8.20 (3 × 3-proton singlets, 3 × $OCOCH_3$); and (*ii*) 1,2,5-tri-*O*-acetyl-3-deoxy-6-*O*-trityl-β-D-*ribo*-hexofuranose (8) (1.2 g), m.p. 137° $[\alpha]_D$ −39.5° (*c*, 2.0 in chloroform), −33.7° (*c*, 1.0 in pyridine); n.m.r. ($CDCl_3$): τ 2.50–2.84 (15-proton multiplet, trityl), 3.90 (1-proton broad singlet, separation < 1 Hz, H-1), 7.87, 7.92, 8.05 (3 × 3-proton singlets, 3 × $OCOCH_3$).

Anal. Calcd. for $C_{31}H_{32}O_8$: C, 69.90; H, 6.05. Found: (**7**): C, 70.25; H, 5.80. Found (**8**): C, 69.66; H, 5.89.

1,2,4-Tri-O-acetyl-3-deoxy-β-deoxy-β-D-ribo-hexopyranose (9)

Treatment of the trityl ether **7** (2.2 g) in acetic acid (20 ml) with hydrogen bromide (45%) in acetic acid (1.1 ml) at 0° for 3 min, followed by normal work-up and crystallization from ether – light petroleum afforded the triacetate **9** (580 mg), m.p. 86–88°, $[\alpha]_D$ −7.2° (*c*, 1.0 in chloroform); n.m.r. ($CDCl_3$): τ 4.40 (1-proton doublet, $J_{1,2}$ = 8 Hz, H-1), 7.90, 7.94, 7.96 (3 × 3-proton singlets, 3 × $OCOCH_3$).

Anal. Calcd. for $C_{12}H_{18}O_8$: C, 49.65; H, 6.20. Found: C, 49.54; H, 6.30.

1,2,4-Tri-O-acetyl-3-deoxy-6-O-(2,3,4,6-tetra-O-acetyl-β-D-glucopyranosyl)-β-D-ribo-hexopyranose (10)

(*a*) Condensation of 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl bromide (386 mg) and trityl ether **7** (500 mg) in nitromethane (15 ml) in the presence of Drierite (0.3 g) and silver perchlorate (0.58 g) at 80° for 10 min, followed by work-up as described previously (1) and crystallization from ethanol furnished the disaccharide derivative **10** (250 mg), m.p. 185–187°, $[\alpha]_D$ −14° (*c*, 1.0 in dichloromethane); n.m.r. ($CDCl_3$): τ 4.33 (1-proton doublet, $J_{1,2}$ = 8 Hz, H-1), 7.87–8.05 (7 × 3-proton singlets, 7 × $OCOCH_3$).

(*b*) Condensation of tetra-*O*-acetyl-α-D-glucopyranosyl bromide (1.1 g) and the triacetate **9** (0.59 g) in benzene (20 ml) in the presence of silver carbonate (0.9 g) and Drierite (2.5 g) for 48 h at room temperature, followed by filtration and concentration, afforded a crystalline product, which was recrystallized from methanol to give the acetylated disaccharide **10** (780 mg), m.p. 195–196°, $[\alpha]_D$ −15° (*c*, 1.0 in chloroform), whose n.m.r. spectrum was indistinguishable from that of the previous sample.

Anal. Calcd. for $C_{26}H_{36}O_{17}$: C, 50.32; H, 5.85. Found: C, 60.60; H, 5.70.

2-Deoxy-5-O-β-D-glucopyranosyl-D-erythro-pentose (4)

Reaction of the acetylated disaccharide **10** (50 mg) in methanol (5 ml) with 0.1 *M* methanolic sodium methoxide (1 ml) for 45 min, followed by treatment with Amberlite resin IR-120(H) and concentration furnished 3-deoxy-6-*O*-β-D-glucopyranosyl-D-*ribo*-hexose, $[\alpha]_D$ −8° (*c*, 1.0 in water). The disaccharide (20 mg) was oxidized in aqueous 0.05 *M* periodic acid (25 ml) at 5° for 3 h (1 mol of reagent was consumed per mole of disaccharide (17)), the solution was neutralized with barium hydroxide, and precipitated barium salts were removed by filtration. The solution was

treated with cation and anion exchangers and concentrated to a syrup, which was shown by paper chromatography to contain only disaccharide **4**, $R_{glucose}$ 1.9 in solvent *A*. The disaccharide was reduced with sodium borohydride, as described previously, and the resulting disaccharide alditol was methylated (15). The methylated disaccharide alditol (**5**) gave a single peak on examination by g.l.c. on column *b* (*T* 0.48) and its mass spectrum was identical with that of the previously prepared sample.

GERALD O. ASPINALL, THINNAYAM N. KRISHNAMURTHY, WALTER MITURA, and MASUO FUNABASHI. Can. J. Chem. **53**, 2182 (1975).

Two methylated disaccharides, methyl [methyl 4-*O*-(2,3,4,6-tetra-*O*-methyl-α-D-glucopyranosyl)-2,3-di-*O*-methyl-β-D-glucopyranosid]uronate (**9**) and methyl 6-*O*-(methyl 2,3,4-tri-*O*-methyl-α-D-galactopyranosyluronate)-2,3,4-tri-*O*-methyl-β-D-glucopyranoside (**15**) have been synthesized and used as model compounds for the study of the base-catalyzed β-elimination of 4-*O*-substituted hexopyranosiduronates without degradation of exposed reducing sugars and of the selective acid hydrolysis of hex-4-enopyranosiduronates.

GERALD O. ASPINALL, THINNAYAM N. KRISHNAMURTHY, WALTER MITURA et MASUO FUNABASHI. Can. J. Chem. **53**, 2182 (1975).

On a synthétisé deux disaccharides méthylés, le méthyl [méthyl 4-*O*-(2,3,4,6-tétra-*O*-méthyl-α-D-glucopyrannosyl)-2,3-di-*O*-méthyl-β-D-glucopyrannoside]uronate (**9**) et le méthyl 6-*O*-(méthyl-2,3,4-tri-*O*-méthyl-α-D-galactopyrannosyluronate)-2,3,4-tri-*O*-méthyl-β-D-glucopyrannoside (**15**). On s'en est ensuite servi comme produits de référence pour l'étude de la β-élimination par catalyse basique des hexopyrannoside uronates *O*-substitués en position 4 sans dégradation des sucres réducteurs exposés. Ces deux composés servent aussi à l'aide de l'hydrolyse acide sélective des hex-4 énopyrannosiduronates.

4-*O*-Substituted hexuronate residues, which are readily formed on esterification of many acidic polysaccharides, are susceptible to base-catalyzed degradation with the formation of unsaturated hexuronates and with the exposure of new reducing groups (1, 2). The reactions outlined in Scheme 1 must be considered if this degradation is to be used effectively to isolate fragments both exterior and interior to points of cleavage, and thus to obtain new structural information on polysaccharides. The first requirement is that the reaction is performed in a nonaqueous solvent using a base of low nucleophilicity towards ester functions ($k_1 \gg k_2$) so that the driving force of the carboalkoxy group is maintained. It is also desirable that protecting groups for hydroxyl functions are stable to the reaction conditions. Since β-elimination results in the exposure of reducing sugar residues the isolation of fragments exterior to the points of cleavage requires that reducing sugars should be either stable under the reaction conditions or protected against further degradation ($k_3 \ll k_4$). The fragments interior to the points of cleavage will be terminated by hex-4-enopyranosyluronate residues and should be amenable to characterization either directly or after selective hydrolysis of the acid-labile hex-4-enopyranosiduronate residues with minimum cleavage of other glycosidic linkages. We report here syntheses of the methylated disaccharides **9** and **15** as model compounds for an examination of these reaction requirements.

The methylated disaccharides **9** and **15** were chosen as model compounds since they would be expected to furnish known compounds on degradation. Attempts to synthesize methyl 2,2′,3,3′,4,6′-hexa-*O*-methyl-β-maltoside (**8**) from 1,6-anhydro-2,2′,3,3′,4,6′-hexa-*O*-methylmaltose involving ring opening by acetolysis, conversion into the glycosyl halide, and glycosidation were unsuccessful due to the acid-lability of the interresidue glycosidic linkage during formation of

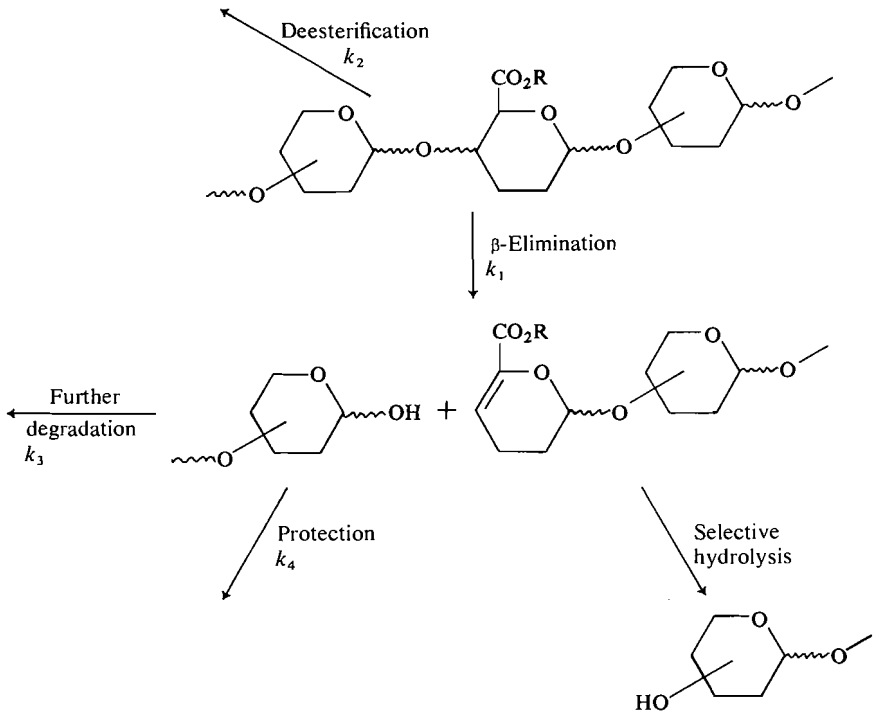

SCHEME 1. Base-catalyzed β-elimination of 4-*O*-substituted hexuronate residues.

the glycosyl halide. The disaccharide derivative **8** was then prepared from methyl β-maltoside in a rather lengthy series of reactions involving *O*-benzylidenation to give **1**, acetylation (to **2**), de-*O*-benzylidenation (to **3**), methylation using diazomethane – boron trifluoride in order to retain base-labile substituents (3) (to **4**), de-*O*-acetylation (to **5**), selective tritylation (to **6**), methylation (to **7**), and de-*O*-tritylation. Oxidation of the hexamethyl ether **8** with chromium trioxide and sulfuric acid in acetone (4) followed by esterification with diazomethane furnished methyl [methyl 4-*O*-(2,3,4,6-tetra-*O*-methyl-α-D-glucopyranosyl)-2,3-di-*O*-methyl-β-D-glucopyranosid]uronate (**9**).

In the above series of reactions it was essential to ensure that 0–6′ was alkylated during the formation of the dimethyl ether **4** and that the process was not accompanied by acetyl migration. Examination of the mass spectrum (5, 6) of the disaccharide derivative provided evidence for the location of the methoxyl substituents. Although the mass spectra of acetylated disaccharides show relatively weak peaks in the high mass range, the following observations (see Scheme 2) supported the proposed structure: (*i*) only a weak molecular ion at *m/e* 594 was observed but fragment ions at *m/e* 563 ($M - CH_3O\cdot$), 562 ($M - CH_3OH$), 535 ($M - CH_3CO_2\cdot$), 534 ($M - CH_3CO_2H$), 503 ($M - CH_3O\cdot - CH_3CO_2H$), 502 ($M - CH_3OH - CH_3CO_2H$), and 475 ($M - CH_3CO_2\cdot - CH_3CO_2H$) provided indirect confirmation of the molecular weight; (*ii*) the fragment ion at *m/e* 549 ($M - CH_3OCH_2\cdot$) pointed to the presence of a primary methoxy substituent; (*iii*) fragment ions of high relative intensity from cleavage of the different bonds at the glycosidic linkage were observed at *m/e* 275 and 303 (*cf.* those from other maltose derivatives (7)); (*iv*) the formation of the fragment ion at *m/e* 275 indicated that the nonreducing residue in the disaccharide **4** contained two methoxyl groups and the successive formation of ions at *m/e* 215 and 173, which was supported by the appearance of the relevant metastable peaks, was consistent with the proposed location of *O*-methyl and *O*-acetyl substituents.

Reaction of the methylated disaccharide **9** with DBU (1,5-diazabicyclo[5.4.0]undec-5-ene) in benzene resulted in β-elimination but under these conditions the liberated 2,3,4,6-tetra-*O*-

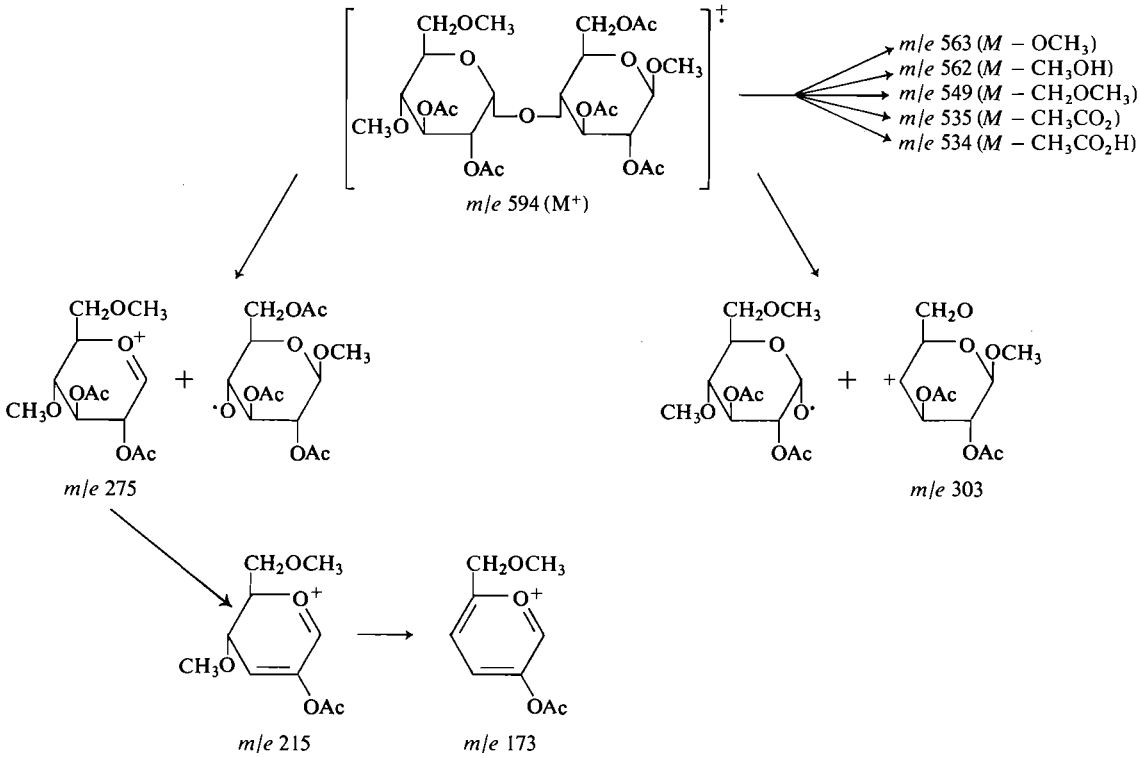
methyl-D-glucose (**11**) was further degraded, probably with formation of 3-deoxy-2,4,6-tri-*O*-methyl-D-*erythro*-hex-2-enopyranose (8, 9). However, similar reaction in the presence of added acetic anhydride resulted in protection of the reducing sugar, and chromatography of the products furnished methyl (methyl 4-deoxy-2,3-di-*O*-methyl-α-L-*threo*-hex-4-enopyranosid)uronate (**10**) (10) and a mixture of 1-acetates from which 2,3,4,6-tetra-*O*-methyl-D-glucose (**11**) was isolated after de-*O*-acetylation.

Methyl 6-*O*-(methyl 2,3,4-tri-*O*-methyl-α-D-galactopyranosyluronate)-2,3,4-tri-*O*-methyl-β-D-glucopyranoside (**15**) was prepared from methyl β-melibioside in a sequence of reactions involving *O*-tritylation to give **12**, methylation (to **13**), de-*O*-tritylation (to **14**), and oxidation with chromium trioxide and sulfuric acid in acetone followed by esterification with diazomethane. Reaction of the methylated disaccharide **15** in boiling benzene with DBU – acetic anhydride or DBU alone afforded the unsaturated di-



SCHEME 2. Mass spectral fragmentation of methyl 2,2′,3,3′,6-penta-*O*-acetyl-4′,6′-di-*O*-methyl-β-maltoside (**4**).

saccharide, methyl 6-*O*-(methyl 4-deoxy-2,3-di-*O*-methyl-β-L-*threo*-hex-4-enopyranosyluronate)-2,3,4-tri-*O*-methyl-β-D-glucopyranoside (**16**). Selective hydrolysis of the hex-4-enopyranosiduronate with no detectable cleavage of the methyl glycosidic linkage occurred on heating with cation exchanger in aqueous acetone at 70° or with aqueous acetic acid at 100° and methyl 2,3,4-tri-*O*-methyl-β-D-glucopyranoside (**17**) was isolated. These latter conditions have been used by Lindberg *et al.* (2) for the selective cleavage of unsaturated hexuronate residues from methylated acidic polysaccharides after degradation with methylsulfinyl carbanion in methyl sulfoxide.

An application of the reactions described here to polysaccharide structure determination is reported in the following paper (11).

Experimental

Unless otherwise stated experimental conditions were as described in part VII (12).

Methyl 4′,6′-O-Benzylidene-β-maltoside (1) and Derived Pentaacetate (2)

Dry methyl β-maltoside (20 g) and freshly crushed zinc chloride sticks (40 g) were shaken in freshly distilled benzaldehyde (200 ml) for 24 h and the reaction mixture was poured into ether. The precipitate was removed by filtration and washed twice with ether to give a powdery residue, a portion of which was recrystallized from ether–methanol to give methyl 4′,6′-*O*-benzylidene-β-maltoside (**1**), m.p. 140–141°, $[\alpha]_D$ +47.6° (*c*, 2.0 in ethanol).

Anal. Calcd. for $C_{20}H_{28}O_{11}$: C, 53.77; H, 6.62; OCH_3, 6.86. Found: C, 54.04; H, 6.35; OCH_3, 7.01.

Powdery **1** was treated with acetic anhydride (300 ml) in pyridine (600 ml) for 2 days, the reaction mixture was worked-up in the usual way, and recrystallization from ethanol furnished methyl 2,2′,3,3′,6-penta-*O*-acetyl-4′,6′-*O*-benzylidene-β-maltoside (**2**) (20 g), m.p. 200–201°, $[\alpha]_D$ +25.4° (*c*, 1.9 in chloroform); M^+, 654; n.m.r. ($CDCl_3$): τ 2.45–2.70 (5-proton multiplet, phenyl), 4.30 (1-proton singlet, benzylidene-methine), 6.50 (3-proton singlet, OCH_3), 7.85–8.22 (15-protons, 5 × $OCOCH_3$).

Anal. Calcd. for $C_{30}H_{38}O_{16}$: C, 55.04; H, 5.85; OCH_3, 4.73. Found: C, 54.94; H, 5.77; OCH_3; 4.66.

Methyl 2,2′,3,3′,6-Penta-O-acetyl-β-maltoside (3)

The benzylidene derivative **2** (20 g) was heated in acetic acid – water (7:3, 250 ml) on the boiling water bath for 30 min. The reaction mixture was diluted with water (2 volumes), extracted with light petroleum, and repeatedly concentrated after addition of water to a residue (14 g) which crystallized in ether. Recrystallization from ether – ethyl acetate afforded the pentaacetate (**3**) (10 mg), m.p. 152–153°, $[\alpha]_D$ +41° (*c*, 1.0 in dichloromethane); n.m.r. ($CDCl_3$): τ 4.75 (1-proton doublet, $J_{1',2'}$ = 4 Hz, H-1′), 5.60 (1-proton doublet, $J_{1,2}$ = 7.6 Hz, H-1), 6.60 (3-proton singlet, OCH_3), 7.93, 7.97, 8.00, 8.03, 8.06 (3-proton singlets, 5 × $OCOCH_3$).

Anal. Calcd. for $C_{23}H_{34}O_{16}$: C, 48.76; H, 6.63. Found: C, 49.04; H, 6.25.

Methyl 2,2′,3,3′,6-Penta-O-acetyl-4′,6′-di-O-methyl-β-maltoside (4)

Diazomethane in ether was added gradually to the pentaacetate (**3**) (5 g) in chloroform (50 ml) containing boron trifluoride etherate (50 mg) until a pale yellow color persisted. Methanol was added to destroy diazomethane and the solution was concentrated to a syrup which was dissolved in chloroform, washed with sodium hydrogen carbonate solution, and concentrated. The resulting syrup crystallized from methanol to give the dimethyl ether **4** (3 g), m.p. 131–132°; n.m.r. ($CDCl_3$): τ 4.67 (1-proton doublet, $J_{1',2'}$ = 4 Hz, H-1′), 5.70 (1-proton doublet, $J_{1,2}$ = 8 Hz, H-1), 6.62–6.66 (3-proton singlets, 3 × OCH_3), 7.95–8.10 (3-proton singlets, 5 × $OCOCH_3$); mass spectrum *m/e* (% relative abundance) 594(0.01) (M^+), 563(0.03) ($M - CH_3O$)$^+$, 562(0.01) ($M - CH_3OH$)$^+$, 549(0.2) ($M - CH_3OCH_2$)$^+$, 535(0.02) ($M - CH_3CO_2$)$^+$, 534(0.02) ($M - CH_3CO_2H$)$^+$, 503(0.1) ($M - CH_3OH - CH_3CO_2$)$^+$, 502(0.07) ($M - CH_3OH - CH_3CO_2H$), 475(4.2) ($M - CH_3CO_2H - CH_3CO_2$)$^+$, 303(64), 275(73), 215(86), 173(93), 43(100) $(CH_3CO)^+$.

Methyl 4′,6′-Di-O-methyl-β-maltoside (5)

The penta-*O*-acetyl dimethyl ether **4** (5 g) in methanol (50 ml) was de-*O*-acetylated by reaction with sodium methoxide (from 0.1 g sodium) in methanol (3 ml) for 16 h. The solution was shaken with Dowex 50(H) resin and concentration of the filtrate gave a syrup (3 g) which crystallized from ether–methanol to give the dimethyl ether **5** (2.1 g), m.p. 154–155°, $[\alpha]_D$ +70.5° (*c*, 1.4 in methanol); n.m.r. ($CDCl_3$): τ 4.65 (1-proton doublet, $J_{1',2'}$ = 4 Hz, H-1′), 5.65 (1-proton doublet, $J_{1,2}$ = 8 Hz, H-1), 6.42 (6-proton singlet, 2 × OCH_3), 6.62 (3-proton singlet, OCH_3).

Anal. Calcd. for $C_{15}H_{28}O_{11}$: C, 46.87; H, 7.34. Found: C, 47.14; H, 7.31.

Methyl 4′,6′-Di-O-methyl-6-O-trityl-β-maltoside (6)

The foregoing dimethyl ether **5** (5 g) in pyridine (50 ml) containing chlorotriphenylmethane (5.5 g) was heated on the boiling water bath for 1 h and kept at room temperature for 24 h. The reaction mixture was poured into ice water to give a syrupy mass which was extracted with chloroform and the chloroform layer was washed with water, dried, and concentrated to a syrup (10 g). Chromatography on silica gel using chloroform–acetone (9:1) as eluant furnished a syrup (7.7 g) which crystallized from methanol to give the dimethyl trityl ether **6** (4.5 g), m.p. 105°, $[\alpha]_D$ +49° (*c*, 2.1 in chloroform); n.m.r. ($CDCl_3$): τ 2.30–2.80 (15-proton multiplet, 3 × phenyl), 6.38, 6.50, 6.70 (3 × 3-proton singlets, 3 × OCH_3).

Anal. Calcd. for $C_{34}H_{42}O_{11}$: OMe, 14.85. Found: OMe, 14.59.

Methyl 2,2′,3,3′,4′,6′-Hexa-O-methyl-6-O-trityl-β-maltoside (7)

Sodium hydride (1 g) was added to the dimethyl trityl ether **6** (4.1 g) in *N*,*N*-dimethylformamide (50 ml) at 0°, the mixture was stirred for 0.5 h, methyl iodide (6 g) was added during 20 min, and the mixture was stirred with cooling for 2 h, and kept at room temperature overnight. Methanol was added to destroy excess of sodium hydride, the mixture was filtered, and the filtrate was concentrated to a syrup which was diluted with chloroform, washed with water, and concentrated again. The resulting hexamethyl trityl ether **7** (4.0 g) was chromatographically pure and had $[\alpha]_D$ +46.5° (*c*, 1.0 in chloroform); n.m.r. ($CDCl_3$): τ 2.40–2.80 (15-proton multiplet, 3 × phenyl), 5.75 (1-proton doublet, $J_{1,2}$ = 8 Hz, H-1), 6.25–6.65 (3-proton singlets, 7 × OCH_3).

Anal. Calcd. for $C_{38}H_{50}O_{11}$: C, 66.84; H, 7.38. Found: C, 66.83, H; 7.51.

Methyl 2,2′,3,3′,4′,6′-Hexa-O-methyl-β-maltoside (8)

The foregoing hexamethyl trityl ether **7** (4 g) in acetic acid – water (100 ml, 7:3) was heated on the boiling water bath for 1 h. The cooled solution was diluted with water, filtered to remove precipitated triphenylmethanol, concentrated to remove acetic acid, diluted again with water, and the whole procedure was repeated twice. The final syrup was dissolved in methanol and the solution was filtered through charcoal and concentrated to give methyl 2,2′,3,3′,4′,6′-hexa-*O*-methyl-β-maltoside (**8**) (2.3 g), $[\alpha]_D$ +67° (*c*, 5.25 in chloroform); n.m.r. ($CDCl_3$): τ 5.75 (1-proton singlet, $J_{1,2}$ = 8 Hz, H-1), 6.30–6.60 (3-proton singlets, 7 × OCH_3).

Anal. Calcd. for $C_{19}H_{36}O_{11}$: C, 51.81; H, 8.24. Found: C, 52.11; H, 8.34.

Methyl [Methyl 4-O-(2,3,4,6-Tetra-O-methyl-β-D-glucopyranosyl)-2,3-di-O-methyl-β-D-glucopyranosid]uronate (9)

Chromium trioxide (3 g) in 3.75 *N* sulfuric acid was added dropwise to methyl hexa-*O*-methyl-β-maltoside (**8**) (2.3 g) in acetone (5 ml) at 5°. Reaction was complete after 12 h and the mixture was chromatographed on a column of silica gel (20 g) using chloroform–acetone (7:3) as eluant to give chromatographically pure acidic disaccharide (2 g). Diazomethane in ether was added with stirring to the acidic disaccharide in ether until t.l.c. showed that esterification was complete. Concentration of the solution afforded chromatographically pure methylated acidic disaccharide **9** (2 g), $[\alpha]_D$ +71° (*c*, 1.0 in chloroform); n.m.r. ($CDCl_2$); τ 5.75 (1-proton doublet, $J_{1,2}$ = 7 Hz, H1), 6.25 (3-proton singlet, ester OCH_3), 6.38–6.60 (3-proton singlets, 7 × OCH_3).

Anal. Calcd. for $C_{20}H_{36}O_{12}$: C, 51.81; H, 8.24. Found: C, 52.11; H, 8.34.

Action of Base on Methyl [Methyl 4-O-(2,3,4,6-Tetra-O-methyl-α-D-glucopyranosyl)-2,3-di-O-methyl-β-D-glucopyranosid]uronate

A sample of methylated acidic disaccharide **9** was heated under reflux in benzene containing 1,5-diazabicyclo[5.4.0]undec-5-ene (DBU). Thin-layer-chromatography indicated the formation of the unsaturated hexuronate **10** and 2,3,4,6-tetra-*O*-methylglucose (**11**) but when reaction was prolonged to ensure disappearance of starting compound a further product with the mobility of 3-deoxy-2,4,6-tri-*O*-methyl-D-*erythro*-hex-2-enopyranose was formed.

Methylated acidic disaccharide **9** (250 mg) was heated under reflux for 24 h in benzene (10 ml) containing DBU (1.6 g) and acetic anhydride (0.9 g). The reaction mixture was separated by preparative-layer chromatography on

silica gel with chloroform–acetone (9:1) to give (*i*) methyl (methyl 4-deoxy-2,3-di-*O*-methyl-α-L-*threo*-hex-4-enopyranosid)uronate (**10**) (61 mg), m.p. and mixture m.p. 51–52°, whose n.m.r., u.v., and mass spectra were identical with those of an authentic specimen; (*ii*) a mixture of α- and β-acetates of 2,3,4,6-tetra-*O*-methyl-D-glucose (98 mg); and (*iii*) an incompletely separated mixture of the compounds in *i* and *ii*. Treatment of the mixed acetates with methanolic sodium methoxide in the usual way furnished 2,3,4,6-tetra-*O*-methyl-D-glucose (**11**), m.p. and mixture m.p. 92–93°, $[\alpha]_D$ +80.5° (*c*, 1.2 in water).

Methyl 6′-O-Trityl-β-melibioside (12)

Reaction of methyl β-melibioside (13) (5 g) with chlorotriphenylmethane in pyridine under standard conditions (14) followed by normal work-up and recrystallization from toluene furnished methyl 6′-*O*-trityl-β-melibioside (**12**), m.p. 211–212°, $[\alpha]_D$ +26° (*c*, 1.0 in methanol); n.m.r. ($CDCl_3$): τ 2.52–2.97 (15-proton multiplet, 3 × phenyl), 6.45 (3-proton singlet, OCH_3).

Anal. Calcd. for $C_{32}H_{38}O_{11}$: C, 64.21; H, 6.35. Found: C, 64.12; H, 6.42.

Methyl 2,2′,3,3′,4,4′-Hexa-O-methyl-6′-O-trityl-β-melibioside (13)

The trityl ether **12** (5 g) was methylated with methyl iodide and sodium hydride in *N,N*-dimethylformamide (15), as described previously, and the desired hexamethyl trityl ether **13** (5.1 g), after recrystallization from ethanol, had m.p. 133–135°, $\alpha[_D]$ +39.6° (*c*, 1.9 in chloroform); n.m.r. ($CDCl_3$): τ 2.52–2.97 (15-proton multiplet, 3 × phenyl), 5.87 (1-proton doublet, $J_{1,2}$ = 7 Hz, H-1), 6.36–6.61 (3-proton singlets, 7 × OCH_3).

Anal. Calcd. for $C_{38}H_{50}O_{11}$: C, 66.84; H, 7.38. Found: C, 67.10; H, 7.31.

Methyl 2,2′,3,3′,4,4′-Hexa-O-methyl-β-melibioside (14)

The foregoing compound **13** (5 g) in acetic acid – water (75 ml, 4:1) was heated on the boiling water bath for 1 h. Normal work-up gave a syrup (ν_{max} (film) 1730 cm^{-1}, ester C=O) in which t.l.c. showed a major product with a small amount of a compound of higher mobility. De-*O*-acetylation of the syrup with methanolic sodium methoxide gave a single product which was recrystallized from ethanol gave the hexamethyl ether **14** (2.6 g), m.p. 110–111°, $[\alpha]_D$ +80° (*c*, 1.1 in chloroform); n.m.r. ($CDCl_3$): τ 4.83 (1-proton doublet, $J_{1',2'}$ = 3.5 Hz, H-1′), 5.83 (1-proton doublet, $J_{1,2}$ = 7.5 Hz, H-1), 6.34, 6.38, 6.40, 6.43, 6.44, 6.46, 6.47 (3-proton singlets, 7 × OCH_3).

Anal. Calcd. for $C_{19}H_{36}O_{11}$: C, 51.81; H, 8.24. Found: C, 51.49; H, 8.36.

Methyl 6-O-(Methyl 2,3,4-Tri-O-methyl-α-D-galactopyranosyluronate)-2,3,4-tri-O-methyl-β-D-glucopyranoside (15)

Chromium trioxide (1.2 g) in 3.75 *N* sulfuric acid was added dropwise to methyl hexa-*O*-methyl-β-melibioside (**14**) (2 g) in acetone (7 ml) at 5°. Reaction was complete after 16 h and the mixture was chromatographed on a column of silica gel using benzene as eluant to give syrupy aldobiouronic acid (1.75 g) (ν_{max} (film) 2800, 1710 cm^{-1} (CO_2H)). Diazomethane in ether was added with stirring to the acidic disaccharide (1.6 g) in ether until t.l.c. showed that reaction was complete. Concentration of the solution followed by crystallization from light petroleum afforded methylated aldobiouronic ester **15** (1.6 g), m.p. 97–98°, $[\alpha]_D$ +82° (*c*, 1.2 in chloroform); ν_{max} (film) 1750 cm^{-1} (ester C=O); n.m.r. ($CDCl_3$): τ 4.83 (1-proton singlet, $J_{1',2'}$ = 3 Hz, H-1′), 5.82 (1-proton singlet, $J_{1,2}$ = 7.5 Hz, H-1), 6.16 (3-proton singlet, ester OCH_3), 6.37–6.46 (3-proton singlets, 7 × OCH_3).

Anal. Calcd. for $C_{20}H_{36}O_{12}$: C, 51.30; H, 7.69. Found: C, 51.52; H, 7.70.

Action of Base on Methyl 6-O-(Methyl 2,3,4-Tri-O-methyl-α-D-galactopyranosyluronate)-2,3,4-tri-O-methyl-β-D-glucopyranoside

Methylated aldobiouronic ester **15** (250 mg) was heated with DBU (0.5 g) in benzene (2 ml) in a sealed tube at 95–100° for 20 h. Thin-layer chromatography showed complete disappearance of starting compound. The solution was chromatographed on a silica gel column and elution with benzene afforded methyl 6-*O*-(methyl 4-deoxy-2,3-di-*O*-methyl-β-L-*threo*-hex-4-enopyranosyluronate)-2,3,4-tri-*O*-methyl-β-D-glucopyranoside (**16**) (185 mg), $[\alpha]_D$ +94° (*c*, 1.4 in chloroform); ν_{max} (film) 1740 (ester C=O), 1660 cm^{-1}; λ_{max} (MeOH) 238 nm (ε 6540); n.m.r. ($CDCl_3$): τ 3.90 (1-proton doublet, $J_{3',4'}$ = 4 Hz, H-4′), 4.75 (1-proton doublet, $J_{1',2'}$ = 3 Hz, H1′), 6.22 (3-proton singlet, ester OCH_3), 6.40–6.55 (6 × 3-proton singlets, 6 × OCH_3). The same reaction took place when methylated aldobiouronic ester **15** was heated with DBU and acetic anhydride in benzene.

Anal. Calcd. for $C_{19}H_{32}O_{11}$: C, 52.30; H, 7.34. Found: C, 51.98; H, 7.25.

Hydrolysis of the Unsaturated Disaccharide 16

Unsaturated disaccharide **16** (30 mg) in 6.7% aqueous acetic acid (3 ml) was heated on the boiling water bath for 1 h. Thin-layer chromatography showed complete disappearance of starting compound with the formation of a single detectable product. Concentration of the solution with repeated additions of water afforded a syrup which crystallized from light petroleum – ethanol to give methyl 2,3,4-tri-*O*-methyl-β-D-glucopyranoside (**17**) (11 mg), m.p. and mixture m.p. 92–93°, $[\alpha]_D$ −23° (*c*, 1.0 in chloroform), which gave a single peak on g.l.c. The unsaturated disaccharide **16** also underwent complete hydrolysis with formation of the glucoside **17** when heated at 70° with stirring with Amberlite resin IR-120(H) in acetone–water (7:3) for 4 h.

Base-catalyzed Degradations of Carbohydrates. X. Degradation by β-Elimination of Methylated Degraded Leiocarpan A[1]

GERALD O. ASPINALL[2] AND ATMARAM S. CHAUDHARI

Department of Chemistry, York University, Downsview, Toronto, Ontario M3J 1P3

Received March 18, 1975

GERALD O. ASPINALL and ATMARAM S. CHAUDHARI. Can. J. Chem. **53**, 2189 (1975).

Treatment of methylated degraded leiocarpan A with 1,5-diazabicyclo[5.4.0]undec-5-ene and acetic anhydride, followed by mild acid hydrolysis and de-*O*-acetylation, furnishes 3,4,6-tri-*O*-methyl-D-mannose and 3,4-di-*O*-methyl-6-*O*-(2,3,4-tri-*O*-methyl-β-D-xylopyranosyl)-D-mannose. The characterization of the methylated disaccharide provides evidence for the site of attachment and anomeric configuration of the D-xylopyranose end groups in the parent polysaccharide.

GERALD O. ASPINALL et ATMARAM S. CHAUDHARI. Can. J. Chem. **53**, 2189 (1975).

Le traitement de la forme méthylée du léiocarpan A dégradé avec le diaza-1,5 bicyclo[5.4.0]-undécène-5 et l'anhydride acétique, suivie d'une hydrolyse acide douce et d'une *O*-déacétylation, conduit aux composés 3,4,6-tri-*O*-méthyl-D-mannose et 3,4-di-*O*-méthyl-6-*O*-(2,3,4-tri-*O*-méthyl-β-D-xylopyrannosyl)-D-mannose. La caractérisation du disaccharide méthylé donne la preuve de la position d'attachement et de la configuration anomérique des groupes terminaux du *D*-xylopyrannose dans la polysaccharide mère.

Leiocarpan A, the major polysaccharide component of the gum exudate from *Anogeissus leiocarpus* contains interior chains of alternating 4-*O*-substituted β-D-glucuronic acid and 2-*O*-substituted α-D-mannopyranose residues (1–3). Previous studies on this polysaccharide showed that side chains of single D-xylopyranose and L-arabinofuranose are probably linked to 0–6 and 0–3, respectively, of some of the D-mannopyranose residues but the evidence was indirect and no information was available on the configuration of the glycosidic linkages. Since partial acid hydrolysis of leiocarpan A (1) and acetolysis of the carboxy-reduced polysaccharide (2) were shown to cause preferential liberation of the pentose sugars in the side chains we have now examined base-catalyzed degradation as an alternative approach to the isolation of oligosaccharides with intact side chains. Using procedures developed using model compounds (4) we describe here the base-catalyzed degradation of methylated degraded leiocarpan A.

Autohydrolysis of leiocarpan A has been shown to be a convenient procedure for the selective cleavage of L-arabinofuranose residues with only partial removal of D-xylopyranose end groups (2). Previous studies (2) established the identity of the component sugars of methylated degraded leiocarpan A. Quantitative analyses of the methylated sugars formed from reduced methylated degraded leiocarpan A (**1**) and from this reduced polysaccharide after remethylation of exposed hydroxyl groups by g.l.c. of the partially methylated alditol acetates (5) have now shown that the major components, 2,3,4-tri-*O*-methyl-D-xylose, 2,3-di-*O*-methyl-D-glucuronic acid, 3,4,6-tri- and 3,4-di-*O*-methyl-D-mannose, are present in the molar ratio of 2:5:3:2. Methylated degraded leiocarpan A was heated with DBU (1,5-diazabicyclo[5.4.0]undec-5-ene) and acetic anhydride in benzene in a sealed tube, the unsaturated hexuronate residues were cleaved by heating with aqueous acetic acid and de-*O*-acetylation gave two neutral sugar fractions which were separated chromatographically to give 3,4,6-tri-*O*-methyl-D-mannose (**2**) and the partially methylated disaccharide, 3,4-di-*O*-methyl-6-*O*-(2,3,4-tri-*O*-methyl-β-D-xylopyranosyl)-D-mannose (**3**) (Scheme 1). The structure of disaccharide **3** was assigned on the basis of the following observations: (*i*) methanolysis gave methyl glycosides of 2,3,4-di-*O*-methylxylose and and 3,4-di-*O*-methylmannose; (*ii*) hydrolysis, followed by reduction with borohydride and acetylation gave peracetates of 2,3,4-tri-*O*-methylxylitol and 3,4-di-*O*-methylmannitol; (*iii*)

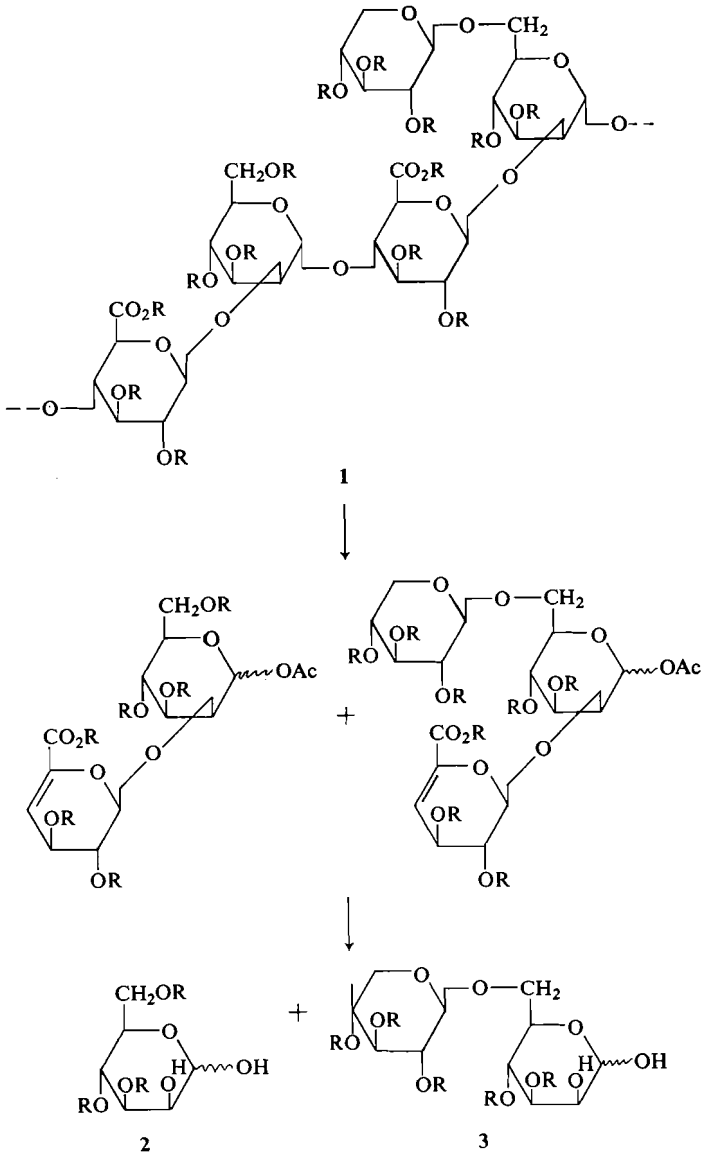

SCHEME 1. Degradation of methylated degraded leiocarpan A (R = CH_3).

reduction with borohydride, methanolysis, and acetylation gave methyl glycosides of 2,3,4-tri-*O*-methylxylose and 3,4-di-*O*-methylmannitol tetraacetate; (*iv*) reduction with borohydride gave a crystalline disaccharide alditol (**4**) which afforded a methylated derivative (**5**) whose n.m.r. spectrum showed a doublet (τ 5.70, J = 7 Hz) characteristic for H-1′ of a β-D-xyloside; (*v*) the mass spectra of methylated (**5**), trideuteriomethylated (**6**), and acetylated (**7**) derivatives whose mass spectra showed primary fragments (Scheme 2) and ions of the type **8**–**10** (6) which were consistent with the assigned structure. Of these derivatives the methylated (**5** and **6**) but not the acetylated (**7**) were sufficiently stable for examination by g.l.c. – mass spectrometry.

These experiments provide direct evidence for the site of attachment and for the glycosidic configuration of the D-xylopyranose end groups in leiocarpan A. The degradative procedure should be applicable to other similar structural problems in polysaccharide chemistry which have so

7 R = $COCH_3$

8 R = CH_3 *m/e* 295
9 R = CD_3 *m/e* 304
10 R = $COCH_3$ *m/e* 379

SCHEME 2. Mass spectral fragmentations of derivatives of 3,4-di-*O*-methyl-6-*O*-(2,3,4-tri-*O*-methyl-β-D-xylopyranosyl)-D-mannitol; *m/e* values are for ions from derivatives **5**, **6**, and **7**, respectively.

far resisted solution and relevant experiments are in progress. In the event that in some instances only limited quantities of methylated acidic polysaccharides might be available, the degradation was repeated using 30 mg[3] of methylated degraded leiocarpan A and the results gave clear information on the type, *i.e.* 1 → 6, but not on the configuration of the intact linkage in the disaccharide (**3**). The crude mixture of products from the methylated polysaccharide, without further purification, was reduced with sodium borohydride, portions of the derived alditols were methylated with (*a*) methyl iodide and (*b*) trideuteriomethyl iodide, and the resulting mixtures were analyzed directly by g.l.c. – mass spectrometry. The two major components gave mass spectra with characteristic fragment ions for hexa-*O*-methylmannitol (or its isotopically labelled derivative) and the methylated disaccharide alditol (**5** or **6**).

Experimental

Unless otherwise stated experimental conditions were as described in part VII (7).

Quantitative Analysis of Sugars from Reduced Methylated Degraded Leiocarpan A and its Remethylated Derivative

Reduced methylated degraded leiocarpan A (**2**) (20 mg) was further methylated with methyl iodide and sodium hydride in methyl sulfoxide (8) to give methylated reduced degraded leiocarpan A (16 mg), $[\alpha]_D$ −1° (*c*, 1.0 in chloroform) (Found: OMe, 42.5%), whose i.r. spectrum showed no hydroxyl absorption. Samples of both methylated polysaccharide derivatives were hydrolyzed, reduced with sodium borohydride, and acetylated to give mixtures of partially methylated alditol acetates (5) which were estimated and identified by g.l.c. on column *c* (see Table 1). Qualitative identification of the sugar components was also obtained by g.l.c. on column *a* of the methyl glycosides formed on methanolysis.

Base-catalyzed Degradation of Methylated Degraded Leiocarpan A

Methylated degraded leiocarpan A (300 mg) in benzene (12 ml) containing DBU (6 ml) and acetic anhydride (3 ml) was heated in a sealed tube at 100° for 24 h. A sample of the reaction product was washed with *M* hydrochloric acid and the benzene layer was washed with water, dried, and concentrated. The resulting syrup was methanolyzed and examination of the mixture of methyl glycosides by g.l.c. on column *a* showed the almost complete absence of derivatives of 2,3-di-*O*-methyl-glucuronic acid. The major part of the reaction product was chromatographed on a column of silica gel with chloroform–ethanol (9:1) as eluant. Coloring matter and much of the DBU was retained on the column, and the eluate was shaken with Amberlite resins IR-120(H) and IR-45(OH) and concentrated to a syrup (610 mg). The crude syrup was heated in aqueous 10% acetic acid at 100° for 1 h, acetic acid was removed by repeated evaporations after addition of water, and the residue was extracted with chloroform, dried, and concentrated. Methanolic sodium methoxide was added dropwise to the syrup (530 mg) in methanol until a permanent alkalinity was maintained and the solution was kept for 4 h, neutralized by treatment with Amberlite resin IR-120(H), and concentrated. The crude syrup (450 mg) was purified by preparative-layer chromatography to give a mixture (180 mg) of reducing sugars in which two major components were present. The syrup was adsorbed on a column (15 × 2.5 cm) of charcoal–Celite (1:1) and the column was eluted with water containing increasing proportions (up to 15%) of butanone. Although complete separation was not achieved subsequent preparative-layer chromatography on silica gel using chloroform–ethanol (9:1) as eluant gave chromatographically homogeneous samples of (*i*) 3,4,6-tri-*O*-methyl-D-mannose (45 mg), which was characterized by g.l.c. of the methyl glycoside on column *a* and of the derived alditol acetate on column *c*, and (*ii*) disaccharide **3** (42 mg), $[\alpha]_D$ −17° (*c*, 1.0 in methanol).

[3]Substantially smaller quantities could be used.

45	35	48	51	73	13

*Relative abundances are quoted with reference to that of the 2,3,4-tri-*O*-methyl-D-xylopyranosyl ion (*m/e* 175) which is common to each spectrum.

Characterization of 3,4-Di-O-methyl-6-O-(2,3,4-tri-O-methyl-β-D-xylopyranosyl)-D-mannose (3)

Methanolysis of the disaccharide gave compounds which had the retention times of methyl glycosides of 2,3,4-tri-*O*-methylxylose (*T* 0.48, 0.55) and 3,4-di-*O*-methylmannose (*T* 5.53) on column *a*. Hydrolysis of the disaccharide, followed by reduction with sodium borohydride and acetylation, gave compounds with the retention times of the peracetates of 2,3,4-tri-*O*-methylxylitol (*T* 0.65) and 3,4-di-*O*-methylmannitol (*T* 5.5) on column *c*. Reduction of the disaccharide with sodium borohydride, followed by methanolysis and acetylation, furnished compounds with the retention times of methyl glycosides of 2,3,4-tri-*O*-methylxylose (*T* 0.48, 0.55 on column *a*) and 3,4-di-*O*-methylmannitol tetraacetate (*T* 5.5 on column *c*).

Reduction of disaccharide **3** (30 mg) with sodium borohydride followed by normal work-up furnished 3,4-di-*O*-methyl-6-*O*-(2,3,4-tri-*O*-methyl-β-D-xylopyranosyl)-D-mannitol (**4**) (27 mg), m.p. 116–118°, $[\alpha]_D$ −20° (*c*, 1.0 in methanol).

Anal. Calcd. for $C_{16}H_{32}O_{10}$: OMe, 40.37. Found: OMe, 40.66.

The disaccharide alditol **4** (20 mg) was methylated with methyl iodide and sodium hydride in *N,N*-dimethylformamide (9) to give 1,2,3,4,5-penta-*O*-methyl-6-*O*-(2,3,4-tri-*O*-methyl-β-D-xylopyranosyl)-D-mannitol (**5**) (19 mg), $[\alpha]_D$ −17° (*c*, 1.0 on methanol); n.m.r. ($CDCl_3$): τ 5.75 (1-proton doublet, $J_{1',2'}$ = 8 Hz, H-1'), 6.37–6.55 (overlapping 3-proton singlets, 8 × OCH_3). The disaccharide alditol **4** was similarly converted into the 1,2,5-tri-*O*-(trideuteriomethyl) derivative **6**. Treatment of the disaccharide alditol **4** with acetic anhydride in pyridine under standard conditions furnished the 1,2,5-tri-*O*-acetyl derivative **7**. The relative intensities of the structurally significant fragment ions (see Scheme 2) observed in the mass spectra of the *O*-methyl (**5**), *O*-trideuteriomethyl (**6**), and *O*-acetyl (**7**) derivatives are shown in Table 2.

Base-catalyzed Degradation of Methylated Degraded Leiocarpan A and Direct Characterization of Products by Gas-Liquid Chromatography – Mass Spectrometry

Methylated degraded leiocarpan A (30 mg) in benzene (1.2 ml) containing DBU (0.6 ml) and acetic anhydride (0.3 ml) was heated in a sealed tube at 100° for 24 h. The reaction product was washed with *M* hydrochloric acid and the benzene layer was washed with water, dried, and concentrated. The resulting syrup was heated with aqueous acetic acid, de-*O*-acetylated with sodium methoxide, and reduced with sodium borohydride as described previously. One portion of the product was methylated with methyl iodide and sodium hydride in *N,N*-dimethylformamide (9) and a second portion was similarly treated

AND
NORMAN CAMERMAN
Department of Biochemistry, University of Toronto, Toronto, M5S 1A8

Received January 30, 1975

ARTHUR CAMERMAN and NORMAN CAMERMAN. Can. J. Chem. **53**, 2194 (1975).

The crystal and molecular structure of sulthiame, (*N*-[4′-sulfamylphenyl]-1,4-butansultam), one of a series of carbonic anhydrase inhibitors that have gained wide use as antiepileptic agents, has been determined in order to compare the stereochemistry of this compound to that of other antiepileptics. Crystals of sulthiame are orthorhombic, space group $Pca2_1$, with cell dimensions $a = 8.267$, $b = 17.750$, $c = 8.651$ Å. The structure was determined by Patterson and Fourier methods and refined to a final R value of 0.039.

Sulthiame molecular conformation differs markedly from that of diphenylhydantoin and other anticonvulsant drugs, suggesting a different mechanism of action for this compound. If the sulfonamide group is removed from sulthiame, however, the resulting molecule, although no longer a carbonic anhydrase inhibitor, does retain weak antiepileptic activity and does bear a weak conformational resemblance to the other noncarbonic anhydrase inhibitor anticonvulsant drugs.

ARTHUR CAMERMAN et NORMAN CAMERMAN. Can. J. Chem. **53**, 2194 (1975).

On a déterminé la structure cristalline et moléculaire du sulthiame (*N*-[sulfamyl-4 phényl]-butanesultame-1,4), l'un des inhibiteurs de l'anhydrase carbonique qui a connu un gain d'intérêt comme agent antiépileptique; nos études ont été entreprises afin de comparer la stéréochimie de ce composé avec celle d'autres antiépileptiques. Les cristaux de sulthiame sont orthorhombiques, groupe d'espace $Pca2_1$; les dimensions de la maille sont: $a = 8.267$, $b = 17.750$ et $c = 8.651$ Å. La structure, déterminée par les méthodes de Patterson et Fourier, a été affinée jusqu'à une valeur de R de 0.039.

La configuration moléculaire du sulthiame diffère considérablement de celle de la diphénylhydantoine et d'autres médicaments anticonvulsifs; cette différence suggère que le mécanisme d'action de ce composé est différent. Si l'on enlève le groupe sulfonamide du sulthiame, la molécule qui en résulte n'est plus un inhibiteur de l'anhydrase carbonique; toutefois elle possède encore une faible activité comme antiépileptique et ressemble vaguement, au point de vue conformationnel, aux autres médicaments anticonvulsifs qui ne sont pas des inhibiteurs d'anhydrase carbonique. [Traduit par le journal]

Introduction

Sulthiame, (*N*-[4′-sulfamylphenyl]-1,4-butansultam) (Ospolot, Conadil; Fig. 2), is one of a group of sulfonamide carbonic anhydrase inhibitors that have been shown to possess anticonvulsant activity. It has been widely and successfully used in Europe, particularly for the treatment of psychomotor epilepsy, usually as an adjunct medication with other antiepileptic drugs. A recent double-blind clinical study (2) suggests, however, that sulthiame is much less useful than diphenylhydantoin (DPH) as a primary anticonvulsant and is of questionable value as a second agent in mixed drug therapy.

It has been demonstrated that the antiepileptic activities of sulfonamide compounds such as acetazolamide and sulthiame are due to inhibition of brain carbonic anhydrase (3–5) with a possible mechanism involving a buildup of excess carbon dioxide which inhibits nerve conduction (6). If this is so, then these compounds act differently from antiepileptic drugs such as diphenylhydantoin and phenobarbital which do not inhibit carbonic anhydrase.

Hansen *et al.* (7) found that when sulthiame is administered to patients already receiving DPH it elevates serum levels of DPH. Olesen

and Jensen (8) confirmed these findings but found no alteration in the rate of degradation of DPH. They suggest that a possible cause of the rise of DPH serum levels may be displacement by sulthiame of DPH from storage depots in the erythrocytes.

As part of our investigations of the stereochemistries of antiepileptic drugs (1, 9–11) we have elucidated the crystal structure of sulthiame so that we may compare the three-dimensional molecular conformation of this compound with those of other anticonvulsant agents.

Methods

Sulthiame powder was dissolved in water, NaOH was added to attain a basic p*H*, and colorless lath-shaped crystals were obtained by solvent evaporation. Cell dimensions and space group information were determined from X-ray photographs and diffractometer measurements; crystal data are listed in Table 1. Intensities were measured on a four-circle automated diffractometer using $\omega/2\theta$ scan technique and Nb-filtered Mo radiation on a crystal approximately $0.10 \times 0.17 \times 0.30$ mm in size. The intensities of all independent reflections with $0 < 2\theta$ (MoKα) $\leq 55°$, corresponding to an interplanar spacing of 0.77 Å, were recorded; of the 1566 reflections in this range, 1333 had intensities-above-background greater than twice their standard deviations. These were classified as observed and subsequently used in structure refinement. Structure amplitudes were obtained in the usual fashion; weights were taken as $w^{1/2} = 1/\sigma_F$. No absorption corrections were applied.

Structure Determination

One sulfur atom was located in a three-dimensional origin-removed sharpened Patterson map and a Fourier synthesis phased from that atomic position showed the locations of the second sulfur and one oxygen atom. The rest of the nonhydrogen atoms were iteratively located from additional Fourier maps phased from successively determined atom positions. The first postulated structure gave a discrepancy factor, *R*, of 0.33 which decreased to 0.14 after two cycles of full-matrix least-squares refinement with individual isotropic thermal parameters and to 0.07 in two cycles with anisotropic thermal parameters. The function minimized was $\sum w(|F_o| - |F_c|)^2$. The 14 hydrogen atoms were located from difference electron-density maps and further least-squares refinement of all atoms with anisotropic thermal parameters for the nonhydrogen atoms and isotropic ones for the hydrogens reduced *R* to 0.039 and $(\sum w(\Delta F)^2/(m - n))^{1/2}$ to 1.58.

Atomic parameters for the nonhydrogen atoms are listed in Table 2, in which the U_{ij}'s are coefficients in the expression

$$\exp[-2\pi^2(h^2U_{11}a^{*2} + \ldots + 2klU_{23}b^*c^*)]$$

Atomic parameters for the hydrogen atoms are listed in Table 3. The table of observed and calculated structure factors is available.[2] Scattering factors used for sulfur (13), hydrogen (14), and the other atoms (15), are as cited. Anomalous dispersion corrections were applied to the sulfur scattering factors.

λ (MoKα) (Å)	0.7107

Results and Discussion

Molecular Structure

The three-dimensional conformation of sulthiame in the crystal is shown by a stereoscopic drawing in Fig. 1. The saturated heterocyclic ring is in the chair conformation and the phenyl ring is planar. Bond lengths and angles are displayed in Fig. 2. Estimated standard deviations are 0.003–0.006 Å and 0.2–0.4° for the bonds and angles, respectively. There are two bond distances in sulthiame which are significantly short and bear special comment. The N(2)—C(9) distance of 1.431 Å suggests there is some double bond character in that bond. There does not appear to be extension of phenyl ring electron delocalization to include S(15); the C(12)—S(15) distance of 1.773 Å is a normal single bond and matches the value for the S(1)—C(6) bond. The second short bond distance is S(15)—N(18) (1.611 Å). This length is considerably shorter than the normal single bond value of 1.67–1.68 Å and indicates electron delocalization within the sulfonamide group. In contrast, the S(1)—N(2) bond distance is 1.670 Å, indicating no double bond character between those atoms.

Comparison with Other Anticonvulsants

In earlier studies in this series we have shown that the molecular conformations of diphenyl-

[2]Tables of final observed and calculated structure factors are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

hydantoin, diazepam, procyclidine, and trihexyphenidyl bear specific structural resemblances to one another. They all contain two hydrophobic rings (phenyl or cyclohexyl) and two electron-donating or hydrogen-bondable atoms (oxygen or nitrogen). When the drugs' three-dimensional structures are compared these chemical groups occupy similar orientations and positions in space: thus these are conformational features which may be necessary for anticonvulsant activity (12).

The three-dimensional molecular conformation of sulthiame, as a whole, is not strikingly similar to the conformations of the other drugs studied in this series and thus is not suggestive of a mechanism of anticonvulsant action for sulthiame similar to that of the diphenylhydantoin type of antiepileptic. These results are wholly consistent with the accumulated evidence that links the anticonvulsant properties of sulthiame and other sulfonamides with their ability to inhibit brain carbonic anhydrase, a property not shared by diphenylhydantoin and the other anticonvulsant drugs we have studied. Figure 3 shows a comparison of a space-filling model of sulthiame constructed from the crystallographic structure with a similar model constructed for diphenylhydantoin. Although it is obvious that the structural features common to the other antiepileptic drugs we have previously studied are not found in sulthiame, it is equally noticeable that if the sulfonamide group were removed from sulthiame, similarity to diphenylhydantoin would be increased: there is then a slight similarity between the location and orientation in space of the phenyl and saturated heterocyclic groups (both hydrophobic) and one of the oxygen atom positions between them of sulthiame, and the two (hydrophobic) phenyl rings with the ketonic oxygen between them of DPH. Removal of the sulfonamide group from sulthiame destroys the carbonic anhydrase inhibitory properties of the molecule, of course, and therefore its anticonvulsant properties via the brain carbonic anhydrase inhibition mechanism. Tanimukai *et al.* (5) compared carbonic anhydrase inhibitory effect and anticonvulsant activity of four aromatic compounds, including sulthiame, with and without the sulfonamide group. They found that sulthiame alone exhibits a weak anticonvulsant effect when the sulfonamide group is removed. As this effect can no longer be ascribed to inhibition of carbonic anhydrase and because of the slight resemblances (Fig. 3) in molecular conformation between diphenylhydantoin and phenylbutansultam (sulthiame with the sulfonamide group removed) it is possible that the weak anticonvulsant

activity of this latter compound is achieved through a mechanism similar to that of the diphenylhydantoin type of antiepileptic drug. We have calculated the distances between the centroids of the two ring groups in phenylbutansultam and the oxygen atoms bonded to the ring sulfur and compared them with distances between phenyl ring centroids and ketonic oxygens in diphenylhydantoin. The comparison is shown in Table 4. There is moderate similarity between the two compounds in those distances involving the phenyl ring of phenylbutansultam but not in those involving the other ring. Since, however, compounds with only one phenyl group such as 5-phenyl-5-ethylhydantoin possess some anticonvulsant activity, it is likely that the moderate conformational similarities involving one ring and the oxygen atoms between DPH and phenylbutansultam, without the large stereochemical dissimilarity caused by the sulfonamide group, are enough to effect phenylbutansultam's weak anticonvulsant properties.

The slight resemblance in stereochemical features between phenylbutansultam and DPH may also be responsible for sulthiame's action in elevating serum DPH levels in patients receiving both drugs. A hypothesis wherein conformational similarities allow a metabolite of sulthiame without the sulfonamide moiety (or even sulthiame itself with the sulfonamide adding increasing binding by interaction with additional parts of the receptor) to diplace DPH from a storage receptor in the erythrocytes or tissues is consistent with the conclusions of Olesen and Jensen (8).

To summarize, we have found little similarity in three-dimensional molecular conformation between sulthiame and the diphenylhydantoin type of antiepileptic. These findings reinforce the pharmacological evidence for different mechanisms for the anticonvulsant activities of these drugs and are consistent with the close parallels between anticonvulsant activity and brain carbonic anhydrase inhibition properties of the sulfonamide drugs. However, the fact that phenylbutansultam is a weak anticonvulsant and our findings that this molecule shares some of the conformation properties we have found in common among other antiepileptics bolsters our previous evidence that these stereochemical features are important for a drug to possess activity against grand mal epilepsy.

Autoxidation and Photooxidation of 1,3-Diphenylisobenzofuran: A Kinetic and Product Study[1]

JAMES A. HOWARD AND G. DAVID MENDENHALL[2]

Division of Chemistry, National Research Council of Canada, Ottawa, Canada K1A 0R9

Received January 20, 1975

JAMES A. HOWARD and G. DAVID MENDENHALL. Can. J. Chem. 53, 2199 (1975).

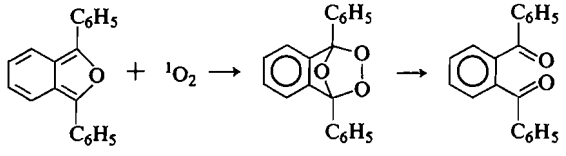
Photooxidation of 1,3-diphenylisobenzofuran (DPBF) in aromatic solvents at 30° gives a monomeric peroxide along with minor amounts of *o*-benzylphenyl benzoate, whereas in CCl_4 *o*-dibenzoylbenzene is the principal reaction product. 1,3-Diphenylisobenzofuran is very susceptible to autoxidation at this temperature $(k_p/(2k_t)^{1/2} = 4\ M^{-1/2}\ s^{-1/2}$, $k_p \sim 10^5\ M^{-1}s^{-1}$, $2k_t \sim 5 \times 10^8\ M^{-1}s^{-1})$ yielding a polyperoxide (50%) and *o*-dibenzoylbenzene (35%). Clearly, in the absence of appropriate control experiments, neither rapid disappearance of DPBF nor production of *o*-dibenzoylbenzene are sufficient to prove the intermediacy of singlet delta oxygen during molecular oxygen oxidations.

JAMES A. HOWARD et G. DAVID MENDENHALL. Can. J. Chem. 53, 2199 (1975).

La photo-oxydation du diphényl-1,3 isobenzofuranne (DPBF) dans les solvants aromatiques à 30° conduit à un peroxyde monomère ainsi qu'à une faible quantité de benzoate de *o*-benzylphényle, tandis que dans le CCl_4 le produit principal de la réaction est le *o*-dibenzoylbenzène. A cette température, le diphényl-1,3 isobenzofuranne est sensible à l'autoxidation $(k_p/(2k_t)^{1/2} = 4\ M^{-1/2}\ s^{-1/2}$, $k_p \sim 10^5\ M^{-1}\ s^{-1}$, $2k_t \sim 5 \times 10^8\ M^{-1}s^{-1})$ ce qui conduit à un polyperoxyde (50%) et au *o*-dibenzoylbenzène (35%). Clairement, en l'absence d'un contrôle approprié, ni la disparition rapide du DPBF ni la production de *o*-dibenzoylbenzène suffisent à démontrer qu'il se forme un intermédiaire oxygène dans l'état singulet delta au cours des oxydations par l'oxygène moléculaire. [Traduit par le journal]

Introduction

1,3-Diphenylisobenzofuran (DPBF) is a popular substrate for photooxidation studies in the liquid phase because of the rapidity with which it reacts with electronically excited singlet delta oxygen ($^1\Delta_g$). There have been several determinations of absolute rate constants for this reaction and it would appear that the 'best' values lie in the range 6–8 × $10^8\ M^{-1}s^{-1}$ (1). It is generally accepted that $^1O_2$ undergoes a 1,4-addition to DPBF to give the *endo*-peroxide **1** which decomposes at ambient temperature to give *o*-dibenzoylbenzene (ODB) (2–7).



DPBF **1** ODB

Chemical evidence for the intermediacy of $^1O_2$ during photooxidation is based, with the appropriate control experiments, on the rapid disappearance of DPBF and/or the production of ODB.

We have recently conducted a thorough kinetic and product study of the autoxidation and photooxidation of DPBF at 30° in the liquid phase. The results of this work and its relevance to diagnostic tests for the intermediacy of singlet oxygen during molecular oxygen oxidations are reported here.

Experimental

1,3-Diphenylisobenzofuran (Aldrich) was purified by recrystallization or zone refining. The solvents (CCl_4, C_6H_6, and *tert*-butylbenzene) were distilled before use.

Oxygen absorptions were followed with the automatic recording apparatus described previously (8). All reactions were performed in solution at 30°. Autoxidations were initiated by thermal decomposition of α,α′-azobisisobutyronitrile (AIBN). Photooxidations were carried out in the presence of the radical scavenger 2,6-di-*tert*-butyl-4-methylphenol with light of a λ > 500 nm.

Polyperoxides were isolated by slow addition of autoxidized DPBF to *n*-pentane and yields were determined by weight. The composition of the polymer depended on the autoxidation chain length (v). For example, autoxidation of DPBF (0.015 *M*) initiated by AIBN (0.036 *M*), v = 1300, gave a polyperoxide with a molecular weight of 1350 ± 50, a m.p. of 127.5–128.5°, and an elemental

*P_{O_2} = 363 Torr.
†This ratio was obtained by following the disappearance of DPBF spectrophotometrically (λ = 413 nm) in the presence of a large excess of oxygen ($\sim 10^{-2}$ M).

analysis of C = 80.54, H = 4.98, and N = 0.62. Yields of *o*-dibenzoylbenzene and *o*-benzoylphenyl benzoate were determined from the intensities of the carbonyl absorptions in the i.r.

Attempts to prepare an analytically pure sample of DPBF endoperoxide were unsuccessful. An elemental analysis of a fraction with a measured molecular weight of 290 ± 10 gave C = 81.1, H = 5.15 whereas the theoretical analysis is C = 79.4, H = 4.67.

The absolute termination rate constant for autoxidation of DPBF was determined from the steady-state peroxy radical concentration and the rate of chain initiation by electron spin resonance techniques (9).

Results and Discussion

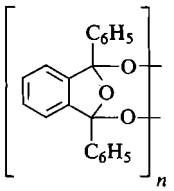
Autoxidation

Le Berre and Ratsimbazafy (10) reported that the self-initiated autoxidation of DPBF in the dark at ambient temperatures yielded a polymeric peroxide with a molecular weight of 2630. We found that solutions of DPBF did not absorb oxygen in the dark in the absence of a free radical initiator at 30°. Kinetic chain lengths were, however, very long when autoxidation was initiated by AIBN. Overall rates of autoxidation were found to fit the general kinetic expression for hydrocarbon autoxidation

$$\frac{-d[O_2]}{dt} = \frac{k_p[RH]R_i^{1/2}}{(2k_t)^{1/2}}$$

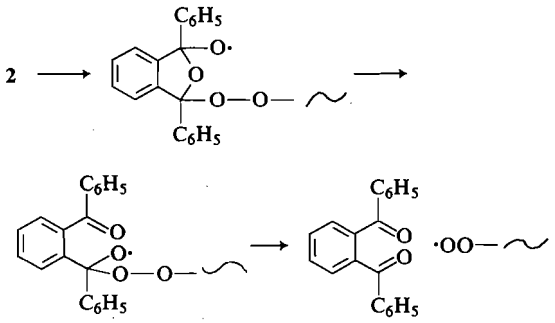
where k_p and $2k_t$ are the rate controlling propagation and termination rate constants, R_i is the rate of chain initiation, and [RH] is the substrate concentration. Kinetic data for autoxidation are given in Table 1. The oxidizability of DPBF at 30° is 4 $M^{-1/2}\ s^{-1/2}$ and since $2k_t$ is $\sim 5 \times 10^8$ $M^{-1}\ s^{-1}$ the reactivity of DPBF to its own peroxy radical is $\sim 10^5$ $M^{-1}\ s^{-1}$. Solutions of DPBF are, therefore, susceptible to autoxidation because of the high reactivity of this substrate to peroxy radicals (*cf.* cyclohexa-1,3-diene which has a homopropagation rate constant of 800 $M^{-1}\ s^{-1}$ at 30° (11)).

DPBF (0.015 M) in *t*-butylbenzene containing AIBN (0.036 M) absorbed 0.012 M of O_2 to give a polyperoxide (50%) and *o*-dibenzoylbenzene (35%). Molecular weight determinations and elemental analyses indicated that the polymer had structure **2** with n = 4–5. The



2

low molecular weight of the polyperoxide relative to the kinetic chain length is probably the result of 0—0 bond cleavage during autoxidation, a common characteristic of polymerizable olefin autoxidation (12). This was supported by the observation that a sample of polyperoxide dissolved in benzene had a half-life of ~72 h at 50° and thermolyzed to give ODB (1 mol per mol of polymer).



Photooxidation

Dufraisse and Ecary (13) reported that photooxidation of DPBF yielded a crystalline *endo*-peroxide which was stable for several hours at −78° but which exploded when the temperature

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12

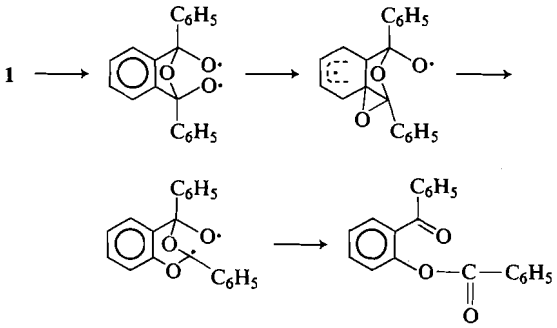
Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

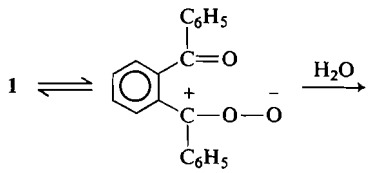
was raised to 18°. We found, however, that the principal stable photooxidation products at 30° depend on the nature of the solvent.

In aromatic solvents, such as benzene and *tert*-butylbenzene, less than 10% of the reaction product contained the carbonyl function(s). The principal product was a white crystalline material which liberated 1 equiv. of iodine from acidified KI and was reduced to ODB by 1 equiv. of triphenylphosphine. The molecular weight of this material and the stoichiometry of the reaction were consistent with a 1 : 1 adduct between oxygen and DPBF. We feel confident that this compound is the *endo*-peroxide **1** although elemental analyses were unsatisfactory. Thermal decomposition of **1** in *tert*-butylbenzene at 20° indicated that it had a $t_{1/2}$ of 100 h at this temperature in this solvent.

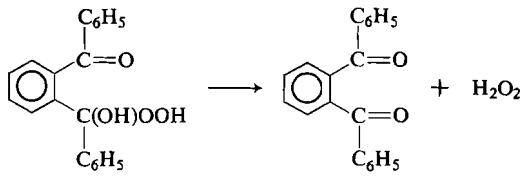
The principal minor product was *o*-benzoylphenyl benzoate which is believed to arise by 0—0 bond cleavage of **1** followed by rearrangement (6).



When photooxidation was performed in CCl_4 or when **1**, prepared in benzene, was dissolved in CCl_4, ODB was produced quantitatively. The loss of an oxygen atom from **1** is not easily explained. However, if **1** is considered to be an ozonide it may exist as the zwitterion **3** which would be readily hydrolyzed to ODB, *e.g.*,



3



Conclusions

It is quite clear from this work that DPBF can react very rapidly with ground state triplet oxygen in the presence of a free radical initiator to give ODB. Great care should, therefore, be exercised to ensure that the disappearance of DPBF or the production of ODB during photooxidation is not due to adventitious autoxidation.

We thank Mr. J. H. B. Chenier for assistance with the experimental work, Mr. H. Seguin for elemental analyses and molecular weights determinations, and a referee for valuable comments.

Polar Radicals. VIII. Kinetic Studies on the Mechanism of the Vapor Phase Bromination of 1-Chlorobutane. The Role of Reversible Hydrogen Abstraction[1]

DENNIS D. TANNER, TONY PACE, and TAMEICHI OCHIAI[2]
Department of Chemistry, University of Alberta, Edmonton, Alberta T6G 2G2
Received February 13, 1975

DENNIS D. TANNER, TONY PACE, and TAMEICHI OCHIAI. Can. J. Chem. 53, 2202 (1975).

A general method for the evaluation of the kinetics of the vapor phase brominations of alkanes and substituted alkanes is presented. The method is applied to the bromination of 1-chlorobutane.

The hydrogen abstraction reaction and its reversal are both found to be deactivated by the polar influence of the substituent; the effect, as predicted, falls off as the distance of the substituent from the C—H bond involved increases. In the vapor phase bromination of 1-chlorobutane, because of this deactivated reversal, transfer with hydrogen bromide cannot compete (< 10%) with transfer with molecular bromine.

There was no evidence for anchimeric assistance by the neighboring chlorine atom during hydrogen abstraction.

DENNIS D. TANNER, TONY PACE et TAMEICHI OCHIAI. Can. J. Chem. 53, 2202 (1975).

On présente une méthode générale d'évaluation des cinétiques de la bromation en phase vapeur d'alkanes substitués et non substitués. La méthode est appliquée à la bromation du chloro-1 butane.

La réaction d'abstraction d'un proton ainsi que la réaction inverse sont toutes les deux désactivées par l'influence polaire du substituant; comme prévu l'effet décroît à mesure que la distance du substituant au lien C—H impliqué s'accroît. Dans le cas de la bromation en phase vapeur du chloro-1 butane, la réaction inverse étant désactivée, le transfert avec l'acide bromhydrique ne peut pas entrer en compétition (< 10%) avec le transfert de brome moléculaire.

Il n'y a pas de preuve d'assistance anchimère par l'atome de chlore voisin au cours de l'abstraction d'un proton. [Traduit par le journal]

Introduction

Hydrogen abstraction from alkanes by bromine atoms has long been recognized by gas phase kinetesists as a reversible reaction (2). The values obtained for the relative rates of substitution and isomer distributions of various alkanes and substituted alkanes by molecular bromine, in general, have been obtained ignoring the effect of the reversibility of the abstraction reaction (3).[3] Attempts to take into account reversible abstraction have recently demonstrated that these reactions cannot be ignored (ref. 4 and references therein) and further, that in solution the reversal reaction is enhanced by the rapid transfer reactions of an alkyl radical with the complex species HBr_3, that is formed during the reaction (5). The mechanism of bromination in solution has been found to be further complicated since cage filtering of radicals by cage reversal can play a significant part in determining the rates observed and products formed in the bromination (6).

In order to obtain meaningful values for the relative rates of abstraction by bromine atoms from alkanes or substituted alkanes, a comparison of the vapor phase and solution kinetics must be obtained (5, 6). In this report a general method for the evaluation of the kinetics for the vapor phase bromination of alkanes and substituted alkanes is presented. The method is applied to the bromination of 1-chlorobutane.

The isomer distributions obtained from the homolytic substitution reactions of electronegatively substituted alkanes are influenced by the electron withdrawing substituent. The molecule is deactivated toward hydrogen abstraction, the effect falling off with the distance of the substituent from the carbon–hydrogen bond involved. The carbon–hydrogen bond strength, in opposition to the former effect, is lowered by electron withdrawal. By a combination of these effects, appropriately weighted to account for the substrates involved, the observed isomer distributions have been rational-

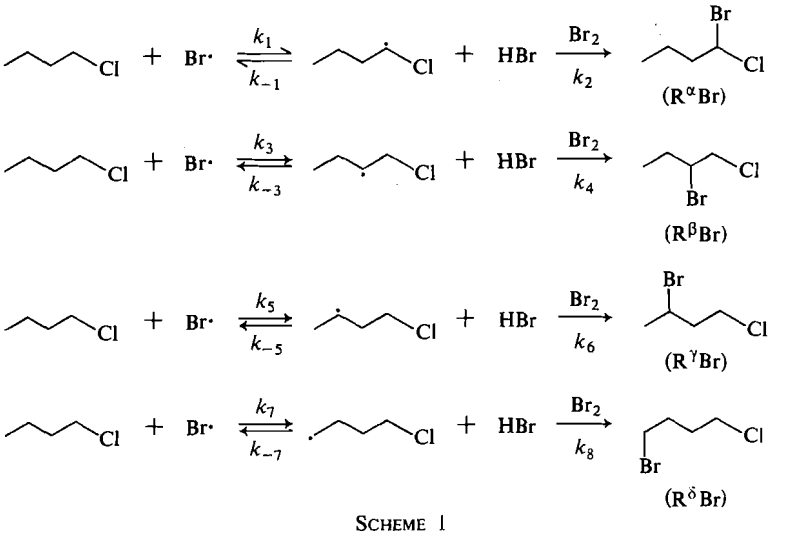

SCHEME 1

ized (7–9). An understanding of the factors governing the isomer distribution obtained in the bromination of haloalkanes is complicated by the proposal that a halogen, bromine (10, 11), or chlorine (3*d*, 12, 13), accelerates by anchimeric assistance the abstraction of the hydrogen located β to these substituents.

The substrate chosen, 1-chlorobutane, tests the method fully, since on bromination it yields four possible isomeric bromides whose distribution is effected by polar interactions, reversible abstraction, and presumably by anchimeric assistance.

Discussion and Results

If one assumes the simplest mechanism to explain the formation of the products formed in the vapor phase bromination of 1-chlorobutane, Scheme 1, then the relative rate of the production of two of the bromo chlorides is given by [1].

$$[1]\quad \frac{d[R^{\alpha}Br]/dt}{d[R^{\gamma}Br]/dt} = \frac{k_1}{k_5}\cdot\frac{k_2}{k_6}\cdot\frac{k_{-5}}{k_{-1}}\left[\frac{1+\dfrac{k_6\ [Br_2]}{k_{-5}\ [HBr]}}{1+\dfrac{k_2\ [Br_2]}{k_{-1}\ [HBr]}}\right]$$

We have been able to evaluate this expression by carrying out the bromination of perdeuterio-1-chlorobutane in the presence of high concentrations of hydrogen bromide and molecular bromine. The relative rates of production of 2-brominated, ($R^{\beta}Br$), to 2-protiated, ($R^{\beta}H$), substrate are given by [2].

$$[2]\quad \frac{d[R^{\beta}Br]/dt}{d[R^{\beta}H]/dt} = \frac{k_4[Br_2]}{k_{-3}[HBr]}$$

At high concentrations of $[Br_2]^0$ and $[HBr]^0$, if the reaction is taken to low conversion, where concentrations do not change appreciably, [2] may be integrated and the value of k_4/k_{-3} can be obtained by an analysis of the ratio of the final concentrations of the two products, [3].

$$[3]\quad \frac{[R^{\beta}Br]}{[R^{\beta}H]-[R^{\beta}H]^0}\cdot\frac{[HBr]^0}{[Br_2]^0} = \frac{k_4}{k_{-3}}$$

A similar operation allowed us to evaluate the k_2/k_{-1} and k_6/k_{-5} ratios by an examination of the substitution products for the reactions in the α- and γ-positions of perdeuterio-1-chlorobutane.

At constant values of $[Br_2]^0$ and $[HBr]^0$ [1], and a similar expression 4 for $(d[R^{\beta}Br]/dt)/(d[R^{\gamma}Br]/dt)$

$$[4]\quad \frac{d[R^{\beta}Br]/dt}{d[R^{\gamma}Br]dt} = \frac{k_3}{k_5}\cdot\frac{k_4}{k_6}\cdot\frac{k_{-5}}{k_{-3}}\left[\frac{1+\dfrac{k_6\ [Br_2]}{k_{-5}\ [HBr]}}{1+\dfrac{k_4\ [Br_2]}{k_{-3}\ [HBr]}}\right]$$

can be evaluated knowing the ratios of 1/3-brominated and 2/3-brominated chlorobutanes.

*[RD(H)] refers to the concentration of perdeuterio-1-chlorobutane, and $[R^iH]$ is the average concentration of the residual protium at position i.
†The values for $[R^iH]$ at the end of the reaction were calculated as: $[R^iH]^0 + 1/2([RD(H)]^0 + [RD(H)]) \times$ (fractional incorporation of H at position i).
‡Not detected by g.l.p.c.
§Per H atom.

By substituting into [1] and [4] the values previously obtained for k_2/k_{-1}, k_6/k_{-5}, and k_4/k_{-3} the values for the relative rates of k_1/k_5 and k_3/k_5 can be calculated. Equation 5

$$[5] \qquad \frac{k_7}{k_5} = \frac{[R^{\delta}H] - [R^{\delta}H]^0}{[R^{\gamma}H] - [R^{\gamma}H]^0 + [R^{\gamma}Br]}$$

was derived to calculate the ratio k_7/k_5, since an expression of the form of [1] could not be evaluated for the δ-position, due to the negligible amount of 4-bromo-1-chlorobutane formed.

The ratio of rate constants for the abstraction of a deuterium atom from perdeuterio-1-chlorobutane in the α-, β-, and γ-positions can be equated to the same ratio of rate constants in the undeuterated substrate if the assumption is made that analogous ratios of rate constants for the two substrates are the same, [6].

$$[6] \qquad k_i^H/k_j^H = k_i^D/k_j^D$$

The photobrominations of perdeuterio-1-chlorobutane were carried out in a 22 l reaction vessel at ambient temperature. The concentrations and values obtained for the kinetic analyses are listed in Table 1.

The reactions were carried out to low conversion where multiple exchange reactions will be negligible. The reaction mixture was condensed, diluted with Freon 113, and an internal standard (*o*-dichlorobenzene) was quantitatively added. The mixture was then freed from hydrogen bromide and molecular bromine by washing with ice-cold aqueous sodium bisulfite. After

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

drying the mixture was subjected to g.l.p.c. analysis. Gas-liquid partition chromatography analysis (see Table 1) showed the presence of only the perdeuterio analogs of 1-bromo-1-chlorobutane, 2-bromo-1-chlorobutane, 3-bromo-1-chlorobutane, and the unbrominated substrate. A synthetic mixture, whose composition corresponded to the mixture of reactants and products obtained from reaction 2 (Table 1) with the addition of 4-bromo-1-chlorobutane (7.95×10^{-6} *M*) and a 1:2.7 mixture of 1,2-dibromo-3-chlorobutane and 2,3-dibromo-1-chlorobutane (3.43×10^{-6} *M*) was introduced, in the absence of light, into the reaction vessel and was subjected to the same isolation and analysis procedures. The yield of the recovered brominated chlorides was >97% for all four of the monobrominated materials and for the trihalides was >99%. The ratio of all the products was the same within the limits of the g.l.p.c. analysis (±2%).

The unbrominated substrate was collected by preparative g.l.p.c. and the amount of incorporated protium at each position (see Table 1) was determined from a comparison of the H^1 100 MHz spectrum of the residual protium in the (Merck, Sharp and Dohme, 98.3 atom% D) starting perdeuterio-1-chlorobutane and the spectrum of the recovered unbrominated substrate (see Fig. 1). The total amount of protium was determined by mass spectrometry for reactions 2 and 3. The n.m.r. method of determining the total protium content of the starting material and the recovered unbrominated substrate was used for reaction 1 (see Table 1).

A test of the kinetics of the bromination of 1-chlorobutane under "normal" conditions, *i.e.*, without excess bromine or added hydrogen bromide, could be achieved. Since the ratio of $[Br_2]/[HBr]$ is a monotonic function of time, $d[R^iBr]/dt = (d[R^iBr]/dx)(dx/dt)$. Using this substitution [1] can be rewritten as [7], where $x = [Br_2]/[HBr]$.

$$[7]\quad \frac{d[R^\alpha Br]/dx}{d[R^\gamma Br]/dx} = \frac{k_1}{k_5}\cdot\frac{k_2}{k_6}\cdot\frac{k_{-5}}{k_{-1}}\cdot\frac{\left(1+\frac{k_6}{k_{-5}}(x)\right)}{\left(1+\frac{k_2}{k_{-1}}(x)\right)} = f^{\alpha/\gamma}$$

A similar expression, [8], can be written for $d[R^\beta Br]/dx/d[R^\gamma Br]/dx = f^{\beta/\gamma}$. Making use of the relative rate constants obtained from the perdeuterio-1-chlorobutane brominations, [7] or [8] may be employed to calculate the ratios of the derivatives $f^{\alpha/\gamma}$ or $f^{\beta/\gamma}$ for any value of x. The consistency of the mechanism used to derive [1], the accuracy of the kinetic values obtained for the bromination of perdeuterio-1-chlorobutane, and their applicability to "normal brominations", can be tested by comparing the calculated ratios of these derivatives with those obtained experimentally. Mixtures of bromine and 1-chlorobutane ("normal brominations") were photolyzed in the vapor phase to varying percentages of reaction and the products of bromination were isolated and analyzed (see Table 2).

From these analyses (see Table 2) plots of the concentration of 2-bromo-1-chlorobutane, $[R^\beta Br]$, 1-bromo-1-chlorobutane, $[R^\alpha Br]$, and 3-bromo-1-chlorobutane, $[R^\gamma Br]$ *vs.* x, $[Br_2]/[HBr]$, could be constructed. The experimental values obtained for the "normal" brominations were fitted manually or by a least squares method to an exponential function $[R^\beta Br]$, $[R^\alpha Br]$, or $[R^\gamma Br] = ae^{-bx} + ce^{-2bx} + de^{-3bx} + fe^{-4bx}$ and the ratios of slopes obtained (graphical differentiation) from these synthesized curves gave the values $d[R^\beta Br]/dx/d[R^\gamma Br]/dx$ and $d[R^\alpha Br]/dx/d[R^\gamma Br]/dx$. A comparison of the calculated values for these functions, $f^{\beta/\gamma}$ and $f^{\alpha/\gamma}$, with those of the experimentally derived values is shown in Figs. 2 and 3.

The error limits shown in Figs. 2 and 3 for the calculated values of $f^{\beta/\gamma}$ and $f^{\alpha/\gamma}$ were obtained using the maximum and minimum values reported for the relative rates of transfer at each position (see Table 1). When the error limits were included for the data (±2%, g.l.p.c. error)

used to determine the observed values of $f^{\beta/\gamma}$ and $f^{\alpha/\gamma}$ (see Table 2) the observed and calculated functions were coincident within the experimental limits (see Figs. 2 and 3).

The coincidence of the calculated values of $f^{\beta/\gamma}$ and $f^{\alpha/\gamma}$ with those of the experimentally determined values demonstrates that the relative rate data obtained for perdeuterio-1-chlorobutane describes adequately the kinetic behavior of the "normal" vapor phase bromination of 1-chlorobutane, and shows that the assumption proposed in [6] must hold.

Mechanistic Conclusions

The relative rates of hydrogen abstraction/H, which include reversible hydrogen transfer, are found to follow the order predicted for the reaction of a selective radical whose reactivity is strongly affected by the polar influence of the electronegative chlorine substituent, *i.e.* α-H, $0.34 <$ β-H, $0.49 <$ γ-H, $1.00 >$ the primary δ-H, 0.04. The relative reactivity of the β/γ hydrogens (0.49/1.00) determined in these brominations is similar to that reported for other substitution reactions, carried out under irreversible conditions, on electronegatively substituted substrates, where the substituent does not have the ability to anchimerically assist in hydrogen abstraction (8). The normality of the β/γ relative reactivity fortifies the conclusion that a neighboring chlorine atom does not accelerate the rate of abstraction of hydrogen by a bromine atom.

The effect of the polar substituent upon the energy of the transition state for hydrogen abstraction will be the same as for reversible transfer of the polar radical with polar hydrogen bromide (microscopic reversibility).

$$[ClC_4H_8\text{---}H\text{---}Br]\cdot\ddagger$$

If the assumption is made that polar interactions are negligible for transfer of the polar radical with a nonpolar molecule of molecular bromine, the order found for competitive transfer of the polar radical with bromine and hydrogen bromide, k_2/k_{-1} (α-position) $> k_4/k_{-3}$ (β-position) $> k_6/k_{-5}$ (γ-position) $> k_8/k_{-7}$ (δ-position), can be rationalized. The magnitude of the rate constant for reversal will increase as the distance from the substituent is increased while the polar influence of the substituent on the rate of transfer with molecular bromine will be negligible.

In the "normal" vapor phase bromination, reversible reactions between the chlorobutyl radicals and hydrogen bromide are small, due to polar deactivation, $k_{Br_2}/k_{HBr} = 9.1$ for the whole molecule, and only 9.0% of the radicals formed will transfer with hydrogen bromide. This value can be compared with the competitive transfer rates determined for the vapor phase bromination of the nonpolar cyclohexyl radical (5), $k_{Br_2}/k_{HBr} = 2.81$, where a significantly higher fraction, 26%, of the radicals transfer with hydrogen bromide.

Experimental

Materials

1-Chlorobutane (BDH) was washed with concentrated sulfuric acid, water, dried over sodium sulfate, and distilled. Gas–liquid partition chromatography (10 ft × 1/4 in. 10% UCON 50 LB 550X) showed it to be >99.9% pure. Perdeuterio-1-chlorobutane was obtained from Merck, Sharp and Dohme, Ltd. Gas–liquid partition chromatography analysis showed it to be 99.5%

pure. Mass spectral analysis (AEI MS9, 15.8 eV) showed it to contain 98.3 atom% D, and n.m.r. spectroscopy, using 1,1-diphenylethylene as standard (see below), showed it to contain 98.0 atom% D.

Molecular bromine (McArthur Chemical Co., reagent grade) was washed with concentrated sulfuric acid and distilled twice from phosphorus pentoxide.

Hydrogen bromide (Matheson) was passed over molecular sieve 4A, degassed, and distilled twice prior to use.

1,1-Diphenylethylene (Aldrich) was distilled prior to use: b.p. 136.5–137.0° (9 mm), n_D^{20} 1.6088 (lit. (14) b.p. 139° (11 mm), n_D^{20} 1.6085); n.m.r. spectroscopy and g.l.p.c. analysis showed it to have no detectable impurities.

A mixture of 1-bromo-, 2-bromo-, and 3-bromo-1-chlorobutane was obtained by preparative g.l.p.c. collection (10 ft × 1/4 in. 10% UCON 50 LB 550X) of the products of the liquid phase bromination of 1-chlorobutane with molecular bromine (3*e*). The products were identified by a comparison of their g.l.p.c. retention times with those of the authentic materials (15). 4-Bromo-1-chlorobutane (Aldrich) was purified by g.l.p.c. collection.

A mixture of 2,3-dibromo-1-chlorobutane and 1,2-dibromo-3-chlorobutane was prepared by the addition of a carbon tetrachloride solution of bromine to commercial crotyl chloride (Aldrich technical grade, containing 20% 3-chloro-1-butene; g.l.p.c. showed the presence of these two compounds in a ratio of 3.0:1.0) in carbon tetrachloride at 0°. The crude product was purified by distillation: b.p. 78–79° (8.7 mm), n_D^{25} 1.5385. The n.m.r. spectrum showed two doublets (τ 8.13, J = 6.3 Hz; τ 8.19, J = 6.6 Hz, 3H) in the ratio of 2.7:1 centered at τ 6.02 (2H) and τ 5.59 (2H). The mixture did not give a parent peak in the mass spectrum (70 eV), but gave peaks at *m/e* 173, 171 (base peak), 169 (P—Br, ratio 3:4:1), 217, 215, 213 (P—Cl), 135, 133 (ratio 1:1) and 91, 89 (ratio 3:1). The two compounds were not separated by g.l.p.c. (10 ft 10% UCON 50 LB 550X), but the g.l.p.c. showed the mixture to be >99.9% pure.

Anal. Calc. for $C_4H_7Br_2Cl$: C, 19.20; H, 2.82. Found: C, 18.93; H, 2.85.

Determination of Relative Rates

1-Chlorobutane-d_9 (~0.5 g) was carefully weighed in a Pyrex breakseal, degassed three times by the freeze-thaw method, and finally sealed. Bromine (about 1.5 g) was weighed into another breakseal, degassed, and sealed. Hydrogen bromide was degassed and distilled in a vacuum line, measured, distilled into a breakseal, and the breakseal sealed. The three breakseals were attached to a 22 l reaction bulb, and the system was degassed. The bulb was isolated from the vacuum line and the breakseals broken in the absence of light (in the order C_4D_9Cl, HBr, Br_2, with 30 min intervals between each breakseal). The mixture of the three substrates was allowed to equilibrate for about 30 min in the absence of light, and then the reaction vessel was irradiated (1 × 100 W incandescent lamp). The contents of the reaction vessel were condensed and an internal standard (*o*-dichlorobenzene) added. The excess bromine and hydrogen bromide were destroyed with cold (0°) sodium bisulfite solution. The organic substrates were dissolved in Freon 113 (about 30 ml), and the Freon solution washed with cold water and dried ($MgSO_4$). The solution was analyzed by g.l.p.c. (6 ft × 1/4 in. 10% UCON 50 LB 550X on Chromosorb P AW, glass column) for starting material and products. The solution was concentrated on a 24 in. Teflon spinning band column to approximately 4 ml, and the unbrominated perdeuterio-1-chlorobutane was collected and then recollected by preparative g.l.p.c. (20 ft × 1/4 in. 10% Carbowax 20 M TPA on Chromosorb P AW, glass column, 50°).

In a control experiment, 5.530×10^{-3} mol 1-chlorobutane, 8.425×10^{-5} mol 1-bromo-1-chlorobutane, 1.005×10^{-4} mol 2-bromo-1-chlorobutane, 1.748×10^{-4} mol 3-bromo-1-chlorobutane, 4.422×10^{-5} mol 4-bromo-1-chlorobutane, 7.550×10^{-5} mol of a mixture of 2,3-dibromo-1-chloro- and 1,2-dibromo-3-chlorobutane, 9.466×10^{-3} mol bromine and 7.484×10^{-2} mol hydrogen bromide were introduced into the reaction bulb (22 l), in the absence of light, and condensed after 2 h. After isolation of the organic material, in the above manner, the mixture was analyzed by g.l.p.c. The material balance was 97.7% for 1-bromo-, 96.9% for 2-bromo-, 97.4% for 3-bromo-, 95.5% for 4-bromo-1-chlorobutane, and 102.2% for the trihalide.

Determination of Residual Protium in 1-Chlorobutane-d_9

Accurately prepared solutions of perdeuterio-1-chlorobutane (150–300 mg) and 1,1-diphenylethylene (3–10 mg) in Freon 113 (~0.3 ml) were analyzed by n.m.r. spectroscopy using a Varian HR 100 spectrometer. Two spectra were run (normal and D decoupled) with the phenyl protons as lock and reference. A small amount of TMS was added, and two more spectra, normal and D decoupled, were run, with TMS as lock and reference. Each spectrum was integrated at least five times, and the average values for the integrated areas were again averaged for the four spectra. Both decoupled and undecoupled spectra gave the same integration values, within experimental error, showing the absence of any experimentally important Overhauser effects. From the relative areas of the chlorobutane protons (τ 9.12, 8.59, 8.32, 6.58) and the olefinic protons of 1,1-diphenylethylene (τ 4.63), the amount of protium in each position of the perdeuterio-1-chlorobutane could be determined. This method was used for reaction 1.

The total protium content was also calculated by mass spectrometry (AEI MS9, 13 eV, slow magnetic scanning) by the method of Biemann (16). The amount of protium in each position was determined using the ratio of the α:β:γ:δ-H^1 signals from the n.m.r. spectra. This method was used for runs 2 and 3 (Table 1), and gave more accurate results than the n.m.r. method described above.

Photobromination of 1-Chlorobutane with Molecular Bromine

Aliquots (0.500 ml) of a solution of 1-chlorobutane (7.447 g, 8.045×10^{-2} mol) and bromine (1.315 g, 8.226×10^{-3} mol) were transferred into each of 12 breakseals. Each breakseal was in turn attached to the 5 l reaction vessel, degassed, and its contents were introduced into the reaction vessel. After equilibration in the dark (30 min), the reaction bulb was photolyzed (100 W incandescent lamp) for the appropriate time, and the contents were condensed. To the isolated mixture was added 20 ml of a 5% potassium iodide solution and an

aliquot of a Freon 113 solution containing a known amount of an internal standard (*o*-dichlorobenzene). The mixture was titrated iodometrically for bromine and hydrogen bromide (17). The organic layer was separated, dried over magnesium sulfate, and analyzed by g.l.p.c. (10% UCON 50 LB 550X). Only 1-bromo-, 2-bromo-, and 3-bromo-1-chlorobutane were observed; the material balance (based on bromine) was always greater than 98.7%.

The authors wish to thank the National Research Council of Canada and the University of Alberta for their generous support of this work.

Base-catalyzed Exchange of Cyclic Diketones under Homoenolization Conditions; Facile Exchange at the Bridgehead and C-7 in 3,3,6,6-Tetramethyl Bicyclo[2.2.1]heptan-2,5-dione

NICK HENRY WERSTIUK

Department of Chemistry, McMaster University, Hamilton, Ontario L8S 4M1

Received March 25, 1975

NICK HENRY WERSTIUK. Can. J. Chem. **53**, 2211 (1975).

Treatment of 3,3,6,6-tetramethyl bicyclo[2.2.1]heptan-2,5-dione (**1**) under mild homoenolization conditions (*t*-BuO$^-$, 175°, 28 h) results in unusually facile exchange at the bridgehead and C-7. 1,4-Homoenolization to an *endo* methyl group, converts **1** into 2,2,5-trimethyl bicyclo[3.2.1]octan-3,8-dione (**3**).

NICK HENRY WERSTIUK. Can. J. Chem. **53**, 2211 (1975).

Dans des conditions douces d'homoénolisation (*t*-BuO$^-$, 175°, 28 h), la tétraméthyl-3,3,6,6 bicyclo[2.2.1.] heptadione-2,5 (**1**) s'échange très facilement au niveau de l'atome de pont et du C-7. Une homoénolisation-1,4 impliquant une groupe méthyle *endo* transforme **1** en triméthyl-2,2,5 bicyclo[3.2.1.] octanedione-3,8 (**3**). [Traduit par le journal]

There are presently chronicled in the literature (1–11) a number of reports on base-catalyzed H–D exchange of C—H bonds situated 1,3 (homoenolization) from a solitary carbonyl group. The studies have quantified the degree of 1,3 or β-homoenolization and the propensity for rearrangement. Several examples of 1,4 or γ-homoenolization (4, 5, 10) have also been documented. However, homoenolization via in concert activation by two or more carbonyl groups has not been observed. Also, in the studies carried out thus far, 1,3-homoenolization to C-7 in bicyclo[2.2.1] heptyl ketones, such as camphenilone (**2***a*) and fenchone (**2***b*), has not been observed. Presumably, this is a consequence of the strain in the homoenolate anion and/or the improper alignment of the C—H bonds at C-7 with the π system of the carbonyl group at C-2. For example, fenchone (**2***b*) resists exchange (<1%) at C-7 even under the forcing conditions of 0.7 *M* *t*-BuO$^-$ maintained at 185° for 2½ weeks (8, 11). Another point of interest is the apparent ease at which bridgehead exchange, α to the carbonyl group, occurs under homoenolization conditions (7, 9, 12–14). However, most of the systems examined thus far do not possess the constraints against bridgehead exchange imposed by the bicyclo[2.2.1]-heptyl system. That is, formal conjugation of the anion at C-1 to a carbonyl group at C-2 in camphenilone (**2***a*) or C-7 in norbornan-7-one is rigorously denied because of strain and the fact that the dihedral angle between the anion and the carbonyl π system is essentially 90°. Only the exchange study on norbornan-7-one and nortricyclanone[1,2] undertaken by Gassman and Zalar (13) presents data on bridgehead exchange in [2.2.1]-ketones. To gain information on the extent of, and the factors which control bridgehead exchange in these systems is important, since such exchange would not be detected directly in camphenilone (**2***a*)[1,2] (1) and the isocamphanone–camphor (8) system and would add to the deuterium incorporated at C-1 and C-6.

To expand the research on the chemistry of

[1]Although there is a good correlation between $J_{^{13}C-H}$ (% s character) and the kinetic acidity of C—H bonds, an exception has recently been reported (15). However, it has not yet been established conclusively (16) whether $J_{^{13}C-H}$ is a good measure of hybridization α to a carbonyl group although Ellis and Maciel (17) have shown that $J_{^{13}C-H}$ α to the carbonyl group in 2,2-dimethyl cyclopropanone (160), cyclobutanone (134.8), and cyclopentanone (129.5) are essentially identical to $J_{^{13}C-H}$ in the corresponding hydrocarbons.

[2]Gassman and Zalar (13) have shown that norbornan-7-one ($J_{^{13}C_1-H}$, 152 ± 1 Hz) (16) and nortricyclanone ($J_{^{13}C_4-H}$, 159 ± 1 Hz) (16) exchange 25% (49 h) and 75% (29 h) of C—H at the bridgehead α to the carbonyl group under homoenolization conditions, what would be expected qualitatively from the magnitudes of $J_{^{13}C-H}$. **2***a* has a $J_{^{13}C_1-H}$ of 152 ± 1 Hz (16).

bicyclic diketones (16, 18) a study was undertaken to establish the propensity of exchange in 3,3,6,6-tetramethyl bicyclo[2.2.1]heptan-2,5-dione (**1**)[3] under "mild" homoenolization conditions (175°, 28 h).

The results in Table 1 establish (*a*) the stability of diketone **1** in strongly basic medium, (*b*) that the exchange at the bridgehead and especially C-7 is unusually facile, (*c*) that 1,4-homoenolization to an *endo* methyl converts[4] **1** into 2,2,5-trimethyl bicyclo[3.2.1]octan-3,8-dione (**3**),[3] and (*d*) one of the methyl groups, likely C-9, in **3** undergoes very rapid H–D exchange.

The high degree of exchange at the bridgehead in **1** is remarkable, when compared to norbornan-7-one and nortricyclanone, since $J_{^{13}C_1-H}$ in **1** is normal at 152 ± 2 Hz. Also, s character effects cannot be the source of the facile exchange at C-7, compared to fenchone, since $J_{^{13}C_7-H}$ in **1** is 138 ± 2 Hz. Is bis-1,3-homoconjugation therefore, as depicted in **4**, responsible for the enhanced reactivity at C-7? The unusual kinetic acidity at the bridgehead perhaps can be ascribed to a decrease in the diheral angle, through a synchro-twist,[5] between the anionic center at C-1 and the π system at C-2. Unfortunately no studies, either experimental or theoretical, have yet been carried out to establish quantitatively the stabilization of an anionic center by a carbonyl group as a function of dihedral angle and hybridization at the anionic site. Possibly the enhanced acidity at C-7 results from *cyclic* delocalization of the developed negative charge through the carbonyl groups conjugated either through three σ bonds (19–22) or through space beneath the bicyclic system.

The 1,4-homoenolization to the *endo* methyl in **1** provides a convenient route to the bicyclo-[3.2.1]octan-3,8-dione system. The facile exchange of the C-9 methyl in **3** likely results from in concert 1,3 and 1,4 activation by the carbonyl groups at C-3 and C-8, the second example (*vide supra*) of bis-activation. It is expected, therefore, that 1,3 and 1,4 multi-activation of remote C—H bonds by three or four carbonyl groups should provide for an enormous increase in kinetic acidity.

Financial assistance by the National Research Council of Canada is gratefully acknowledged. The author wishes to thank Ms. Valerie Meng for preliminary work on the synthesis of **1** and Professor J. B. Stothers who very kindly obtained the ^2H n.m.r. spectra for exchanged **1**.

1,4-Dioxane Hydrate: Dielectric Absorption by a Nondipolar Enclathrated Molecule[1]

S. R. GOUGH, J. A. RIPMEESTER, AND D. W. DAVIDSON
Division of Chemistry, National Research Council of Canada, Ottawa, Canada K1A 0R9

Received March 21, 1975

S. R. GOUGH, J. A. RIPMEESTER, and D. W. DAVIDSON. Can. J. Chem. **53**, 2215 (1975).

X-Ray, continuous-wave and pulsed n.m.r., and dielectric relaxation studies show the hydrate of 1,4-dioxane (D) to be a normal clathrate hydrate of von Stackelberg's structure II with composition $D\cdot\sim 17H_2O$. The reorientation rate of the relatively large D molecule is slower and the effective activation energy (1.6 kcal/mol) larger than for other guest molecules previously studied in hydrates of the same structure. Weak dielectric absorption associated with reorientation of nondipolar D molecules is attributed mainly to the induction of a total dipole moment of ~0.2 D in the 28 water molecules of the large structure II cage by two equal and opposed dipoles in the chair form of D.

S. R. GOUGH, J. A. RIPMEESTER et D. W. DAVIDSON. Can. J. Chem. **53**, 2215 (1975).

Les études par diffraction des rayons X, r.m.n. par ondes continues et par impulsion, et relaxation diélectrique, indiquent que l'hydrate de dioxanne-1,4 (D) est un hydrate de clathrate normal ayant la structure II de von Stackelberg et la composition $D\cdot\sim 17H_2O$. La vitesse de réorientation de cette molécule D relativement grande est plus lente et l'énergie d'activation effective (1.6 kcal/mol) est plus grande que dans le cas des autres molécules encagées déjà étudiées pour des hydrates de même structure. La faible absorption diélectrique associée à la réorientation des molécules D non dipolaires, est attribuée en grande partie à l'induction d'un moment dipolaire total de ~0.2 D dans les 28 molécules d'eau de la grande cage de structure II par deux dipôles égaux et opposés dans la forme chaise de D. [Traduit par le journal]

Formation of a high hydrate of 1,4-dioxane which melts incongruently at −13 °C has recently been reported from thermal analysis and differential scanning calorimetry (1, 2). Its high water content, estimated as 34 (1) or more (2) water molecules per molecule of dioxane, has been said to indicate a structure II-like clathrate hydrate in which the 16-hedral cages are only half-occupied (1) or, alternatively, a hydrate of an entirely different structure (2).

We present here X-ray, n.m.r., and dielectric evidence that 1,4-dioxane forms a type II clathrate hydrate of the usual kind. The dielectric and n.m.r. behavior of this hydrate presents special interest because dioxane is perhaps the largest molecule known to form a simple type II hydrate. At the same time, the absence of a permanent dipole moment in the 1,4-dioxane molecule makes it necessary to devise a mechanism to account for the dielectric absorption observed in this hydrate at low temperatures.

Experimental Methods and Results

Purity of Samples

Because of the presence of weak dielectric absorption in 1,4-dioxane hydrate at low temperatures (see below), it is important to establish the purity of the Eastman Kodak *p*-dioxane

[1]NRCC No. 14664.

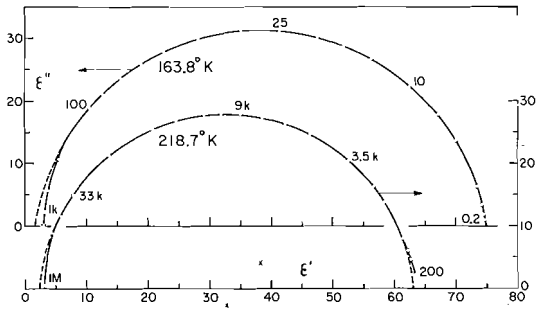

FIG. 3. Cole–Cole plots of the water relaxation region of 1,4-dioxane hydrate.

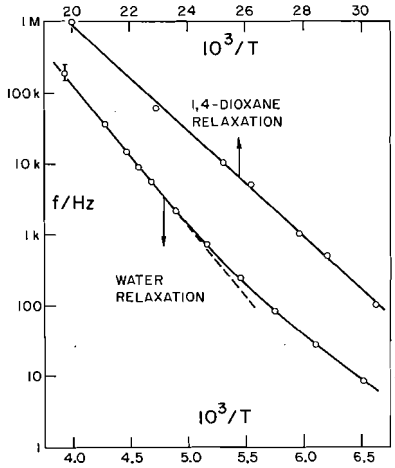

FIG. 4. Temperature dependence of frequencies of maximum dielectric absorption by host and guest molecules of 1,4-dioxane hydrate.

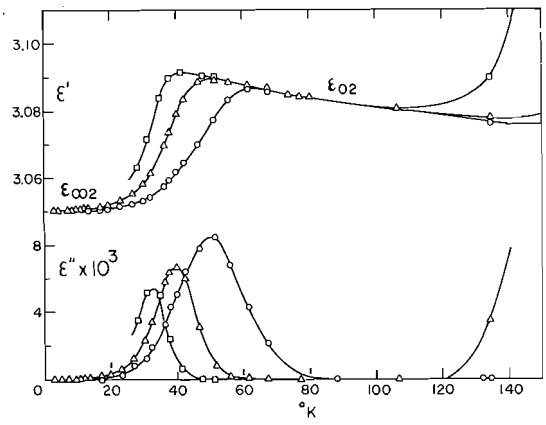

FIG. 5. Low-temperature permittivity and loss curves of 1,4-dioxane hydrate: □, 100 Hz; △, 10 kHz; ○, 1 MHz.

high-temperature side of minimum T_1 (*i.e.*, between 80 and 170 K) is considerably higher (1.55 kcal/mol) than the value (0.92 kcal/mol) obtained for the corresponding region of tetrahydrofuran deuterate. The smaller and temperature-dependent slope to the low-temperature side of minimum T_1 (*e.g.*, ~0.52 kcal/mol between 50 and 35 K) may again (9) be formally associated with a broad and asymmetric distribution of reorientational correlation times with a long tail extending to shorter times. The distribution required is less broad than in the tetrahydrofuran case, the β of the approximate skewed arc representation being about 0.33 in the region of minimum T_1 rather than 0.21 (9).

Dielectric Measurements

Permittivity and loss measurements were made at frequencies between 0.2 Hz and 1 MHz and at temperatures between 3 and 253 K with techniques already described (11). Results are shown in Figs. 3 to 5 for a sample of composition $C_4H_8O_2 \cdot 14.68H_2O$, excess dioxane having been employed to promote hydrate formation (slow for hydrates which form from ice (12)) and to suppress the amount of unreacted ice. After a day of conditioning at −14 °C the dielectric behavior of this sample showed no features which could be identified with the presence of ice.

The complex permittivity loci illustrated in Fig. 3 have the shapes characteristic of the relaxation of water molecules in the structure II hydrate lattice (11, 13). The cell "filling factor" is good for a hydrate which forms incongruently from ice, the static permittivity of 57 at 253 K comparing favorably with the value of 62 expected (11) at this temperature for a type II hydrate of a nonpolar molecule. At least part of the difference may be attributed to the presence of excess solid dioxane of permittivity 2.3 (see below). The increase of permittivity with decrease of temperature (to about 77 at 153 K) is less rapid than expected for complete filling of the interelectrode region. This result is formally attributable to development of an air gap in series with the sample which increased in thickness to about 0.012 of the interelectrode spacing as the temperature fell to 153 K.

The activation energy for reorientation of the water molecules, as derived from the temperature dependence of the frequency of maximum loss (Fig. 4), is 9.1 ± 0.2 kcal/mol for tempera-

tures above 200 K. At lower temperatures the rate plot is no longer linear, but shows the smaller dependence on temperature which is generally found in the relaxation behavior of clathrate hydrates at low temperatures (11, 13). As in ice itself, the relaxation may be controlled at low temperatures by extrinsic or impurity-related Bjerrum defects.

A second region of dielectric relaxation, associated with relatively small but easily measurable absorption and dispersion (Fig. 5), occurs below 80 K. The amplitude of this dispersion ($\varepsilon_{02} - \varepsilon_{\infty 2}$) is about 1% of that found for the low-temperature dispersion of structure II hydrates containing such polar guest molecules as tetrahydrofuran and acetone (11) where the relaxation is associated with reorientation of the guest dipoles. As in the latter cases, the absorption is very broad and asymmetric. The "activation energy" which corresponds to the dependence on temperature of the frequency of maximum absorption (see plot in Fig. 4) is 1.72 ± 0.04 kcal/mol (*cf.* 0.91, 1.25, and 1.44 kcal/mol for the corresponding absorption in the hydrates of tetrahydrofuran (11), isoxazole (14), and cyclobutanone (11), respectively).

Discussion

Nature of the Hydrate

The X-ray, n.m.r., and dielectric results all go to establish that 1,4-dioxane hydrate is a normal structure II clathrate hydrate. Despite the X-ray indication that the lattice may be somewhat "stretched" by the presence of the large guest molecule, the stability of the lattice as measured by the slowness of reorientation of the water molecules and the associated activation energy is only exceeded by one (SF_6 hydrate) of the nine structure II hydrates for which such information is available (11, 14). At the same time the narrow distribution of water-molecule reorientation times reflected in the shape of the complex permittivity locus is, to good experimental accuracy, the same in all these cases.

Although no hydrate composition studies were made, it may be inferred that the value of n in $C_4H_8O_2 \cdot nH_2O$ is much closer to the normal structure II value of 17 (15) than to the value of 34 or more previously suggested (1, 2). For complete equilibration, values of n of 17 and 34 correspond to the presence of 3.4 and 22.7 wt.%, respectively, of excess solid dioxane in the sample of composition $C_4H_8O_2 \cdot 14.68H_2O$. Expressed as a linear function of the permittivities and volume fractions of the two phases, the anticipated static permittivity at 253 K is about 60 in the first case and 48 in the second. Since incomplete filling also lowers the permittivity, the experimental permittivity of 57 is not consistent with any great departure from the normal structure II composition.

A supporting indication is the absence of spurious lines from solid dioxane in the X-ray diffraction patterns.

Origin of the Low-temperature Dielectric Absorption

The dielectric absorption and dispersion shown in Fig. 5 may formally be attributed to reorientation of an encaged molecule which possesses[2] a dipole moment of about 0.19 D. However, there is an accumulation of evidence to show that, at room temperature and below, 1,4-dioxane exists exclusively in the nondipolar chair conformation. See, for example, the results of studies of vapor-phase (17) and liquid-phase (18) electric polarization, liquid-phase infrared and Raman spectra (19), electron diffraction (8), and conformation energies (20). Measurement of a finite dielectric loss at microwave frequencies in liquid dioxane at 20 °C cannot be taken as evidence of a permanent dipole moment of ~0.1 D (21, 22) since this absorption is continuous with the far infrared absorption which reaches a maximum value of ε'' around 40 cm^{-1} (23) and is of the same kind as occurs in such nondipolar liquids as benzene. Moreover, the Boltzmann factor which may permit polar conformations to occur above 473 K (17) is very unfavorable to their existence below 80 K.

Likewise, it does not seem possible to ascribe the present dielectric absorption to polar impurity in the dioxane. Such an impurity would have to consist of relatively large, but still encageable, molecules. For a dipole moment of ~2 D, the concentration would need to be two orders of magnitude larger than the impurity concentrations shown in Table 1.

[2]This estimate is based on the assumption that ($\varepsilon_{02} - \varepsilon_{\infty 2}$), measured at a temperature high enough that reorientation is effectively isotropic, is linear in (dipole moment)^2 of the guest molecule. This relationship adequately applies to the experimental data at 168 K for structure II hydrates of many polar guest molecules (16).

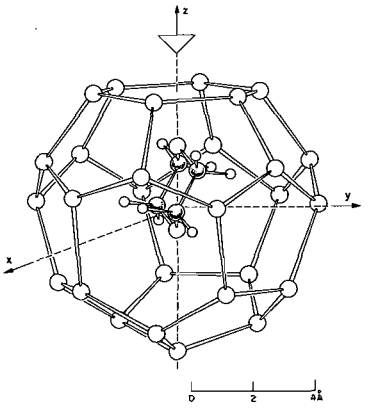

FIG. 6. The 16-hedral cage of water molecules containing a 1,4-dioxane molecule at the position used to estimate the induced dipole moment.

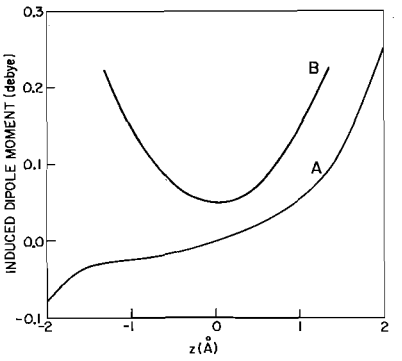

FIG. 7. Total dipole moment induced in the water molecules of the cage by a dipole of 1 D aligned with (*A*) a 3-fold axis of a 16-hedral cage and (*B*) the $\bar{4}$ axis of a 14-hedral cage, as a function of displacement of the dipole along the axis.

It is therefore concluded that the dielectric absorption must originate with the reorientation of the chair form of 1,4-dioxane itself. This conclusion is supported by the good agreement (see below) between the n.m.r. and dielectric information about the reorientation kinetics of the guest molecules.

Mechanism of Dielectric Absorption by 1,4-Dioxane

The most likely mechanism of this absorption is to be found in the dipole moments induced in the water molecules of the cage by the dioxane molecule. To a first approximation the charge distribution of dioxane may be represented by two equal and opposed dipoles, each associated with a C—O—C group. To calculate the magnitude of the total dipole moment induced in the 28 water molecules of the 16-hedral cage, we use a simplified model in which the O--O vector of dioxane is assumed to coincide with one of four 3-fold axes of symmetry of the (average) $\bar{4}3m$ cage which passes through the center of a hexagonal ring of water molecules (see Fig. 6). It has previously been suggested (24) that guest ether molecules tend to have preferred configurations in which the O atoms approach the centers of hexagonal rings to the extent determined by the repulsion between the water molecules and the H atoms on the α C atoms. We further consider only the major component of each C—O—C group dipole which lies along the O--O direction.

We first evaluate the total dipole moment induced in the 28 water molecules of the cage by a single dipole which lies on, and points along, a 3-fold axis of cage symmetry, hereafter called the Z axis. By symmetry, the induced moment has only a Z component which is given by summation of the 28 terms of the form $\alpha m(1 - 3z_i^2)R_i^{-3}$, where α is the polarizability (assumed isotropic) of a water molecule, R_i is the distance of a water molecule from the dipole, and z_i the component of a unit vector in the direction of R_i. The sign is chosen for a negative dipole moment of magnitude m with the hexagonal ring taken at positive Z (Fig. 6).

Figure 7 (curve *A*) shows the variation of induced dipole moment with displacement of a unit guest dipole moment ($m = 1$ D) along the Z axis, with[3] $\alpha = 3.44$ Å^3. It is seen that the sign of the induced moment changes at $Z = 0$, which means that the magnitude of the moment induced by a dipole at a positive Z adds to that induced by an opposite dipole at a negative Z.

To apply the model to dioxane we must estimate the Z coordinates of the two dipoles. An O atom can approach to within about 1.75 Å of the center of a hexagonal ring before the equatorial protons of the adjacent CH_2 groups

[3]This polarizability is derived from an estimated permittivity of the empty structure II lattice of 2.81 (11) and the Clausius–Mossotti equation. It includes full contributions from rotational and translational vibrations of the lattice.

come into van der Waals contact (at about 2.4 Å) with the water molecules. This places one O atom at Z = 2.0 Å and the other at $Z = -0.8$ Å (Fig. 6). The C—O—C dipoles are probably somewhat displaced from the O atoms toward the center of the molecule; we take their positions as $Z = 1.7$ and -0.5 Å. From $m =$ 1.4 D, the Z component of a C—O—C group dipole moment of 1.6 D (the experimental moment of tetrahydropyran), and inspection of Fig. 7 (curve *A*), the induced moment is $1.4 \times (0.16 + 0.02)$ or 0.25 D.

The model is too specific for the result to be of great accuracy. However, it is good enough to show that the observed dielectric absorption may be attributed to relaxation of the dipole moments induced in the water molecules of the lattice.

The magnitude of the total induced moment depends on the symmetry of the arrangement of the water molecules of the cage. Thus, curve *B* of Fig. 7 shows the moment induced in the 24 water molecules of the 14-hedral cage of the structure I lattice by a unit dipole aligned along the $\bar{4}$ axis. Since this curve is symmetric about $Z = 0$, no induced moment or dielectric absorption is expected for a molecule like CO_2 whose charge distribution can be represented by an opposed dipole pair or linear quadrupole located at the cage center and aligned along the $\bar{4}$ axis.

Reorientation of Encaged Dioxane

The shapes of the complex permittivity curves given by the low-temperature dielectric measurements are approximately skewed arcs, with, for example, $\beta \sim 0.14$ at 35 K and ~ 0.17 at 40 K. Shapes of this kind are also found for polar guest molecules (7, 11). Another resemblance to the behavior of hydrates of polar guests is to be found in the failure of ε_{02} (Fig. 5) to increase as $1/T$ at low temperatures, a clear indication of reorientation between energetically nonequivalent sites. In the case of dioxane, the gradients of the electrostatic fields of the water molecules, along with short-range dispersion and overlap forces, may well act to favor some orientations of the opposed-dipole axis at the expense of others. The extent of this distortion of the (average) tetrahedral cage symmetry is expected to vary greatly from cage to cage as a result of the disorder in the orientations of the water molecules and to result in a broad distribution of reorientational jump rates.

The relatively sharp fall in line width of the proton resonance absorption which begins at about 30 K (Fig. 1) requires frequencies of relative proton motion of the order of 50 kHz. Since this frequency is several orders of magnitude higher than the frequency of maximum dielectric absorption at a comparable temperature, the initial narrowing is caused by motions to which the dielectric absorption is not strongly sensitive. This is generally also true of previous results[4] for polar ether and ketone guest molecules and one may infer in these cases that the faster motional process corresponds, roughly speaking, to reorientation about the polar axis in which the O atom tends to be held by its affinity to a hexagonal ring (16, 25). Relatively fast motion of this kind is also expected for dioxane and, to the extent that the model of dielectric absorption presented in the last section is a realistic one, only minor dielectric absorption is expected from reorientation about an axis close to the O--O vector.

At higher temperatures the n.m.r. results show a broad and asymmetric distribution of slower reorientational correlation times similar to those responsible for dielectric relaxation. Thus the value of the distribution parameter β (~ 0.33) suggested by the behavior of T_1 (Fig. 2) in the vicinity of its minimum value is consistent with the value expected from extrapolation of the dielectric β's to considerably higher temperatures. The agreement between the "activation energies" given by the high-temperature T_1 slope (1.55 kcal/mol) and by the temperature dependence of maximum dielectric absorption (1.72 kcal/mol) is sufficiently good as to confirm that both relate to essentially the same reorientational processes. The agreement would have been improved if the effects of variation of β with temperature had been incorporated into the experimental activation energies.

A comparison of dielectric and n.m.r. kinetic parameters for dioxane hydrate is given in Table 2, along with earlier results for tetra-

[4]The case of cyclobutanone hydrate is particularly noteworthy; in it line narrowing begins below 15 K but dielectric absorption reaches a maximum at 50 kHz only at 38 K (11, 25).

TABLE 2. Relaxation parameters at temperature (T_m) of minimum T_1

Parameter	Guest	
	1,4-Dioxane	Tetrahydrofuran
Larmor frequency (MHz)	9.2	10.0
T_m (K)	63.3	43
Approximate β	0.33	0.21
τ_0 (diel.) at T_m (s)	1.0×10^{-8}	1.5×10^{-8}
τ_0 (n.m.r.) at T_m (s)	2.8×10^{-8}	4.6×10^{-8}
Minimum T_1 (exptl.) (ms)	18	36
Minimum T_1 (calcd.) (ms)	10	16

hydrofuran hydrate (9). The value of τ_0, the long-time cut-off value of the dielectric distribution, is estimated by extrapolation of the low-temperature dielectric data to the temperature of minimum T_1, where $\beta = 0.33$ is assumed. For the same value of β it may be shown (9) that $\omega\tau_0 = 1.61$ at the temperature of minimum T_1, with ω the Larmor frequency. Values of τ_0 estimated in this way are seen (Table 2) to be about three times as large for n.m.r. relaxation as for dielectric relaxation in both the dioxane and tetrahydrofuran cases. The difference is probably due to the basic differences in the way individual molecular reorientation processes contribute to the two kinds of relaxation when they are widely distributed (9). The same model predicts values of T_1 at the minimum which are within a factor of about two of the experimental values (Table 2). Here the difference probably arises from a basic weakness of the assumption that the mean square fluctuating local field associated with each relaxation process may be identified with the full value of the second moment (15 G^2) which is removed by motional narrowing.

We are greatly indebted to M. E. Bednas for gas chromatography measurements and to Mrs. F. Lee for X-ray photographs.

Palladium(II) Catalyzed Exchange Reactions. XI. Vinyl Propionate Exchange with Acetic Acid Catalyzed by Palladium(II) Acetate[1]

RAJ N. PANDEY AND PATRICK M. HENRY

Guelph–Water Centre for Graduate Work in Chemistry, University of Guelph, Guelph, Ontario N1G 2W1

Received January 30, 1975

RAJ N. PANDEY and PATRICK M. HENRY. Can. J. Chem. 53, 2223 (1975).

The kinetics of the palladium(II) acetate catalyzed exchange of vinyl propionate with acetic acid solvent to give vinyl acetate has been studied in the sodium acetate concentration range from 0 to 1 *M*. The exchange rate first sharply increases as [NaOAc] increases, reaches a maximum at about 0.2 *M* and then gradually decreases as the sodium acetate concentration is increased to 1.0 *M*. Using previous results on the equilibrium between palladium(II) acetate and sodium acetate in acetic acid it can be shown that the rate expression for exchange is: rate = $(k_o + k_t[Pd_3(OAc)_6] + k_d[Na_2Pd_2(OAc)_6])$ $[CH_2{=}CHO_2CC_2H_5]$ where $k_o = 2 \times 10^{-4}$ s^{-1}, $k_t = 0.045\ M^{-1}$ s^{-1}, and $k_d = 0.089\ M^{-1}$ s^{-1}. A monomeric palladium(II) species, $Na_2Pd(OAc)_4$, formed at high [NaOAc] is unreactive. Since the rate expression does not contain a term in [NaOAc], the sodium acetate serves only to convert one palladium(II) species to another. The lack of a [NaOAc] term in the rate expression for the $Na_2Pd_2(OAc)_6$ catalyzed reaction is believed to result from cancellation of an inhibitory term for π-complex formation by a catalytic term in [NaOAc] in the rate determining conversion of π-complex to σ-complex (acetoxypalladation). Stereochemical studies indicate that acetoxypalladation is nonstereospecific. This result is expected since in the chloride free system acetate is both a ligand and a reactant. Thus it can attack from both inside and outside the coordination sphere of Pd(II).

RAJ N. PANDEY et PATRICK M. HENRY. Can. J. Chem. 53, 2223 (1975).

Les cinétiques de l'échange du propionate de vinyle avec l'acide acétique, catalysée par l'acétate de palladium(II), sont étudiées dans l'acétate de sodium pour des concentrations de 0 à 1 *M*. Au début la vitesse d'échange croît rapidement à mesure que [NaOAc] croît, elle atteint un maximum à environ 0.2 *M*, puis décroit progressivement lorsque la concentration en acétate de sodium augmente jusqu'à 1.0 *M*. Utilisant les résultats antérieurs concernant l'équilibre entre l'acétate de palladium(II) et l'acétate de sodium dans l'acide acétique on peut montrer que l'expression de la vitesse d'échange est: vitesse = $(k_o + k_t[Pd_3(OAc)_6] + k_d[Na_2Pd_2(OAc)_6])$ $[CH_2{=}CHO_2CC_2H_5]$ où $k_o = 2 \times 10^{-4}$ s^{-1}, $k_t = 0.045\ M^{-1}$ s^{-1} et $k_d = 0.089\ M^{-1}$ s^{-1}. Une espèce monomérique du palladium(II), $Na_2Pd(OAc)_4$, formée à haute concentration en NaOAc n'est pas réactive. Puisque l'expression de la vitesse ne contient pas le terme en [NaOAc], l'acétate de sodium sert uniquement à la conversion d'une espèce du palladium(II) en une autre. L'absence du terme [NaOAc] dans l'expression de la vitesse pour la réaction catalysée par $Na_2Pd_2(OAc)_6$ pourrait résulter de l'annulation d'un terme inhibiteur dans la formation d'un complexe π par un terme catalytique en [NaOAc] dans la vitesse déterminante de la conversion du complexe π en un complexe σ (acétoxypalladation). Les études stéréochimiques indiquent que l'acétoxypalladation n'est pas stéréospécifique. Ce résultat est attendu puisque dans le système exempt de chlorure, l'acétate est à la fois ligand et réactif. Ainsi, il peut attaquer de l'intérieur et de l'extérieur de la sphère de coordination du Pd(II).

[Traduit par le journal]

Introduction

Previous papers of this series reported studies of exchange of vinylic and allylic groups with solvent containing chloride ion catalyzed by palladium(II) chloride in acetic acid. The groups exchanged were either chloride or various carboxylic acid groups. These studies indicate that exchange proceeded by an addition elimination mechanism illustrated in reactions 1 and 2 (X, Y = Cl or OOCR).

[1] $Pd(II) + Y^- + CH_2{=}CHX \rightarrow$

$$Pd(II)\text{—}CH_2\text{—}\underset{\displaystyle X}{\overset{\displaystyle Y}{CH}} \rightarrow Pd(II) + X^- + CH_2{=}CHY$$

[2] $Pd(II) + Y^- + CH_2{=}CH{-}CHX \rightarrow YCH_2{-}\underset{\displaystyle Pd(II)}{\underset{|}{CH}}{-}CHX \rightarrow YCH_2{-}CH{=}CH_2 + Pd(II) + X^-$

Since the addition and elimination reactions are basic reactions in Pd(II) catalytic chemistry these studies offer a convenient way of elucidating the detailed mechanism of these reactions. This work has recently been reviewed (1).

For present purposes the important results of this study are the following.

The reactive species is a dimeric olefin π-complex formed by reaction 3 (ol = olefin).

[3] $Li_2Pd_2Cl_6 + ol \overset{K_1}{\leftrightharpoons} LiPd_2Cl_5(ol) + LiCl$

A monomeric π-complex formed by reaction 4 can sometimes be detected but is unreactive.

[4] $Li_2Pd_2Cl_6 + 2ol \overset{K_2}{\leftrightharpoons} 2LiPdCl_3(ol)$

With some olefins such as allylic esters π-complex formation can be detected by spectral measurements. In such cases it is found that K_2 is much larger than K_1 so the predominant species is unreactive monomeric π-complex. Also of interest in regard to the present study, is the fact that attainment of equilibrium in this system is very rapid.

This is the first paper of the series to describe a study of exchange in the chloride free system in acetic acid. A study of the equilibria between palladium(II) acetate and sodium or lithium acetate has been published (2). The equilibria operative in this system are given in reactions 5 and 6 (M = Na or Li).

[5] $Pd_3(OAc)_6 + 6MOAc \overset{K_{32}}{\leftrightharpoons} 3M_2Pd_2(OAc)_6$

[6] $M_2Pd_2(OAc)_6 + 2MOAc \overset{K_{21}}{\leftrightharpoons} 2M_2Pd(OAc)_4$

The conversion of trimer to dimer (reaction 5) is complete at [NaOAc] = 0.2 *M* and [LiOAc] = 0.5 *M*. The conversion of dimer to monomer (reaction 6) is not complete even in solutions saturated in NaOAc or LiOAc. One important feature of these equilibria, as opposed to the chloride containing system, is that the reactions are slow, taking of the order of hours to come to equilibrium. This indicates that acetate bridges are nonlabile.

The interaction of olefins with the dimer, $Na_2Pd_2(OAc)_6$, has also been studied (3). In this case two equilibria were detected, one which attained equilibrium rapidly and a second slow equilibrium. The rapid equilibrium is represented by reaction 7 while the slow equilibrium is given by reaction 8 (ol = $CH_2{=}CHO_2CC_2H_5$, $CH_2{=}CHCH_2O_2CC_2H_5$, $PhCH{=}CH_2$, $(CH_3)_3CCH{=}CH_2$).

[7] $Na_2Pd_2(OAc)_6 + ol \overset{K'_{22}}{\rightleftharpoons} Na^+ \begin{bmatrix} {}^-OAc{-}OAc{-}ol \\ | \quad Pd \quad | \quad Pd \quad | \\ OAc{-}OAc{-}OAc \end{bmatrix} + NaOAc$

[8] $Na_2Pd_2(OAc)_6 + 2ol \overset{K'_{21}}{\rightleftharpoons} 2\left(Na^+ \begin{bmatrix} {}^-OAc{-}ol \\ | \quad Pd \quad | \\ OAc{-}OAc \end{bmatrix} \right)$

This study demonstrates that, while bridging acetates are nonlabile in agreement with the palladium(II) acetate – MOAc study, the terminal acetates are quite labile.

The kinetics of the vinyl ester exchange in the chloride free system described in this paper must be interpreted in light of these two equilibrium studies.

Experimental

Materials

The sources and methods of purification of most reagents, as well as preparation of stock solutions, has been described previously (2, 3). The vinyl propionate (Aldrich Chemical Company) was distilled before use. The mixture of *cis*- and *trans*-propen-1-yl propionate was prepared by procedures analogous to those used for preparation of the corresponding acetates (4). Pure samples of the *cis*- and *trans*-isomers were obtained by preparative vapor phase chromatography (v.p.c.) using a 20 ft 20% Carbowax 20M on 60–80 mesh Chromasorb W column. The column temperature was 120° and the helium flow rate was 60 ml/min. The two isomers were identified by their n.m.r. spectra using the assignments previously determined for the corresponding acetate esters (5).

The enol propionate of cyclopentanone was prepared by refluxing cyclopentanone with propionic anhydride using potassium propionate as catalyst. Pure samples were obtained by preparative v.p.c. using the same Carbowax column at 160°.

Kinetic Runs

All kinetic runs were followed by v.p.c. analysis. The reaction mixture was prepared by mixing known amounts of the palladium(II) acetate and sodium or lithium stock acetate solutions and diluting with acetic acid to the final volume. They were thermostated at 25° and allowed to equilibrate for more than 10 half-lives to obtain complete equilibrium between Pd(II) and acetate (reactions 5 and 6) before the run was started by adding neat vinyl propionate. Usually 10–25 μl of vinyl ester for 2–5 ml of reaction mixture was used. Samples of 10–25 μl were withdrawn periodically for v.p.c. analysis. The vinyl propionate concentration was monitored using a 6 ft 20% Carbowax 20M on 60–80 mesh Chromosorb W column at 80°. Helium flow rate was 60 ml/min. In the [NaOAc] range where dimer was the predominant species, the data gave good first order plots for the entire reaction when the data were plotted as a first-order reaction in vinyl propionate. Since all other reagents remain constant for a given run, the rate constant, k_{ex}, for a given run is a pseudo first-order rate constant in vinyl propionate. The rates of reaction were fast enough so that the reaction was over before appreciable amounts of monomeric π-complex were formed (reaction 8). In the [NaOAc] range in which $Pd_3(OAc)_6$ is the major species, the kinetics displayed an induction period before first-order kinetics were observed. The rate constants were obtained from the region of first-order kinetics.

The propenyl propionate reaction mixtures were also analyzed without workup. However, the acetic acid peak had about the same retention time as cyclopentenyl propionate so for these runs aliquots were removed, diluted with CH_2Cl_2, and washed with water and saturated aqueous $NaHCO_3$ to remove the acetic acid and inorganic salts. After the CH_2Cl_2 was dried with anhydrous $MgSO_4$ an aliquot was analyzed using a 20 ft 20% Lac-2R-446 on 60-80 mesh Chromosorb W column at 160°. Helium flow rate was 60 ml/min.

Saponification (6) and oxidation were side reactions in all exchanges so the yield of vinylic acetates was always less than quantitative. With vinyl propionate these side reactions were not serious. With the propenyl propionates the reaction mixture deposited palladium metal after 1 h, at which time the exchange was about 10% complete. The run was always discontinued after Pd(0) precipitated.

Results

All kinetic measurements were made at 25° in dry acetic acid solvent. The effect of vinyl propionate concentration was tested both in the presence and absence of added sodium acetate. As shown in Table 1, the pseudo first-order rate constant in vinyl propionate remains constant in both cases so the reaction is strictly first order in vinyl propionate.

The determination of order in palladium(II) acetate and sodium acetate is complicated since, as mentioned in the introduction, Pd(II) can exist in three forms (see reactions 5 and 6) and sodium acetate can not only be a potential reactant but also acts as a ligand which converts one Pd(II) species to another. Furthermore, because of the complicated nature of the equilibria at a given [NaOAc], the ratios of the three Pd(II) species will not be the same at different total Pd(II) concentrations ($[Pd(II)]_t$). In initial studies it was found that at a given [NaOAc], the value of k_{ex} increased approximately linearly with increasing $[Pd(II)]_t$.

At a given $[Pd(II)]_t$ the rate first increased sharply with increasing [NaOAc], reached a maximum at *ca.* 0.2 *M* [NaOAc] and then decreased slightly with further increase in [NaOAc]. A typical plot is shown in Fig. 1. This type of profile suggests that less reactive trimer is being converted to more reactive dimer which at higher [NaOAc] is converted to unreactive monomer. Since at low [NaOAc] (<0.02 *M*) the trimer is the only species present in appreciable amounts, while at [NaOAc] = 0.2 *M* over 95% of the Pd(II) is in the dimer form, the rate constants for these two species can be readily estimated. With these values and the values of the

equilibrium constants K_{32} in reaction 5 (7.77×10^4 M^{-5} for NaOAc) and K_{21} in reaction 6 (7.6×10^{-4} M^{-1} for NaOAc), the values of k_{ex} at all values of [NaOAc] can be calculated. These calculations were carried out assuming various orders for sodium acetate in the rate expression. Agreement between calculated and

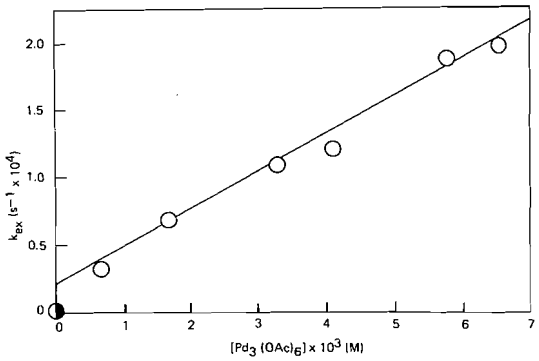

FIG. 3. Plot of exchange rate *vs.* concentration of trimeric Pd(II) acetate: [vinyl ester] = 0.095 M; [NaOAc] = 0. ◑ = Rate in absence of Pd(II). (No measurable exchange in 24 h, some exchange did occur in 7 d.)

observed values of k_{ex} was obtained only if it was assumed that [NaOAc] did not appear in the rate expression. Its only role is thus to convert one Pd(II) species to another. The solid line in Fig. 1 is the calculated rate profile for one value of $[Pd(II)]_t$. At other values of $[Pd(II)]_t$ similar agreement is obtained.

The orders in trimer and dimer can now be checked by varying the Pd(II) concentrations in sodium acetate concentration ranges where either trimer or dimer are the predominant species. The plot for trimer is given in Fig. 2 and the plot for dimer in Fig. 3. In both cases first-order dependence is observed but, surprisingly, each give a positive intercept. This rate might be expected to be the uncatalyzed exchange rate but it can be shown that in the absence of any Pd(II) the exchange rate is much slower than the rate given by the intercept.

Another unexpected result is that addition of even traces of NaOAc causes the rate of exchange to jump to about twice the rate in the absence of any sodium acetate. Data are given in Table 2. Thus, a sodium acetate concentration of 5×10^{-5} M, much less than trimer concentration, causes the rate to rise from 1.80×10^{-4} s^{-1} to *ca.* 4×10^{-4} s^{-1}. Addition of more sodium acetate does not change the rate any further, indicating a zero-order dependence on [NaOAc].

