NICOLE MOREL-DESROSIERS and JEAN-PIERRE MOREL. Can. J. Chem. **59**, 1 (1981).

The Scaled Particle Theory (SPT) is probably the most powerful theory presently available, that enables the calculation of the thermodynamic functions relative to the formation of cavities in liquids. We give the general relationship between the enthalpy of vaporization and the enthalpy of formation of a molecular cavity in a pure normal liquid; the good agreement with the experimental data constitutes one of the strongest arguments justifying the application of SPT to real liquids. However, we show that SPT can lead to uncertain cavity terms if the molecular diameters of the studied liquids are not well-known. We compare, on the other hand, the cavity terms (G and H) calculated from Sinanoglu's theory, since this theory has been used to that end recently, with those obtained from SPT.

NICOLE MOREL-DESROSIERS et JEAN-PIERRE MOREL. Can. J. Chem. **59**, 1 (1981).

La "Scaled Particle Theory" (SPT) est sans doute la théorie la plus puissante disponible actuellement pour calculer les fonctions thermodynamiques relatives à la formation de cavités dans les liquides. Nous établissons la relation générale reliant l'enthalpie de vaporisation et l'enthalpie de création d'une cavité moléculaire pour un liquide normal; le bon accord avec l'expérience constitue un des meilleurs arguments justifiant l'application de la SPT aux liquides réels. Cependant, nous montrons que lorsque les diamètres moléculaires des liquides étudiés sont mal connus, la SPT peut conduire à des résultats incertains. Nous comparons d'autre part les termes de cavité (G et H) obtenus à l'aide de la théorie de Sinanoglu, théorie assez souvent utilisée à cette fin, avec ceux donnés par la SPT.

Introduction

Scaled Particle Theory (SPT) has often been applied, during the last years, to the investigation of solution properties. Recently, it has been used to predict Gibbs free energies, enthalpies, and entropies of transfer of large organic solutes from water to various solvents (1–3). The cavity terms calculated from SPT have also been compared (2, 3) to those obtained, unfortunately in an arguable way, from the macroscopic theory of Sinanoglu (4, 5) and the discrepancy between both sets of results has been used as the argument to question the validity of SPT.

After reading these controversial papers one feels it is necessary to recall some important points, unfortunately too often underestimated, relative to the application of SPT to real solutions and to clearly indicate some of its limitations. SPT is probably the most powerful theory available, at present, to calculate cavity terms corresponding to the introduction of a hard sphere at infinite dilution in a hard sphere fluid (6–8). We shall see that, without making use of any adjustable parameter, it leads, for a pure normal liquid, to an energy of cavity which is equal to the energy of vaporization of the liquid, this being a very important and severe criterion showing the validity of the theory. Of course, as soon as we leave the domain of simple molecules and try to apply SPT to sophisticated systems we cannot reasonably expect an accurate evaluation of the cavity terms. Consequently, we shall clearly indicate how dependent on the accuracy of the molecular parameters of the studied species the calculations are. We shall finally try to seriously compare the cavity terms calculated from SPT with those obtained from the theory of Sinanoglu, taking care to create in both cases cavities of comparable size.

Discussion

Theory

(a) Hard Spheres

The statistical mechanical theory of fluids employing distance scaling as a coupling procedure and hence called Scaled Particle Theory has been developed twenty years ago by Reiss *et al.* (6–8). The formalism of the theory has been extensively given in Reiss' comprehensive review (8). We shall only recall that SPT is concerned primarily with systems of particles having spherical symmetry and hard cores repelling one another with infinite force. It studies the probability that no molecule has its center within a spherical cell of radius r, this cavity being created, for instance, by insertion of a hard molecule of diameter σ_2 within the original fluid of molecules of diameter σ_1. The radius of the cavity is thus given by

$$[1] \qquad r = (\sigma_1 + \sigma_2)/2$$

This theory leads to an approximate expression for the reversible work expended in creating the

cavity (the expression is exact for $r \leq \sigma_1/2$). It also leads to an analytical expression for the equation of state of a hard sphere fluid which is exact up to the third virial coefficient, which agrees over the entire range of fluid density with the equations of state obtained through the medium of machine computation and which is identical to the equation of state obtained from the exact solution of the Percus–Yevick equation (8).

(b) Real Liquids

The theory is extended to the study of real liquids through the introduction of the experimental density and the use of the model which considers the attractive part of the intermolecular potential of a real liquid as acting primarily to establish the density, i.e., the volume of a pseudo-container to which the molecules are confined (8). The real liquid in this pseudo-container may then be considered as a hard sphere fluid which is susceptible to treatment by SPT. However, although the theory gives the possibility to take implicitly into account the soft part (non-hard-core part) of the intermolecular potential of real solvents it requires that the solute molecule be like a hard billiard ball which interacts with solvent molecules only through their hard cores (8).

To check the validity of SPT when applied to real liquids, we shall now limit ourselves to the study of a pure liquid and derive the general relationship between the enthalpy of cavity and the enthalpy of vaporization.

We shall first consider the vaporization, under normal conditions (25°C, 1 atm), of a pure liquid to the ideal vapor. Assuming the internal degrees of freedom are the same in both phases, i.e. limiting our study to the particular case of a normal liquid, and using the results of statistical thermodynamics as expressed by Pierotti (9) for the decomposition of the chemical potentials, we can write

$$[2] \qquad \mu_g^0 = RT \ln q^{-1} + RT \ln \rho_g \Lambda^3$$

$$[3] \qquad \mu_l^0 = RT \ln q^{-1} + \mu_c^0 + \mu_i^0 + RT \ln \rho_l \Lambda^3$$

where $\rho_g = P^0/kT$ and $\rho_l = N/V^0$, P^0 being the pressure (1 atm), T the temperature, V^0 the molar volume of the liquid, k Boltzmann's constant, N Avogadro's number, and R the gas constant. Λ is the thermal de Broglie wavelength and q is the molecular partition function for the internal degrees of freedom. μ_c^0 is the chemical potential corresponding to the creation of a cavity at some fixed position in the fluid whereas μ_i^0 is the chemical potential corresponding to the interaction of one molecule, introduced into the cavity, with the neighbouring molecules. For the molar free energy of vaporization we thus have

$$[4] \qquad \Delta G_v^0 = \mu_g^0 - \mu_l^0 = RT \ln (P^0 V^0/RT) - \mu_c^0 - \mu_i^0$$

By simple derivation we get the standard molar enthalpy of vaporization

$$[5] \qquad \Delta H_v^0 = - H_c^0 - H_i^0 - \alpha RT^2 + RT$$

where H_c^0 and H_i^0 are the enthalpies of cavity and of interaction, respectively, and α is the coefficient of thermal expansion of the pure liquid.

We shall now look at the interaction term. It follows from statistical mechanics that the molar energy of vaporization of a normal liquid is approximately given by (10)

$$[6] \qquad \Delta E_v \simeq -\frac{N\rho}{2} \int u(r) g(r) 4\pi r^2 \, dr$$

where $u(r)$ is a pairwise additive intermolecular potential energy and $g(r)$ is the radial distribution function. On the other hand, the molar energy of interaction can be written as

$$[7] \qquad E_i = N\rho \int u(r) g(r) 4\pi r^2 \, dr$$

Hence, it follows that for such a liquid

$$[8] \qquad \Delta E_v = - E_i/2$$

as qualitatively described by Eyring (11) many years ago. By introducing into eq. [8] the relation $E = H - PV$ we simply get, under standard conditions (since the vapor is ideal and the PV terms for the liquid phase are negligible),

$$[9] \qquad H_i^0 = 2RT - 2\Delta H_v^0$$

Finally, by introducing eq. [9] into eq. [5] we get the following relation for the standard molar enthalpy of vaporization

$$[10] \qquad \Delta H_v^0 = H_c^0 + \alpha RT^2 + RT$$

This general equation should be satisfied by any theory leading to cavity terms.

Let us then check to which extent SPT can satisfy it, the enthalpy of cavity of the pure liquid being given, under standard conditions, by

$$[11] \qquad H_c^0 = \alpha RT^2 \left(\frac{y}{1-y}\right) \times \left\{\frac{6}{(1-y)} + \frac{9y}{(1-y)^2} + 1\right\}$$

where

$$[12] \qquad y = N\pi\sigma_1^3/6V^0$$

By introducing eq. [11] into eq. [10] we get

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

$$[13a] \quad \Delta H_v^0 = RT + \alpha RT^2 + \alpha RT^2\left(\frac{y}{1-y}\right) \times \left\{\frac{6}{(1-y)} + \frac{9y}{(1-y)^2} + 1\right\}$$

$$[13b] \quad = RT + \alpha RT^2\left\{\frac{(1+2y)^2}{(1-y)^3}\right\}$$

Reiss *et al.* (7) have arrived at eq. [13*b*] from a completely different starting-point. In fact, they studied the gas–liquid equilibrium at saturation pressure and differentiated along the line of coexistence between liquid and vapor phases to get the enthalpy of vaporization at this pressure. At the same temperature, their equation and ours give the same result since ΔH_v and α are almost pressure-independent. Wilhelm and Battino (12) have shown that the ΔH_v calculated from Reiss' equation for nonpolar, normal liquids are in good agreement (better than 10%) with the experimental enthalpies of vaporization. This constitutes a severe criterion showing the validity of SPT for the determination of the enthalpy of cavity of real simple systems. More recently, the study of the enthalpy, volume, and heat capacity of cavity of adamantane and of cyclohexane in cyclohexane, *n*-hexane, and carbon tetrachloride has also provided an interesting test of the validity of SPT for simple liquids (13).

Unfortunately, it is much less evident to check whether or not SPT gives satisfactory results when applied to the creation of a spherical cavity into liquids involving strong, directional, and nonadditive interactions. For such liquids, the enthalpy of vaporization method cannot serve as a test since eq. [8] is valid for "normal" liquids only. The enthalpy of vaporization test implies that the "solute" introduced into the cavity is simply one molecule of solvent (since we study pure liquids). Since SPT imperatively requires that the solute be as hard and spherical as possible, it obviously appears that this test cannot be used for liquids such as alcohols, water, dimethyl sulfoxide, etc.

With these solvents, one can look at binary solutions, provided the solute is almost hard sphere. The method devised by Pierotti (14) and using the solubility measurements of many simple gases in various solvents for the determination of the diameter of the solvent molecules constitutes an excellent test of the validity of SPT whatever the solvent. Pierotti has shown that the diameter of water determined in this manner (2.75 Å) is in excellent agreement with the value deduced from second virial coefficient (15). Wilhelm and Battino (16) and de Ligny and van der Veen (17, 18) have used this method to determine the diameter of many polar and nonpolar solvents. The results they have obtained, even for solvents involving strong interactions (e.g., methanol, ethanol, acetone, ...), are in very good agreement with the diameters deduced from various methods (19). Such an agreement for many polar substances cannot be fortuitous and, hence, seems to show that, provided the studied solute is as hard sphere as possible, SPT can also be used for the calculation of cavity terms in solvents involving nonadditive interactions.

We must note, however, that the gaseous solutes used in Pierotti's method are of rather small size. This is a fortunate situation since there seems to be, as we shall see, some restriction on the size of the hard sphere solute when we apply the original version of SPT to solvents involving strong interactions. This has been shown after Stillinger (20) has improved upon SPT original version in the particular case of pure water by explicitly incorporating surface tensions and radial distribution functions. Lucas and Bury (21) have compared the original SPT with Stillinger's modified version for the free energies, enthalpies, and entropies of transfer of hard sphere solutes of various sizes from gaseous state to water at infinite dilution, at 4°C. They have concluded that both versions lead to cavity terms which are pretty close (less than 10% difference) provided σ_2 is smaller than 4 Å. Unfortunately, such a comparison cannot be done, at present, for other liquids involving strong interactions since Stillinger's version requires the knowledge of the radial distribution function and its derivative with temperature.

Anyhow, it seems that SPT can give, provided the solutes are judiciously chosen, satisfactory cavity terms in all solvents. One must, however, be aware of the fact that the calculated cavity terms are extremely dependent on the uncertainty of the molecular diameters of the involved species. Desrosiers and Desnoyers (22) have shown the tremendous dependence of the volume and of the heat capacity of cavity on the diameter of the solvent molecules. Let us now examine the behaviour of the free energy and of the enthalpy.

Uncertainty of the Calculated Cavity Terms

According to SPT the free energy of cavity is given by

$$[14] \quad G_c = K_0 + K_1 r + K_2 r^2 + K_3 r^3$$

where

$$K_0 = RT\left\{-\ln(1-y) + \frac{9}{2}\left(\frac{y}{1-y}\right)^2\right\} - \frac{N\pi\sigma_1^3 P}{6}$$

$$K_1 = -\frac{RT}{\sigma_1}\left\{6\left(\frac{y}{1-y}\right) + 18\left(\frac{y}{1-y}\right)^2\right\} + N\pi\sigma_1^2 P \qquad [15]$$

$$K_2 = \frac{RT}{\sigma_1^2}\left\{12\left(\frac{y}{1-y}\right) + 18\left(\frac{y}{1-y}\right)^2\right\} - 2N\pi\sigma_1 P$$

$$K_3 = \frac{4}{3}N\pi P$$

r being calculated from eq. [1] and y from eq. [12].

The enthalpy of cavity is then

$$H_c = \alpha RT^2\left(\frac{y}{1-y}\right) \times \left\{\frac{6B}{(1-y)} + \frac{36yD}{(1-y)^2} + 1\right\} \qquad [16]$$

where

$$B = 2(r/\sigma_1)^2 - (r/\sigma_1)$$
$$D = (r/\sigma_1)^2 - (r/\sigma_1) + 1/4 \qquad [17]$$

The calculated cavity terms are extremely sensitive to the choice of the diameter of the studied solvent since σ_1 is raised to the sixth power in the calculations. To illustrate this phenomena we have calculated the free energies and the enthalpies of cavity corresponding to the introduction of an arbitrary solute of $\sigma_2 = 4$ Å into four rather different solvents (H_2O, CH_3OH, DMSO, c-C_6H_{12}). We have varied σ_1 by ± 0.1 Å around Wilhelm and Battino's values (16). These results are reported in Fig. 1 and the various parameters used for the calculations are given in Table 1. We see that for a $\delta\sigma_1$ as small as 0.1 Å G_c and H_c can vary by as much as 4 kJ mol^{-1}. This corresponds to a relative uncertainty of 10 to 20% for G_c and of 20 to 30% for H_c depending on the solvent. Furthermore, the uncertainty may be much larger for transfer functions.

On the other hand, it is easy to show from eqs. [14] and [16] that the cavity terms are much less sensitive to the choice of the diameter of the solute. For $\delta\sigma_2 = \pm 0.1$ Å (around $\sigma_2 = 4$ Å) G_c and H_c vary by about 0.5–1.0 kJ mol^{-1}, this corresponding to a relative uncertainty of 4% for each function. However, for a transfer process the uncertainty due to $\delta\sigma_2$ almost cancels.

Finally, we must add that since H_c is directly proportional to α it is necessary to know the thermal expansion coefficient of the pure solvent with good accuracy.

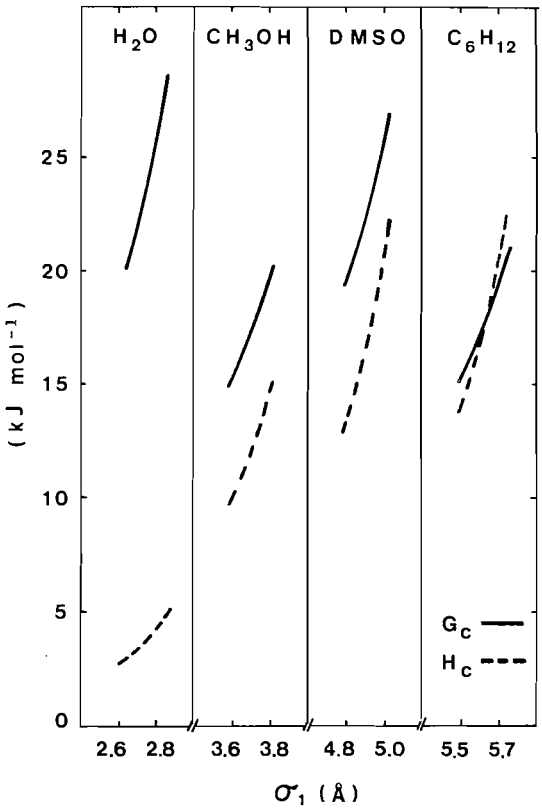

FIG. 1. Variation of the free energy and of the enthalpy of cavity with the diameter of the solvent σ_1, for a solute of $\sigma_2 = 4$ Å in water, methanol, dimethyl sulfoxide, and cyclohexane, at 25°C.

Since the uncertainty in the calculated terms can be very important, it is necessary to be extremely cautious when applying SPT to real systems especially if their molecular parameters are not very well-known. The interaction terms obtained by subtracting the cavity terms from the experimental thermodynamic functions (1, 2) may thus be very dubious and their interpretation hazardous.

Comparison of Cavity Terms Calculated from SPT and from Sinanoglu's Theory

The validity of SPT has been questioned recently (2, 3) on the sole basis of the discrepancy observed between two sets of cavity terms: those calculated from SPT and those obtained from the theory of Sinanoglu (4, 5). Unfortunately, this comparison was misleading since cavities of very different sizes were created in both cases (SPT calculations were done for a solute of $\sigma_2 = 8.4$ Å or $N\pi\sigma_2^3/6 = 187$ cm^3 mol^{-1} whereas Sinanoglu's theory was applied to a solute volume of 296 cm^3 mol^{-1}). thermore, one can wonder if it is realistic to expect the results obtained from a macroscopic theory (relating the bulk surface tension to the energy of formation of a molecular-sized cavity) to be as meaningful as or comparable to those obtained from a theory based on statistical mechanics and using molecular parameters. Anyhow, it can be interesting to calculate both sets of terms in a less questionable way.

The central idea of the development of Sinanoglu's theory is that the work W of expanding the spherical cavity radius from r to $r + \partial r$ can be written as a sum of a volume and a surface contribution. For sufficiently large r it follows that

$$[18] \quad W(r) \simeq \tfrac{4}{3}P\pi r^3 + 4\pi r^2\gamma$$

γ being a surface tension. For cavities of microscopic size a term accounting for the curvature dependence of the surface work must be added. It is important to note, at this point, that γ does not represent the interfacial tension between a liquid and its vapor since the cavity is not a bubble filled with vapor. In fact, the creation of a cavity in a liquid is equivalent to the introduction of a hard sphere and, hence, γ is the interfacial tension between the liquid and a rigid wall (8).

Starting on this basis and neglecting the volume work, Sinanoglu (4) gives for the free energy of cavity formation the following relation

$$[19] \quad G_c = K_1^e S\gamma(1 - X)$$

$$[20] \quad X = \left(1 - \frac{K_1^s}{K_1^e}\right)\left\{\frac{\partial \ln \gamma}{\partial \ln T} + \frac{2}{3}\alpha T\right\}$$

where S is the geometric surface area and α the coefficient of thermal expansion of the cavity. K_1^e and K_1^s are the constants adjusting the planar surface energy and entropy to highly curved microscopic dimensions. The following approximations are made: γ and α are assumed equal to the surface tension and to the coefficient of thermal expansion of the pure solvent. It is hard to estimate the importance of such approximations but we know that the uncertainty in γ will be of primary importance since G_c is directly proportional to the surface tension. With this theory the solvent is a continuum and, hence, the radius of the cavity is assumed equal to the radius of the solute ($r = \sigma_2/2$). Then,

$$[21] \quad S = 4\pi r^2 = 4.836 v_2^{2/3}$$

v_2 being the intrinsic volume of one molecule of solute. Hence, according to Sinanoglu, it follows that the molar free energy of cavity, expressed in J mol^{-1}, is given by

$$[22] \quad G_c(\text{J mol}^{-1}) = 6.023K_1^e 4.836 v_2^{2/3}\gamma_1 \times \left\{1 - \left(1 - \frac{K_1^s}{K_1^e}\right)\left(\frac{\partial \ln \gamma_1}{\partial \ln T} + \frac{2}{3}\alpha_1 T\right)\right\}$$

γ_1 being in dyn cm^{-1} and v_2 in Å^3. In ref. 4 it is indicated that if the solute is not a liquid v_2 is estimated from space-filling models or from X-ray structures whereas if it is a liquid v_2 is obtained from the experimental density d_2 of the liquid. The latter seems rather peculiar since it is straightforward, because of the compacity of the liquid, that

$$[23] \quad v_2 = \tfrac{4}{3}\pi r^3 \neq V_2^0/N = M_2/d_2 N$$

M_2 being the solute molecular weight. One should instead rely, for liquid solutes, on the molecular diameters determined from viscosity data, second virial coefficients, or deduced from various theories of statistical mechanics (19). By no way should v_2 be confused with the experimental molar volume V_2^0 and, *a fortiori*, with a partial molar volume. Abraham and Nasehzadeh (2) have used the partial molar volume of Ph_4As^+ in water (Millero's value (23): 295.6 cm^3 mol^{-1}) instead of the intrinsic volume ($N\pi\sigma_2^3/6 = 187$ cm^3 mol^{-1} (1)) to calculate, using Sinanoglu's theory, the cavity terms of Ph_4As^+ in various solvents. Accordingly their calculated results cannot represent cavity

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

terms and, hence, cannot be compared to SPT results.

The main problem with Sinanoglu's theory is the determination of the constants K_1^e and K_1^s. These functions are approximately given, for nonpolar solvents, by the following relation empirically deduced from the solubility and mixing data of asymmetric systems (5) (K_1 corresponding either to K_1^e or K_1^s)

$$[24] \quad K_1 = 1 + \left(\frac{v_1}{v_2}\right)^{2/3} [K_1(1) - 1]$$

where v_1 and v_2 are the molecular volumes of the solvent and solute, respectively, and $K_1^e(1)$, $K_1^s(1)$ are the adjustable microscopic cavity factors for the pure solvent. The way $K_1^e(1)$ and $K_1^s(1)$ are evaluated is not clearly indicated in Sinanoglu's papers but some of these factors are tabulated, for many common solvents, in ref. 5. Sinanoglu (24) stipulates that these can be used wherever v_1 and v_2 are roughly comparable. To use these factors with very small σ_2 can lead, for many solvents, to negative K_1^e and K_1^s values (which can even be pretty large) and, consequently, to negative free energies and energies of cavity. Furthermore, it is impossible (whereas it is easy to do it with SPT) to estimate the free energy of cavity for a point solute ($\sigma_2 = 0$).

Finally, Sinanoglu uses eq. [24] for polar solvents as well without indicating, however, the uncertainty in K_1^e (directly reflected on G_c) resulting from such an approximation.

The molar energy of cavity is given (4) by the following relation

$$[25] \quad E_c(\text{J mol}^{-1}) = 6.023 K_1^e 4.836 v_2^{2/3} \gamma_1 \times \left\{1 - \frac{\partial \ln \gamma_1}{\partial \ln T} - \frac{2}{3}\alpha_1 T\right\}$$

Using eqs. [22] to [25] (assuming $H_c \simeq E_c$) we have thus calculated the free energy and the enthalpy corresponding to the creation of cavities of diameter increasing from 1 to 10 Å (being aware, for the reasons mentioned in the preceding paragraph, that the results for very small σ_2 may not be meaningful) in two very different solvents: water and cyclohexane. To perform these calculations we have used Sinanoglu's microscopic cavity factors and the physical properties of pure solvents given in Table 1. The molecular volume v_2 is obtained from $\pi\sigma_2^3/6$ whereas the molecular volume of the solvent v_1 is calculated (*a*) from the diameter σ_1 given in Table 1 and, for comparison, (*b*) from (as does Sinanoglu) the molar volume of the pure solvent V_1^0. We have reported all the calculated results

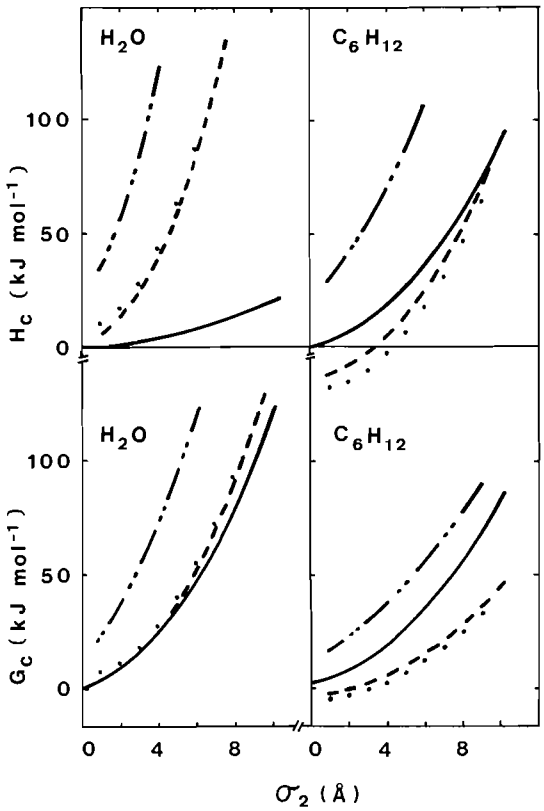

FIG. 2. Comparison of free energies and enthalpies of cavity calculated from SPT (—) and from Sinanoglu's theory (with $r = \sigma_2/2$ and the molecular diameter of the solvent (---); with $r = \sigma_2/2$ and the molar volume of the solvent (· · ·); with $r = (\sigma_1 + \sigma_2)/2$ (----)).

on Fig. 2 along with, for comparison, the corresponding STP cavity terms. We see that the two ways of evaluating v_1 (which appears only in eq. [24]) lead to not very different cavity terms. It is difficult to give the definition of the surface area of a cavity of microscopic dimensions (25). This is why we have also tried to perform the calculations by using eq. [1] to evaluate the cavity radius. The results of Fig. 2 show that G_c and H_c values increase very much by going from $r = \sigma_2/2$ to $r = (\sigma_1 + \sigma_2)/2$.

If we consider the particular process corresponding to the introduction of a molecule of cyclohexane ($\sigma_2 = 5.63$ Å) into pure cyclohexane, we see that H_c calculated from Sinanoglu's theory does not satisfy very well the general equation (eq. [10]) relating the enthalpy of vaporization and the enthalpy of cavity of pure normal liquids whereas the SPT term does ($\Delta H_v(\text{calcd})/\Delta H_v(\text{exp}) = 0.74$ with Sinanoglu's theory and 1.06 with SPT). SPT terms are probably the best cavity terms we can

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

get, at present, and as mentioned previously it may not be realistic to compare them with the cavity terms calculated from the macroscopic theory of Sinanoglu. Hence, we shall not analyse the results of Fig. 2 any more but only mention that the agreement between Sinanoglu (with $r = \sigma_2/2$) and SPT terms is, surprisingly, not so bad (except for H_c in water).

Sinanoglu's theory can thus be used to get gross approximations of the cavity terms but should never be preferred to SPT when the parameters necessary to apply the latter are known or can be evaluated (2, 3, 26).

Conclusion

The application of SPT, because of the bases of the theory, is restricted to the following species: (*a*) the solute must be as hard and spherical as possible and must not, of course, have strong and directional interactions with the solvent molecules. When such interactions are involved, the additivity of the cavity and interaction terms is itself arguable. (*b*) the solvent may be any real liquid. We have underlined, however, the tremendous importance of knowing the diameter of the solvent molecules with good accuracy. Since the various methods allowing the determination of the diameter lead to slightly different results, it is a coherent choice to determine it by applying SPT to gas solubility data (Pierotti's method).

Provided these conditions are respected and one is aware of the possible uncertainty in the results, SPT is the most powerful theory available, at present, to evaluate the thermodynamic data relative to the formation of spherical cavities in real liquids.

Rate processes and nuclear magnetic resonance spectra of amine·SO_2 complexes + H_2O in liquid SO_2

KONRAD T. WU[1] AND ANDREW J. YENCHA[2]

Department of Chemistry, State University of New York at Albany, Albany, NY 12222, U.S.A.

Received March 10, 1980

KONRAD T. WU and ANDREW J. YENCHA. Can. J. Chem. **59**, 8 (1981).

A ^1H dnmr study has been performed on a series of addition compounds formed from the gaseous reactions of di- and trimethyl amine and triethyl amine with sulfur dioxide in the presence of a small amount of water in a liquid sulfur dioxide solvent. The dynamic system involves an equilibrium of the general form: amine·H^+ ⇄ amine·SO_2. The activation parameters for the exchange process were calculated. Large positive entropies of activation were found in the present systems that strongly suggest the formation of an ion pair in the transition state in which the activation process is controlled largely by solvation effects.

KONRAD T. WU et ANDREW J. YENCHA. Can. J. Chem. **59**, 8 (1981).

Faisant appel à la rmn dynamique du ^1H, on a étudié une série de composés d'addition formée au cours de réactions en phase gazeuse entre les di- et tri-méthylamines et triéthylamine et le bioxyde de soufre en présence d'une faible quantité d'eau dans du bioxyde de soufre liquide comme solvant. Le système dynamique implique un équilibre général de la forme: amine H^+ ⇄ amine·SO_2. On a calculé les paramètres d'activation de la réaction d'échange. Dans ces systèmes, on a trouvé que les entropies d'activation sont fortement positives; ceci suggère qu'il y a formation d'une paire d'ions dans l'état de transition dans lequel le processus d'activation est principalement contrôlé par des effets de solvatation.

[Traduit par le journal]

Introduction

It is well known that the protonation of an amine in aqueous solution is a diffusion controlled process (1). Steric hindrance arising from solvation and from formation of the transition-state complex has a noticeable effect on the rate of protonation (2), since the proton-transfer step is so fast that other steps become rate-determining. This steric effect has recently been shown to be responsible for the dramatic reduction in rate (3, 4) and for the large increase in entropy of activation (4) in various cases of protonation of nucleophilic addition reaction of amines. We wish to report an example of a similar type of reaction, i.e. protonation of a charge-transfer complex (amine·SO_2). We have examined this interesting effect employing dynamic nuclear magnetic resonance (dnmr) spectroscopy, which affords additional thermodynamic data and structural information on the protonation processes.

The dnmr method (5) has been used widely for the studies of intra- and intermolecular equilibrium processes of chemical systems involving the transfer of components of ions and molecules among different chemical environments in the solution phase. All of these studies deal with structural rearrangement of chemical exchange processes, either with or without changes in chemical bonding. The dnmr studies of the chemical system of amine·SO_2 + H_2O reported here involve more than one kind of exchange process taking place on the same temperature scale. From the observed dnmr spectra, some properties of these exchange processes can also be understood.

Experimental

The reactions between amines and sulfur dioxide to give molecular complex formation have been studied for many decades (6). Based on careful considerations on the active chemical nature of the species involved in this study and on the solubility of the substances under investigation, liquid sulfur dioxide was chosen as the solvent for this study. Liquid sulfur dioxide has been known as an excellent solvent for many years. A recent detailed discussion of its solvent properties has been given by Burow (7). An extremely successful use of liquid SO_2 as a solvent in nmr studies was demonstrated in the analyses of geometrical configurations of the cyclobutane protons in the study of the photodimers of coumarin and *N*-methylcarbostyril (8). The high solubility of the amine·SO_2 complexes in liquid SO_2 makes it appropriate as a solvent in the present study.

The reactions between the various amines and sulfur dioxide were carried out in a flask on a vacuum system. The mixing of the two reagents resulted in the rapid formation of particles in the gas phase with the evolution of considerable heat. The similar reaction of ammonia with sulfur dioxide has been shown to produce a heat of reaction of −125.5 kJ/mol (9). The reaction products were collected in an nmr tube mounted directly below the reaction vessel. The reaction system was then evacuated and the nmr tube containing the sample cooled to −78°C. Gaseous SO_2 was then slowly bled into the system where it was liquified in the sample tube. A small amount of liquid water (~2% by volume) was added through a septum in the reaction flask using a syringe and needle. The nmr tube was then sealed off and allowed to warm to room temperature.

Elemental analyses of the reaction products between di- and trimethyl amine (DMA and TMA) with SO_2 indicated the formation of a 1:1 adduct. Pure $(CH_3)_2NH·SO_2$ was a yellowish oily

liquid with the following elemental makeup (*Anal.* calcd.: C 22.01, H 6.46, N 12.83, S 29.38, O 29.32; found: C 21.55, H 6.61, N 12.47, S 29.85, O 27.81). The product $(CH_3)_3N{\cdot}SO_2$ was a white crystalline material whose elemental analysis yielded the following results (*Anal.* calcd.: C 29.25, H 7.37, N 11.37, S 26.03, O 25.98; found: C 29.56, H 7.54, N 11.55, S 26.20, O 25.82). Analysis of the reaction product between triethyl amine (TEA) and SO_2 was not performed. The white solid product obtained from the reaction of monomethyl amine (MMA) and SO_2 was found not to dissolve in liquid SO_2, which might indicate the formation of a polymeric compound.[3]

^1H nmr spectra were recorded using a 60-MHz Varian A-60A spectrometer in conjunction with a Varian V-4340 variable temperature probe. Temperature calibration was determined in the usual manner with methanol. A quadratic equation was used to fit the results (12). The readings were accurate to ±2–3°C.

