Possible routes to some of the products are given in Scheme 5. The presence of the ketones among the products is good evidence that 2-phenyl-2-butoxy radicals are formed which then undergo β-sission. The alkoxy radicals must result from the reaction between 2-phenyl-2-butyl radicals and a nitro group. The alkenes **17** and *Z*- and *E*-**18** are not likely to be formed by disproportionation between two 2-phenyl-2-butyl radicals since neither the alkane (±)-**16**, which would be the other product of disproportionation, nor the coupling product **14** is formed. The absence of **14** is good evidence that the radicals never encounter each other since coupling is an important result of such encounters as shown by thermolysis of (±)-**4** and (±)-**7** at lower temperatures. The higher temperature in the thermolysis of (±)-**12** should not be the reason for lack of formation of **14** since in thermolysis of (±)-**7** a slightly higher relative yield of **14** was formed at 125 °C than at 100 °C. The alkenes may be formed by disproportionation of 2-phenyl-2-butyl and 4-nitrophenyldiazenyl radicals in the initial solvent cage.

Since 2-phenyl-2-butyl radicals do not couple under these reaction conditions it is unlikely that 4-nitrophenyl radicals would couple, hence the suggested route to **25** in Scheme 5. The formation of **25** in 79% yield on thermolysis of neat (±)-**12** at 175 °C is consistent with the proposed route. Higher concentrations of the diazene would favor the addition of the nitrophenyl radical to the diazene. Only ~15% total yield of the products of the 2-phenyl-2-butyl radical were detected. The reaction was not done in a sealed tube and these products may have evaporated.

Thermolysis of Optically Active Diazenes

Thermolysis of (−)-(*R*)-**4** in benzene at 110 °C produced (+)-(*S*)-**6** with 6% net retention of configuration, Table 3. In the presence of 0.9 *M* butanethiol (+)-(*S*)-**6** is formed with ~12% net retention of configuration in either benzene or

[d]α_D^{22} + 14.0° (neat, *l* 1 dm), 33% optically pure.
[e](−)-(*R*)-**7** was actually used, $[\alpha]_{436}^{22}$ − 82.9° (*c* 0.567, CCl_4). The material was heated for 22 h, 700 mg recovered material had $[\alpha]_{436}^{22}$ − 81.4° (*c* 0.631, CCl_4).

pentane. In neat butanethiol the degree of retention is also ~12%. These results are very similar to those obtained on thermolysis of **1** and **2**. There is a higher degree of retention in the presence of butanethiol because no racemic coupling product is formed outside the initial solvent cage as in unscavenged runs.

The stereochemistry of the coupling product obtained from thermolysis of (+)-(*S*)-**7** could not be determined. Even the isolated product from scavenged runs had no observable rotation at 310 nm, the position of the peak in the ord curve of optically pure (−)-(*S*)-**11**. At the maximum concentration of coupling product that could be used without overloading the photomultiplier, product with an optical purity of 15% would have given a reading on the ord instrument of ~0.05°. This is similar in magnitude to the baseline noise of the instrument. Thus, the optical purity of the coupling product is less than 15%.

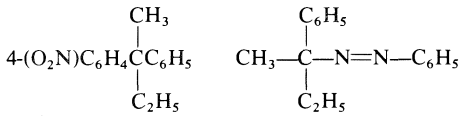
Fortunately, the 2-phenyl-2-butyl radical produced in the reaction is also converted to another product with a chiral center, (−)-(*R*)-**16**, which has an observable rotation. Only in the presence of scavenger was enough (−)-(*R*)-**16** produced to be isolated. The optical activity of this product is due entirely to that fraction of the product that was formed by disproportionation in the original solvent cage. Since scavenging of the 2-phenyl-2-butyl radicals that escape from the original solvent cage must produce (±)-**16** the amount of retention of (−)-(*R*)-**16** formed in the cage must be greater than that indicated in Table 4. The relative amounts of material formed inside and outside the solvent cage were not determined but a reasonable estimate can probably be made. For the 2-phenyl-2-propyl–cyclohexyl radical pair the ratio of the rate of disproportionation to 2-phenylbutane and cyclohexene to the rate of coupling is estimated to be 0.24 (23). This ratio for the 2-phenyl-2-butyl–2-propyl radical pair should be quite similar. From the relative yields of (±)-**16** (64%) and (±)-**11** (36%) formed in the presence of butanethiol it can be reckoned that ~0.24 × 36/64 = ~$\frac{1}{7}$ of the total (±)-**16** was formed in the original solvent cage. Thus, the (−)-(*R*)-**16** that was formed from (+)-(*S*)-**7** in the original solvent cage was produced with ~5–9% net retention of configuration.[4]

Recovery of (−)-(*R*)-**7** after heating at 100 °C in benzene for one half-life of decomposition gave product with 1.8% lower rotation than that of starting material. Since the experimental error

[4]A radical disproportionation giving product with a high degree of retention has been observed already. Cage disproportionation during thermolysis of an optically active diacyl peroxide produced product with 31–37% net retention of configuration (24).

must be of nearly the same magnitude there is no evidence that (−)-(*R*)-**7** racemizes during thermolysis.

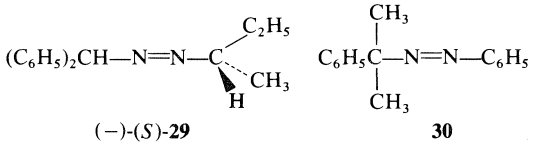
Thermolysis of (±)-**12** produced no coupling product, 2-(4-nitrophenyl)-2-phenylbutane **27** so the only stereochemical result sought was whether (−)-(*R*)-**12** racemized during thermolysis. Recovered (−)-(*R*)-**12** showed no loss of optical activity after heating at 175 °C for 3.5 half-lives of decomposition in cumene. After this experiment had been performed it was reported that optically active **28** racemized during photolysis (6*c*,*d*). The photolysis of (+)-(*S*)-**12** was then carried out. Starting material was recovered after 40% decomposition in hexane or 60% decomposition in hexadecane at 15 °C with no loss of optical activity. In hexadecane a 3% yield of coupling product **27** was formed which showed no optical activity. No attempt was made to isolate the *Z*-isomer of (+)-(*R*)-**12**.



27 **28**

Discussion

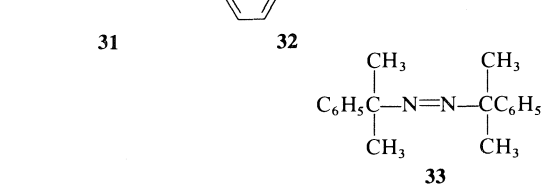
The main purpose of this study was to determine whether **7** and **12** underwent thermolysis by a concerted two-bond [1] or a stepwise one-bond [2] cleavage process. The lack of racemization of the optically active isomers during thermolysis provides no support for the stepwise process. Stereochemical evidence obtained recently indicates that thermolysis of (−)-(*S*)-**29** proceeds by a one-bond cleavage process to give, initially, the diphenylmethyl–2-butyldiazenyl radical pair (21). Viewed in this light thermolysis of **12** also would be expected to proceed in a stepwise manner. The aryl–N bond of **12** is much stronger than the 2-butyl–N bond of (−)-(*S*)-**29** and the difference in the strengths of these two bonds probably is greater than the difference in the strengths of the other two C—N bonds of the two diazenes. Evidence in support of one-bond cleavage in the thermolysis of **12** is the observation that no coupling product **27** was formed. Had the 2-phenyl-2-butyl–4-nitro-phenyl radical pair been formed in the solvent cage some cage recombination very likely would have occurred as cage recombination appears to be a reaction common to all but the most bulky (25) of caged radical pairs. The observation that the *Z*-isomers of **28** and **30** decompose thermolytically by a one-bond cleavage mechanism (6*c*, 6*d*, 9) also lends support to a one-bond cleavage process for thermolysis of **12**.



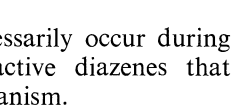
(−)-(*S*)-**29** **30**

It is more difficult to determine from circumstantial evidence whether **7** undergoes thermolysis by a one- or two-bond cleavage process. The enthalpy of activation for thermolysis of the structurally analogous compound **13**, 36 kcal/mol (17), is within experimental error of that for **12**. Thus, breaking of the 2-propyl–N bond of **7** does not appear to be important in the rate determining step. Cage coupling product still could be formed as a result of a one-bond cleavage process if the 2-propyldiazenyl radical has a very short lifetime. It appears that the 2-butyldiazenyl radical decomposes within the original solvent cage (21). Most of the chemistry of **7** can be accounted for in terms of either a one- or a two-bond cleavage process. Only the enthalpy of activation seems to be in favor of a one-bond cleavage process although arguments in favor of a concerted cleavage for **13** have been made (17).

The lack of racemization of (+)-(*S*)-**7** and, especially, of (−)-(*R*)-**12** during thermolysis contrasts with the reported racemization of optically active **31** (6*a*) and **32** (6*b*). It is clear that racemization does not necessarily occur during thermolysis of optically active diazenes that cleave by a one-bond mechanism.



31 **32**



33

The lack of racemization of (+)-(*S*)-**12** during photolysis was also surprising in view of the

racemization of optically active **28** under essentially identical conditions. The latter compound is isomerized on photolysis to the thermally labile *Z*-isomer which then decomposes thermally by a one-bond cleavage process. Recombination of the 2-phenyl-2-butyl radical pair leads to partially racemized starting material (*6d*). The reason for the difference in behavior of (+)-(*S*)-**12** is not clear and a discussion of the possible factors involved would be premature before the *Z*-isomer is isolated and studied.

The ratio of the rate constant for coupling (or disproportionation) of the caged radical pair to that for rotation of the 2-phenyl-2-butyl radical with respect to its caged partner, k_c/k_r, can be estimated for the radicals derived from (−)-(*R*)-**4** and (+)-(*S*)-**7** [6] (1),

$$[6] \qquad k_c/k_r = F(1-f)\left(\frac{\text{retention}}{\text{inversion}} - 1\right)_{\text{cage}}$$

where F is the fraction of radicals which are consumed by coupling and disproportionation before diffusion from the original solvent cage and f is the fraction of radicals consumed in this way that undergo disproportionation. Accurate determinations of the cage effects were not carried out but reasonable estimates for the range of cage effects can be made. For (−)-(*R*)-**4** the minimum value is 15%, the absolute yield of **6** formed in the presence of scavenger. There is very little disproportionation. This value is lower than the values of the cage effect found for **1**, 25–30% at 110 °C (1), **2**, 28% at 105 °C (2, 26), and **33**, 21%, extrapolated to 110 °C (27). The actual cage effect is thus in the range 15–30%. For (+)-(*S*)-**7** the minimum value is 21%, the absolute yield of **11** formed in the presence of scavenger. However, a large amount of disproportionation must also take place. By analogy to the 2-phenyl-2-propyl–cyclohexyl radical pair (23) about 1.5 times as much disproportionation as coupling occurs and the actual cage effect for (+)-(*S*)-**7** must be ~50%. For the radical pair derived from (−)-(*R*)-**4**, k_c/k_r is in the range 0.04–0.08 at 110 °C in benzene and for the radical pair derived from (+)-(*S*)-**7**, k_c/k_r is 0.02–0.04 at 100 °C in benzene. In the latter case k_c actually represents the rate constant for disproportionation to (−)-(*R*)-**16** and propene. These values for k_c/k_r are similar in magnitude to those, ~0.06–0.10, found for the radical pairs derived from **1** and **2**.

Experimental

Boiling points and melting points are uncorrected. Infrared spectra were recorded on Perkin-Elmer model 421 or model 337 recording infrared spectrophotometers. Ultraviolet spectra were measured on a Bausch and Lomb Spectronic 600 spectrophotometer. Nuclear magnetic resonance spectra were recorded on Varian analytical spectrometers, models A-60 and A-56/60. Tetramethylsilane was used as internal reference. Neat optical rotations were taken with a Rudolph polarimeter model 80 and solution optical rotations were taken with a Perkin-Elmer 141 polarimeter. Optical rotatory dispersion curves were taken on a Japan Spectroscopic Company spectropolarimeter model ORD/UV-5. Gas chromatography was carried out on Aerograph 202 and A90-P3 fractometers with a 6 ft × ¼ in. stainless steel column packed with 20% SF96 on 60/80 Chromosorb P, column A, or with 10% Carbowax 20 M on 60/80 Chromosorb P, column B.

Chlorobenzene and bromobenzene were purified by successive shaking with three portions of sulfuric acid, two of water, and two of sodium bicarbonate. The materials were dried over magnesium sulfate and distilled from phosphorus pentoxide through a 4 ft Podbielniak column or a 24 in. Nester–Faust annular Teflon spinning band column. Middle fractions were collected and stored over molecular sieves. Aliquots were distilled from the stored solutions just before use. Benzene, cumene, and cyclohexane were purified and stored in the same manner except that they were distilled from sodium wire. Diphenyl ether was recrystallized twice from pentane.

(±)-1-(1-Methylethylidene)-2-(2-phenyl-2-butyl)diazane

A mixture made from 20 g (2-phenyl-2-butyl)diazane (28), bp 90 °C/1.4 torr, n_D^{25} 1.5365 (lit. (28) bp 81–84 °C/0.4 torr, n_D^{25} 1.5354), 7.5 g magnesium sulfate, and 133 ml acetone was stirred under nitrogen at 45 °C for 2 h and then at 23 °C for 12 h. The reaction mixture was filtered, concentrated, and distilled to yield 21 g (84%) of a light yellow oil bp 82 °C/0.6 torr; n_D^{27} 1.5219; nmr (CCl_4) τ 2.75 (m, 5.0H), 5.5 (br, 0.7H), 8.15 (q, J = 7.5 Hz, 2H), 8.17 (s, 3H), 8.34 (s, 3H), 8.65 (s, 3.1H) and 9.35 (t, J = 7.5 Hz, 3.0H).

(±)-1-(2-Phenyl-2-butyl)-2-(2-propyl)diazene, (±)-7

A solution of 2.0 g (0.01 mol) of the above hydrazone in 20 ml ether was added over 3 h to 0.50 g (0.013 mol) of lithium aluminum hydride in 100 ml ether. The reaction mixture was stirred under nitrogen at reflux for 3 days and then hydrolyzed by successive addition of 0.5 ml water, 1.0 ml 10% potassium hydroxide, and 0.5 ml water. The mixture was filtered and the filtrate was stirred in an unstoppered flask for 8 h, then washed with water, dried over sodium carbonate, and concentrated. The residue was adsorbed on a 30 × 1.5 cm column of neutral alumina. A green band was eluted with 50 ml pentane. Solvent was removed and the residue kept under vacuum as a thin film for several hours to leave 1.1 g (55%) of a green oil, n_D^{25} 1.4932; ir (CCl_4) 1580 cm^{-1} (N=N, weak); λ_{max} (ether) 368 nm, log ε 1.46; nmr (CCl_4) τ 2.62 (m, 5.0H), 6.25 (septet, J = 6.5 Hz, 1.0H) 8.04 (q, J = 7.5 Hz, 2.2H), 8.62 (s, 3.3H), 8.75 (d, J = 6.5 Hz, 6.1H), and 9.34 (t, J = 7.5 Hz, 3.1H).

(+)-(S)-1-(2-Phenyl-2-butyl)-2-(2-propyl)diazene, (+)-(S)-7

Reduction of 30 g of (±)-1-(1-methylethylidene)-2-(2-phenyl-2-butyl)diazane was carried out as described above except that the reaction mixture (1500 ml), after hydrolysis, was filtered into a 2 ℓ flask which contained a cold solution of 45 g dibenzoyl tartaric acid (29); mp 89–90 °C; $[\alpha]_D^{25}$ −115.3° (*c* 1.03, methanol) (lit. (29) mp 89–91 °C; $[\alpha]_D^{25}$ −112.5° (30)). Eight grams of precipitate formed immediately. The remainder of the solution was allowed to stand at 5 °C for 48 h to give 20 g of crystals. The two crops were recrystallized separately twice from 2:1 ethanol–water, 10 ml/g of crystals, to give 1.3 g and 7 g of white, slender needles. Both batches had mp 109–110 °C; $[\alpha]_D^{25}$ −65.2° (*c* 1, chloroform). Further recrystallization did not change the rotation of the salt or that of the diazene prepared from it. *Anal.* calcd. for $C_{31}H_{36}N_2O_8$: C 65.94, H 6.43, N 4.96; found: C 65.65, H 6.23, N 5.08.

The dibenzoyltartrate salt (3 g) was treated with 20 ml 10% potassium hydroxide solution and the hydrazine was extracted into ether (2 × 20 ml). The combined ether extracts were washed with water, dried, and the hydrazine oxidized to the azo compound, which was isolated as described for the preparation of (±)-**7**, to give 0.65 g oil; n_D^{25} 1.4934; α_D^{25} +35.5° (neat, *l* 1 dm); ord (*c* 0.25, cyclohexane) $[\Phi]_{700}$ +98°, $[\Phi]_{589}$ +130°, $[\Phi]_{500}$ +230°, $[\Phi]_{450}$ +408°, $[\Phi]_{410}$ +980°, $[\Phi]_{398}$ +1110°, $[\Phi]_{380}$ +506°, $[\Phi]_{374}$ 0°, $[\Phi]_{360}$ −945°, $[\Phi]_{346}$ −127°, $[\Phi]_{310}$ −620°. *Anal.* calcd. for $C_{13}H_{20}N_2$: C 76.42, H 9.87, N 13.71; found: C 76.12, H 9.86, N 13.86.

(±)-2-Acetoxy-2,3-dimethyl-3-phenylpentane

A solution of 13 g (0.066 mol) of 2-methyl-2-phenylbutanoyl chloride (31) in 90 ml ether was added to a rapidly stirred solution of methyllithium, made from 3.7 g (0.53 mol) lithium and 37.5 g (0.264 mol) methyl iodide in 200 ml ether, at −60 °C. The reaction mixture was allowed to warm to 0 °C, 100 ml saturated ammonium chloride solution was added, and the aqueous solution was extracted with ether. The combined ether solutions were successively washed with solutions of sodium bisulfite and sodium bicarbonate, water, and then dried. The ir spectrum of the oil obtained on concentration of a portion of the ether solution showed moderate carbonyl absorption (1710 cm^{-1}) so the entire solution was treated with excess methyllithium and the reaction mixture worked-up as described above. The ether was removed to give 12 g of an oil which was acetylated (32) with acetyl chloride to give 8.5 g (55%) of product, bp 88–89 °C/0.4 torr; n_D^{25} 1.5034; nmr (CCl_4) τ 2.8 (m, 5.1H), 7.75 (m, 2H), 8.14 (s, 3H), 8.55 (s, 3H), 8.66 (s, 6H), and 9.33 (t, *J* = 7.5 Hz, 3H). *Anal.* calcd. for $C_{15}H_{22}O_2$: C 76.88, H 9.46; found: C 77.06, H 9.17.

(±)-2,3-Dimethyl-3-phenyl-1-pentene, (±)-10

A solution of 1.9 g of the above acetate in 10 ml methanol was pyrolyzed by dropwise addition (33) into a heated 1 in diameter glass tube filled to 12 in with glass helices. The optimum conditions were determined by pyrolyzing small quantities of the solution and analyzing the pyrolysate by gc. An equal volume of water was added to the pyrolysate and the resulting mixture shaken with ether (2 × 20 ml). The combined ether extracts were shaken with sodium bicarbonate solution, dried, and concentrated. The residue was distilled through a microdistillation apparatus to yield 0.9 g (61%) of a colorless oil, bp 107–110 °C/23 torr; n_D^{25} 1.5103; ir (CCl_4) 1635 and 895 cm^{-1} (=CH_2); nmr (CCl_4) τ 2.8 (s, 5.1H), 5.05 (s, 1.9H), 8.12 (q, *J* = 7 Hz, 2.1H), 8.52 (s, 3.1H), 8.66 (s, 3.1H), and 9.21 (t, *J* = 7 Hz, 3.0H). *Anal.* calcd. for $C_{13}H_{18}$: C 89.58, H 10.41; found: C 89.80, H 10.60.

(+)-(S)-2,3-Dimethyl-3-phenyl-1-pentene, (+)-(S)-10

A sample of (−)-(*R*)-2-methyl-2-phenylbutanoic acid (31) of $[\alpha]_D^{25}$ −29.06° (*c* 4.8, benzene) (lit. (31) $[\alpha]_D^{25}$ −30.0° for optically pure material) was converted to the crude 2-acetoxy-2,3-dimethyl-3-phenylpentane as described above. This acetate, which was prepared from ketone free alcohol, was pyrolyzed as described above to give the product bp 105–109 °C/21 torr; n_D^{29} 1.5101; α_D^{25} +11.3° (neat, *l* 1 dm) whose ir and nmr spectra were identical to those of the racemic material.

(±)-2,3-Dimethyl-3-phenylpentane, (±)-11

A mixture of 1 g (±)-**10** in 20 ml ethanol and 0.1 g 5% rhodium on alumina was stirred under hydrogen in a microhydrogenation apparatus for 24 h. The theoretical amount of hydrogen was consumed after 1 h and no more was taken up. The catalyst was filtered, the solvent removed, and the residue distilled through a microdistillation apparatus to give a colorless oil, bp 105–107 °C/21 torr; n_D^{27} 1.5012; nmr (CCl_4) τ 2.86 (s, 5H), 7.9–8.7 (m, 3H), 8.83 (s, 3H), 9.10 (d, *J* = 6.5 Hz, 3H), 9.35 (d, *J* = 6.5 Hz, 3H), and 9.31 (t, *J* = 7 Hz, 3H). *Anal.* calcd. for $C_{13}H_{20}$: C 88.57, H 11.43; found: C 88.89, H 11.48.

(−)-(S)-2,3-Dimethyl-3-phenyl-1-pentane, (−)-(S)-11

Hydrogenation of (+)-(*S*)-**10**, α_D^{25} +11.3°, as described above afforded (−)-(*S*)-**11**, bp 108–111 °C/23 torr; n_D^{26} 1.5012; α_D^{25} −0.4° (neat, *l* 1 dm); ord (*c* 1.05, methanol) $[\Phi]_{350}$ −13°, $[\Phi]_{325}$ −34°, $[\Phi]_{310}$ −58°, $[\Phi]_{300}$ −42°, $[\Phi]_{293}$ 0°. Analysis by gc showed that the compound was >98% pure and contained no starting alkene.

Hydrogenolysis of (+)-(S)-7 to (−)-2-Phenyl-2-butylamine, (−)-(S)-8

A solution of 1.0 g (+)-(*S*)-**7**, α_D^{25} +35.5° (neat, *l* 1 dm), in 100 ml methanol was stirred over 4.5 g of W-2 Raney nickel under a hydrogen atmosphere at 22 °C. After 4 h hydrogen uptake ceased when nearly 1 equiv. was taken up. The contents of the flask were then held under reflux for 11 h. The catalyst was filtered, the methanol removed, and the residue taken up in ether. The ether solution was extracted with hydrochloric acid and the acid layer made basic with potassium hydroxide solution. The resulting mixture was shaken with ether and the ether layer dried over potassium carbonate and concentrated. The product was collected from the effluent of the gas chromatograph to give 200 mg of (−)-(*S*)-**8**; n_D^{25} 1.5146; α_D^{25} −14.0° (neat, *l* 1 dm) (lit. (29) n_D^{25} 1.5148; α_{546}^{25} −18.2° (neat, *l* 1 dm)).

(−)-(S)-2-Phenyl-2-butylamine, (−)-(S)-8

Using the reported procedure (28) (+)-(*S*)-2-methyl-2-phenylbutanoic acid $[\alpha]_D^{25}$ +6.60° (*c* 4.8, benzene) 22% optically pure was converted to (−)-(*S*)-**8**, α_D^{25} −3.42° (neat, *l* 1 dm). On this basis optically pure (−)-(*S*)-**8** would have α_D^{25} −15.7° (neat, *l* 1 dm) (lit. (34) α_D^{25} +16.8° (neat, *l* 1 dm) for (+)-(*R*)-**8** obtained by resolution of the maleate salt).

(±)-1-Benzyl-2-(2-phenyl-2-butyl)diazane

A mixture of 2.5 g (0.015 mol) (2-phenyl-2-butyl)diazane (28), 0.6 g (0.015 mol) benzaldehyde, 2 g magnesium sulfate, and 20 ml anhydrous ether was stirred for 4 h and then filtered. The filtrate was hydrogenated under 1 atm over 0.4 g 5% palladium-on-charcoal until 1 equiv. of hydrogen had been taken up. The mixture was filtered under nitrogen and the residue, after removal of solvent, was distilled to give 2.7 g (67%) of a colorless viscous oil, bp 130–132 °C/0.2 torr; n_D^{25} 1.5582; nmr (CCl_4) τ 2.6–2.9 (m, 10.1H), 6.20 (s, 1.8H), 6.77 (br s, 2.0H, NH), 8.3 (q, $J = 7.5$ Hz) and 8.56 (s) (total 5.2H) and 9.32 (t, $J = 7.5$ Hz, 3.1H). This material was readily oxidized by air and a satisfactory analysis was not obtained.

*(±)-1-Benzyl-2-(2-phenyl-2-butyl)diazene, (±)-**4***

A solution of 0.6 g of the above diazane in 50 ml ether was allowed to stand under an atmosphere of oxygen for 20 h, then washed with water and dried over potassium carbonate. Removal of the ether under reduced pressure left 0.45 g of a yellow oil, n_D^{25} 1.5538; nmr ($CDCl_3$) τ 2.66 (s, 10.0H), 4.97 (s, 2H), 7.98 (q, $J = 7.5$ Hz, 2.1H), 8.57 (s, 3.1H), 9.30 (t, $J = 7.5$ Hz, 3.0H). *Anal.* calcd. for $C_{17}H_{20}N_2$: C 80.91, H 7.99, N 11.10; found: C 80.46, 80.66, H 7.67, 7.68, N 11.06.

*(−)-(R)-1-Benzyl-2-(2-phenyl-2-butyl)diazene,(−)-(R)-**4***

This material was prepared as described for the racemic compound from (+)-(*R*)-**3** (28), α_{546}^{25} 3.52° (neat, *l* 1 dm), 26% optically pure (28). The product, n_D^{25} 1.5528, had an nmr spectrum identical with that of (±)-**4**; $[\alpha]_D^{25}$ −12.88°, $[\alpha]_{546}^{25}$ −16.60°, $[\alpha]_{436}^{25}$ −66.80° (*c* 2.95, C_6H_6); ord (*c* 32.8, C_6H_6) $[\Phi]_{550}$ −165°, $[\Phi]_{500}$ −230°, $[\Phi]_{450}$ −460°, $[\Phi]_{400}$ −1280°, $[\Phi]_{375}$ 0°, $[\Phi]_{350}$ 1680°, $[\Phi]_{300}$ 755°.

*(+)-(S)-**4***

The mother liquor from the first crystallization of the dibenzoyl tartrate salt of (±)-**3** (28) was evaporated and from the residue was isolated (−)-(*S*)-**3**, α_{546}^{25} −2.04° (neat, *l* 1 dm), 15% optically pure. This product was converted to the benzyl derivative, as described above, which was dissolved in a saturated solution of oxalic acid in ethanol. After several days at 5 °C crystals of the oxalate salt were filtered, treated with aqueous potassium hydroxide, and the hydrazine taken up in ether. Oxidation of the hydrazine with oxygen produced (+)-(*S*)-**4**, $[\alpha]_D^{25}$ +28.0° (*c* 1.25, C_6H_6), 56% optically pure. A further batch of the oxalate salt was obtained after concentration of the mother liquor and converted to the diazene, $[\alpha]_D^{25}$ 0.00 (*c* 1.50, C_6H_6). Thus, the oxalate salt had undergone spontaneous resolution.

*(−)-(S)-(2-Phenyl-2-butyl)diazane, (−)-(S)-**3***

A solution of 36.0 g (0.166 mol) menthyl chlorocarbonate (35) in 100 ml ether was added simultaneously with a separate solution of 19.2 g (0.19 mol) triethylamine to a stirred solution of 27.3 g (0.166 mol) (±)-**3** (28) in 150 ml ether under nitrogen. The reaction mixture was stirred overnight and filtered. The filter cake was washed with ether and the combined ether solutions were evaporated to give 58 g of a viscous oil. Five crystallizations at 0 °C from methanol, containing a little water gave material of constant rotation $[\alpha]_{436}^{25}$ −220° (*c* 1.03, CCl_4). Filtration was carried out at 0 °C and the crystals were quickly pressed dry. The crystals melted at ~15 °C. At 0 °C they turned to syrup after a few minutes exposure to air. A satisfactory analysis was not obtained.

A solution of 20 g of this resolved product and 20 g potassium hydroxide in 100 ml methanol was heated under reflux for 4 h and then evaporated to one half its volume. The residue was acidified with dilute hydrochloric acid and the resulting mixture extracted with ether. The aqueous layer was made basic with dilute sodium hydroxide and extracted with ether. The ether layer was dried under nitrogen with sodium sulfate and concentrated to an oil. The oil was distilled to give 3.2 g product, bp 68–69 °C/0.2 torr; n_D^{25} 1.5350; α_D^{25} −11.56° (neat, *l* 1 dm) (lit. (28) for (+)-(*R*)-**3**, α_{546}^{25} +11.8° (neat, *l* 1 dm) for material 80% optically pure).

*(+)-(S)-1,2-Diphenyl-2-methylbutane, (+)-(S)-**6***

A sample of (−)-(*R*)-2-methyl-2-phenylbutanoic acid (31), $[\alpha]_D^{25}$ −29.6° (*c* 4.8, C_6H_6), 98% optically pure, was converted (13) to (−)-(*R*)-1,2-diphenyl-2-methyl-1-butanone, n_D^{25} 1.5705; $[\alpha]_D^{25}$ −61.1° (*c* 6, benzene) (lit. (13) n_D^{25} 1.5700, α_D^{25} −63.7° (neat, *l* 1 dm)). The ketone was reduced to the alcohol with lithium aluminum hydride (13). A mixture of 2.0 g (0.009 mol) of the crude product, 2.5 g (0.017 mol) iodomethane in 100 ml dimethoxyethane, and 0.3 g (0.014 mol) sodium hydride was stirred for 4 h and then heated for 3 h under reflux. Water was added to the cooled reaction mixture and the resulting mixture was extracted with ether. The ether layer was washed several times with water and dried over potassium carbonate. The crude methyl ether left after removal of the ether was stirred with 2 ml sodium potassium alloy in 100 ml ether under nitrogen for 24 h at 21 °C. The red solution was then cooled to 0 °C and a methanol–ether mixture was added slowly until all the alloy was decomposed. The reaction mixture was shaken with water and the ether layer dried over potassium carbonate and concentrated. The product was isolated from the effluent of the gc (column A); $n_D^{26.5}$ 1.5584; $[\alpha]_D^{25}$ +78.3°; $[\alpha]_{546}^{25}$ +94.7°, $[\alpha]_{436}^{25}$ +178° (*c* 4.7, C_6H_6) (lit. (12) n_D^{25} 1.5550; α_D^{25} +67° (neat, *l* 1 dm)); ord (*c* 4.7, C_6H_6)$[\Phi]_{600}$ 118°, $[\Phi]_{550}$ +167°, $[\Phi]_{500}$ +224°, $[\Phi]_{450}$ +326°, $[\Phi]_{400}$ +500°, $[\Phi]_{350}$ +880°, $[\Phi]_{300}$ +1835°.

*(±)-1-(4-Nitrophenyl)-2-(2-phenyl-2-butyl)diazene, (±)-**12***

A mixture of 1.64 g (0.01 mol) (±)-**3**, 1.4 g (0.01 mol) 4-fluoronitrobenzene, and 1.68 g (0.02 mol) sodium bicarbonate in 6 ml dimethyl sulfoxide was stirred under nitrogen at 50 °C for 36 h. The mixture was then cooled and filtered. The filtrate was stirred under air for 12 h and then diluted with 20 ml ether. The resulting mixture was shaken several times with water and the ether layer dried and concentrated. The residue was chromatographed on a 1.5 × 15 cm column of neutral alumina. Elution with 50 ml ether followed by concentration of the eluate under vacuum yielded 1.8 g (65%) of a red oil, n_D^{25} 1.5830; nmr (CCl_4) τ 1.71 (d, $J = 8.8$ Hz, 2H), 2.21 (d, $J = 8.8$ Hz, 2H), 2.63 (m, 5H), 7.86 (m, 2H), 8.42 (s, 3H), 9.22 (t, $J = 7.0$ Hz, 3H). *Anal.* calcd. for $C_{16}H_{17}N_3O_2$: C 67.84, H 6.01, N 14.84; found: C 67.74, H 6.12, N 14.87.

*(−)-(R)-1-(4-Nitrophenyl)-2-(2-phenyl-2-butyl)diazene, (−)-(R)-**12***

The procedure used was identical to that for the pre-

paration of the racemic compound except that (+)-(*R*)-**3** (28), $[\alpha]_D^{25}$ +11.6° (*c* 1.04, $CHCl_3$) was used. The product had n_D^{25} 1.5910; $[\alpha]_D^{25}$ −109° (*c* 1.09, $CHCl_3$).

*(+)-(S)-1-(4-Nitrophenyl)-2-(2-phenyl-2-butyl)diazene, (+)-(S)-**12***

This material was prepared from (−)-(*S*)-**3**, α_D^{22} −11.6° (neat, *l* 1 dm) and had n_D^{26} 1.5910; $[\alpha]_D^{25}$ +120° (*c* 0.582, $CHCl_3$).

*(±)-2-(4-Nitrophenyl)-2-phenylbutane, (±)-**27***

A mixture of 1.0 ml concentrated nitric acid, 1.2 ml concentrated sulfuric acid and 2.0 g 2,2-diphenylbutane (36) was stirred at 60 °C for 20 min. The mixture was poured into 200 ml water. The water was extracted twice with hexane, the combined hexane layers dried and concentrated, and the residual oil chromatographed on a 1.5 × 10 cm column of activity 2 alumina using 1:1 hexane–benzene as eluent. The first 30 ml of eluent contained 700 mg starting material; the second 30 ml contained 250 mg of product contaminated (gc) by ~10% starting material; the third 30 ml afforded 650 mg of pure (gc) product on evaporation; n_D^{29} 1.5819; nmr (CCl_4) τ 1.96 (d, *J* = 8.5 Hz, 2H), 2.71 (d, *J* = 8.5 Hz, 2H), 2.87 (m, 5H), 7.85 (m, 2H), 8.40 (s, 3H), 9.28 (t, *J* = 7 Hz). *Anal.* calcd. for $C_{16}H_{17}NO_2$: C 75.29, H 6.67, N 5.49; found: C 74.97, H 6.67, N 5.69.

*Hydrogenolysis of (+)-(S)-1-(2-Phenyl-2-butyl)-2-(2-propyl)diazene, (+)-S-**12***

A solution of 1.0 g (+)-(*S*)-**12**, α_D^{25} +35.5° (neat, *l* 1 dm) in 100 ml methanol was hydrogenated using 4.5 g Raney nickel at 25 °C under 1 atm. Nearly 1 equiv. of hydrogen was consumed in 4 h when hydrogen uptake ceased. The mixture was then heated under reflux for 11 h, cooled, filtered, and the filtrate concentrated to an oil. The oil was taken up in ether and the resulting solution shaken with hydrochloric acid. The aqueous layer was made basic and then extracted with ether. The ether layer was dried over potassium carbonate, concentrated to an oil, and the product isolated from the effluent of the gc (column A) to give 200 mg (−)-(*S*)-**8**, n_D^{25} 1.5146; α_D^{25} −14.0° (neat, *l* 1 dm). Based on the calculated rotation of α_D^{25} −15.7° (neat, *l* 1 dm) for optically pure material as described above the product was 89% optically pure.

*Interrupted Thermolysis of (−)-(R)-**7***

A solution of 1.4 g (−)-(*R*)-**7**, n_D^{22} 1.4947, in 300 ml benzene was divided equally among three 150 ml pressure bottles. The solutions were boiled for several minutes and the bottles closed and kept at 100 °C for 22 h. The solutions were combined and concentrated through a 4 ft Podbielniak column to ~20 ml volume. The residue was taken up in pentane. Most of the benzene was removed by a series of crystallizations from this solution at −78 °C, concentrating the solution after each crystallization. The final residue was chromatographed on 30 g silica gel at −30 °C. The hydrocarbon products were eluted with pentane, and 2% ether in pentane removed pure (tlc, nmr) (−)-(*R*)-**7**, 0.70 g, n_D^{22} 1.4958. The coupling product **11** was isolated from the concentrated pentane eluent by gc, column A at 170 °C and 150 ml/min He flow. Rotations are given in Table 4.

*Interrupted Thermolysis of (−)-(R)-**12***

Nitrogen was bubbled for 10 min through a solution of 500 mg (−)-(*R*)-**12** (n_D^{25} 1.5910; $[\alpha]_D^{25}$ −108.8° (*c* 1.09, $CHCl_3$)) in 30 ml cumene in a stainless steel bomb which was then sealed and heated at 175 °C for 5 h. Cumene was distilled under reduced pressure and the residue was repeatedly chromatographed on activity I alumina using benzene–hexane as eluent until pure (tlc, nmr) (−)-(*R*)-**12**, 31 mg, was eluted, n_D^{25} 1.5898; $[\alpha]_D^{25}$ −111.7° (*c* 1.02, $CHCl_3$).

*Photolysis of (+)-(S)-**12***

A solution of 400 mg (+)-(*S*)-**12** (n_D^{25} 1.5902; $[\alpha]_D^{25}$ +110.2° (*c* 0.448, $CHCl_3$)) in 50 ml hexadecane was photolyzed at 15 °C under nitrogen in an immersion apparatus fitted with a Pyrex filter using a medium pressure 200 W Hanovia lamp until 60% of the theoretical amount of nitrogen had been evolved. The reaction mixture was concentrated under vacuum and the residue was chromatographed on 75 g activated alumina which had been heated over the full heat of a Bunsen burner for 4 h. The column was washed with 1.2 ℓ pentane and then with pentane containing increasing amounts of benzene. Benzene–pentane, 1:1, removed pure (tlc, nmr) (+)-(*S*)-**12**, 60 mg, n_D^{25} 1.5895; $[\alpha]_D^{25}$ +111° (*c* 0.130, $CHCl_3$).

In a similar way 236 mg (+)-(*S*)-**12**, $[\alpha]_D^{25}$ +120° (*c* 0.400, $CHCl_3$), was recovered from photolysis of 900 mg of the diazene, $[\alpha]_D^{25}$ +119° (*c* 0.590, $CHCl_3$), in hexane for 9 h until 40% of the theoretical amount of nitrogen had been evolved.

The recovered diazenes were combined with fractions from the chromatographies containing impure diazene and the resulting mixture photolyzed in hexadecane until no more diazene remained (tlc). It was necessary twice to remove a brown precipitate when nitrogen evolution ceased before the photolysis was complete. The photolysate was concentrated and the residue chromatographed on a 100 × 1.2 cm column of silica gel using pentane as eluent. A sample, 44 mg (3%), of pure (tlc) **27** was isolated, $[\alpha]_{365}^{25}$ 0.00(*c* 0.18, CCl_4).

*Thermolysis of (+)-(S)-**4** and (−)-(R)-**4***

A solution of 0.97 g of (+)-(*S*)-**4**, $[\alpha]_D^{25}$ +28.0° (*c* 1.25, C_6H_6), and 4.7 g butanethiol in 50 ml benzene in a stainless steel bomb was flushed with nitrogen. The bomb was closed and heated at 102 °C for 30 h, then cooled, and the contents evaporated under reduced pressure. The residue was fractionated by gc using column A. Material which eluted at the retention time of (±)-**6** was collected and found to consist of a liquid and a white solid. This mixture was refractionated using column B to two separate compounds, a small amount of *E*-**19**, identified by its nmr spectrum and gc retention time on both columns, and (−)-(*R*)-**6**, $[\alpha]_D^{25}$ −4.6° (*c* 1.8, C_6H_6), which was formed with 10.7% retention of configuration.

The same procedure was used for the thermolysis of (−)-(*S*)-**4**. The concentrated reaction mixtures were fractionated directly with column B. The results are presented in Table 3.

*Thermolysis of (+)-(S)-**7***

Benzene solutions of (+)-(*S*)-**7** were heated under nitrogen in a stainless steel bomb as described above. After 10 half-lives of decomposition the solvent was distilled slowly through a Vigreaux column. Traces of alkene were removed by heating the residual oil in a solution of 10 ml acetic acid containing 2 ml trichloro-

methylsulfenyl chloride at 85 °C for 60 min. The reaction mixture was taken up in 100 ml pentane and the pentane layer shaken 7 times with water, dried, and concentrated by distillation through a Vigreaux column. The residue was chromatographed on 200 g of activated basic alumina at 0 °C using pentane as eluent. The hydrocarbons **11** and (−)-(*R*)-**16** were isolated from the effluent of the gc using column A. The results are presented in Table 4.

Product Studies

Solutions of ~35 mg (±)-**7** in 0.4 ml benzene or 1 *M* butanethiol in benzene were placed in glass tubes and degassed by three freeze–thaw cycles under 10^{-4} torr. The tubes were sealed and heated at 100 °C for 130 h or at 125 °C for 14 h. The reaction mixtures were then adsorbed on 5 g of neutral activity I alumina and the alumina was washed with 15 ml pentane. Further elution with pentane removed another material, presumably hydrazone, which interfered with subsequent analysis. The eluent was concentrated by distillation through a Vigreaux column, a known amount of bromobenzene was added to the residue which was then analyzed by gc using column A (temperature programmed; initial temperature 90 °C, rate of increase 1.5°C/min, initial He 90 ml/min). Calibrations were made using mixtures of known concentration in benzene. The products were identified on the basis of their retention times. Authentic samples of **17**, *Z*- and *E*-**18** were prepared (37) as were *meso*- and *dl*-**14** (38), which were not separated under the gc conditions used. In the decompositions at 125 °C the relative yield of (±)-**16** was 2% lower and that of **14** was 3% higher than in the decompositions at 100 °C. The relative yields of the other products were the same at the two temperatures.

Solutions of (±)-**4** in the various solvents were placed in a stainless steel bomb and flushed for several minutes with nitrogen. The bomb was closed and heated at 110 °C for 20 h. The reaction mixtures were analyzed directly by gc using column B (temperature programmed; initial temperature 100 °C, rate of increase 3 °C/min, initial He 85 ml/min). The compounds were identified on the basis of their retention times. In one case a known amount of bromobenzene was added just before analysis. Calibrations were made using mixtures of known concentration in benzene.

A solution of 700 mg (±)-**12** in 7 g diphenylether was heated under nitrogen in a stainless steel bomb at 175 °C for 18 h. A known amount of dimethylaniline was added to the reaction mixture and this was analyzed by gc using column B (120 °C, He 50 ml/min). Calibrations were made using mixtures of known concentration in benzene. The volatile compounds were identified by mass spectral analysis as they emerged from the gc. The mass spectral cracking patterns were compared to those of the authentic compounds. The amount of **25** formed was found by adding an aliquot of the reaction mixture to hexane, collecting, and comparing (mp, ir) the precipitate with an authentic sample of **25**.

A 2 g sample of (±)-**12** was heated at 175 °C for 18 h under nitrogen in a 5 ml flask fitted with a condenser. After cooling the residue was stirred several times with small amounts of hexane. The insoluble material, 0.67 g (79%) was nearly pure **25**. Dimethylaniline was added to the combined hexane washings and the solution analyzed by gc.

Kinetic Studies

Rates of evolution of nitrogen from solutions of the diazenes were measured using an apparatus and a procedure similar to that described (39). Rate constants were determined from the slopes of plots of log $(V_\infty - V_0/V_\infty - V_t)$. The results are presented in Table 1.

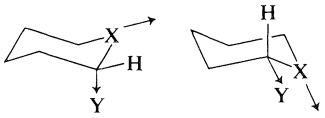
The analysis of the ^{13}C and ^{1}H nuclear magnetic resonance data of 2-substituted methylenecyclohexanes and 3-substituted cyclohexenes demonstrates that a double bond stabilizes the axial conformer for an electronegative substituent. Introduction of a methoxy group on the double bond further increases the relative stability of the axial conformer. These results are interpreted in terms of the 'double bond – no bond' resonance.

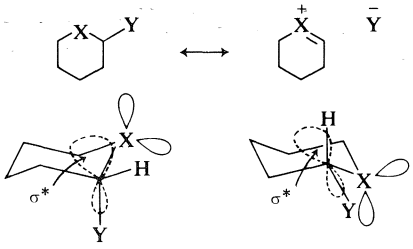
JEAN LESSARD, PHAN VIET MINH TAN, ROBERT MARTINO et JOHN K. SAUNDERS. Can. J. Chem. **55**, 1015 (1977).

L'analyse des spectres de résonance magnétique nucléaire du ^{13}C et du ^{1}H de méthylenecyclohexanes substitués à la position 2 et de cyclohexènes substitués à la position 3 démontre qu'une double liaison stabilise le conformère axial lorsque le substituant est électronégatif. L'introduction d'un groupement méthoxy sur la double liaison augmente d'avantage la stabilité relative du conformère axial. Les résultats sont interprétés en termes de résonance 'double bond – no bond'.

The effect that causes electronegative groups to occupy sterically unfavoured conformations when attached to a carbon bearing an electronegative atom is known as the anomeric effect (1). A number of hypotheses have been advanced in order to explain this effect. These include the dipole–dipole interaction (2) which would favour the axial conformation relative to the equatorial since in the former the two dipoles are virtually



perpendicular, whereas in the latter the two dipoles have the same direction and are in much closer proximity. A second explanation (3), labelled the rabbit-ear effect, states that the interaction lone pair – lone pair is significantly larger than either the interactions lone pair – bonding pair or bonding pair – bonding pair. In the example where both X and Y are oxygens, a conformation can be defined for the axial conformer in which there is no lone pair – lone pair interaction whereas when Y is equatorial all possible conformations have at least one such interaction. Thus again, the conformation in which Y is equatorial is destabilized. A third possible explanation is known as double bond – no bond resonance (4). In this hypothesis, charged resonance forms such as



contribute. This can also be interpreted in term of an overlap between the lone-pair electrons on X and the σ antibonding orbital of the C—Y bond. This should be a maximum when the lone pair on X and the C—Y bond are antiperiplanar and thus this theory predicts that the form with Y axial would be stabilized.

In an attempt to obtain experimental evidence, other than crystallographic data (5), of the importance of the latter postulate, we have studied a number of 2-substituted methylenecyclohexanes and 3-substituted cyclohexenes. If the double bond – no bond resonance makes a significant contribution to the anomeric effect

then a double bond should stabilize the axial conformer when the substituents are electronegative. The results of this study, presented in this paper, do in fact demonstrate that this postulate is important.

Results

The ^{13}C nuclear magnetic resonance (^{13}Cmr) chemical shift data for a number of cyclohexene derivatives is given in Table 1. The spectral assignments were made using the literature values for **1** (6) and (**2**) (7), and normal substituent effects. The spectrum of each compound as a function of temperature was then studied. However, **3** was the only compound to show marked spectral changes with temperature. At room temperatures the two methyl groups appeared as a single peak at 28.4 ppm. As the temperature approached 145 K, this peak broadened and at temperatures below 145 K, the resonances corresponding to each methyl group were observed. The coalescence temperature was estimated to be 145 K and since $\Delta\nu$ is 6.6 ppm (at 22.63 MHz), $\Delta G^{\ddagger}$ was calculated to be 6.5 ± 0.5 kcal/mol using the Eyring equation (8). This value is within experimental error of published values determined for other cyclohexene derivatives (9). The spectra of the other compounds exhibited small chemical shift changes with temperature but since the CF_2Br_2 resonances varied relative to the deuterium signal of CD_2Cl_2, no information could be gleaned from these variations. However, no evidence of coalescence behaviour was observed. This could be due to three factors: (*i*) chemical shift difference too small, (*ii*) decrease in the barrier of interconversion, or (*iii*) essentially one conformer being present. The first possibility can be neglected at least for **2**, **4**, and **5** since the difference at C-5 in these compounds between X pseudo axial or pseudo equatorial would be at least 5 ppm. The introduction of one of these substituents in cyclohexenes (9) and methylenecyclohexanes (10, 11) does not appear to cause a significant variation in the value of $\Delta G^{\ddagger}$ and thus it appears unlikely that the barrier to interconversion in **2**, **4**–**8** is significantly less than that observed in **3** and hence it appears that the second possibility is extremely unlikely. Thus it is reasonable to assume that the lack of observation of coalescence behaviour is due to essentially one isomer being present.

It is of interest to compare the chemical shifts of carbon 5 in compounds **1**, **2**, **4**, and **5**. In compound **2**, this carbon has virtually the same chemical shift as in **1**, whereas in **4** and **5** it is shielded by 4.5 and 4.3 ppm respectively. This is a consequence of the well known γ effect in ^{13}Cmr spectroscopy which causes an upfield shift when the group X and the proton on the γ carbon are 1,3 diaxial. Thus, it appears that in **2** the conformer with the CH_3 group equatorial is preferred, whereas for **2**, **4**, and **5**, it is the conformer with the OR group axial which is predominant. In order to verify these facts, the ^{1}Hmr of these compounds together with several other

[a]Linewidth at half height ±0.5 Hz.

derivatives were studied. In Table 2, the width at half height ($\Delta\nu_{1/2}$) for the 3 proton is given. The observed linewidth will be the sum of $^3J_{3,4a} + {}^3J_{3,4e} + {}^3J_{3,2} + {}^4J_{3,1} + {}^5J_{3,6}$. Using published values of J and dihedral angles (12), these values are for H-3 pseudo axial: $^3J_{3,4a} = 11.0$ Hz, $^3J_{3,4e} = 1.5$ Hz, $^3J_{3,2} = 1.5$ Hz, $^4J_{3,1} = 1.0$ Hz, and $^5J_{3,6} = 1.5$ Hz. For H-3 pseudo equatorial: $^3J_{3,4a} = 1.5$ Hz, $^3J_{3,4e} = 1.0$ Hz, $^3J_{3,2} = 4.0$ Hz, and $^4J_{3,1} + {}^5J_{3,6} < 0.5$ Hz. In the compounds where R′ = CH_3, the CH_3 appeared as a doublet of doublets with coupling constants of 1.5 Hz and 1.4 Hz with the latter corresponding to J_{2,CH_3}. The values of $\Delta\nu_{1/2}$ were then estimated to be 17.0 Hz (R′ = H) and 17.5 Hz (R′ = CH_3) for the group X pseudo equatorial and 6.5 Hz (R′ = H) and 8.0 Hz (R′ = CH_3) for X pseudo axial. Inspection of the data in Table 2 indicates that **6**, **7**, **8**, **11**, and **14** exist predominately, if not almost exclusively, with X in the pseudo equatorial conformation whereas the predominant conformation of **4**, **5**, **9**, **10**, **12**, and **13** is that in which the X group is pseudo axial. It is of interest to note that $\Delta\nu_{1/2}$ in **9** is less than that observed in **4**, **5**, and **10** indicating that the pseudo axial conformer is more highly populated when X = Br then when X is an oxygenated substituent. Also, comparison of **12** and **13** with **10** and **4** demonstrates that the replacement of H at C-1 by an OCH_3 group increases the proportion of X pseudo axial.

The ^{13}Cmr spectral data for the substituted methylenecyclohexanes are given in Table 3. Assignments were made with the aid of single frequency off-resonance decoupled spectra and the published chemical shift data for **15** (13) and **16**[4]. The compounds were then studied as a function of temperature. For **17**, the signals at 26.3 and 36.0 ppm become significantly broadened as the temperature approached 195 K as did the signal at 104.2 ppm. At 170 K, the signals for the two conformers were observed. The Overhauser effect should be the same in both conformers and thus integration of the respective signals can be used to determine the population in each conformation at this temperature. The average equatorial/axial ratio was determined to be 95:5, which leads to a ΔG_0 (axial–equatorial) of 1.0 ± 0.2 kcal/mol. The various absorptions exhibited coalescence temperatures between 185 and 198 K depending on the respective chemical shift difference. The average value for $\Delta G^{\ddagger}$ was found to be 9 ± 0.6 kcal/mol which is slightly higher than that found in dimethyl methylenecyclohexanes (10). Compound **18** also showed coalescence behaviour as can be seen in Fig. 1 in which the spectra recorded at 193 and 163 K are illustrated. The most intense absorption in the spectrum at 193 K is due to CF_2Br_2. At 193 K, the absorptions corresponding to C-4 and C-6 are extremely broad, that corresponding to the OCH_3 is reasonably broad, whereas the absorptions for C-1, C-2, and C-3 are relatively narrow.

[d]$CDCl_3$, ~305 K.

In the spectrum at 163 K, the absorption for the two conformers can be clearly observed and careful integration of several spectra at this temperature gave an axial/equatorial ratio of 3.5 ± 0.3. Thus, the conformer with the OCH_3 group axial is 0.4 ± 0.04 kcal/mol more stable than that in which the OCH_3 is equatorial. From the coalescence temperatures and respective chemical shift difference, $\Delta G^{\neq}$ could be calculated for the coalescence of each pair of resonances and an average value of 9 ± 0.6 kcal/mol was obtained.

In Fig. 2, the spectrum of **19** at 163 K is compared to that of **18** at the same temperature. The spectrum of **19** corresponds to only one conformation being present and the spectrum obtained at 130 K is essentially identical with that shown. In order to verify that the barrier to interconversion had not been drastically lowered by the introduction of the OCH_3 group at C-7, compound **21** was studied as a function of temperature. The coalescence temperature for the signals of the methyl groups is 198 K and since $\Delta\nu = 9.5$ ppm, $\Delta G^{\neq} = 9.0 \pm 0.6$ kcal/mol. Since the barriers to interconversion of compounds **17**, **18**, and **21** have all been calculated to be 9.0 ± 0.6 kcal/mol and since $\Delta\nu$ (axial–equatorial) for C-4 in **19** should be of the order of −4.5 ppm, it is reasonable to conclude that the axial/equatorial ratio at 163 K is at least 17. The predominant conformer present is readily assigned as the axial due to the chemical shifts of C-4 and C-6. Thus ΔG_0 (axial–equatorial) is at least −1.0 kcal/mol.

In order to destabilize the axial conformations, compound **20** and the 4,4-dimethyl analog of **19** were prepared. At low temperatures, only one conformer of **20**, namely the equatorial, was observed. Unfortunately, the dimethyl analog of **19** could not be obtained in a pure state (see Experimental).

Discussion

In cyclohexane derivatives, the A value of a group is a measure of the energy difference between an axial and equatorial orientation for the group in question. For methylenecyclohexanes substituted in the 2 position, we have introduced an interaction between the group X and the hydrogen of the double bond. This interaction is known as the allylic tension $A^{(1,3)}$. Thus, the observed free energy difference for 2-substituted methylenecyclohexanes will be $A - A^{(1,3)}$ provided only steric interactions are involved. The A value of a CH_3 group is 1.7 kcal/mol (14). As seen in the previous section, the free energy difference for 2-methylmethylenecyclohexane (**17**) is 1.0 kcal/mol and since the A value for **17** should be almost identical with that in cyclohexane the allylic interaction $A^{(1,3)}$ is of the order of 0.7 kcal/mol. This value is significantly less than that estimated by ^{1}Hmr spectroscopy (15) although St-Jacques[5] did not observe the axial conformer in the ^{1}Hmr spectrum at low temperatures. The value of 0.7

[5]M. St-Jacques, private communication.

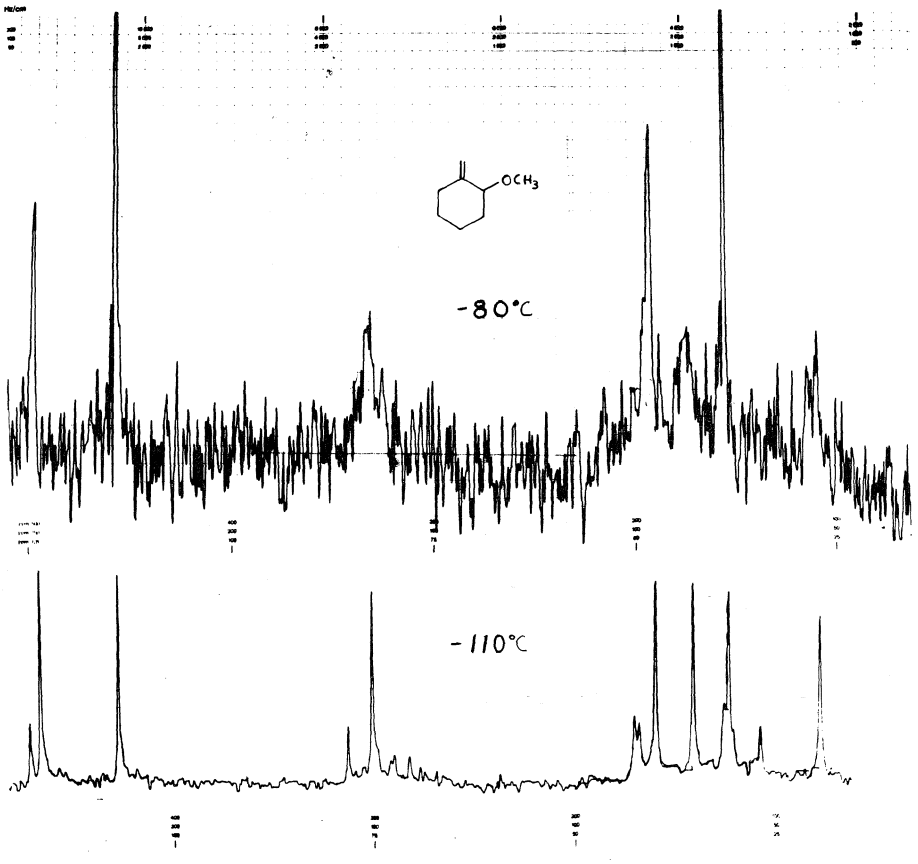

FIG. 1. ^{13}Cmr spectra of **18** at 193 and 163 K.

kcal/mol is reasonably close to the value observed for a 1,3 diaxial CH_3–hydrogen interaction.

The *A* value for an OCH_3 group is 0.8 kcal/mol (14). Thus, if we assume that the $A^{(1,3)}$ interaction for a OCH_3 is of the same order as for a CH_3 group, *i.e.* half the *A* value, then we would predict ΔG_0 (axial–equatorial) = 0.4 kcal/mol for 2-methoxymethylenecyclohexane (**18**). However, experimentally it is −0.4 kcal/mol and thus the conformation in which the OCH_3 is axial is stabilized by approximately 0.8 kcal/mol. Similarly, for **19**, where ΔG_0 (axial–equatorial) > −1.0 kcal/mol, the axial conformer is stabilized by at least 1.4 kcal/mol (0.6 kcal/mol relative to **18**). The difference in energy between that predicted and observed for **18** could be due to either double bond – no bond resonance or an electrostatic interaction between the C—O and C=C bonds. This interaction is either dipole–dipole or dipole–quadrupole in nature. The latter interaction has been proposed (11) in order to explain the conformational equilibrium observed for 3-substituted methylenecyclohexanes. We have carried out simple electrostatic calculations, similar to those performed by Lambert and Clikeman (11), using the standard dipole–dipole and dipole–quadrupole interaction equations (16–18) and have found that the two interactions stabilize the axial conformation of **18** relative to the equatorial conformation with the dipole–quadrupole interaction being more important. Introduction of the oxygen at C-7 will decrease the dipole moment and should also decrease the quadrupole moment (18) of the double bond. Hence, it appears that the difference in conformer population of **19** relative to **18** is not due to an increase in the electrostatic interaction between the C_2—O bond and the C—C double bond. In compound **19**, we have a situation which resembles that of 2-methoxytetrahydropyran. However, the influence of the oxygen–oxygen dipole–dipole interaction on the relative stability of the two conformations is calculated as being negligible

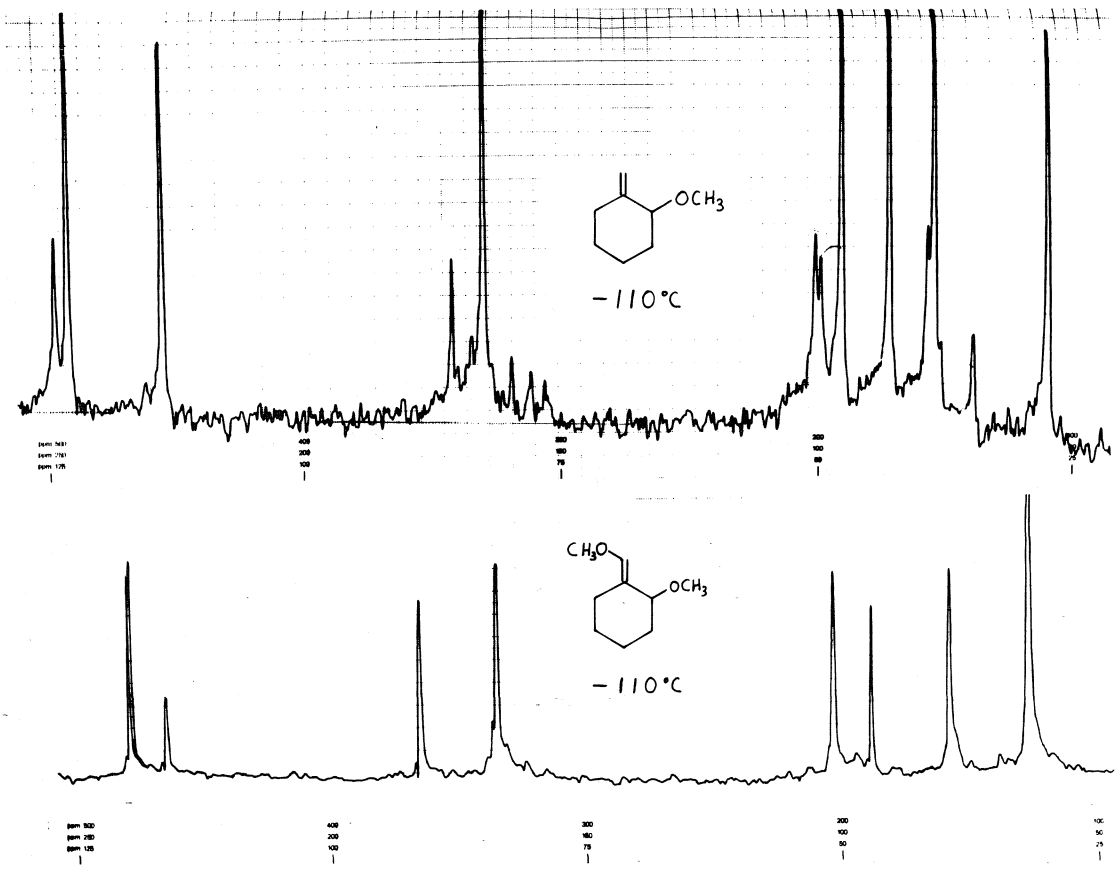

FIG. 2. ^{13}Cmr spectra of **18** and **19** at 163 K.

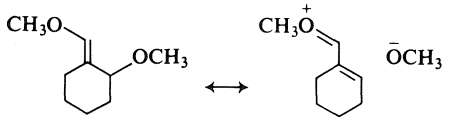
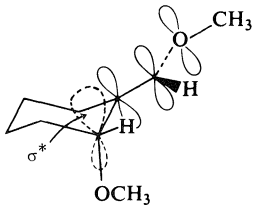
and the rabbit-ear effect can no longer be invoked. Hence we are left with the double bond – no bond resonance since the introduction of an OCH_3 group on the double bond increases its electron density. In order for an overlap to occur between the π molecular orbital of the double bond and the σ^* orbital of the C—O bond, the OCH_3 group must be axial and therefore the axial conformer '**19** ax' is stabilized by double bond – no bond resonance.



19 ax



For 3 substituted cyclohexenes, the results are not quantitative. However, the compounds in which X is an electronegative group and R an hydrogen all have a preponderance of the conformation where X is pseudo axial, whereas when X is a CH_3 group, the preferred conformation is that with X pseudo equatorial. Again, as in the 2-substituted methylenecyclohexanes, the stabilization of the axial conformer by the double bond is adequately explained either in terms of double bond – no bond resonance or the dipole–quadrupole interaction between the C—X and the C=C bonds. Also the extra stabilization afforded by the introduction of the OCH_3 group is interpreted in terms of the former since the dipole–dipole interactions and the rabbit ear effect cannot be invoked and since the introduction of the OCH_3 group on the double bond should decrease its quadrupole moment.

Conclusion

The results obtained for the substituted

methylenecyclohexanes and cyclohexenes demonstrate that the double bond stabilizes the conformer with the electronegative group axial at the allylic position (C-2 and C-3 respectively). Introduction of an OCH_3 group on the double bond at either C-1 (cyclohexene) or C-7 (methylenecyclohexane) further stabilizes the axial conformer. The stabilization by the double bond is evaluated at 0.8 kcal/mol and the introduction of the OCH_3 results in an added stabilization of at least 0.6 kcal/mol. The stabilization by the double bond is interpreted as being due to either double bond – no bond resonance or an electrostatic interaction between the C—X and C=C bonds (predominantly the dipole–quadrupole interaction). However, it has been calculated (17) that when the two entities are in close proximity, the electrostatic interaction is less important which would tend to suggest that the principal factor causing the stabilization is the double bond – no bond resonance. The extra stabilization afforded by the introduction of the OCH_3 group on the double bond is interpreted in terms of double bond – no bond resonance. We would thus expect that in 2-methoxytetrahydropyran, for example, the overlap between the non bonding electron of oxygen and the σ antibonding orbital of the C—O bond to be important.

Experimental

Vapor phase chromatographic analyses and separations were performed on a Hewlett Packard chromatograph model 5750 equipped with both thermal conductivity and flame ionization detectors: an OS-138 column (15% polyphenyl ether on dimethylsilylated Chromosorb W) or an SE-30 column (10% on dimethylsilylated Chromosorb W) with o.d. 0.25 in. (analytical) or 0.375 in. (preparative) and length 6 ft were used. Infrared spectra were taken on a Perkin-Elmer 257 spectrophotometer. Mass spectra were recorded on a Hitachi RMU-6E spectrometer.

Nuclear Magnetic Resonance Spectra

Proton spectra were obtained using either a Varian A-60 spectrometer or a Bruker HX-90 spectrometer. ^{13}C spectra were obtained on a Bruker HX-90 system equipped with a Nicolet 1083 computer operating in the Fourier transform mode. The data were determined for $CDCl_3$ solutions (approximately 0.4 *M*) or in a mixture of 75% CF_2Br_2 – 25% CD_2Cl_2 (approximately 7%). The temperatures were monitored using a calibrated copper–constantin thermocouple and are accurate to ± 3 K.

Materials

Compounds not commercially available were prepared either as described in the literature or by standard procedures. All compounds were pure (> 98%) according to vpc analyses and had ir and ^{1}Hmr spectra consistent with their structure. The methods of preparation together with characteristic ^{1}Hmr absorptions are given below.

*1,5,5-Trimethylcyclohexene (**3**)*—Prepared from isophorone according to the method described by Sneen and Martheny (19). The 1,5,5 isomer was separated from the 3,5,5, isomer by preparative vpc at 80 °C (SE-30 column): δ (CCl_4) 0.90 (s, CH_3 at C-5), 1.65 (m, CH_3 at C-1), 5.40 ppm (m, H-2).

*3-Hydroxycyclohexene (**10**)*—Prepared by treating 3-bromocyclohexene (**9**) with 15% aqueous NaOH at room temperature overnight and also by $LiAlH_4$ reduction of 2-cyclohexenone in ether: bp 68 °C/13 torr (lit. (20) bp 85 °C/25 torr); δ ($CDCl_3$) 4.25 (m, H-3), 5.86 ppm (m, H-1 and H-2).

*3-Methoxycyclohexene (**4**)*—Prepared by treating 3-bromocyclohexene (**9**) with an equimolar quantity of sodium methoxide in refluxing methanol for 5 h and also by methylation of the sodium salt of 3-hydroxycyclohexene (**10**) (reaction with sodium metal in ether) with methyl iodide in ether at room temperature for 30 h: bp 45–50 °C/30 torr. It proved identical (vpc, ir, ^{1}Hmr) to a commercial sample (Pfatz and Bauer); δ ($CDCl_3$) 3.41 (s, OCH_3), 3.83 (m, H-3), 5.93 ppm (m, H-1 and H-2).

*3-Acetoxycyclohexene (**5**)*—Prepared by acetylation (acetic anhydride – sodium acetate) of alcohol **10**: bp 85–87 °C/50 torr (lit. (21) bp 83–84 °C/40 torr); δ ($CDCl_3$) 2.05 (s, $OCOCH_3$), 5.38 (m, H-3), 5.92 ppm (m, H-1 and H-2).

*3-Hydroxy-1,5,5-trimethylcyclohexene (**6**)*—Prepared by $LiAlH_4$ reduction of isophorone (equimolar quantities of reagents) in ether (92% yield); bp 89–90 °C/15 torr; δ ($CDCl_3$) 0.90 and 1.00 (two s, CH_3 at C-5), 1.71 (m, CH_3 at C-1), 4.32 (m, H-3), 5.60 ppm (m, H-2); *m/e* 140 (M^+).

*3-Methoxy-1,5,5-trimethylcyclohexene (**7**)*—Prepared by methylation (CH_3I) of the sodium salt of **6** in ether (80% yield): bp 63–64 °C/22 torr; δ ($CDCl_3$) 0.91 and 1.01 (two s, CH_3 at C-5), 1.72 (m, CH_3 at C-1), 3.42 (s, OCH_3), 3.89 (m, H-3), 5.62 ppm (m, H-2); *m/e* 154 (M^+).

*3-Acetoxy-1,5,5-trimethylcyclohexene (**8**)*—Prepared by acetylation of **6** (acetic anhydride – sodium acetate) (92% yield): bp 88 °C/15 torr; δ ($CDCl_3$) 0.96 and 1.01 (two s, CH_3 at C-5), 1.72 (m, CH_3 at C-1), 2.06 (s, $OCOCH_3$), 5.45 (m, H-3), 5.53 ppm (m, H-2); *m/e* 182 (M^+).

*3-Bromo-1,5,5-trimethylcyclohexene (**11**)*—Prepared from alcohol **6** and phosphorus tribromide (0.35 mol per mol of **6**) at room temperature overnight. The product was isolated from the reaction mixture by distillation. It was purified further by distillation: bp 53–55 °C/2 torr (lit. (22) bp 46–47 °C/1 torr); δ (CCl_4) 0.90 and 1.05 (two s, CH_3 at C-5), 1.75 (m, CH_3 at C-1), 4.80 (m, H-3), 5.72 ppm (m, H-2).

3-Methoxy-2-cyclohexenone—Prepared in a 71% yield from 1,3-cyclohexanedione and methanol following the procedure described for the preparation of 3-ethoxy-2-cyclohexenone (23): bp 114 °C/14 torr; δ ($CDCl_3$) 1.8–2.2 (6H), 3.79 (s, OCH_3), 5.50 ppm (s, H-2).

*3-Hydroxy-1-methoxycyclohexene (**12**)*—Prepared by $LiAlH_4$ reduction of 3-methoxy-2-cyclohexenone (equimolar quantities of reagents) in ether. A complex mixture was obtained from which compound **12** was obtained by repeated fractional distillations: bp 84 °C/1.5 torr; δ ($CDCl_3$) 3.60 (s, OCH_3), 4.32 (m, H-3), 4.90 ppm (d, J = 4.5 Hz, H-2); *m/e* 128 (M^+).

*1,3-Dimethoxycyclohexene (**13**)*—Prepared by methylation of the sodium salt of alcohol **12** with CH_3I in ether (65% yield): bp 67 °C/15 torr; δ ($CDCl_3$) 3.40 and 3.60

(two s, OCH_3 at C-3 and C-1), 3.89 (m, H-3), 4.90 ppm (d, J = 4.5 Hz, H-2); *m/e* 142 (M^+).

3-Methoxy-5,5-dimethyl-2-cyclohexenone—Prepared (98% yield) from 5,5-dimethyl-cyclohexane-1,3-dione and methanol following the procedure described by Gannon and House (23) for the preparation of 3-ethoxy-2-cyclohexenone: bp 124–125 °C/1.5 torr; δ ($CDCl_3$) 1.05 (s, CH_3), 2.22 and 2.32 (two s, H-6 and H-4), 3.78 (s, OCH_3), 5.47 ppm (s, H-2).

3-Hydroxy-1-methoxy-5,5-dimethylcyclohexene—Prepared by $LiAlH_4$ reduction of 3-methoxy-5,5-dimethyl-2-cyclohexenone (equimolar quantities) in ether and obtained pure after repeated fractional distillations: bp 108–112 °C/1.5 torr; δ ($CDCl_3$) 0.95 and 1.05 (two s, CH_3 at C-5), 3.62 (s, OCH_3), 4.46 (m, H-3), 4.83 (m, H-2); *m/e* 156 (M^+).

*1,3-Dimethoxy-5,5-dimethylcyclohexene (**14**)*—Prepared by methylation (CH_3I) of the sodium salt of 3-hydroxy-1-methoxy-5,5-dimethylcyclohexene in ether: bp 84 °C/15 torr; δ ($CDCl_3$) 0.95 and 1.04 (two s, CH_3 at C-5), 3.42 (s, OCH_3), 3.62 (s, OCH_3), 4.10 (m, H-3), 4.85 ppm (m, H-2); *m/e* 170 (M^+).

*2-Methylmethylenecyclohexane (**17**)*—Prepared by a Wittig reaction on 2-methylcyclohexanone (triphenylmethyl phosphonium bromide in ether–benzene (3:7) at −10 °C using phenyllithium) (37% yield): bp 120–122 °C (lit. (24) bp 120 °C); δ ($CDCl_3$) 1.05 (d, J = 6.4 Hz, CH_3), 4.70 ppm (m, 2 olefinic H).

2-Hydroxymethylenecyclohexane—Prepared by $LiAlH_4$ reduction of 2-carbomethoxycyclohexanone (25) as described by Dreiding and Hartman (26): bp 78–80 °C/25 torr (lit. (26) bp 78.5–80 °C/23 torr); δ ($CDCl_3$) 4.13 (m, H-2), 4.80 and 4.97 ppm (two m, olefinic H).

*2-Methoxymethylenecyclohexane (**18**)*—Prepared by methylation (CH_3I) of the sodium salt of 2-hydroxymethylenecyclohexane in ether: bp 66 °C/25 torr (lit. (27) bp 58–59 °C/43 torr); δ ($CDCl_3$) 3.40 (s, OCH_3) 3.80 (m, H-2), 4.95 ppm (m, 2 olefinic H).

2-Hydroxycyclohexanone—Prepared from 2-chlorocyclohexanone and aqueous potassium carbonate at room temperature for 20 h. A solid melting at 83.5 °C was obtained from which 2-hydroxycyclohexanone was distilled: bp 72 °C/15 torr (lit. (28) bp 55–60 °C/0.4 torr); δ ($CDCl_3$) 4.20 ppm (m, H-2).

2-Methoxycyclohexanone—Prepared from 2-hydroxycyclohexanone by the method described by Bergman and Gierth (29): bp 65 °C/15 torr (lit. (30) bp 72–75 °C/14 torr); δ ($CDCl_3$) 3.47 (s, OCH_3), 3.80 ppm (m, H-2); *m/e* 128 (M^+).

*2-Methoxy(methoxymethylene)cyclohexane (**19**)*—Prepared by a Wittig reaction on 2-methoxycyclohexanone (methoxymethyl triphenylphosphonium chloride in ether–benzene (3:7) at −10 °C using phenyllithium) (45% yield): bp 94 °C/44 torr; δ ($CDCl_3$) 3.25 (s, OCH_3), 3.56 (m, H-2), 3.66 (s, OCH_3), 6.07 ppm (olefinic H); *m/e* 156 (M^+).

2-Methoxy-4,4-dimethylcyclohexanone—Prepared by hydrogenation of 2-methoxy-4,4-dimethyl-2-cyclohexenone (30) in ethanol over 5% Pd/charcoal in a Parr apparatus at 20–40 psi (94% yield): bp 64–65 °C/0.5 torr; δ (CCl_4) 1.09 and 1.22 (two s, CH_3 at C-4), 3.40 (s, OCH_3), 3.74 ppm (d of d, ΣJ = 18 Hz, H-2); *m/e* 156 (M^+).

*2-Methoxy-4,4-dimethylmethylenecyclohexane (**20**)*—Prepared by a Wittig reaction on 2-methoxy-4,4-dimethylcyclohexanone (methyl triphenylphosphonium bromide and phenyllithium in ether). The crude product was separated by preparative vpc (OS-138 column): δ ($CDCl_3$) 0.99 and 1.00 (two s, CH_3 at C-4), 3.40 (s, OCH_3), 3.73 (m, H-2), 4.95 ppm (2 olefinic H); *m/e* 154 (M^+).

*4,4-Dimethyl(methoxymethylene)cyclohexane (**21**)*—Prepared by a Wittig reaction on 4,4-dimethylcyclohexanone (31) (methoxymethyl triphenylphosphonium chloride and phenyllithium in ether). The crude product was separated by preparative vpc (OS-138); δ (CCl_4) 0.92 (s, CH_3 at C-4), 1.8–2.4 (4 allylic H), 3.53 (s, OCH_3), 5.77 ppm (m, olefinic H); *m/e* 154 (M^+).

2-Methoxy-4,4-dimethyl(methoxymethylene)cyclohexane—Prepared by a Wittig reaction on 2-methoxy-4,4-dimethylcyclohexanone (methoxymethyl triphenylphosphonium chloride and phenyllithium in ether). The compound could not be obtained pure even after repeated distillation through a spinning band column. The sample thus obtained contained about 80% of the desired product according to vpc and spectral analyses: bp 63 °C/0.3 torr; δ ($CDCl_3$) 0.91 and 1.06 (two s, CH_3 at C-4), 3.30 (s, OCH_3 at C-2), 3.60 (m, H-2), 3.68 (s, OCH_3), 6.11 ppm (olefinic H); *m/e* 184 (M^+).

Secondary α-ferrocenyl substituted carbocations from tertiary carbinols

CHOI CHUCK LEE, SHI-CHOW CHEN, W. JACK PANNEKOEK, AND RONALD G. SUTHERLAND

Department of Chemistry and Chemical Engineering, University of Saskatchewan, Saskatoon, Sask., Canada S7N 0W0

Received September 3, 1976

CHOI CHUCK LEE, SHI-CHOW CHEN, W. JACK PANNEKOEK, and RONALD G. SUTHERLAND. Can. J. Chem. **55**, 1024 (1977).

The same secondary ferrocenylisopropylcarbenium ion was formed from treatment with concentrated H_2SO_4 at 10°C of either ferrocenylisopropylcarbinol or ferrocenylmethyldimethylcarbinol and the same secondary ferrocenyldiphenylmethylcarbenium ion was obtained when either ferrocenyldiphenylmethylcarbinol or ferrocenylmethyldiphenylcarbinol was treated with CF_3COOH at 5°C. The results indicate the occurrence of 1,2-hydride shifts converting tertiary to secondary carbocations.

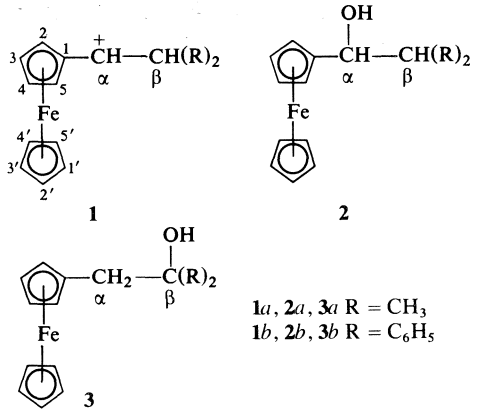
CHOI CHUCK LEE, SHI-CHOW CHEN, W. JACK PANNEKOEK et RONALD G. SUTHERLAND. Can. J. Chem. **55**, 1024 (1977).

On forme le même ion ferrocénylisopropylcarbénium secondaire en traitant soit le ferrocénylisopropylcarbinol ou le ferrocénylméthyldiméthylcarbinol avec de l'acide sulfurique concentré à 10°C. On obtient aussi le même ion ferrocényldiphénylméthylcarbénium secondaire en traitant soit le ferrocényldiphénylméthylcarbinol ou le ferrocénylméthyldiphénylcarbinol avec de l'acide trifluoroacétique à 5°C. Les résultats indiquent l'intervention d'une migration-1,2 d'hydrure convertissant le carbocation tertiaire en carbocation secondaire.

[Traduit par le journal]

It is well known that carbocations can undergo rearrangements to give more stable cations and thus, usually, primary or secondary carbocations rearrange to give the more stable tertiary cations (1, 2). In a demonstration of the extraordinary stability of α-ferrocenyl substituted carbocations,[1] Larsen and Ashkenazi (3) have recently presented calorimetric data to show that primary and secondary α-ferrocenylcarbenium ions are more stable than tertiary cations such as the triphenylmethyl cation. Such findings led to the present work, in which attempts are made to effect rearrangements of tertiary carbocations to more stable secondary α-ferrocenylcarbenium ions, so as to provide some examples of rearrangement of tertiary to secondary cations, a reversal of the usually observed behaviour.

^{13}C nmr studies on a number of α-ferrocenylcarbenium ions generated from treatment of the corresponding alcohols with cold H_2SO_4 have been reported by Olah and Liang (4). A similar technique is utilized in the present work. It was found that the same secondary ferrocenylisopropylcarbenium ion (**1***a*) was obtained when either the secondary ferrocenylisopropylcarbinol (**2***a*) or the tertiary ferrocenylmethyldimethylcarbinol (**3***a*) was treated with concentrated H_2SO_4 at 10°C. The chemical shifts from the ^1H-decoupled ^{13}C nmr spectra of carbinols **2***a* and **3***a*, and carbenium ion **1***a*, are summarized in Table 1.



Braun *et al.* (5) have recently reported the ^{13}C nmr spectrum of **1***a* generated from **2***a* in CF_3COOD. The present data for **1***a* and **2***a* (Table 1) are essentially identical to those observed by these workers (5). It has been pointed out that the asymmetric center at C-α in **2***a* renders the C-2,5 and C-3,4 pairs of carbons diastereotopic, thus giving rise to five signals for the substituted cyclopentadienyl ring

[1]For further discussions on the stability of α-ferrocenylcarbenium ions, see literature cited in ref. 3.

TABLE 1. Data from the ^{1}H-decoupled ^{13}C nmr spectra of ferrocenylisopropylcarbinol (**2***a*), ferrocenylmethyldimethylcarbinol (**3***a*), and the ferrocenylisopropylcarbenium ion (**1***a*)

	Chemical shifts (ppm)*			
	2*a* (Acetone-d_6)	**2***a*† ($CDCl_3$)	**3***a* (Acetone-d_6)	**1***a*† (H_2SO_4)

Aromatic quaternary	143.7,144.3	148.7	—

*Chemical shifts were measured from external TMS in a capillary tube which also contained some CD_3NO_2 as a locking compound in studies with **1***b*.
†Becomes a doublet in off resonance studies, indicating the presence of 1H at C-β.

of **2***a* (5). Similarly, the nonequivalence of the CH_3 groups of **2***a* is also due to the presence of the asymmetric center, a finding that was first observed for asymmetric isopropylcarbinols by Roberts and co-workers (6). The C-2,5 and C-3,4 pairs of carbons and the CH_3 groups are also nonequivalent in the carbenium ion **1***a*, and the origin of this nonequivalence has been attributed to a restricted rotation about the C-1—C-α bond in the α-ferrocenyl substituted carbocation (4, 5). The fact that tertiary carbinol **3***a* also gave rise to **1***a* indicates the occurrence of a 1,2-hydride shift, converting the tertiary ferrocenylmethyldimethylcarbenium ion to the more stable α-ferrocenyl substituted secondary carbocation **1***a*.

In analogous studies with the secondary ferrocenyldiphenylmethylcarbinol (**2***b*) and the tertiary ferrocenylmethyldiphenylcarbinol (**3***b*), it was found that treatment of either of these alcohols with cold concentrated H_2SO_4 gave rise to extensive decomposition. The ferrocenyldiphenylmethylcarbenium ion (**1***b*), however, was obtained by dissolving **2***b* in CF_3COOH at 5°C. When the tertiary carbinol **3***b* was treated with neat CF_3COOH, decomposition also occurred. Ion **1***b* was generated from **3***b* when CF_3-COOH (about 10%) was added to a solution of **3***b* in $CDCl_3$ at 5°C and the ^{13}C nmr spectrum was recorded after a relatively short contact time (about 4000 scans) in order to minimize decomposition. The chemical shifts from the ^{1}H-decoupled ^{13}C nmr spectra of carbinols **2***b* and **3***b*, and carbenium ion **1***b* are given in Table 2,

and the spectra of ions **1***a* and **1***b* are shown in Fig. 1. The identification of **1***b* as the secondary ferrocenyldiphenylmethylcarbenium ion is based on the general similarity of its ^{13}C nmr spectrum with that of **1***a*, the nonequivalence of the C-2,5 and C-3,4 pairs of carbon atoms, and the fact that off resonance gave a doublet for the C-β absorption showing the presence of one H on this carbon. The formation of **1***b* from **3***b* again indicates the occurrence of a 1,2-hydride shift converting the tertiary ferrocenylmethyldiphenylcarbenium ion to the secondary ferrocenyldiphenylmethylcarbenium ion.

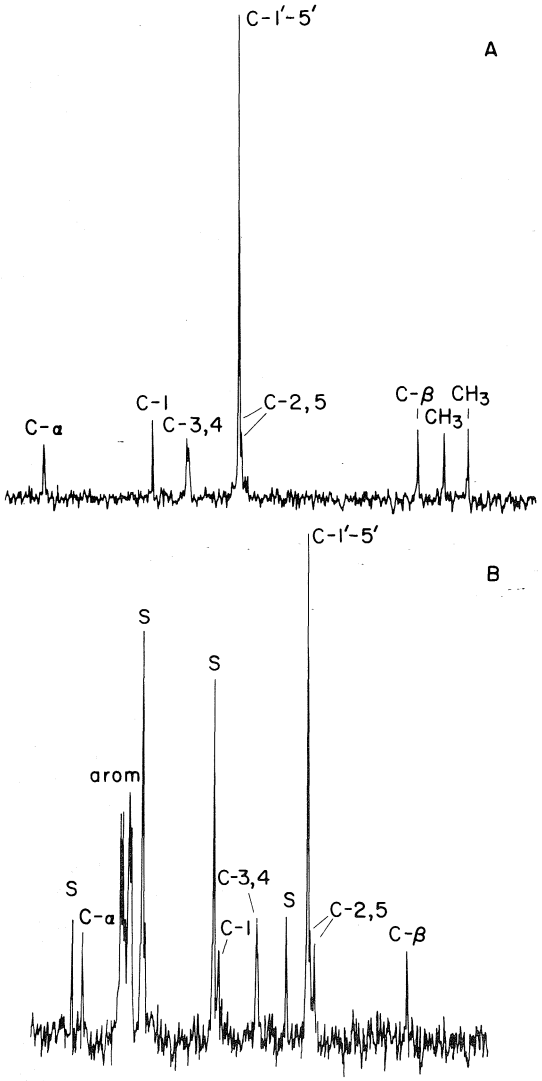

FIG. 1. ^1H-decoupled ^{13}C nmr spectra of the ferrocenylisopropylcarbenium ion (A) and the ferrocenyldiphenylmethylcarbenium ion (B) (the quartet marked S in (B) is due to CF_3 of the CF_3COOH solvent).

Experimental

Ferrocenyl Isopropyl Ketone (4)

To a solution of 2.02 g (19 mmol) of isobutyryl chloride and 3.52 g (19 mmol) of ferrocene in 70 ml of methylene chloride was added, with stirring and under nitrogen, 2.80 g (21 mmol) of aluminum chloride. The deep purple reaction mixture was stirred under nitrogen and at room temperature for 2 h and then heated under reflux for an additional 1 h. After cooling, 50 ml of water was added, the organic layer was separated, and the aqueous layer was extracted with methylene chloride (3 × 30 ml). The combined organic solution was washed with saturated sodium bicarbonate solution and then with water. After drying over Na_2SO_4, removal of the solvent gave 4.3 g of an oily product which was purified by column chromatography through neutral alumina (20 g) Unreacted ferrocene was first removed by elution with *n*-hexane. Subsequent elution with 1:1 (vol.) *n*-hexane–chloroform gave 4.1 g (85%) of the brownish red ketone **4**; ^1H nmr (CCl_4) δ 1.17 (d, J = 6.5 Hz, 6H, CH_3), 3.00 (sept. J = 6.5 Hz, 1H, CH) 4.10 (s, 5H, C_5H_5), 4.40 (t, J = 1.5 Hz, 2H, part of C_5H_4), 4.75 (t, J = 1.5 Hz, 2H, part of C_5H_4). *Anal.* calcd. for $C_{14}H_{10}OFe$: C 65.65, H 6.30; found: C 65.26, H 6.27.

Ferrocenylisopropylcarbinol (2a)

To a solution of 760 mg (20 mmol) of $LiAlH_4$ in 80 ml of anhydrous ether was added a solution of 4.0 g (16 mmol) of **4** in 20 ml of anhydrous ether. The resulting mixture was heated under reflux over N_2 for 4 h, cooled, and then treated with a few ml of H_2O. The ether layer was separated and dried over $MgSO_4$. Removal of the ether gave 3.8 g (94%) of product. Purification through an alumina column with elution by *n*-hexane gave the pure alcohol **2***a* as an orange liquid; ^1H nmr ($CDCl_3$) δ 0.75 (d, J = 7 Hz, 3H, CH_3), 0.93 (d, J = 7 Hz, 3H, CH_3), 1.75 (m, 1H, CH), 2.1 (s, 1H, OH), 4.06 (d, J = 6.5 Hz, 1H, CH), 4.15 (m, 2H, part of C_5H_4), 4.20 (s, 7H, C_5H_5 and part of C_5H_4). *Anal.* calcd. for $C_{14}H_{18}OFe$: C 65.14, H 7.03; found: C 65.26, H 7.01.

Ferrocenyldiphenylmethylcarbinol (2b)

Analogous to the synthesis of ketone **4**, acylation of ferrocene with diphenylacetyl chloride gave a 90% yield of ferrocenyl diphenylmethyl ketone (**5**) as an orange solid, which was recrystallized from tetrahydrofuran–pentane, mp 180–182°C; ^1H nmr ($CDCl_3$) δ 4.30 (s, 5H, C_5H_5), 4.70 (t, J = 2 Hz, 2H, part of C_5H_4), 5.00 (t, J = 2 Hz, 2H, part of C_5H_4) 5.75 (s, 1H, CH), 7.5 (m, 10H, aromatic). *Anal.* calcd. for $C_{24}H_{20}OFe$: C 75.80, H 5.30; found: C 76.11, H 5.24.

Similar to the reduction of **4** to **2***a*, ketone **5** was reduced with $LiA1H_4$ in anhydrous tetrahydrofuran to give 89% yield of carbinol **2***b* as a yellow solid, which was crystallized from chloroform–pentane, mp 125–127°C; ^1H nmr ($CDCl_3$) δ 2.25 (s, 1H, OH), 3.85 (d, J = 8.0 Hz, 1H, CH), 4.0–4.1 (m, 9H, C_5H_5 and C_5H_4), 5.00 (d, J = 8.0 Hz, 1H, CH), 7.15 (s, 5H, aromatic), 7.3 (m, 5H, aromatic). *Anal* calcd. for $C_{24}H_{22}OFe$: C 75.40, H 5.80; found: C 75.46, H 5.57.

Ferrocenylmethyldimethylcarbinol (3a)

Ferrocenylacetic acid (7) was esterified with diazomethane in ether to give methyl ferrocenylacetate (**6**); ^{1}H nmr ($CDCl_3$) δ 3.35 (s, 3H, CH_3), 3.70 (s, 2H, CH_2), 4.10 (s, 9H, C_5H_5 and C_5H_4).

A solution of 1.82 g (70 mmol) of **6** in 30 ml of ether was added dropwise, under N_2, to 2 mol equiv. of CH_3MgI in 50 ml of ether. The resulting mixture was heated under reflux for 2 h. After decomposition with a saturated aqueous solution of NH_4Cl, the ether layer was separated, dried over $MgSO_4$, and evaporated to give 1.72 g (89%) of carbinol **3***a*. Recrystallized from ether, it melted at 51–53°C; ^{1}H nmr ($CDCl_3$) δ 1.15 (s, 6H, CH_3), 1.70 (s, 1H, OH) 2.50 (s, 2H, CH_2), 4.10 (s, 9H, C_5H_5 and C_5H_4). *Anal.* calcd. for $C_{14}H_{13}OFe$: C 65.14, H 7.03; found: C 65.26, H 6.99.

Ferrocenylmethyldiphenylcarbinol (3b)

Carbinol **3***b* was prepared from reaction of **6** with PhMgBr in the same way as in the preparation of **3***a*. A 93% yield of the crude product was obtained as an orange oil. Purification by passage through a salicic acid column, with elution by $CHCl_3$, followed by trituration with *n*-hexane gave the crystalline product, mp103–104°C; ^{1}H nmr (CCl_4) δ 2.65 (s, 1H, OH), 3.33 (s, 2H, CH_2), 3.90 (t, J = 2 Hz, 2H, part of C_5H_4), 4.00 (t, J = 2 Hz, 2H, part of C_5H_4), 4.10 (s, 5H, C_5H_5), 7.1–7.4 (m, 10H, aromatic). *Anal.* calcd. for $C_{24}H_{22}OFe$: C 75.40, H 5.80; found: C 75.66, H 5.57.

Nuclear Magnetic Resonance Spectra

The ^{1}H nmr spectra were taken with a Varian T-60 or HA-100 spectrometer, and the ^{13}C nmr spectra were obtained with a Bruker WP-60 spectrometer with 8K memory. When ion **1***a* was generated from carbinol **2***a* or **3***a* in H_2SO_4 at 10°C, attempts at trapping the ion by pouring the reaction mixture into cold CH_3OH gave only the olefin, 1-ferrocenyl-2-methylpropene, mp (after sublimation) 35–36°C; ^{1}H nmr (CCl_4) δ 1.72 (s, 3H, CH_3), 1.75 (s, 3H, CH_3), 3.90 (s, 5H, C_5H_5), 3.95, 4.05 (m, 4H, C_5H_4), 5.85 (m, 1H, CH). *Anal.* calcd. for $C_{14}H_{16}Fe$: C 70.02, H 6.72; found: C 70.33, H 6.98. No attempts were made to trap ion **1***b* from studies with carbinol **2***b* or **3***b*.

Rates of reaction of the five π donor acids indole-3-acrylic acid (IAA), indole-5-carboxylic acid (ICA), 3,4,5-trimethoxybenzoic acid (TMBA), 2,4-dihydroxybenzoic acid (DHBA), and 3,4,5-trihydroxybenzoic acid (THBA) with 4-chlorodiphenyldiazomethane (4-ClDDM) in ethanol at 30 °C were measured in the presence of the π acceptors 1,3,5-trinitrobenzene (TNB), benzotrifuroxan (BTF), and 1,2,4,5-tetracyanobenzene (TCNB) and in the absence of acceptor. For 12 of the 13 combinations studied, added acceptor produced rate enhancements. The rate data were combined with independently-determined 1:1 acceptor – donor acid association constants to obtain second-order rate constants for reaction of the 1:1 acceptor – donor acid complexes. From the increase in the rate constant resulting from complexation, estimates of the increase in $K_a(H_2O, 25\,°C)$ produced by complexation were obtained for 13 acceptor – donor acid combinations. Second-order rate constants for reaction of 4-ClDDM with 10 other carboxylic acids and *p*-toluenesulfonic acid in ethanol at 30 °C were also measured and the pattern of reactivity shown to parallel very closely that of diphenyldiazomethane.

ALLAN K. COLTER et R. JAMES KERSTING. Can. J. Chem. **55**, 1028 (1977).

On a mesuré les vitesses de réaction de cinq acides donneur π l'acide indole acrylique-3, (IAA), l'acide indole carboxylique-5 (ICA) l'acide triméthoxy-3,4,5 benzoïque (TMBA) l'acide dihydroxy-2,4 benzoïque (DHBA) et l'acide trihydroxy-3,4,5 benzoïque (THBA) avec le chloro-4 diphényldiazométhane (4-ClDDM) dans l'éthanol à 30 °C en présence d'accepteurs π comme le trinitro-1,3,5 benzène (TNB), le benzotrifuroxanne (BTF) et le tétracyano-1,2,4,5 benzène (TCNB) ainsi qu'en l'absence d'accepteur. Dans les cas de 12 des 13 combinaisons étudiées, l'addition d'accepteur conduit à des augmentations de vitesse. On a combiné les données concernant les vitesses avec les constantes d'association acide donneur – accepteur 1:1 déterminé d'une façon indépendante de façon à obtenir les constantes de vitesses du deuxième ordre pour la réaction des complexes acide donneur – accepteur 1:1. A partir des augmentations dans la constante de vitesse par complexation, on a pu estimer l'augmentation dans $K_a(H_2O, 25\,°C)$, produite par une complexation, pour 13 des combinaisons acide donneur – accepteur. On a aussi mesuré les constantes de vitesse du deuxième ordre pour la réaction du 4-ClDDM avec 10 autres acides carboxyliques et l'acide *p*-toluènesulfonique dans l'éthanol à 30 °C; on a montré que les tendances dans la réactivité sont très parallèles avec celles du diphényldiazométhane.

[Traduit par le journal]

Our interest in the chemical effects of molecular complexing (ref. 1 and previous papers in this series) has led us to investigate the influence of molecular complexing on acid–base properties. The previous paper in the series (2) describes an approach to the problem involving potentiometric measurements in aqueous solution. While the potentiometric method is relatively direct, its application is limited in practice to investigations of electrically charged complexing agents, where the total effect of complexation is a result of contributions from both charge-transfer and direct electrostatic interactions.

An objective of the present work was to obtain a measure of the influence of charge-transfer interaction on acid–base properties in weak complexes. How, for example, is the acidity of a benzoic acid affected by complexation with trinitrobenzene? Information of this kind is of interest in relation to recurring questions (3) concerning the contribution of charge-transfer forces to the enthalpy of formation of weak donor – acceptor complexes and the extent of charge transfer in such complexes.

We describe here an indirect approach to the estimation of the effects of complexation on

[1]Present address: Department of Chemistry, University of Guelph, Guelph, Ontario.

acidity which is based on the effect of complexing on the rate of a general acid-catalyzed reaction.

Method

For a series of structurally related acids the catalytic constants k are frequently related to their acidity constants K_a by means of a Brönsted catalysis law expression [1] (4). For a reaction

$$[1] \qquad \log k = \alpha \log K_a + c$$

mixture containing a donor acid, HD, and an acceptor, A, which forms a 1:1 complex with the acid, the reaction will be catalyzed by both complexed and uncomplexed acid. Provided that the acceptor does not interact with the substrate and does not significantly affect the catalytic constant for the uncomplexed donor acid, the observed rate constant in such a mixture is given by [2]

$$[2] \quad \begin{aligned} k_{obs} &= k[HD] + k_c[HD{\cdot}A] \\ &= k\{c_{HD} - [HD{\cdot}A]\} + k_c[HD{\cdot}A] \\ &= kc_{HD} + (k_c - k)[HD{\cdot}A] \end{aligned}$$

where k_c is the catalytic constant for the 1:1 complex, [HD] and [HD·A] are actual concentrations of uncomplexed and complexed donor acid, respectively, and c_{HD} is the stoichiometric concentration of donor acid. Rearrangement of [2] leads to an expression [3] for the catalytic constant of the 1:1 complex. From

$$[3] \qquad k_c = k + \frac{k_{obs} - kc_{HD}}{[HD{\cdot}A]}$$

the equilibrium condition for 1:1 complexation [4] one can obtain an explicit expression for

$$[4] \quad \begin{aligned} K &= \frac{[HD{\cdot}A]}{[HD][A]} \\ &= \frac{[HD{\cdot}A]}{\{c_{HD} - [HD{\cdot}A]\}\{c_A - [HD{\cdot}A]\}} \end{aligned}$$

[HD·A] in terms of K, c_{HD}, and the stoichiometric acceptor concentration c_A. By substitution into [3] one could then obtain an equation containing only two unknowns, k_c and K. In theory, then, measurement of k_{obs} at two or more acceptor concentrations could lead to both k_c and K. However, the success of such an approach requires significant rate effects by added acceptor over a range of acceptor concentrations corresponding to a substantial variation in the fraction of the acid which is complexed (1, 5).

In the present work it was found necessary to determine K spectrophotometrically. Having K, c_{HD}, and c_A for a particular kinetic experiment, [HD·A] can then be calculated. From k_{obs}, k (the rate constant measured in the absence of acceptor), and c_{HD}, the catalytic constant for the 1:1 complex can then be calculated from [3]. Finally, assuming that k_c obeys the Brönsted relation [1], the acidity constant for the 1:1 complex, K_a^c, can be estimated by means of [5].

$$[5] \qquad \log (k_c/k) = \alpha \log (K_a^c/K_a)$$

The reaction chosen for the present investigation was the reaction of diphenyldiazomethane (DDM), or one of its derivatives, with carboxylic acids in ethanol solvent. In addition to its convenience, this reaction has several desirable features for our purposes. It is one of the most extensively studied of all organic reactions with respect to structural influences on the rate (6), it has been thoroughly studied from a mechanistic standpoint (7), and there is strong evidence that the rate determining step involves transfer of a proton from the acid to the DDM. General acid catalysis has been established, and for selected groups of closely related carboxylic acids at least, the rates are well correlated by means of a Brönsted relation (see later discussion, however).

Results

Since the method requires that the reactivity of the substrate be unchanged by the presence of acceptor we first examined mixtures of DDM and 1,3,5-trinitrobenzene (TNB) by uv–visible spectroscopy. The spectrum of a solution containing 0.003 M DDM and 0.051 M TNB shows some enhancement of absorption over the sum of the spectra of solutions of DDM and TNB alone. The DDM absorption band at 520 nm was enhanced and broadened by addition of TNB, indicating a weak interaction between the two compounds. With the hope of reducing the interaction by steric hindrance we synthesized 4,4′-di-*tert*-butyldiphenyldiazomethane and examined its spectrum with an without added TNB. Addition of TNB resulted in an even greater enhancement of the long wavelength absorption of the diazo compound (λ_{max} = 535 nm). In addition, a discrete new absorption band appeared at 465 nm. The failure of the two *tert*-butyl groups to hinder complexing suggests that the interaction must involve

TABLE 1. Rate of reaction of 4-ClDDM with acids in ethanol at 30 °C

Acid	[Acid] (M)	k (ℓ mol^{-1} min^{-1})[a]	pK_a (H_2O, 25 °C)[b]

the diazo group. Interestingly, the thermal stability of 4,4′-di-*tert*-butyldiphenyldiazomethane in ethanol appears to be markedly increased by TNB. Because of the sensitivity of the interaction to substitution, 4-chlorodiphenyldiazomethane (4-ClDDM) was examined. Ultraviolet–visible spectra of mixtures of 4-ClDDM and TNB and of 4-ClDDM and benzotrifuroxan (BTF) showed no evidence of complexing.

Earlier kinetic studies of the reaction of 4-ClDDM with acids (8) have been limited to toluene solvent. We therefore examined the kinetics of reaction of 4-ClDDM with 14 carboxylic acids and *p*-toluenesulfonic acid in ethanol at 30 °C. Rate measurements were carried out under pseudo first-order conditions using an excess of acid and following the disappearance of 4-ClDDM spectrophotometrically. By analogy with the DDM reaction (7) we expect about 0.60 mol of carboxylic acid to be consumed per mol of 4-ClDDM reacting, with the formation of ester and ether in the ratio of about 3:2. In approximate agreement with expectations, reaction of 4-ClDDM with indole-3-acrylic acid was determined by titration to consume 0.54 mol of acid per mol of 4-ClDDM. No curvature in first-order rate plots could be detected under the conditions of our measurements. Second-order rate constants (Table 1), calculated by dividing observed pseudo first-order rate constants by the concentration of acid, showed no significant dependence on acid concentration over the concentration ranges studied. The second-order rate constants for 4-ClDDM can be compared to literature values for DDM (9) under identical conditions for nine of the carboxylic acids in Table 1 (all except *p*-methoxy-*trans*-cinnamic acid and the five donor acids chosen for the present study). For these nine acids k (DDM)/k (4-ClDDM) = 2.09 ± 0.17. Excluding 2-furoic acid (9*c*) (ratio = 2.65) and 2-methoxybenzoic acid (9*e*) (ratio = 1.79) the average ratio is 2.05 ± 0.08. For comparison, Hancock *et al.* (8*a*) found DDM to be 2.07 times as reactive as 4-ClDDM in reaction with benzoic acid in toluene at 25 °C. The very close correspondence in the reactivities of DDM and 4-ClDDM means that we can use the extensive literature data for the former to define the Brönsted relation [1] needed to estimate the influence of complexation on the acidity constant.

Using the reported K_a for benzoic acid in ethanol at 25 °C (6.3×10^{-11}) (10) and the measured catalytic constant for *p*-toluenesulfonic acid, we calculate that less than 1% of the reaction of 4-ClDDM with 0.05 M benzoic acid is due to oxonium ion catalysis. A similar conclusion was reached by Roberts *et al.* (11) for the reaction of benzoic acid with DDM under the same conditions.

Five donor acids were chosen for investigation of the influence of molecular complexing on acidity. These were indole-3-acrylic acid (IAA),

indole-5-carboxylic acid (ICA), 3,4,5-trimethoxybenzoic acid (TMBA), 2,4-dihydroxybenzoic acid (DHBA), and 3,4,5-trihydroxybenzoic acid (THBA). Benzoic acid itself, because of the electron-withdrawing nature of the carboxyl group, is expected to have only very weak π donor properties. It was anticipated that two or three hydroxy or methoxy groups or a fused pyrrole ring would more than neutralize the effect of the carboxyl group providing acids with pronounced π donor properties. In fact, all five donor acids gave visible color enhancement with TNB in ethanol solution. In contrast, *p*-methoxybenzoic, cinnamic, *p*-methoxycinnamic and 2-furoic acids gave no visible evidence for complexing with TNB. In addition to the pronounced π donor properties of the indole ring (13) the choice of IAA and ICA was based on a second consideration. If the donor–acceptor interaction is centred on the pyrrole ring, the substantial separation between the site of complexation and the carboxyl group should reduce the likelihood of steric hindrance by the acceptor in the transition state for reaction of the complexed acid. All five of the donor acids have conveniently measurable second-order rate constants (Table 1).

The acidity of a phenol is expected to be influenced to a greater extent by complexation than the acidity of a substituted benzoic acid since the charge on the phenoxide ion is delocalized onto the aromatic ring. Unfortunately, the π donor phenols are too weakly acidic to study in the 4-ClDDM reaction. For example, the rate of disappearance of 4-ClDDM in the presence of 0.3 *M* 2,6-dimethylphenol in ethanol at 65 °C was identical, within experimental uncertainty to the rate in the absence of phenol.

For the purposes of the present study the π acceptor must have reasonable solubility in ethanol and must be stable in ethanol at least for the time required for the kinetic measurements. Few of the stronger π acceptors meet both criteria. For example, 2,4,7-trinitrofluorenone and chloranil have insufficient solubility in ethanol; tetracyanoethylene and pyromellitic dianhydride solvolyze in ethanol to yield acidic solutions. The acceptors TNB, benzotrifuroxan (BTF) (14), and 1,2,4,5-tetracyanobenzene (TCNB) (15) were chosen for closer scrutiny. As measured by charge-transfer maxima (16), the acceptor strengths of the three acceptors lie in the order TCNB > TNB $\approx$ BTF. The few comparisons which have been made indicate that BTF (14) and TCNB (17) form complexes with aromatic π donors of comparable or greater stability than the corresponding TNB complexes.

In order to distinguish effects due to complexation of donor acid from other medium effects of added acceptor, two kinds of control experiments were carried out. The influence of added acceptor was examined in the reaction of 4-ClDDM with the non-donor acid acetic acid and in the thermal decomposition of 4-ClDDM at 30 °C in the absence of acids. A portion of the results are summarized in Table 2. The results clearly show that any increase in the rate of the acetic acid reaction produced by 0.070 *M* TNB is well within the experimental error. The effect of BTF varied from sample to sample. One sample (Table 2) produced a rate increase of about 12.5% at a concentration of 0.030 *M*. A rate measurement using the same concentration of this sample of BTF alone showed that the increase could be attributed entirely to catalytic activity of the BTF and was therefore not due to an interaction between the acetic acid and the BTF. This catalytic activity is apparently due to an acidic impurity in the BTF, though repeated crystallization from acetic acid and benzene failed to alter its catalytic activity. A second independently prepared sample gave approximately the same rate increase, while a third sample exhibited no effect whatever on the rate of decomposition of 4-ClDDM. This sample was used in the rate runs reported in Table 3. Finally, TCNB at saturation (approximately 0.010 *M*) had no measurable effect on the rate of decomposition of 4-ClDDM.

Tables 3 and 4 summarize the results of rate measurements involving the five donor acids with and without added TNB, BTF, and TCNB. The rate enhancements produced by 0.050 and 0.070 *M* TNB ranged from 12 to 22%, well outside the experimental uncertainty with all five donor acids (Table 3). Also included in Table 3 are the results of some experiments with *p*-methoxy-*trans*-cinnamic acid, an acid expected to have weak π donor properties but which gives no visible evidence for complexing with TNB in ethanol (above). Significantly, the rate increase (5%) was much smaller than that obtained with the other five donor acids, just marginally outside the combined experi-

mental uncertainties of the two rate constants. Even at 0.010 and 0.015 M concentrations of BTF, rate increases well outside the experimental uncertainty (approximately 22, 11, and 13%, respectively) were observed with IAA, ICA, and DHBA. The difficulty in obtaining samples of BTF showing negligible catalysis in the absence of acid limited the scope of our study with this acceptor. For unknown reasons, the kinetics of the reaction of THBA with 4-ClDDM in the presence of BTF were not reproducible. The solubility of TCNB in ethanol in the presence of the donor acids is around 0.010 M. At this low concentration observed rate enhancements were just barely outside the combined experimental uncertainties of the rate constants with and without added acceptor with TMBA, DHBA, and THBA. With ICA a rate increase comparable to the experimental uncertainty was observed, while with IAA, 0.010 M TCNB gave a very small rate decrease, which, however, is well within the limits of the experimental uncertainty.

In addition to the studies with the three uncharged acceptors some preliminary investigations were carried out with one cationic acceptor, *N*-methylquinolinium chloride (NMQ^+Cl^-). In our potentiometric studies of the effects of

molecular complexing on acid–base equilibria (2) it was found that electrostatic effects are generally more important than effects due to charge-transfer interaction in weak complexes involving anionic acceptors. Addition of NMQ^+Cl^- to ethanolic solutions of IAA or THBA produces a visible color change. However, the rates of reaction of 0.040 M acetic acid, 0.040 M IAA, and 0.050 M THBA with 4-ClDDM in the presence of 0.050 M NMQ^+Cl^- were identical within experimental error to the rates of the same reactions in the presence of 0.050 M tetraethylammonium chloride (TEA^+Cl^-), a non-acceptor salt. Furthermore, second-order rate constants for the three acids in the presence of either salt were within 5% of those in the absence of salt. In contrast, Roberts *et al.* found that 0.05 M $LiClO_4$ produced rate increases of around 10–12% in the reaction of DDM with benzoic (11) and acetic (18) acids. It is possible that the NMQ^+ – donor acid complexes do not show the expected catalytic activity because of steric hindrance. However, there is no obvious reason why the NMQ^+ and TNB complexes should be any different in this respect, and no attempt was made to answer this question.

In order to estimate the catalytic constants for the acceptor – donor acid complexes for which kinetic data are available, it is necessary to have an estimate of the concentrations of complexed and uncomplexed acid under the conditions of a particular rate measurement. For this reason, 1:1 association constants for all donor acid – acceptor pairs were measured spectrophotometrically. The results are summarized in Table 5. The determinations were carried out using a modification of the procedure of de Maine and Seawright (19) (Experimental). Where possible, measurements were usually made at three wavelengths. With some systems overlap of the charge-transfer absorption with the acceptor absorption was so severe that measurements were only practical at one or

two wavelengths. For all except three combinations (DHBA–TNB, DHBA–TCNB, and THBA–TCNB) where measurements were carried out at more than one wavelength, average deviations were ±6.5% or less. A more realistic estimate of the uncertainty in K is likely around 10 to 20%, except where average deviations are larger (20).

The 1:1 association constants were then combined with the results of the kinetic studies to calculate the catalytic constant k_c for the 1:1 acceptor – donor acid complex for each combination studied. The results are listed in Table 6 for each set of rate comparisons in Tables 3 and 4. Also listed are values of k_c/k, the factor by which the catalytic constant of the donor acid is increased by complexing. The first step in the calculation of k_c is calculation of the concentration of the 1:1 acceptor – donor acid complex, [HD·A], under the conditions of the rate measurements, from c_{HD}, c_A, and K. The calculated value of [HD·A] is then combined with pseudo first-order rate constants in the presence and absence of acceptor (where k_{obs} in the absence of acceptor $= kc_{HD}$) to calculate k_c by means of [3]. Rate measurements in the presence and absence of acceptor at the same acid concentration were carried out simultaneously and values of k_c/k were calculated from the value of k_{obs} in the absence of acceptor (Tables 3 and 4).

For purposes of comparison of k_c/k ratios it is important to have an estimate of experimental uncertainty, particularly for numbers calculated from small rate enhancements. Such estimates were obtained in the following way. Uncertainties in individual pseudo first-order rate constants were taken as the average deviations for three or four duplicate measurements (Tables 3 and 4), and used to calculate maximum and minimum values for the difference (k_{obs} –

TABLE 7. Estimates of the effect of complexing on the acidity, $K_a^c/K_a(H_2O, 25\ °C)$[a]

[b]See text for abbreviations.

kc_{HD}). Using the average deviation in K as a measure of its experimental uncertainty, minimum and maximum values of [HD·A] were calculated for the conditions of each rate comparison. Where a K was measured at a single wavelength its uncertainty was taken arbitrarily as ±10%. Minimum and maximum values of k_c were then calculated from minimum and maximum values of $(k_{obs} - kc_{HD})$ and maximum and minimum values of [HD·A], respectively. Although uncertainties in K may be underestimated in some cases by this procedure, the calculated uncertainties in k_c and k_c/k reflect mainly uncertainties in the rate increases and are influenced only slightly by a 10% uncertainty in K. We believe, therefore, that our estimates of the uncertainties in k_c and k_c/k are maximum uncertainties. Values of k_c and k_c/k obtained from rate comparisons at different acid and/or acceptor concentrations are generally in good agreement and the ranges of k_c and k_c/k overlap without exception.

Finally, it remains to estimate the effects of molecular complexing on the acidity constant by means of [5]. For this purpose α is the slope of a plot of log k for reaction of 4-ClDDM with carboxylic acids at 30 °C *vs.* log K_a in H_2O at 25 °C. For the 14 carboxylic acids in Table 1 for which the K_a's have been measured, α = 0.59 (standard deviation 0.06). However, since the relative reactivities of 4-ClDDM and DDM are essentially independent of the acid (above) we may use the much more extensive data for the latter to choose an appropriate value of α. Unfortunately, though good correlations are obtained for small groups of closely related carboxylic acids, there is considerable variation of α from one group to another. For example, for selected groups of *meta*- and *para*-substituted benzoic acids α (equal to the Hammett ρ in the case) is 0.93–0.95 (21–24), for phenylacetic acids, 0.72 (23) β-phenylpropionic acids 0.92 (23), phenoxyacetic acids 0.72 (23), *trans*-cinnamic acids 1.0 (23), 3-substituted acrylic acids 0.72–0.74 (24), *ortho*-substituted benzoic acids 0.79 (24), substituted acetic, and propionic acids 0.62 (9*f*). Values of both log k (DDM, ethanol, 30 °C) and K_a (thermodynamic, H_2O, 25 °C) have now been reported in the literature for 19 *meta*- and *para*-substituted benzoic acids. For this group α = 0.91 (standard deviation 0.02, corr. coeff. 0.995) and we have used this value to obtain the estimates of K_a^c/K_a listed in Table 7.

Discussion

The most important result of this work is the demonstration that with a single exception (IAA + TCNB) addition of the π acceptors TNB, BTF, and TCNB to the reactions of five π donor carboxylic acids with 4-ClDDM in ethanol produces measurable rate enhancements. We have interpreted these rate enhancements as resulting from formation of a 1:1 acceptor – donor acid complex which is a stronger acid than the uncomplexed acid. By combining the rate data with independently-determined 1:1 association constants we have calculated the factors, k_c/k, by which the catalytic constants of the acids are increased by complexation, and from these have estimated the factors, K_a^c/K_a, by which the acidity constant is increased by complexation.

Before considering the significance of the derived results in Tables 6 and 7, it is important to review the evidence supporting our interpretation of the rate enhancements. With 0.070 *M* TNB and 0.015 *M* BTF, rate enhancements well outside experimental error were observed with every acid showing visible evidence for

complexing, while the rate of reaction of *p*-methoxy-*trans*-cinnamic acid, a very weak π donor showing no visible evidence for complexing with TNB, was increased only 5 ± 3% by 0.07 *M* TNB. The rate of reaction of the non-donor acid acetic acid was unchanged by 0.070 *M* TNB. The rate of decomposition of 4-ClDDM in ethanol was unaffected by the presence of the three acceptors at concentrations used in the rate enhancement measurements. Finally, values of k_c/k calculated from rate comparisons at different concentrations of TNB or BTF and/or different donor acid concentrations are in good agreement.

The most striking feature of the k_c/k values in Table 6 is their similarity. Average k_c/k values for 8 of the 13 combinations studied lie in the range 2.0 to 3.5 and only 2 values, those for IAA–BTF (8.5) and IAA–TCNB (0) lie outside this range by more than the experimental uncertainty.

Complexing could produce an increase in acidity by means of at least two kinds of electronic effects. The most likely interaction mechanism of general importance is π electron charge-transfer from donor to acceptor, in accordance with the Mulliken description of donor–acceptor complexes (25). The extent of charge-transfer should increase with decreasing donor ionization energy and increasing acceptor electron affinity, however it is likely to be small and reasonably constant for the weak complexes studied in this work. Complexing could also influence acidity through direct electrostatic interaction between polar groups (*e.g.*, NO_2) in the acceptor and the donor carboxyl group. Such field effects could facilitate or impede loss of a proton, depending on the preferred relative orientation of the complexed donor and acceptor, and are more likely to vary from one donor–acceptor combination to another. Changes in equilibrium acidity resulting from complexing could be partly obscured by unfavorable steric effects in the proton transfer transition state. Again, steric effects should vary widely from one donor–acceptor combination to another.

The close similarity of the k_c/k values strongly suggests that steric effects are generally unimportant. On the other hand, steric hindrance appears to be the most plausible explanation for the lack of reactivity of the IAA–TCNB complex. This result is reminiscent of the work of Menger and Bender (26) who found complexes of *N*-(indole-3-acryloyl)imidazole and *p*-nitrophenyl 3-indoleacrylate with 3,5-dinitrobenzoate to be inert in basic hydrolysis. A similar, though somewhat weaker argument can be made for the general unimportance of dipolar field effects, though such effects could be important in either or both of the systems whose k_c/k values lie outside the 2.0–3.5 range. We consider, therefore, that the results of this investigation provide clear evidence for significant charge-transfer in weak donor–acceptor complexes.

Experimental uncertainties in k_c/k make comparisons between donors risky, particularly outside of the TNB results. No clear order of donor or acceptor strengths is discernible from the k_c/k values, nor does any constant pattern of donor or acceptor strengths emerge from the equilibrium studies. As was found in the catalysis of acetolysis of 2,4,7-trinitro-9-fluorenyl *p*-toluenesulfonate by aromatic hydrocarbon donors (1) and by methoxynaphthalene donors (27) there is little relationship between the stability of the complex (as measured by K) and the chemical effect of complexing (k_c/k).

Finally, it is interesting to compare the effects of complexing on acidity with the effects of electron-withdrawing substituents on the acidities of benzoic acids. Log (K_a^c/K_a) values from this work vary over the ranges 0.26–0.56 (TNB), 0.5–1.0 (BTF), and 0.2–0.9 (TCNB). These (presumed) electron-withdrawing effects are therefore similar to those of substituents in the benzoic acids (log K/K_0, or σ), *e.g.*, *p*-Cl (0.26), *m*-CN (0.56), *p*-CN (0.78). These effects are also comparable to the electronic effects of complexing by aromatic donors in acetolysis of 2,4,7-trinitro-9-fluorenyl *p*-toluenesulfonate where, for example, complexation with phenanthrene has about the same effect as removal of the 2-nitro group. The much smaller rate enhancements in the present work are due mostly to the much lower sensitivity of the K_a of benzoic and related acids to electron withdrawal from the benzene ring.

Experimental

Reagents

4-Chlorodiphenyldiazomethane, prepared as described by Schroeder and Katz (28), was purified by crystallizing twice from dry methanol; mp 34.5–35.5 °C, uv λ_{max} (ethanol) = 520 nm. 4,4′-Di-*tert*-butyldiphenyldiazomethane, was prepared by silver oxide oxidation (28)

of the corresponding hydrazone, obtained from 4,4′-di-*tert*-butylbenzophenone (29) by the method of Szmant and McGinnis (30). After crystallization from hexane the diazo compound had mp 95–98 °C, uv λ_{max} (ethanol) = 535 nm.

1,2,4,5-Tetracyanobenzene was prepared by the procedure of Bailey *et al.* (17*a*), mp 265–266 °C (lit. (17*a*) mp 270–272 °C), infrared spectrum identical to published spectrum (17*a*).

Benzotrifuroxan was prepared by the method of Bailey and Case (14), mp 193–195 °C (lit. (14) mp 194–195 °C), infrared spectrum identical to published spectrum.

1,3,5-Trinitrobenzene, all of the carboxylic acids, *p*-toluenesulfonic acid, *N*-methylquinolinium chloride, and tetraethylammonium chloride were obtained from commercial sources and, where necessary, purified by crystallization until their melting points agreed with published (31) values.

Kinetic Measurements

The progress of the reaction was followed by the usual spectrophotometric method (11, 32). Optical density measurements utilized a Guilford model 200 spectrophotometer equipped with a thermostatted cell compartment maintained at 30.00 ± 0.05 °C by circulation of water. The disappearance of 4-ClDDM was generally followed at 530 nm but when a molecular complex had significant absorption at this wavelength a longer wavelength was used. Measurements were carried out under pseudo first-order conditions using an excess of acid and following the reaction through at least two half-lives. Pseudo first-order rate constants were determined both graphically and by computer.

Determination of Association Constants

The association constants were determined spectrophotometrically using a Guilford model 200 spectrophotometer (above). The experimental data were analyzed

by computer using an adaptation of the iterative method of de Maine and Seawright (19), described by Dewar and Thompson (3*a*). The experimental conditions are summarized in Table 8 for each donor–acceptor pair studied.

Total synthesis of ylango sesquiterpenoids: (+)-*cis*- and (+)-*trans*-sativenediol, (+)-helminthosporal, (+)-helminthosporol, prehelminthosporal, prehelminthosporal diethyl acetal, (+)-victoxinine, (+)-isosativenediol

EDWARD PIERS AND HANS-PETER ISENRING

Received October 19, 1976

EDWARD PIERS and HANS-PETER ISENRING. Can. J. Chem. **55**, 1039 (1977).

Oxidation of the previously prepared olefinic alcohol **26** with chromium trioxide – pyridine in dichloromethane containing trifluoroacetic acid gave the tricyclic ketone **29** as the major product. Hydroxylation of the latter, followed by reduction of the resulting α-hydroxy ketone **31**, afforded a 1:1 mixture of (+)-*cis*- (**22**) and (+)-*trans*-sativenediol (**23**). In view of earlier synthetic transformations reported by a number of different researchers, the present work also constitutes formal total syntheses of the enantiomers of the following sesquiterpenoids: (−)-helminthosporal (**1**), (−)-helminthosporol (**2**), prehelminthosporal (**3**), prehelminthosporal diethyl acetal (**4**), (−)-victoxinine (**8**), and (−)-isosativenediol (**19**).

EDWARD PIERS et HANS-PETER ISENRING. Can. J. Chem. **55**, 1039 (1977).

L'oxydation de l'alcool oléfinique **26**, préparé antérieurement, par le complexe oxyde de chrome – pyridine dans le dichlorométhane contenant de l'acide trifluoroacétique conduit à la cétone tricyclique **29** comme produit majeur. L'hydroxylation de ce dernier, suivie par une réduction de l'α-hydroxy cétone **31** qui en résulte, conduit à un mélange 1:1 des sativènediols (+)-*cis* (**22**) et (+)-*trans* (**23**). Si l'on tient compte des transformations synthétiques rapportées antérieurement par un certain nombre de chercheurs différents, le travail actuel constitue aussi une synthèse totale formelle des énantiomères des sesquiterpènes suivants: le (−) helminthosporal (**1**), le (−) helminthosporol (**2**), le préhelminthosporal (**3**), le diéthylacétal de préhelminthosporal (**4**), le (−) victoxinine (**8**) et le (−) isosativènediol (**19**).

[Traduit par le journal]

During the past 15 years, *Helminthosporium sativum*, a fungus which is responsible for assorted deleterious effects on a variety of cereal crops and grasses (1), has been the object of a series of chemical investigations carried out by a number of different research groups. The combined results of this work have shown that the fungus produces a fairly large number of structurally related sesquiterpenoids,[1] some of which have subsequently been obtained by partial or total synthesis.[4] Interestingly, some of these natural products exhibit significant biological activity, particularly as related to regulation of plant growth (4, 5, 9).

The recent isolation and structural elucidation of (−)-*cis*-sativenediol (**11**) was independently reported by two research groups (8, 9). This natural product, isolated from two different fungi (*Helminthosporium sativum* (8, 9) and *Cochliobolus setariae* IFO 6635 (9)) was shown to be a plant growth promotor with gibberellin-like activity (9). At the same time, both groups isolated an isomeric substance, also levorotatory, to which was initially assigned the *trans*-sativenediol structure **21** (8, 9). However, more recently, Dorn and Arigoni have clearly shown (13) that the isomeric compound actually

[1](−)-Helminthosporal (**1**) (1–3),[2] (−)-helminthosporol (**2**) (4, 5),[2] prehelminthosporal (**3**)[3] (6), (−)-prehelminthosporol (**5**) (6–9), (−)-sativene (**6**) (10), 9-hydroxyprehelminthosporol (**7**) (7), (−)-victoxinine (**8**) (11), (−)-longifolene (**9**) and a secolongifolane derivative (**10**) (12), (−)-*cis*-sativenediol (**11**) (8, 9) and related metabolites (**12**–**18**, excluding compound **15***a*) (8), (−)-isosativenediol (**19**) and the related triol (**20**) (13).

[2]It was subsequently reported (6) that **1** and **2** did not actually occur as such in crude extracts of the fungus. They were therefore believed to be artifacts of the isolation procedure.

[3]Prehelminthosporal (**3**) was isolated as the corresponding diethyl acetal **4** (6).

[4](−)-Helminthosporal (**1**) (14), (+)-, (±)-, or (−)-sativene (**6**) (10, 15–20), (−)-victoxinine (**8**) (11), (±)-longifolene (**9**) (21–23).

possesses the isosativenediol structure **19**.[5] We report herein the total synthesis of both (+)-*cis*- and (+)-*trans*-sativenediol (**22** and **23**, respectively).[6,7] Our work fully confirms the structural assignment made with respect to **11**, and also shows that the original assignments (**21**) (8, 9) made in the case of the isomeric compound were indeed incorrect.

It is pertinent to note that the following conversions have previously been accomplished: (*a*) (−)-*cis*-sativenediol (**11**) into prehelminthosporal (**3**) (9), prehelminthosporal diethyl acetal (**4**) (9), and (−)-isosativenediol (**19**) (13); (*b*) compound **4** into (−)-helminthosporal (**1**) (6); (*c*) (−)-helminthosporal (**1**) into (−)-helminthosporol (**2**) (5); (*d*) (−)-prehelminthosporol (**5**) into (−)-victoxinine (**8**) via the diol **15***a* (11), which has also been derived from (−)-*cis*-sativenediol (**11**) (13). In view of these transformations, our work also constitutes the completion of formal total syntheses of the enantiomers of the sesquiterpenoids **1**–**4**, **8**, and **19**.

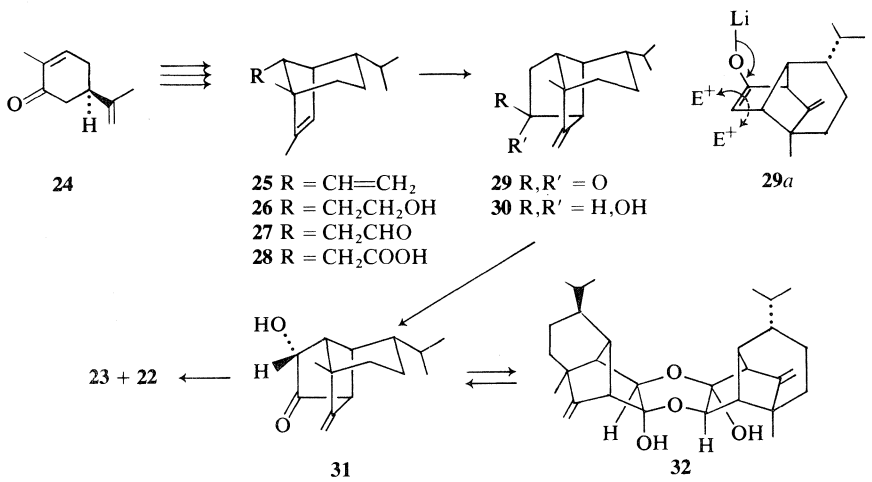
In connection with earlier work concerning the total synthesis of ylango-type[8] sesquiterpenoids, we have already described (18, 19) the preparation of the diene **25** and its conversion into the olefinic alcohol **26**. Since these compounds were synthetically derived from (−)-carvone (**24**), their absolute stereochemistry was firmly established. Although oxidation of **26** with Collins' reagent (27, 28) under carefully controlled conditions produced the corresponding

[5]We are very grateful to Professors Arigoni and Marumo for personal communications regarding this point. We also thank Professor Arigoni for full experimental details regarding the work which he and his co-workers have done in this area.

[6]For a preliminary communication regarding this work, see ref. 24.

[7]McMurry and Silvestri (25) have recently completed a very elegant total synthesis of racemic *cis*-sativenediol via a sequence entirely different from that used in our work. We are grateful to Professor McMurry for a preprint regarding their synthesis.

[8]For an explanation regarding the origin of the term 'ylango', see ref. 26.



aldehyde **27** in good yield, the latter compound was invariably accompanied by a small amount (~5–8%) of another previously unidentified product (19). This minor product was isolated by preparative glc and was subjected to spectral analysis. The ir spectrum showed a strong absorption at 1741 cm^{-1}, indicating the presence of a cyclopentanone-type carbonyl group. Other particularly instructive bands were found at 1651 and 883 cm^{-1}, indicative of an exocyclic methylene functionality. The presence of the latter functional group was confirmed by the ^1H nmr spectrum in which signals due to the two olefinic protons appeared as singlets at τ 4.83 and 5.17. In addition, a one-proton signal at τ 6.83 could readily be attributed to an allylic proton. On the basis of these data, the structure of the minor product obtained from oxidation of **26** could be assigned the tricyclic structure **29**. Clearly, under the conditions of the oxidation reaction, the initially formed olefinic aldehyde **27** was, at least to a small extent, undergoing intramolecular cyclization (internal Prins reaction (29, 30)) to afford the alcohol **30**, which was then further oxidized to the corresponding ketone **29**. Since the latter compound appeared to be an ideal synthetic precursor for (+)-*cis*- (**22**) and (+)-*trans*-sativenediol (**23**), a study was undertaken with the aim of finding conditions for the oxidation of **26** which would give **29** as a major product.

After considerable investigation of various alternatives and reaction conditions, it was found that the overall conversion of **26** into **29** could be carried out in a fairly efficient manner as follows. When the olefinic alcohol **26** was treated with 8 mol equiv. of Collins' reagent (27, 28) in dichloromethane at room temperature, it was found that essentially all of **26** had been converted into the corresponding aldehyde **27** in ~20 min. Since the Prins reaction is known to be acid-catalyzed (29, 30), the reaction mixture was treated with a catalytic amount of trifluoroacetic acid, along with a further 8 equiv. of oxidizing agent. Work-up after an additional reaction time of 4.5 h gave a crude mixture of products which, upon subjection to column chromatography, yielded 30% of the desired tricyclic ketone **29**, 19% of the aldehyde **27**, and a crude oil that contained the olefinic acid **28**. Resubjection of **27** to the oxidizing conditions ($CrO_3 \cdot 2C_5H_5N$, CF_3COOH, CH_2Cl_2) gave a further 10% of **30**. Finally, two successive treatments of the crude acid **28** with oxalyl chloride in benzene, followed by appropriate purification by column chromatography afforded an additional 15% of the desired material **29**. Thus, the latter compound was obtained in 55% overall yield from the diene **25**.

Interestingly, alternative oxidation procedures for the direct conversion of **26** into **29** proved less satisfactory. For example, it is pertinent to note that pyridinium chlorochromate, a reagent recently employed to cyclize citronellol oxidatively to pulegone (31, 32) produced in our case an excellent yield of the aldehyde **27**, even in the presence of excess reagent.

Clearly, the conversion of the tricyclic ketone **29** into the two sativenediols **22** and **23** required only hydroxylation of **29** at the position adjacent to the carbonyl group, followed by reduction of the resulting hydroxy ketone.

Although there are now a number of apparently efficient methods available for effecting α-hydroxylation of a ketone, we chose the neat, experimentally convenient procedure recently introduced by Vedejs (33). Thus, conversion of **29** into the corresponding lithium enolate (lithium diisopropylamide, THF, −70 °C), followed by treatment of the resultant solution with the molybdenum peroxide MoO_5·Py·HMPA (33), afforded, stereoselectively, in 74% yield, the hydroxy ketone **31**. The stereochemistry of the latter compound, predicted to be as shown (approach of the electrophilic reagent from the less hindered side of the enolate anion, *cf.* **29***a*), was fully corroborated by the ^{1}H nmr spectrum. In particular, the carbinol proton in **31** appeared as a sharp singlet at τ 6.06, clearly showing that there was little or no coupling between this proton and the one on the adjacent carbon atom. A molecular model of **31** indicated that the dihedral angle between these two protons was very close to 90° and therefore little or no coupling would be expected (34). On the other hand, the corresponding dihedral angle in the epimeric compound would have been approximately 40–45° and coupling (~3–5 Hz) would have been expected.

It is interesting to note that during purification by column chromatography, or upon standing in solution, compound **31** slowly dimerized. The resultant substance (probably **32**) was only slightly soluble in ether, gave gas–liquid chromatographic retention times identical with those of **31** and, upon distillation, was smoothly transformed into the monomeric hydroxy ketone **31**. The reversible dimerization of α-hydroxy ketones is a well-known phenomenon and these observations therefore deserve no further comment.

Reduction of the hydroxy ketone **31** with lithium aluminum hydride in ether at 0 °C produced, in 90% yield, a 1:1 mixture of (+)-*cis*- (**22**) and (+)-*trans*-sativenediol (**23**). These compounds were cleanly separated by column chromatography on silica gel. The *cis*-diol **22** exhibited ir and ^{1}H nmr spectra identical with those of the naturally occurring enantiomer **11**.[9] The spectra (ir and ^{1}H nmr) obtained from the *trans*-diol **23** were similar to, but clearly distinguishable from, those of (−)-isosativenediol (**19**) and of the *cis*-diol **22**.

[9]We are very grateful to Professor Marumo for copies of the ir and ^{1}H nmr spectra of (−)-*cis*-sativenediol (**11**) and of (−)-isosativenediol (**19**).

Experimental

General

Melting points, which were determined on a Kofler block, and boiling points are uncorrected. Optical rotations were obtained at the sodium D line, using a Perkin-Elmer model 141 automatic polarimeter. Routine ir spectra were recorded on a Perkin-Elmer model 710 spectrophotometer, while comparison spectra were recorded on a Perkin-Elmer model 457 spectrophotometer. Proton magnetic resonance spectra were taken in deuteriochloroform solution on Varian Associates spectrometers, models T-60, HA-100 and/or XL-100. Signal positions are given in the Tiers τ scale, with tetramethylsilane as an internal standard. The multiplicity, integrated peak areas, and proton assignments are indicated in parentheses. Mass spectrometric measurements were carried out on an AEI type MS-9 mass spectrometer. Gas–liquid chromatographic analyses were carried out on a Hewlett-Packard model 5832A gas chromatograph. A variety of stainless steel columns (6 ft × 1/8 in., packed with 5% OV-1, 5% OV-17, 5% OV-210 or 5% SP-1000 on 80-100 mesh Chromosorb W) were employed and a carrier gas (helium) flow rate of 30 ml/min was used in all analyses. Microanalyses were performed by Mr. P. Borda, Microanalytical Laboratory, University of British Columbia, Vancouver, B.C.

Preparation of the Tricyclic Ketone 29

To a solution of freshly distilled 2-methyl-2-butene (2.3 ml, 21.6 mmol) in 35 ml of dry tetrahydrofuran at 0 °C was added 865 μl (9.1 mmol) of borane – methyl sulfide complex, and the resulting solution was stirred under an atmosphere of nitrogen for 30 min. A solution of the diene **25** (880 mg, 4.3 mmol) in 17.5 ml of dry tetrahydrofuran was added, the cooling bath was removed, and the reaction mixture was stirred at room temperature for 2.5 h. The solution was cooled to 0 °C, 9.1 ml of 10% aqueous sodium hydroxide and 7.7 ml of 30% aqueous hydrogen peroxide were carefully added, and the resulting mixture was stirred at room temperature for 1 h. After having been diluted with brine, the reaction mixture was thoroughly extracted with 2:1 petroleum ether (bp 30–60 °C) – ether. The combined extracts were washed with brine and dried over anhydrous magnesium sulfate. Removal of the solvent afforded 950 mg of a nearly colorless oil. Gas–liquid chromatographic analysis of this material showed the absence of starting material **25** and indicated that the product, olefinic alcohol **26**, was >98% pure.

A solution of this material in 9.5 ml of dry dichloromethane was added to a solution of chromium trioxide – dipyridine complex (34.5 mmol) in 86 ml of the same solvent. Examination (glc) of an aliquot indicated that all of the alcohol **26** had been converted into the aldehyde **27** after about 20 min. At this time, pyridine (69 mmol) and chromium trioxide (34.5 mmol) were added, followed after 15 min by 260 μl of trifluoroacetic acid. After 4.5 h, the dark reaction mixture was diluted with brine and the products were extracted with ether. The combined extracts were washed with brine, dried over anhydrous magnesium sulfate, and evaporated under reduced pressure. The residual oil was subjected to chromatog-

raphy on 50 g of silica gel. Elution with 5% ether in petroleum ether (bp 60–110 °C) afforded 180 mg of the olefinic aldehyde **27** and 280 mg (30%) of the tricyclic ketone **29**. Elution with pure ether afforded a crude oil which contained the olefinic acid **28**.

Subjection of the aldehyde **27** to the oxidation conditions described above (13 mmol chromium trioxide – dipyridine complex, 45 μl trifluoroacetic acid, 20 ml dichloromethane, reaction time 1.25 h), followed by chromatography of the crude product afforded an additional 95 mg (10%) of the desired ketone **29**.

The crude oil (~550 mg) containing the olefinic acid **28** (see above) was dissolved in 20 ml of dry benzene. The resulting solution was treated with 1.0 ml of oxalyl chloride and was then stirred at room temperature for 30 min. Removal of the benzene, followed by chromatography (silica gel) of the residual material gave pure cyclic ketone **29**, and a crude mixture containing some acid chloride (corresponding to **28**). Hydrolysis of the latter, followed by resubjection of the resultant crude material to reaction with oxalyl chloride in benzene afforded additional amounts of cyclic ketone. In this way, 140 mg (15%) of the desired material **29** was obtained.

The total yield (based on diene **25**) of the tricyclic ketone **29** was 515 mg (55%). This material exhibited bp 75 °C/0.3 torr; $[\alpha]_D^{22}$ +188° (*c* 1.35 in $CHCl_3$); ir (film) ν_{max} 1741, 1651, 883 cm^{-1}; ^1H nmr τ 4.83, 5.17 (s, s, 2H, olefinic protons), 6.83 (br s, 1H, allylic proton, $w_{1/2}$ = 4.0 Hz), 8.85 (s, 3H, tertiary methyl), 9.09, 9.12 (d, d, 6H, isopropyl methyls, J = 6 Hz). *Mol. Wt.* calcd. for $C_{15}H_{22}O$: 218.1670; found (high resolution mass spectrometry): 218.1701.

*Preparation of the Hydroxy Ketone **31***

To a cold (0 °C) solution of diisopropylamine (1.95 mmol) in 2.0 ml of dry tetrahydrofuran was added 0.72 ml of a solution of *n*-butyllithium in hexane (2.72 *M*). The resultant mixture was cooled to −70 °C, and a solution of the cyclic ketone **29** (327 mg, 1.5 mmol) in 8 ml of dry tetrahydrofuran was added slowly. The reaction mixture was stirred at −70 °C for 30 min, after which time 846 mg (1.95 mmol) of the molybdenum peroxide MoO_5·Py·HMPA (33) was added in one portion. Stirring was continued for 1 h at −70 to −65 °C, the cooling bath was removed, and the reaction mixture was allowed to warm slowly to 0 °C, at which temperature it became homogeneous. Brine was added and the resultant mixture was thoroughly extracted with ether. The combined ether extracts were washed once with 5% aqueous sodium carbonate, once with 5% hydrochloric acid, and then dried over anhydrous magnesium sulfate. Removal of the solvent yielded an oil which was subjected to chromatography on silica gel (16 g). Elution with 92:8 petroleum ether – ether gave 60 mg (18%) of starting material **29**. Elution with 1:1 petroleum ether – ether gave 230 mg of crystalline material. On the basis of the physical characteristics of the latter, it was clear that this material was a mixture of two compounds. One of them (the dimer **32**) was only slightly soluble in ether, while the other gave spectral data in accord with the desired monomeric hydroxy ketone **31**. Both compounds gave the same retention times on glc thus clearly showing that upon subjection to heat, the dimer reverted to the monomer. Distillation of the mixture (bath temperature up to 210 °C) at 0.3 torr afforded 212 mg (74%, based on unrecovered starting material) of pure hydroxy ketone **31**, mp 55 °C; $[\alpha]_D^{22}$ +194° (*c* 1.85 in $CHCl_3$); ir ($CHCl_3$) ν_{max} 3410 (br), 3075, 1750, 1655, 1059, 890 cm^{-1}; ^1H nmr τ 4.90, 5.22 (s, s, 2H, olefinic protons), 6.06 (s, 1H, carbinol proton), 6.83 (br s, 1H, allylic proton, $w_{1/2}$ = 4.0 Hz), 7.35 (br s, 1H, $w_{1/2}$ = 5.0 Hz), 8.86 (s, 3H, tertiary methyl), 9.10, 9.13 (d, d, 6H, isopropyl methyls, J = 6 Hz). *Mol. Wt.* calcd for $C_{15}H_{22}O_2$: 234.1619; found (high resolution mass spectrometry): 234.1644.

*(+)-cis- (**22**) and (+)-trans-Sativenediol (**23**)*

To a cold (0 °C) solution of the hydroxy ketone **31** (142 mg, 0.61 mmol) in 6 ml of dry ether was added 25 mg of lithium aluminum hydride and the mixture was stirred at 0 °C for 10 min. Saturated aqueous ammonium chloride (5 ml) was added carefully and the resulting mixture was stirred for another 5 min. The mixture was diluted with brine and thoroughly extracted with ether. The combined extracts were dried over anhydrous magnesium sulfate. Removal of the solvent yielded an oil which was subjected to chromatography on silica gel (30 g). The column was eluted with petroleum ether – ether (85:15 to 10:90, respectively), yielding *cis*-sativenediol (**22**) (62 mg, 43%), a mixture of **22** and **23** (5 mg), and *trans*-sativenediol (**23**) (63 mg, 44%).

Distillation (air-bath temperature 130 °C/0.3 torr) of *cis*-sativenediol (**22**) gave an oil: $[\alpha]_D^{24}$ +124° (*c* 0.98 in $CHCl_3$); ir (film) ν_{max} 3350 (br), 3065, 1660, 1055, 884 cm^{-1}; ^1H nmr τ 5.10, 5.42 (s, s, 2H, olefinic protons), 6.00 (d, 1H, carbinol proton, J = 6 Hz), 6.39 (d, 1H, carbinol proton, J = 6 Hz), 6.7 (br, 2H, —OH), 7.36 (br s, 1H, $w_{1/2}$ = 5 Hz), 7.59 (br s, 1H, $w_{1/2}$ = 4 Hz), 8.96 (s, 3H, tertiary methyl), 9.06, 9.19 (d, d, 6H, isopropyl methyls, J = 6 Hz). *Anal.* calcd. for $C_{15}H_{24}O_2$: C 76.22, H 10.26; found: C 75.82, H 10.24.

trans-Sativenediol (**23**) (air-bath temperature 135 °C/0.3 torr) was also an oil: $[\alpha]_D^{24}$ +64° (*c* 1.32 in $CHCl_3$); ir (film) ν_{max} 3380 (br), 3065, 1655, 1090, 1073, 1035, 889 cm^{-1}; ^1H nmr τ 5.11, 5.19 (s, s, 2H, olefinic protons), 6.24 (m, 1H, carbinol proton), 6.45 (d, 1H, carbinol proton, J = 2 Hz), 7.3 (br, 2H, —OH), 7.34 (br, 1H, $w_{1/2}$ = 8 Hz), 7.62 (br s, 1H, $w_{1/2}$ = 4 Hz), 8.96 (s, 3H, tertiary methyl), 9.10, 9.16 (d, d, 6H, isopropyl methyls, J = 6 Hz). *Anal.* calcd. for $C_{15}H_{24}O_2$: C 76.22, H 10.26; found: C 76.40, H 10.40.

Selective, homonuclear pulse experiments in the Fourier transform mode: a study of 2′,3′-*O*-isopropylidene uridine[1]

KLAUS BOCK,[2] ROLAND BURTON, AND LAURANCE D. HALL

Department of Chemistry, The University of British Columbia, Vancouver, B.C., Canada V6T 1W5

Received September 17, 1976

KLAUS BOCK, ROLAND BURTON, and LAURANCE D. HALL. Can. J. Chem. **55**, 1045 (1977).

A simple modification of a conventional Fourier transform nmr spectrometer (Varian XL-100) makes it feasible to apply selective, radiofrequency pulses at the resonance frequency of one, or more, proton resonances and to monitor the effects of those perturbations in the usual F.t. fashion. Experiments with 2′,3′-*O*-isopropylidene uridine are used to illustrate the utility of this technique in measurements of selective spin-lattice relaxation rates, to eliminate unwanted resonances by selective saturation or by selective partial relaxation, and to perform the pulse equivalent of a ^1H–^1H INDOR experiment.

KLAUS BOCK, ROLAND BURTON et LAURANCE D. HALL. Can. J. Chem. **55**, 1045 (1977).

Une modification simple d'un spectromètre rmn à transformation de Fourier conventionnel (Varian XL-100) permet d'appliquer des pulsations de fréquences radiosélectives à la fréquence d'une ou de plusieurs résonances du proton et d'évaluer l'effet de ces perturbations dans un mode usuel de transformation de Fourier. On a utilisé des expériences avec la 2′,3′-*O*-isopropylidène uridine pour illustrer les utilités de cette technique dans les mesures de vitesses sélectives de relaxation spin réseau pour éliminer des résonances non-désirées par saturation sélective ou par relaxation partielle sélective, et pour effectuer l'équivalent pulsée d'une expérience INDOR H^1–H^1.

[Traduit par le journal]

Introduction

Two, closely related concepts are fundamental to the design of any pulse Fourier transform (F.t.) nmr experiment, that of the 'flip angle' and that of the 'pulse selectivity'.

The *flip angle* (α) is that angle through which the magnetization vector of a nucleus is turned by a pulse of radiofrequency power of the appropriate frequency. The magnitude of this angle is given by the product of the 'pulse duration' and the 'pulse intensity' and, in principle, an infinite number of combinations of these two variables can be used to provide any chosen value for α. In normal practice the experimental options are restricted somewhat by the desire to sample as wide a spectral region as possible, with a power distribution which is as homogeneous as possible, an experiment hereafter referred to as a *non-selective* pulse F.t. experiment.

Since the effective bandwidth (Δ) in the *frequency domain*, of a 360° flip angle pulse of duration t_{360}-s in the *time domain*, is given by the relationship,

$$\Delta = \gamma H_1/2\pi = 1/t_{360}$$

the *non-selective* pulse F.t. experiment makes use of rather intense pulses (100–200 W), of rather short duration (commonly 20–50 μs for a 90° pulse). Such pulses have a total bandwidth of 5–12 kHz but in common practice a flat, power-frequency distribution is experienced by only a few kHz on either side of the carrier frequency.

With a few notable exceptions, little attention has been directed towards nmr experiments in which highly selective pulses are applied to one, or a few, regions of a spectrum. We refer to these as a *selective-pulse* experiment. It is clear that the pulses for such an experiment should be rather weak, and of very long duration. This approach was first pioneered by Freeman and Wittekoek (2) with their 'audio-modulation' pulse technique; but, as we found to our cost when we used that approach (3), it suffered from the disadvantage that the effects of a perturbation also had to be monitored in a selective fashion, and this was extremely time consuming for multiple-spin nmr spectra. The obvious solution to this problem is to use the audio-modulation technique to provide

[1]Part 10 of a series, "Applications of pulsed nuclear magnetic resonance spectroscopy"; for part 9, see ref. 1. A full account of this study was given at the Canadian Chemical Conference of the Chemical Institute of Canada, Toronto, May 25–28, 1975.

[2]Visiting Associate Professor at U.B.C., 1974–1975. Permanent address, Institute for Organic Chemistry, The Technical University of Denmark, Lyngby, Denmark.

a long, weak, and therefore highly selective perturbation pulse, but to monitor its effect on the remainder of the nmr spectrum using a short, intense, non-selective monitoring pulse available from a conventional pulse F.t. nmr spectrometer. And as we shall see in the following discussion this solution is both simple and effective. However, it is appropriate to mention at this juncture that the 'tailored excitation' technique developed by Hill and Tomlinson (4) is likely to provide an even more effective solution in the future.[3]

It proved convenient for several reasons to use 2′,3′-*O*-isopropylidene uridine (**1**) as a model compound for an evaluation of the utility of various selective-pulse F.t. experiments. The ^1H nmr spectrum of **1** in dimethyl sulphoxide-d_6 at 100 MHz, is reasonably well dispersed. Equally important, the proton spin-lattice relaxation rates for **1** are sufficiently rapid to provide a stringent test of certain relaxation measurements and **1** is related to compounds which are of considerable interest to us in another context.

Results and Discussion

The basic pulse sequence used for all the experiments described here, is summarized in Fig. 1*A*. The selective, *perturbation pulse* is derived either directly, or via one of several different classes of audio-modulation, from the homonuclear decoupler of the spectrometer. The non-selective, *monitoring pulse* and the remainder of the detection system is generally derived from the usual pulse F.t. section of the spectrometer. Both pulses are computer controlled, either via the gates provided with the instrument or via a separate gate controlled by a flag specifically derived from the computer. Minor modifications may be required to obtain appropriately long pulses from the decoupler channel. In our laboratory we also have extensive options available for data storage and subsequent data manipulation, but these are not fundamental to the success of the experiments.

The objective of the first series of experiments, which are illustrated in Figs. 2–4, was to demonstrate experimentally the range of frequency selectivities which could be obtained by varying the pulse duration. In each instance the perturbation corresponded to a 180° pulse, and its effect

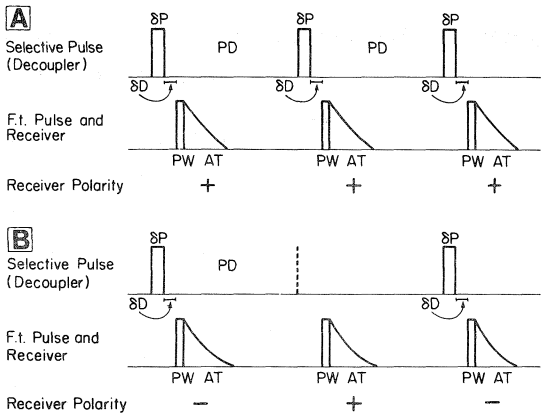

FIG. 1. Diagrammatic representation of the pulse sequences used for most of the experiments described in this paper: δP = width of selective pulse; δD = delay between selective pulse and F.t. pulse; PW = width of F.t. (monitoring) pulse; AT = acquisition time for F.I.D.; PD = pulse delay (four times T_1 value).

was monitored by a non-selective 90° pulse in the usual fashion.[4]

The effects of a 180° pulse applied to the high field component of the H-6 doublet are illustrated in Fig. 2. A pulse of 100 ms provides a reasonable degree of frequency selectivity and any decrease in its duration is accompanied by a rapid decrease in that selectivity. For example the 10 ms pulse applies a 180° flip angle to both components of the H-6 doublet. This is a pity because the shorter pulse clearly tips the H-6 magnetization more effectively than the longer pulse; this is simply because the latter is now sufficiently long for appreciable magnetization to be lost during the duration of the pulse itself. Clearly then, the selective relaxation rate[5] of the transition, or resonance of interest constitutes an effective upper limit for the pulse duration and hence for the frequency selectivity for that particular sample.

The spectra shown in Figs. 3 and 4 indicate the

[3]Since this manuscript was submitted Freeman and co-workers (20) have reported an alternative method for generating 'tailored excitation' sequences that seems to have considerable generality.

[4]A referee prompted us to draw the readers' attention to the work of Ernst and co-workers (21) (and also that of Meakin and Jesson (22)) which discusses the importance of the flip angle of the monitoring pulse used to sample the magnetization of a strongly coupled spin system that has previously been subjected to a selective perturbation. For large flip angles the observed line intensities do not always directly reflect population differences between just two energy levels. A brief discussion of this phenomenon in relation to the homonuclear pulse INDOR experiments is given in ref. 1.

[5]The *selective* relaxation rate of H-6 is 1063 ms^{-1}. Note that this value differs from the *non-selective* R_1-value (5).

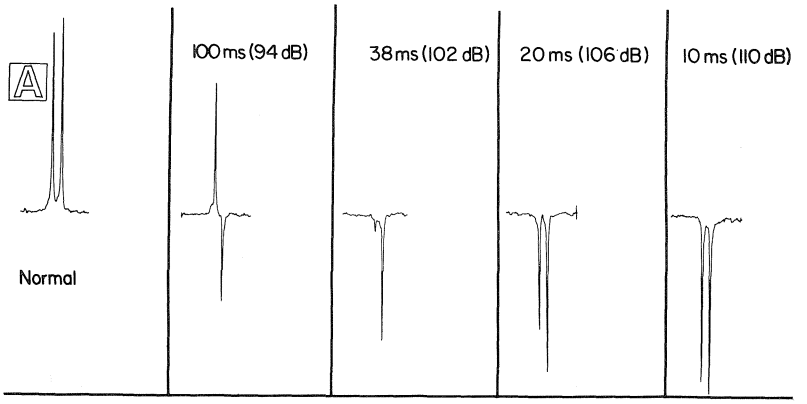

FIG. 2. Inset A shows the normal H-6 resonance of **1** measured with *PW* 75 μs, *PD* 5 s, *AT* 4 s, *NT* 10, and sensitivity enhancement 1.5. The remaining spectra were measured using identical conditions but with prior application, to the upfield transition, of a 180° pulse, the duration and intensity of which are indicated immediately above each resonance. Note that the 10 ms pulse flips *both* the H-6 transitions through 180°.

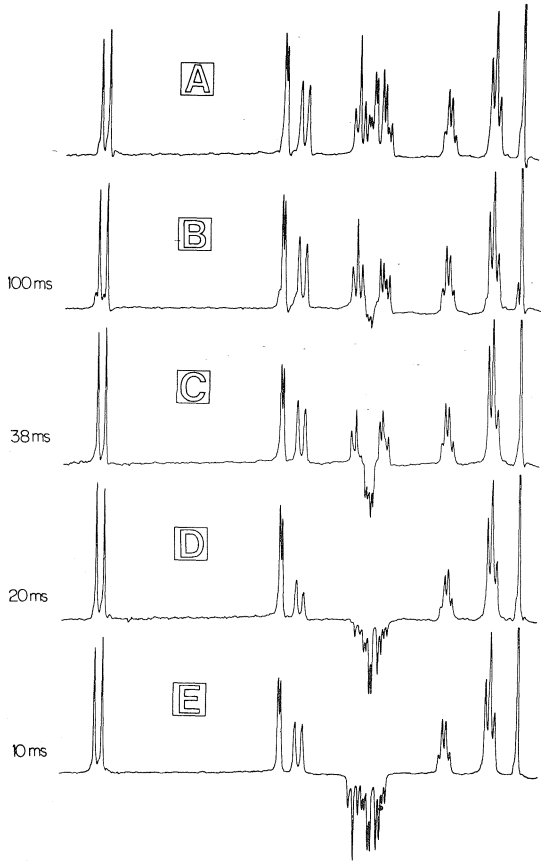

FIG. 3. Spectra showing the effects of changing the duration of a selective 180° pulse applied at the centre of a multiplet resonance (the δP values are listed at the side). The normal ^{1}H spectrum is shown in A. Note that even a 10 ms pulse has no significant effect on the H-5 and H-4′ resonances (the spectra were monitored as for Fig. 2).

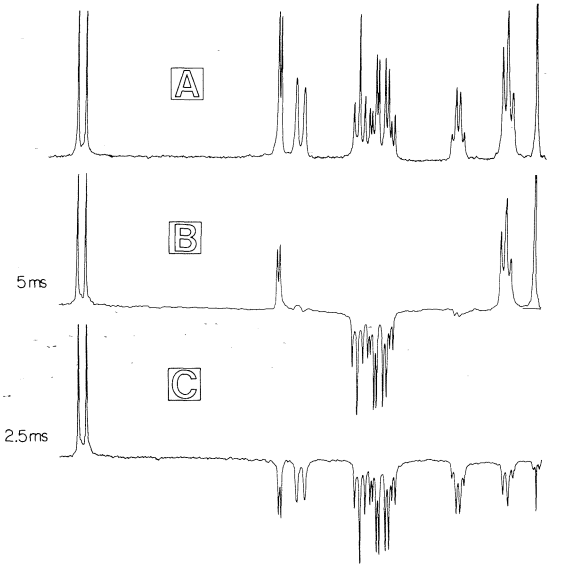

FIG. 4. These spectra show that it is feasible to invert the resonances of a substantial spectral region by applying a suitably short pulse. See Fig. 2 for monitoring conditions.

intermediate ranges of frequency selectivity which are possible; in each instance the decoupler frequency was set at the centre of the H-2′, H-3′, OH′ region. Note that even the 10 ms pulse has little effect on the H-5 and H-4′ resonances which is in accord with expectation since the *total* bandwidth of this pulse should only be 50 Hz.

The final set of spectra, shown in Fig. 4 illustrate that a pulse of 2–5 ms duration can be used to invert a substantial region of a ^{1}H spectrum, but still leave some spectral regions unper-

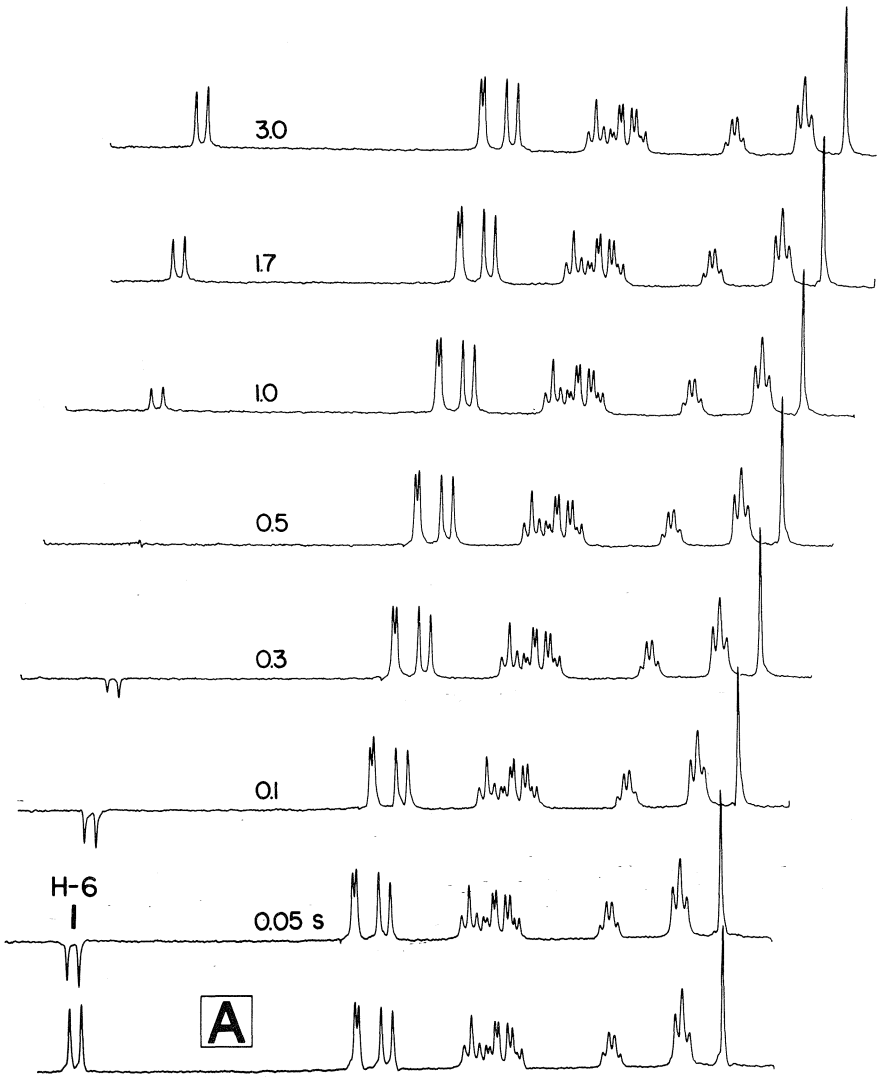

FIG. 5. The inversion-recovery determination of the selective relaxation rate for the H-6 resonances of **1**. A, shows part of the normal F.t. nmr spectrum (*NT* 5, *PW* 75 s, *AT* 4 s, *SE* 1.5). The other spectra were obtained by inverting the spin-states of H-6 with a selective 180° pulse (38 ms, 100 dB) and monitoring the magnetization using the parameters listed above: the pulse delay times are listed against the corresponding spectrum. Note the nearly complete cancellation of the H-6 resonance for the 0.5 s spectrum. The value for $R_1^6(6)$ calculated from these data is 1053 ms^{-1}.

turbed; in this case the H-6 resonance. Note that the 5 ms pulse has an off-resonance field equivalent to a 90° pulse for the H-5 and H-4′ resonances. The possibility of using the decoupler as a convenient source of perturbation pulse of intermediate frequency-bandwidth has many potentially useful applications, particularly in the area of heteronuclear nmr studies.

Selective Measurements of Spin-lattice Relation Rates

The *non-selective*, two-pulse, inversion-recovery sequence used for measuring spin-lattice relaxation rates is now well known (6). All the spins of one nuclear species are simultaneously inverted with a non-selective, 180° pulse and the amount of residual magnetization remaining

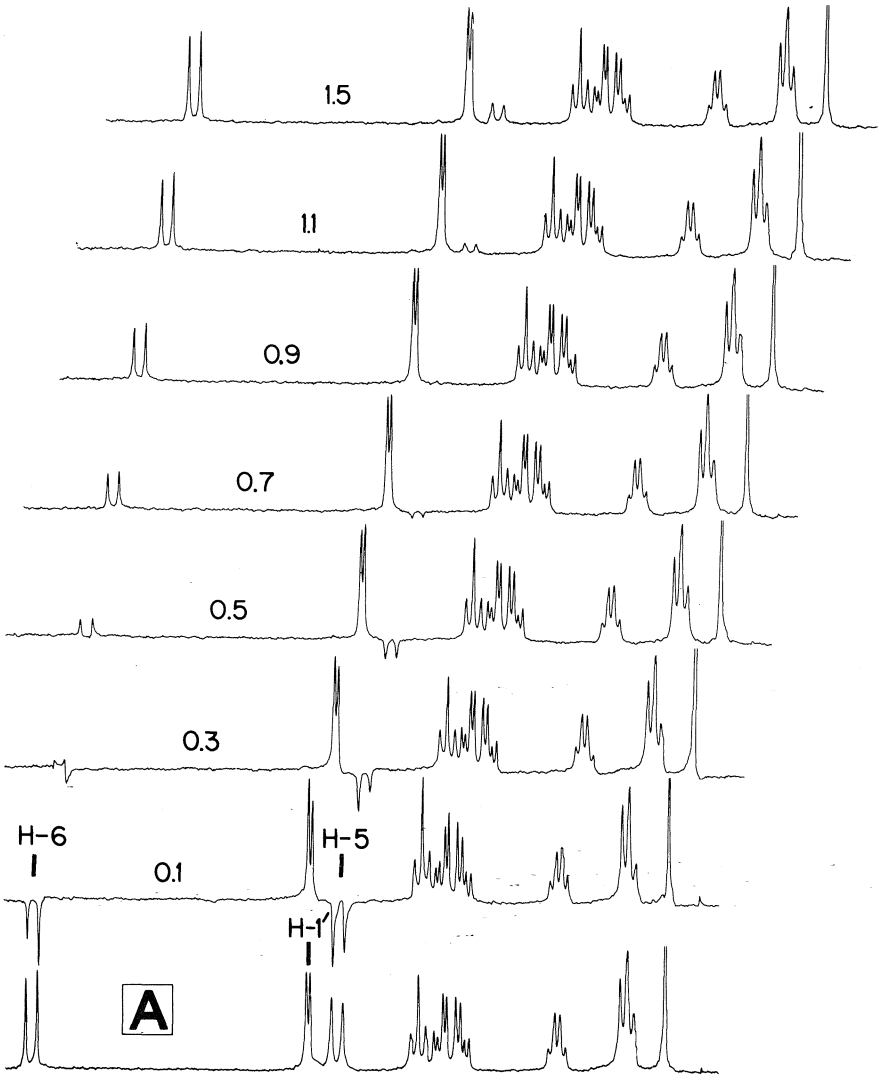

FIG. 6. Spectra showing the determination of the double-selective spin-lattice relaxation rate for the H-6 and H-5 resonances of **1**. The normal spectrum is shown in A (*NT* 5, *PW* 75 s, *AT* 4 s, *SE* 1.5). The remaining spectra show the inversion–recovery sequence following selective inversion of both the H-6 and H-5 resonances with a 180°-pulse (38 ms, 103 dB); these are plotted for delay times for 0.1 to 1.5 s. Note the more rapid relaxation of H-6 and the fact that the H-1′ resonance is not significantly affected by the 180° pulse applied to H-5. Processing these data gave $R_1^6(5,6)$ 1282 ms^{-1} and $R_1^5(5,6)$ 562 ms^{-1}.

after a known delay time (*PD*) is monitored with a non-selective, 90° pulse. The selective measurement merely involves the substitution of a selective 180° pulse from the decoupler for the non-selective pulse from the radiofrequency transmitter. The spectra shown in Fig. 5 illustrate the determination of the selective R_1-value of the H-6 resonance of **1**. The normal spectrum monitored with a non-selective 90° pulse is shown in A, Fig. 5. The partially-relaxed spectra, each accompanied by the appropriate delay time, are displayed in the form of a stack plot even though they were originally stored on a magnetic tape and were separately plotted.

An example of a double-selective, inversion-recovery experiment is given in Fig. 6. In this

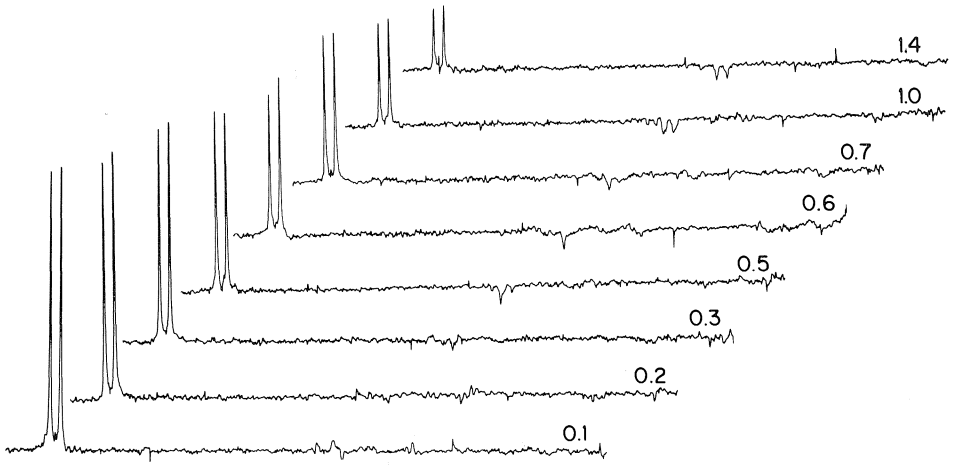

FIG. 7. Illustration of the selective, three-pulse sequences applied to the measurement of the R_1-value of the H-6 resonance of **1**.

case the frequency of the decoupler was set precisely between the H-6 and H-5 resonances and then an audio-modulation frequency, of precisely one half the chemical shift difference between the H-6 and H-5 resonances, was applied to the decoupler. This positioned the first audio-modulation side-bands precisely on the H-6 and H-5 resonances. Simultaneous timing of the audio-modulation pulse derived from both these side bands could be effected by gating either the decoupler or the audio-oscillator, or both. The selectivity of the applied 180° pulse is attested to by the minimal perturbation of the H-1′ resonance by the pulse. And the constancy of the intensity of the other resonances not directly involved in the experiment show that spurious, off-resonance effects are also commendably small.

Clearly there are many alternative procedures for effecting double-, triple-, quadruple-, etc., selective inversion experiments. In this present instance, addition of a second audio-modulation frequency would have produced *four* selective pulses; but these, like those used in the above experiment, would by definition have to have the *same* duration and intensity. For experiments which require several pulses, each of *differing intensity*, an alternate protocol is necessary. Now the decoupler frequency is offset to one side of the entire spectrum and then two, or more, audio-modulation frequencies are applied, each producing a side-band the intensity of which is proportional to the audio-modulation index. With a suitable choice of offset frequency for the decoupler- and audio-frequencies it is generally possible to ensure that only one set of side bands impinges on the entire spectral region. It must be noted, however, that the organization of such experiments is rather more complex than for the experiment summarized in Fig. 6.

It is a trivial matter to extend the above audio-modulation approach to encompass all of the other methods for measuring spin-lattice relaxation times, including the saturation recovery (7) and progressive saturation (8) methods. Although we do not illustrate these experiments here, Fig. 7 shows the efficiency with which a selective, three-pulse inversion-recovery experiment (9) can be performed; that is the sequence $[180°(\text{selective})\text{–}t\text{–}90°\text{–}5T_1\text{–}90°\text{–}5T_1]_n$. Note the efficiency with which this sequence results in the cancellation of the resonance not subjected to the selective, 180° pulse; this point will be discussed again in the next section.

A Pulse Equivalent of the INDOR Experiment

A useful variant on the experiments described in the previous section involves selective irradiation of a single transition of a spin-coupled multiplet. This pulse perturbs the populations of the spin states associated with the irradiated transition and this in turn induces changes in the transition probabilities, and hence transition intensities, of all the spectral components having an energy level in common with those which have been perturbed. This is illustrated diagrammatically for an AX-system in Fig. 8. Application of a 180° pulse to transition A-1 inverts the popula-

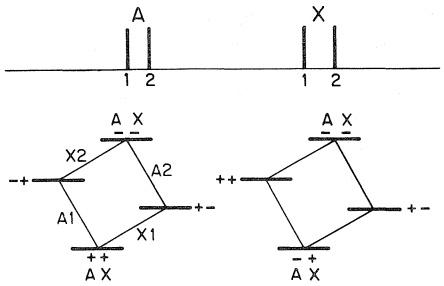

FIG. 8. Diagrammatic representation of the effect of 180° pulse applied to transition A-1 of an AX-spectrum.

tions of the two energy levels and this in turn increases the transition probabilities for X-1 and decreases the probability for X-2. This experiment is formally analogous to the continuous wave INDOR experiment (10) measured under power levels sufficient to cause spin-pumping but too low to cause spin-tickling. Heteronuclear, selective pulse experiments have previously been described by Pachler and Wessels (11) and Jakobsen and co-workers (12) and since we have previously given (1) an extensive discussion of the ^1H–^1H experiment only a brief account will be given here.

The spectra shown in Fig. 9 show the pulse INDOR experiment involving the H-5 and H-6 resonances of **1**. In this case the two transitions of H-5 whose intensities are altered by the perturbation, are both clearly resolved from the rest of the spectrum, and the spectra obtained by using the repetitive pulse sequency given in Fig. 1A can be easily interpreted. However, this direct mode of observation is totally unsuited to the detection of transitions which are obscured by the fortuitous overlap of other nuclear resonances, as is the case in the 'hidden resonance' problem. Now it is necessary to use a differential mode of display which can be obtained by the pulse sequence summarized in Fig. 1B; in essence this display mode subtracts those resonances whose intensities remain unperturbed by the selective pulse, and an example is given in Fig. 9. Note that the subtraction of the normal spectrum is by no means perfect, but there is no ambiguity between the 'residues' and the INDOR-like responses. This pulse experiment has a number of important advantages over c.w. INDOR measurements, not the least being the ease with which the experiments can be effected.

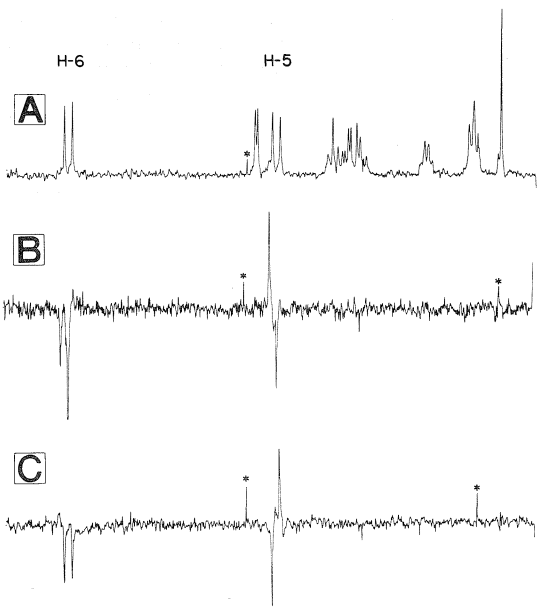

FIG. 9. These spectra illustrate the selective-pulse equivalent of an INDOR experiment, displayed in the difference mode. A shows the normal F.t. spectrum of **1**. B shows the effect of selectively irradiating the low field transition of H-6 with a selective 180° pulse (0.12 s, 93 dB) and monitoring the spectrum in the usual fashion, followed by subtraction of the normal F.t. spectrum measured with the decoupler off. All the resonances unaffected by the selective pulse are removed leaving the H-5 transitions displayed in the familiar, INDOR mode. C shows the effect of a similar experiment involving the high field transition of H-6. The sharp spikes marked * are due to pick up of the line frequency by the spectrometer.

Gated Nuclear Overhauser Experiments

Measurements of nuclear Overhauser enhancements (n.O.e.) factors (13, 14) using a continuous-wave spectrometer are often laborious and time consuming. One of the principal difficulties is that the irradiating field often causes spin decoupling which makes it necessary to measure intensity changes in the integral mode. In an F.t. mode of operation the irradiating field can be gated off during the acquisition of the nmr spectrum, thereby eliminating any spin-decoupling and allowing a direct intercomparison of 'normal' and 'enhanced' spectra by measurement of peak heights (15). The correct choice of pulse-timing is important, for example the acquisition time must be shorter than the relaxation time of the polarized nuclei, but this represents no problem. An example of this class of experiment is given, *inter alia*, in Fig. 10D and

TABLE 1. Nuclear Overhauser enhancement factors (I/I_0 ±5%) for **1**, obtained by gated ^1H–^1H decoupling. A saturation pulse was applied at a chosen frequency for 8 s (110 dB), gated off, and the spectrum sampled with a 90°-monitoring pulse

Nucleus irradiated	Nucleus observed					
	H-1′	H-2′,H-3′,OH′	H-4′	H-5′	H-5	H-6
H-4′	5	5	—	0	0	0
H-5′	0	10	10	—	0	5
H-6	25	5	0	0	45	—

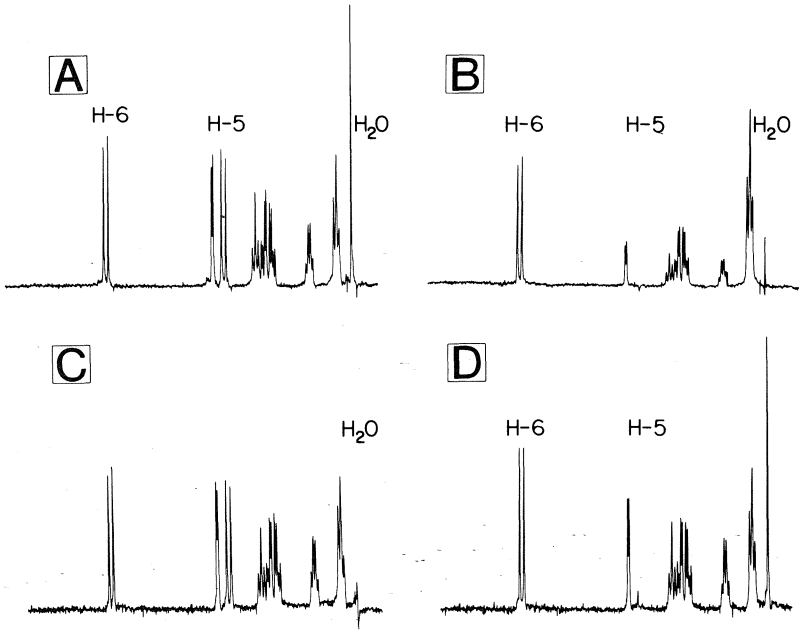

FIG. 10. Illustration of different methods for eliminating the resonance of the water impurity peak from the spectrum of **1** in dimethyl sulphoxide-d_6. The normal F.t. nmr spectrum is shown in A. The spectrum in B was measured using a *non-selective* two-pulse sequence (180°–t–90°) with t = 1.2 s; note that the H-5 resonance, which has approximately the same R_1-value, is also removed and that the relative intensities of the other peaks are perturbed from their normal values. The spectrum in C illustrates the effects of selectively saturating the H_2O resonance with a weak field which was gated off immediately prior to the monitoring pulse. A similar experiment in which the H-5 resonance was irradiated is shown in D; note the enhancement in the intensity of the H-6 resonance due the nuclear Overhauser enhancement.

the data obtained from a series of such experiments is summarized in Table 1.

Selected Removal of Unwanted Resonances

Although measurements of relaxation times are undoubtedly the most important applications of the manipulation of magnetization, the selective removal of unwanted resonances is also particularly useful. Two approaches have been used previously. The first depends on the fact that after application of a 180° pulse, the magnetization of a nucleus must pass through zero intensity; the rate at which different resonances reach their nul point depends on their spin-lattice relaxation times. Patt and Sykes (16) and Feeney and co-workers (17) demonstrated that this approach could be used to eliminate water resonances and Hall and co-workers (18) subsequently showed that overlapping resonances from the *same* molecule could be separately distinguished in the same way.

Powerful as it is, this approach has some important limitations. Principally the relative

intensities of the resonances which are detected depend on the relative values of their spin-lattice relaxation times, which makes interpretation of the spectra rather difficult: this is illustrated in Fig. 10B.

An alternative approach simply requires that the single resonance to be removed be saturated with a suitably powerful radiofrequency field. The principal difficulty here is that this technique indiscriminately eliminates all resonances from the region being irradiated and hence has none of the differential capability of the partial relaxation method. Nevertheless it is effective, as is illustrated in Figs. 10C and 10D. The latter show that the approach can result in a build up of a nuclear Overhauser enhancement of intensity in some instances; fortunately it is a trivial matter to suppress this by only gating the decoupler on during the acquisition time and by allowing a sufficiently long delay between successive pulses for complete relaxation to occur.

Fortunately a selective inversion-recovery experiment combines the best of both the above experiments. A 180° pulse is applied selectively to a particular spectral region and, after a suitable delay time, the spectrum is monitored with a non-selective 90° pulse. The spectra shown in Fig. 11 illustrate that this approach can lead to particularly efficient removal of resonances, and with an absolutely minimal perturbation of nearby resonances; all that is required is sufficient patience in selection of the *PD* value!

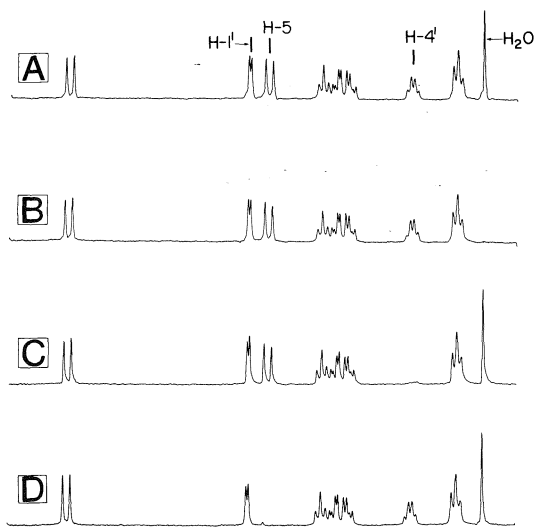

FIG. 11. Illustration of the use of the selective, inversion-recovery method for eliminating specific resonances: all spectra were monitored with a non-selective 90° pulse applied at a suitable time after application of a selective 180° pulse to the appropriate resonance. A, shows part of the F.t. nmr spectrum of **1**. In spectrum B the selective 180° pulse was applied to the H_2O resonance followed, 0.82 s later, by the 90°-pulse. In C, the H-4′ resonance was selectively inverted and the delay time was 0.90 s. In D, the H-5 resonance was irradiated and the delay time was 1.5 s; note that the off-resonance effect on the H-1′ resonance is rather small.

Conclusions

In the above discussion we have illustrated several types of proton nmr experiments in which the spectral responses of principal interest are associated with the prior perturbation of certain spectral transitions by a highly selective 180° pulse. These experiments can all be routinely performed and appear to have appreciable potential in chemical studies.

Several instrumental developments suggest that interest in the experiments described here is likely to increase in the future. Notable amongst these is the development of the elegant 'tailored excitation' method of Tomlinson and Hill (4), which provides a general method for applying perturbing pulses to many regions of an nmr spectrum with unprecedented ease. At a more prosaic level, the development of nmr instruments which only operate in the pulse F.t. mode seems likely to become a dominant one for many reasons and, if this be so, then the further development of pulse equivalents for other c.w. experiments will be imperative.

We have previously illustrated (19) the use of tailored excitation for selective relaxation and nuclear Overhauser enhancement measurements.

Experimental Section

All nmr measurements were made using a Varian Associated XL-100 (15) spectrometer fitted with a Varian 620L(16K) computer and Linc Tape Unit (model C0600).

An otherwise standard Varian programme (994100-D X-2) was modified so that the Gyrocode spin decoupler could be gated to provide the weak pulse required for selective manipulation. Several different modifications have now been used; full details will be given elsewhere.[6] Most of the single-selective experiments described here can be performed with the Varian Gyrocode decoupler working in the gated mode, using the gate provided by Varian. In like fashion double-selective experiments can be performed simply by connecting an audio-oscillator to the external modulation jack on the rear panel of the Gyrocode decoupler.

Velocity separation of isotopic mixtures in underexpanded supersonic beams

A. E. REDPATH AND M. MENZINGER

Department of Chemistry, University of Toronto, Toronto, Ont., Canada M5S 1A1

Received October 4, 1976

A. E. REDPATH and M. MENZINGER. Can. J. Chem. **55**, 1055 (1977).

The velocity distributions of the heavy components in $CD_4/CH_4/He(H_2)$ supersonic beams were measured by time-of-flight and the slippage with respect to the seeding gas was investigated as a function of nozzle pressure and temperature. The isotopic species attain different velocity distributions. Following a proposal by Anderson and Davidovits, isotope separation factors are calculated both for the present system and, by analogy, for $^{235}UF_6/^{238}UF_6/Ar(He,Xe)$.

A. E. REDPATH et M. MENZINGER. Can. J. Chem. **55**, 1055 (1977).

Utilisant le temps de vol, on a mesuré les distributions de vitesse des composants lourds dans les rayons supersoniques de $CD_4/CH_4/He(H_2)$; de plus on a étudié le décalage par rapport aux gaz d'ensemencement en fonction de la pression du jet et de la température. Les diverses espèces isotopiques atteignent une distribution différente de vitesses. En accord avec une proposition de Anderson et Davidovits on a pu calculé des facteurs de séparation isotopique à la fois pour le système actuel et, par analogie, pour $^{235}UF_6/^{238}UF_6/Ar(He,Xe)$.

[Traduit par le journal]

I. Introduction

Partial separation of isotopic mixtures can be achieved by utilizing a number of interrelated gas dynamic phenomena accompanying the free expansion of gas mixtures. The well known spatial enrichment of the heavier components in the beam core, through the more rapid pressure diffusion of the light components out of the beam, forms the basis of the supersonic jet (1, 2) and curved jet (3) methods developed by Becker and co-workers. Apart from this spatial separation, Anderson and Davidovits (4) (AD) have recently pointed out that isotopic components of a seeded beam can be differentially accelerated and attain different final velocities. This separation in velocity space can be utilized for a physical separation via velocity selection which could, according to AD, exceed the spatial effect. Literature data on velocity distributions of a single heavy component in seeded beams, in particular H_2 seeded Xe beams (5), were used (4) together with estimates of the *expected* mass dependent differential acceleration to predict the magnitude of the $^{238}UF_6/^{235}UF_6$ separation factors. The separation of isotopes in velocity space has *de facto* not been proven.

To provide an experimental test of this effect we chose He (and H_2) seeded CH_4/CD_4 mixtures as prototype systems. The velocity distribution of both isotopic components were measured by time-of-flight (TOF) for a range of experimental conditions (*i.e.* mass of the seeding gas, seeding ratio X, nozzle pressure, nozzle temperature). The goal of this work was (*1*) to present data on the properties of underexpanded seeded molecular beams, (*2*) to test Anderson and Davidovits' model for isotope separation, and (*3*) to arrive at new predictions of the separation effects in systems of technical interest.

The velocity separation factor α' (defined in eq. 7) computed from the measured CH_4/CD_4 velocity distributions attains a peak value of 1.4, demonstrating the feasibility of AD's separation scheme.

To obtain projections for the technically interesting $^{235}UF_6/^{238}UF_6$ system, *ad hoc* assumptions were made about the direct transferability of measured velocity distributions to systems of greatly disparate mass. The separation factors estimated thus fall somewhat short of AD's predictions, but they still exceed those of current gas dynamical (2, 3) and gaseous diffusion processes. While the CH_4/CD_4 measurements clearly demonstrate the feasibility of the proposed separation scheme, the assumptions in connection with UF_6 could be questioned, and it is conceivable that the extrapolation to UF_6 employed here actually underestimates the experimentally achievable separation. Detailed gas dynamic calculations (14) support this possibility. Mea-

surements on the real system (or, at least, on model systems SF_6, MoF_6, WF_6/He, Ar) will have to decide this point.

II. Experimental

A supersonic beam (from a He(H_2) seeded CH_4/CD_4 (50:50) mixture) is formed from a 0.01 cm diameter stainless steel converging nozzle and a 0.05 cm diameter conical skimmer, with the nozzle–skimmer separation held fixed at 1.0 cm. The nozzle can be resistively heated and its temperature is measured on a chromel–alumel thermocouple. A high speed chopper (250 Hz, opening time 16 μs every 2 ms, 5 cm downstream from the skimmer) pulses the beam which is ionized after a drift space of 37.2 cm and mass analyzed in a small magnetic 90° sector instrument. Detection is by an electron multiplier (EMI 9643/3B) followed by a high speed amplifier and the repetitive signal is averaged on a PAR TDH-9 wave form eductor. Important dimensions and experimental conditions are given (16) in Table 1.

The time calibration of the TOF measurement was checked with pure supersonic Ar and He beams of known bulk flow velocity. Time-of-flight spectra were recorded for two different mixtures of CH_4:CD_4:He (2:2:96 and 5:5:90) over a range of nozzle pressure (20–400 torr) for two different nozzle temperatures (281 K and 573 K). Some experiments were also performed using H_2 as the seeding gas. In addition, pure He, pure H_2, and pure CH_4 were run under the same conditions. Only 50:50 mixtures of the isotopic components were employed since at the low seeding ratios used here interaction of the heavy components is expected to be small. Measurements were made on both p (parent mass) and p − 1 mass peaks for CH_4 (p and p − 2 for CD_4) and no differences in the TOF spectra were observed.

Typical TOF spectra for the CH_4 and CD_4 components of the seeded beam are shown in Fig. 1*a*. They are characterized by two parameters: t_{max}, the position of the maximum, and $\Delta t_{1/2}$, the full width at half maximum. Rather than inverting the TOF spectra directly (6) and neglecting the apparatus resolution function,[1] the finite resolution was accounted for by the following empirical technique: The (number density) velocity distribution function appropriate to a supersonic beam is traditionally described by (6)

$$[1] \qquad f(v)\,dv = C(v/v_s)^2 \exp -[(v - v_s)S/v_s]^2\,dv$$

in terms of the streaming (= bulk flow) velocity v_s and the speed ratio S which measures the width of the distribution. S is defined as the ratio of bulk flow to the most probable velocity by

$$[2] \qquad S = v_s/(2kT_s/m)^{1/2}$$

where T_s is the (parallel) streaming temperature appropriate to the width of the distribution A number of assumed velocity distributions $f(v; v_s, S)$ were convoluted with the appropriate TOF resolution function[1] and the results were inverted to simulate TOF spectra. Two calibration plots were obtained, one relating the observed

[1]The resolution function accounts for finite chopper opening time, ionizer length, mass spectrometer transit time, and response time of the electronics.

TABLE 1. Apparatus dimensions and operating conditions

Chamber	Parameter	Value
Nozzle	Diameter	0.01 cm
Skimmer	Diameter	0.05 cm
	Inner angle	35°
	Outer angle	40°
	Height	0.3 cm
	Nozzle–skimmer separation	1.0 cm
	TOF flight path	37.2 cm

Chamber	Pump	Typical operating pressures (torr)
Nozzle	VHS-6 (Varian) (unbaffled) 2300 1/s	5×10^{-4}
Main	VHS-6 (Varian) (baffled) 1000 1/s	2×10^{-6}
Mass Spec.	EO-2 (Edwards)	1×10^{-6}

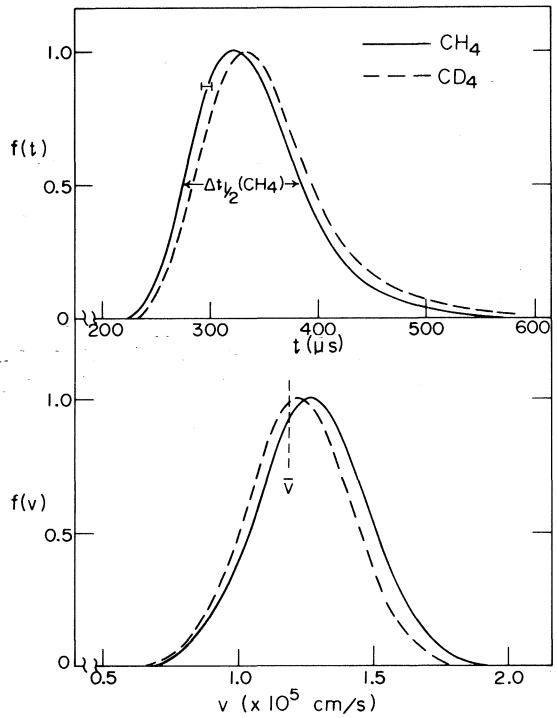

FIG. 1 (*a*) TOF spectra for both isotopic components of a CH_4/CD_4/He (2:2:96) mixture. Source pressure was 60 torr, source temperature 281 K. Signals were normalized at t_{max}. The FWHM, $\Delta t_{1/2}$ is indicated. The experimental uncertainty (one standard deviation) of flight time is typically ±4.5 μs for this data set and it decreases to ±2 μs at higher nozzle pressures ($p_0 > 150$ torr). (*b*) Velocity distributions of CH_4, CD_4 derived from Fig. 1*a* (eq. 1). $\bar{v}$, the separation velocity used is taken as the arithmetic mean of the v_s values. Full curve: CH_4 ($S = 4.21$, $v_s = 1.21 \times 10^5$ cm/s); dashed curve: CD_4 ($S = 4.23$, $v_s = 1.17 \times 10^5$ cm/s).

($t_{max}/\Delta t_{1/2}$) to S, and the other relating t_{max} to v_s for a given S. Given experimental t_{max}, $\Delta t_{1/2}$ values, S and v_s could be directly read off. Typical velocity distributions, derived from the spectra, Fig. 1*a*, are drawn in Fig. 1*b*.

III. Velocity Distributions

The properties of supersonic molecular beams depend markedly upon the source conditions, in particular upon the source number density, the nozzle diameter d, source temperature T_0, and on the skimmer geometry, and pressure in the nozzle and main chambers. The source Knudsen number, $Kn = \lambda/d$, the ratio of mean free path λ to nozzle diameter d, is a convenient characteristic parameter of the nozzle conditions. This representation has the advantage of compacting the experimental variables of P_0, T_0, and d onto one scale. Anderson and Fenn (6) have shown that for pure beams the terminal speed ratio is a linear function of $Kn^{-0.4}$:

$$[3] \qquad S = 2.05(\gamma/2)^{1/2}\varepsilon^{0.4}Kn^{-0.4}$$

where $\varepsilon \leq 1$ is a measure of the 'collision effectiveness' or average logarithmic energy loss per collision (7), that is assumed to be energy independent for a given gas.

The streaming velocity[2] v_S also depends upon the Knudsen number in the following fashion: For high values of the inverse source Knudsen number ($P_0 \sim Kn^{-1} \geq 1000$) the beam expansion is practically complete and both light and heavy components achieve the same isoentropic streaming velocity given by:

$$[4] \qquad v_{iso} = (2\bar{c}_p T_0/\overline{m})^{1/2}$$

where $\bar{c}_p$ and $\overline{m}$ are the mole fraction weighted average heat capacity and mass and T_0 is the source temperature. As the source pressure ($\sim Kn^{-1}$) decreases, fewer collisions take place during the expansion and velocity equilibration is no longer attained: the heavy component lags behind the light seeding gas. This velocity slip phenomenon, expressed in terms of the ratio of streaming velocity to maximum (ideal) isoentropic velocity, v_S/v_{iso}, is conveniently correlated with the mass-weighted slip Knudsen number (8), defined by

$$[5] \qquad Kn_{slip}^{-1} = \sqrt{2}\, n_0 \sigma_{HL} d \left(\frac{\overline{m}}{m_H - m_L}\right) = Kn^{-1}\left(\frac{\overline{m}}{m_H - m_L}\right)$$

Here σ_{HL} is the effective cross section (9) for collisions between heavy and light beam molecules, n_0 the source number density, and $\overline{m}$ the mole fraction weighted mass of the mixture with masses m_H (heavy) and m_L (light = seeding gas).

Under the same source conditions, two heavy isotopic components with masses m_{H1} and m_{H2} have different Kn_{slip}^{-1} due to the mass factor $[\overline{m}/(m_{Hi} - m_L)]$. In the slippage-dominated low P_0 regime the v_S/v_{iso} ratio is a sensitive function of Kn_{slip}^{-1} and two isotopic components reach different streaming velocities v_{S1} and v_{S2}.

According to eqs. 3, 4, and 5, S and (v_S/v_{iso}) were plotted as functions of $Kn^{-0.4}$ and $Kn_{slip}^{-0.4}$ respectively as shown in Figs. 2 and 3. Included in these graphs are data from the literature as explained in the captions.

The speed ratio *vs.* $Kn^{-0.4}$ plot (Fig. 2) shows that for $Kn^{-0.4} \leq 17$ the linear relationship (4) is indeed valid, but the slopes of the various data sets differ appreciably. The question arises to what extent these differences are characteristic of the systems studied (*e.g.*, He; CH_4/CD_4/He; H_2; Xe/H_2) and to what extent they arise from the experimental conditions (*i.e.* the different beam machines having different nozzle–skimmer assemblies, pump speeds, etc.). While Haberland's data (5) (Fig. 2) demonstrate a pronounced dependence on nozzle temperature, the different qualities of supersonic beams achieved in different laboratories (5, 8, 10–12) show that experimental design plays an important role, and that the data sets from different laboratories are not directly comparable. For instance, speed ratios in the range of $S > 50$ have recently been obtained for H_2 and He beams (10, 11).

Velocity distributions of the light components were also measured and were found to agree closely with those of pure beams of seeding gas and it was confirmed (12, 13) that the heavy component was characterized by substantially higher T_S than the seeding gas.

The data of Fig. 3 illustrate the increasing slippage (or decreasing v_S/v_{iso}) with falling source pressure ($P_0^{0.4} \sim Kn_{slip}^{-0.4}$). The lowest velocities measured are only ~40% of the ideal isoentropic expansion value. Figure 4 shows the relative

[2]The velocity v_{max} of the maximum in the distribution, is somewhat greater than v_S:

$$2v_{max} = v_S(1 + \sqrt{1 + 4/S^2})$$

However, for $S > 4$ the difference between the two is <6% and one can use v_S to approximate v_{max}.

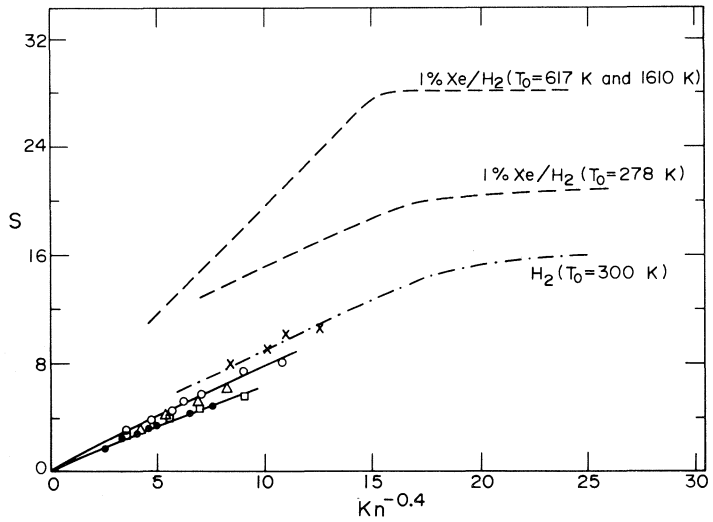

FIG. 2. Speed ratios *vs.* $Kn^{-0.4}$ for pure H_2, He, CH_4 beams and for CH_4/CD_4 and CH_4/CD_4/He mixtures. Also shown are the results for pure H_2 beams (17) and for Xe in Xe/H_2 beams (5). The values plotted for the CH_4/CD_4/He mixtures are the average values of the two components. For (2:2:96) mixtures, S is *ca.* 5% higher than for (5:5:90) mixtures, and CH_4 speed ratios exceed those for CD_4 by a few %. The estimated error of S is 6%. Symbols: × H_2; △ pure He; □ pure CH_4; ○ CH_4/CD_4 in (CH_4/CD_4/He) mixtures, all at T_0 = 281 K. ● CH_4/CD_4 in (CH_4/CD_4/He) mixtures at T_0 = 573 K.

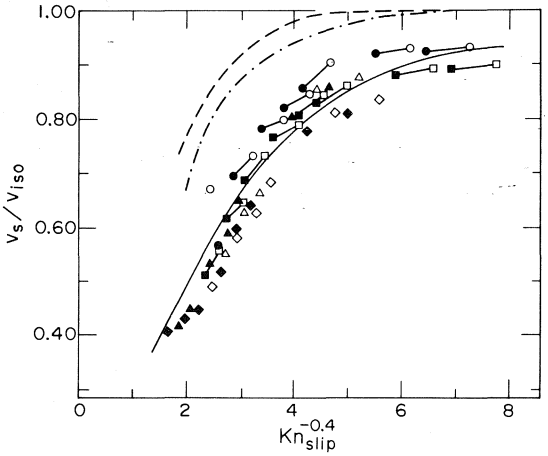

FIG. 3. (v_s/v_{iso}) *vs.* $Kn_{slip}^{-0.4}$ for CH_4/CD_4/He mixtures. Also shown are data from refs. 5 (dashed curve Xe/H_2 beams) and 8,12 (dash–dot curve, several He-seeded gases). The tie lines connect (v_s/v_{iso}) values for the two isotopic components of a given mixture at identical source conditions (shown for T_0 = 281 K only for clarity). The full line represents the fit to eq. 6. Symbols: (CH_4/CD_4/He = 2:2:96; CH_4 data): ○ T_0 = 281 K, △ T_0 = 573 K; (CH_4/CD_4/He = 2:2:96, CD_4 data): ● T_0 = 281 K, ▲ T_0 = 573 K; (CH_4/CD_4/He = 5:5:90; □ T_0 = 281 K, ◇ T_0 = 573 K); (CH_4/CD_4/He = 5:5:90; □ T_0 = 291 K, ◆ T_0 = 573 K).

difference in velocities of the two isotopic heavy components $\Delta v_s/\bar{v}$ plotted as a function of $Kn_{slip}^{-0.4}$. This method of plotting collapses data for different source conditions (T_0, P_0, seeding ratio, etc.) into one band of points. The solid curves represent a visual 'best' fit to the data of Fig. 3 of the form:

$$[6] \qquad (v/v_{iso}) = a[1 - \exp(-bx^c)]$$

with $a = 0.93$, $b = 0.3$, $c = 1.3$, and $x = Kn_{slip}^{-0.4}$. This fit optimally reproduces both the (v/v_{iso}) and ($\Delta v/v$) data of Figs. 3 and 4, the latter essentially being a measure of the slope of Fig. 3.

Systematic deviations from this average curve show, however, that this data compaction is only approximate: the tie lines in Fig. 3 join data points for the CH_4 and CD_4 components of a given mixture, run under a particular set of source conditions. For pairs of data points the difference in velocity of the two components ($\Delta v/v_{iso} = v_{S1}/v_{iso} - v_{S2}/v_{iso}$) is generally slightly smaller than that represented by the solid curve. It is possible that the assumption of independent expansions of the two heavy components at these low seeding ratios is not completely valid and/or

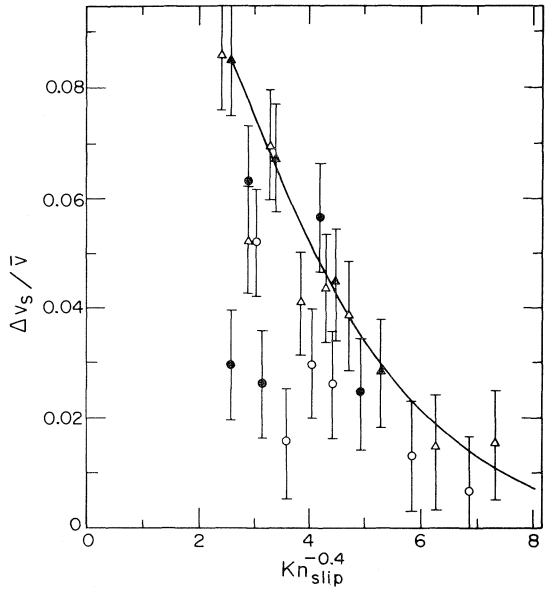

FIG. 4. Relative slippage $\Delta v_s/\bar{v}$ of the isotopic components in CH_4/CD_4/He mixtures (2:2:96 and 5:5:90). Δv_s is the difference in streaming velocities and $\bar{v}$ is their arithmetic mean. The solid curve corresponds to eq. 6. Symbols same as Fig. 3.

that collisions with background gas also diminishes the separation effect.[3] The shift of our results to lower (v/v_{iso}) values compared to literature curves (Xe/H_2 and H_2) demonstrates again the influence of the beam machine.

IV. Isotope Separation Factors

The results of the preceding section are used to calculate the efficiency of the isotope separation effect possible by velocity selection. This efficiency is normally given by the separation factor, α', defined in our case as (1, 3, 4):

$$[7] \qquad \alpha' = \frac{n_{1L}}{n_{1R}} \cdot \frac{n_{2R}}{n_{2L}}$$

where n_{1L} is the number of molecules of mass m_1 having velocities below (*i.e.* to the left of) the separating velocity $\bar{v}$ in Fig. 1*b*,[2] etc. For our calculations $\bar{v}$ was taken as the arithmetic mean of v_{S1} and v_{S2}. A different choice of $\bar{v}$ would, of course, result in a different value for α'. It has been pointed out (15) that for Maxwellian distributions α' can be made very large if the separating velocity is in the region of the high velocity tails, at the expense of a drastically reduced mass throughput. Our choice of $\bar{v}$ would allow close to maximum collection efficiency at the expense of a lower α'.

Anderson and Davidovits give the approximate analytic expression for α' for beams with high speed ratios where $f(v)$ can be approximated by a Gaussian. Their simple formula:

$$[8] \qquad \alpha' \simeq 1 + 4\pi^{-1/2} S \Delta v_S / v$$

shows more clearly than the following analytical expressions the basic dependence on the variables S and $\Delta v_S/\bar{v}$ of the separation effect: α' is a (linear) function of both speed ratio and the relative velocity difference. For the low speed ratios at which $S\Delta v_S/\bar{v}$ is maximized the expansion [8], that has been truncated after the linear term, is no longer valid: instead an exact calculation of n_{1L} etc. yields:

$$[9a] \quad n_{1L} = \int_0^{\bar{v}} n_1 f(v)\, dv = \int_0^{\bar{v}} n_1 N (v/v_{S1})^2 \times \exp -S_1^2 (v/v_{S1} - 1)^2\, dv$$

$$[9b] \quad n_{1R} = \int_{\bar{v}}^{\infty} n_1 N (v/v_{S1})^2 \times \exp -S_1^2 (v/v_{S1} - 1)^2\, dv$$

etc. Evaluation of the integrals leads to:

$$[10a] \quad n_{1L} = n_1 N [(1/2S_1) \exp(-S_1^2) - (a_1/2S_1^2 + 1/S_1) \exp(-a_1^2) + (3\sqrt{\pi}/4)(\operatorname{erf} a_1 + \operatorname{erf} S_1)]$$

$$[10b] \quad n_{1R} = 1 - n_{1L}$$

with

$$a_1 = (\Delta v / v_{S1})(S_1/2)$$

$$N = [(1/2S_1) \exp(-S_1^2) + (3\sqrt{\pi}/4)(1 + \operatorname{erf} S_1)]^{-1}$$

(v_{S1} and S_1 referring to the CH_4 component).

For a given mixture of CH_4:CD_4:He, $Kn_{slip}^{-0.4}$ values for the two heavy components are calculated, and S and v_S values are then derived from Figs. 3 and 4. Equations 10*a*, 10*b*, and 7 are then used to calculate α'. The results are presented in Fig. 5 as $(\alpha' - 1)$ *vs.* $Kn_{slip}^{-0.4}$. With decreasing $Kn_{slip}^{-0.4}$ the curve goes through a maximum at $Kn_{slip}^{-0.4} \sim 3.25$ and appears to drop off for lower $Kn_{slip}^{-0.4}$ values. The actual behaviour of

[3]P. Davidovits, private communication.

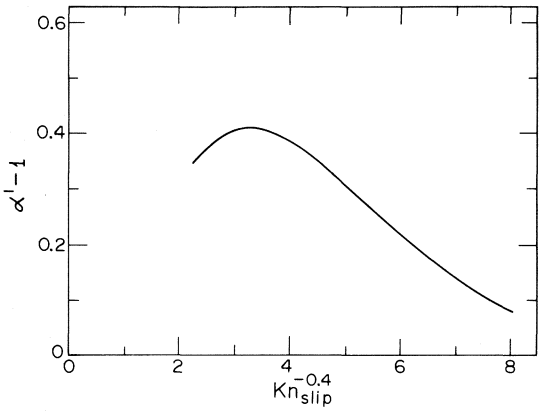

FIG. 5. Separation factor ($\alpha' - 1$) *vs.* $Kn_{slip}^{-0.4}$ calculated for CH_4/CD_4/He mixtures. For classical effusive CH_4/CD_4 beams,[4] $\alpha' - 1 = 0.6$, while for effusive 'garden hose' separation (15) $\alpha' - 1 = 0.46$.

($\alpha' - 1$) in the region of low $Kn_{slip}^{-0.5}$ is, however, uncertain. The isentropic beam expansion model fails in this region where the flow becomes effusive. A gas dynamic calculation by Anderson[4] of $\alpha' = 1.29$ at $Kn^{-0.4} = 5.04$ agrees well with our measurements and lends support to the calculations (14)[4] on heavier systems. The separation factor for classical effusive beams[4] and for 'garden hose' effusive beams (15) are ($\alpha'_{effusive} - 1$) = 0.6 and 0.46 respectively, if one assumes $\bar{v}$ equal to the average of the most probable velocities. The nozzle beam results ought to extrapolate to this value; how they do is not certain. It would appear that effusive beams provide as good, if not better, velocity separation than seeded supersonic beams. Although this is the case for the mass combinations of our system it is not clear at present whether this can be generalized to $^{235}UF_6/^{238}UF_6$.

V. Discussion

Applying the present results and those from the literature (5, 8) to systems of such substantially different mass and molecular structure as UF_6/He calls for a number of assumptions: (*1*) The slippage v/v_{iso} and $\Delta v/\bar{v}$, under identical experimental conditions and $Kn_{slip}^{-0.4}$, is taken to be the same for $^{235}UF_6/^{238}UF_6$ mixtures seeded by He, Ar, Xe as for He-seeded CH_4/CD_4. While the approximate agreement of slippage data for different beam gases (dash–dotted curve of Figs. 3 and 9 of ref. 8) supports this view, a closer examination of Fig. 9 exposes, not unexpectedly, an increased slippage for heavier beams. (*2*) Speed ratio for UF_6 in He were assumed to be given by the CH_4/CD_4/He measurements (Fig. 4), while for Ar- and Xe-seeded SF_6 speed ratios for pure Ar beams (8, 12) were substituted since He beams are known (12, 16) to yield, under comparable source conditions, lower speed ratios than pure H_2 or Ar beams.

Separation factors ($\alpha' - 1$) were calculated from eqs. 7, 10 for He-, Ar-, Xe-seeded (99:1) UF_6 mixtures as a function of Kn_{slip}^{-1} and results are presented in Fig. 6. The predicted maxima ($\alpha' - 1$) lie below the value ($\alpha'_{effusive} - 1$) = 0.018 for 'classical' effusive beams[4] and, with the exception of Xe-seeding also below ($\alpha'_{garden\ hose} - 1$) = 0.015 for 'garden hose' effusive beams (15). Our calculation predicts that α_{max}' increases with the mass of seeding gas, although the position of the maximum does not change. This is a direct consequence of assumption (*1*) that the slippage data (eq. 6) are independent of seeding gas: anything that increases the difference in $Kn_{slip}^{-0.4}$ values will increase α_{max}'. The $Kn_{slip}^{-0.4}$ values for the isotopic components are related by

$$Kn_{slip}^{-0.4}(^{235}UF_6) = Kn_{slip}^{-0.4}(^{238}UF_6)\left(\frac{m_{^{238}UF_6} - m_X}{m_{^{236}UF_6} - m_X}\right)$$

where m_X is the mass of the seeding gas. The bracketted term increases with m_X, predicting enhanced $\Delta Kn_{slip}^{-0.4}$ and α'. This approach leads

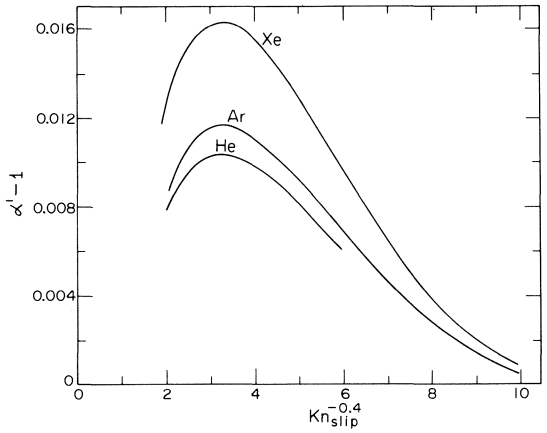

FIG. 6. Separation factor ($\alpha' - 1$) *vs.* $Kn_{slip}^{-0.4}$ predicted for $^{235}UF_6/^{238}UF_6$/X mixtures, where X = He, Ar, Xe, as described in the text. Gas dynamic calculations (14) predict an inverse effect: a decrease of α' with increasing m_X. For classical effusive $^{235}UF_6/^{238}UF_6$ beams[4] $\alpha' - 1 = 0.018$, while 'garden hose separation' (15) yields $\alpha' - 1 = 0.0146$.

[4]J. B. Anderson, private communication.

however to the wrong asymptotic limit $m_X \rightarrow m_{UF_6}$, a fact that strongly suggests an experimental test of assumption (*1*). Gas dynamic calculations (14)[4] indicate a reverse trend, while experiments using $CH_4/CD_4/H_2$ mixtures show indeed a lower α_{max}' for H_2 than for He.

The present calculation predicts α_{max}' values substantially lower than those of AD's original proposal (4) ($\alpha_{max}' = 0.01 - 0.016$ *vs.* 0.1). The major source of this discrepancy lies in the different speed ratios used; ours are *ca.* six times lower than the value $S \sim 24$ taken (4) by AD from the data (5) on Xe/H_2 mixtures. The critical, and most controversial, assumption of our analysis is thus number *2*.

For an estimate of the full potential of the beam separation, the spatial separation factor is estimated from Becker's values (1) extrapolated for pure $^{235}UF_6/^{238}UF_6$ mixtures, α (space) $\sim$ 1.008. An improvement of (α(space) $-$ 1) by 1.7 is predicted (*2b*) for seeding with a gas of a mass 1/10 of the beam gas (*e.g.*, Ar or N_2) .With this the overall separation factor for $^{235}UF_6/^{238}UF_6$/Ar mixtures is predicted to be α(total) = α(space) $\times$ α'(velocity) = 1.025. This value still lies below AD's original prediction (4) of 1.1 and below their more recent values $\alpha' = 1.05 - 1.09$ obtained from detailed gas dynamical calculations (14). However, it exceeds the separation factors of currently attainable gas dynamic and gaseous diffusion methods. Only experiments on UF_6 or on closely related model systems (SF_6, MoF_6, WF_6.../He, Ar...), employing a velocity selector similar to the one proposed (4, 14) (*i.e.* of the slotted disk type) will give an unambiguous assessment of the complicated and interrelated gas dynamic effects involved in the separation of isotopic mixtures.

Acknowledgments

It is a pleasure to acknowledge valuable discussions with Professors J. B. Anderson and R. Davidovits and to thank them for making their manuscript (14) and the calculations[4] available to us prior to publication. This work is supported by the National Research Council of Canada.

The viscosity of concentrated electrolyte solutions. I. Concentration dependence at fixed temperature

DOUGLAS E. GOLDSACK AND RAYMOND FRANCHETTO

Department of Chemistry, Laurentian University, Sudbury, Ont., Canada P3E 2C6

Received October 5, 1976

DOUGLAS E. GOLDSACK and RAYMOND FRANCHETTO. Can. J. Chem. **55**, 1062 (1977).

The absolute rate theory of viscosity for simple fluids has been extended to account for the concentration dependence of the viscosity of concentrated single electrolyte solutions (1–10 *m* region). Graphical and computer techniques for obtaining the two parameters (volume and free energy of activation) which control the concentration dependence of the viscosity of single salt solutions at fixed temperatures are described. The additivity of these parameters for single ions are discussed with reference to the alkali and ammonium halides at 25 °C and the *B* coefficients of the Jones–Dole equation.

DOUGLAS E. GOLDSACK et RAYMOND FRANCHETTO. Can. J. Chem. **55**, 1062 (1977).

Afin de rendre compte de la dépendance qui existe entre la concentration et la viscosité de solutions concentrées (région de 1–10 *m*) d'électrolytes simples, on a étendu la théorie des vitesses absolues de la viscosité à des fluides simples. On décrit des techniques graphiques et par ordinateur qui permettent d'obtenir les deux paramètres (volume et énergie libre d'activation) qui contrôlent la dépendance existant, à température fixe, entre la concentration et la viscosité de solution de sels simples. On discute de l'additivité de ces paramètres pour des ions uniques par référence aux halogénures alcalins et d'ammonium à 25 °C et aux coefficients *B* de l'équation de Jones–Dole.

[Traduit par le journal]

Introduction

Phenomenological Description of the Viscosity of Aqueous Electrolyte Solutions

The viscosity of aqueous electrolyte solutions has been studied in detail continuously since Arrhenius began his investigations of the properties of electrolyte solutions in the 1880's. Three major reviews of the subject have been written (1–3). Aside from the many empirical relations which have been explored for single and mixed electrolyte solutions, the major theoretical thrust for understanding the viscosity of electrolyte solutions has been in the dilute solution region (less than 0.1 *M*).

Einstein (1), in 1906, deduced from the classical principles of hydrodynamics that if the solute were composed of spherical incompressible uncharged particles which were large in comparison to the water molecules, then the viscosity of the solution could be expressed as

$$[1] \qquad \eta = \eta_1(1 + 2.5\theta)$$

where θ denotes the volume fraction of the solute particles, η_1 is the viscosity of the pure solvent, and η is the viscosity of the solution. This equation proved valid only at low concentrations.

Later, Falkenhagen and Dole (1) attacked the problem of the viscosity of electrolyte solutions in terms of the interionic forces in the adjacent layers of an electrolyte solution. They proposed that the electrical forces between ions in the solution tend to establish and maintain a preferred rearrangement and thus to "stiffen" the solution, *i.e.* to increase its viscosity. The mathematical treatment of this effect resulted in the following limiting law for very low concentrations of electrolytes (<0.01 *M*).

$$[2] \qquad \frac{\eta}{\eta_1} = \eta_{rel} = 1 + A\sqrt{c}$$

where the always positive constant A is a function of solvent properties, ionic charges, mobilities and temperature (1). Numerically, A is fairly small (0.005 for KI, 0.0167 for Li_2SO_4 at 25 °C).

Practically, the Falkenhagen equation was of little use in calculating viscosities since the square root term is swamped by a much larger linear term expressed in the empirical equation of Jones and Dole (1)

$$[3] \qquad \eta_{rel} = 1 + A\sqrt{c} + Bc$$

where A is again Falkenhagen's theoretical coefficient while the empirical parameter B

supposedly represents ion–solvent interaction. The B coefficient is found to be greater or less than zero depending on the salt and to be highly specific for both the electrolyte and temperature (*e.g.*, -0.014 for KCl and $+0.567$ for $LaCl_3$ at 25 °C) (1). The B coefficients are fairly accurately additive properties of the constituent ions based on the assumed equal values of -0.007 for K^+ and Cl^- at 25 °C. Negative values for B are found for ions which exert a 'structure-breaking' effect on the solution (*i.e.* they contribute to a considerable increase in the disorder of water when dissolved) such as Rb^+, Cs^+, I^-, ClO_3^-, and NO_3^-. Usually, however, the B values are fairly large and positive and correspond to ions which are strongly hydrated (structure makers) such as Na^+, Li^+, Mg^{2+}, and La^{3+}. The Jones–Dole equation is generally valid up to a few tenths molar concentration. Recently the Jones–Dole equation has also been extended to include higher terms in a power series in M (4, 5). However, no new interpretive information has been revealed by this approach.

In the concentrated solution region (0.1 to 10 M), several features of the viscosity of electrolyte solutions have been noted. For some salts a plot of the viscosity *vs.* the molality at a fixed temperature yields a roughly exponentially increasing function (Figs. 1 and 2). However, for other salts a pronounced minimum in this plot occurs (Figs. 3 and 4). These latter salts fall into the category of structure breakers mentioned previously.

Thus, any equation which proposes to describe the variation of viscosity with concentration in this region must account for both of these phenomena in a quantitative manner.

The effect of concentration on the viscosity of salt solutions in the more concentrated region, and at fixed temperature, has been approached empirically in various ways. Vand (7), for example, extended Einstein's limiting theory to higher concentrations giving

$$[4] \qquad \ln \eta_{rel} = \frac{2.5\theta}{1 - Q\theta}$$

where Q is proposed to be an interaction parameter dealing with the mutual interference between the spheres. Several other equations have been advanced in this direction:

Thomas (8):

$$[5] \qquad \eta_{rel} = 1 + 2.5\theta + 10.05\theta^2$$

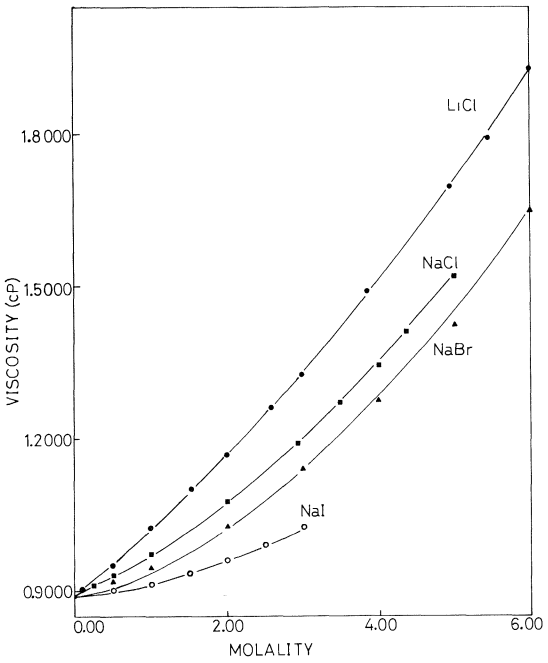

FIG. 1. Observed and calculated viscosities for LiCl, NaCl, NaBr, and NaI. The solid curves are calculated with eq. 20 and the parameters given in Table 3.

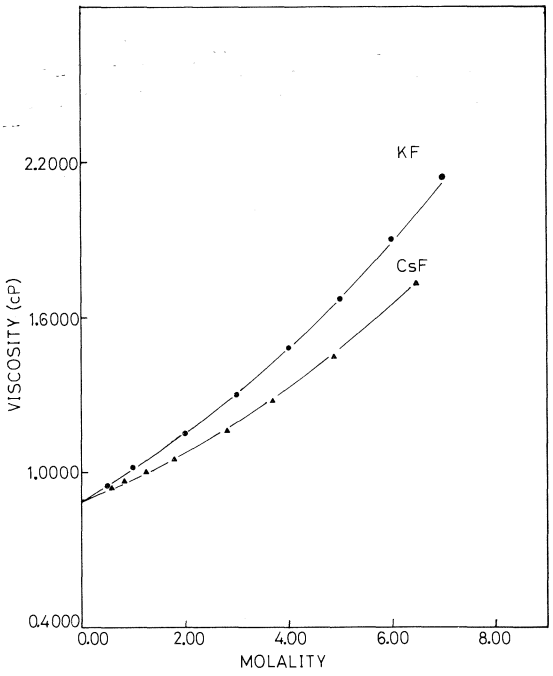

FIG. 2. Observed and calculated viscosities for KF and CsF. Solid curves as in Fig. 1.

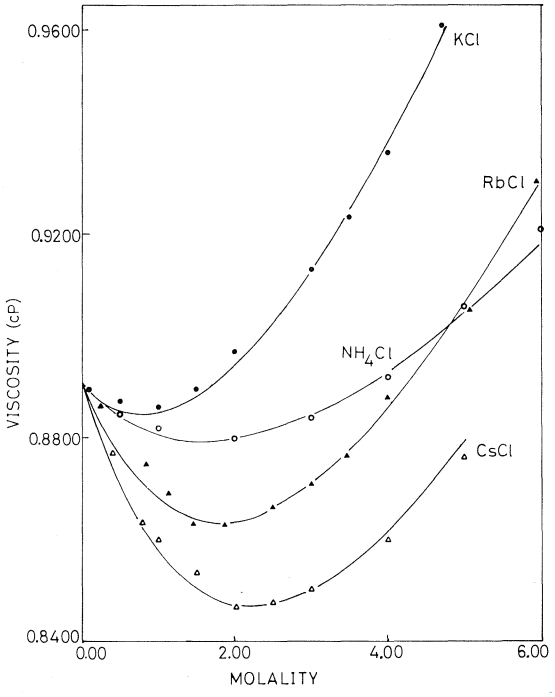

FIG. 3. Observed and calculated viscosities for KCl, RbCl, CsCl, and NH_4Cl. Solid curves as in Fig. 1.

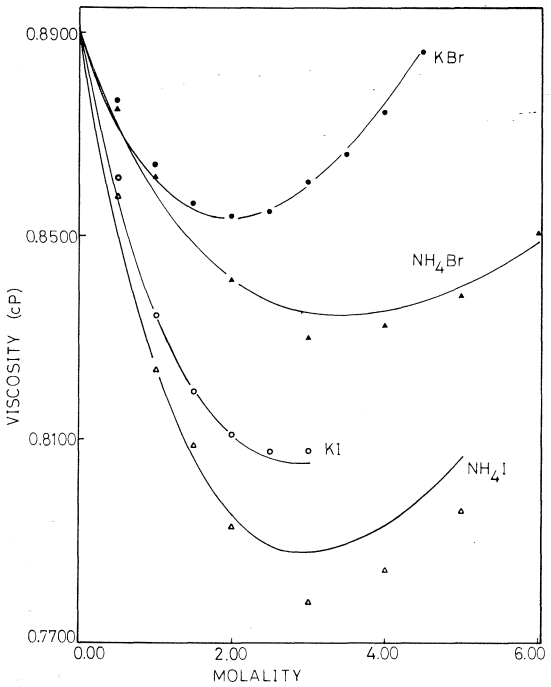

FIG. 4. Observed and calculated viscosities for KBr, KI, NH_4Br, and NH_4I. Solid lines as in Fig. 1.

Moulik (9):

$$[6] \qquad (\eta_{rel})^2 = M + kc^2$$

where M and k are constants.

Bingham (10), by an entirely empirical approach, proposed that the fluidities of one molar electrolyte solutions were composed of additive fluidity constituents of the solvent and ions. That is

$$[7] \qquad \phi = \phi_w + \phi_a + \phi_c$$

where ϕ is the fluidity of the solution, ϕ_w the fluidity of the solvent, ϕ_a the fluidity derived from the anions, and ϕ_c the fluidity derived from the cations. Since the fluidity of water is almost as large as that of the solution at the concentrations (up to 1 N) dealt with by Bingham, he regarded the fluidities of the ions as corrections to the fluidity of water. Equation 7 can then be written as

$$[8] \qquad \Delta_m = \phi - \phi_w = \Delta_a + \Delta_c$$

where Δ_c is the elevation or depression produced in the fluidity of the solution by the presence of one equivalent weight of cations and Δ_a is the corresponding elevation or depression for the anions. Bingham tabulated these ionic parameters at 25 °C assuming the Δ value for the potassium ion was equal to that of the chloride ion as a basis for determining the single ionic Δ parameters. Excellent agreement between calculated and experimental solution fluidities resulted when these values were used to calculate fluidities for a large number of salts at concentrations of 1 N and 0.5 N. While legitimate empirically, this approach lacked a sound molecular and theoretical basis.

Suryanarayana and Venkatesan (11) have observed that the equation

$$[9] \qquad \eta_p = A'' \exp(B''C_p)$$

adequately describes the variation of electrolyte viscosity throughout the high concentration range. Here η_p represents the ratio of the viscosity of the solution at a given concentration relative to that at saturation at the same temperature and C_p the ratio of the mole fraction of the solute at a given concentration to that at saturation at the same temperature. A'' and B'' are experimentally determined constants. However, no theoretical basis was found for this equation.

Another property of these solutions which has been studied in the high concentration region is

the temperature dependence of the viscosity at fixed composition. For pure liquids, the temperature dependence has been accounted for empirically by an equation attributed originally to Andrade (6):

$$[10] \qquad \eta = A' \, e^{B'/T}$$

where A' and B' are constants and T is the absolute temperature. Fixed composition electrolyte solutions of high concentration have also been found to follow this equation.

As a starting point for a molecular interpretation of the viscosity of electrolyte solutions, the approach of Eyring *et al.* has been used by several investigators (1, 12). However, an explanation of both the concentration effects observed in Fig. 1 through Fig. 4 at fixed temperatures or the temperature variation of these effects has not yet appeared. The following section outlines such an approach based on the absolute rate theory of viscosity.

Extension of the Absolute Rate Theory of the Viscosity of Liquids to Concentrated Single Electrolyte Solutions

The basic equation for the viscosity of a fluid from the absolute rate theory approach has been shown to be (14):

$$[11] \qquad \eta = \frac{hN}{V} e^{\Delta G^*/RT}$$

where η is the viscosity of the fluid, h is Planck's constant, N Avogadro's constant, R the gas constant, V the molar volume of the hole in the liquid, and ΔG^* the molar free energy of activation for creating this hole in the liquid by the particle moving in the fluid.

It has also been shown that the viscosity of electrolyte solutions at high fixed concentrations follows the simple temperature dependence of this equation (13). We assume this basic equation can be used therefore to represent the viscosity of an electrolyte solution. It must be kept in mind that, in such a solution, there will be solvent particles as well as anion and cation particles which will contribute to the total viscosity of the medium. Furthermore there are two parameters in this equation which characterize the viscosity of the medium: the volume of the hole in the liquid V, and the free energy of activation involved in forming the hole, ΔG^*. For a mixture of particles, we assume that these parameters are average parameters and that the volume and free energy parameters include solvent, anion, and cation components. We will outline the derivation of the equation first for a solution of a 1:1 salt.

The simplest relation between the average parameters and their sub-components involves the mole fraction of each component. We therefore assume the volume and free energy components are given as

$$[12] \qquad V_T = X_1 V_1 + X_c V_c + X_a V_a$$

$$[13] \qquad \Delta G^* = X_1 \Delta G_1^* + X_c \Delta G_c^* + X_a \Delta G_a^*$$

where X_1 = mole fraction of solvent, X_a = mole fraction of the anion, X_c = mole fraction of the cation, V_1 = molar volume of the solvent molecule hole, V_a = molar volume of the anion hole, V_c = molar volume of the cation hole, ΔG_1^* = free energy of activation for viscous flow per mole of solvent, ΔG_a^* = free energy of activation for viscous flow per mole of anion, and ΔG_c^* = free energy of activation for viscous flow per mole of cation.

Now the mole fraction must take into account all distinct particles in the medium and is therefore, for the mole fraction of cations, given by the equation (14)

$$[14] \qquad X_c = \frac{m_c}{55.51 + 2m}$$

This equation applies to an aqueous solution on the molal scale since there are 55.51 moles of water per kg of water and $2m$ moles of salt particles (anion plus cation) for an m molal solution of a 1:1 salt such as NaCl. For other solvents the appropriate number of moles per kg must be used. Now for a 1:1 salt the following relations are valid:

$$X_c = X_a$$

and

$$X_1 + X_c + X_a = 1$$

Thus,

$$[15] \qquad X_1 = 1 - 2X_c$$

Substitution of eq. 15 into eq. 12 gives

$$[16] \qquad \begin{aligned} V_T &= X_1 V_1 + X_c(V_c + V_a) \\ &= V_1 + X_c(V_c + V_a - 2V_1) \\ &= V_1 + \left[1 + X_c\left(\frac{V_c + V_a}{V_1} - 2\right)\right] \end{aligned}$$

Similarly

$$[17] \qquad \Delta G^* = \Delta G_1^* + X_c(\Delta G_c^* + \Delta G_a^* - 2\Delta G_1^*)$$

Substitution of eqs. 16 and 17 into eq. 11 yields

TABLE 1. Equations to express viscosity of single salt solutions[a]

Salt type	X	F	V
1:1	X_c	$\Delta G_c^* + \Delta G_a^* - 2\Delta G_1^*$	$\frac{V_c + V_a}{V_1} - 2$
1:2	X_c	$\Delta G_c^* + 2\Delta G_a^* - 3\Delta G_1^*$	$\frac{V_c + 2V_a}{V_1} - 3$
2:1	X_a	$2\Delta G_c^* + \Delta G_a^* - 3\Delta G_1^*$	$\frac{2V_c + V_a}{V_1} - 3$
1:3	X_c	$\Delta G_c^* + 3\Delta G_a^* - 4\Delta G_1^*$	$\frac{V_c + 3V_a}{V_1} - 4$
3:1	X_a	$3\Delta G_c^* + \Delta G_a^* - 4\Delta G_1^*$	$\frac{3V_c + V_a}{V_1} - 4$

[a]Basic equation: $\eta = \eta_1 e^{XF/RT}/(1 + XV)$.

the following relation for the viscosity of the solution η.

$$[18] \qquad \eta = hN \frac{\exp\{\Delta G_1^*/RT + X_c[(\Delta G_c^* + \Delta G_a^* - 2\Delta G_1^*)/RT]\}}{V_1\left[1 + X_c\left(\frac{V_c + V_a}{V_1} - 2\right)\right]}$$

For the pure solvent we assume eq. 11 is valid:

$$\eta_1 = \frac{hN}{V_1} e^{\Delta G_1^*/RT}$$

and therefore

$$[19] \qquad \eta = \eta_1 \frac{\exp\{X_c[(\Delta G_c^* + \Delta G_a^* - 2\Delta G_1^*)/RT]\}}{1 + \left[X_c\left(\frac{V_c + V_a}{V_1} - 2\right)\right]}$$

or in simplified form

$$[20] \qquad \eta = \frac{\eta_1 e^{XE}}{1 + XV}$$

where

$$E = (\Delta G_c^* + \Delta G_a^* - 2\Delta G_1^*)/RT$$

$$V = \frac{V_c + V_a}{V_1} - 2$$

$$X = X_c$$

This final equation for the viscosity of an electrolyte solution is in essence a two-parameter equation just as the equation for the viscosity of a pure liquid is a two-parameter equation. Furthermore, all salt types (1:1, 1:2, 1:3, 2:1, 3:1) yield equations of the same form involving two adjustable parameters. The appropriate definitions of the E and V parameters for all salt types are given in Table 1.

The purpose of this paper is to show how this extension of the basic absolute rate theory for the viscosity of fluids accounts quantitatively for the phenomena observed with the viscosities of concentrated electrolyte solutions of single 1:1 salts. The various empirical equations previously discussed which have been observed to account for some of the behaviour of the viscosity of concentrated electrolyte solutions, will be shown to be compatible with these new theoretical equations. Application of these equations to other salt types as well as a discussion of the temperature dependence of these parameters will be left to further papers in this series.

Experimental

The viscosities of concentrated solutions of NaF, KF, NaBr, KBr, NH_4Br, NaI, and KI were measured and are given in Table 2. All salts were certified ACS and were dried for at least 24 h at 110 to 120 °C prior to use. They were then temporarily stored in a glass desiccator over P_2O_5. In the case of the solutions of KF with molalities greater than 2.0, addition of a very slight amount of HF was necessary to adjust the pH of the solutions to within the pH range 6.5 to 7.5. The required amounts of salts

were all weighed on a 5 place balance to yield the exact molality as indicated in Table 2.

For each of these solutions, densities and viscosities were determined at 25.00 ± 0.02 °C in a Cannon constant temperature bath (Model M-1). Density measurements were obtained using 25 ml pycnometers which had been previously calibrated with distilled water at 25 °C. A buoyancy correction (15) was applied in obtaining these densities. Viscosities were determined using Ostwald microviscometers (size 50) which were calibrated with 1.0 ml of distilled water which had been equilibrated to the bath temperature. The solution fall times were obtained with stopwatches accurate to ±0.1 s and in no cases were times less than 100 s. Measurements were repeated until three consecutive readings varying only by ±0.2 s were obtained. Each viscosity measurement on each viscometer was followed by at least five washings with distilled water and three with acetone. The viscometers were frequently cleansed with alcoholic KOH and chromic acid.

Absolute viscosities were calculated in centipoise using the formula:

$$\eta = \frac{\eta_1 dt}{d_1 t_1}$$

where $\eta_1 = 0.8904$ cP for water at 25.00 °C (16), d_1 is the density of water at 25.00 °C, t_1 the fall time for water, d the density of the salt solution, and t the fall time for the salt solution.

The data for other salts were obtained from a variety of sources as indicated in Table 3. Only data with four significant figures were accepted for analysis. Computations and tests of the data were carried out on an IBM 360 computer as indicated in the treatment of data section.

Treatment of Data

Two main approaches were used to obtain the values of the E and V parameters from the viscosities of the salt solutions as a function of concentration. Equation 20 can be rearranged as follows:

$$[21] \quad Y = \ln\left[\frac{\eta}{\eta_1}(1 + XV)\right] = XE$$

If the correct value of V were used to calculate values of $(\eta/\eta_1)(1 + XV)$, then a plot of the natural logarithm of this function *vs.* the mole fraction of cation, X, should give a straight line of slope E and an intercept of zero. To test this equation, a computer program was devised to calculate for each salt the function Y with a fixed value of V for all concentrations corresponding to the measured viscosities. The value of V was varied from 0 to 50 in increments of 0.01. For each value of V, a least-squares plot was performed on the values of the function Y and the values of X to generate a value of E from the slope of this plot. Theoretical values of the viscosities were computed using this fixed value of V and the least-squares value of E in eq. 20. The sum of the differences between the observed and calculated viscosities were then computed. The best value of V and the resultant best E parameter were picked when the minimum sum of deviations between observed and calculated viscosities resulted.

Examples of the plots of the best fit functions Y *vs.* X are given in Figs. 5 and 6 and the best fit parameters E and V for all salts are given in Table 3. Correlation coefficients calculated for the best fit plots of Y *vs.* X exceeded 0.9999 for all salts and all intercepts on this plot were zero within the error of the measurements. Calcu-

lated viscosities for various salts using these best fit parameters are tabulated in Table 2 and graphically shown in Figs. 1 through 4.

Figures 3 and 4 reveal that certain salts yield minimum values on a viscosity *vs.* concentration scale plot. This fact led to the second approach to obtaining the parameters V and E from the minimum values of the viscosity η_{min} and the mole fraction value at this minimum X_{min} on a viscosity mole fraction plot. Equation 20 shows that for a minimum in this plot to occur, the first derivative $\partial\eta/\partial X$ must be zero.

$$[22] \quad \frac{\partial \eta}{\partial X} = \frac{\eta_1 E e^{EX}}{1 + XV} - \frac{\eta_1 V e^{EX}}{(1 + XV)^2} = 0$$

Hence

$$E - \frac{V}{1 + XV} = 0$$

$$[23] \quad X_{min} = \frac{V - E}{VE}$$

Equations 23 and 20 then yield for η_{min} the relation

$$[24] \quad \eta_{min} = \eta_1 \left(\frac{E}{V}\right) e^{(1-(E/V))}$$

From the known values of X_{min} and η_{min} obtained from the curve, distinct values of E and V can be obtained via relations 23 and 24. Theoretical values of the viscosity can then be calculated as a function of concentration to be compared with the observed values. Since in many cases the minimum in the curve of η *vs.* X is a broad minimum, some error occurs in picking the value of X_{min}. The values of E and V obtained in this way can be used however as first estimates of the best E and V values to be used in the computer iteration method previously discussed. It is found that the values of the parameters E and V obtained in this manner agree with those obtained by the least-squares analyses of the function Y *vs.* mole fraction plots.

Discussion

It is apparent from Table 2 and from Figs. 1 through 4 that the two-parameter eq. 20 can reproduce the observed viscosities within experimental error over the high concentration region for all the alkali and ammonium halide salts. Furthermore, eqs. 18 through 20 are of the same form as the empirical equations found to reproduce viscosity data in the high concentration region (11).