The complete rate expression is thus given by

$$[9] \quad \frac{-d[C_2H_3O_2C_3H_5]}{dt} = [C_2H_3O_2C_3H_5](k_0 + k_t[Pd_3(OAc)_6] + k_d[Na_2Pd_2(OAc)_6])$$

where k_0 is *ca.* 2×10^{-4} s^{-1}, k_t is 0.045 M^{-1} s^{-1}, and k_d is 0.089 M^{-1} s^{-1}. The lithium acetate system was studied in somewhat less detail but gave an analogous rate expression. Sample data are given in Table 3. The average value of k_d in this system is 0.18 M^{-1} s^{-1}.

A few words concerning π-complex formation are in order. As mentioned in the introduction and discussed in other papers of this series (7, 8), the first-order dependence indicates the reactive π-complex is the dimeric π-complex formed by equilibrium shown in reaction 7, rather than the monomeric π-complex formed by the equilibrium shown in reaction 8. In fact when the monomeric π-complex is formed in appreciable amounts, as in the allylic ester exchange in the chloride containing system (8), the rate of exchange is actually inhibited. The previously determined (3) values of K'_{22} (reaction 7) and K'_{21} (reaction 8) are 0.07 and 0.51 M^{-1} respectively. The value of K'_{21} is such that at 0.1 M vinyl propionate at complete equilibrium, about one-third of the Pd(II) would be in the form of unreactive $NaPd(OAc)_3(ol)$, so the rate would only be two-thirds that at low vinyl propionate concentrations. However, the rate of exchange is about five times faster than formation of monomeric π-complex according to reaction 8, so the inhibition does not appreciably affect the value of k_{ex}, especially if the data for the early part of the run is used to calculate k_{ex}.

The value of K'_{22} is such that at [NaOAc] = 0.2 M and [vinyl propionate] = 0.2 M about 7% of the $Na_2Pd_2(OAc)_6$ is in the form of $NaPd_2(OAc)_5(VP)$ (VP = vinyl propionate) while at [NaOAc] = 1.0 M and [VP] = 0.2 M about 1.4% is in the form of π-complex. Thus, slight deviations from the dependencies on [NaOAc] and [VP] from that expected if π-complex formation were insignificant should be found. If the data is treated in the usual fashion, assuming rate of exchange = $k[NaPd_2(OAc)_5(VP)]$, [10] is obtained for the region in which dimer is the only reactive species ($[Na_2Pd_2(OAc)_6]_0$ is concentration of dimer before addition of VP). This rate expression was used in

$$[10] \quad \text{rate} = \frac{k_d K'_{22}[Na_2Pd_2(OAc)_6]_0[VP]}{[NaOAc] + K'_{22}[VP]}$$

calculating the curve in Fig. 1. Better agreement with experiment is obtained when this expression is used.

The effect of enol propionate structure on rate was tested by measuring the rate of exchange of *cis*- and *trans*-1-propen-1-yl propionate, and cyclopentyl propionate. Data are listed in Table 4. It was hoped to obtain the exact rate constants for conversion of *cis*- and *trans*-propenyl propionate to *cis*-propenyl acetate and to *trans*-propenyl acetate. However, side reactions such as saponification and oxidation of the ester were more serious than in the chloride containing system so a complete kinetic analysis could not be carried out. However, qualitatively *trans*-propenyl propionate gave mainly *trans*-propenyl acetate while the *cis* isomer gave mainly *cis*-propenyl acetate.

Discussion

The rate expression given by [9] contains three independent terms, all of which are zero order in [NaOAc]. Each term will be considered separately in order of importance.

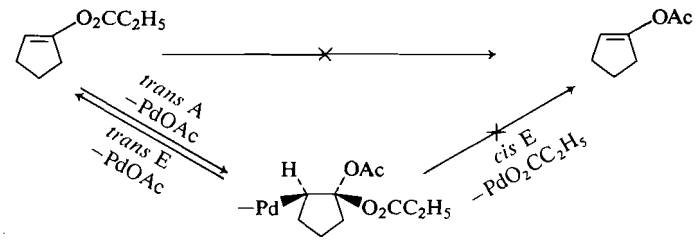
k_d Term

This term represents the exchange catalyzed by the dimeric species, $Na_2Pd_2(OAc)_6$. This term is analogous to the $Li_2Pd_2Cl_6$ catalysis in the chloride system. The two features of this contribution by this term which is different from $Li_2Pd_2Cl_6$ catalysis are (*1*) the lack of a sodium acetate term and (*2*) the stereochemical results. The rate expression for the exchange in the chloride system is given by [11].

[11] $$\text{rate} = \frac{k[Li_2Pd_2Cl_6][VP](k' + k''[LiOAc])}{[LiCl]}$$

Furthermore in the chloride system *cis*-propenyl propionate gave only *trans*-propenyl acetate, and the *trans*-isomer gave *cis*-acetate. Also cyclopentyl propionate did not exchange as a detectable rate. The rate of exchange of the propenyl propionates was at least 10^4 times faster than that for cyclopentyl propionate. The results provided conclusive evidence that acetoxypalladation–deoxypalladation is a very stereospecific process, which other evidence indicated is exclusively *trans* (9). For instance, as shown in reaction 12, cyclopentyl propionate would not be expected to exchange if acetoxypalladation–deacetoxypalladation is stereospecific (A = addition; E = elimination).

[12]



These differences between the two systems are not too surprising in light of the fact that in the chloride system acetate does not effectively compete with chloride as a ligand for Pd(II). As a result it is only a reactant. In the chloride free system acetate is both a ligand and reagent. A better comparison with acetate exchange catalyzed by $Na_2Pd_2(OAc)_6$ might thus be vinyl chloride exchange with radioactive lithium chloride catalyzed by $Li_2Pd_2Cl_6$ (10).

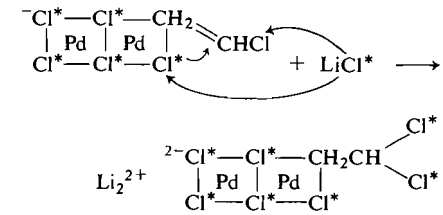
[13] $$CH_2{=}CHCl + LiCl^* \xrightarrow{Li_2Pd_2Cl_6} CH_2{=}CHCl^* + LiCl$$

In this case chloride is also both a ligand and reactant, and the rate expression is analogous to acetate exchange by $Na_2Pd_2(OAc)_6$ in that it does not contain a term in [LiCl]. Also in this case stereochemical studies indicate that chloropalladation, as opposed to acetoxypalladation in this system, is a nonstereospecific process.

[14] $$\text{rate} = k[Li_2Pd_2Cl_6][C_2H_3Cl]$$

The lack of a [LiCl] term must result from the cancellation of an inhibitory term in the π-complex formation step (reaction 3) by a catalytic term in the chloropalladation step. The lack of stereospecificity is explained by the fact chloride can attack from either inside or outside the coordination sphere. Note that both modes of attack require a catalytic term in [LiCl] since the chloride coordinated to Pd(II) cannot complete its transfer to carbon until a chloride from solution fills the incipient vacant coordination site on Pd(II) (1, 10).

[15]



An analogous situation would exist in the chloride free system with acetate now taking the role of chloride. The inhibitory term in reaction 16 would be cancelled by a catalytic term from reaction 17, where acetoxypalladation can now

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

[16] $Na_2Pd_2(OAc)_6 + VP \rightleftharpoons NaPd_2(OAc)_5(VP) + NaOAc$

[17] 
occur from either inside or outside the coordination sphere of Pd(II). This is consistent with the stereochemical results which indicate acetoxy palladation is nonstereospecific in this system.

The present results provide further evidence that addition of Pd(II) and nucleophiles to double bonds is not always stereospecific but depends on reagent, reaction conditions, and probably other more subtle factors such as olefin structure and solvent (11). Thus, a phenyl ligand is convalently bonded to Pd(II) and is constrained to add *cis* to olefin (12). Hydride probably adds *cis* for the same reason. However, reagents such as chloride and acetate can add *cis* or *trans* depending on their ability to coordinate to Pd(II) under the reaction conditions.

k_t Term

Somewhat less is known about this term than the k_d. One problem in defining this term is that no interaction between the trimer and vinyl propionate could be detected spectroscopically so equilibrium studies could not be carried out. This follows from the fact that vinyl esters are poor at complexing Pd(II) as compared with allylic esters or ordinary monosubstituted olefins such as styrene (3).

The reaction is zero-order [NaOAc] and requires an induction period to form a catalytically active species which is presumably an olefin π-complex. It is not suprising there is an induction period since to form a π-complex, acetate bridges must be broken, and it is known (2, 3) that bridging acetates are nonlabile.

Although the data provides little evidence for the exact nature of the reactive intermediate, the two most likely possibilities are given by reactions 18 and 19.

[18] $Pd_3(OAc)_6 + 2VP \rightleftharpoons$ 
[19] $Pd_3(OAc)_6 + VP \rightleftharpoons$ 
The first has some analogy in formation of π-allylic complexes (13).

[20] $Pd_3(OAc)_6 + R_1CH_2CH{=}CHR_2 \longrightarrow$ 
In both cases a [NaOAc] dependent term in the rate expression arising from attack of acetate on the π-complex, might be expected. It is possible that acetate is behaving as a bidentate ligand and reagent in the acetoxypalladation step. With the intermediate formed via reaction 19 the scheme would be given by reaction 21.

[21] 
Such internal attack would be expected to give specific *cis* addition. Unfortunately because of the slowness of exchange and the induction time as compared with rates of side reactions, stereochemical studies are experimentally very difficult with the trimer and were not attempted.

The reason the rate jumps by a factor of about two when trace amounts of sodium acetate are added is not clear but does appear to be a real effect since it is reproducible. Perhaps the sodium acetate catalyzes the formation of the active π-complex.

k_0 Term

This term is the most mysterious of all since it is zero order in Pd(II). There is a temptation to dismiss it as an experimental artifact but the positive intercepts in Figs. 2 and 3 appear to be outside of experimental error. A possible scheme which would give a reaction catalyzed by Pd(II) yet zero order in Pd(II) would be that shown in reaction 22.

$$[22]\quad CH_2{=}CHO_2CC_2H_5 \xrightarrow{\text{slow}} \text{intermediate} \xrightarrow[\text{Pd(II)}]{\text{fast}} \text{products}$$

In any case this term is small and further speculation as to its origin, if in fact it is real, seems unwarranted.

Conclusions

There have been a number of very interesting studies of catalysis by palladium(II) acetate in acetic acid and some intriguing stereochemical and kinetic results have been reported (13–18). The present kinetic study as well as the two preceding equilibria studies (2, 3) demonstrate the complexity of this system with three different Pd(II) species to consider and equilibria which may be either slow or fast. Thus, if the vinyl propionate exchange were slower, the complication of formation of unreactive π-complexes (reaction 8) would arise. This complication actually does arise in allylic propionate exchange and is probably present in olefin oxidation (15). Thus, in order to understand completely the various observations in this system, the various equilibria and rates of attainment of equilibria must be taken into account.

Monosubstituted Derivatives of $(L–L)Fe_2(CO)_6$ (L–L = fluorocarbon bridged ligand)

LIAN SAI CHIA, WILLIAM R. CULLEN, JOHN R. SAMS, AND JAMES C. SCOTT

Chemistry Department, University of British Columbia, Vancouver, British Columbia V6T 1W5

Received January 31, 1975

LIAN SAI CHIA, WILLIAM R. CULLEN, JOHN R. SAMS, and JAMES C. SCOTT. Can. J. Chem. **53**, 2232 (1975).

The reaction of the ditertiary arsines and phosphines $f_n$fars, $f_n$fos, and f_nAsP, (L–L), with $Fe(CO)_5$ at 150° is a superior route to the complexes $(L–L)Fe_2(CO)_6$. Two are reported for the first time (L–L = $f_6$fars, $f_8$fars). The complexes react with monodentate and certain potentially bidentate ligands on u.v. irradiation to afford the monosubstituted derivatives $L(L–L)Fe_2(CO)_5$ and $(L–L)'(L–L)Fe_2(CO)_5$. Spectroscopic studies, in particular magnetically perturbed Mössbauer spectra, indicate that the site of substitution is *trans* to the Fe^A—Fe^B bond and *cis* to the two group V atoms (on Fe^A). Disubstitution seems to result in further displacement of CO from either Fe^A or Fe^B.

LIAN SAI CHIA, WILLIAM R. CULLEN, JOHN R. SAMS et JAMES C. SCOTT. Can. J. Chem. **53**, 2232 (1975).

La réaction des arsines et phosphines ditertiaires $f_n$fars, $f_n$fos et f_nAsP, (L–L), avec $Fe(CO)_5$ à 150° est une excellente manière d'arriver aux complexes $(L–L)Fe_2(CO)_6$. Deux complexes sont décrits pour la première fois (L–L = $f_6$fars, $f_8$fars). Les complexes réagissent avec des ligands monodentates et certains ligands potentiellement bidentates sous irradiation u.v., pour conduire aux dérivés mono-substitués $L(L–L)Fe_2(CO)_5$ et $(L–L)'(L–L)Fe_2(CO)_5$. Les études spectroscopiques, en particulier le spectre Mössbauer magnétiquement perturbé, indiquent que la position de substitution est *trans* par rapport au lien Fe^A—Fe^B et *cis* par rapport aux deux atomes du groupe V (sur Fe^A). La disubstitution semble résulter d'un déplacement ultérieur du CO soit de Fe^A, soit de Fe^B. [Traduit par le journal]

Introduction

The fluorocarbon-bridged ligands $f_n$fars $[(CH_3)_2AsC{=}CAs(CH_3)_2(CF_2)_{n/2}]$, $f_n$fos $[(C_6H_5)_2PC{=}CP(C_6H_5)_2(CF_2)_{n/2}]$, and f_nAsP $[(C_6H_5)_2PC{=}CAs(CH_3)_2(CF_2)_{n/2}]$ have an almost unique ability to form complexes of formula $(L–L)Fe_2(CO)_6$ in which the two group V donor atoms and the double bond of the bridging group are coordinated to the iron atoms (1, 2). The solid state structure of $f_4farsFe_2(CO)_6$ (3) is seen in Fig. 1.

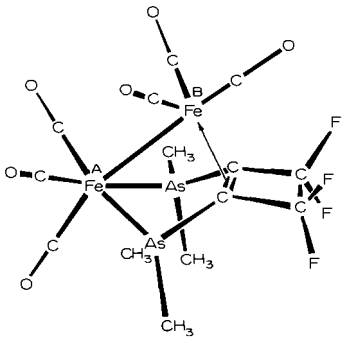

FIG. 1. The solid state structure of $f_4farsFe_2(CO)_6$.

The present investigation describes the preparation of two new $(L–L)Fe_2(CO)_6$ complexes where L–L = $f_6$fars and $f_8$fars and some substitution reactions of the complexes using a variety of Lewis bases, L, which afford $L(L–L)Fe_2(CO)_5$. Magnetically perturbed Mössbauer spectra have been used as an aid in establishing the site of substitution (4).

Experimental

All volatile chemicals were manipulated using a conventional vacuum system. The Carius tubes used in this work, with volumes of about 80 ml, were constructed of thick-walled Pyrex glass. All chromatography was carried out on Florisil columns under a nitrogen atmosphere using nitrogen saturated solvents. The petroleum ether was the 30–60° boiling fraction.

Infrared spectra were recorded on a Perkin–Elmer 457 spectrophotometer and calibrated using polystyrene and cyclohexane. Unless otherwise stated, all n.m.r. spectra were run on a Varian T-60 spectrometer with chemical shifts given in p.p.m. downfield from internal TMS for ^1H, and upfield from internal $CFCl_3$ for ^{19}F spectra. Ultraviolet and visible spectra were run in methylene chloride solution using a Cary 15 spectrophotometer. Mass spectra were measured with an AEI MS-9 mass spectrometer with direct introduction of solid samples. All molecular weights were measured with a Mechrolab

vapor pressure osmometer using benzene as a solvent. Melting points were determined in evacuated capillaries and are uncorrected. Most microanalyses were performed by P. Borda of this department, and some by Pascher Mikroanalytisches Laboratorium, Bonn, Germany.

The Mössbauer spectrometer has been described (2, 4). Spectra in zero applied field were recorded with the $^{57}Co(Cu)$ source at room temperature and the finely powdered absorbers at 80 K in transmission geometry. The data were least-squares fitted to Lorentzian components using unconstrained fitting parameters, and isomer shifts are quoted relative to the centroid of the sodium nitroprusside spectrum. Magnetic perturbation Mössbauer spectra were obtained as described elsewhere (4), employing longitudinal magnetic fields of up to 50 kG.

The iron pentacarbonyl and the more common ligands were obtained commercially and used without further purification. The fluorocarbon-bridged ligands f_nAsP ($n = 4, 6$), and f_nfos and f_nfars ($n = 4, 6, 8$) were prepared using published procedures (2, 5).

Preparation of $(L–L)Fe_2(CO)_6$ Complexes

The method used to obtain $f_6farsFe_2(CO)_6$ is given as an example. A benzene solution (10–15 ml) containing 2.0 mmol of f_6fars and 5 to 10 g of $Fe(CO)_5$ was heated at 150° in an evacuated Carius tube for 1 d. At the end of the reaction period the initially yellow solution had become deep red. The tube was cooled in liquid nitrogen and opened. The volatile contents were removed at reduced pressure. The resulting red residue was dissolved in a minimum amount of methylene chloride and chromatographed on a Florisil column. A 5% diethyl ether – 95% petroleum ether mixture eluted the more soluble iron carbonyl complexes (*e.g.* $(L–L)Fe(CO)_4$, $(L–L)Fe(CO)_3$, etc.). The desired product was eluted with diethyl ether/petroleum ether (1:9) and was obtained as an orange-red solid m.p. 225° in 70% yield. ^1H n.m.r.; singlets at 1.55 and 2.40 p.p.m.

Anal. Calcd. for $C_{15}H_{12}As_2F_6Fe_2O_6$: C, 27.5; H, 2.3. Found: C, 26.8; H, 2.3.

In the same way $f_8farsFe_2(CO)_6$ was obtained as an orange-red solid m.p. 210° in 45% yield after 1 d. ^1H n.m.r.; singlets at 1.57 and 2.53 p.p.m.

Anal. Calcd. for $C_{16}H_{12}As_2F_8Fe_2O_6$: C, 26.9; H, 1.7. Found: C, 27.0; H, 1.9.

Other known $(L–L)Fe_2(CO)_6$ complexes could also be prepared by this new method, *e.g.* $f_4farsFe_2(CO)_6$, reaction time 1 d, yield 20%; $f_4AsPFe_2(CO)_6$, 2 d, 90%; $f_4fosFe_2(CO)_6$, 2 d, 80%; $f_6AsPFe_2(CO)_6$, 1 d, 50%; $f_6fosFe_2(CO)_6$, 2 d, 10%.

Preparation of Monosubstituted Derivatives of $(L–L)Fe_2(CO)_6$

The general procedure was as follows, specific details are given in Table 1. The $(L–L)Fe_2(CO)_6$ complex (1.0 mmol), an equimolar amount of ligand, and acetone (15–20 ml) were sealed under vacuum in a Carius tube. After irradiation for several days with a 100 W u.v. lamp (20 cm from the tube) the tube was opened and the volatile contents were removed. The residue was dissolved in a small amount of methylene chloride and chromatographed on Florisil. The excess ligand and the unreacted $(L–L)Fe_2(CO)_6$ were removed by eluting with diethyl ether/petroleum ether (1:9). The desired product was eluted with the solvent indicated in Table 1. Analytical data for these complexes are also given in Table 1 and some spectroscopic data are listed in Table 2.

Use of a 450 W lamp in a quartz jacket inserted into the reaction solution gave the same products but much shorter reaction times were needed.

The di- and trisubstituted derivatives were obtained by irradiating $(L–L)Fe_2(CO)_6$, $L(L–L)Fe_2(CO)_5$, or $L_2(L–L)Fe_2(CO)_4$ in the presence of excess monodentate ligand, L.

Results and Discussion

$(L–L)Fe_2(CO)_6$ Complexes

The ligands f_6fars and f_8fars react with $Fe(CO)_5$ at 150° to give high yields of $f_6farsFe_2(CO)_6$ and $f_8farsFe_2(CO)_6$. Previously the best method of preparing this type of complex was from the more expensive $Fe_3(CO)_{12}$ (6). The new method is superior in terms of yields and ease of workup.

The two new $(L–L)Fe_2(CO)_6$ complexes have spectroscopic properties which are very similar to those of the others of the same formula and hence are assumed to have an analogous structure (Fig. 1).

During initial studies on the preparation of the $(L–L)Fe_2(CO)_6$ complexes of f_nfos (2) and f_nAsP (6), it was found that the yields decrease with increased ring size (compounds with $n = 8$ are not known). This was originally taken as an indication that as the ring becomes less strained there is less tendency for the double bond to coordinate to Fe^B. However, the good yields of f_6fars and f_8fars derivatives (70% and 45% respectively) suggest that ring strain is not the only factor and that steric hindrance (possibly by bulky $P(C_6H_5)_2$ groups) plays some part. The related unstrained acyclic ligand *cis*-$(CH_3)_2AsC(CF_3)=C(CF_3)As(CH_3)_2$ also forms a $Fe_2(CO)_6$ derivative (7).

The infrared carbonyl bands of the known $(L–L)Fe_2(CO)_6$ complexes are listed in Table 3. Three of the six carbonyl stretching frequencies $\sim$2061, $\sim$2023, and $\sim$1983 cm^{-1}, are relatively insensitive to ligand substitution, the variation in frequency, $\Delta\nu(CO)$, being less than 7 cm^{-1}, while the other three, at $\sim$1997, $\sim$1966, and $\sim$1954 cm^{-1}, vary markedly with ligand substitution ($\Delta\nu(CO) = 12$ to 22 cm^{-1}). Provided no coupling occurs between carbonyl groups on Fe^A and those on Fe^B (Fig. 1), then the three $\nu(CO)$ bands at $\sim$2061, $\sim$2023, and $\sim$1983 cm^{-1} can be assigned to CO groups on Fe^B. The $\nu(CO)$ of the other three carbonyl groups on Fe^A increase in the order $(L–L) = f_nfars < f_nAsP < f_nfos$. This order is expected on the

basis of phosphines being better π-acceptors than arsines (8).

The electronic spectra of the (L–L)$Fe_2(CO)_6$ complexes (Table 4) show two strong bands. Gray and co-workers (9, 10) have assigned an intense band at 244 nm in $Fe(CO)_5$ to the lowest allowed metal-to-ligand charge transfer transition. It is likely that the bands at ~230 nm in the (L–L)$Fe_2(CO)_6$ complexes have the same origin. The other strong bands at ~375 nm are similar, both in energy and extinction coefficient, to the σ–σ* band in $Mn_2(CO)_{10}$ which involves orbitals from the metal–metal bond (11, 12). If this assignment is carried over to the (L–L)$Fe_2(CO)_6$ derivatives then the observed order of λ_{max} $f_nfosFe_2(CO)_6$ < $f_nAsPFe_2(CO)_6$ < $f_nfarsFe_2(CO)_6$ could be an indication that the better donors increase the electron density on Fe^A allowing it to become a better donor in turn to Fe^B thus increasing the strength of the Fe—Fe bond.

^{57}Fe Mössbauer parameters for the (L–L)$Fe_2(CO)_6$ complexes are given in Table 5. In each case the spectra in zero applied magnetic field consist of four lines, and in principle there are three ways of assigning these lines to the two iron atoms. Previously, line assignments in such compounds have been based on known crystallographic data and predicted effects on the Mössbauer parameters of changes in ligand structure. We have recently shown (4) that magnetically perturbed Mössbauer spectra can pro-

vide completely unequivocal assignments of the spectral lines to the two iron atoms in binuclear complexes of this type. Three of the present compounds (L–L = $f_4$fos, f_4AsP, $f_6$fars) have been studied in applied magnetic fields, and the results have confirmed our earlier assignments (2) based on semi-intuitive arguments.

As expected in view of the coordination geometry about the two iron atoms in $f_4farsFe_2(CO)_6$ (Fig. 1), Fe^A shows a smaller quadrupole splitting $|\Delta E_Q|$ than does Fe^B in all the $(L\text{–}L)Fe_2(CO)_6$ complexes. There are two other interesting trends in the $|\Delta E_Q|$ values in Table 5. Firstly, for Fe^A $|\Delta E_Q|$ in the compounds $f_nAsPFe_2(CO)_6$ are larger than the values observed in the derivatives $f_nfosFe_2(CO)_6$ and $f_nfarsFe_2(CO)_6$, where both group V atoms bonded to Fe^A are the same. This behavior presumably reflects differences in σ-donor and π-acceptor abilities of the phosphine and arsine groups in the "mixed" ligands.

Secondly for Fe^B $|\Delta E_Q|$ decreases as the value of n increases in each series of compounds containing $f_n$fos, $f_n$fars, and f_nAsP. The coordination about Fe^B may be regarded as distorted trigonal bipyramidal if the double bond of the ligand is considered as a single entity forming a π-bond with the iron moiety (3). It may also be regarded as distorted octahedral if the carbon atoms at each end of the double bond are considered to form two normal σ-bonds with Fe^B (1). The trend in $|\Delta E_Q|$ for Fe^B may indicate a change from the former bond type to the latter as n increases, since an opening of the angles at the double-bonded carbon atoms would facilitate the formation of σ-bonds to Fe^B.

In all the $(L\text{–}L)Fe_2(CO)_6$ complexes the isomer shift δ of Fe^B is greater than that of Fe^A, showing a smaller s-electron density at the former nucleus. To satisfy the effective atomic number rule, Fe^A can be viewed as forming a dative bond to Fe^B, so it is not surprising that the s-electron density at Fe^B remains somewhat less than that at Fe^A. Although the electronic spectra suggest that the iron–iron bond may be slightly stronger in the phosphine derivatives than in the arsine ones, this is not reflected in the isomer shift data, where δ for Fe^B is constant within experimental error and independent of the nature of the ligand. It is possible, of course, that the admixture of electron density in the $Fe^A \rightarrow Fe^B$ bond is such that any increase in 4s electron donation is effectively counterbalanced by an additional shielding from enhanced 3d donation, leaving the isomer shift of Fe^B constant. On the other hand, δ of Fe^A is fairly sensitive to the nature of the ligand, being lowest for the $f_n$fos derivatives and increasing when arsenic replaces phosphorus as the donor atom. This is the trend usually observed in similar iron carbonyl complexes (2, 13) and reflects the fact that phosphines are better σ-donors and π-acceptors than arsines (8).

For the three $(L\text{–}L)Fe_2(CO)_6$ complexes studied in applied magnetic fields, we find that

the quadrupole coupling constants e^2qQ are negative at Fe^A and positive at Fe^B. Since the quadrupole moment eQ is positive for ^{57m}Fe, e^2qQ carries the same sign as $V_{zz}(= eq)$, the principal component of the electric field gradient (e.f.g.) tensor. Thus, our results indicate that there is an excess of electron density along the z-axis at Fe^A and a deficiency of electron density along the z-axis at Fe^B. Although one does not know the relative orientations of the molecular axes and the principal e.f.g. axes at either site, it does not seem unreasonable to assume that the z-axis of the e.f.g. lies roughly along the iron–iron bond direction in both cases (*vide infra*). If this is so, the signs of V_{zz} at each site are at least consistent with the formulation of an $Fe^A \rightarrow Fe^B$ dative bond.

In fitting the magnetic perturbation spectra we have also attempted to estimate the asymmetry parameters η at each site. Theoretical spectra were computed with $\eta = 0.0$, 0.6, and 0.8 for each iron atom, and all possible combinations of these η values were examined. The preferred solution was that which yielded the smallest value of χ^2. We should stress that this procedure does not necessarily provide the best possible value of η, especially since the computed spectra are rather insensitive to η values less than about 0.5, but merely serves to indicate whether η is large or small at each site. In the three cases examined, best agreement was obtained with $\eta = 0.6$ at Fe^B, although η at Fe^A appears to vary from compound to compound. For $f_6farsFe_2(CO)_6$, $\eta(Fe^A)$ is small (4), but it is large for the other two complexes (see Fig. 2). This is perhaps not surprising for $f_4AsPFe_2(CO)_6$ since the two group V donor atoms differ, but we might have expected $f_4fosFe_2(CO)_6$ to be more like the f_6fars complex. It may be that geometrical factors are quite important in determining η at Fe^A.

Substitution Reactions

All the above (L–L)$Fe_2(CO)_6$ complexes react with various arsines and phosphines under u.v. irradiation to give a number of derivatives which can be classified into eight groups (14). Only those derivatives of monodentate ligands, including potentially bidentate acting in a monodentate fashion, will be considered in this paper (Table 1).

Most of the derivatives are monosubstituted and have the formula (L)(L–L)$Fe_2(CO)_5$. Their

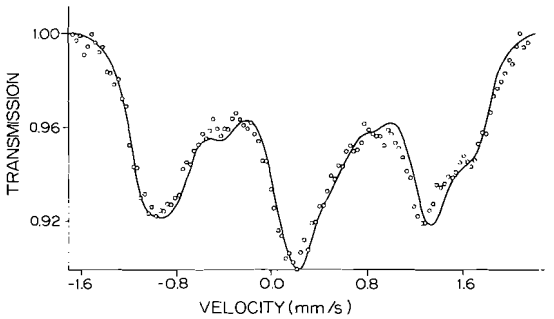

FIG. 2. ^{57}Fe Mössbauer spectrum of $f_4AsPFe_2(CO)_6$ in a parallel magnetic field of 50 kG. Site A, $\Delta E_Q = -0.83$ mm/s, $\eta = 0.8$; site B, $\Delta E_Q = +1.45$ mm/s, $\eta = 0.6$.

infrared spectra show only three ν(CO) bands suggesting a structure with a plane of symmetry. This is confirmed by the ^1H n.m.r. spectra of $(PhO)_3Pf_4farsFe_2(CO)_5$ and $(f_4AsP)^mf_4farsFe_2(CO)_5$ (m indicates monodentate) where the arsenic methyl groups of the f_4fars moiety appear as two singlets at 1.60 and 2.07 p.p.m., and 1.03 and 2.35 p.p.m. respectively. ($f_4farsFe_2(CO)_6$ absorbs at 1.50 and 2.21 p.p.m. (2).)

The f_4AsP compound also has an arsenic methyl singlet at 1.01 p.p.m. indicating that this particular —$As(CH_3)_2$ group is "dangling" so that, not unexpectedly, it is the phosphorus end of the ligand which is coordinating.[1] These results indicate that monosubstitution occurs at one of the "axial" carbonyl groups in Fig. 1 *i.e.* a carbonyl group *trans* to the Fe—Fe bond.

The solid state structure of $(f_4AsP)f_4AsPFe_2(CO)_4$ (15) (Fig. 3) shows that one f_4AsP ligand has displaced two carbonyl groups from $f_4AsPFe_2(CO)_6$ and that the ligand is chelated to Fe^A with the $P(C_6H_5)_2$ moiety *trans* to the Fe—Fe bond. This result also indicates that monosubstitution would take place on Fe^A and that the axial CO group would be displaced. Further substitution of the $Fe_2(CO)_6$ skeleton can be achieved using $(C_6H_5O)_3P$ and $(C_6H_5)_3E$ (E = As, Sb). The trisubstituted complexes are not very stable and are difficult to characterize. The disubstituted derivative $[(C_6H_5O)_3P]_2(f_4AsP)Fe_2(CO)_4$ has an infrared spectrum very similar to that of the chelate derivative $f_4AsP(f_4AsP)Fe_2(CO)_4$. Hence both ligands are prob-

[1]The "dangling" ligand could absorb at 1.03 p.p.m. and the f_4fars at 1.01. The following argument is valid in either case.

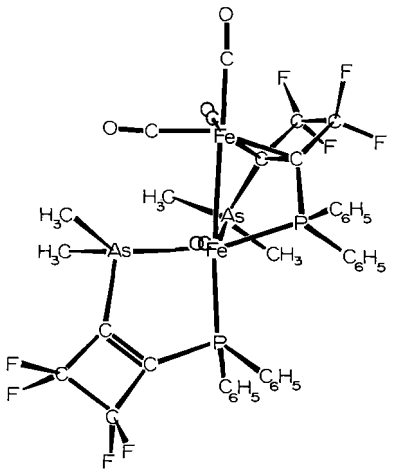

FIG. 3. The solid state structure of $(f_4AsP)f_4AsPFe_2(CO_4)$.

ably attached to Fe^A. Monosubstitution of $f_4AsPFe_2(CO)_6$ by $(C_6H_5O)_3P$ on Fe^A lowers the frequency of ν(CO)(max) on Fe^B by 25 cm^{-1}. Further substitution to give $((C_6H_5O)_3P)_2f_4AsPFe_2(CO)_4$ results in a further drop of ν(CO)(max) by ~27 cm^{-1}. However on substituting $f_4AsPFe_2(CO)_6$ by $(C_6H_5)_3As$, monosubstitution (on Fe^A) lowers ν(CO)(max) by ~25 cm^{-1} but on disubstitution, ν(CO)(max) is decreased by a further ~52 cm^{-1}, indicating that the second ligand is substituting on Fe^B where it can have a more direct effect on the frequency. The resulting spectrum is also very similar to compounds of the type $(L—L)^b(L—L)Fe_2(CO)_4$ where $(L—L)^b$ is believed to be bridging Fe^A and Fe^B.[2]

Mössbauer spectra have been determined for several $(L)(L–L)Fe_2(CO)_5$ derivatives and are similar in appearance to those of the $(L–L)Fe_2(CO)_6$ complexes. A magnetic perturbation Mössbauer spectrum of $(C_6H_5O)_3Pf_4AsPFe_2(CO)_5$ confirmed that the inner pair of lines arise from Fe^A and the outer pair from Fe^B. Using this as a basis the spectral parameters for the monosubstituted derivatives have been deduced and are given in Table 6.

Examination of the data in Tables 5 and 6 shows that the isomer shift of Fe^A increases on going from $(L–L)Fe_2(CO)_6$ to $(L)(L–L)Fe_2(CO)_5$, whereas that of Fe^B shows a very slight decrease. Since substitution of CO by a group V donor atom has always been found to increase δ of the substituted iron atom (2, 13), these results clearly confirm that substitution occurs at Fe^A. Usually, the increase in isomer shift found on replacing CO by an arsine or stibine is greater than that for replacement of CO by a phosphine (16). In going from $f_4farsFe_2(CO)_6$ to $(f_4AsP)^mf_4farsFe_2(CO)_5$ δ of Fe^A increases by 0.06 mm/s, compared to an increase of 0.08 mm/s for $(C_6H_5)_3Pf_4AsPFe_2(CO)_5$ relative to $f_4AsPFe_2(CO)_6$, while the increase for the $(C_6H_5)_3Sb$ derivative is 0.15 mm/s. This supports the previous conclusion that in $(f_4AsP)^m$-$f_4farsFe_2(CO)_5$ the f_4AsP ligand is bonded through phosphorus.

The magnetic perturbation result for $(C_6H_5O)_3Pf_4AsPFe_2(CO)_5$ shows that the signs of e^2qQ at the two iron sites are the same as in the $(L–L)Fe_2(CO)_6$ complexes (Table 6). In general the magnitude of the quadrupole splitting for Fe^A is smaller than that in the corresponding $(L–L)Fe_2(CO)_6$ derivatives, and in particular the reduction in $|\Delta E_Q|$ is very large for the $(C_6H_5)_3$-Sb complex. These results imply that the change in $|\Delta E_Q|$ for Fe^A on substitution arises chiefly from differences in σ- and π-bonding abilities of the substituents relative to CO. Although geometry changes which follow on ligand substitution may play some role in determining the precise value of $|\Delta E_Q|$, they are clearly not the major factor. For most of the monosubstituted derivatives $|\Delta E_Q|$ for Fe^B is somewhat smaller than in the corresponding $(L–L)Fe_2(CO)_6$ complexes. The fact that V_{zz} is opposite in sign at the two sites and that substitution at Fe^A tends to decrease the magnitude of the e.f.g. at both sites, suggests that V_{zz} is directed more or less along the iron–iron bond, as assumed above.

The Mössbauer data, in particular the negative V_{zz} at Fe^A, appear to confirm that substitution in the $(L)(L–L)Fe_2(CO)_5$ complexes occurs *trans* to the Fe—Fe bond. In the $(L–L)^b(L–L)$-$Fe_2(CO)_4$ compounds mentioned above, where the bite of the bridging ligand insures "equatorial" substitution, e^2qQ for Fe^A is dramatically increased in magnitude and is positive in sign.[2] Since ΔE_Q remains small and negative in the $(L)(L–L)Fe_2(CO)_5$ complexes, *trans* substitution seems far more likely.

The electronic spectra of the derivatives of $(L–L)Fe_2(CO)_6$ also have an intense band near 380 nm which is at longer wavelength than in the parent. In the monosubstituted $L(L–L)Fe_2$-

§Analytical data were not obtained for this complex.

$(CO)_5$ complexes the red shift is not particularly sensitive to the nature of the ligand, L. (The range of the red shifts in derivatives of $Mn_2(CO)_{10}$ is wider (17)[3].) The λ_{max} of di- and trisubstituted derivatives increases as the degree of substitution. The considerable difference in λ_{max} for $L_2f_4AsPFe_2(CO)_4$ where L = $(C_6H_5O)_3P$ (402 nm) and $(C_6H_5)_3As$ (432 nm) may be a further indication of substitution at Fe^A and Fe^B in the case of the arsine derivative.

Reçu le 7 janvier 1975

GÉRARD CHAPUT, GEORGES JEMINET ET JEAN JUILLARD. Can. J. Chem. **53**, 2240 (1975).

Les constantes d'association 1:1 avec des cations monovalents d'un certain nombre d'éthers de polyéthylène glycols préparés ici ont été mesurées par potentiométrie avec des électrodes sélectives (Na^+, K^+) et par conductométrie (Cs^+, Tl^+) dans le méthanol à 25 °C.

On montre que l'augmentation du nombre de sites coordinants (oxygènes) entraine un accroissement de la constante d'association K_A et de la sélectivité K^+/Na^+.

Le remplacement de deux groupements méthoxy terminaux dans la chaine par des groupements amide primaire ou ester réduit les propriétés complexantes des ligandes.

La stéréochimie de la coordination des polyéthers biphényliques est discutée.

GÉRARD CHAPUT, GEORGES JEMINET, and JEAN JUILLARD. Can. J. Chem. **53**, 2240 (1975).

We report data concerning the association of monovalent cations with some polyethyleneglycol ethers that we have prepared.

1:1 association constants K_A have been obtained in methyl alcohol at 25 °C using selective glass electrode potentiometric measurements for Na^+ and K^+ and conductimetric measurements for Cs^+ and Tl^+.

The values obtained for K_A and for the selectivity ratio $K_A(K^+)/K_A(Na^+)$ increase with the number of coordinating sites.

Replacement of the two methoxy terminal groups in the chain by primary amide or ester groups reduces the complexing properties of the ligand.

The stereochemistry of the coordination is discussed in the case of some biphenylic polyethers.

Introduction

Dans un travail précédent, nous avons déterminé les constantes d'association des sels neutres formés par la grisorixine (1), un antibiotique polyéther monoacide, en chaîne ouverte, isolé au laboratoire (2). Son mode d'action[1] le situe dans les composés ionophores[2] du groupe de la nigéricine qui induisent un transport cationique à travers les membranes cellulaires.

L'étude de modèles accessibles par la synthèse chimique constituait un prolongement possible et normal du travail entrepris dans le cadre de la recherche d'ionophores nouveaux.

Au cours de cette première investigation, nous nous sommes intéressés aux associations de faible stabilité qui existent entre les polyéthers éthyléniques acycliques sans fonction dissociable et les cations monovalents Na^+, K^+, Cs^+ et Tl^+. Ces molécules simples présentent l'enchaînement structural —O—C—C—O— que l'on rencontre dans les antibiotiques carboxyliques.

Pour quelques éthers méthyliques de polyéthylène glycols ou glymes, des constantes d'association ont été déterminées dans le méthanol (4, 5) ou le tétrahydrofuranne (6). Nous avons étendu ce travail à une série de polyéthers aliphatiques, aromatiques ou fonctionnalisés en bout de chaîne. Les mesures ont été effectuées dans le méthanol anhydre, les effets relatifs sont comparables à ceux obtenus dans l'eau mais les constantes mesurées sont plus élevées.

L'équilibre de l'association 1:1 du polyéther P et du cation M^+ s'écrit:

[1] $$P_{MeOH} + M_{MeOH}^+ + A_{MeOH}^- \rightleftarrows (PM^+)_{MeOH} + A_{MeOH}^-$$

[2] $$K_A = \frac{c_{PM^+}}{c_P c_{M^+}} \frac{y_{PM^+}}{y_P y_{M^+}}$$

y coefficients d'activité, c concentrations.

[1] Travail non publié de R. Durand.

[2] Nomenclature de Pressman et Harris (3).

On a choisi des sels MA présentant une dissociation la plus complète possible dans le milieu. La constance des valeurs K_A obtenues pour des concentrations relatives en P et en M^+ variables montre que la formation des complexes d'ordre supérieur 2P, M^+ ... n'influence pas l'équilibre 1.

Pour la connaissance de l'activité de M^+, seuls les cations Na^+ et K^+ donnent des réponses stables et reproductibles des électrodes de verre sélectives utilisées, en présence des polyéthers. Aussi, une deuxième série de mesures a été effectuée par conductométrie avec Cs^+ et Tl^+.

Partie expérimentale

Produits

Sels et solvants

Le méthanol utilisé est distillé une première fois à l'aide d'une colonne à remplissage, il est traité ensuite à reflux sur du magnésium en présence d'iode. Après une nouvelle distillation, on obtient un solvant présentant les caractéristiques suivantes, $\kappa < 5 \times 10^{-7}\ \Omega^{-1}\ cm^{-2}$, teneur en eau inférieure à 0.1% en poids.

Les sels commerciaux utilisés sont des produits "pour analyses". Avant emploi, NaCl, KI sont séchés 24 h à l'étuve à 200 °C; CsCl et $TlNO_3$ à l'étuve à vide à 100 °C.

Préparation et purification des polyéthers

Composés 1 à 4: A partir des éthers monométhyliques de glycols $CH_3O—(CH_2CH_2O)_nCH_2CH_2OH$, **17**, décrits, on prépare les chlorures $CH_3O—(CH_2CH_2O)_n-CH_2CH_2Cl$, **18**, par la méthode de Pedersen (11) ($SOCl_2$/pyridine).

Composé **18**: $n = 1$ p.é.$_{10}$ 54–55 °C, $n = 2$ p.é.$_1$ 89–90 °C, $n = 3$ p.é.$_{0.8}$ 112–113 °C.

Les glymes sont obtenus par *O*-alcoylation de **17** avec **18** (solvant diméthoxy-1,2 éthane, NaH); rendements moyens 80%.

Composé **1**: produit commercial redistillé p.é.$_{0.3}$ 87–88 °C.

Composé **2**: réaction **17** ($n = 1$) + **18** ($n = 2$), p.é.$_{0.3}$ 108–113 °C, r.m.n.: 3.54 (20H, m), 3.26 (6H, s).

Composé **3**: réaction **17** ($n = 2$) + **18** ($n = 2$), p.é.$_{0.6}$ 145–149 °C, r.m.n.: 3.54 (24H, m), 3.36 (6H, s).

Composé **4**: réaction **17** ($n = 3$) + **18** ($n = 3$), p.é.$_{0.5}$ 160–168 °C, r.m.n.: 3.64 (28H, m), 3.36 (6H, s).

Composé 5: On fait réagir deux molécules du chloroéther **18** ($n = 1$) sur l'hexanediol-1,6.

Composé **5**: huile transparente, r.m.n.: 1.40 (8H, m), 3.39 (6H, s), 3.65 (20H, m).

Composés 6 à 9, 10–11 et 15–16: Nous avons suivi les conditions opératoires décrites par Pedersen (11) (butanol-1, NaOH), en faisant réagir les chloroéthers **18** soit sur le dihydroxy-1,2 benzène, soit sur le dihydroxy-2,2′ biphényle. Le rendement en chacun des produits purs ne dépasse pas 30%. Tous les composés étudiés sont des huiles transparentes.

Composé **6**: r.m.n.: 6.81 (4H, m), 4.10 (4H, m), 3.62 (12H, m), 3.33 (6H, s).

Composé **7**: r.m.n.: 6.85 (4H, m), 4.11 (4H, m), 3.65 (12H, m), 3.53 (4H, q), 1.17 (6H, t).

Composé **8**: r.m.n.: 6.88 (4H, m), 4.11 (4H, m), 3.65 (20H, m), 3.35 (6H, s).

Composé **9**: r.m.n.: 6.85 (4H, m), 4.11 (4H, m), 3.65 (28H, m), 3.35 (6H, s).

Composé **10**: r.m.n.: 7.06 (8H, m), 4.06 (4H, m), 3.40 (12H, m), 3.28 (6H, s).

Composé **11**: r.m.n.: 7.05 (8H, m), 4.05 (4H, m), 3.45 (20H, m), 3.29 (6H, s).

Composé **15**: r.m.n.: 6.88 (5H, m), 4.11 (2H, m), 3.65 (10H, m), 3.35 (3H, s).

Composé **16**: r.m.n.: 6.85 (5H, m), 4.11 (2H, m), 3.65 (14H, m), 3.35 (3H, s).

Composé 14: Par dicyanoéthylation du tétraéthylèneglycol par l'acrylonitrile (19), le dinitrile $CN—(CH_2-CH_2O)_5CH_2CH_2CN$ est obtenu, p.é.$_{0.5}$ 175–185 °C. Il est ensuite soumis à une alcoolyse acide (H_2SO_4/EtOH) pour obtenir le diester éthylique **14**.

Composé **14**: r.m.n.: 4.15 (4H, q), 3.65 (20H, m), 2.56 (4H, t), 1.25 (6H, t).

Composés 12–13: Par une méthode identique à celle utilisée pour la préparation du dinitrile précédent, en substituant l'acrylamide à l'acrylonitrile on récupère un solide blanc parfaitement cristallisé. Cette méthode de préparation, vraisemblablement non décrite, des diamides cristallisés des polyéthylènes glycols peut constituer le point de départ de systèmes polyfonctionnels plus complexes. Le rendement est voisin de 85% après recristallisation.

Composé **12**: p.f. 94–95° (acétone–chloroforme (6:4)), r.m.n.: 7.42 (2H, m), 6.30 (2H, m), 3.65 (16H, m), 2.50 (4H, m).

Composé **13**: p.f. 82–83° (acétone), r.m.n.: 6.96 (2H, m), 6.16 (2H, m), 3.65 (20H, m), 2.48 (4H, m).

La purification finale des composés **1** à **11** et **14–16** a été effectuée en utilisant successivement la chromatographie sur colonne (gel de silice 60 Merck) puis sur plaque de verre (support de 1 à 2 mm d'épaisseur; gel de silice PF Merck).

Les spectres de r.m.n. sont enregistrés à l'aide des appareils Varian A-60 et Perkin Elmer R-24. Le solvant utilisé est $CDCl_3$. Les déplacements chimiques sont donnés en p.p.m. par rapport au TMS pris comme référence interne.

Tous les composés étudiés donnent des analyses centésimales satisfaisantes.

Mesures potentiométriques

Les mesures sont effectuées à l'aide d'un p*H*-mètre Radiometer-4 utilisé en millivoltmètre. La lecture est faite à ± 0.5 mV.

La détermination des constantes est basée sur la mesure de la tension réversible d'une cellule galvanique formée de deux électrodes: une électrode de référence de tension constante et une électrode de verre spécifique aux cations monovalents. L'électrode de référence est une électrode au calomel avec une jonction liquide constituée par une solution 0.1 *M* d'iodure de tétraéthylammonium dans le méthanol. Les électrodes indicatrices sont des électrodes de verre spécifiques d'une part de Na^+ (Beckman n° 39278) d'autre part des cations monovalents (Beckman n° 39137) pour K^+.

Les électrodes sont immergées dans une cellule de 25 ml thermorégulée à 25.0 ± 0.1 °C. Une agitation magnétique est assurée pendant toute la manipulation. Le domaine de travail le plus convenable se situe entre 10^{-2}

et 10^{-3} M en électrolyte. On procède par dilution d'une solution de sel AM environ 0.1 M dans la solution de polyéther environ 0.05 M. Après chaque addition, le potentiel d'électrode est mesuré.

La tension réversible de la cellule utilisée est:

$$[3] \qquad E = E^0 + k \log a_{M^+}$$

avec $k = 0.05916$ V à 25 °C.

$$[4] \qquad a_{M^+} = c_{M^+} y_{M^+}$$

La deuxième loi de Debye–Hückel où l'on utilise comme paramètre de distance le paramètre q de Bjerrum permet d'exprimer le facteur d'activité

$$[5] \qquad \log y_{M^+} = \frac{A\sqrt{c_s}}{1 + Bq\sqrt{c_s}}$$

c_s concentration analytique

En solution diluée, le facteur d'activité de la molécule P est très voisin de 1; $y_P = 1$ et pour les ions $y_{PM^+} = y_{M^+}$, d'où

$$[6] \qquad K_A = \frac{c_{PM^+}}{c_P c_{M^+}}$$

L'ensemble des équations de conservation de la matière et des équations précédentes permet de calculer K_A.

Mesures conductométriques

On utilise une sonde Tacussel CM-02 reliée à un conductomètre Beckman RC 18A permettant la mesure des conductances avec une précision au moins égale à 1 pour 1000. La sonde est immergée dans une cellule de 25 ml thermorégulée au centième de degré.

On opère par dilution à l'aide d'une burette gravimétrique, les pesées étant effectuées à 0.1 mg, d'une solution contenant le polyéther (environ 0.1 M) et le sel AM, dans une quantité pesée de la même solution de sel AM environ 0.005 M. Cette méthode nous permet ainsi de conserver constante la concentration en sel et supprimer le paramètre provenant de la dilution de celui-ci.

L'expression de la constante thermodynamique d'équilibre en fonction de α, coefficient de dissociation est:

$$[7] \qquad K_A = \frac{(1 - \alpha)c}{\alpha(c' - c + \alpha c)}$$

Dans laquelle c est la concentration en sel maintenue constante et c' la concentration variable en polyéther.

Pour chaque valeur de c', nous déterminons la conductivité équivalente Λ qui peut s'écrire:

$$[8] \qquad \Lambda = \alpha\Lambda_{(M^+,A^-)} + (1 - \alpha)\Lambda_{(PM^+,A^-)}$$

d'où

$$[9] \qquad \alpha = \frac{\Lambda - \Lambda_{(PM^+,A^-)}}{\Lambda_{(M^+,A^-)} - \Lambda_{(PM^+,A^-)}}$$

$\Lambda(M^+,A^-)$ est la conductivité équivalente de la solution pure de sel que l'on obtient avant toute addition. $\Lambda(PM^+,A^-)$ est la conductivité équivalente à déterminer du complexe.

On résoud le système d'équations 8 et 9 par itérations en ajustant les deux paramètres α et $\Lambda(PM^+,A^-)$ jusqu'à obtenir une valeur de K_A constante.

Les différences entre $\Lambda_{(PM^+,A^-)}$ et $\Lambda_{(M^+,A^-)}$ sont par exemple pour le composé **4** de 10.6 pour Tl^+ et 18.6 pour Cs^+.

Evans *et al.* (7) ont utilisé récemment une méthode conductométrique semblable pour l'étude de deux polyéthers "couronne".

Résultats

Des exemples détaillés de mesures et de calculs ont été donnés par ailleurs (18). L'ensemble des résultats obtenus se trouve réuni dans les tableaux 1 et 2.

Pour une série de mesures, les valeurs moyennes sont calculées sur 12 à 24 points en potentiométrie et 7 points en conductométrie: pour $0.1 < \log K_A < 1$, l'écart moyen est ± 0.04; pour $1 < \log K_A < 3$, l'écart moyen est ± 0.02.

La reproductibilité entre plusieurs séries de mesures se situe entre les limites 0.01–0.07. Nous estimons toutefois que les résultats obtenus en potentiométrie sont plus faibles que ceux obtenus en conductométrie; en effet, l'hypothèse d'additivité des conductivités équivalentes des électrolytes (éq. 8) n'est qu'une approximation.

Discussion

Polyéthers vrais

Influence du nombre de sites

Nous avons porté sur les graphes de la fig. 1 $\log K_A$ en fonction du nombre d'atomes d'oxygènes présents dans la chaîne. Les courbes obtenues montrent que l'effet coopératif dans la coordination est très comparable entre les deux séries de polyéthers **1–4** et **6–9**. La séquence d'association demeure constante, $K^+ > Tl^+ \simeq Cs^+ > Na^+$.

Dans l'équilibre étudié la relation entre l'enthalpie libre de complexation du cation dans le solvant ΔG_A et les potentiels chimiques μ^0 des différentes espèces s'écrit:

$$\Delta G_A = -RT \log K_A = \mu^0(P,M^+) - \mu^0(P) - \mu^0(M^+)$$

Pour un cation considéré, on peut attendre que la différence $\mu^0(P,M^+) - \mu^0(P)$ augmente en fonction du nombre d'oxygènes pour des raisons purement statistiques.

Une observation très analogue a été faite par Smid et collaborateurs (6) au cours de l'étude de la séparation des paires d'ions fluorényl$^-$, Li^+ et Na^+ par les glymes dans le THF. Ces auteurs

ont discuté en détail les raisons de cet accroissement de stabilité.

Les possibilités d'un examen approfondi des résultats sont limitées par la méconnaissance de l'influence de la solvatation sur la différence $\mu^\theta(PM^+) - \mu^\theta(P)$; de même les valeurs des indices de coordination des cations demeurent un objet de discussions (8, 9). L'intervention d'un effet statistique est cependant l'explication la plus vraisemblable (6, 10).

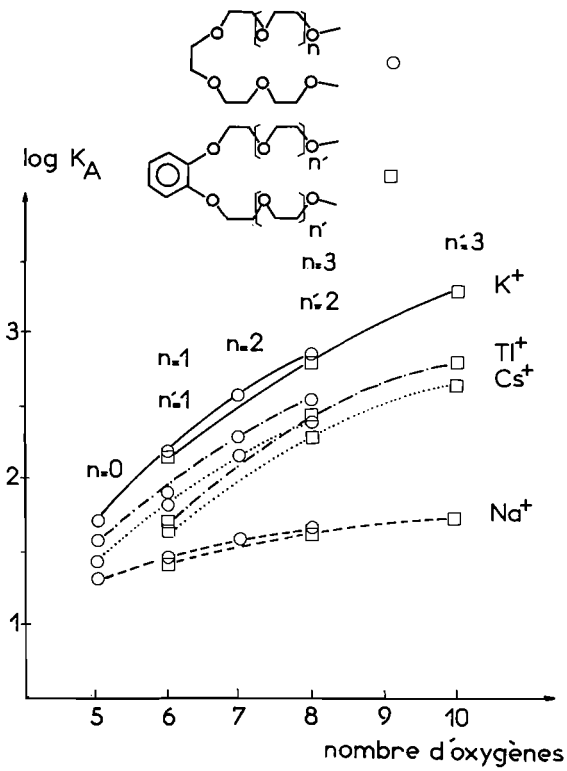

FIG. 1. Variation de l'association des éthers de polyéthylène glycols avec les cations monovalents, en fonction du nombre d'oxygènes de la chaine.

Discrimination K^+/Na^+

Les courbes de la fig. 1 mettent en évidence la discrimination croissante K^+/Na^+ qui s'opère en fonction de la longueur de la chaîne, indépendamment des énergies de solvatation des cations qui demeurent constantes d'une série à l'autre.

Pour le décaéther aromatique **9** la sélectivité K^+/Na^+ atteint 36. Ce composé peut être rapproché du dibenzo-30 couronne-10 préparé par Pedersen (11) étudié récemment par Chock (12) qui donne les constantes suivantes (MeOH, 25 °C, $K^+/Na^+ \sim 280$):

Cation	log K_A
Na^+	2.11
K^+	4.57
Cs^+	4.23
Tl^+	4.50

La conformation repliée adoptée par le macrocycle dans le complexe PM^+ (13) permet une meilleure protection du cation non solvaté, ce qui explique les valeurs supérieures obtenues pour K_A. En outre, il existe un effet macrocyclique qui est essentiellement un changement entropique défavorable pour le polyéther linéaire, si l'on se réfère aux constantes thermo-

dynamiques données par Fruh et Simon (5) pour le pentaglyme **2** et son homologue cyclique le dibenzo-18 couronne-6. Cet effet est cependant beaucoup moins important pour les deux décaéthers comparés ci-dessus. Il est vraisemblable de supposer que les conformations des deux ligandes libres changent nettement pendant la complexation.

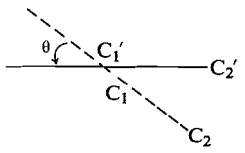
Pour ces deux composés, le mécanisme de la discrimination K^+/Na^+ est identique; il est dû à l'impossibilité stérique de construire une couche de coordination à une distance convenable pour Na^+ dont le faible rayon ionique tend à contracter la cavité complexante et introduire ainsi des répulsions entre les sites (5, 14). Ceci est mis en évidence par l'étude des systèmes acycliques.

La sélectivité K^+/Cs^+ et Tl^+ est faible comme cela pouvait être prévu pour ces ligandes flexibles (14).

Stéréochimie dans la chaîne

Dans les polyéthers biphényliques **10** et **11** la présence de substituants en 2,2′ entraîne la non planéité des cycles aromatiques.

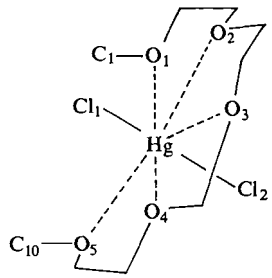
Pour ce type de substitution, une forme croisée est généralement postulée (15), avec un angle θ inférieur à 90°, plutôt qu'une forme où les substituants sont en opposition.



Les constantes d'association mesurées pour ces composés sont favorables à une stéréochimie croisée des cycles, sinon elles seraient nulles, comme on peut l'observer avec **5** où les sites sont séparés en deux groupes par une chaîne hydrocarbonée.

La différence de stabilité marquée des associations cationiques entre les polyéthers aromatiques et biphényliques correspondants est attribuable à la position dans l'espace des oxygènes en 2,2′ sur les cycles. A ce niveau, le processus d'association est perturbé dans le cas des biphényliques par le fait que direction et distance entre paires libres sur O et O′ ne sont pas fixées; l'effet prépondérant n'est pas connu.

Dans la structure cristalline du complexe tétraglyme **1**-$HgCl_2$ publiée récemment (16), la chaîne adopte une conformation à demi-ouverte et les atomes O sont pratiquement dans un même



plan; ils entourent l'atome Hg et les interactions entre les méthyles terminaux sont faibles.

Les complexes des cations monovalents ne sont pas strictement comparables avec ceux de $HgCl_2$; néanmoins la possibilité d'une stéréochimie plane de la coordination, lorsque le cation est totalement associé aux oxygènes du ligande dans les complexes PM^+, n'est pas infirmée par nos résultats. Nous nous proposons de préciser ce problème par l'étude de nouveaux modèles.

Polyéthers fonctionnalisés en bout de chaîne

Le remplacement des groupements $—OCH_3$ terminaux par des sites oxygénés présentant des moments dipolaires plus élevés entraîne dans tous les cas une décroissance marquée des constantes d'association, sauf pour Na^+ avec les composés **15** et **16** ayant une fonction OH terminale.

On a observé récemment par r.m.n. (17) que Li^+ provoque une augmentation de la barrière de rotation dans le diméthylacétamide par une association avec l'oxygène alors que Ag^+ diminue cette barrière en se coordinant à l'azote. Il est possible de retenir une explication du même type pour l'inversion $Tl^+ > K^+$ dans **12** et **13**. K^+ aurait tendance à s'associer au site peu polarisable C=O tandis que Tl^+ avec ses orbitales f vacantes donnerait préférentiellement une coordination forte avec l'azote.

Conclusion

Ce travail avait un double but: l'étude de l'aspect structural et analytique de la complexation des cations monovalents par des systèmes en chaîne ouverte.

La préparation d'un certain nombre d'éthers de polyéthylène-glycols nous a permis de mettre en évidence la sélectivité K^+/Na^+ qui s'opère en fonction du nombre d'oxygène présents. La stéréochimie de la coordination autour du cation a également été discutée. Pour les polyéthers fonctionnalisés en bout de chaîne aucun des

sites étudiés n'augmente les propriétés complexantes des ligandes par rapport aux polyéthers vrais. Cependant, la précision obtenue pour les mesures potentiométriques et conductométriques développées dans ce domaine des faibles associations très peu étudiées, permettra de poursuivre le travail sur des modèles polyfonctionnels nouveaux. Cette méthode d'investigation peut permettre d'étudier la basicité de différents sites polaires vis-à-vis des cations, d'étudier l'influence de la lipophilie des chaînes, dans le but de définir de nouveaux systèmes ionophores.

W. V. F. BROOKS and K. V. L. N. SASTRY. Can. J. Chem. 53, 2247 (1975).

The microwave spectra of glycidol ($\overline{CH_2—O—CH}—CH_2OH$) and its deuterated (—OD) form have been studied in the range 8–40 GHz. The rotational (in MHz) and centrifugal distortion constants (in kHz) of glycidol are: $A = 10\,347.87$, $B = 4102.36$, $C = 3781.95$; $\Delta_J = 2.38$, $\Delta_{JK} = -311$, $\Delta_K = 5.2$, $\delta_J = 0.3159$, $\delta_K = -9.76$. The rotational constants and distortion constants of glycidol (OD) are $A = 10\,010.31$, $B = 4056.73$, $C = 3717.02$; $\Delta_J = 2.53$, $\Delta_{JK} = 197$, $\Delta_K = 7.7$, $\delta_J = 0.3532$, $\delta_K = -7.19$. The dipole moment components of the normal molecule in Debye units are $\mu_a = 0.61$, $\mu_b = 1.20$, $\mu_c = 0.52$, and the total dipole moment is 1.44 D.

A structure is derived with the alcoholic hydrogen atom close (2.5 Å) to the ring oxygen. The structure and the absence of signs of free or hindered rotation, can be accounted for by hydrogen bonding between the proton and the ring oxygen.

On a étudié le spectre microonde de l'hydroxy-1 époxy-2,3 propane ($\overline{CH_2—O—CH}—CH_2OH$) ainsi que sa forme deutériée (—OD) dans la région de 8 à 40 GHz. Les constantes de distortion rotationnelles (en MHz) et de distortion par centrifugation (en kHz) de l'hydroxy-1 époxy-2,3 propane sont: $A = 10\,347.87$, $B = 4102.36$, $C = 3781.95$; $\Delta_J = 2.38$, $\Delta_{JK} = -311$, $\Delta_K = 5.2$, $\delta_J = 0.3159$, $\delta_K = -9.76$. Pour l'hydroxy-1 époxy-2,3 propane (OD) ces constantes sont: $A = 10\,010.31$, $B = 4056.73$, $C = 3717.02$; $\Delta_J = 2.53$, $\Delta_{JK} = 197$, $\Delta_K = 7.7$, $\delta_J = 0.3532$, $\delta_K = -7.19$. Les composantes du moment dipolaire d'une molécule normale en Debye sont $\mu_a = 0.61$, $\mu_b = 1.20$, $\mu_c = 0.52$, et le moment dipolaire total est 1.44 D.

On déduit une structure où l'atome d'hydrogène alcoolique se trouve près (2.5 Å) du cycle oxyrannique. La structure ainsi que l'absence d'indications montrant une rotation libre ou empêchée, peuvent être expliqués par une liaison hydrogène entre le proton et le cycle oxyrannique. [Traduit par le journal]

Introduction

In an earlier paper (1) we reported the microwave spectrum of cyclopropyl carbinol ($\overline{CH_2—CH_2—CH}—CH_2OH$) and the structural interpretation of the data. We found no evidence of internal rotation, and proposed that this is because the electrons of the strained cyclopropyl ring bonds attract the hydroxyl hydrogen atom with sufficient strength to prevent rotation. Glycidol ($\overline{CH_2—O—CH}—CH_2OH$) is similar in geometry to cyclopropyl carbinol, but the presence of an oxygen atom in the ring provides an alternative attraction for the alcoholic hydrogen. If the strained bonds and one of the unshared electron pairs of the oxygen attract the hydrogen to roughly the same degree, then two or possibly three structures might be observed; but if one conformation is considerably more stable than the others, then only that one will be observed. Chemical experience suggests that the hydroxyl proton will be attracted more strongly to an unshared electron pair on the ring oxygen than to the electrons in a strained ring bond.

We have measured the microwave spectra of glycidol and its deuterated (—OD) species in order to investigate the geometry of the molecule in the gas phase.

Experimental

Glycidol was purchased from the Aldrich Chemical Company; the makers described it as 95% pure, and mass, infrared, and n.m.r. spectra all showed the features expected for glycidol. We used the sample without further purification.

The spectra were recorded at room temperature in the pressure range 0.02 to 0.08 Torr. Most lines were measured in this laboratory on a conventional 85 kHz

*Error limits are one standard deviation.

Stark modulated spectrometer with oscilloscope display. Some measurements were made on a Hewlett–Packard spectrometer at Harvard University and the spectrometer at the University of Kiel. The accuracy of most frequency measurements is ±0.1 MHz or better except for very weak lines or cases of interference by nearby lines.

The deuterated (—OD) species was generated in the cell by saturating the Stark cell with D_2O vapor, pumping off, and then admitting glycidol vapor which exchanges rapidly with the D_2O remaining on the walls.

The Stark field for the dipole moment measurements was calibrated by measuring Stark shifts of the OCS $1 \leftarrow 0$ line (2).

Spectra

Since no conformation of glycidol has any planes or axes of symmetry; a-, b-, and c-type lines are possible and preliminary calculations predicted a rich spectrum. The first observations confirmed the prediction and showed no obvious regularities or easily resolved Stark lobes. However, after a few trials, some of the stronger lines were assigned by Q-branch plotting to a series of Q_b transitions. Assigning an R-branch transition was more difficult since the low J lines are relatively weak, but once one was correctly assigned the spectrum presented no further problems.

At each stage, the assigned lines were used as input to a least squares fitting program which calculates the best rotational constants (including quartic and sextic centrifugal constants if desired) and then prints out a predicted spectrum with relative intensities. By following series of lines, and adding quartic constants as the rigid rotor predictions became less accurate we finally assigned more than 275 lines.[1] The rotational constants, moments of inertia, and quartic distortion constants are given in Table 1. At the highest J values assigned, ($J = 60$), consistent errors of about 1 MHz indicate that sextic constants are needed to improve the accuracy, but there did not seem to be sufficient data to determine these higher constants accurately. The quartic constants are not all well determined since most of the high J lines belong to only a few series of Q_c and Q_b transitions.

The fitting and prediction procedure accounts for most of the stronger lines in the range (8 to 40 GHz) studied. While there remain numerous unassigned lines, this is to be expected from excited vibrational states and higher J transitions. Other forms of glycidol and impurities may contribute lines also, but we have found no features that lead to possible assignments.

The deuterated species (—OD) spectrum[1] was analyzed in essentially the same way as the normal molecule, but only 125 lines have been assigned. The constants are also given in Table 1. The spectrum shows the same general features as the normal molecule, and again there are no clear indications that more than one absorbing species is present.

Stark displacements were measured only for the normal molecule. The Stark coefficients and the dipole components as determined by a least squares fitting to the measured coefficients are given in Table 2.

Structure

The six measured rotation constants of the two isotopic species were combined with data from related molecules to construct a model of glycidol. The epoxy ring and attached hydrogens

[1]The assigned and measured lines are available from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa K1A 0S2.

were assumed to have the same geometry as ethylene oxide (3). The C_{ring}—$C_{carbinol}$ distance and the carbinol configuration were taken from the propylene oxide model (4). The $C_{carbinol}$—O distance was taken from methanol (5). With these assumptions, the remaining angles and distances can be adjusted to give a best least squares fit to the observed rotational constants. The structural coordinates and the least squares procedure are based on the coordinate system of Thompson (6).

The variables (to be adjusted) were taken as: (*1*) the angle between the C_{ring}—$C_{carbinol}$ bond and a perpendicular to the epoxy ring plane; (*2*) the C—C—C angle; (*3*) a "torsion" coordinate defining rotation about the C_{ring}—$C_{carbinol}$ bond; (*4*) a "torsion" coordinate for rotation of the hydroxyl hydrogen about the C—O bond; (*5*) the C—O—H angle; (*6*) the O—H distance.

Since the relations between rotational constants and the variables are nonlinear, it is necessary to fit a small number of variables (usually two or three) at a time; by a series permutations of variables, all the variables can be determined. This choice of variables gave reasonable results except that the O—H distance was not very well determined; the value tended to be larger than seems reasonable (1.1 to 1.2 Å at various stages of the fitting) but the final error sum was relatively insensitive to the O—H bond length. The O—H bond must certainly be greater than the 0.9451 Å of methanol (5) and a distance close to 1.0 Å seems reasonable. Therefore, we set the O—H distance to 1.0 Å and fitted only the other five variables.

The transfer of distances and angles must introduce errors. Thus the asymmetric attachment of the carbinol group destroys the symmetry of the epoxy ring, and therefore the two ring C—O distances will not be exactly the same nor will the three ring hydrogens be exactly equivalent. Similarly, the carbinol hydrogens are not equivalent in the final structure and so this group will be less symmetrical than assumed. After a satisfactory structure had been achieved, we tested various other factors as possible variables to see if the goodness of fit might be significantly improved. In all cases, the improvement was insignificant or else (as with ring hydrogen positions) a somewhat better fit could be achieved, but with an unreasonable structure. There is of course no reason to expect that the data should agree perfectly with the proposed structure since the model is a static one while the data are averaged or effective constants of dynamic systems; the data are also subject to errors of measurement. The alcoholic hydrogen position may be particularly ill-determined since

it is a light atom and its amplitude of vibration is large.

The proposed structure is shown in Fig. 1 and the angles and distances are given in Table 3; calculated and measured rotational constants and moments of inertia are given in Table 4. Because of the indeterminate model errors and the arbitrariness involved in the variable choice, no error limits are given. We estimate that the determined angles are probably useful to the nearest degree and the O—H distance lies within the range 0.95 to 1.05 Å.

The feature of greatest interest in the glycidol structure is the position of the OH hydrogen atom. The hydrogen in our proposed model is apparently in a situation appropriate for hydrogen bond formation. The H---O distance is 2.49 Å, the O---O distance is 2.67 Å, and the O—H---O angle is 89.5°. These may be compared to O---O distances from 2.55 to 2.96 Å for a series of intermolecular hydrogen bonds in alcohols (7) and the evidence that linear or approximately linear configurations are more stable (7, 8). However, the molecular geometry of glycidol imposes constraints that make it impossible to form a linear O—H---O configuration; and the hydrogen is presumably attracted, not to the center of the oxygen, but to the unshared pair of electrons which are on the same side of the plane of the ring as the carbinol group. The potential minimum holding the hydrogen (and thus, the entire carbinol group) in position is probably much shallower than the minima of more favorable hydrogen bonds (intermolecular bonds). However, for glycidol to change to another rotational configuration, a motion of the entire carbinol group may be required with the hydrogen moving several angstroms. Thus a shallow but wide barrier for a large group can restrict motion as effectively as a higher but narrower barrier.

We propose that the structure as given here is a good approximation to the most stable molecular configuration. Other rotamers, if present, do not give spectral lines of comparable intensity (due to smaller permanent dipoles or smaller concentrations or both) and have not been identified. Since no form of glycidol is likely to have a much smaller dipole moment, we think it probable that this configuration is the predominant one.

We are grateful to the National Research Council of Canada for financial support. We also wish to thank Professors E. B. Wilson and Helmut H. Dreizler and their research groups for their hospitality and help in running spectra.

Dielectric Models for Porous Adsorbent – Adsorbate Systems

M. J. DIGNAM AND B. RAO
Department of Chemistry, University of Toronto, Toronto, Ontario M5S 1A1
Received December 10, 1974

M. J. DIGNAM and B. RAO. Can. J. Chem. **53**, 2252 (1975).

Equations are derived for the dielectric constant of porous adsorbent – adsorbate systems based on several geometrical models and taking account of both adsorbate molecular orientation and the special geometrical relationship which exists between adsorbed and substrate phases. Isotropic distributions of coated spheres, rods, disks, and their cavity counterparts are treated. Although the equations are based on the above idealized physical models, unlike many previous derivations, no additional intuitive postulates are involved. Furthermore, the equations are correct in the various limiting cases in which two of the three phases are absent, again in contrast with some earlier equations. Some implications of the equations are discussed, particularly as they apply to molecular orientation. The question of a break in the curve of composite dielectric constant *vs.* volume adsorbed at monolayer coverage is also investigated.

M. J. DIGNAM et B. RAO. Can. J. Chem. **53**, 2252 (1975).

On a dérivé des équations pour calculer la constante diélectrique de systèmes adsorbants poreux/adsorbés; ces équations sont basées sur plusieurs modèles géométriques qui tiennent compte à la fois de l'orientation moléculaire de la molécule adsorbée et de la relation geométrique spéciale qui existe entre les phases adsorbées et le substrat. On traite des distributions isotropiques de sphères, de bâtonnets et de disques recouverts de même que leur contrepartie creuse. Quoique les équations soient basées sur les modèles physiques idéalisés mentionnés plus haut, elles ne font appel à aucun autre postulat intuitif et ce, contrairement à plusieurs dérivations antérieures. De plus, les équations sont correctes dans divers cas limites dans lesquels deux des trois phases sont absentes et ceci encore une fois en opposition avec des équations antérieures. On discute de quelques implications de ces équations en particulier en ce qui a trait à l'orientation moléculaire. On examine aussi la question d'un bris dans la courbe reliant la constante diélectrique globale en fonction du volume adsorbé par une couche monomoléculaire.
[Traduit par le journal]

(1) Introduction

There exists in the literature a considerable body of data concerned with the dielectric properties of porous adsorbent – adsorbate systems (1). In the preface to his book (1), McIntosh states that although much data has been amassed, little progress has been made in describing the dielectric properties of the adsorbate, due mainly to the difficulty of analyzing the internal fields which exist within a heterogeneous dielectric. In this paper, an attempt is made to take account of these in a more realistic way than heretofore.

To illustrate the nature of the difficulties which have plagued previous attempts to develop models for the dielectric behavior of porous adsorbent – adsorbate systems, we examine here one of the more successful ones developed by McIntosh *et al.* (2, 3), and based on a method for treating powders due to Böttcher (4). The main assumptions upon which the treatment is based are listed below.

(*1*) The average internal field acting to polarize the material comprising any of the phases making up the composite dielectric is the so-called spherical cavity field, *i.e.* $(\varepsilon_i + 2)/3$ times the mean macroscopic or Maxwell field with the *i*th phase, where ε_i is the dielectric constant of the *i*th phase.

(*2*) The mean internal field, averaged over the entire heterogeneous dielectric, is given by $(\varepsilon + 2)/3$, where ε is the effective dielectric constant of the composite.

(*3*) The field within the void spaces is that for spherical voids within an isotropic continuum of dielectric constant ε.

(*4*) The average internal field within the substrate phase is independent of adsorbate concentration.

This set of postulates contains a number of rather obvious shortcomings. Since they are not based on a specific geometrical model, it is difficult to know under what conditions, if any, they will be valid approximations. Some features of the model upon which the postulates depend im-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

plicitly, however, are apparent. Postulates *1* and *2* imply that all three phases, but in particular the substrate and adsorbed phases, take up the same sort of geometrical configurations within the composite dielectric. Up to one monolayer, however, such an assumption is invalid, since the adsorbed phase will exist as a convoluted layer one molecule in thickness, while the substrate phase will in general have a quite different geometry. The use of the spherical cavity field for the field polarizing the adsorbed species is also clearly inappropriate when they are present as a unimolecular layer. Furthermore, in general the molecules will be partially oriented with respect to the local surface plane, introducing complications which the above set of postulates do not handle. Finally, the set of assumptions is not self-consistent, a fact most easily demonstrated by considering the expression for ε obtained for no adsorbate, and the dielectric constant of the voids set to unity:

$$[1]\quad \frac{\varepsilon + 2}{3} - \frac{3\varepsilon(1 - v_s)}{2\varepsilon + 1} = \frac{(\varepsilon - 1)(\varepsilon_s + 2)}{3(\varepsilon_s - 1)}$$

where ε_s and v_s are the dielectric constant and volume fraction, respectively, of the substrate. For $v_s = 1$, [1] correctly gives $\varepsilon = \varepsilon_s$; however for $v_s = 0$ it gives $\varepsilon = -\varepsilon_s/2$, whereas the correct relation is clearly $\varepsilon = 1$.

Other models have been proposed based on different sets of assumptions, and having in general different shortcomings. Common to all previous models, however, is their failure to take account of the special geometrical relationship that exists between the adsorbed and substrate phases, arising from the fact that one coats the other. In the present paper this geometrical relationship is taken explicitly into account using the procedure developed earlier by Dignam *et al.* (5) in connection with the interpretation of the i.r. absorption spectrum of species adsorbed within porous media. This procedure will be described in relation to a particular model treated there, namely that of a random, isotropic, distribution of spherical particles uniformly coated with the adsorbed phase. On the assumption that monolayers and submonolayers will in general consist of molecules partially oriented with respect to the local surface normal, but isotropically oriented with respect to rotation about this normal, the dielectric tensor for the adsorbed phase was assumed to possess uniaxial symmetry, with the local axis directed normal to the surface of the substrate particle, *i.e.* radially.

The procedure then involved obtaining an expression for the effective polarizability of an isolated coated sphere immersed in a dielectric continuum, by solving the appropriate problem in electrostatics, to obtain

$$[2]\quad \frac{\alpha^{(1)}}{R_2{}^3} = \frac{[(S' + 1)\varepsilon_n + \varepsilon_3][S'\varepsilon_n + \varepsilon_1]q^{2S'+1} - [S'\varepsilon_n - \varepsilon_3][\varepsilon_1 + (S' + 1)\varepsilon_n]}{[(S' + 1)\varepsilon_n + \varepsilon_3][2\varepsilon_1 + S'\varepsilon_n]q^{2S'+1} + [2\varepsilon_1 - (S' + 1)\varepsilon_n][S'\varepsilon_n - \varepsilon_3]}$$

where $S' = (2\varepsilon_t/\varepsilon_n + 1/4)^{1/2} - 1/2$, $q = R_2/(R_2 - d)$, and $\alpha^{(1)}$ is the effective polarizability of a coated sphere of total radius R_2 immersed in a continuum of dielectric constant ε_1, with d the thickness, and ε_n and ε_t the principal components of the dielectric tensor for the film corresponding to directions normal and tangent to the particle surface respectively, and ε_3 the dielectric constant of the particles.

In the limit of small d/R_2, [2] reduces in the case of a coated spherical particle to

$$[3]\quad \alpha^{sp} = R_{sp}{}^3 \frac{\varepsilon_s/\varepsilon_a - 1}{\varepsilon_s/\varepsilon_a + 2} + 3R_{sp}{}^2 \frac{2\gamma_t + (\varepsilon_s/\varepsilon_a)^2\gamma_n}{(\varepsilon_s/\varepsilon_a + 2)^2}$$

where R_{sp} is the radius of the spherical particle, ε_s and ε_a the dielectric constant of the substrate and ambient, respectively, while γ_u, with u = n or t, is 4π times the mean polarization per unit area of the adsorbate in the u-direction relative to the ambient, divided by the field in the u-direction in the absence of the adsorbate, and is given by (6)

$$[4]\quad \gamma_n = (1 - \varepsilon_a/\varepsilon_n)d$$

$$[5]\quad \gamma_t = (\varepsilon_t/\varepsilon_a - 1)d$$

As the concept of an effective polarizability is used throughout this paper, we take some pains at this point to clarify its meaning and use. $\alpha^{(1)}$ is defined through the relationships (5)

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

$$[6] \quad \mu^{(1)} = \alpha^{(1)} E^{(1)}$$

$$[7] \quad \psi_1{}^{(1)} = (-E^{(1)} r + \mu^{(1)}/r^2) \cos \theta$$

where $\psi_1{}^{(1)}$ is the electrostatic potential in the ambient phase resulting from the superposition of the homogeneous polarizing field $E^{(1)}$ (*i.e.* the Maxwell field that would exist in the ambient medium in the absence of the coated sphere being treated) and the field due to the induced dipole moment of the coated sphere. The polar coordinates of the center of the spherical particle are r, θ, and ϕ with $E^{(1)}$ pointing in the $\phi = 0$ direction (making $\psi_1{}^{(1)}$ independent of ϕ). If $E^{(1)}$ were inhomogeneous, then eq. 7 would have to be modified to include higher order multipole contributions from the polarized coated sphere, a point to which we return later. Neglecting moments higher than the dipole moment (*i.e.* neglecting possible field inhomogeniety) it is apparent from the form of eq. 7 that a point dipole of dipole moment $\varepsilon_1 \mu^{(1)}$ in a continuum of dielectric constant ε_1 will produce precisely the same potential distribution in medium 1 (outside the region occupied by the coated sphere) and precisely the same total polarization (in a volume containing the coated sphere) as does the coated sphere. This realization simplifies enormously the calculation of the dielectric constant of an assembly of coated spheres, immersed in a dielectric continuum, which, of course, is the aim of this exercise.

From the above, it follows that the polarization per unit volume for such a dispersion of particles, P, is given by

$$[8] \quad P = \sum \varepsilon_1 \mu_j{}^{(1)} + (\varepsilon_1 - 1) E^{(1)}/4\pi$$

where $\mu_j{}^{(1)}$ is the value of $\mu^{(1)}$ for the jth particle, and the sum is over unit volume. Note also that because of the above noted equivalence, we may immediately identify $E^{(1)}$ as the Maxwell field strength in the dispersion. The field polarizing the jth species *i.e.* the field to use in eq. 6 is $E^{(1)}$ plus the contribution from the other point dipoles. If the particles are isotropically and randomly distributed, the mean polarizing, or local, field is given by (7) $E^{(1)} + (4\pi/3)\sum \mu_j{}^{(1)}$, so that

$$[9] \quad \sum \mu_j{}^{(1)} = [E^{(1)} + (4\pi/3)\sum \mu_j{}^{(1)}] \sum \alpha_j{}^{(1)}$$

Combining eqs. 8 and 9 with the definition of dielectric constant for the dispersion, $\varepsilon = 1 + 4\pi P/E^{(1)}$, then gives

$$[10] \quad \varepsilon/\varepsilon_1 = 1 + \frac{4\pi \sum \alpha_j{}^{(1)}}{1 - (4\pi/3) \sum \alpha_j{}^{(1)}}$$

For the ambient medium vacuum, $\varepsilon_1 = 1$ and $\alpha_j{}^{(1)}$ is the conventional vacuum polarizability of the jth species, so that eq. 10 becomes identically the Lorenz–Lorentz or Clausius–Mossotti equation. Thus through the use of effective polarizabilities, problems relating to polarizable species immersed in dielectric continua can be treated as readily as those involving vacuum. (Note that $\alpha^{(1)}$ as given in eq. 2 is zero for $\varepsilon_n = \varepsilon_t = \varepsilon_3 = \varepsilon_1$.)

As the analysis leading to eq. 10 is not trivial to follow in depth, we offer the following empirical evidence for its essential correctness. Equation 10 combined with eq. 2 leads to the obviously correct result, for any two of the three phases absent (*i.e.* for only phase 3 present, $\varepsilon = \varepsilon_3$ etc.) and also, for all the phases present having the same dielectric constant. The treatment is nevertheless approximate in that it fails to take account of the quadripole and higher moments induced in the coated particles as a result of inhomogenieties in the polarizing field. Just how important these higher moments are is difficult to estimate and we make no attempt to do so here.

Combining eqs. 3 and 10 and setting $\varepsilon_1 = \varepsilon_a$, $\varepsilon_3 = \varepsilon_s$, and $\varepsilon = \varepsilon^{sp}$ then gives (5)

$$[11] \quad \frac{\varepsilon^{sp}/\varepsilon_a - 1}{\varepsilon^{sp}/\varepsilon_a + 2} = v_s \left(\frac{\varepsilon_s/\varepsilon_a - 1}{\varepsilon_s/\varepsilon_a + 2} \right) + a \frac{2\gamma_t + (\varepsilon_s/\varepsilon_a)^2 \gamma_n}{(\varepsilon_s/\varepsilon_a + 2)^2}$$

where a is the surface area per unit volume.

It is apparent that [2] applies equally well to the case of an internally coated spherical cavity, so that for small d/R_2 it becomes in this case

$$[12] \quad \alpha^{sc} = R_{sc}{}^3 \frac{1 - \varepsilon_s/\varepsilon_a}{1 + 2\varepsilon_s/\varepsilon_a} + 3R_{sc}{}^2 \frac{(\varepsilon_s/\varepsilon_a)(2\gamma_t + \gamma_n)}{(1 + 2\varepsilon_s/\varepsilon_a)^2}$$

where R_{sc} is the radius of the spherical cavity. This in turn leads to the following expression for the dielectric constant of a porous body containing a random, isotropic, distribution of coated spherical cavities

$$[13] \quad \frac{\varepsilon^{sc}/\varepsilon_s - 1}{\varepsilon^{sc}/\varepsilon_s + 2} = v_c \frac{1 - \varepsilon_s/\varepsilon_a}{1 + 2\varepsilon_s/\varepsilon_a} + a \frac{(\varepsilon_s/\varepsilon_a)(2\gamma_t + \gamma_n)}{(1 - 2\varepsilon_s/\varepsilon_a)^2}$$

For personal use only.

where v_c is the volume fraction of the empty cavities.

Note that the relative weighting of the adsorbate dielectric parameters, γ_t and γ_n, is different for the cavity and particle models, being 2:1 for the cavity model, while $2:(\varepsilon_s/\varepsilon_a)^2$ for the particle model. When dealing with oriented molecular layers, it is thus apparent that the choice of geometry for the porous adsorbent can have important consequences for the predicted dielectric behavior of the system. Therefore, before considering further these expressions and others which follow directly from them, we will first develop analogous equations for porous systems based on cylindrical, rather than spherical symmetry. Fibrous adsorbates, such as paper, might be modelled more closely by an assembly of cylindrical rods, rather than spherical particles, and porous glass by cylindrical cavities, rather than spherical cavities. Of course, many other particle and cavity shapes are possible. In this paper, however, we shall treat only spherical, cylindrical, and disk-shaped particles and cavities, and admixtures of these, mainly because these are the easiest to treat, but also because by themselves they provide a wide variety of predicted dielectric behavior.

The problem of evaluating the dielectric constant of an assembly of coated rods begins with the determination of the polarizability of an isolated coated rod. To obtain this we first require solutions to div $\boldsymbol{D} = 0$, where $\boldsymbol{D}$ is the electric displacement vector, in all three media, the rod, the film, and the ambient. As this equation reduces to Laplace's for isotropic media, solutions for such media are well-known. We look therefore for acceptable solutions within the oriented film, from which the polarizability problem can be solved by applying the appropriate boundary conditions.

(2) Solution to div $\boldsymbol{D} = 0$ for Uniaxial Medium of Cylindrical Symmetry

Choosing the z-axis to coincide with the axis of the cylindrical rod of infinite length, we assume that the oriented molecular film can be treated as a uniaxial medium with the local optic axis being directed radially, *i.e.* normal to the z-axis. This should be a good representation of an actual film provided that the molecules are isotropically oriented with respect to rotation about a radial axis, and are isotropically distributed in the surface plane (6).

Expansion of div $\boldsymbol{D}$ in cylindrical coordinates yields

$$[14] \quad \text{div } \boldsymbol{D} = \frac{1}{r}\frac{\partial}{\partial r}(rD_r) + \frac{1}{r}\frac{\partial D_\theta}{\partial \theta} + \frac{\partial D_z}{\partial z}$$

where D_r, D_θ, and D_z are the components of $\boldsymbol{D}$ with respect to a set of unit orthogonal vectors directed along a radial line, directed normal to it in the direction of increasing θ, and directed along the z-axis, respectively. We may therefore write[1]

$$[15] \quad D_r = -\varepsilon_n\frac{\partial \psi}{\partial r}$$

$$D_\theta = \frac{-\varepsilon_t}{r}\frac{\partial \psi}{\partial \theta}$$

$$D_z = -\varepsilon_t\frac{\partial \psi}{\partial z}$$

where ψ is the electrostatic potential and ε_n and ε_t the principal components of the dielectric constant tensor for the uniaxial medium. Substituting [15] into [14] and equating div $\boldsymbol{D}$ to zero gives

$$[16] \quad \frac{\partial^2\psi}{\partial r^2} + \frac{1}{r}\frac{\partial \psi}{\partial r} + \frac{s^2}{r^2}\frac{\partial^2\psi}{\partial \theta^2} + s^2\frac{\partial^2\psi}{\partial z^2} = 0$$

where

$$[17] \quad s = \sqrt{\varepsilon_t/\varepsilon_n}$$

Although the general solution of [16] is readily obtained, we require only solutions for which $\partial\psi/\partial z = 0$. Solving [16] by the method of separation of variables for $\partial\psi/\partial z = 0$ yields for the general solution

$$[18] \quad \psi = \sum_{l=0}^{\infty} \psi_l$$

where

$$[19] \quad \psi_l = (a_l r^{ls} + b_l/r^{ls})(c_l \cos \theta l + d_l \sin \theta l)$$

(3) Polarizability per Unit Length of an Isotropic Infinitely Long Cylinder with an Oriented Molecular Film

Taking the direction of the homogeneous field to be normal to the axis of the cylinder in the $\theta = 0$ direction, the appropriate form for the potential in the three phases is obtained from [19] on setting $l = 1$. The validity of this assumption rests on whether or not the boundary conditions can be satisfied on the basis of the assumption.

Identifying the ambient phase, film phase, and

[1]We employ unrationalized e.s.u. throughout.

For personal use only.

rod phase as media 1, 2, and 3 respectively, we have then from [19] for $l = 1$, and noting that by symmetry $d_l = 0$

$$[20]\quad \psi_1^{(1)} = (-E_\perp^{(1)} r + 2\mu_\perp^{(1)}/r)\cos\theta$$

$$[21]\quad \psi_1^{(2)} = (-E_\perp^{(2)} r^s + 2\mu_\perp^{(2)}/r^s)\cos\theta$$

$$[22]\quad \psi_1^{(3)} = (-E_\perp^{(3)} r + 2\mu_\perp^{(3)}/r)\cos\theta$$

where $E_\perp^{(1)}$ and $E_\perp^{(3)}$ are the homogeneous field strengths in media 1 and 3 respectively, $\mu_\perp^{(1)}$ the effective dipole moment per unit length of the coated rod immersed in medium 1, and $E_\perp^{(2)}$, $\mu_\perp^{(2)}$, and $\mu_\perp^{(3)}$ parameters to be evaluated from the boundary conditions.

Since there are no free charges, ψ_1 must be everywhere finite, so that $\mu_\perp^{(3)} = 0$. ψ_1 must also be continuous, leading to

$$[23]\quad -E_\perp^{(1)} R_2 + 2\mu_\perp^{(1)}/R_2 = -E_\perp^{(2)} R_2^s + 2\mu_\perp^{(2)}/R_2^s$$

$$[24]\quad -E_\perp^{(2)} R_3^s + 2\mu_\perp^{(2)}/R_3^s = -E_\perp^{(3)} R_3$$

where R_3 is the radius of the isotropic rod, and R_2 that of the film covered rod.

Applying the condition that the normal component of $\boldsymbol{D}$ (*i.e.* $D_r = -\varepsilon_n \partial\psi/\partial r$) is continuous across the boundaries gives

$$[25]\quad \varepsilon_1 E_\perp^{(1)} + 2\varepsilon_1 \mu_\perp^{(1)}/R_2^2 = s\varepsilon_n E_\perp^{(2)} R_2^{s-1} + 2s\varepsilon_n \mu_\perp^{(2)}/R_2^{s+1}$$

$$[26]\quad s\varepsilon_n E_\perp^{(2)} R_3^{s-1} + 2s\varepsilon_n \mu_\perp^{(2)}/R_3^{s+1} = \varepsilon_3 E_\perp^{(3)}$$

where ε_1 and ε_3 are the dielectric constants of the isotropic media 1 and 3 respectively.

Equations 23 to 26 are four linearly independent linear equations in the four unknown parameters, $\mu_\perp^{(1)}$, $\mu_\perp^{(2)}$, $E_\perp^{(2)}$, and $E_\perp^{(3)}$, which can be solved to yield a solution to the problem satisfying all requirements. Solving for $\mu_\perp^{(1)}$ and setting $\mu_\perp^{(1)} = \alpha_\perp^{(1)} E_\perp^{(1)}$ leads to the following expression for $\alpha_\perp^{(1)}$, the normal component of the effective polarizability-per-unit-length tensor for the film covered rod immersed in a medium of dielectric constant ε_1.

$$[27]\quad \frac{2\alpha_\perp^{(1)}}{R_2^2} = \frac{(s\varepsilon_n + \varepsilon_3)(s\varepsilon_n - \varepsilon_1)q^{2s} - (s\varepsilon_n - \varepsilon_3)(s\varepsilon_n + \varepsilon_1)}{(s\varepsilon_n + \varepsilon_1)(s\varepsilon_n + \varepsilon_3)q^{2s} - (s\varepsilon_n - \varepsilon_3)(s\varepsilon_n - \varepsilon_1)}$$

where $q = R_2/R_3$.

On setting $q = 1$, eq. 27 reduces to the well-known expression for the polarizability per unit length (specific polarizability) for an uncoated rod placed normal to the external field, *viz.*

$$[28]\quad \alpha_\perp^{(1)} = \frac{1}{2} R_2^2 \frac{\varepsilon_3 - \varepsilon_1}{\varepsilon_3 + \varepsilon_1}$$

In the limit $q \to \infty$, [27] reduces to an expression for the specific polarizability of a rod composed entirely of oriented molecular layers, the result being given by

$$[29]\quad \alpha_\perp^{(1)} = \frac{1}{2} R_2^2 \frac{s\varepsilon_n - \varepsilon_1}{s\varepsilon_n + \varepsilon_1}$$

For the isotropic case, (*i.e.* $s = 1$), [29] in turn reduces to a form equivalent to [28], as indeed it must.

Finally, on setting $q = (R_r + d)/R_r$, and $R_2 = R_r + d$, where d is the thickness of the oriented molecular layer and $R_r = R_3$, the radius of the rod, [27] may be expanded in powers of d/R_r to give, on retaining up to first order terms

$$[30]\quad \alpha_\perp^{rp} = \frac{1}{2} R_{rp}^2 \frac{\varepsilon_s/\varepsilon_a - 1}{\varepsilon_s/\varepsilon_a + 1} + R_{rp} \frac{\gamma_t + (\varepsilon_s/\varepsilon_a)^2 \gamma_n}{(\varepsilon_s/\varepsilon_a + 1)^2}$$

where, as before, ε_s and ε_a are the dielectric constant of the substrate and ambient, respectively, and have been substituted for ε_3 and ε_1, and γ_n and γ_t are defined in Section 1. The first term in [30] is the contribution due to the uncoated rod, the second being that due to the coating.

To obtain an expression from [27] for the specific polarizability of a cylindrical cavity with an internally adsorbed oriented molecular film, the substitutions $q = R_{rc}/(R_{rc} - d)$, $\varepsilon_1 = \varepsilon_s$, $\varepsilon_3 = \varepsilon_a$ are made, which on expanding in powers of d/R_{rc} and retaining up to first order terms gives

$$[31]\quad \alpha_\perp^{rc} = \frac{1}{2} R_{rc}^2 \frac{1 - \varepsilon_s/\varepsilon_a}{1 + \varepsilon_s/\varepsilon_a} + R_{rc} \frac{(\varepsilon_s/\varepsilon_a)(\gamma_t + \gamma_n)}{(1 + \varepsilon_s/\varepsilon_a)^2}$$

where $R_{rc} = R_2$ is the radius of the empty cavity.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

As before, the first term in [31] is the contribution to $\alpha_\perp^{(1)}$ made by the empty cavity, the second, that made by the film.

To calculate the parallel component of the effective specific polarizability of a coated rod immersed in a medium of dielectric constant ε_1 is straightforward, since the Maxwell field strengths in all the media must be the same, and only the component ε_t of the film dielectric tensor is involved. Thus the incremental polarizations of media 3 and 2 relative to medium 1 are given by

$$[32] \qquad \Delta P_\parallel^{(3)} = E_\parallel^{(3)}(\varepsilon_3 - \varepsilon_1)/4\pi$$

$$[33] \qquad \Delta P_\parallel^{(2)} = E_\parallel^{(2)}(\varepsilon_t - \varepsilon_1)/4\pi$$

The effective specific polarizability of the coated rod is then given by

$$[34] \quad \varepsilon_1\alpha_\parallel^{(1)} = (V_3/l)(\Delta P_\parallel^{(3)}/E_\parallel^{(1)}) + (V_2/l)(\Delta P_\parallel^{(2)}/E_\parallel^{(1)})$$

where V_3 and V_2 are the volumes of the phases, and l the length of the rod. Substituting appropriately for V_3, V_2, $\Delta P_\parallel^{(3)}$, and $\Delta P_\parallel^{(2)}$ and setting $E_\parallel^{(3)} = E_\parallel^{(2)} = E_\parallel^{(1)}$ then gives

$$[35] \quad \alpha_\parallel^{(1)} = \tfrac{1}{4}R_3^2[(\varepsilon_3/\varepsilon_1 - 1) + (q^2 - 1)(\varepsilon_t/\varepsilon_1 - 1)]$$

Expanding R_3^2 and q^2 as before, gives for the case of a coated rodlike particle.

$$[36] \quad \alpha_\parallel^{rp} = \tfrac{1}{4}R_{rp}^2(\varepsilon_s/\varepsilon_a - 1) + \tfrac{1}{2}R_{rp}\gamma_t$$

while for an internally coated rodlike cavity

$$[37] \quad \alpha_\parallel^{rc} = \tfrac{1}{4}R_{rc}^2(\varepsilon_a/\varepsilon_s - 1) + \tfrac{1}{2}R_{rc}(\varepsilon_a/\varepsilon_s)\gamma_t$$

(4) Dielectric Constant for a Medium Consisting of a Set of Parallel Coated Rods

In order to calculate the dielectric constant for a set of parallel rods, we must take into account the contribution of the polarization of the medium to the field polarizing the rods. This we do in the manner of Lorentz (8), that is by considering the polarizable species to lie within an appropriately shaped cavity within a continuous dielectric, the field within the cavity being taken as the local field polarizing the species. Following the procedure outlined in Section 1, with however the mean polarizing field given by $E^{(1)}[1 + \omega(\varepsilon/\varepsilon_1 - 1)]$ rather than $E^{(1)} + (4\pi/3)\sum\mu_j^{(1)}$, leads to the result

$$[38] \qquad \varepsilon/\varepsilon_1 = 1 + \frac{4\pi\sum\alpha_j^{(1)}}{1 - 4\pi\omega\sum\alpha_j^{(1)}}$$

The term $E^{(1)}\omega(\varepsilon/\varepsilon_1 - 1)$ is the contribution to the polarizing field made by the polarization of the medium, ω being the depolarization factor appropriate to the cavity shape. For spherical cavities, $\omega = 1/3$ and eq. [38] reduces precisely to eq. [10], which is essentially the Lorenz–Lorentz or Clausius–Mossotti expression. For the problem at hand, the cavities must be chosen to be cylindrical in shape. For fields normal to and parallel to the cylinder axis respectively, $\omega = 1/2$ and 0 respectively (8), leading to the result

$$[39] \qquad \varepsilon_\perp/\varepsilon_1 = 1 + \frac{4\pi L\langle\alpha_\perp^{(1)}\rangle}{1 - 2\pi L\langle\alpha_\perp^{(1)}\rangle}$$

$$[40] \qquad \varepsilon_\parallel/\varepsilon_1 = 1 + 4\pi L\langle\alpha_\parallel^{(1)}\rangle$$

where L is the total length of rod per unit volume and $\langle\alpha_\perp^{(1)}\rangle$ the mean effective polarizability per unit length normal to the cylinder axes, etc. Thus using the expressions for $\alpha^{(1)}$ presented in Section 3, we have for a collection of parallel rodlike particles

$$[41] \quad \left(\frac{\varepsilon_\perp^{rp}/\varepsilon_a - 1}{\varepsilon_\perp^{rp}/\varepsilon_a + 1}\right) = v_s\left(\frac{\varepsilon_s/\varepsilon_a - 1}{\varepsilon_s/\varepsilon_a + 1}\right) + a\frac{\gamma_t + (\varepsilon_s/\varepsilon_a)^2\gamma_n}{(\varepsilon_s/\varepsilon_a + 1)^2} = x^{rp}$$

$$[42] \quad (\varepsilon_\parallel^{rp}/\varepsilon_a - 1) = v_s(\varepsilon_s/\varepsilon_a - 1) + a\gamma_t$$

while for a collection of parallel, internally coated rodlike cavities

$$[43] \quad \left(\frac{\varepsilon_\perp^{rc}/\varepsilon_s - 1}{\varepsilon_\perp^{rc}/\varepsilon_s + 1}\right) = v_c\left(\frac{1 - \varepsilon_s/\varepsilon_a}{1 + \varepsilon_s/\varepsilon_a}\right) + a\frac{(\varepsilon_s/\varepsilon_a)(\gamma_t + \gamma_n)}{(1 + \varepsilon_s/\varepsilon_a)^2} = x^{rc}$$

$$[44] \quad (\varepsilon_\parallel^{rc}/\varepsilon_s - 1) = v_c(\varepsilon_a/\varepsilon_s - 1) + a(\varepsilon_a/\varepsilon_s)\gamma_t$$

These expressions take the correct form for the various limiting cases. Thus for example on setting $\gamma_n = 0 = \gamma_t$ (*i.e.* no adsorbed species), then for $v_s = 1$ (or $v_c = 0$), $\varepsilon_\perp^{rp} = \varepsilon_\parallel^{rp} = \varepsilon_\perp^{rc} = \varepsilon_\parallel^{rc} = \varepsilon_s$, while for $v_s = 0$ (or $v_c = 1$), $\varepsilon_\perp^{rp} = \varepsilon_\parallel^{rp} = \varepsilon_\perp^{rc} = \varepsilon_\parallel^{rc} = \varepsilon_a$. It is interesting to note that for any other choices for the depolarization factors (or local polarizing fields) the above conditions are not all satisfied.

(5) Dielectric Constant for a Medium Consisting of a Set of Isotropically Distributed, Coated Rods

There are many ways in which a set of rods can be distributed to yield overall an isotropic distribution. We will exclude regular arrangements from consideration, and treat two limiting cases of a random, isotropic, distribution.

The first is that in which the rods are considered to be randomly oriented with respect to their immediate neighbors. To treat this case, we begin by considering the dipole moment of a typical rod lying within the isotropic dispersion. Since its immediate surround is on average isotropic, we do this by assuming the rod to lie within a cylindrical cavity in an isotropic medium of dielectric constant ε. If the axis of our typical rod, the jth rod, is oriented parallel to the field $E^{(1)}$, its effective dipole moment per unit length will be given by

$$[45] \qquad \mu_{\parallel j}{}^{(1)}/E^{(1)} = \alpha_{\parallel j}{}^{(1)}$$

while if it is oriented normal to $E^{(1)}$ by

$$[46] \quad \mu_{\perp j}{}^{(1)}/E^{(1)} = [1 + \tfrac{1}{2}(\varepsilon/\varepsilon_1 - 1)]\alpha_{\perp j}{}^{(1)}$$

where the term $\frac{1}{2}(\varepsilon/\varepsilon_1 - 1)$ allows for the contribution to the polarizing field made by the polarization of the isotropic medium, $\frac{1}{2}$ being the depolarization factor. The depolarization factor in [45] is of course zero.

Since the dielectric constant for the dispersion is given by

$$[47] \qquad \varepsilon/\varepsilon_1 - 1 = 4\pi\sum\mu_j{}^{(1)}l_j/E^{(1)}$$

where the sum is over unit volume, and the rods are isotropically oriented over unit volume, we may replace $\mu_j{}^{(1)}$ in [47] by its average over all angular orientations of the rod, *i.e.* by $\bar{\mu}_j{}^{(1)}$ where

$$[48] \qquad \bar{\mu}_j{}^{(1)} = (2\mu_{\perp j}{}^{(1)} + \mu_{\parallel j}{}^{(1)})/3$$

Combining [45] with [48] then gives

$$[49] \quad (\varepsilon/\varepsilon_1 - 1) = \frac{4\pi L\langle\bar{\alpha}^{(1)}\rangle}{1 - (4\pi/3)L\langle\alpha_\perp{}^{(1)}\rangle}$$

where $\bar{\alpha}^{(1)} = (2\alpha_\perp{}^{(1)} + \alpha_\parallel{}^{(1)})/3$ and is the polarizability per unit length of a coated rod averaged over all orientations. Although eq. 49 looks rather like the Lorenz–Lorentz (or Clausius–Mossotti) equation, it in fact differs from it since $\langle\bar{\alpha}^{(1)}\rangle$ appears in the numerator while $\langle\alpha_\perp{}^{(1)}\rangle$ appears in the denominator. Substituting for $\alpha^{(1)}$ using the expressions in Section 3 then gives for a random distribution of coated rodlike particles

$$[50] \quad (\varepsilon^{rp}/\varepsilon_a - 1) = \frac{[4x^{rp} + v_s(\varepsilon_s/\varepsilon_a - 1) + a\gamma_t]}{(3 - 2x^{rp})}$$

while for a random distribution of internally coated rodlike cavities

$$[51] \quad (\varepsilon^{rc}/\varepsilon_s - 1) = \frac{[4x^{rc} + v_c(\varepsilon_a/\varepsilon_s - 1) + a(\varepsilon_a/\varepsilon_s)\gamma_t]}{(3 - 2x^{rc})}$$

where x^{rp} and x^{rc} are given by eqs. 41 and 43. Once again eqs. 50 and 51 give the correct results in the limits $v_c = 1$, and $v_s = 1$, $v_c = 0$ respectively, providing support for the results.

The second distribution which we shall consider is that in which the dispersion can be broken up into domains, within each of which the rods may be regarded as essentially straight and parallel, their lengths being much larger than their diameters. For simplicity, we shall take the domains to be spherical in shape, and shall fill all space with such domains. Other possibilities, of course, exist.

The effective polarizability of the ith domain oriented with its optic axis $\parallel$ to the mean Maxwell field within the composite dielectric is given by

$$[52] \qquad \alpha_{\parallel j}{}^{(1)} = R_j{}^3\frac{\varepsilon_\parallel/\varepsilon_1 - 1}{\varepsilon_\parallel/\varepsilon_1 + 2}$$

while if it is oriented $\perp$ to the mean Maxwell field by

$$[53] \qquad \alpha_{\perp j}{}^{(1)} = R_j{}^3\frac{\varepsilon_\perp/\varepsilon_1 - 1}{\varepsilon_\perp/\varepsilon_1 + 2}$$

Proceeding now as for the previous case, except that the depolarization factor is 1/3 for both the parallel and perpendicular orientations, we obtain

$$[54] \quad \frac{\varepsilon/\varepsilon_1 - 1}{\varepsilon/\varepsilon_1 + 2} = 1/3\left(\frac{\varepsilon_\parallel/\varepsilon_1 - 1}{\varepsilon_\parallel/\varepsilon_1 + 2}\right) + 2/3\left(\frac{\varepsilon_\perp/\varepsilon_1 - 1}{\varepsilon_\perp/\varepsilon_1 + 2}\right)$$

Other assumptions concerning the shapes and distribution of the domains will of course lead to different expressions for ε, so that eq. 54 can be considered no more than a particular example.

For personal use only.

(6) Dielectric Constant for a Medium Consisting of a Set of Isotropically Distributed, Coated Disks

As the procedure for obtaining the effective polarizability of a coated thin disk immersed in a medium of dielectric constant ε_1 is straight forward, we present here only the results:

$$[55]\quad \alpha_\perp^{(1)} = (V_3/4\pi)(1 - \varepsilon_1/\varepsilon_3) + (V_2/4\pi)(1 - \varepsilon_1/\varepsilon_n)$$

$$[56]\quad \alpha_\parallel^{(1)} = (V_3/4\pi)(\varepsilon_3/\varepsilon_1 - 1) + (V_2/4\pi)(\varepsilon_t/\varepsilon_1 - 1)$$

where $\alpha_\perp^{(1)}$ and $\alpha_\parallel^{(1)}$ are the effective polarizability components in the principal directions perpendicular and parallel to the plane of the disk respectively, and V_3 and V_2 the volumes of the disk and adsorbed film respectively.

We consider now only the case in which the disks are randomly oriented with respect to their immediate neighbors. Proceeding precisely as for the corresponding case involving rods, we obtain

$$[57]\quad (\varepsilon/\varepsilon_1 - 1) = \frac{4\pi \sum \bar{\alpha}_j^{(1)}}{1 - (4\pi/3)\sum \alpha_{\perp j}^{(1)}}$$

where $\bar{\alpha}_j^{(1)} = (\alpha_{\perp j}^{(1)} + 2\alpha_{\parallel j}^{(1)})/3$. Substituting eqs. 55 and 56 into eq. 57 then gives for an isotropic distribution of disk-shaped particle

$$[58]\quad \frac{\varepsilon^{dp}}{\varepsilon_a} - 1 = \frac{v_s(2\varepsilon_s/\varepsilon_a - \varepsilon_a/\varepsilon_s - 1) + a(2\gamma_t + \gamma_n)}{3 - v_s(1 - \varepsilon_a/\varepsilon_s) + a\gamma_n}$$

while for an isotropic distribution of disk-shaped cavities it gives

$$[59]\quad \frac{\varepsilon^{dc}}{\varepsilon_s} - 1 = \frac{v_c(2\varepsilon_a/\varepsilon_s - \varepsilon_s/\varepsilon_a - 1) + a(2\gamma_t\varepsilon_a/\varepsilon_s + \gamma_n\varepsilon_s/\varepsilon_a)}{3 - v_c(1 - \varepsilon_s/\varepsilon_a) + a\gamma_n\varepsilon_s/\varepsilon_a}$$

Again both these equations give the correct results in the limits $v_s = 0$, $v_c = 1$, and $v_s = 1$, $v_c = 0$.

(7) Discussion

It is apparent from the foregoing, that the dielectric behavior of porous adsorbent – adsorbate systems depends not only on the geometry of the particles and/or cavities which make up the porous adsorbent, but also on the spatial and orientational distribution of these. It would therefore appear to be extremely difficult to model effectively a real system. On the other hand, one can clearly build considerable flexibility into a model using only spherical, cylindrical, and disk-shaped particles and their cavity counterparts, and this may be sufficient to duplicate reasonably well phenomena observed for real systems. Combining spherical, cylindrical, and disk-shaped particles (or cavities) into a single model is straight forward using the procedures of Section 5, though it leads to rather unwieldy expressions. Combining both cavities and particles in a single model presents difficulties and would seem to require one to consider the composite dielectric divided into particle and cavity domains. We do not plan to investigate here the many ramifications resulting from the choice of particle and cavity shapes, their relative proportions, and their spatial and orientational distribution, but will restrict attention to two effects which are predicted by all such models, and are not taken into account by any previous models for porous adsorbent – adsorbate systems. These are: effects of molecular orientation on dielectric properties, and the change in the apparent dielectric properties of the adsorbate on going from the zero-to-one-monolayer region, to the region of capillary condensation. We examine the case of molecular orientation first.

When a polar molecule is adsorbed within a porous adsorbent, its polarizability in the adsorbed state will depend upon the extent to which the molecule is free to orient its permanent dipole along the field direction. This phenomenon is well-known (1) and has been used to attempt to gain information on the nature of the adsorbed state. It is not this orientational effect we discuss here, but rather another which will exist whenever the adsorbed species has an anisotropic polarizability. In investigating this effect, as well as that associated with the transition between monolayer coverage and capillary condensation, we will treat only the random, rodlike cavity model (eq. 51). Similar conclusions arise, however, from treating the other models.

From eq. 51, on substituting for x^{rc} from eq. 43, and for γ_n and γ_t from eqs. 4 and 5 we obtain

$$[60] \quad \varepsilon_m' \equiv \left(\frac{d\varepsilon^{rc}}{dv_f}\right)_{v_f \to 0} = A(\varepsilon_t - 1/\varepsilon_n) + B(\varepsilon_t - 1)$$

where A and B are positive, real-valued, coefficients (for ε_s real valued) characteristic of the adsorbent and are given by

$$[61] \quad A = \frac{2\varepsilon_s[6\varepsilon_s - v_c(\varepsilon_s - 1)]}{[3(\varepsilon_s + 1) + 2v_c(\varepsilon_s - 1)]^2}$$

$$[62] \quad B = \frac{\varepsilon_s + 1}{3(\varepsilon_s + 1) + 2v_c(\varepsilon_s - 1)}$$

and $v_f = ad$ is the volume of adsorbate per unit volume of adsorbent. In obtaining eq. 60, ε_a has been set equal to unity and it has been assumed that ε_t and ε_n are independent of coverage (*i.e.* of v_f) in the range zero to one monolayer, which will be the case only if adsorption occurs in the form of 2-dimensional condensed patches (6).

From the form of eq. 60, it is apparent that the differential dielectric constant for the adsorbed species will in general depend on molecular orientation. Before pursuing this further, however, we shall obtain the expression for the region of capillary condensation, corresponding to eq. 60. To do this, we assume that all subsets of the capillaries, characterized by a particular range of diameters, are randomly oriented and distributed both in relation to members of the set, and to members of any other set. This allows us to break up the sum over polarizabilities in eq. 38 into two sums, one over empty capillaries, the other over full capillaries. The resulting expression for ε^{rc} is thus obtained from eq. 51 on making the following substitutions:

$$\gamma_n = 0 = \gamma_t$$

$$x^{rc} \to [(v_c - v_L)/v_c]x_0^{rc} + [v_L/v_c]x_c^{rc}$$

$$v_c(\varepsilon_a/\varepsilon_s - 1) \to (v_c - v_L)(1/\varepsilon_s - 1) + v_L(\varepsilon_L/\varepsilon_s - 1)$$

where $x_0^{rc} = x^{rc}(\gamma_n = 0 = \gamma_t,\ \varepsilon_a = 1)$, $x_c^{rc} = x^{rc}(\gamma_n = 0 = \gamma_t, \varepsilon_a = \varepsilon_L)$, and v_c is the total volume fraction of the capillaries, v_L that of the filled capillaries, and ε_L the dielectric constant of the adsorbate condensed in the capillaries. In this treatment, we have neglected the effect of the adsorbed layer, as it will not contribute significantly to $d\varepsilon^{rc}/dv_f$ in the region of capillary condensation, and have assumed that the adsorbate molecules condensed within the capillaries are isotropically oriented and distributed. Making the above substitutions, we then obtain for the initial slope in the capillary condensation region

$$[63] \quad \varepsilon_c' \equiv \left(\frac{d\varepsilon^{rc}}{dv_L}\right)_{v_L \to 0} = 2A\frac{(\varepsilon_s + 1)(\varepsilon_L - 1)}{(\varepsilon_s + \varepsilon_L)} + B(\varepsilon_L - 1)$$

where A and B are defined as before. A comparison of eqs. 60 and 63 now allows us to determine the direction of the change in slope on going from the premonolayer region to the capillary condensation region. Various possible cases are considered below.

If the adsorbed film is isotropic, then $\varepsilon_t = \varepsilon_n \simeq \varepsilon_L$ from which we deduce the following:

$$[64] \quad \begin{aligned} &\varepsilon_c'/\varepsilon_m' > 1 \text{ for } (1 - \varepsilon_L/\varepsilon_s) > 0 \\ &\varepsilon_c'/\varepsilon_m' < 1 \text{ for } (1 - \varepsilon_L/\varepsilon_s) < 0 \\ &\varepsilon_c'/\varepsilon_m' = 1 \text{ for } (1 - \varepsilon_L/\varepsilon_s) = 0 \end{aligned}$$

Thus for a nonpolar adsorbate of isotropic polarizability in the adsorbed state, this model predicts in general a change of slope at completion of a monolayer, the sign of the change being given by the sign of $(1 - \varepsilon_L/\varepsilon_s)$. No previous model predicts a change in slope for such circumstances, yet data showing such changes are common (1), and unaccounted for in any quantitative sense except in those instances where polar adsorbates give rise to an increase of slope following completion of a monolayer. The many examples in which a decrease in slope accompanies completion of a monolayer are accounted for by this model, not only for cases in which $\varepsilon_L > \varepsilon_s$, but also for those in which $\varepsilon_s > \varepsilon_L$, since even then ε_c' can be less than ε_m' if the adsorbed species has an anisotropic polarizability. Thus it is easily shown that even for $\varepsilon_s/\varepsilon_L \to \infty$, $\varepsilon_c' < \varepsilon_m'$ provided that $(\varepsilon_t - 1)/(\varepsilon_L - 1) > 9/5$, so that a decrease in slope can occur for $\varepsilon_s/\varepsilon_L > 1$ if the molecules adsorb with their major polarizability axes parallel to the surface.

All of these effects arise, of course, as a result of variations in the local field within the composite dielectric, both with position in the composite dielectric, and with field direction relative to the normal to the local surface element. The advantage of the present treatments of porous adsorbent – adsorbate systems is that for the first time they provide a basis for exploring the

possible range of such local field effects. How well the models can account quantitatively for dielectric measurements remains to be seen. That they can account qualitatively for hitherto surprising results (such as the decrease in slope following monolayer completion) has, however, already been established. A more detailed examination of the consequences of the various models, and the relationship of the models to real systems, is the subject of a current investigation.

The authors are grateful to Dr. T. McMullen of St. Francis Xavier University who provided helpful comments on the first draft of this paper, and to the National Research Council of Canada for supporting this research.

A Micrometer Syringe Dilatometer: Application to the Measurement of the Excess Volumes of some Ethylbenzene Systems at 298.15 K[1]

REIJI TANAKA,[2] OSAMU KIYOHARA,[3] PATRICK J. D'ARCY, AND GEORGE C. BENSON
Division of Chemistry, National Research Council of Canada, Ottawa, Canada K1A 0R6

Received February 25, 1975

REIJI TANAKA, OSAMU KIYOHARA, PATRICK J. D'ARCY, and GEORGE C. BENSON. Can. J. Chem. **53**, 2262 (1975).

A dilatometer using a micrometer syringe to measure small changes in volume at constant pressure is described. Excess volumes determined for cyclohexane + benzene at 298.15 K are in reasonable agreement with values from the literature. Results are also reported for the excess volumes of mixtures of ethylbenzene with benzene, toluene, and the isomeric xylenes.

REIJI TANAKA, OSAMU KIYOHARA, PATRICK J. D'ARCY et GEORGE C. BENSON. Can. J. Chem. **53**, 2262 (1975).

On décrit un dilatomètre constitué d'une micro-seringue pour mesurer de petites variations de volume à pression constante. Les excès de volume déterminés pour un mélange cyclohexane et benzène à 298.15 K sont en bon accord avec les valeurs de la littérature. On rapporte aussi les resultats concernant les excès de volume des mélanges éthylbenzène avec le benzene, le toluène ou les isomères du xylène. [Traduit par le journal]

The volume change accompanying the mixing of nonelectrolytes is often obtained from observations of the position of a meniscus of mercury confining the liquids. In cases where the displacement of the meniscus has a vertical component, it is important to consider the effect of variations in pressure on the observed volumes of the system. For a dilution type dilatometer containing about 100 cm^3 of liquid confined by mercury having a meniscus in a vertical capillary with a 1 mm internal diameter, neglect of the compressibility of the liquid will lead to an error of about 1.5% in the values of the excess volume, V^E. Furthermore, if the liquid is not adequately degassed, pressure variations may cause bubble formation which also obscures the interpretation of the observed changes in volume. Thus for accurate determinations of V^E, it is desirable to maintain constant pressure.

Dilatometers using a micrometer screw to measure the change in volume at constant pressure have been described by Pardo (1) and by Chareyron (2). Recently we constructed a similar dilatometer of somewhat simpler design. Studies of the mixing of cyclohexane with benzene and also of ethylbenzene with benzene, toluene, and the isomeric xylenes indicate that the apparatus is capable of a good accuracy and is well suited to the routine determination of excess volumes.

Experimental

Apparatus

The dilatometer was made of heavy walled Pyrex glass and was securely mounted on a brass frame. A schematic drawing of the dilatometer is given in Fig. 1. The total volume of the mixing cell F is about 120 cm^3. The feed system consists of a 50 cm^3 reservoir E and a 5 cm^3 burette D. The feed liquid enters the cell through a capillary tube H immersed in a cup G containing mercury to prevent diffusion. The cross-sectional area of the burette was determined to an accuracy of $\pm 0.025\%$ by measuring the delivery of mercury. The filling port of the feed system is closed by a Teflon stopper J expanded by a tapered steel core V to ensure a tight seal (see insert in Fig. 1).

The volume of mixing is obtained from readings of the micrometer Q and observations of the level of the mercury in the capillary tube N. The micrometer is attached to a syringe by a brass collar R and surrounded by a plastic tube O to protect it from the bath water. A steel rod extension of the micrometer spindle is keyed to a Teflon tip T which fits snugly into a 3 mm i.d. Tru-bore tube S. Before incorporating the syringe in the dilatometer, its delivery was calibrated by weighing the mercury displaced by manipulations of the micrometer. The calibration constant was determined within an error of $\pm 0.05\%$ and its value was independent of the position of the piston. The capillary N was then calibrated *in situ*, using the micrometer syringe.

Loading and Operation

After the dilatometer has been cleaned and dried, a light coating of silicone grease is applied to the stopcocks

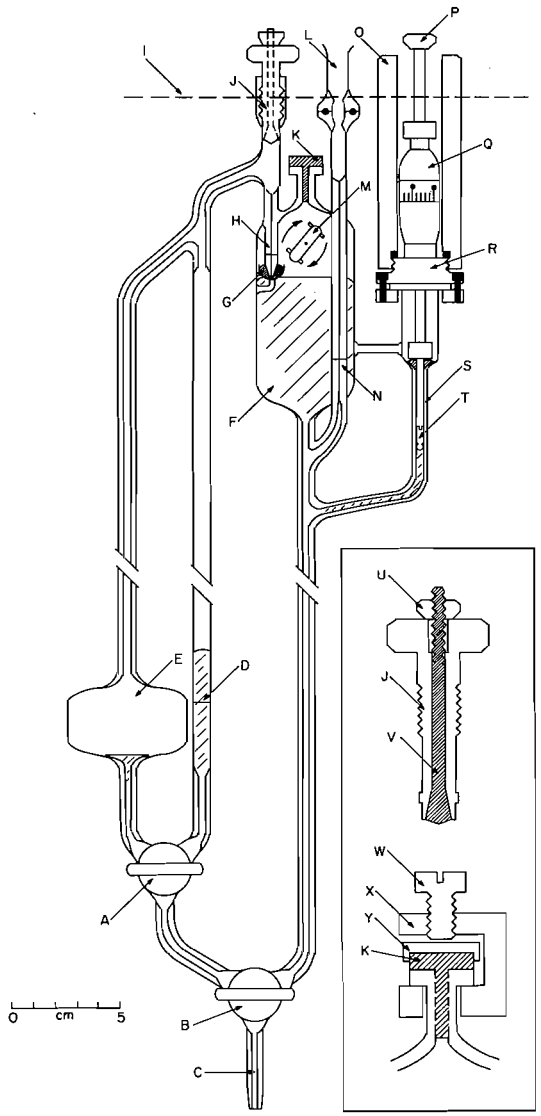

FIG. 1. Schematic diagram of the dilatometer. A and B, three-way taps (Eck and Krebs A-5032); C, drain tube; D, burette with fiducial line (approximately 0.5 cm i.d., volume 5 cm^3); E, feed reservoir (volume 50 cm^3); F, mixing cell (volume 120 cm^3); G, cup for mercury; H, Tru-bore capillary feed tube with fiducial line (approximately 0.05 cm i.d.); I, level of water in thermostat; J and K, Teflon stoppers (see inserts for details); L, extension tube with spherical O-ring joint; M, magnetic stirrer; N, Tru-bore capillary tube with fiducial line (approximately 0.05 cm i.d.); O, Lucite tube; P, extension rod to control micrometer; Q, micrometer (2.5 cm stroke, vernier reading to 10^{-4} cm); R, brass collar for attaching micrometer; S, syringe with barrel made from Tru-bore tube (approximately 0.3 cm i.d.); T, Teflon tip on piston; U and V, brass nut and tapered stainless steel core to tighten stopper J; W, X, and Y, stainless steel screw, yoke and cap to clamp stopper K.

of the taps A and B. A tube with a small tap is attached to the spherical O-ring joint on N and the opening at the top of the mixing cell is connected to a vacuum pump. The two remaining openings are sealed with temporary stoppers and the dilatometer is evacuated, taking care to remove pockets of air trapped in the grease of the stopcocks. Degassed mercury is sucked up slowly through the drain tube C into the feed system and mixing cell until the latter is filled above the level of the cup. Air is then admitted slowly through the cell opening, forcing mercury into the upper parts of the feed system, syringe and capillary.

Sufficient mercury is removed from the cell through the drain tube to make room for the addition of about 35 cm^3 of one component which is introduced from a weighing burette. All weighings are corrected to *vacuo*; the uncertainty in the amount of the cell component due to vapor loss is estimated to be less than 0.01 g. The level of the liquid in the cell is readjusted by adding mercury and/or warming–cooling operations in order to eliminate any air space when the cell is closed with the Teflon stopper K.

The stopper on the syringe opening is removed and mercury is drained out to adjust the level to a suitable position. After a little ethanol is added to the surface of the mercury in the syringe, the micrometer piston is pushed into place and the protective plastic tube installed. The alcohol acts as a lubricant and facilitates removal of air from the surface of the piston as it is inserted.

The top of the feed system is opened and the second component is introduced as mercury is drained from the feed reservoir and burette. The feed system is then sealed with the Teflon stopper J. Finally the small stopcock attached to the capillary N is opened. After the mercury level has been lowered to an appropriate position below the joint, the stopcock is removed and replaced by a glass extension tube L. Before starting a run, tap A is closed and tap B is opened from the cell toward A.

The loaded dilatometer is immersed in a water bath operated at 298.15 $\pm$ 0.01 K and controlled to better than $\pm$0.001 K during a run. The magnetic stirrer in the cell is operated continuously at about 200 r.p.m. After thermal equilibrium is reached, the level of the mercury in H is set close to the reference mark by manipulating A and J. The micrometer is then used to adjust the level in the capillary N to the same height as the meniscus in the cell. By turning tap A, some of the feed component is added slowly to the cell, displacing mercury. During the mixing, the micrometer is readjusted to maintain the mercury level in N close to that in the cell, and the final difference of levels is less than $\pm$0.05 cm. The positions of the menisci in the tubes D, H, and N, relative to the reference lines, are observed through a window in the bath. They are read by means of a cathetometer within an error of $\pm$0.003 cm. The excess volume is calculated from the micrometer readings and differences of the levels in the feed burette and capillary N. A small correction is made for the volume of the mercury in H before the first addition.

During a run, the temperature of the bath was monitored continuously with a quartz crystal thermometer. Cathetometer readings before and after a mixing were always taken within $\pm$0.0005 K of each other, which corresponds to an uncertainty of $\pm$0.00001 cm^3 in the volume.

Bottomley and Scott (3) reported that operations of a greased tap controlling the mercury in a dilution dilatom-

eter increased the apparent volume of the system by up to 0.00005 cm^3 per turn, even though the mercury was not flowing through the tap. Similar volume changes were associated with the operation of tap A in our dilatometer when no mixing occurred, but both increases and decreases of the order of 0.00002 cm^3 were observed. During a run, unnecessary movements of the tap were avoided to reduce to a minimum the uncertainty due to this effect. From dummy measurements in which the cell and burette contained the same liquid, it was found that the volume decreased by (0.00008 ± 0.00006) cm^3 for each mixing. This result appeared to be characteristic of the tap and a correction was added in calculating the volume changes during a run.

Measurements

The dilatometer was tested by measuring the standard system cyclohexane (1) + benzene (2) at 298.15 K. To investigate its performance further, measurements were also made for mixtures of ethylbenzene with benzene, toluene, and isomeric xylenes. The component liquids were commercial reagents (purity >95 mol%) which were further purified chromatographically. Values of the densities and refractive indices characterizing the final materials used for the measurements are given in Table 1, along with values from the literature (4) for comparison. In some cases, our results are averages for several samples prepared during the course of the work. The variations between the samples were less than ±0.00005 g cm^{-3} for the density and ±0.00003 for the refractive index.

Results and Discussion

The experimental results for V^E at 298.15 K are summarized in Table 2. For each system, x_1 denotes the mole fraction of the first named component. The equation

$$[1] \quad V^E = x_1(1 - x_1) \sum_{j=1}^{n} a_j(1 - 2x_1)^{j-1}$$

was fitted to each set of results by the method of least squares, assigning equal weights to all points. Values of the coefficients a_j obtained from the analysis are listed in Table 3, along with the standard error σ for each representation.

The systematic error in the value of V^E was attributed to uncertainties in the weight of the cell component, and in the calibrations of the micrometer syringe, burette, and capillary N. Sources of random error were cathetometer and micrometer readings, temperature fluctuations, and operation of the tap A. The effects of these

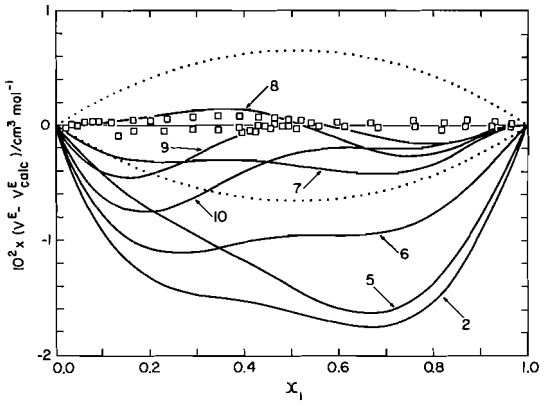

FIG. 2. Comparison of experimental results for the molar excess volume of cyclohexane (1) + benzene (2) mixtures at 298.15 K. Points and curves represent deviations from eq. 1. □, present work. The solid curves represent the smoothed results of other investigations and are labelled with their reference numbers. The dotted curves correspond to deviations of ±1%.

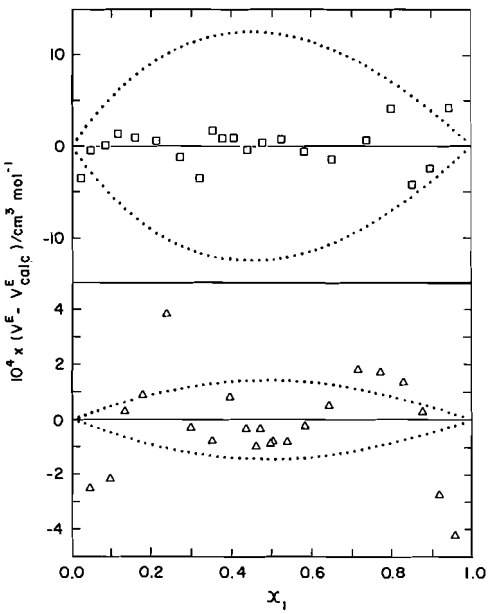

FIG. 3. Molar excess volumes of mixtures at 298.15 K. Points represent deviations of experimental results from eq. 1. □, ethylbenzene (1) + benzene (2); △, ethylbenzene (1) + toluene (2). The dotted curves correspond to deviations of ±1%.

uncertainties were examined directly by inserting their estimates into the computer program used to calculate the results from the experimental observations. The systematic error in V^E was independent of the mole fraction and was about 0.1% for systems with large excess volumes like cyclohexane + benzene and ethylbenzene + benzene, and about 0.25% for systems with small excess volumes like ethylbenzene + *m*-xylene. The random error depended on the mole fraction and was about 0.0003 cm^3 mol^{-1} for an equimolar mixture. This value agrees reasonably well with the standard errors given in Table 3.

Figure 2 gives a comparison between our results for cyclohexane + benzene and a number of the smoothed representations of V^E for this system reported in the recent literature (2, 5–10). The results in references 2, 5, and 6 were obtained with dilution dilatometers of various designs, and none were corrected for pressure changes. They are much lower than our results over the entire range of mole fractions. The data of Chareyron and Clechet (2), whose dilatometer was most similar to ours, show the largest deviations.[4] Our results agree with the other sets (7–10) within 1% over most of the mole fraction range. Quite different techniques were employed in each of these investigations. Stokes *et al.* (7) and Stookey *et al.* (10) used continuous dilution and single point (V-shaped) dilatometers respectively. Corrections for changes of pressure were applied in both studies. In the other two investigations, which were carried out in our laboratory, V^E was

[4]We have assumed that the sign of the coefficient A_1 given in ref. 2 is inappropriate for the authors' use of x for the mole fraction of benzene. The negative value of A_1 would lead to deviations larger than those indicated for $x_1 > 0.5$ in Fig. 2.

obtained from determinations of density by a float method (8) and by an Anton Paar densimeter (9). It is interesting to note that the present results are in excellent agreement with the float data and are systematically slightly higher than those of Stokes *et al.* (7) which are frequently used as a basis for comparison. The discrepancy is larger than the estimated uncertainty of the determinations and must be attributed to differences in the component liquids or to some other unidentified source of systematic error.

Deviations of the experimental results for the five ethylbenzene systems from their smoothed representations by [1] are shown in Figs. 3 and 4. There is very little information about the volume properties of these systems in the literature. Densities of mixtures of ethylbenzene with benzene and toluene at 293.15 and 303.15 K have been reported by Mamedov and Panchenkov (11). However, their precision is too low to allow reliable estimates of V^E. Thus, although it appears that their results for ethylbenzene + benzene agree roughly with ours, their densities for ethylbenzene + toluene lead to values of V^E which differ in sign from our results.

The values of V^E for mixtures of ethylbenzene with toluene and with the xylenes are small and the effect of changes of pressure is relatively unimportant compared to the random error of the measurements. Figure 4 shows that our results for the *o*-xylene and *m*-xylene systems are in good agreement with the smoothed results of Stookey and Smith (12). However, their experimental points are more widely scattered than ours. The excess volumes of ethylbenzene + *p*-xylene are very small and are only about 10 times greater than their standard error. They are therefore subject to much higher percentage uncertainties than those of the other systems.

We wish to thank Mr. J. C. van den Hoff for help in the design and construction of the glass part of the dilatometer, and Mr. C. J. Halpin for preparing the solvents used in our experimental studies.

Pyrolysis of $C_2H_7^+$ and other Ion–Molecule Reactions in Methane containing Traces of Ethane[1]

MARGARET FRENCH AND PAUL KEBARLE
Chemistry Department, University of Alberta, Edmonton, Alberta T6G 2E1
Received February 6, 1975

MARGARET FRENCH and PAUL KEBARLE. Can. J. Chem. **53**, 2668 (1975).

The major reactions in methane containing traces of ethane were studied with a pulsed electron beam high ion source pressure mass spectrometer. The CH_4:C_2H_6 ratios were changed from 50:1 to 100 000:1 at reaction temperatures between 28–210 °C. The reaction 1: $CH_5^+ + C_2H_6 = CH_4 + C_2H_7^+$ still proceeded from left to right even at the highest dilution ratios. Measurement of the $C_2H_7^+/CH_5^+$ ratio under these conditions leads to a lower limit of the proton affinity difference $PA(C_2H_6) - PA(CH_4) > 10$ kcal/mol. This result is in agreement with measurements by Bohme.

It was observed that $C_2H_7^+$ decomposes slowly at 30 °C. The decomposition becomes more rapid at higher temperature. Measurements of the temperature dependence of the thermal reaction 2: $C_2H_7^+ + CH_4 = C_2H_5^+ + H_2 + CH_4$, and an Arrhenius plot of k_2 led to the activation energy $E_2 = 10.5$ kcal/mol and preexponential factor $A_2 = 8.3 \times 10^{-8}$ (cm^3 molecule^{-1} s^{-1}). Assuming $E_2 = \Delta H_2$ one obtains $\Delta H_f(C_2H_7^+) = 208.5 \pm 2$ kcal/mol and $PA(C_2H_7^+) = 137.4 \pm 2$ kcal/mol. This is close to the proton affinity $PA(C_2H_7^+) = 139 \pm 2$ kcal/mol that can be deduced from Bohme's results.

At higher dilution ratios the ion $C_2H_5^+$ was observed to react not only with ethane but also with methane by reaction 6: $C_2H_5^+ + CH_4 = C_3H_7^+ + H_2$, $k_6 \approx 1 \times 10^{-14}$ cm^3 molecule^{-1} s^{-1} at 86 °C. The reaction has positive temperature dependence.

MARGARET FRENCH et PAUL KEBARLE. Can. J. Chem. **53**, 2668 (1975).

On a étudié les réactions principales du méthane contenant des traces d'éthane à l'aide d'un spectromètre de masse à faisceau d'électrons pulsés ayant une source d'ion à haute pression. Les rapports CH_4:C_2H_6 furent variés de 50:1 à 100 000:1 pour des températures de réaction entre 28–210 °C. La réaction 1: $CH_5^+ + C_2H_6 = CH_4 + C_2H_7^+$ a toujours lieu de gauche à droite même aux plus hauts taux de dilution. Dans ces conditions la mesure du rapport $C_2H_7^+/CH_5^+$ conduite à une limite inférieure de la différence d'affinité du proton $AP(C_2H_6) - AP(CH_4) > 10$ kcal/mol. Ce résultat est en accord avec les mesures faites par Bohme.

On a observé que $C_2H_7^+$ se décompose lentement à 30 °C. La décomposition devient plus rapide à plus haute température. Les mesures de la dépendance thermique de la réaction 2: $C_2H_7^+ + CH_4 = C_2H_5^+ + H_2 + CH_4$, ainsi que le graphique d'Arrhénius pour k_2 conduisent à une énergie d'activation $E_2 = 10.5$ kcal/mol et à un facteur pré-exponentiel $A_2 = 8.3 \times 10^{-8}$ (cm^3 molécules^{-1} s^{-1}). En supposant que $E_2 = \Delta H_2$ on obtient $\Delta H_f(C_2H_7^+) = 208.5 \pm 2$ kcal/mol et $AP(C_2H_7^+) = 137.4 \pm 2$ kcal/mol. Ceci est près de la valeur de l'affinité du proton $AP(C_2H_7^+) = 139 \pm 2$ kcal/mol, déduite des résultats de Bohme.

A des taux de dilution plus élevés on a remarqué que l'ion $C_2H_5^+$ réagissait non seulement avec l'éthane mais aussi avec le méthane selon la réaction 6: $C_2H_5^+ + CH_4 = C_3H_7^+ + H_2$, $k_6 \approx 1 \times 10^{-14}$ cm^3 molécules^{-1} s^{-1} à 86 °C. La réaction a une dépendance thermique positive. [Traduit par le journal]

Introduction

The present work, which is based on measurements of ion–molecule reactions of methane containing known traces of ethane, was initiated following the report of Chong and Franklin (1) on the proton transfer equilibrium 1 for which these authors found $\Delta G_1^0 = -1$ kcal/mol ($\sim$340 K). Such a very small difference between

[1] $CH_5^+ + C_2H_6 = CH_4 + C_2H_7^+$

the proton affinity of methane and ethane seemed very unlikely. Considering that a considerable change of structure occurs between CH_5^+ structure **1** and $C_2H_7^+$ structure **2**, a difference as high as 15 kcal/mol would have seemed more likely (2). Therefore we set out to remeasure the equilibrium 1. Before the work was completed Bohme *et al.* (3) showed that $PA(C_2H_6) > PA(CO) = 136$ kcal/mol. Since $PA(CH_4) \approx$

1 2

127 kcal/mol (4) this meant that the proton affinity difference between methane and ethane is larger than 9 kcal/mol in agreement with the theoretical predictions (2).

With such a large proton affinity difference the measurement of K_1 obviously becomes very difficult and possible only in methane containing only traces of ethane. Investigation of the ion–molecule reactions and their temperature dependence under such concentration conditions proved quite rewarding. Apart from information on the equilibrium 1, one other interesting reaction could be studied. This was the pyrolysis of $C_2H_7^+$ formed by reaction 1. Information on the heat of formation of $C_2H_7^+$ and thus on the $PA(C_2H_6)$ could be obtained since the activation energy E_2 for reaction 2

[2] $$C_2H_7^+ = C_2H_5^+ + H_2$$

could be related to ΔH_2.

Experimental

The measurements were made with the pulsed electron beam high pressure ion source reaction chamber shown in Fig. 1. The design is very similar to that used with other high pressure ion sources in our laboratory (5). The only difference is that the filament and associated electrode system are mounted on a small tower and flange which is screwed to the ion source. The filament is sufficiently far away from the ion source as to be ef-

fectively at the pressure of the vacuum chamber. Also the ion source heating effect by the filament is minimal.

The large flange-lid carrying the ion source bolts on to an 8 in. diameter vacuum housing pumped by a 6 in. diffusion pump via a 6 in. vapor trap. An Atlas CH4 magnetic mass spectrometer with a modified ion acceleration system is bolted to the vacuum housing as shown in Fig. 2.

The ion signal was detected with an electron multiplier and ion counting system. A multiscaler whose sweep was synchronized with the electron pulse was used for the determination of the time dependence of ions with a given mass.

Mixtures of methane and ethane were made in the gas handling vacuum system by filling a 5 l glass bulb with 1 atm ultrahigh purity methane. The required volume of ethane was then injected into the bulb and allowed to mix for several hours. Removal of traces of water was achieved by repeated bakeouts of the gas handling system and mass spectrometer and by passage of the methane through a molecular sieve maintained at −78 °C. The gas mixture was passed in slow flow through the ion source. The ion source pressures were generally varied between 1–3.5 Torr but most experiments were done at 2.5 Torr. The pressure was measured with a capacitance manometer. The ethane partial pressures in the ion source were selected between 0.07 to 50 mTorr. Some 47 experiments were made and analyzed in the temperature range 30–210 °C.