Computed dnmr spectra of the di- and trimethyl amine systems were obtained through the use of the classical two-site line shape equations, modified by generating the coalescing multiplets for the corresponding components (5*f*). The signal strength was plotted against the frequency after proper normalization. Simulation spectra were obtained by adjusting the rate constant parameter for the exchange process until a good fit was achieved between the computed and experimental spectra. Linear relationships were assumed for both the population of the species (namely the equilibrium constant dependence) and the linewidth with temperature (13). The equilibrium concentration ratios, amine·H^+/amine·SO_2, at low temperatures were estimated by measuring the peak area of each species. Linear extrapolation ($\log k$ vs. $1/T$) was then made to obtain the population ratios at higher temperatures. The chemical shift difference ($\Delta\nu$) was also assumed to depend linearly upon temperature. Those values at fast exchange rates were thus similarly obtained by extrapolation. Ten experimental points were used in each case for such extrapolation measurements.

The gaseous reactant materials mono-, di-, and trimethyl amine and sulfur dioxide were obtained from Matheson Gas Products. Triethyl amine was obtained from the Eastman Kodak Co. All were of high purity, and no purification was performed.

Results and Discussion

The ^1H dnmr spectra of the TMA and DMA compounds at various temperatures together with the matching calculated spectra for the corresponding exchange rates are shown in Figs. 1 and 2, respectively. The identity of the ionic and complex amine compounds at low temperatures were established by obtaining the spectra in the presence of large amounts of water and in the absence of any water. In the former case, only alkylammonium ion exists. For the latter, the amine·SO_2 charge-transfer complex was the only product species found. The multiplets for the methyl groups attached to nitrogen in the ionic forms were further checked using a 100-MHz spectrometer to confirm that the splittings were caused by the indirect coupling of the N–H protons. At low temperature these components are separated by 5.6 Hz for the dimethylammonium ion and 5.1 Hz for the trimethylammonium ion, which are almost identical to those in aqueous solution (14). The rate of proton exchange increases with increasing temperature resulting in the coalescence of the multiplet components. At the same time, it is observed that the alkylammonium ion and complex compound sig-

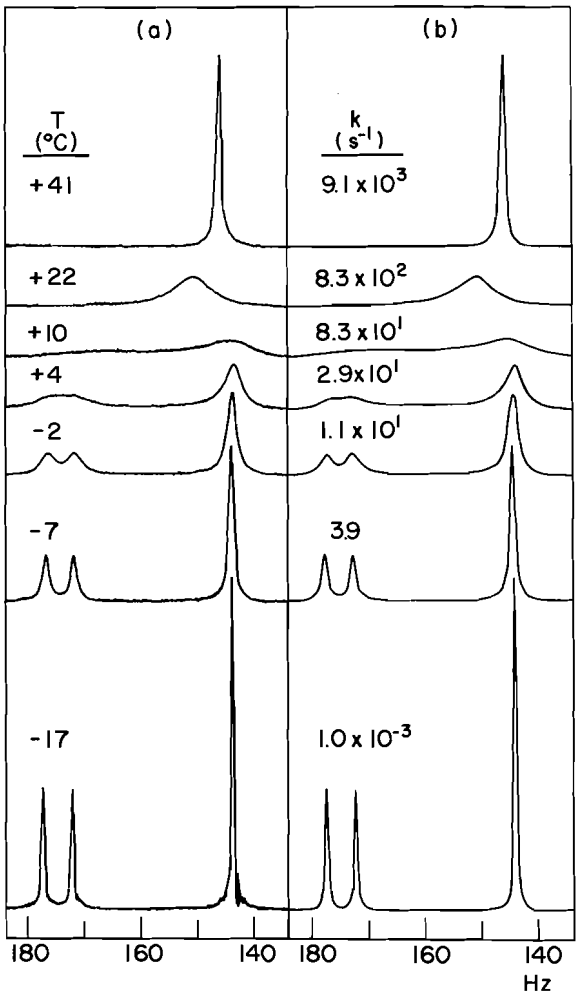

FIG. 1. Experimental 60-MHz ^1H dnmr spectra (*a*) of trimethyl amine·SO_2 + H_2O in liquid SO_2 at various temperatures and the corresponding simulated line-shape spectra, (*b*) with the rate constants for ion–complex exchange.

[3]Kinumaki and Hata (10) have proposed that the reaction of MMA and SO_2 proceeds as follows:

[*i*] $3CH_3NH_2 + 3SO_2 \rightarrow (CH_3NH_3)_2S_2O_5 + CH_3NSO$

where the pyrosulfite product, $(CH_3NH_3)_2S_2O_5$, is a solid and the product CH_3NSO, methylthionylamine, is a gas at room temperature. Since a pyrosulfite is expected to dissolve in liquid SO_2 that contains a small amount of water by virtue of the formation of a sulfite ion according to the equilibrium (11)

[*ii*] $S_2O_5^{2-} + H_2O \rightleftarrows 2HSO_3^-$

it does not appear that the solid product is a pyrosulfite.

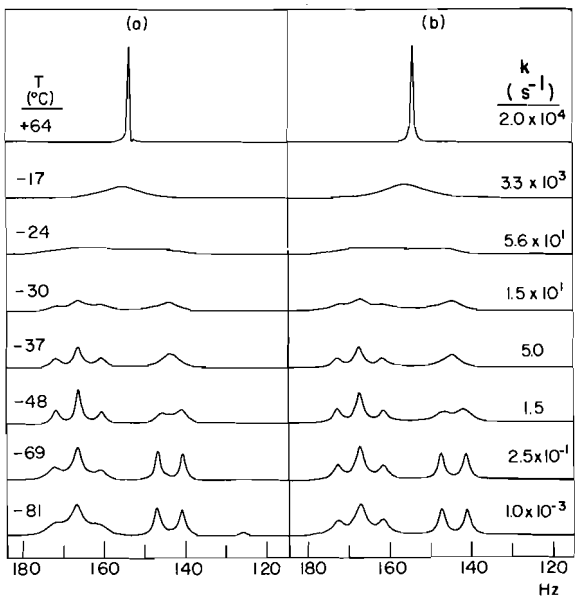

FIG. 2. Experimental 60-MHz ^1H dnmr spectra (*a*) of dimethyl amine·SO_2 + H_2O in liquid SO_2 at various temperatures and the corresponding simulated line-shape spectra, (*b*) with the rate constants for ion–complex exchange.

nals also collapse. This is obviously caused by the exchange of nuclei between different molecules. The broadening of the methyl signals at these intermediate exchange rates is due to the competition between hydrogen bonding to nitrogen and N—S charge-transfer bonding. Beyond these coalescing points, the signal shifts gradually towards higher fields, which results from increased dissociation of the complex compound. All observed exchange processes are reversible in the temperature range of interest.

The N—H proton absorptions of the ionic compounds (not shown in Figs. 1 and 2) were extensively broadened due to quadrupole effects. Integration of their signal strengths, however, confirmed their identity. The broadening of both the N—H proton absorption and the methyl signals of these ionic compounds give some definite indication about the exchange process between the ionic and non-ionic species. The small amount of water present in these systems may play some part in this process. The absence of an acidic proton signal in the spectra may be due to broadening resulting from a rapid equilibrium process. A similar feature has been observed previously in the literature (15). The N—H proton absorption signal of the $(CH_3)_2NH{\cdot}SO_2$ complex (not shown in Fig. 2) was broad in the absence of exchange, undetectable in the transition region, and a sharp line at fast exchange rates. No clear spectral pattern was observed for these N—H proton absorptions, thus a quantitative evaluation of the exchange broadening of these lines was judged to be impracticable.

The spin coupling of the methyl groups with the N—H proton of the DMA·SO_2 complex was also observed at low temperature (see Fig. 2). This coupling constant was measured to be 6.0 Hz. It has been observed that the small peak at 125.6 Hz emerges from beneath the charge-transfer complex peak as the temperature is lowered. Since this peak is quite different from the charge-transfer peak in both amplitude and shape (singlet vs. doublet) at low temperatures, the observed spectral pattern is thus not likely a result of a conformational effect due to a rotational process. The relative shift of these two bands was found to be concentration-dependent. Therefore, this small peak may arise from a polymeric aggregate. Because this peak appears at a much higher field than the doublet of $(CH_3)_2NH{\cdot}SO_2$, the structure of $[(CH_3)_2NH]_n{\cdot}SO_2$ is preferred rather than $[(CH_3)_2NH{\cdot}SO_2]_n$. A similar complex has been found (16) to be formed in the reaction of ammonia with SO_2 in the presence of H_2O. It seems to support our interpretation.

In Fig. 3 are shown the nmr spectra of the TMA compound dissolved in liquid SO_2 with D_2O added (upper trace) and H_2O added (lower trace) at −17°C. From this comparison it is clear that the low-field doublet in the H_2O added system is due to spin–spin splitting of the methyl protons of the ionic compound by an attached proton on the nitrogen atom. The two small peaks indicated by arrows in the D_2O added case are due to a small amount of H_2O impurity in the starting reactant materials. The line-widths of the deuterium compound system are expectedly broader than those of the hydrogen ones.

The dnmr spectra of the TEA system are shown in Fig. 4. As in the cases of the DMA and TMA systems, proton absorptions are detected for the species $(CH_3CH_2)_3NH^+$ and $(CH_3CH_2)_3N{\cdot}SO_2$. In both cases the three ethyl groups are equivalent. At the highest temperature measured, two well-defined groupings appear. At high-field (about 125 Hz), a triplet is observed that is due to methyl protons, while at low-field (about 280 Hz) a quartet is shown that is due to methylene protons. Both of these absorptions represent averaged signals due to rapid exchange between the ionic and complex species. As the temperature is lowered, individual absorptions are observed for the different compounds. As was the case for the DMA and TMA systems, the ionic form is located at a lower field compared to the complex. This is clearly discernible in the methylene proton absorptions. The ex-

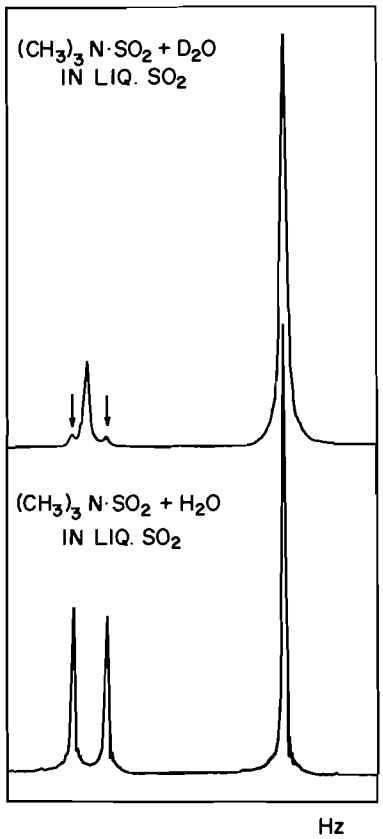

FIG. 3. Comparison of the 60-MHz ^1H nmr spectra at −17°C of $(CH_3)_3N{\cdot}SO_2$ dissolved in liquid SO_2 with D_2O added (upper trace) and H_2O added (lower trace). The two small peaks indicated by arrows in the D_2O added case are due to a small amount of H_2O impurity.

pected two triplet signals due to the methyl protons are not totally resolved in this figure but appear as an unsymmetrical quintet. For simplicity, the rate constant, as well as the free energy of activation at the coalescence temperature of this ion–complex exchange process, were estimated by the coalescing lineshape spectra of a two-site exchange system with unequal populations (5*f*).

In Table 1 are listed the free energies, enthalpies, and entropies of activation along with the Arrhenius activation energies for the ion–complex exchange process for various amine compounds. The $\Delta G_c^{\ddagger}$ values were calculated using the approximated rate constants at the coalescence temperature as given in Figs. 1, 2, and 4. The Arrhenius activation energy E_a for the ion to complex transformation processes for the DMA and TMA systems was determined from plots of log k versus reciprocal absolute temperature from the data given in Figs. 1 and 2. The $\Delta H_c^{\ddagger}$ and $\Delta S_c^{\ddagger}$ values given in Table 1 were calculated from the corresponding $\Delta G_c^{\ddagger}$ and E_a values in the standard way. Errors in the activation parameters were calculated (5*g*) from contributions of errors in rate constants, temperatures, and extrapolation.

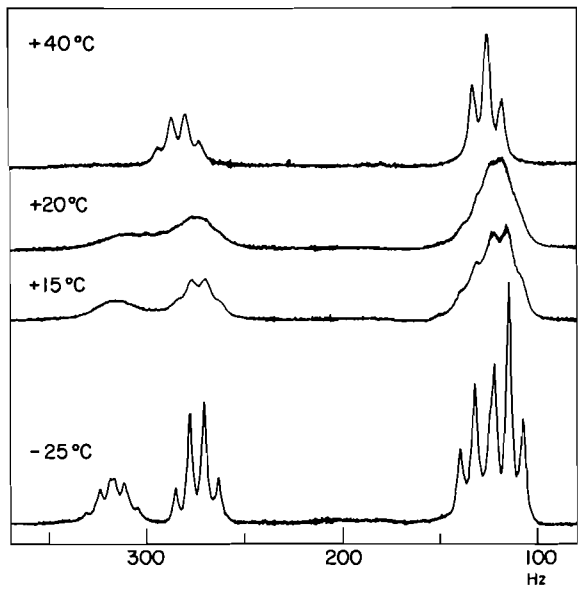

FIG. 4. Experimental 100-MHz ^1H dnmr spectra of triethyl amine·SO_2 + H_2O in liquid SO_2 at various temperatures.

Of considerable note in these data is both the sign and magnitude of the entropies of activation for the cases of DMA and TMA (213.4 ± 23.4 J/K mol and 187.9 ± 49.0 J/K mol, respectively). A positive entropy of activation means that the entropy of the activated complex is greater than the entropy of the reactants. To explain these rather unusual results, it is necessary to realize that we are dealing here with an ionic species that is being transformed into a neutral complex molecule. Solvation effects then are expected to play a major role in the entropy of activation. It is well known that electrostatic interactions in solution reactions have a profound effect on experimentally determined rate parameters (17). This is due to the fact that charged species are more strongly solvated than are neutral species. Thus, if one considers the entropy of activation of a charged reactant going to a less charged or neutral activated complex, a relative increase in entropy would be expected, hence, a positive entropy of activation. The magnitude of the entropy of activation tells us something about the type of electrostatic interaction that is operative in the formation of the activated complex, e.g. ion–dipole versus ion–ion interactions. It is predicted that reactions between oppositely charged ions will have a greater positive entropy of activation due to desolvation in the transition state (17).

TABLE 1. Free energies, enthalpies, and entropies of activation and Arrhenius activation energies for ion–complex exchange for various amine compounds*

Compound	T_c (K)	$\Delta G_c^{\ddagger}$ (kJ/mol)	$\Delta H_c^{\ddagger}$ (kJ/mol)	$\Delta S_c^{\ddagger}$ (J/deg mol)	E_a (kJ/mol)
DMA	249 ± 4	52.3 ± 1.7	105.4 ± 5.9	+213.4 ± 23.4	107.5 ± 5.9
TMA	283 ± 4	59.0 ± 1.7	112.1 ± 13.8	+187.9 ± 49.0	114.6 ± 13.8
TEA	293 ± 5	59.8 ± 2.5	nd	nd	nd

*nd = not determined.

A good example of this effect can be found in the reaction of 2,4,6-trimethyl pyridine (TMP) with iodine in nitrobenzene solvent to give the products $(TMP)_2I^+$ and I^- (18). The entropy of activation for this reaction was determined to be -211.7 ± 54.8 J/K mol. In many ways, the reverse of this reaction, namely iodine ion transfer, is quite analogous to the proton transfer reaction described here. Both the positive sign and magnitude of the entropy of activation of the reverse reaction agree with the results reported here.

By way of a contrast, consider the acid dissociation reaction of trimethylammonium ion in aqueous solution as follows:

[1] $(CH_3)_3NH^+ + H_2O \rightarrow (CH_3)_3N + H_3O^+$

In this case, Grunwald (19) found the entropy of activation to be +74.9 J/K mol compared to the +187.9 J/K mol found here for the acid dissociation for the same trimethylammonium ion but in liquid SO_2 solvent. This profound solvation effect has also been noted by Lichtin (20) in the entropy of activation for the dissociation of KBr in liquid SO_2. He reported a $\Delta S^{\ddagger}$ value of −154.0 J/K mol for this process.

Based on these considerations, we conclude that the formation of the activated complex in the ion → complex transformation involves, as the first step, a bimolecular reaction between a positively charged alkylammonium ion species and a negatively charged species produced from the dissociation of water in liquid SO_2 solvent.[4] The magnitude of the activation energies, as given in Table 1, seems to confirm the notion of electrostatic interaction contributions, for these experimentally determined values are some 25 to 30 kJ/mol higher than "normal" solution reactions and in general agreement with other known activation energies for oppositely charged ion–ion reaction systems (17).

The free energies of activation for the DMA, TMA, and TEA systems, as given in Table 1, suggest that steric factors may play a role in this exchange process. This steric effect may simply arise from different degrees of interference with the solvation of the protonated bases (2). Thus, it would not be unreasonable to rationalize that the formation of the transition state complex resulting from two differently charged species is the rate determining step in the conversion of the molecular ion into the molecular complex, during which solvation plays an important role.

[4]It is well known that H_2O and SO_2 react to produce a strong acid. However, the discussion of its chemical structure is ambiguous. Since the actual identity of the negative ion involved in the mechanism discussed here is not critical, it is thus not given specifically to avoid confusion.

Photo-oxidation of formic, acetic, and propionic acids with aqueous hydrogen peroxide[1]

YOSHIRO OGATA,[2] KOHTARO TOMIZAWA, AND KAORU TAKAGI

Department of Applied Chemistry, Faculty of Engineering, Nagoya University, Chikusa-ku, Nagoya, Japan

Received March 10, 1980

YOSHIRO OGATA, KOHTARO TOMIZAWA, and KAORU TAKAGI. Can. J. Chem. **59**, 14 (1981).

Photolytic oxidation of aliphatic acids with aqueous H_2O_2 has been studied. Formic acid gives CO_2 and H_2O. Acetic acid gives products containing CO_2, methane, formic, glycolic, and tartaric acids. Propionic acid gives CO_2, methane, ethane, acetic, formic, lactic, β-hydroxypropionic, malonic, and glycolic acids. A mechanism involving an initial H-atom abstraction by HO· formed via photo-dissociation of H_2O_2 is postulated and discussed.

YOSHIRO OGATA, KOHTARO TOMIZAWA et KAORU TAKAGI. Can. J. Chem. **59**, 14 (1981).

On a étudié l'oxydation photolytique des acides aliphatiques par du H_2O_2 aqueux. L'acide formique se décompose en CO_2 et H_2O. L'acide acétique donne un mélange de CO_2, de méthane et d'acides formique, glycolique et tartrique. L'acide propionique fournit du CO_2, du méthane, de l'éthane ainsi que les acides acétique, formique, lactique, β-hydroxypropionique, malonique et glycolique. On propose un mécanisme faisant intervenir au départ l'enlèvement d'un atome d'hydrogène par un HO· qui provient de la photodissociation de H_2O_2.

[Traduit par le journal]

Introduction

Recently, the removal of pollutants from waste water has become one of the biggest social problems. In this connection, the authors have reported previously on the photolysis of polyethylene glycol derivatives (1) and benzoic acid (2, 3) in the presence of H_2O_2. In general, lower aliphatic acids are resistant to ordinary chemical oxidation. The present paper deals with the photolysis of formic, acetic, and propionic acids with aqueous H_2O_2.

As to the photolysis of lower fatty acids with uv light (190–245 nm), formic acid gives hydrogen, carbon dioxide, and oxalic acid; acetic acid gives methane and carbon dioxide (4). No information is available on their oxidative photolysis, and we wish to report in the present paper the products and intermediates in the photolytic oxidation of these aliphatic acids with H_2O_2. The probable mechanism will be discussed on the basis of the observed products.

Results and Discussion

Acetic Acid (1)

In order to find the optimum conditions for the oxidation of acetic acid (**1**), the effect of the initial molar concentration ratio, $[H_2O_2]_0/[1]_0$, was examined under irradiation with 254 nm light (a Halos 60 W low-pressure Hg lamp). The estimation of H_2O_2 concentration was done iodometrically and that of **1** was performed with nmr and glc.

In the absence of H_2O_2, decomposition of **1** in aqueous solution did not occur after 15 h irradiation; hence, H_2O_2 was necessary for the decomposition of **1**; peracetic acid (CH_3CO_3H), which is expected from the acid-catalyzed reaction of **1** with H_2O_2, was not detected iodometrically after 15 h. Thus peracetic acid does not participate in this photolysis.

As shown in Table 1, the decomposition of **1** was almost complete with $[H_2O_2]_0/[1]_0 = 4.2$ after 15 h, but the efficiency of H_2O_2 for the decomposition of **1** was 0.23. This efficiency (0.23) is lower than the efficiency at the lower ratios, e.g., 0.47 at the ratio of 1.05, 0.31 at the ratio of 2.1, and 0.27 at the ratio of 3.15. This suggests that H_2O_2(or HO·) is consumed at higher concentration of H_2O_2 during later stages of the oxidation of **1** and/or by the self-decomposition to give O_2 and H_2O.

On the basis of the above results, the product analysis was carried out at the ratio of 4.21. The detected products were glycolic (**2**), tartaric (**3**), and formic acids (**4**), and methane and CO_2. The amounts of photolysis products (except for CO_2) from **1** varied with irradiation time and were so

TABLE 1. Effect of ratio of $[H_2O_2]_0/$[acetic acid (**1**)]$_0$ on the decomposition of **1** at 20°C[a]

$[H_2O_2]_0/[1]_0$	Irradiation time (h)	Dec. $[H_2O_2]$ (%)	Dec. [**1**] (%)
1.05	8	98.0	48.4
2.10	10	93.2	60.1
3.15	12	87.1	77.5
4.21	15	94.0	96.3

[a] Initial concentration of **1** is 0.251–0.304 *M* in aqueous solution under irradiation of 254 nm light.

TABLE 2. Comparison of photolysis of aqueous acetic (1), glycolic (2), and formic acids (4) at 20°C

	CH_3CO_2H (1)	$HOCH_2CO_2H$ (2)	HCO_2H (4)
$[Substrate]_0$ (*M*)	0.304	0.318	0.326
$[H_2O_2]_0$ (*M*)	1.34	0.798	0.372
$[H_2O_2]_0/[substrate]_0$	4.21	2.51	1.14
Irradiation time (h)	15	10	10
Dec. [substrate] (%)	96.3	98.2	100
Dec. $[H_2O_2]$ (%)	94.0	95.4	98.2
Yield of CO_2 (%)	103.8	122.8	86.3
Yield of O_2 (%)[a]	6.5	3.9	4.4

[a] The yield of O_2 is calculated by assuming evolution of 1 mol O_2 from 1 mol H_2O_2.

small that the estimation of their yields was difficult.

As shown in Table 2, glycolic (2) and formic acids (4) are more easily oxidized than acetic acid (1) at lower H_2O_2 concentration; further photo-oxidation of 2 with H_2O_2 gives 4, tartaric acid (3, trace), and glyoxylic acid (5, trace).[3] 5 (as hydrate) reacts with H_2O_2 in the dark to give formic acid (4) and CO_2. Photolysis of 4 in the presence of H_2O_2 gave CO_2 and H_2O. Therefore acetic acid (1) is more stable than the initial products (2 and 4) under these conditions (5, 6), so that only a trace amount of them remained in the products from 1.

Mechanism

The extinction coefficient of H_2O_2 ($\varepsilon_{254\ nm} = 20$) is much higher than that of acetic acid (1, $\varepsilon_{254\ nm} \simeq 0$), and the concentration of H_2O_2 is higher than that of 1, so that it is probable that H_2O_2 is photolyzed at first, forming radical HO·, followed by further reaction such as formation of HOO· etc. (7–10).

[1] $H_2O_2 \xrightarrow{h\nu} 2HO\cdot$

[2] $HO\cdot + H_2O_2 \longrightarrow HOO\cdot + H_2O$

[3] $HOO\cdot + H_2O_2 \longrightarrow HO\cdot + H_2O + O_2$

[4] $2HOO\cdot \longrightarrow H_2O_2 + O_2$

The radicals HO· and HOO· (reactions [1]–[4]) abstract a H-atom from the substrate, initiating the decomposition. The substrate radical thus formed couples with HO· and HOO·, affording more stable observed products as follows.

[5a] CH_3CO_2H (1) $\xrightarrow{HO\cdot} \cdot CH_2CO_2H$ (6) $+ H_2O$

[5b] CH_3CO_2H (1) $\xrightarrow{HO\cdot} CH_3CO_2\cdot$ (or $CH_3\cdot + CO_2$) $+ H_2O$

[5c] CH_3CO_2H (1) $\xrightarrow{h\nu} CH_4 + CO_2$ (trace)

[6a] $\cdot CH_2CO_2H$ (6) $\xrightarrow{HO\cdot} HOCH_2CO_2H$ (2)

[6b] $\cdot CH_2CO_2H$ (6) $\xrightarrow{HOO\cdot} HOOCH_2CO_2H$ (7)

[7] $HOCH_2CO_2H$ (2) $\xrightarrow{HO\cdot} HO\dot{C}HCO_2H$ (8) $+ H_2O$

[8] $HOOCH_2CO_2H$ (7) $\xrightarrow{h\nu} HO\cdot + \cdot OCH_2CO_2H$ (9)

[9a] $HO\dot{C}HCO_2H$ (8) $\xrightarrow{HO\cdot} (HO)_2CHCO_2H$ (10)

[9b] $HO\dot{C}HCO_2H$ (8) $\xrightarrow{\text{coupling}} HO_2CCH(OH)CH(OH)CO_2H$ (3)

The decomposition of acetic acid (**1**) is expected to be initiated both by H-atom abstraction with HO· (reactions [5*a*] and [5*b*]) and by direct photolysis (reaction [5*c*]) (11). In this case, the main path of the decomposition of **1** should be [5*a*] because only a trace amount of methane was observed (reactions [5*b*] and [5*c*]). Substrate radical (·CH_2CO_2H, **6**) formed by reaction [5*a*] undergoes further reactions to give the observed products. α-Hydroperoxyacetic acid ($HOOCH_2CO_2H$, **7**) formed by reaction of radical **6** with HOO· decomposes to afford alkoxy radical **9** (reactions [6*b*] and [8]), which gives formaldehyde (**11**) by β-fission (reaction [10*b*]). Oxidation of the latter yields formic acid (**4**) (reaction [11]). The reaction of radical **12** with H_2O_2 gives CO_2 (reaction [13]) (8). Tartaric acid (**3**) is formed by dimerization of radicals, $HO\dot{C}HCO_2H$ (**8**) (reaction [9*b*]). As stated above, products **2**, **3**, **4**, methane, and CO_2 were detected in this photolysis.

Propionic Acid (13)

The photo-oxidation of propionic acid (**13**, 0.4–0.5 *M* initial concentration) was similarly carried out at various molar ratios of $[H_2O_2]_0/[\mathbf{13}]_0$. When H_2O_2 was completely decomposed, the decomposition of substrate **13** was 57% with equimolar H_2O_2, 75% with twice molar H_2O_2, and 100% with over triplicate molar H_2O_2. Thus, the time/conversion data were measured with 3.1-fold molar H_2O_2 as shown in Table 3.

An aqueous solution of 0.404 *M* **13** and 1.27 *M* H_2O_2 ($[H_2O_2]_0/[\mathbf{13}]_0 = 3.14$) was irradiated with 254 nm light. The products identified by nmr and glc were: CO_2, CH_3CO_2H (**1**), $HOCH_2CO_2H$ (**2**), HCO_2H (**4**), $CH_3CH(OH)CO_2H$ (**14**), $HOCH_2$-CH_2CO_2H (**15**), $HO_2CCH_2CO_2H$ (**16**), and CH_4 (trace). The yields of products dissolved in solution are plotted against the decomposition percentage of propionic acid (**13**) (Fig. 1).

The figure shows that yields of **1**, **2**, **4**, and **16** increase with the progress of the decomposition, while the yields of α- (**14**) and β-hydroxypropionic acids (**15**) decrease gradually after 50% decomposition of **13**. Hence, hydroxypropionic acids may be intermediates in the oxidation of **13** giving **1**, **4**, and others.

As to the evolution of CO_2, 1.15×10^{-2} mol of CO_2 was evolved on irradiation of a mixture of **13** (1.21×10^{-2} mol, 0.404 *M*) and H_2O_2 (3.81×10^{-2} mol, 1.27 *M*) after the consumption of 97.4% of **13**. Hence, CO_2 is evolved simultaneously with the oxidative degradation to lower molecular weight products, which are eventually oxidized to CO_2.

For the examination of the oxidative degradation of the intermediates, the following photo-oxidation of hydroxypropionic acids was carried out under the same conditions.

α-Hydroxypropionic acid (**14**, 0.374 *M*) in H_2O was photolyzed with H_2O_2 (1.24 *M*). The products in the 95% conversion of **14** were: **1** (58%), CO_2, traces of **2** and **4**, and pyruvic acid (**17**). Pyruvic acid is oxidized rapidly with H_2O_2 in the dark to give **1** and CO_2 (12, 13).

β-Hydroxypropionic acid (**15**, 0.374 *M*) in H_2O was photolyzed with H_2O_2 (1.24 *M*). The products in the 98% conversion of **15** were: **1** (10%), **2** (7%), **4** (52%), malonic acid (**16**, 18%), and CO_2.

Comparison of the evolution efficiency of CO_2 from a given amount of the decomposed H_2O_2 im-

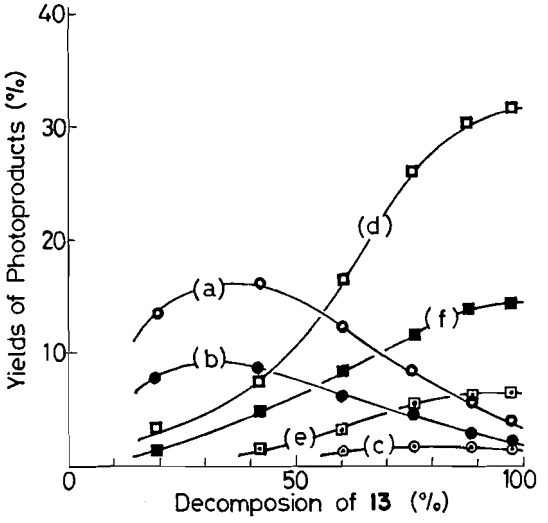

FIG. 1. Yields of products dissolved in solution against the photodecomposition percentage of propionic acid (**13**) with aqueous H_2O_2 at 20°C. Line (*a*), $CH_3CH(OH)CO_2H$ (**14**); (*b*), $HOCH_2CH_2CO_2H$ (**15**); (*c*), $HO_2CCH_2CO_2H$ (**16**); (*d*), CH_3CO_2H (**1**); (*e*), $HOCH_2CO_2H$ (**2**); (*f*), HCO_2H (**4**).

plies that the oxidation efficiency of the α-isomer (**14**) is 1.4 times higher than that of the β-isomer (**15**).

Mechanism

The above results suggest a mechanism which is analogous to that of acetic acid (**1**) and is initiated by the H-atom abstraction with the oxidative species HO· and HOO·. The primary reaction for propionic acid (**13**) degradation may be α- and β-hydrogen atom abstraction with HO·, since HO· is the strongest H-atom abstractor among the radical species in the system.

The radical species thus formed couples with HO· to give α- (**14**) and β-hydroxypropionic acid (**15**), and with HOO· to give the α- (**18**) and β-hydroperoxides (**19**), respectively, in a similar manner as above. Radical **20** ($CH_3\dot{C}(OH)CO_2H$) formed by α-H abstraction from **14** is converted mainly to pyruvic acid (**17**) which reacts easily with H_2O_2 in the dark to give **1** (reactions [16], [17]) (12, 13).

[16] $CH_3CH(OH)CO_2H \xrightarrow[-H_2O]{HO\cdot}$ (**14**)

$CH_3\dot{C}(OH)CO_2H \xrightarrow[-H_2O]{HO\cdot} CH_3COCO_2H$ (**20**, **17**)

[17] $CH_3COCO_2H + H_2O_2 \xrightarrow{dark} CH_3CO_2H + CO_2 + H_2O$ (**17**, **1**)

Diol **21** ($HOCH_2CH(OH)CO_2H$) formed by β-hydrogen abstraction from **14** followed by coupling with HO· leads to glycolic acid (**2**) via **23** similarly to pyruvic acid (**17**) (reactions [18], [19]), and peroxide **24** ($HOOCH_2CH(OH)CO_2H$) from **14** leads to radical **8** and formaldehyde (**11**) by photolytic O–O cleavage followed by β-scission of alkoxy radical (**25**) (reaction [20]) (14, 15).