Since we are concerned with the concentration dependence of the viscosity of concentrated electrolyte solutions at fixed temperature, we shall leave the discussion of the temperature dependence of these effects to another paper. However, as indicated previously it has been found that eq. 10 accounts for the concentration dependence of the viscosity of electrolyte solutions at high concentrations. Equation 20 is compatible with eq. 10 and indeed indicates that eq. 10 is only an approximation to the real concentration dependence of the viscosity of electrolyte solutions. It has been observed that when log η is plotted *vs.* C_p (the ratio of the mole fraction of the salt at a given concentration relative to that at saturation), a straight line is obtained in the high concentration region but that curvature

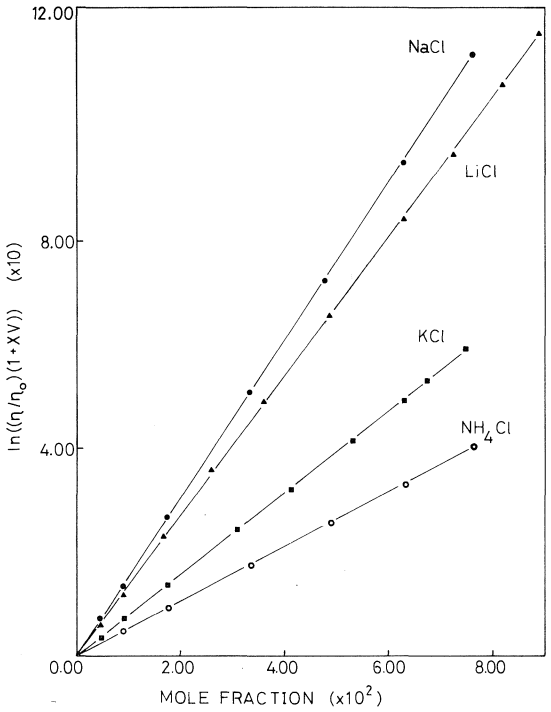

FIG. 5. Test of linearity of eq. 21 for LiCl, NaCl, KCl, and NH_4Cl.

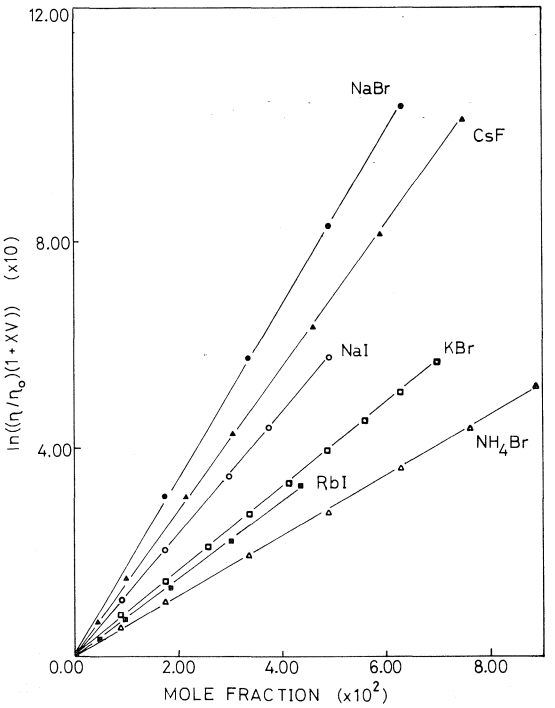

FIG. 6. Test of linearity of eq. 21 for NaBr, NaI, KBr, NH_4Br, and CsF.

in the low concentration region also occurs (11). This is just what would be predicted according to eq. 20. If X_{sat} is the mole fraction of the salt in the solution at saturation, then X/X_{sat} equals C_p and eq. 20 can be re-written as:

$$[25] \qquad \eta = \eta_1 \frac{\exp(X_{sat}EC_p)}{1 + X_{sat}VC_p}$$

If the term $\log \eta$ were plotted against C_p we could not expect a straight line relation from eq. 25 but rather a curve depending on the size of the parameter $X_{sat}V$ for any salt. If $X_{sat}V$ is small enough, then to a first approximation, a straight line relation would be observed at high concentrations, with deviations occurring at low concentrations. In these cases the high concentration slope would be equal to $X_{sat}E/2.303$ and the intercept of the straight portion of the curve at C_p equal to zero would be given by $\log \eta_1$.

If eq. 20 is valid over the whole range of electrolyte concentration, it should account quantitatively for both the high concentration as well as the low concentration viscosity effects. In the low concentration region, the Jones–Dole equation (eq. 3) has been used to describe the viscosity of electrolyte solutions in the region below 0.1 *M*. If we ignore the Falkenhagen term ($A\sqrt{c}$) in this expression and assume that the *B* coefficient is such that it will swamp out and encompass the long range electrostatic effects which are explained by the $A\sqrt{c}$ term, and noting that at concentrations <0.1 the molarity is almost equal to the molality, then we can write the Jones–Dole equation in terms of the molality as:

$$[26] \qquad \frac{\eta}{\eta_1} = 1 + B_c m$$

Here B_c is the corrected *B* coefficient of the Jones–Dole equation. Equation 20 can now be expanded as follows since the mole fraction *X* will be $\ll 1$ in the region of concentration $<0.1\,m$.

$$\frac{\eta}{\eta_1} = \frac{e^{XE}}{1 + XV}$$

$$\frac{\eta}{\eta_1} = \left(1 + XE + \frac{X^2E^2}{2}\right)(1 - XV + X^2V^2)$$

Ignoring terms in X^2 since $X \ll 1$, then

$$[27] \qquad \frac{\eta}{\eta_1} \simeq 1 + (E - V)X$$

Since the molality, *m*, is small, then *X* can be approximated as:

TABLE 4. Comparison between parameters obtained from various viscosity equations for electrolytes at 25 °C

[a]Reference 10.
[b]Reference 4.

$$X = \frac{m}{55.51 + 2m} \simeq \frac{m}{55.51}$$

and therefore

$$[28] \qquad \frac{\eta}{\eta_1} = 1 + \frac{(E - V)}{55.51} m$$

Comparing eqs. 26 and 28 shows that the B coefficient of the Jones–Dole expression should be approximately equal to $(E - V)/55.51$. Table 4 shows the good agreement between the observed B coefficients and the $(E - V)/55.51$ parameters for the salts studied in this paper. Because the B coefficients were obtained with either the full Jones–Dole expression or with an expanded Jones–Dole equation, exact agreement between these two parameters should not be expected.

Equation 20 can also be used to account for the Δ parameters of Bingham (10) which are additive up to 1 m. If we define $(\phi - \phi_1)/m$ as the molal fluidity increment or decrement, depending on the sign of the Δ parameters, then

$$\frac{\phi - \phi_1}{m} = \Delta_a + \Delta_c$$

In terms of viscosities this can be written as

$$[29] \qquad \frac{\frac{1}{\eta} - \frac{1}{\eta_1}}{m} = \frac{\frac{\eta_1}{\eta} - 1}{\eta_1 m} = \Delta_a + \Delta_c$$

Equation 20 can be rearranged and expanded as:

$$\frac{\eta_1}{\eta} = (1 + XV)\, e^{-EX}$$
$$= (1 + XV)\left(1 - EX + \frac{E^2X^2}{2} - \ldots\right)$$

Up to 1 m, the term $EX < 1$, and terms in E^2X^2 can be ignored. Hence

$$[30] \qquad \frac{\eta_1}{\eta} \simeq 1 + (V - E)X$$

If we consider a 1 m solution only to determine the Δ values then:

$$X = \frac{m}{55.51 + 2}$$

and

$$\left(\frac{\eta_1}{\eta} - 1\right) = \frac{(V - E)}{57.51} m$$

or

$$[31] \qquad \frac{\left(\frac{\eta_1}{\eta} - 1\right)}{\eta_1 m} = \frac{(V - E)}{57.51\eta_1}$$

Since η_1 for water at 25 °C is 0.008904 poise, then equating [29] and [31] we obtain for a 1 molal solution:

$$[32] \qquad \Delta_a + \Delta_c = 1.953(V - E)$$

Table 4 lists values of $\Delta_a + \Delta_c$ observed and those calculated using eq. 32.

Furthermore, according to eqs. 32 and 28 the ratio of the $(\Delta_a + \Delta_c)$ parameter to the B parameter for all salts should be a constant.

$$[33] \quad \frac{(\Delta_a + \Delta_c)}{B} = \frac{-55.51}{57.51\eta_1} = -108.4$$

Calculated values of this ratio are given in Table 4 and show good agreement with this prediction. Large differences in these values appear only for KCl, NH_4Cl, RbCl, CsCl. Since there does not appear to be any systematic error in these numbers, then the only possible source of this large error is in the prime data of Bingham (10). Shown in brackets beside these numbers in Table 4 are values calculated using $1.953(V - E)/B$.

It should be noted, in Table 4, in comparing the B values to the $(\Delta_a + \Delta_c)$ parameters of Bingham, that the signs of these parameters for each salt are opposite, *i.e.* if the B coefficient is positive then $(\Delta_a + \Delta_c)$ is negative and vice-versa. This follows from the fact that in the low concentration region, if a salt increases the viscosity relative to that of water at that temperature, such as NaCl, this results in a positive B value. However, since fluidity is the inverse of viscosity, then if the viscosity increases, the fluidity decreases and thus a negative value of $(\Delta_a + \Delta_c)$ results. Similarly if a salt initially decreases the viscosity from that of water, such as KCl, then a negative B value results. However, the fluidity would initially increase and thus yield a positive $(\Delta_a + \Delta_c)$ value.

It is also interesting to note that as the temperature is raised, negative B values found in 'structure-breaking' salts become less negative and eventually become positive. This is due to the fact that as the temperature increases, the initial decrease in viscosity shown in Figs. 3 and 4 is gradually lost until the exponentially increasing function of Figs. 1 and 2 is achieved.

The additivity of the B and $(\Delta_a + \Delta_c)$ parameters has been commented on, mulled over, and dissected in detail over the past 20 years (1, 17–20). Excellent discussions of the various possible component contributions to these parameters are available in these references. The V and E parameters of eq. 20, however, give another insight into the values of the B and Δ parameters. It can be seen from Table 3 that the individual E and V parameters do not show systematic trends or seem to have additive characteristics. However, the difference parameter $(E - V)$ reflects systematic trends and since it is directly proportional to the additive parameters B and Δ, it too must be made of additive components. The definitions of E and V given in eq. 20 and Table 1 for other salt types in fact indicate that the $(E - V)$ parameter should be additive. Thus, for 1:1 salts

$$(E - V) = \frac{\Delta G_c^*}{RT} + \frac{\Delta G_a^*}{RT} - 2\left(\frac{\Delta G_1^*}{RT}\right) - \left(\frac{V_c + V_a}{V_1}\right) - 2$$

$$[34] \quad (E - V) = \left(\frac{\Delta G_c^*}{RT} - \frac{V_c}{V_1}\right) + \left(\frac{\Delta G_a^*}{RT} - \frac{V_a}{V_1}\right) - 2\left(\frac{\Delta G_1^*}{RT} - \frac{V_1}{V_1}\right)$$

Thus, the thrust of any argument over the significance of the B and Δ parameters according to eq. 34 should concern itself with the free energy of activation of viscous flow for the anions, cations, and solvent molecules as well as the volume ratios of the holes created in the liquid structure by these particles during viscous flow.

However, the free energy parameters can only be properly understood in terms of the enthalpy and entropy of activation components according to eq. 35

$$[35] \quad \Delta G^* = \Delta H^* - T\Delta S^*$$

Furthermore, ionic B values show a linear relationship with the partial molar ionic entropies (1), and since the $(E - V)$ parameter is related to these B values, then the $(E - V)$ parameter should also show some kind of relationship to the entropy. Therefore a detailed discussion of the significance of the $(E - V)$ parameters for various salts should be properly deferred until the determination of the temperature dependence of the $(E - V)$ parameters has been carried out.

Conclusions

A simple extension of the transition state theory of viscosity for fluids has led to a two-parameter equation which quantitatively accounts for the viscosity of concentrated solutions of electrolytes. Comparison of this equation with several empirical equations in the high and low concentration regions shows that this new equa-

tion also successfully links the B parameters of the Jones–Dole equation and the Δ parameter of Bingham's equation with the free energy of activation and volume ratio parameters of this new equation.

Studies in the usnic acid series. IV.[1] The base catalyzed usnic acid – isousnic acid rearrangement. Part II. An improved synthesis of (+)-isousnic acid

JAMES P. KUTNEY, IGNACIO H. SANCHEZ, AND TREVOR YEE

Department of Chemistry, University of British Columbia, 2075 Wesbrook Place, Vancouver, B.C., Canada V6T 1W5

Received September 30, 1976

JAMES P. KUTNEY, IGNACIO H. SANCHEZ, and TREVOR YEE. Can. J. Chem. **55**, 1073 (1977).

Investigations concerning the alkaline cleavage of (+)-2*H*-[1,2]oxazocinousnic acid (**3**) are described. These studies provide an interesting rearrangement from the 'normal' (usnic acid) to the 'iso' (isousnic) series and, in turn, a high yielding sequence for the synthesis of (+)-isousnic acid (**1**).

JAMES P. KUTNEY, IGNACIO H. SANCHEZ et TREVOR YEE. Can. J. Chem. **55**, 1073 (1977).

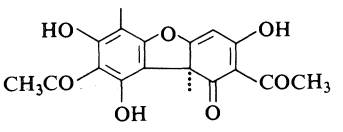
On décrit des études concernant les coupures alcalines de l'acide (+)-2*H*-[1,2]oxazocinousnique (**3**). Ces études fournissent un réarrangement intéressant de la série 'normale' (acide usnique) en série 'iso' (acide isousnique) aussi qu'une méthode pour effectuer la synthèse de l'acide (+)-isousnique (**1**) par une séquence impliquant dé bons rendements.

[Traduit par le journal]

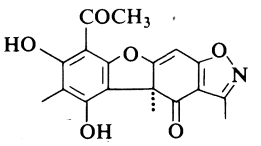
During our continued studies on nitrogen containing usnic acid derivatives (1, 2) as useful synthetic intermediates for the preparation of the several biodegradation products isolated in our laboratories,[2] we have recognized an interesting base-catalyzed usnic acid – isousnic acid rearrangement (3).

The following studies confirm its generality and synthetic usefulness, as seen by the greatly improved preparation of the naturally occurring lichen substance (+)-isousnic acid (**1**) (4–6).

Thus, the alkaline treatment of (+)-2*H*-[1,2]oxazocinousnic acid (**3**) (2) follows a very similar course to that previously observed (3) for the isomeric isoxazole **2** (2) producing **5** as the main component, (Fig. 1) the latter belonging to the isousnic acid series (the 'iso' series). The structural assignment followed from the examination of the relevant spectroscopic properties. For example, in the ^{1}Hmr spectrum one notes the characteristic (3) two-proton AB quartet centered at δ 3.10 ppm (J = 18 Hz) corresponding to the C_4-methylene group of the *cis* B/C ring fused series (C_{4a}-αOH) as shown in **5** and the one-proton singlet at δ 6.08 ppm assigned to the C_8-aromatic proton. Further support for this assignment was derived from its cd spectrum which showed absorption maxima and Cotton effects (see Experimental) comparable in sign and magnitude to those observed for the oxazocine **7** also belonging to the iso series (3).



1



2

The minor components obtained from the basic treatment of **3** result from both Michael addition of water (solvent) to the C_4—C_{4a} double bond and alkali cleavage of the non-enolizable C_1 carbonyl group producing the C_{4a}-hydroxylated derivative **4** and the unsaturated acid **6** respectively (Fig. 1).

Dehydration of compound **5** by means of 0.5% concentrated sulfuric acid in acetic anhydride produced, in 80% yield, the desired olefin **7**. The latter substance shows the olefinic and aromatic protons as sharp singlets at δ 6.02 and 6.76 ppm, respectively, in its ^{1}Hmr spectrum.

Two other minor components were isolated and characterized from the dehydration reaction mixture. One of these (6% yield) revealed a molecular formula, $C_{22}H_{19}O_8N$ and was clearly the result of *C*-acylation of the aromatic ring (**8**, Fig. 2), as evidenced by new absorptions

[1]For part III see ref. 3.

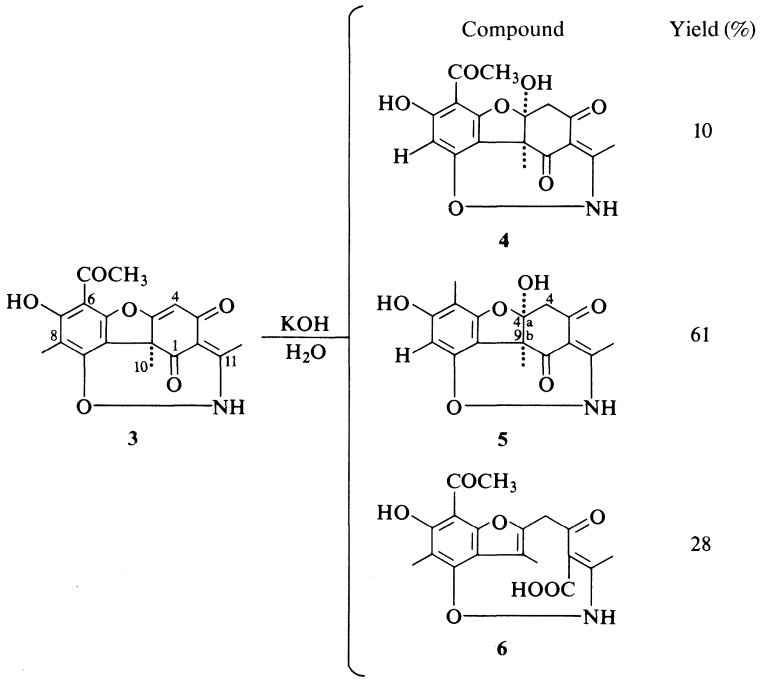

FIG. 1. The base cleavage of (+)-2*H*-[1,2]oxazocinousnic acid (**3**).

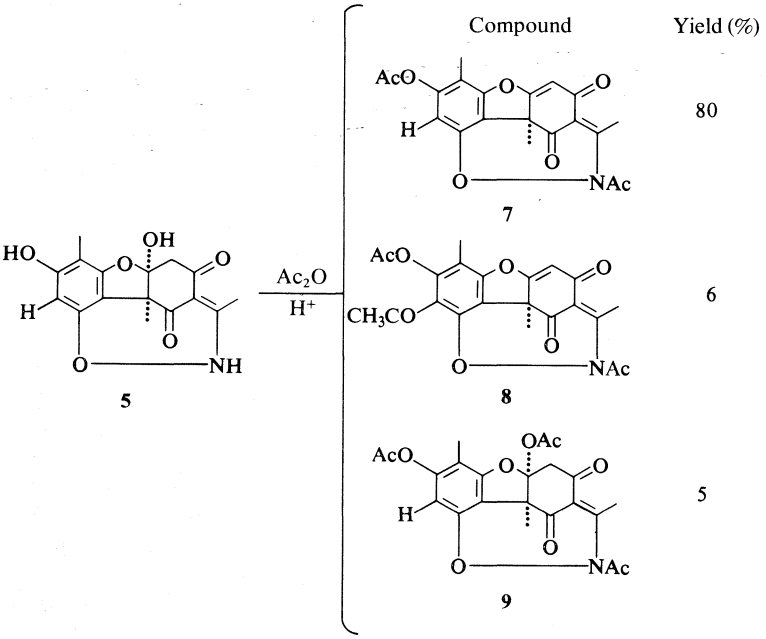

FIG. 2. The acid-catalyzed dehydration of (+)-α-hydroxydesacetyl-2*H*-[1,2]oxazocinoisousnic acid (**5**).

in its infrared spectrum at 1775 (phenolic acetate) and 1690 cm^{-1} (aromatic acetyl group). Its ^{1}Hmr spectrum showed three-proton singlets at δ 2.33, 2.45, and 2.50 ppm, representative of the C_7-phenolic acetate, the aromatic methyl ketone, and the *N*-acetyl group, respectively, with the one-proton singlet at δ 5.90 ppm being assigned to the olefinic proton.

The final component proved to be the acetoxy derivative **9**, for which the C_{4a}-α-configuration (*i.e. cis*-B/C ring junction) could be cleanly derived from the chemical shifts of both the C_4-methylene group protons, observed as an AB quartet centered at δ 3.65 ppm (J = 18 Hz), and the aromatic proton, seen at δ 6.70 ppm. These values are in full agreement with previous ^{1}Hmr data obtained for the isomeric isoxazole series (3).

Alkaline hydrolysis (0.8% aqueous sodium hydroxide in tetrahydrofuran) of the *O*,*N*-diacetate **8** furnished the first 'iso'-series intermediate available for direct comparison with the 'normal' series studied earlier. Thus compound **10** obtained as colorless prisms, mp 170–172°C, $[\alpha]_D^{26}$ +357° (CH_3CN), was shown not to be identical with the known (+)-2*H*-[1,2]oxazocinousnic acid (**3**) (2). Table 1 shows a comparison of the relevant ^{1}Hmr characteristics of these two materials.

Being certain at this point that we were involved with compounds of the iso series, we proceeded to complete the synthesis of (+)-isousnic acid (**1**) (Fig. 3) by performing the hydrogenolytic O—N bond cleavage (2) of

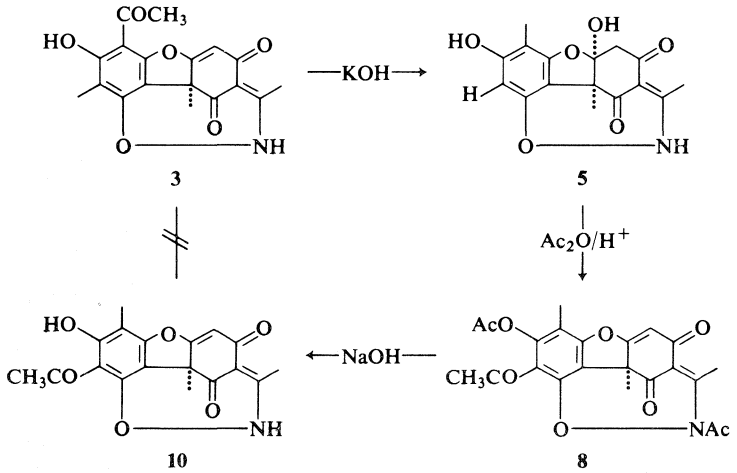
oxazocine **7** followed by immediate alkaline (1 *N* sodium hydroxide in tetrahydrofuran) regeneration of the ring C β-triketone system. In this manner, it was possible to obtain (+)-8-desacetylisousnic acid (**11**), in overall 80% yield. The latter substance was shown to be identical with the product obtained from similar treatment of the [4,5-*b*]isoxazole series in a previous study (3). Since **11** has been successfully converted into (+)-isousnic acid (**1**) by an aluminum-trichloride-catalyzed Fries rearrangement of its corresponding di-*O*-acetyl derivative (3), this sequence represents a much improved synthesis of **1** from the normal usnic acid series.

This base catalyzed interconversion from the normal to the iso series (**3** → **5**) obviously involves fission of the C—O bond in ring B of **3** and recyclization with the aromatic C_9 oxygen as the



3 **5** **10** **8**

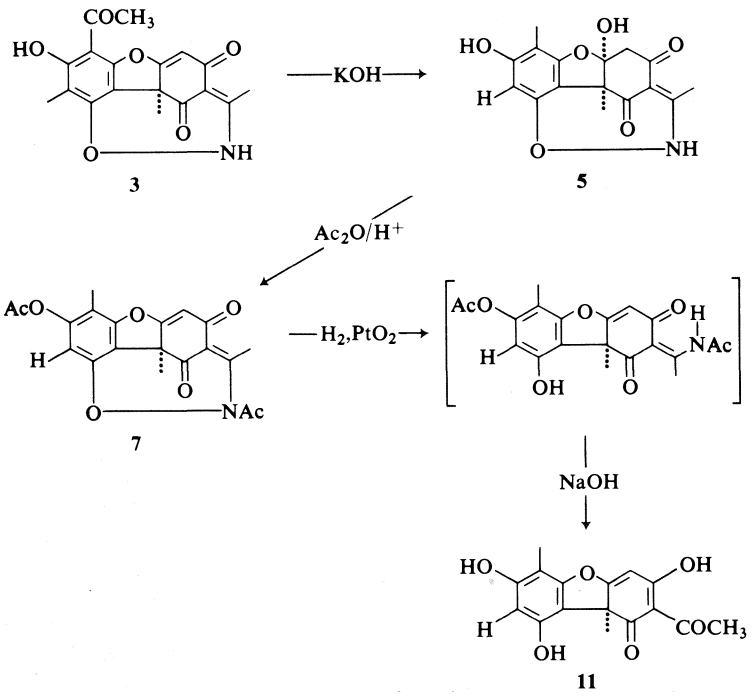


FIG. 3. The preparation of (+)-8-desacetylisousnic acid (**11**) from (+)-2*H*-[1,2]oxazocinousnic acid (**3**).

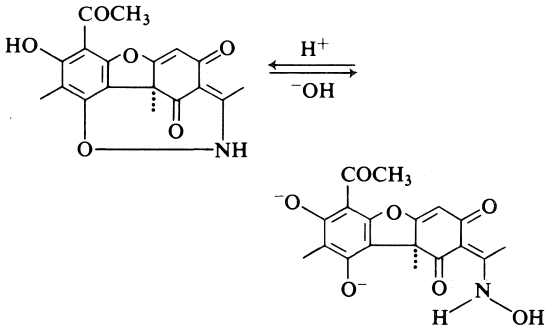
ring B hetero atom in the final product. Clearly such a rearrangement is made possible only if the O—N bond of the oxazocine ring is cleaved under the basic conditions to the corresponding phenolic hydroxylamine derivative, as shown.

It is our hope that the present work will also add some information to the sparse knowledge of oxazocine ring chemistry. Perhaps this interesting protecting group can be employed in other areas of organic synthesis.



Experimental

Melting points were determined on a Kofler block and are uncorrected.

Ultraviolet (uv) spectra were recorded on a Cary 15 spectrophotometer in methanol solution (unless otherwise noted). The wavelength of the absorption maxima are reported in nanometres (nm).

Infrared (ir) spectra were measured routinely on a Perkin-Elmer model 710 spectrophotometer. Analytical or comparison spectra were recorded on a Perkin-Elmer model 457 spectrophotometer using matched cells with a cell path of 0.2 mm in chloroform solution. Calibration was achieved using the 1601 cm^{-1} absorption band of polystyrene. The absorption maxima are quoted in wave numbers (cm^{-1}).

Proton magnetic resonance (^{1}Hmr) spectra were measured in deuterochloroform ($CDCl_3$) solution (unless otherwise indicated) at room temperature. Routine spectra were recorded at 60 MHz on a Varian T-60 spectrometer, and analytical or comparison spectra at 100 MHz on either a Varian HA-100 or a Varian XL-100 spectrometer. All ^{1}Hmr spectra obtained via the Fourier transform (F.t.) technique are so noted and were recorded on a Varian X1-100 spectrometer. Line positions are given in the δ (ppm) scale using tetramethylsilane (TMS) as internal standard. The integrated peak areas, multiplicity, and proton assignments are indicated in parentheses.

Low resolution mass (ms) spectra were determined on either an AEI-902 or an Atlas CH-4B mass spectrometer, with high resolution mass spectra being recorded exclusively on an AEI-MS-902 mass spectrometer.

Circular dichroism (cd) spectra were obtained on a Jasco model J-20 spectropolarimeter in methanol solution (unless otherwise indicated). The wavelength of the absorption maxima is reported in nanometres (nm). The differential molar extinction coefficient ($\Delta\varepsilon$) and the sign of the observed Cotton effect are indicated in parentheses.

Optical rotations ($[\alpha]_D$) were measured on a Perkin-

Elmer model 141 polarimeter at the sodium D line in chloroform solution (unless otherwise noted) using cells with a 0.1 dm path.

Microanalyses were performed by Mr. P. Borda of the Microanalytical Laboratory, University of British Columbia.

Merck silica gel G (acc. to Stahl) impregnated with oxalic acid (2%) and with 2% fluorescent indicator added, was used as adsorbent for thin layer chromatography (tlc), unless otherwise noted. The tlc plates were activated in an oven at 90°C for 4 h before use. For qualitative chromatography layers of 0.3 mm thickness were used and the spots were visualized by viewing under ultraviolet (uv) light or spraying with a 1% ethanolic ferric chloride solution. For preparative (plc) chromatography large (20 × 20 and 20 × 60 cm) plates with a thicker layer (0.7 mm) were used. The developing systems were *A*, petroleum ether (30–60°C) – acetone (4:1), and *B*, chloroform – ethyl acetate (3:2), unless otherwise indicated.

Column chromatography was performed on either Mackerey-Nagel (0.2–0.5 mm grain size) or Merck 60 (0.063–0.2 mm grain size) silica gel.

The usnic acid utilized throughout the course of this study was obtained from Koch-Light Laboratories, England, as the optically active dextrorotatory isomer, (+)-usnic acid, isolated from lichen sources (*Usnea barbata*).

In order to present in a coherent manner the characteristic spectroscopic data for those compounds that are formally derived from usnic acid and retain its basic skeletal features, we have decided to maintain through the course of this work the numbering system recommended for the parent molecule, that is, the approved dibenzofuran numbering (7) instead of using those arising from the corresponding systematic names. In all other instances the latter numbering systems will be used.

*Base Cleavage of (+)-2H-[1,2]Oxazocinousnic Acid (**3**)*

A solution of (+)-2*H*-[1,2]oxazocinousnic acid (**3**) (3.973 g, 11.651 mmol) in freshly prepared 20% aqueous potassium hydroxide (200 ml) was stirred at room temperature under a nitrogen atmosphere for 1.5 h. The dark brown reaction mixture was diluted with cold distilled water (200 ml), acidified with 1 *N* hydrochloric acid, and extracted with ethyl acetate (3 × 120 ml). The combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure to afford a pale yellow foam (4.508 g). Purification by column chromatography on Macherey-Nagel silica gel (160 g) yielded the following pure components.

*Fraction I. (+)-α-Hydroxy-2H-[1,2]oxazocinousnic acid (**4**) (7-Acetyl-5aα,8-dihydroxy-3a,4,10b,11-tetrahydro-3,9,10bα-trimethyl-4,11-dioxo-2H-4,5-dihydro[1,2]-oxazocino[4,5,6,7,8-a,n,l,k]dibenzofuran)*

Colorless prisms from acetone–chloroform (0.423 g, 1.178 mmol; 10%), mp 211.5–212.5°C; $[\alpha]_D^{26}$ (CH_3CN) +158° (*c* 0.1195); uv: λ_{max} (log ε) 330 (3.44), 285 (3.85), 223 (3.92); ir (Nujol): ν_{max} 3500–3100 (OH, chelated), 1685 (C=O, enone system), 1620 (C=O, chelated aromatic acetyl), 1600 (C=C); ^{1}Hmr ($CDCl_3$–DMSO-d_6): δ 1.91 (3H, s, C_{9b}-CH_3), 2.01 (3H, s, C_8-CH_3), 2.37 (3H, s, C_{11}-CH_3), 2.53 (3H, s, C_6-$COCH_3$), 3.10 (1H, br, N-H), 3.12 (2H, AB q, J = 18 Hz, C_4-H_2), 9.36 (1H, br, C_{4a}-αOH), 13.43 ppm (1H, s, C_7-OH); ms: *m/e* 359 (M^+), 236, 234, 128, 118, 85, 83 (base peak), 43. *Anal.* calcd. for $C_{18}H_{17}O_7N$ (0.85 $CHCl_3$): C 49.13, H 3.91, N 3.04, Cl 19.62; found: C 49.14, H 3.92, N 2.97, Cl 19.54. High resolution molecular weight determination calcd. for $C_{18}H_{17}O_7N$: 359.100; found: 359.099; cd: λ_{max} (Δε) 276 (+3.02), 250 (+3.45), 226 (−7.32).

*Fraction II. (+)-α-Hydroxydesacetyl-2H-[1,2]oxazocinoisousnic Acid (**5**) (5aα,8-Dihydroxy-3a,4,5,5a,10b,11-hexahydro-3,7,10bα-trimethyl-4,11-dioxo-2H-4,5-dihydro[1,2]oxazocino[4,5,6,7,8-a,m,l,k]dibenzofuran)*

Colorless prisms from acetone–chloroform (2.250 g, 7.097 mmol; 61%), mp 227–229°C; $[\alpha]_D^{26}$ (CH_3CN) +284° (*c* 0.0845); uv: λ_{max} (log ε) 287 (3.11), 263 (3.26), 217 (3.86); ir (Nujol): ν_{max} 3550, 3500–3100 (OH, NH), 1700, 1630 (C=O), 1600 (C=C); ^{1}Hmr ($CDCl_3$–DMSO-d_6): δ 1.90 (3H, s, C_{9b}-CH_3), 2.16 (3H, s, C_6-CH_3), 2.40 (3H, s, C_{11}-CH_3), 3.10 (2H, AB q, J = 18 Hz, C_4-H_2), 6.08 (1H, s, C_8-H), 6.76 (1H, s, C_{4a}-αOH), 8.16 (1H, br, C_{11}-N—H), 8.56 ppm (1H, s, C_7-OH); ms: *m/e* 317 (M^+, base peak), 302, 289, 275, 260, 230, 219, 178. *Anal.* calcd. for $C_{16}H_{15}O_6N$: C 60.57, H 4.77, N 4.41; found: C 60.25, H 4.71, N 4.12. High resolution molecular weight determination: calcd.: 317.090; found: 317.088; cd: λ_{max} (Δε) 300 (+4.54), 268 (+10.26), 239 (−3.50), 218 (−6.01).

*Fraction III. 8-Acetyl-4-carboxy-9-hydroxy-3,10,12-trimethyl-5-oxo-2H-5,6-dihydro[1,2]oxazocino[7,8,9,10-b,c,d]dibenzofuran (**6**)*

Fluffy pale yellow needles from methanol (1.190 g, 3.314 mmol; 28%), mp 210–212°C; $[\alpha]_D^{26}$ (CH_3OH) 0° (*c* 0.1235); uv: λ_{max} (log ε) 356 (3.07), 287 (3.83), 237 (3.84); ir (Nujol): ν_{max} 3500–2400 (OH, NH), 1685 (C=O, carboxylic acid dimer), 1640 (C=O, chelated aromatic acetyl), 1620 (C=O, enone system), 1590 (C=C); ^{1}Hmr ($CDCl_3$–DMSO-d_6): δ 2.11 (3H, s, C_{10}-CH_3), 2.33 (3H, s, C_{12}-CH_3), 2.46 (3H, s, C_3-CH_3), 2.73 (3H, s, C_8-$COCH_3$), 4.28 (2H, s, C_6-H_2), 6.36 (2H, br, C_4-COOH and C_3-NH), 13.71 ppm (1H, s, C_9-OH); ms: *m/e* 359 (M^+), 317 233, 215, 84, 44 (base peak), 43. *Anal.* calcd. for $C_{18}H_{17}O_7N \cdot \frac{1}{4}H_2O$: C 59.43, H 4.85, N 3.85; found: C 59.56, H 4.72, N 3.69. *Dehydration of (+)-α-Hydroxydesacetyl-2H-[1,2]oxazocinoisousnic Acid (**5**)*

A solution of (+)-α-hydroxydesacetyl-2*H*-[1,2]oxazocinoisousnic acid (**5**) (970 mg, 3.059 mmol) in 0.5% concentrated sulfuric acid in acetic anhydride (10 ml) was heated at 55°C (oil bath temperature) under a nitrogen atmosphere for 1 h. The reaction mixture was poured onto crushed ice (20 g), extracted with ethyl acetate (3 × 10 ml), and the combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure to produce a colorless foam (1.174 g), which upon purification by preparative chromatography afforded the following components.

Fraction I. (+)-N-Acetyldesacetyl-2H-[1,2]oxazocinoisousnic Acid Acetate (7) (N-Acetyl-8-acetoxy-3a,4,10b,11-tetrahydro-3,7,10bα-trimethyl-4,11-dioxo-4,5-dihydro[1,2]-oxazocino[4,5,6,7,8-a,m,l,k]dibenzofuran)

Colorless prisms from ethyl alcohol (934.3 mg, 2.439 mmol; 78%), mp 154–155°C; $[\alpha]_D^{26}$ (CH_3CN) +205° (*c* 0.20); uv: λ_{max} (log ε) 300 (3.40), 243 (3.75), 216 (4.20); ir (Nujol): ν_{max} 1760 (C=O, acetate), 1675 (C=O, enone system), 1660 (C=O, tertiary unsaturated amide), 1620, 1610 (C=O); ^{1}Hmr: δ 1.83 (3H, s, C_{9b}-CH_3), 2.16 (3H, s, C_6-CH_3), 2.32 (3H, s, C_7-$OCOCH_3$), 2.50 (3H, s, C_{11}-

N—$COCH_3$), 2.54 (3H, s, C_{11}-CH_3), 6.02 (1H, s, C_4-H), 6.76 ppm (1H, s, C_8-H); ms: *m/e* 383 (M^+), 341, 299, 284 (base peak), 260, 256, 218, 190, 44, 43. *Anal.* calcd. for $C_{20}H_{17}O_7N$: C 62.66, H 4.47, N 3.65; found: C 62.46, H 4.60, N 3.61. High resolution molecular weight determination calcd.: 383.100; found: 383.098; cd: λ_{max} ($\Delta\varepsilon$) 328 (+17.02), 265 (−7.10), 225 (−16.41).

*Fraction II. (+)-N-Acetyl[1,2]oxazocinoisousnic Acid Acetate (**8**) (N-Acetyl-8-acetoxy-9-acetyl-3a,4,10b,11-tetrahydro-3,7,10bα-trimethyl-4,11-dioxo-4,5-dihydro[1,2]-oxazocino[4,5,6,7,8-a,m,l,k]dibenzofuran)*

Colorless foam that could not be induced to crystallize (83.2 mg, 0.195 mmol; 6%); $[\alpha]_D^{26}$ (CH_3CN) +235° (*c* 0.051); uv: λ_{max} (log ε) 385 (3.18), 310 (3.79), 277 (3.68), 241 (4.13), 227 (4.20); ir: ν_{max} 1775 (C=O, acetate), 1690 (C=O, aromatic acetyl), 1670 (C=O, enone system), 1660 (C=O, tertiary amide), 1610, 1600 (C=C); ^{1}Hmr: δ 1.85 (3H, s, C_{9b}-CH_3), 2.16 (3H, s, C_6-CH_3), 2.33 (3H, s, C_7-$OCOCH_3$), 2.45 (3H, s, C_8-$COCH_3$), 2.50 (3H, s, C_{11}-N—$COCH_3$), 2.55 (3H, s, C_{11}-CH_3), 5.90 ppm (1H, s, C_4-H); ms: *m/e* 425 (M^+), 383, 341, 326 (base peak), 308, 298, 284, 259, 217. *Anal.* calcd. for $C_{22}H_{19}O_8N \cdot H_2O$: C 59.59, H 4.77, N 3.16; found: C 60.00, H 4.39, N 3.00. High resolution molecular weight determination calcd. for $C_{22}H_{19}O_8N$: 425.111; found: 425.103.

*Fraction III. (+)-N-Acetyl-α-acetoxydesacetyl[1,2]-oxazocinoisousnic Acid Acetate (**9**) (N-Acetyl-5aα,8-diacetoxy-3a,4,5,5a,10b,11-hexahydro-3,7,10bα-trimethyl-4,11-dioxo-4,5-dihydro[1,2]oxazocino[4,5,6,7,8-a,m,l,k]-dibenzofuran)*

Colorless prismatic needles from methanol (67 mg, 0.151 mmol; 4.9%, mp 182–183°C; $[\alpha]_D^{26}$ (CH_3CN) +112° (*c* 0.08); uv: λ_{max} (log ε) 280 (3.42), 238 (4.02), 223 (4.28); ir: ν_{max} 1761 (C=O, acetates), 1695 (C=O, enone system), 1630 (C=C); ^{1}Hmr: 1.90 (3H, s, C_{9b}-CH_3), 1.95 (3H, s, C_6-CH_3), 2.04 (3H, s, C_{4a}-α$OCOCH_3$), 2.24 (3H, s, C_7-$OCOCH_3$), 2.38 (3H, s, C_{11}-N—$COCH_3$), 2.41 (3H, s, C_{11}-CH_3), 3.65 (2H, AB q, J = 18 Hz, C_4-H_2), 6.70 ppm (1H, s, C_8-H); ms: *m/e* 443 (M^+), 401, 359, 317 (base peak), 299, 284, 43. *Anal.* calcd. for $C_{22}H_{21}O_9N$: C 59.59, H 4.77, N 3.16; found: C 59.75, H 4.64, N 2.99. High resolution molecular weight determination calcd.: 443.129; found: 443.129.

*Base Hydrolysis of (+)-N-Acetyl-[1,2]oxazocinoisousnic Acid Acetate (7). Formation of (+)-2H-[1,2]Oxazocino-isousnic acid (**10**) (9-Acetyl-8-hydroxy-3a,4,10b,11-tetrahydro-3,7,10bα-trimethyl-4,11-dioxo-2H-4,5-dihydro[1,2]-oxazocino[4,5,6,7,8-a,m,l,k]dibenzofuran)*

A solution of (+)-*N*-acetyl-[1,2]oxazocinoisousnic acid acetate (**7**) (50 mg, 0.118 mmol) in tetrahydrofuran (2 ml) was treated with freshly prepared 0.8% aqueous sodium hydroxide (10 ml) and stirred at room temperature under a nitrogen atmosphere for 40 min. The cold reaction was acidified with 1 *N* hydrochloric acid, extracted with ethyl acetate (2 × 15 ml), and the combined extracts washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure to afford a colorless glass (42.2 mg). Purification by preparative chromatography (silica gel – oxalic acid, solvent system *A*) produced colorless crystals from ethyl acetate of (+)-2*H*-[1,2]oxazocinoisousnic acid (**10**) (6.7 mg, 0.0196 mmol; 17%), mp 170–172°C; mixture mp with (+)-2*H*-[1,2]oxazocinousnic acid (**3**), 125–157°C; $[\alpha]_D^{26}$ (CH_3CN) +357° (*c* 0.014); uv: λ_{max} (log ε) 325 (3.50), 281 (4.24), 233 (4.43); ir (Nujol): ν_{max} 3200–2900 (OH, chelated), 1655 (C=O, diketoenamine system), 1625 (C=O, chelated aromatic acetyl grouping; C=C, enol ether, aromatic ring); ^{1}Hmr δ 1.82 (3H, s, C_{9b}-CH_3), 2.15 (3H, s, C_6-CH_3), 2.58 (3H, s, C_{11}-CH_3), 2.75 (3H, s, C_8-$COCH_3$), 6.01 (1H, s, C_4-H), 7.45 (1H, br, C_{11}-N—H), 13.63 ppm (1H, s, C_7-OH); ms: *m/e* 341 (M^+), 326 (M − 15, base peak), 308, 298, 280, 260, 232, 217. *Anal.* calcd. for $C_{18}H_{15}O_6N$: C 63.34, H 4.43, N 4.10; found: C 63.37, H 4.39, N 3.90. High resolution molecular weight determination: calcd.: 341.090; found: 341.088.

*Reductive Ring Opening and Base Hydrolysis of (+)-N-Acetyldesacetyl-[1,2]oxazocinoisousnic Acid Acetate (7). Preparation of (+)-8-Desacetylisousnic acid (**11**)*

A solution of (+)-*N*-acetyl-[1,2]oxazocinoisousnic acid acetate (**7**) (325 mg, 0.848 mmol) in absolute ethyl alcohol (50 ml) was hydrogenated over platinum oxide (50 mg) at room temperature and atmospheric pressure. After the absorption of 1 mol equiv. of hydrogen (20.7 ml at 25°C) the reaction mixture was filtered through Celite to eliminate the catalyst and the solvent evaporated under reduced pressure. The residue was dissolved in tetrahydrofuran (2 ml), treated with freshly prepared 1 *N* sodium hydroxide (20 ml), and stirred at room temperature under a nitrogen atmosphere for 1 h. The resulting deep green solution was cooled in an ice bath, acidified with 1 *N* hydrochloric acid, and extracted with ethyl acetate (3 × 20 ml). The combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure to produce a yellow foam (245.8 mg), which upon purification by column chromatography on Macherey-Nagel silica gel (20 g) afforded pure (+)-8-desacetylisousnic acid (**11**) (205 mg, 0.678 mmol; 80%), bright yellow small needles from chloroform – petroleum ether (30–60°C), mp 208–209°C (melts partially at 181–183°C and resolidifies as long prismatic needles); mixture mp with authentic (+)-8-desacetylisousnic acid, 208–210°C. All other spectroscopic and chromatographic properties confirmed the identity of the two samples.

Studies in the usnic acid series. V.[1] The base catalyzed usnic acid – isousnic acid rearrangement. Part III. (−)-Usnic acid isomethoxide monoacetate

JAMES P. KUTNEY AND IGNACIO H. SANCHEZ

Department of Chemistry, University of British Columbia, 2075 Wesbrook Place, Vancouver, B.C., Canada V6T 1W5

Received September 30, 1976

JAMES P. KUTNEY and IGNACIO H. SANCHEZ. Can. J. Chem. **55**, 1079 (1977).

Further studies on the base catalyzed usnic acid – isousnic acid rearrangement process clarify the situation concerning (−)-usnic acid isomethoxide monoacetate (**7**). This substance is now shown to be a mixture of the two possible C_{4a} epimers. These and previous data allow a mechanism to be proposed for this interesting rearrangement.

JAMES P. KUTNEY et IGNACIO H. SANCHEZ. Can. J. Chem. **55**, 1079 (1977).

De nouvelles études sur les réarrangements, catalysés par les bases, de l'acide usnique en acide isousnique clarifient la situation concernant le monoacétate de l'isométhylate d'acide (−) usnique. On démontre maintenant que cette substance est un mélange des deux épimères possibles en C_{4a}. Ces données et d'autres publiées antérieurement permettent de proposer un mécanisme pour ce réarrangement intéressant.

[Traduit par le journal]

During the course of our synthetic studies in the usnic acid area (1, 9), we have recognized a novel base catalyzed rearrangement which allows an attractive synthetic pathway from the 'normal', or usnic acid series to the 'iso' or isousnic family of compounds. These studies could then be applied to our initial objective, an efficient synthesis of the naturally occurring lichen substance (+)-isousnic acid (**1**) (2, 3). The present work provides a further understanding of this rearrangement and, in particular, illustrates the effect of substitution at the C_{4a} position on the outcome of this base-catalyzed transformation.

Bearing in mind that the ring C β-triketone system characteristic of usnic acid requires protection against alkaline treatment, an ideally suited starting material for the present study is the isoxazole **2** (4). When this material was treated with 20% methanolic potassium hydroxide at 50°C, a mixture of the epimeric C_{4a}-β- and α-methoxy derivatives **3** and **4** was isolated in approximately 60% yield (relative ratio of **3**:**4** is 1:4). Table 1 shows a comparison of the ^{1}Hmr spectra of both compounds.

However, due to the relatively low yield obtained (4) in the preparation of the isoxazole **2**, it was decided to investigate other synthetic routes leading to C_{4a}-methoxy epimers such as **3** and **4**. In 1953, Takahashi (5) was able to prepare (−)-usnic acid isomethoxide monoacetate (**6**) by an acid-catalyzed methanol addition onto the C_4—C_{4a} double bond of (+)-usnic acid diacetate (**5**) (6) and further converted it into *N*-phenylpyrazole derivatives already possessing the desired substitution. Although the same workers (7) proposed that the splitting observed in the ^{1}Hmr spectrum of **6** was due to the exis-

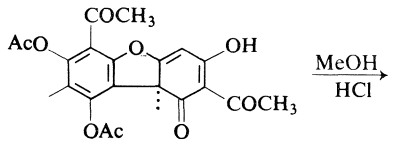
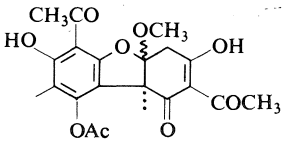
C_8-CH_3	2.06	2.06
C_{11}-CH_3	2.46	2.45
C_6-$COCH_3$	2.60	2.63
C_4-H_2	3.66 (J = 18 Hz)	3.18 (J = 18 Hz)
C_{4a}-αOCH_3	—	3.50
C_{4a}-βOCH_3	3.55	—
C_9-OH	8.61	6.61
C_7-OH	13.33	13.45

tence in solution of ring C keto-enol tautomers, we have now demonstrated that it is indeed caused by epimeric substitution at the C_{4a}-position. In fact, when its ^{1}Hmr spectrum (Table 2) is analyzed according to our present results, a 2:3 epimeric ratio results with the α-methoxy derivative (*i.e. cis*-B/C ring junction) being predominant.



5



6

By means of the following transformations such an epimeric ratio was then shown to remain constant and to be due exclusively to the configuration about the C_{4a}-position. The methoxy monoacetate **6**, whose preparation was greatly improved by carefully controlling the amount of acid present during the reaction, was first treated with hydroxylamine hydrochloride in dry pyridine followed by thermal cyclization of the oxime intermediate in methanolic solution to produce, in 98% yield, an isoxazole generally represented by structure **7**, mp 190–191°C. This material showed infrared absorptions at 1780 (phenolic acetate), 1700 (C_1-carbonyl group),

TABLE 2. Proton magnetic resonance spectrum of (−)-usnic acid isomethoxide monoacetate (**6**)

	δ (ppm)	
Functionality	α-OCH_3	β-OCH_3
C_{9b}-CH_3	1.68	1.79
C_8-CH_3	1.91	1.94
C_9-$OCOCH_3$	2.36	2.40
C_2-$COCH_3$	2.44	2.58
C_6-$COCH_3$	2.64	2.64
C_4-H_2	3.16 (J = 16 Hz)	3.09 (J = 16 Hz)

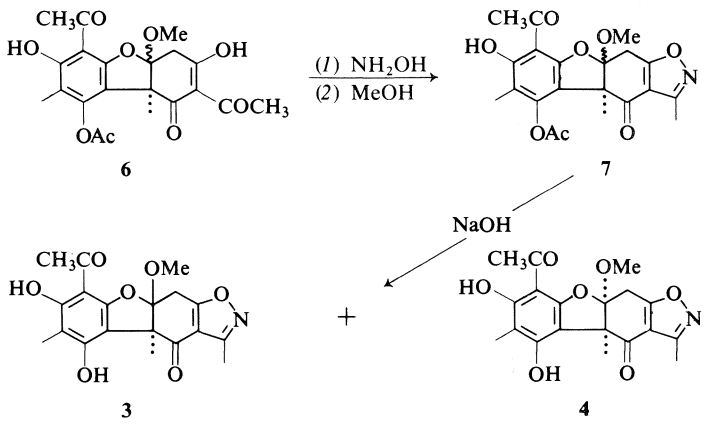
C_7-OH	13.22	13.25
C_3-OH	17.64	18.25

and 1640 cm^{-1} (chelated aromatic methyl ketone) while its ^{1}Hmr spectrum, unexpectedly, consisted of only one set of signals with the C_{4a}-methoxyl appearing at δ 3.50 and the C_4-methylene group protons as an AB quartet centered at δ 3.63 ppm (J = 18 Hz). Moreover, upon alkaline hydrolysis it produced a mixture which after purification provided the pure C_{4a}-β- and α-methoxyisoxazoles **3** and **4**, identical by all standard comparison techniques with the materials isolated directly from isoxazole **2** (*vide supra*). It was now clear that **7** in spite of its sharp melting point and spectroscopic characteristics was a mixture of the two possible C_{4a} epimers.

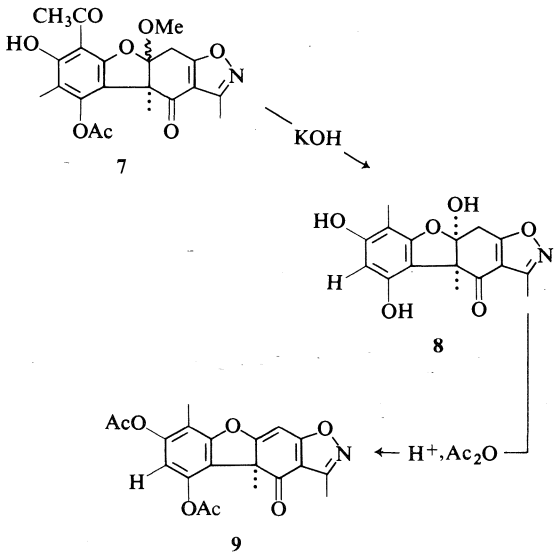
Surprisingly, strong alkaline treatment (KOH, 65°C) of **7** produced not only the expected aromatic deacylation but substitution of the angular methoxyl groups by hydroxyl with concomitant rearrangement. The reaction product, compound **8**, isolated in 86% yield, was shown to be identical with the C_{4a}-α-hydroxylated 'iso' series derivative previously isolated from the direct base treatment of isoxazole **2** (1). Conclusive evidence for the proposed rearrangement was obtained by dehydration (0.5% concentrated sulfuric acid in acetic anhydride) to the known (1) desacetyl diacetate **9**.

It is pertinent to note that alkaline cleavage of the present series does not lead to the formation of carboxylic acids via attack at the non-enolizable C_1 carbonyl group (1 ,9) indicating the competitive and mutually excluding nature of the rearrangement and normal cleavage processes. Thus based on all the information obtained thus far, it is possible to postulate a mechanism for the base-catalyzed usnic acid –



Relative ratio: 40:60

isousnic acid rearrangement, as exemplified for the isoxazole **2**.



Experimental

All details concerning spectral measurements, chromatographic separations, etc., are provided in the accompanying publication (9). The numbering system employed is that approved for the dibenzofuran series (8).

Methanolic Base Treatment of (+)-Isoxazolo[4,5-b]usnic Acid (2)

A suspension of (+)-isoxazolo[4,5-*b*]usnic acid (**2**) (100 mg, 0.293 mmol) in a solution of potassium hydroxide (1 g) in dry methanol (5 ml) was heated at 50°C (oil bath temperature) under a nitrogen atmosphere for 0.5 h. The reaction mixture was diluted with cold water (30 ml), acidified with 1 *N* hydrochloric acid, and extracted with ethyl acetate (3 × 10 ml). The combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure to afford a brown glass (102.8 mg) which upon purification by preparative layer chromatography (silica gel – oxalic acid plates, solvent *A*) produced the following pure products.

Fraction I. (+)-β-Methoxyisoxazolo[4,5-b]usnic Acid (3) (10-Acetyl-7,9-dihydroxy-1aβ-methoxy-1a,2,6,6a-tetrahydro-5,6aα,8-trimethyl-6-oxoisoxazolo[4,5-b]-dibenzofuran)

Colorless prisms from chloroform – petroleum ether (30–60°C) (12.5 mg, 0.033 mmol; 11%), mp 152–154°C; $[\alpha]_D^{26}$ (CH_3CN) +120° (*c* 0.0415); uv: λ_{max} (log ε) 333 (3.26), 283 (3.86), 228 (3.93); ir: ν_{max} 3500–3200 (OH, chelated), 1660 (C=O, enone system), 1620 (C=O, chelated aromatic acetyl; C=C); ^{1}Hmr: δ 1.75 (3H, s, C_{9b}-CH_3), 2.06 (3H, s, C_8-CH_3), 2.46 (3H, s, C_{11}-CH_3), 2.60 (3H, s, C_6-$COCH_3$), 3.55 (3H, s, C_{4a}-βOCH_3), 3.66 (2H, AB q, J = 18 Hz, C_4-H_2), 8.61 (1H, s, C_9-OH), 13.33 ppm (1H, s, C_7-OH); ms: *m/e* 373 (M^+, base peak), 313, 298, 285, 273, 263, 250, 235, 233, 232, 217, 161. *Anal.* Calcd. for $C_{19}H_{19}O_7N$: C 61.12, H 5.12, N 3.75. Found: C 61.25, H 5.20, N 3.71. High resolution molecular weight determination calcd.: 373.116; found: 373.117.

Fraction II. (+)-α-Methoxyisoxazolo[4,5-b]usnic Acid (4) (10-Acetyl-7,9-dihydroxy-1aα-methoxy-1a,2,6,6a-tetrahydro-5,6aα,8-trimethyl-6-oxoisoxazolo[4,5-b]dibenzofuran)

Colorless prisms from chloroform – petroleum ether (30–60°C) (51.7 mg, 0.138 mmol; 47%), mp 222–224°C; $[\alpha]_D^{26}$ (CH_3CN) +188° (*c* 0.03175); uv: λ_{max} (log ε) 328 (3.33), 283 (3.64), 228 (3.74); ir: ν_{max} 3640, 3500–3200 (OH), 1690 (C=O, enone system), 1620 (C=O chelated aromatic acetyl; C=C); ^{1}Hmr: δ 1.75 (3H, s, C_{9b}-CH_3), 2.06 (3H, s, C_8-CH_3), 2.45 (3H, s, C_{11}-CH_3), 2.63 (3H, s, C_6-$COCH_3$), 3.18 (2H, AB q, J = 18 Hz, C_4-H_2), 3.50 (3H, s, C_{4a}-αOCH_3), 6.61 (1H, b, C_9-OH), 13.45 ppm (1H, s, C_7-OH); ms: *m/e* 373 (M^+, base peak), 358, 140, 43. *Anal.* calcd. for $C_{19}H_{19}O_7N$: C 61.12, H 5.12, N 3.75; found: C 61.17, H 5.09, N 3.81. High resolution molecular weight determination calcd.: 373.116; found: 373.112. Relative ratio α-OCH_3:β-OCH_3 (4:1).

Preparation of (+)-Usnic Acid Diacetate (5) (7,9-Diacetoxy-2,6-diacetyl-1,9b-dihydro-8,9bα-dimethyl-3-hydroxy-1-oxodibenzofuran)

A solution of (+)-usnic acid (5.0 g, 14.534 mmol) in a

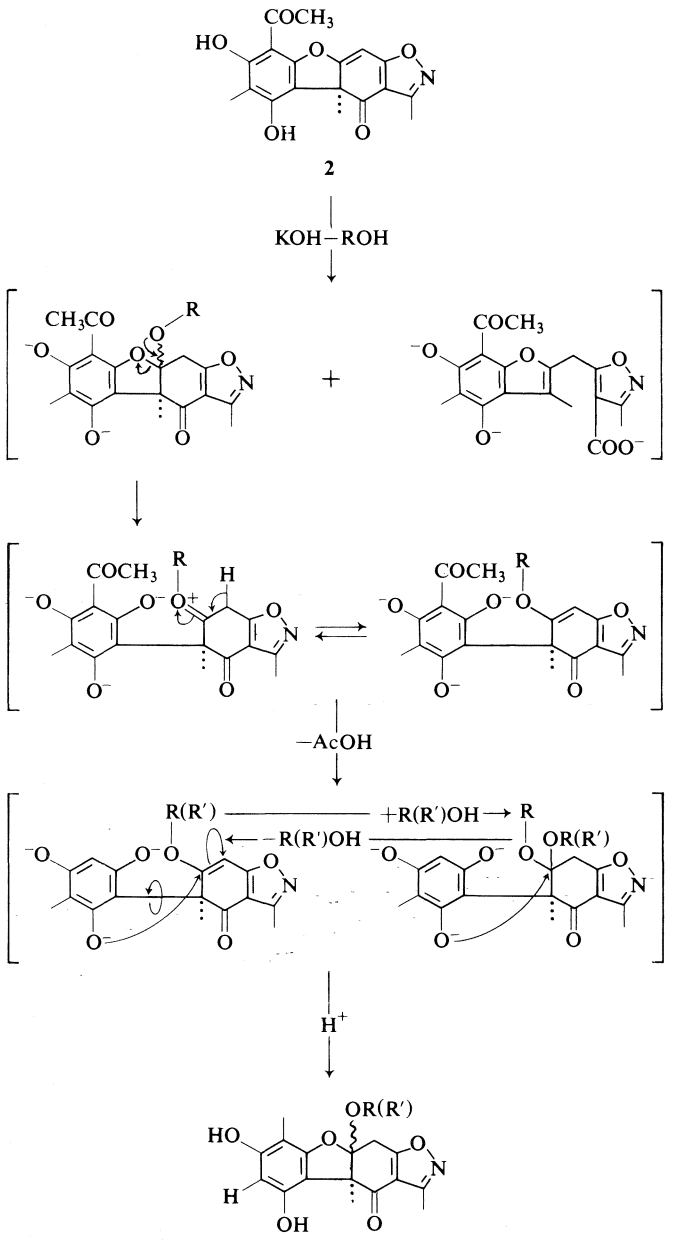


FIG. 1. Proposed mechanism for the base cleavage of (+)-isoxazolo[4,5-*b*]usnic acid (**2**).

mixture of 0.5% concentrated sulfuric acid in acetic anhydride (20 ml) was allowed to stand at room temperature overnight. The resulting dark red solution was poured onto crushed ice (50 g) and extracted with ethyl acetate (3 × 20 ml). The combined extracts were thoroughly washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure. The residue (6.32 g) was crystallized directly from ethyl alcohol–water to produce pure (+)-usnic acid diacetate (**5**) (6.10 g, 14.232 mmol; 98%), fine yellow needles, mp 202–204°C; $[\alpha]_D^{25}$ +250° (*c* 0.1095); uv: λ_{max} (log ε) 305 (3.95), 248 (4.23), 224 (4.41); ir: ν_{max} 3000–2500 (OH, chelated), 1770 (C=O, acetates), 1695 (C=O, enone system), 1660 (C=C), 1540 (C=O, chelated triketone system); ^{1}Hmr: δ 1.83 (3H, s, C_{9b}-CH_3), 2.00 (3H, s, C_8-CH_3), 2.35 (3H, s, C_9-$OCOCH_3$), 2.49 (3H, s, C_7-$OCOCH_3$), 2.56 (3H, s, C_6-$COCH_3$), 2.64 (3H, s, C_2-$COCH_3$), 5.95 (1H, s, C_4-H), 18.45 ppm (1H, s, C_3-OH); ms: *m/e* 428 (M^+), 386 (M − 42), 344, 329, 302, 275, 260, 223 (base peak), 217. *Anal.* calcd. for $C_{22}H_{20}O_9$:

C 61.67, H 4.70; found: C 61.55, H 4.73. High resolution molecular weight determination calcd.: 428.111; found: 428.110.

*Modified Preparation of (−)-Usnic Acid Isomethoxide Monoacetate (**6**) (9-Acetoxy-2,6-diacetyl-3,7-dihydroxy-8,9bα-dimethyl-4a-methoxy-9b,1,4,4a-tetrahydro-1-oxodibenzofuran)*

A suspension of (+)-usnic acid diacetate (**5**) (1.90 g, 4.439 mmol) in 10% methanolic hydrogen chloride (40 ml, prepared by reaction of acetyl chloride and anhydrous methanol) was heated to reflux under a nitrogen atmosphere for 1.5 h. The resulting deep red solution was concentrated under reduced pressure to approximately 10 ml, and after thorough cooling (ice-water bath) the sand-colored crystalline precipitate was removed by suction filtration. Two recrystallizations from methanol produced the pure (−)-usnic acid isomethoxide monoacetate (6) (1.532 g, 3.665 mmol; 82.5%), thin yellow plates, mp 167–168°C (lit. (5) mp 167–168°C); $[\alpha]_D^{25}$ (CH_3CN) −54° (*c* 0.0555) (lit. (5) $[\alpha]_D^{10}$ ($CHCl_3$) −83°); uv: λ_{max} (log ε) 346 (3.31), 267 (4.14); ir: ν_{max} 3200–2400 (OH, chelated), 1760 (C═O, acetate), 1670 (C═O, enone system), 1630 (C═O), 1620 (C═C), 1560 (C═O, chelated triketone system); ^{1}Hmr: α-OCH_3 isomer: δ 1.68 (3H, s, C_{9b}-CH_3), 1.91 (3H, s, C_8-CH_3), 2.36 (3H, s, C_9-$OCOCH_3$), 2.44 (3H, s, C_2-$COCH_3$), 2.64 (3H, s C_6-$COCH_3$), 3.16 (2H, AB q, J = 16 Hz, C_4-H_2), 3.47 (3H, s, C_{4a}-αOCH_3), 13.22 (1H, s, C_7-OH), 17.64 ppm (1H, s, C_3-OH); β-OCH_3 isomer: δ 1.79 (3H, s, C_{9b}-CH_3), 1.94 (3H, s, C_8-CH_3), 2.40 (3H, s, C_9-$OCOCH_3$), 2.58 (3H, s, C_2-$COCH_3$), 2.64 (3H, s, C_6-$COCH_3$), 3.09 (2H, AB q, J = 16 Hz, C_4-H_2), 3.42 (3H, s, C_{4a}-βOCH_3), 13.25 (1H, s, C_7-OH), 18.25 ppm (1H, s, C_3-OH); relative ratio α-OCH_3:β-OCH_3 3:2; ms: *m/e* 418 (M^+), 292 (base peak), 276, 250, 235, 234, 143, 43. *Anal.* calcd. for $C_{21}H_{22}O_9$: C 60.28, H 5.30; found: C 60.30, H 5.31. High resolution molecular weight determination calcd.: 418.126; found: 418.118.

*The reaction of (−)-Usnic Acid Isomethoxide Monoacetate (**6**) with Hydroxylamine Hydrochloride. Formation of (+)-Methoxyisoxazolo[4,5-b]usnic Acid Monoacetate (**7**) (9-Acetoxy-10-acetyl-7-hydroxy-1a-methoxy-1a,2,6,6a-tetrahydro-5,6aα,8-trimethyl-6-oxoisoxazolo[4,5-b]dibenzofuran)*

A solution of (−)-usnic acid isomethoxide monoacetate (**6**) (100 mg, 0.240 mmol) and hydroxylamine hydrochloride (25 mg, 0.360 mmol) in anhydrous pyridine (2 ml) was stirred at room temperature under a nitrogen atmosphere for 0.5 h. The reaction mixture was then diluted with cold water (10 ml), acidified with 1 *N* hydrochloric acid, and extracted with ethyl acetate (2 × 5 ml). The combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure. The residue (123 mg) was dissolved in dry methanol (5 ml) and heated to reflux under a nitrogen atmosphere for 0.75 h. Evaporation of the solvent under reduced pressure produced a pale yellow glass (111.4 mg) which upon purification by preparative chromatography (silica gel – oxalic acid plates, solvent system *A*) afforded (+)-methoxyisoxazolo[4,5-*b*]usnic acid monoacetate (**7**) (97.7 mg, 0.235 mmol; 98%), pale yellow prisms from methanol, mp 190–191°C; $[\alpha]_D^{26}$ (CH_3CN) +105° (*c* 0.05675), uv: λ_{max} (log ε) 346 (3.37), 266 (3.89); ir: ν_{max} 3400–2700 (OH, chelated), 1780 (C═O, acetate), 1700 (C═O, enone system), 1640 (C═O, chelated aromatic acetyl); ^{1}Hmr: δ 1.68 (3H, s, C_{9b}-CH_3), 2.3 (3H, s, C_8-CH_3), 2.43 (3H, s, C_{11}-CH_3), 2.61 (3H, s, C_6-$COCH_3$), 3.50 (3H, s, C_{4a}-OCH_3), 3.63 (2H, AB q, J = 18 Hz, C_4-H_2), 13.16 ppm (1H, s, C_7-OH); ms: *m/e* 415 (M^+, base peak), 373, 341, 313, 292, 285, 251, 236, 217, 43. *Anal.* calcd. for $C_{21}H_{21}O_8N$: C 60.71, H 5.09, N 3.37; found: C 60.91, H 5.11, N 3.30; High resolution molecular weight determination calcd.: 415.127; found: 415.130.

*Base Hydrolysis of (+)-Methoxyisoxazolo[4,5-b]usnic Acid Monoacetate (**7**)*

A solution of the (+)-methoxyisoxazolo compound (**7**) (95 mg, 0.229 mmol) in tetrahydrofuran (0.5 ml) was treated with freshly prepared 1 *N* sodium hydroxide (4 ml) and stirred at room temperature under a nitrogen atmosphere for 1 h. The cold reaction mixture was acidified with 1 *N* hydrochloric acid, extracted with ethyl acetate (2 × 2 ml), and the combined extracts washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure. Purification of the residue (85 mg) by preparative chromatography (silica gel – oxalic acid plates, solvent *A*) afforded three main components.

*Fraction I. (+)-β-Methoxyisoxazolo[4,5-b]usnic Acid (**3**)*

Colorless prisms from chloroform – petroleum ether (30–60°C) (14.0 mg, 0.037 mmol; 22.5%), mp 151–153°C; mixture mp with sample from previous experiments, 151–153°C. The other chromatographic and spectroscopic properties confirmed the identity of both products.

*Fraction II. (+)-Methoxyisoxazolo[4,5-b]usnic Acid Monoacetate (**7**)*

Pale yellow prisms from methanol–water (27.0 mg, 0.065 mmol; 28%), mp 190–192°C; mixture mp with the starting material, 190–192°C. Identity was shown as well by all other spectroscopic properties.

*Fraction III. (+)-α-Methoxyisoxazolo[4,5-b]usnic Acid (**4**)*

Colorless prisms from chloroform – petroleum ether (24.6 mg, 0.0662 mmol; 40%), mp 221–222°C; mixture mp with authentic material from a previous reaction, 220–222°C. Identical spectroscopic characteristics were shown by both samples.

*Base Cleavage of (+)-Methoxyisoxazolo[4,5-b]usnic Acid Monoacetate (**7**)*

To a suspension of (+)-methoxyisoxazolo[4,5-*b*]usnic acid monoacetate (**7**) (100 mg, 0.241 mmol) in methanol (0.5 ml) and water (1.5 ml) was added a solution of potassium hydroxide (1 g) in water (3 ml) and the resulting mixture heated at 65–67°C (oil bath temperature) under a nitrogen atmosphere for 40 min. The reaction mixture was diluted with cold distilled water (10 ml), acidified with 1 *N* hydrochloric acid, and extracted with ethyl acetate (3 × 10 ml). The combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure to produce a pale yellow glass (81 mg). Purification by preparative chromatography (silica gel – oxalic acid plates, petroleum ether – acetone (3:2)) yielded one main component.

*Fraction I. (+)-α-Hydroxydesacetylisoxazolo[4,5-b]-isousnic Acid (**8**)*

Colorless microcrystals from chloroform (65.8 mg,

0.207 mmol; 86%) mp 223–225°C; mixture mp with authentic (+)-α-Hydroxydesacetylisoxazolo[4,5-*b*]-isousnic acid from previous experiments, 222–224°C; $[\alpha]_D^{26}$ (CH_3CN) +304° (*c* 0.1295); uv: λ_{max} (log ε) 286 (2.98), 262 (3.18), 218 (3.90); ir: ν_{max} 3600–3100 (OH, chelated), 1690 (C=O, enone system), 1640, 1600 (C=C); ^{1}Hmr: ($CDCl_3$–DMSO-d_6): δ 1.93 (6H, s, C_{9b}-CH_3 and C_6-CH_3), 2.40 (3H, s, C_{11}-CH_3), 3.08 (2H, AB q, J = 18 Hz, C_4-H_2), 6.09 (1H, s, C_8-H), 6.67 (1H, br, C_{4a}-αOH), 8.28 (1H, br, C_7-OH), 8.50 ppm (1H, br, C_9-OH); ms: *m/e* 317 (M^+, base peak), 275, 260, 246, 219, 194, 178. *Anal.* calcd. for $C_{16}H_{15}O_6N$: C 60.56, H 4.77, N 4.41; found: C 60.59, H 4.75, N 4.39. High resolution molecular weight determination calcd.: 317.090; found: 317.088.

*Acid-catalyzed Dehydration of (+)-α-Hydroxydesacetylisoxazolo[4,5-b]isousnic Acid (**8**)*

A solution of the (+)-α-hydroxy derivative (**8**) (20 mg, 0.0631 mmol) in 0.5% concentrated sulfuric acid in acetic anhydride (1 ml) was heated at 55°C (oil bath temperature) under a nitrogen atmosphere for 1 h. The reaction mixture was then poured onto crushed ice (5 g), extracted with ethyl acetate (2 × 3 ml), and the combined extracts washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure. The residue was purified by preparative layer chromatography (silica gel plates, solvent *B*) to produce (+)-desacetylisoxazolo-[4,5-*b*]isousnic acid diacetate (**9**) (12 mg, 0.0319 mmol; 50.5%) colorless prisms from chloroform–methanol, mp 148–150°C; mixture mp with authentic (+)-desacetylisoxazolo[4,5-*b*]isousnic acid diacetate, 147–149°C; $[\alpha]_D^{26}$ (CH_3CN) +252° (*c* 0.0325); uv: λ_{max} (log ε) 297 (3.34), 246 (3.70), 216 (4.19); ir: ν_{max} 1775 (C=O, acetates), 1670 (C=O, enone system), 1620, 1600 (C=C); ^{1}Hmr: δ 1.83 (3H, s, C_{9b}-CH_3), 2.17 (3H, s, C_6-CH_3), 2.32 (3H, s, C_7-$OCOCH_3$), 2.50 (3H, s, C_9-$OCOCH_3$), 2.55 (3H, s, C_{11}-CH_3), 6.03 (1H, s, C_4-H), 6.78 ppm (1H, s, C_8-H); ms: *m/e* 383 (M^+), 341, 325, 299, 284 (base peak), 256, 220, 190, 43. High resolution molecular weight determination: Calcd. for $C_{20}H_{17}O_7N$: 383.100; found: 383.104.

Studies in the usnic acid series. VI.[1] The preparation of some ether derivatives of (+)-usnic acid

JAMES P. KUTNEY AND IGNACIO H. SANCHEZ

Department of Chemistry, University of British Columbia, 2075 Wesbrook Place, Vancouver, B.C., Canada V6T 1W5

Received October 7, 1976

JAMES P. KUTNEY and IGNACIO H. SANCHEZ. Can. J. Chem. **55**, 1085 (1977).

Studies involving the selective *O*-alkylation of (+)-usnic acid (**1**) have provided high yielding methods for the preparation of mono- and diether derivatives of **1**. With appropriate selection of conditions, either 7- or 9-*O*-alkyl derivatives can be prepared.

JAMES P. KUTNEY et IGNACIO H. SANCHEZ. Can. J. Chem. **55**, 1085 (1977).

Des études impliquant une *O*-alkylation sélective de l'acide (+)-usnique (**1**) fournissent des méthodes, avec de bons rendements, permettant de préparer des dérivés mono- et diéther de **1**. Utilisant des conditions expérimentales appropriées, on peut préparer soit les dérivés 7- ou 9-*O*-alkylés.

[Traduit par le journal]

During investigations (1–5) leading to the synthesis of various biodegradation products of (+)-usnic acid (**1**),[2] it became essential to prepare a series of deacylated derivatives of the 'normal' usnic acid family. The extremely facile rearrangement of the usnic (normal) to the isousnic ('iso') series under a variety of experimental conditions prompted us to study the preparation of suitable ether derivatives which hopefully would prevent such transformations.

An examination of previous work in this area (6–8) showed that the observed products obtained in alkylation studies arise from predominant *C*-alkylation on the aromatic ring A, and Takahashi and co-workers (9–13) were able to demonstrate the generality of the reaction by preparing, under similar conditions, a variety of *C*-alkylated derivatives including (+)-methylusnic acid (**2**) and (+)-methyldihydrousnic acid (**3**). However, it was Bertilsson and Wachtmeister (14) who first prepared, in very low yield, the ether derivative, (+)-7-*O*-methylusnic acid (**4**), by prolonged treatment with excess methyl iodide and potassium carbonate in refluxing acetone. Although the same workers were unable to prepare the corresponding diether derivative, they showed (15) that reaction of **1** with ethereal diazomethane produces, instead, the tetracyclic furan derivative **5** in low yield.

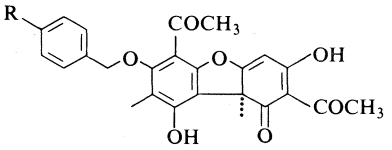
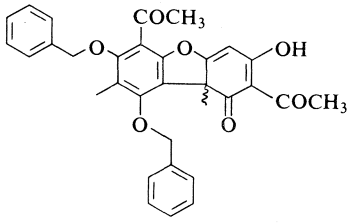
C_9-OH	—	10.78	—	10.81	—	—
C_3-OH	18.80	18.80	17.99	18.82	18.15	18.00

However, in the light of the present knowledge (16–19) on the alkylation of ambident anions, we decided to investigate new high yielding methods, suitable for large scale, of preparing mono- and diether derivatives of usnic acid. Thus, compound **1** was treated with tetramethylammonium hydroxide pentahydrate (20) in dry hexamethylphosphoramide (HMPA) (21, 22) at 0° C, and the resulting phenoxide ion alkylated with benzyl bromide to produce the crystalline (+)-7-*O*-benzylusnic acid (**6**) in 75% yield. The presence of the benzyl group was readily evident from the ^{1}Hmr spectrum (singlet at δ 4.86 ppm). A minor component, isolated in 19% yield, (overall 94% yield of *O*-alkylated products), proved to be the racemic (±)-7,9-di-*O*-benzylusnic acid (**7**), yellow crystals, mp 145–146° C, which in its ^{1}Hmr spectrum showed the methylene groups of the C_7- and C_9-ethers at δ 4.94 (s) and 5.36 ppm (AB q, J = 10 Hz), respectively. This last result is in complete agreement with previous observations on the relative ease of racemization of 7,9-disubstituted usnic acid derivatives (14, 23). Moreover, the determination of the site of alkylation can be easily deduced from the characteristic chemical shift of the remaining functions in the molecule (*i.e.* aromatic acetyl, phenolic and/or enolic hydroxyls, etc.). Table 1 presents a summary of the observed chemical shifts for the various ether derivatives prepared.

The further application of our experimental procedure was evaluated by the alkylation of (+)-usnic acid (**1**) with *p*-bromobenzyl bromide. Thus, (+)-7-*O*-*p*-bromobenzylusnic acid (**8**), mp 122–123° C, was isolated in 82% yield, and there appears little doubt that under the reaction conditions developed ($(CH_3)_4\overset{+}{N}\overset{-}{O}H$, HMPA), predominant *mono-O*-alkylation at the 7-position can be easily achieved.

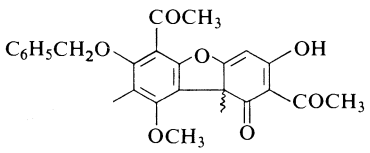


6 R = H
8 R = Br

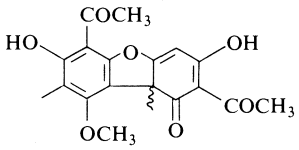


7

Although only low yields of diether derivatives have been achieved directly with the above method, we found that somewhat more vigorous conditions (*i.e.* sodium hydride in dry tetrahydrofuran at 60° C) produce good yields of di-*O*-alkylated materials. A combination of these procedures provides an excellent approach for the preparation of 'mixed' derivatives. Thus when the monobenzyl ether **6** was alkylated under the latter conditions with dimethyl sulfate, a 72% yield of (±)-7-*O*-benzyl-9-*O*-methylusnic acid (**9**) was obtained. This compound showed the methylene protons of the benzyl group at δ 4.89



9



10

ppm (s) and the C_9-methoxyl as a sharp signal at δ 4.06 ppm in the ^{1}Hmr spectrum.

Moreover, pure 9-*O*-alkyl derivatives can be easily prepared from the corresponding 'mixed' diether derivative by selective debenzylation employing an excess of trifluoroacetic acid (TFA) in dichloromethane at room temperature (24, 25). In this manner, a yield of over 90% of (±)-9-*O*-methylusnic acid (**10**) was obtained.

An interesting relationship was also observed from the corresponding ultraviolet spectra, which show absorption maxima characteristic for each series regardless of the nature of the alkyl residue (Table 2).

On the other hand, *O*-alkylation of ring C protected usnic acid derivatives (*i.e.* isoxazoles) presents difficulties due to the higher base sensitivity of the isoxazole system (2–5). However, as a satisfactory complement to our previous methods, we have found that predominant *O*-alkylation of isoxazole derivatives can be achieved by the use of methyl iodide – silver oxide in chloroform (26, 27). In this way the isoxazole **11** was converted in 71% yield into the oily dimethyl ether **12** with complete retention of optical activity. These *O*-methyl substituents were observed as sharp singlets at δ 3.74 and 4.02 ppm, respectively, for the 7- and 9-positions. A minor product, isolated in 16% yield, resulted from di-*C*-alkylation on the aromatic ring A, and on the basis of spectroscopic evidence has been assigned structure **13**. Similar di-*C*-alkylated systems have been obtained (28, 29) by the nuclear methylation of phloroacetophenone under similar conditions. In conclusion we must indicate that the latter method is not directly applicable to (+)-usnic acid (**1**) itself. However, since all three methods seem to complement each other very adequately, the solutions to obtaining the required *O*-alkylated derivatives in the usnic acid series are now available.

TABLE 2. The ultraviolet absorption maxima for ether derivatives of (+)-usnic acid (**1**): λ_{max} (CH_3OH) and log ε in parentheses

6	8	7	9	10

Experimental

Melting points were determined on a Kofler block and are uncorrected.

Ultraviolet (uv) spectra were recorded on a Cary 15 spectrophotometer in methanol solution (unless otherwise noted). The wavelength of the absorption maxima are reported in nanometres (nm).

Infrared (ir) spectra were measured routinely on a Perkin-Elmer model 710 spectrophotometer. Analytical or comparison spectra were recorded on a Perkin-Elmer model 457 spectrophotometer using matched cells with a cell path of 0.2 mm in chloroform solution. Calibration was achieved using the 1601 cm^{-1} absorption band of polystyrene. The absorption maxima are quoted in wave numbers (cm^{-1}).

Proton magnetic resonance (^{1}Hmr) spectra were measured in deuterochloroform ($CDCl_3$) solution (unless otherwise indicated) at room temperature. Routine spectra were recorded at 60 MHz on a Varian T-60 spectrometer, and analytical or comparison spectra at 100 MHz on either a Varian HA-100 or a Varian XL-100 spectrometer. Line positions are given in the δ (ppm) scale using

tetramethylsilane (TMS) as internal standard. The integrated peak areas, multiplicity, and proton assignments are indicated in parentheses.

Low resolution mass (ms) spectra were determined on either an AEI-MS-902 or an Atlas CH-4B mass spectrometer, with high resolution mass spectra being recorded exclusively on an AEI-MS-902 mass spectrometer.

Circular dichroism (cd) spectra were obtained on a Jasco model J-20 spectropolarimeter in methanol solution (unless otherwise indicated). The wavelength of the absorption maxima is reported in nanometres (nm). The differential molar extinction coefficient ($\Delta\varepsilon$) and the sign of the observed Cotton effect are indicated in parentheses.

Optical rotations ($[\alpha]_D$) were measured on a Perkin-Elmer model 141 polarimeter at the sodium D line in chloroform solution (unless otherwise noted) using cells with a 0.1 dm path.

Microanalyses were performed by Mr. P. Borda of the Microanalytical Laboratory, University of British Columbia.

Merck silica gel G (acc. to Stahl) impregnated with oxalic acid (2%) and with 2% fluorescent indicator added, was used as adsorbent for thin layer chromatography (tlc), unless otherwise noted. The tlc plates were activated in an oven at 90°C for 4 h before use. For qualitative chromatography layers of 0.3 mm thickness were used and the spots were visualized by viewing under ultraviolet (uv) light or spraying with a 1% ethanolic ferric chloride solution. For preparative (plc) chromatography large (20 × 20 and 20 × 60 cm) plates with a thicker layer (0.7 mm) were used. The developing systems were *A*, petroleum ether (30–60°C) – acetone (4:1), and *B*, chloroform – ethyl acetate (3:2), unless otherwise indicated.

Column chromatography was performed on either Mackerey-Nagel (0.2–0.5 mm grain size) or Merck 60 (0.063–0.2 mm grain size) silica gel.

The usnic acid utilized throughout the course of this study was obtained from Koch-Light Laboratories, England, as the optically active dextrorotatory isomer, (+)-usnic acid, isolated from lichen sources *Usnea barbata*).

The numbering system employed is that approved for the dibenzofuran series (30).

*Reaction of (+)-Usnic Acid (**1**) with Benzyl Bromide in Hexamethylphosphoramide (HMPA)*

A suspension of (+)-usnic acid (**1**) (2.0 g, 5.813 mmol) and tetramethylammonium hydroxide pentahydrate (3.46 g, 19.116 mmol) in dry hexamethylphosphoramide (60 ml, freshly distilled from lithium aluminum hydride) was stirred at 0°C under a nitrogen atmosphere for 1 h. The dark green solution was then treated with benzyl bromide (3.14 g, 18.362 mmol) and stirring continued at 0°C for 2 h. The resulting suspension was carefully poured into cold distilled water (200 ml) and extracted once with light petroleum ether (50 ml) to eliminate the excess alkylating agent. The aqueous phase was acidified with 1 *N* hydrochloric acid, extracted with ethyl acetate (4 × 100 ml), and the combined extracts were washed thoroughly with water (5 × 50 ml), dried over anhydrous sodium sulfate, and evaporated under reduced pressure to produce a yellow foam (2.748 g). Purification by column chromatography on Macherey-Nagel silica gel (200 g) afforded the following products.

*Fraction I. Recovered (+)-Usnic Acid (**1**)*

Yellow needles from chloroform (218.4 mg, 0.634 mmol; 10%), mp 202–203°C; mixture mp with (+)-usnic acid, 202–204°C. The sample showed superimposable ^{1}Hmr, ir, and uv spectra with those of the starting material.

*Fraction II. (+)-7-O-Benzylusnic Acid (**6**) (7-Benzyloxy-2,6-diacetyl-1,9b-dihydro-3,9-dihydroxy-8,9bα-dimethyl-1-oxodibenzofuran)*

Yellow prisms from acetone–methanol (1.6815 g, 3.874 mmol; 74%), mp 131–133°C; $[\alpha]_D^{26}$ (CH_3CN) +208° (*c* 0.0767); uv: λ_{max} (log ε) 346 (2.99), 266 (4.03), 239 (4.01); ir: ν_{max} 3400–2500 (OH, chelated), 1672 (C=O, aromatic acetyl, enone system), 1600 (C=C), 1540 (C=O, chelated triketone system); ^{1}Hmr: δ 1.76 (3H, s, C_{9b}-CH_3), 2.18 (3H, s, C_8-CH_3), 2.55 (3H, s, C_6-$COCH_3$), 2.64 (3H, s, C_2-$COCH_3$), 4.86 (2H, s, C_7-O—CH_2—C_6H_5), 5.95 (1H, s, C_4-H), 7.41 (5H, s, C_6H_5), 10.78 (1H, s, C_9-OH), 18.80 ppm (1H, s, C_3-OH); ms: *m/e* 434 (M^+), 416, 392, 343, 323, 308, 301, 281, 273, 260, 259, 241, 233, 215, 203, 90 (base peak). *Anal.* calcd. for $C_{25}H_{22}O_7$: C 69.12, H 5.10; found: C 69.08, H 5.06. High resolution molecular weight determination calcd.: 434.136; found: 434.132.

*Fraction III. (±)-7,9-Di-O-benzylusnic Acid (**7**) (2,6-Diacetyl-7,9-dibenzyloxy-1,9b-dihydro-8,9b-dimethyl-3-hydroxy-1-oxodibenzofuran)*

Yellow prisms from acetone – ethyl alcohol (0.505 g, 0.964 mmol; 18%), mp 145–146°C; $[\alpha]_D^{26}$ (CH_3CN) 0° (*c* 0.0272); uv: λ_{max} (log ε) 368 (3.19), 325 (3.56), 259 (4.08), 226 (4.29); ir: ν_{max} 2800–2400 (OH, chelated), 1680 (C=O, aromatic acetyl, enone system), 1610, 1590 (C=C, aromatic rings), 1560 (C=O, chelated triketone system); ^{1}Hmr: δ 1.82 (3H, s, C_{9b}-CH_3), 2.27 (3H, s, C_8-CH_3), 2.50 (3H, s, C_6-$COCH_3$), 2.58 (3H, s, C_2-$COCH_3$), 4.94 (2H, s, C_7-O—CH_2—C_6H_5), 5.36 (2H, AB q, J = 10 Hz, C_9-O—CH_2—C_6H_5), 5.86 (1H, s, C_4-H), 7.20–7.60 (10H, br, 2 × C_6H_5), 17.99 ppm (1H, s, C_3-OH); ms: *m/e* 524 (M^+), 480, 433 (base peak), 432, 390, 350, 343, 341, 323, 307, 259, 233, 231, 181, 90. *Anal.* calcd. for $C_{32}H_{28}O_7$: C 73.27, H 5.38; found: C 73.06, H 5.52, High resolution molecular weight determination calcd.: 524.183; found: 524.183.

*Preparation of (+)-7-O-p-Bromobenzylusnic Acid (**8**) (7-p-Bromobenzyloxy-2,6-diacetyl-1,9b-dihydro-3,9-dihydroxy-8,9bα-dimethyl-1-oxodibenzofuran)*

A suspension of (+)-usnic acid (**1**) (200 mg, 0.582 mmol) and tetramethylammonium hydroxide pentahydrate (346 mg, 1.911 mmol) in dry hexamethylphosphoramide (10 ml) was stirred at room temperature under a nitrogen atmosphere for 0.5 h. To the resulting dark green suspension was added crystalline *p*-bromobenzyl bromide (160 mg, 0.640 mmol) and the reaction allowed to proceed at room temperature under nitrogen for 2 h. The reaction mixture was diluted with cold distilled water (40 ml), acidified with 1 *N* hydrochloric acid, and extracted with ethyl acetate (3 × 20 ml). The combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure. The resulting dark yellow residue (314 mg) was purified by column chromatography on Macherey-Nagel silica gel (30 g) to afford pure (+)-7-*O*-*p*-bromobenzylusnic acid (**8**) (245 mg, 0.476 mmol; 81%), pale yellow-green

plates from ethyl alcohol, mp 122–123°C; $[\alpha]_D^{26}$ (CH_3CN) +245° (*c* 0.061); uv: λ_{max} (log ε) 266 (4.19), 229 (4.36); ir: ν_{max} 3400–2500 (OH, chelated), 1670 (C═O, aromatic acetyl, enone system), 1620, 1600 (C═C), 1530 (C═O, chelated triketone system); ^{1}Hmr: δ 1.78 (3H, s, C_{9b}-CH_3), 2.18 (3H, s, C_8-CH_3), 2.56 (3H, s, C_6-$COCH_3$), 2.66 (3H, s, C_2-$COCH_3$), 4.86 (2H, s, C_7-O—CH_2—C_6H_4—Br), 5.99 (1H, s, C_4-H), 7.45 (4H, AB q, J = 8 Hz, —CH_2—C_6H_4—Br), 10.81 (1H, s, C_9-OH), 18.82 ppm (1H, s, C_3-OH); ms: *m/e* 514 (M^+), 512, 496, 494, 472, 470, 403, 401, 389, 387, 344, 343 (base peak), 301, 260, 259, 233, 231, 171, 159, 90, 43. *Anal.* calcd. for $C_{25}H_{21}O_7Br$: C 58.48, H 4.12, Br 15.56; found: C 58.42, H 4.18, Br 15.47. High resolution molecular weight determination calcd. for $C_{25}H_{21}O_7{}^{79}Br$: 512.052; calcd. for $C_{25}H_{21}O_7{}^{81}Br$: 514.045; found: 512.047, 514.045.

*Preparation of (±)-7-O-Benzyl-9-O-methylusnic acid (**9**) (7-Benzyloxy-2,6-diacetyl-1,9b-dihydro-8,9bα-dimethyl-3-hydroxy-9-methoxy-1-oxodibenzofuran)*

Sodium hydride emulsion (55%, 4.0 g, 91.666 mmol) was washed twice with distilled light petroleum ether (2 × 10 ml) and suspended in dry tetrahydrofuran (600 ml, freshly distilled from lithium aluminum hydride). Under a stream of nitrogen (±)-7-*O*-benzylusnic acid (**6**) (15.0 g, 34.562 mmol) in dry tetrahydrofuran (200 ml) was added dropwise over 45 min and the reaction mixture stirred at room temperature for 1 h. Dimethyl sulfate (8.70 g, 69.00 mmol) in dry tetrahydrofuran (20 ml) was added dropwise and the reaction mixture heated at 60–62°C under a nitrogen atmosphere for 2.75 h. The resulting dark brown solution was slowly poured into an ice–water mixture (2:1), acidified with 1 *N* hydrochloric acid, and extracted with ethyl acetate (3 × 500 ml). The combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure to produce a dark yellow foam (16.892 g), which upon purification on Merck silica gel (600 g), afforded pure (±)-7-*O*-benzyl-9-*O*-methylusnic acid (**9**) (11.22 g, 25.048 mmol; 72%), bright yellow prisms from acetone – ethyl alcohol, mp 112–113°C; $[\alpha]_D^{26}$ (CH_3CN) 0° (*c* 0.065); uv: λ_{max} (log ε) 370 (3.03), 320 (3.57), 259 (4.02), 226 (4.23); ir: ν_{max} 2500–2400 (OH, chelated), 1680 (C═O, aromatic acetyl), 1670 (C═O, enone system), 1600, 1580 (C═C), 1540 (C═O, chelated triketone system); ^{1}Hmr: δ 1.83 (3H, s, C_{9b}-CH_3), 2.25 (3H, s, C_8-CH_3), 2.54 (6H, s, C_2-$COCH_3$ and C_6-$COCH_3$), 4.06 (3H, s, C_9-OCH_3), 4.89 (2H, s, C_7-O—CH_2—C_6H_5), 5.83 (1H, s, C_4-*H*), 7.39 (5H, s, C_6H_5), 18.15 ppm (1H, s, C_3-O*H*); ms: *m/e* 448 (M^+), 406, 391, 387 (base peak), 322, 315, 295, 287, 273, 247, 231, 230, 215, 91. *Anal.* calcd. for $C_{26}H_{24}O_7$: C 69.63, H 5.39; found: C 69.87, H 5.58. High resolution molecular weight determination calcd.: 448.152, found: 448.152.

*The Debenzylation of (±)-7-O-Benzyl-9-O-methylusnic Acid (**9**). Isolation of (±)-9-O-Methylusnic Acid (**10**) (2,6-Diacetyl-1,9b-dihydro-3,7-dihydroxy-8,9bα-dimethyl-9-methoxy-1-oxodibenzofuran) — Experiment I*

A solution of (±)-7-*O*-benzyl-9-*O*-methylusnic acid (**9**) (50 mg, 0.111 mmol) in trifluoroacetic acid (0.5 ml) was stirred at room temperature under a nitrogen atmosphere for 20 min. Excess trifluoroacetic acid was evaporated under reduced pressure (water-bath temperature 40°C). The residue was redissolved in dry benzene (2 ml) and the solvent once more evaporated under reduced pressure to produce a glassy residue which was dissolved in ethyl acetate (10 ml), and the solution thoroughly washed with cold distilled water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure to afford a bright yellow crystalline residue (61.7 mg). Purification by preparative layer chromatography (silica gel – oxalic acid plates, solvent *A*) yielded pure (±)-9-*O*-methylusnic acid (**10**) (37.0 mg, 0.103 mmol; 92%), thick bright yellow prisms from acetone–hexane, mp 195–196°C (dec.); $[\alpha]_D^{26}$ (CH_3CN) 0° (*c* 0.103); uv: λ_{max} (log ε) 345 (3.56), 274 (4.13), 228 (4.24); ir: ν_{max} 3200–2700 (OH, chelated), 1680 (C═O, enone system), 1625 (C═O, chelated aromatic acetyl grouping), 1590 (C═C), 1560 (C═O, chelated triketone system); ^{1}Hmr: δ 1.86 (3H, s, C_{9b}-CH_3), 2.24 (3H, s, C_8-CH_3), 2.56 (3H, s, C_2-$COCH_3$), 2.74 (3H, s, C_6-$COCH_3$), 4.14 (3H, s, C_9-OCH_3), 5.91 (1H, s, C_4-*H*), 13.22 (1H, s, C_7-O*H*), 18.00 ppm (1H, s, C_3-O*H*); ms: *m/e* 358 (M^+), 343 (M − 15), 274, 247 (base peak), 246, 229. *Anal.* calcd. for $C_{19}H_{18}O_7$: C 63.68, H 5.06; found: C 63.65, H 5.06. High resolution molecular weight determination calcd.: 358.105. found: 358.104.

*The Debenzylation of (±)-7-O-Benzyl-9-O-methylusnic Acid (**9**) — Experiment II*

A solution of (±)-7-*O*-benzyl-9-*O*-methylusnic acid (**9**) (50 mg, 0.111 mmol) in dry dichloromethane (4 ml) was treated at room temperature under a nitrogen atmosphere with trifluoroacetic acid (128 mg, 1.122 mmol) and the reaction allowed to proceed with stirring for 3 h. The reaction mixture was then transferred to a separatory funnel, diluted with dichloromethane (4 ml), washed thoroughly with water, dried over anhydrous sodium sulfate, and evaporated under reduced pressure to produce a yellow glass, which upon direct crystallization from acetone–hexane produced pure (±)-9-*O*-methylusnic acid (**10**) (38.5 mg, 0.1075 mmol; 96%), mp 195–197°C; mixture mp with authentic material from previous experiments, 195–197°C. Chromatographic and spectroscopic characteristics were identical for both samples.

*Synthesis of (+)-7,9-Di-O-methylisoxazolo[4,5-b]usnic Acid (**12**) (10-Acetyl-6,6a-dihydro-7,9-dimethoxy-5,6aα,8-trimethyl-6-oxoisoxazolo[4,5-b]dibenzofuran)*

A solution of (+)-isoxazolo[4,5-*b*]usnic acid (**11**) (3.0 g, 8.797 mmol) in dry chloroform (150 ml) was treated with silver oxide (30 g, 129.6 mmol) and iodomethane (10 g, 70.422 mmol), and with mechanical stirring heated at 54–55°C (oil bath temperature) under a nitrogen atmosphere for 20 h. The solid material (salts) was removed by filtration through Celite, and the Celite cake washed with chloroform (2 × 25 ml). The combined filtrates were evaporated under reduced pressure to produce an orange foam (3.721 g). Purification by column chromatography on silica gel Merck (200 g) using 5% acetone in benzene produced the following pure compounds.

*Fraction I. (+)-7,9-Di-O-methylisoxazolo[4,5-b]usnic Acid (**12**)*

Yellow foam that could not be induced to crystallize (2.30 g, 6.233 mmol; 70%); $[\alpha]_D^{26}$ (CH_3CN) (*c* 0.05075);

On the construction of the C,D ring system of chasmanine by the photochemical method

K. WIESNER, I. H. SANCHEZ, K. S. ATWAL, AND S. F. LEE

Natural Products Research Center, University of New Brunswick, P.O. Box 4400, Fredericton, N.B., Canada E3B 5A3

Received October 20, 1976

K. WIESNER, I. H. SANCHEZ, K. S. ATWAL, and S. F. LEE. Can. J. Chem. **55**, 1091 (1977).

Two highly stereoselective syntheses of the methoxy ketal **18**, which had been previously transformed to the chasmanine model compound **IV** are described. Both these processes avoid the equilibration step **VII** ⇄ **VIII** which failed (with compounds **IX** ⇄ **X**) in the actual chasmanine synthesis. There is reason to believe that the second of these routes, remarkable by its brevity, will be applicable in the full chasmanine system.

K. WIESNER, I. H. SANCHEZ, K. S. ATWAL et S. F. LEE. Can. J. Chem. **55**, 1091 (1977).

On décrit deux synthèses hautement stéréosélectives du méthoxy acétal **18** qui a été transformé antérieurement dans le composé **IV**, modèle de la chasmanine. Les deux procédés évitent l'étape d'équilibration **VII** ⇄ **VIII** qui n'avait pas fonctionné (avec les composés **IX** ⇄ **X**) dans la synthèse réelle de la chasmanine. Il y a des raisons de croire que la deuxième de ces routes, remarquable par sa brièveté, pourra être applicable dans le système complet de la chasmanine.

[Traduit par le journal]

Introduction

Some time ago we have described a stereospecific conversion of the model compound **I** to the bromo derivative **II**. This material was then rearranged to **III** and functionalized to the ketone **IV** the structure of which was corroborated by X-ray crystallography (1). Recently we have finally reported (2) the total synthesis of the compound **V** which we hoped to transform by the above technique to the alkaloid chasmanine **VI**.

There was however in the sequence **I** → **II** a step which while perfectly satisfactory in the model series gave rise to some misgivings in the anticipated synthesis proper. It was the equilibration and separation of the epimeric α,β-unsaturated ketones **VII** and **VIII**.

It did not take long to ascertain that this operation in fact causes trouble with the fully functionalized system. Birch reduction, acetylation and acid treatment of the aromatic intermediate **V** yielded the anticipated compound **IX** without difficulty. However, the equilibration of this epimer with the desired epimer **X** could not be performed without some destruction of material and the separation of the two compounds turned out to be exceedingly difficult.

As soon as we realized that the step **IX** → **X** is bound to develop into an unacceptable bottleneck, it became clear that it was necessary to go 'back to the model'. It was our intention to set up the desired configuration (marked with arrow in formula **X**) by a series of irreversible stereospecific steps and thus to avoid the equilibration **IX** → **X**.

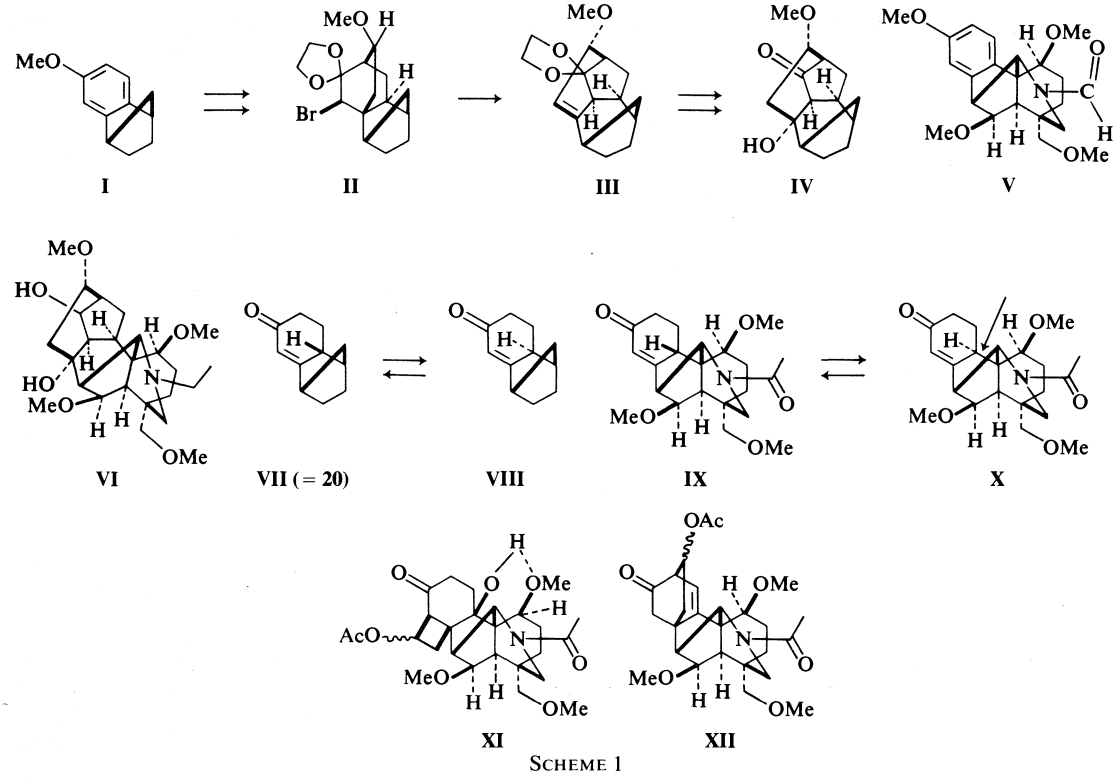
It is perhaps remarkable that both variants of this *detour* which we have worked out are *shorter* than the original route (1). This is primarily due to the operation of our photochemical addition rule (3) which requires that the diastereoisomers **IX** and **X** add photochemically olefins to the β and α face of the molecule respectively. More importantly, this development illustrates the process of refining the synthesis of polysubstituted polybridged compounds to the simplest possible variant by systematic switching between model work and synthesis proper.

Discussion

The starting point of the 'variant A' of our new process was the β,γ-unsaturated ketone **2** (Scheme 2) prepared by Birch reduction and mild acid treatment of the aromatic model compound **1** (1).[1]

Reduction of **2** with sodium borohydride

[1]All spectral data of all compounds are in agreement with the structures assigned and are recorded in the 'Experimental'. Only specially relevant data are presented also in the 'Discussion'.



SCHEME 1

yielded the unsaturated alcohol **3**. The overall yield of the oily material **3** from **1** was approximately 90%. Compound **3** was now transformed to the crystalline hydroxy α,β-unsaturated ketone **4** in a yield of 81% as follows (4). The unsaturated alcohol **3** was first transformed into an *exo*-epoxide by treatment with *m*-chloroperbenzoic acid in dichloromethane. This material was immediately oxidized to the corresponding ketone by the addition of tetramethyl piperidine hydrochloride and more *m*-chloroperbenzoic acid in the same solvent. The conversion to **4** was finally completed by treatment of the epoxy ketone with methanolic sodium methoxide.

The photoaddition of allene to compound **4** gave the crystalline adduct **5** in a yield of 87%. The configuration of this adduct, predictable by the addition rule (3), was confirmed by further transformations to the hemiacetal **8** and finally to the methoxy ketal **18**, an intermediate of our original synthesis (1).

Compound **5** was now converted quantitatively into the dimethyl ketal **6** and this material gave on ozonolysis, borohydride reduction, and acetylation the crystalline acetoxy ketone **7** in an overall yield of 72%. In this sequence the dimethyl ketal function was lost during the work-up of the final acetylation step. In this manner the unstable keto-cyclobutanol functionality which undergoes spontaneous retro aldol cleavage was never completely unmasked. If the acetylation step is omitted and the product of the ozonolysis and borohydride reduction is chromatographed on silica gel the extremely stable crystalline hemiacetal **8** which is useless for further elaboration is obtained in a yield of 84%.

Dehydration of the tertiary alcohol **7** with thionyl chloride and pyridine yielded the oily β,γ-unsaturated ketone **9** in a yield of 71%. A small amount (10%) of the crystalline chloro ketone **10** was also isolated. Compound **9** showed in the infrared (ir) spectrum peaks at 1755, 1715, and 1676 cm^{-1} for the acetate carbonyl, the six-membered ketone, and the double bond. The nuclear magnetic resonance spectrum (nmr) showed a quadruplet centered at $\tau = 4.43$ ppm which corresponded to the vinylic hydrogen.

Treatment of the unsaturated keto acetate **9**

with dilute methanolic potassium hydroxide caused hydrolysis of the acetate group, retro aldol cleavage of the unmasked keto-cyclobutanol functionality, and immediate aldol ring closure of the resulting unsaturated keto-aldehyde to the mixture of epimeric alcohols **11***a,b*. This spontaneous aldol condensation of the enolate ion ***b*** to the aldols **11***a,b* was surprising since we have previously noted (1) that the saturated enolate ***a*** does not aldolize and the aldol condensation of the saturated keto-aldehyde has to be driven by boron trifluoride and acetic anhydride. It may be that the double bond in **11***a,b* diminishes the twist of the condensed system, which is considerable in the saturated skeleton **13** or **14**. In any event, the discovery of this spontaneous ring closure is a great advantage in the anticipated use of the method with polymethoxylated derivatives in the synthesis proper.

Benzoylation of the aldols **11***a,b* yielded the crystalline mixture of benzoates **12***a* and **12***b* and the major isomer **12***a* was purified by crystallization. Compound **12***a* showed in the ir spectrum peaks at 1720 and 1670 cm^{-1} for the benzoate carbonyl and ketone and for the double bond; the nmr spectrum displayed a doublet at $\tau = 4.40$ ppm for the vinylic proton.

Hydrogenation of the epimeric mixture **12***a,b* in methanol with rhodium on alumina yielded the two readily separable crystalline hexahydrobenzoates **13** and **14** in a ratio 3.2:1. The configuration of **13** followed from its conversion to the known compound **18** (Scheme 2) which required an inversion of the alcohol function. Compound **18**, it will be recalled, was an intermediate of our first synthesis (1) and it was transformed to the ketone **IV** (Scheme 1) the structure of which was verified by X-ray crystallography. The configuration of compound **14** differs from that of compound **13** at the ring junction since it could not be transformed to **18** by the appropriate manipulation of the functional groups. Specifically, while compound **13** yielded the keto-ketal **17**, compound **14** was converted by an analogous manipulation of functional groups into a diastereoisomer of **17**.

Compounds **12***a* and **12***b* are difficult to separate and thus we have only investigated the hydrogenation of the mixture. Since it is clear that compound **13** results from the hydrogenation of **12***a* it is reasonable to assume that compound **14** is the hydrogenation product of **12***b* and that the shielding by the benzoate group controls the stereochemistry of the double bond hydrogenation. This assumption is thus the reason for the assignment of the complete configuration to the diastereoisomer **14**. (Only the complete configuration of **13** is rigorously proved by its conversion to the final product **18**.)

The keto-ester **13** was now converted into the crystalline ketal **15** and this material was saponified to the unstable alcohol **16***b* which was immediately oxidized to the oily but homogeneous keto ketal **17**.

Reduction of this last compound with sodium borohydride proceeded stereospecifically and quantitatively to yield the crystalline alcohol **16***a*. Finally methylation of **16***a* gave the known methoxy ketal **18** which was an intermediate in our first synthesis (1).

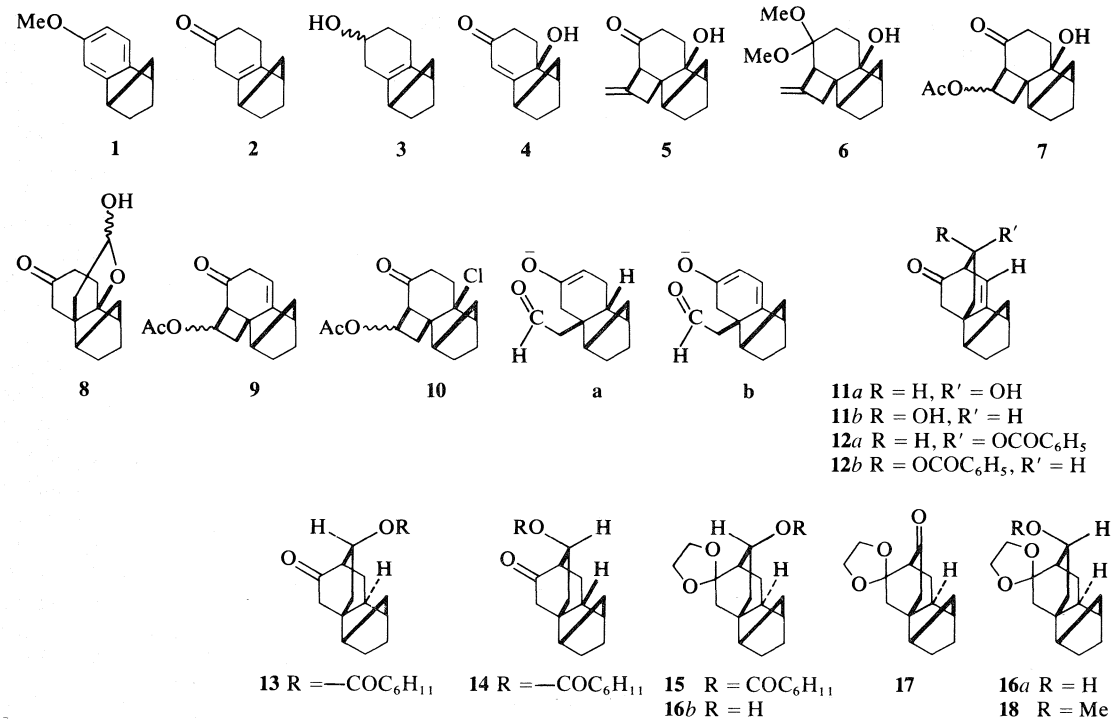
Thus we have reached our objective and devised a route which avoided the equilibration step **VII** → **VIII** and was in fact two steps shorter than the original synthesis. All steps were stereospecific except for **12***a,b* → **13** which was highly stereoselective (3.2:1).

We were in fact so pleased by this method that we have committed an error. We have overlooked that in compound **XI** (Scheme 1), the full fledged analogue of the model intermediate **7**, there is a very serious nonbonded interaction between the tertiary hydroxyl and the ring A methoxy group which might lead to a considerable change in reactivity.

Instead of proceeding with caution Dr. S. F. Lee who was in charge of the synthesis proper converted at the instigation of the senior author almost our entire supply of the aromatic compound **V** into the intermediate **XI**. The transformation **V** → **XI** proceeded exactly as in the model series in excellent yield. Compound **XI**, however, displayed a very sharp singlet at $\tau = 3.5$ ppm for the hydroxyl hydrogen (identified by deuteration) and it was completely resistant to dehydration although all the methods found in the literature were tried. For the second time this meant 'back to the model'.

Our objective now was not to find new methods for dehydrating the tertiary alcohol **7** (practically all methods worked with this model compound) but to discover an entirely new variant which would completely avoid the dehydration step.

Thus, we have discovered 'variant B' which is even simpler than the 'variant A' and most



SCHEME 2

important, it works in the real system. On previous occasions it has not been our custom to discuss the ups and downs of synthetic work in publications. In the present instance the lesson to be drawn from the switches between model and real system seems to justify an exception.

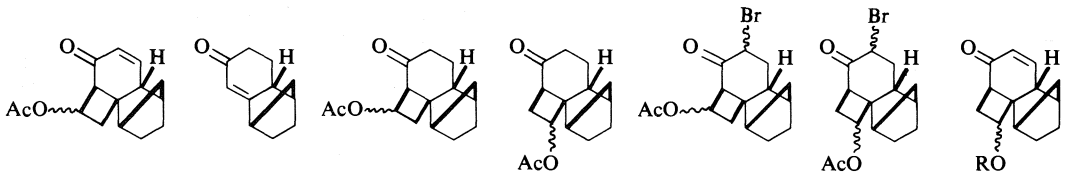
The basis of the second 'variant B' was the α,β-unsaturated ketone **19***a* (Scheme 3). We have first obtained this compound by treatment of the β,γ-unsaturated isomer **9** with hydrochloric acid in chloroform. The ir spectrum of **19***a* showed maxima at 1749 (acetate carbonyl), 1675 (conjugated ketone), and 1652 cm^{-1} (double bond). The nmr spectrum showed a quadruplet centered at $\tau = 3.27$ ppm for the vinylic hydrogen in the β-position and a doublet of narrow doublets at $\tau = 3.92$ ppm for the vinylic hydrogen α to the ketone. The maximum absorption in the ultraviolet (uv) of compound **19***a* was at 235 nm ($\log \varepsilon = 4.16$). It is clear that the conjugated ketone **19***a* and the β,γ-unsaturated ketone **9** should by saponification, dealdolization, and conjugate enolate ion formation give rise to the same species ***b*** (Scheme 2). If this species is indeed an intermediate in the conversion **9** → **11***a*,*b* the reaction **19***a* → **11***a*,*b* should proceed equally well. In fact compound **19***a* gave the same aldols **11***a*,*b* and benzoates **12***a*,*b* in a similar yield as compound **9**.

There is now a very facile way to obtain **19***a* from the readily available (1) compound **20**.[2] Photoaddition of vinyl acetate to the α,β-unsaturated ketone **20** gave a 91% yield of a mixture consisting of approximately equal quantities of the isomers **21***a* and **21***b*. The pure isomer **21***a* was obtained by crystallization of the oily mixture.

It is of course also possible to prepare **21***a* regiospecifically from the allene adduct of **20**. The vinyl acetate addition saves five steps as compared to this allene route and thus would be only moderately inferior in yield; we chose it in this model study because of its brevity. Bromination of **21***a* gave a quantitative yield of the crystalline monobromide **22***a*. Dehydrobromination of **22***a* in anhydrous dimethylformamide with lithium bromide and lithium carbonate (5) gave compound **19***a* in an 82% yield.

We have also carried out a direct conversion of the vinyl acetate adduct mixture **21***a*,*b* to

[2]Compound **20** is obtained by further mild acid treatment of compound **2**.



19*a* **20** **21***a* **21***b* **22***a* **22***b* **19***b* R = Ac; **23** R = H; **24** R = COC_6H_5

SCHEME 3

the pure compound **17**, an intermediate in the 'variant A' synthesis. The overall yield from the α,β-unsaturated ketone **20** to the keto ketal **17** was 13.7%. The details of this process are described in the Experimental. The reaction sequence proceeded via the mixtures **22***a,b* and **19***a,b*. Base treatment of **19***a,b* followed by benzoylation yielded the benzoates **12***a,b* and **24** which were separated by chromatography. Finally the conversion of **12***a,b* to **17** was performed as described above.

We had just enough of the α,β-unsaturated ketone **IX** at this point to subject it to this abbreviated vinyl acetate sequence. The entire operation was uneventful as in the model 'variant B' and the acetate **XII** was reached in a quantity just sufficient to be characterized. (Acetylation was used instead of the benzoylation employed in the model system.) The success of 'variant B' in the full system in which the 'variant A' failed is clearly due to the fact that in the course of the entire sequence no intermediate was needed which would have a serious nonbonded interaction absent from the model series.

We believe that one can derive from these findings an important lesson on how to evaluate critically the chances of a model study to succeed in the full system. Based on this lesson we believe that the chances of compound **XII** in the remaining steps are excellent.

We shall report in detail on the application of this study to the total synthesis of chasmanine and other aconite alkaloids as soon as we reach the corresponding natural products.

Experimental

Preparation of the β,γ-Unsaturated Ketone 2

A solution of compound **1** (1) (13.4 g) in anhydrous tetrahydrofuran (78 ml) and *tert*-butyl alcohol (78 ml) was added dropwise over a period of 45 min to a stirred solution of lithium metal (5.41 g) in distilled liquid ammonia (290 ml). The mixture was stirred at acetone – dry ice temperature for 2½ h. Absolute methanol was added until the blue colour disappeared and the reaction mixture was allowed to stand to evaporate the excess ammonia. The resulting white residue was dissolved in water (200 ml) and extracted thoroughly with ether (4 × 50 ml). The extracts were washed with water and dried over anhydrous potassium carbonate. Evaporation afforded a colorless oil (13.0 g) which was immediately dissolved in cold absolute methanol (250 ml) and treated with aqueous oxalic acid (1 *M* solution, 80 ml). After 45 min at 0°C (ice-bath) the reaction mixture was neutralized by dropwise addition of saturated sodium bicarbonate solution. Work-up by the standard procedure produced the unstable β,γ-unsaturated ketone **2** (11.72 g, 94%) as a colorless oil homogeneous by tlc in several solvent systems. *Mol. Wt.* calcd. for $C_{11}H_{14}O$: 162; found (ms): 162. Infrared (CCl_4): 1715 (six-membered ketone), 1670 cm^{-1} (tetrasubstituted double bond).

Preparation of the β,γ-Unsaturated Alcohol 3

The β,γ-unsaturated ketone **2** (4.60 g) was dissolved in absolute methanol (100 ml) and sodium borohydride (0.57 g) was added portion-wise at 0°C. After an additional ½ h at this temperature the reaction mixture was worked-up by the usual procedure. The resulting oily residue (4.72 g) was purified by chromatography on silica gel. Elution with ether–hexane (1:1, v/v) afforded the pure alcohol **3** (4.21 g, 91%) as a colorless oil homogeneous by tlc in various solvent systems. *Mol. Wt.* calcd. for $C_{11}H_{16}O$: 164; found (ms): 164. Infrared (CCl_4): 3625, 3400 (hydroxyl), 1665 cm^{-1} (double bond); nmr (CCl_4): τ 6.30 ppm (m, 1H, proton unshielded by hydroxyl).

Preparation of the α,β-Unsaturated Ketone 4

To a solution of the alcohol **3** (245 mg) in dry dichloromethane (10 ml) was added dropwise a solution of *m*-chloroperbenzoic acid (325 mg) in the same solvent (15 ml) at 0°C under a nitrogen atmosphere. After an additional hour at this temperature the reaction mixture was treated with freshly prepared 0.2 *M* solution of tetramethyl piperidine hydrochloride (4) (TMP·HCl) in dry dichloromethane (0.3 ml) followed by the dropwise addition of a solution of *m*-chloroperbenzoic acid (350 mg) in the same solvent (15 ml). The reaction was allowed to proceed with stirring for 8 h at room temperature. The resulting pale yellow solution was transferred into a separatory funnel and thoroughly washed with 5% aqueous sodium carbonate and water. The extract was dried over anhydrous magnesium sulfate and evaporated to dryness under reduced pressure to afford a yellowish oil (265 mg) which was taken up in absolute methanol

(5 ml) and treated with a 4 *M* methanolic sodium methoxide solution (0.4 ml) at 0°C for ½ h. The mixture was neutralized with dilute hydrochloric acid, diluted with saturated aqueous sodium chloride (15 ml), and thoroughly extracted with ether (4 × 10 ml). The combined extracts were washed with water, dried over anhydrous magnesium sulfate, and evaporated to dryness. The residue (247 mg) was purified by preparative tlc on silica gel using ether–hexane (2:1, v/v) to yield the pure α,β-unsaturated ketone **4** (215 mg, 81%) as colorless prisms mp 100–101°C from carbon tetrachloride – hexane. *Anal.* calcd. for $C_{11}H_{14}O_2$: C 74.13, H 7.92; found: C 73.89, H 7.89. *Mol. Wt.* calcd.: 178; found (ms): 178. Infrared (CCl_4): 3620, 3410 (hydroxyl), 1665 cm^{-1} (conjugated six-membered ketone); nmr (CCl_4): τ 4.33 (s, 1H, vinylic proton), 6.17 ppm (br, 1H, hydroxyl proton); uv: λ_{max} (MeOH) 237.5 nm (log ε 4.07).

Photoaddition of Allene to Compound 4

A mixture of the α,β-unsaturated ketone **4** (1.0 g) and excess allene (15 g) in anhydrous tetrahydrofuran (25 ml) was irradiated at −78°C with a 200 W Hanovia mercury lamp through a Pyrex filter for 8 h under a stream of nitrogen. Excess allene and solvent were removed by evaporation under reduced pressure and the resulting oily residue was purified by chromatography on silica gel using ether–hexane (2:1, v/v). The photoadduct **5** (1.07 g, 87%) was obtained as thin colorless plates mp 83–85°C from ether–hexane. *Anal.* calcd. for $C_{14}H_{18}O_2$: C 77.03, H 8.31; found: C 76.95, H 8.41. *Mol. Wt.* calcd.: 218; found (ms): 218. Infrared (CCl_4): 3625, 3485 (hydroxyl), 1718 (six-membered ketone), 1675, 875 cm^{-1} (terminal methylene); nmr (CCl_4): τ 5.05 and 5.18 (q, J = 3 and 6 Hz, 1H each, vinylic protons), 7.58 ppm (s, 1H, hydroxyl proton).

Preparation of Dimethyl Acetal 6

The allene photoadduct **5** (100 mg) was dissolved in absolute methanol (10 ml) and to this solution was added dry Rexyn 101-(H) R-204 (10 mg) and trimethylorthoformate (0.2 ml). After 1½ h stirring under nitrogen a second (0.2 ml) portion of orthoformate was added. The reaction mixture was stirred at room temperature for a further 1½ h. The resin was filtered off and the filtrate evaporated under reduced pressure in presence of triethyl amine (3 drops). The yield of the oily acetal **6** is quantitative. *Mol. Wt.* calcd. for $C_{16}H_{24}O_3$: 264; found (ms): 264. Infrared (CCl_4): 3625, 3475 (hydroxyl), 1670, 875 cm^{-1} (terminal methylene); nmr (CCl_4): τ 5.07 (q, J = 3 and 6 Hz, 1H, vinylic proton), 5.25 (q, J = 3 and 6 Hz, 1H, vinylic proton), 6.80, 6.87 ppm (s, 3H each, acetal methyl groups).

Preparation of Keto Acetate 7

The hydroxy acetal **6** (115 mg) was dissolved in absolute methanol (15 ml) and cooled to −70°C. A stream of ozonized oxygen was slowly passed through the solution until it acquired a permanent blue color. After removing excess ozone with a stream of nitrogen the reaction mixture was allowed to warm up to 0°C. Sodium borohydride (400 mg) was then added in portions and the resulting mixture stirred for an additional 1 h at 0°C. The solvent was evaporated under reduced pressure and the residue thoroughly extracted with ether. The combined extracts were washed with brine, dried over anhydrous potassium carbonate, and evaporated to dryness. The oily residue (125 mg) was dissolved in a mixture of pyridine – acetic anhydride (2:1, 3 ml) and allowed to stand at room temperature overnight. The reaction mixture upon acidic work-up (HCl) produced the desired keto acetate **7** (83.03 mg, 72%) as colorless prisms mp 134–135°C from carbon tetrachloride – hexane. *Anal.* calcd. for $C_{15}H_{20}O_4$: C 68.16, H 7.63; found: C 67.89, H 7.70. *Mol. Wt.* calcd.: 264; found (ms): 264. Infrared (CCl_4): 3620, 3500 (hydroxyl), 1750 (acetate), 1710 cm^{-1} (six-membered ketone); nmr ($CDCl_3$): τ 4.83 (q, J = 9 Hz, 1H, proton unshielded by acetoxyl), 7.97 ppm (s, 3H, acetoxy methyl).

Preparation of the Hemiacetal 8

The hydroxy acetal **6** (60 mg) was dissolved in absolute methanol (10 ml) and ozonized at −70°C until a pale blue color persisted. Excess ozone was removed by means of a stream of nitrogen and the cold (0°C) solution was treated with sodium borohydride (150 mg) in small portions with additional stirring at 0°C for 1 h. The solution was then concentrated under reduced pressure, diluted with water (10 ml), and extracted with ether. The combined (wet) ether extracts were treated with anhydrous magnesium sulfate (400 mg) with stirring at room temperature for 1 h. After evaporation of the solvent the residue was purified by preparative tlc on silica gel using ether–hexane (2:1, v/v) to produce the crystalline hemiacetal **8** (42.38 mg, 84%) as a colorless microcrystalline material, mp 125–126°C from ether–hexane, which consists (nmr) of a 3.5:1 mixture of epimers at the hemiacetal carbon. *Anal.* calcd. for $C_{13}H_{18}O_3$: C 70.23, H 8.17; found: C 70.23, H 8.20. *Mol. Wt.* calcd.: 222; found (ms): 222. Infrared (CCl_4): 3630, 3425 (hydroxyl), 1710 cm^{-1} (six-membered ketone); nmr (CCl_4): τ 4.53 (br, 1H, proton unshielded by the hemiacetal oxygen), 5.15 ppm (br, 1H, hemiacetal hydroxyl); nmr ($CDCl_3$): τ 4.49 (m, 1H, proton unshielded by the hemiacetal oxygen), 6.20 and 6.42 ppm (d, J = 4 Hz, 1H, minor and major epimers respectively, hemiacetal hydroxyl).

Preparation of the β,γ-Unsaturated Ketone 9

A solution of the keto acetate **7** (200 mg) in dry pyridine (6 ml) was cooled to 0°C (ice-salt bath) and treated with thionyl chloride (15 drops). After 10 min the pale yellow reaction mixture was poured into cold water (20 ml) and extracted with ether (3 × 10 ml). The combined extracts were washed with dilute hydrochloric acid and water, dried over anhydrous magnesium sulfate, and evaporated to dryness. The residue was purified by preparative tlc on silica gel using ether–hexane (1:1, v/v) to produce the oily β,γ-unsaturated ketone (133 mg, 71%). *Mol. Wt.* calcd. for $C_{15}H_{18}O_3$: 246; found (ms): 246. Infrared (CCl_4): 1755 (acetate), 1715 (six-membered ketone), 1676 cm^{-1} (double bond); nmr (CCl_4): τ 4.43 (dd, J = 2 and 6 Hz, 1H, vinylic proton), 4.80 (q, J = 9 Hz, 1H, proton unshielded by acetoxyl), 8.03 ppm (s, 3H, acetoxy methyl).

From the preparative tlc was also obtained the crystalline chloro ketone **10** (22.0 mg, 10%) mp 162–163°C from carbon tetrachloride – hexane. *Anal.* calcd. for $C_{15}H_{19}O_3Cl \cdot \frac{1}{5}CCl_4$: C 58.22, H 6.11; found: C 58.78, H 6.25. *Mol. Wt.* calcd. for $C_{15}H_{19}O_3Cl$: 282; found (ms): 282. Infrared ($CHCl_3$): 1745 (acetate), 1715 cm^{-1} (six-

membered ketone); nmr ($CDCl_3$): τ 4.90 (q, J = 9 Hz, 1H, proton unshielded by acetoxyl), 7.90 ppm (s, 3H, acetoxy methyl).

Base Treatment of Keto Acetate ***9***

Compound **9** (133 mg) was dissolved in 1% methanolic potassium hydroxide (2 ml) and stirred under nitrogen at room temperature for 20 min. The reaction mixture was diluted with cold water (10 ml) and the methanol evaporated under reduced pressure. The residue was thoroughly extracted with ether (4 × 5 ml) and the combined extracts were washed with brine, dried over anhydrous sodium sulfate, and evaporated to dryness. The residue was purified by preparative tlc on silica gel using ether–hexane (2:1, v/v) to afford the pure aldol mixture **11***a,b* (100 mg, 91%) as a colorless glass. *Mol. Wt.* calcd. for $C_{13}H_{16}O_2$: 204; found (ms): 204. Infrared ($CHCl_3$): 3620, 3420 (hydroxyl), 1735, 1725 (six-membered ring ketone), 1675 cm^{-1} (double bond); nmr (CCl_4): τ 4.50 (d, J = 6 Hz, 1H, vinylic proton), 6.00 (m, 2H, hydroxyl and proton unshielded by hydroxyl), 6.87 ppm (dd, J = 2 and 6 Hz, proton at the ring junction adjacent to the carbonyl grouping).

Benzoylation of Aldol ***11****a,b*

A solution of the mixture **11***a,b* (100 mg) in dry pyridine (2 ml) was cooled to 0°C and treated with freshly distilled benzoyl chloride (103 mg). The reaction was allowed to proceed at the same temperature for 1 h and it was then diluted with cold water (10 ml), neutralized with dilute hydrochloric acid, and extracted with ether (3 × 10 ml). The combined extracts were washed with water, dried over anhydrous magnesium sulfate, and evaporated to dryness. Purification of the residue by preparative tlc on silica gel using ether–hexane (1:2, v/v) produced the crystalline benzoate mixture **12***a,b* (120 mg, 79%), colorless prisms mp 116–123°C from carbon tetrachloride – hexane. *Mol. Wt.* calcd. for $C_{20}H_{20}O_3$: 308; found (ms): 308. Infrared (CCl_4): 1735 (benzoate), 1720 (six-membered ketone), 1670 cm^{-1} (double bond); nmr (CCl_4): τ 1.73 and 2.57 (m, 2 and 3H respectively, aromatic protons), 4.37 (d, J = 6.5 Hz, 1H, vinylic proton), 4.93 (m, 1H, proton unshielded by benzoate), 6.67 ppm (dd, J = 2 and 6 Hz, 1H, proton at the ring junction adjacent to the carbonyl grouping).

For analytical purposes, this epimeric mixture was fractionally recrystallized from carbon tetrachloride – hexane to produce the major benzoate **12***a* as colorless prisms mp 121–122°C. *Anal.* calcd. for $C_{20}H_{20}O_3$: C 77.90, H 6.54; found: C 77.73, H 6.55. *Mol. Wt.* calcd.: 308; found (ms): 308. Infrared ($CHCl_3$): 1720 (benzoate and six-membered ketone), 1670 cm^{-1} (double bond); nmr ($CDCl_3$): τ 1.91 and 2.47 (m, 2 and 3H respectively, aromatic protons), 4.40 (d, J = 6.5 Hz, 1H, vinylic proton), 4.80 (m, 1H, proton unshielded by benzoate), 6.57 ppm (dd, J = 4 and 6.5 Hz, 1H, proton at the ring junction).

Hydrogenation of the Benzoate Mixture ***12****a,b*

A mixture of the epimeric benzoates **12***a,b* (80 mg) and 5% rhodium on alumina catalyst (80 mg) in absolute methanol (4 ml) was hydrogenated at 94 psi for 32 h at room temperature. The resulting suspension was filtered through Celite and the filtering pad washed thoroughly with methanol (20 ml). The combined filtrates were evaporated to dryness and the oily residue was dissolved in dry dichloromethane (3 ml) and added in one portion to a stirred solution of the chromium trioxide – dipyridine complex (430 mg) in the same solvent (15 ml). The reaction was allowed to proceed at room temperature for 1 h, quenched with wet ether (20 ml), and filtered through a neutral alumina–Celite pad (1:1, w/w). The colorless filtrate was evaporated to dryness and purified by preparative tlc on silica gel using ether–hexane (2:3, v/v) to yield the dihydro derivatives **13** and **14** (70 mg, 88%). These compounds were isolated in a 3.2:1 ratio.

Compound ***13***

Colorless prisms mp 88–89°C from *n*-hexane (51 mg). *Anal.* calcd. for $C_{20}H_{28}O_3$: C 75.91, H 8.92; found: C 75.74, H 8.98. *Mol. Wt.* calcd.: 316; found (ms): 316. Infrared (CCl_4): 1740 (ester), 1735 cm^{-1} (six-membered ketone); nmr (CCl_4): τ 5.00 ppm (dd, J = 5 and 8 Hz, 1H, proton unshielded by the ester grouping).

Compound ***14***

Colorless prisms mp 96–97°C from *n*-hexane (16 mg). *Anal.* calcd. for $C_{20}H_{28}O_3$: C 75.91, H 8.92; found: C 75.83, H 9.02. *Mol. Wt.* calcd.: 316; found (ms): 316. Infrared (CCl_4): 1735 cm^{-1} (ester and six-membered ketone); nmr (CCl_4): τ 4.73 ppm (multiplet, 1H, proton unshielded by ester grouping).

Preparation of Ketal ***15***

A solution of the ketoester **13** (325 mg) and *p*-toluenesulfonic acid monohydrate (40 mg) in anhydrous benzene (75 ml) containing dry ethylene glycol (0.93 ml) was heated under reflux with a water separator for 5 h. Work-up by the usual procedure afforded ketal **15** (358 mg, 97%) as colorless prisms mp 105–106°C from methanol. *Anal.* calcd. for $C_{22}H_{32}O_4 \cdot \frac{1}{3}H_2O$: C 72.15, H 8.99; found: C 72.15, H 8.91. *Mol. Wt.* calcd. for $C_{22}H_{32}O_4$: 360; found (ms): 360. Infrared ($CHCl_3$): 1720 cm^{-1} (ester); nmr ($CDCl_3$): τ 5.23 (m, 1H, proton unshielded by ester), 6.17 ppm (br s, 4H, dioxolane protons).

Preparation of Ketone ***17***

Compound **15** (350 mg) was dissolved in 4% methanolic potassium hydroxide (40 ml) and heated to 60°C under nitrogen for 12 h. The resulting colorless solution was diluted with cold water (40 ml) and most of the methanol was evaporated under reduced pressure. The residue was thoroughly extracted with ether (4 × 10 ml). The combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated to dryness. The unstable hydroxy ketal **16***b* (211 mg) was taken up in dry dichloromethane (3 ml) and added in one portion to a stirred solution of the chromium trioxide – dipyridine complex (1400 mg) in the same solvent (50 ml). The reaction mixture was stirred at room temperature for 1 h. Quenching with wet ether (50 ml) and filtration of the crude oxidation mixture through a neutral alumina–Celite pad (1:1, w/w) afforded a colorless filtrate which was evaporated to dryness. Purification of the residue by preparative tlc on silica gel using ether–hexane (1:1, v/v) yielded the oily ketal **17** (197 mg, 82%) as a colorless oil homogeneous by tlc in several solvent systems. *Mol. Wt.* calcd. for $C_{15}H_{20}O_3$: 248; found (ms): 248. Infrared (CCl_4): 1740 cm^{-1} (six-membered ketone); nmr (CCl_4): τ 6.10 ppm (s, 4H, dioxolane protons).

Preparation of Alcohol ***16a***

The ketone **17** (120 mg) was dissolved in absolute methanol (5 ml) and reduced at 0°C (ice bath) with excess sodium borohydride. Usual work-up afforded the crystalline alcohol **16***a* in quantitative yield as colorless prisms mp 98–99°C from *n*-hexane. *Anal.* calcd. for $C_{15}H_{22}O_3$: C 71.97, H 8.86; found: C 71.42, H 8.77. *Mol. Wt.* calcd.: 250; found (ms): 250. Infrared (CCl_4): 3540 cm^{-1} (hydroxyl); nmr (CCl_4): τ 6.13 (s, 4H, dioxolane protons), 6.60 ppm (br s, 1H, hydroxyl proton).

Preparation of Methoxy Ketal ***18***

A mixture of the hydroxy ketal **16***a* (80 mg), sodium hydride (15 mg, prewashed with petroleum ether), and excess methyl iodide (0.5 ml) in anhydrous dioxane (3 ml) was heated at 55°C under nitrogen for 12 h. The cold reaction mixture was quenched with absolute methanol (5 drops), diluted with brine (10 ml), and thoroughly extracted with ether (5 × 5 ml). The combined extracts were washed with water, dried over anhydrous sodium sulfate, and evaporated to dryness. Purification of the residue by preparative tlc on silica gel using ether–hexane (1:1, v/v) afforded the crystalline methoxy ketal **18** (75 mg, 89%) as colorless prisms mp 116–117°C from *n*-hexane, identical by all standard techniques (mixture mp, tlc, infrared, nmr, ms) with a sample previously prepared in our laboratories (1).

Preparation of the α,β*-Unsaturated Ketone* ***19a***

A solution of keto acetate **9** (100 mg) in dry chloroform (10 ml) was treated with concentrated hydrochloric acid (2 drops) and stirred at room temperature under nitrogen for 2 h. The reaction mixture was transferred into a separatory funnel and washed with a saturated sodium bicarbonate solution and water. Drying over anhydrous magnesium sulfate and evaporation gave a quantitative yield of the α,β-unsaturated ketone **19***a* as a colorless oil homogeneous by tlc in several solvent systems. *Mol. Wt.* calcd. for $C_{15}H_{18}O_3$: 246; found (ms): 246. Infrared (CCl_4): 1749 (acetate), 1675 (six-membered unsaturated ketone), 1652 cm^{-1} (double bond); nmr (CCl_4): τ 3.27 (dd, J = 2 and 10 Hz, 1H, vinylic proton at the β-position of the enone), 3.92 (dd, J = 1 and 10 Hz, 1H, vinylic proton at the α-position of the enone), 4.73 (m, 1H, proton unshielded by acetoxyl), 8.03 ppm (s, 3H, acetoxy methyl); uv λ_{max} (MeOH): 213 (sh) (log ε 4.02) and 235 nm (log ε 4.16).

Base Treatment of the α,β*-Unsaturated Ketone* ***19a***

Compound **19***a* (185 mg) was stirred in 1% methanolic potassium hydroxide (5 ml) at room temperature under nitrogen for 15 min. The pale yellow reaction mixture was diluted with cold water (10 ml) and most of the methanol evaporated under reduced pressure. The residue was extracted with ether and the combined extracts washed with water, dried over anhydrous sodium sulfate, and evaporated to dryness. The resulting material was purified by preparative tlc on silica gel using ether–hexane (3:2, v/v) to afford the pure aldol mixture **11***a,b* (145 mg, 95%) as a colorless oil homogeneous by tlc in several solvent systems. By all standard comparison techniques (nmr, ir, tlc, ms) this material was identical with that obtained from the base treatment on the β,γ-unsaturated ketone **9**.

Treatment of this material with benzoyl chloride in pyridine at 0°C (*vide supra*) gave 91% of a benzoate mixture which crystallized from carbon tetrachloride – hexane as colorless prisms mp 116–123°C. This sample showed spectroscopic and chromatographic properties identical to those of **12***a,b* obtained from the enone **9**.

Photoaddition of Vinyl Acetate to the α,β*-Unsaturated Ketone* ***20***

A solution of compound **20** (1) (2 g) and vinyl acetate (40 ml) in freshly distilled dry tetrahydrofuran (50 ml) was cooled to −78°C and irradiated through a Pyrex filter with a 200 W Hanovia mercury lamp for 6 h under nitrogen. The solvent and excess vinyl acetate were evaporated under reduced pressure and the residue was purified by chromatography on silica gel. Elution with ether–hexane (1:1, v/v) afforded the pure photoadduct (2.8 g, 91%) as a thick colorless oil consisting of approximately equal amounts of the isomers **21***a* and **21***b*. *Mol. Wt.* calcd. for $C_{15}H_{20}O_3$: 248; found (ms): 248. Infrared (CCl_4): 1748, 1740 (acetate), 1715, 1710 cm^{-1} (six-membered ketone); nmr ($CDCl_3$): τ 4.85 and 5.08 (q, J = 8 Hz, 1H, proton unshielded by acetoxyl), 7.92 and 8.00 ppm (s, 3H, acetoxy methyl).

The acetate mixture **21***a,b* was crystallized using carbon tetrachloride – hexane to afford the pure isomer **21***a* as colorless prisms, mp 96–98°C. *Anal.* calcd. for $C_{15}H_{20}O_3$: C 72.55, H 8.12; found: C 72.11, H 8.11. *Mol. Wt.* calcd.: 248; found (ms): 248. Infrared (CCl_4): 1740 (acetate), 1710 cm^{-1} (six-membered ketone); nmr ($CDCl_3$): τ 4.82 (q, J = 8 Hz, 1H, proton unshielded by acetoxyl), 7.98 ppm (s, 3H, acetoxy methyl).

Bromination of Keto Acetate ***21a***

A solution of the keto acetate **21***a* (60 mg) in dry tetrahydrofuran (5 ml) was treated in one portion with pyridinium hydrobromide perbromide (92.9 mg) and the resulting mixture stirred at room temperature under nitrogen for ½ h. The colorless reaction mixture was poured into cold saturated aqueous sodium bicarbonate (10 ml), diluted with brine (10 ml), and thoroughly extracted with ether (5 × 10 ml). The combined extracts were washed with dilute hydrochloric acid and water, dried over anhydrous sodium sulfate, and evaporated to dryness to afford the crystalline keto bromide **22***a* as colorless prisms mp 147–149°C from ether–hexane in quantitative yield. *Anal.* calcd. for $C_{15}H_{19}O_3Br$: C 55.06, H 5.85; found: C 54.93, H 5.91. *Mol. Wt.* calcd.: 327; found (ms): 327. Infrared (CCl_4): 1752 (acetate), 1718 cm^{-1} (six-membered ketone); nmr (CCl_4): τ 4.97 (br q, J = 8 Hz, 1H, proton unshielded by acetoxyl), 5.63 (t, J = 2 Hz, 1H, proton unshielded by the bromine atom), 8.02 ppm (s, 3H, acetoxy methyl).

Dehydrobromination of Bromo Ketone ***22a***

A recrystallized sample of the α-bromo ketone **22***a* (60 mg) was added in one portion to a stirred suspension of anhydrous lithium bromide (24.9 mg) and lithium carbonate (33.13 mg) in anhydrous *N,N*-dimethylformamide (2 ml) (5). The resulting mixture was heated to 145°C (oil-bath temperature) under nitrogen for 1 h. The cold reaction mixture was carefully poured into dilute acetic acid (15 ml) and extracted with ether (6 × 10 ml). The organic extracts were washed with water (6 × 10 ml), the aqueous washings back extracted with ether (2 × 10 ml), and the combined extracts

dried over anhydrous magnesium sulfate and evaporated to dryness under reduced pressure. The resulting pale yellow glass (42.2 mg) was purified by preparative tlc on silica gel using ether–hexane (2:1, v/v) to afford the pure α,β-unsaturated ketone **19***a* (36.7 mg, 82%) as a colorless oil. This material proved to be identical with the compound obtained by acid treatment of the β,γ-unsaturated ketone **9** by all standard comparison techniques.

Bromination–Dehydrobromination of the Keto Acetate Mixture ***21****a,b*

The mixture **21***a,b* (140 mg) was brominated in dry tetrahydrofuran (15 ml) with pyridinium hydrobromide perbromide (217 mg) as described for the keto acetate **21***a*. Identical work-up gave the oily bromo ketone mixture **22***a,b* in quantitative yield. *Mol. Wt.* calcd. for $C_{15}H_{19}O_3Br$: 327; found (ms): 327. Infrared (CCl_4): 1748, 1735 (sh) (acetates), 1718 cm^{-1} (six-membered ketone); nmr ($CDCl_3$): τ 4.67 and 5.00 (br q's, $J = 8$ and 9 Hz respectively, 1H, proton unshielded by acetoxyl), 5.57 (m, 1H, proton unshielded by the bromine atom), 7.93 and 7.97 ppm (s, 3H, acetoxy methyl).

The bromo ketone mixture **22***a,b* (91 mg) was dehydrobrominated at 145°C in anhydrous *N,N*-dimethylformamide (3 ml) with anhydrous lithium bromide (37.8 mg) and lithium carbonate (50.2 mg). The reaction was worked-up as before (*vide supra*) and the residue was purified by preparative tlc on silica gel using ether–hexane (2:1, v/v) to yield the mixture of α,β-unsaturated ketones **19***a,b* (55.4 mg, 81%) as a colorless oil.

For analytical purposes the mixture **19***a,b* can be easily separated by preparative tlc on silica gel using ether–hexane (2:3, v/v; run twice) to yield the pure α,β-unsaturated ketones **19***a* and **19***b*.

Compound ***19a***

This sample proved to be identical by all usual comparison standards with the material obtained from the β,γ-unsaturated keto acetate **9** and from the pure keto acetate **21***a*.

Compound ***19b***

Mol. Wt. calcd. for $C_{15}H_{18}O_3$: 246; found (ms): 246. Infrared (CCl_4): 1745 (acetate), 1670 cm^{-1} (six-membered unsaturated ketone); nmr ($CDCl_3$): τ 3.20 (m, 1H, vinylic proton at the β-position of the enone), 3.90 (dd, $J = 2$ and 12 Hz, 1H, vinylic proton at the α-position of the enone), 5.13 (m, 1H, proton unshielded by acetoxyl), 7.90 ppm (s, 3H, acetoxy methyl); uv λ_{max} (MeOH): 213 (sh) (log ε 4.07) and 235 nm (log ε 4.16).

Base Treatment of the Mixture ***19a,b***

The α,β-unsaturated ketone mixture **19***a,b* (1.5 g) was dissolved in 1% methanolic potassium hydroxide (20 ml) and stirred at room temperature under nitrogen for ½ h. Usual work-up and purification of the residue by column chromatography on silica gel using ether–hexane (1:2, v/v) gave a thick colorless oil (1.05 g, 84%) which consisted of a mixture of the aldols **11***a,b* and the α,β-unsaturated ketone **23**. This material was dissolved in dry pyridine (20 ml) and allowed to react at 0°C with freshly distilled benzoyl chloride (1.03 g) for 1 h. Work-up by the standard procedure furnished a crystalline substance (1.491 g) which could be separated by careful chromatography on silica gel using ether–hexane (1:3, v/v) into its two components, the less polar benzoates **12***a,b* (520.3 mg) and the ketoester **24** (754.5 mg).

The benzoates **12***a,b* were obtained as colorless prisms mp 116–123°C from carbon tetrachloride – hexane and presented chromatographic and spectroscopic characteristics identical to those previously recorded for the material prepared via the β,γ-unsaturated ketone **9**.

Benzoate **24** was obtained as colorless prisms mp 89–91°C from carbon tetrachloride – hexane. *Anal.* calcd. for $C_{20}H_{20}O_3$: C 77.90, H 6.54; found: C 77.83, H 6.59. *Mol. Wt.* calcd.: 308; found (ms): 308. Infrared (CCl_4): 1720 (benzoate), 1672 (six-membered unsaturated ketone), 1650 cm^{-1} (double bond); nmr ($CDCl_3$): τ 1.92 and 2.48 (m, 2 and 3H respectively, aromatic protons), 3.18 (dd, $J = 3$ and 11 Hz, 1H, vinylic proton at the β-position of the enone), 3.85 (dd, $J = 1$ and 11 Hz, 1H, vinylic proton at the α-position of the enone), 4.93 ppm (t, $J = 6$ Hz, 1H, proton unshielded by benzoate); uv λ_{max} (MeOH): 214 (log ε 3.64) and 231.5 nm (log ε 4.05).

Conversion of the Benzoates ***12a,b*** *into the Ketal* ***17***

The benzoates **12***a,b* (obtained from the mixture **19***a,b*) were converted to the ketone **17** exactly as described in the case of the same material originating from pure **9** or **19***a*. The homogeneous keto ketal **17** was obtained in an overall yield 13.7% from the α,β-unsaturated ketone **20**. Its identity with the previously prepared material was ascertained by tlc, ir, nmr, and ms.

Acknowledgments

We wish to thank the National Research Council of Canada, Ottawa, and the Hoffmann-La Roche Company, Vaudreuil, Quebec, for the steady support of our systematic synthetic studies over many years.

The synthesis of D-angolosamine

HANS H. BAER AND FAWZY F. Z. GEORGES
Department of Chemistry, University of Ottawa, Ottawa, Ont., Canada K1N 6N5

Received October 20, 1976

HANS H. BAER and FAWZY F. Z. GEORGES. Can. J. Chem. **55**, 1100 (1977).

The synthesis of 2,3,6-trideoxy-3-dimethylamino-D-*arabino*-hexose hydrochloride (**10**) (D-angolosamine, a constituent of the antibiotic, angolamycin) is described. First, a simplified procedure for the preparation of methyl 6-deoxy-α-D-glucopyranoside from methyl α-D-glucopyranoside is recorded. The deoxy derivative served as the starting point for sequential preparation of methyl 3,6-dideoxy-3-nitro-α-D-glucopyranoside (**1**), its 2,4-diacetate (**2**), its 4-monoacetate (**3**), its 2-*O*-mesyl-4-acetate (**4**), its 2-mesylate (**5**), and methyl 2,3,6-trideoxy-3-nitro-α-D-*erythro*-hex-2-enopyranoside (**6**) essentially according to procedures previously established (in part, in the L-series). Treatment of **5** or **6** with sodium borohydride produced methyl 2,3,6-trideoxy-3-nitro-α-D-*arabino*-hexopyranoside (**7**). Catalytic hydrogenation of **7** gave the corresponding 3-amino glycoside hydrochloride (**8**) which was hydrolyzed to furnish 3-amino-2,3,6-trideoxy-D-*arabino*-hexose hydrochloride (**9**) (D-acosamine, the enantiomer of a component of the antibiotic, actinoidin). *N,N*-Dimethylation of **8** followed by hydrolysis afforded the crystalline title compound (**10**).

HANS H. BAER et FAWZY F. Z. GEORGES. Can. J. Chem. **55**, 1100 (1977).

La synthèse de l'hydrochlorure de 2,3,6-tridésoxy-3-diméthylamino-D-*arabino*-hexose (**10**) (D-angolosamine, un constituant de l'antibiotique, angolamycine) est décrite. Tout d'abord, une méthode simplifiée de préparation du methyle 6-désoxy-α-D-glucopyranoside à partir du méthyle α-D-glucopyranoside est présentée. Le dérivé désoxy a servi comme produit de départ pour les préparations séquentielles du méthyle 3,6-didésoxy-3-nitro-α-D-glucopyranoside (**1**), de son 2,4-diacétate (**2**), de son 4-monoacétate (**3**), de son 2-*O*-mésyle-4-acétate (**4**), de son 2-mésylate (**5**) et du méthyle 2,3,6-tridésoxy-3-nitro-α-D-*érythro*-hex-2-énopyranoside (**6**) en suivant essentiellement des méthodes existantes (en partie, pour la série L). Le traitement de **5** ou **6** avec du borohydrure de sodium a produit le méthyle 2,3,6-tridésoxy-3-nitro-α-D-*arabino*-hexopyranoside (**7**). Par hydrogénation catalytique de **7** on a obtenue l'hydrochlorure du 3-amino glycoside correspondant (**8**) qui par hydrolyse a donné l'hydrochlorure de 3-amino-2,3,6-tridésoxy-D-*arabino*-hexose (**9**) (D-acosamine, l'énantiomère d'un composant de l'antibiotique actinoidine). Une *N,N*-diméthylation de **8** suivie d'une hydrolyse a fourni le produit désiré (**10**) sous forme crystalline.

The macrolide antibiotic angolamycin, isolated by Swiss workers (1) from *Streptomyces eurythermus*, was shown (2) to contain two neutral sugar moieties (L-mycarose and D-mycinose) together with a previously unknown amino sugar component (angolosamine) which proved to be 2,3,6-trideoxy-3-dimethylamino-D-*arabino*-hexose (**10**). A structure for the complete antibiotic was proposed (3) in 1972, at which time it was also found that angolamycin and a similar product, shincomycin A (4), appear in fact identical according to mass spectral analysis.

We now report the synthesis of **10**. The synthetic route led through another amino sugar of potential biological interest, namely, 3-amino-2,3,6-trideoxy-D-*arabino*-hexose (**9**). This compound had previously been synthesized by a different approach and characterized as its hydrochloride salt and *N*-acetyl derivative (5); some glycosidic derivatives had also been prepared (5, 6). More recently, the L-enantiomer of **9** was discovered (7) to occur in nature as a constituent of an antibiotic, actinoidin. It has been named acosamine and synthesized (8) along with several glycosidic derivatives (8, 9), but no reference to the known D-enantiomer was made. Synthetically modified analogs of daunorubicin and adriamycin containing L-acosamine in place of daunosamine (the L-*lyxo* isomer) were reported (10) to show interesting biological properties.

Methyl 3,6-dideoxy-3-nitro-α-D-glucopyranoside (**1**) was prepared from methyl 6-deoxy-α-D-glucopyranoside[1] by the nitromethane method as described (11) for its L-enantiomer. Acetylation of **1** to provide the 2,4-diacetate **2**, and selective

[1]The preparation of this starting compound was simplified by use of a procedure which avoids the need of tedious chromatographic purification of its precursor, the corresponding 6-chloro-6-deoxy derivative; see Experimental.

10

de-*O*-acetylation of **2** by means of acid-catalyzed methanolysis giving the 4-acetate **3** were likewise performed as reported (12) for the L-series. Methanesulfonylation of **3** followed by de-*O*-acetylation gave (13) methyl 3,6-dideoxy-2-*O*-methylsulfonyl-3-nitro-α-D-glucopyranoside (**5**) via the mixed ester **4**. All the products **1**–**5** were crystalline and the overall yield based on **1** was *ca.* 38%. The next key intermediate required was methyl 2,3,6-trideoxy-3-nitro-α-D-*arabino*-hexopyranoside (**7**). It was produced in good yield by sodium borohydride reduction of the crystalline nitro olefin **6**, methyl 2,3,6-trideoxy-3-nitro-α-D-*erythro*-hex-2-enopyranoside, which had been obtained before (13) by action of sodium hydrogen carbonate upon **5**. However, it was found unnecessary to prepare first the olefin **6** for this purpose. Direct application of sodium borohydride to the mesylate **5** resulted in a smooth replacement of the 2-mesyloxy group by a hydrogen atom, presumably by way of a reductive elimination proceeding through intermediary **6**. This shorter procedure appears to hold promise for similar syntheses in this area.[2] Unfortunately, the material designated as **7**, which was obtained in either way in about 75% yield, was a non-crystallizable syrup despite chromatographic purification. It did not give wholly correct microanalytical data and displayed some features in its nmr spectrum which may cast doubt on its homogeneity.[3] Nevertheless, the next preparative operation performed with the product confirmed that **7** must have been its chief component. Hydrogenation with Adams catalyst in methanol in the presence of 1 equiv. of anhydrous hydrogen chloride gave a 68% yield of crystalline methyl 3-amino-2,3,6-trideoxy-α-D-*arabino*-hexopyranoside hydrochloride (**8**) which agreed well in its melting point and $[\alpha]_D$-value (with opposite sign) with the known (9), synthetic L-enantiomer (methyl α-L-acosaminide hydrochloride). Acid hydrolysis of **8** afforded D-acosamine hydrochloride (**9**), which crystallized in the downward mutarotating α-form. *N*,*N*-Dimethylation of **8** by the Eschweiler–Clarke procedure (14) and hydrolysis of the product gave 2,3,6-trideoxy-3-dimethylamino-D-*arabino*-hexose that was isolated as a crystalline hydrochloride (**10**). It proved identical with D-angolosamine hydrochloride from angolamycin according to melting point, optical rotation, and an infrared spectrum (in KBr) which showed every detail of the published (2), somewhat less well resolved spectrum of the natural product.

Experimental

Optical rotations were recorded at room temperature in a Perkin-Elmer 141 automatic polarimeter. The nmr data refer to 100-MHz spectra of solutions in $CDCl_3$, internally standardized with tetramethylsilane. Infrared spectra were taken from Nujol mulls unless otherwise indicated. Thin layer chromatography (tlc) was performed on plates coated with silica gel G (E. Merck AG); unless otherwise specified, the developing phase was 5% methanol in chloroform (solvent *A*) or 1:2 ethyl acetate – petroleum ether, bp 30–60°C (solvent *B*).

[2]In the same manner we have converted methyl 3,6-dideoxy-4-*O*-methylsulfonyl-3-nitro-α-D-glucopyranoside (mp 93–94.5°C, $[\alpha]_D$ +96.6° in chloroform) into methyl 3,4,6-trideoxy-3-nitro-α-D-*xylo*-hexopyranoside (mp 55–56°C, $[\alpha]_D$ +197° in chloroform), a convenient intermediate for a new synthesis of D-desosamine (H. H. Baer and F. F. Z. Georges, unpublished results).

[3]The nmr spectrum of the material in chloroform-*d* or pyridine showed the substituent resonances expected of **7**, namely, a 3-proton doublet at high field for C-CH_3 and a 3-proton singlet at lower field for O-CH_3, with a 2-proton multiplet assignable to the C-2 methylene group in the intermediate region. The remaining ring protons, however, gave partially overlapping signals that could not be analyzed satisfactorily. It is possible that the spectra were affected by remnants of boric acid, or that other foreign matter was present, or that the compound displays a conformational behavior not yet understood. In the latter connection it is interesting to note that the specific rotation was positive (+23°) in water but negative (−34.5°) in chloroform solution.

Methyl 2,3,4-Tri-O-acetyl-6-chloro-6-deoxy-α-D-glucopyranoside

Methyl α-D-glucopyranoside was chlorinated to give methyl 6-chloro-6-deoxy-α-D-glucopyranoside essentially as described in the literature (15), but the crude product was converted without prior chromatographic isolation into its 2,3,4-triacetate, as follows. Methanesulfonyl chloride (37.5 ml, 0.5 mol) was added to a stirred solution of the glucoside (19.4 g, 0.1 mol) in *N,N*-dimethylformamide (200 ml) under external cooling (18°C). The cooling bath was removed and the temperature allowed to rise to 70 ± 5°C, at which the reaction mixture was kept for 16 h. Then 1-propanol (80 ml) and water (20 ml) were added, and stirring was continued for another 3 h at the same temperature. The reaction mixture was evaporated to near dryness (50°C bath, water aspirator), and added 1-propanol (50 ml) was evaporated from the residue. The dry solid material was acetylated by stirring it overnight with acetic anhydride (50 ml) in dry pyridine (100 ml), at 25°C. Excess anhydride was thereafter destroyed by the addition of methanol (50 ml) followed, after 1 h, by 1-propanol (50 ml). Coevaporation of the mixture with several additional portions of propanol gave a residue which was then dissolved in chloroform (50 ml). The solution was washed with water (3 × 20 ml), dried over Na_2SO_4, and evaporated to give the crystalline title compound (28 g, 83%), mp 96–97°C after recrystallization from methanol, $[\alpha]_D$ +175.7° (*c* 1, $CHCl_3$) (lit. (15) mp 96–97°C, $[\alpha]_D$ +178°).

The above triacetate (7 g) was reduced (and simultaneously deacetylated) to furnish methyl 6-deoxy-α-D-glucopyranoside as reported (15) for the non-acetylated chloro compound except that 5 + 2 g (instead of 3 + 2 g) of lithium aluminum hydride was employed.

*Methyl 3,6-Dideoxy-3-nitro-α-D-glucopyranoside (**1**)*

Methyl 6-deoxy-α-D-glucopyranoside was oxidized on a 20-g scale with sodium metaperiodate, and the product was cyclized with nitromethane in the presence of sodium methoxide, exactly as detailed for the preparation (11) of the L-enantiomer of **1** from methyl α-L-rhamnopyranoside except that a reaction time of 3 h (instead of 40 min) was allowed for the cyclization. The extended time was chosen in consideration of studies (16) indicating that this will favor formation of **1** over its *manno* isomer. Compound **1** was obtained in 35% yield by direct crystallization from the mixture of products, and processing of the mother liquor by column chromatography (11*a*) was dispensed with; mp 140–142°C, $[\alpha]_D$ +163.2° (*c* 1, water) (lit. (11*a*) for L-**1**, mp 141–143°C, $[\alpha]_D$ −164.3° (water)). The ir spectra of the enantiomers were superimposable.

*Methyl 2,4-Di-O-acetyl-3,6-dideoxy-3-nitro-α-D-glucopyranoside (**2**)*

Compound **2** was obtained in 94–99% yield by boron trifluoride-catalyzed acetylation of **1** with acetic anhydride as described (12) for the L-enantiomer; mp 110–112°C, $[\alpha]_D$ +156° (*c* 1, $CHCl_3$) (lit. (12) for L-**2**: mp 113–113.5°C, $[\alpha]_D$ −155.3° ($CHCl_3$) and (17) mp 109–110°C, $[\alpha]_D$ −154° ($CHCl_3$).

*Methyl 4-O-Acetyl-3,6-dideoxy-3-nitro-α-D-glucopyranoside (**3**)*

The procedure of partial methanolysis reported (12) for the L-series was slightly modified. The diacetate **2** (2.0 g) was dissolved in methanol (20 ml, dried over and distilled from magnesium) and acetone (2 ml, dried over molecular sieves type 4-A). Acetyl chloride (1 ml) was added, and the solution was agitated at 40°C under exclusion of moisture. Progress of the reaction was monitored by tlc (solvent *A*) which indicated complete disappearance of **2** after 3 h and appearance of two slower spots of similar strength (**3** and **1**). The reaction mixture was then evaporated to give a syrup which was chromatographed (solvent *A*) on a column of silica gel (50 g). The faster moving component (**3**) was obtained from the column in pure form (0.85 g, 50%) and crystallized on standing overnight after solvent evaporation; mp 110–111°C, $[\alpha]_D$ +176.5° (*c* 1, $CHCl_3$) (lit. (12) for L-**3**: mp 112–113°C, $[\alpha]_D$ −178.5° ($CHCl_3$)). The ir and nmr data of the two enantiomers were identical.

*Compounds **4**, **5**, and **6***

Mesylation of **3** to give its 2-*O*-methylsulfonyl derivative **4** (80% yield), de-*O*-acetylation of **4** to afford methyl 3,6-dideoxy-2-*O*-methylsulfonyl-3-nitro-α-D-glucopyranoside (**5**) in 98% yield, and conversion of **5** into methyl 2,3,6-trideoxy-3-nitro-α-D-*erythro*-hex-2-enopyranoside (**6**) by treatment with sodium bicarbonate in refluxing benzene (92% yield) have been described (13).

*Methyl 2,3,6-Trideoxy-3-nitro-α-D-arabino-hexopyranoside (**7**)*

*(a) From the Nitro Olefin **6***

Sodium borohydride (0.33 g) was added to a solution of **6** (500 mg) in 99% ethanol (13 ml), which was stirred at room temperature. Examination by tlc (solvent *B*) revealed that the reaction was complete after 10 min. Methanol (3 ml) was added and stirring was continued for another 15 min. The solvent was then evaporated to near dryness of the residue, and the latter was taken up in chloroform (10 ml). The suspension was filtered through a layer of Celite and the filtrate evaporated. The resulting syrup was dissolved in a small amount (1.5 ml) of fresh chloroform, and a voluminous precipitate which formed upon addition of acetone (8 ml) was removed and discarded. The filtrate was evaporated and several portions of methanol were successively evaporated from the remaining residue which was finally passed through a column of silica gel (8 g) by means of chloroform. A fast-moving impurity that had been seen in tlc was thus removed. The chromatographically homogeneous fractions containing the main product yielded a syrup (377 mg, 75%) believed to consist chiefly of **7**. Attempts at crystallization were unsuccessful. The material showed $[\alpha]_D$ +23° (*c* 0.6, water), −34.5° (*c* 0.6, $CHCl_3$); ν_{max} (neat) 3200 (br, OH) and 1550 cm^{-1} (NO_2). The nmr data: 4.50 (2H, unresolved m), 3.83 (1H, m, H-5), 3.5 region (unresolved m), 3.41 (3H, s, O-CH_3), 2.33 (2H, q, H-2,2′), 1.14 (3H, d, J = 6.5 Hz, C-CH_3). *Anal.* calcd. for $C_7H_{13}NO_5$ (191.2): C 43.97, H 6.85, N 7.32; found: C 43.11, H 7.65, N 6.68.

*(b) From the 2-Mesylate **5***

Sodium borohydride (0.66 g) was added in small portions to a stirred solution of **5** (1.65 g) in 99% ethanol (25 ml), with cooling in a cold water bath. The further course of operations was as described under (*a*). There was obtained 829 mg (75%) of a syrup which was identical with the previous preparation according to ir and nmr spectra.

Methyl 3-Amino-2,3,6-trideoxy-α-D-arabino-hexopyranoside Hydrochloride (8)

The syrupy nitro glycoside **7** (150 mg, approximately 0.8 mmol) was dissolved in absolute methanol (15 ml) to which exactly 0.055 ml (0.78 mmol) of acetyl chloride had been previously added to generate hydrogen chloride. The solution was introduced in a high-pressure hydrogenation flask containing platinum catalyst (150 mg of PtO_2 prereduced in a few millilitres of methanol) and shaken for 3 h under hydrogen at 40 psi and room temperature. The filtered solution gave upon evaporation a dry residue which was dissolved in 99% ethanol (1.5 ml). Dropwise addition of ether at 0°C caused crystallization of **8** which was isolated after 3 h. The yield was 105 mg (68%); mp 193–195°C (dec.), $[\alpha]_D$ +112.7° (*c* 0.5, methanol) (lit. (9*a*) for L-**8**: mp 196–198°C (dec.), $[\alpha]_D$ −115.5° (methanol)).

3-Amino-2,3,6-trideoxy-D-arabino-hexose Hydrochloride (9) (D-Acosamine Hydrochloride)

The amino glycoside **8** (50 mg) was hydrolyzed in 0.1 *M* hydrochloric acid (3 ml) for 1 h at 90°C. The hydrolyzate was evaporated to a brownish syrup with the addition of several portions of 40% aqueous ethanol. The product was finally dissolved in ethanol, decolorized with activated charcoal, and recovered by evaporation to near dryness. Trituration of the residue with a few drops of ethyl acetate gave crystalline **9**, $[\alpha]_D$ +31° (initial) → +22° (final, 3 h; *c* 0.7, water) (lit. (8) for L-**9**: $[\alpha]_D$ −18.3° at equilibrium (*c* 0.43, water)). We had previously obtained **9** in a crystalline form (presumably the α-anomer) showing $[\alpha]_D$ +81.7° (in water) without mutarotation (5). We have now hydrolyzed (1 h at 100°C in 0.5 *M* hydrochloric acid) a sample of the *N*-acetyl derivative of **9** that was still available from the previous work (5) and found $[\alpha]_D$ +18° for the product in the hydrolysis solution. The reason for the apparent lack of mutarotation of the earlier sample of **9** is not clear.

2,3,6-Trideoxy-3-dimethylamino-D-arabino-hexose Hydrochloride (10) (D-Angolosamine Hydrochloride)

A solution of the amino glycoside hydrochloride **8** (55 mg) in 37% aqueous formaldehyde (1.5 ml) was slightly basified with a few drops of 0.1 *N* sodium hydroxide solution, and 90% formic acid (3.5 ml) was then added. The mixture was heated to reflux for 5 h and then evaporated and coevaporated with added portions of ethanol. The resultant material was taken up in cold ethanol (1 ml) and kept at 0°C for 30 min, after which time an undissolved residue was filtered off and the filtrate evaporated to dryness. The product was hydrolyzed in 0.1 *M* hydrochloric acid (2 ml) for 1 h at 90°C. Removal of the acid by coevaporation with 40% aqueous ethanol gave a semicrystalline, brownish mass which was decolorized in ethanolic solution with activated charcoal. Concentration of the filtrate, ice cooling, and dropwise addition of absolute ether readily gave crystalline **10** (19 mg, 32%) which was washed repeatedly with cold ether; mp 170–173.5°C, $[\alpha]_D$ +5.5° (equilibrium; *c* 1, water) (lit. (2), mp 172–174°C, $[\alpha]_D$ +4.6° (water)). The infrared spectrum of **10** (in KBr) showed excellent agreement with the depicted (2) spectrum of the natural product.

The molecular structures of dichloro(dimethyl)germane and trichloro(methyl)germane have been determined in the vapour phase by electron diffraction. The principal geometrical parameters for $(CH_3)_2GeCl_2$ are r_g(Ge—Cl) = 2.143 ± 0.004 Å, r_g(Ge—C) = 1.928 ± 0.006 Å, ∠(ClGeCl) = 105 ± 2°, ∠(CGeCl) = 108 ± 2°, and ∠(CGeC) = 121 ± 4°. In the analysis of CH_3GeGl_3 recently reported values of the rotational constants were combined with the electron diffraction data to give r_g(Ge—Cl) = 2.132 ± 0.003 Å, r_g(Ge—C) = 1.893 ± 0.010 Å, ∠(CGeCl) = 112.3 ± 0.9°, and ∠(ClGeCl) = 106.4 ± 0.7°. In both cases the methylgermane geometry was assumed for the methyl group (r_g(C—H) = 1.103 Å and ∠(GeCH) = 110.5°) which was fixed in the staggered configuration with respect to the C_2GeCl_2 and $CGeCl_3$ frames respectively. Both random and systematic errors were included in the uncertainty estimates, which are believed to be approximately at the 95% confidence level. In the case of $(CH_3)_2GeCl_2$ the uncertainties in ∠(ClGeCl), ∠(CGeCl), and ∠(CGeC) were enlarged to four times the least-squares values in order to reflect the difficulty of resolving the Cl...Cl, C...Cl, and C...C distances in the analysis.

JOHN E. DRAKE, J. LAWRENCE HENCHER et QUANG SHEN. Can. J. Chem. **55**, 1104 (1977).

On a déterminé les structures moléculaires du dichloro(diméthyle)germane et du trichloro-(méthyle)germane en phase gazeuse en faisant appel à la diffraction des électrons. Les principaux paramètres géométriques du $(CH_3)_2GeCl_2$ sont r_g(Ge—Cl) = 2.143 ± 0.004 Å, r_g(Ge—C) = 1.928 ± 0.006 Å, ∠(ClGeCl) = 105 ± 2°, ∠(CGeCl) = 108 ± 2° et ∠(CGeC) = 121 ± 4°. Dans l'analyse du CH_3GeCl_3, les valeurs des constantes de rotation, qui ont été rapportées récemment, ont été combinées avec des données de diffractions d'électrons pour conduire aux valeurs r_g(Ge—Cl) = 2.132 ± 0.003 Å, r_g(Ge—C) = 1.893 ± 0.010 Å, ∠(CGeCl) = 112.3 ± 0.9°, et ∠(ClGeCl) = 106.4 ± 0.7°. Dans les deux cas on a fait l'hypothèse que la géométrie du méthyle du méthylgermane est (r_g(C—H) = 1.103 Å et ∠(GeCH) = 110.5°) et on a fixé ce groupe dans une configuration décalée par rapport respectivement aux dispositions des C_2GeCl_2 et $CGeCl_3$. On a inclu les erreurs systématiques ainsi que celles dues au hasard dans les estimés des incertitudes que l'on croit être approximativement au niveau de confiance de 95%. Dans le cas du $(CH_3)_2GeCl_2$, les incertitudes dans les angles ∠(ClGeCl), ∠CGeCl) et ∠(CGeC) sont agrandies jusqu'à un niveau de quatre fois les valeurs des moindres carrés de façon à refléter les difficultés qu'il y a de résoudre les distances Cl...Cl, C...Cl, et C...C dans l'analyse.

[Traduit par le journal]

Introduction

In the recently determined structures of Me_4Ge (1), Me_2GeF_2 and $MeGeF_3$ (2), and Me_2GeBr_2 and $MeGeBr_3$ (3), large variations in the bond lengths and valence angles were observed to depend on the number of halogen atoms. We now report the structures of Me_2GeCl_2 and $MeGeCl_3$ as part of a continuing study of this group of compounds.

Experimental

The samples of both compounds were obtained from Alfa Inorganics Inc. The nmr spectra revealed no known impurities after simple vacuum distillation.

Sectored electron diffraction patterns were recorded on Kodak Electron Image Plates, which were developed and microphotometered as previously described (1, 4). A summary of the experimental conditions is given in Table 1. The s scale ($s = (4\pi/\lambda)\sin(\theta/2)$, λ = electron wavelength) for the diffraction angle, θ, was determined from CS_2 diffraction patterns using the structure suggested by Kuchitsu (5).

The procedure used to extract the experimental molecular intensity, $sI_m^x(s)$, and the details of the corresponding theoretical expression were the same as previously described (1, 2). In the least-squares analysis a set of independent bond lengths and angles, based on the r_g interatomic distances (6), and the root-mean-square amplitudes, l_{ij}, were the parameters. A diagonal weight matrix was employed.

The parameter uncertainties were estimated as $2(\sigma_{1s}^2 + \sigma_{sys}^2)^{1/2}$. The σ_{1s}^2 were obtained from the diagonal elements of the zeroth order, error matrix, M_x^0 as M_x =

TABLE 1. Experimental conditions

Compound	Sample pressure[a] (torr)	Camera length (mm)	Exposure time (s)	Optical density range	Number of plates	Useful range of s values ($Å^{-1}$)	Resolution factor[b]
Me_2GeCl_2	8	296.68	15	0.1–0.3	3	3–16	1.303 (10)
	8	95.24	60, 65, 70	0.3–0.8	3	15–33	1.226 (13)
$MeGeCl_3$	8	296.79	15, 25, 30	0.2–0.4	3	3–16	1.260 (15)
	8	95.22	50, 60, 70	0.3–1.0	3	15–35	1.229 (20)

[a]High voltage 58 kV stabilized to $< 1 \times 10^{-4}$; beam current 1×10^{-7} A; background pressure during exposures, $1–3 \times 10^{-5}$ torr; nozzle temperature, 21°C.
[b]Resolution factor $= \sum(|sI_m(s)|)_{calc} / (|sI_m{}^x(s)|)$. Reference numbers in parentheses.

$R_{aa}M_x{}^0$ where $R_{aa} = 2\gamma/[\Delta s(\gamma^2 + r^2)]$, (6, 7). With $\Delta s = (\pi/10)$ $Å^{-1}$, $\gamma = 1$ Å and r, the bond length, 2 Å (Ge—Cl or Ge—C for example), $R_{aa} \approx 1.3$. The overall systematic error, σ_{sys} due to the s scale uncertainty was estimated to be ± 0.002 Å for an interatomic distance. The factor, 2, estimates the 95% confidence level, assuming that the errors are randomly distributed (7).

Tables of the reduced intensities, backgrounds, and $sI_m(s)$ are available from the Depository of Unpublished Data.[2]

Analyses

Analysis of $MeGeCl_3$

The independent geometrical parameters were r(C—H), r(Ge—C), r(Ge—Cl), ∠(CGeCl), and τ(HCGeCl) (the angle of rotation of the methyl group about the Ge—C bond, relative to the eclipsed configuration). All parameters involving hydrogen were given assumed values and fixed in the least-squares analysis.[3] Simultaneous refinement of the remaining geometrical parameters was only possible when l(C...Cl) and l(Ge—C) were fixed, and led to an uncertain value of r(Ge—C) but good results were obtained for r(Ge—Cl), (2.132 ± 0.003 Å) and ∠(CGeCl) (112 ± 1°). The angle was consistent with the values of ∠(CGeX) in $MeGeF_3$ (2) and $MeGeBr_3$ (3) which were also larger than tetrahedral.

In the course of this work, a partial r_s structure was reported (8), based on rotational constants obtained by microwave spectroscopy. The bond length r_s(Ge—Cl) = 2.135 ± 0.006 Å agreed with our result, barring the difference between the r_s and r_g distance formalisms; however, ∠(CGeCl) was reported to be 106.0 ± 0.7° which is smaller by 6° than our electron diffraction result. Also, the value of r_s(Ge—C) = 1.945 assumed by the authors in their analysis was several hundredths of an Angstrom longer than we have found for $MeGeF_3$ (1.904 ± 0.009 Å) and $MeGeBr_3$ (1.89 ± 0.03 Å). Although there were difficulties in the electron diffraction analysis, as noted above, the angle was thought to be well determined (±1°). There was no evidence of large amplitude vibrational effects such as unusual broadness of the r(Cl...Cl)/r(C...Cl) peak in the radial distribution curve, and the experimental l(Cl...Cl) agreed well with the value calculated from the harmonic force field (8). Moreover, this angle is *predicted to be greater* than 109.5° by both the rehybridization and VSEPR theories, on the basis of the electronegativity arguments (see Discussion below). The reason for the discrepancy is probably the large value assumed for r(Ge—C) in the spectroscopic treatment. In a preliminary analysis of the rotational constants we found that with r(Ge—C) = 1.90 Å fixed, ∠(CGeCl) approached the electron diffraction result.

It was apparent that neither technique could determine all the parameters simultaneously; however, if the electron diffraction results were assumed for r(Ge—Cl) and ∠(CGeCl) and the methyl group geometry (r(C—H), ∠(GeCH), and τ(HCGeCl)) was transferred from methylgermane, only r(Ge—C) would remain to be determined from the rotational constants.

In the combined analysis of the spectroscopic and electron diffraction data, the structural parameters were referred to the distances between the mean atomic positions, $r_\alpha{}^0$ (0 K, electron diffraction) and equivalently r_z (ground vibrational state, spectroscopic) obtained by

[2]Photocopies may be obtained at a nominal charge, upon request, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

[3]The scattering components due to r(C—H), r(Ge...H), etc. were very weak compared to r(Ge—Cl) and r(Cl...Cl) and were not well enough resolved to determine these parameters.

TABLE 2. r_z[a] structure of $MeGeCl_3$ and calculated rotational constants

[e] Taken from the methylgermane structure, see ref. 8.

making corrections for the effects of vibrational averaging on the interatomic distances and rotational constants respectively. The r_α^0 (9) were obtained from

$$[1] \quad r_\alpha^0 = r_g - \tfrac{3}{2}a[(l_{ij}^T)^2 - (l_{ij}^0)^2] - K_{ij}^0$$

where the Morse anharmonicity constants, a, were obtained from the estimated quadratic and cubic force constants (10) as 1.6 $Å^{-1}$ for Ge—Cl and 1.7 $Å^{-1}$ for Ge—C. The l_{ij}^T (T K = sample temperature), l_{ij}^0 (0 K) and K_{ij}^0 (0 K) (the vibrational correction due to the vibrational motion perpendicular to the bond), calculated from the known force field (8) by the methods of Stølevik *et al.* (11), are given in Table 3. The r_z were obtained from the $B_z^{(\alpha)}$ ($\alpha = a$, b, or c axis) (12) which were given by

$$[2] \quad B_z^{(\alpha)} = B_0^{(\alpha)} - \sum_{p=1}^{3N-6} \frac{B^2}{\omega_s}\left[3A_{ss}^{(\alpha\alpha)}\, 4 \sum_{\substack{s' \neq s \\ \omega_{s'} \neq \omega_s}} (\zeta_{ss'}^{(\alpha)})^2 \omega_{s'}^2/(\omega_s^2 - \omega_{s'}^2) - 3 \sum_{s'=s} (\zeta_{ss'}^{(\alpha)})\right]$$

where

$$A_{ss}^{(\alpha\alpha)} = 1 - \sum_i (l_{is}^{(\alpha)})^2$$

$$\zeta_{ss'}^{(\alpha)} = \sum_i (l_{is}^{(\beta)}\, l_{is'}^{(\gamma)} - l_{is}^{(\gamma)} l_{is'}^{(\beta)})$$

and $l_{is}^{(\alpha)}$ is the component of the ith atom in the sth normal mode for axis α. In all cases the x, y, and z axes were transformed to coincide with the inertial axes a, b, and c. The $\zeta_{ss'}^{(\alpha)}$ are the Coriolis coupling constants for normal modes s and s'.[4] A small correction for centrifugal distortion was ignored. As a test, the computer program successfully reproduced the previously reported

[4] Equation 2 differs from the reference in the notation used for the sums. Here, $\omega_{s'} = \omega_s$ indicates degenerate modes.

[a]Distances in Å and angles in degrees are based on the r_g distances and least-squares parameters given in Tables 4 and 5. The quoted uncertainties reflect both random and systematic errors discussed in the text.
[b]r_g values calculated from the r_z distances given in Table 2.
[c]All rms amplitudes calculated from the molecular force fields.
[d]$R = \{\Sigma_s[sM_{expt}(s) - sM_{theor}(s)]^2/\Sigma_s[sM_{expt}(s)]^2\}^{1/2}$.

vibrational parameters and rotational constants for H_2O (13), COF_2 (13), CH_3CN (14), and B_2H_6 (9). The observed and calculated rotational constants and the r_z structural parameters are presented in Table 2.

The differences between the observed and calculated $B_z^{(\alpha)}$'s for the symmetrically substituted species correspond to a ±0.002 Å variation in r_z(Ge—C) if all other parameters are considered exact. The agreement in the $MeGe^{37}Cl^{35}Cl_2$ cases is somewhat worse and may be a reflection of the severe constraints which were adopted. It was found that ±1° variation in ∠(GeCH) resulted in a further ±0.006 variation in r_z(Ge—C). Taking these factors into account it appeared that r_z(Ge—C) = 1.889 ± 0.010 Å was a reasonable estimate.

The r_g(Ge—C) parameter was obtained from r_z(Ge—C) using eq. 1 and fixed in a subsequent least-squares analysis of the electron diffraction data alone. The resulting r_g structure is presented in Table 3 and the matrix of correlation coefficients is given in Table 4. The molecular intensity is presented in Fig. 1.

Analysis of Me_2GeCl_2

The independent geometric parameters selected for Me_2GeCl_2 were r(C—H), r(Ge—C), r(Ge—Cl), ½∠(ClGeCl), ∠(ZGeCl) (π − ½∠(CGeC)), ∠(HCGe), and τ(HCGeCl) (the angle of rotation of the C—H bond about Ge—C relative to Ge—Cl). As in the case of $MeGeCl_3$ all parameters involving hydrogen atoms were given fixed values.[3]

TABLE 4. Correlation matrix for refined parameters of $MeGeCl_3$ (electron diffraction data only)

[a]Least-squares uncertainties representing only random errors in the present electron diffraction data.
[b]k_L, k_S are resolution factors for long and short camera lengths respectively.

In the least-squares analysis it was found that ½∠(ClGeCl), ∠(ZGeC), l(Ge—C), l(Cl...Cl), l(C...Cl), and l(C...C) could not be refined simultaneously because the scattering components due to r(Cl...Cl), r(C...Cl), and r(C...C) could not be resolved. This difficulty was partly overcome by fixing the l_{ij}'s at values calculated from the molecular force field (15). The correlation coefficients of the least-squares parameters are given in Table 5. The molecular

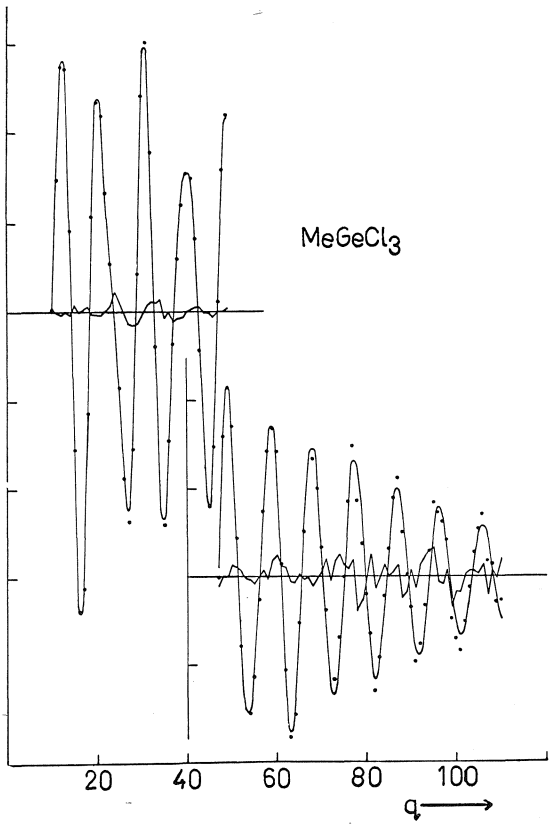

FIG. 1. The molecular intensity of $MeGeCl_3$. (*A*) Experimental (dots), theoretical (solid), and difference curves for the long distance camera. (*B*) Experimental (dots), theoretical (solid), and different curves for the short distance camera. The theoretical curves were calculated from the final structural parameters.

structure, based on these parameters, is given in Table 3. The molecular intensity $sI_m(s)$ is given in Fig. 2.

The difficulty of determining the two angle parameters is clear from the values of the Cl...Cl, C...Cl, and C...C distances given in Table 3, which are within less than a mean square amplitude of each other. Even with r(Ge—Cl) and r(Ge—C) well determined, and with independently obtained l_{ij}'s, these distances cannot be resolved mainly because the weakest component, due to C...C is comparable with the random intensity errors. Moreover, the effects of systematic intensity errors (16) were not evaluated in the present analysis. As a consequence, the uncertainties in the angles were much larger than indicated by the least-squares analysis. As a rough estimate, based on the comparison of trends in these angles within Me_2GeF_2 and Me_2GeBr_2, which were previously determined, the uncertainties in the angles were taken as four times the least-squares estimates.

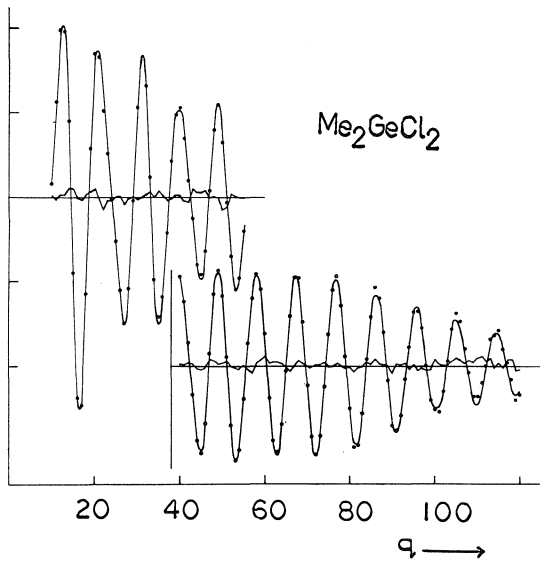

FIG. 2. The molecular intensity of Me_2GeCl_2. (*A*) Experimental (dots), theoretical (solid), and difference curves for the long distance camera. (*B*) Experimental (dots), theoretical (solid), and difference curves for the short distance camera. The theoretical curves were calculated from the final structural parameters.

Discussion

The structures of Me_3GeCl (16), Me_2GeCl_2, $MeGeCl_3$ (see Table 6) follow the same trends as the corresponding fluorides (2) and bromides (3). When successive chlorines are substituted for methyl groups, both the Ge—C and Ge—Cl bonds become shorter, and the angles deviate from the tetrahedron in the way predicted by the valence shell electron pair repulsion model (VSEPR) (18) as discussed previously (2). The observed trends in Ge—C bond length suggest that the change does not depend much on the species of halogen atom. In the trihalides, $MeGeX_3$, r(Ge—C) = 1.89(3) (Br), 1.893(10) (Cl), and 1.904(9) (F), while in the dihalides, Me_2GeX_2, r(Ge—C) = 1.91(1) (Br), 1.924(6) (Cl), and 1.928(3) (F). The overall large variation in bond length depends on the number of halogen atoms, not whether they are F, Cl, or Br. This trend is borne out by the similarities in the angles: XGeX angles ~ 105°, CGeX ~ 107° in the dihalides; and XGeX ~ 106° and CGeX ~ 112° in the trihalides.

The major changes in geometry are strongly correlated with changes in charge distribution. In Table 6, formal atomic charges estimated by equalizing electronegativities (20) are compared with the r(Ge—Cl) and r(Ge—C) of several molecules. The effect of successive halogen substitution in the methyl series is to make *all* the atoms more positive and to increase the difference in charges between germanium and the ligand. The angles between negatively charged ligands tend to be smallest, while those between positively charged ligands tend to be largest (see Table 2) which is consistent with the VSEPR model.

Acknowledgments

The authors wish to thank Dr. L. S. Bartell for very helpful discussions, particularly concerning the error analysis. The financial support of the National Research Council of Canada is also gratefully acknowledged.

Carbohydrates as chiral intermediates in organic synthesis. Two functionalized chemical precursors comprising eight of the ten chiral centers of erythronolide A[1]

STEPHEN HANESSIAN AND GEORGES RANCOURT[2]

Department of Chemistry, University of Montreal, Montreal, P.Q., Canada H3C 3V1

Received December 29, 1976

STEPHEN HANESSIAN and GEORGES RANCOURT. Can. J. Chem. **55**, 1111 (1977).

Two appropriately functionalized branched-chain sugars have been synthesized as potentially useful chemical precursors to erythronolide A, encompassing its C-1–C-6 and C-9–C-15 segments respectively.

STEPHEN HANESSIAN et GEORGES RANCOURT. Can. J. Chem. **55**, 1111 (1977).

La synthèse de deux sucres ramifiés et fonctionnalisés, qui seraient potentiellement utiles comme précurseurs chimiques de l'érythronolide A, et correspondant à ses segments C-1–C-6 et C-9–C-15 respectivement est décrite.

In connection with a long-standing program designed to utilize carbohydrates as chiral intermediates in organic synthesis, we now report the synthesis of two, fully functionalized precursors to erythronolide A, **1**, encompassing its C-1–C-6 and C-9–C-15 segments, respectively. Efforts directed toward the total synthesis of macrolide antibiotics (1) have been recently highlighted by the ingenious development of macrolactonization procedures (2–4), and the first total synthesis of a macrolide antibiotic, methymycin (4), and a partial synthesis of tylonolide hemiacetal (5). The pursuit of equally formidable synthetic objectives will undoubtedly be immensely facilitated in the immediate future, by the availability of appropriately substituted, chiral precursors, in preparatively significant quantities.

The task of overcoming the functional and stereochemical complexities present in erythronolide A, **1**,[3] can be considerably simplified with the recognition of the sequence of chiral centers as two functionalized, acyclic, carbohydrate-derived chains (6). This can be best illustrated in **2**, where C-1–C-6, and C-9–C-15 can be configurationally related to two precursors, I and II, having the L-*ido* and D-*gluco* stereochemistry, respectively. Our synthetic plan for the elabora-

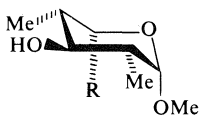
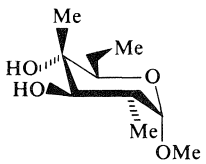
2



Precursor I
R = COOMe, COMe

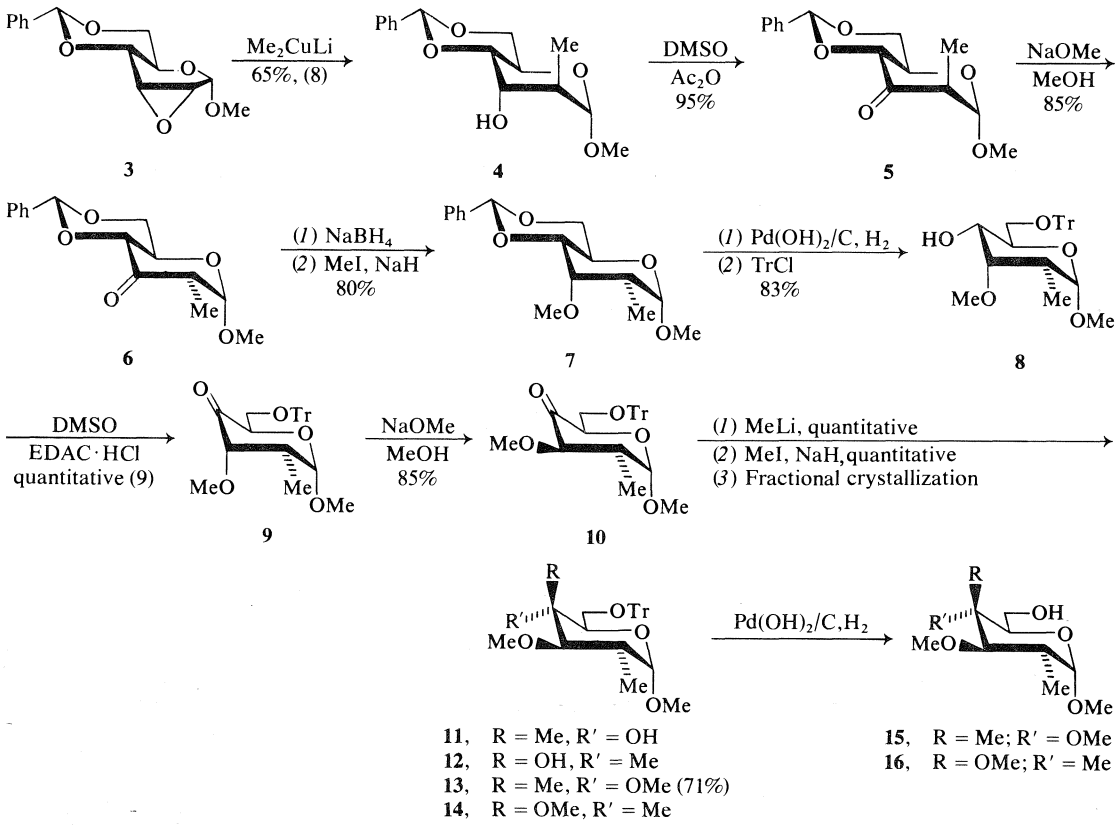


Precursor II

[1]Portions of this work were disclosed at a symposium on Modern research related to asymmetry in carbohydrates, Centennial meeting, Am. Chem. Soc., New York, NY, 1976; see ref. 6.

[2]NRCC predoctoral fellow.

[3]Because of the phenomenon of pseudorotation, the various groups in **1** tend to adopt orientations that depend on the arbitrary choice of conformation (see for example, ref. 7).



SCHEME 1. **4**, mp 111.5–112.5°C, $[\alpha]_D$ +118.1°; **5**, mp 125.5–127°C, $[\alpha]_D$ +75.2°; **6**, mp 199–201°C, $[\alpha]_D$ +143.6°C; **7**, mp 140–141°C, $[\alpha]_D$ +115.4°; **8**, mp 135–137°C, $[\alpha]_D$ +79.8°C; **10**, mp 137.5–139.5°C, $[\alpha]_D$ +130.1°C; **11**, syrup, $[\alpha]_D$ +53.1°C; **12**, mp 133–135°C; **13**, mp 155–157°C, $[\alpha]_D$ +72.9°; **15**, syrup, $[\alpha]_D$ +167°.

tion of these two precursors starts with D-glucose, and is based on the systematic and stereocontrolled introduction of appropriate functional groups as illustrated in Schemes 1 and 2.[4]

Precursor I

Detritylation of the mother liquors resulting from the crystallization of **13**, gave a mixture of **15** and **16**, which was oxidized (10) to the 6-*aldehydo* derivatives **17** (Scheme 2). Treatment of **17** with aqueous calcium hydroxide afforded **18** as a syrup (85–90%); $[\alpha]_D$ +227°, which was converted in high yield to **19** (syrup), $[\alpha]_D$ +184.5° by a known procedure (11). Catalytic hydrogenation of **19**, gave, almost exclusively, the expected product **20**, as a syrup (85–90%); $[\alpha]_D$ +97.3°.[5] Alternatively, treatment of the mixture of **17** with methyllithium, and oxidation (12) of the resulting mixture of epimeric alcohols to the ketones **21**, followed by base-catalyzed elimination (NaOMe), gave **22** as a syrup (64%); $[\alpha]_D$ +193.6°. Catalytic hydrogenation gave the expected product **23** (syrup), $[\alpha]_D$ +157.3°.[5,6]

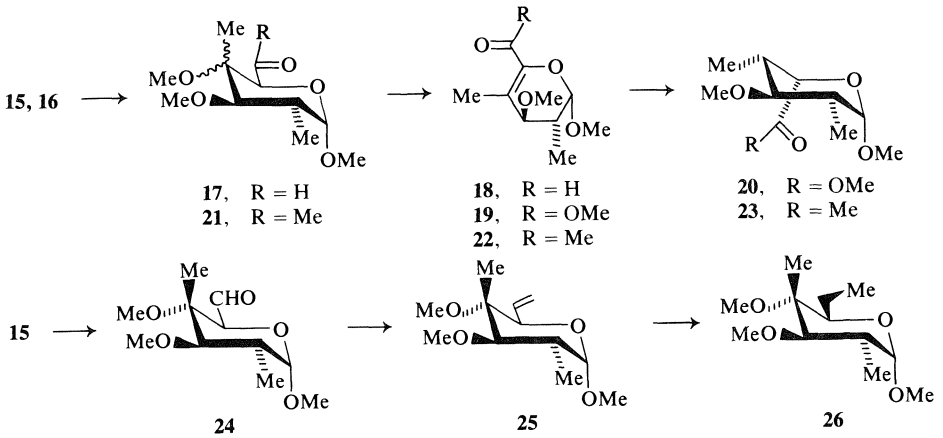
Precursor II

Detritylation of the crystalline isomer **13** gave **15**, which was oxidized (10) to **24** (90–95%), and the latter was transformed via a Wittig reaction into **25** (syrup), $[\alpha]_D$ +190.2°. Catalytic hydro-

[4]New crystalline compounds gave correct microanalyses. All compounds had ^{1}Hmr and mass spectral features that were in accord with their structures. Yields are not optimized and melting points are uncorrected. Optical rotations were measured at 25°C in chloroform, at concentrations of 0.5–1.5%.

[5]A *CI* conformation is indicated from ^{1}Hmr data.

[6]Treatment of **23** with base (NaOMe) effected virtually complete epimerization at C-5.



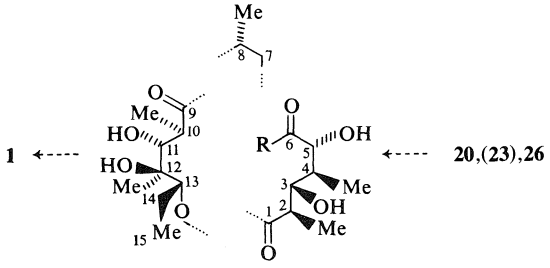
SCHEME 2

genation gave the desired product **26** as a syrup (85%), $[\alpha]_D$ +169.3°.

It is pertinent to note that the easily obtainable **13**, and the mother liquors resulting from its crystallization, are individually used in the preparation of precursors II and I, respectively, thus rendering the entire sequence highly efficient.

Compounds **20** (or **23**) and **26** are suitably protected derivatives of precursors I and II that can be obtained in gram quantities via a synthetic scheme involving crystalline intermediates, without recourse to chromatographic separation. These compounds comprise eight of the ten chiral centers and all but a two-carbon segment bearing a *C*-methyl group present in erythronolide A. The chiral and functional relationships between these compounds and the C-1–C-6 and C-9–C-15 segments of erythronolide A are depicted in Scheme 3.

The particular attributes of this seldom exploited carbohydrate precursor approach to total synthesis, as exemplified in this paper, are its conceptual simplicity, versatility, and practicality.[7] It is also evident that the total synthesis of other macrolide aglycones could be based on a similar approach, involving carbohydrate-derived precursors such as I and II that can be further manipulated and incorporated into the structural framework of these complex molecules.



SCHEME 3

[7]A basically similar approach has been alluded to (13), and has led to a study of chain-branching reactions at C-2 and C-4 in sugar derivatives.

Synthesis and crystal structure of diiodotetraethylthiuramdisulfidemercury(II)

CHUNG CHIEH

Guelph–Waterloo Centre for Graduate Work in Chemistry, Waterloo Campus, University of Waterloo, Waterloo, Ont., Canada N2L 3G1

Received October 18, 1976

CHUNG CHIEH. Can. J. Chem. **55**, 1115 (1977).

Reaction of mercury(II) iodide with tetraethylthiuramdisulfide in chloroform and ethanol mixed solvent produced bis(iodo-*N*,*N*-diethyldithiocarbamatomercury(II)) and diiodotetraethylthiuramdisulfidemercury(II), HgI_2.TETD. The crystal of HgI_2.TETD is orthorhombic with $a = 13.101(9)$, $b = 13.999(9)$, $c = 22.742(15)$ Å; space group *Pbca*. The structure was solved with 1960 observed reflections measured by a G.E. XRD-6 diffractometer. The final R factor was 0.064. The mercury atom is four-coordinated with two identical Hg—I distances of 2.668(1) Å and two Hg—S distances of 2.670(7) and 2.737(7) Å. The coordination is tetrahedral.

CHUNG CHIEH. Can. J. Chem. **55**, 1115 (1977).

La réaction de l'iodure mercurique(II) avec le tétraéthylthiuramdisulfure dans un solvant mixte de chloroforme et d'éthanol conduit au bis(iodo-*N*,*N*-diéthyldithiocarbamatomercure(II)) et au diiodotétraéthylthiuramdisulfure mercure(II), HgI_2.TETD. Le cristal de HgI_2.TETD est orthorhombique avec $a = 13.101(9)$, $b = 13.999(9)$, $c = 22.742(15)$ Å; groupe d'espace *Pbca*. On a résolu la structure à partir des 1960 réflexions observées par des mesures avec un diffractomètre G.E. XRD-6. Le facteur final de R est de 0.064. L'atome de mercure est tétracoordonné avec deux distances Hg—I identiques de 2.668(1) Å et deux distances Hg—S de 2.670(7) et 2.737(7) Å. La coordination est tétraédrique.

Introduction

Chelating agents furnish the basis for medical treatment of many kinds of heavy metal poisoning. For example 2,3-dimercapto-1-propanol or BAL (British Anti-Lewisite) was used as an antidote for arsenic poisoning (1), and it was also found to be effective in the treatment of mercury poisoning. The affinity between mercury and the —SH group led to the use of unithiol, D-penicillamine, and *N*-acetyl-D-penicillamine as therapeutic agents for mercury poisoning but not without problems (2, 3). For a compound to be effective in removing heavy metals from a biological system, it or its metabolic products should form a stable complex and facilitate subsequent excretion. A cautious approach must be taken in the use of chelating agents, for complexation may enhance the toxicity of metal ions (4). Chelating agents containing —SH groups have been used in medicine, but no consideration has been given to compounds containing C=S groups as possible therapeutic agents (1). Thiourea (tu, $SC(NH_2)_2$) forms a series of complexes with mercury(II) chloride of stoichiometry $HgCl_2(tu)n$ ($n = 1$–4) (5, 6). In view of the complicated coordination chemistry between mercury and sulfur, the interaction of mercurials and tetraethylthioperoxydicarbonic diamide, which is better known as tetraethylthiuram disulfide (TETD), was studied. Some of the results have been published (7, 8). The reaction of mercury(II) iodide with TETD

in ethanol–chloroform solution (1:1 by volume) produced diiodotetraethylthiuramdisulfidemercury(II) in addition to bis(iodo-*N*,*N*-diethyldithiocarbamatomercury(II)) (8).

Although the existence of a HgI_2.TETD complex was mentioned by Brinkhoff *et al.* in their nmr studies (9), the formation of $(Et_2NCS_2HgI)_2$ was not mentioned. Both compounds were obtained in the same reaction; however their crystals were different in shape. Crystals of $(Et_2NCS_2HgI)_2$ were hexagonal prisms or sometimes irregular in shape whereas HgI_2.TETD crystals were square plates. The crystal structure of the latter is described in this paper.

Experimental

The red form of mercury(II) iodide was purchased from Fisher Scientific Co. and tetraethylthiuram disulfide from Sigma Chemical Company, St. Louis, MO. Reagent grade chloroform and absolute ethanol were used.

To 50 ml solution of TETD (0.21 g) in chloroform–ethanol (1:1 by volume), red crystalline mercury(II) iodide (0.32 g) was added. At room temperature (25 ± 3°C) the reaction proceeded rather quickly. In about 10 min, yellow square plates were seen under a 30× microscope. Both the red mercury(II) iodide and square plate crystals dissolved slowly resulting in a pale yellow solution in a few hours. The solution was then partially covered to allow slow evaporation. When the solution was reduced to 1 ml, both square plates and hexagonal prisms were obtained after filtration. Due to the fact that both crystals were of the same color, it was a difficult task to obtain enough sample for elemental analysis by separation under the microscope. With mixture, elemental analysis would have been meaningless. However, single crystals suitable for X-ray diffraction studies were easily chosen.

Raman spectra of solids were obtained on a Jarrel-Ash 25-100 spectrometer with argon ion laser excitation.

Cell constants and space groups were determined from photographic measurements; however, the former were refined by least-squares methods based on the 2θ (MoKα, Zr-filtered radiation) values of 17 reflections measured on a G.E. XRD-6 diffractometer.

Crystal Data

$C_{10}H_{20}HgI_2N_2S_4$ fw = 750.9

Orthorhombic, a = 13.101(9), b = 13.999(9), c = 22.742(15) Å, V = 4170.9 Å^3; ρ_m = 2.40(1) (by floatation), Z = 8, ρ_c = 2.391, (25°C, Mo–Kα, λ = 0.7107 Å); mp = 136°C; μ(MoKα) = 109.0 cm^{-1}. Space group *Pbca* (from systematic absences $0kl$, $k = 2n + 1$, $h0l$, $l = 2n + 1$; $hk0$, $h = 2n + 1$).

The crystal used for intensity measurements was approximately a sphere of diameter 0.13 mm cut from a square plate. The crystal was mounted with [111] along the φ axis of the goniostat of a G.E. XRD-6 card-controlled automatic diffractometer, which was equipped with a scintillation counter, pulse height analyzer, and Hewlett-Packard Scaler-Timer (Model 5201L). Intensities of 6044 reflections with 2θ ≤ 60 (Zr-filtered MoKα radiation) were measured using the stationary-crystal stationary-counter method. The scan method was not suitable because of the long c-axis. Four standard reflections (020, 112, 200, and 220) were repeatedly measured after each 100 reflections and showed a fluctuation of ±3% in their intensities throughout the data collection period. An averaged background curve as a function of 2θ was obtained from measurements with the crystal in several orientations. Integrated intensities were calculated by subtracting the corresponding backgrounds from the 30-second-counts for all reflections. Standard deviations $\sigma(I)$ were estimated according to counting statistics. A set of 1960 reflections for which $I > 3\sigma(I)$ was considered as observed and used in the structure determination. Many of the high-angle (2θ ≥ 45°) reflections were unobserved. No absorption correction was made (μ_R = 0.71). Lorentz and polarization correction were applied to derive the structure amplitudes.

The structure was solved by heavy atom methods. The initial x-coordinate for Hg atom was zero, and the Fourier map obtained from the phase of Hg only had false symmetry. When the two iodine atoms were included to calculate the phase, the Fourier map revealed the four sulfur atoms. Other non-hydrogen atoms were located in subsequent Fourier maps. With 19 atoms of Table 1 having isotropic thermal parameters, full-matrix least-squares refinement led to a $R = (\Sigma||F_o| - |F_c||)/\Sigma|F_o| = 0.13$. The revised program written by Doedens and Ibers was used. The atomic scattering factors from Cromer and Waber (10) were used with anomalous dispersion coefficients for Hg and I atoms from Cromer (11). With anisotropic thermal parameters for all atoms and a weighting scheme of $w^{-1} = (90.0 - F_o + 0.001F_o^2)$, the refinements gave $R = 0.064$ and $R_w = (\Sigma w^2(||F_o| - |F_c||)^2/\Sigma w^2|F_o|^2)^{1/2} = 0.083$. The weighting scheme gave uniform errors, $\Sigma w^2(|F_o| - |F_c|)^2/(m - n)$, in all ranges of F_o. In the final refinement, the maximum shift for all the parameters were less than 0.2σ. The final positional and thermal parameters are given in Table 1.[1]

Results and Discussion

The mercury atom forms a four-coordinate complex in HgI_2.TETD. The bond distances and angles are given in Fig. 1. The two Hg—I distances of 2.668(1) Å (twice) are significantly longer than that (2.641(1) Å) of $(Et_2NCS_2HgI)_2$. The Raman spectra of HgI_2.TETD and $(Et_2NCS_2HgI)_2$ in the region 50–1500 cm^{-1} are similar, and ν(Hg—I) are 132 and 139 cm^{-1} respectively. The Hg—S distances of 2.670(7) and 2.737(7) Å are also longer than those (2.422(4) and 2.644(4) Å) of $(Et_2NCS_2HgI)_2$ (8). These differences agree with the fact that the Hg atom is 4-coordinate in HgI_2.TETD and is three-coordinated in $(Et_2NCS_2HgI)_2$. Diiodotetramethylthiuramdisulfidemercury(II) (HgI_2.TMTD),

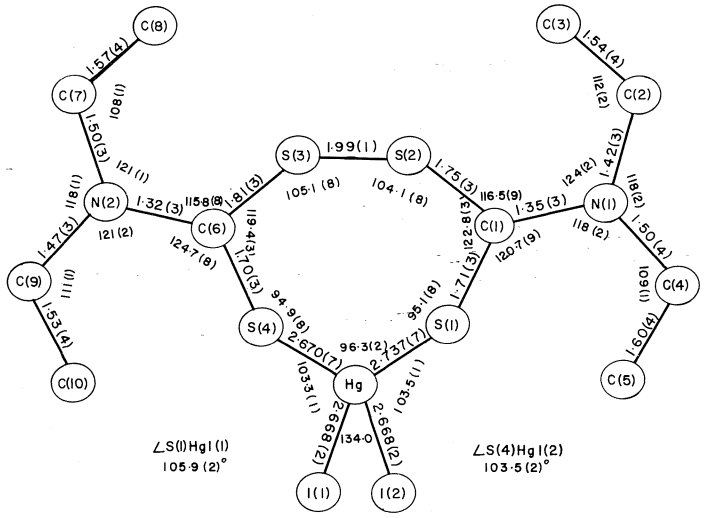

FIG. 1. Bond lengths and angles.

is a similar complex, in which the Hg—I distances are not significantly different (2.661(2), 2.654(2) Å); however, the difference (0.231 Å) in the two Hg—S bond lengths (2.651(7) and 2.882(7) Å) in HgI_2.TMTD, (12) is larger than that (0.067 Å) of HgI_2.TETD, Fig. 1. No simple *ad hoc* explanation can be offered at this time. In both compounds, the Hg—S distances are significantly different due to an unknown reason. Despite the large, I—Hg—I = 134.0(1)°, and small, S—Hg—S = 96.3(2)°, angles (see Fig. 1) the arrangement of the two iodine and the two sulfur atoms around the Hg is approximately tetrahedral. The plane containing HgS_2 is almost perpendicular to the plane containing HgI_2 with an angle of 92.4.

The bond lengths of the ligand, TETD, are essentially the same as those of the free TETD molecule (13) except the C=S bonds. The average C=S distance is 1.65(2) Å in the free molecule and is 1.71(3) Å in the HgI_2.TETD complex. The lengthening is expected as the bonding

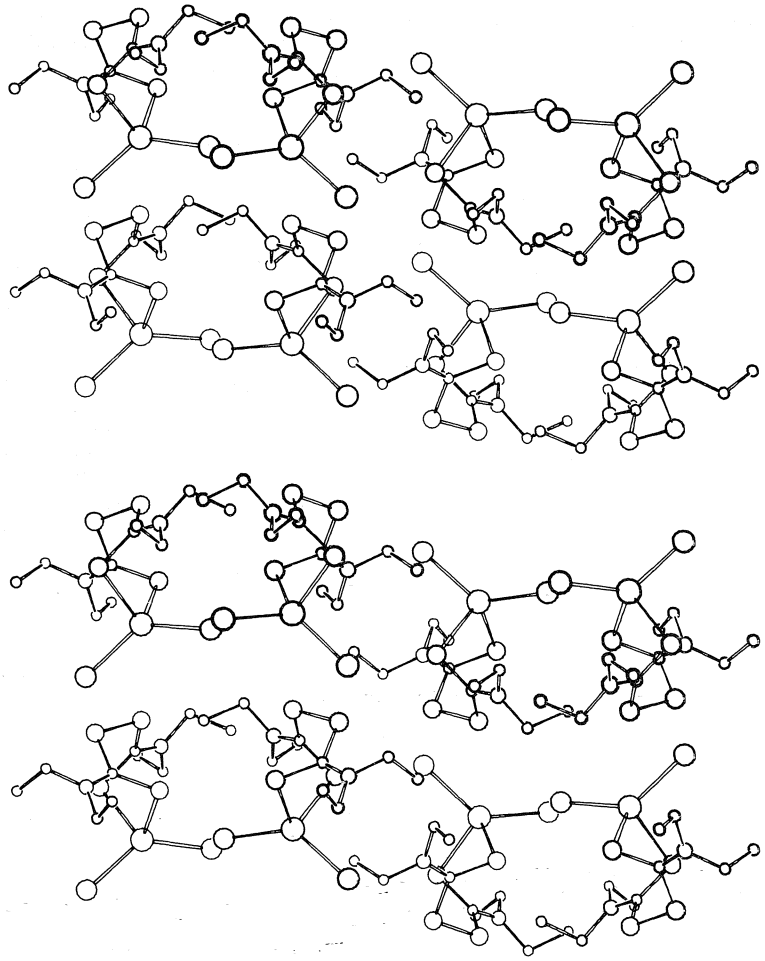

FIG. 2. Stereoview of the packing diagram.

of Hg to the sulfur atoms weakens the double bond character of C=S groups. The configuration of the ligand TETD molecule is not altered either. The shape of each individual molecule can be seen from the packing diagram, Fig. 2. Except for the terminal methyl groups, the ligand

S C
| |

consists of two planar S—C—N—C groups which are nearly perpendicular to each other. The equation of the least-squares plane for $S_2C(1)N(1)C_2$ is $-0.4059X + 0.6556Y - 0.6368Z = 2.685$ and for $S_2C(6)N(2)C_2$ is $0.7032X + 0.6265Y + 0.3362Z = 5.727$ where X, Y, and Z are coordinates in Å in a, b, and c directions. The maximum deviations of atoms for the two planes are 0.07 and 0.03 Å respectively. These deviations are similar to those of the free TETD molecules, and the difference in maximum displacements cannot be regarded as significant. The angle between these planes is 95.1°. The planarity and short N—C distances can be explained by the existence of partial double bond between N and C atoms (13). In diiodotetramethylthiuram-disulfidemercury(II). the corresponding angle is 86.6° (12), whereas in the free TETD molecule, it is 96.4° (13). The mercury atom is approximately at equal distances from the two planes 2.67 and 2.63 Å respectively). The dihedral C—S—S—C angle for HgI_2.TETD, HgI_2.TMTD, and free TETD are 88.5, 89.2, and 90.2° correspondingly. The rigidity of the ligand may restrict the S—Hg—S angle to be small.

In both the methyl and ethyl analogues, the S—S distances remain the same as those of the

free ligands and the average value is 2.00 Å, which is slightly shorter than the S—S distances of S_6 (rhombohedral) or S_8 (orthorhombic α), 2.06 Å (14). In organic disulfides, for example $PhCHCHCH_2S—SCH_2CHCHPh$, the S—S distance is 2.020(2) Å which is a typical value for this type of bonding (15).

A stereo-packing diagram is shown in Fig. 2. It is a molecular crystal with only van der Waals intermolecular attractions. The mercury atom is shielded rather well by the two iodine atoms and the TETD ligand to prevent any further secondary interactions. Atoms C(1) and C(6) are forced by the chelating group to be close to the Hg atom (3.35 and 3.28 Å respectively; see Fig. 1). No other atom is at a distance less than 3.4 Å from the mercury atom.

The formation of both HgI_2.TETD and $(Et_2NCS_2HgI)_2$ by reaction of HgI_2 and TETD demonstrates the complexity of mercuric ion coordination chemistry. It also indicates the flexibility of coordination between mercuric ion and sulfur groups. The existance of HgI_2.TETD provides additional evidence for the postulated mechanism for reducing TETD to thiocarbamate ions leading to the formation of $MeHg(S_2CNEt_2)$ (7). The formation of HgI_2.TETD or $(Et_2NCS_2HgI)_2$ seems to be dependent on the solvent used. The solvent chloroform favored the formation of the latter whereas in absolute or 95% ethanol, pure HgI_2.TETD can be obtained; however, the color of the crystals produced this way is only pale yellow. Recrystallization of HgI_2.TETD from mixed chloroform–ethanol solvent also gave a mixture of HgI_2.TETD and $(Et_2NCS_2HgI)_2$. These phenomena were observed very recently and the solvent dependence of these reactions will be reported in a separate publication. A compound $HgBr_2$.TETD was obtained from $HgBr_2$ and TETD in reaction conditions similar to those given for mercury(II) iodide and TETD. The compound $HgBr_2$.TETD is isostructural with HgI_2.TETD. Cell constants are $a = 13.050(5)$, $b = 13.593(7)$, and $c = 22.373(12)$ Å. The structure is being refined at present and will be published elsewhere. These studies have shown that the Antabuse drug, TETD, may become a chelating agent for mercurials in many ways.

Crystal structure of Sb_2Tl_7

ROLF STOKHUYZEN, CHUNG CHIEH, AND WILLIAM B. PEARSON
Faculty of Science, University of Waterloo, Waterloo, Ont., Canada N2L 3G1

Received November 9, 1976

ROLF STOKHUYZEN, CHUNG CHIEH, and WILLIAM B. PEARSON. Can. J. Chem. **55**, 1120 (1977).

The single-crystal study of Sb_2Tl_7 confirms the work of Morral and Westgren. The crystal is cubic with $a = 11.618(6)$ Å and space group of *Im3m*. There are 54 atoms per unit cell. It is the only known example of this structure type which can be considered as a true superlattice of CsCl. The structure was determined using 106 observed reflections measured on a G.E. XRD-6 diffractometer. The final R and R_w were 0.097 and 0.060, respectively. The Tl–Tl distances range from 3.21 to 3.55 Å and the mean Sb–Tl distance is 3.27 Å. There is no Sb–Sb contact in the structure.

ROLF STOKHUYZEN, CHUNG CHIEH et WILLIAM B. PEARSON. Can. J. Chem. **55**, 1120 (1977).

L'étude d'un mono cristal de Sb_2Tl_7 confirme le travail de Morral et Westgren. Le cristal est cubique avec $a = 11.618(6)$ Å et le groupe d'espace est *Im3m*. Il y a 54 atoms par maille. C'est le seul exemple connu possédant ce type de structure qui peut être considéré comme une surstructure de CsCl. La structure a été déterminée en utilisant 106 reflexions observées mesurées sur un diffractiomètre G.E. XRD-6. Les facteurs d'accord R et R_w sont 0.097 et 0.060 respectivement. Les distances Tl–Tl varient de 3.21 à 3.55 Å et la distance moyenne Sb–Tl est de 3.27 Å. Il n'y a pas de contact Sb–Sb dans cette structure.

[Traduit par le journal]

Introduction

A phase of composition Sb_2Tl_7 was first reported by Persson and Westgren (1), and from powder photographs its structure was shown by Morral and Westgren (2) to be a superstructure composed of 27 CsCl type cells: cubic, *Im3m*, $a = 11.59$, $Z = 6$. Because of our interest in the γ-brass structure which has also been described as a superstructure composed of 27 CsCl type cells with the corner and centre atoms removed (the atom positions, however, are considerably adjusted from those of a stack of 27 CsCl type cells), we have re-examined the structure of Sb_2Tl_7 using single-crystal methods. Our results confirm the earlier work and Sb_2Tl_7 cannot be regarded as a filled up γ-brass; rather it is a true superlattice of CsCl. It is the only known example of this structure type.

Experimental

Since thallium reacts with oxygen and moisture at room temperature (25°C), an argon-filled box was used to weigh and mix 0.9925 g of Sb and 5.8321 g of Tl into a Pyrex tube. Both metal samples are 99.99% pure from A. D. Mackay Inc. The Pyrex tube was then evacuated to 2×10^{-6} torr and the mixture was left at molten state (300°C) for 3 h, with agitation from time to time, in the hope of obtaining homogeneity in the sample. The ingot was then annealed for 428 h at 200°C, followed by quenching in an ice–water bath. The alloy was cut into thin rods of 0.5 mm diameter using a spark cutter. The rods were cut into small pieces with a blade under a microscope. Small fragments were etched and then annealed again for 792 h at 213°C. Some small spherical crystals suitable for X-ray diffraction study were obtained. Weissenberg and precession methods were used to determine the cell constant and space group. The 2θ (Zr-filtered Mo-Kα) values of 6 reflections measured on the G.E. XRD-6 diffractometer were used in the least-squares refinement of a. Crystal data are as follows.

Sb_2Tl_7 fw = 1673.5
Cubic, $a = 11.618(6)$ Å, $V = 1568.1$ Å^3, $D_m = 10.67(9)$, $Z = 6$, $D_c = 10.635$ g cm^{-3}. Systematic absence, $h + k + l = 2n + 1$, space group *Im3m*. (Mo-Kα) = 0.7107 Å, μ(Mo-Kα) = 1131 cm^{-1}.

The crystal used for intensity measurement was an ellipsoid with maximum and minimum radii of 0.026 and 0.028 mm, respectively. It was mounted with [110] along the φ axis. The stationary-crystal stationary-counter method was used because of the small size of the crystal. The counting time was 150 s. Four strong reflections were repeatedly measured after each 100 reflections to monitor the stability of the instrument. Fluctuations in these intensities were less than 7%. The average background curve as a function of 2θ was obtained also by stationary

counting with the crystal in several orientations. A total of 1094 reflections were measured. Some reflections having intensities less than or equal to zero were discarded. The equivalent reflections were averaged. Among 292 reflections with $2\theta < 60°$ (Mo-Kα) measured 106 had net intensity greater than $3\sigma(I)$ and were considered observed and used throughout the structure analyses. The superlattice type structure resulted in many unobserved reflections. The spherical approximation (mean r = 0.027 mm) was assumed for absorption correction, μ_R = 3.0. Lorentz and polarization corrections were applied to derive the structure amplitudes.

Although the structure was reported to be of space group *Im3m*, refinement was carried out with the assumption of other space groups such as $I\bar{4}3m$. The refinement based on *Im3m* gave the best results. The three positional parameters suggested by Morral and Westgren (2) and the overall temperature factor of 1.3 obtained from a Wilson plot were used initially in the full-matrix least-squares refinement. The function minimized was $\Sigma w(|F_o| - |F_c|)^2$ with $w^{-1} = (305.0 - |F_o| + 0.00083|F_o|^2)$. The atomic scattering factors from International Tables for X-ray Crystallography (3) were used with anomalous scattering corrections from the same source. Programs used in the structure analysis have been described elsewhere (4). The final R $(= \Sigma(|F_o| - |F_c|)/\Sigma|F_o|)$ and R_w $(= (\Sigma w^2(|F_o| - |F_c|)^2/\Sigma w^2|F_o|^2)^{1/2})$ are 0.097 and 0.060 respectively. The atomic parameters are given in Table 1.[1]

Results and Discussion

The present single-crystal study confirms the work of Morral and Westgren and attests to the accuracy of their powder diffraction determination carried out 42 years ago.

For convenience in describing the structure of Sb_2Tl_7, the cluster concept for γ-brasses is used (4). It is only an identity for easy reference and bears no resemblance to a molecule. Each unit cell contains two identical clusters centred at 000 and 1/2 1/2 1/2. The atom Tl(ce) at the centre of the cluster is surrounded by 8 Tl(cub) atoms forming a cube. On each face of the cube is a Sb(oh) atom forming an octahedron, followed by a regular cubooctahedron with one Tl(co) atom outside each edge of the cube. The clusters so formed have *m3m* point symmetry and stack along the threefold axis which is the [111] direction of the cubic cell. This arrangement differs from that of the γ-brass structure which has no atom at 000 and 1/2 1/2 1/2 and has two tetrahedra (IT and OT) instead of the cube of atoms. Table 2 shows comparative atomic coordinates for Sb_2Tl_7, a typical γ-brass structure, a stack of 27 CsCl type cells, and the Ir_3Ge_7 structure (5). The latter also resembles the Sb_2Tl_7 structure in having clusters of atoms (cube surrounded by octahedron centred about 000 and 1/2 1/2 1/2) and these clusters are surrounded by truncated octahedra of atoms which form a space filling mesh running throughout the structure, instead of by separate regular cubooctahedra as in Sb_2Tl_7.

The interatomic distances are given in Table 3. The coordination number (CN) for most of the atoms is 8 except for Tl(cub) where it is 10. This also indicates that the relative distortion from stacking of 27 CsCl type cells is small. The Tl–Tl distances range from 3.21 to 3.55 Å and appear to be normal with respect to the size (CN8) of thallium, 3.34 Å (5). In β-Tl, which has a body centred cubic structure (262°C), the Tl–Tl distance is 3.362 Å (6). There is no Sb–Sb contact

[1]Photocopies of the structure factor table are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

TABLE 3. Interatomic distances (standard deviations = 0.01 Å)

From atom	To No. atom(s)	Distance (Å)
Tl(ce)	8 Tl(cub)	3.43
Tl(cub)	1 Tl(ce)	3.43
	3 Sb(oh)	3.26
	3 Tl(cub)	3.21
	3 Tl(co)	3.55
Sb(oh)	4 Tl(cub)	3.26
	4 Tl(co)	3.28
Tl(co)	2 Sb(oh)	3.28
	2 Tl(co)	3.49
	4 Tl(co)	3.39

and the mean Sb–Tl distance of 3.27 Å is also comparable with the sum of metallic (CN8) radii of Sb and Tl, 3.23 Å.

The reactions of isothiazolium salts with selected nucleophilic reagents. The preparation of thieno[2,3-*c*]isothiazolium salts

DAVID M. MCKINNON, MOHAMMED E. R. HASSAN, AND MOHINDER CHAUHAN

Department of Chemistry, University of Manitoba, Winnipeg, Man., Canada R3T 2N2

Received October 14, 1976

DAVID M. MCKINNON, MOHAMMED E. R. HASSAN, and MOHINDER CHAUHAN. Can. J. Chem. **55**, 1123 (1977).

Isothiazolium salts react with a number of carbanions by attack on sulfur. Thiophene derivatives, formed by ring opening and recyclization, are often products but with cyclopentadiene, pseudoazulene products are obtained. 3-Amino-2-acylthiophenes, prepared by suitable nucleophilic attack, are synthetic precursors of thieno[2,3-*c*]isothiazolium salts.

DAVID M. MCKINNON, MOHAMMED E. R. HASSAN et MOHINDER CHAUHAN. Can. J. Chem. **55**, 1123 (1977).

Les sels d'isothiazolium réagissent avec un nombre de carbanions par attaque au niveau du soufre. Les produits comprennent souvent des dérivés du thiophène, qui sont formés par une ouverture de cycle et une recyclisation; avec le cyclopentadiène, ont obtient toutefois des produits pseudoazulènes. Les amino-3 acyl-2 thiophènes, préparés par une attaque nucléophilique appropriée, sont des précurseurs de synthèse des sels de thiéno[2,3-*c*]isothiazolium.

[Traduit par le journal]

In the isothiazolium system **1**, attack by a carbanion on the ring sulfur atom has been demonstrated (1), although attack by nucleophiles at other ring positions has also been postulated (2–5). To provide further information on the positions of attack, and to examine the synthetic utility of these salts, some of which are readily accessible, we have examined their reaction with selected carbanions. In previous work (1) it was found that attack at ring sulfur was followed by ring opening of the isothiazole, then recyclization by condensation of an active methylene group with an imine function (Scheme 1). Thiophene derivatives were the final products. Using this scheme as a rationale, we have used other carbanions capable of similar reactions. Isothiazolium salts used in these reactions were synthesized according to previous work or procedures (1, 6).

2-Methyl-3-methylthio-4,5-diphenylisothiazolium iodide (**1***a*), prepared by treatment of 2-methyl-4,5-diphenylisothiazoline-3-thione with methyl iodide, reacted with the anion of diethyl malonate in ethanol to form diethyl 3,4-diphenyl-3-methylimino-2,3-dihydrothiophene-2,2-dicarboxylate (**2**) and methanethiol. This reaction likely follows the above scheme except that aromatization to a thiophene is impossible and an exocyclic double bond is formed. Thus, in this case a dihydrothiophene is the final product. In this case compound **2** appears to exist as two

geometrical isomers with respect to the exocyclic imine function.

We then examined the reaction of the salts **1** with various stable ylides. 2,4-Diphenylisothiazolium perchlorate (**1***b*) was treated with the anion of diethyl benzylphosphonate in dimethylformamide. It was expected that the reaction would proceed according to the scheme shown, (Scheme 2) with the phosphonate grouping so enhancing the acidity of the Ph—CH-group in the intermediate sulfide as to allow cyclization to the dihydrothiophene. Aromatization in this case would probably occur through the typical four-centered intermediates of Wittig reactions and elimination of an aminophosphorus species. The reaction in fact afforded 2,4-diphenylthiophene, although in low yield.

It was of interest then to examine the effects of various sulfonium ylides on the salts **1**, where such four-centered reactions would be unlikely in view of the different reactions of phosphorus and sulfur ylides (7). In fact, treatment of **1**b and **1***c* with dimethylmethylene sulfurane afforded the thiophenes **5***a* and **5***b*, respectively, which contained methylthio substituents, obviously derived from the original sulfurane. These compounds are probably formed via reaction intermediates of type **3** by isomerism to the more stable ylide **4**, then oxidation followed by demethylation. Although the reactions were performed under nitrogen, it is not unlikely that traces of oxygen were present. Alternatively oxidation by unreacted isothiazolium salt could have occurred. Certainly the structurally and electronically related 1,2-dithiolium salts have this property (8, 9).

When *p*-nitrobenzylidenedimethyl sulfurane was allowed to react with **1***b*, a product was obtained whose analyses and properties were consistent with 2-*p*-nitrophenyl-4-phenylthiophene (**5***c*). While this reaction must have an intermediate **3***c* like the above reactions, oxidation of this is unlikely and the dimethylsulfonio group

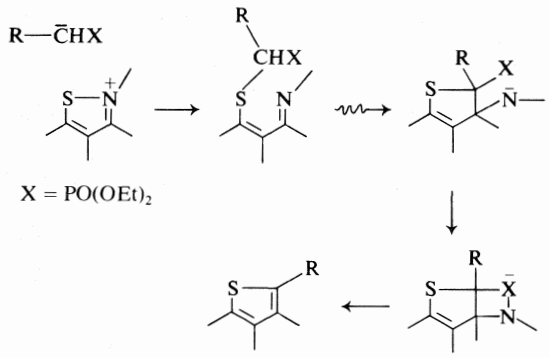


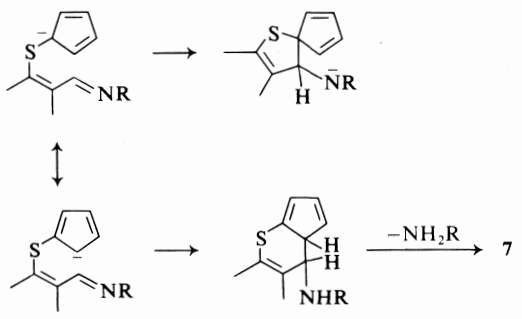
SCHEME 2

is lost, forming **5***c*. The exact mechanistic pathway from **3***c* to **5***c* is not known with certainty, but displacement by the nitrogen anion of dimethyl sulfide leading to a thienoaziridine, with rearrangement to **5***c* is a possibility. Alternatively **3***c* may rearrange to an intermediate **6**, with subsequent loss of dimethyl sulfide.

The reaction of phenacylidenedimethylsulfurane with **1***d* afforded 2-benzoyl-3-anilino-5-phenylthiophene (**5***d*), identical to a sample prepared by reaction of sodium benzoylacetate with 2,5-diphenyl-3-methylthioisothiazolium perchlorate (**1***e*) according to known procedures (1). This approach, where aromatization of the dihydrothiophene intermediate occurs by loss of a group originally on the attacking nucleophile, rather than the isothiazolium salt, is thus a method of making 2-acyl-3-aminothiophenes without using 3-alkylthioisothiazolium salts for which synthetic methods, in contrast to 3-unsubstituted isothiazolium salts, are sometimes unsatisfactory. These 2-acyl-3-aminothiophenes have synthetic potential for the preparation of thieno[3,2-*c*]isothiazolium salts, and further products of this type were made as intermediates (see below).

Treatment of 2,4-diphenylisothiazolium perchlorate (**1***b*) or 5-methylthio-2,4-diphenylisothiazolium perchlorate (**1***c*) with the cyclopentadienyl anion in ether gave dark blue products. The analyses and other data for these were consistent with the pseudoazulene structures **7***a* and **7***b* respectively, formed as above by initial nucleophilic attack on sulfur, with ring opening of the isothiazolium salt. Related pseudoazulenes have been prepared by alternate syntheses (10–12). Two modes of reaction of the initially formed cyclopentadienylthioether are possible, *i.e.* attack on the imine function either by a carbanion on the 1-position of the cyclopentadiene ring, leading to a cyclopentadienospirothiophene, or from a carbanion at position 2, leading to a pseudoazulene (Scheme 3). While anion formation at the 1-position would be favored owing to extra stabilization of the anion by the adjacent sulfur, it is obvious that the alternative reaction is relatively effective. Nevertheless, attack of the indenyl anion on **1***c* failed to give any crystalline product. In this case, an attacking anion (at the 2-position of the cyclopentadiene ring) would be unfavored due to the presence of an *o*-quinonoid structure. The properties of the crude product obtained appear to correspond to the spiran structure **8** formed by alternate cyclization from an attacking anion at the 1-position of the cyclopentadiene ring. These reactions have many analogies with the preparation of azulenes from pyridinium or pyrylium salts (13).

Since isothiazolium salts **1** may be synthesized from β-aminopropeneone derivatives by thionation, then oxidation (9, 14), it was of interest to find if the 2-acyl-3-aminothiophenes synthesized above could be likewise converted to the thieno-[3,2-*c*]isothiazolium system (**9**). Accordingly the compound **5***d* prepared as above was treated with phosphorus pentasulfide in benzene. The crude thione product **5***e* treated with iodine in ethanol afforded the 1,3,5-triphenyl[3,2-*c*]isothiazolium cation (**9***a*), isolated as its perchlorate. Likewise the 1,3,4-triphenyl system (**9***b*), and the 3-methyl-3-phenyl system (**9***c*) were made from 2,4-diphenylisothiazolium perchlorate (**1***b*) and 2-methylisothiazolium perchlorate (**1***f*), respectively. The preparation may also be extended to other sulfonium ylides, and treatment of acetonylidenedimethylsulfurane with **1***d* followed by thionation and oxidation gave the 2,5-diphenyl-



SCHEME 3

3-methylthieno[3,2-*c*]isothiazolium system (**9***d*), isolated as its perchlorate.

Finally, the readily accessible 2-methyl-3-methylthio-4,5-benzisothiazolium perchlorate (**1***g*) reacted with sodium benzoylacetate to give 2-benzoyl-3-methylaminobenzo[*b*]thiophene (**5***f*), which, on thionation followed by oxidation, afforded the benzothienoisothiazolium salt (**9***e*) as its triiodide.

Thus, in the cases described, the products isolated are compatible with initial nucleophilic attack on the sulfur atom of the isothiazolium ring. While attack at the carbon adjacent to nitrogen is favored on coulombic grounds (3), it is difficult to explain the formation of the products above by mechanisms based on such attack.

Experimental

The nmr spectra were obtained on a Varian model 56/60A spectrometer in deuterochloroform using tetramethylsilane as an internal standard. Mass spectra were obtained on a Finnegan 1015 quadrupole mass spectrometer. Chromatography (tlc) was performed on Camag silica gel type D.S.F. 5 supplied by Terochem, Laboratories. Elution, unless otherwise stated, was by benzene with increasing proportions of chloroform. Melting points (mp) were obtained on a precalibrated Thermopan apparatus. Analyses were performed by A. E. Bernhardt. Unless otherwise stated, solutions were dried over anhydrous magnesium sulfate.

*Preparation of 4,5-Diphenyl-2-methyl-3-methylthioisothiazolium Iodide (**1a**)*

The thione (1 g) (1) was dissolved in methyl iodide (10 ml) at room temperature and allowed to stand. After 1 h the pale yellow product was collected by filtration (95%). The product was recrystallized from methyl iodide as pale yellow prisms mp 138–40°C. *Anal.* calcd. for $C_{17}H_{16}NS_2I$: C 48.00, H 3.76, N 3.29, S 15.00; found: C 48.18, H 3.52, N 3.33, S 15.21.

*Reaction of 4,5-Diphenyl-2-methyl-3-methylthioisothiazolium Iodide (**1a**) with Diethyl Malonate*

To a solution of sodium ethoxide, prepared by dissolving sodium (25.3 mg, 1.2 mmol) in ethanol (5 ml), was added diethyl malonate (0.19 g, 1.2 mmol). To this solution with stirring was added **1***a* (0.51 g, 1.2 mmol). The solution became red, then gradually turned yellow, with the evolution of methanethiol. After 10 min the solution was diluted with water and extracted with benzene. The dried extract on evaporation gave a yellow oil which on dissolving in toluene and standing at 0°C afforded **2** as yellow prisms, mp 97°C (39%). *Anal.* calcd. for $C_{23}H_{23}NSO_4$: C 67.48, H 5.62, N 3.42, S 7.82; found: C 67.47, H 5.44, N 3.15, S 7.84. The nmr spectrum: τ 9.1–8.8 (2 superimposed t, methyl), 6.4–6.2 (2q, methylene; 2s, *N*-methyl), 2.91–2.62 (5H, aromatic).

*Reaction of 2,4-Diphenylisothiazolium Perchlorate (**1b**) with Diethyl Benzylphosphonate*

Diethyl benzylphosphonate, prepared by refluxing benzyl chloride (0.316 g, 2.5 mmol) with triethylphosphite (0.415 g, 2.5 mmol) for 1 h was treated in dimethylformamide (5 ml) with sodium methoxide (0.011 g, 2.5 mmol). To the mixture was added 2,4-diphenylisothiazolium perchlorate (**1***b*) (0.84 g, 2.5 mmol) (6). The solution was heated at 60°C for 5 min, then poured into ice water and the orange precipitate collected. Chromatography indicated a number of products but the first yellow band eluted was rechromatographed using 25% benzene in petroleum ether as an eluent and afforded a colorless solid with a blue fluorescence in ultraviolet light; mp 121°C (lit. (14) mp 121°C) (18%). The ms M^+ calcd.: 236; found 236.