Results and Discussion

Major Reactions in Mixture CH_4:C_2H_6 = 50:1 near Room Temperature

The observed concentration changes of the major ions with time at ~30 °C for methane containing traces of ethane are shown in Fig. 3. The methane to ethane ratio in Fig. 3 is 50:1. Under these conditions the primary ions produced by electron impact are almost exclusively due to methane. These are CH_4^+ and CH_3^+ in an expected ratio 5:4. In the present system these ions react very rapidly with methane by the well-known reactions 3 and 4

[3] $$CH_4^+ + CH_4 = CH_5^+ + CH_3$$

[4] $$CH_3^+ + CH_4 = C_2H_5^+ + H_2$$

The resulting CH_5^+ transfers a proton to ethane forming $C_2H_7^+$ by reaction 1. This reaction is also essentially complete in 100 μs, (Fig. 3). The $C_2H_5^+$ reacts with ethane by reaction 5. This reaction has been observed in many previous studies of ethane (6–8).

[5] $$C_2H_5^+ + C_2H_6 = (C_4H_{11}^+)^* \begin{cases} \xrightarrow{d_1} C_4H_9^+ + H_2 \\ \xrightarrow{d_2} C_3H_7^+ + CH_4 \\ \xrightarrow{M} C_4H_{11}^+ \end{cases}$$

The two decomposition products $C_4H_9^+$ and $C_3H_7^+$ in a ratio 3:1 are observed in Fig. 3. Similar ratios were obtained in earlier work (8). The intermediate $C_4H_{11}^+$, stabilized by the third body M, is a minor product at this pressure and temperature.

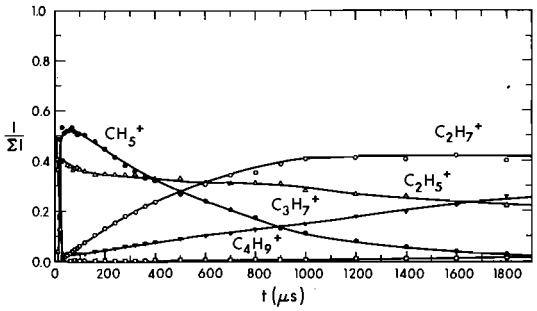

FIG. 4. Time dependence of normalized ion intensities after electron pulse: 28 °C, CH_4 2.3 Torr, CH_4:C_2H_5 = 100 000:1. Same reactant symbols as in Fig. 3.

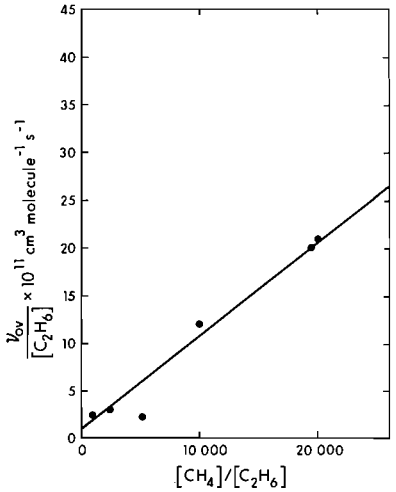

FIG. 5. Plot of pseudo first-order rate constant $\nu_{ov}/[C_2H_6]$ for overall disappearance of $C_2H_5^+$ by reactions, $C_2H_5^+ + C_2H_6 \rightarrow$ products [5], and $C_2H_5^+ + CH_4 = C_3H_7^+ + H_2$ [6]. Slope of straight line leads to k_6 while intercept with y axis equals k_5.

The Equilibrium $CH_5^+ + C_2H_6 = CH_4 + C_2H_7^+$

The ion time profiles for a much higher dilution ratio CH_4:$C_2H_6 \approx 100\,000$:1 at 30 °C are shown in Fig. 4. Even at this dilution, proton transfer from CH_5^+ to C_2H_6 by reaction 1 is still occurring over the total period of observation. The observed $C_2H_7^+/CH_5^+$ ratio at the longest reaction time (1900 μs) is 20. This leads to a low limit for the equilibrium constant $K_1 > 20 \times 100\,000 = 2 \times 10^6$. Chong and Franklin obtained $K_1 = 4.9$ at 67 °C. Assuming $\Delta S_1^0 \approx 0$ this corresponds to $K_1 \approx 5.9$ at 30°C. Evidently the present result, $K_1 > 2 \times 10^6$ at 30°C, is many orders of magnitude higher than the Franklin value. The above K_1 leads to a lower limit of 8.7 kcal/mol for the difference between the proton affinity of ethane and methane. Several experiments with larger dilution ratios were made in an attempt to observe the equilibrium 1. However, this proved impossible since some ethane (~1–10 p.p.m.) was already present in the purified ultrahigh purity methane. This allowed one to set only an approximate lower limit of ~10 kcal/mol for the proton affinity difference. Another difficulty was the slow disappearance of $C_2H_7^+$ by thermal decomposition to $C_2H_5^+ + H_2$, *i.e.* reaction 2 whose temperature dependence will be discussed below. Recently Bohme (9) using the equilibrium

$$HCO^+ + C_2H_6 = CO + C_2H_7^+$$

in combination with other sequential equilibria was able to determine $PA(C_2H_6) - PA(CH_4) = 12 \pm 1$ kcal/mol. This, combined with $PA(CH_4) = 127$ kcal/mol (4) leads to $PA(C_2H_6) = 139 \pm 2$ kcal/mol. The present results for the equilibrium 1 are consistent with these values.

The Reactions: $C_2H_5^+ + CH_4 = C_3H_7^+ + H_2$ and $C_2H_5^+ + C_2H_6 =$ products

It can be noted in Fig. 4 that the ratio of the ion products $C_4H_9^+/C_3H_7^+$ is only about 0.06. The same product ratio was equal to 3 in Fig. 3 which gave results at the same temperature but for a higher ethane concentration. This drastic change can be explained by a slow reaction of $C_2H_5^+$ with methane to give $C_3H_7^+$. At very low ethane concentrations (as in Fig. 4) such a reaction will dominate over the reaction of $C_2H_5^+$ with ethane [5]. Indeed recently the occurrence of the slow reaction 6 was observed in pure methane in our laboratory (10).

[6] $$C_2H_5^+ + CH_4 = C_3H_7^+ + H_2$$

The present observation is thus a confirmation of the earlier finding. The pseudo first-order rate constant ν_{ov} for the overall disappearance of $C_2H_5^+$ by reactions 5 and 6 is given by [7]

[7] $$\nu_{ov} = k_5[C_2H_6] + k_6[CH_4]$$

A plot of $\nu_{ov}/[C_2H_6]$ *vs.* $[CH_4]/[C_2H_6]$ should give a straight line with a slope equal to k_6 and an intercept with the y axis equal to k_5. Such a plot is shown in Fig. 5. The ν_{ov} were obtained from plots of log $[C_2H_5^+]$ *vs.* t.

These experiments were performed above room temperature (86 °C) where reaction 6, which has a positive temperature coefficient (10), is faster and thus more noticeable. The slope obtained is $k_6 \approx 1 \times 10^{-14}$ cm^3 molecule^{-1} s^{-1} which is in fair agreement with $k_6 = 1.6 \times 10^{-14}$ obtained for the same temperature in pure methane (10). The plot in Fig. 5 is obviously not suitable for an accurate determination of k_5 since the line passes close to the origin and there is considerable experimental scatter exactly in this range. The plot indicates $k_5 \approx 1 \times 10^{-11}$ cm^3 molecule^{-1} s^{-1}. An additional complication is the occurrence of the temperature dependent decomposition of $C_2H_7^+$ to $C_2H_5^+ + H_2$, *i.e.* reaction 2 discussed in the next section. The rate of this reaction which is negligible at room temperature becomes significant at 86 °C such that $C_2H_5^+$ is produced by [2] while it reacts by [5] and [6]. This has the effect of lowering the apparent rates of [5] and [6] under conditions where the rates of [2] and of [5] and [6] are comparable.

A more accurate determination of k_5 could be obtained at 300 K with methane to ethane ratios 50:1. Under these conditions both [2] and [6] are much slower than [5]. Plots of log $[C_2H_5^+]$ *vs.* time gave $k_5 = 5 \pm 1 \times 10^{-11}$ cm^3 molecule^{-1} s^{-1} at 300 K. This is in close agreement with a value of $k_5 = 5.1 \pm 1 \times 10^{-11}$ at 300 K reported recently by Bohme *et al.* (11) but lower than the value 2.8×10^{-10} cm^3 molecule^{-1} s^{-1} obtained earlier by Harrison and co-workers (7).

The Pyrolysis of $C_2H_7^+$

The $C_2H_7^+$ ion concentration is found to decrease slowly with time even at room temperature (Fig. 3). At higher temperatures this decrease was observed to become progressively more rapid. A comparison between 32° and 96° is shown in Figs. 6 and 7, where the CH_4:C_2H_6 dilution ratio is 500:1. Under these conditions proton transfer from CH_5^+ to C_2H_6 by [1] is still sufficiently fast so that the $C_2H_7^+$ formation is very rapid. As can be noticed from Figs. 6 and 7, the decrease of $C_2H_7^+$ at the higher temperature is considerably faster. On the other hand the $C_2H_5^+$ ion decreases more slowly at the higher temperature than at the lower temperature. These features can be explained by assuming the occurrence of reaction 2. Since [2] is endothermic it should have

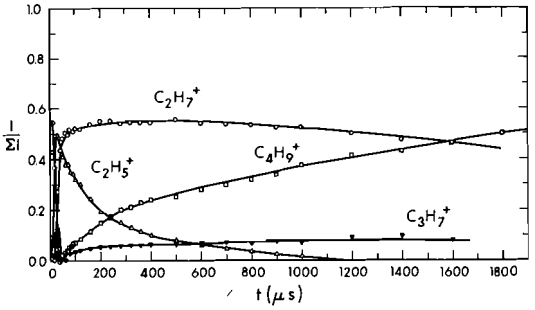

FIG. 6. Time dependence of normalized ion intensities after electron pulse. 32 °C, CH_4 2.3 Torr, CH_4:C_2H_6 = 500:1, ◐, CH_4^+; ◑, CH_3^+; ●, CH_5^+; ○, $C_2H_7^+$; ▽, $C_2H_5^+$; ◇, $C_4H_{11}^+$; □, $C_4H_9^+$; ▼, $C_3H_7^+$.

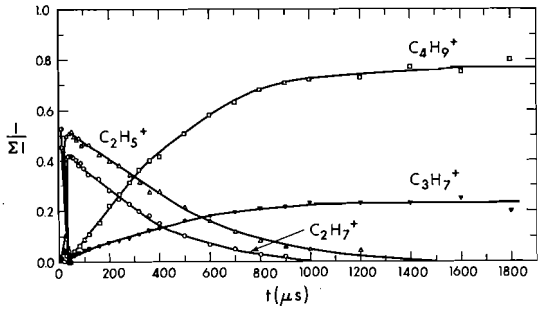

FIG. 7. Approximately the same conditions as in Fig. 6 but at 92 °C. Thermal decomposition of $C_2H_7^+$ by reaction 2, $C_2H_7^+ = C_2H_5^+ + H_2$ very noticeable.

a positive temperature coefficient. The $C_2H_5^+$ formed by [2] reacts with C_2H_6 via [5] to give $C_4H_9^+$ and some $C_3H_7^+$. The disappearance of $C_2H_5^+$ in the high temperature run (Fig. 7) is much slower than in the low temperature run (Fig. 6) since the rate of production of $C_2H_5^+$ by [2] is faster at high temperatures. Furthermore reaction 5 by which $C_2H_5^+$ is removed is faster at lower temperatures (8). This further slows down the disappearance of $C_2H_5^+$ at higher temperatures.

The rate constant k_2 for disappearance of $C_2H_7^+$ could be obtained by plotting log $[C_2H_7^+]$ *vs.* time. Since the pressure of CH_4 could not be varied over a wide enough margin it was assumed that reaction 2 depends on a third body (CH_4) for thermal activation. Reaction 2 in the present pressure regime should be second order and should be written

[2s] $C_2H_7^+ + CH_4 = C_2H_5^+ + H_2 + CH_4$

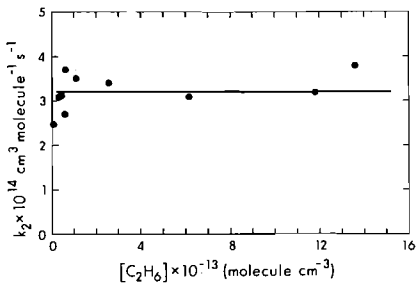

FIG. 8. Plot of k_2 for reaction 2s, $C_2H_7^+ + CH_4 = C_2H_5^+ + H_2 + CH_4$, (where major gas CH_4 involved in thermal activation) *vs.* C_2H_6 concentration. Plot shows k_2 independent of C_2H_6 concentration. Temperature 86 °C.

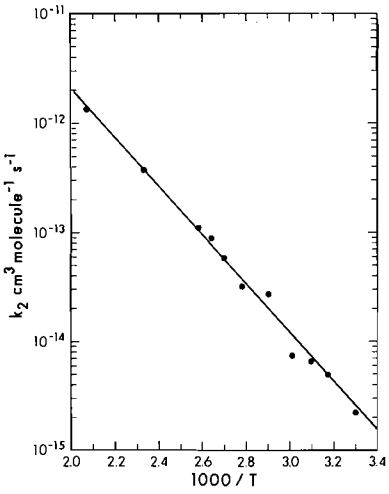

FIG. 9. Arrhenius plot of k_2 for reaction $C_2H_7^+ + CH_4 = C_2H_5^+ + H_2 + CH_4$. Straight line obtained leads to $E_{2s} = +10.5$ kcal/mol and preexponential factor $A_2 = 8.3 \times 10^{-8}$ cm^3 molecule^{-1} s^{-1}.

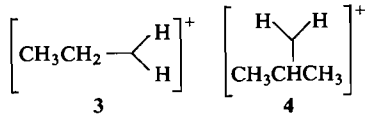
Experiments at constant temperature and different C_2H_6 concentrations showed that [2] is independent of ethane concentration in agreement with the assumptions. Figure 8 summarizes such results for one temperature.

The rate constants k_2 obtained at different temperatures were used to obtain the Arrhenius plot in Fig. 9. The straight line obtained defines the relationship [8].

$$[8] \quad k_2 = 8.3 \times 10^{-8}(\text{cm}^3\ \text{molecule}^{-1}\ \text{s}^{-1}) \times \exp\left(\frac{-10.5}{RT}\ \text{kcal/mol}\right)$$

It is interesting that the preexponential factor of k_2 is almost 10^{-7} and thus appreciably larger than the normal Langevin rate constant 10^{-9}. This is an expected result for bimolecular thermal activation and comes about from the fact that the colliding molecules can exchange not only translational but also internal energy. A recent determination (12) of the temperature dependence for the reaction 9 led to an even larger preexponential factor of 9×10^{-6}.



3 4

[9] $\quad H_5^+ + H_2 = H_3^+ + 2H_2$

Theoretical calculations by Pople and coworkers (2) have shown that structure **2** of $C_2H_7^+$ is some 11 kcal/mol more stable than structure **3**. Since one expects that the dehydrogenation of $C_2H_7^+$ proceeds through a rearrangement from **2** to **3** the activation energy $E_2 = 10.5$ kcal/mol appears of the right magnitude assuming the calculation (2) to be approximately correct and the dissociation from **3** to $C_2H_5^+ + H_2$ to be near thermoneutral. Recent investigations (10) of the dissociation of protonated propane to *sec*-$C_3H_7^+ + H_2$ indicate that the dissociation of the analogous three center bond structure **4** is exothermic. The assumption that the dissociation of H_2 from **3** is near thermoneutral is therefore reasonable. Assuming that the reverse of reaction 2 proceeds without activation energy $E_2 = \Delta H_2 = 10.5$ kcal/mol.

[−2] $\quad H_2 + C_2H_5^+ \rightarrow C_2H_7^+$ (2)

Combined with $\Delta H_f(C_2H_5^+) = 219$ kcal/mol (13) this leads to $\Delta H_f(C_3H_7^+) = 208.5$ kcal/mol and $PA(C_2H_6) = 137.4$ kcal/mol. We estimate the error in the above values to be ± 2 kcal/mol. This proton affinity is close to $PA(C_2H_6) = 139 \pm 2$ kcal/mol that can be deduced from Bohme's (9) measurements quoted earlier.

We believe that the study of thermal decomposition of ions as exemplified by the study of reaction 2 might prove to be a useful source of thermochemical and kinetic data.

The fact that $C_2H_7^+$ decomposes slowly even at room temperature suggests that protonated propane may also be thermally unstable. This is in agreement with findings of a recent study (14) of this species according to which even the most stable form of protonated propane

2-Hydroxy-2,5,5-trimethyl-Δ^3-1,3,4-oxadiazoline. Novel Induced Decomposition by Radical Attack at the Hydroxyl Group

PETER KNITTEL AND JOHN WARKENTIN

Department of Chemistry, McMaster University, Hamilton, Ontario L8S 4M1

Received December 23, 1974

PETER KNITTEL and JOHN WARKENTIN. Can. J. Chem. **53**, 2275 (1975).

Synthesis of 2-hydroxy-2,5,5-trimethyl-Δ^3-1,3,4-oxadiazoline (**3**) is described. It decomposes readily in solution at moderate temperatures, forming nitrogen and isopropyl acetate. Evidence for a concerted, radical-chain, induced decomposition by attack at hydroxyl hydrogen includes trapping of 2-acetoxy-2-propyl radicals by nitrosobenzene and by alkenes, inhibition of decomposition by $(C_6H_5)_3SnH$, and initiation of decomposition by 'stable' free radicals. The novel chain decomposition of **3** is attributed to a concerted mechanism, which brings the heats of formation of nitrogen and of a carbonyl group into play to lower the free energy of activation.

Synthetic utility of **3** is discussed together with a general principle pointing to new reagents for radical-chain additions to unsaturated systems.

PETER KNITTEL et JOHN WARKENTIN. Can. J. Chem. **53**, 2275 (1975).

On décrit la synthèse de l'hydroxy-2 triméthyl-2,5,5 Δ^3-oxadiazoline-1,3,4 (**3**). Ce composé se décompose facilement en solution, à des températures moyennes, pour conduire à de l'azote et à de l'acétate d'isopropyle. Les données indiquent qu'il y a une décomposition induite concertée, impliquant un processus radicalaire en chaîne, commençant par une attaque sur l'hydrogène de l'hydroxyle; la décomposition impliquerait le piégage des radicaux acétoxy-2 propyl-2 par le nitrosobenzène et par les alcènes, une inhibition de la décomposition par $(C_6H_5)_3SnH$ et une initiation de la décomposition par des radicaux libres 'stables'. On attribue la nouvelle décomposition en chaîne de **3** à un mécanisme concerté qui amène les chaleurs de formation de l'azote et du groupe carbonyle en jeu afin d'abaisser l'énergie libre d'activation.

On discute de l'utilité synthétique de **3** en fonction d'un principe général indiquant l'existence de nouveaux réactifs menant à des additions radicalaires en chaîne sur des systèmes monosaturés. [Traduit par le journal]

Azo compounds play an important role in chemistry as sources of free radicals, which are generated from them either thermally or photolytically together with molecular nitrogen. An important feature characterizing such azo chemistry is the rarity of induced decomposition of the parent by its radical offspring. Potential mechanisms for induced decomposition of azo compounds include radical substitution at an atom situated α (eq. 1) or γ (eq. 2) to azo nitrogen.[1] On thermochemical grounds, those processes could be facile if concerted with the formation of N_2

[1] $$R\cdot + X{-}N{=}N{-}R \rightarrow RX + N_2 + R\cdot$$

[2] $$R\cdot + X{-}Y{-}Z{-}N{=}N{-}R \rightarrow RX + Y{=}Z + N_2 + R\cdot$$

(and of YZ, eq. 2). Azo systems which are reported to react according to eq. 1 or 2 are rare. An important reason for this, presumably, is the fact that many common, stable, azo compounds do not have a center (X, eq. 1) that is highly susceptible to radical substitution (S_R) reactions. Although the number of atoms at which S_R reactions have been demonstrated is increasing steadily (3) there are still no examples of such substitution at unstrained, saturated carbon and few, if any, examples of S_R reactions at sp^3 nitrogen (3).

Radical substitution at hydrogen is often a facile process and it is not surprising that diimides (X = H) can decompose according to eq. 1 (4, 5). Other examples that may involve the same reaction are: X = RCO (6), RSO_2 (7), RCO_2 (8), ArS (9), OCH_3 (10*a*), and Cl (10*b*). In some of the latter systems there are other major reactions and radical substitution was not established or suggested as a competitive process. With X = Cl and R = aryl (eq. 1), for

[1]Discussion is restricted here to those induced decompositions of azo compounds which lead to formation of N_2. Induced decomposition by radical substitution at azo nitrogen, to form a new azo compound, is known (1, 2) but will not be considered further in this article.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

example, the yield of ArCl is higher in photochemical than in thermal decomposition (10*b*), possibly, but by no means necessarily because of induced decomposition by aryl radicals in the photochemical process.

Few cases of induced decomposition by radical substitution γ to azo nitrogen (eq. 2) have been reported. Benson and co-workers (11) observed that HCl accelerates the thermal decomposition of azo isobutane and suggested the sequence of reactions in eq. 3. The ready decomposition of

[3] $(CH_3)_3C\cdot + HCl \rightarrow (CH_3)_3CH + Cl\cdot$

$Cl\cdot + (CH_3)_3CN{=}NC(CH_3)_3 \rightarrow HCl + \dot{C}H_2(CH_3)_2CN{=}NC(CH_3)_3$

$\cdot CH_2(CH_3)_2CN{=}NC(CH_3)_3 \rightarrow CH_2{=}C(CH_3)_2 + N_2 + (CH_3)_3C\cdot$

1,1′-dihydroxyazocyclohexane (12) to cyclohexanone, cyclohexanol, hydrazine, and nitrogen may involve induced, chain decomposition as

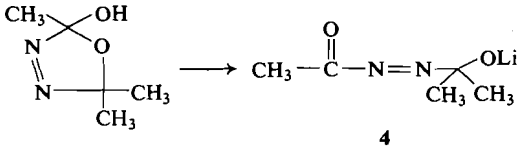
[4] 
one mechanism (eq. 4). Alternatively, cyclohexanol could arise from radical decomposition of 1-hydroxycyclohexyl diimide; the mechanism suggested by the authors (12). It is noteworthy that other α-hydroxyazo systems are more easily isolated and stored (13, 14), possibly because their induced decomposition is not a chain process at all or because the chains are very short.

In this article we report the synthesis of 2-hydroxy-2,5,5-trimethyl-Δ^3-1,3,4-oxadiazoline (**3**) and its radical-chain, induced decomposition to N_2 and isopropyl acetate. That reaction appears to be the first recognized case of induced decomposition of an α-hydroxyazo compound (α-azocarbinol) by radical abstraction of hydroxyl hydrogen.

Results and Discussion

Treatment of 5,5-dimethyl-Δ^3-1,3,4-oxadiazolinone (**1**) (15) with methyl lithium in ether at 0° leads to the lithium salt (**2**), which could be isolated and stored or hydrolyzed directly to **3** (eq. 5). Unlike most acyclic esters or lactones, **1** consumes only 1 equiv. of CH_3Li, even if the latter is added in large excess. We attribute that result to the inductive effect of the azo group which serves to make ring opening of **2**, to form **4**, unusually endothermic. The strong electron withdrawing effect of the azo function is indicated by the high carbonyl stretching frequency (1835 cm^{-1}) of **1** (15) and of other azocarbonyl systems (13*a*). Substituent constants ($\sigma_p = 0.35$ and $\sigma_p^- \simeq 0.70$) for the phenylazo group (16) also attest to the same polar effect of the azo substituent.

[5] 
1 **2**



3 **4**

Product **3** is too unstable to be isolated analytically pure but the structure was readily established from its spectra and from the products of its decomposition. The ^1H n.m.r. spectrum consists of three sharp, high-field singlets (3H each) and a broader singlet (1H) which disappears on addition of D_2O. The i.r. spectrum of **3** in benzene includes a sharp band near 3550 cm^{-1} (free OH), a broad, strong band near 3350 cm^{-1} (bonded OH), and a weak band at 1565 cm^{-1} attributable to the *cis* azo group (13*a*, 17). In benzene solution **3** decomposed at room temperature, with gas evolution, to produce isopropyl acetate in quantitative yield (n.m.r.). A radical process was inferred from the following observations. Some fresh solutions of **3** in benzene were stable at room temperature for some time while others started to decompose spontaneously. Heating an aliquot of a stable solution briefly to 60° started decomposition, which could not be stopped by cooling the aliquot to the temperature of the original solution. Instead the material in the aliquot was totally converted to isopropyl acetate during a time in which the rest of the solution had lost very little of **3**. Such behavior is characteristic of radical chain pro-

For personal use only.

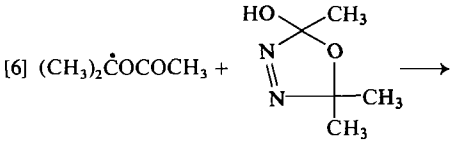
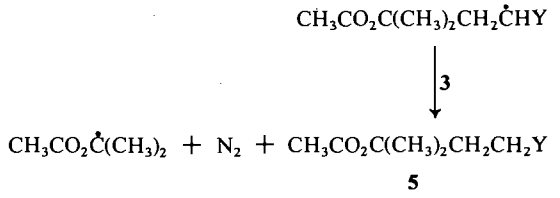
cesses. A radical process was confirmed by adding nitrosobenzene, a spin trap (18), to a solution of **3** in benzene. The strong e.s.r. signal from the resulting solution[2] was a triplet with $g = 2.007$ and $a_N = 11.78$ G. Splitting by nitrogen only is consistent with trapping of a tertiary radical to form the nitroxide radical, $C_6H_5N(O\cdot)C(CH_3)_2O_2CCH_3$. Clean decomposition of **3** to isopropyl acetate in the absence of a spin trap is consistent with a chain-carrying 2-acetoxy-2-propyl radical intermediate (eq. 6). Moreover, **3** in benzene solution could be stabilized



against decomposition by addition of triphenylstannane, a known H donor. Finally, various alkenes added to benzene solutions of **3** are converted to adducts of the type **5** shown in eq. 7.



Loss of N_2 must be concerted with H abstraction to account for the ready decomposition of **3**, for abstraction of hydroxyl hydrogen from alcohols by free radicals, although known (19), is not a favored process in solution.[3] Relatively stable radicals like 2-acetoxy-2-propyl (eq. 6) or α-cyanoalkyl (eq. 7, Y = CN) cannot be expected to abstract hydroxylic hydrogen from **3** unless some driving force from the heat of formation of nitrogen becomes available to lower the free energy of the transition state. Support for concerted H—O and C—N bond ruptures came from experiments in which 2,6-di-*t*-butyl-4-methylphenol (**6**) was added to benzene solutions of **3**. Instead of inhibiting decomposition, **6** acts as an initiator and mild accelerator of the conversion of **3** to isopropyl acetate. We assume that initiation is caused by traces of aryloxy radicals from oxidation of the phenol and that those radicals are efficient chain carriers for the induced decomposition of **3**. Addition of di-*t*-butyl nitroxide to a benzene solution of **3** also initiated gas evolution. Again, the observation that 'stable' free radicals attack **3** is consistent only with concerted HO and C—N bond homolyses.

The chemistry of **3** and other members of the family may be of considerable synthetic utility. First, direct radical addition of esters to olefins (21) involves bond formation primarily α to the acyl carbon, whereas **3** provides an indirect path for adding an ester cleanly through its ether function (eq. 7). Many unsaturated systems have been successfully functionalized via **3** (eq. 7), including Y = CN, COR, CO_2R, OR, and NR_2. Details of most of those experiments will be reported separately. More important, probably, is a general principle regarding radical pathways in synthesis that emerges from those results. *Radical chain addition of the reagent X—Y to unsaturated systems, if impractical because of adverse thermochemisty of the chain-carrying abstraction step, can be made more favorable by using a new reagent which delivers the fragments X and Y, in a chain reaction, by virtue of the altered thermochemistry that results from the formation of stable co-products.*

Reagent **3**, which delivers the fragments $CH_3CO_2C(CH_3)_2$ and H by virtue of the combined heats of formation of N_2 and of a carbonyl group, is just one of many that can be envisioned. The list of potential fragments, X and Y, is very long and other likely, stable co-products include, for example, CO_2, CO, R_2CO, SO_2, aromatic molecules, and those products in combination. Exploratory work is in progress.

Experimental

2-Hydroxy-2,5,5-trimethyl-Δ³-1,3,4-oxadiazoline (3)

To an ice-cooled solution of 5,5-dimethyl-Δ³-1,3,4-oxadiazolin-2-one (**1**) (15) (2.0 g, 18 mmol) in 30 ml of anhydrous ether was added, gradually and with stirring, a solution of methyl lithium (10 ml, *ca.* 1.9 *M*) in ether until the solution in the flask just turned yellow. The addition can be performed like a titration using that

[2]Individual solutions of **3** or of nitrosobenzene in benzene did not themselves give e.s.r. signals.

[3]Exceptional in this respect are cyclopropanols, which are attacked by radicals at hydroxyl hydrogen, with concerted ring opening, in reactions analogous to that of **3** except for the different force (strain relief) that drives the former process (20).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

color change as the end point. Stirring was continued for 10 min more at 0° before ice-cold $(NH_4)_2SO_4$ solution (50 ml, 20%) was added slowly. Cold H_2SO_4 (3 *M*) was then added until the aqueous layer was acidic to litmus. Separation of the ether layer, extraction of the residual aqueous layer twice with ether, drying the combined ether extracts over $MgSO_4$, filtration, addition of 2 drops of triphenylstannane, and evaporation of the ether with a rotary evaporator at room temperature, until the flask became defrosted and had regained room temperature, left **3** as an oil (80% yield, based on **1**). Its p.m.r. spectrum (benzene, TMS) consisted of three singlets (3H each) at δ 1.41, 1.57, and 1.80 as well as a broad singlet (1H) at δ 4.83. The i.r. spectrum (benzene) included bands at 3580 (sharp), 3400 (broad), and 1565 (weak) cm^{-1}.

The n.m.r. spectrum of the same sample, left for 96 h at room temperature, showed that 53% of the original **3** was still present.

Effects of 2,6-Di-t-butyl-4-methylphenol and of Di-t-butylnitroxide

A solution of **3** in benzene, prepared as described above but without added triphenylstannane, was separated into equal portions. One portion was made 0.01 *M* in the phenol and aliquots of both portions were scanned by n.m.r. The initial rate of loss of **3** from the phenol-containing portion was about twice that of the phenol-free portion.

To a solution of **3** in benzene, from which gas was evolving slowly at room temperature, was added a small amount (to make *ca.* 0.01 *M* solution) of di-*t*-butyl nitroxide. An immediate substantial increase in the rate of bubbling resulted. On the other hand, addition of corresponding molar quantities of either triphenyl or tri-*n*-butyl stannane decreased and eventually stopped such bubbling.

Spin Trapping by Nitrosobenzene

To a saturated solution of nitrosobenzene in benzene (0.5 ml) was added 20 mg of **3**. The e.s.r. spectrum of the resulting solution was obtained with a JEOLCO Model JES-3BS-X, e.s.r. instrument, using Mn^{2+} marker. A strong, triplet signal was recorded, with $g = 2.007$ and $a_N = 11.78$ *G*. A portion of the nitrosobenzene solution without added **3** did not produce an e.s.r. signal at the same instrument settings.

Trapping with Crotonaldehyde

A solution of **3** (2.0 g, 0.015 mol) in benzene (30 ml), cooled with ice, was stirred vigorously with a magnetic stirrer. Crotonaldehyde (3.0 g, 0.043 mol) was added all at once, a condenser and a drying tube were fitted to the flask, and the reaction mixture was heated at 40–50°, with constant stirring, until the n.m.r. spectrum of an aliquot showed that all **3** was consumed (about 4 h). Excess crotonaldehyde and the benzene were removed by distillation leaving crude 4-acetoxy-3,4-dimethyl pentanal (80–85%) as an oil. Analytically pure material was obtained by g.l.p.c. (SE 30, 15%, 5 ft × ¼ in., 150° 60 ml min^{-1}): p.m.r. (Varian HA 100, CCl_4) δ 0.95 (d, 3, $J = 7$ Hz), 1.38 (s, 3), and 1.46 (s, 3, diastereotopic *gem*-dimethyl), 1.92 (s, 3, CH_3CO), 1.99–2.75 (m, 3, $\rangle CH—CH_2—$), 9.66 (t, 1, $J = 2.5$ Hz, CHO); i.r. (CCl_4), 2725 (CH of CHO), 1735 (both C=O, unresolved) 1375 + 1362 ($C(CH_3)_2$), and 1255 cm^{-1} (C—O—C).

3,4-Dihydro-*2H*-1,5-benzodioxepins. A Novel Class of β-Adrenergic Stimulants

C. S. ROONEY, R. S. STUART, B. K. WASSON, AND H. W. R. WILLIAMS

Medicinal Chemistry Department, Merck Frosst Laboratories, P.O. Box 1005, Pointe Claire/Dorval, Quebec H9R 4P8

Received January 23, 1975

C. S. ROONEY, R. S. STUART, B. K. WASSON, and H. W. R. WILLIAMS. Can. J. Chem. **53**, 2279 (1975).

A series of 3-substituted-aminomethyl-3-hydroxy-3,4-dihydro-*2H*-1,5-benzodioxepins is described. Members of the series constitute a unique class of β-adrenergic stimulants and possess interesting bronchial dilator activity.

C. S. ROONEY, R. S. STUART, B. K. WASSON et H. W. R. WILLIAMS. Can. J. Chem. **53**, 2279 (1975).

On a préparé une série d'aminométhyl-3 hydroxy-3-dihydro-3,4 (*2H*)-benzodioxepines-1,5 substitué sur l'azote. Les membres de cette série constituent une classe unique de stimulants β-adrénergiques et possèdent une activité broncho-dilatatrice intéressante.

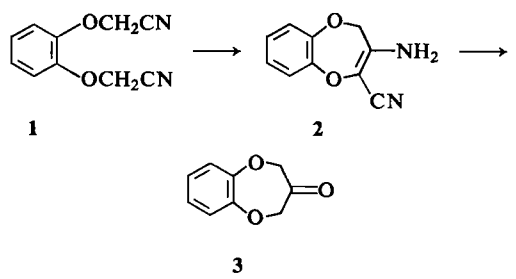
As an extension of an interest in 1-phenoxy-3-amino-2-propanols with β-adrenergic blocking activity, it was decided to prepare as analogs 3,4-dihydro-*2H*-1,5-benzodioxepins (**A**) containing hydroxyl and amino functions in a similar vicinal relationship. Instead of the expected β-adrenergic blocking properties, a number of the compounds displayed β-adrenergic stimulant activity.

A practical preparative method was devised for the key intermediate, 3-oxo-3,4-dihydro-*2H*-1,5-benzodioxepin (**3**) (1), in the syntheses of the desired amino derivatives. Thorpe cyclization of 1,2-di(cyanomethoxy)benzene (**1**) afforded an enamino nitrile (**2**) which was hydrolyzed to the ketone (**3**) in acceptable overall yield. Three similar syntheses have been published recently (2).

From the ketone (**3**), two routes to the final products were developed. The ketone (**3**) was converted to the cyanohydrin (**4**) which, upon reduction, either catalytically or with lithium aluminum hydride, gave the amino alcohol (**5**). Various *N*-alkyl and *N*-aralkyl derivatives of this amine were obtained by reductive alkylations in the presence of aldehydes or ketones and by amide formation followed by lithium aluminum hydride reduction. Alternatively, conversion of the ketone (**3**) to the epoxide (**6**) by treatment with dimethyl sulfoxonium methylide and then reaction of the epoxide with a primary amine afforded an *N*-substituted amino alcohol (**A**). The latter route is more versatile in that the products are not limited to those bearing a primary or secondary alkyl group on the nitrogen atom. Treatment of the amino alcohol (**5**) with nitrous acid provided a convenient method for the large scale preparation of the epoxide (**6**). A small amount of the glycol (**7**) was obtained along with the epoxide but the Tiffeneau–Demjanov ring-expanded product (**8**) was not observed.

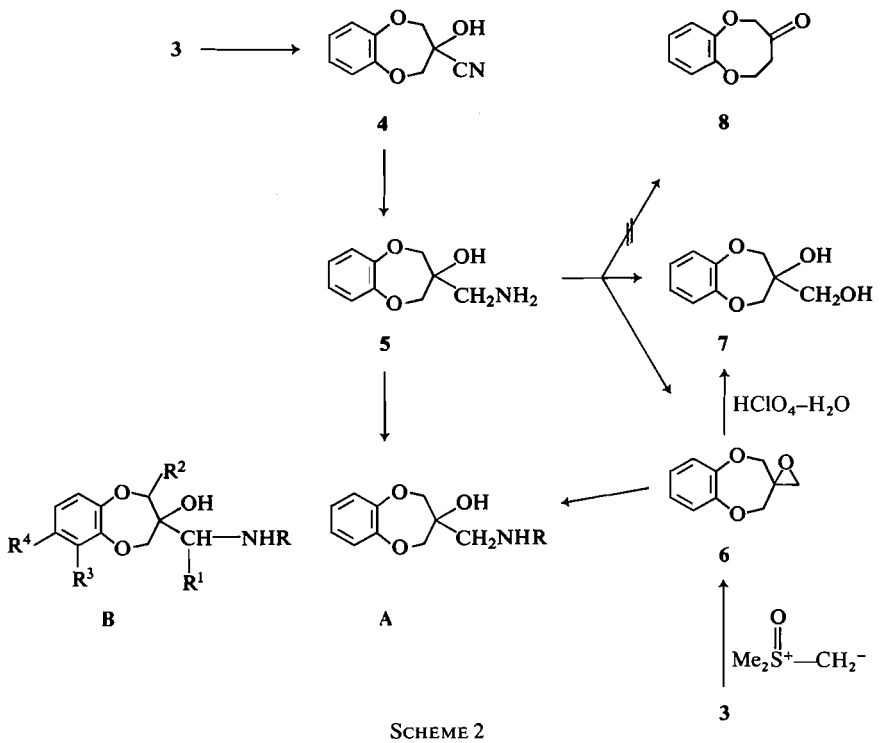


1 **2** **3**

SCHEME 1

Interesting pharmacological activity shown by some of the initial compounds of formula **A** that were made, especially R = *i*-Pr, necessitated the preparation of more highly substituted derivatives (**B**).

A number of readily available substituted catechols served as starting materials for syntheses based on the routes in Schemes 1 and 2. Although cyclization of a 1,2-di(cyanomethoxy)-benzene derived from a mono-substituted catechol could give rise to two isomeric enamino nitriles, in no case were two isolated, neither did



SCHEME 2

thin-layer chromatography nor n.m.r. spectrum suggest the presence of two products. The direction of cyclization of these compounds would be difficult to establish but structural ambiguity disappears when they are hydrolyzed to the ketones. Examples of substituted derivatives of **1–5** are given in Tables 1–5, respectively, and compounds of general formula **B** in Table 6.

Compound **B** (R = *t*-Bu; R^3 = OH; R^1 = R^2 = R^4 = H) was made by demethylating the corresponding 6-methoxy compound with boiling 48% HBr. The stability of the dioxepin system under these conditions is noteworthy, as also is the survival of the 3-hydroxyl group.

Compound **B** (R = *i*-Pr; R^4 = OH; R^1 = R^2 = R^3 = H) was made from **9** (**A**; R = *i*-Pr) as follows. The amino and hydroxyl functions were protected by incorporation into an oxazolidone ring; this derivative (**10**) was nitrated under mild conditions to give **11**, which was converted by conventional reactions to the required hydroxy derivative (**14**). Cleavage of the oxazolidone ring in either **11** or **13** required unusually vigorous conditions.

Access to compounds with a branched side chain (*e.g.* **B**, R^1 = Me—) was achieved by condensation of the ketone (**3**) with a nitro alkane followed by reduction of the nitro group and reductive alkylation.

Introduction of a methyl group into the dioxepin ring (**B**, R^2 = Me—) was effected by partial hydrolysis if the enamino nitrile (**2**) to the keto nitrile (**15**) which was methylated via its thallium salt. This latter procedure did not show its usual

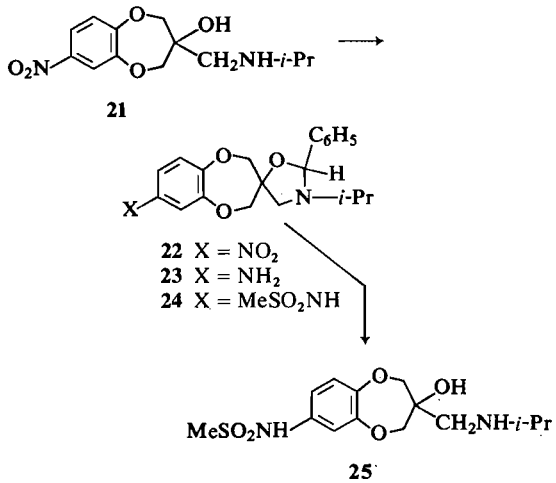
precluded its use as a protective group during synthesis of aryl acyl amido derivatives of **B**. For the synthesis of the methanesulfonamido derivative **25**, the more readily hydrolyzable oxazolidine ring derived from benzaldehyde was employed. A few tertiary amines are described in Table 7.

Biological Activity

In recent years there has been a search for β-adrenergic stimulants showing selective action on the β_2-adrenergic receptors which mediate relaxation of bronchial muscle, rather than action on the β_1-adrenergic receptors which mediate responses of heart muscle.[1] The structures of most of the new β-stimulants described, have been based upon the observation that the 3-phenolic group of the catecholamine molecule can be replaced by a variety of other substituents with retention of pharmacological activity and improved selectivity. In addition, because the modified molecules are not substrates for catechol-*O*-methyltransferase, they exhibit longer duration



SCHEME 5

[a]Based upon the procedures of Rodbell (12) and Korn (13).
[b]Subsequently found to be not very active in the *in vivo* assays.
[c]However, the compound showed activity *in vivo*.

of action. The active compounds described in this paper constitute a novel class of β-stimulants in that there is no functionality present to mimic the phenolic groups of the catecholamines.

The compounds were tested for their ability to stimulate the enzyme adenyl cyclase as evinced by enhanced release of glycerol from rat epididymal adipose tissue (Table 8) and as inhibitors of histamine-induced bronchial constriction in the dog. Bronchial dilator data for some of the more interesting compounds are given in Table 9. As far as the substituent (R) on the nitrogen atom is concerned, the structure activity relationship in this series parallels that observed in other classes of β-stimulants (and in β-adrenergic blocking agents). The most active members of the series are secondary amines (**B**, $R^1 = R^2 = R^3 = R^4 =$ H) in which R is an alkyl or aralkyl group of the type that confers greatest activity on compounds of the catecholamine series (4). Primary or tertiary amines are generally inactive.

Comparison of the dihydrobenzodioxepin compounds with the isomeric benzodioxan derivatives indicates marked differences in pharmacological behavior because the latter are claimed to be β-adrenergic blocking agents (5).

There have been speculations about the molecular mechanism for β-stimulant activity which suggest that the two hydroxyl groups in the catechol nucleus are involved in chelation with a divalent metal ion (*6a*) or that the agonist molecule may bring about a conformational change in the enzymic (or receptor) protein and its associated shell of water molecules by hydrogen bonding at a specific site adjacent to an aromatic binding site (*6b*). While these possibilities could apply to the benzodioxepins also, the different location of the two ether oxygen atoms relative to the side chain, plus their lack of acidity means that significant differences must exist in their interactions at the receptor level. Introduction of acidic substituents on the aromatic ring of the dihydrobenzodioxepins (**14, 25, 51**), in order to increase their resemblance to the catecholamines, resulted in a reduction in biological activity. This was particularly surprising in the case of **51** which, on the basis of a comparison of molecular models, seemed most likely to be capable of interacting like a catecholamine at a receptor site. In view of the difficulty of displacing the 3-hydroxyl group in these compounds, the β-adrenergic agonist theory of Larsen (7) does not seem applicable to this series of β-stimulants.

44		i.v.	220	1	+38	−40
9		i.v.	29	1	+75	−50
54		i.v. i.d.	14 66	3 5	+22 +41	−25 −34
68		i.v.	37	1	+27	−45
71		i.v.	58	1	+39	−39
Salbutamol (11)		i.v. i.d.	4 29	3 5	+68 +67	−70 −55
Isoproterenol		i.v. i.d.	0.08 240	8 5	+76 +37	−57 −35

NOTE: Mongrel dogs were anaesthetized with vinbarbital (60 mg/kg i.v., supplemented by 20 mg/kg intramuscularly). Bronchoconstriction was induced at 15-min intervals by intravenous injection of 20 μg of histamine acid phosphate. Following stabilization of the bronchoconstrictor responses, test substances were injected i.v. cumulatively in threefold increments either 1- (isoproterenol) or 2 min (other compounds) before challenge until a greater than 50% inhibition of bronchoconstriction was observed. In the case of i.d. administration, three dose levels (*e.g.* 10, 30, and 100 μg/kg) calculated to produce 16–84% inhibition of the induced bronchoconstrictor response were used for each compound and five dogs were used at each dose level.

[a]Intravenous (i.v.) or intraduodenal (i.d.).
[b]Effective dose (50).
[c]Change in heart rate (beats per minute).
[d]Change in blood pressure. Results for heart rate and blood pressure are the maximal changes seen over the dose range.

Compound **54**, like salbutamol,[2] shows good absorption from the duodenum (indicated by a low ratio of i.d.[3] activity/i.v. activity in Table 9) and thereby makes up for its lack of intrinsic activity relative to isoproterenol which is very poorly absorbed. Duration of action is good and the moderate chronotropic activity at bronchial dilator dose levels is indicative of a degree of specificity for β_2-receptors.

Experimental

Melting points (uncorrected) up to 220° were taken in a Thomas Hoover capillary melting point apparatus and those above 220° were taken in an Electrothermal apparatus. The i.r. spectra were recorded with a Perkin Elmer 157 spectrometer and n.m.r. spectra with a Varian A60A spectrometer with TMS as internal reference. Mass spectra were provided by Morgan Schaffer Corporation, and microanalyses by Organic Microanalyses Laboratories (Dr. C. Daesslé), both of Montreal. Analyses are within 0.4% of theory unless otherwise stated. A table of analytical data is provided as supplementary material.[4]

1,2-Di-(cyanomethoxy)benzene (1)

To a stirred mixture of catechol (99 g, 0.9 mol), finely powdered K_2CO_3 (168 g, 1.22 mol), and acetone (600 ml) was added chloroacetonitrile (90.6 g, 1.2 mol) over 5 min. The mixture was heated slowly to reflux, then after 1½ h under reflux, the mixture was treated with more K_2CO_3

[2]2-*t*-Butylamino-1-(4-hydroxy-3-hydroxymethylphenyl) ethanol, a selective β-stimulant (11).

[3]Note, i.d. is used as an abbreviation for intraduodenal in this paper, not intradermal.

[4]A complete set of tabular data is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

(84 g, 0.61 mol) and chloroacetonitrile (45.3 g, 0.6 mol). After a further 3½ h under reflux the mixture was filtered, the inorganic solid was washed with acetone (150 ml), and the combined filtrate evaporated to an oil that crystallized and was recrystallized from MeOH–H_2O (400 ml : 50 ml) giving 138 g (73%) of **1**, m.p. 85–85.5°; ν_{max} (KBr) 1500, 1080, 680, no ν CN; δ (CD_3CN) 7.20 (4H, s, aryl H), 4.98 (4H, s, OCH_2); analyzed (C, H, N) for $C_{10}H_8N_2O_2$.

3-Amino-4-cyano-2H-1,5-benzodioxepin (2)

A solution of **1** (9.4 g, 0.05 mol) in dry DMSO (20 ml) was added dropwise to potassium *t*-butoxide (12.3 g, 0.11 mol) in dry DMSO (30 ml) under dry N_2, with external cooling (water bath at room temperature). The mixture was stirred for 2 h and then poured into dilute acetic acid (6.6 ml AcOH in 20 ml H_2O). The crude product was collected, washed with water, dried, and recrystallized from chloroform giving 5.8 g (62%) of **2**, m.p. 162–164°. Pure **2** has m.p. 168–169°; ν_{max} (KBr) 3463, 3360, 2192, 1656, 747, (*cf.* ref. 8); δ (DMSO-d_6) 6.97–6.93 (4H, m, aryl H), 6.58 (2H, bs, NH_2), 4.93 (2H, s, OCH_2). Analyzed (C, H, N) for: $C_{10}H_8N_2O_2$.

3-Oxo-3,4-dihydro-2H-1,5-benzodioxepin (3)

Method A, Table 3

A mixture of **2** (29.75 g, 0.158 mol), water (20 ml), and acetic acid (300 ml) was heated under reflux for ½ h. Phosphoric acid (85%; 120 ml) was added slowly and the mixture refluxed overnight. The solution was cooled to room temperature, poured into ice water (250 ml) and saturated with ammonium sulfate, before continuously extracting with ether for 48 h. The ethereal solution was evaporated, the oily residue dissolved in ether, and the solution treated with charcoal, filtered, extracted with 10% Na_2CO_3 solution, dried ($MgSO_4$), and distilled to give **3** as a colorless oil, 13.15 g (51%), b.p. 64–68°/0.35 Torr, that crystallized on standing, m.p. 33–36°; ν_{max} (CCl_4) 1745, 1490, 1257, 1049 (l); δ ($CDCl_3$) 6.98 (4H, s, aryl H), 4.68 (4H, s, OCH_2).

6-Methoxy-3-oxo-3,4-dihydro-2H-1,5-benzodioxepin (34)

Method B, Table 3

To methanol (450 ml) saturated with HCl was added **31** (61.3 g, 0.28 mol) and the suspension was stirred until solution occurred. The solution was allowed to stand at room temperature for 6 days, then methanol (450 ml) and water (900 ml) were added, and the mixture was heated under reflux for 10 h. Evaporation of the mixture gave 19.1 g (83%) of **34**, m.p. 101–102°; ν_{max} (KBr) 1743, 1500, 1105; δ ($CDCl_3$) 7.07–6.55 (3H, m, aryl H), 4.78, 4.72 (2H and 2H, 2s, OCH_2), 3.87 (3H, s, OCH_3). Analyzed (C, H) for $C_{10}H_{10}O_4$.

3-Cyano-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin (4)

A solution of KCN (13.5 g, 0.208 mol) in water (27 ml) was added dropwise to a solution of **3** (18.7 g, 0.114 mol) in acetic anhydride (19.6 ml) with stirring and cooling (ice bath). The mixture was stirred at room temperature overnight and then basified with 10% Na_2CO_3 solution. Ether extraction of the basified mixture gave **4** as a pale yellow oily solid, 24.3 g (> 100%). This crude material was used in the next step because recrystallization of the solid gave a poor recovery. Crude **4** on recrystallization from CCl_4 (4 parts v/w) afforded a 43% yield of colorless platelets, m.p. 108.5–110°; ν_{max} (KBr) 1505, 1255, 1126, no ν CN. Analyzed (C, H, N) for $C_{10}H_9NO_3$.

3-Aminomethyl-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin Hydrochloride (5)

Method C, Table 5

A solution of crude **4** (4.92 g, 30 mmol) in dry ether (100 ml) was added dropwise with stirring to a slurry of lithium aluminum hydride (3.8 g, 100 mmol) in ether (100 ml) under N_2 during ¾ h. Then the mixture was stirred under reflux for 2¾ h before quenching with water (3.8 ml), followed by 10% NaOH solution (5.7 ml) and more water (11.4 ml). The inorganic solid was filtered off, washed with ether (50 ml), and the combined filtrate was dried ($MgSO_4$) and evaporated to afford crude base **5**, 5.13 g (87%), m.p. 60–63°. This can be recrystallized from benzene to afford platelets, m.p. 66–68°, but the solid appears to absorb water and CO_2 from the air. Accordingly a solution of the base in ether was treated with ethanolic HCl solution to give the hydrochloride, m.p. 235–240° (*i*-PrOH); ν_{max} (KBr) 1499, 1300, 1099, 750. Analyzed (C, H, N) for $C_{10}H_{13}NO_3 \cdot HCl$)

3-Hydroxy-3-isopropylaminomethyl-3,4-dihydro-2H-1,5-benzodioxepin Hydrochloride (9)

Method E, Table 6

A mixture of **5** (3.47 g, 15 mmol), anhydrous sodium acetate (1.23 g, 15 mmol), and ethanol (40 ml) was stirred under N_2 for 10 min. Acetone (960 mg, 16.5 mmol) was added and stirring was continued for 20 min. Hydrogenation of the mixture at 26° and atmospheric pressure in the presence of platinium oxide was carried out until uptake of H_2 was complete. The catalyst was filtered off and the filtrate evaporated to a syrup. Dry ether (60 ml) was added, followed by a slight excess of ethanolic HCl to afford **9**, 3.91 g (95%), m.p. 173–175°. Recrystallization of the solid from isopropanol (75 ml) gave pure **9**, 3.43 g (83%), m.p. 174.5–175.5°; ν_{max} (KBr) 3340, 3295, 1497, 1253, 1055. Analyzed (C, H, N) for $C_{13}H_{19}NO_3 \cdot HCl$.

3,4-Dihydro-2H-1,5-benzodioxepin-3-spirooxirane (6)

Procedure a

Sodium hydride (132 mg, 5.5 mmol) was suspended in dry DMSO (2 ml) and trimethyl sulfoxonium iodide (1.25 g; 5.68 mmol) was added. When H_2 evolution had abated (*ca.* 30 min), a solution of **3** (820 mg, 5 mmol) in DMSO (1.2 ml) was added dropwise and with stirring at room temperature. Stirring was continued for 2 h at 26° and then for 1 h at 50°. The mixture was poured into water (30 ml) and **6** was isolated by extraction with CH_2Cl_2 (2 × 20 ml), 456 mg (51%), m.p. 147–149° (MeOH).

Procedure b

A solution of $NaNO_2$ (6.9 g, 0.1 mol) in water (50 ml) was added slowly with stirring during ½ h to a solution of **5**·HCl (23.17 g, 0.1 mol) in water (200 ml) containing acetic acid (0.1 ml) at −4 to 0°. Then the solution was stirred at room temperature for ½ h and the crude **6** was collected, 14.84 g, m.p. 132–144°. Recrystallization of the solid from MeOH (*ca.* 450 ml) gave 11.65 g (65%) of **6**, m.p. 147–149°; ν_{max} (KBr) 1494, 1242, 1006; δ (DMSO-d_6) 6.98 (4H, s, aryl H), 4.35 and 3.99 (2H and 2H, 2d, OCH_2, J = 13 Hz), 2.89 (2H, s, oxirane H). Analyzed (C, H) for $C_{10}H_{10}O_3$.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

Extraction of the aqueous filtrate with ether afforded an oil (1.3 g) that crystallized from $CHCl_3$ and was recrystallized from water to give 254 mg of **7**, m.p. 124.5–125.5°. This glycol can be obtained by hydrolyzing **6** with dilute $HClO_4$; ν_{max} (KBr) 3420, 1499, 1048; *m/e* 196 (M^+). Analyzed (C, H) for $C_{10}H_{12}O_4$.

6-Methoxy-3,4-dihydro-2H-1,5-benzodioxepin-3-spirooxirane (79)

This was prepared in 28% yield by procedure *a* above, m.p. 106–110° (MeOH) (pure **79** has m.p. 110.5–111.5°); ν_{max} (KBr) 1489, 1472, 1092, 1079; δ (DMSO-d_6) ~7.1–6.5 (3H, m, aryl H), 4.35 and 3.98 (1H and 1H, 2d, OCH_2, J = 13½ Hz), 4.30 and 3.98 (1H and 1H, 2d, OCH_2, J = 13½ Hz), 3.75 (3H, s, OCH_3), 2.89 (2H, s, oxirane H). Analyzed (C, H) for $C_{11}H_{12}O_4$.

3-t-Butylaminomethyl-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin Hydrochloride (54)

Method F, Table 6

A mixture of **6** (1.78 g, 10 mmol), *t*-butylamine (3.2 ml, ~30 mmol), and methanol (25 ml) was stirred at room temperature for 42 h. Evaporation of the solvent, dissolution of the oily residue in ether, and treatment with excess ethanolic HCl solution afforded 3.0 g of **54**, m.p. 169–177°. Recrystallization of the crude product from isopropanol gave 2.15 g (75%) of **54**, m.p. 186.5–188°; ν_{max} (KBr) 3265, 1491, 1253, 1050; δ (DMSO-d_6) ~9.0 (2H, bs, NH_2^+), 7.03 (4H, s, aryl H), 6.37 (1H, bs, OH), 4.46 and 4.12 (2H and 2H, 2d, OCH_2, J = 6 Hz), 3.45 (2H, s, CH_2N), 1.36 (9H, s, *t*-Bu). Analyzed (C, H, Cl, N) for $C_{14}H_{21}NO_3 \cdot HCl$.

3-Formamidomethyl-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin (77)

To a solution of **5** (5.86 g, 30 mmol) in dry ether (60 ml) was added formic acetic anhydride (9) (31.5 mmol) dropwise and the mixture was stirred overnight. The solution was washed successively with water, 10% Na_2CO_3 solution, and water. The product was not completely soluble in ether at this point: after separating the ether layer, an extraction with chloroform was performed. The combined extract yielded 6.1 g (91%) of waxy solid, used without purification in the next step.

3-Methylaminomethyl-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin Hydrochloride (43)

Reduction of **77** (5.80 g, 26 mmol) with lithium aluminum hydride (2.0 g, 52 mmol) in dry ether (110 ml), followed by isolation of the product as the hydrochloride, gave 2.14 g (33%) of **43**, m.p. 217–219° (EtOH); ν_{max} (KBr) 3259, 1500, 1259. Analyzed (C, H, Cl, N) for $C_{11}H_{15}NO_3 \cdot HCl$.

3-Acetamidomethyl-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin (78)

To a solution of **5** (3.20 g, 15.9 mmol) and triethylamine (1.68 g, 16.7 mmol) in dry chloroform was added dropwise acetic anhydride (1.70 g, 16.7 mmol) in dry chloroform. After 1 h at room temperature, the reaction mixture was washed with water, 3.6 *N* sulfuric acid, water, 10% Na_2CO_3 solution, and water. Evaporation of the organic layer yielded 3.41 g (89%) of **78**, m.p. 98–100° ($CHCl_3$); ν_{max} (KBr) 3312, 1635 (br), 1497. Analyzed (C, H, N) for $C_{12}H_{15}NO_4$.

3-Ethylaminomethyl-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin Hydrochloride (44)

Reduction of **78** with lithium aluminum hydride in ether gave 47% of **44**, m.p. 181.5–183° (EtOH); ν_{max} (KBr) 3235, 1497, 1055. Analyzed (C, H, Cl, N) for $C_{12}H_{17}NO_3 \cdot HCl$.

2-Cyano-3-oxo-3,4-dihydro-2H-1,5-benzodioxepin (15)

A mixture of **2** (30.0 g, 0.16 mol), concentrated HCl (90 ml), water (90 ml), and ethanol (450 ml) was heated under reflux for 1¾ h. After evaporation of the mixture, water was added to dissolve NH_4Cl, and the product was extracted with ether (4 × 200 ml). The dried ethereal solution (Na_2SO_4 followed by $CaSO_4$) was evaporated to an oil at 50°/15 Torr and further stripping at 50°/0.1 Torr induced crystallization; 29.2 g (96%) of slightly waxy solid, m.p. 134–136° was obtained. Recrystallization of the crude material either from benzene or from diisopropyl ether containing 5% ethyl acetate gave pure **15**, m.p. 135–136°, but recovery was low; ν_{max} (KBr) 1752, 1489, 1260; no ν CN. Analyzed (C, H, N) for $C_{10}H_7NO_3$.

2-Cyano-2-methyl-3-oxo-3,4-dihydro-2H-1,5-benzodioxepin (16)

To a warm, stirred, solution of **15** (7.95 g, 42 mmol) in benzene (80 ml) was added a solution of thallous ethoxide (10.0 g, 40 mmol) in benzene (40 ml). After 30 min, the solid was collected, washed with benzene, and added to methyl iodide (60 ml). The suspension was heated under reflux for 6 h, filtered, and evaporated to an oil (8.2 g). Chromatography of the oil on 480 g of Baker 3405 silica gel by the dry column technique (10) gave 1.07 g (12%) of enol ether (**17**) as an oil; ν_{max} (neat) 2208 (medium intensity), 1650, 1495, 1240; δ (CCl_4), ~7.1–6.75 (4H, m, aryl H), 4.77 (2H, s, CH_2), 3.97 (3H, s, OCH_3).

The cyano ketone **16** was obtained as a low-melting solid, 5.71 g (67%), m.p. 71–72° ($CHCl_3$–CCl_4); ν_{max} (KBr) 2245 (very small), 1760, 1495, 1251; δ (CCl_4) 6.98 (4H, s, aryl H), 4.70 and 4.65 (2H, 2s, OCH_2), 1.86 (3H, s, CH_3). Analyzed (C, H, N) for $C_{11}H_9NO_3$.

2-Methyl-3-oxo-3,4-dihydro-2H-1,5-benzodioxepin (18)

Hydrolysis of **16** by method *B*, Table 3, gave **18** in 67% yield; ν_{max} (KBr) 1750, 1495, 1265; δ (CCl_4) 6.89 (4H, s, aryl H), 4.95 (1H, quartet, OCH, J = 6½ Hz), 4.76 and 4.40 (2H, 2d, OCH_2, J = 15 Hz), 1.43 (3H, d, CH_3, J = 6½ Hz).

Anal. Calcd. for $C_{10}H_{10}O_3$: H, 5.66. Found: H, 6.09.

3-t-Butylaminomethyl-3-hydroxy-2-methyl-3,4-dihydro-2H-1,5-benzodioxepin Oxalate (20)

On treating **18** (891 mg, 5 mmol) with dimethyl sulfoxonium methylide as described in procedure *a*, there was obtained a very crude product from which **19** could not be isolated. The crude product (672 mg) in methanol (10 ml) was treated with *t*-butylamine (1 ml) and the mixture was allowed to stand for 5 days, then evaporated to dryness. The residue was treated with CH_2Cl_2 (25 ml) and extracted with *N* HCl (10 ml + 5 ml). The acid extract was washed with CH_2Cl_2 (10 ml) and with ether (20 ml); then it was basified with 5 *N* NaOH solution (5 ml) and extracted with ether (2 × 20 ml), giving **20** (free base) as a colorless gum, 119 mg (9%). This material appeared to be homogeneous by t.l.c. but some impurity was evident in the n.m.r. spectrum; δ ($CDCl_3$) ~7.0–6.95 (4H, m,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

aryl H), 4.32–3.97 (3H, m, OCH and OCH_2), 1.33 (3H, d, CH_3, J = 6 Hz), 1.10 (9H, s, *t*-Bu). The CH_2N signal was obscured by impurity. The base was treated with oxalic acid to give **20**, m.p. 229–230° dec. (*i*-PrOH). Analyzed (C, H, N) for $C_{15}H_{23}NO_3 \cdot (COOH)_2$.

*3'-Isopropyl-3,4-dihydro-2H-1,5-benzodioxepin-3-spiro-5'-oxazolidin-2'-one (**10**)*

To a stirred solution of phosgene (15.5 g, 0.157 mol) in chloroform (100 ml) cooled to 5–8° was added dropwise a solution of **9** (24.8 g, 0.105 mol) in chloroform (100 ml). The resulting suspension was treated dropwise with triethylamine (44.7 ml, *ca.* 0.32 mol) at 5–8° and then the reaction mixture was stirred for 1 h at room temperature before being poured into water (200 ml). The chloroform layer was separated and washed in succession with 10% HCl (25 ml), water (25 ml), 5% NaOH solution (25 ml), and water (2 × 25 ml). The solution was dried ($MgSO_4$) and evaporated to give a solid, which was recrystallized from carbon tetrachloride (90 ml) to yield 23.1 g (84%) of **10**, m.p. 118–120° (pure **10** has m.p. 121–122° (*i*-Pr_2O)); ν_{max} (KBr) 1721, 1263, 1051; δ (DMSO-d_6) 6.98 (4H, s, aryl H), 4.25 (4H, s, OCH_2), 3.90 (1H, septet, methine, J = 6½ Hz), 3.43 (2H, s, CH_2N), 1.13 (6H, d, CH_3, J = 6½ Hz). Analyzed (C, H, N) for $C_{14}H_{17}NO_4$.

*3'-Isopropyl-7-nitro-3,4-dihydro-2H-1,5-benzodioxepin-3-spiro-5'-oxazolidin-2'-one (**11**)*

A solution of **10** (24.8 g, 94.2 mmol) in acetic acid (100 ml) was cooled to the freezing point in an ice bath and a mixture of 90% HNO_3 and concentrated H_2SO_4 (54 ml containing 1.2 ml of HNO_3 (*d* 1.5) to each 10 ml of H_2SO_4) was added dropwise with stirring over 10 min. The mixture was stirred for 2 h at 26° and poured into water (400 ml). The crude product was taken up in methylene chloride (3 × 100 ml) and the extract was washed with water (100 ml), 10% Na_2CO_3 (75 ml), water (100 ml), and dried ($MgSO_4$). Evaporation of the solvent and recrystallization of the residue twice from alcohol afforded 16.4 g (56%) of **11** which was used in the next stage (pure **11** has m.p. 148–148.5° (alcohol)); ν_{max} (KBr) 1746, 1357, 1040; δ (DMSO-d_6) ~7.97–7.78 and 7.25–7.11 (2H and 1H, 2m, aryl H), 4.42 and 4.38 (2H and 2H, 2s, OCH_2), 3.89 (1H, septet, methine, J = 6½ Hz), 3.46 (2H, s, CH_2N), 1.12 (6H, d, CH_3, J = 6½ Hz). Analyzed (C, H, N) for $C_{14}H_{16}N_2O_6$.

*7-Amino-3'-isopropyl-3,4-dihydro-2H-1,5-benzodioxepin-3-spiro-5'-oxazolidin-2'-one (**12**)*

A mixture of **11** (960 mg, 3.12 mmol), ethanol (30 ml), and 5% palladium-on-charcoal was hydrogenated at 50 p.s.i. and 26° in a Parr apparatus. Work-up of the reaction mixture afforded 445 mg (51%) of **12**, m.p. 163–164° (alcohol); ν_{max} (KBr) 3450, 3360, 1745, 1510; δ (DMSO-d_6) ~6.78–6.60 and 6.25–6.07 (1H and 2H, 2m, aryl H), 4.79 (2H, s, NH_2), 4.13 and 4.05 (2H and 2H, 2s, OCH_2), 3.88 (1H, septet, methine, J = 6½ Hz), 3.36 (2H, s, CH_2N), 1.10 (6H, d, CH_3, J = 6½ Hz). Analyzed (C, H, N) for $C_{14}H_{18}N_2O_4$.

*7-Hydroxy-3'-isopropyl-3,4-dihydro-2H-1,5-benzodioxepin-3-spiro-5'-oxazolidin-2'-one (**13**)*

A solution of **12** (3.27 g, 11.75 mmol) in 10% H_2SO_4 (65 ml) was diazotized at 0–5° with 20% $NaNO_2$ solution (4.05 ml, 11.75 mmol). After stirring the mixture for 30 min at room temperature, a little urea was added to destroy excess HNO_2 (starch iodide paper as indicator) and the solution was poured into a well-stirred suspension of Baker 3405 silica gel (15 g) in boiling 10% H_2SO_4 (130 ml) during a period of 10 min. The mixture was stirred at the b.p. until a negative alkaline β-naphthol test was obtained (*ca.* 30 min). When cool, the solid was collected, washed with a little water, and dried. The solid was suspended in boiling alcohol (100 ml) and then evaporated to dryness in a rotary evaporator. It was placed on top of a column (18 × 1¼ in.) of Baker silica gel and chromatography was carried out by the dry column technique using 1:1 ether–chloroform. The first 300 ml of eluate contained 1.62 g of crude **13**, which on recrystallization from alcohol (20 ml) afforded 1.41 g of **13** of m.p. 215–217° (pure **13** separates from alcohol in prisms, m.p. 216.5–217.5°); ν_{max} (KBr) 3260 (br), 1710, 1507, 1060, 1051; δ (DMSO-d_6) ~7.02–6.75 and 6.52–6.3 (1H and 2H, 2m, aryl H), 4.17 and 4.13 (2H and 2H, 2s, OCH_2), 3.91 (1H, septet, methine, J = 6½ Hz), 3.39 (2H, s, CH_2N), 1.12 (6H, d, CH_3, J = 6½ Hz). Analyzed (C, H, N) for $C_{14}H_{17}NO_5$.

*3-Hydroxy-3-isopropylaminomethyl-7-nitro-3,4-dihydro-2H-1,5-benzodioxepin (**21**)*

A mixture of **11** (7.98 g, 25.9 mmol), dioxane (60 ml), and 45% KOH solution (16 ml) was heated in a N_2-filled stainless steel bomb at 150–160° for 16 h. When cool, the reaction mixture was extracted with ether (2 × 100 ml) and the extract was washed with saturated NaCl solution (2 × 100 ml) and then with water (100 ml). The ethereal solution was extracted with 2.75 *N* HCl (40 ml) and then with water (2 × 40 ml). Basification of the combined aqueous extract with 2.5 *N* NaOH (70 ml) and extraction with ether (2 × 100 ml), afforded a yellow solid, 6.33 g, m.p. 95–96.5°. Recrystallization of the crude product from diisopropyl ether (63 ml) gave 4.56 g (62%) of **21**, m.p. 97.5–99°; ν_{max} (KBr) 3295, 3080, 1520, 1290, 1275; δ (DMSO-d_6) ~7.90–7.74 and 7.17–7.0 (2H and 1H, 2m, aryl H), 4.23 and 3.56 (2H and 2H, 2s, OCH_2), 2.79 (2H, s, CH_2N), 0.9 (6H, d, CH_3, J = 6½ Hz). The signal for the methine proton was largely obscured by the CH_2—N and DMSO signals, and the OH and NH gave a broad signal centered on 3.5 p.p.m. Analyzed (C, H, N) for $C_{13}H_{18}N_2O_5$.

*7-Amino-3-isopropylaminomethyl-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin (**49**)*

Hydrogenation of **21** (1.5 g, 5.32 mmol) in ethanol (25 ml) at 40 p.s.i. and room temperature in the presence of 5% palladium-on-charcoal (400 mg) gave 990 mg (74%) of **49**, m.p. 96.5–97.5° (benzene); ν_{max} (KBr) 3440, 3358, 1513, 1225, 1067; δ ($CDCl_3$) 6.78–6.63 and 6.35–6.12 (1H and 2H, 2m, aryl H), 4.03 and 3.77 (2H and 2H, 2s, OCH_2), 3.32 (4H, bs, OH, NH and NH_2), 2.91 (2H, s, CH_2N), 2.76 (1H, septet, methine, J = 6 Hz), 1.05 (6H, d, CH_3, J = 6 Hz). Analyzed (C, H, N) for $C_{13}H_{20}N_2O_3$.

*3,7-Dihydroxy-3-isopropylaminomethyl-3,4-dihydro-2H-1,5-benzodioxepin (**14**)*

A mixture of **13** (200 mg, 0.716 mmol), $Ba(OH)_2 \cdot 8H_2O$ (1.08 g, 3.42 mmol), and water (3.2 ml) in an evacuated glass pressure tube was heated at 160–165° for 16 h. The reaction mixture was poured into boiling water (60 ml) with stirring and CO_2 was passed through, until all Ba^{2+} ions had been precipitated. The suspension was filtered

For personal use only.

through Celite and evaporated to a pale brown scale (187 mg). This solid was chromatographed by the dry column technique on Baker 3405 silica gel using 3% methanol in ether as the solvent, affording 70.5 mg (39%) of **14** as the second component to be eluted. After drying in air at 60° the solid has m.p. 108–110° but drying at 80° (0.1 Torr) raises the m.p. to 133–134.5° (pure **14** had m.p. 133.5–135° (benzene)); ν_{max} (KBr), for solid of m.p. 108–110°, 3465, 3360, 3300, 3285, 1510, 1209, 1158; ν_{max} (KBr), for solid of m.p. 133.5–135°, 3450–3260 (v br), 1509, 1470, 1155; δ (CD_3CN) ~6.79–6.61 and 6.36–6.19 (1H and 2H, 2m, aryl H), 4.0 (5H, superimposed singlets, OH, NH, OCH_2), 3.54 (2H, s, OCH_2), 2.84 (2H, s, CH_2N), 2.72 (1H, septet, methine, J = 6 Hz), 1.02 (6H, d, CH_3, J = 6 Hz). Analyzed (C_9H, N) for $C_{13}H_{19}NO_4$.

3,6-Dihydroxy-3-isopropylaminomethyl-3,4-dihydro-2H-1,5-benzodioxepin Hydrobromide (51)

A solution of **50** free base (600 mg, 2.24 mmol) in 48% HBr (10 ml) was heated under reflux for 10 h, then evaporated to dryness at 50–55° (10 Torr). A solution of the residue in alcohol was treated with charcoal, filtered, and evaporated to dryness. Recrystallization of the solid from methanol – ethyl acetate yielded 596 mg (80%) of **51**, m.p. 193–195° (pure **51** has m.p. 196–197° (MeOH–EtOAc)); ν_{max} (KBr) 3430, 3350 (both broad), 1485, 1224, 1059. Analyzed (C, H, Br, N) for $C_{13}H_{19}NO_4 \cdot HBr$.

3-Hydroxy-3-(1-nitroethyl)-3,4-dihydro-2H-1,5-benzodioxepin (80)

Nitroethane (6.32 ml, 88 mmol) was added to a mechanically stirred slurry of potassium *t*-butoxide (8.98 g, 80 mmol) in dry ether (165 ml). To the thick suspension, cooled below 10°, was added a solution of **3** (13.12 g, 80 mmol) in ether (40 ml) slowly over ½ h. After 3 h at room temperature, the reaction mixture was acidified with acetic acid (4.80 g, 80 mmol) in dry ether (40 ml); more ether (500 ml) was added and the mixture filtered. Evaporation of the filtrate gave 16.1 g (83%) of crude **80** used in the next stage.

3-(1-Aminoethyl)-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin Hydrochloride (38)

Method D, Table 5

Crude **80** (16.1 g, 67.3 mmol) in ethanol (100 ml) was hydrogenated in a Parr low pressure hydrogenerator in the presence of 5% palladium-on-charcoal. Hydrogen uptake was about 85% of theory. After filtration and evaporation, the crude product was taken up in ether (125 ml) and extracted with 5 *N* HCl (3 × 15 ml). Basification (20% NaOH solution) of the acid extract and extraction with ether gave an oil which was converted to a hydrochloride salt with HCl in ethanol; 6.0 g (36%) of crude **38** m.p. 192–203° was obtained. Upon recrystallization from ethanol the m.p. was raised to 204–206°; ν_{max} (KBr) 3300, 1492, 1251, 1040, 751; δ (DMSO-d_6) 6.84 (4H, s, aryl H), 4.52 and 4.33 (2H, 2d, OCH_2, J = 12½ Hz), 4.10 and 4.06 (2H, 2d, OCH_2, J = 12½ Hz), 3.60 (1H, quartet, methine, J = 7 Hz), 1.37 (3H, d, CH_3, J = 7 Hz). Analyzed (C, H, Cl, N) for $C_{11}H_{15}NO_3 \cdot HCl$.

3-Hydroxy-3-(1-nitropropyl)-3,4-dihydro-2H-1,5-benzodioxepin (81)

Compound **81** was prepared from **3** and 1-nitropropane by the method described for **80** and was used without purification.

3-(1-Aminopropyl)-3-Hydroxy-3,4-dihydro-2H-1,5-benzodioxepin Hydrochloride (39)

Hydrogenation of **81** at atmospheric pressure in the presence of Raney nickel yielded 31% of **39**, m.p. 197–198°; ν_{max} (KBr) 3305(b), 1502, 1267, 1050, 770. Analyzed (C, H, Cl, N) for $C_{12}H_{17}NO_3 \cdot HCl$.

3-Dimethylaminomethyl-3-hydroxy-3,4-dihydro-2H-1,5-benzodioxepin Hydrochloride (75)

A mixture of **5** free base (3.20 g, 16.4 mmol), 88% formic acid (43 g), and 37% formalin (3.0 ml) was heated under reflux for 17 h. Basification of the reaction mixture with 20% NaOH (10 ml) and extraction with ether (2 × 50 ml) afforded an oil (3.4 g) which was converted to a hydrochloride salt, 2.84 g, m.p. 119–230°. The crude product was recrystallized twice from isopropanol to give 1.64 g (38%) of **75**, m.p. 118–120°, clearing at *ca.* 210°; ν_{max} (KBr) 3225(br), 1501, 1260, 761. Analyzed (C, H, Cl, N) for $C_{12}H_{17}NO_3 \cdot HCl$.

3'-Isopropyl-7-nitro-2'-phenyl-3,4-dihydro-2H-1,5-benzodioxepin-3-spiro-5'-oxazolidine (22)

A mixture of **21** (1.41 g, 5 mmol), benzaldehyde (530 mg, 5 mmol), acetic acid (1 drop), and isopropanol (10 ml) was distilled slowly and isopropanol was added to keep the volume constant. After 3 h, the mixture was set aside at 5° overnight. The product was collected and recrystallized from isopropanol, giving 620 mg of solid, m.p. 151–152°. Further distillation of the mother liquors and work-up as before gave another 490 mg of product, m.p. 150–151° (for a total of 60%) and 430 mg (30%) of **21** was recovered (pure **22** has m.p. 152.5–153.5°); ν_{max} (KBr) 1522, 1347, 1282; δ ($CDCl_3$) 7.95–7.5 (2H, m, aryl H), 7.42 (5H, s, phenyl), 7.03–6.85 (1H, dd, aryl H), 4.88 (1H, s, OCHN), 4.51 (2H, s, OCH_2), 4.07 (1H, dd, 1H of OCH_2, J = 11 Hz, J' = 2 Hz), 3.63 (1H, d, 1H of OCH_2), 3.23 (1H, dd, 1H of CH_2N, J = 10½ Hz, J' = 2 Hz), ~2.75 (1H, septet, methine, J = 7 Hz), 2.68 (1H, d, 1H of CH_2N, J = 10½ Hz), 0.98 (3H, d, CH_3, J = 7 Hz), 0.84 (3H, d, CH_3, J = 7 Hz). The two doublets for CH_3 overlap to form a triplet.[5] Analyzed (C, H, N) for $C_{20}H_{22}N_2O_5$.

7-Amino-3'-isopropyl-2'-phenyl-3,4-dihydro-2H-1,5-benzodioxepin-3-spiro-5'-oxazolidine (23)

A solution of **22** (92.5 mg, 0.25 mmol) in ethyl acetate (5 ml) was hydrogenated at atmospheric pressure in the presence of 5% palladium-on-charcoal (20 mg) until the theoretical amount of hydrogen had been absorbed. Work-up afforded 104 mg of oil. The product was too labile for purification but t.l.c. (silica gel – $CHCl_3$) showed the presence of a trace of **22** as the only impurity in the product.

3-Hydroxy-3-isopropylaminomethyl-7-methanesulfonamido-3,4-dihydro-2H-1,5-benzodioxepin Oxalate (25)

Crude **23** (352 mg, obtained from **22** (376 mg, 1.015 mmol)) was dissolved in dry ether and 1,4-diazabicyclo-

[5]The long-range coupling of one of the dioxepin protons with one of the oxazolidine protons (due to a W arrangement) gives an insight into the conformation of the spiro-fused ring system. This spectrum was recorded at the 220 MHz NMR Centre, Sheridan Park, Ontario.

[2.2.2]octane (118 mg, 1.065 mmol) was added. Methanesulfonyl chloride (105 mg, 1.065 mmol) in dry ether (5 ml) was added dropwise with stirring, and after 1 h the solid was filtered off and discarded. Evaporation of the filtrate afforded crude **24**, 387 mg (91%). Thin-layer chromatography on Eastman silica gel showed the presence of one major and two minor constituents but preparative t.l.c. on a 2-mm silica gel plate did not give a good separation, possibly because of hydrolysis of the product. The crude material from the plate (227 mg, 0.54 mmol) in methanol (3 ml) was treated with oxalic acid dihydrate (70 mg, 0.55 mmol) and the solution was chilled thereby yielding 108 mg (47%) of **25**, m.p. 207–209° dec. (pure **25** has m.p. 214–215° dec.); ν_{max} (KBr) 1500, 1315, 1146; m/e = 330 (M^+).

Anal. Calcd. for $C_{14}H_{22}N_2O_5S\cdot(COOH)_2$: C, 45.70. Found: C, 45.08.

The authors would like to express their thanks to Drs. J. G. Atkinson and C. H. Yates for their advice on various aspects of the chemistry contained in this paper, to Dr. N. N. Share, Mr. R. A. Hall, and (in part) to Drs. R. Robson and H. M. Guirgis and their colleagues for the biological results, to Mr. S.-C. Ho and his colleagues for n.m.r. spectral data, and particularly to Mrs. Evelyn Robbins for her substantial contribution to the synthetic work.

Effect of the *N*-Phenyl Substituent on the Pyrolyses of 1-Phenyl-2-benzothiazolinone and 1-Phenyl-2-benzothiazolinethione

DENIS C. K. LIN, MICHAEL L. THOMSON, AND DON C. DEJONGH[1]

Département de chimie, Université de Montréal, Montréal, Québec H3C 3V1

Received February 5, 1975

DENIS C. K. LIN, MICHAEL L. THOMSON, and DON C. DEJONGH. Can. J. Chem. **53**, 2293 (1975).

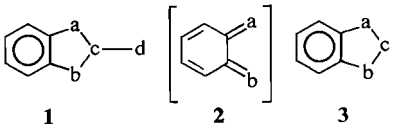
Results from the pyrolyses of 1-phenyl-2-benzothiazolinone (**7**) and 1-phenyl-2-benzothiazolinethione (**8**) are reported and compared with those obtained previously from the corresponding compounds without the *N*-phenyl group. The mass spectra of **7** and **8** are reported, also. The major fragmentation in the mass spectrum of **7** is the loss of CO, followed by loss of S or H·. Pyrolysis of **7** at 750° in a stream of nitrogen gives phenothiazine (**9**, 31%) and carbazole (**10**, 28%), by loss of CO and of CO and S, respectively. Pyrolysis of **9** yields **10**. The major fragmentation in the mass spectrum of **8** is the loss of H·. Pyrolysis of **8** at 750° produces 2-(phenylthio)benzothiazole (**11**, 87%), which is an isomer of **8**, resulting from phenyl migration, and 2-phenylbenzothiazole (**12**, 3%). Pyrolysis of **11** gives **12**.

DENIS C. K. LIN, MICHAEL L. THOMSON et DON C. DEJONGH. Can. J. Chem. **53**, 2293 (1975).

On rapporte les produits de pyrolyse de la phényl-1 benzothiazolinone-2 (**7**) et de la phényl-1 benzothiazolinethione (**8**) et on compare ces résultats avec ceux obtenus et déjà rapportés, des composés sans le groupe phényle. On rapporte aussi les spectres de masse des composés **7** et **8**, tel qu'obtenus par impact électronique. Le patron majeur de fragmentation trouvé dans le spectre de masse du composé **7** résulte de la perte de CO, suivie par perte de S ou de H·. La pyrolyse du composé **7** à 750° dans un courant d'azote conduit à la formation de phénothiazine (**9**, 31%) et de carbazole (**10**, 28%), par perte de CO et de CO et S. La pyrolyse du composé **9** rend le composé **10**. Dans le spectre de masse du composé **8**, le pic de base se forme par perte de H·. Les produits de la pyrolyse du composé **8** à 750° sont le phénylthio-2 benzothiazole (**11**, 87%), qui est un isomère du composé **8** dû à la migration d'un groupe phényle, et le phényl-2 benzothiazole (**12**, 3%). Le composé **11** résulte de la pyrolyse du composé **12**.

Introduction

We have reported the mass spectra and pyrolyses of a number of molecules related to the general *o*-phenylene structure **1**. For example, in the case of *o*-phenylene sulfite (a, b, d = O; c = S), the first molecule eliminated is SO (1, 2), whereas in the case of *o*-phenylene carbonate (a, b, d = O; c = C), the major fragmentation pathway involves elimination of CO_2 (3, 4).



1 **2** **3**

Two other series of compounds described by **1** which we have studied are the 2-ones (d = O) (5) and 2-thiones (d = S) (6) of benzothiazole (a = NH; b = S; c = C), benzimidazole (a = NH; b = NH; c = C), and benzoxazole (a = NH; b = O; c = C). The decompositions of the 2-ones proceed by an elimination of CO giving, initially, intermediate **2** from which the final products form. However, the 2-thiones behave differently: the major products result from desulfurization, yielding compounds of the general structure **3**. Since the products of desulfurization of the 2-thiones are stable molecules (**3**), whereas the primary products (**2**) from the decarbonylation of the 2-ones are unstable under the reaction conditions, the yields from the pyrolyses are much higher in the first case, 40–80% *vs.* 14–23%.

We were able to trap intermediate **2** internally in the pyrolysis of benzimidazolinone (**4**) by placing a phenyl group on one of the nitrogens, in place of hydrogen (7). In the pyrolysis of **4** at 1000°, we recovered 10.2% of starting material and we isolated 14% of $C_6H_4N_2$ isomers, as shown in eq. 1 (5). However, when 1-phenyl-2-

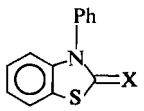
benzimidazolinone (**5**) was pyrolyzed at 950°, 16.3% of **5** was recovered and the major product isolated was phenazine (**6**), as shown in eq. 2 (7). Carbazole was also isolated from the pyrolysis of **5**, in 14% yield. Thus, the *o*-quinoid intermediate cyclized, giving phenazine.

The pyrolysis of 2-benzothiazolinone (**1**, a = NH; b = S; c = C; d = O) presented a special problem (5): no products were isolated that could be related to intermediate **2** (a = NH; b = S). This is probably due to the fact that sulfur is retained and the loss of CO followed by HCN gives products such as cyclopentadienethione which polymerize.

The object of this report is to present results obtained from the study of 1-phenyl-2-benzothiazolinone (**7**) and 1-phenyl-2-benzothiazolinethione (**8**). These results are compared with those obtained from the corresponding molecules without the *N*-phenyl group.

Pyrolyses were performed by sublimation of the samples into a stream of nitrogen which passed through an unpacked quartz tube surrounded by a furnace (8). In general, a flow rate of 0.25 l/min and a system pressure of approximately 1 Torr were used. The pyrolysis of each compound was repeated several times at the same temperature; however, the pyrolyses were first performed at various temperatures to find the one at which the best results were obtained. Where possible, products were isolated and identified by physical and spectroscopic characteristics.

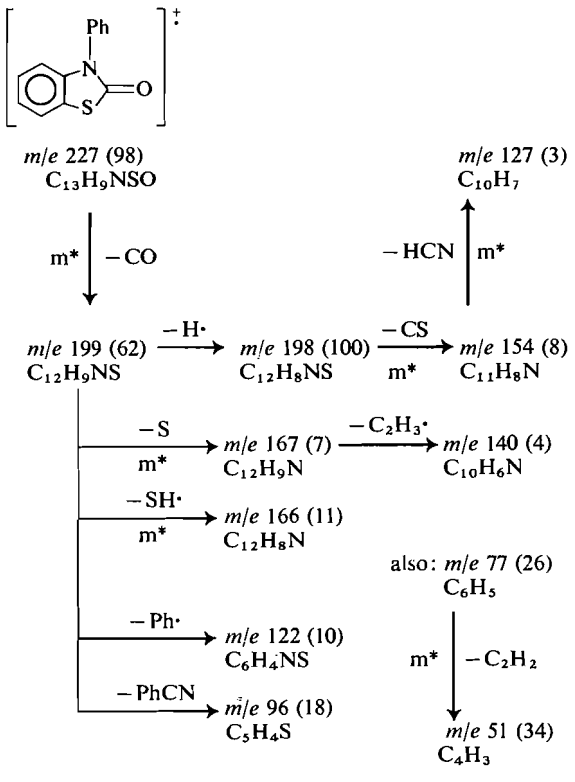


7 X = O
8 X = S

Results

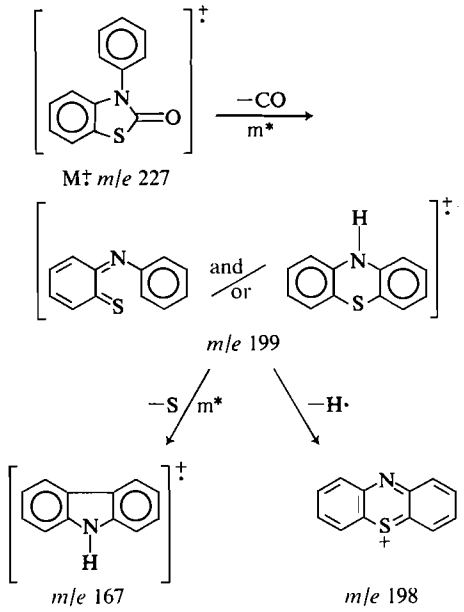
1-Phenyl-2-benzothiazolinone (7)

The 70-eV mass spectrum of **7** is summarized in Scheme 1. The peak at *m/e* 198 is the base peak at 70 eV. At voltages lower than 20 eV the molecular ion forms the base peak at *m/e* 227. The only other ions present at 15 eV are found at *m/e* 199 (19), 198 (9.5), and 167 (0.8). These ions can still be observed at 10 eV with relative intensities of 16, 8, and 0.6%, respectively.



SCHEME 1[2]

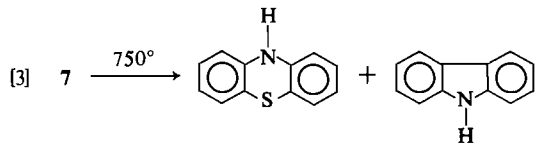
[2]The elemental compositions are the result of exact-mass measurements. The values in parentheses are relative intensities and m* denotes the presence of a metastable peak.

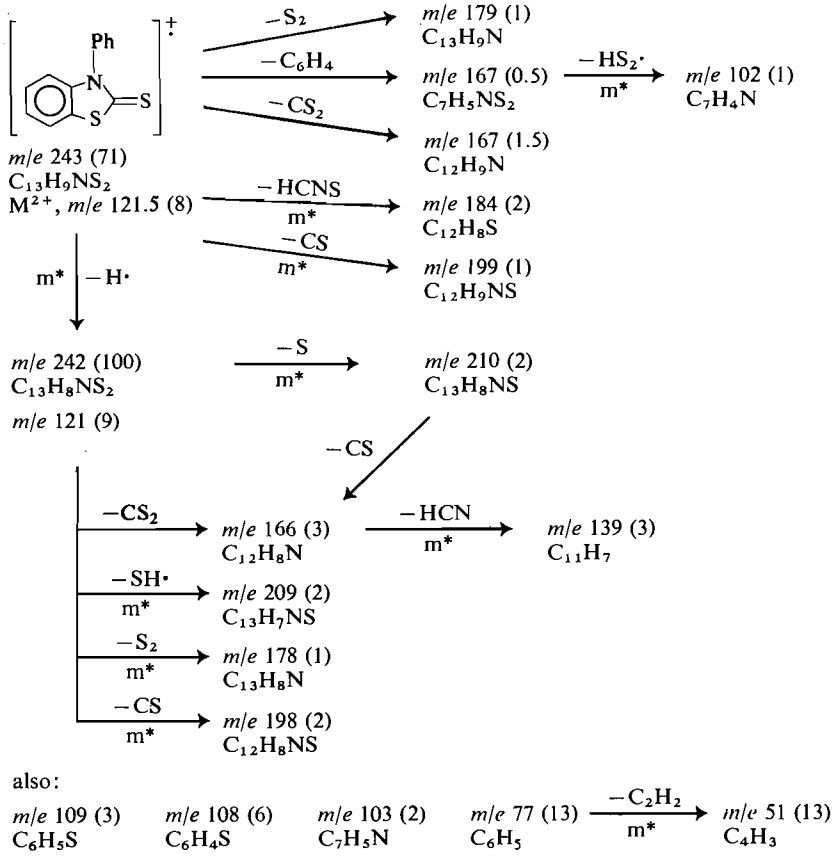


SCHEME 2

The formation of these ions can be rationalized as illustrated in Scheme 2. One of the structures proposed for *m/e* 199 is that of phenothiazine (**9**). The other has the basic *o*-quinoid structure (**2**). The ions at *m/e* 167 and 198 are formed from *m/e* 199 by the loss of S and H·, respectively. The structure shown for the ion at *m/e* 167 corresponds to ionized carbazole (**10**).

Compound **7** was pyrolyzed at 650, 750, 850, and 950°. At 750°, the two major products were **9** and **10** and the yield of each compound, based on the unrecovered starting material, is given in eq. 3. At 650°, the only product formed was phenothiazine (**9**), with 90.0% of **7** being recovered. From the pyrolyses at 850°, neither





SCHEME 3[2]

7 nor **9** was isolated; the only product found was **10**. At an even higher temperature, 950°, the percentage of material accounted for was reduced and the only product was carbazole (**10**).

These results indicate that upon pyrolysis, as upon electron impact, the initial decomposition of **7** is the loss of CO which, in turn, is followed by the loss of S. To test this possibility, we pyrolyzed **9** at 650, 750, and 850°. Only starting material was recovered at 650°. However, at 750° carbazole (**10**) was formed in 38% yield, based on unrecovered starting material. No starting material was recovered at 850° and **10** was isolated in 57% yield.

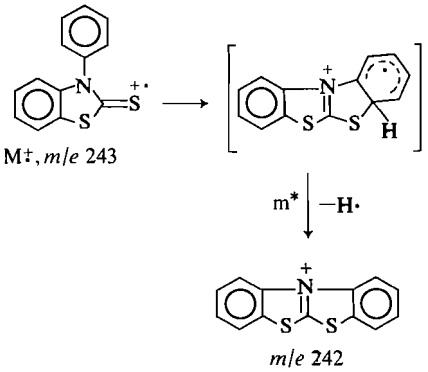
In summary, the major fragmentation in the mass spectrum of **7** consists of the loss of CO from the molecular ion, followed by the loss of S or H·. Pyrolysis of **7** at 750° results in the formation of phenothiazine (**9**) and carbazole (**10**) by the loss of CO and of CO and S, respectively. Carbazole is a pyrolysis product of phenothiazine.

1-Phenyl-2-benzothiazolinethione (8)

The 70-eV mass spectrum of **8** is summarized in Scheme 3. At ionizing voltages ranging from 70 to 10 eV, the molecular ion and $(M - H\cdot)^+$ ion dominate the spectrum. At 70 eV they account for 52% of the total ion current. All the other ions in the spectrum are of much lower intensity; however, many of them persist at reduced ionizing voltages. For example, at 10 eV ions are still found at *m/e* 243 (100), 242 (50), 210 (0.3), 209 (trace), 199 (0.2), 198 (trace), 184 (0.1), 179 (0.2), 167 (0.5), 166 (trace), and 103 (0.7).

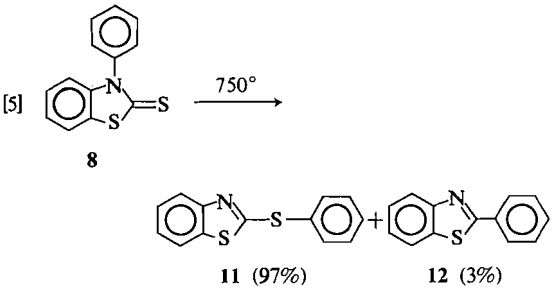
The formation of the most prominent fragment ion, at *m/e* 242, can be visualized as shown in eq. 4. The formation of most of the other fragment ions can be explained by losses of H·, S, S_2, CS, and HCN or combinations of these, from the major ions. It is interesting to note that one of the members of the doublet at *m/e* 167 has the composition $C_7H_5NS_2$. This is either due to the loss of C_6H_4 from the molecular ion of **8** or it could result from the presence of an impurity. However, we attempted to detect 2-benzothiazolinethione, a possible impurity of formula $C_7H_5NS_2$, in the sample of **8** but were unsuccessful. Moreover, the molecular ion of 2-benzothiazolinethione loses S_2 (6), whereas loss of $HS_2\cdot$ occurs from the ion at *m/e* 167 (both with appropriate metastable peaks).

[4]



Pyrolyses of compound **8** were performed at 650, 750, 850, and 950°. At 650°, other than starting material, a trace of 2-(phenylthio)-benzothiazole (**11**) was found. At 750°, there were two products, **11** and 2-phenylbenzothiazole (**12**); the yield of each product, based on unrecovered starting material, is given in eq. 5. At 850°, the yield of **11** decreased to 60%

[5]



while that of **12** increased to 10%. At this temperature there were other products, 2-cyanophenyl phenyl sulfide, dibenzothiophene, phenyl sulfide, benzothiazole, and cyanobenzene. The total percentage of starting material accounted for was 82.4%. At 950° this percentage dropped to 43.6% the two major products being **12** and cyanobenzene. Two other minor products were isolated at 950°: 2-cyanobiphenyl and biphenyl. Traces of cyanodibenzothiophene, carbazole, and acridine were present, also.

Since the yield of **11** drops off with increasing temperature and the yields of the secondary products increase, we pyrolyzed **11** to demonstrate that it was the precursor of **12** and of the minor products. At 850°, 11% of **11** was recovered and the major products were cyanobenzene (10.5%) and 2-phenylbenzothiazole

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

(**12**, 10%). The minor products were 2-cyanophenyl phenyl sulfide (4%), dibenzothiophene (1%), phenyl sulfide (2%), benzothiazole (3%), and a trace of 2-cyanobiphenyl. Therefore, we can conclude that **12** is a pyrolysis product of **11**, although we cannot exclude the possibility that **12** also forms directly from **8**.

Upon pyrolysis at 950°, 2-phenylbenzothiazole (**12**) can be recovered almost quantitatively. The only other compound present is cyanobenzene, in trace amounts.

In summary, the 70-eV mass spectrum of **8** contains many fragment ions but is dominated by the $M^{+\cdot}$ and $(M - H\cdot)^+$ ions. Pyrolysis of **8** at 750° produces two products due to phenyl rearrangement: 2-(phenylthio)benzothiazole (**11**) and 2-phenylbenzothiazole (**12**). The latter is also a pyrolysis product of the former.

Discussion

In the 15-eV mass spectrum of 2-benzothiazolinethione (**1**, a = NH; b and d = S; c = C), the elimination of S is the only fragmentation observed, eq. 6 (6). Sulfur is also lost when this

[6] 
m/e 167 *m/e* 135

compound is pyrolyzed, resulting in the formation of benzothiazole. The only other product isolated was cyanobenzene, a pyrolysis product of benzothiazole. Yields are of the order of 40–45% from the pyrolyses.

There is only one major fragmentation path in the mass spectrum of 2-benzothiazolinone, eq. 7 (5), the loss of CO followed by HCN. However, upon pyrolysis at 950°, no products which could be directly related to intermediate

[7] 
m/e 151 *m/e* 123 *m/e* 96

2 (a = NH; b = S) were isolated: 8.7% of starting material was recovered and 14.4% of products was isolated and identified. The products were cyanonaphthalenes, naphthalene, aniline, cyanobenzene, phenylisocyanate, and 2-thiophenecarbononitrile, each one in less than 3% yield.

We have made the conjecture that the pyrolysis of 2-benzothiazolinone does indeed follow a path involving intermediate **2** but that the major products polymerize and are not isolated. By placing a phenyl group on position 1, we proposed to internally trap the *o*-quinoid intermediate, as was done in the case of 2-benzimidazolinone, eqs. 1 and 2, thereby establishing its formation. This approach turned out to be successful. The results obtained from 1-phenyl-2-benzothiazolinone (**7**) can be explained by initial loss of CO, eq. 8, giving an

[8] 
o-quinoid intermediate which rearranges to phenothiazine (**9**). Phenothiazine is then the precursor of carbazole (**10**). Thus, the *N*-phenyl group alters the fate of the *o*-quinoid intermediate via an internal cyclization process.

In the case of 1-phenyl-2-benzothiazolinethione (**8**) the *N*-phenyl group also plays an important role in determining the paths of fragmentation, both under conditions of pyrolysis and of electron impact. The stability of the $(M - H\cdot)^+$ ion at *m/e* 242 is probably due to the tetracyclic structure formed by reaction of the *N*-phenyl group with the ionized thione group, eq. 4.

The major pyrolysis product of 1-phenyl-2-benzothiazolinethione (**8**), 2-(phenylthio)benzothiazole (**11**), is the result of a phenyl rearrangement from N to S, perhaps through an intermediate such as the one shown in eq. 9. In

[9] 
support of this possibility we can cite (7) the example of the pyrolysis of 1-phenyl-2-benzimidazolinethione (**13**), which at 950° gives a 24% yield of benzimidazo[2,1-*b*]benzothiazole

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12

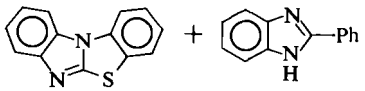
[10] 
13



14 ($13 - H_2$) 15 ($13 - S$)

(**14**) and an 11% yield of 2-phenylbenzimidazole (**15**), eq. 10. In the formation of **14**, a molecule of hydrogen is lost from an NH group and from a rearranged hydrogen atom, a path not possible from the intermediate shown in eq. 9. The formation of **15** is the result of a phenyl rearrangement and desulfurization.

Another possible path for an intramolecular phenyl rearrangement is a spiro intermediate, eq. 11. The suggestion of this possibility is

[11] **8**  **11**

based on an analogy with the phenothiazine rearrangement which has been explained via a spirodienyl intermediate (9).

Phenyl rearrangements have been previously observed under pyrolytic conditions. For example, a S to N phenyl rearrangement occurs when anhydro-*S*-phenylphenothiazinium hydroxide is heated in toluene, eq. 12 (10). The authors proposed that the rearrangement was intramolecular. Also, an intramolecular phenyl migration has been invoked to explain the product of the pyrolysis of *o*-diazoniophenyl-*o*-phenoxyphenyl sulfide, eq. 13 (11). The oxonium salt initially formed supposedly rearranges into a sulfonium salt. Phenyl rearrangements have also been observed upon electron impact (12, 13).

[12] 
[13] 
As part of a general study of the relationship between the reactivity of the thiocarbonyl group and its electronic structure, the photoelectron spectra of three compounds related to structure **16** have been reported (14). In each

16 X = O, S, and N—CH_3

case, the first band (of lowest eV) corresponds to the ionization of a π-electron localized on the extracyclic S atom. Thus, the interaction of the *N*-phenyl group with the S atom of the thiocarbonyl group in **8** and **13** can be explained as a result of initial excitation of the S atom.

In summary, the formation of phenothiazine (**9**) from 1-phenyl-2-benzothiazolinethione (**7**) is best explained as passing through an *o*-quinoid intermediate (eq. 8). This lends support to the suggestion that the pyrolysis of 2-benzothiazolinone gives an *o*-quinoid intermediate also, even though products related to it are not isolated. Even though the major product from the pyrolyses of 1-phenyl-2-benzothiazolinethione (**8**) is 2-(phenylthio)benzothiazole (**11**), comparison with results from the pyrolysis of 1-phenyl-2-benzimidazolinethione (**13**) suggests that **11** forms from a tetracyclic intermediate which further rearranges and is not isolated (eq. 9). The phenyl rearrangement that we have observed provides an alternate synthetic route to 2-(phenylthio)benzothiazole (**11**). Previous syntheses used as starting materials, 2-iodobenzothiazole (15), and 2-chlorobenzothiazole (16).

Basically, pyrolysis and mass spectrometric fragmentation are not similar processes. However, in the series of compounds described by structure **1**, we have found that the species eliminated in the two processes are similar

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

for a particular molecule. We find that this observation is noteworthy and that the mass spectrum of compounds related to structure **1** can be useful, in an empirical sense, for predicting and interpreting results obtained from the pyrolyses.

Experimental

Melting points were determined by the open capillary method using a MEL-TEMP apparatus and were corrected. Infrared spectra were recorded with a Beckman IR8 spectrometer and a Perkin-Elmer Infracord. Nuclear magnetic resonance spectra were taken on a Varian T-60 spectrometer using 1% TMS as an internal standard. Ultraviolet spectra (1 cm path) were determined on a Bausch and Lamb Spectronic 505. Low-resolution mass spectra were obtained from a Hitachi RMU-6D mass spectrometer. Electron voltage readings were taken directly from the dial since more precise values were not needed.

Exact-mass data were obtained from an AEI MS-902 mass spectrometer linked to a PDP-8 computer. All experimental values agreed with the calculated values within ± 0.0015 mass units. Metastable peaks were observed in the low-resolution spectra.

The ion source of the RMU-6D was maintained at 250° and the MS-902 at 150°. Since pyrolysis of the compounds studied does not begin until approximately 600°, pyrolysis in the source cannot account for the fragmentations observed.

The gas chromatographic (g.c.) work was carried out using a Hewlett-Packard 5752B Research Chromatograph with a thermal conductivity detector. Columns were prepared with 0.25 in. copper tubing and 60–80 mesh Chromosorb W as a solid support unless otherwise stated. A total of five g.c. columns were used during the initial stages of analysis of the pyrolysis mixtures. However, only the column that gave the best separations is reported for each analysis. Comparison of the areas under the peaks of the pyrolysis products with the areas under the peaks of solutions of known concentrations of the same compound was used to determine yields. Analyses were performed by Midwest Microlab, Inc., Indianapolis, Indiana.

Chemicals

The following chemicals were purchased and used directly or after recrystallization: 2-aminothiophenol, 2-aminobiphenyl, thiophenol, acridine, phenothiazine (**9**), dibenzothiophene, benzothiazole, and biphenyl (Aldrich); carbazole (**10**) (Fisher); 1,1-diphenylthiourea (Eastman); and phenyl sulfide (Baker).

1-Phenyl-2-benzothiazolinone (7)

Compound **7** was prepared from 1,1-diphenylthiourea by the method of Passing (17). Recrystallization was done in petroleum ether (30–60°): yield, 30%; m.p., 79–80° (lit. (17) m.p. 81–82°). The i.r. spectrum ($HCCl_3$) exhibits strong absorption bands at 1700 and 1680 cm^{-1}. The mass spectrum is summarized in Scheme 1 and discussed in the text.

Anal. Calcd. for $C_{13}H_9NOS$: C, 68.70; H, 3.99. Found: C, 68.66; H, 4.09.

1-Phenyl-2-benzothiazolinethione (8)

Compound **8** was prepared from compound **7** by reaction with P_2S_5 (18). The crude product was recrystallized with ethanol: yield, 40.9%; m.p. 94–95° (lit. (18) m.p. 98–99°). The i.r. spectrum ($HCCl_3$) consists of bands at 2950, 1570, 1485, 1450, 1305, 1255, 1140, and 680 cm^{-1}. The mass spectrum is summarized in Scheme 3 and discussed in the text.

Anal. Calcd. for $C_{13}H_9NS_2$: C, 64.16; H, 3.73. Found: C, 64.46; H, 3.59.

2-(Phenylthio)benzothiazole (11)

Compound **11** was synthesized from 2-iodobenzothiazole using the method of Todesco and Vivarelli (15). It was also synthesized by the pyrolysis of compound **8** at 720°. In the former case, the 2-iodobenzothiazole was prepared from an ethereal solution of 2-benzothiazlyllithium (19, 20). The 2-iodobenzothiazole was then allowed to react with thiophenol for 5 days. The resulting oil was distilled and the portion that came over at 186–187° (3 Torr) was collected (15, 16): yield, 23.3%; m.p. of picrate 107–108° (lit. (15) m.p. of picrate 108–109°); λ_{max} (EtOH) 299.5, 289.5, 281, 247sh, and 238 nm; i.r. (neat) 3100, 1458, 1432, 1313, 1268, 993, 758, and 693 cm^{-1}; δ ($CDCl_3$), 7.73 multiplet; mass spectrum, 70 eV, *m/e* 243 ($C_{13}H_9NS_2$, 44), 242 ($C_{13}H_8NS_2$, 100), 211 ($C_{13}H_9NS$, 2), 210 ($C_{13}H_8NS$, 1), 209 ($C_{13}H_7NS$, 2), 199 ($C_{12}H_9NS$, 1), 198 ($C_{12}H_8NS$, 2), 184 ($C_{12}H_8S$, 1), 179 ($C_{13}H_9N$, 1), 178 ($C_{13}H_8N$, 1), 167 ($C_{12}H_9N$, 1), 166 ($C_{12}H_8N$, 1), 135 (C_7H_5NS, 1), 121.5 ($C_{13}H_9NS_2$ (doubly charged) 4), 121 ($C_{13}H_8NS_2$ (doubly charged) 6), 109 (C_6H_5S, 6), 108 (C_6H_4S, 8), 77 (C_6H_5, 6) and 51 (C_4H_3, 8); molecular ion, *m/e* 243.0176 (calcd. for $C_{13}H_9NS_2$: 243.0176).

In using the pyrolysis method for synthesis of compound **11**, compound **8** was pyrolyzed at 720° to avoid secondary products. Details of the pyrolysis of compound **8** will be given later under that heading; however, the work up procedure in this case is different. Five grams of starting material was used in two portions. Only the products in the first trap and in the quartz tube immediately after the pyrolysis zone were collected. Unreacted starting material was crystallized from a concentrated ethanolic solution of the products and repyrolyzed. The procedure was repeated until there was no starting material left. The crude product of **11** was then vacuum distilled as in the other synthesis. The overall yield was 1.9 g (38.0%).

2-Phenylbenzothiazole (12)

Compound **12** was synthesized from 2-aminothiophenol and benzoic acid with polyphosphoric acid, using the method of Hein *et al.* (21): yield, 46.0%; m.p. 112–113° (lit. (21) m.p. 112.7–113.9°); u.v., n.m.r., and mass spectra were identical to those given in ref. 22. Molecular ion, *m/e* 211.046 (calcd. for $C_{13}H_9NS$: 211.0455).

2-Cyanophenyl Phenyl Sulfide

2-Cyanophenyl phenyl sulfide was synthesized by reacting the diazotized salt of 2-aminophenyl phenyl sulfide with cuprous cyanide (23). 2-Aminophenyl phenyl sulfide was synthesized from aniline and 2-aminothiophenol using the conditions reported by Miller *et al.* (24). The crude product was distilled and the portion that

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

came over at 175–178° (1 Torr) was collected. The liquid crystallized on standing and the crystals were washed sparingly with methanol. The overall yield was 11.2%; m.p. 55°; i.r. ($HCCl_3$) 3080, 2940, 2250, 1585, 1460, 1430, 1275, 1135, 1060, 1017, and 675 cm^{-1}; λ_{max} (EtOH) 239sh, 255, 274sh, 284sh, and 314 nm; δ ($CDCl_3$) multiplet 7.2; mass spectrum, 50 eV, *m/e* 211 ($C_{13}H_9NS$, 100), 210 ($C_{13}H_8NS$, 24), 209 ($C_{13}H_7NS$, 9), 184 ($C_{12}H_8S$, 42), 139 ($C_{11}H_7$, 7), 109 (C_6H_5S, 7), 105.5 ($C_{13}H_9NS$ (doubly charged) 3), 105 ($C_{13}H_8NS$ (doubly charged) 4), 92 ($C_{12}H_8S$ (doubly charged) 11) 77 (C_6H_5, 19), and 51 (C_4H_3, 24); molecular ion *m/e* 211.045 (calcd. for $C_{13}H_9NS$: 211.0455).

2-Cyanobiphenyl

2-Cyanobiphenyl was synthesized by diazotization of 2-aminobiphenyl, followed by reaction with cuprous cyanide (23). The crude product was extracted with ether and decolorized with activated carbon. The ether was evaporated under a vacuum. The product was then distilled and the portion from 98–100° (0.1 Torr) was collected. This light yellow oil crystallized on standing; yield 54.5%; m.p. 35–36°; i.r. spectrum (neat), 3090, 2249, 1600, 1478, 1435, 750, and 695 cm^{-1}; λ_{max} (EtOH) 227, 249, and 287 nm; δ ($CDCl_3$) multiplet 7.55; mass spectrum, 50 eV, *m/e* 179 ($C_{13}H_9N$, 100), 178 ($C_{13}H_8N$, 27), 177 ($C_{13}H_7N$, 15), 152 ($C_{12}H_8$, 17), 151 ($C_{12}H_7$, 16), 150 ($C_{12}H_6$, 7), 89.5 ($C_{13}H_9N$ (doubly charged), 7), 89 ($C_{13}H_8N$ (doubly charged) 7) and 76 (C_6H_4, 15); molecular ion *m/e* 179.073 (calcd. for $C_{13}H_9N$: 179.0734).

Pyrolysis Apparatus and Procedure

The pyrolysis apparatus and procedure were similar to those used in our previous reports (6, 8). The sample (approximately 1 g) was sublimed smoothly into a stream of nitrogen which passed through a hollow quartz tube heated by a 12 in. electric furnace. The flow rate was adjusted to 0.25 l/min at 1 Torr. The vacuum was maintained by a rotary pump. A series of traps were placed between the pyrolysis zone and the pump. It takes approximately an hour for each half gram of sample to be sublimed through the zone. A solution was made in a volumetric flask of the material in the traps; g.c. and t.l.c. were used to separate the compounds in this solution.

Pyrolysis of 1-Phenyl-2-benzothiazolinone (7)

In Table 1 the results and conditions of the pyrolyses of compound 7 are listed. The percentages shown are averages of different trials at the same temperature; good agreement was obtained among the different runs. Approximately 1 g of sample was used for each pyrolysis.

Three traps were used in each pyrolysis; the first one was maintained at room temperature, whereas the next two were cooled by liquid nitrogen. The traps were washed with acetone and chloroform. The g.c. column used to separate the three components was 6 ft 3% OV 225 on Chromosorb W 80–100. The temperature was programmed from 180 to 265° (5 min) at 8°/min. The products were identified by comparison with authentic samples.

good. The presence of acridine, carbazole (**10**), and cyanodibenzothiophene was detected at 850° and 950°, but they were present in trace quantities. In the case of cyanodibenzothiophene, the position of cyano substitution was not determined. There were two isomers but neither gave the same u.v. spectrum as 2-cyanodibenzothiophene (25). Except for cyanodibenzothiophene, all the other products were identified by comparison with authentic materials.

Pyrolysis of 2-(Phenylthio)benzothiazole (11)

Due to the small amount of **11** available, its pyrolyses were done on a smaller scale (0.5 g). The conditions used were the same as in the cases given above. The g.c. column and conditions used were the same as those for compound **8**. The results are listed in Table 4.

Pyrolysis of 2-Phenylbenzothiazole (12)

Compound **12** (1.04 g) was pyrolyzed at 950° using the same conditions as given for previous cases. The g.c. column and conditions used were the same as above. Only a trace of cyanobenzene was detected. The percentage of starting material recovered was 94%.

We thank the National Research Council of Canada for its financial support.

Reaction of 1,2-Dichlorohexafluorocyclopentene with Phenol and *p*-Nitrothiophenol

RICHARD F. STOCKEL

Hydron Laboratories, Inc., New Brunswick, New Jersey 08902

Received May 8, 1974[1]

RICHARD F. STOCKEL. Can. J. Chem. 53, 2302 (1975).

The reaction of phenol with 1,2-dichlorohexafluorocyclopentene gave two major components. These have been identified as 1-chloro-2-phenoxy-3,3,4,4,5,5-hexafluorocyclopentene (**1**) and 1-chloro-3,3,4,4-tetrafluoro-2,5,5-triphenoxycyclopentene (**2**). A third component was detected by g.c. and assumed to be **3**.

With *p*-nitrothiophenol as the reactant only 1,2-bis(*p*-nitrophenylthio)-3,3,4,4,5,5-hexafluorocyclopentene (**4**) was isolated in excellent yields.

RICHARD F. STOCKEL. Can. J. Chem. 53, 2302 (1975).

La réaction du phénol avec le dichloro-1,2 hexafluorocyclopentène conduit à deux produits principaux. On a pu démontrer qu'il s'agit du chloro-1 phénoxy-2 hexafluoro-3,3,4,4,5,5 cyclopentène (**1**) et du chloro-1 tétrafluoro-3,3,4,4 triphénoxy-2,5,5 cyclopentène (**2**). On a détecté par c.p.g. la présence de traces d'un troisième composé et l'on fait l'hypothèse qu'il s'agit de **3**.

Utilisant le *p*-nitrothiophénol comme réactif, on n'isole que le bis(*p*-nitrophénylthio)-1,2 hexafluoro-3,3,4,4,5,5 cyclopentène avec d'excellents rendements. [Traduit par le journal]

Results

A variety of nucleophiles reacting with 1,2-dichlorohexafluorocyclopentene has been extensively studied (1). Despite this versatility the reactions of phenol and thiophenol derivatives have remained virtually unreported for these type alicyclic olefins. This article conclusively shows the diversity of products, which is primarily dependent on the attacking nucleophile and to a lesser extent the reaction conditions.

The results of reacting phenol under basic conditions with 1,2-dichlorohexafluorocyclopentene is analogous to this haloolefin and its homologs reacting with methoxide ion (2). Both the mono- (**1**) and trisubstituted (**2**) unsaturated ethers are formed in 50.8 and 45.8% yields, respectively. Employing milder reaction conditions it was reported (3) that perfluorocyclobutene reacts with phenol to give only the corresponding monounsaturated ether. In fact, with alicyclic olefins of the 1,2-dichloro type, no case has been reported to date whereby saturated ethers are formed. In contrast acyclic perfluoro- and chlorofluoroolefins give both saturated and unsaturated ethers (4, 5).

One other minor product in about 3.4% was

For personal use only.

quantitative conversion of phenol based on the product distribution. Gas chromatography of the crude using a 2′-polyphenylether 3% on 100/120 GIS Chromosorb Q gave the following composition: **1**, 58.8%; **2**, 45.8%; and **3**, 3.4%. Each of the major peaks was checked using authentic samples and comparing retention times. Upon vacuum distillation **1** distilled at 46–48 °C/6 Torr, while **2** distills at 138–139°/0.1 Torr with a melting range of 56–57 °C. Compound **2** was reported (19); however, the method of preparation was not disclosed. Only the ^{19}F n.m.r. and melting point were reported.

Anal. Calcd. for $C_{11}H_5ClF_6O$ (**1**): C, 43.63; H, 2.17; Cl, 11.73. Found: C, 43.85; H, 1.96; Cl, 12.05.

Anal. Calcd. for $C_{23}H_{15}ClF_4O_3$ (**2**): C, 61.26; H, 3.30; Cl, 7.88. Found: C, 60.93; H, 3.16; Cl, 8.02.

Under similar reaction conditions when 3 equiv. of phenol and base were reacted with 1 equiv. of olefin a 91% yield of **2** was obtained with no other products found.

Preparation of 1,2-Bis(p-nitrophenylthio)-3,3,4,4,5,5-hexafluorocyclopentene (5)

A solution of 1,2-dichlorohexafluorocyclopentene (24.5 g, 0.1 mol), *p*-nitrothiophenol (15.1 g, 0.1 mol), and potassium hydroxide (5.6 g, 0.1 mol) was stirred and heated at *55 °C* for 15 h. The contents were then poured into 1 l of water. The bottom organic layer was separated and washed several times with water and finally dried over anhydrous sodium sulfate to give 25.1 g for an overall yield of 91%. This was recrystallized from isopropanol to give a sharp melting range 126–126.5 °C.

Anal. Calcd. for $C_{17}H_8F_6S_2N_2O_4$ (**4**): C, 42.31; H, 1.66; S, 13.27; N, 5.80. Found C, 42.60; H, 1.38; S, 13.27; N, 5.80.

detected by g.c. It is suspected that it is the extremely reactive diether (**3**), which is seldom isolated under basic conditions due to the vinylic fluorine (6). However, a 3-phenoxide (**4**) derivative, resulting from an outward elimination (7) could conceivably be formed, because of a competitive reaction path between the electronically favored inward elimination (**1**) *vs.* the stereochemically favored *trans*-outward elimination (**4**). However, the latter route is very much less influential in the cyclopentene system than in the cyclohexene system. The diether structure is also preferred because its retention time on the g.c. is approximately midway between the mono- and trisubstituted ethers.

Structure proofs are based on physical and analytical data. For structure **1** the ^1H n.m.r. shows only a complex aromatic pattern while the ^{19}F n.m.r. spectrum shows three multiplets of equal intensities at 112.6, 115.9, and 130.4 ϕ. The i.r. gives characteristic bands at 6.02 (C=C stretch), 6.28 (phenyl), 7.80, 8.39, and 8.70 μ (due to CF_2 and C—O—C asymmetric stretch) (8).

The ^1H n.m.r. of the trisubstituted ether **2** shows complex aromatic absorption, while the ^{19}F n.m.r. spectrum gives two identical triplets at 115.5 and 123.6 ϕ with $J_{FF} = 6.2$ Hz. The i.r. gives comparable bands as for **1** with bands at 6.02 (C=C stretch), 6.28 (phenyl), 7.88, 8.38, and 8.80 μ (for CF_2 and C—O—C). Elemental analyses agree for both compounds. No physical data were accumulated on the minor component.

The reaction of 1,2-dichlorohexafluorocyclopentene with *p*-nitrothiophenol proceeds similarly to the previously reported reaction of this same haloolefin with cuprous benzylmercaptide (12, 13). In either case the 1,2-bisthio ethers (**5**) are formed. Interestingly, if the alicyclic olefin is a perfluorocycloalkene substrate, the 1,2-disubstituted products are formed regardless whether the nucleophile is an alkoxide ion (7, 10, 11) or a mercaptide ion (9, 12, 13). In addition to the bisthioether perfluorocyclobutene is reported to give the monosaturated and unsaturated ethers (12). It was found in this study that 1,2-dichlorohexafluorocyclopentene gives the bisether (**5**) exclusively. This same result was true even in the absence of base emphasizing the strong nucleophilic character of bivalent sulfur.

Fairly recent papers illustrate a generalized reaction path leading to the formation of 1,2-disubstituted derivatives on 1,2-dichlorohexafluorocyclopentene with phosphites, phosphonites, and phosphinite esters (14, 15). The explanation why the monosubstituted derivative is not formed with these phosphorus compounds was rationalized by a reversal of the polarization of the double bond due to the P=O moiety. Therefore carbon atom-2 becomes partially positive and subsequently becomes susceptible to nucleophilic attack. This same type of conjugative ability has been postulated in an earlier paper involving a carboxamide group (16). However, this hypothesis does not explain why some 1,2-disubstituted derivatives are obtained in the reactions of secondary phosphines with 1,2-dichlorotetrafluorocyclobutene and 1,2-dichlorohexafluorocyclopentene (17, 18).

It is obvious from this work and those references mentioned in this text, that no single unifying postulate exists to predict *a priori* the exact product formation. Although a recent attempt has been made in this direction (1) the diversity of the haloolefin and attacking nucleophile probably precludes a single working hypothesis.

The ^1H n.m.r. for **5** shows A_2B_2 pattern characteristics of a *p*-disubstituted phenyl compound. The ^{19}F n.m.r. spectrum gives a triplet at 107.6 ϕ and a quintuplet at 130.3 ϕ with a corresponding 2:1 ratio suggesting a symmetrical structure. The i.r. gives bands at 6.22 (phenyl), 6.66 (asymmetric NO_2), 7.44 (symmetric NO_2) with other large absorptions at 8.02, 8.80, 9.21, 9.89, 11.38, 11.7 (shoulder), and 13.50 μ.

Experimental

All reagents were purchased from commercial sources. Analytical results were obtained by our own microanalytical laboratory. Infrared spectra were run as mineral oil mulls or films on a Perkin-Elmer Model 317 spectrophotometer. Nuclear magnetic resonance spectra were recorded with Varian HR-60, ^1H n.m.r. reported as δ values using tetramethylsilane as internal standard, ^{19}F n.m.r. reported as ϕ values using trichlorofluoromethane as an external standard.

Preparation of 1-Chloro-2-phenoxyhexafluorocyclopentene (1) and 1-Chloro-3,3,4,4-tetrafluoro-2,5,5-triphenoxy-1-cyclopentene (2)

Phenol (9.4 g, 0.1 mol), 1,2-dichlorohexafluorocyclopentene (24.5 g, 0.1 mol), and 85% potassium hydroxide (5.6 g, 0.1 mol) were added to 200 ml of dimethylformamide. The solution was stirred at 55 °C for 15 h. The contents were then poured into 1 l of water. The bottom organic layer was separated, washed several times with water, and dried over anhydrous sodium sulfate. Approximately 23.5 g of crude were isolated, which is essentially

Some Reactions of 1-Lithio-2-phenyl-1,2-dihydropyridine. IV. Synthesis of β-Substituted Pyridines[1]

C. S. GIAM, E. E. KNAUS,[2] R. A. LOCKHART,[3] AND I. G. KEENER

C. S. GIAM, E. E. KNAUS, R. A. LOCKHART, and I. G. KEENER. Can. J. Chem. **53**, 2305 (1975).

Alkylation of the ambident anion 1-lithio-2-phenyl-1,2-dihydropyridine (**1***a*) has been investigated. A direct method for introducing an alkyl or arylalkyl group into the β-position of pyridine is described. Reaction of **1***a* with styrene oxide or ethylene oxide afforded 2-(2-phenyl-5-pyridyl)-1-phenylethanol (**10**) and 2-(2-phenyl-5-pyridyl)ethanol (**11**), respectively. With *N*-benzylideneaniline the unexpected 2-phenyl-5-benzylpyridine (**7**) was obtained. When **1***a* was allowed to react with perhalomethanes, conditions conducive to carbene formation, bis(6-phenyl-3-pyridyl)methane (**12**) and 6,6′-diphenyl-3,3′-dipyridyl (**13**) were obtained. Mechanisms for the formation of **7**, **12**, and **13** are discussed. Reactions of **1***a* with other electrophilic substrates are described.

C. S. GIAM, E. E. KNAUS, R. A. LOCKHART et I. G. KEENER. Can. J. Chem. **53**, 2305 (1975).

On a étudié l'alkylation d'un anion bidentate, le lithio-1 phényl-2 dihydro-1,2 pyridine **1***a*. On décrit une méthode d'introduction directe d'un groupe alkyle ou aryle en position β de la pyridine.

La réaction de **1***a* avec l'oxyde de styrène ou l'oxyde d'éthylène conduit respectivement au (phényl-2 pyridyl-5)-2 phényl-1 éthanol (**10**) et (phényl-2 pyridyl-5)-2 éthanol (**11**). Avec la *N*-benzylidènaniline un produit inattendu le phényl-2 benzyl-5 pyridine (7) est obtenu. Lorsque **1***a* est mis à réagir avec les perhalogénométhanes, c'est-à-dire dans des conditions favorables à la formation de carbènes, du bis(phényl-6 pyridyl-3) méthane (**12**) et du diphényl-6,6′ dipyridyl-3,3′ (**13**) se produisent. Les mécanismes pour la formation de **7**, **12** et **13**, sont discutés. On décrit la réaction de **1***a* avec d'autres substrats électrophiles. [Traduit par le journal]

Although β- or 3-substituted pyridines and their derivatives find important applications in biological studies (2), as intermediates in organic synthesis, and in mechanistic studies (3), the synthesis of these compounds has been a problem. The direct introduction of alkyl groups having functional moieties into the 3- or 5-position of the pyridine ring has not been reported. Alkylation and arylation of pyridine by the nucleophilic organolithium or Grignard reagents give 2- or 4-substituted pyridines rather than the 3-substituted derivatives. Free radical substitution, on the other hand, gives a mixture of all three isomers; the 3-substituted isomer is usually the minor component. Finally, alkylation via electrophilic substitution, *e.g.*, Friedel–Crafts reaction, has not been effected in the pyridine series (3, 4).

Recently, we showed that alkyl or aralkyl substituents can be directly introduced into the β-position of pyridines by reacting pyridine with lithium aluminum hydride followed by an alkyl or aralkyl halide. This simple and direct method gave very high yields of β-alkyl and aralkyl pyridines (5). In another study (6), we showed that the σ-intermediates, 1-lithio-2-substituted 1,2-dihydropyridines (**1**) isolated from the reactions of organolithium compounds with pyridine (7), reacted with alkyl, aralkyl, and aryl halides to produce 2,5-disubstituted pyridines (**2**). Although these reactions may be carried out in one step by adding the different organolithium reagents to pyridine followed by the addition of the organic halides, our investigations have concentrated on using the iso-

[1]Presented in part at the XXIII International Congress of Pure and Applied Chemistry, July, 1971, Boston, Massachusetts (1). Also presented in part at the Fourth International Heterocyclic Congress, July, 1973, Salt Lake City, Utah. (1).

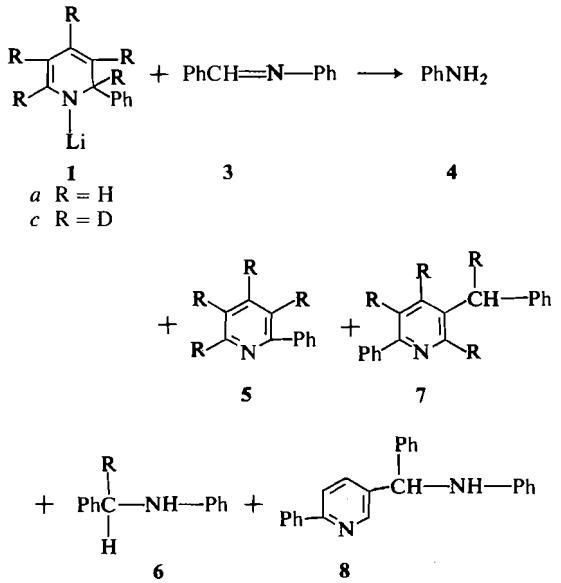
a R = Phenyl
b R = Alkyl

lated 1-lithio-2-phenyl-1,2-dihydropyridine **1***a*. While other 2,5-disubstituted pyridines can be prepared using similar reactions (8, 9), alkyl or arylalkyl substituents with functional groups such as an amino or hydroxyl have not been reported. We wish to present several interesting observations made in our studies to introduce such substituents directly into the β-position of pyridine using crystalline **1***a*.

The reaction of *N*-lithio-2-phenyl-1,2-dihydropyridine with Schiff bases was investigated as a method to introduce substituted alkyl amines into the β-position of pyridine. Treatment of **1***a* with *N*-benzylideneaniline (**3**) afforded aniline (**4**; 38.5%), 2-phenylpyridine (**5***a*; 49.3%), *N*-benzylaniline (**6***a*; 26.5%), 2-phenyl-5-benzylpyridine (**7***a*; 48.8%), and 2-phenyl-5-(α-anilinobenzyl)pyridine (**8**; 1.1%). Although **8** was



1 3 4

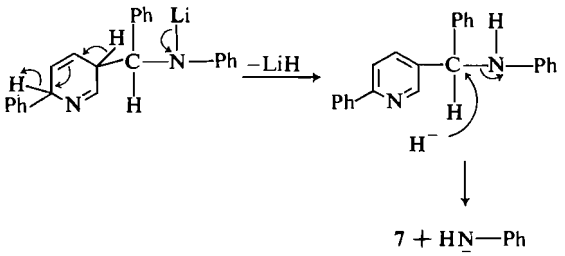
a R = H
c R = D

5 7

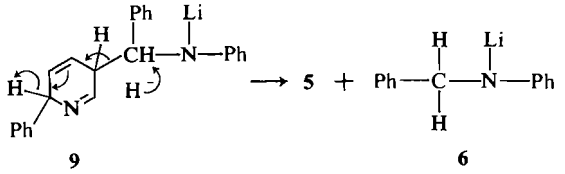
6 8

indeed formed the isolation of 2-phenyl-5-benzylpyridine (**7***a*) as one of the major products was quite unexpected. In a similar reaction, treatment of 1-lithio-2-phenyl-1,2-dihydropyridine-d_5 (**1***c*) with **3** gave rise to **4** (71.5%), 2-phenylpyridine-d_4 (**5***c*; 53.5%), *N*-benzyl-d_1-aniline (**6***c*; 22.4%), and 2-phenyl-5-benzyl-d_1-pyridine-d_3 (**7***c*; 44.5%). None of the deuterated product corresponding to **8** was detected by t.l.c.

One possible pathway for the formation of **7** may involve aromatization of **9** followed by nucleophilic hydride or deuteride attack and elimination of anilide anion to afford **7**. *N*-Benzylaniline (**6***a*) and *N*-benzyl-d_1-aniline (**6***c*) may arise in part or totally from reduction



of the active Schiff base **3** by **1***a* and **1***c*, respectively, since these agents are known to selectively reduce active ketones (10, 11). Support for the proposed pathway leading to the formation of **7** is given by the observation that the combined yields of **6** and **7** exceed that of **5** and to the formation of **6***c* and **7***c*. On the other hand if **4** and **7** share the common precursor **9** their yields should correspond. This observation suggests there may be a second pathway involved whereby **9** is also cleaved to yield **5** and **6**.



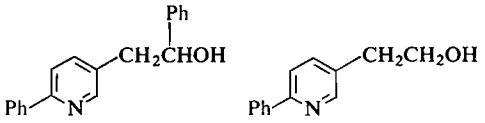
9 6

Treatment of **1***a* with styrene oxide gave **5***a* (31.2%), 2-(2-phenyl-5-pyridyl)-1-phenylethanol (**10**; 21%), and a polymeric product which exhibited a molecular weight (osmetric determination) of 506. In an attempt to reduce the amount of polymeric product, the inverse addition of **1***a* to a solution of styrene oxide

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

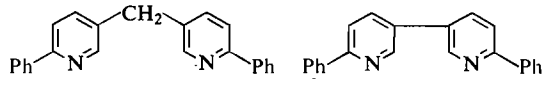
Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

afforded **5***a* (29.7%) and **10** (24.9%). Similarly, reaction with ethylene oxide gave rise to **5***a* (31.2%) and 2-(2-phenyl-5-pyridyl)ethanol (**11**; 17.9%). Inverse addition afforded **5***a* (30.2%) and **11** (25.4%).



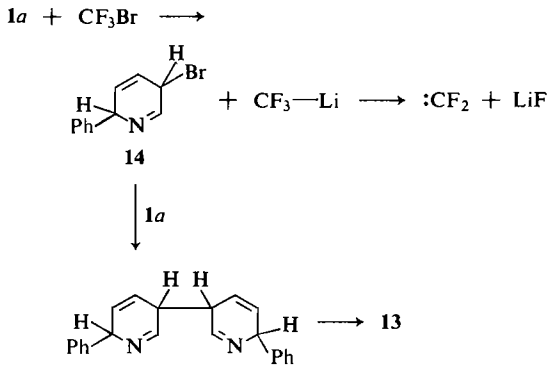
10 **11**

The reaction of **1***a* with methyl bromide provided a useful method for the preparation of 3-methylpyridine (6). In contrast, reaction with trifluoromethyl bromide gave rise to **5***a* (38.4%), a product which exhibits spectral data consistent with that expected for bis(6-phenyl-3-pyridyl)methane **12** (40.5%) and 6,6′-diphenyl-3,3′-dipyridyl **13** (1%). The presence of 2-phenyl-5-trifluoromethylpyridine was not detected by t.l.c. or g.l.c. The structure assigned to **12** was based on its mass, n.m.r., and i.r. spectra. The high resolution mass spectrum exhibited a molecular ion at *m/e* 322.146344; (mass calcd. for $C_{23}H_{18}N_2$: 322.146990 (2 p.p.m.)). The n.m.r. spectrum (CCl_4) was characteristic of a symmetric 2-phenyl-5-substituted pyridine: a 2H doublet ($J_{2,4}$ = 2 Hz) at δ 8.54 due to the C_2-H, a 4H multiplet at δ 8.0 due to the *ortho*-phenyl hydrogens, a 2H doublet ($J_{4,5}$ = 8 Hz) at δ 7.62 attributed to the C_5-H, an 8H multiplet at δ 7.2–7.5 due to the C_4-H, *meta*- and *para*-phenyl hydrogens, and a 2H singlet at δ 4.0 due to the $-CH_2-$ group. Reaction of **1***a* with trifluoromethyl iodide afforded **5***a* (39.4%), **12** (18%), and **13** (1.7%).

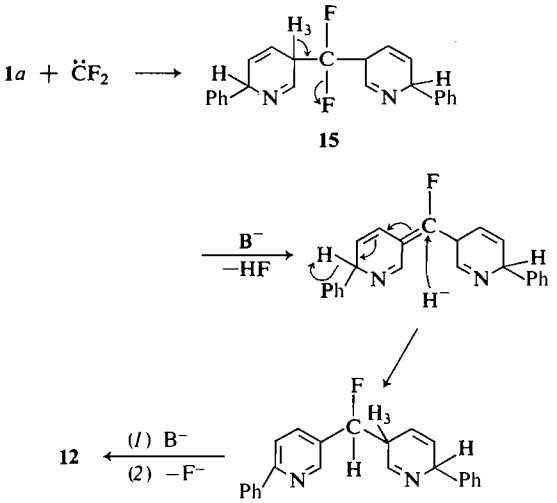


12 **13**

The mechanism of this reaction appears typical of the known reactions of trifluoromethyl halides with organolithium reagents (12–15) *viz.* carbene reactions. The formation of **13** must involve the initial formation of 2-phenyl-5-bromo-2,5-dihydropyridine (**14**) and the unstable trifluoromethyl anion (16) which decomposes to difluorocarbene with loss of fluoride. Further reaction of **14** with **1***a* and subsequent aromatization would give **13**. One pathway for the formation of **12** may involve reaction of highly



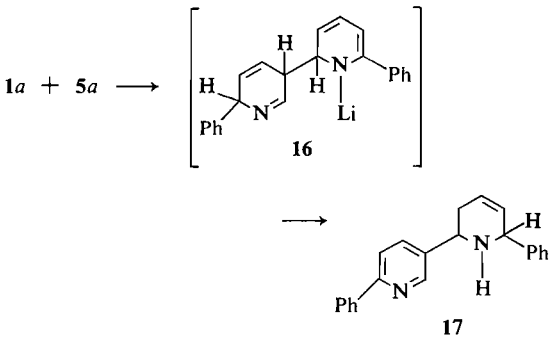
reactive and electrophilic difluorocarbene with **1***a* to yield **15**. Abstraction of the active C-3 proton by base such as 2-phenylpyridine (some of which is always obtained), elimination of fluoride anion and subsequent aromatization would ultimately yield **12**.



Products resulting from lithium–fluoride exchange, which would afford **12** upon hydrolysis, were eliminated since quenching the reaction mixture with deuterium oxide failed to yield deuterated **12**. Further details of this reaction are currently being investigated and will be reported later.

Addition of *N*-bromosuccinimide to **1***a* gave rise to **5***a* (74%) and 6,6′-diphenyl-3,3′-dipyridyl (**13**; 15.9%). Although **13** undoubtedly arises from reaction of **14** with **1***a*, 2-phenyl-5-bromopyridine was not detected (6).

The reaction of **1***a* with pyridines was also studied with the intention of preparing 2,3′-dipyridyls. When **1***a* was allowed to react with a



solution of **5***a* the unexpected tetrahydro product **17** (33.2%) was obtained. The intermediate product **16** must undergo further reduction rather than disproportionation to **17** since 6,6′-diphenyl-2,3′-dipyridyl was not detected.

No *N*-substitution product was detected in any of the reactions described (17). Further studies of organolithium–pyridine adducts and their derivatives are in progress in these laboratories.

Experimental

Melting points were determined with a Büchi capillary apparatus and are uncorrected. Nuclear magnetic resonance spectra were determined for solutions in deuteriochloroform or carbon tetrachloride with tetramethylsilane as an internal standard with a Varian HA-100 spectrometer. Mass spectra were measured with a CEC-21-110 mass spectrometer. Infrared spectra were recorded with a Beckman IR-8 spectrometer. Quantitative g.l.c. analyses were effected with a Hewlett-Packard 5750 or a Varian-Aerograph 1520 dual column gas chromatograph.

1-Lithio-2-phenyl-1,2-dihydropyridine (1a)

Pyridine (7.9 g, 0.1 mol) was carefully added to an ice-cold solution of phenyl lithium (8.4 g, 0.1 mol) in 200 ml of anhydrous ether under a nitrogen atmosphere. The yellow precipitate that formed was redissolved by repeated shaking. Upon cooling to 0°, **1***a* was obtained as a yellow crystalline solid. After washing with 30 ml of dry ether, the crystals were taken up in 100 ml of anhydrous tetrahydrofuran. A 2 ml aliquot of the above solution was decomposed with 10 ml of water and the concentration determined by titration with hydrochloric acid (18).

Aniline (4), 2-Phenylpyridine (5a), N-Benzylaniline (6a) 2-Phenyl-5-benzylpyridine (7a), and 2-Phenyl-5-(α-anilinobenzyl)pyridine (8)

General Procedure

N-Benzylideneaniline (0.82 g, 0.004535 mol) in 2 ml of dry tetrahydrofuran was added dropwise with shaking to a solution of 1-lithio-2-phenyl-1,2-dihydropyridine (0.74 g, 0.004535 mol) in 10 ml of dry tetrahydrofuran under an atmosphere of nitrogen at 0°. The resulting dark green solution was allowed to stand at room temperature for 1 h and then 10 ml of water was added. Extraction with chloroform (5 × 5 ml), drying (Na_2SO_4), and evaporation of the solvent gave an orange oil. Gas–liquid chromatographic analysis of a 5 ft × 1/8 in. column packed with 10% SE-30 on Anakrom ABS (60–80 mesh) with a helium flow rate of 60 ml/min at 102° gave 0.162 g (38.5%) of **4***a*, retention time of 3.25 min; at 162° gave 0.346 g (49.3%) of **5***a*, retention time of 6 min, and 0.22 g (26.5%) of **6***a*, retention time of 16 min; and at 238° gave 0.545 g (48.8%) of **7***a*, retention time of 10.75 min: m.p. 62° (lit. (19), m.p. 63–63.5°); n.m.r. ($CDCl_3$) δ 8.58 (1H, d($J_{4,6}$ = 1.5 Hz), C_6-H), 7.96 (2H, m, $C_{2',6'}$-H), 7.60 (2H, m, $C_{3,4}$-H), 7.42 (3H, m, $C_{3',4',5'}$-H), 7.25 (5H, m, —CH_2—C_6H_5), 3.98 (2H, s, —CH_2—). Aniline and *N*-benzylaniline showed i.r. and n.m.r. spectra identical to those of authentic compounds.