[18] $HOCH_2CH(OH)CO_2H \xrightarrow[-H_2O]{HO\cdot}$ (**21**)

$HOCH_2\dot{C}(OH)CO_2H \xrightarrow[-H_2O]{HO\cdot} HOCH_2COCO_2H$ (**22**, **23**)

[19] $HOCH_2COCO_2H + H_2O_2 \xrightarrow{dark}$ (**23**)

$HOCH_2CO_2H + CO_2 + H_2O$ (**2**)

[20] $HOOCH_2CH(OH)CO_2H \xrightarrow[-HO\cdot]{h\nu}$ (**24**)

$\cdot OCH_2CH(OH)CO_2H \xrightarrow{\beta\text{-scission}} HCHO + HO\dot{C}HCO_2H$ (**25**, **11**, **8**)

β-Hydroxypropionic acid (**15**) also leads to glycolic acid (**2**) either via $HOCH_2COCO_2H$ (**23**) similar to reaction [16] or via hydroperoxide **26** ($HOCH_2CH(OOH)CO_2H$) (reaction [21]). Radical **28** ($HO\dot{C}HCH_2CO_2H$) formed from **15** gives malonic acid (**16**) via **29** (reaction [22]), which is directly decarboxylated to **1** or reacts with HO· to give **6** (11). β-Hydroperoxide ($HOOCH_2CH_2CO_2H$, **19**) leads to glycolic acid (**2**) and formic acid (**4**) analogously to peroxide **24**. Methane and ethane may be formed by photolysis of **1** (reaction [5*c*]) and **13**, respectively, and/or by H-abstraction from the carboxyl group by HO· followed by decarboxylation (11). In this photolysis of **13**, CO_2, **1**, **2**, **4**, **14**, **15**, and **16** should be formed, which were identified as products.

[21] $HOCH_2CH(OOH)CO_2H \xrightarrow[-HO\cdot]{h\nu}$ (**26**)

$HOCH_2\underset{O\cdot}{\overset{|}{C}}HCO_2H \xrightarrow[-H_2O]{HO\cdot} HOCH_2COCO_2H$ (**27**, **23**)

[22] $HO\dot{C}HCH_2CO_2H \xrightarrow{HO\cdot}$ (**28**)

$(HO)_2CHCH_2CO_2H \xrightarrow[-H_2O]{[O]} HO_2CCH_2CO_2H$ (**29**, **16**)

In conclusion, an aqueous solution of **1**, **4**, or **13** in the presence of excess H_2O_2 was decomposed almost completely with 254 nm light. A mechanism is postulated which involves the generation of HO· or HOO· from H_2O_2 followed by their abstraction of a H-atom from acids and/or their addition to substrate radicals.

Experimental

Materials

Formic acid, bp 100.0–101.0°C, acetic acid, bp 116.5–117.5°C, and propionic acid, bp 141.0–142.0°C were purified by fractionation. Hydrogen peroxide (90% guaranteed grade) was purchased from Mitsubishi Gas Chem. Co. Other reagents were of guaranteed reagent grade.

Photolysis

The substrate was mixed with aqueous H_2O_2, the solution was introduced into a quartz cell equipped with a gas buret (300 mL) connected with a capillary tube to the photolysis system, and irradiated with a Halos 60 W low-pressure Hg lamp at 20°C.

The concentration of H_2O_2 was measured by iodometry. The liquid products from the photolysis were identified and estimated *in situ* by nmr (a Hitachi R-24B spectrometer), and/or by glc (a Yanagimoto G 180 gas chromatograph with FID) and gc–ms (a Shimadzu GCMS-7000 mass spectrometer) with a column (2.5 mm × 2 m) packed with PEG 20M and Porapak QS after decomposition of remaining peroxides with $Na_2S_2O_3$, concentration of the solution, and then esterification by diazomethane. The gaseous products were analyzed by glc with FID and TCD using a 2.5 mm × 2 m column packed with Porapak QS and Molecular Sieve 5A with helium as a carrier gas. The evolved CO_2 was estimated by absorbing it in saturated aqueous $Ba(OH)_2$ followed by acidimetry with aqueous HCl. The evolved O_2 was absorbed in alkaline aqueous pyrogallol, and the volume of absorbed O_2 was estimated with a gas buret.

Etude de l'adsorption de surfactants ioniques et non ioniques sur de la matière végétale carbonisée

FRANCIS PERINEAU ET ANTOINE GASET

Laboratoire de Chimie Organique et d'Agrochimie, Ecole Nationale Supérieure de Chimie, Institut National Polytechnique, 118 route de Narbonne, 31077 Toulouse Cedex, France

Reçu le 21 février 1980[1]

FRANCIS PERINEAU et ANTOINE GASET. Can. J. Chem. **59**, 19 (1981).

En vue de la valorisation des déchets ligneux dans le domaine de l'épuration d'effluents, nous avons étudié l'adsorption des trois principaux types de surfactant sur de la matière végétale ayant subi l'opération de carbonisage. Nous avons ainsi déterminé les conditions optimales de pH et de température. L'étude de l'influence de la variation de ces paramètres a en outre permis de mettre en évidence l'intervention de liaisons ioniques et hydrophobes, et d'identifier les groupements responsables de la fixation ionique. Puis l'analyse des courbes traduisant la fixation dans le temps en mileux eau pure et alcoolique nous a amené à proposer un mode d'adsorption. En outre nous avons tenté de caractériser le mode de diffusion des surfactants par le tracé des courbes de fixation en fonction de la racine du temps. Enfin la comparaison de l'adsorption de trois alkylsulfates de longueur de chaîne variable a confirmé la très grande importance des interactions hydrophobes et a permis de la relier à la valeur des cmc tensio-actives.

FRANCIS PERINEAU and ANTOINE GASET. Can. J. Chem. **59**, 19 (1981).

The aim of this investigation was to assess the possible use of sulfuric lignins for the purification of industrial liquid wastes. The adsorption of anionic (SDS), cationic (CPC), and non-ionic (NPPO) surfactants on charred plant material was carried out under various pH and temperature conditions. Ionic and hydrophobic interactions are involved in the adsorption process. The analysis of the adsorption kinetics in aqueous and alcoholic media allowed the mode of adsorption to be characterized. The plot of the surfactant uptake against the square root of time led to the determination of the mode of diffusion. The effect of the chain length of alkylsulfates on their adsorption corroborated the involvement of hydrophobic interactions and could be correlated with the values of their cmc.

Introduction

Dans le cadre de la valorisation du déchet issu de l'opération de carbonisage de la laine dans le domaine de l'épuration d'effluents riches en détergents (1), nous avons étudié l'adsorption de surfactants ioniques et non ioniques sur les lignines sulfuriques composant ce déchet. Le carbonisage a pour but d'éliminer la matière végétale profondément incrustée dans la laine. Cette opération a lieu par actions conjuguées de l'acide sulfurique et de la chaleur (2). Elle donne lieu à un déchet constitué de fibres modifiées et de matière végétale carbonisée et broyée composant en général plus de 50% de ce sous-produit. Celui-ci représente 5% du tonnage des laines carbonisées, soit 0,75% du tonnage des laines commercialisées. Aucune utilisation de ce déchet n'ayant été proposée, et en raison de ses caractéristiques ioniques et apolaires, nos travaux ont pour but de proposer sa valorisation dans le cadre de l'épuration des eaux polluées. Avant d'étudier l'adsorption des tensio-actifs sur le déchet global, nous avons étudié cette fixation sur chacun de ses composants: les fibres kératiniques modifiées et la matière végétale carbonisée. Ceci dans le but de mieux connaître les processus d'adsorption et d'utiliser ce sous-produit de façon optimale. En ce qui concerne plus particulièrement la partie végétale du déchet, le fait qu'elle se rencontre également à l'issue de divers tratitements de déchets d'origine végétale (rafle de maïs) constitue une motivation supplémentaire à cette étude.

Dans de telles conditions (H_2SO_4 29 *N*, 120°C) la matière végétale est hydrolysée. La cellulose et les hémicelluloses libèrent des sucres en C6 et C5. Seul le squelette ligneux est maintenu. Il subit en outre des réactions de sulfatation, ainsi que de façon plus secondaire de sulfonation. La température et le pH acide favorisent ces réactions au niveau de différents groupements fonctionnels (3–6), notamment des groupements alcooliques, des carbones éthyléniques et des noyaux phénoliques.

Parmi les travaux que l'on peut relever dans la littérature concernant l'adsorption de solutés sur les lignines sulfuriques on trouve essentiellement des résultats se rapportant à l'adsorption de phénols. L'analyse des isothermes tracées à différentes températures montre une adsorption physique pour ce produit (9, 10). L'adsorption de phénols a également été envisagée sur la lignine (11) mais il ne s'agit plus dans ce cas d'une simple adsorption puisqu'elle conduit à une condensation (12–14). Par ailleurs la fixation d'un colorant basique sur des fibres lignocellulosiques a été étudiée. Il a été montré que les fibres brutes ont un pouvoir adsorbant deux fois supérieur à celui de la cellulose pure en raison du caractère nucléophile des groupements carboxyliques et phénoliques

ionisés de la lignine (15). Par contre la capacité de fixation des lignines sulfonatées s'est avérée voisine de celle de la cellulose (16). En ce qui concerne l'adsorption de surfactants sur des matières végétales, son étude ne semble avoir été envisagée que sur de la cellulose sulfurique. La fixation de composés cationiques met principalement en oeuvre des liaisons ioniques. L'adsorption faible et réversible des tensio-actifs anioniques et non ioniques a lieu par liaisons hydrogènes (17).

Dans ces conditions il nous a paru intéressant d'étudier l'adsorption de ces trois types de composés tensio-actifs sur des lignines sulfuriques. Nous avons, dans un premier temps, déterminé les conditions optimales de pH et de température. Nous nous sommes ensuite attachés à faire ressortir les principaux types de liaisons mises en jeu, et à caractériser le mode de diffusion.

Partie expérimentale

1. Matériaux

1.1. Le déchet de carbonisage nous a été fourni par l'I.T.F.[2] Suld-Lecarim. La séparation de ses deux composants a lieu par tamisage. La granulométrie de la fraction végétale (lignines sulfuriques acides) recueillie est variable mais faible dans tous les cas. Le matériau est quasi pulvérulent. Il est ensuite lavé en colonne, de manière à éliminer l'acide sulfurique d'absorption avec de l'eau déminéralisée, jusqu'à ce que la valeur du pH d'équilibre soit de 4,2 (photo 1).

Les particules végétales issues du déchet de carbonisage ont été photographiées au microscope électronique. La photographie 1 met en évidence la présence de deux types de particules. Chacun d'eux a ensuite été photographié à un grossissement plus élevé (photos 2 et 3).

1.2. Les surfactants ioniques utilisés sont des produits Merck: dodécylsulfate de sodium (SDS) (réf. 2969); tétradécylsulfate de sodium (STS) (réf. 12 272); *n*-hexadécylsulfate de sodium (SHS) (réf. 12 184); chlorure de *N*-cétylpyridinium (CPC) (réf. 2340).

Le surfactant non ionique utilisé est un nonylphénoxypolyéthylèneoxyéthanol (NPPO) avec une longueur de chaîne correspondant à 9 mol d'oxyde d'éthylène (masse moléculaire 604). Ce produit nous a été fourni par la Société Montanoir.

2. Traitements

Le substrat (2 g) et la solution tensio-active (0,1 dm^3) de concentration 2 g/dm^3 sont mis en agitation mécanique pendant 20 min. Ceci fait exception lors de l'étude de la fixation d'alkylsulfates en fonction de la longueur de la chaîne. En effet, en raison de la mauvaise solubilité des STS et SHS, il n'est pas possible d'utiliser de fortes concentrations. Le substrat (2 g) est dans ce cas mis en agitation pendant 30 min avec 1,5 dm^3 de solution concentrée à 100 mg/dm^3. L'acidification a lieu par addition de H_2SO_4 36 *N* (le carbonisage se déroulant en présence de cet acide), tandis que les valeurs basiques du pH sont obtenues par emploi de NaOH 2 *N*. L'agitateur est placé dans une cuve thermostatée. Lignines sulfuriques et solution ne sont mises en contact que lorsque l'équilibre thermique est atteint. Les solutions alcooliques tensio-actives sont obtenues en dissolvant le surfactant dans un mélange isovolumétrique eau – éthanol.

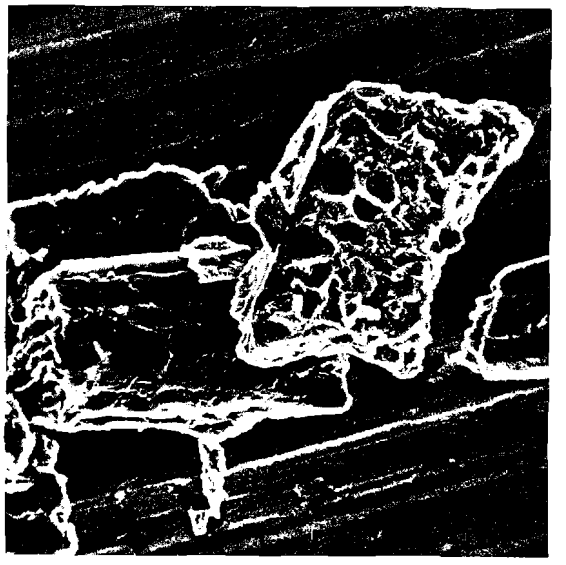

PHOTO 1. Particules végétales issues du déchet de carbonisage (grossies 350 fois).

PHOTO 2. Particule végétale de type tubulaire (grossie 1100 fois).

3. Techniques analytiques

La quantité de surfactant adsorbé (*X*) est calculée en déterminant la concentration résiduelle. Celle-ci est obtenue pour les tensio-actifs ioniques par la méthode de Longwell et Maniece (18). Les résultats ainsi acquis ont été confirmés par la méthode analytique consistant à former avec l'orthophénanthroline cuivrique un complexe extractible dans la méthylisobutylcétone et à le doser par spectrophotométrie d'absorption atomique (19). La concentration résiduelle en surfactant non ionique est déterminée par spectrophotométrie ultra-violette après complexation par le cobaltothyocyanate d'ammonium et extraction dans le benzène (20).

Résultats et discussion

1. Influence du pH sur l'adsorption

1.1. D'un surfactant anionique: le dodécylsulfate de sodium (SDS)

On constate sur la fig. 1 que l'adsorption diminue lorsque le pH croît jusqu'à ce qu'il atteigne une valeur voisine de 9,5. Son importance est divisée par 6,7 entre les pH 0,5 et 9,5. Au-delà de cette valeur du pH, la quantité fixée augmente.

Cette chute de l'adsorption jusqu'à une valeur de pH de 9,5 peut être expliquée par l'intervention de liaisons ioniques. En effet la lignine peut réagir avec les amines pour former des ammoniums quaternaires (21). Ce greffage est favorisé en présence d'acide sulfurique et par action de la chaleur (22), c'est-à-dire par les conditions du carbonisage. De même les groupes méthoxys de la lignine peuvent donner lieu à des ions thiouroniums en présence de thiols aminés (15). Les analyses élémentaires des lignines sulfuriques composant le déchet de carbonisage font apparaître un taux d'azote de 5,1%. La lignine étant exempte de cet élément, on peut raisonnablement attribuer sa présence au greffage d'acides aminés kératiniques lors du carbonisage, dont certains portent une fonction thiol (cystéine provenant de l'hydrolyse de la cystine).

Nous retiendrons donc pour la fixation ionique du SDS à pH acide l'intervention des sites cationiques du type:

$$-CH=\overset{+}{N}-\underset{H}{} \quad \text{et} \quad -CH-S-C=\overset{+}{N}H_2 \qquad NH_2$$

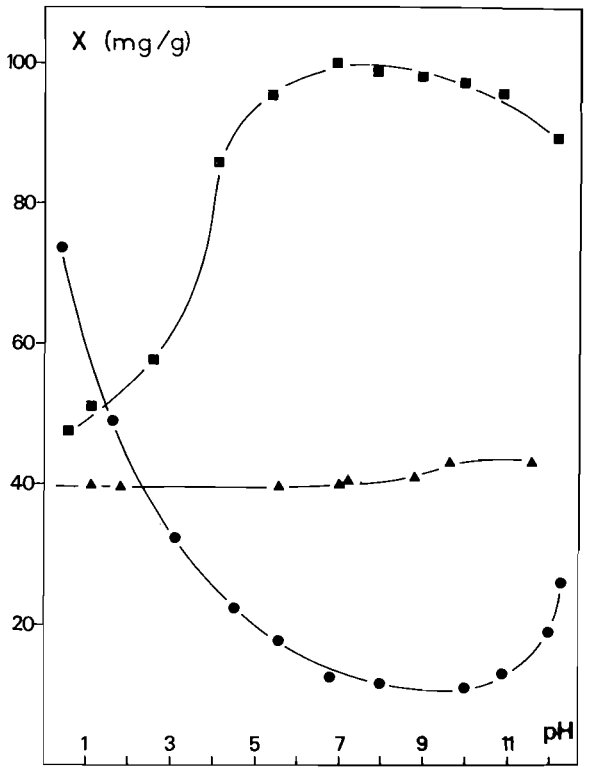

FIG. 1. Effet du pH sur l'adsorption (Co = 2 g/L, t = 20 min, θ = 22°C); ● SDS, ■ CPC, ▲ NPPO.

Au fur et à mesure que la valeur du pH croît, la proportion des sites cationiques mentionnés ci-dessus diminue, de même que l'adsorption du SDS. Son adsorption n'est cependant pas nulle. Ceci sous-entend l'intervention d'un autre type de liaisons telles que les interactions hydrophobes. Il est par contre étonnant de remarquer une augmentation de la fixation en milieu fortement basique. Ce phénomène est certainement lié à l'hydrolyse alcaline connue de la lignine (23, 24) et des lignosulfonates (25–28) que nous avons d'ailleurs observée sous forme d'une solubilisation partielle des particules végétales. Elle se traduit principalement par une dépolymérisation de la macromolécule (23–25). Au niveau des lignines sulfuriques, ce processus s'accompagne aussi d'une désulfonation (25–28). Ceci a pour conséquence de réduire le potentiel électronégatif du substrat et donc la répulsion vis-à-vis des anions. On peut également interpréter cette augmentation de la fixation pour des pH supérieurs à 9,5 par une ouverture de la structure macromoléculaire permettant des interactions hydrophobes substrat – SDS plus nombreuses et mettant en jeu une plus importante surface d'adsorption.

Nous avons pu vérifier que les phénomènes d'ad-

TABLEAU 1. Tensions superficielles de solutions de SDS, CPC et NPPO à 22°C en fonction du pH

	Tension superficielle (dyn/cm)		
pH	SDS (0,2 m*M*/L)	CPC (0,2 m*M*/L)	NPPO (0,156 m*M*/L)
2	58	40	31,5
6,3	64	45	31
11	65	40	31,5

sorption observés en fonction du pH ne sont pas dus à la dégradation de la molécule tensio-active. En effet la valeur de la tension superficielle des trois solutions tensio-actives reste stable sur la gamme de pH considérée (tableau 1). En outre nous avons vérifié que l'amélioration du pouvoir adsorbant liée à l'hydrolyse alcaline est définitive. Ainsi après avoir maintenu le substrat durant 20 min à pH 12,1, ce dernier a ensuite été ramené à 8,6. Le taux de fixation déterminé dans ces conditions est comparable à celui obtenu à pH 12.

1.2. D'un surfactant cationique: le chlorure de N-*cétylpyridinium (CPC)*

Inversement l'adsorption du CPC croît avec le pH. Elle est multipliée par le coefficient 2,1 entre les pH 0,5 et 7 (fig. 1). Ceci est en grande partie attribué à la dissociation des groupements sulfates ainsi qu'à celles des groupements sulfonates et phénoliques de façon secondaire. Notons que des analyses élémentaires du matériau ont fait apparaître une teneur en soufre de 2,6%. Or la lignine est en principe dépourvue de cet élément. Cela confirme donc sa sulfatation lors du carbonisage. Elle représenterait 0,21 mol équivalent pour 100 g de substrat et permettraient dans des conditions d'équilibre et de saturation une fixation de CPC égale à 640 mg/g.

L'adsorption du CPC en milieu acide peut être attribuée à des interactions hydrophobes, à l'intervention des doublets libres des hétéroatomes ainsi qu'à des liaisons ioniques. En effet les sulfates acides et les acides sulfoniques sont forts et certains restent sous forme dissociée à des pH très acides. Un autre argument expliquant cette adsorption en milieu acide met en jeu l'intervention de complexes entre les électrons π des noyaux aromatiques de la lignine et la partie cationique du surfactant (29). Quant à la diminution de la fixation à pH supérieur à 8, elle peut s'expliquer par la désulfonation partielle (25–28) mentionnée auparavant.

1.3. D'un surfactant non-ionique: le nonylphénoxypolyéthylèneoxyéthanol (NPPO)

Un tel soluté non ionique n'est en principe pas concerné par les liaisons ioniques. Son adsorption ne devrait pas être influencée par les variations du pH. Cependant les atomes d'oxygène des liaisons éthers des surfactants non ioniques à chaîne polyoxyéthylène peuvent être protonés à bas pH (29). Il est donc possible que le NPPO se fixe par liaisons ioniques sur les lignines sulfuriques du fait de la force des sulfates acides et des acides sulfoniques. Néanmoins les liaisons hydrogènes et les interactions hydrophobes contribuent certainement de façon plus importante à l'adsorption de ce type de soluté.

D'autre part il peut paraître surprenant d'observer une légère amélioration du taux de fixation (7,5%) à pH supérieur à 7,5 (fig. 1). Ce phénomène peut aussi être expliqué par l'hydrolyse du matériau qui aurait les mêmes conséquences que celles mentionnées pour le SDS. D'ailleurs, comme pour le SDS, nous avons constaté que cette amélioration du taux de fixation se maintient après avoir soumis le substrat à un pH de 11,6. Son pouvoir adsorbant vis-à-vis du NPPO à une valeur du pH ramenée à 1,8 est égale à celui obtenu à pH 11,6. Ceci semble donc confirmer l'hypothèse selon laquelle la plus grande adsorption du NPPO en milieu basique est due à l'hydrolyse du matériau et non pas à la dégradation de la molécule de NPPO dont la stabilité au pH est rapportée dans le tableau 1.

2. Influence de la température sur l'adsorption

Il ressort des résultats portés sur la fig. 2 que l'adsorption des trois surfactants choisis est fortement favorisée par l'élévation de la température. Ceci est particulièrement vrai pour les tensio-actifs ioniques. Les taux de fixation du SDS, CPC et NPPO sont respectivement multipliés entre 20°C et 55°C par 1,7, 1,27 et 1,3, et entre 20°C et 75°C par 1,8, 1,75 et 1,4. Ces résultats peuvent trouver leurs principales justifications au niveau: du substrat (modification de sa structure); du surfactant (modification de sa diffusion); de l'interaction substrat–surfactant.

Il est connu que la macromolécule de lignine gonfle lorsque la température du milieu s'élève, ce qui implique la dilatation des pores (30, 31), d'autant plus que la sulfonation de la lignine induit une destruction des liaisons transversales et donc une ouverture préalable des pores (3–8). Dans de telles conditions le soluté diffuse plus facilement, et la surface d'adsorption augmente. De ce fait le nombre de sites d'adsorption croît. Par ailleurs la concentration micellaire critique (cmc) des surfactant augmente avec la température, de telle sorte que le nombre de molécules tensio-actives indépendantes croît. Leur diffusion à l'intérieur des pores est par conséquent facilitée. Ainsi pour le

For personal use only.

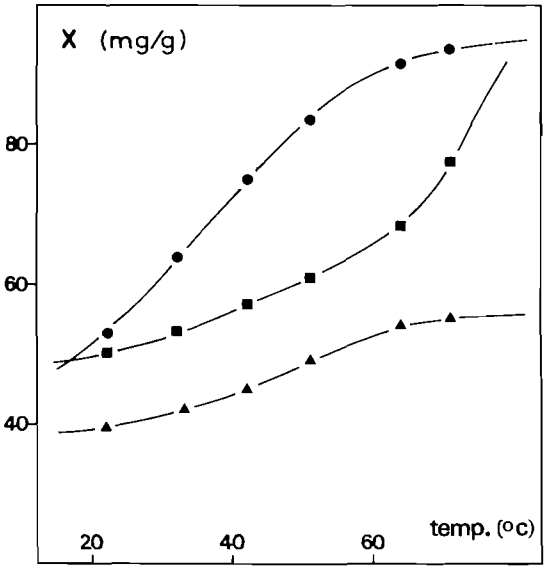

FIG. 2. Effet de la température sur l'adsorption (Co = 2 g/L, t = 20 min, pH = 1,8); ● SDS, ■ CPC, ▲ NPPO.

SDS la cmc passe entre 20°C et 70°C de 8,25 mM/L à 11,4 mM/L. Pour le CPC elle augmente de 0,9 mM/L à 2,36 mM/L entre 25°C et 80°C. Par contre celle du NPPO croît très faiblement de $6{,}23 \times 10^{-2}$ mM/L à $6{,}54 \times 10^{-2}$ mM/L entre 25°C et 75°C (32). Ceci pourrait expliquer l'effet décroissant de la température sur les adsorptions du SDS, CPC et NPPO, d'autant plus que la cmc traduit la possibilité qu'ont les surfactants à réduire leur surface.

Cette amélioration de la fixation liée à l'élévation de la température peut surtout s'expliquer par l'intervention de liaisons endothermiques telles que les interactions hydrophobes. La structure de la lignine est maintenue par des liaisons hydrogènes et des interactions hydrophobes (31). Lorsque la lignine est gonflée par un solvant polaire comme l'eau, les chaînes prennent une conformation telle qu'elle permet la formation d'interactions hydrophobes entre les chaînes apolaires de la lignine (30, 31). On conçoit que ces interactions puissent également s'établir entre les chaînes apolaires des surfactants et de la lignine. Outre celles du type lignine–surfactant, ces interactions hydrophobes peuvent être du type surfactant–surfactant. En effet il est généralement admis que l'adsorption des tensioactifs sur une surface polaire est tout d'abord ionique (29). Les résidus hydrophobes de ces premières molécules adsorbées sont donc orientés vers le solvant. Ils peuvent alors fixer de nouvelles molécules tensio-actives par interactions hydrophobes, selon le processus d'hémicellisation (29). L'adsorption ionique préalable du SDS et du CPC favorise ce phénomène et peut donc également expliquer l'effet plus important de la température sur leur fixation que sur celle du NPPO. Par ailleurs les liaisons hydrogènes entre les groupes acides carboxyliques et phénoliques dissociés et non dissociés de la lignine (31) peuvent être rompues lors de la diffusion des surfactants induisant ainsi une ouverture de la structure de la macromolécule, et par conséquent une accessibilité plus grande de ses sites hydrophobes aux molécules tensio-actives.

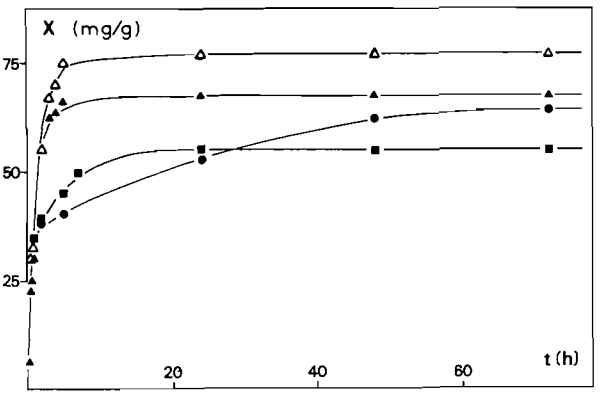

FIG. 3. Influence du temps de réaction sur l'adsorption (Co = 2 g/L, pH = 1,8); ● SDS 22°C, ■ CPC 22°C, ▲ NPPO 22°C, △ NPPO 56°C.

3. Analyse des modes d'adsorption et de diffusion

3.1. D'un surfactant anionique: le SDS

Dans les conditions opératoires choisies, la fixation est très rapide lors des deux premières heures, puis une adsorption lente s'établit jusqu'à l'équilibre atteint en 72 h (fig. 3). L'agrandissement de la première partie de la courbe (fig. 4) fait ressortir deux étapes: une phase rapide lors des 30 premières minutes qui peut être attribuée à l'établissement de liaisons ioniques, comme nous le verrons lors de l'étude de l'adsorption en milieu alcoolique; suivie d'une phase lente qui correspond à l'adsorption hydrophobe. Si on se réfère à la fig. 3,

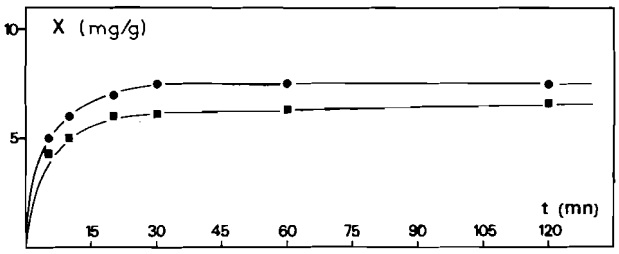

FIG. 5. Adsorption en milieu éthanolique (Co = 2 g/L, pH = 1,8, θ = 22°C); ● SDS, ■ CPC.

on peut remarquer que ces interactions s'établissent rapidement puis lentement après environ 2 h. Les premières semblent donc correspondre à des interactions hydrophobes lignine–SDS, rapides à s'établir en raison de la très grande hydrophobie de certains sites. Les deuxièmes correspondent alors à des interactions hydrophobes de seconde couche soit SDS–SDS à partir des molécules tensio-actives fixées ioniquement, soit lignine–SDS en raison de l'augmentation de l'hydrophobie de certains sites du fait de l'adsorption hydrophobe préalable.

En milieu alcoolique les interactions hydrophobes sont inhibées et la stabilité de la structure de la lignine est assurée par les groupements polaires (30, 31). Dans ces conditions seule l'adsorption ionique peut s'exprimer. On constate que dans un tel milieu la fixation est achevée en 30 min (fig. 5). Ceci semble donc correspondre à la cinétique rapide des liaisons ioniques, et corrobore l'interprétation proposée précédemment en ce qui concerne la succession des modes d'adsorption. Notons que nous avons étudié l'influence de la température sur l'adsorption du SDS en milieu éthanolique et que, conformément à ce qui était attendu, aucune variation de fixation n'a été observée. L'adsorption est dans ces conditions de 7,5 mg/g soit de $2{,}84 \times 10^{-2}$ mM/g. Elle représente seulement 12% de la quantité fixée à l'équilibre et 23% en 30 min en milieu eau pure. Il ne semble donc pas que l'adsorption lors de la première heure soit purement ionique. Ceci permet de penser qu'elle s'accompagne soit d'une adsorption hydrophobe lignine–SDS, soit qu'il s'agit d'une adsorption ionique de micelles, chaque micelle comportant en moyenne 4,25 molécules de SDS.

Par analogie aux études de diffusion de solutés dans la laine (33–35) nous avons tracé les courbes d'adsorption en fonction de la racine du temps ($\sqrt{t}$). Elles donnent lieu pour le SDS à la succession de deux droites avant le palier d'équilibre (fig. 6). Le fait de ne pas obtenir une seule droite peut être interprété en ceci que toutes les particules végétales ne sont pas identiquement accessibles.

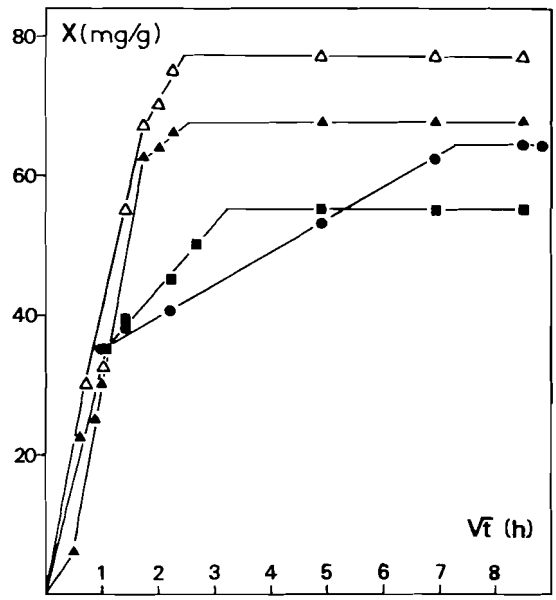

FIG. 6. Influence du temps de réaction sur l'adsorption (Co = 2 g/L, pH = 1,8); ● SDS 22°C, ■ CPC 22°C, ▲ NPPO 22°C, △ NPPO 56°C.