*Reaction of Dimethylmethylenesulfurane with 2,4-Diphenylisothiazolium Perchlorate (**1b**)*

To a stirred suspension of trimethylsulfonium iodide (0.24 g, 1.2 mmol) in tetrahydrofuran (4 ml) at 0°C under nitrogen was added 1.2 ml of molar methyllithium in ether (Ventron). After stirring 5 min the isothiazolium salt (0.404 g, 1.2 mmol) was added and stirring maintained for 30 min at 0°C, then for a further 1 h at 25°C. After dilution of the solution with water, the benzene extract was dried, evaporated, and the resulting oil chromatographed. The most rapidly eluting band gave an orange oil which crystallized on trituration with methanol. It was recrystallized from methanol as orange prisms, mp 204°C (30%). The nmr spectrum for **5***a*: τ 7.21 (3H, s, methyl), 3.10–2.69 (11H, aromatic and heterocyclic), 1.83 (1H, s, amino). The ms M^+ calcd.: 297; found: 297. *Anal.* calcd. for $C_{17}H_{15}NS_2$: C 68.68, H 5.05, N 4.72, S 21.55; found: C 68.56, H 5.41, N 4.67, S 21.76.

*Reaction of Dimethylmethylenesulfurane with 2,4-Diphenyl-5-methylthioisothiazolium Perchlorate (**1c**)*

The reaction was performed as above. 3-Anilino-2,5-bismethylthiothiophene (**5***b*) was obtained as orange prisms mp 198°C (28%). The nmr spectrum for **5***b*: τ 7.25, 7.02 (3H, 2s, methyl), 3.05–2.63 (10H, aromatic), 1.85 (1H, s, amino). The ms M^+ calcd.: 243; found: 243. *Anal.* calcd. for $C_{18}H_{17}NS_3$: C 63.00, H 4.95, N 4.08, S 27.97; found: C 62.71, H 4.81, N 3.86, S 28.25.

*Reaction of p-Nitrobenzylidenedimethylsulfurane with 2,4-Diphenylisothiazolium Perchlorate (**1b**)*

p-Nitrobenzyldimethylsulfonium bromide (0.278 g), (16) 1.2 mmol in dry ethanol was treated with sodium ethoxide (1.0 mmol). A slight excess of the isothiazolium salt (0.404 g, 1.2 mmol) was then added, and the mixture stirred 15 min. Dilution with water and ether extraction gave an oil which was purified by chromatography. The main orange band on extraction and recrystallization from ethanol afforded **5***c* as yellow-orange prisms mp 158°C (42%). The ms M^+ calcd.: 372; found: 372. *Anal.* calcd. for $C_{22}H_{16}NSO_2$: C 70.96, H 4.30, N 7.52, S 8.60; found: C 70.71, H 4.70, N 7.52, S 9.10.

*Reaction of Phenacylidene Dimethylsulfurane with 2,5-Diphenylisothiazolium Perchlorate (**1d**)*

Phenacyldimethylsulfonium bromide (0.25 g, 1 mmol) in dry ethanol (10 ml) was treated with sodium ethoxide (1 mmol). After stirring 5 min, the perchlorate **1***d* (336 g, 1 mmol) (14) was added, and the solution stirred 15 min. The mixture was diluted with water (20 ml) and the ether extract dried and evaporated to yield a yellow oil. Purifi-

cation by chromatography yielded **5***d* as yellow needles mp 180°C (55%). The ms M^+ calcd.: 355; found: 355. *Anal.* calcd. for $C_{23}H_{17}NSO$: C 77.74, H 4.79, N 3.95, S 9.02, found: C 77.81, H 4.85, N 3.62, S 9.21.

*Reaction of Sodium Benzoylacetate with 2,5-Diphenyl-3-methylthioisothiazolium Iodide (**1***e) to Form **5***d*

This reaction was performed according to a known procedure (1). The salt (1 mmol) (17) was treated with sodium benzoylacetate (~1.5 mmol) in ethanol. Work-up afforded **5***d* (61%) identical to that above (mixture mp, ms, and ir).

*Preparation of 2-Methyl-3-methylthio-4,5-benzisothiazolium Perchlorate (**1***g)*

2-Methylbenzisothiazoline-3-thione (1.81 g, 10 mmol) (18) was heated with dimethyl sulfate (2 ml) for 5 min at 100°C. The mixture was diluted with ether and the ether phase decanted off the oily product. This was converted to its perchlorate in acetic acid. Pale yellow needles, mp 173–175°C were obtained (82%). *Anal.* calcd. for $C_9H_{10}NS_2ClO_4$: C 36.54, H 3.38, N 4.73, S 21.69, Cl 12.05; found: C 36.62, H 3.42, N 4.61, S 21.61, Cl 12.21.

*Reaction of 2-Methyl-3-methylthio-4,5-benzisothiazolium Perchlorate (**1***g) with Sodium Benzoylacetate. 2-Benzoyl-3-methylaminobenzothiophene (**5***f)*

This reaction was performed according to standard procedures (1). Work-up and crystallization from petroleum ether, bp 60–80°C, afforded yellow prisms mp 88–89°C (31%). The ms M^+ calcd.: 267; found: 267. The nmr spectrum: τ 6.52 (3H, s, methyl), 1.60–2.76 (9H, aromatic), −0.2 (1H, br s, NH). *Anal.* calcd. for $C_{16}H_{13}NSO$: C 71.91, H 4.87, N 5.24, S 11.98; found: C 71.77, H 4.80, N 5.16, S 11.65.

*Preparation of Thieno[2,3-c]isothiazolium Salts (**9**)*

Procedure a

The appropriate benzoylaminothiophene **5***c* or **5***f* was treated with an approximately equal weight of phosphorus pentasulfide in benzene and the mixture refluxed 4 h. The solvent was filtered off any solid and washed with sodium bicarbonate solution and dried. Evaporation gave the corresponding crude thiones as red oils. These were dissolved in ethanol and titrated with a saturated solution of iodine in ethanol until precipitation was complete. The crude triiodide salts were separated by filtration and in most cases, converted to the corresponding perchlorates in acetic acid or recrystallized from nitromethane. The results are summarized in Table 1.

Procedure b

The starting isothiazolium salts were treated with the appropriate sulfur ylides to afford the appropriate acylaminothiophenes. Thus **1***b* and phenacylidene dimethylsulfurane afforded the benzoylanilinothiophene **5***g*, 2-methylisothiazolium perchlorate **1***f* afforded 2-benzoyl-3-methylaminothiophene **5***h*, and **1***d* with acetonylidenedimethylsulfurane afforded 2-acetyl-3-anilino-5-phenylthiophene **5***i*. None of these were purified but were thionated by the above procedure to give the isothiazolium salts **9***b*, **9***c*, and **9***d* respectively. The results are summarized in Table 1.

In some cases it was difficult to remove all iodine from the perchlorates. This was best achieved by prolonged boiling in an open flask to allow acetic acid fumes to

*Based on crude acylaminothiophenes.

remove iodine vapor. Care was necessary in this case to avoid over concentration of the perchloric acid – acetic acid mixture.

*Reaction of the Cyclopentadienyl Anion with 2,4-Diphenyl-5-methylthioisothiazolium Perchlorate (**1c**)*

Cyclopentadiene was obtained from its dimer according to the method described (19). To a solution of methyllithium (1 mmol) in anhydrous ether was added the cyclopentadiene (66 mg, 1 mmol) under a nitrogen atmosphere. The solution was cooled to −70°C by means of an acetone – dry ice bath and after stirring 5 min, the perchlorate salt **1***c* (383.5 mg, 1 mmol) was added. Stirring was maintained for 30 min and the mixture allowed to reach room temperature. After dilution of the mixture with water, the ether layer was separated, dried, and evaporated to give a dark oil which was examined by chromatography. A fast running dark blue band was removed by chloroform extraction and evaporation yielded **7***b* as a crystalline product mp 278°C (61%). *Anal.* calcd. for $C_{15}H_{12}S_2$: C 70.31, H 4.68, S 25.00; found: C 70.9, H 4.80, S 24.67. The nmr spectrum: τ 7.47 (3H, s, *S*-methyl), 2.87–2.41 (9H, aromatic). The ms M^+ calcd.: 256; found: 256.

Reaction of the Cyclopentadienyl Anion with 2,4-Diphenylisothiazolium Perchlorate

The reaction was performed as above. **7***a* was obtained as grey plates mp 250°C (55%). *Anal.* calcd. for $C_{14}H_{10}S$: C 80.00, H 4.76, S 15.23; found: C 79.80, H 4.97, S 14.91. The nmr spectrum: τ 2.91–2.45 (10H). The ms M^+ calcd.: 210; found: 210.

Reaction of the Indenyl Anion with 2,4-Diphenyl-5-methylthioisothiazolium Perchlorate

The reaction was performed as above. Chromatography indicated a major pink band which on elution and evaporation gave a dark pink oil (20%). This could not be crystallized and was not analyzed. The nmr spectrum: τ 7.65 (1H, s, the single dihydrothiophene proton) τ 7.48 (3H, s, *S*-methyl), 3.21–2.52 (16H, aromatic and amino). The ir spectrum: 3410 cm^{-1} (the NH str). The ms M^+ calcd.: 399; found: 399.

The isolation and identification of makisterone A from the yew, *Taxus cuspidata*

BRENTON GARTH BURNS AND MICHAEL WILSON GILGAN

Environment Canada, Fisheries and Marine Service, 1707 Lower Water Street, P. O. Box 429, Halifax, N.S., Canada B3J 2R3

Received July 6, 1976

BRENTON GARTH BURNS and MICHAEL WILSON GILGAN. Can. J. Chem. **55**, 1129 (1977).

The ecdysteroids were extracted from yew, *Taxus cuspidata*, needles and twigs and recovered from the aqueous extract by reversed phase adsorption. Purification of the ecdysteroids was achieved by a single solvent partition and a dry column chromatogram followed by fractionation on an adsorptive Porasil A (60) column. Makisterone A was a minor component identified by melting point, liquid chromatography, gas chromatography of the trimethylsilyl ether, mass spectrometry, and nuclear magnetic resonance spectrometry. A second minor component was isolated but not identified.

BRENTON GARTH BURNS et MICHAEL WILSON GILGAN. Can. J. Chem. **55**, 1129 (1977).

On a extrait des ecdystéroïdes à partir des aiguilles et des brindilles du yew, *Taxus cuspidata*, et on les a récupérées par une extraction aqueuse par une adsorption de phase renversée. On a effectué la purification des ecdystéroïdes par une partition unique de solvant et une chromatographie sur colonne sèche suivie par un fractionnement sur une colonne d'adsorption de Porasil A (60). On a pu identifier que la makistérone A est un composant mineur; cette identification a été effectuée par point de fusion, chromatographie liquide, chromatographie en phase gazeuse de l'éther triméthylsilyle, par spectrométrie de masse et par spectroscopie de résonance magnétique nucléaire. On a pu isoler un deuxième composant mineur mais il n'a pas été identifié.

[Traduit par le journal]

Introduction

At about the same time as a report by one of the authors (1), T. Takemoto *et al.* (2) reported insect molt hormone activity associated with extracts of yew (*Taxus cuspidata*, 1; *Taxus* sp. 2) leaves. The major components were reported to be an insect molt hormone, ecdysterone **2**, and a closely related compound, ponasterone A **3** (3). Ecdysterone was also reported as a constituent of *Taxus baccata* (4). Except to examine the activity present in *Taxaceans* in surveys (5, 6), the yews have attracted little subsequent interest.

Our purpose in isolating the ecdysteroids from the yew was to make them available for attempted forced molting in lobster (*e.g.*, ref. 7). One of the most important hormones, and the first to have its structure completely determined (8), α-ecdysone **1**, has been isolated from fern extracts (9). We have found it difficult to isolate from this source. Examination of yew extracts, fractionated by adsorptive liquid chromatography, with an insect assay (10), showed that a minor peak conforming approximately with the retention time of α-ecdysone was present in addition to the usual major ecdysterone and ponasterone A peaks. Since we wished to use α-ecdysone in our tests we completed the isolation of this compound. Unfortunately this proved to be makisterone A **4** (11) accompanied by what appears to be makisterone C (lemmasterone, **5**) or D **6** (11, 12). Nevertheless, makisterone A is of con-

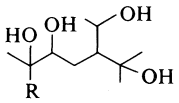
5 Lemmasterone (Makisterone C)



6 Makisterone D

siderable biological interest since it has been reported as a crustacean (13) and insect (14) constituent. The following is a report of the isolation and identification of makisterone A from the yew *Taxus cuspidata*.

Experimental

Extraction

Chopped yew (*Taxus cuspidata*, 2 kg fresh weight, 0.8 kg dry weight, obtained locally September 1973 and stored at −30°C) needles and twigs were stirred overnight in 8 ℓ of distilled water. The solids were removed by filtration through cheese cloth, resuspended as above for 4 h, and the mixture refiltered. The combined water extracts were filtered through Celite 545 (Johns Manville) to give a clear, dark brown solution.

Reversed Phase Adsorption

Amberlite XAD-2 (BDH Chemicals, Ltd.) was slurried and packed into a glass column (38 × 5 cm i.d.) and held in place by stainless steel screens (40 × 40 mesh, Newark Wire Cloth Co., Newark, N.J.) at both ends. The column was washed in a procedure like that of Hori (15).

The combined aqueous yew extracts were passed slowly through the column ($\frac{1}{20}$ bed volume (B.V.) per min) trapping most of the brown material, and the column was then eluted with water, 10% isopropanol – water, 70% isopropanol – water, and isopropanol ($1\frac{1}{2}$ B.V. each). The column was washed with water and the aqueous yew extract passed through the column a second time and the column eluted.

Solvent Fractionation

Water was added to the combined 70% isopropanol eluates, which contained the bulk of the ecdysteroids, to make the isopropanol to water proportion 2:1. The fat soluble materials were then removed by hexane extraction ($\frac{1}{20}$ vol.). The ecdysteroids were extracted with chloroform (proportions: chloroform–isopropanol–water, 2:2:1) and the extraction repeated once. The combined chloroform extracts were washed with *N* NaOH ($\frac{1}{20}$ vol.) and then repeatedly with water ($\frac{1}{20}$ vol.) until the wash was neutral. The alkali and water washes did not contain significant amounts of ecdysteroids as detected by thin-layer chromatography (tlc).

Dry Column Fractionation

Alumina (300 g, ICN, Pharmaceuticals, Inc.) was packed into a 50 mm wide nylon film tube (ICN Pharmaceuticals, Inc., 16). A layer (1 cm) of Celite 545 was packed on the top. A sample (5.0 g) of the dry residue from the combined chloroform extracts was dissolved in ethanol (10 ml), added to 5 g Celite 545, and the ethanol evaporated. The dry sample was then packed on the top of the alumina column and another thin layer of Celite 545 superimposed. The column was developed with ethyl acetate – ethanol (95%) 35:15 (200 ml). Bands were detected with u.v. light (254 nm), cut from the column, and the ecdysteroids eluted from each with chloroform–ethanol 1:1 (200 ml) by filtration. Fine alumina particles were removed by filtration through fine glass-frit funnels.

Thin-layer Chromatography (tlc)

The ecdysteroid composition of interesting bands was checked by tlc (silica gel F, E. Merck; CH_2Cl_2–Methanol 21:4). After observing the uv (254 nm) absorbing zones the plates were sprayed with sulfuric acid – ethanol (1:2) and heated (2–5 min, 120°C). Sulfuric acid treated plates were checked for fluorescence in uv (360 nm) light.

High Pressure Liquid Chromatography (lc)

Preparative

Selected dry column bands were chromatographed with a Waters ALC 100 chromatograph on a Porasil A (60) (Waters Associates, Inc.) column (188 cm × 7.7 mm diameter) with chloroform–ethanol (95%) 4:1 flowing at 2.7 ml/min. Samples (400 mg) were dissolved in chloroform–ethanol (95%) 1:1 and injected via a 0.5 ml loop. The column effluent stream was usually divided by passing it through a tee equipped with a variable resistance on one leg provided by a micrometer valve (Nupro Co., Cleveland, Ohio) to provide stream splitting (*ca.* $\frac{1}{25}$). The minor stream was monitored at 254 nm (Chromatronix photometer, model 200) and the main stream collected with a fraction collector. Each run required *ca.* 130 min.

Final purification of yew V and Va (see Fig. 1) was achieved by recycling the samples through a Porasil A column (180 mm × 4.7 mm diameter) in chloroform–isopropanol 70:30 at 2.0 ml/min. Tailing and resultant sample loss were minimized by adding 1% water. The eluted materials were monitored and collected as above.

Analytical

Normal Phase — Corasil II (Waters Associates, Inc., 37 μm) was packed (17) into a precision bore stainless steel tube (92 cm × 4.7 mm diameter) with fittings (Swagelock) modified to minimize dead volume and containing stainless steel frits (MOTT Metallurgical Corp., Framington, Ma., 5 μm). The column was developed with chloroform–ethanol (95%) 6:1 with a solvent flow of 1.0 ml/min at a nominal pressure of 500 psi. Samples were injected, as ethanol solutions, directly onto the head of the column through a valved injection port (Pierce Chemical Co.). The column effluent was monitored as with the preparative column but without stream splitting.

Reversed Phase — A Bondapak phenyl/Corasil column (Waters Associates Inc., 37–50 μm, 50 cm × 1.0 mm diameter) was prepared, samples injected, and separations monitored as above. Ecdysteroids were eluted with ethanol–water (1:20). The retention times of unknown samples were directly compared with those of known standards.

Gas–Liquid Chromatography (glc)

All glc separations, similar to those of others, (*cf.* refs. 18–20) were conducted with a Hewlett-Packard, model 402 equipped with a flame ionization detector. The silylized glass column (120 cm × 4 mm i.d.) was packed with 3% OV-101 on 80/100 mesh Chromosorb W HP (Pierce Chemical Co.). Separations were conducted at 320°C with a helium flow of 40 ml/min.

All samples (*ca.* 10 μg) were dried over Drierite *in vacuo* and silylized in a 1:1 solution of pyridine–TMSI (*N*-trimethylsilylimidazole, Pierce Chemical Co.) at 50°C for 20 min. Retention times were compared directly with known standards.

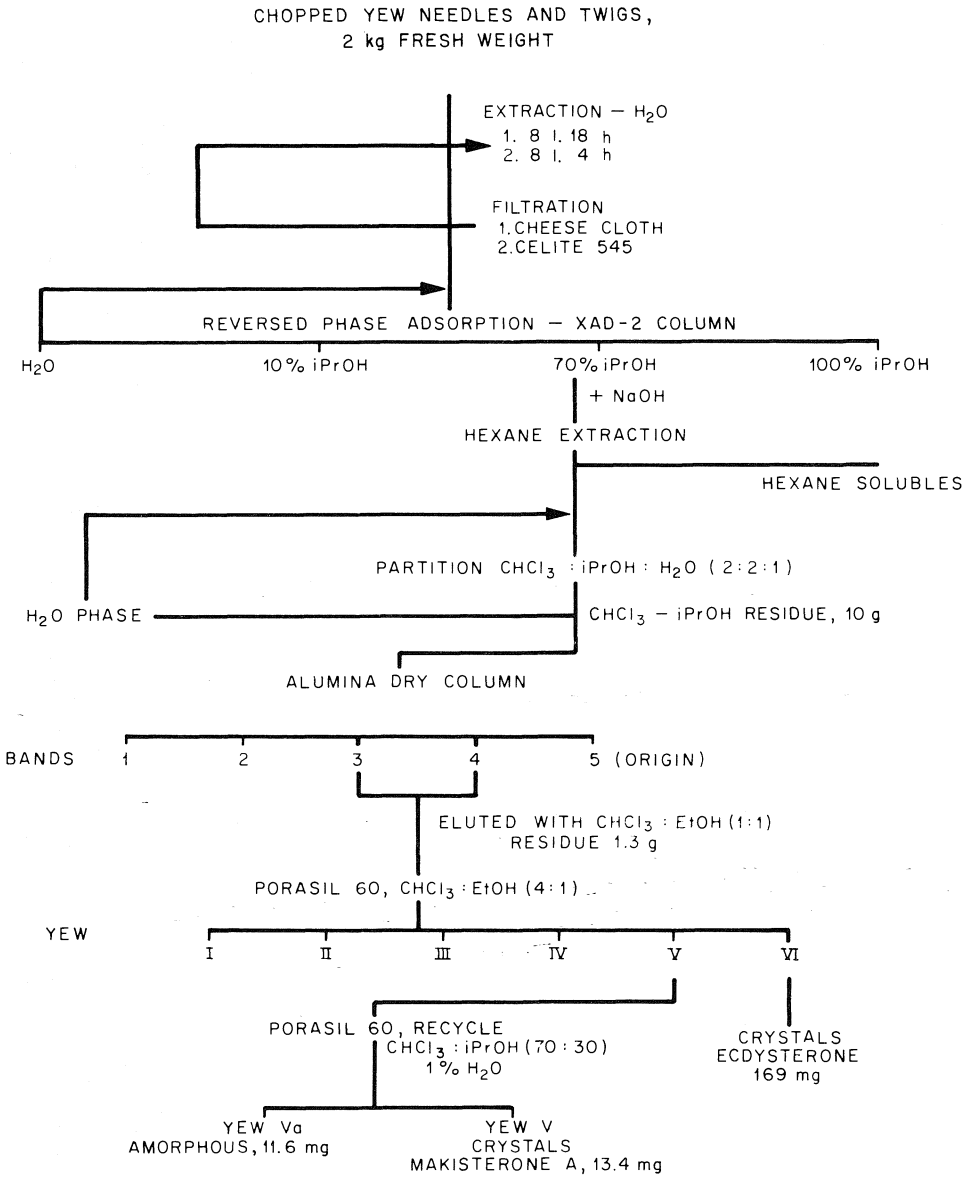


FIG. 1. Flow diagram for the isolation of makisterone A and ecdysterone from yew needles and twigs.

Physical Data

Melting points were determined with an air-bath, melting point apparatus (Gallenkamp). Mass spectra (ms) were determined by electron impact at a beam voltage of 70 eV and direct probe at 240°C with a DuPont/C.E.C., model 21-110 spectrometer). Nuclear magnetic resonance (nmr) spectra were determined with a Varian HA-100 in pyridine-d_5 with TMS as an internal reference. Melting points and spectra were compared with authentic ecdysterone (Schwarz/Mann).

Results and Discussion

An outline of the isolation procedure, detailed in the Experimental, is summarized in the flow diagram (Fig. 1). The coarseness of the yew twigs and needles (chopped rather than ground) permitted ready removal of the bulk of the debris but necessitated the long soaking. Filtration of the liquor through a Celite 545 bed prevented

Yew V	88	18.20	7.98
Yew VI	110	23.94	4.31

clogging of the XAD-2 column. The substitution of stainless steel screens for the usual column fritted disks greatly simplified and speeded the column operation. Removal of the dark brown (presumably tannins) color from the liquor by the XAD-2 column proved to be a useful monitoring device since these pigments behave similarly to the ecdysteroids on the column. They also largely eluted with the ecdysteroids in 70% isopropanol–water but could be conveniently removed by the alkaline wash during chloroform–isopropanol extraction. Back-washing the water washes proved to be unnecessary since no ecdysteroid was detected in the washes by tlc.

The alumina dry column proved valuable since it irreversibly adsorbed colored materials difficult to remove with Porasil A chromatography alone. The dry column technique was limited as we found it difficult to obtain clean separations.

Liquid chromatography of the crude ecdysteroids on Porasil A permitted the nearly complete separation of the major components as indicated by normal and reversed-phase analytical lc (Table 1). While tlc was routinely used for monitoring the separations it was most useful for crude samples, which do not resolve well in the analytical lc, and least useful for the purer fractions since the tlc R_f's (Table 2) are less stable and precise than the lc retention times (Table 1). After separation on Porasil A ecdysteroid fractions were also examined by glc as the TMS ethers (Table 3). This showed that yew V, which appeared to be pure by the other methods, contained a considerable contaminant. This fraction was therefore subjected to recycle chromatography on Porasil A with a modified solvent mixture which separated the two components after three passes through the column. Examination of the fractions by glc indicated they were essentially pure. Yew V and VI were subsequently crystallized from methanol–water and acetone–hexane, respectively. Yew Va remained amorphous. The melting points (V, mp 263.5–265.5°C (dec.); VI, mp 239–240°C (dec.)) were compared directly with that of

[a]Each compound yielded a major and minor TMS-ether peak.

authentic ecdysterone (mp 239–240°C (dec.)). The melting (decomposition) point of yew V agrees with that published for makisterone A (11).

A comparison of the nmr and ms of yew V with those published for makisterone A **4** indicate essential agreement for the methyl chemical shifts and mass fragmentation. The nmr methyl chemical shifts of yew V (1.23, 1.09, 1.57, 1.32/1.29, 1.05) were like those of ecdysterone (1.19, 1.07, 1.57, 1.35 (6H) for C_{18}, C_{19}, C_{21}, $C_{26/27}$) with the one extra peak at 1.05 ppm like the C_{28} methyl of makisterone A **4** (11). The characteristic ms peaks corresponded to the extensive dehydration (allowing no parent peak at *M/e* 494) and the side chain cleavages expected for makisterone A (*M/e* 363, $P - 131$ (6.3%) of base peak at *M/e* 43; 345, $P - 131 - 18$ (14%) and 301, $P - 175 - 18$ (11%) respectively for cleavages at C_{20}—C_{22} and C_{17}—C_{20} with dehydration) with the expected side chain fragments (cleavage at: C_{20}—C_{22}, *M/e* 131 (25%); C_{20}—C_{22} —H_2O, *M/e* 113 (42%) and C_{20}—C_{22} $-2H_2O$, *M/e* 95 (43%)) as interpreted by Imai *et al.* (11). The nmr of yew Va indicated that this compound was closely related to yew V. The ms shows strong peaks at *M/e* 145, 127, and 109 which are 14 units heavier than the corresponding ones for yew V. These could be accounted for by the addition of an extra CH_2-group giving a molecular weight of 508 equivalent to makisterone (lemmasterone, **5**) C or D **6** (12).

The method reported above is similar to that reported by Schooley *et al.* (21) derived from the reverse phase separation work of Hori (15). The high water solubility (for a steroid) of the ecdysteroids allows the bulk of this material to be extracted with water and then concentrated on XAD-2 while many potential contaminants are not extracted or are not adsorbed by the resin. Some purification was also achieved by the selective nature of the extraction with XAD-2 and the subsequent alkali-solvent partition. To ensure complete ecdysteroid recovery, particularly since the XAD-2 columns tend to channel and the column was heavily loaded, the aqueous yew extract was passed through the column a second time and the trapped solutes eluted. After solvent extraction only a minimum volume of solvent had to be evaporated, the readily removed isopropanol and chloroform. The alumina 'dry column' was not suitable for ecdysteroid separation, however, as despite repeated trials the bands could not be sufficiently resolved. After removal of the 'resinous' material with the alumina column the lc fractionation presented no unusual difficulties. The final purification of yew V was most readily achieved by recycle chromatography. This mode of separation seems either to degrade the compound when the solvents are anhydrous or else produces pronounced smearing of the peaks not obvious from the peak uv absorption record because the peak intensities declined markedly with each recycle. We found that the inclusion of a small percentage of water in the solvent largely prevented this decline.

We have concluded that yew V was makisterone A. The crystalline yew V yielded nmr, uv, and ms data and a melting point which agree with the published data (11, 12) for makisterone A. In addition yew V shows the same retention times as authentic makisterone A in two lc systems (Table 1) and as the TMS ether by glc (Table 3).

The identification of makisterone A as a constituent of both insects (14) and crustaceans (13) has increased its significance to endocrinologists. The identification of this compound as a constituent of the common decorative shrub, *Taxus cuspidata*, should make it more readily available for research.

Acknowledgements

The authors thank Prof. K. Nakaniski for a gift of authentic makisterone A. Nuclear magnetic resonance spectra were ably recorded by Dr. A. G. McInnis and D. G. Smith and mass spectra by Dr. D. W. Jamieson and D. Embree of the National Research Council of Canada, Atlantic Regional Laboratory.

Deuterium isotope effects and assignment of ^{13}C chemical shifts in spectra of methyl octadecanoate and the sixteen isomeric oxooctadecanoates[1]

A. P. TULLOCH

Prairie Regional Laboratory, National Research Council of Canada, Saskatoon, Sask., Canada S7N 0W9

Received July 5, 1976

A. P. TULLOCH. Can. J. Chem. **55**, 1135 (1977).

^{13}C nmr spectra of the 16 isomeric *gem*-dideuterooctadecanoates were measured and second and third atom deuterium isotope effects calculated for most of the affected carbons of 12 of the isomers. The average value for the second atom effect was -0.20 ppm and for the third atom effect was -0.05 ppm. From these effects and the changes in spectra caused by introduction of two deuterons at positions along the fatty acid chain, chemical shifts were determined for all carbons of methyl octadecanoate. Spectra of seven dideuterooxooctadecanoates, with both deuterons attached to a carbon γ to the oxo group, were measured, and using isotope effects, unambiguous assignments of chemical shift were made. Chemical shifts were thus assigned to all carbons in the 16 isomeric oxooctadecanoates and these show the effect of the carbonyl group at different positions in the chain. The results indicate that, in addition to large effects on carbons α and β to the oxo group, the γ to θ carbons are all shielded with displacements: γ -0.46, δ -0.30, ε -0.27, ζ -0.13, η -0.09, and θ -0.06 ppm. The effects of the oxo and ester carbonyls extend over seven methylene groups, but shielding due to ester carbonyl is a little smaller. Spectra of 2- to 9-oxo esters showed that interaction between the two carbonyl groups causes relatively greater shielding of carbons situated between the groups.

A. P. TULLOCH. Can. J. Chem. **55**, 1135 (1977).

On a mesuré des spectres rmn du ^{13}C de 16 *gem*-dideutérooctadécanoates isomères; les effets isotopiques du deuterium pour les deuxième et troisième atomes ont pu être calculés pour la plupart des carbones affectés de 12 des isomères. La valeur moyenne de l'effet du deuxième atome est de -0.20 ppm et celle du troisième atome est de -0.05 ppm. A partir de ces effets et des changements dans les spectres obtenus par l'introduction de deux atomes de deutérium à des positions le long de la chaîne d'acides gras, on a déterminé les déplacements chimiques de tous les atomes de carbone de l'octadécanoate de méthyle. On a mesuré les spectres de sept dideutéro-oxooctadécanoates avec deux deuterium attachés à un carbone γ par rapport au groupe oxo et faisant appel aux effets isotopiques, des attributions nonambiguës des déplacements chimiques ont pu être faites. Des déplacements chimiques ont pu être attribués à tous les atomes de carbone des 16 oxooctadécanoates isomères et ces déplacements chimiques montrent l'effet d'un groupement carbonyle à diverses positions de la chaîne. Les résultats indiquent qu'en plus de larges effets sur les carbones α et β par rapport au groupement oxo, les carbones γ jusqu'à θ sont blindés avec les déplacements décroissants: γ -0.46, δ -0.30, ε -0.27, ζ -0.13, η -0.09 et θ -0.06 ppm. Les effets des groupements carbonyles oxo et ester se font sentir sur sept groupes méthylènes mais le blindage dû au groupement carbonyle de l'ester est un peu plus petit. Les spectres des esters oxo-2 jusqu'à 9 montrent que l'interaction entre les deux groupements carbonyles cause des blindages relativement plus grands des carbones situés entre les groupes.

[Traduit par le journal]

Introduction

Application of second and third atom deuterium isotope effects to the assignment of ^{13}C signals in spectra of long chain methyl esters was reported previously (1). Several esters, with a CD_2 group in the chain near the terminal methyl group, and 2-D_2 hexadecanoate showed second atom effects of -0.12 to -0.28 ppm and third atom effects of about -0.04 ppm. Also, line widths of affected signals were increased approximately threefold due probably to ^{13}C–D coupling. Signal broadening facilitated identification of affected signals even when upfield displacements were relatively small. A preliminary application of this method to saturated and unsaturated C_{18} esters resulted in assignment of signals due to C-4, C-5, C-6, and C-15 in the spectrum of methyl octadecanoate (2) but shifts of C-8 to C-14 were not assigned.

Spectra have now been measured for all 16 isomers with D_2 groups at positions along the chain from positions 2 to 17, so that isotope

[1]NRCC No. 15765.

effects could be determined for a much larger number of compounds. The esters examined earlier (1) had the CD_2 group near the ends of the molecule and, for this reason, the effects might have been unusual. From these spectra, chemical shifts have been assigned to all the carbons in methyl octadecanoate.

Preliminary results have indicated the value of ^{13}C nmr spectra in determining structures of oxygenated esters (2). Spectra of seven dideuterooxooctadecanoates have also been used to assign chemical shifts in spectra of all 16 isomeric oxooctadecanoates. It has thus been possible to determine the effect, on the ^{13}C spectrum, of introducing an oxo group at different positions along the fatty acid chain.

Results and Discussion

To obtain chemical shifts for all carbons in methyl octadecanoate, signals in spectra of D_2 esters were assigned either from upfield displacement and broadening of an already visible signal or by the appearance of spectra after several overlapping signals had been removed as a result of deuteration. The spectral changes are illustrated in Fig. 1. The spectrum of octadecanoate shows 5 signals due to C-4, C-5, C-15, C-6, and C-7 and a composite signal due to C-8 to C-14. In the spectrum of 3-D_2 octadecanoate signals due to C-4 and C-5 are displaced and broadened and in the spectrum of 5-D_2 octadecanoate signals due to C-4, C-6, and C-7 are displaced. Signals for the D_2 carbons were not seen in these spectra or in those of any of the other isomers; signals due to dideuterated carbons are not usually observed (1, 3, 4) probably because of excessive signal splitting and increased relaxation times.

In the spectrum of 8-D_2 octadecanoate, signals due to C-6, C-7, and C-9 have been displaced and the signal now assigned to C-14 appears as a single peak at δ 29.66 ppm. The C-14 signal was previously obscured by the C-8, C-9, and C-10 signals which have disappeared or moved upfield. C-11, C-12, and C-13 all have almost the same chemical shift at δ 29.71 ppm. The signal due to C-14 can also be seen in spectra of 7-D_2, 9-D_2, and 10-D_2 esters. In the same way signals due to C-8 and C-9 appear in spectra of 12-D_2 and 13-D_2 esters and the C-12 and C-13 signals in the spectrum of 9-D_2 ester. C-10 and C-11 signals were not clearly observed in any of the spectra.

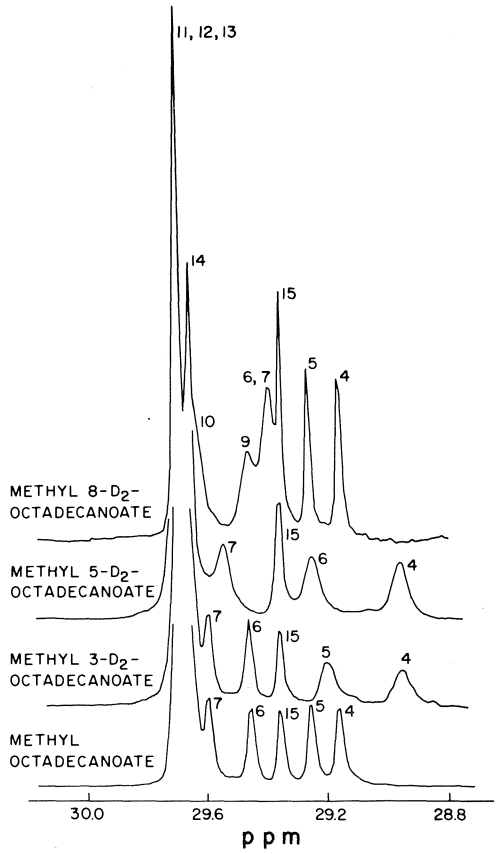

FIG. 1. 28.8 to 30.0 ppm region of ^{13}C nmr spectra of methyl octadecanoate and of methyl 3-D_2, 5-D_2, and 8-D_2 octadecanoates; spectra obtained with spectral width 1 kHz and horizontally expanded 10 times.

Average values of second and third atom effects of the CD_2 group obtained from unobscured and unambiguously assignable signals, which are listed in Table 1, were then used to confirm assignments made as above. Displacements of C-3 and C-4 in the 2-D_2 spectrum, of C-2 and of C-2 and C-3 in spectra of 3-D_2 and 4-D_2 esters, respectively, were lower than the rest, presumably due to their proximity to the ester group, and were excluded from calculation. Signals due to ester carbonyl carbon were observed in spectra of 2-D_2 and 3-D_2 esters, but the intensity was reduced, especially in the 2-D_2 spectrum (*cf.* spectra of D_2 steroid ketones (3)). Isotope effects were not, however, observed for the carbonyl carbons; electronegative substituents have previously been found to reduce isotope effects (1, 5) but the C-2 signal in the spectrum of acetone-d_6 showed an appreciable positive (downfield) isotope effect (6). In spectra

[a]Only clearly measurable effects have been tabulated.
[b]Upfield displacements are negative.

of amino acids with α-ND_2 groups and COOD carboxyl, the carbonyl carbon showed an upfield displacement of about 0.3 ppm (7).

The 14 second atom effects in Table 1 had an average value of −0.20 ppm and the 12 third atom effects an average value of −0.05 ppm. Thus the C-8 signal appears at higher field in spectra of 7-D_2 and 9-D_2 and its approximate value in octadecanoate can be calculated by addition of 0.2 ppm. Similarly C-9 appears in the spectrum of 8-D_2 (see Fig. 1) and (partly obscured) in the spectrum of 10-D_2, C-10 in spectra of 9-D_2 and 11-D_2, C-11 in spectra of 10-D_2 (partly obscured) and 12-D_2, C-12 in spectra of 11-D_2 and 13-D_2 (both partly obscured by other signals), C-13 in spectra of 12-D_2 and 14-D_2 and C-14 in spectra of 13-D_2 and 15-D_2 esters.

Further evidence that the C-11, C-12, and C-13 signals are together at the lowest field part of the large composite peak (see Fig. 1) was obtained from spectra of 11-D_2, 12-D_2, and 13-D_2 esters in which this low field portion was displaced to higher field. The change in the spectrum of 11-D_2 also confirms that C-14 is at higher field than C-11 to C-13. The spectrum of 15-D_2, in which the lower field portion of the composite peak is unchanged, also indicates the relatively high field position of the C-14 signal.

In this way signals in the D_2 isomers were assigned and hence chemical shifts of the seven overlapping signals in the spectrum of octadecanoate were calculated giving the results listed in Table 2. Shifts of C-7 to C-14 were not previously measured but those of C-4 to C-6 and of C-15 are in agreement with previous assignments (1, 2, 8). The shift of C-14 at δ 29.66 ppm, at higher field than the shifts of C-11 to C-13 at δ 29.71 ppm is of interest since the ε effect due to methyl substitution, which appears not to have been previously estimated, can be calculated. The shifts of C-11 to C-18 of octadecanoate (Table 2) show that the effects of methyl substitution are as follows: α effect +8.61, β effect +9.23, γ effect −2.56, δ effect +0.30 and ε effect −0.05 ppm. Since shifts of C-12 and C-11 are the same as that of C-13, and ζ and η effects are zero. The α to δ effects are similar to those of Batchelor *et al.* (8).

The effects of the ester group were also calculated by comparison with a C_{18} alkane (*cf.* ref. 8): C-1 +159.85, C-2 +11.39, C-3 −6.95, C-4 −0.20, C-5 −0.45, C-6 −0.20, C-7 −0.12, C-8 −0.07 and C-9 −0.04. Effects for carbons 4 to 7 are larger than those observed before (8) and those for C-8 and C-9 were not measured before. Thus, the ester group has a small shielding effect on the more distant carbons, detectable as far as C-9, and only C-11 to C-13 are completely unaffected by the ends of the chain.

Spectra of Oxooctadecanoates

There have been only a few previous investigations of the effect of a carbonyl group on spectra of alkanes (9). Chemical shifts were reported for some C_4 to C_{13} ketones (10); comparison of shifts of $RCOR^1$ with RH showed the usual appreciable deshielding of the α carbon and downfield displacement of about 1 ppm of signals of the other carbons (except the γ carbon)

[a]In octadecanoate C-1 was at 174.00 ppm, in 2-D_2 at 174.04 ppm, and in 3-D_2 at 173.95 ppm; separate signals were not observed in spectra of mixtures.
[b]Composite peak, chemical shift not accurate for each component.

up to those separated from the carbonyl by 5 methylene groups. However, the measurements were not accurate enough to decide if the smaller deshielding effects were real (9).

Spectra of all 16 oxoesters, 2-oxo to 17-oxo, were measured. Signals due to carbons α and β to the oxo group could be clearly recognized in the spectrum but in many cases could not be unambiguously assigned to a particular α or β carbon. Also signals of γ, δ, ε, etc., carbons could not be easily assigned in spectra of esters where the oxo group was near the centre of the chain.

Spectra of specifically dideuterated oxo esters, 10-D_2-7-oxo, 5-D_2-8-oxo, 11-D_2-8-oxo, 8-D_2-11-oxo, 14-D_2-11-oxo, 9-D_2-12-oxo, and 16-D_2-13-oxo octadecanoates, were then examined. In each ester the CD_2 group is γ to the oxo group so that second and third atom isotope effects make possible assignment of signals of the two pairs of carbons α and β to the CD_2 group. Isotope effects were measured for signals of all affected carbons except for those of C-6 and C-7 of 8-D_2-11-oxo and C-7 and C-8 of 9-D_2-12-oxo which were obscured by signals of other carbons. Averages were calculated separately (from six values in each case) for isotope effects on carbons between the CD_2 and CO groups and on carbons the other side of the CD_2 group. In each case the average second atom effect was −0.20 and the average third atom effect was −0.05. Again affected signals were broadened approximately threefold. Thus, the isotope effects are the same as in the D_2 octadecanoates and are apparently not affected by the oxo group in contrast to the effect of the ester group on isotope displacement in the 2-D_2, 3-D_2, and 4-D_2 esters.

Using the effects, all signals in spectra of 7-, 8-, 11-, 12- and 13-oxo esters were assigned except for those of C-4 to C-10 in 13-oxo ester. Signals of carbons near the ends of the molecule could also be unambiguously assigned when the oxo group was at positions 2- to 5- and 14- to 17-. Average values for the effect of the oxo group on γ to θ carbons (comparing oxo ester to octadecanoate) were calculated from chemical shifts of carbons in the above esters. Chemical shifts could then be assigned to all carbons in all the oxo esters giving the results in Table 3. Effects of the oxygen on the oxygenated carbon and on carbons on the methyl ester side of the group are listed in Table 4 and effects on α to θ carbons on the terminal methyl side are in Table 5.

Effects on Carbonyl Carbon

Stothers and Lauterbur (11) examined carbonyl shifts in α, β, and γ oxo esters and observed shielding of both CO carbons particularly those in 2-oxo ester. The results in Table 4 for 2-, 3-, and 4-oxo esters are quite similar to these; however, neither CO group reaches a constant shift until 9-oxo ester (in which the ester carbonyl shift is almost the same as that for unsubstituted octadecanoate). It therefore appears that there is a small, and diminishing, but definite shielding effect of one CO group on the other which extends across 7 methylene groups. Thus, comparing 4-oxo with 9-oxo ester, the shifts of ester and ketonic carbonyl carbons of the former are upfield of those of the latter by 0.9 and 2.5 ppm, respectively.

Effects on α and β Carbons

These effects, which are considerably larger than those on more distant carbons, are conveniently considered separately. Unambiguous assignments obtained from spectra of D_2 oxo esters showed that those carbons which have signals at higher field in octadecanoate are also at higher field in the oxo esters. Thus in the spectrum of 13-oxo ester the signal due to C-14 is at higher field than the signal to C-12 by 0.04 ppm, in agreement with the shifts of C-14 and C-12 in the spectrum of octadecanoate (see Tables 2 and 3).

If the effect of the CO group were exactly additive then the differences between chemical shifts of the pairs of α carbons, and the pairs of β carbons, in the oxo esters should be the same as the differences between the corresponding pairs of shifts in the octadecanoate spectrum. Table 6 shows how these differences vary with position of the oxo group.

When the oxo group is at positions 10-, 11-, 12-, or 13-, close to the center of the chain, agreement between observed and calculated values is good. This is presumably because carbons α or β to these positions are little affected by the ester group; as was shown above, the influence of this group extends as far as C-9 but is quite small for C-8 and C-9. When the oxo group replaces one of the last four methylene groups differences between observed and calculated values appear, particularly when the terminal methyl is an α or β group suggesting that the oxo group affects a methyl group more than a methylene group.

[a]In ppm calculated by comparison with methyl octadecanoate. Unitalicized figures were obtained from unambiguous assignments and were used to make the assignments which gave the italicized values.
[b]Average calculated from values for 7-, 8-, 11-, 12-, and 13-oxo esters.

There is an increasing divergence between observed and calculated values when the oxo group is at positions 9- to 4-; Tables 4 and 5 show that this is mainly because α and β carbons on the ester side of the CO group are at higher field than corresponding carbons on the terminal methyl side. The α displacement for 9-oxo ester is +13.02 on the ester side and +13.10 on the methyl side, but for 5-oxo ester the corresponding values are +12.23 and +13.37. Apparently interaction between the two CO groups results in a relative shielding of carbons between the groups and the shielding increases with decrease in separation of the groups. It

TABLE 6. Observed and calculated differences between ^{13}C chemical shifts of pairs of α carbons and pairs of β carbons in spectra of methyl oxooctadecanoates[a]

[a]In ppm, calculated values obtained from shifts of corresponding carbons in spectrum of methyl octadecanoate.

also appears from spectra of 2-oxo to 6-oxo esters that α carbons on the methyl side of the oxo group are shielded to some extent, but, except for the β-carbon of 2-oxo ester, β carbons are not affected.

Effects on γ to θ Carbons

The average values in Tables 4 and 5 were calculated from shifts of carbons on both sides of the oxo group in spectra of 7-, 8-, 11- and 12-oxo esters and from shifts of carbons on the methyl side only in 13-oxo ester (these signals were assigned using the D_2 oxo esters). Then, from assignments made to signals in spectra of other oxo esters (Table 3) effects of the oxo group in these isomers were calculated and are shown in Table 4 and 5 in italics. It is clear that, for most positions of the oxo group, values are quite close to the average. In 2-oxo ester (Table 5) the oxo group has a smaller than average shielding effect on γ to ε carbons. Table 4 also shows that, in the case of 4- to 7-oxo esters, when the carbon under consideration is the ester carbonyl (or C-2 of 5-oxo ester), then the effect is appreciably larger than average.

Effects on carbons on both sides of the oxo group have almost the same average values. They do not decrease regularly since there is a drop of 0.16 ppm from the γ to δ effect, the ε effect is only a little lower and there is a drop of 0.13 ppm to the ζ effect followed by a gradual decline to the θ effect. The results in Tables 4 and 5 show that the longer range effects of ketonic carbonyl are consistently slightly larger than those of ester carbonyl. They also show that effects previously reported for tridecan-7-one (9, 10) were too large and in the wrong direction. Since the average γ to θ effects given in Tables 4 and 5 were calculated from accurately determined and unambiguously assigned chemical shifts they differ slightly from previously reported values (2).

It was concluded by Batchelor *et al.* (12) that an electric field effect of the CO_2CH_3 group could affect the signals of double bond carbons in the spectrum of methyl oleate and it was also thought that this effect could explain the long range influence of the ester group on saturated carbons (8). Whatever the explanation of long range effects, it is clear that the carbonyl group can affect chemical shifts of carbons separated by seven methylene groups. Also the present results obtained for the oxooctadecanoates enable the effects of the oxo group to be related to its position in a long chain molecule and so could be used to determine carbonyl position in long chain natural products.

Experimental

A Varian XL-100-15 spectrometer in the Fourier transform mode at 25.2 MHz, with proton noise decoupling, was used to obtain natural abundance ^{13}C nmr spectra. All deuterated compounds were examined using a data

length of 8192 points, sweep width was 1 kHz and acquisition time 4 s (0.25 Hz/point), the 28.8 to 30.0 ppm region was also observed after 10-fold horizontal expansion; chemical shifts so obtained were accurate to ± 0.01 ppm. A data length of only 4096 points was used with some of the oxo esters and these shifts were accurate to ± 0.03 ppm. To determine shifts of carbonyl carbons, spectral widths of 5 kHz and acquisition times of 0.8 s (1.25 Hz/point) were used; 2-oxooctadecanoate and 3-D_2 octadecanoate also required pulse delays of 1 s and 2-D_2 octadecanoate required a pulse delay of 3 s. Off-resonance proton decoupling was used to assign the signal due to C-18 in the spectrum of methyl 17-oxooctadecanoate. All spectra were measured as 15% solutions in $CDCl_3$ and the solvent also provided the internal deuterium lock. All chemical shifts are downfield from TMS. The oxo esters were synthesized previously (13) and synthesis of the deuterated esters is being reported elsewhere.

A 2% cross-linked divinylbenzene–styrene copolymer, incorporating trityl chloride groups, (**1**), was used in the synthesis of insect sex attractants of Lepidoptera by two independent routes. Polymer **1** reacted with the symmetrical diols 1,6-hexanediol, 1,8-octanediol, and 1,10-decanediol to give the monoblocked polymer-bound diols **5–7**, respectively. Mesylation of **5–7** gave the polymer-bound monomesylates **8–10**, which on coupling with 1-lithio-1-hexyne or 1-lithio-1-butyne gave the polymer-bound alkyne trityl ethers **18–20**. Alkynols, obtained by hydrolysis from polymers **18–20**, were selectively reduced and acetylated to give *cis*-7-dodecen-1-ol acetate (**28**), *cis*-9-tetradecen-1-ol acetate (**29**), and *cis*-11-tetradecen-1-ol acetate (**30**), the sex attractants of *Trichoplusia ni* (Hübner), *Spodoptera frugiperda* (J. E. Smith), and *Argyrotaenia velutinana* (Walker), respectively. Alternatively, polymer-bound 1,7-heptanediol (**33**), polymer-bound 1,9-nonanediol (**34**), and **7** were oxidized with the Sharpless reagent (CrO_2Cl_2/*tert*-butyl alcohol/pyridine) to give polymer-bound aldehydes **35–37**, which on reaction with Wittig reagents and subsequent hydrolysis and acetylation gave **28**, **29**, and 10-tetradecen-1-ol acetate (**47**), the sex attractant of *Archips semiferanus* (Walker). A 'reverse' Wittig synthesis of **47** was achieved by the reaction of polymer **10** with molten triphenylphosphine followed by base and treatment with butyraldehyde. Subsequent cleavage and acetylation gave **47** in high yield and stereoselectivity containing greater than 91% of the *cis* isomer.

CLIFFORD C. LEZNOFF, THOMAS M. FYLES et J. WEATHERSTON. Can. J. Chem. **55**, 1143 (1977).

On a utilisé un copolymère à 2% divinylbenzène–styrène réticulé, et incorporant des groupes chlorure de trityle (**1**) pour la synthèse, par deux routes indépendantes, d'attirants sexuels d'insectes de Lepidoptera. Le polymère **1** réagit avec les diols symétriques hexanediol-1,6 octanediol-1,8 et décanediol-1,10 pour conduire respectivement aux diols **5–7** possédant un lien covalent avec le polymère. La mésylation de **5–7** conduit aux monomésylates **8–10** liés au polymère; par couplage avec le lithio-1 hexyne-1 ou le lithio-1 butyne-1 ils fournissent les éthers tritylés acétyléniques liés au polymère (**18–20**). Les alkynols obtenus par hydrolyse des polymères **18–20** ont pu être réduits sélectivement et acétylés pour conduire aux acétates des dodécèn-7 ol-1 *cis* (**28**), tétradécèn-9 ol-1 *cis* (**29**) et tétradécèn-11 ol-1 *cis* (**30**) qui sont respectivement les attirants sexuels des *Trichoplusia ni* (Hübner), *Spodoptera frugiperda* (J. E. Smith) et *Argyrotaenia velutinana* (Walker). D'une manière alternative, l'heptanediol-1,7 et le nonanediol-1,9 liés au polymère (**33** et **34**) et **7** ont pu être oxydés par le réactif de Sharpless (CrO_2Cl_2/*tert*-butanol/pyridine) pour conduire aux aldéhydes liés au polymère **35–37** qui par réaction avec des réactifs de Wittig suivie d'une hydrolyse ainsi qu'une acétylation fournissent **28**, **29** et l'acétate du tétradécèn-10 ol-1 *cis* (**47**) l'attirant sexuel de *l'Archips semiferanus* (Walker). On a pu réussir une synthèse de Wittig renversée de **47** par la réaction du polymère **10** avec la triphénylphosphine fondue, suivie d'une réaction avec une base et d'un traitement avec le butyraldéhyde. Une coupure subséquente, suivie d'une acétylation, conduit à **47** avec un bon rendement et une bonne stéréosélectivité et contenant plus que 91% de l'isomère *cis*.

Introduction

Insoluble polymer supports are widely used in the synthesis of polypeptides (1) and have been applied to polynucleotide (2) and polysaccharide (3) syntheses as well. All of these syntheses involve the preparation of biopolymers by the repetition of a very few well characterized

[1]For part VII see ref. 8.

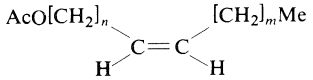
chemical transformations. Although the *number* of reactions required for the synthesis of a typical natural product is relatively small, compared to the synthesis of a polypeptide, such as ribonuclease A (4), the *variety* of chemical reactions is large. Thus one would expect the synthesis of a natural product in eight different steps to be considerably more difficult than that of a pentapeptide involving eight steps but only two different steps. Syntheses of natural products, in general, have not been attempted on solid phases despite the inherent advantages of this method (1, 2, 5), possibly due to the fact that each reaction in the synthetic scheme must be carefully examined with respect to its compatibility with the heterogeneous reaction medium, even though the given reaction under investigation was highly successful in homogeneous phase.

Insect sex attractants (6) of Lepidoptera, having the general formula shown below, are particularly suitable molecules to prepare on solid phases. Not only can one exploit the 'general' advantages of solid phase synthesis described by Merrifield (1) and Letsinger *et al.* (5) (simplicity of reactions, ease of work-up conditions, adaptability to automation), but we and others had previously shown how insoluble polymer supports can be used as monoprotecting groups of symmetrical dials (7, 8) and diols (refs. 9 and 10 and for recent reviews see ref. 11), the simple starting materials used in the synthesis of insect sex attractants.



In a preliminary report of this work (12), we described the synthesis of insect sex attractants on solid phases by an alkyne coupling route. In this report we present the details of the solid phase alkyne route (12) along with several modifications and alternative solid phase syntheses of insect sex attractants based on Wittig condensations.

Results and Discussion

The Alkyne Route

A 2% crosslinked divinylbenzene–styrene copolymer, incorporating trityl chloride functional groups, (**1**) (13), was prepared by our direct lithiation method (9). Polymer **1** was treated with 1,6-hexanediol (**2**), 1,8-octanediol (**3**), and 1,10-decanediol (**4**) for 48 h in pyridine at room temperature to give monoprotected polymer-bound diols **5–7** respectively. It was not possible at this stage to wash out liberated HCl and still maintain unreacted residual polymer-bound trityl chloride (**1**) for the determination of unreacted **1**. The amounts of diols **2–4** attached to polymers **5–7** were determined by cleavage of **5–7** with dry HCl in dioxane, having a titration value of 0.35 *M* HCl (Table 1).

Lithioalkynes can be readily coupled to alkyl halides in tetrahydrofuran – hexamethylphosphoric triamide (THF–HMPT) (14) and hence it was desirable to convert **5–7** to polymer-bound halides. Treatment of **7** with $SOCl_2$ in pyridine or dioxane–pyridine, PBr_3 in pyridine or dioxane–pyridine, PPh_3Br_2 in dimethylformamide (DMF), or even PPh_3 in CCl_4 (15) resulted in complete or partial cleavage of the diol from the polymer and hence these standard procedures for conversion of primary alcohols to halides had to be abandoned. Mesylation of **5–7** with methanesulfonyl chloride in pyridine for 48 h at room temperature gave the polymer-bound symmetrical diol monomesylates **8–10** respectively. The polymer turns brown at this stage and cannot be washed free of all impurities and hence sulfur analysis of **8–10**, for example, would give meaningless results. Acid cleavage of **8–10** as before gave 1,6-hexanediol monomesylate (**11**), 1,8-octanediol monomesylate (**12**), and 1,10-decanediol monomesylate (**13**) in yields of ~30%, ω-chloro-1-alkanols (from displacement of mesylate by Cl^- during cleavage) in yields of ~30%, and some recovered diol (Table 1). Since one can never be certain of the purity of a polymer-bound product we base our yields on cleaved products and intermediates only.[5] It should be mentioned that certain losses occur in the work-up of the products so that the summation of yields of products and recovered starting material usually remains less than 100% of the diol initially bound to the polymer. We feel that small losses occur due to

[5]It may also be true, as a referee suggested, that cleavage is incomplete, but we feel that this viewpoint is unlikely as repetitive cleavages liberate no additional products. In addition, if some diol is uncleavable, then some diol would be irretrievably lost only in the first cycle. If additional diol became uncleavable in subsequent cycles the capacity of the polymer would diminish with each cycle, which is not the case.

cleavage of diol and products from the polymer in intermediate steps in the synthesis. The combined yields of monomesylate and ω-chloro-1-alkanol represent high conversion of **5–7** to **8–10** (and hence **11–13**) as the recovered diols were likely doubly bound to the polymer (9). As previously shown (9) it is possible to prepare a polymer-bound trityl chloride to which symmetrical diols can be bound exclusively at one end only. Acetylation of the free alcohol end gives an almost quantitative yield of the symmetrical diol monoacetate upon cleavage from the polymer. Thus we concluded (9) that the acetylation reaction goes to completion. The acetylation reaction on polymer **1** used in this paper gives us approximately 60% yields of symmetrical diol monoacetates as previously reported (9). We had suggested (9) that the remaining diol was likely doubly-bound since we know that the acetylation reaction is nearly quantitative. In this paper our combined yields of ω-chloro-1-alkanols and symmetrical diol monomesylates via polymer **1** are close to 60% and we feel that these results parallel the acetylation results previously reported (9) and lead us again to the conclusion that the recovered diol was due to double binding to the polymer. Polymer-bound monomesylate (**10**) could be directly converted to a polymer-bound aliphatic bromide (**14**) or iodide (**15**) by treatment of **10** with NaBr or NaI, respectively, in HMPT at 70°C for 48 h in the dark. Halide analysis of polymer-bound aliphatic halides **14** and **15** was achieved using potassium *tert*-butyl alcohol under reflux overnight to ensure complete liberation of halide. These analyses of polymer-bound aliphatic halides are useful in that they distinguish aliphatic halides from ionic, benzylic, or trityl halides. These conditions are much more vigorous than those used in the modified Volhard analysis of polymeric benzylic halides (16), characteristic of Merrifield's polymer (1) or polymer **1**. Since some model preliminary experiments indicated that all attempted reactions on polymer-bound monomesylate **10** worked as well or better than polymer-bound bromide **14** or iodide **15**, all subsequent reactions were done exclusively on mesylates, thus eliminating one step in the reaction sequence.

Polymer-bound monomesylates **8** and **9** were added to 1-lithio-1-hexyne (**16**) and **10** to 1-lithio-1-butyne (**17**) in THF–HMPT (1:1) at −10°C and allowed to stir overnight at room temperature to give polymer-bound alkynes **18–20**, respectively (Scheme 1). Liberation of the alkynes from polymers **18–20** as before gave recovered polymer-bound trityl alcohol (**21**) and the acetylenic alcohols, 7-dodecyn-1-ol (**22**), 9-tetradecyn-1-ol (**23**), and 11-tetradecyn-1-ol (**24**), respectively. Crude **22–24** contaminated with some unreacted **2–4** and **11–13**, were purified at this stage by preparative tlc.[6] Hydrogenation of **22–24** with Pd–$CaCO_3$ treated with quinoline (17) gave 7-dodecen-1-ol (**25**), 9-tetradecen-1-ol (**26**), and 11-tetradecen-1-ol (**27**). Acetylation of **25–27** afforded (Table 1)

[6]Since the only major products recovered at this stage were the single desired product and recovered diol, these compounds could presumably be separated by distillation if the reactions were done on a larger scale.

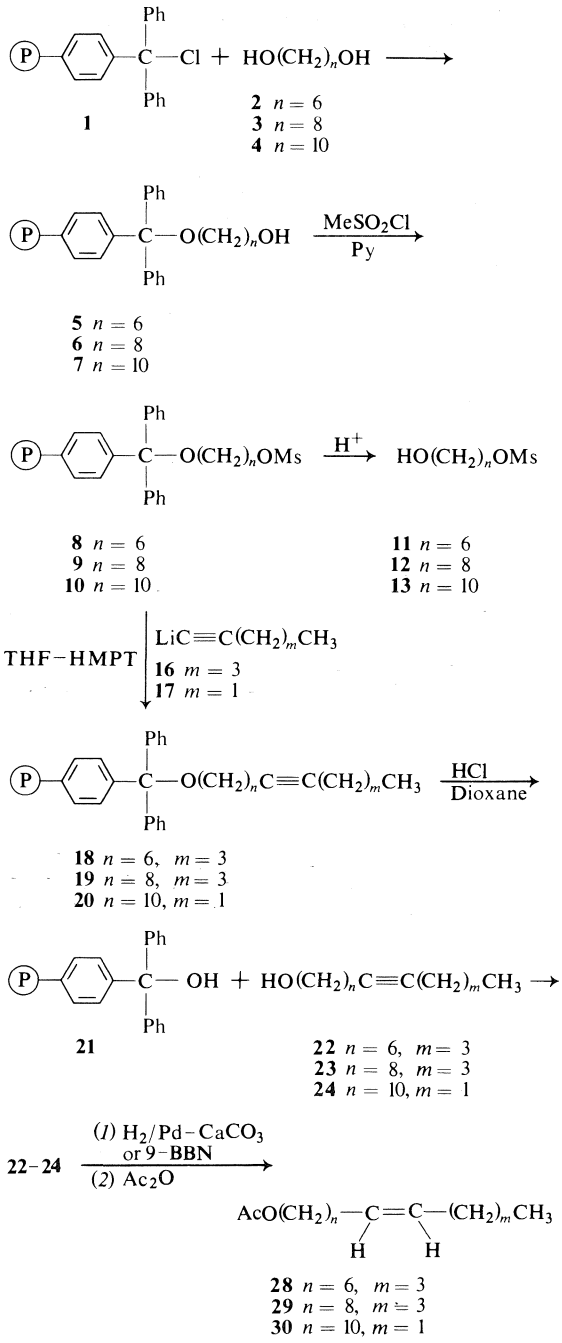
7-dodecen-1-ol acetate (18) (**28**), 9-tetradecen-1-ol acetate (19) (**29**), and 11-tetradecen-1-ol acetate (20) (**30**), the *cis* isomers of which are the sex attractants of the cabbage looper, *Trichoplusia ni* (Hübner), the fall army worm moth, *Spodoptera frugiperda* (J. E. Smith), and the red-banded leaf roller, *Argyrotaenia velutinana* (Walker), respectively. Attractant **30** was also prepared from **24** by acetylation, followed by hydrogenation, but **30**, prepared by this reverse sequence of chemical reactions, was contaminated by considerable amounts of alkyne, alkane, and the *trans* isomer.

Vapour phase chromatography (vpc) on a 10% Silar C column of **29–30** showed significant amounts of their *trans* isomers (Table 2) as well as small amounts of unreacted alkyne and over-reduced alkane-1-ol acetates. High pressure liquid chromatography (hplc), using a μ Bondapak C-18 reverse phase column, has recently been used in the separation of *cis* and *trans* isomers of insect sex attractants (21). Analysis by hplc, confirmed the vpc results entirely for attractants **28–30**, showing that these compounds contained significant amounts of the *trans* isomer. It was recognized that catalytic hydrogenation of **23** to give **26** was not completely stereoselective for the *cis* isomer (18).

It is known that reduction of alkynes with boranes (22) yields *cis*-alkenes exclusively and this procedure has been applied to the stereoselective synthesis of insect sex attractants (23). Hence, treatment[7] of **23** and **24** with 9-BBN in THF gave **26** and **27**, which on acetylation gave exclusively the *cis* isomers of **29** and **30**, as analyzed by hplc and infrared spectroscopy. The mass spectra, taken at an ionization potential of 16 eV, of **28–30** exhibited weak, but detectable parent ions and base peaks corresponding to the loss of acetic acid.

The Wittig Route

The synthesis of insect sex attractants by Wittig reactions in homogeneous phase has been described (25, 26) and we wished to apply this mode of synthesis to solid phases. Polymer **1** reacted with 1,7-heptanediol (**31**), 1,9-nonanediol (**32**), and 1,10-decanediol (**4**) as described above to give the monoprotected polymer-bound diols **33**, **34**, and **7**, respectively. The amounts of diol contained in polymers **33**, **34**, and **7** were determined by acid cleavage with HCl in dioxane (Table 3). Due to the acid



SCHEME 1

[7]Preliminary experiments designed to effect the direct reduction of polymer-bound alkyne **20** to a polymer-bound *cis*-alkene using the homogeneous reducing agents 9-BBN in THF or diisobutylaluminum hydride (24) (DIBAH) in benzene have so far given inconsistent results.

TABLE 2. Purity of insect attractants prepared on solid phases via the alkyne route as determined by vpc and hplc

Attractant	Alkene (%)	*cis* Isomer[a] (%)	Alkyne impurity[b] (%)	Alkane impurity[c] (%)

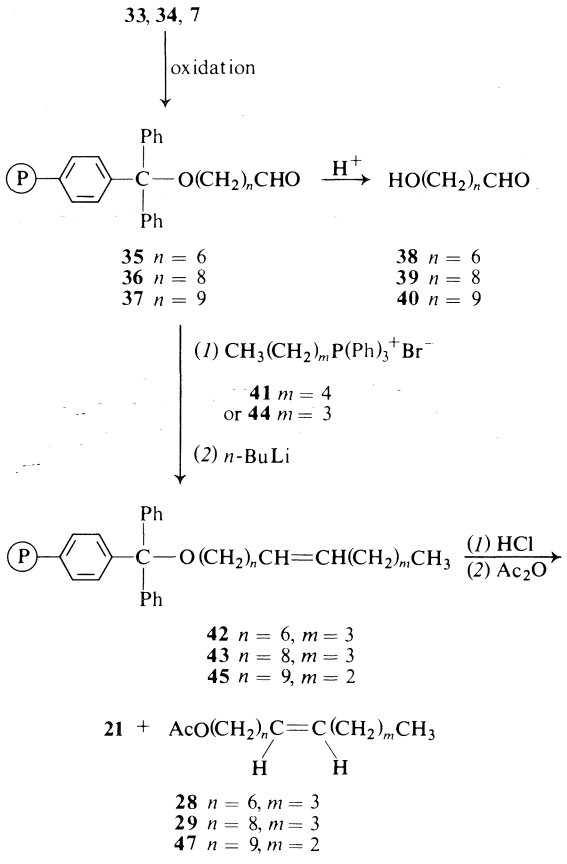
[g]Prepared by catalytic reduction of an alkyn-1-ol acetate.

sensitive trityl blocking group of the polymer, oxidation of **33**, **34**, and **7** to the corresponding aldehydes had to be accomplished under basic or neutral conditions. Furthermore, many oxidizing agents are used in mixtures that are heterogeneous at the beginning of the reaction or precipitate chromium salts during the course of the oxidation. The heterogeneous nature of the oxidizing agent coupled with the insoluble polymer substrate would make the oxidations unfavourable, if not impossible, and precipitated chromium salts would be difficult to separate from the polymer under non-acidic conditions. In addition, since the products of any reaction on the insoluble polymer cannot be purified at intermediate stages in the synthesis it is desirable that each reaction proceed in high yield and be free of side products. We found that these requirements were met using the Sharpless reagent (27) (CrO_2Cl_2, *tert*-butyl alcohol, pyridine in CH_2Cl_2). Thus oxidation of **33**, **34**, and **7** with the Sharpless reagent in CH_2Cl_2 at room temperature overnight gave the polymer-bound aldehydes **35**–**37** respectively. These polymers exhibited strong infrared absorption at 1730 cm^{-1} indicative of an aliphatic aldehyde. Acid hydrolysis of **35**–**37** gave some 7-hydroxyheptanal (28) (**38**), 9-hydroxynonanal (28) (**39**), and 10-hydroxydecanal (28) (**40**), respectively, on purification by preparative tlc but considerable polymerization of **38**–**40** had occurred during the hydrolysis. Due to considerable by-product formation upon cleavage it is difficult to determine yields of **38**–**40** but we can be fairly certain that it cannot be more than approximately 60% of loaded diol since we had previously shown that these polymers contain



SCHEME 2

about 40% doubly bound diol (9). The Wittig reactions of **35** and **36** using *n*-pentyltriphenylphosphonium bromide (**41**) with *n*-BuLi in THF at room temperature overnight have polymer-bound alkenes **42** and **43**. Acid hydrol-

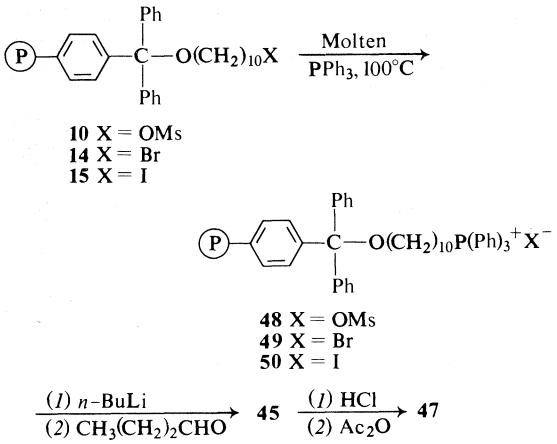
[h]No yields are given in ref. 29.
[i]From 'reverse' Wittig reactions.

ysis of **42** and **43** with HCl in dioxane[8] gave 7-dodecen-1-ol (**25**) and 9-tetradecen-1-ol (**26**), which on acetylation yielded on 7-dodecen-1-ol acetate (18) (**28**), and 9-tetradecen-1-ol acetate (19) (**29**) (Scheme 2). Similarly, **37** reacted with *n*-butyltriphenylphosphonium bromide (**44**) to give a polymer-bound alkene (**45**), which after cleavage from the polymer gave 10-tetradecen-1-ol (**46**). Acetylation yielded 10-tetradecen-1-ol acetate (29) (**47**), the *cis* isomer of which is the sex attractant of the oak leaf roller, *Archips semiferanus* Walker. It is known that the Wittig reaction can afford a predominance of the *cis* isomer and reaction conditions have been worked out giving *cis* products of high stereoselectivity (30). Although we had not concerned ourselves with details of achieving high stereoselectivity in these sequences the ratio of *cis* to *trans* isomers was quite high as determined by vpc and hplc (Table 4).

The 'Reverse' Wittig Route

Since we were successful in synthesizing insect sex attractants by condensation of Wittig reagents with polymer-bound aldehydes, we were interested to see if the Wittig reaction would work in the reverse sense, *i.e.* reaction of a polymer-bound Wittig reagent with aliphatic aldehydes. Treatment of polymer-bound bromide **14** or iodide **15**, derived from polymer-bound 1,10-decanediol (**10**), with triphenylphosphine in refluxing xylene did *not* yield a polymer containing ionic halide. It is possible that the polymer-bound halides **14** and **15** are sufficiently sterically constrained that nucleophilic attack by PPh_3 is very slow under normal conditions (31). The concentration of PPh_3 was increased 10-fold to induce salt formation, but no reaction occurred. We felt that replacing the nucleophilic halide counterion by the mesylate anion and increasing the concentration of triphenylphosphine to its limit might favour salt formation. Thus, treatment of **10** with molten triphenylphosphine at 100°C under argon overnight gave the desired polymer-bound phosphonium salt (**48**) as its mesylate. Similarly, treatment of **14** and **15**, containing 0.22 and 0.24 mmol halide/g, gave the polymer-bound phosphonium salts **49** and **50** containing 0.15 and 0.18 mmol ionic halide/g, as their bromide and iodide, respectively. Polymers **48–50** reacted with *n*-BuLi in dry THF at room temperature overnight to give dark purple polymers, which were either washed free of excess reagents under dry argon or used directly. The addition of butyraldehyde to the polymers suspended in THF discharged the colour after 0.5 h and the mixture was stirred for 8 h to give the same polymer **45** prepared by the 'normal' Wittig route (Scheme 3). As before, acid hydrolysis of **45** gave recovered polymer **21** and **46** which on acetylation yielded **47** (Table 3). Analysis by vpc and hplc of **47** prepared by the 'reverse' Wittig route showed 91.2% stereoselectivity for the *cis* isomer (Table 4). It is somewhat surprising that the 'reverse' Wittig route should be so highly stereoselective especially since

[8]Treatment with AcCl in AcOH can give the attractant acetates directly, but the products are difficult to purify by this procedure.



SCHEME 3

special conditions necessary to promote *cis* stereoselectivity (30) were not followed. We thought that at least in the case of **48** the mesylate counterion might be the cause of this stereoselectivity and hence we repeated the preparation of **47** via the normal Wittig route (Scheme 1) but using *n*-butyltriphenylphosphonium *mesylate* (**51**) as the Wittig reagent. The stereoselectivities of the synthesis of **47** via **51** and **44** were very similar (Table 4) and hence the mesylate counterion does not appreciably affect the stereoselectivity of the Wittig reaction. Used polymer **21** recovered from the synthesis of the sex attractants by the alkyne, Wittig, or 'reverse' Wittig routes can be reconverted to polymer **1** and recycled with no loss of activity (9).[9] It appears that the acid cleavage step strips the polymers of most impurities acquired during the synthetic route and liberates **21** with no reduction in capacity.

Bioassay of 28

A behavioural bioassay (32) performed on **28**, the sex attractant of the cabbage looper, prepared by both the alkyne and Wittig routes showed intense response in over 80% of the males in the 8–10 day age group.

Conclusions

The synthesis of natural products in general and insect sex attractants in particular on solid phases has been demonstrated by three independent routes in yields at least comparable with solution phase methods, despite the fact that most solution phase methods use comparatively expensive or poorly accessible starting materials such as ω-chloro-1-alkanols or ω-chloroalkanoic acids and our solid phase method uses inexpensive 1,ω-alkanediols (Tables 1 and 3). Although problems are sometimes encountered in the restriction that chemical reagents must be soluble and that certain reactions are sluggish under mild conditions, reagents and reaction conditions can usually be found that are compatible with the heterogeneity of reactions on solid phases. On the other hand, unexpected benefits (now becoming more common) sometimes accrue to the researcher attempting synthesis on solid phases. These benefits often include increased stability of chemical intermediates attached to solid phases and, as shown in this paper, enhanced stereoselectivity in a Wittig reaction.

TABLE 4. The amount of *cis* and *trans* isomers of insect attractants prepared on solid phases by the Wittig and 'reverse' Wittig routes as determined by vpc and hplc

Attractant (%)	Alkene (%)	*cis* Isomer (%)
28	98.7	68.6
29	98.6	82.7
47	99.6	67.4
47[a]	92.6	91.2
47[b]	—	90[c]
47[d]	—	78[c]

[a]Prepared via **48**.
[b]Prepared via **49**.
[c]Determined by hplc only.
[d]Prepared via **50**.

Experimental

A Bausch and Lomb Abbé 3L refractometer was used to record the refractive indices. Infrared spectra were recorded on a Unicam SP1000 ir spectrophotometer as neat films between NaCl discs unless otherwise specified. Nuclear magnetic resonance spectra were recorded on a Varian EM360 spectrometer using deuterochloroform as solvent and tetramethylsilane as internal standard. Mass spectra were recorded on a Perkin-Elmer–Hitachi RMU6E mass spectrometer. Silica gel was used for all thin and preparative layer chromatography. Fractions were extracted with ether in a Soxhlet extractor. Filtration was done under vacuum through sintered glass Buchner funnels. Filtration under an inert atmosphere was done as previously described (9). Microanalyses were performed by G. Gygli of Toronto.

[9]Once used polymer often gives higher yields than fresh polymer and we attribute this phenomenon to the cleaning of the polymer, from monomer and other impurities, during the reaction sequence.

Vapour phase chromatograms were run with a Perkin Elmer 990 instrument using a 15 ft × $\frac{1}{8}$ in. column of 10% Silar C on Gaschrom Q(60/80) at a temperature of 170°C and a nitrogen flow rate of 15 ml/min. High pressure liquid chromatograms were run with a Waters Associates model 440 instrument, with an R-400 refractive index detector. A 30 × 0.4 cm reverse phase μ Bondapak C-18 column using 30% water in acetonitrile for C-14 acetates or 40% water in acetonitrile for **28** at a flow rate of 0.8–1.0 ml/min. Spectral and analytical data are given for all new compounds and for known compounds where data are unreported.

Preparation of Polymer-bound Diols ***5–7***, ***33***, *and* ***34***

The above monoprotected polymer-bound diols were prepared by a previously described procedure (9). The amounts of diol/g of polymer were determined by acid cleavage (9) and are listed in Tables 1 and 3.

Preparation of Polymer-bound Diol Monomesylates ***8–10***

In a typical procedure 5 g of **7**, containing 2.6 mmol of **4**, was suspended in 80 ml of dry pyridine and 2.5 ml (32 mmol) of methanesulfonyl chloride and stirred for 48 h at room temperature under anhydrous conditions ($CaCl_2$ drying tube). The polymer was filtered, washed with three 40 ml portions of dry pyridine, three 40 ml portions of ethanol, five 40 ml portions of water, two 20 ml portions of ethanol, two 30 ml portions of dioxane, four 30 ml portions of ether, and dried under vacuum overnight or by heating in benzene under reflux for 3–4 h in a Soxhlet extractor, containing 3A molecular sieves in the thimble, giving polymer-bound monomesylate **10**: ir (KBr) 1180 (broad, w) (O—SO_2) and 1360 cm^{-1} (broad, w) (O—SO_2).

Polymers **8** and **9**, prepared in an identical manner, exhibited similar infrared spectra.

Preparation of Diol Monomesylates ***11–13***

Acid cleavage of 1.0 g of **10** with 0.35 *M* HCl in dioxane as previously described (9) and purification of the filtrate on preparative tlc (eluant ether–benzene, 2:3) afforded, from the slowest moving band, 23 mg of recovered 1,10-decanediol (**4**), from the fastest moving band, 27 mg of 10-chloro-1-decanol, n_D^{25} 1.4575 (lit. (33), n_D^{25} 1.4578), and from the middle band, 35 mg of 1,10-decanediol monomesylate (**13**); mp 45–46°C; ir (KBr) 1170 (O—SO_2), 1360 (O—SO_2) and 3400 cm^{-1} (OH); nmr δ 4.1 (t, 2, J = 8 Hz, CH_2OSO_2), 3.6 (m, 3, CH_2OH), 3.0 (s, 3, CH_3SO_2), and 1.8–1.2 (m, 16). *Anal.* calcd. for $C_{11}H_{24}O_4S$: C 52.35, H 9.59, S 12.71; found: C 52.80, H 9.43, S 12.97.

Similarly, **8** yielded 28 mg of recovered **2**, 10 mg of 6-chloro-1-hexanol, n_D^{25} 1.4548 (lit. (33) n_D^{25} 1.4550), and 15 mg of 1,6-hexanediol monomesylate (**11**) as an oil; ir 1170 (O—SO_2), 1360 (O—SO_2), and 3400 cm^{-1} (OH); nmr δ 4.1 (t, 2, J = 6 Hz, CH_2OSO_2), 3.6 (m, 3, CH_2OH), 3.0 (s, 3, CH_3SO_2), and 1.8–1.2 (m, 8). *Anal.* calcd. for $C_7H_{16}O_4S$: C 42.84, H 8.22, S 16.34; found: C 42.55, H 8.07, S 16.16.

Similarly, **9** gave 27 mg of recovered **3**, 17 mg of 8-chloro-1-octanol, n_D^{25} 1.4558 (lit. (33) n_D^{25} 1.4563), and 24 mg of 1,8-octanediol monomesylate (**12**) as an oil; ir 1170 (O—SO_2), 1360 (O—SO_2), and 3400 cm^{-1} (OH); nmr δ 4.2 (t, 2, J = 8 Hz, CH_2OSO_2), 3.6 (m, 3, CH_2OH), 3.0 (s, 3, CH_3SO_2), and 1.8–1.2 (m, 12). *Anal.* calcd. for $C_9H_{20}O_4S$: C 48.18, H 8.99, S 14.30; found: C 48.46, H 9.14, S 13.92.

Preparation of Polymer-bound Bromide ***14*** *and Iodide* ***15***

In a typical procedure, 1.0 g of polymer-bound monomesylate **10**, containing 0.28 mmol of **13**/g was suspended in 50 ml of HMPT, containing 1.5 g (10 mmol) of sodium iodide, and stirred at 70°C for 48 h in the dark. The polymer was filtered, washed as described for **10**, but omitting the pyridine wash, and dried to give polymer-bound iodide **15**.

Polymer-bound **14** was prepared in a similar manner using sodium bromide. Treatment of 0.2 g of polymers **14** or **15** with 0.5 g of potassium *tert*-butoxide in *tert*-butyl alcohol overnight under reflux and then following the modified Volhard analysis (16) gave values of 0.26 mmol halide/g of **14** and 0.24 mmol/g of **15**.

Preparation of Polymer-bound Alkynes ***18–20***

To a solution of 10 mmol of 1-lithio-1-butyne (**17**), prepared in 40 ml of THF under argon at −10°C from 0.8 ml of 1-butyne in 8 ml THF and 4 ml of 2.5 *M* *n*-butyllithium in 28 ml THF, was added 2.0 g of polymer **10** containing 0.28 mmol of **13**/g of **10**, and 30 ml HMPT. The mixture was stirred overnight at room temperature, filtered, washed with four 25 ml portions of THF–water (1:1), two 25 ml portions of ethanol, two 50 ml portions of water, two 25 ml portions of ethanol, two 25 ml portions of dioxane, and three 25 ml portions of ether, and dried as above to give polymer-bound alkyne **20**.

Polymer-bound alkynes **18** and **19** were prepared in a similar manner using 1-litho-1-hexyne (**16**).

The polymer-bound alkynes **18–20** did not exhibit absorptions at 2200 cm^{-1} typical of a C≡C stretch in infrared spectra.

Preparation of Alkyn-1-ols ***22–24*** *and Their Acetates*

Treatment of 2.0 g of **20**, with acid as described above and purification of the filtrate on preparative tlc (eluant ether–benzene 35:65) afforded 23 mg of recovered diol **4** (R_f 0.15), 8 mg of monomesylate **13** (R_f 0.25), and 44 mg of 11-tetradecyn-1-ol (34) (**24**) (R_f 0.50) as an oil; n_D^{25} 1.4661; ir 1050 (C—O) and 3400 cm^{-1} (OH); nmr δ 3.6 (m, 3, CH_2OH), 20 (m, 4, $CH_2C{\equiv}C$), 18–12 (m, 16), and 0.9 (t, 3, J = 7 Hz, CH_3). Acetylation of 0.1 g of **24**, with 0.5 ml of acetic anhydride in 5 ml of pyridine under reflux for 15 min gave 11-tetradecyn-1-ol acetate as an oil; n_D^{25} 1.4625; ir 1240 (C—O) and 1740 cm^{-1} (ester C=O); nmr δ 4.0 (t, 2, J = 8 Hz, CH_2O), 2.0 (s, 3, $CH_3C{=}O$), 2.0 (m, 4, $CH_2C{\equiv}C$), 1.8–1.2 (m, 16), and 0.9 (t, 3, J = 7.5 Hz, CH_3CH_2); ms (70 eV) *m/e* (rel. intensity) 252(4) (M^+), 192(6.5) (M^+ − AcOH), 43(100). *Anal.* calcd. for $C_{16}H_{28}O_2$: C 76.14, H 11.18; found: C 75.98, H 11.25.

Similarly, **18** yielded 24 mg of **2**, 4 mg of **11**, and 26 mg of 7-dodecyn-1-ol (35) (**22**) as an oil; n_D^{25} 1.4641 (lit. (35) n_D^{25} 1.4638); ir 1060 (C—O) and 3400 cm^{-1} (OH); nmr δ 3.6 (m, 3, CH_2OH), 2.0 (m, 4, $CH_2C{\equiv}C$), 1.8–1.2 (m, 12), and 0.9 (t, 3, J = 5.5 Hz, CH_3). Acetylation of **22** gave 7-dodecyn-1-ol acetate (35) as an oil: n_D^{25} 1.4496 (lit. (35) n_D^{25} 1.4591); ir 1240 (C—O) and 1740 cm^{-1} (ester C—O); nmr δ 4.0 (t, 2, J = 8 Hz, CH_2O), 2.0 (s, 3, $CH_3C{=}O$), 2.0 (m, 4, $CH_2C{\equiv}C$), 1.8–1.1 (m, 12), and 0.9 (t, 3, J = 5 Hz, CH_3CH_2); ms (70 eV) *m/e* (rel. intensity) 224(0.05) (M^+), 164(5.2) (M^+ − AcOH), 43(100).

Similarly, **19** gave 22 mg of **3**, 4 mg of **12** and 36 mg of 9-tetradecyn-1-ol (**23**) as an oil; n_D^{25} 1.4653; ir 1060 (C—O) and 3400 cm^{-1} (OH); nmr δ 3.6 (m, 3, CH_2OH), 2.0 (m, 4, $CH_2C{\equiv}C$), 1.8–1.2 (m, 16), and 0.9 (t, 3,

J = 5.5 Hz, CH_3). *Anal.* calcd. for $C_{14}H_{26}O$: C 79.94, H 12.46; found: C 80.01, H 12.55.

Acetylation of **23** yielded 9-tetradecyn-1-ol acetate as an oil: n_D^{25} 1.4612; ir 1240 (C—O) and 1740 cm^{-1} (ester C=O); nmr δ 4.1 (t, 2, J = 8 Hz, CH_2O), 2.0 (s, 3, CH_3 C=O), 2.0 (m, 4, CH_2 C≡C), 1.8–1.2 (m, 16), and 0.9 (t, 3, J = 5.5 Hz, CH_3); ms (70 eV) *m/e* (rel. intensity) 252(0.025) (M^+), 192(0.23) (M^+ − AcOH), 43(100). *Anal.* calcd. for $C_{16}H_{28}O_2$: C 76.14, H, 11.18; found: C 75.85, H 11.18.

Preparation of Insect Sex Attractants ***28–30***

In a typical procedure (17), 44 mg (0.21 mol) of **24** in 5 ml of ethanol, 15 mg of Pd–$CaCO_3$, and 50 μl quinoline were stirred at room temperature under 1 atm of hydrogen until 1 equiv. (12.7 ml) was taken up. The mixture was filtered, taken up in ether, washed with water, dilute hydrochloric acid, and water, dried ($MgSO_4$), filtered, and evaporated to give *cis*-11-tetradecen-1-ol (**27**) as an unpurified oil. Acetylation of **27** in 0.5 ml of acetic anhydride and 5 ml of pyridine gave an oil, which on purification by preparative tlc (eluant ether–benzene 2:3), yielded 48 mg (0.19 mmol) of pure 11-tetradecen-1-ol acetate (20, 36) (**30**) in high yield (Table 1).

Similarly, hydrogenation and acetylation of **22** gave 7-dodecen-1-ol acetate (18) (**28**); n_D^{25} 1.4476 (lit. (18) n_D^{25} 1.4420); ir 960 (*trans* CH=CH), 1240 (C—O), and 1740 cm^{-1} (ester C=O); nmr δ 5.3 (m, 2, C*H*—C*H*), 4.1 (t, 2, J = 8 Hz, CH_2O), 2.0 (s, 3, CH_3CO), 2.0 (m, 4, $CH_2C{\equiv}C$), 1.8–1.2 (m, 12), and 0.9 (t, 3, J = 5 Hz, CH_3CH_2); ms (16 eV) *m/e* (rel. intensity) 226(0.3) (M^+), 166(100) (M^+ − AcOH), 151(1.1), 137(25), 123(27), 109(48).

Similarly, **23** yielded 9-tetradecen-1-ol acetate (19, 26) (**29**) in high yield (Table 1).

Compounds **28–30** were analyzed by vpc and hplc to determine the amount of *trans* product in the supposedly pure *cis* compounds and the data are recorded in Table 2.

Reduction of Alkyn-1-ols ***22*** *and* ***23*** *with 9-BBN*

In a typical procedure (22, 23), 100 mg (0.48 mmol) of **24** in 2 ml of THF was treated with 5 ml of 9-BBN (0.5 *M*, 2.5 mequiv.) and stirred at room temperature under argon for 4 h. Acetic acid (5 ml) was added, the solution stirred for 2 h, diluted with ether, washed with base, acid, bicarbonate, and saturated sodium chloride, and dried ($MgSO_4$) and evaporated to an oil. To the oil in 5 ml of THF was added 2 ml of 30% sodium hydroxide and 2 ml of 40% hydrogen peroxide and the mixture stirred until cool. The mixture was extracted as above to give an oil which on preparative tlc (eluant ether–benzene 2:3) gave *cis*-11-tetradecen-1-ol (37) (**27**) as an oil; n_D^{25} 1.4598; ir 3400 cm^{-1} (OH); nmr δ 5.3 (m, 2, C*H*≡C*H*), 3.6 (m, 3, CH_2OH), 2.3–2.1 (m, 4, CH_2CH=CHO), 1.8–1.2 (m, 16), and 0.9 (t, 3, J = 7.5 Hz, CH_3-CH_2). *Anal.* calcd. for $C_{14}H_{28}O$: C 79.18, H 13.29; found: C 79.11, H 13.14.

Similarly, reduction of **23** gave pure *cis*-**26**. Alken-1-ols **26** and **27** were acetylated to pure *cis*-**29** and *cis*-**30**, respectively, and analyzed by hplc, showing that **29** and **30** contained not less than 98% of the pure *cis* isomers.

Preparation of Monoprotected Polymer-bound Aldehydes ***35–37***

In a typical procedure, 5 mequiv. of di-*tert*-butyl chromate, prepared according to Sharpless and Akashi (27) in 25 ml of methylene chloride was transferred by a syringe to 2.5 g of polymer **33** in 40 ml of methylene chloride. The very dark mixture was stirred overnight at room temperature, filtered, washed with four 25 ml portions of methylene chloride and twice with 25 ml of ether, and air dried to give the polymer-bound aldehyde **35**; ir (KBr) 1730 cm^{-1} (aldehyde C=O). Polymers **36** and **37**, prepared in a similar manner, exhibited similar infrared spectra.

Preparation of ω*-Hydroxyaldehydes* ***38–40***

Cleavage of **35–37** with HCl in dioxane as before gave crude products. Preparative tlc (eluant ether–benzene 2:3) of the crude mixtures derived from **35–37** gave small amounts, at an R_f value of 0.35, of 6-hydroxyhexanal (**38**), 8-hydroxyoctanal (**39**), and 10-hydroxydecanal (**40**), identical in properties to those previously described (28). Since cleavage of **35–37** resulted in considerably by-product formation the absolute loading of aldehyde on the polymer could not be determined, but could obviously not be more than the polymer-bound diol, and is likely about 60% of the loaded diol value.

Polymer-bound Trityl Ether Alkenes ***42***, ***43***, *and* ***45***

To a mixture of 2.5 g (6 mmol) of *n*-pentyltriphenylphosphonium bromide (**41**) and 2.4 ml of 2.5 *M n*-butyllithium (in hexane) in 60 ml of THF under argon was added 2.0 g, containing not more than 0.9 mmol of aldehyde, (60% of loaded diol) of polymer **35** in 10 ml of THF. The mixture was stirred overnight, quenched with THF–water 1:1, filtered, and washed with two 20 ml portions of THF, one 20 ml portion of ethanol, four 20 ml portions of water, two 20 ml portions of ethanol, two 20 ml portions of dioxane, and three 20 ml portions of ether, and air dried to give polymer-bound alkene **42**, which did not exhibit a carbonyl absorption in its infrared spectrum.

Similarly, the Wittig reaction of **41** with 2.0 g of **36**, containing not more than 1.0 mmol of aldehyde, yielded polymer-bound alkene **43**.

Similarly, the Wittig reaction of *n*-butyltriphenylphosphonium bromide (**44**) with 2.0 g of **37**, containing not more than 0.6 mmol of aldehyde, (60% of loaded diol) yielded polymer-bound alkene **45**.

Preparation of Alken-1-ols ***25***, ***26***, *and* ***46***

Acid hydrolysis of 2.0 g of **42** as before yielded a mixture, which on preparative tlc (eluant ether–benzene 35:65) gave 110 mg (0.84 mmol) of recovered **31** (R_f, 0.15), and 66 mg (0.36 mmol) of 7-dodecen-1-ol (38) (**25**) as an oil; n_D^{25} 1.4538 (lit. (38) n_D^{25} 1.4554); ir 960 (w, *trans*-CH=CH) and 3400 cm^{-1} (OH); nmr δ 5.3 (m, 2, C*H*=C*H*), 3.6 (m, 3, CH_2OH), 2.0 (m, 4, CH_2CH=CH), 1.7–1.2 (m, 12), and 0.9 (t, 3, J = 5 Hz, CH_3CH_2).

Similarly, acid hydrolysis of 2.0 g of **43** gave 86 mg (0.54 mmol) of recovered diol **32** and 134 mg (0.64 mol) of 9-tetradecen-1-ol (38) (**26**) as an oil: n_D^{25} 1.4577 (lit. (38) n_D^{25} 1.4584); ir 960 (w, *trans*-CH=CH) and 3400 cm^{-1} (OH); nmr δ 5.25 (m, 2, C*H*=C*H*), 3.6 (m, 3, CH_2OH), 2.0 (m, 4, CH_2CH=CH), 1.8–1.2 (m, 16), and 0.9 (t, 3, J = 6 Hz, CH_3CH_2).

Similarly, acid hydrolysis of 2.0 g of **45** gave 56 mg (0.32 mmol) of recovered **4** and 76 mg (0.36 mmol) of 10-tetradecen-1-ol (29) (**46**) as an oil; n_D^{25} 1.4589; ir 960 (w, *trans*-CH=CH) and 3400 cm^{-1} (OH); nmr δ 5.25 (m, 2, C*H*=C*H*), 3.6 (m, 3, CH_2OH), 2.0 (m, 4,

$CH_2CH{=}CH$), 1.8–1.2 (m, 16), and 0.9 (t, 3, J = 6.5 Hz, CH_3CH_2). *Anal.* calcd. for $C_{14}H_{28}O$: C 79.18, H 13.29; found: C 79.41, H 13.16.

Preparation of Attractants ***28***, ***29***, *and* ***47*** *by the Wittig Route*

Acetylation of **25**, **26**, and **46** as above yielded attractants **28** and **29**, previously prepared via the alkyne route and a different attractant, 10-tetradecen-1-ol acetate (29) (**47**) as an oil: n_D^{25} 1.4492; ir 960 (w, *trans*-CH=CH), 1240 (C—O), and 1740 cm^{-1} (ester C=O); nmr δ 5.4 (m, 2, $CH{=}CH$), 4.1 (t, 2, J = 8 Hz, CH_2O), 2.0 (m, 4, $CH_2CH{=}CH$), 1.8–1.2 (m, 16), and 0.9 (t, 3, J = 6 Hz, CH_3CH_2); ms (16 eV) *m/e* (rel. intensity) 254(4) (M^+), 194(100) (M^+ − AcOH). *Anal.* calcd. for $C_{16}H_{30}O_2$: C 75.54, H 11.80; found: C 75.34, H 11.70.

Analysis of **28**, **29**, and **47** by vpc and hplc determined the purity and isomeric distribution of the products (Table 4).

Preparation of Polymer-bound Phosphonium Salts ***48–50***

A mixture of 2.5 g of **10**, containing 0.65 mmol of mesylate, and 25 g of triphenylphosphine was heated to 100°C under argon and stirred overnight. The mixture was cooled to 80°C and poured into a Soxhlet thimble. A Soxhlet extraction for 4 h with ether removed the excess triphenylphosphine and gave the polymer-bound phosphonium mesylate (**48**).

Similarly, treatment of polymer-bound bromide (**14**) and iodide (**15**) with molten triphenylphosphine yielded the polymer-bound phosphonium bromide (**49**) and iodide (**50**), respectively. The infrared spectra of **48–50** were uninformative. Analysis of **49** and **50** for ionic halide ion was readily accomplished by treatment of **49** and **50** with 0.1 *M* sodium hydroxide in dioxane–water (1:1), followed by standard analysis (16), to give 0.26 mmol of halide/g of **49** or **50**. These analysis conditions are specific for ionic halide as liberation of halide from **14** or **15** required more drastic treatment (see above).

Preparation of Polymer-bound Alkene ***45*** *by the 'Reverse' Wittig Route*

A suspension of 2 g of polymer-bound phosphonium mesylate (**48**) in 50 ml of dry THF was treated with 2.5 ml (4 mequiv.) of 1.6 *M n*-butyllithium in hexane and stirred overnight at room temperature. The polymer was filtered and washed with three 10 ml portions of dry THF under inert atmosphere conditions (9), to give a dark purple polymer. To the polymer, resuspended in 50 ml of THF was added 2 ml (22 mmol) of butyraldehyde. The dark colour of the polymer was discharged after 0.5 h but the mixture was stirred for an additional 7.5 h. The mixture was filtered, washed as before for polymer **45**, and air dried to give polymer-bound alkene **45**.

Similarly, polymer-bound bromide (**49**) or iodide (**50**), gave polymer **45**. In some experiments, the polymer-bound ylides prepared from **48–50** were not filtered and washed but used directly in reactions with butyraldehyde, giving similar results as before.

Acid cleavage of **45**, prepared from **48–50** gave different samples of alkene-1-ols **46**. Acetylation of the different samples of **46** as before gave samples of the sex attractant **47**, which were analyzed by vpc and hplc (Table 4).

Some thermodynamic properties of the solutions of $ZrCl_4$ and $HfCl_4$ in CsCl melts

D. A. ASVESTAS, P. PINT,[1] AND S. N. FLENGAS

Department of Metallurgy and Materials Science, University of Toronto, Toronto, Ont., Canada M5S 1A4

Received June 21, 1976

D. A. ASVESTAS, P. PINT, and S. N. FLENGAS. Can. J. Chem. **55**, 1154 (1977).

The binary equilibrium phase diagrams of the systems CsCl–Cs_2ZrCl_6, CsCl–Cs_2HfCl_6, and CsCl–KF were established by cryoscopy. A portion of the ternary CsCl–KF–$ZrCl_4$ has also been determined.

Equilibrium vapour pressures of the two pure compounds Cs_2ZrCl_6 and Cs_2HfCl_6, as well as of mixtures of Cs_2HfCl_6 with CsCl, have been measured. The equilibrium reaction is given as

$$Cs_2MCl_6 \rightleftarrows 2CsCl + MCl_4$$

where M represents Zr or Hf.

From the results, activities of CsCl, Cs_2HfCl_6, and $HfCl_4$ were calculated at 825 °C.

The low escaping tendency of the MCl_4 vapour from the CsCl–Cs_2MCl_6 type melts makes these solutions suitable as electrolytes for the recovery of Zr and Hf metal by fused salt electrolysis.

D. A. ASVESTAS, P. PINT et S. N. FLENGAS. Can. J. Chem. **55**, 1154 (1977).

On a établi par cryoscopie les diagrammes de phase d'équilibre binaire des systèmes CsCl–Cs_2ZrCl_6, CsCl–Cs_2HfCl_6 et CsCl–KF. On a aussi déterminé une portion du diagramme ternaire CsCl–KF–$ZrCl_4$.

On a mesuré les pressions de vapeur à l'équilibre des deux composés purs Cs_2ZrCl_6 et Cs_2HfCl_6 de même que celles de mélanges de Cs_2HfCl_6 avec CsCl. On peut représenter la réaction d'équilibre par l'équation

$$Cs_2MCl_6 \rightleftarrows 2CsCl + MCl_4$$

où M est égal à Zr ou Hf.

A partir des résultats, on a calculé, à 825 °C, les activités de CsCl, Cs_2HfCl_6 et $HfCl_4$.

La faible tendance que présente la vapeur de MCl_4 à s'échapper de CsCl–Cs_2MCl_6 fondu rend ces solutions appropriées comme électrolytes pour la récupération des métaux Zr et Hf par l'électrolyse des sels fondus.

Introduction

In previous publications from this laboratory (1, 2) the vapour pressures of $ZrCl_4$ in equilibrium with solutions of $ZrCl_4$ and alkali chlorides, such as LiCl, NaCl, and KCl, and of $HfCl_4$ in equilibrium with solutions containing $HfCl_4$ and LiCl, have been determined by a direct experimental technique involving the use of a molten tin isoteniscope.

In the present investigation the technique has been applied to the determination of the vapour pressures of $ZrCl_4$ and of $HfCl_4$ in equilibrium with solutions of $ZrCl_4$ and of $HfCl_4$ in CsCl.

In addition, part of the phase diagrams of the systems CsCl–$ZrCl_4$, CsCl–$HfCl_4$, CsCl–$ZrCl_4$–KF and of the system CsCl–KF have been determined by cryoscopy. The CsCl–$ZrCl_4$–KF system was investigated for the purpose of finding the effect of KF on the solubility of Cs_2ZrCl_6 in CsCl bearing melts.

These systems are of interest as they may be considered as potential electrolytes for the recovery of Zr and Hf metals by fused salt electrolysis (3), as well as for the separation of Zr from Hf through the vapour transport process established previously in this laboratory (4).

From the results of this study, various thermodynamic properties of the systems have been calculated.

Experimental

At specific partial pressures and temperatures, the vapours of $ZrCl_4$ and $HfCl_4$ react with solid CsCl and produce the stoichiometric solid complex compounds of the general formula Cs_2MCl_6, where M is Zr or Hf, respectively.

[1]Present address: International Nickel Company, Research Laboratories, Sheridan Park, Ontario.

The corresponding reactions may be written as:

[1] $2CsCl\ (solid) + MCl_4\ (vapour) \rightarrow Cs_2MCl_6\ (solid)$
at P, T at P, T at P, T

It should be noted that these complex compounds also exist as congruently melting and appear in the phase diagrams of the corresponding MCl_4–CsCl binary systems.

The method applied for the preparation of the pure stoichiometric compounds was developed in this laboratory earlier (1, 2) and the preparation was conducted in the simple apparatus shown in Fig. 1.

In this process a known amount of CsCl is ground to particle size of less then 325 mesh and is reacted with either $ZrCl_4$ or $HfCl_4$ vapours at a pressure of 1 atm in the previously sealed two compartment reaction cell shown in Fig. 1.

The temperature T_1 in compartment I is adjusted to be the sublimation temperature of $ZrCl_4$ or $HfCl_4$, respectively, and in this manner the pressure of the corresponding MCl_4 vapour in the entire system is kept always at 1 atm. The amounts of MCl_4 and CsCl placed in compartments I and II should be such that the mole ratio MCl_4/CsCl should be greater than the 1/2 predicted by reaction 1, and the reation then should always be able to proceed to completion.

The temperature T_2 in compartment II is the reaction temperature characteristic of a given system and should always be greater than T_1.

For the reaction to be possible thermodynamically the equilibrium pressure of MCl_4 vapour created by the thermal decomposition of the compound Cs_2MCl_6 in compartment II should always be less than the applied pressure of the vapour MCl_4 which is 1 atm.

It is also important to satisfy kinetic requirements and for a given system it is necessary to conduct the reaction at temperatures as high as possible provided that the thermodynamic requirements are not violated.

However, when T_2 is very high in compartment II particle sintering is taking place and the reaction becomes slow. Once sintering has taken place it is necessary to open the cell in a dry box, grind the partially reacted sample, and repeat the reaction until the stoichiometry of the product remains unchanged. The optimum conditions for the preparation of the pure stoichiometric compounds Cs_2ZrCl_6 and Cs_2HfCl_6 were established after several tests. Thus, for Cs_2ZrCl_6 the temperatures T_1 and T_2 were 331 and 475 °C, respectively, while for Cs_2HfCl_6 these were 318 and 475 °C.

At the end of a reaction, the unreacted MCl_4 vapour which remains in the free volume of the apparatus in both compartments I and II is totally condensed in compartment I by a stepwise decrease of the temperatures in the two compartments.

Thus, first the reaction temperature T_2 in compartment II is decreased until it becomes slightly higher than T_1, and then both T_1 and T_2 are decreased stepwise by 20 °C, until room temperature is attained. In this manner all the unreacted MCl_4 vapour is transferred into compartment I without ever decomposing the complex compound Cs_2MCl_6 present in compartment II. The stoichiometry of each compound and its composition is determined simply by weighing the amount of material in compartment II, Fig. 1, before and after reaction.

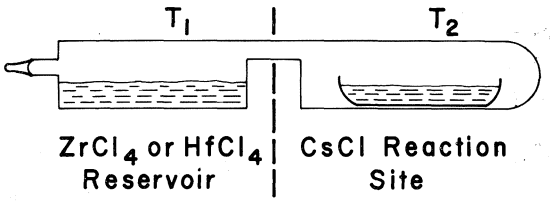

FIG. 1. Reaction cell for the preparation of the compounds Cs_2ZrCl_6 and Cs_2HfCl_6. The reagents are first transferred into their respective compartments and the cell is evacuated and sealed under vacuum prior to heating.

When a reaction has reached completion, the excess weight indicates the amount of MCl_4 vapour reacted with CsCl, and the corresponding mole ratio of CsCl/MCl_4 should be 2/1.

The CsCl used in this work was reaction grade which analyzed 99.9% CsCl after fusion and was pretreated with anhydrous gaseous HCl at 800 °C, followed by evacuation and sublimation to remove all volatile impurities. The KF was of 99% purity reagent grade and was dried under vacuum at 750 °C.

The $ZrCl_4$ and $HfCl_4$ salts were reactor grade and were obtained from the Wah Chung Corporation of America, Albany, NY. Those were further purified by repeated sublimations in vacuum through a molten tin plug, as reported earlier (2).

Solutions of various compositions were prepared by mixing CsCl with the compound Cs_2MCl_6. All handling of materials, preparation of samples, and transfers to the reaction cells were conducted in a dry box filled with argon gas.

The apparatus for the measurement of the vapour pressures of $ZrCl_4$ and $HfCl_4$ in equilibrium with their corresponding solutions in alkali chlorides has been described elsewhere (2). In brief, all vapour pressures were measured by a static method employing a simple isoteniscope with molten tin.

The apparatus is shown in Fig. 2. It consists essentially of a quartz glass cell, A, containing the sample the temperature of which is measured by means of a calibrated chromel–alumel thermocouple, C, placed in the well at the centre. The cell is connected through a graded seal to a Pyrex U-tube, E, filled with molten tin.

The temperature of the hot box containing the molten tin isoteniscope was monitored by two thermocouples to insure that the entire isoteniscope was above the condensation point of the tetrachlorides.

Equilibrium pressure measurements were made during heating and cooling cycles and the values for each individual cycle were in very good agreement at high pressures and temperatures. At temperatures below 600 °C the reproducibility was less satisfactory, as the equilibrium pressures obtained during cooling were always slightly less than those obtained during heating.

The apparatus for determining the phase diagrams for those systems has also been described elsewhere (1, 2). The containers for the mixtures to be measured were heart-shaped quartz cells having the thermocouple well at the centre of the charge and were sealed under vacuum. Cooling rates were 3/4 °C to 1 °C per min.

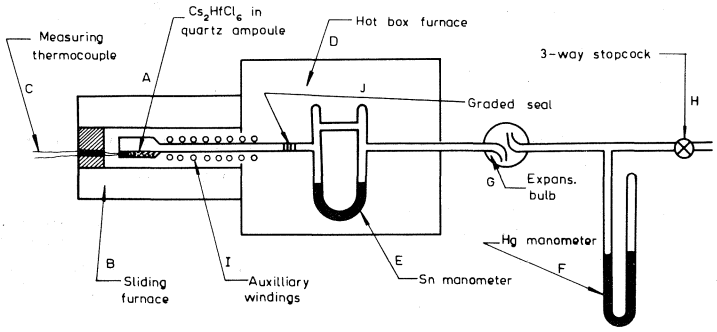

FIG. 2. Apparatus for the measurement of the equilibrium vapour pressures of $ZrCl_4$ and $HfCl_4$ in the CsCl solutions.

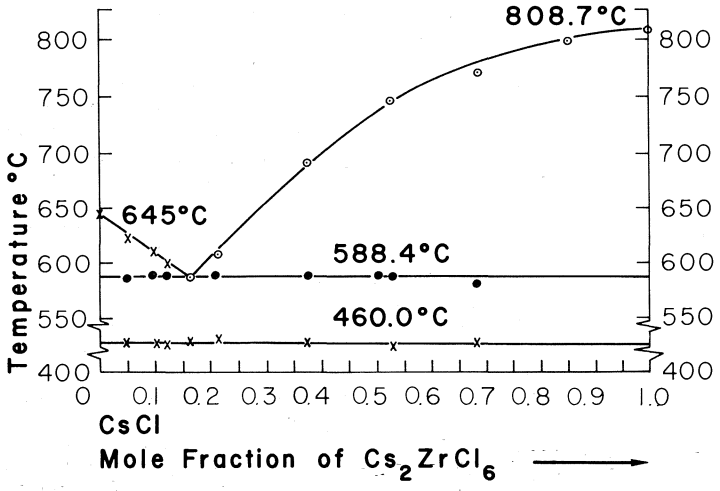

FIG. 3. Phase diagram of the binary system CsCl–Cs_2ZrCl_6.

Experimental Results

Determination of Phase Diagrams

The part of the phase diagrams representing the CsCl–Cs_2ZrCl_6 and the CsCl–Cs_2HfCl_6 subsystems are shown respectively in Figs. 3 and 4.

The characteristic data for these diagrams are given in Table 1. The phase diagram for the subsystem CsCl–Cs_2ZrCl_6 is relatively simple, having one eutectic composition at $X_{Cs_2ZrCl_6} = 0.162$.

The liquidus temperature arrests observed for melts rich in Cs_2ZrCl_6 were poorly defined and in most cases the liquidus at any one composition was repeated four times. The same degree of difficulty was not encountered with melts rich in CsCl. In most cases the eutectic temperature was very well defined except when the melt compositions were far removed from the eutectic composition. The CsCl solid–solid transformation was readily seen on the CsCl-rich side of the diagram and is occurring at 460 °C. No indication of complex compounds other than Cs_2ZrCl_6 was evident.

The phase diagram determined in this work disagrees with the only other available measurements by Morozov and Sun-In-Chzhu (5). In the latter the eutectic was found to be at 21.8 mol% of Cs_2ZrCl_6 instead of 16.2 mol% reported in this work. Similarly the melting point for pure Cs_2ZrCl_6 was given as 805 °C and the eutectic temperature as 572 °C, instead of the values of 808.7 and 588.4 °C, respectively, reported in the present work.

The disagreement may be attributed to the presence of impurities in the Cs_2ZrCl_6, probably in the form of hydrated zirconium oxychlorides, used by those workers. Their method of preparing Cs_2ZrCl_6 consisted of intimately mixing the stoichiometric amounts of $ZrCl_4$ and CsCl

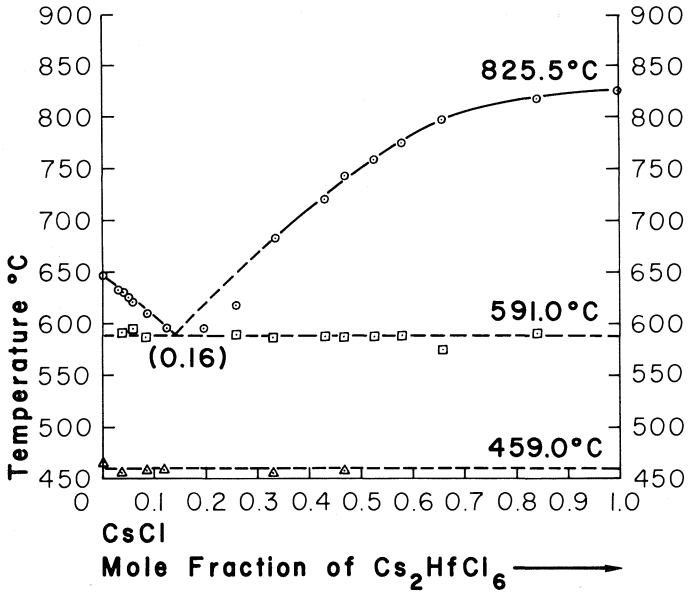

FIG. 4. Phase diagram of the binary system CsCl–Cs_2HfCl_6.

TABLE 1. Characteristics of the phase diagram of the binary systems CsCl–Cs_2ZrCl_6, CsCl–Cs_2HfCl_6, and CsCl–KF

Binary system	Eutectic composition X_{CsCl}	T, eutectic (°C)	T, melting point of Cs_2MCl_6 (°C)
CsCl–Cs_2ZrCl_6	83.8	588.4	808.7
CsCl–Cs_2HfCl_6	84.0	591.0	825.5
CsCl–KF	64.0	500.0	

and the hydrated oxychlorides which are always present in 'pure' zirconium tetrachloride would be expected to remain in the mixture.

The phase diagram of the subsystem CsCl–Cs_2HfCl_6 is shown in Fig. 4.

The melting point of pure Cs_2HfCl_6 given in Fig. 4 is higher than that reported by Morozov and Sun-In-Chzhu (5) by about 5 °C. The Cs_2HfCl_6 used by those authors was again obtained by mixing the stoichiometric amounts of $HfCl_4$ and CsCl and, hence, could contain the aforementioned impurities.

As in the case of the Cs_2ZrCl_6–CsCl subsystem the Cs_2HfCl_6-rich side of the phase diagram was obtained with more difficulty than the CsCl-rich side. The CsCl solid–solid transformation is seen here at 459 °C.

The Cs_2HfCl_6–CsCl subsystem is characterized by a single eutectic at 591 ± 2 °C and at 16.0 mol% Cs_2HfCl_6. The congruently melting compound Cs_2HfCl_6 has a melting point at 825 °C.

Neither phase diagram shows evidence of solid solubility on either side of the eutectic and they resemble the phase diagrams of the other alkali–chlorozirconate or alkali–chlorohafnate systems investigated previously (1, 2).

As indicated earlier, the quartz heart-shaped cells used for containing these melts were sealed under vacuum prior to their use for the cryoscopic measurement. Therefore the phase diagrams reported herein were obtained under the equilibrium pressures of the $ZrCl_4$ or $HfCl_4$ vapours present and not at constant atmospheric pressure.

The phase diagrams of the CsCl–Cs_2ZrCl_6 and CsCl–Cs_2HfCl_6 subsystems are part of the overall binary systems CsCl–$ZrCl_4$ and CsCl–$HfCl_4$, in which the Cs_2ZrCl_6 and Cs_2HfCl_6, respectively, are appearing as con-

TABLE 2. Part of the phase diagram for the system KF–CsCl–$ZrCl_4$

Composition	First temperature arrest (°C)	Second temperature arrest (°C)	Third temperature arrest (°C)
$X_{CsCl} = 0.74$ $X_{KF} = 0.23$ $X_{ZrCl_4} = 0.03$	601		
$X_{CsCl} = 0.86$ $X_{KF} = 0.09$ $X_{ZrCl_4} = 0.05$	626	516	
$X_{CsCl} = 0.75$ $X_{KF} = 0.20$ $X_{ZrCl_4} = 0.05$	607		
$X_{CsCl} = 0.66$ $X_{KF} = 0.30$ $X_{ZrCl_4} = 0.04$	595	537	
$X_{CsCl} = 0.76$ $X_{KF} = 0.10$ $X_{ZrCl_4} = 0.14$	554		485
$X_{CsCl} = 0.68$ $X_{KF} = 0.20$ $X_{ZrCl_4} = 0.12$	535	519	502
$X_{CsCl} = 0.68$ $X_{KF} = 0.20$ $X_{ZrCl_4} = 0.12$	537	522	495
$X_{CsCl} = 0.87$ $X_{KF} = 0.10$ $X_{ZrCl_4} = 0.03$	621	532	

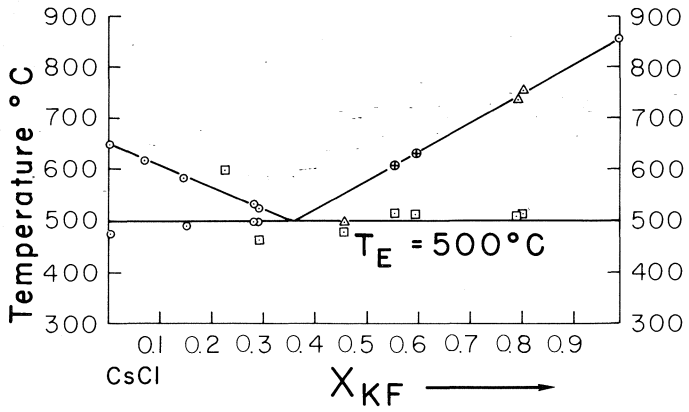

FIG. 5. Phase diagram of the binary system CsCl–KF.

gruently melting compounds. Compositions rich in $ZrCl_4$ or $HfCl_4$ at $X_{MCl_4} > 0.33$ could not be investigated as the solutions exhibit very high decomposition pressures at temperatures higher than about 350 °C.

The binary CsCl–KF system and part of the ternary phase diagram for the system CsCl–$ZrCl_4$–KF were also investigated and the results are given in Figs. 5 and 6, respectively. It is seen that the binary system CsCl–KF is of the simple eutectic type. Its characteristic temperatures are included in Table 1. Details of the characteristic temperatures in the ternary system are given in Table 2. The first temperature arrest represents the ternary liquidus. It may be seen that $ZrCl_4$ has a substantial solubility of about 12–14 mol% in melts containing CsCl and KF at temperatures higher than 550 °C.

Vapour Pressure Measurements

The vapour pressures of $ZrCl_4$ and $HfCl_4$ in equilibrium with the pure compounds

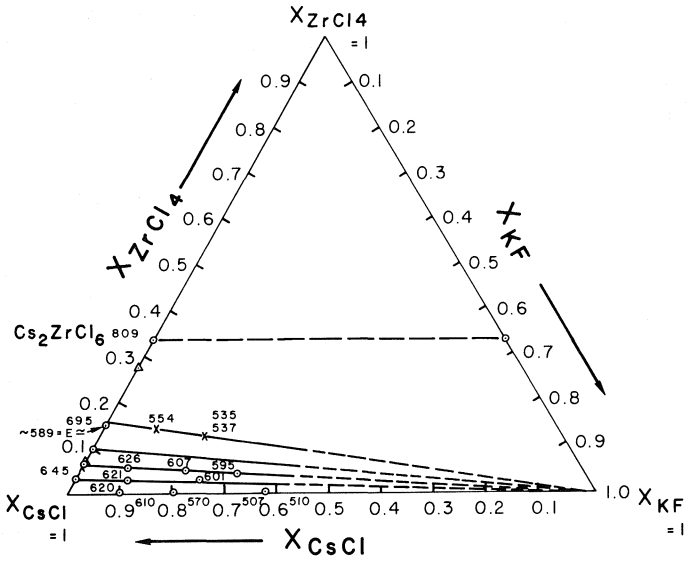

FIG. 6. Part of the phase diagram of the ternary system CsCl–KF–$ZrCl_4$.

Cs_2ZrCl_6 and Cs_2HfCl_6, respectively, have been determined and are shown in Fig. 7. The results are plotted as log P_{MCl_4} *vs.* $1/T$ and the lines shown on the graphs are calculated by the least-squares method while the points are experimental. The corresponding equations for the various equilibria were calculated and are given in Table 3. Reaction 1 in Table 3 defines the equilibrium pressure of $ZrCl_4$ over pure solid Cs_2ZrCl_6 at temperatures higher than the eutectic temperature shown in the phase diagram given in Fig. 3.

During an actual pressure measurement, the $ZrCl_4$ vapour present in the pressure measuring apparatus is created by the thermal decomposition of Cs_2ZrCl_6, and it is inevitable that some small amount of CsCl shall be present. The CsCl thus produced reacts with Cs_2ZrCl_6 to form the liquid phase predicted by the phase diagram. In this sense, the pressures of $ZrCl_4$ reported represent the saturated solutions of Cs_2ZrCl_6 in CsCl. Reaction 2 in Table 3 represents the equilibrium over pure molten Cs_2ZrCl_6 at temperatures higher than its melting point.

Similar considerations apply to Reactions 3 and 4 for Cs_2HfCl_6, given in Table 3. It should be noted that the two linear portions of the pressure curves for Cs_2ZrCl_6 and Cs_2HfCl_6 in Fig. 7 intercept at temperatures which are in agreement with the melting points of the compounds Cs_2ZrCl_6 and Cs_2HfCl_6, respectively.

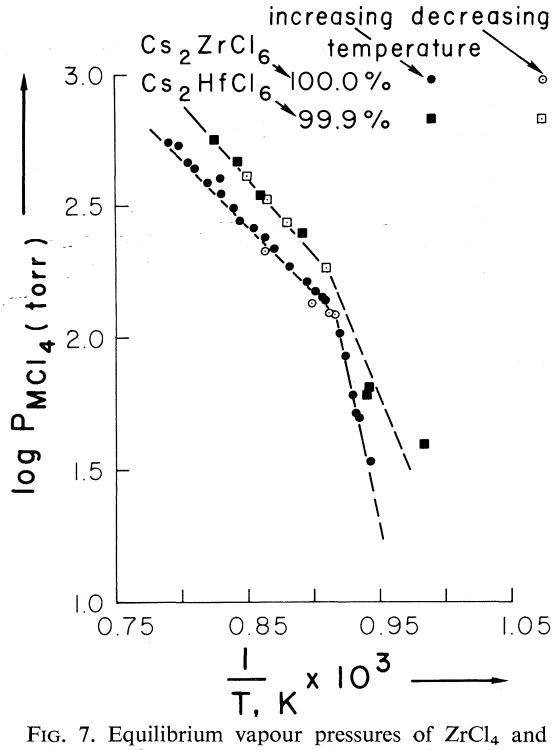

FIG. 7. Equilibrium vapour pressures of $ZrCl_4$ and $HfCl_4$ over the pure compounds Cs_2ZrCl_6 and Cs_2HfCl_6, respectively, given as log P (torr) *vs.* $1/T$ (K).

The vapour pressures in equilibrium with solutions containing Cs_2HfCl_6 and CsCl were also investigated and the plots of P_{HfCl_4} in torr *vs.* T in °C for three compositions on the

7. Cs_2HfCl_6 (in solution) $\rightleftarrows$ 2CsCl (in solution) + $HfCl_4$ (vap.)	62.5	1119–1271	6.152	−0.5149	±0.1258

*Pressure data for this range are shown in Fig. 7. Their accuracy did not warrant a least-squares calculation.

Cs_2HfCl_6-rich side of the eutectic as well as for the pure compound, are given in Fig. 8.

At temperatures $T < T_E$ all four compositions should yield a common vapour pressure curve. The equilibrium then is represented by the reaction

[2] Cs_2HfCl_6 (pure solid) $\rightleftarrows$ CsCl (pure solid) + $HfCl_4$ (vapour)

However, at these low temperatures the equilibrium pressures of $HfCl_4$ are very low and the accuracy of the measurement is affected by the presence of foreign gases which are absorbed by the solid powders used for those experiments, hence the observed scatter of points.

At temperatures above the eutectic and up to the corresponding melting point of a given solution, all compositions are expected to have a common vapour pressure curve since the equilibria which determine such pressures are given by reaction 3 in Table 3.

As the temperature is increased for a given composition the pressure curves are expected to branch off at the corresponding liquidus temperatures. This behaviour was found to be common with all the hexachlorozirconate and hexachlorohafnate systems investigated so far (1, 2).

It should be noted that the accuracy of the measurements of the vapour pressures over the three phase equilibria representing the saturated solutions of Cs_2HfCl_6 was rather poor, as seen from the scatter of points in Fig. 8.

This is probably due to the difficulty of reaching exact equilibrium in a system which changes composition with temperature. However, the expected trends were evident. In the all liquid range the equilibria are given by reactions 4, 5, 6, and 7 in Table 3.

For temperatures corresponding to the homogeneous liquid range, the measured equilibria represent only a liquid and a gas phase, both of which have fixed compositions, and the pressure measurements are extremely reproducible. An exception is the composition containing 62.5 mol% Cs_2HfCl_6, in which some CsCl vaporizes in the pressure measuring cell at the high temperatures of these measurements.

The corresponding equations expressing log P_{HfCl_4} *vs.* $1/T$ for the compositions investigated are also given in Table 3.

Discussion

A. Cryoscopic Calculations

For the dilute solutions of the complex

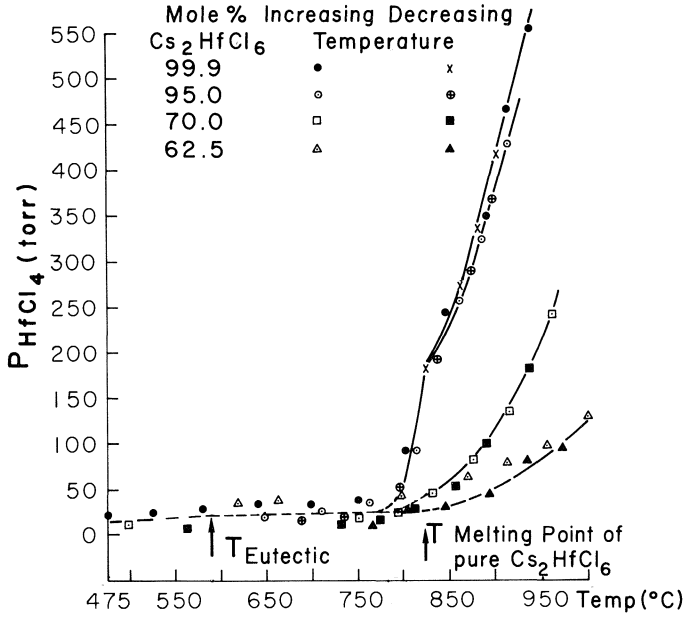

FIG. 8. Equilibrium vapour pressures of $HfCl_4$ over solutions of Cs_2HfCl_6 with CsCl.

compounds of the type Cs_2MCl_6 in CsCl, the depression of the melting point of CsCl is given by the expression

$$[3] \qquad \Delta T = V \frac{RT_F}{\Delta H_F} X_{solute}$$

where V represents the number of foreign ions other than those present in the solvent melt. The derivation of this equation is based on the applicability of Temkin's (6) ideal solution concept to ionic fused salt systems. T_F is the melting point of CsCl; ΔH_F is the heat of fusion of CsCl which is given (7) as 4.9 ± 0.1 kcal/mol, and X_{solute} is the mole fraction of the solute Cs_2MCl_6. This equation was found applicable to the CsCl-rich side of the corresponding phase diagrams for the systems, $CsCl–Cs_2ZrCl_6$ and $CsCl–Cs_2HfCl_6$, for $V = 1$.

This is seen in Fig. 9, where the theoretical liquidus curve calculated from [3] is compared with experimental values for concentrations up to 12 mol% Cs_2MCl_6. For $V = 1$, a number of dissociation schemes may be considered, such as:

$$[4a] \qquad Cs_2MCl_6 \rightleftarrows 2Cs^+ + MCl_6^{2-}$$

or

$$[4b] \qquad Cs_2MCl_6 \rightleftarrows 2Cs^+ + Cl^- + MCl_5^-$$

$$[4c] \qquad Cs_2MCl_6 \rightleftarrows 2Cl^- + (MCl_4) + 2Cs^+$$

Although [3] cannot distinguish between these dissociation schemes, it is clearly indicated that ion-association does not occur in these melts as the latter would require a value for V less than unity.

B. Calculation of Activities

Activities of Cs_2HfCl_6, CsCl, and $HfCl_4$ can be calculated by combining the vapour pressure and phase diagram data. Activities of the complex compound Cs_2HfCl_6 in the $CsCl–Cs_2HfCl_6$ melts may be calculated from the present results following a previously established mathematical treatment (9). Considering the equilibrium

$$Cs_2HfCl_6 \text{ (in solution)} \rightleftarrows 2CsCl \text{ (in solution)} + HfCl_4 \text{ (vapour)}$$

the equilibrium constant is

$$[5] \qquad K = \frac{a_{CsCl}^2 \cdot P_{HfCl_4}}{a_{Cs_2HfCl_6}}$$

Along any isotherm in the homogeneous liquid region of the phase diagram for the system $CsCl–Cs_2HfCl_6$, T = constant, d ln k = 0, and,

$$[6] \qquad 2 \, d \ln a_{CsCl} + d \ln P_{HfCl_4} = d \ln a_{Cs_2HfCl_6}$$

For the overall binary system $CsCl–HfCl_4$, the Gibbs–Duhem expression is written as

$$[7] \qquad X'_{HfCl_4} \, d \ln a_{HfCl_4} + X'_{CsCl} \, d \ln a_{CsCl} = 0$$

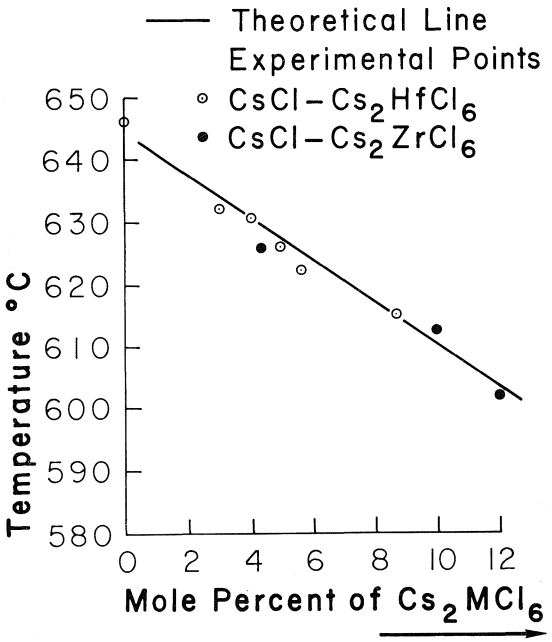

FIG. 9. Comparison of the theoretical liquidus line for $V = 1$ with the experimental data for the systems $CsCl–Cs_2ZrCl_6$ and $CsCl–Cs_2HfCl_6$.

where primed X's represent the mole fractions in the overall system.

It has been shown in a previous publication (8) that at compositions at which X_{MCl_4} is less than 0.33, the Gibbs–Duhem relationship is also applicable to the subsystem $CsCl–Cs_2HfCl_6$ provided that the equation is written as

$$[8] \quad X_{CsCl}\, d \ln a_{CsCl} + X_{Cs_2HfCl_6}\, d \ln a_{Cs_2HfCl_6} = 0$$

where unprimed X's are the new mole fractions which define the composition in the subsystem $CsCl–Cs_2HfCl_6$. Since the subsystem $CsCl–Cs_2HfCl_6$ is created by reacting all the $HfCl_4$ present with excess CsCl according to

$$[9] \quad 2CsCl + HfCl_4 \rightarrow Cs_2HfCl_6$$

the relationship between primed and unprimed X's is found by a mass balance calculation based on the stoichiometry of reaction 9.

These are:

$$[10] \quad X'_{CsCl} = \frac{2 - X_{CsCl}}{3 - 2X_{CsCl}} \qquad X'_{HfCl_4} = \frac{1 - X_{CsCl}}{3 - 2X_{CsCl}}$$

The final expression for the activity of Cs_2HfCl_6 is obtained from eqs. 6 and 8, and is given as,

$$[11] \quad d \ln a_{Cs_2HfCl_6} = \frac{X_{CsCl}}{1 + X_{Cs_2HfCl_6}}\, d \ln P_{HfCl_4}$$

which is applicable at T = constant. This expression may be integrated graphically for solutions at temperatures in the homogeneous liquid range.

Thus for $X_{Cs_2HfCl_6} = 1$ and $a_{Cs_2HfCl_6} = 1$

$$Q = \frac{X_{CsCl}}{1 + X_{Cs_2HfCl_6}} = 0$$

where Q is a concentration parameter. Then P_{HfCl_4} is the vapour pressure of $HfCl_4$ measured over pure molten Cs_2HfCl_6 at the chosen temperature. At $X_{Cs_2HfCl_6} = 0$, $a_{Cs_2HfCl_6} = 0$, and

$$Q = \frac{X_{CsCl}}{1 + X_{Cs_2HfCl_6}} = 1$$

Hence the integral is well defined at one end.

The standard states of the components CsCl and Cs_2HfCl_6 for activities calculated by this method are the real states of the components at the temperature at which the integration is conducted. For the gaseous $HfCl_4$, the standard state is the vapour at 1 atm pressure at all temperatures.

Values of P_{HfCl_4} at 825, 875, 900, and 925 °C were calculated from the log P_{HfCl_4} expressions shown in Table 3 and are given in Fig. 10 for compositions from 99.9 mol% to 62.5 mol% of Cs_2HfCl_6. The plot of Q *vs.* log P_{HfCl_4} obtained from the pressure data at 825 °C is shown in Fig. 11. The area under the curve yields the activities of Cs_2HfCl_6 at the corresponding compositions.

At 825.5 °C, which is the melting point of Cs_2HfCl_6, pure CsCl is molten, and solid Cs_2HfCl_6 is in equilibrium with liquid. Hence the standard states calculated at this isotherm should be the pure solid or liquid Cs_2HfCl_6 at the melting point and the pure liquid CsCl.

Activities calculated at 825 °C and at compositions between 99.9 and 62.5 mol% Cs_2HfCl_6 are given in Fig. 12.

Activities for Cs_2HfCl_6 may also be calculated from the phase diagram using the van't Hoff relationship in the form;

$$[12] \quad \ln a_{Cs_2HfCl_6} = -\frac{\Delta H_F}{R}\left(\frac{1}{T_L} - \frac{1}{T_F}\right)$$

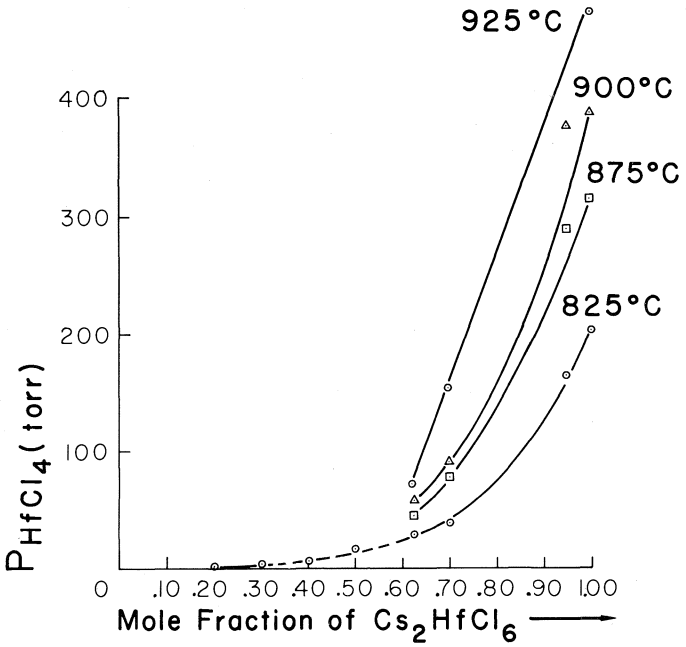

FIG. 10. Equilibrium vapour pressures of $HfCl_4$ plotted *vs.* the mole fraction of Cs_2HfCl_6 at the temperatures of 825, 875, 900, and 925 °C. The dotted line for 825 °C represents pressures calculated from the equilibrium constant K.

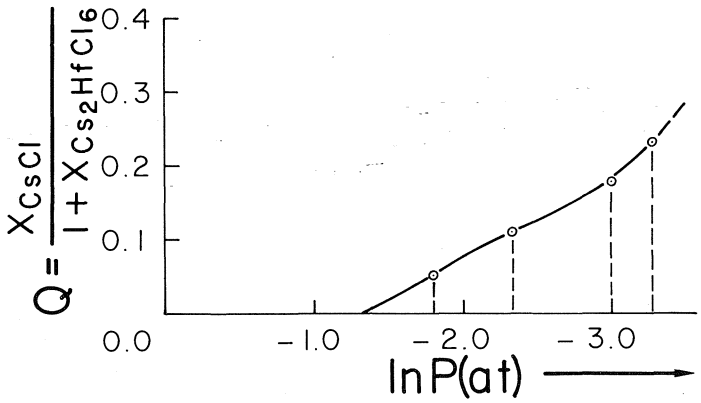

FIG. 11. Plot of the concentration parameter $Q = X_{CsCl}/(1 + X_{Cs_2HfCl_6})$ *vs.* ln P_{HfCl_4} (atm). The area under the curve allows the calculation of activities for Cs_2HfCl_6.

where ΔH_F is the heat of fusion of Cs_2HfCl_6. Although this value is not available in the literature, it has been assumed (9) that it should be similar to the heat of fusion of Cs_2ZrCl_6 which has been measured calorimetrically previously and is given as 17.53 ± 0.58 kcal/mol (10).

The activities for Cs_2HfCl_6 calculated from the phase diagram for compositions between 30 to 100 mol% Cs_2ZrCl_6 are also included in Fig. 12. Although these activities are non-isothermal, they represent a temperature range of about 150 °C, and compare well with those determined from pressure at 825 °C.

The activity data for Cs_2HfCl_6 in Fig. 12 indicate positive deviations from ideality at the Cs_2HfCl_6-rich end, while solutions containing less than 50 mol% Cs_2HfCl_6 behave ideally.

*From cryoscopic data.

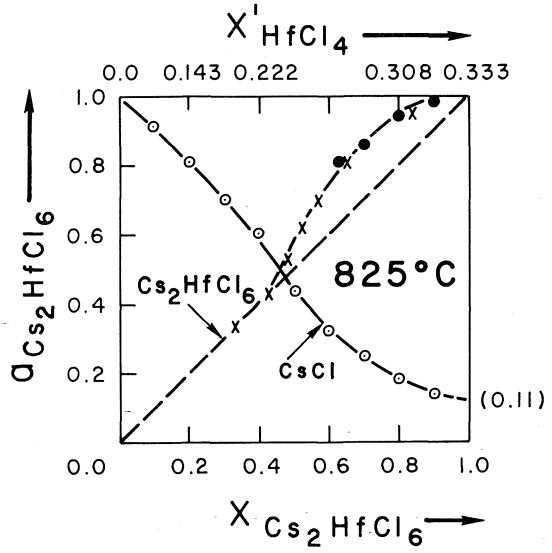

FIG. 12. The activities of Cs_2HfCl_6 and of CsCl at 825 °C. Lower concentration scale refers to the CsCl–Cs_2HfCl_6 subsystem while the upper concentration scale corresponds to the overall system CsCl–$HfCl_4$. The extrapolated activity for CsCl at $X_{Cs_2HfCl_6} = 1$ given as 0.11 represents the activity of CsCl in pure liquid Cs_2HfCl_6.

This ideal behaviour indicates an increased stabilization of $HfCl_4$ in CsCl-rich solutions, and also indicates that Cs_2HfCl_6 dissociates in melts containing more than 50 mol% CsCl into the species Cs^+ and the $HfCl_6^{2-}$.

Approximate activities of CsCl in the CsCl–Cs_2HfCl_6 subsystem have also been calculated at 825 °C using the Gibbs–Duhem eq. 8, and the results of these calculations are given in Fig. 12 and Table 4.

Activities of $HfCl_4$ in the CsCl–Cs_2HfCl_6 binary system have been calculated at 825 °C from the well known expression

$$[13] \qquad a_{HfCl_4} = \frac{P_{HfCl_4}}{P^0_{HfCl_4}}$$

where P_{HfCl_4} is the vapour pressure in equilibrium with a solution of given composition and temperature, and $P^0_{HfCl_4}$ is the pressure in equilibrium with pure solid $HfCl_4$ at the same temperature. This is given (7) by

$$[14] \qquad \log P^0_{HfCl_4}(\text{torr}) = -\frac{5197}{T} + 11.71$$

This equation is strictly valid only in the temperature range 476 to 681 K, and extrapolations were made when necessary.

To calculate the activities, the values for P_{HfCl_4} were selected at the mole fractions 1.0, 0.9, 0.8, 0.7, and 0.6. The results of these calculations for compositions in the investigated range are given in Table 4 and represent approximate values for the a_{HfCl_4} because of the long extrapolations involved in the calculation of $P^0_{HfCl_4}$ at the selected temperatures.

For these calculations, pressures were used instead of fugacities since the $HfCl_4$ vapour has been found to be monomeric and to obey the ideal gas laws at high temperatures (7).

The activities for $HfCl_4$ shown in Table 4 are very low and indicate the pronounced chemical stability of $HfCl_4$ in the CsCl–$HfCl_4$ solutions. Thus, at 700 °C, a solution containing 29 mol% of $HfCl_4$ has a decomposition pressure of 17 torr while pure $HfCl_4$ at the same temperature is calculated to have an equilibrium pressure of 2.33×10^6 torr.

This pronounced chemical stabilization of $HfCl_4$ in CsCl melts should be attributed to the presence of the complex compound Cs_2HfCl_6. Activities of $ZrCl_4$ and of Cs_2ZrCl_6 in the CsCl–Cs_2ZrCl_6 system have not been calculated, as the pressures of $ZrCl_4$ vapour in

equilibrium with solution containing various amounts of CsCl have not been measured.

From the activity values in Fig. 12 and the available equilibrium pressure data, the equilibrium constant K for the reaction

$$Cs_2HfCl_6 \text{ (solid)} \rightarrow 2CsCl \text{ (liquid)} + HfCl_4 \text{ (vapour)}$$

has been calculated at 825 °C from the data for the four compositions investigated, and the values are given in Table 4. It is seen that K is almost constant in the concentration range studied, and had the average value of $3.6 \pm 0.6 \times 10^{-3}$.

K may be used to calculate the equilibrium pressures of $HfCl_4$ at 825 °C over solutions containing less than 60 mol% of Cs_2HfCl_6. Those pressure values have also been included in Fig. 12.

It is of interest to compare the thermodynamic stability for all the alkali and alkaline earth chlorozirconate and chlorohafnate systems investigated so far in this laboratory.

Table 5 contains a list of the compounds of $ZrCl_4$ and $HfCl_4$ with various alkali, and alkaline earth chlorides. T_{dec} describes the temperature at which the pressure of $ZrCl_4$ or $HfCl_4$ in equilibrium with a given compound reaches 1 atm.

If T_{dec} is taken as a measure of thermal stability, then it is apparent that the zirconium and hafnium compounds with CsCl are the most stable of the series. Comparing the zirconium with the corresponding hafnium compounds, it is also seen that while Li_2ZrCl_6 is less stable than Li_2HfCl_6, Cs_2ZrCl_6 is more stable than Cs_2HfCl_6.

TABLE 5. Thermal stability of hexachlorozirconates and hexachlorohafnates, expressed as T_{dec} °C, as a function of the ionic radius of the complexing alkali or alkaline earth metal

Compound	T_{dec} (°C)	Ionic radius* for alkali and alkaline earth metal cation in Å
$SrZrCl_6$	410	1.13
$BaZrCl_6$	455	1.35
Li_2ZrCl_6	501	0.60
Li_2HfCl_6	513	
Na_2ZrCl_6	634	0.95
K_2ZrCl_6	831	1.33
Rb_2ZrCl_6	904	1.48
Cs_2ZrCl_6	1040	1.69
Cs_2HfCl_6	953	

*These are the crystal radii of Pauling (11).

Considering the effect of the size of the alkali metal cation on the thermodynamic stability of a given A_2MCl_6 type compound, the available data for the zirconium compounds indicate that their stability increases with increasing size of the alkali metal cation. This reflects a strengthening in the Zr—Cl bonds, and is the result of decreasing attraction between the alkali cations and the chloride species in the complex compound. It is also evident from the data in Table 5 that the compounds with the divalent alkaline earth chlorides are the least stable of the series, as expected.

Conclusions

From the results it has been established that $ZrCl_4$ and $HfCl_4$ have extended solubility in melts containing CsCl or CsCl and KF, and the solutions are thermodynamically stable. This becomes evident from the low values of the equilibrium vapour pressures of $ZrCl_4$ and $HfCl_4$ over such melts. The pure compounds Cs_2ZrCl_6 and Cs_2HfCl_6 have been synthesized.

From the measured vapour pressures of $HfCl_4$ in equilibrium with CsCl–Cs_2HfCl_6 melts at different compositions and temperatures, and from the cryoscopic data, the activities of Cs_2HfCl_4, CsCl, and $HfCl_4$ were calculated at 825 °C.

It has been found for solutions rich in Cs_2HfCl_6 the activity of Cs_2HfCl_6 exhibits positive deviations from ideality, while for solutions containing less than 50 mol% Cs_2HfCl_6 the solutions behave ideally.

The activities for $HfCl_4$ are extremely low, indicating the high stability of the melts due to the formation of the complex compound Cs_2HfCl_6. The equilibrium constant K for the decomposition of this compound has been calculated to be $(3.6 \pm 0.6) \times 10^{-3}$ at 825 °C.

A comparison between available data indicates that the Cs_2ZrCl_6 and Cs_2HfCl_6 compounds are the most stable of the alkali and alkaline earth series.

The CsCl–Cs_2ZrCl_6, or CsCl–Cs_2HfCl_6 mixtures with or without KF appear to be suitable as electrolytes for the recovery of Zr or Hf metals by fused salt electrolysis as they represent thermodynamically stable solutions of the volatile vapours of $ZrCl_4$ or $HfCl_4$. In addition, the cryoscopic results indicate the ionic character of those systems.

Nuclear magnetic resonance study of catalyzed intermolecular fluorine exchange in the methyltetrafluorosilicate anion[1]

RONALD KIRK MARAT AND ALEXANDER F. JANZEN
Department of Chemistry, University of Manitoba, Winnipeg, Man., Canada R3T 2N2

Received September 27, 1976

RONALD KIRK MARAT and ALEXANDER F. JANZEN. Can. J. Chem. **55**, 1167 (1977).

The effect of HF, MeOH, H_2O, F^-, pyridine, $Pr_4N^+MeSiF_4^-$, and temperature on the rate of intermolecular fluorine exchange in the methyltetrafluorosilicate anion has been studied by the dynamic nuclear magnetic resonance technique. The exchange was found to be catalyzed by HF and, to a lesser extent, MeOH and H_2O, but inhibited by F^-, pyridine, and $Pr_4N^+MeSiF_4^-$. The results are analyzed in terms of the coordination model of reaction mechanisms.

RONALD KIRK MARAT et ALEXANDER F. JANZEN. Can. J. Chem. **55**, 1167 (1977).

On a étudié, par la technique de la résonance magnétique nucléaire dynamique, l'effet de HF, MeOH, H_2O, F^-, pyridine, $Pr_4N^+MeSiF_4^-$ et de la température sur les vitesses d'échange de fluor intermoléculaire dans l'anion méthyltétrafluorosilicate. On a trouvé que l'échange est catalysé par HF et à un degré moindre par MeOH et H_2O mais est inhibé par F^-, la pyridine et $Pr_4N^+MeSiF_4^-$. On analyse les résultats en termes d'un modèle de coordination des mécanismes de réaction.

[Traduit par le journal]

Introduction

Ligand exchange processes in phosphorus, sulfur, and silicon compounds are rapid in the presence of H_2O, HF, and base catalysts (1–3) and we have described the results in terms of the coordination model of reaction mechanisms[2] which emphasizes the coordination changes of the elements during a chemical reaction and classifies such changes into intermolecular or intramolecular (*n*-center) reactions.

As a further test of these mechanistic proposals we have studied catalyzed intermolecular fluorine exchange in $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$, particularly the effect of HF, CH_3OH, H_2O, F^-, and pyridine on the rate of silicon–fluorine bond cleavage in $CH_3SiF_4^-$. This compound was first prepared by Klanberg and Muetterties who found that $CH_3SiF_4^-$ underwent both axial–equatorial and intermolecular fluorine exchange (4). The axial–equatorial exchange is typical of trigonal bipyramidal molecules and the structure of $CH_3SiF_4^-$, while not yet determined, is probably trigonal bipyramidal in view of the structure of analogous compounds such as $(C_6H_5)_2SiF_3^-$ (4), SiF_5^- (5), and isoelectronic CH_3PF_4 (6). Rapid axial–equatorial exchange equilibrates the four fluorine substituents in $CH_3SiF_4^-$ and simplifies the calculation of the methyl resonance line shape for the intermolecular exchange process.

Results

Calculation of the Exchange Broadened Spectra

It was necessary to generate proton magnetic resonance line shapes for a group of three equivalent protons coupled to a group of four equivalent fluorines undergoing intermolecular exchange. Line shapes were calculated by a matrix formulation of the McConnell–Bloch equations, similar to that of Reeves and Shaw (7). The Bloch equations, although not strictly valid for cases of spin–spin coupling, may be used since all nuclear spin isochromats are independent except for the effects of chemical exchange.

The F–Si–C–H coupling constant, in the absence of intermolecular exchange, is 4.73 ± 0.05 Hz and is independent, within experimental error, of temperature and concentration. The ^{29}Si–C–H coupling constant is 9.3 ± 0.2 Hz in the slow and fast exchange limits. Chemical shifts were found to be constant to within 2 Hz over the temperature and concentration range studied. Satellite peaks resulting from the ^{29}Si compound (relative abundance 4.67%) were included in all line shape calculations. Examples

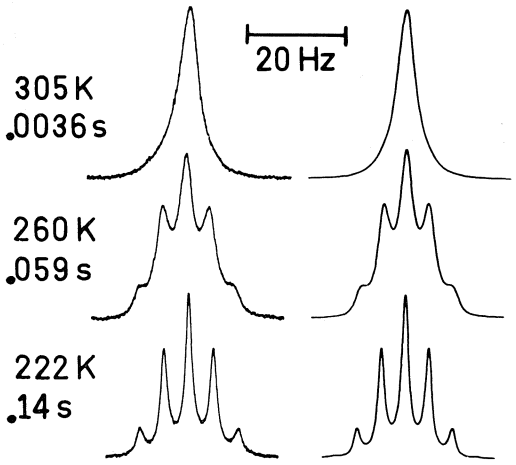

FIG. 1. A comparison of the calculated (right) and experimental (left) methyl proton resonance of $CH_3SiF_4^-$ undergoing intermolecular fluorine exchange. Sample contained $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$ (1.0 *M*) and CH_3OH (1.0 *M*) in CH_2Cl_2 solvent.

of calculated[3] and experimental spectra are shown in Fig. 1.

Effect of HF, MeOH, H_2O, $Pr_4N^+MeSiF_4^-$, F^-, Pyridine, and Temperature on the Exchange Rate

The pre-exchange lifetime (τ) may be related to the kinetics of the exchange reaction by [1],

$$[1] \qquad (f\tau)^{-1} = k[A]^{a-1}[B]^b[C]^c \ldots$$

where A is the species being observed (Pr_4N^+-$MeSiF_4^-$) and B, C, ... are other species involved in the exchange reaction but not observed in the exchange broadened nmr spectrum; *a*, *b*, *c*, ... are the kinetic orders, *k* is the specific rate constant, and *f* is a statistical factor which relates the magnetic pre-exchange lifetime (τ) of A to the chemical preexchange lifetime (9). *f* includes a factor of $\frac{1}{4}$ because four fluorines can undergo exchange, and a factor of $\frac{1}{2}$ because there is a 50% probability that after exchange the fluorine may have the same spin state. Our calculations include the factor of $\frac{1}{2}$ in the exchange probability matrix.

The effect of any reagent on the fluorine exchange process in $MeSiF_4^-$ may thus be determined by varying the concentration of the reagent and observing its influence on τ; a plot of ln $1/\tau$ *vs.* ln [concentration] then gives the order in that reagent. This technique was used in the following experiments.

(i) Effect of HF

Figure 2 shows a plot of ln [HF] *vs.* ln $1/\tau$ at three temperatures. The slopes (least square) and orders in HF are 2.5 ± 0.2 at +33°C, 2.9 ± 0.2 at +3°C and, 3.4 ± 0.3 at −7°C, thus the orders increase at lower temperature. HF produced a very rapid rate of exchange and therefore studies were carried out at low HF concentration, generally from 10^{-1} to 10^{-3} *M*. The difficulty of working with such small quantities of HF is assumed to be the main reason for the large experimental errors in Fig. 2. Reaction of HF with the glass wall of the nmr tube is a minor cause for error because samples could be left at room temperature for several hours without appreciable change in the exchange rate.

(ii) Effect of Methanol

Figure 3 shows a plot of ln [MeOH] *vs.* ln $1/\tau$ at two temperatures. The orders in MeOH are 1.95 ± 0.05 at +31.5°C and 2.5 ± 0.1 at 0°C, thus the order increases at lower temperature. A comparison of HF (Fig. 2) and MeOH (Fig. 3) catalyzed reactions shows that about 10^2 to 10^3 times as much MeOH as HF must be used to produce comparable rates of exchange.

(iii) Effect of Water

The effect of water on the exchange rate was

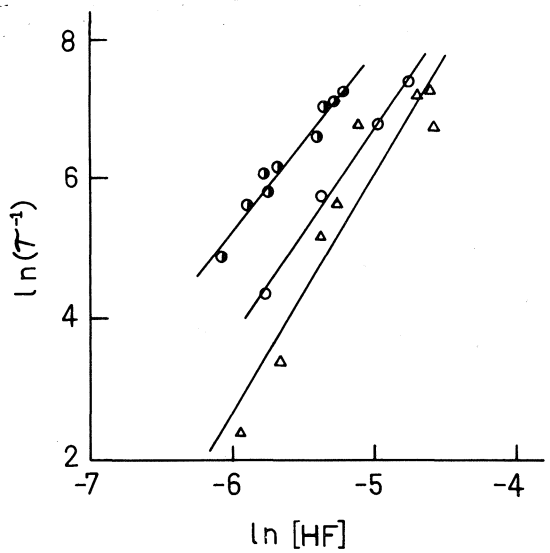

FIG. 2. Plot of ln $1/\tau$ *vs.* ln [HF] at three temperatures and at 0.66 *M* $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$: ◑ +33°C; ○ +3°C; △ −7°C.

[3]A detailed description of the line shape calculations is found in ref. 8.

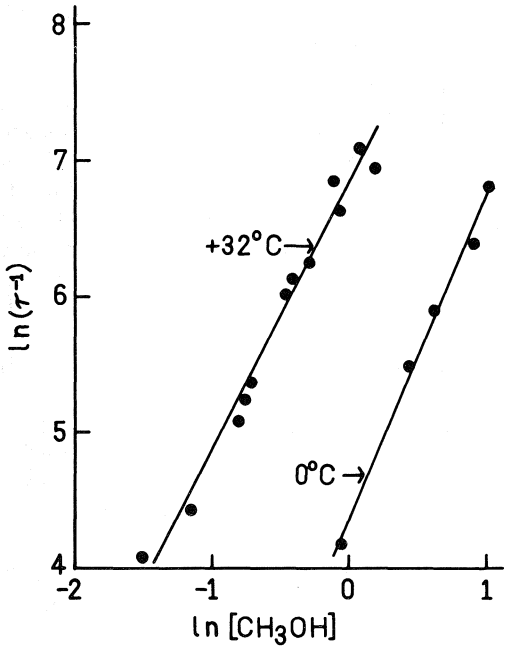

FIG. 3. Plot of ln $1/\tau$ *vs.* ln [CH_3OH] at two temperatures and 0.66 *M* $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$.

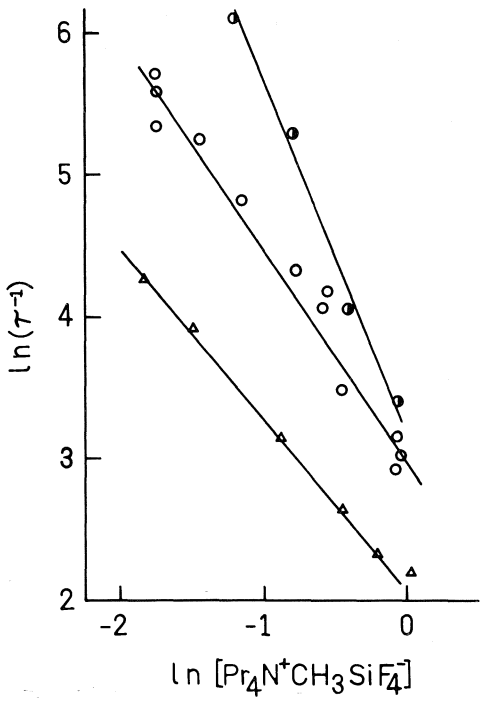

FIG. 4. Plot of ln $1/\tau$ *vs.* ln $[(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-]$ for HF and CH_3OH catalyzed exchange reactions: ◑ [HF] = 2.2×10^{-3} *M*, +31.5°C; ○ [CH_3OH] = 1.0 *M*, −17°C; △ [CH_3OH] = 1.0 *M*, −25°C.

briefly studied and found to be similar to that of MeOH. A comparison of the rates of HF, MeOH, and H_2O catalyzed reactions at constant temperature and $Pr_4N^+MeSiF_4^-$ concentration is shown in Table 1. It may be seen that HF, at only 5.0×10^{-3} *M*, produces a $1/\tau$ value of 2300 s^{-1}, whereas 1.0 *M* MeOH and H_2O produce $1/\tau$ values of 800 and 900 s^{-1}, respectively.

(iv) Effect of $Pr_4N^+MeSiF_4^-$

Figure 4 shows a plot of ln $1/\tau$ *vs.* ln [$Pr_4N^+MeSiF_4^-$] for HF and MeOH catalyzed reactions, the latter at two temperatures. It may be seen that addition of $Pr_4N^+MeSiF_4^-$ inhibits exchange and the orders ($a - 1$ in eq. 1) in this reagent are -1.5 ± 0.2 at +31.5°C for HF catalyzed exchange, and -0.5 ± 0.2 at −17°C and -0.2 ± 0.1 at −25°C for MeOH catalyzed exchange. Inhibition is more pronounced for the HF than for the MeOH catalyzed reaction.

TABLE 1. Relative rates of exchange at +31.5°C and 0.66 *M* $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$

Reagent	Concentration	$1/\tau(\pm 10\%)$
HF	5.0×10^{-3} *M*	2300
H_2O	1.0 *M*	900
CH_3OH	1.0 *M*	800

(v) Effect of Fluoride Ion and Pyridine

Figure 5 shows a plot of $1/\tau$ *vs.* fluoride ion (as $Pr_4N^+F^-$) or pyridine for the HF and MeOH catalyzed reactions. Both F^- and pyridine inhibit exchange in the HF and MeOH catalyzed reactions, but the concentrations of $Pr_4N^+F^-$ and HF are approximately 10^2 to 10^3 times lower than concentrations of pyridine and MeOH. The most effective inhibition is produced by addition of F^- to HF catalyzed reactions, *e.g.*, it may be estimated from Fig. 5 that $1/\tau$ is reduced by 50% after addition of about 1.3×10^{-3} *M* F^- to a sample containing 3.95×10^{-3} *M* HF.

(vi) Effect of Temperature

Figure 6 shows a plot of ln $1/\tau$ *vs.* $1/T$ for HF and MeOH catalyzed exchange reactions. The temperature dependency of the two systems is very similar, but the concentration of HF is only 3.3×10^{-3} *M* whereas that of MeOH is 1.0 *M*. The high temperature straight line portion of the plot (above ~ -25°C) gives an apparent activation energy $E_a = 12.3 \pm 0.4$ kcal/mol for the HF catalyzed reaction and $E_a = 10.2 \pm 0.3$

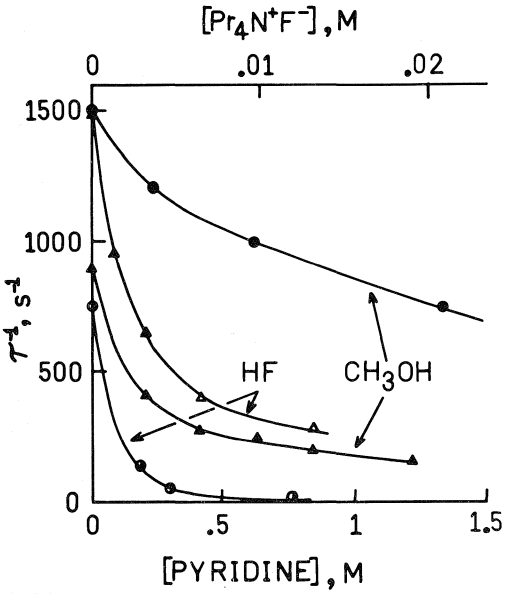

FIG. 5. Inhibition of HF and CH_3OH catalyzed exchange reactions by $(n\text{-}C_3H_7)_4N^+F^-$ and pyridine at +33°C and 0.66 *M* $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$: ● $[CH_3OH] = 1.65$ *M*, F^- inhibition; ◑ $[HF] = 3.95 \times 10^{-3}$ *M*, F^- inhibition; △ $[HF] = 5.25 \times 10^{-3}$ *M*, pyridine inhibition; ▲ $[CH_3OH] = 1.0$ *M*, pyridine inhibition.

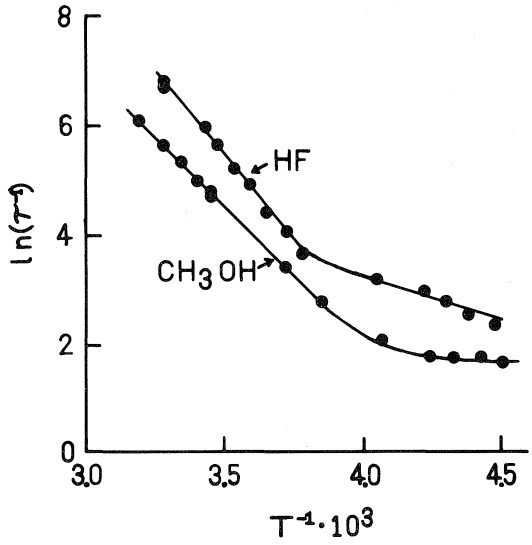

FIG. 6. The effect of temperature on the HF and CH_3OH catalyzed exchange reactions at 1.0 *M* $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$: $[HF] = 3.3 \times 10^{-3}$ *M* and $[CH_3OH] = 1.0$ *M*.

kcal/mol for the MeOH catalyzed reaction. At lower temperatures (below ~ −25°C), the apparent activation energy is about 2 kcal/mol for the HF catalyzed reaction and about 0.4 kcal/mol for the MeOH catalyzed reaction.

(vii) Effect of 2,6-Di-tert-butylpyridine

A sample containing 0.66 *M* $Pr_4N^+MeSiF_4^-$ and 1.0 *M* MeOH showed no discernible change in the exchange rate upon addition of 2,6-di-*tert*-butylpyridine over a concentration range 0 to 0.52 *M*.

(viii) Effect of Hexamethyldisilazane

Fluorine exchange in an HF catalyzed reaction was immediately stopped on addition of $[Me_3Si]_2NH$; some Me_3SiF was produced and identified by nmr. In a separate experiment it was shown that $[Me_3Si]_2NH$ reacts very rapidly with a dilute solution of HF to produce Me_3SiF. Fluorine exchange in a MeOH catalyzed reaction was also slowed down, but at a reduced rate; some Me_3SiF was formed and it was separated on the vacuum line and identified by nmr and mass spectrometry. In a separate experiment it was shown that $[Me_3Si]_2NH$ reacts very slowly, over a period of several days, with MeOH.

Discussion

Possible Mechanism of Catalyzed Intermolecular Fluorine Exchange

The experimental results discussed above, particularly the high orders in HF and MeOH, the negative fractional order in $Pr_4N^+MeSiF_4^-$, and the change in order with temperature, suggest that intermolecular fluorine exchange in $MeSiF_4^-$ is a complex process and a quantitative kinetic analysis will not be attempted. Nevertheless, it is possible to offer a qualitative but consistent explanation of the experimental results.

In the first place, the results definitely show that unimolecular ionization of $MeSiF_4^-$, [2],

$$[2] \qquad MeSiF_4^- \rightleftharpoons MeSiF_3 + F^-$$

or bimolecular fluorine exchange of $MeSiF_4^-$, [3], cannot be mechanisms of exchange which

$$[3] \quad MeSiF_4^- + MeSiF^*{}_4^- \rightleftharpoons MeSiF_3F^{*-} + MeSiF^*{}_3F^-$$

are rapid on the nmr time scale because negligible exchange occurs unless HF, MeOH, or H_2O are added. Since $MeSiF_4^-$ is actually prepared from $MeSiF_3$ and F^-, it must be concluded that [2] lies essentially to the left and that loss of F^- is hindered by a high activation barrier.

Secondly, it can be stated quite confidently that HF is responsible for very rapid fluorine

exchange in $MeSiF_4^-$; Table 1 and Figs. 2 and 3 demonstrate that much lower concentrations of HF than MeOH or H_2O are required to bring about comparable rates of exchange, therefore, it is reasonable to conclude that MeOH or H_2O reacts with $MeSiF_4^-$ to generate HF, [4] and [5], and HF then becomes the dominant fluorine

[4] $MeSiF_4^- + MeOH \rightleftharpoons MeSiF_3OMe^- + HF$

[5] $MeSiF_4^- + H_2O \rightleftharpoons MeSiF_3OH^- + HF$

transfer reagent in the exchange reaction. The equilibrium of [4] and [5] must lie predominantly to the left to explain the decrease of 10^2 to 10^3 in the rate of MeOH or H_2O catalyzed exchange, furthermore, the synthesis of $MeSiF_4^-$ may be carried out in methanol solution without any apparent formation of $MeSiF_3OMe^-$, and there is only a small change in the chemical shift (less than 2 Hz) of $MeSiF_4^-$ as MeOH is added.

If HF is responsible for rapid fluorine exchange then any reduction in its equilibrium concentration must result in a reduced rate of exchange. Thus adding $[Me_3Si]_2NH$ to a MeOH or HF catalyzed reaction removes HF as Me_3SiF, [6], while addition of small amounts of

[6] $[Me_3Si]_2NH + 2HF \rightleftharpoons 2Me_3SiF + NH_3$

fluoride, as $Pr_4N^+F^-$, inhibits exchange (Fig. 5) because HF is converted to bifluoride, [7]. There

[7] $F^- + HF \rightleftharpoons F—H—F^-$

are many reports in the literature that HF may be complexed as bifluoride and that fluorine exchange is slowed down by this procedure.

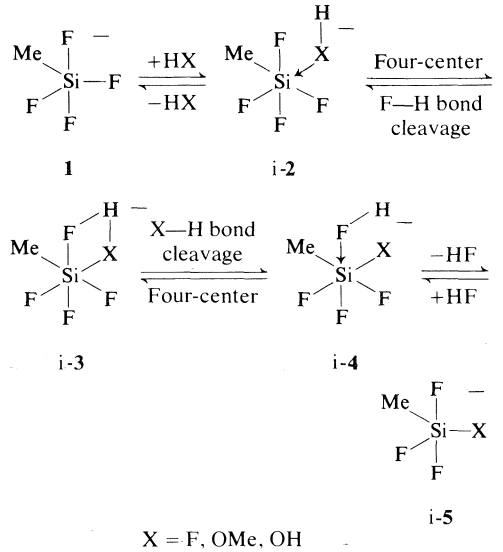
Pyridine may also tie up HF as $C_5H_5NH^+F^-$ or, in view of the large amount of pyridine that must be added to observe inhibition (Fig. 5), it is also possible that inhibition is due to the formation of $MeSiF_4(base)^-$, [8]. Previous nmr and

[8] $MeSiF_4^- + base \rightleftharpoons MeSiF_4(base)^-$

thermochemical studies have shown that bases such as NH_3 and amines may interact strongly with SiF_5^- to give six-coordinate silicon adducts (1, 10). That inhibition is not observed with bases such as 2,6-di-*tert*-butylpyridine suggests that this base is probably too bulky to coordinate to $MeSiF_4^-$ and too weakly basic to complex out HF (11).

In order to account for some of the more complex features of the exchange process, such as the high orders in HF and MeOH (Figs. 2 and 3), negative order in $Pr_4N^+MeSiF_4^-$ (Fig. 4), and temperature effects (Fig. 6), it is useful to consider the most likely coordination changes[2] of all elements taking part in the reactions; these are probably[4] Si $4 \rightleftharpoons 5 \rightleftharpoons 6$, H $1 \rightleftharpoons 2$, F $1 \rightleftharpoons 2$, and O $2 \rightleftharpoons 3$. The coordination changes may occur via the fluorine exchange mechanism of [9] which postulates initial attack of HF, MeOH, or H_2O on $MeSiF_4^-$ to give a six-coordinate intermediate (i) i-**2**, followed by a four-center reaction to give i-**3**. X—H bond cleavage and loss of HF then gives i-**5**.

[9]



1 i-**2** i-**3** i-**4** i-**5**

X = F, OMe, OH

The high order in HF could be ascribed to $(HF)_n$ aggregates, or, it may reflect the reaction of HF with $Pr_4N^+MeSiF_4^-$ which may shift the equilibrium, [10], to the right. The molecular

[10] $Pr_4N^+MeSiF_4^- + nHF \rightleftharpoons Pr_4N^+ + MeSiF_4(HF)_n^-$

weight of $Pr_4N^+MeSiF_4^-$ in CH_2Cl_2 solution was found to be 330 ± 20, as determined by vapour pressure measurement, *i.e.* about 8% greater than the molecular weight of the ion-pair. Previously, Brownstein and Bornais found that $Bu_4N^+PF_6^-$ and $Bu_4N^+AsF_6^-$ had apparent

[4]That hydrogen and fluorine may form two-coordinate intermediates is reasonable in view of the many stable compounds of similar coordination number, *e.g.*, FHF^-, B_2H_6, $(CO)_5CrHCr(CO)_5^-$ (12), $Et_3AlFAlEt_3^-$(13), polymeric SbF_5, etc. Three-coordinate oxygen is found in H_3O^+, R_3O^+, and dimeric $(RO)_3Al$ and six-coordinate silicon in SiF_6^{2-}, $Si(acac)_3^+$ and $SiX_4 \cdot 2base$. Corriu and Leard's study of racemization of chlorosilanes (14) provides a good example of coordination changes Si $4 \rightleftharpoons 5 \rightleftharpoons 6$.

molecular weights about 5% greater than the formula weight (15).

If HF is produced in the MeOH catalyzed reaction, [4], then the order in MeOH should be one-half[5] that of the order in HF. This is in reasonable agreement with experiment since the orders in MeOH are 1.95 ± 0.05 to 2.5 ± 0.1 (Fig. 3) while the orders in HF are 2.5 ± 0.2 to 3.4 ± 0.3 (Fig. 2).

At lower temperature the order in HF (Fig. 2) and MeOH (Fig. 3) increases, perhaps because the average number of associated HF molecules in $MeSiF_4(HF)_n^-$ increases. Increasing the concentration of $Pr_4N^+MeSiF_4^-$ at constant HF concentration may result in a decreased rate of fluorine exchange (Fig. 4) because more HF is tied up as $MeSiF_4(HF)_n^-$. That inhibition by $Pr_4N^+MeSiF_4^-$ is less pronounced for the MeOH than for the HF catalyzed reaction (Fig. 4) suggests that the large concentration of MeOH might favour the production of $MeSiF_4(HOMe)_n^-$, rather than $MeSiF_4(HF)_n^-$, therefore, the equilibrium concentration of HF would not be reduced as effectively in a MeOH catalyzed reaction. Complexes such as $SiF_4 \cdot 4MeOH$ have been described previously by Guertin and Onyszchuk (16).

The mechanism of [9], modified to include intermediates such as $MeSiF_4(HF)_n^-$, is assumed to be responsible for rapid HF catalyzed exchange and all the results discussed above appear to be consistent with this view. The activation energy plot (Fig. 6), however, suggests that there are two parallel pathways of fluorine exchange, one dominant above $\sim -25°C$, with apparent activation energy 10.2–12.3 kcal/mol, which is assumed to be the HF catalyzed process discussed so far, the other, dominant below $\sim -25°C$, has an apparent activation energy of about 0.4 to 2 kcal/mol. Other reactions which might also produce fluorine exchange are [11] and [12]. Recent studies in our laboratory have

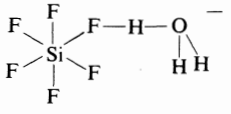
$$[11] \qquad MeSiF_4^- + HF \rightleftharpoons MeSiF_3 + FHF^-$$

$$[12] \qquad MeSiF_4^- + MeSiF^*{}_3 \rightleftharpoons MeSiF_3 + MeSiF^*{}_3F^-$$

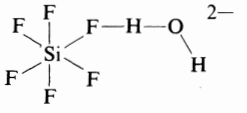
shown that fluorine exchange, in the absence of catalysts, is very rapid in the system $MeSiF_4^-$–$MeSiF_3$ (17), therefore, any reaction which liberates $MeSiF_3$, even in small amounts, may be an important pathway of fluorine exchange.

Comparison with Other Catalyzed Exchange Processes

Fluorine exchange occurs in an acidified aqueous solution of $(NH_4)_2SiF_6$ (18) and SiF_5^- salts can be precipitated from fluorosilicic acid solutions (19). Presumably, H_3O^+ and SiF_6^{2-} give intermediate-**6**, which may undergo cleavage at three-coordinate oxygen and two-coordinate hydrogen (O 2 ⇌ 3, H 1 ⇌ 2). Loss of H_2O from i-**6** gives an intermediate which is entirely analogous to intermediate-**2** in [9]. In the absence of an acid catalyst, H_2O and SiF_6^{2-} probably give intermediate-**7**, but cleavage of the F—H bond in i-**7** (F 1 ⇌ 2, H 1 ⇌ 2) does not result in fluorine transfer.

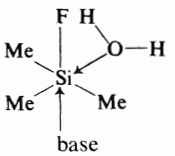


i-**6**

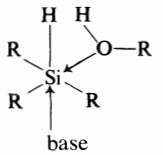


i-**7**

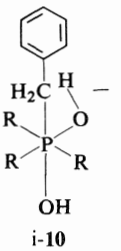
It may appear contradictory that exchange in $MeSiF_4^-$ is inhibited by fluoride or pyridine, whereas other reactions of silicon or phosphorus compounds are generally catalyzed by bases, *e.g.*, hydrolysis and fluorine exchange of Me_3SiF is catalyzed by diethylamine (3), reaction of alcohols with R_3SiH is catalyzed by fluoride or alkoxide (20), and decomposition of phosphonium salts is catalyzed by hydroxide (21). However, this apparent conflict may be resolved by assuming that four-center reactions are accelerated if the central silicon or phosphorus atom achieves six coordination.[2] In that case, Me_3SiF, R_3SiH, or $R_3(C_6H_5CH_2)P^+$ require base catalysts in order to increase the coordination around silicon or phosphorus. The formation of intermediates such as i-**8**, i-**9**, and i-**10** may then be



i-**8**



i-**9**



i-**10**

followed by rapid four-center reactions and loss of HF from i-**8** (Si 4 ⇌ 5 ⇌ 6, H 1 ⇌ 2, F 1 ⇌ 2, O 2 ⇌ 3), loss of H_2 from i-**9** (Si 4 ⇌

[5]If [HF] = [$MeSiF_3OMe^-$] and [$MeSiF_4^-$] is constant in the equilibrium constant expression for [4], then [HF] $\propto K_{eq}^{1/2}$[MeOH]$^{1/2}$. If rate $\propto$ [HF]^n, then rate $\propto K_{eq}^{1/2\,n}$[MeOH]$^{1/2\,n}$.

$5 \rightleftharpoons 6$, H $1 \rightleftharpoons 2$, O $2 \rightleftharpoons 3$), and loss of toluene from i-**10** (P $4 \rightleftharpoons 5 \rightleftharpoons 6$, H $1 \rightleftharpoons 2$, O $1 \rightleftharpoons 2$, C $4 \rightleftharpoons 5$). Since $MeSiF_4^-$ is already five-coordinate, any attack on silicon by a base such as pyridine will merely compete with reagents such as water, alcohol, or hydrogen fluoride and inhibit further reaction.

Experimental

Materials

Methyltrifluorosilane (PCR), 10% aqueous $(n\text{-}C_3H_7)_4NOH$ (Eastman), 49% aqueous HF (Fisher), anhydrous HF (Matheson), and hexamethyldisilazane (Aldrich) were used without further purification. Methanol was distilled from sodium, methylene chloride from P_2O_5, and 1,2-dimethoxyethane was poured through a column of 3A molecular sieves and distilled from lithium aluminum hydride; all were stored over 3A molecular sieves prior to use, including acetonitrile.

Dilute solutions of HF were prepared by bubbling gaseous anhydrous HF into a 1:1 (v/v) mixture of acetonitrile and methylene chloride, in which HF was readily soluble. These solutions were standardized acidimetrically and, when stored at 0°C, showed no decomposition after several weeks. In a separate experiment it was shown that addition of acetonitrile had no effect on the exchange rate. Dilute solutions of water were made up in a 10% (v/v) mixture of acetonitrile and methylene chloride.

Tetra-*n*-propylammonium methyltetrafluorosilicate was prepared by the method of Klanberg and Muetterties (4). Neutralization of $(n\text{-}C_3H_7)_4NOH$ (75 ml of a 3% solution) with 1% aqueous HF was monitored with a glass electrode p*H* meter to ensure that no excess HF was introduced. The white, hygroscopic powder, $(n\text{-}C_3H_7)_4N^+F^-$ (2.7 g) was handled in a dry box at all times. $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$ (40–50% yield) was recrystallized from 1,2-dimethoxyethane, washed with diethyl ether, and identified by its ^1H and ^{19}F nmr spectrum (4) and mp 157–159°C (lit. (4) mp 161–164°C).

Samples of $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$ with $1/\tau$ values less than 2 or 3 s^{-1} at +33°C were sufficiently pure for kinetic studies. On a number of occasions, however, only impure samples were obtained, most likely because of the introduction of HF or H_2O or perhaps because of the presence of CH_3SiF_3 or methylchlorofluorosilanes (from reaction of SbF_3 with CH_3SiCl_3). Chloride contamination of $(CH_3)_4N^+F^-$ has been mentioned previously (4).

Preparation of Nuclear Magnetic Resonance Samples

The 5 mm nmr tubes, calibrated to contain exactly 0.3 or 0.4 ml, were cleaned with CH_2Cl_2, treated with hexamethyldisilazane (1), and dried at 220°C for at least 24 h. $(n\text{-}C_3H_7)_4N^+CH_3SiF_4^-$ was weighed into the nmr tube, catalysts or other reagents were added by means of a microlitre syringe, and the total volume adjusted by adding CH_2Cl_2 up to the calibration mark. The tube was capped, inverted several times to ensure thorough mixing, and equilibrated for 20 min at probe temperature.

During concentration runs the volume of reagent added (2–10 μl) was always small compared to the total sample volume (300 or 400 μl) and the error of ~3% was ignored. Volume changes with temperature were also ignored. Samples for the determination of activation parameters were sealed under vacuum and stored at −196°C until required. This was necessary to avoid the effects of sample aging.

Instrumental

All proton magnetic resonance spectra were recorded on a Varian HA-100-D spectrometer at 100 MHz using CH_2Cl_2 as the internal lock. Frequencies were measured with a Hewlett-Packard 5323-A frequency counter and are considered accurate to ±0.02 Hz. Spectra were recorded at a sweep rate of 0.1 Hz/s and a sweep width of 2 Hz/cm with a minimum amount of filtering. The R.F. field strength was 0.025 mG as determined by the method of Harris and Worvill (22). Spectra run with a threefold increase in field strength showed negligible distortion due to saturation effects. Every point in the figures represents the average of at least three, sometimes up to seven, scans of the nmr spectrum.

Wilmad 503-ps nmr tubes were chosen for their reproducible spinning characteristics and were employed for all nmr studies. Temperatures were determined with an iron–constantan thermocouple placed at sample depth in a 'dummy' sample of CH_2Cl_2.

Mass spectra were obtained on a Finnigan 1015 quadrupole mass spectrometer.

Calculation of Line Shapes

All calculated spectra were produced with a modified version of Dr. G. M. Whitesides' computer program EXCHYS (23). The computations were performed with an IBM 370-158 computer and the Fortran-H compiler. The digital output was plotted on a Calcomp 750-563 or Versatec D1200-A plotter.

Due to the large number of spectra that had to be compared and the high symmetry of the spectra, a numerical procedure was employed for comparison of the spectra. For spectra past the point of coalescence, the half-height width of the experimental spectrum was compared with a graph of calculated half-height widths as a function of $1/\tau$. Graphs of this type were made for a number of different T_2 values. T_2 values were estimated from natural abundance $^{13}CH_2Cl_2$ and varied from 0.5 to 1.3 s. For slower exchange rates, graphs were prepared of 'valley-to-peak' ratios as a function of $1/\tau$ for a range of T_2 values. Spectra at intermediate exchange rates were analyzed by visual comparison of experimental and calculated spectra.[3] The lifetime values determined by this method are considered accurate to ±10%.

An electron spin resonance and CIDNP study of the structure and reactivity of some excited triplet biphenyl ketones

HARISH M. VYAS AND JEFFREY K. S. WAN

Department of Chemistry, Queen's University, Kingston, Ont., Canada K7L 3N6

Received September 20, 1976

HARISH M. VYAS and JEFFREY K. S. WAN. Can. J. Chem. **55**, 1175 (1977).

The correlation of structure and reactivity of some excited triplet biphenyl ketones was approached by a combined esr and CIDNP study. The low temperature esr study confirmed the assignment of the triplet π,π^* as the lowest triplet state in these biphenyl ketones. An analysis of the zero-field energies suggests that these π,π^* triplets have a structure with both the biphenyl and the carbonyl groups being coplanar. Consequently a substantial unpaired spin density may result at the carbonyl oxygen atom which could lead to abstraction reactions. The CIDNP results are consistent with the triplet photoreduction mechanism. The polarization is mainly due to the cage products and the polarization magnitude is therefore dependent upon the light intensity.

HARISH M. VYAS et JEFFREY K. S. WAN. Can. J. Chem. **55**, 1175 (1977).

On a examiné une corrélation de structure et de réactivité de quelques triplets excités de biphényl cétones à l'aide d'une étude combinée de rpe et de CIDNP. Des études de rpe à basse température ont confirmé l'attribution de l'état triplet π,π^* comme étant l'état triplet le plus bas de ces biphényl cétones. Une analyse des énergies à champ zéro suggère que ces états triplets π,π^* ont une structure dans laquelle les groupes biphényles et carbonyles sont coplanaires. En conséquence, une densité importante de spin non-pairé peut se retrouver au niveau de l'atome d'oxygène du carbonyle ce qui pourrait conduire alors aux réactions d'enlèvement. Les résultats CINDP sont en accord avec le mécanisme de la photoréduction triplet. La polarisation est principalement due aux produits formés dans la cage et l'amplitude de la polarisation dépend donc de l'intensité lumineuse.

[Traduit par le journal]

Introduction

The structure and reactivity of excited organic triplet states in photochemical reactions have received much theoretical and experimental attention in the past 15 years. In liquid photochemical systems the triplet state is normally populated via rapid intersystem crossing from the lowest excited singlet to the sublevels of the triplet state. When more than one triplet state are available below the first excited singlet, it is not easy to establish which of the triplet states is mainly responsible for the observed chemical reaction. A classical example is the photochemistry of 4-benzoylbiphenyl. This system has been extensively studied (1). Some of the interesting features known are that 4-benzoylbiphenyl has two excited triplet states below the first excited singlet and the lowest triplet is characteristic of a π,π^* state. Turro and Lee (2) have demonstrated that this triplet state can abstract hydrogen atoms from alcohol solvent, although its reactivity is much less than that of the corresponding n,π^* triplet reaction of benzophenone. Arguments have been put forward (1*b*, 3) that the low lying π,π^* triplet states have some intrinsic chemical property. Direct evidence, however, is still lacking.

Recently we have been concerned with the establishment of the role of the triplet state in CIDEP (4) and CIDNP (5) systems involving carbonyl compounds. We wish to extend the application of esr and magnetic polarization studies to the correlation of structure and reactivity of the 4-benzoylbiphenyl triplet. The triplet esr study reveals a systematic and subtle correlation between biphenyl and a series of 4-phenyl substituted aromatic and alkyl aromatic ketones. The meager intrinsic chemical property of these ketones may be related to the structures of their characteristic π,π^* triplets. The high sensitivity of CIDNP technique in the present study afforded the direct investigation of the minor chemical reactions of these π,π^* triplets. No experimental evidence of CIDEP was observed in the 4-benzoylbiphenyl system and this is consistent with our theory (4) since the chemical rate involving the π,π^* triplet is too slow compared to its depolarization rate via spin–lattice relaxation.

TABLE 1. Experimental zero-field parameters (in 10^{-4} cm^{-1}) for triplet biphenyl ketones in ethanol glass at 77 K

Parameter	Biphenyl	4-Benzoyl biphenyl	4-Phenyl acetophenone	*p*-Phenyl γ-methyl valerophenone	Benzophenone[a] (n,π* triplet)

[a]The D and E values for benzophenone n,π* triplet are taken from ref. 19 and are given here for comparison.
[b]The values are taken from ref. 11.
[c]The values are taken from ref. 12.

Experimental

Samples of the carbonyl compounds were repeatedly recrystallized before use. For the triplet esr studies, ethanol solutions containing approximately 0.01 M of the carbonyl compound in 3 mm suprasil tubes were degassed under vacuum. The samples were irradiated at 77 K within the cavity of a Varian E-3 spectrometer. The light source was a 1 kW super pressure mercury lamp. The triplet spectra were recorded at 9.30 GHz and were calibrated against the known triplet biphenyl spectrum. Kinetic measurements of the triplets were made at a constant field ($\Delta M = 2$) using a rotating sector and an instrument computer described previously (6).

CIDNP studies were carried out using a Bruker HX60 nmr spectrometer and a modified probe to allow light irradiation via a reflecting mirror and lens assembly. The light source was the 1 kW mercury lamp. Sample solutions were degassed before use. Isopropanol used in the CIDNP experiments was purified by passing through an alumina column. Variation of light intensity in the CIDNP experiments was accomplished by using a set of calibrated screen filters.

Results and Discussion

1. Triplet Electron Spin Resonance Studies at 77 K

Photolysis at 77 K of both 4-phenylacetophenone and 4-benzoylbiphenyl, respectively, gave readily detectable $\Delta M = 2$ esr signals. Of the six possible high field ($\Delta M = 1$) signals only four (corresponding to the x and y features) were observed. The z features were too weak for detection as they are usually the weakest of the high field transitions. The approximate values of the zero field parameters $|D|$ and $|E|$ can, however, be calculated from the observed x and y transitions, which have a doublet splitting approximately equal to $(D - 3E)$ and $(D + 3E)$, respectively. These values are given in Table 1.

The decay kinetics of the triplet 4-phenylacetophenone and 4-benzoylbiphenyl were found to be first-order with a half-life τ of 0.23 s for the triplet phenylacetophenone and 0.24 s for the triplet benzoylbiphenyl. The long half-life values together with the observed zero-field parameters strongly suggest that the lowest triplet state of these two ketones is the π,π* configuration. This assignment is consistent with those reported in literature (1, 7). However, in the case of 4-benzoylbiphenyl the π,π* triplet state was assigned to the biphenyl moiety exclusively (1*a*), as concluded from the evidence that the phosphorescence spectrum of 4-benzoylbiphenyl is very similar to that of hydroxybiphenyl. An alternative assignment to the conjugated system involving both the biphenyl and the carbonyl groups was rejected by the authors (1*a*) based on the infrared spectroscopic evidence that the carbonyl and the biphenyl groups are non-coplanar in the ground state molecule (8). Since the geometry of the triplet molecule need not be the same as that of the ground state, we must argue that the conjugation between the carbonyl and the biphenyl moieties in the triplet 4-benzoylbiphenyl cannot be excluded by the phosphorescence study alone. For example, while the ground state of the molecule biphenyl is known to be nonplanar (9), Wagner (10) has shown that the triplet biphenyl is planar.

Similar triplet esr observations were made in the photolysis of *p*-phenyl-γ-methylvalerophenone. Table 1 presents a correlation of the zero-field parameters between biphenyl and the three biphenyl ketones. The coordinates for the biphenyl ketones are the same as those in biphenyl (11). Hence $D = -\frac{3}{2}z$ and $E = (y - x)/2$. The high field lines will then appear in the order $H_z^- < H_x^- < H_y^- < H_y^+ < H_x^+ < H_z^+$, here

the superscripts + and − refer to the higher and lower magnetic field.

The correlation presented in Table 1 reveals a few very important points. The zero-field energies x and $(z + y)$ have almost identical values for biphenyl and the ketones. Furthermore, the experimental observation showed that the positions of the high field signals H_x^- and H_x^+ appeared at nearly the same magnetic field for all these compounds and that the corresponding separations $H_x^+ - H_x^-$ are always equal to $-\frac{3}{2}$ (z − x + y). On the other hand, the zero-field energies y and z for the ketones are significantly different from the values of biphenyl. However, the relative changes in y and z values for the ketones are comparable to the corresponding change in biphenyl. This implies that the free spin delocalization in the xz and the xy molecular planes of the biphenyl ketones occurs to the same extent, as in biphenyl. Among the series of the biphenyl ketones studied, the results indicated that the zero-field energies are not affected by the group R bonded to the carbonyl.

In order to understand the significance of the correlation between the biphenyl and the biphenyl ketones listed in Table 1, it is worthwhile to consider a similar relationship between the zero-field parameters of biphenyl and *p*-terphenyl. Here we take the D and E values of the biphenyl and *p*-terphenyl from a theoretical calculation by Orloff and Brinen (13) and we work out the corresponding energies for x, y, z, and $(z + x)$. It should be noted that the theoretical values of E were given a positive sign by the authors (13) but their coordinate systems were the same as used throughout this paper. Despite the difference in the sign of the E values, we will show that the trend of the zero-field energies will give some insight to the structure of the biphenyl ketone triplets. The calculated energies for biphenyl and *p*-terphenyl are given in Table 2. It can be seen that the presumed order in which the $\Delta M = 1$ signals appear should be the same as that observed in the biphenyl ketone triplets. The calculated values for y and for $(z + x)$ are almost identical for both biphenyl and *p*-terphenyl. Thus the high field signals H_y^- and H_y^+ for both biphenyl and *p*-terphenyl would appear at approximately the same field and their doublet splittings $H_y^+ - H_y^-$ would be approximately equal to $-\frac{3}{2}(z + x - y)$. The relative changes in the parameters between the biphenyl and *p*-terphenyl are similar in trend and in magnitude as those between biphenyl and the biphenyl ketones. The similarity is indeed striking. In Table 1 the near stationary values of the signals H_x^- and H_x^+ are observed. In Table 2 the predicted stationary lines are the H_y^- and H_y^+. This is merely due to the different signs for the E values used in the two tables.

TABLE 2. Calculated zero-field parameters (in 10^{-4} cm^{-1}) for the triplet biphenyl and the triplet *p*-terphenyl

Parameter	Biphenyl	*p*-Terphenyl
D	1160[a]	1030[a]
E	60[a]	10[a]
x	440	350
y	320	330
z	−760	−680
$z + x$	−320	−330

[a]These values are taken from the theoretical calculations in ref. 13.

The correlation presented in Table 2 takes into account the planarity of the biphenyl and the terphenyl triplets and the consequent assumption of a double bond character for the carbon–carbon bond between the phenyl rings. It is expected that the zero-field energies are sensitive to a torsion of the central bond and to the nature of the carbon–carbon bond between the rings (13). The lower D and E values in *p*-terphenyl relative to the biphenyl clearly reflect the free spin delocalization onto the third coplanar phenyl ring. By analogy, the observed lower values in the biphenyl ketones as compared to biphenyl suggest some delocalization of the free spin onto the carbonyl group, probably achieved in a similar manner as in *p*-terphenyl:

$^3\pi\pi^*$ **B**

Here the triplet biphenyl ketone represented by the valence bond resonance structure **B** requires that the biphenyl and the carbonyl groups be coplanar with substantial spin density at the carbonyl oxygen atom. It is thought that it is the contribution of this resonance structure in the triplet that leads to the hydrogen abstraction reaction. It should be noted that the resonance structure **B** may also be derived from the n,π* triplet state, but the extent of the contribution

may be entirely different in different triplet states.

CIDNP Studies

Despite the low overall chemical reactivity of the triplet biphenyl ketones, the extremely high sensitivity of the CIDNP technique afforded a direct probe of the mechanism of these chemical reactions. During the photolysis of a 0.01 *M* solution of 4-benzoylbiphenyl in isopropanol, the aromatic protons of the parent ketone exhibited CIDNP in the enhanced absorption mode (Fig. 1). When a similar isopropanol solution of 4-phenylacetophenone was photolyzed, only the methyl protons of the ketone exhibited polarization in the emissive mode. However, when pentachlorophenol was added to the solution as a more efficient hydrogen donor, both the methyl protons and the aromatic protons of the ketone showed polarization with the methyl protons in emission and the *ortho* protons enhanced absorption (Fig. 2). The polarization of the methyl protons observed in the presence of pentachlorophenol as the hydrogen donor was very much larger than that in isopropanol alone. Similarly,

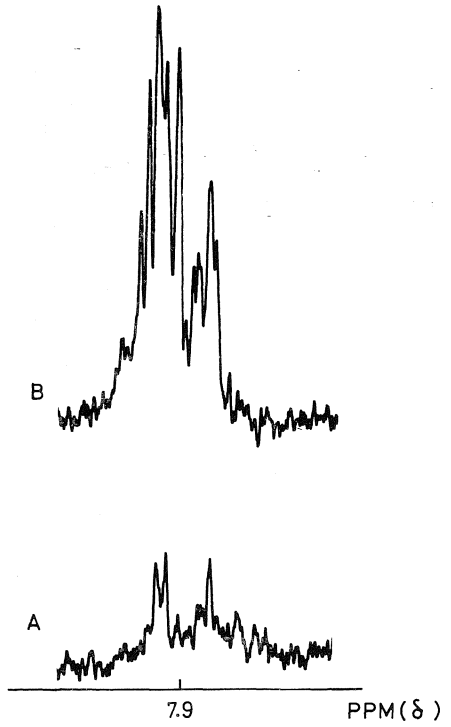

FIG. 1. Nuclear magnetic resonance spectra recorded before (A) and during (B) the photolysis of 4-benzoylbiphenyl in isopropanol.

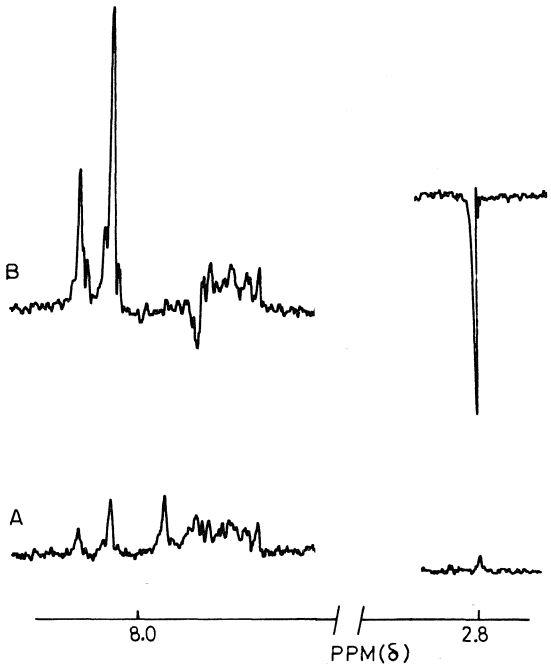

FIG. 2. Nuclear magnetic resonance spectra recorded before (A) and during (B) the photolysis of 4-phenylacetophenone and pentachlorophenol in isopropanol. The methyl proton spectrum at δ 2.8 was recorded at a much lower sensitivity than that of the aromatic protons at δ 8.0.

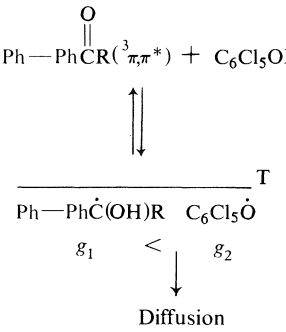
the addition of pentachlorophenol to the isopropanol solution of 4-benzoylbiphenyl increased the polarization magnitude.

These CIDNP observations in the biphenyl ketone – chlorophenyl systems can be readily explained by the Kaptein's rules at high field (14) according to the following reaction scheme:



For the 4-benzoylbiphenyl, R is a phenyl group. For the 4-phenylacetophenone, R is a methyl group. From esr measurements it was found that the *g*-value for the pentachlorophenoxy radical is greater than that of the ketyl radical. By

analogy to the benzophenone (15) and isopropyl ketyl radicals (16), the hyperfine coupling constants are assumed to be positive for the methyl protons ($a_{CH_3} = +17$ G) and the *meta* protons ($a_H^{meta} = +1.2$ G), and negative for the *ortho* and *para* protons ($a_H^{ortho} = -3.24$ G, $a_H^{para} = -3.7$ G). With these parameters and the triplet ketone as the precursor, the cage product (which is the parent ketone) would exhibit CIDNP with the methyl protons strongly emissive and the *ortho* protons enhanced absorptive.

Further evidence that the observed CIDNP originates from the cage reaction is provided by the steady-state CIDNP intensity dependence on the irradiating light intensity. This is shown in Fig. 3 for the methyl proton CIDNP intensity as a linear function of light intensity.

It should be mentioned here that during the photolysis of 4-phenylacetophenone and pentachlorophenol in acetone-d_6 or in CD_3CN, no CIDNP from the enol of the parent ketone was ever observed.

While the presence of the ketyl and phenoxy radical intermediates can be inferred from the CIDNP experiments, the primary photochemical abstraction reactions of the triplet biphenyl ketones can be studied directly by esr. For example, during the photolysis of 4-benzoylbiphenyl in the presence of 2,6-di-*tert*-butylphenol, the esr spectrum of the corresponding phenoxy radical was readily observed. However, unlike the benzophenone and phenol system (17), the counter phenoxy radical did not exhibit any polarization. CIDEP was not expected to be observed in the present systems, since the chemical reaction rate would be too slow compared to the triplet depolarization rate.

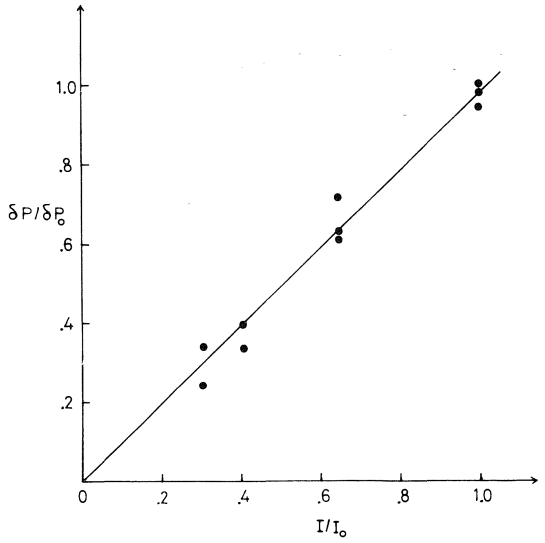


FIG. 3. The CIDNP intensity ($\delta P/\delta P_0$) of the methyl protons in the photolysis of 4-phenylacetophenone as a function of light intensity (I/I_0). δP is the steady-state emission intensity at light intensity I; δP_0 is the corresponding CIDNP intensity at the unattenuated light intensity I_0.

The CIDNP experiments together with the triplet esr study clearly demonstrated that the biphenyl ketones with their lowest π,π^* triplet states can undergo photoreduction, similar to those ketones with lowest n,π^* triplet states. An immediate question arose. Does the chemical reactivity of the biphenyl ketones truly involve the lowest π,π^* triplet? Wagner and co-workers (12) have discussed the various probable pathways by which triplet reactivity can manifest in phenyl ketones with lowest triplet π,π^* state. Analysis of the reactivity of various *p*-methoxy phenyl ketones (7) strongly suggests that the hydrogen abstraction reaction involves the upper n,π^* triplet state, populated via a thermal equilibration with the lower π,π^* triplet state. The thermal relaxation mechanism in these methoxy phenyl ketone systems is not unreasonable, since the separation between the upper n,π^* and the lower π,π^* triplet states is of the order of 3 kcal/mol (7). However, in the present biphenyl ketone systems the separation between the two triplet states can be as high as 9 to 14 kcal/mol, as estimated from the phosphorescence data (1*a*, 4). It would then appear unlikely that the photoreduction of these biphenyl ketones involves the upper n,π^* triplets via thermal relaxation from the lower π,π^* triplets.

Another mechanism which can impart triplet reactivity for ketones with lowest π,π^* triplet state is the vibronic coupling between the lower π,π^* and the upper n,π^* triplet states (18). This mechanism is again not likely to be significant in the biphenyl ketone systems due to the large separation between the two triplet states. Furthermore, the relative insensitivity of the phosphorescence life-times of the biphenyl ketones (1*b*, 7, 12) to the nature of the medium supports this conclusion.

Finally, we are inclined to believe that in these biphenyl ketones the photoreduction originates from the lower π,π^* triplet without the involvement of the upper n,π^* triplet state. The chemical reactivity of these π,π^* triplets may well be

due to their coplanar structure which leads to a substantial unpaired spin density at the carbonyl oxygen atom.

Uniform quality constrained gaussian basis sets

PAUL G. MEZEY AND IMRE G. CSIZMADIA
Department of Chemistry, University of Toronto, Toronto, Ont., Canada M5S 1A1

Received October 8, 1976

PAUL G. MEZEY and IMRE G. CSIZMADIA. Can. J. Chem. **55**, 1181 (1977).

Uniformly balanced (6^s3^p), (7^s3^p), and (8^s4^p) gaussian basis sets with identical exponent sets for functions describing the $2s$ and $2p$ subshells have been obtained for the first row atoms. The basis sets have been determined using a direct optimization technique; they are thoroughly balanced and satisfy a rigorous quality criterion. These uniform quality constrained basis sets were designed for applications in *ab initio* programs of the type of the GAUSSIAN 70 program system, that may utilize the integration-time saving constraint $\alpha_{2s} = \alpha_{2p}$.

PAUL G. MEZEY et IMRE G. CSIZMADIA. Can. J. Chem. **55**, 1181 (1977).

On a obtenu des ensembles (6^s3^p), (7^s3^p) et (8^s4^p) à base gaussienne balancés d'une façon uniforme comportant des ensembles d'exposants identiques pour les fonctions décrivant les sous-couches $2s$ et $2p$ des atomes de la première rangée. On a déterminé les ensembles de base en utilisant une technique d'optimisation directe; ils sont bien balancés et satisfont un critère de qualité rigoureux. On a développé ces ensembles de base de qualité uniforme contrainte afin de les utiliser dans des programmes *ab initio* du type du système de programme "Gaussian 70" qui peuvent être utilisés pour la contrainte $\alpha_{2s} = \alpha_{2p}$ qui permet de sauver du temps lors de l'intégration.

[Traduit par le journal]

Introduction

Since the introduction of gaussian basis sets with identical radial parts for $2s$ and $2p$ type functions (1), the simplification thus resulted in the evaluation of integrals in *ab initio* calculations has brought about a dramatic increase in the number of *ab initio* MO studies undertaken. The fact that this constraint introduced in the basis sets has only a relatively minor effect on the accuracy of the calculated results and also the ready applicability of the Gaussian 70 program system, developed by Pople and co-workers (2) for the utilization of such basis sets, encouraged many theoretical investigations, mostly in the field of organic chemistry. Consequently, the application of constrained basis sets has proven to be a major breakthrough in computational theoretical chemistry.

In a recent study on gaussian basis sets (3, 4) several uniform quality bases have been proposed for a series of atoms. The quality of these basis sets has been defined in terms of the "balance" of the exponents, as expressed by the logarithmic energy gradients (with components $G_i = \partial E/\partial \log \alpha_i$) in the space of the orbital exponents, α_i. For a fully optimized basis set these "forces" in the exponent space are at "balance", *i.e.* the gradient vector $\boldsymbol{G}$ is zero. The degree of optimization, the quality or "balance" of any basis set may be characterized by these "forces", *i.e.* by the length of the corresponding gradient vector. Previous studies (5) indicated that a "5×10^{-5} quality" (*i.e.* $|\boldsymbol{g}| \equiv |\boldsymbol{G}|/\sqrt{n} \leqslant 5 \times 10^{-5}$) is sufficient to ensure the convergence of total energy as well as various one-electron properties to the limits inherent in the size (n) of the basis set.

Results and Discussion

Due to the particular importance of constrained basis sets this study has been undertaken to apply the above quality characterization and the uniform quality principle to constrained gaussian bases. For the gaussian type functions describing the $2s$ and $2p$ subshells the integration-time saving $\alpha_{2s} = \alpha_{2p}$ constraint has been applied. In the present work three series of uniform quality *constrained* basis sets are reported for the first row atoms from B to F. These constrained basis sets are compatible with previously published uniform quality basis sets for Li and Be (and H) where the constraint does not apply (3, 4). The previously unpublished (7^s) Li and Be bases are reported here.

In the direct optimization procedure for the open shell energy functional $E(\alpha)$ described elsewhere (5) appropriate modifications have been carried out to accomodate this constraint.

Since the conjugate gradient optimization technique (6) in the basis set optimization method is applicable to unconstrained variables only, exponents $\alpha_{i(2s)}$, $\alpha_{i(2p_x)}$, $\alpha_{i(2p_y)}$, and $\alpha_{i(2p_z)}$ were regarded as one single variable α_i. The corresponding element of the gradient was taken as

$$[1] \quad G_i = \frac{\partial E}{\partial \log \alpha_i} = \frac{\partial E}{\partial \log \alpha_{i(2s)}} + \frac{\partial E}{\partial \log \alpha_{i(2p_x)}} + \frac{\partial E}{\partial \log \alpha_{i(2p_y)}} + \frac{\partial E}{\partial \log \alpha_{i(2p_z)}}$$

This definition of component G_i results in appropriate weighting as compared to components belonging to the 1*s* subset.

In general, the optimum of a fully relaxed basis set ($\alpha_{i(2s)} \neq \alpha_{i(2p)}$ allowed) is different from the optimum of a constrained basis ($\alpha_{i(2s)} = \alpha_{i(2p)}$). At the optimum of a fully relaxed basis set the individual terms on the right side of eq. 1 are all zero. For a constrained set, however, only the sum of these terms is required to be zero. The individual energy-gradient components have been calculated using the same technique as described earlier (5). For the joint optimization of the linear parameters (MO coefficients) and nonlinear parameters (orbital exponents) a combination of Roothaan's open shell technique (7) and the method of conjugate gradients has been used (5).

A computer program has been developed for the outlined quasi-constrained optimization problem of the open shell energy functional. All calculations reported in the present study have been carried out on the IBM 370/165 computer at the University of Toronto.

Throughout the optimizations the condition

$$|g| \leqslant 5 \times 10^{-5}$$

has been regarded as the final quality criterion. The optimized (6^s3^p), (7^s3^p), and (8^s4^p) uniform quality (U.Q.) constrained gaussian basis sets are listed in Tables 1, 2, and 3, respectively. Along the orbital exponents the calculated total energy, orbital energies and virial coefficient are also included in the tables.[1]

It is noteworthy that at the actual optimum points of the various basis spaces, the additive terms on the right side of expression [1], *i.e.* most of the gradient components formally belonging to the valence shell, are rather large. A magnitude of the order of 2×10^{-2} is characteristic. As gradient lengths of this order are characteristic of rather crude basis sets, this finding indicates that optima of the constrained sets are, indeed, far from being balanced if the constraints are removed.

A close inspection of the linear coefficients of the calculated optimum wavefunctions revealed several "natural" contraction schemes for the U.Q. constrained bases. These natural contractions follow the most closely the grouping and general pattern of uncontracted linear coefficients as shown by their sign changes and ratios. The various contraction schemes and contraction coefficients for basis series (6^s3^p), (7^s3^p), and (8^s4^p) are presented in Tables 4, 5, and 6, respectively. While "split valence shell" contractions (B), (C), and (D) are recommended for MO calculations, "minimum" contraction (A) appears to represent the valence region poorly. Any different "non-natural" minimum contraction scheme, however, may introduce a significant strain on the carefully balanced exponent set itself and the uniform quality principle would no longer apply. This type of interrelation between optimum contractions and optimum exponent sets is the subject of a study, now under way (8).

In Table 7 total energies calculated with previously published, *unconstrained* uniform quality basis sets (3, 4) are compared with the present values. In general, the constraint results in a larger increase in energy if more electrons are in the valence shell. For the (6^s3^p) basis series the energy difference appears to be roughly proportional to the calculated total energy, the (8^s4^p) series shows larger deviations from such a proportionality. Also, for the latter series the deviations are significantly larger, indicating that for larger basis sets the constraint represents a more serious restriction. Though for $n \rightarrow \infty$ the energies calculated with constrained and unconstrained basis sets both converge to the *sp* limit, the above observation casts some doubt on the overall effectiveness of applying the constraint on significantly larger basis sets, as the improvement of the $n \rightarrow n + 1$ extension of a constrained basis relative to that of the unconstrained basis may become much too inferior for larger *n*.

[1]The FORTRAN subroutines that incorporate the new basis sets and are compatible with the corresponding GAUSSIAN 70 routines will be submitted to QCPE (Indiana University, Bloomington, IN) shortly.

Cathodic luminescence of oxide covered aluminium and tantalum electrodes in various electrolyte solutions was measured at low amplitude (0 to 10 V) ac excitation. Oxygen or hydrogen peroxide are necessary constituents of the solution for high levels of light emission. For the aluminium electrode in tartrate solutions, copper enhanced light emission at concentrations down to 10 ppb.

The tantalum electrode gave fairly high luminescence in solutions containing sodium perchlorate, perchloric acid, and hydrogen peroxide, but copper had no influence on the luminescence output. A mechanism based on the electrogeneration of singlet oxygen and its subsequent radiative transition to the triplet state is suggested.

JOUKO J. KANKARE, DOUGLAS E. RYAN et BERNHARD J. FÜRST. Can. J. Chem. **55**, 1193 (1977).

On a mesuré à des amplitudes basses (0 à 10 V) d'excitation ac, la luminescence cathodique dans diverses solutions d'électrolytes, d'électrodes d'aluminium et de tantale couvertes par de l'oxyde. La présence d'oxygène ou de peroxyde d'hydrogène est nécessaire dans les solutions pour obtenir des hauts niveaux d'émission de lumière. Dans le cas d'électrodes d'aluminium dans des solutions de tartrate, le cuivre augmente l'émission de lumière à des concentrations allant jusqu'à 10 ppb.

L'électrode de tantale fournit des luminescences assez élevées dans des solutions contenant du perchlorate de sodium, d'acide perchlorique et du peroxyde d'hydrogène mais le cuivre n'a aucune influence sur le rendement de luminescence. On suggère un mécanisme basé sur une électrogénération de l'oxygène à l'état singulet et sa transition radiative subséquente vers l'état triplet.

[Traduit par le journal]

The electroluminescence or galvanoluminescence of valve metals, of which Al and Ta are the most familiar, has been known for a long time (1). By placing two electrodes into an electrolyte solution, one of which is aluminium (and the other any conductive material), and applying direct current so that the aluminium electrode is positive, light is emitted from the aluminium surface at sufficiently high voltages. It was later noted that light was emitted momentarily also when the polarity was changed. Aluminium could be substituted by other metals capable of forming insulating oxide coatings, although light was brightest with aluminium.

Electroluminescence of valve metals has not been a subject of intensive research work and the number of articles dealing with this phenomenon is relatively low. However, various theories have been put forth about the origin of light. The first hypothesis (2) was that the light was due to electric discharges inside the minute gas bubbles formed on the surface of the electrode. This hypothesis was later rejected by Anderson (3) because the spectrum of light was found to be independent of the composition of the solution. Anderson's theory was based on the combination of ionic and electronic currents with the radiation being due to the electron–hole recombination within the supposedly semiconducting oxide layer. Though published in the early forties, the theory was surprisingly modern and it was subject to only minor modifications as a result of the extensive studies of van Geel and co-workers (4) in 1957. Further support for the solid state electroluminescence character of the anodic luminescence was provided by two rather recent articles by Ganley and co-workers (5, 6). Ganley showed that the spectrum of the light emitted by an aluminium anode depends on the impurities in the metal. The striking discovery was that the spectrum of the cathodic luminescence was essentially independent of the impurities. Ganley suggested that the cathodic luminescence may

[1]On sabbatical leave from the University of Turku, Finland.

[2]To whom correspondence should be addressed.

not be electroluminescence at all but did not give any hypothesis on an alternative mechanism. A comprehensive and up-to-date review article on the subject is available (7).

This study was initially undertaken in order to find possible analytical applications of electroluminescence. Later on, when certain interesting results emerged from the study, the character of the work became of a more fundamental nature.

Methods of Measurement

Both direct and alternating currents have been used in studies of electroluminescence. The use of dc has been mostly confined to anodic luminescence, partly because the 'continuous cathodic glow' is extremely weak. The oxide layer is gradually damaged during the continuous cathodic high current conditions. With ac, a kind of steady state (where the oxide layer is restored during the positive half-periods) is hopefully achieved. In order to render the capacitive effects harmless and also to be able to sample the dark current of the photomultiplier tube, it is useful to include a region with zero volts between the pulses. The pulse train of the shape shown in Fig. 1 has also been used by van Geel and co-workers (4); this allows the use of a lock-in amplifier, a powerful tool in picking up a weak signal from the background noise. The total period of the pulse train is four times the original period.

There are two different approaches for measuring the light emission from the electrode. One is to apply a pulse train of a constant amplitude and record the decay of the light emission as a function of time. Another method is to scan the amplitude of the pulses and record the light intensity.

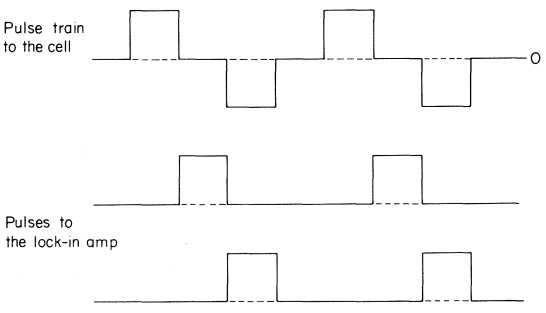

FIG. 1. Pulse trains applied to the cell and the lock-in amplifier.

Experimental

Cell

Figure 2 shows the structure of the cell and electrodes. The valve metal electrode was a 20 mm diameter circle cut from metal foil of 0.25 mm thickness. The foil was cemented to a brass shaft using silver-epoxy. The brass shaft was embedded and cemented into a Teflon® piece to insulate it from the solution. The materials used for the electrodes were aluminium of 99.999% purity (Alfa-Ventron) and tantalum of 99.98% purity (Alfa-Ventron).

The electrodes were polished mechanically using γ-alumina (Gamal®, Fisher, particle size <0.1 μm). The aluminium electrode was polished chemically in a mixture of 14 parts of 85% *o*-phosphoric acid, 5 parts of 18 F sulfuric acid and 1 part of 12 F nitric acid at 85°C. The composition of the solution used for chemical polishing of tantalum was 5 parts of sulfuric acid, 2 parts of nitric acid, and 2 parts of 50% hydrofluoric acid.

The anodization of the aluminium electrode was performed in the same supporting electrolyte as in the accompanying experiments. The anodization was done at a constant current (*ca.* 1 mA/cm^2) until a cell voltage of 11.5 V was attained and continued at this voltage until the current was below 50 μA. In the case of the tantalum electrode, the anodization was done in 0.1 *M* sulfuric acid until a 3 to 4 μA current was attained.

Apparatus

Figure 3 shows a block diagram of the apparatus used. The normal square wave from a function generator (Wavetek, Model 180) was divided by four in order to obtain the gate pulses for the lock-in amplifier and waveform generator. The wavelength generator consists of an adjustable ramp generator and a power amplifier. The photomultiplier (PM) tube was EMI 9592 B with an S 10 spectral response. The power supply for the PM tube was Kepco ABC 1500. The output of the PM tube was amplified by using a simple FET switched lock-in amplifier and recorded on a Fisher X–Y recorder (Model 100 XY).

A Jarrell-Ash monochromator (Model 82-410), with both the input and output slits removed, was used to record the spectrum. The spectral resolution of *ca.* 40 nm was determined using a mercury calibration

source. In this case the output from the lock-in amplifier was integrated using a simple op amp integrator.

Results and Discussion

Aluminium Electrode

Measurements in tartrate solutions were made at *ca.* p*H* 6, because the influence of copper on the light intensity had a broad maximum at this p*H*. The length of the pulses applied to the cell was maintained at 10 ms; no radical change in the light intensity or curve shape was found on varying the pulse length from 50 to 2 ms.

In order to swamp the possible influence of the supporting electrolyte, its concentration was maintained at 0.1 *M* in all of the experiments. Figure 4 shows the influence of 0.1 ppm copper on the luminescence. The shape of the curve bears some resemblance to the voltammetric curves on a stationary electrode and suggests a diffusion controlled process. The removal of oxygen by bubbling nitrogen through the solution had a profound effect on the light intensity (Fig. 5).

These experimental results suggest that the cathodic luminescence, at voltage levels of less than −10 V, is due to electrogenerated chemiluminescence. Luminescence is, however, observed in such different kinds of solutions that it restricts the possible chemiluminescent reactions to the electrogeneration of singlet oxygen, $^1O_2$, and its subsequent radiative transition to the triplet ground state. Search of previous publications shows that none of the authors has paid particular attention to removing oxygen from their solutions.

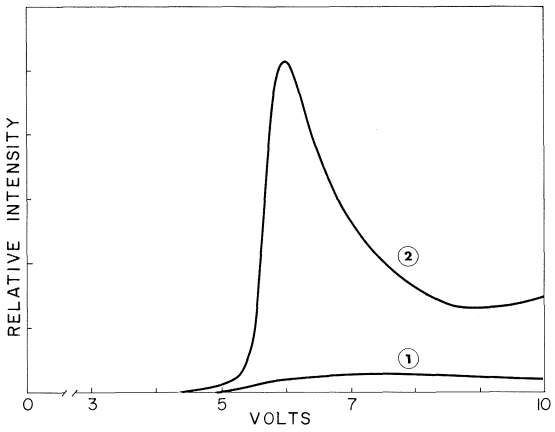

FIG. 4. Influence of copper on the electroluminescence. Curve *1*: 0.1 *M* solution of sodium tartrate at p*H* 6.2. Curve *2*: 0.1 ppm Cu(II) added to the solution.

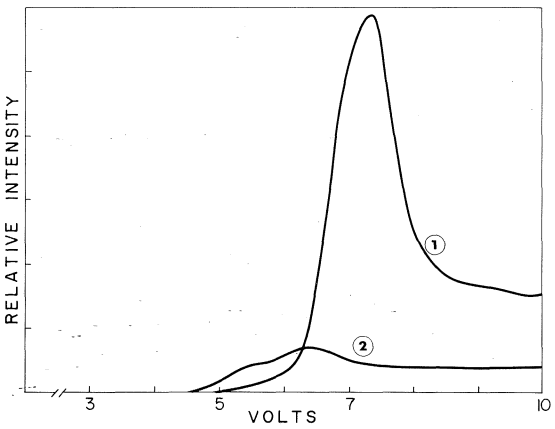

FIG. 5. Influence of the removal of oxygen on the electroluminescence. Curve *1*: 0.1 ppm Cu(II) in 0.1 *M* sodium tartrate at p*H* 6.2. Curve *2*: the same solution but nitrogen bubbled through for 30 min.

Some examples of copper catalyzed chemiluminescent reactions are reported in the literature. Stauff and co-worker showed that copper catalyzes the auto-oxidation of sulfite (8) and cystein (9) reactions which produce light. They proposed a mechanism which is based on the generation and radiative transition of singlet oxygen dimer. The role of the copper complex is to form mixed ligand complexes with oxygen radicals HO· and HO_2· thus prolonging their lifetime. In the present study, the possible copper complex may be either homogeneous copper tartrate in solution or a copper species adsorbed on the surface of the electrode. In the latter case the surface would become com-

pletely covered at a low concentration level and the light intensity would level off with increasing copper concentration.

That this is indeed the case can be seen in Fig. 6. The plot of light intensity *vs.* copper concentration is quite linear up to *ca.* 10^{-5} *M*, has a maximum at *ca.* 3×10^{-5} *M*, and then the intensity continuously decreases with increasing copper concentration. This decrease can be explained on the basis of competition of the surface-bound and soluble copper for HO· and HO_2· radicals. If the phenomenon is due to a sorbed copper species, there are several alternatives as to the structure of the species. The simplest possibility is copper chemisorbed on alumina. Aluminium oxide is known to form fairly stable complexes with copper(II) ions (10). The presence of this species could be checked by studying the influence of supporting electrolyte. If the catalyzing species is copper chemisorbed on alumina, then the better the complexing agent used as electrolyte the weaker should be the influence of copper on the light emission. This was tested by using a series of three dicarboxylic acids (tartaric, malic, and succinic acids); these acids were selected because of their similar carbon skeletons, but different complexing abilities. In the presence of malic and succinic acids (measured at p*H* 6.1 to 6.3 in 0.1 *M* solutions) copper does not enhance the luminescence, although the stability constants of the copper malate and succinate are considerably lower than that of copper tartrate.

An additional experiment with acetate showed that also in this medium, copper did not enhance the luminescence. Thus the catalyzing species presumably is not copper chemisorbed on alumina.

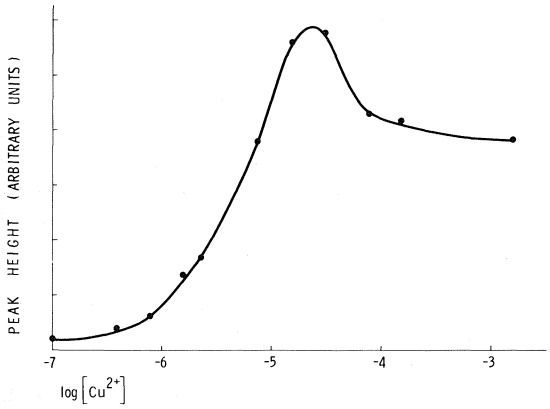

FIG. 6. Influence of copper on the peak height of the electroluminescence curve. Supporting electrolyte is 0.1 *M* sodium tartrate at p*H* 6.2.

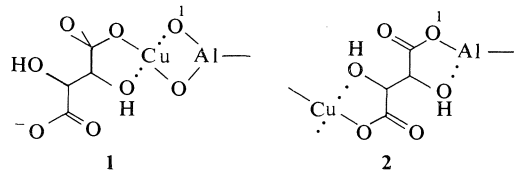
The second possible structure for the copper species is chemisorbed copper tartrate. This complexation may occur in two different ways:



1 2

There are facts in support of structure **2**. Structure **1** does not explain the special status of tartrate; there are no obvious reasons why the other ligands are ineffective in promoting luminescence together with copper ions. On the other hand, copper ions and tartrate are known to form polymeric complexes, and it is assumed that in these complexes there is an analogous tartrate bridge as in structure **2** (11).

Malate forms also a dimeric complex with copper but in this complex the two copper atoms are linked together by an oxygen bridge. Thus structure **2** seems to have a capability of explaining the unique behaviour of tartrate.

Tantalum Electrode

The surface of aluminium is easily corroded and during the experiments the surface must be frequently polished and reanodized. Tantalum is chemically more resistant; it forms a tough oxide layer and it is known to be electroluminescent. In the hope that more reproducible results could be obtained, further experiments were directed to the study of the feasibility of the tantalum electrode. Surprisingly, the first experiments with several electrolytes using a freshly anodized electrode gave nearly no luminescence. After several repeated scans from 0 to 10 V, during which the light emission continuously increased, the output curve of the emission attained a constant form. As with aluminium, it was also found that the intensity of the light emission was highly dependent on the concentration of oxygen in the solution; oxygen could be replaced by hydrogen peroxide and its concentration could be more easily varied.

Tartrate was found to provide a favourable medium for electroluminescence studies with the tantalum electrode. Copper, however, had no significant influence on the intensity of the

light emission (this might be attributed to the poor chemisorption of copper tartrate on the tantalum pentoxide surface).

Studies were now directed to electroluminescence in perchlorate solutions. This medium was chosen because it was felt that more information could be gained about the basic phenomenon in a simple inorganic non-complexing solution. In the first experiments the acidity was varied and the ionic strength was maintained at one with sodium perchlorate; the concentration of hydrogen peroxide was 10^{-3} *M*. Figure 7 shows the electroluminescence curves obtained by scanning the pulse amplitude. The curve at the lowest acid concentration, 0.002 *M*, is seen to be composed of one peak or two overlapping peaks. At higher acid concentrations, the peaks are separated so that the position of the peak at lower voltage is maintained nearly constant whereas the peak at higher voltage is shifted, flattened, and eventually disappears. The reduction of the light intensity to nearly zero at higher voltages cannot be easily explained by solid state electroluminescence. If the origin of light is solid state electroluminescence then it is probable that the light intensity is a monotonously increasing function of current. However, the Faradaic current (as estimated from an oscilloscopic trace) is *ca.* five times higher at 9 V than at 4 V, although the light intensity itself is nearly zero (Fig. 7). If we adopt the *ad hoc* hypothesis that the light arises from a chemiluminescent reaction involving oxygen radicals, there are several alternative explanations.

One possibility is that the two maxima are due to two different reduction mechanisms

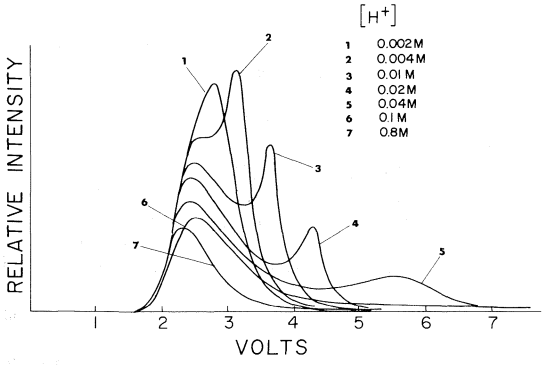


FIG. 7. Electroluminescence curves of the tantalum electrode at different acid concentrations. $[ClO^-_4] = 1\ M$ $[H_2O_2] = 10^{-3}\ M$.

which become prevalent at different voltages. The last stage before the very fast light emitting step should be the electron transfer to the substrate, because no light is emitted during the positive pulses. The reduction step should be a one-electron transfer in order to lead to light emitting species (9). However, it is not easily conceivable that from the same reagent (hydrogen peroxide) we get the same product (singlet oxygen) via two different mechanisms. It is more likely that one of the peaks is due to the reduction of hydrogen peroxide, the other due to oxygen. Schematically, without taking into account the possible complex formation with tantalum pentoxide, we can write the mechanisms:

$$H_2O_2 + e \rightarrow HO\cdot + HO^-$$

$$H_2O_2 + HO\cdot \rightarrow HO_2\cdot + H_2O$$

$$O_2 + e \rightarrow O_2^-$$

$$O_2^- + H^+ \rightleftarrows HO_2\cdot$$

$$2HO_2\cdot \rightarrow H_2O_2 + {}^1O_2$$

$$2{}^1O_2 \rightarrow ({}^1O_2)_2 \rightarrow 2{}^3O_2 + h\nu$$

At higher potential the rate of the electrochemical reduction of the oxygen radicals competes with the formation of singlet oxygen thus reducing the chemiluminescence.

The other alternative is that the first peak is due to the reduction of chemisorbed hydrogen peroxide (or oxygen) and the second peak due to the diffusion controlled reaction. In order to study this possibility, an experimental arrangement analogous to chronocoulometric measurement was assembled. The cell was subjected to a constant amplitude pulse train and the output from the lock-in amplifier was integrated before recording on the X–Y recorder. At low potential (3 V) the integral is a strictly linear function of time showing that diffusion is not the rate determining step in the reaction chain leading to light emission; at higher potentials, the linear relationship does not hold. If the reaction is diffusion controlled, the integral of the light emission should be a linear function of the square root of time. This is not the case, however, and the curves seem to be composed of two straight lines (Fig. 8); this may be due to the slow rate of chemisorption.

If the light emission is due to singlet oxygen, it should have a characteristic spectrum (12). There are two principal difficulties, however,

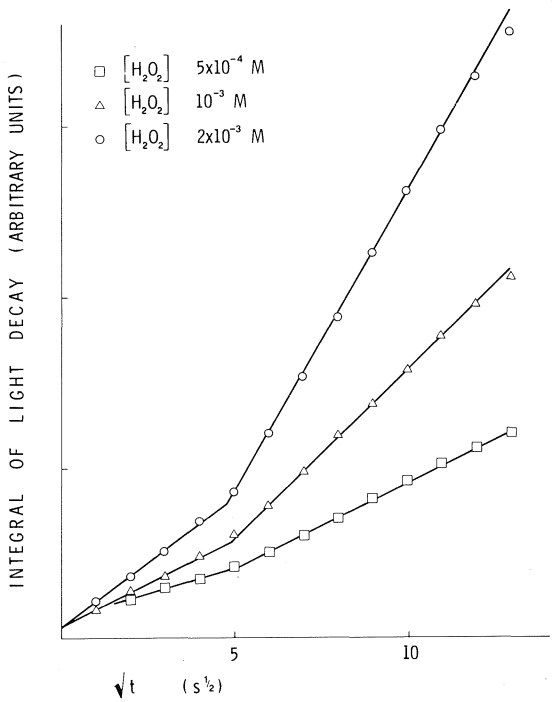

FIG. 8. Integrals of the light decay curves measured with the tantalum electrode in solutions which contain 0.96 mol of $NaClO_4$ and 0.04 mol of $HClO_4$ per ℓ and varying amounts of H_2O_2. The amplitude of the pulses is 6 V.

in determining this spectrum. Firstly, the intensity is very low so that a long integration time should be used for each spectrum point.

Secondly, the light emission is time-dependent unless very low voltages are used. At 3 V, the light intensity given by a tantalum electrode is relatively constant although small. Figure 9 shows the spectrum recorded for the electroluminescence of the tantalum electrode in a solution containing 0.02 *M* H_2O_2 and 0.04 *M* $HClO_4$ in 1 *M* $NaClO_4$. The known maxima of the emission spectrum of singlet oxygen are shown in Fig. 9 as a column diagram. The relative intensities of the maxima are known to vary depending upon the source and medium of singlet oxygen. Due to the poor resolution the spectrum does not provide the unambiguous answer, but it does not preclude the leading role of singlet oxygen.

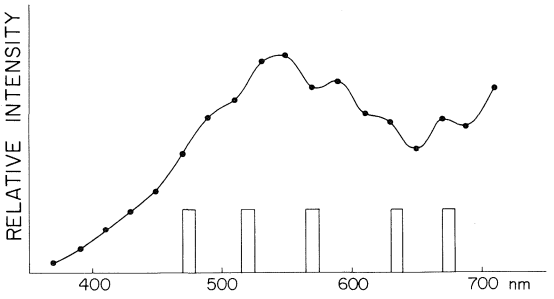

FIG. 9. The spectrum of the cathodic luminescence of the tantalum electrode in a solution which contains 0.04 mol of $HClO_4$, 0.96 mol of $NaClO_4$, and 0.02 mol of H_2O_2 per ℓ.

Conclusions

Cathodic luminescence at low voltages can be explained by the generation and radiative transition of singlet oxygen. The phenomena described are observed only at voltages of less than 10 V; this may be why they have escaped the attention of previous workers who used voltages greater than 30 V (for higher light intensity). It may be that electrogenerated chemiluminescence is predominant at low voltages and solid state luminescence at high.

The influence of trace concentrations of copper on the luminescence with an aluminium cathode in tartrate solutions is of analytical interest. However, the rather poor reproducibility (of electrode surface) and the sensitivity limit of 0.1 μg ml^{-1} makes its practical use questionable.

The high sensitivity of luminescence, with the tantalum electrode, to oxygen and hydrogen peroxide may be of analytical value.

Nuclear magnetic resonance investigation of the conformational dynamic properties of benzocycloheptenones and related compounds

G. BODENNEC[1] AND M. ST-JACQUES[2]

Département de Chimie, Université de Montréal, Montréal (Qué.), Canada H3C 3V1

Received October 19, 1976

G. BODENNEC and M. ST-JACQUES. Can. J. Chem. **55**, 1199 (1977).

Free energy barriers for ring inversion were determined from dnmr studies of 3,4-benzocycloheptenone (**4**) and for deuterated derivatives **6** and **7** of 4,5-benzocycloheptenone (**5**). The investigation of 2,3-benzocycloheptenone (**3**) revealed negative results. The magnitude of $\Delta G^{\ddagger}$ for **4** and the trend observed for **5**, **6**, and **7** strongly suggest that the chair conformation of these molecules interconverts through a wagging motion of the C(5) end of the benzocycloheptene seven-membered ring.

G. BODENNEC et M. ST-JACQUES. Can. J. Chem. **55**, 1199 (1977).

On a déterminé les barrières d'énergie libre pour l'inversion de cycles à partir d'études rmn dynamique de la benzo-3,4 cyclohepténone (**4**) et des dérivés deutérés **6** et **7** de la benzo-4,5 cyclohepténone (**5**). L'étude de la benzo-2,3 cyclohepténone (**3**) n'a apportée que des résultats négatifs. L'amplitude de $\Delta G^{\ddagger}$ pour **4** et la tendance observée pour **5**, **6** et **7** suggèrent fortement que la conformation chaise de ces molécules s'interconvertit par un mouvement de battement de la portion C(5) du cycle à sept chaînons du benzocycloheptène.

[Traduit par le journal]

We have witnessed, in the last decade, a constant progression of our knowledge of the stereochemical, conformational, and dynamic properties of several classes of seven-membered cyclic molecules (1–18). The dnmr method (1), in particular, has been extremely useful to study those molecules possessing conformational averaging processes characterized by free energies of activation barriers greater than 5 kcal/mol. Among the various classes of compounds studied, cycloheptene (**1**) and benzocycloheptene (**2**) have received much attention because of their limited number of possible conformations characterized by readily defined geometries and symmetry properties together with reasonably high interconversion activation energies. It is now well known that both **1** and **2** exist preferentially in the chair conformation (11, 14) characterized by different inversion $\Delta G^{\ddagger}$, namely 5.0 kcal/mol (13) for **1** and 10.9 kcal/mol (18) for **2**.

Attempts to rationalize this large $\Delta G^{\ddagger}$ difference diverge in their description of the dynamic behaviour of benzocycloheptene. Different conformational energy calculations (7–10) agree in their suggestion that the cycloheptene chair interconverts through a wagging motion of the double bond. As for benzocycloheptene, Allinger and Sprague (7) have suggested that it also inverts through a wagging motion of the benzo double bond and that the smaller relief of torsional strain about the C(sp^2)—C(sp^3) bonds compared to cycloheptene accounts for the higher barrier of **2**. In contrast, Favini and Nava (10), have calculated, using the MINDO/2 approximation, that the C(5) wagging motion is easier than the benzo wag and conclude that the change in inversion mechanism is responsible for the large $\Delta G^{\ddagger}$ difference.

Experimental data bearing on this question appear to be scarce. A dnmr study (15) of the substituent effect of *gem*-dimethyl groups revealed parallel $\Delta G^{\ddagger}$ trends for analogous derivatives in each series and this observation was interpreted in terms of similar inversion pathways for both groups of compounds. However, owing to the small $\Delta G^{\ddagger}$ variations observed within each series, it seemed desirable, in light of recent calculations (10), to obtain additional data bearing on the divergent point.

We now wish to report the results of our dnmr study of the simple derivatives **3**, **4**, **5**, **6**, and **7** of benzocycloheptene.

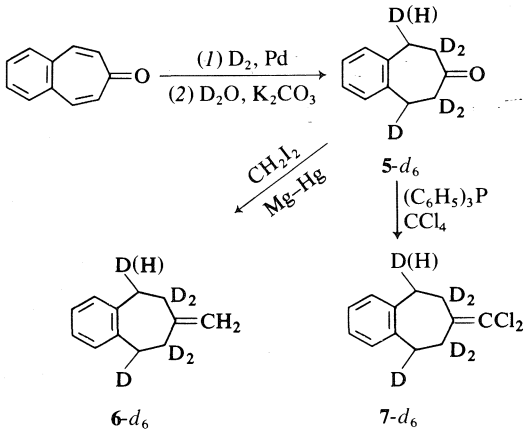
Results

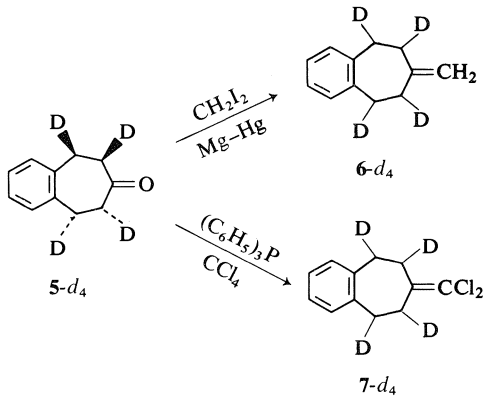
Selectively deuterated derivatives of **5**, **6**, and **7** were prepared for easier analysis of the ^{1}Hmr spectral modifications occurring at low temperatures. The key reaction involved a catalytic reduction of double bonds with deuterium gas; it is expected to place vicinal deuterium atoms in a predominantly *cis* arrangement (14, 16). As these compounds were prepared at different times, the isotopic purity varied according to the experimental conditions. Attempts to maximize isotopic purity were not always made when the dynamic parameters could be obtained reliably from samples containing several identified isotopic species.

Scheme 1 illustrates the preparation of compounds identified as **5**-d_6, **6**-d_6, and **7**-d_6 but for which mass spectral analysis indicated the presence of appreciable quantities of d_4 and d_5 species and for which the ^{1}Hmr spectral region of the benzylic protons showed two peaks separated by 2.2 Hz, thus suggesting that the species CH_2CD_2 give rise to the taller lowfield line while the species $CHDCD_2$ give rise to the smaller upfield line as seen clearly in the spectrum at 25°C for **6**-d_6 (Fig. 1). The separation between these peaks is the normal isotopic shift of the α-deuterium atom (19).



SCHEME 1

Changing the solvent from ethanol to anhydrous tetrahydrofuran improved the isotopic composition of **5**-d_4 which, however, still contained appreciable quantities of d_3 and d_5 species (see Experimental section). The deuterium content was nevertheless sufficient for our proposed ^{1}Hmr investigation of **5**-d_4, **6**-d_4, and **7**-d_4 (Scheme 2) as will be described later.



SCHEME 2

It is important to point out that each of the compounds prepared actually contains essentially equal amounts of *syn* and *anti* isomers, but because the ^{1}Hmr signals of each side of the ring are essentially independent (14, 16), only the *anti* isomers have been shown in the schemes.

Spectral Analysis

Spectral changes were observed for compounds **4**, **6**-d_4, **6**-d_6, and **7**-d_4, whereas the ^{1}Hmr spectra of **3**, **5**, **5**-d_4, **5**-d_6, and **7**-d_6 showed no discernable spectral modification (down to −170°C) resulting from the slowing down of conformational averaging processes.

The ^{1}Hmr spectral behaviour of the non-aromatic signals of 3,4-benzocycloheptenone (**4**) (2-benzosuberone) in CHF_2Cl at low temperatures has revealed that both the lowfield singlet (δ 3.67) and the high field multiplet (centered at δ 1.98) show clearcut splitting below −162°C. The lowfield singlet, attributed to protons on C-2, has split into two broad bands separated by about 90 Hz at −168°C. The low temperature spectrum actually consists of a broadened AB pattern whose lines could not all be resolved at such low temperatures. Nevertheless, the use of approximate equations (20) for two exchanging sites and a transmission coefficient of one give an estimate of 5.1 kcal/mol for $\Delta G^{\ddagger}$ at −162°C (T_c).