Isolation of 2-Phenyl-5-(α-anilinobenzyl)pyridine (8)

The residue from the above reaction was chromatographed on a 2 × 11 cm alumina column. Elution with hexane–benzene (1:1, v/v) (1000 ml) gave a mixture of **4**, **5**, **6**, and **7**. Further elution with the same solvent (600 ml) and then benzene (500 ml) gave an oil which was subjected to preparative t.l.c. on an 8 × 8 in. silica gel G plate, 0.2 mm film thickness, with benzene as the developing solvent. Extraction of the fraction with R_f of 0.6 gave 0.017 g (1.1%) of **8**: m.p. 46–48°; i.r. (KBr) 3390 cm^{-1} (NH); n.m.r. ($CDCl_3$) δ 8.7 (1H, d ($J_{4,6}$ = 2 Hz), C_6-H), 7.98 (2H, m, $C_{2'}$-H), 7.0–7.7 (11H, m, $C_{3,4}$-H and phenyl hydrogens), 6.5–6.8 (4H, m, phenyl hydrogens), 5.59 (1H, broad s, —C*H*—), 4.24 (1H, broad s, —NH—, exchanges with deuterium).

Mass Calcd. for $C_{24}H_{20}N_2$: 336.162640. Found: 336.161672.

Aniline (4), 2-Phenylpyridine-d_4 (5c), N-Benzyl-d_1-aniline (6c), and 2-Phenyl-5-benzyl-d_1-pyridine-d_3 (7c)

N-Benzylideneaniline (0.82 g, 0.00489 mol) in 2 ml of dry tetrahydrofuran was added to a solution of 0.80 g (0.00489 mol) of **1***c* in 10 ml of dry tetrahydrofuran at −65°. The reaction was completed and the g.l.c. analysis was effected as above to yield compound **4**, 0.326 g (71.5%), retention time of 2.8 min; 0.42 g (53.5%) of **5***c*, retention time of 5.25 min: b.p. 98°/0.8 Torr; n.m.r. (CCl_4) δ 8.02 (2H, m, *o*-phenyl hydrogens), 7.41 (3H, m, *m*- and *p*-phenyl hydrogens).

Mass Calcd. for $C_{11}H_5D_4N$: 159.09857. Found: 159.098936.

Compound **6***c*, 0.020 g (22.4%), retention time of 14 min: b.p. 119°/0.8 Torr; i.r. (film) 3400 cm^{-1} (NH); n.m.r. (CCl_4) δ 7.25 (5H, s, —CH—C_6H_5), 7.05 (2H, d ($J_{5,6}$ = $J_{2,3}$ = 7 Hz), $C_{2,6}$-H), 6.60 (3H, d ($J_{3,4}$ = 9 Hz) of d ($J_{2,3}$ = 7 Hz) of d ($J_{2,4}$ = $J_{4,6}$ = 2 Hz), $C_{3,4,5}$-H), 4.3 (1H, s, C_6H_5—C*H*—), 3.8 (1H, broad s, N—H, exchanges with deuterium).

Mass Calcd. for $C_{13}H_{12}DN$: 184.11101. Found: 184.110495.

Compound **7***c*, 0.544 g (44.5%), retention time 9.2 min: m.p. 54°; n.m.r. ($CDCl_3$) δ 7.98 (2H, m, *o*-phenyl hydrogens), 7.44 (3H, m, *m*- and *p*-phenyl hydrogens), 7.26 (5H, m, —CH—C_6H_5), 4.0 (1H, s, C_6H_5—C—*H*).

Mass Calcd. for $C_{18}H_{11}D_4N$: 249.14549. Found: 249.145042.

2-Phenylpyridine (5a) and 2-(2-Phenyl-5-pyridyl)-1-phenylethanol (10)

Styrene oxide (0.49 g, 0.004047 mol) in 2 ml of dry tetrahydrofuran was added to a solution of **1a** (0.66 g, 0.004047 mol) in 10 ml of dry tetrahydrofuran at −65° and the reaction was completed as above. Gas–liquid chromatographic analysis on a 2 ft × 1/8 in. column packed with 10% OV-17 on Gas Chrom P (60–80 mesh) at 200°, helium flow rate of 60 ml/min, afforded 0.196 g (31.2%) of **5a**, retention time of 3 min; and at 280° gave 0.234 g (21%) of **10**, retention time of 8.8 min: m.p. 140–142°; i.r. (KBr) 3200 cm^{-1} (OH); n.m.r. ($CDCl_3$) δ 8.41 (1H, d ($J_{4,6}$ = 2 Hz), C_6-H), 7.92 (2H, m, $C_{2',6'}$-H), 7.4 (10H, m, $C_{3',4',5'}$-H and $C_{3,4}$-H and —CH—C_6H_5), 4.83 (1H, t (J = 6 Hz), C_6H_5—C*H*), 2.98 (2H, d (J = 6 Hz), —CH_2—), 2.76 (1H, s, —OH, exchanges with deuterium).

Anal. Calcd. for $C_{19}H_{17}NO$: C, 82.88; H, 6.22; N, 5.09. Found: C, 82.63; H, 6.45; N, 5.00.

Isolation of Polymeric Product

Styrene oxide (0.8 g, 0.006712 mol) was added to **1a** (1.09 g, 0.006712 mol) as above to give an orange oil which was chromatographed on a 2.5 × 20 cm alumina column. Elution with benzene (600 ml) gave **5a**. Further elution with benzene–ether (3:1, v/v) (1200 ml) gave **10**. Elution with ether (400 ml), ether–methanol (3:1, v/v) (400 ml), and then methanol (300 ml) gave 0.5 g of a polymeric product: m.p. 60–90° (after precipitation from benzene by addition of hexane).

Mol. Wt. Found (osmetric determination): 506.

Anal. Found: C, 78.23; H, 7.00; N, 3.47. No structure was assigned to this polymer.

Similarly, the inverse addition of **1a** (1.09 g, 0.006712 mol) to styrene oxide (0.8 g, 0.006712 mol) in 5 ml of dry tetrahydrofuran afforded 0.186 g (29.7%) of **5a** and 0.275 g (24.9%) of **10** when subjected to g.l.c. analysis as described above.

2-Phenylpyridine (5a) and 2-(2-Phenyl-5-pyridyl)ethanol (11)

Ethylene oxide (0.18 g, 0.004047 mol) in 5 ml of dry tetrahydrofuran was added to a solution of **1a** (0.66 g, 0.004047 mol) in 10 ml of dry tetrahydrofuran at −65°. The reaction was completed and the g.l.c. analysis was effected as above at 200° to give 0.2 g (32.1%) of **5a**, and at 220° yielded 0.144 g (17.9%) of **11**, emergence time of 13.75 min: b.p. 188°/1.2 Torr; i.r. (film) 3300 cm^{-1} (OH); n.m.r. (CCl_4) δ 8.31 (1H, s, C_6-H), 7.82 (2H, m, *o*-phenyl hydrogens), 7.36 (5H, m, $C_{3,4}$-H and *m*- and *p*-phenyl hydrogens), 3.96 (1H, s, OH, exchanges with deuterium), 3.64 (2H, t (J = 6 Hz), HOC*H*$_2$—), 2.66 (2H, t (J = 6 Hz), —CH_2—).

Mass Calcd. for $C_{13}H_{13}NO$: 199.09964, Found: 199.099245.

Similarly, the inverse addition of **1a** (0.66 g, 0.004047 mol) in 10 ml of dry tetrahydrofuran to ethylene oxide (0.18 g, 0.004047 mol) in 5 ml of dry tetrahydrofuran at −65° afforded 0.188 g (30.2%) of **5a** and 0.205 g (25.4%) of **11** when subjected to g.l.c. analysis as described above.

2-Phenylpyridine (5a), Bis(6-phenyl-3-pyridyl)methane (12), and 6,6'-Diphenyl-3,3'-dipyridyl (13)

Trifluoromethyl bromide was bubbled slowly into a solution of **1a** (0.452 g, 0.002764 mol) in 10 ml of dry tetrahydrofuran at −65° until the dark brown color disappeared and the solution turned a yellow color. The reaction was completed as above and the reaction mixture was chromatographed on a 2.5 × 20 cm silica gel column. Elution with hexane–benzene (1:1, v/v) (900 ml) and then benzene (600 ml) gave 0.165 g (38.4%) of **5a**. Elution with benzene–ether (2:1, v/v) (300 ml) gave an oil which was purified further by t.l.c. using silica gel G plates (1.0 mm film thickness) and benzene–ether (5:1, v/v) as the developing solvent. Extraction of the fraction having an R_f of 0.25–0.55 afforded 0.18 g (40.5%) of **12**: m.p. 137–139°. Extraction of the fraction with R_f of 0.6 gave 0.004 g (1%) of **13**: m.p. 221–223°; n.m.r. ($CDCl_3$) δ 9.02 (2H, d ($J_{2,4}$ = 2 Hz), $C_{2,2'}$-H), 7.7–8.2 (8H, m, $C_{4,4',5,5'}$-H) and *o*-phenyl hydrogens), 7.4–7.6 (6H, m, *m*- and *p*-phenyl hydrogens).

Mass Calcd. for $C_{22}H_{16}N_2$: 308.131340. Found: 308.130428.

Similarly, the addition of trifluoromethyl iodide to **1a** (0.452 g, 0.002764 mol) in 10 ml of dry tetrahydrofuran and then isolation of the products as described above gave 0.169 g (39.4%) of **5a**; 0.08 g (18%) of **12**; and 0.007 g (1.7%) of **13**.

2-Phenylpyridine (5a) and 6,6'-Diphenyl-3,3'-dipyridyl (13)

N-Bromosuccinimide (0.91 g, 0.0051 mol) in 12 ml of dry tetrahydrofuran was added to **1a** (0.83 g, 0.0051 mol) in 10 ml of dry tetrahydrofuran at −65° and the reaction was completed as above. Recrystallization of the reaction mixture from 95% EtOH afforded 0.125 g (15.9%) of **13**: m.p. 221–223°; identical (i.r., n.m.r., and mass spectrum) with the same product obtained previously. The residue from the mother liquor was chromatographed on a 2.5 × 20 cm alumina column. Elution with benzene (800 ml) gave 0.566 g (75%) of **5a**.

2-Phenylpyridine (5a) and 6,6'-Diphenyl-1,2,3,6-tetrahydro-2,3'-dipyridyl (17)

2-Phenylpyridine (1.03 g, 0.00663 mol) was added to **1a** (1.08 g, 0.00663 mol) in 10 ml of dry tetrahydrofuran at 0°. The reaction was completed as above and the residue was chromatographed on a 2.5 × 25 cm silica gel column. Elution with benzene (1200 ml) gave 1.082 g (52.7%) of **5a**. Elution with benzene–ether (2:1, v/v) (700 ml) afforded 0.683 g (33.2%) of **17**: m.p. 61–63°; n.m.r. ($CDCl_3$) δ 8.74 (1H, d ($J_{2',4'}$ = 2 Hz), $C_{2'}$-H), 7.2–8.1 (12H, m, $C_{4',5'}$-H and phenyl hydrogens), 5.9 (2H, m, $C_{4,5}$-H), 4.76 (1H, m, C_6-H), 4.2 (1H, d ($J_{2,3}$ = 8.75 Hz) of d ($J_{1,2}$ = 5.75 Hz), C_2-H), 2.34 (2H, m, C_3-H), 2.18 (1H, broad s, N–H, exchanges with deuterium).

Mass Calcd. for $C_{22}H_{20}N_2$: 312.162640. Found: 312.161591.

The Infrared Spectrum and Force Field of Matrix Isolated *cis*-Thionylimide (HNSO)

PETER O. TCHIR AND RICHARD D. SPRATLEY

Department of Chemistry, University of British Columbia, Vancouver, British Columbia V6T 1W5

Received December 3, 1974

PETER O. TCHIR and RICHARD D. SPRATLEY. Can. J. Chem. **53**, 2311 (1975).

Infrared spectra of *cis*-HNSO and several deuterium, ^{15}N, and ^{34}S isotopically substituted homologs have been obtained in argon and nitrogen matrices. The Fermi resonance between ν_4 and $2\nu_5$ is discussed. A force field has been calculated.

PETER O. TCHIR et RICHARD D. SPRATLEY. Can. J. Chem. **53**, 2311 (1975).

On a obtenu les spectres infra-rouges du HNSO *cis* et de ses homologues isotopiques ^{2}H, ^{15}N et ^{34}S dans des matrices d'argon et d'azote. On discute de la résonnance de Fermi entre ν_4 et $2\nu_5$. On a calculé le champ de force. [Traduit par le journal]

Introduction

A detailed study of the photolysis of matrix-isolated *cis*-thionylimide (HNSO) has been carried out in this laboratory (1). During the course of this work it became necessary to be able to interpret the infrared spectrum of HNSO under the high-resolution conditions provided by the matrix-isolation technique. It was also necessary to have available a reliable force field for HNSO to allow the transfer of force constants to similar molecules formed on photolysis.

Force fields based on the gas phase spectra of HNSO and DNSO have been published (2) but these are unsatisfactory for several reasons. Firstly, the molecular parameters assumed in these calculations differ significantly from those determined more recently by microwave spectroscopy (3). Secondly, and more important, Eysel (2) employed a computational technique devised by Becher and Mattes (4) which must be regarded with suspicion. Although a perfect frequency fit is guaranteed at each stage of their calculation, the problem is underdetermined; seven force constants are calculated from the six observed frequencies (HNSO and DNSO are treated separately). Thus the force fields reported represent only one choice from among the infinity of possibilities generated by their method. A detailed and incisive critique of this approach has been published by Averbukh *et al.* (5).

In this work an 11 constant force field has been adjusted by a conventional least squares technique (6) to fit 29 observed frequencies from HNSO and six isotopically substituted homologs containing deuterium, ^{15}N and ^{34}S.

Experimental

The experiments were performed in an Andonian Dewar (Model MND-3L-15N) cooled with liquid helium. Samples were isolated in argon and nitrogen matrices (Matheson prepurified grades). Mole ratios of matrix gas to HNSO (M/R) ranged from 200 to 1000 in different experiments. Deposition was carried out from a mercury free vacuum system at rates averaging 2 mmol total sample per hour. Spectra were recorded on a Perkin-Elmer Model 225 infrared spectrometer with a frequency accuracy of $\pm 2\ cm^{-1}$ on survey scans and $\pm 0.5\ cm^{-1}$ under high resolution conditions. Spectral slit widths ranged from 0.2 to 0.5 cm^{-1} for high resolution scans.

HNSO was prepared in the gas phase by the method of Schenk (7)

$$3NH_3(g) + SOCl_2(g) \rightarrow HNSO(g) + 2NH_4Cl(s)$$

Since monomeric HNSO polymerizes on condensation, samples were stored in the gas phase at room temperature. Over a period of a few weeks, a slight decomposition of HNSO was observed indicated by an increase in SO_2, the only infrared active impurity present in measurable amounts. Deuterium and ^{15}N substitution were achieved using ND_3 (Merck, Sharp and Dohme) and $^{15}NH_3$ (Isomet Corporation, 95% purity) respectively.

Results

Sample Isolation and ^{34}S Absorption

Because HNSO is polymeric as a low temperature solid, it was essential to find matrix conditions which guaranteed isolation of the monomeric species. Fortunately, as is discussed below, the NH stretching mode of HNSO proved to be an excellent indicator of monomer isolation. Figure 1 shows a survey of HNSO deposited in argon at relatively high dilution ($M/R = 800$). All the absorptions can be assigned to either HNSO (12) or the SO_2 impurity.

The two sharp, weak absorptions at 1233.4 and

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12

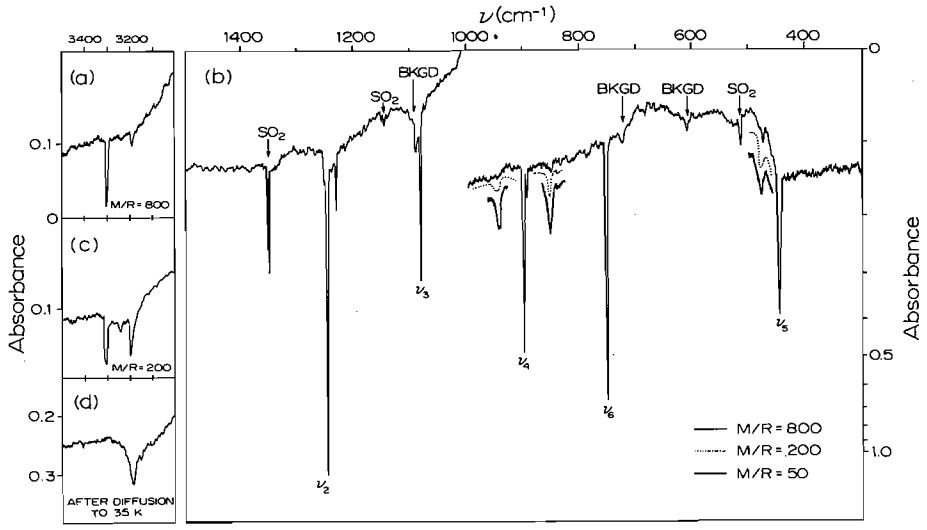

FIG. 1. The infrared spectrum of *cis*-HNSO in argon matrices.

895.7 cm^{-1} shifted slightly to low frequency of the ν_2 and ν_4 absorptions of HNSO are due to molecules containing ^{34}S in natural abundance. From the high resolution spectrum the estimated integrated intensity ratio for the 1233.4 cm^{-1} ($HN^{34}SO$) peak to the 1248.7 cm^{-1} ($HN^{32}SO$) peak is about 7%. The natural abundance of ^{34}S is 4%. Difficulties in estimating intensities are assumed to account for the discrepancy. Figure 2 shows a high resolution scan of the 900 cm^{-1} region. The 895.7 cm^{-1} absorption appears together with an overlapping peak at 893.8 cm^{-1}. The ratio of the combined intensities of these two peaks to that of the 900.4 cm^{-1} peak is about 12%. To account for this large difference from 4% the two peaks are assigned separately, the 895.7 cm^{-1} to the ^{34}S molecule and the 893.8 cm^{-1} to the overtone of ν_5 which is observed because of a slight Fermi resonance with the ν_4 vibrational level. This resonance is further discussed in the next section. An estimated intensity for the single 895.7 cm^{-1} peak gives a ratio of about 6% to the 900.4 cm^{-1} peak.

In the region above 3000 cm^{-1} Fig. 1*a* reveals a broad, weak absorption at 3200 cm^{-1}, 100 cm^{-1} below the NH stretch at 3308.5 cm^{-1}. At lower dilution the intensity of this feature is greatly enhanced as shown in Fig. 1*c* for $M/R = 200$. The spectrum in Fig. 1*d* resulted when this sample was warmed to about 35 K and recooled. The absorption at 3200 cm^{-1}, favored at low dilution, has broadened and gained intensity while the feature at 3308.5 cm^{-1} has disappeared. This behavior is characteristic of aggregation in a matrix and suggests that the 3308.5 cm^{-1} peak

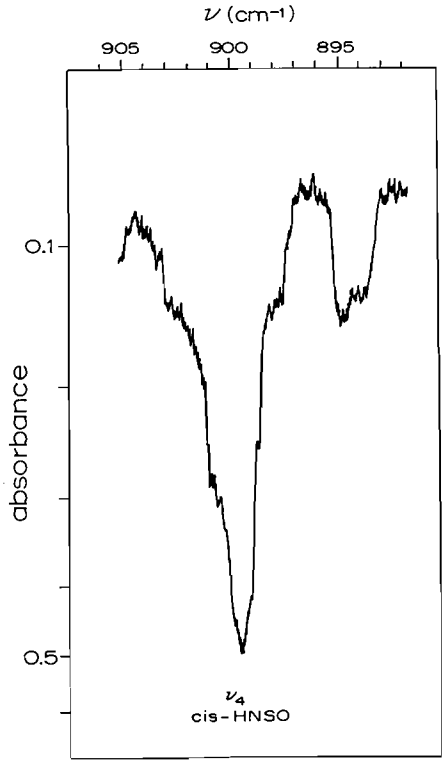

FIG. 2. The high resolution spectrum of ν_4 of *cis*-HNSO showing both the ^{34}S isotopic splitting and the $2\nu_5$ overtone.

ν_6	759	754.7	−4	852	774	+15

*From ref. 12.
†Δ = ν(matrix) − ν(gas).

can be identified with the monomer and the 3200 cm^{-1} peak with the dimer or higher aggregates of HNSO. It is tempting to consider the HNSO dimer as a hydrogen bonded eight membered ring.

It has been pointed out by Pimentel and McClellan (8) that hydrogen stretching modes are most strongly affected by hydrogen bonding. Large decreases in stretching frequencies and broadening of peaks coupled with dramatic intensity enhancements are generally observed. The 3200 cm^{-1} feature shows the necessary shift and broadening. Therefore, the intensity enhancement suggests that even though the 3200 and 3308.5 cm^{-1} absorptions are of near equal intensity at $M/R = 200$, the actual concentration of dimer is still quite small. Thus this peak is a sensitive measure of isolation.

The above conclusions then allow the assignment of other weaker, but still broad and concentration dependent, features in the $M/R = 200$ spectrum to the same dimer. These are shown as a broken line in Fig. 1*b* at 945, 852, and 478 cm^{-1}. On dimerization the SO and NS stretches at 1248.7 and 1082.7 cm^{-1}, since they are least involved in the hydrogen bonding, show only slight broadening to low frequencies while the other absorptions show large shifts. The peak at 945 cm^{-1} is the HNS bend shifted up from 900.4 cm^{-1}, at 852 cm^{-1} is the torsion, or out of plane mode, shifted up from 754.7 cm^{-1}, and at 478 cm^{-1} is the NSO bend shifted down from 447.4 cm^{-1}. These absorptions show shifts that are characteristic for each type of mode (8). They also show the characteristic broadening for hydrogen bonded dimer absorptions.

A spectrum at $M/R = 50$ shows these absorptions to be still more intense and also contains numerous other broad features that can likely be assigned to higher aggregates or to aggregation with SO_2. The 945, 852, and 478 cm^{-1} peaks at $M/R = 50$ are shown in Fig. 1*b* as heavy lines. Although this aspect was not further pursued, the absorptions assigned to the HNSO dimer are listed in Table 1.

Using the relatively large intensity of the concentration dependent feature at 3200 cm^{-1} as a measure of aggregation, a dilution of $M/R = 400$ was found to provide satisfactory isolation and was used for most of the experiments reported here.

Matrix Splitting

The HN stretch, ν_1, the torsion, ν_6, and the asymmetric stretch of SO_2 appear as doublets in argon matrices. The splittings are 5.1 cm^{-1} for ν(HN), 1.7 cm^{-1} for ν(torsion), and 4.1 cm^{-1} for ν_3 of SO_2. These doublets do not show the characteristics of splittings that are due to association. The possibility that these splittings are due to rotation within a matrix cannot be ruled out without careful temperature studies which were not possible in this work. However, it is generally felt that molecules as large as HNSO will not rotate in a matrix and the rotational splitting of ν_3 of SO_2, only 0.5 cm^{-1} in krypton matrices (10), is not expected to be as large as 4.1 cm^{-1}.

Therefore, the observed splittings have been ascribed to the occupancy of different sites within the argon lattice. This type of matrix splitting is characteristic of argon matrices (11).

Matrix Shifts: Ar and N_2 Matrices

Table 1 gives the observed frequencies of HNSO in argon and nitrogen matrices and the shifts from the gas phase values (12). These results are consistent with other observations of matrix effects (14): the average absolute shift is

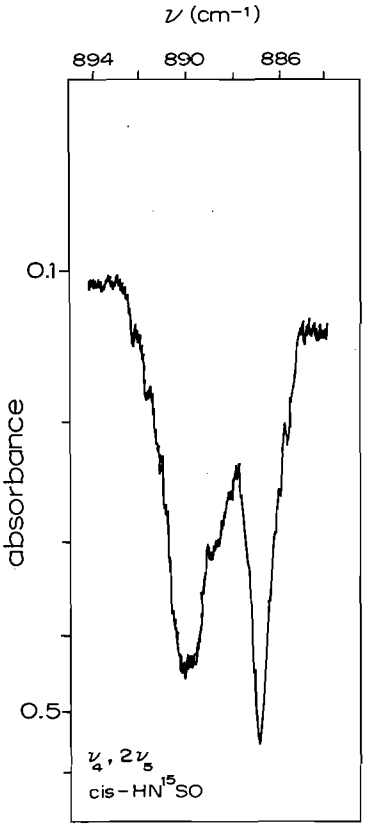

FIG. 3. The Fermi resonance doublet of ν_4 and $2\nu_5$ of *cis*-$H^{15}NSO$.

slightly less in argon (13 cm^{-1}) than in nitrogen (16 cm^{-1}); the argon frequencies are consistently lower than the gas phase frequencies whereas both positive and negative shifts are found in nitrogen; and modes involving hydrogen show particularly large shifts in nitrogen.

A comparison of the matrix shifts of HNSO and DNSO in argon reveals that ν_2, ν_3, and ν_5 have almost identical shifts for H and D; ν_1, ν_4, and ν_6 show significantly smaller shifts for D than for H. The latter modes, which involve a large hydrogen displacement, decrease in amplitude upon substitution of deuterium; therefore, the interaction with the matrix is decreased.

The results of photolysis of HNSO in solid N_2 were greatly confused by the apparent interaction of the photolysis products with the matrix. For this reason argon was chosen as the most suitable matrix material and the majority of the results were obtained in solid argon.

Fermi Resonance of ν_4 *and* $2\nu_5$

A weak absorption at 893.8 cm^{-1} in the $H^{14}NSO$ spectrum has been assigned above to the overtone of ν_5, the NSO bend. The peak is seen only because it has gained a small amount of intensity from ν_4 as a result of a Fermi resonance interaction. In $H^{15}NSO$ the effect becomes much larger and a near equal intensity doublet results as is seen in Fig. 3. Since the doublet components are of near equal intensity, the mixing of the $v_4 = 1$ and $v_5 = 2$ states resulting from the interaction is complete and the value of ν_4 must be taken as an average of the 890.6 and 887.7 cm^{-1} peaks. This is 889.2 cm^{-1}.

Table 2 shows the differences between ν_4 and $2\nu_5$ for the various isotopes of HNSO in argon and nitrogen matrices. For the ^{15}N substituted molecule in argon the separation is only 0.4 cm^{-1} and thus a strong resonance occurs while for the ^{14}N molecule the difference is 5.6 cm^{-1} and there is a weak interaction. For the deuterated species and for nitrogen matrices no resonance was seen.

Of interest is the closeness of the observed overtone to two times the fundamental which suggests a low anharmonicity in the ν_5 mode. Fermi resonance, which results from a breakdown of the harmonic oscillator approximation, also depends on anharmonicity. Perturbation theory shows that the separation of the resonance doublet depends on the cubic force constant in normal coordinates, K_{455} (9). For $H^{15}NSO$, where the zero order separation is estimated at 0.4 cm^{-1} and the intensities suggest a complete mixing of the zero order states, the resonance only causes a splitting of 2.9 cm^{-1}. By comparison, in CO_2 where a strong resonance is observed the separation of the doublet is 102.8 cm^{-1}. Thus it is evident that the resonance between $2\nu_5$ and ν_4 of HNSO is very weak. This requires that the cubic force constant K_{455} be small, *i.e.* the anharmonicity is small. Thus the frequency of the overtone and the extent of the resonance both suggest that the ν_5 potential function is nearly harmonic.

Force Field

Table 3 lists the frequencies measured for *cis*-HNSO and its isotopic homologs isolated in solid argon. Complete spectra were recorded for molecules containing ^{15}N and deuterium while for ^{34}S only peaks with large enough separation from ^{32}S peaks and with sufficient intensity to be seen in natural abundance (4%) were observed.

†Accuracy of ±2 cm^{-1}.

These 29 frequencies were fitted with a harmonic potential energy expression using 11 constants by means of the least squares refinement program FPERT written by Schachtschneider (6). The structural parameters used were those determined by Kirchhoff (3): $r_{NH} = 1.03$ Å, $r_{NS} = 1.51$ Å, $r_{SO} = 1.45$ Å, $\alpha_{HNS} = 116°$, $\alpha_{NSO} = 120°$, $\tau = 0°$ (*i.e.* planar).

While calculating the modified force field for this molecule, the following criteria were used: reasonable force constants with small errors; good agreement between observed and calculated data; a sensible vibrational assignment revealed through the potential energy distribution (13). The first two criteria are quite easily satisfied for a force field where many interaction constants are set equal to zero; the third is often a sensitive indication of the relative success or failure of a particular calculation.

Once calculations were begun, it soon became apparent that a single force field would not be able to fit both the hydrogen containing molecules and their deuterium homologs. The results gave poor frequency fits for ν_1 and peculiar potential energy distributions for the strongly interacting modes near 1000 cm^{-1} (*viz.* ν_2, ν_3, and ν_4). The problem stems, of course, from the use of observed rather than harmonic frequencies in the calculations. The effects of anharmonicity are greatest in the high amplitude hydrogen modes ν_1 and ν_4. Assignments indicate that ν_1 involves almost completely the HN stretching coordinate while ν_4 has a large contribution from the HNS bend. On deuteration, these vibrations sample significantly different parts of the potential energy surface, hence their force constants are not isotopic invariants. Thus the "effective" force constants for these modes will change on deuteration. Bearing these points in mind we permitted refinement of different values of the diagonal force constants f_{HN}, f_{HNS}, and $f_{torsion}$ for H- and D-containing molecules. Given this

freedom, the problem soon converged. The best set of force constants so obtained is given in Table 4.

It should be noted that the force constants quoted in Table 4 are not bond length weighted but are in the convenient m.k.s. system of units: aJ/Å² (10^5 dynes/cm) for stretches, aJ (10^{-11} ergs) for bends, and aJ/Å (10^{-3} ergs/cm) for bend–stretch interactions. The potential energy distribution (hence vibrational assignment) for the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12

common isotopic homolog of HNSO is given in Table 5. The calculated frequencies are listed for all the isotopic species of *cis*-HNSO in Table 3. The average frequency error using the force constants in Table 4 is 1.8 cm^{-1}.

The values of f_{DN} and f_{DNS} are, as expected, slightly larger (by 2%) than their hydrogenic counterparts; the deuterium vibrations are sampling a lower portion of the potential function which when fitted to a harmonic function results in a more steeply curved parabola. The torsion constant for DNSO did not differ significantly from that of HNSO so only one value was allowed in later refinements. This presumably indicates a low anharmonicity in the torsional coordinate. Every off-diagonal force constant (except those involving the HN stretching coordinate) was tried in the calculation at one time or another. Only those to which the results were significantly sensitive were retained.

Thermodynamic Functions

The thermodynamic functions calculated for *cis*-HNSO over the temperature range 100 to 1500 K are given in Table 6. These calculations were made using the vibrational frequencies taken from the argon matrix experiments.

The Photolysis of Matrix Isolated *cis*-Thionylimide. 1. The Identification and Infrared Spectra of *cis*-HOSN, HSNO, and SNO

PETER O. TCHIR AND RICHARD D. SPRATLEY

Department of Chemistry, University of British Columbia, Vancouver, British Columbia V6T 1W5

Received December 3, 1974

PETER O. TCHIR and RICHARD D. SPRATLEY. Can. J. Chem. 53, 2318 (1975).

cis-HNSO has been photolyzed in argon matrices using a medium pressure mercury lamp. Examination of the infrared spectra has revealed the presence of four photolysis products. With the aid of isotopic substitution these species have been identified as *cis*-HOSN, *cis*-HSNO, *trans*-HSNO, and SNO, all previously unknown. Assignments have been made for all four products and force fields calculated for *cis*-HOSN and *trans*-HSNO. The following reaction scheme has been postulated for the photolysis induced process: *cis*-HNSO → *cis*-HOSN → *cis*-HSNO + *trans*-HSNO → SNO. The extent of this reaction sequence has been found to depend on reaction time and photolysis energy.

PETER O. TCHIR et RICHARD D. SPRATLEY. Can. J. Chem. 53, 2318 (1975).

On a photolysé le HNSO *cis* dans une matrice d'argon à l'aide d'une lampe à mercure de pression moyenne. L'examen du spectre infra-rouge révèle la présence de quatre produits de photolyse. Utilisant le remplacement isotopique, ces espèces son identifiées comme étant le HOSN *cis*, le HSNO *cis*, le HSNO *trans* et le SNO, tous jusqu'ici inconnues. Les attributions sont faites pour les quatre produits et les champs de force calculés pour le HOSN *cis* et HSNO *trans*. La séquence réactionnelle suivante, est proposée pour le processus photolytiques induit: HNSO *cis* → HOSN *cis* → HSNO *cis* + HSNO *trans* → SNO. L'importance de ce cheminement réactionnel dépend du temps de réaction et de l'énergie requise pour la photolyse.

[Traduit par le journal]

Introduction

In the ultraviolet spectrum of *cis*-HNSO only one diffuse absorption and one continuum were observed (1). From this observation it was deduced that photolysis of the molecule was occurring. Since it was possible that the hydrogen was being removed to give the NSO radical, this photolysis appeared to be an ideal system for a study utilizing the matrix isolation technique. In this technique a hydrogen atom can diffuse away through the matrix to leave behind the isolated, stabilized radical. On the other hand, if the product or products were unstable isomers of *cis*-HNSO, they might also be stabilized at the low temperature of the matrix.

In this paper we describe the results of the mercury arc photolysis of *cis*-HNSO in argon matrices: in part I the infrared results are presented and four new molecular species are identified; in part II the reactions taking place in the matrix are considered.

Experimental

The production of *cis*-HNSO, the matrix isolation apparatus, and the infrared spectrometer (Perkin-Elmer 225) have been described previously (2). Photolysis was carried out using a 100 W PEK medium pressure mercury lamp (#112-2118) powered by a PEK model 401 power supply.

In some special cases photolysis was done with a vacuum ultraviolet lamp similar to that of Davis and Braum (3). Using a discharged flow of 1 part hydrogen to 9 parts helium at a pressure of approximately 0.5 Torr this lamp gave good yields of 1216 Å radiation (3). In this study it was used for photolysis with simultaneous deposition of the *cis*-HNSO/Ar sample. This lamp and its use are further described by Tchir (4).

I. Identification of Products

The mercury lamp photolysis of *cis*-HNSO isolated in an argon matrix ($M/R = 400$) resulted in 17 new absorptions in the infrared spectrum. Obviously several new molecules were being produced. The intensities of these absorptions were studied as a function of photolysis time to determine which absorptions belonged to each molecule. It was found that all the absorptions followed one of the three growth curves shown in Fig. 1 and on this basis, all observed absorptions were grouped as shown in Table 1.

The groups of absorptions were then considered separately and, for the purpose of identification and normal coordinate analysis,

isotopic substitution was carried out. Table 1 also lists the frequencies and frequency shifts observed on deuteration and ^{15}N substitution.

The observed vibrational frequencies and their shifts on isotopic substitution were used to identify the product species. Structures were proposed using bond lengths and angles from analogous molecules and vibrational analyses were carried out using the programs of Schachtschneider (5). In the following sections the

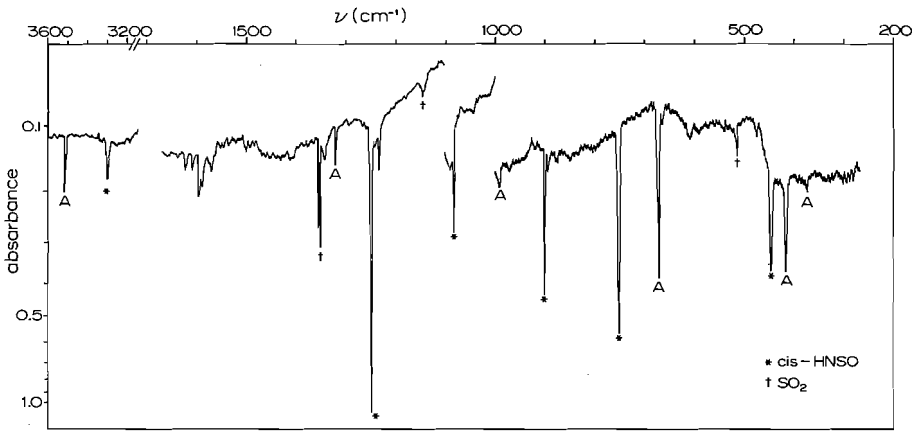

FIG. 2. Spectrum following the 1 min Hg lamp photolysis of *cis*-HNSO in argon (M/R = 400).

identification and force field calculations for each of the new molecules are discussed.

Molecule A

Identification

Figure 2 shows the spectrum of a sample of *cis*-HNSO in argon (M/R = 400) following 1 min photolysis. The peaks labelled A and grouped in Table 1 have grown very rapidly, 1 min is a very short photolysis time by matrix isolation standards where times of several hours are usual. The substitution of ^{15}N and deuterium resulted in the frequencies and shifts given in Table 1. Since the spectrum of molecule A contains 6 absorptions, molecule A is most likely tetraatomic, probably a simple isomer of *cis*-HNSO.

The first structure to come to mind is *trans*-HNSO. However, this possibility is quickly discredited when one tries to make an assignment consistent with the observed frequencies of *cis*-HNSO, the intensities, and the isotopic shifts. Firstly, the ^{15}N shift of the 3520 cm^{-1} absorption is only 0.5 cm^{-1}. This is too low for an HN stretch if one considers that the shift in *cis*-HNSO is 7.4 cm^{-1}. Also, the comparison with *cis*-HNSO requires that the 1321 cm^{-1} absorption be the SO stretch. But whereas the SO stretch in *cis*-HNSO is by far its most intense absorption, the 1321 cm^{-1} absorption is one of the weakest in the spectrum of molecule A. Similarly it is not possible to make meaningful assignments of the four low frequency absorptions to the molecule *trans*-HNSO.

A careful examination of the frequency, the intensity, and the isotopic shifts of each absorption is necessary. The absorption at 3519.8 cm^{-1} must be either an HN or HO stretch. HS stretches are always much lower (~2600 cm^{-1}) and even HN stretches are seldom this high. On substitution with ^{15}N, the mode shows almost no shift, thus demonstrating that it is an HO rather than an HN stretch.

The absorption at 1320.8 cm^{-1} may be a multiply bonded SO, SN, or NO stretch or possibly a hydrogen bend. The deuterium shift of 1.8 cm^{-1} removes the possibility of a hydrogen bend and the ^{15}N shift of 26.5 cm^{-1} eliminates an SO stretch. The possibility that it is either a low energy NO stretch or a high energy SN stretch still remains. However, it is generally found that NO stretches are very intense because of the large contribution made by this polar bond to the overall dipole moment of the molecule. Because S and N have similar electronegativities, their bonds are less polar and usually give lower intensities. Since the 1320.8 cm^{-1} absorption has a low intensity compared with the other absorptions of molecule A it is assigned to an SN stretch. By comparison, for the molecule FSN the stretching frequency of the SN triple bond is 1372 cm^{-1} (6). Thus molecule A seems to have an SN triple bond.

The next peak is at 991.8 cm^{-1}. It has a shift of only 0.7 cm^{-1} on ^{15}N substitution which suggests that the mode does not involve much nitrogen displacement. The absorption is in the appropriate region for a hydrogen bending mode but since it is not observed on deuterium substitution nothing definite can be said at this stage.

The 673.9 cm^{-1} absorption, the most intense

†f_τ = 0.0854 aJ.

in the spectrum of molecule A, shows little ^{15}N or D shift (0.6 and 2.6 cm^{-1} respectively). These small shifts eliminate all possibilities except an SO stretch. This assignment fits the intensity observation for a polar SO bond would be expected to give an intense stretching absorption. As well, it is in the frequency range expected for an SO single bond stretch.

The next peak, 417.5 cm^{-1}, has medium intensity. It shows a large D shift of 92.3 cm^{-1} but a small ^{15}N shift of 1.0 cm^{-1}. This large D shift requires a large hydrogen movement on vibration and for the frequency to be this low, it can only be a torsional type of mode.

The remaining peak is very weak and is not observed in the D experiments because of the small quantities of sample. However, its low frequency and the medium ^{15}N shift of 6 cm^{-1} suggest assignment to a bending vibration involving a nitrogen atom.

The above discussion shows that the molecule possesses an HO bond, an SO single bond, and an SN triple bond. Molecule A must be HOSN. The assignments discussed above are given along with the frequencies in Table 1. Unfortunately, this data alone does not allow for the choice of the *cis*, *trans*, or out of plane configuration.

Normal Coordinate Analysis

Based upon comparisons with similar molecules the structure of HOSN was approximated with the following parameters (4): r_{HO} = 0.96 Å, r_{OS} = 1.62 Å, r_{SN} = 1.46 Å, α_{HOS} = 100°, and α_{OSN} = 115°. The choice of dihedral angle is very important. If the molecule is planar the torsional coordinate is of a different symmetry than the other coordinates and thus will not mix with the OSN bend which is of similar energy. In the nonplanar case the mixing of these internal coordinates will result in complicated normal coordinates and a more difficult calculation.

Accordingly, using the above structure attempts were made to fit the observed frequencies to *cis*, *trans*, and 90° out of plane molecules. In all models the four high energy modes could be well fit. However, in the out of plane molecule the fit to the 417.5 and 374 cm^{-1} absorptions had large errors without a torsion – OSN bend interaction constant while with this constant the least squares iteration would not converge. These results appear to rule out a nonplanar molecule. This is not surprising since isoelectronic molecules such as HONO and HNSO are all planar. In both the *cis* and *trans* planar models convergence and good fit could be obtained. The best source of comparison between the two is the torsional mode. Since it is the only out of plane mode of the molecule, isotopic substitution results in as good a comparison as it does for diatomic molecules. Table 2 gives the observed and best calculated frequencies for the torsional mode using *cis* and *trans* forms of HOSN. Assuming that errors in the structure have not resulted in bad G matrix elements, the fit is better for the *cis* isomer. For this reason it is felt that the molecule is *cis*-HOSN. Some further evidence favoring the *cis* structure is presented in part II of this paper.

Table 3 gives the force constants and their least squares estimated errors for *cis*-HOSN and

Table 4 gives the calculated frequencies and differences from observed frequencies for the various isotopes. The p.e.d. and resulting assignments are given in Table 5.

In these calculations the HO and DO force constants were fitted separately while the constraint that the DOS bend constant was 1.03 times the HOS bend constant was used. Both of these conditions were used to account for differences in anharmonicity. The latter constraint was needed because the DOS bending absorption was not observed so insufficient data

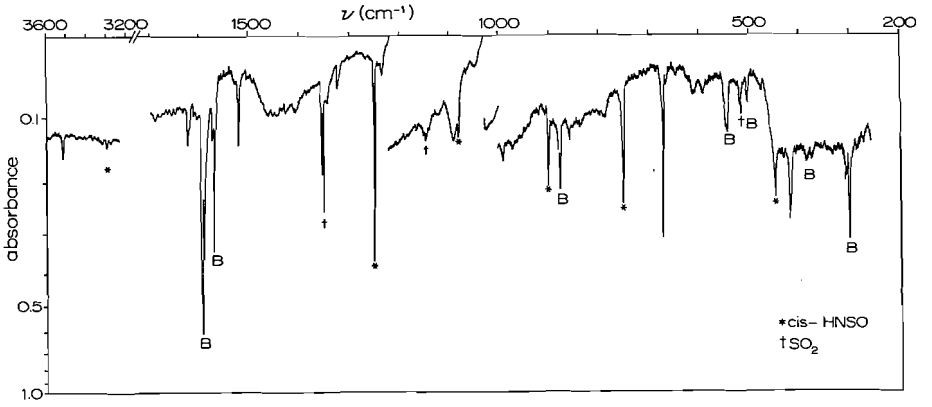

FIG. 3. Spectrum following the 42 min Hg lamp photolysis of *cis*-HNSO in argon (M/R = 400).

was available to calculate f_{DOS}. It was also found that an HOS bend – OS stretch interaction constant was necessary to obtain a good fit of the 991.8 and 673.9 cm^{-1} absorptions. Therefore eight constants were calculated from 16 observed frequencies.

Thermodynamic Functions

The availability of a complete set of frequencies allowed the calculation of the thermodynamic functions S, C_p, $-(G - H_0)/T$, and $(H - H_0)/T$. The principal moments of inertia were calculated from the approximated structure for *cis*-HOSN. These moments and the thermodynamic functions from 100 to 1500 K are given in Table 6.

Discussion

In Fig. 2 a weak absorption can be seen at 1342 cm^{-1}. It is assigned to the overtone of the SO stretching fundamental of *cis*-HOSN ($2\nu_{SO}$ = 1348 cm^{-1}). For this absorption to be seen the overtone must be in Fermi resonance with the SN stretching fundamental at 1321 cm^{-1}.

In the photolysis of isocyanic acid, HNCO, in a matrix, Jacox and Milligan (7) observed the formation of HOCN. This reaction is similar to the one suggested above, *i.e.* HNSO → HOSN, and thus provides additional support for the identification of molecule A as *cis*-HOSN.

Molecule B

Identification

Figure 3 shows the sample seen in Fig. 2 following a further 41 min photolysis with the mercury lamp. The peaks between 1500 and 1600 cm^{-1} have gained considerable intensity while those belonging to *cis*-HNSO and *cis*-HOSN have decreased. Several absorptions at lower frequencies have also grown. By careful study of these absorptions at intermediate photolysis times and in particular by looking at Fig. 1 it is seen that the 1523 and 790 cm^{-1} absorptions belong to a separate species which is discussed later. The remaining absorptions, which all follow curve B, are listed for all isotopes in Table 1.

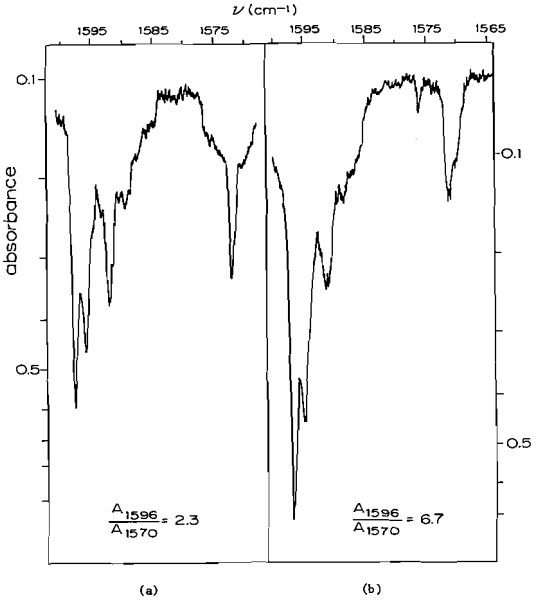

FIG. 4. The 1596 and 1570 cm^{-1} absorptions: (*a*) Hg lamp photolysis; (*b*) hydrogen resonance lamp photolysis with spray on.

The problem of at least two absorptions near 1600 cm^{-1} must first be resolved, for it would not

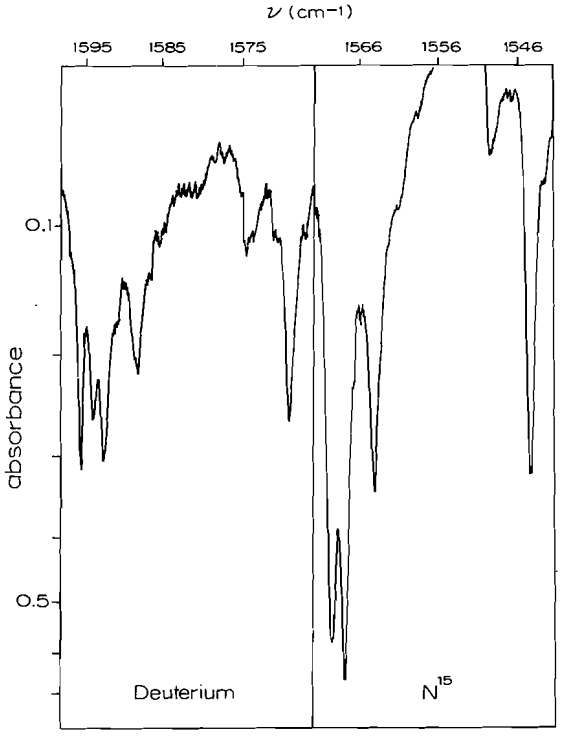

FIG. 5. Spectra of the NO stretching region for DSNO and HS^{15}NO.

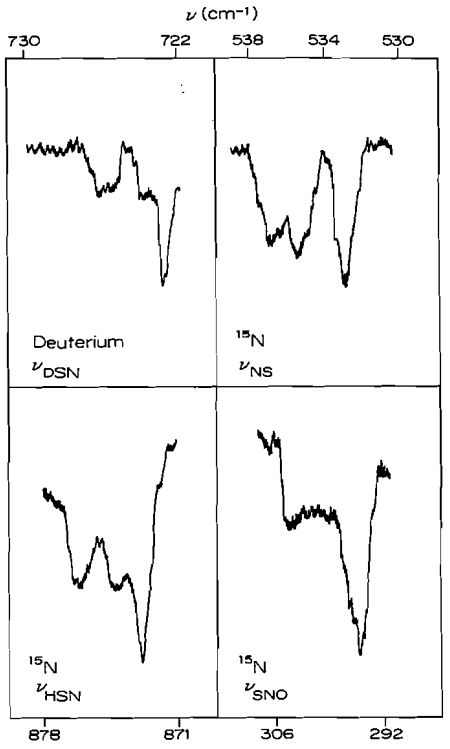

FIG. 6. The high resolution spectra of several *trans*-HSNO absorptions showing the complex splitting.

be expected that one molecule, isolated in a matrix and containing only an H, an S, an N, and an O atom, could give two absorptions in this region. Not surprisingly, a comparison of the two spectra of products produced by mercury lamp photolysis after isolation and by hydrogen resonance lamp photolysis during spray on (Fig. 4) shows that 1597 and 1571 cm^{-1} belong to different absorbers. Figures 4 and 5, showing these absorptions under high resolution for the various isotopes, demonstrate their complexity. These spectra also show that although peak heights suggest similar intensities, integrated intensities of the 1597 cm^{-1} multiplet are always much greater than those of the 1571 cm^{-1} multiplet.

The remaining absorptions of molecule B are weak and broad. High resolution of some of those absorptions in experiments where enough intensity was obtained to give good spectra show that they possess complex splitting similar to that of the 1597 cm^{-1} peak, principally a triplet structure and splittings of 3 to 10 cm^{-1} (Fig. 6). Excluding peaks labeled very, very weak in Table 1, all absorptions except 500 cm^{-1} definitely show this similarity with 1597 cm^{-1}. Unfortunately low intensity of the 500 cm^{-1} absorption made high resolution spectra unobtainable. Further, as was pointed out above, the 1597 cm^{-1} peak is much more intense than the 1571 cm^{-1} peak so that one might expect to see absorptions associated with it long before those associated with 1571 cm^{-1}. For these reasons, except for the v.v.w. peaks, all the absorptions listed for molecule B in Table 1, including 500 cm^{-1}, will be associated with the 1597 cm^{-1} absorption.

Now that the grouping is established, it is necessary to make the assignments and identification. Both the 1597 and 1571 cm^{-1} absorptions are very intense and show similar shifts of about 2 cm^{-1} on deuteration and 27 cm^{-1} on ^{15}N substitution. The frequencies, intensities, and isotopic shifts are all compatible with doubly bonded NO stretching modes. The next absorption, at 876 cm^{-1} for the common isotopes, shows a large shift of 153 cm^{-1} on deuteration so it must be a hydrogen bend. However, since no other high frequency absorptions are seen, it is felt that besides the NO double bond, no other

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12

For personal use only.

multiple bonds are present in this molecule. For this to be so, sulfur must be divalent and this can only happen if it is bonded to a hydrogen atom. Therefore, since the ^{15}N shift of 3 cm^{-1} requires the involvement of nitrogen in the bend, it must be of an HSN angle. An HSN bend and an NO double bond stretch would require the molecule to be HSNO, either *cis* or *trans*. Again, by comparison with isoelectronic molecules, HSNO is expected to be planar.

Following the *cis–trans* correlations of the similar molecule HONO which has ν_{NO} of 1699 cm^{-1} for the *trans* and 1640 cm^{-1} for the *cis* (8), it is not unlikely that the 1597 cm^{-1} and associated absorptions belong with *trans*-HSNO while the 1571 cm^{-1} absorption belongs to *cis*-HSNO. However, because the remaining peaks associated with 1597 cm^{-1} are very close together, complex normal coordinates are expected making assignments difficult. Even the isotopic shifts are of little help. Therefore, intuitive assignments were made by taking the SNO bend to be the lowest, 298 cm^{-1}, and the NS stretch to be the highest, 542 cm^{-1}, with the torsion at 500 cm^{-1}. These assignments are given in Table 1. It was hoped that the force field calculation might resolve the uncertainty. For *cis*-HSNO the only absorption that can be assigned with any certainty is the 1571.0 cm^{-1} to the NO stretch.

Normal Coordinate Analysis

Although uncertainties in the spectrum of HSNO exist, attempts were made to fit the assignments suggested in Table 1. A structure was approximated with the following parameters obtained by comparison with similar molecules (4): r_{HS} = 1.33 Å, r_{NS} = 1.70 Å, r_{NO} = 1.15 Å, α_{HSN} = 95°, and α_{SNO} = 115°. Fits were attempted for only the *cis* and *trans* planar forms since the similar molecule HONO is known to be planar.

For the *trans* molecule the calculation converged with the use of one interaction constant, f_{HSN-SN}. The HS stretch constant was held fixed since ν_{HS} was not observed, and the value for the DSN bend constant was constrained to 1.03 times the HSN bend constant to account for anharmonicity differences. Thus, six constants were used to fit 14 observed frequencies. The force constants are listed in Table 7. The observed frequencies and calculated frequencies of *trans*-HSNO are given in Table 8. The potential energy distribution and assignments are given in Table 9.

Attempts at fitting a *cis* structure to the same data were unsuccessful even with additional interaction constants. It is felt that this is because the approximated *cis* structure is not compatible with the observed isotopic shifts. This could be as a result of poorly chosen parameters, incorrect or insufficient data, or the inacceptability of the *cis* form. The fact that the *trans* isomer did fit the data suggests the last reason thus supporting the *trans*-HSNO identification.

Discussion

As is discussed above, many of the absorptions assigned to *trans*-HSNO and *cis*-HSNO are not single peaks but complex multiplets. It is most

likely that the multiplets result from matrix splitting. It would not be surprising to find that a reaction involving the complex rearrangement that yields *trans*-HSNO from *cis*-HOSN would also result in local disruptions of the argon lattice and thus the creation of multiple trapping sites.

Molecule C

Identification

On continuing photolysis two more peaks were observed to grow in intensity after the rate of production of HSNO had decreased. This can be seen from a comparison of curves B and C in Fig. 1. However, the greatest intensity for these peaks was observed when the high-energy vacuum u.v. photolysis source was used. The two peaks were in the same positions (1523.0 and 789.7 cm^{-1}) when both HNSO and DNSO were photolyzed and at 1498.1 and 777.6 cm^{-1} when $H^{15}NSO$ was used.

The molecule appears to be a triatomic containing no hydrogen. There are three possibilities: SON, NSO, and SNO. SON is unlikely because the much more electronegative oxygen is not expected to be found in the middle. The 1523.0 cm^{-1} absorption shows an ^{15}N shift of 25 cm^{-1}, compatible with either an NS or NO stretch. However, a frequency this high would not be expected for an NS stretch (*e.g.* the SN triple bond of FSN absorbs at only 1372 cm^{-1} (6)) and it is felt that molecule C is not NSO. On the other hand, the observed frequencies are compatible with the radical SNO.

An NO stretching frequency of 1523.0 cm^{-1} is reasonable and the ^{15}N shift is appropriate. The high intensity observed is consistent with an NO stretch and the low intensity expected for the SN stretch accounts for it not being seen. The frequency of 789.7 cm^{-1} and the ^{15}N shift of

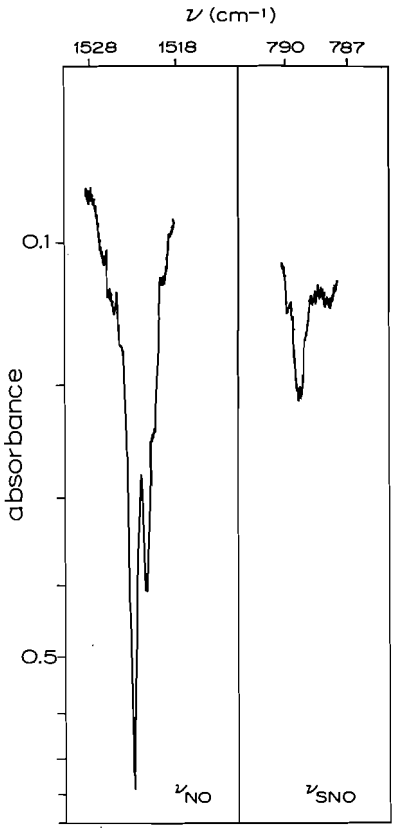

FIG. 7. The NO stretch and SNO bend of SNO.

12 cm^{-1} are reasonable for an SNO bend. Also, since the radical is produced late in the photolysis reaction, it is likely formed from HSNO. Since sulfur–hydrogen bonds are relatively weak, the removal of a hydrogen to give SNO would not be unexpected.

Both the 1523.0 and 789.7 cm^{-1} absorptions are shown in Fig. 7. The doublet character of the 1523.0 cm^{-1} absorption is characteristic of the

splittings of the asymmetric stretching modes of bent triatomics in argon matrices (4). The remaining absorption, probably the symmetric stretch consisting largely of NS stretching coordinate, is expected to be weak and has not been observed. The observed frequencies and assignments for SNO are given in Table 1.

Normal Coordinate Analysis

Because of the lack of an NS stretching frequency, it was not possible to obtain a force field for SNO. Since a great deal of mixing of internal coordinates is expected, not even approximate force constants based on characteristic frequencies would be meaningful.

Discussion

The removal of the hydrogen from *trans*-HSNO to give SNO has resulted in a shift of the NO stretching frequency from 1597 to 1523 cm^{-1}. In a similar system, going from *trans*-HONO to NO_2 shifts this stretch from 1696 to 1618 cm^{-1} (8). The similarity in shift supports the identification of SNO. The lower NO frequency can be explained by the following simple scheme. The removal of the hydrogen atom releases sulfur electron density into the delocalized π orbitals of the new SNO system. The SN bond thus increases in strength. At the same time, electrons that were in localized π bonding orbitals in the double NO bond of *trans*-HSNO now also become delocalized. Since only one of the π orbitals occupied in SNO is a bonding orbital, the NO bond order decreases with an accompanying decrease in vibrational frequency.

II. The Reactions

In part I it was shown that the u.v. photolysis of *cis*-HNSO in argon matrices results in the production of *cis*-HOSN, *cis*-HSNO, *trans*-HSNO, and SNO. The infrared absorptions associated with each of the new species were grouped by observing the rates of growth of the absorption peaks as a function of photolysis times and energies. In this section the growth-rate data will be further discussed. A mechanism for the reactions taking place on photolysis will be proposed on the basis of the kinetic information thus revealed.

Results

Figure 8 is a plot of the absorbance of the 447 cm^{-1} peak of *cis*-HNSO, the 674 cm^{-1} peak of *cis*-HOSN, the 1597 cm^{-1} peak of *trans*-HSNO, and the 1523 cm^{-1} peak of SNO as a function of photolysis time during a single experiment. In the case of the products the most intense absorption in each spectrum was chosen. For ease of presentation the intensities have been normalized to their own maximum absorption within the experiment. Figure 9 is a similar plot of the *cis*-HOSN and *trans*-HSNO absorptions when photolysis was carried out through a Corning 0-54 filter with low wavelength cut-off of 3000 Å. This in effect expanded the time scale by slowing the reactions and allowed a careful study of the product growth rates in the early stages of photolysis.

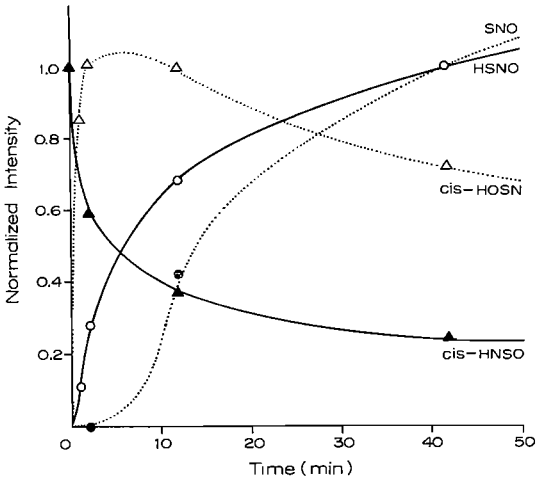

FIG. 8. Intensity of absorptions as a function of photolysis time for $\lambda > 2000$ Å.

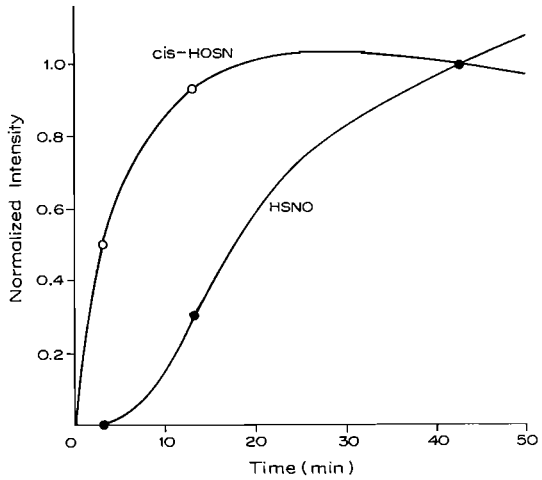

FIG. 9. Intensity of absorptions as a function of photolysis time for $\lambda > 3000$ Å.

Since the molecules involved in the reactions are isolated in the matrix, they cannot react with one another and since the film is very thin ($<10^{-2}$ cm) and the concentration very low ($\sim 5 \times 10^{-3}$ *M*), the amount of the light absorbed should be nearly proportional to the concentration of the absorbing species. Therefore, the reactions should be nearly first order, *i.e.* rate α [reactant]. The following analysis will be based upon this assumption.

Two features of the plots in Figs. 8 and 9 are important: (*1*) *cis*-HOSN is produced very quickly, reaches a maximum concentration, and is then removed by further photolysis; (*2*) both HSNO and SNO show inflection points in their growth curves. The presence of inflection points in concentration *vs.* time plots is an indication of consecutive reactions (9). Since the inflection point in the HSNO curve falls near the maximum in *cis*-HOSN concentration, it must be produced from *cis*-HOSN. Since the inflection point of SNO comes later, it must be produced from HSNO. The reactions can thus be written in the following sequence:

[1] *cis*-HNSO $\rightarrow$ *cis*-HOSN ($\xrightarrow{\text{reaction } 1a}$) $\rightarrow$ *cis*-HSNO ($\xrightarrow{\text{reaction } 1b}$) + *trans*-HSNO $\rightarrow$ SNO ($\xrightarrow{\text{reaction } 1c}$)

Each of these proposed reactions will be discussed.

Reaction 1a

Observations

(*i*) This reaction is very fast on the time scale of matrix photolysis reactions which commonly require several hours.

(*ii*) Only *cis*-HOSN has been observed in this reaction; neither *trans*-HOSN nor the dissociation product NSO appears to be formed by the u.v. photolysis of *cis*-HNSO.

(*iii*) The reaction is very fast with light of $\lambda > 2000$ Å but considerably slower when only light of $\lambda > 3000$ Å is used. The photolysis takes place over a fairly large wavelength region, most of which is under 3000 Å. It has also been observed by Allegretti and Merer (1) that *cis*-HNSO has a strong electronic absorption at 2700 Å which involves excitation of electrons occupying orbitals centered in the NSO part of the molecule.

(*iv*) While *cis*-HNSO is easily synthesized at room temperature using NH_3 and $SOCl_2$, *cis*-HOSN has not been produced and isolated. Glemser and Richert (10) have studied the room temperature hydrolysis of FSN. Although the product was entirely *cis*-HNSO, they proposed the existence of HOSN as a reaction intermediate.

[2] $H_2O + FSN \rightarrow [HF + HOSN] \rightarrow$ *cis*-HNSO

Thus if their mechanism is correct, HOSN is unstable with respect to *cis*-HNSO at room temperature with only a small activation energy. At 4 K in a matrix, however, *cis*-HOSN could be stabilized.

Discussion

From observation *iii* it is certain that the 2700 Å absorption of *cis*-HNSO leads to the formation of *cis*-HOSN. Since no *trans*-HOSN nor NSO is produced, it is most likely that the pathway is not via a dissociation of the hydrogen followed by a recombination at a new site, but rather by a concerted transfer of the hydrogen from the nitrogen to the oxygen. This simple pathway would be favored by the interaction between H and O, very likely present in *cis*-HNSO (11) and possibly enhanced in the excited state, and explain why reaction 1*a* is so fast. This reaction would yield *cis*-HOSN rather than *trans*-HOSN and thus support the earlier identification.

Since *cis*-HNSO is more stable than *cis*-HOSN at room temperature, at 4 K this rearrangement must be prevented by the lack of sufficient thermal energy. However, Fig. 10 shows a plot of the log of the intensity of a *cis*-HNSO absorption *vs.* time. The fact that this plot is not linear, as would be expected for a first-order reaction, suggests a reverse photolytic reaction yielding *cis*-HNSO is occurring as follows:

[3] 
Reaction 1b

Observations

(*i*) The photolysis of *cis*-HOSN yields HSNO.

(*ii*) Within the limits of the measurements it appears that both the *trans* and *cis* isomers of HSNO are produced at the same time but at different rates.

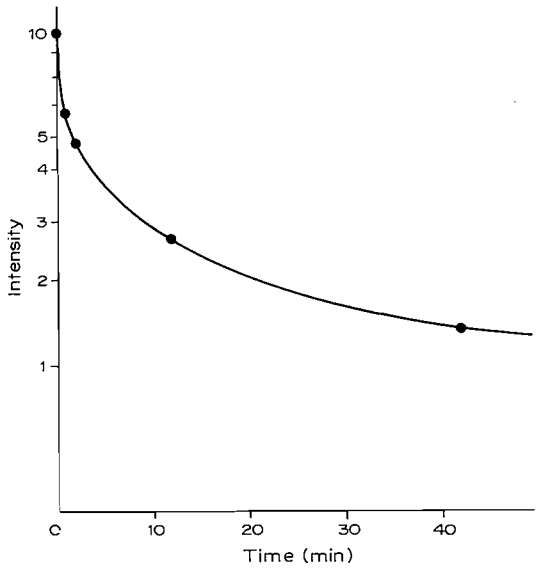

FIG. 10. Disappearance of *cis*-HNSO on photolysis with $\lambda > 2000$ Å.

(*iii*) The rearrangement is complex; two bonds are broken and two new ones are formed.

(*iv*) The i.r. absorptions of *trans*-HSNO show complex matrix splittings possibly from the occupancy of different sites in the matrix.

(*v*) No OSN resulting from the mercury lamp photolysis of *cis*-HOSN has been observed nor have the diatomic fragments HO and SN been observed in any experiments.

(*vi*) The OS force constant of *cis*-HOSN, 2.97 aJ/Å^2, indicates an OS single bond. With a probable bond energy of 60–70 kcal/mol, this is the weakest bond in the molecule.

(*vii*) The use of light of $\lambda > 3000$ Å for photolysis results in slower reactions. However, the maximum amount of *cis*-HOSN produced was much less with $\lambda > 3000$ Å than with $\lambda > 2000$ Å. This suggests that reaction 1*a* was slowed more by the use of the filter than was reaction 1*b*.

(*viii*) The use of vacuum u.v. photolysis with simultaneous spray on increases the ratio of *cis*-HSNO to *trans*-HSNO.

(*ix*) Attempts to carry out the photolysis of *cis*-HNSO in a nitrogen matrix failed. Although reaction 1*a* proceeded without complication, the further photolysis resulted in the complete disappearance of all i.r. absorptions (those of *cis*-HNSO and those of *cis*-HOSN) without the appearance of any new absorptions. Identical results were obtained in three separate experiments. However, data was not sufficient to hazard an explanation.

Discussion

From observation *vii* it appears that an electronic transition of *cis*-HOSN centered in the wavelength region just below 3000 Å results in its photolysis to give *cis*- and *trans*-HSNO. The reaction is complex; observation *iii* suggests several steps and observations *v* and *vi* show that the initial step is probably the rupture of the SO bond rather than the HO bond. It is felt that in the matrix cage the two fragments, unable to separate (a fact attested to by the absence of OH and NS i.r. absorptions), would recombine to give both *cis*- and *trans*-HSNO and possibly *cis*-HOSN and *cis*-HNSO as well. Since *cis*- and *trans*-HSNO would be produced simultaneously, the requirement of observation *ii* would be met.

[4] *cis*-HOSN → [HO + SN] → HSNO, HOSN, HNSO

The increase in *cis* to *trans* ratio when vacuum u.v. photolysis with simultaneous spray on is used, observation *viii*, could be due either to the greater light energy or to the photolysis, as a result of this technique, of more loosely trapped molecules in the not yet completely cooled surface layer. Either reason could feasibly lead to a new ratio.

Reaction 1c

The third reaction of the sequence is

$$\text{[5]} \qquad \text{HSNO} \xrightarrow{h\nu} \cdot\text{SNO} + \text{H}$$

The HS bond is probably of the order of 80 kcal/mol and so is weak enough to be broken with radiation from a mercury lamp leaving the hydrogen atom with sufficient kinetic energy to break from the matrix cage. This type of diffusion reaction is often found in matrix photolysis and is usually slow, accounting for the relatively slow production of SNO. When vacuum u.v. photolysis with simultaneous spray on is used, more energy is available for the diffusion process, and more SNO is observed. On low energy photolysis ($\lambda > 3000$ Å) very little SNO is observed; few H atoms have sufficient kinetic energy to escape the cage.

Conclusions

In part I the identification of *cis*-HOSN, *cis*-HSNO, *trans*-HSNO, and SNO resulting from the photolysis of *cis*-HNSO in argon matrices

The Photolysis of Matrix Isolated *cis*-Thionylimide. 2. The Identification and Infrared Spectra of *trans*-HNSO and NSO

PETER O. TCHIR AND RICHARD D. SPRATLEY

Department of Chemistry, University of British Columbia, Vancouver, British Columbia V6T 1W5

Received December 3, 1974

PETER O. TCHIR and RICHARD D. SPRATLEY. Can. J. Chem. **53**, 2331 (1975).

It is shown that the low energy ($\lambda > 3000$ Å) photolysis of *cis*-HNSO in an argon matrix leads to formation of *trans*-HNSO. Four i.r. absorptions are observed and assigned for *trans*-HNSO and an approximate partial force field is calculated using data from isotopic substitutions. A comparison is made of the i.r. spectra of *cis*- and *trans*-HNSO using the intramolecular hydrogen bond of the *cis* form as a basis for explanation of the differences. Photolysis of *cis*-HNSO in argon matrices using vacuum u.v. light (1216 Å) has resulted in a single i.r. absorption at 1195 cm^{-1} which has been assigned to the radical, NSO.

PETER O. TCHIR et RICHARD D. SPRATLEY. Can. J. Chem. **53**, 2331 (1975).

On a montré que la photolyse à faible énergie ($\lambda > 3000$ Å) du HNSO *cis* dans une matrice d'argon conduit à la formation du HNSO *trans*. Quatre absorptions i.r. sont observées et attribuées au HNSO *trans*. On a calculé un champ de force partiel, approximatif, en utilisant les résultats des remplacements isotopiques. On a fait une comparaison des spectres i.r. du HNSO *cis* et *trans*. On explique les différences en faisant appel à une liaison hydrogène intramoléculaire dans la forme *cis*. La photolyse du HNSO *cis* dans une matrice d'argon par une lampe u.v. à vide (1216 Å), ne donne qu'une seule absorption i.r. à 1195 cm^{-1} que l'on attribue au radical NSO. [Traduit par le journal]

Introduction

In a previous paper (1) we have described the results of the photolysis of *cis*-HNSO in argon matrices using a medium pressure mercury arc as a source; that is with light of $\lambda > 2000$ Å. The products *cis*-HOSN, *trans*-HSNO, *cis*-HSNO, and SNO were identified from their i.r. spectra and, where enough vibrations were observed, approximate force fields were calculated. The kinetics and the mechanisms of the photolysis reactions were discussed.

Investigation of the i.r. absorptions produced on photolysis with high energy (1216 Å) or lower energy ($\lambda > 3000$ Å) light permitted the identification of two further molecules. This paper presents the results of this study.

Experimental

The matrix isolation apparatus (2), the i.r. spectrometer (Perkin-Elmer 225) (2), and the photolysis apparatus (1) have been described previously. To obtain low energy radiation ($\lambda > 3000$ Å) a Corning #0-54 filter was used in conjunction with a 100 W PEK medium pressure mercury lamp (#112-2118). High energy radiation (1216 Å) was obtained from a microwave discharge of a flow of a hydrogen–helium mixture (1:9).

Results

trans-HNSO

Identification

The photolysis of matrix isolated *cis*-HNSO with light limited to wavelengths greater than 3000 Å resulted in a slow reaction yielding numerous absorptions. If a period of this low energy photolysis was followed by higher energy photolysis ($\lambda > 2000$ Å), most of the absorptions grew rapidly (1). However, four of the weak absorption peaks decreased in intensity with this secondary photolysis. Figure 1 shows new peaks produced by the photolysis of *cis*-$H^{14}NSO$ for 45 min using a mercury lamp and filter ($\lambda > 3000$ Å) as well as their disappearance on further photolysis for 5 min without the filter ($\lambda > 2000$ Å). Figure 1 also shows similar results (1 h at $\lambda > 3000$ Å followed by 3 min at $\lambda > 2000$ Å) for ^{15}N substituted *cis*-HNSO. The use of ^{15}N proved that the doublet absorptions at 986 and 881 cm^{-1} in the ^{14}N sample were indeed caused by overlapping absorptions of two separate molecules. On photolysis without filter one component of each doublet decreased in intensity along with the *cis*-HNSO absorptions while the other component increased.

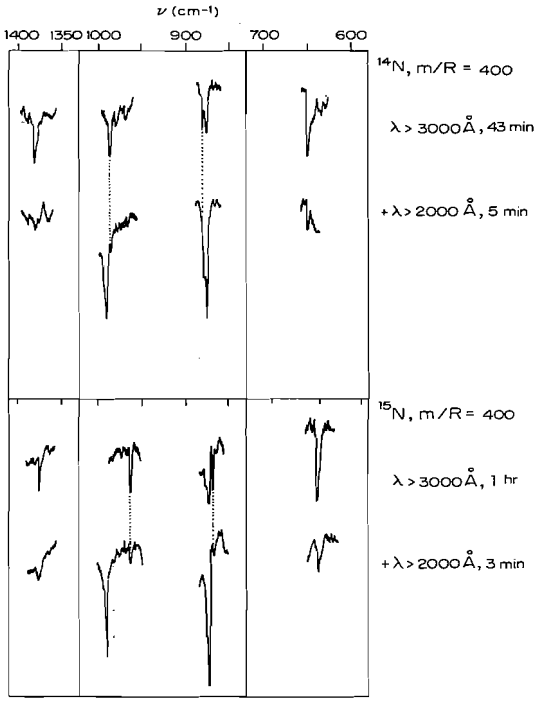

FIG. 1. The four observed absorptions of *trans*-HNSO, production with photolysis using $\lambda > 3000$ Å and disappearance using $\lambda > 2000$ Å.

Table 1 lists the measured frequencies of these four vibrations when starting with *cis*-$H^{14}NSO$, *cis*-$H^{15}NSO$, and *cis*-$D^{14}NSO$. Since four absorptions are observed apparently belonging to a single species, the molecule cannot be triatomic and, since it shows shifts of absorptions on deuterium and ^{15}N substitution, both these atoms are constituents. Since the peaks, though weak, are fairly sharp, it is assumed that isolation was maintained during the reaction. The M/R of 400 had been found to be adequate for the initial isolation of *cis*-HNSO (2). The absorbing species is most likely a simple isomer of *cis*-HNSO and it must be assumed that its two remaining absorptions are not observed due to low intensity or overlapping with intense absorptions.

Consider first the 1382 cm^{-1} absorption. This region suggests either an S=O stretch, an S≡N stretch, or a hydrogen bend. The ^{15}N shift of 3 cm^{-1} is too small for an SN stretch and the deuterium shift of 2 cm^{-1} shows that it is not a hydrogen bend. The peak at 1382 cm^{-1} must then be assigned to an S=O stretch.

TABLE 1. The observed absorption frequencies (cm^{-1}) of *trans*-HNSO in an argon matrix

HNSO	$H^{15}NSO$	DNSO	Assignment
1382	1379	1380	SO stretch
986	963	951	SN stretch
881	868		HNS bend
651	650		Torsion

Numerous vibrations could absorb in the region of the next peak, 986 cm^{-1}. The two major possibilities are an S=N stretch and a hydrogen bend. The ^{15}N shift of 23 cm^{-1} is reasonable for an S=N stretch while the D shift of 13 cm^{-1} is consistent with an S=N stretch but is certainly too small for a hydrogen bending mode. The peak at 986 cm^{-1} is assigned to an S=N stretch.

Similarly, numerous vibrations can occur at 881 cm^{-1} although multiple bonded sulfur, oxygen, and nitrogen stretches would probably be at higher frequency and single bonds involving these atoms would probably be lower; a hydrogen bend is most likely. The ^{15}N shift of 13 cm^{-1} is similar to that found for the HNS bend of *cis*-HNSO (11 cm^{-1}). The fact that this peak was not observed on deuteration suggests both a shift to another region where it could not be seen and a lowering of intensity. These observations are consistent with assignment of the 881 cm^{-1} absorption to a hydrogen bend in which hydrogen is attached to a nitrogen.

The remaining peak, at 651 cm^{-1}, is consistent with a single bond stretch, a bend, or a torsion. The small ^{15}N shift of 1 cm^{-1} suggests that it is not a bending or stretching mode involving nitrogen. Since the molecule has only four atoms, this excludes the majority of the bends and stretches. The disappearance of the peak on deuteration is probably due to a large shift to a different region. For this reason the vibration must be a torsion about a multiple bond involving large hydrogen displacements.

With a weak NS stretch, a strong SO stretch, an HNS bend and a torsion, the molecule is likely an isomer of HNSO, presumably the *trans* planar configuration:

TABLE 2. Comparison of *cis–trans* frequency shifts (cm^{-1}) for HNSO and HONO

HNSO		HONO*	
Mode	Shift	Mode	Shift
ν_{SO}	−133	$\nu_{N=O}$	−61
ν_{SN}	97	ν_{N-O}	62
ν_{HNS}	19	ν_{HON}	97
ν_{τ}	104	ν_{τ}	93

*HONO frequencies from ref. 3.

The assignments are indicated in Table 1; the HN stretch and the NSO bend are not observed. It is assumed that a large mixing will be found for the 986 and 881 cm^{-1} absorptions, thus confusing their assignments. However, from the data available, the given assignments are most probable.

As a further piece of evidence for this identification, a comparison of *cis–trans* frequency shifts for HNSO and the structurally similar molecule HONO is made in Table 2. The HONO values are taken from D'Or and Tarte (3). Since both molecules are planar and might be expected to have similar bonded and nonbonded interactions, it is believed that they should show comparable *cis–trans* shifts. The similarities in the shifts shown in Table 2 are consistent with the assignments made for *trans*-HNSO.

Normal Coordinate Analysis

An attempt to fit a force field to the data in Table 1 has been made using the program of Schachtschneider (4). The structure used was that of *cis*-HNSO (2) taking the dihedral angle at 180°. The shortage of data, especially the absence of any NSO bend frequency, restricts the quality of the calculation. Only two deuterium modes are observed which, due to low intensity, have large uncertainties. However, an approximate force field has been obtained which gives a good frequency fit and reasonable potential energy distribution.

TABLE 3. Force field for *trans*-HNSO with that of *cis*-HNSO included for comparison (2). Constants in units of aJ/coordinate^2

496		491		474	

*Average frequency error = 1.4 cm^{-1} (0.16%).

Because of the absence of the corresponding frequencies, the HN stretch and NSO bend force constants were held fixed to values obtained for *cis*-HNSO (2). The DNS bend force constant was constrained to 1.03 times the HNS bend constant to improve the fit by taking into account the difference in anharmonicity of this coordinate for the two isotopes. As expected, the closeness of the 986 and 881 cm^{-1} absorptions resulted in a

For personal use only.

great deal of mixing so that an HNS bend – NS stretch interaction constant was required. This meant that five force constants were adjusted to fit 10 frequencies. Table 3 lists the force constants and their least squares estimated errors obtained for *trans*-HNSO along with their corresponding values for *cis*-HNSO (2). Table 4 gives the calculated frequencies and differences between calculated and observed frequencies for the various isotopes while the diagonal constant potential energy distribution is given for each vibration of *trans*-$H^{14}NSO$ in Table 5.

Discussion

(*i*) The shift in the SO stretching frequency from 1248.7 to 1382 cm^{-1} in going from *cis*-HNSO to *trans*-HNSO has resulted in a change of SO force constant from 9.0 to 11.6 aJ/Å^2. At the same time the NS stretch constant has decreased from 6.5 to 5.3 aJ/Å^2. This suggests a change in the bonding has occurred, an increase in bonding between sulfur and oxygen and a decrease between sulfur and nitrogen. A possible explanation is the following. In the *cis* form there is a hydrogen bond type interaction between hydrogen and oxygen. This would account for the *cis* isomer's apparent greater stability which results in the absence of any *trans* isomer in the gas phase. This could also be one reason for the larger torsional constant for the *cis* compared to the *trans* isomer (0.225 and 0.193 aJ). This hydrogen bonding shifts some oxygen electron density away from the SO bond, thus weakening the bond and releasing sulfur electrons for greater NS bonding. In the *trans* form the oxygen electrons are released, in the absence of hydrogen bonding, into the SO bond, thus strengthening it. The increased availability of the oxygen electrons attracts sulfur electrons away from the NS bond, which is weakened. This is also reflected in the lower torsional constant and lower NS stretching constant for the trans isomer.

Following the formulation of the above interaction scheme, Cox *et al.* (5) presented a similar explanation to account for the structural differences found in *cis*- and *trans*-HONO. Further work by Finnigan *et al.* (6) has also yielded a similar force constant relationship for *cis* and *trans*-HONO. This interaction has been discussed in the previous paper on the photolysis of *cis*-HNSO to *cis*-HOSN (1).

(*ii*) The lack of an NSO bending mode may result in some error in the force constants which would not be reflected in the least squares error estimates. In *cis*-HNSO (2), some interaction does take place between the HNS bend and the NSO bend so that their interaction constant was important. The other problem is the assignment of the 986 and 881 cm^{-1} absorptions. The assignment of these two modes is reversed in the p.e.d. of the ^{15}N and ^{14}N molecules. However, in the deuterated molecule, where the separation of these modes is much larger and thus their interaction is less, the assignment in Tables 1 and 5 is followed. This is the assignment chosen here for *trans*-HNSO.

(*iii*) Because this molecule is produced with low energy light and because no NSO is observed as a result of this photolysis, it is consistent to postulate a *cis–trans* rotation rather than an HN bond cleavage. The disappearance of this molecule with higher energy photolysis follows the disappearance of *cis*-HNSO. This would, of course, be expected for *trans*-HNSO. An equilibrium between the *cis* and *trans* isomers would account for the limited amount of the *trans* isomer that is produced in these experiments.

The 1195 cm^{-1} Doublet, NSO

Identification

Photolysis with the hydrogen 1216 Å emission during sample deposition resulted in the formation of a new absorption at 1195 cm^{-1}. This feature was broad under low resolution but easily resolved into a doublet. Figure 2 shows this absorption for the photolysis of *cis*-HNSO, *cis*-DNSO, and *cis*-$H^{15}NSO$. Since deuterium substitution did not cause a frequency shift, the molecule probably does not contain hydrogen. Absorption at 1195 cm^{-1} suggests either an SO or NS bond stretch. In fact it has the correct frequency to be the diatomic molecule NS (observed at 1205 cm^{-1} in the gas phase (7)), but the ^{15}N shift of 9.4 cm^{-1} is too small. Since this would be true for any NS stretch, this absorption is probably due to an SO stretching mode.

The remaining evidence for this molecule is that it was only produced with vacuum u.v. photolysis and that following its production, short exposure (2 min) to mercury lamp radiation caused it to disappear. This is shown in Fig. 2*a*. Milligan and Jacox (8) have shown the same

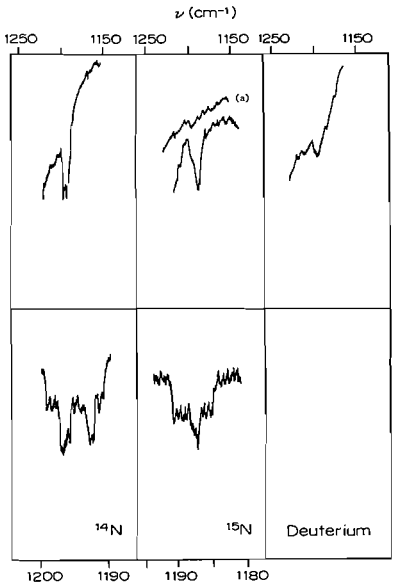

FIG. 2. The SO stretching mode of NSO produced by vacuum u.v. photolysis of *cis*-HNSO. The upper spectra under normal resolution and the lower spectra under high resolution. The spectrum marked (a) shows the disappearance of the absorption following mercury lamp photolysis.

behavior for the 1240 cm^{-1} absorption resulting from the vacuum u.v. photolysis of NO_2 which was assigned to the NO_2^- ion. Therefore, the possibility that the 1190 cm^{-1} band is due to the SNO^- ion with this absorption assigned to the NO stretch has been considered. However, the low ^{15}N shift makes this unlikely since the observed shift is 25 cm^{-1} in the neutral SNO molecule (1).

The most likely alternative is that the absorption is due to the SO stretching mode of NSO which is produced by the photodissociation of *cis*-HNSO. Further photolysis in the 2000–4000 Å region then causes the NSO to rearrange to SNO (1) or to decompose to some other fragments not seen. The other possibility that the species is the NSO^- ion is unlikely because its disappearance would require the appearance of new absorptions due to NSO. This is not observed.

The position of the absorption and the ^{15}N shift are both compatible with assignment to the NSO radical. As in the case of HSNO–SNO and HONO–ONO (1), the removal of the hydrogen from HNSO tends to increase the bonding between the nitrogen and sulfur and weaken that between the sulfur and oxygen, shifting the SO stretching vibration to lower frequency. The resulting proximity of the NS and SO (or symmetric and asymmetric) stretching frequencies would increase the mixing of these coordinates and allow the SO stretch to have a shift of 9.4 cm^{-1} on ^{15}N substitution. The SO stretch would have the greatest intensity so it is reasonable the NS stretch and NSO bend are not observed.

Discussion

The above arguments suggest that NSO is formed on vacuum u.v. photolysis of *cis*-HNSO. This would require breaking the HN bond and giving the hydrogen enough energy to escape the cage, certainly possible with 1216 Å radiation. The loose trapping in the surface layer, the layer in which most of the photolysis occurs in this technique, would also aid in the hydrogen escape and thus favor NSO production. However, since the reaction rate would still be controlled by diffusion of the hydrogen atoms, it would be slow in comparison to the fast rearrangement reaction giving *cis*-HOSN. Subsequent photolysis with lower energy radiation, $\lambda > 2000$ Å, results in the disappearance of NSO and it is suggested on little evidence that SNO is produced. The reaction can be written as follows:

$$[1] \quad \textit{cis}\text{-HNSO} \xrightarrow{\lambda = 1216\,\text{Å}} \text{NSO} \xrightarrow{\lambda > 2000\,\text{Å}} \text{SNO}$$

A reaction in which NSO is removed would further account for the small amount of NSO observed even with hydrogen resonance lamp photolysis. No NSO is observed with only mercury lamp photolysis.

Conclusions

It has thus been shown that the photolysis of matrix isolated *cis*-HNSO with low energy u.v. light leads to the production of *trans*-HNSO while with vacuum u.v. light the NSO radical is formed. These then compliment the previously published results (1) of the photolysis of *cis*-HNSO using a mercury lamp in which *cis*-HOSN, *trans*-HSNO, *cis*-HSNO, and SNO were identified.

D. J. CARLSSON, L. H. GAN, and D. M. WILES. Can. J. Chem. **53**, 2337 (1975).

The 254 nm photolyses of ethanol solutions of four fully aromatic amides were followed by liquid chromatography and u.v. spectroscopy, and quantum yields for the major products calculated. The photolysis of benzanilide was examined in detail at various wavelengths and in several solvents, both in the presence and absence of oxygen. Quantum yields for 2- and 4-aminobenzophenones and products from free radical precursors decreased with increasing solvent polarity and with increasing incident wavelength of irradiation. Oxygen had no affect on aminobenzophenone formation but produced benzoic acid from free radical fragments which escaped the solvent cage. The results are tentatively interpreted in terms of an energy dependent radiationless conversion to a reactive $^1\pi^*$-carbonyl which then cleaves the N—C bond to give caged free radicals, rather than by a concerted, nonradical rearrangement.

D. J. CARLSSON, L. H. GAN et D. M. WILES. Can. J. Chem. **53**, 2337 (1975).

On a suivie par chromatographie liquide et par spectroscopie u.v. les photolyses à 254 nm de solutions éthanoliques de quatre amides entièrement aromatiques. Les rendements quantiques des produits majeurs sont calculés. La photolyse de la benzanilide est examinée en détail à différentes longeurs d'onde et dans plusieurs solvants en présence et en absence d'oxygène. Les rendements quantiques pour les amino-2 et amino-4 benzophénones et les produits provenant des radicaux libres précurseurs, décroissent avec une augmentation de la polarité du solvant et augmentent avec la longueur d'onde d'irradiation. L'oxygène n'affecte pas la formation d'aminobenzophénone, mais produit de l'acide benzoïque à partir des fragments à radicaux libres qui s'échappent de l'enceinte du solvant. Les résultats sont provisoirement interprétés en termes d'une conversion sans émission de radiation, mais dépendant de l'énergie, en une espèce réactive carbonyle-$^1\pi^*$ laquelle scinde la liaison N—C pour donner des radicaux libres piégés dans la cage à solvant, plutôt que par un réarrangement concerté non-radicalaire.

[Traduit par le journal]

Introduction

Some of the photolysis products from benzanilide have been previously reported (1, 2), although product analyses were only made after prolonged irradiation, with no control over second photolysis (1), and few quantitative data were reported (2). A detailed understanding of the photolyses of fully aromatic amides in strongly hydrogen bonding environments is relevant to the photodegradation of commercially important aromatic polyamides such as poly(1,3-phenylene isophthalamide) (3, 4). In this work we report an investigation of the photolyses of the amides **1–4** (which are models for some commercial polymeric materials), with a detailed investigation of the products from **1** and **2** produced by photolysis in the absence and presence of O_2.

Experimental

The amides were prepared from their respective amines and the appropriate acid chlorides in methylene chloride, and recrystallized from ethanol (**1**, **2**, and **3**) or aqueous *N*,*N*-dimethylacetamide (for **4**). Melting points were 162 °C (**1**), 159 °C (**2**), 245 °C (**3**), and 333 °C (**4**) which agreed well with published values (*5a*). Spectroscopic methods and liquid chromatography (l.c.) indicated the absence of impurities. Phenanthridone was prepared by the method of Walls (*5b*). Other standards for l.c. were recrystallized commercial products. Absolute alcohols and spectro grade solvents were used throughout.

Ethanol solutions in 0.1 cm path quartz cells were irradiated with a 254 ± 10 nm beam from a Bausch and Lomb High Intensity Monochrometer (200 W SP mercury lamp). Some irradiations were performed in these cells with an unfiltered, collimated 500 W Osram super pressure mercury lamp. Incident light intensities were measured with a calibrated Eppley thermopile. Ultraviolet changes accompanying irradiation were measured on a Cary 15 spectrometer.

Most irradiation products were separated by high speed l.c. on a Waters Associates ALC 201, equipped with a Varian septumless injector, a Pharmacia u.v. detector (254 nm), and a 5-μ Si-60 Lichrosorb (SiO_2) column (25 cm × 2.1 mm i.d.). The eluent was a 10 vol% ethanol–hexane mixture. At a flow rate of 0.3 ml min^{-1}, retention times (min) were 2.4 (solvent front), 3.8 (benzene), 4.1 (ethyl benzoate), 5.5 (2-aminobenzophenone), 6.4 (phenanthridone), 7.5 (aniline), 9.8 (benzanilide), 19.5 (4-aminobenzophenone), and 21.0 (benzamide). The retention times for the methyl analogs of the compounds listed above were identical to those of the unsubstituted compounds. Benzoic acid did not elute from the Lichrosorb column and was estimated by a separate analysis using reverse phase l.c., with a 2 ft C-18 Bondapak column (Water Associates) and elution with an aqueous solution (p*H* 4.0) of 9 wt.% acetonitrile, 0.013 wt.% sodium acetate, and 0.072 wt.% acetic acid. At a flow rate of 0.50 ml min^{-1}, retention times (min) were 1.3 (solvent front, amides, amines, and aminobenzophenones) and 2.6 (benzoic acid). The products separated by l.c. were identified by comparison of retention times with those of standards and by the analysis of fractions collected immediately after the u.v. detector of the chromatograph, using u.v. spectroscopy in semimicro cells and (in the few cases possible) by mass spectrometry.

Emission spectra were recorded on a Farrand MK1 spectrofluorometer, fitted with a xenon arc source, IP 28 photomultiplier, a low temperature attachment, and fixed speed light chopper. Samples were dissolved in EPA (ethyl ether – isopentane – ethanol in 5:5:2 ratio by volume). Excitation and emission band widths were set at 5 nm. Spectra at 77 K were measured on 1 cm path quartz cells.

Results

Ultraviolet irradiation at 254 ± 10 nm of **1**, **2**, or **3** in O_2-free ethanol solutions (evacuated, or under N_2) resulted in the u.v. absorption changes shown in Fig. 1, with sharp isosbestic points, except in the case of **3**. Separations of the photolysis products from **1** by l.c. showed that 2- and 4-aminobenzophenones and aniline accounted for 90–100% of the photolyzed **1** (Fig. 2). Small l.c. peaks eluted with the retention times expected for benzene and ethyl benzoate but could not be further characterized (very weak u.v. absorptions and too volatile for concentration and mass spectrometry). Reverse phase l.c. indicated the absence of benzoic acid (<10% of **1** photolyzed; low sensitivity because of low molar extinction coefficient (ε) at the detector wavelength).

Quantum yields for product formation and amide loss calculated from the l.c. data for **1**, are shown in Table 1. Only 2- and 4-aminobenzophenones contribute to the u.v. absorption changes above 330 nm (Fig. 1*a*), so that yields of these products can also be calculated from their overlapping spectra (ε_{375} 5.70 × 10^3 and ε_{335} 2.5 × 10^3 for 2-aminobenzophenone and ε_{375} 4.48 × 10^3 and ε_{335} 1.71 × 10^4 M^{-1} cm^{-1} for 4-aminobenzophenone in ethanol). These u.v. changes (at <10% conversion) were also used to calculate quantum yield values as listed in Table 1. Quantum yields for the consumption of **1** (up to 10% conversion) were also calculated from u.v. changes at its 265 nm absorption maximum (ε 1.25 × 10^4 M^{-1} cm^{-1}) and are in good agreement with values calculated from the l.c. analyses (Table 1). This agreement is consistent with the small absorption expected at 265 nm from the products (all have ε values at 265 nm below that of **1**).

The u.v. changes for **2** (Fig. 1*b*) are consistent with the formation of only the 2-aminobenzophenone product (absorption maximum ~385 nm) with no 4-amino detectable (absorption maximum ~340 nm) and this was confirmed by l.c. Quantum yields (Φ) calculated from l.c. and u.v. data for the photolysis of **2** are shown in Table 1. Values for 2-amino-5-methylbenzophenone were calculated from u.v. data using the ε value of unsubstituted 2-aminobenzophenone. The quantum yield for the loss of amide **2** calculated from u.v. changes is significantly less than the value from l.c. data, possibly due to the formation of trace products absorbing strongly at the u.v. maximum of **2** (270 nm).

The u.v. changes for **3** (Fig. 1*c*) are consistent

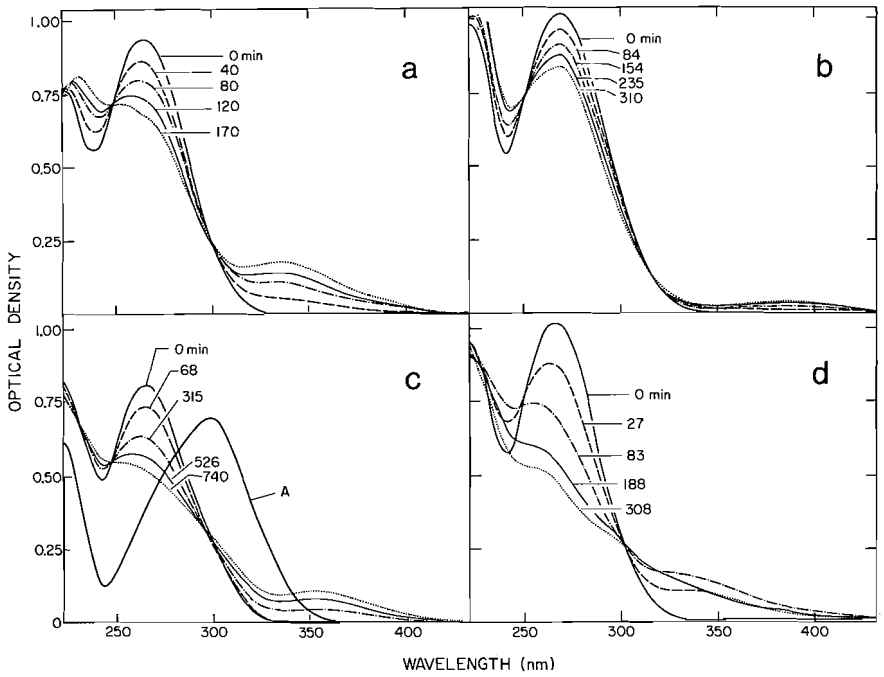

FIG. 1. Ultraviolet absorption changes during the photolysis of amide solutions. Ethanol solutions 24 °C, 254 ± 10 nm irradiation of amide (initial concentration): (*a*) **1** (7.4×10^{-4} *M*); (*b*) **2** (7.5×10^{-4} *M*); (*c*) **3** (3.4×10^{-4} *M*) curve *A*: **4** (3.0×10^{-4} *M*) (after 0 h and 10 h full mercury arc irradiation); (*d*) full mercury arc irradiation of amide **1** (8.3×10^{-4} *M*).

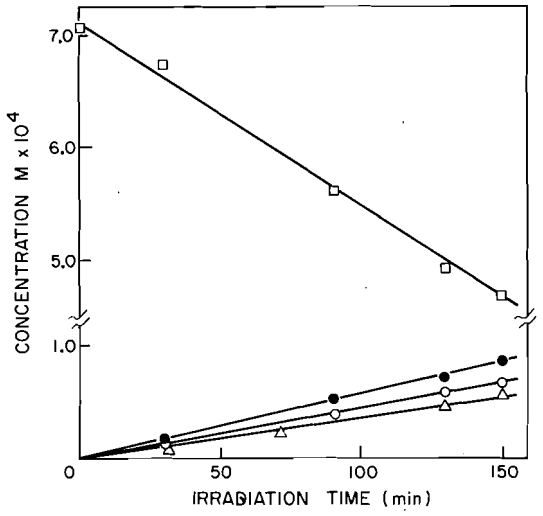

FIG. 2. Photolysis products from benzanilide (**1**). O_2-free ethanol solution, irradiated at 254 ± 10 nm, 24 °C. Incident intensity 6.9×10^{-9} einstein s^{-1} ml^{-1}. Concentrations from l.c. analysis: □, benzanilide; ●, 4-aminobenzophenone; ○, 2-aminobenzophenone; △, aniline.

with 2- and 4-aminobenzophenone formation but the poor isosbestic point probably indicates extensive secondary photolysis of the aminobenzoyl products so that quantum yields cannot be derived from these u.v. data. The general u.v. sensitivity of **3** should, however, be compared with the behavior of **4** where negligible change in u.v. absorption (curve *A*, Fig. 1*c*) was detected after 10 h of 254 nm irradiation.

For all four amides, 254 ± 10 nm irradiation of O_2- or air-saturated ethanol solutions resulted in u.v. changes identical to those found in O_2-free solutions. However, l.c. analysis of solutions of **1** and **2** indicated the presence of only small amounts of benzene, ethyl benzoate, aniline, or *p*-toluidine, but much benzoic acid. Some quantum yields in the presence of O_2 are shown in Table 1. Prolonged (~40 h) irradiation at 254 nm of 2- and 4-aminobenzophenone solutions in ethanol ($\sim 1 \times 10^{-3}$ *M*) resulted in no detectable changes of the u.v. spectra of the solutions.

The effects of incident wavelength and solvent on the photolysis of **1** in the presence of air

2 O_2 free	0.9±0.1 (1.0±0.1)	<0.02 (<0.05)	0.9±0.2	<0.4	2.5±0.3 (1.6±0.1)
2 O_2 saturated	1.0±0.1 (1.0±0.1)	<0.02 (<0.05)	0.12±0.04	0.8±0.2	2.6±0.3 (1.6±0.1)

[a]In absolute ethanol, amide concentration 7×10^{-5}–1×10^{-3} *M*. Incident intensity of 254 ± 10 nm radiation ~7.0×10^{-9} einstein s^{-1} ml^{-1}. Calculated from l.c. analysis data at < 10% conversion; values in parentheses from u.v. changes. Error limits largely determined by scatter in product concentrations from l.c.
[b]For 1, R = H; for 2, R = CH_3.

are shown by the quantum yield data in Table 2. Liquid chromatographic analysis showed that the quantum yields for aniline production from O_2-free solutions were 0.9 (254 nm) and 0.04 (300 nm), respectively.

Irradiation of O_2-saturated or O_2-free ethanol solutions of **1** with the unfiltered mercury arc resulted in the u.v. changes shown in Fig. 1*d*. After ~350 min of irradiation of an air-saturated solution, l.c. analysis indicated the presence of trace amounts of 2- and 4-aminobenzophenones (<3% of **1** photolyzed), some nitrobenzene (~5% of **1** photolyzed), much benzoic acid (~50% of **1** photolyzed) and the absence of aniline. The differences between 254 nm and the full arc irradiations of **1** could result from the photolysis of the primary products. This was confirmed when O_2-saturated and O_2-free ethanol solutions of both 2- and 4-aminobenzophenone were found to photolyze rapidly themselves on full arc irradiation. The initial concentrations of $\sim 1 \times 10^{-3}$ *M* were reduced to virtually zero in ~100 min (4-aminobenzophenone $\Phi \sim 1 \times 10^{-4}$ mol einstein^{-1}) and ~400 min (2-aminobenzophenone $\Phi \sim 2.5 \times 10^{-5}$ mol einstein^{-1}). In each case, O_2-saturated solutions gave 20–25% benzoic acid, with none detectable from O_2-free irradiated solutions. The approximate quantum yields for aminobenzophenone losses were calculated from the known spectral output of the mercury arc and the low Φ values are con-

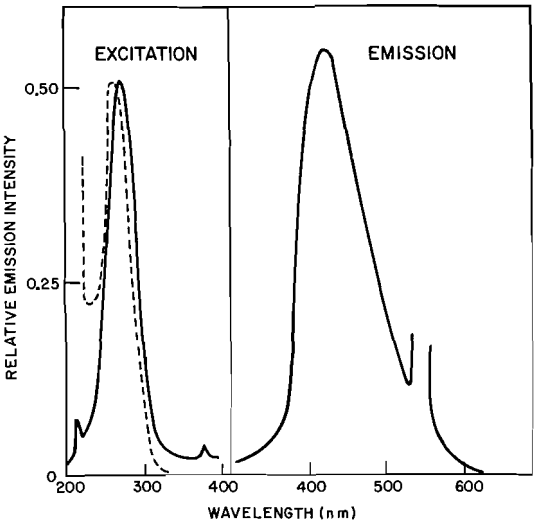

FIG. 3. Emission and excitation spectra of benzanilide. Benzanilide (4.3×10^{-6} *M*) in EPA at 77 K. Excitation spectra measured with emission at 435 nm; — uncorrected; --- corrected. Emission spectrum with excitation at 278 nm.

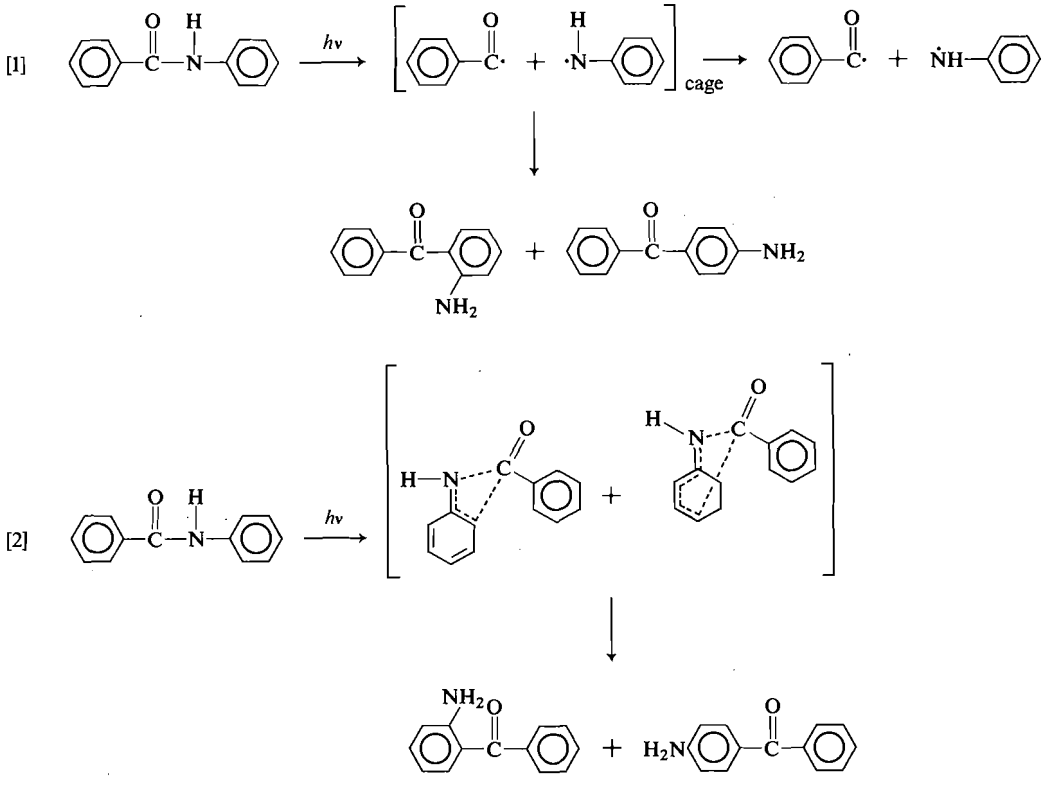
sistent with the reported absence of the reactive n–π* triplet state in ethanolic solutions (6).

Uncorrected emission and excitation spectra from EPA solutions of benzanilide (**1**) are shown in Fig. 3. No fluorescence was detected, and the phosphorescence emission at ~435 nm (half-life $\sim 10^{-3}$ s) was only observed at 77 K. A corrected excitation spectrum was calculated from the observed phosphorescence, the xenon arc intensity distribution, the u.v. absorption of the EPA solution, and the excitation monochromator transmission efficiency at selected wavelengths. This corrected excitation spectrum is shown in Fig. 3 and coincides well with the u.v. absorption spectrum (Fig. 1*a*).

Discussion

N-Aryl amides, aryl esters, and various other carboxylic acid derivatives are known to undergo the photo Fries rearrangement on u.v. irradiation (1, 2, 7, 8). Both a scission to give caged free radicals (reaction 1) and a concerted



Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

rearrangement (reaction 2) have been proposed to lead to the major photo Fries products (8). For aryl esters, the reaction analogous to reaction 1 was suggested by Bellus (7) to proceed from a higher excited state than reaction 2. From flash photolysis data, Humphrey and Roller (9) have suggested that the reaction analogous to [2] proceeds from the aryloxy $^1\pi^*$ state, whereas homolysis [1] results from the $^1\pi^*$-carbonyl state of diaryl carbonates.

The analytical results obtained under our experimental conditions for amides **1** and **2** can be interpreted in terms of processes 1 and possibly also 2. The formation of aniline and *p*-toluidine (in the absence of O_2) and benzoic acid (from O_2-containing solutions, discussed below) can only result from amide homolysis (reaction 1). The importance of aminobenzophenones from the concerted process (as well as cage recombination in reaction 1) cannot be established in the absence of direct evidence for the cyclic intermediate (from, say, flash photolysis). However, the approximate constancy in the ratios of aminobenzophenones to aniline (on average ~1.2:1.0:0.6 for 2-amino–4-amino–aniline) with irradiation wavelength and the roughly constant proportions of 2- and 4-aminobenzophenones (~1.2:1.0, Table 2) at all wavelengths and in all solvents might indicate the predominance of reaction via the homolysis 1, after conversion to the $^1\pi^*$-carbonyl state of amide **1**, as suggested for carbonate photo rearrangement (9). Reaction from the excited singlet has also been suggested by Shizuka and Tanaka (8) for acetanilide photo Fries rearrangement and the absence of an effect of O_2 on the quantum yields for 2- and 4-aminobenzophenones (Table 1) is consistent with this.

Sensitization of amide photoreactions by low concentrations of benzene (a common impurity in ethanol) has been reported (8) but deliberate doping of ethanol solutions of **1** with $5 \times 10^{-3}\,M$ of benzene resulted in identical quantum yields at 254 and 300 nm as benzene 'free' ($< 1 \times 10^{-5}\,M$ by u.v.) solution. This implies that sensitization by trace benzene impurities was negligible under our experimental conditions.

The pronounced wavelength dependence of the product quantum yields for amide **1** shown in Table 2 is apparent in all of the solvents studied, was unaffected by repeated recrystallization of **1**, and so would appear to be genuine. The strong (ε $1.25 \times 10^4\,M^{-1}\,cm^{-1}$) absorption of **1** centered at 265 nm in ethanol is probably a π–$^1\pi^*$ transition localized on a phenyl group, although a small red shift was observed in cyclohexane (λ_{max} 267 nm). By analogy with the carbonate data of Humphrey and Roller (9), the wavelength dependence can be tentatively interpreted in terms of an enhanced radiationless conversion to a reactive $^1\pi^*$-carbonyl state at shorter wavelengths. Relative quantum yields for phosphorescence at 435 nm calculated from the excitation spectrum in Fig. 3 are 0.9 (240 nm), 1.0 (260 nm), 0.7 (280 nm), and 0.3 (310 nm). This wavelength dependence roughly parallels the wavelength dependence of the product quantum yields, although the absence of fluorescence prevents the more meaningful correlation between fluorescence quantum yield and product quantum yields.

Shizuka (10) has previously observed a solvent polarity effect on the photo Fries rearrangement of acetanilide similar to that shown in Table 2 for amide **1**. The drop in quantum yield with increased solvent polarity was then interpreted to indicate the photolysis products resulted from an initial dissociation at the C—N bond into radical fragments.

Our data indicate that O_2 cannot prevent the cage recombination of the primary radicals from process 1 to give aminobenzophenones but can only react with radicals which escape the cage (from reaction 1). In particular, benzoyl radicals will be scavenged by O_2 to give benzoic acid, probably via the u.v.-unstable perbenzoic acid (reaction 3) as suggested by Kan and Furey (2).

[3] $C_6H_5\dot{C}O + O_2 \longrightarrow$

$$C_6H_5C(=O)-OO\cdot \xrightarrow{\text{solvent}} C_6H_5C(=O)-OOH \xrightarrow{h\nu}$$

$$C_6H_5C(=O)-O\cdot \xrightarrow{\text{solvent}} C_6H_5C(=O)-OH$$

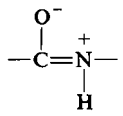
Oxygen has been reported to have no effect on the formation of 2- and 4-aminoacetophenones during the photo Fries rearrangement of acetanilide (8) and no effect on the photo Fries rearrangement in general (7). In the absence of oxygen $C_6H_5\dot{C}O$ radicals which escape the cage

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

probably eliminate CO (11, 12) and give phenyl radicals which will hydrogen abstract from the solvent to give benzene (13). In the presence of dissolved oxygen, aniline and *o*-toluidine are probably destroyed by the attack of peroxy radicals generated from the solvent after benzoyl or anilino radical attack (14).

Previous work has indicated that the prolonged photolysis of **1** with a full mercury arc in N_2-saturated ethanol gave only low yields of the 2- and 4-aminobenzophenones (~14% of each based on the amount of **1** consumed), together with a trace amount of aniline and a higher yield of benzoic acid (27% of **1** consumed) for a 32% loss of **1** (1). This earlier work can be reconciled with our data if trace amounts of O_2 were present in the previous workers' system, so that $C_6H_5\dot{C}O$ interception by O_2 to give benzoic acid as a final product could have occurred, together with extensive secondary photolysis of the aminobenzophenones. Kan and Furey (2) have also attributed benzoic acid formation to the presence of O_2 and have observed products similar to those identified in our work when ethanolic solutions of **1** were irradiated in the presence of O_2. However, only low yields of aminobenzophenones (<10%) were reported by Kan and Furey and the benzamide detected in their work by g.p.c. was not found in our reaction products after 254 nm irradiation in the presence or absence of O_2. Phenanthridone has been detected as the major product from irradiation of benzene solutions of **1** in the presence of iodine (15) but none was detected under our irradiation conditions.

The prevention of photo Fries rearrangement to the 4-position by the presence of a blocking methyl group (amide **2**) has previously been observed with substituted acetanilides (16). The much greater photostability of **4** in comparison to **3** may result from increased conjugation through



forms of the amide groups of **4** as suggested by Belyakov *et al.* (17) promoting greater delocalization of the absorbed u.v. energy. The u.v. absorption maxima of **4** (300 nm) and **3** (267 nm) are consistent with increased conjugation in the all-*para* isomer.

In conclusion, the photolysis of fully aromatic amides under controlled conditions at low conversions has been shown to yield 2- and 4-aminobenzophenone products via a photo Fries rearrangement. Formation of these products is not affected by the presence of O_2, whereas aniline which probably results from free radical scission products is only detected in O_2 free solutions. Only in the presence of O_2, is benzoic acid observed, again presumably from scission products. Meaningful quantum yields for these products are reported for the first time. Previously reported products and product yields (1) are shown to result from extensive secondary photolyses of the primary products in the presence of O_2.

Amide **3**, a model for poly(1,3-phenylene isophthalamide) (Nomex, Du Pont trade name) was found to undergo a similar photo Fries rearrangement to benzanilide (**1**) although extensive secondary photo rearrangement and cleavage of the amino products made quantitative comparison difficult. Amide **4**, a model for poly(1,4-phenylene terephthalamide) (Kevlar B, Du Pont trade name) was found to be extremely photostable. The importance of these results in the unravelling of the photooxidative degradation mechanisms of these two commercially important polymers will be discussed in a future communication (18).

Received March 14, 1975

MONIQUE AUTHIER-MARTIN and ANDRÉ L. BEAUCHAMP. Can. J. Chem. **53**, 2345 (1975).

The title compound belongs to space group $P2_1/c$ with $a = 23.99(1)$, $b = 4.245(2)$, $c = 25.98(1)$ Å, $\beta = 117.58(7)°$, and $Z = 8$. The structure was solved by the heavy-atom method and refined by block-diagonal least squares on 2589 independent observed reflections. All non-hydrogen atoms were refined anisotropically and some of the hydrogen atoms were located but their parameters were not refined. The final values of R and R_w were 0.042 and 0.047, respectively.

The two nonequivalent mercury atoms have very similar environments. Two short Hg—Cl bonds (2.34–2.38 Å) at ~165° define a quasi-molecular $HgCl_2$ unit. Overall octahedral coordination is completed with two chloride ions at 2.76–2.84 Å and two chlorine atoms at 3.19–3.26 Å on neighboring $HgCl_2$ quasi-molecules. $HgCl_6$ octahedra share edges to form twofold ribbons in the b direction. This pattern of octahedra is identical with the one reported for β-NH_4HgCl_3. The cations are pairs of N(1)-protonated adenine molecules linked by two N(10)—H(10) . . . N(7) hydrogen bonds and stacked in the b direction. Water molecules act as acceptors in moderately strong hydrogen bonds with acidic protons H(1) and H(9) of adeninium ions. Other generally weaker hydrogen bonds exist between the various parts of the structure.

MONIQUE AUTHIER-MARTIN et ANDRÉ L. BEAUCHAMP. Can. J. Chem. **53**, 2345 (1975).

Le composé cristallise dans le groupe $P2_1/c$ et les paramètres de maille sont: $a = 23.99(1)$, $b = 4.245(2)$, $c = 25.98(1)$ Å, $\beta = 117.58(7)°$ et $Z = 8$. La structure a été résolue par la méthode de l'atome lourd et affinée par moindres carrés (matrice à blocs diagonaux) au moyen de 2589 réflexions observées non-équivalentes. Certains des atomes d'hydrogène ont été repérés sur la carte de Fourier, mais leurs paramètres n'ont pas été affinés. L'affinement anisotrope de tous les autres atomes a été effectué et les valeurs finales de R et R_w sont 0.042 et 0.047 respectivement.

La maille renferme deux atomes de mercure indépendants, non-équivalents ayant des environnements très semblables. Deux liens courts (2.34–2.38 Å) à ~165° l'un de l'autre définissent une quasi-molécule $HgCl_2$. La coordination effective octaédrique du métal comporte en outre deux ions chlorures à 2.76–2.84 Å, ainsi que deux atomes de chlore à 3.19–3.26 Å appartenant à des quasimolécules voisines. Les octaèdres $HgCl_6$ ont des arêtes communes et forment une double chaîne parallèle à l'axe b. La disposition des octaèdres est semblable à celle de la forme β de NH_4HgCl_3. Les cations du composé sont des molécules d'adénine protonées en N(1) et réunies par paires grâce à deux ponts hydrogène N(10)—H(10) . . . N(7). Ces paires d'ions adéninium sont empilées dans la direction de l'axe b. Les molécules d'eau jouent le rôle d'accepteur dans des ponts hydrogène modérément forts avec les protons acides H(1) et H(9) des ions adéninium. Plusieurs autres ponts hydrogène souvent assez faibles existent entre les diverses espèces présentes dans la structure.

Introduction

Adenine or 6-aminopurine (HAd), a constituent of DNA and RNA, is known to react with various metal ions (1). A recent crystallographic work (2) has shown that the ligand is N(7)-coordinated in the zwitterionic complex $(H_2Ad)ZnCl_3$ obtained from dilute hydrochloric acid solutions. We have investigated the reactions of mercuric chloride with the same molecule and isolated under similar conditions the corresponding compound $(H_2Ad)HgCl_3 \cdot 1\frac{1}{2}H_2O$. The structure of this compound is reported in the present paper.

Experimental

Crystal Data

$C_5H_6N_5Cl_3Hg \cdot 1\frac{1}{2}H_2O$ f.w. = 470.12

Monoclinic, space group $P2_1/c$, $a = 23.99(1)$, $b = 4.245(2)$, $c = 25.98(1)$ Å, $\beta = 117.58(7)°$, $V = 2344$ Å^3, $Z = 8$, $D_c = 2.66$ g cm^{-3}, $D_o = 2.57(1)$ g cm^{-3} (flotation in CH_2Br_2–$CHBr_3$ mixture). μ(MoKα) = 126 cm^{-1}; λ(MoK$\bar{\alpha}$) = 0.71068 Å (graphite monochromator).

Preparation

Hot aqueous solutions of adenine (Aldrich Co.) and mercuric chloride are mixed together (molar ratio 1:3) and 0.5 M HCl is added to redissolve the precipitate initially formed. On cooling at room temperature, a colorless precipitate $(HAd)_2Hg_3Cl_6$ is obtained. This com-

pound is dissolved in a warm 1:1 mixture of acetone and 0.1 *M* aqueous HCl. By slow evaporation at room temperature, crystals of the title compound are obtained as very thin needles elongated along the *b* axis. They are stable in air. A crystal of dimensions 0.006 × 0.003 × 0.8 mm was selected for crystallographic work.

Crystallographic Measurements

Space group $P2_1/c$ was established from precession and Weissenberg photographs. Accurate cell parameters and intensity measurements were obtained with a Picker FACS-1 automatic diffractometer. Experimental details are given elsewhere (3). A total of 7470 measurements (standards included) were collected (*hkl*, $hk\bar{l}$, $\bar{h}kl$, and $\bar{h}k\bar{l}$) in a sphere $2\theta \leqslant 46°$. Three standard reflections ($01\bar{5}$, 604, $10\,1\,\bar{3}$) measured every 30 reflections showed maximum fluctuations of ±5% during data collection. Preliminary calculations indicated that the transmission factor varies from 0.93 to 0.96. Therefore, no absorption correction was applied. The data were reduced to two octants (*hkl* and $hk\bar{l}$) by averaging equivalent reflections. All reflections with net intensities $I < 2\sigma(I)$ (3) were considered as unobserved. The reduced set of data consisted of 2589 observed and 689 unobserved reflections.

Resolution of the Structure

Two general positions of group $P2_1/c$ are needed to hold the eight mercury atoms of the unit cell. The coordinates of the two nonequivalent mercury atoms were calculated from a three-dimensional Patterson map. At this stage, particular values (0 or ½) for the *y* coordinates introduced pseudo-mirrors in the unit cell. The starting model corresponded to group $A2/m$ and the phases of all reflections with $k + l \neq 2n$ were undefined. On the Fourier map calculated with phased reflections only, all six independent chlorine atoms were easily recognized, but they were very close to the pseudo-mirrors and the pseudo-symmetry problem still remained. The structure was solved as follows: the *x* and *z* coordinates and isotropic temperature factors *U* for the two mercury and the six chlorine atoms were first refined by full-matrix least squares using the reflections originally phased. The *y* coordinate of Hg(1) was then shifted arbitrarily from 0 to 0.001, which fixed the origin along the *b* axis. Parameters *x*, *y*, *z*, and *U* were refined for Hg(1) and Hg(2) in the first step, then for all mercury and chlorine atoms. Refinement converged to $R = \Sigma||F_o| - |F_c||/\Sigma|F_o| = 0.243$. The carbon, nitrogen, and oxygen atoms were located on the next Fourier map. Isotropic refinement of all nonhydrogen atoms converged to $R = 0.069$.

Anisotropic refinement was carried out by block-diagonal least squares. The real and imaginary contributions to anomalous dispersion were included for mercury and chlorine (4). Hydrogen atoms attached to N(1), C(2), C(8), and N(9) were fixed at the calculated positions on both adenine rings (C—H or N—H distances of 0.92 Å).

TABLE 1. Refined fractional coordinates (× 10^4) and anisotropic temperature factors (× 10^4), t.f. = exp $\{-(U_{11}a^{*2}h^2 + U_{22}b^{*2}k^2 + U_{33}c^{*2}l^2 + 2U_{12}a^*b^*hk + 2U_{13}a^*c^*hl + 2U_{23}b^*c^*kl)\}$

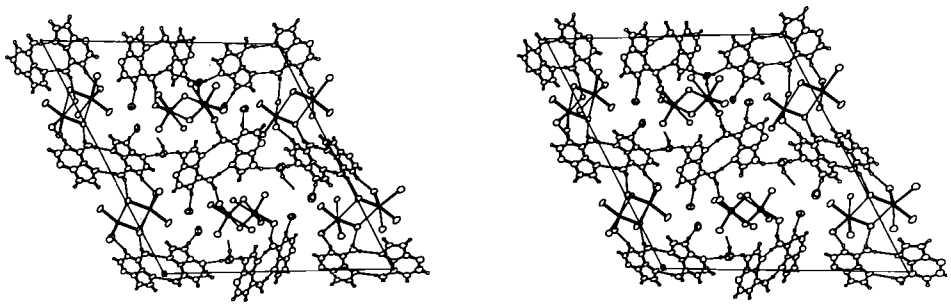

FIG. 1. Projection of the unit cell down the *b* axis. The origin is represented by a black dot. The *a* axis is horizontal, *c* is vertical, and *b* is perpendicular to the drawing, away from the reader. The mercury atoms are dark spheres surrounded with octahedra of chlorine atoms. The oxygen atoms of the water molecules are represented by darker ellipsoids.

Constant temperature factors (6 Å^2) were used. Their coordinates were not varied, but the shifts on the corresponding carbon or nitrogen coordinates were applied to the hydrogen atoms as well. Anisotropic refinement of mercury and chlorine atoms and isotropic refinement of the remaining nonhydrogen atoms reduced R to 0.048. At the latest stage of the refinement, individual weights $w = 1/\sigma_F^2$ (5) were applied to each reflection. Anisotropic refinement of all nonhydrogen atoms converged to $R = 0.042$ and $R_w = \{\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2\}^{1/2} = 0.047$ (observed reflections only). On the final difference–Fourier map, four peaks of ± 0.8 e/Å^3 were found close to mercury, all other peaks were lower than ± 0.5 e/Å^3. The refined parameters are given in Table 1 and the list of structure factors is available upon request.[1] The form factors used in this work were those of Cromer and Waber (6) and the computer programs utilized are listed elsewhere (7).

The final difference–Fourier map was examined for possible locations of the missing hydrogen atoms. Electron density of 0.4 e/Å^3 was found close to the positions expected for amino hydrogens, assuming that the groups are planar and in the plane of the adeninium rings. For water molecules, the lines joining oxygen to all possible hydrogen-bond acceptors were carefully searched. Peaks were found at reasonable positions around O(2), but no indications concerning the hydrogen atoms of O(1) and O(3) could be found. The list of hydrogen coordinates is included in the unpublished material.[1]

Results and Discussion

Figure 1 shows a projection of the unit cell down the *b* axis. The compound is a salt and adenine is not coordinated to mercury. The anionic part $(HgCl_3)_x^{x-}$ is located in layers parallel to the *ab* plane at $c = \frac{1}{4}$ and $\frac{3}{4}$. Other layers at $c = 0$ and $\frac{1}{2}$ contain adeninium cations linked in pairs via hydrogen bonding.

[1]The structure factor table and the list of hydrogen coordinates are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

Mercury Coordination

The two independent mercury atoms are similarly surrounded with chlorine atoms. Bond lengths and angles are given in Fig. 2. Two short bonds (2.34–2.38 Å) at 164–165° define a quasi-molecular $HgCl_2$ unit. An approximate octahedron is completed with two chloride ions at 2.76–2.84 Å and two longer contacts (3.19–3.26 Å) involving chlorine atoms of neighboring quasi-molecules. Other examples of this type of coordination are found in mercury chemistry (8), for instance, in double salts $MHgCl_3$ and M_2HgCl_4, where M is an alkali cation or NH_4^+. $HgCl_6$ octahedra share edges to form twofold ribbons in the direction of the *b* axis. The pattern of octahedra observed here is similar to the one reported for the β form of NH_4HgCl_3 (9).

Adeninium Ions

The two independent adeninium ions have identical geometries within experimental errors (Fig. 3). In both cases, pairs of symmetrically equivalent ions are linked by hydrogen bonding and the middle of the dimer is an inversion center of the unit cell. Mean planes were calculated through the carbon and nitrogen atoms of either individual adeninium ions or ion pairs. Deviations from planarity were within 2σ (or 0.030 Å), except for amino nitrogen N(10)′, where the distance (0.049(14) Å) is more significant.

Although the presence of the extra proton on N(1) (and N(1)′) could not be ascertained from the electron density map, protonation of that position is highly probable for the following reasons: (*i*) protons were found on N(1) in adeninium hydrochloride (10) and nucleosides containing protonated 9-adenylyl groups (11, 12). It is also the protonation site in $(H_2Ad)ZnCl_3$ (2), $(9\text{-}CH_3HAd)PtCl_3$ (13), $(H_2Ad)_2Cu_3Cl_8$ ·

*e.s.d. = 0.5°; ^{e} = $x, 1\frac{1}{2} - y, \frac{1}{2} + z$; ^{f} = $1 - x, 1 - y, 1 - z$; ^{g} = $x, \frac{1}{2} - y, \frac{1}{2} + z$; ^{h} = $x, \frac{1}{2} - y, -\frac{1}{2} + z$; ^{j} = $1 - x, -y, 1 - z$; ^{k} = $x, -1 + y, z$.

angles have been recalculated including more recent data (16). No significant conclusions can be drawn from bond lengths, because the two forms are expected to show maximum differences of 0.02 Å, which correspond to 1σ in the present structure. Bond angles appear to be more sensitive to protonation. Differences attaining 4.3°, or 2.5 times our standard deviations, are expected. Comparison of the angles in the pyrimidine rings (Table 2) shows a better agreement with the N(1)-protonated pattern.

Hydrogen Bonds

Ion-pairing in the adeninium dimers involves two N(10)—H(10) . . . N(7) (or N(10)′—H(10)′ . . . N(7)′) hydrogen bonds (Fig. 3). Identical pairing has been observed in other adenine derivatives (15, 17) with similar N . . . N distances. The second amino hydrogens interact more weakly with chlorine atoms at 3.21 Å (N(10) . . . Cl(5)) and 3.47 Å (N(10)′—Cl(3)).

One of the acidic ring protons, H(1)′, forms a moderately strong bond to Cl(1) (N . . . Cl = 3.11 Å), whereas the other three (H(1), H(9), and H(9)′) bind to oxygen atoms of water molecules with N . . . O distances in the range 2.76–2.84 Å. Hydration of acidic protons appears to be the primary purpose of the water molecules, since their own hydrogen atoms are not involved in strong hydrogen bonding. For instance, the hydrogen atoms attached to O(2) (Fig. 4) interact only moderately with Cl(2) (O . . . Cl = 3.19 Å) and very weakly with N(3)′(3.04 Å). The pattern around O(1) and O(3) was not determined unambiguously (Fig. 4 and Table 3). In spite of the small N(9)′—O(1)—Cl(6) angle (76°), the short Cl(6) . . . O(1) distance (3.13 Å) is probably indicative of some hydrogen bonding. Two Cl(2)

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

atoms at 3.28 and 3.29 Å from O(1) may be considered as potential acceptors. Around O(3), which is already attached to H(1), two reasonable pairs of acceptors are found: O(1) and Cl(6)^k or O(1)^k and Cl(6). On the basis of the oxygen-acceptor distances and the set of angles, both alternatives are equally reasonable. Such pairs of hydrogen-bonding patterns might result in crystal disorder, which would explain that no indications concerning those particular hydrogen atoms could be obtained from the electron density map.

Conclusion

In contrast with zinc and platinum, for which N(7)-coordination has been obs rved in (9-CH_3HAd)$PtCl_3$ (13) and (H_2Ad)$ZnCl_3$ (2), mercury is surrounded only with chlorine atoms and adenine is not coordinated in the present compound. This effect undoubtedly results from a delicate balance of many factors, but it is worth mentioning that such a behavior is consistent with the relative affinities of the above metals for chlorine and nitrogen donors respectively, as measured from solution equilibrium data. Formation constants β_{Cl} and β_{NH_3} are available for the $[MCl_4]^{2-}$ and $[M(NH_3)_4]^{2+}$ complexes (18, 19) and the displacement reaction

$$[MCl_4]^{2-} + 4NH_3 \rightleftarrows [M(NH_3)_4]^{2+} + 4Cl^-$$

can be characterized by the ratio $K = \beta_{NH_3}/\beta_{Cl}$:Pt = 10^{18}, Zn = 10^9, Hg = 10^3. The lower value of K for mercury suggests that replacement of chlorine by a nitrogen donor may not take place even though it does occur with platinum and zinc under similar conditions. This does not imply that mercury is devoid of affinity for adenine. A lower chloride concentration (to shift the above equilibrium to the right) and a higher pH (to deprotonate adenine) should favor interactions with mercury. Work on such systems is now in progress in this laboratory.

The Use of the *n*-Propylammonium and *n*-Butylammonium Salts of *d*-10-Camphorsulfonic Acid for the Calibration of Spectropolarimeters: Circular Dichrometer Calibration[1]

MICHAEL F. GILLEN AND ROSS E. WILLIAMS[2]

Division of Biological Sciences, National Research Council of Canada, Ottawa, Canada K1A 0R6

Received February 28, 1975

MICHAEL F. GILLEN and ROSS E. WILLIAMS. Can. J. Chem. 53, 2351 (1975).

Two, easily prepared, nondeliquescent salts of *d*-10-camphorsulfonic acid have been used to improve the precision of the calibration of circular dichrometers.

MICHAEL F. GILLEN et ROSS E. WILLIAMS. Can. J. Chem. 53, 2351 (1975).

Deux sels non-déliquescents de l'acide *d*-camphresulfonique-10 qui sont facilement préparés ont été employés pour améliorer la précision de la calibration des dichromètres circulaires.

For personal use only.

During a recent attempt at calibrating a circular dichrometer it became obvious to us that one of the compounds used for calibration purposes, namely *d*-10-camphorsulfonic acid, was troublesome to purify and, in addition, did not possess adequate criteria of chemical purity. These two inadequacies were mainly associated with the compound's extremely deliquescent nature. Indeed, the disparity of ellipticities quoted for use in calibration of circular dichrometers is likely, in part, a reflection of this deliquescent behavior (1–5). In this communication we wish to describe two easily prepared, water-soluble, derivatives of *d*-10-camphorsulfonic acid, both of which overcome the problems associated with use of the parent compound as a chiroptical standard.

We reasoned that the deliquescent nature of *d*-10-camphorsulfonic acid (CSA) was associated with the presence of the free sulfonic acid group in the compound and that neutralization of this group by salt formation would stop the deliquescent behavior. Preparation of the ammonium salt of CSA gave a water-soluble derivative in which the deliquescent behavior was blocked. However, the melting point of this derivative was high (m.p. 245–246 °C) and considerable decomposition, as evidenced by browning, occurred upon melting, thus making a satisfactory determination of chemical purity by this method difficult. Since it might be expected that the crystal lattice forces in simple alkyl ammonium salts of CSA would be less than those in the unsubstituted ammonium salt, such derivatives ought to have lower melting points and might also melt without decomposition. In fact, we found that the *n*-propyl- and *n*-butylammonium salts of CSA possessed desirably low melting points without apparent decomposition (*i.e.* no browning). In addition, these derivatives exhibited no observable deliquescent behavior. These salts were easily formed in high yield as follows. A slight molar excess of the *n*-alkylamine was mixed with crystallized (ethyl acetate), dehydrated CSA in methanol solution at room temperature. Evaporation of the methanol gave the desired salt which was crystallized from methanol solution (2 ml per gram) by the addition of at least 10 volumes of diethyl ether. The physical constants, which may be used for characterization of the compounds, are found in Table 1.

So that the compounds might be used to calibrate circular dichrometers comparison of their chiroptical properties was made with a sample of purified, but hydrated, CSA. This CSA sample was obtained as follows. CSA (Aldrich Chemical Co., U.S.A. Lot No. 121137) was crystallized twice from ethyl acetate. The resulting material was dried and dehydrated (80 °C, high vacuum, 24 h) and then analyzed 4.5 min after removal from the vacuum oven. The analytical figures (Table 1) implied that a slight impurity was present in the sample. If, however, these figures were corrected for the experimentally determined weight gain (assumed to be H_2O) which occurred during the 4.5 min before analysis they indicated that the compound was chemically pure (Table 1). This CSA sample was

TABLE 1. Physical constants[a] and elemental analyses of *d*-10-camphorsulfonic acid (CSA), its *n*-propylammonium (*n*-PrA CSA), and *n*-butylammonium (*n*-BuA CSA) salts

Compound	Melting point (uncorr.)[b] (°C)	$[\alpha]_D^{25}$ (deg)[d]	Elemental analysis (%)[h] Calculated C	H	N	S	Found C	H	N	S
CSA (anhydrous)	—	+22.4[e]	51.70	6.94	—	13.80	51.72[j]	7.03[j]	—	—
CSA (hydrated)	198–199 (dec.) (G)[c]	+20.8(*c*, 4.30)[f]	48.18[i]	7.23[i]	—	12.86[i]	48.20	7.40	—	12.74
n-PrA CSA	140.5–141.5(F-J,G)	+17.6(*c*, 5.00)[g]	53.58	8.65	4.81	11.00	53.37	8.73	4.66	10.79
n-BuA CSA	140.0–141.0(F-J,G)	+16.6(*c*, 5.29)[g]	55.05	8.91	4.59	10.50	54.93	8.92	4.58	10.32

[a]Physical constants were determined to be constant after three crystallizations and drying at 60 °C under high vacuum.
[b]Determined either on a heated block (Fisher–Johns apparatus) (F-J) or in an open capillary tube (Gallenkamp apparatus) (G).
[c]Literature m.p. 195–197 °C (dec.) (2), 191–192 °C (dec.) (7).
[d]Determined on a sucrose-calibrated Perkin-Elmer spectropolarimeter, model 141, (1 dm tube). Error limits, expressed as standard deviations and calculated from three measurements were ±0.1 deg in all cases.
[e]Calculated from the hydrate assuming 7.3% by weight H_2O. Literature values, $[\alpha]_D^{25}$ 22.1 (*c* 1.0, H_2O) (2), 21.63 (T = 16 °C), 23.11 (T = 20 °C) (6).
[f]Measurements made in glass distilled water.
[g]Measurements made in 0.1 *N* HCl and unaffected by twofold dilution.
[h]Microanalyses were performed by M. Hector Seguin of these laboratories. Combustion analyses for C, H, and N were done on a Perkin-Elmer analyzer, model 240 and for S by a standard oxygen flask technique (8).
[i]Calculated assuming CSA contained 7.3% H_2O by weight.
[j]Calculated from the analytical figures (C, 51.47; H, 7.08) determined 4.5 min after removal of a dehydrated sample from the vacuum oven. Account has been taken of the observed water gain during this time (0.49% by weight).

TABLE 2. Chiroptical properties of *d*-10-camphorsulfonic acid (CSA), its *n*-propylammonium (*n*-PrA CSA), and *n*-butylammonium (*n*-BuA CSA) salts

Compound	Ellipticity $[\theta]_\lambda$[a,b] (deg-cm^2 per decimole)	
	$[\theta]_{290}$	$[\theta]_{192}$
CSA (hydrated)	7400 ± 150[c]	14 400 ± 700[c]
CSA (anhydrous)	7900 ± 200[c,d]	15 500 ± 800[c,d]
n-PrA CSA	8180 ± 50	15 800 ± 300
n-BuA CSA	8130 ± 60	15 800 ± 300

[a]All measurements were made on a Cary-Varian circular dichrometer, model 61, serial No. 53. Sample concentrations in glass distilled water were either 75 mg (approximately) per 50.0 ml (solution A) or 3 mg (approximately) per 50.0 ml (solution B). Solution B was derived from solution A by volumetric dilution (10.0 → 250 ml). In all cases commercially available volumetric glassware was used without recalibration. Quartz cells (Pyrocell Manufacturing Co., U.S.A.) of the following path lengths were used: 1.0 cm path (350–235 nm, solution A; 250–185 nm, solution B), 10.0 cm path (350–235 nm, solution B), 2.0 cm (350–185 nm, solution B). The temperature of all solutions was maintained by a thermostat at 27.0 ± 0.1 °C. The ellipticities given are either an average of at least three determinations (CSA hydrate) or an average of at least eight determinations (CSA salts). For conversion of molar ellipticity value to $E_L - E_R$ (cm^{-1} M^{-1}) divide values given by 3298 (5).

[b]Error limits given are standard deviations.

[c]Literature values: At 290 nm: 8219 (2); 7775 (3); 7840 (5); 7300 (estimated) (4); 7260 (1). At 192 nm: 15 620 (3); 14 500 (estimated.(4).

[d]Calculated from the CSA (hydrate) values assuming 7.3% H_2O by weight.

then allowed to hydrate for 3 d at room temperature (60% relative humidity) until no further weight gain was observed. Reanalysis (Table 1) showed that the water gain (7.3% by weight) was identical to that found previously (3). The chiroptical properties of this hydrated sample were measured and corrected for this water content (Table 2). The corrected ellipticity (290 mm) was similar to that which had been reported for two samples of pure, dry CSA (3, 5). The chiroptical properties of the two pure, dry *n*-alkylammonium salts of CSA were then measured under conditions identical to those used to measure the chiroptical properties of CSA. The results are reported in Table 2. At both 290 and 192 nm the specific ellipticities, [θ], were similar to those associated with the pure parent compound. The ellipticities at 290 nm were also apparently unaffected by 25-fold dilution of the sample since the results obtained using either sample A (1.0 cm path) or sample B (10 cm path) (see footnote [a], Table 2) were the same within the determined experimental error (0.6%). It should also be noted that an improvement in the precision with which the ellipticities can be determined results from the use of these nondeliquescent salts, perhaps because errors associated with the determination of sample purity now no longer play an important part in the determination of the overall experimental error associated with the measurements.

Finally, the ease of preparation, purification and characterization of the *n*-propyl- and *n*-butylammonium salts of *d*-10-camphorsulfonic acid, the retention by these salts of the desirable aqueous solubility and chiroptical properties associated with the parent compound and the improvement in the precision of circular dichrometer calibrations resulting from the use of these salts all suggest that either of these two nondeliquescent salts could profitably be used in place of the parent compound for the calibration of circular dichrometers.