En effet leur granulométrie est suffisamment différente pour que le temps nécessaire à la diffusion dans les particules soit variable. Il est en outre apparu à travers les photos 1 à 3 que les particules végétales comportent des porosités de types différents. Ceci peut aussi être la cause de vitesses de diffusion différentes. Par ailleurs on constate l'absence d'une phase lente d'initiation. On peut pour cette raison préconiser la formation très rapide d'une couche à la surface des particules du fait de liaisons ioniques puis une diffusion par échanges ioniques et ouverture des liens hydrophobes dans toute la masse de la lignine.

3.2. D'un surfactant cationique: le CPC

En se référant aux figs 3 et 4, on retrouve les mêmes étapes d'adsorption pour le CPC que celles observées pour le SDS. La fixation du CPC en milieu alcoolique (fig. 5) s'élève à 6 mg/g en 30 min et à 6,5 mg/g en 120 min. Ceci confirme l'intervention de liaisons ioniques entre le CPC et les lignines sulfuriques à pH très acide. L'absence d'équilibre rapide peut s'expliquer par la mise en jeu d'interactions entre les groupements ammoniums du CPC et les doublets des hétéroatomes du substrat. Les taux de fixation du CPC en milieu alcoolique par rapport aux taux obtenus en milieu eau pure en 30 min et à l'équilibre sont respectivement de 11% et 20,7%. Comme pour le SDS il semble donc que l'adsorption lors de la première demi-heure ne soit pas strictement ionique, mais qu'elle s'accom-

For personal use only.

pagne d'une adsorption hydrophobe. L'hypothèse d'une adsorption ionique de micelles n'est toutefois pas à exclure. Dans ce cas les micelles comporteraient en moyenne 4,85 molécules tensio-actives, c'est-à-dire un peu plus que les micelles de SDS. Cette plus grande taille des agrégats cationiques est en accord avec les pouvoirs de micellisation de ces surfactants traduits par les valeurs de leur cmc.

En se référant à la fig. 6 on observe une courbe analogue à celle du SDS, témoignant donc de l'hétérogénéité des particules végétales et d'un même mode de diffusion.

3.3. D'un surfactant non ionique: le NPPO

Il est normal de constater une adsorption nulle du NPPO en milieu alcoolique. Par ailleurs, si on considère la fixation en début de réaction (fig. 4), on remarque que la variation de la pente de la tangente en chaque point de la courbe du NPPO est négligeable par rapport à celles du SDS et du CPC. Cette observation semble confirmer le rôle prépondérant des liaisons ioniques en début de réaction pour les surfactants ioniques. D'autre part si on se réfère à la fig. 6 on note que son allure est la même que celle des courbes du SDS et du CPC. Son interprétation est donc analogue. Remarquons néanmoins qu'une phase d'initiation apparait en début de réaction (figs 4, 6). Sa cinétique est moins rapide que celle de la phase suivante de diffusion. On peut expliquer cette phase d'initiation non observée pour les surfactants ioniques par l'absence de la formation très rapide d'une couche de molécules tensio-actives à la surface des particules par liaisons ioniques.

A 56°C l'adsorption du NPPO est plus rapide du fait de l'absence de la phase lente d'initiation, et plus importante (figs 3, 6). Ces deux observations peuvent être interprétées d'une part par la dilatation des pores permettant une diffusion rapide dès le début de la réaction et induisant un accroissement de la surface d'adsorption, d'autre part par le caractère endothermique des interactions hydrophobes. De plus l'augmentation de la cmc a pour conséquence une diffusion plus rapide et une possibilité plus grande pour la molécule tensio-active de réduire sa surface.

Remarque: influence de la longueur de la chaîne tensio-active sur l'adsorption

Il apparaît dans le tableau 2 que l'adsorption des alkylsulfates de sodium croît avec la longueur de la chaîne tensio-active. Des résultats analogues ont été obtenus avec d'autres substrats (29). Par contre la cmc est inversement proportionnelle à la longueur de la chaîne (32). Celle des alkylsulfates est divisée par quatre lorsque la chaîne hydrophobe augmente de deux atomes de carbone (tableau 2).

TABLEAU 2. Comparaison de l'adsorption d'alkylsulfates de sodium de différentes longueurs de chaîne

Alkylsulfates	SDS	STS	SHS
cmc à 40°C (mM/L) (36)	8,60	2,21	0,54
x/m (μM/g)	124,8	142,2	187,2

Cela correspond à une diminution de la solubilité des surfactants dans l'eau et à un accroissement de leur pouvoir tensio-actif qui conduisent tout naturellement les molécules tensio-actives à s'adsorber sur les surfaces des matériaux en présence desquelles elles sont. Par ailleurs l'énergie libre du surfactant décroît d'où une augmentation de l'adsorption du fait de l'augmentation du nombre de forces dispersées mises en jeu (29). D'autre part la surface de la molécule tensio-active augmentant, l'établissement de liaisons de Van der Waals entre chaînes hydrophobes augmente. Ainsi l'augmentation de la longueur de la chaîne tensio-active se traduit par une accroissement des interactions hydrophobes tant lignine–surfactant que surfactant–surfactant conduisant à une adsorption pseudo-micellaire, c'est-à-dire à une adsorption par micellisation hydrophobe du surfactant sur les chaînes hydrophobes tensio-actives préalablement fixées.

Conclusion

L'influence importante du pH sur l'adsorption du SDS a mis en évidence l'intervention de liaisons ioniques, ce qui permet de proposer la formation d'ammoniums quaternaires et d'ions thiouroniums sur la lignine lors du carbonisage par réaction avec les acides aminés kératiniques. L'effet de ce paramètre sur la fixation du CPC a fait ressortir le rôle d'une très importante sulfatation de la lignine lors du carbonisage. Par ailleurs une légère amélioration du taux de fixation du NPPO à pH basique indique une hydrolyse alcaline du substrat également observée lors de l'adsorption du SDS se traduisant par un accroissement de sa fixation, et lors de l'adsorption du CPC se traduisant par une diminution de sa fixation.

L'étude de l'influence de la température sur l'adsorption des trois surfactants a montré l'intervention d'interactions hydrophobes, également mise en évidence lorsqu'on a fait varier la longueur de la chaîne tensio-active. Cette adsorption hydrophobe en relation inversement proportionnelle avec la cmc des surfactants s'avère plus importante pour le NPPO que pour les tensio-actifs ioniques, ce qui ressort de l'étude de la fixation dans le temps.

Le mode d'adsorption des surfactants ioniques est successivement ionique et hydrophobe. Enfin l'étude de la diffusion du SDS, CPC et NPPO

réalisée à partir des courbes d'adsorption tracées en fonction de $\sqrt{t}$ a mis en évidence l'hétérogénéité de la granulométrie et de la porosité des particules végétales. Elle a également fait apparaître l'absence de phase d'initiation en ce qui concerne le SDS et le CPC en raison de l'intervention rapide de liaisons ioniques. Quant à la phase d'initiation observée à 22°C pour le NPPO, elle disparaît à 56°C du fait de l'ouverture des pores du substrat, et du plus grand nombre d'interactions hydrophobes.

Remerciements

Ce travail a été réalisé grâce à l'aide financière du Ministère de l'Environnement et du Cadre de Vie. Nous remercions également l'ITF Sud Lecarim à travers la personne de Monsieur Sergent.

Synthesis of tris(aminomethyl)phosphine oxide and its carbon dioxide adduct from tetrakis(hydroxymethyl)phosphonium salts via their methyl carbamate derivatives[1]

ARLEN W. FRANK

Southern Regional Research Center[2], New Orleans, LA 70179, U.S.A.

Received March 3, 1980

ARLEN W. FRANK. Can. J. Chem. **59**, 27 (1981).

Tris(aminomethyl)phosphine oxide (**6**) can be synthesized from octakis(hydroxymethyl)diphosphonium sulfate (**1*b***) in an overall yield of 54.6% via the methyl carbamate derivatives **2*b***, **3**, and **4**. On a preparative scale, the last step is complicated by the formation of a cyclic by-product **8** in amounts up to 20% of the total. The triamine **6** forms a 1:1 adduct (**11**) with carbon dioxide, whose structure, established by ^{1}H and ^{13}C nmr, consists of equimolar amounts of carbamate **A** and dicarbamate **BC**. The components **A**, **B**, and **C** can be separated by ion exchange. Thermolysis of **11** regenerates **6** smoothly, providing a convenient method for purifying the triamine.

ARLEN W. FRANK. Can. J. Chem. **59**, 27 (1981).

On peut synthétiser l'oxyde de tris(aminoéthyl)phosphine (**6**) avec un rendement global de 54,6% à partir du sulfate d'octakis-(hydroxyméthyl)diphosphonium (**1*b***) par l'intermédiaire des dérivés **2*b***, **3** et **4** du carbamate de méthyle. A l'échelle préparative, la formation du produit cyclique secondaire **8** dans une proportion de 20% complique la dernière étape. La triamine **6** forme avec le bioxyde de carbone un adduit 1:1 (**11**) dont on a établi la structure par la rmn du ^{1}H et du ^{13}C. Cet adduit consiste en des quantités équimoléculaires de carbamate **A** et de dicarbamate **BC**. On peut séparer les composants **A**, **B** et **C** des résidus par échangeurs d'ions. La thermolyse du composé **11** regénère le composé **6** de façon douce, fournissant ainsi une méthode de purification de la triamine.

[Traduit par le journal]

Introduction

As part of a program on the synthesis of new flame retardants for cotton, a supply of tris-(aminomethyl)phosphine oxide (**6**) was needed in quantities suitable for fabric testing. Until recently, **6** was accessible only from tetrakis(hydroxymethyl)phosphonium chloride (THPC, **1*a***)[3] by a five-step synthesis via tris(chloromethyl)phosphine oxide in a overall yield of 28.8% (1–5). The last step of this synthesis, a Gabriel reaction (5), was ill suited for scale-up. Recently, we described an alternate synthesis of **6** from **1*a*** via the four-step carbamate route outlined in Scheme 1. The overall yield of **6**, isolated as the crystalline trihydrobromide **7*b***, was 44.5% (6, 7).

In this paper, I describe some improvements in the carbamate method, changes that make it useful for synthesizing **6** in the laboratory on a preparative scale. The most significant changes are (*i*) substitution of THPS (**1*b***) for **1*a*** as the starting material, (*ii*) oxidation of the tertiary phosphine **3** with aqueous hydrogen peroxide *in situ*, and (*iii*) hydrolysis of the tertiary phosphine oxide **4** under alkaline rather than acid conditions. Finally, I describe a novel method of purifying **6** through its 1:1 adduct with carbon dioxide, a method that is potentially useful for the purification of other water-soluble, non-volatile primary or secondary amines.

Results and Discussion

The original starting material, THPC (**1*a***), is no longer manufactured in the United States because it is a potential source of formaldehyde and hydrogen chloride, precursors of the carcinogen bis-(chloromethyl) ether (8). In its place, other tetrakis-(hydroxymethyl)phosphonium salts are available commercially: the sulfate (**1*b***) THPS (Hooker Chemicals and Plastics Corp., Niagara Falls, NY) or TKO, the oxalate TKS, and the mixed phosphate/acetate TKP (Pyroset Series, American Cyanamid Co., Bound Brook, NJ). THPC is still available from foreign sources (Tetrakis-80, Aceto Chemical Co., Inc., Flushing, NY).

Reaction of methyl carbamate with **1*b*** under the conditions employed with **1*a*** (6) gave a quantitative yield of the diphosphonium sulfate **2*b***. This product, unlike the phosphonium chloride **2*a***, could not be induced to crystallize. It was characterized by ir and nmr spectroscopy and by conversion to **2*a*** with barium chloride.

Hydrolysis of **2*b*** with ammonium hydroxide under the conditions employed with **2*a*** (6) gave a quantitative yield of the tertiary phosphine **3**, mp 110–115°C, identical (ir, nmr) to the product obtained from **2*a***.

Oxidation of the tertiary phosphine **3** with hy-

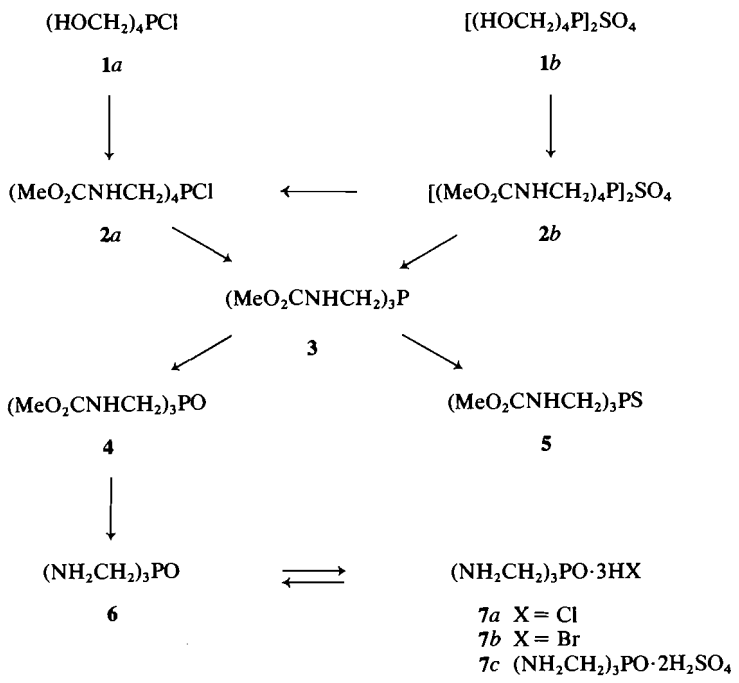

SCHEME 1. Synthesis of **6** from **1***a* or **1***b* via the carbamate route.

drogen peroxide in acetone, as described previously (6), gives the tertiary phosphine oxide **4** in yields of 69% to 84%. Although I have carried out this oxidation on numerous occasions without incident, the use of acetone poses a hazard because mixtures of acetone and hydrogen peroxide are potentially explosive (9). Water is just as effective as a solvent, and the hydrolysis by-products need not be removed before oxidation. Hydrolysis of **2***b* with ammonium hydroxide, followed by oxidation *in situ* with hydrogen peroxide, gave **4** in 88% yield, compared to 89% when the excess ammonium hydroxide and by-products were removed before oxidation. The phosphonium salts **2***a* and **2***b* are stable to hydrogen peroxide in the absence of base. The preferred procedure, described in the Experimental, gave a 70.6% yield of recrystallized **4**, based on **1***b*, without pausing to isolate either of the intermediates **2***b* or **3**.

The tertiary phosphine sulfide **5**, previously prepared in 73.4% yield by the reaction of **3** with sulfur in benzene (6), was prepared from **1***b* in 48.9% overall yield by condensation with methyl carbamate, hydrolysis with ammonium hydroxide, and sulfurization *in situ* with ammonium polysulfide.

Hydrolytic cleavage of carbamates to primary amines under alkaline conditions is practiced much less frequently than cleavage under acid conditions (10, 11). Hydrolysis of the tertiary phosphine oxide **4** with sodium hydroxide for 5 h at 100°C produced no visible change, but extensive gassing occurred when the solution was acidified. The product, identified by ir and nmr, was the triamine trihydrochloride **7***a*. The product was difficult to separate from the sodium chloride because of their similar solubility characteristics; the mixture was therefore neutralized with sodium hydroxide, giving the triamine **6** in 81.7% yield.

This difficulty was avoided by hydrolyzing **4** with barium hydroxide instead of sodium hydroxide. Barium carbonate separated during the reaction, enabling the progress of the reaction to be observed (eq. [1]). The excess base was destroyed by carbonation with Dry Ice while the reaction mixture was still hot. No gassing occurred when the filtrate was acidified, and the triamine trihydrochloride **7***a* was obtained in 93.2% yield. Neutralization of **7***a* with sodium hydroxide gave pure **6** in quantitative yield.

$$[1]\quad \underset{\mathbf{4}}{(MeO_2CNHCH_2)_3PO} + 3Ba(OH)_2 \rightarrow \underset{\mathbf{6}}{(NH_2CH_2)_3PO} + 3BaCO_3 + 3MeOH$$

If the filtrate was acidified with sulfuric acid instead of hydrochloric acid, the triamine was isolated as the crystalline bis(dihydrogen sulfate) **7***c* in 90.3% yield. Neutralization with barium hydroxide, followed by carbonation with Dry Ice at 100°C to destroy the excess base, gave pure **6** in quantitative yield.

If the filtrate was not acidified, the triamine **6** could be isolated directly. The crude product was

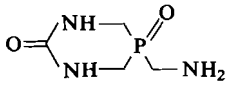
almost pure **6**, together with a by-product from which it was easily separated. The by-product was 5-aminomethyl-1,3-diaza-5-phosphorinan-2,5-dione (**8**).[4]



8

This by-product is a white, crystalline solid, mp 204–206°C, that forms crystalline 1:1 salts (**9***a*,*b*) with hydrochloric acid and sulfuric acid. The formation of **8**, a cyclic monomeric urea derivative, was surprising in view of a study of the condensation of urea with **1***a*. In that study (12), the products and their derivatives were invariably polymeric. Because the starting material **4** contained no **8** (by nmr), the by-product must have been formed during the hydrolysis, probably by degradation of a carbomethoxylamino group to an isocyanate group, followed by ring closure with an adjacent amino group. The yield of the by-product was highest (15–20%) in the preparative scale reactions. Attempts to hydrolyze **8** to **6** or to synthesize **8** from **6** and urea (13) were unsuccessful.

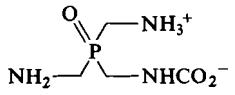
For large-scale preparations, it was more convenient to use calcium hydroxide as the base. The yield of **6**, isolated as the hydrate, was 74.8% based on **4**, or 54.6% overall based on **1***b*.

Reaction of 6 with Carbon Dioxide

Pure **6** did not absorb carbon dioxide in the absence of a solvent, but when a stream of carbon dioxide was passed into a solution of **6** in methanol or ethanol, a white solid separated immediately. The product was a fluffy solid (**10**), mp 57°C, that changed into a compact solid (**11**), mp 138°C dec., on exposure to the air. The final product (**11**) was a 1:1 adduct of **6** and carbon dioxide. Its elemental composition, molecular weight, and ir and ^{1}H nmr spectra are consistent with structure **A**, an intramolecular carbamate salt.

The ^{1}H nmr spectrum of **11** in D_2O showed a pair of doublets for the three methylene groups in a ratio of 4:2. The stronger doublet, δ 3.38 (J = 6.0 Hz), appearing slightly downfield of the doublet in **6**, represents the two aminomethylene groups, averaged by proton exchange between the nitrogens. The weaker doublet, δ 3.77 (J = 7.5 Hz), appearing further downfield. represents the carboxylaminomethylene group. These assignments were verified by subsequent experiments.

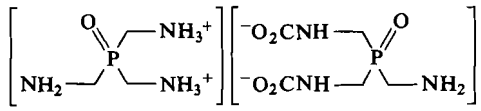
The ^{13}C nmr spectrum of **11** in D_2O (Table 1) exhibited separate signals for the three methylene groups, each split into a doublet of triplets because of coupling with phosphorus (1:1) and hydrogen (1:2:1). A small unsplit signal for the carboxyl carbon *d* appeared far downfield at δ 164.3. The weak doublet at δ 38.0 was assigned to the carboxylaminomethylene carbon *c*. The intensities of the signals were consistent with the assignments, but the nonequivalence of the aminomethylene carbons *b* was incompatible with structure **A**.



A

Addition of NaOD to a solution of **11** in D_2O altered its ^{1}H nmr spectrum, shifting the weak doublet to δ 3.66 (J = 5.5 Hz) and splitting the strong doublet into a pair of equal overlapping doublets, δ 3.15 (J = 5.5 Hz) and 3.17 (J = 6.0 Hz). The doublet at δ 3.17 coincided with **6**. No barium carbonate separated when barium chloride was added. The spectrum remained unchanged as the temperature was raised from 30°C to 60°C, but at 70°C it changed irreversibly, the doublet at δ 3.17 increasing in intensity at the expense of the other doublets. Similar behavior was produced by other strong bases such as ammonia or trimethylamine, but not by weak bases such as pyridine. Bases have a stabilizing influence on carbamates (14).

These experiments ruled out nonequivalence of the methylene hydrogens caused by restricted rotation or internal asymmetry (15). The displacement of **6** from **11** without hydrolysis suggested the alternate structure **BC**, an intermolecular dicarbamate salt.



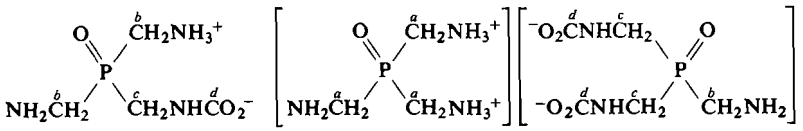
B **C**

This structure is compatible with the elemental composition, molecular weight, and ir and nmr spectra of **11**, but not with the molar ratios observed after treatment with base. The spectra can, however, be reconciled if **11** is comprised of structures **A** and **BC** in a 1:1 molar ratio. At this ratio, there are three *a* groups in structure **B**, and three *b*, *c*, and *d* groups apiece distributed between structures **A** and **C**. Separate signals are observed for the four groups in the ^{13}C nmr spectrum. The signals for *a* and *b* coincide in the ^{1}H nmr spectrum, but separate when base is added, liberating **B** as the free amine **6**.

It occurred to me that Kunin's method for

[4]Models of this compound have a rigid ring structure with no boat or chair forms. The P oxygen, however, may be axial or equatorial.

TABLE 1. ^{13}C nmr data for **6** and its derivatives



A **B** **C**

Compound	Formula	Intensity (%)	Assignment	δ_C (ppm)	J_{PC} (Hz)	J_{HC} (Hz)
6	$(NH_2\overset{a}{C}H_2)_3PO$	100	*a*	35.7	66.9	137.0
7a	$(NH_3^+\overset{a}{C}H_2)_3PO\ 3Cl^-$	100	*a*	36.8	71.4	144.8
11	**A** + **BC**	100	*a* (or *b*)	35.8	65.4	140.9
		85	*b* (or *a*)	36.0	72.3	139.3
		60	*c*	38.0	72.9	139.2
		17	*d*	164.3	0	0

separating the amino acids into acid, neutral, and basic classes by ion exchange (16, 17) might be useful for separating **11** into its components **A**, **B**, and **C**. Cation exchange resins and acidic reagents were avoided because of the sensitivity of carbamates to acids. Rexyn 203, a weak base anion exchange resin, did not adsorb any of the components, but Rexyn 201, a strong base anion exchange resin, adsorbed the acid component **C**, allowing the neutral component **A** and the basic component **B** (displaced as **6**) to pass through. The dicarbamate **C** could be displaced from the resin by sodium hydroxide but not by ammonium hydroxide; barium hydroxide gave an insoluble precipitate. Two-thirds (67%) of the carbon dioxide in **11** was present as the dicarbamate, confirming a 1:1 stoichiometry for **A**:**BC**.

Analogous structures have been invoked for the 1:1 adducts of carbon dioxide with ethylenediamine (18, 19) and other diamines (18, 20) to explain their behavior toward reagents such as phosgene and diazomethane. Estimates of the percentage of carbon dioxide present as the dicarbamate ranged from 20% (19) to 50% (18), falling to 0% after aging (20).

The initial fluffy product (**10**) of the reaction of **6** and carbon dioxide could be isolated by vacuum drying, preferably after rinsing with carbon tetrachloride. It seemed to be stable indefinitely if not exposed to the air; the original sample was unchanged after storage for a year. The composition, ^1H nmr spectrum, and behavior of **10** toward barium chloride, NaOD, and ammonia were identical to those of **11**, but the ir spectra differed in the 800–900 cm^{-1} region.

The transformation of **10** to **11** upon exposure to air (moisture) is seen to be a hydrogen bond breaking process that allows the product to rearrange to a more compact crystalline form. The transformation can be accelerated by adding a little water to the solution of **6** in ethanol before passing in the carbon dioxide.

Treatment of **6** with carbon dioxide in an aqueous solution at room temperature yielded no solids, but after stripping the product was a 3:1 mixture of **6** and **11**. No carbamate formed in boiling water, methanol, or ethanol. A slurry of **11** in ethanol decomposed to **6** and carbon dioxide when heated to reflux. If the carbon dioxide was swept out with argon, nothing separated on cooling, but if the reaction was carried out in a carbon dioxide atmosphere, the carbamate **10** separated on cooling.

In a paper ionophoresis study of the reaction of mono-, di-, and polyamines with carbon dioxide, Frahn and Mills (21) reported that polyamines form mixtures of mono-, di-, and polycarbamates. The upper limit for each was equal to the number of amino groups the polyamine contained. To see if **6** was capable of forming a tricarbamate, the monocarbamate **11** was dissolved in D_2O and saturated with carbon dioxide; the ratio of the doublets in the ^1H nmr spectrum changed from 2:1 to 1:1. If every free amino group in **A** and **BC** acquired either a carboxyl anion or a proton, the product would be a sesquicarbamate (3:2 adduct of CO_2 and **6**) whose *a*,*b*:*c* ratio is 1:1. No further reaction is possible.

When a solution of **11** in D_2O was treated with ammonia before saturation with carbon dioxide, however, the *a*,*b* doublet was almost completely suppressed in favor of a strong *c* doublet at δ 3.64 (J = 4.5 Hz). The product, which was not isolated, was presumably the ammonium salt $[NH_4^+]_3[P(O)(CH_2NHCO_2^-)_3]$ (**12**). Similar spectra, though not as sharply defined, were produced by solutions

of **11** in D_2O containing ammonium carbonate, or sodium carbonate after saturation with carbon dioxide.

Thermolysis of 11

The carbamate **11** decomposed cleanly when heated gently over a gas flame, leaving pure **6** as a colorless, anhydrous oil. This way to purify **6** is more convenient than the other methods available, provided that care is taken to prevent the reabsorption of carbon dioxide on cooling. Thermolysis proceeded smoothly when the solid was heated in an oil bath under vacuum, or in a drying pistol with a high boiling solvent such as xylene.

Pure **6** is a colorless hygroscopic oil, n_D^{20} 1.5682. On exposure to air, it rapidly forms a hydrate, n_D^{20} 1.5628. Neither substance has the properties ascribed to **6** in the literature (5). The hydrate, the product isolated when aqueous reagents are employed, can be dehydrated by drying under vacuum at 100°C or by azeotropic distillation with benzene. The carbamates **10** and **11** yield the anhydrous product directly.

A 20% solution of **6** in water is almost neutral (pH 7.80). The ^{13}C nmr spectrum, which has not been reported previously, exhibits only one signal for the three methylene carbons, split into a doublet of triplets because of coupling with phosphorus (1:1) and hydrogen (1:2:1). The spectrum of the trihydrochloride **7***a* exhibits a similar pattern, slightly expanded and slightly downfield (Table 1). Other properties of **6** and its salts are reported elsewhere (7).

Hydrolysis of Other Compounds

Hydrolysis of **2***a*, **2***b*, or **3** with barium hydroxide under the conditions employed with **4** gave the tertiary phosphine oxide **6**, isolated as the trihydrochloride **7***a*, in 75% to 78% yield, even though air was excluded and the excess base was destroyed with carbon dioxide from a cylinder instead of Dry Ice. There was no evidence of alkyl-nitrogen fission. Hydrolysis of the tertiary phosphine sulfide **5** with barium hydroxide was complete in 2 h, but the product was a mixture of unidentified amine salts.

Urea derivatives of **1***a* and **1***b* were difficult to hydrolyze and gave even poorer results. Hydrolysis of the urea derivative **13***a* (22) with barium hydroxide was 55% complete after 4 h refluxing and 84% complete after 10 h (eq. [2]). The yield of **14***a*, isolated as the trihydrochloride **7***a*, was 52%. Hydrolysis of the 1,3-dimethylurea derivative **13***b* (22) with barium hydroxide was 58% complete after 16 h refluxing. The products, separated into neutral and amine salt fractions by ion exchange chromatography (6), were complex mixtures whose high CH_3/CH_2 ratios, coupled with the identification of 1,1,3-trimethylurea as one of the products, provided evidence of C—P bond cleavage. The use of 75% ethylene glycol to raise the bp to 120°C increased the extent of hydrolysis to 87% after 30 h refluxing, but the product (**14***b*) was destroyed. The results were no better when the urea derivatives were hydrolyzed with sodium hydroxide or hydrobromic acid.

[2] $$\underset{\mathbf{13}}{[RNHCON(R)CH_2]_3PO} + 3Ba(OH)_2 \rightarrow \underset{\mathbf{14}}{(RNHCH_2)_3PO} + 3BaCO_3 + 3RNH_2$$

a R = H
b R = CH_3

Experimental

Melting points were corrected. Elemental analyses were performed by Galbraith Laboratories, Inc., Knoxville, TN. The ir spectra were taken on a Perkin-Elmer 137B (w weak, m medium, s strong, vs very strong); ^1H nmr spectra were taken on a Varian EM-360L with DSS as an internal lock, ^{13}C nmr spectra on a Varian CFT-20 with dioxane as an internal reference, and ^{31}P nmr spectra on a JEOL C60-HL at 24.3 MHz with 85% H_3PO_4 as an external reference (s singlet, d doublet, t triplet, m multiplet). All reagents were used as obtained.

Octakis(N-carbomethoxylaminomethyl)diphosphonium Sulfate (2b)

A mixture of 75% aqueous **1***b* (270.8 g, 0.5 mol) and methyl carbamate (300.2 g, 4 mol) was heated to reflux with constant stirring, held at 100–108°C for 2 h, allowed to cool, and stripped of water under reduced pressure, giving 443.8 g (102.9%) of **2***b* as an almost colorless tacky glass. Infrared (KBr): 1010 (m), 1110 (s), 1250 (vs), 1515 (s) (NH, amide II), 1720 (vs) (C=O, amide I), and 3300 m (NH) cm^{-1}; ^1H nmr (D_2O) δ: 3.74 (br s, 24H, CH_3) and 4.41 (br s, 16H, CH_2) ppm; ^{31}P nmr (H_2O) δ: 28.8 ppm.

On a fivefold scale it is advisable to add the methyl carbamate in 3 to 4 portions to the **1***b* at 70°C and heat to reflux between additions.

Tetrakis(N-carbomethoxylaminomethyl)phosphonium Chloride (2a)

A solution of **2***b* (8.88 g, 0.01 mol) in water (25 mL) was mixed with a solution of barium chloride (2.08 g, 0.01 mol) in water (25 mL), resulting in an immediate separation of solids. The mixture was heated to boiling to coagulate the solids, allowed to cool, and filtered, giving 2.31 g (99.0%) of barium sulfate. The filtrate, stripped under vacuum, left a crystalline residue that was rinsed with ethanol and dried, giving 5.62 g (67.1%) of **2***a*, mp 187.5–188°C dec., identical (ir, ^1H nmr) to the product prepared from **1***a* (6).

Tris(N-carbomethoxylaminomethyl)phosphine (3)

A solution of **2***b* (400.0 g, 0.464 mol) in water (500 mL) was purged with argon and treated with concentrated ammonium hydroxide (200 mL) over 15 min at 21–26°C. Solids started to separate after a few min, and after 2 h another 200 mL of water was added to facilitate stirring. After 4 h the solids were collected on a filter, rinsed with water, and dried, giving 280.0 g

For personal use only.

(102.2%) of crystalline **3**, mp 110–115°C, identical (ir, ^{1}H nmr) to the product prepared from **2***a* (6).

*Tris(*N*-carbomethoxylaminomethyl)phosphine Oxide (4)*

A. From 3

Hydrogen peroxide (30%) was added dropwise to a well-stirred slurry of **3** (1476.2 g, 5 mol) in water (2000 mL) under an argon atmosphere, with ice-bath cooling applied as needed to keep the reaction temperature between 20 and 30°C. The addition was stopped after 3.5 h, when 550.6 g (4.85 mol) of hydrogen peroxide had been added; an iodine test for unreacted **3** was negative, and the product, which had separated during the reaction, abruptly foamed to the surface. The solids were collected on a filter, rinsed with water, and air-dried, giving 826.6 g (53.1%) of crystalline **4**, mp 179–180°C; ^{1}H nmr (Me_2SO-d_6) δ: 3.60 (s, 9H, CH_3), 3.55 (t, 6H, CH_2, J = 5.0 Hz), and 7.34 (m, 3H, NH) ppm, identical to the product prepared with acetone as the solvent (6).[5]

*B. From 2*b

A solution of **2**b (1078.4 g, 1.25 mol) in water (1600 mL) was purged with argon, stirred, and treated with concentrated ammonium hydroxide (500 mL) over 5 min at room temperature. In a few min, solids started to separate and the mixture warmed to the touch. After 2 h, the mixture, still containing the excess ammonia and by-products, was treated dropwise with 30% hydrogen peroxide (283.4 g, 2.5 mol) over a 2 h period, with ice-bath cooling applied as needed to keep the temperature below 30°C. The next day, the solids were collected on a filter, rinsed with ethanol, and air-dried, giving 435.9 g (56.0%) of crystalline **4**, mp 176–178°C dec. Work-up of the filtrate gave another 131.8 g (16.9%) of **4**, for a total yield of 73.0%. The products were combined and recrystallized from water (550 mL), giving 549.1 g (70.6%) of **4**, mp 180–181°C, identical (ir, ^{1}H nmr) to the product prepared from **3**.