Figure 1 shows the spectra of benzylic signal of **6**-d_6 in CHF_2Cl at several temperatures. The spectrum at 25°C indicates the presence of two singlets separated by 2.2 Hz; the taller line is due to CH_2CD_2 species while the shorter starred line arises from $CHDCD_2$ species. Both lines split at low temperatures, the taller giving an AB quartet (J = −14.3 Hz and $\Delta\nu$ = 11.7 Hz)

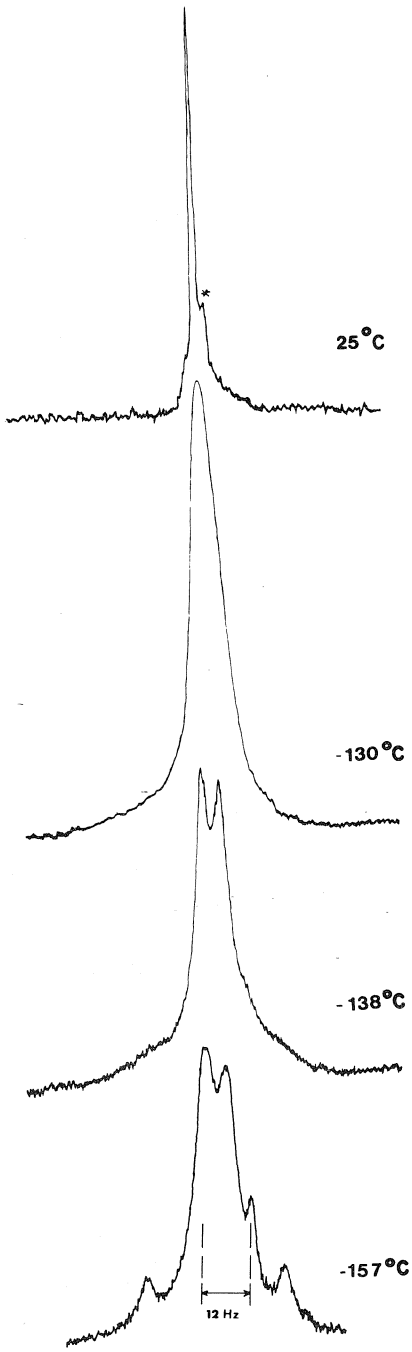


FIG. 1. 100 MHz deuterium decoupled ^{1}Hmr spectra of **6**-d_6 (10% in CHF_2Cl) at several temperatures. The stick diagram under the spectra at -157°C identifies the doublet arising from the splitting of the starred line in the spectrum at 25°C.

at -157°C and the shorter giving a doublet identified by the stick diagram. Standard equations (20) afforded a $\Delta G^{\ddagger}$ value of 6.9 kcal/mol at -130°C (T_c). A series of spectra for **7**-d_6 down to -170°C showed broadening greater than for the TMS line but no clearcut splitting was observed.

The low temperature spectrum of non-deuterated **6** gave indications that the chemical shift separation is larger for the two non-equivalent methylene protons next to the *exo* double bond than at the benzylic positions. Consequently a comparative study of **6**-d_4 and **7**-d_4 was undertaken.

Figure 2 shows several ^{1}Hmr spectra for **6**-d_4 (right side) and **7**-d_4 (left side). It is readily apparent that the isotopic purity of these compounds is not sufficient (see Experimental section) to give the AX pattern at $+25$°C for CHDCHD (*cis*) arrangements expected for each compound (14, 16). Nevertheless the extent of deuteration is sufficient to remove much of the strong coupling and thus enable relatively easy detection and overall analysis of the splitting observed for the high field band. It is seen that the upfield signal of **6**-d_4 splits into two broad bands separated by about 65 Hz below -122°C (T_c). The use of standard equations (20) provided the estimate $\Delta G^{\ddagger} = 7.1$ kcal/mol. The observation that this value is very close to the $\Delta G^{\ddagger}$ value calculated earlier for **6**-d_6 (Fig. 1) suggests that the approach using **6**-d_4 and **7**-d_4 should lead to acceptable $\Delta G^{\ddagger}$ estimates.

Solubility problems made the study of **7**-d_4 slightly more difficult but a spectral change (Fig. 2 left side) was nevertheless observed for a solution in a mixture of CHF_2Cl–$CHFCl_2$ (1:1) and a direct comparison with that of **6**-d_4 shows that $T_c \approx -155$°C and $\Delta\nu \approx 60$ Hz so that $\Delta G^{\ddagger} = 5.5$ kcal/mol can be calculated.

A careful examination of the ^{1}Hmr spectrum of **5**-d_4 in CCl_4 at room temperature showed several lines attributable to isotopic impurities of the type CHD—CHD (*cis*) CHD—CHD (*trans*), $CHDCH_2$, and $CHDCD_2$ as anticipated (14) and confirmed by the mass spectral analysis which revealed the presence of significant amounts of d_3, d_4, and d_5 species (namely 25, 42, and 24% respectively). Having identified the peaks belonging to $CHDCH_2$ species from the spectrum of a sample of 3,6-dideutero-4,5-benzocycloheptenone it was possible to identify the more intense doublets of the AX pattern of the

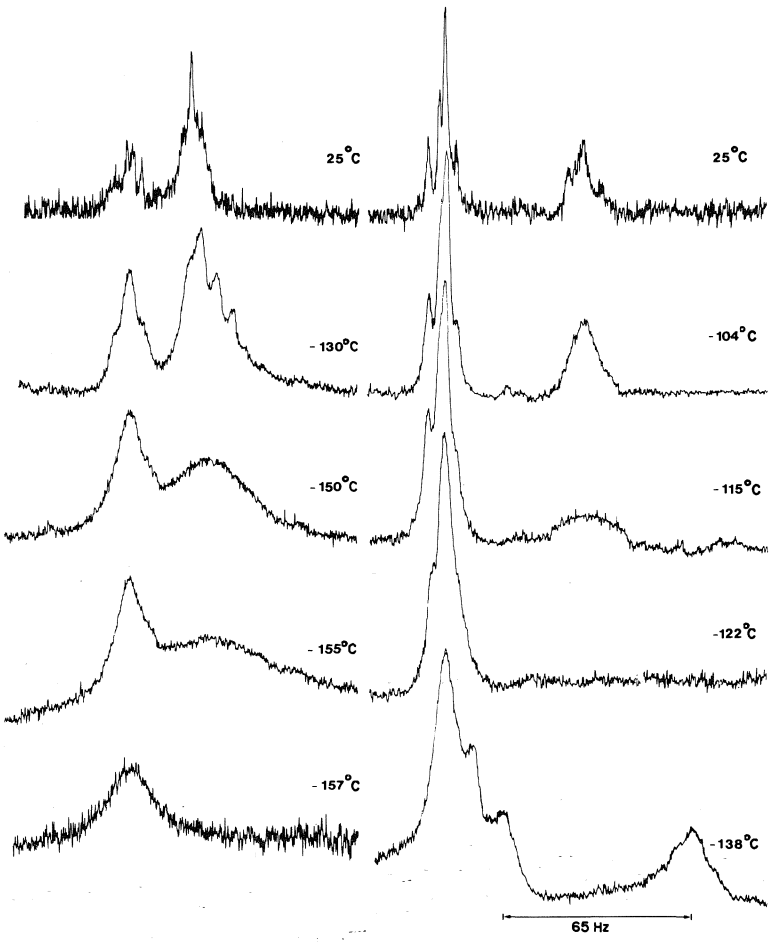

FIG. 2. 100 MHz deuterium decoupled ^{1}Hmr spectra of **6**-d_4 (10% in CHF_2Cl) (right side) and **7**-d_4 (3% in a 1:1 mixture of CHF_2Cl and $CHFCl_2$) (left side) at several temperatures. Both series of spectra were recorded on the same scale.

CHDCHD (*cis*) species (14) whose splitting is equal to the averaged coupling constant J_{cis} = 2.2 Hz, as well as the less intense doublets of the AX pattern of the CHDCHD (*trans*) species characterized by the averaged coupling constant J_{trans} = 9.9 Hz. The R-value (21) $R = J_{trans}/J_{cis} = 4.5$ was calculated with a reasonable degree of confidence based on the verification of this approach for a similarly deuterated benzocycloheptene derivative (14, 16).

The spectra of **6**-d_4 and **7**-d_4 were much less well defined than that of **5**-d_4 owing to a greater isotopic distribution so that R cannot be calculated reliably. As seen in Fig. 2 only the lowfield signal of **6**-d_4 at +25°C reveals clearly the doublet components of the two AX patterns in question.

Discussion

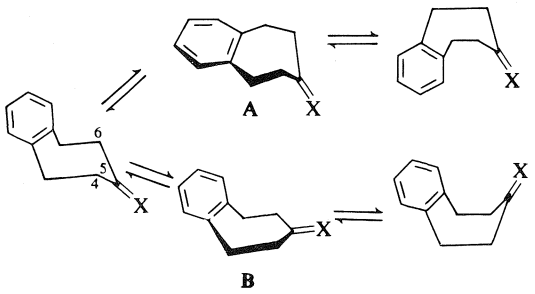
It is well known that benzocycloheptene exists in the chair conformation (14) and it has been deduced from dipole moment studies (6) that **5** exists as a mixture of chair (92%) and boat (8%) conformations in benzene solution. Owing to the inherent uncertainties associated with that method, the exact amount of boat conformation is open to question and in fact may be quite small. There is, however, no reason to believe that the chair is not the predominant conformation. Consequently the R-value of 4.5 calculated

from the ^{1}Hmr spectrum of **5**-d_4 suggests that the carbonyl group has flattened the chair relative to that of benzocycloheptene (14) for which $R = 8.7$. In fact, this change in R-value corresponds to a reduction of the internal torsional angle (21) (ψ) from 74° in benzocycloheptene to 68° in the conformation of **5**. This angular change is very similar to the flattening effect of the carbonyl group in cyclohexanone ($\psi = 50°$) relative to cyclohexane ($\psi = 56$–$58°$) (21).

Although R-values could not be obtained confidently for **6**-d_4 and **7**-d_4, an estimated value from the lowfield signal in the spectrum of **6**-d_4 at +25° (Fig. 2) suggests that it is very similar to that of **5**-d_4. Furthermore, the benzylic coupling of 14.3 Hz determined for **6**-d_6 (Fig. 1) is very similar to the value of 14.1 Hz determined for the chair conformation of benzocycloheptene (14). It therefore appears certain that **4**, **5**, **6**, and **7** exist predominantly as chair conformations.

The nature of the most stable conformation of **3** is more uncertain. Nuclear Overhauser enhancement experiments (22) on two isomeric tetrabromo-2,3-benzocycloheptenones were interpreted in terms of a skew and a twist-boat conformation. The significance of these results with respect to the conformation of **3** is not obvious. The dnmr results having been negative for **3**, we are unable to specify unambiguously the geometry of its most stable conformation.

The inversion scheme for benzocycloheptene has already been described (23). It involves a rate-determining chair-to-boat step and a less energetic pseudorotation motion between boat and twist-boat forms. Two different pathways have been suggested for the rate determining chair-to-boat step (7, 10). Scheme 3 illustrates the difference clearly. It is shown that one possibility involves the wagging motion of the benzo group through conformation A which possesses six coplanar ring carbon atoms. The other possibility involves the wagging of C(5) through conformation B having five coplanar ring carbon atoms. (The numbering convention used in this section refers to the parent compound even when used for its derivatives. It should not be associated with the nomenclature numbering convention of the derivatives investigated.)



SCHEME 3

It is seen that only pathway B involves appreciable rotation of the C(4)—C(5) and C(5)—C(6) bonds in the rate determining step. Provided rotational energy is an important contributor to the activation energy, any structural modification resulting in easier rotation about these bonds is expected to decrease the overall $\Delta G^{\ddagger}$ for ring inversion of molecules favoring this path. In fact it has been shown (4*a*) that torsional energy accounts for a large part of the energy difference between the chair and the inversion transition state of cyclohexane. The variation in $\Delta G^{\ddagger}$ values of the six-membered cyclic compounds listed in Table 1 was consequently rationalized convincingly in terms of the ease of rotation of the bonds adjacent to the sp^2 carbon (24, 25).

Table 1 reveals a very similar trend for both the six- and seven-membered cyclic compounds listed, such that it is very tempting to suggest that inversion in the second series of compounds also proceeds through a pathway involving appreciable rotation of the bonds adjacent to the sp^2 carbon atom and consequently that the chair conformation of these compounds inter-

TABLE 1. Summary of $\Delta G^{\ddagger}$ values for the ring inversion of some six, seven, and eight-membered compounds

[e]Estimate from unpublished dnmr results by G. Bodennec.

convert via pathway B. Supporting evidence is provided by the observation that the same chemical modifications in the eight-membered compounds listed in Table 1 do not lead to a significant variation in $\Delta G^{\ddagger}$ for ring inversion, most probably because the rate determining step involves little rotation about the bonds adjacent to the sp^2 carbon (ref. 2, p. 568).

Furthermore, the higher $\Delta G^{\ddagger}$ value determined for **4** compared to **5** is consistent with a C(5) wag. Reaching B involves appreciable rotation about only one bond adjacent to the carbonyl group of **4**, whereas two such bonds rotate in **5**.

While it appears certain that the chair conformations of **4**, **5**, **6**, and **7** invert through a C(5) wag, it is not as clear that the extrapolation to **2** suggested by the data in Table 1 is a valid one. In fact calculations (7–10) have shown that both the benzo and the C(5) wags should be more energetic than the double bond wag of cycloheptene and it is possible that both A and B would require very similar energy for benzocycloheptene. Unfortunately Allinger's calculations (7) were not sufficiently complete to prove otherwise while Favini's calculations (10) suggest that the C(5) wag is the easier process but, because agreement with the experimental barrier is very poor (6.0 kcal/mol compared to the 10.9 kcal/mol observed for **3**), it is difficult to be convinced. Recent calculations (26) for 1,5-cyclooctadiene and its dibenzo analog afford a better estimate of the energy difference between a double bond wag and benzo wag as involved for the boat-to-chair interconversion. The enthalpy values calculated are 5.2 and 11.4 kcal/mol for the diene and dibenzo compound respectively. These results together with the data in Table 1 suggest that both pathways A and B for benzocycloheptene might indeed be of comparable energy.

The lack of knowledge on the geometry of the most stable conformation of **3**, the negative dnmr results, and the better stabilization expected for some conformations through resonance between the carbonyl group and the aromatic ring suggest that the conformational dynamic properties of **3** may be different from those of **4** and **5**.

We therefore conclude that **1** inverts through pathway A while **4**, **5**, **6**, and **7** invert through pathway B. As for **2**, it is clear that both pathways are expected to involve relatively higher and comparable activation energies and it appears that the qualitative interpretation of the substituent effects determined in this work cannot tell with certainty which of the two ring motions is rate determining.

Experimental

The vpc analyses and separations were carried out on a Varian-aerograph A90-P3 instrument using ¼ in. silicone DC 550 (15%) columns and helium as carrier gas. Mass spectral analyses were performed on an Hitachi–Perkin-Elmer model RMU-6D instrument operating at 70 and 12 eV.

Routine analytical ^{1}Hmr spectra were recorded on a JEOL C-60H spectrometer operating at 60 MHz in the external lock mode. The low temperature ^{1}Hmr spectra were obtained at 100 MHz using a JEOL JNM-4H-100 spectrometer. Solutions containing a small quantity of TMS were degassed and sealed. Deuterium decoupling, when required, was effected by means of the JEOL Hetero Spin Decoupler model JNM-SD-HC.

Temperatures were monitored by means of a JEOL temperature control unit model JES-VT-3 and determined accurately with a calibrated thermocouple placed inside a solvent-containing dummy nmr tube.

2,3-Benzocycloheptenone (3)

This compound was obtained from Aldrich Chemical Co. as 1-benzosuberone and used without further purification.

3,4-Benzocycloheptenone (4)

This compound was prepared from **3** by the method of Huisgen *et al.* (27). Its ^{1}Hmr spectrum in $CDCl_3$ at 60 MHz is entirely consistent with that expected for **4**: δ 7.1 (4H, aromatic), 3.65 (2H, s), 2.90 (2H, m), 2.47 (2H, t), and 1.95 (2H, m).

4,5-Benzotropone

This compound was prepared as previously described (6, 14) and found to be identical to other samples previously prepared in this laboratory.

Preparation of 6-d_6 and 7-d_6 (Scheme 1)

A solution of 4,5-benzotropone (2.1 g) in 120 ml of ethanol containing 0.60 g of paladium-on-charcoal (5%) catalyst was placed in a compact deuteration apparatus (14) for about 16 h. Deuterium gas absorption had then ceased and the mixture was filtered on diatomaceous earth. Evaporation of the solvent gave a product which was shown by vpc analysis to have a retention time equal to that of authentic 4,5-benzocycloheptenone (14).

The above ketone was then added to a solution of 4.0 g of potassium carbonate in 40 ml of D_2O. After 5 h of reflux, the product was isolated in the usual manner (14). This procedure was repeated once and the product expected to be **5**-d_6 was isolated. The deuterium decoupled 100 MHz ^{1}Hmr spectrum in CHF_2Cl showed two benzylic singlets (near δ 2.8) separated by 2.2 Hz and in the ratio 70:30 (peak heights). Thus the sample contained a large quantity of CH_2CD_2 species (more

intense lowfield line) and $CHDCD_2$ species (less intense upfield line).

Compound **6**-d_6 was prepared from the above sample of **5**-d_6 by the reaction of methylene iodide and magnesium amalgam as previously described by Bertini *et al.* (28). An ether solution (20 ml) of 0.50 g (3.0 mmol) of ketone **5**-d_6 and 0.88 g (3.3 mmol) of methylene iodide was added with stirring, at room temperature under a nitrogen atmosphere, to previously prepared magnesium amalgam (0.160 g of Mg and 5 ml of Hg). After reaction work-up (28) and evaporation of the ether solvent, a vpc analysis of the crude product revealed a mixture of **6**-d_6 (70%) and the starting ketone (30%). Chemically pure **6**-d_6 was obtained by preparative vpc and its deuterium decoupled ^{1}Hmr spectrum (10% in CHF_2Cl) showed a characteristic singlet at δ 4.7 ($C{=}CH_2$) and another signal at δ 2.8 (benzylic CH_2CD_2 and $CHDCD_2$) in the ratio 2:2.2. The upfield signal (Fig. 1) consists of two singlets separated by 2.2 Hz, the more intense line belonging to CH_2CD_2 species and the other one to the $CHDCD_2$ species. A mass spectral analysis at 12 eV revealed the following isotopic distribution: d_3 = 5%, d_4 = 42%, d_5 = 23%, d_6 = 21%, d_7 = 7%, d_8 = 2%.

Compound **7**-d_6 was prepared from **5**-d_6 by a reaction with carbon tetrachloride and triphenylphosphine according to the method of Rabinowitz and Marcus (29). Thus, a solution of 0.48 g of **5**-d_6 (3 mmol) and 1.6 g of triphenylphosphine in 30 ml of carbon tetrachloride was heated to 80°C for 10 h. After work-up (29), 0.35 g of crude product was obtained. Analysis by vpc showed that it possessed a retention time equal to that of authentic 5-exodichloromethylenebenzocycloheptene (**7**) mp 103–104°C. The mass spectrum showed a cluster of peaks near *m/e* 232 thus confirming the identity of the compound, but we were not able to get a very meaningful isotopic distribution.

Preparation of **5**-d_4, **6**-d_4, *and* **7**-d_4 *(Scheme 3)*

A solution of 4,5-benzotropone (1.6 g) in 90 ml of tetrahydrofuran (freshly distilled over $LiAlH_4$) containing 100 mg of palladium-on-charcoal (5%) catalyst was reacted with deuterium gas as described earlier. After filtration of the catalyst and evaporation of the solvent, 1.5 g of ketone expected to be **5**-d_4 was obtained. Analysis by vpc showed a retention time identical to authentic 4,5-benzocycloheptenone (14). The deuterium decoupled ^{1}Hmr spectrum at 100 MHz (5% in CHF_2Cl) showed two characteristic signals for the non-aromatic protons: δ 2.5 (H next to carbonyl) and δ 2.8 (benzylic H) of essentially equal surface. A mass spectral analysis revealed the following isotopic distribution: d_1 = 4%, d_2 = 5%, d_3 = 25%, d_4 = 42%, d_5 = 24%.

Compound **6**-d_4 was prepared from a sample of 0.6 g of **5**-d_4 by a reaction with methylene iodide and magnesium amalgam as described earlier. After work-up 0.45 g of crude product was obtained. Chemically pure **6**-d_4 was obtained by vpc purification. A 100 MHz deuterium decoupled ^{1}Hmr spectrum of **6**-d_4 (Fig. 2) as a 10% solution in CHF_2Cl showed the following characteristic signals: δ 2.3 (H next to $C{=}CH_2$) 2.8 (benzylic H), and 4.7 ($=CH_2$). The mass spectral analysis revealed the following isotopic composition: d_1 = 1%, d_2 = 9%, d_3 = 27%, d_4 = 35%, d_5 = 19%, d_6 = 7%, d_7 = 2%.

Compound **7**-d_4 was prepared from a sample of 0.41 g of **5**-d_4 by a reaction with 1.3 g of triphenylphosphine in 30 ml of carbon tetrachloride as previously described. The product was identified by comparison of its vpc retention time with a sample of authentic 5-dichloromethylenebenzocycloheptene and then purified by preparative vpc. The 100 MHz deuterium decoupled ^{1}Hmr spectrum of this compound (Fig. 2) in a mixture of CHF_2Cl and $CHFCl_2$ (1:1) showed two non-aromatic signals at δ 2.6 (protons next to $C{=}CCl_2$) and 2.8 (benzylic protons). The mass spectrum showed a cluster of peaks near *m/e* 230 thus confirming the identity of the compound, but we were not able to get a very meaningful isotopic distribution.

Acknowledgment

We wish to acknowledge the collaboration of D. Montecalvo and C. Vaziri in the preliminary stages of this work, and R. Mayer for assistance in recording the low temperature spectra. We are very grateful for the financial assistance of the National Research Council of Canada and of the Quebec government for a Quebec–France exchange fellowship to G.B.

The irradiation of ferric perchlorate in the presence of *tert*-amyl alcohol produces Fe(II) with a quantum yield of 0.110 ± 0.002, 12% lower than the yield obtained when *tert*-butyl alcohol was used as scavenger. Other tertiary alcohols studied, 3-methyl-2-pentanol and 3-ethyl-3-pentanol, exhibited similar lower yields. It is shown that this reduction is due to the formation of γ-hydroxyalkyl radicals which do not reduce ferric ion to ferrous. The addition of copper causes these radicals to be oxidized. The Fe(II) quantum yield for the irradiation with tertiary amyl alcohol as scavenger in the presence of copper is in good agreement with the tertiary butyl alcohol results in the absence of copper (0.124 ± 0.003).

Quantum yields are observed which are independent of scavenger concentration indicating outer sphere photooxidations are not taking place. This result supports the suggestion that an H on the carbon bearing oxygen is necessary for direct reaction between scavenger and the ferric charge transfer excited state.

JOHN H. CAREY, BARRY G. OLIVER et COOPER H. LANGFORD. Can. J. Chem. **55**, 1207 (1977).

L'irradiation du perchlorate ferrique en présence d'alcool amylique tertiaire conduit à la formation de Fe(II) avec un rendement quantique de 0.110 ± 0.002 soit 12% de moins que le rendement obtenu quand on utilise l'alcool butylique tertiaire comme piège. Les autres alcools tertiaires étudiés, soit le méthyl-3 pentanol-2 et l'éthyl-3 pentanol-3, présentent aussi des rendements plus bas. On montre que cette réduction est due à la formation de radicaux γ-hydroxyalkyles qui ne réduisent pas l'ion ferrique en ion ferreux. L'addition de cuivre cause l'oxydation de ces radicaux. Le rendement quantique de Fe(II) pour l'irradiation avec l'alcool amylique tertiaire comme piège en présence de cuivre est en bon accord avec les résultats obtenus pour l'alcool butylique tertiaire en absence de cuivre (0.124 ± 0.003).

On a observé des rendements quantiques qui sont indépendants de la concentration de piège; ces résultats indiquent qu'il n'y a pas de photooxydation qui se produit dans les couches extérieures. Ces résultats supportent l'hypothèse qu'un hydrogène sur le carbone portant l'oxygène est nécessaire pour la réaction directe entre le piège et l'état excité de transfert de charge de l'ion ferrique.

[Traduit par le journal]

Introduction

The ultraviolet irradiation of strongly acidic solutions of ferric perchlorate leads to the production of hydroxyl radicals by a process represented by reaction 1

$$[1] \qquad Fe^{3+}_{aq} \underset{k_{-1}}{\overset{h\nu}{\rightleftharpoons}} Fe^{3+*}_{aq} \xrightarrow[H_2O]{k_1} Fe^{2+}_{aq} + H^+ + \cdot OH$$

In the absence of scavengers, a back reaction represented by reaction 2 predominates and the net iron(II) yield is very low.

$$[2] \qquad \cdot OH + Fe^{2+}_{aq} + H^+ \xrightarrow{k_2} Fe^{3+}_{aq} + H_2O$$

In order to determine the quantum yield of the primary photochemical processes, organic molecules may be added as hydroxyl radical scavengers. Adamson *et al.* (1) have discussed the requirements for successful use of such scavengers. Since the scavanger molecule invariably forms a new radical in the scavenging reaction, it is essential that the chemistry of the new radical be known so that its fate can be accurately predicted. Other requirements are that no new light absorbing species be introduced in the system

[1] To whom correspondence should be addressed.

and that the scavenger itself be photochemically inert in the wavelength region of interest.

A further complication in the use of scavengers is that at the high concentrations necessary for complete scavenging, reactions may occur between the scavenger and excited state (2). Such a reaction has now been observed in the ferric perchlorate/perchloric acid system when methanol, isopropanol, and formic acid were used as scavengers (3, 4). Of the scavengers studied, *tert*-butyl alcohol was the only one that was efficient enough to react with all hydroxyl radicals and yet not undergo reaction directly with the excited state. It seemed likely that an H on the hydroxyl-bearing C was a requirement for the reaction between scavenger and excited state (4). The reaction path for *tert*-butyl alcohol can be represented by:

$$[3]\quad \cdot OH + HOC(CH_3)_3 \xrightarrow{k_3} H_2O + HOC(CH_3)_2CH_2\cdot$$

$$[4]\quad HOC(CH_3)_2CH_2\cdot + Fe^{3+}_{aq} \xrightarrow{k_4} Fe^{2+}_{aq} + \text{products}$$

The establishment of structure-reactivity relationships such as this can aid in evaluating the importance of the photochemical process in complex systems such as natural waters. To explore this relationship further, we have studied the irradiation of ferric perchlorate in the presence of other alcohols lacking an α-hydrogen.

Experimental

Irradiation Procedures

Solutions to be irradiated were 0.02 *M* ferric perchlorate, 2.00 *M* $HClO_4$, and various copper and alcohol concentrations. Commercial ferric perchlorate (K and K, non-yellow) and cupric perchlorate (Alfa) were used to prepared stock solutions, the concentrations of which were determined by atomic absorption techniques. Spectrophotometric grade *tert*-butyl alcohol was used without further purification whereas *tert*-amyl alcohol (Fisher, reagent), 3-methyl-3-pentanol (Eastman), and 3-ethyl-3-pentanol (Eastman) were fractionally distilled prior to use. Irradiations were performed in a cylindrical quartz cell with an outer jacket through which distilled water from a heating bath could be circulated to maintain the photolyte temperature at 30.0 ± 0.1°C. High purity nitrogen was passed through the solutions for 20 min prior to irradiation. The photoreactor (Ultraviolet Products Inc., San Gabriel, CA) contained four low pressure mercury lamps. Light intensities were determined by ferrioxalate actinometry (6) with potassium ferrioxalate (K and K) recrystallized twice from water.

Analytical Procedures

The iron(II) yields were determined using *o*-phenanthroline and the neutralization dilution technique previously described (3). When copper was present, a blue crystalline precipitate usually formed during the analysis. A check of the analytical system, using samples containing ferrous ammonium sulfate revealed that the precipitate did not contain iron(II). A calibration plot obtained by measuring the absorbance of the supernatant after allowing the blue precipitate to settle gave a molar absorptivity of 1.09×10^4 at 510 nm based on iron(II) concentration. This is in excellent agreement with the value of 1.10×10^4 reported by Hatchard and Parker (5). Thus, the blue precipitate and the presence of copper did not interfere with the iron(II) determination at 510 nm. It was necessary at high copper concentrations to increase the quantity of phenanthroline used in order to achieve complete complexation of the ferrous ion. This behaviour leads us to conclude that the blue precipitate was a copper-phenanthroline complex, probably precipitated as the perchlorate salt.

Photolyte samples were analyzed for products by gas chromatography. After neutralization, the aqueous samples were injected directly into a gas chromatograph equipped with either a Tenax-GC (Enka N.V., Holland) or Chromosorb 101 (Johns-Manville) column and flame ionization detectors.

For example, a sample of the photolysis solution containing 0.10 *M* *tert*-butyl alcohol was irradiated to 10% conversion based on iron. The photolyte was neutralized with KOH and the precipitate (iron oxide and potassium perchlorate) was removed by decantation. The clear, colourless supernatant was injected directly onto a 1.83 m Tenax column operated at 170°C. Adequate separation of the resulting products from the much larger parent alcohol peak could be achieved at this temperature for both the *tert*-butyl and *tert*-amyl alcohol systems. Alternatively, the neutralized supernatant could be evaporated under vacuum at 35°C and the residue extracted several times with ether.

To obtain the mass spectra of the products, concentrated samples were injected into a Finnigan GC-MS system with TENAX column. Mass spectra and gas chromatographic behaviour of the observed products were compared with those of the following diols.

Isobutylene Glycol: Synthesized from methallyl alcohol (Pfaltz and Bauer) following literature procedures (6).

2-Methyl-1,2-butanediol and 2-methyl-2,3-butanediol: Synthesized from 2-methyl-1-butene and 2-methyl-2-butene, respectively, by akaline permanganate oxidation at low temperature.

2,7-Dimethyl-2,7-octanediol (ICN Pharmaceuticals) and 3-methyl-1,3-butanediol (BASF) were used as received.

The identity of the three synthesized glycols was confirmed by periodate cleavage (7) and analysis of the resulting carbonyl products by thin layer chromatography of their 2,4-dinitrophenylhydrazine derivatives on alumina with solvent cyclohexane–nitrobenzene (2:1). Cleavage of isobutylene glycol led to formaldehyde and acetone, while 2-methyl-1,2-butanediol gave formaldehyde and methyl ethyl ketone and cleavage of 2-methyl-2,3-butanediol yielded acetaldehyde and acetone.

Results and Discussion

Previous studies on the 2537 Å irradiation of ferric perchlorate in the presence of *tert*-butyl alcohol, performed on undegassed solutions

over a temperature range of 35–40°C, established a limiting quantum yield for iron(III) reduction to be 0.130 ± 0.003 (3). From this value, a primary quantum yield for free ·OH was calculated to be 0.065. We have studied the scavenging behaviour of three other tertiary alcohols in this system by irradiating a deaerated photolyte at a temperature of 30.0 ± 0.1°C. For the purpose of comparison, *tert*-butyl alcohol was also studied under these conditions. For all tertiary alcohols studied, the concentration of iron(II) increases linearly with irradiation time for conversions less than 10%. Although concentrations were limited by solubility, in all cases a yield could be reached which was independent of scavenger concentration. These yields are summarized in Table 1. It can be seen that the limiting yield for iron(II) production drops as substitution on the alcohol increases. Such an effect is unexpected based on reaction scheme 1–4.

It may be possible for tertiary alcohol structure to exert some influence on the primary reaction by affecting k_1 and k_{-1}. Since it was previously demonstrated (4) that methanol, isopropyl alcohol, and *tert*-butyl alcohol did not enter the primary coordination sphere of the iron, such an effect is unlikely. Instead, it seems probable that the reaction of hydroxyl radicals with higher tertiary alcohols produces some radicals, which do not react with Fe(III) to produce Fe(II) via reaction 4.

Walling and co-workers (8–10) have discussed the types of radicals formed in the Fenton's reagent (ferrous ion – hydrogen peroxide) oxidation of alcohols and characterized them according to their reaction with Fe(III). He has concluded that radicals formed by abstraction of an α-hydrogen from alcohols are oxidized by Fe(III) at diffusion controlled rates, while radicals which arise by abstraction of β-hydrogens are oxidized with more difficulty. Radicals formed by abstraction of hydrogens further removed from the hydroxyl group resemble alkyl radicals in that neither is oxidized by Fe(III). These radicals can, however, be oxidized by Cu(II) which will produce Fe(II) via reactions 5 and 6.

$$[5] \qquad R\cdot + Cu^{2+}_{aq} \xrightarrow[H_2O]{} ROH + Cu^{+}_{aq} + H^{+}$$

$$[6] \qquad Cu^{+}_{aq} + Fe^{3+}_{aq} \rightarrow Cu^{2+}_{aq} + Fe^{2+}_{aq}$$

The addition of copper can, however, cause other changes in the reaction mechanism. Bhatia and Schuler (11) found that the hydroxycyclohexadienyl radical could be quantitatively oxidized by ferricyanide, while lower yields and other complications were present when copper was used as oxidant. Some of these complications were due to the buildup of cuprous ion in the system. Such a buildup will not occur in the present system since the cuprous ion will react with Fe(III).

Walling *et al.* (10) have reported that the addition of high copper concentrations can affect results in the Fenton's reagent system in a manner suggestive of the reaction of hydroxyl radicals with Cu(II).

$$[7] \qquad Cu^{2+}_{aq} + \cdot OH \rightleftarrows Cu(III) + OH^{-}$$

In acid solution, Cu(III) rapidly reverts to hydroxyl radicals and Cu(II) (12). Since the present studies were performed in 2 *M* $HClO_4$, if any Cu(III) formed, it should decompose too rapidly to oxidize Fe(II) and thus affect the Fe(II) yield.

In order to check the effect of adding copper on the *tert*-butyl alcohol scavenging system, studies were performed at 30.0°C over a range of copper concentrations from 0.01 to 0.05 *M*. The concentrations of *tert*-butyl alcohol used were previously shown to be sufficient to scavenge all hydroxyl radicals (3). The quantum yield for iron(II) production is 0.124 ± 0.003 and is independent of copper concentration.

The addition of copper to the tertiary amyl system caused an increase in the rate at which Fe(II) was formed on irradiation. Identical results were obtained for a copper concentration of 0.002 and 0.005 *M*. The quantum yield is calculated to be 0.124 ± 0.002, in good agreement with the value obtained for *tert*-butyl alcohol scavenging at this temperature. The quantum yields for the other tertiary alcohols also exhibited a similar increase. These results are summarized in Table 1.

Attempts were made to identify the organic products resulting from both *tert*-butyl and *tert*-amyl alcohol scavenging in this system. In a previous paper (3), it was reasoned that isobutylene glycol and Fe(II) were the likely products from the reaction of a 2-methyl-2-hydroxypropyl radical with Fe(III). Similarly, reaction between Fe(III) and radicals produced by β-hydrogen abstraction from *tert*-amyl alcohol may also lead to diols as expected products.

TABLE 1

(*a*) Quantum yields for photoreduction at various scavenger concentrations

Scavenger	Scavenger concentration (mol/ℓ)	Copper concentration (mol/ℓ)	$\Phi_{Fe(II)}$
tert-Butyl alcohol	0.106	0	0.126±0.003
	0.536	0	0.125±0.003

[8] $$\cdot CH_2-\underset{\displaystyle CH_3}{\overset{\displaystyle OH}{\overset{|}{\underset{|}{C}}}}-CH_2CH_3 + Fe^{3+}_{aq} \rightarrow \underset{\displaystyle HO}{\overset{|}{CH_2}}-\underset{\displaystyle CH_3}{\overset{\displaystyle OH}{\overset{|}{\underset{|}{C}}}}-CH_2CH_3 + Fe^{2+}_{aq} + H^+$$

1

[9] $$CH_3-\underset{\displaystyle CH_3}{\overset{\displaystyle OH}{\overset{|}{\underset{|}{C}}}}-\dot{C}HCH_3 + Fe^{3+}_{aq} \rightarrow CH_3-\underset{\displaystyle CH_3}{\overset{\displaystyle HO}{\overset{|}{\underset{|}{C}}}}-\overset{\displaystyle OH}{\overset{|}{CH}}CH_3 + Fe^{2+}_{aq} + H^+$$

2

The reaction of the 3-methyl-3-hydroxybutyl radical with Cu(II) will likewise result in diol formation.

[10] $$CH_3-\underset{\displaystyle CH_3}{\overset{\displaystyle OH}{\overset{|}{\underset{|}{C}}}}-CH_2\dot{C}H_2 + Cu^{2+}_{aq} \rightarrow CH_3-\underset{\displaystyle CH_3}{\overset{\displaystyle HO}{\overset{|}{\underset{|}{C}}}}-\overset{\displaystyle OH}{\overset{|}{CH_2}}CH_2 + Cu^{+}_{aq} + H^+$$

3

For *tert*-butyl alcohol, comparison of retention times and mass spectra of the scavenging product and a synthetic sample of isobutylene glycol confirm that the latter is the major organic product of the photolysis. There was no noticeable difference between aerated and deaerated samples, with or without copper.

In the *tert*-amyl alcohol case, two products are easily detected by gas chromatography of a photolyte containing no copper. A third product can be observed at higher temperature and long retention times. The first two observed products have retention times and mass spectra identical to synthetic samples of the expected glycols 2-methyl-1,2-butanediol (**1**) and 2-methyl-2,3-butanediol (**2**). The third product has identical retention times on two different GC columns to a commercial sample of 2,7-dimethyl-2,7-octanediol and indicates that in the absence of copper, the 3-methyl-3-hydroxybutyl radical undergoes a radical–radical reaction 11.

[11] $$2\ CH_3-\underset{\displaystyle CH_3}{\overset{\displaystyle OH}{\overset{|}{\underset{|}{C}}}}-CH_2\dot{C}H_2 \longrightarrow CH_3-\underset{\displaystyle CH_3}{\overset{\displaystyle OH}{\overset{|}{\underset{|}{C}}}}-CH_2CH_2CH_2CH_2-\underset{\displaystyle CH_3}{\overset{\displaystyle OH}{\overset{|}{\underset{|}{C}}}}-CH_3$$

4

Products **1** and **2** are also found in the photolysis of a solution containing copper. No change in the ratio or position of the peaks was apparent. Product **4** from the radical–radical reaction is not present in the photolyte containing copper but has been replaced by a new product of only slightly longer GC retention time than **2**. Comparison of GC retention times and mass spectra of this product with a commercial sample reveals that this product is 3-methyl-1,3-butanediol **3**. Since the glycol products could be susceptible to pinacol type rearrangements in the acid medium, no attempt was made to determine quantum yields of the organic products. The mass spectra obtained for the reaction products and synthesized diols are shown in Table 1 (*b*) and (*c*).

In the irradiation of 0.01 *M* ferric perchlorate in the presence of benzoic acid, it was found that *o*-, *m*-, and *p*-hydroxybenzoic acids were formed corresponding to the statistical 2:2:1 ratio (13). To evaluate the possibility that the hydroxyl radical abstracts hydrogen from these tertiary alcohols on a statistical basis, we have calculated the fraction of γ-hydrogens relative to the total number of β- and γ-hydrogens in the molecule and from these values predicted quantum yields for Fe(II) based on statistical abstraction. These yields were 0.105 for *tert*-amyl alcohol, 0.094 for 3-methyl-3-pentanol, and 0.085 for 3-ethyl-3-pentanol. For the latter two alcohols, the observed yields in Table 1 are higher than those predicted, indicating some preference towards the abstraction of β-hydrogen rather than γ.

A recent esr study of the photolysis of ferric perchlorate in neat alcohol glasses revealed that methyl radicals were formed from *tert*-butyl alcohol (14). Methyl radicals are inert towards iron(III) and would dimerize without producing iron(II). However, in the presence of copper, the reaction of methyl radicals with copper(II) would result in iron(II) production via reaction 6. It can be seen in Table 1 that there is no effect of copper on the iron yield for *tert*-butyl alcohol scavenging and thus methyl radicals are not produced in the photolysis in aqueous solution. The methyl radicals observed in neat alcohol glasses may result from excitation of an alcohol-to-iron charge transfer transition. Such a transition is unlikely in dilute aqueous solution where it has previously been demonstrated that *tert*-butyl alcohol does not enter the primary coordination sphere of iron(III) (4).

There is no evidence for outer-sphere reaction between any of the tertiary alcohols studied and the ferric CT excited state. This result supports the suggestion that an H on the carbon bearing oxygen is necessary for the excited state reaction (4).

It is evident that differences in reactivity of radicals towards various metal oxidants may allow individual radicals to be observed. This may prove to be an important tool for mechanistic interpretation. We intend to explore this possibility further.

Crystal structure of a dimeric 1-methylcytosine mercuric chloride complex

MONIQUE AUTHIER-MARTIN AND ANDRÉ L. BEAUCHAMP

Département de Chimie, Université de Montréal, Montréal (Qué.), Canada H3C 3V1

Received August 12, 1976

MONIQUE AUTHIER-MARTIN and ANDRÉ L. BEAUCHAMP. Can. J. Chem. **55**, 1213 (1977).

Di-μ-chloro-bis[chloro(1-methylcytosine-O,N^3)mercury(II)] belongs to space group $P2_1/c$ with cell dimensions $a = 9.932(2)$, $b = 14.051(3)$, $c = 9.198(2)$ Å, and $\beta = 135.41(2)°$. The structure was solved by the heavy-atom method and refined to an R factor of 0.027 for 1271 independent reflections. The crystal is composed of centrosymmetric dimeric molecules in which two mercury atoms are attached by a pair of symmetrical chlorine bridges. The 1-methylcytosine ligand is bidentate *via* N(3) and O(2). The metal atom has a (2 + 3) coordination with a very distorted trigonal bipyramid geometry. A chlorine atom at 2.322(3) Å and ring nitrogen N(3) at 2.17(1) Å form strong axial bonds with mercury. Two bridging chlorine atoms at 2.719(2) and 2.745(3) Å, and carbonyl oxygen O(2) at 2.84(1) Å form weaker equatorial bonds. The amino group is hydrogen-bonded to a bridging chlorine of the same molecule (N···Cl = 3.23(1) Å) and a carbonyl oxygen of a neighboring molecule (N···O = 2.86(2) Å).

MONIQUE AUTHIER-MARTIN et ANDRÉ L. BEAUCHAMP. Can. J. Chem. **55**, 1213 (1977).

Les cristaux de di-μ-chloro-bis[chloro(méthyl-1-cytosine-O,N^3)mercure(II)] appartiennent au groupe spatial $P2_1/c$ et les dimensions de la maille élémentaire sont $a = 9.932(2)$, $b = 14.051(3)$, $c = 9.198(2)$ Å et $\beta = 135.41(2)°$. La structure a été résolue par la méthode de l'atome lourd. L'affinement effectué au moyen de 1271 réflexions indépendantes a convergé à un facteur R de 0.027. Le cristal est constitué de molécules dimères centrosymétriques dans lesquelles les deux atomes de mercure sont réunis par deux ponts chlore symétriques. La méthyl-1-cytosine forme un chélate par l'intermédiaire de N(3) et O(2). Le métal possède une coordination (2 + 3) correspondant à une bipyramide triangulaire très déformée. Un atome de chlore à 2.322(3) Å et l'atome N(3) du coordinat à 2.17(1) Å forment des liaisons axiales fortes avec le mercure. Les deux atomes de chlore des ponts à 2.719(2) et 2.745(3) Å, ainsi que l'atome O(2) du groupement carbonyle à 2.84(1) Å, établissent les liaisons équatoriales plus faibles. Les deux atomes d'hydrogène du groupement amino participent à des liaisons hydrogène, l'une intramoléculaire avec le chlore d'un pont (N···Cl = 3.23(1) Å), l'autre intermoléculaire avec l'oxygène du groupement carbonyle (N···O = 2.86(2) Å).

Introduction

As part of our research on metal complexes with purine and pyrimidine bases of DNA, mercuric chloride was found to form a 1:1 addition compound with 1-methylcytosine. Other workers (1) have identified ring nitrogen N(3) as the primary target for Hg^{2+} and CH_3Hg^+ ions in solutions of N(1)-substituted cytosines. X-Ray work on complexes with other metals (2–4) has also shown binding at N(3), but in some cases chelate formation through the adjacent carbonyl group takes place. The present crystal structure was studied in order to ascertain N(3)-coordination and to determine whether the carbonyl group is bonded to mercury.

Experimental

Crystal Data

$C_5H_7N_3OCl_2Hg$ f.w. = 396.63

Monoclinic, space group $P2_1/c$, $a = 9.932(2)$, $b = 14.051(3)$, $c = 9.198(2)$ Å, $\beta = 135.41(2)°$, $V = 901.1$ Å^3, $Z = 4$ monomers (or 2 dimers), $D_c = 2.924$ g cm^{-3}, $D_o = 2.91(1)$ g cm^{-3} (flotation in $CHBr_3$–$Br_2CHCHBr_2$ mixture), $\mu(MoK\alpha) = 171$ cm^{-1}, $\lambda(MoK\bar{\alpha}) = 0.71068$ (graphite monochromator), $t = 23°C$.

Preparation

Mercuric chloride and 1-methylcytosine (0.4 mmol each) were dissolved in 40 ml of water at 80°C. Upon cooling at room temperature, colorless crystals of composition $(MC)HgCl_2$ (where MC = 1-methylcytosine) precipitated. *Anal.* calcd.: Hg 50.57, Cl 17.88, C 15.14, N 10.60, H 1.78; found (Schwarzkopf Lab.): Hg 50.14, Cl 17.50, C 14.96, N 10.81, H 2.04.

The crystal chosen for data collection was a small plate of dimensions 0.37 mm × 0.04 mm × 0.15 mm measured perpendicular to {001}, {010}, and {31$\bar{2}$}. The last set of very small faces was not identified unambiguously, but the absorption correction is not sensitive to its exact positioning.

Crystallographic Measurements

Space group $P2_1/c$ and preliminary cell constants were determined from precession photographs. Refined cell parameters and intensity measurements were obtained

TABLE 1. Refined fractional coordinates ($\times 10^3$, Cl $\times 10^4$, Hg $\times 10^5$) and anisotropic temperature factors ($\times 10^3$, Hg $\times 10^4$), t.f. = exp $\{-(U_{11}a^{*2}h^2 + U_{22}b^{*2}k^2 + U_{33}c^{*2}l^2 + 2U_{12}a^*b^*hk + 2U_{13}a^*c^*hl + 2U_{23}b^*c^*kl)$. with a Syntex P$\bar{1}$ automatic diffractometer. A set of 15 reflections ($11 < 2\theta < 24°$) were automatically centered and indexed according to the standard procedure. Least-squares refinement on the setting angles of those reflections led to the cell parameters given above and to the orientation matrix for data collection. Oscillation photographs taken along each of the three axes showed the expected symmetry and spacing, and confirmed our choice of axes.

All hkl and $hk\bar{l}$ reflections within a sphere of $2\theta < 50°$ were measured. The $\theta/2\theta$ scan technique was used and the scan speed (from 1° to 24° (2θ)/mn) was automatically selected according to peak height. The 2θ scan was from $[2\theta(K\alpha_1) - 1.2°]$ to $[2\theta(K\alpha_2) + 1.2°]$ (Syntex autocollection program). Background counts were taken at each limit and the background time-to-scan time ratio was 0.4. Three standard reflections (002, $\bar{1}\bar{1}1$, $\bar{1}02$) measured every 45 reflections showed variations $< \pm 5\%$ from their respective means. The reduced set of data consisted of 1589 unique reflections. A total of 1271 reflections with net intensities $I \geq 2.5\sigma(I)$ (5) were used to solve the structure. The data were corrected for Lorentz and polarization effects. Absorption corrections based on the equations of the crystal faces were applied at a later stage. A grid of $5 \times 5 \times 10$ was used and the transmission factor ranged from 0.10 to 0.49 (Program NRC-3, Ahmed and Singh).

Resolution of the Structure

The structure was solved by the heavy-atom method. Successive Fourier maps and structure factor calculations revealed the positions of all nonhydrogen atoms. The function minimized in least-squares calculations was $\sum w(|F_o| - |F_c|)^2$. Full-matrix refinement with isotropic temperature factors and weights $w = 1.0$ converged to

$$R = \sum||F_o| - |F_c||/\sum|F_o| = 0.166$$

An absorption correction was introduced and R decreased to 0.086. Anisotropic refinement of all nonhydrogen atoms was carried out using block-diagonal least squares. At this stage, all hydrogen atoms were visible on a ΔF map. They were placed at their calculated positions (C—H and N—H = 0.95 Å) with temperature factors $B = 6.0$ Å^2 ($U = 0.076$ Å^2). Their parameters were not refined, but the shifts on the coordinates of the corresponding carbon or nitrogen atoms were applied to those of hydrogen as well.[1] In the last cycles of refinement, individual weights $w = 1/\sigma_F^2$ (5) were applied to each reflection. Refinement of the scale factor, the secondary extinction coefficient (6), the coordinates, and anisotropic temperature factors of all nonhydrogen atoms converged to $R = 0.027$ and

$$R_w = [\sum w(|F_o| - |F_c|)^2/\sum w|F_o|^2]^{1/2} = 0.031$$

The validity of the weighting scheme was confirmed by the absence of systematic variations of $w(|F_o| - |F_c|)^2$ as a function of $\sin\theta/\lambda$ and $|F_o|$. The final ΔF map showed a few peaks of 1.0 e/Å^3 near mercury and one peak of 0.9 e/Å^3 in the neighborhood of O(2). Elsewhere, the background was lower than ± 0.6 e/Å^3.

The refined parameters are given in Table 1 and a list of structure factors is available upon request.[1] The scattering curves used were those of Cromer and Waber (7) for nonhydrogen atoms and of Stewart *et al.* (8) for hydrogen. The anomalous dispersion coefficients $\Delta f'$ and $\Delta f''$ of Hg and Cl (9) were included in the calculations.

Local versions of the following computer programs were used in this work: F. R. Ahmed and C. P. Huber, NRC-2 (Data Reduction); F. R. Ahmed and P. Singh, NRC-3 (Absorption Correction); R. J. Doedens and J. A. Ibers, NUCLS (Least-squares refinement), with block-diagonal option introduced by J. Sygusch; A. Zalkin, FORDAP (Fourier maps); C. K. Johnson, ORTEP (Stereo drawings).

Description of the Structure and Discussion

The structure consists of centrosymmetric chlorine-bridged dimers where 1-methylcytosine acts as a bidentate ligand (Fig. 1). The five

[1]The structure factor table and the list of hydrogen coordinates are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

TABLE 2. Distances and angles around mercury

Atoms	Distance (Å)	Bonds	Angle (deg)

		N(3)—Hg—O(2)	51.8(4)

[a] $a = x,y,z$.

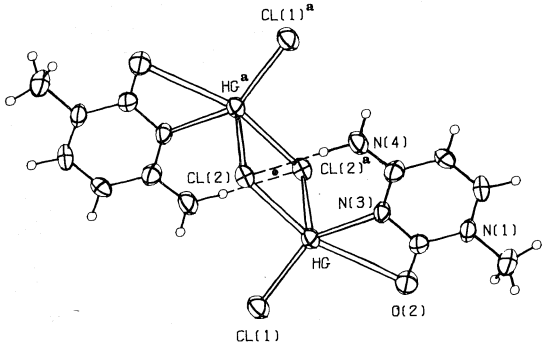

FIG. 1. Structure of the dimer. The left part of the molecule is related to the right part by a crystallographic inversion center shown as a black spot. Dashed lines represent hydrogen bonds. $a = (\bar{x}, \bar{y}, \bar{z})$.

donor atoms within bonding distances do not define a regular polyhedron around mercury (Table 2). On the basis of bond strength, the compound is best described in terms of a (2 + 3) coordination with a highly distorted trigonal bipyramid geometry. Mercury is strongly bonded to Cl(1) and N(3) occupying 'axial positions', whereas O(2) and two crystallographically equivalent Cl(2) atoms form three weaker bonds in the 'equatorial plane'.

It is common to recognize two sets of bonds in the coordination sphere of mercury. For instance, a number of addition compounds contain Cl—Hg—Cl units with strong bonds at ~180° and as many as four weak bonds or contacts in the equatorial plane completing a (2 + 4) octahedral coordination (11–15). The Hg—Cl(1) distance observed here (2.322(3) Å) is typical of such strong bonds. The most unexpected feature of the present structure is that the second strong bond is formed with N(3) instead of Cl(2). The Hg—N(3) distance (2.17(1) Å) is normal for pyridine-type nitrogen (16). Shorter distances, as observed in bis(1-methylthyminato)mercury(II) (2.04 Å) (17), are normally found only when mercury reacts by substitution of an acidic hydrogen atom.

The two Hg—Cl(2) bonds in the equatorial plane are much stronger than Hg—O(2). This produces a displacement of the axial bonds in the direction that increases the Cl(2)—Hg–axial angles above 90° and, as a consequence, the axial–Hg–axial angle is reduced to 148.0(3)°.

The Hg—O(2) distance (2.84(1) Å) is less, although not much, than the sum of the van der Waals radii (3.0 Å) (11). Similar or slightly shorter distances have been reported for complexes with uracil (2.71 Å) (18), dihydrouracil (2.88 Å) (18), and cyclohexanedione (2.79 Å) (14). Consequently, there is a significant oxygen–metal interaction as found in copper–cytosine complexes (3). A comparison of these chelates with the monodentate platinum complex (4) reveals a striking difference between the exocyclic angles at N(3). Pt—N(3)—C(2) and Pt—N(3)—C(4) are 115.3 and 125.1° respectively. The difference of 10° is probably due to steric effect of hydrogen atoms which make the amino group bulkier than a carbonyl group. In the copper complexes, the angles differ by 17.5° and 22.2° (3) and a still greater difference (24°) is found here. This is probably due to chelate formation because such large differences in exocyclic angles are needed to take the carbonyl oxygen close enough to the metal atom. The C(2)—O(2)—Hg angle of 80.6(8)° would also be acceptable, the direction of maximum basicity theoretically predicted by Bonaccorsi *et al.* (19) being at 55° from the C—O bond. In the present case, unequal exocyclic angles also promote intramolecular hydrogen bonding of the amino group with a bridging chlorine

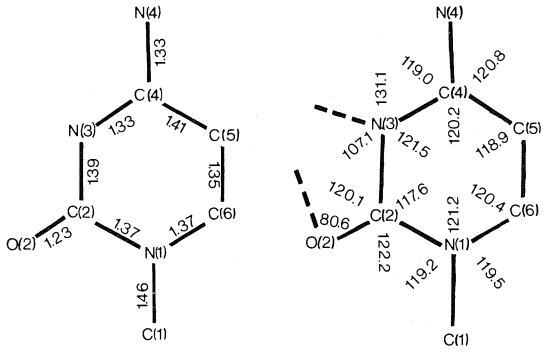

FIG. 2. Interatomic distances and bond angles of the coordinated ligand. The e.s.d.'s are 0.01–0.02 Å on bond lengths and 1.0° on bond angles.

atom: Cl(2)—N(4) = 3.23(1) Å, C(4)—N(4)—Cl(2) = 117.0(9)°.

Most of the Hg—Cl—Hg bridges reported in the literature are either symmetrical, as observed here, with two equivalent Hg—Cl distances of ~2.8 Å, or highly unsymmetrical with one short bond of ~2.3 Å and one weak contact >3.0 Å. The latter type, which is more common, is observed in $HgCl_2$ (11), many of its addition compounds (11–15) and the complex of Cl_3CHgCl with 1,10-phenanthroline (20). Both types of bridges are present in $MHgCl_3$ salts (with M = univalent cation), where octahedral $HgCl_6$ units sharing edges form infinite chains or ribbons (11, 21). To our knowledge, this is the first example of mercury being symmetrically bridged by a pair of chlorine atoms in a discrete molecule.

The geometry of the coordinated ligand is shown in Fig. 2. Bond lengths and bond angles in neutral and protonated cytosine rings have been discussed by Sundaralingam and coworkers (10). The two forms exhibit differences in bond lengths not much greater than the e.s.d.'s of the present work. Our values do not differ significantly from those of either type of ring, except for C(2)—N(3) (1.39(1) Å), which is probably greater than the distance of the neutral form (1.356 Å) and close to that of the protonated form (1.389 Å). In the case of angles, our e.s.d.'s are smaller compared with the differences for the most sensitive angles. Our results (N(1)—C(2)—N(3) = 117.6(1.0)°, C(2)—N(3)—C(4) = 121.5(9)°, N(3)—C(4)—C(5) = 120.2(1.0)°) are more like those of the neutral form (119.1, 120.2, 121.7°) than those of the protonated form (114.8, 124.8, 117.7°).

The amino and methyl groups are in the plane of the six-membered ring within 1σ and their exocyclic angles are normal. The carbonyl group is significantly out of that plane with distances of 0.026 Å (3σ) and 0.042 Å (6σ) for C(2) and O(2) respectively. The exocyclic angles around C(2) are affected by protonation, complexation at N(3), and hydrogen bonding (3, 22). In this case, additional effects are expected from chelation and our results cannot be related in a simple manner to those various phenomena.

A packing diagram (Fig. 3) shows dimers linked by strong intermolecular N—H···O hydrogen bonds: N—O = 2.86(2) Å, C(4)—N(4)—O(2) = 112.5(9)°. All other contacts are normal. It is noteworthy that the organic ligands are approximately parallel within the dimer and in the rest of the structure. Neverthe-

less, the rings are not above each other and there is apparently little direct effect of base stacking as frequently observed with this type of ligands.

Acknowledgments

We wish to thank Dr. Fernande Rochon for permission to use the diffractometer and her valuable assistance in collecting data. This work was supported by the National Research Council of Canada and the Ministère de l'Education du Québec.

The stereochemistry of the Wittig reactions of allylic phosphoranes and phosphonate esters with aldehydes

RICHARD NEVILLE GEDYE, KENNETH CHARLES WESTAWAY, PARKASH ARORA, ROBERT BISSON, AND ALY HAMDY KHALIL

Department of Chemistry, Laurentian University, Sudbury, Ont., Canada P3E 2C6

Received July 23, 1976

RICHARD NEVILLE GEDYE, KENNETH CHARLES WESTAWAY, PARKASH ARORA, ROBERT BISSON, and ALY HAMDY KHALIL. Can. J. Chem. **55**, 1218 (1977).

Methyl *Z*- and *E*-4-bromo-3-methylbut-2-enoate **13** and **14** react with triethyl phosphite stereospecifically with retention of configuration to give the corresponding *Z*- and *E*-phosphonate esters **8** and **9**. The *Z*- and *E*-phosphonates react with aldehydes with extensive stereomutation of the double bond. Rapid equilibration to a mixture of one part *E*-phosphonate to two parts *Z*-phosphonate occurs when either geometric isomer is treated with base. Despite this, the *E*-2,*E*-4 ester **16** is the chief product of the reaction. Methyl *E*-β-ionylideneacetate **16***b* is the major product of the reaction of either isomer with β-cyclocitral and with cyclohexene carboxaldehyde only the *E*-2,*E*-4 isomer **16***c* is formed. Benzaldehyde reacts with the phosphonates to give a mixture of the *E*-2,*E*-4 and *Z*-2,*E*-4 isomers **16***a* and **15***a* in a 4:1 ratio. Although the corresponding *Z*- and *E*-phosphonium salts **6** and **7**, obtained stereospecifically from the bromo esters, react by the same general mechanism as the phosphonates the main product with benzaldehyde is the *Z*-2,*Z*-4 isomer **17***a*.

RICHARD NEVILLE GEDYE, KENNETH CHARLES WESTAWAY, PARKASH ARORA, ROBERT BISSON et ALY HAMDY KHALIL. Can. J. Chem. **55**, 1218 (1977).

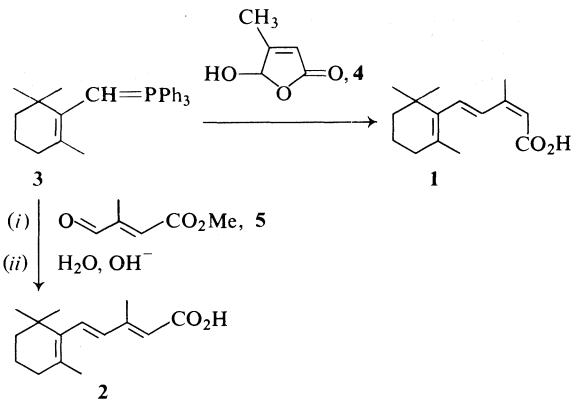
Les *Z* et *E* bromo-4 méthyl-3 buténoate-2 de méthyle (**13** et **14**) réagissent stéréospécifiquement avec le triéthyle phosphite avec rétention de configuration pour conduire aux phosphonates esters *Z* et *E* correspondants (**8** et **9**). Les phosphonates *Z* et *E* réagissent avec les aldéhydes avec une grande stéréomutation de la double liaison. L'équilibration rapide vers un mélange d'une partie de phosphonate *E* par rapport à deux parties de phosphonate *Z* se produit chaque fois qu'un des isomères géométriques est traité avec une base. Malgré ces résultats, l'ester *E*-2,*E*-4 est le produit principal de la réaction. Le *E*-β-ionylidèneacétate de méthyle **16***b* est le produit majeur de la réaction de chacun des isomères avec le β-cyclocitral; avec le cyclohexène carboxaldéhyde, il n'y a que l'isomère *E*-2,*E*-4 (**16***c*) qui est formé. Le benzaldéhyde réagit avec les phosphonates pour conduire à un mélange des isomères *E*-2,*E*-4 et *Z*-2,*E*-4 (**16***a* et **15***a*) dans un rapport de 4:1. Quoique les sels de phosphonium *Z* et *E* correspondants (**6** et **7**), obtenus stéréospécifiquement à partir des bromo esters, réagissent par le même mécanisme général que les phosphonates, le produit principal avec le benzaldéhyde est l'isomère de *Z*-2,*Z*-4 (**17***a*).

[Traduit par le journal]

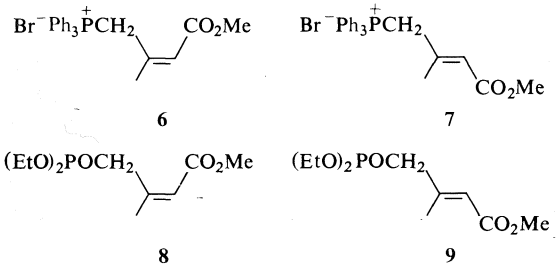
The Wittig reaction of β-ionylideneacetaldehyde with the phosphorane derived from (3-methoxycarbonylprop-2-enyl)triphenylphosphonium bromide (1), and the Horner modification of the Wittig reaction using β-ionylideneacetaldehyde and triesters of 4-phosphono-3-methylbut-2-enoic acid (2, 3) have been used in the synthesis of vitamin A and related compounds. Until recently however, little attention has been given to the stereochemical aspects of these reactions.

Of the methods available for the synthesis of the vitamin A precursor, β-ionylideneacetic acid, the Reformatsky reaction (4–9) and modified Wittig reactions (10, 11) have received particular attention. These reactions are not generally stereospecific and tend to give a mixture of the *Z*- and *E*-isomers of β-ionylideneacetic acid **1** and **2**. The *Z*- and *E*-β-ionylideneacetic acids have recently been prepared stereospecifically in good yield by the reaction of the Wittig reagent **3**, from triphenyl-β-cyclogeranylphosphonium bromide, with 4-hydroxy-3-methylbut-2-enolide **4** and methyl *E*-formylcrotonate **5**, respectively (9). Since the starting materials for these syntheses are not readily available and are tedious to prepare, an alternate stereospecific route is desirable.

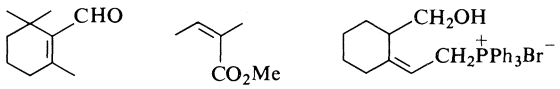
The Wittig reactions of the pure *Z*- and *E*-phosphonium bromides **6** and **7** and of the pure *Z*- and *E*-phosphonate esters **8** and **9** in the Horner modification of the Wittig reaction with β-cyclocitral appeared to provide attractive



routes to a stereospecific synthesis of the *Z*- and *E*-β-ionylideneacetic acids, and hence to the geometrical isomers of vitamin A. In the present study, the stereochemistry of the Wittig reactions of **6**–**9** with β-cyclocitral **10** and other aldehydes has been investigated.

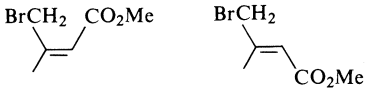


The stereospecificity of the formation of allylic Wittig reagents by the reaction of triphenylphosphine with allylic halides and of the subsequent condensations with carbonyl compounds appears to be in doubt. In an attempted preparation of *Z*-allylic Wittig reagents from the allylic bromide formed by treating methyl *Z*-2-methylbut-2-enoate **11** with *N*-bromosuccinimide, and from methyl *Z*-4-chlorobut-2-enoate, Pattenden and Weedon (12) observed complete inversion of configuration resulting in the formation of the corresponding *E*-phosphonium salts.



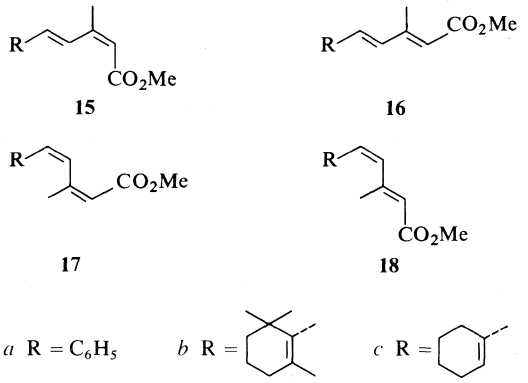
Howe (13) observed retention of configuration during the conversion of mixtures of *Z*- and *E*-isomers of ethyl 4-bromo-3-methylbut-2-enoate to the corresponding phosphonium salts, but found that the *Z*- and *E*-phosphonium salts gave the same mixture of products when condensed with benzaldehyde in the presence of base. Harrison and Lythgoe (14), observed almost complete retention of configuration during the reaction of the *Z*-phosphonium salt **12** with a ketone. It should be noted, however, that the ylide from **12** does not have a resonance stabilizing carbomethoxy group.

In the present study, the *Z*- and the *E*-isomers of methyl 4-bromo-3-methylbut-2-enoate (9), **13** and **14**, were converted with complete retention of configuration into the corresponding phosphonium bromides **6** and **7** at room temperature.



This conclusion was based on the evidence obtained from the nmr spectra of the bromoesters and the phosphonium salts (13, 15).

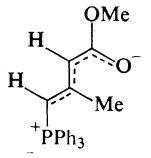
Attention was then focused on the stereochemistry of the Wittig reactions of the phosphonium salts **6** and **7**, in the presence of sodium methoxide, with benzaldehyde and β-cyclocitral. The reactions of the *Z*- and *E*-phosphonium salts with benzaldehyde in the presence of sodium methoxide, although carried out under milder conditions than those conducted by Howe (at 20°C rather than at reflux temperatures), proved to be completely non-stereospecific. The same mixture of isomeric products **15***a*–**18***a* were formed from both **6** and **7** with the *Z*-2,*Z*-4 isomer **17***a* being the principal product.



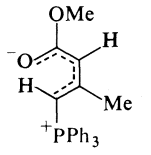
In order to further investigate the observed stereomutations in these Wittig reactions, the ylide **19** was prepared by treating a suspension of the *Z*- and *E*-phosphonium salts **6** and **7** in benzene with an equimolar amount of dilute aque-

ous alkali. The solid isolated from both reactions had identical ir, uv, and nmr spectra. Moreover the nmr spectrum showed only one type of β-methyl group, a situation which would be different if it was a mixture of *Z*- and *E*-isomers (13, 15). Thus it was concluded that **6** and **7** gave the same phosphorane. The isolated phosphorane is a yellow solid which is stable enough to be kept for long periods without decomposition. Participation of the ester group in charge delocalization is evident from the shift of the carbonyl absorption in the infrared from 1700 cm^{-1} in the salt, to 1669 cm^{-1} in the phosphorane.

Corey and Erickson (15) isolated a phosphorane of considerably lower melting point (near 135°C) than that obtained in this investigation (176–180°C). Their product which was formed in basic aqueous acetonitrile was shown by nmr analysis to be a 2:1 mixture of the *Z*- and *E*-phosphoranes, for which the structures **19***b* and **19***a*, respectively, were assigned.



19*a*



19*b*

The nmr spectrum of the crystalline ylide formed in the present study was similar to that of the *Z*-isomer **19***b* (13, 15) and no signals corresponding to those quoted for the *E*-isomer were observed.

The formation of predominantly *Z*-2 isomers in the above Wittig reaction is consistent with the formation, *in situ*, of mainly the *Z*-ylide **19***b* from both the *Z*- and *E*-phosphonium salts **6** and **7**. It should be noted that the isolated ylide reacted with benzaldehyde in benzene solution to give essentially the same isomeric mixture as that obtained in the condensation of **6** and **7** with benzaldehyde.

β-cyclocitral, on the other hand, failed to react with the phosphonium salts **6** and **7** under normal conditions, and on prolonged refluxing with the isolated ylide gave a complex mixture of products. Because of this lack of reactivity, attention was turned to the reactions of the allylic phosphonate esters **8** and **9** with aldehydes since it has been reported (16) that phosphonate carbanions are generally more reactive than the conventional Wittig reagents towards carbonyl compounds.

In their studies of the synthesis of compounds related to vitamin A using triesters of 4-phosphono-3-methylbut-2-enoic acid, Machleidt and Wessendorf (3) have suggested that the reaction may be stereospecific and that the stereochemistry of the product depends on the *Z*- to *E*-ratio of the phosphonate used. Pattenden and Weedon (17), however, found that in the reaction of the *E*-phosphonate **9** with certain aldehydes the expected *E*-2-esters were formed whereas similar reactions with the *Z*-phosphonate **8** were accompanied by extensive stereomutation and only *ca.* 25% of the resulting esters possessed the *Z*-2 configuration. Corey and Erickson (15), on the other hand, found that even the *E*-phosphonate **9** did not give a stereochemically pure product since they observed that the reaction of *n*-hexanal with the *E*-phosphonate gave a mixture of the *E*-2,*E*-4 and *Z*-2,*E*-4 isomers in a 6:1 ratio.

The *Z*- and *E*-phosphonates were prepared by the Michaelis–Arbuzov reaction (18) of the corresponding *Z*- and *E*-isomers of methyl 4-bromo-3-methylbut-2-enoate (9) **13** and **14** with triethyl phosphite. In agreement with the work of Corey and Erickson (15), it was shown by glc and nmr spectroscopy that these reactions occurred with complete retention of configuration. It should be noted that retention of configuration has also been reported in the reaction of nerol bromide with triethyl phosphite (19).

The reactions of the *Z*- and *E*-phosphonates **8** and **9** with benzaldehyde gave results which differed from those of Pattenden and Weedon in that each isomer gave an identical mixture of products. The reactions were carried out in the presence of sodium methoxide in a mixture of methanol and dimethyl formamide and gave, in each case, a mixture of approximately 80% of the *E*-2,*E*-4 isomer **16***a* and 20% of the *Z*-2,*E*-4 isomer **15***a*. Similar results were obtained using sodium amide in tetrahydrofuran.

The reactions of the *Z*- and *E*-phosphonates with β-cyclocitral in the presence of sodium methoxide in methanol and dimethylformamide failed to give any of the expected isomers of methyl-β-ionylideneacetate. When the reactions were carried out using the stronger base sodium amide in tetrahydrofuran a rather complex mixture of products was obtained, of which methyl *E*-β-ionylideneacetate **16***b* was the main com-

ponent. A small amount of the *Z*-isomer **15***b* was also detected. While the product ratio varied slightly in different runs, it was apparent that the *Z*- and *E*-phosphonates again gave essentially the same products.

Both the *Z*- and *E*-phosphonates reacted with cyclohexene carboxaldehyde in the presence of sodium amide in tetrahydrofuran to give a high yield of methyl 5-(cyclohexen-1-yl)-3-methylpenta-*E*-2,*E*-4-dienoate **16***c*. No other isomers were detected by glc or nmr.

It was observed, using a glc analysis, that a rapid isomerization of the *Z*- and *E*-phosphonates giving a mixture of about two parts of the *Z*- to one part of the *E*-isomer occurred in the early stages of the reaction between the phosphonates and these aldehydes. Further investigations showed that the phosphonates equilibrated rapidly with several different bases including aqueous sodium hydroxide, sodium methoxide in methanol, and sodium amide in tetrahydrofuran. In every case a ratio of *Z*- to *E*-phosphonate of approximately 2:1 was obtained. It was noted also that no appreciable equilibration occurred in these solvents in the absence of base. Contrary to previous reports (3, 17), this isomerization would suggest that any particular aldehyde should react with the equilibrium mixture of the *Z*- and *E*-phosphonates to give the same mixture of isomeric products. This is in fact, what was observed.

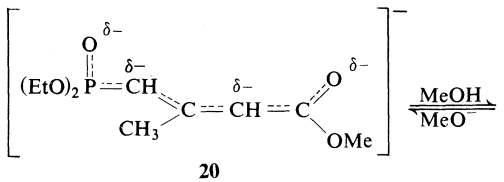
It is generally accepted (20) that the Horner modification of the Wittig reaction involves the formation of a phosphonate carbanion which then undergoes nucleophilic attack on the carbonyl compound. The presence of the phosphonate anions in this reaction was demonstrated by deuterium exchange studies (see below) and by the fact that treatment of the *Z*- and *E*-phosphonate esters with excess *n*-butyllithium in diethyl ether led to new absorptions at longer wavelength in the uv. The *Z*-phosphonate (λ_{max} 226 nm, ε 6500) gave a new absorption initially at 280 nm while the *E*-phosphonate (λ_{max} 219 nm, ε 14 000) gave a new absorption initially at 340 nm. The increase in the λ_{max} is larger for the *E*-isomer which forms a more linear carbanion than the *Z*-isomer (21). On standing, both of the longer wavelength absorptions were observed, thus confirming that the phosphonate esters were isomerizing under the conditions of the experiment. The stronger absorption at 280 nm is consistent with the *Z*-phosphonate ester anion being in higher yield at equilibrium (the *E*-anion should have the larger extinction coefficient (21)). The greater stability of the carbanion from the *Z*-phosphonate, which is U-shaped, than that of the carbanion from the *E*-phosphonate, which is W-shaped, follows observed stabilities of simple allylic carbanions (22).

Since the *Z*- and *E*-phosphonate esters **8** and **9** isomerized rapidly with sodium methoxide in methanol, and since the methylene protons were expected to be quite acidic it was thought that the *Z*- and *E*-carbanions would be present in fairly high concentrations. Three experiments illustrated that this was not the case. First, it was impossible to titrate either the *Z*- or the *E*-phosphonate with sodium methoxide, *i.e.* no measurable amount of the anions was formed. Secondly, it was not possible to detect the uv absorptions of either the *Z*- or the *E*-carbanion when the phosphonate esters were treated with an excess of sodium methoxide in methanol. Thirdly, when an excess of a much stronger base, *n*-butyllithium, was added to a solution of the phosphonate esters in ether, the uv absorbance of the phosphonate ester was not appreciably reduced even though the new absorptions resulting from the carbanions were observed. Thus the isomerization and condensation reaction must occur via the carbanion intermediate which is present in very low concentration. It should also be noted that in selected cases of the Wittig–Horner reaction, carbanion formation does not occur unless the carbonyl reactant is present in solution (20).

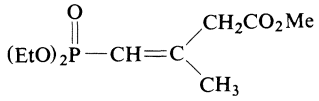
Although the isomerization of the phosphonate esters could occur in two ways, it is certain that it must involve the delocalized carbanion **20**. The α,β bond in the anion **20** will only have partial double bond character and thus one possibility is that isomerization could occur by rotation about this bond.

A second possibility is that the isomerization reaction occurs by way of the β,γ-unsaturated ester **21**, which would form if the carbanion **20** was protonated at the α-carbon.

This mechanism is possible because a deuterium exchange study of both the *Z*- and *E*-phosphonate esters using sodium methoxide in CH_3OD demonstrated that the reactions shown in the above equation were occurring. These exchange tests also illustrated that the rates of



20

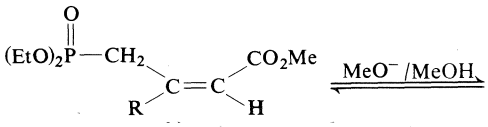


21

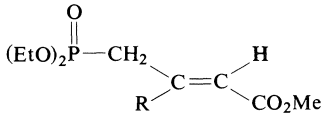
exchange were different; the methylene protons adjacent to the phosphonate group were exchanged almost instantaneously whereas the vinyl hydrogen was exchanged at a much lower rate.

The relative rates of exchange and isomerization were determined in an attempt to distinguish between the two possible mechanisms. If isomerization occurred by way of the β,γ-unsaturated ester **21**, exchange at the vinyl hydrogen would have to occur at least as rapidly as the isomerization. It was found that exchange of the vinyl hydrogen was complete before the equilibrium of the *Z*- and *E*-phosphonates was fully established (Table 1). Since these results indicate that **21** is an intermediate in this reaction and since exchange occurs faster than isomerization, it is probable that isomerization occurs via rotation about the α,β bond in **21**.

The fact that the *Z*-phosphonate predominates in the base-catalyzed equilibration is thought to be due to the increased steric crowding that exists in the *E*-phosphonate. Space-filling models indicate that the steric hindrance between the CH_3 group (at C-3) and the $-CO_2CH_3$ group in the *E*-isomer is larger than between the $-CH_2PO(OEt)_2$ group and the $-CO_2CH_3$ group in the *Z*-isomer. In order to check this hypothesis stereomutation studies were also carried out on the *Z*- and *E*-phosphonates **8***a* and **9***a* derived from the reaction of the *Z*- and *E*-isomers of methyl 4-bromocrotonate with triethylphosphite. The previously unreported methyl *Z*-4-bromo-3-methylcrotonate was obtained in small amounts when the product of the reaction of methyl crotonate and *N*-bromosuccinimide was distilled on an annular spinning band column. The stereochemistry of both the *Z*-bromo ester and the *Z*-phosphonate **8***a* was confirmed by nmr studies which showed a considerable downfield shift in the absorption of the $-CH_2Br$ and the $-CH_2PO$ protons in the *Z*-isomers compared with the corresponding *E*-isomers. This is due to a greater degree of deshielding of the methylene protons by the carboxymethyl group in the *Z*-isomers (21). It was shown, using a glc analysis, that both **8***a* and **9***a* isomerized rapidly in the presence of a catalytic amount of sodium methoxide in methanol[1] giving a mixture of ten parts of the *E*-isomer **9***a* to one part of the *Z*-isomer **8***a*.



8 (R = CH_3) 65%
8*a* (R = H) 10%



9 (R = CH_3) 36%
9*a* (R = H) 90%

These results substantiate the above hypothesis[2] because replacement of the CH_3 (in **9**) by H (in **9***a*) would remove the steric hindrance between the substituent at C-3 and the carbometh-

TABLE 1. Exchange and isomerization studies[a] in the reactions of methyl *Z*-and *E*-4-phosphono-3-methylbut-2-enoate, **8** and **9**, with CH_3ONa in CH_3OD (analysis by nmr)

Starting ester	*Z*-Isomer (%)	*E*-Isomer (%)	Exchange at vinyl CH (%)
Z	81	19	44
Z	78	22	60
Z	71	29	100
Z	64	36	100
E	50	50	60
E	62	38	100
E	63	37	100

[a]The equilibrium mixture contained 64% of the *Z*-isomer and 36% of the *E*-isomer.

[1]These isomers did not appear to be stable in the presence of sodium methoxide, since neither isomer could be detected in the reaction mixture after standing for 1 h.

[2]A second possibility to explain the relative stabilities of the *Z*- and *E*-isomers *i.e.* that a six-membered ring in which the carbonyl oxygen is coordinated with the phosphorus as in the ylide **19***b*, was ruled out because the frequencies of the infrared absorptions of both the C=O and the P=O groups were identical in both the *Z*- and *E*-phosphonates **8** and **9** and also because of the results of these stereomutation studies.

oxy group and would result in increased stability of the *E*-isomer. In the case of the 4-phosphonocrotonates steric hindrance would only be expected to be significant in the *Z*-isomer, where the $—CH_2PO(OEt)_2$ and the $—CO_2Me$ group are on the same side of the double bond. Thus the *Z*-isomer should be much less stable than the *E*-isomer. This is illustrated by the high concentration of the *E*-isomer **9***a* in the base-catalyzed equilibrium mixture, and by the fact that the *Z*-isomer isomerized to give an appreciable amount of the *E*-isomer on standing at room temperature for a few days.

Attention was then turned to the stereochemistry of the condensation of the *Z*- and *E*-phosphonate esters **8** and **9** with benzaldehyde, β-cyclocitral, and cyclohexene carboxaldehyde. The product ratio in the base-catalyzed isomerization of the methyl 4-phosphono-3-methylbut-2-enoates might lead to the prediction that predominantly *Z*-2,*E*-4 products would be formed in these modified Wittig reactions regardless of the stereochemistry of the initial phosphonate ester. However, in all the reactions investigated, the *E*-2,*E*-4 products predominated, suggesting either that a second stereomutation of the products occurred or that the *E*-phosphonate anion reacts more rapidly than the *Z*-phosphonate anion with aldehydes.

Control experiments (Table 2) showed that methyl *Z*-2,*E*-4-5-phenyl-2,4-pentadienoate **15***a* underwent a slow isomerization in the presence of sodium methoxide in methanol and dimethylformamide to give an equilibrium mixture of 35% of the *Z*-2,*E*-4 isomer and 65% of the *E*-2,*E*-4 isomer **16***a* (by glc).

On the other hand, the reaction of benzaldehyde with either the *Z*-phosphonate **8** or the *E*-phosphonate **9** (Table 3) gave, after a few minutes, a small amount of a mixture of approximately 85% of the *E*-2,*E*-4 isomer **16***a* and 15% of the *Z*-2,*E*-4 isomer **15***a*. These proportions cannot be explained by a second stereomutation of **15***a* or **16***a* since the control experiment above showed that such a stereomutation would be comparatively slow. The gradual decrease of the proportion of the *E*-2,*E*-4 isomer with time (Table 3) is consistent with the results of the control experiment. It must be concluded, therefore, that the *E*-phosphonate anion reacts more rapidly with aldehydes than the *Z*-phosphonate anion. The fact that the newly formed double bond (at C-4) had entirely the *E*-configuration is consistent with the stereochemical course proposed by Boutagy and Thomas (20) for the Wittig–Horner reaction (Scheme 1).

TABLE 2. Isomerization of methyl *Z*-2,*E*-4-5-phenyl-2,4-pentadienoate with sodium methoxide in methanol and DMF at 25°C (analysis by glc)

Time (h)	*Z*-2,*E*-4 Isomer (%)	*E*-2,*E*-4 Isomer (%)
0	100	0
1	46	54
4	39	61
8	38	62
12.5	37	63
24	35	65

TABLE 3. Product ratios observed from the reaction of methyl *Z*- and *E*-4-phosphono-3-methylbut-2-enoate with benzaldehyde in the presence of sodium methoxide in methanol and DMF at 25°C (by glc)

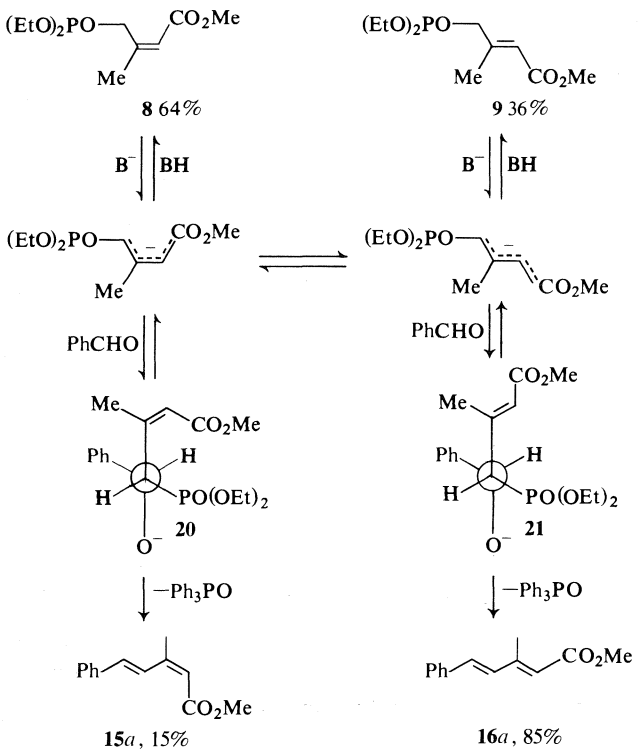
Time (min)	Ratio *Z*-2,*E*-4/*E*-2,*E*-4 from *Z* (%)	Ratio *Z*-2,*E*-4/*E*-2,*E*-4 from *E* (%)
2	16/84	14/86
30	20/80	21/79
60	25/75	25/75

The formation of the *Z*-and *E-threo* betaines **20** and **21** by the addition of the *Z*- and *E*-phosphonate carbanions to benzaldehyde would be expected to be faster than the formation of the *Z*- and *E-erythro* betaines, which are more sterically hindered. Since the rate of decomposition of the *threo* betaines would also be expected to be greater than that of the *erythro* betaines (20), the *Z*-2,*E*-4 and *E*-2,*E*-4 **15***a* and **16***a* isomers would be expected to be the chief products of the reaction.

The fact that the *E*-2,*E*-4 isomer **16***a* is formed more rapidly than the *Z*-2,*E*-4 isomer **15***a*, despite the lower equilibrium concentration of the *E*-phosphonate can be explained by the greater steric crowding in the *Z-threo* betaine **20** than in the *E-threo* betaine **21**. Also, since the *E*-2,*E*-4 isomer is thermodynamically more stable than the *Z*-2,*E*-4 isomer, it would be expected to be the chief product of the reaction under equilibrium conditions.

In conclusion, these studies have illustrated the following points.

(*a*) The reactions of the *Z*- and *E*-phosphonium salts **6** and **7** with aldehydes proceed with



SCHEME 1

extensive stereomutation giving the same mixture of products from either isomer. The reaction involves the intermediate formation of the *Z*-ylide and in the case of the reaction with benzaldehyde results in products with predominantly the *Z*-2 configuration.

(*b*) The Horner phosphonate ester modification of the Wittig reaction gives the same mixture of isomeric products when either the *Z*- or the *E*-phosphonate esters **8** and **9** are reacted with a particular aldehyde. This result is observed because the carbanion, which is present in a low concentration, isomerizes rapidly to give an equilibrium mixture of the phosphonate esters in the initial stages of the reaction.

(*c*) The above reactions thus do not offer an improved route for the synthesis of vitamin A or its precursors because of their lack of stereospecificity. Although the *E*,*E*-isomer is the principle product from Horner modification of the Wittig reaction with β-cyclocitral, the yield is only fair under the conditions used in this investigation.

Experimental

All boiling points and melting points are uncorrected. Infrared spectra were recorded with a Beckman IR-10 double beam spectrophotometer. The nmr spectra were obtained with a Varian A-60 in deuterochloroform unless otherwise stated, with tetramethylsilane as an internal reference. Ultraviolet spectra were recorded with a Hitachi–Perkin-Elmer model 124 double beam spectrophotometer. Gas chromatography was carried out on a Varian Aerograph model 90-P using a 160 × 6 mm column of 3% SE-30 silicone gum rubber on Chromosorb W. Elemental analyses were carried out in the School of Chemistry, University of Bristol, England.

(Z-3-Methoxycarbonyl-2-methylprop-2-enyl)triphenylphosphonium Bromide **6**

To a well stirred suspension of triphenylphosphine (26.6 g, 0.1 mol) in dry ether or dry benzene (150 ml) was added dropwise methyl *Z*-4-bromo-3-methylbut-2-enoate (9) **13** (19.3 g, 0.1 mol) in dry ether (30 ml). The mixture was stirred for 24 h at room temperature. The crude phosphonium salt was filtered, washed with dry ether, and finally dried for 6 h at 40°C/10 torr, giving the *Z*-phosphonium salt **6** (38.0 g, 83%), mp 140–143°C. The analytical sample, obtained by recrystallization from methanol – ethyl acetate and dried at 40°C/10 torr for 6 h, had mp 134–136°C, λ_{max} (EtOH) 203, 222.5, 262, 267.5, and 275 nm; ν_{max} (KBr) 1705vs, 1645s, 1585w, 1480m, 1438vs,

1385m, 1360m, 1245s, 1225vs, 1195w, 1168m, 1150vs, 1105vs, 1030s, 990m, 895s, 850m, 745vs, 715s, 703m-s, 682s, and 650s cm^{-1}; nmr ($F_3C—CO_2H$) δ 7.65–7.80 (m, aryl H), 6.07 (br d, J = 5 Hz, C:CH), 4.87 (d, J = 16 Hz, $\overset{+}{P}CH_2$), 3.45 (s, OMe), and 1.97 (m, MeC:C). *Anal.* calcd. for $C_{24}H_{24}BrO_2P$: C 63.29, H 5.31, Br 17.55; found: C 62.96, H 5.56, Br 17.23.

(E-3-Methoxycarbonyl-2-methylprop-2-enyl)triphenylphosphonium Bromide 7

Repetition of the above procedure using *E*-bromoester **14** gave the *E*-phosphonium salt **7** (40.0 g, 99%), mp 178–181°C. The analytical sample which was obtained by recrystallization from methanol – ethyl acetate and dried at 40°C/10 torr for 6 h, had mp 177–179°C, (lit. (15) bp 183–184°C); λ_{max} (EtOH) 204, 224, 268, and 275 nm; ν_{max} (KBr) 1700vs, 1645s, 1545w, 1440s, 1430s, 1280vs, 1155w, 1105vs, 1032w, 885w, 815w, 768s, 750s, 740m, 712s, and 680 cm^{-1}; nmr ($F_3C—CO_2H$) δ 7.77–7.92 (m, aryl H), 5.92 (br d, J = 5 Hz, C:CH), 4.27 (d, J = 16 Hz, $\overset{+}{P}CH_2$), 3.90 (s, OMe), and 2.08 (MeC:C). *Anal.* found: C 63.27, H 5.40, Br 17.89.

When an unseparated mixture of *Z*- and *E*-bromoesters, **13** and **14** was treated in the same manner as above a phosphonium salt of mp 162°C was obtained (lit. (24) mp 160°C). Nuclear magnetic resonance spectroscopy showed that this salt is a mixture of the phosphonium salts **6** and **7**.

Z-Diethyl 3-Methoxycarbonyl-2-methylprop-2-enylphosphonate 8

The *Z*-bromoester **13** (38.6 g, 0.2 mol) was added slowly to triethyl phosphite (33.2 g, 0.2 mol). The mixture was heated gradually to 150°C and maintained at this temperature for 1 h. Distillation of the residue gave only the *Z*-phosphonate ester **8** (43.5 g, 87%) bp 99–100°C/1 torr; glc showed only one peak; n_D^{24} 1.4590 (lit. (12) bp 82°C (bath/10^{-2} torr, n_D^{21} 1.4591); λ_{max} (MeOH) 227 nm (ε 6.5 × 10^3); ν_{max} (neat) 1714vs, 1650s, 1436s 1249vs, 1161vs, 1051vs, 1030vs, 960s, and 780mw cm^{-1}; nmr δ 5.83 (br d, J = 5 Hz, C=CH), 4.11 (2, J = 7 Hz, O—CH_2Me), 3.70 (s, OMe), 3.47 (d, J = 23 Hz, CH_2, —PO<), 2.07 (dd, J = 1.5 and *ca.* 4 Hz, MeC=C), 1.29 (t, J = 7 Hz, CH_3CH_2O—). *Anal.* calcd. for $C_{10}H_{19}O_5$: C 48.0, H 7.61; found: C 47.9, H 7.7.

E-Diethyl 3-Methoxycarbonyl-2-methylprop-2-enylphosphonate 9

Repetition of the preceding experiment using *E*-bromoester **14** gave the *E*-phosphonate **9**, bp 107–108°C/1 torr (lit. (15) bp 112°C/0.12 torr); glc showed only one peak of longer retention time than the *Z*-phosphonate **8**; n_D^{24} 1.4617; λ_{max} (MeOH) 219 nm (ε 13.8 × 10^3); ν_{max} (neat) 1719vs, 1650s, 1438s, 1243vs, 1216vs, 1150vs, 1050vs, 1030vs, 960s, 870m, 850w, 833w, 780m cm^{-1}; nmr δ 5.83 (br d, J = 5 Hz, C=CH—), 4.14 (q, J = 7 Hz, O—CH_2Me), 3.71 (s, OMe), 2.69 (d, J = 23 Hz, CH_2—PO<), 2.30 (dd, J = 1.5 and *ca.* 4 Hz, Me—C=C), and 1.31 (t, J = 7 Hz, CH_3CH_2O—). *Anal.* calcd. for $C_{10}H_{19}O_5$: C 48.0, H 7.61; found: C 47.8, H 7.65.

(3-Methoxycarbonyl-2-methylprop-2-enyllidene)triphenylphosphorane 19

(*E*-3-Methoxycarbonyl-2-methylprop-2-enyl)triphenyl phosphonium bromide **7** (45.5 g, 0.1 mol) was suspended in water (200 ml) and benzene (250 ml) was added. The well stirred mixture was brought to the phenolphthalein equivalence point by the addition of aqueous sodium hydroxide solution (3%). The two layers were separated. The deep yellow coloured benzene layer was dried over anhydrous sodium sulphate, and concentrated to a small volume. Careful addition of dry petroleum ether (bp 30–60°C) caused crystallization of the ylide **19** as shiny yellow needles. The ylide was filtered and dried at 25°C/10 torr for 1 h giving 26.3 g (70%), mp 174–180°C with sintering at 166°C (lit. (15) mp near 135°C); λ_{max} (CH_3CN) 227 nm; ν_{max} (KBr) 1669vs, 1645vs, 1503vs, 1448vs, 1390m, 1210w, 1181s, 1119vs, 1095m, 1015m, 999w, 932m, 899m, 805w, 775w, 715s, and 690 cm^{-1}; nmr δ 7.33–7.93 (m, aryl H), 4.70 (br, C=CH—), 3.62 (s, OMe), 3.41 (only half of the —CH=P— doublet can be seen), and 1.63 (MeC=C). *Anal.* calcd. for $C_{24}H_{23}O_2P$: C 76.99, H 6.19; found: C 76.75, H 6.23.

When the above experiment was repeated using (*Z*-methoxycarbonyl-2-methylprop-2-enyl)triphenylphosphonium bromide **6** the same ylide **19** was obtained as shown by uv, ir, and nmr spectroscopy.

The Wittig Reaction of the Z-and E-Phosphonium Salts 6 and 7 with Benzaldehyde

(*i*) A stirred solution of (*Z*-3-methoxycarbonyl-2-methylprop-2-enyl)triphenylphosphonium bromide **6** (0.2 g, 0.4 mmol) in 1 ml of absolute methanol was treated with a solution of sodium methoxide (0.4 mmol) (from 10 mg sodium in 1 ml absolute methanol) whereupon the yellow colour of the ylide developed immediately. The yellow solution was stirred for 15–20 min at 20°C, and then benzaldehyde (44 mg, 0.4 mmol) in methanol (1 ml) was added rapidly. The reaction mixture was stirred for 3 h, concentrated under reduced pressure, and the residue was taken up in ether. The ethereal solution was washed with water, dried over anhydrous sodium sulphate, evaporated, and then extracted with hexane. Evaporation of the hexane gave a semi solid product of which the solid portion was shown to be mainly triphenylphosphine oxide. Gas–liquid chromatography of the liquid portion showed three peaks in an approximately 6:1:1 ratio. The first peak was shown to be due to a mixture of the *Z*-2,*Z*-4 ester **17***a* and the *E*-2,*Z*-4 isomer **18***a*, the second peak the *Z*-2,*E*-4 isomer **15***a*, and the third peak the *E*-2,*E*-4 isomer **16***a* by comparison with reference compounds (see below). The nmr spectrum (in CCl_4) was taken and compared with the spectra of the reference compounds which agreed with the literature values (25). The analysis was performed by integration of the signals due to the 3-methyl groups which appeared at δ 1.76 (*Z*-2,*Z*-4 isomer), δ 2.10 (*Z*-2,*E*-4 and *E*-2,*Z*-4 isomers), and δ 2.36 (*E*-2,*E*-4 isomer). A combination of the glc and nmr analyses showed that the product contained 48% *Z*-2,*Z*-4 **17***a*, 23% *E*-2,*Z*-4 **18***a* 15% *Z*-2,*E*-4 **15***a*, and 14% *E*-2,*E*-4 **16***a* isomers of methyl 3-methyl-5-phenylpenta-2,4-dienoate.

(*ii*) Repetition of the above procedure using the *E*-phosphonium salt gave a product of the same composition (glc assay) as that obtained in the above experiment.

The Wittig Reaction of the Ylide 19 with Benzaldehyde

To the ylide **19** (14.0 g, 0.037 mol) in dry benzene (100 ml) was added benzaldehyde (7.84 g, 0.074 mol) in ben-

zene (25 ml). The mixture was stirred for 1 h under nitrogen at room temperature and then refluxed for 72 h. The excess solvent was evaporated under reduced pressure, the residue diluted with 100 ml of petroleum ether (bp 30–60°C), and the precipitated triphenylphosphine oxide (mp 157–158°C) collected by filtration. The filtrate was dried over anhydrous sodium sulphate. Evaporation of the solvent and distillation of the residue gave a pale yellow oil (3.97 g), bp 110–114°C/1 torr. The product was shown by glc to be a mixture of 45% *Z*-2,*Z*-4 **17***a*, 25% *E*-2,*Z*-4 **18***a*, 14% *Z*-2,*E*-4 **15***a*, and 14% *E*-2,*E*-4 **16***a* isomers of methyl 3-methyl-5-phenylpenta-2,4-dienoate (yield 53%).

The yield was slightly improved (61%) when the reaction was carried out in a sealed tube at 170°C in the presence of benzoic acid and excess benzaldehyde (2 equiv.) (26).

*Reaction of the Z- and E-Phosphonate Esters **8** and **9** with Benzaldehyde*

(*i*) To a well stirred suspension of sodium amide (1.0 g, 0.025 mol) in tetrahydrofuran (20 ml) was added a mixture of benzaldehyde (2.65 g, 0.025 mol) and the *Z*-phosphonate **8** (5.48 g, 0.022 mol) in tetrahydrofuran (20 ml) during 15 min. The reaction mixture was stirred at 0°C for 30 min, and then at 30–40°C for an additional 30 min. The mixture was cooled to 0°C, and then saturated sodium chloride solution (50 ml) added. The product was taken up in petroleum ether (bp 30–60°C), washed with water, dried, and evaporated. Distillation of the residue gave a pale yellow oil (4.5 g) bp 85–90°C/0.03 torr. The product was shown by glc to be a mixture of 20% *Z*-2,*E*-4 **15***a* and 80% *E*-2,*E*-4 **16***a*, isomers of methyl 3-methyl-5-phenylpenta-2,4-dienoate (yield 82%).

(*ii*) Repetition of the preceding reaction with the *E*-phosphonate gave a colourless oil (4.2 g) bp 86–90°C/0.03 torr. The product was shown by glc to be a mixture of 20% *Z*-2,*E*-4 **15***a* and 80% of the *E*-2,*E*-4 **16***a*, isomers of methyl 3-methyl-5-phenyl-2,4-dienoate (yield 76%).

(*iii*) To a solution of benzaldehyde (40 mg, 0.38 mmol) and the *Z*-phosphonate **8** (130 mg, 0.52 mmol) in dimethylformamide (5 ml) was added dropwise over a period of 5 min a solution of sodium (0.015 g) in methanol (1 ml) (0.65 mmol of sodium methoxide). The mixture was stirred at room temperature for 1 h, aliquots being taken at various time intervals and analyzed by glc (Table 3). The product was diluted with water and extracted with petroleum ether (bp 60–80°C). The extracts were evaporated, washed with sodium chloride solution, dried over anhydrous magnesium sulfate, and evaporated giving a yellow oil. Gas–liquid chromatographic analysis of the oil showed the presence of methyl *E*-2,*E*-4-3-methyl-5-phenylpenta-2,4-dienoate **16***a* (80%) and the *Z*-2,*E*-4 isomer **17***a* (20%). Nuclear magnetic resonance spectroscopy (by integration of the CH_3—C= signal) showed the presence of 84% of the *E*-2,*E*-4-isomer and 16% of the *Z*-2,*E*-4 isomer.

(*iv*) Repetition of the above reaction using the *E*-phosphonate **9** gave a yellow oil, shown by glc and nmr analysis to contain the *E*-2,*E*-4 isomer (79%) and the *Z*-2,*E*-4 isomer (21%).

Isomerization of Methyl Z-2,E-4-3-Methyl-5-phenylpenta-2,4-dienoate with Sodium Methoxide

To the diene ester (50 mg, 0.25 mmol) in dimethylformamide (5 ml) was added a solution of sodium (7 mg) in methanol (1 ml) (0.3 mmol of CH_3ONa) over a period of 4 min. The mixture was stirred at room temperature for 24 h and aliquots taken at various time intervals. The percentage of the *Z*-2,*E*-4 and *E*-2,*E*-4 isomers **15***a* and **16***a* in the aliquots were determined by glc analysis (Table 2).

*The Reaction of the Z- and E-phosphonates **8** and **9** with β-cyclocitral*

(*i*) A mixture of β-cyclocitral (3.8 g; 0.025 mol) and *Z*-diethyl 3-methoxycarbonyl-2-methylprop-2-enylphosphonate **8** (6.5 g, 0.027 mol) in tetrahydrofuran (20 ml) was added during 15 min to a well stirred suspension of sodium amide (1.0 g, 0.025 mol) in tetrahydrofuran (20 ml) at 0°C. The reaction mixture was stirred at 0°C for 30 min, and then at 30–40°C for an additional 30 min. The mixture was cooled to 0°C, and saturated sodium chloride solution (50 ml) was added. The product was taken up in petroleum ether (bp 30–60°C), washed thoroughly with water, dried, and then evaporated. Distillation of the residue gave a pale yellow oil (4.9 g), bp 156–162°C/5 torr. The product was shown by glc to contain about 50% methyl *E*-β-ionylideneacetate, 10% methyl *Z*-β-ionylideneacetate and several other unidentified products.

(*ii*) Repetition of the preceding experiment with the *E*-phosphonate **9** gave a pale yellow oil (4.5 g), bp 158–164°C/5 torr. The product was shown by glc to have the same composition as that obtained above from the *Z*-phosphonate.

(*iii*) To a solution of β-cyclocitral (68 mg, 0.45 mmol) and the *Z*-phosphonate **8** (130 mg, 0.52 mmol) in dimethylformamide (5 ml), was added dropwise over a period of 5 min a solution of sodium (15 mg) in methanol (1 ml) (0.65 mmol of sodium methoxide). The mixture, which became orange after a few minutes, was stirred for 1 h at room temperature, diluted with sodium chloride solution, and extracted with petroleum ether. The extracts were washed with water, dried over anhydrous magnesium sulfate, and evaporated giving a viscous pale green oil. The product was shown to contain no methyl *Z*- or *E*-β-ionylideneacetate, although two products with much longer retention times were detected by glc analysis.

(*iv*) The above experiment was repeated using the *E*-phosphonate **9**. Similar results were obtained.

*The Reaction of Cyclohexenecarboxaldehyde with the Z- and E-Phosphonates **8** and **9***

(*i*) A mixture of cyclohexenecarboxyldehyde (2.75 g, 0.025 mol) and *Z*-diethyl 3-methoxycarbonyl-2-methylprop-2-enylphosphonate (6.5 g, 0.027 mol) in tetrahydrofuran (20 ml) was added during 15 min to a well stirred suspension of sodium amide (1.0 g, 0.025 mol) in tetrahydrofuran (20 ml) at 0°C. The reaction mixture was stirred at 0°C for 30 min, and then at 30–40°C for an additional 30 min. The mixture was cooled to 0°C, and saturated sodium chloride solution (50 ml) was added. The product was taken up in petroleum ether (bp 30–60°C), washed thoroughly with water, dried, and then evaporated. Distillation of the residue gave an oil (4.8 g, 92%), bp 116–119°C/3 torr. The product was shown by glc and nmr spectroscopy to be methyl 5-(cyclohexen-2-yl)-3-methylpenta-*E*-2,*E*-4-dienoate **16***c* when compared with a sample prepared from methyl *E*-formylcrotonate (9).

(*ii*) On repetition of the preceding experiment using the *Z*-phosphonate, only the *E*-2,*E*-4 isomer was obtained. No other isomer could be detected by glc or nmr.

*Isomerization and Exchange Studies on the Z- and E-Phosphonates **8** and **9***

(i) With Sodium Methoxide in Methanol

The *E*-phosphonate (71 mg, 0.28 mmol) in methanol (0.1 ml) was treated with 0.4 ml of a solution of sodium (15 mg) in methanol (1 ml) (0.26 mmol of CH_3ONa). Aliquots of the reaction were analyzed on glc after 1 min, 2 min, and 10 min. In each case the mixture contained 65% of the *Z*-phosphonate and 35% of the *E*-phosphonate (higher retention time).

Repetition of the reaction using the *Z*-phosphonate gave the same proportion of isomers. The use of a catalytic amount of sodium methoxide also gave the same product ratio.

(ii) With Other Bases

A similar isomerization was observed using sodium amide, sodium hydride, or sodium hydroxide as the base, and in each case an approximately 2:1 ratio of the *Z*- to *E*-isomer was detected using glc analysis.

(iii) With Sodium Methoxide in CH_3OD

In a typical procedure the *Z*-phosphonate (26 mg, 0.1 mmol) was treated with sodium methoxide (3 mg, 0.05 mmol) in CH_3OD (7 ml). The reaction was quenched by adding DCl in D_2O after 3 min. The mixture was extracted with ether and the ether extracts washed with D_2O, dried over anhydrous magnesium sulfate, and evaporated giving a pale yellow oil, which was analyzed by nmr spectroscopy. Integration of the peaks at δ 2.07 ppm ($CH_3C{=}C$, *Z*-isomer) and δ 2.30 ppm ($CH_3C{=}C$, *E*-isomer) showed the presence of the *Z*-isomer (81%) and the *E*-isomer (19%). Integration of the peak at δ 5.83 ppm (C=CH, *Z*- and *E*-isomer) showed that the vinyl hydrogen was 44% exchanged. The absence of the peaks at δ 3.47 ppm (CH_3PO, *Z*-isomer) and 2.69 ppm (CH_2PO, *E*-isomer) showed that the methylene protons were completely exchanged. For a summary of results of different runs, see Table 1.

Methyl Z- and E-4-Bromocrotonate

Methyl crotonate (28.5 g, 0.285 mol) in anhydrous carbon tetrachloride (100 ml) was refluxed with *N*-bromosuccinimide (46 g, 0.26 mol) in the presence of benzoyl peroxide (0.1 g) for 12 h. The succinimide was collected by filtration and the filtrate evaporated. Distillation gave a methyl 4-bromocrotonate (33.3 g, 72%) bp 82–91°C/12 torr. A glc analysis of the distillate indicated that the product was a mixture of approximately 1 part of the *Z*-isomer (lower retention time) to 20 parts of the *E*-isomer.

The product was fractionated using an annular spinning band column with approximately 100 theoretical plates giving two main fractions: (*1*) 0.30 g, bp 56–57°C/8.5 torr (>90% *Z*-isomer, glc and nmr); (*2*) 12.5 g, bp 66–67°C/8.5 torr (pure *E*-isomer, glc and nmr) (lit. (27) bp 83.5–85.5°C/15 torr). Fraction *1*: ir ν_{max} 1726vs, 1648s, 1441s, 1400s, 1296m, 1200vs, 1075m, 940m, 920s, 735m cm^{-1}; nmr δ 6.20 (br, HC= at C-3), 5.63 (d, J = 12 Hz, $=CHCO_2Me$), 4.40 (d, J = 7 Hz, CH_2Br), 3.59 (s, CO_2CH_3). Fraction *2*: ir ν_{max} 1729s, 1660s, 1439s, 1320s, 1280s, 1200s, 1135s, 1034s, 1007m, 975s, 722s cm^{-1}; nmr δ 6.81 (q, J = 7.6 Hz, HC= at C-3), 5.92 (d, J = 15 Hz, =CH—CO_2Me), 3.97 (e, J = 7.2 Hz, $BrCH_2$—), 3.60 (s, CO_2CH_3).

Methyl Z- and E-4-Phosphonocrotonate

(*i*) A mixture of methyl 4-bromocrotonate (14.6 g, 0.08 mol) (containing approximately 20 parts of the *E*- to 1 part of the *Z*-isomer) and triethylphosphite (13.7 g, 0.08 mol) was heated gradually to 150°C during 2 h. The product was distilled giving methyl 4-phosphonocrotonate (17.7 g, 95%) bp 127–134°C/3 torr (lit. (28) 115–130°C/0.3 torr). Gas–liquid chromatographic analysis indicated an approximate ratio of 1 part of the *Z*- to 20 parts of the *E*-isomer. Fractionation of the product using the annular spinning band column gave the following main fractions: (*1*) 0.25 g, bp 121–122°C/3 torr (glc 90% *Z*-isomer); (*2*) 0.95 g, bp 127–132°C/3 torr (glc mixture of *Z*-, *E*-, and a third component; (*3*) 8.5 g, bp 134–135°C/3 torr (glc 95% *E*-isomer); nmr 6.78 (m, 1H, CH vinyl), 5.90 (br d, 1H, J = 14 Hz, CH vinyl), 4.10 (q, 4H, J = 8 Hz, OCH_2Me), 3.72 (s, 3H, CO_2CH_3), 2.75 (dd, 2H, J = 8 Hz, CH_2PO) and 1.33 (t, 6H, J = 6 Hz, OCH_2CH_3). Fraction *1*, assumed to be chiefly the *Z*-isomer proved unstable and after 24 h isomerized to give about 50% *E*-isomer.

(*ii*) A mixture of methyl *Z*-4-bromocrotonate (0.76 g, 4.2 mmol) and triethylphosphite (0.75 g, 4.5 mmol) was heated gradually to 120°C during 1 h. Gas–liquid chromatographic analysis showed the presence of the *Z*-isomer **8***a* with a trace of the *E*-isomer **8***b* (higher retention time); nmr (neat) 5.75–6.63 (m, 2H, vinyl CH), 4.06 (q, 4H, J = 8 Hz, OCH_2Me) 3.74 (s, 3H, CO_2CH_3), 3.32 (dd, 2H, J = 5 and 7 Hz, CH_2PO) and 1.33 (t, 6H, J = 6 Hz, OCH_2CH_3).

*Isomerization of Methyl Z- and E-4-Phosphonocrotonate **8a** and **9a** with Sodium Methoxide*

The *Z*-phosphonate (10 mg, 0.042 mmol) in methanol (0.03 ml) was treated with 0.01 ml (0.0065 mmol) of a solution of sodium (15 mg) in methanol (1 ml). After 1 min the solution was analyzed by glc, and shown to be a mixture of the *Z*-isomer (10%) and the *E*-isomer (90%). No further change in the product composition was observed after 10 min. (On standing longer the peaks due to both isomers gradually decreased in size, with the appearance of new peaks in the glc. When equimolar amounts of phosphonate and sodium methoxide were mixed, only a small amount of the isomers could be detected after a few minutes.)

Repetition of the experiment using the *E*-isomer gave the same product composition.

Preparation of the Reference Compounds

*The Geometrical Isomers of Methyl 3-Methyl-5-phenylpenta-2,4-dienoate (**15a**, **16a**, **17a**, and **18a**)*

The four isomeric acids (*Z*-2,*E*-4, *E*-2,*E*-4, *Z*-2,*Z*-4, and *E*-2,*Z*-4 isomers) were prepared according to the method of Pattenden and Weedon (17) and converted into the corresponding methyl esters with diazomethane (9).

*Methyl Z- and E-β-Ionylideneacetate (**15b** and **16b**)*

(*i*) The *Z*- and *E*-isomers **15***b* and **16***b* were prepared by the reaction of triphenylcyclogeranyl bromide with 4-hydroxy-3-methylbut-2-enolide and methyl *E*-3-formylcrotonate respectively (9). The *Z*-acid formed in the first of these reactions was converted into the methyl ester with diazomethane.

(*ii*) *Z*-β-Ionylideneacetic acid was prepared by the hy-

drolysis of the δ-lactone of 5-hydroxy-3-methyl-5-(2,6,6-trimethyl-1-cyclohexen-1-yl)-2-pentonoic acid (9), and converted to the methyl **15***b* using diazomethane.

(*iii*) *E*-β-Ionylideneacetic acid was prepared by the method of Ishikawa (10) and converted into the methyl ester **16***b* with diazomethane.

*The Z-2,E-4 and E-2,E-4 Isomers of Methyl 3-Methyl-5-(cyclohexen-1-yl)pentadienoic Acid (**15***a and **16***a)*

These compounds were prepared according to the procedures in (*i*) for methyl *Z*- and *E*-β-ionylideneacetate (above (9)).

Effect of aza-substitution on the geometry and electrocyclization of pentadienyl anions: an apparent exception to the Woodward–Hoffmann rules?

D. H. HUNTER, S. K. SIM,[1] AND R. P. STEINER[2]

Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received August 13, 1976

D. H. HUNTER, S. K. SIM, and R. P. STEINER. Can. J. Chem. **55**, 1229 (1977).

Two geometrical isomers of 1,3,5-triphenyl-1,3-pentadiene **1** have been prepared and characterized; *trans,cis*-**1** and *trans,trans*-**1**. These have been used to prepare and characterize the 1,3,5-triphenylpentadienyl anion by quenching the lithium salt in THF and by following hydrogen–deuterium exchange in methanol-*O-d* with potassium methoxide. Attempts to induce electrocyclization (130°C in THF or 200°C in KO*t*Bu–HO*t*Bu) have proven unsuccessful. A comparison of the behaviour of this anion with the 2-aza and 2,4-diaza analogues has helped in elucidating the mechanisms for their electrocyclization and the apparent exception to the Woodward–Hoffmann rules.

D. H. HUNTER, S. K. SIM et R. P. STEINER. Can. J. Chem. **55**, 1229 (1977).

On a préparé et caractérisé deux isomères géométriques du triphényl-1,3,5 pentadiène-1,3 (**1**); il s'agit des isomères *trans,cis* **1** et *trans,trans* **1**. On les a utilisé pour préparer et caractériser l'anion triphényl-1,3,5 pentadiényle en piégeant le sel de lithium dans le THF et en faisant suivre cette réaction par un échange hydrogène–deutérium dans le méthanol *O-d* avec le méthylate de potassium. Tous les essais effectués dans le but d'induire de l'électrocyclisation (130°C, dans du THF ou 200°C, dans le KO*t*Bu–*t*BuOH) se sont soldés par des insuccès. Une comparaison du comportement de cet anion avec ses analogues aza-2 et diaza-2,4 a permis d'élucider les mécanismes de leurs électrocyclisations et l'exception apparente aux règles de Woodward–Hoffmann.

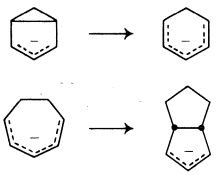
Introduction

Many examples of electrocyclization reactions of delocalized carbanions have appeared in recent years (1) and these have provided evidence on the thermodynamics, the dynamics, and the stereochemistry of these reactions. In contrast to the three center system (*e.g.*, allyl ⇌ cyclopropyl) and the seven center system (*e.g.*, heptatrienyl ⇌ cycloheptadienyl), there have been significantly fewer examples from the five center system (*e.g.*, pentadienyl ⇌ cyclopentenyl). Although many open-chain pentadienyl anions have been prepared and characterized, with but one exception (2), cyclization has not been observed. The cycloreversion reactions of cyclopentenyl anions have not been reported to date.

Electrocyclization reactions involving pentadienyl anions in cyclic systems have been observed in two cases; the cyclooctadienyl anion (3) and the cyclohexadienyl (4) anion. These show opposite thermodynamics, the anion in the eight-membered ring prefers the closed form



but the six-membered ring prefers the open form. These contrasting results are presumably a consequence of the strain peculiar to these ring sizes. Both reactions occur in the anticipated disrotatory manner (5) but this stereochemistry is also imposed by ring strain. In fact, there are a number (6) of electrocyclic reactions that occur in the direction required by ring strain in spite of contrary orbital symmetry demands.

In contrast to the all-carbon systems, aza-substitution at the 2 and 4 position in pentadienyl anions suffices to induce electrocyclization (7, 8). It has also been possible to observe the stereochemistry of these reactions and marked changes have been observed in both the rate and stereoselectivity of the electrocyclization process. In an attempt to sort out the factors responsible for these changes, the all-carbon system has now been prepared and studied. We wish to report on the behaviour of the 1,3,5-triphenylpenta-

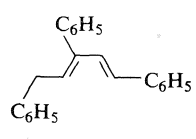
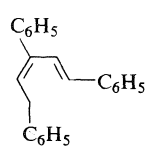
Results

Preparation and Characterization of the 1,3,5-Triphenyl-1,3-pentadienes

As illustrated in Scheme 1 both 1,3,5-triphenyl-*trans,trans*-1,3-pentadiene (*trans,trans*-**1**) and 1,3,5-triphenyl-*trans,cis*-1,3-pentadiene (*trans,cis*-**1**) were prepared from chalcone using variants of the Wittig reaction. Reaction of the Wittig reagent from (2-phenylethyl)triphenylphosphonium bromide with an equimolar amount of chalcone provided an initial mixture of *trans,trans*-**1** and *trans,cis*-**1** in a ratio of 6:1. A 30% yield of *trans,trans*-**1** was obtained after purification. In contrast, the reagent from diethyl 2-phenylethylphosphonate with chalcone produced a 1:7 mixture of *trans,trans*-**1** to *trans,cis*-**1** which provided a 16% yield of purified *trans,cis*-**1**. The ^{1}H nmr spectra of both dienes were consistent with a *trans* configuration at the terminal double bond ($J_{12} \sim 17$ Hz). The configuration at the internal double bond was assigned from the relative reactivity of the two dienes with dienophiles with the assumption that *trans,cis*-**1** would be more reluctant than *trans,trans*-**1** to adopt the conformation needed for a Diels–Alder reaction.



trans,trans-**1**



trans,cis-**1**

The relative reactivity of *trans,trans*-**1** and *trans,cis*-**1** with dienophiles was measured by nmr monitoring of changes in the ratio of *trans,trans*-**1** to *trans,cis*-**1** upon addition of less than an equimolar amount of a dienophile. As indicated in Table 1 three dienophiles were used to test the generality of the reactivity preference. With 2-butyne, benzoquinone, and *N*-phenylmaleimide one of the dienes was consistently more reactive than the other. The more reactive diene was assigned the *trans,trans* configuration in accord with the expected conformational preferences. The apparent differences in relative reactivity of *trans,trans*-**1** and *trans,cis*-**1** upon changing the dienophile are probably not significant. These rate ratios are minimum values since the observed ratio of unreacted dienes will be sensitive to the extent of reaction.

To clarify further the relative reactivities, the two dienes were reacted separately with *N*-phenylmaleimide. Treatment of *trans,trans*-**1** in benzene with *N*-phenylmaleimide at 80°C for 42 h provided the Diels–Alder adduct in 74% isolated yield. In contrast, heating to 155°C for 74 h was required to result in reaction of *trans,cis*-**1**. This reaction yielded a mixture which seemed, by mass spectrometry, to contain a 1:1 adduct but no pure component could be isolated. Thus *trans,trans*-**1** reacts cleanly to give a Diels–Alder adduct while *trans,cis*-**1** is much less reactive and less selective when it finally reacts.

Geometry of the Pentadienes and Azapentadienes

The relative stability of *trans,trans*-**1** and *trans,cis*-**1** was determined by equilibration at 60°C in potassium methoxide – methanol. Starting with either diene the same mixture was obtained (73% *trans,trans*-**1** and 27% *trans,cis*-**1**) as indicated by the results of runs 1–6 of Table 2. Figure 1 summarizes the results obtained for the analogous azapentadienes and diazapentadiene. In the case of **4** only one geometry has been observed (7) although it has been treated under the same conditions which equilibrated the geometries of **1**, **2**, and **3** and which resulted in hydrogen–deuterium exchange of **4**. Attempts to induce geometrical isomerization in **4** by irradiation, both sensitized (triphenylene) and unsensitized, also failed. Thus it is probable that

TABLE 1. Changes in the ratio of *trans,trans*-**1** to *trans,cis*-**1** on reaction[a] with a dieneophile

Dieneophile	*trans,trans*-**1**/*trans,cis*-**1**

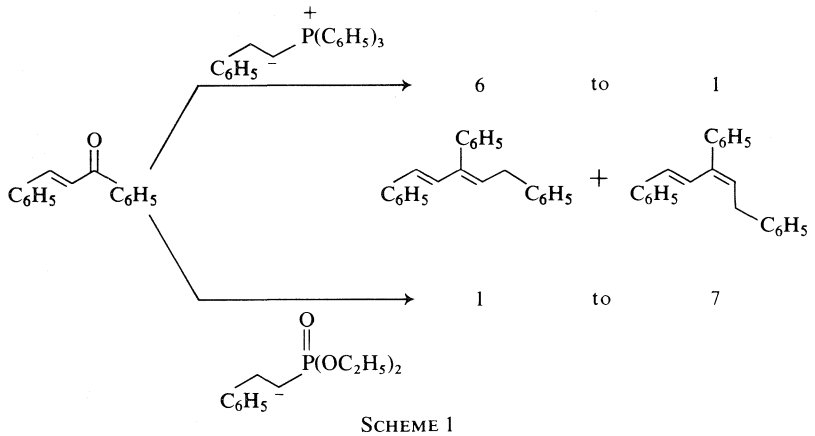

SCHEME 1

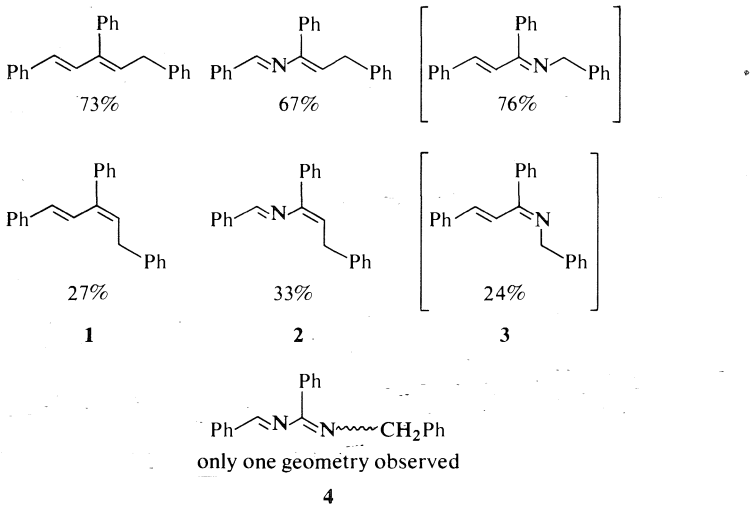

FIG. 1. Equilibrium percentages of azapentadienes and pentadienes at 60°C in $KOCH_3$–$HOCH_3$.

the one geometry observed for **4** is the thermodynamically preferred geometry but its actual configuration remains undetermined.

As described previously (8), the geometries of **1** and also **2** were assigned using Diels–Alder relative reactivity. The geometries of **3** could not be assigned in a similar manner and thus remain uncertain except for the *trans* arrangement across the carbon–carbon double bond. Analogy with **1** and **2** led to the assumption shown in brackets in Fig. 1.

Geometry of the Pentadienyl and Azapentadienyl Anions

Treatment of either *trans,trans*-**1** or *trans,cis*-**1** with lithium 2,2,6,6-tetramethylpiperidide (LiTMP) in THF led to a deep blue solution which was characterized by quenching experiments (acetic acid) and variable temperature nmr (9). As indicated in runs 7–11 of Table 2 quenching of the anion from either geometry of **1** at varying times led to the same mixture of *trans,trans*-**1** (45%) and *trans,cis*-**1** (55%). A material balance of run 8 resulted in a 93% recovery of **1** and quenching with acetic acid-*O*-*d* resulted in **1** containing 94%-d_1 and 6%-d_0 by mass spectrometry.

A variable temperature ^1H and ^{13}C nmr study (9) of 1,3,5-triphenylpentadienyllithium **5** in THF-d_8 indicated the presence of both the S and W shapes with the S predominating by a factor of about 2.3. The nmr and quenching results are summarized in Scheme 2. If the rate of quenching exceeds the rate of interconversion of S and W

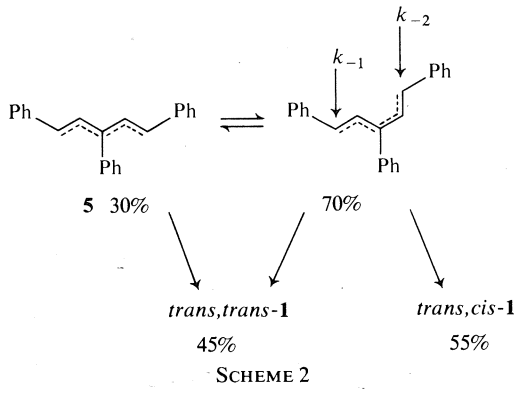
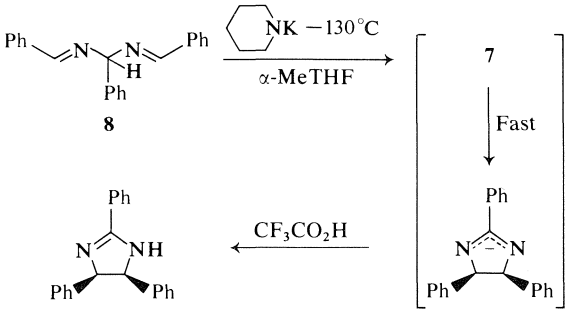


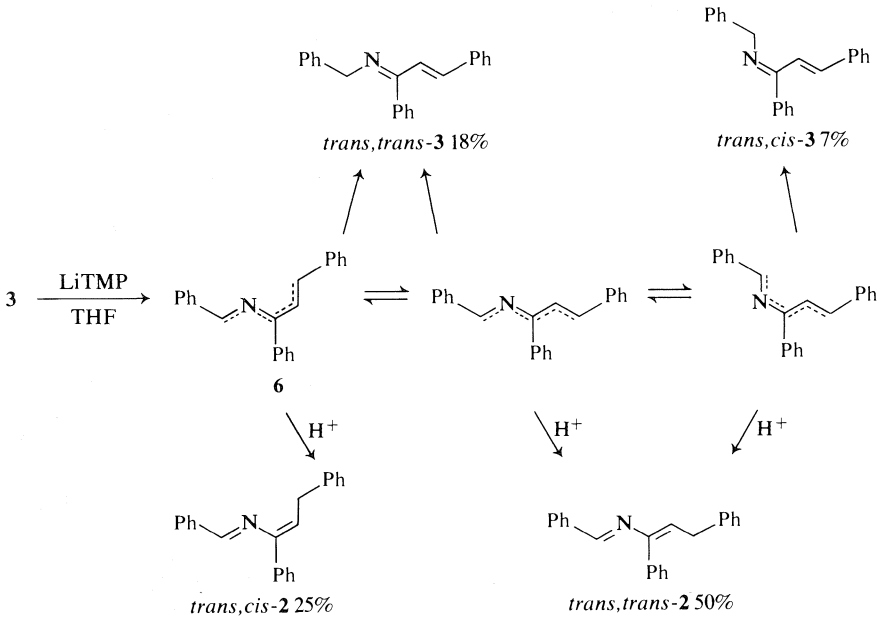
SCHEME 2

shapes (k_1(S ⇌ W) ~ 10^3 s^{-1} at 25°C), then the quenching preference of the S shape can be calculated. From the anion composition and the proportions of **1** upon quenching, it is found that k_{-1}/k_{-2} ~ 0.3. As with the 2-azapentadienyl anions (from **2** and **3**) and the 2,4-diazapentadienyl anion (from **4** and hydrobenzamide **8**), no products are observed due to protonation at the central carbon. This contrasts with the behaviour of cyclohexadienyl anions (10) (*e.g.*, in Birch reductions).

Analogous quenching results are observed for 2-azapentadienyllithium **6** in THF (8). Since **6** electrocyclizes near 0°C, it was not studied by nmr and quenching with acetic acid was used to determine the geometries of **6**. The products of quench (Scheme 3) clearly indicate the presence of more than one geometry for **6**. Although there are insufficient data to calculate the actual proportions of the geometries of **6** that are present, the S forms are present and may predominate as in the case of **5**.

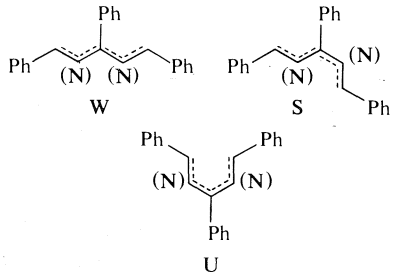
Attempts to characterize the geometries of 2,4-diazapentadienyllithium **7** have proven much less successful because of its propensity to electrocyclize (7). Attempts were made to generate **7** from hydrobenzamide **8** and to quench before electrocyclization. Using organolithium bases in THF down to the freezing point of THF (~ −110°C), intense color was observed but quenching showed that anion formation was the slow step and, at most, only traces (<1%) of quench product **4** could be obtained. In a further effort to characterize **7**, potassium piperidide in α-methyltetrahydrofuran down to −130°C has now been used. This is clearly a kinetically much more active base since no unreacted starting material **8** was recovered even upon quenching at 5 min with trifluoroacetic acid. Again, however, in spite of intense color no **4** could be observed (<5%) accompanying the product of electrocyclization, amarine.





SCHEME 3

The results of the nmr and quenching studies of the three anions **5**, **6**, and **7** show that both **5** and **6** exist in more than one geometry and these geometries are of comparable stability. One of these geometries is unsymmetrical, the S-shape,



and the other symmetrical, the W- or U-shapes. Of the two possibilities for the symmetrical species, the W seems more probable than the U, first, from inspection of space-filling models and second, since a variety of pentadienyl anions have been shown to adopt the W-shape some with a small amount of the S-shape present (1*b*). The geometrical preferences of **7** could not be observed because of its reactivity but can only be inferred by analogy with **5** and **6**.

Kinetic Acidity of the Pentadienes

The base-catalyzed H–D exchange and isomerization reactions of the structurally related pentadiene (*trans,cis*-**1**), azapentadiene (**3**), and diazapentadiene (**4**) have been followed in CH_3OK–CH_3OD at 60°C. A comparison of the ease of deprotonation in the three systems should yield a rough estimate of the relative stabilities of the anions **5**, **6**, and **7**. As detailed in Table 3, the rate of total exchange and isomerization of the thermodynamically less stable *trans,cis*-**1** to *trans,trans*-**1** was followed by a combination of nmr and mass spectrometry. Qualitatively, exchange was somewhat faster than isomerization in agreement with the quenching experiments for the S-shape ($k_{-1}/k_{-2} \sim 0.3$). A maximum of 3 atoms D/molecule was observed under these conditions and exchange occurred exclusively at the 1 and 5 positions consistent with reaction via **5**. On the basis of the data in Table 3, a rough estimate of the rate constant for H–D exchange could be made (Fig. 2).

The azapentadienes have also been studied and Fig. 2 contains the rate constant for H–D exchange for the 4-aza isomer (**3**) which is by far the minor component at equilibrium with the 2-aza isomer (**2**). Exchange of **2** occurs more slowly than **3** and although not determined directly seems to be more comparable in rate to **4**. It should be noted that a direct comparison of *trans,cis*-**3** with *trans,cis*-**1** cannot be made since the first reaction of **3** under these conditions

TABLE 3. Base-catalyzed exchange and isomerization of *trans,cis*-**1** in $KOCH_3$–$DOCH_3$[a] at 60°C

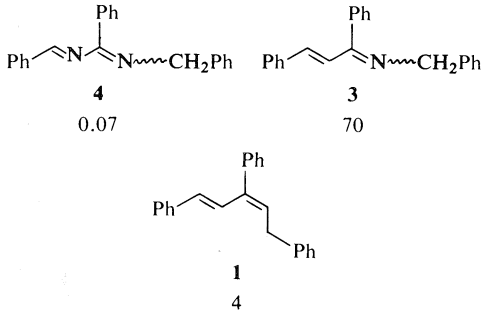

FIG. 2. Second-order rate constants ($\times 10^4$) M^{-1} s^{-1} for hydrogen–deuterium exchange in $KOCH_3$–$DOCH_3$ at 60°C.

is *syn–anti* equilibration and so the reported rate constant is for the mixture of geometries.

The rate constant for exchange of the diazapentadiene (**4**) is also shown in Fig. 2 but in the case of **4**, both electrocyclization and exchange occur competitively through anion **7**. Thus, exchange only measures about one-third of the acts of carbanion formation, which implies that the actual kinetic acidity is about three times greater ($k_2 \sim 0.2 \times 10^{-4}$ M^{-1} s^{-1}) than indicated in Fig. 2. Again in the case of **4** it is not clear which geometry is adopted although in this case only one geometrical isomer is observed.

However, in spite of the uncertainty as to the geometry of **3** and **4**, it seems clear that **1**, **3**, and **4** all deprotonate within a reactivity range of about 300. In as far as anion stabilities can be deduced from kinetic acidities, these exchange rates imply that the anions **5**, **6**, and **7** are of comparable stability relative to the dienes **1**, **3**, and **4**. Thus aza-substitution at the 2 and 4 positions in a pentadienyl anion has modest effects on the stability of the anion. This is in accord with simple valence bond or molecular orbital concepts which place the negative charge at the 1, 3, and 5 positions in a pentadienyl chain.

Electrocyclization of **5**

Attempts to induce **5** to cyclize both thermally and photochemically resulted in failure. As indicated in runs 10 and 11 of Table 2, heating of THF solutions of **5** to 120°C resulted in reduced yields of recovered **1**, but no other 'monomeric' products could be observed. Upon heating to 150°C for 16 h followed by quenching, no dienes **1** could be observed and at the same time no monomeric hydrocarbons could be isolated. Similarly heating of *trans,trans*-**1** in a degassed solution of 0.7 *M* potassium *tert*-butoxide in *tert*-butyl alcohol for 18 h at 200°C resulted in nearly complete loss of **1** and no product attributable to cyclization could be isolated. Reaction at lower temperature resulted in varying loss of **1** but no product of cyclization.

Solutions of **5** in both THF and *N,N,N',N'*-tetramethylethylenediamine in quartz cells were irradiated using a Hanovia 1000 W high pressure mercury lamp. Experiments were attempted both isolating the long wavelength absorption band of **5** at 585 nm and using the total wavelength range available. In these experiments only **1** was obtained on quenching. Thus all attempts to persuade **5** to electrocyclize were unsuccessful although **6** and **7** react with ease.

Discussion

The preparation of the *trans,trans* and *trans,cis* isomers of **1** and of the derived anion **5** has provided the final comparison in evaluating the significance of 2- and 4-aza substitution of the reactivity of pentadienyl anions. Effects upon the geometry and stability of the open-chain anion and the dienes are not large, but dramatic effects have been noted for the electrocyclization reaction. There are marked changes in both the propensity to undergo cyclization and in the stereochemistry of the product of cyclization. In dis-

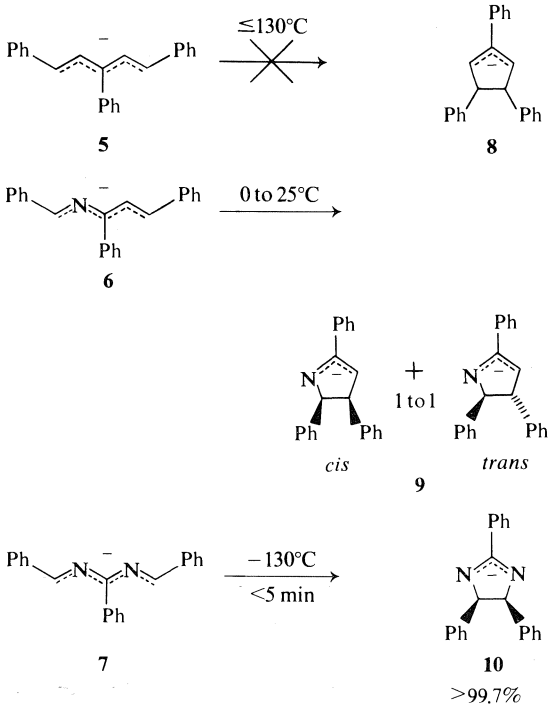
cussing the results of the study of **5**, their impact upon the electrocyclization reactions will be emphasized, first by comparing and contrasting the diaza, monoaza, and all-carbon systems. Then, possible mechanistic interpretations of the observed reactivity pattern will be presented in light of these new results.

Rates of Electrocyclization

The lithium salts of the open-chain 1,3,5-triphenylpentadienyl anions and their aza analogues (**5**, **6**, and **7**) have been prepared in THF from the corresponding carbon acids using amide bases at low temperatures. The all-carbon anion **5** undergoes no conversion to a cyclic form in the temperature range of −80 to +130°C. The 2-aza anion **6**, on the other hand, remains in the open-chain form at temperatures below 0°C but in the temperature range 0 to 25°C converts completely to cyclic isomers. Remarkably the 2,4-diaza anion **7** has only been observed as a fleeting intermediate on the way to cyclized product at temperatures as low as −130°C. The evidences for the existence of **7** are: the intense color (λ_{max} = 592 nm) observed; the isolation in one case (the tris *p*-Cl compound) of small amounts (~1%) of the quench product, tri-*p*-Cl-**4**, and its hydrolysis product; and, of course, chemical intuition as to the most likely proton abstraction reaction.

Reactions in protic media provide a further comparison of the relative rates of cyclization of **6** and **7**. As mentioned earlier KOMe–HOMe at 60°C suffices to produce **6** or **7** from the corresponding carbon acids at similar rates, but the rate of production of cyclized product is quite different. As judged from the fact that hydrogen–deuterium exchange and cyclization are competitive for **4**, the diaza anion **7** would seem to cyclize and protonate at about the same rate. Thus cyclization of **7** must be occurring with a rate constant (k_1) of at least 10^5 s^{-1} (11). In contrast while KOMe–DOMe at 60°C suffices to effect exchange and isomerization of **3**, KO*t*Bu–HO*t*Bu at 120°C must be used to generate cyclized product. Since KO*t*Bu–HO*t*Bu is judged to be a kinetically much stronger base than KOMe–HOMe (12), it is possible to estimate that cyclization is occurring some 10^6 slower than protonation.

It seems likely that the large changes in rate upon aza substitution reflect changes in the



5 **8** **6** **9** **7** **10**

thermodynamic stability of the cyclic anions relative to the open-chain anions. As presented earlier, the rate of formation of the open-chain anions (**5**, **6**, and **7**) by base-catalyzed deprotonation with CH_3OK–CH_3OH covers a range of about 300. In contrast, the cyclization reaction rates for **6** and **7** differ by about 10^6 and **5** does not cyclize. On this basis it seems more reasonable to attribute the changes in the cyclization rates to changes in the stability of the cyclized form with the open-chain anions having comparable relative stabilities.

It is possible to construct a qualitative free energy diagram (Fig. 3) consistent with the observed results. Although none of the spacings are known directly, several approximate free energy values can be assigned by analogy. It is likely that the cyclopentene forms are more stable than the pentadiene forms since cyclopentene (ΔG_f^{298}(g) = 26.48 kcal/mol) is 8.36 kcal/mol more stable than *trans*-1,3-pentadiene (ΔG_f^{298}(g) = 34.84) (13). The phenyl substituents should presumably serve to narrow this gap. The introduction of one nitrogen should have similar effects upon both the open and closed forms while in the diaza case delocalization should serve to selectively stabilize the cy-

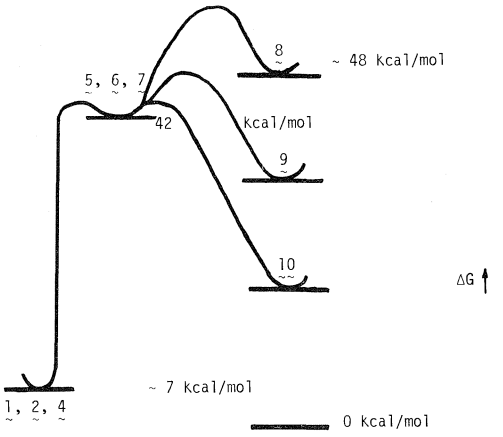


FIG. 3. Free energy profile showing effect of aza-substitution on the cyclization reactions.

clized form. The extent of this stabilization is not certain.

The free energy of the open-chain anions relative to the dienes is available through an estimate of the pK_a. All three pentadienes have kinetic acidities similar to methyl acetates (14) which places their pK_a near 26. The free energy of the all-carbon closed anion relative to the cyclopentene is also available through a pK_a estimate of propene ($\sim$35) (15). We were unable to find estimates for the pK_a of imines or amidines[3] but the fact that the cyclization reactions occur, places their energy below that of the open form. Undoubtedly the amidines will be more acidic than imines. From this kind of analysis, admittedly approximate in nature, it is certainly tempting to suggest that it is the product stability that determines the cyclization reaction rate.

The reluctance of the all-carbon anion to cyclize is consistent with the observations for other pentadienyl anions. Recent gas phase measurements of proton affinities of 1,3-pentadiene (18) and propene (19) suggest that the open form of the anion would be favoured at equilibrium. The only example (2) of a possible cyclization involves the 1,5-diphenylpentadienyl anion which can be postulated as an intermediate in the high temperature Wolf–Kishner reduction of dibenzylidene acetone yielding diphenylcyclopentenes. The results with dibenzylidene acetone could well reflect kinetic rather than thermodynamic control, if the reaction does proceed through anionic intermediates.

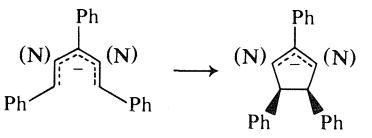
[3]Alkyl and arylamidines are reported to form salts with $NaNH_2$ and KNH_2 (16) while *N,N'*-diarylformamidines are converted to their salts by OH^- (17).

Stereochemistry of Electrocyclization

Concurrent with the marked change in cyclization rates, there is a marked change in cyclization stereochemistry. The diaza anion **7** cyclizes to produce (7) the *cis* isomer **10** exclusively (>99.7%) whereas the monoaza anion **6** produces (8) both the *cis* and *trans* isomers (*cis*-**9** and *trans*-**9**) in approximately equal amounts. In both cases, **9** and **10**, the *cis* form is thermodynamically less favoured than the *trans* form ($K_{eq} \approx 25$). So while cyclization *rates* reflect product stability, cyclization *stereochemistry* does not.

The cyclization stereochemistry of **7** does not show any observable temperature sensitivity since reaction at −130°C (THF) or at 60°C (KOMe–HOMe) produces only the *cis* product. The 1:1 mixture of *cis*- and *trans*-**9** does not change significantly with extent of reaction, consistent with kinetic control without subsequent conversion of *cis* to *trans* isomers. These controls point to a real difference in the mode of cyclization of the diaza anion **7** and the monoaza anion **6**, with the relative rates of production of the *cis* and *trans* closed forms changing by at least 300.

The cyclization reactions of **6** and **7** seem best categorized as electrocyclization reactions and consequently the stereoselectivity of the reactions can be analyzed in terms of orbital symmetry control. The typical approach to the analysis of electrocyclization reactions involves considering interconversion of the all-*cis* open form with the cyclic form. With this premise both the Woodward–Hoffmann rules and orbital correlation using simple Huckel molecular orbitals predict a disrotatory mode of ring closure for the pentadienyl anion **5** as well as the diaza and monoaza anions, **6** and **7**. Clearly the dramatic change in



reaction stereochemistry with aza-substitution requires a modification from this simple approach. Two possible explanations seem appropriate: more than one geometry of the open-

chain anions is involved or a more sophisticated orbital correlation analysis is needed.

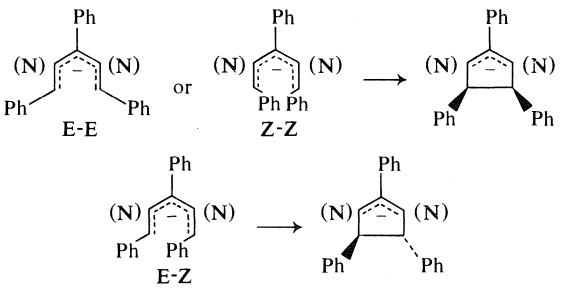
Role of Anion Geometries

The formation of both the *cis* and *trans* forms of the closed anion **9** can be rationalized by assuming that reaction occurs from more than one geometry of **6** but always in a disrotatory manner while in contrast, the diaza anion **7** should be reacting from just one geometry. Thus it seemed desirable to explore the effect of aza-substitution on the geometries adopted by the open-chain anions. Unfortunately, as mentioned earlier, **7** reacts so fast that neither nmr nor quenching experiments could be used successfully to determine the geometry of **7**.

The intermediate reactivity of **6** allowed quenching experiments to be carried out and these were consistent with the presence of more than one geometry of **6**. In fact, it appeared that the W (or U) form and both the S forms were present and these were present in similar amounts. The lack of reactivity of **5** ruled out a study of the cyclization stereochemistry, but allowed a determination of the geometry of **5** both by nmr and quenching. A comparison of **5** and **6** should then show whether aza-substitution greatly effects the geometry adopted by pentadienyl anions. Nuclear magnetic resonance and quenching results on **5** were consistent with the presence of both the S and W (or U) forms with the S predominating by about a factor of 2. The similarity between the geometries adopted by both **5** and **6**, thus, provides no support for the proposal of a unique geometry of **7**. Nonetheless, it is worth considering specific mechanistic possibilities involving different geometries.

One geometrical modification of the all-*cis* U-form involves isomerism around the terminal bonds which results in three possible isomers, of which the *E-E* form should be the most stable. A mechanism consistent with the observations would have anion **7** react exclusively through the *E-E* form but **6** react roughly equally through the *E-E* and *E-Z* forms. It is this kind of proposal that seems inconsistent with the geometrical observation on **5** and **6**. Aza-substitution does not greatly effect geometrical preferences.

A second modification involves rotation around the inner bonds of the *E-E* form to produce the W and S forms. The nmr study (9) of the lithium salt of **5** in THF-d_8 shows that the W



and S forms are of roughly equal energy and the rate constants for isomerization are about 10^2 to 10^3 at -20 to -5°C. While, in principle, the W and U forms could lead directly to the *cis*-closed isomer and the S could lead to the *trans*-closed isomer, again it becomes necessary to postulate an unsubstantiated unique geometry for the diaza anion **7**. Direct cyclization from either the W or S forms also seems unlikely in terms of the large distance between one and five carbon atoms and the number of atoms that would have to move in such a concerted process.

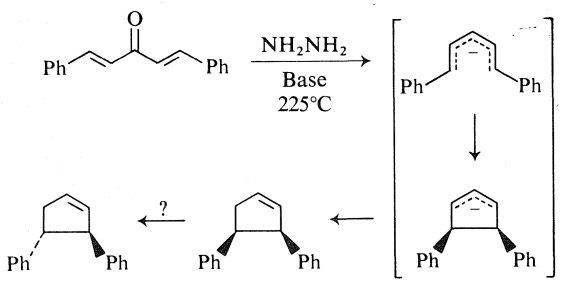
If the anion geometries are interconverting rapidly before cyclization occurs, an analysis involving the Hammond–Leffler postulate may be valid (the validity of this postulate has been seriously questioned recently, see ref. 20). For the most exothermic reaction (**7** → **10**) the transition state leading to the less stable isomer is observed to be lower in energy than the transition state leading to the more stable (*trans*-**10**) isomer. As the reaction becomes less exothermic (**6** → **9**) the stability of the products could become more important in determining the relative reaction rates. Consequently the transition state leading to the more stable isomer (*trans*-**9**) could approach that leading to the less stable isomer (*cis*-**9**) and result in lower stereoselectivity as observed. While the trend in the stereoselectivity is consistent with this analysis, the results seem unusual in two respects: first, the change in stereoselectivity (≥ 300) is rather large for two exothermic processes and, second, the more exothermic process is the one that shows the higher stereoselectivity.

Concurrent Disrotatory and Conrotatory Reactions

If indeed both **6** and **7** adopt the same geometries for cyclization, then it becomes necessary to postulate a violation of the Woodward–Hoffmann rules. Such a suggestion is not without

precedent although direct analogies are not yet available. The simplest approach is to assume that all reaction occurs through the *E-E* configuration of the U-form but while **7** reacts in just a disrotatory manner, **6** proceeds in both a conrotatory and disrotatory mode. The basis for this proposal resides in the fact that **7** is a symmetrical species (C_{2v}) while **6** has no analogous symmetry. Both Schilling and Snyder (21) using extended Huckel or CNDO/INDO and Epiotis (22) using configuration interaction have concluded that asymmetric substitution of electron-withdrawing or -donating groups can lead, in the extreme, to a reversal of the stereochemistry of an electrocyclic reaction. However, *we* are not in a position to estimate whether the aza-substitution discussed here represents a sufficient perturbation.

As must be clear by now, the stereochemistry of electrocyclization of the symmetrical all-carbon anion **5** would have provided more conclusive evidence as to the correct explanation for the observed changes. However, **5** refused to electrocyclize. Interestingly cyclization during the high temperature Wolf–Kishner reduction of *trans, trans*-dibenzylidene acetone has been observed (2). The 1,5-diphenylpentadienyl anion has been postulated as an intermediate in this reaction which is run at 225°C using powdered potassium *tert*-butoxide, sodium methoxide, or potassium hydroxide. In all cases both the *cis*- and *trans*-



3,4-diphenyl cyclopentenes were among the reaction products. However, controls established that the products isomerize under the reaction conditions, leaving ambiguous the kinetic stereoselectivity in this cyclization reaction. Indeed, as the author suggests, the reaction may be proceeding initially through the *cis* anion, but at the present this is merely conjectural.

In summary, the study of the 1,3,5-triphenylpentadienyl anion has helped confirm the geometrical preferences for such open-chain delocalized anions and, indirectly, provided support for the hypothesis that molecular asymmetry can lead to a change in the stereochemical demands imposed by orbital symmetry.

Experimental

Solvents and Bases

The methanol was distilled from magnesium and the methanol-*O-d* was prepared from dimethylcarbonate (23). Base solutions were prepared by reaction of the alcohol under argon with freshly cut potassium. Tetrahydrofuran was freshly distilled from lithium aluminum hydride before use. THF and α-methyltetrahydrofuran used for bulb-to-bulb distillation were stored over sodium/potassium alloy with added benzophenone as indicator.

Solutions of potassium piperidide in THF or α-methyl THF were prepared by dissolving the residue obtained after evaporating the solvent from an aliquot of a solution of potassium piperidide in piperidine (~1 *M*). The potassium piperidide in piperidine was prepared by heating potassium hydride (washed free of oil) with piperidine (freshly distilled from potassium) at reflux for about 1 h under argon. Although colored, these solutions of potassium piperidide in piperidine remained active for up to 3 weeks without significantly changing their titre.

Preparation of trans,cis-1,3,5-Triphenyl-1,3-pentadiene

(a) Diethyl 2-Phenylethylphosphonate

A mixture of triethylphosphite (freshly distilled, 5.5 g, 33 mmol) and 2-phenylethylbromide (6 g, 33 mmol) was heated under an argon atmosphere first at 130°C for 1 h, then at 170°C for 1 h, and then at 220°C for 3 h. After cooling the reaction mixture was distilled and the fraction of bp 130–134°C/0.03 torr was collected yielding 4.1 g (17 mmol, 51% yield) of product.

The mass spectrum gave *m/e* 242 for the molecular ion. The nmr spectrum (CCl_4) showed the following: δ 1.01 (6H, t), 1.5–3.1 (4H, m), 4.0 (4H, m) 7.03 (5H, s). The infrared spectrum (neat) gave major bands at 3004, 1248, 1030, and 962 cm^{-1}.

(b) trans,cis-1,3,5-Triphenyl-1,3-pentadiene

To the diethyl 2-phenylethylphosphonate (2.7 g, 11 mmol) in 25 ml of THF (freshly distilled) at −20°C was added 11 mmol of *n*-butyllithium. After stirring at −20°C for 4 h the solution was warmed to ambient temperature and chalcone (2.4 g, 11 mmol) in 25 ml THF was added. Stirring was continued for 15 h followed by work-up using an ether–water extraction. The crude oil obtained after solvent removal was chromatographed (silica gel, 10% ether–pentane) and the *trans,cis*-**1** was recrystallized from pentane to yield white needles of mp 72–75°C (16% yield).

The mass spectrum gave *m/e* 296 for the molecular ion. The nmr spectrum (CCl_4) showed an AX_2 with ν_A = 5.68 ppm, ν_X = 3.75 ppm, and J_{AX} = 7.0 Hz; an AB with one half visible with ν_A = 6.38 ppm and J_{AB} = 17 Hz; and a 16 H multiplet in the region 7.0–7.4 ppm. The infrared spectrum ($CHCl_3$, cm^{-1}) showed major bands at 3021, 2970, 1600, 1500, 1449, and 972.

An analysis of the nmr spectrum of the crude reaction product indicated a ratio of *trans,cis*-**1** to *trans,trans*-**1** of 7.

Preparation of trans, trans-1,3,5-Triphenyl-1,3-pentadiene

(a) Triphenyl-(2-phenylethyl)phosphonium Bromide

After refluxing for 6 days a solution of 2-phenylethyl bromide (5 g, 27 mmol) and triphenylphosphine (6.9 g, 27 mmol) in 125 ml of benzene under argon, the reaction mixture was allowed to crystallize by cooling for several hours. After filtration the filtrate yielded 0.7 g of unreacted 2-phenylethyl bromide. The crystals, after washing with cold benzene, yielded 4.5 g (42% yield) of product of mp 78–83°C. This hygroscopic material was used without further purification.

The nmr spectrum ($CDCl_3$, δ) showed the following: 2.8–3.2 (2H, m), 3.8–4.2 (2H, m), and 6.8–8.0 ppm (20H, m). The infrared spectrum ($CHCl_3$, cm^{-1}) showed major bands at 2910, 1440, and 1100.

(b) trans,trans-1,3,5-Triphenyl-1,3-pentadiene

To the previously prepared phosphonium salt (4.5 g, 10 mmol) suspended in 120 ml of THF (freshly distilled from $LiAlH_4$) under an argon atmosphere at −20°C was added 11 mmol of *n*-butyllithium in hexane. At this point all the material had gone into solution. After stirring for an additional 90 min at −20°C, the solution was warmed to ambient temperature and chalcone (2.1 g, 10 mmol) in 20 ml of THF was added. After stirring for 15 min, water was added to quench the reaction mixture and the reaction was worked up using an ether–water extraction. The residual oil obtained after solvent removal was chromatographed (silica gel eluted with 10% ether in pentane) and the appropriate material was recrystallized from pentane to yield 0.84 g (30% yield) of white plates mp 75–77°C.

The mass spectrum gave *m/e* 296 for the molecular ion. The nmr spectrum (CCl_4) showed an AX_2 with ν_A = 5.91 ppm, ν_X = 3.26 ppm, and J_{AX} = 7.5 Hz; an AB with ν_A = 5.97 ppm, ν_B = 6.90 ppm, and J_{ab} = 16.3 Hz; and a 15 H multiplet δ 7.0–7.4 ppm. The infrared spectrum ($CHCl_3$, cm^{-1}) showed major bands at 3090, 3070, 3040, 3010, 1595, 1492, 1444, 972, and 695.

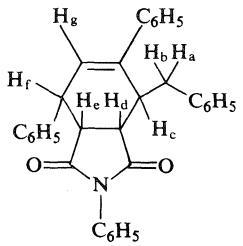
An analysis of the nmr spectrum of the crude reaction product indicated a ratio of *trans,trans*-**1** to *trans,cis*-**1** of about 6.

Diels–Alder Reactions of 1

(a) With N-Phenylmaleimide

(i) trans,trans-1—A solution of 58 mg (0.34 mmol) of purified *N*-phenylmaleimide and 100 mg (0.34 mmol) *trans,trans*-**1** in 4 ml of benzene was sealed in an evacuated thick-walled tube after degassing. After heating at 80°C for 42 h, the benzene was evaporated and the residue recrystallized from ether to yield 93 mg. A second crop was obtained after tlc (silica gel, chloroform) and recrystallization to provide a total yield of 117 mg (74%) of mp 190–192°C.

The mass spectrum showed a molecular ion at *m/e* 469 consistent with a 1:1 adduct. The nmr spectrum (CCl_4) was complex with δ 7.1–7.9 (20 H, m), 6.2–6.3 (1H, m), and 2.7–3.9 ppm (6H, m). The composition of the 6H multiplet was clarified through the use of europium shift reagent ($Eu(fod)_3$) which separated it into six distinct signals. These signals were assigned on the basis of decoupling experiments and their multiplicity and a typical spectrum showed H_e (6.23 ppm, t), H_f (5.44 ppm, q), H_a (4.74 ppm, t), H_d (4.57 ppm, d of d), H_c (3.95 ppm, m);



and H_b (3.64 ppm, d of d). No attempt was made to obtain coupling constants since the multiplets were not first order. The infrared spectrum ($CHCl_3$, cm^{-1}) showed major bands at 2924, 1670, 1590, 1455, 1432, 1360, 1150, and 700 cm^{-1}.

(ii) trans,cis-1—In sealed evacuated tubes, degassed solutions of *trans,cis*-**1** and *N*-phenylmaleimide in equimolar amounts in benzene were heated for 22 h at 80°C and 69 h at 125°C. Nuclear magnetic resonance analysis of the reaction mixture indicated little to no reaction had occurred. Heating for 74 h at 155°C resulted in loss of starting materials and production of a white crystalline solid which proved to be a mixture. Purification by tlc (silica gel, methylene chloride) and repeated recrystallization from hexane resulted in isolation of material with a broad melting range (82–86°C).

The mass spectrum of this material was consistent with a 1:1 adduct (molecular ion *m/e* 469) and showed a fragmentation pattern very similar to the 1:1 adduct obtained from *trans,trans*-**1** and *N*-phenylmaleimide. However, we were unable to isolate any single pure material, perhaps because of a mixture of diastereomers or because of rearrangement during purification.

(iii) trans,trans-1 and trans,cis-1—A mixture of the dienes (120 mg, 0.4 mmol, 7:1 ratio of *trans,trans*-**1** to *trans,cis*-**1**) and *N*-phenylmaleimide (60 mg, 0.35 mmol) in 0.5 ml of carbon tetrachloride was refluxed for 4 h. After separation by tlc (silica gel, 10% ether in hexane), the lead band containing both dienes showed a ratio of 1:4.25 of *trans,trans*-**1** *to trans,cis*-**1** by nmr integration. The baseline band yielded material identical to the 1:1 adduct of *trans,trans*-**1** and *N*-phenylmaleimide as shown by mixture mp and mp.

(b) With Benzoquinone

To a mixture of *trans,trans*-**1** and *trans,cis*-**1** in a ratio of 2:1 (50 mg, 0.17 mmol) in 0.5 ml of carbon tetrachloride in an nmr tube was added 6 mg (0.06 mmol) of benzoquinone. After heating to 60°C for 4–5 h, the progress of the reaction was monitored by nmr. Over a 37 h period 30 mg of benzoquinone was added and the reaction mixture was then separated by tlc (silica gel, 10% ether in hexane). The lead fraction containing the dienes was analyzed to be a 1:3 mixture of *trans,trans*-**1** to *trans,cis*-**1**. No attempt was made to isolate or characterize the adduct.

(c) With 2-Butyne

As above 50 mg of a 2:1 mixture of *trans,trans*-**1** and *trans,cis*-**1** was heated in an nmr tube with a twofold excess of 2-butyne in 0.5 ml of carbon tetrachloride. After 6 days at 60°C, the diene mixture was separated by tlc and showed a ratio of 1:10 favouring *trans,cis*-**1**. No attempt was made to isolate and characterize the adduct.

*Isomerization and Exchange of **1** in Methanol (Tables 2 and 3)*

To either *trans,trans*-**1** or *trans,cis*-**1** dissolved in ~25 μl of THF, was added 0.22 *M* potassium methoxide–methanol (or methanol-*O-d*). This solution was cooled to −80°C, twice degassed, and an argon atmosphere introduced. The solution was then warmed to 60°C for the reported time period. The reaction was quenched by pouring into ether–H_2O. After the ether layer was washed twice with H_2O, once with saturated sodium chloride, and dried with magnesium sulfate, the solvent was evaporated. The proportions of the isomers of **1** was determined by nmr with careful and repeated integration.

Material for mass spectrometric analyses was further treated by tlc and a mass spectrum was obtained on the mixture of isomers of **1**. A combination of nmr and mass spectrometry allowed an estimate of the percentage of isomerization and of isotopic exchange.

*Isomerization and Exchange of **1** using Lithium 2,2,6,6-Tetramethylpiperidide (Table 2)*

A one-necked reaction vessel to which was attached either an nmr tube, a quartz cell, or a reaction tube was used for the reactions not run near room temperature. For those reactions to be run in sealed tubes or cells the selected isomer of **1** was placed in the tube and the solution of lithium tetramethylpiperidide (TMP) in THF was prepared in the reaction vessel. Solutions of lithium TMP in THF (1–2 *M*) were prepared by adding a 1.1-fold amount of *n*-butyllithium (Ventron) to a cooled solution (~ −20°C) of TMP in THF followed by stirring for 1 h from −20°C up to ambient temperature. This base solution was then tipped into the tube or cell which was then sealed. For those reactions run at 25°C, the selected isomers of **1** in a small amount of THF was added to the base solution.

The reactions were quenched by adding a slight excess of acetic acid or acetic acid-*O-d*. Work-up involved pouring the now colorless reaction mixture into ether–water. The ether layer was washed twice with water, once with saturated sodium chloride, dried with magnesium sulfate, and the solvent evaporated. This material was analyzed by nmr before and after tlc.

Reaction of Hydrobenzamide with Potassium Piperidide

The reaction vessel consisted of two bulbs connected by a neck with a sintered glass frit. The reaction bulb was equipped with a side arm through which the hydrobenzamide **8** (~100 mg) in 1.5 ml of α-methyltetrahydrofuran (MTHF) could be added. This side arm had a break seal and the solution of **8** had been prepared by bulb-to-bulb distillation of MTHF. The reaction bulb also had a side arm with a Teflon Rotaflo stopcock for the introduction of MTHF by bulb-to-bulb distillation, the evaporation of solvent, the introduction of argon, and the introduction of deuterochloroform by bulb-to-bulb distillation. The second bulb was equipped with an nmr tube and a side arm with a Rotaflo stopcock for evacuation purposes.

The reaction was run by cooling a solution of LiTMP in MTHF to −130°C and introducing the solution of **8** by breaking the break seal. Color formation (purple) was immediate. After stirring the reaction for about 5 min an argon atmosphere was introduced followed by a 1.1 excess of dried trifluoroacetic acid. Complete loss of color usually took about 2–3 min. The solvent was then evaporated and dried deuterochloroform was introduced. This solution was then filtered into the second bulb and sealed in the nmr tube.

The contents of the nmr tube were analyzed and revealed no starting material or products expected to arise from quenching of the open-chain anion. Instead, the sole product appeared to be amarine, the closed form with *cis*-phenyl rings.

Raman study of the structural properties of KNO_3(II)

M. H. BROOKER

Chemistry Department, Memorial University of Newfoundland, St. John's, Nfld., Canada A1C 5S7

Received August 13, 1976

M. H. BROOKER. Can. J. Chem. **55**, 1242 (1977).

Raman spectra of oriented single crystals of KNO_3(II) have been recorded at 298 and 77 K. At both temperatures the data are in excellent agreement with the factor group analysis based on the generally accepted *Pmcn* space group. Additional spectral features observed near room temperature suggest the presence of a significant number of disordered nitrate groups on alternate lattice sites, although the majority of nitrate groups occupy the ordered sites. As the temperature is lowered, the disordered groups freeze out until near the temperature of reported electrical anomalies (213 K) only the ordered sites are occupied. Improved resolution has resulted in detection of a number of new spectral features while improved depolarization data have resulted in reassignment of several peaks.

M. H. BROOKER. Can. J. Chem. **55**, 1242 (1977).

On a enregistré, à 298 et à 77 K, les spectres Raman de cristaux uniques orientés de KNO_3(II). Aux deux températures les données sont en excellent accord avec l'analyse de facteur de groupe basée sur le groupe d'espace *Pmcn* généralement accepté. Des données spectrales additionnelles observées près de la température de la pièce suggèrent la présence d'un nombre important de groupes nitrates désordonnés à des sites alternés du réseau; toutefois la majorité des groupes nitrates occupent des sites ordonnés. A mesure que la température est abaissée, les groupes désordonnés sont gelés jusqu'à une température proche de celle rapportée pour des anomalies électriques (213 K) alors que les sites ordonnés sont les seuls qui soient occupés. Une résolution accrue a permis de détecter un certain nombre de caractéristiques spectrales nouvelles alors que des donnés de dépolarisation améliorées ont permis une réattribution de divers pics.

[Traduit par le journal]

Elucidation of the mechanisms of solid–solid and solid–liquid phase transformations requires the knowledge of all possible structural properties of the various phases. Although considerable effort has been expended on the structure of KNO_3 in the room temperature phase (KNO_3(II)) several anomalies remain. Accurate X-ray analysis of KNO_3 by Nimmo and Lucas (1) confirmed the *Pmcn* space group proposed by Edwards (2) but these authors reported that the nitrate group was non-planar and did not have its horizontal mirror plane coincident with the *ab* crystallographic plane. Fermor and Kjekshus (3) reported anomalous values for electrical resistivity and dielectric measurements as a function of temperature and suggested the existence of a phase transition in the vicinity of 213 K and tentatively designated the low temperature phase as KNO_3(VIII). Limited X-ray data were insufficient to determine whether the low temperature phase belonged to a different space group from that of phase II. The same authors (4) reported similar results for the other anhydrous univalent nitrates but subsequent calorimetric and neutron diffraction studies on $RbNO_3$ and $CsNO_3$ by Owen and Kennard (5) failed to reveal any transitions and the electrical anomalies of Fermor and Kjekshus were ascribed to thermal hysteresis. Recently, however, Badr *et al.* (6) detected subtle changes in the Raman spectra for the region of the external lattice modes of $RbNO_3$ and $CsNO_3$ which occurred close to the temperature of the low-temperature anomaly of the electrical measurements. The same authors (7) have proposed that the room temperature forms of $NaNO_3$ and $CsNO_3$ contain a significant number of NO_3^- groups on disordered alternate sites which freeze out at lower temperatures.

Previous vibrational studies of KNO_3(II) have been primarily restricted to room temperature and above (8–15) although Karpov and Shultin (11, 12) have measured the infrared spectrum at 77 K. Raman studies of oriented single crystals have been performed (8–10, 15) but poor depolarization measurements have resulted in several uncertain assignments and were of little use for assessment of the reported anomalies. Accurate oriented single crystal

Raman studies at 298 and 77 K were undertaken to investigate the nature of the reported phase transition at 213 K and to ascertain whether the poor depolarization ratios measured in previous studies were due to crystal imperfections and misalignment, or to real structural features of the type described by Nimmo and Lucas.

Experimental

Single crystals of KNO_3(II) were grown from saturated aqueous solution by slow evaporation at room temperature. Experiments were performed on a number of large crystals of varied dimensions. Orientations were determined from crystal morphology (16). Crystals grew with well developed 010 planes; 110, 100, and 001 planes were easily identified; however, 100 and 001 faces of suitable size could only be obtained by polishing. The structure of KNO_3(II) is normally reported in the non-standard setting *Pmcn*; $a = 5.414$, $b = 9.164$, and $c = 6.431$; $z = 4$. In this setting '*a*' has been chosen as the axis of highest symmetry and the crystallographic mirror plane is in *bc*. The horizontal plane of the NO_3^- group is in *ab*. Normally one would classify as B_{1g}, normal modes which are symmetric with respect to the mirror plane of the D_{2h} factor group which in this case is *bc* (17). However, it has been accepted practice to identify as B_{1g} those modes which are symmetric to the NO_3^- plane, the *ab* plane. The full factor group analysis for KNO_3 has been given by a number of workers (9–11, 13, 15) and will not be reproduced here.

Polarized Raman spectra were measured with a Coderg PHO Raman spectrometer after sample excitation with the 488.0 nm line of a Control Laser, model 553A argon ion laser. Plasma lines from the laser were removed with a narrow-band-pass interference filter. Peak positions were calibrated against laser plasma lines and are probably accurate to ± 0.5 cm^{-1}. Power levels at the sample were approximately 600 mW. Polarization of the incident beam was controlled by a half-wave plate, and the scattered light was analyzed with a Polaroid film placed before the monochromator slit. Crystals were carefully mounted on the metal tip of a vacuum cryostat (18) and spectra were obtained for samples at room temperature, ice temperature, dry ice temperature, and liquid nitrogen temperature. Quoted temperature values are for the coolant. The actual sample temperatures were difficult to determine accurately but calibration with compounds with known melting points and phase transition temperatures suggested that the sample temperatures were within 5° of the coolant temperature. For high temperature studies crystals were sealed in glass tubing and heated with a coil of nichrome wire. Temperatures were monitored with a chromel–alumel thermocouple outside the tube. Spectra were recorded for light scattered at 90°, *i.e.* $x(zz)y$, and for light scattered at 180° (back scattering, *i.e.* $x(zz)x$) to the incident beam. The back scattering technique had the advantage of permitting measurement of pairs of symmetric tensors without realignment of the crystal. The crystals were aligned roughly by inspection and then adjusted by carefully minimizing the depolarization ratios for peaks at 1050 cm^{-1}, α_{ab}/α_{aa}; 52 cm^{-1}, α_{bc}/α_{ac}; and 1359, α_{ab}/α_{aa}. Depolarization data were extremely sensitive to crystal quality and orientation but excellent depolarization ratios were obtained from a number of large ($1 \times 2 \times 3$ mm) clear crystals. In this regard it would appear that the poor depolarization ratios obtained by previous authors were due to crystal imperfections. Potassium nitrate tends to occlude water to give a striated crystal with grains along the *c* axis and crystals of this type gave much poorer depolarization ratios. Relative intensities (peak height times half-width) for each setting were first normalized to the off-diagonal α_{ac} component at 83 cm^{-1} (298 K), 91.4 cm^{-1} (77 K). Within experimental error the α_{aa} and α_{bb} components of ν_1 (A_g) were identical and both were set equal to 1000. For the 77 K intensity data, 1.0 cm^{-1} slits were employed and 2.0 cm^{-1} slits for the 298 K data. Half-widths were not corrected but if necessary relative intensities were corrected for the difference in grating response for the $\parallel$ and $\perp$ scattered light since a polarization scrambler was not employed. Resolution of components of peaks ~ 90 cm^{-1} and 715 cm^{-1} was achieved with 0.25 cm^{-1} slits.

Raman spectra were also obtained for samples of ^{15}N-enriched ($\sim 98\%$, ^{15}N) KNO_3 at 77 K to aid the assignment of the lattice modes. Spectra of oriented single crystals of $K^{14}NO_3$ and $K^{15}NO_3$ were recorded for the $c(bc)b$ orientation (spill-over from α_{ba} and α_{ac} was evident). Each sample was recorded twice in alternate fashion and peak positions calibrated to the 221.7 argon – ion plasma line. Lower laser power was employed as a precaution to guard against localized heating since the $K^{15}NO_3$ crystal was not of highest optical quality. A precision of ± 0.1 cm was realized.

Results and Discussion

Raman spectra for KNO_3(II) are shown in Figs. 1 to 4, while peak position, intensity, and half-width data for 298 and 77 K are collected in Tables 1 and 2. Although minor but significant differences exist between the spectra obtained at 298 and 77 K both sets of data are in excellent agreement with the predictions of a factor group analysis based on the *Pmcn* space group. It would appear that the differences between the 298 and 77 K results are due to minor structural changes. Relative intensity data represent the best extinction of unwanted lines obtained and is an average of at least two independent measurements, but even at this the actual values are probably uncertain by 10%. Spill-over of α_{ab} into the α_{bb} spectra and of α_{bc} into α_{ac} was most severe but was eliminated for several exceptionally clear crystals. Spill-over was somewhat worse for samples recorded at 77 K since most crystals fractured on cooling. Nevertheless, it was possible to show that the mode at 52 cm^{-1} is active only in α_{ac} but not in α_{bc} and that the 1344 cm^{-1} mode is active only

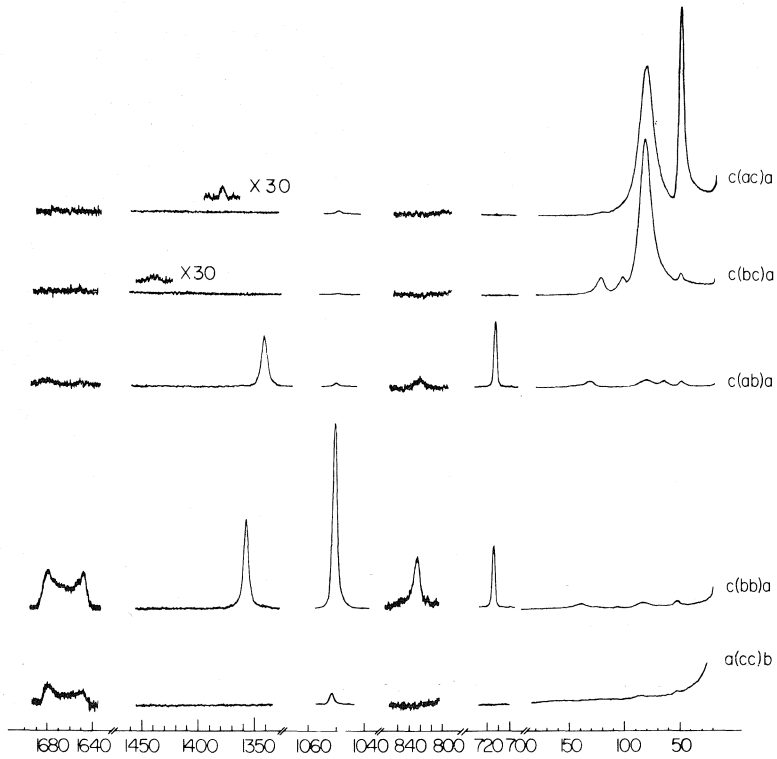

FIG. 1. Raman spectra obtained from oriented single crystals of KNO_3(II) at 298 K. Relative intensities within spectral regions are comparable. Slit-widths were 1.0 cm^{-1} for the 1050 cm^{-1} region, 4.0 cm^{-1} for the 800 cm^{-1} region, and 2.0 cm^{-1} for other regions.

in α_{ab} while the 1359 cm^{-1} mode is active in α_{aa} and α_{bb} (Figs. 1, 2; Tables 1, 2). The present room temperature data are in reasonable agreement with previous work although weak peaks at 108 cm^{-1} (A_g) and 150 cm^{-1} (B_{1g}) have not previously been reported. Raman data for KNO_3 at 77 K have not previously been reported and our spectra show peaks at 122.6 cm^{-1} (B_{1g}), 137.0 cm^{-1} (B_{3g}), 158.2 (B_{1g}), and 162.5 (B_{3g}) which have no counterpart in the room temperature spectrum. A weak peak of B_{2g} or B_{3g} symmetry was occasionally detected at 81 cm^{-1}. The peak at ~90 cm^{-1} has been resolved into two components 91.8 (B_{2g}) and 93.4 (B_{3g}) and two components have clearly been resolved in the ν_4 region 713.2 (B_{1g}) and 714.5 (A_{1g}), Fig. 3. With the exception of the $2\nu_2$ region the A_g modes were essentially absent for α_{cc}. Two other significant observations of the room temperature study were the presence of a weak shoulder of A_g symmetry on the ν_1 (A_g) peak and a broad asymmetry on the low frequency side of the lattice mode at 52 cm^{-1}. Both features were absent from the spectra obtained at liquid nitrogen temperature (Fig. 4).

Raman peaks for $K^{15}NO_3$ were observed at 55.3, 72.4, 91.8, 93.4, 111.2, 132.3, 713, 1051, 1312 (B_{1g}), 1326 (A_g), 1354 (vw, B_{2g}), 1415 (vw, B_{3g}), 1428 ($2\nu_4$), 1608, and 1637 cm^{-1} ($2\nu_2$). No special effort was made to detect the weaker lattice modes since the uncertainty of measurement of these weak peaks would have resulted in little additional information.

Internal Modes

ν_1 *Region*

In the ν_1 symmetric stretching mode of the NO_3^- ion, two infrared and two Raman modes are predicted by the unit cell group analysis. Karpov and Shultin (11) have identified infrared components B_{1u}, 1051.0 cm^{-1} and B_{2u}, 1049.9 cm^{-1}. The A_g mode occurs at 1050.6 in the Raman with $\alpha_{aa} \simeq \alpha_{bb} \gg \alpha_{cc}$ but the B_{3g} mode has not been detected. The values of α_{aa}, α_{bb}, and α_{cc} suggest that the σ_h plane of NO_3^- does not depart significantly from the *ab*

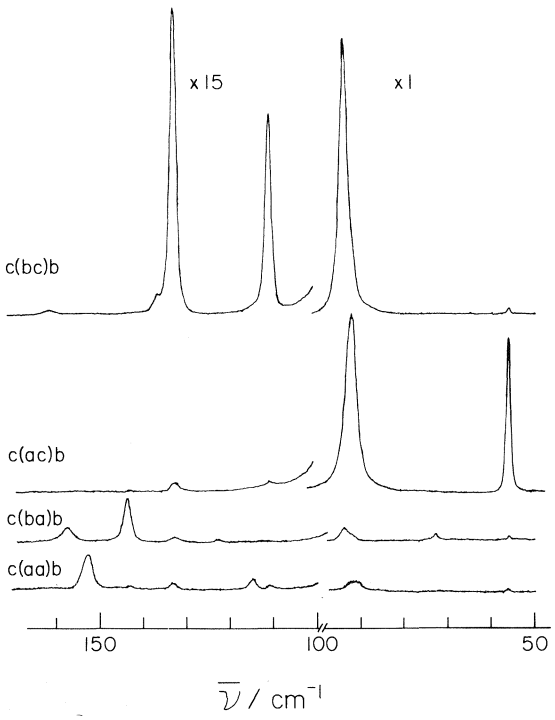

FIG. 2. Raman spectra of lattice region of KNO_3(II) at 77 K. Silt-width was 1.0 cm^{-1} from 0 to 100 cm^{-1}, 2 cm^{-1} from 100 to 170 cm^{-1}.

crystallographic plane. Previously (14) we have assigned the weak shoulder on the ν_1 mode of a number of metal nitrates at room temperature to a correlation field component and in particular for KNO_3 a shoulder at $\sim$1047 cm^{-1} was assigned to the B_{3g} component. Although the assignment for the cubic nitrates, $Ca(NO_3)_2$, $Sr(NO_3)_2$, and $Pb(NO_3)_2$, appears valid and F_{2g} symmetry has been confirmed by depolarization measurements (19),[1] for the alkali metal, silver and thallium nitrates the shoulders have A_g symmetry and *cannot* be due to correlation field components and these features must be reassigned. Badr *et al.* (7) have observed similar features in $NaNO_3$ and $CsNO_3$ crystals. These authors observed that the ratio of the intensity of the low frequency component, I', to the high frequency component, I, increased with increased temperature but could be frozen out at 213 K. "Energetically distinguishable alternate structures" were proposed with different types of coordination which were responsible for differences between the local fields and altered the frequency of the vibration. Clusters with aragonite and calcite coordination were proposed. James *et al.* (20) have assigned similar features to hot bands. Our studies support the alternate structures explanation. Limited temperature variation studies for KNO_3(II) indicate that I'/I increases with increased temperature with values 0, 0.05_4, 0.070, 0.08_5, and 0.13 at 195, 275, 300, 335, and 383 K, respectively.[2] A hot band of the type $\nu_1 = 1 \rightarrow \nu_1 = 2$ is unlikely since the observed intensity is over ten times that expected by Boltzman distribution although a 3 cm^{-1} anharmonicity would not be too large. A hot band involving a combination of ν_1 with a lattice mode 'hot band' is more difficult to discount. However, one would not expect these modes to freeze out at temperatures as high as 213 K since upper states of lattice modes are still appreciably populated at this temperature. The marked temperature dependence near phase transitions (7) is not consistent with a hot band origin for these peaks. It should be noted that although the peak separation is almost identical for $NaNO_3$, KNO_3, and $CsNO_3$, 4, 3, and 3 cm^{-1}, the intensity ratio I'/I at room temperature is not constant but increases with cation size, 0.05_8, 0.07_0, and 0.09_5.

It is interesting to note that the temperature at which the low frequency shoulder freezes out for KNO_3 is approximately equal to the temperature of the phase transition (213 K) reported by Fermor and Kjekshus (3) from dielectric and conductivity studies. Phase transitions of a similar type for all of the alkali metal nitrates have been reported by Fermor and Kjekshus (4) but these have previously received little credence since no evidence for a structural change was detected from neutron diffraction studies (5). Badr *et al.* (6) have since shown that subtle change in Raman peak intensities of two peaks near 38 cm^{-1} of $RbNO_3$ occurs between 203 and 205 K which is near the transition temperature of 228 K reported by Fermor and Kjekshus. The possibility must be considered that these transitions are associated with the final 'freezing out' of a small fraction of 'disordered' sites. The presence of such sites would be difficult to detect by con-

[1]It is possible that weak shoulders also exist for the cubic nitrates but they would be obscured by the F_g mode.

[2]Integrated intensities were measured from band areas.

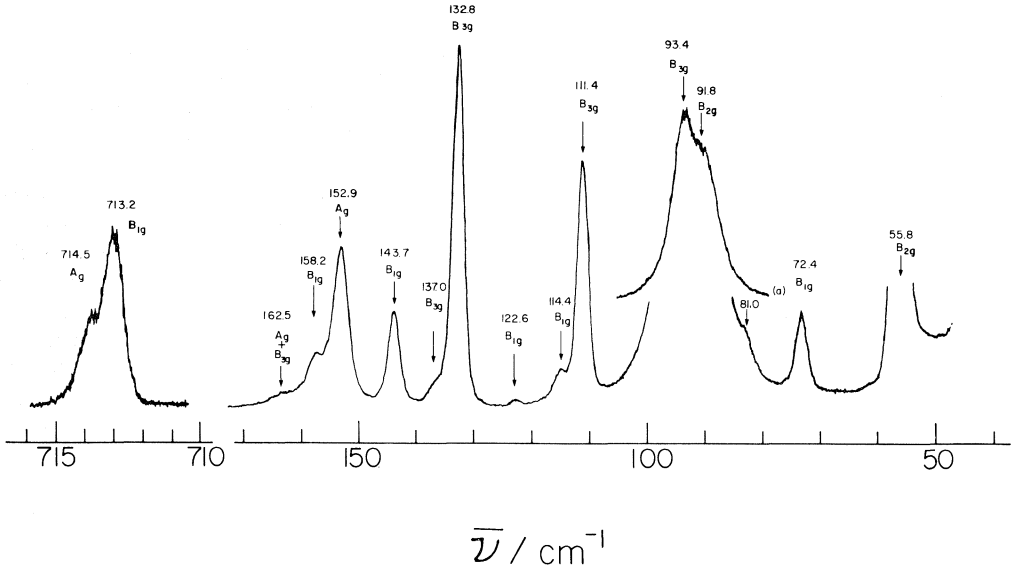

FIG. 3. Raman spectra for a poorly oriented KNO_3(II) crystal at 77 K. The orientation is primarily *c*(*ba*)*b*. The insert at about 90 cm^{-1} has abcissa expansion of 2×. Slits were 0.5 cm^{-1} for the 90 and 715 cm^{-1} regions, 1.0 cm^{-1} from 30 to 90 cm^{-1}, and 2 cm^{-1} from 100 to 170 cm^{-1}.

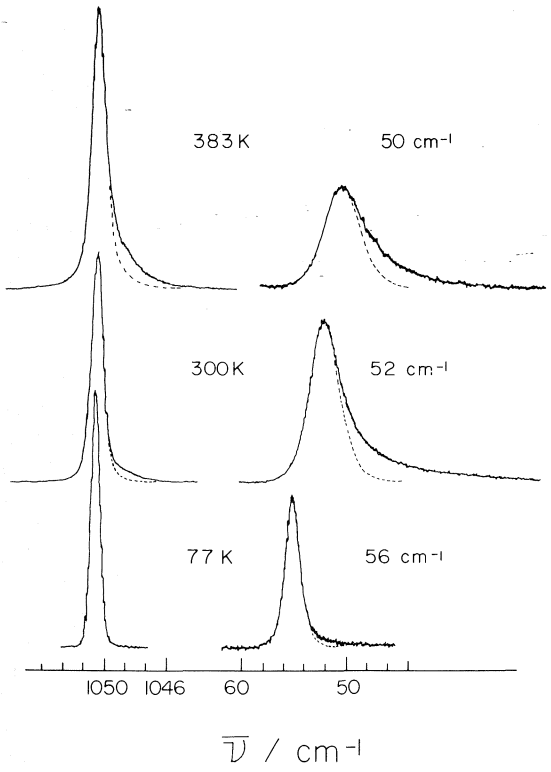

FIG. 4. Raman spectra of the 1050 and 50 cm^{-1} regions at selected temperatures.

ventional diffraction or spectroscopic methods since both phases would have identical crystal structures. For instance, in the present study there is no indication that the space group of KNO_3(II) is other than *Pmcn* at both room temperature and liquid nitrogen temperature but the shoulder on the ν_1 mode and the asymmetry of the 52 cm^{-1} lattice mode suggest the presence of a small fraction of alternate sites in KNO_3 at room temperature. Multiple site occupancy by anions in simple crystals is not unusual; in fact, for $RbNO_3$ and $CsNO_3$ the space group requires the NO_3^- groups to be on three sets of non-equivalent C_1 sites (21, 22) and peak multiplicity due to this multiple site effect has been detected by infrared (21) and Raman (23) spectroscopy. A two-site model has been proposed (24) for the disordered high temperature phase, KNO_3(I), and Strømme (25) has suggested that even the ordered phase, KNO_3(III), contains NO_3^- groups statistically distributed between two twofold disordered non-equivalent positions. Our Raman results[3] for KNO_3(I) and KNO_3(III) support Strømme's model and further suggest that KNO_3(II) has a small fraction of NO_3^- groups on disordered positions.

ν_2 *Region*

Two infrared and two Raman modes are predicted for the ν_2 region of KNO_3(II). Karpov and Shultin (11) have assigned the infrared modes at 829 cm^{-1} (B_{1u}) and 844 cm^{-1} (B_{2u}) and from dipole sum calculations (12) estimated the Raman modes to be at 844.6 cm^{-1} (B_{3g}) and 825 cm^{-1} (A_g). We have observed the A_g mode at 825.2 cm^{-1} for both α_{aa} and α_{bb} ($\alpha_{cc} \simeq 0$) but the B_{3g} mode could not be detected in α_{bc}. Occasionally, in poorly aligned samples we observed a weak feature ~843 cm^{-1} in α_{ab} which may be B_{3g}; however, the depolarization characteristics were never correct. We have been unable to confirm the presence of a peak at 829 cm^{-1} which Frech and Devlin (15) have assigned to B_{3g}. Often in a poorly aligned crystal the 825 cm^{-1} peak was observed in α_{ab} where it appeared somewhat broader than in α_{aa} but we did not detect any frequency shift for this mode for different tensor components.

The overtone region, $2\nu_2$, also suggests the essential correctness of the Shultin and Karpov assignments since a broad envelope is observed with peak maxima at 1652 and 1691 cm^{-1} at 77 K which correspond to 2×826 and 2×845 cm^{-1}. Considerable intensity occurs between the maxima but no attempt has been made to further resolve this envelope in the present study. This intensity may be due to combinations involving non-zone-centre modes. The static field value of ν_2 appears to be approximately 835 cm^{-1} which is close to the value of ν_2 for $LiNO_3$ and $NaNO_3$. It is interesting that the high frequency component of $2\nu_2$ shifts from 1686 to 1691 cm^{-1} when the crystal is cooled from 298 to 77 K, whereas, the 1652 cm^{-1} component remains constant. Shultin and Karpov report an analogous result for the ν_2 fundamental region with the peak at 843 shifting to 846 cm^{-1} when the crystal was cooled to 77 K.

ν_3 *Region*

Assignment of the five observed Raman peaks in the ν_3 region are identical to those reported by Frech and Devlin (15). The B_{2g} and B_{3g} modes are associated with non-planar motions of the nitrate group. The extremely small relative intensity values of these peaks suggest that nitrate retains its planar character

in KNO_3. Two infrared peaks at 1340 and 1375 cm^{-1} have been identified but no assignments were possible (13). The most intense longitudinal optional (LO) mode of ν_3 has been detected at 1445 cm^{-1} in the infrared spectrum (26). Since KNO_3(II) is centrosymmetric LO peaks are not Raman allowed. A weak peak at 1431 cm^{-1} with A_g symmetry was assigned to $2\nu_4$.

ν_4 Region

Only two of the four predicted Raman peaks have been detected in this region. At 77 K the assignments are 713.2 (B_{1g}) and 714.5 (A_g) which implies a site splitting of 1.3 cm^{-1} which is larger than the 0.5 cm^{-1} value estimated by Frech and Devlin (15). The intensities of the out-of-plane modes B_{2g} and B_{3g} appear to be identically zero. Karpov and Shultin (11) have reported infrared peaks at 715.2 (B_{2u}) and 714.5 (B_{3u}). The B_{1u} mode although theoretically allowed was not detected.

External Region

Even at 77 K only 13 of the 18 predicted Raman modes were observed. Improved depolarization studies indicate that the 55.8 cm^{-1} mode has B_{2g} symmetry only while the band ~90 cm^{-1} contains two components 91.8 (B_{2g}) and 93.4 (B_{3g}). The 93.4 cm^{-1} mode has been assigned to a rotatory mode of nitrate about the *a* axis while the 91.8 cm^{-1} mode has been assigned to the rotatory mode of nitrate about *b*. It is interesting to note that the relative intensities of the two components are about equal but the higher frequency mode of the pair has a 20% smaller halfwidth than the lower frequency component. The similarity of the two components is in accord with the crystal packing since KNO_3(II) has a pseudo-hexagonal unit cell. The optical anisotropy in the *ab* plane is very small with refractive indices of 1.513, 1.512, and 1.336. The rotatory motion of the nitrate group about the *c* axis should be active in α_{ab} and it is possible that the weak peak at 72.4 cm^{-1} corresponds to this mode. A rotatory motion about the C_3 axis will have a small polarizability change associated with it and one would expect a weak, broad peak at lower energy than rotatory motions about *a* or *b*. The 55.8 cm^{-1} (B_{2g}) mode has been assigned to a trans-

latory motion of the K^+ sublattice against the NO_3^- sublattice. Most of the peaks above 100 cm^{-1} must belong to other translatory modes. When ^{15}N was substituted for ^{14}N the peaks at 55.8, 111.4, and 132.8 were shifted by 0.5, 0.2, and 0.5 cm^{-1} but the peaks 72.4, 91.8, and 93.4 cm^{-1} remained unshifted ($\sim$0.1 cm^{-1}). These results are consistent with the above assignments. Simple harmonic oscillator calculations suggest that translatory modes should shift by $\sim$0.8% and rotatory modes should remain unshifted. Rousseau *et al.* (27) have obtained similar results for lattice modes of $NaNO_3$ and confirmed that the rotatory mode of NO_3^- was at 185 cm^{-1}, whereas the translatory mode was at a lower position, 98 cm^{-1}.

The most significant changes that occur in the Raman spectrum between 298 and 77 K occur in the lattice region. The halfwidths and relative intensities of all of the peaks decreased considerably with decreased temperature and several new components were detected. Peak positions increased by about 10% when the temperature was lowered from 298 to 77 K and this effect can probably be attributed to lattice contraction. It would appear that at room temperature the thermal motion is quite considerable. In the room temperature phase of $AgNO_3$, X-ray studies suggest that the NO_3^- ion has a root mean square oscillation of $\sim$8° (28). Undoubtedly the thermal disorder contributes significantly to the marked asymmetry of the 52 cm^{-1} mode at room temperature. It is doubtful that the asymmetry can be assigned to simple hot bands since calculations based on Boltzmann statistics do not reproduce the asymmetry even for large values of the anharmonicity constant. If one assumes a symmetric peak about the peak maximum, the excess area, I', may be used as an indication of asymmetry. The value of I'/I_{total} has a minimum, almost zero, value at 77 K and increases to a maximum value of 0.33 at 390 K; at 401 K the phase transition to KNO_3(I) occurs and the peak abruptly disappears. Values of I'/I_{total} obtained were: 0.075 at 77 K; 0.19 at 195 K; 0.26 at 275 K; 0.30 at 300 K; 0.33 at 370 K; and 0.35 at 390 K.[4] A possible explanation for the observed asymmetry is that it is associated with disordered sites of the lattice. Since the 52 cm^{-1} peak appears to be due to a lattice translatory mode, disordering of the K^+ and NO_3^- positions could give rise to a range of modes in this region. Wegdam *et al.* (29)[5] have shown that low energy phonons in warm crystals have amplitudes which are an appreciable fraction of the magnitude of the lattice distances. As a result of the large amplitudes local symmetries will change continuously within the time interval of the phonon lifetime. Thus a large amplitude and anharmonicity of the 52 cm^{-1} mode could explain the asymmetry in this mode and also result in a range of symmetries available to the NO_3^- groups which would contribute to the ν_1 band asymmetry. Although the anomalous features of the 1050 cm^{-1} and 52 cm^{-1} peaks are similar there is not a direct correspondence since the intensity ratio changes of the two features do not match.

The considerable decrease in halfwidth which occurs for all lattice modes when the temperature is lowered to 77 K and the corresponding intensity decrease of the 52 and 83 cm^{-1} modes (Tables 1 and 2) suggest that in the room temperature form of KNO_3(II) thermal motion is quite significant. There is no evidence to suggest that the NO_3^- group loses its planarity nor was there any evidence to suggest that the plane of the NO_3^- is not on the *ab* crystallographic plane although it must be admitted that Raman spectroscopy does not measure positional properties with accuracy. Possibly the anomalous features of the X-ray determination are due to the positional and thermal disordering noted above. Anharmonicities in the thermally induced motions of the NO_3^- groups could easily account for the small departure from planarity of the NO_3^- as determined from the X-ray analysis. The observed temperature dependence of the out-of-plane character of the nitrogen atom (0.019 Å at 298 K, 0.036 Å at 398 K) as determined in the X-ray analysis (1) is consistent with the concept of thermally induced anharmonic motions and a moderate degree of disorder in the room temperature phase. The fact that the Raman spectra for KNO_3 at both 77 and 298 K are best interpreted in terms of the *Pmcn* space-group suggests that the phase transition at 213 K proposed by Fermor and Kjekshus involves only a minor structural

[4]Values of I'/I may be used to estimate activation energies of the alternate orientations. See ref. 7. If this is done the present data lead to a value of approximately 1.6 kcal mol^{-1} at 298 K.

[5]The applicability of this reference was suggested by one of the referees.

change, quite possibly the "freezing out" of the disordered nitrate groups. Since X-ray measurements are time-averaged over a long time it is not surprising that the disorder was not detected by X-ray diffraction.

Nucleic acid related compounds. 24. Transformation of tubercidin 2′,3′-*O*-orthoacetate into halo, deoxy, epoxide, and unsaturated sugar nucleosides[1,2]

MORRIS J. ROBINS, ROGER A. JONES, AND RUDOLF MENGEL[3]

Department of Chemistry, The University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received November 4, 1976

MORRIS J. ROBINS, ROGER A. JONES, and RUDOLF MENGEL. Can. J. Chem. **55**, 1251 (1977).

Treatment of tubercidin (4-amino-7-β-D-ribofuranosylpyrrolo[2,3-*d*]pyrimidine) (**1**) with methyl orthoacetate gave the 2′,3′-*O*-orthoester, **2**. Pivalic acid chloride in refluxing pyridine converted **2** into a mixture containing 4-*N*-pivalamido-7-(3-chloro-3-deoxy-2-*O*-acetyl-5-*O*-pivalyl-β-D-xylofuranosyl)pyrrolo[2,3-*d*)pyrimidine (**3***a*) and the corresponding 2′-*O*-(4,4-dimethyl-3-pivaloxypent-2-enoyl) (DMPP) compound (**3***b*) via acetoxonium ion intermediates. Treatment of **2** with sodium iodide/pivalyl chloride/pyridine gave the iodo analog (**3***c*) of DMPP derivative **3***b* plus the 3′,4′-unsaturated nucleoside (**5***a*). Treatment of **3***a–c* with methanolic sodium methoxide gave the *ribo*-epoxide **4**, which underwent $N^1 \rightarrow 3'$ intramolecular cyclization readily. Dehalogenation of **3** and deprotection gave 3′-deoxytubercidin (**8**). Deblocking of **5***a* gave **5***b* which was hydrogenated to give **8** plus its 4′-epimer **9**. Heating of **3***c* or **5***a* produced 4-*N*-pivalamido-7-(5-pivaloxymethylfuran-2-yl)pyrrolo[2,3-*d*]pyrimidine (**10***a*). Deblocking of **10***a* gave **10***d* which was hydrogenated to give racemic 4-amino-7-(2,3-dideoxy-β-D,L-*glycero*-pentofuranosyl)pyrrolo[2,3-*d*]pyrimidine (**7**,**11**). The 2′,3′-unsaturated nucleoside (**6**) was obtained and hydrogenated to produce 2′,3′-dideoxytubercidin (**7**). Spectroscopic identification of products, epoxide instability, and comparison with other procedures are discussed.

MORRIS J. ROBINS, ROGER A. JONES et RUDOLF MENGEL. Can. J. Chem. **55**, 1251 (1977).

La réaction de la tubercidine (amino-4 β-D-ribofuranosyl-7 pyrrolo[2,3-*d*]pyrimidine (**1**)) avec l'orthoacétate de méthyle donne l'*O*-orthoester-2′,3′. Celui-ci est transformé en un mélange contenant la *N*-pivalamido-4 (chloro-3 déoxy-3 *O*-acétyl-2 *O*-pivalyl-5 β-D-xylofuranosyl)-7 pyrrolo[2,3-*d*]pyrimidine (**3***a*) et le composé correspondant *O*-(diméthyl-4,4 pivaloxy-3 pentènoyl-2)-2′ (DMPP) (**3***b*), via l'intermédiaire d'ions acétoxonium, par action du chlorure de pivalyle dans la pyridine à reflux. L'action sur **2** du mélange iodure de sodium/chlorure de pivalyle/pyridine donne l'analogue iodé (**3***c*) du dérivé DMPP **3***b* plus le nucléoside insaturé-3′,4′ (**5***a*). Par traitement de **3***a–c* avec le méthylate de sodium méthanolique, l'époxyde *ribo* **4** est obtenu, ce dernier subissant une cyclisation $N^1 \rightarrow 3'$ intramoléculaire rapide. Déhalogénation de **3** et déprotection donne la déoxy-3′ tubercidine (**8**). Déblocage de **5***a* donne **5***b* qui est hydrogéné et donne **8** avec son épimère-4′ (**9**). La *N*-pivalamido-4 (pivaloxyméthyl-5 furanyl-2)-7 pyrrolo[2,3-*d*]pyrimidine (**10***a*) est produire lors du chauffage de **3***c* ou **5***a*. Déblocage de **10***a* donne **10***d* qui est hydrogéné et donne le racémique amino-4 (didéoxy-2,3 β-D,L-*glycero*-pentofuranosyl)-7 pyrrolo[2,3-*d*]pyrimidine (**7**,**11**). Le nucléoside insaturé-2′,3′ (**6**) est obtenu et, hydrogéné, donne la didéoxy-2′,3′ tubercidine (**7**). L'identification spectroscopique des produits, l'instabilité de l'époxyde et la comparaison avec d'autres procédés sont discutées.

The nucleoside antibiotic tubercidin (7-deazaadenosine; 4-amino-7-β-D-ribofuranosylpyrrolo-[2,3-*d*]pyrimidine) (**1**) has been studied extensively both chemically and from a biochemical-medical viewpoint. An excellent comprehensive review covers both aspects (1). Tubercidin is closely related to adenosine structurally and chemically, and is a substrate for many enzymes concerned with biosynthetic processes involving adenosine and phosphorylated metabolites. Two notable exceptions are its complete resistance to adenosine deaminase and the absence of enzymic phosphorolysis of the glycosyl bond (1). The latter two pathways represent major catabolic degradation (inactivation) modes for adenosine and biologically active analogs. Modification of the heterocyclic base of tubercidin has been studied systematically (2), and coupling syntheses of the pyrrolo[2,3-*d*]pyrimidine anti-

[1]Abstracted in part from the Ph.D. dissertation of R. A. Jones, The University of Alberta, Edmonton, Alta., Spring, 1974.

[2]For the previous paper in this series see ref. 12.

[3]Postdoctoral Fellow, 1969–1971. Present address: Fachbereich Chemie, Universität Konstanz, 7750 Konstanz, West Germany.

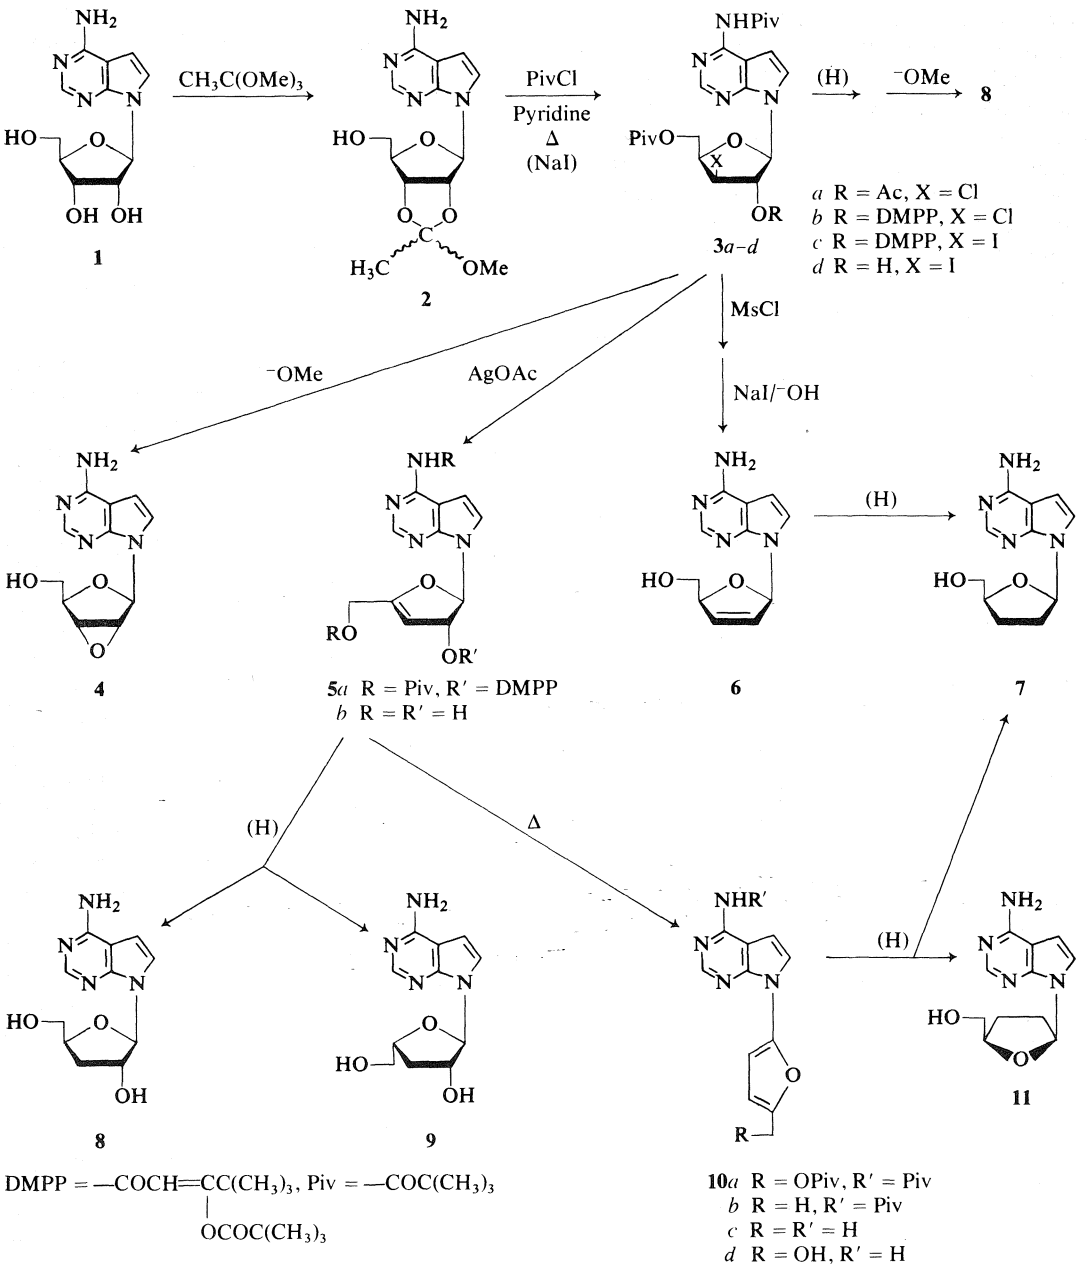
biotics have been achieved (2*c*). However, little work has been reported concerning the sugar moiety of tubercidin (3–6). Although the well established sugar–base coupling methods have been used extensively in the synthesis of modified sugar analogs of adenosine (7), no such parallel studies have appeared with related tubercidin compounds. The lack of coupling stereoselectivity with certain sugars, the instability of unsaturated carbohydrate derivatives, and the extensive heterocyclic transformations involved before and after coupling in the total synthesis routes make this approach rather uninviting for the study of a variety of modified-sugar nucleoside antibiotics.

We have been interested in developing procedures and reactions for the transformation of the sugar moiety of intact nucleosides into stereochemically inverted, unsaturated, and deoxy derivatives. This allows the retention of pre-existing stereochemistry at non-functionalized sites and the use of starting materials which are accessible on a practical scale via fermentation. We now wish to describe details of the successful application of the ortho ester – acyl halide (acyloxonium ion) approach to the sugar modification of tubercidin (for a preliminary account see ref. 8).

Treatment of tubercidin (**1**) with trimethyl orthoacetate under acid catalysis gave 2′,3′-*O*-methoxyethylidenetubercidin (**2**) quantitatively as a mixture of orthoester diastereomers. (See Scheme 1.) This product mixture was treated with pivalic acid chloride in refluxing pyridine (9) to give 4-*N*-pivalamido-7-(3-chloro-3-deoxy-2-*O*-acetyl-5-*O*-pivalyl-β-D-xylofuranosyl)-pyrrolo[2,3-*d*]pyrimidine (**3***a*) and the corresponding 2′-*O*-(4,4-dimethyl-3-pivaloxypent-2-enoyl) (DMPP) derivative **3***b* in 89% combined yield and in a ratio of ~16:1, respectively. In contrast to the corresponding reaction of the adenosine orthoester (9), no 2′-chloro isomers were detected. The absence of nucleophilic attack at the 2′-position of tubercidin has been noted previously in acetoxonium ion mediated reactions (5, 6). The use of free radical dechlorination conditions (10) (tri-*n*-butyltin hydride plus α,α′-azobisisobutyronitrile as initiator) with **3***a* followed by deblocking gave 3′-deoxytubercidin (**8**) (5, 6) in 51% yield. This allows use of the blocked chloro nucleosides for syntheses of specific deoxy derivatives whereas catalytic hydrogenolysis of chloro compounds has been generally unsuccessful (6, 11). Treatment of the unpurified mixture of **3***a*,**3***b* with methanolic sodium methoxide gave the *ribo*-epoxide (2′,3′-anhydrotubercidin) (**4**) (6, 8) in 72% overall yield from **1**. This verified the *trans* orientation of the 3′-chloro and 2′-acyloxy groups and provided alternative access to the useful intermediate **4**.

Reaction of **2** with excess sodium iodide and pivalyl chloride in refluxing pyridine gave 4-*N*-pivalamido-7-(3-iodo-3-deoxy-2-*O*-[4,4-dimethyl-3-pivaloxypent-2-enoyl]-5-*O*-pivalyl-β-D-xylofuranosyl)pyrrolo[2,3-*d*]pyrimidine (**3***c*) plus a small quantity of the 3′,4′-unsaturated product **5***a* formed by loss of hydrogen iodide from **3***c*. As in the corresponding adenosine series (9), no 2′-*O*-acetyl product was formed using pivalyl iodide (generated *in situ*). In contrast, detectable 2′-iodo substitution did not occur. Treatment of **3***c* with methanolic sodium methoxide gave a product which was identical to **4** by thin layer chromatography (tlc) and mass spectroscopy. Hydrogenolysis of **3***c* followed by deblocking gave **8** in 79% yield. Treatment of **3***c* in refluxing pyridine or with 1,5-diazabicyclo-[4.3.0]non-5-ene (DBN) in pyridine at ambient temperature gave a mixture of **5***a* and the furan derivative **10***a*. Selective elimination of hydrogen iodide from **3***c* was effected smoothly using silver acetate (12) to give **5***a* quantitatively. Deblocking of **5***a* gave crystalline 4-amino-7-(3-deoxy-β-D-*glycero*-pent-3-enofuranosyl)pyrrolo[2,3,-*d*]-pyrimidine (**5***b*). Hydrogenation of **5***b* gave **8** plus its 4′-epimer (**9**) in a ratio of 1:1.4 and in 91% combined yield. These epimers were separated cleanly and conveniently on the Dekker anion exchange column (13).

Extended heating of **3***c* in pyridine or neat fusion of **5***a* at 180°C gave **10***a*. Hydrogenolysis of the pivaloxy–methyl bond of **10***a* occurred very readily to give **10***b* which was deblocked to give 4-amino-7-(5-methylfuran-2-yl)pyrrolo[2,3-*d*]pyrimidine (**10***c*). Prior deblocking of **10***a* gave the hydroxymethylfuran derivative (**10***d*) which underwent hydrogenation of the furan ring to give racemic 4-amino-7-(2,3-dideoxy-β-D,L-*glycero*-pentofuranosyl)pyrrolo[2,3-*d*]pyrimidine (**7**,**11**). The *cis* orientation of the base (1′) and hydroxymethyl (4′) substituents of **7**,**11** was verified by 5′-*O*-tosylation followed by quantitative cyclization (tlc, uv) to the $N^1 \rightarrow 5'$-cyclonucleosides (3, 9, 14). Selective deblocking of the 2′-hydroxyl of **3***c* was effected by oxidative



SCHEME 1

removal of the DMPP group using potassium permanganate in cold aqueous pyridine (12). The resulting *trans* iodohydrin (**3***d*) was mesylated and then treated with sodium iodide in cold aqueous base. Elimination of iodo and mesylate with concomitant deblocking occurred (12) to give 4-amino-7-(2,3-dideoxy-β-D-*glycero*-pent-2-enofuranosyl)pyrrolo[2,3-*d*]pyrimidine (**6**) in 55% yield. Hydrogenation of **6** gave amorphous 2′,3′-dideoxytubercidin (**7**), which was previously reported (also in a non-crystalline state) as a by-product of the hydrogenolysis of a blocked 3′-bromo-2′-*O*-acetyl xylo derivative (6).

Although not mentioned by Moffatt and co-workers (6), 2′,3′-anhydrotubercidin (**4**) is an extremely sensitive compound which readily

undergoes intramolecular degradation especially in hydroxylic solvents. By analogy with the adenosine *ribo*-epoxide (15), it is assumed that nucleophilic attack by N-1 at C-3′ of the epoxide gives transitory $N^1 \rightarrow 3'$-cyclonucleoside formation. Attack of water at C-2 of the positively charged pyrimidine ring followed by ring opening would be expected to lead to an amino carboxamidine substituted pyrrole. However, the expected product of this degradation apparently undergoes further reactions and a red-purple coloration slowly develops in crystalline samples of **4**, and rapidly in amorphous products or solutions. As seen in Fig. 1, the kinetic degradation of **4** (uv λ_{max} ~270 nm) to product(s) (uv λ_{max} > 300 nm) in aqueous solution qualitatively parallels that of the analogous adenosine *ribo*-epoxide (15). However, the reaction proceeds much more readily and attempts to isolate and purify the product were unsuccessful. The absence of a sharp isosbestic point at ~290 nm suggests the possible formation of more than one ring-opened species. Evaporation of a warmed solution of **4** in methanol followed by drying the residue *in vacuo* gave a solid whose mass spectrum contained peaks at *m/e* 238.1069 (calcd. for $C_{10}H_{14}N_4O_3$: 238.1066) and *m/e* 221.0813 (calcd. for $C_{10}H_{11}N_3O_3$: 221.0800). By analogy

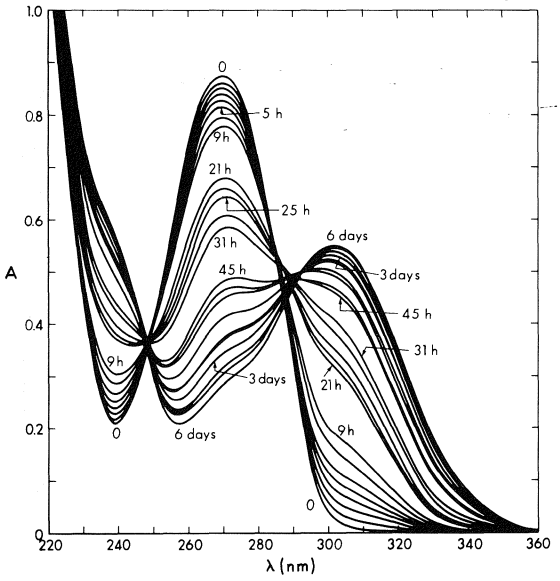


FIG. 1. Ultraviolet absorption *vs.* wavelength of an aqueous solution (1.9 mg/100 ml) of **4** at room temperature measured at various times. At 80°C the change in spectra (from 0 – corresponding to 6 days) was complete in 1 h.

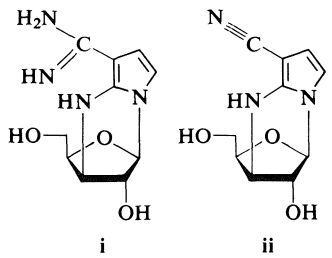
with the adenosine series, these formulas could correspond to structures **i** and **ii**, respectively. It



is noteworthy that the peaks at *m/e* 221 and 238 do not appear in the mass spectrum of a carefully purified sample of **4**. However, the presence of the *m/e* 221 ion was noted in the previously reported mass spectrum of **4** and attributed to the loss of HCN from the parent ion (6). It appears unlikely that this postulated fragmentation would occur with **4** since in an extensive mass spectral investigation of adenosine derivatives and analogs the loss of HCN was shown to arise later from the B+H ion (16). An alternative explanation for the presence of the *m/e* 221 peak in the reported (6) spectrum of **4** is partial prior decomposition of **4** to **i** which in turn could give rise to **ii** (*m/e* 221). Nucleophilic substitution reactions of **4** at C-3′ could not be effected directly in practical yields owing to the rapid rate of decomposition, whereas several such reactions were successful with the corresponding adenosine epoxide (15).

Mass and ^1H nmr spectra of all tubercidin compounds described in this study are closely analogous to their adenosine counterparts (9, 12). The mass spectra can generally be inferred from those of the adenosine analogs with all heterocyclic base-containing fragments occurring at one atomic mass unit lower in this series (^{14}N *vs.* $^{12}C^1H$ at the 7-position, adenosine numbering). The mechanisms of the ortho-ester – pivalyl halide reactions involving acyloxonium ion and ketene acetal intermediates and proofs of structures of the products are discussed in detail in ref. 9. The pertinent literature and new procedures for deoxy and unsaturated compounds are described in ref. 12.

The present study demonstrates that carbohydrate transformations of naturally occurring nucleoside antibiotics into halo, deoxy, epoxy, and unsaturated sugar products can be effected directly on a practically convenient scale using chloro and iodo intermediates generated from

the methyl-2′,3′-*O*-orthoacetate and pivalyl halides. Thus, a viable semisynthetic alternative to sugar–base coupling has been realized with this fermentation derived biomolecule.

Experimental

Melting points were determined on a Reichert microstage apparatus and are uncorrected. ^{1}H nmr spectra were recorded on Varian A-60 and HA-100 instruments with TMS as internal reference. Furan protons are given primed numbers corresponding to nucleoside sugar numbering in nmr data. Ultraviolet (uv) spectra were recorded on Cary 14 or 15 spectrophotometers. Accurately weighed uv spectral samples were dissolved in a minimum volume of MeOH and then diluted with at least 9 volumes of the designated solvent or solution. Optical rotations were measured on a Perkin-Elmer model 141 polarimeter using a 10 cm, 1 ml microcell. Mass spectra were obtained by the mass spectroscopy laboratory of this department on AEI MS-2, MS-9, or MS-12 instruments via direct probe sample introduction at 70 eV and 150 to 230°C. Elemental analyses were determined by the microanalytical laboratory of this department or by Schwarzkopf Microanalytical Laboratory, Woodside, NY. Thin layer chromatography (tlc) was performed on Eastman Chromatogram sheets (silica gel No. 13181, indicator No. 6060). Developed chromatograms were evaluated under uv (2537 Å) light. Evaporations were carried out using a Büchler rotating evaporator with a dry ice cooled Dewar condenser under aspirator or oil pump vacuum, at 40°C or less. Hydrogenations were effected using a Parr shaking apparatus at room temperature, under the specified hydrogen pressure with Matheson, Coleman and Bell 5 or 10% palladium-on-carbon as catalyst. Silica column chromatography was performed on Mallinckrodt SilicAR CC-7 or Woelm (0.063–0.1 mm) silica gel. Unless specified, 'silica' refers to the Mallinckrodt CC-7 adsorbent. Carbon chromatography was effected on Barnebey-Cheney AU-4 carbon which was refluxed with 1 *N* HCl for several hours, washed with water, and refluxed with 1 *N* NaOH. The carbon was then washed with water until the filtrate was neutral, followed by methanol, chloroform, and methylene chloride, and allowed to air dry. 'Ether' refers to Mallinckrodt diethyl ether in all cases. Pyridine was refluxed over and then distilled from calcium hydride and stored over linde 4A molecular sieves (dried at 200°C). Sodium iodide was dried in the presence of phosphorous pentoxide at room temperature under high vacuum for at least 24 h. Pivalyl chloride was distilled before use. Tubercidin was purchased from the Upjohn Company, Kalamazoo, Michigan.

'Diffusion crystallization' (9, 17) was effected using methanol–ether. A concentrated solution of the nucleoside (warming was sometimes necessary) in methanol contained in a beaker or small wide mouth Erlenmeyer flask was allowed to stand in a closed desiccator containing a large volume of ether. Crystallization was allowed to proceed at room temperature for 2–5 days and the crystals were then collected, without cooling. In no case was it necessary to collect more than two crops, with the first crop generally giving ~90% of the material obtained.

2′,3′-O-Methoxyethylidenetubercidin (2)

To a suspension of 2.6 g (0.0098 mol) of **1** in 50 ml of dry dioxane was added 4.75 g (0.040 mol) of trimethyl orthoacetate and 4.5 g (0.028 mol) of trichloracetic acid. The mixture was heated at 50°C for 15 min and the resulting clear solution was cooled and neutralized with 30 ml of 10% aqueous $NaHCO_3$ plus 5 drops of 25% aqueous NH_3. Most of the dioxane was evaporated and the aqueous solution was extracted with 5 × 40 ml of $CHCl_3$. The combined organic phase was dried over Na_2SO_4, filtered, and evaporated to give a colorless solid foam (quantitative). This crude material could be used without further purification in subsequent reactions. Purification of this product was effected by chromatography on a column (2.3 × 15 cm, 24 g) of Woelm silica gel packed in $CHCl_3$ containing 1.5% of saturated MeOH–NH_3 and developed with the same solvent mixture. Fractions (50 ml) 6–14 gave (after evaporation and drying at 0.1 torr) 2.09 g (66%) of **2** as a colorless solid foam. A sample of this material was dissolved in H_2O (adjusted to and maintained at p*H* 8 with NH_4OH) and the solution was frozen. On melting, colorless crystals of **2** were obtained, mp 97–98°C; uv (MeOH)-λ_{max} 268 nm (ε 12 100); nmr (DMSO-d_6) δ 1.51, 1.63 (*exo*, *endo*, s, s, 3, C-CH_3), 3.34, 3.16 (*exo*, *endo*, s, s, 3, OCH_3), 3.56 (m, 2, H-5′, H-5″), 4.10 (m, 1, H-4′), 4.84–5.38 (m, 3, H-2′, H-3′, 5′-OH), 6.34, 6.16 (*exo*, *endo*, d, d, $J_{1'-2'}$ = 4 Hz, 1, H-1′), 6.60 (d, J_{5-6} = 4 Hz, 1, H-5), 7.35 (d, J_{6-5} = 4 Hz, 1, H-6), 7.04 (s, 2, 4-NH_2), 8.04 (s, 1, H-2); ratio of *exo*:*endo* diastereomers 1:2. *Anal.* calcd. for $C_{14}H_{18}N_4O_5$: C 52.17, H 5.63, N 17.38; found: C 51.88, H 5.38, N 17.07.

4-N-Pivalamido-7-(3-chloro-3-deoxy-2-O-acetyl-5-O-pivalyl-β-D-xylofuranosyl)pyrrolo[2,3-d]pyrimidine (3a) and 4-N-Pivalamido-7-(3-chloro-3-deoxy-5-O-pivalyl-2-O-[4,4-dimethyl-3-pivaloxypent-2-enoyl]-β-D-xylofuranosyl)pyrrolo[2,3-d]pyrimidine (3b)

To a solution of 1 g (0.003 mol) of crude **2** in 100 ml of pyridine was added 5.5 ml (0.045 mol) of pivalyl chloride with stirring and cooling. The mixture was heated at 80°C for 5 min and the solution was then refluxed for 1 h. After cooling in an ice bath, 10 ml of MeOH was added slowly and the mixture was stirred at room temperature for 10 min. The solution was evaporated until precipitation of solid began and then 150 ml of Et_2O was added. The mixture was filtered and the filtrate was washed with 100 ml of 10% aqueous $NaHCO_3$ solution. The aqueous phase was separated and extracted with Et_2O. The combined organic phase was dried over Na_2SO_4, filtered, and evaporated to give a pale yellow solid foam composed primarily of **3***a* and **3***b*. This foam was applied to a silica gel column (2.4 × 42 cm, 60 g) packed in Et_2O – petroleum ether 1:1. The column was developed successively with 300 ml portions of this solvent mixture, Et_2O – petroleum ether 3:1, and then Et_2O. Fractions (25 ml) 13–16 contained **3***b*, 17–27 a mixture of several components (tlc) which were not identified, and 28–40 contained **3***a*.

Evaporation of the first combined fractions and drying the residue at 0.1 torr gave 103 mg (5.2%) of **3***b*. This material melted at ~82°C (dec.); uv (MeOH)λ_{max} 285; 219 (ε 8820; 45 400), shoulder 229 nm (ε 28 200); nmr ($CDCl_3$) δ 1.12 (s, 9, C=C-*tert*-Bu) 1.20 and 1.23 (s and s, 9 and 9, 5′-OPiv and C=COPiv), 1.36 (s, 9, 4-NPiv),

4.32–4.66 (m, 4, H-3′–H-5′′), 5.46 (m, 1, H-2′), 5.75 (s, 1, CH=C), 6.59 (d, $J_{1'-2'} \sim 3$ Hz, 1, H-1′), 7.08 (d, $J_{5-6} = 4$ Hz, 1, H-5), 7.52 (d, $J_{6-5} = 4$ Hz, 1, H-6), 8.16 (s, 1, H-2), 8.46 (s, 1, 4-NH); ms calcd. for M^+: 662.3083; found (*m/e*): 662.3062 (^{35}Cl). *Anal.* calcd. for $C_{33}H_{47}ClN_4O_8$: C 59.76, H 7.15, N 8.45; found: C 60.00, H 7.15, N 8.39.

Analogous treatment of the third combined fractions gave 1.25 g (84%) of **3***a* which melted at ~75°C; uv (MeOH) λ_{max} 285; 218 (ε 8400; 32 700) shoulder 229 nm (ε 17 500); nmr ($CDCl_3$) δ 1.23 (s, 9, 5′-OPiv), 1.39 (s, 9, 4-NPiv), 2.16 (s, 3, 2′-OAc), 4.38–4.62 (m, 4, H-3′–H-5′′), 5.54 (m, 1, H-2′), 6.58 (d, $J_{1'-2'} \sim 4$ Hz, 1, H-1′), 7.13 (d, $J_{5-6} = 4$ Hz, 1, H-5), 7.53 (d, $J_{6-5} = 4$ Hz, 1, H-6), 8.18 (br s, 1, 4-NH), 8.50 (s, 1, H-2); ms calcd. for M^+: 494.1933; found (*m/e*): 494.1925. *Anal.* calcd. for $C_{23}H_{31}ClN_4O_6$: C 55.81, H 6.31, N 11.32; found: C 55.78, H 6.37, N 11.32.

4-Amino-7-(2,3-anhydro-β-D-ribofuranosyl)pyrrolo-[2,3-d]pyrimidine (4)

A 1.2 g (0.0045 mol) sample of **1** was converted to **2** and then to **3***a* + **3***b* as described above without purification of intermediates. The solid glass (**3***a*,*b*) was dissolved in 100 ml of MeOH and a solution of 3 g of NaOMe in 50 ml of MeOH was added. The solution was allowed to stand for 20 h at room temperature and then was neutralized with HOAc and evaporated to dryness. The residue was partitioned between H_2O and Et_2O. The aqueous layer was evaporated to dryness and the residue was stirred with 2 × 125 ml of boiling EtOAc (dry). Insoluble salts were filtered and the filtrate was cooled to 0°C. A brown precipitate which separated upon standing was filtered and discarded. The filtrate was dried over $MgSO_4$ and Na_2SO_4, filtered, and evaporated to give 0.80 g (72% overall from **1**) of crude **4** as an off-white solid. This chromatographically homogeneous (tlc) material was dissolved in dry EtOAc, filtered through Na_2SO_4, and the filtrate was partially evaporated. Crystallization of **4** occurred to give product, mp 167–170°C (dec.); $[\alpha]_D^{24}$ −71.8° (*c* 1, H_2O) during first ~20 min, rising to +1.3° after 3 days; tlc and spectroscopic properties identical to those of a sample prepared by a different procedure (18). *Anal.* calcd. for $C_{11}H_{12}N_4O_3$: C 53.22, H 4.86, N 22.57; found: C 53.50, H 4.82, N 22.87.

4-N-Pivalamido-7-(3-iodo-3-deoxy-5-O-pivalyl-2-O-[4,4-dimethyl-3-pivaloxypent-2-enoyl]-β-D-xylo-furanosyl)pyrrolo[2,3-d]pyrimidine (3c)

To a solution of 644 mg (0.002 mol) of **2** in 40 ml of pyridine was added 6 g (0.04 mol) of NaI and the vigorously stirred solution was heated to reflux. Pivalyl chloride (2.4 ml, 0.02 mol) was added and the mixture was heated at reflux for 4 min, allowed to cool for 20 min, and 10 ml of MeOH was added. The red solution was stirred for ~3 h and poured into 100 ml of H_2O containing 5 g of $NaHCO_3$ and 0.5 g of $Na_2S_2O_3$. The resulting yellow solution was extracted with 100 ml of Et_2O. The ether phase was washed with H_2O and back extracted as indicated by tlc. The combined organic phase was evaporated and the resulting gum was co-evaporated using toluene and then 98% EtOH to give 1.38 g of a yellow solid foam. This material was dissolved in EtOAc and applied to a column (2.2 × 28 cm, 40 g) of activated carbon packed in EtOAc and eluted with $CHCl_3$–EtOAc (1:1). Fractions comprising 100 to 500 ml contained 987 mg (65%) of **3***c* as a white solid foam containing only a trace amount of **5***a* (tlc, silica, 20% pentane – Et_2O). An analytically pure sample of **3***c* was obtained by chromatography of 500 mg of this material on a silica column (2.2 × 31 cm, 52 g) packed in Et_2O–pentane (1:1) and eluted with 275 ml of this mixture followed by 225 ml of 25% pentane – Et_2O. Evaporation of fractions from 350 to 500 ml gave 380 mg of pure **3***c* as a white solid foam, uv (MeOH)λ_{max} 287; 219 (ε 8700; 45 600) shoulder 229 (ε 29 800)λ_{min} 256 (ε 5600), (0.1 *N* HCl)λ_{max} 291; 222 (ε 11 700; 40 300)λ_{min} 263 (ε 9900), (0.1 *N* NaOH)λ_{max} 285–305; 243 (ε 10 600; 29 900) shoulder 232 (ε 27 300)λ_{min} 268 nm (ε 10 000); nmr ($CDCl_3$) δ 1.11 (s, 9, C=C-*tert*-Bu), 1.21 and 1.23 (s and s, 9 and 9, 5′-OPiv and C=COPiv), 1.35 (s, 9, 4-NPiv), 3.88 (m, 1, H-4′), 4.32 (m, 3, H-3′–H-5′′), 5.69 (d of d, $J_{2'-1'} = 3.5$ Hz, $J_{2'-3'} = 2$ Hz, 1, H-2′), 5.74 (s, 1, CH=C), 6.53 (d, $J_{1'-2'} = 3.5$ Hz, 1, H-1′), 7.10 (d, $J_{5-6} = 4$ Hz, 1, H-5), 7.64 (d, $J_{6-5} = 4$ Hz, 1, *H*-6), 8.23 (s, 1, 4-NH), 8.50 (s, 1, H-2); ms calcd. for M^+: 754.2339; found (*m/e*): 754.2376. *Anal.* calcd. for $C_{33}H_{47}IN_4O_8$: C 52.52, H 6.28, I 16.82, N 7.43; found: C 52.45, H 6.40, I 16.98, N 7.37.

A 6 g (0.023 mol) sample of **1** was subjected to the above conditions (**1** → **2** → **3***c*) without purification of **2**. A 62.5% overall yield of pure **3***c* (after chromatography on silica gel) was obtained.

4-N-Pivalamido-7-(3-deoxy-5-O-pivalyl-2-O-[4,4-dimethyl-3-pivaloxypent-2-enoyl]-β-D-glycero-pent-3-enofuranosyl)pyrrolo[2,3-d]pyrimidine (5a)

A 1.51 g (0.002 mol) portion of **3***c* and 1.67 g (0.01 mol) of silver acetate were dissolved in 60 ml of pyridine and stirred in a water bath at 16°C for ~19 h. The resulting dark solution was poured into 120 ml of 5% aqueous $NaHCO_3$. The mixture, containing precipitated silver salts, was extracted with Et_2O and the organic layer was washed with H_2O. The combined organic phase was evaporated and coevaporated using toluene and then 98% EtOH. The residue was dissolved in $CHCl_3$, filtered through Celite, and evaporated to give 1.3 g of a brown solid foam. This material was dissolved in 25% pentane – Et_2O and applied to a silica gel column (2.2 × 46 cm, 75 g) packed in and eluted with the same solvent mixture. Fractions comprising 150 to 270 ml were evaporated to give 1.26 g (quantitative) of **5***a* as a white solid foam, uv (MeOH)λ_{max} 287; 218 (ε 9000; 50 500) shoulder 230 (ε 32 000)λ_{min}254 nm (ε 5200); nmr ($CDCl_3$) δ 1.15 (s, 9, C=C-*tert*-Bu), 1.22 and 1.28 (s and s, 9 and 9, 5′-OPiv and C=COPiv), 1.39 (s, 9, 4-NPiv), 4.70 (s, 2, H-5′, H-5′′), 5.38 (m, 1, H-3′), 5.74 (s, 1, CH=C), 5.94 (m, 1, H-2′), 6.94 (d, $J_{1'-2'} = 2.0$ Hz, 1, H-1′), 7.02 (d, $J_{5-6} = 4.0$ Hz, 1, H-5), 7.12 (d, $J_{6-5} = 4.0$ Hz, 1, H-6), 8.57 (s, 1, 4-NH), 8.89 (s, 1, H-2). *Anal.* calcd. for $C_{33}H_{46}N_4O_8$: C 63.24, H 7.40, N 8.94; found: C 63.26, H 7.60, N 8.84.

4-Amino-7-(3-deoxy-β-D-glycero-pent-3-enofuranosyl)-pyrrolo[2,3-d]pyrimidine (5b)

To 1.26 g (0.002 mol) of **5***a* dissolved in 20 ml of MeOH was added 0.5 g of NaOMe. The reaction was stirred overnight at room temperature and evaporated to dryness. The residue was dissolved in H_2O, applied to a column (1.3 × 16 cm) of Dowex 1-X2(OH^-) resin, and

eluted with 650 ml of H_2O followed by 300 ml of 30% MeOH–H_2O. Evaporation of fractions comprising 300 to 950 ml gave 376 mg (75%) of **5***b*. Crystallization of this material from MeOH (with diffusion of Et_2O) gave 257 mg, mp 196–198°C; $[\alpha]_D^{26}$ −413° (*c* 0.12, H_2O), −457° (*c* 0.98, DMF); uv (MeOH or H_2O)λ_{max} 268 (ε 13 900)-λ_{min} 238 (ε 3100), (0.1 *N* HCl)λ_{max} 270; 226 (ε 12 700; 27 900)λ_{min} 246 (ε 5400), (0.1 *N* NaOH)λ_{max} 268 (ε 13 400) λ_{min} 240 nm (ε 3700); nmr (DMSO-d_6)δ 3.99 (d, $J_{5',5''-OH}$ = 5.5 Hz, 2, H-5′, H-5″), 5.03 (m, 1, H-2′), 5.20 (m, 2, H-3′, 5′-OH), 5.64 (d, $J_{OH-2'}$ = 6 Hz, 1, 2′-OH), 6.45 (d, $J_{1'-2'}$ = 2.5 Hz, 1, H-1′), 6.64 (d, J_{5-6} = 3.5 Hz, H-5), 7.04 (m, 3, 4-NH_2, H-6), 8.07 (s, 1, H-2). *Anal.* calcd. for $C_{11}H_{12}N_4O_3$: C 53.22, H 4.87, N 22.57; found: C 53.43, H 5.05, N 22.46.

*3′-Deoxytubercidin (**8**) and 4-amino-7-(3-deoxy-α-L-threo-pentofuranosyl)pyrrolo[2,3-d]pyrimidine (**9**)*

A 248 mg (0.001 mol) sample of **5***b*, 250 mg of 10% Pd/C, and 50 ml of H_2O–EtOH (1:1) were hydrogenated at 10 psi for 2 h. The mixture was filtered through Celite, the catalyst was washed with 50 ml of H_2O–EtOH (1:1), and the filtrate was evaporated. The residue was dissolved in 30% MeOH–H_2O and applied to a column (2.4 × 95 cm) of Dowex 1-X2(OH^-) resin packed in and eluted with the same solvent mixture. Evaporation of fractions from 2100 to 2900 ml gave 94 mg (38%) of solid. Crystallization of this product from MeOH (with diffusion of Et_2O) gave 80 mg of **8**, mp 182–183°C; $[\alpha]_D^{26}$ −73.4° (*c* 0.93, 95% EtOH); uv (MeOH or 0.1 *N* NaOH)λ_{max} 269 (ε 11 400) λ_{min} 239 (ε 2700), (0.1 *N* HCl)λ_{max} 272; 227 (ε 10 700; 24 000) λ_{min} 246 nm (ε 4300); nmr (DMSO-d_6) δ 1.89 (d of q, $J_{3''-3'}$ = 13 Hz, $J_{3''-2'}$ = 6.5 Hz, $J_{3''-4'}$ = 4 Hz, 1, H-3″) 2.19 ('septet', $J_{3'-3''}$ = 13 Hz, $J_{3'-2'}$ = 8 Hz, $J_{3'-4'}$ = 6 Hz, 1, H-3′), 3.56 (m, 2, H-5′, H-5″), 4.33 (m, 2, H-2′, H-4′), 5.05 (t, $J_{OH-5',5''}$ = 5.5 Hz, 1, 5′-OH), 5.50 (d, $J_{OH-2'}$ = 5.5 Hz, 1, 2′-OH), 6.01 (d, $J_{1'-2'}$ = 3 Hz, 1, H-1′), 6.57 (d, J_{5-6} = 4 Hz, 1, H-5), 6.98 (s, 2, 4-NH_2), 7.32 (d, J_{6-5} = 4 Hz, 1, H-6), 8.09 (s, 1, H-2), (lit. (5) mp 180–181°C; $[\alpha]_D^{27}$ −75.1° (*c* 1, EtOH)). *Anal.* calcd. for $C_{11}H_{14}N_4O_3$: C 52.79, H 5.64, N 22.39; found: C 52.78, H 5.66 N 22.12.

Evaporation of fractions from 4800 to 6300 ml gave 133 mg (58%) of solid. Crystallization of this material from MeOH (with diffusion of Et_2O) gave 102 mg of **9**, mp 191–193°C; $[\alpha]_D^{26}$ −80.0° (*c* 0.73, 95% EtOH); uv (MeOH or 0.1 *N* NaOH) λ_{max} 269 (ε 11 200) λ_{min} 239 (ε 2600), (0.1 *N* HCl) λ_{max} 271; 227 (ε 10 300; 23 500) λ_{min} 246 nm (ε 4200); nmr (DMSO-d_6) δ 1.82 ('quintet', $J_{3''-3'}$ = 13 Hz, $J_{3''-4'}$ = 7 Hz, $J_{3''-2'}$ = 5 Hz, 1, H-3″), 2.34 (m, $J_{3'-4'} = J_{3'-2'}$ = 6 Hz, 1, H-3′), 3.51 ('t', $J_{apparent}$ = 5 Hz, 2, H-5′, H-5″), 4.39 (m, 1, H-4′), 4.66 (m, 1, H-2′), 4.92 (t, $J_{OH-5',5''}$ = 5.5 Hz, 1, 5′-OH), 5.52 (d, $J_{OH-2'}$ = 5.5 Hz, 1, 2′-OH), 6.05 (d, $J_{1'-2'}$ = 4 Hz, 1, H-1′), 6.60 (d, J_{5-6} = 4 Hz, 1, H-5), 6.97 (s, 2, 4-NH_2), 7.14 (d, J_{6-5} = 4 Hz, 1, H-6), 8.90 (s, 1, H-2). *Anal.* calcd. for $C_{11}H_{14}N_4O_3$: C 52.79, H 5.64, N 22.39; found: C 52.78, H 5.37, N 22.09.

*3′-Deoxytubercidin (**8**)*

Method A

To 0.47 g (0.00095 mol) of **3***a* dissolved in 25 ml of benzene was added 30 mg of α-α′-azobisisobutyronitrile and 1.5 ml of tri-*n*-butyltin hydride. The mixture was heated for 1.5 h at reflux, evaporated, and the residue was triturated with 2 × 15 ml of pentane. The pentane washes were discarded and 40 ml of 2.5% NaOMe–MeOH solution was added to the residue. The mixture was stirred for 20 h at room temperature, evaporated, and the residue was dissolved in H_2O and applied to a column (2.3 × 43 cm) of Dowex 1-X2(OH^-) resin packed in H_2O. The column was developed with 400 ml of H_2O followed by 15% MeOH–H_2O. The appropriate fractions (15% MeOH–H_2O) were evaporated and the residue was crystallized from EtOAc to give 0.12 g (51%) of **8**, mp 176–179°C. This product was identical to that prepared above (**5***b* → **8** + **9**) by tlc, uv, nmr, and ms. *Anal.* calcd. for $C_{11}H_{14}N_4O_3$: C 52.79, H 5.64, N 22.39; found: C 52.64, H 5.58, N 22.40.