Models for the Role of Magnesium in Enzymic Catalysis. The Effect of Magnesium Ion on the General Base Catalyzed Enolization of Methyl Acetonylphosphonate

RONALD KLUGER AND ANDREA WAYDA

Department of Chemistry, University of Toronto, Toronto, Ontario M5S 1A1

Received January 21, 1975

RONALD KLUGER and ANDREA WAYDA. Can. J. Chem. 53, 2354 (1975).

Magnesium ion promotes the general base catalyzed iodination of methyl acetonylphosphonate (MAP), **1**. Although the concentration of complex is very low, definite rate constant increases are observed. The rate determining step under the experimental conditions is enolization of the substrate. Acceleration is observed for both charged and uncharged bases. The acceleration for charged bases is about twice that for uncharged bases. Thus, electrostatic effects are probably important but not exclusive. It is proposed that efficient catalysis by magnesium ion in related enzymic reactions is a consequence of the ability of magnesium ion to form a stabilizing complex with an enolate-like transition state and to reduce repulsive electrostatic interactions of the substrate and a catalytic base.

RONALD KLUGER et ANDREA WAYDA. Can. J. Chem. 53, 2354 (1975).

L'ion de magnésium favorise la catalyse basique de l'iodation de l'acétonylphosphonate de méthyle (MAP), **1**. Bien que la concentration en complexe soit très faible, on note un accroissement non négligeable de la constante de vitesse. Dans ces conditions expérimentales l'étape déterminante est l'énolisation du substrat. On observe une accélération pour les bases chargées et neutres. Pour les bases chargées, l'accélération est environ le double de celle des bases neutres. Ainsi les effets électrostatiques sont probablement importants, mais ne sont pas les seuls. L'efficacité de l'ion magnésium comme catalyseur dans les réactions de type enzymatique serait une conséquence de la capacité de cet ion à former un complexe stabilisateur dans un état de transition du genre énolate et à réduire les intéractions électrostatiques répulsives du substrat et d'une base catalytique. [Traduit par le journal]

Magnesium ion plays an important role in many reactions subject to enzymic catalysis. A major function for magnesium ion in most enzymic reactions involves facilitation of electrophilic addition reactions, such as phosphorylation (1). Another important but less well-known function proposed for magnesium ion involves the stabilization of transition states leading to formation of enolate ions in condensation (2) and decarboxylation processes (3). To obtain an understanding of the mechanism whereby metal ions facilitate the latter class of reactions, we have examined several factors controlling the effectiveness of magnesium ion catalysis of enolization.

It has been demonstrated that magnesium ion promotes the enolization of acetonylphosphonate in reactions involving anionic bases (4). A mechanism similar to that proposed by Pedersen (5), for the copper-catalyzed bromination of ethyl acetoacetate, stabilization of an incipient enolate as the metal ion complex, was considered likely. Similar conclusions for related systems have been reached by Schellenberger's group (6), who have studied the enolization of α-keto acids and recently by Cox (7), who investigated the reactions of 2-acetylpyridine. All these studies have concentrated on catalysis of enolization by metal ions in reactions involving a few anionic bases.

It has been suggested (4) that the function of the metal ion can be divided further into two general functions, Lewis acid or 'superacid' catalysis where the metal ion fulfills a role analogous to that of a proton in specific acid catalysis, and electrostatic attraction (or minimization of repulsions) of a charged base to the substrate. Since catalytic bases of enzymes are not necessarily anionic and enolates result from decarboxylation without base, it would be of interest to determine in one magnesium-catalyzed system the relative magnitudes of these two roles.

Since the enolization of ketones catalyzed by uncharged bases has been studied thoroughly (8), we have incorporated methods used in those studies to evaluate the role of magnesium ion in catalysis of the enolization of methyl acetonyl-

1

phosphonate (MAP), **1** (9). This compound binds magnesium definitely but weakly ($K_{assoc} \sim 1\ M^{-1}$(10)) as is necessary for efficient turnover in a catalytic system. The rather low affinity of MAP for magnesium ion keeps the effective concentration of active complex low. Fortunately, since MAP is a very weak base (pK_a of methyl acetonylphosphonic acid $\simeq 2$(10)), its reactions are not complicated by bimolecular reactions of the substrate as are the enolization reactions of the unesterified compound, acetonylphosphonate (4).

Experimental

Materials

Methyl acetonylphosphonate (sodium salt) was prepared and carefully purified as previously reported (10). All pyridine bases were obtained from the Aldrich Chemical Company or from Eastman Kodak and were distilled. Purity of the bases was determined by gas chromatography (Hewlett Packard 5700 dual flame ionization detector, 0.125 in. × 12 ft diisodecyl phthalate on bentone 34, 140°).

Other organic chemicals and all inorganic materials were of highest commercial purity grades and were used as obtained. Water was redistilled in a Corning redistillation unit. Magnesium ion was introduced as anhydrous magnesium sulfate.

Methods

The p*H* of solutions was estimated by means of a Radiometer PHM26 expanded scale meter with a GK202C electrode. No correction for ionic strength was made in p*H* measurements. Sodium ion corrections were made for alkaline solutions as described in the Radiometer manual. Solutions of sodium hydroxide and hydrogen chloride were used to adjust the p*H* of reaction mixtures.

Enolization of MAP was followed by a procedure based on the methods of Feather and Gold (11) and of Bell and co-workers (12–14). An equilibrium of triiodide with iodine and iodide was established using potassium iodide and iodine. This minimizes formation of complexes between iodine and pyridines (11, 14), taking advantage of the rapid equilibrium attained between iodide, iodine, and triiodide. We found that in our experiments addition of iodide, at the ionic strength of our experiments, did not affect the observed rate of iodine consumption. Therefore sufficient iodine was readily available from the equilibrium system. The iodine–triiodide solution was always added fresh to the solution of base followed by addition of substrate. This avoided the complication that could be introduced due to the tendency of alkyl pyridines to undergo halogenation slowly (14). In no instance was a background rate due to reaction of iodine with pyridine base observed before substrate was added. Initial rate conditions were used (*vide infra*), minimizing the possibility of our results being affected by back reactions of the products.

A solution of p*H*-adjusted base was combined with an iodine–triiodide solution. The solution was brought to reaction temperature (35°) in a cuvette held in the well-thermostatted cell compartment of a Unicam SP1800A spectrophotometer equipped with a program controller and an AR25 recorder. Absorbance at 353 nm due to triiodide in the iodine–triiodide equilibrium was recorded. Sodium MAP in a small volume of water was then added. The rate of decrease of absorbance was determined to be zero order in iodine in all cases since changing iodine concentration by factors of 1.5 and 0.5 in both the slowest and fastest reactions studied gave no change in observed rate. This assures that iodination occurs after rate-determining enolization (see Results). Furthermore, the requirement that the reaction be first order in substrate and first order in base was also confirmed by doubling those concentrations and observing that initial rates of iodine disappearance doubled.

We employed initial rate procedures since we used rather dilute solutions of substrate, due to its high reactivity. Bell and Barnes (14) discuss the high reactivity of the related β-keto acid, acetonylsulfonate, and the similar requirement for dilute solutions in that system. The reaction therefore becomes pseudo first order in substrate, requiring either that first order methods or initial rate methods be used. The initial rate approximation (15) appears to be most convenient for our system and is valid since the substrate is pure as well as highly reactive. Our results are reproducible within ±5% using this method.

Typically, a run without magnesium ion was done with 2.75 ml of 0.1 *M* potassium iodide, 0.1 ml of p*H*-adjusted base (1 *M* and less), 0.1 ml of 1.56×10^{-3} *M* iodine in 0.3 *M* potassium iodide solution, and 0.05 ml of 0.05 *M* MAP. A run with magnesium ion contained typically 2.65 ml of 0.1 *M* potassium iodide, 0.1 ml p*H*-adjusted base (1 *M* and less), 0.1 ml 1.56×10^{-3} *M* iodine in 0.3 *M* potassium iodide, 0.1 ml of 0.5 *M* magnesium sulfate, and 0.05 ml of 0.05 *M* MAP. The p*H* was checked at the end of each run. A brief induction period (11) was observed in a few cases before a linear decrease in absorbance at 353 nm was recorded; the initial linear portion (between absorbances of 1.5 and 1.0) was used to obtain initial rates. A slightly hyperbolic decay followed until nearly all iodine was depleted (below 0.1 o.d.) at which time, a sharply curved plot occurred presumably due to the low iodine concentration causing iodination of the enol to become rate limiting. The observed zero-order rate constant for the initial linear portion of triiodide disappearance was obtained from the equation (11):

$$[1] \qquad k_{obs} = (\Delta A/\Delta t)(1/\varepsilon_{353}) = \Delta[I_2]/\Delta t = \mathrm{d}[I_2]/\mathrm{d}t$$

A value of ε_{353} 26 768 was used. Beer's law was found to be obeyed in this system although it has been shown to be disobeyed in cases involving iodination of nitropropanes (16). Apparent second-order rate constants for the reaction of MAP with bases both in the presence and absence of magnesium were determined from eq. 2. The second-

For personal use only.

[2] $k_2 = k_{obs}/[\text{free base}][\text{MAP}]$

order rate constants, corrected for reaction due to catalysis by water and by hydroxide, were use to generate Brønsted plots. General acid catalyzed processes were assumed to be insignificant under our experimental conditions based on findings for other β-keto acid derivatives (8). Water and hydroxide catalysis rate constants were determined by taking results obtained at a particular pH over a range of four buffer concentrations and extrapolating the linear plot to the point corresponding to a buffer concentration of zero (17).

In analyzing our data, we have assumed that as in the case of other β-keto acid derivatives (12, 18), only one atom of iodine is added at the 2 position (between carbonyl and ester) and this occurs prior to any significant reaction at the 4 position. We used low concentrations of magnesium ion to avoid complications arising from multiple metal ion binding as found in related systems (19). This precaution, however, also leads to low monomeric concentrations of magnesium–MAP since the affinity of the two species is rather low (10). In addition, we cannot determine what fraction of the stoichiometric complex is in an array that will promote enolization. Therefore we have only considered the effect of magnesium ion on the apparent second-order rate constants for enolization of MAP due to general bases.

Titration of pyridine and picolines in the presence and absence of large amounts of magnesium sulfate gave apparently identical pK_a values at comparable ionic strength (using potassium chloride). Therefore no apparent affinity for pyridines of magnesium ion is considered. Although acetate binds weakly to magnesium ion, magnesium acetate should account for less than 10% of magnesium present, based on published values of K_{assoc} (20). Whether catalysis is in fact due partially to $MgOAc^+$ or a transition state arising from magnesium and acetate which arrive separately cannot be distinguished by our kinetics and does not affect our use of apparent second-order rate constants.

Results and Discussion

Background Rates

As discussed in the experimental section, a pH–rate profile was determined in order to allow for corrections due to water and hydroxide catalyzed processes. The bases used for the Brønsted plots (to be described) and tris(hydroxymethylamino)methane were used. The data obtained are plotted in Figs. 1 and 2. The rate constants obtained from fitting k(extrapolated) = $k_{OH^-} + k_{H_2O}$ are summarized in Table 1.

Brønsted Plots

Data obtained as described under Methods was used to obtain the Brønsted plot in Fig. 3. Only results for 'well behaved' monofunctional bases (8, 16) are included. Pyridines alkylated in the 2 position show negative deviations from Brønsted plots for enolization (8, 16) due to steric effects and have therefore been omitted

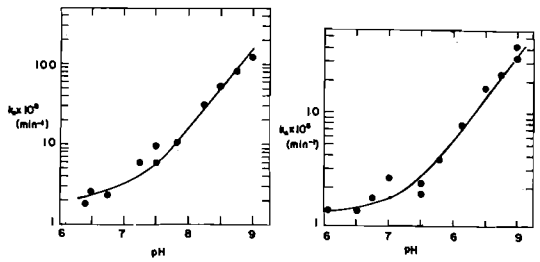

FIG. 1. The pH – rate constant profile for the iodination of (8.3×10^{-4} M) MAP at 35°. Plotted points were obtained from extrapolation to zero buffer of buffer-dependent kinetic data. The curve follows the expression $k_{obs} = k_{H_2O} + k_{OH^-}[OH^-]$ using the appropriate values in Table 1.

FIG. 2. The pH – rate constant profile for the iodination of (8.3×10^{-4} M) MAP in the presence of (1.7×10^{-2} M) magnesium sulfate. Plotted points were obtained by extrapolating buffer dependent results. The curve follows the expression $k_{obs} = k_{H_2O} + k_{OH^-}[OH^-]$ using the appropriate values in Table 1.

TABLE 1. Apparent rate constants for iodination of MAP (8.3×10^{-4} M) at 35°, 0.5 M ionic strength where enolization is rate limiting

$MgSO_4$ (M)	k_{OH^-} ($M^{-1}\,min^{-1}$)	$k_{H_2O} \times 10^6$ (min^{-1})
0.000	40	1

(a study of the steric sensitivity of magnesium ion catalysis is in progress). The plots for k_2 and k_2' (see Kinetic Equations) are nearly parallel (slope ~0.4) through the substituted pyridines. The plot for the reaction in the presence of magnesium ion (k_2') reflects an enhancement of about 1.7 compared to the reaction in the absence of magnesium (k_2). The points for acetate and propionate, the anionic bases tested, show negative deviations from the Brønsted plot of k_2 for the uncharged bases with the anionic substrate, MAP. For the reaction in the presence of magnesium ion, smaller deviations occur (from the Brønsted plot for k_2'). A discussion of these deviations is presented under Acceleration Factors.

Kinetic Equations

We assume that the enhanced rate of enolization of MAP in the present of magnesium ion results from complex formation leading to a lowering of the energy of the transition state for proton removal by a base. It is probable that any stoichiometric complex of magnesium and MAP

TABLE 2. Apparent acceleration due to presence of magnesium ion ($1.7 \times 10^{-2} M$) on rate constant for general base-catalyzed iodination of MAP ($8.3 \times 10^{-4} M$) at 35°

Base	pK*	k_2(no Mg) (M^{-1} min^{-1})	k_2'(+Mg) (M^{-1} min^{-1})	Acceleration k_2'/k_2
Pyridine	5.17	0.17	0.24	1.4
3-Picoline	5.97	0.30	0.43	1.4
4-Picoline	6.02	0.50	0.62	1.3
3,5-Lutidine	6.14	0.47	0.79	1.7
3,4-Lutidine	6.52	0.72	1.21	1.7
Acetate	4.75	0.013	0.043	3.2
Propionate	4.88	0.016	0.053	3.3

*pK_a of conjugate acid.

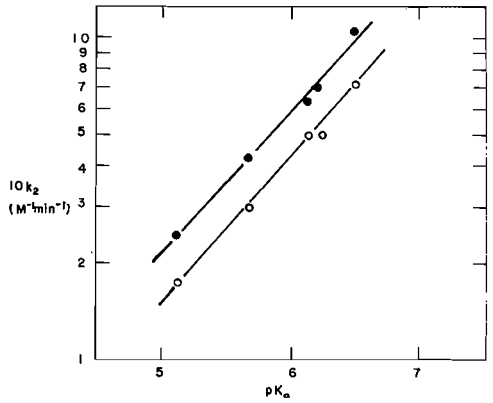

FIG. 3. Base catalysis rate constants (see Table 2) for iodination of MAP in presence (●) and absence (○) of magnesium ion as function of the pK_a of the conjugate acid of the catalytic base. Slopes are approximately 0.4.

will consist of a distribution of species. That component of the stoichiometric array which is catalytically active [(MgMAP$^+$)*] should be related to bulk concentrations by the (unknown) equilibrium constant, K_c (eq. 3),

$$[3] \quad K_c = [(MgMAP^+)^*]/[Mg^{2+}][MAP^-]$$

In the absence of magnesium ion, the system obeys the kinetic scheme of eq. 4, where B is a

$$[4] \quad MAP^- + B \xrightarrow{k_1} MAP^{2-}(\text{enolate}) + BH^+ \xrightarrow{k_0 I_2} MAPI^- + I^-$$

general base. In the presence of magnesium, the reaction of eq. 5 coexists with that of [4].

$$[5] \quad (MAPMg^+)^* + B \xrightarrow{k_1'} MAPMg(\text{enolate}) + BH^+ \xrightarrow[\text{fast}]{k_0' I_2} MAPI^- + I^- + Mg^{2+}$$

Therefore, in general, when rates due to catalysis by water and hydroxide are eliminated:

$$[6] \quad -d[I_2]/dt = k_{obs} = k_1[B][MAP^-] + k_1'[B][(MgMAP^+)^*]$$

$$[7] \quad k_{obs} = (k_1 + k_1'K_c[Mg^{2+}])[B][MAP^-]$$

The acceleration due to magnesium of iodine disappearance is given by eq. 8, the ratio of k_2' and k_2, where k_2' and k_2 result from dividing k_{obs} by [MAP] and [B].

$$[8] \quad \text{Acceleration} = k_2'/k_2 = (k_1 + k_1'K_c[Mg^{2+}])/k_1 = 1 + (k_1'K_c[Mg^{2+}])/k_1$$

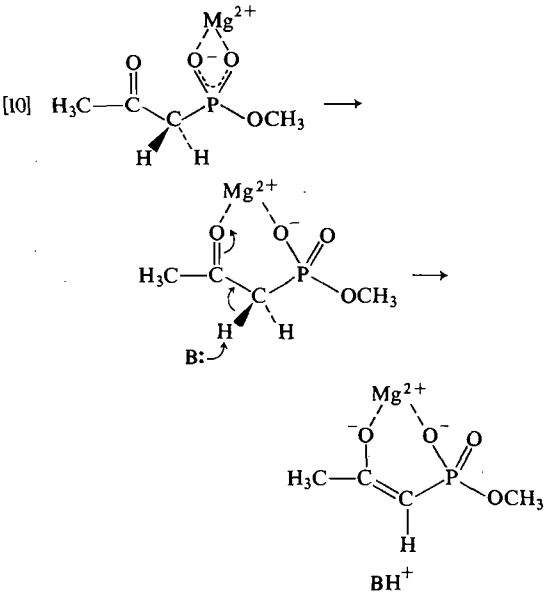
We assume K_c is small since K_{assoc} is small. Therefore $[(MgMAP^+)^*] \ll [MAP^-]$. To observe acceleration, $k_2'/k_2 > 1$; therefore k_1' must be $\gg k_1$. If as an upper limit $K_c = K_{assoc}$, which is about 1 M^{-1} (10), then k_2'/k_2 is about 200 when an acceleration of 3 (see Table 2) is observed under the conditions of our experiments.

Acceleration Factors

Table 2 contains a summary of observed enhancements due to the presence of magnesium ion of rate constants for enolization of MAP (k_2'/k_2) in the presence of basic catalysts. The acceleration observed for anionic bases is about twice that observed for reactions with uncharged bases. This indicates that the electrostatic effect of magnesium ion in this system is separable from the 'Lewis acid' effect (4) which is independent of charge, suggesting the approximate simplified equation for the effect of magnesium:

$$[9] \quad \Delta\Delta G^{\ddagger}_{Mg^{2+}} = \Delta\Delta G^{\ddagger}(\text{electrostatic}) + \Delta\Delta G^{\ddagger}(\text{Lewis acid})$$

In conclusion our results indicate that the base-catalyzed enolization of MAP is enhanced by the addition of magnesium ion whether the catalytic base is charged or uncharged. It is therefore likely that a major function of magnesium ion is analogous to that of a proton in specific acid-catalyzed enolization (21): coordination of the carbonyl group by the metal ion (*vs.* hydrogen bonding to hydronium ion) stabilizes the transition state leading to formation of the enolate. Since it is likely that MAP coordinates initially to magnesium ion principally through the phosphonate functional group (10), catalysis probably results from a minor complex, $(MgMAP^+)^*$ of eqs. 3 and 5, in which bidentate coordination occurs (eq. 10). Mag-



nesium ion also enhances enolization of MAP that is catalyzed by anionic bases by reducing electrostatic repulsions between the base and substrate. The optimal position for magnesium ion in this function is affected by the location of the anionic portion of MAP.

In an enzymic reaction, the site of association of magnesium ion and substrate is affected by forces introduced by the enzymic environment. Therefore, the metal ion can be bound in a position relative to the substrate which is most effective for catalysis, rather than in that which is thermodynamically defined in the absence of enzyme. In the case of an enolization reaction which is catalyzed by an uncharged base such as the histidine residue of a protein, the metal should function most effectively as a Lewis acid if it associates with the carbonyl group of the substrate to stabilize the enolate-like transition state. If the base component is negatively charged, such as the carboxylate moiety of a glutamate or aspartate residue, the optimal site for coordination of a metal ion will depend on the location of charges within the substrate as well as on the location of the potential enolate. Magnesium ion can be particularly effective in both roles because of its high positive charge density. Furthermore, since magnesium ion associates weakly with many substrates in the absence of enzyme (10), the directing effects of the enzymic environment need not operate against large preassociative barriers.

This work was initiated as a continuation of a project begun by R. K. at the University of Chicago under the sponsorship of the National Science Foundation. The work described in this paper was performed at the University of Toronto where support was from unrestricted funds awarded to R. K. by the Alfred P. Sloan Foundation.

An Electron Spin Resonance Study of Some Reactions of Pentafluorosulfuranyl (SF_5)[1]

JOHN CHARLES TAIT[2] AND JAMES ANTHONY HOWARD

Division of Chemistry, National Research Council of Canada, Ottawa, Canada K1A 0R9

Received March 14, 1975

JOHN CHARLES TAIT and JAMES ANTHONY HOWARD. Can. J. Chem. **53**, 2361 (1975).

A kinetic electron spin resonance study of the self-reaction of SF_5 and a spectroscopic and kinetic e.s.r. study of the reaction of SF_5 with 1,1-di-*t*-butylethylene are reported. This radical undergoes self-reaction by a second-order process and the rate constants are given by the Arrhenius equation $\log 2k_1(M^{-1}\,s^{-1}) = (10.3 \pm 0.5) - (1.7 \pm 0.5)/\theta$ where $\theta = 2.303RT$ kcal mol^{-1}. It adds to 1,1-di-*t*-butylethylene to give $(t\text{-Bu})_2\dot{C}CH_2SF_5$ which decomposes by a first-order process with rate constants that obey the expression $\log k_2\,(s^{-1}) = (13 \pm 0.4) - (10 \pm 0.2)/\theta$. Both these rate constants are pertinent to kinetic studies of the photoinduced addition of SF_5Cl to olefins.

JOHN CHARLES TAIT et JAMES ANTHONY HOWARD. Can. J. Chem. **53**, 2361 (1975).

On décrit l'étude cinétique par résonance paraélectronique de l'auto-réaction de SF_5 ainsi que l'étude spectroscopique et cinétique par r.p.e. de la réaction de SF_5 avec le di-*t*-butyl-1,1 éthylène. Ce radical réagit avec lui-même par un processus du second ordre. Les constantes de vitesse sont données par l'équation d'Arrhénius $\log 2k_1\,(M^{-1}\,s^{-1}) = (10.3 \pm 0.5) - (1.7 \pm 0.5)/\theta$ où $\theta = 2.303RT$ kcal mol^{-1}. Le radical s'additionne aussi sur le di-*t*-butyl-1,1 éthylène conduisant ainsi au $(t\text{-Bu})_2\dot{C}CH_2SF_5$. Ce produit se décompose par un processus du premier order dont les constantes de vitesse obéissent à l'expression $\log k_2\,(s^{-1}) = (13 \pm 0.4) - (10 \pm 0.2)/\theta$. Ces deux constantes de vitesse sont pertinentes aux études cinétiques de l'addition photo-induite du SF_5Cl sur les oléfines. [Traduit par le journal]

Introduction

Pentafluorosulfuranyl (SF_5) is one of the intermediates involved in the light induced and peroxide initiated addition of SF_5Cl to olefins (1–4), in the radiolysis of SF_6 (5–7), and reaction of alkali metal atoms with SF_6 (8–10).

The electron spin resonance spectrum of SF_5 has recently been detected during liquid-phase photolysis of SF_5Cl and by reaction of photochemically generated F· with SF_4 (11). This radical is a particularly interesting species from a theoretical standpoint (12) because the isotropic e.s.r. spectrum shows a hyperfine pattern due to the interaction of four equivalent fluorine atoms, the fifth fluorine showing no detectable isotropic hyperfine interaction.

Apart from some relative reactivity data obtained in the gas phase (2–4) little is known about the kinetics of reactions of SF_5 (and for that matter other sulfur centered radicals). We have, therefore, measured absolute rate constants for the self reaction of SF_5 in solution and rate constants for the β-scission of 1,1-di-*t*-butyl-2-pentafluorosulfuranylethyl, $(t\text{-Bu})_2\dot{C}CH_2SF_5$. The results of this work are reported here.

Experimental

Pentafluorosulfuranyl was prepared *in situ* in the cavity of a Varian E-4 EPR spectrometer either by photolysis of

pentafluorosulfur chloride (Chemicals Procurement Laboratories Inc.) in a deoxygenated solvent (isopentane, dichlorodifluoromethane, and cyclopropane)

$$SF_5Cl \xrightarrow{h\nu} SF_5 + Cl$$

or by photolysis of pentafluorosulfur peroxide (13) in the presence of phosphorus trifluoride in deoxygenated CF_2Cl_2.[3]

$$SF_5OOSF_5 \xrightarrow{h\nu} 2SF_5O\cdot$$

$$SF_5O\cdot + PF_3 \rightarrow [SF_5O\dot{P}F_3] \rightarrow SF_5 + OPF_3$$

Absolute rate constants for self-reaction of SF_5 were determined by kinetic electron spin resonance spectroscopy, k.e.s.r., (15) with the aid of a rotating sector and a Fabri-Tek 1072 Signal Averager. Steady state SF_5 concentrations were determined by comparing the doubly integrated first derivative spectrum with a similarly integrated spectrum of a standard solution of DPPH.

1,1-Di-*t*-butyl-2-pentafluorosulfuranylethyl radical was prepared by photolysis of SF_5Cl in isopentane or cyclopropane containing 1,1-di-*t*-butylethylene. Decays of this species were followed by k.e.s.r. using the X-Y recorder provided with the spectrometer.

Results and Discussion

SF_5 + SF_5

The concentration of SF_5 rapidly attained a steady state when the radical was generated by either of the methods described above. Steady-state radical concentrations were proportional to the square-root of the light intensity, indicating that the disappearance of SF_5 in these systems followed second-order kinetics, *i.e.*

$$[1] \qquad \frac{-d[SF_5]}{dt} = 2k_1[SF_5]^2$$

The order of this reaction was confirmed by the linearity of plots of $1/[SF_5]$ as a function of time after the initiating light was shuttered (Fig. 1).

Values of $2k_1$ were determined in three solvents, isopentane, cyclopropane, and dichlorodifluoromethane from 153 to 233 K. The values in cyclopropane and CF_2Cl_2 were identical, within experimental error, and were independent of the method of radical generation (see Table 1). The rate constants were found to fit the equation

$$\log 2k_1\,(M^{-1}\,s^{-1}) = (10.3 \pm 0.6) - (1.7 \pm 0.5)/\theta$$

where $\theta = 2.303RT$ kcal mol^{-1}, as determined from a least-squares fitting procedure on the Arrhenius plot.

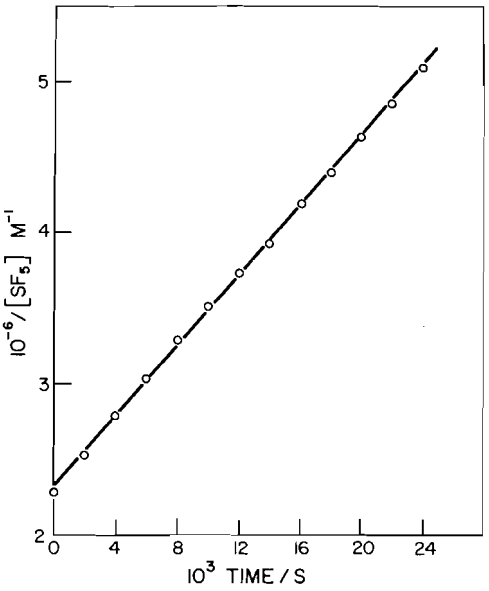

FIG. 1. The reciprocal radical concentration as a function of time for the self-reaction of SF_5 in cyclopropane at 183 K.

These Arrhenius parameters are very similar to the values of $A_1 = 10^{10}\,M^{-1}\,s^{-1}$ and $E_1 = 0$ predicted by Siddebottom *et al.* (2) and used by these workers to calculate Arrhenius parameters for addition of SF_5 to olefins.

Rate constants determined in isopentane were not reproducible and radical decays often deviated from second-order. The reason for poor kinetic data in isopentane is not clear at present and rate constants obtained in this solvent were not included in the Arrhenius plot.

Extrapolation of the Arrhenius equation gives a value of $2k_1 = 1 \times 10^9\,M^{-1}\,s^{-1}$ at 298 K somewhat less than the calculated diffusion-controlled limit for simple radicals in solution (16). A comparison of this value with absolute rate constants for self-reaction of other small radicals reveals that $2k_1$ is about 10 times smaller than the rate constant for CH_3 and about 10 times larger than the rate constant for CCl_3 (16). This difference between SF_5 and CCl_3 does, however, seem unreasonable. Relative rate constant measurements (17), which are inherently more accurate for comparing rate constants than individual rate constant measurements, indicate that the rate constant for self-reaction of CCl_3 is about $2 \times 10^9\,M^{-1}\,s^{-1}$ which implies that

[3]Photolysis of other peroxides in the presence of PF_3 gave alkoxytrifluorophosphoranyls, $ROPF_3$, (14). However, $SF_5O\dot{P}F_3$ is apparently too unstable to detect and SF_5 was the only species that could be detected.

TABLE 1. Rate constants for the self-reaction of SF_5

Radical source	Solvent	Temperature (°C)	$[SF_5]_0 \times 10^7$ (M)	$2k_1 \times 10^{-8}$ (M^{-1} s^{-1})
SF_5OOSF_5/PF_3	CCl_2F_2	−104	2.5	1.3
SF_5Cl	CCl_2F_2	−120	2.2	1.2
SF_5Cl	CCl_2F_2	− 90	2.2	3.7
SF_5Cl	CCl_2F_2	− 40	2.2	9.5
SF_5Cl	c-C_3H_6	−120	6.0	0.52
SF_5Cl	c-C_3H_6	−104	6.6	0.48
SF_5Cl	c-C_3H_6	− 90	1.6	0.94
SF_5Cl	c-C_3H_6	− 90	4.8	1.3
SF_5Cl	c-C_3H_6	− 90	5.2	1.1
SF_5Cl	c-C_3H_6	− 40	4.6	3.2

CCl_3 and SF_5 have termination rate constants of a similar magnitude.

Values of $2k_1$ that can be calculated from the Arrhenius equation should be applicable to gas-phase systems involving SF_5 since there is no reason to believe that going from the liquid to the gas-phase would significantly influence the magnitude of this rate constant.

$(t\text{-Bu})_2\dot{C}CH_2SF_5$

Griller and Ingold (18, 19) have shown that persistent 1,1-di-*t*-butyl-2-substituted-ethyl radicals are readily obtained when a variety of free radicals are generated in the presence of 1,1-di-*t*-butylethylene, **1**. Photolysis of SF_5Cl in the presence of **1** (5%) in isopentane from 133 to 173 K gave a 15-lined e.s.r. spectrum which could be interpreted as arising from the interaction of two equivalent hydrogen atoms with four equivalent fluorine atoms, consistent with the radical structure $(t\text{-Bu})_2\dot{C}CH_2SF_5$, **2**. The agreement between the observed and computer simulated spectra with $a_H(2) = 9.75 \pm 0.05$ G, $a_F(4) = 14.12 \pm 0.05$ G, $g = 2.0032$, and a linewidth of 3 G was excellent.

The absence of a hyperfine coupling from the fluorine *trans*- to the C—S bond is not surprising as it has been shown in several cases that the hyperfine coupling from this fluorine is very small (<0.5 G) (11, 20). It was also possible to observe the ^{33}S hyperfine coupling ($a^{33}S = 91.7$ G) in natural abundance. Only the $\pm\frac{3}{2}$ transitions were observable, the $\pm\frac{1}{2}$ transitions being hidden beneath the main spectrum. This coupling, when compared with the $8\pi/3\gamma_e\gamma_N\psi_{3s}(O)^2$ for ^{33}S of 969 G, represents a 10% contribution from the sulfur 3s orbital to the unpaired electron orbital.

The magnitude of the β-proton hyperfine coupling can be attributed to two effects. The steric effect of the SF_5 substituent will force the groups around the β-carbon into a locked conformation in which the SF_5 group is eclipsed with the α-carbon p-orbital containing the unpaired electron as is the case with other radicals of this type (21). This will tend to decrease the β-proton coupling from that which would be expected if there was free rotation about the C_α—C_β bond. The further effect of an electron-withdrawing group on the β-carbon will withdraw electron density from these protons further decreasing the proton coupling. The large ^{33}S hyperfine coupling observed is consistent with this explanation.

The steady-state concentration of **2** had an intensity exponent of 1.0 and radical decays were first order when the initiating light was shuttered, *i.e.*

$$\frac{-d[\mathbf{2}]}{dt} = k_2[\mathbf{2}]$$

$(t\text{-Bu})_2\dot{C}CH_2SF_5$ must, therefore, decay by the unimolecular β-scission process

[2] $$\mathbf{2} \rightarrow (t\text{-Bu})_2C{=}CH_2 + SF_5$$

rather than by the bimolecular disproportionation

[3] $$\mathbf{2} \rightarrow (t\text{-Bu})_2CHCH_2SF_5 + (t\text{-Bu})_2C{=}CHSF_5$$

Absolute values of k_2 were measured from 133 to 173 K and are summarized in Table 2. An Arrhenius plot of this data yielded the expression

$$\log k_2\,(s^{-1}) = (13 \pm 0.4) - (10 \pm 0.2/\theta)$$

The magnitude of A_2 is consistent with a unimolecular β-scission process and the low value of E_2 is in keeping with the reversible addition of sulfur centered radicals to olefins (22, 23). Sidde-

bottom *et al.* have in fact had to invoke the reversibility of the addition of SF_5 to olefins to account for the product distribution found for addition of SF_5Cl to olefins (2–4).

SF_5Cl was also photolyzed in the presence of ethylene and isobutylene. An e.s.r. signal could not be detected in isobutylene and although a signal was detected in ethylene it was too weak to permit analysis. The low intenisty of the e.s.r. signals in these olefins is probably because SF_5Cl is rapidly consumed by a chain reaction. The overall rate of reaction must be rapid at these low temperatures because even after a few minutes photolysis, SF_5Cl and the olefin were converted almost quantitatively to $SF_5CH_2CH_2Cl$ and $SF_5CH_2C(CH_3)_2Cl$, as shown by the correspondence of the ^{19}F and ^1H n.m.r. spectra of the products with those analyzed previously by Boden *et al.* (24). In the case of di-*t*-butylethylene, no ^{19}F resonance was observable, indicating that **2** is too sterically hindered to abstract a chlorine atom from SF_5Cl.

Received January 7, 1975

DON BETOWSKI, GERVASE MACKAY, JOHN PAYZANT, and DIETHARD BOHME. Can. J. Chem. **53**, 2365 (1975).

The rate constants and equilibrium constant for the proton transfer reaction $SH^- + HCN \rightleftarrows CN^- + H_2S$ have been measured at 296 ± 2 K using the flowing afterglow technique: $k_{forward} = (2.9 \pm 0.6) \times 10^{-9}$ cm^3 molecule^{-1} s^{-1}, $k_{reverse} = (1.8 \pm 0.4) \times 10^{-10}$ cm^3 molecule^{-1} s^{-1}, and $K = 16 \pm 2$. The measured value of K corresponds to a standard free energy change, ΔG_{296}^0, of −1.6 0.1 kcal mol^{-1} which provides values for the standard enthalpy change, $\Delta H_{298}^0 = -1.0$ 0.2 kcal mol^{-1}. the bond dissociation energy, D_0^0(H—CN) = 124 2 kcal mol^{-1}, and the proton affinity, p.a.(CN^-) = 350 1 kcal mol^{-1}.

DON BETOWSKI, GERVASE MACKAY, JOHN PAYZANT et DIETHARD BOHME. Can. J. Chem. **53**, 2365 (1975).

Les constantes de vitesse et la constante d'équilibre de la réaction du transfert de proton, $SH^- + HCN \rightleftarrows CN^- + H_2S$, ont été mesurées à 296 ± 2 K par la technique "flowing afterglow": $k_{droite} = (2.9 \pm 0.6) \times 10^{-9}$ cm^3 molécule^{-1} s^{-1}, $k_{gauche} = (1.8 \pm 0.4) \times 10^{-10}$ cm^3 molécule^{-1} s^{-1} et $K = 16 \pm 2$. La valeur de K mesurée correspond à une variation de l'énergie libre standard ΔG_{296}^0, de -1.6 ± 0.1 kcal mol^{-1} qui permet de calculer la variation de l'enthalpie standard, $\Delta H_{298}^0 = -1.0 \pm 0.2$ kcal mol^{-1}, l'énergie de dissociation de liaison, D_0^0 (H—CN) = 124 ± 2 kcal mol^{-1}, et l'affinité du proton, a.p.(CN^-) = 350 ± 1 kcal mol^{-1}. [Traduit par le journal]

Introduction

Recent experimental investigations carried out in this laboratory (1, 2) and elsewhere (3–6) of the equilibria of proton transfer reactions of the type

[1] $$X^- + YH \rightleftarrows Y^- + XH$$

proceeding in the gas phase, have indicated that such studies provide a valuable new method for the determination or corroboration of fundamental thermochemical properties of both charged and uncharged molecular species, *viz.* heats of formation (ΔH_f^0), electron affinities (e.a.), proton affinities (p.a.), and bond dissociation energies (D^0). The method involves the determination of the exothermicity (ΔH^0) of the proton transfer reaction from rate and/or equilibrium constant measurements at one or more temperatures. The value established for ΔH^0 is then combined with reliable values for thermochemical properties of one or more of the individual reacting species to arrive at the desired thermochemical property. The accuracies of the thermochemical quantities determined in this way often supersede those attained with other, more established, methods. In this paper we report measurements of rate and equilibrium constants at 296 ± 2 K for the proton transfer reaction

[2] $$SH^- + HCN \rightleftarrows CN^- + H_2S$$

and the derivation of values for D_0^0(H—CN) and p.a.(CN^-).

This study also provides an (as yet rare) opportunity to compare rate and equilibrium constants obtained for reactions of type 1 proceeding under quite different conditions of ion and neutral concentrations, total pressure, reaction time, ion history, and ambient electric fields. Reaction 2 has been previously investigated by McIver and Eyler (4) with the pulsed ion – cyclotron resonance (i.c.r.) technique. The gaseous ions are formed by electron impact and reaction proceeds at low pressures ($< 10^{-5}$ Torr) while the ions are trapped in an analyzer cell by the combined effects of magnetic and electric fields for periods as long as 1 s. In the present investigation reaction 2 proceeds in a flowing plasma containing HCN, H_2S, and an excess of He at total pressures of *ca.* 0.3 Torr and at a fixed reaction time of a few ms. In the determination of rate and/or equilibrium constants for reactions of type 1 using either technique it is important to establish that the reactant ions are thermalized to the ambient temperature prior to

reaction in either direction and consequently that the observed rate constants correspond to Maxwell–Boltzmann energy distributions and that the observed steady-state ion signals are a true measure of equilibrium concentrations.

Experimental

The experiments were performed using the flowing afterglow (f.a.) technique. The details of the apparatus and the methods of data analysis have been described previously (7, 8). Reactant ions are produced in a flowing plasma either by electron impact or by secondary ionization or ion–molecule reactions. In these experiments the plasma was generated with ionizing electrons having energies of *ca.* 60 eV. The filament emission of the electron gun was 0.5 mA. The neutral reactant is introduced sufficiently downstream of the ion production region to ensure that the reactant ions have undergone enough collisions with the carrier gas (helium was used in the experiments reported here) to become thermalized at the ambient room temperature (296 ± 2 K). The plasma communicates with a quadrupole mass spectrometer through a small orifice mounted at the tip of a sampling nose cone. Rate constants and equilibrium constants for reactions of ions with molecules are determined by measuring changes in ion signals as a function of the addition of neutral reactant molecules.

The gases used were He (Linde, Prepurified Grade, 99.995% He), H_2S (Matheson, C.P. Grade, 99.5% H_2S), $C_2H_5NH_2$ (Matheson, 98.5% $C_2H_5NH_2$), and HCN prepared in this laboratory from the action of sulfuric acid on an aqueous solution of KCN (9). The HCN was dried over anhydrous $CaCl_2$ and purified further by distillation *in vacuo*.

Results

Reaction 2 was investigated independently in both directions. The ratio of rate constants, k_2/k_{-2}, and the equilibrium constant, K_2, were determined in each direction. The results are summarized in Table 1. The sources of error have been described previously (7). The individual rate constants at 296 ± 2 K were determined to be $k_2 = (2.9 \pm 0.6) \times 10^{-9}$ cm^3 molecule^{-1} s^{-1} and $k_{-2} = (1.8 \pm 0.4) \times 10^{-10}$ cm^3 molecule^{-1} s^{-1}.

In the remainder of this section the best estimate of a true value is taken to be the mean of a series of measurements. The limits given along with the mean value represent the best estimate of the precision (10).

$$SH^- + HCN \rightleftarrows CN^- + H_2S$$

In the study of the attainment of equilibrium for reaction 2 in the forward direction, H_2S was added to the helium buffer upstream of the electron gun and was ionized directly according to one or more of the following processes:

$$[3a] \qquad H_2S + e \rightarrow SH^- + H$$

$$[3b] \qquad \rightarrow SH^- + H^+ + e$$

$$[4] \qquad He(2^3S, 2^1S) + H_2S \rightarrow SH^- + H^+ + He$$

In addition to SH^-, the mass spectrum of the negative ions sampled downstream contained several multisulfur ions of the type S_n^- or S_nH^-. The mode of formation of these ions remains unclear and will be the subject of a separate study. Only the SH^- ions were observed to react with HCN upon addition of the latter into the reaction region. The concomitant appearance of only one ion signal at *m/e* 26 dictated that the reaction of SH^- with HCN proceeded entirely via proton transfer. There was no indication that other competing reactions were occurring. Figure 1 shows the behavior observed for the SH^- and CN^- ion signals as HCN is added into the reaction region. The curvature of the SH^- decay can be attributed to the occurrence of the reverse reaction −2. The solid curve drawn through the data points for the SH^- decay represents the best fit obtained using Analysis B of ref. 7. and provides a measure of the ratio of rate constants, k_2/k_{-2}. The determination of unique values for k_2 and k_{-2} was precluded in this case since reaction 2 was observed to be in equilibrium already at low additions of HCN. This is demonstrated by the ratio plot shown in Fig. 2 which is linear over almost the entire range of HCN flows. The slope of this line affords a direct determination of the equilibrium constant from equilibrium concentrations (ref. 7, Analysis C). The ratio of ion signals, $I(CN^-)$/

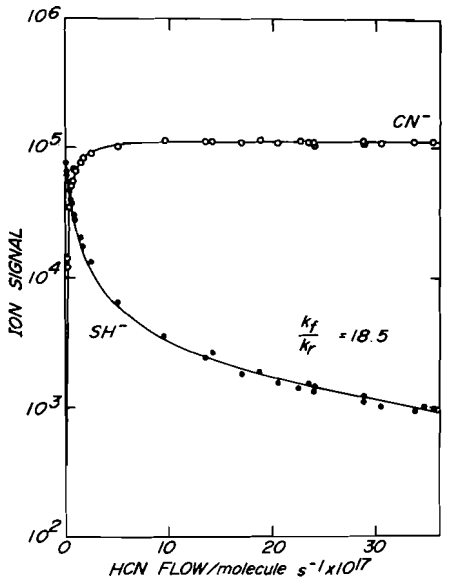

FIG. 1. The determination of the ratio of rate constants for the reaction $SH^- + HCN \rightleftarrows CN^- + H_2S$ from a fit (solid line) to the observed decay (solid points) of the SH^- signal upon addition of HCN at a constant flow of the neutral back-reactant, H_2S. H_2S flow = 8.4×10^{17} molecule s^{-1}, $T = 296$ K, $P = 0.329$ Torr, $\bar{v} = 8.7 \times 10^3$ cm s^{-1}, and $L = 59$ cm.

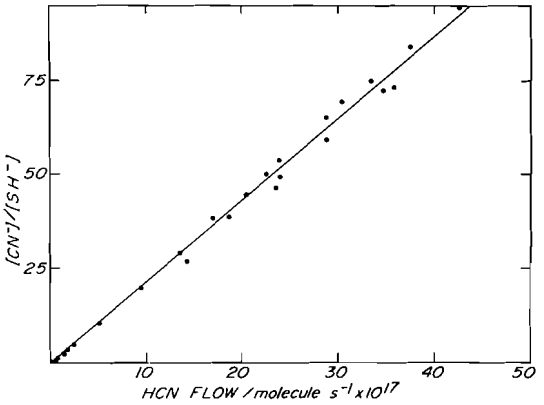

FIG. 2. The observed variation (solid points) of the ratio of the product to the reactant ion signals (corrected for mass discrimination) for the reaction $SH^- + HCN \rightleftarrows CN^- + H_2S$ with the flow of HCN at a constant flow of the neutral back-reactant, H_2S. H_2S flow = 8.4×10^{17} molecule s^{-1}. The least squares fit (solid line) provides a value for the equilibrium constant, $K = 18$. $T = 296$ K, $P = 0.329$ Torr, $\bar{v} = 8.7 \times 10^3$ cm s^{-1}, and $L = 59$ cm.

$I(SH^-)$, corrected for mass discrimination, provides a measure of the ratio of ion concentrations, $[CN^-]/[SH^-]$. An equilibrium constant, K_2, of 18 was obtained from the data shown in Fig. 2.

In two other experiments the amounts of H_2S and HCN added were lowered sufficiently to prevent attainment of equilibrium. In these cases the best fits to the SH^- decays provided unique values for k_2 and k_{-2} of $(2.9 \pm 0.3) \times 10^{-9}$ and $(1.8 \pm 0.2) \times 10^{-10}$ cm^3 molecule^{-1} s^{-1}, respectively.

The additions of H_2S in the three experiments ranged from 4.39 to 8.6×10^{17} molecule s^{-1}. The effective reaction length, L, was always 59 cm, the total gas pressure, P, was 0.329 Torr, and the gas velocity, $\bar{v}$, was 8.7×10^3 cm s^{-1}. The three experiments resulted in an average value for the ratio of rate constants, k_2/k_{-2}, of 17.8 ± 0.7.

$CN^- + H_2S \rightleftarrows SH^- + HCN$

In the studies of reaction 2 in the reverse direction the reactant ion, CN^-, was generated from HCN which was added to the helium buffer upstream of the electron gun. The processes which lead to the formation of CN^- under these conditions include one or more of the following:

[6a] $$HCN + e \rightarrow CN^- + H$$

[6b] $$\rightarrow CN^- + H^+ + e$$

[7] $$He(2^3S, 2^1S) + HCN \rightarrow CN^- + H^+ + He$$

H_2S was added into the reaction region downstream of the electron gun and the decay of the CN^- signal was recorded along with the rise of the SH^- signal at various additions of H_2S. There was no evidence for the further reaction of SH^- with H_2S which suggests that the reaction

[8] $$SH^- + H_2S \rightarrow S_2H^- + H_2$$

is endothermic, in which case $\Delta H_{f298}{}^0(S_2H^-)$ should be $\geqslant 25 \pm 4$ kcal mol^{-1}. (Values for $\Delta H_{f298}{}^0(SH)$ and $\Delta H_{f298}{}^0(H_2S)$ were taken from ref. 11 and the electron affinity of SH was taken from ref. 12.)

Figure 3 shows the behavior observed for the CN^- and SH^- ion signals as H_2S is added into the reaction region at a flow of back reactant, HCN, of 2.01×10^{17} molecule s^{-1}. The experiment was repeated at a slightly lower addition of HCN of 1.03×10^{17} molecule s^{-1}. In both experiments the effective reaction length, L, was 85 cm, $P = 0.344$ Torr, and $\bar{v} = 8.3 \times 10^3$ cm s^{-1}. Figure 4 demonstrates that under these conditions equilibrium is attained already at the lowest additions of H_2S which again precludes the determination of unique values for k_2 and k_{-2} from a fit to the decay of CN^-. The value for the ratio of rate constants, $k_2/k_{-2} = 14.6 \pm 1.9$,

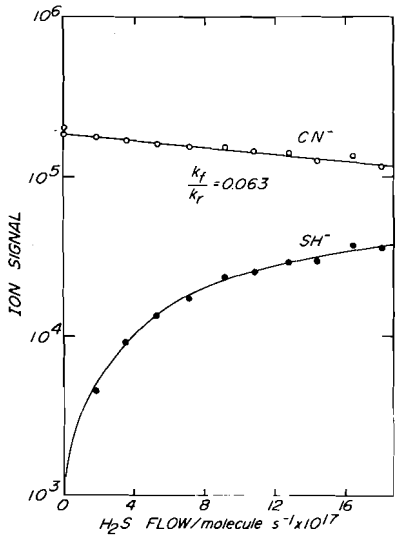

FIG. 3. The determination of the ratio of rate constants for the reaction $CN^- + H_2S \rightleftarrows SH^- + HCN$ from a fit (solid line) to the observed decay (open circles) of the CN^- signal upon addition of H_2S at a constant flow of the neutral back-reactant, HCN. HCN flow = 2.01×10^{17} molecule s^{-1}, $T = 297$ K, $P = 0.344$ Torr, $\bar{v} = 8.3 \times 10^3$ cm s^{-1}, and $L = 85$ cm.

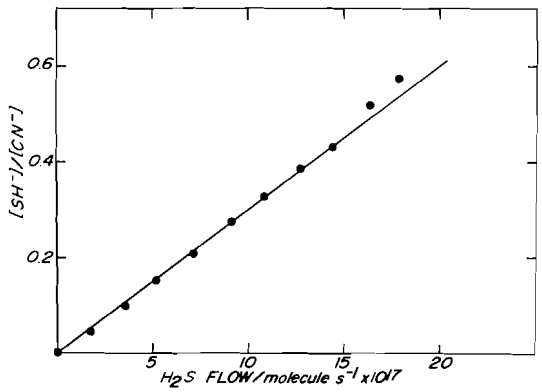

FIG. 4. The observed variation (solid points) of the ratio of the product to the reactant ion signals (corrected for mass discrimination) for the reaction $CN^- + H_2S \rightleftarrows SH^- + HCN$ with the flow of H_2S at a constant flow of neutral back-reactant, HCN. HCN flow = 2.01×10^{17} molecule s^{-1}. The least squares fit (solid line) provides a value for the equilibrium constant, $K = 0.062$. $T = 297$ K, $P = 0.344$ Torr, $\bar{v} = 8.3 \times 10^3$ cm s^{-1}, and $L = 85$ cm.

derived from the CN^- decays was found to agree with the value for the equilibrium constant, $K_2 = 14.3 \pm 2.6$, obtained from an analysis of the corresponding ratio plots. The latter determination again involves a correction for mass discrimination in the sampling region between the CN^- and SH^- ions (7).

Reaction -2 was also investigated in the absence of significant amounts of back reaction to provide an independent measure of k_{-2}. In this case CN^- was generated from $C_2H_5NH_2$ rather than HCN under otherwise similar operating conditions. Three experiments provided a value for k_{-2} of $(1.8 \pm 0.2) \times 10^{-10}$ cm^3 $molecule^{-1}$ s^{-1} which is in good agreement with the value for k_{-2} determined from the study of reaction 2 in the forward direction.

Discussion

The true equilibrium constant for the elementary reaction 2 should be independent of time, total pressure, direction of approach to equilibrium, and concentration of the reacting species if these behave as ideal gases. Furthermore, since the thermodynamic equilibrium constant relates to Maxwell–Boltzmann (M–B) energy distributions for both reactants and products, K_2 will be equal to the ratio of rate constants, k_2/k_{-2}, if the individual rate constants also correspond to such energy distributions. In the present experiments the spatial separation of the ion production and reaction regions ensures that the ions undergo many collisions (primarily with the buffer gas atoms) prior to reaction (7). The neutral reactant is added already in thermal equilibrium at the ambient (room) temperature. Consequently, both reacting species are expected to possess room temperature M–B distributions of translational and internal energies. Such a condition will not exist immediately after the reaction has occurred. However, in the presence of a large excess of buffer gas, the rate of relaxation of the product ions initially formed in disequilibrium exceeds the rate of proton transfer in the reverse direction. Furthermore, the neutral product is added in thermal equilibrium at room temperature in large excess to that generated by reaction. Under these conditions k_{-2} should also correspond to M–B energy distributions (7). The results obtained in the present study for reaction 2 are consistent, within experimental error, with these expectations:

(*1*) The ratio of rate constants, k_2/k_{-2}, was observed to be equal to the equilibrium constant determined from equilibrium concentrations, K_2, in both directions of approach to equilibrium. We would like to emphasize here that the determination of k_2/k_{-2} in the manner described does not require the correction for mass discrimination necessary in the determination of K_2 from equilibrium concentrations.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/05/12
For personal use only.

(*2*) k_2/k_{-2} and K_2 were observed to be independent of the concentrations of the two neutral constituents within the range of experimental operating conditions.

(*3*) k_2/k_{-2} and K_2 were observed to be independent of the direction of approach to equilibrium at different reaction times.

(*4*) The value of k_{-2} determined from an equilibrium study of reaction 2 in the forward direction was in agreement with the value of k_{-2} obtained in an independent study of reaction -2 in the absence of reverse reaction.

The values of k_2/k_{-2} and K_2 determined independently in both directions of reaction 2 provide a best estimate (9) of the true value (a weighted mean) of the equilibrium constant at 296 ± 2 K of 16 with a standard error of ±2.

Reaction 2 has been previously investigated by McIver and Eyler (4) with the pulsed i.c.r. technique under considerably different conditions of ion and neutral concentrations, total pressure, reaction time, ion history, and ambient electric fields. The ions CN^- and SH^- were produced either directly by electron impact (in the case of SH^-) or indirectly by the reaction of F^- (produced by electron impact on NF_3) with HCN and H_2S respectively. Steady-state ion signals measured at large reaction times (>200 ms) in various mixtures of HCN and H_2S (both pure and diluted with NF_3) at total pressures $\leqslant 2 \times 10^{-6}$ Torr were believed to be proportional to equilibrium ion concentrations. Accordingly McIver and Eyler reported a value for K_2 at 298 K of 9.5 ± 1.5 which was observed to be consistent with the value for k_2/k_{-2} of 8.9 ± 0.5 determined from rate constant measurements involving selective ion ejection (5). Values for the individual rate constants were not reported. Concerns have been expressed both by these authors (5) and others[1] (13) regarding the extent of thermalization of ions prior to reaction in experiments of this type, *i.e.* the extent to which the observed steady-state ion signals are a measure of true equilibrium concentrations and the extent to which the observed rate constants correspond to M–B energy distributions. Bowers[1] has estimated the i.c.r. relative velocity distribution in the limit of zero collisions and found it to have a high velocity tail greater than the room-temperature Maxwellian. One might therefore expect to observe that K_2(i.c.r.) < K_2(f.a.) even in the presence of several collisions. In fact, a comparison of the values for K_2 obtained with these two techniques should provide some indication of the extent to which the room-temperature Maxwellian is perturbed. For example, if one can characterize the i.c.r. equilibrium state in terms of an "effective" temperature, then a Van't Hoff calculation using $K_2 = 16$ at 296 K and the value for $\Delta H^0 = -1.0$ kcal mol^{-1} obtained in this study predicts a value for $K_2 = 9.5$ at an effective temperature of 427 K.

An equilibrium constant of 16 ± 2 for reaction 2 leads to a standard free energy change, $\Delta G_{296}{}^0 = -1.6 \pm 0.1$ kcal mol^{-1}. The standard entropy change, $\Delta S_{298}{}^0$, may be estimated from the reported values of the standard entropies of HCN, H_2S, CN^-, and HCl (12). $S_{298}{}^0(SH^-)$ is assumed to be equal to the standard entropy of the isoelectronic species HCl. The resulting value for $\Delta S_{298}{}^0 = +2.1$ e.u. is estimated to be uncertain to ±0.5 e.u. and can be combined with the value of $\Delta G_{296}{}^0$ determined in this study to provide a value for $\Delta H_{298}{}^0$ of -1.0 ± 0.2 kcal mol^{-1}.

The combination of the value obtained for $\Delta H_{298}{}^0$ with the most reliable values currently available for e.a.(CN), e.a.(SH) and $D_0{}^0$(H—CN) according to the equation:

$$[9] \quad D_0{}^0(\text{H—CN}) = D_0{}^0(\text{H—SH}) + \text{e.a.(CN)} - \text{e.a.(SH)} + \Delta H_{298}{}^0 - \int_0^{298} \Delta C_p \mathrm{d}T$$

where ΔC_p is the change in heat capacity for reaction 2 at constant pressure. A value for $D_0{}^0$(H—CN) of 124 ± 2 kcal mol^{-1} is obtained when the values for $D_0{}^0$(H—SH) = 90 ± 1 kcal mol^{-1} (14), e.a.(CN) = 88.1 ± 0.5 kcal mol^{-1} (15), and e.a.(SH) = 53.50 ± 0.23 (13) are adopted and the integral is neglected.[2] Darwent has selected a slightly larger value for $D_0{}^0$(H—CN) of 127 ± 5 kcal mol^{-1} in his compilation of bond dissociation energies (14). The values for $\Delta H_{f0}{}^0$-(H, CN, HCN) adopted in the JANAF tables (11) provide a value for $D_0{}^0$(H—CN) of 123.2 ± 4.5 kcal mol^{-1} which is in good agreement with the value determined in this study.

The exothermicity of reaction 2 is a measure of the difference in the proton affinities of CN^- and SH^-, *viz.*

[1]M.T. Bowers. Private communication.

[2]A comparison of $\Delta H_{298}{}^0$ with $\Delta H_0{}^0$ for the analogous reaction: SH + HCN → CN + H_2S indicates a value for $\int_0^{298} \Delta C_p \mathrm{d}T < 0.1$ kcal mol^{-1}.

[10] ΔH_{298}^{0} = p.a.(CN^-) − p.a.(SH^-) = -1.0 ± 0.2 kcal mol^{-1}

A value for p.a.(SH^-) of 351 ± 1 kcal mol^{-1} may be calculated from the available thermochemical data for D_{298}^{0}(H—SH), e.a.(SH), and i.p.(H^+), all of which have been established to within an uncertainty ⩽1 kcal mol^{-1}. Consequently p.a.(CN^-), which is a measure of the gas-phase acidity of HCN, is equal to 350 ± 1 kcal mol^{-1}.

The authors are not aware of any previous report of the rate constant for reaction 2. The value obtained in the present study at 296 K, *viz.* $(2.9 \pm 0.6) \times 10^{-9}$ cm^3 $molecule^{-1}$ s^{-1} is in excellent accord with the value predicted on the basis of the average-dipole-orientation theory of Su and Bowers (16, 17), *viz.* 2.84×10^{-9} cm^3 $molecule^{-1}$ s^{-1}. We have adopted a value for α(HCN) = 2.59 $Å^3$ (18) and μ_D(HCN) = 2.98 D (19).

The Crystal Structure of *cis*-Dichlorobis(dimethylsulfoxide)platinum(II)

ROBERT MELANSON AND FERNANDE D. ROCHON

Département de Chimie, Université du Québec à Montréal, C.P. 8888, Montréal, Québec H3C 3P8

Received March 5, 1975

ROBERT MELANSON and FERNANDE D. ROCHON. Can. J. Chem. **53**, 2371 (1975).

The molecular and crystal structure of *cis*-dichlorobis(dimethylsulfoxide)platinum(II), *cis*-$[PtCl_2(DMSO)_2]$, has been studied by X-ray diffraction. The compound belongs to the monoclinic $P2_1/c$ space group and the cell parameters are: $a = 8.653$, $b = 13.580$, $c = 10.914$ Å, $\beta = 123.43°$, and $Z = 4$. The refinement of the positional and anisotropic thermal parameters, carried out by full matrix least-squares calculations, converged to $R = 0.029$ and $R_w = 0.027$.

The coordination around the platinum atom is planar. As expected, the DMSO molecules are bonded to the platinum atom through sulfur. The bond distances found are: Pt—Cl = 2.306, 2.312 Å; Pt—S = 2.244, 2.229 Å; S—O = 1.469, 1.454 Å, and S—C = 1.77 to 1.79 Å. The crystal consists of layers of molecules parallel to the *ac* plane.

ROBERT MELANSON et FERNANDE D. ROCHON. Can. J. Chem. **53**, 2371 (1975).

La structure moléculaire et cristalline du complexe *cis*-$[PtCl_2(DMSO)_2]$ (DMSO = diméthylsulphoxyde) a été étudiée par diffraction des rayons X. Le composé cristallise dans le groupe spatial $P2_1/c$ du système monoclinique. Les paramètres de maille sont: $a = 8.653$, $b = 13.580$, $c = 10.914$ Å, $\beta = 123.43°$ et $Z = 4$. Les coordonnées atomiques et les facteurs thermiques anisotropes ont été affinés par moindres carrés (matrice entière) jusqu'à $R = 0.029$ et $R_w = 0.027$.

La coordination autour de l'atome de platine est plane. Comme prévu, les molécules DMSO sont liées au platine par les atomes de soufre. Les distances entre les atomes formant des liaisons sont: Pt—Cl = 2.306, 2.312 Å; Pt—S = 2.244, 2.229 Å; S—O = 1.469, 1.454 Å et S—C = 1.77 à 1.79 Å. Le cristal est formé de couches de molécules parallèles au plan *ac*.

Introduction

$PtCl_2(DMSO)_2$, obtained as yellow crystals from the reaction between K_2PtCl_4 and dimethylsulfoxide has variously been assigned the *cis* (1, 2) and the *trans* (3) configuration. The complex is not isomorphous with the corresponding Pd(II) complex which is known, from X-ray diffraction studies, to have a *trans* configuration (4). Although the infrared spectrum indicates a *cis* configuration, the chemical behavior is more in keeping with a *trans* configuration (ref. 5, a note added in proof, confirmed the assignment of a *cis* configuration since the authors had just synthesized the *trans* isomer). There is general agreement that in the platinum(II) complexes with one or two dimethylsulfoxide molecules, the ligands are bonded to platinum through sulfur. A strong peak around 1125 cm^{-1} in the infrared spectrum has been assigned to the S—O stretching vibration, indicating bonding through sulfur (6), since it is shifted to higher frequency than the corresponding vibration in the free ligand.

Recently, we have decided to study the reactions between $PtCl_2(DMSO)_2$ and some nucleosides. In order to know the exact nature of $PtCl_2(DMSO)_2$, we have undertaken the study of the crystals by X-ray diffraction.

Experimental Section

Crystal Data

$PtCl_2C_4H_{12}S_2O_2$ f.w. = 422.26

Monoclinic $P2_1/c$, $a = 8.653(3)$, $b = 13.580(5)$, $c = 10.914(4)$ Å, $\beta = 123.43(3)°$, $Z = 4$, $V = 1070.3(7)$ Å^3, $\rho_o = 2.59(3)$ g/cm^3 (flotation), $\rho_c = 2.620$ g/cm^3, λMoKα = 0.71069 Å, μMoKα = 143.28 cm^{-1}, $T = 22°$.

Crystals of *cis*-dichlorobis(dimethylsulfoxide)platinum(II) were obtained directly from the reaction of K_2PtCl_4 in aqueous dimethylsulfoxide as previously described (1). A set of precession photographs indicated that the $h0l$, $l = 2n + 1$ and $0k0$, $k = 2n + 1$ reflections are systematic absences indicating the $P2_1/c$ space group. The cell parameters were calculated by least-squares refinement from the setting angles of 15 automatically centered reflections (MoKα radiation) on a Syntex P$\bar{1}$ diffractometer equipped with a graphite monochromator.

Collection and Reduction of Intensity Data

The intensity data were collected from a crystal of dimensions 0.106 × 0.120 × 0.434 mm. A total of 3461 independent reflections were measured in the region of $2\theta < 60°$ by the $2\theta/\theta$ scan technique using MoKα radiation. The data collection was done at a variable speed (24° to 1 deg/min) depending on the intensity of the reflection (Syntex $2\theta/\theta$ autocollection program). The majority of the reflections were measured at a speed of 1 deg/min. A 2θ scan range of 1.2 below Kα_1 and 1.2 over Kα_2 was se-

*The anisotropic thermal parameters are in the form $\exp(-h^2\beta_{11} - k^2\beta_{22} - l^2\beta_{33} - 2hk\beta_{12} - 2hl\beta_{13} - 2kl\beta_{23})$.
†Standard deviations are given in parentheses.

lected. The background time to scan time ratio was 0.30. During the data collection, three standard reflections (0, 6, 1; 3, 1, −1; and 0, 1, −3) were measured after every 47 reflections. Their variations were less than 2% from their respective means. The 3461 independent measurements reduced to a set of 3307 independent reflections after taking out the systematically absent reflections. The 703 reflections for which the intensity was less than 2.5 $\sigma(I)$ were considered as unobserved. The standard deviation $\sigma(I)$ was calculated in the following manner.

$$\sigma^2(I) = \frac{1}{\tau}\left\{\left(T + \frac{B}{(\mathrm{BSR})^2}\right)\mathrm{SCRT}^2 + (pN)^2\right\}$$

τ = transmission coefficient, T = total count, B = total background count, N = net count, BSR = background to scan time ratio, SCRT = scan rate, p = 0.04 long term instability constant. Finally, 2622 independent observed reflections remained. An absorption correction based on the equations of the crystal faces was then applied. The transmission factors varied from 0.2123 to 0.2988. The data were finally corrected for the Lorentz and polarization effects. The scattering factors for platinum, chlorine, sulfur, oxygen, and carbon were those of Cromer and Waber (7). The anomalous dispersion terms of platinum ($\Delta f' = -2.05$, $\Delta f'' = 8.43$), chlorine ($\Delta f' = +0.15$, $\Delta f'' = 0.19$), and sulfur ($\Delta f' = +0.13$, $\Delta f'' = 0.16$) (8) were included in the calculations.

Structure Determination

The platinum atom was easily located from the three-dimensional Patterson map. The positions of all other atoms except the hydrogen atoms, were obtained by structure factor and Fourier map calculations. The refinement of the parameters was carried out by full matrix least-squares calculations. In the early stages of refinement, unit weight was assigned to all observed reflections. Individual weights w according to the equation $1/w = a + bF_o + cF_o^2$ were later calculated. a, b, and c were adjusted to make the distribution of $w|\Delta F|^2$ constant with respect to $|F_o|$ and $\sin\theta/\lambda$ ($a = 35.0$, $b = -0.52$, and $c = 0.022$). An isotropic secondary extinction correction (9) was also introduced. The hydrogen atoms on the terminal methyl groups could not be localized. The refinement of the scale factor, the coordinates, and anisotropic temperature factors of all nonhydrogen atoms converged to $R = \Sigma(|F_o| - |F_c|)/\Sigma|F_o|$ of 0.029 and a weighted residual $R_w = [\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2]^{1/2}$ of 0.027.[1] The standard deviation of an observation of unit weight is 0.809. The final difference Fourier map using all observed reflections did not show peaks higher than ±1 e/Å^3. The refined parameters are given in Table 1.

The calculations were performed with a CDC 6400 computer. The following programs were used: NRC crystallographic programs (10), NUCLS, a modified version of ORFLS, and Zalkin (FORDAP).

Results and Discussion

As expected, the analyzed complex is the *cis* compound and the dimethylsulfoxide molecules are bonded to the platinum atom through sulfur. A stereoscopic view of the molecule is shown in Fig. 1. Two chlorine and two sulfur atoms form the square planar coordination expected for Pt(II) complexes. The weighted best plane was calculated through the platinum, the two chlorine, and the two sulfur atoms. The deviations from this plane are: Pt, 0.0038 (3); Cl_1, −0.120 (2); Cl_2, −0.012 (3); S_1, −0.077 (2); and S_2, −0.007 (2).

The bond distances and angles are listed in Table 2. The angles around the platinum atom are close to the expected 90 and 180°, but there seems to be some slight deviation from the ideal square planar coordination (angles Cl_1—Pt—S_1 = 174.84° and Cl_2—Pt—S_2 = 176.29°).

The Pt—Cl bonds (2.306 and 2.312 Å) are of normal lengths (11–13). The Pt—S bonds (2.244 and 2.229 Å) seem also normal. To our knowledge, this is the first crystal structure work on a platinum complex with DMSO. Two similar structures in which DMSO is complexed to

palladium have been reported (4, 14). The Pt—S distances are identical to the Pd—S distances found for *cis*-[$Pd(NO_3)_2(DMSO)_2$] (2.231 and 2.253 Å) (14) and slightly shorter than the Pd—S bonds found for *trans*-[$PdCl_2(DMSO)_2$] (2.299 and 2.291 Å) (4).

The sulfur atoms in the DMSO molecules are in an approximate tetrahedral environment with angles ranging from 99.5 to 110.3°. The structure of the coordinated molecules is very similar to the structure of DMSO itself. Two determinations of the crystal structure of free DMSO have yielded S—O distances of 1.471 Å (ref. 15, determined at −60°) and 1.531 Å (ref. 16, determined at +5°). It has been suggested (4) that the latter value is more reliable for comparison with structures determined at room temperature. The S—O distances for the platinum complex are 1.469 and 1.454 Å. These distances are very similar to the S—O distances found for *trans*-

Cinétique de la formation de la métalloporphyrine Cu(II) – hématoporphyrine IX dans l'acide acétique aqueux

GUY PAQUETTE ET MIKLOS ZADOR

Département de Chimie, Université de Montréal, C.P. 6210, Station A, Montréal, Québec H3C 3V1

Reçu le 28 février, 1975

GUY PAQUETTE et MIKLOS ZADOR. Can. J. Chem. **53**, 2375 (1975).

La cinétique de l'interaction de l'hématoporphyrine IX avec le Cu(II) a été étudiée dans un mélange acide acétique – eau (50%–50% v/v). La réaction est d'ordre un par rapport à la porphyrine et d'ordre inférieur à un par rapport au perchlorate cuivrique. Ceci est expliqué en tenant compte de l'interaction de l'ion Cu^{2+} avec l'acide acétique. Les espèces réactives sont Cu^{2+}, $CuOAc^{+}$ et la porphyrine libre. Le mécanisme de la réaction est comparé à ceux proposés pour d'autres systèmes similaires.

GUY PAQUETTE and MIKLOS ZADOR. Can. J. Chem. **53**, 2375 (1975).

The kinetics of interaction of hematoporphyrin IX with Cu(II) has been studied in an acetic acid – water solvent (50%–50% v/v). The reaction is of first order with respect to the porphyrin whereas the order with respect to copper(II) perchlorate is smaller than one. This is explained by taking into account the interaction between Cu^{2+} and acetic acid. The reactive species are Cu^{2+}, $CuOAc^{+}$, and free porphyrin. The mechanism of the reaction is compared to those proposed for similar systems.

Introduction

Les métalloporphyrines jouent un rôle important dans les organismes vivants, aussi bien animaux (*e.g.* l'hémoglobine dans le sang) que végétaux (*e.g.* la chlorophylle des plantes vertes). Le mécanisme de formation des métalloporphyrines n'est pas encore connu avec certitude (1). En général leur vitesse de formation est de plusieurs ordres de grandeur plus faible que celle de complexes impliquant des bases azotées simples.

Dans l'étude du mécanisme de formation des métalloporphyrines, un des problèmes principaux vient du fait qu'en général les porphyrines sont très peu solubles dans l'eau; l'utilisation d'autres solvants entraîne des problèmes quant à la nature des espèces réactives. Il est difficile, par exemple, de comparer les résultats obtenus dans l'eau, avec une porphyrine soluble, avec ceux obtenus dans l'acide acétique glacial; dans ce dernier solvant la porphyrine (telle l'hématoporphyrine IX) porte deux charges positives et, en plus, les ions métalliques se trouvent souvent sous forme de dimères (2–8).

Dans ce travail, les résultats concernant l'interaction de l'hématoporphyrine IX avec le Cu(II) dans l'acide acétique aqueux (50% v/v), sont présentés. Un des aspects de cette réaction qui a été approfondi concerne l'influence des interactions acide acétique – Cu(II) sur la cinétique de la réaction étudiée.

Partie expérimentale

Réactifs

La solution de perchlorate cuivrique a été obtenue en additionnant la quantité requise d'acide perchlorique (J. T. Baker) à la solution du sel double $CuCO_3 \cdot Cu(OH)_2$ (B.D.H.) en amenant le p*H* final à 4. L'hématoporphyrine IX (Nutritional Biochemicals) a été utilisée sans purification.

Les solutions finales sont constituées d'eau et d'acide acétique (C-I-L, Reagent) 50%–50% (v/v).

Méthode cinétique

Les réactions sont étudiées à 45° par spectrophotométrie en enregistrant la diminution de l'absorption de la bande Soret de l'hématoporphyrine ($\lambda = 407$ nm), due à la formation de la métalloporphyrine. Un spectrophotomètre Zeiss PMQ II, avec un compartiment à cellules thermostaté a été utilisé. La température à l'intérieur des cellules a été mesurée à l'aide d'un thermocouple. Les résultats ont été enregistrés sur un enregistreur logarithmique Sargent Welsh modèle SRLG. La concentration en porphyrine utilisée était de 4.0×10^{-6} *M*, tandis que celle de Cu(II) variait de 2.5×10^{-4} à 2.5×10^{-2} *M*. Les constantes de vitesse ont été obtenues à partir de la relation $kt = \ln [(D_0 - D_\infty)/(D - D_\infty)]$ où D_0, D et D_∞ représentent les densités optiques au temps 0, t et infini, respectivement. On obtenait des relations linéaires sur plus de trois demi-réactions. La force ionique des solutions a été maintenue constante ($\mu = 0.5$ *M*) à l'aide de perchlorate de lithium (Alpha Inorganics). Ceci est indispensable, étant donné que les expériences ont montré que l'augmentation de la force ionique entraîne une diminution de la vitesse de réaction.

Résultats et discussion

La réaction de l'hématoporphyrine IX (PH_2) avec le Cu(II) se fait d'après l'équation:

[1] $$PH_2 + Cu(II) \rightarrow P \cdot Cu(II) + 2H^+$$

Quand la réaction est réalisée en présence d'un grand excès de Cu(II), on obtient une cinétique d'ordre un par rapport à la porphyrine.

$$d[P \cdot Cu(II)]/dt = k_{exp}[PH_2]_{total}$$

La constante de vitesse expérimentale, k_{exp} varie linéairement avec la concentration en Cu(II) aux basses concentrations; à plus haute concentration en Cu(II) on observe un écart important à la linéarité, comme l'indique la fig. 1.

Un ordre de réaction inférieur à un par rapport au sel métallique a souvent été observé dans l'acide acétique glacial (2–6); on l'a expliqué de manière satisfaisante en admettant une dimérisation prononcée du sel utilisé. La concentration du monomère réactif est donnée par la relation $[Me(OAc)_2] = \sqrt{K[(Me(OAc)_2)_2]}$, ce qui conduit à un ordre $\frac{1}{2}$. Dans un solvant, contenant 50% (v/v) d'eau et 50% (v/v) d'acide acétique, on ne peut pas retenir cette explication. En effet les données concernant l'acide acétique aqueux, indiquent (7, 8) que dans nos conditions, même à la concentration la plus élevée, il y a moins de 10% de dimère.

On peut expliquer nos résultats en tenant compte de l'interaction du Cu(II) avec le solvant, soit l'acide acétique. L'ion Cu^{2+}, provenant du perchlorate cuivrique utilisé, réagit avec l'acide acétique pour donner les espèces $Cu(OAc)^+$ et $Cu(OAc)_2$.[1]

[2] $$Cu^{2+} + HOAc \rightleftharpoons CuOAc^+ + H^+$$
$$K_1 = [CuOAC^+]/[Cu^{2+}][OAc^-]$$

[3] $$CuOAc^+ + HOAc \rightleftharpoons Cu(OAc)_2 + H^+$$
$$K_2 = [Cu(OAc)_2]/[CuOAc^+][OAc^-]$$

Les protons libérés dans les réactions 2 et 3 déplacent l'équilibre de protonation de la porphyrine vers la formation de PH_4^{2+}, d'après la réaction 4.

[4] $$PH_2 + 2H^+ \rightleftharpoons PH_4^{2+}$$
$$K_3 = [PH_4^{2+}]/[PH_2][H^+]^2$$

Déjà dans l'acide acétique – eau 50%–50% (v/v), correspondant à une concentration en $H^+ = 1.5 \times 10^{-2}$ M d'après la constante dissociation de l'acide acétique obtenue par interpolation des valeurs de la littérature (9), l'équilibre 4 est déplacé vers la droite. En effet, la solution de l'hématoporphyrine présente deux bandes dans le visible, ce qui est caractéristique du diacide, PH_4^{2+}; les résultats de la littérature (10) indiquent une constante de protonation ($pK_a = 4.7$) qui serait en accord avec cette hypothèse.

La quantité de protons libérés augmente avec la concentration en Cu(II), contribuant ainsi à diminuer la concentration de la forme réactive de la porphyrine, PH_2. Ceci explique qualitativement l'ordre un à basse concentration en Cu(II) et l'écart subséquent à la linéarité à la fig. 1.

Pour confirmer ces hypothèses on a étudié l'influence de l'acide perchlorique à basse concentration en Cu(II) (5×10^{-4} M). Dans ces conditions, la quantité de protons libérés dans [2] et [3] est négligeable. Les résultats sont montrés à la fig. 2.

La concentration en H^+ représente celle à l'équilibre, calculée en tenant compte de l'acide fort ajouté et de la dissociation de l'acide acétique. Il y a une inhibition marquée, correspondant à un ordre approximatif -2 par rapport à H^+. De plus, à haute concentration en $HClO_4$, (1 M) la vitesse de réaction est négligeable; à une concentration en Cu(II) de 2.5×10^{-2} M il y a moins de 1% de réaction en deux jours. Ceci indique que pour l'hématoporphyrine IX la pro-

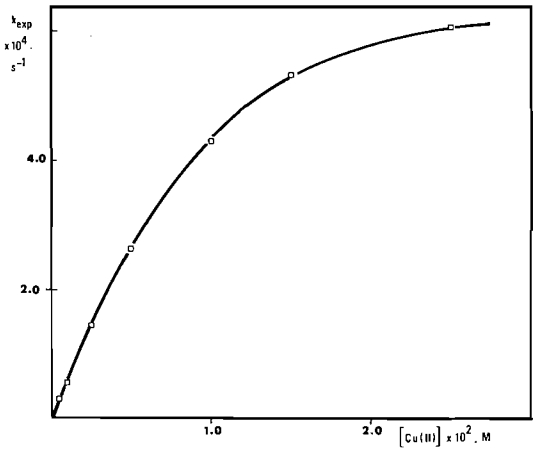

FIG. 1. Influence de la concentration en Cu(II) sur k_{exp}. $T = 45°$, $[PH_2] = 4.0 \times 10^{-6}$ M; solvant: CH_3COOH–H_2O 50%–50% (v/v).

[1]La constante d'équilibre des réactions 2 et 3 est reliée aux constantes de stabilité des complexes $CuOAc^+$ et $Cu(OAc)_2$ en tenant compte de la dissociation de l'acide acétique.

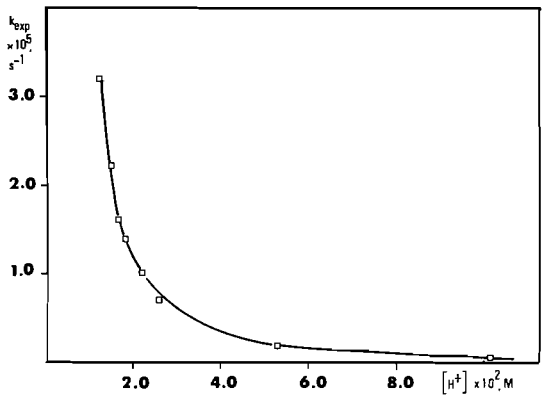

FIG. 2. Influence de l'acidité sur k_{exp} à basse concentration en Cu(II). $T = 45°$, $[PH_2] = 4.0 \times 10^{-6}$ M, [Cu(II)] $= 5.0 \times 10^{-4}$ M; solvant: CH_3COOH–H_2O 50%–50% (v/v).

tonation conduit à une espèce (PH_4^{2+}) très peu réactive dont la contribution à la vitesse peut être négligée, même à une acidité de 0.1 M.

L'espèce monoprotonée, PH_3^+ ne semble pas avoir une contribution. Cette espèce a été observée dans l'acide acétique glacial en présence d'ions métalliques, mais disparaît immédiatement lors de l'addition d'eau au solvant (11). Dans notre cas les spectres observés sont ceux de PH_4^{2+}, et ceci même en présence de Cu^{2+}. Si PH_3^+ contribuait à la vitesse de manière importante, l'inhibition par H^+ devrait correspondre à un ordre -1, au lieu de l'ordre -2 qui a été observé.

Quand on étudie la réaction à cette acidité de 0.1 M la contribution des protons libérés lors de l'interaction du Cu(II) avec l'acide acétique est moins importante; l'ordre par rapport au Cu(II) est alors très près de un dans toute la gamme de concentration (5×10^{-4} à 2.5×10^{-2} M). L'interprétation quantitative des résultats est donc basée sur les hypothèses suivantes: (*i*) PH_2 est la seule forme réactive de la porphyrine; (*ii*) les espèces réactives du Cu(II) sont Cu^{2+}, $CuOAc^+$ et $Cu(OAc)_2$; ceci conduit à l'éq. 5.

$$[5]\quad d[P \cdot Cu(II)]/dt = (k_1[Cu^{2+}] + k_2[CuOAc^+] + k_3[Cu(OAc)_2])[PH_2]$$

En tenant compte des éqs. 1–4 on obtient l'éq. 6.

$$[6]\quad k_{exp} = \frac{k_1 + k_2K_1K_a[HOAc]/[H^+] + k_3K_1K_2K_a^2[HOAc]^2/[H^+]^2}{(1 + K_3[H^+]^2)(1 + K_1K_a[HOAc]/[H^+] + K_1K_2K_a^2[HOAc]^2/[H^+]^2)}\,[Cu(II)]_{total}$$

Evidemment, pour que l'éq. 6 puisse être utilisée à haute concentration en Cu(II), il faut tenir compte, dans le calcul de la concentration en H^+ à l'équilibre, de la contribution des protons libérés dans les réactions 2 et 3. Malheureusement, on ne connait pas la valeur des constantes d'équilibre K_a, K_1 et K_2 dans le solvant utilisé et à la force ionique de 0.5 M.

On a donc procédé par une méthode itérative, en prenant, comme première approximation, les valeurs de constantes dans l'eau, c'est-à-dire $K_1 = 46$ et $K_2 = 10$ (12), et $K_a[HOAc] = 2.25 \times 10^{-4}$ donnée pour ce solvant à force ionique nulle (9). De plus, on a négligé 1 devant $K_3[H^+]^2$, ce qui est justifié comme on l'a vu plus haut.

Pour pouvoir obtenir des valeurs significatives des paramètres, les constantes de vitesse ont été déterminées à huit acidités différentes; à chaque acidité on a étudié sept concentrations en Cu(II). L'ajustement final des paramètres a été effectué par ordinateur.[2]

On a obtenu les valeurs suivantes des paramètres $k_1/K_3 = 8.2 \times 10^{-6}$ $M\,s^{-1}$, $k_2/K_3 = 1.2 \times 10^{-5}$ $M\ s^{-1}$, $K_a[HOAc] = 1.6 \times 10^{-4}$ M, $K_1 = 100\ M^{-1}$, $K_2 = 2\ M^{-1}$. L'accord entre les résultats expérimentaux et calculés est satisfaisant, comme on peut le constater sur le tableau 1. Il est significatif que, dans un domaine où les constantes de vitesse varient d'un facteur de plus de mille, on obtienne un bon accord. Compte tenu de l'erreur expérimentale, la valeur de k_3/K_3 est négligeable devant les autres valeurs; $Cu(OAc)_2$ n'a donc pas de contribution à la vitesse dans nos conditions. De plus, $Cu(OAc)_2$ n'est pas une espèce dominante, ce qui rend impossible la détermination de k_3/K_3, déjà petit.

[2]Le programme consiste à résoudre l'équation de quatrième degré donnant la concentration en H^+ à l'équilibre pour l'ensemble des paramètres K_a, K_1 et K_2; la concentration en H^+ et les paramètres sont introduits dans l'éq. 6 et les valeurs de k_1/K_3, k_2/K_3 et k_3/K_3 sont obtenues par une méthode de régression. L'écart entre les valeurs des constantes de vitesse calculées à l'aide de l'éq. 6, et expérimentales est minimisé par une méthode d'itération. Le programme a été mis au point par le professeur Urs Maag, du département d'informatique de l'Université de Montréal.

Ceci n'exclue cependant pas la possibilité que $Cu(OAc)_2$ soit l'espèce responsable de l'incorporation dans l'acide acétique glacial, tel que suggéré par plusieurs auteurs (5, 6); dans ces conditions les concentrations en Cu^{2+} et $CuOAc^+$ seraient de loin inférieures à celle de $Cu(OAc)_2$, et malgré une constante de vitesse plus faible, $Cu(OAc)_2$ peut contribuer de manière prépondérante à la réaction dans ce solvant.

Il faut également ajouter que la valeur de la constante de vitesse calculée est relativement peu sensible à la valeur de K_2; cette constante est donc entachée d'une erreur assez grande ($\pm 100\%$).

L'écart entre résultats expérimentaux et valeurs calculées dépend de manière très sensible des valeurs de K_1 et de K_a[HOAc]; ces constantes sont obtenues avec beaucoup moins d'incertitude ($\pm 20\%$); ceci est également valable pour k_1/K_3 et k_2/K_3. Il est regrettable que K_3 ne puisse pas être connu, mais dans le solvant, l'hématoporphyrine est déjà protonée. De plus, la valeur absolue obtenue dans l'eau, ou dans l'eau contenant 10% (v/v) d'éthanol (10) ne peut pas être utilisée dans notre solvant, d'autant plus que la possibilité de formation de dimères, aux concentrations relativement élevées utilisées par les auteurs, ne peut pas être exclue.

Il est intéressant de comparer nos résultats avec ceux de Hambright et collaborateurs (13) qui ont étudié l'incorporation du Cu(II) dans la tétra(*p*-sulfophényl)porphine, en présence d'acide acétique et d'ions acétate dans l'eau.

Tout d'abord on constate quelques analogies; dans les deux cas on a, comme espèces réactives, l'ion Cu^{2+} et le complexe $CuOAc^+$. La constante de vitesse de ces deux espèces est identique chez les auteurs ($k_1 = k_2$), tandis que nous trouvons une différence, $k_2 > k_1$; les deux constantes sont toutefois du même ordre de grandeur. Il est à noter que ceci est probablement le résultat de la différence de charge entre les deux porphyrines. Dans notre cas, la porphyrine réagissant n'est pas chargée et $CuOAc^+$ est le plus réactionnel; les quatre charges négatives des groupes $-SO_3^-$ de la tétra(*p*-sulfophényl)-porphine, devraient favoriser, sur la base d'interactions électrostatiques, l'espèce ayant la charge la plus élevée, c'est-à-dire le Cu^{2+}; ceci explique donc qualitativement les différences observées.

Il y a toutefois des différences considérables entre les deux systèmes. Hambright et collaborateurs trouvent une contribution importante à la vitesse d'incorporation, de l'espèce diprotonée, correspondant à PH_4^{2+}. En effet la constante de vitesse d'incorporation du $CuOAc^+$ ne diminue que d'un facteur d'environ 40 quand on passe de PH_2 à PH_4^{2+} (13).[3] Ceci amène les auteurs à proposer que l'acide acétique est un bon solvant pour la formation des métalloporphyrines, parce que l'ion acétate présent catalyse la réaction du Cu(II) avec les porphyrines diprotonées.

Dans notre cas la réactivité de PH_4^{2+} n'est pas mesurable. Si l'on tient compte du fait que $CuOAc^+$ représente environ 16% du Cu(II) à une concentration en $HClO_4$ de 0.1 *M* il est clair que l'absence de contribution d'une réaction entre PH_4^{2+} et $CuOAc^+$ est due au fait que la forme diprotonée de l'hématoporphyrine IX est inerte. D'ailleurs c'était également la conclusion d'une étude précédente de Hambright et James sur cette porphyrine (6). La réactivité relativement élevée de la forme diprotonée de la tétra(*p*-sulfophényl)porphine est facile à comprendre, si l'on tient compte de la délocalisation des charges dans ce système conjugué; en effet, la charge totale est de -2 (entre p*H* 3.5 et 5), si l'on tient compte des quatre charges négatives; il est normal alors qu'elle soit réactive. Il est normal aussi que, relativement au cas de la forme non-protonée, l'ion $CuOAc^+$ soit plus réactif que l'ion Cu^{2+}. Evidemment, il n'est pas facile d'expliquer pourquoi la réactivité tombe à zéro pour le Cu^{2+} (13).

La comparaison de nos résultats avec ceux impliquant d'une part l'hématoporphyrine IX dans l'acide acétique glacial (5, 6) et, d'autre part, la tétra(*p*-sulfophényl)porphine dans l'eau (13) indique qu'il n'est pas possible de faire des généralisations quant au mécanisme d'incorporation du métal. Notamment la nature exacte des espèces réactives dépend de la porphyrine considérée et du solvant utilisé.

Les auteurs remercient le Conseil national de recherches du Canada pour la subvention accordée (M.Z.) et pour la bourse d'études post-graduées (G.P.). Le Ministère de l'Education du Québec est remercié pour la subvention accordée (M.Z.). Le professeur Urs Maag, du département d'informatique, de l'Université de Montréal est remercié pour avoir mis au point le programme utilisé.

[3]L'explication originale des auteurs (12) implique une réaction avec Cu^{2+}, catalysée par l'ion OAc^-, qui ne peut pas être distinguée cinétiquement d'une réaction impliquant $CuOAc^+$.

Iminosulfuranes (Sulfilimines) Infrared and Ultraviolet Spectroscopic Studies

JITENDRA J. SHAH

Woodson-Tenent Laboratories, Inc., P.O. Box 2135, Memphis, Tennessee 38101

Received February 10, 1975

JITENDRA J. SHAH. Can. J. Chem. **53**, 2381 (1975).

This paper reports the i.r. and u.v. spectra of several *N*-*p*-tolylsulfonylsulfilimines and several new *N*-*p*-ethylbenzenesulfonylsulfilimines have been examined.

JITENDRA J. SHAH. Can. J. Chem. **53**, 2381 (1975).

On a étudié plusieurs *N*-*p*-toluènesulfonyl et *N*-*p*-éthylbenzènesulfonylsulfilimines par spectroscopie infra-rouge et ultraviolette. [Traduit par le journal]

Introduction

Sulfilimines are known as sulfur–nitrogen ylides or ylenes. The *N*-acyl derivatives are especially well known compounds and i.r. (1), u.v. (2), and X-ray data (3) of these have been accumulated in recent years. Four characteristic i.r. absorption bands due to both sulfonyl and sulfilimino groups have been observed and those due to both N—S (IV) and N—S (VI) stretching vibrations appear at nearly the same positions and overlap each other. The configuration of *N*-sulfonylsulfilimine is not established, though the S—N bond has been postulated from an i.r. spectroscopic study (1) to have a double bond character. The u.v. spectra suggest that the sulfilimino group is not an electron donor but an electron acceptor group when conjugated with a phenyl ring.

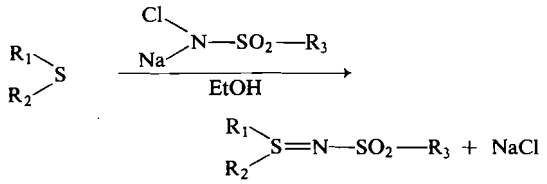
We have found the amino acids L-methionine and L-cysteine, thioxanthone, diphenylenemethane sulfide, phenothiazine, and phenarsazine chloride to react with chloramine-B, chloramine-T, and a new reagent *N*-chloro-*N*-sodio-*p*-ethylbenzenesulfonamide to obtain the corresponding sulfilimines. We have examined i.r. and u.v. spectra of various sulfilimines and P, As, and Sb analogs.

This paper describes some new data and their relation to structures of different types of sulfilimines.

Experimental

Preparation of Sulfilimines (4)

All the sulfilimines were prepared from the corresponding sulfides and chloramines in the presence of ethyl alcohol. The melting points of sulfilimines are listed in Table 1.



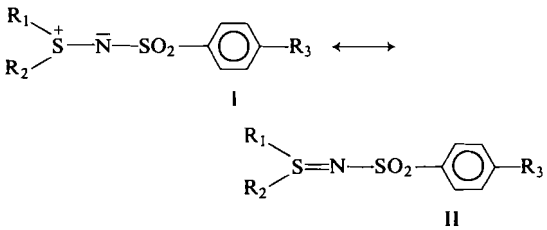
Preparation of Arsinimines and Stibinimines (5)

All the arsinimines and stibinimines were prepared from the reaction of corresponding arsines or stibines with chloramines in the presence of alcohol. The melting points of arsinimines and stibinimines are listed in Table 1.

Results and Discussion

Infrared Spectra

The general *N*-sulfonylsulfilimines may be formulated by either the ylide structure, the ylene structure, or by the resonance hybrid of both.



All the sulfilimines have four strong characteristic i.r. absorption bands at around 930–970, 1070–1090, 1130–1140, and 1260–1280 cm^{-1}, respectively. Tsujihara (6) and others have recently examined i.r., u.v., and n.m.r. spectra of various *N*-sulfonylsulfilimines. The two bands 1130–1140 and 1260–1280 cm^{-1} are assigned to symmetrical and asymmetrical stretching vibrations of the SO_2 group. The first band 939–

980 cm^{-1} has been assigned to the stretching vibration of the N—S(IV) group by Kucsman *et al.* (1) though there are controversies in the assignment of the absorption of S—N stretching vibrations (7, 8).

In the i.r. spectra of *N*-sulfonylsulfilimines ($R_1R_2SNSO_2C_6H_4R_3$, R_1,R_2 = alkyl or aryl group; R_3 = —H, —CH_3, —C_2H_5) the S—N band appears at 930–1012 cm^{-1}. The R_3 groups exert on the S—N and SO_2 groups an inductive effect whereas the R_1 and R_2 groups exert on the S—N group both inductive and conjugative effects. In some of these *N*-*p*-tolyl- and *N*-benzylsulfonylsulfilimines the S—N band appears in the narrow range at 935–987 cm^{-1} (slightly higher wave numbers for the *N*-benzyl derivatives) suggesting the S—N double bond of structure **II** rather than the semipolar bond of structure **I**. The exact position of the band shifts with the nature of R_1 and R_2, generally to lower wave numbers with donor groups and to higher wave numbers with acceptors. In a series of dihaloacetyl sulfilimines ($X_2CHCON{=}SR_1R_2$, where X = Cl,Br) the S—N band is shifted to about 800 cm^{-1} and its position is not influenced by the nature of R_1 and R_2.

The formation of S=N bond is connected with a band near 974 cm^{-1} in the spectra of *S*,*S*-diallyl-*N*-*p*-tolylsulfonylsulfilimines and the spectra of *N*-allyl-*N*-allylthio-*p*-tolylsulfonylsulfilimines. Migration of the allyl absorption appears to have occurred out of the region (9) and instead of this a new band at 830 cm^{-1} appears which corresponds to the $-\overset{+}{S}-\bar{N}-$ single bond. In the spectrum of *S*,*S*-diallyl-*N*-*p*-tolylsulfonylsulfilimine the S—N band is obtained at 974 cm^{-1} between two other bands at 933 and 985 cm^{-1}.

The latter are the wagging vibrations of the hydrogen atoms of the $CH_2{=}CH{-}CH_2$— group. Kucsman argued that the SO_2* band in sulfilimine appears at a wave number considerably higher than that in sulfonate although it might be predicted that both SO_2 bands in the system $-SO_2-\bar{N}$ and $-SO_2-\bar{O}$ would appear in the same region. In the reactions (10) of sulfur dichloride with aromatic and heterocyclic amines and with carboxyamides and sulfamides containing substituents that are stable to chlorination, the corresponding *N*-substituted-*S*,*S*-dichlorosulfilimines are obtained. These sulfilimines have a higher frequency for the S=N band than for other sulfilimines.

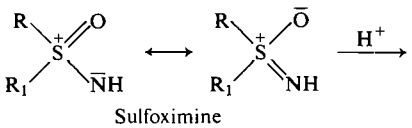
$$SO_2^* = \tfrac{1}{2}(\nu_{sym}\,SO_2 + \nu_{asym}\,SO_2)$$

Chloramine-T has four characteristic bands at (ν_{asym} SO_2) 1255 cm^{-1}, (ν_{sym} SO_2) 1130, 1083 cm^{-1}, (ν S=N) 929 cm^{-1}, while a new *N*-chloro-*N*-sodio-*p*-ethylbenzenesulfonamide has also four characteristic bands at (ν_{asym} SO_2) 1250 cm^{-1}, (ν_{sym} SO_2) 1145, 1090 cm^{-1}, (ν S=N) 935 cm^{-1}.

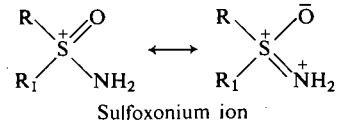
The characteristic i.r. spectra of several sulfilimines, a new *N*-chloro-*N*-sodio-*p*-ethylbenzenesulfonamide and other related compounds are listed in Table 1.

Ultraviolet Spectra

In the u.v. spectra there is practically no shift of λ_{max} when R_1 and R_2 change from dialkyl to alkylphenyl or diphenyl. The resonance interaction between the lone pair of electrons on the sulfur atom with the phenyl ring is well known in sulfides (11*a* and 11*b*, p. 474). The u.v. spectra of a series of oxysulfilimines have been reported (12) and claimed to provide evidence for the use of 3d orbitals of sulfur. The sulfoximines have been assigned a near tetrahedral configuration (13, 14), and by analogy with the known sulfone geometry (15), a coplanar conformation of the two phenyl rings has a low probability.



Sulfoximine



Sulfoxonium ion

The conjugation mechanism indicated is donation of carbon p orbitals into suitable unoccupied sulfur d orbitals (11*b*, p. 466). The sulfur atom again acts as an acceptor. This postulated donor–acceptor mechanism is strengthened by the enhanced bathochromic shift of when R = $H_2N{-}C_6H_4$— and R_1 = C_6H_5. In aqueous solution the spectra are very similar to those in ethanol, but in acid the sulfoximines showed slight

bathochromic shifts. It is known that the spectra of 4-*p*-aminophenyl methyl sulfone (16) and 4-aminophenyl sulfone (17) revert precisely to that of the parent sulfone in acid solution, the added proton forming the corresponding anilium ions. The spectra of the aminophenyl sulfoximines show that the site of attachment of the proton is the sulfoximine nitrogen. This will increase the formal charge near or on the sulfur and the bathochromic shifts observed are thus due to this enhancement in the acceptor capacity of the sulfur. The improved interaction of d orbitals with p or π orbitals with increased positive charge on the element containing the d orbital has been discussed theoretically (18).

The characteristic u.v. spectra of several sulfilimines, a new *N*-chloro-*N*-sodio-*p*-ethylbenzenesulfonamide and other related compounds are listed in Table 1.

From these i.r. and u.v. spectroscopic studies, *N*-sulfonylsulfilimine is considered to be represented better by the ylide structure in which the charges on the S atom and the N atom are considerably delocalized with strong dπ conjugation into S(IV)—N—S(VI) bondings. Therefore the S—N bond of the sulfilimino group is considered to be essentially semipolar.

The author wishes to thank Woodson-Tenent Laboratories, Inc., for their cooperation and research facilities.

Thione Photochemistry: The *Peri* Cyclization of some Polycyclic Aromatic Thiones[1,2]

A. Cox,[3] D. R. Kemp, R. Lapouyade,[4] P. de Mayo, J. Joussot-Dubien,[5] and R. Bonneau[5]

Photochemistry Unit, Department of Chemistry, The University of Western Ontario, London N6A 5B7

Received March 10, 1975

A. Cox, D. R. Kemp, R. Lapouyade, P. de Mayo, J. Joussot-Dubien, and R. Bonneau. Can. J. Chem. **53**, 2386 (1975).

A number of polycyclic aromatic thiones have been prepared from the corresponding ketones. Several of the thiones in which there is a free *peri* position cyclize, on excitation in the $\pi^* \leftarrow n$ band, to give thiophene derivatives. The structures of these were proven by application of physical methods and by desulfurization to the corresponding benzyl derivatives. The formal hydrogen 1,3 migration involved was, in one case, shown to be intermolecular by the incorporation of deuterium, from deuterium oxide, during the irradiation. In the case of the α-naphthyl derivative, the mechanism of the reaction has been investigated and it has been concluded that the n,π^* singlet is the responsible entity.

A. Cox, D. R. Kemp, R. Lapouyade, P. de Mayo, J. Joussot-Dubien et R. Bonneau. Can. J. Chem. **53**, 2386 (1975).

On a préparé un nombre de thiones polycycliques aromatiques à partir des cétones correspondantes. Plusieurs des thiones, ayant une position *péri* libre, cyclisent par excitation de la bande $\pi^* \leftarrow n$ et conduisent ainsi à des dérivés du thiophène. La preuve de la structure de ces dérivés est obtenue par des méthodes physiques et par désulfurisation jusqu'au dérivés benzyliques correspondants. On a démontré, en incorporant un deutérium par l'eau deutériée pendant l'irradiation, que la migration 1,3 impliquée, dans un cas, se fait par un mécanisme intermoléculaire. Le mécanisme de la réaction est étudié sur le dérivé α-naphtyl; on en déduit que l'état singulet, n,π^* est l'entité responsable. [Traduit par le journal]

The literature records extensive preoccupation over the last 50 years with the photochemistry of the carbonyl group. Only much more recently has the thiocarbonyl group attracted attention and then for a very limited selection of environmental situations.[6]

Up to the present, studies of aromatic thiones have been restricted, essentially, to that of thiobenzophenone and, indeed, with the exception of certain substituted thiobenzophenones and of 1-thiobenzoylnapthalene (2), no other simple substituted aryl thiones were known. We have shown that for the former the lowest triplet state was most probably n,π^*[7] and it is this state that has been generally invoked in the photochemical cycloadditions of most aromatic thiones (4, 5).[8]

We report here the preparation of some polycyclic aromatic thiones and a photocyclization of these substances proceeding through the n,π^* singlet state.

Results and Discussion

The thiones **1***b*–**9***b* were prepared by benzoylation of the appropriate aromatic hydrocarbon, followed by conversion of the ketone to thione with hydrogen chloride and hydrogen sulfide. The ketones, with the exception of **7***a* were known substances. The position of the functional group had, however, not been unambiguously established in the cases of **5***a* and **6***a* (7, 8) and confirmation was obtained as follows. Compound **5***a* was prepared by an alternative route from 3-bromofluoranthene by reaction with cuprous cyanide, followed by Grignard reaction with phenylmagnesium bromide. The structure of 3-bromofluoranthene appeared to be assured

(9, 10). Compound **6***a* was shown to have the indicated structure by oxidation to the known 2-benzoylanthraquinone. Compound **7***a* was not known and assignment of the position of the benzoyl group rests on the known preferred position of attack in perylene and the co-formation of 3,9-dibenzoylperylene.

The salient features of the absorption spectra of the thiones are listed in Table 1. At room temperature all compounds exhibit a relatively weak, structureless, long wavelength absorption which (except for **2***b*) shows a blue shift with increasing solvent polarity (Table 1). This band is characteristic of aromatic thiocarbonyl compounds and has been assigned to the n,π* state (11, see also footnote 7). The absorption spectrum of **1***b* has been previously reported (12).

At 77 K in a rigid matrix of EPA (ether–isopentane–ethanol, 5:5:2), the first absorption band is partially resolved into vibronic bands as has been observed for a number of thioketones and, assuming that the first resolved band is the O—O band, the singlet energies are given in Table 1 together with the spacings between the vibronic bands. In the case of **1***b*, **2***b*, and possibly also in **4***b*, a weak band appeared on the long wavelength side of the (n,π*) band at 77 K. A similar band had previously been observed for a number of thiocarbonyl compounds (13) and has been tentatively assigned to the singlet → triplet transition. Attempts to observe a similar band in the other compounds using more concentrated solutions proved unsuccessful owing to their low solubility.

The luminescent properties of all the compounds have also been measured. These were determined at 77 K in EPA, with the exception of **7***b* where, due to its low solubility, methyl acetate – ether (2:3) was used as solvent. The emission spectrum of **2***b*, observed following excitation at 390 or 550 nm, is shown in Fig. 1, (τ 66 μs). The emission from compound **1***b* is similar to that from **2***b* (see Fig. 1). Compounds **3***b*, **4***b*, and **5***b* show rather weak luminescence, the shape of which is similar to **1***b*, but no lifetime measurements were possible. No thione

luminescence could be detected from **6***b*, **7***b*, and **8***b*. The spectral position and general similarity to the emission observed from other thioketones[7] suggests that the emission is phosphorescence from a $^3(n,\pi^*)$ state. Assuming this to be true, the triplet energies (E_T) are given in Table 1.

All the thiones were excited by irradiation (>520 nm) into the long wavelength (n,π*) band. Products were found for thiones **1***b*, **3***b*, **4***b*, and **7***b*, whereas irradiation 5–10 times longer of the others, led only to recovery of starting material. All the reactive compounds had free *peri* positions, (and were derived from alternant hydrocarbons) and the structures of the products, **1***c*, **3***c*, and **4***c*, indicated that cyclization had occurred at this position; that in **7***c* is assumed by analogy. The structures of the cyclized products followed from their constitutions, their Raney nickel desulfurization to the corresponding known benzyl derivatives and the observation of a signal for a benzylic proton in their n.m.r. spectra close to 6.2 p.p.m. (14) (except in the case of **7***c*, which was found too insoluble for n.m.r. spectrum determination). SCHEME 1

hydrogen atom must be transferred. This could be, in principle, a photochemical 1,3-proton shift (suprafacial) or a two-step intermolecular process. We were able to demonstrate that the transfer could involve a discrete intermediate by showing that the hydrogen transfer could be intermolecular. Irradiation of **1***b* in acetonitrile containing deuterium oxide led, essentially quantitatively, to the incorporation of one deuteron at the benzylic position. We conclude tentatively that the species represented by the formalism **10** is a singlet and dipolar. This, in itself, does not require that the reaction pathway only include singlets since intersystem crossing along the reaction coordinate, facilitated by the presence of the sulfur atom, is not to be excluded.

The multiplicity of the reaction was then studied. The number of triplet quenchers available having suitable energies, chemical and spectroscopic properties are few: two, of different types, were selected. The quantum yield of the reaction in benzene is 1.2×10^{-3} (excitation ~577 nm). In the presence of 1.2×10^{-2} M perylene (E_T = 150.5 kJ/mol) a value of 1.29×10^{-3} was obtained: identical with the unquenched reaction within experimental error. In the presence of cyclooctatetraene (0.29 M) the quantum yield remained at 1.28×10^{-3} and increase of quencher concentration to 0.59 M produced no change. Now, in the case of quenching by perylene, assuming the quenching to be diffusion controlled, then it should have been observed with a species of lifetime of the order of 10^{-8} s, or longer. With the same assumption for cyclooctatetraene, quenching should have been observed for a triplet of lifetime $> 10^{-9}$ s. Some doubt is attached to the use of cyclooctatetraene since its triplet energy is not known exactly. It has been shown, however, that it will quench the lowest triplets of thiobenzophenone and Michler's thione at slightly lower than diffusion controlled rates (16).

It was, thus, necessary to show that the triplet of **1***b* had, indeed, a lifetime which would have permitted quenching.

Several of the compounds were studied by flash photolytic techniques. Using a doubled ruby laser (16) the triplet decay rates determined in cyclohexane at the concentrations used are given in Table 2. A more detailed study was made of compound **1***b* using a tripled neodymium laser (λ 353 nm).[9] In benzene solution and using concentrations up to 1.5×10^{-3} M, a plot was obtained, monitoring the transient at 550 nm, of reciprocal lifetime against concentration. A

[9]The technique used has already been described: see ref. 17.

TABLE 3. Quantum yields of cyclization of **1***b*

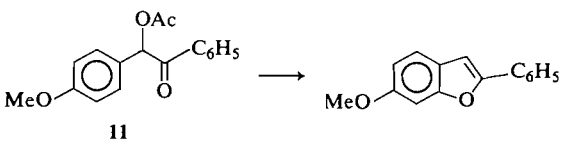
Concentration ($M \times 10^3$)	Solvent	Quantum yield ($\Phi \times 10^3$)
4.8	Benzene	1.20±0.1
4.4	Benzene–MeOH (4:1)	1.80±0.1
4.3	Benzene–HOAc (4:1)	1.47
4.4	CH_3CN	2.61
4.4	CH_3CN–HOAc (4:1)	3.0
4.8	Benzene (1.2×10^{-2} perylene)	1.29
4.8	Benzene (0.29 *M* COT)	1.28
4.8	Benzene (0.588 COT)	1.30

unimolecular decay rate of $1.0 \pm 0.1 \times 10^7\ s^{-1}$ resulted, together with a bimolecular rate constant for quenching of the triplet by ground state thione of $1.8 \pm 1 \times 10^9\ M^{-1}\ s^{-1}$. The latter as observed with the triplets of other aromatic thiones (16) and of adamantanethione (18) was close to diffusion controlled. The large error in these determinations is a consequence of the limited concentration range possible.

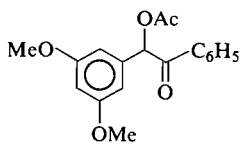
The lifetime of $\sim 10^{-7}$ s should have permitted quenching and it was indeed shown that in $10^{-3}\ M$ solution in benzene, the transient could be quenched by cyclooctatetraene with a bimolecular rate constant of $2.2 \pm 1 \times 10^9\ M^{-1}\ s^{-1}$, also close to diffusion controlled. Since no quenching was observed in the quantum yield of cyclization measurements one must conclude that the triplet is not involved in this transformation and that the responsible species is the n,π* singlet.

The mechanism as formulated involves charge separation and so might be thought to be facilitated by a polar solvent. Small increases were indeed observed (Table 3) but in the most polar system used, which contained the proton donor acetic acid, the quantum yield was rather more than 2½ times that in benzene, yet nevertheless remained very small. The inefficiency of the process may be due to at least two factors. In the first place the intermediate **10** may be formed inefficiently, the greater part of the singlet energy being lost in rapid intersystem crossing. Alternatively, it may be that the intermediate **10** is formed efficiently but reverts almost equally efficiently to the ground state, the overall process being an intramolecular chemical quenching. Under such circumstances the intersystem crossing yield would be low and this would be compatible with the weak emissions observed and in particular with the important difference in intensity of emission between **1***b* and **2***b*.

The question arises as to why a similar reaction is not observed for ketones. The explanation may be, aside from geometrical changes caused by changing oxygen for sulfur, that a lowest n,π* state is required, and that in virtually all polycyclic aromatic ketones in which this might be observed the lowest energy singlet state is π,π*. The exception is that of the 1-benzoylnaphthalene but even here the n,π* and π,π* states may be close enough to perturb each other.



11



12

To induce the cyclization with a ketone it is required that the aromatic nucleus be separated from the ketone by a saturated carbon to provide both the equivalent of a *peri* position, and to maintain a lowest n,π* singlet state. Such a process has, in fact, been realized by Sheehan *et al.* (19). In their case, however, that of **11**, the reaction is completely quenchable whilst that of **12** is not. As discussed by the authors this either indicates a change of state, or a lifetime $> 10^{-10}$ s for a reactive triplet in the second case.

Experimental Section

General

Melting points were determined on a Kofler block and are uncorrected. Mass spectra were obtained on a Varian M66 spectrometer.

The apparatus used for the recording of emission spectra has been described elsewhere.[7] For the present work an RCA C31034 photomultiplier was used cooled to $-35°$. Samples for emission studies or flash photolysis were degassed by the freeze–pump–thaw method to a residual pressure of $< 5 \times 10^{-5}$ Torr.

The apparatus for nanosecond flash photolysis incorporated a pulsed ruby laser, frequency doubler, a model 82-410 Jarrell-Ash monochromator, together with a Xe arc pulsing unit (Northern Precision). The microsecond flash apparatus utilized a Spex monochromator equipped with an EMI 6256B photomultiplier.

Materials

1-Benzoylnaphthalene (**1***a*) was prepared as described previously (20), m.p. 75° (lit. (20) m.p. 76°) and shown to be free of the 2-benzoyl derivative by t.l.c. The 2-benzoylnaphthalene (**2***a*) (Pfalz and Bauer) was crystallized from MeOH, m.p. 80° (lit. (21) m.p. 81°). 1-Benzoylpyrene (**3***a*), prepared by a reported method (22) was obtained (from ethanol) in two crystalline forms m.p. 127–128° (lit. (22) m.p. 126°) and 118°. The latter on melting and resolidifying had m.p. 127–128° and the latter form was also obtained on sublimation. 6-Benzoylchrysene (**4***a*) (23) had m.p. 191° (lit. (23) m.p. 192°) from benzene–alcohol. 3-Benzoylfluoranthene (**5***a*) (24) was purified by chromatography and crystallized from ethanol, m.p. 128–129° (lit. (24) m.p. 129–130°). 1-Benzoylazulene (**8***a*) (25), 1-amino-4-benzoylnaphthalene (**9***a*) (26), and 1-thiobenzoylnaphthalene (**2***c*) (12) were prepared by reported methods.

3-Cyanofluoranthene

3-Bromofluoranthene (6 g) and CuCN (5 g) in *N*-methylpyrrolidone (50 ml) was maintained at 180° for 5 h and the product poured into aqueous ammonia. Isolation with benzene and chromatography on alumina gave the cyanide, m.p. 114° (lit. (24) m.p. 112°).

3-Benzoylfluoranthene

3-Cyanofluoranthene (2 g) in anhydrous benzene (50 ml) was added to the Grignard reagent from bromobenzene (7.9 g) and magnesium turnings (1.2 g) in 100 ml ether. The mixture was refluxed (4 h) and then decomposed with aqueous sulfuric acid (100 ml, 10 *N*) followed by 5 h further reflux. Isolation with benzene followed by chromatography on alumina gave **5***a* (47%) identical in all respects with that obtained by the previously described procedure.

2-Benzoyl-9,10-dimethylanthracene (8)

This compound (**6***a*) was obtained in two crystalline forms, m.p. 141–142° and 131° (lit. (8) m.p. 145°) from benzene–ethanol. Oxidation with chromic acid in acetic acid gave the anthraquinone, m.p. 217° (lit. (8) m.p. 216–217°).

3-Benzoylperylene (7a)

Anhydrous aluminum chloride (1 g) was added to a solution of perylene (1.8 g) and benzoyl chloride (1 g) in CS_2 (100 ml) and stirred for 3 h at room temperature. After decomposition with water and chromatography of the product on alumina, perylene (67%), **7***a* (20%), and 3,9-dibenzoylperylene (1.5%) (m.p. 291–292°; lit. (27) m.p. 293°) were obtained. The monobenzoyl derivative had m.p. 208°.

Anal. Calcd. for $C_{27}H_{16}O$: C, 90.98; H, 4.53; O, 4.49. Found: C, 90.84; H, 4.57; O, 4.80.

2-Thiobenzoylnaphthalene (2b)

2-Benzoylnaphthalene (1.1 g) was dissolved in 100 ml methanol at $-5°$ (N_2) and HCl and H_2S passed through for 4 h, H_2S passage being continued for a further 4 h. The blue crystals were filtered, dried, and sublimed to give **2***b* (0.9 g) m.p. 79°, whose i.r. spectrum showed no carbonyl band.

Anal. Calcd. for $C_{17}H_{12}S$: C, 82.24; H, 4.87; S, 12.89. Found: C, 82.01; H, 4.76; S, 12.21.

1-Thiobenzoylpyrene (3b)

1-Benzoylpyrene (2 g) was dissolved in a mixtue of 20 ml benzene and 100 ml alcohol, and HCl–H_2S passed through for 5½ h at 0°. After neutralization ($NaHCO_3$) the product was chromatographed on Florisil. Elution with CCl_4 – light petroleum gave black crystals (1.46 g), m.p. 141° (methanol).

Anal. Calcd. for $C_{23}H_{14}S$: C, 85.70; H, 4.38; S, 9.93. Found: C, 85.34; H, 4.56; S, 9.99.

6-Thiobenzoylchrysene (4b)

6-Benzoylchrysene was converted into the thione as described for (**2***b*). The green crystals (2 g, 94%; m.p. 184–185° (benzene–methanol)) showed carbonyl stretch in the i.r.

Anal. Calcd. for $C_{25}H_{16}S$: C, 86.18; H, 4.43; S, 9.19. Found: C, 86.21; H, 4.57; S, 9.48.

3-Thiobenzoylfluoranthene (5b)

This was prepared as was **3***b* in 90% yield and the green crystals had m.p. 142° (benzene–ethanol).

Anal. Calcd. for $C_{23}H_{14}S$: C, 85.70; H, 4.38; S, 9.93. Found: C, 85.85; H, 4.38; S, 10.01.

9,10-Dimethyl-2-thiobenzoylanthracene (6b)

This was prepared as described for **3***b*. It was obtained as black crystals (methanol), m.p. 144–146° (86%). The continuing presence of ketone (i.r.) made it impossible to obtain satisfactory analyses for this compound.

3-Thiobenzoylperylene (7b)

The ketone was treated, in methanol–benzene solution, as for **3***b*. The precipitate which formed (95%) as brown crystals, insoluble in the usual solvents, had m.p. 258°.

Anal. Calcd. for $C_{27}H_{16}S$: C, 81.08; H, 4.33; S, 8.59. Found: C, 81.21; H, 4.43; S, 8.30.

1-Thiobenzoylazulene (8b)

The ketone (560 mg) in 80 ml MeOH was treated at 0° with HCl–H_2S for 4 h (HCl) and 6 h (H_2S). After neutralization ($NaHCO_3$) and isolation with chloroform the product was chromatographed on Florisil. Light petroleum elution gave **8***b* as black crystals (98 mg, 16%), m.p. 68° (light petroleum).

Anal. Calcd. for $C_{17}H_{12}S$: C, 82.24; H, 4.87; S, 12.89. Found: C, 81.60; H, 5.07; S, 12.70.

1-Amino-4-thiobenzoylnaphthalene (9b)

The ketone (3 g) was dissolved in MeOH (100 ml) and HCl and H_2S passed through for 4 and 8 h, respectively, at 0°. The crystalline precipitate was collected, being the hydrochloride (2.8 g).

For personal use only.

Anal. Calcd. for $C_{17}H_{14}NSCl$: C, 68.10; H, 4.66; N, 4.66; S, 10.68; Cl, 11.85. Found: C, 67.78; H, 4.73; N, 4.60; S, 10.72; Cl, 11.95.

The hydrochloride (1.4 g) in MeOH was neutralized with aqueous sodium bicarbonate and, after isolation, the product was crystallized from methanol (0.91 g, 74%) in brown crystals, m.p. 74°.

Anal. Calcd. for $C_{17}H_{13}NS$: C, 77.56; H, 4.94; N, 5.32. Found: C, 77.86; h, 5.22; N, 5.26.

Cyclizations

These were performed using a 450 W medium pressure lamp in conjunction with a Corning filter C53-68 to absorb wavelengths below 520 nm. Solutions were degassed and irradiated until decolorized.

2-Phenyl-2H-naphtho[1,8bc]thiophene (1c)

The thione (240 mg) in 15 ml benzene was irradiated for 26 h. The product was chromatographed through Florisil to give pale yellow crystals (51%; m.p. 101°; lit. (15*c*) m.p. 100–101°).

Anal. Calcd. for $C_{17}H_{12}S$: C, 82.24; H, 4.87; S, 12.89. Found: C, 82.25; H, 4.42; S, 12.42.

The same product was obtained using MeCN as solvent (20 ml) containing 1 ml MeOH or water. In the presence of 1 ml D_2O, 2-phenyl-2*D*-naphtho [1,8*bc*] thiophene was obtained. The n.m.r. was identical in all respects with the protium compound except for the complete absence of a singlet at δ 6.18; mol. wt. (mass spectrum) 249.

The possibility of H/D exchange occurring in the final product was excluded by the appropriate control.

2-Phenyl-2H-pyreno[1,10bc]thiophene (3c)

This was obtained in 59% yield, after similar irradiation, as pale yellow crystals, m.p. 155° (methanol); $\lambda_{max}(C_6H_{12})$ 386, 367, 361, 349, 292, 230 nm (ε 5400, 1500, 13 800, 15 300, 12 350, 42 500); *m/e* (M^+) 322; singlet at 6.25 p.p.m. in the n.m.r. spectrum.

Anal. Calcd. for $C_{23}H_{14}S$: C, 85.70; H, 4.38; S, 9.93. Found: C, 86.14; H, 4.42; S, 9.47.

2-Phenyl-2H-chryseno[1,2bc]thiophen (4c)

This was similarly obtained in 58% yield, m.p. 183–184° (benzene); $\lambda_{max}(C_6H_{12})$ 377, 360, 344, 316, 275, 267 nm (ε 5000, 9700, 10 800, 6400, 44 450, 45 000); *m/e* 348 (M^+); singlet at 6.2 p.p.m. in the n.m.r. spectrum.

Anal. Calcd. for $C_{25}H_{16}S$: C, 86.18; H, 4.63; S, 9.19. Found: C, 86.18; H, 4.95; S, 9.02.

2-Phenyl-2H-peryleno[1,12bc]thiophen (7c)

The thione (28 mg) was suspended in 20 ml benzene and irradiated for 3 h with shaking after which all the material was in solution. After chromatography on silica the product was obtained as brown crystals (60%) m.p. > 350°; $\lambda_{max}(C_6H_{12})$ 473, 445, 422, 357, 338, 240, 228, 218 nm (ε 18 600, 16 200, 10 000, 11 000, 13 800, 5900, 7700, 90 000); *m/e* 372.09823 (M^+) (calcd. 372.09726).

Desulfurization of the Thiophene Derivatives

A solution of the thiophene in ethanol was refluxed with Raney nickel previously deactivated by heating for 3 h with acetone. The reactions were followed by t.l.c. and interrupted before the appearance of over-reduction compounds. The results are given in Table 4.

Oxidation of 2-Phenyl-2H-naphtho[1,8bc]thiophen

The thiophen (264 mg) *m*-chloroperbenzoic acid (0.48 g) and sodium carbonate (800 mg) were stirred in 10 ml ethylene dichloride for 2 h at room temperature. Isolation of the product after dilution with water and washing gave the corresponding sulfoxide (97%), m.p. 167–168° (lit. 168–169° (15*c*)).

Quantum Yields

For irradiations ~577 nm the light from a mercury source (HBO 200 W) was passed through a potassium dichromate–copper sulfate filter solution (29). The actinometric solution was Reinecke's salt (30). For the 366 nm line Corning filter CS-52 and CS-7-60 were employed and ferrioxalate actinometry (31). Solutions of **1***b* were degassed. After irradiation the solution was evaporated under nitrogen and a solution of 100 mg hydroxylamine hydrochloride in 20 ml methanol containing 5 drops of pyridine was added and with the disappearance of the thione color the solvent was evaporated below 40° under nitrogen. The residue was dissolved in benzene and filtered through 20 g silica gel.

A solution of known concentration of fluoranthene was added to the eluent after evaporation and analysis performed by vapor phase chromatography using a glass column packed with 3% SE 30 on Chromasorb W at 180°.

Control experiments indicated that the maximum error introduced by this treatment was ±6%. The above sequence was necessary since no means was found of separating the thione and cyclized material by v.p.c.

The authors wish to thank Ms. J. Pereyre for assistance with the neodymium flash photolyses and the National Research Council of Canada and CNRS (France) for funds under an exchange travel agreement.

TABLE 4. Raney nickel desulfurizations of thiophenes

Thiophene	Time (h)	Yield of benzyl derivative (%)	Recovered thiophene (%)	Melting point (°C)	
				Experiment	Literature (ref. no.)
1*c*	12	39	45	55–56	55(28)
3*c*	24	37	44	89	89(22)
4*c*	24	60	27	200	200–203(23)
7*c*	24	42	36	177	*(present work)

*Anal. Calcd. for $C_{27}H_{18}$: C, 94.70; H, 5.30. Found: C, 94.66; H, 5.33. This substance was also obtained by refluxing 3-benzoylperylene, 99% hydrazine hydrate and potassium hydroxide in diethylene glycol.

The Ultrasonic Degradation of Thymine[1]

ERIC L. MEAD, RONALD G. SUTHERLAND, AND RONALD E. VERRALL
Department of Chemistry and Chemical Engineering, University of Saskatchewan, Saskatoon, Saskatchewan S7N 0W0
Received March 6, 1975

ERIC L. MEAD, RONALD G. SUTHERLAND, and RONALD E. VERRALL. Can. J. Chem. **53**, 2394 (1975).

Sonolysis at 450 kHz degrades an aqueous solution of thymine into at least six products of which four, 5-hydroxymethyluracil, *cis*- and *trans*-5,6-dihydroxy-5,6-dihydrothymine, and urea have been identified and a fifth tentatively assigned as *N*-formyl-*N'*-pyruvylurea. A mechanism of sonolytic degradation is proposed.

ERIC L. MEAD, RONALD G. SUTHERLAND et RONALD E. VERRALL. Can. J. Chem. **53**, 2394 (1975).

La sonolyse à 450 kHz dégrade une solution aqueuse de thymine en au moins six produits dont quatre sont identifiés comme étant l'hydroxy-5 méthyluracile, le dihydroxy-5,6 dihydro-5,6 thymine *cis* et *trans* et l'urée; le cinquième a été tentativement identifié à la *N*-formyl *N'*-pyruvylurée. On propose un mécanisme de la dégradation sonolytique.
[Traduit par le journal]

Chemical reactions that occur in liquids subjected to ultrasonic irradiation (insonation) of sufficient intensity to induce cavitation, have been attributed (1) to a number of processes; the reactive species produced in water and aqueous solutions during cavitation are hydroxyl radicals (2), hydrated electrons (3), hydroperoxyl radicals (4), and hydrogen atoms (5). These species are also produced during the radiolysis of water and in this paper we show that the sonolysis of thymine may be correlated with its radiolytic degradation.

The radiolysis of aqueous thymine solutions has been the subject of numerous investigations and studies by Teoule and co-workers (6–11) identified more than 26 products formed during ^{60}Co-γ irradiation. Hydroxyl radicals produced by ionizing radiation react with thymine to give 6-hydroxy-5,6-dihydro-5-thyml and 5-hydroxy-5,6-dihydro-6-thymyl radicals; hydrogen atoms (or $e_{aq}^- + H_3O^+$) react with thymine to give (5-uracyl)methyl, 5,6-dihydro-5-thyml, and 5,6-dihydro-6-thyml radicals (11). These radicals react very rapidly with dissolved oxygen (*e.g.* $K(\dot{T}OH + O_2) = 1.5 \times 10^9\ M^{-1}\ s^{-1}$ (12) to produce hydroperoxide radicals which are reduced to the hydroperoxyhydroxydihydro products (Fig. 1) (**5** and **6**) and the hydroperoxide products (**7**, 5-hydroperoxy-5,6-dihydrothymine, *cis*- and *trans*-6-hydroperoxy-5,6-dihydrothymine). The peroxide products are relatively unstable (11) and decompose to give various alcohols (*cis*- and *trans*-**9**, **8**, 5-hydroxy-5,6-dihydrothymine, *cis*- and *trans*-6-hydroxy-5,6-dihydrothymine). In addition, the hydroxyhydroperoxides decompose to give 5-hydroxy-5-methylbarbituric acid and *N*-formyl-*N'*- pyruvylurea and the remaining products result from decomposition of *N*-formyl-*N'*-pyruvylurea to give pyruvylurea, urea, and formylurea.

El'piner (1) was the first to investigate the effect of ultrasound on purine and pyrimidine bases. He insonated (500 kHz) aqueous solutions of the bases at an intensity of 5 W cm^{-2} in the presence of various gases. In the u.v. spectra of the insonated bases, the absorption maxima were reduced and the minima shifted to longer wavelengths. Uracil was found to be the most sensitive, adenine and guanine less so. In a later study, El'piner and Sokol'skaya (13) insonated aqueous solutions of cytosine, uracil, thymine, and adenine and investigated the products of sonolysis chromatographically but no degradation products were identified. The reduction in intensity of the u.v. absorption band of the various purines and pyrimidines was attributed to ring cleavage (1). Since the effect was considerably reduced in the presence of gases other than oxygen, it was suggested that molecular oxygen played an important role and a smaller oxidative role was assigned to hydroxyl radicals.

This study was undertaken to reinvestigate the sonolysis of aerated aqueous thymine solutions

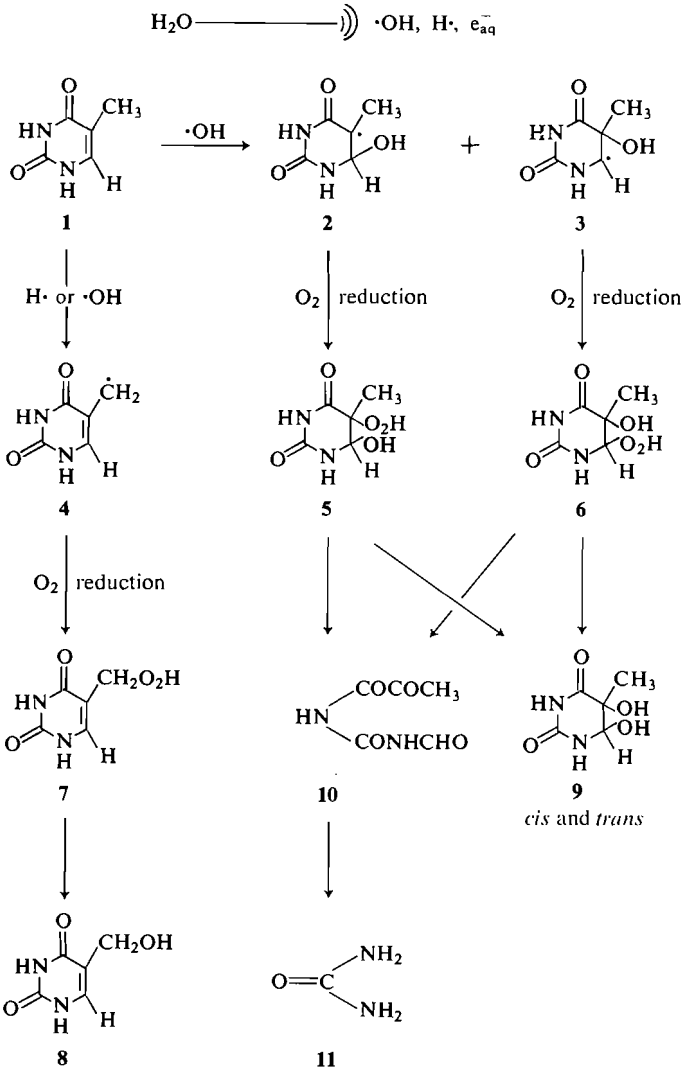

FIG. 1. Proposed sonolytic mechanism of degration of aqueous thymine solutions.

in light of the mechanism proposed for the radiolysis of thymine.

Experimental

Ultrasonic irradiation was carried out using a Multisons MC500-1 (Macrosonics Corporation, Cartaret, N.J.) broad band generator coupled to a cobalt barium titanate transducer operated at 447.5 ± 0.6 kHz with an average power output of 5 W cm^{-2} based on calorimetric measurements. The total acoustic power absorbed is not a useful measure of the energy available for chemical reactions since only a very small fraction is used in the formation of free radicals (14).

Aliquots (50 ml) of aqueous thymine solutions were insonated in a glass cell equipped with a Mylar 500A plastic window, similar to the design of Spurlock and Reifsneider (15). The temperature inside the cell was kept relatively constant at 25 °C by circulating the coupling water, transmitting the acoustic energy to the cell, through a constant temperature (25 ± 0.5 °C) bath.

The water used in this study was prepared by distillation of previously deionized water from alkaline permanganate. Thymine (Aldrich Chemical Co.) was recrystallized from distilled water. 5-Hydroxymethyluracil (16) and 5,6-dihydroxy-5,6-dihydrothymine (17) were prepared by literature procedures. These procedures give the *cis* isomer only (18). A mixture of isomers was obtained by refluxing an aqueous solution of the *cis* isomer at 90 °C for 4 h (18). Reagent grade urea was used without further purification. Chromatography was carried out on commercially prepared silica gel G and MN300 cellulose thin-layer (250 μm, 20 × 20 cm) plates and Whatman No. 1 paper.

Thymine and derivatives that retain the 5,6-double bond were located using a u.v. lamp with a maximum

emission band at 254 nm. The dihydrothymine derivatives urea, and substituted ureas were detected by spraying the chromatograms with 0.5 *N* aqueous sodium hydroxide, air drying for 30 min, and respraying with a solution of *p*-dimethylaminobenzaldehyde (PDAB) (1 g in 100 ml 95% ethanol plus 10 ml concentrated hydrochloric acid), after the method of Fink *et al.* (19). Iodine vapor was used to detect products on silica gel plates.

Ultraviolet spectra of aqueous thymine and insonated thymine solutions were obtained on a Cary 14 recording spectrophotometer using a variable path length cell (model BC14, Research and Industrial Instruments Company, London).

The following methods were used in the quantitative analyses of products. The *cis* and *trans* isomers of compound **9** were determined by a modification (20) of the method of Roberts and Friedkin (21). The original method determined thymine levels by hypobromination of the heterocyclic ring, followed by base hydrolysis to give the glycol. Continued base hydrolysis of the glycol yielded acetol which was condensed with *o*-aminobenzaldehyde to form 3-hydroxyquinaldine. Elimination of the hypobromination step in this work permitted the quantitation of thymine glycol in the presence of thymine. The fluorescence was measured at 440 nm (excitation at 310 nm) in a 1.0 cm quartz cell using an Aminco-Bowman spectrophotofluorimeter.

Total peroxides were measured as hydrogen peroxide using the molybdate catalyzed oxidation of iodide to the triiodide anion (22) which was measured spectrophotometrically at 350 nm in a 1.0 cm quartz cell. Hydrogen peroxide was determined spectrophotometrically following the method of Schumb *et al.* (23) using acidic titanium sulfate. Although not as sensitive as the triiodide anion method, it is specific for hydrogen peroxide in the presence of organic peroxides (24). Both methods for the determination of peroxide obeyed Beer's law in the concentration range 0–1 $\times 10^{-3}$ *M*.

Urea was determined spectrophotometrically by measuring the visible absorption at 420 nm arising from the reaction of urea with *p*-dimethylaminobenzaldehyde (25).

Results

Aqueous thymine solutions (2×10^{-3} to 2×10^{-2} *M*) showed a linear decrease with time in the u.v. absorption maximum at 264 nm during insonation at constant ultrasonic intensity. The characteristic changes observed were reduction of the band at 264 nm; reduction and shift to longer wavelengths of the minimum; increase and shift to shorter wavelengths of the band at 204 nm.

Semiquantitative data on the rate of degradation of thymine and relative yields of products were obtained. Figure 2 shows that the degradation rate, measured spectrophotometrically for three different initial concentrations, was constant over at least a 2-h insonation period. However, one of the products (**8**) (Fig. 1) has a molar extinction coefficient (ε 8.00 $\times 10^3$ M^{-1} cm^{-1}, λ_{max} 261 nm, 0.01 *N* HCl (16)) comparable to that of thymine and contributes to the measured absorption at 264 nm as the degradation proceeds. Attempts to determine the yield of **8** and unreacted thymine by spectrophotometric measurements of solutions, obtained by eluting the separated compounds from chromatograms, did not give accurate data. Table 1 contains some data on the product yields for two initial thymine concentrations. The methods used for the analysis were previously outlined in the experimental section.

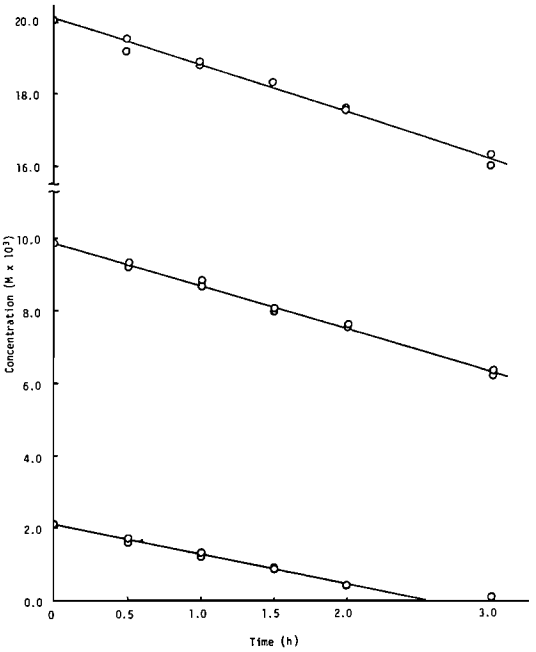

FIG. 2. Rate of degradation of aqueous thymine solutions at 447.5 kHz.

The products were separated and identified by cochromatography with synthetic samples and by their reaction to spraying with *p*-dimethylaminobenzaldehyde. The products separated and positively identified are *cis*- and *trans*-5,6-dihydroxy-5,6-dihydrothymine (thymine glycol), 5-hydroxymethyluracil, and urea. At least two more products, one tentatively identified as *N*-pyruvyl-*N'*-formylurea and the other unidentified, have also been isolated. Table 2 tabulates the R_f values measured for each of the above products on a variety of stationary and mobile phases.

The formation of 5-hydroxymethyluracil during sonolysis was verified by cochromatography with synthetic samples. As well, samples were

TABLE 1. Product yields* from two initial thymine concentrations

Time (h)	Thymine ($M \times 10^3$)	Thymine glycol ($M \times 10^3$)	Total peroxide ($M \times 10^3$)	Hydrogen peroxide ($M \times 10^3$)	Urea ($M \times 10^3$)	Thymine decomposed ($M \times 10^3$)

eluted from developed chromatograms for spectral comparison by the method of Cline *et al.* (16). The ratio of the absorbances at 280/260 and 250/260 were calculated; for the eluted sample, the ratios were 280/260 = 0.40 and 250/260 = 0.74, whereas for the synthetic mixture the ratios were 0.38 and 0.77, respectively, in methanol.

The *cis* and *trans* isomeric glycols were identified by cochromatography and by their reaction to spraying with PDAB after base hydrolysis, which gave a blue-green color for each.

Urea was also identified by cochromatography and by the bright lemon color obtained by spraying the chromatogram with PDAB without prior base hydrolysis.

The product T.1 is thought to probably be *N*-pyruvyl-*N'*-formylurea due to its color reaction (yellow-red) after spraying with PDAB after base hydrolysis while the R_f values for this product on systems II and VI were similar to those reported by Teoule and Cadet (6). The product T.2 has not yet been identified.

Discussion

The results of this work have shown that sonolysis of aqueous thymine solutions in the concentration range 2×10^{-3} to 2×10^{-2} *M* gives rise to products identical to those produced by radiolysis. The degradation of thymine was found to vary linearly with insonation time with a small dependence on initial concentration as was observed for the radiolysis of thymine (6).

Analysis of the initial rate data shown in Fig. 2 was carried out for all but the highest initial concentration of thymine. If the initial rate of reaction, *r*, is related to the reactant concentration, *c*, by the relation $r = k\,[c]^n$, then a value of the order of reaction, *n*, can be calculated from two initial rate conditions. The value obtained was 0.1 ± 0.15 and within experimental error the decomposition follows apparent zero-order kinetics. The large error in *n* includes some estimate of error arising out of the interference by product **8** in the spectrophotometric determination of thymine. A value of $1.8 \pm 0.3 \times 10^{-5}$ *M* min^{-1} was obtained for the zero-order rate constant.

The data in Table 1 are insufficient to carry out any meaningful kinetic analysis. However, some general observations can be made. After one hour of insonation approximately the same amounts of the thymine glycols, *cis*- and *trans*-**9**, were found for two different intial thymine concentrations. The method used in this study to determine the amounts of **9** appeared to be free from interference from thymine on monohydroxythymine derivatives. The initial yields of hydrogen peroxide are in agreement with those previously reported (2, 15) for air-saturated water insonated at approximately the same frequency. An estimate of the organic peroxide concentration was obtained from the difference between total peroxide and hydrogen peroxide concentrations. The organic peroxide precursors of the stable products of thymine degradation appear to never form more than *ca.* 5% of the total amount of thymine decomposed. Teoule and Cadet (6) found that at a high dose of ^{60}Co-γ irradiation, the total peroxide radiochemical yield G(peroxide) = 0.5 as compared to $G(-T) = 3.05$.