*Tris(*N*-carbomethoxylaminomethyl)phosphine Sulfide (5)*

Concentrated ammonium hydroxide (500 mL) was added to a solution of **2***b* (1078.4 g, 1.25 mol) in water (1500 mL) in an apparatus previously purged with argon. Solids started to separate within min. After 2 h, the mixture, still containing the excess ammonia and by-products, was treated dropwise with 20% ammonium polysulfide (977 g, 2.87 mol) over 2 h at 25–30°C. The next day, the solids were collected on a filter, rinsed thoroughly with water, and air-dried, giving 521.4 g of crude **5**, mp 120–125°C. One recrystallization from ethanol gave 398.3 g (48.9%) of **5**, mp 132–135°C, identical (ir, ^{1}H nmr) to the product prepared from **3** (6).

Tris(aminomethyl)phosphine Oxide (6)

A. From 4

A slurry of **4** (311.2 g, 1 mol), calcium hydroxide (237.1 g, 3.2 mol), and water (2500 mL) was heated to reflux in an apparatus fitted with a mechanical stirrer and a K-head reflux condenser. Some of the methanol-containing distillate was drawn off from time to time and replaced by sufficient water to maintain the original volume. After 5 h at 98°C, the mixture was carbonated with Dry Ice until neutral through a tube extending through the reflux condenser and under the surface. The mixture was then purged with argon[6] and allowed to cool. The next day, the mixture was filtered to remove the calcium carbonate (323.5 g, 101.0%) and stripped under reduced pressure. After drying, the residue was shaken with ethanol, filtered to remove the by-product **8** (see below), and stripped again, giving 116.0 g (74.8%) of **6** hydrate as a colorless oil, n_D^{20} 1.5655, identical (ir, ^{1}H nmr) to the product prepared from **7***a* (7).

A portion of the product was dried by azeotropic distillation with benzene, with an efficient stirrer, an oil bath, and a Dean-Stark trap to collect the water. The refractive index (n_D^{20}) of the dried product was 1.5682. Another portion of the product was recovered unchanged after 5 h refluxing with calcium hydroxide.

*B. From 7*c

A hot solution of barium hydroxide octahydrate (31.55 g, 0.1 mol) in water (250 mL) was added to a hot solution of **7***c* (13.33 g, 0.04 mol) in water (250 mL). Solids separated at once. After 1 h at 65°C, the excess base was destroyed by passing a stream of carbon dioxide from a Dry Ice generator under the surface of the mixture until the contents were neutral. The mixture was heated to boiling, filtered through Celite filter aid, and stripped under vacuum, giving 6.20 g (100.0%) of **6** hydrate as a colorless oil, n_D^{20} 1.5538, identical (ir, ^{1}H nmr) to the product prepared from **7***a* (7). A portion of the product, dried in a drying pistol at 100°C, had a refractive index (n_D^{20}) of 1.5684.

C. From 11 (or 10)

Two 1-g samples of **11** were weighed in small vials and heated in a drying pistol by xylene (bp 139°C) at 0.7 Torr until the effervescence ceased. Weight loss, calcd.: 24.30%; found: 25.05, 24.88%. The product was a colorless oil, n_D^{20} 1.5681, identified as **6** by ir and ^{1}H nmr. Under the same conditions, **10** lost 30.00% of its weight, giving **6** as a colorless oil, n_D^{20} 1.5687, identical (ir, ^{1}H nmr) to the product obtained from **11**.

5-Aminomethyl-1,3-diaza-5-phosphorinan-2,5-dione (8)

The ethanol-insoluble by-product of the hydrolysis of **4** with calcium hydroxide (see **6**, method A, above) was a white, crystalline solid, 23.9 g (14.6%), mp 198–200°C. A portion of the substance was recrystallized from ethanol–water for analysis, mp 204–206°C; ir (KBr): 760–780 (s), 927 (m), 1155 (vs) (P=O), 1235 (s), 1290 (m), 1410 (m), 1520 (s) (NH, amide II), 1640 (m), 1670 (vs) (C=O, amide I), 2900 (m), 3100 (s), and 3270 (vs) (NH) cm^{-1}; ^{1}H nmr (D_2O) δ: 3.37 (d, 2H, chain CH_2, J = 5.5 Hz), 3.62 (t, 2H, J = 1.5 Hz), and 3.82 (s, 2H) ppm.

Anal. calcd. for $C_4H_{10}N_3O_2P$: C 29.45, H 6.18, N 25.77, P 18.99; *Mol. Wt.* 163.12; found: C 29.13, H 6.30, N 25.99, P 18.98; *Mol. Wt.* (osmometric in H_2O) 162.

The product (**8**) is soluble in water and insoluble in organic solvents. After 5 h refluxing with calcium hydroxide in water, most of it (86.9%) was recovered unchanged; the remainder contained no **6**.

Salts of 8

A solution of **8** (4.89 g, 0.03 mol) in water (15 mL) was treated with concentrated hydrochloric acid (25 mL), stripped under vacuum, shaken with ethanol, and filtered, giving 5.39 g (90.0%) of the HCl salt **9***a* as a white, crystalline solid, dec. 244°C. Infrared (Nujol): 746 (m), 834 (m), 935 (m), 1075 (m), 1115 (m), 1175 (vs) (P=O), 1240 (s), 1510 (vs) (NH, amide II), 1600 (s), 1650 (vs) (C=O, amide I), and 3130 (vs) (NH) cm^{-1}; ^{1}H nmr (D_2O) δ: 3.85 (d, 2H, chain CH_2, J = 7.5 Hz) and 3.92 (d, 4H, ring CH_2, J = 12.0 Hz) ppm.

Anal. calcd. for $C_4H_{11}ClN_3O_2P$: C 24.07, H 5.56, Cl 17.77, N 21.06, P 15.52; found: C 24.04, H 5.66, Cl 17.95, N 20.83, P 15.56.

The H_2SO_4 salt **9***b*, a white, crystalline solid, dec. 237°C, was similarly prepared from **8** and concentrated sulfuric acid in 98.8% yield. Infrared (Nujol): 862 (m), 1040 (s), 1170 (s) (P=O),

[5]The ^{1}H nmr spectrum of **4** was erroneously reported to show a signal for the CH_2 hydrogens at δ 3.47 (t, 6H, CH_2, J = 9.0 Hz) ppm (6). The corrected values for the original spectrum are identical to those of the present paper.

[6]Purging with an inert gas was necessary to prevent the carbon dioxide from reacting with the product after the mixture was cooled.

For personal use only.

1240 (m), 1495 (s) (NH, amide II), 1650 (s) (C=O, amide I), and 3200 (s) (NH) cm^{-1}; ^1H nmr (D_2O) δ: 3.85 (d, 2H, chain CH_2, $J = 7.5$ Hz) and 3.92 (d, 4H, ring CH_2, $J = 12.0$ Hz) ppm.

The salts **9***a* and **9***b* are soluble in water and insoluble in organic solvents. Unlike **7***a* and **7***c*, they are also soluble in concentrated HCl and H_2SO_4, respectively. Neutralization with a base such as sodium hydroxide or calcium hydroxide regenerates the amine (**8**) quantitatively.

(Bis(aminomethyl)phosphinyl)methylcarbamic Acid (11)

A stream of carbon dioxide from a Dry Ice generator was passed into a solution of **6** (13.71 g, 0.1 mol) in ethanol (300 mL) over 1 h with constant stirring. Solids started to separate at once. The solids were collected on a filter, rinsed thoroughly with ethanol, sucked dry, and set aside for 24 h in an uncovered dish. On standing, the product changed from a light, fluffy solid to a compact solid covered with a layer of ethanol. The solids were once again collected on a filter, rinsed with ethanol, and dried under vacuum, giving 15.97 g (88.2%) of **11** as a white, crystalline solid, mp 138°C dec. Infrared (KBr): 840 (m), 880 (s), 1115 (s), 1140 (vs) (P=O), 1330 (vs), 1375 (w), 1470 (s), 1570 (vs) (C=O), 2950 (m), and 3300 (s) (NH) cm^{-1}; ^1H nmr (D_2O) δ: 3.38 (d, 4H, $C_{a,b}H_2$, $J = 6.0$ Hz) and 3.77 (d, 2H, C_cH_2, $J = 4.5$ Hz) ppm; see Table 1 for ^{13}C nmr data and identification of carbon atoms *a–c*.

Anal. calcd. for $C_4H_{12}N_3O_3P$: C 26.52, H 6.68, N 23.20, P 17.10; *Mol. Wt.* 181.14; found: C 26.64, H 6.61, N 23.24, P 17.10; *Mot. Wt.* (osmometric in H_2O) 190.

The carbamate **11** is soluble in water and insoluble in organic solvents. Its aqueous solution is neutral. Acids such as acetic acid produce gassing, but bases such as sodium hydroxide or barium hydroxide give stable solutions. Efforts to recrystallize the carbamate were unsuccessful. The product oils out from ethanol–water but solidifies on standing and can be recovered unchanged.

Separation of 11 into its Components

A solution of **11** (3.26 g, 18 mmol) in water (5 mL) was transferred to a 50-mL buret containing a 17-cm column of Rexyn 201 (OH form) ion exchange resin and eluted at a flow rate of 1 mL/min. The effluent (250 mL) was stripped to low volume under vacuum, treated cautiously (gassing) with concentrated HCl (50 mL), diluted with ethanol (50 mL), and filtered, giving 2.97 g (12.05 mmol, 100.4%) of **7***a*. The resin was then eluted with 4% NaOH. The effluent (200 mL) was treated with barium chloride (5.00 g, 24 mmol), boiled for 1 h, cooled, and filtered, giving 2.32 g (11.76 mmol, 98.0%) of barium carbonate.

Received June 27, 1980

STEWART MCLEAN, RENUKA MISRA, VIJAYA KUMAR, and JOHN A. LAMBERTON. Can. J. Chem. **59**, 34 (1981).

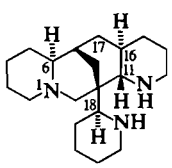
The major alkaloids of *Podopetalum ormondii* have been shown to be (−)-podopetaline, (−)-ormosanine, and 6-epipodopetaline. A constant-melting substance, mp 160–161°C, isolated from the extract proved to be a quasiracemate of (−)-podopetaline and (−)-ormosanine; the absolute configuration of (−)-ormosanine consequently followed from the established absolute configuration of (−)-podopetaline. Both (−)-6-epipodopetaline, mp 118–119°C, and its racemic form, mp 174–175°C, were isolated from the extract. A constant-melting ternary mixture, mp 178–179°C, of the three major alkaloids has also been isolated.

STEWART MCLEAN, RENUKA MISRA, VIJAYA KUMAR et JOHN A. LAMBERTON. Can. J. Chem. **59**, 34 (1981).

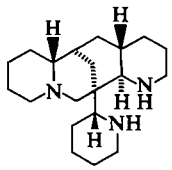
On a montré que les alcaloides principaux de la *Podopétalum ormondii* sont la (−)podopétaline, la (−)ormosanine et l'épi-6 podopétaline. Des extraits bruts, on a isolé une substance qui a été recristallisé jusqu'à un point de fusion constant de 160–161°C et qui semble être le quasi racémate de la (−)podopétaline et de la (−)ormosanine. On en a donc déduit la configuration absolue de la (−)ormosanine, basée sur la configuration connue de la (−)podopétaline. Des extraits bruts, on a isolé la (−) épi-6 podopétaline de pf 118–119°C et son racémique de pf 174–175°C. On a également isolé un mélange ternaire à point de fusion constant pf 178–179°C comprenant les trois alcaloides principaux.

[Traduit par le journal]

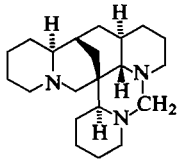
The Ormosia alkaloids (1) are a group of bases structurally related to the pentacyclic $C_{20}H_{35}N_3$ alkaloid ormosanine (I); they were originally isolated from *Ormosia* species, but have subsequently been found in a number of related leguminous plants. Structural variations have not been common in this group of alkaloids and most of the complexity has arisen from stereochemical features. Ormosanine is a member of a set of diastereoisomers containing sixteen pairs of enantiomers, of which four other members have been identified as natural products and most of the rest have been obtained synthetically or semisynthetically. Since these compounds are saturated and contain three basic nitrogens, the shortage of suitable functional groups has made investigation by chemical methods extremely challenging and the common spectroscopic techniques provide little useful information. X-ray analysis has consequently been of paramount importance in structural studies, the first of these analyses (2) being of (±)-jamine (II), the so-called homo derivative of ormosanine, formed by condensation with formaldehyde. With the skeletal features of this key alkaloid established, much subsequent work was carried out using both chemical methods and X-ray analysis to determine the stereochemistry of other members of the diastereoisomeric set. It became apparent during this study that some alkaloids occur as racemic modifications in some plants and as single enantiomers in others.



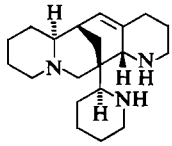
I [ormosanine]



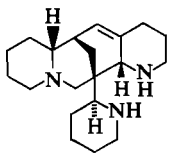
I′ [(−)-ormosanine]



II [jamine]



III[(−)-podopetaline]



IV [6-epipodopetaline]

Note. Where the absolute configuration of an alkaloid has been established, the sign of rotation is indicated and the proper absolute configuration is depicted; otherwise, only the relative configuration is implied.

One of the few structural variants found in the

Ormosia alkaloids is the presence of an ethylenic double bond between carbon atoms 16 and 17. These $C_{20}H_{33}N_3$ alkaloids belong to a second set of diastereoisomers containing eight pairs of enantiomers, each formally related to a pair of C-16 epimers of the ormosanine set.

In an earlier investigation of the alkaloids of *Podopetalum ormondii* (3), podopetaline (III), a $C_{20}H_{33}N_3$ base, was isolated and shown to be identical with one of the alkaloids of *O. semicastrata* (4). The structure and absolute configuration of (−)-podopetaline from *P. ormondii* was established by X-ray analysis of its hydrobromide (3). We now report on our further studies of the *P. ormondii* alkaloids.

A gc–ms examination of the total basic extract revealed that the strongest gc peak had the same retention time as podopetaline and showed ms peaks corresponding only to material of formula $C_{20}H_{33}N_3$ (M^+ 315). There were two other prominent gc peaks: the first was resolved from the podopetaline peak only under optimal conditions and corresponded to $C_{20}H_{35}N_3$ (M^+ 317) material; the second corresponded to $C_{20}H_{33}N_3$ material. A number of much smaller gc peaks indicated the presence of other alkaloids of this group, but it appeared unlikely that isolation of these alkaloids would be feasible. We have used a variety of techniques for separating the alkaloids of the total extract and we have identified three chemically distinct alkaloids, each corresponding to one of the major gc peaks; it is almost certain, therefore, that these peaks correspond to chemically homogeneous substances. The major alkaloid is clearly podopetaline (III), the $C_{20}H_{35}N_3$ alkaloid is ormosanine (I), and the second $C_{20}H_{33}N_3$ alkaloid is 6-epipodopetaline (IV). However, during the investigation other crystalline substances were isolated that initially suggested that the extract contained other isolable alkaloids. Our present results show that this is not the case, but the nature of these crystalline substances is intrinsically interesting and provides information of particular significance to the study of Ormosia alkaloids.

The major alkaloid, (−)-podopetaline (III) was readily isolated by any of the techniques we used. We isolated (−)-6-epipodopetaline (IV), mp 118–119°C, by first partitioning the total extract between an alkaline buffer and ether, and then fractionally crystallizing the material obtained from the organic phase. The structure and relative configuration of this alkaloid were determined by X-ray crystal structure analysis using the direct method (5). This analysis did not provide the absolute configuration of the molecule but it is clear that the crystal examined was configurationally homogeneous. The melting point of the sample remained constant after repeated recrystallizations, and despite the low value of its optical rotation, $[\alpha]_D$ −3.2° (MeOH), this material appears to consist of a single enantiomer. In another separation which employed chromatography and fractional crystallizations of the original alkaloidal extract, a small amount of a crystalline fraction, mp 174–175°C, $[\alpha]_D$ 0°, was isolated. This material proved to have the same spectroscopic and chromatographic properties as (−)-6-epipodopetaline, and is consequently identified as (±)-6-epipodopetaline. It follows that the 6-epipodopetaline of *P. ormondii* is partially racemic with a large excess of the levorotatory enantiomer.

Another fraction, obtained from the ether phase after the total extract had been partitioned between an alkaline buffer and ether, was obtained crystalline, mp 160–161°C, and this melting point was constant after repeated recrystallizations. However, it was clear from gc–ms analysis that this was not a homogeneous compound but a mixture of a $C_{20}H_{33}N_3$ component with the same retention time as podopetaline and a $C_{20}H_{35}N_3$ component with the same retention time as ormosanine. These components were conveniently separated by first converting them to their "homo" derivatives (see II) by condensation with formaldehyde. By this means it was established that the two components are (−)-podopetaline and ormosanine. The co-crystal was of considerable crystallographic interest since it was made up of a monoclinic component sandwiched between triclinic components. This provided a challenging problem for X-ray crystal analysis that was solved by Nyburg and his colleagues (6). The analysis confirmed the structural assignments made above, but went further by showing that the components form a quasiracemate of podopetaline and ormosanine of opposite absolute configurations. The co-crystal is levorotatory in methanol, $[\alpha]_D$ −33.9°; the podopetaline component has been shown to be (−)-podopetaline, $[\alpha]_D$ −48°, by its conversion to (−)-homopodopetaline; the ormosanine component has not been isolated directly, but was converted to (−)-homoormosanine (i.e. (−)-jamine). It follows from these figures that the ormosanine component is also levorotatory. Since the absolute configuration of (−)-podopetaline (shown in III) has been established previously (3), the absolute configuration of (−)-ormosanine follows from the X-ray crystal analysis, and is shown here as I′. This assignment

For personal use only.

corroborates that made by Cannon *et al.* (7), who interrelated (−)-ormosanine and (−)-templetine. (−)-Ormosanine, $[\alpha]_D$ −19°, has been obtained by chemical reduction of (−)-panamine (8), and we have previously isolated ormosanine with $[\alpha]_D$ −9° from *O. semicastrata*; (−)-jamine has been obtained from *O. costulata* (9).

The separation procedure that provided the binary mixture also afforded a small amount of a crystalline fraction, mp 178–179°C, which also proved to be a constant-melting mixture, this time apparently of three components. The gc–ms analysis of this material indicates that it is composed of the three major alkaloids in the extract, podopetaline, 6-epipodopetaline, and ormosanine, but no further work has been carried out on this material.

It is clear from the results reported here that the Ormosia alkaloids have a strong tendency to co-crystallize. Furthermore, as has been noted previously, there are difficulties in using the spectroscopic techniques to provide criteria of purity and identity. It is probable that other investigations have been made more difficult because of these features, and this may have led to some of the confusion in the literature in this field. The existence of alkaloids in either an optically active or a racemic form, the melting points of which may be quite different, is a further possible source of confusion. Our present results take this point a step further by demonstrating that an alkaloid may be found in a partially racemic form. Whether or not the racemic form and the enantiomer present in excess can be separated by fractional crystallization depends on their crystal properties. The observation of optical activity does not, therefore, provide evidence that a single enantiomer has been isolated, and the differences in rotations reported for some alkaloids may arise in this way.

The biogenesis of these alkaloids has been a matter for conjecture only (10, 11), but in a reasonable hypothesis it has been proposed that there is a route to a symmetrical intermediate that incorporates all of the skeletal atoms of the Ormosia alkaloids, and subsequent ring-closure steps determine the chirality at each centre in the alkaloid and its absolute configuration. It appears improbable that separate enzyme-mediated routes exist that lead in one case to a racemic alkaloid and in another to a single enantiomer. Podopetaline and ormosanine are obviously structurally closely related, but the present study shows that they occur together with opposite absolute configurations. It seems even more improbable that two enzymatic systems of opposite chirality coexist to form these two alkaloids. The original hypothesis (10) can therefore be extended by the postulate that the common biosynthetic route leads all the way to racemic alkaloids, and it is in the subsequent metabolism of these alkaloids that chiral selection occurs. Thus (±)-ormosanine could be formed first and then (+)-ormosanine could be oxidized selectively to (−)-podopetaline. Conversely, if (±)-podopetaline were formed first, the next step would require a stereospecific reduction of one enantiomer. Now that we have demonstrated the presence in *P. ormondii* of partially racemic 6-epipodopetaline, with a large excess of the levorotatory isomer, the postulate that the dextrorotatory isomer has been stereospecifically but incompletely metabolized is attractive.

This type of phenomenon may be common in some other alkaloidal families, but it may have gone unrecognized because of the absence of reliable information concerning the absolute configuration of the alkaloids. Examples of partially racemic alkaloids are known, and the case of (±)-kreysigine and (−)-floramultine, two homoaporphines of *Kreysigia multiflora*, may be cited (12) as an example of the co-occurrence in a single plant of an optically active alkaloid and a closely related but racemic congener. It is recognized, however, that in those cases where there is a common precursor that can racemize by equilibration of one chiral centre (or possibly a limited number of such centres), different reaction channels may lead from the common precursor to either racemic or optically active products. It may be difficult to find other examples corresponding to the case of the Ormosia alkaloids where such racemization can be ruled out and the co-occurrence of optically active and racemic alkaloids requires effectively the resolution of a complex racemic precursor possessing a number of chiral centres by selective metabolism of one enantiomer to produce the optically active alkaloid.

Experimental

Melting points were determined on a Thomas-Kofler micro hot stage. A CEC 21-490 mass spectrometer was used for routine spectra and an AEI MS902 spectrometer was used for mass measurements. For gc–ms measurements a 2 m × 2 mm-id glass column containing 3% OV-17 on GCQ was used with linear temperature programming (200–250°C at 12°C/min) and coupled to the 21-490 spectrometer.

Isolation Procedures

The total bases of the bark of *P. ormondii* were extracted by standard procedures and obtained as a brownish syrup.

(The Toronto and Melbourne laboratories used different isolation procedures. In each laboratory attention was focussed on selected fractions; subsequently it has become apparent that fractions that were initially set aside can provide substances that were isolated more conveniently by a different procedure. This

For personal use only.

report confines itself to a description of the procedures used to isolate materials discussed in this paper.)

(a) Chromatography

A solution of the crude basic extract in benzene was chromatographed on alumina (Woelm activity 1, pretreated with 1% of water). Elution with benzene and then 9:1 benzene–ether provided fractions from which crystalline podopetaline (3), mp 77.5–79°C, $[\alpha]_D$ −48° (*c* 0.95, methanol) was isolated (7.5%). Elution with chloroform provided fractions which contained the binary mixture of podopetaline and ormosanine. Elution with 9:1 chloroform–methanol provided fractions from which a crystalline material (~0.25%) was obtained; repeated recrystallization from acetone of this material gave (±)-6-epipodopetaline, mp 174–175°C; $[\alpha]_D$ 0° (*c* 0.29, methanol); M^+ at *m/e* 315. *Anal.* calcd. for $C_{20}H_{33}N_3$: C 76.1, H 10.5, N 13.3; found: C 76.3, H 10.6, N 12.8.

(b) Liquid–Liquid Extraction

The crude basic extract was dissolved in a minimum of dilute hydrochloric acid, and the solution was brought to pH 8.4 by the addition of a glycine – sodium hydroxide buffer. This solution was continuously extracted with ether; the ether was periodically removed, the aqueous solution was treated with sodium hydroxide to raise the pH by about 0.2 units, and this solution was extracted with fresh ether. Evaporation of the ether extracts afforded a series of alkaloidal fractions. Fractional crystallization of the first fraction (~10% of total crude) gave a small amount (~0.25%) of a crystalline substance, mp 178–179°C; gc–ms analysis showed that this was a mixture of three components in about equal amounts and with characteristics corresponding to podopetaline, 6-epipodopetaline, and ormosanine. This fractional crystallization also afforded a material (~1%) which was recrystallized from acetone to give (−)-6-epipodopetaline, mp 118–110°C; $[\alpha]_D$ −3.2° (methanol); M^+ at *m/e* 315 (315.2674). *Anal.* calcd. for $C_{20}H_{33}N_3$: C 76.14, H 10.54, N 13.32; found: C 75.95, H 10.38, N 13.60. This material showed the same ir, uv, nmr, and tlc characteristics as the racemic material, mp 174–175°C, described in (*a*) above.

The second fraction from the continuous extraction provided a material (~60% of total crude) which appeared on gc–ms examination to consist of two main components (*m/e* 317 and 315). Repeated recrystallization of this material from acetone provided a substance, mp 160–161°C; this melting point remained constant after further recrystallizations. This material $[\alpha]_D$ −33.9° (methanol), consisted of (−)-podopetaline and (−)-ormosanine in approximately equal amounts. (A sample was submitted for X-ray crystal structure analysis (6).)

Separation of Podopetaline/Ormosanine as "Homo" Derivatives

A solution of the above mixture of podopetaline and ormosanine (125 mg) in 5 mL of 88% formic acid and 3 mL of 37% formaldehyde was refluxed for 2.5 h; additional formic acid (2.5 mL) and formaldehyde (1.5 mL) were added and reflux was continued for a further 18 h. The solution was cooled and diluted with 75 mL of water, extracted with ether, made basic with ammonia, and thoroughly extracted with ether. The latter ether extract afforded a solid residue (127 mg) which was separated by preparative layer chromatography on silica gel with elution by diethylamine–hexane (1:18, then 1:9). The homopodopetaline fraction was obtained, after recrystallization from acetone, as plates (64 mg), mp 117–118.5°C; $[\alpha]_D$ −147.7° (*c* 0.2, methanol); ms *m/e*: 327 (100), 326 (28), 312 (11), 284 (15), 270 (8), 244 (31), 233 (29), 230 (19), 229 (51), 98 (75), and 84 (28). *Anal.* calcd. for $C_{21}H_{33}N_3$: C 77.01, H 10.16, N 12.83; found: C 76.82, H 10.06, N 12.64. This material was identical in every respect with a sample prepared in the same way from authentic (−)-podopetaline.

The ormosanine derivative, jamine (II), was recrystallized from acetone and obtained as needles (29 mg), mp 125–126.5°C; $[\alpha]_D$ −81° (*c* 0.3, methanol). This material was identical with a sample of (−)-jamine (9) obtained through the courtesy of Dr. K. L. Rinehart, Jr.

Solid state properties of poly-β-hydroxybutyrate and of its oligomers[1]

R. H. MARCHESSAULT,[2] SUZANNE COULOMBE, HIROMICHI MORIKAWA, KEIZO OKAMURA, AND J. F. REVOL

Department of Chemistry, Université de Montréal, C.P. 6210, Succ. A, Montréal (Qué.), Canada H3C 3V1

Received November 29, 1979[3]

R. H. MARCHESSAULT, SUZANNE COULOMBE, HIROMICHI MORIKAWA, KEIZO OKAMURA, and J. F. REVOL. Can. J. Chem. **59**, 38 (1981).

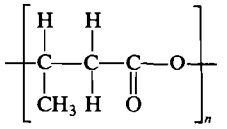
The solid state properties of poly-β-hydroxybutyrate (PHB) were investigated for samples with degrees of polymerization ($\overline{DP_n}$) from 4 to 994. The observed melting points ranged from 47°C to 180°C. Electron diffractograms on carefully prepared single crystals of a high molecular weight sample provided data which confirmed the reported *a* and *b* parameters from X-ray fiber diffraction and provided clear justification for the $P2_12_12_1$ space group. The observed intensities in the electron diffractogram, corresponding to (*hk*0) reflections, were compared with the predicted intensities for two proposed structures in the literature. The observed and calculated structure factors for both structures were in good agreement. Small angle X-ray diffraction of the meridional maximum for annealed "cold drawn" and "hot drawn" fibers showed a distinctly different dependence on temperature than the maximum for stacks of lamellar single crystals. For oligomers a long spacing was observed which was about twice the length of the sample $\overline{DP_n}$ multiplied by the crystalline advance per monomer.

R. H. MARCHESSAULT, SUZANNE COULOMBE, HIROMICHI MORIKAWA, KEIZO OKAMURA et J. F. REVOL. Can. J. Chem. **59**, 38 (1981).

Les propriétés de cristaux du poly-β-hydroxybutyrate (PHB) d'un degré de polymérisation ($\overline{DP_n}$) allant de 4 à 994 sont rapportées. Les points de fusion vont de 47°C à 180°C. Les absences systématiques observées en diffraction éléctronique sur monocristaux de forte masse confirment le groupe spatiale $P2_12_12_1$ proposé à partir du diagramme à fibre (rayons-X). Les intensités observées des réflections (*hk*0) du cliché de diffraction électronique sont en accord avec celles prédites à partir de deux structures crystallines proposées dans la literature et basées sur les données du diagramme à fibre. La diffusion méridionale des rayons-X aux petits angles pour des fibres étirées "à froid" et "à chaud" a été enrégistrée et la variation des maxima de diffusion, en fonction de la température, diffère sensiblement de ce qui est observé pour la variation de l'épaisseur de lamelles monocristallines. Pour des oligomères cristallins l'observation d'une tache de diffraction dont l'espacement est deux fois la longueur de la chaine dans sa conformation crystalline mène à proposer une maille avec deux chaines bout à bout selon l'axe *c*.

Introduction

Poly-β-hydroxybutyrate (PHB), discovered by Lemoigne (1) in 1927, is an important storage material in a wide variety of bacteria. It has been shown (2–5) that PHB is a linear head-to-tail polyester based on D(−)β-hydroxybutyric acid with the following formula:



This optically active polymer occurs in bacteria in a native form which is described as crystalline hydrophobic granules (6). The size, shape, and internal morphology of these granules have been discussed in a paper which proposed a spherulite model for the granules with tangentially oriented and fibrillar organized chains (7). It was proposed that during biosynthesis simultaneous polymerization and crystallization limited chain-folding in the crystalline native granules (7). From X-ray diffraction studies, it was found that, in the crystalline state, PHB adopts a regular helical conformation with space group $P2_12_12_1$ which implies antiparallel chains for this polar macromolecule. The orthorhombic unit cell with dimensions $a = 5.76$ Å, $b = 13.20$ Å, and c(fiber axis) = 5.96 Å contains two antiparallel chains (8–10). The crystalline structure of PHB was refined by energy minimization methods (9, 10).

As reported in the present paper, the solid state properties of PHB and of its oligomers were investigated by differential scanning calorimetry, small and wide angle X-ray diffraction, and electron microscopy and diffraction. From these studies basic information on the crystallizing behaviour of this uniquely stereoregular and chiral polymer is sought in order to better understand the native morphology and its process of morphogenesis.

Experimental

Samples

The physical characteristics of PHB samples used in this study are referred to in Table 1. A to H samples (isolated from different bacterial cultures using different extraction recipes) and I to M samples (prepared by fractionating a low molecular

weight sample ($\overline{M}_n$ = 694) on a Sephadex LH-20 column) are polydisperse and their number average molecular weight were measured with a Mechrolab High Speed Membrane Osmometer Model 501 and a Mechrolab Vapor Pressure Osmometer. N to R samples are monodisperse samples of PHB oligomers from octamer to tetramer. These monodisperse oligomer samples, isolated and purified by thin-layer chromatography (11), were provided by M. Bernard Hauttecoeur, Institut Pasteur, Paris.

Annealing

The single crystal powder was placed in a glass capillary and annealed in an oven whose temperature could be controlled to ±1°C. A system of purified, dry nitrogen was circulated at all times after initial evacuation-flushing. A thermometer near the sample registered the temperature. A typical heating schedule required about 30 min to reach the annealing temperature which was then maintained for 2 h. The samples were then gradually cooled to room temperature over a period of about 1 h by turning off the heating elements.

Melting Point and Differential Scanning Calorimetry

The melting point of the polymer samples was determined with a Mel-Temp melting point apparatus of which the heating rate was adjusted to 2°C/min.

The melting point and heat of fusion were also measured with a Perkin-Elmer differential scanning calorimeter model 1B. Indium was used as a melting point (156.4°C) and heat of fusion (12.43 cal/g) standard. A peak area of fusion which is proportional to heat of fusion was measured with Keuffel and Esser Compensating Polar Planimeters. The scanning speed of 10°C/min was used both for the standard (indium) and samples.