Method B

A mixture of 2.8 g (0.0037 mol) of **3***c*, 3 g (0.036 mol) of $NaHCO_3$, 3 g of 5% Pd/C, and 130 ml of EtOH–H_2O (10:3) was hydrogenated at 50 psi until hydrogen uptake ceased. The mixture was filtered and the catalyst was washed with EtOH. The combined filtrate was evaporated, H_2O and Et_2O were added, and the mixture was stirred until all solids dissolved. The ether layer was separated, dried over Na_2SO_4, filtered, and the filtrate was evaporated to give 2.03 g (87%) of 4-*N*-pivalamido-7-(3-deoxy-5-*O*-pivalyl-2-*O*-[4,4-dimethyl-3-pivaloxypent-2-enoyl]-β-D-*erythro*-pentofuranosyl)pyrrolo[2,3-*d*]pyrimidine as a colorless solid foam, uv (MeOH) λ_{max} 289 (ε 7100) shoulder 230 nm (ε 24 000); nmr ($CDCl_3$) δ 1.12 (s, 9, C═C-*tert*-Bu), 1.21 and 1.26 (s and s, 9 and 9, 5′-OPiv and C═COPiv), 1.36 (s, 9, 4-NPiv), 2.28 (br m, 2, H-3′, H-3″), 4.28 (m, 2, H-5′, H-5″), 4.54 (m, 1, H-4′), 5.50 (sextet, 1, H-2′), 5.73 (s, 1, CH═C), 6.37 (d, $J_{1'-2'}$ = 2.2 Hz, 1, H-1′), 7.16 (d of d, J_{5-6} ~ 4 Hz, 2, H-5, H-6), 8.26 (s, 1, 4-NH), 8.51 (s, 1, H-2); ms (M^+ = 628) analogous to that of the adenosine analog (**9**) (with B-containing (*m/e* 133) peaks at 1-amu lower than with B = adeninyl (*m/e* 134)).

The above solid glass and 2 g of NaOMe were dissolved in 200 ml of MeOH, stirred for 12 h at room temperature, and evaporated to dryness. The residue was treated with 120 ml of H_2O, neutralized with IRC-50(H^+) resin, and extracted with Et_2O. The aqueous layer was evaporated and the residue was refluxed with 2 × 200 ml of dry EtOAc. The insoluble residue was filtered and the combined filtrate was evaporated to yield **8** as a tan solid. This material was recrystallized from EtOAc to give 0.73 g (79% overall from **3***c*) of **8**; mp 178–180°C; $[\alpha]_D^{24}$ −77.5° (*c* 1, H_2O); spectral and tlc properties were identical to those of the sample prepared by method A. *Anal.* found: C 52.73, H 5.50, N 22.09.

*4-N-Pivalamido-7-(3-iodo-3-deoxy-5-O-pivalyl-β-D-xylofuranosyl)pyrrolo[2,3-d]pyrimidine (**3***d*)*

To a cooled (−5°C), stirred solution of 4.03 g (0.0053 mol) of **3***c* in 140 ml of pyridine–H_2O (5:2) was added 4 g (0.025 mol) of $KMnO_4$. After 90 min the reaction mixture was allowed to warm to 0°C, and 40 ml of 95% EtOH was added. After stirring overnight, the MnO_2 was filtered using a Celite pad and the filter cake was washed with EtOH. The combined filtrate was evaporated to give a brown residue which was stirred with Et_2O and H_2O. The organic layer was separated and washed with H_2O. The combined aqueous layers were extracted with Et_2O. The combined organic phase was evaporated and the

residue was dissolved in Et_2O and applied to a silica column (2.2 × 44 cm, 50 g) packed in and eluted with Et_2O. Fractions (50 ml) 3–8 were evaporated and the resulting colorless solid foam was dried at 0.1 torr to give 2.08 g (72%) of **3***d*. A 100 mg sample of this material was dissolved in 1 ml of Et_2O and 0.8 ml of pentane was added. The supernatant was decanted from the oily product which was washed with 2 ml of pentane and then dried over Paraffin to give a colorless solid foam; uv (MeOH) λ_{max} 285; 218 (ε 8500; 33 600) shoulder 230 (ε 19 600) λ_{min} 253 nm (ε 4400); nmr ($CDCl_3$) δ 1.08 (s, 9, 5′-OPiv), 1.36 (s, 9, 4-NPiv), 4.42 (m, 4, H-3′–H-5′′), 4.88 (m, 1, H-2′), 6.00 (d, $J_{1'-2'} \sim 5$ Hz, 1, H-1′), 7.04 (d, $J_{5-6} \sim 4$ Hz, 1, H-5), 7.42 (d, $J_{6-5} \sim 4$ Hz, 1, H-6), 8.18 (br, 1, 4-NH), 8.24 (s, 1, H-2); ms calcd. for M^+: 544.1283; found (*m*/*e*): 544.1255. *Anal.* calcd. for $C_{21}H_{29}IN_4O_5$: C 46.37, H 5.37, N 10.30; found: C 46.56, H 5.28, N 10.20.

*4-Amino-7-(2,3-dideoxy-β-D-glycero-pent-2-enofuranosyl)pyrrolo[2,3-d]pyrimidine (**6**)*

To an ice-cold solution of 1.09 g (0.002 mol) of **3***d* in 5 ml of pyridine was added 1 ml (0.013 mol) of mesyl chloride and the solution was stirred for 1 h at 0°C. A solution of 1.8 g (0.0045 mol) of NaOH and 1.5 g (0.01 mol) of NaI in 25 ml of ice-cold water was added and stirring was continued for 1 h at 0°C and then at room temperature for 16 h. The red-brown mixture was evaporated and the residue (in ~30 ml of H_2O) was applied to a column (3 × 83 cm) of Dowex 1-X8(OH^-) packed in H_2O. The column was developed with 1400 ml of H_2O, 100 ml of 5%, 1250 ml of 10%, 320 ml of 20%, 3 ℓ of 30%, and 700 ml of 40% MeOH–H_2O. Evaporation of the appropriate fractions (30% MeOH) gave 257 mg (55%) of a colorless product, mp 202–203°C. Recrystallization of a sample of this solid from MeOH–Et_2O followed by drying at 60°C/0.1 torr gave colorless needles of **6**, mp 206–208°C; $[\alpha]_D^{23}$ −27.3° (*c* 0.8, MeOH); uv (p*H* 1) λ_{max} 271; 226 (ε 11 400; 24 600) λ_{min} 243 (ε 3400), (p*H* 7) λ_{max} 269 (ε 11 400) λ_{min} 238 nm (ε 3000); nmr (DMSO-d_6) δ 3.54 (m, 2, H-5′, H-5′′), 4.79 (m, 1, H-4′), 4.95 ('t', $J_{OH-5',5''} = 5.5$ Hz, 1, 5′-OH), 6.01 (d of d of d, $J_{3'-2'} \sim 6$ Hz, $J_{3'-4'} \sim 2$ Hz, $J_{3'-1'} \sim 1.5$ Hz, 1, H-3′), 6.44 (d of d of d, $J_{2'-3'} \sim 6$ Hz, $J_{2'-1'} \sim 2$ Hz, $J_{2'-4'} \sim 1.5$ Hz, 1, H-2′), 6.56 (d, $J_{5-6} = 4$ Hz, 1, H-5), 6.96 (s, 2, 4-NH_2), 7.10 (m, overlapped with H-6, decoupling shows $J_{1'-2'} \sim 2$ Hz, $J_{1'-3'} \sim 1.5$ Hz, 1, H-1′), 7.17 (d, $J_{6-5} = 4$ Hz, 1, H-6), 8.06 (s, 1, H-2); ms calcd. for M^+: 232.0960; found (*m*/*e*): 232.0967. *Anal.* calcd. for $C_{11}H_{12}N_4O_2$: C 56.89, H 5.21, N 24.13; found: C 56.76, H 5.21, N 23.87.

*4-N-Pivalamido-7-(5-pivaloxymethylfuran-2-yl)pyrrolo-[2,3-d]pyrimidine (**10***a*)*

A 626 mg (0.001 mol) sample of **5***a* was heated in an oil bath at 180°C for 2 min. The residue was cooled, dissolved in $CHCl_3$, and evaporated to a yellow powder. Ether (15 ml) was added and the mixture was filtered to give a first crop of 130 mg of **10***a*. Concentration of the mother liquors gave an additional 150 mg (in three crops) for a total yield of 280 mg (71%) of small white crystals of **10***a*, mp 159–160°C; uv (MeOH λ_{max} 262; 218 (ε 28 600; 24 300) shoulder 290 (ε 8400) λ_{min} 233 (ε 12 700), (0.1 *N* NaOH) shoulders 280; 248 (ε 15 400; 20 000), (0.1 *N* HCl) λ_{max} 286; 235 (ε 24 900; 17 500) shoulder 265 (ε 21 300), λ_{min} 245; 220 nm (ε 15 400; 15 400); nmr ($CDCl_3$) δ 1.16 (s, 9, 5′-OPiv), 1.33 (s, 9, 4-NPiv), 5.03 (s, 2, H-5′, H-5′′), 6.49 (d, $J_{3'-2'} = 3$ Hz, 1, H-3′), 6.68 (d, $J_{2'-3'} = 3$ Hz, 1, H-2′), 7.14 (d, $J_{5-6} = 4$ Hz, 1, H-5), 7.50 (d, $J_{6-5} = 4$ Hz, 1, H-6), 8.20 (br, 1, 4-NH), 8.56 (s, 1, H-2). *Anal.* calcd. for $C_{12}H_{26}N_4O_4$: C 63.30, H 6.58, N 14.06; found: C 63.37, H 6.87, N 13.92.

*4-N-Pivalamido-7-(5-methylfuran-2-yl)pyrrolo[2,3-d]-pyrimidine (**10***b*)*

A 100 mg (0.00025 mol) sample of **10***a*, 84 mg (0.001 mol) of $NaHCO_3$, 100 mg of 5% Pd/C, and 50 ml of H_2O–EtOH (1:4) were hydrogenated at 3 psi for 3 min. The mixture was filtered through Celite and the catalyst was washed with MeOH and then $CHCl_3$. After evaporation of the combined filtrate, the residue was partitioned between H_2O and $CHCl_3$. The water layer was extracted with $CHCl_3$ and the combined organic phase was evaporated to give 81 mg of a yellow gum. This gum was dissolved in Et_2O and applied to a silica column (1.3 × 20 cm, 10 g), packed in, and eluted with Et_2O. Upon evaporation of the fractions comprising 20 to 50 ml, 61 mg (82%) of **10***b* crystallized, mp 127–128°C; uv (MeOH) λ_{max} 262; 217 (ε 22 800; 28 100) shoulder 295 (ε 7400) λ_{min} 238 nm (ε 13 200); nmr ($CDCl_3$) δ 1.38 (s, 9, 4-NPiv), 2.33 (d, $J_{CH_3-3'} = 1$ Hz, 3, 5′-CH_3), 6.07 (d of q, $J_{3'-CH_3} = 1$ Hz, $J_{3'-2'} = 3$ Hz, 1, H-3′), 6.49 (d, $J_{2'-3'} = 3$ Hz, 1, H-2′), 7.11 (d, $J_{5-6} = 4$ Hz, 1, H-5), 7.41 (d, $J_{6-5} = 4$ Hz, 1, H-6), 8.30 (br, 1, 4-NH), 8.56 (s, 1, H-2). *Anal.* calcd. for $C_{16}H_{18}N_4O_2$: C 64.41, H 6.08, N 18.78; found: C 64.66, H 6.21, N 18.82.

*4-Amino-7-(5-methylfuran-2-yl)pyrrolo[2,3-d]pyrimidine (**10***c*)*

A 150 mg (0.0005 mol) sample of **10***b* was dissolved in 100 ml of MeOH–Et_3N–H_2O (45:10:45) and stirred at room temperature for 2 days. The solution was evaporated to dryness and the residue crystallized from 5 ml of MeOH (with diffusion of Et_2O) to give a first crop of 66 mg of **10***c*. The mother liquors were evaporated to dryness and the residue dissolved in 3% MeOH–$CHCl_3$ and applied to a column of silica gel (0.8 × 16 cm, 3 g) packed in and eluted with the same solvent mixture. Upon evaporation of the fractions comprising 10 to 30 ml, 36 mg of **10***c* crystallized, for a total yield of 102 mg (94%), mp 127–130°C; uv (MeOH) λ_{max} 248 (ε 25 000) shoulder 285 (ε 9400) λ_{min} 223 (ε 16 200), (0.1 *N* HCl) λ_{max} 253; 221 (ε 23 000; 15 100) λ_{min} 232 (ε 13 300), (0.1 *N* NaOH) λ_{max} 246 (ε 20 900) shoulders 232; 280 nm (ε 16 800; 10 300); nmr (DMSO-d_6) δ 2.26 (d, $J_{CH_3-3'} = 1$ Hz, 3, 5′-CH_3), 6.18 (d of q, $J_{3'-CH_3} = 1$ Hz, $J_{3'-2'} = 3$ Hz, 1, H-3′), 6.43 (d, $J_{2'-3'} = 3$ Hz, 1, H-2′), 6.73 (d, $J_{5-6} = 4$ Hz, 1, H-5), 7.17 (br, 2, 4-NH_2), 7.54 (d, $J_{6-5} = 4$ Hz, 1, H-6), 8.11 (s, 1, H-2), 1.07 (t, $J = 7$ Hz, 0.75, OCH_2CH_3), 2.94 (q, $J = 7$ Hz, 0.5, OCH_2CH_3). *Anal.* calcd. for $C_{11}H_{10}N_4O \cdot \frac{1}{4}Et_2O$: C 61.92, H 5.41, N 24.07; found: C 61.80, H 5.44, N 24.12.

*4-Amino-7-(5-hydroxymethylfuran-2-yl)pyrrolo[2,3-d]-pyrimidine (**10***d*)*

To 796 mg (0.002 mol) of **10***a* dissolved in 20 ml of MeOH was added 250 mg of NaOMe. The mixture was stirred at room temperature for 18 h and evaporated to dryness. The residue was stirred with 15 ml of H_2O and filtered. The filter cake was washed with H_2O until the

filtrate was neutral (~15 ml) and then was crystallized from MeOH and Et_2O to give 426 mg (93%) of **10***d* in two crops, mp 178–180°C; uv (MeOH) λ_{max} 249 (ε 28 500) shoulder 285 (ε 10 300) λ_{min} 223 nm (ε 15 700); nmr (DMSO-d_6) δ 4.40 (s, 2, H-5′, H-5″), 5.25 (br, 1, 5′-OH), 6.42 (d, $J_{3'-2'}$ = 3.5 Hz, 1, H-3′), 6.54 (d, $J_{2'-3'}$ = 3.5 Hz, 1, H-2′), 6.77 (d, J_{5-6} = 4 Hz, 1, H-5), 7.17 (s, 2, 4-NH_2), 7.40 (d, J_{6-5} = 4 Hz, 1, H-6), 8.16 (s, 1, H-2). *Anal.* calcd. for $C_{11}H_{10}N_4O_2$: C 57.38, H 4.38, N 24.34; found: C 57.11, H 4.26, N 24.28.

4-Amino-7-(2,3-dideoxy-β-D,L-glycero-pentofuranosyl)-pyrrolo[2,3-d]pyrimidine (7,11)

A mixture of 230 mg (0.001 mol) of **10***d*, 250 mg (0.003 mol) of $NaHCO_3$, 460 mg of 10% Pd/C, and 50 ml of H_2O–MeOH (1:4) was hydrogenated at 60 psi for 16 h. The mixture was filtered through Celite and the catalyst was washed with MeOH. The filtrate was evaporated to dryness, dissolved in H_2O, and applied to a column (1.3 × 43 cm) of Dowex 1-X2(OH^-) resin packed in H_2O and eluted with 60 ml of H_2O followed by 90 ml of 30% MeOH–H_2O. Evaporation of fractions from 40 to 140 ml gave 181 mg (77%) of **7,11**. Crystallization of this racemate from MeOH (with diffusion of Et_2O) gave 90 mg of fine crystals, mp 70–73°C; uv (MeOH or 0.1 *N* NaOH) λ_{max} 270 (ε 11 400) λ_{min} 240 (ε 2700), (0.1 *N* HCl) λ_{max} 272; 227 (ε 10 600; 24 000) λ_{min} 246 nm (ε 4100); nmr (DMSO-d_6) δ 2.03 (m, 2, H-3′, H-3″), 2.26 (m, 2, H-2′, H-2″), 3.52 (m, 2, H-5′, H-5″), 4.04 (m, 1, H-4′), 4.96 (m, 1, 5′-OH), 6.33 ('t', $J_{apparent}$ = 6 Hz, 1, H-1′), 6.56 (d, J_{5-6} = 3.5 Hz, 1, H-5), 6.95 (s, 2, 4-NH_2), 7.32 (d, J_{6-5} = 3.5 Hz, 1, H-6), 8.05 (s, 1, H-2). *Anal.* calcd. for $C_{11}H_{14}N_4O_2$: C 56.40, H 6.02, N 23.92; found: C 56.22, H 6.10, N 23.71.

The nmr spectrum reported (6) for **7** is in agreement with that of this racemate. Treatment of a small sample of this racemate with tosyl chloride in pyridine followed by heating the isolated tosylate in acetone to effect cyclonucleoside formation (14) proceeded quantitatively (tlc) and gave a product having uv (H_2O) λ_{max} 293, shoulder 273 nm (3).

2′,3′-Dideoxytubercidin (7)

To a solution of 165 mg (0.71 mmol) of **6** and 180 mg of $NaHCO_3$ in 30 ml of EtOH–H_2O (1:1) was added 400 mg of 5% Pd/C and the mixture was hydrogenated at 40 psi for 24 h. The mixture was filtered using a Celite pad and the filter cake was washed with EtOH. The filtrate was evaporated and the residue was dissolved in H_2O and applied to a column (2.3 × 15 cm) of Dowex 1-X2(OH^-) resin packed in H_2O. The column was eluted with 300 ml of H_2O followed by 15% MeOH–H_2O. The appropriate fractions (15% MeOH) were pooled and evaporated. The residue resisted crystallization and was dissolved in H_2O and freeze-dried. The amorphous solid was dried over P_2O_5 at room temperature/0.1 torr for 2 days to give 115 mg (69%) of **7**, $[\alpha]_D^{23}$ −35.6° (*c* 0.28, MeOH); uv and ^1H nmr spectral properties were the same as for the above **7,11** racemate. *Anal.* calcd. for $C_{11}H_{14}N_4O_2$: C 56.40, H 6.02, N 23.92; found: C 56.11, H 6.01, N 23.94.

Treatment of the *trans* iodohydrin acetate, 4-amino-7-(3-iodo-3-deoxy-2-*O*-acetyl-5-*O*-[2,5,5-trimethyl-1,3-dioxolan-4-on-2-yl]-β-D-xylofuranosyl)pyrrolo[2,3-*d*]pyrimidine (**2**) with methanolic ammonia gave 2′,3′-anhydrotubercidin (**3**) in 96% yield. N^4,N^4,$O^{5'}$-Tribenzoylation of **3** gave **4**, which is stabilized against intramolecular cyclization. Treatment of **4** with boron trifluoride etherate (3′,5′-benzoxonium ion formation) followed by deblocking gave 4-amino-7-β-D-xylofuranosylpyrrolo[2,3-*d*]pyrimidine (**5**) in 91% overall yield from tubercidin (**1**). The 3′,5′-*O*-isopropylidene derivative (**6***a*) of **5** was mesylated to give **6***b* which was deprotected in acid and the resulting *trans* hydroxy mesylate was treated with base to give 4-amino-7-(2,3-anhydro-β-D-lyxofuranosyl)pyrrolo[2,3-*d*]pyrimidine (**7**). This *lyxo* epoxide was treated with sodium benzoate in DMF to give 4-amino-7-β-D-arabinofuranosylpyrrolo[2,3-*d*]pyrimidine (**8**). Biochemical, spectroscopic, and chemical properties of these semisynthetic antibiotic analogues of biologically active adenine nucleosides are discussed.

MORRIS J. ROBINS, YVES FOURON et WOLFGANG H. MUHS. Can. J. Chem. **55**, 1260 (1977).

Par traitement de l'acétate de *trans* iodohydrine, amino-4 (iodo-3 deoxy-3 *O*-acétyl-2-*O* [triméthyl-2,5,5 dioxolan-1,3 on-4 yl-2]-5 β-D-xylofuranosyl)-7 pyrrolo[2,3-*d*]pyrimidine (**2**) avec de l'ammoniac méthanolique on obtient, avec un rendement de 96%, l'anhydro-2′,3′ tubercidine (**3**). Par tribenzoylation en N^4,N^4,$O^{5'}$, **3** conduit à **4** qui est ainsi stabilisé contre une cyclisation intramoléculaire. Par traitement de **4** avec l'éthérate de trifluorure de bore (formation de l'ion benzoxonium-3′,5′), suivit du déblocage, on obtient l'amino-4 β-D-xylofuranosyl-7 pyrrolo[2,3-*d*]pyrimidine (**5**) avec un rendement global, à partir de la tubercidine (**1**), de 91%. Le dérivé *O*-isopropylidène-3′,5′ (**6***a*) de **5** est mésylé et donne **6***b* qui est déprotégé en milieu acide. Le *trans* hydroxy mésylate résultant, par traitement basique, donne l'amino-4 (anhydro-2,3 β-D-lyxofuranosyl)-7 pyrrolo[2,3-*d*]pyrimidine (**7**). Cet époxyde *lyxo* fournit l'amino-4 β-D-arabinofuranosyl-7 pyrrolo[2,3-*d*]pyrimidine (**8**) sous l'action du benzoate de sodium dans la DMF. Les propriétés biochimiques, spectroscopiques, et chimiques de ces analogues semi-synthétiques de nucléosides à activité biologique de l'adénine sont discutées.

Tubercidin (4-amino-7-β-D-ribofuranosylpyrrolo[2,3-*d*]pyrimidine) (**1**), the 7-deaza analog of adenosine, is closely related to adenosine chemically as well as structurally. This antibiotic is also found to act as a substrate for many enzymes involved with biosynthetic reactions of adenosine and phosphorylated adenosine biomolecules. Two significant exceptions are the complete resistance of **1** to deamination by adenosine deaminase, and to phosphorolytic cleavage of the glycosyl bond. An excellent review covers both chemical and biological aspects (1). Since deamination and phosphorolysis of the sugar–base bond represent major catabolic degradation (inactivation) modes for adenosine and most biologically active derivatives, the corresponding tubercidin products represent significant 'rational drug design' targets. The well established sugar–base coupling methods have been used extensively in syntheses of modified sugar analogs of adenosine (2), and this approach was successfully employed using ribose in syntheses of the naturally occurring pyrrolo[2,3-*d*]pyrimidine antibiotics (3). However, the lack of 'correct' stereospecificity in coupling reactions with certain diastereomeric sugar derivatives (see, for example, ref. 4) and the extensive heterocyclic transformations involved before and after coupling in the total synthesis routes (3) make this approach rather uninviting for preparation of arabinosyl and xylosyl sugar analogs; which probably accounts for the previous absence of their synthesis and biological evaluation. We now wish to describe their syntheses using acyloxonium ion mediated transformations of preformed nucleosides (5, 6).

[1]Abstracted in part from the Ph.D. dissertation of Y. Fouron, The University of Alberta, spring, 1975.

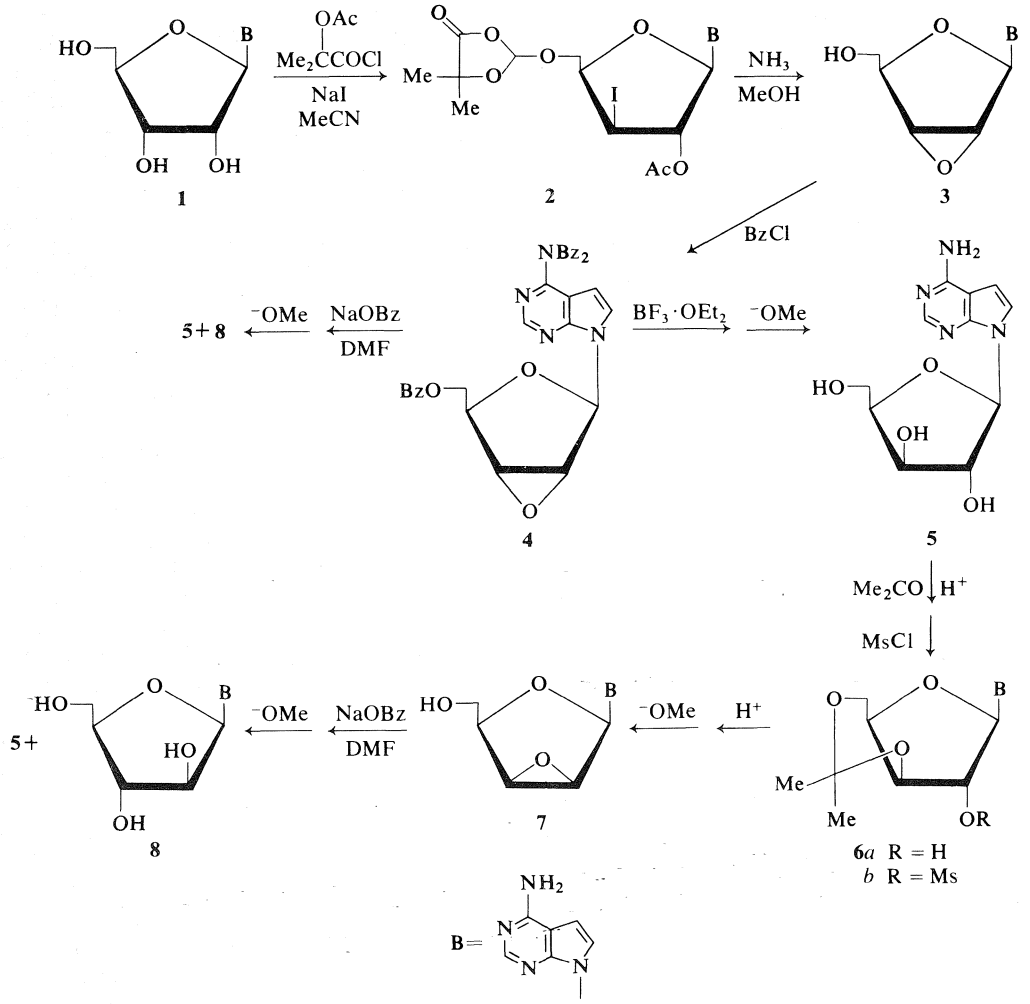


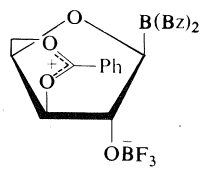
SCHEME 1

Although treatment of the crude mixture of 4-*N*-pivalamido-7-(3-chloro-3-deoxy-2-*O*-acetyl-5-*O*-pivalyl-β-D-xylofuranosyl)pyrrolo[2,3-*d*]-pyrimidine and its 2′-*O*-(4,4-dimethyl-3-pivaloxypent-2-enoyl) derivative (5*g*) with methanolic sodium methoxide gave 2′,3′-anhydrotubercidin (**3**); yields (maximum 72%) were variable and significant degradation via N-1→C-3′ intramolecular cyclization (5*d*,*g*) frequently occurred. It was found to be more experimentally convenient and economical to use the iodo product **2**, obtained by treatment of tubercidin (**1**) with α-acetoxyisobutyryl chloride and excess sodium iodide (5*b*). This is in contrast with reactions involving *adenosine* in which the orthoester/pivalyl chloride route proceeds smoothly (5*d*) and avoids problems of incomplete reaction, multiple acylation, and significant glycosyl bond cleavage noted with the Mattocks–Moffatt procedure (6, 7).

In situ generation of α-acetoxyisobutyryl iodide in acetonitrile provided smooth reaction with **1** at room temperature to give 4-amino-7-(3-iodo-3-deoxy-2-*O*-acetyl-5-*O*-[2,5,5-trimethyldioxolan-4-on-2-yl]-β-D-xylofuranosyl)-pyrrolo[2,3-*d*]pyrimidine (**2**) in quantitative yield (5*b*) (see Scheme 1). Treatment of the amorphous product (**2**) with methanolic ammonia at room temperature gave the *ribo*-epoxide (**3**) in 96% yield after column chromatographic purification. Deblocking of **2** occurred in methanolic ammonia at −20°C to give crystalline 4-amino-7-

(3-iodo-3-deoxy-β-D-xylofuranosyl)pyrrolo-[2,3-*d*]pyrimidine (66%).

Benzoylation of **3** produced the stable (5*d*) and readily crystallized tribenzoyl derivative (presumably (8) dibenzimide **4**) quantitatively (89% crystalline). Treatment of **4** with sodium benzoate in hot moist *N*,*N*-dimethylformamide (DMF) (9) followed by deblocking gave 4-amino-7-β-D-xylofuranosylpyrrolo[2,3-*d*]pyrimidine (xyloTb) (**5**) in 68% crystalline yield after purification on the Dekker anion exchange column (10). Unexpectedly, elution of the column with 70% methanol–water gave 6.8% of the arabino isomer, **8**. Although a minor amount of 9-β-D-arabinofuranosyladenine is produced in the parallel reaction with 2′,3′-anhydroadenosine (11), no nucleophilic reactions at C-2′ of tubercidin have been observed previously (5*a*,*b*,*g*, 12), and only very recently has an intramolecular participation route provided access to the elusive 2′-deoxytubercidin (13). Treatment of **4** with boron trifluoride etherate in acetonitrile gave a benzoate ester, presumably via the 3′,5′-benzoxonium ion species (**i**) (14), which was deblocked with methanolic sodium methoxide to give **5**, exclusively, in 95% yield (91% overall from **1**).



i

It had been reported (15) that the *arabino* and *xylo* diastereomers of adenosine were incompletely resolved on the Dekker column. Two mixtures of araA and xyloA with ratios of 1:11 and 11:1 were prepared and subjected to the ion exchange conditions used to separate **5** and **8**. In both cases, the isomers were resolved cleanly and completely as indicated by the uv absorption profiles and quantitative recovery of electrophoretically homogeneous (*vide infra*) products upon evaporation of appropriately pooled fractions (11). Acid-catalyzed hydrolysis of these separated nucleosides and paper chromatographic analysis (16) of the aldopentose sugars released, corroborated the complete separation efficiency (11).

Blocking of **5** with acetone and 2,2-dimethoxypropane gave **6***a* quantitatively and this crystalline 3′,5′-*O*-isopropylidene derivative was mesylated to give amorphous **6***b*. Deketalization of **6***b* proceeded smoothly in 90% trifluoroacetic acid – water (17) and the resulting *trans* hydroxy mesylate was cyclized in methanolic sodium methoxide to give 4-amino-7-(2,3-anhydro-β-D-lyxofuranosyl)pyrrolo[2,3-*d*]pyrimidine (**7**) in 82% yield. Treatment of the *lyxo*-epoxide (**7**) with sodium benzoate – DMF followed by deblocking gave crystalline 4-amino-7-β-D-arabinofuranosylpyrrolo[2,3-*d*]pyrimidine (araTb) (**8**) in 73% yield plus 4.5% of xyloTb (**5**). It is interesting to note that comparable yields of the minor products are formed presumably by nucleophilic attack of benzoate at C-2′ of the *ribo* (**4**→**8**) and *lyxo* (**7**→**5**) epoxides. The base at C-1′ of **4** is *cis* to the incoming benzoate nucleophile whereas *trans* (base to benzoate) attack occurs with **7**. In contrast, presumed nucleophilic attack on a *lyxo* 2′,3′-thiiranium ion species (episulfonium ion) gave a ratio of ~3:2 for C-3′ to C-2′ substitution by benzoate (13). A complex balance of steric (short C-1′—N-7 glycosyl bond) (see ref. 18*a* and, for a comparison of glycosyl bond lengths, ref. 18*b*), electronic (including extent of bond formation *vs.* breaking) (19) and hydrophobic factors apparently control the normally prohibited nucleophilic attack at C-2′ of tubercidin derivatives (5*a*,*b*,*g*, 12).

The structures indicated in these transformations are compatible with uv, nmr, and mass spectral data as well as elemental analyses. As noted previously (5*d*, 6, 12), there is no observed coupling of H-1′ and H-2′ in the *ribo*-epoxides of adenosine or tubercidin. However, it is noteworthy to point out that there is also no observed coupling of H-1′ and H-2′ in the *lyxo*-epoxides of adenosine (5*d*) or tubercidin (see Experimental section). It has been generally assumed that a coupling constant of less than 1 Hz was diagnostic for a *trans* orientation of H-1′ and H-2′ in a furanosyl nucleoside (20). Compound **7** and the analogous adenosine series product (5*d*) clearly violate this empirical expectation. An X-ray crystallographic study of these diastereomeric epoxide products would be of interest.

The nmr and mass spectroscopic patterns of **5** and **8** (see Experimental section) are closely analogous to those of the corresponding 9-β-D-xylofuranosyl- and arabinofuranosyladenine nucleosides (21–23) and are individually unique from those of the ribofuranosyl products. As well, **5** and **8** do not react detectably in 5 h with

sodium periodate solution (24) (whereas the *cis* diol **1** cleaves completely within 20 min under identical conditions). Paper electrophoresis of **5** in a borate buffer at p*H* 9 shows migration toward the anode comparable to that of **1**, whereas borate addition has a much smaller effect on the migration of **8** (*i.e.* formation of a 3′,5′-*O*-borate complex with **5** is comparable to that of the 2′,3′-*O*-borate complex of **1**). Paper chromatographic (25) mobilities of the adenosine and tubercidin compounds are also parallel (see Table 1).

The synthesis (9, 26) and biological inhibitory activity (27, 28) of 9-β-D-arabinofuranosyladenine (araA) were reported several years before its isolation from microbiological culture fermentation (29) and evaluation as a promising antiviral drug (30). Synthetic 9-β-D-xylofuranosyladenine (xyloA) (4*b*, 31) was also shown to exhibit inhibitory activity against neoplastic cells (32). However, both araA and xyloA are rapidly converted to the corresponding 6-oxo (hypoxanthine) analogs by adenosine deaminase (33–35), an enzyme with high activity in both mammalian blood and intestinal loci. The incorporation of radioactivity into inosine monophosphate (IMP) and ribonucleic acid (RNA) after treatment with purine-labeled araA has subsequently been shown to result from enzymatic deamination, glycosyl bond cleavage (presumably phosphorolysis), and effective reutilization of the purine moiety as 'salvaged' ribonucleotides (34, 35). The absence of substrate activity of tubercidin with adenosine deaminase and glycosyl phosphorolysis enzymes (1) renders the presumably degradation resistant araTb (**8**) and xyloTb (**5**) compounds of heightened biochemical and biological interest. As anticipated, even high levels of adenosine deaminase had no effect on **5** or **8** as indicated by uv spectroscopy.

TABLE 1. Paper chromatography and electrophoresis of isomeric nucleosides

Compound	Paper chromatography[a] (R_{araA} or R^{*}_{araTb})[b]	Electrophoretic mobility[c] Distance (mm) migrated toward anode
riboA	0.86	80
araA	1.0	0
xyloA	0.86	75
riboTb (**1**)	0.67	97
araTb (**8**)	1.0	32
xyloTb (**5**)	0.90	85

[a]Descending on the same sheet of Whatman No. 1 paper using 60 ml of (1 *M* NH_4OAc containing 0.01 *M* EDTA disodium salt adjusted to p*H* 9 with NH_4OH and saturated with sodium tetraborate) mixed with 140 ml of 90% EtOH. The mixture was allowed to stand for 1 h and was then filtered before use (25).

[b]$R_{arabino} = R_{F(compound)}/R_{F(arabino)}$

[c]Performed on a Savant flatplate apparatus (HV-3000A) using Whatman No. 1 paper and 0.1 *M* sodium borate at p*H* 9 at 1.5 KV (27 V/cm) 30–35 mA, 90 min.

The present study demonstrates that transformations of naturally occurring nucleoside antibiotics into epoxide sugar products can be effected in high yields on a practically convenient scale. Application of benzoate nucleophilic displacement or boron trifluoride induced acyloxonium participation on 2′,3′-anhydro (epoxide) nucleosides provides configurationally inverted antibiotic structures. Such *arabino* and *xylo* diastereomers, even in the purine series, were available prior to our work (5*d*) only through base–sugar coupling sequences (4*b*,*c*, 9, 23, 26, 31, 36). Successful application of these acyloxonium ion–nucleophilic displacement procedures to other commonly occurring nucleosides[4] (14*b*, 37) and results of biological and biochemical investigations will be reported separately.

Experimental

General methods are described in detail in ref. 5*g*. J. T. Baker 3405 silica gel was used for column chromatography. All nmr spectra were determined in Me_2SO-d_6 with Me_4Si internal standard. See refs. 5*e*,*g*, and 38 for descriptions of 'diffusion crystallization'. Tubercidin was purchased from the Upjohn Company, Kalamazoo, Michigan. Adenosine deaminase (Grade II) was purchased from Sigma Chemical Company, St. Louis, MO.

*4-Amino-7-(3-iodo-3-deoxy-*β*-D-xylofuranosyl)pyrrolo[2,3-d]pyrimidine*

A 0.54 g (0.001 mol) sample of **2** (5*b*) was dissolved in 100 ml of MeOH presaturated with NH_3 at −20°C and allowed to stand at that temperature for 3 h. Ammonia was evaporated *in vacuo* at −20°C and 2 g of silica gel was added to the solution. The mixture was evaporated to dryness and the impregnated powder was added to a column (2 × 26 cm, 40 g) of silica. The column was washed with $CHCl_3$ and the wash discarded. The product was eluted using $CHCl_3$–MeOH (98:2). Evaporation of appropriate fractions gave 0.25 g (66%) of the title compound as a white powder. A sample for analysis was recrystallized from 95% EtOH (with diffusion of Et_2O) and had mp 175–176°C; $[\alpha]_D^{24}$ −5° (*c* 0.6, DMF); uv (0.1 *N* HCl) λ_{max} 265; 225 (ε 11 300; 22 200) λ_{min} 245 (ε 5250), (H_2O) λ_{max} 268 (ε 12 300) λ_{min} 238 (ε 3200), (0.1 *N* NaOH) λ_{max} 268 (ε 11 700) λ_{min} 242 nm (ε 6000); nmr δ 3.70 (br, s, 2, H-5′, H-5″), 3.90 (m, 1, H-4′), 4.46 ('t', $J_{3'-2'} = J_{3'-4'} = 5.5$ Hz, 1, H-3′), 4.83 (m, 1, H-2′), 5.40 ('t', $J_{OH-5',5''} = 5.5$ Hz, 1, 5′-OH), 5.91 (d, $J_{1'-2'} = 5$ Hz,

[4]R. Mengel *et al.*, work to be published.

1, H-1′), 6.14 (d, $J_{OH-2'} \sim 3$ Hz, 1, 2′-OH), 6.65 (d, $J_{5-6} = 4$ Hz, 1, H-5), 7.10 (br s, 2, 4-NH_2), 7.40 (d, $J_{6-5} = 4$ Hz, 1, H-6), 8.10 (s, 1, H-2); ms (180°C) *m/e* (relative intensity, ion) 376(8, M), 248(8, $M-128$), 230(4, $M-(128+18)$), 219(12, $M-(127+30)$), 189(2), 164(44, BHCHO(1′)), 147(4, BCH_2), 135(28, B+2H), 134(100, B+H). *Anal.* calcd. for $C_{11}H_{13}IN_4O_3$: C 35.12, H 3.48, I 33.74, N 14.89; found: C 35.12, H 3.84, I 33.87, N 14.61.

4-Amino-7-(2,3-anhydro-β-D-ribofuranosyl)pyrrolo[2,3-d]pyrimidine (3)

To 100 ml of absolute MeOH saturated with NH_3 (at −5°C) was added 1.64 g (0.003 mol) of **2** (*5b*). The flask was securely stoppered and allowed to stand at room temperature for 6 h. Completion of the reaction was verified by tlc (silica gel, 5% MeOH–$CHCl_3$). The solution was evaporated (water aspirator) to ~20 ml and 4 g of silica gel was added. The mixture was evaporated to dryness at room temperature and the impregnated powder was added to a column (4 × 20 cm, 60 g) of silica gel. The column was washed with 2000 ml of CH_2Cl_2[5] and the wash was discarded. The product was eluted using CH_2Cl_2–MeOH (20:1) and 100 ml fractions were collected. Evaporation (at room temperature) of fractions 9–14 gave a white powder which was dried *in vacuo* for 12 h at room temperature to give 0.765 g (96%) of **3**·monohydrate (^{1}H nmr). A sample for analysis was *rapidly* (*5d,g*) recrystallized from 95% EtOH (with diffusion of Et_2O) to give **3** as white needles, mp 170–173°C; $[\alpha]_D^{24}$ −46° (*c* 0.22, MeOH); uv (MeOH) λ_{max} 271 (ε 11 500) λ_{min} 227 nm (ε 2410); nmr δ 3.50 (m, 2, H-5′, H-5″), 4.12 (t, $J_{4'-5',5''} \sim 6$ Hz, 1, H-4′), 4.20 (d, $J_{3'-2'} = 2.5$ Hz, 1, H-3′), 4.28 (d, $J_{2'-3'} \sim 2.5$ Hz, 1, H-2′), 5.04 (br s, 1, 5′-OH), 6.28 (s, 1, H-1′), 6.60 (d, 1, H-5), 7.05 (s, 2, 4-NH_2), 7.35 (d, 1, H-6), 8.08 (s, 1, H-2); ms (190°C) *m/e* (% relative intensity, ion) 248(11.5, M), 218(2, $M-CHO(5')$), 217(3, $M-31$), 201(0.5, $M-CHO-17$), 189(3), 163(50, BHCHO(1′)), 147(6.5, BCH_2), 135(21, B+2H), 134(100, B+H); (lit. (12) mp 145–176°C; $[\alpha]_D^{23}$ −42.6° (*c* 0.2, MeOH)). *Anal.* calcd. for $C_{11}H_{12}N_4O_3$; C 53.22, H 4.86, N 22.57; found: C 53.17, H 4.62, N 22.34.

4-N,N-Dibenzimido-7-(5-O-benzoyl-2,3-anhydro-β-D-ribofuranosyl)pyrrolo[2,3-d]pyrimidine (4)

To a suspension of 1 g (0.004 mol) of crude **3** in 30 ml of dry pyridine was added 3 ml (0.026 mol) of freshly distilled benzoyl chloride and the resulting clear solution was stirred for 8 h at room temperature. Ice chips were added and the solution was poured slowly into 2000 ml of ice and H_2O with vigorous stirring. The resulting white precipitate was filtered, washed with 1000 ml of cold H_2O, and dried (finally *in vacuo* at 50°C) to give 2 g (89%) of **4**. Recrystallization of 65 mg of this product from 5 ml of EtOH–$CHCl_3$ gave 60 mg of pure **4**, mp 201–202°C; uv (MeOH) shoulder 270 (ε 17 500), λ_{max} 215 nm (ε 59 500); nmr δ 4.2–4.6 (m, 5, H-2′–H-5″), 6.38 (d, $J_{5-6} = 4$ Hz, 1, H-5), 6.48 (s, 1, H-1′), 7.3–7.95 (m, 16, benzoate, H-6), 8.56 (s, 1, H-2); ms (200°C) *m/e* (relative intensity, ion) 560(68, M), 455(100, $M-COC_6H_5$), 439(23, $M-OCOC_6H_5$), 218(40, sugar fragment). *Anal.* calcd. for $C_{32}H_{24}N_4O_6$: C 68.56, H 4.31, N 9.99; found: C 68.43, H 4.54, N 10.27.

4-Amino-7-β-D-xylofuranosylpyrrolo[2,3-d]pyrimidine (5) (xyloTb)

Method A

To a solution of 0.56 g (0.001 mol) of **4** in 50 ml of DMF containing 1 ml of H_2O was added 0.35 g (0.002 mol) of sodium benzoate. This mixture was heated with stirring at 100°C for 34 h and was then evaporated *in vacuo*. The resulting gum was dissolved in 240 ml of MeOH and 0.6 g (0.025 g at.) of sodium was added. The solution was stirred for 21 h at room temperature, neutralized with HOAc, and evaporated. The residue was partitioned between H_2O and Et_2O and the aqueous phase was applied to a column (2.5 × 22 cm) of Dowex 1-X2(OH^-) resin packed in H_2O. The column was washed with H_2O (2 ℓ) and then with 10% MeOH–H_2O. The amount of MeOH in H_2O was gradually increased to 60% which eluted the product. Evaporation of the appropriate fractions gave 0.19 g (71%) of **5** which was crystallized from MeOH (with diffusion of Et_2O) to give 0.18 g (68%) of **5**, mp 223–224°C; $[\alpha]_D^{24}$ −135°C (*c* 0.5, DMF); uv (0.1 *N* HCl) λ_{max} 270; 227 (ε 10 600; 22 400) λ_{min} 245 (ε 3950), (H_2O) λ_{max} 270 (ε 11 500) λ_{min} 237 (ε 1950), (0.1 *N* NaOH) λ_{max} 270 (ε 11 400) λ_{min} 240 nm (ε 3550); nmr δ 3.6–3.7 (m, 2, H-5′, H-5″), 3.95–4.10 (m, 2, H-3′, H-4′), 4.22 (br s, 1, H-2′), 5.15 ('t', $J_{OH-5',5''} \sim 5$ Hz, 1, 5′-OH), 5.7 (d, 1, 2′-OH), 5.88 (s, 1, 3′-OH), 5.94 (d, $J_{1'-2'} = 2$ Hz, 1, H-1′), 6.55 (d, $J_{5-6} = 4$ Hz, 1, H-5), 7.0 (br s, 2, 4-NH_2), 7.38 (d, 1, $J_{6-5} = 4$ Hz, H-6), 8.08 (s, 1, H-2); ms (170°C) *m/e* (relative intensity, ion) 266(3, M), 177(45, $BHCH_2CHO$), 163(66, BHCHO(1′)), 147(19.5, BCH_2), 135(2, B+2H), 134(100, B+H). *Anal.* calcd. for $C_{11}H_{14}N_4O_4$: C 49.62, H 5.30, N 21.04; found: C 49.42, H 5.32, N 20.75.

Further elution with 70% MeOH–H_2O gave 0.018 g (6.8%) of the arabino isomer **8**. This product had identical mobility to a sample of **8** (prepared below) by tlc, paper chromatography, and electrophoresis. The mass spectrum was identical to that of **8** and the nmr spectrum of the product obtained from similar experimental runs was identical to that of **8** (H-1′ at δ 6.42, $J_{1'-2'} = 4$ Hz).

Method B

To a solution of 280 mg (0.5 mmol) of **4** in 10 ml of dry MeCN (distilled from P_2O_5 and stored over 3A molecular sieves) was added 1 ml of freshly distilled $BF_3 \cdot OEt_2$ and the mixture was stirred for 10 min at room temperature. Absolute MeOH (5 ml) was added and stirring was continued for 1 h. The mixture was poured into 100 ml of saturated aqueous $NaHCO_3$ solution and the milky suspension was extracted with 3 × 50 ml of CH_2Cl_2. The combined organic phase was washed with 50 ml of H_2O, dried over Na_2SO_4, and evaporated to dryness. The resulting yellow glass (homogeneous on tlc, cyclohexane–Me_2CO 1:1) (300 mg) was stirred for 15 h at room temperature with 0.2 *N* NaOMe – MeOH. This solution was neutralized with 600 mg of HOAc and evaporated to a heavy oil. This residue was partitioned between H_2O and Et_2O, and the organic phase was extracted with an additional 30 ml of H_2O. The combined aqueous phase was evaporated to ~10 ml and applied to a column (2 × 25 cm) of Dowex 1-X2(OH^-). Elution was effected using 1 ℓ of H_2O, 300 ml each of 10%, 20%, and

[5]The use of methylene chloride appears to be essential. Substitution of chloroform resulted in lower yields of less pure epoxide.

30%, 1.5 ℓ of 40%, 1 ℓ of 50%, and 2 ℓ of 70% MeOH–H_2O. Fractions (20 ml) 113–160 were pooled and evaporated to give 126 mg (95%) of **5** after drying *in vacuo*. This solid product had identical spectral, chromatographic, and electrophoretic properties to that of method A and could be used without further purification.

No araTb (**8**) was detected in the 70% MeOH–H_2O or earlier eluates.

*4-Amino-7-(3,5-O-isopropylidene-β-D-xylofuranosyl)pyrrolo[2,3-d]pyrimidine (**6a**)*

To a stirred solution of 6 ml of freshly distilled acetone containing 0.84 g of *p*-toluenesulfonic acid and 1.5 ml (0.014 mol) of 2,2-dimethoxypropane was added 0.3 g (0.0011 mol) of **5**. The flask was stoppered and stirred for 20 h. The red solution was poured into a stirred solution (30 ml) of saturated aqueous $NaHCO_3$. This solution was extracted with 7 × 30 ml of $CHCl_3$. White crystals separated upon concentration of the combined organic phase. These were filtered to yield 0.34 g (100%) of **6a**, mp 251–252°C; $[\alpha]_D^{24}$ −81.5° (*c* 0.5, DMF); uv (0.1 *N* HCl) λ_{max} 266; 225 (ε 10 300; 21 400) λ_{min} 242 (ε 4000); (H_2O) λ_{max} 270 (ε 11 100) λ_{min} 237 (ε 280), (0.1 *N* NaOH) λ_{max} 267 (ε 10 800) λ_{min} 240 nm (ε 4000); nmr δ 1.34, 1.44 (s, s; 3, 3; CMe_2), 3.8–4.3 (m, 5, H-2′–H5′′), 5.90 (br s, 1, 2′-OH), 6.16 (s, 1, H-1′), 6.52 (d, J_{5-6} = 4 Hz, 1, H-5), 6.96 (br s, 2, 4-NH_2), 7.42 (d, J_{6-5} = 4 Hz, 1, H-6), 8.08 (s, 1, H-2); ms (185°C) *m/e* (% relative intensity, ion) 306(8.5, M), 291(4, *M*−15), 219(1), 193(2), 177(5.5, $BHCH_2CHO$), 163(70, BHCHO(1′)), 147(3, BCH_2), 135(32, B+2H), 134(100, B+H). *Anal.* calcd. for $C_{14}H_{18}N_4O_4$: C 54.89, H 5.92, N 18.29; found: C 55.09, H 6.13, N 18.02.

*4-Amino-7-(3,5-O-isopropylidene-2-O-methanesulfonyl-β-D-xylofuranosyl)pyrrolo[2,3-d]pyrimidine (**6b**)*

To a stirred solution of 0.6 g (0.0019 mol) of **6a** in 10 ml of dry freshly distilled pyridine was added 0.6 ml (0.007 mol) of mesyl chloride. The flask was stoppered and stirred for 3 h. The solution was poured into 150 ml of ice and H_2O and this mixture was extracted with 4 × 50 ml of $CHCl_3$. The combined organic phase was washed with saturated aqueous $NaHCO_3$, H_2O, dried over Na_2SO_4, filtered, and evaporated *in vacuo* to give a white powder. This powder was dissolved in 5 ml of $CHCl_3$ and applied to a column of silica (2.3 × 50 cm, 100 g). The column was washed with 200 ml of $CHCl_3$ and the compound was then eluted with MeOH–$CHCl_3$ (3:97). The appropriate fractions were evaporated to give 0.58 g (79%) of **6b** as a white powder, mp 80–83°C; uv (MeOH) λ_{max} 270 (ε 11 200) λ_{min} 230 nm (ε 3670); nmr δ 1.32, 1.50 (s, s; 3, 3; CMe_2), 3.48 (s, 3, OMs), 3.9–4.3 (m, 3, H-4′–H-5′′), 4.65 (d, $J_{3'-4'}$ = 2 Hz, 1, H-3′), 5.05 (s, 1, H-2′), 6.40 (s, 1, H-1′), 6.60 (d, J_{5-6} ~ 3.8 Hz, 1, H-5), 7.1 (br s, 2, 4-NH_2), 7.40 (d, J_{6-5} ~ 3.8 Hz, 1, H-6), 8.08 (s, 1, H-2); ms (180°C) calcd. for M^+ ($C_{15}H_{20}N_4O_6S$): 384.1103; found (*m/e*): 384.1111; *m/e* (% relative intensity, ion) 384(5.5, M), 369(3.5, *M*−15), 247(5.5), 231(7), 217(2), 201(11), 163(95, BHCHO(1′)), 147(9, BCH_2), 135(32, B+2H), 134(100, B+H).

4-Amino-7-(2-O-methanesulfonyl-β-D-xylofuranosyl)pyrrolo[2,3-d]pyrimidine

A 0.55 g (0.0014 mol) sample of **6b** was dissolved in 50 ml of 90% trifluoroacetic acid – H_2O. The solution was stirred at room temperature for 20 min and was then evaporated. After removal of traces of H_2O and acid by coevaporation of the residue with benzene, 0.42 g (87%) of the title compound was obtained as a white solid foam, mp 179–180°C; uv (MeOH) λ_{max} 270 (ε 11 200) λ_{min} 230 nm (ε 3670); nmr δ 3.22 (s, 3, OMs), 3.71 (m, 2, H-5′, H-5′′), 4.09 (m, 1, H-4′), 4.42 (m, 1, H-3′), 4.91 ('t', $J_{OH-5',5''}$ = 5 Hz, 1, 5′-OH), 5.21 ('t', $J_{2'-3'} = J_{2'-1'}$ = 2.5 Hz, 1, H-2′), 6.25 (d, $J_{1'-2'}$ = 2.5 Hz, 1, H-1′), 6.35 (d, $J_{OH-2'}$ = 5.5 Hz, 1, 2′-OH), 6.60 (d, J_{5-6} = 4 Hz, 1, H-5), 7.12 (br s, 2, 4-NH_2), 7.36 (d, J_{6-5} = 4 Hz, 1, H-6), 8.08 (s, 1, H-2); ms (200°C) calcd. for M^+: 344.0791; found (*m/e*): 344.0798; *m/e* (% relative intensity, ion) 344(2.5, M), 248(27, M−(OMs and OH)), 217(7, 248–31), 201(6), 189(9), 163(93, BHCHO(1′)), 147(18, BCH_2), 135(50, B + 2H), 134(100, B + H). *Anal.* calcd. for $C_{12}H_{16}N_4O_6S$: C 41.85, H 4.68, N 16.27, S 9.31; found: C 41.67, H 4.47, N 16.00, S 9.28.

*4-Amino-7-(2,3-anhydro-β-D-lyxofuranosyl)pyrrolo[2,3-d]pyrimidine (**7**)*

To a solution of 0.237 g (0.0007 mol) of the above mesylate product in 80 ml of MeOH was added 0.2 g (0.009 g at.) of sodium. The solution was stirred at room temperature for 12 h, neutralized with HOAc, and evaporated to dryness. The residue was dissolved in 25 ml of H_2O and the solution was applied to a column (2 × 60 cm) of Dowex 1-X2(OH^-) resin. Elution with H_2O and evaporation of appropriately pooled fractions gave 0.14 g (82%) of **7**. Recrystallization of this material from 95% EtOH gave crystals of **7**, mp 110–112°C (dec.); $[\alpha]_D^{24}$ −50.5° (*c* 0.4, DMF); uv (0.1 *N* HCl) λ_{max} 270; 225 (ε 11 100; 23 000) λ_{min} 245 (ε 4250), (H_2O) λ_{max} 270 (ε 12 500) λ_{min} 247 (ε 7500), (0.1 *N* NaOH) λ_{max} 270 (ε 12 000) λ_{min} 238 nm (ε 4100); nmr δ 3.58 (d, 2, H-5′, H-5′′), 3.95–4.2 (m, 3, H-2′–H-4′), 5.00 (br s, 1, 5′-OH), 6.40 (s, 1, H-1′), 6.65 (d, J_{5-6} = 4 Hz, 1, H-5), 7.08 (br s, 2, 4-NH_2), 7.30 (d, J_{6-5} = 4 Hz, 1, H-6), 8.12 (s, 1, H-2); ms (140°C) calcd. for M^+: 248.0909; found (*m/e*): 248.0905; *m/e* (% relative intensity, ion) 248 (12, M), 231(1.5, *M* − 17), 218(5.5, *MH* − CHO(5′)), 217(8.5, *M* − 31), 201(5.5, *MH* − CHO − 17), 189(8.5), 163(97, BHCHO(1′)), 147(23, BCH_2), 135(49, B + 2H), 134(100, B + H). *Anal.* calcd. for $C_{11}H_{12}N_4O_3$: C 53.22, H 4.86, N 22.57; found: C 53.04, H 5.09, N 22.81.

*4-Amino-7-β-D-arabinofuranosylpyrrolo[2,3-d]pyrimidine (**8**) (araTb)*

To a solution of 0.13 g (0.0005 mol) of **7** in 25 ml of DMF containing 1 ml of H_2O was added 0.15 g (0.001 mol) of sodium benzoate. This mixture was heated at 100°C for 12 h with stirring and was then evaporated *in vacuo*. The residue was dissolved in 40 ml of MeOH and 0.07 g (0.003 g at.) of sodium was added. The solution was stirred for 1 h at room temperature, neutralized with HOAc, and evaporated. The residue was dissolved in 25 ml of H_2O and the solution was applied to a column (2 × 32 cm) of Dowex 1-X2(OH^-) resin. The column was washed with H_2O (2 ℓ) and then with 10% MeOH–H_2O. The concentration of MeOH in H_2O was gradually increased. A small quantity, 0.006 g (4.5%) of material identical to **5** by tlc, paper chromatography, electrophoresis, mass spectrometry, and nmr was eluted with 60% MeOH–H_2O. Further elution gave 0.102 g (77%) of **8**. Recrystallization of 0.1 g of this material from MeOH

(with diffusion of Et_2O) gave 0.095 g of crystalline **8**, mp 125–126°C; $[\alpha]_D^{24}$ 6.9° (*c* 0.5, DMF); uv (0.1 *N* HCl) λ_{max} 268; 225 (ε 11 100; 23 800) λ_{min} 245 (ε 4150), (H_2O) λ_{max} 268 (ε 11 900) λ_{min} 240 (ε 4500), (0.1 *N* NaOH) λ_{max} 270 (ε 11 200) λ_{min} 240 nm (ε 4150); nmr δ 3.55–3.80 (m, 3, H-3′, H-5′, H-5″), 3.95–4.20 (m, 2, H-2′, H-4′), 5.01 (t, 1, 5′-OH), 5.41 (d, 2, 2′-OH, 3′-OH), 6.42 (d, $J_{1'-2'}$ = 4 Hz, 1, H-1′), 6.52 (d, J_{5-6} = 4 Hz, 1, H-5), 6.90 (br s, 2, 4-NH_2), 7.29 (d, J_{6-5} = 4 Hz, 1, H-6), 8.05 (s, 1, H-2), ms (200°C) *m/e* (% relative intensity, ion) 266(7, M), 236(1, *MH* − CHO(5′)), 193(1), 190(0.5), 177(11, $BHCH_2$-CHO), 163(60, BHCHO(1′)), 147(8, BCH_2), 135(32, B + 2H), 134(100, B + H). *Anal.* calcd. for $C_{11}H_{14}N_4O_4$: C 49.62, H 5.30, N 21.04; found: C 49.92, H 5.40, N 20.86.

*Treatment of **1**, **5**, and **8** with periodate*

Solutions of **1**, **5**, and **8** in H_2O were placed (sequentially) in a cuvette and an aqueous solution of $NaIO_4$ was added. The solutions were mixed rapidly and the cuvette was placed in a uv spectrometer. The change in optical density at 227 nm was observed as a function of time as described (24).

Tubercidin (**1**) was oxidized completely in ~20 min, whereas **5** and **8** caused no change in the uv absorption of the periodate ion over an extended period of time.

*Treatment of **1**, **5**, and **8** with Adenosine Deaminase*

Solutions of **1**, **5**, and **8** in 0.05 *M* KH_2PO_4 buffer (p*H* 7.0) were treated with a solution of adenosine deaminase[6] in 0.05 *M* Tris-HCl buffer (p*H* 8). After standing at room temperature for 30 h, aliquots were diluted, and uv spectra were determined. These spectra were superimposable with those of control solutions of **1**, **5**, and **8**. Under these conditions, adenosine was *rapidly* and completely converted to inosine ($\Delta\varepsilon_{265\ nm} \sim -8600$).

Formation of ketenes from carboxylic acids in strong acids. Intermediacy of ketenes in the acid-catalyzed α-chlorination of carboxylic acids[1]

YOSHIRO OGATA, TAIRA HARADA, AND TOSHIYUKI SUGIMOTO

Department of Applied Chemistry, Faculty of Engineering, Nagoya University, Chikusa-ku, Nagoya, Japan

Received August 31, 1976

YOSHIRO OGATA, TAIRA HARADA, and TOSHIYUKI SUGIMOTO. Can. J. Chem. **55**, 1268 (1977).

Evidence (chemical trapping by aniline, and nmr and laser–Raman spectroscopy) is presented for the presence of ketenes in heated solutions of carboxylic acids in fuming H_2SO_4. The intermediacy of ketenes in α-chlorination catalyzed by strong acids is suggested.

YOSHIRO OGATA, TAIRA HARADA et TOSHIYUKI SUGIMOTO. Can. J. Chem. **55**, 1268 (1977).

On présente quelques résultats (piégeage chimique par l'aniline et spectres Raman–laser et rmn) indiquant la présence de cétènes dans des solutions d'acides carboxyliques chauffés en présence d'acide sulfurique fumant. On suggère que des cétènes sont présents sous forme d'intermédiaire lors de la chloration-α catalysée par des acides forts.

[Traduit par le journal]

The α-halogenation of ketones and aldehydes, and probably acid halides, is said to proceed through the corresponding enols. The present authors recently reported a novel method for α-chlorination of aliphatic acids in the presence of molecular oxygen, chlorosulfonic acid, and chloranil which may also proceed via enolized acids (1, 2). The enols of acids $RCH{=}C(OH)_2$ when dehydrated, may produce ketenes which may then participate in this halogenation (3, 4). Little *et al.* (3) suggested two mechanisms for the PCl_3-catalyzed α-chlorination of cyclohexanecarboxylic acid, one involving enolization of the acid chloride followed by rate-determining addition of chlorine and the other involving ketenes, but no evidence for either suggestion has been presented.

The present authors have studied the behavior of fatty acids in fuming H_2SO_4 and wish to report evidence that ketenes may be involved in the acid-catalyzed chlorination. The behavior of carboxylic acids in these strong acids has been studied earlier (5–9); in particular, Deno *et al.* used nmr spectroscopy to observe protonated carboxylic acids and acyl cations, the latter being predominant in solutions containing more than 20% SO_3 in H_2SO_4 (8*a*). They also predicted an equilibrium formation of ketenes from acyl

[1] $$RCH_2CO_2H + H^+ \rightleftharpoons RCH_2\overset{+}{C}(OH)_2 \rightleftharpoons RCH_2\overset{+}{C}O + H_2O$$

[2] $$RCH_2\overset{+}{C}O \rightleftharpoons RCH{=}C{=}O + \overset{+}{H}$$

cations. Recently, Deno and Friedman[2] found evidence in favor of the presence of ketenes: (*a*) a decrease of the nmr band (3.29 δ), characteristic of CH_3CO^+, on the addition of D_2SO_4, which suggests the conversion:

$$CH_3CO^+ \overset{-H^+}{\rightleftharpoons} CH_2{=}C{=}O \overset{D^+}{\rightleftharpoons} CH_2D\overset{+}{C}O$$

(*b*) similar nmr observation of H–D exchange at the α-CH_2 of $CH_3CH_2CO^+$ but no exchange at the β-CH_3, (*c*) H–D exchange at the C-4 methyl, but no exchange at C-2 and C-3 of the crotonyl cation, suggesting 4-proton elimination:

$$CH_3CH{=}CH{-}\overset{+}{C}O \overset{-H^+}{\rightleftharpoons} CH_2{=}CH{-}CH{=}C{=}O$$

(*d*) the same nmr spectrum was obtained for both *cis*- and *trans*-crotonic acid dissolved in fuming H_2SO_4, suggesting the presence of $CH_2{=}CH{-}CH{=}C{=}O$.

Discussion of Results

The present authors wished to confirm the presence of ketenes from carboxylic acids in strong acid media by way of (*i*) the trap of a ketene by aniline, (*ii*) nmr spectroscopy, and (*iii*) laser–Raman spectroscopy.

(*i*) A mixture of fuming H_2SO_4 and acetic acid was heated at 80°C and the vapor was introduced into aniline with N_2 under reduced pressure as a

[1]Contribution No. 226 from the Department of Applied Chemistry, Faculty of Engineering, Nagoya University.

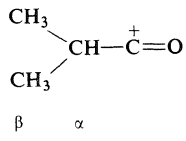
[2]N. C. Deno and N. Friedman, personal communication.

carrier. Product analysis by glc indicated the presence of acetanilide, whereas a mixture of acetic acid and aniline gave no acetanilide in these conditions even in the presence of a catalytic amount of fuming H_2SO_4. This confirms the formation of ketene which acetylates aniline (10). The possibility of participation of acetic anhydride in this acetylation (11) was also ruled out by the following results. (*a*) The nmr spectrum of a mixture of acetic acid and fuming H_2SO_4 after heating at 80°C showed no peaks due to the acetic anhydride or protonated acetic anhydride, but only a singlet at 3.93 δ due to the acyl cation, $CH_3—\overset{+}{C}=O$ (8), in agreement with the reported chemical shift. (*b*) Vapors from a heated mixture of acetic anhydride and fuming H_2SO_4 were passed, using N_2, into aniline, but no acetanilide was detected. The observed low yield of acetanilide could be ascribed to the unfavorable equilibrium for formation of ketene (reaction 2) in this system and presumably to side reactions of the ketene produced in hot fuming H_2SO_4. Ketene has been reported to react with sulfuric acid to give acetylsulfoacetic acid as a red viscous oil (12).

$$H_2SO_4 + 2CH_2=C=O \rightarrow CH_3CO_2SO_2CH_2CO_2H$$

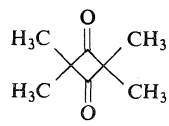
Indeed, the nmr spectrum of the red viscous oil which was obtained as a residue after heating acetic acid in fuming H_2SO_4 showed only two singlets at 4.41 (2H) and 2.63 δ (3H); this implies the formation of acetylsulfoacetic acid as a side product. Attempts to collect ketene vapor in a cold trap were unsuccessful, probably because ketene itself has a very low boiling point (−56°C), so that most would be expelled by carrier N_2, even with cooling. The authors also attempted to trap dimethylketene, assuming its formation from isobutyric acid in fuming H_2SO_4 by an analogous method, but the isolation of acetylated product, $PhNH—CO—CH(CH_3)_2$, was unsuccessful, probably because of the higher boiling point (34°C) and the higher solubility of dimethylketene in fuming H_2SO_4 compared with that of ketene itself.

(*ii*) The details of the nmr spectrum of a mixture of isobutyric acid and fuming H_2SO_4 (50% SO_3) are as follows: δ 1.92 (d, J = 7.1 Hz, 6H), 4.20 (septet, J = 7.1 Hz, 1H), 1.67 (s, ~1H), 1.80 (s, ~1H), and 3.90 (s, ~1H). The septet centered at 4.20 δ and the doublet centered at 1.92 δ were assigned to α-H and β-H of the acyl cation **1**, respectively. Deno reported that isobutyric acid was completely converted to the corresponding acyl cation **1** in 50% SO_3 in H_2SO_4 and that chemical shifts of α-H and β-H for the acyl cation are 4.23 (septet, J = 7.0 Hz) and 1.90 δ (d, J = 7.1 Hz), respectively (8), which agrees with our results.

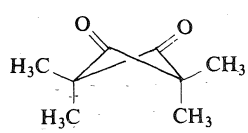


1

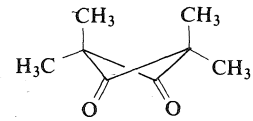
It is known that ketoketenes $R_2C=C=O$ dimerize to cyclobutane-type dimers (13). The observed two weak singlets at 1.67 and 1.80 δ suggest the presence of a dimer of the type 2,2,4,4-tetramethyl-1,3-butanedione (**2**). The nmr shift of **2** in $CDCl_3$ was reported to be 1.29 δ because of the oscillation of the flexible four-membered ring between **2***a* and **2***b* (15). The dimer,



2



2*a*



2*b*

prepared in our hands (14), gave the same peaks at 1.83 and 1.68 δ in fuming H_2SO_4, but gave only one peak at 1.80 δ in 95% H_2SO_4 as shown in Table 1. This value (1.83 δ), which is larger than 1.30, implies *O*-protonation in strong acid, because a similar phenomenon was observed in simple ketones; *e.g.*, the peak due to the methyl protons of acetone in SbF_5/HSO_3F appears at 3.25 δ which is considerably deshielded (*ca.* 1.2 δ) compared with that in ordinary organic solvents (16). The peak at 1.68 δ may be caused by an unknown product derived from the dimer **2**.

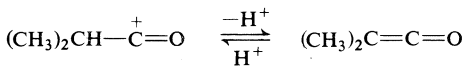
The nmr peak at 3.90 δ is ascribed to the dimethylketene monomer or its derivative on the basis of the following. On introduction of dimethylketene, prepared by an alternative method (17), to fuming H_2SO_4 at room temperature the nmr spectrum of the resulting solution exhibited the 3.90 δ peak: δ 3.90 (sharp s), 4.00 (br s), and

TABLE 1. The nmr spectrum of a solution of 2,2,4,4-tetramethyl-1,3-butanedione (**2**) in 95% H_2SO_4 or fuming H_2SO_4

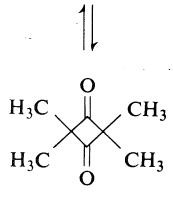
Solvent system		
SO_3 (%)	H_2SO_4 (%)	Spectral data
30	70	1.83(s), 1.68(s)*
15	85	1.83(s), 1.67(s)
10	90	1.82(s), 1.65(s)
7	93	1.78(s), 3.26(septet, J=7 Hz, 1H), 1.30(d, J=7 Hz, 6H)
—	95†	1.80(s), 3.36(septet, J=7 Hz, 1H), 1.31(d, J=7 Hz, 6H)

*The peak at 1.68 δ increased in size when the solution was heated at 110°C for 10 min, and other weak peaks appeared at 5.47, 4.81, and 4.00 δ.
†5% H_2O.

5.10 (br s). The dimer **2** can decompose on heating to its monomer, $(CH_3)_2C{=}C{=}O$ (18). The solution of isobutyric acid in fuming H_2SO_4 was heated to 50°C for 30 min as in the chlorination system (2), and the observed nmr shifts are as follows: δ 1.62 (weak s), 1.74 (weak s), 3.90 (sharp s, 1.5H), 4.00 (br s, 2H), 4.85 (br s, 3H), 5.45 (br s, 2H). This shows that the peaks due to the acyl cation **1** have disappeared, while the two weak singlets at 1.62 and 1.74 δ still remained, suggesting the presence of dimer **2**. The peaks at



1



2

5.45, 4.85, and 4.00 δ for isobutyric acid in heated fuming H_2SO_4 cannot be assigned, but they suggest the presence of unknown products from dimer **2** in fuming H_2SO_4, since similar peaks of 5.47, 4.81, and 4.00 δ were also observed in a heated solution of dimer **2** in fuming H_2SO_4.

(*iii*) The laser–Raman spectrum of isobutyric acid in fuming H_2SO_4 (molar ratio 1:5.7) which had been heated at 50°C for 10 min had a sharp and strong band at 2160 cm^{-1} and this band was assigned to the asymmetric C=C=O stretch, since liquid samples of ketenes have generally a band at 2116 cm^{-1} (19). It was confirmed that other major bands (Fig. 1) were due to fuming H_2SO_4 by direct comparison with an authentic sample. The sample which gave the Raman band at 2160 cm^{-1} gave no nmr peaks corresponding to acyl cation **1**, but only the peaks corresponding to ketene monomer and its dimer and the above-mentioned peaks at 5.45, 4.85, and 4.00 δ. Hence this band cannot be assigned to the acyl cation.

It is concluded from these results that ketene may be formed according to reactions 1 and 2 in our reaction conditions. The authors have previously reported that fuming H_2SO_4-catalyzed chlorination of isovaleric acid by molecular chlorine gave the corresponding α-chlorination (20). Therefore, the authors suggest that α-chlorination of a carboxylic acid may proceed via the corresponding ketenes, since the enol, *i.e.* ketene hydrated at C=O, seems to be more unstable in fuming H_2SO_4 and hence is present, if at all, at a lower concentration. Indeed, reaction of ketene with molecular chlorine has been reported to give α-chlorinated acetyl chloride (21).

Experimental

General

Glacial acetic acid (bp 47°C/48 torr), isobutyric acid (bp 70–72°C/29 torr), acetic anhydride (bp 138–139°C), and aniline (bp 86–87°C/20 torr) were commercial reagents and were distilled before use. 2,2,4,4-Tetramethyl-1,3-butanedione (**2**) was prepared according to the literature (15), mp 114–116°C (lit. (15) mp 115–116°C). Commercially available (1st grade) fuming sulfuric acid (50% SO_3) was used without further purification.

Nuclear magnetic resonance spectra were measured on a 60 MHz JEOL C 60 HL nmr spectrometer at 25°C using capillary benzene as an external standard and a 60 MHz Hitachi R-24B nmr spectrometer at 35°C using TMS in $CHCl_3$ as an external standard. Chemical shifts (δ) are expressed in ppm.

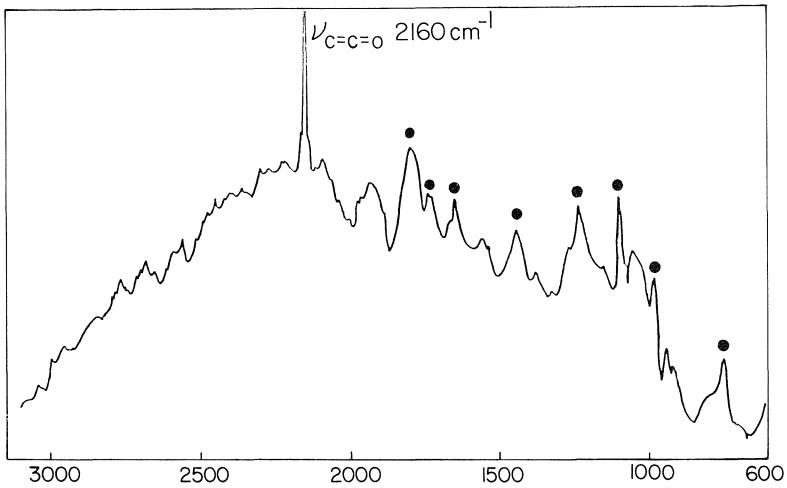


FIG. 1. The Raman spectrum, at room temperature, of the 3200–600 cm^{-1} region of dimethylketene produced from the isobutyric acid – fuming H_2SO_4 system. It was confirmed that marked (●) bands were due to fuming H_2SO_4 by direct comparison with an authentic sample.

The laser–Raman spectra were measured at room temperature by a JASCO R-300 laser–Raman spectrophotometer with an argon ion model 251 CW laser source. The 5145 Å exciting line was used for the 4000–600 cm^{-1} spectral region.

Analysis of reaction products was done on a Yanagimoto model GCG 550 gas chromatograph employing a flame ionization detector. The columns were a 1.3 m × 3 mm copper column packed with PEG 20 M 10% on Chromosorb W, 60–80 mesh, and a 1.5 m × 3 mm copper column packed with Apiezon grease L 15% on Celite 545, 80–100 mesh. The glc analysis conditions were as follows: N_2 flow rate was 30 ml/min and the temperature programmed at 8°C/min from 50–240°C.

Trapping of Ketene with Aniline

To stirred and cooled (0°C) glacial acetic acid (14.8 g, 0.25 mol) was added 2.0 g of fuming H_2SO_4 (50% SO_3) dropwise over a 0.5 h period. Stirring at 0°C was continued for additional 1 h. Immediately after warming to room temperature over a 0.5 h period, the system was evacuated (*ca.* 250 torr) and the temperature of the mixture rose slowly to 80°C. Dry nitrogen was bubbled gradually into this flask and then into aniline (23.0 g, 0.25 mol); after 5 h, the procedure was stopped. The resulting aniline solution was then analyzed by glc on the above mentioned two columns; the peak due to the acetanilide produced was identified by comparison with an authentic sample and the yield (*ca.* 2.3% based on acetic acid) was determined by the internal standard method. The reaction of aniline (8.0 g, 0.086 mol) with glacial acetic acid (0.32 g, 0.005 mol) was attempted for 6 h with magnetic stirring at room temperature and the solution obtained was analyzed by glc on a column packed with PEG 20M; no peak due to acetanilide was found. A similar result was obtained even on addition of a few drops of fuming sulfuric acid to the aniline – acetic acid mixture. Attempts to acetylate aniline with acetic anhydride were carried out as follows. Acetic anhydride (3.8 g, 0.037 mol) was added dropwise to cooled (0°C) fuming H_2SO_4 (14.0 g). The system was evacuated (*ca.* 250 torr) and allowed to warm to 80°C. The N_2 was bubbled gradually to this system and thence into aniline (20.0 g, 0.125 mol) for 5 h. No acetanilide was detected by glc analysis of the resulting aniline solution.

Studies on thermodynamics of solution by gas chromatography: solubility measurements of hydrocarbons in cycloalkanols

RAKESH K. KUCHHAL, KANAI L. MALLIK,[1] AND PYARE L. GUPTA[2]

Indian Institute of Petroleum, Dehradun-248005, India

Received July 6, 1976

RAKESH K. KUCHHAL, KANAI L. MALLIK, and PYARE L. GUPTA. Can. J. Chem. **55**, 1273 (1977).

Activity coefficients at infinite dilution have been determined by gas–liquid chromatography for nine hydrocarbons solutes in cyclopentanol, cyclohexanol, cycloheptanol, benzyl alcohol, and *n*-heptanol at 25 °C. Experimental results for cyclopentane and cyclohexane in cycloalkanols compare favourably with the values obtained by extrapolation to infinite dilution of activity coefficient data calculated from Benson *et al.*'s static (vapour–liquid equilibrium) measurements. Some characteristics of the solute–solvent interaction in the systems are discussed in light of statistical approaches (thermal and athermal contributions).

RAKESH K. KUCHHAL, KANAI L. MALLIK et PYARE L. GUPTA. Can. J. Chem. **55**, 1273 (1977).

On a déterminé les coefficients d'activité à dilution infinie en faisant appel à la chromatographie gaz–liquide; ces mesures ont été faites pour neuf hydrocarbures en solution dans le cyclopentanol, le cyclohexanol, le cycloheptanol, l'alcool benzylique et le *n*-heptanol à 25 °C. Les résultats expérimentaux obtenus pour le cyclopentane et le cyclohexane dans les cycloalkanols se comparent avantageusement avec les valeurs obtenues par extrapolation à dilution infinie de coefficients d'activité calculés à partir des mesures statiques (équilibre liquide–vapeur) effectuées par Benson et ses collaborateurs. On discute, à la lumière d'approches statistiques (contributions thermiques et athermiques), de quelques caractéristiques de l'interaction soluté–solvant dans les systèmes.

[Traduit par le journal]

Introduction

Studies on thermodynamics of solution comprising alcohol–hydrocarbon systems have been undertaken by several investigators during the last twenty-five years (1–7). Most of the studies in this field were devoted to aliphatic/aromatic alcohol–hydrocarbon mixtures, and little information is available for cycloalkanol–hydrocarbon systems (8) and there remains a paucity of thermodynamic data in this area. Such thermodynamic data are of considerable importance as they can indicate the potential use of the certain solvents as extraction agents. It is worth mentioning that use of cyclohexanol has already been reported as an extraction solvent for the recovery of cyclohexane from benzene-rich petroleum fractions (9).

The gas chromatographic (GC) technique has been well established as an advantageous method for determination of the thermodynamic properties at infinite dilution for binary non-electrolyte solutions (10–13). Such thermodynamic data may be conveniently determined by using a conventional GC equipment, employing cycloalkanols or other alcohols as the stationary phase. In the present paper, attempts have been made to study activity coefficients at infinite dilution for nine hydrocarbons in three cycloalkanols (cyclopentanol, cyclohexanol, and cycloheptanol) and two other aliphatic and aromatic alcohols, namely, *n*-heptyl and benzyl alcohols at 25 °C.

Experimental Section

The gas chromatographic apparatus and experimental procedure used for determining solute specific retention volumes have been reported in an earlier communication (11). Stationary phases (solvent components) (five solvents) obtained either from Fluka (Germany) or BDH (England): cyclopentanol, cyclohexanol, cycloheptanol, *n*-heptyl alcohol, and benzyl alcohol were used without any further treatment. The physical properties of the solvents (mostly literature values) are shown in Table 1. Approximately 25–30% coating on Chromosorb P (60–80 mesh size) were used for the present studies. To eliminate the problem of solvent depletion, caution was taken to connect a precolumn (about 20 cm in length and 3 mm in diameter) packed with about 35% of the desired solvent-coated support material with the

Benzyl alcohol	108.13	205.10	1.5404	1.0416	<1

main column. The carrier gas (H_2) was thus saturated with solvent prior to the point of injection. As in earlier cases (11, 12), satisfactory functioning of the presaturator column was observed in the present studies. The temperature of the column oven was maintained at 25 °C with variation of 0.1 °C as checked with an ASTM thermometer periodically.

Results

Solute activity coefficients at infinite dilution in the liquid phase ($\gamma_{2,p}^{\infty}$) were determined from the expression (14),

$$[1] \qquad \gamma_{2,p}^{\infty} = \frac{1.704 \times 10^7}{M p_0 V_g^0}$$

where $\gamma_{2,p}$ = activity coefficient for solute, M = solvent molecular weight, p_0 = vapour pressure of the pure saturated solute vapour in torr, and V_g^0 = specific retention volume of solute in ml, of carrier gas per gram of liquid in ml. This equation was discussed in detail elsewhere (11). The vapour pressures were calculated from the Antoine equation using the constants as reported in Dreisbach compilation (15).

Activity coefficients corrected for vapour phase nonideality ($\gamma_{2,f}^{\infty}$), is given by (16)

$$[2] \quad \ln \gamma_{2,f}^{\infty} = \ln \gamma_{2,p}^{\infty} + \frac{(V_2 - \beta_{22})(p_0 - p_1)}{RT} + \frac{\beta_{22}^2(p_0^2 - p_1^2)}{(RT)^2}$$

where $\gamma_{2,f}$ = activity coefficient corrected for vapour phase imperfection, superscript ∞ denotes infinite dilution, V_2 = molar volume of solute in ml, β_{22} = second virial coefficient for pure solute, 2, at temperature T in cm^3 mol^{-1}, p_0 = vapour pressure of pure solute in torr, p_1 = vapour pressure of pure solvent, in torr (negligible at operating temperature (Table 1)). Furthermore the last term of eq. 2 can be ignored as β_{22}^2 makes an insignificant contribution. The virial coefficients were computed from the modified corresponding states equation of McGlashan and co-workers (17, 18).

$$[3] \quad \frac{\beta_{22}}{V_c} = 0.430 - 0.886\left(\frac{T_c}{T}\right) - 0.694\left(\frac{T_c}{T}\right)^2 - 0.0375(n-1)\left(\frac{T_c}{T}\right)^{4.5}$$

where V_c and T_c are the critical volume and critical temperature of solute, n the effective carbon number of the solute. V_c and T_c data are obtained from Dreishbach's compilation (15).

Discussion

When used as stationary phases, all the five solvents could resolve the lower hydrocarbon mixture in a relatively short time. The chromatogram of all these compounds showed symmetrical peaks useful for analytical purposes.

The validity of any data under the equilibrium conditions can be substantiated by comparison with existing results in the literature but no direct data for comparison from GC or from conventional classical techniques, are available for these solvents. However, it was considered worthwhile to compare our results with the extrapolated values of activity coefficients obtained from the vapour liquid equilibrium data reported by Benson *et al.* (8, 19). Activity coefficients at finite concentrations were calculated from vapour–liquid equilibrium data, using the well known expression

$$[4] \qquad \gamma_{2,p} = \frac{y_2 P}{x_2 p_0}$$

where y_2 = mole fraction of solute in vapour phase, x_2 = mole fraction of solute in liquid phase, P = total vapour pressure in torr. The $\gamma_{2,p}^{\infty}$ values thus obtained were found to be in fair agreement as is evident from Table 2. Chevalley (20) also reported activity coeffi-

cients at finite concentration for the cyclohexane–cyclohexanol system in the temperature range of 35–55 °C. By extrapolating their values to 25 °C, the $\gamma_{2,p}^{\infty}$ value comes out to be 3.7, which compares favourably to our experimental data of 3.51. Similarly, our GC data on benzene–*n*-heptyl alcohol system also show the same consistent trend in $\gamma_{2,p}^{\infty}$ values when compared with the extrapolated data of Wehe and Coates (21) for the benzene–*n*-alcohol systems at their boiling points. Thus, the activity coefficient of benzene in methanol system was found to be 13.26, benzene–ethanol 10.48, and benzene–*n*-butanol 3.84 as compared to our datum, 2.12 in benzene–*n*-heptanol.

Table 3 lists the activity coefficients at infinite dilution for nine hydrocarbons at 25 °C. Data reported here are the mean of at least three experimental runs. The reproducibility of $\gamma_{2,p}^{\infty}$ was found to be within 2–3%. The data indicate that all the compounds studied exhibit a marked positive deviation from Raoult's law. Interestingly, $\gamma_{2,f}^{\infty}$ values of saturated hydrocarbons in cycloalkanols lie in between those of benzyl alcohol and *n*-heptanol. The activity coefficient is related to the excess partial molar free energy $\Delta\bar{g}_e^{\infty}$ by the well known relation

$$[5] \qquad \Delta\bar{g}_e^{\infty} = RT \ln \gamma_{2,f}^{\infty}$$

As $\Delta\bar{g}_e^{\infty}$ is exponentially related to the activity coefficient, the trends observed in Table 3 are somewhat normalized in Fig. 1 showing an incremental relationship between free energy and molecular structure for hydrocarbon solutes at 25 °C. It is evident from Table 3 that $\gamma_{2,f}^{\infty}$ values in all the cycloalkanols are larger for the *n*-alkanes than for the aromatic hydrocarbon solute which can be best explained on the basis of their respective cohesive energy densities (22, 23). Another interesting aspect of the data is that the activity coefficients at infinite dilution of all the solutes are decreasing numerically from cyclopentanol to cycloheptanol (and as a matter of fact in *n*-heptanol also), indicating the decrease in polarity of the solvent. Comparing the $\gamma_{2,f}^{\infty}$ data for cyclohexane and benzene in any one of the alcohols, it is evident that nonideality is less in the case of benzene solution. Depending upon environments, hydroxyl group can act both as proton donor or acceptor. It is usually observed that the proton accepting ability of hydroxyl group is very strong (24), but in the vicinity of benzene

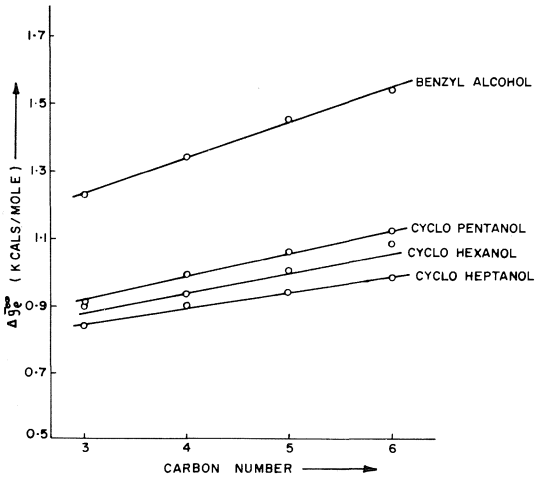

FIG. 1. Incremental relation between excess free energy and molecular structure for *n*-paraffins in monohydroxy solvents.

molecule it acts as a proton donor as benzene may act here as proton acceptor (25), causing C—OH- - -π interaction. Interestingly, $\gamma_{2,f}^{\infty}$ for benzene in benzyl alcohol is found to be lower than that in cycloalkanols, whereas for other hydrocarbon solutes it is always higher in benzyl alcohol. This observation is in accordance with the theoretical consideration for π-bond interactions.

Experimental determination of thermodynamic parameters serves as an important check on the various theories. The GC technique, which provides a rapid and convenient means to determine thermodynamic parameter, has also now been widely used (26) in testing the solution theories, particularly in very low concentration region where other methods like vapour pressure measurements (27, 28) or sensitive microbalance techniques (16) are least accurate. A number of theories have been put forward to predict the solution behaviour. Some of them are quite elaborate and require detailed information about the physical properties of solute and solvent molecules. Based on quasi-lattice theory, Everett and co-workers (29, 30) have explained the deviation from Raoult's law as due to combination of two completely independent factors, namely disparity in molecular size of solute and solvent (combinatorial or configurational term or the athermal part) and secondly, due to difference in intermolecular forces (the thermal part).

$$[6] \quad \ln \gamma_{2,f}^{\infty} = \ln \gamma_2^{\infty,\text{config}} + \ln \gamma_2^{\infty,\text{therm}}$$

The configurational term can be calculated from the Flory–Huggins equation (derived from a lattice model)

$$[7] \quad \ln \gamma_2^{\infty,\text{config}} = \ln \frac{1}{r} + \left(1 - \frac{1}{r}\right)$$

where r is taken as the ratio of the molar volume of the solvent to that of the solute V_1/V_2. Values for $\ln \gamma_2^{\infty,\text{config}}$ calculated to 25 °C are tabulated in Table 4.

According to the Flory–Huggins theory, the thermal term, $\ln \gamma_2^{\infty,\text{therm}}$ is directly related to the interaction parameter which is strictly a free energy term (30, 31)

$$[8] \quad \ln \gamma_2^{\infty,\text{therm}} = \chi \phi_1^2$$

where χ = interaction parameter; at infinite dilution, $\phi_1 = 1$, where ϕ_1 represents volume fraction of solvent.

By subtracting the thermal contribution, $\ln \gamma_2^{\infty,\text{config}}$, given in Table 4 from the logarithm of the experimental activity coefficient, the interaction parameters at 25 °C can be determined and are also presented in Table 4. The combinatorial part, as expected, indicates negative contribution to solution non-ideality. The data further show that the interaction parameter is positive for all the systems studied indicating that overall interchange free energies are positive. Two features of the interaction parameter data are worth mentioning. χ is increasing uniformly for *n*-paraffins in a particular solvent which means that as the number of contact sites or segments increase in a system the interaction parameter also increases thus providing that either the contact point lattice model (32) or the Barkers' model (33) can explain the phenomenon. The other interesting point to note is that for a particular solute the interaction parameter decreases with increase in molecular weight of the cycloalkanol solvent, which is a little difficult to explain with the experimental data available at the moment. It is likely that with increase in the molecular weight, some of the contact points may not be fully accessible for interaction.

Based on an earlier statistical approach of Longuet-Higgins (34), Martire *et al.* (35) have proposed that the interaction parameter χ can be obtained from the perturbation treatment, where the difference in intermolecular attrac-

tions between two solutes, a reference and a perturbed one in a solvent at infinite dilution, is given by the expression

$$[9] \quad \chi = \chi' = \frac{V_2'}{RT}\left[\frac{E_1}{V_1} - \frac{E_2'}{V_2'}\right]\left[\frac{T_{c,2}}{T_{c,2}'} - 1\right]$$

where V = molar volume in ml, E = molar intermolecular cohesive energy, R = gas constant, subscripts 1 and 2 refer to solvent and solute, respectively, and primed and unprimed terms represent the reference and perturbed state, respectively. This model was suggested on the assumption that the two solute states, the reference and the perturbed ones, differ only in intermolecular attractions between primed solute–solvent and unprimed solute–solvent molecules. It is evident that the interaction parameter for a series of solutes in a given solvent at a particular temperature should show a linear relationship with the solute critical temperature, $T_{c,2}$ or with potential well depth for the bigger molecules. Figure 2 demonstrates the linearity between χ values for our systems *vs.* the critical temperature of the solutes studied indicating that this model can also work for such systems.

Another simpler approach, Regular solution model, based on the cohesive energy density

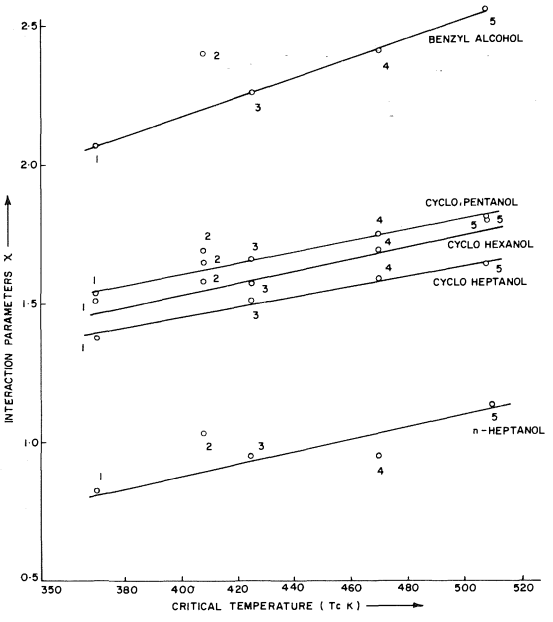

FIG. 2. Interaction parameters *vs.* critical temperature of solutes: *1*, propane; *2*, isobutane; *3*, *n*-butane; *4*, *n*-pentane; *5*, *n*-hexane.

concept initially proposed by Hildebrand and Scott (36), which was later extended by Weimer and Prausnitz (37), was also tested on the cyclohexanol and benzyl alcohol systems (for other alcohols, accurate solubility parameter data were not available in the literature). In the case of the nonpolar–polar mixture, the interaction parameter χ can be expressed as

$$[10] \quad \chi = \frac{V_2}{RT}[(\lambda_1 - \lambda_2)^2 + \Gamma_1^2 - 2\psi_{12}]$$

where λ and Γ represent the nonpolar and polar solubility parameters, and ψ_{12} is an adjustable parameter. Except the ψ_{12} term, other terms on the right hand side of the equation are known. The data for ψ_{12} were taken from the published literature (37–39). Appreciable differences between the experimental and calculated χ values were observed. However, with a limited objective, this model provides a good approach for the qualitative picture of a solute–solvent system. The limited usefulness of the solubility parameter theory has also been observed by Scott (40).

X-Ray photoelectron spectroscopy of monosubstituted perfluorobenzenes

BARRY C. TRUDELL AND S. JAMES W. PRICE[1]

Department of Chemistry, University of Windsor, Windsor, Ont., Canada N9B 3P4

Received September 1, 1976

BARRY C. TRUDELL and S. JAMES W. PRICE. Can. J. Chem. **55**, 1279 (1977).

The gas phase X-ray photoelectron spectra, XPS, were observed for the series C_6F_5X (X = F, Cl, I, Br, H). Binding energies were determined from the spectra using the ESCAPLOT Program. Charge calculations were carried out using Equalization of Electronegativity, CNDO/2, and ACHARGE approaches on each molecule. The more sophisticated analysis leads to the following equation correlating the (C 1*s*) binding energies and the atomic charges q_i

$$E_i(\text{C } 1s) = 290.23 + 22.32q_i + \sum_{i \neq j} q_j/R_{ij}$$

BARRY C. TRUDELL et S. JAMES W. PRICE. Can. J. Chem. **55**, 1279 (1977).

On a observé les spectres photoélectroniques de rayons-X en phase gazeuse (XPS) pour une série de C_6F_5X (X = F, Cl, I, Br, H). On a déterminé les énergies de liaison à partir des spectres et faisant appel au programme ESCAPLOT. On a effectué des calculs de charge, pour chaque molécule, à l'aide des approaches d'égalisation d'électronégativé, CNDO/2 et ACHARGE. Les analyses les plus sophistiquées conduisent à l'équation suivante qui permet de relier les énergies de liaison (C 1*s*) et les charges atomiques q_i

$$E_i(\text{C } 1s) = 290.23 + 22.32q_i + \sum_{i \neq j} q_j/R_{ij}$$

[Traduit par le journal]

Introduction

One of the most sought after characteristics of a molecule is its charge distribution and the changes of this distribution with substitution of different groups. Until the development of XPS, the charge distributions were usually derived theoretically, but now since it has been well established that 'chemical shifts' in XPS are definitely and precisely related to the charge distributions in molecules, we can calculate the charges on atoms in a molecule using experimental data.

Several investigations of this nature have been carried out on benzene derivatives. Clark *et al.* (1, 2) have studied both the fluoro and chlorobenzenes in the frozen solid state and correlated the CNDO/2 charge distribution with observed binding energies. However such solid studies are affected by 'solid state effects', so that there is always some doubt in the analyses of the data. Thomas (3) and Davis *et al.* (4) have all studied the fluorobenzenes and Ohta and co-workers (5) have studied the monosubstituted benzenes in the gaseous state. All have studied the charge distribution in the molecules by means of XPS.

In this paper we report the XPS data for a series of monosubstituted perfluorobenzenes and will discuss the result in terms of the electrostatic potential model, equalization of electronegativity calculation, and CNDO/2 results.

[1]To whom correspondence should be addressed.

Experimental

All of the perfluorobenzenes were obtained from the Imperial Smelting Corporation. The chemicals were distilled twice, with only middle fractions taken to ensure purity. Boiling points agreed with literature values (6).

Spectra were measured using a McPherson Esca 36 spectrometer[2] employing MgK_α radiation (1253.6 eV). The sample was out-gassed by freezing and pumping, and introduced into the spectrometer by means of a needle valve. The sample pressure in the vacuum chamber was always 5×10^{-5} torr. An additional 2×10^{-5} torr of argon was added as a standard (7) (argon $2p_{3/2}$ = 248.62 eV). The actual pressure in the collision region near the inlet nozzle was probably around two orders of magnitude greater; however we were not able to measure the pressure at that point and we assume that the pressure in the vacuum chamber reflects that of the nozzle region, *i.e.* they are proportional. The spectra for each level were reproducible to within ± 0.1 eV.

Raw data from the spectrometer were converted from "odd bit" to "even bit" using a PDP11 computer and then were fed into an IBM 360/65 computer along with the ESCAPLOT program.[3] This program deconvolutes and returns data on each individual peak as well as plotting out the spectra on a Calcomp 65 plotter. All of the spectra were also plotted out by the spectrometer. The data returned by the program includes XMAX (peak position in eV), YMAX (height of peak in number of counts), FWHM (line width at half height), GFAC (gaussian fraction; the program assumes the peak to be a Gauss–Lorentz combination band), and AREA (area of the peak).

Results and Discussion

The result of taking benzene spectra at various pressures is presented in Table 1. No significant pressure effects as reported by Siegbahn *et al.* (8) could be detected in the range presented in agreement with the results of Davis *et al.* (4).The binding energies of the C_6F_5X series are reported in Table 2. A calibration of the spectrometer with C_6H_6, Ar, and CF_4 ensured the linearity of the energy scale. The linearity of the spectrometer showed a deviation not greater than ± 0.1 eV over the range 248–700 eV. Although we have reported some energy levels lower than 248.0 eV we see no reason to doubt the validity of these numbers.

Figure 1 shows (*a*) spectra plotted by the spectrometer and (*b*) the deconvoluted spectra

[2]Located at the University of Western Ontario, London, Ontario.

[3]The ESCAPLOT program accepts the modified spectrometer data (*i.e.* binding energy *vs.* number of counts) and given initial estimates of XMAX, YMAX, GFAC, and FWHM for each peak then iterates until values for XMAX, YMAX, GFAC, FWHM, and AREA are returned with a convergence criteria of 0.00001. A number of baseline types may also be chosen.

TABLE 1. C 1*s* binding energies for benzene vapor relative to Ar $2p_{3/2}$ = 284.62 eV at various pressures

Binding energies[a] (eV)	Pressure[b] (torr)
290.4	1×10^{-4}
290.4	5×10^{-5}
290.3	3×10^{-5}
290.3	1×10^{-5}
290.3	8.5×10^{-6}

[a]Values in parentheses are the uncertainties calculated by the ESCAPLOT program.
[b]All binding energies relative to argon $2p_{3/2} = 248.62$ eV.

produced by the ESCAPLOT program for the C 1*s* levels of C_6F_5I. The straight lines in the computer spectra are error bars. In addition to error calculations the program refines the binding energy values and permits comparison of peak area ratios with the theoretical values.

The values of C 1*s* (C_6H_6) and F 1*s* (C_6F_6) binding energies agree with those of Davis *et al.* (4). The C 1*s* peaks in C_6F_5X (X = H, I, Br, Cl) were assigned on the basis of peak areas which were in reasonable agreement with the theoretical value of 5:1 within the error limits.

Differences in the F 1*s* binding energies in the ortho, meta, and para positions of the molecules were too small to be detected as separate peaks. The resulting single peaks are however somewhat broader in the case of C_6F_5Cl, C_6F_5Br, and C_6F_5I.

The pattern of the chemical shifts relative to benzene for the C 1*s* levels of the carbon to which X is attached (C_1) is what one would expect, *i.e.* the shifts are in the order F > Cl > Br > I > H.

In all cases the C_1 1*s* binding energies are higher than in the equivalent C_6H_5X compound. This is presumably a result of the general environment created by the fluorine atoms and of their electron withdrawing power moderated by back donation of electron density by a +M (mesomeric) effect. When charge distributions calculated by CNDO/2 for C_6F_5H, C_6F_5Cl, and C_6F_6 are compared with those for C_6H_6, C_6H_5Cl, and C_6H_5F respectively an almost constant difference (0.08–0.09) is obtained for the C_1 carbons. This would seem to imply a fairly constant +M effect in the C_6F_5X compounds.

Equalization of Electronegativity Calculations

The method of Huheey (9) can be used to calculate partial atomic charges in molecules. In order to calculate the charge on the carbon atom bonded to X in the series C_6F_5X (X = F, Cl, Br, I, H) it is convenient to assume that the C_5F_5 part of the molecule is identical in each case. Looking at the C 1*s* and F 1*s* binding energy levels one can see little variation of the values from molecule to molecule which perhaps supports this concept.

In Huheey's method, the orbital electronegativity is defined as:

$$\chi = a + b\delta$$

where a and b are known parameters and δ is the partial charge of the atom in question. For example, for the C—Cl bond in C_6F_5Cl we have:

$$\chi_C = 8.79 + 13.67\delta_C$$

$$\chi_{Cl} = 9.38 + 11.30\delta_{Cl}$$

and

$$\delta_C + \delta_{Cl} = 0 \quad \text{(neutral molecule)}$$

$$8.79 + 13.67\delta_C = 9.38 - 11.30\delta_C$$

$$\delta_C = +0.024$$

The results for such a calculation for each molecule are shown in Table 3. These partial charges are not absolute values as those calculated by CNDO/2 or the electrostatic potential model given later, but do provide a simple good correlation with the binding energy data as shown in Fig. 2. The line of best fit for the data given, gives the following equation

[1] Partial charge = 0.0588 (Binding energy) − 17.146

CNDO/2 Calculations and Chemical Shifts

According to the electrostatic potential model, the binding energy of a core electron E_i, is given by the following equation

$$[2] \qquad E_i = E_0 + k_A q_i + \sum_{i \neq j} q_j/R_{ij}$$

when E_0 and k_A are constants dependent on the kind of atom and R_{ij} is the internuclear distance and q_i the charge. The values of these two constants have been established by Ohta (5) for monosubstituted benzenes to be 22.67 for k_A and 290.2 eV for E_0 for the carbon atoms.

TABLE 3. Relative partial charges in the carbon atom attached to X in C_6F_5X (X = H, I, Br, Cl, F)

X	δ_C	δ_C' [a]
H	−0.060	0.0
I	−0.035	0.025
Br	−0.017	0.043
Cl	0.024	0.084
F	0.109	0.169

[a]Value of δ_C C_6F_5H set equal to 0.0.

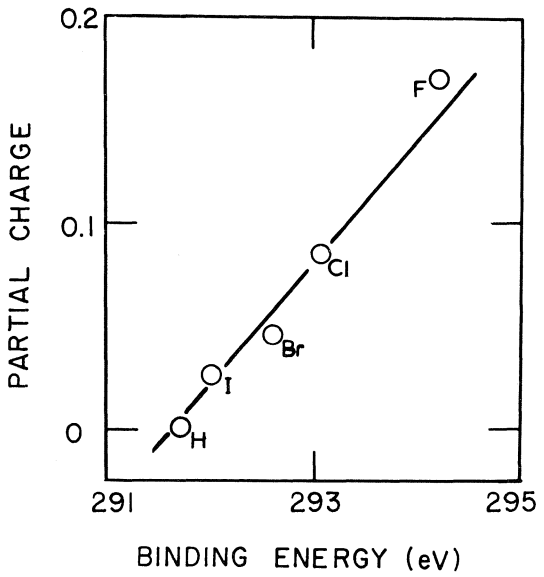

FIG. 2. Partial atomic charge on the carbon attached to X in C_6F_5X as a function of the C 1*s* binding energy of this carbon atom. Partial charge was calculated assuming a constant contribution from C_5F_5 and is expressed relative to the corresponding C 1*s* value in C_6F_5H.

Equation 2 may be rewritten in the form

$$[3] \qquad E_i - \sum_{i \neq j} q_j/R_{ij} = E_0 + k_A q_i$$

Thus a plot of the term on the left *vs.* q_i should yield a straight line with slope k_A and intercept E_0. To do this one needs q and R_{ij} values.

We have obtained the charge densities of the atoms in the series C_6F_5X (X = H, I, Br, Cl, F) using the CNDO/2 calculation. The calculation was carried out using QCPE No. 290[4] which varies the geometry of the molecule to obtain a minimum of energy. The basis set for the calculation involves 1*s* for H; 2*s*, 2*p* for C, F; 3*s*, 2*p*, 3*d* for Cl; 4*s*, 4*p*, and 3*d* for Br; and 5*s*, 5*p*, and 4*d* for I. We believe this to be the first calculation of this type on Br and I used in conjunction with XPS. The CNDO/2 charges are reported in Table 4.

Substituting the values for q_i calculated by CNDO/2 and the necessary R_{ij} one obtains the plot in Fig. 3. As can be seen the values for C_6F_5Br are far off the line. Deviations similar to this have been noted by Ohta (5) for C 1*s* cal-

[4]Developed by Dr. D. Rinaldi, Université de Nancy. Available through Quantum Chemistry Program Exchange, University of Indiana.

TABLE 4. Charge densities of  as determined by CNDO/2

Compound	Atom	Charge density	Atom	Charge density
C_6F_5I	C_1	−0.045	F_5	−0.176
	C_2	0.186	F_6	−0.166
	C_3	0.146	F_7	−0.163
	C_4	0.160	X	0.066
C_6F_5Br	C_1	−0.435	F_5	−0.245
	C_2	0.201	F_6	−0.191
	C_3	0.122	F_7	−0.190
	C_4	0.141	X	0.712

	C_2	0.208	F_6	−0.162
	C_3	0.136	F_7	−0.162
	C_4	0.174	X	0.062

culations when the group attached to the carbon atom is Cl, NO_2, or CN. Inadequate parameters for these groups in the CNDO/2 programmes were held responsible. Omitting the points for C_6F_5Br, least squares analysis of the data gives

$$[4] \quad E_i(\text{C } 1s) = 290.19 + 22.24q_i + \sum_{j \neq i} q_j/R_{ij}$$

which is in excellent agreement with Ohta's results of

$$[5] \quad E_i(\text{C } 1s) = 290.2 + 22.67q_i + \sum_{j \neq i} q_j/R_{ij}$$

for C 1*s* binding energies in benzene type systems.

Because of the discrepancies with the charge distribution in C_6F_5Br we decided to calculate the charge distribution using the electrostatic potential model.

Atomic Charge Analysis

Using chemical shift data and a knowledge of molecular geometry atomic charges may also be calculated by ACHARGE analysis (1–5). In the present cases ΔE is required for C 1*s* and F 1*s* levels.

In the preceding section we calculated the E_0 and k_A values for C 1*s* only. A variety of values

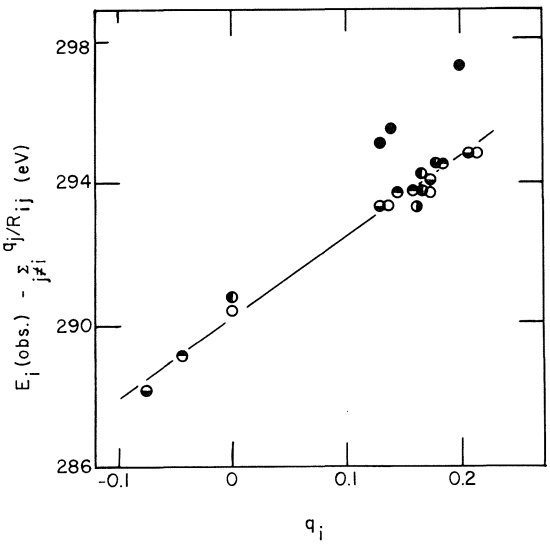

FIG. 3. Binding energies of C 1*s* electrons in C_6F_5X (X = F, Cl, Br, I, H) corrected for interatomic potentials *vs.* the charge on the respective carbon atom. ◑ C_6F_6, ○ C_6F_5Cl, ● C_6F_5Br, ○ C_6F_5I, ○ C_5F_6H. All preceding points are based on q_i values from CNDO/2 calculations. ◐ C_6F_5Br from ACHARGE.

for E_0 and k_A for F 1*s* levels has been used. We have decided to use Siegbahn's value (8) of $k_F = 35.1$ eV/e and have calculated E_0 for F 1*s* to be 697.4 eV in a method similar to that in the paper of Davis *et al.* (4). There is no need to know the E_0 and k_A values for the 'X' substituent, if we assume that

$$[6] \quad \sum_j q_j = 0$$

i.e. neutrality of the molecule. We may also reduce the problem from a 12 × 12 matrix to a 8 × 8 matrix by symmetry.

The charge densities calculated by the analyses of the C 1*s* and F 1*s* levels of the C_6F_5X series are shown in Table 5. In all of the compounds, except C_6F_5Br, there is satisfactory agreement between the ACHARGE and CNDO/2 results.

In both the ACHARGE and CNDO/2 charge calculations, the carbon atom joined to X in C_6F_5X (X = H, I, Br, Cl) is the least positive carbons in the structures in agreement with the +M effects of the fluorines. Also in the CNDO/2 charges the *o*, *p* carbons are more positive than the meta carbon consistent with this idea. The

TABLE 5. Charge densities of  as determined by ACHARGE

Molecule	Atom	Charge density	Atom	Charge density
C_6F_6	C	0.157	F	−0.157
C_6F_5Br	C_1	−0.010	F_5	−0.137
	C_2	0.176	F_6	−0.182
	C_3	0.153	F_7	−0.141
	C_4	0.152	X	−0.022
C_6F_5Cl	C_1	0.014	F_5	−0.144
	C_2	0.176	F_6	−0.190
	C_3	0.160	F_7	−0.147
	C_4	0.158	X	−0.028
C_6F_5I	C_1	−0.047	F_5	−0.131
	C_2	0.181	F_6	−0.176
	C_3	0.148	F_7	−0.136
	C_4	0.148	X	−0.007
C_6F_5H	C_1	−0.136	F_5	−0.155
	C_2	0.205	F_6	−0.200
	C_3	0.160	F_7	−0.154
	C_4	0.162	X	0.108

ACHARGE analysis does not show these trends as clearly.

In order to clarify the results of the charge calculation of C_6F_5Br, it was decided to put the ACHARGE charge densities for this molecule to an analysis identical to the CNDO/2 charges. It was found that the points calculated with the ACHARGE values fit very well on the graph on Fig. 3.

Because of the agreement between the CNDO/2 and ACHARGE calculations for every molecule except C_6F_5Br, we offer this as evidence that the CNDO/2 calculation for this molecule may be in error. It is recognized that if there are any excited state contributions to the experimental C 1*s* bonding energies this will be reflected in the ACHARGE calculation and would lead to disagreement with CNDO/2 results. However, it seems unlikely that in the series of C_6F_5X compounds studied excited state contributions in C_6F_5Br should be of such a unique character. The equation for the line derived by a least squares calculation including the points for C_6F_5Br derived from ACHARGE calculations yields the following equation

$$[7] \quad E_i(\mathrm{C}\,1s) = 290.23 + 22.32q_i + \sum_{i \neq j} q_j/R_{ij}$$

which is still in excellent agreement with previous published work on aromatic systems and quite similar to eq. 4. We regard eq. 7 as the general equation for perfluorobenzene systems.

In conclusion, it would seem that the Equalization of Electronegativity calculations, although easily carried out with good correlations with the present XPS data, provide little realistic information about the molecule. On the other hand, XPS data are used to calculate charge distributions on molecules in the ACHARGE approach and these are usually comparable to CNDO/2 calculations.

Toward an understanding of rates of crystal nucleation from solution with a variable driving force

RONALD E. MASSEY AND O. E. HILEMAN, JR.

Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received July 7, 1975[1]

RONALD E. MASSEY and O. E. HILEMAN, JR. Can. J. Chem. **55**, 1285 (1977).

'Number-time' data obtained during studies on the nucleation from aqueous solution of $CaSO_4 \cdot 2H_2O$ (gypsum) using the droplet technique and a variable driving force are reported. Sulfate ion was generated, *in situ*, by the reaction between $S_2O_8^{2-}$ and $S_2O_3^{2-}$ in the presence of Ca^{2+}. The rate of the reaction was determined from polarographic data. The stoichiometry and solubility of the precipitate in the aqueous matrix were determined.

Problems which arise during analysis of 'number-time' data obtained from droplet experiments with a large spread in individual droplet volumes and a variable driving force using techniques suggested in the literature are commented upon. A new technique was developed and applied to the analysis of our data. The effects of a non-steady state rate of nucleation, variable lag times and a decreasing cation:anion ratio on the derived results are discussed.

RONALD E. MASSEY et O. E. HILEMAN, JR. Can. J. Chem. **55**, 1285 (1977).

On rapporte des données de "nombre-temps" obtenues durant des études sur la nucléation à partir de solution aqueuse de $CaSO_4 \cdot 2H_2O$ (gypsum) utilisant la technique des gouttelettes et une force motrice variable. On a généré l'ion sulfate *in situ* par la réaction entre $S_2O_8^{2-}$ et $S_2O_3^{2-}$ en présence de Ca^{2+}. On a déterminé la vitesse de la réaction à partir de données polarographiques. On a déterminé la stoechiométrie et la solubilité du précipité dans la matrice aqueuse.

On fait des commentaires sur les problèmes qui se développent au cours de l'analyse des données de "nombre-temps" obtenues à partir d'expériences avec des gouttelettes impliquant un large éventail dans le volume des gouttelettes individuelles et une force matrice variable et utilisant les techniques suggérées dans la littérature. On a développé une nouvelle technique et on l'a appliquée à l'analyse de nos données. On discute des effets d'un état de non-équilibre de vitesse de nucléation, de temps de retard variables et d'un décroissement du rapport cation/anion sur les résultats qui en découlent.

[Traduit par le journal]

Introduction

Data obtained during nucleation studies employing miniaturization techniques are usually collected as increasing number of detected events occurring in the droplet population as a function of increasing experimental time. Interpretation of such "number-time" data has been the subject of several publications (1–5). Generally, the problem is considered from a probabilistic point of view and the results are summarized by expressions similar to [1].

$$[1] \qquad J(t_e) = \frac{1}{v}\frac{1}{N - n_{t,v}}\frac{dn_{t,v}}{dt_e}$$

where J is a theoretical rate of nucleation dependent on supersaturation and temperature but independent of matrix effects, t_e is time lapse from the initiation of the nucleation experiment, v is droplet volume, N is the total number of droplets of the same volume in a population, and $n_{t,v}$ is the total number of droplets in a population with a certain volume which contain crystals at a given time.

Variations with time of one or both of the driving force and the nucleation rate as well as a supersaturation dependent 'time-lag' limit the applicability of this type of approach. Time-dependent supersaturation levels and the "time-lag" have been considered by several authors (3, 6–8). Carte (3), for example, suggested that eq. 1 be modified into the form shown as eq. 2 for data analysis in systems with a time-dependent supersaturation.

$$[2] \qquad J(S,t_e) = \frac{1}{v}\frac{1}{N - n_{t,v}}\frac{\partial n_{t,v}}{\partial S}\frac{\partial S}{\partial t_e}$$

where S is supersaturation level = $[(\text{I.P.}) \times (K_{sp}^{-1})]^{1/2}$ (I.P. = ion product = $[Ca^{2+}][SO_4^{2-}]$).

[1]Revision received September 17, 1976.

Kashchiev (6) extended the applicability of the Zeldovich equation (9), using Szilard's scheme for embryo build-up (10), to nucleation rates and total numbers of nuclei formed in systems undergoing homogeneous nucleation at a linear time-dependent supersaturation. Frisch and Carlier (8) have presented a theoretical derivation showing the relationship between the time lag and the time-independent supersaturation being experienced by a system.

Recently, results from work in our laboratory focused on crystal nucleation from solution using modifications of Vonegut's droplet technique have revealed difficulties which arise when using interpretive schemes based on eqs. 1 and 2 and 'pooled data'. In this paper, we report a general interpretive approach applicable to "number-time" data. The new scheme is applied to the interpretation of data obtained during studies on $CaSO_4 \cdot 2H_2O$ nucleation from solution under conditions of a variable driving force and an initial non-steady state nucleation rate. The influences of a non-steady state nucleation rate and a variable time lag on the magnitude of derived macroscopic parameters are discussed.

Experimental

A droplet experiment can be divided into a series of steps: preparation of an aqueous solution containing the precursors for generation of the supersaturation; dispersion of a small, known amount of this solution in an immiscible oil; selection and subsequent preparation of a population of droplets for microscopic observation; generation of the supersaturation; notation of "number-time" data and subsequent data analysis and interpretation. Additionally, the rate of formation of the supersaturation and the equilibrium solubility of the crystalline product in the aqueous medium must be measured.

The reaction between $S_2O_3^{2-}$ and an excess of $S_2O_8^{2-}$ was used to generate SO_4^{2-}, *in situ*, in the presence of Ca^{2+}. Results obtained from polarographic analysis of 'beaker' experiments performed in parallel were used to infer supersaturation data for a droplet population. The appearance of crystals within the droplet population was recorded photomicrographically. For analysis, the 'number-time' data were separated on the basis of narrow droplet volume ranges.

Reagents and Apparatus

Reagents

All salts ($Ca(NO_3)_2 \cdot 4H_2O$ (Baker), $K_2S_2O_8$ (Allied), $Na_2S_2O_3 \cdot 5H_2O$ (BDH), and EDTA (Fisher)) were of 'Reagent grade' quality. Solutions prepared from them were pressure filtered (N_2) through a 0.3 μ PVC filter (Sartorius). Solution 'A' was prepared by mixing, immediately before use, equal volumes of the $Ca(NO_3)_2 \cdot 4H_2O$ and the $K_2S_2O_8$ solutions. Solution 'B' contained $Na_2S_2O_3$. Light and heavy mineral oils (BDH) were used as supplied.

Apparatus

Dispersions of the aqueous solutions were made with the aid of a Virtis micro-homogenizer (Fisher) in a 6 ml homogenizing flask.

Isolation of certain droplet size ranges was accomplished by using a centrifuge (International Clinical Centrifuge) and a 15 ml centrifuge tube.

The observation vessel was a Nessler cup of 31 mm OD, 26 mm height with an optically flat bottom. The inside bottom surface was made hydrophobic with a coating of Drifilm SC-87 (Pierce Chemical Co.).

One of the two microscopes used was a Vickers M15 polarizing microscope (Vickers Instruments) with a magnification of 75× (5× objective, 10× eyepiece, 1½× analyser). The light source was a 500 W super-high pressure mercury vapour lamp (Philips Electronics). Cooling water was pumped through a water jacket housing the lamp and primary condenser; the polarizer was protected by two heat absorbing filters. The other microscope used was a Vickers M41 (Vickers Instruments) with a magnification of 200× (250×) (20× objective, 10× eyepiece, 1.00× (1.25×) analyser). The light source was a 12 V, 100 W tungsten–halogen lamp (Philips Electronics). The lamp unit had its own heat and light filters. A dark field illumination technique was used.

Nessler cups were fitted into cell holders, then placed onto a micrometer stage (Vickers Instruments) equipped with a micrometer dial of range 0.01 to 20 mm.

A thermostatted cell holder, which would hold a Nessler cup, was manufactured from an aluminum rod (Fig. 1). A tight fitting O-ring was attached to the Nessler cup before it was placed in the cell holder. An outside collar, with an opening greater than the diameter of the Nessler cup, was screwed down thereby forcing the O-ring onto a lip and sealing the inner compartment formed by the walls of the Nessler cup and the cell holder.

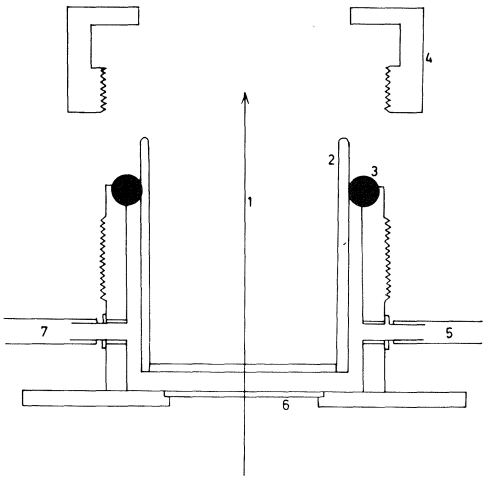

FIG. 1. The thermostatted cell holder for droplet observation under the microscope. *1*, optical axis; *2*, Nessler cup; *3*, O ring; *4*, collar; *5*, inlet; *6*, window; *7*, outlet.

TABLE 1. Summary of experimental conditions for nucleation experiments

Experiment[a]	Concentration (mol/ℓ)						
	Ca^{2+}	$S_2O_8^{2-}$	$S_2O_3^{2-}$	K^+	Na^+	NO_3^-	μ^b
E_1	0.250	0.100	0.250	0.200	0.500	0.500	1.80
E_2	0.475	0.157	0.433	0.314	0.866	0.950	3.20

[a]Experiments performed at 295 ± 1 K.
[b]μ = ionic strength of the solution from which the crystals formed.

Thermostatted water was passed through this compartment via nozzles placed directly opposite each other. The base of the cell holder was formed from an aluminum plate, with a 25 mm diameter window into which a thin quartz circular cover glass was affixed.

The camera, an Autowind 35 mm (Vickers Instruments), was controlled by an autoexposure unit J-35 (Vickers Instruments). Ansochrome D-500 and D-200 colour reversal film (G.A.F.) was used.

The photomicrographs were projected onto a pinboard (60 × 90 cm) using a Pradovit projector (Lietz), equipped with either a 150 mm or a 50 mm lens, and a Ansochrome 940 projector (G.A.F.), equipped with a 150 mm lens.

Solubility of $CaSO_4 \cdot 2H_2O$

A synthetic matrix was prepared which contained 0.2 *M* $Na_2S_4O_6$ and 0.05 *M* $Na_2S_2O_3$. An excess of freshly prepared $CaSO_4 \cdot 2H_2O$ was added, the solution was stirred for 24 h, then pressure filtered. Aliquots of the resulting filtrate were titrated with 0.0100 *M* EDTA to an EBT end point.

Determination of Supersaturation Data

The rate of change in the thiosulfate concentration in solution was determined polarographically using the free dissolution wave of Hg ($E_{1/2} = -0.2$ V *vs.* SCE) as the indicator. The sulfate ion concentration was calculated from the resulting data.

Calibration

A thiosulfate solution was prepared and standardized against $K_2Cr_2O_7$. Exactly 0, 5, 10, 20 and 25 ml portions of this solution were pipetted into separate 250 ml volumetric flasks containing approximately 200 ml of KNO_3 solution, enough $S_2O_8^{2-}$ to duplicate the initial conditions of each experiment, and Triton-X100. After dilution to volume the polarograms were determined over a range of +0.1 to −0.5 V *vs.* SCE.

Procedure

Solutions A and B, previously described, were mixed and at certain time intervals 3.0 ml of the solution were transferred into separate 250 ml volumetric flasks containing 200 ml of water to quench the reaction. After addition of KNO_3 and Triton-X100 and upon dilution to volume, the polarograms of these solutions were recorded. The diffusion current of each solution was measured at the same potential as the calibration standards. The diffusion current of the first aliquot was observed initially and was subsequently recorded over a period of 2 h.

Droplet Experiments

The following procedure was used to prepare a large population of non-communicating droplets. The population must exhibit a narrow volume range and, to aid in microscopic observation of events taking place within it, the population should be situated on an optically flat surface. The experimental conditions used are summarized in Table 1.

Procedure

Both solution A, containing calcium and peroxydisulfate, and solution B, containing thiosulfate, were pressure filtered through a 0.3 μ PVC filter. Equal aliquots of each were withdrawn, combined together and thoroughly mixed. This solution was drawn into a dropping pipette and 2 drops of it were placed in a 6 ml homogenizing flask containing 5 ml of light mineral oil. The solution was dispersed by means of a microhomogenizer rotating at approximately 40 000 rpm for 10 s. The contents of the homogenizing flask were then poured into a 15 ml centrifuge tube containing 11 ml of heavy mineral oil. This mixture was rotated at 4000 rpm in a centrifuge for 2–5 min. An eye dropper was used to transfer 3–4 ml of the mixture to the bottom of a Nessler cup which contained 1 ml of the heavier oil. The cup and contents were rotated at 4000 rpm for 3–4 min and then the oil was decanted off until a depth of 3 mm remained.

The observation cup was placed in a cell holder on the microscope stage and fields of view were selected for observation. Micrometer dial settings for each field of view were noted so that accurate readjustment for observation of multiple fields of view was possible.

Each field of view was photographed and the time, relative to experimental time zero, was recorded. Data recording was terminated when most of the droplets contained crystals or at the lapse of a predetermined time interval. Finally, a photograph was taken of a millimeter slide using the same magnification factor.

Data Collection

The 35 mm slides were sorted into fields of view, arranged into correct time sequence, labelled, and mounted in trays. The absolute droplet sizes were measured by comparing observed diameters with the distance measured between rulings on the projected millimeter slide.

A slide showing all the droplets from one field of view was projected on the screen and the droplet population was divided into volume ranges. The droplets in each range were identified with pins of a specific colour. All the slides taken of the one field of view were then projected in correct time sequence. As each slide was displayed, a search was made for those droplets which contained a crystal not visible in the previous slide. If such a droplet were found, the pin associated with it was removed and placed in a container holding all those

removed for that particular slide. This procedure was repeated for all slides in all fields of view.

The data observed from corresponding volumes and times from all fields of view were combined. These data were then summed over time to give $n_{t,v}$, the total number of droplets of volume 'v' containing crystals at time 't_e'.

Results

Preliminary experiments established $CaSO_4 \cdot 2H_2O$ to be the sparingly soluble product of reaction between $S_2O_3^{2-}$ and $S_2O_8^{2-}$ in the presence of Ca^{2+}. The measured K_{sp} value for $CaSO_4 \cdot 2H_2O$ at 295 ± 1 K was found to be invariant, within experimental error, as the ionic strength of the aqueous matrix changed from 1.80 to 3.20. Thus, an average value of 8.47×10^{-4} was used in the calculation of the supersaturation levels reported in this study.

Supersaturation *vs.* time data calculated from results of the polarographic determination of $S_2O_3^{2-}$ concentration levels in bulk reaction mixtures are shown in Fig. 2. The maximum supersaturation attained for experiments E_1 and E_2 was found to be 7.7 and 13, respectively. These supersaturation values were obtained at an ionic strength of 1.80 (E_1) and 3.20 (E_2).

Typical results selected from droplet experiments performed under each set of experimental conditions listed in Table 1 are shown as $n_{t,v}/N$ *vs.* time curves in Figs. 3 and 4. The data for each curve are taken from one experimental run with the total population divided into several volume ranges. For statistical reasons, the minimum population for each volume range required for subsequent data analysis was 100 droplets; data arising from volume ranges with fewer than 100 droplets were disregarded.

Discussion

Bigg (2) suggests that $n_{t,v}$ *vs.* time data collected by observation of nucleation events in a droplet population comprised of a multiplicity of individual droplet volumes may be combined if the mean crystallization time in each volume range is reduced to that of a droplet of standard size. From the following argument, in contrast, we conclude that rate calculations must be performed within each individual volume range.

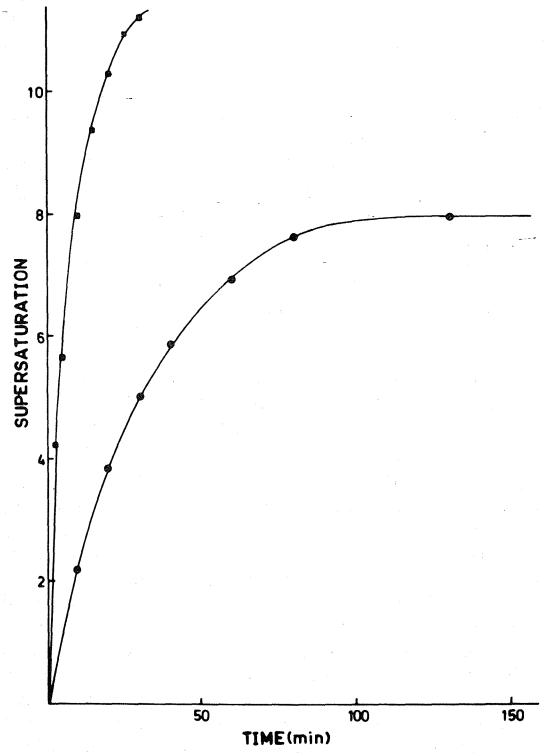

FIG. 2. Plots of the supersaturation *vs.* time for experiments E_1 and E_2: ● = E_1, ■ = E_2.

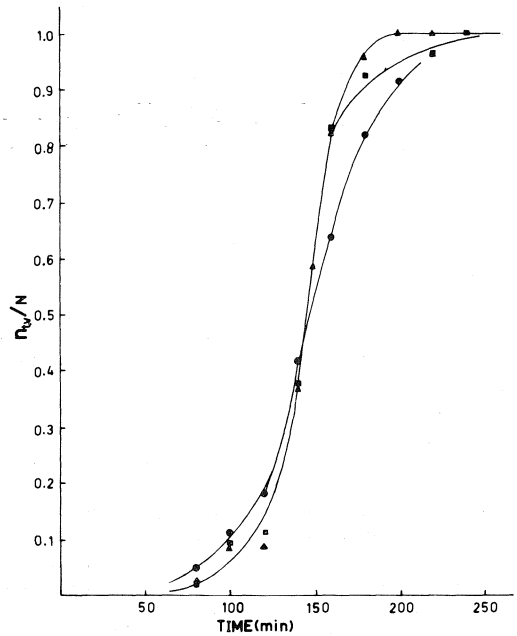

FIG. 3. Plots of $n_{t,v}/N$ *vs.* time measured for three volume ranges in experiment E_1. Legend: ●, $v = 2.57 \times 10^{-9}$ cm^3; ■, $v = 4.85 \times 10^{-9}$ cm^3; ▲, $v = 8.18 \times 10^{-9}$ cm^3.

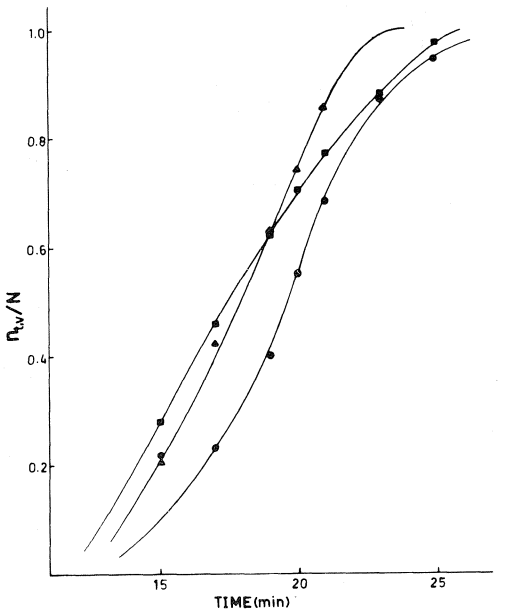

FIG. 4. Plots of $n_{t,v}/N$ *vs.* time measured for three volume ranges in experiment E_2. Legend: ●, $v = 5.24 \times 10^{-10}$ cm^3; ■, $v = 4.19 \times 10^{-9}$ cm^3; ▲, $v = 1.41 \times 10^{-8}$ cm^3.

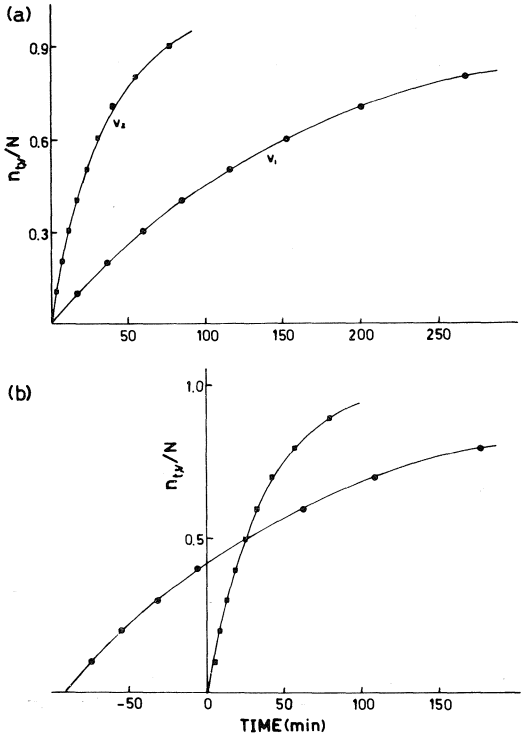

FIG. 5. (*a*) The $n_{t,v}/N$ *vs.* time plots of two droplet populations v_1 and v_2. (*b*) The mean crystallization time of v_1 reduced to that of v_2. Legend: ●, $v_1 = 1.0 \times 10^{-10}$ cm^3; ■, $v_2 = 5.0 \times 10^{-10}$ cm^3.

If the supersaturation is constant during the nucleation experiment, eq. 1 may be integrated over time to give eq. 3.

$$[3] \qquad n_{t,v} = N[1 - \exp(-Jvt_e)]$$

By setting $J = 10^6$ cm^{-3} s^{-1}, selecting various values of v and using [3], hypothetical 'number-time' data for each droplet volume range can be generated. Sample data for $v_1 = 1 \times 10^{-10}$ cm^3 and $v_2 = 5 \times 10^{-10}$ cm^3 are shown in Fig. 5*a*. The mean crystallization time, defined as that point in experimental time when $n_{t,v}/N = 0.5$, for these data is 6930 s for v_1 and 1380 s for v_2. The curve labelled v_1 in Fig. 5 was shifted along the time axis using the procedure suggested by Bigg (2): 5550 s were subtracted from all t_e values. The result is shown as Fig. 5*b*. Summation of the two curves in this figure produces a distorted, S-shaped curve with an apparent initial non-steady state rate of nucleation even though the data were generated assuming a steady-state rate. Such manipulations, therefore, do not seem to be useful as the basis of a scheme for the analysis and interpretation of number-time data obtained from experiments with droplet populations made up of diverse individual volumes. In this study, the data observed for the individual volume ranges were not combined together for subsequent data analysis and parameter estimation.

More serious problems arise in the interpretation of number-time data if the supersaturation level being experienced by the system significantly changes with time during the nucleation experiment. A suggested scheme for the analysis of data gathered under this condition follows.

Figure 6 depicts, in three dimensions, the inter-relationships between the laboratory observables $n_{t,v}$, S, and t_e during a hypothetical nucleation experiment that has such a variable driving force. A dummy variable, z, is introduced for ease of algebraic manipulation. The vector components of dn_z, the tangential vector, are $dn_{t,v}$, dS, and dt_e. The orthogonal projection of dn_z onto the S,t_e plane is dz. If the angle between dz and dt_e is θ, the following trigonometric relations will then hold:

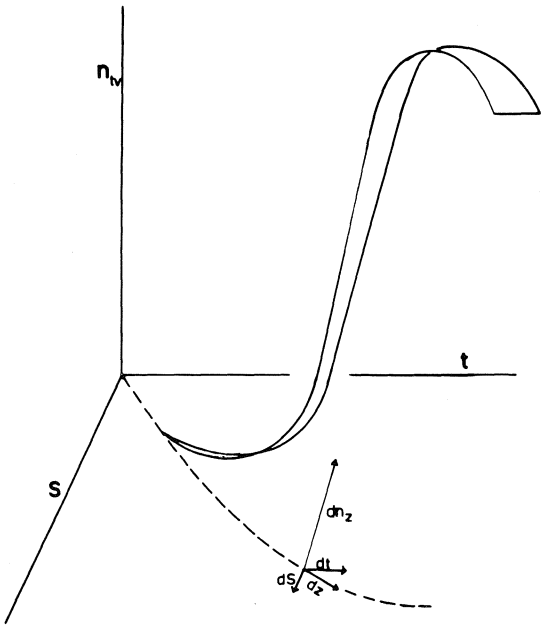

FIG. 6. The inter-relationships between $n_{t,v}$, t, and S in an experiment that has a variable driving force.

$$\frac{dt_e}{dz} = \cos\theta$$

$$\frac{dS}{dz} = \sin\theta$$

$$\frac{dS}{dt_e} = \tan\theta$$

A dimensional analysis of the above relations suggests that dt_e, dS, and dz must be dimensionless. Thus a dimensionless quantity 't' is introduced such that

$$t = \frac{t_e}{t_{0.5} - t_0}$$

where t_0 is the time (t_e) at which the curve given by eq. 3 fitted to the steady state portion of the $n_{t,v}/N$ *vs.* t_e curve intersects the t_e axis, and $t_{0.5}$ is the time (t_e) at which $n_{t,v}/N$ attained a value of 0.5. Then,

[4] $$\frac{dn_{t,v}}{dz} = \frac{\partial n_{t,v}}{\partial t}\cos\theta = \frac{\partial n_{t,v}}{\partial t}\left[\left(\frac{dS}{dt}\right)^2 + 1\right]^{-1/2}$$

and

[5] $$\frac{dn_{t,v}}{dz} = \frac{\partial n_{t,v}}{\partial S}\sin\theta = \frac{\partial n_{t,v}}{\partial S}\left[\left(\frac{dS}{dt}\right)^{-2} + 1\right]^{-1/2}$$

To an observer in the S,t plane the rate of nucleation would appear to obey eq. 6.

[6] $$J'(z) = \frac{1}{v}\frac{1}{N - n_{t,v}}\frac{dn_{t,v}}{dz}$$

where J' = an experimental rate of nucleation calculated from each datum point on the $n_{t,v}/N$ *vs.* time curve which reflects the effects of variable non-steady state rates, cation:anion ratios, lag times, and other matrix effects.

Substitution, in turn, of eqs. 4 and 5 into eq. 6 yields, respectively,

[7] $$J'(S,t) = \frac{1}{v}\frac{1}{N - n_{t,v}}\frac{\partial n_{t,v}}{\partial t} \times \left[\left(\frac{dS}{dt}\right)^2 + 1\right]^{-1/2}$$

and

[8] $$J'(S,t) = \frac{1}{v}\frac{1}{N - n_{t,v}}\frac{\partial n_{t,v}}{\partial S} \times \left[\left(\frac{dS}{dt}\right)^{-2} + 1\right]^{-1/2}$$

At very low dS/dt, that is, as $[(dS/dt)^2 + 1]^{-1/2}$ approaches one, and as $[(dS/dt)^{-2} + 1]^{-1/2}$ approaches dS/dt, eqs. 7 and 8 reduce to eqs. 9 and 10 respectively.

[9] $$J'(t) = \frac{1}{v}\frac{1}{N - n_{t,v}}\frac{\partial n_{t,v}}{\partial t}$$

[10] $$J'(S,t) = \frac{1}{v}\frac{1}{N - n_{t,v}}\frac{\partial n_{t,v}}{\partial S}\frac{dS}{dt}$$

At very high dS/dt, that is as $[(dS/dt)^2 + 1]^{-1/2}$ approaches (dt/dS), and as $[(dS/dt)^{-2} + 1]^{-1/2}$ approaches one, eqs. 7 and 8 reduce to eqs. 11 and 12 respectively.

[11] $$J'(S,t) = \frac{1}{v}\frac{1}{N - n_{t,v}}\frac{\partial n_{t,v}}{\partial t}\frac{dt}{dS}$$

[12] $$J'(S) = \frac{1}{v}\frac{1}{N - n_{t,v}}\frac{\partial n_{t,v}}{\partial S}$$

Equation 2, therefore, is a special case of a more general expression for the rate of nucleation with a variable driving force. And, compared with

TABLE 2. Selected data for experiments E_1 and E_2

Parameter	Value					
	E_1			E_2		
	v_1	v_2	v_3	v_1	v_2	v_3
V (cm^3)	2.57×10^{-9}	4.85×10^{-9}	8.18×10^{-9}	5.24×10^{-10}	4.19×10^{-9}	1.41×10^{-8}
t_0 (s)	6540	7380	7380	987	732	834

$J_f'v$ (s^{-1})[b]	6.6×10^{-4}	5.1×10^{-4}	1.3×10^{-3}	6.8×10^{-3}	6.2×10^{-3}	5.1×10^{-3}

[a]These values taken at the t_0 time for each volume range.
[b]J_f' is an experimental rate of nucleation calculated by fitting eq. 3 to the 'number-time' data which reflects the effect of variable non-steady state rates, cation:anion ratios, lag times, and other matrix effects.

eq. 9, it is less appropriate for use in data analysis because of the errors introduced by multiplying together a large number $\partial n_{t,v}/\partial S$ and a small number dS/dt.

Shown in Table 2 are the data required for the calculation of a dimensionless time scale and the selection of an appropriate model to be used in the calculation of J' for three typical volume ranges in each of experiments E_1 and E_2. Best values of $J_f'v$ estimated by fitting [3] to the data are also included in Table 2.

Experiment E_1 was performed under conditions of low dS/dt (Table 2); hence eq. 9 was used to calculate values of J'. These values coupled with S *vs.* time data were used to prepare the E_1 plots in Figs. 7 and 8. Experiment E_2 was performed under conditions of moderate dS/dt (Table 2); hence neither set of approximate relations, eqs. 9 and 10 nor eqs. 11 and 12, would appear appropriate for the calculation of J' values. But, owing to the scatter in the 'number-time' data, the slope and intercept values of the ln J' *vs.* $(\ln S)^{-2}$ and ln J' *vs.* ln S plots prepared using J' values calculated with eq. 7 did not exhibit statistically significant differences from these parameters of the same plots prepared using J' values calculated with eq. 9. Consequently the E_2 plots in Figs. 7 and 8 were prepared from J' values calculated using eq. 9.

The apparent discrepancy within the parameters listed in Table 3, derived from the $n_{t,v}/N$ *vs.* time data collected under conditions of low dS/dt (E_1) and moderate dS/dt (E_2) must arise from additional factors not included in the

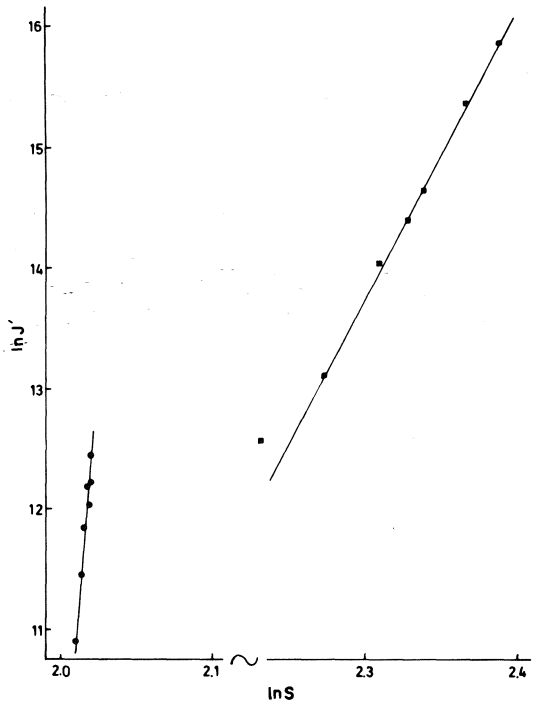

FIG. 7. Plots of ln J' *vs.* ln S for experiments E_1 and E_2: ● = E_1, ■ = E_2.

model. Some of these factors may be: changing Ca^{2+}:SO_4^{2-} ratios during an experiment, non-steady state rates of nucleation, and changing lag times.

Calcium ion was in excess from the beginning of each experiment but the Ca^{2+}:SO_4^{2-} ratio approached one as the experiments proceeded. In a subsequent report, it will be shown that the nucleation rate at any one ion product varies with the Ca^{2+}:SO_4^{2-} ratio. Measurement of the rate of nucleation as the cation:anion ratio was decreasing had the effect of increasing the slope of the ln J' *vs.* (ln S)$^{-2}$ plot. The curve would also be shifted upwards if the critical supersaturation were reached simultaneously with that Ca^{2+}:SO_4^{2-} ratio which gives a maximum rate.

Non-steady state rates of nucleation of $CaSO_4 \cdot 2H_2O$ generally occurred at very low supersaturations and high values of the Ca^{2+}:SO_4^{2-} ratio. This effectively lengthened the lag time.

Large, but rapidly decreasing, lag times resulting from low, but increasing, supersaturations that exist early in variable driving force experiments are a major source of uncertainty in the analysis of 'number-time' data. Frisch and Carlier (8) have shown that the lag time is a complex function of (ln S)$^{-2}$; thus, our calculated nucleation rates correspond to S measurements of a prior time and this gap increases at lower supersaturation levels. The gap narrows as S increases and eventually becomes negligible.

'Number-time' data will exhibit the influence of a changing lag time during their collection through deviations in both the shape of the $n_{t,v}/N$ *vs.* time curve and the apparent lag time from those expected when S is not changing. These deviations lead to an ever decreasing underestimation of J at increasing values of S; this results in non-linear ln J' *vs.* (ln S)$^{-2}$ curves and overestimation of σ, ΔG^*, S^*, and A (σ = a surface energy, ΔG^* = critical free energy of an embryo, S^* = a critical supersaturation, and A = pre-exponential factor). The data of Table 3 tend to confirm this.

The design of successful nucleation from solution experiments employing a variable driving force depends upon a comparison between the effects of supersaturation and the rate of change of supersaturation on the laboratory observables. The former effects become significant as supersaturation increases whereas the latter are major at lower supersaturations. In most cases, then, it is necessary to achieve some optimum balance between the two. Con-

sequently for our studies on calcium sulfate nucleation from solution using a variable driving force, it seems necessary to generate high final supersaturation levels rapidly thereby causing negligible lag times and non-steady state rate effects.

Polymorphism in phenol under pressure: dielectric properties and molar polarizations of polycrystalline phenol I and II

JOHN E. BERTIE AND PETER R. TREMAINE[1]

Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received November 12, 1976

JOHN E. BERTIE and PETER R. TREMAINE. Can. J. Chem. **55**, 1294 (1977).

The dielectric properties of phenol I have been measured as isothermal functions of pressure between 140 and 1520 bar and between +35 and −10°C. No dielectric relaxation was observed. The static (50 kHz) permittivity at 10°C is given with a precision of 0.3% by

$$\varepsilon_0' = 2.882 + 4.4 \times 10^{-5}P - 3 \times 10^{-9}P^2$$

where P is in bar. The extrapolated value at 1 bar is 2.882 ± 0.009 which compares with literature values between 2.74 and 2.84. The 50 kHz molar polarization, $\bar{P}$, at 10°C is given by

$$\bar{P}/\text{cm}^3 = 20.30 + 11.75\ V/V_0$$

where V and V_0 are the molar volumes at pressures P and 1 bar, respectively. At 10°C and 1 bar, the electronic and atomic polarizations are estimated to be 26.9 ± 0.3 cm³ and 5.1 ± 0.4 cm³, respectively. Expressions for the isobaric temperature dependence of ε_0' are reported for several pressures. Below 1500 bar, $(\partial\varepsilon_0'/\partial T)_P$ is negative, as expected from the density change but in contrast with previous results and with results obtained while varying the temperature under a constant applied pressure of 1 kbar. The accuracy of the temperature dependence at 1 bar is not high, judging from the thermal expansivity calculated from it.

ε_0' of phenol II at 10°C and an estimated pressure of 2000 bar is 3.10 ± 0.06, with the corresponding molar polarization 30.75 ± 0.5 cm³. No intrinsic dielectric relaxation was observed in phenol II and the molar polarization shows no marked discontinuity at the transition. Phenol II is, therefore, like phenol I, a hydrogen-bonded solid in which the hydroxyl hydrogen atoms are ordered, either fully or in chains. The dielectric parameters and Arrhenius activation energies of two transient dispersions which appeared whenever phenol II formed are discussed.

JOHN E. BERTIE et PETER R. TREMAINE. Can. J. Chem, **55**, 1294 (1977).

On a mesuré les propriétés diélectriques du phénol I comme une fonction isotherme de la pression entre 140 et 1520 bar et entre +35 et −10°C. On n'a observé aucune relaxation diélectrique. On rapporte la permitivité statique (50 kHz) à 10°C avec une précision de 0.3% par l'équation

$$\varepsilon_0' = 2.882 + 4.4 \times 10^{-5}P - 3 \times 10^{-9}P^2$$

où P est exprimé en bar. La valeur extrapolée à 1 bar est de 2.882 ± 0.009 qui se compare avec les valeurs de 2.74 à 2.84 trouvées dans la littérature. La polarisation molaire 50 kHz, $\bar{P}$, à 10°C est représentée par l'équation

$$\bar{P}/\text{cm}^3 = 20.30 + 11.75\ V/V_0$$

où V et V_0 représentent les volumes molaires respectivement aux pressions P et 1 bar. A 10°C et une bar, on estime que les polarisations électroniques et atomiques sont respectivement de 26.9 ± 0.3 cm³ et 5.1 ± 0.4 cm³. On rapporte pour plusieurs pressions des expressions pour la relation isobarique entre la température et ε_0'. Tel que prévu à partir des changements de densité mais en opposition avec les résultats antérieurs et les résultats obtenus lorsque l'on fait varier la température à pression appliquée constante de 1 kbar, la valeur de $(\partial\varepsilon_0'/\partial T)_P$ est négative en dessous de 1500 bar. La précision de la dépendance sur la température à 1 bar n'est pas élevée si l'on en juge à partir de l'expansivité thermique que l'on peut calculer à partir de cette valeur.

ε_0' du phénol II à 10°C et une pression estimée de 2000 bar est de 3.10 ± 0.06 avec une polarisation molaire correspondante de 30.75 ± 0.5 cm³. On n'a observé aucune relaxation diélectrique intrinsèque dans le phénol II et la polarisation molaire ne montre aucune discontinuité importante au niveau de la transition. Le phénol II est donc, comme le phénol I, un

solide lié par des ponts hydrogène dans lesquels les atomes de l'hydrogène de l'hydroxyle sont ordonnés soit complètement soit en chaînes. On discute des paramètres diélectriques et des énergies d'activation d'Arrhénius des deux dispersions transitoires qui apparaissent chaque fois que la phénol II est formé.

[Traduit par le journal]

Introduction

The literature concerning the physico-chemical properties and polymorphs of phenol under pressure has been summarized in previous papers (1, 2) which presented results from this study (3).[2] This paper reports the dielectric properties at frequencies below 100 kHz of polycrystalline phenol I and its high pressure polymorph phenol II. Specifically, the static (50 kHz) dielectric permittivity is reported for phenol I at temperatures between -10 and ± 35°C and pressures up to 1.5 kbar, and for phenol II at 10°C and 2 kbar. The corresponding molar polarizations, or Clausius–Mossotti functions, are reported for each phase at 10°C. Also reported are the parameters of two transient dispersions which appeared after the phenol I to II transition had occurred.

The dielectric properties of phenol under pressure have not been studied previously. The dielectric constant of phenol I at atmospheric pressure has been reported to increase slightly with decreasing frequency between 60 and 0.2 kHz (4–6), undoubtedly due to space charge polarization effects (7–9), and to decrease (4, 5), or to remain essentially constant (6), with decreasing temperature from a value of 2.79 $\pm$ 0.05 at $+10$°C and 50 to 60 kHz (4, 5). Although exceptions are known (10–12) the dielectric constant of a solid is expected to increase as the density increases with decreasing temperature (13), but the temperature dependence reported (4–6) for phenol is commonly observed when the solid is at atmospheric pressure because of the formation of cracks in the sample (13–15). The correct temperature dependence can be obtained if the solid is above atmospheric pressure (14, 15).

Experimental

Analar analytical reagent grade phenol was purified in evacuated glass tubes, by directional freezing followed by zone refining in the dark (3). Like Timmermans and Hennaut-Roland (16) we found the melting point to be an unreliable criterion of purity. The purified samples contained less than 0.02 weight percent of water (Karl Fischer titration). The sodium-D line refractive index of the purified samples was 1.5401 at 45.6°C compared with 1.5404 for the commercial product, both measured in a dry atmosphere to an estimated accuracy of ± 0.0001. Timmermans' (16) value is 1.5400. The specific conductivity at 10 kHz decreased from 3.5×10^{-5} μmho cm^{-1} for the commercial product to less than 1.5×10^{-5} μmho cm^{-1} after purification. Mallinckrodt analytical reagent grade phenol was found to be distinctly less pure than the Analar phenol by the above criteria but the samples purified from the two commercial products were identical.

Two piston and cylinder, three terminal, high-pressure dielectric cells were used in conjunction with the 20 ton press which, with the pressure calibration, has been described (1). The coaxial dielectric cell was similar to that described by Whalley *et al.* (17), and is shown in Fig. 1. The cylinder and all steel parts were of Vascomax 350, 18% Ni maraging steel, heat treated to 54 Rockwell C. The taper on electrode a reduced the considerable nonuniformity of the pressure in the cell. Electrode a was joined to its support b by epoxy resin about a mica insulator, which formed an 'unsupported area' pressure seal (18). The two brass backing rings between parts g and h were 0.030 in. apart in the middle of the annulus. The nonconducting coolant which filled the thermostat jacket j was kerosene, either pure or mixed with Skelly C petroleum ether for temperatures below -20°C. The temperature was measured by a calibrated (1) (to ± 0.1°C) thermocouple set in a copper block clamped around the cylinder The parallel-plate cell was that described previously (1), slightly modified to reduce the 'dead space', *i.e.* the cell volume when the electrodes touch, and to reduce intrusion of the sample between the electrodes and the pistons. This cell was thermostatted and its temperature was measured in the way described for the coaxial cell. Temperature gradients were found to occur across both cells and, consequently, the temperatures are only accurate to ± 0.5°C at -40°C and ± 0.1°C at $+10$°C.

Capacitance and conductance were measured by a General Radio 1615A capacitance bridge in conjunction with a General Radio 1310B oscillator, a Rhode and Schwartz UBM tunable indicating amplifier, and a Hewlett-Packard 5321B frequency counter. All connections were coaxial cable whose shields were joined to the common ground of the capacitance bridge through General Radio 847 connectors. The bridge was calibrated against a General Radio 1404B, 100 pF reference standard capacitor, and reproduced the capacitances of a factory-calibrated General Radio 1422CD precision variable capacitor to within 0.003 pF in the 1 to 20 pF capacitance range used in this work. The factory calibration of the dissipation factor, D, and conductance, G, controls was used; values of the dielectric loss calculated from D agreed with those calculated from G to within 1%.

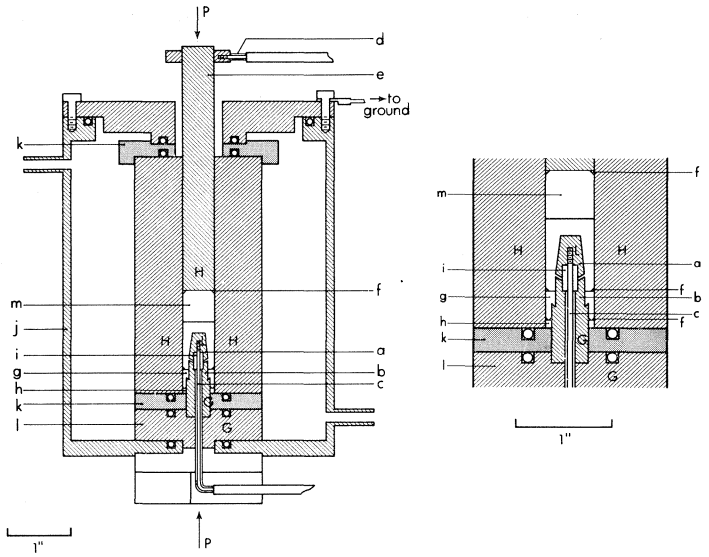

FIG. 1. The coaxial, three terminal, high-pressure dielectric cell. The letters indicate: H, L, G, high, low, and ground potentials; a, steel electrode; b, steel support and guard electrode; c, teflon-insulated low potential lead; d, high potential lead; e, steel piston; f, brass backing ring; g, teflon support; h, bakelite support; i, teflon cylinder; j, stainless steel thermostat jacket; k, bakelite discs; l, steel support disc; m, teflon plug; p, applied pressure. The open circles are Buna-N O-rings.

Cell Constants

Calibration of the coaxial cell with Baker, and Eastman, spectrograde carbon tetrachloride and cyclohexane as dielectric constant standards (19) showed the lead capacitance to be negligible. Therefore the cell constant at atmospheric pressure, about 1 pF, was measured with the cell containing air. This was done at each frequency, because the bridge calibration changed by about 0.8% from 20 to 100 kHz. The cell constant was independent of temperature to within 0.05% between 10 and 35°C and was assumed to remain so to −10°C. The cell constant was also constant provided the top piston was at least 0.5 in. away from the top of the central electrode, a in Fig. 1. The piston was therefore kept 0.75 in. away from the central electrode and the 0.5 in. long teflon plug, m, was used to minimize friction.

The pressure dependence of the coaxial cell constant was calculated from the values 29.1×10^6 p.s.i., 0.26, and 7.17×10^{-7} bar^{-1} for Youngs modulus (20), Poisson's ratio (20), and the compressibility (21), respectively, of the maraging steel. The formula (22)

$$\frac{C}{C_0} = \frac{L}{L_0}\frac{\log (a_0/r_0)}{\log (a/r)}$$

was used, where C, L, r, and a denote the cell constant, length and radius of the inner electrode (a in Fig. 1), and the radius of the bore of the pressure vessel, respectively, at pressure P, and the subscripted entries denote the corresponding atmospheric pressure values. The pressure expansion of the bore of the pressure vessel, $a - a_0$, was taken as 0.75 of the ideal elastic expansion which was calculated as described previously (2). The factor 0.75 was selected because the sample's length-to-radius ratio was 2.8 in the coaxial cell compared with 0.5 in the compression cell for which the factor was, experimentally (2), 0.38. An error of ±0.25 in this factor causes errors of 0.03% and 0.08% in the cell constants at 1000 and 3000 bar, respectively. The length and radius of the inner electrode at pressure P were calculated by multiplying the atmospheric pressure values by $(1 - \beta P/3)$, where β is the compressibility. The radius of the inner electrode varied uniformly from 0.146 in. to 0.115 in. over its length; this electrode was regarded as n cylindrical electrodes in parallel, and $n = 10$ gave sufficient precision. C_0/C varied essentially linearly with pressure and was 1.00288 at 2000 bar.

The cell constant of the parallel-plate cell was only required for +10°C. The capacitance of this cell containing a sample of dielectric constant ε is (23)

$$C = 8.854 \times 10^{-2}\, \varepsilon A/S \text{ pF}$$

The area of the guarded electrode, A (cm^2), was determined from the cell dimensions and was assumed to be independent of pressure. The distance between the electrodes, S (cm), was determined at 750 bar from the measured capacitance and the dielectric constant of phenol at 750 bar and 10°C which was determined using the coaxial cell. The volume of phenol present at 750 bar was calculated from the equation

$$V_{750} = \pi a_{750}^2 S + k$$

where a_{750} is the radius of the bore of the pressure vessel at 750 bar and k is the dead space. k was calculated from the cell dimensions to be 0.11068 ± 0.00010 cm^3 and was assumed to be independent of pressure. The radius, a_{750}, was calculated from the atmospheric pressure value as described previously (2), using 0.38 of ideal elastic expansion because the length-to-radius ratio of the dielec-

[a] P is the pressure in bar.
[b] The data were taken after phenol II had been formed and transformed back to phenol I, and ε was smaller than at 6.5 and 24.5°C indicating that the cell constant had changed in the transitions. The data were corrected by multiplying by 1.00183, on the assumption that ε at 750 bar varies linearly with temperature between 6.5 and 24.5°C.

tric sample was close to that of the compression sample (2). At other pressures, P, the volume of the sample was calculated from the compression results (2) so the dielectric constant was calculated from the equation

$$\varepsilon_P = \varepsilon_{750}(C_P/C_{750})[(V_P - k)/(V_{750} - k)](a_{750}^2/a_P^2)$$

where C_P and C_{750} are the capacitances of the cell at P and 750 bar, respectively.

Results and Discussion

Phenol I: General

The coaxial cell was assembled under dry nitrogen, using about 2 g of polycrystalline phenol. Each sample was annealed overnight at +35°C and an apparent pressure of 1500 bar. The dielectric constant and loss of phenol I between 100 Hz and 100 kHz were then determined isothermally as functions of increasing pressure and decreasing pressure, neglecting the pressure dependence of the cell constant. The apparent pressure was changed by 125 bar every half hour, and the measurements were made 25 min after the pressure change. When phenol I had been studied at each required temperature, phenol II was formed at +35°C and 2000 bar and was studied as described later.

No dielectric relaxation between 10^2 and 10^5 Hz was found in phenol I between −70 and +40°C. The dielectric constants at 50 kHz were not affected by space charge polarization, except at the lowest pressures when the temperature was above 30°C, so they are used as the static dielectric constants, ε_0'. For each sample at each temperature, ε_0' was plotted against apparent pressure on large graphs, smooth curves were drawn through the points, and the approximately 500 bar hysteresis in the apparent pressure for a given value of ε_0' was removed by averaging the two apparent pressures. The dielectric constants and the averaged pressures were corrected for the deformation of the cell under pressure, and ε_0' was fitted to quadratic equations in pressure by the least-squares method. In all cases the standard and maximum deviations of the observed and calculated dielectric constants were less than 0.00012 and 0.00018 respectively, and the individual deviations were random. The resulting equations are given in Table 1, with the highest and lowest average pressures of the data, and the number of points used to derive each equation. The original dielectric constants and further details are given elsewhere (3).

Phenol I at 10°C

The three equations for 10.0 ± 0.1°C (Table 1) were averaged to give

$$[1]\quad \varepsilon_0' = 2.8824 + 4.4278\times10^{-5}P - 2.9302\times10^{-9}P^2$$

where P is in bar, for the static (50 kHz) dielectric constant of phenol I. Averaged values of ε_0' and $(\partial\varepsilon_0'/\partial P)_{10°C}$ are given in Table 2, with the maximum deviations from the average; the average data have precisions of about 0.3% and 8% which are satisfyingly close, although inferior, to those obtained for alkali halides (11,

[a]From ref. 2.

12, 24) by the superior (25) techniques that can be used for those solids.

Estimates of $(\partial\varepsilon_0'/\partial P)_{10°C}$ were also obtained using the parallel-plate cell. The 50 kHz capacitance of about 5 g of phenol at 10°C was determined as a function of average pressure (the hysteresis was ~350 bar), and was converted to dielectric constant as described earlier, assuming that $\varepsilon' = 2.914$ (eq. 1 and Table 2) at 750 bar. The results are compared in Fig. 2 with the line given by eq. 1. The values of $(\partial\varepsilon_0'/\partial P)_{10°C}$ measured using the two cells disagree by more than the estimated errors, particularly below 750 bar, suggesting that the accuracy of the values listed in Table 2 may be considerably poorer than the precision. This disagreement presumably arises from the defects of both types of cell (25) for such measurements.

The molar polarization, $\bar{P}$, of phenol I at 10°C was calculated from ε_0' (Table 2) through the Clausius–Mossotti equation. The molar volumes at pressures P and atmospheric, V and V_0, were calculated from the volume compressions (2) and the value, 1.132 g cm^{-3} (26), of the density at atmospheric pressure and 25°C, assuming this to be unchanged at 10°C. The molar polarizations in cm^3 are described by the equation

$$[2] \qquad \bar{P} = 20.30 + 11.75\, V/V_0$$

are tabulated in Table 2 and shown in Fig. 3. No dielectric relaxation was detected between +40 and −70°C below 100 kHz in either cell, so the polarization is undoubtedly the sum of electronic and atomic polarizations only. The reduction in the polarization with increasing pressure is the dependence usually observed (11, 12, 24, 25, 27), and it may indicate a reduction in the electronic and atomic polarizations or reflect the inadequacy of the Lorentz local field

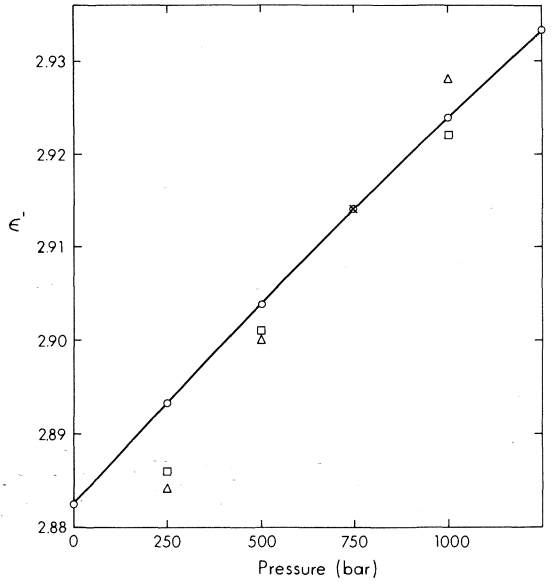

FIG. 2. The 50 kHz dielectric constant of phenol I at 10°C measured using the coaxial cell (line and circles) and the parallel-plate cell (squares and triangles). The values from the two cells were forced to agree at 750 bar.

for the monoclinic (pseudo-orthorhombic) (2 and references cited therein) phenol I. At atmospheric pressure, $\bar{P}$ is 32.05 ± 0.1 cm^3, the electronic polarization was estimated to be 26.9 ± 0.3 cm^3 as described in the next paragraph, so the atomic polarization is 5.1 ± 0.4 cm^3.

The refractive indices are known as a function of wavelength for liquid phenol at 45°C and atmospheric pressure (16, 28) and were fitted to within 0.0002 by the Sellmeier equation (29)

$$n^2 = n_\infty{}^2 + \frac{B}{\lambda^2 - \lambda_0{}^2}$$

where n and n_∞ are the refractive indices at

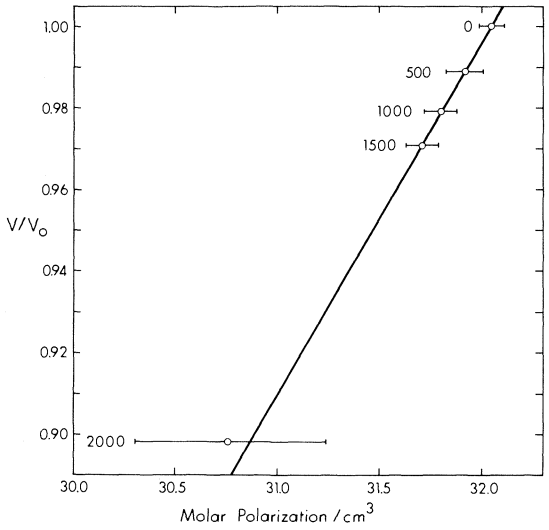

FIG. 3. The 50 kHz molar polarization of phenol I at 10°C plotted against the fractional molar volumes at the pressures (bar) shown to the left of the points. The error bars show the standard deviations. The line represents eq. 2. The 2000 bar point is for phenol II.

wavelengths λ and infinity, $B = 2.4132 \times 10^4$ nm^2, $\lambda_0 = 184.43$ nm, and $n_\infty = 1.5151$. This value of n_∞ and the density of liquid phenol at 45°C, 1.05446 g cm^{-3} (16, 28), yield 26.91 $\pm$ 0.02 cm^3 for the electronic polarization of liquid phenol at 45°C, through the Lorentz–Lorentz equation (30). The only refractive index of phenol I that is known is 1.5930 at the melting point, where that of the liquid is 1.5400; these values were reported (31) for 41°C and unspecified, but probably sodium-D, radiation and, from a comparison with Timmermans' values (16, 28), are probably accurate to $\pm$0.0025. If the density of phenol I at 41°C is assumed to be the same as at 25°C, 1.132 g cm^{-3} (26), the molar polarization of phenol I at 41°C for sodium-D radiation is 28.2 $\pm$ 0.1 cm^3, within 1% of that of liquid phenol at 41°C which is, from Timmermans' data (16, 28), 28.0 $\pm$ 0.2 cm^3. We therefore assume that the electronic polarization of phenol I at 10°C is within 1% of that of liquid phenol at 45°C, and is 26.9 $\pm$ 0.3 cm^3.

Phenol I: Temperature Dependence

The isobaric temperature dependence of ε_0' was calculated from the expressions in Table 1. The expressions for each temperature were multiplied by 1.00196, 1.00127, and 0.99682 for samples 1, 2, and 3, respectively, the factors being those required to yield 2.914 for the dielectric constant at 10°C and 750 bar for each sample. The justification for this is that about half of the difference between different samples appeared to be due to errors in the cell constant. The resulting expressions gave the data shown in Fig. 4. The 50 kHz dielectric constants above 30°C were influenced by electrode polarization, and the same was probably true of the values for sample 2 at 25.0°C. These points were omitted from least-squares fits of the data which gave the expressions shown in Table 3 and the lines drawn in Fig. 4.

The positive value of $(\partial\varepsilon_0'/\partial T)_{1500\text{ bar}}$ (Table 3, Fig. 4, line *A*) is clearly unreliable, because the standard deviation of the fit is of the order of the total change in the dielectric constant. At the lower pressures $(\partial\varepsilon_0'/\partial T)_P$ is negative as expected, confirming that the opposite temperature dependences previously reported (Introduction) are incorrect. Further, the dielectric constant at 10°C and atmospheric pressure found in this work,

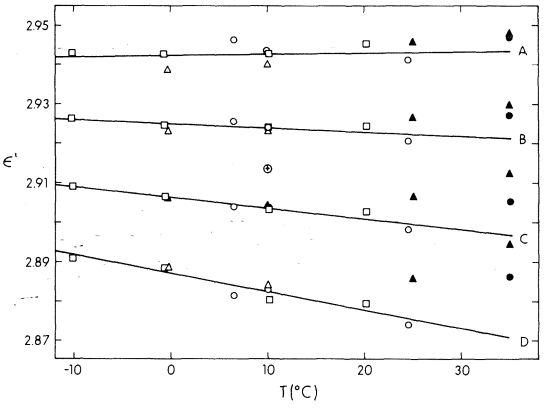

FIG. 4. The 50 kHz dielectric constants of phenol I at *A*, 1500 bar; *B*, 1000 bar; *C*, 500 bar; and *D*, 1 bar, corrected for errors in the cell constants. Symbols ○, △, □, and ⊕ indicate data from samples 1, 2, and 3, respectively, and the value common to all samples. The solid lines represent the expressions given in Table 3.

TABLE 3. Expressions for the isobaric temperature dependence of the 50 kHz dielectric constant of phenol I

Pressure (bar)	Dielectric constant (ε')[a]	Standard deviation
1	$2.8870-4.66\times10^{-4}\,T$	0.0018
500	$2.9063-2.63\times10^{-4}\,T$	0.0010
1000	$2.9248-9.69\times10^{-5}\,T$	0.0014
1500	$2.9424+3.81\times10^{-5}\,T$	0.0026

[a]Calculated from all of the data below 24.9°C. *T* is the temperature (°C).

2.882, is higher than that reported previously, 2.79 ± 0.5 (4, 5), which suggests (13–15) that the previous errors were due to cracks in the samples.

Following Chan and Chew (14, 15) ε_0' of phenol I was also measured as a function of temperature under a constant apparent pressure of 1000 bar in the coaxial cell. The results obtained are shown in Fig. 5 as the curves *XY* (cooling curve) and *YZX* (warming curve) together with Smyth and Hitchcock's data (4) as curve *A*, and the 1000 bar and 1 bar isobars from Fig. 4 and Table 3 as lines *B* and *D*. It is clear that cracks formed in the sample even under a constant apparent pressure of 1 kbar. Thus, although the correct temperature dependence of the dielectric constant of plastic crystals can be determined by applying a small (~10 bar) constant pressure to the sample (14), far more care is required for the more common, harder molecular crystals like phenol and the low-temperature phases of compounds that form plastic crystals (15).

The accuracies of the isobaric temperature dependences of ε_0' below 1500 bar (Table 3, Fig. 4) cannot be high and are difficult to assess. A rough evaluation was made for $(\partial\varepsilon/\partial T)_0$ by using it, through the Clausius–Mossotti equation, to calculate the isobaric thermal expansivity at atmospheric pressure, $\alpha = 1/V_0(\partial V/\partial T)_0$, where V_0 is the molar volume at atmospheric pressure. The molar polarization, $\bar{P}$, was first assumed to be independent of temperature, and this yielded (14) $\alpha = 1.5 \times 10^{-4}$ $(K)^{-1}$ at +10°C. Second, $\bar{P}$ was assumed to depend only on density, so that $(\partial\bar{P}/\partial V)_P = (\partial\bar{P}/\partial V)_T = (1/V_0)(\partial\bar{P}/\partial(V/V_0))_T$ and the following equation was obtained.

$$\alpha = \frac{\dfrac{V}{V_0}\dfrac{-3}{(\varepsilon - 1)(\varepsilon + 2)}\left(\dfrac{\partial\varepsilon}{\partial T}\right)_P}{1 - \dfrac{V}{V_0}\dfrac{1}{\bar{P}}\left(\dfrac{\partial\bar{P}}{\partial(V/V_0)}\right)_T}$$

where V, ε, and $\bar{P}$ are the molar volume, dielectric constant, and molar polarization at pressure P. For atmospheric pressure V/V_0 is unity, $(\partial\bar{P}/\partial(V/V_0))_{10°C}$ is 11.75 ± 0.01 cm^3 for all pressures (eq. 2), and the remaining data given in Tables 2 and 3 yield $\alpha = 2.4 \times 10^{-4}$ $(K)^{-1}$ at 10°C. The only known value of the thermal expansivity of phenol is the mean expansivity between −190°C and +20°C at atmospheric pressure, which is $(2.6 \pm 0.8) \times 10^{-4}$ $(K)^{-1}$ from X-ray data (2). The thermal expansivity increases with increasing temperature, so its value at +10°C must be considerably greater than 2.6×10^{-4} $(K)^{-1}$. We must conclude that either the magnitude of $(\partial\varepsilon_0'/\partial T)_0$ given in Table 3 is too small, or the assumptions used to relate it to the thermal expansivity are poor.

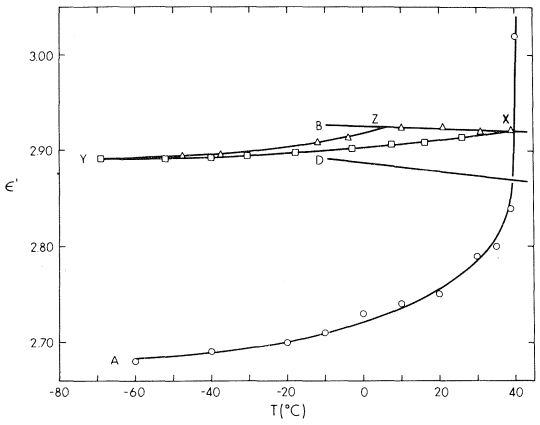

FIG. 5. The dielectric constant of phenol I as a function of temperature. Curve *A* is from ref. 4. Lines *B* and *D* are the 1000 and 1 bar isobars from Fig. 4 and Table 3. *XY* is the cooling and *YZX* the warming curve for phenol under a constant applied pressure of 1 kbar in the coaxial cell.

Phenol II at 10°C

Phenol I was converted to phenol II at +38°C over several hours. These conditions minimized the amplitude of a transient dispersion which always accompanied the formation of phenol II and which is discussed later. Phenol II was then left at +38°C and 2000 bar for the several days required for the dispersion to decrease sufficiently not to influence the measured dielectric constants. The capacitance and conductance were measured at +10°C as functions of frequency, for increasing and decreasing apparent pressures between 1250 and 6000 bar in the coaxial cell and between 1250 and 2500 bar in the parallel-plate cell. The apparent pressure was changed by 300 bar for the coaxial cell, and 125 bar for the parallel-plate cell, every 30 min and the measurements were made 25 min later.

No intrinsic (permanent) dielectric relaxation was detected in phenol II at 10°C between 0.1 and 100 kHz. The apparent pressure ranges used were the maximum available but the 50 kHz capacitance showed little pressure dependence and no pressure-hysteresis in either cell. The pressure dependence of the dielectric constant

of phenol II could not, therefore, be determined. It was argued that the essentially constant measured capacitance was appropriate to a pressure close to the transition pressure, since the pressure uniformity in the cell should be greatest during the transition, and the measured capacitance at an apparent pressure of 2000 bar was assumed to correspond to a true pressure of 2000 bar. The average of three measurements in the coaxial cell and two in the parallel-plate cell gave the 50 kHz dielectric constant of phenol II at +10°C and approximately 2000 bar as 3.10 with a standard deviation of 0.06. From this value, the molar polarization is 30.75 ± 0.5 cm^3 since, from the data used earlier, the density of phenol II at +10°C and 2000 bar is 1.260 g cm^{-3}. This value is included in Fig. 3, and the polarization clearly does not change its volume dependence greatly at the phase transition. This, plus the absence of intrinsic dielectric relaxation in either phase, suggests that phenol II is like phenol I, a hydrogen-bonded solid in which the hydroxyl hydrogen atoms are ordered, either fully or in chains (2 and references cited therein), and are not free to change positions readily. Our failure to observe any pressure dependence of the capacitance of the cells containing phenol II indicates that phenol II is much harder than phenol I.

Phenol II: Transient Dielectric Dispersion

The transient dielectric loss which accompanied the formation of phenol II showed two maxima, at 9 kHz and above 100 kHz at 10°C, and yielded two incompletely resolved Cole–Cole arcs. Its decay with time varied from sample to sample, and in some samples it did not disappear completely. The lower frequency of maximum loss, at a given temperature and pressure, did not change as the loss decayed. The magnitude of the loss was smallest when phenol II was made at high temperature, and the rate of decay was fastest when it occurred at high temperature and low pressure. To determine the Arrhenius activation energies, the real, C', and imaginary, C'', capacitances were measured as functions of temperature for two samples in the parallel-plate cell at a constant apparent pressure of 2000 bar. The data were inadequate to permit an analytical resolution (32) of the two dispersions, so the high- or low-frequency points on the Cole–Cole plots were fitted to a circular arc by bisecting chords drawn between data points. The data from one sample and the fitted arcs are shown in Fig. 6. The relaxation times were calculated from the parameters which defined the circular arcs by the method of Cole and Cole (33, 34), and their logarithms are plotted against reciprocal temperature in Fig. 7. The lines drawn were fitted by the method of least-squares and correspond to the equations

$$[3] \quad \log \tau_1 = 2.730 \times 10^3/T - 14.278$$

and

$$[4] \quad \log \tau_2 = 1.094 \times 10^3/T - 10.213$$

for the low and high frequency dispersions, with standard deviations 0.086 and 0.076 and corresponding Arrhenius activation energies 12.5 ± 0.6 and 5.0 ± 0.5 kcal/mol, respectively.

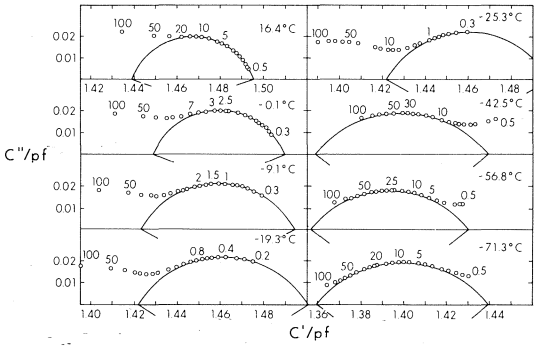

FIG. 6. Cole–Cole plots of the transient dielectric dispersion in phenol II at a constant apparent pressure of 2000 bar in the parallel-plate cell. The numbers beside the points give the frequencies in kHz. The circular arcs fitted to the data are shown.

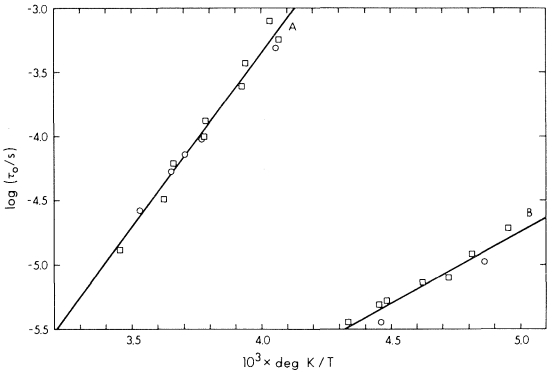

FIG. 7. The temperature dependence of the relaxation times of the two transient dispersions in phenol II at an apparent pressure of 2000 bar. The squares and circles indicate data from different samples. Lines *A* and *B* correspond to eqs. 3 and 4.

These transient dispersions may be due to Maxwell–Wagner effects caused by the precipitation of impurities during the transition (1), and/or to dipolar reorientation at either the phenol II – impurity interface or the phenol II – phenol II interface. Since there were two distinct dispersions, neither of which appeared alone, both mechanisms were likely present. The decay of the Maxwell–Wagner dispersion would result from the slow (1) redissolution of the impurities or from their coalescence from parallel sheets along the particle boundaries into spheres (35). The decay of the interfacial relaxation would result from the decrease in the impurity – phenol II contact area accompanying the above processes, or from an increase in the phenol II particle size by self-annealing which is undoubtedly slow since phenol II is very hard (see above). The well-resolved non-spotty X-ray diffraction lines which we obtained from unground samples of quenched phenol II (2, 3) indicate that phenol II formed with a particle size of 10 to 0.1 μm (36). The room temperature value for τ_1 is typical of Maxwell–Wagner dispersions (35). The 5.0 kcal mol^{-1} activation energy of the high frequency dispersion is consistent with an activation step involving breaking one hydrogen bond to permit hydroxyl rotation at the phenol II interface.

Nuclear magnetic resonance relaxation and anisotropic reorientation in liquid dimethylmercury

CLAUDE R. LASSIGNE AND E. J. WELLS

Chemistry Department, Simon Fraser University, Burnaby 2, B.C., Canada V5A 1S6

Received October 29, 1976

CLAUDE R. LASSIGNE and E. J. WELLS. Can. J. Chem. **55**, 1303 (1977).

Spin–lattice relaxation times of ^{1}H, D, and ^{199}Hg have been measured between 234 and 333 K in liquid dimethylmercury and its isotopic modifications. These measurements have allowed the relaxation mechanisms to be separated. It was found that the spin–rotation interaction is the dominating mechanism for the ^{199}Hg relaxation at 14.1 kG even at low temperatures. We have estimated the spin–rotation constants, $C_{\parallel} = -120 \pm 60$ kHz and $C_{\perp} = -23 \pm 3$ kHz along with the chemical shift anisotropy $\Delta\sigma = \sigma_{\parallel} - \sigma_{\perp} = +4600 \pm 1000$ ppm. It is concluded that reorientation about the symmetry axis is not well described by molecular diffusion. Reorientation of the methyl group about its symmetry axis is found to be approximately forty times faster than the reorientation about the perpendicular axis.

CLAUDE R. LASSIGNE et E. J. WELLS. Can. J. Chem. **55**, 1303 (1977).

On a mesuré, entre 234 et 333 K, les temps de relaxation spin–réseau de ^{1}H, D et ^{199}Hg dans le diméthylmercure liquide et dans ses modifications isotopiques. Ces mesures ont permis de séparer les mécanismes de relaxation. On a trouvé que l'interaction spin–rotation est le mécanisme dominant pour la relaxation du ^{199}Hg à 14.1 kG même à basse température. On a estimé les valeurs des constantes spin–rotation $C_{\parallel} = -120 \pm 60$ kHz et $C_{\perp} = -23 \pm 3$ kHz ainsi que l'anisotropie du déplacement chimique $\Delta\sigma = \sigma_{\parallel} - \sigma_{\perp} = +4600 \pm 1000$ ppm. On en conclut que la réorientation autour de l'axe de symétrie n'est pas bien décrite par la diffusion moléculaire. La réorientation du groupe méthyle autour de l'axe de symétrie est approximativement 40 fois plus rapide que la réorientation autour de l'axe perpendiculaire.

Introduction

Nuclear magnetic resonance is a convenient probe for the study of the rotation of molecules in liquids (1) because the nuclear spin-relaxation time depends on the molecular motion although there is still some question as to the validity of the various proposed models. In a molecule in the liquid phase, the more nuclei whose relaxation time can be measured, the more information one can obtain about the motions of that particular molecule (2, 3). For nuclei of spin $I \geq 1$ the quadrupolar relaxation is generally the dominant mechanism in the spin–lattice relaxation time. However, for nuclei of spin 1/2 the problem is more complicated because of the various possible mechanisms which may contribute to the total relaxation rate.

In a number of studies involving nuclei of spin 1/2, ^{13}C (4–7), ^{19}F (8), ^{31}P (9), ^{15}N (10), ^{119}Sn (11, 12), and ^{207}Pb (13), it has been shown that the spin–rotation contribution to the spin–lattice relaxation rate is the dominant mechanism. There appears to be a trend showing that the spin–rotation interaction ($I \cdot C_0 \cdot J$) becomes more important for the higher Z nuclei of spin 1/2, however, studies involving these higher Z nuclei have rarely been reported in the literature. If indeed this interaction is large it should be reflected in the value for the spin–rotation constant C_0 for the ^{199}Hg nucleus in $Hg(CH_3)_2$.

Along with the study of the relaxation of the ^{199}Hg nucleus we have also studied the ^{1}H and D temperature dependence of the spin–lattice relaxation times and thus derived the anisotropic reorientational motion of the dimethylmercury molecule.

Experimental

Measurement of Relaxation Times

The proton spin–lattice relaxation times T_1 were measured by the saturation recovery method (14) and rapid adiabatic passage with sampling (15) on a Varian A56/60 high resolution nmr spectrometer operating at 60 MHz. The D spin–lattice relaxation times were measured at 15.4 MHz by rapid adiabatic passage with sampling on a Varian XL-100 nmr spectrometer.

The ^{199}Hg (16.84%, $I = 1/2$) relaxation times were measured indirectly by the modified rotary echo method of Wells and Abramson (16*a*) and Chan (16*b*) on the *proton* multiplet components. $R_{2r}(\equiv T_{2r}^{-1})$ for protons

was obtained at 60 MHz (14.1 kG). The relaxation rate is given in the rotating frame by

$$[1] \qquad R_{2r} = \tfrac{1}{2}(R_{1H} + R_{2H})$$

Therefore by performing a selective rotary echo experiment on the central proton signal due to the dimethylmercury molecules containing non-magnetic Hg ($I = 0$) we obtain,

$$[2] \qquad R_{2r}^{I} = \tfrac{1}{2}(R_{1H}^{I} + R_{2H}^{I})$$

For this case the value of $R_{2r}(H)$ was found to be the same as $R_1(H)$ which means that $R_{1H}^{I} = R_{2H}^{I}$.

Also performing a selective rotary echo experiment on either member of the proton doublet due to $^{199}Hg(CH_3)_2$ molecules (see Fig. 1) we obtain

$$[3] \qquad R_{2r}^{II} = \tfrac{1}{2}(R_{1H}^{II} + R_{2H}^{II})$$

Here $R_{1H}^{II} = R_{1H}^{I}$ since both dipole and scalar T_1 contributions from ^{199}Hg to ^1H are negligible, and $R_{2H}^{II} = R_{1H}^{II} + R_1(^{199}Hg)$; where $R_1(^{199}Hg)$ is the mercury-199 scalar contribution to the proton R_{2H} in the slow relaxation limit ($R_1(^{199}Hg) \ll 2\pi J_{^1H-^{199}Hg}$) which is well satisfied here.

The ^{201}Hg isotope (13.22%, $I = 3/2$) is scalar coupled to ^1H but collapsed in the spectrum, and affords a scalar R_2 mechanism to the ^1H which is included with the rotary echo measurement on Hg ($I = 0$) resonance. Assuming the reasonable value of 500 MHz for the quadrupole coupling constant of ^{201}Hg in $Hg(CH_3)_2$, we estimate $T_1(^{201}Hg) \approx 10^{-7}$ s and since $J_{^{201}Hg-H}$ is ≈ 38 Hz, it can be shown that the effect of the collapsed ^{201}Hg multiplet on the central ^1H component is to modify the observed R_2 by only a negligible 2%.

Therefore using these two selective rotary echo experiments we can indirectly obtain values of $R_1(^{199}Hg)$.

$$[4] \quad R_1(^{119}Hg) = 2(\Delta R_{2r}) = 2(R_{2r}^{II} - R_{2r}^{I})$$

For the mixtures of $Hg(CH_3)_2$ and $Hg(CD_3)_2$ there was no evidence of any of the mixed species such as CH_3—Hg—CH_2D etc. or CH_3—Hg—CD_3 so that in the separation of the various mechanisms possible H–D or CH_3–CD_3 exchange could be neglected.

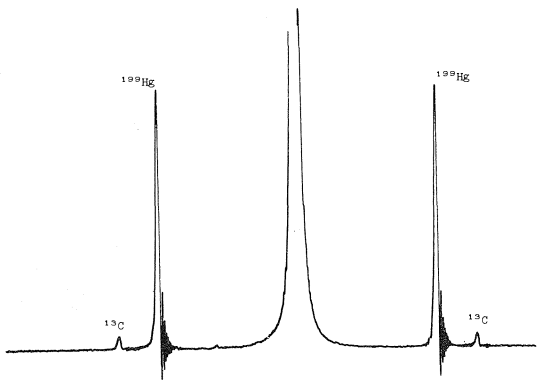

FIG. 1. ^1H spectrum of neat liquid $Hg(CH_3)_2$ at 60 MHz.

Temperature control was accomplished using the Varian V-6040 temperature nmr probe accessory. Temperatures were measured using a copper constantan thermocouple and temperature readings were stable to $\pm 1°C$.

Synthesis of $Hg(CD_3)_2$

The dimethylmercury-d_6 was prepared according to Gilman and Brown's Grignard method (17) with minor modifications. In a dry 100 cc flask fitted with "Drierite" was added 2.0 g of Mg turnings. To this was added 10 cc of dry (absolute) ether and 2.0 g of dry methyl iodide-d_3 (Merck, Sharp and Dohme of Canada). As soon as the reaction had started, a solution of 8.0 g of CD_3I in 40 cc of dry (absolute) ether was slowly added. An ice bath was used to cool the reaction flask when the reaction proceeded too vigorously. When spontaneous refluxing had ceased, the mixture was further refluxed for 30 min to drive the reaction to completion.

The Grignard reagent was carefully decanted from the excess Mg into a 500 cc flask fitted with a condenser and heated until refluxing had begun. To this was attached a Soxhlet extractor containing 7.15 g of $HgCl_2$; 75 cc of dry (absolute) ether was added to the flask. This was allowed to reflux for 3 days to improve the yield of the dimethylmercury-d_6.

After 3 days of refluxing the solution was cooled in ice and the excess Grignard reagent was destroyed by the addition of about 25 cc of water through the condenser. The water had to be carefully added to keep the reaction from becoming too vigorous. Next the ether layer was separated and the aqueous layer extracted with 20 cc of dry (absolute) ether. The combined ether extract was washed with 25 cc of water, separated, and dried over $CaCl_2$. The ether was carefully distilled off using a 'spiral' column. The remaining traces of ether were separated out using preparative vapor phase chromatography. The yield was 3.92 g of $Hg(CD_3)_2$ (57% yield); bp 88–89°C (uncorrected).

The $Hg(CH_3)_2$ was obtained from Alfa Inorganics. The samples were degassed in 5 mm tubes by the usual freeze–pump–thaw cycles under vacuum. The viscosity and density were measured by standard methods.

Spin–Spin Coupling Constants and Chemical Shifts in $Hg(CH_3)_2$ and $Hg(CD_3)_2$

We have measured the various nuclear spin–spin coupling constants for $Hg(CH_3)_2$ and $Hg(CD_3)_2$ using ^1H and ^{13}C nmr. These values are tabulated in Table 1.

The first four coupling constants are in excellent agreement with the results of Dean and McFarlane (18). The last two coupling constants have not been previously reported. The value of $H_{^1H-^2D} = 1.9 \pm 0.1$ Hz indicates that the $\angle$H—C—D is very close to 109.5° since the geminal coupling constant is very sensitive to small changes in the $\angle$H—C—H angle (19).

The ratio J_{C-H}/J_{C-D} is always close to the value predicted by the gyromagnetic ratios $\gamma_H/\gamma_D =$

TABLE 1. Nuclear spin–spin coupling constants in $Hg(CH_3)_2$ and $Hg(CD_3)_2$*

Parameter	Value (Hz)	Source
$^1J_{^1H-^{13}C}$	129.5 ±0.2	^1H spectrum
$^2J_{^1H-^{199}Hg}$	101.5 ±0.2	^1H spectrum
$^1J_{^{13}C-^{199}Hg}$	684.6 ±0.3	^{13}C–{^1H} decoupled
$^4J_{^1H-^1H}$	0.43±0.03	^1H spectrum
$^1J_{^1H-^2D}$	1.9 ±0.1	^1H spectrum
$^1J_{^{13}C-^2D}$	19.8 ±0.6	^{13}C undecoupled spectrum

*^1H spectrum obtained on Varian A56/60 at 60 MHz and ^{13}C spectrum obtained on XL-100 operating at 25.1 MHz in FT mode.

6.5144 (20). We find the value of $J_{C-H} - 6.5144 \times J_{C-D}$ as $+0.6 \pm 4.0$ Hz. Thus it appears that there is no significant isotope effect on the coupling constants. These results are in agreement with those observed for a variety of deuterated organic compounds (21).

We have also measured the deuterium isotope shift on both ^{13}C and ^1H resonances of $Hg(CH_3)_2$ and modified species. The values obtained are $\delta_{isot}(^{13}C) = 0.95 \pm 0.07$ ppm (upfield on deuteration) and $\delta_{isot}(^1H)$ $(CH_3 \rightarrow CHD_2) = 0.040 \pm 0.003$ ppm (also upfield). The isotope shifts in the ^1H and ^{13}C spectra are representative of the differences of ranges in chemical shifts ($^{13}C \approx 600$ ppm and $^1H \approx 20$ ppm).

Results and Analysis

For most nuclei of spin 1/2 the relaxation is caused by a combination of mechanisms: intermolecular and intramolecular dipolar coupling, spin–rotation interaction, and possibly chemical shift anisotropy. The proton relaxation data in Table 2 and Fig. 2 indicate the presence of at least two mechanisms in the relaxation rate.

The form of the chemical shift anisotropy contribution is

$$R_1^{CSA} = \frac{2}{15}\gamma^2 H_0^2(\sigma_{\parallel} - \sigma_{\perp})^2\tau_c$$

since $\tau_c \approx 10^{-12}$ s and $(\sigma_{\parallel} - \sigma_{\perp}) \approx 1$–5 ppm for protons usually, $R_1^{CSA} \approx 10^{-9}$ s^{-1} for protons is negligible. For ^{199}Hg the chemical shift anisotropy $(\sigma_{\parallel} - \sigma_{\perp})$ may be as large as 5000 ppm. This value gives $R_1^{CSA} \approx 0.1$ s^{-1} which is small but may not be negligible.

Extrapolation from data by standard type of dilution studies (22) of $Hg(CH_3)_2$ in $Hg(CD_3)_2$ allows the separation of intermolecular dipole–dipole effects from intramolecular mechanisms for protons. In the ^{199}Hg relaxation in dimethylmercury it is safe to assume that the intermolecular ^1H–^{199}Hg dipole–dipole relaxation is insignificant as in the ^{13}C relaxation (23) because of the much increased intermolecular nuclear separation. Thus we are left with the separation of the intramolecular contributions to both the ^1H and ^{199}Hg relaxation rates.

Proton Relaxation

The temperature-dependent proton relaxation times are shown in Fig. 2 for pure $Hg(CH_3)_2$ and mixtures containing 27 and 60% mole fraction $Hg(CH_3)_2$ in $Hg(CD_3)_2$ respectively. The intermolecular relaxation rate for the mixtures is given as,

$$[5] \quad R_{1inter}^{H} = R_{1inter}^{H-H} + R_{1inter}^{H-D} + R_{1inter}^{^1H-^{199}Hg}$$

Since $\gamma_H^2 = 42.5\gamma_D^2$ and the spin values are different, the deuterium in dimethylmercury-d_6 will contribute 1/24 as much to the intermolecular relaxation as the hydrogens in dimethylmercury-h_6. The total proton relaxation is then

$$[6] \quad R_{1total}^{H} = \frac{23C + 1}{24} R_{1inter}^{H-H} + R_{1inter}^{^1H-^{199}Hg} + R_{1intra}^{dd} + R_1^{SR}$$

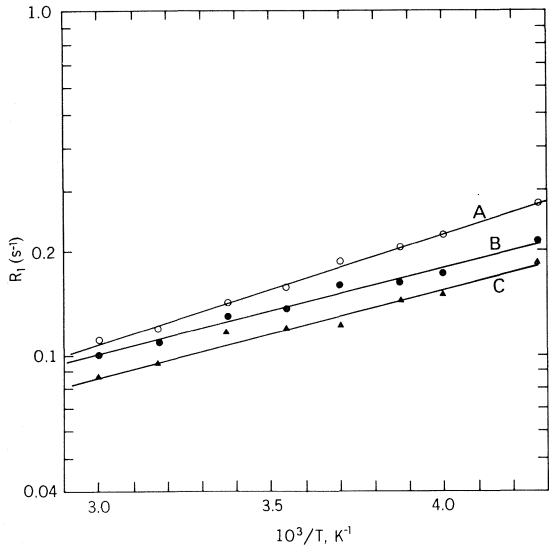

FIG. 2. Experimental relaxation rates for ^1H in dimethylmercury; (*A*) neat $Hg(CH_3)_2$; (*B*) 60% $Hg(CH_3)_2$ in $Hg(CD_3)_2$; (*C*) 27% $Hg(CH_3)_2$ in $Hg(CD_3)_2$.

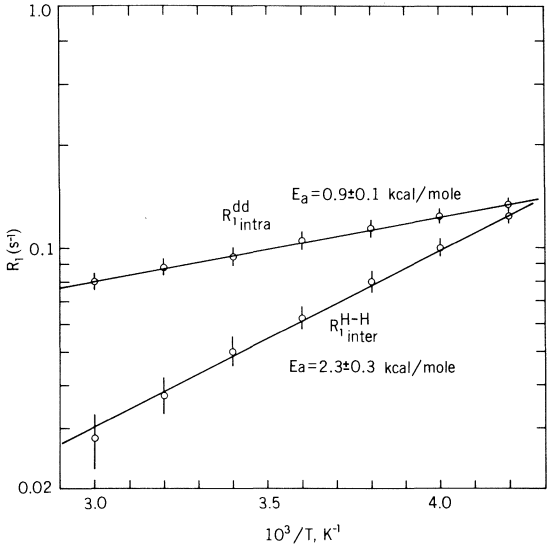

FIG. 3. Separation of $R_{1\,inter}^{H-H}$ from R_{intra}^{dd} for the ^1H relaxation rate in $Hg(CH_3)_2$.

where C is the mole fraction of dimethylmercury-h_6. A plot of $R_1{}^H$ *vs.* $23C/24$ yields

$$[7] \qquad \text{Slope} = R_{1\,inter}^{H-H}$$

$$[8] \qquad \text{Intercept} = \tfrac{1}{24} R_{1\,inter}^{H-H} + R_{1\,inter}^{H-^{199}Hg} + R_{1\,intra}^{dd} + R_1{}^{SR}$$

We may eliminate $R_{1\,inter}^{H-^{199}Hg}$ if we assume that d^0_{H-Hg} equals d^0_{H-H} (in fact d^0_{H-Hg} will actually be greater than d^0_{H-H}), we must also keep in mind that ^{199}Hg is only 16.86% natural abundance, whence

$$[9] \qquad R_{1\,inter}^{H-^{199}Hg} \approx 0.024 R_{1\,inter}^{H-H}$$

We are then left with separating $R_{1\,intra}^{dd}$ from $R_1{}^{SR}$. The plots of Fig. 2 show no curvature, which would normally be present if we had a mixture of intramolecular dipole–dipole and spin–rotation interactions since these two mechanisms have opposite temperature dependence. It appears safe to assume that at least over the temperature range studied the spin–rotation contribution is negligible for protons and that the only relaxation mechanisms present are those due to inter- and intramolecular dipole–dipole interactions. The separation of these two mechanisms is shown in Fig. 3. For the intermolecular interaction the energy of activation is 2.3 ± 0.3 kcal/mol and for the intramolecular dipole–dipole it is 0.9 ± 0.1 kcal/mol. The data indicate the intermolecular dipole–dipole mechanism to be predominant at the higher temperatures.

Anisotropic Rotational Diffusion Tensor for $Hg(CD_3)_2$

The usual method of obtaining the anisotropic rotational diffusion tensor of a symmetric top molecule involves the measurement of the relaxation time of two quadrupolar nuclei which have different bond angles with respect to the symmetry axis of the molecule (24–27). Thus in our molecule we could determine the anisotropic rotational diffusion tensor for dimethylmercury-d_6 from quadrupolar relaxation of both D and ^{201}Hg. The equations that relate the measured relaxation rate of a nucleus to the diffusion tensor components and the relative orientation to the electric field gradient are, in the rotational diffusion limit (28):

$$[10] \qquad R_{1Q} = \frac{3\pi^2(2I+3)}{10I^2(2I-1)} (e^2qQ/h)^2 \tau_c$$

$$[11] \qquad \tau_c = \frac{\frac{1}{4}(3\cos^2\theta - 1)^2}{6D_\perp} + \frac{3\sin^2\theta\cos^2\theta}{5D_\perp + D_\parallel} + \frac{\frac{3}{4}\sin^4\theta}{2D_\perp + 4D_\parallel}$$

The problem is that the ^{201}Hg resonance is not observable either directly or indirectly because of its very short relaxation time due to its pre-

sumably large quadrupole coupling constant. We must therefore find a different method of obtaining $D_\perp$ and $D_\parallel$. First we use the D relaxation times of Fig. 4, the approximate D quadrupole coupling constant for molecules containing methyl groups (165 kHz) and eq. 10 to obtain τ_c(D).

It has been shown experimentally (29) that $D_\parallel$ is invariant to deuteration in acetonitrile and we assume the same to be true here. However, this does not matter much since τ_c(H–H) and τ_c(D) are quite insensitive to changes in $D_\parallel$ because in the calculation of τ_c(H–H) and τ_c(D) using eq. 11 $\sim$90% and $\sim$70% respectively come from the first term which is solely dependent on $D_\perp$. The term $D_\perp$ has been found to be about 7% different in going from CH_3CN to CD_3CN (29) and for our $Hg(CH_3)_2$ case we calculate the difference in $D_\perp$'s to be $\sim$12% which we will assume is negligible. With these points in mind we will proceed with our analysis for $D_\parallel$ and $D_\perp$.

We use Powles' expression (30),

$$[12] \qquad R_{1\,\mathrm{intra}}^{\mathrm{H-H}} = \frac{3\gamma_H{}^4\hbar^2}{r_{\mathrm{H-H}}^6}\,\tau_c(\mathrm{H\text{–}H})$$

(which assumes independent pairwise interactions and neglects symmetry effects) to obtain τ_c(H–H). This is the effective correlation time for reorientation of the proton internuclear vector. For this correlation time $\theta = 90°$ in eq. 11 because the pertinent proton relaxation interaction occurs in the plane of the methyl hydrogens. This plane is normal to the major axis. Using the appropriate values for the constants and $r_{\mathrm{H-H}}$ (from Table 3) in eq. 12 we obtain

$$[13] \qquad R_{1\,\mathrm{intra}}^{\mathrm{H-H}} = 4.86 \times 10^{10}\tau_c(\mathrm{H\text{–}H})$$

Using eq. 11, the experimental values for τ_c(H–H), τ_c(D), $\theta = 90°$ for τ_c(H–H) and $\theta = 109° 28'$ for τ_c(D) we can solve for the temperature dependence of both $D_\perp$ and $D_\parallel$. These are given in Fig. 5. We find E_a for $D_\perp$ is 0.85 $\pm$ 0.15 kcal/mol and for $D_\parallel$, E_a = 1.30 $\pm$ 0.60 kcal/mol. Also the reorientation *about* the figure axis is about forty times faster than reorientation *of* the figure axis. The values for $D_\parallel$ have a great uncertainty because τ_c(D) and τ_c(H–H) are largely dependent on the value of $D_\perp$; hence large changes in $D_\parallel$ have very little effect on either τ_c(D) or τ_c(H–H). The value of $E_a(D_\parallel)$ = 1.30 $\pm$ 0.60 kcal/mol would appear a bit high since in most cases involving methyl group reorientation $E_a(D_\parallel) = \sim$0.8 kcal/mol (2, 4, 7, 24, 25), however a value of 0.8 kcal/mol is *within* the uncertainty of our analysis.

The error limits given for the $D_\parallel$ and $D_\perp$ activation energies are derived from the assumptions that the correlation times τ_c(H–H) and τ_c(D) have a $\pm$5% error and thus in the solution of the two simultaneous equations one obtains a range of $D_\perp$'s and $D_\parallel$'s and thus error limits in the E_a's.

Although our E_a's for $D_\parallel$ and $D_\perp$ appear quite different from that found for CH_3CN and CH_3I (2, 4) there are reasonable explanations. In CH_3CN and CH_3I (2, 4) the energy of activation for $D_\perp$ was found to be $\sim$1.7 kcal/mol while in

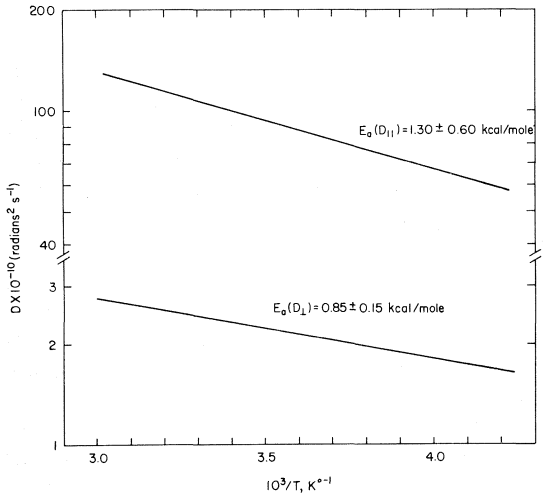

FIG. 5. Rotational rate constants ($D_{\|}$, $D_{\perp}$) for Hg-$(CD_3)_2$.

dimethylmercury we found $E_a(D_{\perp})$ to be only 0.9 kcal/mol. A possible reason for this low value may have been that at the higher temperatures a small amount of spin–rotation may have been present in the proton relaxation rate. Subtraction of this R_1^{SR} contribution from $R_{1\,intra}^{H}$ would give us a smaller $R_{1\,intra}^{dd}$ and thus a smaller value for the correlation time τ_c(H–H) which would mean $E_a(D_{\perp})$ would then be greater than the measured 0.9 kcal/mol.

In the past the nmr rotational correlation time, τ_θ, for the isotropic rotation of a spherical molecule was given in terms of the viscosity η,

$$[14] \qquad \tau_\theta = \frac{4\pi a^3 \eta}{3kT}$$

However, it has been found that the activation energies (31, 32) of τ_θ and η/T do not always agree, as is the case here, $E_a(\eta/T) \cong 2$ kcal/mol while $E_a(\tau_\theta) \approx 0.9$ kcal/mol. This is not surprising since τ_θ is a measure of the rotational motion and η is a measure of the translational motion. The inadequacy of eq. 14 has recently been observed in the pressure dependence of τ_θ and η (33–36). The conclusions were that agreement between the temperature and pressure dependences of η/T and τ_θ will only occur if the rotational and translational motions are highly coupled. Their results on monosubstituted benzenes (35) and toluene-d_8 (36) indicate that molecular shape is the decisive factor in determining the degree of coupling between the rotational and translational motions in liquids.

χ-*Test*

Since eqs. 10 and 11 are derived from the assumption of rotational diffusion, we can test the results by the so-called χ-test (27) to check that this method is a good approximation of the reorientations. The χ-test consists of calculating the ratio of the reorientational correlation time about a particular axis to the theoretical free gas reorientational time about the same axis assuming rotational equipartition. If χ is large compared to 1, the rotational diffusion limit applies. For dimethylmercury application of the χ-test to the perpendicular motion gives values ranging from 15–22 indicating rotational diffusion for this motion. However for the parallel motion the range of $\chi_{\|}$ is only 1.4–3.0 indicating possible inertial effects due to the much smaller moment of inertia about this axis.

^{199}*Hg Spin–Lattice Relaxation*

For the ^{199}Hg relaxation it is safe to assume that the intermolecular dipole–dipole relaxation is insignificant as previously mentioned. Therefore the T_1's of ^{199}Hg in dimethylmercury (Fig. 6) come only from intramolecular interactions. The dipolar contribution can be written as,

$$[15] \qquad R_{1\,intra}^{dd} = \frac{6\gamma_H{}^2\gamma_{^{199}Hg}{}^2\hbar^2}{r_{H-Hg}^6}\tau_c(\text{Hg–H})$$

Using the appropriate values for the constants and intermolecular distances (Table 3) we obtain

$$[16] \qquad R_{1\,intra}^{dd} = 3.36 \times 10^8 \tau_c(\text{Hg–H})$$

where τ_c(Hg–H) can be calculated using eq. 11

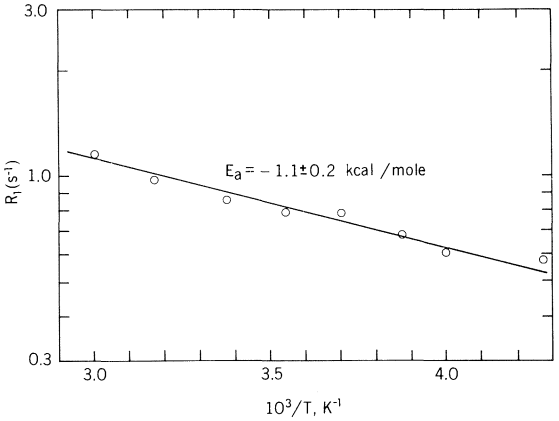

FIG. 6. ^{199}Hg spin–lattice relaxation rate in ^{199}Hg-$(CH_3)_2$.

along with $D_\perp$, $D_\parallel$, and $\theta = 23.5°$. The calculated contribution at 313 K is $R_{1\,\text{intra}}^{\text{dd}} = 0.0014$ s^{-1} which is negligible, due to the large Hg–H separation. The temperature dependence in Fig. 6 indicates that the major operative spin–lattice relaxation mechanism is that due to the spin–rotation interaction. It shows an Arrhenius behaviour with an energy of activation of -1.1 ± 0.2 kcal/mol. There is a slight contribution due to the chemical shift anisotropy mechanism which will be discussed in a later section.

Discussion

Proton–Proton Intermolecular Dipole Relaxation

An approximate isotropic theory of translational diffusion of a spherical molecule through a viscous medium leads (37) to the following expression for the intermolecular dipole relaxation,

$$[17] \qquad R_{1\,\text{inter}}^{\text{H–H}} = \frac{9\pi^2\hbar^2\gamma_H{}^4\eta N}{2kT}$$

Here η is the viscosity and N is the number density of molecules. Our measured values of the temperature dependence of the density and viscosity are given in Table 4. These values in eq. 17 yield the calculated values of intermolecular dipole relaxation times that are compared in Table 5 with the measured values from the dilution extrapolation. The agreement is surprisingly good, and perhaps fortuitous in view of the simplified model. The calculated activation energy for the interaction is 2.2 kcal/mol and the experimental value is 2.3 ± 0.3 kcal/mol.

^{199}Hg Spin–Rotation Constants

Since we have established that the relaxation of the ^{199}Hg nucleus in dimethylmercury is governed mainly by the spin–rotation interaction we should be able to obtain the spin–rotation tensor.

Bender and Zeidler (38) have derived an equation relating the spin–rotation relaxation of a nucleus in symmetric top molecules to the rotational diffusion constants of the molecule. Their result is

$$[18] \quad R_1^{\text{SR}} = \frac{8\pi^2}{3\hbar^2}(I_\parallel{}^2 C_\parallel{}^2 D_\parallel + 2I_\perp{}^2 C_\perp{}^2 D_\perp)$$

where all symbols have their usual meaning. The derivation of this equation is based on the assumption that both diffusion constants are in the rotational diffusion limit, which is reasonable for $D_\perp$ but possibly not for $D_\parallel$ because of possible inertial effects for this motion. However, with this in mind we will proceed with this treatment.

Table 4. Density and viscosity for liquid $Hg(CH_3)_2$

T (K)	ρ (g/ml)	η (cP)
273	3.1403	1.308
288	3.0903	1.115
298	3.0787	1.040
308	3.0620	0.956

Table 5. Theoretical and experimental values for $T_{1\,\text{inter}}^{\text{H–H}}$

	Value (s)	
T (K)	Theory	Experimental
273	13.9	15.1
288	17.5	18.9
298	19.6	21.7
308	22.2	24.6

If the temperature dependent data for $D_\parallel$, $D_\perp$, and R_1^{SR} are known, one can obtain the values for $C_\parallel$ and $C_\perp$ using eq. 18. From eq. 18 and the necessary values for R_1^{SR}, $D_\parallel$, and $D_\perp$ we obtain,

At 313 K

$$[19a] \quad C_\parallel{}^2 + 19.3C_\perp{}^2 = 2.70 \times 10^{10}$$

At 238 K

$$[19b] \quad C_\parallel{}^2 + 26.3C_\perp{}^2 = 3.15 \times 10^{10}$$

The values for $C_\parallel$ and $C_\perp$ are obtained from the intersection of the temperature dependent ellipses plotted in Fig. 7. The values obtained are:

$$|C_\parallel| = 120 \pm 60 \text{ kHz}$$

and

$$|C_\perp| = 26 \pm 3 \text{ kHz}$$

We emphasize that although $D_\perp$ is in the rotational diffusion limit, $D_\parallel$ probably *is not* and one must be cautious with the value obtained for $C_\parallel$ in view of the large error associated with the solution for $D_\parallel$ through τ_c(H–H) and τ_c(D) in eq. 11.

Absolute Shielding Scale of ^{199}Hg

The magnetic shielding constant has been related to the spin–rotation constant through the second order paramagnetic term of Ram-

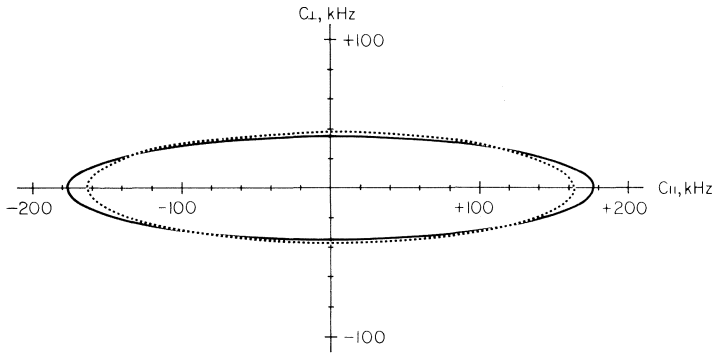

FIG. 7. Temperature dependent ellipses (----313 K and —238 K) of $C_{\parallel}$ and $C_{\perp}$ for ^{199}Hg in $Hg(CH_3)_2$.

sey's shielding expression (39–41). Deverell (42) has rewritten this expression for symmetric top molecules,

$$[20]\quad \sigma_{ave} = \sigma_d' + \sigma_p' = \frac{e^2}{3mc^2} \times \left\{\left\langle 0 \left| \sum_k \frac{1}{r_k} \right| 0 \right\rangle - \sum_j (Z_j/r_{ij})\right\} + \frac{e^2}{6mc^2}\left\{\frac{\pi}{m\mu_N\gamma_I}(2C_{\perp}I_{\perp} + C_{\parallel}I_{\parallel})\right\}$$

using Deverell's notation. This relation has been used to obtain the absolute chemical shift scale for ^{31}P (42, 43); ^{19}F (42); ^{119}Sn (11); and ^{207}Pb (44). The above expression suggests that the σ_p' is the only portion of the shielding constant that is sensitive to the chemical environment changes and thus changes in the spin–rotation constant (C).

Using the second term of eq. 20 along with the appropriate values for the constants, $C_{\parallel}$ and $C_{\perp}$, we obtain σ_p' for ^{199}Hg in $Hg(CH_3)_2$. We assume σ_p' to be negative in order to have a net deshielding effect and thus there are two solutions for σ_p':

If

$$C_{\parallel} = -120 \text{ kHz}$$

$$C_{\perp} = -26 \text{ kHz}$$

Then

$$\sigma_p' = -5050 \text{ ppm}$$

If

$$C_{\parallel} = +120 \text{ kHz}$$

$$C_{\perp} = -26 \text{ kHz}$$

Then

$$\sigma_p' = -4100 \text{ ppm}$$

The average total shielding constant can be calculated from Deverell's formula along with the value of σ_d' for the free atom tabulated by Ramsey (40). Ramsey gives $\sigma_d' = 9650$ ppm for Hg and therefore $\sigma_{ave} = 4600$ or 5550 ppm. The shielding scale obtained is shown in Fig. 8 and shows that the resonances of the non-metallic mercury compounds are found between the resonances of the bare nucleus and the free mercury atom.

Chemical Shift Anisotropy

If we use the paramagnetic term of eq. 20 along with the relationship,

$$\sigma_p' = \tfrac{1}{3}(2\sigma_{\perp} + \sigma_{\parallel})$$

we obtain for the ^{199}Hg nucleus,

$$[21]\quad 2\sigma_{\perp} + \sigma_{\parallel} = 1.10 \times 10^{31}(2I_{\perp}C_{\perp} + I_{\parallel}C_{\parallel})$$

and therefore

$$[22a]\qquad \sigma_{\perp} = 1.10 \times 10^{31} I_{\perp}C_{\perp}$$

$$[22b]\qquad \sigma_{\parallel} = 1.10 \times 10^{31} I_{\parallel}C_{\parallel}$$

Making use of eqs. [22*a*, *b*] along with the moments of inertia and spin–rotation constants we can calculate the chemical shift anisotropy ($\Delta\sigma = \sigma_{\parallel} - \sigma_{\perp}$). If we use $C_{\parallel} = -120$ kHz and $C_{\perp} = -26$ kHz we obtain $\Delta\sigma = +5415 \pm 1515$ ppm, while the second set of solutions $C_{\parallel} = +120$ kHz and $C_{\perp} = -26$ kHz yields $\Delta\sigma = +8300 \pm 1515$ ppm. From these estimates of $\Delta\sigma$ for the ^{199}Hg nucleus we can estimate the chemical shift anisotropy contribution to the ^{199}Hg spin–lattice relaxation rate. These various contributions are shown in Table 6.

As is shown in Fig. 6 there is no sign of any curvature in the temperature dependence of $R_1(^{199}\text{Hg})$ which indicates that almost all relaxation is due to the spin–rotation interaction and there appears to be very little chemical shift

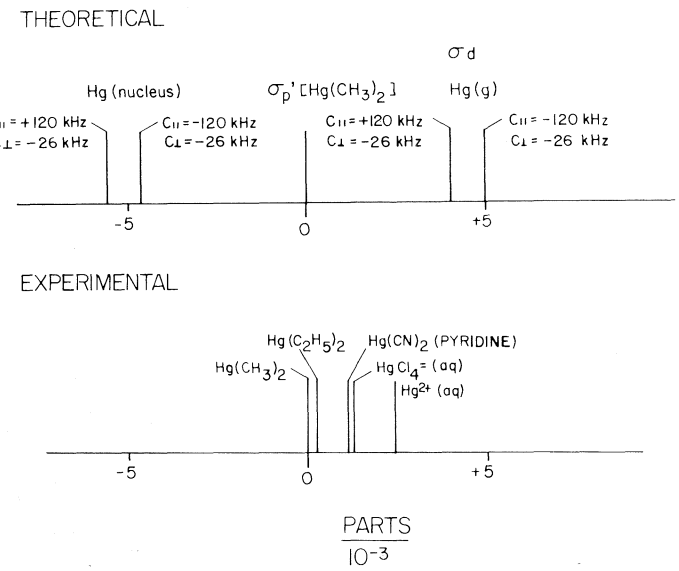

FIG. 8. ^{199}Hg shielding scales. Experimental scale values obtained from ref. 42. Theoretical scale derived from experimental values for $C_{\|}$ and $C_{\perp}$ along with eq. 19.

TABLE 6. Chemical shift anisotropy contributions to the relaxation rate of the ^{199}Hg nucleus at 14.1 kG*

10.2	234	+5400	0.178
10.2	234	+6900	0.292
10.2	234	+8300	0.419

*$\tau_c = (6D_{\perp})^{-1}$ for Hg atom since it lies on the main symmetry axis and $\theta = 0°$.

anisotropy contribution. This would then certainly eliminate $\Delta\sigma = +8300$ ppm since this would contribute significantly to the ^{199}Hg relaxation at low temperatures.

In Table 7 are shown the chemical shift anisotropy (CSA) and spin–rotation (SR) contributions to the ^{199}Hg relaxation rate for the most reasonable values of $C_{\|}$, $C_{\perp}$, and $\Delta\sigma$. Comparison of these calculated values of $R_1^{total}(^{199}Hg)$ with the experimental $R_1(^{199}Hg)$ values at both temperatures indicates that the most reasonable choice is that of $\Delta\sigma = +4640$ ppm and $C_{\|} = -120$ kHz and $C_{\perp} = -23$ kHz. For this value of $\Delta\sigma$ at 300 K the CSA mechanism would contribute only 10% to the total relaxation rate and at 234 K it would be 20%. Our final value of $\Delta\sigma = +4600$ ppm appears quite reasonable by comparison with the only other measurement of $\Delta\sigma(^{199}Hg) = +5345 \pm 25$ ppm by Kennedy and McFarlane (45) in CH_3HgBr. Thus our best estimates for the spin–rotation tensor are: $C_{\|} = -120 \pm 60$ kHz and $C_{\perp} = -23 \pm 3$ kHz. Use of these values along with $D_{\|}$ and $D_{\perp}$ in eq. 18 shows that about 50% of the ^{199}Hg spin–rotation interaction comes from the methyl group reorientation and 50% from the overall tumbling motion of the dimethylmercury molecule.

It has been pointed out (46) that the (**IC**) tensor for ^{13}C spins in many non-linear molecules is near isotropic *i.e.* $(\mathbf{IC})_t \cong I_{\|}C_{\|} \cong I_{\perp}C_{\perp}$. This is true only for the cases where $\Delta\sigma$ is small compared to σ_p'. We emphasize that such is not the case for ^{199}Hg in dimethylmercury since $\Delta\sigma = +4600$ ppm and $\sigma_p' = -4500$ ppm. In fact for our case $(\mathbf{IC})_{\perp}$ is about four times $(\mathbf{IC})_{\|}$.

Using our values of $\Delta\sigma$, $C_{\|}$, and $C_{\perp}$ we can estimate the point at which $R_1^{SR} = R_1^{CSA}$ at 23.5 kG (*i.e.* the point at which $R_1(^{199}Hg)$ reaches a maximum). This should occur at about −45°C calculated from our values of $\Delta\sigma$ and spin–rotation constants. Thus $R_1(^{199}Hg)$ behaviour at higher fields should display observable effects due to the large chemical shift anisotropy in $Hg(CH_3)_2$.

TABLE 7. Chemical shift anisotropy and spin–rotation contributions to the relaxation rate of the ^{199}Hg nucleus (at 14.1 kG) for various values of $C_{\parallel}$ and $C_{\perp}$*

(*a*) At 300 K

$C_{\parallel}$ (kHz)	$C_{\perp}$ (kHz)	$\Delta\sigma$ (ppm)	R_1^{SR} (s^{-1})	R_1^{CSA} (s^{-1})	R_1^{total} (s^{-1})
−60	−23	+5366	0.466	0.117	0.583
−120	−23	+4640	0.775	0.087	0.862

(*b*) At 234 K

$C_{\parallel}$ (kHz)	$C_{\perp}$ (kHz)	$\Delta\sigma$ (ppm)	R_1^{SR} (s^{-1})	R_1^{CSA} (s^{-1})	R_1^{total} (s^{-1})
−60	−23	+5366	0.313	0.175	0.488
−120	−23	+4640	0.505	0.132	0.637
−180	−23	+3914	0.825	0.093	0.918
−180	−26	+4712	0.892	0.138	1.030
−120	−26	+5438	0.572	0.178	0.760

*R_1^{SR} calculated using eq. 17.

A recent nmr study of ^{199}Hg (47) has yielded an atomic reference scale for all measured nmr line shifts of mercury. The resulting shielding constant is $\sigma_p' = -4686$ ppm for $^{199}Hg(CH_3)_2$ *vs.* ^{199}Hg atom. Using our best fit values for $C_{\perp}$ and $C_{\parallel}$ ($C_{\parallel} = -120$ kHz and $C_{\perp} = -23$ kHz) along with eq. 21 and the relationship $\sigma_p' = \frac{1}{3}(2\sigma_{\perp} + \sigma_{\parallel})$ we obtain $\sigma_p' = -4550$ ppm, in excellent agreement with the reported value of −4686 ppm.

The hydrolysis of 1- and 2-adamantyl nitrate in water: limiting values of $\Delta C_p^{\neq}$ for displacement of the nitrate ion in water

KALAVELIL MATTHEW KOSHY,[1] RAJANI KANTA MOHANTY,[2] AND ROSS ELMORE ROBERTSON[3]

Department of Chemistry, University of Calgary, Calgary, Alta., Canada T2N 1N4

Received July 13, 1976

KALAVELIL MATTHEW KOSHY, RAJANI KANTA MOHANTY, and ROSS ELMORE ROBERTSON. Can. J. Chem. **55**, 1314 (1977).

Values of $\Delta C_p^{\neq}$ have been obtained for the hydrolysis of 1- and 2-adamantyl nitrate in water and of 1-adamantyl nitrate in 0.2 mol fraction ethanol–water and acetonitrile–water. The limiting value of $\Delta C_p^{\neq}$ for displacement of the NO_3^- ions in water is more negative than -130 cal mol^{-1} deg^{-1}. Much less negative values in mixed solvents show that the large negative values obtained for hydrolysis in water derive in some manner from the structural properties of water. The mechanistic implications of these facts are discussed.

KALAVELIL MATTHEW KOSHY, RAJANI KANTA MOHANTY et ROSS ELMORE ROBERTSON. Can. J. Chem. **55,** 1314 (1977).

On a obtenu des valeurs de $\Delta C_p^{\neq}$ pour l'hydrolyse des nitrates d'adamantyle-1 et -2 dans l'eau et du nitrate d'adamantyle-1 dans des mélanges éthanol–eau et acétonitrile–eau de 0.2 fraction molaire. La valeur limite de $\Delta C_p^{\neq}$ pour le déplacement des ions NO_3^- dans l'eau est plus négative que -130 cal mol^{-1} deg^{-1}. Des valeurs beaucoup plus négatives dans les solvants mixtes montrent que les valeurs très négatives obtenues pour l'hydrolyse dans l'eau proviennent d'une manière quelconque des propriétés structurales de l'eau. On discute des implications mécanistiques de ces faits.

[Traduit par le journal]

In this paper we examine the mechanistic implications of the values of $\Delta C_p^{\neq}$ derived from the hydrolysis of the 1- and 2-adamantyl nitrates in water and in mixed solvents. In solvolytic displacement reactions, the adamantyl structure ensures the absence of rear-side nucleophilic interaction (1) and since participation by H or Me is unlikely (2), displacement from the adamantyl structure makes certain that the mechanism is S_N1 (3–5), Lim (6), or k_c (7), as one chooses. Because the 2-adamantyl structure thus eliminates the possibility of 'border-line mechanism' and mixed kinetics (ref. 5, pp. 320–321) which had been recognized in earlier discussions of displacement from secondary carbons, the 2-adamantyl structure was proposed by Schleyer *et al.* as a limiting standard for evaluating the mechanism for displacement from secondary carbons (2).

The mechanism of such solvolytic S_N displacements is recognized to depend on the structure of the reactant, the group being displaced, and the nucleophilic and ionizing properties of the solvent. The latter consideration, though long recognized (9), is not always observed. Water is a unique solvent in this respect. Because of the tendency to form transient structures about weakly polar solutes (10) and the further characteristic that these structures are sensitive to temperature and to the development of charge on the anion, we are provided, through $\Delta C_p^{\neq}$ values, with a 'handle' for evaluating the degree of charge development at the transition state (11).

Very early in studying their proposed S_N1/S_N2 mechanistic classification of nucleophilic displacement reactions, Hughes and Ingold recognized the need for a range of charge development at the transition state and for the possibility of 'shielding' and mixed kinetics (5). This logical extension of the simplistic S_N1/S_N2 mechanistic classification was provided with a formalism and a firmer experimental justification by Winstein and co-workers in the course of an extensive investigation, largely in the solvent acetic acid (12, 13). The possible existence of parallel pathways (k_Δ, k_s, k_c, in Winstein's nomenclature (7)) for hydrolytic displacement from secon-

*T in Kelvins.
†$\Delta C_p^{\ddagger}$ in water = 101 cal mol^{-1} deg^{-1}.

dary substrates in water would be expected to alter values of $\Delta C_p^{\ddagger}$ to less negative values (14). Hence the proposal that 2-adamantyl-X provided a 'standard' for evaluating the displacement of other secondaries was intriguing and encouraged us to determine the $\Delta C_p^{\ddagger}$ for the hydrolysis of 2-adamantyl nitrate in water. While in one sense the results obtained were not too surprising since we already knew the value of $\Delta C_p^{\ddagger}$ for the hydrolysis of 1-adamantyl nitrate, we believe these results raise important questions with regard to the interpretation of $\Delta C_p^{\ddagger}$ not only with reference to those reported here but with respect to the significance of this coefficient as a mechanistic probe in general (11).

The rate data were determined as previously (15) and the rate–temperature relationships were obtained by fitting these data to the empirical equation

$$[1] \qquad \log k_1 = A_1 + A_2/T + A_3 \log T$$

The values of the constants are given in Table 1. Derived values (11) of $\Delta H^{\ddagger}$, $\Delta S^{\ddagger}$, and $\Delta C_p^{\ddagger}$ are given in Table 2. The value of $\Delta C_p^{\ddagger}$ for 1-adamantyl nitrate is at once seen to be the most negative value of this coefficient reported to date. The value of $\Delta C_p^{\ddagger}$ found for the 2-adamantyl nitrate is about the same as was found for the 2,6-dimethylbenzyl nitrate (16) and possibly a little less negative than that of the 1-adamantyl nitrate. Such a small difference would be consistent with the smaller 'm' value and k_{EtOH}/k_{AcOH} ratio reported in Schleyer's paper (2).

In accord with our earlier assumption that large negative values of $\Delta C_p^{\ddagger}$ reflected a correspondingly large reorganization of the water structure adjacent to the developing nitrate ion in the activation process (11), and following earlier experience with *tert*-BuCl (17) $\Delta C_p^{\ddagger}$ values were determined for the hydrolysis of the 1-adamantyl nitrate and 4-Me-benzyl nitrate in 0.2 mol fraction acetonitrile in water and in 0.2 mol fraction ethanol in water. The values of $\Delta C_p^{\ddagger}$ obtained in these mixed solvents may be compared with those found for *tert*-butyl chloride hydrolyzing in the same media (Table 3). For reasons which will be apparent, it was not considered necessary to repeat this work with the 2-adamantyl nitrate, since there is no cause to believe that the results would be significantly different.

The values of $\Delta C_p^{\ddagger}$ found for the solvolysis of 1- and 2-adamantyl nitrate hydrolyzing in water are far more negative than what was previously regarded as limiting (18). That such large negative values could be attributed to the breakdown of the total hydrophobic solvent shell is unacceptable, even though Ahlywalia and co-workers have shown (19, 20) that $\Delta C^0_{p,s}$ for the solvation of tetra-*n*-butyl ammonium chloride changes on the addition of co-solvent in the same manner as $\Delta C_p^{\ddagger}$ reported here (Table 2). The large values of $\Delta C^0_{p,s}$ for the solvation of the ammonium salts in water relate to the temperature sensitivity of the hydrophobic shell about the cation while in the kinetic study, the larger the cation the more likely the initial state solvation will be shielded from the effects of charge development in the activation process and hence remain unchanged.

In Table (4) the values of $\Delta C^0_{p,s}$ are given for a number of alkali nitrates. If +30 cal mol^{-1}

deg^{-1} is taken as a reasonable estimate for the values $\Delta C_{p,s}^{0}$ associated with hydrophobic solvation of the neutral NO_3 group,[4] the values of $\Delta C_p^{\ddagger}$ reported in Table 2 for the hydrolysis of adamantyl nitrates are seen to be far more negative that can be accounted for by the separation of a fully charged nitrate ion.[5] It seems reasonable that experimental values of $\Delta C_p^{\ddagger}$ in the range $-130 \rightarrow -150$ must contain factors derived from kinetic complexities and the nature of the limiting mechanism in water.

Several authors have recognized that if solvolytic reactions partition between two pathways having different critical energies, there will be a positive contribution to $\Delta C_p^{\ddagger}$ (14, 22, 23) but only for the case of ion-pair return is a negative 'spurious' contribution anticipated (24).[6]

While Albery and Robinson (24) neglected the possibility of a contribution to $\Delta C_p^{\ddagger}$ from solvent reorganization, they noted that where there was an equilibrium involving ion-pair return, such as proposed by Winstein and coworkers, a negative temperature coefficient would be found. This suggestion provides a ready explanation for that part of $\Delta C_p^{\ddagger}$ to be attributed to kinetic complexity. But there are difficulties with this hypothesis, the most obvious being to account for the large reduction in $\Delta C_p^{\ddagger}$ on the addition of a co-solvent (Table 2, and refs. 17 and 18). Winstein and his coworkers showed that ion-pair return depends markedly on the solvent employed (13, 25) and that this phenomenon was favoured by solvents of low solvating power and weak nucleophilicity. Water fits neither category. Our results show that on changing to a more favorable environment for ion-pair return, the effect in question largely disappears. Nor is it clear that water in a solvent-separated ion-pair will not be a stronger nucleophile rather than otherwise. Such enhanced nucleophilicity predicates no ion-pair return after initial front-side displacement. Here our evidence involves product forma-

[4]It is assumed that this +30 cal mol^{-1} deg^{-1} would contribute −30 cal mol^{-1} deg^{-1} to $\Delta C_p^{\ddagger}$ in the activation process (11).

[5]A probable value might be 80 cal mol^{-1} deg^{-1} based on −30 as a base value unrelated to water structure, −30 from hydrophobic bonding about neutral NO_3, and −20 from Table 4.

[6]A discussion of various possible contributions to $\Delta C_p^{\ddagger}$ from such kinetic complexities is given in a previous paper (23).

tion with the activated methyl rather than the adamantyl group. In the reaction of methyl iodide catalyzed by Ag^+ ion, the rate of reaction was found to be accelerated by excess nitrate ion. Hammond and co-workers (26) and Colcleugh and Moelwyn-Hughes (27) postulated the formation of an intermediate of the form $(NO_3^-)MeI(Ag^+)$. Since methanol was the only organic product, an alternative hypothesis would postulate $NO_3^- \cdots H_2O \cdots Me \cdots I \cdots Ag^+$, the Ag^+ being partially desolvated but the nucleophilic water molecule forming part of the NO_3^- solvation shell. This water molecule is then rendered more active by the presence of the NO_3^- group. Such a possibility is not inconsistent with the specific salt effects reported by Bunton and co-workers (28, 29) and provides a guide to the probable reason that evidence for ion-pair return from the solvent-separated ion-pair is not observed in solvents of fair nucleophilicity. Both of the foregoing arguments weigh against the ion-pair return hypothesis as a logical possibility to account for the large negative values of $\Delta C_p^{\ddagger}$ reported here but provide no clear alternative.

These arguments do not exclude the existence of contributions to $\Delta C_p^{\ddagger}$ from kinetic complexities associated with front-side displacement and water structure. Hence, in the absence of a better understanding, the significance of this empirical term ($\Delta C_p^{\ddagger}$) can still serve as a useful mechanistic probe giving an indication of the degree of charge development where the mechanism involves some degree of nucleophilic interaction and signalling front-side displacement where structural features permit or require this alternative.

Experimental

1-Adamantyl Nitrate

This compound was prepared from 1-adamantyl bromide (Aldrich Chemical Co. Inc.). 1-Adamantyl bromide (8 g, 0.041 mol) dissolved in 50 ml of dry ether was stirred with 10 g (0.059 mol) of powdered silver nitrate for 12 h at room temperature. After removal of the precipitated silver bromide the product was recovered by evaporation of the ether. Recrystallization from cyclohexane gave 5 g of 1-adamantyl nitrate. It was further purified by vacuum sublimation (65°C/0.1 torr), mp 103–104°C, nmr_{TMS} (CCl_4) δ 2.4–2.95 (m, 9, CH_2, CH), 2.05 (m, 6, CH_2). *Anal.* calcd. for $C_{10}H_{15}NO_3$: C 60.91, H 7.61, N 7.11; found: C 60.93, H 7.82, N 7.12.

2-Adamantyl Nitrate

A 2-adamantanol (Aldrich Chem. Co. Inc.) solution was refluxed with 48% HBr in the presence of concentrated H_2SO_4, for 24 h. The bromide thus obtained (95% yield) was extracted with ether. The nitrate was prepared from the bromide following the same procedure as in the case of 1-adamantyl nitrate, except for the fact that the stirring with silver nitrate was done for 24 h. The conversion was found to be 100% (no C—Br peak in the ir). The nitrate was crystallized from ether by removing part of the ether under vacuum. Further purification was done by vacuum sublimation; mp 30°C. *Anal.* calcd.: C 60.91, H 7.61, N 7.11; found: C 60.86, H 7.63, N 7.12.

para-Methylbenzyl nitrate was prepared and purified as before (8).

Solvent Mixtures

All solvent mixtures were prepared by mixing the two components, the volumes of which were calculated on the basis of their densities at the temperature of mixing (20°C). Ethanol was obtained from Standard Chemicals (absolute alcohol, 99.9%) and was used as such. Acetoni-

trile was of spectro quality obtained from Matheson, Coleman and Bell.

The water used was distilled water passed through an ion exchange column (Rexyn R208-1-300-H-OH).

An examination of two solvation parameters: $\Delta C_p^{\ddagger}$ and '*m*'

RAJANI KANTA MOHANTY[1] AND ROSS ELMORE ROBERTSON[2]

Department of Chemistry, University of Calgary, Calgary, Alta., Canada T2N 1N4

Received August 31, 1976

RAJANI KANTA MOHANTY and ROSS ELMORE ROBERTSON. Can. J. Chem. **55**, 1319 (1977).

The empirical '*m*' values from the Grunwald–Winstein solvent correlation equation for S_N displacement reactons show a fair correlation with corresponding $\Delta C_p^{\ddagger}$ values obtained from hydrolysis in water. The correlation plots separate according to the nature of the displaced groups, a consequence of different relative effects of anions on water structure. The mechanistic significance of the correlation is examined.

RAJANI KANTA MOHANTY et ROSS ELMORE ROBERTSON. Can. J. Chem. **55**, 1319 (1977).

Les valeurs '*m*' empiriques obtenues à partir de l'équation de corrélation de solvant de Grunwald–Winstein pour des réactions de déplacements S_N montrent une bonne relation avec les valeurs correspondants de $\Delta C_p^{\ddagger}$ obtenues à partir de l'hydrolyse dans l'eau. Les courbes de corrélation se séparent, suivant la nature des groupes déplacés; ce résultat est une conséquence des différents effets relatifs des anions sur la structure de l'eau. On examine la signification mécanistique de cette corrélation.

[Traduit par le journal]

A qualitative relationship between the ionizing properties of solvolyzing media and the rate of S_N displacement reactions was published over 40 years ago by Hughes and Ingold (1). During the intervening years various attempts have been made to formulate a more quantitative correlation (2–7). Among these, the linear free energy solvent correlation

$$[1] \qquad (\log k = \log k_0 + mY)$$

of Grunwald and Winstein has attracted the most lasting attention, possibly because of its apparent simplicity. The authors, themselves, recognized that this correlation was not entirely satisfactory (4, 8), a fact they illustrated by showing that various solvent mixtures produced a dispersion of plots (see also refs. 9–11). Equation 1 illustrates the inherent difficulty in attempting to reduce a number of interacting complexities to a simple expression. In such a simplification fine structure tends to be neglected.