The amounts of urea formed during sonolysis of aqueous thymine solutions did not exceed 20% of the amount of decomposed thymine and appeared to decrease with increasing insonation time. This small amount of urea formed is in agreement with the radiochemical yield of urea,

TABLE 2. Chromatographic R_f values of products on a variety of stationary and mobile phases

Stationary phase*	Mobile phase†	R_f						
		Thymine	Urea	5-Hydroxymethyl-uracil	*trans*-5,6-Dihydroxy-5,6-dihydrothymine	*cis*-5,6-Dihydroxy-5,6-dihydrothymine	T.1	T.2
I	*1*	0.69	0.50	0.59	0.69	0.63	0.86	0.78
II	*2*	0.63	0.31	0.50	0.67	0.58	0.94	0.86
III	*3*	0.74		0.56				
IV	*4*	0.65		0.44				
V	*1*	0.57		0.27	0.48	0.34		
VI	*5*	0.52		0.26			0.68	0.41
VII	*6*	0.64		0.40				
VIII	*7*	0.64		0.41				

*Stationary phases: I, II: silica gel G; III, IV: MN 300 cellulose; V–VII: Whatman No. 1 paper.
†Mobile phases: *1*, acetonitrile – phosphate buffer (0.2 *M* Na_2HPO_4 and 0.2 *M* NaH_2PO_4) (85:15, v/v); *2*, ethyl acetate – isopropyl alcohol – water (75:16:9); *3*, *n*-propyl alcohol – water (10:3); *4*, *n*-butyl alcohol – methanol – water – ammonium hydroxide (60:20:20:1); *5*, *n*-butyl alcohol – water (86:14); *6*, *tert*-butyl alcohol – methyl ethyl ketone – water – formic acid (40:30:15:15); *7*, *tert*-butyl alcohol – methyl ethyl ketone – water – ammonium hydroxide (40:30:15:15). All proportions of the mobile phases are by volume.

G(urea) = 0.075 (10). The decrease in urea concentration with increasing insonation time may be accounted for in this work by further reaction of urea with nitrous acid, which is a product of the insonation of air-saturated water (26).

Although the amount of **8** could not be measured quantitatively it was possible, by visual comparison of the fluorescence intensity under u.v. illumination of chromatographic spots from aliquots of standard solution and insonated solutions, to estimate the maximum concentration of **8** to be 1×10^{-3} M.

From the results obtained in this work it appears that the radiolysis mechanism of thymine destruction proposed by Teoule *et al.* (10) may be adapted to the sonolytic degradation of thymine (Fig. 1). Cavitation produces the reactive species ·OH, H·, and e_{aq}^-; all of the sonolytic products may be accounted for by reaction of hydroxyl radicals and/or hydrogen atoms with thymine. Hydroxyl radicals undergo additional reactions with thymine to produce 6-hydroxy-5,6-dihydro-5-thymyl (**2**) and 5-hydroxy-5,6-dihydro-6-thyml (**3**) radicals; hydrogen atoms (or hydroxyl radicals) undergo abstraction reactions with thymine to give (5-uracyl)methyl radicals (**4**). These radicals react very rapidly with dissolved oxygen to produce the hydroperoxy radicals which are reduced to the hydroperoxide products, **5**, **6**, and **7**. The hydroperoxide products decompose to 5-hydroxymethyluracil (**8**) and *cis*- and *trans*-5,6-dihydroxy-5,6-dihydrothymine (**9**). In addition, the *cis*- and *trans*-5 (or 6)hydroperoxy-6(or 5)-dihydrothymines (**5** and **6**) probably undergo ring opening to give *N*-formyl-*N'*-pyruvylurea (**10**) which decomposes to urea (**11**).

The above mechanism accounts for all of the identified products in this study.

Charge Distributions and Chemical Effects. IX. On the Charge Dependence of C-13 Chemical Shifts in Alkylcyclohexanes and Cyclopropane

RÉAL ROBERGE AND SÁNDOR FLISZÁR

Département de Chimie, Université de Montréal, Montréal, Québec H3C 3V1

Received February 7, 1975

RÉAL ROBERGE and SÁNDOR FLISZÁR. Can. J. Chem. **53**, 2400 (1975).

The analysis of *ab initio* charge distributions in cyclohexane and selected methylcyclohexanes indicates that no effect other than that described by the relationship $\delta_C = -237.1q_C + 242.64$ between C-13 chemical shifts and C net charges (as determined for the alkanes) contributes to any significant extent to the shielding of the carbon atoms. This is no longer true for cyclopropane.

RÉAL ROBERGE et SÁNDOR FLISZÁR. Can. J. Chem. **53**, 2400 (1975).

L'analyse des distributions de charges *ab initio* du cyclohexane et de quelques méthylcyclohexanes montre qu'aucun effet particulier, autre que celui décrit par l'équation déduite pour les alcanes $\delta_C = -237.1q_C + 242.64$ reliant les déplacements chimiques aux charges nettes, ne participe de manière significative à l'écran des atomes de carbone. Tel n'est pas le cas pour le cyclopropane.

A theory has been recently developed (1) for calculating charge distributions in simple alkanes from the knowledge of the inductive effects of alkyl groups. These 'inductive' charges were found to be in agreement with those derived from both semiempirical and *ab initio* quantum mechanical methods. With *optimized* STO-3G results (2), the agreement is virtually perfect. On a scale of relative units defined by setting the C net charge of ethane equal to 1 arbitrary unit, the carbon and hydrogen net (*i.e.*, nuclear minus gross) charges are functions of a parameter, n.[1] The various quantum chemical results simply correspond to different values for n. For example, comparisons which were made with theoretical charges satisfying Mulliken's scheme indicated that $n = 1.3325$ generates the *optimized* STO-3G charges, whereas the 'standard' STO-3G results correspond to $n \simeq 1$ (1). Multiplication of charges relative to q_C(ethane) = 1 by a unity factor, β = C net charge of ethane, yields charge distributions in charge units. The β value also differs from theoretical method to method (1).

The n value is critical in any comparison of a property with C charges: the use of any theoretical set of charge distributions corresponding to an n value other than the 'proper' one is bound to fail in showing the expected property–charge correlation (1). Postulating that in alkane molecules the various C atoms of the set are as similar as possible, it is found (3) that $n \simeq -4.4$. This n value appears to correspond to real physical situations. Indeed, from C-13 chemical shifts it was found that $n = -4.4122$, whereas adiabatic ionization potentials (4) lead to $n = -4.4083$. Similarly, the enthalpies of formation of the alkanes can be calculated using charges derived from the relation between C-13 chemical shifts

$$[1] \quad \delta_C = -237.1q_C + 242.64 \text{ p.p.m. from TMS}$$

and relative net charges, q_C (5).

The accuracy of [1] can best be evaluated by observing that a 1% error in q_C corresponds to an error of ~2.4 p.p.m., while the standard deviation is only 0.3 p.p.m. (3). Here, this relation between charges and C-13 chemical shifts is used for determining, in the case of cycloalkanes, whether any special effect due to the ring structure contributes to the C-13 shieldings which are observed.

Basic Formulas for Comparing Chemical Shifts with Net Charges

Any choice of a particular theoretical method for calculating charges was shown (1) to define a particular value for n, *i.e.*, that corresponding to the method selected. Let n^0, β^0, and q_C^0 be the quantities which correspond to a particular theoretical method and n, β, q_C those which are deduced from the former under the assumption of a nonequal partitioning of the overlap populations between bonded C and H atoms, along

[1]For example, $q_C(CH_4) = 4(n + 1)/3n$, $q_C(C_2H_6) = 1$, $q_C(C_3H_8,\text{sec}) = (2n - 3.8)/3n$, $q_C(\text{iso-}C_4H_{10}, \text{tert}) = (n - 7.7)/3n$, and $q_C(\text{neo-}C_5H_{12},\text{quat}) = -4/n$ (1).

*The results for the acyclic alkanes are those of ref. 2.

the lines described in ref. 3. The following equations enable a simple calculation of the charges corresponding to any n value of our choice from the original theoretical charges q_C^0.

$$[2] \qquad \beta/n = \beta^0/n^0$$

$$[3] \qquad p = (\beta-\beta^0)/3$$

$$[4] \qquad q_C = q_C^0 + Np$$

where N = number of H atoms bonded to C.

$$[5] \qquad q_C \text{ (rel)} = q_C \text{ (charge units)}/\beta$$

It has been stated above that calculated C-13 chemical shifts are very sensitive to small errors in q_C. Therefore, to obtain accurate results for the δ_C values, it is important to use accurate charges q_C^0 for calculating the q_C values. It was shown for alkanes that the *optimized* STO-3G charges (2) qualify as 'excellent' since the modified set which is deduced from the original STO-3G results by an appropriate mode of partitioning C-H overlap populations [2–4] exhibit a virtually perfect correlation with carbon chemical shifts [1]. Unfortunately, it appears that the STO-3G calculations implying optimization of all variational parameters are practically not feasible for methylcyclohexanes.[2] We are, therefore, forced to extract useful information from the less precise standard[3] STO-3G calculations for these molecules.

This, indeed, can be done under the following premises: if the set of the standard exponents, ζ_{st}, is not too different from the corresponding optimized exponents, ζ_{opt}, then we can apply, in a limited range (which, however, is difficult to define precisely), a Taylor series:

$$[6] \quad q_{opt} = q_0 + (q_{st}-q_0)\, dq_{opt}/dq_{st} + (\tfrac{1}{2})\,(q_{st}-q_0)^2 d^2q_{opt}/dq_{st}^2 + \ldots$$

The advantage resulting from the use of such a relation can be inferred from a comparison between the optimized and standard charges calculated for the alkanes (Table 1, Fig. 1).

Of course, no perfect linear relationship between these two sets of results should be expected, as the divergences between optimized and standard exponents are not the same for the various atoms involved in this comparison (2). On the contrary, we feel that this correlation is even better than what would have been hoped for *a priori*. We can, therefore, take advantage of this property in the present study of the methylcyclohexanes.

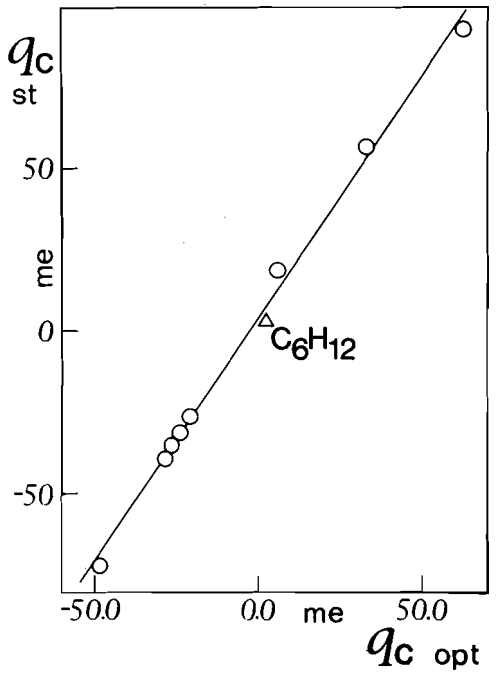

FIG. 1. Comparison between carbon net charges deduced from standard and optimized STO-3G calculations.

Results

Cyclohexane

The standard STO-3G calculation according to Pople's recipe (6), using r_{CC} = 1.540 Å, r_{CH} = 1.091 Å, ∠CCC = ∠HCH = 109.47°, ζ_C-

[2]For example, one single standard calculation of 1-*cis*-3-*cis*-5-trimethylcyclohexane requires ~10 h computer time, using the CDC CYBER 74 computer.

[3]The 'standard' STO-3G mode of calculation is defined in ref. 6. Details about the differences between standard and optimized results are given in ref. 2.

(s_K) = 5.67, $\zeta_C(s_L,p)$ = 1.76, and ζ_H = 1.18, yields the following net charges (in 10^{-3} electron units): q_C = 3.39, q_H(axial) = −2.61, and q_H(equatorial) = −0.77. For this molecule, the optimization was carried out following the scheme which was applied earlier for the alkanes (2). First, the geometry was optimized using the above standard scale factors (Table 2).

Next, the scale factors were optimized using the optimized geometry given in Table 2, until stable charges were obtained. In this optimization, the total energy drops from −231.4943057 (standard) to −231.504629 a.u. The net charges deduced from the optimized geometry and the optimized scale factors $\zeta_C(s_K)$ = 5.705, $\zeta_C(s_L,p)$ = 1.75375, ζ_H(e) = 1.1736, and ζ_H(a) = 1.16986 are (in 10^{-3} electron units): q_C = 2.76, q_H(e) = 1.76, and q_H(a) = −4.52. These optimized charges which were deduced following Mulliken's population analysis (7), correspond, in principle, to those calculated for the alkanes (2), for which n = 1.3325.

The carbon-13 chemical shift can now be calculated from [1–5], which involve the modified population analysis (3) for deducing the C charge corresponding to n = − 4.4122 from that corresponding to n = 1.3325. First, $\beta(n = -4.4122)$ is calculated by means of [2]: β = −4.4122 (−20.96/1.3325) = 69.40 me. Then (eq. 3), it is found that p = 30.12 me and (eq. 4) $q_C = 2.76 + 2p$ = 63.00 me. In the scale of relative units, this charge is q_C(rel) = 63.00/β = 0.9078 (eq. 5). Finally, inserting this q_C charge in [1], yields δ_C = 27.4, which compares favorably with the experimental value (8) δ_C = 27.7 p.p.m. from TMS.

This result indicates clearly that for cyclohexane the same relation holds between carbon net charges and C-13 n.m.r. shifts as that observed for the alkanes (3). Hence, no special effect seems to contribute significantly to the chemical shift, specifically because of the cyclic structure of cyclohexane. This good charge–δ_C correspondence further indicates that no special importance should be attributed to the fact that the direct comparison between standard and optimized charges yields for cyclohexane a point which is slightly off the best line shown for the alkanes in Fig. 1.

Alkyl-substituted Cyclohexanes

Table 3 reports the STO-3G results for methyl-, 1-*cis*-3-*cis*-5-trimethyl-, and 1,1,3-trimethylcyclohexane obtained from the use of standard geometries and exponents. Since it is virtually not feasible to calculate the corresponding optimized charges, the latter are estimated from the carbon-13 n.m.r. shifts by performing in reversed order the operations just described for cyclohexane. Clearly, the latter charges are those to be expected from optimized calculations, *unless the chemical shifts for cyclohexanes depend also on an effect which is not accounted for in the simple* δ_C*–charge relation* [1].

The optimized charges thus calculated from C-13 n.m.r. data are compared in Fig. 2 with the standard charges in the same way that the optimized and standard charges of the alkanes were compared in Fig. 1.

The comparison presented in Fig. 2 indicates that between these two sets of charges the same relation holds as between the standard and the STO-3G optimized charges. Therefore, within the precision of the present type of analysis, there is no indication that any effect other than that described by [1] contributes to any signifi-

cant extent to the C-13 n.m.r. shifts of these cyclohexanes.

Present results indicate clearly that no effects other than those described for the acyclic alkanes participate in determining charge distributions and carbon n.m.r. shifts in methylcyclohexanes. This raises the obvious question about cyclopropane.

Cyclopropane

The comparison of the standard carbon net charge (−19.01 m*e*) with the optimized one (Table 4) yields a point which is far off the lines given in Figs. 1 and 2. Moreover, the calculation of the C-13 shift from the optimized C charge (−87.67 m*e*) by means of [1–5] yields δ_C =336 p.p.m. from TMS, which is grossly in error, the experimental value (9) being −2.6 p.p.m. from TMS.

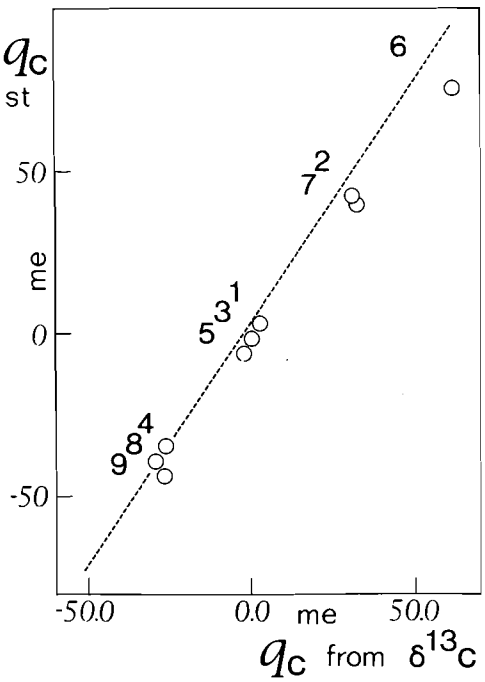

FIG. 2. Comparison of standard net C charges (STO-3G) with charges deduced from n.m.r. shifts, for $n = 1.3325$. The dotted line is that of Fig. 1.

*Extracted from ref. 2.
†Equatorial.

The unusual properties of this molecule have been the object of a number of studies (10). Present results support the view that cyclopropane possesses some characters of unsaturation. This is indicated by the comparison of population analyses given in Table 5 and the behavior of the optimized scale factors (Table 6). Moreover, the C—C overlap population in cyclopropane (0.60663 *e*) is significantly lower than those calculated for cyclohexane (0.73602), ethane (0.74682), and ethylene (1.22014 *e*) (2).[4] It is then not surprising that the δ_C–q_C relationship [1] for alkane molecules is not obeyed by cyclopropane.

Conclusions

STO-3G calculations without optimization of all variational parameters are not sufficiently precise for calculating C-13 n.m.r. shifts via the simple δ_C–q_C relationship. Nevertheless, present results suggest that no special effect, for which the six-membered ring structure could be held responsible, participates to the shielding of the carbon atoms, at least not to any significant extent. This is clearly confirmed by the optimized calculation on cyclohexane. These results do not contradict current arguments in terms of spatial proximity of neighboring atoms on C-13 shieldings, *gauche* γ interactions, etc., but tend to indicate that all these effects are ultimately reflected in the electron populations which, in turn, are simply related to the n.m.r. shifts by the same equation which applies to the acyclic alkanes. Chemical shift is a property of the interaction of the charge density with an external magnetic field. Therefore, it depends not only on the value of the integrated charge density (or 'charge') in the neighborhood of a nucleus but also on the magnetic susceptibility of that charge density. This is why the δ_C–q_C correlation used here is perforce limited to a set of very similar molecules. It is then not surprising that cyclopropane has a totally different behavior from what would be expected from [1].

[4]These results are in agreement with those given in ref. 11.

AND

HENRY H. MANTSCH[3] AND IAN C. P. SMITH[4]

Division of Biological Sciences, National Research Council of Canada, Ottawa, Canada K1A 0R6

Received January 28, 1975

ROY D. LAPPER, HENRY H. MANTSCH, and IAN C. P. SMITH. Can. J. Chem. **53**, 2406 (1975).

The ^{13}C chemical shifts and ^{13}C–^{31}P spin–spin couplings (where applicable) are reported for pyridoxine, pyridoxamine, pyridoxal, pyridoxamine phosphate, and pyridoxal phosphate. Resonance assignments are made by consideration of substituent chemical shift effects, as tested on an analogous series of pyridine derivatives. Increased shielding of the C4′ and C5′ methylene groups of the vitamin B_6 compounds and the methyl groups of 3,4-dimethylpyridine relative to the predicted values are attributed to steric compression. In aqueous solution pyridoxal exists as the hemiacetal form, although at high p*H* it is in rapid equilibrium with a significant amount of the aldehyde form. Pyridoxal phosphate exists as the aldehyde at high p*H*, as the hydrated aldehyde at low p*H*, and in a slow equilibrium between detectable amounts of both species at p*H* 4. The ^{13}C–^{31}P couplings through two bonds lie in the range 4.5 ± 0.5 Hz found for a variety of other organic phosphates. The couplings through three bonds indicate a preference for a *trans* arrangement of the phosphorus and ring carbon-5.

ROY D. LAPPER, HENRY H. MANTSCH et IAN C. P. SMITH. Can. J. Chem. **53**, 2406 (1975).

On a mesuré les déplacements chimiques du ^{13}C et les constantes de couplage spin–spin entre ^{13}C et ^{31}P (dans les phosphates) pour la pyridoxine, pyridoxamine, pyridoxal, phosphate de pyridoxamine et phosphate de pyridoxal. Les attributions sont faites en considérant les effets des substituants sur le déplacement chimique dans une série analogue des pyridines substituées. L'accroissement du blindage des carbones méthyléniques 4′ et 5′ des composés de la vitamine B_6 et des groupes méthyles du diméthyl-3,4 pyridine par rapport aux valeurs calculées, est attribué à une compression stérique. En solution aqueuse le pyridoxal existe sous la forme hémiacétale bien qu'à p*H* élevé l'hémiacétale soit en équilibre rapide avec une quantité importante d'aldéhyde. A p*H* élevé, le phosphate de pyridoxal existe sous la forme aldéhyde, à p*H* faible sous forme aldéhyde hydraté, et à p*H* 4 on a un équilibre lent entre des quantités décelables des deux espèces. Les constantes de couplage de ^{13}C–^{31}P à travers deux liaisons, se situent aux alentours de 4.5 ± 0.5 Hz. Cette valeur correspond aux valeurs trouvées pour divers phosphates organiques. Les couplages à travers trois liaisons suggèrent une forte préférence pour un arrangement *trans* du phosphore par rapport au carbone-5 du cycle.

[Traduit par le journal]

Introduction

The vitamin B_6 group of compounds consists of pyridoxine, pyridoxamine, and pyridoxal and their phosphates.[5] Of these various forms the most active and effective over a large range of organisms appears to be pyridoxal 5′-phosphate, also known as codecarboxylase or cotransaminase. This compound represents the coenzyme form of vitamin B_6 and is essential for a series of reactions involving amino acids, *e.g.* transamination, decarboxylation, and racemization. The unphosphorylated forms of the vitamin owe their activity mainly to the ability of organisms to convert them through enzymatic pathways to the coenzyme form although pyridoxamine phosphate itself is known to 'catalyze' certain transaminase reactions.

	R_1	R_2
Pyridoxine	$-CH_2OH$	$-H$
Pyridoxamine	$-CH_2NH_2$	$-H$
Pyridoxamine 5′-phosphate	$-CH_2NH_2$	$-PO_3H_2$
Pyridoxal	$-CHO$	$-H$
Pyridoxal 5′-phosphate	$-CHO$	$-PO_3H_2$

The general theory of the mechanism of action of enzymes using pyridoxal 5′-phosphate as a coenzyme has been put forward by Braunstein *et al.* (1, 2) and by Snell and co-workers (3–5). It involves reaction of the aldehyde function and the amino group of an amino acid to form a Schiff base. The electronic aspects of how such a Schiff base can then give rise to a series of different reaction products has been given by Pullman and co-workers (6, 7). However, the important first step in such reactions is always the formation of the Schiff base. In pyridoxal, formation of an internal hemiacetal occurs, reducing the amount of free aldehyde present, and thus decreasing the reactive nature of this compound. Pyridoxal phosphate, however, cannot form such a hemiacetal and hence is most active.

The effect of p*H* on vitamin B_6 compounds has been studied by ^1H n.m.r. (8, 9) and by u.v. absorption spectroscopy (10–15). We have undertaken this study by carbon-13 nuclear magnetic resonance (n.m.r.) spectroscopy to study the effect of p*H* on the conformation of the 5-carbinol phosphate side chain relative to the pyridine ring and, since ^{13}C chemical shifts are known to reflect electron densities in aromatic ring systems, to study the influence of p*H* on the pyridine ring. The ^{13}C spectra are indicative of the state of the aldehyde group at different p*H* values. This study serves as a necessary prelude to those in which the coenzyme is interacting with the apoenzyme.

Experimental

The compounds studied were obtained from Sigma Chemical Co., St. Louis, Missouri, and from Koch-Light Laboratories, Colnbrook, England, and were used as received. Samples were made up in D_2O solution and p*D* adjusted using NaOD and DCl solutions. Solutions were 0.3–0.5 *M* where solubility allowed and otherwise saturated solutions. Proton noise-decoupled carbon-13 spectra were run on Varian XL-100-15 n.m.r. spectrometers with 8K or 16K Varian 620L computers. Chemical shifts are accurate to ± 0.05 p.p.m. and coupling constants to ± 0.2 Hz. Tetramethylsilane (Me_4Si) in a tube of 5 mm o.d. concentric with the 12 mm sample tube was used as a chemical shift reference. The probe temperature was 32°.

Results and Discussion

To aid the assignment of the carbon-13 resonances in the vitamin B_6 compounds the ^{13}C n.m.r. spectra of some monosubstituted pyridines and benzenes at acid, neutral, and alkaline p*H* values were run. Assignment of the resonances in these latter compounds (Table 1) was made by use of literature substituent chemical shift (s.c.s.) effects for pyridine and benzene derivatives (16–18). Additivity of aromatic s.c.s. effects was then used to aid assignments in the vitamin B_6 derivatives.

In all the spectra of the derivatives studied the C6 carbon resonance was clearly recognizable by its high intensity relative to the others. This is because the quaternary carbons have long spin–lattice relaxation times owing to the lack of a directly-attached proton and are partially saturated under conditions of rapid acquisition. In the case of pyridoxal and pyridoxamine phosphates the C5 resonances could be recognized by the presence of a coupling to phosphorus. A further assignment which could be made throughout the series was that of the resonance due to C3, the carbon with a directly-bonded hydroxy group; predicting the shifts on the basis of additivity of s.c.s. effects clearly indicates that at all p*H* values this resonance is to lowest field in the range 150–170 p.p.m. Comparisons of the expected shift changes from derivative to derivative and especially from acid to alkaline p*H* based on the s.c.s. additivity principle allowed the final assignments given in Table 2 although some ambiguities were evident where chemical shifts were similar.

The additivity of the s.c.s. effects obtained from Table 1, applied to predicting the ^{13}C chemical shifts in the vitamin B_6 derivatives, yields a fairly good fit to the observed chemical shifts in the cases of acid and alkaline solution. The fit is often not good in the case of the solutions at about p*H* 7 because of the varying pK_a values in the compounds studied and the uncertainty as to which position in the equilibria one is observing. In the former cases the calculated shifts are within ± 2 p.p.m. of the observed

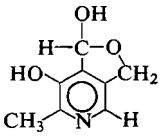
shifts except noticeably in the case of the C4 carbon where the calculated shifts are about 7 p.p.m. greater than the observed shifts in pyridoxine and pyridoxamine. It is also of note that the C4 and C5 side-chain CH_2 carbons in these derivatives are more shielded than the corresponding carbons in the monosubstituted benzene and pyridine derivatives. This must reflect a considerable change in the environment of the groups at C4 and to a lesser extent at C5 in the vitamin B_6 derivatives over those in the monosubstituted compounds. Stereochemically these side chains in the former cases are much more crowded than in the monosubstituted derivatives, and part of these shift anomalies may well be due to steric compression shifts. Why the C4 and side-chain carbons should reflect this more than the neighboring C5 carbon and CH_2 side-chain carbon remains speculative in the absence of a clear cut theory for such effects (19).

To investigate the applicability of steric compression shifts especially between C4 and C5 substituents of the vitamin B_6 derivatives, the ^{13}C n.m.r. spectra of the corresponding pyridine derivatives, 3-methyl-, 4-methyl-, and 3,4-dimethylpyridine, were studied at selected p*H* values. The lack of solubility of the dimethylpyridine at p*H* values greater than 6.0 made the study only possible at low p*H* values but the results obtained appear to be generally applicable (similar conclusions were reached for chloroform solutions). If the ^{13}C chemical shifts are calculated for 3,4-dimethylpyridine at p*H* 1.2, on an additivity basis from the methyl s.c.s. effects obtained from the monomethylpyridines, discrepancies from the observed shifts of up to 4 p.p.m. are evident. These steric compression effects are as expected from earlier work (20–23), *i.e.* greater shielding at 4-CH_3 (−2.3 p.p.m.), 3-CH_3 (−1.8 p.p.m.), C4 (−3.8 p.p.m.), and C3 (−2.1 p.p.m.), and effects of a smaller magnitude and either sign on the other ring carbons. It is interesting to note that the effects are largest on C4 and the 4-CH_3. The unsymmetrical nature of steric compression shifts in nitrogen heterocycles has been observed previously (23). A lack of reciprocity in steric shifts has been observed recently in 3-methylcholanthrene (24). Although the corresponding carbons (C4 and C5) in the side chains are not methyl groups but methylene functions in the vitamin B_6 derivatives, such sizeable steric compression shifts would be expected, perhaps of slightly smaller magnitude (23). Taking into account such effects in the calculations to predict the chemical shifts of the vitamin B_6 compounds yields a better fit between observed and calculated shifts thus reinforcing the assignments made (Table 2).



The major problem encountered in obtaining studies over the complete p*H* range was that pyridoxal at neutral p*H* and pyridoxal phosphate below p*H* 4.0 were virtually insoluble; even protracted accumulation (>24 h) of spectra did not yield measurable resonances for the quaternary ring carbons. Nevertheless it was clear from the ^{13}C spectra obtained for these compounds that at all p*H* values pyridoxal does not exist as the free aldehyde but as the hemiacetal form. This is indicated by the chemical shift of the 'aldehydic' carbon C4′ (100 p.p.m.). At p*H* 12.5 no resonance for the aldehydic carbon exists in either the normal range (~195 p.p.m.) nor in the hemiacetal region (~90 p.p.m.). A small peak does occur at 134.0 p.p.m. This may be a time average chemical shift for this carbon, in which case its position would indicate that the aldehyde to hemiacetal equilibrium is rapid and at alkaline p*H* values more free aldehyde form is present than at acid or neutral p*H* values. This is consistent with the results found from ^1H n.m.r. (8, 9) and u.v. spectroscopy (10), as discussed in detail by Korytnyk and Ahrens (8).

Pyridoxal phosphate clearly cannot form an intramolecular hemiacetal and the ^{13}C n.m.r. spectra are consistent with this; the aldehydic carbon resonance is at 197 p.p.m. However, although this compound is very insoluble at acid p*H* values it was possible to observe two forms of the aldehyde carbon at p*H* 4.0 and only one form at p*H* 1.7 which was different from that at neutral or alkaline p*H* values. At the former p*H* of 4.0 the free aldehyde and a hydrated form exist whereas at p*H* 1.7 only the hydrated form (δ 88.85 p.p.m.) is present in solution (*cf.* ref. 10).

The three-bond phosphorus–carbon couplings in the 5′-phosphates of pyridoxamine and pyri-

doxal contain conformational information. It has been shown in nucleotides (25–27) that vicinal $^{31}POC^{13}C$ couplings depend on the dihedral angle θ between the ^{31}POC and $OC^{13}C$ planes. An approximate relationship that can be used qualitatively for such compounds is (28):

$$^3J_{^{31}POC^{13}C} = J_0 \cos^2 \theta,$$

where J_0 was estimated from rigid cyclic nucleotides to be 8 Hz. Thus a large coupling (7–9 Hz) can be taken to indicate an average dihedral angle of 0° (eclipsed) or 180° (*trans* or *anti*) whereas a small coupling (1–2 Hz) is indicative of a 60° angle (*gauche*). Couplings between these extreme values are less straightforward to interpret, being possibly due to rapid interconversions between classical staggered rotamers or simply to a nonclassical dihedral angle. Also, the relationship above was tested only for nucleotides, and one cannot expect the same J_0 values when one carbon atom of the path is sp^2 hybridized. Nevertheless, the large values of the couplings observed for the vitamin B_6 derivatives strongly suggest that the phosphate group has a strong preference for the rotamer about the O—C5′ bond in which the phosphorus atom is *trans* to ring carbon C5. The eclipsed rotamer is excluded on steric grounds. The *trans* or extended rotamer has also been found to be preferred for the exocyclic phosphate groups of nucleotides (25, 27, 29), polynucleotides (25, 27, 29, 30), hexose 6-phosphates (31, 32), and polysaccharides (33). The small variation of the $^{31}POC^{13}C$ couplings with p*H* is similar to that found for nucleotides (29); it is due to effects of ionization of the phosphate group on the coupling constants and/or small changes in equilibrium conformation. Nevertheless, the strong preference for the *trans* rotamer is still evident at all p*H* values reported in Table 3.

The values of the two bond couplings, $^2J_{^{31}PO^{13}C}$, lie within the range 4.5 ± 0.5 Hz found for nucleotides (25, 27, 29) and hexose phosphates (31, 32). They thus provide valuable information in the case of difficult assignments.

In conclusion, substituent chemical shifts can be used to assign the ^{13}C resonances of substituted pyridines and vitamin B_6 derivatives. Changes in chemical shift are observed towards high field (low frequency, smaller chemical shift with respect to Me_4Si) due to steric interaction between the C4′ and C5′ methylene groups of the vitamin B_6 derivatives and the methyl groups of 3,4-dimethylpyridine. Pyridoxal exists in aqueous solution principally in the hemiacetal form; at high p*H* this is in rapid equilibrium with an appreciable population of the aldehyde form. Pyridoxal phosphate shows a preference for the free aldehyde form at high p*H*, a mixture of free and hydrated aldehydes at p*H* 4, and the hydrated aldehyde at p*H* 1.7. The phosphate groups of pyridoxamine 5′-phosphate and pyridoxal 5′-phosphate have a strong preference for the rotamer with the phosphorus atom *trans* to the ring carbon-5 at all p*H* values.

TABLE 3. ^{31}P–^{13}C coupling constants[a]

	p*H*	$^2J_{POC}$	$^3J_{POCC}$

The Crystal and Molecular Structure of the Dihydrochloride of 2-*trans*-6-Diethyl-2,4,4,6,8,8-hexamethylcyclotetraphosphazene

HARRY P. CALHOUN,[1] RICHARD T. OAKLEY, NORMAN L. PADDOCK,[2] AND JAMES TROTTER

Department of Chemistry, University of British Columbia, 2075 Wesbrook Place, Vancouver, British Columbia V6T 1W5

Received March 11, 1975

HARRY P. CALHOUN, RICHARD T. OAKLEY, NORMAN L. PADDOCK, and JAMES TROTTER. Can. J. Chem. **53**, 2413 (1975).

Octamethylcyclotetraphosphazene is deprotonated by methyllithium to form carbanions, which react with methyl iodide to give ethyl derivatives $N_4P_4Me_{8-n}Et_n$, $n \neq 4$; the structure of the dihydrochloride of the diethyl derivative, $N_4P_4Me_6Et_2 \cdot 2HCl$ has been determined. Its crystals are monoclinic, $a = 9.928(5)$, $b = 15.482(6)$, $c = 6.329(2)$ Å, $\beta = 103.29(2)°$, space group $P2_1/n$. The structure was determined from diffractometer X-ray data and refined by full-matrix least squares methods to R 0.079 for 715 observed reflections. The $N_4P_4Me_6Et_2H_2^{2+}$ ion lies on a crystallographic center of symmetry and the eight-membered phosphazene ring has the "chair" conformation. There are two significantly different P—N bond lengths, 1.665(6) and 1.572(7) Å, and two significantly different P—N—P angles, 126.7(6) and 139.8(6)°. The mean P—C bond length is 1.801(7) Å, and the mean N—P—N and C—P—C angles are 112.2(4) and 107.6° respectively. Bond lengths and angles in the phosphazene ring show the characteristic effects of π-electron localization found in other protonated phosphazene derivatives. The two ethyl groups are in *trans*-antipodal positions, corresponding to the least intramolecular electrostatic repulsion in the carbanion.

HARRY P. CALHOUN, RICHARD T. OAKLEY, NORMAN L. PADDOCK et JAMES TROTTER. Can. J. Chem. **53**, 2413 (1975).

L'octaméthylcyclotétraphosphazène est déprotoné par le méthyllithium formant ainsi des carbanions qui réagissent ensuite avec l'iodure de méthyle pour conduire à des dérivés éthylés $N_4P_4Me_{8-n}Et_n$, $n \neq 4$; on a déterminé la structure du chlorhydrate du dérivé diéthylé, $N_4P_4Me_6Et_2 \cdot 2HCl$. Les cristaux sont monocliniques $a = 9.928(5)$, $b = 15.482(6)$, $c = 6.329(2)$ Å, $\beta = 103.29(2)°$; groupe spatial $P2_1/n$. La structure a été déterminée par diffraction de rayons X à partir de mesures faites au diffractomètre. L'affinement par moindres carrés (matrice entière) conduit au facteur de reliabilité $R = 0.079$ pour 715 réflexions observées. L'ion $N_4P_4Me_6Et_2H_2^{2+}$ possède un centre de symétrie cristallographique et le cycle à huit membres du phosphazène à la conformation chaise. Il y a deux sortes de liens P—N significativement différents (1.665(6) et 1.572(7) Å) les uns des autres, et deux sortes d'angles P—N—P (126.7(6) et 139.8(6)°). La longueur moyenne du lien P—C est 1.801(7) Å, et les valeurs moyennes des angles N—P—N et C—P—C sont respectivement de 112.2(4) et de 107.6°. Les distances et les angles entre atomes du cycle phosphazénique montrent bien les effets caractéristiques de la localisation des électrons π tels qu'on les observe dans d'autres dérivés protonés du phosphazène. Les deux groupes éthyles sont en position *trans* et diamétralement opposés; cet arrangement correspond au minimum des répulsions électrostatiques intramoléculaires du carbanion. [Traduit par le journal]

Introduction

The substituent groups in the cyclic methylphosphazenes $(NPMe_2)_n$ are not inert, but react with methyllithium to form carbanions. The tetramer gives $N_4P_4(CH_3)_4(CH_2^-)_4$, from which such derivatives as $N_4P_4Me_4(CH_2XMe_3)_4$ (X = Si, Ge, Sn) are produced by reaction with Me_3XCl (1). Treatment of the carbanion with methyl iodide gives mainly the tetraethyl derivative $N_4P_4Me_4Et_4$, but a small amount of the diethyl derivative is also found. The structure of its dihydrochloride $N_4P_4Me_6Et_2 \cdot 2HCl$ is the first to have been determined of a diprotonated cyclotetraphosphazene, and is informative about the stereochemical course of carbanion formation in this series.

Experimental

Crystals of $N_4P_4Me_6Et_2 \cdot 2HCl$ were obtained from acetonitrile/benzene as colorless cubes. A crystal of approximate dimensions 0.20 × 0.20 × 0.35 mm was sealed in a thin-walled glass capillary tube. Crystal data:

$C_{10}H_{30}Cl_2N_4P_4$ f.w. = 401.18

Monoclinic, $a = 9.928(5)$, $b = 15.482(6)$, $c = 6.329(2)$ Å, $\beta = 103.29(2)°$, $U = 946.8(7)$ Å^3, $Z = 2$, $D_c = 1.407(1)$ g cm^{-3}, $F(000) = 424$. Space group $P2_1/n$ (C_{2h}^5). MoK_α radiation, $\lambda = 0.71069$ Å, $\mu(MoK_\alpha) = 6.8$ cm^{-1}.

A preliminary survey by film and diffractometer methods indicated that the crystal was suitable for data collection. Unit-cell parameters were obtained by least-squares refinement of 17 $\sin^2\theta$ (hkl) values measured on a General Electric XRD 6 diffractometer. Intensity data were measured on a Datex-automated General Electric XRD 6 diffractometer with zirconium filtered MoK_α radiation. All reflections with $2\theta(MoK_\alpha) < 45°$ were measured by use of a θ–2θ scan at 2 deg min^{-1} in 2θ over a range in 2θ of $(1.80 + 0.86 \tan\theta)°$, with 20 s background counts taken on either side of every scan. A check reflection, monitored every 30 reflections, was used to place the data on the same relative scale. The intensity of the check reflection showed only small fluctuations and was *ca.* 4% greater than its starting value at the end of the data collection. Of 1220 independent reflections measured 716 (59%) had intensities $> 3\sigma(I)$ above background, where $\sigma^2(I) = S + B + (0.05S)^2$, with S = scan count and B = background count (corrected to the time of the scan). These reflections were classified as observed. Lorentz and polarization corrections were applied and structure amplitudes derived. No corrections were made for absorption.

Structure Analysis

The molecule is required to have C_i symmetry. The structure was solved by direct methods. Sixteen sets of signs for 167 reflections with $|E| > 1.50$ were determined by a computer program which uses Sayre relationships in an iterative procedure (2). The starting set of reflections is given in Table 1.[3] One set of signs converged in 3 cycles and had the highest consistency index (2) (0.97) with 83 positive signs and 84 negative signs. An E map was computed using the 167 signed values of E from this set, and the positions of the chlorine atom and the two phosphorus atoms were obtained from the map. The two nitrogen and five carbon atoms were then located from a difference map. The structure was refined by full-matrix least-squares methods, initially with isotropic temperature factors and finally with anisotropic temperature factors for all nonhydrogen atoms. Hydrogen atoms could not be located with certainty from difference syntheses calculated at various stages of the refinement, and were not included in the calculations; a final difference map showed no exceptional features. Convergence was reached at R 0.079 for 715 observed reflections (one reflection, 101, was omitted from the refinement because of a suspected extinction error). On the last cycle of refinement no parameter shift was $> 0.4\sigma$.

Least-squares refinement was based on the minimization of $\Sigma w(|F_o| - |F_c|)^2$. Scattering factors were obtained from ref. 3. During the final stages of refinement, a weighting scheme of the form $w = [A + B|F_o| + C|F_o|^2 + D|F_o|^3]^{-1}$ was employed. The coefficients A, B, C, and D were adjusted to give uniform values of $\Sigma w(|F_o| - |F_c|)^2$ as a function of $|F_o|$, and this led also to uniformity with respect to $\sin\theta/\lambda$ and Miller indices; the values used in the final cycle were -2.719, 0.7890, -0.0359, and 0.00071, respectively. Unobserved reflections were given a weight of zero.

Final positional and thermal parameters are given in Table 2. A list of measured and calculated structure factors has been placed in the Depository of Unpublished Data.[3]

Results and Discussion

Bond lengths and angles (no thermal motion corrections) are given in Table 3, with their standard deviations. General views of its structure are shown in Figs. 1 and 2, a stereoview of the unit cell in Fig. 3.

The crystal structure consists of a $N_4P_4Me_6Et_2H_2^{2+}$ ion joined to two Cl^- ions by N^+—H. . .Cl^- hydrogen bonds. The geometry involving hydrogen bonded atoms is given in Table 4. The N(1). . .Cl distance, 3.06(1) Å, is quite short for a N^+—H. . .Cl^- hydrogen bond (4) and indicates that strong hydrogen bonds are formed in the present structure. Apart from the close contacts between hydrogen-bonded atoms the intermolecular distances are of the normal van der Waals type. Cl. . .C distances less than 3.8 Å include:[4] Cl. . .C(3) 3.69, Cl. . .C(1) 3.70, Cl. . .C(3)^{I} 3.76, Cl. . .C(4)^{II} 3.78, Cl. . .C(5)^{III} 3.79 Å. The shortest C. . .C intermolecular contact is C(1). . .C(4)^{II}, 3.79 Å. The structure of the cation can therefore be considered in isolation.

The $N_4P_4Me_6Et_2H_2^{2+}$ ion has exact C_i symmetry, both the protonated ring nitrogen atoms and the PMeEt groups being antipodal. In addition, C_i symmetry requires the ethyl groups to be in the *trans* configuration. Bond length and angle variations in the phosphazene ring and close N. . .Cl contacts indicate that the protonated atoms are N(1), N(1′). Six of the ring atoms, P(2), P(2′), N(1), N(1′), N(2), and N(2′), are nearly coplanar (Table 5), the deviations from their unweighted mean plane being 0.05–0.07 Å. The other two ring atoms, P(1) and P(1′), lie 0.74 Å above and below this plane. The "chair" conformation of the phosphazene ring can be seen in Fig. 2.

The centrosymmetrical structure is not un-

common in phosphazene chemistry. Its occurrence in this molecule can be understood in terms of electrostatic repulsion between the CH_2^- groups of the carbanion, with the assumption that the further reaction with methyl iodide does not induce proton migration. Model calculations on molecules with the conformations found in 8-membered phosphazene rings (saddle, D_{2d}; tub, S_4; chair, C_{2h}; crown, C_{4v}) show that, for normal values of bond angles, repulsion in the dicarbanion is least in the *trans*-antipodal chair conformation, as found in the diethyl derivative. Coordination of lithium ions to both the methylene groups and the ring nitrogen atoms would also be especially easy for the chair conformation.

The more detailed structure can usefully be considered in relation to that of certain other

phosphazenes (Table 6). Structures **1**–**6** have exact C_i symmetry; the present structure resembles **4** and **5** most closely. All three deviate from $2/m$ (C_{2h}) symmetry, as shown in Table 7; for $2/m$ symmetry the torsion angles about the two bonds meeting at a given phosphorus atom are required to be numerically equal. The deviation from equality is greatest in $N_4P_4Me_6Et_2H_2^{2+}$, partly because of the bond length inequalities induced by protonation. Nevertheless, the conformations of the three molecules are very similar, probably for steric reasons. At N(1) only the p_z orbital is available for π-bonding, and, because of the large difference in the dihedral angles about P(1)N(1) and N(1)P(2), it overlaps different d-orbital combinations at P(1) and P(2). The two bond lengths are nevertheless equal within experimental error, so that any difference between the d-orbitals is too small to have an observable structural effect. A similar result was found for $N_4P_4Me_8H^+$ (12), and justifies the separate consideration of bond lengths and conformation.

There are two distinct P—N bond lengths in the phosphazene ring. The bonds meeting at the

protonated nitrogen atoms, mean 1.665(6) Å, are significantly longer than the other P—N bonds, mean 1.572(7) Å. Some of the difference can be attributed to σ-hybridization effects, since the P(2′)N(2)P(1) angle, 139.8(6)°, is much larger than the P(1)N(1)P(2) angle, 126.7(6)°, indicating greater s-character in the hybrid orbitals at N(2), N(2′), but a substantial inequality remains after correction. The results are qualitatively consistent with a simple model, in which four electrons of one π-system are localized by the protonation of two antipodal nitrogen atoms. The bond lengths to these nitrogen atoms (1.665(6) Å) are similar to those in other protonated phosphazenes (Table 6): **7**, 1.666(5) Å; **8**, 1.695(15) Å; **9**, 1.670(14) Å; **10**, 1.671(12) Å; **11**, 1.669(6) Å. All correspond quite closely to the length of a PN bond in which only one π-system is operative. Calculations of bond order based on this model show that the

For personal use only.

bonds to N(2) (1.572(7) Å) should be shorter than those in the neutral compound (1.596(5) Å in $N_4P_4Me_8$ (16)). The localization of π-electrons is expected, nevertheless, to increase the mean PN bond length, and it is consistent (since $CuCl_3^-$ is a poorer acceptor than H^+) that the mean bond length should increase in the series $N_4P_4Me_8$, $N_4P_4Me_8H^+$ (1.607 Å (12)), $N_4P_4Me_8HCuCl_3$ (1.614 Å (13)), $N_4P_4Me_6Et_2H_2^{2+}$ (1.620 Å).

The PNP bond angles, 126.7(6) and 139.8(6)° are significantly different from that in $N_4P_4Me_8$, 132.0(3)°. The angle at the protonated nitrogen atom is small, as in other protonated tetrameric and pentameric phosphazenes (**8**, mean 126.2°; **9**, 127.3(14)°; **10**, 129.0(4)° and 127.3(5)°). The NPN angles are equal within experimental error, the mean value, 112.2(4)°, being significantly smaller than the NPN angle in $N_4P_4Me_8$(119.8(2)°). Phosphazenes **8**–**10** also have small mean values for NPN angles; **8**, 115.5; **9**, 114.0; **10**, 112.7°. In a general way the results suggest a drift of electrons from phosphorus to nitrogen, to form either a localized pair or a stronger π-bond. The exocyclic CPC angles increase, ($N_4P_4Me_8$, 104.1(2)°); **8**, mean 106.4°; **9**, mean 106.6°; **10**, mean 107.4°; $N_4P_4Me_6Et_2H_2^{2+}$, 107.6°, to compensate the changes of NPN angle, so that the σ-bond structure is also changed as a result of protonation.

The P—C bonds are all equal to within experimental error, and the mean value, 1.801(7) Å, is similar to the P—C bond length in $N_4P_4Me_8$, mean value 1.805(8) Å. The C—C length, 1.48(3) Å, is shorter than expected. However, the anisotropic temperature factors for atom C(5) are approximately twice as large as those for the other atoms in the structure (Table 2). Some lengthening of the C(1)C(5) bond can be expected if correction for thermal motion is applied. Using a riding model, with C(5) riding on C(1) (which may not be completely valid because of the omission of hydrogen atoms), the C(1)C(5) bond is lengthened to 1.53(3) Å, close to the expected value for a $C(sp^3)$—$C(sp^3)$ single bond.

Conclusion

The electronic effects discussed above are similar to those found in many other phosphazene derivatives, and are compatible with models developed previously (17, 18) in which electrons of the ring nitrogen atoms and of the exocyclic groups compete for the acceptor orbitals of the phosphorus atoms, forming a double cyclic π-system. It is already known that the dimethylamino-group releases electrons conjugatively to the ring, and it can be expected that the CH_2^- group will do so even more strongly. The resultant spreading of the charge may well be a contributory cause of the stability of the multiply-charged carbanions; the electrostatic control of the stereochemistry shows that a substantial part of the charge is still localized on carbon.

Emission from Electronically Excited C_2

S. J. ARNOLD, G. H. KIMBELL, AND D. R. SNELLING

Defence Research Establishment Valcartier, P.O. Box 880, Courcelette, Quebec G0A 1R0

Received February 25, 1975

S. J. ARNOLD, G. H. KIMBELL, and D. R. SNELLING. Can. J. Chem. **53**, 2419 (1975).

Chemiluminescence attributable to the Swan, Phillips, and Ballik–Ramsay bands of C_2 was observed when halomethanes of the form $CH_{2-n}X_{2+n}$ (X = Cl, Br, I) were introduced into a stream of hydrogen atoms. The relative population of the $v' = 0$ levels of the $A\,^3\Pi_g$, $b\,^1\Pi_u$, and $A'\,^3\Sigma_g^-$ states are 10:400:1000 with the total rate of formation into all three states being approximately equal. The principal step for the formation of C_2^* is believed to be

$$C + CX \rightarrow C_2^* + X \text{ (X = halogen or hydrogen)}$$

S. J. ARNOLD, G. H. KIMBELL et D. R. SNELLING. Can. J. Chem. **53**, 2419 (1975).

La chimiluminescence attribuable aux bandes de Swan, Philipps et Ballik–Ramsay du C_2 est observée lorsque les méthanes halogénés de composition $CH_{2-n}X_{2+n}$ (X = Cl, Br, I) sont introduits dans un courant d'atomes d'hydrogène. La population relative des niveaux $v' = 0$ de chacun des états $A\,^3\Pi_g$, $b\,^1\Pi_u$, et $A'\,^3\Sigma_g^-$ est 10:400:1000, la vitesse totale de formation dans les trois états étant à peu près la même. On croit que l'étape déterminante de la formation de C_2^* est:

$$C + CX \rightarrow C_2^* + X \text{ (X = halogène ou hydrogène)}$$

[Traduit par le journal]

Introduction

Recently infrared chemiluminescence from the reactions of oxygen atoms with chloromethanes (1) and chloroethylenes (2) was reported. In the present study visible and infrared chemiluminescence from the reactions of hydrogen atoms with chloro, bromo, and iodomethanes is discussed. In 1952 Gaydon and Wolfhard (3) briefly discussed the visible chemiluminescence (250–600 nm) from the reaction of hydrogen atoms with CCl_4, $CHCl_3$, and $CHBr_3$. They observed strong emission attributable to the Swan ($A\,^3\Pi_g$–$X'\,^3\Pi_u$) system of C_2 as well as CH. In the present study C_2 emission from the Swan, Phillips ($b\,^1\Pi_u$–$X'\,^1\Sigma_g^+$), and Ballik–Ramsay ($A'\,^3\Sigma_g^-$–$X'\,^3\Pi_u$) systems was observed when hydrogen atoms reacted with CCl_4, $CHCl_3$, CH_2Cl_2, CBr_4, and $CHBr_3$ and from the Swan system when hydrogen atoms reacted with CH_2Br_2, CHI_3, and CH_2I_2.

Experimental

The experimental assembly is essentially identical to that shown in Fig. 1 of ref. 4. The reaction cell consisted of a 1.5 in. glass "tee" equipped with either an NaCl or quartz window and pumped by an Edwards 660 l/min two-stage pump. Hydrogen atoms, produced by passage of a hydrogen–helium mixture through a 2450 MHz microwave discharge, entered the cell through the center tube of the concentric mixer inlet jet. The organic halide in a helium buffer entered through five holes in the outer tube of the concentric mixer.

Initial low resolution spectroscopic studies of the wavelength region 1500–4000 nm were made with a McPherson Model 218, 0.3-m, *f*/5.3 monochromator equipped with a 300 lines/mm grating blazed at 3000 nm, a Dry Ice – acetone cooled PbS detector and PAR Model HR-8 amplifier. High resolution spectra were recorded using a Czerny–Turner 1.3-m *f*/7.5 spectrometer of local construction equipped with a 600 lines/mm grating blazed at 1600 nm. Mercury lines from a low pressure mercury lamp were used to obtain the wavelength calibration. The detectors, used with a phase-sensitive PAR Model HR-8 amplifier, were a Dry Ice – acetone cooled PbS, an R.C.A. liquid-nitrogen-cooled intrinsic germanium detector and a cooled EMI 9558 photomultiplier with an extended S-20 response. This assembly permitted spectroscopic study of the region 450–2000 nm, depending on the detector and filters used. The relative intensity of each band was determined by calibrating the detection system with a standard quartz–iodine lamp supplied by Eppley Laboratories Inc. (lamp number EPI 1057).

All gases were of the highest purity available from Matheson and were used without further purification. The CCl_4, $CHBr_3$, CHI_3, and CH_2I_2 were supplied by the J.T. Baker Chemical Co., the CHI_3 and CH_2Cl_2 by Fisher Scientific Co., and the CBr_4 by Matheson, Coleman and Bell.

The pressure for all experiments was (5.9 ± 0.1) Torr. The flow rates of inert buffer, He, of H_2, and of halomethane were 3.07, 1.88×10^{-1}, and 1.0×10^{-2} mmol s^{-1} respectively.

Results

When halomethanes of the form $CH_{2-n}X_{2+n}$ (X = Cl, Br, I) were introduced into a hydrogen atom stream, chemiluminescence attributable to the C_2 molecule was observed. Depending on the

halomethane used, emission was observed from the Swan ($A\,^3\Pi_g$–$X'\,^3\Pi_u$), Phillips ($b\,^1\Pi_u$–$X\,^1\Sigma_g^+$), and Ballik–Ramsay ($A'\,^3\Sigma_g^-$–$X'\,^3\Pi_u$) systems of C_2. The observed bands are given in Table 1.

A portion of the spectra showing the $\Delta v = 1$ sequence of the Ballik–Ramsay bands is shown in Fig. 1. Rotational structure of the (1,0), (2,1), and (3,2) bands is clearly visible. Analysis of the band structure can be made by direct comparison with the more completely resolved spectra of Ballik and Ramsay (5). Values of J up to about 30 can clearly be identified as well as the characteristic triplet P, Q, R structure of the $^3\Sigma$–$^3\Pi$ transition.

Figure 2 shows a portion of the $\Delta v = 2$ sequence of the Phillips bands. The rotational structure of the (2,0), (3,1), and (4,2) bands has

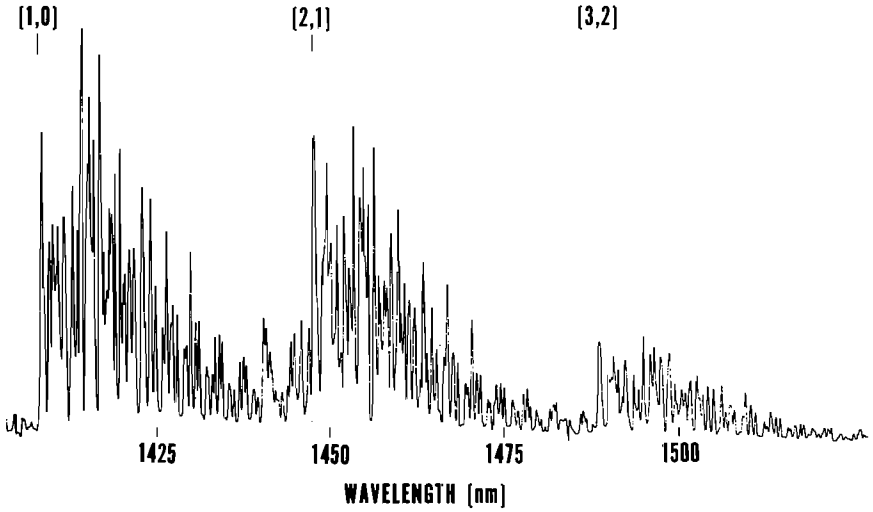

FIG. 1. A portion of the emission spectrum observed from the reaction of $CHBr_3$ with hydrogen atoms showing the $\Delta v = 1$ sequence of the Ballik–Ramsay ($A'\,^3\Sigma_g^- - X'\,^3\Pi_u$) system, recorded using a Czerny–Turner 1.3 m *f*/7.5 spectrometer.

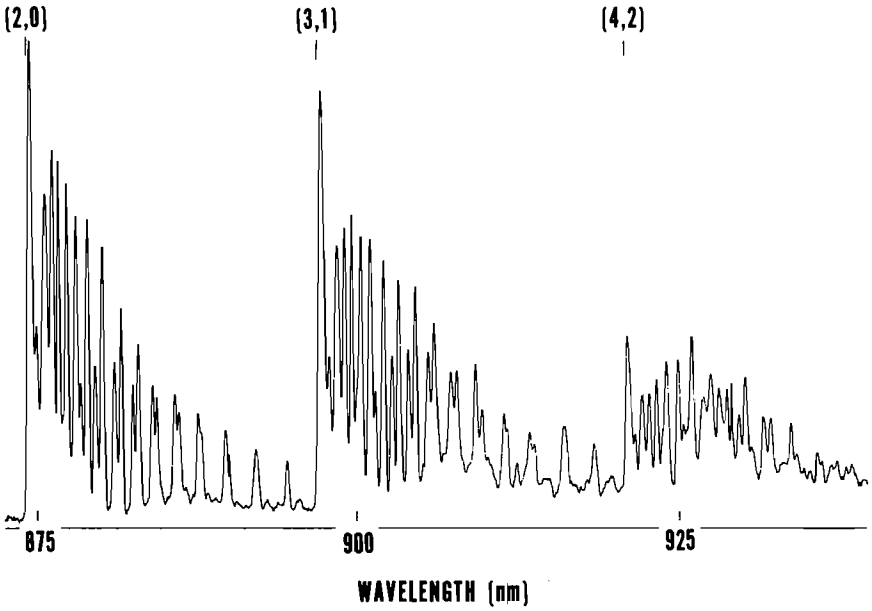

FIG. 2. A portion of the emission spectrum observed from the reaction of $CHBr_3$ with hydrogen atoms showing the $\Delta v = 2$ sequence of the Phillips ($b\,^1\Pi_u - X\,^1\Sigma_g^-$) system, recorded using a Czerny–Turner 1.3 m *f*/7.5 spectrometer.

been partially resolved. Band assignments were made by comparison with the data of Ballik and Ramsay (6).

The Swan bands were identified by comparison of the wavelengths of the band heads with those given by Tyte *et al.* (7).

Discussion

Jansson (8) has claimed that the C_2 Swan bands observed by Gaydon and Wolfhard in CCl_4 – H atom, $CHCl_3$ – H atom, and $CHBr_3$ – H atom flames were due to oxygen atoms originating from water vapor present in the hydrogen.

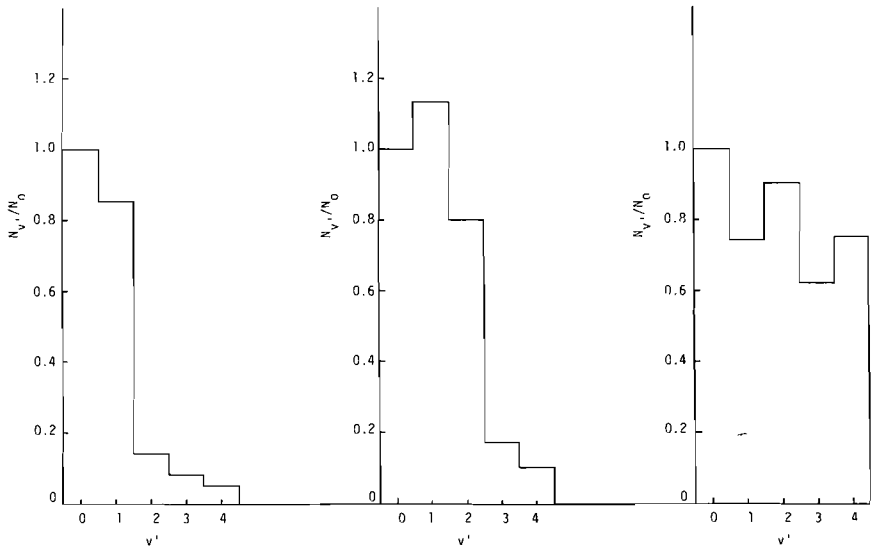

FIG. 3. Relative population distributions of C_2 in vibrational levels of the $A^3\Pi_g$ state, left to right CCl_4 – H atom system, $CHBr_3$ – H atom system, CH_2I_2 – H atom system.

In the present experiments the hydrogen–helium mixture was passed through three liquid nitrogen traps prior to passing through the microwave discharge. Contrary to Jansson's observations in a similar experiment, C_2 emission was observed in all three systems. It was not observed, however, when the hydrogen atoms were replaced by oxygen atoms. These observations suggest that the work of Jansson is in error.

Swan System

Emission of the C_2 Swan system was observed from each of the halomethane–hydrogen atom systems studied. The most intense emission for each halomethane was from the tetrahalide and the least intense from the dihalide. The maximum degree of excitation of C_2 was up to $v' = 5$ for the CBr_4–H system with excitation to $v' = 4$ being observed in all other systems.

The relative population distribution of C_2 in the vibrational levels $v' = 0$ to $v' = 4$ of the $A\,^3\Pi_g$ state is given for the CCl_4 – H atom system, the $CHBr_3$ – H atom system, and the CH_2I_2 – H atom system in Fig. 3. The population distributions were determined from the relative intensity measurements made on the $\Delta v = -1$ sequence of the Swan bands, corrected for differences in the spectral sensitivity of the detection system. The relative population ($N_{v'}/N_0$ = number of molecules in v'/number of molecules in $v' = 0$) was calculated from the expression:

$$[1] \qquad \frac{N_{v'}}{N_0} = \frac{I(v'v'')}{I(0v'')} \times \frac{\lambda(v'v'')}{\lambda(0v'')} \times \frac{A(0v'')}{A(v'v'')}$$

where I = intensity, λ = wavelength, A = Einstein A factor, as determined by Danylewych and Nicholls (9), and ($v'v''$) designates the band. The intensities were obtained from band area measurements, with ten data sets being measured in each case. The λ is included to convert the relative intensities from power units to photon units.

The relative population distribution appears to be a function of the halogen atom, with markedly different distributions being observed for the CCl_4 – H atom, $CHBr_3$ – H atom, and CH_2I_2 – H atom systems. For the CCl_4 – H atom system there is no indication of a population inversion with the maximum population being in the $v' = 0$ level. For the $CHBr_3$ – H atom system, there is an apparent population inversion with the $v' = 1$ level being preferentially populated. For the CH_2I_2 – H atom system, population maxima occur for $v' = 0$, $v' = 2$, and $v' = 4$. These distributions appear to be independent of the number of halogen atoms in the halomethane, *e.g.* there is no significant difference in the distribution obtained from the CBr_4–H atom system and from the $CHBr_3$–H atom system.

Assuming steady state conditions in the viewed region of the reaction vessel, the rate of formation of C_2 into a given vibrational level, R_v is given by

$$[2] \quad R_v = N_v \sum_{n=0}^{n} A(v, n) + N_v \sum_i k_v{}^i Q_i$$

where the second term represents the loss due to collisional deactivation ($k_v{}^i$ is the quenching rate constant and Q_i the concentration of the quencher). The radiative lifetime for molecules in the $A\,^3\Pi_g$ state is $\sim 1.5 \times 10^{-7}$ s. Under experimental conditions (pressure <6 Torr) a C_2 molecule in this state will undergo less than 10 collisions before radiating. In this and subsequent calculations hard sphere collision rates with helium as the predominant collision partner are quoted. Collision diameters used are 2.16 Å for helium and 3.72 Å for C_2, the latter being an assumed value by analogy with N_2 and CO. Collisional quenching is unlikely to proceed at the hard sphere collision rate. Thus the collisional quenching term can probably be neglected for molecules in the $A\,^3\Pi_g$ state. The loss term due to pumping of the excited molecules out of the reaction vessel has been neglected since this process is much slower than the radiative removal of excited species for all the bands considered. The values of N_v/N_1 ($v = 0$ to 4) obtained as in [1] were used in [2] to obtain the relative R_v's shown in Table 2. Collisional quenching has been neglected.

TABLE 2. Rate of formation of C_2 into vibrational levels of the $A\,^3\Pi_g$ state

	v				
System	0	1	2	3	4
CH_2I_2–H	1	0.72	0.84	0.55	0.65
$CHBr_3$–H	1	1.10	0.74	0.15	0.09
CCl_4–H	1	0.84	0.13	0.07	0.05

Phillips and Ballik–Ramsay Bands

Emission of the C_2 Phillips and Ballik–Ramsay systems was observed when hydrogen atoms were added to CH_2Cl_2, $CHCl_3$, CCl_4, $CHBr_3$, and CBr_4. No emission from either system could be detected when hydrogen atoms were added to CH_2Br_2, CH_2I_2, or CHI_3. This observation is consistent with the generally weaker emission observed from these chemical systems. The expected emission intensity would be below that capable of being detected by the experimental assembly employed. As in the case of the C_2 Swan system the most intense emission was from the tetrahalide.

The relative population of C_2 in each state was calculated from [1]. The required Einstein A factors were determined from the Franck–Condon factors calculated by Nicholls (10) and the electronic transition moments measured by Cooper and Nicholls.[1] The calculation of the relative populations for the Phillips and Ballik–Ramsay bands is less exact than the corresponding calculations for the Swan system. This results from the fact that the variation of the electronic transition moment with internuclear separation is not known for the Ballik–Ramsay and Phillips systems. When the additional errors arising from the band intensity measurements are taken into account the error in the relative populations of the Ballik–Ramsay and Phillips systems is probably of the order of $\pm 20\%$. For the $A'\,^3\Sigma_g{}^-$ state, the relative populations in the levels $v' = 0$ to $v' = 3$ were 1:0.8:0.9:0.5 for the CCl_4 – H atom system with a similar distribution being observed for the $CHBr_3$ – H atom system. For the $b\,^1\Pi_u$ state, the relative populations in levels $v' = 0$ to $v' = 8$ were 1:0.5:0.5:0.4:0.3:0.2:0.1:0.1 for the $CHBr_3$ – H atom system. A similar distribution was observed for the CCl_4 – H atom system.

For the $b\,^1\Pi_u$ state the radiative lifetime is $\sim 5 \times 10^{-6}$ s. Under experimental conditions a C_2 molecule in this state undergoes ~ 300 collisions before radiating. For the $A'\,^3\Sigma_g{}^-$ state the radiative lifetime is $\sim 1.5 \times 10^{-5}$ s with a molecule undergoing ~ 900 collisions before radiating. The assumption that collisional deactivation can be neglected when calculating the rate of formation into these states is not as justified as in the case of the $A\,^3\Pi_g$ state. However, when this assumption is made, the rate of formation into levels $v = 0$ to $v = 8$ of the $b\,^1\Pi_u$ state for the $CHBr_3$ – H atom system is 1:0.6:0.7:0.7:0.6:0.5:0.4:0.3:0.2 and into levels $v = 0$ to $v = 3$ of the $A'\,^3\Sigma_g{}^-$ state 1:1:1.1:0.7.

Since it was possible to measure bands from two different electronic transitions under identical experimental conditions, an estimate of the relative steady state populations of the $v' = 0$ levels of the $A\,^3\Pi_g$, $b\,^1\Pi_u$, and $A'\,^3\Sigma_g{}^-$ states

[1]D. M. Cooper and R. W. Nicholls. Private communication.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

could be made. The relative populations are 10:400:1000 with the relative rates of formation into the $v' = 0$ level being 1.5:0.9:1.0 for the $CHBr_3 - H$ atom system. The overall rate of formation of the three states

$$\sum_{v=0}^{v(\max)} R_v$$

is approximately equal. The overall rate of formation into the $A'\,^3\Sigma_g^-$ and $b\,^1\Pi_u$ states may be underestimated because of the increased importance of collisional deactivation for these states.

Mechanism

The chemistry of these systems is sufficiently ill-defined to allow only a certain amount of speculation on the nature of the mechanism.

The initial step is most likely abstraction of a halogen atom by hydrogen

[3] $$H + CH_{2-n}X_{2+n} \rightarrow HX + CH_{2-n}X_{1+n}$$

Subsequent abstraction reactions from the parent compound or free radical intermediate by hydrogen or halogen atoms, formed via H + HX, lead to formation of CH and/or CX radicals (see refs. 1 and 11 for a discussion of these reactions). Atomic carbon can be formed by

[4] $$CX_1 + CX_2 \rightarrow C + CX_1X_2$$
(X_1, X_2 = halogen or hydrogen)

There is no evidence for the formation of $C(^1D)$ atoms from this reaction although the reaction is sufficiently exothermic to permit their formation. C_2 can then be formed in a variety of ways:

[5] $$C + C + M \rightarrow C_2 + M + 141.5 \text{ kcal/mol}$$

[6] $$C + CX \rightarrow C_2^* + X$$

[7] $$C + CH \rightarrow C_2^* + H + 60.5 \text{ kcal/mol}$$

[8] $$CX_1 + CX_2 \rightarrow C_2^* + X_1X_2$$

[9] $$CH + CH \rightarrow C_2^* + H_2 + 83.8 \text{ kcal/mol}$$

The principal step in the formation of C_2^* must be sufficiently exothermic to populate the highest observed level of the $A\,^3\Pi_g$ state and be capable of explaining the differences in the observed population maxima as a function of halogen for the $A\,^3\Pi_g$ state. The three-body association of C atoms, reaction 5, although certainly occurring, is not favored by the low pressures in the experimental system. It can also be rejected as the principal reaction for the formation of C_2 because it would lead to identical population distributions in all chemical systems. The four centered reactions 8 and 9 are probably less likely than the corresponding disproportionation reaction 4. Reaction 9 can also be rejected because it would lead to identical population distributions with varying halogen. Reaction 8 for $X_1 = X_2 =$ halogen is also ruled out because only in the case of X = I is it sufficiently exothermic to populate the $A\,^3\Pi_g$ state. For $X_1 = H$ and $X_2 =$ halogen, reaction 8 is sufficiently exothermic to populate up to $v' = 5$ for X = Cl ($\Delta H = -84$ kcal/mol), $v' = 2$ for X = Br ($\Delta H = -72 \pm 15$ kcal/mol), and $v' = 3$ for X = I ($\Delta H = -76$ kcal/mol). Reaction 7 can populate the $v' = 0$ level of the $A\,^3\Pi_g$ state and reaction 6 the $v' = 0$ level for X = Cl ($\Delta H \approx -61.8$ kcal/mol), up to $v' = 1$ for X = Br ($\Delta H = -66$ kcal/mol), and up to $v' = 5$ for I ($\Delta H = -85$ kcal/mol). Thus it appears that reaction 6 is the dominant reaction for the formation of C_2^* with a possible small contribution from reaction 8 when $X_1 = H$.

Palmer *et al.* (12) have observed emission from the C_2 Swan system in alkali metal atom – halomethane flames. The population distributions for the C_2 Swan bands observed in these flames are substantially different from those reported in Fig. 3. Palmer stated that the levels $v' \geq 6$ were populated by the C_2 molecule crossing from the $A'\,^3\Sigma_g^-$ state to the $A\,^3\Pi_g$ state. He claimed that if the contribution from these high pressure bands ($v' \geq 6$) (as observed in the alkali metal atom – CCl_4 flame) was subtracted from the distribution observed for the alkali metal atom – CBr_4 and the alkali metal atom – CI_4 flames, the resulting distribution was characteristic of reaction 6 with small contributions from the reaction sequence

[10] $$C + A_2 \rightarrow CA + A \quad (A = \text{alkali metal})$$

[11] $$CA + C \rightarrow C_2 + A$$

Palmer's resulting distribution for the alkali metal atom – CBr_4 flame is similar to that observed for the $CHBr_3 - H$ atom system with the differences being accounted for by the sequence 10 to 11.

Summary and Conclusions

When halomethanes of the form $CH_{2-n}X_{2+n}$ (X = Cl, Br, I) are added to a hydrogen atom stream chemiluminescence attributable to C_2^* is observed. Depending on the halomethane used, emission can be detected from just the Swan system or from the Swan, Phillips, and Ballik–Ramsay systems.

The relative population of vibrational levels of the $A\,^3\Pi_g$ state of C_2 is dependent upon the halogen atom present.

The relative population of the $v' = 0$ levels of the $A\,^3\Pi_g$, $b\,^1\Pi_u$, and $A'\,^3\Sigma_g^-$ states are 10:400:1000 with the total rate of formation into all three states being approximately equal.

The principal step for the formation of C_2* is believed to be

$$C + CX \rightarrow C_2 + X \quad (X = \text{halogen or hydrogen})$$

with contributions from

$$CH + CX \rightarrow C_2 + HX \quad (X = \text{halogen})$$

Metal Halide Ammines. III. Thermal Analyses and Calorimetry of Fluorosilicate Ammines and Hydrates of Bivalent Metals. Infrared Spectra of the Ammines

KASHINATH C. PATIL AND ETALO A. SECCO[1]

Department of Chemistry, St. Francis Xavier University, Antigonish, Nova Scotia B0H 1C0

Received March 10, 1975

KASHINATH C. PATIL and ETALO A. SECCO. Can. J. Chem. **53**, 2426 (1975).

Bivalent metal fluorosilicate ammines have been prepared. The thermal analyses of the dodecammines reveal the decomposition to occur via the pentammine and/or tetrammine. The final ammonia loss is concomitant with fluorosilicate decomposition. Calorimetric data are given for the decomposition reactions. Some fluorosilicate hydrates are included for comparison purposes.

The infrared spectral data of the ammines are presented with their assignments.

KASHINATH C. PATIL et ETALO A. SECCO. Can. J. Chem. **53**, 2426 (1975).

On a préparé des fluorosilicates d'ammines de métaux bivalents. Les analyses thermiques des dodécammines montrent que la décomposition se fait en passant par une pentammine et/ou une tétrammine. La perte finale d'ammoniac se fait en même temps que la décomposition du fluorosilicate. On présente les données calorimétriques des réactions de décomposition. On a inclus quelques fluorosilicates hydratés à des fins de comparaison.

On présente l'interprétation des spectres infra-rouge des ammines.

[Traduit par le journal]

Introduction

The physico-chemical properties and the infrared spectra of metal fluorosilicate hydrates have been described in the literature (1–4). The crystal structures of Fe(II) and Co(II) fluorosilicate hydrates indicate strong H-bonding (5, 6). To our knowledge no study of fluorosilicate ammines is recorded since their preparation is precluded by the instability of SiF_6^{2-} in an alkaline medium (3).

Recently, we prepared fluorosilicate ammines by the simple displacement reaction reported earlier (7), *i.e.* reacting fluoride hydrates with liquid ammonia. The purpose of this paper is to report on the thermal decomposition, heat of decomposition, relative stability, and infrared spectra of fluorosilicate ammines of some bivalent metals; the analogous hydrates were also reinvestigated and included for comparison purposes.

Experimental

All the metal fluorosilicate hydrates studied were prepared by the reaction of the corresponding oxide or carbonate with fluorosilicic acid (1). The fluorosilicates of Mg, Mn, Fe, Co, Ni, Zn, Cu, and Cd crystallized as hexahydrates; Ca and Sr formed dihydrates whereas Ba precipitated as the anhydrous salt.

Transition metal fluorosilicate hexahydrates refluxed with anhydrous liquid ammonia (7) yielded dodecammines; magnesium fluorosilicate hexahydrate formed hexammine while Ca and Sr hydrates converted to diammines. The ammines were characterized by their infrared spectra, Table 1, and thermogravimetric data, Table 3.

All our measurements were done with freshly prepared samples; the dodecammines were observed to decompose on prolonged storage at room temperature.

The heating traces were recorded on a duPont Thermal Analyzer DTA-900 and TGA-950 described earlier (8); the heats of decomposition were determined using a duPont calorimeter cell (9). X-ray diffraction patterns of solid specimens were obtained using CuK_α and MoK_α radiation (10). Infrared spectra were recorded on a Perkin-Elmer Model-180 spectrophotometer using the standard pellet technique with KBr as the matrix material.

Results and Discussion

Thermal Analyses

The thermogravimetric (t.g.) and differential thermal analysis (d.t.a.) results for the hydrates are presented in Table 2. The results for the transition metal compounds are consistent with a single step decomposition, *viz.*

[1] $$MSiF_6 \cdot 6H_2O_{(s)} \rightarrow MF_{2(s)} + SiF_{4(g)} + 6H_2O_{(g)}$$

where M = Mn, Fe, Co, Ni, Cu, Zn, Cd, and Mg. The metal fluoride residue in each case was confirmed by X-ray diffraction. The alkaline earth metal fluorosilicate hydrates undergo strict dehydration followed by decomposition of the fluorosilicate at a higher temperature,

*$(6NH_3)$ and $(2NH_3)$ indicate fluorosilicate hexammine and diammine, respectively.
†All endotherms.

[2*a*] $MSiF_6 \cdot 2H_2O_{(s)} \rightarrow MSiF_{6(s)} + 2H_2O_{(g)}$ M = Ca, Sr

[2*b*] $MSiF_{6(s)} \rightarrow MF_{2(s)} + SiF_{4(g)}$ M = Ca, Sr, and Ba

The solids from [2*a*] and [2*b*], $MSiF_6$ and MF_2, were identified by infrared and X-ray diffraction.

The decomposition temperatures of the fluorosilicates observed in this work are higher than those reported elsewhere (3).

The t.g. and d.t.a. results for the ammines are summarized in Table 3. The transition metal dodecammines decompose via the pentammine and/or tetrammine intermediate, *i.e.*

[3*a*] $MSiF_6 \cdot 12NH_{3(s)} \rightarrow MSiF_6 \cdot xNH_{3(s)} + (12 - x)NH_{3(g)}$

[3*b*] $MSiF_6 \cdot 5NH_{3(s)} \rightarrow MSiF_6 \cdot 4NH_{3(s)} + NH_{3(g)}$

[3*c*] $MSiF_6 \cdot 4NH_{3(s)} \rightarrow MF_{2(s)} + SiF_{4(g)} + 4NH_{3(g)}$

where $x = 5$ for Co, Ni, Cu, and Zn and $x = 4$ for Mn and Cd. The NH_3 molecules are so strongly bound to SiF_6 in the tetrammine that the release of NH_3 effects a breakdown of the SiF_6 unit. The evolved gases were identified as NH_3 and SiF_4; the solids were identified by infrared and X-ray diffraction.

$MgSiF_6 \cdot 6NH_3$ decomposes via the diammine intermediate to the fluoride according to [4],

[4] $MSiF_6 \cdot 2NH_{3(s)} \rightarrow MF_{2(s)} + SiF_{4(s)} + 2NH_{3(g)}$

where M = Mg, Ca, and Sr. Assuming the N—H. . .F hydrogen bond analog of O—H. . .F is present, the release of the final NH_3 effects a concomitant rupture of the SiF_6^{2-} unit suggesting increased overlap by the NH_3 molecules with SiF_6 relative to H_2O in the hydrates for Ca and Sr compounds.

Calorimetric Studies

The calorimetric results along with related enthalpic values for the decomposition of metal fluorosilicate hydrates and ammines are given in Table 4; the calculated enthalpy of formation values for the compounds are also included.

Infrared Spectral Data

The infrared absorption frequencies of the fluorosilicate ammines in Table 1 show the characteristic frequencies of coordinated ammonia and SiF_6^{2-}. The observed frequency $\sim 320\ cm^{-1}$ for Co and Ni fluorosilicate ammines is assigned to $\nu_{(M-N)}$ mode. While we are prompted to assign the band $\sim 420\ cm^{-1}$ to $\nu_{(M-F)}$ as in the fluoride ammines (7), this assignment may be inconsistent with some fluorosilicate hydrates (6) where no direct M—F interaction is observed.

The Charge Transfer Photochemistry of the Hexaaquoiron(III) Ion, the Chloropentaaquoiron(III) Ion, and the μ-Dihydroxo Dimer Explored with *tert*-Butyl Alcohol Scavenging[1]

COOPER H. LANGFORD[2] AND JOHN H. CAREY

Department of Chemistry, Carleton University, Ottawa, Canada K1S 5B6

Received February 21, 1975

COOPER H. LANGFORD and JOHN H. CAREY. Can. J. Chem. **53**, 2430 (1975).

There have been several studies of the charge transfer photochemistry of aqueous Fe^{3+} but the complexity of hydrolytic equilibria and the requirement for scavengers to render the primary photochemical processes observable has left several issues moot as recent reports show. Using *tert*-butyl alcohol as a scavenger, it is shown that (at 35 °C), charge transfer irradiation at 254 nm of $Fe(OH_2)_6^{3+}$ gives free ·OH with a quantum yield of 0.065, charge transfer irradiation of $Fe(OH_2)_5Cl^{2+}$ at 350 nm gives free Cl· with a quantum yield of 0.093, and that as a result of the combined patterns of extinction coefficients and hydrolytic equilibria it is difficult to make $Fe(OH_2)_5OH^+$ the main absorbing species at either wavelength. The dihydroxo-bridged dimer gives only a small radical yield. The scavenger, *tert*-butyl alcohol, appears to react with ·OH or Cl· to give $\cdot CH_2—C(CH_3)_2OH$ which, on reaction with a second $Fe(OH_2)_6^{3+}$ gives $HOCH_2C(CH_3)_2OH$.

COOPER H. LANGFORD et JOHN H. CAREY. Can. J. Chem. **53**, 2430 (1975).

Il existe plusieurs études sur le transfert de charge photochimique de Fe^{3+} en solution aqueuses. La complexité de l'équilibre hydrolytique et la nécessité pour les agent piégeurs de rendre les processus photochimiques primaires observables ont laissé plusieurs questions controversées comme le montrent des communications récentes. Utilisant l'alcool *tert*-butylique comme piège, on montre qu'à 35 °C le transfert de charge de $[Fe(OH_2)_6]^{3+}$ par une irradiation à 254 nm donne le radical libre ·OH avec un rendement quantique de 0.065; l'irradiation à 350 nm de $[Fe(OH_2)_5Cl]^{2+}$ produit le radical libre Cl· avec un rendement quantique de 0.093. En conséquence de la combinaison des variations des coefficients d'extinction et des équilibres hydrolytiques en peut difficilement affirmer que $[Fe(OH_2)_5OH]^+$ est l'absorbant principal à l'une ou l'autre des longueurs d'onde. Le dimère ponté dihydroxo donne seulement un faible rendement en radicaux. L'agent piégeur (l'alcool *tert*-butylique) semble réagir avec ·OH ou ·Cl pour donner $\cdot CH_2—C(CH_3)_2OH$, qui par réaction avec un autre $[Fe(OH_2)_6]^{3+}$ conduit à $HOCH_2C(CH_3)_2OH$. [Traduit par le journal]

Introduction

When the $Fe(OH_2)_6^{3+}$ ion is irradiated at 254 nm, excitation corresponds, in first approximation, to promotion of an electron from a ligand centered orbital to a metal centered orbital. This is a so-called l.m.c.t. transition. Such transitions are frequently associated with a photochemistry of metal reduction and ligand oxidation (1). In the chemistry of Fe(III), reduction produces Fe(II) and ligand oxidation which in the absence of scavengers leads to liberation of O_2. The quantum yield for Fe(II) formation is quite small in the absence of scavengers ($\sim 10^{-4}$), but it is not immediately clear what is the significance of a small yield since a primary process producing Fe(II) and hydroxyl radicals would be subject to thermal reversal. To determine the primary yield for Fe(III) reduction to Fe(II) various workers have explored iron isotope exchanges between the two oxidation states (1), radical initiation of polymerization (2), and alcohol scavenging (3). Unfortunately, the role of scavengers has not been fully interpreted over wide concentration ranges and ambiguity remains.

In another area, there are also serious outstanding ambiguities connected with the nature of the absorbing species responsible for photoreactions. A recent communication (4) in which Fe(II) yields were examined as a function of p*H* and chloride ion concentration concluded that reaction followed on absorption by $Fe(OH_2)_5OH^{2+}$ but *not* $Fe(OH_2)_5Cl^{2+}$. Since polymerization initiated in chloride-containing solutions produces polymers with both —Cl and —OH terminal groups, there is reason to consider both

hydroxyl radicals and chlorine atoms as products of the primary photo process.

In this paper, the use of *tert*-butyl alcohol as a scavenger is explored. It is shown to be a scavenger with "simple" behavior in that its *only* reaction is with free ·OH and ·Cl radicals in solution. With the aid of *tert*-butyl alcohol scavenging, the reactivities of $Fe(OH_2)_6^{3+}$, $Fe(OH_2)_5Cl^{2+}$, and the dihydroxo-bridged dimer are elucidated. We note that although the hydroxo monomer $Fe(OH_2)_5OH^{2+}$ is known to have an absorption maximum at 300 nm (5) this species could not be selectively irradiated in our cells. At concentrations required for near total absorbance, the monomer is predominantly converted to the dimer and the dimer is the strongest absorbing species in the solution.

Results and Discussion

The absorption spectra of iron(III) species irradiated in this study are as follows. The spectrum of $Fe(H_2O)_6^{3+}$, obtained in strongly acidic media, agrees well with that previously reported (5). There is only one major peak, occurring at $\lambda = 240$ nm ($\varepsilon = 4350$) corresponding to the water to iron charge transfer band. This transition was excited using 254 nm light. The spectrum obtained in weakly acidic solutions exhibits another band at 335 nm ($\varepsilon = 8300$) which is attributed to the dihydroxo-bridged dimer (6). Irradiations performed at 350 nm excite this band since $Fe(H_2O)_6^{3+}$ absorbs very weakly at this wavelength. Although the hydroxo monomer, $Fe(H_2O)_5OH^{2+}$ is known to have a maximum at 300 nm (5), this species could not be selectively irradiated since at the high concentrations needed to assure total absorbance over short path lengths, most of the hydroxo monomer underwent dimerization and the dimer was the strongest absorbing species in solution.

The absorption spectra of iron(III) solutions in 2.25 *M* $HClO_4$ containing varying concentrations of Cl^- are shown in Fig. 1. The chloride dependent peak at 335 nm ($\varepsilon = 1490$) is assigned as the chloride to metal charge transfer band. Irradiations performed at 350 nm allowed examination of the photochemistry of chloride to metal excitation.

The irradiation of $Fe(H_2O)_6^{3+}$ at 254 nm in the absence of scavengers produced Fe(II) as a product at a rate which initially was not constant but after several minutes attained a constant value. This behavior has been observed

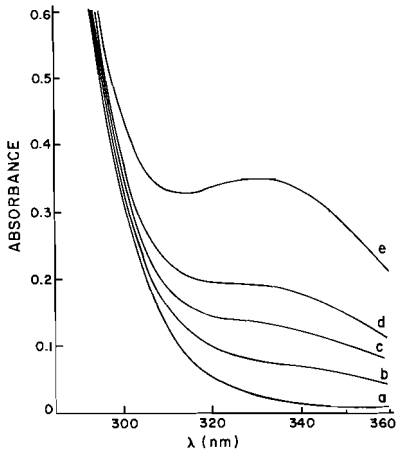

FIG. 1. Absorption spectra for ferric perchlorate in (*a*) 0, (*b*) 0.0020, (*c*) 0.0040, (*d*) 0.0060, (*e*) 0.0100, HCl; 2.10 *M* $HClO_4$, and 0.80 *M* $NaClO_4$. Cell path length is 0.10 cm.

in the photochemistry of Fe(II) where the initially increased rate is due to impurities acting as scavengers (7). The net quantum yield is determined from the slope in the region where production of Fe(II) is linear with time of irradiation after the impurities have been consumed (after 5 min of irradiation). The quantum yield calculated from the slope, $\Phi_{Fe(II)}$, is 0.0012.

As observed in other studies, the addition of organic compounds caused an increase in the rate at which Fe(II) was produced. The quantum yields observed at various scavenger concentrations for a variety of organic scavengers are given in Table 1. The largest increases in quantum yields were observed using alcohols and formic acid as scavengers. *tert*-Butyl alcohol was particularly interesting since a plateau was reached after which $\Phi_{Fe(II)}$ became independent of alcohol concentration. The value of the quantum yield on this plateau, $\Phi_{Fe(II)} = 0.130$, is taken to be twice the primary quantum yield for free ·OH. The value agrees well with the Fe isotope exchange estimate of Dainton and co-workers (1) for this primary yield of 0.07 ± 0.03 at 25 °C ($2 \times 0.07 = 0.14$).

The assignment of the limiting yield for Fe(II) as being twice the primary yield for OH is based on the following reaction path.

$$[1] \quad Fe_{aq}^{3+} \xrightarrow{h\nu} {}^*Fe_{aq}^{3+} \xrightarrow[k_1]{H_2O} Fe^{2+} + \cdot OH + H^+$$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

[2] $H^+ + \cdot OH + Fe_{aq}^{2+} \xrightarrow{k_2} Fe^{3+} + OH^-$

[3] $\cdot OH + HS \xrightarrow{k_3} \cdot S + H_2O$

[4] $\cdot S + Fe^{3+} \xrightarrow{k_4} Fe^{2+} + SOH + H^+$

[5] $\cdot S + Fe^{2+} \xrightarrow{k_5} Fe^{3+} + HS + OH^-$

There exists a competition, as indicated in reactions 4 and 5, between Fe(III) and Fe(II) for S·. In the initial stages of irradiation, the high concentration of Fe(III) compared to Fe(II) ensures that reaction 4 will predominate over reaction 5. Therefore, reaction 5 may be omitted for low conversions. Reactions 2 and 3 indicate there is also a competition between Fe(II) and HS for the hydroxyl radicals. Applying a steady state treatment to this scheme gives the following kinetics:

[6] $\Phi_{Fe(II)} = V/I \times d[Fe(II)]/dt$

[7] $= \left(\frac{V}{I} \frac{2k_1k_3[Fe^{3+}][HS]}{k_2[Fe^{2+}] + k_3[HS]}\right)$

where V represents volume and I light intensity in einstein s^{-1}. If I, V, and $[Fe^{3+}]$ are assumed constant

[8] $\Phi_{Fe(II)} = \frac{c[HS]}{k_2[Fe^{2+}] + k_3[HS]}$

It can be seen from this expression that if the Fe^{2+} is kept low (limited irradiation), and the scavenger concentration is increased, a point will be reached where $k_3[HS] \gg k_2[Fe^{2+}]$ and the expression will simplify to $\Phi_{Fe(II)}$ = constant. The quantum yield becomes independent of scavenger concentration giving rise to the observed plateau. Since there are two iron ions reduced for each ·OH scavenged, this limiting quantum yield represents twice the primary yield of free ·OH.

The results from the irradiation of $Fe(OH_2)_6^{3+}$ in the presence of various organic scavengers clearly suggest that *tert*-butyl alcohol is the scavenger of choice for the determination of primary yields for hydroxyl radical formation. Fe(II) yields for methanol, 2-propanol, and formic acid scavenging continue to increase at high scavenger concentration in a way indicative of reactions above and beyond those of reactions 1 to 5. This is discussed in an accompanying paper (8). Degassing had no measurable effect. Moderate concentrations of acetone, acetic acid, and malonic acid each caused a small increase in quantum yield but the limiting plateau was not attained. This seems reasonable since hydroxyl radical attack on acetic acid and acetone produced radicals which are not oxidized further, even in the presence of added cupric ion, but are reduced back to starting material by ferrous ion (9). In view of this limitation, acetone, acetic acid, and malonic acid were dropped from the study. On the basis of its simple behavior, *tert*-butyl alcohol is selected for elucidation of the primary photochemistry of the other Fe(III) species.

The organic product of the *tert*-butyl alcohol scavenging was somewhat difficult to determine.

Neither acetone nor methanol were produced indicating that elimination of a methyl radical was not a reaction pathway. There was a small yield of isobutyraldehyde which was identified by g.c. in comparison with a known sample. Neutralization, filtration, and evaporation of both an irradiated and an unirradiated sample left a white solid (mainly $NaClO_4$). Carbon tetrachloride extracts of this solid showed the presence of organic material for the irradiated sample but not for the unirradiated one. There were two peaks in the n.m.r. in the 2–2.5 p.p.m. region of approximate 3:1 intensity.

The high boiling nature of this organic product as well as the nature of the other product, isobutyraldehyde, are indications that it is isobutylene glycol. This is, in fact, the expected product. Walling and Kato (10) reported it in the *tert*-butyl alcohol scavenging of ·OH in the presence of Fe^{3+} and Cu^{2+}. In an experiment suggested by Walling's results, solutions 0.5 *M* alcohol, 0.020 *M* Fe^{3+}, 2 *M* $HClO_4$ with and without 0.002 *M* Cu^{2+} were irradiated to 5% conversion (based on Fe^{2+}). CCl_4 extracts from these solutions were injected onto a Chromosorb 101 column at 250 °C. A product was found which has a retention time longer than ethylene glycol, which is oxidizable by dilute $KMnO_4$. These results support isobutylene glycol. It is important to note that the simple combination of two *tert*-hydroxybutyl radicals would not produce an intercept of 0.130 for $\Phi_{Fe(II)}$. The production of two Fe(II) for each hydroxyl radical scavenged indicates that the reaction of hydroxyl radicals with *tert*-butyl alcohol produces a radical which is capable of being further oxidized by Fe(III). The reaction path is most probably

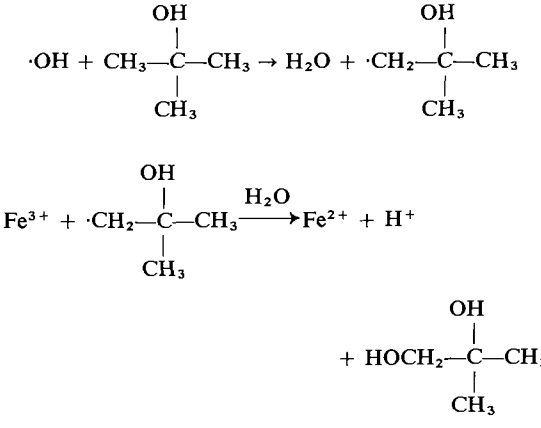

TABLE 2. Quantum yields irradiation of the dihydroxo-bridged dimer at 3500 Å

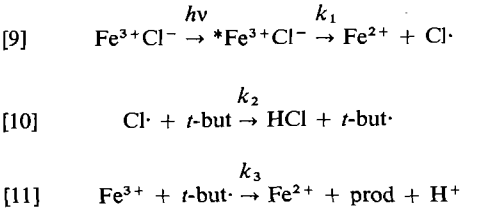
Scavenger	Scavenger concentration (*M*)	$\Phi_{Fe(II)}$
Methanol	0	0.010
	0.988	0.030
	1.975	0.035
t-Butyl alcohol	0.408	0.014
	0.816	0.013

with the isobutyraldehyde resulting from a pinacol type rearrangement of the glycol or some rearrangement of the radical prior to reaction with Fe^{3+}. We would underline for the reader the lack of quantitative accounting of organic product in these results.

Results of irradiations performed on solutions containing the dihydroxo-bridged dimer at 350 nm are given in Table 2. The yield observed in the presence of *tert*-butyl alcohol is close to the yield for unscavenged dimer irradiation. The primary yield of hydroxyl radical as indicated by *tert*-butyl alcohol scavenging is 0.007 at 350 nm. The reduced yield for the bridged dimer (as compared to the aquo monomer) is analogous to behavior reported for Fe(III) complexes of nitrilotriacetic acid (11) and ethylenediaminetetraacetic acid (12).

The irradiation of solutions of Fe(III) in 2.25 *M* $HClO_4$ with added Cl^- at 350 nm in the absence of scavengers results in photoreduction with a net quantum yield near 0.002. The results of the irradiation of $Fe(H_2O)_5Cl^{2+}$ in *tert*-butyl alcohol solutions are listed in Table 3. There is a complicated dependence of $\Phi_{Fe(II)}$ upon both concentration of scavenger and concentration of chloride. This suggests competition between the two species for the photoproduced radicals since increase in *tert*-butyl alcohol at constant chloride concentration results in an increased yield while increasing chloride for a constant *tert*-butyl alcohol concentration decreases the yield. In order to explain this behavior, the following reactions are considered:



Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

[12] $$Cl\cdot + Cl^- \xrightarrow{k_4} Cl_2^-$$

[13] $$Cl_2^- + Fe^{2+} \xrightarrow{k_5} Fe^{3+}Cl^- + Cl^-$$

where but = *tert*-butyl alcohol and prod = the oxidized organic product.

This scheme gives the following kinetics from a steady state treatment:

$$[14]\quad \Phi_{Fe(II)} = V/I \times d[Fe(II)]/dt = \left(\frac{V}{I}\frac{2k_1k_2[Fe^{3+}Cl^-][t\text{-but}]}{k_2[t\text{-but}] + k_4[Cl^-]}\right)$$

$$[15]\quad \frac{1}{\Phi_{Fe(II)}} = \frac{I}{V}\frac{k_2[t\text{-but}]}{2k_1k_2[Fe^{3+}Cl^-][t\text{-but}]} + \frac{k_4[Cl^-]}{2k_1k_2[Fe^{3+}Cl^-][t\text{-but}]}$$

If I, V, and $[Fe^{3+}Cl^-]$ are constant then [15] has the form of [16].

$$[16]\quad \frac{1}{\Phi_{Fe(II)}} = C_1 + \frac{C_2[Cl^-]}{[t\text{-but}]}$$

A plot of $1/\Phi$ *vs.* $[Cl^-]$ should be linear and have a slope dependent on each *tert*-butyl alcohol concentration. The intercept obtained from extrapolation to zero chloride concentration would represent the limiting quantum yield since contributions from reaction 12 (and reaction 13) would be eliminated. If the limiting quantum yield is independent of *tert*-butyl alcohol concentration, a plot of $1/\Phi$ *vs.* $[Cl^-]/[t\text{-but}]$ would be linear.

These plots are shown in Figs. 2 and 3 and are in excellent agreement with the above predictions. The limiting yield of Fe(II) is 0.186 from the extrapolation and thus the primary yield of chlorine atoms is 0.093 (*i.e.* 0.186/2). As a confirmation, the chloride concentration may be lowered relative to the *tert*-butyl alcohol concentration. The chloride dependent term will then become smaller and the quantum yield may be determined directly. Irradiations of this system in 0.01 *M* NaCl and 0.424, 0.636, and 0.848 *M* *tert*-butyl alcohol gave $\Phi_{Fe(II)}$ of 0.186, 0.182, and 0.182 respectively.

Finally, it may be useful to summarize some

TABLE 3. Quantum yields at 3500 Å as a function of scavenger and chloride concentrations. $[Fe]^{3+} = 0.0248$ *M*

general conclusions about Fe(III) c.t. photochemistry. (*1*) Alcohol scavenging in general may prove complicated and methanol and 2-propanol are to be avoided in attempts to determine primary free radical quantum yields. (*2*) *tert*-Butyl alcohol scavenging of hydroxy radicals is simple and indicates primary quantum yields in good agreement with those from iron isotope exchange studies. (*3*) $Fe(OH_2)_5Cl^{2+}$ is reactive on excitation of the chloride to metal charge transfer band at 350 nm. The primary yield of ·Cl is higher than the hydroxyl radical yield from irradiation of $Fe(OH_2)_6^{3+}$ at 254 nm. Confusions have arisen previously (4) from neglect of the role of Cl^- in reactions 12 and 13. (*4*) The dihydroxo-bridged dimer is relatively unreactive in the lowest c.t. band. This may result from initial formation of an ·OH radical in a bridging position where it remains coordinated to a relatively nonlabile Fe^{3+} and is neighbor to an Fe(II) center. Such circumstances should certainly favor a reaction analogous to reaction 2.

Experimental

Materials

The source of iron was ferric sulfate. Ferric perchlorate solutions were prepared by precipitation with NaOH, thorough washing, and dissolution in $HClO_4$. Iron content of stock solutions was determined by two methods. In the first, an excess of EDTA was added and absorbance at 260 nm was measured (13). In the second, reduction was effected by prolonged irradiation at 2537 Å. After a thiocyanate test indicated absence of Fe(III), Fe(II) was determined with *o*-phenanthroline (14). Other materials were best available commercial reagents used without further purification.

Irradiation Procedures

Solutions for irradiation were prepared freshly from stock solutions. Deaeration, when desired, was accomplished by freeze–thaw cycles or bubbling free nitrogen (introduced through a serum cap with stainless steel needles) through the solution for 20 min. Irradiation at 2537 Å was carried out in a cylindrical quartz vessel in a Rayonnet photoreactor (Southern New England Ultraviolet Co., Middletown, Conn.). Ulfiltered light from medium pressure Hg lamps in this apparatus is approximately 98% at 2537 Å. The temperature in the irradiation zone stabilized at 35 °C. Irradiations at 3500 Å were similar except that lamps were changed to Rayonnet fluorescent-coated Hg lamps with peak intensity at 3500 Å. Irradiations for quantum yield determination were limited to less than 5% conversion. Concentrations were chosen to assure large excesses over the minima required for >99% absorption of light at the desired wavelengths. Actinometry was carried out with ferrioxalate (15).

Analytical Procedures

The most common analysis was that for Fe(II) carried out with *o*-phenanthroline (phen) (14). In several cases, large excesses of acid had to be neutralized before the normal procedure was carried out. Direct neutralization of irradiated solutions caused precipitation. As an alternative, 2.5 ml of 1.00 *M* NaOH per ml of photolyte and 2 ml of buffered phenanthroline, which was a more concentrated version of that used by Hatchard and Parker (15), were added to 90 ml of distilled water in a 100 ml volumetric flask. Photolyte (1 or 2 ml) was added and the solution made up to 100 ml. The solution was stored in the dark for 30 min prior to recording absorbance at 510 nm. It was verified that ClO_4^- did not interfere in the analysis.

Gas chromatographic identification of isobutyraldehyde by retention time comparison with an authentic sample was carried out on CCl_4 or $CHCl_3$ extracts using a Beckmann GC2 equipped with a 5 ft, 10% ethofat on Chromosorb W column operated at room temperature. Other organic analyses were described above.

Outer Sphere Oxidations of Alcohols and Formic Acid by Charge Transfer Excited States of Iron(III) Species[1]

JOHN H. CAREY AND COOPER H. LANGFORD[2]
Department of Chemistry, Carleton University, Ottawa, Canada K1S 5B6
Received February 21, 1975

JOHN H. CAREY and COOPER H. LANGFORD. Can. J. Chem. **53**, 2436 (1975).

When methanol, 2-propanol, and formic acid are used as scavengers in the ligand to metal charge transfer (l.m.c.t.) photolysis of $Fe(OH_2)_6^{3+}$, $Fe(OH_2)_5Cl^{2+}$, $Fe_2(OH_2)_8(OH)_2^{4+}$, or FeEDTA, there is a linear relationship between quantum yield for Fe(II) production and scavenger concentration, [S], at higher [S] values. Extrapolation of the linear portions to [S] = 0 gives an intercept corresponding to the limiting yields observed for scavenging with *tert*-butyl alcohol. Butanol scavenging at the limit has been shown to give the primary free radical yields from photolysis of aquo iron(III) species. Nuclear magnetic resonance relaxation time studies show that alcohols do not coordinate to Fe(III) and calculations from known stability constants indicate that formic acid does not coordinate under the experimental conditions. The increase of Fe(II) yields with [S] is attributed to an outer sphere oxidation of noncoordinated organic species by the charge transfer excited states of Fe(III) species. There is no discrimination among the organic reductants. The results may be understood without postulating a long lifetime for the Fe(III) l.m.c.t. states if the reaction is assumed to occur only with organic molecules in encounter with the Fe(III) complex at the time of excitation. Organic products were formaldehyde from methanol oxidation and acetone from 2-propanol oxidation. The Fe(II):formaldehyde stoichiometry was 2:1.

JOHN H. CAREY et COOPER H. LANGFORD. Can. J. Chem. **53**, 2436 (1975).

La photolyse du transfert de charge du ligand au métal (t.c.l.m.) de $Fe(OH_2)_6^{3+}$, $Fe(OH_2)_5Cl^{2+}$, $Fe(OH_2)_8(OH)_2^{4+}$ ou de FeEDTA est étudiée en se servant du méthanol, du propanol-2 et de l'acide formique comme agents piégeurs. On observe une relation linéaire entre le rendement quantique de la formation de Fe(II) et la concentration [S] en agent piégeur, pour les fortes concentrations en [S]. L'extrapolation à [S] = 0 des portions linéaires permet de retrouver les rendements limites observés dans le cas du piégeage par l'alcool *tert*-butylique. Il a été montré qu'à la limite, le piégeage par l'alcool *tert*-butylique conduit aux rendements en radical libre primaire, à partir de la photolyse d'espèces aquo fer(III). Les études du temps de relaxation par r.m.n. montrent que les alcools ne se coordonnent pas au Fe(III). Les calculs basés sur les constantes de stabilité connues indiquent que l'acide formique ne se coordonne pas non plus dans ces conditions expérimentales. L'augmentation du rendement en Fe(II) avec [S] est attribué à une oxydation externe, par transfert de charge des états excités des espèces Fe(III), de composés organiques non coordonnés. Il n'y a pas de distinction entre les réducteurs organiques. Ces résultats peuvent être interprétés sans avoir à postuler une longue durée de vie pour les états t.c.l.m. de Fe(III) si l'on admet que la réaction se fait seulement entre des molécules organiques rencontrant un complexe de Fe(III) au moment de l'excitation. Les produits organiques étaient la formaldéhyde provenant de l'oxydation du méthanol et l'acétone venant de l'oxydation du propanol-2. La stoechiométrie de Fe(II):formaldéhyde est 2:1.
[Traduit par le journal]

Introduction

In many photochemical reactions, those of charge transfer excited states of metal complexes included, identification of radicals produced in primary photo processes and determination of primary quantum yields requires introduction of scavengers. Frequently, rather large scavenger concentrations (large [S]) are required to achieve complete scavenging of the desired radical. But, there is a special feature of large scavenger concentrations. The scavengers may frequently be the encounter partner in the solvent cage of the molecule absorbing light, a phenomenon described in an organic photochemical example by Waits and Hammond (1). Encounter with scavengers can be important at surprisingly low concentration. Modeling encounter equilibrium between a complex ion and a molecule using the Eigen–Fuoss equation which is successful in the description of complex formation reactions (2), assumption of a center to center

encounter distance of only 5 Å gives an equilibrium constant, K_E, of 0.3. To see the implication of this value, consider a dilute aqueous solution of $Fe(OH_2)_6^{3+}$, containing 1 *M* CH_3OH. In this circumstance, 25% of the complex ions $Fe(OH_2)_6^{3+}$ have an alcohol molecule in encounter (in the second coordination sphere or solvation sphere) at any time. This means that ¼ of all $Fe(OH_2)_6^{3+}$ complexes absorbing photons from the 254 nm line of a mercury lamp may be expected to arrive in the ligand to metal charge transfer (l.m.c.t.) excited state with an alcohol molecule as a nearest neighbor. Under these circumstances there is *no need* to assume that the l.m.c.t. excited state has a substantial lifetime in order to account for a direct reaction between that state and the alcohol.

In this report we describe the reaction at high [S] between the l.m.c.t. excited states of several Fe(III) species and oxidizable organic scavengers which do not penetrate the primary coordination sphere. We will analyze the results for these outer sphere redox processes in terms of the encounter model described above because they do not become prominent except at high [S] and because this model does not require a long life for the l.m.c.t. excited states. The treatment is analogous to "static" quenching of emission (3). We note here that the alternative of "dynamic" quenching and a long-lived l.m.c.t. excited state is not excluded. It simply seems less likely.

Results and Discussion

In the preceding paper (4), we noted that the quantum yield for the reaction shown in reaction 1 could be determined simply by using *tert*-butyl alcohol as a scavenger. When methanol,

$$[1] \qquad Fe^{3+} + H_2O \xrightarrow[254\text{ nm}]{h\nu} Fe^{2+} + \cdot OH + H^+$$

2-propanol, and formic acid are employed as scavengers, the quantum yield for Fe^{2+} production does not approach a limit at high [S]. Instead, it becomes linearly dependent upon [S]. This behavior is illustrated in Fig. 1 for acid solution of $Fe(OH_2)_6^{3+}$ irradiated at 254 nm and for $Fe(OH_2)_5Cl^{2+}$ irradiated at 350 nm. Corresponding results for $Fe_2(OH_2)_8(OH)_2^{4+}$ irradiated at 350 nm and $Fe(EDTA)OH_2^-$ irradiated at 350 nm are shown in Figs. 2 and 3. The [S] = 0 intercept of the line in Fig. 1 is seen to be 0.125. This is within experimental

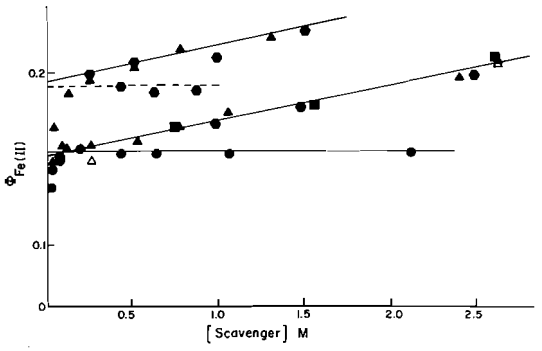

FIG. 1. Quantum yields for production of Fe(II) as a function of scavenger concentration using (●) *tert*-butyl alcohol, (■) formic acid, (▲) isopropyl alcohol, and (⬢) methanol as scavengers. Deoxygenated runs with isopropyl alcohol are shown by (△). The upper two curves refer to $Fe(OH_2)_5Cl^{2+}$. The lower two curves refer to $Fe(OH_2)_6^{3+}$.

error of the yield of Fe(II) determined with *tert*-butyl alcohol scavenging in the limit of high alcohol concentration (0.130) where all hydroxyl radicals escaping the solvent cage are scavenged and none react with Fe^{2+} to regenerate the initial complex. The increase in quantum yield for Fe(II) production above this intercept involves a process not included in the kinetic schemes of the preceding paper. An immediate possibility is that methanol, 2-propanol, and formic acid form complexes with $Fe(OH_2)_6^{3+}$ and that we observe photochemistry of these new species. (It is more difficult to entertain this suggestion for FeEDTA.) The idea may be tested easily in the case of formic acid and $Fe(OH_2)_6^{3+}$. The stability constant of the formatoiron(III) complex is known (5) and is 8.5×10^{-4} at 25°. Less than 0.1% of the formate

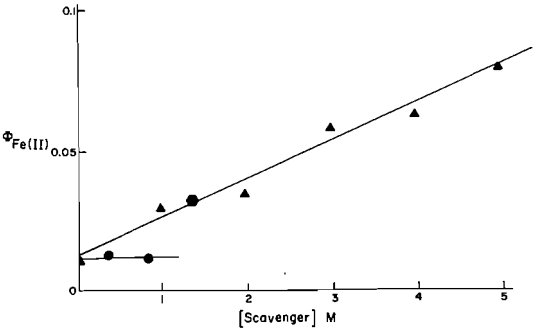

FIG. 2. Quantum yields for production of Fe(II) as a function of scavenger concentration for irradiation of the dihydroxo-bridged dimer. Symbols for scavengers as in Fig. 1.

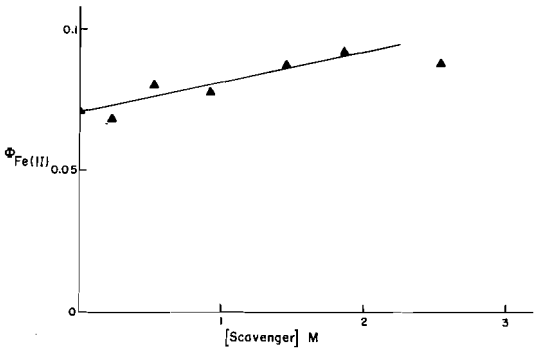

FIG. 3. Quantum yields for Fe(II) as a function of scavenger concentration (symbols as in Fig. 1) for irradiation of FeEDTA.

would be coordinated at unit hydrogen ion activity. The medium in the photolysis experiments is 2.25 *M* $HClO_4$. Formic acid is reacting in an outer sphere reaction in the sense that the effective photons cannot be exciting formato complexes. The similarity of behavior between formic acid and the alcohols suggests a similar assignment, but it is possible to be somewhat more specific.

The $Fe(OH_2)_6^{3+}$ ion is paramagnetic and its hydroxyl protons are exchanging rapidly with hydroxylic protons in the bulk solvent in this acidic medium. There is a single n.m.r. hydroxyl proton signal which is moderately broadened by the paramagnetic center. Now, as the alcohol is introduced, if alcohol molecules are *excluded* from the first coordination of Fe(III), the number of bulk hydroxylic sites will decrease without a corresponding decrease in the number of hydroxylic sites in the *paramagnetic* neighborhood of Fe(III). The result will be enhanced paramagnetic broadening of the hydroxylic protons. In other words, if Fe(III) is "preferentially solvated" in the coordination sphere by H_2O, the hydroxylic proton n.m.r. signal will become broader as alcohol concentration increases. (This discussion has neglected broadening arising from protons in the secondary solvation shell which may be as large as 5–10% of that from the primary coordination sphere.) Quantitative treatment of this effect has been given several times (6–8) and is moderately lengthy. Using the procedures indicated in the references, hydroxy proton line widths were calculated on the assumption that $Fe(OH_2)_6^{3+}$ was the only iron complex present in solutions containing alcohols. In Fig. 4, experimental

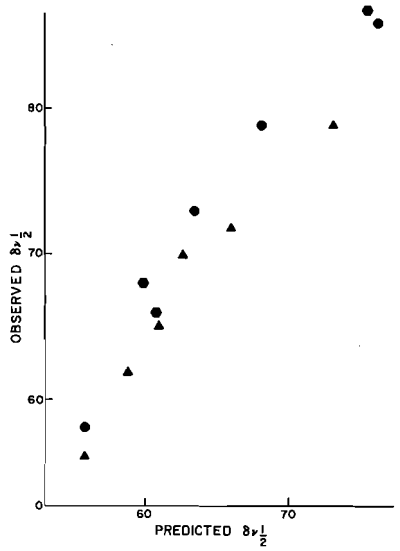

FIG. 4. Observed n.m.r. linewidths *vs.* predicted linewidths for (▲) methanol, (●) *tert*-butyl alcohol, and (⬣) isopropyl alcohol.

linewidths are plotted against calculated linewidths. Any disagreement is in the direction of lines too broad which is inconsistent with alcohol coordination and probably explained by the neglect of outer sphere broadening. Like the formic acid reactions, reactions with methanol and 2-propanol do not arise from excitation of the inner sphere complexes of the substrate undergoing oxidation.

The next result to which attention should be drawn is the similarity of the dependence of quantum yields for Fe(II) production on [S] in various cases. When $Fe(OH_2)_6^{3+}$ is excited at 254 nm, slopes for methanol, 2-propanol, and formic acid are *indistinguishable*! In turn, this value is indistinguishable from the slope describing experiments in which $Fe(OH_2)_5Cl^{2+}$ is irradiated at 350 nm.

The simplest interpretation of an equality of reactivity over several systems is the assumption that all have reached an "upper limit" of some sort. That is, we wish to test the assumption that all of the three organic molecules are oxidized with a quantum yield approaching unity (the theoretical upper limit) for the reactive excited state, not necessarily the primary one. Looking back at the argument in the introduction, it is apparent that the entity reacting with a quantum yield of unity cannot be the one-to-one encounter species (or outer sphere

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12

complex) involving the primary excited state if the Fuoss–Eigen equation is approximately correct. According to that equation, the species with one alcohol (or formic acid) molecule in the solvation shell of $Fe(OH_2)_6^{3+}$ would account for 25% of all $Fe(OH_2)_6^{3+}$ species at 1 *M* alcohol. The implication would be a primary radical quantum yield of the order of 0.25 rising to nearly 0.5 at 2 *M* alcohol[3] and approaching a limit shortly thereafter contrary to the results in Fig. 1. To see the weakness of this simple conception, it is useful to consider $Fe(OH_2)_5Cl^{2+}$ first.

In the case of $Fe(OH_2)_5Cl^{2+}$ the c.t. transition occurs primarily between Cl^- and Fe^{3+} leading to a "chlorine atom" center as oxidant at least in so far as the release of Cl atoms to the solution (4) implies the nature of the primary excited state. If a molecule of an oxidizable substance, *e.g.* methanol, is in encounter with (or solvates) $Fe(OH_2)_5Cl^{2+}$ on the side away from the Cl, it is unlikely to be oxidized by a short-lived excited state. The quantum yield for oxidation will not be expected to approach unity until *all* outer sphere sites are occupied by the oxidizable species (*e.g.* methanol). Thus, before we can estimate the limiting reactivity of an excited state of $Fe(OH_2)_5Cl^{2+}$ we need to estimate a statistical factor for the chance that an alcohol molecule in encounter occupies the reactive site. On the assumption that the reactive site is unique and that distribution of alcohol molecules over outer sphere sites is random, the correct statistical factor is simply the outer sphere solvation number which has been variously estimated as lying between 4 and 12. A similar statistical factor was introduced by Langford and Muir and considered by Pearson and Ellgen in discussion of the interchange mechanism of thermal ligand substitution at Co(III) and Ni(II) centers (9). The factor which seems to apply in thermal reactions is between 5 and 10. On this basis, the 1.0 *M* value of the primary radical yield, or the slope of the primary radical quantum yield – alcohol concentration function should lie between 0.025 and 0.050. If these are correct, the experimental slopes for Fe(II) production (2 × primary radical) should lie between 0.050 and 0.100. In other words, we estimate a slope for a reaction of unit efficiency nearly *twice* the experimental value in Fig. 1.

It is important to recall that there was a strong reason to look for a way of regarding the slopes in Fig. 1 as representing unit efficiency. There is a very significant *lack* of discrimination among a fairly wide variety of oxidizable organic species. If the calculations of the previous paragraph are correct, they represent a limiting efficiency of about 50%. This could be rationalized if the state reacting with unit efficiency is not the primary excited state but some successor reached with comparable efficiency in all cases. Such a proposal was made by Endicott (10) to explain the behavior of acetatopentaamminecobalt(III) on c.t. excitation. Co(II) yields (but not acetate decomposition yields) increased in this case on addition of isopropyl alcohol approaching a limiting value of 0.5. *However*, the calculations in the previous paragraph depend upon the Fuoss–Eigen equation. That equation is based on a simple hard sphere encounter theory and a factor of two error is not unexpected. If the Fe(III) complexes are preferentially solvated by water to a slight extent, the observed slope could well correspond to a limiting yield of unity.

We note that the alternative of a dynamic mechanism (as opposed to the static encounter mechanism outlined above) requires that the rate constant for reaction of a longer lived excited state with a scavenger must be the same for excited states of at least two Fe(III) complexes of different structure and for the several different scavengers. The relative implausibility of this is one reason for focusing attention on encounter.

Returning to $Fe(OH_2)_6^{3+}$, we ask what is the geometrically suitable site corresponding to that of $Fe(OH_2)_5Cl^{2+}$? This is not a major difficulty. The six water molecules are equivalent only in the geometry of the ground state. It was to be expected (although there has not been experimental evidence before) that the vibrationally equilibrated excited state would be distorted in such a way that a particular water molecule has become the electron deficient one which might be visualized as "on its way toward oxidation".

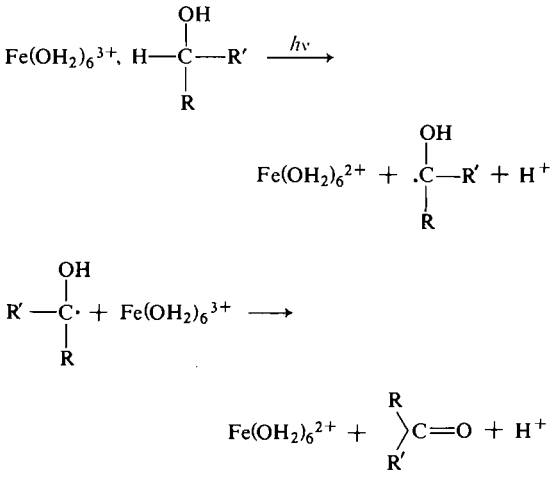
Having speculated on the excited state responsible for the outer sphere oxidation, its scope is worth comment. The reaction has appeared following excitation of the c.t. transitions of all iron(III) species we have irradiated at either

[3]Recall that a primary radical yield of 0.25 implies an experimental Fe(II) yield of 0.50.

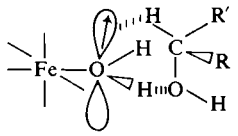
Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

2537 or 3500 Å. The list includes $Fe(OH_2)_6^{3+}$, $Fe(OH_2)_5Cl^{2+}$, $Fe_2(OH_2)_8(OH)_2^{4+}$, and Fe(EDTA). (We shall present evidence elsewhere that the reaction extends to Co(EDTA).) It is not without precedent. In alcohol glasses, irradiation of cyano (11) and nitrosyl (12) complexes of Fe(III) has been shown by e.s.r. to produce radicals derived by removal of α-hydrogens and Fe(II). The present examples differ mainly in that net reactions are observable in fluids near room temperature. This probably indicates that recombination reactions of Fe(II) species and radicals dominate the other systems.

Oxidizable organic species so far appear to include methanol, 2-propanol, and formic acid, but not *tert*-butyl alcohol. It seems likely that an H on the carbon bearing the oxygen is a requirement.[4] The reaction scheme may be written as follows.



[4]A referee has suggested the following intermediate structure for a scavenger assisted reaction:



i.e. minimum strain via six member ring. Obviously *tert*-BuOH cannot form such a structure. We thank the referee.

In agreement with this scheme gas chromatography on CCl_4 or $CHCl_3$ extracts from irradiation of $Fe(OH_2)_6^{3+}$ identified as organic products only formaldehyde from methanol and acetone from 2-propanol. 2,4-Dinitrophenylhydrazone derivatives of these were also isolated. Spectrophotometric determination of the formaldehyde yield via the examination of the 2,4-dinitrophenylhydrazone in basic media (12) indicates a stoichiometry of two moles Fe(II) per mole of formaldehyde (±10%) for irradiations in presence of methanol, as required.

Experimental

Materials and solutions were prepared as described in ref. 4. Irradiation procedures were also indicated there. The temperature was 35 °C in the reaction vessels. Analyses were carried out as before (4) except that assay of formaldehyde produced was by the spectrophotometric procedures of Lappin and Clark (13). The n.m.r. procedures for preferential solvation studies have been extensively described (6–8). The treatment is lengthy and will not be reproduced here. Spectra used here were recorded on a Varian T-60 at 25 °C at an $Fe(OH_2)_6(ClO_4)_3$ concentration of 0.0200 *M* and an alcohol concentration range corresponding to that in irradiation experiments, 0.5 to 3.5 *M*.

Synthesis of *cis*-9-Cyano-1,10-dimethyl-6-ethylenedioxy-1-octalin and its Conversion into an Intermediate for a Synthesis of Thelepogine

RONALD B. KELLY, SANDRA J. ALWARD, AND JIRI ZAMECNIK
Department of Chemistry, University of New Brunswick, Saint John, New Brunswick E2L 4L5

Received April 10, 1975

RONALD B. KELLY, SANDRA J. ALWARD, and JIRI ZAMECNIK. Can. J. Chem. **53**, 2441 (1975).

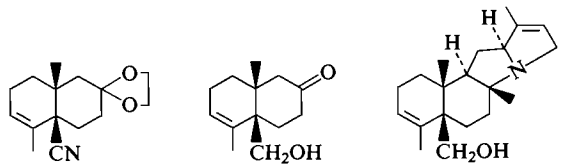
The synthesis of *cis*-9-cyano-1,10-dimethyl-6-ethylenedioxy-1-octalin, the structure of which has been determined by X-ray crystallography, is described. Also described is the conversion of this compound into an octalone having the functionality and stereochemistry appropriate to its use as an intermediate in a total synthesis of thelepogine.

RONALD B. KELLY, SANDRA J. ALWARD et JIRI ZAMECNIK. Can. J. Chem. **53**, 2441 (1975).

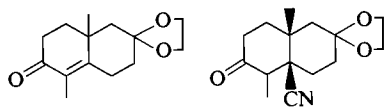
On décrit la synthèse du cyano-9 diméthyl-1,10 éthylènedioxy-6 octaline-1 *cis* dont la structure a été déterminée par diffraction de rayons X. On décrit aussi la conversion de ce composé en une octalone dont la fonctionalité et la stéréochimie permettent son emploi comme intermédiaire dans la synthèse totale de la thélépogine. [Traduit par le journal]

Very recently, Lynton and Siew (1) described the structure determination of the octalin **1** by X-ray crystallographic analysis. We are prompted by the appearance of this publication to describe the synthesis of **1** which was the source of the crystals used for the X-ray study (1). At the same time we wish to report some related work.

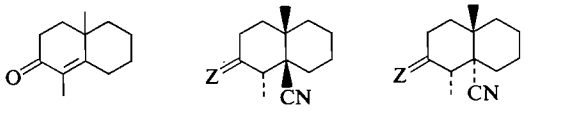
The octalone **2** constitutes a moiety of the novel structure (**3**) assigned to the diterpenoidal alkaloid thelepogine (2). Because of this we undertook a synthesis of **2** as part of some work directed towards the total synthesis of thelepogine (**3**). We now wish to describe a synthesis of **2** through the intermediacy of **1**.



1 **2** **3**



4 **5**



6 **7** Z = O **8** Z = O

9 Z = $O(CH_2)_2O$ **10** Z = $O(CH_2)_2O$

Our plan for the synthesis of the octalin **2** required, at the outset, a stereospecific conjugate cyanation of the ketal octalone **4** (3) to give the *cis*-cyano keto ketal **5**. Before attempting the cyanation of **4**, we carried out model cyanation studies on the octalone **6** (4) because the products (**7** and **8**) of conjugate cyanation are known (5) and are readily distinguishable by n.m.r. spectroscopy (5, 6). It has been shown (5, 6) that, with 9-cyano-10-methyl-2-decalones, the n.m.r. singlet for the angular methyl group of the *cis* isomer is deshielded by 13–15 Hz relative to the corresponding singlet for the *trans* isomer (see first two entries in Table 1). The conversion of **6** into two cyano ketones with potassium cyanide and the identification of these cyano ketones as the *cis*- (**7**) and the *trans*-decalone (**8**) has been reported but the reported yield of the *cis* isomer was only 18% (5).

By employing diethylaluminum cyanide (7) as cyanating agent and by adjusting the reaction conditions, we were able to convert **6**, at will, into either the *cis*-cyano decalone **7** in 64% yield or the *trans* isomer **8** in 67% yield.[1] Thus, treatment of **6** in benzene with diethylaluminum cyanide for 16 h at room temperature, followed by 1 h at 45°, afforded **7** (5). On the other hand,

[1]The i.r. and n.m.r. spectra of all compounds are consistent with assigned structures (see Experimental).

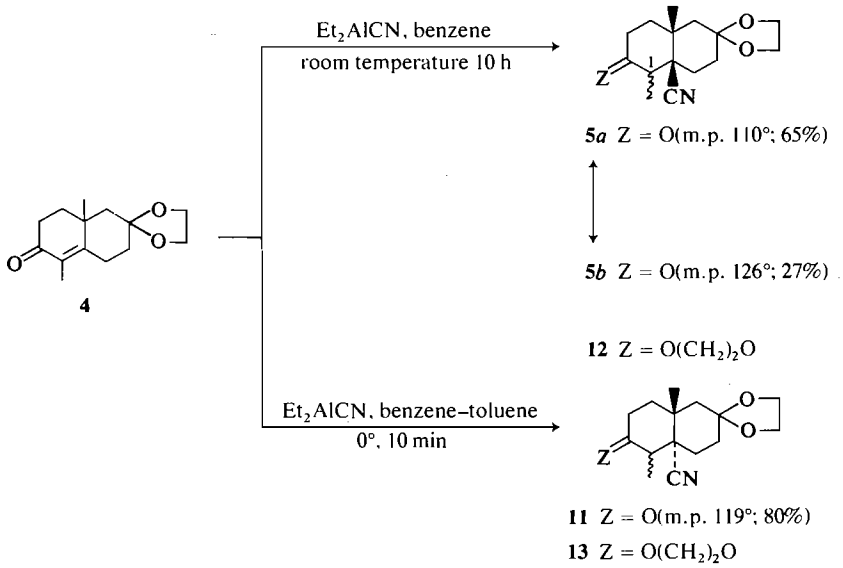


SCHEME 1

TABLE 1. Comparison of chemical shifts of angular methyl groups

Compounds (Chemical shifts* in parentheses)				Difference in chemical shift (Hz)
7	(1.48)	**8**	(1.24)	14.4
9	(1.24)	**10**	(1.02)	13.2
5*a*	(1.50)	**11**	(1.35)	9.0
5*b*	(1.39)	**11**	(1.35)	2.4
12	(1.23)	**13**	(1.15)	4.8

*In p.p.m. downfield from TMS as internal standard.

treatment of 6 in benzene–toluene with the same reagent at 0° for 10 min afforded **8** (5). These results could, to a certain extent, be anticipated from the work of Nagata *et al.* (7).

The cyano decalones **7** and **8** were converted into their respective ketals **9** and **10** for comparison of their n.m.r. spectra. The data in Table 1 show that the method (*vide supra*) for distinguishing between such *cis* and *trans* isomers by comparison of the chemical shifts of the angular methyl groups is applicable in this instance; the pertinent signal for the *cis* isomer is 13.2 Hz downfield relative to the corresponding signal for the *trans* isomer.

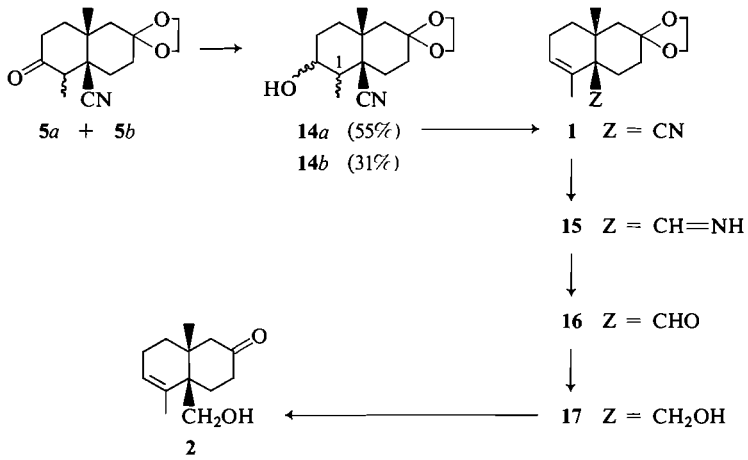
Having worked out satisfactory procedures for stereospecific conjugate cyanations by model studies, we now applied these procedures to the cyanation of the ketal octalone **4** (see Scheme 1). Treatment of **4** with diethylaluminum cyanide in benzene for 10 h at room temperature afforded two crystalline isomeric cyano ketones. A major isomer (**5***a*, m.p. 110°) was obtained in 65% yield while a minor isomer (**5***b*, m.p. 126°) was obtained in 27% yield. Since either of these isomers could be converted by base to the same equilibrium mixture of **5***a* and *b*, it would appear that they are C-1 epimers and that they are both either *cis* or *trans* isomers. It will be shown in the sequel that, as expected by analogy with the model experiments (*vide supra*), the former is the case.

Treatment of **4** with diethylaluminum cyanide in benzene–toluene at 0° for 10 min afforded a single crystalline cyano ketone (**11**, m.p. 119°) in 80% yield. This cyano ketone was distinctly different from those previously encountered (**5***a* and *b*). Since **5***a* and *b* proved to be *cis* isomers (*vide infra*), **11** must be a *trans* isomer as would be expected by analogy with the model experiments.

By analogy with the model experiments (*vide supra*) we suspected that **5***a* and *b* were *cis* isomers. But, since a *cis*-cyano ketone or a mixture of epimeric *cis*-cyano ketones was required, we sought assurance on this point by comparison of the chemical shifts of the angular methyl groups of the isomeric cyano ketones. This method (*vide supra*) failed to provide the assurance we sought.

A comparison of the data in Table 1 for **5***a*

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.



SCHEME 2

and **11** suggested that the former was indeed a *cis* isomer but, since the difference in chemical shifts was only 9 Hz, we felt that corroborative evidence was necessary. We therefore compared the pertinent n.m.r. data (Table 1) for **5***b* and **11** and finally for the ketals **12** and **13** which were derived from **5***a* and **11**, respectively. In neither case could any reliable conclusions be drawn because of the even smaller differences (less than 5 Hz) in the chemical shifts of the angular methyl groups. Consequently, it was decided to proceed with the synthesis on the assumption that **5***a* and *b* were *cis* isomers, hoping for an opportunity to test this assumption at a later stage.

The conversion of **5***a* and *b* into the desired octalone **2** is outlined in Scheme 2. Reduction of either **5***a* or a mixture of **5***a* and *b* with lithium aluminum hydride afford a crystalline alcohol **14***a* (m.p. 146°; 55%) and an oily mixture of epimers (**14***b*). Dehydration of the alcohol (**14***a*) with phosphorus oxychloride in pyridine smoothly converted it into the crystalline olefinic nitrile **1** in 76% yield. The mixture (**14***b*) failed to dehydrate satisfactorily under a variety of conditions.

An X-ray crystallographic study of the olefinic nitrile showed that it had structure **1** with the required *cis* ring fusion (1). This structure determination afforded assurance that the final product **2** would also have the desired *cis* ring fusion and provided proof that **5***a* and *b*, as suspected, were *cis*-cyano ketones and that, consequently, **11** was a *trans* isomer.

Partial reduction of the cyano group of **1** with lithium aluminum hydride to the imine **15** followed by hydrolysis in buffered solution afforded the aldehyde **16** in 71% yield. Reduction of **16** with lithium aluminum hydride gave the alcohol **17** (77%). Finally, treatment of **17** with acid afforded the desired compound **2** (86%) having the required *cis* ring fusion.

Experimental

Methods and Materials

The n.m.r. chemical shifts are expressed in parts per million (δ values) downfield from the signal for tetramethylsilane which is used as an internal standard.

Reaction products were isolated by the following procedure. The product was extracted into the specified solvent and the extract was washed three times with appropriate aqueous solutions as indicated. The original aqueous layer (if any) and the aqueous washings were extracted three times with the solvent and the combined extracts were dried over anhydrous magnesium sulfate, filtered, and evaporated *in vacuo* on a rotary evaporator.

Petroleum ether refers to the fraction with b.p. range 30–60°.

Brine refers to a saturated solution of sodium chloride.

cis-Cyano Decalone 7

A solution of 2.3 g of the octalone **6** (4) in 100 ml of benzene under a dry nitrogen atmosphere was treated with 3.5 g of diethylaluminum cyanide (7) in 27 ml of benzene. The reaction solution was left at room temperature for 16 h then heated at 45° for 1 h. The reaction solution was diluted with a mixture of 1250 g of ice and water containing 50 g of dissolved sodium hydroxide. The alkaline solution was extracted with chloroform and the extract evaporated *in vacuo*. Crystallization of the residue from ether afforded 1.70 g (64%) of **7**, m.p. 109° (lit. (5) m.p. 107–108.5°); ν_{max} (KBr) 2228 (CN) and 1710 cm^{-1} (ketone); n.m.r. ($CDCl_3$), δ 1.16 (d, J = 6.5 Hz, 3H, secondary methyl), 1.48 (s, 3H, angular methyl), 3.05 (q, J = 6.5 Hz, 1H, methine coupled to methyl). The i.r. and n.m.r. spectra were identical with

the spectra[2] of a cyano ketone of established (5) stereostructure as represented by 7.

Anal. Calcd. for $C_{13}H_{19}NO$: C, 76.06; H, 9.33; N, 6.82. Found: C, 76.26; H, 9.55; N, 6.83.

cis-Cyano Ketal ***9***

A solution of 600 mg of the *cis*-cyano ketone 7, 48 mg of *p*-toluenesulfonic acid monohydrate, and 1.40 g of ethylene glycol in 100 ml of benzene was refluxed under a nitrogen atmosphere for 20 h. The solution was cooled to room temperature and treated, with stirring, with 150 mg of solid sodium bicarbonate. The benzene solution was washed with saturated sodium bicarbonate solution and with brine. The aqueous washings were extracted with ether. Evaporation of the dried extracts gave an oil which, on crystallization from ether – petroleum ether afforded 528 mg (81%) of **9**, m.p. 75–76°; ν_{max} (Nujol) 2220 cm^{-1} (CN); n.m.r. ($CDCl_3$), δ 1.00 (d, J = 6.5 Hz, 3H, secondary methyl), 1.24 (s, 3H, angular methyl) 2.37 (q, J = 6.5 Hz, 1H, methine coupled to methyl), 3.84 (m, 4H, ethylene of ketal).

Anal. Calcd. for $C_{15}H_{23}NO_2$: C, 72.25; H, 9.30; N, 5.62. Found: C, 72.75; H, 9.47; N, 5.50.

trans-Cyano Decalone ***8***

A solution of 461 mg of the octalone **6** (4) in 16 ml of benzene and 8.5 ml of toluene was cooled on an ice bath to 0° and treated with 1.73 g of diethylaluminum cyanide (7) in 22 ml of benzene. The reaction solution was kept at 0° for 10 min then poured into 250 g of a mixture of ice and water containing 10 g of dissolved sodium hydroxide. The cold aqueous solution was worked up with chloroform and brine in the usual manner. Crystallization of the crude product, an oil, from ether – petroleum ether afforded 356 mg (67%) of **8**, m.p. 100.5° (lit. (5) m.p. 101–102°); ν_{max} (KBr) 2225 (CN) and 1705 cm^{-1} (ketone); n.m.r. ($CDCl_3$), δ 1.16 (d, J = 6.5 Hz, 3H, secondary methyl), 1.24 (s, 3H, angular methyl), 2.50 (q, J = 6.5 Hz, methine coupled to methyl). The i.r. and n.m.r. spectra[2] were identical with the spectra of a cyano ketone of established (5) stereostructure represented by **8**.

Anal. Calcd. for $C_{13}H_{19}NO$: C, 76.06; H, 9.33; N, 6.82. Found: C, 75.69; H, 9.31; N, 6.68.

trans-Cyano Ketal ***10***

The *trans*-cyano ketone **8** (2.85 g) was converted to the ketal **10** by the same procedure as was used in the case of the *cis*-cyano ketone (*vide supra*). Chromatography of the crude product on a column of 140 g of basic alumina (grade III) with 0.5% of ether in benzene as solvent and crystallization of the eluted product from ether–pentane afforded 2.74 g (78%) of **10**, m.p. 101–102°; ν_{max} (Nujol) 2220 cm^{-1} (CN); n.m.r. ($CDCl_3$), δ 0.93 (d, J = 6.5 Hz, 3H, secondary methyl), 1.02 (s, 3H, angular methyl), 3.96 (m, 4H, ethylene of ketal).

Anal. Calcd. for $C_{15}H_{23}NO_2$: C, 72.25; H, 9.30; N, 5.62. Found: C, 72.40; H, 9.49; N, 5.75.

cis-Cyano Keto Ketals 5a and b

The keto ketal **4** (3) (236 mg) was dissolved in 10 ml of dry benzene in a nitrogen atmosphere. A benzene solution (2.5 ml) of diethylaluminum cyanide (333 mg) was added and the reaction mixture was stirred at room temperature for 10 h. The reaction solution was diluted with a mixture of 125 ml of ice and water containing 5 g of dissolved sodium hydroxide. The resulting aqueous solution was extracted with chloroform and the extract evaporated *in vacuo*. Purification of the residue by silica gel preparative t.l.c. with 10% of ether in benzene as solvent, gave 170 mg (65%) of epimer ***5a***, m.p. 110°; ν_{max} (KBr) 2225 (CN) and 1720 cm^{-1} (ketone); n.m.r. ($CDCl_3$), δ 1.19 (d, J = 6.0 Hz, 3H, secondary methyl), 1.50 (s, 3H, angular methyl), 2.97 (q, J = 6.0 Hz, 1H, methine coupled to methyl), 3.89 (m, 4H, ethylene of ketal).

Anal. Calcd. for $C_{15}H_{21}NO_3$: C, 68.42; H, 8.03; N, 5.32. Found: C, 68.25; H, 7.72; N, 5.34.

There was also obtained 70 mg (27%) of epimer ***5b***, m.p. 126°; ν_{max} (KBr) 2225 (CN) and 1720 cm^{-1} (ketone); n.m.r. ($CDCl_3$) δ 1.19 (d, J = 6.0 Hz, 3H, secondary methyl), 1.39 (s, 3H, angular methyl), 2.72 (q, J = 6.0 Hz, 1H, methine coupled to methyl), 3.93 (m, 4H, ethylene of ketal).

Anal. Calcd. for $C_{15}H_{21}NO_3$: N, 5.32. Found: N, 5.50.

Treatment of either ***5a*** or ***b*** with 0.1 *N* methanolic potassium hydroxide at room temperature resulted in a mixture of both isomers as shown by t.l.c. on silica with ether as solvent.

trans-Cyano Keto Ketal ***11***

A solution of 236 mg of the keto ketal **4** (3) in 7 ml of benzene and 4 ml of toluene was cooled on an ice bath to 0° and treated with 555 mg of diethylaluminum cyanide in 4.2 ml of benzene. The reaction solution was kept at 0° for 10 min then poured into 125 g of a mixture of ice and water containing 5 g of dissolved sodium hydroxide. The cold aqueous solution was worked up with chloroform and brine in the usual manner. Evaporation of the chloroform extracts *in vacuo* yielded 250 mg of crystalline material which was recrystallized from ether – petroleum ether to give 210 mg (80%) of **11**, m.p. 118–120°; ν_{max} (KBr) 2220 (CN) and 1715 cm^{-1} (ketone); n.m.r. ($CDCl_3$), δ 1.18 (d, J = 5.5 Hz, 3H, secondary methyl), 1.35 (s, 3H, angular methyl), 2.47 (q, J = 5.5 Hz, 1H, methine coupled to methyl), 3.91 (m, 4H, ethylene of ketal).