Wide Angle X-ray Diffraction

Crystalline oligomers (N to R samples) were submitted to wide angle X-ray diffraction. Powder diagrams were recorded on a cylindrical Debye-Scherrer camera which had a radius of 57.3 mm. A Philips X-ray unit operated at 40 kV and 20 mA was used with a Cu-tube as a radiation source. The Cu-K_α radiation (λ = 1.541 Å) was monochromatized by means of a Ni-filter. All samples were exposed to the X-ray beam for 7 h.

[a]Differential scanning calorimetry.

Single Crystal Growth

The preparation of PHB single crystals has been previously reported (6, 10). In order to obtain monolamellar single crystals, the growth conditions were optimized in the following way. One milligram of PHB was dissolved in 4 mL of a mixture of ethanol and chloroform (2:1, v/v) in a sealed tube at a temperature of 73°C. The solution was then cooled to 60°C and kept at this temperature for 24 h. In order to selfseed the solution, the precipitate formed was dissolved again at 73°C. Immediately after the disappearance of the precipitate, the solution was again cooled to 60°C and kept at this temperature for 24 h.

Small Angle X-ray Diffraction

A to M samples were studied by small angle X-ray diffraction in order to determine the thickness of polymer single crystal lamellae. For each sample from A to M, a single crystal suspension was made and sedimented to form a mat under suction. Small angle X-ray diffraction from these mats with the X-ray beam parallel to the mat plane gave a very sharp small angle maximum from which "*d*" spacing, the lamella thickness, was deduced.

A Warhus camera with double pinhole collimation and adjustable specimen to film distance (17–29 cm) was used. A Norelco X-ray unit operated at 35 kV and 20 mA was used with a fine focus Cu-tube as a radiation source. The Cu-K_α line (1.542 Å) was monochromatized by means of a Ni-filter. The exposure time ranged from 8 to 48 h depending upon the specimen size, the film to specimen distance, and the diameter of collimator.

Electron Microscopy and Diffraction

Samples C, M, and N were studied by electron microscopy and electron diffraction. Drops of the crystal suspension were deposited on carbon-coated grids and the solvent was allowed to evaporate. Observations were made with a Philips EM 300 electron microscope operating at 80 kV for images and at 100 kV for diffraction. The crystals were observed either unshadowed or after shadowing with tungsten. Gold was evaporated on the crystal preparations for diffraction calibration. The intensities of the observed reflections were measured by integration with a Joyce-Loebl recording microdensitometer.

Results and Discussion

Electron Diffraction Studies of the Crystalline Structure of PHB and of its Oligomers

The electron micrograph and diffractogram of sample C illustrated in Fig. 1 is characteristic of PHB single crystals. The crystal thickness was estimated to be 50 Å from the shadow length. A total of 28 reflections were observed in a quadrant of the diffractogram. From this diffraction pattern, the unit cell base plane parameters *a* and *b* were respectively 5.76 Å and 13.20 Å which agrees with those reported by previous authors (8–10) based on the analysis of the PHB X-ray fiber diagram. Consequently the electron diffractogram is an (*hk*0) section of the PHB reciprocal lattice and indicates (6, 8) that in the crystal and molecular chains are perpendicular to the lamella surface. The diffractogram also confirmed the *pgg* base plane symmetry since only even reflections are observed along (*h*00) and (0*k*0) directions. This confirms the

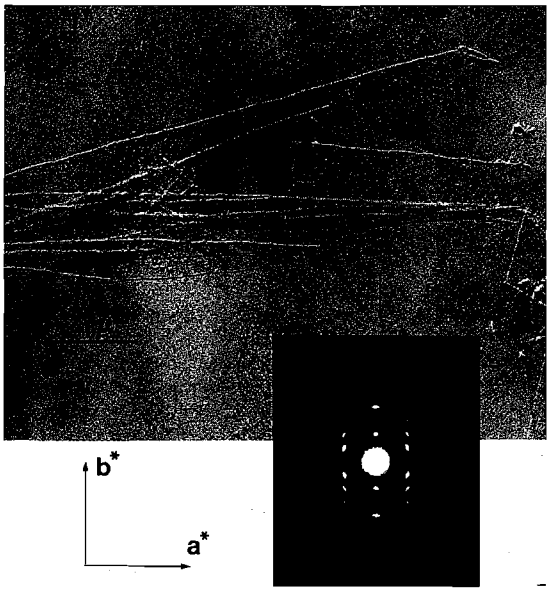

FIG. 1. Electron micrograph and diffractogram of sample C ($\bar{M}_n$ = 42 000 g/mol) where the PHB single crystals were shadowed with tungsten. The arrow in the micrograph points from the crystal region where the diffractogram was recorded with the orientation shown.

proposed orthorhombic $P2_12_12_1$ space group (8–10).

Cornibert and Marchessault (9) and Yokouchi *et al.* (10) independently proposed crystalline structure models of PHB based on X-ray diffraction and conformational analysis. Between these models the atomic coordinates of the C and O atoms in the asymmetric unit are in good agreement: the largest observed difference in the coordinates of the atoms was less than 0.18 Å. We next attempted a refinement of the models against the electron diffraction data using a least-squares refinement procedure with a scale factor K and an overall isotropic temperature factor B. Minimization of the quantity $\Sigma(F_o - F_c)^2$ was examined where F_o and F_c are the observed and calculated structure factors, respectively. F_o was derived from the observed intensity I_o by assuming $F_o = (I_o)^{1/2}$ (12). The electron scattering factors for C, O, and H atoms were taken from International tables for X-ray crystallography, vol. IV (13).

The lowest value of the discrepancy factor, defined by $R = \Sigma|F_o - F_c|/\Sigma F_o$ was 0.33 ± 0.01 with $K = 6.0 \pm 1.0$ and $B = 9.0 \pm 3.0$ Å^2 for the model of Yokouchi *et al.* (10). The same result was obtained with the Cornibert and Marchessault model (9) in which the scattering factor of oxygen was used for the methyl group since the exact coordinates of the hydrogen atoms of the group are not described. The F_o and F_c values are listed in Table 2. The assigned temperature factor of 9.0 ± 3.0 Å^2 is reasonable (10, 14) and the discrepancy factor R of 0.33 is acceptable in view of the fact that no effort was made to refine the structure, e.g., a small rotational movement of the chains about their axes has an important effect on ($hk0$) intensities.

Much lower values of the R factor have been reported by refinement of the models against X-ray diffraction data (9, 10). Cornibert and Marchessault (9) have reported that the R_I factor, defined $R_I = \Sigma|I_o - I_c|/\Sigma I_o$ where I_o and I_c are the observed and calculated intensities, respectively, is 0.24 by using all reflections in the diffractogram and an overall temperature factor for all atoms. Yokouchi *et al.* (10) have reported that the R factor is reduced to 0.135 by refinement of the atomic coordinates and temperature factors by the diagonal least-squares method.

It is noteworthy that the (120) reflection which

For personal use only.

was very weak or unobservable in the X-ray diffraction pattern (9, 10), was clearly present in the electron diffractogram (see Table 2). The observed difference in the "sensitivity" of this reflection with respect to X-rays vs. electrons is explainable in terms of the structure factors based on the polymer crystal structure (9, 10). Whatever the reason for the intensity weakness of this observed X-ray reflection, the normalized calculated structure factor of the (120) reflection for X-rays is 20.1 (10). Furthermore the normalized structure factor for electrons is 60.3 (derived from data in column 4 of Table 2), where the structure factor for the (110) reflection is taken as 100. The better agreement between calculated and observed intensities of the (120) reflection is an example of how electron diffraction on polymer single crystals can add to one's confidence in polymer crystal structure determination.

Finally, a packing analysis to optimize molecular position in the unit cell in accordance with the method described by Williams (15) and modified by Sarko and Zugenmaier (16) was undertaken. The atomic coordinates of Yokouchi *et al.* (10) were used for the trial packing molecular model which aimed at minimization of the interchain interaction energy by changing rotational and translational positioning of the chains. In order to avoid local minima, different starting positions of the chains were examined. The degree of interaction between atoms of adjacent chains is measured by the packing index: $R_p = \Sigma w(d_0 - d_{ij})^2$ where d_0 is an empirical cut-off distance, d_{ij} is the distance between atoms i and j for the current trial model, and w is a weighting factor. The values of d_0 and w used here were those of Sarko and Zugenmaier (16). The minimum value of the index R_p obtained was 7.68 kcal mol^{-1}, which was very close to the value of 9.10 kcal mol^{-1} obtained with the model proposed by Yokouchi *et al.* (10). This result clearly indicates that in the model the chains are packed in close vicinity of the position of minimum packing energy.

In conclusion, all of these results indicate that the two independent structure determinations for PHB (9, 10) are in good agreement and account satisfactorily for the observed electron diffraction data. Furthermore, the electron diffraction approach, here outlined, with the single crystals is recommended as a valuable complement to X-ray diffraction analysis of polymer fibers.

The PHB octamer (sample N) electron diffraction pattern reveals that the plane *ab* of the octamer unit cell is a rectangular one. From this electron diffraction pattern, octamer unit cell dimensions in plane *ab* have been calculated: $a = 5.67$ Å and $b = 13.19$ Å. If we compare these results with those obtained for PHB polymer (orthorhombic unit cell with $a = 5.76$ Å and $b = 13.20$ Å), we can state that the octamer unit cell is similar to that of the polymer in the plane *ab*.

The sample M ($\overline{DP}_n = 4.2$) electron diffraction data are exactly the same as those of the polymer single crystal with systematic absences in the two dimensional reciprocal net up to the tenth order along the *b* axis. This confirms that the oligomers have the same crystal structure as the polymer at least as regards helical conformation and packing in the *ab* plane.

Lamella Thickness and Annealing of Single Crystals

The measured heats of fusion listed as Δh_f^* in Table 1 reflect differences in degree of crystallinity. This is an extensive quantity and could be used to evaluate the crystalline fraction if Δh_f (heat of fusion of the perfect crystal) were known.

Lamella thickness (long period) of single crystals prepared from samples A to M were determined from small angle X-ray diffraction patterns obtained with the X-ray beam parallel to the plane of the mat. These lamella thickness data are plotted against the number average molecular weight in Fig. 2. The molecular length calculated for each oligomer from $\overline{DP}_n$ and the repeat distance of 2.98 Å found from PHB polymer X-ray data for the structural unit is also shown in Fig 2 where it can be seen that the lamella thickness at first increases with increasing molecular weight and then becomes constant. For PHB molecules greater than $\overline{DP}_n = 12$ ($\overline{M}_n = 1000$), we observe that the length of the molecule is longer than the lamella thickness in keeping with the chainfolding hypothesis. Interestingly, the lamella thickness or the long period of oligomers from dimer to hexamer is approximately twice as much as their molecular length. This suggests, as illustrated in Fig. 3, that with these oligomers the lamella involves two molecules with the polar groups oriented toward each other. When these oligomers were annealed at a temperature 10°C below their melting point in a nitrogen atmosphere no increase of long period was observed which indicates that the molecules are extended in the crystal. Finally for oligomers from heptamer to undecamer, we can assume that the oligomer behaves in the lamella in a way intermediate between the two cases mentioned above.

It is well known that the long period, and thus the thickness of polyethylene lamellae, is dependent on the temperature of crystallization. The closer the

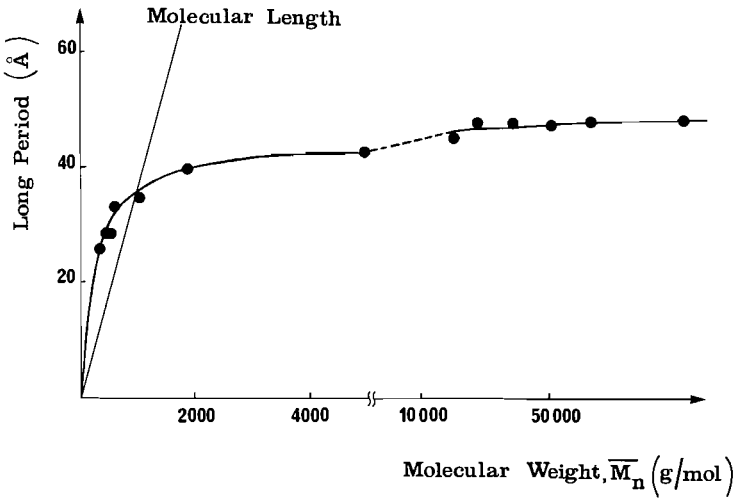

FIG. 2. Observed long period (lamella thickness) for single crystals of PHB as a function of number average molecular weight. For reference, the straight line corresponding to the calculated molecular length of the crystalline state is shown.

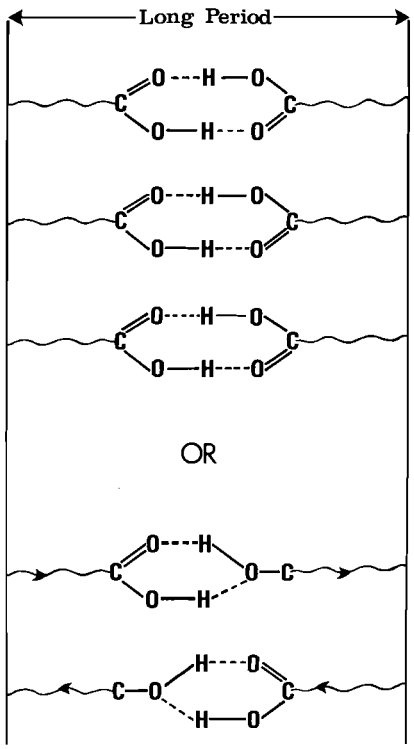

FIG. 3. Schematic representation of molecular arrangement in single crystals of extended chain PHB oligomers. Two possible arrangements are shown with either "head-to-tail" or "head-to-head" packing.

latter to the true melting point, the greater is the lamella thickness (17). Evidence has been presented that the long period of polyethylene single crystal lamellae can be increased by annealing at a temperature below the melting point (18).

Annealing studies were conducted on sample D single crystals ($\overline{M}_n$ = 31 360 g/mol). The X-ray results showed a nearly twofold increase in lamellar thickness over the temperature range studied. Theory predicts (19) development of infinitely long folds, i.e. completely extended chains, as the annealing temperature approaches more and more closely to the true melting point. The crystallization temperature, T_x, can be expressed by the following equation

$$T_x = T_m^0\left(1 - \frac{2\sigma_e}{\Delta h_f L^*}\right)$$

where T_m^0 = the melting point of a crystal of infinite fold period (K), σ_e = end surface free energy (erg/cm^2), Δh_f = the heat of fusion (erg/cm^3), L^* = the equilibrium fold length (cm). Figure 4 is a plot of the crystallization temperature against the reciprocal value of the observed fold length for PHB single crystals. The intercept leads to a predicted value of T_m^0 close to 200°C. For comparison, the same plot for oriented fibers is included which leads to the same predicted value for T_m^0 but the slope is considerably greater. Since the latter is the ratio $\sigma_e/\Delta h_f$ it must be concluded that the "end surface free energy" is much greater for the fiber orientation (melt crystallized) than for the single crystals (solution crystallized). This observation is in keeping with recent concepts concerning chainfold organization in these two systems (20, 21).

X-ray Diffraction Studies of PHB Oligomers

Crystalline Structure

Powder diagrams of all monodisperse samples of oligomers (from tetramer to octamer) were re-

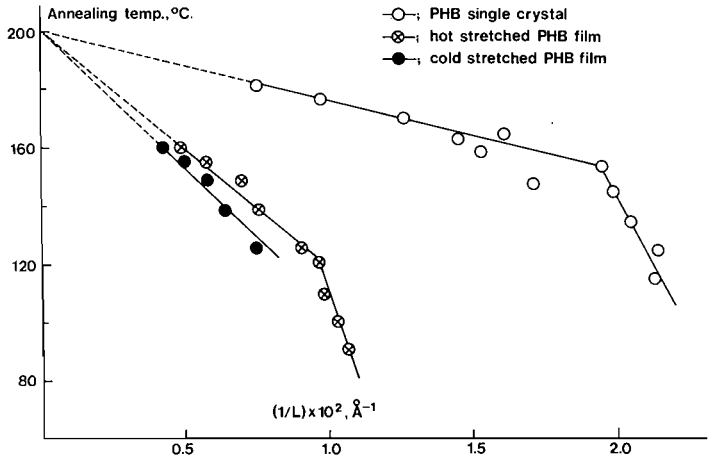

FIG. 4. Dependence of the long period for PHB on the annealing temperature for single crystals (lamellar thickness) and "drawn" film strips.

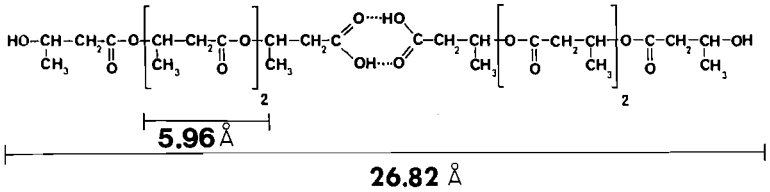

FIG. 5. Representation of the two tetramers contained along the *c* axis of the unit cell and bound together by a hydrogen bond.

corded. From the studies of these powder diagrams combined with the electron diffraction results it is assumed that oligomers crystallize as the polymer, i.e. in an orthorhombic unit cell with parameters $a = 5.76$ Å and $b = 13.20$ Å and with space group $P2_12_12_1$ and that only unit cell dimension c changes from one oligomer to the other. Starting with the tetramer powder diagram and considering the systematic extinctions of the space group $P2_12_12_1$ and the value of unit cell dimensions a and b, we assign the first line of the powder diagram as (002) so that the unit cell dimension c is found to be 26.6 Å.

These tetramer unit cell parameters were refined by minimizing the sum of the squares of the differences between the d-spacings (n of them) derived from the location of the diffraction spots and those calculated from the unit cell. An R-factor, which must be as small as possible for a good refinement, is defined by the following equation:

$$R = \frac{\sum|\sin^2 \theta_{obs} - \sin^2 \theta_{cal}|^{1/2}}{n - 3}$$

The refinement of the tetramer unit cell parameters leading to an R-factor of 1.7% yields the following results: $a = 5.76$ Å, $b = 13.14$ Å, $c = 26.82$ Å.

The c axis parameter of 26.82 Å thus obtained corresponds approximately to the length of eight (two tetramers) repeating units of the polymer (2.98 Å × 8) plus the length of one hydrogen bond (ca. 2.9 Å). In the light of this result and considering the small angle X-ray diffraction data, which suggest that two tetramers make up one lamella, it is reasonable to assume that the unit cell contains two tetramer molecules bound together by a hydrogen-bond along the c axis (Fig. 5). In this model the length of the terminal structural units (i.e. the hydroxyl and carboxylic acid end) should be different from that of the internal structural unit which corresponds to the repeat distance of the polymer. Accordingly the two end structural units of one tetramer taken together must equal a length of 7.45 Å.

We next attempted a calculation of the c parameters for the other oligomers (pentamer to octamer) by using the same refinement method as described for the tetramer. In the calculation two extreme cases were examined: the unit cell contains along the c axis either two oligomers bound together by a hydrogen bond or just one oligomer. For each of these two cases, the starting c parameter for each oligomer was derived by using the same values of the lengths of internal and terminal structural units as assumed for the tetramer model

TABLE 3. Unit cell parameters and R-factor for PHB oligomers

	If unit cell contains just one oligomer along c axis				If unit cell contains along c axis two oligomers bound together by a H bond			
Polymer	a	b	c	R	a	b	c	R
Tetramer[a]	3.21	7.43	8.00	11.4	5.76	13.14	26.82	1.7
Pentamer	5.81	13.4	16.42	2.9	5.75	13.19	32.3	1.8
Hexamer	5.73	13.19	19.64	2.1	5.79	13.24	38.67	2.1
Heptamer	5.67	13.18	22.39	1.7	5.69	13.18	44.74	2.0
Octamer	5.77	13.19	25.23	1.6	5.84	13.40	49.62	4

[a]Since electron diffraction data (8) clearly showed that $a = 5.76$ and $b = 13.2$, the very high value of R and the unacceptable refined values of a and b indicate either an error in measurement of certain reflections in the powder pattern or the total unacceptability of the "one chain" unit cell for the tetramer.

in Fig. 5. The same values of the a and b parameters as those for the polymer unit cell were again assumed for these oligomers. The refined unit cell parameters and R-factors for the oligomers are summarized in Table 3.

The data in Table 3 for the tetramer and pentamer case support the model where along the c axis two oligomers are bound together by a hydrogen bond. For the octamer, the model in which the unit cell contains just one oligomer along the c axis is preferred. For hexamer and heptamer, it is impossible with the results shown in Table 3 to find which form is preferred because the R-factor is the same in the two cases. Clearly one is seeing the results of a delicate energetic balance between "packing" energy and "surface" free energy for a polymer with a chain "sense". Once a minimum molecular weight is reached, chain folding is the dominant mechanism for achieving a packing with alternating chain "sense" as required by the space group.

The retroaldol reaction of 3-penten-2-one: equilibrium constant for hydration and rate constants for the hydration and retroaldol reactions in base

J. PETER GUTHRIE[1]

Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received April 24, 1980

J. PETER GUTHRIE. Can. J. Chem. **59**, 45 (1981).

In aqueous sodium hydroxide solutions at 25°C, 3-penten-2-one undergoes retroaldol cleavage to acetone and acetaldehyde. The kinetics can be followed spectrophotometrically, and show two exponential phases with rather different rate constants. By a new analysis of the mathematical solution to this system we have been able to derive an improved method for calculating the microscopic rate constants. These rate constants are $k_{hyd} = 2.89 \times 10^{-3}\ M^{-1}\ s^{-1}$, $k_{dehyd} = 4.04 \times 10^{-4}\ M^{-1}\ s^{-1}$, and $k_{retro} = 3.36 \times 10^{-4}\ M^{-1}\ s^{-1}$. The equilibrium constant for hydration of 3-penten-2-one (standard state for water is the pure liquid) is 7.13.

J. PETER GUTHRIE. Can. J. Chem. **59**, 45 (1981).

Dans des solutions aqueuses d'hydroxyde de sodium à 25°C, la pentèn-3 one-2 subit une rupture rétroaldolique et conduit à l'acétone et à l'acétaldéhyde. Les données cinétiques obtenues par spectrophotométrie montrent deux phases exponentielles avec des vitesses différentes. A l'aide d'une nouvelle analyse de la solution mathématique de ce système, nous avons pu mettre au point une meilleure méthode de calcul des constantes de vitesse microscopique. Ces constantes sont: $K_{hyd} = 2{,}89 \times 10^{-3}\ M^{-1}\ s^{-1}$, $K_{déhyd} = 4{,}04 \times 10^{-4}\ M^{-1}\ s^{-1}$ et $K_{rétro} = 3{,}36 \times 10^{-4}\ M^{-1}\ s^{-1}$. La constante d'équilibre d'hydratation de la pentèn-3 one-2 (l'état normal pour l'eau est le liquide à l'état pur) est de 7,13.

[Traduit par le journal]

Introduction

We recently published the results of an indirect evaluation of the equilibrium constants for aldol condensation reactions of simple compounds (1). In order to investigate the possibility of finding useful rate–equilibrium correlations we plan to study the rates of the aldol or retroaldol reactions of as many as possible of the systems for which equilibrium constants are now available. As part of this program, we have examined the behavior of 3-penten-2-one, for which some studies have been reported (2, 3), although in the published work the retroaldol reaction was not of primary interest. To our surprise, our results are not in satisfactory agreement with the literature values. Accordingly it seemed important to publish the results of the present investigation without delay. In analysing our kinetic data we have devised a better algebraic approach to extracting the microscopic rate constants from the experimental parameters than that which we reported previously (4).

Results and Discussion

The kinetics showed biphasic behavior as shown in Fig. 1. The experimental points were fitted to eq. [1] by the method of least squares (4–7). For the

$$[1] \quad OD = OD_\infty + \alpha \exp(-\lambda_2 t) + \beta \exp(-\lambda_3 t)$$

mechanism shown in Scheme 1, we can derive integrated rate equations for the concentrations of the three species (4), following the method of Frost and Pearson (8); this gives eqs. [2]–[4]. Then it is possible to derive an expression, eq. [6], for the optical density (OD) as a function of time:

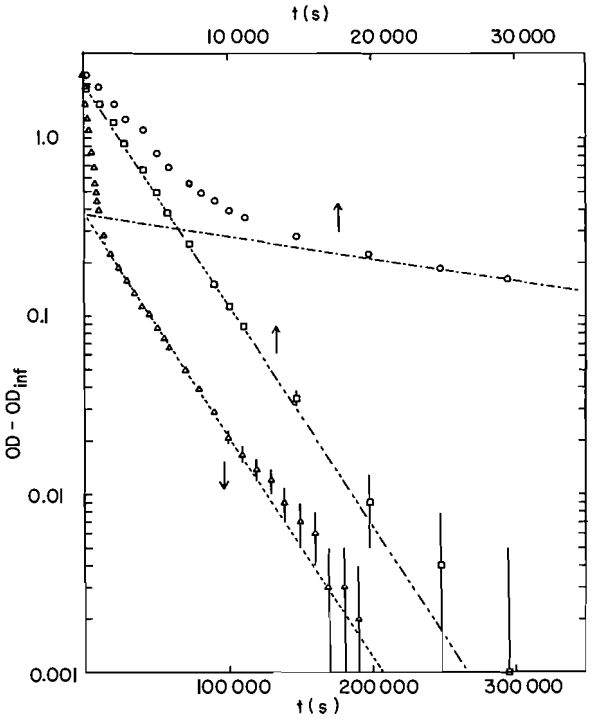

FIG. 1. First order plots, showing the two phase nature of the kinetics. (---) Lower abscissa, $OD - OD_{inf}$; (— · —) upper abscissa, $OD - OD_{inf}$; (— · · —) upper abscissa ($OD - OD_{inf}$) observed – extrapolated. 3-Penten-2-one in 0.1 *M* NaOH at ionic strength 1.0 *M*.

$$[2]\quad [A_1] = [A_1]^0\left\{\frac{k_{12}(\lambda_2 - k_{23})}{\lambda_2(\lambda_2 - \lambda_3)}\exp(-\lambda_2 t) + \frac{k_{12}(k_{23} - \lambda_3)}{\lambda_3(\lambda_2 - \lambda_3)}\exp(-\lambda_3 t)\right\}$$

$$[3]\quad [A_1] = [A_1]^0\left\{-\frac{k_{12}}{\lambda_2 - \lambda_3}\exp(-\lambda_2 t) + \frac{k_{12}}{\lambda_2 - \lambda_3}\exp(-\lambda_3 t)\right\}$$

$$[4]\quad [A_3] = [A_1]^0\left\{\frac{k_{12}k_{23}}{\lambda_2\lambda_3} + \frac{k_{12}k_{23}}{\lambda_2(\lambda_2 - \lambda_3)} \times \exp(-\lambda_2 t) - \frac{k_{12}k_{23}}{\lambda_3(\lambda_2 - \lambda_3)}\exp(-\lambda_3 t)\right\}$$

$$[5]\quad OD = \varepsilon_1[A_1] + \varepsilon_2[A_2] + \varepsilon_3[A_3]$$

$$[6]\quad OD = [A_1]^0\varepsilon_3 + \alpha\exp(-\lambda_2 t) + \beta\exp(-\lambda_3 t)$$

where

$$[7]\quad \alpha = \frac{[A_1]^0 k_{12}(\lambda_2 - k_{23})\varepsilon_1}{\lambda_2(\lambda_2 - \lambda_3)} \times \left\{1 - \frac{\varepsilon_2}{\varepsilon_1}\frac{\lambda_2}{\lambda_2 - k_{23}} + \frac{\varepsilon_3}{\varepsilon_1}\frac{k_{23}}{\lambda_2 - k_{23}}\right\}$$

$$[8]\quad \beta = \frac{[A_1]^0 k_{12}(k_{23} - \lambda_3)\varepsilon_1}{\lambda_2(\lambda_2 - \lambda_3)} \times \left\{1 - \frac{\varepsilon_2}{\varepsilon_1}\frac{\lambda_3}{k_{23} - \lambda_3} - \frac{\varepsilon_3}{\varepsilon_1}\frac{k_{23}}{k_{23} - \lambda_3}\right\}$$

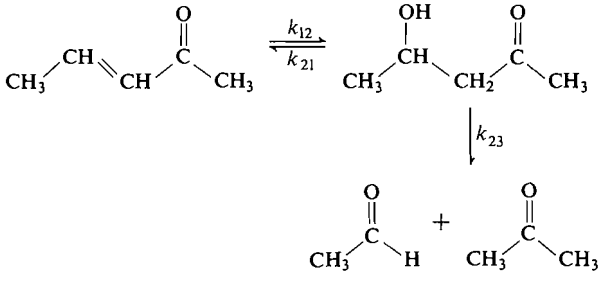
$$[9]\quad \lambda_{2,3} = (p \pm q)/2$$

$$[10]\quad p = k_{12} + k_{21} + k_{23}$$

$$[11]\quad q = (p^2 - 4k_{12}k_{23})^{1/2}$$

Thus far the derivation is rigorously correct for Scheme 1. Equations [7] and [8] are too complicated for convenient manipulation; fortunately it is possible in the present case to simplify these equations without serious error.

Since the extinction coefficient for 4-hydroxy-2-pentanone, ε_2, will be approximately equal to that



SCHEME 1

for acetone, and ε_3,' the sum of the apparent extinction coefficients for acetone and acetaldehyde, will be similar to that for acetone because much of the acetaldehyde will be present as the hydrate or hydrate anion (4, 9, 10) we make the simplifying approximation that $\varepsilon_2 = \varepsilon_3$. In any case these extinction coefficients are small at 225 nm.[2] Then we may write:

$$[12]\quad \alpha = \frac{[A_1]^0 k_{12}(\lambda_2 - k_{23})\varepsilon_1}{\lambda_2(\lambda_2 - \lambda_3)}\left\{1 - \frac{\varepsilon_3}{\varepsilon_1}\right\}$$

$$[13]\quad \beta = \frac{[A_1]^0 k_{12}(k_{23} - \lambda_3)\varepsilon_1}{\lambda_3(\lambda_2 - \lambda_3)}\left\{1 - \frac{\varepsilon_3}{\varepsilon_1}\right\}$$

Substitution of the values of the rate constants, derived by making the assumption that $\varepsilon_3 = \varepsilon_2$, into eqs. [7] and [8] shows that the error introduced by the approximation is, for any reasonable ε values, quite negligible, being less than 1%.

One can now derive a solution based upon eqs. [9], [12], and [13]. First we note that:

$$[14]\quad \lambda_2 + \lambda_3 = k_{12} + k_{21} + k_{23}$$

$$[15]\quad \lambda_2\lambda_3 = k_{12}k_{23}$$

$$[16]\quad \frac{\alpha}{\beta} = \frac{\lambda_3(\lambda_2 - k_{23})}{\lambda_2(k_{23} - \lambda_3)}$$

These three equations can now be solved for the three unknowns:

$$[17]\quad k_{23} = \left\{\lambda_2 + \lambda_3\left(\frac{\alpha\lambda_2}{\beta\lambda_3}\right)\right\} \Big/ \left\{1 + \left(\frac{\alpha\lambda_2}{\beta\lambda_3}\right)\right\}$$

$$[18]\quad k_{12} = \lambda_2\lambda_3/k_{23}$$

$$[19]\quad k_{21} = \lambda_2 + \lambda_3 - k_{12} - k_{23}$$

In order to assess the precision of these pseudo first order rate constants, we carried out a full error analysis (5) using the covariance matrix generated by the least squares program (6–8).

The kinetics results are found in Table 1; the derived rate constants are found in Table 2. Figure 2 shows that the microscopic rate constants are first order in hydroxide, as expected. The figure shows that there is some scatter in the values of the rate constants from run to run, particularly in the case of k_{23}. However, all values which deviated from the line had markedly larger estimated standard deviations from the least squares procedure. Clearly the calculations do not adequately determine the uncertainties in k_{23} etc., because the error bars do not reach the best fit line. On the other hand the relative

[2]The spectrum for 2-butanone in water, which should be a good model, shows an extinction coefficient of about 1 at 225 nm (11).