While these more general attempts were being made to compass solvent effects on S_N reactions, we have examined the solvent effects on ionogenic S_N reactions hydrolyzing, mainly in water, using the semi-empirical parameter, $\Delta C_p^{\ddagger}$, as a measure of charge development at the transition state (12). Originally we thought that this coefficient ($d\Delta H^{\ddagger}/dT = \Delta C_p^{\ddagger}$) was determined wholly by the difference in heat capacity between the initial and transition states of the surrounding aqueous solvent shell ($\Delta C_p^{\ddagger} = (\bar{C}_{p\ \text{T.S.}} - \bar{C}_{p\ \text{I.S.}})$ induced by the external effects of charge development on the activated quasi-ion pair. This is an over-simplification. The temperature coefficient of $\Delta H^{\ddagger}$ is necessarily complex and empirical in spite of the apparent certitude engendered by transition state terminology. The latter fact may limit but does not cancel the value of $\Delta C_p^{\ddagger}$ as a useful indicator of the detailed mechanism of hydrolysis in water. Among the modifications to the initial hypothesis (13) was the recognition that a base value of about -30 cal mol^{-1} deg^{-1} was present apparently unrelated to solvent structure in water and that $\Delta C_p^{\ddagger}{}_{\text{str}} = (\Delta C_p^{\ddagger} - 30)$ was determined largely (if not entirely) by charge development on the quasi anion (14). The latter modification was based in part on the observation that those reactants, RX, in which R possessed the greatest capacity to distribute positive charge and hinder nucleophilic attack (*e.g.*, 1-adamantyl nitrate (15, 16)) were just those which yielded the most negative values of $\Delta C_p^{\ddagger}$ yet were also just those cases where the positive charge was least likely to break down water structure. One of the more illuminating studies correlating $\Delta C_p^{\ddagger}$ with the probable charge on the quasi anion at the transition state and with corresponding changes on the central carbon atom at the transition state was published in two papers by Koshy and Robert-

son (13, 17). From these, and related data it was concluded that for such displacements the transition state corresponded to some critical level of positive charge becoming available[3] on the central carbon. This simple operative condition provides an external mechanism (S_N2) for a reduction of internal electrostatic interaction and a transfer of electrons permitting the eventual front-side displacement of X. The kinetic solvent isotope effect (19) and the above noted correlation (17) both support the conclusion that the transition state coincides with the initial establishment of nucleophilic interaction *and* if nucleophilic interaction is possible it will be established.[4] The alternative to that seeming tautology will be the limiting mechanism where front-side displacement precedes nucleophilic interaction. We shall return to this point in connection with the hydrolysis of *tert*-butyl chloride. It follows that the more efficient the charge dispersal in $R^{\delta+}$ of the activated RX, the greater the reduction in internal electrostatic interaction between $R^{\delta+}$ and $X^{\delta-}$. Such dispersal will have two important mechanistic consequences. (*i*) There will be a corresponding enhancement of external effects of $X^{\delta-}$ on the adjacent solvent shell (the ionizing properties of the solvent will become increasingly important) and (*ii*) there will be a delay in establishing nucleophilic interaction relative to the reaction coordinate. This simple analysis was sufficient to account for the $\Delta C_p^{\ddagger}$ *vs.* k_H/k_D correlation (17) noted above for the hydrolysis of a series of benzyl nitrates in water and we would assume will apply also to solvolysis in organo–aqueous mixtures. Solvolysis in acetic acid and similar media tends to enhance the possibility of ion-pair complications (20, 21) which are not important in water and hence are neglected here. The above hypothesis at once provides a basis for understanding why the transition state is reached at a later stage for displacement through the series *prim* < *sec* < *tert* and why there is a corresponding shift to more negative values of $\Delta C_p^{\ddagger}$ and leads to the structural condition predicating a limiting mechanism. These general conclusions reached from a consideration of $\Delta C_p^{\ddagger}$ values provide a basis for examining the '*m*' values of the Grunwald–Winstein correlation [1].

Granted the above analysis for hydrolytic S_N displacements in water approximates solvolytic displacements in general, then '*m*' is necessarily complex. This term reflects the ability of the R groups to disperse electron deficiency, steric factors which influence the initiation of nucleophilic interaction, and some portion of inherent nucleophilic activity of the solvent not included in *Y*.

Originally (2, 3) the *Y*-values were expected to characterize the ionizing properties of the solvent. However, since it is doubtful if *tert*-butyl chloride hydrolyzes by a limiting mechanism in water (see below) it is less likely to do so in 80/20 v/v ethanol–water, the original standard solvent. Hence *Y* will contain some varying specific nucleophilic contribution and the dispersion noted by Grunwald and co-workers is not surprising. What was much less obvious at first sight was that '*m*' values determined using the displacement of a halide or a tosylate were about the same (16) when we knew that the interaction of these displaced groups on hydrolysis in water was quite different (1, 5). It was this seeming contradiction which led to the present comparison between $\Delta C_p^{\ddagger}$ and '*m*' values for hydrolysis.

Results and Discussion

The $\Delta C_p^{\ddagger}$ values were known for a series of substituted benzyl nitrates in water (13) and since these provided a basis for the mechanistic conclusions outlined above, corresponding '*m*' values were determined from solvolytic rate data obtained in various (two or three) ethanol–water mixtures by a conductance method (22). This limited series together with the water data was judged sufficient for an approximate value of '*m*' in view of the inherent uncertainties in the latter term (8). With the exception of the 2,6-dimethyl substituent the benzyl series had the advantage of low, and similar steric requirements. Rate data and corresponding '*m*' values are given in Table 1. A plot of the latter *vs.* $\Delta C_p^{\ddagger}$ for hydrolysis in water is given in Fig. 1. On the same figure are included plots for corresponding data for a number of halides and sulfonates. It is at once evident that a fair correlation exists, divided according to the nature of the displaced groups. This division is the natural consequence of the fact that $\Delta C_p^{\ddagger}$ reflects the specific exter-

[3]In the general case, 'available' will include allowance for steric factors which in the noted benzyl series were low with exception of the 2,6-dimethyl substituent (15, 18).

[4]NOTE ADDED IN PROOF: J. L. Kurn reaches a similar conclusion from a different premise (Acc. Chem. Res. **5**, 1 (1972)).

nal effects of a given charge on the particular group being displaced while '*m*' reflects the *relative* effect of particular displacement to that corresponding to an assumed limiting case for the same anion.

The correlation of $\Delta C_p^{\neq}$ and '*m*' for the benzyl nitrate series is seen to be quite satisfactory while that for the sulfonates shows a lack of sensitivity presumably because the internal charge dispersal in the sulfonate group reduces internal interaction and at the same time minimizes external effects (12, 19, 23). The '*m*' values reflect the degree of overall charge on the R group when the critical charge on the central carbon corresponds to that necessary to initiate nucleophilic interaction.[5] The examples on the halide plot show a greater degree of scatter. This was expected since there is considerable variation in the steric contribution to '*m*' through this series. A notable example is *tert*-butyl chloride which is more widely displaced than might be expected. We attribute this to the fact that *tert*-butyl chloride in water does not give a limiting value of $\Delta C_p^{\neq}$ for displacement of a halide (24), a fact which suggests that the mechanism of hydrolysis for this compound in water is not limiting; *i.e.* in the absence of obtrusive steric factors nucleo-

[5]The kinetic solvent isotope effects (k_{H_2O}/k_{D_2O}) for displacement of the sulfonic group are about 1.1 in all cases examined (19).

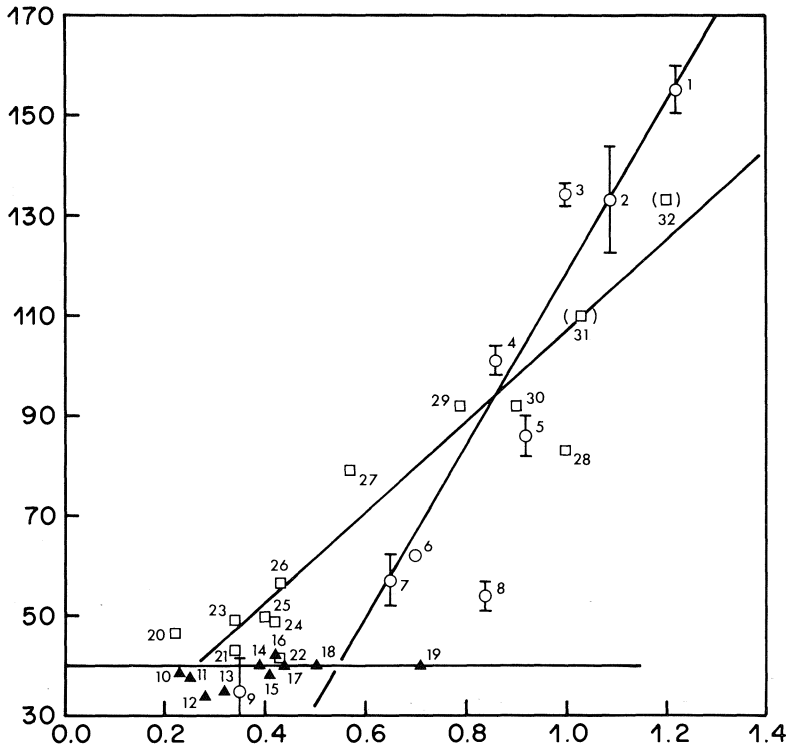

FIG. 1. A correlation of $\Delta C_p^{\ddagger}$ and 'm' for the solvolytic displacement of a series of nitrates, halides, and sulfonates: (*1*) 1-adamantyl nitrate (this work, Table 1); (*2*) 2-adamantyl nitrate (this work, Table 1); (*3*) 2,6-dimethylbenzyl nitrate (this work, Table 1); (*4*) 4-methylbenzyl nitrate (this work, Table 1); (*5*) 2-methylbenzyl nitrate (this work, Table 1); (*6*) benzyl nitrate (this work, Table 1); (*7*) trifluoromethylbenzyl nitrate (this work, Table 1); (*8*) 3-methylbenzyl nitrate (this work, Table 1); (*9*) 4-nitrobenzyl nitrate (this work, Table 1); (*10*) methyl tosylate (12, 27); (*11*) ethyl tosylate (12, 27); (*12*) ethyl benzenesulfonate (12, 28); (*13*) *n*-butyl brosylate (12, 28); (*14*) benzyl tosylate ($\Delta C_p^{\ddagger}$ assumed) (12, 28); (*15*) 2-propyl brosylate (12, 28); (*16*) 2-propyl tosylate (12, 27); (*17*) cyclohexyl tosylate ($\Delta C_p^{\ddagger}$ assumed) (27); (*18*) cyclopropyl tosylate ($\Delta C_p^{\ddagger}$ assumed) (29); (*19*) 3,3-dimethyl-2-butyl brosylate ($\Delta C_p^{\ddagger}$ assumed) (30); (*20*) methyl bromide (12, 16); (*21*) *n*-propyl bromide (12, 28); (*22*) benzyl chloride (28, 32); (*23*) ethyl bromide (12, 16); (*24*) β-methylallyl chloride (28, 31); (*25*) allyl chloride (28, 31); (*26*) 2-propyl bromide (12, 16); (*27*) 4-methylbenzyl chloride (28, 32); (*28*) *tert*-butyl chloride (2, 12); (*29*) α-methylallyl chloride (28, 31); (*30*) *tert*-amyl bromide ($\Delta C_p^{\ddagger}$ assumed) (12, 28); (*31*) 2-adamantyl bromide ($\Delta C_p^{\ddagger}$ estimated) (16); (*32*) 1-adamantyl bromide ($\Delta C_p^{\ddagger}$ estimated) (16).

The values of $\Delta C_p^{\ddagger}$ for all sulfonates examined are in the range 35 ± 6 cal mol^{-1} deg^{-1}. $\Delta C_p^{\ddagger}$ for 4-methylbenzyl chloride was 20 cal mol^{-1} deg^{-1} less negative than the value for the corresponding nitrate. This fact provided the basis for the estimated values of the adamantyl bromides, which regrettably were too insoluble in water to study.

philic interaction is established (and transition state reached) prior to full charge development on the Cl^- ion. We do not have a $\Delta C_p^{\ddagger}$ value for 1-adamantyl bromide (which would certainly react by a limiting mechanism) but judging from the difference in $\Delta C_p^{\ddagger}$ for *p*-methylbenzyl nitrate and chloride (13) the point for this limiting compound would lie very close to the curve shown for the halides. Where the same difference in $\Delta C_p^{\ddagger}$ is allowed between 2-adamantyl nitrate and bromide as between 4-methyl benzyl nitrate and chloride, the point for 2-adamantyl bromide falls on the halide plot. A direct determination of $\Delta C_p^{\ddagger}$ for 2-adamantyl bromide failed because of solubility problems.

That 'm' and $\Delta C_p^{\ddagger}$ are found to show a fair correlation dependent on the displaced group provides a method for estimating the probable value of $\Delta C_p^{\ddagger}$ for hydrolysis in water without the necessity of a rather demanding kinetic study, or for cases where such a study is impractical. In our view, the much greater value of this

study comes from the insight which the comparison provides with regard to the critical condition necessary for S_N displacement reactions and for the significance of '*m*'.

Experimental

Water

Ordinary distilled water was passed through an ion exchange resin (Fisher Research Grade Rexyn I-300) and subsequently redistilled.

Ethanol

Absolute ethanol supplied by Standard Chemicals, 99.9% pure, was used as such.

Nitrate Esters

All nitrate esters were prepared by either the heterogeneous or homogeneous method (17) starting from the chloride or the bromide, except for *ortho*, *meta*, and *para* and 2,4-dimethyl benzyl nitrates which were available. They were purified before use either by distillation under reduced pressure (25) or by crystallization from a suitable solvent depending on whether the nitrate was a liquid or solid. Details have been reported (26). The different solvent mixtures were prepared by mixing the two components (v/v) at room temperature. The first-order rate constants were determined by using Queen type cells either at one common temperature (48°C) or through extrapolation from other temperatures. Extrapolation was not attempted in cases where the rate was either too slow or too fast because of the high error involved. The rate data were obtained by a conductance method. The error involved in the rates was much less than $\pm 0.5\%$ except in case of *p*-NO_2-benzyl nitrate and 2-butyl nitrate where an error of ± 0.7 to $\pm 0.8\%$ was encountered in some of the rates.

The *Y* values for different solvent mixtures were obtained from the literature (4). The '*m*' values were obtained from the plots of log *k* in water and at least two aqueous ethanol solvents *vs.* *Y* (slope = '*m*'). A good straight line was obtained in most cases except for *p*-methylbenzyl nitrate where the best possible straight line was used.

C-Alkylation of 1,3-dihydroxyanthraquinones. Total syntheses of (±)-averufin and (±)-bipolarin

ANDRÉ CASTONGUAY AND PAUL BRASSARD

Département de Chimie, Université Laval, Québec (Qué.), Canada G1K 7P4

Received July 19, 1976

ANDRÉ CASTONGUAY and PAUL BRASSARD. Can. J. Chem. **55**, 1324 (1977).

Various methods of substituting 1,3-dihydroxyanthraquinones in the 2-position were investigated. It was eventually found that direct hydroxyalkylation in the presence of definite amounts of sodium bicarbonate could be carried out. The reaction of 1,3,6,8-tetrahydroxyanthraquinone with 5-oxohexanal or 4-hydroxybutanal gave, respectively, among other products, (±)-averufin and (±)-bipolarin.

ANDRÉ CASTONGUAY et PAUL BRASSARD. Can. J. Chem. **55**, 1324 (1977).

Diverses façons de substituer les dihydroxy-1,3 anthraquinones en position 2 ont été étudiées. Eventuellement, l'hydroxyalkylation directe s'est avérée réalisable en présence de quantités définies de bicarbonate de sodium dans l'eau. Ainsi les réactions de la tétrahydroxy-1,3,6,8 anthraquinone avec l'oxo-5 hexanal ou l'hydroxy-4 butanal donnent respectivement, entre autres produits, l'(±)-avérufine et la (±)-bipolarine.

A number of naturally occurring anthraquinones such as averantin (1), bipolarin (2), avermutin (1), versicorufin (3), and averufin (1) and its derivatives (2, 3) can be considered formally as hydroxyalkylation products of 1,3,6,8-tetrahydroxyanthraquinone (**25**). Averantin has previously been prepared by the reduction of solorinic acid (4), however none of the other proposed structures have been obtained or confirmed by synthesis. Hydroxymethylation of xanthopurpurin or its derivatives has been successful (5) but no reaction using higher homologs of formaldehyde appears to have been described.

Even though 1,3,6,8-tetrahydroxyanthraquinone has recently become quite readily available (6), most work of an exploratory nature was carried out with the more common xanthopurpurin (**1**). Several methods of preparing this compound exist, but in our hands only one, very succinct, was found to be satisfactory (7). This procedure involving the hydrosulfite reduction of the commercial dye purpurin was found to be simple and to give a high yield (85%) of the desired product.

The first attempts to do substitution on the system centered on the alkylation, with 1-chloro-1-methoxybutane, or the acylation of 1,3,9,10-tetraacetoxyanthracene (**2**). Various modifications of Friedel–Crafts conditions produced no useful result; however, a Fries rearrangement of the substrate did give the 2-acetyl derivative (**3**) in low yield (15%) which could not be improved.

31 $R^1 = R^3 = H, R^2 = CH{=}CH(CH_2)_3CH_3$

Attempts to carry out the process photochemically did not give the expected product.

Alkylation of the anthracene nucleus at the required position was next envisaged by first lithiating the 1,3,9,10-tetramethoxy derivative (**7**). It is well known that di-*O*-methylresorcinol

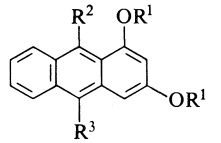
is metallated in position 2 (8) and although anthracene itself gives rise to a 9,10-addition of ethyllithium (9), it was expected that the methoxyl groups would decrease the affinity of these positions sufficiently to permit the desired metallation. The reactions of 1,3,9,10-tetramethoxyanthracene with either butyl- or phenyllithium gave products unsubstituted in position 2 and which obviously were produced by 9,10-addition of the reagents followed by elimination of lithium methoxide. Electronic effects allowed the prediction that the alkyl or aryl group would occupy the 9-position. This was confirmed at least in the case of the phenyl derivative since the nmr spectrum shows a strong upfield shift for the 1-methoxyl group (δ 3.37).

In was then sought to modify the anthraquinoid structure by converting it to the diketal. This could conveniently be carried out by electrochemical oxidation of the corresponding hydroquinone diether. Modification of earlier work (10) improved the yield of anthraquinone tetramethyl diketal (78%), however, some of the monoketal was also isolated (15%). An attempt to extend the reaction to 1,3,9,10-tetramethoxyanthracene proved to be impractical since a large number of products were detected.

Use of the Wittig reaction in the course of the alkylation of xanthopurpurin was also investigated since lucidin (**10**) and its analogs can readily be prepared (5). Methylation of the hydroxymethylated compound **10** and oxidation gave the aldehyde **12** which reacted with *n*-pentylenetriphenylphosphorane. Under the conditions used, a 70% yield of the expected di-*O*-methyl-bis-deoxyaverythrin (**14**) was obtained along with 12% of 3-butoxy 2-(*trans*-hex-1-enyl)-1-methoxyanthraquinone (**13**), the product of an unusual type of transetherification (the identity of the latter is derived mainly from its mass and the nmr spectrum which shows in particular the disappearance of the 3-methoxyl group and the presence of a triplet at δ 3.92 attributed to the oxymethylene part of the butoxy substituent). An extended use of this method depended on the possibility of protecting the phenolic groups reversibly during the condensation and all attempts at methoxymethylation of both lucidin (**10**) and nordamnacanthal (**15**) succeeded only in O-alkylating the 3-hydroxyl functions.

The Claisen rearrangement provides another versatile method for alkylating anthraquinones and its use has been illustrated in a recent synthesis of islandicin (11). More hindered systems such as 1-allyloxy-3-methoxyanthraquinone (**16**) and 1-allyloxy-3-(tetrahydropyran-2-yloxy)anthraquinone (**17**) have now been found to rearrange smoothly to the expected products **19** and **20** in boiling 1,2-dichlorobenzene (in the latter case with loss of the protecting group). Moreover xanthopurpurin can be selectively O-allylated in position 3 and then converted although slowly upon heating to the 2-allyl derivative (**20**). Isomerization of the double bond in this compound into conjugation with the aromatic ring proved to be surprisingly difficult but was eventually carried out with the use of rhodium trichloride (12). The resulting 2-(*trans*-prop-1-enyl) derivative (**21**) when treated with osmium tetroxide gave a *threo*-diol (**22**) having one of the partial arrangements analogous to those required in an eventual synthesis of nidurufin. One attempt to introduce a longer side-chain by O-alkylating xanthopurpurin with 3-chlorohex-1-ene was unsuccessful and only the rearranged hex-2-enyl diether could be isolated.

Attention was then turned to the hydroxyalkylation of 1,3-dihydroxyanthraquinones by



2 $R^1 = COCH_3$, $R^2 = R^3 = OCOCH_3$

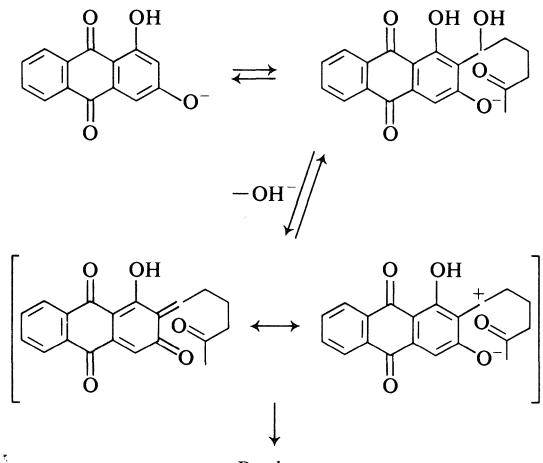
aldehydes in basic media. The method had previously been successful in the case of formaldehyde, but attempts to apply it to other aldehydes under a variety of conditions did not provide a trace of the expected product. A number of hypotheses were then made which eventually led to successful hydroxyalkylations: (*a*) the products of C-hydroxyalkylation were assumed to be highly hindered and particularly prone to fragmentation, (*b*) strong or excess base was expected to promote the reverse reaction, (*c*) the presence of another function capable of trapping the secondary alcohol or the corresponding carbonium ion was thought to favor the reaction, and finally (*d*) it was anticipated that the use of a polar protic solvent would facilitate C-alkylation by strongly solvating the aryl oxide oxygen.

These prerequisites were taken into account in an experiment involving xanthopurpurin, 1 equiv. of sodium bicarbonate, and an excess of 5-oxohexanal in water at about 95°C. It was expected that if hydroxyalkylation occurred the secondary alcohol would combine with the ketone and form a fairly stable cyclic hemiketal (Scheme 1). Chromatography of the crude reaction product provided three compounds, one of which revealed that the reaction had indeed gone one step further than anticipated and had given an 11% yield of the analog of averufin, bis-deoxyaverufin (**23**). The nmr spectrum of this substance is in good agreement in part with that of averufin while its mass spectrum is almost superimposable on that of the latter when shifted by 32 mass units. From the top of the column a very polar and highly insoluble compound (31%) was isolated and converted to the tetramethyl ether. This derivative was identified as the 6,6-di(1,3-dimethoxyanthraquinon-2-yl)hexan-2-one (**24**) by its molecular mass (632) and its nmr spectrum which shows an acetyl group (δ 2.11), a single benzylic proton as a triplet (δ 5.13), and the absence of the characteristic signal for 2-H in xanthopurpurin. Forty percent of the starting material was also recovered from a median fraction.

The synthesis of (±)-averufin (**26**) required 1,3,6,8-tetrahydroxyanthraquinone (**25**) which was obtained in a 92% yield from the tetramethyl ether (6) by a brief treatment with a molten mixture of sodium and aluminum chlorides. The hydroxyalkylation of this quinone with 5-oxohexanal was found to require 2 equiv. of bicarbonate, a much longer reaction time (11 h) and a lower temperature (~85°C). Under these conditions a 6.5% yield of the desired product was isolated along with a large amount of unreacted starting material (48%). Some of the corresponding dianthraquinonylhexanone was also undoubtedly formed but was not isolated. Racemic averufin was indistinguishable from the natural product (tlc in four solvent systems and comparison of the ir and mass spectra).



SCHEME 1

The ketoaldehyde used in the preceding syntheses was then replaced by the readily accessible 5-hydroxypentanal in order to determine whether 2-(tetrahydropyran-2-yl) derivatives of 1,3-dihydroxyanthraquinone of the type of avermutin could be obtained by this modification of the method. Dry column chromatography of the crude products gave a fast moving zone which, when rechromatographed, gave a substance (20%) identified as bis-deoxynoravermutin (**27**). The nature of the substance was confirmed by its mass spectrum which shows a fragmentation pattern almost identical to that of avermutin but shifted by 46 mass units. In the nmr spectrum, the absence of a signal corresponding to the proton in position 2 and the presence of a broad doublet at δ 5.05 (J_{aa} = 8 Hz), a multiplet at δ 3.64 collapsing to a broad doublet (J_{gem} = 11 Hz) by irradiation of the other axial hydrogens, and a broad doublet at δ 4.24 corresponding respectively to the 2′ axial, 6′ axial, and 6′ equatorial protons corroborate the assigned structure. The data also suggest that the tetrahydropyranyl ring is essentially rigid and attached to the anthraquinone in the equatorial position.

From the second column, 26% of the starting material was also recovered along with a small

amount (5%) of a dehydration product, 2-(5-hydroxy-*trans*-pent-1-enyl)-1,3-dihydroxyanthraquinone (**28**) which was identified straightforwardly from the spectra of the corresponding dimethyl ether. Finally a fourth product, the dianthraquinonylpentanol (**29**) was isolated from the top of the first column.

The foregoing results suggested that the racemic modification of another natural product, bipolarin (**30**), could now be prepared very easily by this method. The required 4-hydroxybutanal was obtained in a crude form by reducing γ-butyrolactone with diisobutylaluminum hydride (13) and reacted with 1,3,6,8-tetrahydroxyanthraquinone under conditions similar to those used for the synthesis of (±)-averufin. Preparative thin layer chromatography of the crude products gave a fast moving zone which consisted of (±)-bipolarin (**30**) (22%). Some starting material (8%) was recovered from a second band but other fractions were not examined. An authentic sample of bipolarin was unavailable but the physical and spectral properties of the synthetic substance are in excellent agreement with those of the natural product (with the exception of one ir band obtained by a different method).

Under the described conditions, aldehydes incapable of forming cyclic derivatives were nonetheless found to react with xanthopurpurin. With *n*-hexanal the process was very slow but afforded a 23% yield of bis-deoxyaverythrin (2-(*trans*-hex-1-enyl)-1,3-dihydroxyanthraquinone (**31**)) which after methylation was found to be identical to a product prepared earlier by a Wittig reaction. Other experiments carried out in media containing substances capable of intercepting the intermediate benzylic alcohol were unsuccessful. In aqueous acetone the reaction proceeded more rapidly than in water. The same product (26%) was obtained as before but uncontaminated with starting material. A 4% yield of a second unidentified product was also obtained which according to the mass spectrum is dimeric. In a 1:1 mixture of methanol and water a very little (4.5%) of the usual product was encountered along with the dianthraquinonylhexane (**32**) and much starting material. All attempts to substitute 1,3,6,8-tetrahydroxyanthraquinone by analogous means failed.

Experimental

Melting points were taken for samples in capillary tubes with a Thomas–Hoover apparatus (calibrated thermometer). The ir and uv spectra were determined with Beckman IR-12 and DK-1A spectrophotometers respectively. The nmr spectra were recorded with Varian A-60 and Bruker HX-90 spectrometers (tetramethylsilane as internal standard). The mass spectra were obtained with a Varian M-66 spectrometer. Davison silica gel No. 923 was used for column chromatography, Baker-7G silica gel for preparative tlc, and Woelm silica gel, activity III, for dry column chromatography.

*Xanthopurpurin (**1**)*

To a solution of purpurin (50.0 g, 0.195 mol) in water (2 ℓ) and concentrated ammonia (100 ml) at 0–5°C was added sodium hydrosulfite (100 g) over a period of 1 h. The mixture was stirred at this temperature for 4.5 h, allowed to stand overnight, aerated for 12 h, acidified with hydrochloric acid, and filtered. The washed and dried residue can be recrystallized in portions from a large volume of 1,2-dichloroethane and consists of xanthopurpurin (40 g, 85%), mp 270–271°C (lit. (14) mp 262–263°C; lit. (15) mp 268–270°C); δ (90 MHz, C_5D_5N) 6.93 (1H, d, J = 2.5 Hz, 2-H), 7.39–7.78 (2H, m, 6,7-H), 7.62 (1H, d, J = 2.5 Hz, 4-H), and 8.00–8.42 (2H, m, 5,8-H); *m/e* 240 (M^+), 212, 184.

*1,3,9,10-Tetraacetoxyanthracene (**2**)*

A mixture of 1,3-diacetoxyanthraquinone (3.72 g, 11.5 mmol), anhydrous sodium acetate (220 mg, 2.68 mmol), activated zinc (11 g), and acetic anhydride (100 ml) was refluxed for 35 min, filtered, poured into water, and neutralized with sodium bicarbonate. Extraction of the aqueous suspension with benzene gave the tetraacetate **2** (4.0 g, 85%), mp 191–193°C (toluene); λ_{max} ($CHCl_3$) 252, 258, 360, 375, 395 nm (log ε 4.97, 5.25, 3.73, 3.83, 3.82); ν_{max} (KBr) 1760 (acetate) and 1635 (aromatic C=C) cm^{-1}; δ (60 MHz, $CDCl_3$) 2.32, 2.42, 2.50, and 2.57 (4 × 3H, 4s, 1,3,9,10-OAc), 7.02 (1H, d, J = 2.5 Hz, 2-H), 7.40 (1H, d, J = 2.5 Hz, 4-H), 7.48–7.66 (2H, m, 6,7-H), and 7.72–7.95 (2H, m, 5,8-H); *m/e* 410 (M^+), 368, 326, 284. *Anal.* calcd. for $C_{22}H_{18}O_8$: C 64.39, H 4.42; found: C 64.58, H 4.32.

*2-Acetyl-1,3-dihydroxyanthraquinone (**3**)*

1,3,9,10-Tetraacetoxyanthracene (**2**) (410 mg, 1.00 mmol) was added to anhydrous aluminum chloride (665 mg, 5.00 mmol) in nitrobenzene (2 g) at 0–5°C. The mixture was stirred at room temperature for 15 h and poured into water (100 ml). After elimination of the nitrobenzene by washing with petroleum ether (bp 30–60°C), the aqueous phase was extracted with ethyl acetate (3 × 100 ml). The residue obtained after evaporation of the solvent was chromatographed on silica gel (dry column, chloroform – ethyl acetate 4:1) and gave the rearranged quinone (**3**) (41 mg, 15%), mp 188–189°C (1,2-dichloroethane); λ_{max} (chloroform) 258, 298, 430 nm (log ε 4.50, 4.27, 3.77); ν_{max} (KBr) 1670 (quinone C=O) and 1620 (chelated C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 2.82 (3H, s, $COCH_3$), 7.31 (1H, s, 4-H), 7.72–7.91 (2H, m, 6,7-H), and 8.19–8.38 (2H, m, 5,8-H); *m/e* 282 (M^+), 267. Diacetate (Ac_2O:H_2SO_4), mp 185–186°C (ethanol–water). *Anal.* calcd. for $C_{20}H_{14}O_7$: C 65.57, H 3.85; found: C 65.35, H 3.73.

*1-Hydroxy-3-(methoxymethoxy)anthraquinone (**4**)*

The silver salt of xanthopurpurin was first prepared from a solution of the quinone (240 mg, 1.00 mmol) in

aqueous 0.2 *N* sodium hydroxide by addition of silver nitrate (170 mg, 1.00 mmol) in water (3 ml). A suspension of the well dried silver salt in a mixture of chloromethoxymethane (240 mg, 3 mmol) and anhydrous benzene (10 ml) was stirred at room temperature for 2 days and then poured into water. The residue of the ether extract was chromatographed on silica gel (dry column, benzene) and gave the 3-methoxymethyl ether (**4**) (228 mg, 80%), mp 135–136°C (toluene); ν_{max} (KBr) 1670 (quinone C=O) and 1630 (chelated C=O) cm^{-1}; δ (60 MHz, $CDCl_3$) 3.48 (3H, s, OCH_3), 5.23 (2H, s, $—OCH_2O—$), 6.80 (1H, d, J = 2.5 Hz, 2-H), 7.38 (1H, d, J = 2.5 Hz, 4-H), 7.50–7.80 (2H, m, 6,7-H), and 8.05–8.33 (2H, m, 5,8-H); *m/e* 284 (M^+). *Anal.* calcd. for $C_{16}H_{12}O_5$: C 67.50, H 4.26; found: C 67.46, H 4.22.

*1,3-Di(methoxymethoxy)anthraquinone (**5**)*

The disodium salt of xanthopurpurin was obtained by evaporating to dryness a solution of the quinone (240 mg, 1.00 mmol) and sodium hydroxide (80 mg, 2.00 mmol) in aqueous methanol. To a stirred suspension of the dried salt in chloromethoxymethane (160 mg, 2.00 mmol) and anhydrous 1,2-dimethoxyethane (10 ml) were added alternately small portions of sodium and chloromethoxymethane until the yellow colour of the mixture was no longer altered by addition of the metal (24 h). Dilution of the reaction mixture with chloroform, extraction with 1% aqueous sodium hydroxide, and evaporation of the organic solvents gave the mixed diacetal **5** (297 mg, 90%), mp 158–159°C (ether – petroleum ether, bp 30–60°C); ν_{max} (KBr) 1655 (quinone C=O) cm^{-1}; δ (60 MHz, $CDCl_3$) 3.48 and 3.55 (2 × 3H, 2s, OCH_3), 5.27 and 5.33 (2 × 2H, 2s, $—OCH_2O—$), 7.13 (1H, d, J = 3.0 Hz, 2-H), 7.60 (1H, d, J = 3.0 Hz, 4-H), 7.55–7.87 (2H, m, 6,7-H), and 8.05–8.38 (2H, m, 5,8-H); *m/e* 328 (M^+), 313. *Anal.* calcd. for $C_{18}H_{16}O_6$: C 65.85, H 4.91; found: C 65.63, H 4.97.

*9,10-Dimethoxy-1,3-di(methoxymethoxy)anthracene (**6**)*

To a mixture of 1,3-di(methoxymethoxy)anthraquinone (264 mg, 0.80 mmol), absolute ethanol (0.5 ml), 20% aqueous sodium hydroxide (2 ml), and activated zinc (80 mg), stirred under nitrogen and kept at 86°C, was added methyl *p*-toluenesulfonate (1.45 g) in portions over a period of 3 h. After one more hour the reaction mixture was extracted several times with benzene and the latter evaporated. The residue was chromatographed on basic alumina (Brockman, activity I) and gave the anthracene **6** as an unstable oil (125 mg, 43%); δ (60 MHz, $CDCl_3$) 3.47 and 3.55 (2 × 3H, 2s, $—CH_2OCH_3$), 3.95 and 3.97 (2 × 3H, 2 s, 9,10-OCH_3), 5.25 and 5.32 (2 × 2H, 2s, $—OCH_2O—$), 6.82 (1H, d, J = 2.5 Hz, 2-H), 7.18–7.47 (2H, m, 6,7-H), 7.40 (1H, d, J = 2.5 Hz, 4-H), and 7.90–8.38 (2H, m, 5,8-H).

*1,3,9,10-Tetramethoxyanthracene (**7**)*

To a mixture of 1,3-dimethoxyanthraquinone (1.13 g, 4.22 mmol), ethanol (2.5 ml), 20% aqueous sodium hydroxide (10 ml), and activated zinc (415 mg), heated to refluxing under nitrogen for 4 h was added methyl *p*-toluenesulfonate (8.05 g) in portions over a period of 3 h. The residue obtained by evaporation of a chloroform extract of the reaction mixture was chromatographed on neutral alumina (50 g) (Woelm, activity I) (benzene–ether 1:1) and gave the tetramethyl ether **7** (683 mg, 54%), mp 120–121°C (ether); δ (60 MHz, $CDCl_3$–C_6D_6 4:1) 3.82, 3.85, 3.90, and 3.93 (4 × 3H, 4s, 1,3,9,10-OCH_3), 6.42 (1H, d, J = 2.5 Hz, 2-H), 7.07 (1H, d, J = 2.5 Hz, 4-H), 7.02–7.47 (2H, m, 6,7-H), and 8.03–8.43 (2H, m, 5,8-H); *m/e* 298 (M^+), 283. *Anal.* calcd. for $C_{18}H_{18}O_4$: C 72.46, H 6.08; found: C 72.53, H 5.93.

*1,3,10-Trimethoxy-9-phenylanthracene (**8**)*

To a well stirred solution of 1,3,9,10-tetramethoxyanthracene (149 mg, 0.50 mmol) in anhydrous ether (2 ml) was added under nitrogen an ether solution of phenyllithium (0.5 mmol). The reaction mixture was allowed to stand for several hours and poured into water (50 ml). The crude solid was chromatographed on neutral alumina (20 g, Woelm, activity I) (benzene–chloroform) and gave the phenylanthracene **8** (130 mg, 76%), mp 190–192°C (ether); δ (60 MHz, $CDCl_3$) 3.37 (3H, s, 1-OCH_3), 3.97 and 4.12 (2 × 3H, 2s, 3,10-OCH_3), 6.37 (1H, d, J = 2.5 Hz, 2-H), 7.20 (1H, d, J = 2.5 Hz, 4-H), 7.33 (5H, s, 9-C_6H_5), 7.27–7.50 (2H, m, 6,7-H), and 8.17–8.40 (2H, m, 5,8-H); *m/e* 344 (M^+), 329, 314. *Anal.* calcd. for $C_{23}H_{20}O_3$: C 80.21, H 5.85; found: C 80.47, H 5.86.

*9-Butyl-1,3,10-trimethoxyanthracene (**9**)*

An analogous preparation (1.00 mmol of 1,3,9,10-tetramethoxyanthracene and 1.00 mmol of butyllithium) gave the butylanthracene **9** (322 mg, 99%); δ (60 MHz, $CDCl_3$) 1.03 (3H, t, J = 7.0 Hz, 4′-H_3), 1.30 and 1.66 (6H, 2m, 1′,2′,3′-H_2), 3.80, 3.87, and 3.97 (3 × 3H, 3s, 1,3,10-OCH_3), 6.40 (1H, d, J = 3.0 Hz, 2-H), 7.10 (1H, d, J = 3.0 Hz, 4-H), 7.25–7.48 (2H, m, 6,7-H), and 8.07–8.33 (2H, m, 5,8-H); *m/e* 324 (M^+). *Anal.* calcd. for $C_{21}H_{24}O_3$: C 77.75, H 7.46; found: C 77.83, H 7.60.

*2-Hydroxymethyl-1,3-dimethoxyanthraquinone (**11**)*

Methylation of lucidin (5) (**10**) (270 mg, 1.00 mmol) by a standard procedure (anhydrous potassium carbonate (6.0 g), dimethyl sulfate (0.5 ml), and boiling acetone (200 ml) (24 h)) gave the dimethyl ether **11** (212 mg, 71%), after chromatography of the crude product on silica gel (benzene – ethyl acetate 1:1), mp 173.5–174.0°C (lit. (16) mp 175°C) (ether – petroleum ether, bp 30–60°C); λ_{max} ($CHCl_3$) 247, 274, 390 nm (log ε 4.24, 4.42, 3.56); ν_{max} (KBr) 3440 (hydroxyl) and 1670 (quinone C=O) cm^{-1}; δ (60 MHz, $CDCl_3$) 3.98 and 4.02 (2 × 3H, 2s, 1,3-OCH_3), 4.84 (2H, s, 2-CH_2), 7.65 (1H, s, 4-H), 7.60–7.85 (2H, m 6,7-H) and 8.07–8.42 (2H, m, 5,8-H); *m/e* 298 (M^+).

*2-Formyl-1,3-dimethoxyanthraquinone (**12**)*

A mixture of lucidin 1,3-dimethyl ether (**11**) (298 mg, 1.00 mmol), activated manganese dioxide (17) (1.2 g), and anhydrous benzene (50 ml) when refluxed for 16 h, filtered, and evaporated, gave the aldehyde **12** (264 mg, 89%), mp 184.5–185.5°C (ethanol); λ_{max} ($CHCl_3$) 280, 335, 370, 490 nm (log ε 4.45, 3.65, 3.53, 3.20); ν_{max} (KBr) 1695 (aldehyde) and 1670 (quinone C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 4.05 and 4.09 (2 × 3H, 2s, 1,3-OCH_3), 7.71 (1H, s, 4-H), 7.63–7.85 (2H, m, 6,7-H), 8.17–8.37 (2H, m, 5,8-H), and 10.52 (1H, s, CHO); *m/e* 296 (M^+). *Anal.* calcd. for $C_{17}H_{12}O_5$: C 68.91, H 4.08; found: C 68.78, H 4.06.

*2-(trans-Hex-1-enyl)-1,3-dimethoxyanthraquinone (**14**)*

To a stirred suspension of *n*-pentyltriphenylphosphonium bromide (413 mg, 1.00 mmol) in anhydrous tetrahydrofuran (20 ml) under nitrogen was added an ether

solution of butyllithium (1.25 mmol) followed at 0°C by 2-formyl-1,3-dimethoxyanthraquinone (**12**) (296 mg, 1.00 mmol). The reaction mixture was stirred for 20 min, poured into water, and extracted with ether. The crude products were separated by preparative thin-layer chromatography (silica gel – benzene). A fast-moving band consisted of 3-butoxy-2-(hex-1-enyl)-1-methoxyanthraquinone (**13**) (47 mg, 12%), mp 121–122°C (ethanol–water); λ_{max} ($CHCl_3$) 290, 299 sh, 380 nm (log ε 4.46, 4.27, 3.77); ν_{max} (KBr) 1665 (quinone C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 1.01 (6H, t, J = ~6.5 Hz, 4′,6′′-H_3), 1.33–2.04 (8H, m, 2′,3′,4′′,5′′-H_2), 2.14–2.38 (2H, m, 3′′-H_2), 3.92 (2H, t, J = 7.0 Hz, 1′-H_2), 4.02 (3H, s, 3-OCH_3), 6.69 [2H, AB part of an ABX_2 system, J_{AB} = 16.0 Hz (Δν = 17.9 Hz), J_{BX} = 6.0 Hz, 1′′-H (6.49) and 2′′-H (6.89)], 7.62 (1H, s, 4-H), 7.58–7.78 (2H, m, 6,7-H), and 8.12–8.32 (2H, m, 5,8-H); *m/e* 392 (M^+), 335, 279. *Anal.* calcd. for $C_{25}H_{28}O_4$: C 76.50, H 7.19; found: C 76.38, H 7.21.

A second zone contained the expected hexenylanthraquinone **14** (244 mg, 70%), mp 112–113°C (ethanol–water); λ_{max} ($CHCl_3$) 291, 300, 390 nm (log ε 4.59, 4.58, 3.68); ν_{max} (KBr) 1665 (quinone C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 0.93 (3H, t, J = ~7.0 Hz, 6′-H_3), 1.20–1.70 (4H, m, 4′,5′-H_2), 2.14–2.42 (2H, m, 3′-H_2), 3.85 (3H, s, 3-OCH_3), 4.02 (3H, s, 1-OCH_3), 6.72 [2H, AB part of an ABX_2 system, J_{AX} = 16.5 Hz (Δν = 20.7 Hz), J_{BX} = 6.0 Hz, 1′-H (6.49) and 2′-H (6.95)], 7.63 (1H, s, 4-H), 7.63–7.85 (2H, m, 6,7-H), and 8.12–8.33 (2H, m, 5,8-H); *m/e* 350 (M^+), 335. *Anal.* calcd. for $C_{22}H_{22}O_4$: C 75.41, H 6.33; found: C 75.53, H 6.45.

*1-Allyloxy-3-methoxyanthraquinone (**16**)*

The crude 3-methyl ether obtained from xanthopurpurin (960 mg, 4.00 mmol), dimethyl sulfate (1 g, 8 mmol), anhydrous potassium carbonate (1.38 mg, 1.00 mmol), and 1,2-dimethoxyethane (40 ml) at 50°C (8 h) was heated to reflux for 10 h with allyl bromide (1.74 g, 14.4 mmol), potassium iodide (2.0 g, 12.0 mmol), and anhydrous potassium carbonate (1.6 g, 11.6 mmol) in 1,2-dimethoxyethane (25 ml). The crude product was chromatographed on silica gel (dry column, benzene – ethyl acetate 4:1) and gave the allyl ether **16** (782 mg, 66%), mp 146–147°C (methanol); λ_{max} (ethanol) 230 sh, 238, 247 sh, 277, 330, 390 nm (log ε 4.25, 4.27, 4.22, 4.80, 3.50, 3.67); ν_{max} (KBr) 1665 (quinone C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 3.92 (3H, s, 3-OCH_3), 4.62–4.78 (2H, m, 1′-H_2), 5.27–5.80 (2H, m, 3′-H_2), 6.22 (1H, m, 2′-H), 6.76 (1H, d, J = 3.0 Hz, 2-H), 7.43 (1H, d, J = 3.0 Hz, 4-H), 7.61–7.78 (2H, m, 6,7-H) and 8.11–8.31 (2H, m, 5,8-H); *m/e* 294 (M^+). *Anal.* calcd. for $C_{18}H_{14}O_4$: C 73.46, H 4.80; found: C 73.29, H 5.01.

1-Hydroxy-3-(tetrahydropyran-2-yloxy)anthraquinone

A mixture of xanthopurpurin (240 mg, 1.00 mmol), dihydropyran (2 ml), a trace of *p*-toluenesulfonic acid, and chloroform (1 ml), was stirred at room temperature for 2 h, washed with water, evaporated, and gave the 3-(tetrahydropyran-2-yl) ether (293 mg, 90%), mp 151–152°C (ethanol–water), λ_{max} (ethanol) 230, 240, 245, 264, 277, 331, 400 nm (log ε 4.24, 4.37, 4.36, 4.30, 4.29, 3.28, 3.75); ν_{max} (KBr) 1670 (quinone C=O) and 1630 (chelated C=O) cm^{-1}; δ (60 MHz, $CDCl_3$) 1.47–2.03 (6H, m, 3′,4′,5′-H_2), 3.57–3.90 (2H, m, 6′-H_2), 5.43–5.66 (1H, m, 2′-H), 6.85 (1H, d, J = 2.5 Hz, 2-H), 7.40 (1H, d, J = 2.5 Hz, 4-H), 7.57–7.87 (2H, m, 6,7-H), 8.03–8.40 (2H, m, 5,8-H), and 12.75 (1H, s, 1-OH); *m/e* 324 (M^+). *Anal.* calcd. for $C_{19}H_{16}O_5$: C 70.36, H 4.98; found: C 70.46, H 5.02.

*1-Allyloxy-3-(tetrahydropyran-2-yloxy)anthraquinone (**17**)*

In a preparation analogous to that of the allyl ether **16**, the foregoing quinone (1.0 g, 3.1 mmol), allyl bromide (1.45 g, 12.0 mmol), potassium iodide (1.98 g, 11.9 mmol), anhydrous potassium carbonate (4.14 g, 30.0 mmol), and 1,2-dimethoxyethane (25 ml) at reflux temperature (8 h) gave the allyl ether **17** (933 mg, 83%), mp 121.5–122.5°C (methanol); λ_{max} (ethanol) 230, 238, 245 sh, 276, 327, 395 nm (log ε 4.34, 4.36, 4.32, 4.41, 3.57, 3.73); ν_{max} (KBr) 1660 (quinone C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 1.48–2.00 (6H, m, 3′′,4′′,5′′-H_2), 3.47–3.91 (2H, m, 6′′-H_2), 4.73 (2H, dt, J = 4.5, 1.5 Hz, 1′-H_2), 5.28–5.82 (2H, m, 3′-H_2), 5.61 (1H, m, 2′′-H), 6.12 (1H, m, 2′-H), 6.95 (1H, d, J = 2.5 Hz, 2-H), 7.59 (1H, d, J = 2.5 Hz, 4-H), 7.57–7.78 (2H, m, 6,7-H), and 8.13–8.33 (2H, m, 5,8-H); *m/e* 364 (M^+), 280. *Anal.* calcd. for $C_{22}H_{20}O_5$: C 72.51, H 5.53; found: C 72.48, H 5.58.

*3-Allyloxy-1-hydroxyanthraquinone (**18**)*

The direct O-allylation of xanthopurpurin by the foregoing method gave the 3-allyl ether, mp 155–156°C (ether – petroleum ether, bp 30–60°C); λ_{max} (ethanol) 231, 241, 245, 266, 280, 324, 405 nm (log ε 4.32, 4.38, 4.42, 4.31, 4.36, 3.46, 3.84); ν_{max} (KBr) 1670 (quinone C=O) and 1635 (chelated C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 4.65 (2H, dt, J = 5.5, 1.0 Hz, 1′-H_2), 5.25–5.59 (2H, m, 3′-H_2), 6.28 (1H, m, 2′-H), 6.69 (1H, d, J = 2.5 Hz, 2-H), 7.35 (1H, d, J = 2.5 Hz, 4-H), 7.68–7.89 (2H, m, 6,7-H), and 8.17–8.39 (2H, m, 5,8-H); *m/e* 280 (M^+). *Anal.* calcd. for $C_{17}H_{12}O_4$: C 72.85, H 4.32; found: C 72.56, H 4.41.

*2-Allyl-1-hydroxy-3-methoxyanthraquinone (**19**)*

A solution of 1-allyloxy-3-methoxyanthraquinone (**16**) (100 mg, 0.340 mmol) in *o*-dichlorobenzene (25 ml) was refluxed for 16 h and evaporated under vacuum (0.5 torr). Chromatography of the residue on silica gel (dry column, benzene) gave the rearranged product **19** (76 mg, 76%), mp 140–141°C (ether – petroleum ether, bp 30–60°C); λ_{max} (ethanol) 241 sh, 246, 274, 335, 410 (log ε 4.32, 4.34, 4.49, 3.45, 3.82); ν_{max} (KBr) 1660 (quinone C=O), and 1630 (chelated C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 3.47 (2H, dt, J = 6.0, 1.5 Hz, 1′-H_2), 3.97 (3H, s, 3-OCH_3), 4.90–5.21 (2H, m, 3′-H_2), 5.93 (1H, m, 2′-H), 7.36 (1H, s, 4-H), 7.66–7.83 (2H, m, 6,7-H), 8.11–8.33 (2H, m, 5,8-H), and 12.87 (1H, s, 1-OH); *m/e* 294 (M^+). *Anal.* calcd. for $C_{18}H_{14}O_4$: C 73.46, H 4.80; found: C 73.45, H 4.87.

*2-Allyl-1,3-dihydroxyanthraquinone (**20**)*

An analogous reaction with the allyl ether **17** (20.3 g, 55.8 mmol) and *o*-dichlorobenzene (900 ml) (15 h) gave the crude 2-allylanthraquinone **20** which was recrystallized from a mixture of 1,2-dichloroethane and ethyl acetate (12.6 g, 81%), mp 256–257°C (1,2-dichloroethane); λ_{max} (chloroform) 249, 281, 420 nm (log ε 4.38, 4.44, 3.80); ν_{max} (KBr) 3395 (hydroxyl), 1660 (quinone C=O), and 1635 (chelated C=O) cm^{-1}; δ (90 MHz, C_5D_5N) 3.85 (2H, dt, J = 6.0, 1.0 Hz, 1′-H_2), 5.04–5.80 (2H, m,

3′-H_2), 6.23 (1H, m, 2′-H), 7.63 (1H, s, 4-H), 7.50–7.77 (2H, m, 6,7-H), and 8.12–8.37 (2H, m, 5,8-H); *m/e* 280 (M^+). *Anal.* calcd. for $C_{17}H_{12}O_4$: C 72.85, H 4.32; found: C 72.61, H 4.55.

The same product and yield were obtained from xanthopurpurin 3-allyl ether **18** (900 mg) after refluxing for 46 h in the same solvent (50 ml) and purifying the crude product by chromatography on silica gel (dry column, benzene – chloroform – ethyl acetate 5:3:2).

2-Allyl-1,3-dimethoxyanthraquinone

The dimethyl ether was obtained in the usual way from the 2-allyl compound **20** (679 mg, 2.43 mmol) dimethyl sulfate (1.2 ml), anhydrous sodium carbonate (3.0 g), and refluxing acetone (100 ml, 7.5 h) after chromatography on silica gel (dry column, benzene – ethyl acetate 4:1) (668 mg, 89%), mp 132.5–133.5°C (methanol); λ_{max} (ethanol 239, 245, 275, 350 nm (log ε 4.13, 4.09, 4.58, 3.63); ν_{max} (KBr) 1670 (quinone C=O) and 1640 (vinyl) cm^{-1}; δ (60 MHz, $CDCl_3$) 3.53 (2H, dt, J = 6.0, 1.0 Hz, 1′-H_2), 3.92 and 3.98 (2 × 3H, 2s, 1,3-OCH_3), 4.83–5.27 (2H, m, 3′-H_2), 5.99 (1H, m, 2′-H), 7.60 (1H, s, 4-H), 7.60–7.83 (2H, m, 6,7-H), and 8.03–8.38 (2H, m, 5,8-H); *m/e* 308 (M^+). *Anal.* calcd. for $C_{19}H_{16}O_4$: C 74.01, H 5.23; found: C 73.87, H 5.31.

*1,3-Dihydroxy-2-(trans-prop-1-enyl)anthraquinone (**21**)*

A mixture of 2-allyl-1,3-dihydroxyanthraquinone (**20**) (500 mg, 1.79 mmol), rhodium trichloride trihydrate (25 mg), and absolute ethanol (25 ml) stirred at 75°C for 2 h, diluted with boiling water, cooled, and filtered gave the isomerized quinone **21** (363 mg, 73%), mp 237–238°C (1,2-dichloroethane); λ_{max} (chloroform) 253, 299, 430 nm (log ε 4.64, 4.74, 4.20); ν_{max} (KBr) 3340 (hydroxyl), 1665 (quinone C=O), and 1645 (chelated C=O) cm^{-1}; δ (90 MHz, C_5D_5N) 0.95 (3H, d, J = 6.0 Hz, 3′-H_3), 6.94–7.38 (2H, m, 1′,2′-H), 7.51–7.77 (2H, m, 6,7-H), 7.70 (1H, s, 4-H), and 8.17–8.41 (2H, m, 5,8-H). *Anal.* calcd. for $C_{17}H_{12}O_4$: C 72.85, H 4.32; found: C 72.75, H 4.53.

*1,3-Dihydroxy-2-(threo-1,2-dihydroxypropyl)anthraquinone (**22**)*

A mixture of 1,3-dihydroxy-2-(*trans*-prop-1-enyl)anthraquinone (**21**) (281 mg, 1.00 mmol) and osmium tetroxide (256 mg, 1.01 mmol) in pyridine (4 ml) was stirred at room temperature for 30 min. The reaction mixture, after addition of pyridine (4.8 ml) and an aqueous solution (8 ml) of sodium bisulfite (460 mg, 4.42 mmol), was allowed to stand for 5 min then diluted with water (100 ml) and extracted with ethyl acetate. The residue obtained by evaporation of the organic solvent was chromatographed on silica gel (50 g) (ethyl acetate) and gave the diol **22** (252 mg, 80%), mp 260–261°C (1,2-dichloroethane); λ_{max} (ethanol) 246, 281, 405 nm (lo ε 4.85, 4.47, 3.89); ν_{max} (KBr) 3500, 3200 (hydroxyls), 1680 (quinone C=O), and 1625 (chelated C=O) cm^{-1}; δ (90 MHz, $(CD_3)_2SO$) 1.11 (3H, d, J = 6.5 Hz, 3′-H_3). 4.05 (1H, dq, J = 5.5, 6.5 Hz, 2′-H; collapses to a doublet (J = 5.5 Hz) by irradiation at δ 1.11 and to a quartet (J = 6.5 Hz) by irradiation at δ 4.95), 4.95 (1H, d, J = 5.5 Hz, 1′-H), 7.78–7.95 (2H, m, 6,7-H), and 8.00–8.31 (2H, m, 5,8-H); *m/e* 314 (M^+). *Anal.* calcd. for $C_{17}H_{12}O_6$: C 64.96, H 4.49; found: C 64.80, H 4.49.

Hydroxyalkylation of Xanthopurpurin with 5-Oxohexanal

A mixture of xanthopurpurin (480 mg, 2.00 mmol), sodium bicarbonate (178 mg, 2.12 mmol), 5-oxohexanal (18) (456 mg, 4.00 mmol), and water (4 ml) was stirred under nitrogen and kept at an external temperature of 100°C for 2.5 h. Two more portion (480 mg each) of the aldehyde were added after 1 h and 1.5 h. The reaction mixture was then poured into water and acidified with dilute hydrochloric acid. Cyclohexenone (528 mg) can be isolated from the filtrate after saturating with salt and extracting repeatedly with ether. The crude products were chromatographed on silica gel (dry column, benzene) and gave a fast moving band consisting of 5-hydroxy-2-methyl-2,4-propano-6,11-dihydro-4*H*-anthra[2,3-*d*]*m*-dioxine-6,11-dione (bis-deoxyaverufin) (**23**) (73 mg, 11%), mp 179.0–179.5°C (ether – petroleum ether, bp 30–60°C); λ_{max} ($CHCl_3$) 247, 281, 400 nm (log ε 4.59, 4.57, 3.94); ν_{max} (KBr) 1665 (quinone C=O) and 1625 (chelated C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 1.58 (3H, s, 2-CH_3), 1.55–2.17 (6H, m, 2,4-propano), 5.36 (1H, m, 4-H), 7.23 (1H, s, 12-H), 7.68–7.82 (2H, m, 8,9-H), 8.17–8.31 (2H, m, 7,10-H), and 13.00 (1H, s, 5-OH); *m/e* 336 (M^+), 318, 293, 279, 278, 265, 254, 253. *Anal.* calcd. for $C_{20}H_{16}O_5$: C 71.42, H 4 80; found: C 71.45, H 4.73. Xanthopurpurin (187 mg, 39%) can be recovered from a median zone.

From the top of the column was extracted 6,6-bis-(1,3-dihydroxyanthraquinone-2-yl)hexan-2-one (**24**) (178 mg, 31%) which was converted in the usual way (dimethyl sulfate, anhydrous potassium carbonate, and acetone) to the tetramethyl ether, mp 210–212°C (aqueous ethanol); λ_{max} (ethanol) 281, 360 nm (log ε 5.04, 4.21); ν_{max} (KBr) 1710 (aliphatic C=O) and 1670 (quinone C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 1 50–1.83 (4H, m, 4,5-H_2), 2.11 (3H, s, 1-H_3), 2.51 (2H, t, J = 7.5 Hz, 3-H_2), 3.63 (6H, s, 3′,3″-OCH_3), 4.03 (6H, s, 1′,1″-OCH_3), 5.13 (1H, t, J = 7.5 Hz, 6-H), 7.61–7.75 (4H, m, 6′,6″, 7′,7″-H), 7.66 (2H, s, 4′,4″-H), and 8.28 (4H, m, 5′,5″,8′,8″-H); *m/e* 632 (M^+), 546, 281. *Anal.* calcd. for $C_{38}H_{32}O_9$: C 72.14, H 5.10; found: C 71.84, H 5.24.

*1,3,6,8-Tetrahydroxyanthraquinone (**25**)*

1,3,6,8-Tetramethoxyanthraquinone (2.82 g, 8.60 mmol) was added to a melt of anhydrous aluminum chloride (282 g) and sodium chloride (56 g) at 140°C. The temperature was then raised to 180°C for 30 s. The residue obtained from an ethyl acetate extract of the crude product was chromatographed on silica gel (100 g, benzene – ethyl acetate 4:1) and gave the tetrahydroxy compound **25** (2.13 g, 91%), mp >340°C (lit. (19, 20) mp >360°C; lit. (21) dec. 353°C); λ_{max} (ethanol) 220, 251, 262, 294, 318, 450 nm (log ε 4.48, 3.89, 3.85, 4.34, 3.85, 3.81); ν_{max} (KBr) 3350 (hydroxyl), 1670 (quinone C=O), and 1620 (chelated C=O) cm^{-1}; δ (90 MHz, C_5D_5N) 6.93 (2H, d, J = 2.5 Hz, 2,7-H) and 7.60 (2H, d, J = 2.5 Hz, 4,5-H).

*(±)-Averufin (**26**)*

A solution of 1,3,6,8-tetrahydroxyanthraquinone (**25**) (400 mg, 1.47 mmol), sodium bicarbonate (248 mg, 2.95 mmol), and 5-oxohexanal (18) (336 mg, 2.95 mmol) was stirred under nitrogen at an external temperature of 90°C for 14 h. Seven similar portions of aldehyde were added at regular intervals. The reaction mixture was then poured into water and extracted with ethyl acetate. The crude

products were chromatographed on silica gel (dry column, benzene – ethyl acetate 1:1). A fast moving zone contained a small amount of an unidentified yellow product. The median zone was purified by preparative tlc on silica gel (benzene – ethyl acetate 50:1, 4 migrations) and gave (±)-averufin (35 mg, 6.5%) (acetone–benzene) which decomposes >280°C (lit. (22) mp dec. 280–282°C; lit. (2) mp 280°C, lit. (23) dec. 283–289°C); λ_{max} (ethanol) 223, 255, 265, 294, 320, 451 nm (log ε 4.46, 4.15, 4.20, 4.43, 4.14, 3.94); ν_{max} (KBr) 3360 (hydroxyl), 1670 (quinone C=O) and 1625 (chelated C=O) cm^{-1}; δ (90 MHz, $(CD_3)_2SO$) 1.52 (3H, s, 2-CH_3), 1.44–2.17 (6H, m, 2,4-propano-), 5.11–5.28 (1H, m, 4-H), 6.50 (1H, d, J = 2.5 Hz, 8-H), 6.89 (1H, s, 12-H), and 7.00 (1H, d, J = 2.5 Hz, 10-H); *m/e* 368 (M^+), 350, 325, 311, 310, 297, 286, 285. *Anal.* calcd. for $C_{20}H_{16}O_7$: C 65.21, H 4.38; found: C 65.13, H 4.60. From the top of the original column a large part of tetrahydroxyanthraquinone (191 mg, 48%) could be recovered by extraction (benzene – ethyl acetate 5:1).

Hydroxyalkylation of Xanthopurpurin with 5-Hydroxypentanal

A mixture of xanthopurpurin (480 mg, 2.00 mmol), sodium bicarbonate (178 mg, 2.12 mmol), and 5-hydroxypentanal (24) (408 mg, 4.00 mmol) in water (4 ml) was stirred under nitrogen at an external temperature of 100°C for 7 h. Two more portions of aldehyde (400 mg each) were added after the first and second hours. The reaction mixture was then poured into water, acidified, and extracted with ethyl acetate. The crude products were chromatographed on silica gel (dry column, benzene – ethyl acetate 9:1). A fast moving band was rechromatographed by the same procedure and allowed the separation of three products. The substance with the highest R_f was identified as 1,3-dihydroxy-2-(tetrahydropyran-2-yl)anthraquinone (bis-deoxynoravermutin) (**27**) (130 mg, 20%), mp 190.5–191.5°C (ether); λ_{max} ($CHCl_3$) 280, 410 nm (log ε 4.47, 3.89); ν_{max} (KBr) 3210 (hydroxyl), 1680 (quinone C=O) and 1620 (chelated C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 1.51–2.17 (6H, 2m, 3′,4′,5′-H_2), 3.46–3.82 (1H, m, 6′-H axial; collapses to a broad doublet by irradiation at δ 1.69, J_{gem} = 11.0 Hz), 4.24 (1H, br d, 6′-H equatorial; gives a doublet by irradiation at δ 1.69, J_{gem} = 11.0Hz), 5.05 (1H, br d, J = 8.0 Hz, 2′-H axial), 7.21 (1H, s, 4-H), 7.61–7.81 (2H, m, 6,7-H), 8.11–8.31 (2H, m, 5,8-H), 9.72 (1H, s, 3-OH), and 13.23 (1H, s, 1-OH); *m/e* 324 (M+), 306, 279, 278, 267, 265, 254, 253, 241, 240. *Anal.* calcd. for $C_{19}H_{16}O_5$: C 70.36, H 4.98; found: C 70.39, H 4.89. A second band consisted of xanthopurpurin (124 mg, 26%). Extraction of the top of this second column with ethyl acetate gave 1,3-dihydroxy-2-(5-hydroxy-*trans*-pent-1-enyl)anthraquinone (**28**) (31 mg, 4.8%), mp 212–213°C (ethyl acetate – benzene); λ_{max} ($CHCl_3$) 250, 291, 420 nm (log ε 4.30, 4.34, 3.75); ν_{max} (KBr) 3500 (hydroxyl), 1650 (quinone C=O) and 1620 (chelated C=O) cm^{-1}. Methylation of this product (dimethyl sulfate, anhydrous sodium carbonate and acetone) gave the corresponding 1,3-dimethyl ether, mp 140.0–141.5°C (ether – petroleum ether, bp 30–60°C), λ_{max} (chloroform) 291, 300, 390 nm (log ε 4.59, 4.58, 3.68); δ (90 MHz, $CDCl_3$) 1.63–1.98 (2H, m, 4′-H_2), 2.29–2.55 (2H, m, 3′-H_2), 3.74 (2H, t, J = 6.5 Hz, 5′-H_2), 3.81 (3H, s, 3-OCH_3), 4.03 (3H, s, 1-OCH_3), 6.77 [2H, AB part of an ABX_2 system, J_{AB} = 17.0 Hz ($\Delta\nu$ = 16.9 Hz), J_{BX} = 5.5 Hz, 1′-H (6.63) and 2′-H (6.90)], 7.63–7.89 (2H, m, 6,7-H), 7.66 (1H, s, 4-H), and 8.16–8.33 (2H, m, 5,8-H). *Anal.* calcd. for $C_{21}H_{22}O_6 \cdot H_2O$: C 68.09, H 5.99; found: C 68.36, H 5.54.

From the top of the first column a red oil was obtained by extraction with absolute ethanol, which was methylated in the usual way and gave, after chromatography on silica gel (dry column, benzene – ethyl acetate 2:1), a trimethyl ether of 5,5-bis-(1,3-dihydroxyanthraquinon-2-yl) pentanol-1 (**29**), mp 144–145°C (ethanol); λ_{max} (chloroform) 285, 395 nm (log ε 4.96, 4.08); ν_{max} (KBr) 1670 (quinone C=O) and 1630 (chelated C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 1.41–1.91 (6H, m, 2,3,4-H_2), 3.66 (2H, t, J = 6.0 Hz, 1-H), 3.80 and 3.92 (2 × 3H, 2s, 3′,3″-OCH_3), 3.97 (3H, s, 1″-OCH_3), 5.10 (1H, t, J = 7.5 Hz, 5-H), 7.37 (1H, s, 4′-H), 7.61 (1H, s, 4″-H), 7.60–7.83 (4H, m, 6′,6″,7′,7″-H), 8.11–8.33 (4H, m, 5′,5″,8′,8″-H), and 13.32 (1H, s, 1′-OH). *Anal.* calcd. for $C_{36}H_{30}O_9$: C 71.28, H 4.99; found: C 71.26, H 4.95.

4-Hydroxybutanal

To a well stirred solution of γ-butyrolactone (8.6 g, 0.1 mol) in pentane at −63°C and under dry nitrogen was added over a period of 1 h a 20% solution of diisobutylaluminum hydride in hexane (21.3 g, 0.15 mol). After 2 h, the reaction mixture was allowed to come to room temperature, diluted with 2-propanol (5 ml) and water (5 ml), filtered, and evaporated. The residue was constituted essentially of 4-hydroxybutanal (2.85 g, 32%); ν_{max} (film) 3390 (hydroxyl) cm^{-1}; δ (60 MHz, $CDCl_3$) 1.55–1.97 (4H, m, 2,3-H_2), 3.47–4.12 (2H, m, 4-H_2), and 5.18–5.60 (2H, 2m, 1-H and 1-OH). The substance is known to be unstable and could not be further purified (25).

*(±)-Bipolarin (**30**)*

A solution of 1,3,6,8-tetrahydroxyanthraquinone (**25**) (300 mg, 1.10 mmol), 4-hydroxybutanal (540 mg, 6.14 mmol), and sodium bicarbonate (186 mg, 2.21 mmol) in water (3 ml) was stirred under nitrogen for 16 h at an external temperature of 90°C. Supplemental portions of hydroxybutanal (540 mg each) were added after 0.5, 1, 2, 4, and 8 h. The crude products obtained after dilution of the reaction mixture with water (100 ml) and acidification were separated by preparative tlc (silica gel, benzene – ethyl acetate 20:1, 3 migrations). The band with the highest R_f consisted of (±)-bipolarin (**30**), (95 mg, 25%), mp 261–262°C (acetone) (lit. (2) mp 261°C); λ_{max} (ethanol) 223, 254, 265, 293, 320, 450 nm (log ε 4.45, 4.12, 4.18, 4.42, 4.02, 3.90); ν_{max} (KBr) 3400 (hydroxyl), 1665 (quinone C=O) and 1625 (chelated C=O) cm^{-1}; δ (90 MHz, $(CD_3)_2SO$) 1.81–2.26 (4H, m, 3′,4′-H_2), 3.62–4.20 (2H, 2m, 5′-H_2), 5.17–5.41 (1H, m, 2′-H), 6.52 (1H, d, J = 2.0 Hz, 7-H), 7.05 (1H, d, J = 2.0 Hz, 5-H), and 7.13 (1H, s, 4-H); *m/e* 342 (M^+), 314, 311, 299, 297, 286, 285, 272. *Anal.* calcd. for $C_{18}H_{14}O_7$: C 63.16, H 4.12; found: C 63.27, H 4.43. A small amount of 1,3,6,8-tetrahydroxyanthraquinone (25 mg, 8%) can also be recovered.

Alkylation of Xanthopurpurin with n-Hexanal

Method A

A solution of xanthopurpurin (120 mg, 0.50 mmol), *n*-hexanal (100 mg, 1.00 mmol), and sodium bicarbonate

(42 mg, 0.50 mmol) in water (1 ml) was stirred at 100°C (external) for 95 h. Further portions of aldehyde (2 × 100 mg and 2 × 200 mg) were added after 2, 5, 26, and 48 h. The crude product was chromatographed on silica gel (dry column, benzene – ethyl acetate 25:1). Separation of a fast moving zone by preparative tlc (silica gel, benzene – ethyl acetate 50:1, 2 migrations) gave 2-(*trans*-hex-1-enyl)-1,3-dihydroxyanthraquinone (**31**) (38 mg, 24%), mp 210.0–211.5°C (ether – petroleum ether bp 30–60°C); λ_{max} (chloroform) 252, 295, 430 nm (log ε 4.35, 4.40, 3.74); ν_{max} (KBr) 3380 (hydroxyl), 1660 (quinone C=O) and 1640 (chelated C=O) cm^{-1}; δ (90 MHz, $(CD_3)_2SO$) 1.90 (3H, t, J = 6.0 Hz, 6′-H_3), 1.16–1.50 (4H, m, 4′,5′-H_2), 2.04–2.37 (2H, m, 3′-H_2), 6.77 [2H, AB part of an ABX_2 system, J_{AB} = 17.0 Hz ($\Delta\nu$ = 25.9 Hz) J_{BX} = 6.5 Hz, 1′-H (6.63) and 2′-H (6.81)], 7.29 (1H, s, 4-H), 7.81–8.00 (2H, m, 6,7-H), and 8.00–8.24 (2H, m, 5,8-H); *m/e* 322 (M^+), 293, 279, 265, 253. *Anal.* calcd. for $C_{20}H_{18}O_4$: C 74.52, H 5.63; found: C 74.27, H 5.52. Methylation of this product gave a substance identical to that prepared earlier.

Method B

When the foregoing reaction between xanthopurpurin (2.00 mmol), *n*-hexanal (12 mmol), and sodium bicarbonate (2.00 mmol) was conducted in water (3 ml) and acetone (1 ml) under pressure (sealed tube) for 112 h at 100°C, the principal product, obtained by chromatography (silica gel, benzene – ethyl acetate 50:1), was the same hexenyl compound **31** (170 mg, 26%). Elution with benzene – ethyl acetate 25:1 gave an unidentified red solid purified by preparative tlc (silica gel, benzene – ethyl acetate 100:1), mp 178–179°C (26 mg); λ_{max} (chloroform) 274, 278, 420 nm (log ε 4.74, 4.86, 4.22); ν_{max} (KBr) 3380, 1665, 1625, 1590, 1475 cm^{-1}; *m/e* 644, 573, 391, 323, 293, 279, 265, 253.

Method C

The preceding experiment was conducted (24 h) in a mixture of methanol (2 ml) and water (2 ml) and the crude products were chromatographed on silica gel (dry column, benzene – ethyl acetate 9:1). Separation of a fast moving zone by preparative tlc gave xanthopurpurin (259 mg, 54%) and 2-(*trans*-hex-1-enyl)-1,3-dihydroxyanthraquinone (**31**), (29 mg, 4.5%). The top of the original column contained 1,1-bis(1,3-dihydroxyanthraquinon-2-yl)hexane (**32**). Methylation of this material by the usual means (dimethyl sulfate, anhydrous sodium carbonate, and acetone) gave the corresponding tetramethyl ether, mp 214.5–215.0°C (ether – petroleum ether, bp 30–60°C); λ_{max} (chloroform) 274, 281, 360 nm (log ε 4.96, 4.97, 4.15); ν_{max} (KBr) 1670 (quinone C=O) cm^{-1}; δ (90 MHz, $CDCl_3$) 0.88 (3H, t, J = 6.0 Hz, 6-H_3), 1.22–1.48 (8H, m, 2,3,4,5-H_2), 3.66 (6H, s, 3′,3″-OCH_3), 4.05 (6H, s, 1′,1″-OCH_3), 5.17 (1H, t, J = 7.5 Hz, 1-H), 7.58–7.73 (4H, m, 6′,6″,7′,7″-H), 7.66 (2H, s, 4′,4″-H), and 8.09–8.26 (4H, m, 5′,5″,8′,8″-H). *Anal.* calcd. for $C_{38}H_{34}O_8$: C 73.77, H 5.54; found: C 73.72, H 5.58.

Acknowledgments

The authors wish to thank Dr. P. S. Steyn for a sample of averufin. Financial support from the Ministère de l'Education du Québec and the award of National Research Council of Canada scholarships to one of us (A.C.) are acknowledged.

The reflection method in predissociation

ANDRÉ D. BANDRAUK AND JEAN-PIERRE LAPLANTE[1]

Département de chimie, Université de Sherbrooke, Sherbrooke (Qué.), Canada J1K 2R1

Received November 29, 1976

ANDRÉ D. BANDRAUK and JEAN-PIERRE LAPLANTE. Can. J. Chem. **55**, 1333 (1977).

The reflection method is used to calculate energy shifts and linewidths in predissociation by a linear continuum. The analytic results of this method are compared to the exact analytic calculations. It is found that, as in semiclassical calculations, energy shifts and linewidths usually vanish at the same energies. The spectroscopic implications of this finding are pointed out.

ANDRÉ D. BANDRAUK et JEAN-PIERRE LAPLANTE. Can. J. Chem. **55**, 1333 (1977).

La méthode de réflexion est appliquée aux calculs de déplacement d'énergie et de largeur des raies pour des systèmes prédissociés par un continuum linéaire. Les résultats analytiques de cette méthode sont comparés aux résultats exacts. En général, les déplacements d'énergie et les largeurs sont nul aux mêmes énergies. Les implications de ce résultat sont soulignés pour la spectroscopie de prédissociation.

Introduction

Predissociation is now a well established phenomenon in the electronic spectroscopy of molecules (1, 2). It is an example of a bound state embedded in a continuum. The influence of the continuum on such a discrete level is observed in the absorption spectra by the broadening and the shift of the level. Recent analytical expressions have been obtained for the linewidth Γ, responsible for the broadening, and the energy shift ΔE of such levels (3). It was found that these results compare well to a previous semiclassical treatment of this phenomenon (4).

In as much as one is dealing with transitions from a bound state to a continuum in a process such as predissociation, such transitions involve calculations of overlap integrals between bound state wave functions and rapidly oscillating continuum functions. One popular approximation, called the reflection method, corresponds to replacing the continuum function by a delta function. This method was analyzed by numerical calculations originally by Coolidge *et al.* (5) in a study of the Franck–Condon principle. These authors pointed out that this method appears to be very satisfactory, despite the difficulty of setting up a formal justification for it. Since then this method has been used many times in Franck–Condon factor calculations (6–8), in resonant Raman scattering by a continuum (9, 10), as well as in photodissociation (11). In a recent communication (12) we have shown the approximations inherent in such an approach by using a model depicted in Fig. 1. Thus in this model one has a bound state function $\phi_r(X)$ interacting with a continuum function $\phi_c(X)$. As the continuum is assumed to be linear around the interaction or crossing point X_c, the functions $\phi_c(X)$ are the well-known Airy functions (13, 14). In this way we were able to show that the reflection method corresponds to neglecting the kinetic energy of the nuclei in the continuum state. This is therefore a *rigorous* justification for the classical ideas of Condon (5). This model also enabled us to derive the appropriate corrections to the reflection method in the linear potential approximation.

In this work we wish to apply this method to predissociation in a diatomic molecule as shown in Fig. 1. Previous studies of this phenomenon were done assuming that both the bound state potential $V_r(X)$ and the continuum potential $V_c(X)$ were linear around the crossing point X_c, (3, 4, 15). This is therefore inaccurate for low lying vibrational levels, in particular for the ground vibrational state $v = 0$. We shall therefore first apply the reflection method to the linear model of the bound state and compare it to the rigorous analytic results obtained in ref. 3. Finally we shall calculate by the reflection method the predissociation linewidth Γ and the energy shift ΔE for a harmonic oscillator as a function of vibrational quantum number.

[1]Present address: Service de Chimie Physique II, Université Libre, Bruxelles, Belgium.

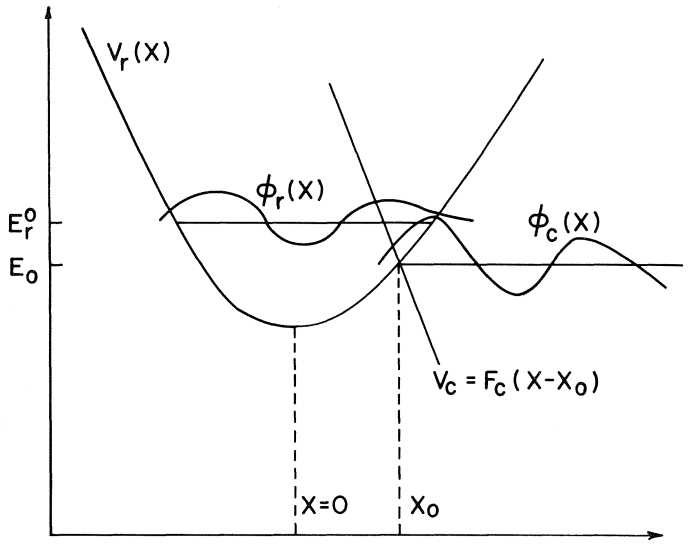

FIG. 1. Potentials and functions in X-space.

Linear Potentials and the Reflection Method

We consider the potential system illustrated in Fig. 1, where we have a potential $V_r(X)$, supporting bound states with functions $\phi_r(X)$, intersected by a linear continuum potential $V_c(X)$ with functions $\phi_c(X)$. X is the internuclear coordinate for a particular vibration in a molecule.

The continuum eigenfunctions $\phi_c(X)$ are the eigensolutions for the linear potential defined by

$$V_c(X) = E_0 - F_c(X - X_0) \quad [1]$$

where E_0 is the crossing point energy with respect to the minimum of the bound state potential, X_0 is the crossing point, and F_c is the absolute value of the slope of $V_c(X)$. The Schröedinger equation in momentum space becomes for this potential (we set $\hbar = 1$)

$$\left[\frac{p^2}{2\mu} + \left(E_0 + F_cX_0 - iF_c\frac{d}{dp}\right)\right]\phi_c(E_c,p) = E_c\phi_c(E_c,p) \quad [2]$$

where $\phi_c(E_c,p)$ is the Fourier momentum transform of $\phi_c(E_c,X)$ and μ is the reduced mass. We thus obtain,

$$\phi_c(E_c,X) = 2\pi^{1/2}N_cA_i(-q_c) \quad [3]$$

where

$$q_c = a_c\left(X + \frac{E_c - (E_0 + F_cX_0)}{F_c}\right)$$

$$N_c = a_c/(2\pi F_c)^{1/2} \quad [4]$$

$$a_c = (2\mu F_c)^{1/3}$$

$A_i(-q)$ is the Airy function defined in ref. 14 by,

$$2\pi^{1/2}A_i(-q) = \int_{-\infty}^{\infty} \exp\left[i(p^3/3 - pq)\right] dp \quad [5]$$

The continuum functions are normalized to the energy delta function, *i.e.*

$$\langle\phi_c(E_c',X)|\phi_c(E_c,X)\rangle = \delta(E_c - E_c') \quad [6]$$

It is to be noted that the factor $p^3/3$ in the exponential of [5] comes from integrating the kinetic energy term $p^2/2\mu$, in [2]. Hence, setting this kinetic term equal to zero, or correspondingly $p^3 \equiv 0$, one obtains

$$\phi_c(E_c,X) = (F_c)^{-1/2}\delta(X - X_c) \quad [7]$$

X_c is the classical turning point, *i.e.* where $q_c \equiv 0$, so that from [4] we have,

$$X_c = \frac{E_0 + F_cX_0 - E_c}{F_c} \quad [8]$$

This simple model shows us that the reflection method comes from neglecting the nuclear kinetic energy of the continuum state.

Having defined the linear potential eigenfunctions, we will now use these to calculate the relevant parameters in predissociation, *i.e.* the linewidth Γ and the energy shift ΔE. These are obtainable in second order perturbation theory from the integral (2)

$$G(E) = (\alpha_n)^2 \lim_{\varepsilon \to 0} \int_{-\infty}^{\infty} \frac{|\langle \phi_r(E_r^0,X)|\phi_c(E_c,X)\rangle|^2}{E - E_c + i\varepsilon} dE_c \quad [9]$$

where α_n is the nonadiabatic electronic matrix element assumed to be independent of nuclear distance, and the limit is taken after the integration is performed in order to avoid the singularity in the denominator. The expressions for the energy shift ΔE and linewidth Γ follow directly from the integral $G(E)$ in eq. 9,

$$\Delta E = \text{Re } G(E) = \alpha_n^2 \text{ PP} \int_{-\infty}^{\infty} \frac{|\langle \phi_r(E_r^0,X)|\phi_c(E_c,X)\rangle|^2}{E - E_c} dE_c$$

$$\tfrac{1}{2}\Gamma(E) = -\text{Im } G(E) = \alpha_n^2\pi \int \delta(E - E_c)|\langle \phi_r(E_r^0,X)|\phi_c(E_c,X)\rangle|^2 dE_c \quad [10]$$

where Re and Im stand for real and imaginary parts, and finally PP is the principal part integral.

We will now assume that the potential $V_r(X)$ is linear around the bound state energy E_r^0. This should be acceptable for high vibrational quantum levels. In particular, this model leads to Landau–Zener predissociation when treated by semiclassical scattering theory (4). Thus, from Fig. 1, we define

$$V_r(X) = E_0 + F_r(X - X_0) \quad [11]$$

The slope F_r is now positive as compared to the potential $V_c(X)$ in [1]. The eigenfunctions of $V_r(X)$ now become also Airy functions,

$$\phi_r(E_r^0,X) = 2\pi^{1/2}N_rA_i(-q_r) \quad [12]$$

where

$$q_r = a_r\left(X - \frac{E_r^0 - (E_0 - F_rX_0)}{F_r}\right)$$

$$N_r = \frac{(\pi\omega_r)^{1/2}a_r}{2\pi(F_r)^{1/2}} \quad [13]$$

$$a_r = (2\mu F_r)^{1/3}$$

and ω_r is the frequency of the bound state at E_r^0.

The normalization of these functions is such that (13)

$$\langle \phi_r(E_r^0,X)|\phi_r(E_r^0,X)\rangle = 1 \quad [14]$$

Introducing the functions [3] and [12] into the integral [9], one obtains (Appendix I),

[15] $$G(E) = -(1 + i)\frac{\omega_r\alpha_n^2}{2F_r}\left(\frac{\pi}{2aF_c}\right)^{1/2}\int_0^\infty t^{-1/2}\exp(-ibt^3 + i\kappa t)\,dt$$

where

$$a = \frac{1}{2\mu}\left(\frac{1}{F_c} + \frac{1}{F_r}\right)$$

[16] $$b = aF_c^3/12$$

$$\kappa = \frac{(E_r^0 - E^0)F_c}{F_r} + E - E_0$$

The singular integral in [15] can be recognized as the linear potential Green's function studied by Aspnes (16). Using his results one obtains (3)

[17] $$G(E_r^0) = \frac{\pi\omega_r\alpha_n^2}{(F_rF_c)^{1/3}}\left(\frac{2\mu}{F_r + F_c}\right)^{2/3}[-iA_i^2(-k) - A_i(-k)B_i(-k)]$$

where

[18] $$k = (2\mu)^{1/3}\left(\frac{F_rF_c}{F_rF_c}\right)^{2/3}(E_r^0 - E_0)$$

The functions A_i and B_i are the regular and irregular Airy functions defined in ref. 14. This gives for ΔE and Γ, following the definitions in [10],

[19] $$\Delta E(E_r^0) = -\alpha A_i(-k)B_i(-k)$$
$$\tfrac{1}{2}\Gamma(E_r^0) = \alpha A_i^2(-k)$$

where

$$\alpha = \frac{\pi\omega_r\alpha_n^2}{(F_rF_c)^{1/3}}\left(\frac{2\mu}{F_r + F_c}\right)^{2/3}$$

Let us now do this calculation in the reflection method, *i.e.* we set in the integral [9] for the continuum functions $\phi_o(E_c,X)$,

[20] $$\exp(ip^3/6\mu F_c) = 1$$

As shown in Appendix I, this has the effect of converting the factor a as defined in [16] to

[21] $$a = a_r' = (\tfrac{1}{2}\mu F_r)$$

It is to be observed that one could have obtained this result by setting $F_c \to \infty$ in the definition of a, *i.e.* the reflection method becomes *exact* for steep potentials. This result had been anticipated by Coolidge *et al.* (5) in their numerical calculations. Our derivation gives therefore a formal justification for this conclusion.

The final result for G_R obtained by the reflection method is therefore (Appendix I),

[22] $$G_R(E_r^0) = \alpha_R[-iA_i^2(-k_R) - A_i(-k_R)B_i(-k_R)]$$

where

$$k_R = (2\mu)^{1/3}\frac{(F_r + F_c)}{F_cF_r^{2/3}}(E_r^0 - E^0)$$

[23] $$\alpha_R = \frac{\pi\omega_r\alpha_n^2(2\mu)^{2/3}}{F_c(F_r)^{1/3}}$$

From our definitions of the linewidth and energy shifts in [10] we obtain,

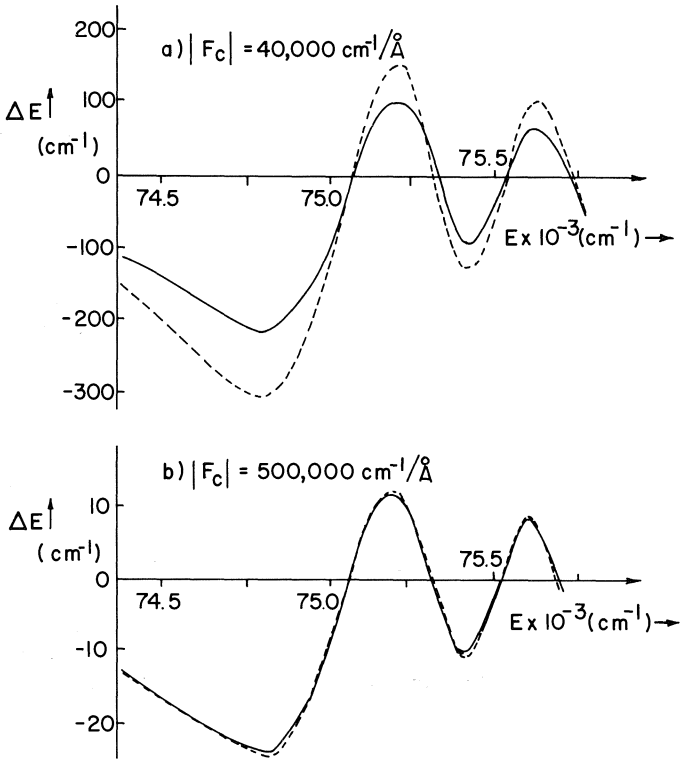

FIG. 2. $\Delta E_r(E)$ for $E_r^0 = 75\,000\ \text{cm}^{-1}$, $E_0 = 74\,800\ \text{cm}^{-1}$, $\omega_r = 1000\ \text{cm}^{-1}$, $\mu = 7.5$, $\alpha_n = 300\ \text{cm}^{-1}$, $F_r = 28\,000\ \text{cm}^{-1}/\text{Å}$; exact calculations (—), reflection method (-----).

[24]
$$\tfrac{1}{2}\Gamma(E_r^0) = +\alpha_R A_i^2(-k_R)$$
$$\Delta E_R(E_r^0) = -\alpha_R A_i(-k_R) B_i(-k_R)$$

A comparison of the two expressions shows that in the limit $F_c \gg F_r$, the exact result in [19] goes over into the reflection results in [24].

In Fig. 2, a numerical comparison of the two methods is illustrated for ΔE. The curves for the steep continuum, Fig. 2*b*, corroborate the conclusion that in this case the reflection method is excellent. In the intermediate slope case, Fig. 2*a*, the reflection method tends to overestimate the integrals. In other words, this method neglects the oscillatory tail of the continuum formations which diminish the integrals. The numerical calculations of Coolidge *et al.* (5) on reflection absorption intensities indicate that this method always overestimates absorption intensities. Our calculations show therefore that this is a general feature of this method. Nevertheless, what is *remarkable*, is that the reflection method follows faithfully the oscillatory pattern of ΔE and Γ obtained exactly. This can be seen readily in the mathematical expressions [19] and [24] for these parameters. The argument of the Airy functions changes only in magnitude but not in phase. The immediate conclusion from this is that ΔE and Γ will have identical zeroes occurring at the zeroes of $A_i(-k)$.

Another possibility is to apply a total reflection method, *i.e.* to both functions ϕ_r and ϕ_c. This could happen for instance in the case of heavy molecules. Since the singular integrand in the integral [15] is very large at small t, then an expansion of $\exp(-ibt^3)$ in powers of b should converge for large μ since $b \propto \mu^{-1}$ (eq. 16). We therefore write

[25]
$$\exp(-ibt^3) = \sum_{n=0}^{\infty} \frac{(-ib)^n}{n!} t^{3n}$$

and using the definition of the gamma function (14)

$$[26] \qquad \Gamma(Z) = k^Z \int_0^\infty t^{Z-1} e^{-kt} dt$$

one arrives at the following result for $G(E)$, eq. 15,

$$[27] \qquad G(E) = \frac{-i\omega_r(\pi\mu)^{1/2}}{[2F_r(F_r + F_c)]^{1/2}} \sum_{n=0}^{\infty} (-1)^n \left(\frac{F_r + F_c}{4\mu F_r F_c}\right)^n \frac{\Gamma(3n + \frac{1}{2})}{n!\kappa^{3n+\frac{1}{2}}}$$

κ has been defined in eq. 16.

Taking the first term, $n = 0$, of this series corresponds to using the total reflection method. The other terms are therefore the corrections arising from the nuclear kinetic energy. Thus, in the total reflection method, one obtains from the $n = 0$ term in [27],

$$[28] \qquad \Delta E = \frac{-i\omega_r\alpha_n{}^2\pi\mu^{1/2}}{[2F_r(F_r + F_c)]^{1/2}} \kappa^{-1/2}$$

This result is only valid provided $E_r{}^0 < E_0$, *i.e.* for energies below the crossing point. In fact the expression [27] is discontinuous, going from real values for $\kappa < 0$ to purely imaginary values for $\kappa > 0$. Therefore it cannot be used for $E_r{}^0 > E_0$ as the series then becomes incorrect.

The result (eq. 28) is interesting in that it was first derived by Ben-Aryeh (15) for the predissociation in the NO molecule by using asymptotic expressions for the Airy functions at large negative parameters in [10]. One therefore sees that this expression is only valid for large mass systems as it is an expansion in powers of μ^{-1}. In particular this approximation at the resonance energy $E_r{}^0$ gives

$$[29] \qquad \Delta E(E_r{}^0) = \frac{-\omega_r\alpha_n{}^2\pi\mu^{1/2}}{\sqrt{2}(F_r + F_c)|E_r{}^0 - E_0|^{1/2}}$$

In as much as $\omega_r \propto \mu^{-1/2}$, one sees that this approximation gives very little isotope dependence in the energy shifts.

The Harmonic Oscillator

We will now discuss predissociation of the harmonic oscillator in the reflection method. Our starting point will be the definition in [7] of the continuum function $\phi_c(E_c,X)$ in the delta function approximation. Hence any overlap integral with the vth eigenfunction of the oscillator will be

$$[30] \qquad \langle\phi_v(E_v{}^0,X)|\phi_c(E_c,X)\rangle = N_v F_c{}^{-1/2} H_v(\sqrt{\beta}X_c) \exp\left[-\tfrac{1}{2}(\sqrt{\beta}X_c)^2\right]$$

where

$$\beta = \sqrt{\mu k}$$

$$N_v = [\sqrt{\beta/\pi}/2^v v!]^{1/2}$$

are the usual parameters for a harmonic oscillator of force constant k, and H_v is the Hermite polynomial for the level v. X_c corresponds to the classical turning point of the linear potential at energy E_c and has been defined in [8].

In this model, the integral $G(E)$ of [9] can be shown to reduce to (Appendix II),

$$[31] \qquad G(E) = \frac{N_v{}^2}{F_c} \lim_{\varepsilon \to 0} \int_{-\infty}^{\infty} \frac{(H_v(X))^2 e^{-X^2}}{E' - X + i\varepsilon} dX$$

where

$$[32] \qquad E' = \frac{\sqrt{\beta}}{F_c}(E - E_0 - F_c X_0)$$

It should be mentioned in passing that this integral can also be used to calculate resonant Raman scattering cross sections by a continuum since the integrals are formally the same (9, 17). Using the

integral representation for the denominator,

$$[33] \qquad \frac{1}{E' - X + i\varepsilon} = -i \int_0^\infty e^{it(E' - X + i\varepsilon)}\, dt$$

one obtains the following results from Appendix II.

$v = 0$:

$$[34] \qquad G_0(E) = \frac{\alpha_n^2 N_0^2}{F_c}\left[-i\pi\, e^{-E'^2} + 2\pi^{1/2}\, e^{-E'^2} \sum_{n=0}^{\infty} \frac{(E')^{2n+1}}{(2n+1)n!} \right]$$

$v \neq 0$:

$$[35] \quad G_v(E) = \frac{\alpha_n^2 N_v^2}{F_c}\left[-i\pi\, e^{-E'^2}[H_v(E')]^2 + \frac{\pi}{\sqrt{2}} e^{-E'^2} H_v(E')[H_{v+1}(E') - 2vH_{v-1}(E')] \right]$$

Defining $E' = -X_E\sqrt{\beta}$ where E' is given in [32], one has finally, from the definitions in [35],

$$\Delta E_v(E) = \frac{\alpha_n^2 N_v^2 \pi}{F_c\sqrt{2}} e^{-\beta X_E^2}\{H_v(-\sqrt{\beta}X_E)[H_{v+1}(-\sqrt{\beta}X_E) - 2vH_{v-1}(-\sqrt{\beta}X_E)]\}$$

$$[36] \qquad \tfrac{1}{2}\Gamma_0(E) = \frac{\alpha_n^2 N_v^2 \pi}{F_c} e^{-\beta X_E^2}[H_v(-\sqrt{\beta}X_E)]^2$$

Comparing these results to the exact results for the linear potential models, eq. 19, one notices the formal similarity between the two. In other words, both ΔE and Γ have a common energy dependence in the functions A_i or H_v. The implications of this result is that these parameters will have similar oscillatory behavior with common zeroes. Subsidiary zeroes may appear for ΔE, *i.e.* the energy shift is a more rapidly varying parameter than the linewidth Γ as reflected in [36]. Our results for the predissociation of the harmonic oscillator therefore corroborate the numerical findings of Julienne and Krauss (18) for O_2 that Γ and ΔE are oscillatory functions even for low vibrational levels.

Conclusions

We have derived analytic expressions in the reflection method for linewidths Γ and energy shifts ΔE for two different models: a linear potential model valid for high vibrational quanta and the harmonic oscillator potential valid for low vibrational quanta. The mathematical structure illustrated in [19] and [30] shows that in all cases Γ and ΔE have common zeroes. In addition ΔE has additional zeroes which imply that this parameter is a more sensitive function of energy than the linewidth Γ. As shown previously for the linear potential model, this can introduce important asymmetries in lineshapes (3).

We have furthermore shown that the reflection method should be an excellent approximation for steep repulsive potentials. The method tends to overestimate the Franck–Condon factors and therefore the parameters ΔE and Γ for intermediate slopes. On the other hand, the reflection method seems to preserve the phase oscillations of these parameters when compared to the exact results. Furthermore a total reflection method, *i.e.* applied to both bound states and continuum states, results in discontinuous and therefore erroneous results for ΔE.

As a final conclusion we wish to reiterate an important finding. We have seen that Γ and ΔE have common zeroes, *i.e.* they vanish at identical energies. From an experimental viewpoint, this means that sharp levels in a predissociated spectrum undergo no energy shifts. Hence one should be able to reconstruct the 'unperturbed' potential curve by just analysing the positions of sharp levels. From thereon, one should be able to calculate from the spectrum the energy shifts of the broadened levels with respect to the unperturbed potential levels and thus calculate the perturbation parameters via our formulae.

Appendix I

We wish to evaluate the integral $G(E)$, eq. 9, which becomes, after introducing the appropriate functions and the integral representation, eq. 33,

$$[I.1]\quad G(E) = \frac{-i\omega_r}{2\pi F_r F_c} \lim_{\varepsilon\to 0} \int_0^\infty \int_{-\infty}^\infty \int_{-\infty}^\infty dt\, dp\, dp' \exp\left[it(E + i\varepsilon)\right] \times \exp\left[ia\left(\frac{-p^3}{3} + \frac{p'^3}{3}\right) + i(p - p')\left(\frac{E_r^0 - E_0}{F_r} - \frac{E_0}{F_c}\right)\right] \int_{-\infty}^\infty \exp iE_c\left(\frac{p}{F_c} - t - \frac{p'}{F_r}\right) dE_c$$

where

$$a = \frac{1}{2\mu}(1/F_c + 1/F_r) = a_r' + a_c'$$

Since the coefficient a multiplies the p^3 terms in the exponential, then setting $F_c = \infty$, *i.e.* $a = a_r'$, corresponds to neglecting the p^3 terms and hence the kinetic energy in the continuum functions $\phi_c(E_c, p)$. This is therefore the *reflection* method for the continuum.

The last integral in $G(E)$ reduces to a delta function. The ensuing calculation gives

$$[I.2]\quad G(E) = \frac{-i\omega_r}{2F_r} \lim_{\varepsilon\to 0} \int_0^\infty dt \exp\left[it(E + i\varepsilon)\right] \exp\left[-ia\frac{F_c^3 t^3}{3} + iF_c t\left(\frac{E_r^0 - E_0}{F_r} - \frac{E_0}{F_c}\right)\right] \times \int_{-\infty}^\infty dp \exp\left[-iaF_c tp^2 + iaF_c^2 t^2 p\right]$$

Furthermore, setting $r = F_c t$, the last integral gives

$$[I.3]\quad \int_{-\infty}^\infty \exp\left[-irap^2 + ira^2 p\right] dp = \left(\frac{\pi}{ra}\right)^{1/2} (1 - i) \exp\left(\frac{ira^3}{4}\right)$$

With this result, $G(E)$ finally becomes

$$[I.4]\quad G(E) = -(1 + i)\frac{\omega_r}{2F_r}\left(\frac{\pi}{2aF_c}\right)^{1/2} \int_0^\infty t^{-1/2} \exp\left[-ibt^3 + it(\kappa + i\varepsilon)\right] dt$$

where

$$b = aF_c^3/12$$

$$\kappa = (E_r^0 - E_0)(F_c/F_r) + (E - E_0)$$

Appendix II

We wish to evaluate the integral

$$[II.1] \qquad I(E) = \lim_{\varepsilon \to 0} \int_{-\infty}^{\infty} \frac{[H_v(X)]^2}{(E - X + i\varepsilon)} e^{-X^2} dX$$

By introducing the integral representation [33] for the denominator, $I(E)$ now becomes the double integral,

$$[II.2] \qquad I(E) = -i \lim_{\varepsilon \to 0} \int_0^{\infty} e^{-\varepsilon t} dt \int_{-\infty}^{\infty} [H_v(X)]^2 \exp(-X^2 - iXt) dX$$

From tables of integral transforms (19), we rapidly evaluate the Fourier transform in the integral to give,

$$[II.3] \qquad I(E) = -i2^v \pi^{1/2} v! \int_0^{\infty} dt\, L_v(t^2/2) \exp(iEt - \varepsilon t - t^2/4)$$

where L_v is the generalized Laguerre polynomial (14)

$$[II.4] \qquad L_v(t) = (v!)^{-1} e^t \frac{d^v}{dt^v}(t^v e^{-t})$$

The integral [II.3] is tabulated in Erdelyi (19) in terms of sine and cosine Fourier transforms. Using these results one obtains finally

$$[II.5] \qquad I(E) = -i\pi e^{-E^2}[H_v(E)]^2 + \frac{\pi}{\sqrt{2}} e^{-E^2} H_v(E)[H_{v+1}(E) - 2vH_{v-1}(E)]$$

The case $v = 0$ requires a more careful calculation since one cannot use recurrence formulae for $L_0(t)$. We start with eq. II.3,

$$[II.6] \qquad I_1(E) = \lim_{\varepsilon \to 0} \int_0^{\infty} t^v \exp(-t^2/4 - \varepsilon t) \cos Et\, dt = \pi^{1/2} e^{-E^2} H_v(E)$$

$$[II.7] \qquad I_2(E) = i \lim_{\varepsilon \to 0} \int_0^{\infty} t^v \exp(-t^2/4 - \varepsilon t) \sin Et\, dt$$

$$= 2^{v+1}\Gamma\left(\frac{v+2}{2}\right) E e^{-E^2} {}_1F_1\left[\frac{1}{2} - \frac{v}{2}; \frac{3}{2}; E^2\right]$$

where ${}_1F_1(a;b;z)$ is the confluent hypergeometric function defined in (14). Evaluating this function, one obtains for $v = 0$,

$$[II.8] \qquad {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; E^2\right) = \sum_{n=0}^{\infty} \frac{E^{2n}}{(2n+1)n!}$$

Collecting the results [II.6] and [II.7] one obtains for $v = 0$,

$$[II.9] \qquad I(E) = i\pi e^{-E^2} + 2\pi^{1/2} e^{-E^2} \sum_{n=0}^{\infty} \frac{E^{2n+1}}{(2n+1)n!}$$

Kinetics and mechanism of decarboxylation of some pyridinecarboxylic acids in aqueous solution. II

GERALD E. DUNN AND HARALD F. THIMM

Department of Chemistry, University of Manitoba, Winnipeg, Manitoba, Canada R3T 2N2

Received July 12, 1976

GERALD E. DUNN and HARALD F. THIMM. Can. J. Chem. **55**, 1342 (1977).

Six 3-substituted picolinic acids were synthesized and decarboxylated in buffered aqueous solutions of ionic strength 1.0 at 150 and/or 95°C. 3-Amino- and 3-hydroxypicolinic acids appear to decarboxylate by initial protonation, but the others fit the requirements of the Hammick mechanism for picolinic acid decarboxylation. Both electron-withdrawing and electron-releasing 3-substituents accelerate decarboxylation in picolinic acids but inhibit decarboxylation in their anions. Acceleration in the acids is considered to be the result of interference by 3-substituents with coplanarity of the carboxyl group and the aromatic nucleus. This reduces the order of the bond between the carboxyl group and the ring, thus facilitating bond breaking. In decarboxylation of the anions water appears to play a critical role, since picolinate ions have not been observed to decarboxylate in any other solvent, including ethylene glycol. It is proposed that water forms a hydrogen-bonded bridge between carboxylate oxygen and aromatic nitrogen, so that as the carbon–carbon bond breaks a nitrogen–hydrogen bond is formed. This may provide a lower energy path through an ylide intermediate than would be required if the picolinate ion were to decarboxylate to a 2-pyridyl carbanion.

GERALD E. DUNN et HARALD F. THIMM. Can. J. Chem. **55**, 1342 (1977).

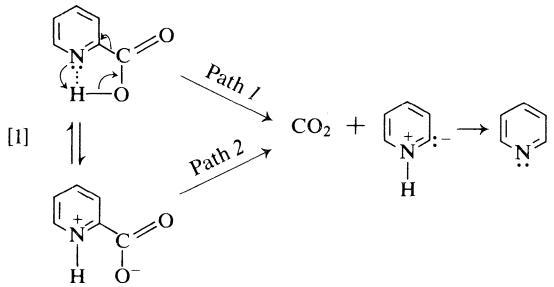
On a synthétisé six acides picoliniques substitués en position 3 et on les a décarboxylés dans des solutions aqueuses tamponnés de force ionique 1.0, à 150 et/ou 95°C. Il semble que les acides amino-3 et hydroxy-3 picoliniques se décarboxylent par une protonation initiale; toutefois les autres présentent les caractéristiques nécessaires pour le mécanisme proposé par Hammick pour la décarboxylation de l'acide picolinique. Les substituants en position 3 qui attirent les électrons ainsi que ceux qui repoussent les électrons accélèrent la décarboxylation des acides picoliniques mais inhibent la décarboxylation de leurs anions. On considère que l'accélération dans les acides provient d'une interférence, par les substituants en position 3, sur la coplanarité du groupe carboxyle et du noyau aromatique. Cet effet réduit l'ordre de la liaison entre le groupement carboxyle et le cycle et facilite ainsi le bris du lien. Dans le cas de la décarboxylation des anions, il semble que l'eau joue un rôle critique puisque l'on n'a jamais observé la décarboxylation des ions picolinates dans d'autres solvants, même l'éthylène glycol. On suggère que l'eau forme des ponts hydrogène entre l'oxygène du carboxylate et l'azote du cycle aromatique provoquant la formation d'un lien azote–hydrogène au moment où le lien carbone–carbone se brise. Ce processus pourrait fournir une voie requérant une énergie plus basse, via un ylide intermédiaire, que celle qui serait requise si l'ion picolinate se décarboxylait par l'intermédiaire d'un carbanion pyridyle-2.

[Traduit par le journal]

Introduction

The mechanism first proposed by Hammick for the decarboxylation of picolinic and quinaldinic acids in organic solvents, is that shown in reaction 1, with Hammick's preference being for path *2* (1). Others have favored path *1* (2, 3).

A previous paper from this laboratory reported a study of the reaction in aqueous solution (4). The rate *vs.* p*H* curve goes through a maximum at the isoelectric p*H*, and there is a ^{13}C kinetic isotope effect at p*H*'s both above and below the isoelectric point. These observations are predicted by the Hammick mechanism, but others are not so readily interpreted. For example, since the Hammick mechanism depends on



positively charged nitrogen for stabilization of the transition state leading to the ylide, it was surprising to find that the picolinate anion, for which no such stabilization is apparent, decarboxylates almost half as fast as the acid itself.

On the other hand, homarine, the methylbetaine of picolinic acid, where positive charge on nitrogen is assured, was found to decarboxylate about a hundred times faster than picolinic acid. Thus, in its decarboxylation picolinic acid appears to resemble its anion more than its betaine. This was at first thought to mean that at the reaction temperature (150°C) picolinic acid is mainly in the non-zwitterionic form, but ultraviolet spectra at that temperature did not support this hypothesis.

Even the 100-fold increase in rate produced by N-methylation appeared surprisingly small when it was found that quinolinic acid under the same conditions decarboxylates at least a thousand times faster than picolinic acid. (4) Thus a 3-carboxyl group has a tenfold larger effect on the rate of decarboxylation than does quaternization of the 1-nitrogen atom. On the other hand, 4-, 5-, and 6-carboxyl, 5-nitro, and 6-methyl groups have very small effects (factor of two) on the rate of decarboxylation of picolinic acid. The present work was undertaken in an attempt to sort out the factors involved in substituent effects on the decarboxylation of picolinic acids.

Results

In previous work a 3-carboxyl substituent had produced what appeared to be an anomalously large rate increase (4), so attention was concentrated on 3-substituents. Six 3-substituted picolinic acids were synthesized: amino, benzoyl, bromo, hydroxy, methyl, and nitro. These were decarboxylated in buffered aqueous solutions of ionic strength 1.0 at 150 and/or 95°C. The 3-amino- and 3-hydroxypicolinic acids gave p*H*–rate profiles very different from those of picolinic and the other substituted picolinic acids. It is thought that they decarboxylate by a different mechanism from the rest, probably a ring-protonation mechanism like those of the amino- and hydroxybenzoic acids, and they will not be discussed further here.

3-Methylpicolinic Acid

The p*H*–rate profile for 3-methylpicolinic acid at 150°C is given in Fig. 1. It shows the same rate maximum at intermediate p*H* as that shown by picolinic acid (4) but, unlike the curve for picolinic acid, this one does not level off at high p*H*. Apparently the 3-methylpicolinate anion does not decarboxylate. To confirm this difference between picolinic and 3-methylpicolinic acids, both were run at p*H* 9.2. For picolinic acid the rate constant was 5×10^{-7} s^{-1}; for 3-methylpicolinic no reaction was detected after 330 h ($k < 1 \times 10^{-8}$ s^{-1}).

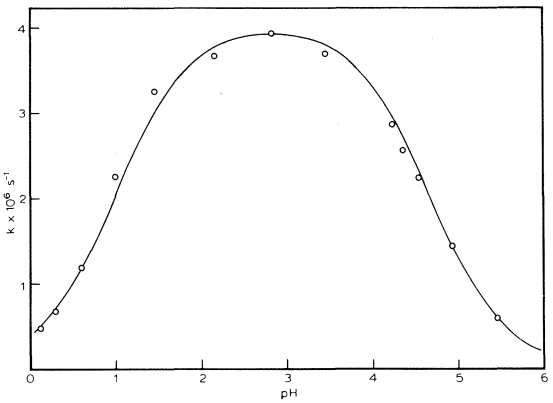


FIG. 1. First-order rate constants for the decarboxylation of 3-methylpicolinic acid at 150°C, $\mu = 1.0$. Circles represent experimental points and the solid line is calculated from [6].

To derive the p*H* dependence of rate constant for the Hammick mechanism, let H_2A^+ represent protonated amino acid, HA represent isoelectric species (neutral acid plus zwitterion), and A^- represent amino acid anion. k_{HA} is the rate constant for decarboxylation of the isoelectric species and k_A that for the anion. Then [2] and [3] define the amino acid ionization constants and [4] gives the stoichiometric concentration of amino acid [C].

$$[2] \qquad H_2A^+ \overset{K_1}{\rightleftharpoons} H^+ + HA$$

$$[3] \qquad HA \overset{K_2}{\rightleftharpoons} H^+ + A^-$$

$$[4] \qquad [H_2A^+] + [HA] + [A^-] = [C]$$

If only the isoelectric species decarboxylates, the rate may be expressed in terms of either [C] or [HA], as in [5].

$$[5] \qquad d[CO_2]/dt = k[C] = k_{HA}[HA]$$

Combination of [2]–[5] gives [6], the dependence of the stoichiometric rate constant, k, on hydrogen-ion concentration:

$$[6] \qquad k = \frac{k_{HA}}{\frac{[H^+]}{K_1} + 1 + \frac{K_2}{[H^+]}}$$

At low p*H*, where $[H^+] \gg K_2$, [6] reduces to [7]

$$[7] \qquad \frac{1}{k} = \frac{[H^+]}{k_{HA}K_1} + \frac{1}{k_{HA}}$$

and at high pH, where $[H^+] \ll K_1$, [6] reduces to [8]

$$[8] \qquad \frac{1}{k} = \frac{K_2}{k_{HA}[H^+]} + \frac{1}{k_{HA}}$$

The data for 3-methylpicolinic acid give straight-line plots for [7] and [8] in the pH regions 0–2.1 and 2.8–5.5, respectively. The values found for k_{HA} are 4.08×10^{-6} s^{-1} from [7] and 4.00×10^{-6} s^{-1} from [8]. The same plots give $pK_1 = 0.99$ and $pK_2 = 4.68$. Use of these three numbers in [6] generates the solid line in Fig. 1.

Other 3-Substituted Picolinic Acids

Decarboxylation of 3-bromopicolinic acid was studied by the method used for the 3-methyl derivative, but the reaction is much faster, so the reaction temperature was lowered to 95°C to get convenient rates. 3-Bromopicolinic acid is light sensitive, so the uncertainty in rate constants is estimated to be about ±7% instead of the usual ±2%.

A complete rate profile was not done for 3-benzoylpicolinic acid. Rate constants at 150°C and $\mu = 1.0$ were 2.0×10^4, 4.5×10^{-4}, and 3.0×10^{-4} s^{-1} at pH's of 0.37, 1.22, and 2.19, respectively, from which it is evident that $k_{HA} \geq 4.5 \times 10^{-4}$ s^{-1}.

3-Nitropicolinic acid decarboxylated so rapidly, even at 95°C, that accurate measurements were not possible. At pH 0.3 decarboxylation was complete in 2 h, so that $k > 1 \times 10^{-3}$ s^{-1} and, of course, $k_{HA} \geq k$. Both the 3-nitro and 5-nitro anions underwent some reaction other than decarboxylation at pH 9.2.

None of the 3-substituted picolinate anions examined in this work decarboxylated detectably at 150°C and pH 9.2 during a period equal to ten or more half-lives of the isoelectric species. These results, together with some previously reported (4), are collected in Table 1.

TABLE 1. First-order rate constants for decarboxylation of substituted picolinic acids at ionic strength 1.0

Substituent	Temperature (°C)	Acid k_{HA} (s^{-1})	Anion k_A (s^{-1})
None	150	1.1×10^{-6}	5.0×10^{-7}
1-Methyl	150	1.3×10^{-4}	
3-Methyl	150	4.0×10^{-6}	Very small*
5-Methyl	150	4.4×10^{-7}	3×10^{-8}
6-Methyl	150	7.7×10^{-7}	3.7×10^{-7}
3-Benzoyl	150	$\geq 4.5 \times 10^{-4}$	Very small*
4-Carboxyl	150	1.5×10^{-6}	
5-Carboxyl	150	1.8×10^{-6}	
5-Nitro	150	2.2×10^{-6}	$< 3.8 \times 10^{-7}$
6-Carboxyl	150	1.3×10^{-6}	
3-Carboxyl	150	$\geq 1.2 \times 10^{-3}$	
	95	3.3×10^{-6}	1.0×10^{-6}
3-Bromo	95	1.5×10^{-5}	Very small*
3-Nitro	95	$\geq 1 \times 10^{-3}$	Very small*

*Very small means $k_A \leq k_{HA} \times 10^{-3}$.

Discussion

It had been noted in previous work (4) that a carboxyl substituent anywhere on the ring increases the rate of decarboxylation of picolinic acid, but the effect is a thousand times greater in the 3-position than elsewhere. This could be an electronic, steric, or neighboring-group effect. The data on Table 1 show that other electron-withdrawing 3-substituents cause similar or larger rate increases although their structures are very different. This makes it very unlikely that the acceleration is a neighboring-group effect.

The data for 6-methyl, 5-nitro, and 4-, 5-, and 6-carboxyl substituents show that the usual electronic effects found in aromatic systems (Hammett's σ) are present, but small. Electron-withdrawing substituents accelerate, and electron-releasing substituents retard, as might be expected from the Hammick mechanism in which there is an increase of negative charge at the 2-position of the transition state.

The effect of substituents at the 3-position is quite different, however. Electron-attracting substituents (3-benzoyl, 3-carboxyl, 3-bromo, 3-nitro) produce rate increases of several orders of magnitude. This effect is at least partly steric, since a methyl substituent switches from retarding in the 5- and 6-positions to accelerating in the 3-position. However, it is also largely electronic, as is shown by the much larger rate increase produced by 3-bromo than by 3-methyl, although they are comparable in size. Furthermore, the electronic effect must be composed more of electrostatic (inductive and/or field) effects than delocalization (resonance) effects, since nitro and carboxyl substituents have such enormously larger effects in the 3- than in the 5-position. These observations are consistent with the Hammick mechanism, in which negative charge at the 2-position of an ylide-like transition state can be stabilized electrostatically by positive charge at the 1- or 3-positions, but cannot be delocalized by the usual resonance structures on to

substituents at the 3- or 5-positions except by making the 2-position a carbene.

The steric accelerating effect of a 3-methyl group shows that the more pronounced accelerating effect of a 1-methyl group is not entirely due to the positive charge introduced on nitrogen by quaternization. In previous work (4) it was thought surprising that the 1-methylpicolinate betaine (homarine) decarboxylates more than a hundred times faster than the picolinic acid zwitterion, although both have a unit positive charge on nitrogen. It is now evident that a fairer comparison would be between the betaine and 3-methylpicolinic acid, where the ratio is only 33. It has been estimated (4) that the fraction of picolinic acid present as zwitterion at 150°C and $\mu = 1.0$ may be as low as 40%. A similar percentage for the 3-methyl acid would leave a ratio of only 10–15 to be explained by solvation or other effects.

The most significant feature of the data in Table 1 is found in the column for picolinate anion decarboxylation. The anions of picolinic acid and its 6-methyl, 3-carboxy, 5-methyl, and 5-nitro derivatives decarboxylate slower than the corresponding acids by factors of about two to ten, but none of the other 3-substituted acids decarboxylate detectably at all. Since the 3-carboxy mono-anion is probably a zwitterion as indicated in reaction 9, it is safe to say that no

[9] 
3-substituted picolinic acid decarboxylates as anion (neither nitrogen or carboxyl protonated). The contrast between the behavior of the acids, where all 3-substituents accelerate, and their anions, where all 3-substituents inhibit, is very striking.

Since both the acceleration for acids and inhibition for anions occur with either electron-releasing or electron-attracting substituents, both effects would appear to be at least partly steric. The obvious steric effect of a 3-substituent is to prevent coplanarity between the 2-carboxyl group and the aromatic nucleus, thus reducing the order of the bond between carboxyl group and ring. It could also interfere with hydrogen bonding between carboxyl group and aromatic nitrogen. The reduced bond order would contribute to the accelerating effect of a 3-substituent on the acid by any mechanism but, according to the Hammick mechanism, [1], a decrease of hydrogen bonding should have a retarding effect on path *1* by interfering with the cyclic intramolecular electron shift. Evidently intramolecular hydrogen bonding is not an important feature of picolinic acid decarboxylation in water.

Clearly, neither decreased bond order nor decreased intramolecular hydrogen bonding can account for the inhibitory effect of a 3-substituent on decarboxylation of picolinate anions. There remains the possibility that a 3-substituent interferes with the approach of solvent molecules to the carboxylate group. It is noteworthy, in this respect, that in the many studies of picolinic acid decarboxylation in organic solvents no mention has been made of decarboxylation of picolinate anion. In fact, Brown and Hammick have reported that quinaldinate ion does not decarboxylate at 184.4°C in ethylene glycol, although the acid readily does so. (5) Attempts to determine whether or not quinaldinic acid decarboxylates in aqueous base at 150°C failed because both the acid and quinoline undergo some other reaction under these conditions. As an alternative, the behavior of picolinate ion in ethylene glycol was investigated. A 2×10^{-4} *M* solution of sodium picolinate in glycol showed no decarboxylation after 48 h, a period in which the acid would be 75% decarboxylated (6). In other words, if k_A is the rate constant for decarboxylation of the anion, $k_A < 0.015\, k_{HA}$. Apparently aqueous solvent is essential to the decarboxylation of picolinate anion, and a 3-substituent interferes with the action of the solvent.

The role of water in the decarboxylation is difficult to determine. Several possibilities come to mind. Water or hydroxide ion could add to the carboxylate group, leading to loss of bicarbonate as in reaction 10. A 3-substituent could interfere with formation of the tetrahedral intermediate. Clark has long maintained that decar-

[10] 
boxylation of picolinic and other acids in the isoelectric form involves nucleophilic attack by solvent on the carboxyl carbon (2), but the nucleophilic solvent is not limited to water and it is difficult to see why glycol could not play this role.

Another possibility is that water forms a hydrogen-bonded bridge between the carboxylate oxygen and ring nitrogen as in reaction 11. A

[11] 
3-substituent, by pushing the carboxylate group out of coplanarity with the ring, could interfere with the formation of the hydrogen-bonded complex. Both mechanisms have the advantage that the intermediate formed on loss of carbon dioxide is an ylide rather than an aryl carbanion. The mechanism of [11] has the additional advantage that the geometry of the complex could be such as to make water a unique solvent for the decarboxylation of picolinate anions.

In the preceding paper on picolinic acid decarboxylation (4) concern was expressed over an apparent discrepancy between the relative ease of formation of 2- and 6-pyridyl carbanions by decarboxylation ($2 \gg 4$) and by deprotonation ($4 > 2$) as evidenced by base-catalyzed deuterium exchange. (7) It is now noteworthy that, if either of the above mechanisms for picolinate anion decarboxylation is correct, the discrepancy disappears. This is because these mechanisms make ylide rather than carbanion the immediate product of decarboxylation of the picolinate anion as well as of picolinic acid, and the relative ease of formation of the ylides is $2 \gg 4$ by either decarboxylation or deprotonation (7).

In conclusion, then, the opposite effects of 3-substitution on the rates of decarboxylation of picolinic acid and its anion may be accounted for by mechanisms such as those represented by [10] and [11], with [11] having some advantages over [10]. On the other hand, the unique ability of water to facilitate decarboxylation of the picolinate anion may reside in its polarity and geometry which in some way make it especially suitable for solvation of a transition state with developing negative charge at position 2, or for providing proton at position 2. The mechanism represented by [11] is attractive, but by no means compelling.

Experimental

Materials

The acids listed below were synthesized as described; others were commercial products.

3-Methylpicolinic Acid

2-Amino-3-picoline was diazotized and converted to 2-bromo-3-picoline by the method of Craig (8) in 57% yield. This, in turn, was converted to 2-cyano-3-picoline by the procedure of Friedman and Shechter, method *C*, (9) in 95% yield. The 2-cyano-3-picoline was hydrolyzed by refluxing in 13 *M* HCl for 4 h. Removal of the solvent under reduced pressure left light tan crystals (86%). These were purified by sublimation at 20 torr, followed by two recrystallizations from 95% ethanol, to give fine white crystals, mp 117–118°C (lit. (10) mp 111°C). *Anal.* calcd. for $C_7H_7NO_2 \cdot H_2O$: C 54.2, H 5.81, N 9.04, neut. equiv. 155.1; found: C 54.2, H 5.85, N 9.18, neut. equiv. 155.4.

3-Aminopicolinic Acid

3-Aminopicolinic acid, mp 211–212°C (lit. (11) mp 210°C) was prepared from quinolinic anhydride by the method of Sucharda (11).

3-Bromopicolinic Acid

3-Aminopicolinic acid (10 g) was diazotized in 48% HBr (30 ml) containing ice by dropwise addition of sodium nitrite (6 g in 40 ml H_2O) at 0–1°C. The resulting solution was poured into a solution of cuprous bromide (8.8 g) in 48% HBr (20 ml) containing ice (100 g). When reaction was complete a silvery blue precipitate was filtered off and washed with cold water. An aqueous suspension of this solid was decomposed with H_2S, the cupric sulfide filtered off, and the filtrate reduced to low volume on a rotary evaporator. Its p*H* was adjusted to 2–3 and, on standing, brown crystals were collected, recrystallized from water, and sublimed at 0.2 torr to yield a white powder (0.7 g, 10%), mp 130–131°C (dec.). *Anal.* calcd. for $C_6H_4NO_2Br$: C 35.6, H 1.98, N 6.94, Br 39.6; found: C 35.9, H 2.01, N 6.77, Br 39.6.

3-Benzoylpicolinic Acid

This acid was synthesized from quinolinic anhydride by the method of Jeiteles (12), mp 148.5–149.5°C (lit. (12) mp 147°C).

3-Nitropicolinic Acid

This compound was obtained by oxidation of 3-nitropicoline prepared from 2-chloro-3-nitropyridine by treatment with sodium diethylmalonate.

Sodium metal (3.5 g) was added to diethylmalonate (75 g) at 60°C. 2-Chloro-3-nitropyridine (25 g) was added with cooling to keep the temperature below 95°C. The mixture was kept at 60°C for 2 h, then allowed to stand at room temperature for 24 h. Excess starting materials were removed by fractionation at 1 torr (38–52°C), leaving a red-brown oil and sodium chloride. The oil gave the right mass and nmr spectra for 2-(3-nitropyridyl)diethylmalonate, and was hydrolyzed without further purification by heating 5 h on a steam bath with water (32 ml) and sulfuric acid (18 ml). After standing overnight, the

mixture was made alkaline with solid sodium carbonate and steam distilled. The steam distillate was extracted with ether and the extract dried and evaporated to leave a yellow oil with the right mass and nmr spectra for 3-nitro-2-picoline (70%). The crude 3-nitro-2-picoline was oxidized to 3-nitropicolinic acid with potassium permanganate as described by Brown (13). Yield 8%, mp 120–121°C (lit. (14) mp 105°C). Because of the discrepancy with the literature melting point, the product was analyzed. *Anal.* calcd. for $C_6H_4N_2O_4$: C 42.9, H 2.40, N 16.7; found: C 43.0, H 2.51, N 16.5. Mass spectrum, *m/e* (relative intensity): 168(1), 151(1.5), 124(50), 94(17), 78(100).

5-Methylpicolinic Acid

2,5-Lutidine (7.7 g) was refluxed with selenium dioxide (14.3 g) and pyridine (40 ml) for 2 h, then filtered and steam distilled. The residue was acidified with glacial acetic acid (10 ml) and concentrated to 15 ml under reduced pressure. This was filtered into a suspension of cupric acetate (20 g) in water (100 ml). After standing a day, the precipitate was filtered off, washed with water, and treated in aqueous suspension with H_2S. CuS was filtered off and washed with water. Combined filtrate and washings were taken to low volume under reduced pressure, filtered, and evaporated to dryness. The residue was recrystallized from benzene to give white crystals (9%), mp 166–168°C (lit. (14) mp 163–164°C), ms, *m/e* (relative intensity): 137(5), 93(100), 92(30), 66(52), 65(55).

Rate Measurements

Rates were followed spectrophotometrically as previously described (4) in solutions buffered with HCl, NaH_2PO_4, Na_2HPO_4, and adjusted to constant ionic strength with KCl. Good first-order plots were obtained up to at least 3 half-lives, and the ultraviolet spectrum of the product coincided with that of the appropriate substituted pyridine in each case.

The preparation of some potential intermediates for syntheses of aminopolydeoxy sugars related to antibiotics[1]

HANS H. BAER AND FAWZY F. Z. GEORGES
Department of Chemistry, University of Ottawa, Ont., Canada K1N 6N5

Received December 20, 1976

HANS H. BAER and FAWZY F. Z. GEORGES. Can. J. Chem. **55**, 1348 (1977).

Starting from methyl 3,6-dideoxy-3-nitro-α-D-glucopyranoside (**1**) and proceeding through its 4-mesylate (**2**) and 2,4-dimesylate (**3**), respectively, methyl 3,4,6-trideoxy-3-nitro-α-D-*xylo*-hexopyranoside (**4**) and methyl 2-*O*-acetyl-3,4,6-trideoxy-3-nitro-α-D-*threo*-hex-3-enopyranoside (**5**) were prepared. The 4,6-*O*-benzylidene derivatives (**6**, **8**, and **10**) of methyl 2-*O*-acetyl-3-deoxy-3-nitro-β-D-glucopyranoside, methyl 3-deoxy-3-nitro-α-D-glucopyranoside, and methyl 2,3-dideoxy-3-nitro-α-D-*arabino*-hexopyranoside were found to undergo without difficulty the Hanessian–Hullar reaction with *N*-bromosuccinimide, to give good yields of the corresponding 6-bromo-4-benzoates (**7**, **9**, and **11**). Partial anomerization giving the β-anomer **12** of **11** was observed under certain circumstances.

HANS H. BAER et FAWZY F. Z. GEORGES. Can. J. Chem. **55**, 1348 (1977).

En partant du méthyle 3,6-didésoxy-3-nitro-α-D-glucopyranoside (**1**) et en passant par le 4-mésylate (**2**) et le 2,4-dimésylate (**3**), respectivement, on a preparé le méthyle 3,4,6-tridésoxy-3-nitro-α-D-*xylo*-hexopyranoside (**4**) et le méthyle 2-*O*-acétyl-3,4,6-tridésoxy-3-nitro-α-D-*thréo*-hex-3-énopyranoside (**5**). On a trouvé que les dérivés 4,6-*O*-benzylidénés (**6**, **8**, et **10**) du méthyle 2-*O*-acétyl-3-désoxy-3-nitro-β-D-glucopyranoside, du méthyle 3-désoxy-3-nitro-α-D-glucopyranoside, et du méthyle 2,3-didésoxy-3-nitro-α-D-*arabino*-hexopyranoside réagissaient sans difficultés avec la *N*-bromosuccinimide par la réaction de Hanessian–Hullar et donnaient en bons rendements les 6-bromo-4-benzoates correspondants. Dans certains cas on a observé anomérisation partielle donnant l'anomère **12** du composé **11**.

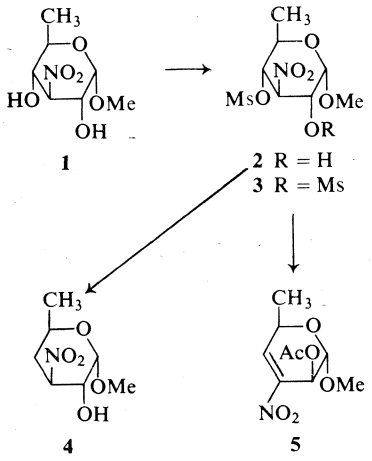
Previous work in this laboratory has dealt with the utilization of nitro sugars as readily accessible points of departure for syntheses of aminopolydeoxy sugars that represent building stones of antibiotics or are structurally related to such natural products. We obtained by this approach the following sugars, as free amines, hydrochlorides, or *N*-acetyl derivatives: 3-amino-2,3,6-trideoxy-D-*lyxo*-hexose (D-daunosamine) (1) and its D-*arabino* isomer (D-acosamine) (1, 2), 2,3,6-trideoxy-3-dimethylamino-D-*arabino*-hexose (D-angolosamine) (2), 3,4,6-trideoxy-3-dimethylamino-L-*xylo*-hexose (L-desosamine) (3), and methyl 3-amino-3,4,6-trideoxy-2-*O*-methyl-α-L-*xylo*-hexopyranoside (4) which is a positional isomer of methyl actinosaminide, the corresponding 2,3,6-trideoxy-4-*O*-methyl-L-*arabino* derivative (5). Facile synthetic access to carbohydrate moieties of this kind should aid in research directed toward the modification of biological properties in antibiotics by partial syntheses using modified components, as has been done successfully for instance in studies on daunorubicin and adriamycin (6).

We now report the preparation of some further nitro sugar derivatives which should be convertible without difficulty into amino sugars by procedures already well established. For a synthesis of the natural D-enantiomer of desosamine analogous to the recently described (3) synthesis of the L-enantiomer, methyl 3,4,6-trideoxy-3-nitro-α-D-*xylo*-hexopyranoside (**4**) would be the required precursor. The L-enantiomer of **4** had been prepared (3) by a nearly quantitative reduction, with sodium borohydride, of the corresponding 3,4-unsaturated glycoside but, unfortunately, the latter was obtained (7) in only about 10% over-all yield from a primary starting compound, methyl 3,6-dideoxy-3-nitro-α-L-glucopyranoside.[2] Performance in the D-series called for a more economical utilization of the costlier methyl 3,6-dideoxy-3-nitro-α-D-glucopyranoside (**1**) whose practical preparation (2) is somewhat

[1]Part 38 in a series on reactions of nitro sugars. For part 37 see ref. 8.

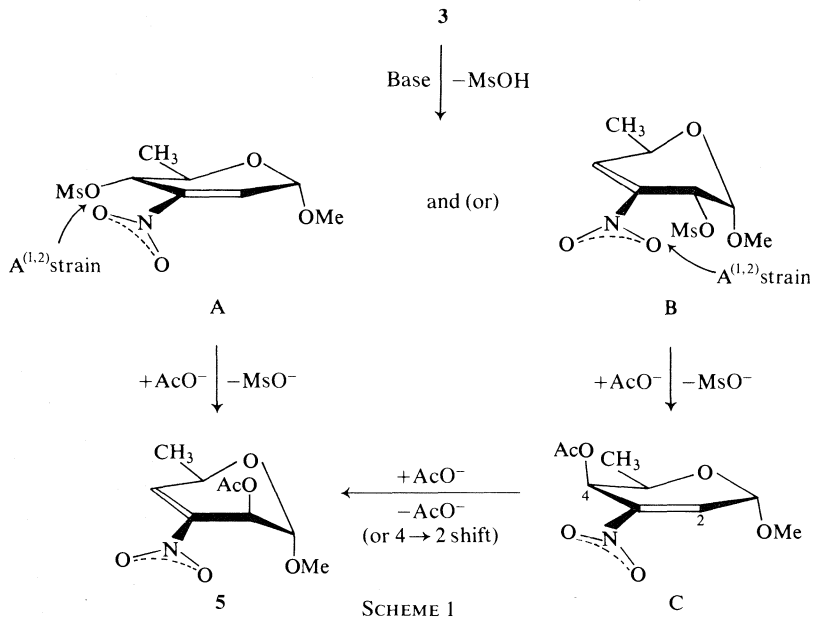
[2]The ultimate source of this readily prepared starting compound is reasonably priced, commercial L-rhamnose. This factor, and the nearly complete recovery, for possible recycling, of unreacted nitro glycoside in the olefination step mitigated the disadvantage of the low yield.

more involved. A superior way of generating the desired 4-deoxy function has now emanated from our studies on nitro sugar methanesulfonates (8) in the course of which the 2,4-di-*O*-methylsulfonyl derivative **3** of **1** had been obtained. The rate of mesylation in **1** has now been found to be considerably greater at position 4 than at position 2, so that upon interruption of the reaction after an appropriate period of time the 4-mono-*O*-mesyl derivative **2** could be isolated in 36% yield, with 60% of unchanged **1** being recoverable for re-use. The site of preferential mesylation followed from non-identity of the product (mp 93–94.5°C, $[\alpha]_D$ + 96.6°) with the known (8) 2-*O*-mesyl isomer (mp 106–107°C, $[\alpha]_D$ +148°). Reductive dehydromethylsulfonyloxylation (2) of **2** with sodium borohydride then afforded a 60% yield of crystalline **4**, identified by comparison with the known L-enantiomer. Compound **4** should be convertible into the dimethylamino sugar, D-desosamine, as elaborated (3) in the L-series.



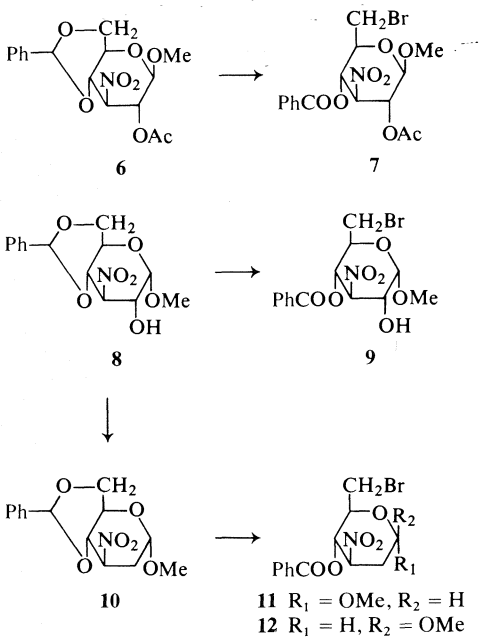
The preparative usefulness of nitro sugar mesylates (2, 8, 9) was underscored by another interesting, and surprisingly facile, transformation. When the dimesylate **3** was heated for 10 min in acetone containing acetic acid and sodium acetate, methyl 2-*O*-acetyl-3,4,6-trideoxy-3-nitro-α-D-*threo*-hex-3-enopyranoside (**5**) was produced in 75% yield. Evidently, configurational inversion at C-2 accompanied the constitutional change. This was not unexpected in view of earlier observations. Thus, the L-enantiomer of **5** had been produced (7) in modest yield (21%) from the corresponding 2,4-diacetate having the α-D-*gluco* configuration, by prolonged treatment with sodium bicarbonate in refluxing benzene (40 h), and the remarkable inversion at C-2 was considered to be a manifestation of the $A^{(1,2)}$ effect (10) that renders a pseudoaxial substituent vicinal to an endocyclic nitroalkene grouping more favorable than a pseudoequatorial one. A mechanism for the formation of the α-L-*threo* product in that reaction has been proposed (11), and it may be applied *mutatis mutandis* to the present case (Scheme 1). The product **5** doubtless arises by a first elimination of a molecule of methanesulfonic acid to give unsaturated monomesylate, either A or B, or both, and subsequent addition of acetate ion with concomitant elimination of the second mesylate function, to give **5** and (or) its isomer C. The latter, if formed, would isomerize to **5** by acetate elimination–addition. It is an open question whether the reaction takes both of the pathways shown or favors one. (In the aforementioned dehydroacetoxylation, which gave mainly L-**5**, the 2-acetate corresponding to B was isolated as a minor product in 4% yield.) Both of the primary structures A and B are encumbered by $A^{(1,2)}$ strain which should provide part of the driving force for their transformation into **5** and C, respectively. Isomerization of C to **5** is thought to be favored electronically; the inductive effect of the anomeric center will enhance electron deficiency at C-2, promoting nucleophilic attack at that site and rendering **5** more stable than C. The rearrangement could be induced by an intermolecular attack of acetate ion as depicted or, alternatively, could involve intramolecular acetoxy group migration through a six-membered, cyclic transition state. Compound **5** should be a potential preparative precursor for the D-*lyxo* isomer of D-desosamine.

In order to explore possibilities of entry into the series of nitrogenous 6-deoxy-D-hexose derivatives through key intermediates other than **1** it was envisaged to depart from readily available 4,6-*O*-benzylidenated 3-deoxy-3-nitro-D-hexopyranosides (12) and examine whether the elegant method (13) of converting such acetals by *N*-bromosuccinimide into 6-bromo-6-deoxy-4-benzoates is applicable in this particular case. Methyl 2-*O*-acetyl-4,6-*O*-benzylidene-3-deoxy-3-nitro-β-D-glucopyranoside (**6**), methyl 4,6-*O*-benzylidene-3-deoxy-3-nitro-α-D-glucopyranoside (**8**), and methyl 4,6-*O*-benzylidene-2,3-dideoxy-3-nitro-α-D-*arabino*-hexopyranoside (**10**) were selected as objects of study. The question as to whether nitro sugars such as these would without



SCHEME 1

complications be compatible with the planned operation was not a trivial one in view of possible competing bromination at the nitromethine carbon atom (14). Compound **6** and numerous similar compounds had proved to undergo bromination at C-3 by the action of *N*-bromoacetamide (and in the one case examined also by *N*-bromosuccinimide) to give *gem*-bromonitro derivatives while the benzylidene acetal structure remained unaffected.[3] However, the conditions under which the geminal halogenations were performed differed from those of the Hanessian reaction in that they promoted an ionic process (protic solvent and catalysis by sodium acetate). It has now been found that **6**, **8**, and **10** do react with NBS in refluxing carbon tetrachloride in the presence of barium carbonate, affording the desired 6-bromo-6-deoxy-4-*O*-benzoyl derivatives in yields of 56–80%. Whereas single products (**7** and **9**) were obtained from **6** and **8**, respectively, the 2-deoxy sugar **10** in first experiments gave the expected α-glycoside **11** (64%) but also a second product which was revealed to be the β-glycoside **12** (16%). Evidently, traces of acid engendered in the medium and not efficaciously neutralized by solid barium carbonate were responsible for partial anomerization. 2-Deoxyglycosides are generally more prone to acid-catalyzed anomerization than ordinary glycosides; a similar observation had been made (1) in a reductive debromination of a 6-bromo-2,6-dideoxy glycoside. The formation of **12** was suppressed by an increased amount of acid scavenger. Configurational correlation of **11** and **12** was made on the basis of specific ro-



[3]The α-D-glucoside **8** resisted this type of bromination. The 2-deoxy derivative **10** was not examined but its β-anomer as well as α- and β-D-*lyxo* isomers reacted readily.

tations (+71.5° and +26.5°, respectively), and by nmr spectra which showed for the anomeric proton in **11** a narrow multiplet ($J_{1,2a}$ and $J_{1,2e}$ both small) and in **12**, a quartet ($J_{1,2a}$ = 10, $J_{1,2e}$ = 2 Hz) indicating equatorial and axial orientations, respectively, for H-1. In accord with this, the signals of the anomeric methoxyl protons (τ 6.56 in **11**, 6.41 in **12**; in chloroform-*d*) were in the relative positions normally found in α- and β-glycosides of this type (14).

Incidentally the glycoside **10**, which had previously been synthesized from **8** by the sequence of *O*-acetylation followed by dehydroacetoxylation and reduction, can now be prepared more conveniently thanks to the new, smooth olefination (8, 9) with methanesulfonyl chloride followed by borohydride reduction. We record here its preparation from **8**, achieved in 91% yield without isolation of intermediates.

Experimental

All reactions were monitored by tlc on 7.5-cm plates coated with silica gel G and irrigated, unless otherwise specified, with (v/v) 1:4 ethyl acetate – carbon tetrachloride (solvent *A*), 1:20 methanol–chloroform (solvent *B*), or 1:2 ethyl acetate – petroleum ether (solvent *C*). The spots were made visible by use of a spray of 1% ceric sulfate in 10% sulfuric acid, and heating the plates. Infrared data refer to spectra of Nujol mulls. Optical rotations were recorded at room temperature from chloroform solutions, *c* 0.4–1.3. The nmr data refer to 100 MHz spectra of $CDCl_3$ solutions containing tetramethylsilane as internal standard.

Methyl 3,6-Dideoxy-4-O-methylsulfonyl-3-nitro-α-D-glucopyranoside (2)

The glycoside **1** (2) (2.0 g) and methylsulfonyl chloride (0.75 ml, 1 mol equiv.) were stirred together in dichloromethane (60 ml), with external cooling to 10–15°C, and triethylamine (1.3 ml) was added after 5 min. As no sign of reaction was detected by tlc (solvent *B*) after another 5 min, cooling was discontinued and three additional 0.7-ml portions of mesyl chloride along with equivalent amounts of triethylamine were introduced in 15-min intervals. Gradually during this operation a faster spot representing **2** appeared in tlc, and the intensity of the spot due to **1** diminished. Eventually a faint spot (still faster) corresponding to known (8) dimesylate **3** began to show. At this stage the reaction was quenched by the addition of methanol (5 ml), and after 1 h the mixture was evaporated. Several portions of 1-propanol were successively added to and evaporated from the syrupy residue which was finally dissolved in chloroform (3 ml) and chromatographed on silica gel (85 g) by means of chloroform as eluent. Fractions containing the fast-moving, minor product **3** were discarded. The subsequent fractions that contained only **2** were combined and evaporated to give a syrup which crystallized overnight upon trituration with hexane (10 ml). The material (1.00 g, 36%) was recrystallized from ethyl acetate – petroleum ether giving sharp needles, mp 93–93.5°C; $[\alpha]_D$ +96.6°; ν_{max} 3300 (OH), 1550 (NO_2), and 1170 cm^{-1} (OMs). The nmr data: δ 4.75–5.00 (m, 3H, ill resolved, H-1, H-3, H-4), 4.2 (br m, H-2), 3.85 (br m, H-5), 3.49 (s, 3H, OMe), 2.96 (s, 3H, OMs), 2.48 (d, *J* = 11 Hz, removable with D_2O, OH), 1.43 (d, 3H, *J* = 6 Hz, C-Me). *Anal.* calcd. for $C_8H_{15}NO_8S$ (285.2): C 33.68, H 5.30, S 11.24; found: C 33.74, H 5.30, 11.15. Continued elution of the column with ether furnished 1.20 g (60%) of unchanged **1**.

Methyl 3,4,6-Trideoxy-3-nitro-α-D-xylo-hexopyranoside (4)

To a magnetically stirred, ice cooled solution of the mesylate **2** (800 mg) in ethanol (20 ml) was added sodium borohydride (0.14 g) in small portions. The reaction was then allowed to continue for 30 min at 25°C. Examination by tlc (solvent *C*) revealed total consumption of **2** and formation of a fast-moving product (**4**) accompanied by traces of faster and slower impurities. The solution was deionized with 5 ml of Amberlite IR-120(H^+) whereby it became acidic. It was neutralized carefully with triethylamine and evaporated. Numerous portions of methanol were then evaporated from the residue for removal of boric acid, after which the material was chromatographed on a column of silica gel (17 g) by use of chloroform as eluent. Early fractions containing the high-mobility contaminants were discarded, and the fractions containing the main product were evaporated to give 320 mg (60%) of a colorless syrup of **4**. It crystallized from ether – petroleum ether as long needles, mp 55–56°C, $[\alpha]_D$ +197°. Reported (3) for L-**4**, mp 56–57°C and $[\alpha]_D$ −198°. Spectral data of **4** accorded with those of the enantiomer.

Methyl 2-O-Acetyl-3,4,6-trideoxy-3-nitro-α-D-threo-hex-3-enopyranoside (5)

A mixture of the 2,4-di-*O*-mesyl glycoside **3** (8) (200 mg), sodium acetate (50 mg), and glacial acetic acid (10 small drops) in acetone (5 ml) was heated at reflux for 10 min. Complete conversion of **3** into a new product was revealed by tlc (chloroform). The reaction mixture was evaporated and the residue extracted with ether. The filtered extract was coevaporated with several portions of ethanol to give a syrup which was taken up in ethanol (0.5 ml) and kept overnight at 0°C. Compound **5** (95 mg, 75%) was deposited in crystalline form and recrystallized from ethyl acetate – petroleum ether; mp 81–82°C, $[\alpha]_D$ +163°. Reported (7) for L-**5**: mp 81–81.5°C, $[\alpha]_D$ −165°.

Methyl 2-O-Acetyl-4-O-benzoyl-6-bromo-3,6-dideoxy-3-nitro-β-D-glucopyranoside (7)

A suspension of benzylidene acetal **6** (12) (1.00 g) and barium carbonate (0.50 g) in carbon tetrachloride (25 ml) containing *N*-bromosuccinimide (0.70 g) was refluxed with magnetic stirring for 2 h. The hot reaction mixture was filtered and the solid residue washed with hot carbon tetrachloride (2 × 15 ml). The combined filtrate was evaporated to dryness and a solution of the resultant syrup in ether (25 ml) was washed with water (15 ml) and dried ($CaCl_2$). Partial evaporation of solvent then furnished several crops of crystalline **7**. The concentrated mother liquor was treated with some pentane which produced a yellowish oil that was decanted and triturated with fresh pentane; this gave an additional crop of crystals, the total yield being 0.67 g (56%). Recrystallized from chloroform – petroleum ether the product showed

mp 181–182°C, $[\alpha]_D$ −45.7°, ν_{max} 1715 (CO) and 1565 cm^{-1} (NO_2). The nmr data: δ 7.95 and 7.47 (m, 2 + 3H, PhCO), 5.65 (t, $J_{3,4} = J_{4,5} = 10$ Hz, H-4), 5.48 (q, $J_{1,2} = 8$, $J_{2,3} = 10$ Hz, H-2), 4.98 (t, $J = 10$ Hz, H-3), 4.56 (d, $J_{1,2} = 8$ Hz, H-1), 3.90 (m, H-5), 3.59 (s, 3H, OMe), 3.54–3.46 (m, 2H, H-6, H-6′), 2.10 (s, 3H, OAc). *Anal.* calcd. for $C_{16}H_{18}BrNO_8$ (432.2): C 44.46, H 4.19, Br 18.49; found: C 44.28, H 4.07, Br 18.38.

*Methyl 4-O-Benzoyl-6-bromo-3,6-dideoxy-3-nitro-α-D-glucopyranoside (**9**)*

The benzylidene acetal **8** (15) (2.00 g), *N*-bromosuccinimide (1.50 g), and barium carbonate (1.0 g) were refluxed with magnetic stirring in carbon tetrachloride (100 ml) for 3 h. The hot solution was filtered, the inorganic residue washed with hot carbon tetrachloride (2 × 20 ml), and the filtrate evaporated. The syrupy product was purified by passage through a column of silica gel (50 g) with solvent *A* and was thereafter crystallized from carbon tetrachloride at 0°C. The prisms (1.50 g, 60%) had mp 126°C, $[\alpha]_D$ +84°; ν_{max} 3470 (OH), 1720 (CO), and 1560 cm^{-1} (NO_2). The nmr data: δ 7.95 and 7.45 (m, 2 + 3H, PhCO), 5.56 (t, $J_{3,4} = J_{4,5} = 10$ Hz, H-4), 4.97 (t, $J_{2,3} = J_{3,4} = 10$ Hz, H-3), 4.95 (d, $J_{1,2} = 4$ Hz, H-1), 4.30 (octet, $J_{1,2} = 4$, $J_{2,3} = 10$, $J_{2,OH} = 11$ Hz, collapsing to q on D_2O exchange–H-2), 4.10 (septet, H-5), 3.60 (s, 3H, OMe), 3.51–3.44 (m, 2H, H-6, H-6′), 2.46 (d, $J = 11$ Hz, removed on D_2O exchange, O-H). *Anal.* calcd. for $C_{14}H_{16}BrNO_7$ (390.2): C 43.09, H 4.13, Br 20.48; found: C 43.05, H 4.04, Br 20.72.

*Methyl 4,6-O-Benzylidene-2,3-dideoxy-3-nitro-α-D-arabino-hexopyranoside (**10**)*

A solution of **8** (15) (1.80 g) in anhydrous ether (50 ml) containing triethylamine (2.7 ml) was cooled to 10–15°C, and methylsulfonyl chloride (1.3 ml) was added dropwise with stirring during 30 min. Thin layer chromatography (solvent *C*) then indicated complete conversion of **8** into the faster-moving product of dehydration (see ref. 8). The reaction mixture was filtered and the filtrate evaporated to give a yellowish oil which was dissolved in dichloromethane (10 ml). Careful addition of triethylamine (2 ml) at 10–15°C, followed by anhydrous ether (25 ml) gave a precipitate of salts. This was filtered off and the filtrate set aside. The precipitate was washed with water in which it largely dissolved (to be discarded), and the water-insoluble part was dissolved in ether (3 ml) and, after drying over $CaCl_2$, combined with the main solution containing the product. Solvent evaporation gave a solid which was immediately dissolved in absolute ethanol (50 ml) and treated with sodium borohydride (1.0 g) in small portions at 15°C. After stirring for 2 h the reaction mixture was filtered, the filter residue washed with ethanol (2 × 10 ml), and the combined filtrate evaporated. The syrupy material containing some solid was extracted twice with 15 ml of ethyl acetate. Evaporation of the extract furnished crystalline **10** (1.55 g, 91%), mp 107–109°C, $[\alpha]_D$ +68.5° (lit. (16) mp 108–111°C, $[\alpha]_D$ +67.0°).

*Methyl 4-O-Benzoyl-6-bromo-2,3,6-trideoxy-3-nitro-α-D-arabino-hexopyranoside (**11**)*

The acetal **10** (1.55 g), *N*-bromosuccinimide (1.60 g), and barium carbonate (2.0 g) were magnetically stirred in boiling carbon tetrachloride (100 ml) for 3 h. Filtration, washing of the residue with hot chloroform (10 ml), and evaporation of the combined filtrate gave a yellow syrup. This was dissolved in ether (20 ml) which was then washed with water (2 × 5 ml), dried (Na_2SO_4), and evaporated again. The pale yellow residue was taken up in methanol (5 ml) from which **11** crystallized as needles after several hours at 0°C. The air-dried product (1.57 g, 80%) had mp 93–93.5°C, $[\alpha]_D$ +70.5°.

In an earlier experiment, 2.00 g of **10** and 1.50 g of *N*-bromosuccinimide but only 1.0 g of barium carbonate were used under conditions otherwise identical with those just described. Thin layer chromatography (solvent *A*) indicated the presence of a more slowly moving by-product (**12**) besides **11**. The syrup obtained upon solvent evaporation was therefore chromatographed on a column of silica gel (50 g) using solvent *A* as irrigant. The fractions containing the (faster moving) main product furnished **11**, which crystallized from methanol as above, in a yield of 1.63 g (64%); mp 93°C, $[\alpha]_D$ +71.5; ν_{max} 1732 (CO) and 1550 cm^{-1} (NO_2). The nmr data: δ 8.0 and 7.5 (m, 2 + 3H, PhCO), 5.58 (t, $J_{3,4} = J_{4,5} = 10$ Hz, H-4), 5.2 (m, $J_{3,4} = 10$, $J_{2a,3} = 6$, $J_{2e,3} = 4$ Hz, H-3), 5.00 (narrow m, H-1), 4.1 (m, $J_{4,5} = 10$ Hz, H-5), 3.5 region (overlapping signals, 5H, H-6, H-6′ and, at δ 3.44, OMe), 2.6–2.2 (m, ill resolved, 2H, H-2, H-2′). *Anal.* calcd. for $C_{14}H_{16}BrNO_6$ (374.2): C 44.93, H 4.31, Br 21.36; found: C 45.06, H 4.19, Br 21.61.

*Methyl 4-O-Benzoyl-6-bromo-2,3,6-trideoxy-3-nitro-β-D-arabino-hexopyranoside (**12**)*

Continued elution of the column mentioned in the second experiment of the preceding section yielded the β-anomer **12** which crystallized upon solvent evaporation and was recrystallized from ethyl acetate – petroleum ether. The yield was 400 mg (16%), mp 182–183°C, $[\alpha]_D$ +26.5°, ν_{max} 1715 (CO) and 1560 cm^{-1} (NO_2). The nmr data: δ 8.00 and 7.55 (m, 2 + 3H, PhCO), 5.57 (t, $J_{3,4} = J_{4,5} = 10$ Hz, H-4), 4.87 (octet, $J_{3,4} = 10$, $J_{2a,3} = 8$, $J_{2e,3} = 5$ Hz, H-3), 4.60 (q, $J_{1,2a} = 10$, $J_{1,2e} = 2$ Hz, H-1), 3.79 (m, $J_{4,5} = 10$ Hz, H-5), 3.59 (s, 3H, OMe), 3.53 (m, 2H, overlapping the OMe signal, H-6, H-6′), 2.5 region (br m, 2H, H-2, H-2′). *Anal.* calcd. for $C_{14}H_{16}BrNO_6$ (374.2): C 44.93, H 4.31, N 3.74; found: C 44.59, H 4.43, N 3.82.

Excess enthalpies and volumes of water + tetrahydrofuran mixtures at 298.15 K[1]

OSAMU KIYOHARA[2] AND GEORGE C. BENSON

Division of Chemistry, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received October 22, 1976

OSAMU KIYOHARA and GEORGE C. BENSON. Can. J. Chem. **55**, 1354 (1977).

Excess enthalpies and volumes of water + tetrahydrofuran mixtures were measured at 298.15 K, using an LKB flow microcalorimeter and a successive dilution dilatometer. The effect of flow rate on the enthalpy results was investigated. Partial molar excess enthalpies and volumes were derived from the results, and their significance is discussed with reference to the molecular interactions in the mixture.

OSAMU KIYOHARA et GEORGE C. BENSON. Can. J. Chem. **55**, 1354 (1977).

On a mesuré, à 298.15 K, les enthalpies et les volumes d'excès de mélange eau + tétrahydrofuranne en utilisant un microcalorimètre continue LKB et un dilatomètre à dilutions successives. On a étudié l'effet de la vitesse d'écoulement sur les résultats d'enthalpie. On a dérivé des enthalpies et des volumes d'excès molaires partiels à partir des résultats et on discute de leur signification par rapport aux interactions moléculaires dans le mélange.

[Traduit par le journal]

A number of investigations of the interactions between nonelectrolytes and water have examined the thermodynamic properties of aqueous tetrahydrofuran (THF) mixtures (1–6). At 298.15 K the excess enthalpy curve is S-shaped with a zero value near 0.4 mole fraction of H_2O (1–3). The excess Gibbs free energy is positive (5) and the excess entropy and volume are negative (4–6) over the whole mole fraction range.

The thermal behavior of the system H_2O + THF is of special interest because its determination has been suggested as a test of mixing calorimeters (7). There are, however, fairly large discrepancies between the published excess enthalpy results (1–3), and it is evident that further independent studies are needed before this system can be established as a calorimetric standard.

Our laboratory is currently investigating the thermodynamic properties of H_2O + THF mixtures. The present paper reports the results of careful determinations of excess enthalpy and excess volume, both at 298.15 K.

Experimental

Materials

Tetrahydrofuran (Fisher Scientific Co., certified reagent) was further purified by glc using a column containing 20% silicone oil DC200 on Chromosorb P. It was stored over a molecular sieve (BDH Type 4A, 8–12 mesh beads) and under dry nitrogen gas. The final product had a very slight yellow tinge, but at 298.15 K its density, $d = 881.95\ \mathrm{kg\ m^{-3}}$, and refractive index, $n_D = 1.40474$, were in reasonable agreement with literature data (d/kg m^{-3}: 882.2 (4), 882.1 (5), 882.3 (8), 881.94 (9); n_D: 1.4051 (4), 1.4048 (5), 1.4041 (8), 1.4045 (9)).

Mixtures were made with deionized distilled water. Both components were partially degassed by agitation under reduced pressure prior to their use.

Calorimetric Measurements

Excess enthalpies, H^E, were determined in an LKB flow microcalorimeter (Model 10700-1). Details of the equipment and operating procedure have been described previously (10). The error of the determination of H^E/J mol^{-1} is estimated to be less than $0.1 + 0.005|H^E/\mathrm{J\ mol^{-1}}|$.

For the present system it was not appropriate to assume that the calibration constant for a mixture was a volume fraction average of the constants determined for the pure components at the same flow rate. Instead, it was necessary to determine calibration constants with several mixtures of known composition flowing through the calorimeter at various flow rates. These results were smoothed so that appropriate calibration constants for other mixtures could be interpolated. Despite this precaution, we found that the values of H^E depended on the total flow rate used in their determination, particularly in the water-rich region. This variation appeared to be due to incomplete mixing. Although a total flow rate $f = 5.0\ \mathrm{mm^3\ s^{-1}}$ (stated in terms of the unmixed components) had been satisfactory in most of our previous work, it was necessary to operate at lower rates for H_2O + THF and measurements were made with $f = 2.0$, 1.5, and $1.0\ \mathrm{mm^3\ s^{-1}}$. For x_1 (the mole fraction of H_2O) ≤ 0.6, the values of H^E measured at the

[1]NRCC No. 15597. This work was presented in part at the 31st Annual Calorimetry Conference, Argonne National Laboratory, Argonne, Illinois, U.S.A., September 29 – October 2, 1976.

[2]NRCC Research Associate from 1975.

three flow rates agreed within their estimated experimental error; but for $x_1 > 0.6$, significant systematic differences appeared, with the absolute values of H^E increasing with decreasing flow rate. Empirically it was found that the results for H^E at these low flow rates varied approximately linearly with the square of the flow rate, and this fact was used to extrapolate the results to zero flow. The differences of the extrapolated values from the results at the lowest flow rate are in most cases less than their estimated experimental error, but we believe that the observed systematic variation justifies the extrapolation.

Dilatometric Measurements

Excess volumes, V^E, were determined at constant pressure by a successive dilution method using a micrometer syringe dilatometer. The apparatus and operating technique have been described by Tanaka *et al.* (11). For the present system, the error of the determination of $V^E/cm^3\ mol^{-1}$ is estimated to be less than $0.0003 + 0.001|V^E/cm^3\ mol^{-1}|$.

Results

Excess Enthalpies

Values of H^E for H_2O (1) + THF (2) mixtures at 298.15 K are listed in Table 1, where x_1 indicates the mole fraction of H_2O. All the results given for mixtures with $x_1 \leq 0.6$ were determined at the same total flow rate $f = 2.0\ mm^3\ s^{-1}$, since as pointed out above, the results of exploratory measurements at lower flow rates were not significantly different in this mole fraction range. For $x_1 > 0.6$, measurements were made with flow rates of 2.0, 1.5, and 1.0 $mm^3\ s^{-1}$, but only the results at the lowest flow rate are reported in detail.

The empirical equation

$$[1]\quad H^E/J\ mol^{-1} = x_1(1 - x_1)\sum_{j=1}^{n} a_j(1 - 2x_1)^{j-1}$$

was fitted to the results for $x_1 \leq 0.6$ combined with each set for $x_1 > 0.6$. Values of the coefficients were determined by the method of least-squares with all points weighted equally. The three sets of coefficients a_j, each labelled with the relevant flow rate, are given in Table 2, along with the standard error

$$[2]\quad \sigma = \{\sum[H^E - H^E(\text{eq. } 1)]^2/(m - n)\}^{1/2}$$

where m is the number of results and n is the number of coefficients in the representation by [1].

The results for $f = 1.0\ mm^3\ s^{-1}$ were extrapolated to zero flow rate as described in the preceding section. The corrections applied in this extrapolation are given in parentheses in Table 1.

*Results for $x_1 \leq 0.6$ determined at $f = 2.0\ mm^3\ s^{-1}$. Results for $x_1 > 0.6$ determined at $f = 1.0\ mm^3\ s^{-1}$; add values in parentheses to correct to zero flow.

Table 1. Coefficients for the representation of the extrapolated values by [1] are included in Table 2. The extrema of the H^E curve (for $f = 0$) are 311.8 J mol^{-1} at $x_1 = 0.150$ and −743.1 J mol^{-1} at $x_1 = 0.858$; H^E vanishes near $x_1 = 0.392$.

Deviations of the results given in Table 1 from the smoothing function for zero flow rate are plotted in Fig. 1. The solid curves in this figure show deviations of the smoothed results at $f = 2.0$, 1.5, and 1.0 $mm^3\ s^{-1}$. For the highest flow rate, discrepancies of more than 1% occur.

There have been several previous investigations of the excess enthalpy of H_2O + THF mixtures at 298.15 K (1–3). These results, apart from those of Erva (1) which are only reported graphically, are included in Fig. 1 for comparison. The results of Glew and Watts (3) are within 1% of ours over most of the mole fraction range. Deviations of the results reported by Nakayama and Shinoda (2) are mainly negative and relatively large.

Excess Volumes

The experimental values of V^E are summarized in Table 3. Some difficulty was experienced in finding a suitable smoothing equation for these results. Representation by a form analogous to [1] required the use of a large number of coefficients. Replacing mole fractions by volume or mass fractions led to better representations

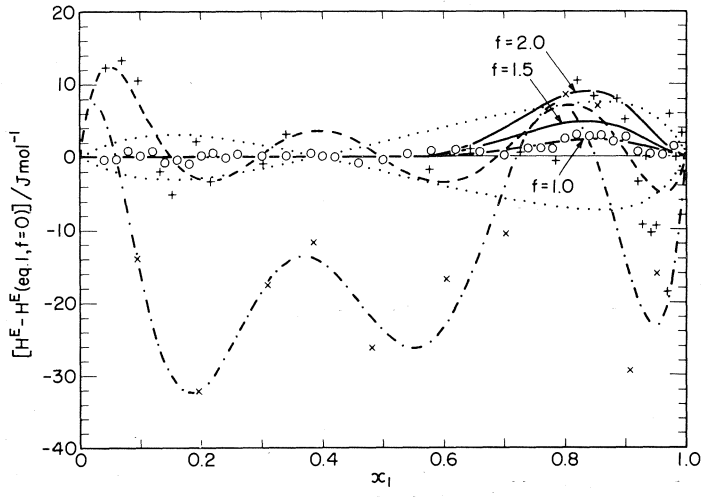

FIG. 1. Comparison of experimental results for the molar excess enthalpy of H_2O (1) + THF (2) mixtures at 298.15 K. Points and curves represent deviations from eq. 1 with coefficients for $f = 0$. Points: ○, present work; +, Glew and Watts (3); ×, Nakayama and Shinoda (2). Curves are smoothed results: —, present work (at flow rates 2.0, 1.5, and 1.0 mm^3 s^{-1}); ---, ref. 3; -·-, ref. 2. The dotted curves correspond to deviations of ±1%.

with fewer coefficients. However, the best representation was obtained with the form

$$[3] \quad V^E/\text{cm}^3\ \text{mol}^{-1} = x_1(1 - x_1) \sum_{j=1}^{n} a_j(1 - x_1)^{(j-1)/2}$$

Values of the coefficients and standard error for this representetation are given in the last column of Table 2.

Figure 2 shows that the deviations of our results from their representation by [3] are, for the most part, less than 1%; however, they appear to vary systematically with mole fraction and are larger on a percentage basis at both ends of the range. Deviations of V^E results from the literature (4–6) are also plotted in Fig. 2. Most of the results of Singer *et al.* (5) give large negative deviations which fall below the lower limit of the plot, but the other sets of data (4, 6) are in fair agreement with our results.

Discussion

In discussing the present results it is convenient to refer to the partial molar excess enthalpies $H_i^E(x_1)$ and volumes $V_i^E(x_1)$. Plots of these derived quantities are given in Figs. 3 and 4. Although the representations of H^E and V^E by [1] and [3] are adequate for most purposes, they are not very suitable for evaluating the slopes of these functions (particularly of V^E) near the ends of the mole fraction range. The curves for the partial molar excess enthalpies and volumes were therefore obtained from least-

squares analyses in which the experimental results were fitted with a set of cubic splines (12).

At infinite dilution, our value of $H_2^E(1) = -15.3$ kJ mol^{-1} is about 0.4 kJ mol^{-1} lower than the value (-14.93 ± 0.17) kJ mol^{-1} determined by Franks *et al.* (13). The insert to Fig. 4 shows the behavior of $V_2^E(x_1)$ for dilute THF mixtures. The intercept $V_2^E(1) = -4.8$ cm^3 mol^{-1} is in good agreement with the results of magnetic float densitometer studies (−4.68 cm^3 mol^{-1} (13) and −4.9 cm^3 mol^{-1} (14)). A sharp minimum of $V_2^E(x_1)$ occurs near $x_1 = 0.975$ and a broad minimum of $V_1^E(x_1)$ at low mole fractions of water. The latter behavior is similar to that observed for several other water + nonelectrolyte mixtures (15, 16).

A qualitative interpretation of our results can be given in terms of the so-called "flickering

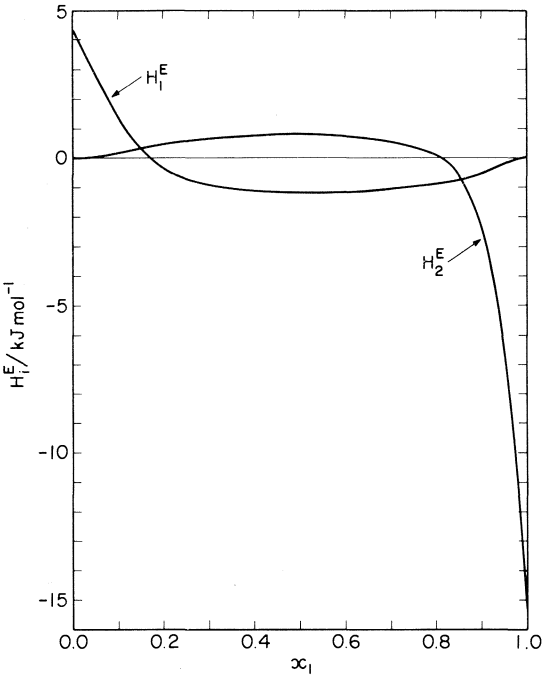

FIG. 3. Partial molar excess enthalpies of water and THF in H_2O (1) + THF (2) mixtures at 298.15 K. Curves calculated from least-squares splines.

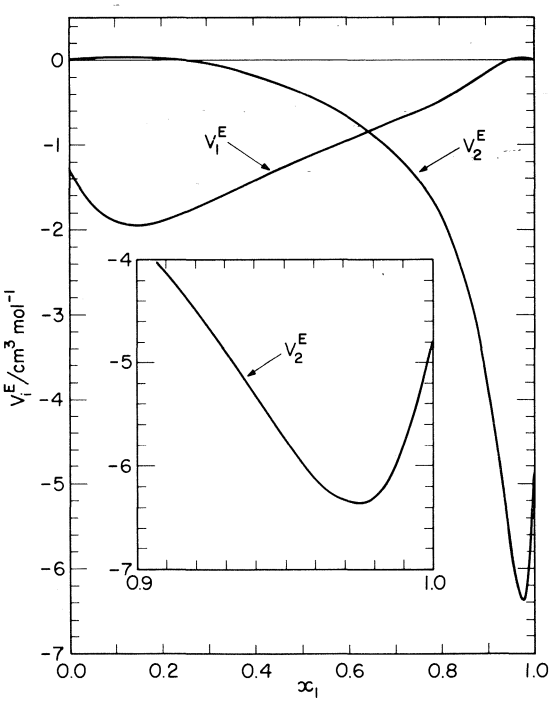

FIG. 4. Partial molar excess volumes of water and THF in H_2O (1) + THF (2) mixtures at 298.15 K. Curves calculated from least-squares splines.

cluster" model of liquid water (17). According to this model, water is composed of microscopic clusters of hydrogen-bonded molecules in dynamic equilibrium with more weakly bonded water molecules occupying cavities within the clusters and interstitial positions between them. Although the structural details of the model are still controversial, its general features are in accord with a variety of experimental results.

When water is the solvent for a nonelectrolyte, deviations of the properties of the solution from ideality in the water-rich region reflect the influence of the added species on the cluster equilibrium. The addition of an apolar or mixed type of nonelectrolyte (18) may initially promote or stabilize cluster formation in a cooperative manner since the solute tends to occupy the cavities and to displace the weakly bonded water molecules which can form more hydrogen-bonded clusters. In the present system the large negative values of $H_2^E(x_1)$ for water-rich mixtures are a consequence of enhanced hydrogen bonding. It has been suggested that the minimum in the $V_2^E(x_1)$ curve occurs when there are no more cavities to support the full structuring ability of the solute molecules (18). Further solute addition then has a disruptive influence on the water structure.

Figure 3 shows that over a broad central mole fraction range, $H_1^E(x_1)$ and $H_2^E(x_1)$ become nearly constant. A similar region has been observed for H_2O + ethanol mixtures, and Larkin has described it as a pseudo two-phase system (19). In the present case, the pseudo phases consist of the stabilized water clusters in equilibrium with a random mixture of H_2O + THF. The molecular environment experienced by added quantities of H_2O or THF remains essentially constant since only the relative amounts of the phases are changed. When water is added to pure THF, water–water hydrogen bonds are broken and water–THF hydrogen bonds are formed. The positive values of $H_1^E(x_1)$ observed at low x_1 suggest that the mixed bonding is weaker (or less extensive) than the bonding in pure water.

Finally, we wish to express some reservations about the suitability of using H_2O + THF to test mixing calorimeters. Apart from the problem of obtaining and storing THF in a suitably pure state, our work indicates that it is inherently difficult to form homogeneous H_2O + THF mixtures with $x_1 > 0.6$. It is known that this system has regions of limited

solubility above 345 K (4) and below 286 K (20), and it seems likely that an incipient phase separation (demixing) occurs even at 298.15 K. It appears that the time needed to establish equilibrium on a microscopic level can lead to erroneous H^E results, particularly in flow type mixing calorimeters. It is very desirable to have a variety of test mixtures, but it is important to make clear the nature of the test which each provides. The thermal behavior of the mixture selected to test a calorimeter should be reasonably similar to that of the mixture which it is proposed to measure. From this point of view we believe that, in many cases, H_2O + THF may present an unnecessary challenge.

Viscosities of mixtures of SnR_4 compounds and of some other large globular molecules. Effect of size difference

CLAUDE JAMBON[1] AND GENEVIÈVE DELMAS

Université du Québec à Montréal, Département de chimie, C.P. 8888, Montréal (Qué), Canada H3C 3P8

Received July 5, 1976

CLAUDE JAMBON and GENEVIÈVE DELMAS. Can. J. Chem. **55**, 1360 (1977).

Solution viscosities have been measured at 25 °C on seven I systems of SnR_4 compounds: $SnBut_4$ with $SnMe_4$, $SnEt_4$, $SnPr_4$, $SnOct_4$, $SnLaur_4$ and $SnLaur_4$ with $SnEt_4$ and $SnPr_4$. The effect of shape difference on excess solution viscosities was investigated. The experimental value $\Delta \ln \eta_{exp} = \ln \eta_s - x_1 \ln \eta_1 - x_2 \ln \eta_2$ was compared to $\Delta \ln \eta_{th}$. $\Delta \ln \eta_{th}$ was obtained using ΔG_M(mixing) in place of $G_M^{\neq}$(activation) and free volume theories. Experimental heats of mixing have been measured and are used in $\Delta \ln \eta_{th}$. It was found that with the Van der Waals model for the energy, the difference $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$, indicative of the agreement between the predicted and experimental value, is relatively small for mixtures of molecules not having a large size difference. However, for systems different in size, $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$ is positive and large and is shown to be an increasing function of the size difference. $\Delta \ln \eta_{th}$ could be adjusted to $\Delta \ln \eta_{exp}$ by adding a term $\ln \eta_{\Delta V^*} = c(V_1^{*1/2} - V_2^{*1/2})^2$ where V^* is the core volume. To confirm the validity of $\ln \eta_{\Delta V^*}$, the seven II systems chosen in order to present a large range $(V_1^{*1/2} - V_2^{*1/2})$ were measured: $SnBut_4$ + squalane, $Si(OEt)_4$ + $Si(OOct)_4$, n-C_{10} + $Si(OOct)_4$, $Si(OEt)_4$ + squalane, n-C_{12} + $SnOct_4$, $Si(OMe)_4$ + $Si(OOct)_4$, n-C_{16} + benzene. A c value of 5.3×10^{-3} cm^3 appears to be adequate for all the systems studied in this work. The 'condensation effect' of $SnEt_4$ and $SnPr_4$ observed by calorimetry is possibly seen here in the series $SnLaur_4$ with $SnEt_4$, $SnPr_4$, $SnBut_4$.

CLAUDE JAMBON et GENEVIÈVE DELMAS. Can. J. Chem. **55**, 1360 (1977).

Des mesures de viscosités ont été faites sur les composés SnR_4 et leurs mélanges. Sept systèmes I $SnBut_4$ avec $SnMe_4$, $SnEt_4$, $SnPr_4$, $SnOct_4$, $SnLaur_4$ ainsi que $SnLaur_4$ avec $SnEt_4$ et $SnPr_4$ ont été étudiés. Nous nous interessions à l'effet de la forme des molécules sur la viscosité d'excès. La valeur expérimentale $\Delta \ln \eta_{exp} = \ln \eta_s - x_1 \ln \eta_1 - x_2 \ln \eta_2$ est comparée à $\Delta \ln \eta_{th}$. Pour obtenir $\Delta \ln \eta_{th}$, on se sert de théories de volume libre et de ΔG_M(énergie libre de mélange) au lieu de $G_M^{\neq}$ d'activation. Les chaleurs de mélanges utilisées dans $\Delta \ln \eta_{th}$ ont été mesurées. On trouve qu'avec le modèle de Van der Waals pour l'energie, la différence $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$, caractéristique du bon accord entre les valeurs expérimentales et théoriques, est petite pour les mélanges de molécules qui ont des tailles assez voisines. Au contraire pour des mélanges de molécules de tailles différentes, la valeur de $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$ est grande et positive; elle est aussi une fonction croissante de la différence de taille. $\Delta \ln \eta_{th}$ peut être ajusté à $\Delta \ln \eta_{exp}$ en ajoutant un terme $\ln \eta_{\Delta V^*} = c(V_1^{*1/2} - V_2^{*1/2})$ où V^* est le volume à 0 K. Pour confirmer l'expression pour $\ln \eta_{\Delta V^*}$, sept autres systèmes II ont été étudiés. Les systèmes (II) ont été choisis de façon à avoir une grande différence de V^*. Ce sont: $SnBut_4$ + squalane, $Si(OEt)_4$ + $Si(OOct)_4$, n-C_{10} + $Si(OOct)_4$, $Si(OEt)_4$ + squalane, n-C_{12} + $SnOct_4$, $Si(OMe)_4$ + $Si(OOct)_4$, n-C_{16} + benzène. Une valeur de c de 5.3×10^{-3} cm^3 semble convenir approximativement pour les systems présentés ici. L'effet de condensation de $SnEt_4$ et $SnPr_4$, observé par calorimétrie, peut sans doute se voir sur la série, $SnLaur_4$ avec $SnEt_4$, $SnPr_4$, $SnBut_4$.

Introduction

Recent theories of solutions (1–4) have emphasized the importance of the free volume difference between the two components of the mixture. The diverse contributions arising from the free volume difference can be understood qualitatively in the following way. The more volatile compound is 'condensed' in the presence of the denser one or its free volume is diminished. As a result, there is a negative contribution to the excess volumes and a negative or exothermic contribution to the heats of mixing and to the entropies of mixing. The contribution to the heats or to the volumes of mixing derived from the difference in cohesive energy of the two components cannot yet be calculated adequately. However, a test of the free volume theories can be made by using the experimental heats of mixing. In this case, the predicted excess volumes, for instance, are in good agreement with the experimental ones.

[1]Present address: Laboratoire de Chimie Analytique I, Département de chimie et biochimie de L'Université Claude-Bernard de Lyon I, 43, boulevard du 11-novembre 1918, 69621 Villeurbanne.

It would be interesting to investigate if measurements of viscosities of binary mixtures combined with free volume theories could give some information on the importance of free volume terms in viscosities of mixtures. Bloomfield and Dewan (5) have used the calculated free energy of mixing as an approximation to the free energy of activation. They have shown, on systems with relatively small differences in free volume, that there is a good agreement between the calculated and experimental excess viscosities. Recently (6), it has been shown that the free volume theory using a Van der Waals model gives quite good excess viscosity predictions even for systems with large free volume differences. This later work seemed to show that excess viscosities were sensitive to the shape of the molecules.

It has seemed worthwhile to us to study the viscosities of mixtures of non-polar globular molecules such as the SnR_4 compounds. Heats of mixing (7) of SnR_4 (with R = CH_3, C_2H_5, C_4H_9) with the alkanes have shown that these compounds have properties similar to those of the alkanes. Furthermore, the shape of the molecules of the SnR_4 compounds is changed gradually from globular to elongated when the chain-length of the R group is increased. This work presents the results of excess viscosity measurements of seven SnR_4 mixtures (I). Since the difference between experimental and calculated excess viscosities shows a correlation with the difference of size of the two components, six other systems have been studied to confirm this correlation. These systems (II) were chosen mainly because of size differences. The seven I systems are $SnBut_4$ with $SnMe_4$, $SnEt_4$, $SnPr_4$, $SnOct_4$, $SnLaur_4$ and $SnLaur_4$ with $SnEt_4$ and $SnPr_4$, the six II systems are $SnBut_4$ + squalane ($C_{30}H_{62}$), $Si(OMe)_4$ + $Si(OOct)_4$, $Si(OEt)_4$ + $Si(OOct)_4$, $Si(OEt)_4$ + squalane, $Si(OOct)_4$ + n-C_{10}, $SnOct_4$ + n-C_{12}. The seventh II system n-C_{16} + benzene was in the literature.

Experimental

Apparatus

The viscosimeters were of the Ubbelholde type from the Cannon Instrument Co. (State College, PA). The flow times were not lower than 80 s. Calibration of the viscosimeters was made as in previous work (6). For highly viscous liquids, the calibration constants were checked by measurements of viscosities of viscous liquids reported in the literature, such as oleic acid. Special care was taken with liquids of high viscosities to assure a good mixing of the solutions. The calorimeter used for heats of mixing measurements and the densitometer used for density and expansion coefficient measurements have been described previously (7).

Solvents

The methyl, ethyl, propyl derivatives were obtained from the K and K Co. (99%). Tetrabutyl tin was either from the Aldrich or K and K Companies. The octyl and lauryl derivatives were obtained at the Chemical Procurement Laboratories (College Point, N.Y.). The alkanes were purchased from the Aldrich Co.; the squalane and the $Si(OR)_4$ from the K and K Co. Densities of the compounds were measured as a test of their purity.

Table 1 gives some physicochemical data and parameters about the pure components: density, expansion coefficient, viscosity, pressure reduction parameter P^*, volume reduction parameter V^*. The calculations to obtain V^* and P^* are described later. The density of $SnOct_4$ has been omitted because it was outside the range of literature values. However, the two systems with $SnOct_4$ have been kept since they seemed to follow the general trend on Fig. 1.

Theory

Theories relate the viscosities of liquids either to the activation energy required for the molecule to overcome the attractive forces of its neighbours and flow to a new position (absolute reaction rate theory) or the probability that an empty site exists near a molecule (free volume theory). In a recent theory, Macedo and Litovitz (8) have made the hypothesis that the two effects are combined so that the probability for viscous flow is taken as the product of probabilities for acquiring sufficient activation energy and of the occurrence of an empty site. Similar assumptions are made for the solutions. Furthermore, a bridge can be made to the thermodynamic functions of mixing by assuming a simple relation between the solution activation energy $\Delta G,^{\neq}$ the pure liquid activation energies $\Delta G_1^{\neq}$, $\Delta G_2^{\neq}$, and the excess free energy of mixing ΔG_M^R.

$$[1] \quad \Delta G^{\neq} = x_1 \Delta G_1^{\neq} + x_2 \Delta G_2^{\neq} - \Delta G_M^R$$

For the pure components and the solution the viscosities η_i are defined as:

$$[2] \quad \eta_i = A \exp [\Delta G_i^{\neq}/RT + (\tilde{v}_i - 1)^{-1}]$$

where $\tilde{v}_i$ is the reduced volume.

$$[3] \quad \ln \eta_i = \ln A + \Delta G_i^{\neq}/RT + (\tilde{v}_i - 1)^{-1}$$

Equation 3 can be applied to the solution and the pure components to obtain:

$$[4] \quad \Delta \ln \eta = \ln \eta_{sol} - (x_1 \ln \eta_1 + x_2 \ln \eta_2)$$

If eqs. 1 and 2 are used in eq. 4, the activation energies are eliminated and $\Delta \ln \eta$ is related to the free energy of mixing by:

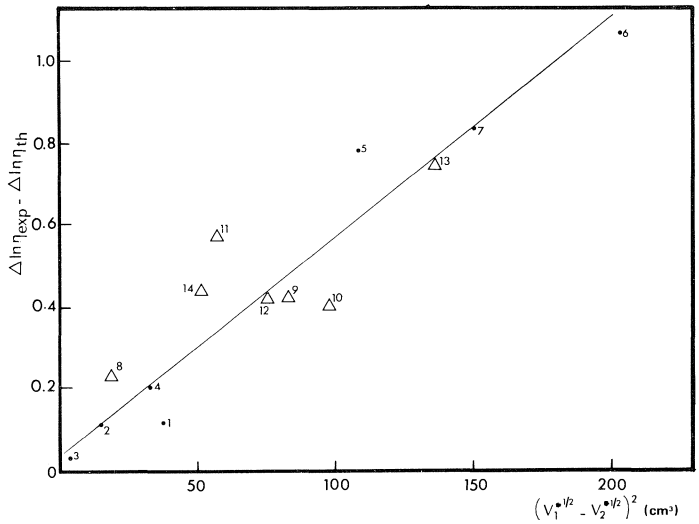

FIG. 1. $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$ from eqs. 4 and 5 *vs.* the difference in core volume of the two components $(V_1^{*1/2} - V_2^{*1/2})^2$, ● SnR_4 systems (points 1 to 7), △, other systems (points 8 to 14). The systems corresponding to the numbers can be found in Table 2.

$$[5] \quad \Delta \ln \eta_{th} = -\Delta G_M^R/RT + \frac{1}{\tilde{v} - 1} - \frac{x_1}{\tilde{v}_1 - 1} - \frac{x_2}{\tilde{v}_2 - 1}$$

$\tilde{v}$ is the reduced volume of the solution. One can say here that if the reduced volumes of the two components are not the same, the solution is not ideal from the viscosity point of view ($\Delta \ln \eta \neq 0$) even if $\Delta G_M^R = 0$. Comparison between experiment and theory will be made between eq. 5 and the experimental quantity $\Delta \ln \eta_{exp} = \ln \eta_{sol} - x_1 \ln \eta_1 - x_2 \ln \eta_2$ where η_{sol}, η_1, and η_2 are the measured values.

For ΔG_M^R in eq. 5, the experimental ΔH_M will be used and ΔS_M calculated. Different models (4) have been proposed for the energy–volume relationship but the Van der Waals relation $U = -1/V$, widely used by Flory (3), gives good results with relatively simple calculations. The $\tilde{v}$ of the solution depends not only on the difference in the reduced volume of the pure components $\tilde{v}_1$ and $\tilde{v}_2$ but also on the heats of mixing of the solution through the X_{12} parameter (eq. 38 of ref. 3*b*). In this work, $\tilde{v}$ is obtained by a simpler approximation detailed in refs. 4 and 9. The expression for ΔS_M^R, the excess entropy of mixing is (3):

$$[6] \quad \Delta S_M^R = 3x_1 \frac{P_1^* V_1^*}{RT_1^*} \ln \frac{\tilde{v}_1^{1/3} - 1}{\tilde{v}^{1/3} - 1} + 3x_2 \frac{P_2^* V_2^*}{RT_2^*} \ln \frac{\tilde{v}_2^{1/3} - 1}{\tilde{v}^{1/3} - 1}$$

P^*, V^*, and T^* are respectively the pressure, volume, temperature reduction parameters. They are obtained for the pure component as described below. To simplify, the following nomenclature is used:

$$[7] \quad \Delta \ln \eta_{th} = -\frac{\Delta H_M}{RT} + \frac{\Delta S_M^R}{R} + f(\tilde{v}) = \ln \eta_H + \ln \eta_S + \ln \eta_V$$

where

$$\ln \eta_H = -\Delta H_M/RT$$

$$\ln \eta_S = \Delta S_M^R/R$$

and

$$\ln \eta_V = f(\tilde{v}) = \frac{1}{\tilde{v} - 1} - \frac{x_1}{\tilde{v}_1 - 1} - \frac{x_2}{\tilde{v}_2 - 1}$$

Parameters for the Pure Components

The expansion coefficient and the density are necessary to obtain (3) $\tilde{v}$ and V^* through the equations

$$\tilde{v}^{1/3} = (\tfrac{4}{3}\alpha T + 1)/(\alpha T + 1)$$

and

$$V^* = V/\tilde{v}$$

$\tilde{T}$ is obtained by $\tilde{T} = \tilde{v}^{-1}(1 - \tilde{v}^{-1/3})$ and $T^* = T/\tilde{T}$. P^* is derived by the thermal pressure coefficient γ and $P^* = \gamma \tilde{v}^2 T$. For systems with little free volume differences, $\tilde{v}$ is near $\tilde{v}_1$ and $\tilde{v}_2$ which makes small the contribution of the term containing P^*, $\ln \eta_s$, in eq 7. Table 1 gives the parameters used in the calculations. The T^* have not been tabulated because they can be obtained easily from the above equations.

Results and Discussion

Pure Viscosities

Viscosities of the pure components are given in Table 1. Viscosities of the *n*-alkanes agree with published literature values (10). It is interesting to note that the viscosities depend so much on molecular shape and flexibility of the atomic bonds. The comparison of the viscosities (in cP) of four molecules having not too different molecular weights such as squalane (η = 28.9), $SnOct_4$ (η = 15.2), $Si(OOct)_4$ (η = 9.51), and 9*n*-octylheptadecane (η = 10.0) (11) illustrates this point. Low viscosities seem to be a characteristic of molecules with a central atom tetrasubstituted with identical groups.

Solution Viscosities

Table 2 shows the overall results for the systems. The different columns of Table 2 give respectively the maximum of $\Delta \ln \eta_{exp}$, the concentration at which the maximum occurs, the coefficients A_0, A_1, A_2, of the experimental concentration dependance of $\Delta \ln \eta_{exp}$:

$$[8] \quad \Delta \ln \eta_{exp} = x_1 x_2 (A_0 + A_1 x_1 + A_2 x_2^2)$$

$\Delta \ln \eta_{th}$ and the different contributions in eq. 7, $\ln \eta_H$, $\ln \eta_S$, $\ln \eta_V$, are tabulated in the other columns. The contact energy parameter X_{12} has been calculated (12) and is given in the next column divided by s_1, the surface-to-volume ratio of component 1. The last three columns give $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$, $(V_1^{*1/2} - V_2^{*1/2})^2$ a function of the difference in core volume of 1 and 2 and the number corresponding to each system on the graph. The experimental heats of mixing, used to obtain values of $\ln \eta_H$, are published separately (12) or will be published later (for the II systems).

The maximum of the heats has been used and no correction has been made for the fact that the maximum of $\Delta \ln \eta$ is not exactly at the same concentration as the maximum of the heats.

Characteristics of the SnR_4 Mixtures (Seven Systems)

(*1*) For the first system, $SnBut_4 + SnMe_4$, where there is a relatively large free volume difference, $\Delta \ln \eta$ is positive and large, due to the free volume contribution. This result had been found in the previous work (6). (*2*) For the next three systems for which the heats of mixing and free volume differences are small, $\Delta \ln \eta$ is predicted to be very small while the experimental values are larger and positive (for two systems). (*3*) For the last three systems of class I, the negative contribution coming from the large heats of mixing is almost balanced by the positive one due to the difference in free volume, so that $\Delta \ln \eta_{th}$ is predicted to be quite small. It is then surprising to obtain experimentally very large positive values of $\Delta \ln \eta$. This result had not been seen or was not so apparent in mixtures of $SnBut_4$ and long alkanes (6) for which a large heat of mixing was accompanied by a negative value of $\Delta \ln \eta$. Inspection of Table 2 indicates that the value of the difference $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$ is an increasing function of the difference of volumes between the two components.

It has been shown that long chain alkanes (7), long chain alcohols (14), and long chain tin com-

[c] Calculated as in ref. 12.

pounds (13) exhibit an order between the chains. A branched alkane, on the other hand, and presumably a tin derivative with a branched alkyl substituent, does not show this order due to its more isotropic character. It does not seem possible, as in ref. 6, to explain from these results the specific effect of the shape difference between the globular shorter tin derivatives and the ordered $SnLaur_4$ on $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$. The reason for this must be that, in the I systems, the molecules with shape differences have, in addition, very large size differences. The size effect must mask the shape effect. Comparison of $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$ for two compounds having the same size but different shapes such as $SnLaur_4$ and one of its branched isomers would be informative but is not possible due to the non-availability of one of these isomers.

Effect of the Size Difference on Excess Viscosities

To obtain a more quantitative correlation between the size difference and the 'error' in the theory, $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$ was plotted in Fig. 1 against the values $(V_1^{*1/2} - V_2^{*1/2})^2$. For the seven I systems, there is a reasonably linear relationship. The extrapolation to 0 of $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$ when $V_1^* = V_2^*$ shows that the value of $\ln \eta_{th}$, as calculated by eq. 7, describes the experimental results well, except for large size differences. To correct for this, one should add the term $\ln \eta_{\Delta V^*}$ to the calculated value so that

$$[9] \quad \Delta \ln \eta_{th} = \ln \eta_H + \ln \eta_S + \ln \eta_V + \ln \eta_{\Delta V^*}$$

$$\ln \eta_{\Delta V^*} = c(V_1^{*1/2} - V_2^{*1/2})^2$$

This expression was tried by analogy with the cohesive energy difference in solution.

Confirmation with Other Systems of the Validity of the Empirical Term $\ln \eta_{\Delta V^*}$ Added in Eq. 9

The next six systems have been chosen so that their $(V_1^{*1/2} - V_2^{*1/2})^2$ values would be spread between 50 and 200 cm^3. Heats of mixing, excess viscosities, and excess volumes have been measured and $\Delta \ln \eta_{th}$ obtained. One can see in Fig. 1 that these points fall reasonably well on the line obtained with the SnR_4 compounds. It is interesting to note that the $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$ values agree with the curve of Fig. 1 regardless of the sizes of the other contributions. For two systems, the free volume contributions are large and for three other systems $\Delta \ln \eta_H$ is important. The mixture, n-C_{16} + benzene, was added in Table 2, the agreement with eq. 9 being quite good even for this moderately polar system.

The scatter of the points on Fig. 1 around the straight line reflects undoubtedly the too great a simplicity of the expression for $\ln \eta_{\Delta V^*}$. One would have liked to have several slopes in Fig. 1 related to the shape of the mixed molecules but more experiments seem necessary to test this possibility. On the theoretical side, it would be interesting to understand the origin of $\ln \eta_{\Delta V^*}$. It is possible that the solution viscosity is increased when the molecules have large size differences because the probability of a suitable empty site near a molecule diminishes. On the other hand, excess volume measurements[2] show that a negative contribution occurs for the same systems for which $\ln \eta_{\Delta V^*}$ is important. In this case, it is likely that a good fitting of the small molecules in between the spaces left by the large ones is the source of the increased viscosity and decreased volume.

Condensation Effect with $SnEt_4$ and $SnPr_4$

Heats of mixing of the first four homologs of the SnR_4 series with the ordered chain compound $SnLaur_4$ have shown that there is a minimum of the heats per mole with $SnEt_4$ and $SnPr_4$. The same result is found if another ordered liquid like hexadecane is mixed with the same series. This is interpreted as the presence of an exothermic contribution to the heats which is larger for $SnEt_4$ and $SnPr_4$ than for the other members. Due to the presence of four alkyl groups on the Sn atom, $SnEt_4$ and $SnPr_4$ are sterically hindered and have low mobilities and large cohesive energies. The higher values of P^* for $SnEt_4$ (455) and $SnPr_4$ (481) J cm^{-3} compared to the values for the two nearest members of the same series $SnMe_4$ (415) and $SnBut_4$ (439) are macroscopic evidences of this distinctive character of $SnEt_4$ and $SnPr_4$. When they are mixed with a chain molecule as n-C_{16} or even a shorter alkane, they have the ability to diminish the mobility or 'condense' the other molecule. This characteristic has been found recently (16) on other sterically hindered molecules such as the alkanes substituted on the same carbon atom or neighbouring carbon atoms. The condensation effect gives a definite contribution to the excess volume: the diminution of the mobility is accompanied by a contraction which decreases the total volume.[2] It would be interesting to see if the excess viscosities would show a special contribution due to

[2]Cl. Jambon, G. Delmas, and Nguyen Hong Phuong. To be published.

the condensation effect. One would have liked to see a special contribution for the systems involving the $SnEt_4$ and $SnPr_4$ compared to the $SnBut_4$ and $SnMe_4$ ones. The system $SnLaur_4$ + $SnMe_4$ has not been investigated because the different contributions $\Delta \ln \eta_{th}$, $\ln \eta_H$, $\ln \eta_V$, $\ln \eta_{\Delta V^*}$ are so large that $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$ would perhaps not have been very significant. However, inspection of the three other systems (points 5, 6, 7) on Fig. 1 shows that there is indeed an irregularity in the series; the points corresponding to $SnEt_4$ and $SnPr_4$ are lower than that for $SnBut_4$ as it would be expected from a contribution coming from the condensation effect. On the other end, the low values of $\ln \eta_{exp} - \ln \eta_{th}$ for the points 6 and 7 may be related to an inadequacy of $\ln \eta_{\Delta V^*}$ for large values of $(V_1^{*1/2} - V_2^{*1/2})^2$ and not to the condensation effect. Another test of the presence of this effect was made using n-C_{16} as the condensable molecule instead of $SnLaur_4$. In the mixtures of n-C_{16} with $SnEt_4$, $SnPr_4$, and $SnBut_4$, the molar volumes of the two components are similar so that $\ln \eta_{\Delta V^*}$ is negligible. The same calculations as for the other systems give, respectively for $\Delta \ln \eta_{exp} - \Delta \ln \eta_{th}$, 0.169, 0.112, 0.124. This time, it appears, that the system involving $SnPr_4$ is not in between those with $SnEt_4$ and $SnBut_4$ as would have been expected. However, the difference with the expected value is rather small and does not permit a definite conclusion. The condensation effect is related to some kind of couplage between the motions of the condensing molecule (SnR_4) and the condensated ($SnLaur_4$, n-C_{16}). Since the short SnR_4 molecules have the same shape it is possible that the maximum of the effect does not happen with the same SnR_4 when the condensated molecule is changed. The condensation effect may have some importance in other terms of the excess viscosities not included in the change of the reduced volume ($\ln \eta_v$) and of the free energy ($\ln \eta_H + \Delta \ln \eta_S$) with the mixing.

A toxic alkaloid, anatoxin-*a*, has been isolated from mass cultures of a unialgal clone, NRC-44h, of the freshwater blue-green algae *Anabaena flos-aquae* (Lyngb.) de Bréb., and its structure determined.

J. P. DEVLIN, O. E. EDWARDS, P. R. GORHAM, N. R. HUNTER, R. K. PIKE et B. STAVRIC. Can. J. Chem. **55**, 1367 (1977).

On a isolé et déterminé la structure d'un alcaloïde toxique, l'anatoxine *a*, extrait de cultures massives d'un clone à une algue, NRC-44h, de l'algue bleue-verte d'eau potable *Anabaena flos-aquae* (Lyngb.) de Bréb.

[Traduit par le journal]

Ingestion of blooms of toxic freshwater algae are periodically responsible for the death of livestock, waterfowl, fish, and other wildlife (1–4). The chemical nature of the toxins from at least six species of freshwater algae have been studied to date (4–11).

Toxic strains of the filamentous blue-green alga, *Anabaena flos-aquae* (Lyngb.) de Bréb., have been obtained from a bloom that had poisoned cattle (12). They produced a toxin that killed mice in 2 to 5 min, preceded by gasps and tremors. It was called, therefore, Very Fast Death Factor (VFDF), and was shown by comparative tests to be indistinguishable in its effects from other toxic blooms that had killed livestock, waterfowl, and other species of wildlife (13). Using the medium and techniques worked out for the mass culture and bio-assay of the toxicity of these toxic strains, the following study was carried out to determine the structure of anatoxin-*a* (VFDF) produced by a unialgal clone NRC-44h that was obtained by a single-filament isolation from toxic strain NRC-44. Assay by intraperitoneal (ip) injection of mice was used to monitor toxin production and to follow the early stages of isolation.

In a preliminary study (14) Stavric and Gorham showed that the toxin was a low molecular weight amine probably containing an enone system (λ_{max} 227 nm). In subsequent work this absorption and a characteristic infrared band at 1670 cm^{-1} were used to monitor the final stages of purification of the toxin. The highest toxicity observed was LD_{min} (ip, mouse) of 0.25 mg/kg.

A variety of techniques were explored for the isolation and enrichment of the toxin. Because significant amounts of toxin were produced only as cultures matured (14 days) and 20 to 90% might be found in the medium at that time (14) it was decided to lyse the alga and isolate the toxin from the resulting aqueous suspension by ion-exchange chromatography. The simplest lysing technique proved to be the addition of Triton-X to the aqueous suspension. The toxin was absorbed from the lysed suspension onto the acid form of the carboxylic acid ion-exchange resin, Duolite. It was then eluted from the resin using alcoholic hydrogen chloride. Gentle concentration of the eluate *in vacuo* gave a syrup. A cold, aqueous solution of this syrup was adjusted to p*H* 8.5–9, the base rapidly extracted into methylene chloride, then at once reextracted into dilute hydrochloric acid. Evaporation of the acid solution left a glass rich in toxin hydrochloride (30% recovery of toxic material).

[4]Present address, Department of Botany, the University of Alberta, Edmonton, Alta. T6G 2E9. To whom enquiries about phycology and toxinology should be addressed.

Alternatively, the first syrup was triturated with benzene to remove neutral components, then triturated repeatedly with ¾% ethanol in chloroform. The latter removed much of the toxin hydrochloride.

However, the most efficient and reliable isolation procedure was to adjust the p*H* of the suspension of the mature algae to 5, concentrate this, then finally freeze-dry. The resulting green powder was extracted with dilute hydrogen chloride in methanol. Gentle evaporation of the extract left a syrup which was treated by the benzene–chloroform trituration described above. By this procedure a 73% recovery of toxin as hydrochloride was realized, as estimated by the LD_{min} for mice. Final purification was achieved by preparative thin-layer chromatography on silica gel using 20% methanol in chloroform for development.

Properties and Structure

The toxin hydrochloride was a nearly colorless glass with strong $R_2NH_2^+$ absorption below 3000 cm^{-1} and peaks at 1665 (str), 1638 (wk), and 1580 (med) cm^{-1} for a chloroform solution. This and its uv absorption (λ_{max} 227 nm, ε approximately 10 000) suggested the presence of a disubstituted α,β-unsaturated ketone. Since the toxin gave *N*-benzoyl and *N*-acetyl derivatives which had no NH group (ir) it was a secondary base. It absorbed only 1 mol of hydrogen over platinum, and its ^{13}C nmr spectrum showed the presence of only one C–C double bond. Mass spectra[5] and analyses showed its empirical formula to be $C_{10}H_{15}N$, hence it was a bicyclic compound.

Structure **1** was deduced for anatoxin-*a* on the basis of the above evidence and analysis of its ^1H nmr spectrum (see below). This was soon confirmed by X-ray crystallographic analysis of the *N*-acetyl derivative and absolute stereochemistry assigned (15). Because of this the arguments leading to structure **1** will be omitted, and only comments on the spectra given.

The vital evidence from chemical shifts and coupling obtained from 100 MHz[6] and 220 MHz ^1H nmr spectra of the *N*-acetyl derivative is illustrated on structure **2**, in which the double-ended arrows indicate demonstrated large coupling constants between the hydrogens. Attempts to demonstrate the vicinal nature of the methylenes resonating near 1.7 and 2.5 Hz failed. The ^{13}C nmr was not definitive for structure proof (see Experimental).

TABLE 1. The major fragment ions with high *m/e* of anatoxin-*a*

Formula	Mass	
	Calculated	Found
$C_{10}H_{15}NO$	165.1154	165.1138
$C_9H_{12}NO$	150.0919	150.0971
$C_8H_{10}NO$	136.0762	136.0758
C_7H_8NO	122.0606	122.0601

The major fragment ions with high *m/e* in the electron-impact mass spectrum[5] of anatoxin-*a* are given in Table 1. These were misleading in that they seemed likely to be pyridine derivatives. However, on the basis of **1** we formulate them as **3**, **4**, and **5**. Fragment ions from the *N*-acetyl derivatives are given in Table 2. These probably have structures **6** ($C_{10}H_{12}O^+$), **4** ($C_8H_{10}NO^+$), **7** ($C_8H_{12}N^+$), **8** ($C_8H_9^+$), **9** C_6H_8N), and **10** (C_5H_8N).

A synthesis of anatoxin-*a* from cocaine has now been achieved, confirming both the structure and absolute stereochemistry (16). The activity of the toxin as a post-synaptic depolarizing neuromuscular blocking agent has been reported (17).

A systematic name for anatoxin-*a* is 2-acetyl-9-azabicyclo[4.2.1.]non-2-ene.

[5]We are grateful to Dr. W. D. Jamieson, Atlantic Regional Laboratory, National Research Council of Canada for the high resolution mass spectra.

[6]We thank Dr. R. R. Fraser, Department of Chemistry, University of Ottawa for these decoupling experiments.

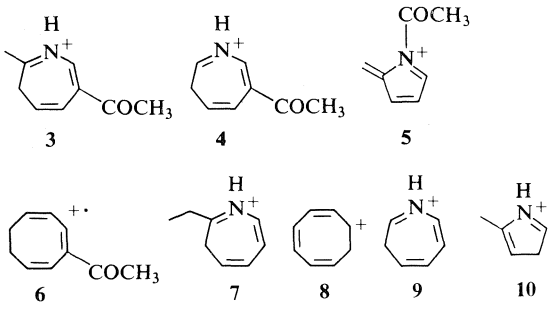

TABLE 2. Fragment ions from the *N*-acetyl derivative

Formula	Mass

Experimental

Bio-assay of Toxin

The regular method was similar to that described previously (7). Duplicate 20-g male mice, Connaught Laboratories or Alberta Laboratory Animal Services strains, were given graded dosages of algal suspensions or extracts by intraperitoneal injection. They were observed for toxinological signs and survival times for periods of 30 min or longer. Since the toxin has virtually an all-or-none effect, minimum lethal dose LD_{min} or LD_{100}, rather than 50% lethal dose, LD_{50}, was used to express toxicity. Mouse units (MU) used to determine recoveries were calculated on the basis of minimal dosage to kill a 25-g mouse. A few extracts were assayed using five replicates per dose to establish the LD_{min}'s a bit more precisely.

Anabaena flos-aquae NRC-44h

The toxic unialgal (bacterized) clone, *Anabaena flos-aquae* NRC-44h, was obtained by single-filament isolation in ASM-1 medium from the toxic colony isolate NRC-44 (14). *Anabaena flos-aquae* NRC-44 was one of eight toxic strains out of 12 that grew in shake flasks in ASM medium, 22°C, 1750 lux continuous, cool white fluorescent lamps, from a sample of a poisonous bloom collected from Burton Lake, Saskatchewan, June 20, 1961 (14). The bloom had an LD_{min} (ip) mouse = 80 mg/kg and an LD_{min} (oral) mouse = 800 mg/kg. Survival times were 5 to 6 min (ip or oral) preceded by a few gasps or tremors without violent convulsions. There were no detectable changes upon autopsy. Strain NRC-44 had an LD_{min} (ip) mouse = 640 mg/kg (12). It produced the same signs and survival times as the parent bloom. NRC-44h was the one clone out of 18, all toxic to varying degrees, which produced the greatest amount of anatoxin-*a* (90 to 120 MU/ℓ) when mass-cultured for 14 days in ASM-1 medium. Therefore, it was selected for further study.

Mass culture of Anabaena flos-aquae NRC-44h

Mass cultures were grown in 9-ℓ Pyrex bottles fitted with glass aerators inserted through a hole in the large rubber stopper that plugged the mouth. Eight litres of ASM-1 medium (12), p*H* 7.8, was autoclaved for 1 h in the bottle, cooled, and 100 ml of mature inoculum, that had been grown in shake flasks under similar conditions, was added aseptically. Batch cultures consisting of many bottles were grown in a temperature-controlled room at 21 ± 1°C with continuous illumination from three rows of 40-W cool white fluorescent lamps that were situated behind or between the bottles (Fig. 2 of ref. 18). The cultures were continuously aerated and stirred by sparging with filtered compressed air at 5 psi (0.35 kg/cm²) supplied from distribution manifolds at 1.0 to 1.5 ℓ/min.

Cultures were inoculated and harvested singly or in groups, as required, at about the peak of algal growth and toxin production, which was 14 days. If not lysed and treated with ion-exchange resin, mass cultures were acidified with HCl to p*H* 5 or 6, concentrated by vacuum distillation at 35°C with a Majonnier evaporator or a small cyclic still, and then freeze-dried from a starting temperature of −40°C or lower in a large commercial or a small laboratory apparatus. Frozen concentrates were sometimes stored at −40°C for several days or weeks prior to freeze-drying without loss of potency. Freeze-dried cultures were ground in a mortar to remove lumps, and stored in dark bottles at 5°C until used. There was a measurable loss of potency if stored for many months under these conditions, however. Different batches of freeze-dried NRC-44h had initial LD_{min}'s that varied from 80 to 160 mg/kg or even higher. The cause of this variability was subsequently shown to be the bacterial contaminants (19).

Isolation of the Toxin

(*A1*) To each 8 ℓ bottle of culture was added 1 ml of Triton-X followed by 25–30 g of the carboxylic acid ion-exchange resin Duolite C-100 (40–100 mesh, previously washed successively with sodium hydroxide solution, water, 3 *N* hydrochloric acid, ethanol, then water). The suspension was stirred for 17 h, then the solids separated by filtration through a sand bed in a glass chromatographic column. The bed of solids was washed with one column volume of water, then the toxin was eluted with 200 ml of 1.5 *N* hydrochloric acid in 50% ethanol–water. The eluate was evaporated in a Craig rotating evaporator in a 35°C bath. The residual syrup now contained an average of 52% of the original toxic compound (mouse assay). The cold aqueous solution of the syrup was quickly adjusted to p*H* 9, the toxin extracted rapidly into methylene chloride, then immediately back into 1 *N* hydrochloric acid. The acid solution was evaporated on a rotating evaporator (35°C bath), leaving a thick brown syrup, which now contained an average of 29% of the original toxicity. The final enrichment was by preparative thin layer chromatography on methanol-washed, reactivated fluorescent Chromar sheets using 1:8 methanol in methylene chloride (R_f 0.45) or on fluorescent (G_{254}) silica gel plates using 1:4 methanol–chloroform

for elution (R_f 0.3). The toxin rich zone was replated once for further enrichment.

An alternate procedure was devised to avoid the handling of the free base.

(*A2*) The syrup recovered from the ion-exchange resin (see *A1*) was triturated with benzene, which removed less polar non-toxic components. The insoluble part was dissolved in a minimum amount of ethanol, then chloroform added until precipitation stopped. The bulk of the toxin remained in the chloroform. After filtration, the filtrate was evaporated. The residue was resuspended in chloroform (¾% ethanol) and the solution filtered through sodium sulfate, then evaporated. The resulting gum was suspended in water containing a trace of hydrochloric acid, then filtered. The markedly enriched extract (LD_{min} = 25 mg/kg) recovered by evaporation of the filtrate on a rotating evaporator, was further enriched by preparative thin layer chromatography as described in *A1*.

(*B*) An 8 ℓ culture of algae was freeze-dried and ground (see above) leaving a free-flowing green powder (13.8 g, LD_{min} = 160 mg/kg, 3450 MU). This was shaken for 0.5 h with 200 ml of ¾% ethanol in chloroform. The suspension was filtered, then the extraction repeated twice. Evaporation of the reddish green chloroform solution in a bath at room temperature left a gum. This was taken up in 100 ml of methanol and the p*H* adjusted to 2 using 3 *N* hydrochloric acid in methanol. The suspension was filtered and the filtrate evaporated under reduced pressure. The residue was distributed between 150 ml of water and 50 ml of chloroform, then the chloroform washed with 150 ml of water. The combined aqueous layers were washed with 25 ml of chloroform. The aqueous solution was evaporated to dryness, then the bulk of the toxin extracted from the residue by two triturations with ¾% ethanol in chloroform giving 28 mg of chloroform-soluble material. This was again extracted with chloroform followed by filtration through sodium sulfate to give 22 mg (LD_{min} = 0.3 mg/kg) with λ_{max} at 225 nm (ε 6000) (2900 MU). Preparative tlc purification of this gave 13 mg containing 2600 MU (near 100% purity, recovery 70% of original toxic component). If the p*H* of the culture was not reduced to below 7 before the removal of the water, much loss of toxin resulted.

Properties of Anatoxin-a Hydrochloride

The purest material from preparative tlc had LD_{min} (intraperitoneal mouse assay) of 0.25 mg/kg; λ_{max} ($CHCl_3$) 2300–2800 (NH_2^+), 1670 (str), 1645 (wk), and 1588 (med) cm^{-1}; λ_{max} (95% ethanol) 227 nm, ε near 10 000. Its 60 MHz proton nmr spectrum in deuterium oxide had 1H signals at δ 7.1 (t, J = 6 Hz), 4.7 (d, J = 6 Hz) and 3.9 (br) relative to a 3H singlet arbitrarily set at δ 2.0 ($COCH_3$). The mass spectrum of the hydrochloride (direct inlet, 98°C) had peaks at *m/e* (relative intensity): 166(22), 165(100), 164(9), 151(6), 150(28), 137(22), 136(38), 123(10), 122(54), 108(12), 94(26), 93(7), 83(8), 82(31), 81(8), 69(31), 68(28), 67(10). Its ^{13}C nmr spectrum in D_2O had signals at 24.5, 25.9, 28.0, 28.5, 31.0, 53.9, 60.7, 143.9, 152.0, 207.5 ppm from TMS.

Anatoxin-a

The base was recovered by addition of ice-cold sodium hydroxide solution to a cold aqueous solution of the hydrochloride, followed by rapid extraction into pure ether. The resulting oil had ν_{max} (CH_2Cl_2) 1664 cm^{-1}. Its high resolution mass spectrum (direct inlet, −5°C) gave peaks at 165.1138 ($C_{10}H_{15}NO$), 150.0917 ($C_9H_{12}NO$), 136.0758 ($C_8H_{10}NO$), and 122.0601 (C_7H_8NO).

Dihydroanatoxin-a Hydrochloride

Anatoxin-*a* hydrochloride (10 mg) was added to 3 ml of acetic acid containing platinum from 10 mg of Adam's platinum oxide under a hydrogen atmosphere. After 1.5 h stirring at room temperature 1.0 mol equiv. of hydrogen had been absorbed. The catalyst was removed by filtration then the solvent removed *in vacuo*. The amorphous product had ν_{max} (CH_2Cl_2) 1717 cm^{-1}.

N-Benzoyl Anatoxin-a

Benzoyl chloride (300 mg) was added to a solution of 33 mg of anatoxin-*a* hydrochloride in 2 ml of pyridine at 0°C. The temperature was raised gradually to 50°C and maintained there for 4 h. After cooling, then the addition of 3 ml of water, the solution was stirred for 5 h. The product was extracted into methylene chloride, and the organic layers washed with 1 *N* sulfuric acid (3 × 4 ml), water (4 ml), and 5% sodium carbonate (2 × 4 ml). The dried methylene chloride solution yielded 25 mg of viscous oil, which was distilled over a short path at 120°C/1 × 10^{-5} torr. It had ν_{max} (methylene chloride) 1667 and 1625 cm^{-1}. Its high resolution mass spectrum[5] had peaks at 269.1411 ($C_{17}H_{19}NO_2$), 166.1237 ($C_{10}H_{16}NO$), and 164.1086 ($C_{10}H_{14}NO$).

N-Acetyl Anatoxin-a

To 0.5 ml of acetic anhydride containing 100 mg of anhydrous sodium acetate was added 18 mg of anatoxin-*a* hydrochloride. The mixture was maintained at 60°C for 3 h, then left overnight at room temperature. The bulk of the acetic anhydride was removed under reduced pressure. One millilitre of methanol was added. After 0.5 h the methanol was removed under reduced pressure then the residue taken up in 0.5 ml of water. The solution was made basic using solid sodium carbonate, then the product extracted into methylene chloride. The 22 mg of pale brown gum crystallized spontaneously. This was distilled over a short path at 85°C/5 × 10^{-4} torr giving a mixture of crystals and oil. A small amount of dry ether removed 3 mg of oil leaving 12 mg of colorless crystals. After two recrystallizations from acetone–hexane the *N*-acetyl derivative melted at 117–118°C and had $[\alpha]_D$ −127° (*c*, 4.8 in ethanol). It had ν_{max} ($CHCl_3$) 1664 (med) and 1624 (str) cm^{-1}, and λ_{max} 226 nm, ε 10 500. Its 60 MHz ^1H nmr spectrum had signals at δ 7.05 (1H, *t*, J = 6 Hz), 5.28 (1H, d, J = 8 Hz), 4.83 (1H, $W_{1/2}$ = 12 Hz), 2.35 (3H, s), and 1.98 (3H, s). Chemical shift assignments and coupling constants derived from its 220 MHz ^1H nmr spectrum with spin decoupling studies are displayed on formula **2**. Its mass spectrum (direct inlet) had peaks at *m/e* (relative intensity): 207(100), 165(89), 164(62), 150(56), 149(64). The accurate mass[5] of other important ions in the electron impact mass spectrum of *N*-acetyl anatoxin-*a* are given in Table 2.

Acknowledgements

The authors wish to express their gratitude for the expert technical assistance of Mr. D'Arcy Wright who carried out most of the mass culturing and toxicity assays. Dr. W. E. Sneader

worked on the development of the methods for large-scale lysis and ion-exchange chromatography. Messrs. A. Holland and P. Hurdle, and Dr. W. W. Carmichael deserve thanks for their help in the final stages of the investigation. We thank Mr. H. Seguin for microanalyses, Dr. W. G. Jamieson for the high resolution mass spectra, and Dr. I. C. P. Smith and associates for the ^{13}C nmr spectra.

Synthesis of nor-anatoxin-*a* and anatoxin-*a*[1]

HENRY F. CAMPBELL,[2] OLIVER E. EDWARDS, AND RALPH KOLT

Division of Biological Sciences, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received September 9, 1976

HENRY F. CAMPBELL, OLIVER E. EDWARDS, and RALPH KOLT. Can. J. Chem. **55**, 1372 (1977).

The neuro-muscular post-synaptic depolarizing agent anatoxin-*a* from *Anabaena flos-aquae* (Lyngb.) de Bréb. has been synthesized from cocaine.

HENRY F. CAMPBELL, OLIVER E. EDWARDS et RALPH KOLT. Can. J. Chem. **55**, 1372 (1977).

On a synthétisé, à partir de la cocaine, l'agent dépolarisant post-synaptique neuro-musculaire, anatoxine-*a*, obtenu à partir de l'*Anabaena flos-aquae* (Lyngb.) de Bréb.

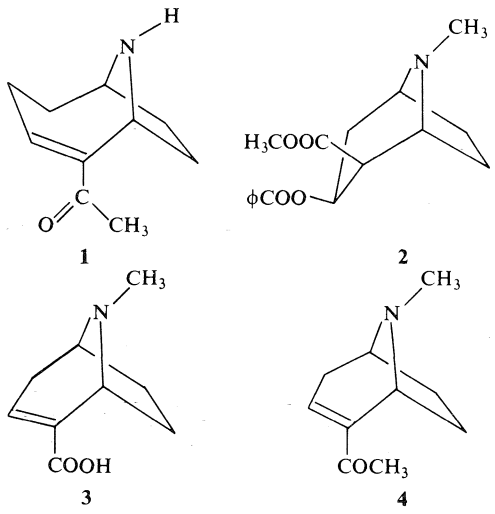
[Traduit par le journal]

Some strains of the fresh-water blue-green algae *Anabaena flos-aquae* (Lyngb.) de Bréb. produce a toxin which has been named anatoxin-*a*. This proved to be a homotropane derivative **1** (1, 2). Anatoxin is of considerable pharmacological interest because of its activity as a post-synaptic depolarizing agent (3). We now report a synthesis of optically active anatoxin-*a* from cocaine (**2**). Since the absolute configuration of the toxin had been determined by X-ray analysis (2), the synthesis confirms the absolute stereochemistry which had been assigned to cocaine (4).

Cocaine was converted by known procedures (5) into the α,β-unsaturated acid **3**. Reaction of the lithium salt of **3** with methyllithium (6) produced the methyl ketone **4** in 76% yield. When this ketone was treated with sodium dimethyloxosulfonium methylide in dimethyl sulfoxide (7) it gave a 65% yield of the *endo* cyclopropane derivative **5** and 35% of the *exo* isomer **6**. Occasionally small amounts of a product with properties corresponding to those expected for the epoxide **7** were produced.

The structures of the two cyclopropanes were assigned on the basis of the ^{1}H nmr shifts shown on the figures. The greater proximity of the acetyl group to the *N*-methyl group and one bridgehead hydrogen, resulting in downfield shifts, identifies the *endo* isomer. The course of the photolysis of the two isomers (see below) made the assignments certain.

Attempts to remove the *N*-methyl group of **5** using 2,2,2-trichloroethyl chloroformate or phosgene led to complications apparently due to attack on the cyclopropane ring. The *exo* isomer **6** proved inert to 2,2,2-trichloroethyl chloroformate at room temperature. Hence the demethylation was deferred to a later stage.



Two methods were successful in opening of the cyclopropane ring of **5**, reductive fission using lithium in liquid ammonia or photolytic cleavage. There was reason to expect that the reductive opening of **5** would result in the ring expanded product (see Discussion). Indeed, the action of lithium in ammonia did convert **5** into the enolate anions of the saturated ketone **8**. These were directly converted by acetic anhydride into mixtures of the two enol acetates **9** and **10**. Alternatively, the ketone **8** was isolated, then converted into the enol acetates by acetic anhydride in the presence of hydrogen bromide. Addition of bromine to the enol acetates, followed by aqueous work-up gave the bromo ketone **11**. Elimination of hydrogen bromide

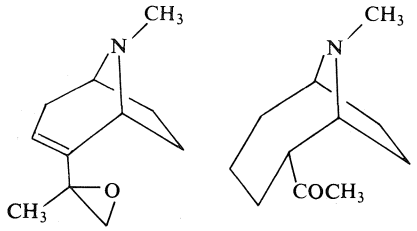
5 6

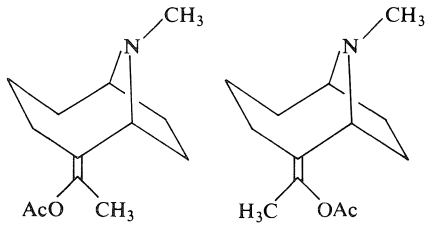


7 8

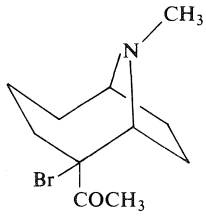
from **11** was achieved by the action of lithium bromide and lithium carbonate in dimethyl formamide, giving *N*-methyl anatoxin-*a* (**12**).

In contrast to the behavior of the *endo* isomer, the action of lithium in ammonia on the *exo* isomer **6** only resulted in reduction of the carbonyl group.

There was literature precedent for the photolytic opening of cyclopropyl ketones to the α,β-unsaturated ketone[3] (8–10). When an aqueous solution of the hydrochloride of the *endo* isomer **5** was irradiated using light with maximum intensity at 300 nm, a 75% yield of the ring expanded *N*-methyl anatoxin-*a* (**12**) resulted.



9 10



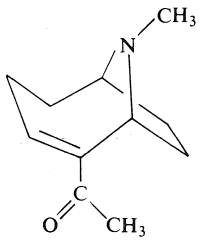
11

[3]We are grateful to Dr. P. W. Jeffs for drawing our attention to this possibility.

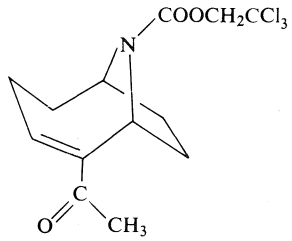
The *exo* isomer **6** photolyzed much more slowly than **5** under comparable conditions, and the reaction took a different course (see below).

De-*N*-methylation of *N*-methyl anatoxin using 2,2,2-trichloroethoxycarbonyl chloride (11) proved to be erratic, and the zinc deblocking of the nitrogen was not clean, so this method was not pursued further.

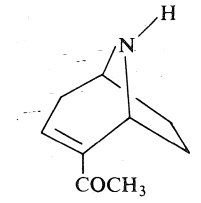
De-*N*-methylation using phosgene has been reported (13). Preliminary experiments with the methyl ketone **4** (*N*-methyl nor-anatoxin-*a*) showed that phosgene in benzene at room temperature gave extensive demethylation in 0.5 h. The major product, nor-anatoxin-*a* (14) was characterized as its hydrochloride after work-up. However, comparable treatment of *N*-methyl anatoxin-*a* gave messy mixtures of products which have not been characterized.



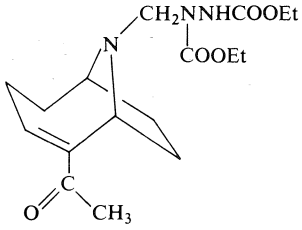
12



13



14



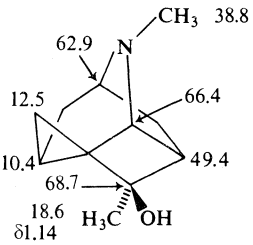
15

The successful preparation of anatoxin-*a* resulted from the action of diethyl azodicarboxylate (diethyl azodiformate) on the *N*-methyl derivative (14). A benzene solution of **12** and the azo compound was refluxed for 2.5 h, the intermediate (presumably **15**) was hydrolyzed by hydrogen chloride in aqueous ethanol and the products separated by preparative tlc. A 30% yield of anatoxin-*a* hydrochloride was obtained. Its infrared, ultraviolet, and nmr spectra and its toxicity[4] coincided with those of natural anatoxin-*a* hydrochloride. The base was converted to its crystalline *N*-acetyl derivative, which had a melting

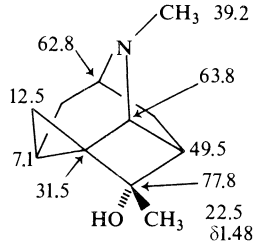
[4]Personal communication from Professor P. R. Gorham.

point, spectra, and rotation identical to those of the *N*-acetyl derivative of natural anatoxin-*a* (1).

The photolysis of the *exo*-cyclopropylketone **6** gave no significant amount of enone. Instead two alcohols isomeric with the parent ketone were produced. The ^{1}H and ^{13}C nmr spectra gave convincing evidence that the structures of these were the epimeric alcohols **16** and **17**.



16



17

Discussion

In reaction **1** we outline the possible routes for lithium–ammonia reduction of a cyclopropyl ketone. An equilibrium has been written for path (*c*) since this would only approach delocalization (resonance) if the geometry was ideal for overlap. Path *a* is written as irreversible since the charge repulsion would make the charge-separated ring-opened structure of considerably lower energy.

The accumulated evidence (15, 16) seems only consistent with rapid reduction to the dianion (path *a*). If the geometry is ideal for overlap of the unshared pair on carbon with one bond of the cyclopropane ring, the ring opening may be synchronous with the addition of the second electron.

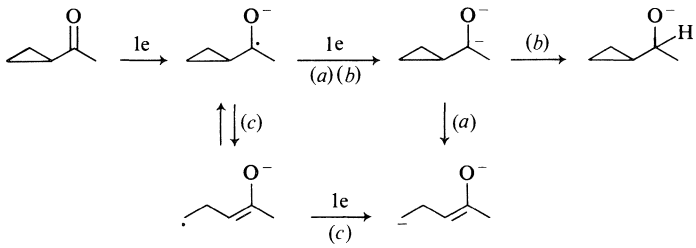
We are surprised that the reversible process *c* is not more important. Indeed for a number of cases, including that of the *endo* isomer **5**, one could argue that it is the more stable ring-open radical anion which is being preferentially formed. However the observation of Dauben and Wolff (16) that *trans* 1-acetyl-2-methylcyclopropane gave 94% of *tert*-butyl acetone is incompatible with this possibility.

The simple reduction of the carbonyl in the case of the *exo* isomer **6** appears to result from poor overlap of the carbanion with the bonds of the cyclopropane ring. It is hence protonated on the carbonyl carbon as in path *b*.

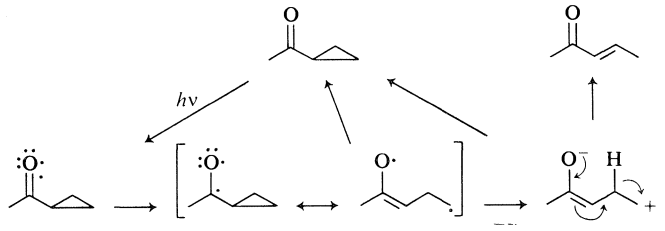
The generally accepted picture of the photoreaction of conjugated cyclopropyl ketones involves excitation to an n–π* singlet followed by transformation into a triplet diradical [2] (17). The question of which of the two possible cyclopropane bonds is cleaved depends on their ability to overlap with the π orbitals of the carbonyl, and the sensing in the transition state of the relative stability of the two possible diradicals (18, 19). Our observations can be explained using these factors and a third, the proximity to the oxygen of an abstractable hydrogen.

The overlap in the favored rotamer **18** and the higher stability of the secondary rather than primary radical combine to cause predominant formation of the ring-expanded product **12** from the *endo* isomer **5**. The formation of an α,β

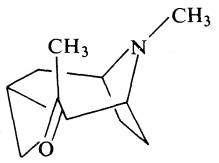
[1]



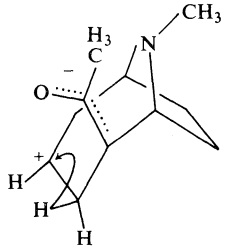
[2]



unsaturated ketone from a diradical is most attractively explained [2] by a 1,3-electron jump to give the zwitterion **19**. The zwitterion **19** derived from **18** then undergoes a 1,2-hydride shift to give the observed product. The postulated 1,3-electron jump corresponds to the 'electron



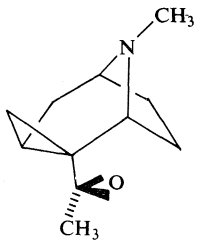
18



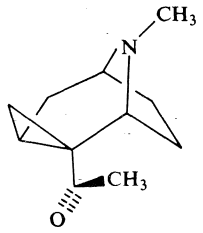
19

demotion' concept of Zimmerman and co-workers (12). Winter and Lindauer have produced evidence that the conjugated enones are formed by 1,2 hydrogen shifts (9).

The fate of the *exo* isomer **6** seems to be the resultant of the fact that the most favorable rotamers **20** and **21** would lead to a higher-energy primary radical on ring fission, and that the *endo* hydrogen on C-8 can be brought into



20



21

close proximity to the carbonyl oxygen. Consequently hydrogen abstraction followed by cyclization was the dominant reaction [3]. This striking difference in photochemical behavior is so clearly associated with the different geometry of the two isomers, that no ambiguity is left as to which is which.

[3]  → **16** + **17**

Experimental

Infrared spectra were of chloroform solutions, ultraviolet spectra of solutions in 95% ethanol, and unless otherwise stated ^{1}H nmr and ^{13}C nmr spectra were of deuterochloroform solutions with TMS as internal reference. Thin layer and preparative layer chromatography were done using silica gel containing a fluorescent indicator (G_{254}). Gas–liquid chromatography (glc) was on 6 ft × $\frac{1}{4}$ in. column of 10% silicone rubber on silanized Chromosorb W (SE30).

*Anhydroecgonine (**3**)*

This was prepared by hydrolysis of cocaine (**2**) in refluxing concentrated hydrochloric acid (5). It was converted to its methyl ester using dry methanol saturated with anhydrous hydrogen chloride at 0°C. This distilled at 55°C/0.5 torr, and had ν_{max} 1710 and 1640 cm^{-1}, λ_{max} 218 nm (ε 10 850), $[\alpha]_D$ −43° (*c* 1.5, methanol), and gave ^{1}H nmr signals at δ 2.38 (s, 3H), 3.75 (s, 3H), and 6.85 (1H).

Lithium Salt of Anhydroecgonine

To a solution of 3.62 g (20 mmol) of redistilled methyl ester of anhydroecgonine in 10 ml of 5% water in methanol was added 880 mg of lithium hydroxide monohydrate (20.1 mmol). After 2 h refluxing the solvent was removed and the solid dried *in vacuo*. After two triturations with ether it was redried at 80°C/0.1 torr for 4 h giving 3.46 g (100%).

Alternatively, an aqueous solution of the hydrochloride of anhydroecgonine was treated with 2 mol equiv. of lithium hydroxide, the water removed under reduced pressure, and the mixture of salts dried at 100°C under 0.1 torr pressure.

*Methyl Ketone **4***

To a stirred suspension of 2.9 g (16.8 mmol) of the lithium salt of anhydroecgonine in 50 ml of pure dry 1,2-dimethoxyethane under nitrogen at 5°C was added 13.5 ml of methyllithium solution (1.8 *M* in ether). The mixture was stirred for 5 h at room temperature then taken to near dryness under reduced pressure. The products were distributed between ice-cold 2 *N* hydrochloric acid and ether. The aqueous layers were made basic and the product extracted into methylene chloride, giving 2.1 g of nearly pure methyl ketone (79%).

This was converted to its hydrochloride, which after recrystallization from ethanol – ethyl acetate mixture had mp 161–163°C and $[\alpha]_D$ −70°C (*c* 1, methanol). It had λ_{max} 224 nm (ε 12 000). *Anal.* calcd. for $C_{10}H_{16}ClNO$: C 59.54, H 8.00, N 6.95, Cl 17.58; found: C 59.36, H 8.08, N 7.01, Cl 17.34. The free base recovered from the hydrochloride had ν_{max} ($CHCl_3$) 1665 and 1630 cm^{-1} and ^{1}H nmr signals at δ 2.32 (3H), 2.38 (3H), 3.35 (m, 1H), 4.0 (br d, 1H), 6.93 (t, 1H).

Cyclopropyl Ketone Formation

A mineral oil dispersion of sodium hydride (1.01 g, 50%, 21 mmol) was washed three times with pentane. To this was added 4.62 g of trimethyloxosulfonium iodide (21 mmol) then the flask flushed thoroughly with nitrogen. Dry dimethyl sulfoxide (25 ml) was added slowly through a septum using a syringe, while the mixture was stirred magnetically. After 20 min stirring at room temperature,

vigorous hydrogen evolution had ceased. A solution of 3.30 g (20 mmol) of the α,β-unsaturated ketone **4** in 5 ml of dioxane was added through the septum. The reaction mixture was stirred under nitrogen for 2 h at room temperature then 1 h at 50°C. It was poured into 80 ml of cold water then extracted five times with ether. The oil remaining after removal of the ether was distilled. The main fraction, collected between 55 and 80°C under 0.05 torr weighed 2.82 g. Gas–liquid chromatography on SE-30 at 170°C showed this to consist of starting material (9% recovery) and a mixture of the *endo* cyclopropyl ketone **5** (43% yield) and the *exo* isomer **6** (27% yield).

The mixture of products could be partially separated by chromatography on a 65-fold ratio of tlc silica gel using a 10:1 mixture of chloroform and methanol. The order of elution was *exo* isomer, starting material, then *endo* isomer. A slightly better resolution was achieved using a 35-fold ratio of neutral alumina (activity II) and pentane–ether mixtures for elution. The same elution order was observed. In one run a sizeable by-product was observed. It was isolated by chromatography of the base hydrochlorides on silica gel using 3:1 methanol – acetic acid for elution. It was tentatively assigned the epoxide structure **7**.

Epoxide 7

The free base had no carbonyl absorption in its infrared spectrum. Its ^{1}H nmr spectrum had peaks at δ 1.31 (3H), 2.35 (3H), and 5.55 (1H, t, J = 4 Hz).

Endo Cyclopropyl Ketone 5

This was distilled over a short path at 80°C/0.1 torr. It had ν_{max} 1680 cm^{-1} and gave ^{1}H nmr signals at δ 2.03 (s, 3H) and 2.33 (s, 3H) and broad 1H signals at δ 3.15 and 4.4. Its hydrochloride after recrystallization from methanol – ethyl acetate had mp 188–193°C, $[\alpha]_D$ +99° (*c* 1, methanol) and λ_{max} 271 nm (ε 20 with ε_{210} 710). It gave ^{1}H nmr signals (in D_2O, HOD set at δ 4.70) at 2.0 and 2.7 (3H, s's) and 3.8 and 5.0 (1H, m's).

Exo Cyclopropyl Ketone 6

The early eluates from the chromatograms were nearly pure *exo* isomer. This was distilled over a short path at 80°C/1 torr pressure. It had ν_{max} 1680 cm^{-1} and gave ^{1}H nmr signals at δ 2.01 (s, 3H), 2.17 (s, 3H) and broad 1H signals at 2.9 and 3.6.

It gave a hydrochloride which after recrystallization from methanol – ethyl acetate had mp 192–194°C, $[\alpha]_D^{20}$ −76° (*c* 1, methanol) and λ_{max} 275 nm (ε 25, with ε_{210} 1220). It gave ^{1}H nmr signals (in D_2O, HOD set at δ 4.70) at 2.01 and 2.75 (3H, s's) and 3.8 and 4.4 (1H, m's). *Anal.* calcd. for $C_{11}H_{18}ClNO$: C 61.25, H 8.41, N 6.50; found: C 61.38, H 8.38, N 6.30.

Reactions of the Endo Isomer 5

Lithium–Ammonia Reduction

Approximately 500 ml of liquid ammonia, distilled from sodium, was collected in a double-walled 2 ℓ flask under a dry ice condensor. The flask was flushed with dry nitrogen, then 4.16 g (60 mmol) of clean lithium metal was added. The mixture was stirred briefly, then a solution of 6.0 g of the *endo* isomer in 150 ml of ether was added slowly with stirring. The mixture was stirred for 3 h, then 67 g of ammonium chloride added. The ammonia was evaporated overnight in a slow stream of nitrogen. The residue was taken up in 900 ml of ether and 900 ml of saturated aqueous sodium chloride solution. The aqueous phase was extracted four times with ether. The dried ether layers gave 5.6 g of crude product (93%). This was placed on top of a column of 500 g of tlc silica gel, then eluted with a 10:1 benzene–diethylamine mixture. The composition of the fractions was monitored using glc (SE-30 at 170°C). After somewhat impure fractions (439 mg) the main product (3.5 g, 58%) was eluted, followed by fractions contaminated with alcohols.

De-N-methylation of Endo Cyclopropyl Ketone 5

A solution of 99 mg of *endo* cyclopropyl ketone **5** and 125 mg of diethylazodicarboxylate (DAD) in 7.5 ml of dry benzene was refluxed for 11 h. At this point only a small amount of starting material remained (tlc in 4:1 benzene–methanol). An extra 30 mg of DAD was added, the solution refluxed for 15 min, then left at room temperature for 10 h. The benzene was removed *in vacuo*, then a solution of the residue in a mixture of 2.5 ml of 2 *N* hydrochloric acid and 2.5 ml of 95% ethanol refluxed for 2.5 h. The resulting solution was taken to a syrup on a rotating evaporator *in vacuo*. The residue was chromatographed on two 20 × 20 cm 500 μm plates using methanol for development. A zone with R_f 0.2–0.5 was extracted with hot 3:2 methanol – acetic acid mixture. Removal of the solvent gave 62 mg of the hydrochloride of the desired de-*N*-methylated base. It had a sharp ^{1}H nmr signal at δ 1.90 relative to the HOD signal (set at δ 4.7).

The corresponding base had ν_{max} 1675 cm^{-1} and gave ^{1}H nmr signals at 2.10 (3H, s) and 0.85, 3.5, and 4.7 (1H, m's).

Ring Expanded Ketone 8

The major product from the lithium–ammonia reduction had ν_{max} 1705 cm^{-1} and gave ^{1}H nmr signals at δ 2.09 and 2.12 (s's, ratio 1:2), 2.38 and 2.48 (s's, ratio 1:2) corresponding to two epimeric ketones. The bases were converted to hydrochlorides using hydrogen chloride in methanol. The major component gave a salt with mp 152–155°C, $[\alpha]_D$ −11° (*c* 1, methanol). The salt gave ^{1}H nmr signals in heavy water with δ 2.22 (s, 3H) and 2.91 (s, 3H) relative to DSS.

Enol Acetates 9 and 10

(*a*) The lithium in ammonia reduction of the *endo* cyclopropyl ketone **5** (895 mg, 5.0 mmol) was conducted as described above, but the ammonium chloride addition was done carefully until the blue color was just destroyed. The ammonia was then evaporated over 4.5 h in a stream of dry nitrogen. The residue was suspended in 50 ml of pure 1,2-dimethoxyethane, the solution cooled in an ice bath, then added to 5 ml of acetic anhydride. The mixture was stirred for 3 h at room temperature, then poured into a cold mixture of saturated sodium bicarbonate solution and ether. This mixture was stirred for 0.5 h. The ether layer was separated and the aqueous layer extracted twice with fresh ether. The dried ether layers yielded 1.0 g of yellow liquid.