Anal. Calcd. for $C_{15}H_{21}NO_3$: C, 68.42; H, 8.03; N, 5.32. Found: C, 68.27; H, 7.83; N, 5.27.

cis-Cyano Diketal ***12***

A solution of 376 mg of *cis*-cyano keto ketal ***5a***, 56 mg of *p*-toluenesulfonic acid monohydrate, and 2.4 ml of ethylene glycol in 60 ml of benzene was refluxed under a nitrogen atmosphere for 24 h. The benzene solution was washed with saturated sodium bicarbonate solution and with brine. The aqueous washings were extracted with ether. Evaporation of the dried extracts gave 441 mg of an oil which when purified by silica gel preparative t.l.c., with 5% of ether in benzene as solvent, gave 368 mg (83%) of **12**, m.p. 152–153°; ν_{max} (CCl_4) 2210 cm^{-1} (CN); n.m.r. (CCl_4) δ 1.04 (d, J = 6.0 Hz, 3H, secondary methyl), 1.23 (s, 3H, angular methyl), 2.33 (q, J = 6.0 Hz, 1H, methine coupled to methyl), 3.82 (m, 8H, ethylene of ketals).

Anal. Calcd. for $C_{17}H_{25}NO_4$: C, 66.43; H, 8.20: N, 4.56. Found: C, 66.27; H, 8.31; N, 4.41.

trans-Cyano Diketal ***13***

The *trans*-cyano keto ketal **11** (94 mg) was converted to the *trans*-cyano diketal **13** by the procedure given in the

[2]The i.r. and n.m.r. spectra were provided by N. J. Johnston (see ref. 5).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

preceding experiment. This yielded 120 mg of a crystalline compound which was recrystallized from ether – petroleum ether to give 100 mg (91%) of **13**, m.p. 157–158°; ν_{max} (CCl_4) 2210 cm^{-1} (weak CN); n.m.r. (CCl_4) δ 0.98 (d, J = 6.0 Hz, 3H, secondary methyl), 1.15 (s, 3H, angular methyl), 3.83 (m, 8H, ethylene of ketals).

Anal. Calcd. for $C_{17}H_{25}NO_4$: C, 66.42; H, 8.20; N, 4.56. Found: C, 66.79; H, 8.60; N, 4.55.

*Cyano Alcohols **14a** and **b***

A mixture of 248 mg of **5***a* and *b*, 10 ml of tetrahydrofuran, 120 mg of sodium borohydride, and 0.8 ml of water was stirred at room temperature for 4.5 h. Then 100 ml of water was added and the mixture stirred for another 3 h. The reaction mixture was worked up with chloroform and brine in the usual manner to yield 225 mg of a mixture of isomeric cyano alcohols. Purification of the product by silica gel preparative t.l.c., with ether as solvent, gave 137 mg (55%) of the faster moving isomer **14***a*, m.p. 144–148°. Spectral data showed **14***a* to be a single epimer, thus, ν_{max} ($CHCl_3$) 3600 and 3475 (OH) and 2215 cm^{-1} (CN); n.m.r. ($CHCl_3$) δ 1.17 (s, 3H, angular methyl), 1.22 (d, J = 5.5 Hz, 3H, secondary methyl), 3.88 (m, 4H, ethylene of ketal).

Anal. Calcd. for $C_{15}H_{23}NO_3$: C, 67.90; H, 8.73; N, 5.28. Found: C, 67.77; H, 8.92; N, 5.10.

The slower moving material (78 mg of **14***b*) was still a mixture of isomers as shown by a complex methyl signal in the n.m.r. spectrum ($CDCl_3$); ν_{max} 3350 (OH) and 2215 cm^{-1} (CN).

*Olefinic Nitrile **1***

A solution of 106 mg of **14***a* in 2.4 ml of pyridine was cooled in an ice bath and treated with 0.2 ml of phosphorus oxychloride. After stirring for 1.5 h at room temperature in the dark, the mixture was diluted with a mixture of ice and water and stirred for 15 min. The cold aqueous mixture was extracted with chloroform and the extracts were worked-up in the usual manner with cold 1 *M* hydrochloric acid and cold saturated sodium bicarbonate solution. Evaporation of the dried extracts afforded 100 mg of an oil which crystallized from ether – petroleum ether to give 75 mg (76%) of **1**, m.p. 68–69°; ν_{max} ($CHCl_3$), 2215 cm^{-1} (CN); n.m.r. ($CDCl_3$) δ 1.18 (s, 3H, angular methyl), 1.85 (d, J = *ca.* 2 Hz, 3H, vinylic methyl), 3.90 (m, 4H, ethylene of ketal), 5.55 (m, 1H, vinylic proton).

Anal. Calcd. for $C_{15}H_{21}NO_2$: C, 72.84; H, 8.56; N, 5.66. Found: C, 72.54; H, 8.55; N, 5.48.

*Olefinic Alcohol **17***

The olefinic nitrile **1** (266 mg) was refluxed in 50 ml of dry tetrahydrofuran with 250 mg of lithium aluminum hydride under a nitrogen atmosphere for 1 h. After cooling to room temperature and addition of 110 ml of ether, 0.1 ml of a saturated solution of sodium sulfate was added. The mixture was stirred for 1 h then 1 g anhydrous sodium sulfate was added and stirring was continued for another 30 min. The solid material was filtered off and the solvent evaporated to give 268 mg of olefinic imine **15**; ν_{max} (neat) 1625 cm^{-1} (C=N).

The imine **15** (268 mg) was dissolved in 8 ml of tetrahydrofuran and 8 ml of methanol. Then 660 mg of sodium acetate trihydrate and 10 ml of 5% aqueous acetic acid was added and the mixture was refluxed for 20 min. The cooled reaction mixture was extracted with chloroform and the extracts were worked up in the usual manner with 2 *M* sodium hydroxide and brine. Evaporation of the dried extracts afforded 190 mg of the aldehyde **16**; ν_{max} (neat) 2700 and 1720 (aldehyde) and 1650 cm^{-1} (olefin); n.m.r. ($CDCl_3$) δ 1.10 (s, 3H, angular methyl), 1.55 (d, J = *ca.* 2 Hz, 3H, vinylic methyl), 3.90 (s, 4H, ethylene of ketal), 5.88 (m, 1H, vinylic proton), 9.58 (s, 1H, aldehyde).

A mixture of 190 mg of the aldehyde **16**, 50 ml of ether, and 125 mg of lithium aluminum hydride was refluxed for 30 min. The cooled mixture was treated with 0.1 ml of saturated sodium sulfate solution, stirred for 1 h, and treated with 1 g sodium sulfate. The solid material was removed by filtration and washed with ether. Evaporation of the combined filtrate and washings gave 193 mg of oil. Purification of the product by silica gel t.l.c., with 50% of ether in benzene as solvent, gave 148 mg of the olefinic alcohol **17** as an oil (55% yield from the olefinic nitrile **1**); ν_{max} (neat) 3460 (OH) and 1650 cm^{-1} (olefin); n.m.r. ($CDCl_3$) δ 1.12 (s, 3H, angular methyl), 1.67 (d, J = *ca.* 2 Hz, 3H, vinylic methyl), 3.30 and 3.57 (doublets, J = 12 Hz, 1H each, CH_2—OH), 3.88 (m, 4H, ethylene of ketal), 5.73 (m, 1H, vinylic proton).

*Octalone **2***

A solution of 252 mg of the olefinic alcohol **17**, 10 ml of tetrahydrofuran, and 6 ml of 1 *M* aqueous hydrochloric acid was left at room temperature under nitrogen atmosphere for 1.5 h. The reaction mixture was worked up with chloroform, saturated sodium bicarbonate, and brine in the usual manner to give 247 mg of an oil. Purification of the product on silica gel preparative t.l.c. with 50% of ether in benzene as solvent, yielded 178 mg (86%) of octalone **2**, m.p. 102–103°; ν_{max} ($CHCl_3$) 3600 and 3545 (OH) and 1720 cm^{-1} (ketone); n.m.r. ($CDCl_3$) δ 1.05 (s, 3H, angular methyl), 1.80 (d, J = *ca.* 2 Hz, 3H, vinylic methyl), 3.53 (s, 2H, CH_2OH), 5.85 (m, 1H, vinylic proton).

Anal. Calcd. for $C_{13}H_{20}O_2$: C, 74.97; H, 9.67. Found: C, 74.91; H, 9.73.

We are grateful to Dr. H. Lynton, University of New Brunswick, for determining the structure of compound **1** by X-ray crystallographic analysis, and to Dr. N. J. Johnston for assistance in establishing the structures of compounds **7** and **8**. Also, we wish to thank the National Research Council of Canada for financial support and for the Postgraduate Scholarship awarded to S.J.A.

A Photoelectron Investigation of Acyl Silanes: The Photoelectron Spectra of Trimethylsilyl Phenyl Ketone and Phenyl *tert*-Butyl Ketone

R. S. BROWN

Department of Chemistry, University of Alberta, Edmonton, Alberta T6G 2E1

Received February 13, 1975

R. S. BROWN. Can. J. Chem. **53**, 2446 (1975).

The photoelectron spectra of trimethylsilyl phenyl ketone and phenyl *tert*-butyl ketone are presented and analyzed in terms of their constituent orbitals. A hyperconjugative interpretation for the low energy ionization potentials of the acyl silanes is postulated. A combination of p.e. spectroscopy and u.v. data are used to infer the level of the LUMO in these systems and to construct a partial energy level diagram.

R. S. BROWN. Can. J. Chem. **53**, 2446 (1975).

On présente l'analyse du spectre photoelectronique de la triméthylsilyl phényl cétone et *tert*-butyl phényl cétone en termes de leurs orbitales constituantes. En se basant sur l'hyperconjugaison, on propose une interprétation des potentiels d'ionisation à faible énergie des acylsilanes. Une combinaison des données spectroscopiques p.e. et u.v. est utilisée pour déduire le niveau de LUMO dans ces systèmes et pour construire un diagramme partiel des niveaux d'énergie. During the course of a study initiated to investigate the photoelectron spectra (p.e.) of acyl silanes (1), we became aware of an article by Ramsey *et al.* (2*a*) offering a reinterpretation of the mechanism (2*b*, *c*) by which the trimethylsilyl group interacts with β nonbonding orbitals as in **1***b*.

1
a X = C
b X = Si

2
a X = C
b X = Si

The above study prompted us to reveal our findings concerning **1** and the analogous series **2**. Compounds **1***b* and **2***b* are similar but differ in the following way. In both series, the n_0 orbital and the C—Si$(CH_3)_3$ σ bond are coplanar but **2***b* possesses an additional set of β orbitals in its phenyl group which are *potentially* capable of a similar interaction. If such an interaction is present, p.e. spectroscopy should detect it.

The p.e. spectra for compounds **1** and **2** are presented in Figs. 1 and 2, respectively, while the corresponding vertical ionization potentials and the interpretation of the orbitals which gave rise to these ionizations are presented in Tables 1 and 2.

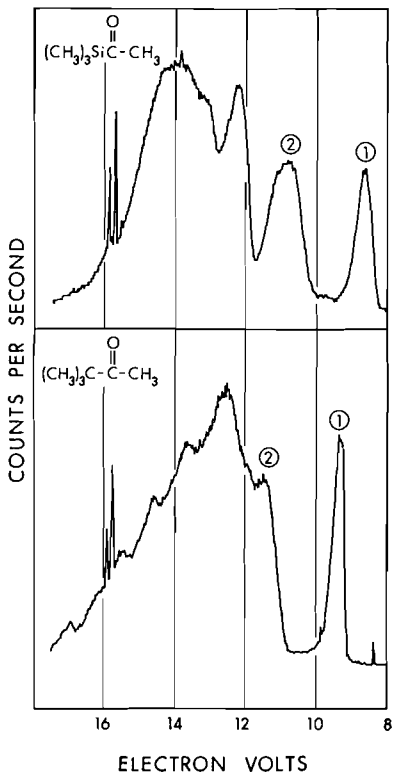

FIG. 1. Photoelectron spectra of methyl *tert*-butyl ketone (**1***a*) and methyl trimethylsilyl ketone (**1***b*) using argon as a calibrating gas.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

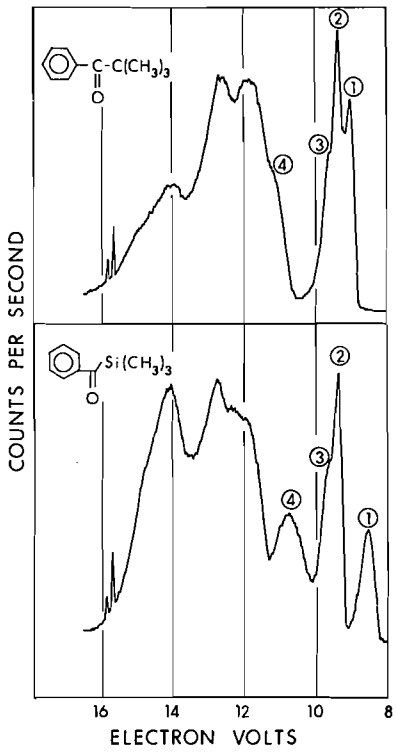

FIG. 2. Photoelectron spectra for *tert*-butyl phenyl ketone (**2***a*) and trimethylsilyl phenyl ketone (**2***b*) using argon as a calibrating gas.

TABLE 1. Vertical ionization potentials of methyl *tert*-butyl ketone (**1***a*) and methyl trimethylsilyl ketone **1***b*

Band	Vertical i.p. (eV) **1***a*	**1***b*	Assignment
1[a]	9.24	8.64	"n_0"
2	11.44	10.94	*e* symmetry orbital of $X(CH_3)_3$
3	11.86	12.26	
4	12.59	12.56	

[a]The onset potential of band 1 is 9.00 eV for **1***a* and 8.09 eV for **1***b*.

Since the spectrum of **1***b* has been presented (2*a*) only the following points need be made. Band 1 can most certainly be assigned to ionization of an electron residing in a nonbonding orbital (n_0) primarily located on oxygen. The large half-width of band 1 in **1***b* tentatively implies a large difference in the geometry of the unionized and ionized states, usually indicative of the removal of a strongly bonding or antibonding electron (3). Calculations on this system (2*a*) indicate that this orbital possesses components of both the localized n_0 and C—Si$\lessdot$ orbitals and is antibonding. The high resolution p.e. spectra indicate no discernible vibrational fine structure for band 1 and hence cannot experimentally confirm the 'antibonding' nature.

TABLE 2. Vertical ionization potentials for *tert*-butyl phenyl ketone (**2***a*) and trimethylsilyl phenyl ketone (**2***b*)

Band	Vertical i.p. (eV) **2***a*	**2***b*	Assignment
1[a]	8.98	8.41	"n_0"
2	9.33	9.29	phenyl b_1
3	9.61	9.59	phenyl a_2
4	11.16	10.71	*e* orbital of $X(CH_3)_3$
5	11.89	11.96	
6	12.66	12.34	
7		12.76	

[a]Onset of band 1 is 8.70 and 7.96 eV for **2***a* and **2***b*, respectively.

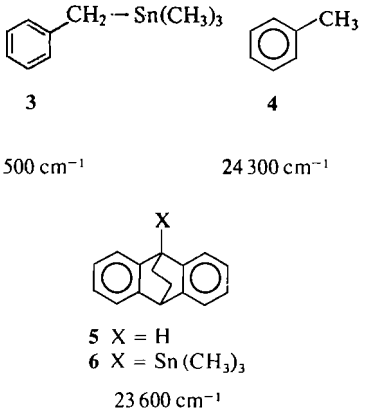
We visualize, as do others (2*a* and *c*, 4) that the raising of the n_0 orbital in the acyl silanes relative to the α-*tert*-butyl ketones can best be visualized as a hyperconjugative interaction between the coplanar carbon–silicon bond and the adjacent n_0 orbital. The C—Si$\lessdot$ bond is of net higher energy than the analogous C—C$\lessdot$ bond[1] and hence is closer in energy to an isolated n_0 orbital, allowing a greater interaction in the α-trimethylsilyl ketones than in the α-*tert*-butyl ketones and a correspondingly lower i.p. in the former.

A hyperconjugative interaction, like all conjugative interactions requires coplanarity of orbitals for maximum effect. Interestingly, the results of Hanstein *et al.* (7) clearly demonstrate this requirement since the charge-transfer absorption frequency for **3** is much lower than **4**, whereas the charge-transfer frequencies of **5** and **6** are equal (Scheme 1).[2]

While the geometry of **1***b* is such that the n_0

[1]Using Koopman's theorem (5), one can assign a value of 10.6 eV to the C—Si$\lessdot$ bond based upon the average vertical i.p. for the $3t_2$ level of tetramethylsilane (6). Similarly a value of 11.2 eV can be obtained for the C—C$\lessdot$ bond based upon tetramethylmethane (6).

[2]The above results were obtained with the trimethyltin analogs, however it is expected that the corresponding trimethylsilicon compounds will show similar trends only differing in magnitude.



SCHEME 1. Charge-transfer frequencies for compounds **3**–**6**.

orbital and the C—Si< bond are syncoplanar, **2***b* contains a phenyl group whose π system is perpendicular to the C—Si< bond. If the mechanism of the interaction is indeed conjugative in nature, one would expect that the only differences in perturbation of the phenyl orbitals in series **2** will be due to electronegativity differences between the trimethylsilylacyl and the *tert*-butylacyl substituents.

Ultraviolet Data

The u.v. absorption data for ketones **1***a* and **1***b* have been extensively reviewed (1*f*) and are presented in Table 3 for convenient reference.

Using Table 3 one can quickly determine that $\Delta(n \rightarrow \pi^*) = 0.98$ eV for compounds **1***a* and **1***b*.

TABLE 3.[a] Ultraviolet absorption maxima for $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions of ketones **1***a* and **1***b*

	$n \rightarrow \pi^*$		$\pi \rightarrow \pi^*$	
Ketone[b]	ν_{max} (cm^{-1})	ΔE (eV)	ν_{max} (cm^{-1})	ΔE (eV)
	34 800	4.32	53 800	6.68
	26 900	3.34	51 200	6.35

[a]Reference 1*f*.
[b]Determined in *n*-heptane.

The p.e. data are presented in Table 1. A difference in the n_0 orbital of 0.60 eV is noticed in passing from **1***a* to **1***b*. Since this difference does not fully account for the $\Delta(n \rightarrow \pi^*)$ absorption between these two ketones, it is evident that π^* in **1***b* must be lowered in energy by 0.38 eV relative to π^* in **1***a*. In accordance with Pitt (2*c*) and Bock *et al.* (2*b*), we suggest that the C=O π^* orbital is stabilized by interaction with d and/or σ^* orbitals located primarily on the trialkyl silicon moiety. CNDO/2 calculations in similar systems (2*c*) reveal that the highest occupied σ-bonding orbital contains significant Si 3p contributions while the LUMO contains both Si 3p and Si 3d components.

Phenyl Ketones 2a and 2b

Inspection of Fig. 2 indicates that the low binding energy regions of the spectra exhibit four well-defined bands which can be assigned as follows. Band I in the p.e. spectrum of **2***a* and **2***b* appears at 8.98 and 8.41 eV, respectively, and can be assigned (as in series **1**) to an orbital comprised of the n_0 orbital and the adjacent C—X(CH$_3$)$_3$ σ bond. Substitution of the trimethylsilyl group for a *tert*-butyl group raises this orbital by 0.57 eV, identical within experimental error to the raising in passing from **1***a* to **1***b*.

Bands 2 and 3 located at 9.31 ± 0.02 and 9.60 ± 0.01 eV, respectively, in both **2***a* and **2***b* can without doubt be assigned to ionizations arising primarily from orbitals located on the aromatic ring. According to CNDO/2 calculations on similar systems (8), these two orbitals are assigned to be of b_1 and a_2 symmetry, b_1 being of lower ionization energy than a_2. It is interesting to see that these phenyl bands appear to be unperturbed in changing from **2***a* to **2***b*.

The source for this coincidence may arise from the fact that the phenyl π system being orthogonal to the C—Si< bond has no conjugative interaction with it, and therefore remains unperturbed in passing from **2***a* to **2***b*. Alternatively, π donation of the entire trimethylsilylacyl group may exactly compensate an inductive σ withdrawal of the group leaving no difference in perturbation of the aromatic ring between **2***a* and **2***b*. This study then provides corroborative experimental evidence for the calculations of Yates *et al.* (1*f*) who concluded that there is little or no perturbation of the phenyl orbitals in changing from **2***a* to **2***b*.

Band 4 apears at 11.16 eV in **2***a* and 10.76 eV in **2***b* and can be assigned to ionization arising from an *e* symmetry orbital located on the *tert*-

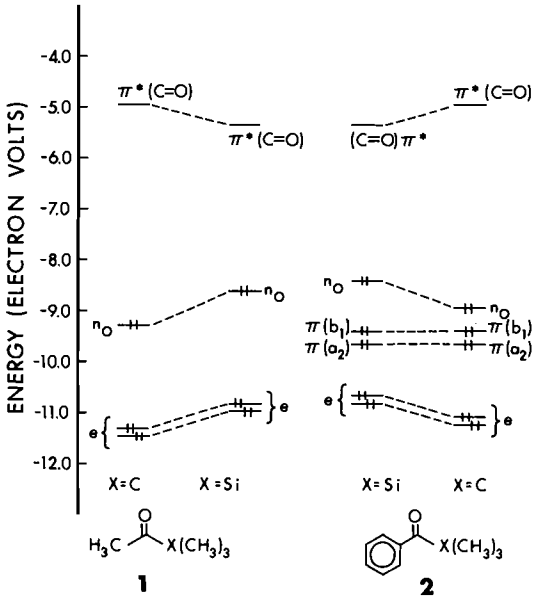

FIG. 3. Partial energy level diagrams for ketones **1** and **2**, assuming the validity of Koopman's theorem (5). Note that the above diagram differs slightly from that presented in ref. 1*f*, in that extended Hückel calculations predict another σ orbital between n_O and $\pi(b_1)$ in ketones **2**.

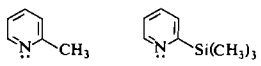
butyl and trimethylsilyl groups, respectively (6, 10).

Utilizing a combination of p.e. spectroscopy and u.v. data, we can now draw a partial energy level diagram for these ketones based entirely upon experimental results. Such a diagram is illustrated in Fig. 3.[3]

[3]Another related yet different example of this type of interaction is that evident in the p.e. spectrum of α-picoline (**7**) and α-trimethylsilylpyridine (**8**) (9). The n_N orbital of **7** is obscured and assumed to lie under the bands



7 ($E(n_N)$ = 9–10 eV) **8** ($E(n_N)$ = 8.5 eV)

arising from the ionization of π electrons but is strongly raised in energy in **8**. While this fact was interpreted as being due to a (+)-inductive effect of the trimethylsilyl group, it is also consistent with a hyperconjugative interaction (2*a* and *c*, 4).

Experimental

Literature procedures were used to prepare derivatives **1***a* (11), **1***b* (1*c*), **2***a* (12), and **2***b* (1*b*). Photoelectron spectra were obtained using a McPherson Model 36 ESCA spectrometer equipped with a He(I) ionization source. Under optimum conditions the resolution of the $Ar_{1/2}$–$Ar_{3/2}$ doublet was 16 meV at 60 000 counts per second but was found to be between 24 and 28 meV while recording spectra.

Alkaline Hydrolysis Products of *N*-Substituted Phthalimides

S. KHAQAN HASAN AND S. AHMAD ABBAS

Chemical Research Division, P.C.S.I.R. Laboratories, Karachi-39, Pakistan

Received March 27, 1975

S. KHAQAN HASAN and S. AHMAD ABBAS. Can. J. Chem. **53**, 2450 (1975).

Products of alkaline hydrolysis of *N*-substituted phthalimides are described. Five isomeric compounds, 1,6-diketo-3,4,5,6-tetrahydro-1*H*-2,5-benzoxazocine (**1**), 2-(*o*-carboxyphenyl)-Δ^2-oxazoline (**7**), 2-phthalimidoethanol (**3**), *N*-vinylphthalamic acid (**8**), and *N*-(*o*-carboxybenzoyl)-aziridine (**9**), are possible from the alkaline hydrolysis of 2-bromoethylphthalimide (**2**). Gabriel claimed in 1905 that **1** was formed on alkaline hydrolysis of **2** but later structure **7** was suggested for the product. The interest in the synthesis of **1** has led to a reinvestigation of this hydrolysis and structure **7** is confirmed for the initial product of the hydrolysis but it converts on warming during recrystallization into **1** which affords **3** on heating above melting point.

Hydrolysis of 2-chloroethylphthalimide (**4**) and 2-phthalimidoethyl-*p*-toluenesulfonate (**5**) also afforded **7**. Attempted preparation of **1** from intramolecular cyclization of 2-hydroxyethylphthalamic acid (**11**) was not successful and only **3** was obtained.

Reaction of phthalic anhydride with 2-aminoethylsulfuric acid (**14**) at 150° afforded diphthalimidoethyl phthalate (**13**) instead of 2-phthalimidoethylsulfuric acid (**6**). Isolation of **13** indicates formation of **3** as an intermediate product in this reaction.

S. KHAQAN HASAN et S. AHMAD ABBAS. Can. J. Chem. **53**, 2450 (1975).

On décrit les produits résultants de l'hydrolyse alkaline des phtalimides *N*-substituées. L'hydrolyse alkaline du bromo-2 éthylphtalimide (**2**) peut conduire à cinq isomères qui sont: la dioxo-1,6 tétrahydro-3,4,5,6 1*H*-benzoxazocine-2,5 (**1**), (*o*-carboxyphényl)-2 Δ^2-oxazoline (**7**), phtalimido-2 éthanol (**3**), acide *N*-vinylphtalamique (**8**) et la *N*-(*o*-carboxybenzoyl) aziridine (**9**). Gabriel déclara en 1905 que **1** se forme par l'hydrolyse basique de **2**. Plus tard, la structure **7** fut proposée pour le produit. L'intérêt de la synthèse de **1** nous a amené à réexaminer cette hydrolyse. La structure **7** est confirmée pour le produit initial de l'hydrolyse, mais le composé **7** se transforme en **1** par chauffage au cours de la recristallisation. Ce dernier se transforme en **3** par chauffage au delà du point de fusion.

L'hydrolyse du chloro-2 éthylphtalimide (**4**) et du phtalimido-2 éthyl *p*-toluènesulfonate (**5**) conduit aussi à **7**. La préparation de **1** par cyclisation intramoléculaire de l'acide hydroxy-2 éthylphtalamique (**11**) n'a pas été réussie. Seulement **3** a été obtenu.

La réaction de l'anhydride phtalique avec l'acide amino-2 éthylsulfurique (**14**) à 150° produit le diphtalimidoéthyl phtalate (**13**) au lieu de l'acide phtalimido-2 éthylsulfurique (**6**). La séparation de **13** indique que **3** est un intermédiaire dans cette réaction.

[Traduit par le journal]

Synthesis of 1,6-diketo-3,4,5,6-tetrahydro-1*H*-2,5-benzoxazocine (**1**) appeared to us interesting because of the reported pharmacological activity of the derivatives of benzoxazocines (1–4). Gabriel (5) in 1905 claimed the synthesis of **1** by alkaline hydrolysis of 2-bromoethylphthalimide (**2**) but it was shown later (6) that this hydrolysis afforded 2-(*o*-carboxyphenyl)-Δ^2-oxazoline (**7**) instead of **1**.

In view of these conflicting reports, this hydrolysis has been repeated to determine structures of the products by modern spectrometric methods and we wish to report here our results from the hydrolysis of **2** and other related *N*-substituted phthalimides.

Hydrolysis of **2** is also interesting owing to the possibility of the formation of three other isomeric products, 2-phthalimidoethanol (**3**), *N*-vinylphthalamic acid (**8**), and *N*-(*o*-carboxybenzoyl)aziridine **9** in addition to **1** and **7**. These products could be formed after the initial hydrolysis of **2** to bromoethylphthalamic acid (**10**). Nucleophilic displacement of bromo group by carboxyl oxygen could yield **1** while **7** could be obtained by displacement of leaving group by amide oxygen. Elimination of hydrogen bromide could give **8** while nucleophilic displacement of bromo group by amide nitrogen could afford **9**. The aziridine **9** could also rearrange to **7** and such rearrangements are known (7). The suggested isomers could also rearrange to **1** and then to **3**.

Treatment of **2** with aqueous potassium hydroxide solution followed by acidification resulted in the precipitation of a product whose

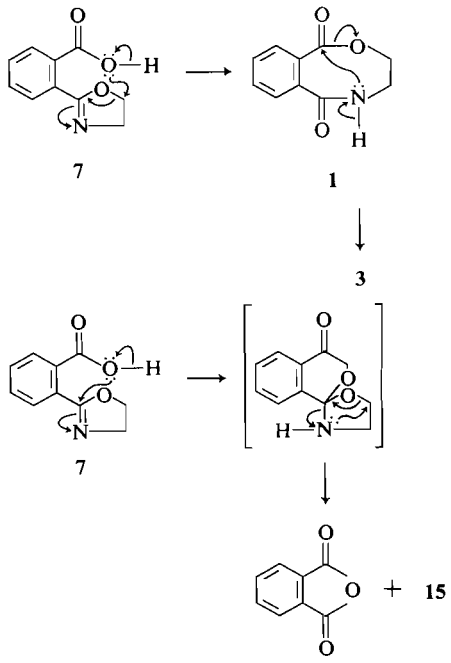
i.r. spectrum was the same as published earlier (8) for the material isolated from this hydrolysis. It shows carboxyl group absorption at 1700 cm^{-1} and another absorption at 1625 cm^{-1}. Cyclic conjugated compounds show C=N stretching absorption at 1575–1630 cm^{-1} (9) indicating **7** as the structure of the isolated product. The n.m.r. spectrum of this compound in alkaline deuterium oxide solution (p*H* 8) shows methylene triplets at δ 3.91 (J = 8.0 Hz) and 4.46 (J = 8.0 Hz) and aromatic protons at δ 7.28–7.71 as a multiplet.

Warming during recrystallization of **7** from 95% ethanol converted it into a rearranged product which shows ester carbonyl group absorption at 1740 cm^{-1} and secondary amide absorption at 1640 and 1540 cm^{-1} suggesting **1** as the structure of the compound. The n.m.r. spectrum of **1**, taken under the same conditions as utilized for **7**, shows two methylene triplets at δ 3.21 (J = 5.0 Hz) and 4.41 (J = 5.0 Hz) and aromatic protons at δ 7.31–7.86 as a multiplet. Both **1** and **7** show methylene and aromatic protons also in their n.m.r. spectra in deuterium oxide and deuterated dimethyl sulfoxide solutions.

Heating **1** and **7** above their melting points afforded **3** but **7** also gave a small amount of diphthalimidoethyl phthalate (**13**) which was not detected in the residue obtained on melting **1**. Isolation of **13** indicated formation of a small amount of phthalic anhydride on heating **7** as condensation of phthalic anhydride with **3** affords **13** (10).

Rearrangement of **7** to **1** appears to occur by the nucleophilic attack of carboxyl oxygen on C-5 of oxazoline in **7** resulting in the ring enlarged compound **1** which could further rearrange to **3** by nucleophilic attack of amide nitrogen on the ester carbonyl group.

Isolation of **13** from **7**, however, indicates nucleophilic attack of carboxyl oxygen on C-2 of oxazoline also resulting in the production of phthalic anhydride and elimination of the elements of aziridine but this attack on C-2 appears to be less favored in comparison to the attack on C-5 as evident by the small yield of **13** in comparison to the yield of **3** obtained on heating **7**.



SCHEME 1

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

Alkaline hydrolysis of 2-chloroethylphthalimide **4** and 2-phthalimidoethyl *p*-toluenesulfonate (**5**) also afforded initially **7** indicating its preferential formation in comparison to **1** from *N*-substituted ethylphthalimides.

Another route for the synthesis of **1** appeared to be the cyclization of 2-hydroxyethylphthalamic acid (**11**) which was isolated from the alkaline hydrolysis of **3**. It cyclized to the starting material on heating above melting point. Treatment of **11** with diazomethane or an ethanolic solution of hydrogen chloride only afforded **3**. It is known that esters of phthalamic acids easily cyclize to phthalimides (11, 12). Dicyclohexylcarbodiimide is also used for esterification (13) but only **3** was isolated on the treatment of **11** with this reagent indicating a preference for the formation of five-membered phthalimide ring over eight-membered benzoxazocine ring systems.

Synthesis of another possible isomer **9** from the hydrolysis of **2** was also attempted by the hydrolysis of 2-phthalimidoethylsulfuric acid **6**. It is known that alkaline hydrolysis of 2-aminoethylsulfuric acid (**14**) yields aziridine **15** (14). Synthesis of **6** was attempted by the condensation of phthalic anhydride with **14**. This reaction should initially afford **12** but phthalamic acids cyclize to phthalimides on heating (15–17) therefore **6** could be expected as the product of the condensation. Hydrolysis of **6** could afford **9** or **7** as a result of the rearrangement of **9** or nucleophilic displacement of sulfuric acid group by carbonyl oxygen. Product **3** could also be expected in the condensation as a result of the initial rearrangement of **7** to **1** followed by its further rearrangement to **3**.

Interestingly, only diphthalimidoethyl phthalate (**13**) was obtained instead of **6** on heating phthalic anhydride with **14** at 150°. It indicated thus intermediate formation in the reaction of **3** followed by its condensation with phthalic anhydride to yield **13**.

This work thus confirms Gabriel's suggestion of the formation of a benzoxazocine **1** which appears to be an interesting compound easily available from the hydrolysis of **2**.

Experimental

The i.r. spectra were recorded on a Perkin-Elmer i.r. model 137E spectrometer and calibrated against the 6.238 μm peak of polystyrene. Ultraviolet spectra were recorded on a Beckman DB instrument. The n.m.r. spectra were obtained on a Varian A-60 analytical spectrometer. Mass spectra were determined on an Associated Electrical Industries MS-9 double focusing high resolution mass spectrometer. Microanalyses were performed by the microanalytical section of PCSIR Laboratories at Karachi. Melting points were determined on a Gallenkamp melting point apparatus and are uncorrected.

Reported procedures were used for the preparation of 2-bromoethylphthalimide (**2**) (18), 2-phthalimidoethanol (**3**) (19), 2-chloroethylphthalimide (**4**) (19), 2-phthalimidoethyl *p*-toluenesulfonate (**5**) (20), diphthalimidoethyl phthalate (**13**) (10), and 2-aminoethylsulfuric acid (**14**) (14).

Hydrolysis Products of 2-Bromoethylphthalimide (2)

2-Bromoethylphthalimide (2.0 g, 0.008 mol) was dissolved in 15% potassium hydroxide solution (15 ml, 0.04 mol) by heating on a water bath. Acidification of this reaction mixture to p*H* 2 with 4 *N* hydrochloric acid at 0° gave a precipitate of **7** (840 mg, 55%), m.p. 137–139° (lit. (6) m.p. 141–142°); λ_{max} in 95% EtOH (log ε) 206 (3.97), 277 (3.03) nm; ν_{max} (KBr): 2860–2120, 1700, 1625 cm^{-1}; n.m.r. (D_2O) δ: 4.21 (m, 2H), 5.06 (m, 2H), 7.5–7.83 (m, 4H); (D_2O, K_2CO_3, p*H* 8) δ: 3.91 (t, 2H, J = 8.0 Hz), 4.46 (t, 2H, J = 8.0 Hz), 7.28–7.71 (m, 4H); (DMSO-d_6) δ: 4.15 (m, 4H), 7.41–7.8 (m, 4H).

Anal. Calcd. for $C_{10}H_9NO_3$ (mol. wt. 191.0582): C, 62.8; H, 4.7; N, 7.3. Found (mass spectrum, 191.0574): C, 62.7; H, 4.9; N, 7.6.

Recrystallization of this product (1.0 g, 0.005 mol) from 95% ethanol afforded **1** (770 mg, 77%), m.p. 139–141° (lit. (5) m.p. 139°); λ_{max} in 95% EtOH (log ε): 202 (4.16), 275 (3.04) nm; ν_{max} (KBr): 3330–2500, 1740, 1640, 1540 cm^{-1}; n.m.r. (D_2O) δ: 3.38 (m, 2H), 4.53 (m, 2H), 7.33–7.86 (m, 4H); (D_2O, K_2CO_3, p*H* 8) δ: 3.21 (t, 2H, J = 5.0 Hz), 4.41 (t, 2H, J = 5.0 Hz), 7.31–7.86 (m, 4H); (DMSO-d_6) δ: 3.2 (m, 2H), 4.48 (m, 2H), 7.33–7.8 (m, 4H).

Anal. Calcd. for $C_{10}H_9NO_3 \cdot H_2O$ (mol. wt. 191.0582): C, 57.4; H, 5.2; N, 6.6. Found (mass spectrum, 191.0578): C, 57.6; H, 4.7; N, 7.0.

Action of Heat on 7

Compound **7** (643 mg, 0.0033 mol) was heated at 150° for 15 min and the reaction mixture was chromatographed on a column of silica gel (10 g). The column was eluted by 45 ml fractions of petroleum ether, benzene and chloroform. Evaporation of petroleum ether fraction gave a solid (378 mg) which, on crystallization from 95% ethanol, afforded diphthalimidoethyl phthalate (**13**) (39 mg), m.p. 160–161° (lit. (10) m.p. 161–162°); identified from its m.p., mixture m.p., and i.r. spectrum.

Evaporation of the mother liquor and crystallization of the residue from chloroform – petroleum ether gave **3** (254 mg). 2-Phthalimidoethanol obtained from other fractions was also combined and this material gave purer product (153 mg) on recrystallization from chloroform – petroleum ether, m.p. 125–126° (lit. (20) m.p. 127–128°); identified from its m.p., mixture m.p., and i.r. spectrum.

Action of Heat on 1

Compound **1** (490 mg, 0.0023 mol) was heated at 150–160° for 15 min. Thin-layer chromatography of the residue (developing solvent: chloroform – ethyl acetate 1:1) indicated formation of only one product. Chro-

For personal use only.

matography on silica gel (12 g) by progressive elution with solvents, as used for the residue obtained on heating **7**, gave the product (435 mg, 99%; m.p. 128°) on elution with chloroform – ethyl acetate 1:1 (50 ml). Recrystallization of this material from 95% ethanol afforded **3** (269 mg; m.p. 127–128°) identified from its m.p. and i.r. and n.m.r. spectra.

Hydrolysis of 2-Chloroethylphthalimide (4)

2-Chloroethylphthalimide (1.0 g, 0.004 mol) was dissolved in 15% potassium hydroxide solution (4 ml, 0.01 mol), filtered and acidification of the filtrate to p*H* 5 at 0° with 4 *N* hydrochloric acid afforded the product (792 mg, 86%), m.p. 123–126°, whose i.r. spectrum was the same as that of **7**.

Hydrolysis of 2-Phthalimidoethyl p-Toluenesulfonate (5)

2-Phthalimidoethyl *p*-toluenesulfonate (1.0 g, 0.0035 mol) was dissolved in 15% aqueous potassium hydroxide solution (8.5 ml, 0.021 mol) by heating on a flame and the aqueous solution was then filtered and the filtrate was acidified at 0° to p*H* 2 by 4 *N* hydrochloric acid. Extraction with three 50 ml portions of chloroform followed by the evaporation of the dried extract gave a residue (555 mg, 72%), m.p. 120–128°, whose i.r. spectrum was the same as that of **7**.

2-Hydroxyethylphthalamic Acid (11)

2-Phthalimidoethanol (20 g, 0.1 mol) was dissolved in 10% potassium hydroxide solution (100 ml, 0.17 mol). A few crystals remained insoluble and were removed by decantation. A crystalline substance appeared on scratching the sides of the flask after acidification of the solution to p*H* 2 at 0° with 4 *N* hydrochloric acid. It was collected and dried. Recrystallization from methanol–ether afforded **11** (14.7 g, 67%) as colorless crystals, m.p. 113°, λ_{max} in 95% EtOH (log ε): 214 (3.99), 270 (3.04) nm; ν_{max} (KBr): 3450, 3330, 1725, 1665, 1560 cm^{-1}; n.m.r. (D_2O) δ: 3.6–4.1 (m, 4H), 7.45–7.9 (m, 4H).

Anal. Calcd. for $C_{10}H_{11}NO_4$: C, 57.4; H, 5.2; N, 6.6; Found: C, 57.6; H, 5.5, N, 6.5.

Attempted Preparation of the Esters of 11

Methyl Ester

2-Hydroxyethylphthalamic acid (1.0 g) was dissolved in dry methanol and the solution was esterified by diazomethane. Evaporation of the reaction mixture and crystallization of the residue from ethanol gave **3**, m.p. 124–126°.

Ethyl Ester

2-Hydroxyethylphthalamic acid (110 mg) was added to a saturated solution of hydrogen chloride in ethanol (6 ml) and the reaction mixture was evaporated. The i.r. spectrum of the residue was the same as that of **3**.

Cyclization of 2-Hydroxyethylphthalamic Acid (11)

With Dicyclohexylcarbodiimide

To a solution of **11** (200 mg) in dry dioxane (10 ml) was added a solution of dicyclohexylcarbodiimide (320 mg) in dry dioxane (25 ml). The reaction mixture was stirred for 2 h and then filtered to remove dicyclohexylurea (200 mg). Evaporation of the reaction mixture gave a residue which was triturated with acetone twice to remove more dicyclohexylurea. The insoluble residue on recrystallization from ethanol gave a product (51 mg), m.p. 114–124°. Further trituration with acetone raised the m.p. of this material to 120–124°. The i.r. spectrum, m.p. and mixture m.p. of the product indicated that it was 2-phthalimidoethanol (**3**).

By Heating

2-Hydroxyethylphthalamic acid (10.0 mg) was heated at 150° for 3 min. The i.r. spectrum of the heated material, m.p. 123–126°, was the same as that of **3**.

Reaction of Phthalic Anhydride with 2-Aminoethylsulfuric Acid (14)

2-Aminoethylsulfuric acid (12.5 g, 0.11 mol) and phthalic anhydride (14.8 g, 0.1 mol) were powdered and mixed together. The reaction mixture was then heated for 1 h at 130–150° and extracted with hot ethanol on cooling. A white solid (2.3 g) was obtained on keeping the ethanol extract overnight. Recrystallization of this material from ethanol afforded **13** (358 mg, 1.4%), m.p. 157–160° (lit. (10) m.p. 161–162°) identified from its m.p. and i.r. spectrum.

The authors are grateful to Prof. S. Wolfe (Queen's University, Kingston, Canada) and Prof. J. W. Lown (Univ. of Alberta, Edmonton, Canada) for their assistance in obtaining n.m.r. and mass spectra and to Mr. Moiz A. Warsi (PCSIR Laboratories, Karachi) for his technical assistance in the study of the reaction of phthalic anhydride with 2-aminoethylsulfuric acid.

Structure cristalline de Tl_2CO_3

RENÉ MARCHAND, YVES PIFFARD ET MICHEL TOURNOUX

Laboratoire de Chimie Minérale B, Equipe de Recherche associée au C.N.R.S., U.E.R. de Chimie, Faculté des Sciences de Nantes, B.P. 1044, 44 037, Nantes Cedex, France

Reçu le 17 juillet 1974[1]

RENÉ MARCHAND, YVES PIFFARD et MICHEL TOURNOUX. Can. J. Chem. **53**, 2454 (1975).

Le carbonate de thallium Tl_2CO_3 cristallise dans le système monoclinique (groupe spatial $C2/m$). Les paramètres de la maille sont $a = 12.486$ Å, $b = 5.382$ Å, $c = 7.530$ Å et $\beta = 122.35°$; $Z = 4$. La structure a été déterminée à partir de 655 réflexions indépendantes mesurées à l'aide d'un diffractomètre automatique.

Le doublet solitaire du thallium(I) manifeste une activité stéréochimique dans cette structure. Il se dispose dans des tunnels parallèles à [010]. Les groupements plans CO_3 sont parallèles à [100].

RENÉ MARCHAND, YVES PIFFARD, and MICHEL TOURNOUX. Can. J. Chem. **53**, 2454 (1975).

Thallium carbonate, Tl_2CO_3, crystallizes in the monoclinic system, space group $C2/m$. The parameters of the unit cell are $a = 12.486$ Å, $b = 5.382$ Å, $c = 7.530$ Å, and $\beta = 122.35°$; $Z = 4$. The structure was determined using 655 independent reflections which were measured on an automatic diffractometer.

The lone pair of thallium(I) shows a stereochemical influence in this structure. It is arranged in tunnels parallel to [010]. The planar carbonate groups are parallel to [100].

[Journal translation]

Introduction

Les structures cristallines des carbonates Li_2CO_3 (1), Na_2CO_3-α, Na_2CO_3-γ (2) et K_2CO_3 (3) ont été déterminées. Gatehouse et Lloyd (3) ont récemment montré que les structures des carbonates de sodium et de potassium pouvaient se décrire en termes d'empilement hexagonal compact légèrement distordu d'ions carbonate: un ion M^+ est au centre d'un octaèdre, l'autre au centre d'une bipyramide trigonale, les sommets de ces polyèdres sont occupés par des ions carbonate.

La détermination de la structure cristalline de Tl_2CO_3 a été entreprise dans le cadre d'une étude très générale portant sur la comparaison entre les composés oxygénés du thallium(I) et ceux du potassium.

Partie expérimentale

Le cristal étudié est représenté sur la fig. 1 avec l'indexation des faces et leurs dimensions en centimètres. Il a été obtenu par recristallisation du produit commercial.

Données cristallographiques de:
Tl_2CO_3 p.m. = 468.8
monoclinique, $C2/m$, $a = 12.486(3)$ Å, $b = 5.382(2)$ Å, $c = 7.530(2)$ Å, $\beta = 122.35°(2)$, $V = 425.4$ Å^3, $\rho_{mes} = 7.25$ g/cm^3, $\rho_{rx} = 7.32$ g/cm^3, $Z = 4$, $\mu = 770$ cm^{-1} (20 °C, MoK$_\alpha$, $\lambda = 0.70926$ Å).

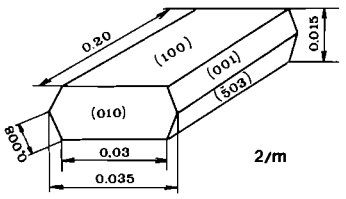

FIG. 1. Indexation et dimensions en cm des faces du cristal étudié.

Les paramètres ont été affinés à partir du diagramme de poudre. La condition d'existence observée sur les clichés de Weissenberg hkl, $h + k = 2n$, est compatible avec les groupes spatiaux $C2/m$, $C2$, Cm. Les tests physiques: piézoélectricité et doublage de fréquence laser effectués au C.N.E.T. de Lannion se sont avérés négatifs. La maille élémentaire définie par les vecteurs $\boldsymbol{a}$, $\boldsymbol{b}$, et $\boldsymbol{c}$ se déduit de celle de type I proposée par des auteurs antérieurs (4, 5), par les relations $\boldsymbol{a} = \boldsymbol{a}_1 + \boldsymbol{c}_1$, $\boldsymbol{b} = \boldsymbol{b}_1$ et $\boldsymbol{c} = -\boldsymbol{a}_1$.

L'enregistrement des intensités diffractées a été effectué au moyen d'un diffractomètre automatique Nonius CAD-3, utilisant le rayonnement MoK$_\alpha$, dans la demi-sphère réciproque comprise entre $\theta = 3.5°$ et $\theta = 40°$, les intensités de 3340 réflexions ont été mesurées avec un balayage θ–2θ. Elles correspondent à 1437 réflexions indépendantes. Après correction de Lorentz et de polarisation, des tests statistiques ont été effectués pour tenter de lever l'ambiguïté au niveau du groupe spatial. Le test portant sur la distribution des facteurs de structure normalisés n'est pas assez significatif, par contre la valeur moyenne de la quantité M définie par $|\overline{F_o}^2|/|\overline{F_o}|^2$ (6), égale à 0.610 est proche de la valeur théorique caractérisant les groupes centrosymétriques

TABLEAU 1. Distribution $N(z)$ pour Tl_2CO_3

z	$N(z)$
0.1	0.34
0.2	0.41
0.3	0.44
0.4	0.49
0.5	0.52
0.6	0.55
0.7	0.58
0.8	0.60
0.9	0.64
1.0	0.67

($M = 0.637$), de plus l'étude de la répartition de $N(z)$ (7), tableau 1, confirme la centrosymétrie. L'affinement a été conduit dans le groupe $C2/m$.

Les écarts-type sont évalués par application de la statistique de Poisson régissant les mesures de comptage. Le rapport $\sigma(I)/I$ est donné par la relation

$$\sigma(I)/I = \frac{[T + \tau^2(F_1' + F_2')]^{1/2}}{T - \tau(F_1' + F_2')}$$

où T est l'intensité brute de la réflexion, F_1' et F_2' les intensités des fonds continus de part et d'autre et $\tau = t/2t'$ le rapport des temps de comptage de la réflexion et des fonds continus est égal à 1/2 pour ce travail.

Détermination de la structure

Une fonction de Patterson tridimensionnelle a été calculée avec les 755 réflexions répondant au critère $\sigma(I)/I \leqslant 0.50$. Son interprétation a permis de retenir deux positions $4i$ pour les atomes de thallium et pour les atomes d'oxygène une position générale $8j$ et une position $4i$.

L'affinement des paramètres atomiques et des coefficients d'agitation thermique a été réalisé par la méthode des moindres carrés (matrice complète) en minimisant la quantité $s = \Sigma w(|F_o| - Z|F_c|)^2$ où Z est le facteur d'échelle et w le facteur de pondération qui s'exprime en fonction de la variance σ par la relation $w = 1/\sigma^2$. Le facteur de reliabilité classique et le facteur de reliabilité pondéré s'écrivent respectivement:

$$R = \Sigma(|F_o| - Z|F_c|)/\Sigma|F_o|$$

et

$$Rw = [\Sigma w(|F_o| - Z|F_c|)^2/\Sigma w(|F_o|)^2]^{1/2}$$

Seules les 655 réflexions telles que $\sigma(I)/I \leqslant 0.25$ ont été retenues pour l'affinement. Les facteurs de reliabilité R et Rw sont respectivement 0.151 et 0.174 après quatre cycles d'affinement des coordonnées atomiques et des facteurs d'agitation thermique isotrope des deux thallium. A ce niveau, une projection de la synthèse de Fourier a confirmé la position des groupements carbonate. L'affinement de tous les paramètres atomiques et des facteurs d'agitation thermique isotrope conduit à $R = 0.139$ et $Rw = 0.158$.

L'introduction des coefficients d'agitation thermique anisotrope sur les thallium conduit à $R = 0.105$ et $Rw = 0.127$. Jusqu'à ce stade nous avons utilisé des facteurs de pondération unitaires ($w = 1$). L'examen des facteurs de structure calculés et observés indiquait l'influence de l'absorption, cette correction a été faite à l'aide du programme DATA P1 (8). Après quatre cycles d'affinement avec les valeurs corrigées, les facteurs de reliabilité s'abaissent à $R = 0.046$ et $Rw = 0.061$. La pondération des taches faibles selon le schéma de Hughes (9) avec les bornes $F_1 = 33$, $F_2 = 34$, $F_3 = 1000$, $F_4 = 2000$ et la correction de l'extinction secondaire (10) amènent R et Rw à, respectivement, 0.033 et 0.045. Un calcul effectué en prenant en considération les 1437 réflexions indépendantes mesurées conduit pour R et Rw à 0.088 et 0.051. Pour ce calcul les réflexions dont la mesure n'a pas été significative ont été affectées d'une intensité égale à la moitié de la plus faible mesurée.

Ces calculs ont été effectués à l'aide du programme SFLS-5 sur IBM 370 (11). Les facteurs de diffusion atomique sont tirés des tables de Moore (12). La liste des facteurs de structure observés et calculés a été versée au dépôt des données non publiées.

Les valeurs des différents paramètres atomiques sont données dans le tableau 2.

Description de la structure

La fig. 2 représente la projection de la structure selon l'axe [010]. Les principaux angles et distances interatomiques sont rassemblés dans le tableau 3.

Tous les atomes, à l'exception des atomes d'oxygène notés O(2) en position générale, sont situés dans les plans miroirs correspondant à la position $4i$ du groupe $C2/m$.

Le calcul de la distance entre l'atome C(1) et le plan formé par ses trois proches voisins oxygène conduit à une valeur qui peut être considérée comme nulle (0.006 Å (0.010)). Il en est de même pour le calcul de l'angle entre le plan [100] et celui des groupements CO_3 (1° (1.5)). Ces groupements se disposent en files parallèles à [010]. L'atome Tl (1) relie trois groupements CO_3 appartenant à deux files différentes, chacun des deux groupements appartenant à une même file est lié par deux liaisons Tl—O alors que le troisième groupement n'exerce qu'une liaison de ce type. L'atome Tl(2) relie trois groupements CO_3 appartenant à deux files différentes. Il exerce une liaison Tl—O avec chacun des deux groupements d'une même file et deux liaisons de ce type avec le troisième groupement.

Sur les figs. 3 et 4 ces environnements sont complétés par de faibles liaisons correspondant à des distantes Tl—O supérieures à 3.20 Å.

Les cinq plus proches voisins oxygène de Tl(1) sont situés d'un même côté par rapport au cation. Trois des distances Tl—O sont voisines de la somme des rayons ioniques: 2.80 Å (13),

$Tl^0_{(21)}$—$O^0_{(12)}$	3.240(20)		
$C^0_{(11)}$—$O^0_{(11)}$	1.24(3)		
$C^0_{(11)}$—$O^0_{(26)}$	1.28(2)†		

*Dans ce tableau chaque atome est affecté d'indices inférieurs et supérieurs. Le premier indice inférieur correspond à celui donné dans le tableau 2, le second indice est attribué conformément à l'ordre des positions équivalentes des tables internationales de cristallographie. L'indice supérieur 0, 1, 2, 3 ou 4 a la signification suivante: 0, l'atome est dans la maille; 1, l'atome a subi une réflexion dans un miroir situé en cote $y = 0$; 2, l'atome a subi une translation de $-c$; 3, l'atome a subi les deux opérations précédentes; 4, l'atome a subi une translation de b.

†Ces distances interviennent deux fois dans la coordinence.

les deux autres sont nettement inférieures, ce qui traduit une participation covalente plus importante.

Les quatre plus proches voisins oxygène de Tl(2) sont situés d'un même côté par rapport à celui-ci et à des distances peu différentes: 2.67 et 2.69 Å. Deux autres atomes d'oxygène situés de l'autre côté du cation et à grande distance de celui-ci: 3.24 et 3.36 Å, participent à l'environnement de deux Tl(2).

Dans cette structure le doublet du thallium au degré d'oxydation un présente un début d'activité stéréochimique. En effet, certaines distances Tl—O sont inférieures à la somme des rayons ioniques et les atomes d'oxygène fortement liés au thallium sont tous situés d'un même côté par rapport à celui-ci conformément aux prévisions de la théorie de Gillespie et Nyholm (14). Les atomes de thallium délimitent dans la structure des tunnels parallèles à [010] à l'intérieur desquels se disposent les doublets solitaires. Dans les structures telles que celles de Tl_3BO_3 (15), Tl_3PO_4 (16), Tl_4O_3 (17), Tl_2TiO_3 (18) et Tl_2SnO_3 (19) où l'activité

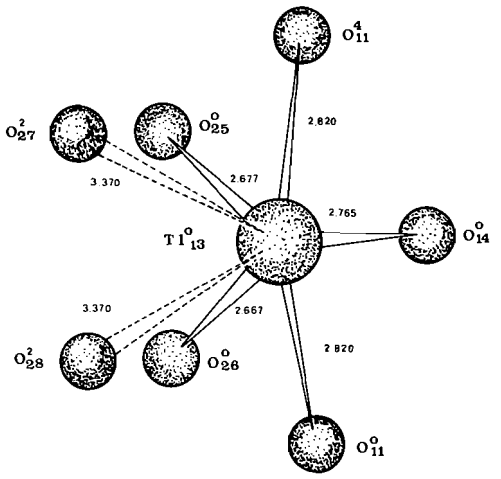

FIG. 3. Environnement oxygéné du Tl(1).

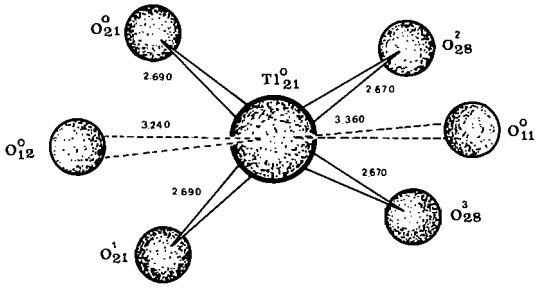

FIG. 4. Environnement oxygéné du Tl(2).

stéréochimique du doublet se manifeste nettement le thallium n'est souvent lié qu'à trois atomes d'oxygène et les distances Tl—O sont comprises entre 2.40 et 2.50 Å, au contraire lorsque le doublet est stéréochimiquement inactif la coordinence du thallium(I) est élevée. C'est le cas pour les composés oxygénés pauvres en thallium qui sont souvent isotypes des composés des alcalins de même formulation.

Le comportement cristallochimique du thallium(I) dans les composés riches en thallium est bien illustré par la structure cristalline de Tl_2CO_3 qui est très différente de celle des carbonates de sodium et de potassium.

Chemically Induced Dynamic Nuclear Polarization During Irradiation of Phenol in the Presence of Amides

SHIV P. VAISH, HOLGER E. CHEN, MICHA TOMKIEWICZ, ROBERT D. MCALPINE, AND MICHAEL COCIVERA

Department of Chemistry, University of Guelph, Guelph, Ontario N1G 2W1

Received February 26, 1975

SHIV P. VAISH, HOLGER E. CHEN, MICHA TOMKIEWICZ, ROBERT D. MCALPINE, and MICHAEL COCIVERA. Can. J. Chem. **53**, 2459 (1975).

Irradiation of D_2O solutions containing various phenols with aliphatic amides at p*H* values between 9 and 12 results in nuclear spin polarization which is observed as n.m.r. emission signals during irradiation. No polarization is observed for the phenols which include tyrosine, cresol, *p*-hydroxybenzoic acid, phenol, and others. For the amides which include acetamide, propionamide, *N*-methylacetamide, and *N*,*N*-dimethylacetamide, polarization was observed for only the protons on the carbon bonded to the carbonyl group. Because excited phenolate ions are known to eject electrons, it is proposed that the radical $R\dot{C}(O^-)NR_2$ is formed by reaction of the amide with the hydrated electron. The polarization observed for the amides can be explained by reaction of $R\dot{C}(O^-)NR_2$ with a benzosemiquinone radical via a radical pair.

SHIV P. VAISH, HOLGER E. CHEN, MICHA TOMKIEWICZ, ROBERT D. MCALPINE et MICHAEL COCIVERA. Can. J. Chem. **53**, 2459 (1975).

L'irradiation de solutions dans D_2O de différents phénols avec des amides aliphatiques à des p*H* se situant entre 9 et 12, produit une polarisation du spin nucléaire. Ce phénomène est observable par une émission de signaux r.m.n. pendant l'irradiation. On n'observe pas de polarisation pour les phénols tels que la tyrosine, le crésol, l'acide *p*-hydroxybenzoïque, le phénol et autres. Une polarisation est observée seulement pour les protons du carbone lié au groupe carbonyle pour les amides telles que l'acétamide, le propionamide, la *N*-méthylacétamide et la *N*,*N*-diméthylacétamide. Sachant que les ions phénolate excités émettent des électrons, on propose que le radical $R\dot{C}(O^-)NR_2$ résulte de la réaction de l'amide avec un électron hydraté. On peut expliquer la polarisation observée pour les amides, par la réaction de $R\dot{C}(O^-)NR_2$ avec un radical benzosemiquinone par l'intermédiaire d'une paire radicalaire.

[Traduit par le journal]

Introduction

Radiation induced electron transfer from phenol and substituted phenols to water has been the subject of a number of studies (1–3). Studies into the details of the electron transfer process are of particular interest in view of the role played by tyrosine in the photochemistry of some proteins (4–6). The nature of the precursor leading to the electron transfer step is of interest for this reason.

Jortner *et al.* (2*b*) have argued against a charge transfer to solvent transition in the case of phenolate ion. In the case of the β-naphthoate anion whose fluorescence could be studied, electron transfer to water appears to occur via an excited singlet state (7). More recently in a study of the phenolate anion, it was concluded that electron transfer to water occurred via an excited triplet state since 2,4-hexadiene reduces the concentration of phenoxyl radical (3*a*). Compounds containing disulfide linkages can act as electron acceptors, also. The data for the tyrosine–lipoate system have been used as evidence for electron transfer via an excited triplet state of tyrosine (8). The present paper presents results of a chemically induced dynamic nuclear polarization (c.i.d.n.p.) study which indicates that aliphatic amides may act as electron acceptors, too. The nature of the nuclear spin polarization observed by proton n.m.r. can be interpreted to mean that the mechanism which is responsible for the polarization probably involves hydrated electron formation followed by capture by the amide. Thus, the present c.i.d.n.p. results seem to provide no information concerning interaction of amide with excited phenolate ion.

Experimental

The chemicals and their suppliers are: β-naphthol, *p*-hydroxybenzyl alcohol, and *p*-methoxybenzyl alcohol (Aldrich); aniline, $K_4Fe(CN)_6$, *p*,*p*′-biphenol, and *p*-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

bromophenol (Baker); *p*-cresol, tyrosine, ascorbic acid, and acetophenone (BDH); N_2O (Canox); *N*-acetyltyrosine (Cyclochemical); *N*-methylacetamide, *N*,*N*-dimethylacetamide, propionamide, and *p*-hydroxybenzoic acid (Eastman); pyridine and benzoic acid (Fisher); acetamide, phenol, and KI (Mallinckrodt); and D_2O (Stohler). Where possible the chemicals were reagent grade. Purification of the compounds by distillation or recrystallization was done when deemed necessary.

The proton n.m.r. spectra at 100 MHz were obtained using a Varian HA-100-15 spectrometer which we have modified; details are given elsewhere (9).

While the temperature of the probe was maintained at 15°, the sample was at a somewhat higher temperature at the spot of irradiation. The spectra were obtained before, during, and after irradiation. The radiation source is a 1000 W Hanovia mercury xenon lamp. Except when a Pyrex plate was used as a filter, the sample was irradiated with the full spectrum of the lamp.

Results

During irradiation of D_2O solutions containing acetamide plus phenol or substituted phenols at p*H* greater than 9.0, the n.m.r. spectrum differs from the spectrum in the absence of radiation in that the CH_3-proton resonance appears as an emission signal. Examples of the types of spectra obtained during irradiation are given in Fig. 1. These spectra were obtained at 100 MHz using air saturated solutions. Figure 1*A* was obtained using a solution containing 0.1 *M* phenol and 0.1 *M* acetamide at p*H* 11.8. The sweep-width was 10 p.p.m. starting at the tetramethylsilane, TMS, signal. The field strength increases from left to right. The dashed lines indicate the signal heights after irradiation for about 60 s. The assignment of signals relative to TMS is: ring protons of phenolate ion 6.85 p.p.m.; HDO, 4.55 p.p.m.; and CH_3-protons of acetamide, 2.00 p.p.m. As indicated by the emission signal, only the signal due to the CH_3 of acetamide is affected during irradiation. This system was studied under a variety of conditions. Phenolate concentration was usually 0.05 *M*. The effect of the presence of O_2 in the solution was checked by degassing the solution to less than 2 μ. Under these conditions the spectrum appeared similar to Fig. 1*A*. The p*H* was varied from 7 to 12, and below p*H* 9 no polarization was observed. At p*H* 9 the polarization was small and increased with increase in p*H* to a maximum at p*H* 11.5. Saturating the solution with N_2O quenches the polarization. The polarization returns when the solution is purged with N_2. This process was repeated several times. When a Pyrex plate was used to remove light having wavelength less than 300 nm

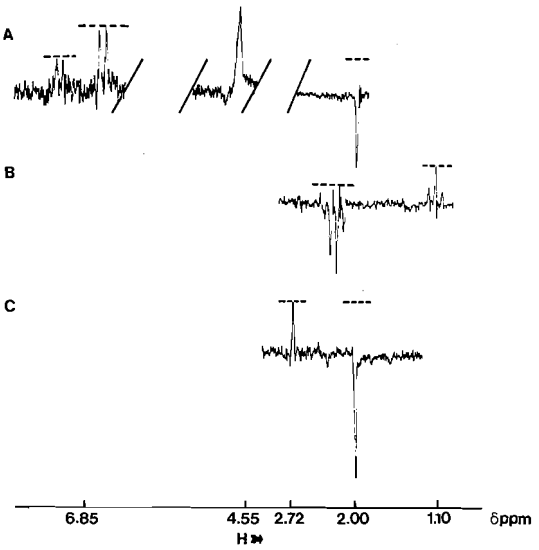

FIG. 1. Proton n.m.r. spectra obtained at 100 MHz for irradiation of D_2O solutions of phenolate ion plus amide at p*H* 11.5. (*A*) Acetamide: CH_3-protons, 2.00 p.p.m.; HDO, 4.55 p.p.m.; and phenyl ring protons, 6.85 p.p.m. (*B*) Propionamide: CH_3-protons, 1.10 p.p.m.; CH_2-protons, 2.23 p.p.m. (*C*) *N*-Methylacetamide: CH_3CO-protons, 2.00 p.p.m.; *N*-methyl protons, 2.72 p.p.m. As indicated by the signal to noise ratios, different gains were used to record the signals.

no polarization was observed. No polarization was observed during the irradiation of a solution containing only 0.1 *M* acetamide at p*H* 11.5.

Polarization of the CH_3 of acetamide was observed for a number of acetamide solutions containing various substituted phenols at p*H* values around 11.5. The list of phenols which gave polarization included: *p*,*p*′-biphenol, 2,4,6-trimethylphenol, *p*-cresol, *p*-hydroxybenzoic acid, *p*-hydroxybenzyl alcohol, tyrosine, and *N*-acetyl tyrosine. In addition, polarization was observed during the irradiation of a solution containing 0.05 *M* aniline plus 0.1 *M* acetamide at p*H* 7.0 and 10.5. On the other hand, no polarization of the CH_3 of acetamide was observed during irradiation of solutions of acetamide plus a number of other compounds including: *p*-methoxybenzyl alcohol, pyridine, benzoic acid, *p*-bromophenol, acetophenone, $K_4Fe(CN)_6$, KI, β-naphthol, and ascorbic acid.

Since the emission signal of the CH_3-proton of acetamide indicates the formation of a radical from acetamide, additional experiments were performed to identify the site of the unpaired electron. These experiments involved the study

For personal use only.

of solutions at p*H* 11.5 containing 0.05 *M* phenol plus 0.1 *M* *N*-methylacetamide or *N*,*N*-dimethylacetamide or propionamide. In the case of propionamide, only the CH_2-protons are polarized. This can be seen in Fig. 1*B* which illustrates the spectrum obtained during irradiation of an air saturated aqueous solution containing phenol plus propionamide. The emission quartet at 2.23 p.p.m. is due to the CH_2-protons, and the absorption triplet at 1.1 p.p.m. is due to the CH_3-protons. The dashed lines indicate the signal heights of the largest lines of the multiplets after irradiation. Thus no polarization is observed for the CH_3-protons of propionamide. For both *N*-methyl- and *N*,*N*-dimethylacetamide no polarization was observed for the *N*-methyl protons whereas emission was still observed for the CH_3CO-protons as illustrated in Fig. 1*C* for the *N*-methylacetamide (*N*-methyl proton resonance at 2.72 p.p.m.).

Discussion

The emission signals observed for the amides are indicative of non-Boltzmann nuclear spin polarization. The radical pair model used to explain the occurrence of such polarization has been described in detail (9, 10) and only a general description will be presented in this paper. According to the radical pair model, non-Boltzmann nuclear spin polarization occurs as a result of reaction via a radical pair in which the singlet and triplet electronic spin states are mixed. Because of scalar interactions (electron–nuclear hyperfine coupling), the spin states of the nuclei on the radicals affect the mixing. The probability for product formation depends on the singlet character of the radical pair electronic spin state. Consequently, since the singlet character depends in part on the nuclear spin state, the nuclear spin states of the product can have non-Boltzmann populations. Thus, according to the radical pair model, the emission signals of the amides are indicative of the formation of radicals.

The nature of the radical(s) formed by the amides can be decided by comparing the polarization observed for each amide. For acetamide the CH_3-proton is observed to be polarized. For, *N*-methyl- and *N*,*N*-dimethylacetamide, only the CH_3CO-protons are polarized; no polarization is observed of *N*-methyl protons of either amide. On the basis of this information, we conclude that the electron–nuclear hyperfine coupling between the unpaired electron and the *N*-methyl protons is too small to cause nuclear spin polarization. Since α and β hyperfine coupling constants are usually not small (11), the *N*-methyl protons cannot be α or β to the site of the unpaired electron. Therefore radicals for which the nitrogen is the site of the unpaired electron (such as $R\dot{C}ONR$ and $\dot{N}R_2$) can be ruled out. Likewise since only the CH_2-protons of propionamide are polarized, the CH_3-protons cannot be α or β to the site of the unpaired electron, and radicals such as $CH_3\dot{C}HCONH_2$, $\dot{C}H_3$, and $CH_3\dot{C}H_2$ can be precluded. Thus, it seems unlikely that the amides are undergoing bond rupture or losing a hydrogen atom as a result of irradiation.

Since the methyl-protons of acetamide and the CH_2-protons of propionamide are polarized, they must be β to the site of the unpaired electron. Because of the structures of these molecules and the arguments presented above, these protons cannot be γ to the site. Furthermore, they cannot be α since the radicals, $CH_3\dot{C}H_2$ and $CH_3\dot{C}HCONH_2$, have been ruled out. Since phenolate ions and aniline are known to undergo radiation induced electron ejection (1–3) we suggest that the radical is either $R\dot{C}(O^-)NR_2$ or $R\dot{C}(OH)NR_2$. These structures have been suggested for the transients detected during the pulse radiolysis of aqueous solutions containing amides (12, 13). Furthermore, the structure $CH_3\dot{C}(O^-)NH_2$ has been assigned to a radical detected at 77 K by e.s.r. after u.v. irradiation of H_2O solid containing $K_4Fe(CN)_6$ and acetamide (14).

The other substituted phenolate ions which cause polarization of acetamide are sufficiently similar to the phenolate ion to suspect that they also undergo electron ejection when irradiated. An alternative mechanism which we also have considered involves electronic excitation of the phenolate ion followed by electron transfer from excited phenolate ion to the amide. From the arguments given below, the former mechanism seems preferable.

We will consider the electron ejection mechanism first. As indicated above nuclear polarization occurs as a result of irradiation of a number of compounds which are known to undergo electron ejection. On the other hand, a number of compounds such as KI, $K_4Fe(CN)_6$, β-naphthol, benzoic acid, and ascorbic acid did not cause polarization even though they are known to undergo photoelectron ejection (1, 2*a*, 15). How-

ever, these results do not rule out the proposed mechanism since the absence of polarization can be explained either by spin–orbit coupling or the presence of more reactive hydrated electron scavengers. Thus, heavy atoms such as I and Fe can either prevent or reduce the polarization via spin–orbit coupling. For acetamide, benzoate, and naphthoate ions at $pH \geqslant 10.9$, the rate constants for reaction with hydrated electrons are 1.7×10^7, 3.6×10^9, and 9.5×10^9 (16), respectively. Thus the benzoate and naphthoate ions can compete effectively with acetamide for the hydrated electron. For ascorbic acid, a similar mechanism may be in operation; however, the rate constant does not appear to be available.

The main aspect to consider is that polarization is observed for only the amide. According to the radical pair model, no nuclear polarization of the amide would occur as a result of the addition of the hydrated electron to the amide. Consequently, the polarization would have to occur via a subsequent reaction of $R\dot{C}(O^-)NR_2$ with another radical having a different *g*-factor. Since only the amide protons are observed to be polarized, the other radical must result in a diamagnetic compound having little or no nuclear polarization. This possibility can occur either if the radical has a structure in which the protons are coupled only very weakly to the unpaired electron, and/or if the polarization is removed more rapidly than the rate of excitation (by a relaxation process). The phenoxyl radical does not satisfy either of these conditions. The hyperfine coupling constants for the ring protons are not small (17, 18), and the phenoxide ion which would result from the phenoxyl radical should not have proton relaxation rates which are competitive with the rate of excitation. Therefore, we conclude that the amide polarization probably does not occur via the radical pair $[Ph\dot{O}\ R\dot{C}(O^-)NR_2]^F$ where F indicates a free radical precursor.

In previous work (19), we have found that the irradiation of phenolate ion in water results in the formation of a variety of semiquinone radicals: *ortho*-, *para*-, oxy-, and dioxybenzosemiquinones. Reaction of $R\dot{C}(O^-)NR_2$ with any or all of these radicals could account for the amide nuclear polarization and for the absence of any detectable polarization in any other compound. The reaction would involve disproportionation via the radical pair $[\dot{S}\ R\dot{C}(O^-)NR_2]^F$ in which $\dot{S}$ indicates the semiquinone. This reaction results in the formation of the amide and an anion of the hydroquinone derived from the semiquinone. The resultant polarization for the protons of this anion is expected to be smaller than that for the amide protons since the hyperfine coupling constants for the semiquinones are smaller. However, this polarization for the anion would not be negligible relative to the amide polarization. The fact that no polarization is detected could be caused by nuclear relaxation effects resulting from an equilibration between the anion of hydroquinone and the remaining semiquinone radicals. Thus, with this mechanism it is possible to account for the detection of polarization for only the amide.

The quenching of the amide nuclear polarization by N_2O, chloroform, and acetone provides support for the mechanism involving reaction of the amide with the hydrated electron. All of the compounds have rate constants for reaction with the hydrated electron which are substantially higher than that for the amide. For example, the value of the rate constant for N_2O is 5.6×10^9 *vs.* 1.7×10^7 for acetamide (16). Since the concentration of N_2O was 2.4×10^{-2} *M vs.* 0.1 *M* for acetamide, N_2O reacts with the hydrated electron about 100 times faster than does acetamide under these conditions. Thus, the quenching of the amide polarization by N_2O and the other compounds is consistent with the proposed mechanism. Of course, this conclusion presupposes that these compounds do not quench an excited state of the phenolate ion. This seems to be a reasonable assumption since Stein (2*a*) has found that N_2O did not affect directly the fluoresence yield of the naphthoate ion. Furthermore while Feitelson and Hayon (8) report that the lipoate anion quenches the fluorescence of tyrosine, they apparently did not detect any quenching by N_2O. Thus in view of the evidence and arguments presented above, we propose the following mechanism, Scheme 1.

$$ArO^- \xrightarrow{h\nu} {}^*ArO^-$$

$${}^*ArO^- \rightarrow Ar\dot{O} + e_{aq}$$

$$RCONR_2' + e_{aq} \rightarrow R\dot{C}(O^-)NR_2'$$

$$R\dot{C}(O^-)NR_2' + \dot{S} \rightleftharpoons [R\dot{C}(O^-)NR_2'\ \dot{S}]^F$$

$$RCONR_2' + S^- \leftarrow$$

SCHEME 1

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

In this mechanism, ArO^- is the phenolate ion (with or without substitution) and $\dot{S}$ is a benzosemiquinone radical which is formed as suggested previously (19). According to this mechanism, electron ejection from an electronically excited phenolate ion results in the formation of the hydrated electron which reacts with the amide to form $R\dot{C}(O^-)NR_2'$ which subsequently reacts with $\dot{S}$ via the radical pair $[R\dot{C}(O^-)NR_2'\ \dot{S}]^F$ to give the amide and the anion of the hydroquinone S^-. Although $R\dot{C}(O^-)NR_2'$ is specified in the mechanism, it is quite possible that $R\dot{C}(OH)NR_2'$ may be involved since its pK_a was measured to be $\geqslant 13.5$ (13) and the pH of our solutions was usually 11.5 or lower.

For the CH_3-protons of acetamide, emission is calculated for reaction via this radical pair, in agreement with the observed spectrum. This polarization was calculated from equations derived using the Closs Kaptein Oosterhoff theory (10). For this calculation, the g-factor and CH_3 hyperfine coupling constant for the radical $CH_3\dot{C}(O^-)NH_2$ are 2.0030 and $+13.5$ G, respectively (14). We do not expect that these values would change appreciably for the protonated species. A positive sign is chosen for the coupling constant since the protons are bonded to a β-carbon (17) as in the case of the analogous ketyl radicals produced during the photolysis of aliphatic aldehydes (20, 21). The g-factors for *o*- and *p*-benzosemiquinones are 2.0047 and 2.0044, respectively (22). The other semiquinones observed under these conditions have similar g-factors (19).

Another possibility involves electronic excitation of the phenolate ion followed by electron transfer to ground state amide. An analogous mechanism has been proposed for a reaction involving tyrosine and the lipoate ion (8). In the case of the amide, this mechanism would involve the formation of the radical pair $[Ar\dot{O}\ R\dot{C}(O^-)NR_2']$. Disproportionation of this radical pair would result in nuclear polarization for both the amide and the phenolate ion. Since no polarization could be detected for the ring protons of the phenolate ion, this path requires an additional step, *i.e.* dissociation of the radical pair followed by trapping of $R\dot{C}(O^-)NR_2$ before the nuclear polarization is lost. This mechanism is less attractive for several reasons. First, emission is calculated for the amide only if the radical pair has a singlet precursor. Feitelson and Hayon (3*b*, 8) have concluded that electron transfer from excited phenolate ion to both water and lipoate ion occurs via the triplet state. Second, the quenching of polarization by N_2O could not be explained unless quenching of the excited singlet state is postulated. As discussed above, this path seems unlikely. Third, this mechanism could not account for the absence of amide polarization when β-naphthoate and benzoic acid are excited. Consequently, the reaction of amide with the hydrated electron seems more attractive.

The polarization results for the aniline plus amide system are somewhat different from the phenolate ion results in that polarization is observed for the ring protons of the aniline in addition to the acetamide CH_3-protons. Thus, reaction with the hydrated electron need not necessarily be invoked. The analysis of this system has not been attempted. In addition, it seems likely that the results for the other amides may be explained by the same mechanism (Scheme 1) used for acetamide. Although the e.s.r. spectra do not appear to be available for the radical anions derived from these amides, there is no reason to expect that the g-factors and the sign of the appropriate hyperfine coupling constant for each of these radicals should differ from those for $CH_3\dot{C}(O^-)NH_2$. Furthermore, since a Pyrex filter prevents polarization, the process does not involve direct excitation of an amide – phenolate ion complex having an absorption spectrum above 300 nm. This conclusion is supported by the observation that amide–phenol complexes have been detected in nonpolar solvents but not in water (23). Finally in the absence of amide, irradiation of a D_2O solution of phenolate ion results in emission for HDO and the ring protons (19). In the presence of amide, the intensity of the HDO signal is reduced but the ring protons appear unaffected. Presumably, the amide causes additional reactions which compete with those proposed in its absence.

This work was supported in part by the National Research Council of Canada and the Petroleum Research Fund administered by the American Chemical Society.

Conformational Analysis of *N*-Nitrosopiperidines by ^{13}C Nuclear Magnetic Resonance. The Orientation Preference of an α-Methyl Group

ROBERT R. FRASER AND T. BRUCE GRINDLEY[1]

Department of Chemistry, University of Ottawa, Ottawa, Canada K1N 6N5

Received February 19, 1975

ROBERT R. FRASER and T. BRUCE GRINDLEY. Can. J. Chem. **53**, 2465 (1975).

The ^{13}C shielding parameters for *N*-nitroso-4-phenylpiperidine and four α-methyl derivatives have been measured. From these data a number of methyl substituent parameters have been obtained. A comparison of the observed spectra of *syn*- and *anti*-*N*-nitroso-2-methylpiperidines with those calculated from the substituent parameters and the shieldings in *N*-nitrosopiperidine established the *syn* isomer to exist exclusively in the conformation having the methyl group axial; the *anti* isomer has the methyl group predominantly axial (59%). It is proposed that the large differential shielding between α carbons *syn* and *anti* to the nitroso group is caused by steric compression at the *syn* carbon. Large dilution effects on the carbon shieldings (up to 1.3 p.p.m.) have been encountered in these nitrosamines.

ROBERT R. FRASER et T. BRUCE GRINDLEY. Can. J. Chem. **53**, 2465 (1975).

Les paramètres d'écran du ^{13}C de la *N*-nitroso phényl-4 pipéridine et de quatre dérivés α méthylés ont été déterminés. Un certain nombre de paramètres pour les substituants méthyles ont été déduits à partir de ces données. La comparaison des spectres observés des *N*-nitroso méthyl-2 pipéridines *syn* et *anti* et des spectres calculés à l'aide des paramètres des substituants et des paramètres d'écran de la *N*-nitroso pipéridine, démontre que l'isomère *syn* adopte uniquement la conformation où le groupe méthyle est axial et que 59% de l'isomère *anti* adopte cette même conformation. La grande différence de blindage entre les carbones α *syn* ou *anti* et le groupe nitroso serait due à l'encombrement stérique au niveau du carbone *syn*. Les paramètres d'écran de ces nitrosamines sont fortement affectés par la dilution (jusqu'à 1.3 p.p.m.).

[Traduit par le journal]

Currently, ^{13}C n.m.r. spectroscopy (c.m.r.) constitutes an informative and important method of conformational analysis. The shielding parameters for carbons have been shown to be very sensitive to environment (1) so that shifts for the axial *vs.* equatorial conformers are usually distinctively different. Our interest in the reactions of anions α to the nitrosoamino function (2, 3) has led to the need for increased knowledge of the conformational properties of a methyl group in the α position of *N*-nitrosopiperidines. In this paper we wish to examine a series of methylated nitrosopiperidines of known conformation with a view to establishing a correlation between shifts and conformation. Such data would then provide information on conformational equilibria in mobile systems.

Previous studies of the c.m.r. spectra of nitrosamines by Pregosin and Randall (4) and by Ellis *et al.* (5) have dealt primarily with the gross characteristics of the shielding parameters. Pregosin and Randall noted a large difference (6–10 p.p.m.) in the shieldings of the *syn* and *anti* α carbons in simple dialkyl nitrosamines. The more recent work of Ellis *et al.* (5) included the examination of nitrosamines of 2-, 3-, and 4-methylpiperidine, *cis*-2,6-dimethylpiperidine, and several piperazines. Their attention was focussed on an assessment of the contribution of the electric field and anisotropy effects to the differential shieldings of the α carbons. Their calculations of shifts, however, were in poor agreement with the spectral parameters. Our studies provide additional data pertaining to the cause of *syn vs. anti* differential shieldings.

Model Compounds: Configurational and Conformational Properties

The models used in this study are *N*-nitroso-4-phenylpiperidine (**1**) and its mono- and dimethyl derivatives (**2**–**5**). Methylation of **1** produces a 45:55 mixture of the *syn* and *anti* isomers **2** and **3**. These compounds, like most nitrosamines (6), have a barrier to interconversion of about 23 kcal/mol (3). Methylation of this mixture produced **4** which was then isomerized with base

to give **5**. The accompanying paper (3) describes the details of their synthesis and some of the ^{1}H n.m.r. (p.m.r.) characteristics of these derivatives upon which their stereochemical assignments are based. The axial orientation (*trans* to phenyl) of the methyl group in **2** and **3** is indicated by the magnitudes of the vicinal splittings for the methine proton at C-2 with the methylene protons at C-3. Couplings of 3.5 and <1 Hz indicate an equatorial methine, hence an axial methyl group. For compound **4**, the configurations of both methyls are assigned *trans* to the phenyl at C-4 and the molecule exists in the conformation having both methyls axial. Although this conformation is highly strained by the 1,3-diaxial methyl–methyl interaction, *N*-nitroso-*cis*-2,6-dimethylpiperidine was also found to exist 'predominantly' in the chair form having both methyls axial (7,8) and the strain due to this diaxial orientation has been estimated to be 3.9 kcal/mol (8). To confirm unambiguously the conformational and configurational assignments for **4**, a detailed analysis of its p.m.r. spectrum was carried out.

The 220 MHz spectrum of **4** was measured in $CDCl_3$.[2] That portion of the spectrum showing all but the aromatic and methine absorptions appears in Fig. 1*A*. The theoretical spectrum for the seven protons on the piperidine ring was calculated using the LAOCN3 program and the parameters listed in Table 1. The resultant

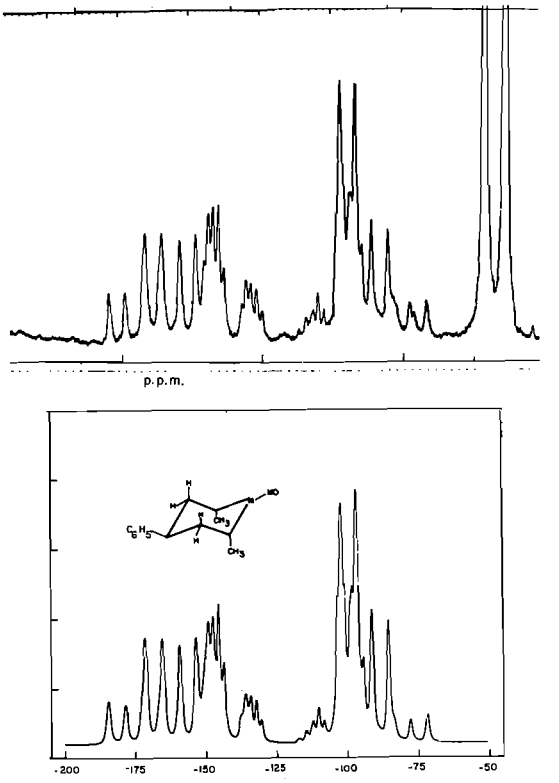

FIG. 1. (*A*) The absorption of the protons at C-3 and C-5 in **4** measured at 220 MHz. (*B*) The absorption of these protons calculated from the parameters in Table 1.

spectrum for the protons at C-3 and C-5 is shown in Fig. 1*B*. An iterative method of fitting by the computer could not be employed, as the assignment of peaks to be matched was complicated by the presence of unresolved long-range couplings. Instead, trial and error calculations were employed until agreement between all experimental and calculated line positions was $\leqslant 0.1$ Hz. Included in the calculation was a first-order perturbation by the two methyl groups on both the vicinal (methine) protons and the next nearest protons.

It can be seen in Table 1 that coupling constants between protons at carbons 3, 4, and 5 have values typical of protons on a cyclohexane ring. However, couplings between protons on carbons 2 and 3 (and 5 and 6) are not normal for a piperidine ring, *i.e.*, J_{ae} should be 3–3.5 Hz (9) and one can estimate, by considering effects of electronegativity and their orientation dependence (10), a value for J_{ee} of 2.2 Hz. The observed J_{ee} (1.5) and J_{ae} values (6.3, 6.5), indicate

[2]The authors thank the 220 MHz Centre at Sheridan Park for measurement of this spectrum.

*Chemical shifts in p.p.m. from TMS; LIS values in p.p.m.; all spectra run on *M* solutions in $CDCl_3$.
†LIS shifts for protons are numbered according to the carbon to which they are attached; shifts were measured on solutions in $CDCl_3$ and $CDCl_3$ + $Eu(fod)_3$.
‡The numbering of the ring carbon atoms is given in the formulae.

the presence of a distortion because of the severe repulsive 1,3-diaxial methyl–methyl interaction. Should this distortion produce a 10° increase in the dihedral angle between the two equatorial protons (ϕ_{ee}) and a concomitant decrease in ϕ_{ea}, the predicted values for J_{ee} and J_{ea} would change to 1.0 and 5.2 Hz. Thus, a distortion of this type can account, at least qualitatively, for the observed vicinal coupling constants.

The conclusion that the nitrosamine **4** exists in a distorted chair conformation having two methyl groups axial, substantiates the similar proposals of Harris and Spragg (7) and Chow *et al.* (8) for the nitrosamine of *cis*-2,6-dimethylpiperidine. Furthermore, the parameters obtained for **4** rule out the presence of boat conformations to greater than a few percent for this molecule.[3]

Since compound **5** is thermodynamically more stable than **4** (3), it, too, will exist exclusively in a chair conformation.

^{13}C Spectra of 1–5

The ^{13}C chemical shifts for all ring and methyl carbons in **1–5** are listed in Table 2. Since all spectra were measured in the FT mode with complete proton decoupling, it was necessary to obtain unambiguous evidence regarding peak assignments. For this reason, the spectrum of

[3]Specifically, the axial proton at C-4 shows vicinal splittings of 3.2, 3.2, 12.6, and 13.0 Hz, which magnitudes are very close to those found in cyclohexane, *i.e.* J_{ae} = 3.7, J_{aa} = 13.1 Hz (23).

anti-Axial*	$4^6 - 2^6 = 8.0$	$4^5 - 2^5 = 4.4$	$4^4 - 2^4 = -4.9$ $4^2 - 2^2 = 0.9$	$4^3 - 2^3 = 0.4$ $4^{CH_3(syn)} - 2^{CH_3(syn)} = 3.4$
anti-Equatorial*	$5^6 - 2^6 = 7.0$	$5^5 - 2^5 = 9.8$	$5^4 - 2^4 = 0.4$ $5^2 - 2^2 = 0.1$	$5^3 - 2^3 = 0.2$ $5^{CH_3(syn)} - 2^{CH_3(syn)} = 0.6$

*These classes, involving substitution in a highly hindered position, are not comparable with normal substitution effects.

each of compounds **1**–**4** was also measured in the presence of $Eu(fod)_3$. The downfield shifts of the carbon resonances caused by the added shift reagent are also given in Table 2 under the heading LIS_C. The possibility exists that some contribution to the observed carbon shifts by a contact mechanism might be present, as in the case of amines (11). For this reason, the effects of a shift reagent on the α protons shifts (LIS_H) were also determined in the case of **1** and **4**. A comparison of the LIS_C and LIS_H values shows their magnitudes to be consistent with their relative distances from the shift reagent, thus excluding any significant contact contribution. For the purpose of arriving at our shift assignments, we need only rely on the well-established distance-dependent effect of the shift reagent (12) in a qualitative fashion. Thus, the possible limitations in the accuracy of LIS values as summarized by Horrocks and Sipe (13) will not affect the conclusions made here.

In a few instances where LIS_C values alone could not distinguish between two possible assignments, other considerations frequently permitted an unambiguous conclusion. For example, in **1**, although C-3 and C-6 might have the reverse assignments on the basis of LIS_C values, the fact that a carbon *anti* to the nitroso group occurs at much lower field than the *syn* (4) removes any ambiguity in this case. In the spectra of **2** and **3** not all carbons could be assigned with certainty. Those signals at δ 36.7 and 37.0 for which several alternative assignments are possible, are given in parentheses. Assignments for **5** were made by assuming negligible δ or γ effects (<1 p.p.m.) of an equatorial methyl group. That C-2 and C-5 or C-3 and C-4 might have reverse assignments is not too important, as the shifts for each pair are very similar and none of the conclusions to follow would be altered by a reversal.

Methyl Substituent Parameters

The data in Table 2 can be used to obtain a set of substituent effects caused by replacement of hydrogen by a methyl group having three different orientations. These effects, classified as α, β, γ, or δ effects in the standard way (1), are listed in Table 3. The following example illustrates how they have been obtained. If one substitutes a methyl group at the *anti* carbon (C-6) of **1** an upfield shift is produced at the *syn* α carbon atom (C-6 in **3**, abbreviated as $\mathbf{3}^6$) relative to the same carbon (C-2) in **1**. From Table 2, this γ effect is seen to be $3^6 - 1^2 = -4.1$ p.p.m.

The α effects in Table 3 are all larger (3.6–8.6 p.p.m.) than the same effect in cyclohexanes and piperidines, normally, 1–2 p.p.m. (14, 15) for an axial methyl. In **4**, where the methyls are *syn* diaxial, the α effect is double that found in an unstrained chair. Similarly, the γ effects involving **4** also differ from the norm while the β effects appear to be comparable to those in cyclohexanes. Other than in **4**, both γ and δ effects also have magnitudes similar to those in methyl cyclohexanes. The δ effects of one *syn* axial methyl on the other is deshielding and the magnitude is similar (3–4 p.p.m.) but slightly larger than that observed by Stothers and

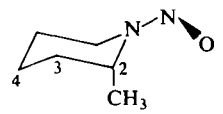
co-workers (16) (~2.3 p.p.m.) in methylated cyclohexanones.

N-Nitroso-2-methylpiperidine

The *syn* (**6**) and *anti* (**7**) isomers of this nitrosamine have been reported to exist in the ratio 23:77 at equilibrium in $CDCl_3$ (7); (repeated integrations of the same spectrum on our instrument gave a ratio of 33:67). The conformation properties of these two isomers are both intriguing and controversial. On the basis of proton chemical shifts, Harris and Spragg (7) and later Chow *et al.* (8), concluded that the methyl group in the *syn* isomer existed exclusively in the axial orientation. The *anti* isomer was also estimated to have at least a 50% population for the axial methyl conformer (7). In conflict with this assessment, measurement of the LIS_H values in *N*-nitroso-2-methylpiperidine compared with those of the rigid *N*-nitroso-4-*t*-butylpiperidine led Forrest *et al.* (17) to conclude that the *syn* isomer **6** contained 85% of the conformer having an axial methyl group and that the *anti* isomer **7** was a 50:50 mixture of conformers. In view of the known limitations in the accuracy of LIS data[4], the conclusions thus derived remain in doubt.[5]

We have measured the c.m.r. spectrum of this nitrosamine in $CDCl_3$ and the parameters obtained are recorded in Table 4, along with those for *N*-nitrosopiperidine (**8**). Distinction between peaks from **6** *vs.* those from **7** was readily provided by the consistent 1:2 intensity



6

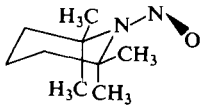
8



9

ratio. Individual resonances were assigned using the data in Table 2 and assuming that the phenyl would exert a negligible γ effect and equal β effects at C-3 and C-5 (the equality of the differential shieldings at C-3 and C-5 in **1** and **8** support the latter assumption). The assignments for **8**, substantiated by the LIS_C values, are also recorded in Table 4.

Two of our assignments for **7** differ from those of Ellis and co-workers (5) in that the shifts for C-4 and C-5 are reversed. From their data, the γ effect of the *anti* CH_3 on C-4 is +0.9 p.p.m. (deshielding), whereas our assignments and data give a value of −3.0 (shielding) for the γ effect, which is the normal effect (1). Further support for our assignment comes from the agreement between all three calculated conformational equilibrium constants for **7** (see Table 5).

[4]In the application in question, the greatest weakness would appear to be the possibility that the conformational populations in the complex differ from those of the free nitrosamine, as has been found for several other shift reagent–substrate complexes (18).

[5]An additional argument can be made against the likelihood of a significant proportion of the *syn*-equatorial conformer of **6**. If the *anti* methyl has little conformational preference and the *syn* methyl does adopt the equatorial configuration, then the *trans* derivative **5** should contain a measurable amount of the isomer with a *syn*-equatorial methyl. None could be seen in the p.m.r. spectrum of **5**.

A close examination of the shieldings for **6** reveals evidence against any significant amount of equatorial conformation. For example, one can predict the shieldings for each conformer utilizing the measured shieldings of nitrosopiperidine (**8**) and the substitution effects in Table 4. These predicted shieldings and their derivations are presented in Table 5. The shieldings for three of the carbons, C-4, C-6, and the methyl carbon can be estimated for both conformers. In each case, the observed shieldings agree to 0.4 p.p.m. or less with those predicted for the axial isomer and in two of the cases, are not even intermediate between the predicted axial and equatorial shieldings. It can be concluded that no signficant amount (<2%) of the equatorial conformer is present.

For three of the carbons of **7**, the shieldings in both conformers can be predicted. The data in Table 5 show a very good agreement, all three sets of data indicating the presence of 41 ± 2% of the equatorial conformer. This isomer distribution supports the conclusions of Harris and Spragg (7) but is not too different from the percentage estimated by Forrest *et al.* (17). Nevertheless, for **7** as well as **6**, we feel certain the results derived from c.m.r. are considerably more accurate than those derived on the basis of quantitative use of lanthanide induced shifts.

A further example of the utility of c.m.r. when applied to nitrosamines is provided by the spectral data for **9**, *N*-nitrosotetramethylpiperidine. Most striking is the Δ_{sa} of 1.7 p.p.m. for the α carbons of this compound. Clearly, the molecule must exist in a nonchair conformation as was proposed by Harris and Spragg (7).

Syn–anti Differential Shielding (Δ_{sa})

Both previous papers on nitrosamines (4, 5) have suggested that the large difference in shieldings of the *syn* and *anti* α carbons is due primarily to an electric field effect, although attempts to substantiate this with calculations failed (5). Currently, the accepted cause of the related Δ_{sa} values in amides (19, 20) and oximes (19, 21) is steric compression. The same should be true for nitrosamines. This view is strongly supported by the fact that the Δ_{sa} values given in Table 6 are about 11 p.p.m. for each rigid nitrosamine, but of reduced magnitude in the more flexible dialkyl nitrosamines studied by Pregosin and Randall (4). It is simply another example of a γ effect, equivalent in magnitude to that recently described by Tori *et al.* (22) in a highly rigid norbornene.

TABLE 6. The difference in ^{13}C shieldings for α carbons *syn* and *anti* to the oxygen atoms

Model	δ_{syn}	δ_{anti}	Δ_{sa}
1	39.2	50.2	11.0
4	43.7	54.6	10.9
C-2 in **2** and **3**	42.8	54.4	11.6
C-6 in **2** and **3**	35.1	46.4	11.5
		Average Δ_{sa}	11.2

Solvent Effects on Shielding Parameters

We have examined the spectrum of *N*-nitrosopiperidine both as a 5 *M* and as a 1 *M* solution in $CDCl_3$. There was a significant difference in the carbon shieldings in that all resonances appeared at higher fields in the 5 *M* solutions by 0.9–1.3 p.p.m. For this reason, all data reported in this paper were obtained using 1 *M* solutions in $CDCl_3$. It is to be noted that the spectra reported by Ellis *et al.* (5) were run on either neat liquids or 'concentrated solutions.' Their failure to specify the conditions under which each of their spectra was measured means that there is an uncertainty of at least 1 p.p.m. in their shift data and undoubtedly accounts for the differences in their data and ours for compounds **6**, **7** and **8**.

Experimental

Spectra were obtained on 1 *M* solutions of the nitrosamine in $CDCl_3$, using either a Varian XL-100 equipped with a **TT-100** accessory or a Varian CFT-20 instrument. Pulse angles of 55° and pulse delays of 4 s were employed. All peaks are reported in δ units (TMS = 0) and were referenced with respect to the central peak of $CDCl_3$ (δ 77.3).

The authors thank the National Research Council of Canada for financial support. We also wish to thank Dr. I. C. P. Smith of NRCC for use of the CFT-20.

Stereoselectivity in the Reactions of Nitrosopiperidine Carbanions. Steric *vs*. Stereoelectronic Control

ROBERT R. FRASER, T. BRUCE GRINDLEY, AND SALVATORE PASSANNANTI
Department of Chemistry, University of Ottawa, Ottawa, Canada K1N 6N5

Received February 19, 1975

ROBERT R. FRASER, T. BRUCE GRINDLEY, and SALVATORE PASSANNANTI. Can. J. Chem. **53**, 2473 (1975).

The anion of *N*-nitroso-4-phenylpiperidine reacts with methyl iodide, carbon dioxide, and benzophenone to give solely the axial substitution product. A second methylation of the monomethyl derivative gave the 2,6-diaxial derivative. None of the isomer having *trans* methyl groups could be detected. This *trans* isomer dominates over *cis* by 75:25 at equilibrium. From a consideration of the steric interactions present in these nitrosamines, it can be concluded that they alone cannot explain the observed high stereoselectivity. It is proposed that stereoelectronic control contributes significantly to the exclusive axial attack.

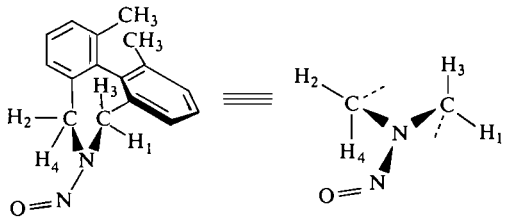
ROBERT R. FRASER, T. BRUCE GRINDLEY et SALVATORE PASSANNANTI. Can. J. Chem. **53**, 2473 (1975).

L'anion du *N*-nitroso phényl-4 pipéridine réagit avec l'iodure de méthyle, le dioxyde de carbone et la benzophénone et conduit exclusivement au produit de substitution axial. Une seconde méthylation du dérivé monométhylé conduit au dérivé diaxial-2,6. Aucun isomère ayant un groupe méthylé *trans* n'a pu être détecté. A l'équilibre, le rapport isomère *trans* : isomère *cis* est de 75:25. La haute stéréospécificité observée ne peut pas être expliquée en considérant seulement les interactions stériques présentes dans ces nitroamines. On propose que le contrôle stéréoélectronique contribue notablement à l'attaque exlusive en axial.

[Traduit par le journal]

Evidence that a carbanion in the α position of a nitrosamine exhibits appreciable stability was provided by two independent studies (1, 2). In each case base-catalyzed H–D exchange was observed α to the nitrosamino function. In addition, Keefer and Fodor (1) reported that α alkylation using ethyl iodide and base was also possible, albeit in poor yield (15%). Subsequently, extensive work by Seebach and Enders (3) demonstrated the synthetic potential of nitrosamino carbanions. These authors reported high yields in the reaction of the anions of *N*-nitrosodimethylamine (3) and many additional nitrosamines (4) with a wide range of electrophiles.[1] Concurrent with their studies, work in this laboratory showed similar results for the reactions of the anion of *N*-nitrosodibenzylamine (6).

An interesting aspect of these carbanions α to nitrogen is their stereochemical behavior. We have shown that the base-catalyzed H–D exchange of the *N*-nitrosoazepine **1** is remarkably stereoselective (6). The four α protons all reside



1

FIG. 1. Environments of the four α protons in *N*-nitroazepine **1**.

in the different environments shown in Fig. 1, since the barrier to rotation about the N—N bond is high (23 kcal/mol). The relative rates of exchange of the protons H_1, H_2, H_3, H_4 in *t*-butyl alcohol O-*d* and potassium *t*-butoxide are in the ratio $1:10^3:10^2:10^5$ (6). Thus, removal of the *syn*-axial proton (H_4) is a highly stereoselective process.[2] Although the stereoselectivity of proton abstraction may be the result of several factors, evidence was presented (6) that the enhanced stability of the carbanion due to nitrosation of

[1]A comprehensive review of the preparation, properties, and reactions of nitrosamines, with emphasis on anionic reactions has recently appeared (5).

[2]The preliminary account (6) of this work set only a lower limit to the selectivity. The more accurate measurements quoted above will be published shortly (8).

the nitrogen atom results from a contribution of structure *c* to the hybrid anion of **1** (see *a*, *b*, *c*).

When the anion of **1** was formed by treatment with lithium diisopropylamide (LDA) in THF at −78°, subsequent methylation and carboxylation produced *syn*-axial substitution only (7). In view of the synthetic potential of these anions, it seemed important to broaden our studies of their stereoselectivity. We now wish to report the stereochemical course of several reactions of *N*-nitroso-4-phenylpiperidine (**2**). This molecule, being conformationally homogeneous, should provide useful information on the stereoselectivity of these anion reactions.

Reactions of 2

The anion of **2** was generated by reaction with LDA in THF at −78° for 4–30 min (see Experimental). Subsequent addition of the electrophile followed by a reaction time of up to 1 h, then work-up, gave good yields of α-substituted products. For example, carboxylation, methylation and condensation with benzophenone proceeded in yields of 76, 79, and 72%, respectively. The important feature of all three reactions is the exclusive formation of *trans* products, **3**, **4**, and **5** (axial substitution only).

We can estimate that more than 1% of *cis* product would have been detected by n.m.r. or the careful t.l.c. search. Thus, these three reactions of **2** are highly stereoselective.[3]

We next examined the reactions of *N*-nitroso-*r*-2-methyl-*t*-4-phenylpiperidine (**4**). Methylation by the standard procedure gave the dimethyl derivative (**6**) in 62% yield and carboxylation of **4** gave **7** in 33% yield. Again, in both reactions, substitution gave only axial product. Owing to the greater complexity in the methyl region of the p.m.r. spectrum of **6**, as much as 2% of **8**, the product of equatorial attack, might be undetected. The fact that no trace of **8** could be found by t.l.c. indicates that <1% is a more probable upper limit.

Equilibration of 6

To further our understanding of the stereoselective methylation, information on product stabilities was sought. A sample of **6** was subjected to isomerization conditions (potassium *t*-butoxide in DMSO at 90° for 24 h). At the end of this time, the proportion of **8** to **6** was 74:26. Pure **8** was then isolated and subjected to the same isomerization conditions. A *trans* to *cis* ratio of 75:25 was produced. Some darkening of the solution occurred during both equilibrations, indicative perhaps of decomposition. However, 63% of material was recovered after isomerization. We can conclude that the observed proportion of *trans* to *cis* is quite close to the equilibrium value.

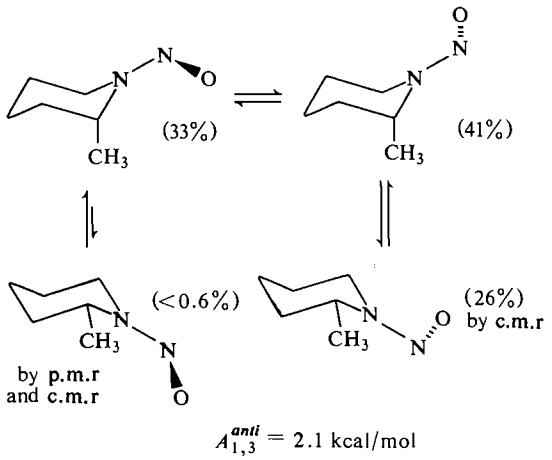

FIG. 2. The conformational properties of *N*-nitroso-2-methylpiperidine.

In the accompanying paper (9), both ^1H and ^{13}C spectral evidence established the chair conformation and the orientation for the methyl groups of the three nitrosamines **4**, **6**, **8**. Using these ^{13}C data, it was possible to determine the conformational properties of *N*-nitroso-2-methylpiperidine, with a degree of certainty which previous work in the literature lacked (10, 11). Our c.m.r. analysis coupled with a careful integration of the p.m.r. methyl region (*syn*:*anti* ratio, 33:67) established the distribution of stereoisomers of this nitrosamine as 33% *syn*-axial, 41% *anti*-axial, and 26% *anti*-equatorial, as depicted in Fig. 2. No evidence of the *syn*-equatorial isomer could be found. These results allow us to assign 0.2 kcal/mol of greater strain energy[4] to

[3]Since methylation of **1** was shown to be exclusively *syn*, we have not attempted to verify the *syn* selectivity in the reactions of **2**. We have observed a predominance of *syn* isomer in the methylation of **2** and assume the small amount of *anti* results from rotation about the N—N bond during work-up. The half-life for this process, as measured by equilibration of the dominant *syn* isomer **4**, is 2 h.

[4]We consider only strain energy, as defined by Westheimer (13), since it is highly unlikely that other factors would contribute to the stability of a methyl group in the various conformers.

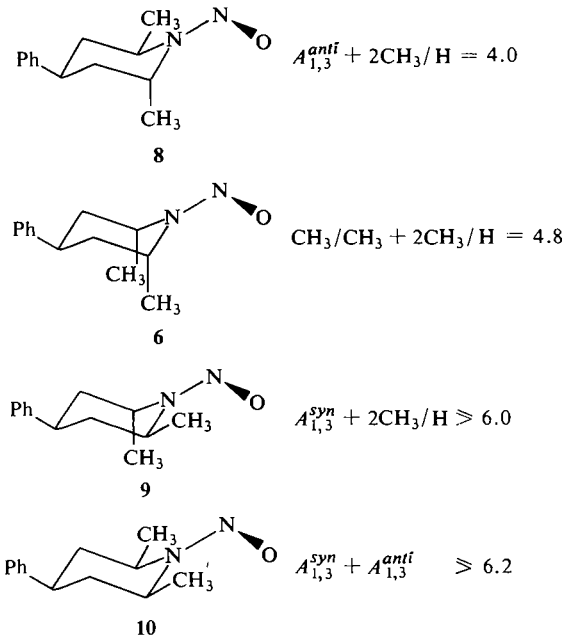

FIG. 3. Strain energies (kcal/mol) of the four isomeric 2,6-dimethyl derivatives of *N*-nitroso-4-phenylpiperidine.

the *anti*-equatorial conformer than its *anti*-axial partner. We have recently (12) determined the strain energy for an axial methyl group in the 2 position of *N*-acetylpiperidine (relative to the strain-free equatorial conformation in the transition state for amide rotation) to be 1.9 kcal/mol. If we assume the strain in this model[5] to be equal to the strain in the axial conformer of *anti*-*N*-nitroso-2-methylpiperidine, then the strain in the equatorial conformer will be 0.2 kcal/mol greater *i.e.*, 2.1 kcal/mol, (calculated from the equilibrium constant K = [equatorial]/[average axial]).

The strain in the *anti*-equatorial conformer is a type of $A_{1,3}$ strain (14) involving repulsion between the methyl group and the nitrogen 'lone pair'. It is interesting that this interaction should be so much greater than its analog involving a methyl group and the lone pair of a carbonyl oxygen (essentially zero (15)).

From this data the strain energies (in kcal/mol) of the four isomeric 2,6-dimethyl derivatives of *N*-nitroso-4-phenylpiperidine can be estimated. The results presented in Fig. 3 are arrived at in the following way. Compound **8** will possess strain because of (*a*) an axial methyl = 1.9 and (*b*) an $A_{1,3}$ strain for the *anti*-equatorial methyl = 2.1 for a total of 4.0. From the position of the equilibrium between **6** and **8** at 80°, **6** is calculated to possess 0.8 kcal/mol more strain, total = 4.8. Since **8** and **9** can interconvert by rotation about the *N*-nitroso bond, yet no trace of **9** could be detected by n.m.r. (<3% at 30°), **9** must be less stable than **8** by at least 2 kcal/mol, *i.e.* total strain ⩾6.0. Since **10** differs from **9** by encountering $A_{1,3}$ strain while removing the axial methyl interaction (difference, 0.2) it must be 0.2 kcal less stable than **9**, total ⩾6.2.

The above values are consistent with related evidence in the literature. For example, Chow *et al.* (16) estimated the strain in the 1,3-diaxial conformation of *cis*-2,6-dimethylpiperidine to be 3.9 kcal/mol, the difference in activation energies for the barrier to rotation of its nitrosamine (19.4) relative to that of dimethylnitrosamine (23.3). A better model for comparison is now available from the detailed study of Cooney *et al.* (17). Using their result of 23.8 kcal/mol for $\Delta G^{\ddagger}_{373}$, the value for the strain of the 1,3-diaxial methyl groups changes to 4.4 which agrees within experimental error with our estimate of 4.8 kcal/mol.[6] A corollary to the assignment of ⩾6.0 for the strain in **9**, is the requirement that the $A_{1,3}$ strain for a *syn*-equatorial methyl group be >4.1 kcal/mol. This agrees favorably with the estimate of >3.7 kcal/mol for the originally defined $A_{1,3}$ strain between two methyls (14).

Origin of Pronounced Stereoselectivity

Highly stereoselective organic reactions are only rarely encountered, particularly in the case of alkylations. Eliel *et al.* (20) recently disclosed that the reaction of a 2-lithio-1,3-dithiane belongs in this category in that methylation occurs in the equatorial position exclusively (>99%). Another example is provided by the work of Durst *et al.* (21) who report that methylation of benzyl *t*-butyl sulfoxide gives only one diastereomer (>99%). Methylation of other sulfoxides are often less selective (22, 23). In systems more

[5]The use of the *N*-acetyl derivative as a model for the *N*-nitrosamine can be justified on the basis of the similarity in hybridization at the nitrogen atom (both have high rotational barriers about the exocyclic nitrogen bond) and similar exclusive axial orientation of the alpha methyl group *syn* to oxygen, (9, 12).

[6]It is to be noted that the strain of 4.8 kcal/mol is made up of two axial CH_3–H and one 1,3-diaxial CH_3–CH_3 interactions. It follows that the magnitude of the CH_3–CH_3 interaction is 4.8–1.9 = 2.9 kcal/mol. This value is slightly larger than that of 2.2 kcal/mol reported for a 1,3-diaxial interaction in cyclohexane (18). In 2-bromo-2,6,6-trimethylcyclohexanone, Allinger *et al.* estimated the 1,3-diaxial interaction to be >2.0 kcal/mol (19).

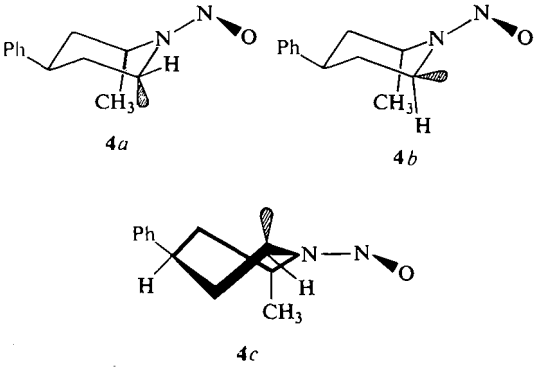

FIG. 4. Possible anion configurations of **4**.

closely related to the nitrosamino carbanions, marked stereoselectivity is lacking. For example, ethylation of lithio-4-*t*-butylcyclohexanone gives 51% axial attack by ethyl iodide (24). The pyrrolidine enamine of the same ketone showed some stereoselectivity in its alkylation, the proportion of axial product being 70, 90, and 93% in the reactions with methyl, propyl, and allyl halides, respectively (25). In view of the synthetic potential of these reactions, it is of considerable practical as well as theoretical importance to ascertain the reasons behind the abnormally high stereoselectivity.

These variations in stereoselectivity must, in some way, reflect differences in transition state geometry. Since the six-membered ring of the cyclic enolate has a half-chair conformation, the experimental results strongly imply that the nitrosamino carbanion does not, but rather retains some sp^3 character at the carbon bearing the negative charge (see Fig. 4). This seems reasonable since there would be an increase in steric repulsion between the remaining α hydrogen and the *syn* oxygen atom in a planar form. The large difference in the shieldings of the *syn* and *anti* α carbons of **6** is a strong indication that this interaction is appreciable even in the staggered chair conformation (9). It then becomes obvious that of two possible anions (**4***a* and *b*), anion **4***a* would be much more stable, since it possesses proper alignment for overlap with the π system of the N—N—O function. Such overlap is geometrically restricted in *b*. Although effective interaction would also be achievable in the twist-boat form *c*, this conformation should be less stable by at least 2.7 kcal/mol, as calculated by Allinger *et al.* (26).[7] The intermediate stereoselectivity in the enamine alkylation (25) is consistent with a finite but lesser degree of steric inhibition of co-planarity. And, as House points out (24), since the enolate is planar, the transition state for protonation or alkylation will not differ greatly from this configuration, in which the stereoelectronic effect is the same for either axial or equatorial attack. Thus, steric influences can determine the dominant stereochemical result.

The above argument is essentially a reapplication of the principle of stereoelectronic control put forward many years ago by Corey and Sneen (28). Several years ago, Bordwell and Scamehorn (29) pointed out that evidence in support of the principle has been equivocal in that the influences of steric and stereoelectronic effects have been difficult to separate. Indeed, arguments in favor of dominant steric factors in H–D exchanges of cyclohexanones have been made (30). A recent communication on the H–D exchange of 4-*t*-butylcyclohexanone ($k_a/k_e = 5.1$) again attributed the stereoselectivity to stereoelectronic control (31).

Obviously, interpretation of our results could also be made on the basis of steric effects. Since methylation of the anion **4***b* would yield **9**, and **9** is at least 1.2 kcal/mol less stable than the actual product **6**, predominant formation of **6** is to be expected; *i.e.*, the factors destabilizing **9** must also be present in the transition state for its formation. Let us suppose that the $A_{1,3}$ strain in **9** could be as high as 5.1 kcal/mol and that **9** is then 2.2 kcal/mol less stable than **6**. Even the most generous estimate of the amount of this strain present in the transition states would be < 1.3 kcal/mol.[8] In such a case, there should have been at least 3% of **9** formed but none could be detected. While these arguments are admittedly speculative, they do suggest that some factor besides the steric one contributes to the stereoselectivity in the methylation of **4**. In our view, stereoelectronic control is that factor.

[7]Recent work of Anet *et al.* (27) reinforces the validity of Allinger's calculations, in that they found the barrier ring inversion of cyclohexanone to be 4.0 kcal/mol, 0.1 kcal/mol more than predicted (26).

[8]Steric repulsive interactions fall off rapidly with increasing distance, so that a more realistic estimate would be < 1 kcal/mol for the transition state free energy differences.

A Cautionary Note: The Source of Alkyllithium

Considerable difficulties have been encountered in obtaining reproducible yields in the methylation of the anions of dibenzylbenzamide (7) and *N*-nitroso-4-phenylpiperidine. The difficulties began after our supply of 2.2 *M* solution of CH_3Li in ether (Ventron) was exhausted. Thereafter, using a 1.82 *M* solution of CH_3Li in ether (Ventron), yields were variable and lower. After eliminating other reagents from consideration, it was concluded that the new CH_3Li must be at fault, probably due to the presence of LiBr (soluble in ether). Durst and Molin have reported large differences in the stereoselectivity of lithiation, then deuteration of benzyl methyl sulfoxide as a function of the amount of LiBr present (32). We suspect our original supply of CH_3Li had been made from CH_3Cl and was thus free of LiCl (insoluble in ether). Subsequently, successful methylations of both substrates were achieved by using *either* CH_3Li from Foote Corp. (made from CH_3Cl) *or* butyllithium in hexane from Ventron (no LiBr, since it is insoluble in hexane). Table 1 summarizes these results. No effects on stereoselectivity were encountered.

Experimental

General Methods

Melting points were measured on a Gallenkamp melting point apparatus and are corrected. The n.m.r. spectra were recorded on either a Varian T-60 or HA-100 spectrometer, using deuteriochloroform as solvent unless otherwise noted. Chemical shifts are expressed in δ units (p.p.m. downfield from tetramethylsilane).

All reactions involving methyllithium were carried out under an atmosphere of dry nitrogen using carefully dried equipment and reagents. The term hexanes indicates the isomeric mixture, b.p. 65.1–67.3° of Fisher Scientific. Tetrahydrofuran was distilled from lithium aluminum hydride just before use. Methyllithium, obtained from Alpha Inorganics, Inc., as a 2.2 *M* solution in ether was injected by needle and syringe into the reaction vessel through a rubber septum. The volume of methyllithium solution used per millimole of substrate was the minimum volume required to convert 1 mmol *N*-benzoyldibenzylamine to its anion in >90% yield as measured by the yield of carboxylation described earlier (7) and the methyllithium solution was checked periodically in this fashion.

N-Nitroso-4-phenylpiperidine-2-carboxylic acid (3)

Method I

To a solution of *N*-nitroso-4-phenylpiperidine (**2**, m.p. 64.5–65.5° (lit. (33) 61.5–62.5°); 190 mg, 1 mmol) stirred in THF (30 ml) at −78° was added diisopropylamine (0.15 ml, 1.05 mmol) then the methyllithium solution (1 equiv.) After the solution was stirred for a period (see Table 2) at −78°, dry carbon dioxide was bubbled through it for 10 min, and it was stirred a further 10 min at −78°. The solution was quenched with moist ether (60 ml) and concentrated to a syrup which was taken up in a 5% aqueous sodium carbonate solution (30 ml). This solu-

TABLE 1. Experimental details of anion methylation

Compound	Source of RLi*	Yield of methylation (%)
DBBA	Ventron (2.2 *M* in ether)	>90
DBBA	Ventron (1.82 *M* in ether)	<50
DBBA	Foote (1.8 *M* in ether)	>90
NPP	Ventron (2.2 *M* in ether)	79
NPP	Ventron (1.82 *M* in ether)	0–25
NPP	Foote (1.82 *M* in ether)	75
NPP	Butyllithium from Ventron (1.82 *M* in hexane)	85

*RLi represents methyllithium except in last entry; method III was used throughout; DBBA, dibenzylbenzamide; NPP, *N*-nitroso-4-phenylpiperidine.

tion was washed with chloroform (3 × 20 ml), neutralized (5% HCl solution) and extracted with chloroform (3 × 30 ml). The chloroform extracts were combined, dried, and concentrated to a syrup which solidified on standing; for yield, see Table 2. The solid was recrystallized from petroleum ether and gave m.p. 120–122° (dec.).

Method II

To THF (30 ml) stirred under nitrogen at −78° was added diisopropylamine (0.165 ml, 1.15 mol), then the methyllithium solution (1 equiv.). Ten minutes later, a solution of compound **2** (1 ml of a 1 mmol/ml solution) was injected and the solution was stirred for a further period at −78° as described in Table 2. The remainder of this procedure was as in method I.

Method III

To THF (30 ml) stirred at room temperature, was added diisopropylamine (0.165 ml, 1.15 mol), then the methyllithium solution. After being stirred 5 min at room temperature, the solution was cooled to −95° and stirred for 10 min to allow temperature equilibration.

Then a solution of compound **2** (1 mmol/ml) was injected and stirring was continued for the period stated in Table 2. The remainder of this procedure is as in method I; n.m.r. of **3**: 1.40–3.10 (m, H_3, H_4, and H_5 and *anti*[9] H_6 axial), 4.05 (triplet of doublets, J's = 3.6, 12.8, 12.8 Hz, *syn* H_6 axial), 4.85–5.25 (m, *syn* and *anti* H_6 equatorial), 5.71 (d, J = 5.7 Hz, *anti* H_2 equatorial), 5.93 (d, J = 6.0 Hz, *syn* H_2 equatorial), (ratio of *syn* to *anti* is 6:4), 7.00–7.42, phenyl protons; i.r. (CCl_4), 3040, 2930, 3300–2450 br, 1723 (C=O), 1452 (NNO).

This product (**3**) (295 mg) was cleaved as described earlier (7) by bubbling dry hydrogen chloride gas through a stirred benzene solution (100 ml). The amorphous product was recrystallized from ethanol–hexane, then from ethanol to give *trans*-2-carboxy-4-phenylpiperidine hydrochloride, m.p. 230–233° (dec.).

Anal. Calcd. for $C_{12}H_{16}ClNO_2$: C, 59.63; H, 6.67; N, 5.79. Found: C, 59.48; H, 6.58; N, 5.67.

N-Nitroso-trans-2-methyl-4-phenylpiperidine (4)

The anion of **2** (1.456 g, 7.64 mmol) was generated at −95° as in method III. Then after 10 min methyl iodide (3 ml, 5 equiv.) was added and the solution was stirred 40 min at −95°, 30 min at −78°, and allowed to warm up over 15 min. It was quenched with water (0.2 ml) then concentrated to a syrup. The syrup was taken up in methylene chloride (50 ml) which was washed with water (2 × 50 ml). The combined aqueous washings were extracted with methylene chloride (30 ml) and the combined methylene chloride fractions were dried (Na_2SO_4) and concentrated. Column chromatography using hexanes – ethyl acetate (3:1) as eluent yielded pure syrup, *N*-nitroso-*trans*-2-methyl-4-phenylpiperidine (**3**), yield 1.24 g, (79%). The product crystallized on standing and was recrystallized from ethanol–water, m.p. 53–55°; i.r. (film) 3070, 3030, 3020, 2960, 2920, 2840, 1590, 1570, 1485, 1450 (NNO); n.m.r. 1.19 (d, J = 7.0 Hz, *syn* CH_3), 1.50 (d, J = 7.0 Hz, *anti* CH_3), 1.5–2.2 (complex multiplets), 2.72 (triplet of doublets, J = 4.0, 12.5, 12.5 Hz, H_6^a in *anti*), 3.11 (m, H_4), 3.86 (triplet of doublets, J = 4.0, 12.5, 12.5 Hz, H_6^a in *syn*), 4.76 (octet, J = 12.7, 2.1, 4.5 Hz, H_6^e in *syn*), 5.07 (octet, J = 13.0, 2.0, 4.5 Hz, H_6^e in *anti*), 5.41 (m, H_2^e in *syn* and *anti*), 7.08–7.42 (m, ArH).

This reaction was carried out exactly as before, except that the column chromatography was carried out rapidly at 5° instead of room temperature. The ratio of *syn* to *anti* after this process was ~75% *syn*, 25% *anti* and confirms the proton assignments in the n.m.r. spectra. After 2 days at room temperature, the ratio of *syn* to *anti* isomers at equilibrium was 45:55.

2-Methyl-4-phenyl-N-p-toluenesulfonylpiperidine

Into a solution of compound **4** (95 mg) in dry benzene (30 ml) was bubbled dry hydrogen chloride for 15 min, then dry nitrogen for 10 min. The solution was washed with a 10% NaOH solution (2 × 30 ml) which was in turn washed with methylene chloride (15 ml). The benzene and methylene chloride layers were combined, dried (Na_2SO_4), and concentrated to a syrup (80 mg). This syrup, in 2.5 ml of 10% NaOH solution and ethanol (2.5 ml) was treated with recrystallized toluenesulfonyl chloride (104 mg, 1.2 equiv.) and stirred for 4 h. The solid product **4** was removed by filtration (150 mg, 98%) and recrystallized twice from ethanol–water to give 2-methyl-4-phenyl-*N*-toluenesulfonylpiperidine (**4**), yield 110 mg, 72%, m.p. 72–74°.

Anal. Calcd. for $C_{14}H_{23}NO_2S$: C, 69.82; H, 7.04; N, 4.25. Found: C, 69.48; H, 7.06; N, 4.17.

N-Nitroso-trans-2-(hydroxydiphenylmethyl)-4-phenylpiperidine (5)

The anion was generated from **2** (380 mg, 2 mmol) by method I. After 4 min, a solution of benzophenone (455 mg, 2.5 equiv.) in THF (5 ml) was added and the reaction was stirred 1 h at −78°, then allowed to warm to room temperature over 1 h. Water was added (0.1 ml) and the reaction mixture was concentrated to dryness and taken up in methylene chloride (40 ml) which was washed with water (2 × 30 ml). The methylene chloride layer was dried (Na_2SO_4) and concentrated. Thin-layer chromatography in hexanes – ethyl acetate 2:1 showed one compound in the concentrate besides starting materials and this product was isolated using column chromatography and the same eluent; yield 505 mg, 54%. The product was recrystallized from EtOH–water and from benzene – petroleum ether (60–80°) to give a solid, m.p. 185–187°; n.m.r. (acetone-d_6) 1.6–2.3 (complex multiplets) 3.4 (m, H_4), 4.0 (H_6^a in *syn*), 4.8 (H_6^e), 5.2 (H_6^e), 6.0 (d, J = 6.5 Hz, H_2^e in *syn*), 6.38 (d, J = 6.5 Hz, H_2^e in *anti*), 7.0–7.4 (m, ArH), *syn*:*anti* ratio is 1:2.

TABLE 2. Experimental details for the formation of *N*-nitroso-4-phenylpiperidine-2-carboxylic acid

Time for anion formation (min)	Yield (%)		
	Method I	Method II	Method III
4	64, 69	63, 65	59

N-Nitroso-r-2,c-6-dimethyl-t-4-phenylpiperidine (6)

To freshly distilled THF (35 ml) was added diisopropylamine (0.25 ml, 1.15 equiv.) and methyllithium solution (1 equiv.). The solution was stirred 8 min at −78°, then a solution of **4** (306 mg) in THF (1.5 ml) was added and it was stirred a further 4 min at −78°. Methyl iodide (0.7 ml, 5 equiv.) was added and the solution stirred 2 h at −78°, then 2 h at −45°. Water (0.1 ml) was added and the solution was concentrated to dryness and taken up in methylene chloride (30 ml) which was washed with water (3 × 30 ml). The combined aqueous layers were extracted with methylene chloride and the combined methylene chloride layers were dried (Na_2SO_4) and concentrated to a syrup (351 mg). The products were separated on a column of silica gel using petroleum ether (60–80°) – ethyl acetate 5:1 as eluent. The compounds obtained were 203 mg (62%) of **6**, R_f 0.44; 85 mg (26%) of starting material R_f 0.34; and minor amounts of two slower moving impurities. The major product **6** crystallized on standing and was recrystallized from ethanol–water, m.p. 63–65°; i.r. (CCl_4) 3095, 3065, 3030, 2975, 2940, 2860, 1595, 1485, 1440 (NNO); n.m.r. described in detail in ref. 9.

N-p-Toluenesulfonyl-r-2,c-6-dimethyl-t-4-phenylpiperidine

Through a solution of **6** (65 mg) in dry benzene (20 ml) was bubbled dry hydrogen chloride for 15 min and dry nitrogen for 5 min. The benzene solution was washed with 10% NaOH solutions (2 × 20 ml) which were combined and extracted with methylene chloride. The combined methylene chloride and benzene layers were dried (Na_2SO_4) and concentrated to a syrup. The syrup in ethanol (1 ml) and 10% NaOH solution (1 ml) was treated with *p*-toluenesulfonyl chloride (65 mg, 1.5 equiv.) and stirred for 3 h. The solution was extracted with chloroform (3 × 5 ml) and the combined extracts were washed with water (5 ml) and concentrated. The product, after purification from *p*-toluenesulfonyl anhydride by preparative t.l.c. chromatography on silica gel using *p*-dioxane–hexanes, 1:5 as eluent; crystallized (27 mg) and was recrystallized twice from ethanol–water to give needles (22 mg), m.p. 96–97°.

Anal. Calcd. for $C_{20}H_{25}NO_2S$: C, 69.94; H, 7.34; N, 4.08. Found: C, 69.97; H, 7.43; N, 4.02.

Equilibration of 6

To a solution of the above compound (252 mg) in DMSO (1.5 ml) was added potassium *t*-butoxide (300 mg) and the mixture was magnetically stirred 60 h at 90° under nitrogen. Preparative t.l.c. chromatography using silica gel plates and hexanes – ethyl acetate 3:1 as eluent yielded a mixture of 150 mg, (60%) *cis*-**6** and *trans* **8** isomers. Integration of n.m.r. signals indicated that the mixture contained 74% *trans*. The following absorptions were clearly attributable to the *trans* isomer; 1.18 (d, J = 7.0 Hz, *syn* CH_3), 1.68 (3H, d, J = 6.1 Hz, *anti* CH_3), 2.99–3.46 (complex multiplet, H_4), 4.13 (12-line pattern, J = 12.3, 6.1, 3.3 Hz, H_2^a), 5.51 (octet, J = 7.1, 4.1 Hz, H_6^e), 7.04–7.40 (5H m, ArH).

Through a solution of this mixture in dry benzene (30 ml), bubbled dry hydrogen chloride for 30 min and then dry nitrogen for 5 min. The product was washed with 10% NaOH solutions (2 × 20 ml) which were, in turn, washed with methylene chloride. The combined benzene and methylene chloride layers were dried (Na_2SO_4) and concentrated to a syrup which was separated into two components using preparative t.l.c. on silica gel with cyclohexane–chloroform–diethylamine 5:4:1 as eluent.

The faster moving spot was collected from the plate, isolated (37 mg), and identified as *cis* by n.m.r. (one type CH_3 absorption). The slower moving spot (89 mg, showing two CH_3 doublets in its n.m.r.) was converted to its hydrochloride using HCl in benzene. Crystallization was induced by addition of ether. Recrystallization from ethanol–water gave 65 mg of solid, m.p. 252–254°.

Anal. Calcd. for $C_{13}H_{20}NCl$: C, 69.16; H, 8.92; N, 6.20. Found: C, 68.98; H, 8.91; N, 6.11.

Equilibration of N-Nitroso-r-2,t-6-dimethyl-C-4-phenylpiperidine 8

The above *trans* amine (40 mg) was nitrosated and subjected to the same equilibration treatment as for the *cis* isomer **6**. From the n.m.r. of the isolated mixture, it was estimated by integration that the proportion of *cis* to *trans* was 25:75.

N-Nitroso-r-2-carboxy-c-6-methyl-4-t-phenylpiperidine 7

Diisopropylamine (0.08 ml, 0.5 mmol) and methyllithium (1 equiv.) were added to freshly distilled THF stirred at −78°. After 12 min, a solution of **4** (87 mg, 0.43 mmol) in THF (0.85 ml) was added and the solution stirred a further 10 min at −78°. Dry carbon dioxide was bubbled in for 10 min and then the reaction was stirred a further 10 min at −78°, then allowed to warm to room temperature over 15 min. It was concentrated to a syrup which was taken up in 5% Na_2CO_3 solution (30 ml), which was washed wih methylene chloride (2 × 20 ml), made slightly acidic with HCl (0.5 *N*) ,and extracted with methylene chloride (3 × 20 ml). The latter methylene chloride extracts were combined, dried (Na_2SO_4) and concentrated to a yellow (30 mg, 30%) solid which was recrystallized from ethanol–water, m.p. 128–129° (dec.); n.m.r. 1.21 (d, J = 7.5 Hz, *syn* CH_3), 1.56 (d, J = 7.5 Hz, *anti* CH_3), 1.6–2.8 (unresolved m), 3.22 (m, H_4), 5.33 (br, m, H_6 *syn* and *anti*), 5.67 (d, J = 5.8 Hz, H_2^e *syn* or *anti*), 5.78 (d, J = 6.1 Hz, H_2^e), 7.26 (s, Ar H). Conversion to the amine hydrochloride gave a solid which, after three recrystallizations from ethanol–acetone, had m.p. 268–270° (dec.).

Anal. Calcd. for $C_{13}H_{18}NO_2Cl$: C, 61.06; H, 7.10; N, 5.47. Found: C, 61.23; H, 7.19; N, 5.45.

Studies of β-Diketone Complexes of Rhenium. VIII. The Reaction of β-Diketones with Chloropentacarbonylrhenium(I), and the Preparation of Complexes of the Type $Re(CO)_4(dik)$, $Re_2(CO)_6(dik)_2$, $Re_2(CO)_6Cl_2(dikH)_2$, $Re(CO)_3L(dik)$, and $Re(CO)_2(dik)L_2$ [1]

MAURICE CONRAD FREDETTE AND COLIN JAMES LYNE LOCK[2]

Institute for Materials Research, McMaster University, Hamilton, Ontario L8S 4M1

Received February 11, 1975

MAURICE CONRAD FREDETTE and COLIN JAMES LYNE LOCK. Can. J. Chem. **53**, 2481 (1975).

The reaction of β-diketones with $Re(CO)_5Cl$ gave compounds of stoichiometries $Re_2(CO)_6dik_2$ or $Re_2Cl_2(CO)_6(dikH)_2$. Reaction of the former compounds with carbon monoxide at high pressure gave $Re(CO)_4dik$, while with donor ligands such as pyridine or triphenylphosphine they gave compounds of stoichiometry $Re(CO)_3dikL$. With triphenylphosphine further reaction gave $Re(CO)_2dik[P(C_6H_5)_3]_2$. Compounds were investigated by infrared spectroscopy and mass spectroscopy, and a Cotton–Kraihanzel analysis was made of the carbonyl vibrational spectra in order to get an estimate of the π-acceptor ability of the β-ketoenolate ligands.

MAURICE CONRAD FREDETTE et COLIN JAMES LYNE LOCK. Can. J. Chem. **53**, 2481 (1975).

La réaction des β-dicétones avec $Re(CO)_5Cl$ donne des composés de stoechiométries $Re(CO)_6dik_2$ ou $Re_2Cl_2(CO)_6(dikH)_2$. La réaction des composés précédents avec le monoxyde de carbone à pression élevée donne $Re(CO)_4dik$, alors qu'avec un ligand donneur comme la pyridine ou la triphénylphosphine les composés précédents conduisent à des produits de stoechiométrie $Re(CO)_3dikL$. Avec la triphénylphospine, une réaction ultérieure conduit au composé $Re(CO)_2dik[P(C_6H_5)_3]_2$. Ces composés ont été étudiés par spectroscopie infrarouge et par spectrométrie de masse. Une analyse Cotton–Kraihanzel a été faite sur le spectre vibratoire du carbonyle dans le but d'évaluer la propriété π-accepteur des ligands β-cétoénolate.

[Traduit par le journal]

Introduction

Because of the difficulty (1) of obtaining $Re(acac)_3$ by the published method (2, 3) we considered the possibility of obtaining the compound by the reaction of $Re_2(CO)_{10}$ and acetylacetone. Molybdenum, chromium, and iron trisacetylacetonates had been prepared from the simple carbonyls (4, 5). Little if any reaction was observed, however, between $Re_2(CO)_{10}$ and acetylacetone up to 373 K and so further reactions were attempted with diketones and $Re(CO)_5Cl$. The desired product, $Re(acac)_3$, was never obtained, but two series of compounds were isolated, which were clearly different in type from $Mn(CO)_4hfac$ isolated from the reaction of $Mn(CO)_5Cl$ and hexafluoroacetylacetone (6). In this paper we describe the preparation and physical properties of the two series of compounds and some of their chemical reactions.

Experiments

Analyses for carbon, hydrogen, nitrogen, fluorine, chlorine, and sulfur were done by Galbraith Laboratories Inc., Knoxville, Tennessee and A.B. Gygli, Toronto, Ontario. Rough rhenium and chlorine percentages and accurate rhenium–chlorine atom ratios were determined by neutron activation analysis (7). Infrared spectra were recorded for solid samples ground into a mull with Nujol. The Nujol had been dried by refluxing with phosphorus pentoxide followed by vacuum distillation. The mull samples were mounted between potassium bromide or polyethylene plates and spectra were recorded on Perkin–Elmer 337, 521, and 301 spectrometers. Magnetic susceptibility measurements were carried out on 10 cm length powdered sample packed into 3 mm (o.d.) tubes. Calibrations were made using mercury–thiocyanatecobaltate. The measurements were made by the Gouy method and the apparatus has been described

[1]The following abbreviations are used in this paper: L, monodentate ligand; py, pyridine, C_5H_5N; Ph, phenyl, $\cdot C_6H_5$; dik, β-ketoenolate anion; dikH, corresponding neutral β-diketone or β-ketoenol tautomer; acac, pentane-2,4-dionate anion, $C_5H_7O_2^-$; tfac, 1,1,1-trifluoropentane-2,4-dionate anion, $C_5H_4F_3O_2^-$; hfac, 1,1,1,5,5,5-hexafluoropentane-2,4-dionate anion; ttfa, 4,4,4-trifluoro-1-thienylbutane-1,3-dionate anion, $C_8H_4F_3SO_2^-$; tfba, 4,4,4-trifluoro-1-phenylbutane-1,3-dionate anion, $C_{10}H_6F_3O_2^-$; bam, 1-phenylbutane-1,3-dionate anion, $C_{10}H_9O_2^-$; dbm, dibenzoylmethanate anion, $C_{15}H_{11}O_2^-$.

previously (8). As all samples were diamagnetic, or had very low paramagnetism, measurements were made only at 296 and 77 K. Corrections for the diamagnetism of the ligand were taken from Selwood (9) and Foëx *et al.* (10). The value for Re(I) was obtained by comparison with other metals and extrapolation of data for other rhenium oxidation states and was assumed to be -56×10^{-6} cm^3 mol^{-1}. Mass spectra were recorded on a Consolidated Electrodynamics Corp. Model 21-110B instrument. All solvents and reagents used were reagent grade and were not purified further.

Yields are not reported for the reactions described below as they varied from one experiment to the next. Some unreacted $Re(CO)_5Cl$ was usually recovered from each preparation in which it was used as a starting material. Yields based on the amount of $Re(CO)_5Cl$ which had reacted were usually at least 50%. Derivatives made by further reaction of new compounds reported here usually had yields of about 80%. Analyses and melting points of new compounds are given in Table 1.

Bis(μ-O-pentane-2,4-dionato)tricarbonylrhenium(I)) (1)

Chloropentacarbonylrhenium(I) (1 mmol) and acetylacetone (3 mmol) were refluxed in benzene (~75 ml) for 2 weeks. The pale yellow solution gradually turned dark brown. Evaporation of the solvent (~20°, ~15 mm), followed by addition of ether (~100 ml) and filtration, served to remove any unreacted chloropentacarbonylrhenium(I). The filtrate was evaporated and the residues were dissolved in the minimum amount of chloroform or ether. Addition of enough petroleum ether (30–60°) to cause cloudiness produced a brown powder which was collected on a filter and recrystallized from dichloromethane or ether, giving small white needles.

Bis(μ-O-1,3-diphenylpropane-1,3-dionato)tricarbonylrhenium(I)) (2)

Chloropentacarbonylrhenium(I) (1 mmol) and dibenzoylmethane (3 mmol) were refluxed for 3–4 weeks in benzene (~75 ml). Bright orange crystals of the product were removed on a filter and washed with hot benzene. More product was sometimes obtained by heating the dried residues *in vacuo* with a heat lamp for 2–3 h and then washing the melt with hot benzene.

Bis(μ-O-4,4,4-trifluoro-1-phenyl-1,3-butanedionato)tricarbonylrhenium(I)) (3)

Chloropentacarbonylrhenium(I) (0.5 g) and trifluorobenzoylacetone (1 g) were refluxed in benzene (50 ml) for 1 week. The solution was cooled, filtered, and evaporated to dryness. The residues were dissolved in ether and the solution was filtered and evaporated to dryness. These procedures served to remove any unreacted $Re(CO)_5Cl$. The brown residues from the ether solution were stirred with a minimum amount of chloroform or dichloromethane for a few seconds. A brown solution was formed as the residues dissolved, leaving the yellow product as a powder in the bottom of the flask. The solid yellow product was collected on a filter as rapidly as possible because it would also dissolve within a few minutes. The brown filtrate usually contained a fair amount of the yellow product which had dissolved in the chloroform. Thus, the filtrate could be evaporated to dryness to give a brown residue from which more yellow solid could be obtained, by repeating the process of stirring with a minimum amount of solvent and filtering.

Bis(μ-O-4,4,4-trifluoro-1-thienylbutane-1,3-dionato)tricarbonylrhenium(I)) (4)

This yellow compound was prepared by the same method as **3** using chloropentacarbonylrhenium(I) and thenoyltrifluoroacetone as starting materials.