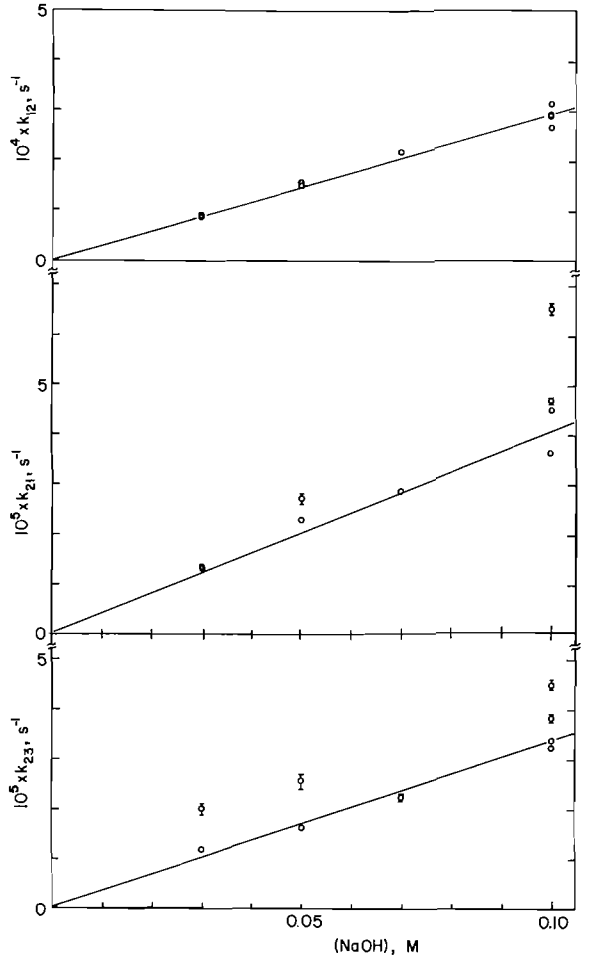

FIG. 2. Observed pseudo first order rate constants as a function of hydroxide concentration for ionic strength 0.1 *M*. Error bars are drawn using the standard deviations from Table 2.

reliability of different k values seems to be correct. There was no obvious reason to discard the runs given rise to these aberrant points. However weighted least squares fitting gave rise to the lines shown in Fig. 2, and the less reliable points have had little effect. (Weights were based on the least squares standard deviations in Table 2.)

The second phase of the reaction, for which the apparent rate constant is λ_3, is slow at 25°C, and the optical density change is small. This presumably makes the results sensitive to artefacts and leads to the observed scatter. The derived values of k_{21} and k_{23} are dependent upon the value of λ_3, whereas k_{12} is much less sensitive to it, being largely determined by λ_2.

The corresponding second order rate constants are found in Table 2; these values were calculated by least squares. Experiments were carried out at ionic strengths of 0.1 and 1.0 (maintained by KCl); the effect of ionic strength is seen to be small, but cannot be neglected. Table 2 also gives the equilibrium constant for hydration. The rate constant (3) and equilibrium constant (2) for hydration which have been reported by other workers are given in Table 2. The agreement is reasonable for k_{hyd}, not bad for K and k_{21} (considering the extrapolations involved) but is poor for k_{23}. Our work was carried out over a period of time, using several batches of pentenone independently purified by preparative gas chromatography. The pentenone used for kinetics showed clean nmr spectra totally consistent with the structure. Accordingly we feel that our numbers are correct, although we do not know the reason for the discrepancy.

Experimental

3-Penten-2-one (tech) from Aldrich could not be purified by distillation (a second component which we believe to be mesityl oxide was not separable), but could be obtained pure by preparative gas chromatography (SE30 column at 100°C). The pure material had a suitable nmr spectrum ($CDCl_3$) δ 1.9, doublet (each peak broadened) J = 7 Hz, 3H; δ 2.2, singlet, 3H; 6.0 doublet (each peak broadened) half of an AB quartet, J = 16 Hz; 6.8 doublet of quartets, other half of the AB quartet, J_{AB} = 16 Hz, J_{BX} = 7 Hz.

Stock solutions of the enone were prepared in tetrahydrofuran which had been freshly purified by passage through Grade I neutral alumina (Fisher). NaOH solutions were prepared from Fisher concentrates to give 0.1 or 1.0 *N* solutions. Other concentrations were prepared by dilution with the appropriate KCl solution. Samples of NaOH (3.0 mL) in quartz cuvettes with Teflon stoppers (1 cm path length) were thermostatted in the cell compartment of a Gilford Model 240 spectrophotometer equipped with an automatic sample changer. Reactions were initiated by addition of a suitable volume of the enone solution (Hamilton syringe). The reactions were followed at 225 nm and either recorded on a Heath Model SR205 recorder or else punched on paper tape using a Digitizer built in this department for use with the Gilford. Calculations were carried out on a Xitan microcomputer using programs written in BASIC or FORTRAN.

Acknowledgments

I wish to thank the Natural Sciences and Engineering Research Council of Canada, the Academic Development Fund of the University of Western Ontario, and the Alfred P. Sloan Foundation for financial support of this work. Technical assistance by Susan F. Vice and some preliminary experiments carried out in the course of a fourth year thesis project by Kevin J. Cooper are gratefully acknowledged.

^{31}P nmr has been used to show that, in $MeNO_2$, $M(SbF_6)_2$ (M = Sn or Pb) forms 1:1 complexes with $Ph_2P(CH_2)_2PPh_2$, $PhP[(CH_2)_2PPh_2]_2$, $MeC(CH_2PPh_2)_3$, $[Ph_2P(CH_2)_2]_2P(CH_2)_2\overset{+}{P}HPh_2$, $Ph_2P[(CH_2)_2PPh]_2(CH_2)_2\overset{+}{P}HPh_2$, $P[(CH_2)_2PPh_2]_3$, and $Ph_2P[(CH_2)_2PPh]_2(CH_2)_2PPh_2$. The phosphonium ligands are formed *in situ*. Spectra characteristics of slow inter- and intramolecular exchange were obtained in all cases except, perhaps, those involving the last two ligands, which may be involved in rapid intramolecular exchange. For the first five ligands, the maximum denticity is achieved and unambiguous one-bond M(II)—^{31}P (M = $^{117/119}Sn$ or ^{207}Pb) coupling constants are reported and discussed. In the presence of $M(SbF_6)_2$ (M = Sn or Pb), PPh_3 is protonated in $MeNO_2$, while in acetone $Sn(SbF_6)_2$ forms a 1:1 complex with PPh_3 which appears to be solvent-inserted, $[Sn—O—CMe_2PPh_3]^{2+}$.

Reduced temperature ^{31}P nmr spectroscopy has allowed the detection of 1:2 and 1:3 (M:L) complexes of $OPPh_3$, and 1:1 complexes of $Ph_2P(O)(CH_2)_2P(O)Ph_2$, $PhP(O)[(CH_2)_2P(O)Ph_2]_2$, and $(O)P[(CH_2)_2P(O)Ph_2]_3$, with both tin(II) and lead(II). The 1:1 complexes with polydentate ligands are isolable; nmr shows that the maximum denticity occurs except with the last ligand which behaves in a tridentate manner. Several two-bond M—O—P coupling constants have been obtained. Also, the changes which complexation produces in the P—P couplings are compared with changes produced in the analogous phosphine complexes.

The synthesis and characterization of $Ph_2P(E)[(CH_2)_2P(E)Ph]_2(CH_2)_2P(E)Ph_2$ (E = S or Se) and $(Se)P[(CH_2)_2P(Se)Ph_2]_3$ are reported. The ^{31}P nmr spectra of these compounds are compared with those of the parent tetraphosphines and other members of the corresponding tetraoxide–tetrachalcogenide series.

PHILIP A. W. DEAN, DONALD D. PHILLIPS et LIJANA POLENSEK. Can. J. Chem. **59**, 50 (1981).

On a utilisé la rmn du ^{31}P pour montrer que dans le $MeNO_2$, le $M(SbF_6)_2$ (M = Sn ou Pb) forme des complexes 1:1 avec les composés suivants: $Ph_2P(CH_2)_2PPh_2$, $PhP[(CH_2)_2PPh_2]_2$, $MeC(CH_2PPh_2)_3$, $[Ph_2P(CH_2)_2]_2P(CH_2)_2\overset{+}{P}HPh_2$, $Ph_2P[(CH_2)_2PPh]_2(CH_2)_2\overset{+}{P}HPh_2$, $P[(CH_2)_2PPh_2]_3$ et $Ph_2P[(CH_2)_2PPh]_2(CH_2)_2PPh_2$. Les ligands phosphonium sont formés *in situ*. Dans tous les cas, excepté peut être dans les cas des deux derniers ligands qui peuvent subir un échange intermoléculaire rapide, on a observé des spectres caractéristiques d'échanges inter- et intramoléculaire lents. Dans les cas des 5 premiers ligands tous les points d'attaches sont utilisés; on a aussi observé d'une façon non ambigue des constantes de couplage pour une liaison simple M(II)—^{31}P (M = $^{117/119}Sn$ ou ^{207}Pb que l'on discute. En présence du $M(SbF_6)_2$ (M = Sn ou Pb), PPh_3 est protoné dans le $MeNO_2$ alors que dans l'acétone le composé $Sn(SbF_6)_2$ forme un complexe 1:1 avec le PPh_3 qui semble être inséré dans le solvant, $[Sn—O—CMe_2PPh_3]^{2+}$.

A basse température, la spectroscopie de rmn du ^{31}P permet de déceler les complexes 1:2 et 1:3 (M:L) du $OPPh_3$ et les complexes 1:1 des composés $Ph_2P(O)(CH_2)_2P(O)Ph_2$, $PhP(O)[(CH_2)_2P(O)Ph_2]_2$ et $(O)P(CH_2)_2P(O)Ph_2]_3$ avec l'étain(II) ainsi que le plomb(II). On peut isoler les complexes 1:1 impliquant des ligands polydentates; la rmn montre que tous les sites des ligands sont liés à l'exception du dernier ligand qui se comporte de manière tridentate. On a obtenu plusieurs constantes de couplage MOP à travers deux liaisons. On a également comparé les changements produits par la complexation sur les constantes de couplage P—P avec les changements produits dans les complexes analogues de phosphines.

On rapporte la synthèse et la caractérisation du $Ph_2P(E)[(CH_2)_2P(E)Ph]_2(CH_2)_2P(E)Ph_2$ (E = S ou Se) et $(Se)P[(CH_2)_2P(Se)Ph_2]_3$. On a comparé les spectres de rmn du ^{31}P de ces composés à ceux des tétraphosphines apparentées et à ceux d'autres membres des séries correspondantes de tétraoxyde–tétrachalcogénures.

[Traduit par le journal]

Introduction

We report here an nmr spectroscopic investigation, involving primarily ^{31}P nmr, of the complexation of tin(II) and lead(II) by a variety of phosphorus donor ligands, most notably chelating tertiary phosphines. The primary object of this work, successfully achieved, was to establish the hitherto unknown (1–3) MP_n kernels for the two divalent Group IVA elements. During this study, we have been able to measure several one-bond tin(II)– and lead(II)–phosphorus coupling constants. (^{119}Sn, ^{117}Sn, and ^{207}Pb, all have spin $I = 1/2$, and natural abundances of 8.68, 7.67, and 21.11%, respectively.) These appear to be the first unambiguous examples of such couplings; the couplings involving tin(II) can usefully be compared with Sn–P coupling in tin(IV)–phosphine complexes (4, 5). In addition, the ^{31}P nmr spectra of complexes with

some of the polydentate phosphines yield P–P coupling constants which can be correlated with those found in complexes of other elements (e.g. refs. 6–9).

In the present study, strong acid salts of tin(II) and lead(II) have been used to minimize ligand–counterion competition at the coordination sites. Similarly, solvents of low Donor Number (10) were chosen, to reduce ligand–solvent competition. Nitromethane proved useful in many instances. It was thought that some oxidation of the ligands might occur in this medium, however, so as a precaution the ^{31}P nmr spectra of the related phosphine oxide complexes have been obtained; they are given here also. We could find no earlier report of the ^{31}P nmr spectra of two of the polydentate phosphine oxides used, $(O)P[(CH_2)_2P(O)Ph_2]_3$ and $Ph_2P(O)[(CH_2)_2P(O)Ph]_2(CH_2)_2P(O)Ph_2$; the spectra are given here together with those of the corresponding tetra-sulfides and -selenides (three of which seem to be new compounds) for comparison.

To our knowledge the only lead(II)–phosphine complexes which have been reported previously are $PbBr_2(dppe)$ and $[Pb(dppe)_2](ClO_4)_2$ (11)[5]; no nmr data are available for these compounds. At the outset of our study, tin(II)–phosphine complexes, in contrast to their tin(IV) analogs, had been little studied (1, 2). More recently, the only tin(II)–phosphine complexes which have been well-characterized are a limited number of 1:1 complexes of monodentate phosphines with stannous halides (12–14). In solution, even the complexes with such strongly basic phosphines as Bu^t_3P and $(Me_2N)_3P$ are labile on the nmr timescale (12, 13) and are partly solvolyzed by THF (12). However, when $SnCl_2(PBu^t_3)$ is coordinated to $W(CO)_5$ through tin, exchange of the phosphine is slow and no solvolysis by THF occurs (15). These last observations suggest that stable non-labile tin(II)–phosphine complexes should be preparable when the Lewis acidity of the tin centre is high. Our results demonstrate that this is so for tin and that analogous lead complexes can be prepared under similar conditions.

[5]Abbreviations used in this paper: $P(OMe)_3$ = tmp; $OP(OMe)_3$ = tmpO; $OPMe(OMe)_2$ = dmmp; $Ph_2P(CH_2)_2PPh_2$ = dppe; $Ph_2P(O)(CH_2)_2P(O)Ph_2$ = $dppeO_2$; $(Ph_2PCH_2)_3CMe$ = tripod; $[Ph_2P(CH_2)_2]_2PPh$ = etp; $[Ph_2P(CH_2)_2]_3P$ = PP_3; $[Ph_2P(O)(CH_2)_2]_3PO$ = PP_3O_4; $[Ph_2P(CH_2)_2]_2PPh(CH_2)_2\overset{+}{P}HPh_2]$ = $PP_2(PH)^+$; $[Ph_2P(CH_2)_2PPhCH_2]_2$ = P_2P_2; $Ph_2P(CH_2)_2PPh(CH_2)_2PPh(CH_2)_2\overset{+}{P}HPh_2$ = $PPP(PH)^+$; $[Ph_2P(O)(CH_2)_2P(O)PhCH_2]_2$ = $P_2P_2O_4$.

Experimental

Materials

The purity of all ligands was checked by ^{31}P and/or ^1H nmr. All liquids (except SbF_5) were stored over 3A Molecular Sieves.

Triphenylphosphine (Eastmen Kodak Co.) and tris(4-fluorophenyl)phosphine (Maybridge Chemical Co.) were recrystallized from ethanol. Dimethyl methylphosphonate (dmmp) and trimethyl phosphate (tmpO), both from Aldrich Chemical Co. Inc., were purified by distillation under dry N_2 at 1 atm. Trimethyl phosphite (tmp) (Strem Chemicals, Inc.) showed no significant impurity after reduced pressure distillation under dry N_2. Phosphorus-31 nmr showed the absence of appreciable impurities in 1,1,1-tris(diphenylphosphinomethyl)-ethane (tripod) and bis(2-diphenylphosphinoethyl)phenyl-phosphine (etp), both from Strem Chemicals, Inc., as well as tris(2-diphenylphosphinoethyl)phosphine, "Tetraphos II" (PP_3) and 1,1,4,7,10,10-hexaphenyl-1,4-7,10-tetraphosphadecane, "Tetraphos I" (P_2P_2),[6] both from Pressure Chemical Co.; these were pumped *in vacuo*, but otherwise were used as received.

1,2-Bis(diphenylphosphino)ethane was prepared by the standard method (17). Several of the phosphine oxides were prepared as part of an earlier study (18). PP_3O_4 (19) was prepared using I_2/OH^-, as previously. $P_2P_2O_4$ was prepared by the literature method (20). For comparison with the ^{31}P nmr spectra[7] of PP_3O_4 and $P_2P_2O_4$ (Table 1), the analogous tetrachalcogenides have been prepared. PP_3S_4 is a known compound (19). $P_2P_2S_4$ was obtained from a mixture of P_2P_2 and a slight deficiency of sulfur under reflux in benzene; the product was recrystallized from CH_2Cl_2–Bu^nOH.M.Pt (uncorr) 285–288°C. $P_2P_2Se_4$ was prepared by refluxing P_2P_2 with excess Se shot in benzene. After removal of solvent, the crude product was triturated with boiling Bu^nOH.M.Pt. (uncorr) 256–258°C. PP_3Se_4 was prepared similarly and recrystallized from Bu^nOH.M.Pt (uncorr) 203–204°C. The ^{31}P nmr spectra given in Table 1 characterize the new ligands.

Nitro-benzene and -methane were purified by distillation. Acetone-d_6 and nitromethane-d_3 (both MSD) and methylene chloride (Fisher "Spectranalyzed") were dried at least 12 h over 3A Molecular Sieves before use. Sulfur dioxide (Matheson Anhydrous Grade) was dried by standing in the gas phase over 3A Molecular Sieves for at least 12 h.

Antimony pentafluoride (PCR) was distilled twice under dry N_2, while arsenic pentafluoride (Ozark-Mahoning Co.), pure by tensimetry, was used as bought.

SnF_2 and PbF_2, both "Ultrapure" grade, were from Alfa-Ventron. $Sn(SbF_6)_2$ was synthesized by the literature method (23).

Manipulations

All glassware was baked out at 140°C for 12–24 h before use. Liquid SbF_5 was dispensed in a dry-N_2 filled glove box using an all glass syringe. Solids for the preparation of nmr samples were weighed out in the glove box. Solvents (except SO_2) and liquid ligands were added by standard N_2-vacuum techniques or in a dry-N_2 filled glovebag. SO_2 was condensed into samples and preparative mixtures from a glass–Teflon vacuum line.

Preparation of Lead Salts

Lead(II) hexafluoroantimonate, $Pb(SbF_6)_2$, was synthesized in a manner exactly analogous to that used for $Sn(SbF_6)_2$ (23); it

[6]This is thought to be the *meso*-form (16); our nmr data are consistent with the presence of a single isomer.

[7]These were not reported previously due to poor solubility in the solvents used (19).

[a]At 308 K in CH_2Cl_2 unless otherwise noted.
[b]P_2P_2, $P_2P_2O_4$, and ^{77}Se-free $P_2P_2Se_4$ give rise to AA'BB' spectra, PP_3, PP_3O_4, PP_3S_4, and ^{77}Se-free PP_3Se_4 to A_3B spectra; the ^{77}Se satellites of $P_2P_2Se_4$ constitute two superimposed AA'BB'X spectra, those of PP_3Se_4 superimposed AA'$_2$BX and A_3BX spectra.
[c]Relative to external 2% $OP(OMe)_3$ in $(CD_3)_2CO$ ($\delta_{OP(OMe)_3} = \delta_{H_3PO_4} - 1.72$ ppm); all errors in δ are < 0.1 ppm.
[d]P_A = —PPh_2 or —$P(E)Ph_2$; P_B = >PPh, >P(E)Ph, >P—, or >P(E)—; assignments for P_2P_2 and $P_2P_2E_4$ (E = O, S, or Se) are made by comparison with the spectra of etp and $etpE_3$, respectively (19, 21).
[e]$^6J(P—P)$ = 0 (21).
[f]$^1J(P—Se)$ is known to be negative (22).
[g]The various $^4J(P—^{77}Se)$ could not be determined with confidence due to signal overlap; they are probably small (21).
[h]In liquid SO_2; the compound is poorly soluble in CH_2Cl_2.
[i]A partial ^{31}P nmr spectrum of this compound has been reported previously (19).

is insoluble in SO_2. *Anal.* calcd. for $F_{12}PbSb_2$: Pb 30.49; found (by AA): Pb 30.3 ± 0.2.

The very SO_2-soluble $Pb(AsF_6)_2 \cdot xSO_2$ was prepared similarly, from PbF_2 and an excess of AsF_5 in SO_2. On removal of volatiles *in vacuo*, the product was of variable composition, the strongly held SO_2 of solvation being difficult to remove. Because of this variability, the AsF_6^- salt was not used further in the present work. A typical sample showed Pb (by AA): AsF_6^- (by precipitation as the Ph_4As^+ salt (24)): SO_2 (by difference) = 1:2.04:0.95. The presence of SO_2 in the solid was confirmed by the occurrence of a strong band at 1164 ± 2 cm^{-1} in the infrared spectrum.

Isolation of Tin(II) and Lead(II) Complexes with Polydentate Phosphine Oxides

Partial dissolution of insoluble $Sn(SbF_6)_2$ on $Pb(SbF_6)_2$ occurs on adding an SO_2 solution of a slightly less than equimolar amount of the appropriate ligand to a slurry of the metal salt in SO_2 in an H-shaped filter apparatus of a type described earlier (23). After stirring the mixture for ca. 5 min, filtration and removal of solvent from the filtrate yields the product. This method was used to prepare $Sn(SbF_6)_2(dppeO_2)$ (*Anal.* calcd. for $C_{26}H_{24}F_{12}O_2P_2Sb_2Sn$: C 30.60, H 2.37; found: C 30.30, H 2.27), $Pb(SbF_6)_2(dppeO_2)$ (*Anal.* calcd. for $C_{26}H_{24}F_{12}O_2P_2PbSb_2$: C 28.16, H 2.18, Pb 18.68; found: C 27.96, H 2.31, Pb 19.0), and $Pb(SbF_6)_2(PP_3O_4)$ (*Anal.* calcd. for $C_{42}H_{42}F_{12}O_4P_4PbSb_2$: C 35.67, H 2.99; found: C 36.15, H 3.10). Similarly, 1:1 complexes are formed between $Sn(SbF_6)_2$ and $etpO_3$ or PP_3O_4, and $Pb(SbF_6)_2$ and $etpO_3$; these appear to be solvated. (Elemental analyses (C and H) correspond to $Sn(SbF_6)_2 \cdot etpO_3 \cdot 2SO_2$, $Sn(SbF_6)_2 \cdot PP_3O_4 \cdot 3.5SO_2$, and $Pb(SbF_6)_2 \cdot etpO_3 \cdot SO_2$.)

Preparation of Nuclear Magnetic Resonance Samples

Proton nmr samples were made up in standard 5 mm od nmr tubes using CH_2Cl_2 as internal reference ($\delta_{CH_2Cl_2}(int) = \delta_{TMS}(int) - 4.72$ ppm (25)), and ^{13}C nmr samples similarly. For the latter, the residual solvent ($(CD_3)_2CO$) signal was used as internal reference ($\delta_{((CD_3)_2CO)}(int) = \delta_{TMS}(int) - 29.8$ ppm). Fluorine-19 nmr samples were prepared in medium-walled 5 mm od nmr tubes attached to 9 mm od special walled tubing to facilitate filling and heat sealing (see following); C_6F_6 was added from a vacuum line as internal reference ($\delta_{C_6F_6}(int) = \delta_{CFCl_3}(int) + 164.9$ ppm). Phosphorus-31 nmr samples of ligands alone were prepared in tubes handmade from 10 mm od Pyrex tubing. Ligand–metal salt mixtures were usually made up in similar tubes to which was attached a length of 9 mm od special wall tubing to facilitate sealing under vacuum as described earlier (21); however, samples containing insoluble excess metal salt in SO_2 were prepared in a filter apparatus of a previously described (26) type.

Nuclear Magnetic Resonance Spectra

Ambient probe temperature CW ^1H nmr spectra were measured using either a Varian T-60, or a Varian EM-360 or a Varian XL-100-12 Spectrometer System. The XL-100-12 Spectrometer System was used for all CW ^{19}F and FT ^{31}P spectra. An XL-100-15A Spectrometer System was used to provide ^{13}C-{^1H} spectra.

For spectral analysis of P_2P_2, $P_2P_2O_4$, $P_2P_2S_4$, $P_2P_2Se_4$, PP_3S_4, and PP_3Se_4, the program LOACN3 (27) was used; most probable errors are quoted.

Infrared Spectra

A Perkin-Elmer 621 Infrared Spectrophotometer was used to obtain infrared spectra. Samples were prepared as (dry) Nujol mulls between AgCl plates.

Elemental Analysis

Lead analyses were performed using a Varian Techtron Model 1200 AA Spectrometer. Carbon and hydrogen microanalyses were carried out by either the Analytische Laboratorien, Elbach, W. Germany or Schwarzkopf Microanalytical Laboratory, N.Y.C.

Results and Discussion

Complexes with Polydentate Phosphines

Both $Sn(SbF_6)_2$ and $Pb(SbF_6)_2$ are soluble exothermically in nitromethane. Dppe, etp, tripod, PP_3, and P_2P_2 have moderate to poor solubility in this solvent, but in the presence of an equimolar or

greater than equimolar amount of either metal salt, significant enhancement of solubility occurs.[5] The Sn(or Pb)$(SbF_6)_2$ – polydentate phosphine solutions in $MeNO_2$ are stable indefinitely at or below about 273 K. At 308 K all the solutions except those containing P_2P_2 show little decomposition during the time (a few hours at most) required to collect nmr data, but they gel on standing for longer periods. The spectra of the P_2P_2 solutions indicate extensive decomposition at room temperature.

The ^{31}P nmr spectra of freshly-made solutions containing L/M ≤ 1 (L = dppe, etp, or tripod; M = Sn or Pb) provided unambiguous evidence for the formation of 1:1 complexes; these undergo rapid intermolecular ligand exchange with the soluble part of any excess ligand when L/M > 1. A typical spectrum, that of $Pb(etp)^{2+}$, is shown in Fig. 1(*a*). Details of the ^{31}P nmr spectra of the various complexes are given in Table 2. From the data in this table, the qualitative similarity of the spectral patterns for analogous tin and lead complexes can be seen. Oxidation of Pb(II) to Pb(IV) in the medium used is very unlikely, and thus we surmise that all the complexes contain the central element in the divalent oxidation state. (We note that, in the same medium, or in liquid SO_2, no oxidation of the divalent metals occurs using phosphine oxides as ligands (see below)). The magnitude of the ^{119}Sn–^{31}P and ^{207}Pb–^{31}P coupling constants (1279–1665 Hz and 1714–1863 Hz for the ^{119}Sn and ^{207}Pb satellite splittings, respectively) confirms that direct metal–phosphorus bond formation occurs. comparison, $|^1J(^{119}Sn—^{31}P)|$ is 2280, 2383, and 2256 Hz when R_3 is Bu^n_3, Et_3, and Et_2Ph, respectively, in *trans*-$SnCl_4(PR_3)_2$ (4, 5, 28), and 1560 Hz in $(OC)_5WSnCl_2(PBu^t_3)$ (which could be regarded as a tin(II) complex) (15), while two-bond $^{117/119}Sn—^{31}P$ and $^{207}Pb—^{31}P$ couplings are an order of magnitude smaller than observed in the phosphine complexes, as discussed below. The comparatively small ranges observed for the metal–phosphorous couplings are evidence that dppe, etp, and tripod each achieve their maximum denticities in the 1:1 complexes, probably in complexes of similar stereochemistry. The coordination geometry cannot be deduced from our results, but in the etp and tripod complexes, at least, is most probably pseudotetrahedral with a pyramidal MP_3 kernel and a stereochemically-active lone pair of electrons. In the dppe complexes, a coordination number exceeding two may be achieved by solvent/counterion coordination.

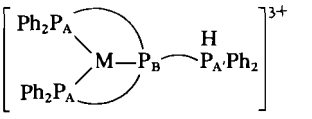
The order of complexation shifts, i.e., Pb > Sn, is consistent with that observed for monophosphine complexes of tin(II) and germanium(II) halides (12, 13), i.e., Sn > Ge. For a constant metal ion, the complexation shifts of phosphorus atoms involved in five-membered chelate rings (in the dppe and etp complexes) are significantly larger than the shift found for the phosphorus atoms of $M(tripod)^{2+}$, which are involved in six-membered chelate ring formation. The unusually large (and cumulative) ^{31}P nmr deshielding associated with five-membered chelate ring formation has been extensively documented, for example, in refs. 29 and 30.

Two different complexes involving PP_3 were identified for both tin and lead. For both elements, the ^{31}P nmr spectrum found when $PP_3/M \lesssim 0.5$ had three regions of resonance, as exemplified by the spectrum of the lead complex given in Fig. 1(*b*). As can be seen by a comparison of Fig. 1 (*a*) and (*b*), the most deshielded resonance, a doublet of triplets, intensity 1, had both chemical shift and metal satellite splitting very close to those of P_B of the corresponding etp complex. Similarly, a doublet, intensity 2, had chemical shift and satellite splitting resembling those of P_A of the etp analogue. The third, most shielded, resonance, intensity 1, was satellite-free; in the $^{31}P-\{^1H\}$ nmr spectrum it was a doublet from three-bond P—P coupling, but showed an additional doublet splitting of ca. 500 Hz in the coupled spectrum. This large coupling is good proof of the occurrence of a protonated phosphine (31). We interpret this spectrum in terms of the formation, in the metal-rich mixtures, of the complex $M(PP_2(PH))^{3+}$, with the ligand bound as shown schematically in **1** (in which a pyramidal $M(P_A)_2P_B$ kernel is likely (see above)).

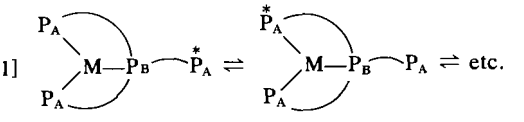


1

Details of the spectra of the $M(PP_2(PH))^{3+}$ complexes are given in Table 2.

To our surprise, the solvent $MeNO_2$ is not the source of the proton used in formation of $M(PP_2(PH))^{3+}$: the proton-coupled ^{31}P nmr spectra are unchanged on switching from CH_3NO_2 to CD_3NO_2 as solvent.[8] We were unable to identify the active protonic acid unambiguously, though it clearly involves the metal salts. However, reproducible results for $M(PP_2(PH))^{3+}$ and other protonated species (see below) were obtained using various batches of metal salts, ligands, and solvent.[8]

In the range $1 \gtrsim PP_3/M > 0.5$, tin and lead both form a second, 1:1, complex, which, at L/M > 1, exchanges with excess ligand. In each case this second complex gives a ^{31}P nmr spectrum consisting of a doublet, intensity 3, coupled to a quartet, intensity 1, both resonances having metal satellites. The spectrum of the lead complex is given in Fig. 1(*c*), and the spectral parameters of the two $M(PP_3)^{2+}$ complexes are included in Table 2. The most obvious interpretation of the doublet–quartet spectrum is in terms of a complex having the MP_4 kernel, with the ligand behaving in a tetradentate manner. The one-bond $M–P_A$ coupling appears anomalously small compared with the one-bond couplings found in the analogous dppe, etp, tripod, and $PP_2(PH)^+$ complexes, but the effect of an increase in coordination number is difficult to assess. A second possible interpretation is in terms of a complex in which PP_3 is tridentate and intramolecular P_A(bound)–P_A(free) exchange occurs rapidly:



[8]We thank a referee for suggesting the experiments with CD_3NO_2 as solvent. The acidic proton cannot come from coordinated $CD_xH_{3-x}NO_2$, resulting from proton exchange between CD_3NO_2 and adventitious trace amounts of water: even after several days at RT no proton exchange is evident by ^1H nmr in $M(SbF_6)_2/CD_3NO_2/H_2O$ ($\approx$2/23/1) solutions. Also, no water could be detected by ^1H nmr in the dry CD_3NO_2 itself; the amount present is certainly less than required for the protonation observed. However, the coordinated water in the $M(SbF_6)_2/CD_3NO_2/H_2O$ solutions *is* clearly acidic: addition of the salt causes proton deshielding by ~6.4 and ~3.7 ppm for the tin- and lead-containing samples respectively.

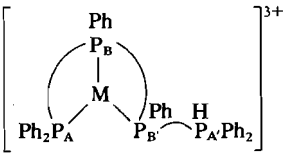
(It should be noted that the "normal" chemical shift of P_B and value of $|^1J(M—^{31}P_B)|$ suggest that P_B is always bound.) In $Pb(PP_3)^{2+}$, at least, the broadness of the signal from P_A, compared with that for P_B (ca. 20 Hz vs. $\leq$5 Hz) (see Fig. 1(*c*)) suggests the presence of an exchange process, but the limited liquid range of $MeNO_2$ precluded further study.

Our spectra of $M(PP_2(PH))^{3+}$ and $M(etp)^{2+}$ (Table 2 and Fig. 1 (*a*) and (*b*)) show that the chemical shifts and satellite splittings of the bound phosphorus atoms are quite insensitive to the substituent on P_B (and vice versa), and Meek and co-workers, in very recent work on tridentate PP_3 and etp (*inter alia*) complexes of rhodium(I), have demonstrated similar insensitivities in that case also (9). Therefore the averaging process shown in ref. 2 should give parameters for P_B very similar to those in $M(etp)^{2+}$, while δ_{P_A} and $|^1J(M—^{31}P_A)|$ should be given by $((2/3)\delta_{P_A(M(etp))^{2+}} + (1/3)\delta_{P_A(PP_3(free))})$ (i.e. 11.7 ppm for Sn, 39.2 ppm for Pb), and $(2/3)|^1J(M—P_{A(M(etp))^{2+}}|$ (i.e. 853 Hz for Sn, 1191 Hz for Pb). In addition, $|^3J(P_A—P_B)|$ in $M(PP_3)$ should be given by $((2/3)|^3J(P_A—P_B)|_{M(etp)^{2+}} + (1/3) \times |^3J(P_A—P_B)|_{PP_3})$ (i.e. $\gtrsim$ 15 Hz for Sn, $\gtrsim$ 13 Hz for Pb). The correlation between calculated and found values is sufficiently poor as to disfavour a complex involving tridentate PP_3, in favour of one having the ligand tetradentate. However, it is possible that in solution there exists more than one species involved in rapid intramolecular exchange. Much more work will be necessary to resolve the structural ambiguity presented by $M(PP_3)^{2+}$.