Gas–liquid chromatography (SE-30, 175°C) showed the absence of cyclopropyl ketone and the presence of only a few percent of ring-expanded ketone. Two enol acetates were present in the ratio of 1:3 (identities unknown). A sample distilled over a short path at 100–125°C/0.02 torr had ν_{max} 1740, 1670 cm^{-1}. The bulk of residual acetic anhydride was removed under 0.05 torr during 6 h. The resulting oil gave ^{1}H nmr singlets at δ 2.51 (N—CH_3),

2.13 (CH_3COO), and 2.00 (CH_3—C═C). Signals at δ 2.18 and 1.90 appear to arise from the minor isomer.

(*b*) Ketone **8** hydrochloride (365 mg) was dissolved in 10 ml of acetic anhydride. Hydrogen bromide was bubbled through the solution for 1 min (*ca.* 1 bubble/s). The solution was then heated at 80°C for 24 h. It was evaporated under reduced pressure giving 487 mg of the desired enol acetates as hydrobromides. The mixture had ν_{max} 1755 and 1670 cm^{-1} and gave ^1H nmr signals at δ 1.91 (vinyl methyl), 2.22 (acetate), and a pair of doublets (J = 5 Hz) centered at δ 2.25 and δ 3.0 attributable to the N-CH_3 in the isomers.

*Bromo Ketone **11***

A 0.174 *M* solution of bromine in chloroform was prepared. Ten millilitres of this at 0°C was added to 461 mg of the enol acetate hydrobromides (**9** + **10**) during the course of 15 min. After 2 h at room temperature the ^1H nmr spectrum showed complete bromination. Water was added and the mixture stirred for 1 h, then the solvents evaporated under reduced pressure. The 569 mg of crude bromo ketone hydrobromide was a mixture of two isomers as shown by ^1H nmr signals at δ 1.68 and 1.74 and at δ 2.15 and 2.22 (relative to HOD set at 4.70). One component (the isomer giving the lower-field N-CH_3 and CH_3CO signals) crystallized from acetone giving 224 mg (49%), mp 138–141°C. It gave ^1H nmr signals at δ 2.57 (3H), 2.97 (3H), 5.0 (br s, 1H) and 5.5 (br s, 1H). *Anal.* calcd. for $C_{11}H_{19}Br_3NO$: C 38.74, H 5.61, N 4.11, Br 46.85; found: C 38.59, H 5.72, N 4.19, Br 46.69.

*Dehydrobromination of **11** (N-Methyl Anatoxin-a)*

Bromo ketone hydrobromide (569 mg, 1.67 mmol) and 610 mg (7 mmol) of dry lithium bromide was dried briefly at 100°C/1 × 10^{-2} torr, then 16 ml of dry dimethyl formamide added. The mixture was heated at 60°C for 17 h, and at 130°C for 1 h. The bulk of the dimethyl formamide was removed at 70°C/0.5 torr pressure. The residue was dissolved in 5 ml of water, made basic with solid sodium carbonate, then strongly alkaline with ice-cold 40% sodium hydroxide solution. The product was quickly extracted into ether (4–10 ml portions). After drying and distillation of the ether, the product was converted to its hydrobromide in methanol. This was purified on four 1000 μm plates using 2:1 chloroform–methanol. The most visible band under uv light was collected. This gave 173 mg rich in α,β unsaturated ketone (**12**). This had ν_{max} 1670 cm^{-1} and gave ^1H nmr signals (D_2O) at δ 2.35 (s, 3H), 2.75 (s, 3H), and 7.50 (t, J = 7 Hz, 1H). Repeated purification attempts using silica gel plates failed to remove saturated ketone (ν_{max} 1705 cm^{-1}) and other impurities completely.

*Photolysis of Endo Hydrochloride **5** (N-Methyl Anatoxin-a)*

The *endo* cyclopropyl ketone **5** (105 mg) was converted to its hydrochloride. This was dissolved in 10 ml of water and irradiated in a Vycor flask at 20°C using a Rayonet apparatus with lamps giving peak emission at 300 nm. Reaction was complete in 24 h. The water was removed *in vacuo*, then the product purified using two 20 cm^2, 1 mm thick plates using 4:1 chloroform–methanol as eluate under argon. The broad uv active zone with R_f 0.2 yielded 48 mg (46%) rich in *N*-methyl anatoxin-*a*. This was dissolved in 10:1 chloroform–methanol, filtered, then evaporated and dried *in vacuo*. The glassy solid had $[\alpha]_D$ +42° (*c* 1, methanol); ν_{max} 1670 cm^{-1}; λ_{max} 228 nm (ε 6200); ^1H nmr signals at 2.38 (s, 3H), 2.60 (s, 3H), 3.9 (m, 1H), 4.9 (br d, 1H), and 7.3 (t, J = 6 Hz, 1H).

*De-N-methylation of **12** (Anatoxin-a)*

N-Methyl anatoxin-*a* (**12**) hydrochloride (155 mg) was dissolved in 5 ml of water, the solution made strongly alkaline with cold sodium hydroxide solution, then the base extracted rapidly into methylene chloride. After drying and removal of the solvent, the base was dissolved in 10 ml of dry benzene. After addition of 190 mg of diethylazodicarboxylate the solution was refluxed for 2.5 h. The benzene was removed under reduced pressure and the residue taken up in a mixture of 4 ml of 95% ethanol and 4 ml of 2 *N* hydrochloric acid. This was refluxed for 3 h, then evaporated to dryness on a rotating evaporator. The products were separated on three 20 cm × 20 cm plates (thickness 1 mm) using 4:1 chloroform–methanol under argon. The desired product had R_f approximately 0.2. This zone (65 mg) was replated on one 20 cm × 20 cm × 1 mm plate under the same conditions giving 42 mg (29%) of quite pure anatoxin-*a* hydrochloride (**1**). This had $[\alpha]_D$ +36° (*c* 0.85, ethanol); λ_{max} 226 nm (ε 8500); ν_{max} 1670, 1642, and 1588 cm^{-1}. Its ^1H nmr spectrum had signals at δ 2.40 (s, 3H), 4.4 (m, 1H), 5.3 (m, 1H), 7.3 (t, J = 5 Hz, 1H), and a broad 2H signal between δ 8.3 and 9.0 (2H). These spectra corresponded well to those of natural anatoxin-*a* (**1**).

*N-Acetyl Derivative of **1** (N-Acetyl Anatoxin-a)*

The above hydrochloride (42 mg) was dissolved in 1 ml of acetic anhydride containing 200 mg of sodium acetate. This was heated 1 h at 60°C then left for 60 h at room temperature. The excess anhydride was removed under reduced pressure, the residue warmed with methanol, and the evaporation repeated. The residue was distributed between 5% sodium carbonate and methylene chloride. The organic phase gave 35 mg of product. This crystallized in part from acetone–hexane. The crystals were sublimed over a short path at 95°C/1 × 10^{-4} torr. The crystalline sublimate was washed once with ether, leaving 10 mg of crystals. These were recrystallized once from acetone–hexane. The *N*-acetyl derivative had mp 113–114°C, $[\alpha]_D$ −125 (*c* 0.6, ethanol), ν_{max} 1622 and 1663 cm^{-1} and λ_{max} 226 nm (ε 10 800). Its ^1H nmr spectrum had signals at δ 2.0 (s, 3H), 2.37 (s, 3H), 4.81 (br m, 1H), 5.29 (d, J = 8 Hz, 1H), and 7.02 (t, J = 6 Hz, 1H). Its spectra were identical to those of *N*-acetyl anatoxin-*a* (**1**) and a mixture mp showed no depression. *Anal.* calcd. for $C_{12}H_{17}O_2N$: C 69.54, H 8.27, N 6.75; found: C 69.71, H 8.39, N 6.58.

*Nor-anatoxin-a (**14**)*

(*a*) The *N*-methyl ketone **4** (98 mg, 9.59 mmol) in 1 ml of dry benzene and 0.2 ml of a benzene solution of phosgene (1 mmol) were mixed in an nmr tube in an ice bath, a small precipitate formed. After 30 min at 20°C the *N*-methyl signal had disappeared and a new methyl signal at lower field had appeared (CH_3Cl). After a further 30 min at 20°C the solvent was removed under reduced pressure. The residue was dissolved in water, and the solution left overnight at room temperature. After removal of the water, the product was sublimed at 100°C/1 × 10^{-4} torr. The partially crystalline sublimate was recrystallized from methanol – ethyl acetate mixture giving 15 mg, mp 232–235°C and 40 mg of less pure product.

The crystals had $[\alpha]_D$ −80° (*c* 1.62, methanol) and λ_{max} 225 nm (ε 10 600). Their ^1H nmr spectrum in D_2O had a 3H singlet 2.3 ppm upfield from the HOD signal (approximately δ 4.70) and a 1H triplet 2.45 ppm downfield from this reference signal. *Anal.* calcd. for $C_9H_{14}ClNO$: C 57.60, H 7.52, N 7.46; found: C 57.42, H 7.50, N 7.92.

The ^1H nmr spectrum of the free base **14** had signals at δ 2.27 (3H, s), 3.70 (1H, m), 4.27 (1H, m), and 6.68 (1H, t, J = 4 Hz).

(*b*) A solution of 207 mg of the *N*-methyl ketone **4** and 366 mg of diethylazodicarboxylate in 10 ml of dry benzene was refluxed for 18 h. After removal of the benzene *in vacuo* the residue was dissolved in a mixture of 6 ml of 2 *N* hydrochloric acid and 6 ml of 95% ethanol. The solution was refluxed for 4.5 h, then concentrated *in vacuo*, dilute sodium hydroxide added, and the base extracted into benzene. It was quickly reconverted to the hydrochloride. Only part was soluble in water, hence the solution was filtered. The filtrate was taken to dryness *in vacuo* then the residue crystallized from methanol – ethyl acetate giving 81 mg of nor-anatoxin-*a* hydrochloride mp 229–231°C. It proved identical to the product from (*a*).

Reactions of Exo Cyclopropyl Ketone ***6***

Photolysis of Exo Cyclopropyl Ketone ***6***

A solution of 373 mg of the hydrochloride of **6** in 12 ml of methanol was irradiated in a Vycor flask with lamps peaked at 300 nm in a Rayonet apparatus for 28 h. At the end of this time tlc showed absence of starting material and the presence of two more polar compounds as major products. The solvent was removed under reduced pressure, aqueous sodium hydroxide added, and the base extracted into methylene chloride. It was purified using six 0.5 mm × 20 cm × 20 cm plates with chloroform, acetone, methanol, and diethylamine (15:10:5:1) as developing solvent. The two major products had R_f 0.7 (84 mg) and 0.5 (114 mg). On some silica gel plates (more acidic?) the fast moving product appeared to be destroyed giving a more polar unsaturated alcohol which has not been fully characterized. Photolysis in water gave essentially the same products as above.

Tetracyclic Alcohol ***17***

The compound with high R_f was sublimed at 100°C 0.1 torr; mp 131°C $[\alpha]_D$ −54° (*c* 1.71, methanol), ν_{max} 3595 cm^{-1}. Its ^1H nmr spectrum had signals at δ 3.27 (d, J = 4 Hz, H_A), 3.17 (br m, $W_{1/2}$ 12 Hz, H_B), 2.87 (br m, $W_{1/2}$ 16 Hz, H_C), 2.28 (1H, s, OH), 2.10 (s, NCH_3), 1.50 (s, 3H), and signals for 2.7 hydrogens between δ 0.5 and 1.1. Tentative ^{13}C nmr chemical shift assignments based in part on multiplicities determined using off-resonance decoupling are indicated on the structure **17**. *Anal.* calcd. for $C_{11}H_{19}NO$: C 73.70, H 9.56, N 7.81; found: C 73.58, H 9.70, N 7.69. Yield 22%.

Tetracyclic Alcohol ***16***

The compound with lower R_f from the photolysis of **6** was distilled over a short path at 100°C/0.1 torr. The distillate crystallized in part. It had $[\alpha]_D$ −43° (*c* 0.97 methanol) and ν_{max} 3595 cm^{-1}. Its ^1H nmr spectrum had signals at 3.94 (d, J = 4 Hz, H_A), 3.1 (br m, $W_{1/2}$ = 14 Hz, H_B), 2.8 (br m, $W_{1/2}$ = 17 Hz, H_C), 2.46 (s, OH), 2.10 (s, N—CH_3), 1.13 (s, CH_3) and signals for 3.3H between δ 0.3 and 1.05. Tentative assignments of its ^{13}C nmr spectrum based on multiplicities from an off-resonance decoupled spectrum are indicated on the structure **16**. *Anal.* calcd. for $C_{11}H_{19}NO$: C 73.70, H 9.56, N 7.81; found: C 73.56, H 9.76, N 7.66. Yield 31%.

Lithium in Ammonia on Exo-cyclopropyl Ketone ***6***

A solution of 1.2 g of lithium in 250 ml of liquid ammonia (distilled over sodium) was prepared in a double-walled flask. To this was slowly added 1.57 g of the *exo* isomer **6** (>90% purity) in 50 ml of ether. The mixture was stirred for 3.5 h after completion of the addition, then 20 g of ammonium chloride added cautiously. After disappearance of the blue color the ammonia was evaporated in a stream of nitrogen. Water (100 ml) was cautiously added to the residue. This was saturated with sodium chloride, then extracted with five 100 ml portions of ether. The ether layers yielded 1.2 g (76%) of product consisting mainly of alcohols (ν_{max} 3600 cm^{-1}) but containing some unchanged cyclopropyl ketones (ν_{max} 1680 cm^{-1}). Its ^1H nmr spectrum had signals at δ 1.02 (d, J = 6 Hz) and 1.2 (d, J = 6 Hz) of almost equal intensity, total 3H; 2.14 (s, 3H) and a 6-line multiplet (probably a pair of partially superimposed quartets) at δ 3.9. There were signals for approximately two hydrogens between δ 0.25 and 1.0 (cyclopropane hydrogens).

The structure of these alcohols as simple products of reduction of the carbonyl was confirmed by oxidation. A solution of 113 mg of the alcohol mixture and 53 mg of chromium trioxide in 2 ml of acetic acid and 0.2 ml of water was heated at 45°C for 15 min, then stirred for 1 h at room temperature. The excess reagent was destroyed with methanol then the bulk of the solvents removed under reduced pressure. The residue was made strongly basic with 15% sodium hydroxide solution, then extracted with ether. The 78 mg of product had M^+ 179, and ^1H nmr and ir spectra nearly identical to those of *exo*-cyclopropyl ketone **6**.

Sodium in ethanol reduction of the *exo*-cyclopropyl ketone also gave a 1:1 mixture of the two alcohols.

The photodissociation of ammonia in the $\tilde{A} \leftarrow \tilde{X}$ absorption system. Part I. Deuterium isotope effects in the photodissociation[1]

S. KODA[2] AND R. A. BACK

Division of Chemistry, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received August 9, 1976

S. KODA and R. A. BACK. Can. J. Chem. **55**, 1380 (1977).

The photolyses of mixtures of NH_3, NH_2D, NHD_2, and ND_3 have been studied at wavelengths of 2144, 2139, 2062, and 1850 Å in the presence of C_3H_8 as a hydrogen atom scavenger. Quantum yields of dissociation have the same values for all four species, presumably unity. Analysis of the H_2 and HD produced permitted evaluation of intramolecular deuterium isotope effects in the photodissociation of NH_2D and ND_2H. At the two shortest wavelengths dissociation of H was favored by a factor of 2 or 3, while at 2144 and 2139 Å the isotope effect was much larger. Implications for the mechanism of the predissociation of the $\tilde{A}$-state of ammonia are discussed briefly. The system does not appear to be useful for the photochemical separation of deuterium.

S. KODA et R. A. BACK. Can. J. Chem. **55**, 1380 (1977).

On a étudié la photolyse de mélanges de NH_3, NH_2D, NHD_2 et ND_3 à des longueurs d'onde de 2144, 2139, 2062 et 1850 Å en présence de C_3H_8 servant de piège pour les atomes d'hydrogène. Les rendements quantiques de dissociation ont les mêmes valeurs pour les quatre espèces et sont probablement égales à l'unité. L'analyse de H_2 et de HD permet d'évaluer les effets isotopiques intramoléculaires du deutérium dans la photodissociation de NH_2D et ND_2H. Aux deux longueurs d'onde les plus courtes, la dissociation de H est favorisée par un facteur de 2 ou 3 alors qu'à 2144 et 2139 Å l'effet isotopique est beaucoup plus grand. On discute brièvement des implications pour le mécanisme de la prédissociation de l'état $\tilde{A}$ de l'ammoniac. Ce système ne semble pas utile pour la séparation photochimique du deutérium.

[Traduit par le journal]

Introduction

The photolysis of ammonia in its first absorption region ($\tilde{A} \leftarrow \tilde{X}$, ~2200–1700 Å) has been extensively studied, and the general features of the primary photodissociation are well established (1–3). The dissociation products are almost exclusively (>99%) H + NH_2, and the quantum yield is close to unity and independent of pressure. The absorption spectrum shows well-resolved vibrational bands in a long progression arising from excitation of the symmetric out-of-plane bending mode (ν_2') of the planar $\tilde{A}$ state (4, 5). In the case of NH_3 these bands are almost completely diffuse, showing no rotational fine structure; with ND_3, however, rotational lines are well resolved in the bands corresponding to $v_2' = 0$ or 1 (all higher members of the progression are diffuse) (5). It is apparent that the upper state is strongly predissociated, even in ND_3, as the rotational lines are considerably broadened, and the quantum yield of dissociation of unity, independent of pressure, confirms that the excited state must be very short-lived.

While it is agreed that the photolysis of ammonia proceeds through a predissociation, there is some uncertainty about the repulsive state involved, and the precise details of the predissociation are not clear (4–6). The striking difference in the spectra of NH_3 and ND_3 suggests that there could be a large deuterium isotope effect in the photodissociation, and the present work was undertaken to explore this possibility, and to gain a better understanding of the predissociation process. A further purpose was to explore the potential of the ammonia photolysis for photochemical isotope separation.

Experimental and Results

Apparatus

Ammonia was photolyzed in several cylindrical quartz reaction vessels, 5 cm in diameter, with plane Suprasil windows, and varying from 1 to 20 cm in length. These were sometimes used

[1]NRCC No. 15813.

[2]NRCC Postdoctoral Fellow, 1972–1974; present address: Division of Reaction Chemistry, Faculty of Engineering, University of Tokyo, Tokyo, Japan.

in simple static systems, and in other experiments were incorporated into a closed circulation loop with a ballast volume. Conditions were chosen, contingent upon the wavelength of the exciting light, the extinction coefficients, the light intensity, and the ammonia pressure, to ensure low conversion and moderately homogeneous absorption of light.

Light Sources

Four light sources were employed:

(*i*) A flat-spiral cadmium resonance lamp operated at 280°C. A 1 cm filter cell containing cadmium vapor at 500°C removed the 2288 Å resonance line, so that the effective light was almost entirely at 2144 Å.

(*ii*) A Philips Spectral zinc lamp, used with a 1 cm filter cell filled with about 75 torr each of NH_3 and ND_3. The filter removed the 2026 Å line completely and reduced the 2062 Å line to less than 0.4% of the 2139 Å radiation; the effective light was essentially pure 2139 Å radiation.

(*iii*) An iodine–argon microwave discharge lamp with a liquid water filter, which gave virtually monochromatic 2062 Å radiation (7).

(*iv*) A low-pressure flat-spiral mercury-resonance lamp, used as a source of 1850 Å radiation. The light path was flushed with N_2 to prevent absorption by O_2, O_3, and water vapor, and the system was mercury-free to avoid photosensitization by 1850 or 2537 Å light. Ammonia is transparent to the latter, so that the effective light was almost pure 1850 Å radiation.

The spectral purity of the light sources was determined with a 0.5 m grating monochromator and a photomultiplier, which were also used to monitor light intensity and absorption during the photolyses. A platinum-cathode phototube was sometimes used for the latter purpose with the iodine lamp (8).

Analysis

After irradiation, N_2 and H_2 were removed through a trap at −196°C and measured in a gas burette. The composition of the gas was determined by separating H_2 through a hot palladium thimble. When necessary, the isotopic composition of the hydrogen was measured by gas chromatography, using an alumina column, treated with $MnCl_3$, at −196°C (9). Isotopic composition of deuteriated ammonia was determined by decomposing the gas by a Tesla discharge, at the same time removing hydrogen through a hot palladium thimble, until the decomposition was complete, and finally measuring the isotopic composition of the hydrogen by gas chromatography as before.

Materials

Ammonia was obtained from Matheson, and ammonia-d_3 (99 atom% D) from Merck, Sharp and Dohme of Canada Ltd. Both were used after rigorous degassing and trap-to-trap distillation. The partially deuteriated ammonias, NH_2D and NHD_2, cannot be isolated, as H–D equilibration occurs within seconds of mixing the gases. To study these species, NH_3 and ND_3 were mixed in a known ratio, and equilibrium concentrations were calculated from equations based on the data of Pyper *et al.* (10). All the spectroscopic and photochemical experiments with NH_2D and NHD_2 were done with the four ammonias present at equilibrium; by suitable variation of the initial proportions of NH_3 and ND_3 and thence of the two mixed species, the properties of each of the latter could be determined, essentially in each case by solving two equations in two unknowns.

Propane was Research-grade, obtained from Matheson, and used without further purification. Gas chromatography confirmed that olefin content was negligible.

Ultraviolet Absorption Spectra

While the photographic spectra of both NH_3 and ND_3 are well known, quantitative extinction coefficients have apparently been reported only for NH_3 (11). The only information about the spectra of NH_2D and ND_2H comes from the work of Walsh and Warsop (4), who measured the wavelength of a few band heads from a plate in which the spectra of the four isotopic ammonias were badly overlapped. Since the present study required quantitative absorption spectra for the four species, low resolution spectra were measured on a Cary spectrophotometer, and are shown in Figs. 1 and 2. Each of the two isotopically mixed ammonias required a special technique to separate its spectrum from those of the other three components always present. Thus to measure the spectrum of NH_2D, NH_3 and ND_3 were mixed in a ratio of ~4/1, giving an $NH_3/NH_2D/NHD_2/ND_3$ ratio of about 50/39/10/1 in the sample cell. The reference cell of the double-beam instrument was then filled with NH_3 at a pressure calculated to balance exactly the partial pressure of NH_3 in the

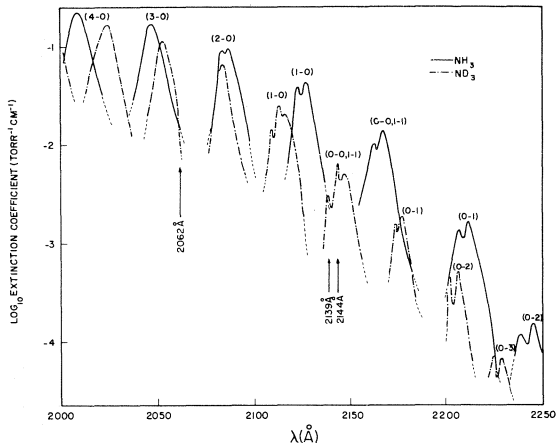

FIG. 1. Low resolution absorption spectra of NH_3 and ND_3. Values of v_2' and v_2'' are shown in parentheses for each band.

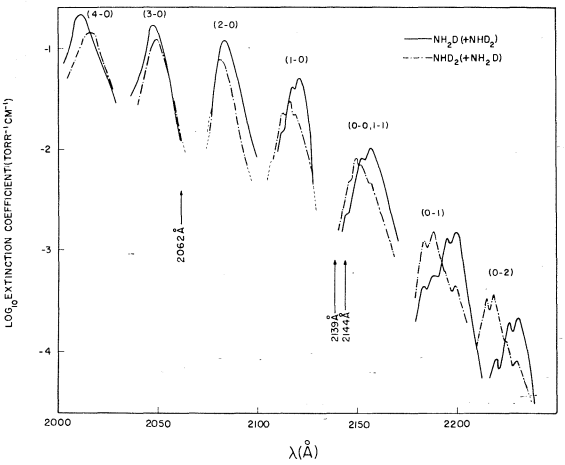

FIG. 2. Low resolution absorption spectra of NH_2D and NHD_2. Values of v_2' and v_2'' are shown in parentheses for each band.

sample, so that the measured difference spectrum was that of NH_2D with a small (20%) NHD_2 component and an almost negligible (2%) amount of ND_3. The spectrum of NHD_2 was obtained in a similar way with ND_3 in the reference cell. The spectra of the mixed ammonias in Fig. 2 have not been corrected for the minor component, and the ND_3 spectrum in Fig. 1 has not been corrected for the presence of a 12% ND_2H impurity.

The photolysis experiments required accurate values of the extinction coefficients for each of the isotopic ammonias at each of the four wavelengths employed. These were measured in the photolysis cells, using the photolytic light sources and a 0.5 m monochromator and photomultiplier to measure transmitted light intensity. Accurately linear Beer's Law behaviour was observed over a wide range of pressure and for each of a number of isotopic compositions. Values of ε for NH_3 were obtained directly, and those for ND_3 almost directly with only a small correction for the 3% of NDH_2 impurity. For the mixed ammonias, NH_3 and ND_3 were mixed in known proportions, and equilibrium compositions calculated. From Beer's Law plots at several compositions, making corrections for absorption by NH_3 and ND_3, extinction coefficients for NH_2D and NHD_2 were obtained by solving pairs of equations in two unknowns. Values of the molar decadic extinction coefficients for the four ammonias at the four photolysis wavelengths are shown in Table 1.

TABLE 1. Molar decadic extinction coefficients of isotopic ammonias

Wavelength (Å)	ε			
	NH_3	NH_2D	NHD_2	ND_3
2144	16.2	9.51	39.1	46.3
2139	43.2	13.8	9.25	31.7
2062	292	279	221	250
1850	1330	2500	3085	1750

While it is known that in the spectrum of ND_3, bands arising from $v_2' = 0$ or 1 show well-resolved rotational fine structure, and that with NH_3 all bands are almost completely diffuse,[3] the behaviour of NH_2D and NHD_2 had not been established, although it seemed probable that their spectra would be diffuse. Spectra of NH_3–ND_3 mixtures were therefore photographed at high dispersion, using the first order of a 10 m grating spectrograph.[4] From Fig. 2 it was possible to identify the bands due to the mixed ammonias, and it was clear that neither NH_2D nor NHD_2 shows any rotational fine structure. This was seen most clearly for the 0,1 band of ND_2H, which is almost free of overlap by the same band of ND_3. Other bands are more badly overlapped, but in no instance were sharp rotational features observed which

[3]Dixon (12) observed extremely faint rotational structure in the spectrum of NH_3. All four isotopic ammonias show broad rotational features at low resolution (Figs. 1 and 2) the double-headed band contours for all bands with $v_2' \leq 2$ arising from the P and R branch structure.

[4]We are grateful to Mr. F. Alberti of the Herzberg Institute for photographing these spectra.

could not be assigned to ND_3. Thus it appears that substitution of a single atom of D by H in ND_3 increases the rate of predissociation enough to completely obscure the rotational fine structure through the line broadening associated with the reduced lifetime of the excited state.

Photochemical Measurements

In order to measure the rate of the primary dissociation,

[1] $$NH_3 + h\nu \rightarrow NH_2 + H$$

the reaction with propane

[2] $$H + C_3H_8 \rightarrow H_2 + C_3H_7$$

was used, and the hydrogen produced was easily separated and measured. This system has been thoroughly studied by Schindler and coworkers (2, 3) and our results are in good accord with theirs. In order to make reaction 2 quantitative and therefore the H_2 a true measure of reaction 1, conditions must be carefully controlled. Propane pressure must be high enough, and the light intensity low enough, that loss of H by reaction with C_3H_7 or NH_2 is negligible. Conversion must also be kept low enough to avoid build-up of propylene from the disproportionation of C_3H_7 to concentrations at which loss of H by addition to the olefin becomes significant, and also to avoid secondary photolysis of hydrazine or propylamine. Figure 3 shows typical plots of $H_2 + HD$ and N_2 *vs.* propane pressure from the photolysis of an equimolar NH_3–ND_3 mixture, and it is seen that the yield of $H_2 + HD$ becomes constant above about 200 torr. It was also observed that under these conditions production of $H_2 + HD$ was a linear function of time and of light intensity, showing that the secondary reactions of products (which would be time-dependent) and reactions of H with C_3H_7 or NH_2 (which would be intensity dependent) were not important. It appears from these observations that essentially all of the H atoms formed in reaction 1 were reacting to form H_2.

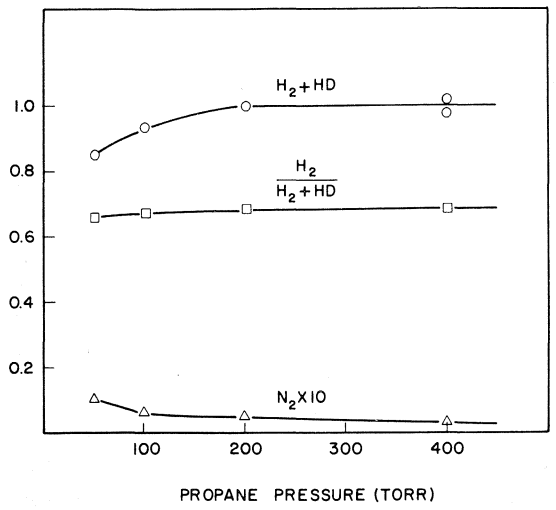

FIG. 3. Dependence of product yields on propane pressure, for photolysis of equimolar NH_3–ND_3 at 20 torr pressure, irradiated at 2139 Å.

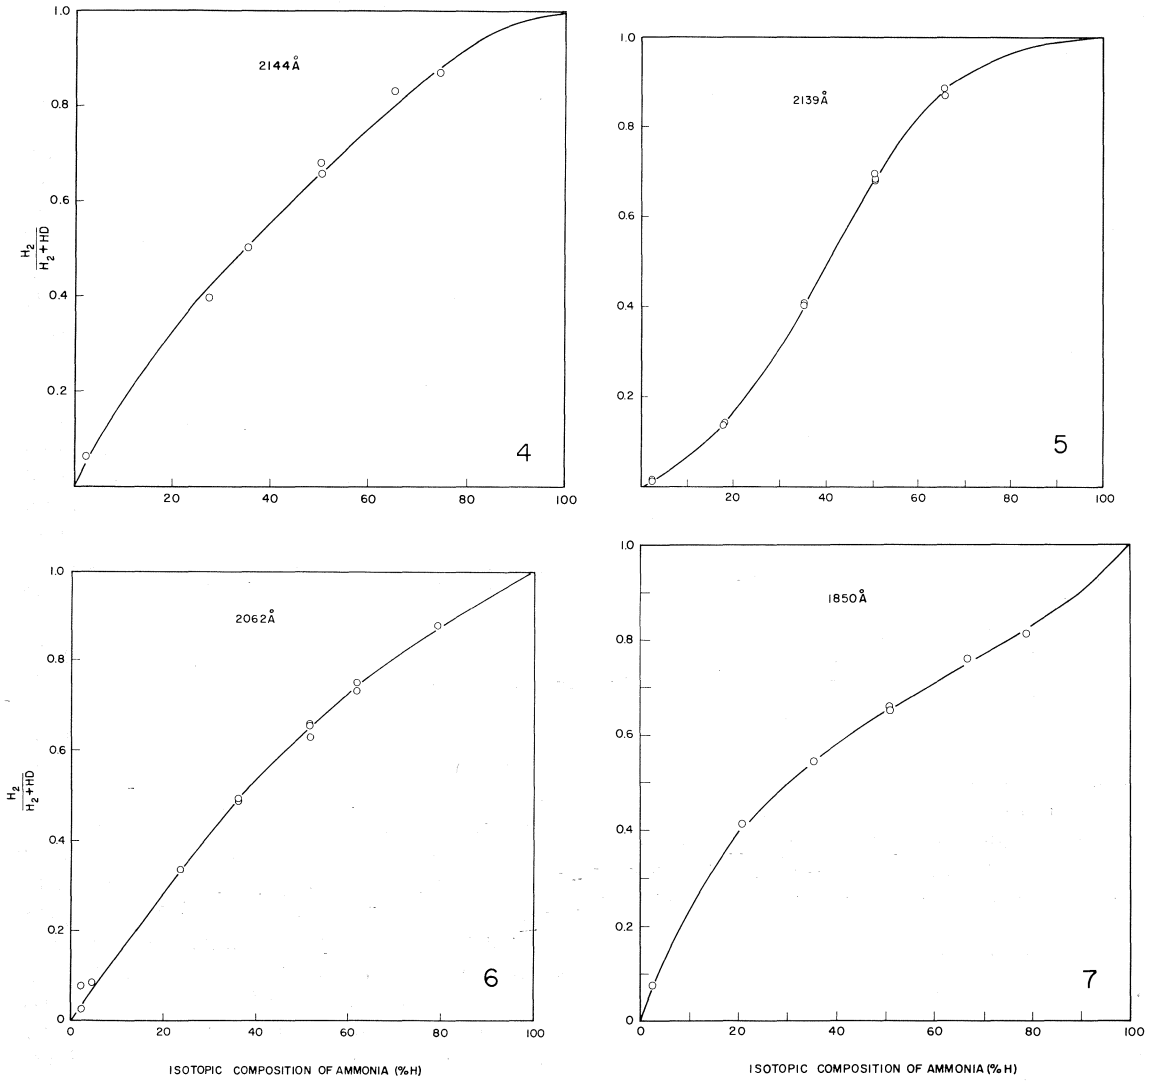
Before the yield of H_2 can be equated to the rate of reaction 1, the possibility of direct formation of H_2 as a primary photolysis product must be considered. It is well established that reaction 1 is the main process, and the present study confirms this. However, very careful measurements of the yield of D_2 from the photolysis of ND_3 in the presence of excess propane or ethylene (13) indicate the occurrence of a molecular process with a quantum yield ranging from ≤ 0.003 at 2139 Å to ≤ 0.009 at 1849 Å. Very small corrections for this process have been applied to the present results, assuming that these quantum yields are the same in the four isotopic ammonias.

Finally, in the experiments with the isotopically mixed ammonias, it is essential that H or D atoms produced in the primary photodissociation do not undergo exchange with either propane or ammonia before reacting with propane, so that the yields of HD and H_2 accurately reflect the primary yields of D and H respectively. Absence of exchange with propane is shown by the low yields of H_2 in the photolysis of ND_3 in the presence of propane which corresponded closely to that expected from the isotopic H impurity in the ND_3. Absence of exchange with ammonia is less easily demonstrated, but the self-consistent behaviour of the isotopically mixed systems over a wide range of conditions and the agreement with calculations that presume no such exchange are probably the best proof. Another possible source of error in the isotopic experiments is the reaction of H or D with hydrazine; the very low yields of D_2 from the photolysis of ND_3 in the presence of propane, in which hydrazine would be largely N_2D_4, show that this did not occur. Hydrazine concentration was low in the present system because of the low light intensity and high



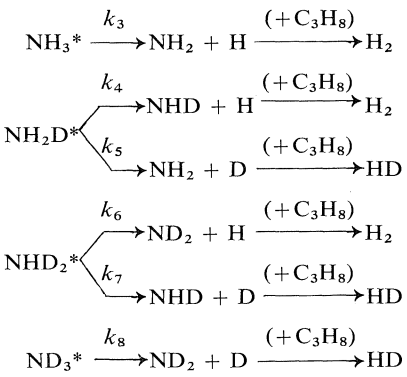
FIGS. 4, 5, 6, and 7. Isotopic composition of hydrogen from the photolysis of NH_3, NH_2D, NHD_2, and ND_3 in the presence of C_3H_8. Points are experimental, curves are calculated (see text).

propane pressure, which favor reaction of NH_2 radicals with propane rather than combination to form hydrazine (2); destruction of hydrazine by reaction with propyl radicals, leading eventually to N_2, is also a factor. The low yield of N_2 observed (Fig. 3) reflects the low concentration of hydrazine in the system.

Primary photodissociation yields of H and D atoms, based on the production of H_2 and HD by reaction with propane, were measured for mixtures of the isotopic ammonias ranging from pure NH_3 to 97% ND_3. The results are shown in Figs. 4, 5, 6, and 7 for photolysis at 2144, 2139, 2062, and 1850 Å respectively. In each figure are shown plots of the ratio $H_2/(H_2 + HD)$ against the atom% H in the ammonia mixture. The quantum yields of H_2 and HD were measured relative to that of H_2 from NH_3, taking this to be unity; no absolute quantum yields were measured. The quantum yield of total hydrogen (H_2 + HD) was independent of isotopic composition, showing that the quantum yield of dissociation has the same value in each of the four isotopic species (presumably unity) and therefore no intermolecular isotope effect can be observed.

Discussion

The photodissociation processes occurring in the mixtures of isotopic ammonias are the following:



[3] $NH_3^* \xrightarrow{k_3} NH_2 + H \xrightarrow{(+C_3H_8)} H_2$

[4] $NH_2D^* \xrightarrow{k_4} NHD + H \xrightarrow{(+C_3H_8)} H_2$

[5] $NH_2D^* \xrightarrow{k_5} NH_2 + D \xrightarrow{(+C_3H_8)} HD$

[6] $NHD_2^* \xrightarrow{k_6} ND_2 + H \xrightarrow{(+C_3H_8)} H_2$

[7] $NHD_2^* \xrightarrow{k_7} NHD + D \xrightarrow{(+C_3H_8)} HD$

[8] $ND_3^* \xrightarrow{k_8} ND_2 + D \xrightarrow{(+C_3H_8)} HD$

The variation of $H_2/(H_2 + HD)$ with isotopic composition at each wavelength depends on the extinction coefficients for each of the four ammonias, and on the intramolecular isotope effect in the photodissociation of NH_2D and NHD_2. The data points in Figs. 4 to 7 are experimental values; the smooth curves through them are calculated, in the following way. For a given atom% D in the ammonia mixture, relative concentrations of NH_3, NH_2D, NHD_2, and ND_3 were calculated from the equilibrium constants. Relative absorption of light by each species at each wavelength was then calculated, using the measured extinction coefficients (Table 1); then, assuming a quantum yield of unity, the relative amount of each species dissociated was obtained. Dissociation of NH_3 and ND_3 lead unambiguously to H_2 and HD respectively in amounts that are thus simply calculated. The remainder of the H_2 and HD must then arise from dissociation of the two mixed ammonias, reactions 4 to 7. The primary intramolecular isotope effect, I, in the photodissociation may be defined as $I_{NH_2D} = k_4/2k_5$ for NH_2D, and $I_{NHD_2} = 2k_6/k_7$ for NHD_2. For any two data points shown in Figs. 4 to 7, values of I_{NH_2D} and I_{NHD_2} can be obtained by solving two equations in two unknowns. In practice, the values of I for the two species were varied until the best least-squares fit to all the experimental points was achieved at each wavelength. The calculated curves shown in Figs. 4 to 7 correspond to these values, which are summarized in Table 2; also listed in parentheses are estimated limits of uncertainty.

TABLE 2. Intramolecular isotope effect, I, in the photolysis of NH_2D and NHD_2

λ (Å)	v_2'	I_{NH_2D}	I_{NHD_2}
2144	0, 1	Large	8.05 (6.3–10.7)
2139	0, 1	10.9 (2.1–large)	2.64 (1.5–19.3)
2062	3	1.90 (1.55–2.16)	2.32 (2.06–2.68)
1850	9, 10	1.95 (1.62–2.41)	3.15 (2.63–3.81)

Values of I_{NH_2D} are listed as 'large' when the yield of HD was entirely accounted for by the estimated production of D atoms from the other isotopic ammonias, leaving a yield of zero, within experimental accuracy, from the photolysis of NH_2D. The values of I in Table 2 show a significant dependence on the exciting wavelength. For the two shortest wavelengths the best estimates are within the range 1.9–3.2, which can be regarded as a fairly normal primary kinetic deuterium isotope effect. There is also probably a significant difference between NH_2D and NHD_2 at these wavelengths, which can be interpreted as a preference for the dissociation of the lone hydrogen isotope from each species, *i.e.*, D from NH_2D and H from NHD_2, superimposed on the primary isotope effect. Values of I at 2139 Å are rather uncertain because of the small fraction of light absorbed by the mixed species (Table 1) and consequent large correction for H and D produced by dissociation of NH_3 and ND_3. The data are not incompatible, however, with fairly large values of I. At 2144 Å, I is unmistakably much larger than at the two shorter wavelengths.

The present experiments thus show a sizeable intramolecular deuterium isotope effect in the photodecomposition of NH_2D and NHD_2, complementing the earlier spectroscopic observation of a large intermolecular isotope effect between NH_3 and ND_3. It is interesting that the abnormally large effects at 2139 and 2144 Å correspond to dissociation from the $v_2' = 0$ and $v_2' = 1$ levels of the $\tilde{A}$ state, the same levels which in ND_3 show resolved rotational structure indicative of a long lifetime. The large isotope effect suggests a tunnelling process, either through a barrier or between potential energy surfaces, while the lower, more normal values of I at 2062 and 1850 Å are more characteristic

of passage over a potential barrier. The detailed mechanism of the predissociation will be discussed in a subsequent paper (13).

Finally, the possibility of using the photolysis of ammonia for hydrogen–deuterium separation may be assessed. It is clear that separation of deuterium by selective photolysis of the ~0.03% of NH_2D present in natural ammonia is not promising. Overlap of the spectra of NH_3 and NH_2D (Figs. 1 and 2) would probably limit selectivity in the absorption of light in an equimolar mixture to no better than a factor of 10; it has been seen that dissociation of H rather than D from NH_2D is strongly favored, and it is not apparent how to trap the NHD fragment in a form which will not readily exchange its hydrogen with ammonia, the starting material. On the other hand, photochemical removal of quite small fractions of NHD_2 from ND_3 appears much more favorable; the discrete nature of the ND_3 spectrum would permit highly selective photolysis of NHD_2 at appropriate wavelengths, and the H atoms preferentially dissociated in the photolysis could be easily trapped by a hydrocarbon scavenger, or, with some loss of efficiency, simply by reaction with the hydrazine formed in the photolysis. There would seem to be little practical value in such a separation, however, unless for some reason ND_3 of very high isotopic purity were required.

The photolyses of NH_3 and ND_3 have been studied at 2139, 2062, and 1850 Å in the presence of propane and ethylene. Upper limits (none was actually observed) were established for the quantum yields of molecular dissociation of D_2 from ND_3 of 0.003 and 0.004 at 2139 and 2062 Å, while at 1850 Å a definite yield of 0.009 was obtained. Similar results were observed with NH_3. From the dependence of hydrogen yields on the ratio of ethylene to propane, it was concluded that H and D atoms were produced in the photolysis with excess translational energy. Values of the integrated reaction probability (IRP) of hot H atoms with propane were estimated to be 0.078, 0.070, and 0.045 at 2139, 2062, and 1850 Å respectively, while corresponding values for hot D atoms from ND_3 were 0.083, 0.062, and 0.029. Implications of the decrease in IRP with increasing photon energy are discussed, and it is concluded that at the shorter wavelengths a second dissociation channel leading to $NH_2(^2A_1)$ becomes important. A mechanism for the predissociation of the $\tilde{A}$-state of ammonia is presented which accounts for this behaviour and for the deuterium isotope effects observed previously. It is suggested that the dissociation does not follow the state correlation rules for dissociation in the plane of the molecule, at least when the ν_2 out-of-plane bending vibration in the $\tilde{A}$-state is excited to levels of $v_2 = 2$ or higher.

R. A. BACK et S. KODA. Can. J. Chem. **55**, 1387 (1977).

On a étudié la photolyse de NH_3 et ND_3 à 2139, 2062 et 1850 Å en présence du propane et d'éthylène. On a établi que les limites supérieures (en fait aucun n'a été observé) pour les rendements quantiques de la dissociation moléculaire de D_2 à partir de ND_3 sont égales à 0.003 et 0.004 à 2139 et 2062 Å alors qu'à 1850 Å un rendement bien défini de 0.009 peut être obtenu. On a pu observé des résultats semblables avec NH_3. A partir de la dépendance des rendements d'hydrogène sur les rapports d'éthylène sur propane, on peut conclure que les atomes de H et de D peuvent être produits lors de la photolyse avec une énergie de translation en excès. On a estimé que les valeurs des probabilités de réaction intégrée (PRI) des atomes d'hydrogène chauds avec le propane sont respectivement de 0.078, 0.070 et 0.045 à 2139, 2062 et 1850 Å alors que les valeurs correspondantes pour les atomes de deutérium chauds à partir de ND_3 sont 0.083, 0.062 et 0.029. On discute des implications de la diminution des PRI avec une augmentation de l'énergie photonique et on en conclut qu'aux longueurs d'ondes les plus courtes, un second chemin de dissociation conduisant à $NH_2(^2A_1)$ devient important. On présente un mécanisme pour la prédissociation de l'état $\tilde{A}$ de l'ammoniac qui tient compte de ce comportement ainsi que des effets isotopiques du deutérium observés antérieurement. On suggère que la dissociation ne suit pas les règles de corrélation d'état pour la dissociation dans le plan de la molécule, au moins lorsque la vibration de déformation angulaire hors-plan, ν_2, de l'état $\tilde{A}$ est excité à des niveaux de $v_2 = 2$ ou plus élevé.

Introduction

The present papers are concerned with the mechanism of the photodissociation of ammonia in its first absorption band, the $\tilde{A} \leftarrow \tilde{X}$ transition. Part I described the measurement of deuterium isotope effects in the photodissociation (1). It is well established that much of the excess energy released in the photolysis of simple hydrides such as HBr, HI, or H_2S appears as translational energy of the hydrogen atoms produced (2–13). With increasing molecular complexity, more of the excess energy may be distributed among the vibrational and rotational modes of the fragments, and knowledge of the translational energy of the hydrogen atoms should yield valuable information about this distribution and about the way in which the molecule dissociates. The present paper describes an experimental estimation of the

translational energy of the hydrogen atoms formed in the photodissociation of ammonia.

Experimental

Light sources, reaction vessels, and experimental procedures were essentially as previously described (1). Wavelengths employed were 2139, 2062, and 1850 Å, and all experiments were at 295 K. Ammonia pressures were low (5 to 20 torr) and in most experiments a high pressure, usually 300 torr, of propane was present; light intensities and conversions were such that in the absence of ethylene, essentially all the hydrogen atoms produced reacted with propane to form H_2 (1). The translational energy of the hydrogen atoms was estimated by adding ethylene to the system and studying the competition between their reactions with ethylene and propane. Other experiments were done with ammonia–ethylene mixtures, without propane, to assess the yield of molecular H_2 in the photodissociation, and appropriate blank experiments were done to permit corrections to be made for H or H_2 arising from the photolysis of propane or ethylene. Quantum yields were measured relative to the yield of H_2 from photolysis of NH_3 in the presence of 300 torr of propane, which was assumed to be unity (1).

Results and Discussion

Molecular Hydrogen Formation

Because formation of molecular hydrogen in the photodissociation can lead to experimental observations in the ammonia–propane–ethylene system very similar to those expected for translationally hot hydrogen atoms, this will be dealt with first. Ethylene is known to react rapidly with thermal hydrogen atoms to form ethyl radicals which disappear in secondary reactions yielding no H_2. In the photolysis of ammonia–ethylene mixtures, limiting yields of H_2 at high pressures of ethylene can arise from (*a*) photodissociation of ammonia to yield H_2, (*b*) photodissociation of ethylene to yield H_2, (*c*) abstraction of H from ethylene by hot H atoms, and (*d*) abstraction of H from ammonia by hot H atoms. Process (*b*) can be corrected for by blank photolyses of ethylene alone, and the best estimates of (*a*) come from experiments with ND_3–C_2H_4 mixtures, in which the yield of D_2 should be an unambiguous measure of the molecular dissociation if (*d*) can be neglected. Results are shown in Table 1. At the two longest wavelengths, total noncondensible gas was barely measurable and could not be analyzed for D_2 content; only upper limits for the yield of D_2 are shown, and there is no positive evidence that molecular elimination of D_2 occurs at all. At 1850 Å, however, there is definite evidence for molecular elimination with a quantum yield of about 0.009. The low yields of D_2 at 2139 and 2062 Å put upper limits on (*d*), the abstraction of D from ND_3 by translationally hot D atoms. It will be seen that this is probably even less likely at 1850 Å, as the D atoms have less translational energy, and there is no evidence that it occurs at all.

Values of the quantum yield of D_2 in Table 1 should at least be firm upper limits for the molecular dissociation of D_2 from ND_3. Experiments with NH_3 were in substantial agreement, although less accurate, and there seems to be no large isotope effect in this process. The upper limit of 0.003 at 2062 Å is in good agreement with similar limits of 0.003 and 0.005 for ND_3 and NH_3 respectively reported by Schindler and co-workers (14) and confirm that molecular elimination is virtually negligible at this wavelength. Our value of 0.009 at 1850 Å is significantly lower than the value $<4\%$ reported by McNesby *et al.* (15) for NH_3. The latter value, however, was based on a yield of H_2 from a NH_3–C_2D_4 mixture, which was about 3.5% of that from pure NH_3; the quantum yield of H_2 from pure NH_3 is certainly less than unity (14), and could be as low as 0.3 at the relatively high light intensities employed, which would lead to an absolute quantum yield for molecular H_2 production of about 1%, in good agreement with our value.

Estimation of Translational Energy of Hydrogen Atoms

Figure 1 shows Φ_{H_2}/Φ_H in the NH_3–C_3H_8–C_2H_4 system, plotted against the C_2H_4/C_3H_8 ratio, for photolysis at 2139, 2062, and 1850 Å. Values of Φ_H are based on the hydrogen yield from the system in the absence of ethylene, under conditions where H atoms are quantitatively converted to H_2 (1). Both Φ_H and Φ_{H_2} at 2062 and 1850 Å are corrected for maximum molecular hydrogen formed directly from the photolysis of NH_3, C_2H_4, and C_3H_8, evaluated in suitable blank experiments as discussed above. The vertical bars indicate the uncertainty associated with this correction, which becomes appreciable at 1850 as the photolysis of ethylene becomes more important. Corrections at 2139 were well within the accuracy of the measurement and none were made.

If the reduction in Φ_{H_2}/Φ_H shown in Fig. 1 arose from a simple competition between ethylene and propane for thermally equilibrated H

TABLE 1. Hydrogen yields from photolysis of ND_3–C_2H_4 mixtures

λ (Å)	P_{ND_3} (torr)	$P_{C_2H_4}$ (torr)	Yield (%) H_2	HD	D_2	D_2 (quantum yield)
2139	11.2	53.2	(Not measurable)			<0.0030
	10.9	126.6	(Not measurable)			<0.0026
2062	10.9	142.4	(Not measurable)			<0.0036
	11.1	50.6	(Not measurable)			<0.0044
1850	10.2	53.3	93.8	—	6.2	<0.0085
	10.1	142.4	97.1	—	2.9	<0.0099

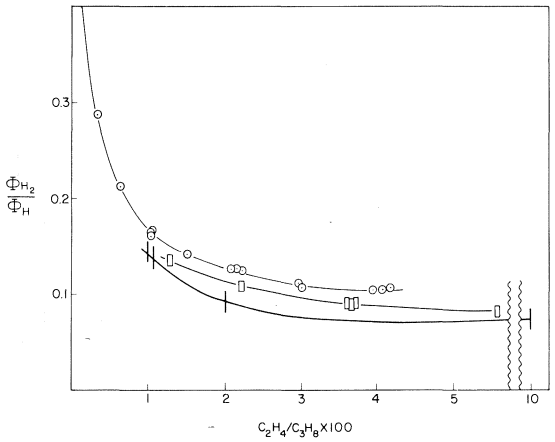

FIG. 1. Dependence of H_2 yield from the photolysis of NH_3 on the ethylene/propane ratio. Propane pressure = 200–500 torr, NH_3 pressure = 5–20 torr. ○ = 2139 Å, □ = 2062 Å, ■ = 1850 Å.

atoms, a steady reduction with increasing C_2H_4/C_3H_8 ratio would be expected, tending in the limit towards zero. It can easily be shown also that a reciprocal plot of the same data should be linear with an intercept of unity; Fig. 2 shows such a plot. It is clear from Figs. 1 and 2 that the behaviour observed is not characteristic of thermal H atoms; in simple terms, the H atoms become progressively more difficult to scavenge with ethylene as more and more ethylene is added. It has been seen that formation of molecular hydrogen, which might account for these observations, is small and has been corrected for, and it appears that the presence of translationally excited H atoms offers the only reasonable explanation. The following reactions must then be considered in the NH_3–C_2H_4–C_3H_8 system:

[1] $NH_3 + h\nu \rightarrow NH_2 + H^*$

[2] $H^* + C_3H_8 \rightarrow H_2 + C_3H_7$

[3] $\rightarrow H + C_3H_8$

[4] $H^* + C_2H_4 \rightarrow C_2H_5$

[5] $\rightarrow H + C_2H_4$

[6] $H + C_3H_8 \rightarrow H_2 + C_3H_7$

[7] $H + C_2H_4 \rightarrow C_2H_5$

where H^* represents a translationally hot hydrogen atom. It can be seen that

[8] $$\Phi_{H_2} = \frac{k_2P + [k_6P(k_3P + k_5E)/(k_6P + k_7E)]}{(k_2 + k_3)P + (k_4 + k_5)E}$$

where P and E are pressures of propane and

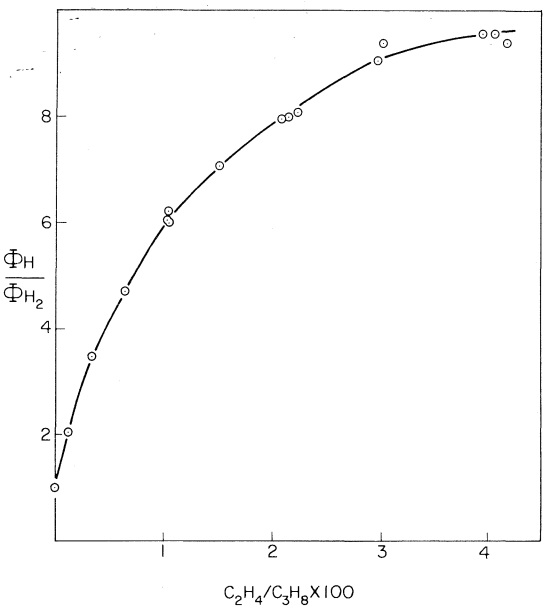

FIG. 2. Reciprocal plot of the data from Fig. 1; this should be linear for H-atoms with thermal energies.

ethylene, from which one obtains

$$[9]\quad \frac{\Phi_{H_2}}{1-\Phi_{H_2}} = \frac{(k_2+k_3)k_6P^2 + (k_2k_7+k_5k_6)PE}{(k_4k_6+k_3k_7)PE + (k_4+k_5)k_7E^2}$$

If k_3, k_4, and k_5 are all about the same order of magnitude, as seems probable, and $P \gg E$ as in the present experiments, the second term in the denominator can to a good approximation be neglected. Then

$$[10]\quad \phi/(1-\phi) = \alpha + \beta(P/E)$$

where

$$\alpha = (k_2k_7 + k_5k_6)/(k_4k_6 + k_3k_7) \approx k_2/k_3$$

(as it will be seen that $k_2k_7 \gg k_5k_6$ and $k_3k_7 \gg k_4k_6$) and

$$\beta = (k_2+k_3)k_6/(k_4k_6+k_3k_7) \approx (k_6/k_7) \times (1 + (k_2/k_3))$$

(since $k_7 \gg k_6$). Figure 3 shows plots of $\phi/(1-\phi)$ *vs.* P/E for both NH_3 and ND_3 for the photolysis at 2139 Å; these are linear within the accuracy of the data. Figure 4 shows similar plots for the less accurate and less extensive data at the two shorter wavelengths together with the straight lines taken from Fig. 3 for comparison. Table 2 shows values of α and β, and approximate values of k_2/k_3 and k_6/k_7 derived from the plots in Figs. 3 and 4 via eq. 10. Values of the integrated reaction probability (IRP) for reaction with propane, given in our system by $k_2/(k_2+k_3)$ are also shown, and in Table 3 values of IRP are shown which were obtained with some diatomic photolytic sources of hot H or D atoms in which the translational energy was well defined.

The foregoing treatment of the experimental data is an approximate one, but sufficiently accurate for present purposes. It should be noted that k_2, k_3, k_4, and k_5 are not simple rate constants but are effective mean values appropriate to the actual distribution of translational energies of atoms in the system. The latter is a complex function of the original distribution formed in the photolysis, the energy-loss processes (reactions 3 and 5) which reduce the translational energy towards its thermal equilibrium value, and the reactions, 2 and 4, which remove atoms from the system. The IRP is the average probability that an atom will react with propane to form H_2 between the time of its formation in the photolysis and the time at which its energy has been reduced to the thermal equilibrium value (6). The values of k_6/k_7 obtained (Table 2) are in fair agreement, con-

sidering the errors and approximations involved, with a value of about 0.6×10^{-3} for H atoms which may be extrapolated from Yang's measurements (16). It is interesting to note the inverse isotope effect of about 2.7 in the k_6/k_7 ratio. Since one expects a normal isotope effect in both reactions, the inverse effect in the ratio must arise from a difference between the two, which probably implies a quite large normal isotope effect in the addition reaction.

The present results provide strong evidence for the formation of translationally hot hydrogen atoms in the photolysis of ammonia. The values of the IRP obtained are lower than those reported for other hot-atom systems (Table 3), so that the latter cannot provide an accurate calibration for the present system. A comparison of the data, however, suggest that the highest values of the IRP observed (at 2139 Å) must correspond to translational energies of no more than 20 kcal/mol and probably rather less; this may be compared with a theoretical maximum value of about 26 kcal/mol. The most striking feature of the data in Table 2 is the decrease in IRP, and thence presumably in the translational energy of H or D, with decreasing wavelength. This result was unexpected and difficult to explain, and will be seen to lead to important conclusions about the mechanism of the predissociation. It is not an artifact of our treatment of the data; it is evident from the simple experimental results in Fig. 1 that hydrogen atoms are more easily scavenged by ethylene at the shorter wavelengths. While the uncertainty in the data at 2062 and 1850 Å is considerable, the downward trend in the IRP seems well beyond the limits of experimental error.

The values of the IRP are closely similar in the NH_3 and ND_3 systems, with those in the latter perhaps falling off significantly faster with decreasing wavelength. The maximum energy theoretically available for translational excitation of H and D is almost the same, so that the similar IRP values imply small isotope effects in the k_2/k_3 ratio. Since both reactions 2 and 3 might be expected to show sizeable isotope effects, these must approximately cancel in the ratio.

The Mechanism of the Predissociation

There has been some uncertainty about the electronic structure of the first excited singlet state, $\tilde{A}$, of ammonia and the mechanism of its predissociation (17–20). It has been shown that the $\tilde{A}$-state is planar (D_{3h}) with electronic symmetry A_2''. It is agreed that it is formed by excitation of a lone-pair electron to an orbital of a_1' symmetry and thus has an electron configuration $\ldots (2a_1')^2\sigma_{N-H}.(1e')^4\sigma_{N-H}.(1a_2'')n.(3a_1')$. The uncertainty has concerned the identity and nature of the $3a_1'$ orbital. As Walsh and Warsop pointed out (17), there will be two valence-shell orbitals (*i.e.*, derived from the 2*p* orbitals of N), essentially antibonding (σ^*), complimentary to the bonding $2a_1'$ and $1e'$ orbitals, and the lowest of these will be of a a_1' symmetry. There will also be a Rydberg orbital, again of a_1' symmetry, derived from and closely resembling the 3*s* orbital of the N atom. Walsh suggested that the $\tilde{A}$-state was the Rydberg state formed by excitation of a lone-pair electron to this orbital and that it was predissociated by interaction with the σ^* state formed by excitation to the σ^* orbital. Others (18, 19) have argued that there is only one orbital of a_1' symmetry expected at this energy level, and therefore only a single excited state. Robin (20), however, has discussed such "conjugate pairs" of Rydberg and valence-shell orbitals in some detail, and it seems clear that there should indeed

be two distinct orbitals, both with a_1' symmetry and having very similar nodal structure; the bonding properties however will be quite different, with the Rydberg orbital almost non-bonding and the σ^* orbital strongly anti-bonding.

While the existence of two distinct orbitals, Rydberg and σ^*, seems clear, they are probably very strongly mixed in the $\tilde{A}$-state (20). Calculations by Horsley and Flouquet (21) for example indicated a state largely Rydberg in character at small H—NH_2 displacements and mostly σ^* as the H—NH_2 bond is stretched. Thus the two states interact so strongly that the crossing will be totally avoided, and the predissociation cannot be described as that of one state by another, but rather as the homogeneous vibrational predissociation of a single state (Herzberg's Case II predissociation (19)). This description of the $\tilde{A}$-state is in accord with the fact that it is strongly bound with respect to symmetric bending; vibrational structure arising from excitation of ν_2' remains well defined throughout the absorption band, showing in fact slight negative anharmonicity (17) and a value of ν_2' not greatly reduced from that in the ground state. The symmetric stretching vibration is also probably excited in the transition (22, 23). Yet the molecule is strongly predissociated even from the (0000) level. The description is also in accord with the observation that the $\tilde{A}$-state is much less subject to pressure broadening than would be expected for a pure Rydberg state although showing typical Rydberg behaviour in some other respects (20).

Any model for the predissociation of the $\tilde{A}$-state must take into account the following observations:

(*1*) Decomposition into $NH_2 + H$ occurs with a quantum yield of one from all levels of the $\tilde{A}$-state. Lifetimes of 2 and 7 ps can be estimated from linewidths (18, 23) for the (0000) and (0100) vibrational levels of ND_3, *i.e.*, the (0000) level decomposes *faster* than the vibrationally excited (0100) level. Higher levels of ND_3 are all much shorter lived, while the longest lifetime of any excited level of NH_3 must be less than about 0.5 ps. The lifetimes of ND_3 in its two lowest levels are short but nevertheless correspond to many vibrations of the molecule; there must therefore be a potential well of appreciable depth in the D—ND_2 co-ordinate.

(*2*) There is a very large intramolecular isotope effect in the decomposition of NH_2D and NHD_2 from $v_2' = 0$ and 1, favouring the dissociation of H; from higher vibrational levels a more normal value of 2 or 3 is found (1). There is also a very large intermolecular isotope effect between NH_3 and ND_3, again evident only in the lowest vibrational levels.

(*3*) The present study has shown that the translational energy of the H or D atom produced in the photolysis *decreases* with increasing photon energy, from 2139 to 2062 to 1850 Å.

The simplest model that might be considered for the predissociation is shown in Fig. 5 for ND_3; this is very similar to that suggested by Douglas (18). If the potential barrier in the $\tilde{A}$-state lies between $v_2 = 1$ and $v_2 = 2$, then dissociation from $v_2 \geq 2$ would involve simple passage over the barrier, accounting for the short lifetime and the small isotope effect. Dissociation from $v_2 = 0$ or 1 would have to occur by "tunnelling" through the barrier, a slower process typically associated with a large deuterium isotope effect, as observed. The observation that decomposition from the $v_2 = 0$ level is about 3 times faster than from $v_2 = 1$ is

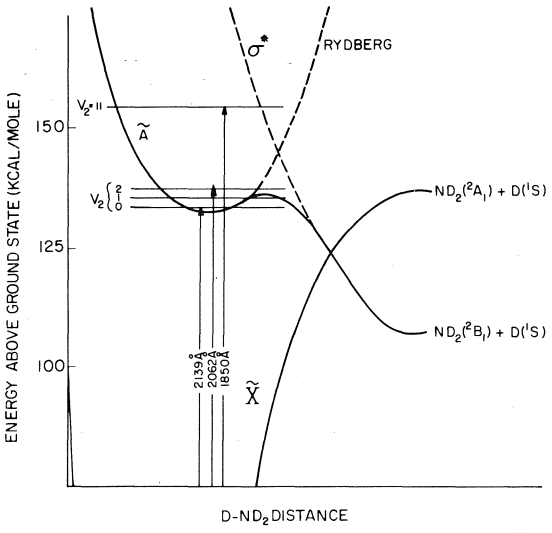

FIG. 5. Model for the predissociation of the $\tilde{A}$-state of ND_3. Correlation with products is for dissociation in the plane of the molecule. Energy levels are accurate, based on $\Delta H_f^0(ND_2) = 46.2$ kcal/mol at 0 K, and spectroscopic data for the $\tilde{A}$-state (18) and ND_2 (27). Potential curves are qualitative. Dotted lines represent hypothetical unperturbed Rydberg and σ^* states.

most plausibly explained by the fact, first pointed out by Longuet-Higgins (as quoted by Herzberg (ref. 19, p. 466)), that dissociation into ND_2 and D in their ground states is vibronically forbidden for odd values of v_2.

While the model shown in Fig. 5 can thus account for most of the features of the predissociation, it appears incapable of explaining the decrease in translational energy of the D or H atoms with increasing photon energy. It can be argued that the excess energy is initially in the v_2 out-of-plane bending vibration, and on dissociation will tend to go into rotational and vibrational excitation of the ND_2 or NH_2 radical rather than appearing as translational energy of the dissociating fragments. While this could lead to a hydrogen atom energy almost independent of photon energy, it is difficult to see how it could yield the observed inverse dependence. The most probable explanation of the latter would appear to be decomposition of the $\tilde{A}$-state by two channels, forming not only the ground-state products as shown in Fig. 5, but also $ND_2(^2A_1) + D$. At 2139 Å only the ground-state channel is energetically possible, but at 2062 and 1850 Å, ND_2 or NH_2 could be excited to the $^2A_1$ state. In the latter process much less translational energy could be imparted to the fragments, and if this channel became progressively more important at 2062 and 1850 Å, the observed dependence of translational energy on wavelength could be accounted for. Formation of excited ND_2 radicals by dissociation of the $\tilde{A}$-state is of course not allowed by the symmetry correlations shown in Fig. 5. These correlations however are based on dissociation in the plane of the molecule (18), and it may be questioned how strictly they apply if dissociation occurs out of the molecular plane, as appears not unlikely at 2062 and 1850 Å when the out-of-plane vibration is highly excited ($v_2 = 3$ and 9 respectively). There is some quite independent evidence that the planar state-correlations are not in fact obeyed in the ammonia system. From Fig. 5 it is clear that in-plane interaction of H with NH_2 in their ground states would not correlate with the ground state of NH_3, and one would expect the combination reaction to be slow, involving an intersystem crossing and probably a potential barrier. There is good experimental evidence that this and other combination reactions of NH_2 which would encounter the same difficulty are in fact very fast, occurring almost at the collision rate. Evleth has very recently considered this problem (25) and has shown by potential surface calculations that if the interaction is not constrained to planar geometry, NH_2 and H in their ground states interact on a smooth attractive surface to form the ground state of NH_3; *i.e.*, the $\tilde{A}$-state and the ground state interact strongly near their dissociation limits and the crossing shown in Fig. 5 is totally avoided. A corollary of course is that the $\tilde{A}$-state when not restricted to dissociation in the molecular plane can correlate with $NH_2(^2A_1) + H$. This leads to a model for the predissociation of the $\tilde{A}$-state, shown in Fig. 6 for ND_3, which appears to offer a much more satisfactory explanation of the experimental facts. The potential curve for the $\tilde{A}$-state is now determined by the interaction of 3 electronic states; the Rydberg and the valence-shell states strongly mixed as before, and what is formally the ground state in planar geometry interacting strongly as the dissociation limit is approached, leading to dissociation into $ND_2(^2A_1) + D$. The rapid predissociation of all levels of the $\tilde{A}$-state with $v_2 > 1$ now has a simple explanation; if $\Delta H_f^0(ND_2)$ at 0 K = 46.2 kcal/mol, a value which can be roughly estimated from $\Delta H_f^0(NH_2)$ at 298 K = 45.0 (26), then the dissociation limit of the $\tilde{A}$-state lies between $v_2 = 1$

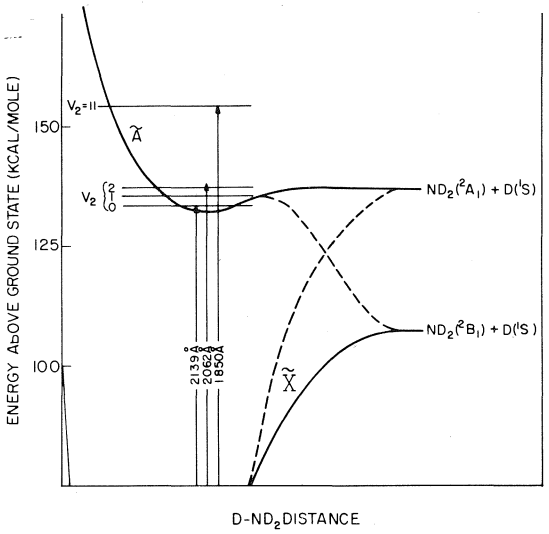

FIG. 6. Model for the predissociation of the $\tilde{A}$-state of ND_3, as in Fig. 5 but with product correlations for non-planar dissociation.

and $v_2 = 2$, so that above $v_2 = 1$ the molecule can dissociate rapidly by a vibrational predissociation, *i.e.* a simple unimolecular decomposition. For the $v_2 = 0$ and 1 levels this is energetically impossible and the predissociation must proceed by crossing to the ground state; this will be slower and should show a strong deuterium isotope effect, as observed, as the H or D atom tunnels between the potential surfaces. Dissociation to ground-state products from these levels may also be favoured because the out-of-plane vibration is not highly excited and the dissociation will therefore tend to occur not far out of the molecular plane and to follow the channel predicted by the planar symmetry correlations. The slower dissociation from the $v_2 = 1$ level can probably be explained as before by the influence of vibronic selection rules.

The predissociation mechanism shown in Fig. 6 provides a reasonable explanation of the translational excitation of the D or H atoms produced. At 2139 Å the $\tilde{A}$-state is excited to the $v_2 = 0$ level in ND_3 and the $v_2 = 0$ or 1 levels in NH_3, in which absorption in the $(0100) \leftarrow (01^+00)$ hot band is appreciable. Energy of about 28 to 30 kcal/mol is released on dissociation to ground-state $NH_2 + H$ or $ND_2 + D$, and from conservation of momentum a maximum of between 25 and 28 kcal/mol could be converted to translational energy of the H or D atom. As noted earlier the present experiments did not permit a precise measurement of translational energies, but it was probably something less than 20 kcal/mol at 2139 Å. The remainder of the energy released may be assumed to go into vibrational and rotational excitation of the amino radical in what appears a reasonable partition of energy. Dissociation at 2062 Å ($v_2 = 3$) to give amino radicals in the $^2A_1$ state can release very little translational energy, no more than 3 kcal/mol, and the observed reduction in the translational energy of the H and D atoms can be attributed to the onset of this process. The fact that there is still evidently considerable hot-atom reaction at 2062 Å indicates that some of the dissociation is still proceeding by the lower channel. The further decrease in translational energy at 1850 Å suggests that predissociation by the lower channel competes less and less effectively with the unimolecular decomposition as the latter becomes faster with increasing vibrational excitation of the $\tilde{A}$-state. Little of the energy of excitation of ν_2 will be converted to translational energy of the fragments in the latter process because in a unimolecular decomposition of this sort the molecule will tend to dissociate with minimal energy in the reaction co-ordinate, only slightly in excess of the dissociation energy. The suggested competition between the two dissociation channels can also account for the sharper fall-off in translation energy of D from ND_3 evident in Table 2; the predissociation of ND_3 is slower than that of NH_3, so that predissociation to ground-state products will compete less effectively with the higher-energy channel as the latter should show a smaller isotope effect.

The mechanism that thus emerges for the predissociation of the $\tilde{A}$-state may be summarized. Excitation to levels of $v_2 = 0$ or 1 leads to relatively slow predissociation essentially by an intersystem crossing to the ground state, yielding $H + NH_2(^2B_1)$. At levels above $v_2 = 1$, the higher-energy channel leading to $H + NH_2(^2A_1)$ becomes accessible, and the $\tilde{A}$-state begins to dissociate by a simple unimolecular decomposition in competition with the lower-energy channel. With increasing photon energy, ν_2 and probably ν_1 are excited to higher levels, the unimolecular decomposition becomes faster, and the low-energy channel competes less and less effectively. This mechanism appears to offer the most plausible explanation of the experimental facts. It is of course an oversimplification of a complex system; in particular, no single potential energy curve such as those of Figs. 5 and 6 can predict the dynamics of the predissociation as the out-of-plane angle of the dissociation co-ordinate is varied widely. The latter angle may be closely coupled to the level of excitation of ν_2, and it is possible that the predissociation from low levels of ν_2 may approximate more closely to the model in Fig. 5, while with increasing excitation of ν_2 the system will tend to follow the model in Fig. 6. A dynamic calculation based on potential energy surfaces for each level of excitation of ν_2 and for a range of out-of-plane dissociation angles would be required to settle this question. The proposed mechanism predicts that emission from the $(^2A_1)$ state of the amino radical should be observed at all excitation wavelengths below about 2100 Å. Okabe and Lenzi (24) failed to observe such emission, but their detection system was only sensitive to about 6000 Å. For excitation at 2062 and 1850 Å, the minimum *possible* wavelengths for NH_2 emission are about 9400 and 6000 Å

respectively, and the Franck–Condon factors in the transition will shift the emission *maximum* far to the red. Observation of emission at these wavelengths could be difficult experimentally but would lend strong support to the proposed mechanism. Quantitative measurements of the emission could yield detailed information about the predissociation, and it is hoped to attempt such measurements in the near future.

The ultraviolet absorption spectrum of methyl diimide vapor[1]

S.K. VIDYARTHI,[2] C. WILLIS, AND R.A. BACK

Division of Chemistry, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received October 22, 1976

S. K. VIDYARTHI, C. WILLIS, and R. A. BACK. Can. J. Chem. **55**, 1396 (1977).

The vapor phase absorption spectra of $CH_3N{=}NH$ and $CH_3N{=}ND$ have been measured from 160–450 nm. There are three prominent features centered at 360 nm ($\varepsilon = 6\ M^{-1}\ cm^{-1}$), 208 nm ($\varepsilon = 710\ M^{-1}\ cm^{-1}$), and 170 nm ($\varepsilon = 2080\ M^{-1}\ cm^{-1}$). The weak near-uv band is assigned to the valence shell transition $\pi^* \leftarrow n_+$ while the two far-uv bands are attributed to the $3s \leftarrow n_+$ and $3p \leftarrow n_+$ Rydberg transitions. The band at 208 nm has resolved vibrational structure on the long wavelength tail and a vibrational analysis shows the main progression excited is the ν_{10}' CNN deformation mode.

S. K. VIDYARTHI, C. WILLIS et R. A. BACK. Can. J. Chem. **55**, 1396 (1977).

On a mesuré, de 160–450 nm, le spectre d'absorption en phase vapeur de $CH_3N{=}NH$ et $CH_3N{=}ND$. Il y a trois caractéristiques principales qui sont centrées à 360 nm ($\varepsilon = 6\ M^{-1}\ cm^{-1}$), 208 nm ($\varepsilon = 710\ M^{-1}\ cm^{-1}$) et 170 nm ($\varepsilon = 2080\ M^{-1}\ cm^{-1}$). On a attribué la bande faible dans le proche ultra-violet à une transition de couche de valence $\pi^* \leftarrow n_+$ alors que les deux bandes d'ultra-violet lointain sont attribuées à des transitions $3s \leftarrow n_+$ et $3p \leftarrow n_+$ de Rydberg. La bande à 208 nm a une structure vibrationnelle résolue sur la queue à grande longueur d'onde et une analyse vibrationnelle montre que la progression principale qui est excitée est le mode de déformation CNN ν_{10}'.

[Traduit par le journal]

Introduction

There has been sustained interest in the ultraviolet spectroscopy of azo compounds including the prototype molecule diimide, N_2H_2. Methyldiimide, $CH_3N{=}NH$, is the first member of a series of unstable monoalkyl diimides which have been prepared by Ackermann and coworkers (1), Kosower (2), and others. These compounds show typical weak azo absorption in the near ultraviolet but their far-uv absorption spectra have not been reported. Methyldiimide is of particular interest as a compound intermediate between diimide and azomethane whose far-uv spectra have both been studied in some detail (3–5) and the photoelectron spectrum of all three have recently been reported (6).

Experimental

Samples of $CH_3N{=}NH$ and $CH_3N{=}ND$ were prepared as described elsewhere (7). Traces of ammonia were removed by treatment with P_2O_5. Methyldiimide decays both thermally and photochemically to form N_2 and CH_4, both transparent above 160 nm so that a useful criterion of purity was the absence of residual absorption after complete decomposition of the sample. Absolute extinction coefficients were based on measurement of final pressures of N_2 and CH_4; because of the thermal instability of methyldiimide and its great sensitivity to light, there is an uncertainty of $\pm 10\%$ in these absolute values.

Absorption spectra above 200 nm were measured in a Cary-15 spectrophotometer, and below 200 nm with a helium-flushed McPherson 0.5 m grating monochromator system using absorption cells with sapphire windows. Spectra above 200 nm were also photographed with a medium Hilger quartz-prism spectrograph.

Results

The near-uv spectrum of $CH_3N{=}NH$, measured at room temperature and about 50 torr pressure is shown in Fig. 1. The molar decadic extinction coefficient at the maximum at 360 nm was $6 \pm 2\ M^{-1}\ cm^{-1}$. Essentially the same spectrum was observed with $CH_3N{=}ND$. No fine structure was discernible in the spectrum of either compound, either in the spectrophotometer traces or in the photographic spectra of the same region. The spectrum is apparently completely diffuse,[3] like that of azomethane, showing none of the sharp vibrational structure evident with N_2H_2.

[2]NRCC Postdoctoral Fellow 1973–1975. Present address: Domtar Research, Senneville, P.Q.

[3]Ackermann and co-workers reported faint structure in the near-uv band of $CH_3N{=}NH$; it seems possible that this was due to the presence of a small N_2H_2 impurity, as there is some evidence that this can be formed in the synthesis of $CH_3N{=}NH$ by the method employed (8).

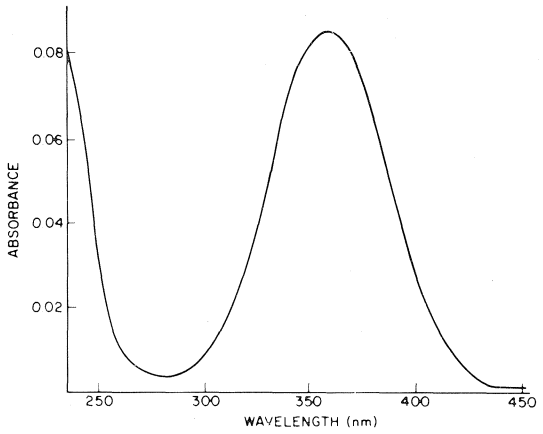

FIG. 1. Near-uv absorption spectrum of methyldiimide.

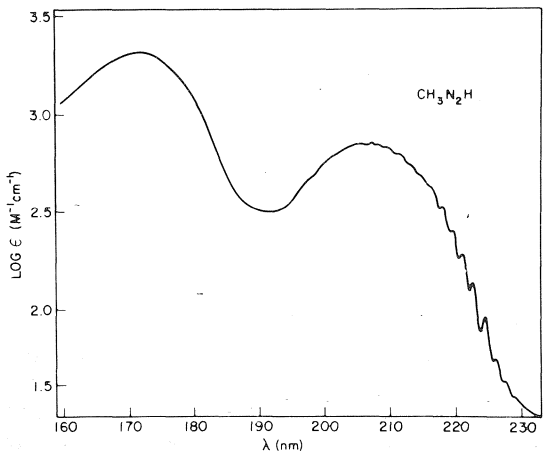

FIG. 2. Far-uv absorption spectrum of methyldiimide.

Two much stronger broad absorption bands were observed in the far-uv spectrum (Fig. 2) with maxima at 208 and 172 nm, and values of ε_{max} of about 710 and 2080 M^{-1} cm^{-1} respectively. The band at 208 nm shows vibrational structure on the long-wavelength side, while the band at 172 nm is completely diffuse. The 208 nm band is shown at higher resolution in Fig. 3 for both $CH_3N{=}NH$ and $CH_3N{=}ND$, exhibiting a blue shift of about 2 nm on deuteriation. The frequencies of the vibrational band maxima were measured from photographic plates, calibrated with a standard iron arc, and are listed in Tables 1 and 2 for $CH_3N{=}NH$ and $CH_3N{=}ND$.

Discussion

Vibrational Analysis of the 208 nm Band

The vibrational structure in the 208 nm band

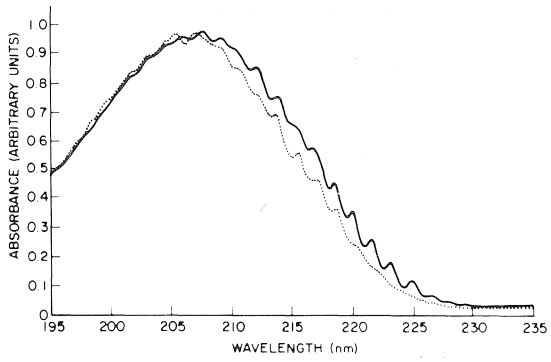

FIG. 3. The 208 nm band of methyldiimide and methyldiimide-d_1; solid line, $CH_3N{=}NH$; dotted line, $CH_3N{=}ND$.

of $CH_3N{=}NH$ consists largely of a single long strong progression which is evident in Fig. 3. Upon closer inspection of the photographic spectrum, however, it could be seen that this was overlapped by two other weaker progressions having the same band interval. Band frequencies and intervals for the three progressions are listed in Table 1. The first, strong progression is in column 1; the second, in column 2, was much weaker; while the third (column 3) was weaker still with fewer members detectable. The average band interval from all three progressions is 324 cm^{-1}. The spectrum of $CH_3N{=}ND$ follows an entirely analogous pattern (Table 2) with a band interval of 326 cm^{-1}. The considerable scatter in the values for the intervals between bands for both molecules reflects the inaccuracy in estimating the positions of the band maxima for bands which were largely overlapped, often weak, and distorted by the sharp increase in the absorption with decreasing wavelength.

The only reasonable interpretation of the long progressions in Tables 1 and 2 is that they arise from excitation of the ν_{10}' CNN deformation (bending) vibration of the upper state. In the ground state this has a frequency of 557 cm^{-1} (1), and the observed value of 325 cm^{-1} represents a very considerable reduction. Excitation of the equivalent CNN bending vibration has been suggested recently in the analogous transition in azomethane (4), with frequencies of 470 and 590 cm^{-1} in the upper and ground states respectively, while in both the near- (9) and far- (3) uv transitions of N_2H_2, the symmetric HNN bending vibration is strongly excited.

The two weaker progressions (columns 2 and

3) are most probably hot bands arising from thermal excitation of ν_{15}'', the methyl torsional vibration, in the ground state, which has been tentatively identified by Ackermann and coworkers (1) from combination bands in the ir spectrum. Its frequency of about $170\ cm^{-1}$ is reasonably close, within the accuracy of the two measurements, to the average separation of $204\ cm^{-1}$ between the progressions in Tables 1 and 2, and the Boltzmann factors of ~0.4 and ~0.2 at 25°C for $v_{15}'' = 1$ and 2 are in approximate accord with the relative intensities of the three progressions. Spectra measured at 85°C showed no marked change from room temperature, which is not incompatible with the presence of ν_{15}'' hot bands, since the expected increases of about 10 and 30% in these weak, overlapped bands in the second and third progressions would have been difficult to detect. This probably does rule out the alternative possibility that the weak progressions arise from thermal excitation of ν_{10}'' in the ground state; the average interval between the progressions could be $204 + 325 = 529\ cm^{-1}$, not far from the infrared value of 557 for ν_{10}'', but raising the temperature to 85°C should have increased the intensity of the $v_{10}'' = 1$ hot bands by 50% and increased that for $v_{10}'' = 2$ by a factor of 2.5, which should have been detected. It also does not appear reasonable to assign the weak progressions to excitation of a second vibration, the N—N stretch for example, in the excited state, as this would require displacement of the progressions relative to one another in an impossible manner.

Values of v_{10}' in Tables 1 and 2 have been assigned on the assumption that the first bands in the first two progressions in each case correspond to $v_{10}' = 0$ corresponding to band origins of 43 675 and 43 668 cm^{-1} for $CH_3N{=}NH$ and $CH_3N{=}ND$ respectively. This is probably correct, as no other bands could be detected at longer wavelengths, but must be regarded as still somewhat tentative.

Assignment of the Electronic Transitions

By analogy with the equivalent absorptions in *trans*-N_2H_2 (λ_{max} = 365 nm (9)) and in *trans*-azomethane (λ_{max} = 340 nm (10)), the weak

	170	$3p \leftarrow n_+$	19000 ± 500	0.6_0	2080
$CH_3N{=}NCH_3$	227	$3s \leftarrow n_+$[b]	28400	1.0_3	≤ 0.5[c]
	185	$3p \leftarrow n_+$[b]	18400	0.5_6	≈ 7000

[a]Derived from $E_{vert}^{p.e.} - E_{vert}^{uv} = R/(n - \delta)^2$ where $E_{vert}^{p.e.}$ is the vertical IP taken from photoelectron spectrum (6) and E_{vert}^{uv} is maximum of uv absorption.
[b]These assignments are taken from Robin (5).
[c]See ref. 12.

structureless band in methyldiimide with $\lambda_{max} = 360$ nm can comfortably be assigned to the $\pi^* \leftarrow n_+$ transition.

The two far-uv absorption bands can probably be assigned respectively to $3s \leftarrow n_+$ and $3p \leftarrow n_+$ Rydberg transitions. The term values and quantum defects, given in Table 3, are what would be expected and agree closely with those derived from the absorption spectra of azomethane for which Robin (5) convincingly argues that the first two short wavelength absorptions (weak shoulder with $E_{max} = 44\,100\ cm^{-1}$ and strong band with $E_{max} = 54\,000\ cm^{-1}$) are Rydberg in nature. The very different relative intensities for the absorption due to the $3s \leftarrow n_+$ transition in azomethane and methyldiimide is as expected. The transition is $g \leftarrow g$ parity forbidden for C_{2h} symmetry (azomethane) but fully allowed for C_s symmetry (methyldiimide). Although the second short wavelength band in methyldiimide

centered around 170 nm fits very well with the assignment to the $3p \leftarrow n_+$ transition, involvement of the valence shell transition $\pi^* \leftarrow n_-$ cannot be ruled out. The observed band maximum is $E_{max} = 58\,000\ cm^{-1}$ which is very close to that predicted for the $^1(\pi^* \leftarrow n_-)$ transition in diimide (11). It has been recently suggested (6) that the 170 nm band in N_2H_2 can be assigned to the $3p \leftarrow n_+$ Rydberg transition.

Solvent effect correlations and the mechanism of solvolysis of alkyl chlorosulfates[1]

ERWIN BUNCEL, J. PETER MILLINGTON, AND JAMES F. WILTSHIRE
Department of Chemistry, Queen's University, Kingston, Ont., Canada K7L 3N6

Received September 15, 1976

ERWIN BUNCEL, J. PETER MILLINGTON, and JAMES F. WILTSHIRE. Can. J. Chem. **55**, 1401 (1977).

The rate of hydrolysis of the series of alkyl chlorosulfates $ROSO_2Cl$ (R = ethyl, *n*-propyl, isobutyl, neopentyl) has been measured as a function of solvent composition in dioxane–water media. The solvent effect is examined from the viewpoint of dielectric constant, solvation number, and solvent ionizing power. The results point to a continuous variation of solvolytic mechanisms (from S_N2, through borderline, to S_N1) along the series. The correlations are also considered with respect to the 'entropy criterion' for multiple bond scission previously advanced for solvolysis of the alkyl chlorosulfates. Solute–solvent interactions are identified as a possible alternative origin of the abnormally large $\Delta S^{\neq}$ values observed in chlorosulfate solvolysis.

ERWIN BUNCEL, J. PETER MILLINGTON et JAMES F. WILTSHIRE. Can. J. Chem. **55**, 1401 (1977).

On a mesuré les vitesses d'hydrolyse d'une série de chlorosulfates d'alkyles $ROSCO_2Cl$ (R = éthyle, *n*-propyle, isobutyle, néopentyle) en fonction de la composition du solvant dans un milieu dioxanne–eau. On a examiné l'effet du solvant à partir du point de vue de la constante diélectrique, du nombre de solvatation et du pouvoir ionisant du solvant. Les résultats indiquent qu'il y a une variation continue des mécanismes de solvolyse (à partir de S_N2 et passant par des cas intermédiaires jusqu'à S_N1) tout le long de la série. On considère aussi des corrélations par rapport avec le 'critère d'entropie' pour les scissions de liens multiples qui ont été proposé antérieurement pour la solvolyse des chlorosulfates d'alkyles. On a identifié les interactions soluté–solvant comme une origine alternative possible pour les valeurs de $\Delta S^{\neq}$ qui sont anormalement grandes et qui ont été observées pour la solvolyse des chlorosulfates.
[Traduit par le journal]

Although many discussions of solvent effects on reaction rates of nucleophilic substitution processes have been reported, systematic investigations of reaction series are relatively few in number (1–5). Previously we reported on the mechanism of solvolysis of a series of primary alkyl chlorosulfates, $ROSO_2Cl$, in aqueous dioxane (6–8). A normal mode of solvolysis, that is bimolecular or unimolecular displacement on carbon with $^-OSO_2Cl$ as the leaving group, was indicated by (*i*) the effect of nucleophiles on the rate of hydrolysis of *n*-propyl chlorosulfate; (*ii*) the observation of a large lyate ion effect ($k_{OH^-}/k_{H_2O} = 380$) for *n*-propyl chlorosulfate but an absence of a lyate ion effect ($k_{OH^-}/k_{H_2O} = 1$) for neopentyl chlorosulfate; (*iii*) the occurrence of rearrangement in the hydrolysis of neopentyl chlorosulfate; (*iv*) the relative reactivities of the series of primary alkyl chlorosulfates (methyl > ethyl > *n*-propyl > isobutyl > neopentyl). These observations were in accord with the solvolytic transition states **1** and **2** (uni- and bimolecular mechanisms, respectively, with Nu as the nucleophilic species). However, the observation of 'abnormally' large entropies of activation suggested that ternary fission (fragmentation (9)) was occurring, *i.e.* transition states **3** and **4** with both carbon–oxygen and sulfur–chlorine bond weakenings.

Further work has been undertaken in order to obtain additional information on the nature of the solvolytic mechanism of alkyl chlorosulfates, and to shed light on the validity of the entropy criterion of fragmentation. The present paper describes the results of the application of solvent

[1]Bond scission in sulfur compounds. Part XI. For part X see ref. 42.

effect correlations to the problem. Related mechanistic studies of chlorosulfates have been reported from this as well as other laboratories (10–12). Solvolytic studies of sulfonyl chlorides (13–16) also have a bearing on this work.

Results and Discussion

In Table 1 are presented the data for the conductimetrically determined rates of hydrolysis of ethyl, *n*-propyl, isobutyl, and neopentyl chlorosulfate in various dioxane–water media at 25°C. In the ensuing discussion, the influence of solvent composition on velocity of reaction will be considered from the following viewpoints: (*1*) electrostatic theory; (*2*) solvation numbers; (*3*) solvent ionizing power. The information derived from these treatments will then be considered with respect to the abnormal $\Delta S^{\ddagger}$ values which have been observed for this reaction series. Finally, we will consider the application of the $\Delta S^{\ddagger}$ criterion in other systems. The availability of comparable data in the literature on the response of reaction rates to medium changes serves as a useful reference point in interpretation of the present results.

Correlations with Dielectric Constant

According to electrostatic theory of reaction kinetics, the velocity of a solvolytic reaction should increase with increasing dielectric constant of the medium (17–20). For an S_N1 reaction occurring in a medium of dielectric constant ε the electrostatic component of the free energy of activation, $\Delta G_{es}^{\ddagger}$, is given by (20) [1][2] in which σ is the separation of charges z_Ae and z_Be in the quasi-ionic activated complex, which is assumed to be in the form of a double sphere with radii r_A and r_B:

$$[1] \qquad \Delta G_{es}^{\ddagger} = \frac{z_A^2e^2}{2\varepsilon r_A} + \frac{z_B^2e^2}{2\varepsilon r_B} + \frac{z_Az_Be^2}{\sigma\varepsilon}$$

For the simplified case that $r_A = r_B = r$, $\sigma = 2r$ and $z_A = 1$, $z_B = -1$, this expression reduces to

$$[2] \qquad \Delta G_{es}^{\ddagger} = \frac{e^2}{2\varepsilon r}$$

Equation 2 predicts that a linear plot will result between the logarithm of the rate constant and the reciprocal of the dielectric constant, with slope $e^2/2r$. In practice such plots are somewhat

[2]Equation 1 corresponds to the 'double sphere' model of ref. 20, which is deemed to be more applicable to the present problem than the 'single sphere' model (20). The final expressions for the two models, however, only differ by a small numerical factor. The derivations are based on the assumption of a continuous dielectric medium (*cf.* ref. 21).

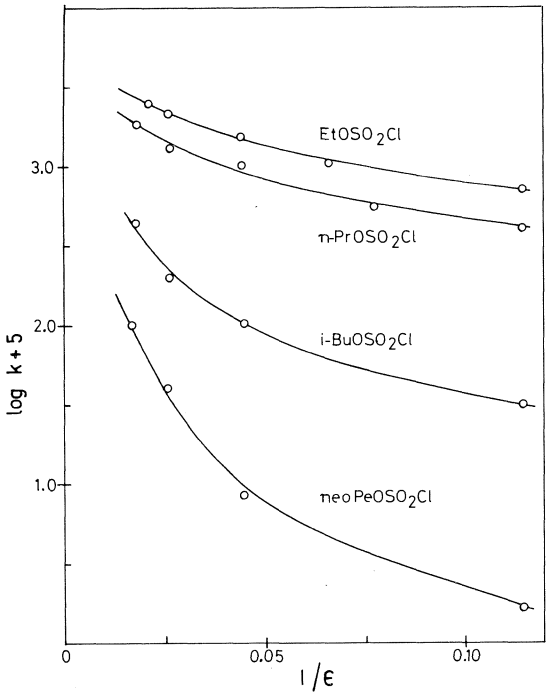

FIG. 1. Correlation between the logarithm of the rate constant and the inverse of the dielectric constant for the hydrolysis of alkyl chlorosulfates in dioxane–water mixtures.

curved, the slope decreasing in the region of low ε values, and it may be suggested that this is caused by the intrusion of S_N2 character in media of low polarity.

The log *k vs.* 1/ε plots for solvolysis of the alkyl chlorosulfates are presented in Fig. 1. The plots reveal a family of curves with increasing dependence of rate on dielectric constant, the dependence being least for ethyl chlorosulfate and greatest for neopentyl chlorosulfate. This behaviour can be rationalized by the designation of a bimolecular (S_N2) and a unimolecular (S_N1) mechanism to the two extreme types of behaviour, with a borderline or intermediate ($S_N1/2$) mechanism in between. Specifically, the increments in the magnitudes of the initial slope values along the series (Table 2) are indicative of the following operative mechanisms: bimolecular for ethyl and *n*-propyl chlorosulfate, unimolecular for neopentyl, and intermediate for the isobutyl compound.

Table 2 presents, in addition to data for the chlorosulfate series, the slopes of log *k vs.* 1/ε plots and the derived $r_\pm$ values (20) for solvolysis of some alkyl halides, based on measurements

TABLE 2. Dielectric constant correlations: comparison of slopes and $r_\pm$ values[a]

	d(log *k*)/d (1/ε)	$r_\pm$ (Å)

tert-BuBr	−238.4	0.51

[a]Calculations according to ref. 20; the data for EtBr, *tert*-BuCl and *tert*-BuBr are taken from refs. 20 and 22*c*.

in the high dielectric constant region of acetone–water mixtures (22*c*). The larger $r_\pm$ value for ethyl bromide compared with the *tert*-butyl halides is in accord with the bimolecular mechanism of solvolysis. Comparison of the data for the chlorosulfates with those for the alkyl halides shows that for the former the slopes are much smaller and the $r_\pm$ values are much greater.

The large $r_\pm$ values for the chlorosulfate series are consistent with the proposal of multiple bond scission in the transition state. The ion pair formed by ternary scission, $[R^+SO_3\ Cl^-]$, would have the ionic species separated by a greater distance than in the case of a simple ion pair such as $[R^+Cl^-]$; this would lead to a greater effective radius of the activated complex and hence a larger apparent $r_\pm$ value for chlorosulfate solvolysis. Hence, according to this treatment the reason for the smaller slope in the log *k vs.* 1/ε plot for neopentyl chlorosulfate as compared to the *tert*-butyl chloride or bromide case is a greater effective $r_\pm$ value due to multiple bond scission. For ethyl and *n*-propyl chlorosulfate the $r_\pm$ values appear to be unreasonably large, but this is probably an artifact of the model used, as it is noted that [1] is not strictly applicable to the bimolecular mechanism of solvolysis.

A weakness of the electrostatic model is that it treats the medium as a continuous dielectric and thus ignores the operation of specific solute–solvent interactions. Alternative approaches employ empirical solvent parameters, and since these are based on selected model processes (*e.g.*, the solvolysis of *tert*-butyl chloride), they can serve as probes of solute–solvent interactions. An investigation, using these alternative approaches, of the solute–solvent interactions in the hydrolysis of alkyl chlorosulfates is given below.

TABLE 3. Comparison of solvation numbers and $\Delta S^{\neq}$ values for chlorosulfates and other alkyl derivatives in aqueous dioxane or aqueous acetone[a]

[a]Solvation numbers (n) are derived from kinetic data (via [3]) over a range of solvent compositions, while $\Delta S^{\neq}$ values refer to media with a 10 M water content.

Solvation Numbers

Solvation numbers, n, derived from [3] in which k_1 is the measured pseudo first-order rate constant, have been obtained for many hydrolytic reactions in dioxane–water or acetone–water mixtures.[3] Although for a number of reasons n cannot be directly equated with molecularity with respect to water (*e.g.*, use of activities rather

$$[3] \qquad \log k_1 = \log k' + n \log [H_2O]$$

than concentrations leads to much steeper curves), nevertheless values of n provide a useful empirical criterion of mechanism (22–26). Thus unimolecular solvolysis is associated with larger solvation numbers than bimolecular solvolysis. The data in Table 3 show that for common alkyl derivatives n is typically 5–7 in unimolecular solvolysis and 2–3 in bimolecular solvolysis.[4] These results may be attributed to a specific solvation of the transition state by the water molecules, bearing in mind that in the unimolecular mechanism the carbonium ion is formed within a solvation shell of water. The critical number of water molecules required in the unimolecular mechanism will be greater than in the bimolecular mechanism, since in the latter case the role of water molecules is limited to solvation of the incipient anion and to nucleophilic participation.

The log k *vs.* log $[H_2O]$ plots for the alkyl chlorosulfates (Fig. 2) are linear; the derived n values are given in Table 3. The striking aspect about the data of Table 3 are the low n values for the alkyl chlorosulfates. It appears that in the chlorosulfate series the bimolecular mechanism is associated with $n = 1$ and the unimolecular mechanism with $n = 3$. It has been noted previously (24, 27) that substrates which are highly solvated due to hydrogen bonding require fewer additional water molecules in solvation of the transition state, so that a lesser degree of solvent reorganization is entailed. This could provide a possible explanation for the low solvation numbers with the alkyl chlorosulfates since the polar OSO_2Cl group is expected to be extensively solvated.[5] For ethyl or *n*-propyl chlorosulfate the molecules of water which would solvate the departing anion are already present in the initial state and only one additional water molecule is needed to act as the nucleophile in the displacement process. Similarly, the unimolecularly reacting neopentyl chlorosulfate would require the reorganization of fewer water molecules in comparison with *tert*-butyl chloride, for example, which should be reflected in a smaller n value, as is observed.

m–Y Correlations

A plot of log k *vs.* Y, the solvent ionizing

[3]Alternative derivations of solvation numbers are given by Moelwyn-Hughes (23) and by Kohnstam (24).

[4]In Table 3 reactions which can be supposed to proceed by the S_N2, an intermediate ($S_N1/2$), and the S_N1 mechanism have been grouped together.

[5]A dissection of the initial state and the transition state solvation terms is possible through measurement of thermodynamic transfer functions (29–32).

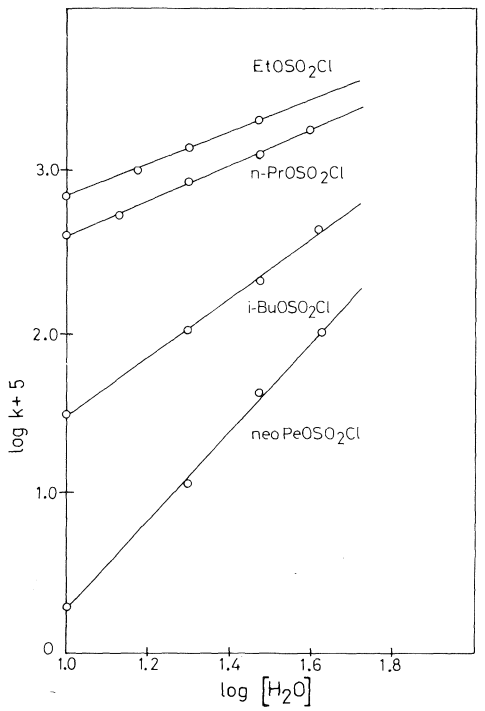

FIG. 2. Correlation between the logarithm of the rate constant and the logarithm of the water molarity for the hydrolysis of alkyl chlorosulfates in aqueous dioxane.

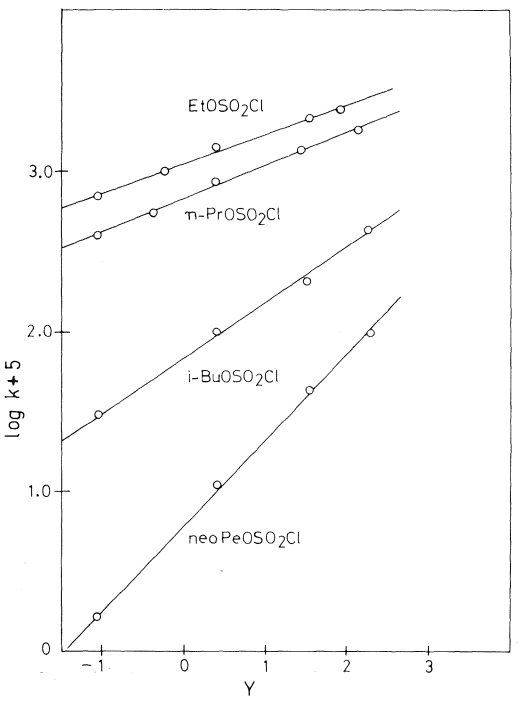

FIG. 3. Correlation between the logarithm of the rate constant and the medium ionizing power Y for hydrolysis of alkyl chlorosulfates in aqueous dioxane.

power (33*a*), for the series of alkyl chlorosulfates is shown in Fig. 3. The similarity with the log k *vs.* log [H_2O] plot (Fig. 2) is striking. However, the similarity is a consequence of the fact that, for the solvent range under consideration, Y is linearly related to log [H_2O]. The derived values of m, the substrate constant, are shown in Table 4 together with corresponding values for other alkyl derivatives, which were taken directly from the sources quoted or calculated from data therein.

The m values for the chlorosulfates are seen to be generally lower than for other alkyl derivatives solvolyzing by a particular mechanism. For S_N2 solvolysis in the chlorosulfate series $m \simeq 0.2$, compared with 0.3–0.4 for the arenesulfonates and halides. For S_N1 solvolysis $m \simeq 0.5$ for the chlorosulfates, 0.5–0.7 for the arenesulfonates, and 0.9–1.1 for the halides. The obvious deduction is that the chlorosulfates are less dependent on the inonizing power of the medium than are other alkyl derivatives. This could be interpreted to mean that the chlorosulfates fit into the part of the mechanistic spectrum between S_N2 and the borderline region. However, such an interpretation is contrary to previous conclusions (6–8). A more plausible explanation is connected with the low solvation number values. Since Y and log [H_2O] vary correspondingly over the range of solvent composition studied, the relative insensitivity of solvolysis rates of the alkyl chlorosulfates to the ionizing power of the medium appears to be due to the more extensive solvation of the initial state.[6] The relevance of this solvation factor to $\Delta S^{\neq}$ in chlorosulfate solvolysis is considered in the next section.

$\Delta S^{\neq}$ *in Chlorosulfate Solvolysis: Multiple Bond Scission vs. Initial State Solvation*

In our first investigation of the solvolysis of the alkyl chlorosulfates, the discovery of abnormally large $\Delta S^{\neq}$ values led to the proposal of multiple bond scission (7, 8). It appeared plausible that $\Delta S^{\neq}$ could provide a criterion of the concerted fragmentation pathway, due to the

[6]Similarly, the lower m values observed for alkyl arenesulfonates in comparison with alkyl halides are in accord with a greater solvation of the initial state in the former series (27); see, however, ref. 28 for the possible effect of neighbouring group participation on m values.

increase in the degrees of freedom expected in the transition state of a process involving the formation of several particles. In the present study support has been obtained for the above proposal by application of an electrostatic treatment to the effect of solvent composition on the rate of reaction. The treatment shows in effect that chlorosulfate solvolysis is characterized by the large $r_{\pm}$ values which would be expected if multiple bond scission were operative.

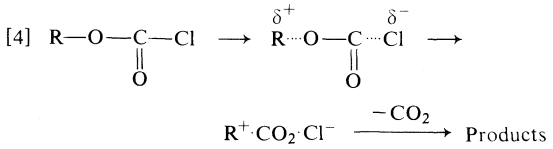
It now becomes pertinent to consider the alternate possibility that the large initial state solvation of the alkyl chlorosulfates, which is reflected in low substrate values (m) and in small solvation numbers (n), might be responsible for the abnormally large entropies of activation characteristic of chlorosulfate solvolysis. Solvation numbers reflect the degree of reorganization of solvent molecules necessary in the formation of the transition state; the greater the solvent reorganization, the more negative might $\Delta S^{\ddagger}$ be expected to be (27, 34). Hence the abnormally positive $\Delta S^{\ddagger}$ values for chlorosulfate solvolysis might be considered to be due to the relatively small solvation numbers. The literature data for a number of alkyl derivatives given in Table 3 can be interpreted on that basis. It is seen that within each of the S_N2 and S_N1 groupings the abnormally positive (or less negative) $\Delta S^{\ddagger}$ values for the chlorosulfate derivatives are indeed paralleled by relatively small n values. This parallelism between $\Delta S^{\ddagger}$ and n values supports the contention that the abnormal values exhibited by the chlorosulfate derivatives may arise from the same factor, *i.e.* extensive initial state solvation. It is noted that this correlation is not obscured by the different ranges of $\Delta S^{\ddagger}$ values which are characteristic of the S_N1/S_N2 pathways. Thus it is found that initial state solvation is in fact a reasonable alternative origin of the abnormal $\Delta S^{\ddagger}$ values in chlorosulfate solvolysis.

At present a choice between the alternatives of multiple bond scission or initial state solvation (or the further possibility that both are operative factors) cannot readily be made. The major drawback is that there is no independent criterion for fragmentation in the solvolysis of chlorosulfates, such as could be provided by the measurement of kinetic isotope effects or $\Delta V^{\ddagger}$ values (*vide infra*). Furthermore, the differing viewpoints held by different workers (1–5) on solvation effects in solvolytic processes attest to the intrinsic difficulty in correlating more quantitatively $\Delta S^{\ddagger}$ and n values in solvolytic processes.

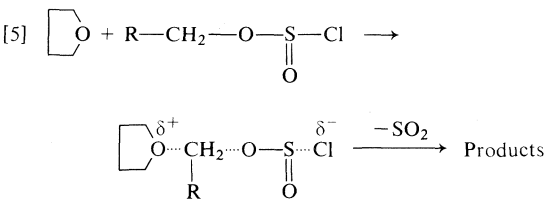
The Application of the $\Delta S^{\ddagger}$ Fragmentation Criterion in Other Systems

Since the entropy of activation criterion was first proposed as a result of our investigation of chlorosulfate solvolysis (7, 8) several studies have appeared in the literature (35–39) relating to application of this mechanistic criterion to other systems. Of closest analogy are the studies with the structurally related chloroformates (36) and chlorosulfites (37). The entropy of activation for the solvolysis–decomposition of 1-adamantyl chloroformate in 80% aqueous ethanol has been found to be 16–20 eu more positive than cor-

responding values for solvolysis of 1-adamantyl halides in this solvent (36), in accord with an ionization–fragmentation process:



The cleavage reaction of cyclic ethers by alkyl chlorosulfites in benzene proceeds with a more positive $\Delta S^{\neq}$ (10–20 eu) compared with analogous S_N2 displacements and this has been interpreted on the basis of the fragmentation mechanism in [5] which entails simultaneous



fission of C—O and S—Cl bonds (37). Formation of incipient SO_2 in the transition state is considered to provide substantial driving force for the reaction. In view of the results obtained in the present study, an investigation of the importance of solvent effects in the systems [4] and [5] would be in order to ascertain whether solute–solvent interactions could provide a valid alternative explanation of the abnormally large $\Delta S^{\neq}$ values.

The point was made previously by us that in certain structural situations the parallelism between fragmentation and abnormal $\Delta S^{\neq}$ values is not expected to hold.[7] It has also been noted that the nature of the leaving group can have a marked effect on entropies of activation and hence on the interpretation of abnormally large $\Delta S^{\neq}$ values (40).[8] Especially important in this regard is the study of le Noble *et al.* (41), which relates to the *volume of activation* ($\Delta V^{\neq}$) as a criterion of fragmentation. In this study it was stressed that beyond the intuitive nature of the $\Delta V^{\neq}$ criterion, a number of relevant factors must be explicitly considered in the evaluation of any given reaction system. It is clear that such an approach should also be taken when using the $\Delta S^{\neq}$ criterion.

Conclusions

Examination of the solvolysis of alkyl chlorosulfates from different viewpoints has provided alternative interpretations of the solvolytic mechanism. Application of electrostatic theory to the rate variation as a function of solvent composition in aqueous dioxane mixtures leads to the designation of bimolecular, unimolecular, and intermediate mechanistic types along the reaction series. Furthermore, comparison of the data for the chlorosulfates with those for alkyl halides via [1] and [2] points to the operation of a fragmentation mechanism for the chlorosulfate series, previously advanced on the basis of the abnormally large entropies of activation (6–8). However, the solvation numbers (n) derived via [3] are smaller than for other alkyl derivatives, and application of Winstein's m–Y correlation also yields lower m values for the alkyl chlorosulfates. It is proposed that the relatively small n and m values arise as a result of extensive initial state solvation and that the abnormally large $\Delta S^{\neq}$ values in chlorosulfate solvolysis may also have this factor as origin. Since independent criteria of multiple bond fission in these and in related solvolytic processes are lacking, it is suggested that caution be exercised in application of $\Delta S^{\neq}$ values as an indication of the fragmentation mechanism, *e.g.*, in reactions of chloroformates (36) or chlorosulfites (37). Similar caution has recently been advocated in application of volumes of activation as indications of fragmentation in solvolytic processes (41).

Experimental

The alkyl chlorosulfates were prepared from the respective alcohols and sulfuryl chloride as described previously (6) and were stored at 0–5°C. Dioxane was purified by refluxing over sodium and fractional distillation. The water used was distilled and deionized using a mixed bed ion exchange resin.

The kinetic data were determined conductimetrically.

[7]It was noted (39) that it is conceivable that multiple bond fission may create steric *restrictions* in the transition state, as in the case of a departing phenyl group which stabilizes the transition state by charge delocalization and is consequently restricted to a given spatial orientation (38). In such cases unusually high entropies of activation would, of course, not be expected; in fact $\Delta S^{\neq}$ values smaller than the normal size may result from the reduction in internal degrees of freedom in the transition state.

[8]D. N. Kevill, K. C. Kolwych, D. M. Shold, and C.-B. Kim, unpublished results quoted in ref. 40, footnote 218.

A Phillips P.R. 9501 direct reading conductivity bridge was used and was coupled to a chart recorder for measurement of relatively fast reaction rates. A dip-type conductivity cell was employed. The concentration of chlorosulfate used was *ca.* 0.01 *M*. Reaction solutions were thermostatted to ± 0.01°C. The rate data were calculated as previously described (6, 7).

Transition metal complexes of deprotonated 2-mercaptobenzoxazole. Study of the thiol–thioketo form equilibrium

CARLO PRETI AND GIUSEPPE TOSI

Istituto di Chimica Generale ed Inorganica, University of Modena, 41100 Modena, Italy

Received October 6, 1976

CARLO PRETI and GIUSEPPE TOSI. Can. J. Chem. **55**, 1409 (1977).

Complexes of 2-mercaptobenzoxazole (mbo) with Zn(II), Cd(II), Hg(II), Cu(I), Ag(I), Au(I), Ni(II), Pd(II), Pt(II), Co(II), Rh(III), and Ir(III) were prepared and characterized. Their structures have been assigned on the basis of chemical analysis, ir and far ir spectroscopy, electronic spectra, and magnetic susceptibility measurements. The ligand always bonds through both the sulphur and the nitrogen heteroatoms. The ligand field parameters have been evaluated and are in keeping with the proposed structures confirming the presence of MS_2N_2 and MS_3N_3 chromophores.

CARLO PRETI et GIUSEPPE TOSI. Can. J. Chem. **55**, 1409 (1977).

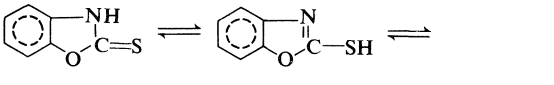
On a préparé et caractérisé les complexes du mercapto-2 benzoxazole (mbo) avec Zn(II), Cd(II), Hg(II), Cu(I), Ag(I), Au(I), Ni(II), Pd(II), Pt(II), Co(II), Rh(III) et Ir(III). On leur a attribué des structures en se basant sur l'analyse chimique, la spectroscopie ir et ir lointain, les spectres électroniques et des mesures de susceptibilité magnétique. Le ligand est toujours attaché par l'intermédiaire des hétéroatomes du soufre et d'azote. On a évalué les paramètres de champ de ligands et ils sont en accord avec les structures proposées confirmant aisni la présence de chromophores MS_2N_2 et MS_3N_3.

[Traduit par le journal]

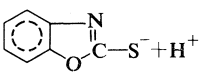
Introduction

In view of the importance of the oxazole group in biological systems, in industry, and in medicine and as an analytical reagent (1–5) we are interested in the study of the coordination behaviour of 2-mercaptobenzoxazole (mbo).

The complexing properties of the HNCS group with metal ions have been studied in our laboratory and we have obtained a variety of interesting complexes with the ligand acting as N-bonding (6, 7). The ligand exists as two tautomeric conformations exhibiting thiol–thione isomerism involving —N=C—SH and —NH—C=S groups in a thione–thiol equilibrium:



a *b*



c

The examination of the complexing properties of the mbo ligand with metal ions is the aim of the present paper in order to further our present knowledge in the field of ligands which exhibit the thiol–thione equilibrium reported above (8, 9).

It is possible that in this molecule only two atoms could act as bonding sites, *i.e.* the sulphur exocyclic atom and the cyclic nitrogen atom. Since the lone pairs on the oxygen atom present in the skeleton of the ring are involved in the resonating structures of the molecule, it is expected that it should have very weak coordinating ability (10).

We present in this work the investigation of the structural aspects of the complexes of deprotonated 2-mercaptobenzoxazole with the metal ions Zn(II), Cd(II), Hg(II), Cu(I), Ag(I), Au(I), Ni(II), Pd(II), Pt(II), Co(II), Rh(III), and Ir(III). Their structures have been tentatively assigned on the basis of chemical analysis, ir and far ir spectroscopy, electronic spectra, and magnetic susceptibility data.

Results and Discussion

The complexes, their analytical data, room temperature magnetic moments, and other physical properties are reported in Table 1. The solid state electronic spectra are listed in Table 2, while the most important ir bands in the range 4000–50 cm^{-1} are listed in Table 3. The complexes are powdery and insoluble in the most common organic solvents. This insolubility suggests that these derivatives could be polymeric with more than one ligand molecule coordinated to the metal ion. Because of the general in-

[a]X = metal for zinc, cadmium, and mercury derivatives; X = nitrogen for all the remaining derivatives.

solubility of the complexes, studies by such means as nmr, molecular weight, and molar conductivity measurements have not been carried out.

Electronic Spectra and Magnetic Susceptibility Studies

The spectral and magnetic properties of the complexes were studied in order to understand the spatial arrangement of the ligands around the metal ions. The derivatives of zinc(II), cadmium(II), mercury(II), copper(I), silver(I), and gold(I) were found to be diamagnetic which is expected as these metal ions belong to a d^{10} system. These metals do not show *d–d* transitions and therefore the stereochemistry of their complexes cannot be derived from diffuse reflectance spectra.

The nickel complex $Ni(mbo)_2 \cdot H_2O$ is diamagnetic; this fact could be indicative of a spatial arrangement of the mbo around the nickel ion in a square planar or five-coordinated geometry. The five-coordination should be possible only with water coordinated to the metal, but this fact can be excluded, because, from a detailed analysis of the infrared spectra, see below, the water observed is clearly uncoordinated lattice water. Furthermore, this water is lost at 100°C while, if coordinated, should be lost near 150°C (11).

The absence of electronic transitions below 10 000 cm^{-1} indicates very strongly that the spatial arrangement of the mbo around the nickel ion is square planar. The assignment of the bands in the electronic spectrum, Table 2, is made by assuming the convention that the metal *x*- and *y*-axes lie between the metal–ligand bonds (12). The band at 25 000 cm^{-1} is charge transfer in character and not a *d–d* transition because of its high intensity.

The calculated orbital parameter Δ_1 (13) from the $x^2 - y^2 \rightarrow xy$ in-plane transition is in the 19 000–20 000 cm^{-1} range, assuming reasonable values for the correction factor, thus placing the ligand in the expected sulphur and nitrogen donor range (14, 15).

The magnetic moment of the inner cobalt derivative, 4.4 μ_B, lies well within the range of tetrahedral complexes (16); the turquoise colour of the complex also indicates the tetrahedral geometry of this derivative. The reflectance spectrum shows two bands at 7635 (ν_2) and 16 890 cm^{-1} (ν_3) typical of a tetrahedral configuration. It is reasonable to suppose its structure to be that of an infinite polymer with the ligand forming bridges between cobalt ions. A similar structure has been suggested for inner complexes of cobalt(II) with imidazole and benzimidazole (17, 18). Using the values of ν_2 and ν_3, the ligand field parameters *Dq* and *B'* have been evaluated (Table 2).

By comparison of *Dq* values reported for CoL_4 groups, we can see that for CoS_4 chromophores *Dq* lies in the range 316–425 cm^{-1}, while the corresponding range for CoN_4 chromophores is 467–538 cm^{-1}; the complex $Co(mbo)_2 \cdot H_2O$ shows a *Dq* value that is, using the 'law of the average environment', typical of a CoS_2N_2 chromophore (14, 19).

The Pd(II) and Pt(II) ions, with d^8 configuration, have square planar arrangements of ligand molecules around them in a large number of their

[a]Calculated value.
[b]*B* is taken to be 967, 720, and 660 cm^{-1} for the Co^{2+}, Rh^{3+}, and Ir^{3+} free ions respectively.

complexes. In the electronic spectrum of the palladium(II) derivative, recorded in the solid state as a Nujol mull, only the band at 23 255 cm^{-1} can be considered a *d–d* transition of the type $^1A_g \rightarrow {}^1B_{1g}$ ($x^2 - y^2 \rightarrow xy$). The value of Δ_1, by the standard treatment, is 26 355 cm^{-1} (20). Assignments have not been possible in the case of the platinum(II) derivative.

The derivatives $Rh(mbo)_3 \cdot 2H_2O$ and $Ir(mbo)_3 \cdot 5H_2O$ are low-spin type (t_{2g}^6). Solid state electronic spectra confirm an octahedral symmetry of the central atom. The two observed absorption bands are in the ranges expected for the two spin-allowed transitions from the ground state $^1A_{1g}$; the ratio ν_2/ν_1 is 1.16 both for rhodium and iridium complexes. By means of the equations (21):

$$\nu_1 = \Delta - 4B' + 86(B')^2/\Delta$$

and

$$\nu_2 = \Delta + 12B' + 2(B')^2/\Delta$$

the ligand field parameters Δ, *B'*, and β have been evaluated and have been reported in Table 2. The value of Δ is higher than those found for the rhodium and iridium complexes with sulphur containing ligands (22) and could be indicative of an octahedral symmetry with metal–nitrogen and metal–sulphur bonds in polymeric materials. The *B'* values of the order of 39 and 45% of the free ion value in rhodium and iridium derivatives, respectively, suggest a strong covalency in the metal–ligand σ bond.

It is known that decreasing values of β are associated with a reduction in the effective positive charge of the metal ion and with an increasing tendency to be reduced to the next lower oxidation state. For the second-row transition metals the variation of the Racah interelectronic repulsion parameter with cation charge *Z** and the number *q* of electrons in the partly filled *d* shell, is expressed by the relation (21):

$$B'(cm^{-1}) = 472 + 28q + 50(Z^* + 1) - 500/(Z^* + 1)$$

This gave the effective ionic charge in the rhodium derivative as 0.20, considerably below the formal +3 oxidation state of the metal.

Infrared Spectra

The infrared spectra of the complexes do not display the bands due to ν(NH) and δ(NH), clearly indicating the absence of imino-hydrogen in these derivatives. Furthermore it is worthwhile examining the fact that the mode of coordination of the ligand could be distinguished by the analysis of the positions and intensities of the thioamide bands (23–26) and of the bands at 1095 cm^{-1} and 820 cm^{-1} attributed to the prevailing contribution of ν(COC) asymmetric and symmetric, Table 3. The directions of the shifts of all the bands in the spectra of the complexes are the same and this fact clearly indicates that the bonding pattern must be the same in all the complexes.

TABLE 3. Infrared absorption bands (cm^{-1})

Compound	Thioamide I	Thioamide II	ν(COC) asym.	Thioamide III	ν(COC) sym.	Thioamide IV	ν(M—N)	ν(M—S)	Other bands

[a]Overlapping a ligand band which is markedly reinforced.

Thioamide I band has a predominant contribution from ν(C═N) + δ(CH), band II has a predominant contribution from ν(C⋯N) + δ(CH) + ν(C⋯S), band III has a contribution from ν(C⋯N) + ν(C⋯S), while thioamide IV has a major contribution from ν(C⋯S). The major changes in the spectra of the complexes as compared to that of the ligand are a red shift of the thioamide I band of about 20 cm^{-1} and a blue shift of band II. The thioamide III band appears unchanged at the same wavenumbers, while the thioamide IV band undergoes a red shift.

The bands at 1095 and 820 cm^{-1} attributed to the prevailing contribution of ν(COC) asymmetric and symmetric are at the same wavenumbers or show small positive shifts, thus excluding the possibility of coordination through the oxygen atom of the oxazole ring.

According to literature data (8, 27–30) the shifts reported above clearly allow us to suggest both N- and S-coordination. A chelate form is difficult to envisage because of the high strain that appears from the molecular model of a four-membered ring of the type , taking into account that the carbon and nitrogen atoms already belong to a five-membered ring. We propose, for all the complexes, a bridged configuration with the ligands linked to two different metal atoms.

The low frequency spectral data give further confirmation of N- and S-bonding to the metals. In the spectra of N-bonded and S-bonded complexes, absorptions due to ν(M—N) and ν(M—S) are usually present in the range 350–150 cm^{-1}. In our spectra new bands are present in the low frequency region, Table 3, that are assigned to ν(M—N) and ν(M—S) according to literature data for similar complexes (8, 31–41).

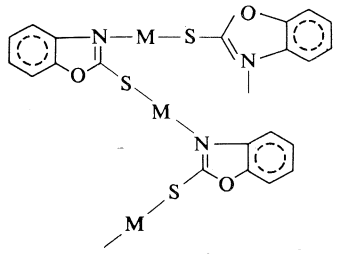
In all the water containing complexes, bands due to ν(OH) and δ(HOH) are present at 3500 cm^{-1} (broad) and at 1600 cm^{-1} (broad) clearly indicating the presence of lattice water. Twisting, wagging, and rocking, vibrational modes of the coordinated water are not present in the expected ranges (11).

Conclusions

It appears that in acid medium this ligand

coordinates in the form **a** through the nitrogen heteroatom only (6, 7); when operating in basic medium the anionic ligand **c** obtained from the form **b** bonds via both sulphur and nitrogen. This behaviour could be explained by an attack of the sulphur anion, followed by the coordination of the cyclic nitrogen.

We can propose for the diamagnetic derivatives $Zn(mbo)_2$, $Cd(mbo)_2 \cdot H_2O$, and $Hg(mbo)_2 \cdot 2H_2O$ a tetrahedral arrangement of the ligand molecules in polymeric structures. On the basis of ir studies the structure of the copper(I) complex may be represented in the form of a polymeric structure through ligand bridging, sulphur and nitrogen bonded, in which Cu(I) tends to achieve its maximum coordination number. The formation of the chelate with a four-membered ring structure is not very probable because of its high strain. Silver(I) and gold(I) complexes have a linear structure of the type:



The derivatives of nickel(II), palladium(II), and platinum(II) are square planar, while the cobalt(II) complex is tetrahedral; rhodium(III) and iridium(III) complexes are of low-spin type in an octahedral symmetry. Rhodium(III) salts afford with mbo only substitution reactions, although the presence of thiol, a classical reducing agent, can also lead to reduction of the metal. This fact could be explained by admitting that the octahedral environment of the complex $Rh(mbo)_3 \cdot 2H_2O$ stabilizes the d^6 electronic configuration.

The insolubility of these derivatives in water and even in organic solvents provides further confirmation of a polymeric intermolecular linkage of the ligand.

In general the structures suggested seem the most reasonable ones; however, these suggestions are only tentative as the evidence supporting, for example, bridging ligands is at the moment not sufficient to be definitive.

Experimental

Purification of the Ligand

2-Mercaptobenzoxazole (mbo), supplied by Fluka, was purified by recrystallization from ethanol; mp 192–194°C (lit. (42) mp 193°C).

Preparation of the Complexes

Method A

An aqueous solution of the metal chloride or nitrate or acetate, maintained at a p*H* value lower than that of precipitation of the corresponding hydroxide, was treated with an aqueous ethanol solution of the ligand with the metal:ligand stoichiometric ratio of 1:1, 1:2, and 1:3 depending on the oxidation number of the starting metal. The p*H* value was checked by a p*H*meter Polymetron 42B during the preparation. The chloride, nitrate, or acetate ions were never present in the resulting complexes.

Method B

The metal salts were dissolved in ethanol and added dropwise to a stirred solution of mbo in a mixture of ethanol and dimethyl sulfoxide in the ratio 20:3.

The complexes obtained were purified by means of repeated washing with ethanol and dried over P_4O_{10}.

Infrared Measurements

The ir spectra were recorded in the range 4000–50 cm^{-1} with Perkin-Elmer 457 and 225 and Hitachi–Perkin-Elmer FIS3 spectrophotometers. The spectra in the range 4000–400 cm^{-1} were measured as KBr discs or a $CHCl_3$ solution. Far ir spectra were measured as Nujol mulls supported between polyethylene sheets. Atmospheric water was removed from the spectrophotometer housing by flushing with dry nitrogen.

Ultraviolet–Visible Spectra

The electronic spectra were recorded with a Shimadzu MPS-50L spectrophotometer in the solid state in the range 4000–35000 cm^{-1}.

Magnetic Susceptibility Measurements

These were carried out by Gouy's method at room temperature. Molecular susceptibilities were corrected for diamagnetism of the component atoms by use of Pascal's constants (43). This correction was not used for the temperature independent paramagnetism because it does not influence the assignment of the configurations, and, in any event, is not very accurate.

A laser interferometric study of the diffusion of O_2, N_2, H_2, and Ar into water

ROBERT NEVILLE O'BRIEN AND WILLIAM FRANK HYSLOP

Chemistry Department, University of Victoria, P.O. Box 1700, Victoria, B.C., Canada V8W 2Y2

Received November 11, 1976

ROBERT NEVILLE O'BRIEN and WILLIAM FRANK HYSLOP. Can. J. Chem. **55**, 1415 (1977).

The diffusion constants of O_2, N_2, H_2, and Ar at 24°C in H_2O are calculated from interferometric data. The question of surface resistance to diffusion of O_2 into water is discussed. There appears to be no such resistance.

ROBERT NEVILLE O'BRIEN et WILLIAM FRANK HYSLOP. Can. J. Chem. **55**, 1415 (1977).

Utilisant des données interférométriques, on a calculé, à 24°C, les constantes de diffusion de O_2, N_2, H_2 et Ar dans H_2O. On discute de la question de la résistance de surface à la diffusion de l'oxygène dans l'eau. Il semble qu'une telle résistance n'existe pas.

[Traduit par le journal]

The diffusion of gases into liquids has been studied for a very long time, but until recently gas analysis has been laborious and often inaccurate. This has resulted in a wide scatter in published results. The diffusion coefficients of gases in liquids and the scatter of the data has been recorded by Himmeblau (1) in 1964 and more recently by Tham, Walker, and Gubbins (2) in 1970. Further indications of the uncertainties are given by Danckwerts (3) and by the recent (1972) publication (4) of data for the O_2–H_2O system differing by seventy percent from the "generally accepted value".

The interest in good diffusion data arises from many sources of which the following are topical. The fuel cell which is currently most used is the hydrogen–oxygen cell and diffusion rates of dissolved gases are necessary data for design calculations. The rate of ingress of O_2 in natural waters limits the safe man-induced biological or chemical oxygen demand that can be tolerated. The rate of diffusional relaxation of supersaturation downstream from dams on natural waterways influences the incidence of fish bubble disease in the fish in these waters, and the rate of aerobic oxidation of sewage in sewage oxidation systems is dependent finally on oxygen diffusion rates in water.

All of the methods of measuring gas diffusion in water to date have depended on measuring the bulk concentration after a predetermined and rather long time. The extended times produce problems such as securing homogeneity in the solution, maintaining constant pressure and temperature, and general isolation of the system from the surroundings.

Multiple beam interferometry runs are of the order of minutes rather than hours and transient systems can be followed for very long relative times because the method requires no destructive sampling and determinations are made at motion picture camera speed, *i.e.* 16 frames per second. Zero time is easily found and, since a concentration gradient results, various regions of the liquid layer can be investigated including positions very near the surface. The literature has several references to an apparent surface resistance (3, 5, 6) which interferometry is uniquely capable of investigating.

Theory

The diffusion constant D ($cm^2\ s^{-1}$) of a species is determined by the nature of the medium as embodied in the viscosity, η ($g\ cm^{-1}\ s^{-1}$), the size of the diffusing species, r (cm), and the temperature, T (K). Usually the first two are fixed, but viscosity of course varies with temperature. Fick's Second Law expression which arises from closer consideration of the rate of change of concentration by diffusion

$$\frac{\partial C}{\partial t} = D\frac{\partial^2 C}{\partial x^2} \qquad [1]$$

where C is the concentration ($mol\ cm^{-3}$), t is the time (s), and x is the distance perpendicular to the gas–liquid interface (cm) must be solved for the initial conditions

$$C = C_0 \quad x > 0, t = 0$$

It is assumed as a boundary condition that the surface layer of liquid is immediately saturated

with gas or $C = C_s$ at a sudden pressure increase. It is also assumed that before a sudden increase in pressure the concentration of gas is uniform throughout the mass of solution ($C = C_0$) and that at a great distance ($x = \infty$) from the interface the concentration is still C_0 for the time the experiment lasts or the boundary conditions for semi-infinite or unrestricted diffusion are

$$t > 0, x \to \infty; \quad C \to C_0$$
$$t > 0, x = 0; \quad C = C_s$$

The solution of eq. 1 by Laplace transforms for these boundary conditions is

$$[2] \qquad C - C_0 = (C_s - C_0) \operatorname{erfc} \frac{x}{2\sqrt{Dt}}$$

Here erfc is the complement of the error function whose values are tabulated in a number of publications (3, 6). If Henry's Law is assumed (a good approximation for sparingly soluble gases) then

$$[3] \qquad m = kp$$

where m is the mass of gas dissolved by a unit volume of solution (mol ℓ^{-1}), k is the Henry's Law constant (mol ℓ^{-1} atm^{-1}), and p is the pressure (atm). There are plenty of data in the literature (3) and handbooks to provide C_0 and C_s. Concentration *vs.* refractive index plots are available (8). The mathematical manipulations leading to the solution of eq. 1 are also available (8).

A further assumption is made that no natural convection occurs. Since the liquid is heavier than the gas as in the case of O_2 dissolving in water, it is assumed that the oxygen solution is lighter than the pure water resulting in stable, density-layering down from the interface. This has been proven to be true. The refractive index of unreactive gas–water solutions is less than water (8) and from the Lorentz–Lorenz Law

$$[4] \qquad R = \frac{M}{\rho}\left(\frac{n^2 - 1}{n^2 + 2}\right)$$

where R is the molar refraction (cm^3), M the molecular weight (g), ρ the density (g cm^{-3}), and n is the refractive index of the pure water or solution; it is clear that it should be so. Indeed densities have been calculated from refractive index data (9).

Experimental

The apparatus used, a specially designed Fabry-Perot interferometer enclosed in a pressure jacket and partially filled with water, has been described previously (7). Briefly the coated glass flats were 5 cm apart and each had a 90% reflecting dichroic coating on the inner surfaces and anti-reflection coatings on the outer surfaces. The interferometer body was of stainless steel, the pressure compensating jacket was of mild steel. A special gas diffusing inlet allowed pressure to be applied rapidly by the quick opening valve with only moderate agitation of the water. The pressure system was arranged so that a high quality gas from a cylinder could be held in a large enough separate reservoir at the desired pressure so that on opening the fast opening valve, the pressure drop was undetectable.

Fringes were obtained vertically oriented to the meniscus and conveniently spaced at about 3 fringes per mm. The interferograms were recorded with a Bolex Paillard 16 mm camera at 16 frames per s for an initial

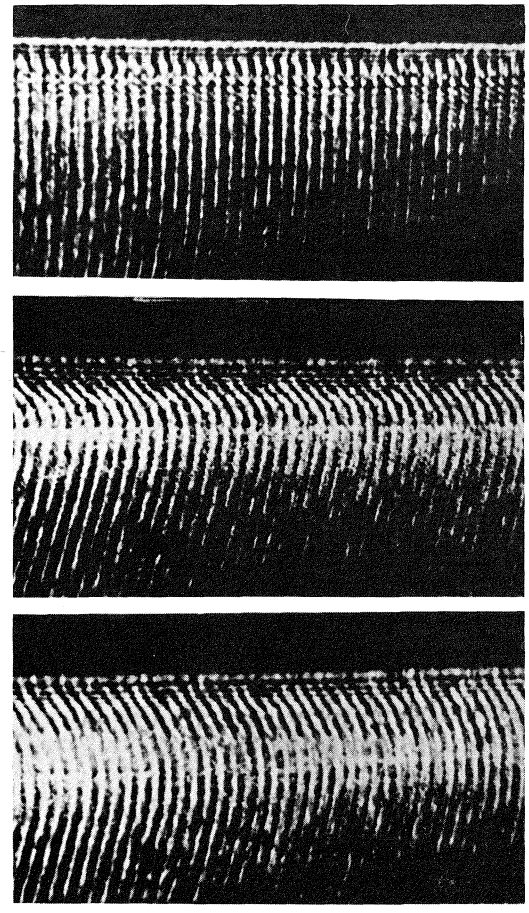

FIG. 1. Interferograms recorded at 0.0 s, 120 s, and 300 s after application of 8.27×10^5 N m^{-2}, O_2 pressure to a 0.5 M solution of Me_4NBr.

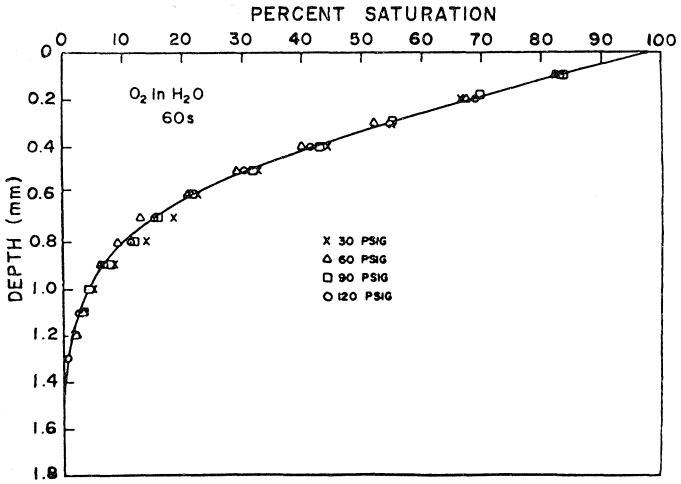

FIG. 2. Percent saturation of a solution of O_2 in H_2O *vs.* depth of H_2O at 60 s. The pressures used were 2.07×10^5 N m^{-2} (×), 4.14×10^5 N m^{-2} (△), 6.21×10^5 N m^{-2} (□), 8.27×10^5 N m^{-2} (○). The solid line was computer generated using $D = 2.0 \times 10^{-5}$ cm^2 s^{-1}.

15 s burst, then in 10 s bursts around the time at which it was desired to analyse a frame.

On application of the pressure jump, the gas temperature as measured by a miniature thermistor rose as much as 5°C. In the liquid the temperature rose 0.03°C, calculated from the refractive index change, and relaxed in about 1 to 1.5 s. The agreement of the known thermal conductivity (10) of water with the relaxation times permitted a rough calculation of the work of compression on the gas above the liquid. With allowance made for thermal capacity and conductivity of the metal walls reasonable agreement was found.

In a typical run, no thermal isolation was attempted. The room was thermostatted at 22 ± 0.5°C but no variation in the temperature of the solution was detected either by thermistor or optically over the 10–30 min of a run.

After a 100 ft roll of film had been developed, frames at selected times were analysed by projecting the frames onto a plotting table. The fringes were hand drawn at magnifications of ×50 or ×100 on large size mm graph paper and fringe shifts converted to concentration using refractive index *vs.* concentration data (7) and a modified Bragg expression

$$[5] \qquad 2nd \cos\theta = N\lambda$$

where n is the refractive index, d the thickness (cm), cos θ is almost exactly one since the angle of incidence must not deviate appreciably from 90° for good fringes, and N is the order of interference or twice the number of wavelengths λ (cm) in the thickness t.

At the pressure jump, the solution was compressed as well as heated. The compressibility of water at these low pressures (0–10 atm applied pressure) was obtained and has been published (9). The compressibility of solutions of O_2 was also obtained and is shown in Table 1. It is to be compared to $K_t \times 10^{10} = 3.97$ Pa for pure water (7) or for higher pressures Bridgman's value (11) of $K_t \times 10^{10} = 4.42$ or Kell's 4.39 (12). The average values for O_2 saturated solutions at 22°C were: at 1.03×10^5 Pa, 4.01; at 2.07×10^5 Pa, 3.91; and at 4.14×10^5 Pa, 3.99. It seems likely that the effect of O_2 in the solution is small.

TABLE 1. Isothermal compressibility of water saturated with oxygen at 4.14×10^5 Pa^{-1}

Applied pressure in psig	Pa^{-1}	F	$\Delta\rho$/N m^{-2} (× 10^7)	$10^{10} K_t$ (Pa^{-1})

81	5.583	13.0	4.027	4.038

Results and Discussion

Figure 1 is a series of interferograms at 8.3×10^5 Pa O_2 pressure in 0.5 M tetramethyl ammonium bromide solution at 22°C. They were photographed at 0 s, 120 s, and 300 s. They are presented as typical of the interferograms obtained during this study. The field of view was approximately 8 × 5 mm; the major change in fringe direction in the second frame is at about 1 mm depth.

Figures 2 and 3 give a measure of the precision of measurement. Figure 2 is percent saturation of water with O_2 *vs.* depth at 22°C and 2.07, 4.13,

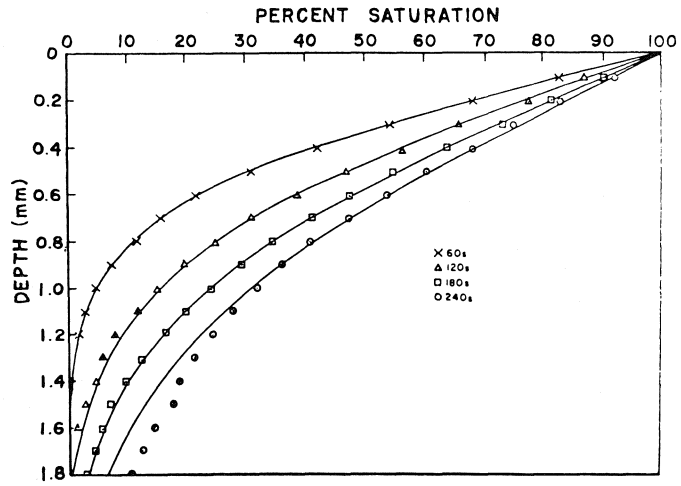

FIG. 3. Complete averaging at various times (60 s (×), 120 s (△), 180 s (□), 240 s (○)) *vs.* depth of all runs at all four pressures used, 2.07, 4.14, 6.21, and 8.27 × 10^5 N m^{-2}. The solid line was computer generated using $D = 2.0 \times 10^{-5}$ cm^2 s^{-1}.

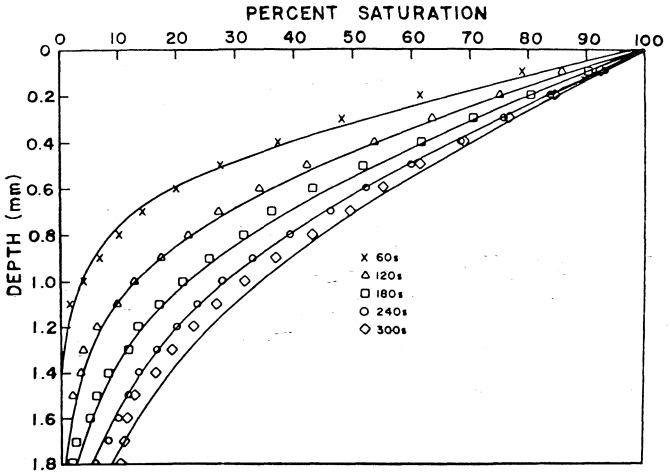

FIG. 4. Average percent saturation of N_2 in H_2O *vs.* depth for several runs at four pressures (2.07, 4.14, 6.21, 8.27 × 10^5 N m^{-2}) at 60 s (×), 120 s (△), 180 s (□), 240 s (○), and 300 s (◇). The solid line was computer generated using $D = 2.0 \times 10^{-5}$ cm^2 s^{-1}.

6.20 and 8.27 × 10^5 Pa pressure and 60 s. Figure 3 shows the same systems (except for 6.20 × 10^5 Pa) at 120 s, but completely averaged for all times and all pressures. The solid line in both cases is computer-generated from eq. 2. If averages are now taken and longer times considered, serious deviation begins at 240 s. This is believed to be due to having so short an extent of straight fringe in the frame that it is difficult to decide what represents zero change in refractive index or this is a systematic mechanical measurement error. A test of reproducibility of data was arranged by re-evaluating several runs after six months had elapsed. The reproducibility for short times was about ±0.6%.

The plot for N_2 average percent saturations in H_2O at 22°C at various depths for 8.27 × 10^5 Pa (120 psig) shows (Fig. 4) the same inaccuracies at longer times. Argon (Fig. 5) shows deviation from the theoretical at shorter times and hydrogen (Fig. 6) has only one time, 60 s, when good agreement is obtained.

This is the expected trend for more rapid diffusion rates which result in shorter straight

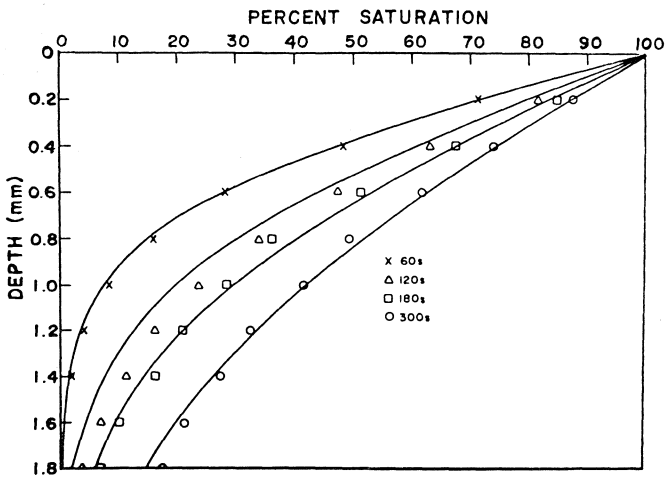

FIG. 5. Average percent saturation of Ar in H_2O *vs.* depth for several runs at various pressures (2.07, 4.14, and 6.21 × 10^5 N m^{-2}) at 60 s (×), 120 s (△), 180 s (□), 300 s (○). The solid line was computer generated using 2.5 × 10^{-5} cm^2 s^{-1}.

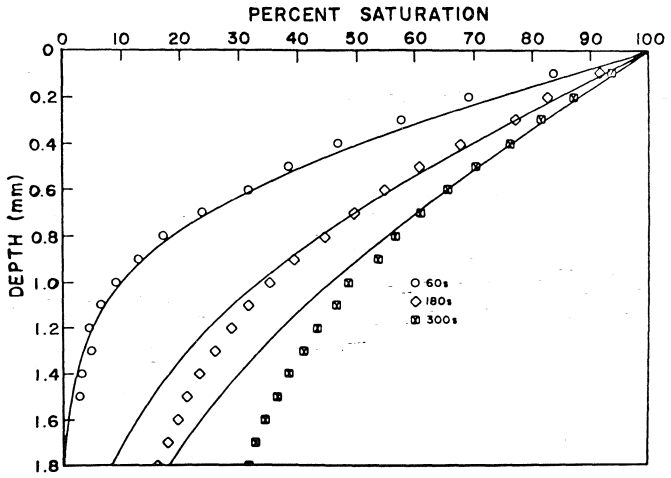

FIG. 6. Average percent saturation of H_2 in H_2O *vs.* depth for several runs at various pressures (2.07, 4.14, and 6.21 × 10^5 N m^{-2}) at 60 s (○), 180 s (□), and 300 s (⊠). The solid line was computer generated using D = 3.0 × 10^{-5} cm^2 s^{-1}.

portions of fringe in the field of view. It is also the natural result of a careful hand-measuring by a conscientious person attempting to fail safe. New machine measuring techniques presently being tested reduce the reproducibility range markedly and also are expected to effectively eliminate this problem. Figure 7 shows percent saturation of O_2 in H_2O at 1 mm and 1.5 mm depths at long times, up to 5400 s. The experiment was an attempt to link the present transient experiments with equilibrium type experiments. The fringes at 1.5 mm passed behind a fiduciary point placed in the optical system soon after 600 s. Only about 1.5% deviation from the theoretical line was found at 90 h (nearly 4 days), and 80% saturation, or there is reason to believe that values obtained by this transient method would be acceptably near equilibrium values found by other, bulk value methods.

Table 2 presents the values of diffusion constants found. The method of arriving at these values was to pick reasonable values of D the diffusion constant for the various systems, calculate the concentration expected at a given

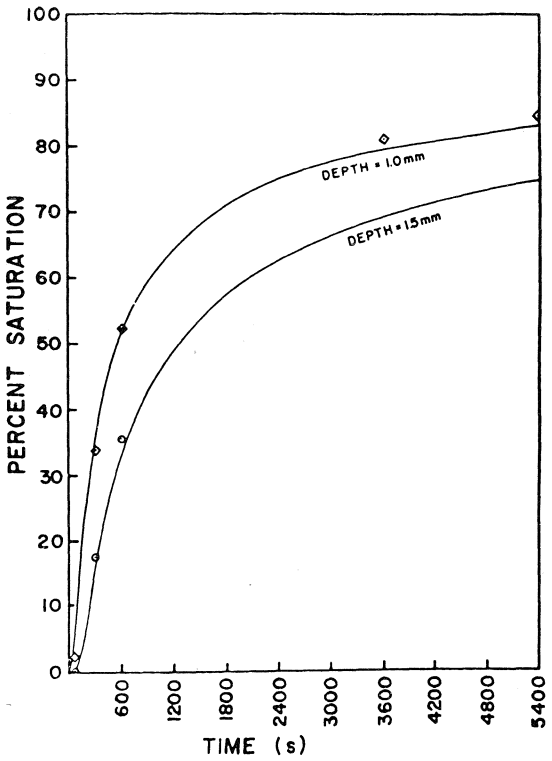

FIG. 7. Percent saturation of O_2 in H_2O at long times at two depths, 1.0 mm (◇) and 1.5 mm (○). The solid lines were computer generated using $D = 2.0 \times 10^{-5}$ cm^2 s^{-1}.

depth and time using eq. 2, and subtract these from the experimentally determined value. Figure 8 shows such a plot for O_2 in H_2O at 22°C, 60 psig for various depths and various values of D. $D = 2.0 \times 10^{-5}$ cm^2 s^{-1} obviously

TABLE 2. Diffusion coefficients of gases in liquids

Gas	Solvent	Temperature (°C)	D (cm^2 s^{-1})
Oxygen	Water	22	2.0×10^{-5}
Nitrogen	Water	22	1.8×10^{-5}
Argon	Water	22	2.5×10^{-5}
Hydrogen	Water	22	3.0×10^{-5}

fits the data best and the scatter suggests the data do not merit refinement to 2.05 or 1.95. A least-squares approximation of data showed minimum deviation at 2.0 with the deviations close to symmetrical about that value. All other systems were evaluated in the same way. The values in Table 2 agree well with the best literature values except our hydrogen–water value is slightly low. The optical anomalies investigated by McLarnon, Muller, and Tobias (13) which suggest that in cells of thickness of several centimetres significant errors could occur for refractive index gradients of 1×10^{-2} cm^{-1} do not apply since our gradient $\simeq 2.3 \times 10^{-3}$ cm^{-1}.

Conclusions

No significant deviation from theoretically calculated values at short distances below the surface were found. Nor were there short time anomalies. It is therefore concluded that no surface resistance exists at clean surfaces, though it has been shown that a monolayer of surfactant does create an appreciable barrier (14). Because of the good agreement with literature values found by other methods it is concluded that transient experiments by interferometry are as accurate as and more convenient than equili-

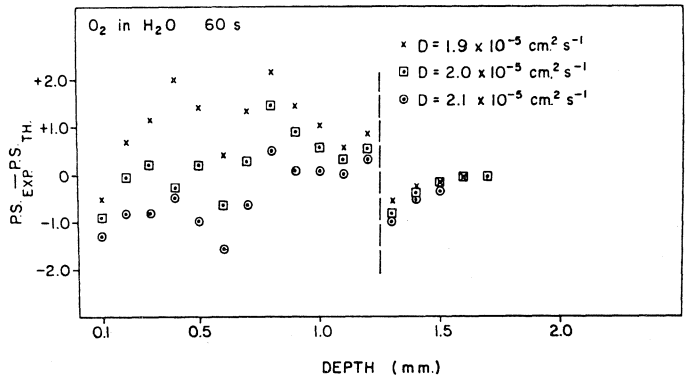

FIG. 8. The difference between experimental ($P.S._{exp}$) and calculated ($P.S._{th}$) percent saturation for O_2 in H_2O *vs.* depth at 60 s for various calculated values using $D = 1.9 \times 10^{-5}$ cm s^{-1} (×), $D = 2.0 \times 10^{-5}$ cm^2 s^{-1}, and $D = 2.1 \times 10^{-5}$ cm^2 s^{-1}.

brium values. Recently experiments have been recorded on video tape and an automatic system of evaluation of interferograms seems possible which should make the system more accurate and also much faster. Future experiments will explore other systems at other temperatures including solutions such as those in Fig. 1 and gas clathrates.

Received November 19, 1976

R. A. F. MATHESON, A. W. MCCULLOCH, A. G. MCINNES, and D. G. SMITH. Can. J. Chem. **55**, 1422 (1977).

Direct irradiation (2537 Å) of methyl 1,4-diphenyl-1,4-epoxy-1,4-dihydronaphthalene-2-carboxylate (**13***b*) affords methyl 2,4-diphenyl-3-benzoxepine-1-carboxylate (**17***b*) and methyl 1-benzoyl-3-phenylindene-2-carboxylate (**19***b*), while acetone-sensitized irradiation yields chiefly **19***b*. The latter can be converted to methyl 3-phenylindene-2-carboxylate (**21***b*).

Direct irradiation of dimethyl 1,4-diphenyl-1,4-epoxy-1,4-dihydronaphthalene-2,3-dicarboxylate (**13***a*) affords a mixture of dimethyl 2,4-diphenyl-3-benzoxepine-1,5-dicarboxylate (**17***a*), dimethyl 1-benzoyl-3-phenylindene-1,2-dicarboxylate (**19***a*), and dimethyl 1-benzoyl-2-phenylindene-1,3-dicarboxylate (**18**). The latter two products cleave readily to give dimethyl 3-phenylindene-1,2-dicarboxylate (**21***a*) and dimethyl 2-phenylindene-1,3-dicarboxylate (**20**) respectively. Sensitized irradiation yields mainly **19***a*. The formation of **19***a* and **19***b* as major products of photorearrangement of **13***a* and **13***b* is consistent with a di-π-methane pathway producing methyl 4,6-diphenyl-5-oxatetracyclo[5.4.0.0.^{2,4}0^{3,6}]undeca-1(7),8,10-triene 2-carboxylate and 2,3-dicarboxylate (**25***a*,*b*), intermediates similar to those previously observed by other workers for benzonorbornadienes and 7-azabenzonorbornadienes. Compound **18** is derived by photo-induced rearrangement of the benzoxepine **17***a*.

The $AlCl_3$-catalyzed rearrangement of **13***a* yields a mixture of dimethyl 2,4-diphenyl-1(2*H*)-naphthalenone-2,3-dicarboxylate (**15**) and methyl 1,3-diphenyl-4-hydroxynaphthalene-2-carboxylate (**16**), while that of **13***b* affords only **16**.

R. A. F. MATHESON, A. W. MCCULLOCH, A. G. MCINNES et D. G. SMITH. Can. J. Chem. **55**, 1422 (1977).

L'irradiation directe (2537 Å) du diphényl-1,4 époxy-1,4 dihydro-1,4 naphtalènecarboxylate-2 de méthyle (**13***b*) conduit au diphényl-2,4 benzoxépine-3 carboxylate-1 de méthyle (**17***b*) et au benzoyl-1 phényl-3 indènecarboxylate-2 de méthyle (**19***b*) alors que l'irradiation sensibilisée par l'acétone fournit principalement **19***b*. On peut convertir ce dernier en phényl-3 indènecarboxylate-2 de méthyle (**21***b*).

L'irradiation directe du diphényl-1,4 époxy-1,4 dihydro-1,4 naphtalènedicarboxylate-2,3 de méthyle (**13***a*) conduit à un mélange de diphényl-2,4 benzoxépine-3 dicarboxylate-1,5 de méthyle (**17***a*), du benzoyl-1 phényl-3 indènedicarboxylate-1,2 de méthyle (**19***a*) et du benzoyl-1 phényl-2 indènedicarboxylate-1,3 de méthyle (**18**). Ces deux derniers produits se coupent rapidement pour conduire respectivement au phényl-3 indènedicarboxylate-1,2 de méthyle (**21***a*) et au phényl-2 indènedicarboxylate-1,3 de méthyle (**20**). L'irradiation sensibilisée conduit principalement à **19***a*. La formation de **19***a* et de **19***b* comme produits majeurs des photoréarrangements de **13***a* et de **13***b* est en accord avec un chemin di-π-méthane produisant les diphényl-4,6 oxa-5 tétracyclo[5.4.0.0.^{2,4}0^{3,6}]undécatriène-1(7),8,10 carboxylate-2 et dicarboxylate-2,3 de méthyle (**25***a*,*b*), des intermédiaires semblables à ceux observés antérieurement par d'autres chercheurs pour des benzonorbornadiènes et des aza-7 benzonorbornadiènes. Le composé **18** dérive d'un réarrangement photoinduit de la benzoxépine **17***a*.

Le réarrangement catalysé par $AlCl_3$ de **13***a* conduit à un mélange de diphényl-2,4 1(2*H*) napthtalènonedicarboxylate-2,3 de méthyle (**15**) et de diphényl-1,3 hydroxy-4 naphtalènecarboxylate-2 de méthyle (**16**) alors que celle de **13***b* conduit uniquement à **16**.

Introduction

There has been considerable interest in recent years in the photochemistry of the benzonorbornadiene system (1–8). Sensitized irradiation of benzonorbornadiene **1***a* (1) and some substituted derivatives **1***b–e* (2) has been shown to afford good yields of the corresponding tetracyclic compounds **2***a–e*.

Prinzbach and his co-workers have studied the photochemical behavior of the three 7-azabenzonorbornadiene derivatives **3***a–c*. Direct irradia-

tion of **3***a*,*b* gave chiefly the anticipated benzazepine **4***a*,*b*, while irradiation of **3***c* afforded a mixture of **4***c* (9%) and the benzofulvene **5***c* (40%). Acetone-sensitized irradiation of **3***a* gave a mixture of the isomeric fulvenes **5***a* and **6***a* (3). Recent work by Swenton and his co-workers on the direct and sensitized photochemistry of the 7-aza derivative **3***d* has clarified the behavior of the above compounds (5, 6). While direct irradiation of **3***d* gave the benzazepine **4***d*, the acetone-sensitized reaction under carefully controlled conditions led to isolation of the tetracyclic azetidine **7***d* (94%), which underwent facile (acid-catalyzed) isomerization to the benzofulvene **5***d*. All attempts to isolate compounds of type **7** from the reactions of **3***a* or the 1,4-dimethyl derivative of **3***d* were unsuccessful, and it was suggested that this was probably due to their instability (6).

The photochemical behavior of simple 7-oxabenzonorbornadienes has received relatively little attention.[3] Ziegler and Hammond found that direct irradiation of 7-oxabenzonorbornadiene **9** afforded the corresponding benzoxepine **10** (4–6%), while the sensitized reaction gave a dimer (8%) resulting from intermolecular 2 + 2 cycloaddition of **9**, together with a large amount of intractable material (7, 8). Edman has suggested that formation of polymer in the latter reaction may be due to formation of the reactive tetracyclic ether **11** (1).

In the course of an investigation of the influence of $AlCl_3$ on the Diels–Alder reactions of a number of heterocyclic dienes, we have studied the reactions of 1,3-diphenylisobenzofuran **12** with dimethyl acetylenedicarboxylate (DMAD) and methyl propiolate (MP). We have also carried out a study of the photochemical behavior of the 1,4-diphenyl-1,4-epoxy-1,4-dihydronaphthalene adducts **13***a* and **13***b*. These 7-oxabenzonorbornadienes are of particular interest since it was anticipated that the presence of the bridgehead aryl substituents might enhance the stability of certain radical intermediates, and would certainly preclude formation of a benzofulvene. Our results are given below, together with some discussion of the $AlCl_3$-catalyzed rearrangements of these compounds.

[3]Prinzbach *et al.* have studied the photochemistry of the annellated oxanorbornadiene **8** (9).

Results and Discussion

Preparation of the 7-Oxabenzonorbornadienes 13a,b

Diene **12** reacted readily with DMAD or MP to give the expected Diels–Alder adducts **13***a* and **13***b*. It was difficult to stop the reaction at this stage in the case of **13***b* due to the enhanced dienophilicity of the oxanorbornadiene-2-carboxylate system (*cf.* ref. 10). Formation of **13***b* was favored at low temperatures and high dienophile concentration: at higher reaction temperatures and lower concentrations of MP the diadduct **14** was favored. A diacid analogous to **14**, resulting from the reaction of **12** with acetylenedicarboxylic acid, has been previously reported by Berson (11).

As expected $AlCl_3$ caused a significant enhancement in the rate of Diels–Alder addition of **12** to both dienophiles. Reactions of **12** with DMAD in the presence of $AlCl_3$ gave, depending on the reaction parameters (see Table 1), the adduct **13***a*, the naphthalenone **15**, and the naphthol **16**. Similar reactions of **12** with MP gave **13***b*, **14**, and **16**. Additional experiments established that **15** and **16** could be obtained in good yield on treatment of **13***a* and **13***b*, respectively, with Lewis acids. Mechanisms for this type of rearrangement have been discussed previously (12–15).

The isolation of **16** from reaction of **12** with DMAD is, however, unexpected. This product must arise via decarboxylation of the β-keto ester **15**, and indeed we have shown that treatment of **15** with $AlCl_3$ gives **16**.

Photochemistry of the 7-Oxabenzonorbornadienes 13a,b

Observations

Direct irradiation (2537 Å; Et_2O) of **13***b* gave as major product (40%) the indene **19***b* together with the benzoxepine **17***b* (20%); the yield of **19***b* increased (55%) in the acetone-sensitized reaction.

Direct irradiation (Et_2O or CH_2Cl_2) of **13***a* gave the benzoxepine **17***a* as a minor product (15–20% yield, based on the amount of starting material consumed).[4] The major component of the crude reaction product, the indene **19***a*, was readily converted to **21***a* during work-up. A third product, indene **18**, was similarly converted to **20** (see Experimental). Because of their reactivity we were unable to obtain **18** and **19***a* in pure state. The conversions of **18** and **19***a* to **20** and **21***a* took place slowly on standing and were catalyzed by acid or base.[5] Benzoic acid was identified as a by-product in each case. The facility of the rearrangements of **18** and **19***a* is consistent with their β-keto ester structures. In contrast, compound **19***b*, which does not possess a β-keto ester moiety, proved to be relatively stable to acid, base, and moisture; it was, however, converted in part to **21***b* during thin-layer chromatography on alumina plates.

Acetone-sensitized irradiation of **13***a* gave as predominant product the indene **19***a* and only a small amount of **17***a*. The percentage of light capture by the sensitizer during both this irradiation and the acetone-sensitized irradiation of **13***b* above was calculated to be 90–95%.

For comparison purposes we investigated the acetone-sensitized irradiation of the diaryl-substituted oxanorbornadiene **22**. We had previously shown that this compound was converted on direct irradiation chiefly to the oxepine **23***a*, with a small amount of the 6-hydroxyfulvene **24** as by-product (16). Use of acetone as a sensitizer caused reversal of the product ratio, the product now being almost exclusively **24**, with only a very low yield of **23***a*.

The light-catalyzed reaction of **22** in the presence of iodine is known to proceed readily to give a high yield of **24** (16). The benzo derivative **13***a* was, however, surprisingly inert under similar experimental conditions.

Mechanisms

Triplet-sensitized irradiations of benzonor-

TABLE 1. Reaction of 1,3-diphenylisobenzofuran (**12**) with DMAD in the presence of $AlCl_3$ (molar ratio of reactants 1:1:2)[a]

Time (min)	T (°C)	Product yields (%)[b] **13***a*	**15**	**16**
10	−20	81	9	—
30	0	18	75	—

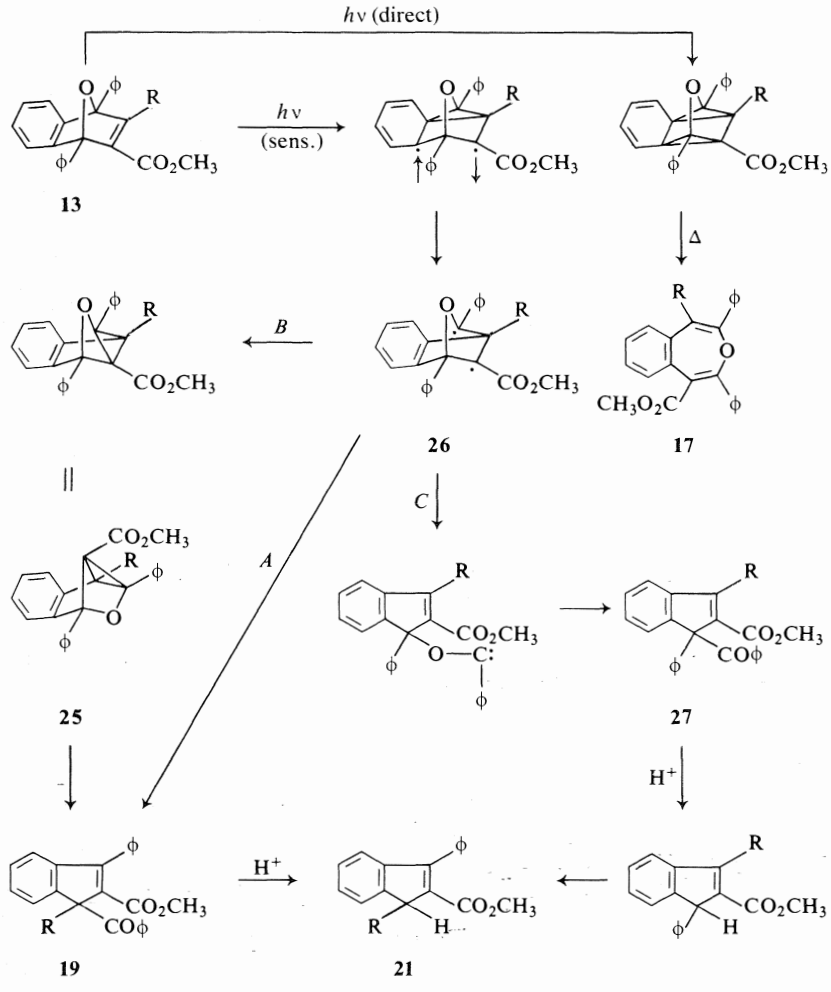
240	40	—	5	75

[a]Concentration of **12** 0.061 *M* in CH_2Cl_2.
[b]Yields based on **12**.

[4]Prinzbach *et al.* have reported that direct irradiation of **13***a* produces a 40–50% conversion to **17***a*, although no details were given (footnote in ref. 3).

[5]Although the base-catalyzed reactions proceeded rapidly the products were base-sensitive. In the case of **21***a*, the 1-hydroxyindene **29** was identified as an oxidative breakdown product (see Experimental).



a, R = CO_2CH_3 *b*, R = H

SCHEME 1

bornadienes **1** (1, 2) and of the 7-aza analog **3***d* (6) afford the tetracyclic products **2** and **7***d*, respectively. The observed subsequent rearrangement of **7***d* to the benzofulvene **5***d* must proceed by way of a tautomeric indene intermediate (6). If the sensitized photorearrangements of **13***a* and **13***b* are to parallel those above we would expect (*i*) formation of the tetracyclic oxetanes **25***a* and **25***b* via the di-π-methane intermediates **26***a* and **26***b* (Scheme 1, pathway *B*), and (*ii*) their subsequent rearrangement to the keto indenes **19***a* and **19***b*.

Alternative less likely mechanisms of indene formation from **13** via intermediate **26** (*cf.* refs. 6, 16–18) are 1,4-radical cleavage leading directly to **19** (Scheme 1, pathway *A*) and 1,2-cleavage to a carbene intermediate and migration to give **27** (Scheme 1, pathway *C*). Hydrolytic cleavage of **27** could afford **21***a* via its tautomer.

None of the pathways shown in Scheme 1 account for the formation of indene **18**. We have found that this compound arises through photorearrangement of the benzoxepine **17***a*. A ring-contraction mechanism, involving transannular 1,4-bond formation similar to that observed during photo-induced rearrangement of simple oxepines and azepines (19) and of 1-benzothiepine (20), is shown in Scheme 2.

Structures of Products

The structures of all products were based mainly on spectroscopic evidence (see Experi-

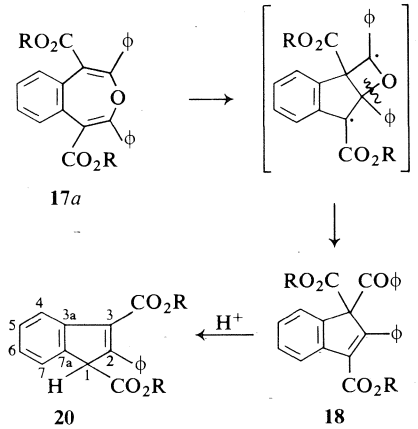

SCHEME 2

mental). ^{1}H nmr data are detailed in Table 2 and relevant ^{13}C nmr data have been included in the experimental section. Detailed tabulated ^{13}C data (in $CDCl_3$) for compounds **15**, **16**, **17***a*, **17***b*, **19***b*, **20**, **21***a*, **21***b*, and **29**, as well as for indene itself, have been deposited in the Depository of Unpublished Data.[6]

(a) Adducts 13a, 13b, and 14

These compounds are all formed via well-recognized pathways. Their mass spectra show weak molecular ions and as expected are also characterized by strong ions at *m/e* 270 derived by Diels–Alder retrogression to **12**. In addition these compounds show the anticipated ^{1}H nmr signals for aromatic, carbomethoxyl, olefinic (**13***b*), and ring-junction (**14**) hydrogens. No attempt was made to unequivocally establish the stereochemistry of the central ring-junction in **14**, although by analogy with our previous work on the Diels–Alder additions of furans to oxonorbornadienes (10, 21), we have tentatively assigned the *endo–exo* stereochemistry shown.

(b) Naphthalenone 15 and Naphthol 16

The acid-catalyzed rearrangement of fully substituted oxanorbornadienes to cyclohexadienones is known (12), as is the corresponding rearrangement of lesser substituted oxanorbornadienes to substituted phenols (12–15). Analogous rearrangements of **13***a* and **13***b* would be expected to yield **15** and **16**, respectively. The spectroscopic evidence given below established that these products were in fact obtained.

In the case of **16** the presence of a phenolic hydroxyl group is indicated by its ir (3540 cm^{-1}) and ^{1}H nmr (δ 5.68, exchangeable by D_2O) spectra. This hydroxyl is not hydrogen bonded to the conjugated ester group (1724 cm^{-1}), establishing that these two substituents are not in an *ortho* relationship. Strong evidence that the hydroxyl group is located at C-1 is derived from the low-field shift (δ 8.33) of one aromatic proton (H-5), a characteristic of 1-naphthol (22). Finally, the exceptionally high-field shift (δ 3.19) of the protons of the carbomethoxyl group is consistent with shielding by two vicinal aryl substituents (*cf.* ref. 14).

In the case of the naphthalenone **15** the ir

[6]The tabular data are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

spectrum shows absorptions for conjugated ester (1698 cm^{-1}), non-conjugated ester (1734 cm^{-1}), and ketone (1668 cm^{-1}) carbonyl groups. The ^1H nmr spectrum shows two methoxyl resonances, at δ 3.78 and 3.35. The high-field shift of the latter is again due to its shielding by the *ortho* phenyl substituent. The conversion of **15** to **16** on treatment with Lewis acids suggests that the ketone carbonyl must be at C-1 of the naphthalene ring, and the ease of this decarboxylative conversion strongly indicates the presence of a β-keto ester system in **15**.

Although it is impossible to assign most of the individual carbon resonances of **15** and **16**, due to extensive signal overlap in their high-resolution ^{13}C nmr spectra, some significant observations can be made which serve to confirm these structures. In the case of **16** the signal for the hydroxyl-substituted C-1 appears as expected at low field (147.9 ppm). This chemical shift is similar to that of C-1 in 1-naphthol (23). The signal for C-2 of **16** is at 118.3 ppm, due to a combination of shielding by the hydroxyl group at C-1 (*cf.* C-2 of 1-naphthol (23)) and deshielding by the attached aryl substituent. The main features of the spectrum of **15** are the three carbonyl resonances at 167.0 and 169.5 (both ester), and 193.9 (ring ketone) ppm, and the saturated carbon resonance (C-2) at 68.0 ppm.

(c) Benzoxepines 17a and 17b

The spectral properties of these compounds are similar to those of the related oxepines **23***a*,*b* (16). The mass spectra show the expected molecular ions, with base peaks at *m*/*e* 105, due to the tendency of these molecules to readily lose a benzoyl fragment. The ir spectra show absorptions for conjugated ester carbonyl groups and the ^1H nmr spectra are characterized in each case by an aromatic envelope (14H) and by the appropriate signals for methoxyl (6H singlet for **17***a*) and oxepine ring (**17***b*) hydrogens. The ^{13}C nmr spectra especially that of **17***b*, are complicated by overlapping signals for the many aromatic resonances. The carbons directly attached to the ring oxygen and also substituted by aryl groups (C-2 and C-4) appear as expected well downfield at 157–159 ppm. In the case of **17***b* the unsubstituted ring carbon (C-5) resonates at 114.1 ppm (^1J = 156.8 Hz) consistent with its position β to the ring oxygen.

Indenes 18, 19a, 19b, 20, 21a, 21b, and 29

The structure of **21***a* was unequivocally established by X-ray analysis, full details of which will be published elsewhere (28). Prior spectroscopic evidence strongly indicative of this structure included: (*a*) a molecular ion in the mass spectrum corresponding to the molecular formula $C_{19}H_{16}O_4$; (*b*) ir absorptions for α,β-unsaturated (1721 cm^{-1}) and non-conjugated (1735 cm^{-1}) ester carbonyl groups; (*c*) strong ultraviolet absorption maxima at *ca.* 235 and 290 nm, consistent with its substituted indene chromophore; (*d*) ^1H nmr signals for nine aromatic hydrogens (envelope), two methoxyl groups, and a single methine proton (δ 4.87); and (*e*) its ^{13}C nmr spectrum which is consistent with the types of carbons present (indene, phenyl, and carbomethoxyl) and is similar in many respects to the spectrum of indene itself.

Although it is not possible to make unambiguous assignments of all the carbons of the indene skeleton of **21***a*, due to signal overlap in the high-resolution spectrum, such assignments can be readily made in the case of C-1, C-2, and C-3. The methine carbon (C-1) appears at 55.7 ppm, reflecting the deshielding effect of the carbomethoxyl substituent. The resonance for C-2 can be assigned on the basis of its chemical shift (129.6 ppm; deshielded by the attached ester group, but shielded by the β-phenyl substituent). This carbon is geminally coupled (^2J = 6.1 Hz) to H-1.[7] As expected the phenyl-substituted carbon, C-3, appears well downfield (155.2 ppm; deshielded by both the phenyl group and the ester substituent at C-2) as a multiplet (possible coupling with the *ortho* hydrogens of the aryl substituent as well as to H-1 and H-4).

The ester carbonyl carbon bonded to C-1 can also be differentiated on the basis of its geminal coupling (^2J = 11.0 Hz) with H-1.

Compound **21***a* has been suggested previously as a product of photolysis of **28** (27). The similarity between the recorded properties and those of our product confirms this assignment.

The structures of the four indene derivatives **19***b*, **20**, **21***b*, and **29**, have been deduced mainly through comparison of their ^{13}C nmr spectra with that of **21***a* (see below). Supporting evidence for each structure is also obtained (see Experimental) from: (*a*) their mass spectra, each of which exhibits a molecular ion corresponding to the expected molecular formula; (*b*) their ir

[7]The observation of similar spacing (5.8 Hz) in the resonance at 133.9 ppm in the spectrum of indene confirms its assignment to C-2. This resonance has previously been assigned to C-2 (24, 25) or C-3 (26).

29

spectra which show absorptions for α,β-unsaturated ester (all four compounds), non-conjugated ester (**20**), and ketonic (**19***b*) carbonyl groups; (*c*) their uv absorption spectra all of which have comparable maxima at *ca.* 235 and 290 nm; and (*d*) their ^{1}H nmr spectra (Table 2) which are characterized by the expected signals for aromatic, methoxyl, and methine (or methylene) hydrogens.

As stated above the structures of **19***b*, **20**, **21***b*, and **29** were elucidated largely on the basis of their ^{13}C nmr spectra and comparison with the data obtained for the established structure **21***a*. In the case of the structurally-related **21***b* most of the carbon resonances can be readily compared to those of the corresponding carbons of **21***a*. The most significant features of **21***b* are: (*i*) the chemical shift and multiplicity of C-1, confirming the methylene nature of this carbon, and (*ii*) the characteristic geminal coupling between C-2 (130.6 ppm, triplet, ^2J = 6.9 Hz) and the two hydrogens at C-1. The chemical shift and the absence of any other observable long-range coupling involving C-2 proves that the ester grouping must be at this carbon.

The structure of the 1-benzoyl indene **19***b*, which is a direct precursor of **21***b* and must therefore have the same relative orientation of the ester and phenyl substituents as the latter, follows again from comparison of its ^{13}C nmr spectrum with that of **21***a*. In this case it was not possible to determine the coupling between C-2 and H-1 (due to signal overlap), but the geminal coupling between H-1 and the ketone carbonyl carbon at C-1 (^2J = 8.1 Hz) could be readily observed.

In the case of the 1-hydroxy derivative **29** the only major ^{13}C nmr spectral differences are (*i*) the chemical shift of C-1, now moved downfield (to 83.9 ppm) in accord with deshielding by the hydroxyl substituent, and (*ii*) the absence of geminal coupling in the ester carbonyl carbon which is bonded to C-1, which shows that the hydroxyl is located at C-1. The presence of the hydroxyl group is confirmed by ir absorption at 3480 cm^{-1}, and a ^{1}H nmr signal at δ 4.30, replaceable by D_2O.

The isomeric nature of **20** and **21***a* is clearly evidenced by their ir, uv, ^{1}H nmr, and ^{13}C nmr spectra. Since the geminal coupling in the ester carbonyl carbon and the chemical shift of C-1 are essentially the same in both compounds the difference can only be in the position of the ester and phenyl substituents. Thus **20** must have the ester grouping at C-3, and in accord with this both C-2 and C-3 now appear as multiplets since both of these carbons will now be long-range coupled to at least two hydrogens.

As mentioned previously compounds **18** and **19***a* could not be isolated in a pure state due to their ease of rearrangement to **20** and **21***a*. However, by analogy with the closely related conversion of **19***b* to **21***b*, we can assign precursors **18** and **19***a* the structures shown. Supporting evidence was obtained from studies of samples rich in these compounds. The ^{1}H nmr spectra both show aromatic envelopes and singlets for the hydrogens of two methoxyl groups; the mass spectra show strong ions at *m/e* 105 (base peak), reflecting the very facile cleavage of the benzoyl grouping.

Experimental

The ^{1}H nmr spectra were obtained on a Varian A-60A spectrometer, using $CDCl_3$ as solvent and tetramethylsilane as internal standard. ^{13}C nmr spectra at 25.16 MHz were recorded in $CDCl_3$ on a Varian XL-100-15 spectrometer equipped with a VFT-100 data system. The deuterium resonance from the solvent was used for field-frequency lock. Spectral width was 5120 Hz with an acquisition time of 0.8 s, and an 8K transform was used. In addition to proton noise decoupled spectra, high-resolution spectra enhanced by gated noise decoupling were used to obtain coupling constants ($J_{^{13}C-^1H}$).

Infrared absorptions (in $CHCl_3$ solution, unless otherwise stated) were measured on a Perkin–Elmer 521 spectrometer. Ultraviolet spectra were recorded in 95% EtOH on a Unicam SP 8000 spectrophotometer. The high-resolution mass spectral measurements were made

using a Dupont-C.E.C. 21-110B double focussing mass spectrometer.

All column chromatography was carried out using Mallinckrodt silicic acid (100 mesh) with $CHCl_3$ as eluant unless stated otherwise. Preparative thin-layer chromatography (plc) was performed on Merck silica gel F-254 precoated plates using 2 mm layers.

Irradiation experiments were conducted in a Rayonet photochemical reactor, using quartz reaction vessels, a 2537 Å light source, and an operating temperature of 30°C. Fisher spectral grade acetone (ε at 254 nm = 11) was employed in the sensitized irradiations.

Reaction of 1,3-Diphenylisobenzofuran with Dimethyl Acetylenedicarboxylate (DMAD)

(a) Thermal Reaction

A mixture of **12** (3.25 g, 0.012 mol) and DMAD (1.88 g, 0.013 mol) was refluxed in benzene (125 ml) for 4 h. Removal of the solvent and recrystallization of the crude product from ethyl acetate – pentane gave the 7-oxabenzonorbornadiene **13***a* as cream-colored prisms (4.30 g, 87%), mp 158–160°C. Molecular ion (< 1%) at *m/e* 412.1310 ($C_{26}H_{20}O_5$ requires 412.13108); base peak at *m/e* 105 ($C_6H_5CO^+$); significant ions at *m/e* (%) 380(5), 336(5), 270(36), 241(6), 239(4), 189(7), 165(5), 135(4), and 77(19). ν_{max} 1718, 1626 cm^{-1}. λ_{max} (ε) 207 (36 900), 218 (30 400) nm; ε at 254 nm, 2900.

(b) $AlCl_3$-Promoted Reaction

The Lewis acid promoted reaction was conducted using a variety of reaction parameters: a summary of the experimental conditions and product compositions is given in Table 1. A typical procedure follows.

A solution of **12** (2.07 g, 0.0077 mol) in CH_2Cl_2 (25 ml) was added to a stirred mixture of DMAD (1.16 g, 0.0082 mol) and $AlCl_3$ (2.22 g, 0.0167 mol) in CH_2Cl_2 (100 ml) at 25°C. Reaction was allowed to continue for 30 min, and was terminated by pouring into ice-water. The organic layer was separated, dried (Na_2SO_4), and the solvent removed under reduced pressure. The oily residue (3.08 g) was chromatographed. From the column, in order of elution, were obtained: (*i*) unreacted DMAD (0.12 g); (*ii*) adduct **13***a* (0.22 g, 7%); (*iii*) the naphthalenone **15**, isolated as a colorless solid (2.18 g, 69%), mp 206–207°C. Molecular ion (29%) at *m/e* 412.1302 ($C_{26}H_{20}O_5$ requires 412.13108); base peak at *m/e* 293; significant ions at *m/e* (%) 380(31), 352(68), 321(73), 265(57), 263(30), and 105(22). ν_{max} 1734, 1698, 1668 cm^{-1}. δ_c (ppm) 68.0 (br t, 3.0, C-2), 167.0 (q, 4.0, ester C=O), 169.5 (q, 4.1, ester C=O), 193.9 (dd, 3.6, 1.6, C-1); (*iv*) a fraction which was further purified by plc (25% acetone – petroleum ether) to give the naphthol **16** as a colorless solid (0.41 g, 15%), mp 92–94°C. Molecular ion (100%) at *m/e* 354.1254 ($C_{24}H_{18}O_3$ requires 354.12560); significant ions at *m/e* (%) 323(14), 321(12), 265(13), 209(12), 161(9), 147(20), 85(8), 83(11), and 59(8). ν_{max} 3540, 1724, 1589, 1570 cm^{-1}. δ_c (ppm) 118.3 (s, C-2), 147.9 (br s, C-1).

Reaction of 1,3-Diphenylisobenzofuran with Methyl Propiolate (MP)

(a) Thermal Reaction

To a stirred solution of MP (2.61 g, 0.0311 mol) in CH_2Cl_2 (10 ml) at 0°C was added dropwise over a period of 30 min a solution of **12** (1.06 g, 0.0039 mol) in CH_2Cl_2 (25 ml). The mixture was stirred for a further 1 h at 0°C and the solvent then removed at low temperature under reduced pressure. Column chromatography of the yellow oily residue afforded the following, in order of elution.

(*i*) A colorless solid (823 mg), crystallization of which from ethyl acetate – petroleum ether gave the 2:1 adduct **14** as colorless prisms (732 mg, 59%), mp 220–222°C (dependent on rate of heating). Molecular ion (≪1%) at *m/e* 624 ($C_{44}H_{32}O_4$ requires 624); base peak at *m/e* 270 (1,3-diphenylisobenzofuran$^+$); significant ions at *m/e* (%) 241(21), 239(17), 218(5), 189(10), 165(13), 135(11), 105(69), and 77(14). ν_{max} 1721, 1600 cm^{-1}.

(*ii*) A colorless oil (448 mg), crystallization of which from ethyl acetate – petroleum ether gave the mono-adduct **13***b* as cream-colored prisms (357 mg, 26%), double mp, with partial liquefaction at 121–125°C and melting at 142–146°C. Molecular ion (3%) at *m/e* 354.1247 ($C_{24}H_{18}O_3$ requires 354.12560); base peak at *m/e* 105 ($C_6H_5CO^+$); significant ions at *m/e* (%) 322(4), 294(4), 270(29), 241(4), 239(4), 218(5), 189(10), 165(5), 135(3), and 77(15). ν_{max} 1720, 1604, 1584 cm^{-1}. λ_{max} (ε) 208 (35 400), 218 (33 300) nm; ε at 254 nm, 2300.

Reaction of equimolar amounts of **12** and MP at 40°C for 90 min gave a 77% yield of **14** and negligible **13***b*.

(b) $AlCl_3$-Promoted Reaction

Compound **12** (1.05 g, 0.0039 mol) in CH_2Cl_2 (30 ml) was cooled to −30°C and added dropwise over 2 min to a similarly cooled, vigorously stirred mixture of MP (0.33 g, 0.0039 mol) and $AlCl_3$ (1.04 g, 0.0078 mol) in CH_2Cl_2 (50 ml). The reaction mixture was stirred at −30°C for a further 8 min, and then treated with ice water (20 ml). The organic layer was separated, dried (Na_2SO_4), and the solvent evaporated under reduced pressure. The dark oily residue was chromatographed and fractions recovered as follows: (*i*) unreacted MP (0.13 g); (*ii*) a mixture of **13***b* and **14**. Preparative thin-layer chromatography (25% acetone – petroleum ether) gave **13***b* (0.12 g, 9%) and **14** (0.63 g, 52%); (*iii*) the naphthol **16** (0.11 g, 8%).

*Reaction of **13***b* with 1,3-Diphenylisobenzofuran*

Adduct **13***b* (0.36 g, 0.001 mol) and **12** (0.27 g, 0.001 mol) were heated at 40°C in CH_2Cl_2 (15 ml) for 2 h. Evaporation of the solvent and crystallization of the residue from petroleum ether gave **14** (0.48 g, 77%).

*Rearrangement of **13***a* to **15***

(*a*) The benzonorbornadiene **13***a* (0.73 g, 0.0018 mol) and $AlCl_3$ (0.49 g, 0.0037 mol) in CH_2Cl_2 (30 ml) were stirred at 25°C for 90 min. Ice water (15 ml) was added to destroy the $AlCl_3$ and the organic layer then separated, dried (Na_2SO_4), and evaporated. The crude product was chromatographed. Collected from the column, in order of elution, were unreacted **13***a* (0.08 g), **15** (0.48 g, 66%), and **16** (0.11 g, 17%).

(*b*) Gaseous BF_3 was bubbled through a solution of **13***a* (0.73 g) in CH_2Cl_2 (30 ml) for 10 min. Work-up and chromatography as above afforded starting material (0.15 g) and **15** (0.51 g, 70%).

*Rearrangement of **13***b* to **16***

$AlCl_3$ (0.49 g, 0.0037 mol) was added to a solution of **13***b* (0.41 g, 0.0012 mol) in CH_2Cl_2 (30 ml), and the stirred mixture heated at 40°C for 30 min. After hydrolysis with ice water, the organic layer was separated, dried

(Na_2SO_4), and the solvent removed under reduced pressure. Chromatography afforded **16** (0.23 g, 56%).

*Rearrangement of **15** to **16***

Naphthalenone **15** (0.54 g, 0.0013 mol) and $AlCl_3$ (0.57 g, 0.0043 mol) in CH_2Cl_2 (25 ml) were stirred at 40°C for 3 h. After removal of the Lewis acid by ice water, the organic layer was separated, dried (Na_2SO_4), and evaporated. Column chromatography afforded unreacted **15** (0.19 g) and the naphthol **16** (0.22 g, 48%).

*Direct Irradiation of Oxabenzonorbornadiene **13b***

A solution of **13***b* (150 mg, 0.00042 mol) in ether (150 ml) was irradiated for 6 h. The residue obtained on removal of the solvent was chromatographed. Fractions eluted as follows.

(*i*) Benzoxepine **17***b* (30 mg, 20%), obtained as a colorless solid, mp 117–119°C. Molecular ion (7%) at *m/e* 354 ($C_{24}H_{18}O_3$ requires 354); base peak at *m/e* 105 ($C_6H_5CO^+$); *m/e* 77(27%); all other ions <4%. ν_{max} 1719 cm^{-1}. λ_{max} (ε) 205 (32 500), 273 (34 300), 315 sh (7500) nm. δ_c (ppm) 114.1 (br d, 156.8, C-5), 157.5 (q, 4.4, C-4), 158.2 (m, C-2).

(*ii*) A 1:1 mixture (26 mg) of **17***b* and **13***b*.

(*iii*) Slightly impure **19***b* (61 mg) (see below).

*Sensitized Irradiation of **13b***

Compound **13***b* (500 mg, 0.00141 mol) in acetone (300 ml) was irradiated for 3 h. The yellow oil obtained on evaporation was submitted to plc ($CHCl_3$). This afforded the following.

(*i*) A mixture (41 mg) of **13***b* and **17***b*.

(*ii*) Slightly impure **19***b* (316 mg). Repeated plc as above gave **19***b* as a yellow oil (276 mg, 55%) which could not be induced to crystallize, but was obtained as a glassy solid, liquefying <55°C. Molecular ion (2%) at *m/e* 354.1251 ($C_{24}H_{18}O_3$ requires 354.12560); base peak at *m/e* 105 ($C_6H_5CO^+$); significant ions at *m/e* (%) 322(7), 286(2), 265(3), 233(8), 218(8), 189(10), and 77(23). ν_{max} 1717, 1686 cm^{-1}. λ_{max} (ε) 205 (34 600), 241 (19 300), 287 (9800) nm. δ_c (ppm) 59.5 (br d, 133.7, C-1), 132.0 (m not observable, C-2), 155.5 (m, C-3), 164.2 (q, 3.7, ester C=O at C-2), 195.9 (dt, 8.1, 3.9, ketone C=O at C-1).

*Direct Irradiation of 7-Oxabenzonorbornadiene **13a***

(*a*) A solution of **13***a* (3.00 g, 0.0073 mol) in ether (425 ml) was irradiated for 3½ h. Removal of the solvent gave a yellow oil. Compounds **18** and **19***a* were indicated as major products (ratio *ca.* 1:5) by ^1H nmr signals for their methoxyl protons, while the absence of **20** and **21***a* was confirmed by the lack of signals between 4.0 and 6.0 δ. Treatment of the crude product with cyclohexane gave a colorless solid (212 mg); recrystallization from ethyl acetate – pentane gave the benzoxepine **17***a* as colorless prisms (166 mg, 6%), mp 174–176°C. Molecular ion (1%) at *m/e* 412.1298 ($C_{26}H_{20}O_5$ requires 412.13108); base peak at *m/e* 105 ($C_6H_5CO^+$); *m/e* 77 (16%), all other ions <3%. ν_{max} 1724 cm^{-1}. λ_{max} (ε) 205 (35 900), 271 (42 400), 312 sh (9200) nm. δ_c (ppm) 123.1 (d, 4.4, C-1/C-5), 159.0 (t, 4.0, C-2/C-4).

The remainder of the product was chromatographed (successive elutions with 2%, 10%, and 20% $CHCl_3$–benzene). Significant fractions obtained from the column were as follows.

Fraction *i*. Crystallization from petroleum ether gave unreacted. **13***a* (696 mg).

Fraction *ii*. Initial treatment with cyclohexane, followed by recrystallization (ethyl acetate – pentane) gave further **17***a* (103 mg, 3.4%); treatment of the residue from the mother liquors with petroleum ether afforded **13***a* (100 mg).

Fraction *iii*. Initial treatment and crystallization as in *ii* above gave **17***a* (82 mg, 2.7%). The pentane-insoluble portion (45 mg) of the remainder of this fraction was characterized by strong methoxyl signals at 3.67 and 3.71 δ; during purification these signals decreased in intensity and were replaced by signals for **20**. Repeated plc (30% acetone – petroleum ether) gave **20**, slightly contaminated by **18**, as a colorless solid (22 mg), and a fraction (12 mg) of lower R_f, consisting mainly of **18**. (Molecular ion at *m/e* 412 (<1%), base peak at *m/e* 105 ($C_6H_5CO^+$), *m/e* 77 (21%), all other ions <5%.) Final purification by plc (30% acetone – petroleum ether; 0.25 mm layer) afforded pure **20** as colorless prisms (9 mg), mp 135–137°C. Molecular ion (100%) at *m/e* 308.1039 ($C_{19}H_{16}O_4$ requires 308.10486); significant ions at *m/e* (%) 276(81), 249(87), 218(43), 205(30), and 189(71). ν_{max} ($CHCl_3$) 1735 cm^{-1} (broad); (KBr) 1732, 1714 cm^{-1}. λ_{max} (ε) 205 (24 600), 235 (14 400), 303 (10 500) nm. δ_c (ppm) 59.1 (dd, 133.5, 2.4, C-1), 132.5 (m, C-3), 151.0 (m, C-2), 165.3 (q, 3.9, ester C=O at C-3), 169.7 (dq, 10.8, 4.1, ester C=O at C-1).

Fraction *iv*. 168 mg, consisting mainly of the indene **18**.

Fraction *v*. 511 mg, consisting mainly of the indene **21***a*.

Fraction *vi*. 490 mg, being predominantly a mixture of **21***a* and benzoic acid. Removal of the acid by washing with $NaHCO_3$ gave **21***a* (307 mg). Crystallization from ethyl acetate – petroleum ether gave colorless prisms, mp 88–90°C (lit. (27) mp 93–94°C). Molecular ion (77%) at *m/e* 308.1048 ($C_{19}H_{16}O_4$ requires 308.10485); base peak at *m/e* 249.0919 ($C_{17}H_{13}O_2$ requires 249.09156); significant ions at *m/e* (%) 276(27), 250(23), 232(16), 221(25), 219(36), 218(28), 205(45), 189(70), and 94.5(20). ν_{max} ($CHCl_3$) 1735, 1721 cm^{-1}; (KBr) 1740, 1710 cm^{-1}. λ_{max} (ε) 206 (24 400), 234 (15 900), 293 (12 900) nm. δ_c (ppm) 55.7 (br d, 135.6, C-1), 129.6 (d, 6.1, C-2), 155.2 (m, C-3), 164.4 (q, 3.8, ester C=O at C-2), 170.2 (dq, 11.0, 4.0, ester C=O at C-1).

The benzoic acid was recovered after reacidification of the bicarbonate washings and ether extraction, as a colorless solid, identified by mp, mixture mp (121–123°C), and ^1H nmr.

In a separate experiment plc (30% acetone – petroleum ether) afforded a fraction (24 mg) rich in compound **19***a*. (Molecular ion at *m/e* 412, very intense base peak at *m/e* 105, with strong peak at *m/e* 77. Ease of conversion to **21***a* results in appearance of *m/e* 308 and other peaks due to **21***a*.)

(*b*) Adduct **13***a* (310 mg, 0.00075 mol) in CH_2Cl_2 (200 ml) was irradiated for 5 h. Evaporation gave a viscous yellow oil. This was dissolved in methanol (20 ml) and water (1 ml) and concentrated HCl (6 drops) added. The mixture was allowed to stand at room temperature for 72 h. Concentration and extraction with CH_2Cl_2 afforded a yellow oil. Trituration with ethyl acetate – petroleum ether gave **17***a* as a colorless solid (57 mg, 18%). The soluble fraction on repeated plc ($CHCl_3$; 2% MeOH–$CHCl_3$) gave the indenes **21***a* (115 mg, 50%) and **20** (28 mg, 12%).

*Sensitized Irradiation of **13a***

Compound **13***a* (500 mg, 0.0012 mol) in acetone (400 ml) was irradiated for 5 h. The crude product, a

yellow oil, appeared from ^{1}H nmr to consist of **13***a*, **17***a*, and **19***a* in a ratio of 19:14:67. This was taken up in methanol (20 ml) and water (1 ml) and concentrated HCl (10 drops) added. The mixture was then allowed to stand for 72 h. The benzoxepine **17***a* (27 mg, 5%) crystallized from solution. Evaporation gave a yellow gum, repeated plc ($CHCl_3$) of which afforded **21***a* (332 mg, 66%).

*Attempted Rearrangement of **13***a* in the Presence of Iodine*

Compound **13***a* (200 mg, 0.00049 mol) and iodine (43 mg, 0.00017 mol) in ether (40 ml) were allowed to stand in daylight for 30 min. The mixture was washed with sodium bisulfite, then water, and dried (Na_2SO_4). Evaporation of solvent gave a colorless solid (194 mg), shown by ^{1}H nmr to be unreacted **13***a*.

Reactions for 4 days at room temperature, or for 10 h in refluxing cyclohexane, were also unsuccessful.

*Sensitized Irradiation of Dimethyl 1,4-Diphenyl-7-Oxanorbornadiene-2,3-dicarboxylate **22***

The oxanorbornadiene **22** (100 mg, 0.00028 mol) in acetone (100 ml) was irradiated for 3 h. Removal of the solvent and successive plc (1% MeOH–$CHCl_3$; 30% acetone–benzene) gave dimethyl 3,6-diphenyl-6-hydroxyfulvene 1,2-dicarboxylate **24** as a bright orange solid (70 mg, 70%) mp 141–142°C, and only a very small quantity of dimethyl 2,7-diphenyloxepine-4,5-dicarboxylate **23***a* (*cf.* ref. 16).

*Irradiation of the Benzoxepine **17***a*

A solution of **17***a* (100 mg, 0.00024 mol) in CH_2Cl_2 (300 ml) was irradiated for 3¼ h. Evaporation gave a yellow oil, shown by ^{1}H nmr to be mainly **18**. This product was dissolved in methanol (10 ml) and water (1 ml) and concentrated HCl (6 drops) added. The mixture was allowed to stand for 72 h. After evaporation and extraction with CH_2Cl_2 the product was submitted to repeated plc (2% MeOH–$CHCl_3$); this afforded **20** (30 mg, 40%).

*Conversion of **21***a* to **29***

A solution of **21***a* (115 mg, 0.00037 mol) in methanol (10 ml) was treated with 2 *N* NaOH (10 drops). The now deep yellow solution was allowed to stand at room temperature for 2 h. The solution was concentrated and the residue taken up in ether. Drying (Na_2SO_4) and evaporation gave a yellow oily residue, plc (2% MeOH–$CHCl_3$) of which gave (*i*) unreacted **21***a* (43 mg), and (*ii*) **29** as an almost colorless oil (46 mg, 38%) which slowly crystallized. Recrystallization from ethyl acetate – petroleum ether gave colorless cubes, mp 157–158°C. Molecular ion (1%) at *m/e* 324.0998 ($C_{19}H_{16}O_5$ requires 324.09978); base peak at *m/e* 233; significant ions at *m/e* (%) 308(1), 276(1), 265(15), 249(2), 176(15), and 151(6). ν_{max} (KBr): 3480, 1723, 1693 cm^{-1}. δ_c (ppm) 83.9 (br s, C-1), 132.6 or 133.2 (m not observable, C-2), 155.8 (m, C-3), 164.0 (q, 3.9, ester C=O at C-2), 173.3 (quint., 3.9, ester C=O at C-1).

The above reaction was repeated under a N_2 atmosphere for 4 h. In this case **21***a* was recovered quantitatively.

*Rearrangements of **18** to **20** and of **19***a* to **21***a*

These conversions occurred slowly on standing at room temperature. They were most efficiently carried out by treatment with aqueous methanolic HCl (see above). Both rearrangements occurred rapidly on treatment of a methanolic solution with a few drops of NaOH, but the products, especially **21***a*, were base-sensitive (see above).

*Attempted Rearrangement of **19***b* to **21***b*

(*a*) A solution of **19***b* (150 mg) in MeOH (5 ml) was treated with 2 *N* NaOH (8 drops). The now bright orange solution was allowed to stand at room temperature for 4 h. Acidification, evaporation, and extraction with CH_2Cl_2 gave an almost quantitative recovery of **19***b*.

(*b*) A solution of **19***b* (150 mg) in MeOH (8 ml) and H_2O (1 ml) was treated with concentrated HCl (6 drops). The yellow solution was allowed to stand at room temperature for 96 h. Evaporation and extraction with CH_2Cl_2 afforded only unreacted **19***b* in near quantitative yield.

*Rearrangement of **19***b* to **21***b*

Attempted purification of **19***b* (300 mg, 0.00085 mol) on alumina plates (Merck aluminum oxide GF 254 Type E, 1.25 mm; 30% acetone – petroleum ether) gave a main band (169 mg). Further plc (SiO_2; $CHCl_3$) afforded **21***b* (30 mg, 14%) which was crystallized from ethyl acetate – petroleum ether as cream-colored needles, mp 113.5–115°C. Molecular ion (64%) at *m/e* 250.0987 ($C_{17}H_{14}O_2$ requires 250.09938); base peak at *m/e* 191 $(M - CO_2CH_3)^+$; significant ions at *m/e* (%) 235(4), 219(12), 218(11), 189(32), and 165(11). ν_{max} 1704 cm^{-1}. λ_{max} (ε) 206 (23 700), 233 (12 700), 293 (14 200) nm. δ_c (ppm) 39.5 (td, 130.9, 2.5, C-1), 130.6 (t, 6.9, C-2), 153.6 (m, C-3), 165.3 (q, 3.9, ester C=O).

Acknowledgments

We wish to acknowledge the excellent technical assistance of Mr. J. Van Ingen. We also thank Miss J. Riley (NRCC summer student, 1973) for her contribution to this work. Our thanks go also to Mr. D. J. Embree (for high-resolution mass spectra), Dr. I. Oxton (for assistance with infrared measurements), and Mrs. M. G. Flack (for experimental assistance).

We are grateful to Dr. A. W. Hanson of the Division of Biological Sciences, National Research Council of Canada, Ottawa, for the X-ray structural information on the indene **21***a*.

N-Ethylamino acid synthesis and *N*-acylamino acid cleavage using Meerwein's reagent[1]

FRANCIS M.F. CHEN AND N. LEO BENOITON

Department of Biochemistry, University of Ottawa, Ottawa, Ont., Canada K1N 9A9

Received July 8, 1976[2]

FRANCIS M. F. CHEN and N. LEO BENOITON. Can. J. Chem. **55**, 1433 (1977).

N-Ethylamino acids have been prepared by reaction of *N*-acetylamino acids with trimethyloxonium tetrafluoroborate (Meerwein's reagent) giving imino ether fluoroborates, followed by reduction with sodium borohydride. The use of Meerwein's reagent for the deacylation of *N*-acylamino and *N*-acyl,*N*-methylamino acid derivatives has been investigated.

FRANCIS M. F. CHEN et N. LEO BENOITON. Can. J. Chem. **55**, 1433 (1977).

On a préparé des acides *N*-éthylaminés par réaction des acides *N*-acétylaminés avec le tétrafluoroborate de triméthyloxonium (réactif de Meerwein) conduisant aux fluoroborates iminoéthers qui sont ensuite réduits par le borohydrure de sodium. On a étudié l'utilisation du réactif de Meerwein pour la déacylation des dérivés acides *N*-acylaminés et *N*-acyl,*N*-méthylaminés.

[Traduit par le journal]

The alkylating power of trialkyloxonium tetrafluoroborate (Meerwein's reagent) is well known (1, 2). Amongst other things, it reacts with an amide to give an imino ether fluoroborate, thus converting the rather intractable amide into a highly reactive and versatile intermediate for further synthetic manoeuvers. In this paper, we describe studies on two applications of this in the amino acid field, namely, the conversion of *N*-acetylamino acids into *N*-ethylamino acids, and the use of Meerwein's reagent for the deacylation of amino and *N*-methylamino acid derivatives.

Direct ethylation of a free amino acid is likely to give mixed products of mono- and diethylation (3),[3,4] while ethylation of an *N*-protected amino acid is complicated by the side reaction of β-elimination of the ethylating agent.[5]

N-Ethylamino acids have been obtained here in moderate yields by reaction of *N*-acetylamino acids with trimethyloxonium tetrafluoroborate followed by reduction of the resulting imino ether fluoroborate with sodium borohydride. The results are given in Table 1. Each product

$$CH_3—CO—NH—CHR—COOH \xrightarrow{Me_3OBF_4}$$

$$CH_3—C(OMe)=\overset{+}{N}H—CHR—COOH\cdot BF_4^- \xrightarrow{NaBH_4}$$

$$CH_3—CH_2—NH—CHR—COOH$$

contained 0.6–0.8% of unalkylated amino acid as contaminant. The small amount (10–15%) of ester formed during the alkylation (1) was removed during the work-up. The chirality of the starting material was preserved during the reaction for *N*-ethylleucine but not for *N*-ethylphenylalanine. A sample of L-valine obtained by hydrolysis of the corresponding imino ether intermediate was shown (9) to have an optical purity of ≃96% (2% D-isomer). Borch has converted amides to amines in good yield in this manner (10). Monteiro applied this to a synthesis of L-proline from L-pyroglutamic acid (11). We have confirmed the latter work, with similar results. We have also observed in a control experiment that *N*-acetylleucine was converted into *N*-ethylleucine in 6% yield by sodium borohydride even in the absence of Meerwein's reagent.

The free amino acid side product from each reaction is probably the result of hydrolysis of

[1]Supported by a grant from the Medical Research Council of Canada. N.L.B. is an Associate of the MRCC.

[2]Revision received January 20, 1977.

[3]Reductive methylation of amines leads to dimethylation (3, 4).

[4]Kanao (5) synthesized several *N*-ethyl- and *N*,*N*-diethylamino acids by reductive alkylation using hydrogen and a platinum oxide catalyst giving very few details. Bowman (6) obtained monoethylation for valine and diethylation for alanine by the same reaction under nonforcing condition.

[5]Complete *N*-methylation of an *N*-benzyloxycarbonylamino acid is easily achieved using methyl iodide and sodium hydride (7), but *N*-ethylation is far from complete.

TABLE 1. Properties of *N*-ethylamino acids

Compound	Yield (%) A[a]	Yield (%) B[b]	Analysis (%) Calculated C	Calculated H	Calculated N	Found C	Found H	Found N	Chromatographic data[c] Color constant	Chromatographic data[c] Elution time (min)

the imino ether fluoroborate by moisture. It is known that imino ether fluoroborates are readily hydrolyzed to free amino groups in aqueous acid or base (12, 13). This in fact led to our interest in the second application of these intermediates. We were interested in finding some means for removing acetyl and/or benzoyl groups from amino and *N*-methylamino acids, with the hope of achieving selectivity if possible. Muxfeldt *et al.* have cleaved a benzamide (12) and Hanessian, *N*-acetamino sugars (13) in good yield by this method. The high sensitivity to hydrolysis of imino ether fluoroborates of tertiary amides has been pointed out (10).

$$R'—CO—NR''—CHR—COOMe \xrightarrow{Me_3OBF_4} R'—C(OMe)=\overset{+}{N}R''—CHR—COOMe\cdot BF_4^- \xrightarrow[H^+ \text{ or } OH^-]{H_2O} R'—COOMe + R''NH—CHR—COOMe$$

R′ = Me or Ph R″ = H or Me

Experiments were monitored by nmr[6] spectroscopy, and carried out on the acylamino acid methyl esters to simplify quantitation. The results appear in Table 2. The conversion to imino ether intermediate was never complete, under the conditions employed, even in the presence of excess reagent. On hydrolysis, most of the intermediate gave rise to deacylated product, but a small portion (5–15%) was converted back into starting material. The amount of starting material recovered was 25–35% for the acetyl derivatives, whether methylated or unmethylated (R′ = Me; R″ = H or Me), less for the *N*-benzoyl,*N*-methyl derivatives (R′ = Ph; R″ = Me), and twice as much for the unmethylated benzoyl derivatives (R′ = Ph; R″ = H). No clear selectivity between amino and *N*-methylamino acid derivatives was obtained; only a large difference in reactivity between the benzoyl derivatives. The relative susceptibility to cleavage is therefore Bz-MeX-OR > Ac-MeX-OR = Ac-X-OR > Bz-X-OR where X = an amino acid residue. It is seen in Table 2 that, except for undergoing partial esterification, an unesterified derivative gave the same result. Because of the incomplete reaction, this approach for cleavage of acylamino acid derivatives leaves much to be desired, but it might find use when other methods are inapplicable.

The results are in general agreement with those of Pilotti *et al.* (14) who succeeded with the deacetylation but failed with the debenzoylation of acylamines, and Hanessian (13) who cleaved acetamino sugars by this method. They are also in agreement with the synthetic work of Borch (10). But one difference or discrepancy exists in that both Borch (10) and Muxfeldt *et al.* (12) reported a high reactivity for a secondary benzoylamide.

Experimental

The *N*-acylamino acid esters were obtained from the acids using methanolic HCl; the *N*-methylamino acid derivatives, from the same acids using methyl iodide and sodium hydride (15).

Acylamino Acid Ester Cleavage

A suspension of substrate (1 mmol) and trimethyloxonium tetrafluoroborate (1.1 mmol) (2) in 20 ml of dichloromethane (dried over $CaCl_2$, and distilled) was stirred at room temperature under nitrogen for 24 h. The solvent was removed under reduced pressure, and

[6]Proton nuclear magnetic resonance (60 MHz).

TABLE 2. Cleavage of acylamines via imino ether fluoroborates

[a]Percent, determined by nmr, assuming $A + B = 100$; $C + D = 100$. D corresponds to $B + (A - C)$. Hydrolysis with 3% aqueous acetic acid.
[b]100% excess reagent.
[c]13% of ester formed.

an nmr spectrum was recorded to determine the ratio between the amount of imino ether product and the amount of starting material. The mixture was then stirred in 20 ml of 3% aqueous acetic acid for 3 h. A second nmr spectrum recorded after removal of the solvents gave the ratio between the amount of deacylated product and the amount of starting material. There was no evidence for side-reactions other than those discussed.

Synthesis of N-Ethylamino Acids

A solution of *N*-acetylamino acid (0.01 mol) and trimethyloxonium tetrafluoroborate (0.011 mol) in 20 ml of dichloromethane was stirred under nitrogen at 23°C for 16 h. The solvent was removed under reduced pressure, the residue was dissolved in 25 ml of ethanol, the solution was cooled in an ice-bath, and 1 g of powdered sodium borohydride was added in small portions to the stirred solution. After stirring an additional 30 min in the cold and 30 min at 23°C, the mixture was acidified to Congo red with ethanolic HCl. The precipitate was filtered off and the filtrate was evaporated to dryness. The residue was analyzed for amino acid at this stage (8) or the product was isolated from an aqueous solution by absorption on to a resin (Dowex 50, 20–50 mesh; 50 ml) followed by elution with 50 ml of 5 *N* NH_4OH. The *N*-ethylamino acid was obtained by crystallization from ethanol after evaporation of the eluate. All products had nmr spectra (D_2O) consistent with their assigned structures.

Sign reversal of geminal $^{13}CH_3$–C–^{15}N coupling in configurationally isomeric fragments[1]

GERALD W. BUCHANAN AND BRIAN A. DAWSON

Department of Chemistry, Carleton University, Ottawa, Ont., Canada K1S 5B6

Received November 25, 1976

GERALD W. BUCHANAN and BRIAN A. DAWSON. Can. J. Chem. **55**, 1437 (1977).

The signs of geminal ^{15}N–C–$^{13}CH_3$ couplings in configurationally isomeric acetophenone oximes have been determined relative to those of the vicinal ^{15}N–C–C–H interactions using an off resonance proton decoupling technique. In the *Z*-isomer where the nitrogen lone pair is *cis* to the coupled carbon, the coupling is large and negative, whereas in the *E*-isomer, the geminal ^{15}N–C–$^{13}CH_3$ coupling is small and positive in sign.

GERALD W. BUCHANAN et BRIAN A. DAWSON. Can. J. Chem. **55**, 1437 (1977).

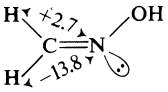
On a déterminé les signes des couplages ^{15}N–C–$^{13}CH_3$ géminés dans des oximes de l'acétophénone qui sont isomères au point de vue configurationnel; ces déterminations ont été effectuées par rapport à celles des interactions ^{15}N–C–C–H vicinales en faisant appel à la technique "off resonance" de découplage du proton. Dans l'isomère *Z*, où la paire libre de l'azote est *cis* par rapport au carbone qui est couplé, le couplage est grand et négatif alors que dans l'isomère *E* le couplage géminé ^{15}N–C–$^{13}CH_3$ est petit et de signe positif.

[Traduit par le journal]

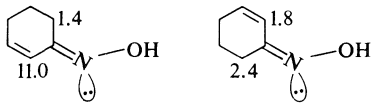
Introduction

There has been a good deal of recent interest in the magnitudes and signs of geminal coupling constants involving ^{15}N and other magnetic nuclei. The influence of the nitrogen lone pair is clearly pronounced (1). For both saturated and unsaturated compounds, $^2J_{^{15}N-H}$ is calculated to be large and negative when the nitrogen lone pair is *cis* to the coupled proton, whereas this coupling is small and can be of either sign when the lone pair is *trans* to the coupled proton (2). In the case of formaldoxime, $^2J_{^{15}N-H}$ is -13.8 Hz for the former coupling and $+2.7$ Hz for the latter (3). A similar trend has been observed for isomeric acetaldoximes (4, 5).

With regard to geminal ^{13}C–^{15}N interactions,



Lichter *et al.* (6) have demonstrated the sensitivity of this parameter to N lone pair geometry in the *Z*- and *E*-2-cyclohexenone oximes shown below.



In an earlier study Bundgaard and Jakobsen (7) determined the sign of $^2J_{^{13}C^{15}N}$ relative to $^3J_{^{15}NH}$ in ^{15}N-enriched pyridine and some derivatives. These authors predicted, that in cases where a geometrically rigid CCN fragment was present, a sign change in the geminal ^{13}C–^{15}N coupling would be observed between members of an isomeric pair. We wish to report the first

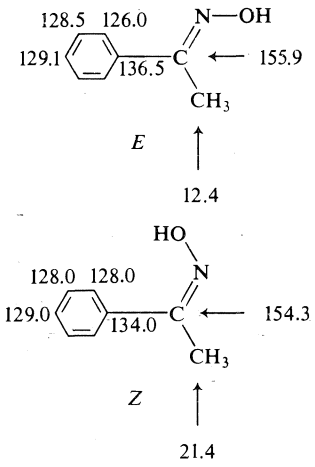
[1]Presented in part at the 59th Canadian Chemical Conference of the Chemical Institute of Canada, London, Ontario, June 1976.

experimental verification of this prediction using *Z*- and *E*-acetophenone oximes as model compounds. This work represents an extension of our earlier study (8) which involved exclusively *E*-isomers.

Results and Discussion

(a) Chemical Shifts

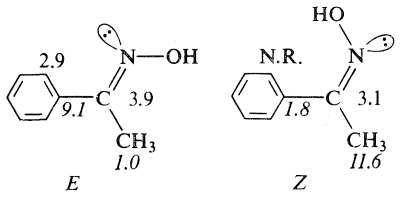
Below are compared the ^{13}C chemical shifts (δ_c from TMS ± 0.1) for the *Z*- and *E*-isomers. Most notable is the increased shielding of the CH_3 resonance of 9 ppm in the *E*-isomer relative to the *Z* case, which reflects its *syn* relationship to the OH function in the former compound. Similar findings have been reported by Roberts and co-workers (9) for other configurationally isomeric oximes. In the *Z*-isomer the quaternary aromatic carbon is shielded by 2.5 ppm relative to the *E* case, again a consequence of the *syn*-OH moiety.



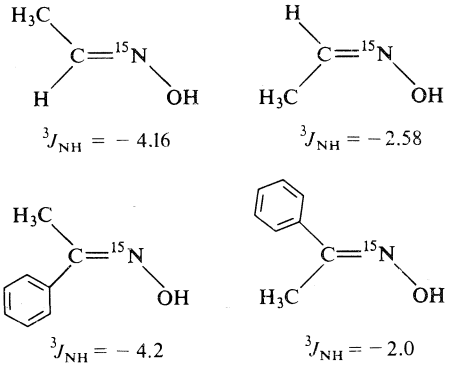
(b) Coupling Constants

The absolute values of the ^{13}C–^{15}N *J*'s are presented below. For the *Z*-isomer it was not possible to measure the vicinal coupling to the *ortho* carbons due to peak overlap with the *meta* resonance. Clearly there is a dramatic effect of N lone pair geometry on the magnitude of the geminal interactions. When the lone pair is *cis* to the coupled carbon, as in the quaternary carbon of the *E*-isomer and the CH_3 of the *Z*, the absolute values of ^2J are much greater than in the cases where the lone pair is *trans*.

In this work we have used the off resonance proton decoupling procedure described by Jakobsen *et al.* (7, 10, 11) to determine the signs of the geminal ^{15}N–C–$^{13}CH_3$ couplings relative



to those for the vicinal ^{15}N–C–C–H interactions. The latter are known to be negative (3) in isomeric acetaldoximes and are assumed negative for the present acetophenone oximes due to the close agreement in experimental findings for the isomeric pairs illustrated. Additional support for



this assumption comes from the results of INDO MO calculations (2) which indicate negative vicinal ^{15}N–H *J*'s in fragments such as these.

The Jakobsen technique (10) is applicable for determining the relative sign of $^nJ_{CX}$ and the corresponding $^{n+1}J_{HX}$ spin couplings, where X is a spin $\frac{1}{2}$ nucleus (*i.e.* ^{15}N). Use is made of the *difference* observed for the reduced splittings, $J_{\text{residual (CH)}} = 2\pi\Delta\nu J_{CH}/\gamma H_2$ in the ^{13}C spectrum of the $J_{^{13}C-X}$ doublet. In the case of the *Z*-isomer, off resonance ^1H decoupling on the high field side ($\Delta\nu = 65$ Hz, $\gamma H_2 \approx 1600$), caused a reduction in the residual coupling for the high field lines indicating the same sign for $^3J_{NH}$ and $^2J_{CN}$ (*i.e.* negative). As a check, off resonance decoupling on the low field side did indeed cause a reduction of the residual J_{CH} for the low field lines.

Conversely for the *E*-isomer, off resonance decoupling on the high field side ($\Delta\nu \approx 50$, $\gamma H_2 \approx 2000$) reduced J_{CH} preferentially on the low field side, whereas low field irradiation reduced J_{CH} on the high field side. Therefore in the *E*-isomer, $^2J_{CN}$ must be positive. A typical spectrum is shown in Fig. 1, illustrating the result of high field ^1H irradiation. Since $^2J_{CN}$ will

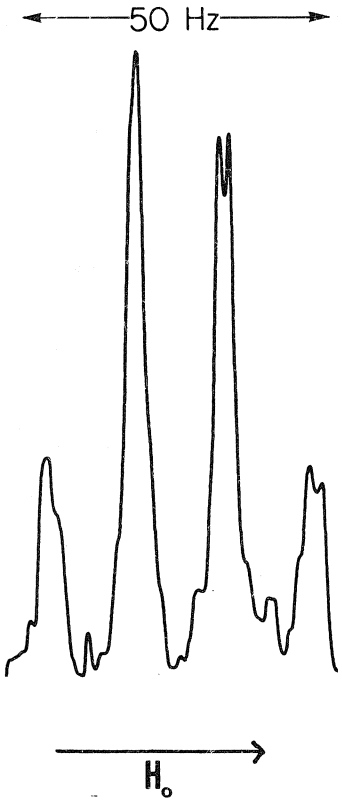


FIG. 1. Methyl region of the ^{13}C spectrum for ^{15}N enriched *E*-acetophenone oxime. Spectrum recorded with off resonance ^1H decoupling, $\gamma H_2 \approx 2000$ and $\Delta\nu \approx 50$ Hz to the high field side of the ^1H resonance of the CH_3 group.

not be affected by ^1H decoupling, the reduced splitting on the low field side must be due to a preferential reduction of $^1J_{CH}$.

The present results for $^2J_{CN}$ in oximes parallel those for $^2J_{NH}$. Specifically, geminal J's are large and negative when the N lone pair is *cis* to the coupled carbon, and small and positive when the lone pair is *trans* to the $^{13}CH_3$.

Recently Schulman and Venanzi (13), have demonstrated that $^2J_{CN}$ and $^3J_{CN}$ are dominated by the Fermi contact term in contrast to $^1J_{CN}$ for a variety of compounds, although the only oxime considered has been that derived from formaldehyde. At present, we are carrying out INDO MO calculations to evaluate the Fermi contact contributions to the observed couplings in aromatic oximes and related materials. Results will be communicated in the near future.

Experimental

Materials

Preparation of the *E*-isomer was reported in our previous study (8). The *Z*-isomer was prepared according to the procedure of Smith and Kaiser (14), using 95% ^{15}N enriched hydroxylamine hydrochloride obtained from Merck, Sharpe, and Dohme (Canada).

Spectra

Spectra were recorded using a Varian XL-100-12 nmr spectrometer equipped with the Nicolet TT-100 Fourier transform data system. Samples were examined as 0.1 *M* solutions in $CDCl_3$ solution in 5 mm sample tubes. Spectral widths were commonly 2000 Hz and a minimum of 8K data points were used. For the off resonance experiments the noise modulation was removed and the decoupler high power level reduced to 50% which gave a γH_2 value of *ca.* 1600.

ERNST BOCK, GARNETTE SUTHERLAND, DAVID MCKINNON, and EDWARD TOMCHUK. Can. J. Chem. **55**, 1440 (1977).

The electric dipole moments of the bis-1,3-dioxolyl molecule were determined in dilute decahydronaphthalene solution at 25 and 100°C and in dilute benzene solution at 25°C. From the temperature dependence of the dipole moment it is concluded that the *trans* rotamer of the molecule is more stable in both solvents than the *gauche* rotamer by ~4.5 kJ mol^{-1}. The conformational behavior of the molecule is discussed in terms of a recently proposed solvation theory.

ERNST BOCK, GARNETTE SUTHERLAND, DAVID MCKINNON et EDWARD TOMCHUK. Can. J. Chem. **55**, 1440 (1977).

On a déterminé, en solution diluée de décahydronaphtalène, à 25 et à 100°C, et dans des solutions diluées de benzène, à 25°C, les moments électriques dipolaires de la molécule bis-dioxolyl-1,3. En se basant sur la dépendance du moment dipolaire sur la température, on en conclut que le rotamère *trans* de la molécule est plus stable, dans les deux solvants, que le rotamère *gauche*; la différence est ~4.5 kJ mol^{-1}. On discute du comportement conformationnel de la molécule en termes d'une théorie de solvatation qui a été proposée récemment.
[Traduit par le journal]

Introduction

In a recent paper published in this journal (1) it was suggested that in acetone solution the *trans* rotamer of bis-1,3-dioxolyl is more stable than the *gauche* rotamer and that the difference in enthalpy between the two rotamers in acetone was approximately 700–1300 J mol^{-1}. The above authors based their conclusions on the temperature dependence of certain proton nmr coupling constants. But because it proved impossible to measure independently the coupling constants for the two rotamers the authors could obtain an approximate value only for the conformational energy difference. However, the marked increase in the value of ^3J(H,H) with decrease in temperature suggested strongly that the *trans* conformer was the energetically more favoured one, at least in acetone solution.

Another technique which may be used to determine relative stabilities of rotamers makes use of molecular electric dipole moments. Although this technique suffers from a number of disadvantages compared to the nmr technique, *viz.*, solution dipole moments can rarely be determined with an accuracy of better than 3.33×10^{-32} C m (0.01 D), both conformers may have dipole moments of comparable magnitude, etc., it is nevertheless particularly suitable in this case because the *trans* rotamer has no dipole moment whereas the *gauche* rotamer can be expected to have a dipole moment of $5.0 \times 10^{-30} - 6.7 \times 10^{-30}$ C m (1.5 – 2.0 D) as calculated by the INDO–MO theory (1) and estimated from bond-moment vector-model calculations. (See Fig. 1.) Details of the INDO–MO calculations are given in ref. 1 and need not be repeated here. The vector-model dipole moment was estimated using the following bond moments: C—O 0.7 D, C^-—H^+ 0.4 D, C=C^-—H^+ 0.7 D (2), and the molecular coordinates for the *gauche* rotamer of Schaefer *et al.* (1). Thus if the energy barrier separating the two rotamers is not too large, *i.e.*, if a significant change in the population of the two forms can be realised in a reasonable temperature interval, then it is possible to obtain the energy difference between the two forms from the observed temperature dependence of the

[1]Revision received January 24, 1977.

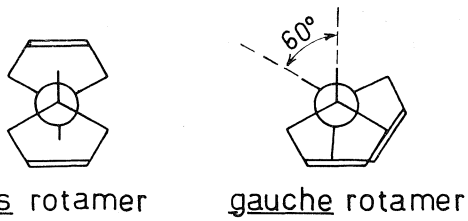

FIG. 1. The *trans* and *gauche* rotamers of bis-1,3-dioxolyl.

molecular dipole moment. The relationship between the dipole moments and the energy difference, $\Delta E = E_g - E_t$, of the *gauche* and *trans* rotamers respectively, the measured dipole moment, m, at a temperature, T, is given by (3):

$$[1] \qquad m^2 = \frac{\mu_t^2 + \mu_g^2 \omega\, e^{-\Delta E/RT}}{1 + \omega\, e^{-\Delta E/RT}}$$

Here ω is the ratio of the partition functions of the *gauche* to *trans* rotamers. In the absence of microwave and infrared data ω may be approximated to the product of the ratio of the statistical weights of the two rotamers and the square root of the ratio of the products of the principal moments of inertia of the two rotamers; *i.e.*, we assume here that the vibrational contributions to the partition functions are the same for both rotamers. The statistical weight of the *gauche* rotamer is 2 since there are two non-superimposable forms of this rotamer. And the statistical weight of the *trans* rotamer is 1. Using the coordinates of Schaefer *et al.* (1) for the two rotamers the product of the principal moments of inertia, $I_A I_B I_C$, of the *gauche* and *trans* rotamer results as 2.94×10^{-38} kg m^2 and 1.82×10^{-38} kg m^2, respectively. Combination of these values then yield a value for $\omega = 2.54$. With this approximation and setting μ_t equal to zero [1] becomes:

$$[2] \qquad m^2 = \frac{2.54\mu_g^2\, e^{-\Delta E/RT}}{1 + 2.54\, e^{-\Delta E/RT}}$$

Equation 2 contains two unknown quantities: ΔE and μ_g. Both can be determined by measuring the dipole moment, m, at two different and preferably widely separated temperatures. It is this method which we chose for the determination of ΔE.

Experimental

The experimental technique used in the determination of the solution dipole moment has been described elsewhere (4). The bis-1,3-dioxolyl was prepared after the method of Fuchs and Hauptmann (5). To ensure as wide a temperature interval as possible decahydronaphthalene was chosen as solvent. The choice of solvent was dictated by its low volatility, nonpolarity, and ready availability in highly purified state. It was obtained from Fisher Scientific Co., under their label 'Spectroquality', and was used without further purification. The uncertainty in the experimental dipole moment is estimated to be 3.3×10^{-32} C m (0.01 D). The estimate of the uncertainty is based on the sum of the measured standard deviations in the Smith (6) polarization parameters α and ν. The error in the temperature was less than 0.01°C and the error in the weight fraction was negligibly small.

Results and Discussion

The experimental results are shown in Table 1 and the derived quantities based on these results are summarized in Table 2. INDO–MO calculations predict the *gauche* form to be more stable in the vapor phase but experimental measurements in solution show that the *trans* form is more stable. The experimental observations are in qualitative agreement with the nmr studies referred to above (1).

It is interesting to speculate on the reasons for

the observed conformational preference in solution.

According to a recently proposed solvation theory (7), which regards the solvent as a dielectric continuum and the solvent molecule as a collection of electric charges, the solute–solvent interaction energy may be written as a sum of three interaction terms, *viz.*, a polar term, a dipolar term, and a quadrupolar term. The polar term is usually small and for nonpolar solvents may be set equal to zero. The dipolar term is proportional to the square of the dipole moment of the solute molecule; this term therefore, in the present case, will favour the *gauche* form because the *trans* form has a zero dipole moment. Finally, the quadrupolar term is proportional to the square of the molecular quadrupole moment and will stabilize the rotamer with the largest molecular quadrupole moment. It is relatively easy to compute the dipolar term. The computation of the quadrupolar term is much more complicated. However, from an examination of molecular models and from a comparison of calculated molecular quadrupole moments of *sym* tetrasubstituted ethanes (7), molecules the structures of which are similar to the structure of bis-1,3-dioxolyl, it is clear that in the present case the quadrupolar term must be considerably larger for the *trans* conformer compared to the *gauche* conformer. Thus the stabilization of the *trans* conformer in solution must be due entirely to the quadrupolar interaction. The energy of this interaction may be estimated as follows. Using the dipole moment of the *gauche* form as calculated by [2], and a molecular radius of 3.2×10^{-10} m, as estimated from molecular models and standard bond lengths, and published bond polarizability data (8) one obtains the following values for the k and l parameters of Abraham (7): $k = 8.0$ kJ mol^{-1}, $l = 0.75$. Using these values and setting $x = 0.218$ the dipolar interaction results as 2.1 kJ mol^{-1}. If this value is subtracted from the difference of the conformational energy difference in the vapour and solution phase, respectively, one obtains an estimate for the quadrupolar interaction term, *i.e.*,

$$\Delta E^v - \Delta E^s - \text{dipolar term} = \text{quadrupolar term}$$

Here ΔE^v and ΔE^s are the energy differences between the *gauche* and *trans* conformations in the vapor and solution phase, respectively. In the absence of experimental data for ΔE^v we set this term equal to the INDO calculated value, *i.e.* $\Delta E^v = -4.2$ kJ mol^{-1}. From Table 2 ΔE^s in decahydronaphthalene is 4.5 kJ mol^{-1}. Thus the quadrupolar term in this solvent results as -10.8 kJ mol^{-1}. This seems a rather large value for this interaction; it implies an unreasonably large quadrupole parameter, h, of some 75 kJ mol^{-1}. However, it should be kept in mind that this estimate is critically dependent on the correct estimate of ΔE^v. Now it is well known that INDO–MO predicted conformational energy differences are not always reliable since they are derived from the difference of two very large numbers (the total molecular energies of each conformer) of almost equal magnitude (9). For instance, in the present case, the total energy, *i.e.*, the energy of the molecule relative to the free nuclei and electrons, is -3.0479735×10^5 kJ mol^{-1} and -3.0479317×10^5 kJ mol^{-1} for the *gauche* and *trans* conformer, respectively, which gives

$$\Delta E = E_g - E_t = -4.2 \text{ kJ mol}^{-1}$$

Thus a small error in one or both total energy estimates may result in quite a large error in ΔE.

The resonance Raman spectra and excitation profiles of some 4-sulfamylazobenzenes[1]

KAMAL KUMAR AND P. R. CAREY[2]

Division of Biological Sciences, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received November 17, 1976

KAMAL KUMAR and P. R. CAREY. Can. J. Chem. **55**, 1444 (1977).

The resonance Raman spectra of three pharmacologically important sulfonamides, 4-sulfamyl-4′-dimethylaminoazobenzene (**1**), 4-sulfamyl-4′-hydroxyazobenzene (**2**), and 4-sulfamyl-4′-aminoazobenzene (**3**), are compared with those of analogues lacking the sulfonamide group. The $—SO_2NH_2$ moiety does not directly contribute intense or moderately intense bands to the resonance Raman spectra of **1**, **2**, and **3**. However, $—SO_2NH_2$ ionization is reflected by frequency changes in a band near 1140 cm^{-1} and intensity changes in the 1420 cm^{-1} region. The normal Raman spectrum of **2** confirms that the intensity changes reflect $—SO_2NH_2$ ionization rather than unrelated changes in vibronic coupling. The effect of —OH ionization on the resonance Raman spectrum of **2** emphasizes that caution must be exercised when relating spectral perturbations to changes in contributions from valence bond type structures. Resonance Raman excitation profiles for the 1138, 1387, and 1416 cm^{-1} bands of **2** show that these bands gain intensity by coupling with the electronic transitions in the 240 to 450 nm region and that, more than 1000 cm^{-1} to the red of λ_{max}, the wavelength dependence can be closely reproduced by the F_B type terms of Albrecht and Hutley. The excitation profile for each band shows evidence for structure in the 470 nm region, although lack of sufficient excitation wavelengths prevents accurate estimation of the spacing. Under conditions of rigorous resonance the intense Raman lines all occur in the 1400 cm^{-1} region, *i.e.* they are 'bunched' in the region known to contain the —N=N— stretching vibration.

KAMAL KUMAR et P. R. CAREY. Can. J. Chem. **55**, 1444 (1977).

On compare les spectres de résonance Raman de trois sulfonamides pharmacologiquement importantes, sulfamyl-4 diméthylamino-4′ azobenzène (**1**), sulfamyl-4 hydroxy-4′ azobenzène (**2**) et sulfamyl-4 amino-4′ azobenzène (**3**) avec ceux d'analogues ne contenant pas le groupe sulfonamide. La portion $—SO_2NH_2$ ne contribue pas directement de bandes intenses ou modérément intenses au spectre de résonance Raman de **1**, **2** et **3**. Toutefois l'ionization de $—SO_2NH_2$ se réflète par des changements de fréquence dans la bande près de 1140 cm^{-1} et par des changements d'intensité dans la région de 1420 cm^{-1}. Le spectre Raman normal de **2** confirme que les changements d'intensité sont un reflet de l'ionization du $—SO_2NH_2$ plutôt que des changements du couplage vibronique qui ne sont pas reliés à l'ionisation. L'effet de l'ionization du —OH sur le spectre de résonance Raman de **2** met en relief les précautions qui doivent être prises lorsqu'on essaie de relier des perturbations de spectre avec des changements dans la contribution provenant de structures de type de lien de valence. Les profils d'excitation de la résonance Raman pour les bandes à 1138, 1387 et 1416 cm^{-1} de **2** montrent que ces bandes gagnent de l'intensité par couplage avec les transitions électroniques dans la région de 240 à 450 nm et que plus de 1000 cm^{-1} vers le rouge du λ_{max}, la relation avec la longueur d'onde peut être très bien reproduite par des termes du type F_B de Albrecht et Hutley. Le profil d'excitation de chaque bande montre des indications pour la structure dans la région de 470 nm quoique un manque de suffisantes longueurs d'onde pour l'excitation empêche un estimé précis de l'espacement. Dans des conditions de résonance rigoureuse, les lignes Raman intenses se produisent toutes dans la région de 1400 cm^{-1} c'est-à-dire qu'elles sont toutes concentrées dans la région qui est connue pour contenir les vibrations de fréquence —N=N—.

Introduction

Certain aromatic sulfonamides are very powerful and selective inhibitors of the enzyme carbonic anhydrase (1). Because of their highly specific interaction with the active site they have proved extremely useful in work on the physicochemistry and mechanism of action of carbonic anhydrase (2). Comparison of the resonance Raman spectra of free aqueous aromatic sulfonamides with those of the drugs bound to the enzyme reveals several differences in band posi-

[1]NRCC No. 15825.

[2]To whom correspondence should be addressed.

tions and intensities (3, 4). These spectral differences may be used to delineate the chemical changes occurring in the sulfonamide molecule upon binding. The aim of the present paper is to establish several points relating the chemistry of **1**, **2**, and **3** (Fig. 1) to their resonance Raman spectra which were omitted or only touched upon in the earlier biochemically oriented work (3, 4). Furthermore, the variation of Raman intensities with excitation wavelength, the excitation profiles, have been measured for **2** to provide a quantitative estimate of Raman intensity enhancement for comparison with existing theories.

Materials and Methods

The azobenzene sulfonamides studied in this work are shown in Fig. 1. Compounds **1**, **2**, and **3** were synthesized and generously donated by Dr. R. W. King; **4** and **5** were purchased from Eastman Kodak Co., Rochester, NY; **6** was purchased from K and K, Plainview, NY, and **7** and **8** were purchased from Pfaltz and Bauer, Flushing, NY; *p*-carboxybenzenesulfonamide was purchased from Aldrich, Milwaukee, WI.

Raman spectra were obtained with a Jarrell-Ash 25-400 spectrophotometer using a RCA 310304A-02 photomultiplier tube and photon counting detection. The excitation sources were Spectra-Physics Model 185 He–Cd ion and Model 164 Ar^+ and Kr^+ lasers. Peak frequencies were calibrated using emission lines from Ar, Xe, and Ne lamps and are believed to be accurate to ± 2 cm^{-1} for well resolved bands. In the 1100 cm^{-1} region the accuracy is ± 1 cm^{-1}. Band intensities were measured by band heights and intensities reported for the excitation profiles are the average of at least three runs. Solutions for the excitation profile measurements contained *N*/10 KOH and 25% MeOH. The MeOH band at 1017 cm^{-1} was taken as an internal reference. Since the internal standard was close to the lines measured and solutions were of low optical density (~ 0.6 at 457.9 nm) neither a λ^4 correction nor a self-absorption correction was necessary.

The Raman spectra showed excellent reproducibility and neither photodecomposition nor photoisomerisation were detected. Absorption spectra were recorded on Cary 14 and 15 spectrophotometers and infrared spectra were recorded on a Perkin Elmer 521 grating spectrophotometer. The IR band positions are accurate to ± 2 cm^{-1}.

Results and Discussion

The Absorption Spectra

Above 300 nm the compounds **1** → **8** have similar absorption spectra with two features between 300 and 500 nm (Fig. 2, refs. 3 and 4). For **3** → **8** the spectra are characterized by a λ_{max} near 380 nm with a shoulder near 430 nm. **1** has a λ_{max} near 470 nm and a shoulder close to 440 nm while for **2** λ_{max} is near 450 nm with a shoulder near 425 nm. It is probable that mixing of the electronic transitions occurs and each of the above bands contains contributions from more than one transition, thus definitive assignments are not possible at present. However, the following comments may be made. The high energy band near 400 nm is probably related to the transition found in azobenzene near 320 nm (5) while the band near 450 nm may be identified with the 440 nm $n \rightarrow \pi^*$ transition of azobenzene (5) which in the present compounds gains intensity by mixing with the available $\pi \rightarrow \pi^*$ transitions. The appearance in the resonance Raman spectra (*vide infra*) of intense features from the benzene and azo moieties suggests that both chromophores make important contributions to the absorption spectra in the 450 nm region.

*Evidence that Intense Features from —SO_2NH_2 do not Appear in the Resonance Raman Spectra of **1**, **2**, and **3***

This evidence is obtained from analogues in which the —SO_2NH_2 is absent, from the comparison of ir and Raman data and from the Raman spectrum of **2** when —OH → —O^-. The resonance Raman spectra of **6**, **7**, and **8** (Fig. 3), where the —SO_2NH_2 of **3** is replaced by —CO_2^-, —SO_3^-, and AsO_3^{2-} respectively are very similar and exhibit all the features seen in the spectrum of the —SO_2NH_2 compound; thus there are no extra features in the latter spectrum to assign to contributions from the sulfonamide group. The band at 1130 (**6**), 1122 (**7**), and 1096 cm^{-1} (**8**) is probably a variable CH in plane bending mode (*vide infra*) and is present, as a weak feature, in **1**, **2**, and **3** (Fig. 4 and refs. 3 and 4). Comparison of the resonance Raman spectrum of **3** with that of **4** where H replaces —SO_2NH_2 (Fig. 4) shows that the only additional feature in the sulfonamide spectrum is at

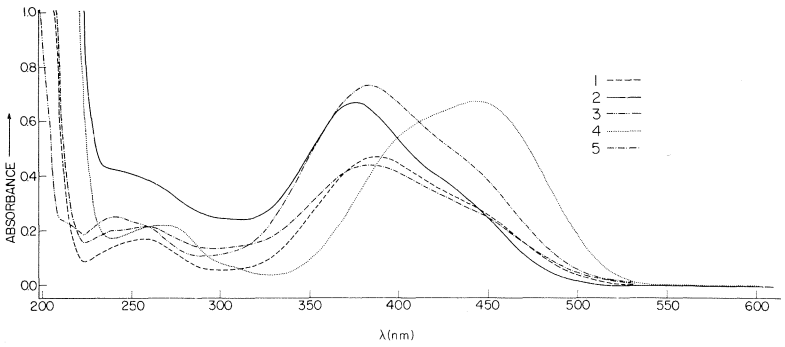

FIG. 2. Absorption spectra of (*1*) **7**, 3.7×10^{-5} *M*, tris-HCl buffer, p*H* 8.3; (*2*) **4**, 1.5×10^{-4} *M*, H_2O; (*3*) **8**, 3.4×10^{-5} *M*, *N*/10 KOH; (*4*) **2**, 1.9×10^{-5} *M* in 75% *N*/10 KOH, 25% methanol; (*5*) **6**, 3.5×10^{-5} *M*, tris-HCl, p*H* 8.2.