Bis(μ-O-1,1,1-trifluoropentane-2,4-dionato)tricarbonylrhenium(I)) (5)

This yellow compound was prepared by the same method as (**1**) using chloropentacarbonylrhenium(I) and trifluoroacetylacetone as starting materials.

Bis(μ-O-1,1,1,5,5,5-hexafluoro-2,4-pentanedionato)tricarbonylrhenium(I))

This yellow-orange compound was prepared by the same method as **1** using chloropentacarbonylrhenium(I) and hexafluoroacetylacetone as starting materials.

Bis(μ-chlorotricarbonyl(1-phenyl-1-hydroxobut-1-ene-3-one)rhenium(I))

Chloropentacarbonylrhenium(I) (2 g) and benzoylacetone (1.5 g) were refluxed in benzene (~150 ml) for 1 d. The pale yellow solution gradually turned green. The solution was evaporated to near dryness, dichloromethane (20 ml) was added and the solution was filtered, and the filtrate evaporated to near dryness. A mixture (1:1 v/v) of dichloromethane and petroleum ether (40–60°) was added and the resulting solution allowed to evaporate slowly over a few days to give a yellow-green powder. The powder was recrystallized from dichloromethane – petroleum ether to give crystals of the title compound which were usually six-sided plates or occasionally rhomb-shaped needles.

Bis(μ-chlorotricarbonyl(2-hydroxopent-2-ene-4-one)rhenium(I))

Chloropentacarbonylrhenium(I) (1 mmol) and acetylacetone (3 mmol) were refluxed in benzene (~75 ml) for 5 h and the white product was filtered off. We have been unable to repeat this preparation.

Pentane-2,4-dionatotetracarbonylrhenium(I) (6)

Compound **1** (0.5 g) was sealed in a stainless steel pressure vessel with 200 atm of carbon monoxide and was heated to 150 °C for 24 h. The pressure vessel was cooled, dismantled, and washed out with ether. Evaporation of the ether gave the white product.

1,3-Diphenylpropane-1,3-dionatotetracarbonylrhenium(I)

The green-yellow compound was prepared similarly to **6** using compound **2** as starting material.

4,4,4-Trifluoro-1-phenyl-1,3-butanedionatotetracarbonylrhenium(I)

The green-yellow compound was prepared similarly to **6** using compound **3** as starting material.

4,4,4-Trifluoro-1-thienylbutane-1,3-dionatotetracarbonylrhenium(I)

The green-yellow compound was prepared similarly to **6** using compound **4** as starting material.

1,1,1-Trifluoropentane-2,4-dionatotetracarbonylrhenium(I)

This pale yellow compound was prepared similarly to **6** using compound **5** as starting material.

1,1,1,5,5,5-Hexafluoro-2,4-pentanedionatotetracarbonylrhenium(I)

Chloropentacarbonylrhenium(I) (1 mmol) and hexa-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

fluoroacetylacetone (3 mmol) were refluxed in benzene (~75 ml) for 12 h. The resulting solution was then treated as for compound **1** giving yellow crystals of the product (0.2 g).

1,3-Diphenylpropane-1,3-dionatotricarbonylpyridine-rhenium(I)

Compound **2** and an excess of pyridine (1 ml) were refluxed in benzene (50 ml). The orange solution turned yellow-green overnight. The solution was then evaporated to dryness. The residues were dissolved in methanol and petroleum ether (30–60°), producing an orange solution. Partial evaporation and cooling of this solution produced orange crystals which were recrystallized from ether and petroleum ether (30–60°).

1,3-Diphenylpropane-1,3-dionatotricarbonyltriphenyl-phosphinerhenium(I)

Stoichiometric quantities of compound **2** (0.5 g) and triphenylphosphine (0.27 g) were refluxed in benzene (100 ml) for 1½ h. The hot solution was filtered and then evaporated to dryness. The residues were washed with methanol and the impure solid orange product was captured on a filter and washed with ether. These crystals were dissolved in acetone and the solution was filtered. The filtrate was allowed to evaporate slowly over 2–3 d and orange crystals of the pure product were obtained.

1,1,1-Trifluoropentane-2,4-dionatodicarbonylbis(triphenylphosphine)rhenium(I)

Compound **5** (0.5 g) and an excess of triphenylphosphine (1.0 g) were refluxed in benzene (50 ml). The green solution turned yellow-green overnight. The solution was then evaporated to dryness. The residues were dissolved in methanol and petroleum ether (30–60°). Partial evaporation and cooling of this solution produced orange crystals of the product. The product was recrystallized from ether.

1,3-Diphenylpropane-1,3-dionatodicarbonylbis(triphenylphosphine)rhenium(I)

Compound **2** (0.5 g) and an excess of triphenylphosphine (1.0 g) were refluxed in benzene (50 ml) for 12 h. The orange solution turned orange-red within the first 2 h. The solution wss evaporated to dryness and the residues were washed with methanol, which left orange crystals of the product in the bottom of the flask. These crystals were collected on a filter and washed with ether.

Other Reactions

$Re_2(CO)_6Cl_2(bamH)_2$ (0.5 g) was sealed in a 1 l bomb with 200 atm of carbon monoxide and was heated to 150 °C for 24 h. The products were identified by infrared spectroscopy and were $(Re(CO)_4Cl)_2$ and bamH.

$$Re_2(CO)_6Cl_2(bamH)_2 \xrightarrow{2CO} Re_2(CO)_8Cl_2 + 2bamH$$

$Re_2(CO)_6Cl_2(bamH)_2$ (0.5 g) was refluxed in benzene (50 ml) with sodium carbonate (2.0 g) for 3 d in an attempt to remove HCl and form $Re_2(CO)_6bam_2$. The infrared spectrum of the dried residues showed that no change had taken place.

$Re_2(CO)_6Cl_2(bamH)_2$ was heated *in vacuo* up to 135 °C in a sublimation apparatus fitted with a water cooled cold finger. Initially, some bamH condensed on the cold finger. Later, some light yellow unidentified species condensed on the cold finger; it showed some C≡O and various other bands in an infrared spectrum. A brown glass was left in the bottom of the sublime and this could be purified to give mainly the original $Re_2(CO)_6Cl_2(bamH)_2$. No $Re_2(CO)_6(bam)_2$ was formed.

$Re_2(CO)_6(dbm)_2$ (0.5 g) was sealed in a bomb with 200 atm of nitrogen and was heated to 150 °C for 24 h. $Re_2(CO)_6(dbm)_2$ was recovered unchanged.

$Re(CO)_4dbm$ (0.5 g) was sealed in a bomb with 200 atm of nitrogen and was heated to 150 °C for 24 h. $Re_2(CO)_6(dbm)_2$ was the only product found.

$Re(CO)_2(dbm)(Ph_3P)_2$ was heated to 185 °C *in vacuo* in a sublimation apparatus fitted with a water cooled cold finger. The residue in the bottom was mainly $Re(CO)_2(dbm)(Ph_3P)_2$ and there were traces everywhere in the apparatus of other decomposition products, but it was not possible to obtain enough sample to identify them.

$[Ph_2SRe(CO)_3Cl]_2$ and $[(Ph—S—CH_2—Ph)Re(CO)_3Cl]_2$ were prepared by Hieber's method (ref. 11 and references therein). $[Ph_2SRe(CO)_3Cl]_2$ was heated to 185 °C *in vacuo* in a sublimation apparatus but no $[Re(CO)_3Cl]_x$ (11) could be isolated. The starting product was found unchanged in all parts of the apparatus. $[(Ph—S—CH_2—Ph)Re(CO)_3Cl]_2$ was heated to 230 °C *in vacuo* in a sublimation apparatus. Again, no $[Re(CO)_3Cl]_x$ was formed and the starting material was recovered everywhere in the sublimation apparatus. $[Ph_2SRe(CO)_3Cl]_2$ was melted at 140 °C *in vacuo* overnight together with some bamH. Only the starting products were recovered.

Results and Discussion

Two types of compounds could be obtained by the reaction of $Re(CO)_5Cl$ and a diketone in benzene at elevated temperatures. Six were of stoichiometry $Re_2(CO)_6dik_2$ and two of stoichiometry $Re_2Cl_2(CO)_6(dikH)_2$. X-Ray diffraction studies have shown the structures to be those in Fig. 1 (12, 13).

The structure of $Re_2(CO)_6(dik)_2$ was similar to that of $(Re(CO)_4Cl)_2$ if one end of the β-ketoenolate group replaced the halogen atom and the other end a carbonyl group. The structural similarity suggested it should be possible to cleave the bridge bonds with either carbon monoxide or donor ligands as can be done for $[Re(CO)_4X]_2$ (14).

$$[Re(CO)_4X]_2 \underset{-2CO}{\overset{+2CO}{\rightleftharpoons}} 2Re(CO)_5Cl$$

$$[Re(CO)_4X]_2 \xrightarrow{2L} 2L\ Re(CO)_4X$$

In the second reaction it was possible to proceed further and replace another CO group to give $ReL_2(CO)_3X$.

A series of $Re(CO)_4dik$ compounds was prepared by the action of carbon monoxide on the dimers at high pressure. The $Re(CO)_4dik$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

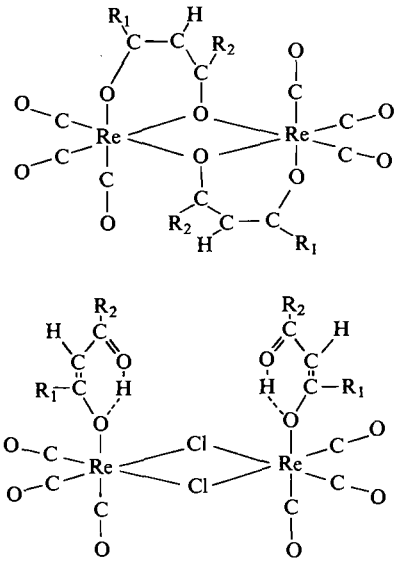

FIG. 1. The molecular structures of $Re_2(CO)_6dik_2$ and $Re_2(CO)_6Cl_2(dikH)_2$.

complexes were relatively unstable and readily lost CO (complete decomposition in 15 min in boiling benzene) to regenerate the dimers. The infrared spectra were very similar, in the carbonyl region, to $Mn(CO)_4hfac$ (6). Ligands such as triphenylphosphine and pyridine readily cleaved the dimer giving monomeric $Re(CO)_3dikL$, and in the case of triphenylphosphine it was possible to displace a CO group to give $Re(CO)_2dik(PPh_3)_2$. For donor oxygen and phosphine ligands it was relatively difficult to prepare metal complexes with less than three carbonyl groups using displacement methods, because the relatively poor π-acceptor ligands added tend to strengthen the M—CO bond for the remaining groups (15). The ease with which one could make $Re(CO)_2dikL_2$ suggests that our picture of dik being equivalent to a halogen and a CO group is qualitatively correct (*vide infra*). Despite the ease of reaction with CO and donor ligands it was not possible to react any of the compounds with dinitrogen.

The question arose early in this work as to why we obtained the dimer compounds, $Re_2(CO)_6(dik)_2$. Under the reaction conditions (refluxing benzene for almost 2 weeks) two likely pathways are

$$[1]\quad 2Re(CO)_5Cl + 2\,dikH \xrightarrow{\text{slow}} 2Re(CO)_4dik + 2HCl$$
$$\downarrow \text{fast}$$
$$Re_2(CO)_6dik_2 + 2CO$$

$$[2]\quad 2Re(CO)_5Cl \xrightarrow{12\,h} [Re(CO)_4Cl]_2 + 2CO$$
$$\downarrow 2dikH$$
$$Re_2Cl_2(CO)_6(dikH)_2$$
$$\downarrow$$
$$Re_2(CO)_6(dik)_2 + 2HCl$$

The reaction of $Mn(CO)_5Cl$ and hfacH gave only $Mn(CO)_4hfac$ (6) which is similar to the first step in reaction 1. Very careful reactions conducted for short times allowed isolation of small amounts of $Re(CO)_4hfac$, although no similar compound could be isolated for any other β-diketone. However, other $Re(CO)_4dik$ compounds lost CO very easily in boiling benzene to give the dimeric compounds and thus [1] is clearly an acceptable pathway. One cannot rule out pathway [2] because we have shown that the first step occurred in 12 h in boiling benzene and also that $[Re(CO)_4Cl]_2$ gave $Re_2(CO)_6(dik)_2$ when reacted with a β-diketone. We have not established the intermediate step since the only chloro compound we have fully characterized, $Re_2(CO)_6Cl_2(bamH)_2$, does not undergo decomposition to $Re_2(CO)_6(bam)_2$.

It is surprising that acetylacetone and dibenzoylmethane gave isolable complexes of the type $Re_2(CO)_6dik_2$ whereas benzoylacetylmethane did not. The only suggestion we can offer is based on the structures of the two types of compound. In the $Re_2(CO)_6dik_2$ compounds the two β-diketone groups were *trans* with respect to the Re—Re axis, whereas in $Re_2Cl_2(CO)_6(bamH)_2$ the two diketone groups were *cis*. It is assumed that the conversion of the intermediate $Re_2Cl_2(CO)_6(dikH)_2$ to $Re_2(CO)_6dik_2$ proceeded as shown in Fig. 2. HCl elimination was followed by the oxygen atom coming into the bridging position. To get the observed $Re_2(CO)_6dik_2$ structure the two β-ketoenol groups would have to be arranged *trans* in the $ReCl_2(CO)_6(dikH)_2$ compound.

We suggest that the reason that the *cis* complexes did not eliminate HCl, even in the presence of Na_2CO_3, was because of steric hindrance. A calculation, assuming the β-diketone–

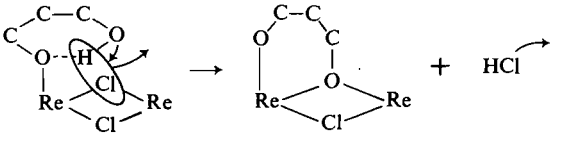

FIG. 2. A possible mechanism for conversion of *trans*-$Re_2(CO)_6Cl_2(dikH)_2$ to $Re_2(CO)_6dik_2$.

TABLE 2. Magnetic susceptibility data

Compound	χ_m(corr) ($\times 10^{-6}$) (c.g.s.u.) 77 K	296 K
$Re_2(CO)_6(bamH)_2Cl_2$	90	−70
$Re_2(CO)_6(dbm)_2$	−46	−122

β-diketone contacts were greater than twice the carbon van der Waals radius, and based on the geometries determined previously (12, 13), showed that for *cis*-$Re_2(CO)_6dik_2$ the β-diketone plane would be bent about 55° from the OReO plane (*cf.* the previous highest value of 34° (12)) and thus would make the ReOC angles about 100 and 80°, far smaller than any previously reported value for MOC angles in metal β-ketoenolate complexes.

Both series of compounds, $Re_2(CO)_6dik_2$ and $Re_2(CO)_6Cl_2(dikH)_2$, were diamagnetic, as would be expected for Re(I) complexes with roughly octahedral geometry and high field ligands. Typical results are shown in Table 2.

In retrospect, the spectroscopic data recorded for the compounds were satisfactorily explained in terms of their structures, although the data did not provide a sufficient basis for predicting the structures. The infrared spectra are reported in Table 3.[3] The compounds of the type $Re_2(CO)_6dik_2$ gave spectra in the carbonyl region which were very similar to those reported for $Repy_2(CO)_3Cl$ (14) (2041, 1934, 1891 cm^{-1}). Thus, it appears there was insignificant vibrational coupling between the C—O groups on each half of the dimer. In the $\nu_{C=C}$ and $\nu_{C=O}$ region for the β-ketoenolate group, two or three bands of varying intensity were observed for each compound. Fluorination of the ligand caused a shift to higher frequency of the highest band and a marked drop in intensity of all the bands in this region, as was observed by Nakamoto *et al.* for copper complexes (16).

The carbonyl region of the spectrum of $Re_2(CO)_6Cl_2(bamH)_2$ was expected to be similar to those of the above compounds since this molecule also contains two sets of 1,2,3-carbonyl groups. Bands were observed at similar frequencies, but there was evidence of coupling, since two of the bands are split. It is noteworthy that $Re_2(CO)_6Cl_2(bamH)_2$ contained two *neutral* ketoenol groups and yet there was no really significant difference in the spectrum in the 1500–1600 cm^{-1} region compared to those recorded for the $Re_2(CO)_6(dik)_2$ compounds. Indeed, an examination of the complete spectrum down to 250 cm^{-1} and a comparison with $Re_2(CO)_6(dbm)_2$ and $Re_2(CO)_6(acac)_2$ showed very little difference. The only differences were that for $Re_2(CO)_6Cl_2(bamH)_2$ the band caused by the Re—Cl stretch was seen at 266 cm^{-1} and no bands were observed in the 900–1000 cm^{-1} region. Most β-ketoenolate complexes show at least one band in this region, in particular a medium weak band at 930 ± 10 cm^{-1} (17–19).

Because the β-ketoenolate ligand must occupy two *cis* positions we expected the $Re(CO)_4dik$ complexes to have spectra in the carbonyl region very similar to $[Re(CO)_4Cl_2]_2$ (2114w, 2032s, 2000m, 1954m cm^{-1}). Four bands were observed for $Re(CO)_4dik$ but in general the three lowest energy bands were about 10–20 cm^{-1} lower than the corresponding bands in $[Re(CO)_4Cl]_2$. The complexes of the type $Re(CO)_3dikL$ (L = py, Ph_3P) had CO spectra very similar to $Repy_2(CO)_3I$ although in this case the upper bands were ~30 cm^{-1}, and the second bands ~15 cm^{-1}, lower than the corresponding bands in $Repy_2(CO)_3I$. The complexes of the type $Re(CO)_2dik(PPh_3)_2$ showed two strong bands in the CO region, which was consistent with a *cis* arrangement of the carbonyl ligands.

We have analyzed the carbonyl region of the spectra of the above compounds by the method of Cotton and Kraihanzel (20–22) and the results are summarized in Table 4. Comparison of the force constants for the $(Re(CO)_3dik)_2$ complexes with the results listed by Cotton (22) for *cis*-$L_3M(CO)_3$ showed that the β-ketoenolate ligand was about equivalent to phosphites or chlorophosphines; in other words it is a fair π-acceptor. The highest stretch force constants and lowest K_i (postulated by Cotton to indicate a ligand with good π-acceptor properties) were observed for the hexafluoroacetylacetone complex, which is what would be expected, since the electronegative fluorine atoms should tend to pull electron density off the metal atom. These results show the difference between the β-keto-

[3]Only the sections of the spectra discussed herein are published in Table 3. The full set of spectral data (Table 3*a*) is available at a nominal charge from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

enolate ion and other oxygen ligands which have essentially no π-acceptor ability (22).

The only acceptable assignment of bands for the $Re(CO)_4dik$ complexes was similar to that made by Cotton for the spectra of $[Mn(CO)_4X]_2$ complexes, rather than that proposed for *cis*-$L_2M(CO)_4$ (22). Comparison of the derived force constants with those for *cis*-$L_2M(CO)_4$ again showed that the β-ketoenolate ligand was equivalent to phosphite ligands or chlorophosphines. Again the hexafluoroacetylacetone ligand showed the smallest value of K_i, and K_2 was significantly larger than other values although K_1 was comparable. In this case however the agreement between the calculated and observed wave numbers of the bands most sensitive to K_1 was not very good.

The mass spectra of selected compounds are

shown in Tables 5 and 6. The main decomposition pathway of the $Re_2(CO)_6dik_2$ compounds appears to be the splitting of the dimer to give the five coordinate $Re(CO)_3dik^+$ fragment. Subsequent loss of carbonyl groups gave fragments of the type $Re(CO)_ndik^+$ with the most stable fragment having $n = 0$. For the more volatile complexes dimeric fragments of the type $Re_2(CO)_mdik_2^+$ were observed, corresponding to the loss of carbonyl groups, but for the dibenzoylmethane complex the highest peak observed in this series was when $m = 0$. Only for the acetylacetone complex was there any sign of fragmentation in which both diketone groups remain on one metal atom ($Redik_2^+$).

The mass spectra of complexes of the type $Re(CO)_3dikL$ showed some contrast depending on the type of ligand. When L was triphenylphosphine the fragmentation pattern could be explained entirely by the loss of CO groups in the series $Re(CO)_ndikL^+$, with $n = 0$ being the most stable fragment. When L is pyridine, however, two series were obtained. The series, $Re(CO)_ndik^+$, which involved loss of pyridine and CO groups had about four times the intensity of the $Re(CO)_ndikpy^+$ series which involved loss of CO groups only. Thus pyridine was more readily lost than carbon monoxide.

The spectrum of $Re(CO)_4hfac$, the only diketone complex of this stoichiometry which could be volatilized without decomposition to the dimer, was relatively complex. A comparison of the peaks of stoichiometry $Re(CO)_ndik^+$ for $Re_2(CO)_6tfac$ and $Re(CO)_4hfac$, showed similar intensities, suggesting the ease with which carbonyl groups were lost was similar. The spectrum of $Re(CO)_4hfac$ was much richer in fragments which involved decomposition of the diketone ligand. A comparison with the spectrum of $Re(hfac)_3$ (1) showed considerable differences in intensity for corresponding peaks. Although most of the peaks observed for $Re(CO)_4hfac$ can be explained in terms of the decomposition pathway

Studies on Hydrogen–Oxygen Systems in the Electrical Discharge. VII. Deuterium Isotope Effects in the Chemistry of the Hydrogen Polyoxides

JOSÉ L. ARNAU[1] AND PAUL A. GIGUÈRE

Département de Chimie, Université Laval, Québec, Québec G1K 7P4

Received February 24, 1975

JOSÉ L. ARNAU and PAUL A. GIGUÈRE. Can. J. Chem. **53**, 2490 (1975).

The kinetics of oxygen evolution on warming the trapped products (at −196 °C) from water or hydrogen peroxide vapor dissociated in a glow discharge were studied by the manometric method. Under closely controlled conditions it was possible to distinguish clearly the decomposition of the two intermediates, H_2O_3 and H_2O_4. The latter begins to decompose measurably following crystallization of the glassy solid at about −115°; the trioxide decomposes readily between −50 and −35°. Typically, the yields of H_2O_3 from dissociated water vapor were of the order of 3 to 5 mol%; those of H_2O_4, only about one-tenth as much. Varying the distance between the microwave discharge and the cold trap was found to affect differently the yields of the various products. Those of water and peroxide showed a simple, direct correlation; the minor constituents H_2O_3 and H_2O_4 followed entirely different patterns. Only a small fraction of the peroxide is formed via the H_2O_4 intermediate in these systems. Less water, and more of the higher oxides, were obtained from dissociated hydrogen peroxide than from water vapor.

The deuterated systems showed some unusual isotope effects. The yields of D_2O_3 were always higher (up to twice and even more) than those of H_2O_3 under similar conditions. The other products showed little or no such effect, except for occluded oxygen and ozone which decreased by about half. Finally, the deuterium polyoxides decompose at slightly higher temperatures (10 to 15°) than their hydrogen analogs. Mechanisms are proposed for the formation and decomposition of the polyoxides.

JOSÉ L. ARNAU et PAUL A. GIGUÈRE. Can. J. Chem. **53**, 2490 (1975).

On a étudié le dégagement d'oxygène au réchauffement des produits piégés (à −196 °C) de la vapeur d'eau ou de peroxyde d'hydrogène dissociée dans une décharge électrique. On a pu ainsi distinguer nettement entre les deux intermédiaires métastables, H_2O_3 et H_2O_4. La décomposition de ce dernier commence avec la cristallisation du solide vitreux vers −115 °C; vient ensuite celle du trioxyde entre −50 et −35 °C. Les rendements en H_2O_3 à partir de la vapeur d'eau dissociée sont de l'ordre de 3 à 5% (mol), et ceux en H_2O_4, environ dix fois moindres. Par ailleurs, les rendements de tous les produits piégés varient différemment selon la distance entre la décharge microonde et le piège froid. Ainsi, le peroxyde d'hydrogène croît d'abord jusqu'à un maximum, puis décroît régulièrement; pour l'eau, c'est l'inverse. Les constituants mineurs, H_2O_3 et H_2O_4, se comportent tout autrement. On en conclut qu'une très faible fraction seulement du peroxyde formé dans ces systèmes provient du tétroxyde. Le peroxyde d'hydrogène dissocié donne moins d'eau et plus de polyoxydes que la vapeur d'eau.

Les systèmes deutériés présentent des effets isotopiques remarquables. Ainsi les rendements en D_2O_3 sont toujours plus forts (jusqu'à deux fois et même davantage) que ceux en H_2O_3 dans les mêmes conditions. Les autres produits ne montrent pas ou peu d'effet semblable, sauf l'oxygène et l'ozone occlus qui sont à moitié moins abondants. Les polyoxydes de deutérium se décomposent à des températures un peu plus élevées (de 10 à 15 °C) que ceux d'hydrogène. On propose des mécanismes pour la formation et la décomposition des polyoxydes.

Introduction

In contrast with the thermal reaction between hydrogen and oxygen the reaction mechanism in electrically dissociated water vapor is not very well understood. Our knowledge of such fundamental questions as the composition of the dissociated vapor, its evolution downstream, and the surface recombination of atoms and radicals, is rather deductive and sketchy. One valid approach to that problem is the study of the products formed on quick freezing at low enough temperature (liquid N_2). A variety of physicochemical methods have been applied to that effect, particularly over the last two decades. For an exhaustive review up to 1968, *cf.* ref. 1. Following the spectroscopic identification of the polyoxides, H_2O_3 and H_2O_4, as metastable intermediates in these systems (2–4), it seemed appropriate to reinterpret and supplement the

existing data. Unexpectedly, this study has brought forth a remarkable deuterium isotope effect in the formation of the trioxide. It is now clear why early attempts to detect the polyoxides by infrared spectroscopy remained fruitless until deuterated systems were investigated.

Experimental

The discharge-flow system was essentially the same as before (5), except for a larger capacity vacuum system featuring a three-stage mercury diffusion pump (Leybold) with 45 l s^{-1} maximum capacity around 0.1 Torr (6). A large, spherical-shape, liquid nitrogen trap prevented back-streaming of mercury vapor. The sample of distilled water or peroxide was held in a 20 ml glass bulb fitted with a tiny O-ring joint for precise weighing. Its temperature was kept constant, *viz.* near 0 °C for water, and at room temperature for the peroxide (99% H_2O_2, ~95% D_2O_2). A Teflon-plug stopcock (Quickfit, Rotaflo) was used to control the rate of vapor flow. The pressure in the discharge tube was kept at about 0.2 Torr, which, from previous workers' (7) and our own experience, is the most suitable for a microwave discharge. It was monitored near the vapor inlet point by means of a Barocell Electronic Manometer, type 1033 (Datametrics Inc.), and a pressure sensor with three full-range scales: 1, 3, and 10 Torr. This instrument gave continuous readings, unaffected by the glow discharge nearby. It also served to follow the oxygen evolution from the condensed products on warming.

The discharge tube of Pyrex glass, 12 mm o.d., was sealed to the inlet stopcock, and connected through a taper ground joint to the cold trap. The latter, 12 cm long and 4 cm o.d. of the conventional concentric tube type, was made of thin-wall glass tubing for more precise weighing of the residue (to a few percent). The dissociated vapor stream entered through the central tube to give a uniform glassy deposit at the bottom of the trap. This arrangement was found to be preferable for a good separation of the various decomposition steps. Furthermore, it made possible a faster warming rate, (about 3 deg min^{-1}) than in previous studies (8, 9). In the reverse arrangement, condensation on the outer wall of the trap led to fractionation of the products, and an irregular deposit, even with a constant level device for liquid nitrogen. One disadvantage was that the distance from the discharge zone to the cold surface could not be reduced below a certain minimum, *viz.* 35 cm.

A typical run lasted 1 h, during which some 20 to 30 mmol of water (or half as much of peroxide) were dissociated in a microwave discharge (10) of 100 W. To minimize the effect of surface disintegration of the discharge tube, or "sputtering", a phenomenon previously described (5, 11), the discharge was always run blank for about 1 h before cooling the small trap with liquid nitrogen. Since the glassy deposit was only 0.1 mm thick on the average, the various reactions taking place therein did not affect noticeably the rate of warming. The temperature during the warming process was followed by means of a tiny copper–constantan thermocouple cemented to the bottom of the glass trap, and connected to a strip-chart recorder. The peroxide concentration in the residue was determined, to within 0.2%, from the refractive index.

Results

One major difficulty with these systems is the poor reproducibility of the data (1), due mostly to the important role of surface reactions. Although particular attention was paid this time to all possible variables, still the above mentioned "sputtering" effect, due to bombardment by the highly excited hydrogen atoms, caused some slight drift of the results for successive runs. With a different discharge tube, the results varied somewhat, but they always showed the same general trends.

Kinetics Curves

The oxygen evolution curves in Fig. 1 have been normalized to the same amount of input material, *viz.* 30 mmol of O_2 per hour, for comparison purposes. In the hydrogen systems, the two main steps reported by previous workers (9, 11) were always clearly distinguishable. A novel feature was the small maximum around −100°, following crystallization of the glassy deposit (12). Although always present, this minor feature showed poor reproducibility. In particular, it seemed very sensitive to surface conditions in the discharge tube. In spite of this, its relative intensity appeared on the average, to be at least twice as large in dissociated peroxide as in water vapor, and likewise in hydrogen as in deuterium systems. On the whole, these are the same characteristics as we observed before for the Raman bands of occluded ozone and molecular oxygen (13). Accordingly, the first minute evolution of gas is ascribed to outgassing of these two

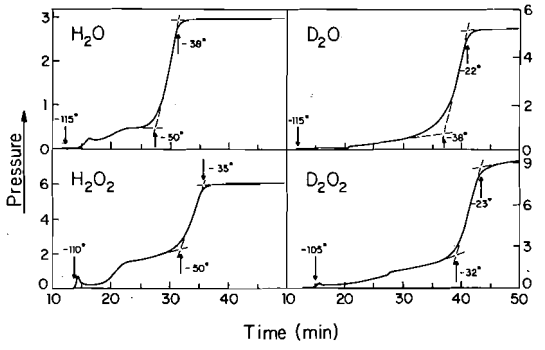

FIG. 1. Kinetics of oxygen evolution on warming the condensed products from various dissociated systems. Pressures in the same arbitrary unit throughout. (Note the different ordinate scale in each case.)

TABLE 1. Typical composition of the products condensed from various dissociated systems

System	Product	Mol%	System	Product	Mol%
H_2O	H_2O	52	D_2O	D_2O	47
	H_2O_2	42		D_2O_2	43
	H_2O_3	5		D_2O_3	8
	H_2O_4	~0.6		D_2O_4	~0.6
	$O_2 + O_3$	~0.4		$O_2 + O_3$	~0.2
	O_2 (total)*	105		O_2 (total)*	110
	H_2 (total)*	66		D_2 (total)*	70
H_2O_2	H_2O	46	D_2O_2	D_2O	41
	H_2O_2	40		D_2O_2	40
	H_2O_3	9		D_2O_3	16
	H_2O_4	~3		D_2O_4	~2.5
	$O_2 + O_3$	~1.5		$O_2 + O_3$	~0.5
	O_2 (total)*	82		O_2 (total)*	83
	H_2 (total)*	98		D_2 (total)*	97

*Percent of the O_2 and H_2 (or D_2) input accounted for in the condensed products.

species. Incidentally, ozone had previously been detected by smell in the gas given off by the condensed products of dissociated water vapor (11). The slight drop following the first pressure surge must be due to adsorption on the large (~0.15 m^2) surface of the gas measuring system, usually evacuated to 10^{-4} Torr prior to warming up. The amounts involved correspond approximately to a monolayer of adsorbed oxygen, and the time interval is of the right magnitude.

Decomposition of the Polyoxides

The two main steps in the oxygen evolution curves (Fig. 1) can now be assigned unambiguously to the decomposition of the two intermediates; first H_2O_4, then H_2O_3. This interpretation, based mainly on our spectroscopic data (2–4), is also in accordance with the predictions of thermochemistry as explained in the discussion. Of the various other hypotheses put forward over the years (1), the one closest to the truth suggested that only one species was involved, namely H_2O_4, which decomposed at different rates in the solid and the liquid phase (9, 14). It is true that the transition between the two steps, at least in the hydrogen systems, occurs in the temperature range of the two eutectics of the H_2O–H_2O_2 binary system, *viz.* −51 and −56 °C. However, this is a mere coincidence, with little or no bearing on the decomposition process, as confirmed by the following observations: (*a*) The condensed products begin to melt well below the eutectic temperatures, for instance between −73 (15) and −65° (16), depending on their composition; (*b*) The rate of gas evolution increases very little upon melting; (*c*) With the deuterated compounds (Fig. 1), the second step begins some 10 to 15° higher than with the hydrogen compounds; yet the eutectic temperatures in the two isotopic binary systems differ by less than 2° (17); (*d*) The ratio of the pressure increase in the two steps varies within wide limits depending on the composition of the systems, and other experimental conditions, as will be seen below.

Hereafter, the oxygen given off in the two main steps is taken as originating solely in the two reactions:

[1] $$H_2O_4 \rightarrow H_2O_2 + O_2$$

and

[2] $$H_2O_3 \rightarrow H_2O + O_2$$

Any possible contribution from some slight decomposition of the hydrogen peroxide present is considered negligible in view of its much greater chemical stability. In this investigation, as in the previous one (8, 9, 11, 18), the yields from the first main step were consistently smaller than those from step two, sometimes by as much as one order of magnitude (Table 1). As a result, and also because reaction 1 is obscured, at the start by the out-gassing process, and near the end by overlap of reaction 2, the present estimates for the tetroxide yields are less accurate than those for the trioxide.

Distance Effect

Previous studies of these systems (1, 5, 7, 19) have shown a marked dependence of the water

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

and hydrogen peroxide yields on the "time of flight" of the vapor through the discharge zone. That effect has often been described in terms of the "traversed volume". However, this is only one of the many parameters involved. For instance, the shape of that volume, the ratio of surface to volume, the rate of flow, etc. are also important in view of the dominant role of surface recombination of atoms. Under a steady flow rate, at constant pressure of the vapor, through a straight tube of constant section (to minimize turbulence in the laminar flow), as was the case here, the distance from the microwave cavity to the cold surface at the bottom of the trap is a meaningful parameter for discussing that effect.

As observed previously, upon increasing that distance the peroxide yield increased almost linearly up to a maximum for a certain "critical" distance, and then decreased. The water yield varied contrariwise (Fig. 2). Incidentally, the data in Fig. 2 (and also in Table 1) represent in fact the composition of the condensed products, *not* the yields based on the oxygen input. The latter are somewhat ambiguous because their total often exceeds 100% (by as much as 10 or 12%), due to the "sputtering" phenomenon already mentioned. In contrast, the minor constituents, H_2O_3 and H_2O_4, follow quite different patterns. With the trioxide, there is at first an increase in concentration with distance, but a maximum is reached sooner than for the peroxide. The same peculiarity had already been observed by Jones *et al.* (7) in the curve of evolved oxygen. As for the tetroxide, its low *yield* increases slightly with distance.

Isotope Effect

The first obvious consequence of deuterium substitution is a sharp increase in the trioxide yields, almost double at the minimum distance (Fig. 1). By comparison the tetroxide is hardly affected at all. As a consequence, the decomposition curve of D_2O_4 is largely overlapped by that of D_2O_3. Then, the latter is shifted some 10 to 15° higher than that of H_2O_3. Another isotope effect, minor but very real, is the reduction, by roughly one-half, in the amount of occluded O_2 and O_3. This had already been detected in the Raman spectra of the condensed products (13).

However, the most striking difference between the hydrogen and the deuterium systems of compounds is to be found in the distance effect.

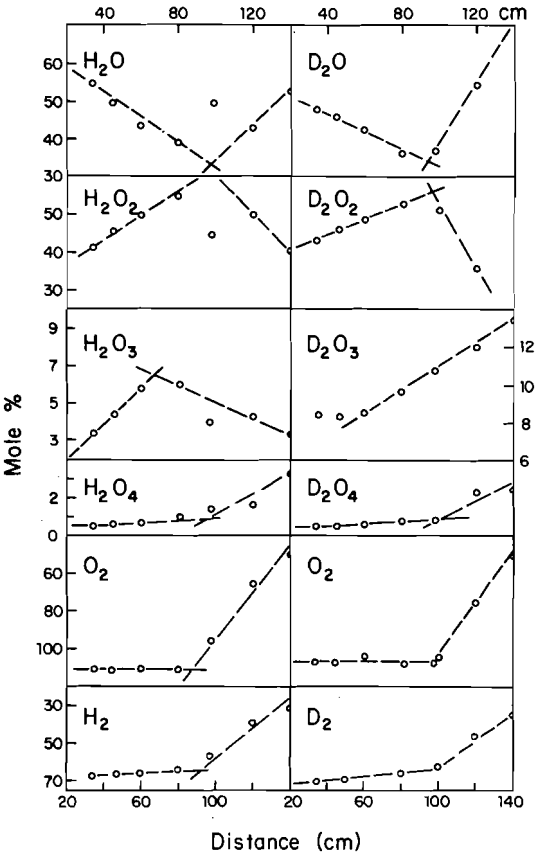

FIG. 2. Effect of distance from discharge to cold surface on the composition of condensed products from dissociated H_2O and D_2O vapor. (Note the different ordinate scales for H_2O_3 and D_2O_3.) The two bottom curves show the fraction of input oxygen and hydrogen found in the condensate.

Whereas the concentrations of water, peroxide, and tetroxide are little changed by deuteration, those of H_2O_3 and D_2O_3 show an entirely different behavior (Fig. 2). First, with H_2O_3 the linear concentration plot passes through the origin on extrapolation. On the contrary that of D_2O_3 showed a leveling off, or even an upward trend for distances shorter than 50 cm. It was not possible, unfortunately, with the present experimental arrangement to pursue this investigation to very short distances. Nevertheless, numerous runs with two different discharge tubes confirmed that peculiarity, even if the scatter of experimental points was wider than usual. Then, at longer distances, the *concentration* of D_2O_3 kept increasing linearly, without any sign of a maximum as with H_2O_3. Note however, that the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

yield, based on the oxygen input, begins to decrease beyond the "critical" distance of 1 m. Because the loss of permanent gases increased rapidly beyond that point, the study of that effect became progressively more difficult and uncertain. Further investigation is planned under different experimental conditions: *i.e.* with faster flow, larger discharge tube, etc.

One last observation about the deuterium system: the "critical" distance seemed a little longer: *i.e.* 1 m *vs.* 0.9 m for the hydrogen system.

Dissociated Peroxide Vapor

Previous investigations (20–22) have shown that electrical discharges in hydrogen peroxide vapor yield less water and more evolved oxygen, *viz.* polyoxides, than discharges in water vapor. This is as expected for a more oxidizing atmosphere. Likewise, the preliminary results reported here (Fig. 1 and Table 1) show a substantial increase in the polyoxides, particularly the tetroxide, at the expense of water. Also noteworthy is an approximately threefold increase in occluded oxygen and ozone. As for the deuterium isotope effect, it follows the same pattern as in the case of dissociated H_2O and D_2O. The hydrogen recovery is nearly quantitative, while that of oxygen has dropped by nearly 20%. Whether or not the "sputtering" phenomenon is as important in the peroxide as in the water vapor discharge is not known, however. It would be instructive to study further this system as a function of pressure, distance, and power input, specially at low power level. Indeed, from mass spectrometric data (23) a mild discharge in hydrogen peroxide vapor is the best source of HO_2 radicals.

Discussion

The present results are significant mainly from four different viewpoints.

Composition of the Condensate

First, is the composition of the products from low temperature reactions in dissociated water vapor and related systems, particularly the minor constituents, H_2O_3 and H_2O_4. Previous estimates (1) had been deduced only from analysis of the final products. They rested perforce on some unconfirmed hypotheses and misleading criteria, such as the ratio of evolved oxygen to final hydrogen peroxide. The present data, although still of limited precision, are the first ones based on direct experimental evidence, namely molecular spectroscopy. Indeed, our infrared and Raman spectra (2–4) have revealed some six new O—O vibrational bands in the condensed products. From their temperature and composition behavior these bands were found to belong to two different molecular species; one, much less abundant, identified as the tetroxide, the other, as the trioxide. Furthermore, a warming up experiment (2) showed the infrared band of D_2O_4 at 820 cm^{-1} to disappear first in the crystallized solid, whereas that of D_2O_3 at 760 cm^{-1} had a half-life of some 5 h at about $-65°$, quite compatible with the present data.

From relative intensities of infrared bands we had previously estimated at 4 to 5 mol% the total concentration of the polyoxides (2). At that time, however, nothing was known of the importance of certain experimental parameters, nor of the unusual deuterium isotope effect. The failure of early attempts to detect the polyoxides by infrared absorption was then blamed on interference of the strong libration bands of water and hydrogen peroxide molecules in the glassy solid. It is now clear that this was not the only, and probably not the main obstacle, as illustrated by the spectra in Fig. 3. These two spectra,[2] taken under fairly similar conditions, show comparable intensity of the weak peroxide band at 880 cm^{-1}. In contrast, the characteristic trioxide band at 760 cm^{-1} (antisymmetric O—O stretch) is many times stronger in dissociated D_2O than that in H_2O. Indeed, in the latter it is barely visible on top of the strong, but not complete, absorption from the libration–torsion modes.

Reaction Mechanism

The second question on which this study throws some much needed light is the complex reaction mechanism in dissociated water vapor, particularly as regards the formation of hydrogen peroxide and the polyoxides. For instance, the Geib and Harteck (24) mechanism

$$[3] \qquad H + O_2 \xrightarrow[\text{wall}]{\text{cold}} HO_2$$

$$[4] \qquad H + HO_2 \xrightarrow[\text{wall}]{\text{cold}} H_2O_2$$

is further confirmed as the only important one

[2]K. Herman. Unpublished results.

For personal use only.

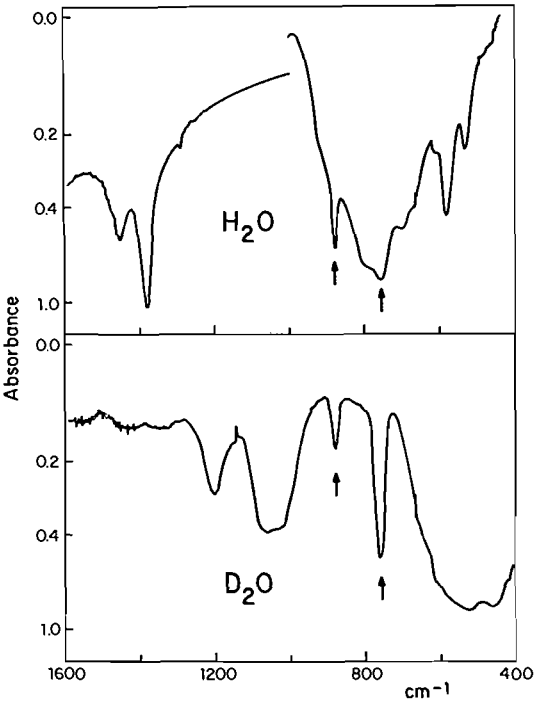

FIG. 3. Infrared absorptions of thin films of the glassy deposit condensed at liquid N_2 temperature from dissociated water and heavy water vapor in a microwave discharge.

in these systems from the distance effect. As pointed out before by Jones *et al.* (7), the peroxide increase at first can be explained by an increase in O_2 concentration from recombination (mostly on the walls) of O atoms, one of the main products of the discharge in water (25). Over that range, H atoms are in large excess, so much so that nearly one-third of the hydrogen input is lost by the system. The subsequent decrease in peroxide, beyond the "critical" distance, follows from a progressive drop in H atom concentration by recombination in the long discharge zone. Incidentally, the average linear velocity of the dissociated stream was of the order of 3 to 5 m s^{-1} in our system. Because of its high exothermicity the above mechanism becomes operative only at temperatures below $-120°$ (20). In addition to the heat of the gaseous reactions 3 and 4, respectively 46 and 89 kcal mol^{-1}, there is the heat of condensation of the products, some 18 kcal mol^{-1} (26) to be dissipated, plus any residual excitation energy of the reagent atoms and molecules.

Of the other conceivable mechanisms, the reaction first invoked by Rodebush and Wahl (27)

[5] $$OH + OH \rightarrow H_2O_2$$

makes no significant contribution here because of the low concentration of OH radicals in the dissociated stream, and the competition of other, very fast reactions (25, 28). Characteristically, no correlation whatsoever was found between OH concentration, from microwave absorption, and the amount of peroxide formed in a liquid nitrogen trap (29). As for the tetroxide mechanism proposed by Ohara (14)

[6] $$HO_2 + HO_2 \rightarrow H_2O_4,$$

our results (Table 1) indicate that it contributes only a small fraction of the *final* peroxide yield: less than 2% in dissociated water, and 6 to 8% in dissociated peroxide vapor.

Although it has little or no activation energy, reaction 6 is handicapped, requiring, as it does, simultaneous formation of two adjacent HO_2 radicals. On the other hand, the tetroxide cannot be a precursor of peroxide in the frozen products since, once stabilized, it does not decompose at a measurable rate at that low temperature, as may be gathered from our warming curves.

As for the other intermediate H_2O_3, it can only be formed by combination of OH and HO_2 radicals:

[7] $$HO_2 + OH \rightarrow H_2O_3$$

An HO_3 radical would be too unstable to exist (30), and there is no known mechanism for its formation. In dissociated water vapor the HO_2 radicals are formed at the cold surface only. In dissociated hydrogen peroxide, low concentrations of HO_2 have been detected by mass spectrometry (1), which may explain the higher yields of tetroxide in these systems (Table 1).

Lastly, regarding the occluded oxygen and ozone, the present results lend further support to our previous conclusion (13) as to the *in situ* origin of these species. Indeed, their yields show no significant increase beyond the "critical" distance; that is, when the concentration of O_2 in the dissociated vapor increases considerably. On the other hand, the deuterium isotope effect is also consistent with the proposed mechanism for oxygen atom production

[8] $$OH + OH \rightarrow H_2O + O$$

considering the rate ratio $k_H/k_D = 1.6$ found by Westenberg and Wilson (31) for that reaction.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

Thermodynamic Stability

The third question to which the new results are also relevant is the chemical stability of the two intermediates, H_2O_3 and H_2O_4. From bond energy considerations Benson (30) had predicted that the latter, being endothermic, would be too unstable to exist; the trioxide might be formed at low temperature if suitable conditions were found. However, these conclusions apply to the free molecules. In condensed phase, hydrogen bond formation stabilizes both intermediates (26). Experimental confirmation of this was secured recently by the matrix isolation technique. The products of a discharge through heavy water vapor and argon trapped at 10 K showed weak infrared bands due to the polyoxides, but only at concentrations sufficient for formation of hydrogen bonded polymers (32). From the enthalpy and free energy relationships in the homologous series of the hydrogen oxides (26, 33) one might expect a greater difference between the decomposition temperature of the trioxide and the tetroxide. However, with heterogeneous reactions such as these, the kinetics do not always parallel the thermodynamics.

Preliminary measurements of the rate of decomposition of H_2O_3 at fixed temperatures between -55 and $-45°$ indicated an activation energy of the order of 15 kcal mol^{-1} in fair agreement with previous results (14, 18). From isothermal measurements at $-80°$ Jones *et al.* (18) have found a ratio of about 300 for the rates of the two oxygen evolution processes. This must be a minimum for the two corresponding decomposition reactions, because the first measured process comprised also any occluded O_2 and O_3. Again, these low activation energies bear no direct relationship to chemical stability. The latter is best considered in terms of bond dissociation energy, and by comparison with hydrogen peroxide.

Although the three molecules, H_2O_2, H_2O_3, and H_2O_4, feature the same type of O—O bond, as explained before (4), dissociation of the last two only, *viz.*

[9] $$H_2O_3 \rightarrow OH + HO_2 \rightarrow H_2O + O_2$$

and

[10] $$H_2O_4 \rightarrow 2HO_2 \rightarrow H_2O_2 + O_2$$

is accompanied by an important electron rearrangement, which makes easier a transfer of hydrogen between the two fragments. Indeed, the peroxide bond becomes a superoxide (three-electron) bond in HO_2, and the O—H bond of the latter is weakened considerably, as confirmed by spectroscopy, and the dissociation energies: $D_{HO-O} = 63$, and $D_{H-O_2} = 47$ kcal mol^{-1}, compared with $D_{HO-OH} = 50$, and $D_{H-O_2H} = 90$ kcal mol^{-1}. For an up-to-date review, *cf.* ref. 33, pp. 66, 84.

Isotope Effect

The fourth, and certainly most surprising result, is the large deuterium isotope effect in the trioxide formation. Although the present data are insufficient to arrive at a detailed explanation, a few generalizations are warranted. From the following observations, it seems that the OH radicals in the dissociated stream are responsible for this isotope effect. (*a*) Only hydrogen trioxide, and to a lesser extent, occluded oxygen and ozone, show a large deuterium isotope effect. Now, according to our proposed mechanism these species are formed from OH radicals, in contrast with hydrogen peroxide and tetroxide. (*b*) Spectroscopic studies (25, 28) have shown hydroxyls to be the only radicals present in electrically dissociated water vapor, their concentration fluctuating rapidly due to fast reactions downstream. No such investigation has been reported yet for OD radicals, but appreciable differences in the lifetime of the two isotopic species may be expected. Because these radicals are in highly excited states, population distribution among the vibrational levels will be different in OH and OD. In that connection, a spectroscopic study of the OD kinetics in these systems would certainly be useful.

As for the deuterium isotope effect in the decomposition of the two polyoxides, it must be ascribed to zero-point energy differences of the species involved. A similar effect has been detected in a few sketchy studies of deuterium peroxide kinetics (34).

Conclusions

The experimental technique used in this investigation may be regarded as an application of the "temperature jump" method. Its efficiency in freezing the system far from equilibrium is exemplified in the formation of some ozone from the strongly reducing atmosphere of dissociated water vapor.

The present results provide the first semi-quantitative data on the chemical stability of

the two polyoxides, H_2O_3 and H_2O_4. Isolation of these fragile species in measurable mounts is possible because of hydrogen bonding, which prevents diffusion of the free radicals formed at the cold surface.

The proposed reaction mechanism can account satisfactorily, if not uniquely, for the bulk of experimental observations, in particular for the variations of yields with "time of flight" in the dissociated vapor. The HO_2 radical, or hydrogen superoxide, appears as the ubiquitous intermediate in the formation and decomposition of the polyoxides as well as of hydrogen peroxide.

Finally, the remarkable isotope effect in the formation of D_2O_3 is no doubt the largest reported so far in any oxy–hydrogen system. It calls for further study, specially by spectroscopy.

Theory of the Spin Hamiltonian Parameters for Low Spin Cobalt(II) Complexes

B. R. McGARVEY
Department of Chemistry, University of Windsor, Windsor, Ontario N9B 3P4

Received March 11, 1975

B. R. McGARVEY. Can. J. Chem. **53**, 2498 (1975).

The theory for the spin Hamiltonian parameters of low spin cobalt(II), d^7, complexes has been developed to third order in perturbation theory for all reasonable ground states. Two extensions beyond previous treatments have been made: (*1*) the spin–orbit mixing of excited quartet states into the doublet ground state has been considered and (*2*) configuration interaction involving mixing of d_{z^2} and $d_{x^2-y^2}$ orbitals in lower symmetry has been included. In the case of axial complexes a more complete calculation has been made to assess the errors incurred in only going to third order in perturbation theory. The theory has been applied to porphyrin and phthalocyanine complexes and is shown to adequately account for the observed data on these complexes. The excited quartet states are much higher in energy than the ground state for the four coordinate porphyrin complexes but become much lower in energy when basic adducts are complexed along the z axis. Further there is mixing of the 4s orbital with the $3d_{z^2}$ orbital for the four coordinate complexes which is completely removed when basic adducts are complexed to the porphyrin system. Application of equations to lower symmetry complexes is considered and it is shown that is is difficult to make an unambiguous assignment of ground state on the basis of g and ^{59}Co hyperfine splitting values alone, although the relative values of g_y and g_z do seem to provide some clue as to the correct ground state.

B. R. McGARVEY. Can. J. Chem. **53**, 2498 (1975).

La théorie des paramètres hamiltoniens de spin pour les complexes d^7 du cobalt(II) à spin bas a été développée en théorie des perturbations du troisième ordre pour tous les états fondamentaux. Deux points ont été étudiés au-delà des traitements précédents: (*1*) on a considéré le mélange spin–orbite des états quadruplets excités en doublet de l'état fondamental et (*2*) l'interaction de configuration impliquant le mélange des orbitales d_{z^2} et $d_{x^2-y^2}$ dans une symétrie plus basse. Un calcul plus complexe a été fait dans le cas des complexes axiaux afin d'évaluer les erreurs qui résultent du passage au troisième ordre de la théorie des perturbations. Cette théorie a été appliquée aux complexes phorphyrines et phtalocyanines et elle rend bien compte des données observées avec ces complexes. Pour les complexes tétracoordonnées de la porphyrine on observe une énergie beaucoup plus élevée pour les états quadruplets excités que pour l'état fondamental. Cette énergie diminue quand des ligands basiques sont coordonnés le long de l'axe z. D'autre part, on observe le mélange des orbitales 4s et $3d_{z^2}$ du complexe tétracoordonné. Ce mélange disparait complètement quand des ligands basiques sont coordonnés au système porphyrine. L'application des équations à des complexes de symétrie plus basse a été considérée. Il n'est pas possible de faire une attribution inéquivoque de l'état fondamental en se servant seulement de g et des valeurs de la scission hyperfine du ^{59}Co, bien que les valeurs relatives de g_y et g_z semblent apporter des indices pour le choix de l'état fondamental correct. [Traduit par le journal]

Introduction

The low spin Co(II) complexes have excited considerable interest in the last few years due to the ability of some to reversibly absorb O_2. The complexes are planar four coordinate and mainly of the forms CoN_2O_2, CoN_4, or CoS_4. Many have the ability to bond to Lewis bases to form five coordinate species and it is this form that absorbs O_2.

Many e.s.r. studies have been done on these complexes and the results show a wide variation in g and A values. The phthalocyanines (1, 2) and porphyrins (3–8) which have a fourfold symmetry axis perpendicular to the plane have $g_\perp \sim 3$ and $g_\parallel$ less than 2.0 when uncomplexed. Both $A_\parallel$ and $A_\perp$ are large with $A_\parallel$ generally smaller than $A_\perp$. When complexed to nitrogen and phosphine bases, $g_\perp$ drops to 2.2–2.3 and $g_\parallel$ becomes greater than 2.0. $A_\parallel$ and $A_\perp$ decrease with the greatest change occurring for $A_\perp$. In addition, ^{14}N and ^{31}P hyperfine is often observed for the nitrogen or phosphorous atom of the complexing base.

Complexes with symmetry of D_{2h} or less always have one g value from 2.6 to 3.8 and the other two g values are near 2.0. No regular pattern is observed in the hyperfine A values. In the few single crystal studies done (9–13), the large g value is always found to be in the plane de-

For personal use only.

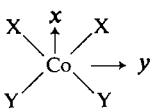
fined by the coordinating ligands. This is also true for the two studies using frozen nematic solvents (14, 15). Many of the Schiff base complexes can become five coordinate by bonding to a Lewis base. In this case (14, 16–20) two g values are found in the range 2.3–2.5 and a third value is $\sim$2.0. For nitrogen Lewis bases the ^{14}N hyperfine is often observed as for the phthalocyanines and porphyrins. The assignment of spin Hamiltonian parameters to specific molecular axes is very uncertain in the case of Schiff base complexes because only one single crystal study (13) has been done and the two studies (14, 15) using frozen nematic solvents disagree as to which molecular axis is the alignment axis.

The assignment of ground states by e.s.r. has followed the method set out by Maki *et al.* (10) who derived equations for the spin Hamiltonian parameters expected for each possible ground state. The ground state is then determined as that which most closely predicts the experimental spin Hamiltonian parameters using reasonable values of $\langle r^{-3}\rangle_{av}$ and $(\lambda/\Delta E)$'s. $\langle r^{-3}\rangle_{av}$ is the average of r^{-3} for the d orbital and $(\lambda/\Delta E)_i$ is the ratio of spin–orbit coupling constant to the energy of excited doublet states which are coupled to the ground state by the spin–orbit interaction. All of the complexes studied are of the following type



with X = Y in some instances. With one exception (9) the symmetry of the complexes requires that the principal axes x and y bisect the bond axes as shown above.

Using the above coordinate system the ground state of $(d_{x^2-y^2})^2(d_{xz})^2(d_{z^2})^2(d_{yz})$ has been reported for four cobalt complexes (10, 12, 13, 21). With one exception (13) this assignment must be considered doubtful, however, because there are errors in the equations reported for this ground state. The ground state $(d_{x^2-y^2})^2(d_{xz})^2(d_{yz})^2(d_{z^2})$ has been attributed to most other complexes (11, 14, 16, 17, 22–24). In the case of one type of CoN_4 complex, Engelhardt *et al.* (23) have proposed a $(d_{xz})^2(d_{yz})^2(d_{z^2})^2(d_{x^2-y^2})$ ground state while Urbach *et al.* (15) have proposed the more usual $(d_{x^2-y^2})^2(d_{xz})^2(d_{yz})^2(d_{z^2})$ ground state. In most instances the agreement between theory and experiment is less than satisfactory in the assignment of ground states and inconsistencies are often glossed over or ignored.

It is evident from the appearance of ^{14}N hyperfine when nitrogen bases are complexed to the porphyrins and phthalocyanines that the ground state must be $(d_{x^2-y^2})^2(d_{xz})^2(d_{yz})^2(d_{z^2})$ in these axially symmetric complexes. Walker (3) has, however, pointed out that present theories do not adequately account for the variation in hyperfine values observed when these compounds are complexed with various adducts. Present theories, also, do not account for the fact that $g_\parallel$ in these complexes becomes significantly greater than the free spin value when complexed to strong Lewis bases. Engelhardt and Green (22) and Busetto *et al.* (20) have done ligand field calculations for D_{4h} symmetry using an extended basis set and have shown that $g_\parallel$ can become greater than the free spin value for certain axial distortions. They fail to point out, however, that this could only occur when there is a significant mixing into the ground state of an excited quartet state. They also did not calculate hyperfine terms from their extended basis set.

For complexes with D_{2h} symmetry or lower no one has taken into account configuration interaction among states belonging to the same irreducible representations. Such interactions have been found to be necessary to account for **g** and **A** assymmetries observed in d^1 tetrahedral complexes (25–27) in which the ground state is predominantly d_{z^2}. Bentley *et al.* (9) did derive equations for the **g** tensor assuming a mixing of d_{z^2} and $d_{x^2-y^2}$ in C_{2v} symmetry but then assumed such mixing was negligible for the compound they were studying. Application of existing theories to the low symmetry complexes has resulted in values of $(\lambda/\Delta E)$ which required an unreasonably large difference in the energies of the d_{xz} and d_{yz} orbital to explain the large differences in g_x and g_y. Such large differences are difficult to explain, particularly when we realize that they are not found in Cu^{2+} when bound to the same ligands. It was considered likely when this work was initiated that much of the difference in g_x and g_y might result from configuration mixing rather than excessively large differences in the energy of d_{xz} and d_{yz} orbitals.

In this article the spin Hamiltonian parameters are derived for different possible ground states of strong field d^7 configurations considering the possible mixing of d_{z^2} and $d_{x^2-y^2}$ allowed by

lower symmetries. No one has previously recognized the possible importance of low lying quartet states and their related doublet states which can be coupled to the doublet ground state by the spin–orbit interaction. These states contribute to the g values only in third order or higher but contribute to the hyperfine terms in second order and hence can be as important as the excited doublet states normally included in previous calculations. These states have, therefore, been included in the following computations also.

Theory of Spin Hamiltonian

In the following discussion two ground state functions will be considered: $(ad_{x^2-y^2} - bd_{z^2})^2 (d_{xz})^2(d_{yz})^2(ad_{z^2} + bd_{x^2-y^2})$ and $(d_{x^2-y^2})^2(d_{z^2})^2(d_{xz})^2(d_{yz})$. Since $0 \leq a \leq 1$ in the first function it really represents the $(d_{x^2-y^2})^2(d_{xz})^2(d_{yz})^2(d_{z^2})$ and $(d_{z^2})^2(d_{xz})^2(d_{yz})^2(d_{x^2-y^2})$ states and all possible mixtures. The second function also represents the state $(d_{x^2-y^2})^2(d_{z^2})^2(d_{yz})^2(d_{xz})$ by a simple interchange of x and y axes. States in which one or more electrons occupy the d_{xy} orbital are not considered reasonable states for these complexes and have not been considered.

In deriving the following equations for the spin Hamiltonian parameters, the parametric approach has been used in which wave functions using only d orbitals are used and the effects of covalency appear indirectly in the altered values of the spin–orbit interaction parameter and $\langle r^{-3} \rangle_{av}$. This is the same approach used by Maki *et al.* (10). Previous studies have used the hole formalism but we shall use the wave functions themselves. This procedure is only slightly more difficult and makes it easier to assure that no important excited states are overlooked. It also results in all parameters involving the spin–orbit interaction having positive values instead of the negative values required by the hole formalism approach.

The perturbation method will be used in the calculations and where appropriate will be carried out to third order. It is possible to set up the calculations for higher orders but this becomes exceedingly complex, particularly since it may be necessary for some systems to consider up to five separate excited states to higher than second order.

$^2A_1$ *Ground State*

In designating the following states we will use the symmetry designation appropriate to C_{2v} symmetry. The ground state will be taken to be

$$[1] \qquad {}^2A_1{}^{\pm} = (d_{xz})^2(d_{yz})^2(ad_{x^2-y^2} - bd_{z^2})^2(ad^{\pm}{}_{z^2} + bd^{\pm}{}_{x^2-y^2})$$

where superscript $\pm$ refers to spin state of $\pm 1/2$. The function is taken to be a Slater's determinant and $a^2 + b^2 = 1$. This admixture of d_{z^2} and $d_{x^2-y^2}$ is allowed in C_{2v}, D_{2h}, and lower symmetries because they both belong to the same irreducible representation. The spin–orbit interaction is

$$[2] \qquad \mathcal{H}_{LS} = \sum_i \xi \boldsymbol{l}_i \cdot \boldsymbol{s}_i$$

where $\boldsymbol{l}_i$ = orbital angular momentum operator for ith electron, $\boldsymbol{s}_i$ is the spin operator for the ith electron, and ξ is the single electron spin–orbit constant (which is always positive). This interaction couples both quartet and doublet excited states with the ground state. The $l_z s_z$ term in $\mathcal{H}_{LS}$ couples the following excited states:

$$[3] \qquad {}^2A_2{}^{\pm} = (d_{xz})^2(d_{yz})^2(ad_{x^2-y^2} - bd_{z^2})^2(d_{xy}{}^{\pm})$$

$$[4] \qquad {}^4A_2\left(\pm\frac{3}{2}\right) = (d_{xz})^2(d_{yz})^2(ad^{\pm}{}_{x^2-y^2} - bd^{\pm}{}_{z^2})(ad^{\pm}{}_{z^2} + bd^{\pm}{}_{x^2-y^2})(d^{\pm}{}_{xy})$$

$$[5] \qquad {}^4A_2\left(\pm\frac{1}{2}\right) = \frac{1}{\sqrt{3}}(d_{xz})^2(d_{yz})^2\{(ad^{\pm}{}_{x^2-y^2} - bd^{\pm}{}_{z^2})(ad^{\pm}{}_{z^2} + bd^{\pm}{}_{x^2-y^2})(d^{\mp}{}_{xy}) + (ad^{\pm}{}_{x^2-y^2} - bd^{\pm}{}_{z^2})(ad^{\mp}{}_{z^2} + bd^{\mp}{}_{x^2-y^2})(d^{\pm}{}_{xy}) + (ad^{\mp}{}_{x^2-y^2} - bd^{\mp}{}_{z^2}) \times (ad^{\pm}{}_{z^2} + bd^{\pm}{}_{x^2-y^2})(d^{\pm}{}_{xy})\}$$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

$$[6]\quad {}^2A_2{}^{\pm}(1,2) = (d_{xz})^2(d_{yz})^2\{d_{1,2}(ad^{\pm}_{x^2-y^2} - bd^{\pm}_{z^2})(ad^{\pm}_{z^2} + bd^{\pm}_{x^2-y^2})(d^{\mp}_{xy}) + e_{1,2}(ad^{\pm}_{x^2-y^2} - bd^{\pm}_{z^2})(ad^{\mp}_{z^2} + bd^{\mp}_{x^2-y^2})(d^{\pm}_{xy}) + f_{1,2}(ad^{\mp}_{x^2-y^2} - bd^{\mp}_{z^2})(ad^{\pm}_{z^2} + bd^{\pm}_{x^2-y^2})(d^{\pm}_{xy})\}$$

The ${}^4A_2$ and ${}^2A_2$ (1, 2) states have not previously been considered in calculations on d^7 systems. The coefficients d_i, e_i, and f_i are determined by repulsive energy terms. All we know about them is that their sum must be zero. Further on in this article we will show that to a good approximation we will not need to know their exact values.

The x and y portions of $\mathcal{H}_{LS}$ causes the ${}^2A_1$ state to couple with the following excited states:

$$[7]\quad {}^2B_1{}^{\pm} = (d_{yz})^2(d_{x^2-y^2})^2(d_{z^2})^2(d^{\pm}_{xz})$$

$$[8]\quad {}^2B_2{}^{\pm} = (d_{xz})^2(d_{x^2-y^2})^2(d_{z^2})^2(d^{\pm}_{yz})$$

$$[9]\quad {}^4B_1\left(\pm\frac{3}{2}\right) = (d_{xz})^2(ad_{x^2-y^2} - bd_{z^2})^2(d^{\pm}_{yz})(ad^{\pm}_{z^2} + bd^{\pm}_{x^2-y^2})(d^{\pm}_{xy})$$

$$[10]\quad {}^4B_1\left(\pm\frac{1}{2}\right) = \frac{1}{\sqrt{3}}(d_{xz})^2(ad_{x^2-y^2} - bd_{z^2})^2\{(d^{\pm}_{yz})(ad^{\pm}_{z^2} + bd^{\pm}_{x^2-y^2})(d^{\mp}_{xy}) + (d^{\pm}_{yz})(ad^{\mp}_{z^2} + bd^{\mp}_{x^2-y^2})(d^{\pm}_{xy}) + (d^{\mp}_{yz})(ad^{\pm}_{z^2} + bd^{\pm}_{x^2-y^2})(d^{\pm}_{xy})\}$$

$$[11]\quad {}^4B_2(M_s) = \text{same as } {}^4B_1(M_s) \text{ with } d_{xz} \text{ and } d_{yz} \text{ interchanged}$$

$$[12]\quad {}^2B_1{}^{\pm}(1,2) = (d_{xz})^2(ad_{x^2-y^2} - bd_{z^2})^2\{d_{1,2}(d^{\pm}_{yz})(ad^{\pm}_{z^2} + bd^{\pm}_{x^2-y^2})(d^{\mp}_{xy}) + e_{1,2}(d^{\pm}_{yz})(ad^{\mp}_{z^2} + bd^{\mp}_{x^2-y^2})(d^{\pm}_{xy}) + f_{1,2}(d^{\mp}_{yz})(ad^{\pm}_{z^2} + bd^{\pm}_{x^2-y^2})(d^{\pm}_{xy})\}$$

$$[13]\quad {}^2B_2{}^{\pm}(1,2) = \text{same as } {}^2B_1{}^{\pm}(1,2) \text{ with } d_{xz} \text{ and } d_{yz} \text{ interchanged}$$

The ${}^4B_1$, ${}^4B_2$, ${}^2B_1$ (1, 2,),and ${}^2B_2$(1,2) states also have not previously been considered. In writing eqs. 7 and 8 use has been made of the simplification that if both the $(ad_{x^2-y^2} - bd_{z^2})$ and $(ad_{z^2} + bd_{x^2-y^2})$ orbitals are filled the determinental function is equivalent to the simpler form given above.

The spin–orbit interaction mixes the above excited states into the ground state, producing wave functions for the ground state Kramer's doublet of the following form

$$[14]\quad \psi_{\pm} = \sum_{m=0} a_m{}^{\pm}\psi_m$$

where ψ_0 is the ground state function in the absence of a spin–orbit interaction and $\psi_{m\neq 0}$ are the excited state functions. To third order, perturbation theory gives for the coefficients a_m

$$[15]\quad a_0 = 1 - \frac{1}{2}\sum_n \frac{H_{0n}H_{n0}}{(E_0 - E_n)^2}$$

$$[16]\quad a_{m\neq 0} = \frac{H_{m0}}{E_0 - E_m} - \frac{H_{m0}H_{00}}{(E_0 - E_m)^2} + \sum_{n\neq 0}\frac{H_{mn}H_{n0}}{(E_0 - E_m)(E_0 - E_n)}$$

$$[17]\quad H_{mn} = \langle\psi_m|\mathcal{H}_{LS}|\psi_n\rangle$$

The rest of the calculation involves finding the spin Hamiltonian parameters by standard procedures (28) in terms of the a_m coefficients. We then substitute eqs. 15 and 16 keeping only terms of order $(\xi/\Delta E)^2$. It seems reasonable to expect that the ${}^2A_2$, ${}^2A_2$(1,2), ${}^2B_1$(1,2), and ${}^2B_2$(1,2) states are high in energy, so that it was assumed for these states that only terms of order $(\xi/\Delta E)$ need to be retained. Further, for the pairs of doublet states related to a quartet state such as ${}^2A_2$(1,2) it was assumed that both states in the pair had the same energy. Preliminary computations show that these states are about 15 000 cm^{-1} above the corresponding quartet state and are never separated by more

than about 1500 cm^{-1} in energy. It is this assumption that makes it unnecessary for us to know the correct values of the coefficients $e_{1,2}$, $d_{1,2}$, and $f_{1,2}$ in eqs. 6, 11, and 13.

If we define the following constants

$$\begin{aligned} c_1 &= \xi/\Delta(^2B_1) & c_6 &= \xi/\Delta(^2A_2) \\ c_2 &= \xi/\Delta(^2B_2) & c_3' &= \xi/\Delta(^2B_1(1,2)) \\ c_3 &= \xi/\Delta(^4B_1) & c_4' &= \xi/\Delta(^2B_2(1,2)) \\ c_4 &= \xi/\Delta(^4B_2) & c_5' &= \xi/\Delta(^2A_2(1,2)) \\ c_5 &= \xi/\Delta(^4A_2) \end{aligned} \quad [18]$$

where $\Delta(^2B_1)$ is the energy difference between the $^2B_1$ state and the ground state and ξ is the one electron spin–orbit constant, then the **g** tensor components are given by the equations:

$$g_z = 2.0023 + \frac{2}{3}(c_3^2 + c_4^2 + c_3c_4) + (3a^2 - b^2)c_1c_2 - (\sqrt{3}a + b)^2c_2^2 - (\sqrt{3}a - b)^2c_1^2 - 8b^2c_6 \quad [19]$$

$$g_x = 2.0023 + \frac{2}{3}c_3^2 + \frac{8}{3}a^2c_5^2 - \frac{4}{3}a(a - \sqrt{3}b)c_3c_5 + \frac{4}{3}b(\sqrt{3}a + b)c_3c_2 - (3a^2 - b^2)c_1c_2 - (\sqrt{3}a - b)^2c_1^2 + 2(\sqrt{3}a + b)^2c_2 \quad [20]$$

$$g_y = 2.0023 + \frac{2}{3}c_4^2 + \frac{8}{3}a^2c_5^2 - \frac{4}{3}a(a + \sqrt{3}b)c_4c_5 - \frac{4}{3}b(\sqrt{3}a - b)c_4c_1 - (3a^2 - b^2)c_1c_2 - (\sqrt{3}a + b)^2c_2^2 + 2(\sqrt{3}a - b)^2c_1 \quad [21]$$

The corresponding hyperfine tensor components are:

$$\begin{aligned} A_z = K + P\Big\{&\frac{4}{7}(a^2 - b^2) - \frac{2}{7}(c_3 - c_3') - \frac{2}{7}(c_4 - c_4') \\ &- \frac{1}{7}(3a^2 - 3b^2 + 2\sqrt{3}ab)c_1 - \frac{1}{7}(3a^2 - 3b^2 - 2\sqrt{3}ab)c_2 - 8b^2c_6 \\ &- \frac{8}{63}a^2(c_3^2 + c_4^2) - \frac{32}{63}a^2(2 - 3b^2)c_5^2 - \frac{3}{14}(\sqrt{3}a + b)^2c_2^2 - \frac{3}{14}(\sqrt{3}a - b)^2c_1^2 \\ &+ \frac{2}{7}c_3c_4 + \frac{4}{7}(6 - 7b^2)c_1c_2 + \frac{4\sqrt{3}}{63}a(\sqrt{3}a - b)c_5(c_3 + c_4) \\ &+ \frac{4\sqrt{3}}{21}b(\sqrt{3}b + a)c_3c_2 + \frac{4\sqrt{3}}{21}b(\sqrt{3}b - a)c_4c_1\Big\} \end{aligned} \quad [22]$$

$$\begin{aligned} A_x = K + P\Big\{&-\frac{2}{7}(a^2 - b^2) - \frac{4\sqrt{3}}{7}ab(1 + c_6) + 2(\sqrt{3}a + b)^2c_2 \\ &+ \frac{1}{7}(3a^2 - 3b^2 + 2\sqrt{3}ab)c_1 \\ &+ \frac{2}{7}(c_3 - c_3') - \frac{8\sqrt{3}}{21}ab(c_5 - c_5') - \frac{2}{63}(1 + 2b^2 - 2\sqrt{3}ab)c_3^2 \\ &+ \frac{8}{63}a(a + \sqrt{3}b)c_4^2 + \frac{8}{63}a^2(5 - 6b^2 + 6\sqrt{3}ab)c_5^2 \\ &- \frac{1}{14}(1 + 2b^2 - 2\sqrt{3}ab)(\sqrt{3}a + b)^2c_2^2 + \frac{1}{7}b(\sqrt{3}a - b)^3c_1^2 + \frac{2}{21}c_3c_4 \\ &- \frac{1}{63}(108a - 5\sqrt{3}b)(a - \sqrt{3}b)c_5c_3 + \frac{1}{21}(2 + 3b^2 + \sqrt{3}ab)c_5c_4 \\ &- \frac{1}{7}(27 - 34b^2 + 2\sqrt{3}ab)c_1c_2 + \frac{2}{21}(\sqrt{3}a + b)(\sqrt{3}a + 20b)c_3c_2 - \frac{2}{7}c_4c_1\Big\} \end{aligned} \quad [23]$$

$$[24]\quad A_y = K + P\left\{-\frac{2}{7}(a^2 - b^2) + \frac{4\sqrt{3}}{7}ab(1 + c_6) + 2(\sqrt{3}a - b)^2c_1 + \frac{1}{7}(3a^2 - 3b^2 - 2\sqrt{3}ab)c_2 + \frac{2}{7}(c_4 - c_4') + \frac{8\sqrt{3}}{21}ab(c_5 - c_5') + \frac{8}{63}a(a - \sqrt{3}b)c_3^2 - \frac{2}{63}(1 + 2b^2 + 2\sqrt{3}ab)c_4^2 + \frac{2}{21}c_3c_4 + \frac{8}{63}a^2(5 - 6b^2 - 6\sqrt{3}ab)c_5^2 - \frac{1}{7}b(\sqrt{3}a + b)^3c_2^2 - \frac{1}{14}(1 + 2b^2 + 2\sqrt{3}ab)(\sqrt{3}a - b)^2c_1^2 - \frac{1}{7}(27 - 34b^2 - 2\sqrt{3}ab)c_1c_2 + \frac{1}{21}(2 + 3b^2 - \sqrt{3}ab)c_5c_3 - \frac{1}{63}(a + \sqrt{3}b)(108a + 5\sqrt{3}b)c_5c_4 - \frac{2}{21}(6 - 3b^2 + \sqrt{3}ab)c_3c_2 + \frac{4}{21}(\sqrt{3}a - b)(\sqrt{3}a - 10b)c_4c_1\right\}$$

$$[25]\quad P = 2.0023\, g_N\beta_e\beta_N\langle r^{-3}\rangle_{av}$$

K in eqs. 22–24 is the isotropic Fermi contact interaction. An assumption has been made in just writing a constant K for the Fermi contact term in eqs. 22–24. The Fermi term for an unpaired electron in the $(ad_{z^2} + bd_{x^2-y^2})$ and $(ad_{x^2-y^2} - bd_{z^2})$ orbitals should be different than that in the d_{xy}, d_{xz}, or d_{yz} orbitals because these two orbitals are allowed to mix with the 4s orbital in C_{2v} or lower symmetries. Thus for the A_z term the Fermi term should more correctly take the form

$$[26]\quad K_0\left[1 - \frac{1}{9}(c_3^2 + c_4^2 + 8a^2c_5^2)\right] + \frac{4}{9}a^2c_5^2K_1 + K_2\left[\frac{4}{9}(c_3^2 + c_4^2) - \frac{1}{4}(\sqrt{3}a + b)^2c_2^2 - \frac{1}{4}(\sqrt{3}a - b)^2c_1^2\right]$$

where K_0 is the Fermi term for electron in $(ad_{z^2} + bd_{x^2-y^2})$ orbital, K_1 is the term in $ad_{(x^2-y^2} - bd_{z^2})$ orbital, and K_2 is the term for d_{xy}, d_{xz}, and d_{yz} orbitals. We would expect K_0 and K_1 to be positive for considerable 4s mixing and negative if not. K_2 should be negative. Since only 3rd order terms appear in this expression outside of K_0 we have assumed the Fermi term to be identical for A_x, A_y, and A_z.

In eqs. 18–25 there are twelve parameters needed to determine six experimental spin Hamiltonian parameters. Application of these equations to experiment will require a judicious choice of assumptions about the relative values of at least six of these parameters. Previous treatments have made explicit or implicit assumptions about seven of these parameters. Since the quartet states and their associated doublet states were overlooked there was the implicit assumption that c_3, c_4, c_5, c_3', c_4', and c_6' were zero. In addition it was always explicitly assumed that $a = 1$ or $b = 1$. Examination of eqs. 19–24 shows that the quartet states only contribute to the g values in third order but contribute to the hyperfine terms in second order. Since there is good reason to expect c_3, c_4, and c_5 to have magnitudes similar to c_1, c_2, and c_6 one is not justified in neglecting these quartet terms.

In the case of axial symmetry a considerable simplification occurs in the above equations since $c_1 = c_2$, $c_3 = c_4$, $c_3' = c_4'$, and $a = 1$ or $b = 1$. For $a = 1$

$$[27]\quad g_\parallel = 2.0023 + 2c_3^2 - 3c_1^2$$

$$[28]\quad g_\perp = 2.0023 + \frac{2}{3}c_3^2 + \frac{8}{3}c_5^2 - \frac{4}{3}c_3c_5 - 6c_1^2 + 6c_1$$

$$[29]\quad A_\parallel = K + P\left\{\frac{4}{7} - \frac{4}{7}(c_3 - c_3') - \frac{6}{7}c_1 + \frac{2}{63}c_3^2 - \frac{64}{63}c_5^2 + \frac{15}{7}c_1^2 + \frac{8}{21}c_5c_3\right\}$$

$$[30]\quad A_\perp = K + P\left\{-\frac{2}{7} + \frac{45}{7}c_1 + \frac{2}{7}(c_3 - c_3') + \frac{4}{21}c_3^2 + \frac{40}{63}c_5^2 - \frac{57}{14}c_1^2 - \frac{34}{21}c_5c_3\right\}$$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12

For $b = 1$ we obtain

[31] $$g_{\parallel} = 2.0023 + 2c_3^2 - 3c_1^2 - 8c_6$$

[32] $$g_{\perp} = 2.0023 + \frac{2}{3}c_3(c_3 + 2c_1) + 2c_1$$

[33] $$A_{\parallel} = K + P\left\{-\frac{4}{7} - \frac{4}{7}(c_3 - c_3') + \frac{6}{7}c_1 - 8c_6 + \frac{2}{7}c_3^2 - c_1^2 + \frac{8}{7}c_3c_1\right\}$$

[34] $$A_{\perp} = K + P\left\{\frac{2}{7} + \frac{11}{7}c_1 + \frac{2}{7}(c_3 - c_3') + \frac{9}{14}c_1^2 + \frac{34}{21}c_3c_1\right\}$$

$^2B_2$ Ground State

For this ground state the z portion of $\mathcal{H}_{LS}$ couples with the $^2B_1$, $^4B_1$, and $^2B_1(1,2)$ states while the x,y portion couples with $^2A_1$ and the following states which have not previously been considered in the $^2A_1$ ground state theory

[35] $$^2A_2^{\pm}(xy) = (d_{xz})^2(d_{z^2})^2(d_{x^2-y^2})^2(d^{\pm}_{xy})$$

[36] $$^2A_1^{\pm}(x^2 - y^2) = (d_{xz})^2(d_{yz})^2(ad_{z^2} + bd_{x^2-y^2})^2(ad^{\pm}_{x^2-y^2} - bd^{\pm}_{z^2})$$

[37] $$^4A_1\left(\pm\frac{3}{2}\right) = (d_{z^2})^2(d_{x^2-y^2})^2(d^{\pm}_{xy})(d^{\pm}_{xz})(d^{\pm}_{yz})$$

[38] $$^4A_1\left(\pm\frac{1}{2}\right) = \frac{1}{\sqrt{3}}(d_{z^2})^2(d_{x^2-y^2})^2\{(d^{\pm}_{xy})(d^{\pm}_{xz})(d^{\mp}_{yz}) + (d^{\pm}_{xy})(d^{\mp}_{xz})(d^{\pm}_{yz}) + (d^{\mp}_{xy})(d^{\pm}_{xz})(d^{\pm}_{yz})\}$$

[39] $$^2A_1^{\pm}(1,2) = (d_{z^2})^2(d_{x^2-y^2})^2\{e_{1,2}(d^{\pm}_{xy})(d^{\pm}_{xz})(d^{\mp}_{yz}) + d_{1,2}(d^{\pm}_{xy})(d^{\mp}_{xz})(d^{\pm}_{yz}) + f_{1,2}(d^{\mp}_{xy})(d^{\pm}_{xz})(d^{\pm}_{yz})\}$$

In this calculation a has been taken as unity because the mixing coefficients a and b appear only in a few terms and do not appreciably affect the results.

If we define the following constants

[40]
$$\eta_1 = \xi/\Delta(^2A_2(xy)) \qquad \eta_5 = \xi/\Delta(^4A_1)$$
$$\eta_2 = \xi/\Delta(^2B_1) \qquad \eta_6 = \xi/\Delta(^4B_1)$$
$$\eta_3 = \xi/\Delta(^2A_1) \qquad \eta_5' = \xi/\Delta(^2A_1(1,2))$$
$$\eta_4 = \xi/\Delta(^2A_1(x^2 - y^2))$$

the **g** tensor components will be given as

[41] $$g_z = 2.0023 + \frac{2}{3}\eta_5^2 - 3\eta_3^2 - \frac{2}{3}\eta_2\eta_5 - 3\eta_2\eta_3 + 2\eta_2$$

[42] $$g_x = 2.0023 - 2\eta_2^2 - 3\eta_2\eta_3 + 6\eta_3 + 2\eta_4$$

[43] $$g_y = 2.0023 + \frac{2}{3}\eta_5^2 - 3\eta_3^2 - 2\eta_1$$

In these calculations, third order terms only for the $^2A_1$, $^2B_1$, $^4A_1$, and $^4B_1$ states have been retained. The corresponding **A** tensor components are:

[44] $$A_z = K + P\left\{\frac{2}{7}(1 - \eta_5 + \eta_5') + \frac{3}{7}(\eta_3 - \eta_4 + \eta_1) + 2\eta_2 - \frac{2}{21}\eta_5^2 - \frac{9}{14}\eta_3^2 - \frac{8}{21}\eta_5\eta_2 - \frac{45}{14}\eta_3\eta_2\right\}$$

$$[45]\quad A_x = K + P\left\{-\frac{4}{7} + 6\eta_3 + 2\eta_4 + \frac{3}{7}(\eta_2 - \eta_1) + \frac{4}{21}\eta_5^2 + \frac{3}{14}\eta_3^2 - \frac{2}{21}\eta_5\eta_6 + \frac{4}{7}\eta_3\eta_6 - \frac{6}{7}\eta_2\eta_3 - \frac{2}{7}\eta_2\eta_5\right\}$$

$$[46]\quad A_y = K + P\left\{\frac{2}{7}(1 + \eta_5 - \eta_5') - \frac{3}{7}(\eta_2 + \eta_3 - \eta_4) - 2\eta_1 - \frac{2}{21}\eta_5^2 - \frac{8}{21}\eta_5\eta_6 + \frac{2}{7}\eta_3\eta_6 + \frac{1}{7}\eta_2\eta_5 + \frac{3}{14}\eta_2\eta_3\right\}$$

In this case there are nine adjustable parameters and judicious approximations will also be required to make use of these equations.

Applications

Co(II) Porphyrins and Phthalocyanines

These complexes are axially symmetric so that we can use frozen solution results with some confidence. Further, it is clear from previous studies (1–8) that the ground state is $^2A_1$ so that we can use eqs. 27–30 to analyze the results. An examination of eqs. 27 and 28 shows that the introduction of quartet states into the calculation has allowed us to qualitatively explain the behavior of g values as stronger bases are complexed at the fifth and sixth coordination sites. Introduction of a base along the z axis destabilizes the d_{z^2} orbital relative to the d_{xz} and d_{yz} orbitals, thus decreasing c_1. As c_1 decreases $g_\perp$ becomes smaller while $g_\parallel$ increases. When $c_3 > c_1$, $g_\parallel$ will become greater than 2.0023 as is observed experimentally. In fact, careful examination of the theory shows that for the $^2A_1$ state the only way $g_\parallel$ can become greater than 2.0023 is by mixing of higher multiplet states into the ground state. It is presumed that such a mixing is what produced $g_\parallel$ values greater than 2.0023 in the ligand field calculations of Engelhardt and Green (22) and Busetto *et al.* (20).

There are six parameters in eqs. 27–30 for only four equations. Since c_5 is certainly smaller than c_3 and appears only in third order terms we will assume it to be zero. Further, we will take c_3' as zero since it should be much smaller than c_3. With these approximations we can calculate c_1 and c_3 from $g_\parallel$ and $g_\perp$ and then find K and P from $A_\parallel$ and $A_\perp$. The results from such computations are given in Table 1 for some Co(II) porphyrin and phthalocyanine complexes reported in the literature.

The value of P for the free Co^{2+} ion (29) is 254×10^{-4} cm^{-1} and it is encouraging to note that the majority of P values in Table 1 are between 200 and 300 $\times 10^{-4}$ cm^{-1}. The variations in P in Table 1 are primarily due to errors in determining the spin Hamiltonian parameters because P is determined from the equation

$$[47]\quad P = (A_\parallel - A_\perp)\Big/\left\{\frac{6}{7}(1 - c_3) - \frac{51}{7}c_1 - \frac{10}{21}c_3^2 + \frac{87}{14}c_1^2\right\}$$

where we are computing the ratio of two differences. The errors in this calculation become appreciable when c_1 is in the range of 0.15 to 0.07 because both numerator and denominator are small. For example, P for Co(p-CH_3)TPP plus 1,3,5-trimethoxybenzene changes from 521 to 430×10^{-4} cm^{-1} when $g_\parallel$ is changed from the reported value of 2.652 to 2.660.

It should be mentioned that in obtaining the values of P and K in Table 1, $A_\parallel$ and $A_\perp$ were assumed to be positive except for those complexes for which $c_1 < 0.05$, in which it was necessary to assume $A_\perp$ negative to obtain expected values of P. Further, the effect of assuming $c_5 = 0$ was estimated by redoing the computations assuming $c_5 = c_3$. The values of the parameters obtained were only slightly changed from those in Table 1 showing, as expected, that our assumption has little effect on the final results.

The values of c_1 and c_3 are large enough in some instances to suggest that even a third order perturbation calculation may not be sufficient and therefore an exact calculation was undertaken for this system assuming $c_5 = c_3' = 0$. For the axial symmetry case of the $^2A_1$ ground state an exact calculation results in the following

equations for $g_\parallel$ and $g_\perp$

[48] $$g_\parallel = 2.0023 + 6(\beta^2 - \gamma^2) - 2\delta^2$$

[49] $$g_\perp = 2.0023\,(\alpha^2 + 2\sqrt{3}\beta\gamma) - 2\sqrt{6}\alpha\delta$$

where

[50] $$\beta = \left\{c_1/\sqrt{2}\left[(c_1/c_3) - \frac{1}{2}c_1 - \varepsilon\right]\right\}\alpha$$

[51] $$\gamma = \left\{c_1/\sqrt{6}\left[(c_1/c_3) - \frac{1}{6}c_1 - \varepsilon\right]\right\}\alpha$$

[52] $$\delta = -\left\{\sqrt{3}c_1/\sqrt{2}\left(1 + \frac{1}{2}c_1 - \varepsilon\right)\right\}\alpha$$

[53] $$\alpha^2 = 1 - \beta^2 - \gamma^2 - \delta^2$$

and ε is found by solving the determinant

[54] $$\begin{vmatrix} -\varepsilon & -c_1/\sqrt{2} & -c_1/\sqrt{6} & \sqrt{3/2}c_1 \\ -c_1/\sqrt{2} & (c_1/c_3) - \frac{1}{2}c_1 - \varepsilon & 0 & 0 \\ -c_1/\sqrt{6} & 0 & (c_1/c_3) - \frac{1}{6}c_1 - \varepsilon & 0 \\ \sqrt{3/2}c_1 & 0 & 0 & 1 + \frac{1}{2}c_1 - \varepsilon \end{vmatrix} = 0$$

and taking the lowest value of the four ε's obtained. The K and P values can be obtained from the equations

[55] $$(A_\parallel - A_\perp) = P\left\{\frac{6}{7} + \frac{17}{14}(2.0023 - g_\perp) - \frac{5}{14}(2.0023 - g_\parallel) - \frac{22}{7}\beta^2 - \frac{68}{21}\gamma^2 - \frac{6\sqrt{2}}{7}\alpha\beta - \frac{32}{7}\sqrt{3}\beta\gamma\right\}$$

[56] $$(A_\parallel + 2A_\perp)/3 = K + P\left\{\frac{2}{3}(g_\perp - g_\parallel) + \frac{128}{21}\beta^2 - \frac{4}{63}\gamma^2 - \frac{6\sqrt{2}}{7}\alpha\beta + \frac{2\sqrt{6}}{7}\alpha\gamma + \frac{52}{21}\sqrt{3}\beta\gamma\right\}$$

The spin Hamiltonian parameters $g_\parallel$ and $g_\perp$ have been calculated from eqs. 48–54 for various values of c_1 and c_1/c_3. The results of such calculations are given in Fig. 1 where $g_\parallel$ is plotted against $g_\perp$. The values of c_1 and c_1/c_3 for a given complex are readily estimated from Fig. 1. Values of c_1, c_3, P, and K obtained using eqs. 48–56 are listed in Table 1 along with the corresponding values obtained from the perturbation equations.

It will be observed in Table 1 that the results from the exact calculation differ very little from the perturbation calculation. Values of c_1 determined exactly are always larger than those determined from the perturbation calculation but the difference becomes significant only for values of c_1 greater than 0.2. The only significant difference between the two sets of results is found in the values of c_3. The perturbation equations seriously overestimate the value of c_3 for complexes in which $c_1 > 0.2$. The perturbation calculation gives a nearly constant value of c_3 while the exact calculation shows c_3 to be increasing in magnitude as c_1 decreases. This latter behavior is the expected one because an increasing value of c_3 means the energy separation between the quartet state and the $^2A_1$ state is decreasing as the separation of the d_{z^2} and $d_{xz,yz}$ orbitals is increasing Since the quartet state is the ground state in an octahedral crystal field we would expect the energy separation of the quartet state and the $^2A_1$ state to diminish as the crystal field approaches an octahedral field due to basic adducts along the z axis.

The value of K fluctuates considerably due to large errors in the P term but it appears that K goes from $\sim +50 \times 10^{-4}$ cm^{-1} to $\sim -50 \times 10^{-4}$ cm^{-1} as c_1 varies from 0.3 to 0.03. The

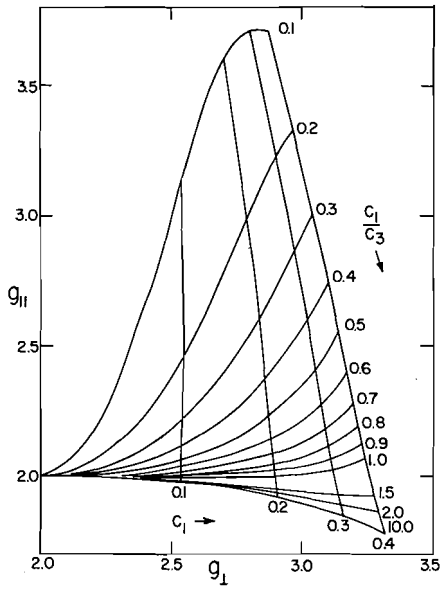

FIG. 1. Plot of $g_{\parallel}$ *vs.* $g_{\perp}$ for different values of c_1 and c_1/c_3 as obtained from the exact calculation for axial complexes with a $^2A_1$ ground state.

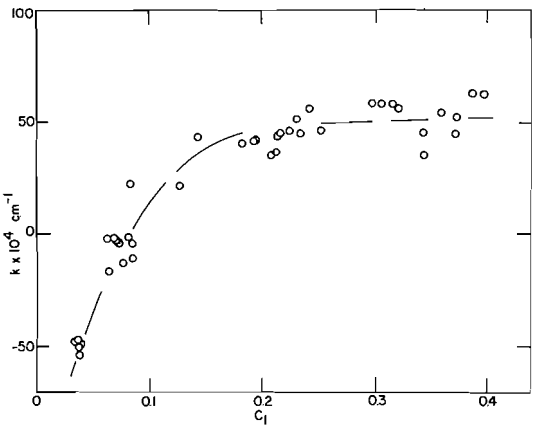

FIG. 2. K(ave.) *vs.* c_1 for porphyrin and phthalocyanine complexes.

variation in K becomes more clearly defined if we assume a constant P and use eq. 56 to determine K. This has been done using the average value ($P = 264 \times 10^{-4}$ cm^{-1}) determined from P values in Table 1. Values of K determined this way are given as K(ave.) in Table 1 and are plotted *vs.* c_1 in Fig. 2. In this plot we see that K remains nearly constant at $+50 \times 10^{-4}$ cm^{-1} above $c_1 = 0.2$ but changes rapidly to negative values when c_1 is below 0.1. A plus value of K means an admixture of the 4s orbital with the d_{z^2} orbital and therefore we must interpret Fig. 2 as showing that there is a strong admixture of the 4s orbital with the $3d_{z^2}$ orbital in the pure porphyrin or the porphyrin complexed with aromatic adducts, but this admixture is quickly reduced when bases are complexed with the porphyrin system.

Thus we see that by including the spin–orbit coupling between the doublet ground state and an excited quartet state and carrying the calculation to higher orders of perturbation, it is possible to explain the whole variation of spin Hamiltonian parameters of Co(II) porphyrins and phthalocyanines in a coherent and reasonable manner.

Nonaxial Co(II) Complexes

The problem of nonaxial complexes is difficult due to the large number of variables present in the spin Hamiltonian equations. A fair number of assumptions must be made to reduce the parameters to a manageable number and one is left with the feeling that existing data could probably be fitted to both ground states. There is one difference between the spin Hamiltonian equations for the two ground states that may be useful in distinguishing between them and this is the relative values of g_y and g_z. If one makes the reasonable assumption that the largest terms in eqs. 19, 21, 41, and 43 are those in which $(\xi/\Delta E_i)$ are raised to the first power then g_z should be less than g_y in the $^2A_1$ state while the reverse would be true for the $^2B_2$ ground state. It is possible to have values for the parameters for which this is not true but this generally requires the assumption that the d_{yz} and d_{xz} orbitals are very much different in energy. Since e.s.r. studies on copper complexes (13) of the same ligands show the d_{xz} and d_{yz} orbitals to be nearly degenerate, it seems unreasonable to accept interpretations of Co(II) e.s.r. data that require very large energy differences in these orbitals.

There are only three complexes for which g_y and g_z have been unambiguously assigned[1] in the literature. Two of them, bis(thioacetylacetanato)-cobalt(II) [Co(sacsac)$_2$] (11) and the bis(maleonitriledithiolato)cobaltate(II) ion [Co(mnt)$_2^{2-}$] (10), have $g_y > g_z$ while the third, *N,N'*-ethylenebis(salicylideneiminato)cobalt(II) [Co(salen)]

[1]The complex Co(PEt$_2$Ph)$_2$(mesityl)$_2$ (9) has the principal x and y axes directed along the bond axes and cannot therefore be treated by the present equations without modification.

TABLE 2. Values of parameters for two complexes assumed to have the $^2A_1$ ground state

Complex	c_1	c_2	c_6	b^2	K (10^{-4} cm^{-1})	P (10^{-4} cm^{-1})
Co(sacsac)$_2$	0.013	0.166	~0	0.438	−51	208
Co(mnt)$_2^{2-}$	0.031	0.101	~0	0.217	−133	341

(13), has $g_z > g_y$. The spin Hamiltonian parameters for the first two have been fitted to eqs. 19–24 for the $^2A_1$ ground state and the values obtained for the parameters are given in Table 2. In obtaining these parameters it was assumed that since the quartet terms were small for the uncomplexed porphyrins that they would be small for these complexes also so that we can take c_3, c_4, c_5, c_3', c_4', and c_5' to be zero. The sign for A_z was taken to be negative for Co(sacsac)$_2$ and Co(mnt)$_2^{2-}$ while A_x and A_y were assumed positive for Co(sacsac)$_2$ and negative for Co(mnt)$_2^{2-}$. Other assignments of sign give either smaller values of c_1 or poorer values of P.

We see from Table 2 that the e.s.r. data for both complexes can be fitted to a $^2A_1$ ground state only for a sizeable mixing of d_{z^2} and $d_{x^2-y^2}$ in the orbital containing the unpaired electron. Gregson *et al.* (11) claimed that the data for Co(sacsac)$_2$ could be fitted to a $^2A_1$ ground state with $b^2 = 0$, $c_1 = 0.04$, and $c_2 = 0.21$, but these values give $g_y = 2.17$ using eq. 21 which is in poor agreement with the experimental value of 1.904. To understand the significance of the b^2 values in Table 2, it should be noted that when $b^2 = 0.25$ the orbital containing the unpaired electron becomes the $d_{z^2-y^2}$ orbital and for $b^2 = 0.75$ it becomes the $d_{3y^2-r^2}$ orbital. The ratio of c_2 to c_1 is still large, particularly in the case of Co(sacsac)$_2$, indicating a large energy separation in the d_{xz} and d_{yz} orbitals unless the effective value of ξ is very much reduced from the free ion value.

No attempt has been made to fit the data for Co(salen) to either ground state because von Zelewsky and Fierz (13) claim to have done this for an exact calculation which implicitly ignored the quartet states. They show that the $^2B_2$ ground state is the only one which will fit the data.

Conclusion

It has been shown that to adequately explain the e.s.r. data on low spin Co(II) complexes, it is necessary to include the spin–orbit mixing of excited quartet states into the doublet ground state and that this mixing becomes important for those complexes which have formed 1:1 or 2:1 molecular complexes with basic molecules attached along the z axis. Further it has been shown that for low symmetry complexes the large anisotropy in g and A values may result from the extensive mixing of d_{z^2} and $d_{x^2-y^2}$ orbitals which is allowed in lower symmetries.

Perhaps the major conclusion to be reached is that it may be impossible to unambiguously assign ground states to low symmetry Co(II) complexes on the basis of g values and ^{59}Co hyperfine splittings alone due to the large number of variables to be adjusted in the theory. It is certainly clear that one must have g and A values clearly assigned to a particular molecular axis before one begins to interpret the data. It is not enough to take g and A from frozen glasses and to then try all combinations of assignment to molecular axes to see which gives the best fit because it will always be possible to fit the equations given here to several possible combinations. One useful piece of data which appears to be missing from systems reported upon up to the present, is the hyperfine interaction with ligand nuclei in the xy plane. Such interactions would be negligible for the $^2B_2$ ground state but should be measurable in some instances for the $^2A_1$ ground state. The d_{z^2} orbital can be written as

$$[57] \qquad d_{z^2} = (\sqrt{3})^{-1} [d_{z^2-y^2} + d_{z^2-x^2}]$$

Thus it would be reasonable to expect the hyperfine interaction from a nucleus in the xy plane to be approximately one-third that observed for a corresponding copper complex which has the unpaired electron in a $d_{x^2-y^2}$ type orbital pointed towards the nucleus. In copper complexes ^{14}N hyperfine values are typically of the order of 15×10^{-4} cm^{-1} and therefore it would seem reasonable to expect hyperfine values of $\sim 5 \times 10^{-4}$ cm^{-1} for an unpaired electron in a d_{z^2} orbital. Even if such a splitting is not resolvable it is large enough to produce a measureable broadening of the resonance in some cases and

hence should, in principle, be detectable. Unfortunately, no mention of line widths is made in the single crystal studies of complexes (12, 13) containing ^{14}N nuclei.

The structure of paniculatine, an alkaloid of *L. paniculatum*, has been elucidated. It has a skeletal structure different from other alkaloids of the *Lycopodium* family.

M. CASTILLO, G. MORALES, L. A. LOYOLA, I. SINGH, C. CALVO, H. L. HOLLAND et D. B. MACLEAN. Can. J. Chem. **53**, 2513 (1975).

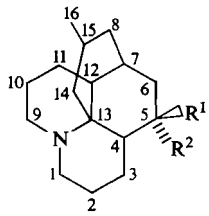
On a determiné la structure de la paniculatine, un alkaloide isolé du *L. paniculatum*. Le squelette de ce composé diffère de celui des autres alkaloides du *Lycopodium*.

[Traduit par le journal]

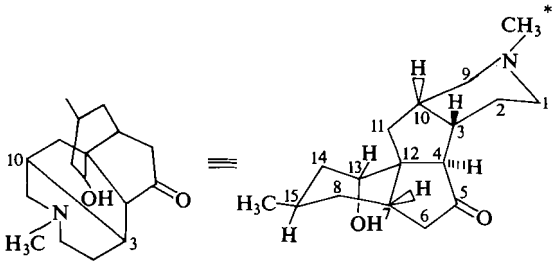
Examination of *Lycopodium paniculatum* Desvaux has revealed the presence of the alkaloids, lycopodine (**1**), dihydrolycopodine (**2**), acetyldihydrolycopodine (**3**), and three hitherto unreported bases. The structure of one of these new bases, to which we have assigned the trivial name, paniculatine, has been determined by spectral analysis and by an X-ray crystallographic study of the hydrobromide salt.

Paniculatine ($C_{17}H_{27}NO_2$),[2] m.p. 180–181 °C, exhibited infrared absorption ($CHCl_3$ solution) at 3620, 3600–3000, 1720, and 1040 cm^{-1}, indicating the presence of hydroxyl and carbonyl functions. The p.m.r. spectrum (100 MHz, $CDCl_3$ solution) showed the presence of *N*-methyl (δ 2.18, s) and a secondary *C*-methyl (δ 0.90, d, $J = 6.5$ Hz). A signal at δ 3.78 (broad s, $W_{1/2} = 8$ Hz) was attributed to a hydrogen geminal to hydroxyl in a secondary alcohol. Double irradiation data suggested the presence of the part structure —$CH(CH_3)$—CH_2—CH(OH)—.

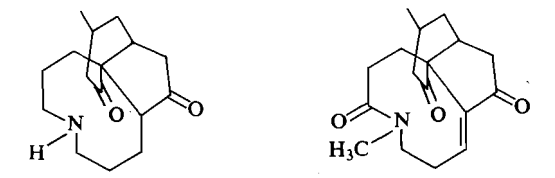
The mass spectrum of paniculatine had a molecular ion at *m/e* 277 (18%, $C_{17}H_{27}NO_2$) and a series of intense ions at *m/e* 58 (100%, C_3H_8N),[3] 71 (25%, C_4H_9N), 96 (21%, $C_6H_{10}N$),



1 $R^1, R^2 = O$
2 $R^1 = OH; R^2 = H$
3 $R^1 = OAc; R^2 = H$



4 **4**



5 **6**

*The absolute configuration has not been established and may be enantiomeric to the structure shown.

[1]Present address: Department of Chemistry, Mohawk College, Hamilton, Ontario.

[2]The formula was established by high resolution mass spectrometry and by combustion analysis.

[3]Fragment ion compositions were determined by high resolution mass spectrometry.

and 110 (11%, $C_7H_{12}N$), indicative of the presence of the *N*-methyl group in a saturated heterocycle (1). The remainder of the mass spectrum, which included ions at *m/e* 262 (10%, $M - CH_3$), 248 (5%, $M - CHO$), 204 (29%, $M - C_4H_9O$), and 192 (17%, $M - C_5H_9O$), was different from the pattern established for the mass spectral fragmentation of other *Lycopodium* alkaloids of established structure (2, 3), inferring that paniculatine is a new structural type. X-ray analysis of the hydrobromide salt of paniculatine (m.p. 310–313 °C, i.r. (KBr) 3370, 2800–2400, 1725, 1040 cm^{-1}) showed that the free base has structure **4**.

A crystal of paniculatine hydrobromide, $C_{17}H_{27}NO_2 \cdot HBr$, having approximate dimensions 0.04 × 0.02 × 0.02 cm^3 was used for the X-ray measurements. The space group was uniquely determined as $P_{2_1}(C_2^2)$ from systematic absences. The monoclinic crystals had a = 11.27(2), b = 7.520(8), c = 10.58(2), β = 102.2(2), V = 876.52 $Å^3$, Z = 2, $\lambda(MoK_\alpha)$ = 0.71069. A total of 1183 unique reflections lying in the range of $0 < 2\phi < 45°$ were measured on a $P\bar{1}$ Syntex automatic diffractometer using graphite monochromatized MoK_α radiation. The data were corrected for Lorentz and polarization effects but not for absorption. The structure was solved by locating the positions of bromide ions from the Patterson function and subsequently locating the C, N, and O atoms by a combination of Fourier and difference Fourier methods. The structure was refined by a full-matrix least-squares approach to a current R = 0.089. The three dimensional structure, shown in Fig. 1, accords with the spectral data.

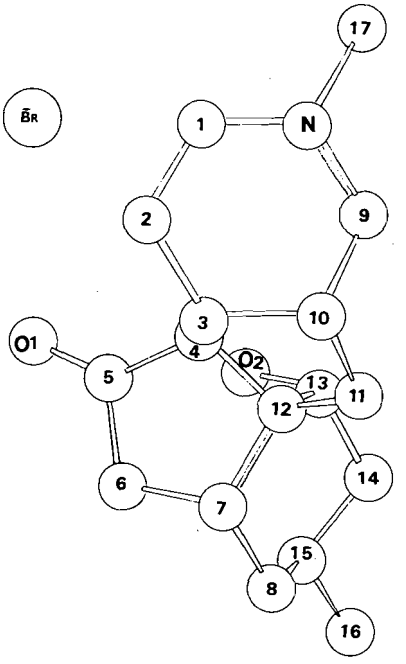


FIG. 1. The three dimensional structure of paniculatine hydrobromide.

Paniculatine bears the formal relationship to lycopodine shown in the formulas but is more closely related to fawcettimine (**5**) shown here in the open form rather than the carbinolamine (4). It differs in skeletal structure from the latter through the presence of the bond from C-3 to C-10 and by the presence of the *N*-methyl group. The C-3 to C-10 bond distinguishes paniculatine from other *Lycopodium* alkaloids of established structure (3). The formation of the C-3 to C-10 bond from a fawcettimine derivative, *e.g.* (**6**), is readily envisaged.

We thank the National Research Council of Canada for financial assistance.

Synthetic Morphinans and Hasubanans. Part IV.[1] Total Synthesis of 3,14-Dihydroxyisomorphinans, 3-Methoxy-$\Delta^{8,14}$-morphinans, and 9α-Hydroxy-3-methoxyhasubanan

IVO MONKOVIĆ,[2] HENRY WONG, BERNARD BELLEAU, IRWIN J. PACHTER,[3] AND YVON G. PERRON
Bristol Laboratories of Canada, Candiac, Quebec J5R 1J1

Received February 28, 1975

IVO MONKOVIĆ, HENRY WONG, BERNARD BELLEAU, IRWIN J. PACHTER, and YVON G. PERRON. Can. J. Chem. **53**, 2515 (1975).

The synthesis of a versatile intermediate 4a-(2-aminoethyl)-1,2,3,4,4a,9-hexahydro-6-methoxyphenanthrene (**3***a*) and its utilization in the synthesis of 9α-hydroxy-3-methoxy-17-methylhasubanan (**10**), 3,14-dimethoxy-17-methylisomorphinan (**9***l*), various 14-hydroxyisomorphinans (**9**), and 3-methoxy-$\Delta^{8,14}$-morphinan (**11***b*) is described. A number of 17-alkyl-3,14-dihydroxyisomorphinans were prepared and tested for narcotic antagonist and analgesic activities in laboratory animals. Some of these new compounds have exhibited significant activities.

IVO MONKOVIĆ, HENRY WONG, BERNARD BELLEAU, IRWIN J. PACHTER et YVON G. PERRON. Can. J. Chem. **53**, 2515 (1975).

On décrit la synthèse de l'intermédiaire versatile (aminoéthyl-2)-4a hexahydro-1,2,3,4,4a,9 méthoxy-6 phénanthrène (**3***a*) de même que son usage dans la préparation de l'hydroxy-9α méthoxy-3 méthyl-17 hasubanane (**10**), du diméthoxy-3,14 méthyl-17 isomorphinane **9***l*, de divers hydroxy-14 isomorphinanes (**9**) ainsi que du méthoxy-3 $\Delta^{8,14}$-morphinane (**11***b*). On a préparé un certain nombre d'alkyl-17 dihydroxy-3,14 isomorphinanes dont on a examiné l'activité sur des animaux de laboratoire comme antagoniste de narcotiques et comme analgésique. Quelques-uns de ces composés ont démontré des activités importantes.

[Traduit par le journal]

Introduction

At the outset of our studies on narcotic antagonists some years ago, the most exciting agent in this field was naloxone **I** (Scheme 1). Cumulative reports on its powerful antagonist activity not only against morphine but also against side effects (analgesia, psychotomimetic disorders) of other narcotic antagonists such as levalorphan (**II***a*), cyclorphan (**II***b*), cyclazocine (**III**), and others (see ref. 3 for a review) have placed naloxone in a class of its own *i.e.* a 'pure' or 'total' narcotic antagonist.

However, a more critical examination of the pharmacological properties of naloxone revealed that it suffers from a number of drawbacks: although parenterally highly potent, it is short acting, it is very poorly absorbed by the oral route, and from the chemical standpoint it is derived from thebaine which is only a minor constituent of opium. On the other hand, some totally synthetic analogs such as cyclazocine are known to be long acting and orally effective,

[1]Reference 1 is regarded as part III. For part II see ref. 2.

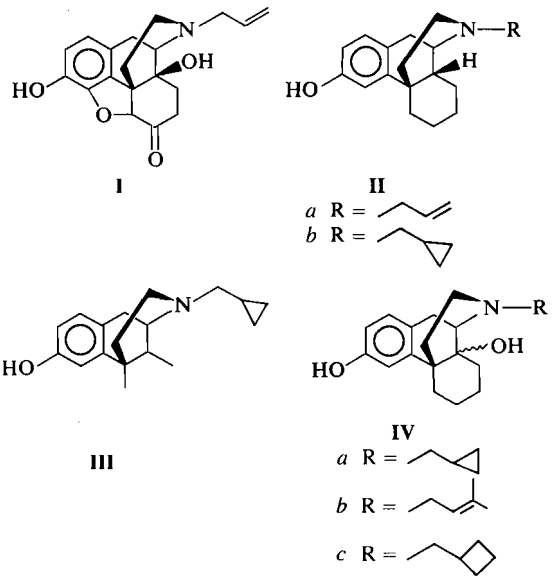
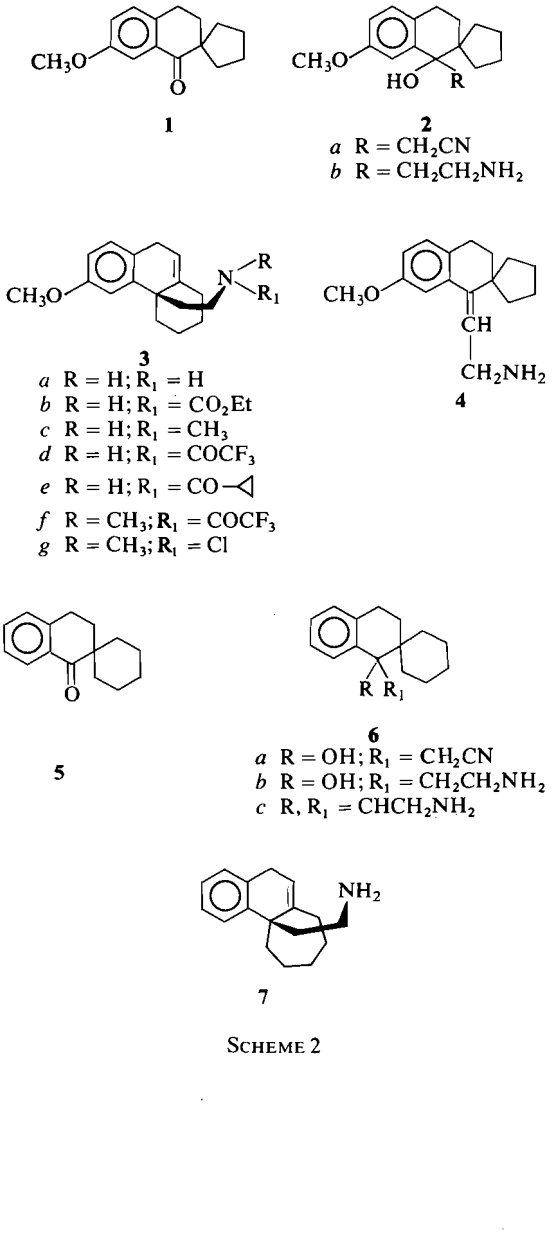


SCHEME 1

even though adverse psychomomimetic side effects have been observed with them. It seemed desirable then to prepare by total synthesis (so as to avoid opium-based starting materials) some representative 3,14-dihydroxymorphinans (**IV***a–c*) which by definition incorporate the carbon skeleton and the 14-hydroxyl substituent of naloxone as well as the nitrogen substituents of cyclazocine and pentazocine. In addition, a flexible synthetic method was desirable, which would allow for the preparation of both, 14β- and 14α-hydroxymorphinans. The latter have not been reported in the tetracyclic morphine-related structures, even though certain 14-unsubstituted isomorphinans have shown potent analgesic (4) and narcotic antagonist activities (5).

The choice of practical synthetic approaches to this end appeared to be between a classical Grewe synthesis (6, 7) which did not appear attractive to us[4] and that of a modification of thebaine, which we rejected for the already stated reasons.[5]

Consequently, we decided to utilize a synthetic approach which was initiated by one of us some years ago (10) and recently developed in our laboratories toward a successful total synthesis of D-normorphinan systems (11, 12). This approach proved to be fruitful and flexible, allowing for the preparation of various 3,14-dihydroxymorphinans (13), 3,14-dihydroxyisomorphinans (1), and a number of hasubanan derivatives (1, 2). It is the purpose of this communication to describe in full the synthesis of the common key intermediate 4a-(2-aminoethyl)-1,2,3,4,4a,9-hexahydro-6-methoxyphenanthrene **3***a* (Scheme 2), our initial studies on the intramolecular oxidative cyclization of **3***a* to morphinan and hasubanan systems, and the synthesis of a number of 3,14-dihydroxyisomorphinans, some of which exhibited moderate narcotic antagonist and analgesic activities.



SCHEME 2

[4]Attempt along these lines has been published recently by Onda *et al.* (8).

[5]Successful conversion of thebaine to 3,14-dihydroxymorphinan derivatives was described by Sawa and Tada (9).

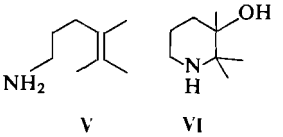
Results and Discussion

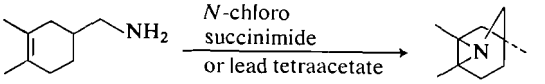
Our synthetic approach to various morphinan systems may be divided into two parts. The first consists in the successful practical synthesis of the unsaturated amine **3***a* a key intermediate analogous to the 3-unsubstituted analog already described (11). The starting material, 7-methoxy-1-tetralone (14) was alkylated by the method of Mousseron *et al.* (15) to give the spiro ketone **1** in high yield. Cyanomethylation of **1** (16) readily gave the hydroxy nitrile **2***a*, which was reduced *in situ* with lithium aluminum hydride to the amino alcohol **2***b*. Wagner–Meerwein rearrangement of **2***b* at 40° (in a refluxing mixture of concentrated hydrochloric acid and ether for 24 h), afforded unsaturated amine **3***a* in excellent yields. At room temperature, this reaction resulted in a 9:1 mixture of **3***a* and its positional isomer **4** which eventually rearranged to **3***a* at higher temperature. The characteristic n.m.r. absorptions of **3***a* at δ 5.71 (t, J = 3.5 Hz, olefinic proton at 10) and at δ 3.32 (broad singlet) for the benzylic protons can only be consistent with structure **3***a* (11). The isomeric olefin **4** was readily distinguished from **3***a* by the downfield shift of the olefinic proton signal (δ 5.35, J = 6 Hz) and the stronger coupling with its neighboring methylene protons (δ 3.43, J = 6 Hz). Attempted extension of the Wagner–Meerwein rearrangement to the homologous six-membered spiro intermediate **6***b* prepared from spiro ketone **5** by similar methods proved unsuccessful, the product of dehydration **6***c* as opposed to the rearranged product **7** being formed exclusively under our experimental conditions.

The second part of our synthesis consists in the oxidative cyclization of unsaturated amine **3***a* to the 14-hydroxymorphinan system **IV**. As far as we are aware, there are no direct methods for the conversion in a single step of γ,δ-unsaturated amines of general structure **V** to the corresponding 3-hydroxy piperidines **VI**. Accordingly, a stepwise approach had to be devised.



V VI

Our extensive experience in these laboratories with bromocyclizations of various β,γ- (17) and γ,δ-unsaturated systems (18, 19) proved of little use initially as regards the unsaturated amine **3***a*.[6] Attempts at the preparation of bridged aziridine systems such as **VIII** by the method of Nagata *et al.* (20) led mostly to the formation of intractable mixtures.



VII VIII

Our first successful formation of a morphinan functionalized at position 14 was accomplished by the method of Gassman *et al.* (21). The unsaturated amine **3***a* was first transformed into the *N*-ethoxycarbonyl derivative **3***b* followed by reduction to the *N*-methyl unsaturated amine **3***c*. This was converted to the chloramine **3***g* by reaction with *N*-chlorosuccinimide followed by methanolysis in hot methanol to give in low yield 3,14-dimethoxy-17-methylisomorphinan **9***l* (Scheme 3).

Another approach based on the intramolecular opening of an epoxide of **3***c* by the amino function was explored. In this respect it was essential to initially protect the amino function, followed by stereoselective epoxidation of the double bond in a *trans* fashion with respect to the amino ethane substituent. Next, deblocking of the nitrogen without affecting the epoxide function was desirable. Finally, it was necessary that the free amino group attack the epoxide ring regioselectively so as to give a 14-hydroxyisomorphinan rather than a 9α-hydroxyhasubanan. To this end, the unsaturated amine **3***c* was protected with a trifluoroacetyl group to give **3***f* which was then epoxidized with *m*-chloroperbenzoic acid to afford the α-epoxide **8***d* (Scheme 3). Hydrolysis of the amide function with potassium carbonate presumably gave the desired amino epoxide **8***e* which spontaneously cyclized to a 1:1 mixture of 14-hydroxyisomorphinan **9***f* and 9α-hydroxyhasubanan **10**. This approach was eventually modified so as to effect direct base-catalyzed cyclization of epoxy amides **8***a*, **8***b*, and **8***c* derived from the unsaturated amides **3***b*, **3***c*, and **3***d*. In this manner, these epoxy amides led to practical yields of the 14-hydroxy-

[6]However, subsequent experiments by Dr. T. T. Conway of these laboratories led to the successful bromocyclization of **3***a* to 9α-bromo-3-methoxyhasubanan hydrobromide, a key intermediate in our previously reported total synthesis of **11***b* (13).

isomorphinans **9***a*, **9***b*, and **9***c* when treated with sodium *t*-pentoxide in hot benzene (for **8***a* and **8***b*) or sodium hydride in DMSO (for **8***c*). Subsequent reduction of **9***a* and **9***c* with lithium aluminum hydride afforded the corresponding bases **9***f* and **9***g*. Alternatively, alkaline hydrolysis of **9***a* and **9***c* afforded the 14-hydroxy-3-methoxyisomorphinan **9***d* which was conveniently alkylated to **9***m* or acylated to **9***e* followed by reduction to **9***k*. Finally, cleavage of the ether function at the 3 position was accomplished with boron tribromide (22) in dichloromethane or with hot 48% hydrobromic acid. The 3,14-dihydroxyisomorphinans **9***j*, *k*, *n*, and **9***c* thus obtained, were tested for narcotic antagonist and analgesic activities in laboratory animals. Moderate activities comparable to those of pentazocine were observed with **9***j* and **9***h*.

While the general approach represented by scheme **3** → **8** → **9** provides a convenient entry into the 14-hydroxyisomorphinan system further modifications were required in order to synthesize the isomeric 14-hydroxymorphinans. This was initially accomplished by dehydrating **9***a* with phosphorus oxychloride in pyridine to give the $\Delta^{8,14}$-morphinan **11***a* which after hydrolysis to **11***b* was further transformed into various 14-hydroxymorphinans as previously described (13). Subsequently, a more elegant and practical synthesis of **11***a* was developed (see footnote 6).

Experimental

The melting points were determined on a Gallenkamp apparatus and are not corrected. The infrared (i.r.) spectra were recorded on a Unicam Sp-200G grating i.r. spectrometer. The n.m.r. spectra were recorded on a Varian A-60A spectrometer using deuteriochloroform as a solvent. The chemical shifts are expressed in δ values using tetramethylsilane as internal reference. Microanalysis were performed by Micro-Tech Laboratories Inc., Skokie, Ill.

3,4-Dihydro-7-methoxy-2,2-tetramethylene-1 (2H)-naphthalenone (1)

A suspension of sodium hydride (269 g of ≃56% washed with hexane) in benzene (3.75 l) was heated under reflux under nitrogen and to it was added dropwise *t*-amyl alcohol (220 g) followed by a solution of 7-methoxy-1-tetralone (440 g) in benzene (1.5 l). The mixture was stirred and heated under reflux for 45 min, followed by the rapid addition of a solution of 1,4-dibromobutane (650 g) in benzene (3 l). Stirring and heating were continued for 50 h, after which time the mixture was cooled and the excess of sodium hydride carefully decomposed with water. The benzene layer was washed with water, dried ($MgSO_4$), and concentrated *in vacuo*. The residual oil was fractionally distilled to give 455 g of **1**, b.p. 120–125°/0.1 Torr; i.r. (neat) 1725, 3340 cm^{-1}; n.m.r. δ 7.55 (1H, broad s), 7.05 (2H, m) 3.82 (3H, s), 2.9 (2H, t, J = 6 Hz), 2.0 (2H, t, J = 6 Hz), 1.1–2.3 (8H, m).

1-Hydroxy-7-methoxy-1,2,3,4-tetrahydro-2,2-tetramethylene-1-naphthaleneacetonitrile (2a) and 1-(2-Aminoethyl)-7-methoxy-1,2,3,4-tetrahydro-2,2-tetramethylene-1-naphtol (2b)

To a cooled (−80°), stirred solution of 1.6 *M* butyl lithium in hexane (1345 ml) under nitrogen was added anhydrous THF (1340 ml) followed by acetonitrile (88 g) in THF (1 l) and stirring continued for 1 h at −80°. To the resulting white suspension was added a solution of spiro ketone **1** (485 g) in THF (1.8 l). The cold bath was removed and the solution was stirred for 20 min. At this point the hydroxy nitrile *2a* can be isolated, or directly

reduced *in situ* to the amino alcohol **2***b*. Thus, the reaction mixture was poured onto cold dilute hydrochloric acid and extracted with benzene, followed by drying and evaporation of solvent to yield crude **2***a*. The pure product was obtained by recrystallization from chloroform (80% yield), m.p. 140–142°; i.r. (neat) 2260, 3420 cm^{-1}; n.m.r. δ 7.42 (1H, d, J = 2 Hz), 6.75–7.17 (2H, m), 3.85 (3H, s), 2.6–3.2 (4H, m), 1.1–2.2 (10H, m).

Anal. Calcd. for $C_{17}H_{21}NO_2$: C, 75.24; H, 7.80; N, 5.16. Found: C, 75.12; H, 7.91; N, 4.89.

Alternatively, to the above solution of **2***a* in THF was added lithium aluminum hydride (122 g) and the mixture was stirred for 2.5 h. It was then treated consecutively with water (122 ml), 5 *N* sodium hydroxide (122 ml), and again water (244 ml). The solids were removed by filtration, washed with ether, and the filtrate concentrated *in vacuo* to give 530 g of crude **2***b* as an oil which was used in the next step without further purification; i.r. (neat) 3200 cm^{-1}; n.m.r. δ 7.26 (1H, t, J = 2.5 Hz), 6.5–7.1 (2H, m), 3.83 (3H, s), 2.5–3.2 (4H, m), 1.0–2.2 (12H, m).

The oxalate salt was prepared in acetone and recrystallized from methanol, m.p. 179–180°.

Anal. Calcd. for $C_{17}H_{25}NO_2 \cdot C_2H_2O_4 \cdot CH_3OH$: C, 63.31; H, 7.70; N, 3.69. Found: C, 63.41; H, 7.43; N, 3.79.

4a-(2-Aminoethyl)-1,2,3,4,4a,9-hexahydro-6-methoxyphenanthrene (3a)

To a cooled and stirred solution of **2***b* (530 g) in ether (1 l) was added concentrated hydrochloric acid (530 ml). The cooling bath was removed and the two-phase mixture heated under reflux (steam bath) for 18 h. It was cooled, the ether layer separated, and the aqueous layer diluted with water (1 l) followed by stirring for 18 h. The deposited solid was collected by filtration, washed with acetonitrile, and dried to give 342 g of unsaturated amine hydrochloride **3***a*, m.p. 130°; i.r. (free base, neat) 3200 cm^{-1}; n.m.r. δ 6.6–7.2 (3H, m) 5.71 (1H, t, J = 3.5 Hz), 3.78 (3H, s), 3.32 (2H, broad s), 1.2–3.0 (12H).

The analytical sample was recrystallized from methanol–ether, m.p. 135°.

Anal. Calcd. for $C_{17}H_{23}NO \cdot HCl \cdot CH_3OH$: C, 66.34; H, 8.66; N, 4.29. Found: C, 66.34; H, 8.62; N, 4.26.

1-(2-Aminoethylidene)-1,2,3,4-tetrahydro-2,2-tetramethylenenaphthalene (4)

When the above rearrangement of **2***b* was carried out at room temperature for 24 h, **2***b* was all consumed but the yield of **3***a* was only 62%. However, the mother liquors contained a mixture of **3***a* and **4** in a 1:1 ratio. The unsaturated amine **4** was isolated by chromatography over alumina in 8% yield, as an oil; i.r. (neat) 3420 cm^{-1}; n.m.r. (CCl_4) δ 6.4–7.0 (3H, m), 5.35 (1H, t, J = 6 Hz), 3.67 (3H, s) 3.43 (2H, d, J = 6 Hz), 2.72 (2H, t, J = 7 Hz), 1.7 (2H, t, J = 7 Hz), 1.6 (8H, b, s).

The oxalate salt was recrystallized from methanol, m.p. 199°.

Anal. Calcd. for $C_{17}H_{23}NO \cdot C_2H_2O_4$: C, 65.69; H, 7.25; N, 4.03. Found: C, 65.81; H, 7.40; N, 4.04.

4a-[2-(Ethoxycarbonylamino)ethyl]-1,2,3,4,4a,9-hexahydro-6-methoxyphenanthrene (3b)

To a cooled (ice bath), stirred solution of unsaturated amine **3***a* (51.4 g, 0.2 mol) and triethylamine (22.2 g, 0.22 mol) in dichloromethane (200 ml) was added dropwise ethyl chloroformate (23.0 g, 0.21 mol). The mixture was stirred for 10 min and then washed with dilute hydrochloric acid (100 ml, 1 *N*) followed by water, dried, and evaporated *in vacuo*. The residual oil was dissolved in a 1:3 mixture of ether and petroleum ether (b.p. 30–60°) and the solution filtered through charcoal. The filtrate was concentrated to give 65.8 g of **3***b* as a pale yellow oil; i.r. (neat) 1725, 3340 cm^{-1}; n.m.r. δ 6.55–7.15 (3H, m), 5.7 (1H, t, J = 2.5 Hz), 4.56 (1H, m), 4.01 (2H, q, J = 7 Hz), 3.78 (3H, s), 3.25 (2H, s), 1.2–3.0 (12H, m), 1.15 (3H, t, J = 7 Hz).

Anal. Calcd. for $C_{20}H_{27}NO_3$: C, 72.9; H, 8.26; N, 4.25. Found: C, 72.71; H, 8.27; N, 4.25.

4a-[2-(Methylamino)ethyl]-1,2,3,4,4a,9-hexahydro-6-methoxyphenanthrene (3c)

To a suspension of lithium aluminum hydride (2.3 g) in dry ether (50 ml) was added dropwise under nitrogen a solution of urethane **2***b* (9.87 g) in ether (100 ml). The mixture was heated under reflux for 18 h, after which time it was worked-up in the usual manner to afford the unsaturated amine **3***c* as an oil (8.0 g); n.m.r. δ 5.60 (1H, t, J = 6 Hz, 10-H), 2.22 (3H, s, N—CH_3).

The hydrochloride salt was recrystallized from methanol–ether, m.p. 190–191°.

Anal. Calcd. for $C_{18}H_{25}NO \cdot HCl$: C, 70.22; H, 8.51; N, 4.55. Found: C, 70.39; H, 8.71; N, 4.48.

Amides 3d–3f

Amides **3***d*–**3***f* were prepared by a procedure similar to that described above for the preparation of **3***b*.

4a-[2-(Trifluoroacetylamino)ethyl]-1,2,3,4,4a,9-hexahydro-6-methoxyphenanthrene (3d)

White solid from ether – petroleum ether (89%), m.p. 99–101°.

Anal. Calcd. for $C_{19}H_{22}F_3NO_2$: C, 64.58; H, 6.28; N, 3.96. Found: C, 64.82; H, 6.25; N, 3.82.

4a-[2-(Cyclopropylcarbonylamino)ethyl]-1,2,3,4,4a,9-hexahydro-6-methoxyphenanthrene (3e)

White solid (79%) from methanol, m.p. 126–130°.

Anal. Calcd. for $C_{21}H_{27}NO_2$: C, 77.50; H, 8.36; N, 4.30. Found: C, 77.21; H, 8.40; N, 4.09.

3,4-Dihydro-2,2-pentamethylene-1(2H)-naphthalenone (5)

To a cooled stirred (ice-salt) suspension of sodium hydride (21.3 g of ≃ 56%, washed with hexane) in DMF (300 ml) was added dropwise a solution of 1-tetralone (36.55 g) and 1,5-dibromopentane (57.5 g) in DMF (150 ml) over a 2 h period. The internal temperature during the addition was maintained at 5–10°. When the addition was completed, the mixture was stirred for 30 min at 8–12° and then for 2 h at room temperature. It was then partitioned between water and petroleum ether and the organic layer washed with water, dried, and evaporated. The residual oil was distilled to give 29.5 g of spiro ketone **5**, b.p. 115–120°/0.05 Torr; i.r. (neat), 1680 cm^{-1}; n.m.r. (CCl_4), δ 7.9–8.1 (1H, m), 7.0–7.5 (3H, m), 2.93, (2H, t, J = 6 Hz), 20 (2H, t, J = 6 Hz), 1.15–2.0 (10H, m). This product was probably contaminated with some dibromopentane, as judged from the empirical analysis (carbon lower by 0.6%). It was used in the next step without further purification.

1-Hydroxy-1,2,3,4-tetrahydro-2,2-pentamethylen-1-naphthaleneacetonitrile (6a)

The hydroxynitrile **6***a* was obtained in 83% yield by a

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/05/12
For personal use only.

similar procedure as given for the preparation of **2***a*, m.p. 128–131° (from benzene); i.r. 2260, 3440 cm^{-1}; n.m.r. ($CDCl_3$) δ, 7.7–7.9 (1H, m), 7.0–7.4 (3H, m), 2.6–3.1 (4H, m), 2.0–2.5 (2H, m), 1.1–1.9 (10H, m).

Anal. Calcd. for $C_{17}H_{21}NO$: C, 79.96; H, 8.29; N, 5.48. Found: C, 79.74; H, 8.28; N, 5.41.

1-(2-Aminoethyl)-1,2,3,4-tetrahydro-2,2-pentamethylene-1-naphtol (6b)

The amino alcohol **6***b* was obtained in a quantitative yield from hydroxynitrile **6***a* by the procedure described above for the preparation of **2***b*; i.r. (neat) 3220, 3470 cm^{-1}; n.m.r. ($CDCl_3$), δ 7.45–7.7 (1H, m), 6.9–7.4 (3H, m), 2.55–3.0 (4H, m), 0.8–2.5 (12H, m). The oxalate salt was prepared in ether, m.p. 167–171°.

Anal. Calcd. for $C_{17}H_{25}NO \cdot C_2H_2O_4 \cdot \frac{1}{2}H_2O$: C, 63.67; H, 7.67; N, 3.01. Found: C, 63.43; H, 7.53; N, 4.06.

1-(2-Amino-1-ethylidene)-1,2,3,4-tetrahydro-2,2-pentamethylenenaphthalene (6c)

A solution of the amino alcohol **6***b* (2.0 g) in methanol (60 ml) was added dropwise with stirring to concentrated hydrochloric acid (60 ml). The internal temperature during the addition was maintained at 30–36°. After addition was completed, stirring was continued for 15 min at the same temperature whereupon the mixture was poured onto water, basified with ammonium hydroxide, and extracted with benzene. The extract was dried and concentrated *in vacuo* to give 1.6 g of crude **6***c*; i.r. (neat) 3200 cm^{-1}; n.m.r. ($CDCl_3$) δ 7.1–7.4 (4H, m), 5.7 (1H, t, J = 7 Hz), 3.74 (2H, d, J = 7 Hz), 2.8 (2H, t, J = 6 Hz), 1.73 (2H, t, J = 6 Hz), 1.44 (10H, s).

The hydrochloride salt was prepared in ether and recrystallized from methanol–ether, m.p. 206–208°.

Anal. Calcd. for $C_{17}H_{23}N \cdot HCl$: C, 73.49; H, 8.71; N, 5.04. Found: C, 73.18; H, 8.89; N, 5.06.

10,10a-α-Epoxy-4a-[2-(ethoxycarbonylamino)ethyl]-1,2,3,4,4a,9,10,10a-octahydro-6-methoxyphenanthrene (8a)

To a cooled (5–10°) stirred solution of the urethane **3***b* (55.8 g) in dichloromethane (150 ml) was added in small portions 45 g of *m*-chloroperbenzoic acid (85% purity) and the mixture left at room temperature for 5 h. The precipitated solid was removed by filtration and the filtrate washed with aqueous sodium sulfite followed by 5% aqueous sodium bicarbonate and finally with water. Drying and evaporation of the solvent afforded an oil, which was dissolved in ether followed by the addition of petroleum ether. After filtration through Celite–charcoal and concentration of the filtrate *in vacuo*, there was obtained 65.8 g of epoxide **8***a* as an oil which solidified on standing, m.p. 75–77° (ether).

Anal. Calcd. for $C_{20}H_{27}NO_4$: C, 69.54; H, 7.77; N, 4.05. Found: C, 69.30; H, 7.95; N, 3.90.

10,10a-α-Epoxy-4a-[2-(trifluoroacetylamino)ethyl]-1,2,3,4,4a,9,10,10a-octahydro-6-methoxyphenanthrene (8b)

To a solution of amide **3***d* (7.06 g) in dichloromethane (140 ml) was added in small portions with stirring and cooling (5–10°) *m*-chloroperbenzoic acid (4.2 g, 85% purity). The mixture was left at room temperature for 18 h and then worked-up as described for the isolation of **8***a* to give 7.36 g of epoxide 7*b* as an amorphous solid. A sample was prepared for analysis by dissolving in ether followed by precipitation with excess petroleum ether; the syrup was dried under high vacuum to yield amorphous solid, m.p. 45–50°.

Anal. Calcd. for $C_{19}H_{23}F_3NO_3$: C, 61.79; H, 6.00; N, 3.79. Found: C, 62.02; H, 6.07; N, 3.74.

10,10a-α-Epoxy-4-[2-(cyclopropylcarbonylamino)ethyl]-1,2,3,4,4a,9,10,10a-octahydro-6-methoxyphenanthrene (8c)

The epoxide **8***c* was obtained in 78% yield from amide **3***c* by a procedure similar to that given for the preparation of **8***b* except that purification was accomplished by crystallization from ether, m.p. 130–132°.

Anal. Calcd. for $C_{21}H_{27}NO_3$: C, 73.87; H, 7.97; N, 4.10. Found: C, 73.71; H, 8.06; N, 4.20.

10,10a-α-Epoxy-4a-[2-(N-trifluoroacetyl-N-methylamino)ethyl]-1,2,3,4,4a,9,10,10a-octahydro-6-methoxyphenanthrene (8d)

The epoxide **8***d* was obtained as an oil in a quantitative yield by a procedure similar to that given for the preparation of **8***b*, except that the time required for completion of the reaction was 1 h.

Anal. Calcd. for $C_{20}H_{24}F_3NO_3$: C, 62.65; H, 6.31; N, 3.65. Found: C, 62.89; H, 6.48; N, 3.66.

17-Ethoxycarbonyl-14-hydroxy-3-methoxyisomorphinan (9a)

To a stirred boiling suspension of sodium hydride (3.15 g of ≃56%, washed with hexene) in dry benzene, under nitrogen atmosphere, was added a solution of anhydrous *t*-amyl alcohol (5.87 g) in benzene (50 ml). When the hydrogen evolution had subsided (*ca.* 15 min), a solution of epoxide **8***a* (23.0 g) in benzene (500 ml) was added dropwise over a 4 h period and stirring and heating were continued for 18 h. After cooling, the mixture was washed with water, dried, and concentrated *in vacuo*. The residual oil was dissolved in ether and the resulting solution was diluted with petroleum ether. The cloudy mixture was filtered through Celite–charcoal cake and the filtrate evaporated to dryness to give 20.0 g of the isomorphinan **9***a* as a yellow oil. A sample solidified after distillation at 100°/0.05 Torr, m.p. 50°; i.r. (Nujol) 1690, 3300 cm^{-1}; n.m.r. δ 6.5–7.2 (3H, m), 4.15 (2H, q, J = 7 Hz), 3.78 (3H, s), 2.3–3.8 (5H, m), 1.3–2.3 (10H, m), 1.26 (3H, t, J = 7 Hz).

Anal. Calcd. for $C_{20}H_{27}NO_4$: C, 69.54; H, 7.88; N, 4.05. Found: C, 69.21; H, 8.01; N, 3.95.

14-Hydroxy-3-methoxy-17-trifluoroacetylisomorphinan (9b)

The hydroxy amide **9***b*, an amorphous solid, was obtained from **8***b* in 68% yield together with the product of hydrolysis **8***d* (8%) by a procedure similar to that given for the preparation of **9***a* except that the reaction time was 3.5 h.

Mol. Wt. Calcd. for $C_{19}H_{23}F_3NO_3$: 369. Found (mass spectrometry): 369.

17-Cyclopropylcarbonyl-14-hydroxy-3-methoxyisomorphinan (9c)

To a stirred and cooled (5–8°) suspension of sodium hydride (1.8 g, hexane washed) in a mixture of anhydrous THF (200 ml) and DMSO (200 ml) was added epoxide **8***c* (13.08 g). The mixture was stirred at 5–8° for 3 h and

then for 1 h at room temperature. It was then poured onto water and extracted with benzene. The organic layer was washed with water several times, dried, and concentrated *in vacuo*. The residual oil was crystallized from ether to yield 6.56 g of isomorphinan **9c** (50%) as a white solid, m.p. 162–64°; i.r. (Nujol), 1640, 3410 cm^{-1}.

Anal. Calcd. for $C_{21}H_{27}NO_3$: C, 73.87; H, 7.97; N, 4.10. Found: C, 73.70, H, 8.13; N, 4.02.

14-Hydroxy-3-methoxyisomorphinan (9d)

A mixture of **9a** (10.0 g) and potassium hydroxide pellets (6.0 g) in 1-octanol (50 ml) was heated under reflux for 30 min under nitrogen. After cooling, the mixture was poured onto water and extracted with ether. The organic layer was extracted with 2 *N* hydrochloric acid (2 × 60 ml) and the extract washed with ether to remove 1-octanol. The aqueous layer was made alkaline and extracted with ether to give after drying and concentration 7.5 g of crude **9d** as an oil. The hydrochloride salt was recrystallized from isopropyl aclcohol – ether to afford 5.2 g (58%) of pure product, m.p. 261–271°; i.r. (free base), 3360 and 3460 cm^{-1}; n.m.r. ($CDCl_3$) δ 6.6–7.3 (3H, m), 3.78 (3H, s), 3.55 (1H, d, J = 7 Hz), 3.25 (1H, d, J = 7 Hz), 0.8–3.0 (13H, m).