1398 cm^{-1}, this is almost certainly a ring mode characteristic of a *p*—*p'* substituted azobenzene (Fig. 3, ref. 6) and does not contain a significant contribution from $—SO_2NH_2$. Comparison of **1** and **5** (not shown) yields an identical result; there are no additional features in the spectrum of **1** attributable to $—SO_2NH_2$.

In the infrared the $—SO_2—$ symmetric stretch of $—SO_2NH_2$ has been assigned by a number of workers (7) to the range 1152–1169 cm^{-1}. The infrared spectra of **1**, **2**, and **3** (Fig. 5) all show an intense peak in this region and on the basis of the literature values (see, *e.g.*, ref. 7) these are assigned to the $—SO_2—$ symmetric stretch with the added possibility that a CH in plane bend (8) may make a minor contribution to the main $—SO_2—$ peak. The intense ir peak near 1140 cm^{-1} for **1**, **2**, and **3** (Fig. 5) coincides, within experimental error, with the Raman band assigned to Ph—N stretch (3, 4). Because **1** and **3** had high luminescent backgrounds only **2** gave a satisfactory Raman spectrum in the solid phase for comparison with the infrared data. For solid **2**, neither the normal (4) nor the resonance (Fig. 6 and ref. 4) Raman spectra have an intense peak near 1165 cm^{-1}. The very weak peak near 1165 cm^{-1} (Fig. 6) could possibly be $—SO_2—$ stretch but, on the basis of comparison of the three forms of **2** —OH,$—SO_2NH_2$; $—O^-$,$—SO_2NH_2$; and O^-,$—SO_2NH^-$, it is more likely to be a CH in plane bending mode (see next section). Additional evidence for the absence of the $—SO_2—$ mode comes from the normal Raman spectrum of $^-O_2C—Ph—SO_2NH_2$ (Fig. 7); no band is detected near 1160 cm^{-1} where the $—SO_2—$ stretch, insensitive to substituent effects (7), is expected.

In summary it appears certain that the $—SO_2NH_2$ does not contribute an intense or even a moderately intense mode to the resonance Raman spectra of **1**, **2**, or **3**. However, if distortion takes place in the $—SO_2NH_2$ group, increased conjugation between the sulfonamide and the ring could produce an intensity enhanced sulfonamide or Ph—S mode and this has been proposed as the mechanism for the appearance of a new resonance Raman band near 1125 cm^{-1} when **1**, **2**, and **3** separately bind to the enzyme carbonic anhydrase (4).

Effect of —OH and $—SO_2NH_2$ Ionization on the Resonance Raman Spectrum of 2

The high quality resonance Raman spectra of **2** in its HO—Ph—N=N—Ph—SO_2NH_2, O^-—Ph—N=N—Ph—SO_2NH_2, and O^-—Ph—N=N—Ph—SO_2NH^- forms (Fig. 6) permit an assessment of the effect of group ionization on the spectra. In particular the validity of correlating spectral changes with the relative importance of valence bond structures such as quinonoid (9) may be tested.

Ionization of —OH

There is a substantial body of evidence indicating that the Raman and resonance Raman spectra of *p*–*p'* disubstituted azobenzenes contain a feature with a high degree of —N=N— stretch near 1430 cm^{-1} and a mode with a high degree of Ph—N stretch occurs near 1140 cm^{-1} (3, 4, 10, 11, and references therein). For HO—Ph—N=N—Ph—SO_2NH_2 these modes are ascribed to the 1438 and 1139 cm^{-1} features respectively (Fig. 6). The marked change in the absorption spectrum of **2** when —OH → $—O^-$ (λ_{max} goes from ~360 to ~450 nm) is accom-

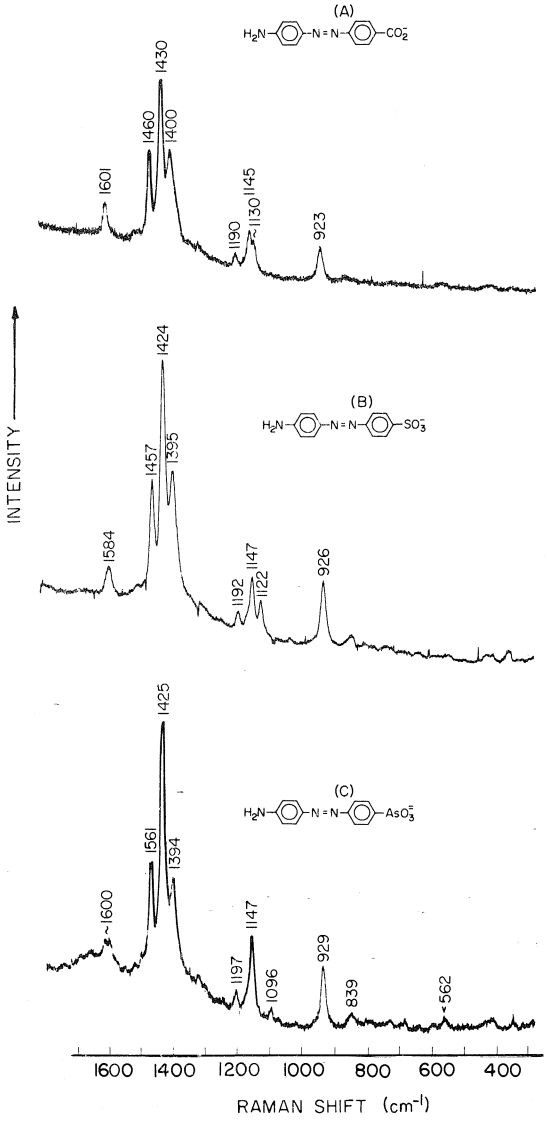

FIG. 3. Resonance Raman spectra (441.6 nm excitation) of (*A*) **6**, 3.3×10^{-4} *M* in *N*/10 KOH; (*B*) **7**, 6.9×10^{-4} *M* in tris buffer p*H* 7.4; (*C*) **8**, 2×10^{-5} *M* in *N*/10 KOH. Laser power ~60 mW, spectral slit width ~9 cm^{-1}, scan speed 0.5 cm^{-1}/s.

panied by striking changes in the relative intensities of the resonance Raman bands (Fig. 6). Two classes of frequency changes are detected in the resonance Raman spectrum upon ionization. The three bands in the —N=N— stretching region, 1400–1465 cm^{-1}, move approximately 20 cm^{-1} to low frequency while shifts to low frequency of 0–8 cm^{-1} are observed for the main Ph—N mode at 1139 cm^{-1} and its satellites at

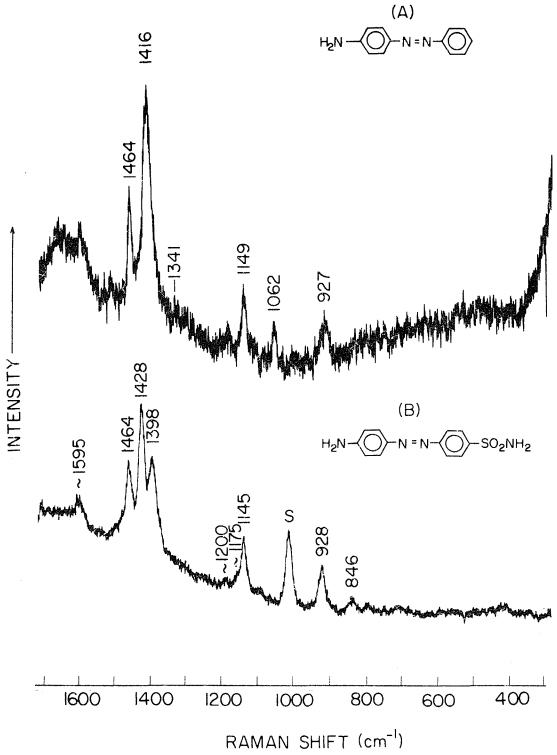

FIG. 4. Resonance Raman spectra (441.6 nm excitation) of (*A*) saturated solution of **4**, p*H* 13.0; (*B*) **3**, 4×10^{-5} *M*, p*H* 7.0, tris buffer 75%, methanol 25% (v/v). 40 mW laser power, spectral slit width 9 cm^{-1}, scan speed 0.5 cm^{-1}/s.

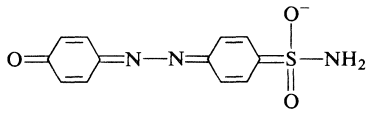
~1165 and 1098 cm^{-1}. The observed shifts for the N=N is compatible with the simple idea of a decrease in —N=N— bond order caused by increased importance of quinonoid forms of the type



However, for Ph—N the observed shift is clearly incompatible with the increased bond order expected on the basis of the quinonoid arguments. This emphasises that considerable care needs to be exercised when interpreting spectral changes in terms of contributions from valence bond structures. The bands flanking the N=N mode, at 1465, 1400 cm^{-1} in —OH and 1446, 1384 cm^{-1} in —O^-, are assigned to benzene ring modes, each ring contributing one band. Upon —OH → O^- the marked intensity gain of

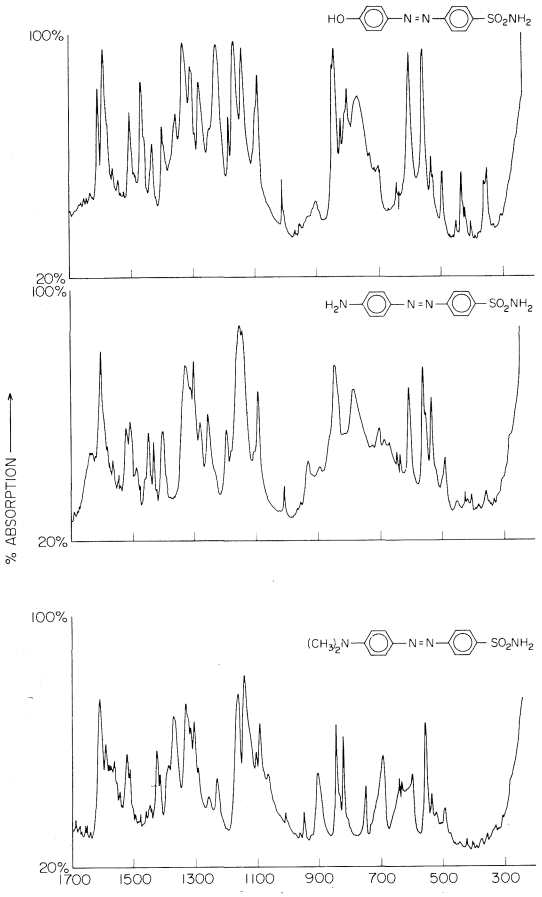


FIG. 5. Infrared spectra of compounds **1**, **2**, and **3** in KBr matrices.

these bands is evidence that they are coupled to the chromophore or chromophores responsible for intensity enhancement in the $—O^-$ form, while their frequency shifts similar to N=N indicate that they are vibrationally coupled to the N=N. This vibrational coupling may provide a mechanism for intensity enhancement of the ring modes. The 1165 and 1098 cm^{-1} bands flanking the intense 1139 cm^{-1} Ph—N feature in the —OH (Fig. 6) are ascribed to CH in plane bending modes 9*a* and 18*b* (or 15 see ref. 8) for *p–p′* disubstituted benzenes. The intensity increase for the 1190 cm^{-1}, in addition to the 1165 and 1098 cm^{-1} bands, upon OH → O^-, suggests that all three features share a common origin and may be CH in plane bends which are intensity-enhanced by coupling to the Ph—N stretching vibration. Further evidence for a coupling of this nature is found in the Raman spectral changes seen upon $—SO_2NH_2$ ionization.

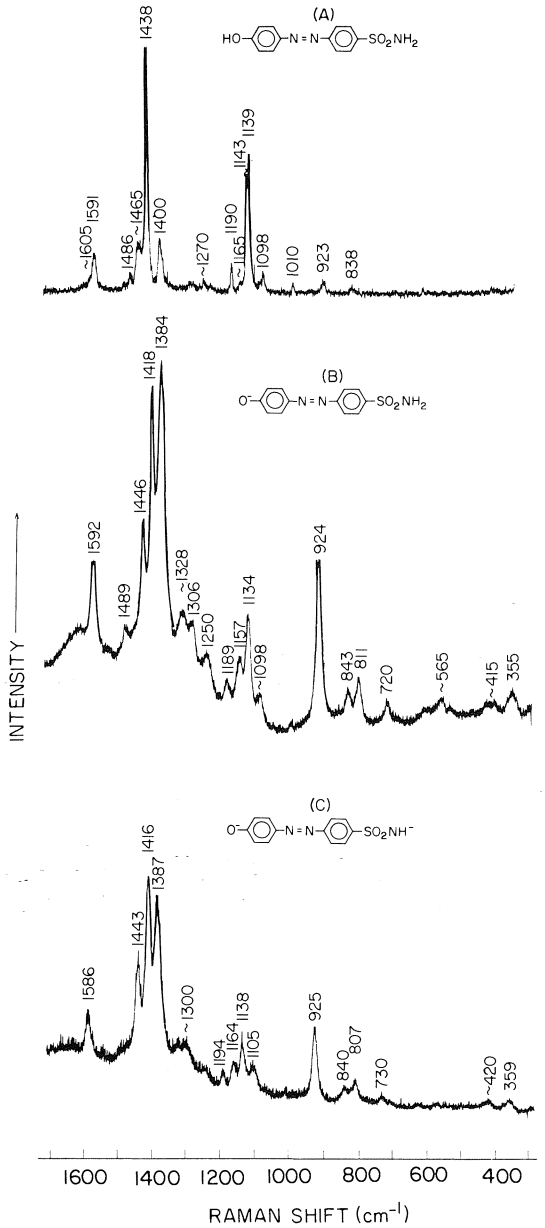

FIG. 6. Resonance Raman (441.6 nm excitation) spectra of compound **2** (*A*) solid (—OH, SO_2NH_2 form), (*B*) 1.1×10^{-4} *M* in tris-sulfate buffer p*H* 8.2 ($—O^-$, $—SO_2NH_2$ form), (*C*) 7.7×10^{-5} *M*, *N*/10 KOH ($—O^-$, $—SO_2NH^-$ form). Laser power ~40 mW. Spectral slit width (*A*) ~4 cm^{-1}, (*B*) ~5 cm^{-1}, (*C*) ~9 cm^{-1}, scan speed 0.5 cm^{-1}/s.

Ionization of $—SO_2NH_2$

The changes in the resonance Raman spectrum of **2** upon sulfonamide ionization have been dealt with at some length (3, 4) and only the 1150 cm^{-1} region will be mentioned here. The

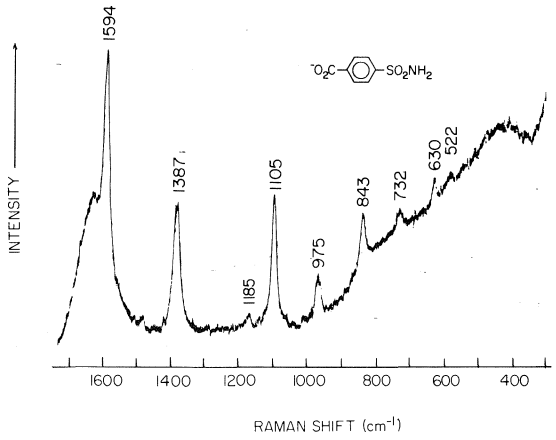

FIG. 7. Normal Raman spectra (441.6 nm excitation) of O_2^-C—Ph—SO_2NH^-, aqueous solution pH 12.6. Laser power 60 mW, spectral slit width ~9 cm^{-1}, scan speed 0.5 cm^{-1}/s.

main Ph—N band at 1134 cm^{-1} (Fig. 6) moves to 1138 cm^{-1} in —SO_2NH^-; this small shift is real and is reproduced in the 20 spectra obtained at various times with differing laser excitation wavelengths. Additionally the weak bands at 1157, 1098, and 1195 cm^{-1} assigned to CH in plane bending modes move to a higher frequency by approximately 7 cm^{-1} in the —SO_2NH^- providing further evidence for coupling to the Ph—N stretch.

It is interesting that for both —OH and —SO_2NH_2 ionization the lines grouped around the main —N=N— and Ph—N modes appear to act in concert.

Possible assignments for **1**, **2**, and **3**, based on Raman, ir, and literature data are summarized in Table 1, using Wilson's mode numbering (given in ref. 12, p. 341). It must be stressed that the assignments are tentative and that the bands in the 1400 and 1150 cm^{-1} regions are probably highly mixed. It is suggested that the great majority of the ring modes seen come from the ring containing the —O^-, —NH_2, or —$N(CH_3)_2$ chromophore. The other benzene ring is thought to make a major contribution only in the 1400 cm^{-1} region of the resonance Raman spectrum. The band at 1370 cm^{-1} in **1** is ascribed to the Ph—$N(CH_3)_2$ group and may arise as a result of the very strong conjugation between the dimethylamino and phenyl systems. The assignments suggested here are in substantive agreement with those tentatively proposed by Dupaix *et al.* (13).

*Evidence that Intensity Changes in the Resonance Raman Spectra of **1**, **2**, and **3** may be used to Follow Sulfonamide Ionization Independently of Vibronic Effects*

For compounds **1**, **2**, and **3** upon —SO_2NH_2 becoming —SO_2NH^- the ratio of the resonance Raman band intensities for the features near 1420 and 1390 cm^{-1} increases (4). This resonance Raman intensity change may be used to follow ionization of the sulfonamide group upon

binding to the enzyme carbonic anhydrase. It is thus important to find out if it is a reliable monitor of the change in chemistry or whether it simply reflects an unrelated change in vibronic coupling ensuing from the different absorption spectrum of the $-SO_2NH^-$ form (3, 4). The normal Raman spectra of **2** with 647.1 nm excitation (Fig. 8), which are not expected to be subject to subtle changes in vibronic interactions, indicate the increase of Int$\sim$1420/Int$\sim$1390 can be taken as a reliable monitor of sulfonamide ionization. Figure 8 shows that Int$\sim$1420/$\sim$1390 goes from 0.72 to 0.94, upon ionization, compared to 0.97 and 1.16 in the respective resonance (441.6 nm excitation) cases (4). Band positions in the normal and resonance Raman spectra are the same to within the limits of experimental error.

Excitation Profiles

The variation of Raman intensities with excitation wavelength, the excitation profile, is capable of providing information on vibronic structure which lies unresolved in an absorption spectrum. Excitation profiles can indicate the identity of an absorption band responsible for the intensity enhancement of Raman bands, the position of the vibronic component (*e.g.*, 0–0) responsible for maximum enhancement (14) and, in favorable cases, the 0–0 to 0–1 to 0–2 etc. spacing (15). It is also of considerable current interest to compare experimental Raman intensity enhancements with those predicted by theory.

The frequency dependence of the Raman lines in the preresonance region can be computed from the form of the scattering tensor derived by Albrecht and co-worker (16). Albrecht and Hutley derived two frequency dependent factors F_A and F_B which involve one and two excited electronic states respectively:

$$F_A = \nu^2 \frac{(\nu_e^2 + \nu_0^2)}{(\nu_e^2 - \nu_0^2)^2}$$

$$F_B = 2\nu^2 \frac{(\nu_e\nu_s + \nu_0^2)}{(\nu_e^2 - \nu_0^2)(\nu_s^2 - \nu_0^2)}$$

where ν_0 is the excitation frequency, ν_e is the frequency of the major active virtual electronic state (made equal to the frequency of the coupled lowest energy electronic transition), and ν_s is the frequency of another virtual state

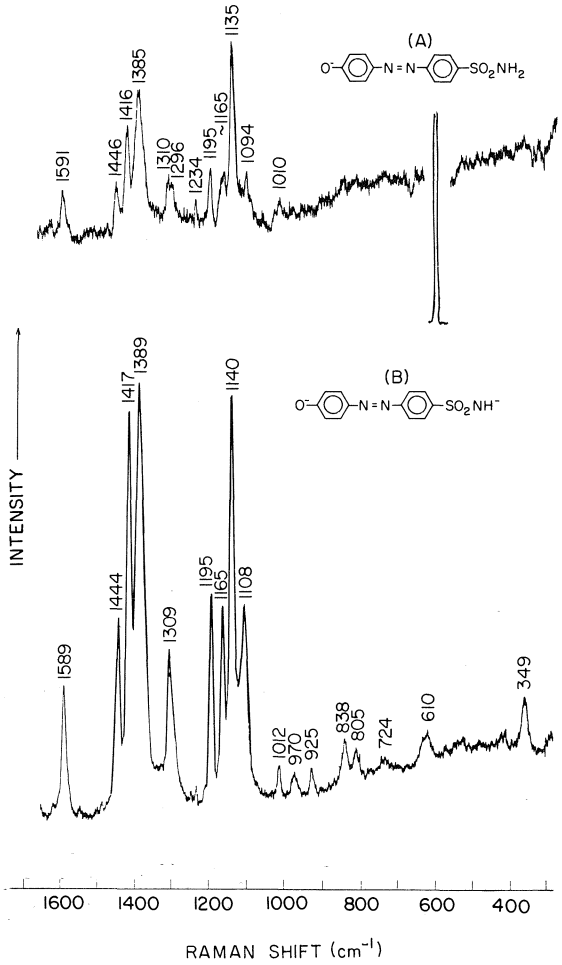

FIG. 8. Normal Raman spectra (647.1 nm excitation) of (*A*) $\sim 2.5 \times 10^{-2}$ *M* O^-—Ph—N=N—$PhSO_2NH_2$ in tris-sulfate buffer p*H* 9.1, (*B*) $\sim 7 \times 10^{-2}$ *M* $^-$O—Ph—N=N—$PhSO_2NH^-$ in *N*/10 KOH. Laser power $\sim$80 mW, spectral slit 5 cm^{-1}.

(derived from the higher energy absorption spectrum).

The frequency dependence of the intensity of a transition, I_{mn} is given by

$$I_{mn} \propto F_A^2 \quad \text{or} \quad I_{mn} \propto F_B^2$$

Albrecht and Hutley's formulism requires that only one diagonal component of the polarizability tensor be active. This criterion may be tested by measuring depolarization ratios. Under resonance conditions if only one component of the tensor is responsible for scattering the depolarization ratio is 0.33 (17). The average of two sets of measurements for **2** (at p*H* 8.0, with

TABLE 2. Comparison of experimental and theoretical (16) Raman intensities as a function of exciting wavelength (λ_0), for the 1416, 1387, and 1138 cm^{-1} lines of compound **2**. Intensities for 514.5 nm excitation are arbitrarily taken as 1.0. pH = 13.0

*For the calculation of frequency factors ν_e = 22.47 kK and ν_s = 37.31 kK.

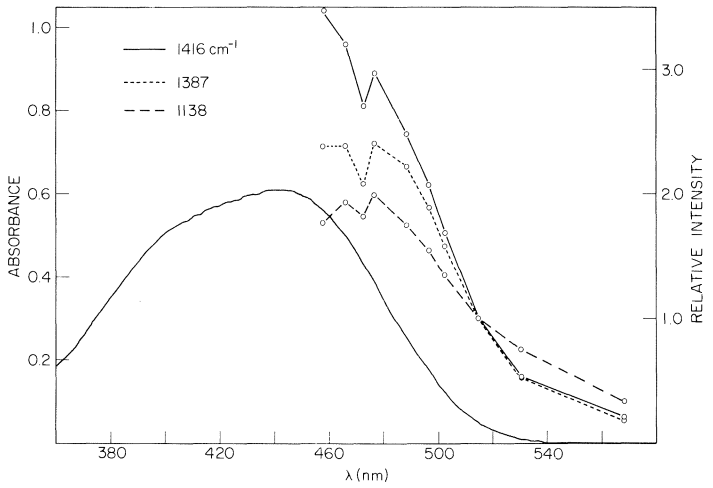

FIG. 9. Absorption spectrum and excitation profiles (for 1416, 1387, and 1138 cm^{-1} lines) of compound **2** p*H* 13.0, $\sim 2 \times 10^{-5}$ *M*.

441.6 nm excitation) gave $\rho_{1134} = 0.32 \pm 0.03$, $\rho_{1384} = 0.34 \pm 0.03$, $\rho_{1417} = 0.33 \pm 0.03$. Thus it is very likely that only one component of the polarizability tensor is dominant under resonance conditions.

Table 2 shows the calculated and measured intensities of the 1138, 1387, and 1416 cm^{-1} bands of **2**. Each band gains intensity with decrease in excitation wavelength with the 1387 and 1416 cm^{-1} features showing the greater increase. The results show that the intensity variations are better determined by F_B rather than F_A term. The point at which the pre-resonance Raman region moves into the rigorous resonance Raman case has not been well defined. For the rigorous resonance Raman case damping constants, obtainable from structured absorption spectra or overtones in the Raman spectra, must be used to calculate relative intensity enhancement. The unavailability of this experimental data prevented the use of damping constants in the present work and without this it is apparent that the agreement between theoretical F_B^2 terms and experimental intensities breaks down at about 1000 cm^{-1} from λ_{max}, or when $\lambda_{exciting}$ is lower than 488.0 nm. This point may, of course, be taken as the simple empirical definition of the boundary between pre- and rigorous-resonance.

The development of structure in the excitation profile is evident in Table 2 and Fig. 9; all three of the lines measured show a minimum at 472.6 nm excitation. Measurements at additional wavelengths, unobtainable with our existing equipment, are needed to quantify the spacing in the structure. However small spacing evident from the present data does indicate that vibrational spacing, rather than two electronic transitions, is being resolved.

Finally it is noted, as an experimental observation, that under rigorous resonance Raman conditions, most of the Raman intensity is seen in the 1400 cm^{-1} region, where the stretching vibration of the N=N group occurs.

Acknowledgements

Crystals of the 3′-*S* isomer of the title compound are orthorhombic, $a = 23.004(5)$, $b = 11.103(1)$, $c = 7.616(3)$ Å, $Z = 4$, space group $P2_12_12_1$. Crystals of the 3′-*R* isomer are orthorhombic, $a = 24.898(1)$, $b = 10.4122(4)$, $c = 7.6467(6)$ Å, $Z = 4$, space group $P2_12_12_1$. The structures were solved by direct methods and were refined by full-matrix least squares procedures to final *R* values of 0.038 for 1466 and 1996 reflections with $I \geq 3\sigma(I)$ for the 3′-*S* and 3′-*R* isomers respectively. Both crystal structures consist of discrete molecules linked by systems of intermolecular N—H...O hydrogen bonds and possible weak C—H...O interactions.

STEVEN J. RETTIG et JAMES TROTTER. Can. J. Chem. **55**, 1454 (1977).

Les cristaux de l'isomère 3′-*S* du composé mentionné dans le titre sont orthorhombiques, $a = 23.004(5)$, $b = 11.103(1)$, $c = 7.616(3)$ Å, $Z = 4$, groupe d'espace $P2_12_12_1$. Les cristaux de l'isomère 3′-*R* sont orthorhombiques, $a = 24.898(1)$, $b = 10.4122(4)$, $c = 7.6467(6)$ Å, $Z = 4$, groupe d'espace $P2_12_12_1$. On a résolu les structures par des méthodes directes et on les a affinées par la méthode des moindres carrés (matrice complète) jusqu'à des valeurs finales de *R* respectives de 0.038 pour 1466 et 1996 réflexions avec $I \geq 3\sigma(I)$ pour les isomères 3′-*S* et 3′-*R*. Les deux structures cristallines comprennent des molécules distinctes liées par des systèmes de ponts hydrogène N—H...O intermoléculaires et possiblement des interactions C—H...O qui sont faibles.

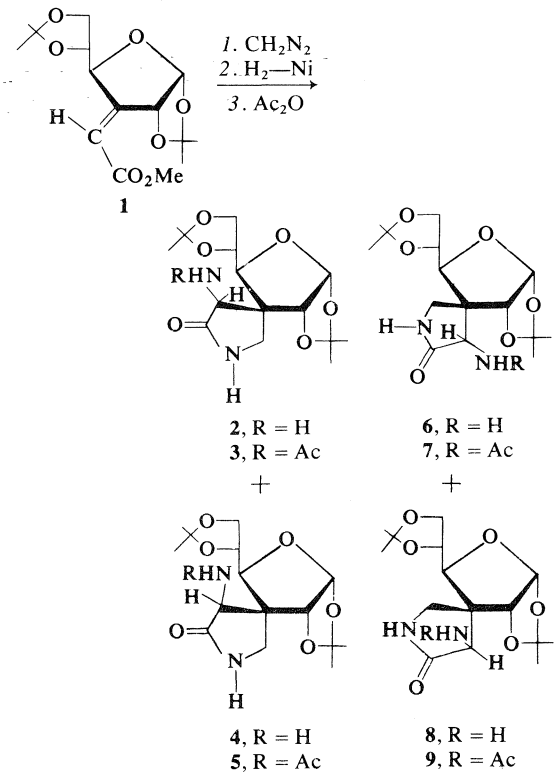
Introduction

The reaction of (*Z*)-3-deoxy-3-*C*-methoxycarbonylmethylene-1,2:5,6-di-*O*-isopropylidene-α-D-*ribo*-hexafuranose, **1**, with diazomethane followed by hydrogenation was found to yield four diastereomeric pyrrolidones **2**, **4**, **6**, and **8** (1). Conversion of these four compounds to the *N*-acetyl derivatives afforded the crystalline products **3**, **5**, **7**, and **9**. Because of uncertainties in structural assignments by conventional methods the X-ray crystallographic analysis of two of these products, namely **7** and **9**, has been undertaken.



Experimental

3′-S Isomer (9)

The crystal chosen for study was mounted with *c* parallel to the goniostat axis and had dimensions of *ca.* 0.4 × 0.4 × 0.6 mm. Unit-cell and space group data were obtained from film and diffractometer measurements. The unit-cell parameters were refined by a least squares treatment of $\sin^2\theta$ values for 12 reflections measured on a diffractometer with Cu K_α radiation. Crystal data are:

$C_{17}H_{26}N_2O_7$ fw = 370.4

Orthorhombic, $a = 23.004(5)$, $b = 11.103(1)$, $c = 7.616(3)$ Å, $V = 1945.2(9)$ Å^3, $Z = 4$, $\rho_c = 1.265(1)$ g cm^{-3}, $F(000) = 792$ (22°C, Cu K_α, $\lambda = 1.5418$ Å, $\mu = 8.4$ cm^{-1}), mp 284–286°C, $[\alpha]_D^{25}$ +98.3°. Absent reflections:

$h00$, $h \neq 2n$, $0k0$, $k \neq 2n$, and $00l$, $l \neq 2n$ define uniquely the space group $P2_12_12_1$ (D_2^4, No. 19).

Intensities were measured with nickel-filtered Cu K_α radiation on a Datex-automated General Electric XRD-6 diffractometer. A θ–2θ scan at 2° min^{-1} over a range of $(1.80 + 0.86 \tan \theta)$ degrees in 2θ was employed. Background counts of 20 s were measured at each end of the scan. Data were measured to $2\theta = 145°$ (minimum interplanar spacing 0.81 Å). The intensity of the check reflection, measured every 40 reflections throughout the data collection, remained constant to within ±2%. Lorentz and polarization corrections and check reflection scaling

were applied, and the structure amplitudes were derived. No absorption correction was made in view of the low value of μ. Of the 2229 independent reflections measured, 1478 had intensities greater than $3\sigma(I)$ above background where $\sigma^2(I) = S + B + (0.06S)^2$ with S = scan count and B = time averaged background count. These reflections were used in the solution and refinement of the structure.

The structure was solved by direct methods using tangent formula refinement (2–4).[1] Thirty-two sets of phases for 322 reflections with $|E| \geq 1.425$ were determined. One set of phases was outstanding in that it had the lowest value of R_k (0.25) and the greatest number of phases determined (296). An *E*-map calculated from this set of phases clearly gave the positions of the 26 non-hydrogen atoms among the 29 highest peaks. Two cycles of full-matrix least-squares refinement of the positional and isotropic thermal parameters of the non-hydrogen atoms gave $R = 0.130$. Three cycles of anisotropic refinement reduced R to 0.080. The coordinates of the 26 hydrogen atoms were revealed on a difference map calculated at this point. The entire structure (H atoms with isotropic temperature factors) was refined for 6 cycles giving a final R of 0.038 and R_w of 0.048 for 1466 reflections with $I \geq 3\sigma(I)$ (1 unobserved and 12 observed reflections which had $|F_o| - |F_c| > 3\sigma(F)$ were removed from the data set in the final stages of refinement; for all 2229 reflections $R = 0.070$ and $R_w = 0.060$).

The least squares refinement was based on the minimization of $\Sigma w[|F_o| - |F_c|/(1 + gI)|]^2$ where g is the extinction parameter and I the uncorrected intensity. The final value of g was $2.4(1) \times 10^{-7}$. The scattering factors of ref. 5 were used for the non-hydrogen atoms and those of ref. 6 for the hydrogen atoms. Anomalous scattering factors from ref. 7 were used for the non-hydrogen atoms. The anisotropic thermal parameters employed in the refinement are U_{ij} in the expression:

$$f = f^0 \exp[-2\pi^2(U_{11}h^2a^{*2} + U_{22}k^2b^{*2} + U_{33}l^2c^{*2} + 2U_{12}hka^*b^* + 2U_{13}hla^*c^* + 2U_{23}klb^*c^*)]$$

where f^0 is the tabulated scattering factor and f is that corrected for thermal motion (for H atoms $f = f^0 \exp[-8\pi^2 U \sin^2\theta/\lambda^2]$). The weighting scheme: $w = 1/\sigma^2(F)$ where $\sigma^2(F)$ is derived from the previously defined $\sigma^2(I)$ gave uniform average values of $w(|F_o| - |F_c|)^2$ over ranges of $|F_c|$ and was employed in the final stages of refinement. The absolute configuration of the molecule was determined from that known for the D-*ribo*-hexafuranose moiety.

On the final cycle of refinement the mean parameter shift was 0.10σ with no shifts greater than 0.43σ. The mean error in an observation of unit weight was 1.095. A

final difference map showed maximum fluctuations of ± 0.2 e Å^{-3}.

3′-R Isomer (7)

Experimental details are the same as for the 3′-*S* isomer except where noted. The crystal used for data collection was mounted with *c* parallel to the goniostat axis and had dimensions of *ca.* 0.4 × 0.5 × 0.8 mm. Twenty-one reflections were used in the refinement of the unit-cell parameters. Crystal data are:

Orthorhombic, $a = 24.898(1)$, $b = 10.4122(4)$, $c = 7.6467(6)$ Å, $V = 1982.3(2)$ Å^3, $Z = 4$, $\rho_c = 1.2411(3)$ g cm^{-3}, $\mu = 8.2$ cm^{-1}, space group $P2_12_12_1$, mp 261–263°C, $[\alpha]_D^{25} +108.5°$.

The intensity of the check reflection remained constant to within ±2.5% during the data collection. Of 2268 independent reflections measured, 2011 had intensities greater than $3\sigma(I)$ above background.

The structure was solved by direct methods. Four sets of phases for 328 reflections with $|E| \geq 1.40$ were determined. One set was outstanding in that it had the lowest value of R_k (0.20) and the greatest number of phases determined (316). An *E*-map calculated from this set of phases gave the positions of the 26 non-hydrogen atoms among the 36 highest peaks. Three cycles of isotropic refinement of the C, N, and O atoms gave $R = 0.149$. Two cycles of anisotropic refinement reduced *R* to 0.070 and a difference map revealed the positions of 23 of the 26 hydrogen atoms. The remaining hydrogen coordinates (all associated with C(15)) were placed in staggered positions. The entire structure was refined for 8 cycles giving a final *R* of 0.038 and R_w of 0.048 for 1996 reflections with $I \geq 3\sigma(I)$ (15 observed and 3 unobserved reflections which had $(|F_o| - |F_c|) > 3\sigma(F)$ were removed from the data set in the final stages of refinement; for all 2268 reflections $R = 0.050$ and $R_w = 0.053$). The final value of the extinction parameter *g* was $4.07(15) \times 10^{-7}$ and the mean error in an observation of unit weight was 1.270. The final positional parameters for both compounds are given in Table 1 and the thermal parameters in Table 2. Measured and calculated structure factors have been placed in the Depository of Unpublished Data.[2]

The thermal motions of both compounds have been analysed in terms of rigid-body modes of translation, libration, and screw motion (8) using the computer program MGTLS. Rigid-body analyses were successful for the 15 atom group O(1), O(4), O(5), N(1′), N(2), C(1)–C(5), C(8), C(2′), C(3′), C(5′), and C(12) (rms $\sigma U_{ij} = 0.0024$ and 0.0023 Å^2, rms $\Delta U_{ij} = 0.0046$ and 0.0062 Å^2 respectively for the 3′-*S* and 3′-*R* isomers). There is considerable thermal motion in the 'free' isopropylidene group of the 3′-*R* isomer. The C(7) coordination group (C(7), O(2), O(3), C(14), and C(15)) behaves as a rigid-body in the 3′-*R* isomer (rms $\Delta U_{ij} = 0.0042$ Å^2), but not in the 3′-*S* isomer where the libration tensor is not positive-definite. Bond distances have been corrected for libration (9, 10) and independent motion based on the ΔU_{ij} (11, 12) and appear along with uncorrected values in Table 3.

[2]The structure factor table is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

(*c*) Summary of bond lengths involving hydrogen

Bond	Distance (Å)	Mean (Å)
N—H	0.92–0.94(3–7)	0.93
C—H	0.84–1.38(2–10)	0.98

Results and Discussion

Figures 1 and 2 show general views of the 3′-*S* and 3′-*R* isomers respectively and the packing arrangements viewed in the *b* direction are shown in Figs. 3 and 4. Bond angles are given in Table 4 and intraannular torsion angles in Table 5. Table 6 gives details of the hydrogen-bonding schemes and selected nonbonded distances. Individual bond lengths (Table 3*b*) and angles

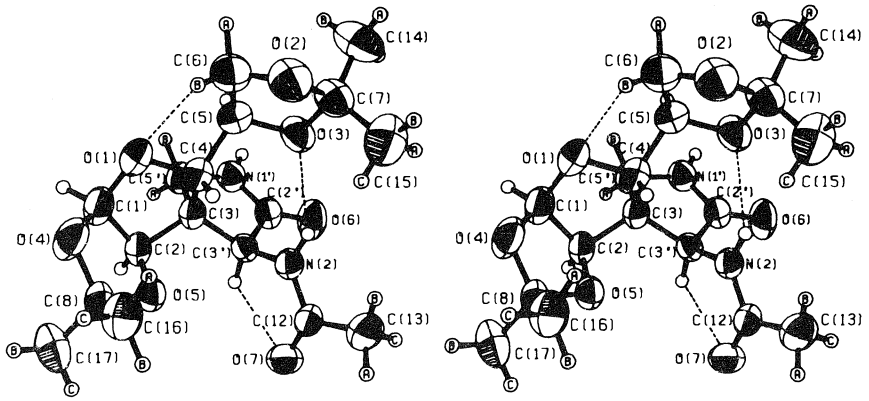

FIG. 1. A stereo view of the 3′-*S* isomer. 50% ellipsoids are shown for the non-hydrogen atoms.

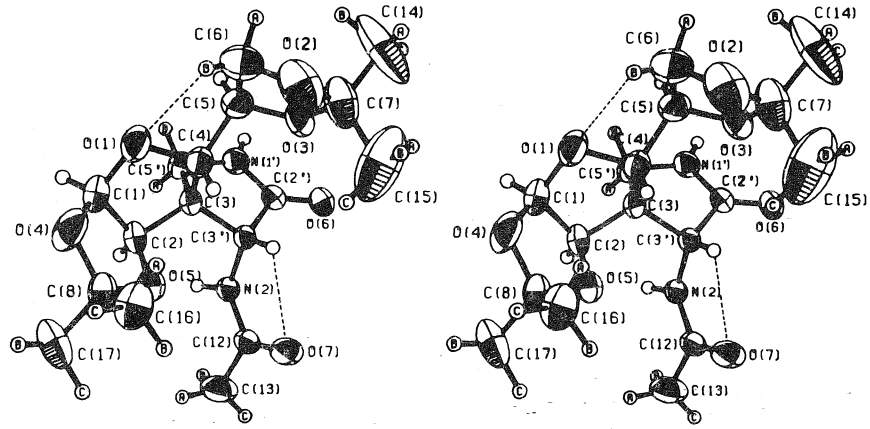

FIG. 2. A stereo view of the 3′-*R* isomer. 50% ellipsoids are shown for the non-hydrogen atoms.

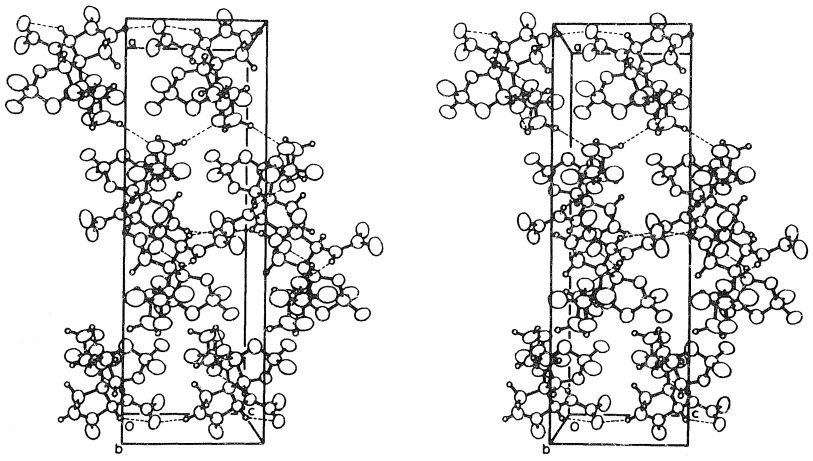

FIG. 3. The crystal structure of the 3′-*S* isomer viewed in the *b* direction. Broken lines represent hydrogen bonds.

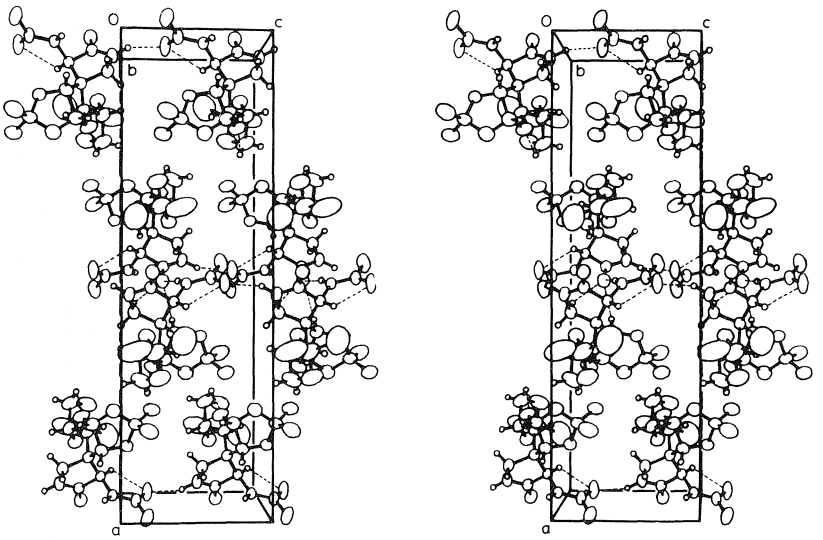

FIG. 4. The crystal structure of the 3′-*R* isomer viewed in the *b* direction. Broken lines represent hydrogen bonds.

(Table 4*b*) involving hydrogen atoms and equations of weighted least-squares mean planes (Table 7) have been deposited along with the structure factors (see footnote 2).

The structural identification of compounds **7** and **9** has enabled the structural assignments to be made by chemical tests for the two remaining pyrrolidones **3** and **5** which have *S* rather than *R* chirality at the spiro junction (C(3)) (1).

Both crystal structures consist of discrete molecules linked by a network of N—H...O hydrogen bonds, with some possible weak C—H...O interactions. There is remarkable similarity between the packing arrangements for the two isomers (see Figs. 3 and 4). Both isomers feature intermolecular N(1′)—H(N1′)...O(7) hydrogen bonds (N...O = 2.849(5) Å for the 3′-*S* isomer and 2.822(3) Å for the 3′-*R* isomer) and possible weak intermolecular C—H...O interactions, C(2)—H(2)...O(6) and C(5′)—H(5′)...O(6) (C...O = 3.219(5) and 3.292(5) Å for the 3′-*S* isomer and 3.256(3) and 3.425(3) Å for the 3′-*R* isomer), as well as two intramolecular C—H...O interactions, C(6)—H(6)...O(1) and C(3′)—H(3′)...O(7). The major difference is that H(N2) is involved in an intramolecular N—H...O hydrogen bond with O(3) in the 3′-*S* isomer (N...O = 2.998(4) Å) and an intermolecular hydrogen bond with O(6) in the 3′-*R* isomer (N...O = 2.972(2) Å). The 3′-*S* isomer has a third possible C—H...O interaction C(6)—H(6a)...O(2) (C...O = 3.520(6) Å) which is not present in the 3′-*R* isomer. The large thermal motion of the C(7) coordination group, apparent in the 3′-*R* isomer, is considerably subdued by the intramolecular N—H...O hydrogen bond (and possibly by the intermolecular C(6)—H(6a)...O(2) interaction) in the 3′-*S* isomer.

The furanose rings in the two isomeric molecules have similar, but significantly different, conformations (see Table 5). The bond lengths and angles in the furanose rings of the two molecules are equal within experimental error, while some of the exocyclic angles at ring junction atoms C(1), C(2), and C(3) differ significantly. In both rings the C(1)—O(1) bond is significantly shorter than the C(4)—O(1) bond. The C(3)—C(4) bonds (1.557(5) and 1.549(3) Å for the 3′-*S* and 3′-*R* isomers respectively) are longer, and the C(4)—C(5) bonds (1.516(6) and 1.519(4) Å) are shorter than usual. These differences probably arise from a combination of steric and σ-hybridization effects (13).

Bond lengths and angles in both fused and free isopropylidene rings of the two structures are in good agreement with the mean values tabulated for isopropylidene groups fused to sugar molecules (14). The weighted mean C—C, C—O, and C—CH_3 distances (standard deviation of the mean in parentheses) are: 1.526(2), 1.432(3), and 1.513(7) Å in the present structures compared to

The pyrrolidone rings in the two molecules both have envelope conformation with C(3) out of the plane of the other four atoms. The four atom group C(5′), N(1′), C(2′), and C(3′) is planar within experimental error in the 3′-*S* isomer and is slightly, but significantly, non-planar in the 3′-*R* isomer. The difference in chirality at C(3′) and the resultant changes in the hydrogen bonding schemes appear to be responsible for significant differences between corresponding bond lengths in the pyrrolidone rings and *N*-acetyl side chains. The strong N(2)—H(N2)...O(6) intermolecular hydrogen bond which exists in the 3′-*R* isomer is believed to be responsible for a significant lengthening of the C(3′)—N(2) and C(2′)—O(6) bonds (1.462(3) and 1.233(3) Å) and a shortening of the C(2′)—N(1′) and N(2)—C(12) bonds (1.322(3) and 1.339(3) Å) relative to the distances of 1.441(5), 1.213(4), 1.352(6), and 1.355(5) Å respectively in the 3′-*S* isomer. The geometry of the amide groups is normal. The coordination groups of the four sp^2 atoms (N(1′), N(2), C(2′), and C(12)) are planar within experimental error in the 3′-*S* isomer while only the C(12) group is rigorously planar in the 3′-*R* isomer.

(+)-1-Bromo-2-methylbutane undergoes autoxidation at 1 atm of oxygen and 30°C to give, after reduction with triphenylphosphine, 1-bromo-2-methyl-2-butanol with a (+) to (−) enantiomer ratio of 1.9 ± 0.2. The optically active 1-bromo-2-methyl-2-butyl radical is, therefore, partially trapped by oxygen at this pressure before it has time to completely racemize. The half-life for racemization of the preferred conformation is approximately 2×10^{-8} s^{-1} at 30°C. At 100 atm of oxygen the yield of (+)-$CH_3CH_2COH(CH_3)CH_2Br$ is >90% and the reaction appears to proceed with retention of configuration. A small percentage of (−)-1-bromo-2-methyl-2-butanol is, however, still produced, presumably by inversion of configuration.

J. A. HOWARD, J. H. B. CHENIER et D. A. HOLDEN. Can. J. Chem. **55**, 1463 (1977).

Le (+) bromo-1 méthyl-2 butane subit une autoxydation à 1 atm d'oxygène et à 30°C pour conduire après réduction avec la triphénylphosphine au bromo-1 méthyl-2 butanol-2 avec un rapport d'énantiomères (+) à (−) de 1.9 ± 0.2. On peut donc en conclure que le radical optiquement actif bromo-1 méthyl-2 butyle-2 est partiellement piégé par l'oxygène à cette pression avant d'avoir le temps de se racémiser complètement. La demi-vie pour la racémisation de la conformation privilégiée est approximativement 2×10^{-8} s^{-1} à 30°C. A 100 atm d'oxygène, le rendement de (+)-$CH_3CH_2COH(CH_3)CH_2Br$ est >90% et il semble que la réaction se produit avec rétention de configuration. Toutefois un petit pourcentage de (−)-bromo-1 méthyl-2 butanol-2 se produit, probablement par une inversion de configuration.
[Traduit par le journal]

Introduction

Free-radical metathesis reactions are generally nonstereospecific because the intermediate radical either has a planar arrangement of atoms attached to the radical centre or because it has a very low energy barrier to inversion (1–3). Autoxidations are consistent with this generalization since optically active organic (4) and organometallic (5, 6) compounds produce optically inactive products although Bartlett and co-workers (7) have shown that the *cis*-decalyl radical can be trapped by high pressures of oxygen during thermolysis of *cis*-9-carbo-*tert*-butylperoxydecalin.

The majority of exceptions to this rule have been observed in free-radical brominations (8, 9). Thus Skell and Shea found that bromination of (+)-$CH_3CH_2CH(CH_3)CH_2Br$ and (+)-$CH_3CH_2CH(CH_3)CH_2Cl$ occurs with a high degree of stereochemical control. Retention of optical activity in these reactions has been attributed to the intermediacy of unsymmetrically 'bridged' β-haloalkyl radicals (8, 9).

If 'bridged' β-haloalkyl radicals are a general phenomenon in free-radical chemistry, autoxidation of optically active alkyl halides such as (+)-$CH_3CH_2CH(CH_3)CH_2Br$ at the asymmetric centre should give an optically active hydroperoxide, provided reaction of the radical with oxygen is faster than racemization.

We report here a product study of the autoxidation of (+)-1-bromo-2-methylbutane which confirms this prediction and which also confirms the half-life for racemization of optically active 1-bromo-2-methyl-2-butyl that was estimated from the bromination studies (9).

Results

(+)-1-Bromo-2-methylbutane (8.08 *M*) containing α,α′-azobisisobutyronitrile (0.18 *M*) absorbed oxygen at atmospheric pressure and 30°C with an initial rate of 6.12×10^{-8} *M* s^{-1}, implying a kinetic chain length of about three. After 59 days 0.31 *M* of oxygen had been absorbed. The final reaction mixture gave an iodometric titration for active oxygen of 0.24 *M*, indicating that hydroperoxide was formed in ~80% yield based on the oxygen absorbed. Reduction of the hydroperoxide with a slight excess of triphenylphosphine gave 1-bromo-2-

[1]Issued as NRCC No. 15835.

methyl-2-butanol (0.25 *M*). We can, therefore, conclude that (+)-$CH_3CH_2CH(CH_3)CH_2Br$ undergoes autoxidation almost exclusively at the carbon β to the bromine substituent.

$$CH_3CH_2CH(CH_3)CH_2Br \xrightarrow{O_2} CH_3CH_2\underset{\displaystyle OOH}{\underset{|}{C}}(CH_3)CH_2Br \xrightarrow{Ph_3P} CH_3CH_2\underset{\displaystyle OH}{\underset{|}{C}}(CH_3)CH_2Br$$

1-Bromo-2-methyl-2-butanol was isolated 99% pure by preparative gas-liquid chromatography. Specific rotations of carbon tetrachloride solutions of the starting and recovered alkyl bromide and the bromohydrin were determined and are given in Table 1. The bromohydrin was quite clearly dextrorotatory and some optical activity was, therefore, retained upon autoxidation at the asymmetric centre.

The nmr spectrum of the recovered bromohydrin was recorded in the absence and presence of the optically active lanthanide shift reagent tris[3 - heptafluoropropylhydroxymethylene - *d* - camphorato]europium, $Eu(HFC)_3$. The spectrum of the bromohydrin in the presence of $Eu(HFC)_3$ was shifted downfield relative to the uncoordinated compound. Moreover, some of the transitions, especially the triplet from the primary protons of the ethyl group, were split into contributions from (+) and (−) forms of $CH_3CH_2COH(CH_3)CH_2Br$. The nmr transitions from these protons for the racemic alcohol and the alcohol prepared at 1 atm of O_2 are shown in Figs. 1*A* and 1*B*. It is obvious from a comparison of these two spectra that the bromohydrin prepared by autoxidation of the alkyl bromide is richer in one of the enantiomers. Since the recovered bromohydrin was dextrorotatory this must be (+)-$CH_3CH_2COH(CH_3)CH_2Br$. The ratio of (+) to (−) enantiomers prepared by autoxidation was estimated from an expanded form of the nmr spectrum and found to be 1.9 ± 0.2.

TABLE 1. Specific rotations of the 1-bromo-2-methyl-2-butanol produced by autoxidation of (+)-1-bromo-2-methylbutane at different oxygen pressures[a]

		[α] (deg.)		
O_2 pressure (atm)	λ (nm)	Starting material	Recovered bromide	1-Bromo-2-methyl-2-butanol
1	589	+3.86	+3.87	+1.39
	365	+9.82	+9.91	+4.12
10	589	+3.7	+3.77	+2.44
	365	—	+9.24	+7.77
100	589	+3.91	+3.72	+2.87
	365	—	+9.07	+9.33

[a]Specific rotation at 30°C in carbon tetrachloride.

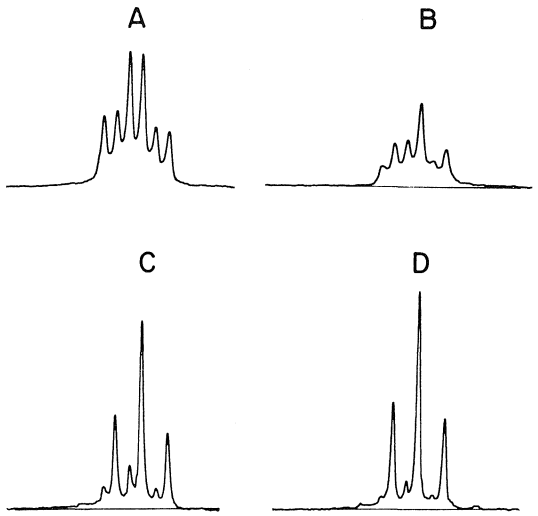

FIG. 1. Part of the ^1H nmr spectrum of 1-bromo-2-methyl-2-butanol (~0.5 *M*, CCl_4) in the presence of $Eu(HFC)_3$ (~0.07 *M*): racemic alcohol (*A*); prepared by autoxidation of (+)-$CH_3CH_2CH(CH_3)CH_2Br$ at 1 atm of O_2 (*B*); at 10 atm of O_2 (*C*); and at 100 atm of O_2 (*D*).

This result proves conclusively that the optically active 1-bromo-2-methyl-2-butyl radical formed during autoxidation of (+)-$CH_3CH_2CH(CH_3)CH_2Br$ can be trapped stereospecifically by oxygen before it undergoes complete racemization. Since there will be a competition between these two processes, increasing the oxygen concentration should favour the bimolecular reaction. Autoxidations were performed at 10 and 100 atm of oxygen and the optical activity of the recovered bromohydrin and ratio of (+)- to (−)-$CH_3CH_2COH(CH_3)CH_2Br$ were measured and they were both found to increase as expected (Tables 1 and 2).

Discussion

We believe that autoxidation of (+)-$CH_3CH_2CH(CH_3)CH_2Br$ to an optically active hydroperoxide is the first example of stereochemical control for this reaction. This result is, however, not unexpected in view of Skell's work on the photobromination of this compound. Thus if optically active 1-bromo-2-methyl-2-butyl

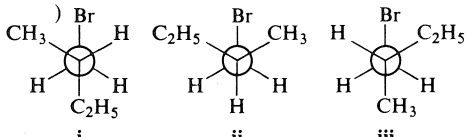
radicals live long enough to abstract a bromine atom from bromine they should live long enough to react stereospecifically with oxygen. The present work is, however, of intrinsic importance because it does confirm Skell's postulation that this β-bromoalkyl radical is formed in a preferred conformation for a reaction that is mechanistically less ambiguous than photobromination.

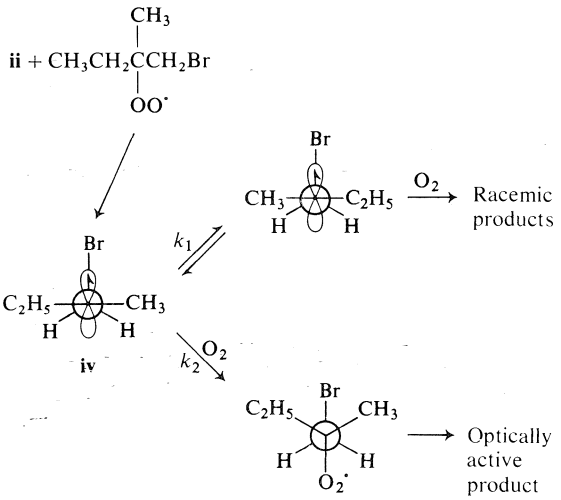
Skell (9) found that photobromination of (+)-$CH_3CH_2CH(CH_3)CH_2Br$ gave (−)-$CH_3CH_2CBr(CH_3)CH_2Br$ and invoked Brewster's rules (10) to conclude that the reaction proceeded with retention of configuration. By analogy autoxidation of (+)-$CH_3CH_2CH(CH_3)CH_2Br$ should also occur with retention of configuration. This would appear to be the case since (+)-$CH_3CH_2COH(CH_3)CH_2Br$ is the major reaction product and according to Brewster's rules, replacement of H by OH in (+)-$CH_3CH_2CH(CH_3)CH_2Br$ without changing the configuration should give a bromohydrin with retention of sign and a slightly smaller specific rotation.

The optically active 1-bromo-2-methylbutane used in our study was prepared from (−)-2-methyl-1-butanol which has been shown to have an *S* configuration (11).[2] The configuration of (+)-$CH_3CH_2CH(CH_3)CH_2Br$ should also be *S* and may be represented by conformations **i, ii,** and **iii**.



Although conformer stability increases in the order **ii** < **iii** < **i** the chain propagating radical must react preferentially with **ii** because of the influence of the β-bromine substituent on the rate of reaction with peroxy radicals. Thus the relative rate constants for abstraction of the tertiary hydrogen from $CH_3CH_2CH(CH_3)CH_2Br$ and $CH_3CH_2CH(CH_3)CH_2CH_3$ by the *tert*-butylperoxy radical are 2.8:1.[3] There must, therefore, be a specific interaction between the bromine substituent and the semioccupied orbital which stabilizes the incipient radical. Furthermore, reaction with **i** and **iii** would lead to a product with inversion of configuration while the principal product appears to have retained the configuration of the reactant (*vide supra*).

The 1-bromo-2-methyl-2-butyl radical produced from **ii** in the rate controlling propagation reaction can be represented by **iv** and it will



either react stereospecifically with oxygen by backside attack to give an optically active product with retention of configuration or racemize to give a racemic mixture of products. The ratio of (+)- to (−)-enantiomeric products should, therefore, be given by

$$[1]\quad \frac{[(+)\text{-}CH_3CH_2COH(CH_3)CH_2Br]}{[(-)\text{-}CH_3CH_2COH(CH_3)CH_2Br]} = \frac{2k_2[O_2]}{k_1} + 1$$

[2]We thank Professor A. G. Davies for bringing this to our attention. Some of the stereochemical arguments presented in this paper are based on suggestions by Professor Davies.

[3]The absolute rate constants for abstraction of the tertiary hydrogen from $CH_3CH_2CH(CH_3)CH_2Br$ and $CH_3CH_2CH(CH_3)CH_2CH_3$ by $(CH_3)_3COO\cdot$ at 30°C are 0.018 M^{-1} s^{-1} and 0.0064 M^{-1} s^{-1}, respectively (J. A. Howard, J. H. B. Chenier, and D. A. Holden, unpublished results).

This equation must, however, give an oversimplified description of the relative product ratio because if $[(+)]/[(-)] = 1.9$ at 1 atm of O_2 it should be ~ 190 at 100 atm whereas it is ~ 13 (Table 2). We originally believed this discrepancy was due to levorotatory impurity in the starting material. However, the alcohol from which the bromide was prepared had a specific rotation, $(\alpha)_D^{23} = -5.8°$ (lit. (12) $[\alpha]_D^{20} = -5.9°$) and was, therefore, optically pure. Since there is no reason to believe that any optical activity was lost in the preparation of (+)-$CH_3CH_2CH(CH_3)CH_2Br$ we can assume that this compound was optically pure.

There are two plausible explanations for the $\sim 7\%$ yield of (−)-$CH_3CH_2COH(CH_3)CH_2Br$ at 100 atm of O_2. First, there could be some reaction with conformers **i** and **iii** to give this product. Secondly, although oxygen probably reacts with **iv** by backside attack a small amount of (−)-$CH_3CH_2COH(CH_3)CH_2Br$ could be produced by frontside attack, since reaction of most alkyl radicals with oxygen occurs on every encounter (13). At the present time we cannot distinguish between these two possibilities but the least favoured process appears to account for *ca.* 7% of the product.

If the ratio of (+)-$CH_3CH_2COH(CH_3)CH_2Br$ to (−)-$CH_3CH_2COH(CH_3)CH_2Br$ produced at ~ 1 atm of O_2 is corrected for (−) enantiomer formed in a stereospecific reaction, [1] can be used to calculate a value of k_1 (the rate constant for racemization) $= 3.7 \times 10^7\ s^{-1}$, taking $k_2 = 10^{9.5}\ M^{-1}\ s^{-1}$ (13) and $[O_2] = 10^{-5} \times$ the pressure of oxygen in torr (14). The half-life for racemization of optically active 1-bromo-2-methyl-2-butyl is, therefore, approximately 2×10^{-8} s at 30°C which is in excellent agreement with the value of 10^{-8} s calculated by Skell from his bromination studies (9). If we make the same correction to the ratio of enantiomers produced at 10 atm of O_2 a value of $k_2 = 5.8 \times 10^7\ M^{-1}\ s^{-1}$ can be calculated which is in reasonable agreement with the lower pressure value.

Experimental

Materials

(−)-*2-Methyl-1-butanol* (Aldrich) $[\alpha]_D^{23}$ (obsvd.) $= -5.8°$ (undiluted) (lit. (12) $[\alpha]_D^{20} = -5.90°$) was used after drying over barium oxide. (+)-*1-Bromo-2-methylbutane* was prepared from (−)-2-methylbutanol and PBr_3 by the method of Crombie and Harper (15) and was purified by glpc. The specific rotations of this compound are given in Table 1. It is difficult to ascertain the optical purity of this compound because of the discrepancy in published specific rotations (2, 12, 16, 17). It does, however, seem reasonable to assume that it has the same optical purity as the starting alcohol, *viz.*, 100%. *1-Bromo-2-methyl-2-butanol* was synthesized from isopentene by the method of Suter and Zook (18).

Products

(+)-1-Bromo-2-methylbutane (5.0 ml) and α,α′-azobisisobutyronitrile (0.15 g) were allowed to react at 30°C with 1, 10, and 100 atm of oxygen above the liquid. Reactions at 1 atm were conducted in our automatic recording oxygen absorption apparatus (19), while high pressure experiments were performed in glass-lined stainless steel vessels. The reactions were allowed to proceed for 40–60 days after which time the hydroperoxide concentration was determined by iodometric titration. The hydroperoxide was reduced with a slight excess of freshly sublimed triphenylphosphine (20). The reaction mixture was then pumped into a trap maintained at the temperature of liquid nitrogen. The yield of alcohol was determined by gas-liquid chromatography (Varian 2800) relative to standard solutions of authentic 1-bromo-2-methyl-2-butanol. The alcohol was separated from the reaction mixture by preparative glc and was >99% by analytical glc. The optical activity was measured on a Perkin Elmer digital polarimeter at 30°C and λ 589 nm and 365 nm. The nmr signals of the (+) and (−) enantiomers resolved with the aid of the optically active lanthanide shift reagent tris[3-heptafluoropropylhydroxymethylene)-*d*-camphorato]europium (Stohler Isotope Chemicals) (21, 22). Relative concentrations were estimated from expanded spectra using a line shape simulation programme (23).

Flow nuclear magnetic resonance detection and characterization of an intermediate on the reaction pathway in a nucleophilic aromatic substitution reaction

C. A. FYFE, A. KOLL, S. W. H. DAMJI, C. D. MALKIEWICH, AND P. A. FORTE

Guelph–Waterloo Centre for Graduate Work in Chemistry, Guelph Campus, Department of Chemistry, University of Guelph, Guelph, Ont., Canada N1G 2W1

Received October 26, 1976

C. A. FYFE, A. KOLL, S. W. H. DAMJI, C. D. MALKIEWICH, and P. A. FORTE. Can. J. Chem. **55**, 1468 (1977).

The use of high resolution flow nmr has made possible the detection and characterization by nmr of the transient intermediate σ-complex on the actual substitution pathway in the nucleophilic aromatic substitution reaction of 1-ethoxy-2,4-dinitronaphthalene (**3**) with *n*-butylamine, and the assignment of its uv–visible spectrum. The intermediate is unambiguously identified as the σ-complex (**4**) and the reaction is one where the two-step mechanism is clearly applicable.

C. A. FYFE, A. KOLL, S. W. H. DAMJI, C. D. MALKIEWICH et P. A. FORTE. Can. J. Chem. **55**, 1468 (1977).

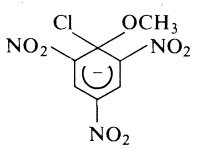
L'utilisation de la rmn continue à haute résolution a rendu possible la détection et la caractérisation par rmn de complexes σ intermédiaires de transition sur le chemin de substitution réel lors de la réaction de substitution aromatique nucléophile de l'éthoxy-1 dinitro-2,4 naphtalène (**3**) par la *n*-butylamine et l'attribution de son spectre uv–visible. On a identifié d'une façon non-ambigue l'intermédiaire comme étant un complexe σ (**4**) et la réaction en est une où le mécanisme en deux étapes peut très bien être appliqué.

[Traduit par le journal]

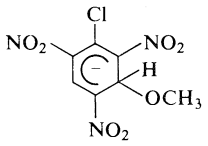
Introduction

There has been interest for several years in the mechanism of nucleophilic aromatic substitution reactions (1), particularly in the correctness of the 'two-step' mechanism for the reaction proposed by Bunnett and Zahler (2). Considerable effort has been made in the investigation and characterization of Meisenheimer complexes (3) which are formally analogous to the σ-complex postulated in the two-step mechanism, but where further reaction is unfavourable. It has been found generally that uv–visible spectroscopy and nuclear magnetic resonance spectroscopy are the best techniques for the detection and characterization of these species.

More recently, there have been claims of the successful detection of these species during actual substitution reactions. Thus, in an investigation using optical spectroscopy it has been claimed (5) that the complex **1** had been detected during the reaction of picrylchloride with methoxide ion because a two-banded spectrum characteristic of a trinitro-substituted Meisenheimer complex was observed. However, it was subsequently shown by Crampton *et al.* (4) using nmr spectroscopy that the σ-complex formed was in fact probably the 1,3-complex **2**, although the conditions of the two experiments were somewhat different. This example illustrates the difficulties involved with structural assignments based on uv–visible spectroscopy.

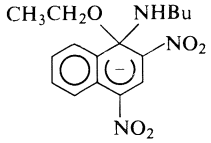


1



2

More recently, Orvik and Bunnett (6) have reported the detection, using uv–visible spectroscopy, of an intermediate species in the reaction of 1-ethoxy-2,4-dinitronaphthalene (**3**) with *n*-butylamine in dimethyl sulphoxide (DMSO) solution and examined the kinetics of its decomposition. On the basis of its uv–visible spectrum, they proposed structure **4** for this species.



4

Sekiguchi and co-workers have examined the interaction of the same substrate with secondary amines (7, 8) and have concluded that complexes analogous to **4** are formed and that they are quite stable when secondary amines are used.

We have developed and used the technique of flow nmr spectroscopy which allows good high resolution nmr spectra of reliable intensities to be measured in rapidly flowing, chemically reacting mixtures (9, 10). We have used this technique in the past to detect and to characterize transient species (11–15) in several different organic reactions. Nuclear magnetic resonance is in general a much superior technique to uv–visible spectroscopy for the characterization of chemical compounds and the development of flow nmr techniques transfers this advantage to the characterization of very short-lived species.

The purpose of the present work was to use these techniques to try and detect the transient species reported by Bunnett and to determine unambiguously its structure by high resolution nmr.

Experimental

Nuclear magnetic resonance spectra were recorded on a Varian HA100 spectrometer and uv–visible spectra on a Unicam SP800 spectrometer. With the exception of 1-ethoxy-2,4-dinitronaphthalene, all materials were from commercial sources or were prepared by literature techniques and had mp's and nmr spectra consistent with their proposed structures.

Flow nmr and uv spectra were obtained using the techniques and equipment previously described (9, 10). In the flow nmr technique, the flow nmr tube is not spun, giving somewhat broader lines than usual. There is additional line-broadening from the flow, but the spectra are quite adequate for structural assignments. In particular, since the reactants are preequilibrated in the magnetic field, the relative intensities of the lines are reasonably reliable and will be proportional to the concentrations of the appropriate species.

Preparation of 1-Ethoxy-2,4-dinitronaphthalene (3)

Difficulties were encountered in the preparation of this compound by literature procedures from 1-chloro-2,4-dinitronaphthalene and the following alternative procedure was developed.

2,4-Dinitronaphthol (100 g, 0.427 mol) was added to 300 ml *N*,*N*-diethylaniline in a 1 ℓ round bottomed flask fitted with a reflux condenser. The temperature of the solution was raised to 80°C with constant stirring and 95 g toluenesulphonyl chloride (0.5 mol) added. The solution was then continuously stirred at 80°C for 8 h. The reaction mixture was poured onto 500 ml of ice – aqueous acid yielding a brownish precipitate. This was collected by filtration, washed with ice-cold aqueous acid, twice with cold water, and then dried overnight in a vacuum desiccator. This crude material consists of mainly 2,4-dinitronaphthyl tosylate with some 1-chloro-2,4-dinitronaphthalene.

This material was dissolved in the minimum quantity of DMSO and an equivalent amount of freshly prepared 2 *M* sodium ethoxide in ethanol was added. After stirring for 1 h, the mixture was poured into aqueous acid. A solid and some oily material precipitated and the oil later solidified. After filtration and washing with ice-cold water, the crude product was dissolved in benzene and shaken with 10% aqueous $NaHCO_3$ in a separatory funnel. An orange precipitate resulted which was the sodium salt of 2,4-dinitronaphthol from unreacted starting material. After removal of this precipitate the benzene solution was washed twice with water in the separating funnel and dried over anhydrous Na_2SO_4. The volume of the solution was reduced by evaporation and light petroleum ether added until an oily solid precipitated. The solid was filtered and then recrystallized from 95% ethanol yielding 70.6 g of 1-ethoxy-2,4-dinitronaphthalene (60% overall yield) mp 90°C.

Results and Discussion

(A) Flow Nuclear Magnetic Resonance Measurements

These were made at 20°C using DMSO as solvent and at 0°C in a solvent mixture of 75% DMSO and 25% methanol. The latter system was chosen to obtain lower temperatures and also to see if the reaction mechanism would be altered by the presence of a substantial proportion of alcoholic solvent. Essentially the same results were obtained in both cases. Figure 1 shows representative spectra obtained in the mixed solvent system at 0°C, using a 4:1 ratio of amine–substrate.

The top spectrum in Fig. 1 shows the ring proton absorptions of 1-ethoxy-2,4-dinitronaphthalene obtained under static conditions. The proton H_3 between the two nitro groups is at δ 8.8 and is easily identified by its lowfield shift and lack of large couplings to any other nuclei. The middle spectra were obtained under flowing conditions at the indicated time intervals after mixing and all three show signals due to three species, one of which is the reactant. This may be deduced from the presence at low field of three single absorptions at δ 8.8, 8.9, and 9.1 which must be due to the hydrogen H_3 between the two nitro groups in three different species as only H_3 shows no large couplings to other nuclei.

On stopping the flow, there is the immediate appearance of the bottom spectrum, which is that of the product mixture from the reaction and the species responsible for the absorption

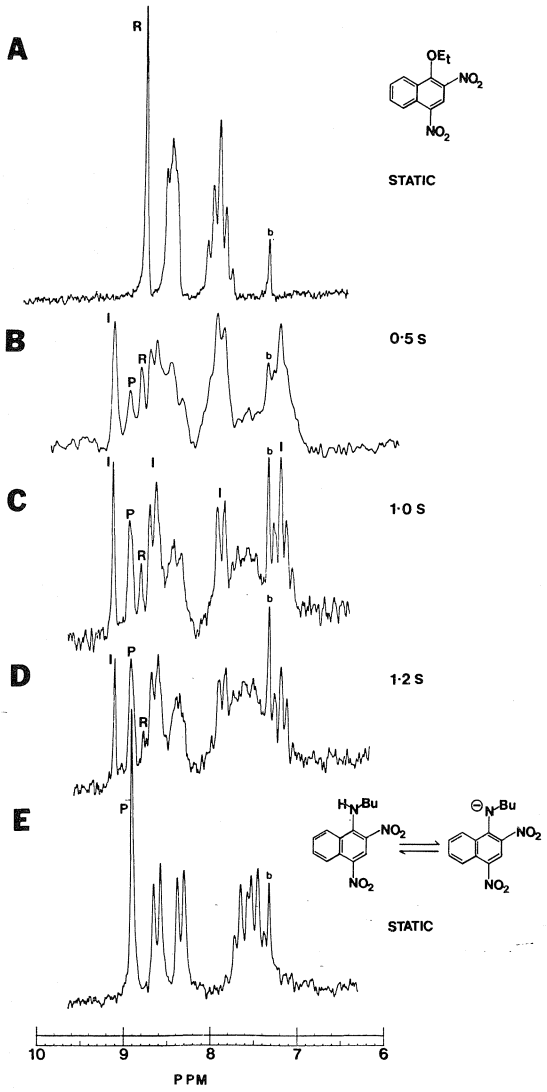


FIG. 1. 100 MHz proton nmr spectra of the aromatic region during the reaction of 0.20 *M* 1-ethoxy-2,4-dinitronaphthalene (in 75% DMSO – 25% MeOH) with *n*-butylamine (0.8 *M* in 75% DMSO – 25% MeOH) at 0°C: (A) 1-ethoxy-2,4-dinitronaphthalene. Static spectrum before mixing; (B) flow nmr spectrum, 0.5 s after mixing; (C) flow nmr spectrum, 1.0 s after mixing; (D) flow nmr spectrum, 1.2 s after mixing; (E) static spectrum immediately on stopping the flow. The small peak at δ 7.3(b) is due to a benzene reference.

at δ 8.9 in the flowing spectrum. By comparison of the three spectra, the signals due to the transient intermediate in the flowing spectrum may be identified. This species shows signals at δ 9.09 (s, H_3), 8.62 (d, H_8), 7.83 (d, H_5), and 7.14 (m, H_6,H_7). Compared to the reactant molecule, there has been a downfield shift of H_3 which is characteristic of the formation of a Meisenheimer complex based on the spectra of known Meisenheimer complexes in these systems (3). The other signals are shifted to higher fields, again characteristic of such complexes. The results are in agreement with the intermediate species having structure **4**. In particular, the presence of the H_3 resonance at low fields rules out the possibility that a σ-complex might have been formed from attack at C_3 as in the case of picryl chloride, as this species would have given a spectrum with a single sharp resonance due to H_3 at high field.

In some chemical systems the intermediates are long enough lived that their decay can be measured by stopping the flow and quickly and repeatedly scanning a small spectral region containing one signal due to the intermediate and one due to the product. In the present case, however, the intermediate is very short-lived and its decay must be measured in a continuously flowing system. The time between mixing and observation can be altered both by changing the flow-rate and also by increasing the distance (and thus the volume of solution) between the mixing chamber and detection coils by the use of spacers (12). The permutation of these two variables should yield a self consistent set of data, and the complete time-evolution of the system may be determined (Fig. 2). Figure 2 shows the complete time dependence of the relative concentrations of the reactant, intermediate, and product species, and thus illustrates an additional advantage of using nmr for investigations of reaction mechanisms, which is that the concentrations of several species may be monitored independently and simultaneously. The general profiles for the reactant, intermediate, and product concentrations are in agreement with the proposed reaction scheme [1] although it must be emphasized that this detection of an intermediate species in a reaction mixture does not prove that it is involved in the reaction pathway yielding the products, as a scheme with a side equilibrium involving this species would give exactly the same kinetic behaviour. The concentration of the intermediate reaches a maximum after only 1 s and then very quickly decays. Thus, characterization of this species by nmr spectroscopy can only be made using the present techniques.

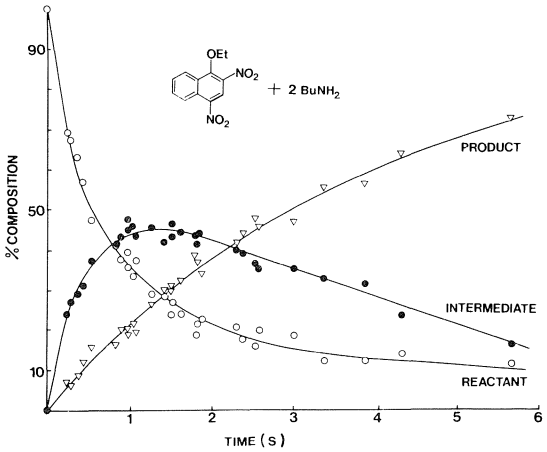

FIG. 2. Percentage composition of the reaction mixture during the reaction of 0.20 *M* 1-ethoxy-2,4-dinitronaphthalene (75% DMSO – 25% MeOH) with *n*-butylamine (0.4 *M* in 75% DMSO – 25% MeOH) at 0°C, from measurement of the relative intensities of the singlet low field absorptions assigned to the H_3 protons of the reactant, intermediate, and product species.

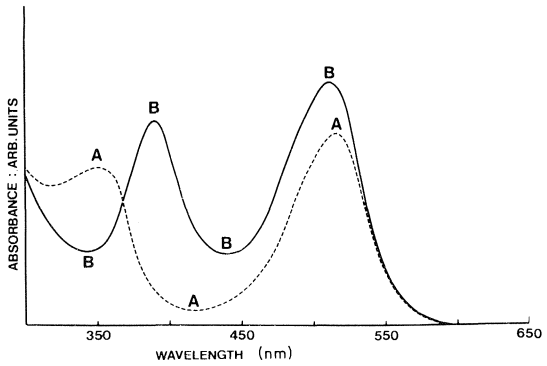

FIG. 3. Ultraviolet–visible spectral changes during the reaction of 1-ethoxy-2,4-dinitronaphthalene (0.01 *M* in 75% DMSO – 25% MeOH) with *n*-butylamine (0.1 *M* in 75% DMSO – 25% MeOH) at 0°C: (A) flow uv–visible spectrum recorded approximately 0.3 s after mixing; (B) static spectrum of the equilibrium product mixture recorded 3 min after reaction.

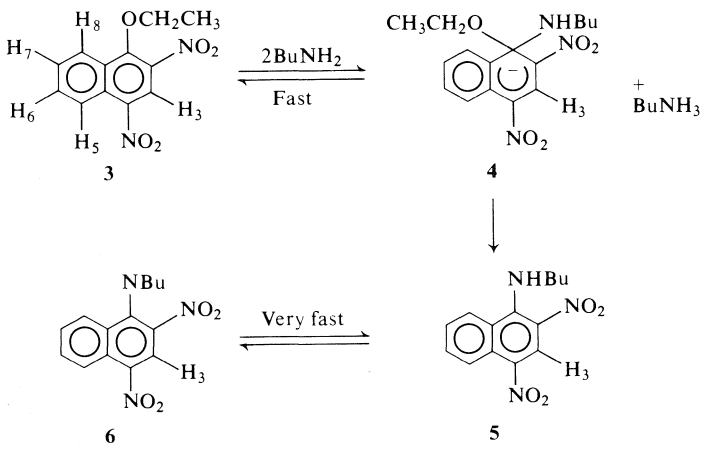
(B) Flow Ultraviolet–Visible Measurements

The extinction coefficient of the intermediate species is so large that it was not possible to use solutions of exactly the same concentration as used in the nmr experiments even using the very short pathlength flow uv cell previously described. The maximum possible concentration that could be used was 0.01 *M* in substrate. It was checked that there were no substantial changes in the general sequence of spectral changes observed during the reaction over a hundred fold change in concentration up to 0.01 *M* and it was assumed that there would be no change up to the nmr concentration. The results of the flow uv–visible investigation are shown in Fig. 3. Curve A shows the spectrum recorded during the reaction of 0.01 *M* 1-ethoxy-2,4-dinitronaphthalene with a tenfold excess of *n*-butylamine at 0°C in 75% DMSO – 25% MeOH. The spectrum was recorded under flowing conditions at a flow rate of 60 ml/min (approximately 0.3 s after mixing). Curve B shows the spectrum of this solution static after reaction and represents the limiting spectrum for the system at equilibrium. The general spectral profiles and changes observed are very similar to those reported by Orvik and Bunnett. There is the immediate appearance of a large single absorption (λ_{max} 520 nm) and a smaller broad absorption (λ_{max} 350 nm) (Curve A). The equilibrium spectrum shows a large single absorption (λ_{max} 514 nm) and a smaller single absorption (λ_{max} 390 nm). Curve A is thought to be due mainly to the intermediate σ-complex although there may be a small amount of reactant present as it shows a weak absorption at 350 nm. It is unlikely that there is any product species present as there is no absorption evident at 390 nm. Curve B is due to the equilibrium product mixture in which it is known both **5** and **6** are present. The use of 4:1 and 2:1 excesses of amine gives the same two absorptions in the spectra of the equilibrium mixtures, but the peak at 390 nm increases in intensity relative to that at 514 nm and shows evidence of a shoulder developing on the high wavelength side. Thus, the neutral product must contribute to the 390 nm absorption in curve B. It was not possible to increase the amine concentration to a large enough excess to convert all of the product to the anion species as in the previous uv–visible investigation. Taking into account the changes which will be caused by the difference in concentration from that used in previous work, it is thought that the uv–visible spectral changes observed here are similar to those reported previously for dilute solutions and that this, together with the flow nmr data, indicates that the colour producing species are mainly **4** and **6**.

(C) Quenching Experiments: Product Identification

Quenching the product mixture by addition



[1]

of water or aqueous acid yielded 1-(*N*-butylamino)-2,4-dinitronaphthalene (**5**) identified by its mp and nmr spectrum. The nmr spectrum of **5** is, however, different from that of the final product mixture shown in Fig. 1. In the reaction excess amine is present, and **5** will be in equilibrium with its conjugate base **6** as discussed by Bunnett (6). The spectrum of isolated **5** redissolved in the solvent mixture (0.2 *M* in 75% DMS; 25% MeOH) with 1 equiv. of *n*-butylamine added is identical to that from the product mixture shown in Fig. 1, confirming this assignment.

(D) Conclusions

The results obtained are all compatible with reaction [1] originally proposed by Orvik and Bunnett (6). In particular, the flow nmr data are quite diagnostic of the structure of the intermediate **4** and it is felt that this system is one where the 'two-step' mechanism is clearly applicable for the substitution which occurs. The nmr spectra of the intermediate could only be obtained by the flow nmr technique.

The complexity of the nmr spectra in this type of system makes it relatively difficult to use nmr techniques and we have investigated the reaction of 2,4,6-trinitroanisole by the flow nmr technique under similar conditions to try to obtain data of this type on other systems where the nmr spectra obtained will be much simpler.[1]

Cryoscopic and nuclear magnetic resonance studies of interaction between acetylacetone and water in benzene

MASANAO KATO, HITOSHI WATARAI, AND NOBUO SUZUKI[1]

Department of Chemistry, Faculty of Science, Tohoku University, Sendai, 980 Japan

Received January 5, 1976[2]

MASANAO KATO, HITOSHI WATARAI, and NOBUO SUZUKI. Can. J. Chem. **55**, 1473 (1977).

The interaction between acetylacetone and water in benzene solution has been examined by freezing point depression and nuclear magnetic resonance spectroscopy. The experimental results suggest that a 1:1 associated complex between acetylacetone and water is formed in benzene solution saturated with water, and the association constant is estimated to be 2.4 ± 0.1 (kg solvent/mol). By comparison with the results of methylacetylacetone and dimethylacetylacetone, it is suggested that the enol tautomer of acetylacetone preferentially associates with water.

MASANAO KATO, HITOSHI WATARAI et NOBUO SUZUKI. Can. J. Chem. **55**, 1473 (1977).

On a étudié l'interaction entre l'acétylacétone et l'eau dans des solutions benzéniques par la méthode cryoscopique et par spectrométrie rmn. Les résultats expérimentaux suggèrent qu'il y a formation d'un complexe d'association 1:1 entre l'acétylacétone et l'eau dans des solutions benzéniques saturées par de l'eau et que l'on peut estimer la constante d'association à 2.4 ± 0.1 (kg solvent/mol). Par comparaison de ces résultats avec ceux obtenus avec la méthylacétylacétone et la diméthylacétylacétone, on croit que le tautomère énolique de l'acétylacétone s'associe d'une façon préférentielle avec l'eau.

Introduction

Many research works on the liquid–liquid extraction systems involving β-diketones has been made. In most studies, however, the liquid–liquid distribution of acetylacetone between aqueous and organic phases has been represented by the following simple scheme

[1]
$$\begin{array}{ll} HAA & \text{org.} \\ \uparrow\downarrow & \\ HAA \rightleftharpoons AA^- + H^+ & \text{aq.} \end{array}$$

where HAA denotes acetylacetone and org. and aq. indicate organic and aqueous phases, respectively. The partition coefficient of acetylacetone is ordinarily defined as concentration ratio of undissociated form in two phases. But it is necessary to consider that acetylacetone exists as a mixture of keto and enol tautomers. Furthermore, in order to clarify the mechanism of distribution of acetylacetone, an interaction between acetylacetone and water must be considered.

Lin *et al.* (1) have suggested the existence of the associated complexes between acetylacetone and water in carbon tetrachloride solution by liquid–liquid partition method. However, they did not pay any attention to the keto–enol tautomerism of acetylacetone. It has been suggested from nmr spectroscopic measurements that acetylacetone associates with some protic solvents (2–4), but an interaction between acetylacetone and water has not yet been studied in detail.

In this study we estimated the association constant between acetylacetone and water by freezing point depression method in benzene solution, and examined the structure of the associated complex by nmr spectroscopy. The freezing point depression method has been adopted because an activity of solvent can be precisely measured by a simple apparatus. Benzene is employed as non-aqueous solvent because it is widely used in liquid–liquid partition experiments and dissolves a proper amount of water in present investigation. In order to examine the preferential interaction of one of two tautomers of acetylacetone with water, methylacetylacetone (MAA; 3-methyl-2,4-pentanedione) and dimethylacetylacetone (DMAA; 3,3-dimethyl-2,4-pentanedione) were synthesized and employed for measurement of nmr spectra and freezing point depression of benzene solution.

[2]Revision received January 3, 1977.

Experimental

Materials

Acetylacetone (Wako Junyaku GR) was washed by diluted aqueous ammonia and water, dried with anhydrous Na_2SO_4 or $CaSO_4$ (Drierite), and then fractionally distilled under dried nitrogen atmosphere prior to use ($d_4^{25} = 0.9678$).

Redistilled water was used.

Benzene (Wako Junyaku GR) was fractionally crystallized and dried with metal sodium, and then fractionally distilled prior to use.

Impurity did not appear on gas chromatography in all substances.

MAA and DMAA were synthesized by Bloomfield's stepwise reaction (5). MAA was purified twice by fractional distillation under reduced pressure. DMAA was purified by recrystallization and fractional distillation under reduced pressure. The products were identified by nmr spectra and no impurity was observed by gas chromatography.

Instruments

Freezing point depressions have been measured by a Beckman thermometer attached to Teflon capped freezing tube in a thermostated room at 25 ± 1°C. The contents in the inner tube were agitated by an externally driven Teflon coated magnetic stirrer. Although the freezing point depression was not measured under dry atmosphere, the water content change in test solutions through the measurement did not exceed 0.0008 mol/kg solvent. The observed values are the average of two independent measurements. The reproducibility of experimental values were ±0.004°C for binary systems and ±0.006°C for ternary systems.

All solutions were prepared by weight.

The concentration of water was determined by Karl Fischer titration. Since the keto tautomer of acetylacetone does not exert an appreciable interference to the end point in this titration, an ordinary Karl Fischer reagent was used for samples containing acetylacetone (Mitsubishi Chem. Ind., Karl Fischer reagent SS and unhydrated methanol). For samples containing MAA or DMAA a modified Karl Fischer reagent (Mitsubishi Chem. Ind., unhydrated solvent PE) was used to avoid the fading of the end point.

Nuclear magnetic resonance spectra were obtained on Varian A-60 spectrometer. The measurement of benzene solution was performed at 5.5°C and the main peak of benzene protons was employed as internal standard. The chemical shifts are reported in cps units within ±1 cps. Equilibrium constants of tautomerism have been obtained from intensity ratio of resonance peaks of methyl protons of both tautomers. For the system composed of acetylacetone and water, the chemical shifts and equilibrium constants of keto–enol tautomerism have been measured at 39 ± 1°C. Methyl groups of enol tautomer were used as the internal standard without employing an auxiliary standard like tetramethylsilane, after having verified that the methyl signal was not affected by water concentration.

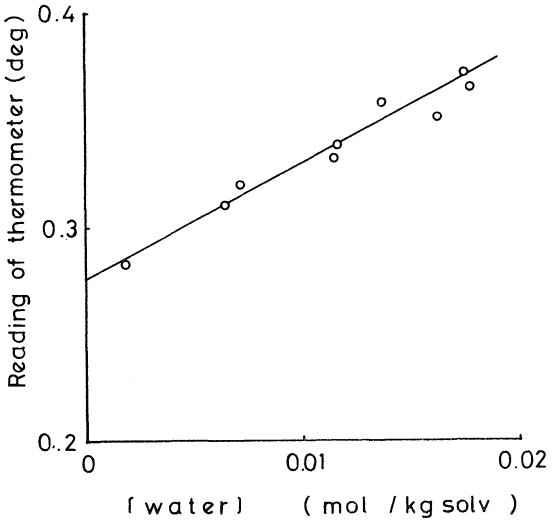

FIG. 1. Freezing point depressions of benzene by water.

Results and Discussion[3]

Freezing Point Depression Measurements

The observed freezing point depressions of benzene solutions of water are shown in Fig. 1. The slope of 5.130 (deg/mol/kg solvent) agrees with the molar freezing point depression constant of benzene ($K_f = 5.128$) (6). This proves that the dissolved water in benzene behaves as monomer in the concentration range up to 0.02 mol/kg solvent (7).

In Table 1 and Fig. 2, the observed freezing point depressions of benzene solutions of acetylacetone are demonstrated in the concentration range up to nearly 1 mol/kg solvent. The plots show a curved line departing from the straight line of slope 5.128.

Generally, the freezing point depression of solution is represented in terms of solvent activity coefficient, γ_s.

$$[2] \qquad \frac{\theta}{T} = -\frac{T_s^m R}{\Delta H_s^m} \ln X_s \gamma_s$$

where T_s^m, H_s^m, and X_s indicate the freezing point of solvent, the latent heat of fusion of solvent, and the mole fraction of solvent, respectively; and θ and T denote the freezing point depression and the freezing point of solu-

[3]The original freezing point data of the binary and ternary systems, a detailed calculation of the estimation of the formation constants for the parallel reactions between acetylacetone and water, chemical shifts of β-diketones and water concentration of the binary and ternary systems are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

TABLE 1. Freezing point depressions of acetylacetone–benzene systems

Acetylaceton concentration (mol/kg solvent)	θ (°C)
0.128	0.638
0.196	0.965
0.294	1.429
0.471	2.209
0.746	3.393
0.899	4.031

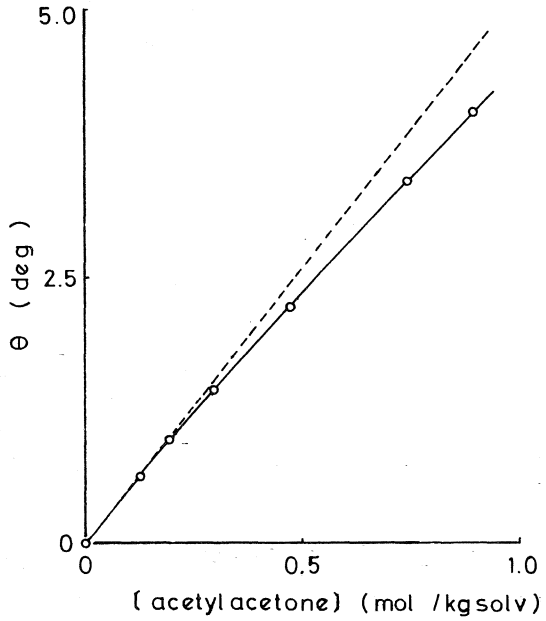

FIG. 2. Freezing point depressions of benzene by acetylacetone.

tion. Since the logarithmic term of eq. 2 can be expanded in powers of solute mole fraction, $X_i = 1 - X_s$, as follows

$$[3] \quad \ln X_s\gamma_s = -X_i - \tfrac{1}{2}X_i^2 - \tfrac{1}{3}X_i^3 - \ldots \ldots + \frac{1}{RT}(\alpha X_i^2 + \alpha' X_i^3 + \ldots)$$

the next approximated equation is obtained by neglecting the higher terms,

$$[4] \quad \frac{\theta}{X_i} = \frac{T^2R}{\Delta H_s^m}\left\{1 + \left(\frac{1}{2} - \frac{\alpha}{RT}\right)X_i\right\}$$

in which T_s^m is assumed to be identical to T. The parameter α represents the extent of the interaction including solute–solute and solute–solvent interaction. The observed freezing point data for the benzene–acetylacetone system are plotted in Fig. 3 on the basis of eq. 4. A linear relation obtained in dilute region shows that eq. 4 is a good approximation up to $X_i \simeq 0.03$. From the slope, α is obtained as 920 cal/mol. In this study we are concerned with the activity coefficient of benzene in relatively concentrated solution and disregard to a polymerization of acetylacetone which was suggested by Lin *et al.* (1) based on the postulation of solution ideality.

The observed freezing point depressions of the acetylacetone–water–benzene ternary system are shown in Fig. 4 and Table 2. The acetylacetone concentration varied up to 0.14 mol/kg solvent but the water concentration in benzene was held constant at 0.0188 ± 0.0002 mol/kg solvent which is below the saturation concentration of water. The line 0 in Fig. 4 indicates the ideal case in which no association between the components occurs and the activity coefficient of benzene is equal to unity. The line *1* indicates a hypothetical case that acetylacetone molecules completely associate with water. The observed freezing point depressions are less than the predicted values from the next equation derived by assuming no interaction between water (X_w) and acetylacetone (X_A).

$$[5] \quad \theta = \frac{T^2R}{\Delta H_s^m}\left\{X_w + X_A + \tfrac{1}{2}(X_w + X_A)^2 - \frac{920}{RT}X_A^2\right\}$$

So it is suggested that acetylacetone associates with water in benzene. Figure 4 seems to suggest that an associated complex predominantly consists of one molecule of acetylacetone and one molecule of water in accordance with the analysis of Kaufman and Singleterry (8).

Estimation of the Association Constant

The freezing point depressions of non-associ-

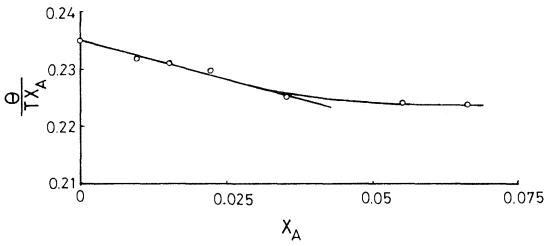

FIG. 3. Relation between acetylacetone mole fraction, X_A, and the term of θ/TX_A.

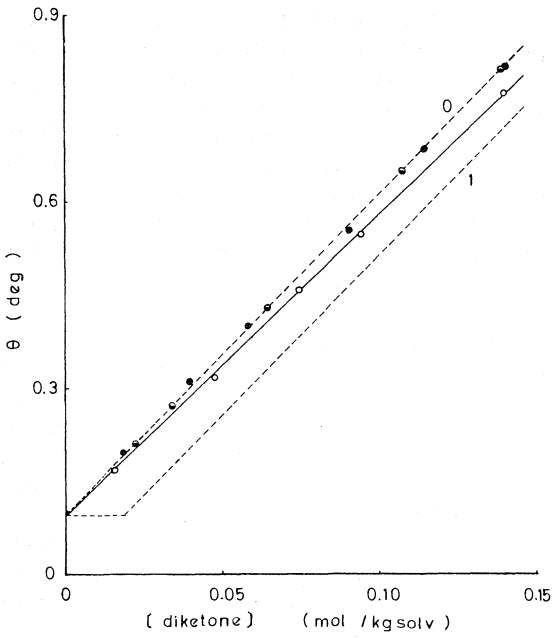

FIG. 4. Freezing point depressions of acetylacetone–water–benzene (○), MAA–water–benzene (◒), and DMAA–water–benzene (●) systems. Water concentration is 0.0188 mol/kg solvent.

TABLE 2. Freezing point depressions of water–acetylacetone–benzene systems

Acetylacetone concentration (mol/kg solvent)	Water concentration (mol/kg solvent)	θ (°C)
0.0156	0.0188	0.168
0.0477	0.0188	0.322
0.0746	0.0188	0.460
0.0945	0.0188	0.548
0.1401	0.0188	0.776

ated solutions are given by eq. 5. Similarly, the observed freezing point depressions, θ_{obs}, of the associated solutions are represented by

$$[6] \qquad \theta_{obs} = -\frac{RT^2}{\Delta H_s^{m}} \ln X_s' \gamma_s$$

where X_s' is the mole fraction of benzene in the associated solution. In eq. 6, the activity coefficient of benzene in associated solution is assumed to be equal to that in non-associated solution. The difference between θ and θ_{obs} is related to the ratio of X_s/X_s',

$$[7] \qquad \theta - \theta_{obs} = -\frac{RT^2}{\Delta H_s^{m}} \ln \frac{X_s}{X_s'}$$

The mole fraction X_s is given by

$$[8] \qquad X_s = \frac{n_s}{n_s + n_a^{0} + n_w^{0}}$$

where n_s, n_a^{0}, and n_w^{0} are the number of moles of benzene, acetylacetone, and water, respectively. On the other hand, X_s' is represented by eq. 9 considering the following equilibria,

$$\mathrm{HAA} + \mathrm{H_2O} \rightleftharpoons (\mathrm{HAA})(\mathrm{H_2O})$$
$$2\mathrm{HAA} + \mathrm{H_2O} \rightleftharpoons (\mathrm{HAA})_2(\mathrm{H_2O})$$
$$\vdots \qquad\qquad \vdots$$
$$j\mathrm{HAA} + k\mathrm{H_2O} \rightleftharpoons (\mathrm{HAA})_j(\mathrm{H_2O})_k$$

$$[9] \qquad X_s' = \frac{n_s}{n_s + n_a + n_w + \sum_{j,k} n_{jk}}$$

where n_a, n_w are the number of moles of free acetylacetone and free water respectively and n_{jk} is that of the associated complex $(\mathrm{HAA})_j(\mathrm{H_2O})_k$. From above relations the next equation is derived,

$$[10] \qquad -\ln \frac{X_s}{X_s'} = \ln \left\{ 1 + \sum_{j,k} (j + k - 1) X_{jk} \right\}$$

where X_{jk} is the mole fraction of the associated complex. By substituting the eq. 10 into eq. 7 and expanding the logarithmic term, we get the next equation,

$$[11] \qquad \theta - \theta_{obs} = \frac{RT^2}{\Delta H_s^{m}} \sum_{j,k} (j + k - 1) X_{jk}$$

or on a molality scale, m,

$$[12] \qquad \theta - \theta_{obs} = K_f \sum_{j,k} (j + k - 1) m_{jk}$$

where K_f is the molar freezing point depression constant. Here we can represent the association constant, $K_{jk} = m_{jk}/m_a^{j} m_w^{k}$, by

$$[13] \qquad K_{jk} = \frac{m_{jk}}{\left(m_a^{0} - \sum_{j,k} j m_{jk} \right)^{j} \left(m_w^{0} - \sum_{j,k} k m_{jk} \right)^{k}}$$

TABLE 3. Estimation of association constants from the observed freezing point depressions[a]

Acetylacetone concentration (mol/kg solvent)	$\frac{\theta - \theta_{obs}}{K_f}$[b] (mol/kg solvent)	K_{11}[c] (kg solvent/mol)^2	K_{21}[c] (kg solvent/mol)^2	K_{12}[c] (kg solvent/mol)^2	m_{11}[c,d] (K_{11} = 2.4)
0.0156	0.00144	5.8_7	199	321	0.00065
0.0477	0.00302	4.2_9	43	131	0.00186
0.0746	0.00234	1.9_7	25.0_4	588	0.00276
0.0945	0.00442	3.4_2	1.4_8	110	0.00337
0.1401	0.00360	1.7_4	5.6_8	56	0.00461

[a]Water concentration is 0.0188 mol/kg solvent.
[b]Total concentration of associated complexes obtained from eq. 12.
[c]Estimated association constant from assumption of only one associated complex.
[d]The best values of calculated complex concentration at $K_{11} = 2.4 \pm 0.1$ and $\sigma = 0.006$.

The calculated association constant for each process of K_{11}, K_{21}, K_{12} are summarized in Table 3. We tried also to estimate the association constant for a higher associated complex which might also be present, but the calculation gives negative association constants. From Table 3, the association between two molecules of acetylacetone and one molecule of water is unlikely because the calculated association constants, K_{21}, do not give a constant value at different concentrations, and also the association of one molecule of acetylacetone and two molecules of water is impossible since the data for K_{12} are too large and show fairly large scatter. So it is most reasonable to assume that the association of one molecule of acetylacetone and one molecule of water occurs in this system.

The best fit calculation of the K_{11} was carried out as follows. In this case, the concentrations of associated complex, $m_{11}{}^c$, are represented from eq. 13 as follows.

$$[14] \qquad m_{11}{}^c = \frac{K_{11}(m_a{}^0 + m_w{}^0) + 1 - \sqrt{\{K_{11}(m_a{}^0 + m_w{}^0) + 1\}^2 - 4K_{11}m_a{}^0m_w{}^0}}{2K_{11}}$$

Hence, the difference between calculated and observed freezing point depression, $d\theta$, is defined as a function of K_{11}. So, the fittest value of K_{11} is determined by minimizing the deviation of the calculated freezing point depression, $\theta - K_f m_{11}{}^c$, from the observed one. The deviation, σ, is defined as

$$[15] \qquad \sigma = \sqrt{\frac{d\theta^2}{N - 2}}$$

where N is the number of observed points. The obtained best value is 2.4 ± 0.1 (kg solvent/mol), as shown in Table 3. The smooth line in Fig. 4 is a calculated one for $K_{11} = 2.4$.

Comparison with MAA and DMAA

The observed freezing point depressions of benzene by MAA and DMAA are plotted in Fig. 5 together with that for naphthalene. The straight line with slope of 5.130 means that these β-diketones cause no change of benzene activity up to nearly 0.15 mol/kg solvent.

In Fig. 4, the observed freezing point depressions of MAA–water–benzene and DMAA–water–benzene ternary systems are shown. Since all the observed values are on line *0*, it is found that MAA and DMAA do not associate with water. Taking into account that these β-diketones are nearly composed of keto tautomer, we can expect that the keto tautomer of acetylacetone does not participate in the association of

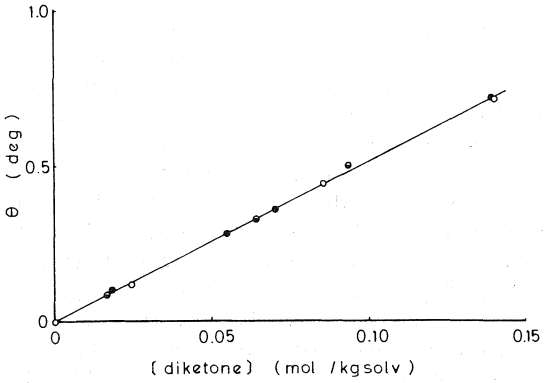

FIG. 5. Freezing point depressions of benzene by MAA (●), DMAA (○), and naphthalene (◒).

TABLE 4. Water concentration dependence of chemical shift and band width of hydroxyl proton of enol tautomer of acetylacetone and methylacetylacetone in benzene solution at 5.5°C

acetylacetone with water. Accordingly, it is presumed that the 1:1 associated complex between acetylacetone and water may consist of enol tautomer and water.

This argument is supported by the nmr study of the water concentration dependence of the chemical shifts of enol tautomer.

Nuclear Magnetic Resonance Measurements

In order to investigate the structure of the associated complex, the water concentration dependence of the chemical shifts of acetylacetone and MAA in benzene at 5.5°C were examined. The results are shown in Table 4. It is found that the chemical shifts of acetylacetone and MAA are independent of water concentration. In preliminary experiment, a distinct high-field shift of the hydroxyl proton of enol tautomer of acetylacetone in carbontetrachloride was observed with increasing water concentration. Thus it seems that the chemical shift of the hydroxyl proton in benzene solution is affected by the paramagnetic effect of benzene ring as proposed by Rogers and Burdett (9). The enol content of acetylacetone is 93.1% and that of MAA is 20.1% under the condition described in Table 4. But the signal width at half intensity of hydroxyl proton of acetylacetone is broadening with increasing water concentration. Signals of the other protons of acetylacetone and MAA, however, remain constant and the signal of water proton is not observed. These results suggest a hydrogen bonding interaction between water and the enol tautomer of acetylacetone.

Since the nmr spectra of acetylacetone–benzene–water ternary system did not give clear information about the interaction between acetylacetone and water because of a poor S/N ratio, we investigated the acetylacetone–water binary system. The water concentration dependence of the nmr spectra of acetylacetone was examined and the results are shown in Table 5 and Fig. 6. The signal of the hydroxyl proton of enol tautomer shifts to high magnetic field and broadens with an increase of water concentration. The peak area of its signal also increases with an increase of water concentration. Chemi-

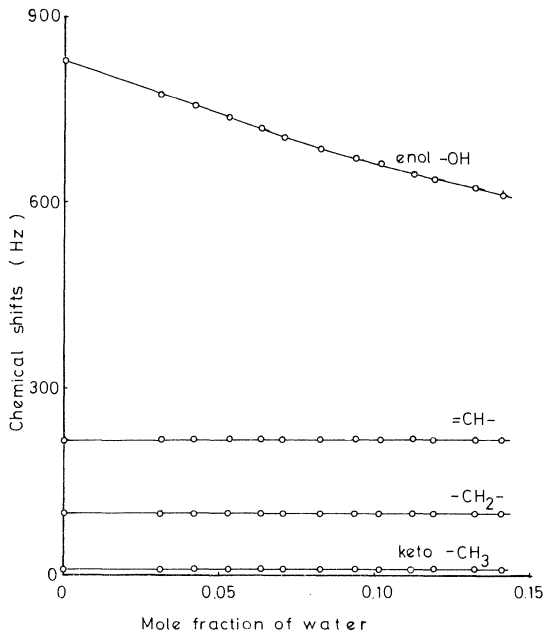

FIG. 6. The water concentration dependence of the chemical shifts of acetylacetone at 39°C. Chemical shifts are relative to the methyl protons of enol form.

cal shifts of other protons, however, remain constant and the signal of water protons is not observed individually because of the probable exchange with the hydroxyl proton of enol tautomer as shown in Table 5. Enol content in acetylacetone–water system also remains constant at 78.8% in the concentration range of water up to $X_w = 0.1339$. These results emphasize the interaction between water and enol tautomer as described above. The evidence on the interaction between water and keto tautomer was not obtained since the chemical shifts of keto tautomer remained constant as concentration of water was varied.

Interpretation from the nmr spectra agrees with the results of the other systems (2, 4). In the acetylacetone–dimethylamine system (2), it has been reported that the signal of the enol hydroxyl proton shifts to high magnetic field with increasing concentration of dimethylamine. This result and the fact that acetylacetone forms no associated complex with triethylamine (4), which is a strong aprotic base, support the present conclusion that protons of water molecule play an essential role in interaction between enol tautomer and water.

Partition of Acetylacetone

Now the apparent partition coefficient, P, of undissociated forms of acetylacetone is expressed as follows

$$[16] \qquad P = \frac{[HAA]_{org}}{[HAA]_{aq}}$$

$$[17] \qquad = \frac{[keto]_{org} + [enol]_{org} + [enol - H_2O]_{org}}{[keto]_{aq} + [enol - H_2O]_{aq}}$$

The fraction of unhydrated enol tautomer in aqueous phase may be negligible in a diluted solution of acetylacetone. When a benzene solution of acetylacetone, for example 0.001 mol/kg solvent, was equilibrated with water, about 10% of acetylacetone in benzene phase may occur as the 1:1 associated complex with water. As a conclusion, the formation of the associated complex in benzene phase should not be overlooked in exact understanding of the partition equilibrium involving acetylacetone.

Reaction of both *peri*-dilithionaphthalene and *peri*-dilithioacenaphthalene with acenaphthenequinone and pyracenequinone yielded the dihydroxy derivatives of acenaphth[1,2-*a*]-acenaphthylene **11***a*, **11***b*, **11***c* with no, one, and two ace-bridges respectively. These could be converted either by the Corey thionocarbonate method or with anhydrous liquid hydrogen fluoride to the three alkenes **12***a,b,c* and with $Pb(OAc)_4$ to the three diketones **13***a,b,c*. The latter on Wolff-Kishner reduction yielded alkenes **12***a,b* and mono ketones **15***b,c*. The uv, ir, ^{1}Hmr spectra and electrode reduction potentials for the four series of compounds in which the ace-bridges add increments of strain were examined and possible effects which might be due to strain were noted. Several areas in which theoretical calculations are lacking were noted.

REGINALD H. MITCHELL, THOMAS FYLES et LEONARD M. RALPH. Can. J. Chem. **55**, 1480 (1977).

La réaction des *péri*-dilithionaphtalènes et *péri*-dilithioacénaphtalènes avec l'acénaphtènequinone et pyracènequinone conduit aux dérivés dihydroxylés **11***a*, **11***b* et **11***c* de l'acénaphtène[1,2-*a*]acénaphthylène qui comportent respectivement aucun, un et deux ponts acé. Ces composés peuvent conduire, soit par la méthode des thionocarbonates de Corey soit avec l'aide de l'acide fluorhydrique liquide anhydre, aux trois alcènes **12***a,b,c*, et, avec $Pb(OAc)_4$, trois dicétones **13***a,b,c*. La réduction de Wolff–Kishner de ces dernières conduit aux alcènes **12***a,b* et aux mono-cétones **15***b,c*. On a examiné les spectres uv, ir, et rm^{1}H et les potentiels de réduction d'électrode des quatre séries de composés dans lesquelles les ponts acé ajoutent des éléments de contraintes et on a noté les effets qui peuvent ressortir de ces contraintes. On note plusieurs champs dans lesquels il manque des calculs théoriques.

[Traduit par le journal]

Introduction

One of the more interesting aspects of naphthalene chemistry is the so-called *peri*-interaction which occurs between 1,8-disubstituted naphthalenes due to the restricted geometry imposed by the naphthalene nucleus (for an extensive review see ref. 1). The effects are summarized as shown in Table 1.

In naphthalene itself the distance between the 1,8(*peri*) hydrogens is 244 pm. Substitution of these hydrogens by methyls increases this distance to 293 pm, and distorts the naphthalene framework, the angles α and β opening some 4–5° while the opposite angles δ and γ close by several degrees. Correspondingly when the X—X distance is shortened to 154 pm as in acenaphthene, angles α and β close considerably while δ opens. It can be seen that the strain introduced in the molecule is accommodated by this scissor movement of the central naphthalene carbons. Addition of the second bridge in pyracene clearly prevents this relief of strain and while the X—X distance now lengthens a little beyond the normal C—C bond length to 159 pm, the angles α and β remain severely distorted from the normal 120° values. Pyracene **1** is thus strained, and indeed up until 1952 when Anderson and Wade (2) synthesized it, it was thought that this geometrical scissoring would be sufficiently exacting to prevent closure of the second five-membered ring. Whilst no strain energy calculations appear to have been made on **1**, Dauben (3) has calculated the strain energy of pyracylene **3** to be *ca.* 50 kcal/mol. Using Dauben's potential function (3, 4) we calculate the strain in pyracene due to the bond angle deformations to be about 36 kcal/mol. This seems reasonable in that introduction of unsaturation into the *peri*-bridges would be expected to shorten the X—X distance to *ca.* 135 pm (5) and hence introduce more angle strain. Indeed, although Anderson

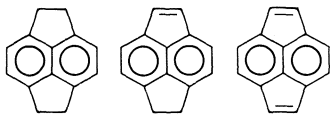
[2]Presented in preliminary form at the 30th Northwest Regional Meeting of the American Chemical Society, University of Hawaii, June 13, 1975.

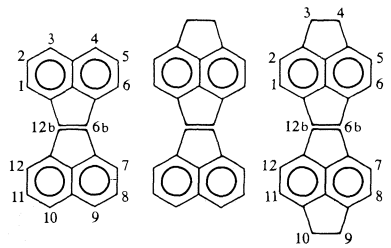
[3]Author to whom correspondence should be addressed.

(6) was able to synthesize 1,2-dihydropyracylene **2** in 1957, it was a further 10 years before Trost and co-workers (7, 8) reported the synthesis of pyracylene **3** itself. Whereas pyracene **1** is quite stable, **2** decomposes slowly at room temperature in the solid state, and pyracylene **3** could only be isolated in solution, nicely reflecting the increasing strain in the series **1–3**.

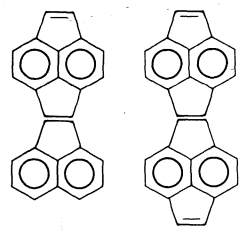


1 **2** **3**

A further potentially interesting series in which to study the effects of strain is derived from the interesting hydrocarbon acenaphth[1,2-*a*]acenaphthylene **4** first reported by Letsinger and Gilpin (9) in 1964. Addition of bridges across the *peri*-positions of **4** leads to the series of compounds **5–8** which should have progressively increased strains. Compound **8** is of further special interest since it consists of two pyracylene molecules ('4*n*' compounds) fused along one edge and thus should (10) be an aromatic '4*n* + 2' compound. Examples of fused ('4*n* + 4*n*') compounds are rare in the literature (see, for example, ref. 11) and on the whole have proved disappointingly olefinic as Wilcox *et al.* (12) point out. However such examples do not contain benzenoid rings which, at least as far as 4*n* and 4*n* + 2 systems are concerned, seem to exert a stabilizing effect (for example see refs. 4 and 8). Compounds containing a pentalene nucleus are non-alternate hydrocarbons and ones with a potential (4*n* + 2) π periphery such as **8** are indeed rare, Vogel's (13) dicyclohepta-[*cd*,*gh*]pentalene being the only example known to us. In fact, despite the myriad (see, for example, ref. 14) of calculations on similar systems both known and hypothetical, **8** seems to have been neglected.



4 **5** **6**



7 **8**

This paper reports the synthesis of **5** and **6** and another synthesis of **4** and our interpretation of their spectral properties in terms of strain, as well as our (as yet unsuccessful) attempts to convert **6** to the fully unsaturated hydrocarbon **8**.

Nomenclature

Since all of the following derivatives of **4** have unwieldy names and as comparisons will be made between the three series of compounds corresponding to **4**, **5**, and **6** we will refer to **4** as an unbridged-alkene and its derivatives will all have *a* numbers, **5** as a monobridged-alkene, the *b* series and **6** as a bisbridged-alkene, the *c* series. In this way for example the diols all have the number **11**, and **11***a* is unbridged-diol, **11***b* is monobridged-diol, and so on. For each compound a probable Chemical Abstract name is given in the experimental section.

Results

I. Syntheses

Unbridged-alkene **4** has been synthesized (9, 15) by two routes from the unbridged-diol **11***a*, derived from condensation of 1,8-dilithionaphthalene **9***a* (16) with acenaphthenequinone **10***a*. Since the second route (15) involves a transannular intramolecular ring closure across the *peri*-positions of **13***a*, we expected that it might be sensitive to the distance between the carbonyl groups of **13** and bring about a synthetic verification of our predictions derived from Table 1.

We found that 1,8-dilithionaphthalene **9***a* was more conveniently prepared from 1,8-diiodonaphthalene (17) and then, using essentially Letsinger's conditions, we obtained unbridged-diol **11***a* from **9***a* and **10***a* in 12–14% yield, monobridged-diol **11***b* from 5,6-dilithioacenaphthene **9***c*[4] and **10***a* in 10–20% yield, and bisbridged-diol **11***c* from **9***c* and pyracene-

[4]Letsinger (16) also attempted to prepare 5,6-dilithioacenaphthene, but was using 3,5-dibromoacenaphthene (mp 138–140°C) (18) and not authentic 5,6-dibromoacenaphthene (19, 20) best prepared from 5-bromoacenaphthene (21).

quinone **10***c* (22) in 13–26% yield. All three diols show an absence of carbonyl absorption, strong —OH stretch bands at *ca.* 3350 cm^{-1} in their infrared spectra and strong M^+ molecular ions in their mass spectra. Their uv spectra, which are similar, will be discussed below.[5]

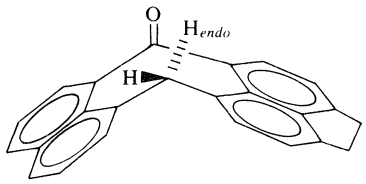
Preparation of the Alkenes Through the Wolff–Kishner Route

Unlike (9) unbridged-diol **11***a*, lead tetraacetate cleavage of monobridged-diol **11***b* to monobridged-diketone **13***b* was both sluggish and low yielding and moreover almost no **13***c* was formed from the bisbridged-diol **11***c*. Addition of trichloroacetic acid (23), however, completed all three reactions in *ca.* 30 min in 71–76% yields. The structures of the diketones **13** were readily confirmed by the absence of —OH bands and presence of strong C=O absorption *ca.* 1690 cm^{-1} in their ir spectra, base peak molecular ions in their mass spectra, and similarities in their uv spectra.

Reaction of unbridged-diketone **13***a* with hydrazine as described by Agosta (15), but using a longer reaction time, improved the yield of **12***a* to 83%. The uv spectrum of purple **12***a* agrees with the maxima that are reported (9, 15), except that both papers omitted to report a number of maxima (log ε 2–3) in the 500–620 nm region.

Agreeing with Agosta's (15) observation we usually obtained a small amount (~4%) of unbridged-alkane **14***a* as a by-product. We could not isolate any unbridged-monoketone **15***a* in this reaction (*cf.* below).

When monobridged-diketone **13***b* was subjected to these reaction conditions the purple monobridged-alkene **12***b* (≡5), mp 274–276°C was obtained in 22% yield. Its structure was proved by its uv (very similar to that of **12***a*, see below), by its ^{1}Hmr spectrum (essentially first order), and its correct molecular ion at *m/e* 302 in its mass spectrum. There was also obtained the yellow monobridged-monoketone **15***b*, mp 233–234°C in 33% yield. Its structure was assigned on the basis of the molecular ion at *m/e* 320 in the mass spectrum, with peaks corresponding to loss of CO and CHO, the strong ir band 1665 cm^{-1}, and the ^{1}Hmr spectrum in which two non-equivalent methylene protons can be seen as doublets, J = 14 Hz at δ 4.96 and 4.38. Consideration of the geometry of **15***b* clearly indicates that the two hydrogens at C-14 should be different, H_{endo} being in the shielding

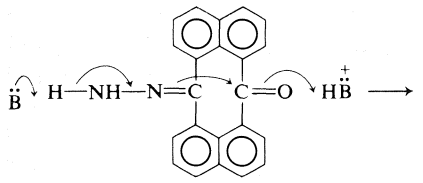


15*b*

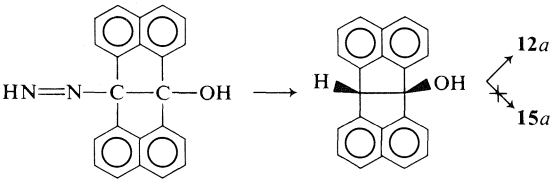
cone (24) of the C-7 carbonyl group. These results are in excellent agreement with the spectra obtained for the known (25*a*) 6-methyl derivative of **15***a* and are consistent with the spectra obtained for the corresponding thiocin derivative (C=O replaced by S=O) reported by Johnson and Vegh (25*b*) and the 7,12-dihydropleidenes (25*c*) where similar geometries exist. Extending the initial heating period of **13***b* with hydrazine increased the yield of **12***b* to 27%, when only little ketone **15***b* was detected. Finally, reaction of the bisbridged-diketone **13***c* gave no purple products, even after long reflux times, the only product isolated being the yellow bisbridged-monoketone **15***c*, mp 284–287°C (dec.) in 29% yield. The structure was again assigned on the basis of the molecular ion at *m/e* 346 in the mass spectrum, with peaks corresponding to loss of CO and CHO, the strong ir band at 1660 cm^{-1} (C=O), and the ^{1}Hmr spectrum which showed the 14-protons as an AB double doublet at δ 4.85 and 4.35, with H_{endo} being shielded.

These results are interesting in view of Agosta's (15) mechanism for the transformation of **13***a* into **12***a* in which he proposes the monohydrazone **16***a* to be an intermediate, which undergoes transannular attack on the carbonyl group to give **17***a* which after loss of N_2 gives alcohol **18***a* (isolable) and hence the alkene **12***a*. He could not (and neither could we) isolate any unbridged-monoketone **15***a*. Addition of the extra *peri*-bridges must, as we suggest, widen the distance across the bridge, making the transannular attack more difficult for **16***b*, consistent with the longer reflux time necessary for the reaction. In the case of **16***c*, transannular reaction seems not to occur at all. There could, however, be a more interesting alternative explanation: alcohol **18** could be regarded as the 'homoenol' of ketone **15**, and as

[5]Only spectral information relative to the structure will be given here. More detailed comparisons between series will be made in the sections to follow. Unless otherwise stated all new compounds gave satisfactory analyses (see Experimental), and correct molecular ions in their mass spectra.

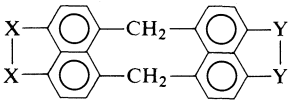


16*a*



17*a* 18

such could ketonize to **15** breaking the transannular bond, thus relieving strain rather than dehydrating to alkene **12**. In the *c* series the strain should be greatest and hence we are more likely to observe ketone **15***c* as the product rather than alkene **12***c*; the intermediate monobridged *b* series giving both **15***b* and **12***b*. Though we could not isolate any alcohol **18***b* or **18***c* to support this argument (Agosta did isolate **18***a* and showed it gave **12***a* under the reaction conditions and not **15***a*), it does not prevent this mechanism from being the operative one. We were unable to conclusively isolate any fully reduced products *i.e.* **19***b* or *c*, which might be expected to form by further reaction of the monohydrazone **16***b*,*c* to bishydrazones and hence on to product **19**. We could in fact see a short lived



19

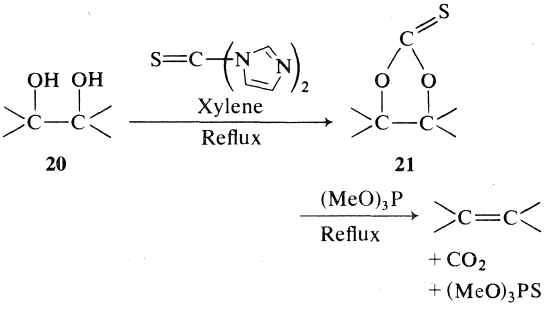
product in the ^{1}Hmr spectrum of the crude reaction mixture leading to **15***c*, which showed AB doublets at δ 5.87 and 4.12 (J = 15 Hz) as well as the aromatic and *peri*-bridged protons. Unfortunately we could not isolate this product after chromatography. The ^{1}Hmr spectrum is consistent with the structure of **19***c* and agrees very well with that reported (25*a*) for the 6-methyl derivative of **19***a*.

Preparation of the Alkenes Through Halide and Other Intermediates

With the failure of the Wolff–Kishner conditions to yield bisbridged-alkene **12***c*, we decided that a more likely route would probably stem directly from the diols **11** themselves, since the **6***b*–**12***b* bridge is already in place, and hence a part of the strain present in **12** is already overcome. A likely approach seemed conversion of diols **11** into dihalides and subsequent dehalogenation to alkenes **12**. In fact Kuhn and Winterstein (26) had introduced P_2I_4 as a reagent to effect this very transformation in one step in 1928. Indeed for unbridged and monobridged-diols **11***a*,*b* the reaction succeeded and gave the previously obtained alkenes **12***a*,*b* in yields that ranged from 16–96% for no apparent reason. An average yield over ten experiments was *ca.* 50%. Consistently, however, we could not generate any bisbridged-alkene **12***c*.

Surprisingly, neither thionyl chloride nor anhydrous HCl in chloroform gave isolable dichloride from **11***a*,*b* and no alkene **12***a*,*b* could be detected when the product was treated with NaI in acetone (27, 28), a procedure that was successful for the preparation of 1,2-diphenylacenaphthylene from 1,2-diphenylacenaphthene-1,2-diol (28). Similarly, no dihalide was obtained when **11***a* was treated with dimethylsulphide and *N*-chlorosuccinimide (Corey *et al.* (29)) or triphenylphosphine dibromide in dimethylformamide (Wiley *et al.* (30)) or phosphorous tribromide. Further, the products of these reactions did not give alkene **12***a* on treatment with Cr(II) (31). It appears that neither an S_N2 displacement in which attack from the back would have to be between the V of the aromatic rings, nor an S_N1 process, which by consideration of molecular models indicates that the monocation derived from **11***a* is more strained than **11***a* itself, are favoured.

Application of Corey's (32) thionocarbonate procedure (in which a *cis*-1,2-diol **20** is refluxed in xylene with *N*,*N*′-thiocarbonyldiimidazole to yield the cyclic thionocarbonate **21** and then subsequently refluxed with trimethylphosphite to yield the alkene), on the three *cis*-diols **11***a*,*b*,*c*



20 21

successfully gave the three alkenes **12***a,b,c* in yields from 12–20%. We found that use of the more reactive (33) tris(diethylamino)phosphine in place of trimethyl phosphite in the second step increased the yields of **12** to about 30% for each alkene. We did not find prior isolation of the *N,N'*-thiocarbonyldiimidazole **22** very easy nor necessary, since the compound seems to decompose even on standing in the freezer. However, we confirmed Pullukat and Urry's report (34) that it is easier to isolate **22** from the reaction of trimethylsilylimidazole and thiophosgene than from imidazole and thiophosgene itself (35).

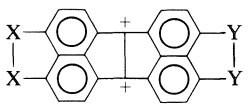
In our procedure we prepared **22** *in situ* from imidazole and thiophosgene and used it in xylene without prior isolation with diols **11** with no decrease in yield. Alternative methods of decomposing the intermediate thionocarbonates (21) have been described more recently, however, we found that use of iron pentacarbonyl in place of phosphine as described by Daub *et al.* (36) gave reduced yield of alkenes **12** (12–20%) whereas use of isopropyl iodide – zinc as described by Vedejs and Wu (37) gave no alkenes.

The structure of the now obtained bisbridged-alkene **12***c*, obtained as purple crystals, mp > 350°C, followed from its ^{1}Hmr spectrum which showed an aromatic AB quartet at δ 8.00 and 7.45 with the methylene protons at δ 3.52, the mass spectrum with parent molecular ion at *m/e* 328 as base peak, and the uv spectrum very similar to that of alkenes **12***a,b*.

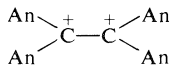
Attempted use of the low valent titanium species described by McMurrey and Fleming (38) to reduce ketones and *vic*-diols to alkenes gave 15% yield of the monobridged-alkane **14***b*, identical to that obtained on hydrogenating alkene **12***b*. However, we were later (39) to learn that this reagent has proved highly variable depending on the bottle of $TiCl_3$ used, and a better reagent, probably Ti(0) from the action of potassium on $TiCl_3$ gives more reliable results. We also tried a number of other methods of converting 1,2-diols into olefins (40) but in our hands these were not successful.

Reaction of Diols 11 with Anhydrous Hydrogen Fluoride: Simplest Preparation of Alkenes 12

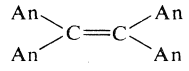
Le singer (9) reported that diol **11***a* gave a 29% yield of alkene **12***a* on treatment with liquid hydrogen fluoride in a copper vessel at 0°C for 45 min followed by ice water quench. We have found that this yield can be increased to 68% by allowing the diol **11***a* to stand in liquid hydrogen fluoride in a polyethylene flask overnight such that all of the HF has evaporated before water is added. A dark precipitate is obtained which slowly dissolves in CH_2Cl_2–aq-Na_2CO_3 solution on shaking to give a deep red organic layer containing the alkene **12**. Very few (41) reactions have been described in which a 1,2-diol is converted to an alkene under such conditions, more commonly halide intermediates (see above) are utilized, and it is thus interesting to speculate on the nature of the intermediate. One possibility is a dication **23**. It has been



23



24



25

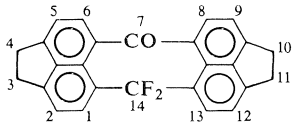
An = *p*-MeO—C_6H_5—

claimed (42) that dication **24** forms alkene **25** under similar conditions, though we have not yet been able to repeat this to our satisfaction (43).[6] Forsyth and Olah (44) have shown that aromatic dications can readily form in strongly acidic media, and in the case of **23** such a dication could be planar and hence stabilized. In a future paper we hope to describe the generation of the dications of **12** (*i.e.* **23**) as well as the radical cations and anions to compare with this reaction intermediate in the hope that we can elucidate the mechanism of thi s reaction.

Also obtained from the reaction of bisbridged-diol **11***c* with liquid HF as described above was 2% of a yellow compound mp > 350°C, which showed a molecular ion in its mass spectrum at *m/e* 382 with peaks corresponding to loss of H, O, F, and CO from M^+. Its uv spectrum was very similar to the bisbridged-monoketone **15***c*, and together with the presence of a strong carbonyl absorption at 1680 cm^{-1} in its ir spectrum led us to assign the structure of the difluoro ketone **26***c* to this compound. This was supported by its ^{1}Hmr spectrum in which the lowfield absorption at δ 7.83 corresponds to H-1 and 13 with coupling to the *ortho* H-2 (7.5 Hz) as well as the F-14 (1.5 Hz), a doublet at δ 7.64 corre-

[6]Manuscript in preparation.

sponds to H-6 and 8, deshielded by the adjacent carbonyl and coupled to the *ortho* H-5 or -9 (7.2 Hz), coincidental doublets at δ 7.27 (J = 7–7.5 Hz) corresponding to H-2, 5, 9, and 12, and



26*c*

a singlet at δ 3.30 for H-3, 4, 10, 12. The main difference between the ir spectra of **15***c* and **26***c* is a strong band at 1043 cm^{-1}; this is consistent with a C—F stretch (45).

'Magic-acid', FSO_3H, gave only a 15% yield of **12***a* from **11***a*.

Hydrogenation of the Alkenes ***12***

Hydrogenation in benzene using PtO_2 (not pre-reduced) was most convenient and essentially gave quantitative reduction in less than 2 h. The three alkenes **14** were readily identified by the appearance of the 6b,12b-methine protons close to δ 6 in their ^{1}Hmr spectra, and the correct molecular ions in their mass spectra. They gave similar uv spectra, and that of **14***a* agreed with that reported (15).

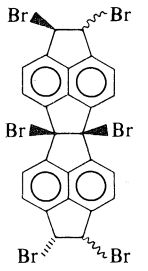
Attempted Dehydrogenation of Bisbridged-alkene ***6*** *(****12****c) to Pyrace[1,2-a]pyracylene(****8****)*

Harvey and Cho (46) have shown that a variety of dihydroaromatic compounds (*e.g.*, acenaphthene, 9,10-dihydrophenanthrene, 4,5,-9,10-tetrahydropyrene) readily form dianions in the presence of alkyllithium–TMEDA complex, and that on addition of oxidant (*e.g.*, Cu(II)), the corresponding aromatic compounds (*i.e.* acenaphthylene, phenanthrene, and pyrene, respectively) are formed in good yields. Trost *et al.* (47) have also shown that with *n*-butyllithium (with or without TMEDA) 1,2-dihydropyracylene **2** forms pyracylene dianion (green in solution) which on protonation reforms **2**. However, the report does not indicate whether **3** could be obtained by addition of oxidant to the green solution of $\mathbf{3}^{2-}$.

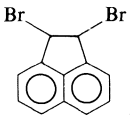
In the event, when we added *n*-BuLi/TMEDA to a cyclohexane solution of **6** a deep blue colour formed immediately and this, after standing at room temperature for *ca.* 12 h or after reflux for 1 h, turned deep red in colour. Quenching experiments with water did not return any of **6**; mainly a tar was formed. On such addition of Cu(II) the colour turns dark green and subsequently black. After protonation yellowish-red products which rapidly tarred were obtained, none of which could be identified.

Trost *et al.* (8) were able to convert pyracene **1** into pyracylene **3** by a bromination–debromination sequence.

Reaction of bisbridged-alkene **6** with **5** mol equiv. of bromine in CCl_4 under irradiation with a tungsten lamp gave a yellow solid which in its ^{1}Hmr spectrum showed an AB double doublet at δ 7.88 and 7.57 (8H, J = 7 Hz, aromatic protons) and two singlets at δ 5.85 and 5.81 (~2H each, -CHBr) which is consistent with the structure of the hexabromide **27** as a *cis/trans* mixture. For comparison, the methine protons of 1,2-dibromoacenaphthene **28** occur at δ 5.98. However, we were not able to



27



28

obtain a satisfactory mass spectrum for **27**. Reaction of **27** with NaI and $Na_2S_2O_3$ in acetone as described by Trost (8) or in DMF or by the use of Zn dust or Cr(II) in DMF has not yet yielded product that can be assigned structure **8**. However, we intend to pursue our efforts to obtain this compound, as well as **7** from **5**, which were likewise unsuccessful.

II. Discussion of Spectra in Terms of Strain

Unfortunately X-ray crystallographic structures of 1,2-dihydropyracylene **2** and unbridged-alkene **4** have not yet been reported, and further acenaphthylene forms a disordered crystal (48), so calculations of the strain energy of **4**–**6** would at best be guesses. Indeed even with such data they are hazardous, for example using the X-ray crystal data (49) for acenaphthene and Dauben's potential function mentioned earlier we calculate the strain energy of acenaphthene to be about 15 kcal/mol, whereas heat of formation measurements (50) suggest that it is in the order of 9 kcal/mol. However, such calculations rely on the accuracy of the X-ray data and that for acenaphthene has

TABLE 2. *p*-Band shifts in the uv spectra

changed markedly over the years (49). Using the data for 1,8-dimethylnaphthalene (Table 1) which were obtained in 1973, much better agreement between calculated (6 kcal/mol) and actual (7 kcal/mol (50)) strain energy is obtained. Since the X-ray structure of pyracene was performed back in 1960, the calculated strain energy may also be over-estimated as in the case for acenaphthene. However, there can be no doubt that addition of the second *peri*-bridge to acenaphthene substantially increases the strain energy, and hence can be expected to do the same for compound **4**.

The remainder of this paper will be spent discussing the changes in properties that occur on *peri*-bridging **4** and assessing any likelihood that they are related to strain.

Ultraviolet and Visible Spectra

It has been well documented (51) that introduction of a methyl group into an alternate hydrocarbon results in a bathochromic shift of the *para*-band[7] (52) in the ultraviolet spectrum, and this can be quite well accounted for theoretically (53). In a non-alternate hydrocarbon, however, the shift can be either bathochromic or hypsochromic depending on the position of substitution (54). If introduction of the substituent strains the molecule, further complications arise; both hypsochromic (55) and bathochromic (53) shifts have been observed and either a loss (56) or gain (57) in fine structure can occur. The latter are more clearly defined than the former. When substituents are present which prevent the molecule from becoming planar, *i.e.* reduce the π-orbital overlap, a loss of fine structure is usually observed together with a bathochromic shift *e.g.*, in certain methyl phenanthrenes, benzophenanthrenes, and chrysenes (53, 56) as well as in many of the cyclophanes (58).

However, when substituents are present such as methylene or dimethylene (ace) bridges which do not deform the molecule from planarity, but introduce strain, then usually an increase in fine structure results (57). Lewis and Calvin (59) explain this effect in terms of 'loose bolts', *i.e.* when a system has saturated substituents the dissipation of the energy of the electronically activated system is facilitated by the many possible vibrationally active states. Introduction of a strained bridge hinders this dissipation of energy resulting in the appearance of the fine structure, and usually a bathochromic shift somewhat greater than the effect of the corresponding dimethyl derivative (51).

For acenaphthene, addition of a second bridge to form pyracene causes a considerably smaller bathochromic shift (*ca.* 700 cm^{-1}) (see Table 2) in the *p*-band than the *ca.* 1800 cm^{-1} shift of adding the first bridge to naphthalene, whereas addition of two and then a further two methyl groups to naphthalene gives nearly equal shifts of *ca.* 1300 cm^{-1} each; the total shift for two ace-bridges or 4-methyl groups being about the same. It would be interesting to know whether this is caused by the change in bond angles of the naphthalene ring or whether it is due to the relative abilities of the methyl group and the

[7]Clar's (52) *p*-bands are the intense (log ε 3–4) long wavelength bands associated with the HOMO–LUMO transition.

ace-bridge to hyperconjugate with the ring. The behaviour of the three alkenes, **12**, is quite different, producing nearly equal shifts for each bridge addition; the shifts comparing quite well with those for ace-bridging acenaphthylene to give 1,2-dihydropyracylene. This may be a result of the lower flexibility of the alkene bridge present in these systems, indicating an increase in strain.

The spectra (see Fig. 1) also reveal a considerable increase in fine structure on adding ace-bridges to **12***a* consistent with the molecule remaining nearly planar but being held more rigidly as discussed above. Although calculations (60, 62) have been carried out on **12***a*, the 'purple band' (probably a combination difference band (61) and not the HOMO–LUMO transition as suggested (60)) is not well accounted for and no attention has been paid to the actual geometry of the system. Since there now exist a number of papers (63) which can compute the best geometries with minimum strain, it would be interesting to recalculate the spectra using such data, though at present this is beyond our capabilities here.

All of the other compounds to be discussed are bent and belong to the two classes of compounds of type A and B. The diols **11** (X = OH) and alkanes **14** (X = H) are of type A. Agosta (15) has reproduced the spectra of both **11***a* and **14***a* and compared them to acenaphthene. In fact the spectra are quite different from the latter, the position of the main maxima being both bathochromically shifted some 15–30 nm and

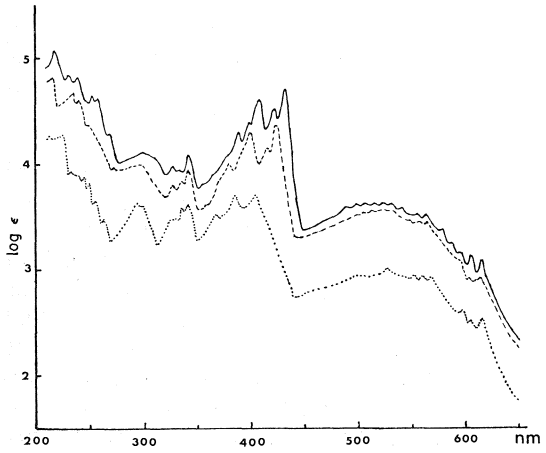

FIG. 1. Ultraviolet absorption spectra in cyclohexane solution for **12***c*—(log ε displaced +0.5); **12***b* --- ; **12***a* · · · (log ε displaced −0.5).

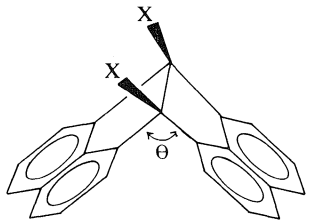
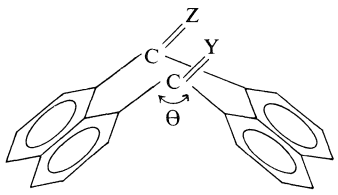
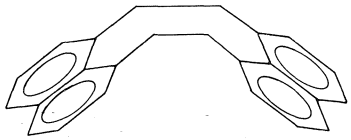


A



B

twice as intense. This is consistent with extensive interactions between the π systems of the two naphthalene rings as is seen in the naphthalene derivative **29** (64) and resembles that seen in the cyclophanes (58, 65) except that since the aromatic rings are not expected to be bent in A no loss of intensity is seen.



29

For both the diol **11***a* and alkane **14***a* addition of the first acebridge to give **11***b* and **14***b*, respectively, produces only a small 4–7 nm (535–780 cm^{-1}) bathochromic shift in each *p*-band absorption, similar to that discussed above for pyracene. Addition of the second ace-bridge to give **11***c* and **14***c* respectively produces an even smaller shift of 1–5 nm (108–601 cm^{-1}), in contrast to the case for the alkenes. This would appear to suggest that the saturated central bridge does accommodate the strain better than an unsaturated bridge, especially in light of the fact that the overall shape (*i.e.* number of maxima and relative intensities) of the spectra of **11** and **14** hardly change on bridging. This would seem to indicate that both the interactions between the rings are not affected, *i.e.* presumably the inter-ring angle θ does not change by much, and the molecule is not 'tightened up' much. This is interesting considering the bond angle changes that have to occur in the naphthalene nucleus.

TABLE 3. Selected infrared bands

Compound	C=C band (cm^{-1})	Compound	C=O band (cm^{-1})	Ref.
Tetraphenylethylene	1600	**13***a*	1689	
1,2-Diphenylacenaphthylene	1602	**13***b*	1688	
12*a*	1604	**13***c*	1690	
12*b*	1610	6-Me-**15***a*	1655	25*b*
12*c*	1615	**15***b*	1660	
		15*c*	1660	
		26*c*	1675	
		1,8-Dibenzoylnaphthalene	1664	9
		Di-1-naphthylketone	1653	66
		Benzophenone	1645	66

The diketones (B, Y=Z=O) also show this same effect where in the absence of a central bridge, the molecule should be able to twist. This twisting seems more severe in the monoketones **15***b,c* in which H_{endo} projects towards the carbonyl group, when an additional intense ($\varepsilon \sim 10^4$) maximum at *ca.* 360 nm appears (also in difluoroketone **26***c*) (probably an electron transfer band). This twisting is further supported by the ir data.

Infrared Spectra

For the planar alkenes **12** the 1600 cm^{-1} 'aromatic' (ref. 45, p. 69) band is intense and well defined. Qualitatively, all other things being equal, one would expect this to move to higher frequency as the stiffness in each C=C bond increased. Indeed for the alkenes **12** this is exactly what happens (Table 3). Addition of each bridge to **12***a* produces a small (5–6 cm^{-1}) shift to higher frequency, consistent with the idea that each bond tightens up to absorb the strain on introducing the bridge indicated in the uv spectra above. Whilst in general the 1600 cm^{-1} band can appear between 1625–1575 cm^{-1} for most aromatics (ref. 45, p. 71), it would seem that on comparison to the two model compounds tetraphenylethylene and 1,2-diphenylacenaphthylene there is a definite shift. Whilst it is doubtful that much can be drawn from the ir spectra of the bent alkanes **14***a,b,c*, it is interesting that they show bands at 1596, 1584, and 1585 cm^{-1}, respectively, consistent with Cram's idea (66) that an out of plane distortion of the aromatic ring as in [2.2]paracyclophane, shifts the band to lower frequencies.

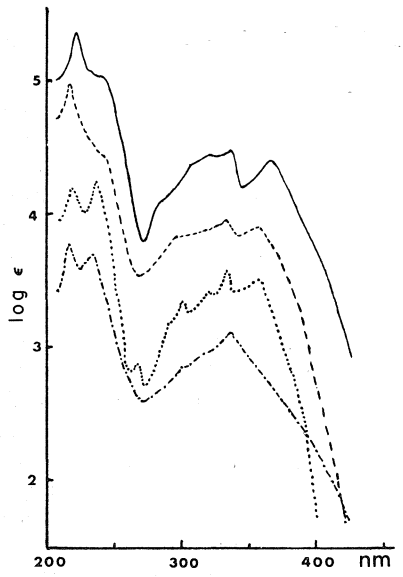


FIG. 2. Ultraviolet absorption spectra in cyclohexane solution for **15***c* — (log ε displaced +1); **15***b* --- (log ε displaced +0.5); **26***c* ··· ; **13***c* ·-·-·- (log ε displaced −0.5).

The absorptions due to the carbonyl bands in compounds **13**, **15**, and **26***c* are interesting (Table 3). Aryl conjugation to the carbonyl group reduces the frequency provided the groups can become co-planar (ref. 45, p. 137). Letsinger (9) pointed out that diketone **13***a* absorbed at 25 cm^{-1} higher than in 1,8-dibenzoylnaphthalene, which in fact itself absorbs considerably higher than benzophenone (67). Addition of the bridges to **13***a* to give **13***b,c* does not affect the carbonyl absorption, supporting the uv data that θ of B does not change very much. Of considerable significance, however, is the fact that the $\diagdown$C=O$\diagup$ band for the monoketones **15** is close to 1660 cm^{-1}, comparable to that in 1,8-dibenzoylnaphthalene. This supports the uv data and clearly indicates that the carbonyl

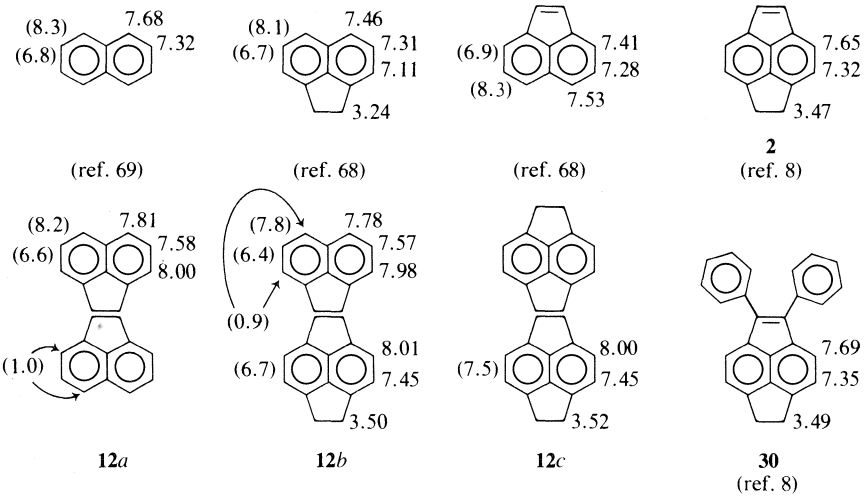

CHART 1. Proton chemical shifts, δ, and coupling constants (Hz).

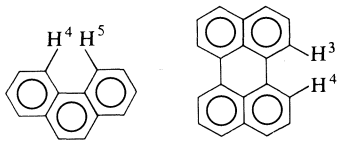
group is conjugating with the ring. The change of one carbonyl group of **13** to the methylene group of **15** must twist the rings more than simple (Dreiding) molecular models would suggest. The higher frequency $\rangle C{=}O$ of **26***c* (1675 cm^{-1}) is consistent with the shorter wavelength λ_{max} in the uv spectrum, indicating a partial twist in this compound.

Nuclear Magnetic Resonance Spectra

The assignment of ^{1}Hmr spectra was made on the basis of known coupling constants and chemical shifts for the parent systems and for compound **2** and are shown in Chart 1.

Whilst evidence has been found (69, 70) for a steric effect on proton ^3J coupling constants, the values obtained in the series studied do not seem to be exceptional, however, some of the observed chemical shifts are of note. In 1,2-dihydropyracylene **2** and 5,6-dihydro-1,2-diphenylpyracylene **30** the chemical shifts of the naphthalene protons correspond within *ca.* 0.04 ppm, and are deshielded somewhat from those of acenaphthylene. The protons of **12**, however, are all considerably deshielded beyond those of **30**. In particular the protons next to the pentalene rings (H-1, 6, 7, 12) appear at δ 8.02–7.98, deshielded by 0.6–0.8 ppm from typical β-naphthene protons. Whilst the other ring protons are also deshielded, the effect is not so marked. Such large deshielding effects are most commonly seen (71) where protons suffer steric compression as in the 4,5-protons of phenanthrene **31**, δ 8.42, (69) and the 3,4-protons of perylene **32**, δ 8.03, (69). An alternative explanation is of course that the deshielding observed is due to the



31 **32**

sum of all the ring currents involved and is larger for **12** than **2** because of the increase in rings. Some comment is then required for **30**: if steric effects prevent coplanarity of the benzene rings with the acenaphthylene system then clearly the protons would not feel the deshielding effects of the substituent rings, whereas in compounds **12** they are planar and thus the full effect could be felt. Whilst calculations to substantiate this idea are well advanced for benzenoid systems (see, for example, ref. 72) application to other systems is more recent and not easy (see, for example, ref. 73). Analyses of the ^{13}Cmr spectra of aromatic compounds have appeared (74) and both chemical shifts and coupling constants appear useful in elucidating steric effects. The ^{13}Cmr spectra for the alkenes **12** are shown in Chart 2 together with the calculated spectra (in parentheses) using Trost and Herdle's (75) additivity relationships. Clearly, excellent agreement is obtained. The values for the quaternary carbon atoms which might be expected to show the greatest strain effect have not yet been determined because of low solubility and long relaxation times,

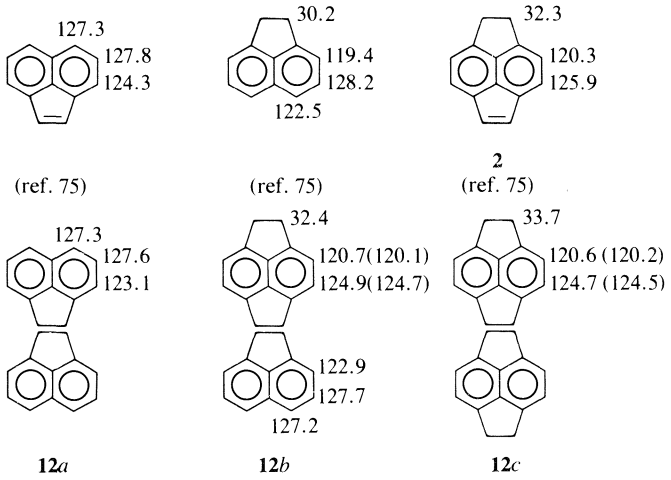


CHART 2. ^{13}C chemical shifts of proton decoupled spectra. All chemical shifts are given in ppm downfield from TMS, recorded in $CDCl_3$ on a Nicolet TT-14 60 MHz ft-spectrometer. Values in parentheses are calculated using additivity relationships (75).

although we have not given up hope of obtaining this data.

Apart from compounds **12**, the other fused naphthalenes are all bent as in structures A and B. A normal consequence of bringing aromatic rings face to face is to see a shielding of the aromatic protons (58, 64, 76, 77). By contrast the chemical shifts of the aromatic protons of compounds **11**, **13**, **14**, and **15** seem unexceptional. It is possible that the deshielding observed in compounds **12** is present also in these compounds and counteracts the above shielding. An alternative is that overlap of benzenoid rings must be extensive before any effect is observed.

Electrode Reduction Potentials

The three alkenes **12***a*,*b*,*c* can be reduced at the dropping mercury electrode and give reproducible (± 0.003 V) half-wave potentials. Each alkene gives two reduction waves corresponding to addition of one and two electrons to the compound. The measurements were made in 100% dimethylformamide to overcome solubility problems, but Given (78) has shown that such values only differ by a few hundredths of a volt from other solvents such as aqueous dioxane. The results are shown in Table 4 and are consistent with values for related systems (ref. 61, p. 178).

Macoll (79) was one of the earliest to point out that polarographic half wave reduction potentials ($\varepsilon_{1/2}$) are linearly correlated with the HMO energy of the lowest unoccupied MO (LUMO). Arising from this, it has been shown (80; also ref. 61, p. 176) that for a large number of aromatic hydrocarbons, even including some nonalternate ones that the $\varepsilon_{1/2}$ values so obtained (in aqueous dioxane) are related to the energy of the LUMO, $\varepsilon_{m+1} = \alpha + m_{m+1}\beta$, by the equation

$$[1] \qquad \varepsilon_{1/2} = 2.368 m_{m+1} - 0.924$$

where the effective value of β is about -55 kcal/mol. Since Watson and Matsen (81) have also shown that there is an excellent linear correlation between the frequency of the *p*-band in the uv spectrum and the $\varepsilon_{1/2}$ values for aromatic hydrocarbons, and that a plot of the frequency of the *p*-band against the HMO energy difference between the highest occupied orbital (HOMO) and the LUMO shows an excellent linear correlation given by equation 2 (ref. 61, p. 217)

$$[2] \quad \nu(p\text{-band, cm}^{-1}) = 19020\Delta m + 10520$$

where

$$\varepsilon_m = \alpha + m_m\beta$$

and

$$[3] \qquad \Delta m = m_m - m_{m+1}$$

(again β has value *ca.* -55 kcal/mol), we can use a combination of these equations to determine experimentally the energy of the HOMO, $\varepsilon_m = \alpha + m_m\beta$.

It can be seen from Table 4 that the results give

TABLE 4. Half-wave electrode reduction potentials and molecular orbital energies

Compound	$-\varepsilon_{1/2}$ *vs.* SCE (V)	$-m_{m+1}$*	ν *p*-band (cm^{-1})	Δm*	m_m*

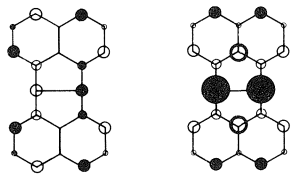
†Second wave.

for **12***a* a value of $m_m = 0.58$ which compares reasonably well with the calculated value (60) of 0.50 when the approximations involved[8] are considered.

It can be seen that the values obtained for m_m and m_{m+1} are not just opposite in sign but of greatly different magnitude. This is correct for non-alternate hydrocarbons (ref. 61, p. 46).

We can see from Table 4 that addition of the ace-bridges makes reduction more difficult. This is consistent with previous data (ref. 61, p. 178) where the difference between naphthalene and acenaphthene, $-\Delta\varepsilon_{1/2} = 0.17$ V. Addition of a methyl group to acenaphthene gives $-\Delta\varepsilon_{1/2} = 0.11$ V. The $-\Delta\varepsilon_{1/2}$ values for ace-bridging **12***a* are 0.05 to 0.07 V, somewhat smaller than expected from above. This might be indicative of strain in the system changing the σ-bonding which in turn will affect the π-bonding and hence the orbital energies or alternatively it suggests that the incoming electron goes into an orbital in this system in which the coefficients of the atoms to which the bridges are attached are small.

That however is not consistent with the published (82) LUMO and HOMO shown schematically. Consider the lowest antibonding orbital (ψ_a). Electron density in the radical anion of **12***a* will be high at the *peri*-positions despite the destabilizing effects of the alkyl groups. The small increase in $\varepsilon_{1/2}$ values observed relative to other systems may be because there is a node between the 6b–12b carbons. Bridging the *peri*-positions tends to stretch the 6b–12b bond and thus perhaps lowers the energy of ψ_a relative to ψ_b where it is strongly bonded. This effect may counteract the normal destabilizing effect of the alkyl groups on ψ_a relative to ψ_b and hence reduce $\varepsilon_{1/2}$. The proposed 'strain effect' of the ace-bridges is thus opposite in effect to the more normally observed 'inductive/hyperconjugative effect' of alkyl groups, and thus may support the unusual uv data in which addition of bridges to alkenes **12** produces approximately equal bathochromic shifts, whereas in all the other systems discussed which have no central π-bridge, the bathochromic shift for the second bridge is much smaller than that for the first.



LUMO ψ_a HOMO ψ_b

[8]The equations 1 and 2 apply strictly to alternate hydrocarbons, though they work well for some non-alternates such as fluoranthenes (ref. 61, pp. 181, 217). Comparison of orbital energies when in one case an electron is promoted from a lower to a higher orbital and in a second an extra electron is added is perhaps dangerous, anyway.

Conclusions

We have prepared four series of strained compounds in which the differences amount to adding first one and then a second ace-bridge in the *peri*-positions such that further increments of strain are added and have documented changes in uv, ir, and ^{1}Hmr spectra and $\varepsilon_{1/2}$ values that we observe. We have then attempted to explain these changes in properties by relation to structurally similar molecules and hence suggest effects which might be strain related. The results so obtained have pointed out several areas in which good calculations are lacking and should receive attention by competent theoreticians.

Experimental

All melting points were determined on a Kofler hot stage and are uncorrected. The ^{1}Hmr spectra were determined in $CDCl_3$ (unless otherwise stated) on a Perkin-Elmer R12A (60 MHz) or R32 (90 MHz) spectrometer

and reported in ppm downfield from tetramethylsilane as internal standard. Mass spectra[9] were determined on a Hitachi–Perkin-Elmer RMU-7 or Finnigan 3300 mass spectrometer at 70 eV. The ir[9] spectra were recorded on a Pye-Unicam SP1000 spectrophotometer and the uv spectra on a Cary 17 spectrophotometer. The ir bands quoted in Table 2 were measured on a Beckman IR-4 as an average of ten values calibrated with polystyrene. Microanalyses were performed by this department. All evaporations were carried out under reduced pressure on a rotary evaporator at *ca.* 40°C. Extracts were dried with anhydrous sodium sulfate.

5-Bromoacenaphthene

This was prepared in 84% yield by the method of Ross *et al.* (21) from acenaphthene and *N*-bromosuccinimide in dimethylformamide, as white crystals from ethanol, mp 53.5–55°C (lit. (21) mp 51–52°C); ^{1}Hmr δ (60 MHz), 7.8–6.9 (5H, m, Ar*H*), and 3.25 (4H, s, -CH_2-).

5,6-Dibromoacenaphthene

This was obtained in 30–60% crude yield by the method of Constantine *et al.* (20) using 5-bromoacenaphthene, bromine, and Ag_2SO_4 in dioxane – perchloric acid solvent. Extensive chromatography on silica gel was required to remove all traces of the major impurity, orange acenaphthylenes. The pure product so obtained (25–40% yield) as very pale yellow crystals from benzene had mp 173–175°C (lit. (20) mp 165–168°C; (19) mp 173–174°C); ^{1}Hmr δ (60 MHz) 7.78 (2H, d, J = 8 Hz, *o*-Br-Ar*H*), 7.04 (2H, d, J = 8Hz, *o*-CH_2-Ar*H*), and 3.24 (4H, s, -CH_2-).

Unbridged-diol ***11a****, cis-6b,12b-Dihydroxy-6b,12b-dihydroacenaphth[1,2-a]acenaphthylene*

This was prepared essentially by the method of Letsinger and Gilpin (9) with modifications to make it more convenient. *n*-BuLi (46 mmol in 25 ml hexane) was injected into a solution of 1,8-diiodonaphthalene (17) (8.62 g, 22.7 mmol) in anhydrous ether (400 ml) and stirred under N_2 for 15–30 min to generate 1,8-dilithionaphthalene **9***a*. Acenaphthenequinone **10***a* (Aldrich, 4.14 g, 22.7 mmol) was then added and the reaction mixture stirred at room temperature for 14 h and/or refluxed for 6 h. After addition of saturated NH_4Cl solution the organic layer was separated, dried and evaporated. Any residue remaining in the aqueous layer was extracted with CH_2Cl_2. The combined residues from the organic layers were extracted with hot $CHCl_3$ and cooled, when nearly colourless product deposited in 12–14% yield, mp 300–305°C, almost free of carbonyl absorption in its ir spectrum. A further recrystallization from $CHCl_3$ gave pure product, mp > 310°C (lit. (9) mp 319–321°C); ^{1}Hmr δ (90 MHz) 8.0–7.5 (aromatic protons; -OH protons could not be clearly seen, sample only slightly soluble); uv (cyclohexane) λ_{max} (log ε_{max}) 323 nm (4.10), 320 sh (4.08), 308 (4.09), 281 (3.87), 270 (3.76), 260 (3.52), 250 sh (3.39), and 226 sh (4.67).

[9]Infrared bands and mass spectral data are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

Monobridged-diol ***11b****, cis-6b,12b-Dihydroxy-3,4,6b,12b-tetrahydrocyclopent[f,g]acenaphth[1,2-a]acenaphthylene*

From *n*-BuLi (65 mmol in 35 ml hexane), 5,6-dibromoacenaphthene (10.0 g, 32.1 mmol), anhydrous ether (900 ml) and acenaphthenequinone (Aldrich, 5.85 g, 32.1 mmol) product **11***b* could be isolated in 10–20% yield as described above for **11***a*, as off-white crystals mp 290–295°C. Recrystallization from acetone or chloroform gave **11***b* as a white powder mp 304–308°C (dec.); ^{1}Hmr δ (60 MHz) 7.9–7.2(m, aromatic protons) and 3.38 (s, -CH_2-) the -OH protons could not be clearly discerned, the sample being only slightly soluble; uv (cyclohexane) λ_{max} (log ε_{max}) 329 nm (4.12), 315 (4.08), 286 (3.84), 274 (3.72), 264 (3.51), 254 sh (3.32), and 227 sh (4.19); *Anal.* calcd. for $C_{24}H_{16}O_2$: C 85.69, H 4.79; found: C 85.46, H 5.01.

Bisbridged-diol ***11c****, cis-6b,12b-Dihydroxy-3,4,6b,9,10,12b-hexahydrodicyclopent[f,g:f′,g′]acenaphth[1,2-a]-acenaphthylene*

This was carried out exactly as described above for **11***b* except that pyracenequinone **10***c* (22) (6.68 g, 32.1 mmol) replaced the acenaphthenequinone. The product **11***c* was obtained in 13–26% yield as a cream powder mp 295–305°C. Recrystallization from $CHCl_3$ gave white powdery crystals, mp 316–320°C (dec.); ^{1}Hmr δ (90 MHz, DMSO-d_6) 7.96 (4H, d, J = 7 Hz, 1-Ar*H*), 7.58 (4H, d, J = 7 Hz, 2-ArH), 6.34 (2H, s, -OH), and 3.60 (8H, s, -CH_2-); uv (cyclohexane) λ_{max} (log ε_{max}) 333 nm (3.83), 319 (3.78), 291 (3.55). 279 (3.36), 268 (3.10), 259 sh (2.86), and 228 (4.36). *Anal.* calcd. for $C_{26}H_{18}O_2$: C 86.17, H 5.01; found: C 85.98, C 4.97.

Unbridged-diketone ***13a****, 1,8-(1′,8′)-Naphthalylnaphthalene*

This was prepared essentially as described by Letsinger (9) except that the reaction was carried out at room temperature for 4 h. Crystallization of the product from benzene yielded 75% of **13***a*, mp 334–334.5°C (lit. (9) mp 333–334°C); ^{1}Hmr δ (90 MHz) 8.00–7.75 (4H, m, α-Ar-*H*) and 7.65–7.30 (8H, m, β-Ar*H*); uv (cyclohexane) λ_{max} (log ε_{max}) 318 nm sh (4.10), 311 (4.11), 282 sh (3.84), 268 sh (3.78) 224 (4.80), and 210 (4.98).

Monobridged-diketone ***13b****, 5,6-(1′,8′)-Naphthalylacenaphthene*

This could be prepared as described for **13***a* above in 30–60% yield. The following procedure was found to be more efficient. Lead tetraacetate (5 g, 11 mmol) was added to a stirred suspension of diol **11***b* (1.75 g, 5.22 mmol) and trichloracetic acid (20 mg) in dry (Na) benzene (250 ml) at room temperature. After 30 min CH_2Cl_2 and dilute HCl were added. The organic layer was washed (aqueous HCl, aqueous NaOH, H_2O), dried, and evaporated. The residue was recrystallized from benzene to yield 1.32 g (76%) of product **13***b* as pale yellow crystals, mp 330–334°C (dec.); ^{1}Hmr δ (60 MHz) 8.0–7.6 (2H, m, α-ArH), 7.6–7.2 (8H, m, β-ArH), and 3.39 (4H, s, -CH_2-); uv (cyclohexane) λ_{max} (log ε_{max}) 331 nm (4.07), 324 sh (4.05) 282 sh (3.81) 276 sh (3.72) 226 sh (4.66), and 213 (4.82); *Anal.* calcd. for $C_{24}H_{14}O_2$: C 86.21, H 4.22; found: C 85.88, H 4.27.

Bisbridged-diketone ***13c****, 5,6-(5′,6′)-Acenaphthalyl-acenaphthene*

This was carried out using CCl_3COOH as catalyst exactly as described above for **13***a*, and gave a 71% yield of product **13***c* as yellow crystals from benzene–chloroform, mp > 330°C (dec.); ^{1}Hmr δ (90 MHz, CD_2Cl_2) 7.45 (4H, d, J = 7 Hz, *o*-CO-Ar*H*), 7.30 (4H, d, J = 7 Hz, *o*-CH_2-Ar*H*), and 3.34 (8H, s, -CH_2-); uv (cyclohexane) λ_{max} (log ε_{max}) 336 nm (4.12), 301 sh (3.86), 232 (4.70), and 215 (4.78); *Anal.* calcd. for $C_{26}H_{26}O_2$: C 86.65, H 4.47; found: C 86.80, H 4.76.

Wolff–Kishner Reduction of ***13a****: Preparation of Unbridged-alkene* ***12a****, Acenaphth[1,2-a]acenaphthylene*

This was carried out essentially as described by Agosta (15). After chromatography on silica gel, recrystallization of the product from xylene yielded 83% of **13***a*, mp 287–288°C (lit. (15) mp 284–286°C; (9) mp 285–286.5°C); ^{1}Hmr (90 MHz, CD_2Cl_2), see Chart 1; uv (cyclohexane) λ_{max} (log ε_{max}) 616 nm (2.62), 605 (2.59), 597 (2.61), 568 (2.92), 560 (2.92), 551 (2.92), 528 (3.00), 500 sh (2.93), 404.5 (4.21), 384.5 (4.21), 367 (4.02), 342 (4.12), 336.5 (4.09), 330 (3.97), 325 sh (3.96), 322 sh (3.92), 300 sh (4.10), 294 (4.14), 263 (3.97), 255 (4.15), 250 (4.30), 245 (4.37), 240 sh (4.38), 232.5 (4.43), 225 (4.78), 220 sh (4.75), and 212.5 (4.76); *Anal.* calcd. for $C_{22}H_{12}$: C 95.62, H 4.38; found: C 95.75, H 4.28.

The mother liquors from the above recrystallization usually contained a little of the dihydrocompound **14***a* as noted by Agosta (15).

Wolff–Kishner Reduction of ***13b****: Preparation of Monobridged-alkene* ***12b****, Pyraceno[1,2-a]acenaphthylene, (3,4-Dihydrocyclopent[f,g]acenaphth[1,2-a]acenaphthylene) and Monobridged-monoketone* ***15b****, 3,4-Dihydrocyclopent[d,e]naphtho[2,3,4-i,j]naphtho[6,7,8-d′,e′]cyclooctan-7-one*

(a) Short Reflux: Less Alkene ***12b****, More Ketone* ***15b***

Monobridged-diketone **13***b* (109 mg, 0.33 mmol), KOH (0.25 g), 97% hydrazine hydrate (1 ml, 20 mmol), ethylene glycol (5 ml), and water (2.5 ml) were heated to *ca.* 110°C for 1 h under N_2. The water was then distilled out in a N_2 stream, the temperature rising to about 180°C when it was purple. After 2 h at 180°C, the reaction was cooled and diluted with water. The products were extracted into CH_2Cl_2 and the organic layer was washed, dried, and evaporated. The residue was chromatographed on silica gel using benzene as eluant.

Eluted first was the mono-bridged alkene **12***b*, which, after removal of solvent, yielded 22 mg (22%) of purple crystals. Recrystallization from xylene yielded 10 mg (10%) of dark purple crystals, mp 274–276°C; ^{1}Hmr (90 MHz, CD_2Cl_2), see Chart 1; uv (cyclohexane) λ_{max} (log ε_{max}) 615 nm (2.54), 605 (2.54), 595 (2.58), 566 (2.94), 558 (2.94), 550 (2.95), 540 sh (2.99), 533 sh (3.04), 526 (3.05), 520 sh (3.04), 512 (3.03), 505 (3.02), 499 sh (3.01), 425 (4.35), 416 (4.13), 401 (4.28), 393 sh (4.10), 380 (3.99), 380 (3.82), 373 sh (3.82), 361 sh (3.63), 343 (3.94), 336 (3.83), 327 (3.80), 320 sh (3.69), 297 (39.8), 271 (3.90), 250 sh (4.36), 246 (4.36), 236 (4.60), 229 (4.67), and 213 (4.82); *Anal.* calcd. for $C_{24}H_{14}$: C 95.33, H 4.67; found: C 95.21, H 4.41.

Eluted next was a yellow band which on concentration and crystallization from $CHCl_3$–acetone gave bright yellow crystals of monobridged-monoketone **15***b* (34 mg, 33%), mp 233–234°C; ^{1}Hmr δ (90 MHz) 7.8–7.1 (10H, m, Ar*H*), 4.96 (1H, d, J = 14 Hz, *exo*-14-H), 4.38 (1H, d, J = 14 Hz, *endo*-14-H), and 3.24 (4H, s, -CH_2-); uv (cyclohexane) λ_{max} (log ε_{max}) 356 nm (3.91), 332 (3.96), 325 sh (3.91), 317 sh (3.89), 295 (3.83), 241 sh (4.49), and 216 (4.97); *Anal.* calcd. for $C_{24}H_{16}O$: C 89.97, H 5.03; found: C 90.28, H 5.09.

(b) Long Reflux: More Alkene ***12b****, Less Ketone* ***15b***

Monobridged-diketone **13***b* (1.25 g, 3.74 mmol), KOH (18 g), 97% hydrazine hydrate (35 ml, 0.7 mol), ethylene glycol (190 ml), and water (45 ml) were heated at 110–120°C for 8 h under N_2. The reaction was continued as described in (*a*) above, heating at 180–210°C for 3 h. After work-up and chromatography the red band yielded on crystallization from benzene 325 mg (27%) of dark purple crystals of **12***b*. Rechromatography over silica gel of the mother liquors from this crystallization using pentane as eluant gave first a yellow band, which on crystallization yielded 47 mg (4%) of pale yellow needles, mp 223–226°C, found to be identical to the monobridged-alkane **14***b*, obtained by hydrogenation of **12***b* described below. Next, more (5–10%) of the purple alkene **12***b* was eluted.

Wolff–Kishner Reduction of ***13c****: Preparation of Bisbridged-monoketone* ***15c****, (3,4,10,11-Tetrahydrodicyclopent[d,e:d′,e′]dinaphthocyclooctan-7-one)*

Bisbridged-diketone **13***c* (250 mg, 0.69 mmol), KOH (8 g), 97% hydrazine hydrate (15 ml, 0.3 mol), ethylene glycol (50 ml), and water (20 ml) were heated at *ca.* 120°C for 6 h under N_2. The water was then distilled out in a N_2 stream, the temperature rising to 180°C over 90 min. The reaction was heated at *ca.* 180°C for 12 h, during which time a bright yellow precipitate formed but no purple colour. After cooling H_2O and CH_2Cl_2 were added. The organic layer was washed, dried, and evaporated. Crystallization of the yellow residue from acetone–tetrahydrofuran (1:3) gave product **15***c* as bright yellow crystals 70 mg (29%) mp 284–287°C (dec.); ^{1}Hmr δ (90 MHz) 7.6–7.1 (8H, m, ArH), 4.85 (1H, d, J = 14 Hz, *exo*-7-H), 4.35 (1H, d, J = 14 Hz, *endo*-7-H), and 3.27 (8H, s, -CH_2-); uv (cyclohexane) λ_{max} (log ε_{max}) 364 nm (3.92), 334 (3.98), 320 (3.95), 305 sh (3.87), 282 sh (3.61), 239 sh (4.54), 230 sh (4.63), and 219 (4.86); *Anal.* calcd. for $C_{26}H_{18}O$: C 90.14, H 5.24; found: C 90.28, H 5.08.

Reaction of Diols ***11a****,* ***11b****,* ***11c*** *with HF*
General Procedure

Liquid anhydrous H_2F_2 (Matheson, 50 ml) was added directly from a cylinder to the diol in a polyethylene flask under N_2 cooled to −70°C. The reaction mixture, which went dark instantly, was allowed to warm to room temperature overnight in a N_2 stream such that all the H_2F_2 evaporated. The dark residue was then taken up in CH_2Cl_2 and aqueous Na_2CO_3 solution added. The organic layer became redder over a period of hours (0.5–6 h), after which it was washed, dried, and evaporated. Each residue was treated as described below.

(a) Diol ***11a****: Preparation of Unbridged-alkene* ***12a***—From diol **11***a* (50 mg, 0.16 mmol) after filtration through a silica gel column in benzene there was obtained 31 mg (68%) of alkene **12***a*, identical to the sample previously obtained.

(b) Diol ***11b****: Preparation of Monobridged-alkene* ***12b***—From diol **11***b* (600 mg, 1.8 mmol) after chromatography

on silica gel using benzene as eluant there was obtained 228 mg (42%) of alkene **12***b*, identical to the sample previously obtained.

*(c) Diol **11**c: Preparation of Bisbridged-alkene **12**c, Pyraceno[1,2-a]-5,6-dihydropyracylene (3,4,9,10-Tetrahydrodicyclopent[f,g:f′,g′]acenaphth[1,2-a]acenaphthylene)*— From diol **11***c*, (1.4 g, 3.9 mmol) after chromatography on silica gel using CH_2Cl_2 as eluant the red band yielded 400 mg (32%) of alkene **12***c*, as dark purple crystals mp > 350°C from benzene (or xylene); ^{1}Hmr (90 MHz, CD_2Cl_2) see Chart 1; uv (cyclohexane) λ_{max} (log ε_{max}) 615 nm (2.56), 606 (2.62), 596 (2.65), 587 (2.74), 578 sh (2.86), 565 (3.00), 556 (3.01), 542 (3.07), 533 (3.11), 524 (3.12), 516 (3.12), 506 (3.12), 498 sh (3.11), 490 sh (3.09), 434 (4.20), 424 (4.01), 410 (4.10), 401 (3.88), 388 (3.79), 380 sh (3.56), 368 sh (3.39), 360 sh (3.20), 343 (3.59), 334 (3.44), 328 (3.47), 311 sh (3.55), 305 sh (3.55), 305 sh (3.59), 300 (3.60), 269 (3.79), 258.5 (4.12), 252 (4.14), 246 (4.10), 239 (4.32), 231 (4.34), and 217 (4.56); *Anal.* calcd. for $C_{26}H_{16}$: C 95.09, H 4.91; found: C 95.16, H 4.84.

Eluted next from the column was a yellow band which after concentration and crystallization from benzene and then chloroform yielded 28 mg (2%) of pale yellow crystals, mp > 350°C assigned the structure of the bisbridged-difluoro monoketone **26***c*, 3,4,10,11-tetrahydrodicyclopent[*d*,*e*:*d*′,*e*′]dinaphtho-14,14-difluorocyclooctan-7-one; ^{1}Hmr (90 MHz) see text; uv (cyclohexane) λ_{max} (log ε_{max}) 356 nm (4.02), 332 (4.08), 318 (3.93), 300 (3.85), 289 sh (3.74), 267 sh (3.37), 257 (3.39), 250 sh (3.94), 231 (4.75), and 217 (4.70); *Anal.* calcd. for $C_{26}H_{16}F_2O$: C 81.67, H 4.22; found: C 81.88, H 4.23.

*Reaction of Unbridged-diol **11**a with 'Magic Acid'*

The diol **11***a* (50 mg, 0.16 mmol) was added at 0°C under N_2 to FSO_3H (Magic acid, 5 ml). The reaction turned black at once, and was stirred at 0°C for 2 h before pouring onto ice. The products were extracted with CH_2Cl_2, washed, dried, and evaporated. A quantitative uv indicated 6.6 mg of product **12***a* was present, a yield of 15%.

*Preparation of the Alkenes **12**a, **12**b, and **12**c Through the Corey Thionocarbonate Procedure (32)*

An In Situ General Procedure

Thiophosgene (0.1 ml, 1.3 mmol) was injected into a solution of imidazole (340 mg, 5 mmol) in 20 ml of *o*-xylene (dry) under N_2 at room temperature. After stirring for 2 h the suspension was removed by filtration and the diol (50 mg) was added to the filtrate and heated to 100°C for 12 h. Tris(diethylamino)phosphine (1 ml) was then added and the reaction heated to reflux for 2 h. After cooling and addition of H_2O and CH_2Cl_2 the organic layer was washed, dried, and evaporated. The residue was chromatographed on a small column of silica gel in benzene, the red-purple band yielding on concentration crystalline product in *ca.* 30% yield for each alkene **12***a*, **12***b*, and **12***c* identical to the samples previously obtained.

*Reaction of the Diols **11**a, **11**b, and **11**c wtih P_2I_4: Preparation of Alkenes **12**a and **12**b*

General Procedure

The diol (500 mg) and P_2I_4 (83) (500 mg) were stirred for 12 h in dry ether (100 ml) or THF (80 ml) and then the red-orange solution was heated under reflux for 4 h. After cooling the iodine was removed by washing with $Na_2S_2O_3$ solution; CH_2Cl_2 was added if necessary. The organic layer was washed, dried, and evaporated and the residue chromatographed on silica gel in benzene. Concentration of the red-purple band yielded crystalline product. The yields were very variable and ranged from 16–96% for alkenes **12***a* and **12***b*; none of alkene **12***c* could be detected. The average yield over ten experiments was 49% for **12***b*.

*Reaction of Monobridged-diol **11**b, with Low-valent Titanium Species (38): Preparation of the Monobridged Alkane **14**b*

$LiAlH_4$ (65 mg, 1.7 mmol) was added to a suspension of $TiCl_3$ (400 mg, 2.6 mmol) in dry THF (15 ml) and stirred under N_2 for 30 min. The diol **11***b* (95 mg, 0.28 mmol) was then added and the mixture heated under reflux for 6 h. After cooling, CH_2Cl_2 and H_2O were added and the orange organic layer was washed, dried, and evaporated. The residue was chromatographed on silica gel. From the first yellow band there was obtained 13 mg (15%) of monobridged-alkane **14***b*.

*Hydrogenation of the Alkenes **12**a, **12**b, and **12**c: Preparation of the Alkanes **14**a, **14**b, and **14**c*

The alkene (80 mg) in benzene (25–50 ml) was stirred under a hydrogen atmosphere (770 torr) in presence of PtO_2 (~25 mg). The purple colour faded to yellow within 2 h. Removal of catalyst and then solvent left crystals of product alkanes in near quantitative yield. The products were recrystallized from cyclohexane to yield the following.

(*a*) From alkene **12***a* unbridged-alkane **14***a*, *cis*-6b,12b-dihydroacenaphth[1,2-*a*]acenaphthylene as long white needles, mp 213–215°C (lit. (15) mp 216–219°C); ^{1}Hmr δ (90 MHz) 7.8–7.4 (12H, m, ArH) and 5.71 (2H, s, —CH—); uv (cyclohexane) λ_{max} (log ε_{max}), 308 nm (4.05), 303 (4.08), 296 (4.11), 282 (3.96), 271 (3.76), 260 (3.60), 222 sh (5.06), and 217 (5.09).

(*b*) From alkene **12***b*, monobridged-alkane **14***b*, pyraceno[1,2-*a*]acenaphthene (3,4,6b,12b-tetrahydrocyclopent[f,g]acenaphth[1,2-*a*]acenaphthylene) as fluffy white needles mp 233–235°C; ^{1}Hmr δ (90 MHz) 7.6–7.0 (10H, m, ArH), 5.73 (2H, s, —CH—), and 3.36 (4H, s, -CH_2-); uv (cyclohexane) λ_{max} (log ε_{max}) 360 nm (2.94), 343 (3.07), 316 sh (4.04), 314 (4.04), 308 (4,08), 303 (4.11), 291 sh (3.97), 286 sh (3.96), 275 sh (3.71), 264 sh (3.61), and 223 (5.05); *Anal.* calcd. for $C_{24}H_{16}$: C 94.70, H 5.30; found: C 94.51, H 5.40.

(*c*) From alkene **12***c*, bisbridged-alkane **14***c*, pyraceno-[1,2-*a*]pyracene, (3,4,6b,9,10,12b-hexahydrodicyclopent-[f,g:f′,g′]acenaphth[1,2-*a*]acenaphthylene) as white crystals mp 282–283°C; ^{1}Hmr δ (90 MHz) 7.48 (4H, d, J = 7 Hz, H-1,6,7,12), 7.18 (4H, d, J = 7 Hz, H-2,5,8,11), 5.93 (2H, s, —CH—), and 3.31 (8H, s, -CH_2-); uv (cyclohexane) λ_{max} (log ε_{max}) 327 nm (3.91), 317 (4.11), 310 (4.14), 304 (4.16), 290 (4.02), 280 sh (3.80), 268 sh (3.61), 255 (3.51), and 228 (5.00); *Anal.* calcd. for $C_{26}H_{18}$: C 94.51, H 5.49; found: C 93.99, H 5.41. (This sample burnt with extreme difficulty.)

Measurement of Electrode Reduction Potentials

The values quoted in Table 4 were measured on a Metrohm-Polarecord E261 as 0.002 *M* solutions of hydrocarbon in anhydrous dimethylformamide which was 0.175 *M* in tetra *n*-butylammonium iodide using a dropping mercury electrode relative to the standard calomel electrode.

A theoretical study of the Curtius rearrangement. The electronic structures and interconversions of the CHNO species

ARVI RAUK AND PAUL F. ALEWOOD

Department of Chemistry, The University of Calgary, Calgary, Alta., Canada T2N 1N4

Received June 10, 1976[1]

ARVI RAUK and PAUL F. ALEWOOD. Can. J. Chem. **55**, 1498 (1977).

The thermal and photochemical decomposition of formyl azide in the Curtius rearrangement has been studied by means of RHF–LCAO–MO–SCF calculations augmented by CI. The lower electronic states of carbonyl azides, carbonyl nitrenes, isocyanates, cyanates, oxazirenes, nitrile oxides (fulminates), and isofulminates are discussed on the basis of the results for formyl azide and the corresponding isomers of formula CHNO. The discovery of two nearly degenerate states of A'' symmetry for formyl azide which may channel decomposition products directly to both isocyanates and carbonyl nitrenes explains some puzzling features of the photolytic Curtius rearrangement. The interconvertibility of the CHNO isomers (and the RCNO isomers) is discussed in terms of the energetics and intended correlations of the accessible electronic states of these species.

ARVI RAUK et PAUL F. ALEWOOD. Can. J. Chem. **55**, 1498 (1977).

Faisant appel à des calculs RHF–LCAO–MO–SCF complétés par CI, on a étudié les décompositions thermiques et photochimiques de l'azoture de formyle au cours du réarrangement de Curtius. On discute des états électroniques les plus bas des azotures de carbonyle, des nitrènes de carbonyle, des isocyanates, des cyanates, des oxazirènes des oxydes de nitrile (fulminates) et des isofulminates sur la base des résultats obtenus avec l'azoture de formyle et des isomères correspondants de formule CHNO. La découverte de deux états presque dégénérés de symétrie A'' pour l'azoture de formyle, qui peuvent servir directement de canaux pour les produits de décompositions tant pour les isocyanates que les nitrènes de carbonyle, explique quelques caractéristiques embarrassantes du réarrangement de Curtius photochimique. On discute de l'interconvertibilité des isomères CHNO (et des isomères RCNO) en termes des corrélations énergétiques et perspectives des états électroniques accessibles de ces espèces.

[Traduit par le journal]

Introduction

Electron deficient substances are rarely stable and rarely amenable to direct study. Their intermediacy is often postulated in reactions which frequently involve intricate rearrangements of the molecular skeleton. The proof of their intermediacy is far more than just an academic exercise but lends valuable and difficult-to-obtain evidence regarding their chemical and physical properties.

In Scheme 1 are summarized the synthetically important Curtius, Hofmann, and Lossen rearrangements (1). For each of these reactions, a mechanism can be written which involves an intermediate carbonyl nitrene that subsequently rearranges to an isocyanate. Evidence, in the form of insertion and abstraction products, for the intermediacy of carbonyl nitrenes in the photolytic Curtius rearrangement is well documented. Likewise, thermal decomposition of 'rigid' azides such as azidoformates leads to the formation of nitrene trapping products. However, thermolysis of other acyl azides leads initially only to isocyanates (2, 3). The scope of the Curtius reaction is summarized in Scheme 2.

Failure to observe nitrene trapping products has led to the current thinking that migration of the alkyl or acyl group is concurrent with loss of halide in the Hofmann rearrangement and with loss of hydroxide (or carboxylate) in the case of the Lossen rearrangement. Because of the similarity of the three reactions (Scheme 1) the question arises as to whether, in the case of the Curtius reaction, the nitrenes are being generated by an alternative and competing decomposition of the acyl azide, with rearrangement to isocyanate being simultaneous with loss of nitrogen, in a manner completely analogous to the mechanism proposed for the Hofmann and Lossen reactions. Certainly, the migrating group is never kinetically free (4–6). An elegant study of isotope effects in the decomposition

[1]Revision received January 3, 1977.

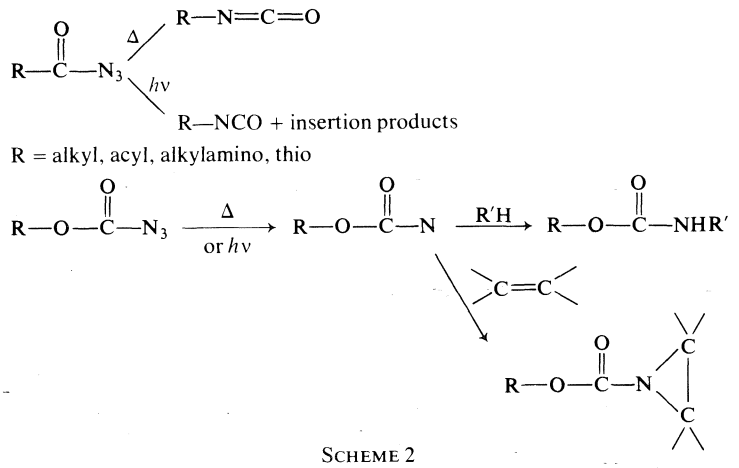


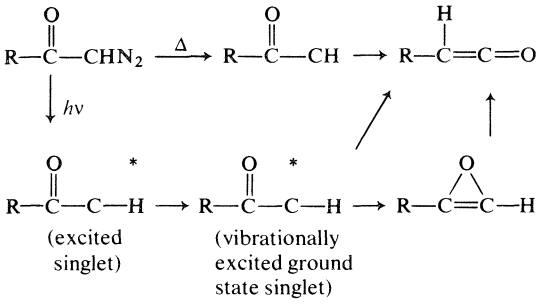
SCHEME 2

and rearrangement of benzoyl azide provides compelling evidence for the view that rearrangement and expulsion of nitrogen occur concurrently (7). That nitrenes may be generated by a different route is also supported by a study of the photolysis of pivaloyl azide in a variety of solvents (3). In this case the yields of isocyanate were essentially constant under all conditions while the yield of nitrene trapping products varied appreciably. Similar results have been obtained during the photolysis of benzoyl azide (8).

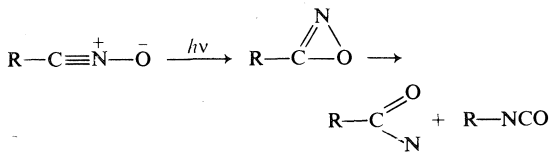
However, earlier evidence which suggested a non-concerted mechanism for the rearrangement-decomposition cannot easily be reinterpreted. Kinetic measurements of the thermally induced decomposition-rearrangement of *m*- and *p*-substituted benzoyl azides revealed no Hammett correlation (9). The substituents influenced the rate of nitrogen evolution in an unpredictable fashion (9). The results are contrary to the results obtained for the Hofmann and Lossen rearrangements (10, 11), and can be interpreted as evidence for a lack of aryl migration in the transition state. In the same vein, a small positive value in the volume change of activation in the thermal Curtius rearrangement of benzoyl azide has been cited as evidence that the reaction has a non-polar transition state in which extensive bond breaking (*i.e.* leading to nitrene) has taken place (12). Theoretical (13, 14) and experimental (15) investigations into the mechanism of the entirely analogous Wolff rearrangement (Scheme 3) has led to the general conclusion that the rearrangement is not concerted. From computed MO and state energies together with symmetry correlation it was concluded that the Wolff rearrangement does involve a ketocarbene, but when performed photolytically an oxirene intermediate is also involved. An oxirene intermediate is not formed in the thermal decomposition as the initially formed ketocarbene lacks sufficient vibrational energy to achieve cyclization.

Just and Zehetner (16, 17) have demonstrated the formation of acyl nitrenes as well as isocyanates upon irradiation of *O*-methylpodo-carponitrile oxide and mesitonitrile oxides. They suggested the mechanistic pathway shown in Scheme 4 and showed that isocyanate was

Wolff rearrangement

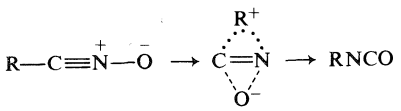


SCHEME 3



SCHEME 4

not appreciably converted to acylnitrene under the reaction conditions. The *thermal* isomerization of nitrile oxides (17) to isocyanates has been known for more than sixty years and has been recently reinvestigated by Grundmann and Dean (18) who achieved the clean rearrangement of substituted aryl nitrile oxides by refluxing them in a high boiling solvent. It was demonstrated that the mechanism involves an intramolecular rearrangement in which bond breaking and bond making are apparently synchronous (19). Grundmann suggested the following mechanism for the rearrangement:



Alkyl isocyanates R—NCO are also readily produced from alkyl cyanates (20), ROCN, by an exothermic rearrangement (21). The tendency toward isomerization can be minimized if the alkyl carbonium ion R^+ is primary or bridgehead (21). Aryl cyanates do not rearrange thermally to aryl isocyanates. By analogy to the well studied thiocyanate to isothiocyanate rearrangement, the mechanism probably involves heterolytic bond cleavage, as below:

The electronic structures of carbonyl nitrenes have been studied by means of non-empirical MO computations (22, 23) and the mechanism of insertion and abstraction reactions discussed (22). We here present a study of the thermal and photolytic decomposition of formyl azide and the electronic structures and energetics of compounds isomeric to isocyanic acid, and discuss the possible pathways of interconversion.

Method

Restricted Hartree–Fock–Roothaan LCAO–MO–SCF (24) calculations were performed on the following compounds whose structures are shown in Fig. 1: formyl azide **1**, formyl nitrene **2**, isocyanic acid **3**, cyanic acid **4**, oxazirene **5**, fulminic acid **6**, and isofulminic acid **7**. Calculations on formyl nitrene **2** have previously

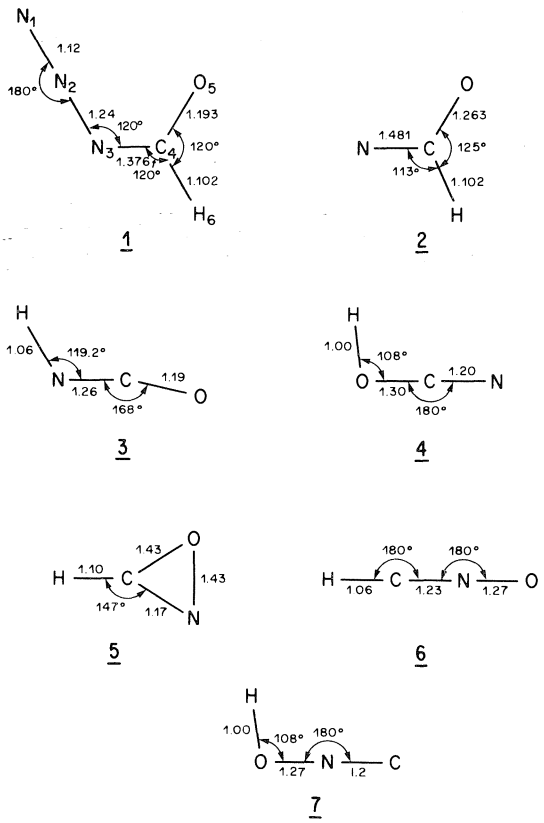


FIG. 1. Structures of the compounds **1**–**7** used in the study: bond lengths in Angstroms; angles in degrees.

been reported (22, 23). The geometry of **2** has been optimized by Harrison and Shalhoub (23). Further geometry variations were performed on **2** in order to establish which deformations of this molecule are relatively unhindered. Although the geometry of **3** has been reported (25), some geometry variation was performed on this system as a consequence of recent experimental (on ClNCO) (26) and theoretical (27, 28) indications that the NCO fragment may be appreciably non-linear. Limited geometry searches were performed on compounds **4** and **5** for which specific experimental data on geometries are lacking. The experimental geometry for **6** (29) and an 'idealized' geometry for **7** were adopted. For **1**, bond lengths were taken from formamide (30) and methyl azide (30) and idealized angles of 120° were used. Some geometry variation, to be discussed later, was performed. The geometries of the compounds for which results are reported in the text and in other figures are shown in Fig. 1.

In the present *ab initio* method, all one- and two-centre integrals are computed over a minimal basis set of exponential-type functions (STO). All three- and four-centre integrals are computed using Pople's (31) STO-3G Gaussian expansion of the STO's[2]. Slater exponents were employed for all atoms except hydrogen where an exponent of 1.2 was chosen. For reasons which are discussed below, calculations were also performed on compounds **2** and **3** using an extended basis set ($9s5p/4s$ contracted to $4s2p/2s$ (32)).

Since recent reports on electron deficient cationic systems (33, 34) have suggested that correlation energy may not adequately cancel when comparing calculated RHF energies of constitutional isomers, we decided to include correlation energies for the ground states of various species by perturbation theory. The correlation energy is taken as the second order correction to the RHF energy, which implies inclusion of all double excited configurations. The relative advantages and disadvantages of Rayleigh–Schrödinger (RS) and Brillouin–Wigner (BW) expansions and of Moller–Plesset (MP) and Epstein–Nesbet (EN) partitions of the Hamiltonian have recently been discussed by Ostlund and Bowen (34) and will not be repeated here. Suffice it to say that the BW–EN combination gives better convergence and includes higher order terms in a many-body sense than other combinations and is equivalent to the exact diagonalization of the double excited CI matrix if one neglects non-zero elements between double excited configurations. Use of the BW–EN procedure allows one to incorporate most of the correlation energy, for a given basis. This is the procedure we have adopted. All single determinantal double excited configurations except those involving core orbitals are included.

In the calculation of the energies of the excited states, all single excitations, excluding those involving core orbitals, are included. In many cases, heavy mixing between different single excited configurations occurs. It was necessary to include those configurations in the zero order description of the excited state and perform the exact diagonalization of the zero-order block of the CI matrix. The contributions of those configurations which mix only weakly were incorporated through Rayleigh–Schrödinger perturbation theory as second order corrections to the energy.

Excitation energies were calculated as the difference between the all-single-excitations CI energy for the excited state and the ground state RHF–SCF energy, rather than the energy which includes the correlation correction. This procedure is justified theoretically because terms coming from triply-excited configuration contributions to the excited state largely cancel those from doubly-excited configuration contributions to the ground state (35). As seen below, where comparisons can be made, good agreement with experimentally obtained excitation energies is obtained.

Results and Discussion

The results of Mulliken population analyses on the SCF configurations of compounds **1–7** are shown in Fig. 2. The valence molecular orbitals of compounds **3–6**, displayed as linear combinations of hybridized atomic orbitals, are shown in Figs. 3–6, respectively, as are the energies of the individual molecular orbitals. The orbitals have been classified as belonging to one or the other of the irreducible representations (a' or σ, a'' or π) of the point group C_s. Special features of the seven structures are dis-

[2]It was earlier determined (22) by using the STO-4G expansion that approximation of the smaller three- and four-centre integrals in this way does not lead to anomalous results in the electronic structure or relative energies.

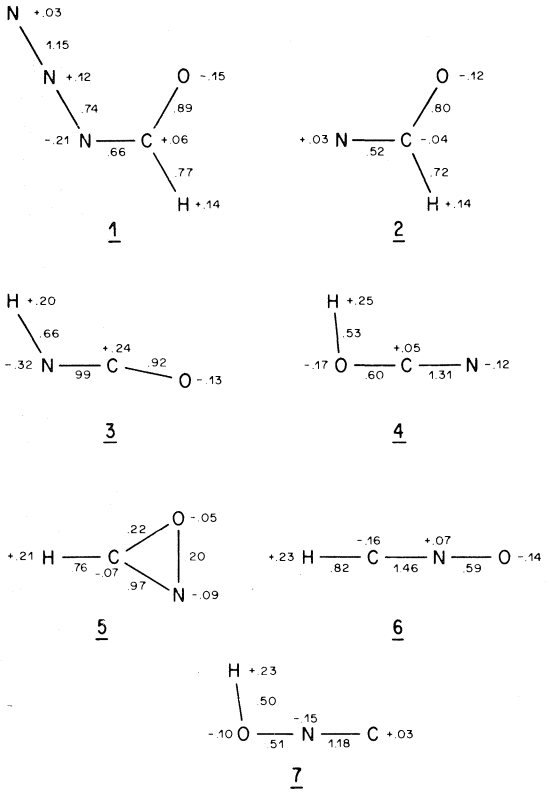

FIG. 2. Mulliken population analyses for compounds **1–7**. Net charges are indicated at the atomic positions and bond overlap populations on the bonds.

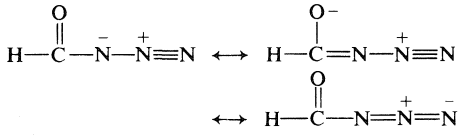
cussed separately in the sections immediately following. This is followed by a general discussion of the possible roles of these substances in the thermal and photolytic Curtius reactions.

Formyl Azide 1

The results of a Mulliken population analysis (Fig. 2) indicate that, of the various resonance forms for **1**, the



last shown is the least important. The ground state configuration of the molecule is $...(14\sigma)^2(15\sigma)^2(3\pi)^2$. The highest occupied molecular orbital in the ground state configuration (3π) is a π MO localized largely to the $N_1—N_2—N_3$ fragment with a node close to N_2. The second highest occupied MO (15σ, Fig. 7) is also π-like in the $N_1—N_2—N_3$ fragment, with a node near N_2, but has a contribution from an in-plane p orbital on oxygen.

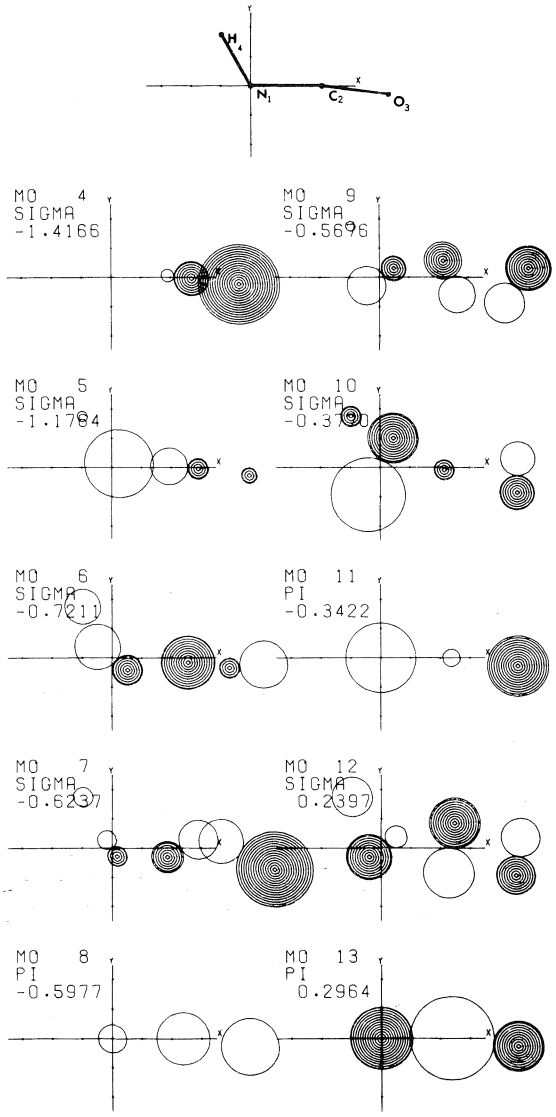


FIG. 3. The valence molecular orbitals of isocyanic acid **3** are displayed as linear combinations of hybridized atomic orbitals. The magnitude of each atomic orbital is directly proportional to the magnitude of its coefficient in the LCAO expansion of the MO. Only the top lobes of each PI (a'') orbital are shown. The MO energy is in hartree units (1 hartree = 627.71 kcal/mol = 27.21 eV).

Calculations allowing interaction among all singly excited configurations (except those involving excitations from the five core orbitals) yield four excited singlet states that lie less than 7 eV above the ground state. These are: $^1A_1''$

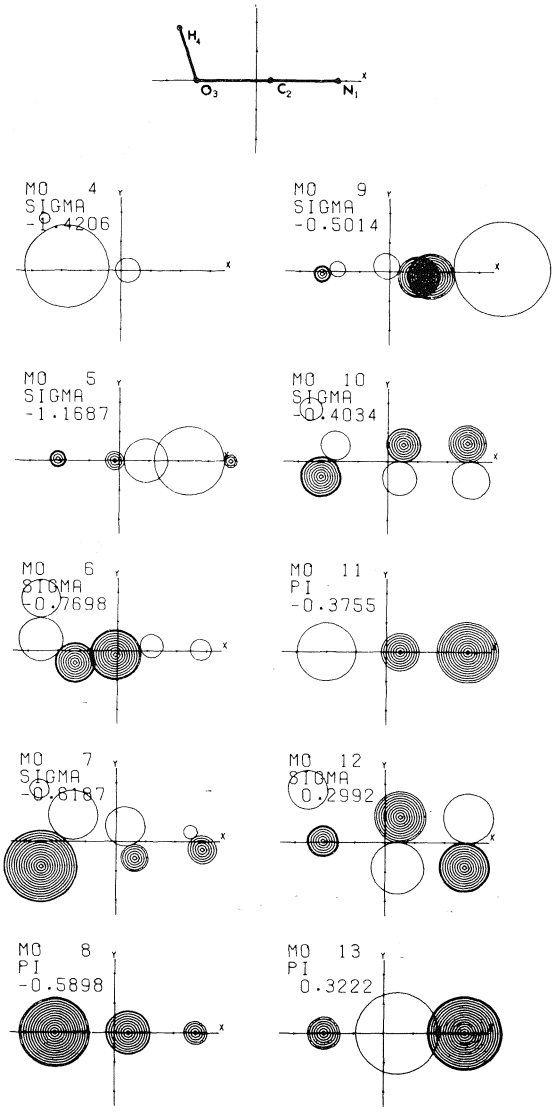

FIG. 4. The valence molecular orbitals of cyanic acid **4** are displayed as linear combinations of hybridized atomic orbitals. The magnitude of each atomic orbital is directly proportional to the magnitude of its coefficient in the LCAO expansion of the MO. Only the top lobes of each PI (a'') orbital are shown. The MO energy is in hartree units (1 hartree = 627.71 kcal/mol = 27.21 eV).

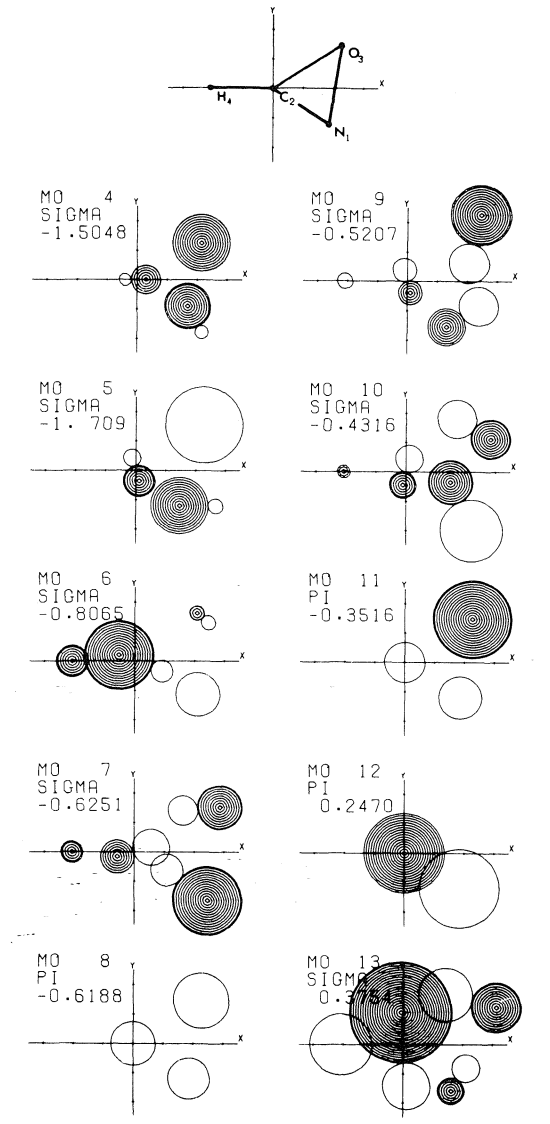

FIG. 5. The valence molecular orbitals of oxazirene **5** are displayed as linear combinations of hybridized atomic orbitals. The magnitude of each atomic orbital is directly proportional to the magnitude of its coefficient in the LCAO expansion of the MO. Only the top lobes of each PI (a'') orbital are shown. The MO energy is in hartree units (1 hartree = 627.71 kcal/mol = 27.21 eV).

4.44 eV; $^1A_2''$ 4.60 eV; $^1A_2'$ 5.96 eV; $^1A_3''$ 6.69 eV. In spite of the extensive photochemical studies of acyl azides that have been reported, we can find no reports of the uv spectra of these compounds. Methyl azidoformate, $CH_3OC(O)N_3$, has a weak band ($\varepsilon \sim 40$) at 4.8 eV (36). Alkyl azides exhibit two absorption bands in the near-uv region, a weak band ($\varepsilon \sim 25$) at 4.3 eV and a stronger band ($\varepsilon \sim 500$) at 5.7 eV (37). Both transitions are assigned to $\pi_x \rightarrow \pi_y^*$-type transitions ($A''$ symmetry) of the azide group, which correlate with orbital symmetry forbidden transitions of the azide anion. Our calculations indicate that the origin of the two

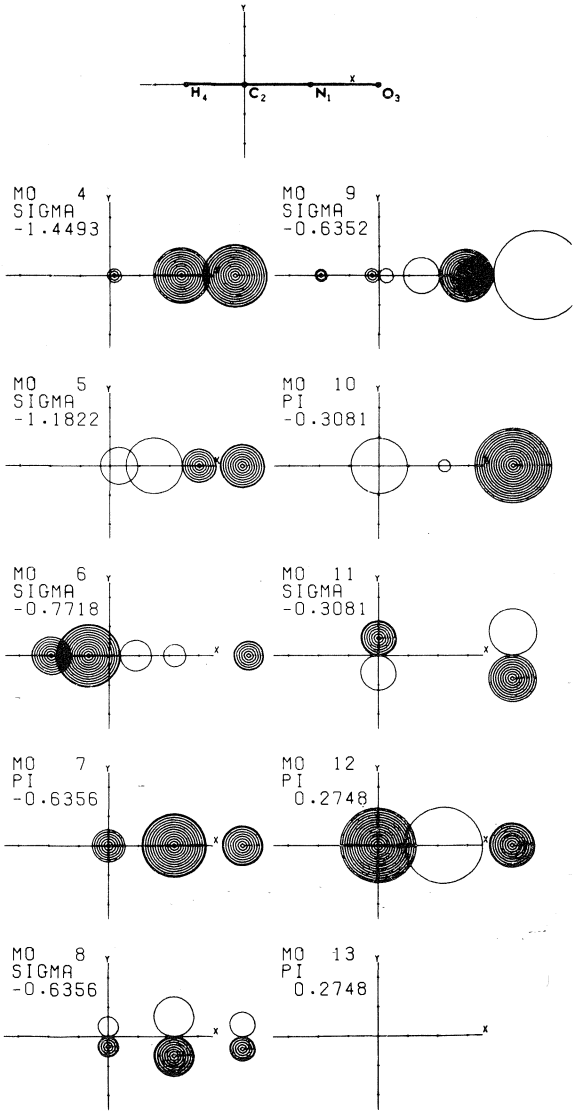

FIG. 6. The valence molecular orbitals of fulminic acid **6** are displayed as linear combinations of hybridized atomic orbitals. The magnitude of each atomic orbital is directly proportional to the magnitude of its coefficient in the LCAO expansion of the MO. Only the top lobes of each PI (a'') orbital are shown. The MO energy is in hartree units (1 hartree = 627.71 kcal/mol = 27.21 eV).

lowest nearly degenerate A'' transitions of formyl azide **1** is the same except that considerable mixing of other configurations of the same symmetry occurs. The transitions which give rise to the principal configurations for the two states $^1A_1''$ and $^1A_2''$, as well as the $^1A_2'$ state, are shown schematically in Fig. 7. The $^1A_2'$ state has almost equal contributions from

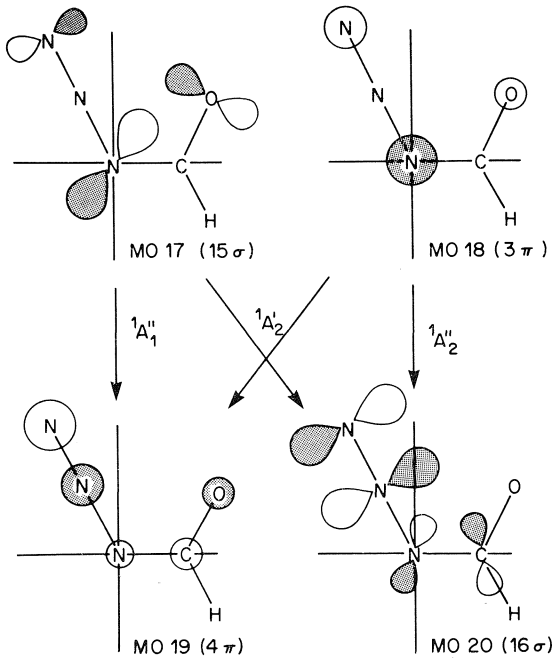

FIG. 7. The two highest occupied and two lowest unoccupied MO's of formyl azide **1**. The excitations which make major contributions to the first three excited states of **1** are indicated by the arrows.

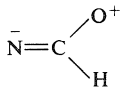
the two configurations arising from the two $\pi \rightarrow \pi^*$-like transitions shown in Fig. 7.

The thermal and photolytic decomposition of the azide is discussed in the second to last section.

Formyl Nitrene 2

Although formyl nitrene has been discussed in detail previously (22, 23) some of the salient features bear repeating in the present context. The results of a Mulliken population analysis (Fig. 2) indicate that the nitrogen atom, though electron-deficient, does not compete effectively with oxygen for electrons. The contribution of the resonance structure



to the electronic structure of **2** is unimportant.

Examination of Fig. 2 of ref. 22 reveals that the electrons are missing from a non-bonded σ orbital (MO 12) highly localized to the nitrogen.[3]

[3]Electron spin resonance evidence (38) confirms that the extra electron in acetyl nitrene radical anion is in a nitrogen p orbital in the carbonyl plane.

There are four electrons in the π system of **2** (MO's 8 and 11). A resonance structure such as that above would only be important if either of MO 10 (oxygen non-bonded electron pair) or MO 11 (nitrogen non-bonded electron pair) were unoccupied.

One expects that the doubly-excited electronic configuration $...(1\pi)^2(8\sigma)^2(9\sigma)^2(2\pi)^0(10\sigma)^2$ would contribute strongly to the electronic structure of the $^1A_1'$ state of **2**, thereby reducing the anisotropy in the electron distribution about nitrogen. Recent natural orbital calculations by Harrison and Shalhoub (23) suggest an occupancy of 0.74 electrons for the natural orbital corresponding to MO 12 of the SCF calculation. Indeed, Harrison and Shalhoub find that the electronic state whose dominant configuration is that shown above is only 1.52 eV above the lowest singlet state of **2**. Since straightforward interaction of the SCF configuration with the $...(9\sigma)^2(10\sigma)^2$ configuration, when the latter is constructed from the orbitals of the former, yields the result that the states so generated are separated by 6.91 eV (6.83 eV with the larger basis set), it was necessary to perform an MCSCF (39) calculation involving the two configurations. Using the larger basis set, the energy of the lower closed shell singlet state is reduced relative to the SCF value by a small amount, 0.0166 hartree, yielding the MSCF energy −167.5613 hartree. However, the energy of the upper closed shell singlet is lowered to −167.4901 hartree. Thus the energy separation calculated by the MCSCF procedure is 1.83 eV, in satisfactory agreement with that found by Harrison and Shalhoub (23). Likewise, the composition of the lower state, $^1A_1'$, corresponds to 73% of the $...(9\sigma)^2(2\pi)^2$ configuration and 27% of the $...(9\sigma)^2(10\sigma)^2$ configuration. The upper closed shell state, $^1A_2'$, has the composition, 29% $...(9\sigma)^2(2\pi)^2$, 71% $...(9\sigma)^2(10\sigma)^2$. The $^1A_1''$ state of **2** is calculated to be 0.09 eV above the $^1A_1'$ state if one includes the lowering of the latter due to the MCSCF calculation. The dominant configuration of the $^1A_1''$ state is $...(9\sigma)^2(2\pi)^1(10\sigma)^1$. The fourth singlet state, $^1A_3'$, is 3.16 eV above the $^1A_1'$ state and corresponds mainly to the configuration $...(9\sigma)^1(2\pi)^2(10\sigma)^1$. The fifth state, $^1A_2''$, is 5.74 eV above the first singlet state and arises from the configuration $...(9\sigma)^1(2\pi)^2(3\pi)^1$. Except for the position of the $^1A_2'$ state, as explained above, similar results are obtained using the smaller STO basis, without MCSCF. The energies (in eV) obtained with the STO basis, relative to the $^1A_1'$ state are: $^1A_1''$ −0.82; $^1A_3'$ 3.32; $^1A_2''$ 4.21.

The possible intermediacy of carbonyl nitrenes, such as **2** in the thermal and photolytic Curtius reaction, is discussed later.

Isocyanic Acid **3**

Isocyanic acid is calculated to be the most stable isomer of formula HNCO, 91 kcal/mol more stable than formyl nitrene **2**. Separate calculations using various values for the CNO angle verified previous reports (26–28) that this angle in isocyanates is appreciably non-linear. Although one would not expect linearity of the heavy atom skeleton in any of the systems **1**, **3**–**7**, except **6**, since the NCO units (N_3 for **1**) do not reside in an axially symmetric potential, it was of interest to determine the extent of non-linearity and look for the cause of the unusually large deviation. The equilibrium value of the NCO angle of **3** (Fig. 1) is found to be 168°. The ground state electron distribution (Fig. 2) shows that the central carbon atom is much more electron deficient than in any of the other species considered. This is due to the fact that the two highest occupied molecular orbitals (MO's 10 and 11) are π-like orbitals with a node very near the carbon atom, and has the consequence that the NCO fragment has a very low bending force constant (40).

The calculated dipole moment is 1.70 D, in reasonable agreement with the experimental value of 2.1 D (41).

The near ultraviolet absorption spectrum of isocyanic acid **3** (as well as alkyl and inorganic isocyanates) has been previously analyzed (42, 43). Although only the first transition in isocyanic acid is observable (at 5.90 eV), many more states of the closely related alkyl isocyanates are seen. Excitation energies (in eV), computed with the large basis, are as follows (experimental values (42) for ethyl isocyanate are in parentheses): $^1A_1''$ 5.89 (5.95); $^1A_2'$ 7.38 (6.82); $^1A_2''$ 8.53 (7.13). The values obtained using the STO basis are: $^1A_1''$ 5.06; $^1A_2'$ 6.88; $^1A_2''$ 7.95.

The states $^1A_1''$ and $^1A_2''$ originate almost entirely from the transitions $2\pi \rightarrow 10\sigma$ (MO 11 to MO 12, Fig. 3) and $9\sigma \rightarrow 3\pi$ (MO 10 to MO 13, Fig. 3), respectively. The same four orbitals are involved in the description of the

state, $^1A_2'$, whose major configuration is that from $9\sigma \rightarrow 10\sigma$ but which has 42% contribution from the $2\pi \rightarrow 3\pi$ configuration.

Cyanic Acid **4**

Cyanic acid is computed to be 1 kcal/mol less stable than isocyanic acid. The results of population analysis of cyanic acid, shown in Fig. 2, and the molecular orbitals, shown in Fig. 4, support the usual valence bond description, C—O single bond, C—N triple bond.

The energies in eV, relative to the ground state, of the three lowest singlet states of cyanic acid are: A'' 6.78; A' 7.84; A'' 8.14. There are no published experimental uv spectroscopic data on **4** or alkyl cyanates.

The dipole moment of **4** is computed to be 2.96 D.

Oxazirene **5**

The anti-aromatic character expected for a conjugated three membered ring with 4π electrons is evident upon inspection of the results of population analysis of oxazirene (Fig. 2). The second occupied π orbital has a node which bisects the C—O and N—O bonds and leads to very small bond overlap populations for these two bonds. The total electronic energy of oxazirene is computed to be within 1 kcal/mol of the closed shell $^1A_1'$ state of formyl nitrene. The computations reveal that there are no singlet electronic states of oxazirene that are less than 7 eV above its ground state. There are no experimental data on this compound.

The dipole moment of **5** is computed to be 2.16 D.

Fulminic Acid **6**

Fulminic acid, a model for alkyl nitrile oxides is calculated to be 60 kcal/mol less stable than isocyanic acid.[4] The population analysis shown in Fig. 2 supports the usual valence bond description: C—N triple bond, N—O single bond. However, the charge separation in the N—O bond is not nearly as great as might have been expected of a formal dative bond. Molecular orbitals of **6** are shown in Fig. 6.

The computed dipole moment is 3.65 D (experimental 3.06 D (*29a*)).

[4]Not much significance should be attached to the absolute and relative energies of **3**, **6**, and **7** since no geometry optimization was performed on either **6** or **7**.

The gas phase uv spectrum of **6** shows a band progression between 4.4 and 5.1 eV (44). The two lowest excited singlet states, A_2 and E_1, are 4.95 and 5.52 eV, respectively, above the ground state. Both states are primarily linear combinations of configurations derived from the $\pi \rightarrow \pi^*$ transitions from the two highest occupied MO's of **6** to the two lowest unoccupied MO's (Fig. 6).

Isofulminic Acid **7**

Isofulminic acid is included for the sake of completeness. It is computed to be 13 kcal/mol more stable than fulminic acid and 47 kcal/mol less stable than isocyanic acid.[4] The population analysis (Fig. 2) indicates the electronic structure of the ground state as best described by the first resonance structure below with little contribution from the second.

$$\text{H—O—N=C} \leftrightarrow \text{H—O—}\overset{+}{\text{N}}\equiv\overset{-}{\text{C}}$$

The lowest unoccupied molecular orbital is a π^*-like orbital of the N—C fragment in the plane of the molecule. The largest single contribution to the LUMO is a p orbital of the carbon suggesting that the compound should be highly susceptible to nucleophilic attack at that site. Although alkyl isofulminates are not known, typical reactions of alkyl isonitriles, RNC do involve addition of nucleophiles to the carbon atom.

The computed dipole moment is 3.09 D.

The energies in eV, of the three lowest lying singlet excited states, relative to the ground state are: $^1A_1''$ 6.29; $^1A_2'$ 7.24; $^1A_2''$ 7.46.

The Curtius Reaction

In Fig. 8 is shown the molecular orbital energy level diagram for formyl azide **1**, N_2, formylnitrene **2**, and isocyanic acid **3**. The correlations are based on inspection of the phase properties of the molecular orbitals. There is no indication from the diagram in Fig. 8 that **1** should not decompose thermally to yield formyl nitrene or isocyanic acid directly in their ground states. The state correlation diagram for the decomposition of **1** to formyl nitrene + N_2 and isocyanic acid is shown in Fig. 9. The decomposition of **1** is simulated by stretching the N_2—N_3 bond (Fig. 1) by 0.26 Å, 0.53 Å, and 1.94 Å (points *b*, *c*, and *d*, respectively, in Fig. 9) beyond the equilibrium value

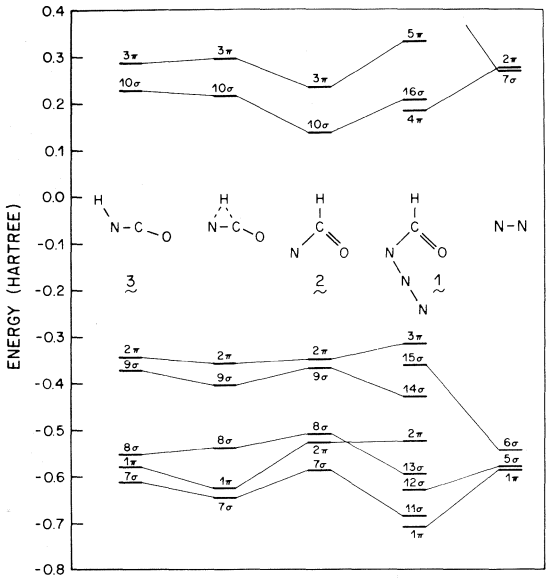


FIG. 8. The molecular orbital correlation diagram for the decomposition of formyl azide **1**.

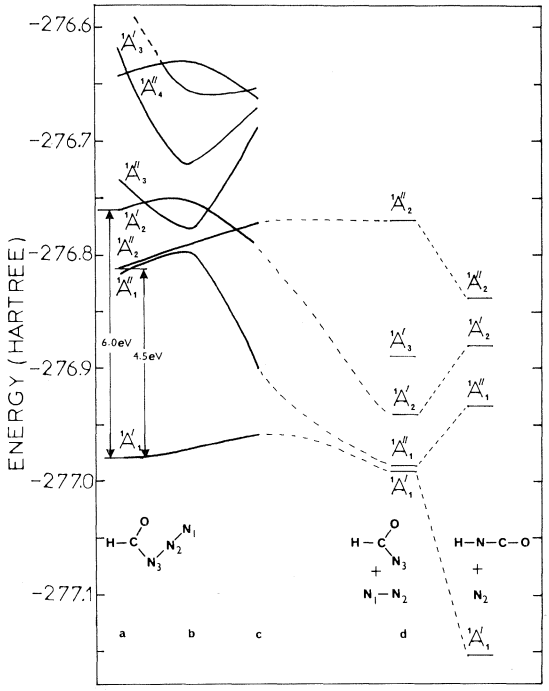

FIG. 9. The state correlation diagram for the decomposition of formyl azide **1**: point *a*, structure shown in Fig. 1; point *b*, same structure as at point *a* except that N_2—N_3 is stretched by 0.26 Å; point *c*, same structure as at point *a* except that N_2—N_3 is stretched by 0.53 Å; point *d*, N_2 and N_3 are 3.18 Å apart, the structure of **2** is as given in Fig. 1, and N_1—N_2 is the experimental value for elemental nitrogen.

(point *a* in Fig. 9).[5] Besides the N_2—N_3 bond, the geometry of the rest of the system is that of **1** for points *b* and *c*. It was not feasible to optimize the geometry at points *b* and *c*. As a result, the energies of the ground and excited states at the initial stages of decomposition are probably higher than they should be, relative to the energy of **1**. At the last point, *d*, decomposition is essentially complete. The geometry of the nitrene fragment is the same as **2** (Fig. 1) and the experimental bond length (30) of N_2 (1.098 Å) is used. The total SCF energy at point *d* is 2.5 kcal/mol higher than the sum of the SCF energies from separate calculations on **2** and N_2. The energy of the $^1A_1'$ state of isocyanic acid **3** was positioned in Fig. 9 by comparing the relative BW–EN corrected $^1A_1'$ state energies of **2** and **3** in the same (STO) basis. The positions of the other electronic states of **2** and **3** plotted in Fig. 9 were obtained from the larger basis set results, although the conclusions are not altered if one uses the smaller basis set data.

The first excited state of N_2 is calculated to be at 9.0 eV (experimental value 9.3 eV (45)) and is not shown. Pyrolysis of the azide to nitrene is calculated to be essentially isoenergetic with a low activation energy. Since the usual light sources for photolysis (*e.g.*, Rayonet reactor or Hanover lamps) provide energy in the vicinity of 4.5 eV and virtually nothing above 6.5 eV, the decomposition, whether thermal or photolytic, must eject the N_2 in its ground state.

The ground state of the azide $^1A_1'$ correlates directly with the $^1A_1'$ state of formyl nitrene. The nitrene in this state is calculated to have an anisotropic charge distribution about the nitrogen atom. The [1,2]-sigmatropic shift of hydride (or alkyl) group in this state is an orbital symmetry allowed process and computations on an intermediate structure (Fig. 8) suggest that, as in carbo cationic systems, there is little or no activation energy for the process. As the nitrene would probably be reached in a vibrationally excited state in the thermal Curtius reaction, it is likely that the highly exothermic rearrange-

[5]Calculations were also performed on the *trans* geometry of **1**. The ordering and positions of the excited states of the *trans* isomer were essentially the same as for the *cis* isomer at all stages of the simulated decomposition. Accordingly, only the data for the slightly more stable *cis* form are illustrated in Fig. 9 and discussed in the text.

ment to isocyanate takes place spontaneously or perhaps more likely still, is concerted with expulsion of N_2. This would explain the universal lack of evidence for nitrene intermediates in the thermolysis of acyl azides.

The two lowest excited states of the acyl azide **1** are nearly degenerate, at about 4.5 eV above the ground state. As stated earlier, both can be identified with transitions of the azide group which are electric dipole forbidden in the azide anion. Although the basis set is too crude to yield reliable values for electric dipole oscillator strengths, the calculations do indicate that the oscillator strengths for those two states, as well as the $^1A_2'$ state at 6.0 eV, are about $f \simeq 0.001$, corresponding to weakly allowed transitions. Since the radiation typically used in photolysis has energy of 4.9 eV (Hg 253.7 nm line), it is probable that the photolytic Curtius reaction proceeds entirely by excitation to the $^1A_1''$ and $^1A_2''$ states.

The behavior of the $^1A_1''$ and $^1A_2''$ states during the decomposition is of special significance. The near degeneracy suggests that the two states should both be populated upon photolysis, or by equilibration after photolysis. The two states remain nearly degenerate in the early part of the decomposition (in fact there is a weakly avoided crossing) and then diverge rapidly. One correlates with the $^1A_1''$ state of **2** whose dominant configuration is $...(9\sigma)^2(2\pi)^1(10\sigma)^1$ in a highly exothermic process. The other correlates with the $^1A_2''$ state whose dominant configuration is $...(9\sigma)^1(2\pi)^2(3\pi)^1$ which corresponds to the $n \rightarrow \pi^*$ transition of the carbonyl moiety.

The descending $^1A_1''$ state of the decomposing azide yields the $^1A_1''$ state of the nitrene. Rearrangement to the $^1A_1''$ state of isocyanic acid is an endothermic process and should be hindered if collisional deactivation is rapid. The fate of the reactive nitrene intermediate will depend on the nature of the solvent and the presence of nitrene traps.

On the other hand, the $^1A_2''$ state of the acyl azide correlates with the $^1A_2''$ state of the carbonyl nitrene. The nitrene can rearrange to the isocyanate in a substantially exothermic process. It was not possible to do geometry optimization (energy minimization) along the reaction coordinate so it is probable that the calculated activation energies for the decomposition of the acyl azide states $^1A_1''$ and $^1A_2''$ are not as high as calculated. It is intriguing that if decomposition along the two pathways were competitive, the $^1A_2''$ path would lead directly to isocyanate and the yield of isocyanate would depend only on the internal partitioning of the photolyzed azide between the two states, rather than on external effects. It was found in photolyses of pivaloyl azide (3) and benzoyl azide (8) that yields of isocyanate were essentially constant under a variety of conditions but that yields of nitrene trapping products were sensitive to reaction conditions.

Interconversions Between the HCNO Isomers

Compounds **2**–**7** represent the only isomers of HCNO for which reasonable valence bond structures can be written. At least some alkyl or aryl derivatives of all except **5** and **7** are known. As discussed in the Introduction, clean rearrangements can be effected between all known isomeric forms. However, without quantitative calculations of the complete HCNO hypersurface for each of the electronic states of the generalized HCNO structure, it is not possible to make more than some general remarks about the interconversions of the isomeric species.

The calculated energies of ground and excited states of **2**–**7**, rearranged for the sake of the discussion which follows, are shown plotted on the same energy scale in Fig. 10. Intended correlations between states of species which are close together on the potential hypersurface can in some cases be deduced by connecting states of like symmetry and by taking into account the nodal and symmetry properties of the molecular orbitals from which the principal contributing configurations are derived. The latter distinction is difficult to make if, as happens often in the present system, the CI calculations indicate that two or more configurations contribute strongly to the description of the state wave function.

We enumerate here, without detailed rationalization, those interconversions which can be expected with reasonable confidence on the basis of the calculations performed in the present study. These remarks should also apply to the alkyl derivatives of the parent HCNO structures.

(*1*) **2** $\rightleftarrows$ **3**. Carbonyl nitrenes **2** will rearrange to isocyanates **3** via their $^1A_1'$ states with little or no activation energy. Isocyanates should be convertible to nitrenes via their $^1A_1''$ states.

(*2*) **3** $\rightleftarrows$ **4**. The ground states, $^1A_1'$, of cyanates

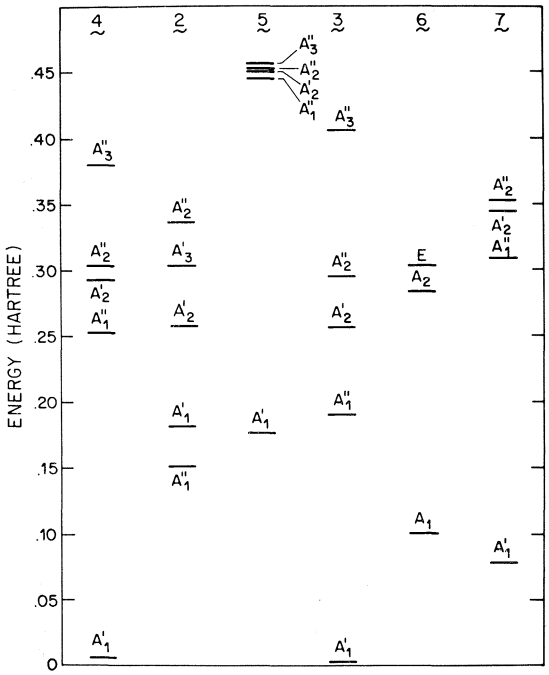

FIG. 10. The calculated state energies of compounds **2**–**7** shown on the same scale.

and isocyanates do not correlate with each other. Our results support the conclusion, stated previously, that the observed rearrangement of alkyl cyanates to isocyanates (20) probably occurs by a dissociative mechanism involving carbonium ions. The equilibrium favours the isocyanate, apparently by more than the calculated amount of 1 kcal/mol. There appears to be no direct photochemical route for interconversion either, since the $^1A_1''$ states do not correlate with each other (46).

(*3*) **3** ⇄ **6**. Fulminic acid and isocyanic acid are not close to each other on the potential hypersurface but, as reviewed in the Introduction, nitrile oxides have been reported to rearrange to isocyanates both thermally (17–19) and photochemically (16, 17). In the thermal rearrangement, a transition state in which both oxygen and alkyl group migration occur simultaneously has been implicated by studies of isotope effects (19). To explore the possibility of such a low energy pathway would require an extensive search of the nuclear configuration space and is beyond the scope of the present study. The stepwise rearrangement **6** → **5** → **2** → **3** does not appear to be feasible on energetic and electronic grounds.

Any rearrangement which involves **5** must proceed by way of the ground state of this species. Since the $^1A_2$ state of **6** does correlate directly with the $^1A_1'$ state of **5** we expect nitrile oxides to be converted to oxazirenes upon photolysis. The oxazirenes should be metastable since the $^1A_1'$ state of **5** would tend to correlate with a higher $^1A'$ state of **2**. An avoided crossing ultimately connects the $^1A_1'$ states of **5** and **2** and allows rearrangement to the more stable isocyanate **3**. The observation of nitrene trapping products in the photochemical conversion of nitrile oxides to isocyanates supports this route (16).

Acknowledgments

We are indebted to the National Research Council of Canada for financial support of this work, and to the University of Calgary for the receipt of a generous computing grant. We give special thanks to José M. Barriel who wrote the computer programs for the configuration interaction part of the study, and to M. A. Robb, Queen Elizabeth College, University of London, who did the MCSCF calculations for us.

IAN DAVID BROWN, HELEN ELAINE HOWARD-LOCK, and MAHADEVAN NATARAJAN. Can. J. Chem. **55**, 1511 (1977).

The crystal structure of Rb_2AgI_3, space group *Pnma*, $a = 10.258(2)$, $b = 4.886(4)$, $c = 20.063(10)$ Å, has been refined. It is isostructural with K_2AgI_3 with chains of corner linked AgI_4 tetrahedra (Ag—I(bridge) = 2.881 Å, Ag—I(terminal) = 2.834 Å) running along *b*. The average bonding distance around the two seven coordinate Rb atoms is 3.722 Å. The polarised Raman spectrum shows the expected 36 modes which are assigned to four different symmetry species. All modes occur with frequencies less than 112 cm^{-1}.

IAN DAVID BROWN, HELEN ELAINE HOWARD-LOCK et MAHADEVAN NATARAJAN. Can. J. Chem. **55**, 1511 (1977).

On a affiné la structure cristalline de Rb_2AgI_3, groupe d'espace *Pnma*, $a = 10.258(2)$, $b = 4.886(4)$, $c = 20.063(10)$ Å. Elle est isostructurale avec celle du K_2AgI_3 et comporte des chaînes de AgI_4 tétraédriques reliées par les coins (Ag—I(pont) = 2.881 Å, Ag—I(bout de chaine) = 2.834 Å) le long de l'axe *b*. La distance de liaison moyenne autour des deux atomes de Rb heptacoordonnés est de 3.722 Å. Le spectre Raman polarisé présente les 36 modes attendus qui sont attribués aux quatre espèces de symétrie différente. Tous les modes se produisent avec des fréquences de moins de 112 cm^{-1}.

Introduction

In 1952 Brink and Stenfert Kroese (1) reported that Rb_2AgI_3 was isostructural with K_2AgI_3. We have undertaken the refinement of this structure because of the paucity of accurate measurements of Rb—I distances. The spectral work reported in this paper is part of a study on the lattice vibrations of moderately complex inorganic solids.

Procedures and Discussion

X-Ray Procedure

Following the method of Brink and Stenfert Kroese (1), crystals of Rb_2AgI_3 were grown from a warm saturated aqueous solution of RbI with AgI. The resulting colourless needles of Rb_2AgI_3 elongated along *b* were used for the structure refinement. Precession photographs showed orthorhombic symmetry and systematic absences $hk0$, $h = 2n + 1$; $0kl$, $k + l = 2n + 1$, indicating space groups *Pnma* or $Pn2_1a$. The former space group was assumed following Brink and Stenfert Kroese (1) and was found to give a satisfactory refinement. Accurate lattice parameters (Table 1) were obtained by a least-squares fit to the angular settings of 15 reflections ($20° < 2\theta < 30°$) measured on a syntex $P\bar{1}$ diffractometer with graphite crystal monochromated MoKα radiation ($\lambda = 0.71069$ Å). X-ray intensities of 2499 reflections in a single quadrant (hkl and $hk\bar{l}$) were measured on the same instrument from a crystal ground to a sphere of radius 0.05 mm. The intensities were corrected for absorption ($\mu R = 1.06$), Lorentz and polarization effects, and symmetry related reflections were averaged to give 1321 non-equivalent intensities.

†Measured by displacement in methylene iodide.

The atomic parameters taken from K_2AgI_3 (1) were then refined by the locally written full-matrix least-squares program CUDLS (CDC 6400) to yield final agreement indices $R_1 (= \sum ||F_o| - |F_c|| / \sum |F_o|) = 0.089$ and $R_2 (= \sum \omega (F_o - F_c)^2 / \sum \omega F_o^2)^{1/2} = 0.069$. In the final round $\omega = (\sigma_c^2 + (0.2F_o)^2)^{-1}$ where σ_c is the standard

*The temperature factor is given by $T = \exp(-2\pi^2 \Sigma_i \Sigma_j U_{ij} H_i H_j a_i^* a_j^*)$, where U_{ij} are the thermal coordinates.

deviation arising from the counting statistics. The final atom parameters are given in Table 2, those not fixed by symmetry were refined together with a scale factor and the parameter used in the extinction correction $F^* = F(1 + 1.3 \times 10^{-7} \times \beta(2\sigma)F^2)^{1/2}$ (2). The scattering curves for Rb^+, Ag^+, and I^- ions corrected for anomalous dispersion were taken from International Tables for X-ray Crystallography (3). The observed and final calculated structure factors have been placed in the Depository of Unpublished Data.[1]

Discussion of the Structure

Bond lengths and angles are presented in Table 3. Rb_2AgI_3 is isostructural with K_2AgI_3 which has been well described by Shoemaker (4). The temperature factors indicate no large anisotropic motion, the rms deviation of all atoms from their mean position lying between 0.15 and 0.21 Å. The temperature factor for Ag is slightly, but significantly larger than that of the other atoms, a result also found in K_2AgI_3 (5). A bond valence analysis (Table 4) gives valence sums around each atom that show a standard deviation of 0.07 valence units from the atomic valence. As in K_2AgI_3, the angles at the silver atom deviate significantly from tetrahedral but in a sense opposite to that usually found (6). The large I(bridging)—Ag—I(bridging) angle (116°) is determined by the b axis length while the smaller I(terminal)—Ag—I(terminal) angle (107°) is opposite the only edge of the tetrahedron that is shared with two other coordination polyhedra. Figure 1 shows a projection of the unit cell of Rb_2AgI_3 in the ac plane.

Polarised Raman Spectrum of Rb_2AgI_3

The factor group of crystalline Rb_2AgI_3 is

Ag—I(3)—Ag′	116.0(1)

D_{2h} for which the Raman active modes all have g symmetry and the infrared modes u symmetry. Since the AgI_3 moiety of the structure exists in the form of chains of corner shared AgI_4 tetrahedra it is inappropriate to divide the modes into internal and lattice modes. The number of Raman active modes and their symmetries are shown by factor group analysis to be

$$12A_g + 6B_{1g} + 12B_{2g} + 6B_{3g}$$

Following the procedure outlined by Adams and Newton (9) the translatory lattice modes are found to be

$$2A_g + B_{1g} + 2B_{2g} + B_{3g} + A_u + 2B_{1u} + B_{2u} + 2B_{3u}$$

of which $B_{1u} + B_{2u} + B_{3u}$ are the three acoustic modes. All 36 g modes are active and symmetry-allowed in the Raman spectrum.