The behaviour of the systems P_2P_2–$M(SbF_6)_2$–$MeNO_2$ (M = Sn or Pb) resembles that of the PP_3-containing systems in that, depending on the L/M ratio, one or the other or both of two complexes can be formed for each metal. In general, the P_2P_2 systems were more difficult to study because formation of side products is more extensive than in the PP_3-containing systems. When $P_2P_2/M \lesssim 0.5$, the major species formed for each element shows in the $^{31}P-\{^1H\}$ nmr spectrum four regions of resonance, all equally intense. The three less shielded resonances exhibit metal satellites, while the fourth signal is in the same region as $P_{A'}$ of **1**. Thus by comparison with the data for $M(etp)^{2+}$ and $M(PP_2(PH))^{3+}$, the species formed in these metal-rich mixtures is readily identified from its spectrum as $M(PPP(PH))^{3+}$, with the ligand bound as shown schematically in **2** which contains a tri-coordinate, probably pseudotetrahedrally coordinated ion. The spectral parameters for the two $M(PPP(PH))^{3+}$ complexes are listed in Table 2. Particularly noteworthy in both cases is the comparatively large

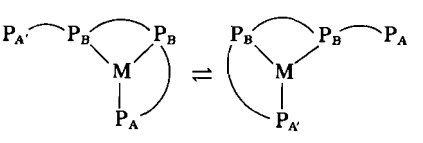


2

coupling between P_A and $P_{B'}$, which are separated by six bonds on the ligand backbone: this coupling must be transmitted largely via the metal. The difference in the chemical shifts of P_B and $P_{B'}$ in the spectra of the $M(PPP(PH))^{3+}$ complexes is a manifestation of the cumulative nature of the ^{31}P nmr five-membered chelate effect mentioned above: P_B, with the larger complexation shift, is involved in two chelate rings, while $P_{B'}$, with the smaller, is involved in only one.

In the region $0.5 < L/M \lesssim 1$, a second major species occurs, which, when $L/M > 1$, exchanges with excess ligand. The second species is evidently of 1:1 stoichiometry: for both tin and lead it is characterized in the ^{31}P nmr spectrum by two equally intense resonances, both "triplets". ^{207}Pb satellites are evident about both resonances in the spectrum of the lead complex but the $^{117/119}Sn$ satellites of P_A in the tin complex were obscured by the spectra of various side products. The 1:1 complex appears to be $M(P_2P_2)^{2+}$ in which the ligand has C_2 symmetry at least on a time average: the triplets then constitute a deceptively simple AA'XX' spectrum. Ambiguities arise about the structure of $M(P_2P_2)^{2+}$, as they did for $M(PP_3)^{2+}$. Compared with the data for metal-bound phosphorus in the analogous dppe, etp, $PP_2(PH)^+$, and $PPP(PH)^+$ complexes, $|^1J(M—P_B)|$ and $\delta_{P_B}(\Delta\delta_{P_B})$ fall in the "normal" range for both tin and lead. However, in $Pb(P_2P_2)^{2+}$, $|^1J(^{207}Pb—^{31}P_A)|$ appears anomalously small, and $\delta_{P_A}(\Delta\delta_{P_A})$ are subnormal for both the tin and the lead complex.

As in the case of $M(PP_3)^{2+}$ (see above), basically two interpretations of the spectra of $M(P_2P_2)^{2+}$ are possible: either the ligand could be behaving in a tetradentate manner or rapid free-bound intramolecular exchange could be occurring in a complex involving tridentate P_2P_2, as in [2]:



3a ***3b***

By comparison with the data for $M(PPP(PH))^{3+}$, and using our previous logic, the exchange process [2] should give rise to $\delta_{P_B} = (\delta_{P_B(M(PPP(PH))^{3+})} + \delta_{P_{B'}(M(PPP)PH))^{3+}})/2$ (i.e. 27.3 ppm for Sn, 71.9 ppm

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

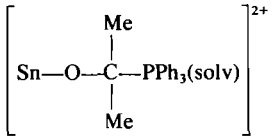
for Pb), $|^1J(M—P_B)| = |^1J(M—P_B)_{(M(PPP(PH))^{3+})} + {}^1J(M—P_{B'})_{(M(PPP)PH))^{3+}}|/2$ (i.e. ~ 1470 Hz for Sn, ~ 1700 Hz for Pb), $\delta_{P_A} = (\delta_{P_A(M(PPP(PH))^{3+})} + \delta_{P_A(P_2P_2)})/2$ (i.e. 4.8 ppm for Sn, 25.9 ppm for Pb), and $^1J(M—P_A) = (^1J(M—P_A)_{(M(PPP(PH))^{3+})}/2$ (i.e. ~ 750 Hz for Sn, ~ 860 Hz for Pb). The expected results of averaging the chemical shifts and one-bond M–P coupling constants via [3] are in semi-quantitative agreement with those observed, and for that reason we hold a slight preference for structure **3** for the complexes $M(P_2P_2)^{2+}$. However, the values of the apparent P–P coupling are larger than can reasonably be explained, even though estimation is difficult because of a lack of information on the signs of the various couplings, and it must be emphasized that we have not ruled out with any certainty the occurrence of an MP_4 kernel.

Attempts to Prepare Complexes with Monodentate Phosphorus-donor Ligands

We were unable to obtain unambiguous evidence for the formation of a direct tin(or lead)–phosphorus bond with any monodentate phosphorus-donor ligand studied.

In acetone, $MeNO_2$, or $PhNO_2$ solutions of tmp–$M(SbF_6)_2$ at ambient probe temperature, a rearrangement of the tmp to dmmp occurs;[9] this is an example of the well-known Arbusov rearrangement which requires a cationic catalyst (32). In $MeNO_2$ solutions of $M(SbF_6)_2$ with PPh_3, the major product species was $HPPh_3^+$, identified by comparison of its ^1H-coupled and -decoupled ^{31}P nmr spectra with those reported in the literature (31).

In an attempt to reduce protonation arising in $MeNO_2$ as solvent (see above), PPh_3–$M(SbF_6)_2$ mixtures were investigated further using acetone as a solvent.[10] No evidence for any coordination of PPh_3 was found in acetone solutions containing $Pb(SbF_6)_2$. However, ^{31}P and ^{13}C nmr showed that in acetone $Sn(SbF_6)_2$ forms a 1:1 complex with PPh_3, which, at ca. 233 K or below, does not exchange with excess ligand.[11] In the ^{31}P nmr spectrum, δ_P and $\Delta\delta_P$ are 26.1 and 32.3 ppm, respectively, while in the ^{13}C spectrum the chemical shifts of the 1-, 2-, 3-, and 4-aryl carbons are 117.5, 135.2, 130.6, 135.4 ppm, respectively, the corresponding complexation shifts, $\Delta\delta_C(=\delta_{C,bound} - \delta_{C,free})$, being −19.5, 1.4, 1.5, and 6.0 ppm. In addition, the ^{13}C spectrum shows that changes in the various ^{31}P—^{13}C couplings are associated with complexation: $^1J(P—C)$, $^2J(P—C)$, $^3J(P—C)$, and $^4J(P—C)$ are 11, 19, 7, and ~0 Hz in the free ligand, but 78, ~9, 12, and ~0 Hz in the complexed ligand. Qualitatively, the changes in the ^{31}P and ^{13}C spectra of PPh_3 are those expected for coordination via the phosphorus atom, but no $^{117/119}Sn$ satellites were observed in the slow-exchange ^{31}P nmr spectrum, whereas $^1J(^{117/119}Sn—^{31}P)$ should be ca. 1500 Hz (see Table 2) for formation of a direct Sn—P bond. For this reason we suggest that the 1:1 complex is not $[Sn—PPh_3]^{2+}$, but is the solvent-inserted species



The ^{31}P and ^{13}C nmr parameters of the coordinated PPh_3 are close to those of, for instance, $MePPh_3^+$ (33),[12] and nucleophilic attack of phosphorus donors at carbonyl carbons is a well-established reaction (e.g. refs. 35–37).[13] We are presently extending our studies of acetone-inserted metal phosphine complexes.

Complexes of Phosphine Oxides

Both nitromethane and SO_2 were investigated as solvents for the tin(II) and lead(II) complexes of the phosphine oxides $OPPh_3$, $dppeO_2$, $etpO_3$, PP_3O_4, and $P_2P_2O_4$. $Sn(SbF_6)_2$ and $Pb(SbF_6)_2$ are soluble in nitromethane as noted earlier, but are insoluble in SO_2. However, the addition of an appropriate amount (see below) of phosphine oxide causes dissolution in SO_2, and over their common temperature range essentially identical nmr spectra are obtained using either solvent. As the phosphine oxide complexes are more labile than the analogous phosphine complexes (see above), SO_2, with its lower freezing point, was the better solvent for our study. Earlier, SO_2 has been used as a solvent for complexes of Cd(II) and Hg(II) with several polyphosphine oxides (18).

Addition of ca. 1.5 mol of $OPPh_3$ per mol of metal salt causes the complete dissolution of $Sn(SbF_6)_2$ or

[9]Separate experiments confirmed that the final metal-containing product is $M(dmmp)_3^{2+}$, and that no tmpO is formed. Detailed study of the tin(II) systems showed that δ_P and $\Delta\delta_P$ are 38.0 and 6.5, and −5.4 and −5.7 ppm, for $Sn(dmmp)_3^{2+}$ and $Sn(tmpO)_3^{2+}$, respectively, in $PhNO_2$ at 308 K.

[10]In acetone at 233 K, dppe forms at 1:1 complex with Sn^{2+} having δ_P and $\Delta\delta_P$ = 28.0 and 41.5 ppm respectively, and $|^1J(^{119}Sn—^{31}P)| = 1810$ Hz.

[11]^{19}F nmr of $Sn(SbF_6)_2$—$P(p\text{-}C_6H_4F)_3$ in acetone produces similar results. At 253 K, the *p*-fluorine of the complex is shielded by 10.4 ppm, from a shift of −113.9 (from $CFCl_3$) for the free ligand, and concurrently $^5J(^{31}P—^{19}F)$ is reduced in magnitude, from 4.5 Hz in the free ligand to $\lesssim 1$ Hz in the complex.

[12]Note, however, that direct coordination to some metals produces similar results; see, e.g., ref. 34.

[13]Other σ-donors attack coordinated carbonyl groups also. See, e.g., refs. 38 and 39.

$Pb(SbF_6)_2$ in SO_2. In the reduced temperature ^{31}P nmr spectra, evidence was found for the 1:3 and 1:2 complexes, $M(OPPh_3)_3^{2+}$ and $M(OPPh_3)_2^{2+}$, as the major species when L/M = 3 and 2, respectively. The ^{31}P nmr spectral parameters of these complexes are given in Table 3. When $2 < L/M < 3$, the 1:3 and 1:2 complexes coexist, while the 1:2 species persists as the major species when $1.5 \lesssim L/M < 2$. We were unable to identify the other species formed in the salt-rich solutions. ^{19}F nmr provided evidence for 1:3 and 1:2 complexes in the system $Sn(SbF_6)_2$–$OP(p\text{-}C_6H_4F)_3$–SO_2 also. At 233 K, the ^{19}F chemical shifts of the 1:3 and 1:2 complexes are −100.6 and −101.3 ppm, respectively (from $CFCl_3$), deshielded by 4.5 and 3.8 ppm, respectively, from the free ligand resonance. $^5J(^{31}P—^{19}F)$ is not affected significantly by the complexation.

In both $OPPh_3$–Sn(II) and $OP(p\text{-}C_6H_4F)_3$–Sn(II) mixtures, exchange is rapid at ambient probe temperature for all L/M ratios, and at reduced temperatures for L/M > 3. In the latter instance, the spectrum obtained is a weighted average of the free ligand and SnL_3^{2+} spectra. Three is clearly the highest number of the monodentate phosphine oxides which can be stably bound in these systems, and the rapid intermolecular exchange which occurs only in the presence of excess ligand shows that the 1:3 complexes undergo ligand exchange by an associative process, which seems reasonable as coordination numbers above the very common three are well-established for tin(II) (2, 3, 40).

The ^{207}Pb satellites of $Pb(OPPh_3)_3^{2+}$ are observed only when $OPPh_3$/Pb is very close to 3, and we were unable to observe the ^{207}Pb satellites of $Pb(OPPh_3)_2^{2+}$ in any solution studied. When $OPPh_3$/Pb > 3, $Pb(OPPh_3)_3^{2+}$ exchanges slowly: no ^{207}Pb satellites are observed, but the chemical shift is unchanged. The species with which this exchange occurs is not simply excess $OPPh_3$: the position of the second line observed moves towards that of free $OPPh_3$ as $OPPh_3$/Pb is increased. Apparently higher than 3 coordination of lead(II) by $OPPh_3$ is possible, but we were unable to identify the complex(es) involved.

The chelating polyphosphine oxides $dppeO_2$, $etpO_3$, and PP_3O_4 all cause dissolution of $Sn(SbF_6)_2$ or $Pb(SbF_6)_2$ in SO_2 when present in equimolar amounts or greater. The 1:1 complexes can be isolated from the supernatant liquor of mixtures where L/M < 1 (see Experimental Section). The 1:1 complexes of tin(II) are further characterized by slow-exchange ^{13}P nmr spectra which are obtained at reduced temperature. Details of the spectra of $Sn(dppeO_2)^{2+}$, $Sn(etpO_3)^{2+}$, and $Sn(PP_3O_4)^{2+}$ are

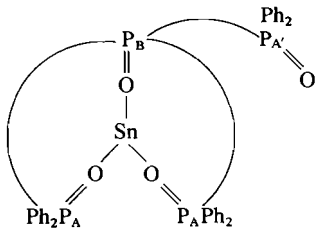
given in Table 3. The observation of $^{117/119}$Sn satellites at the bound phosphoryl groups is good evidence that intermolecular exchange is slow at 209 K. On warming these solutions from 209 K, gradual collapse of the satellites occurs until at ca. 273 K an exchange-averaged spectrum is observed. Also, exchange-averaged spectra are observed at all temperatures when L/Sn > 1.

The spectrum of $Sn(PP_3O_4)^{2+}$ deserves further comment. At 209 K it consists of three regions of resonance with $\delta_{OP(OMe)_3}$ = 50.5, 58.5, and 71.0 ppm, and relative intensities 2, 1, and 1. The upper and lower resonances have complexation shifts close to those of $Sn(etpO_3)^{2+}$ (see Table 3) and only these two resonances have $^{117/119}$Sn satellites and thus have their origin in bound phosphoryl groups. The three-bond P–P coupling between the bound phosphoryl groups is small, as it is in $Sn(etpO_3)^{2+}$, but the unbound P=O group shows a large coupling to the least shielded resonance. The spectrum of $Sn(PP_3O_4)^{2+}$ is in accord with the ligand being bound as shown schematically in **4**, in which the potentially tetradentate PP_3O_4 behaves in a tridentate manner, though the sizeable downfield "coordination" shift of the free phosphoryl phosphorus, $P_{A'}$, seems odd. The SnO_3 kernel in **4** is probably pyramidal (see below). Consis-



4

tent with intermolecular exchange (or a combination of inter- and intra-molecular exchange) involving **4**, two lines from the least shielded, broad "doublet" resonance of P_B (the small $^3J(P_A—P_B)$ is not resolved for either P_A or P_B at 209 K) remain sharp as the temperature is raised, while the two more shielded resonances, from P_A and $P_{A'}$, collapse together. From the two sharp lines of the P_B resonance the magnitude of $^3J(P_A—P_B)$ and relative signs of $^3J(P_A—P_B)$ and $^3J(P_{A'}—P_B)$ can be established.

The tridenticity of PP_3O_4 in $Sn(PP_3O_4)^{2+}$ again suggests that a maximum of three phosphoryl groups can be accommodated about tin under the conditions used in our experiments. Our results provide no evidence for the coordination geometry around the tin, but, as suggested for the chelating phosphines (see earlier), a pseudotetrahedral stereochemistry seems probable.

The 1:1 complexes of lead(II) with $dppeO_2$, $etpO_3$, and PP_3O_4 apparently are more labile than either their tin(II) analogues or $Pb(OPPh_3)_3^{2+}$: in their ^{31}P nmr spectra no ^{207}Pb satellites were observed even at reduced temperature in the absence of excess ligand. Though $|^2J(^{207}Pb—^{31}P)| < |^2J(^{117/119}Sn—^{31}P)|$ in $M(OPPh_3)_3^{2+}$ (see Table 3), it seems unlikely that the ^{207}Pb satellite splitting is too small to observe in all three polyphosphine oxide complexes of lead; thus we conclude that intermolecular exchange of ligand between lead centres is rapid. The complexation shifts of the lead complexes are similar to, though a little smaller than, those of their tin analogues with which they are probably isostructural.

$Sn(SbF_6)_2$ and $Pb(SbF_6)_2$ are soluble in SO_2 solutions containing $P_2P_2O_4$, when $P_2P_2O_4/M \gtrsim 0.33$, and it seems likely therefore that $P_2P_2O_4$ behaves as a bridging ligand, at least in metal-rich mixtures. At low temperatures the ^{31}P nmr spectra of the system $Pb(SbF_6)_2$–$P_2P_2O_4$ generally gave broad lines, while the system $Sn(SbF_6)_2$–$P_2P_2O_4$ either gave similar results, or gave complicated spectra which we were unable to analyze. As a result of these problems, no structural information is available on the $P_2P_2O_4$ complexes. However, from the sharp, exchange-averaged spectra observed at 308 K, it is evident that complexation is associated with a large decrease in $|^1J(P_A—P_B) + {}^3J(P_A—P_{B'})|$, from 56 Hz in free $P_2P_2O_4$ (Table 1) to ~6 Hz in the Sn(II) system and ~9 Hz in the Pb(II) system at L/M = 1.

Phosphorus–Phosphorus Coupling in Complexes of Polydentate Phosphines and Phosphine Oxides

There is ample evidence to show that coupling between adjacent phosphorus atoms changes in magnitude on formation of a chelate ring about a transition element, e.g. refs. 6–9, and a change of sign may occur also (6, 7). For the formation of a five-membered chelate ring with a hydrocarbon backbone, a reduction in magnitude is found (e.g. refs. 6, 8, 9) and a change in sign is thought to occur (6). Grim and co-workers (6, 7) have suggested that the through-ligand contribution to J(P—P) is unchanged on coordination (implying minimal conformation dependence (6)), but that chelate ring formation introduces a new coupling mechanism, through the metal, which is of opposite sign to the coupling through the ligand backbone. Our results for Sn(II) and Pb(II) complexes of etp, $PP_2(PH)^+$, and $PPP(PH)^+$ (see Table 2) show that "$^3J(P_A—P_B)$" (and, for the $PPP(PH)^+$ complexes,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

"$^3J(P_B—P_{B'})$") is greatly reduced in magnitude on coordination, suggesting that the trends outlined hold for these two Main Group elements also. Further, as described above, our analysis of the spectra of the two M(PPP(PH))$^{3+}$ complexes shows the existence of a sizeable through-metal coupling from P_A to $P_{B'}$, in concert with the suggestion of Grim *et al.* (6, 7). It is disconcerting, therefore, to find that the coupling between adjacent phosphorus atoms of polyphosphine oxides is reduced markedly on chelate ring formation also (Table 3 and ref. 18). These results suggest either that the four-bond P—O—M—O—P coupling is significant, which would be surprising, or that there is a conformation dependence for the through-ligand coupling in chelate rings formed by polyphosphine oxides, when none exists, apparently, for rings formed by the corresponding polyphosphines. Both these possibilities are currently under investigation.

One-bond Metal–Phosphine Coupling Constants in Tin(II)), Tin(IV), and Lead(II) Phosphine Complexes

$|^1J(^{119}Sn—^{31}P)|$ in the tin(II) phosphine complexes ranges in magnitude from 705–1665 Hz (Table 2), outside the observed range (2256–2383 Hz) of $|^1J(^{119}Sn—^{31}P)|$ in the relatively few tin(IV) phosphine complexes which have been studied by ^{31}P nmr to date (4, 5). This difference may be of some diagnostic value. For example the combined data suggest that $(OC)_5WSnCl_2(PBu^t_3)$, for which $|^1J(^{119}Sn—^{31}P)|$ is 1560 Hz (15), is best regarded as a tin(II) complex. It should be noted though, that values of $|^1J(^{119}Sn—^{31}P)| \gtrsim 50$ Hz are known;[14] in all cases where the sign has been determined $^1J(^{119}Sn—^{31}P)$ is absolutely positive (42). It has been suggested (28) that the Sn(IV)—P bond in *trans*-$SnCl_4(PR_3)_2$ contains extensive tin 5*s* character. If this is true for the Sn(II)—P bond also, then the smaller magnitude of $|^1J(^{119}Sn—^{31}P)|$ in the tin(II) complexes may reflect mainly the expected reduction in $\Psi_{5s}^2(O)$ on changing from Sn(IV) to Sn(II).

The close similarity between the variation in $|^1J(^{119}Sn—^{31}P)|$ and $|^1J(^{207}Pb—^{31}P)|$ over a range of analogous complexes has been mentioned above. The magnetogyric ratios of ^{207}Pb and $^{117/119}Sn$ are of opposite sign, so it appears that $^1J(^{207}Pb—^{31}P)$ and $^1J(^{117/119}Sn—^{31}P)$ must be also. (The reduced coupling constants, $K_{M—P}$, will be of the same sign.) In general, the one-bond M—P couplings are larger in magnitude for ^{207}Pb than for ^{119}Sn, e.g. for the first three lead(II) complexes in Table 2, $|^1J(^{207}Pb—^{31}P)|_{ave} = 1800$ Hz, while for the tin(II) analogues $|^1J(^{119}Sn—^{31}P)|_{ave} = 1475$ Hz. Using these average values, $(K_{Pb—P}/K_{Sn—P})^{1/2} = 1.78$, reasonably close to Z_{Pb}/Z_{Sn} (= 1.64). Thus, using the arguments of Reeves and Wells (43), it appears that differences in $\Psi_{nx}^2(O)$ between tin(II) and lead(II) in the basically isostructural complexes are responsible for the different values of $K_{M—P}$.

[14]Reference 41 gives an up-to-date tabulation.

The fortuitous direct electrochemical synthesis of some copper(I) complexes

FAROUQ F. SAID AND DENNIS G. TUCK
Department of Chemistry, University of Windsor, Windsor, Ont., Canada N9B 3P4

Received June 9, 1980

FAROUQ F. SAID and DENNIS G. TUCK. Can. J. Chem. **59**, 62 (1981).

The electrochemical oxidation of copper in the presence of RX (R = CH_3, C_6H_5, $C_6H_5CH_2$; X = Cl, Br, I, not all combinations) and either 2,2′-bipyridine or $(C_2H_5)_4NX$ gives rise to neutral or anionic copper(I) halide complexes. The current efficiency shows that CuX is produced at the anode; the subsequent solution chemistry influences the complex formation processes.

FAROUQ F. SAID et DENNIS G. TUCK. Can. J. Chem. **59**, 62 (1981).

L'oxydation électrochimique du cuivre en présence de RX (R = CH_3, C_6H_5, $C_6H_5CH_2$; X = Cl, Br, I, pas toutes les combinaisons) et de bipyridine-2,2′ ou du $(C_2H_5)_4NX$ conduit à la formation de complexes halogénés du cuivre(I) sous la forme neutre ou sous la forme anionique. L'efficacité du courant montre qu'il se forme du CuX à l'anode; la solution chimique résultante influence le mode de formation du complexe.

[Traduit par le journal]

Introduction

In previous papers from this laboratory on the direct electrochemical synthesis of organometallic compounds, we have described the use of cells of the type $Pt_{(-)}$/RX + organic solvent/$M_{(+)}$ to prepare a variety of organometallic halides of main group metals (1–5). Less attention has been given to parallel studies of transition metals, although RMX (M = Ni, Pd) (6) and R_2MX_2 (M = Ti, Zr, Hf) (7) derivatives have been obtained by these methods. We have recently turned our attention to the electrochemical oxidation of the coinage metals, in the hope of once again synthesizing organohalides of these elements.

The present paper shows that in the case of copper expectation outran performance, in that although oxidation occurred the products were generally anionic or neutral inorganic complexes of copper(I). In one system (RX = C_6H_5Br) both copper(I) and copper(II) derivatives were isolated.

Experimental

General

Copper metal was in the form of turnings, approximately 1 cm^2 area, 1 g mass. The purification of solvents, etc., and the spectroscopic investigation of product materials, were carried out as described in earlier papers (1–7). All experiments were carried out under dry nitrogen.

Copper analysis was by atomic absorption spectrophotometry, and halide analysis by Volhard titration. Microanalysis was carried out by Guelph Chemical Laboratories Ltd. The presence of the tetraethylammonium cation, or of 2,2′-bipyridine (bipy), in the appropriate products was confirmed by conventional infrared spectroscopy.

Electrochemical Synthesis

A piece of copper, suspended on a platinum wire, formed the anode of a cell of the general type

$$Pt_{(-)}/CH_3CN + RX + bipy/Cu_{(+)}$$

or

$$Pt_{(-)}/CH_3CN + RX + (C_2H_5)_4NX/Cu_{(+)}$$

The actual solution compositions used are shown in Table 1, together with the initial applied voltage and current, and the weight of copper dissolved. The isolation of the anionic complexes followed conventional routes, as dictated by the solubilities involved. Reduction of the volume of the electrolyte phase by approximately 50% resulted in the precipitation of a solid, which was washed and/or recrystallized and dried *in vacuo*. The yields were of the order of 80%, based on the quantity of copper consumed.

$Cu/CH_4CN + C_6H_5Br$ + 2,2′-Bipyridine

This system merits special description in view of the findings. Early studies using an undivided cell yielded products which could not be characterized, and later experiments were therefore performed in a two-arm cell, with the electrode compartments joined via a narrow arm (2 mm id) lightly plugged with glass wool. For the experimental conditions listed in line 6 of Table 1, we observed the formation of a brown solution phase, together with a green solid which deposited in the anode compartment. The brown solution, on treatment with diethyl ether, yielded solid CuBr·bipy. The green solid is not apparently a single compound; microanalysis showed C, H, and N in the ratios required for 2,2′-bipyridine, but neither the absolute values for these elements, nor those for Cu and Br, lead to any obvious stoichiometry. In one experiment, however, a green single crystal grew on the copper anode, and X-ray studies (8) identified this as $[Cu(bipy)_2Br]Br$. We therefore conclude that the non-stoichiometric green solids referred to above are probably mixtures of this copper(II) salt with CuBr·bipy; for example, one product had C 43.3, H 3.5, N 10.5, and a mixture of 40% CuBr·bipy and 60% $CuBr_2$·2bipy requires C 43.5, H 2.9, N 10.2.

Results and Discussion

The organometallic chemistry of copper is apparently restricted to those compounds in which the element is the +I oxidation state (9), and it is therefore not surprising that the electrochemical oxidation did not give rise to the RCuX species which might have been expected by analogy with other previous experiments. The two main discus-

sion points to be addressed are the reaction pathway, and the structure of the products obtained.

The anionic copper(I) complexes listed in Table 2 are generally of known stoichiometries (cf. ref. 11), although few, if any, have been stabilized with bulky organic cations in previous studies. The structures of the various anionic copper(I) complexes are based on linked tetrahedra (10); the anion CuI_4^{3-}, which apparently has not been reported previously, may be a rare example of an isolated mononuclear anionic copper(I) tetrahedral species. No doubt salts with cations other than $(C_2H_5)_4N^+$ could be prepared by the electrochemical method, although the uncertainties about the solution chemistry involved (see below) require clarification before any claim can be made about predicting the identity of any products.

As in our previous work, we have measured the current efficiency, here expressed as moles of copper dissolved per Faraday of charge, for two typical systems, namely

$$Pt_{(-)}/CH_3CN + C_6H_5Cl + (C_2H_5)_4NCl/Cu_{(+)}$$
$$Pt_{(-)}/CH_3CN + C_6H_5Br + (C_2H_5)_4NBr/Cu_{(+)}$$

for which $E_F = 1.06$ and 1.10 mol F^{-1} respectively. These values correspond to the anode reaction

[1] $X^- + Cu \rightarrow CuX + e$

and in those systems where $(C_2H_5)_4NX$ is present in some quantity, the anion is clearly derived from this salt. In other cases, the reduction $RX + e \rightarrow R' + X^-$ is a source of halide ion (1, 11); there is a resultant significant difference in the operating voltage depending upon the presence or absence of $(C_2H_5)_4NX$ (see Table 1).

The disproportionation of copper(I) species formed by the anode reaction (1) will not occur in acetonitrile solution (12), and complex formation can then occur by reaction with excess halide ion, or with 2,2′-bipyridine. The absence of stable organo-copper(II) compounds eliminates reactions such as $CuX + RX \rightarrow RCuX + X$, but the presence of the organic halide is apparently crucial in the formation of the copper(I) complexes isolated, since cells which contain R_4NX but no RX give rise to a different group of copper compounds (yet to be characterized (13)) which precipitate immediately, in contrast to the present systems in which precipitation only occurs during the work-up following electrolysis. It is worth noting in this context that the exchange reaction between aryl halide and copper(I) halide has been discussed in terms of possible solvated four-centre ArXCuY intermediate species (14), so that the stabilization and solvation of similar complexes, or of analogues

For personal use only.

involving CuX_2^-, etc. may well play an important role in the present syntheses. In general, this point apart, it seems that the production of CuX, and the subsequent complex formation, are in keeping with the known chemistry of the element.

The formation of copper(II) species was only observed in the presence of 2,2′-bipyridine, and we therefore tentatively conclude that complexing by this ligand allows the reaction

[2] $2CuX{\cdot}bipy \rightarrow Cu(bipy)_2X_2 + Cu$

to proceed significantly, even in acetonitrile. The insolubility of $Cu(bipy)_2X_2$ in acetonitrile may be important in this respect.

N. J. CURTIS and R. S. BROWN. Can. J. Chem. **59**, 65 (1981).

Several compounds of the title class have been synthesized as small-molecule analogues for the metal-binding sites in such biochemical systems as ADH. The ligands containing pyridine and two thioethers do not bind divalent metals (Co^{2+}, Zn^{2+}, Cu^{2+}, Ni^{2+}), strongly suggesting that thioethers are poorly chelated. However, the analogues containing free SH groups bind divalent metals very strongly, producing complexes with limited solubility at pH values in excess of 6. Titration of the latter ligands in the presence of 1 equiv. Zn^{2+} indicates the consumption of 3 equiv. OH^- by pH 6, one for the $\overset{+}{N}$—H → N: ionization, and one for each S—H bound to Zn^{2+}. On the basis of these data the resulting complexes are considered to neutral bis-thiolates. The relationship of these data to the state of ionization of the Zn^{2+}-cysteine SH's in ADH is discussed.

N. J. CURTIS et R. S. BROWN. Can. J. Chem. **59**, 65 (1981).

On a synthétisé plusieurs composés de la classe de ceux mentionnés dans le titre en tant qu'analogue des petites molécules des sites de liaison métallique de certains systèmes tel le ADH. Les ligands contenant la pyridine et deux thioéthers ne se lient pas au métaux bivalents (Co^{2+}, Zn^{2+}, Cu^{2+}, Ni^{2+}) suggérant ainsi fortement que les thioéthers sont chélatés faiblement. Cependant les analogues contenant des groupes SH libres se lient fortement aux métaux bivalents, produisant des complexes à solubilité limitée à un pH supérieur à 6. Le titrage des derniers ligands en présence de 1 éq. de Zn^{2+} démontrent qu'à un pH de 6, trois éq. de OH^- sont utilisés; un éq. pour l'ionisation de $\overset{+}{N}$—H→N: et un pour chacun des groupes S—H lié au Zn^{2+}. En se basant sur ces données, on en a déduit que les complexes résultant sont des bis-thiolates neutres. On discute de la relation entre ces données et l'état d'ionisation de la Zn^{2+}–cystéine SH dans l'ADH.

[Traduit par le journal]

Introduction

Many biological systems contain metal-binding sites containing (along with other residues) cysteine sulfhydryl and/or methionine thiomethyl groups (1, 2). Among these are the Zn-containing enzymes aspartate transcarbamylase (1*a*), superoxide dismutase (1*b*), metallothioneine (1*c*), porphobilinogen synthase (1*d*), and the alcohol dehydrogenases (1*e*–*h*). The structure of an inhibited ternary complex of horse liver alcohol dehydrogenase (HLADH), reduced nicotinamide adenine dinucleotide (NADH), and dimethyl sulfoxide shows that the catalytic Zn^{2+} ion is bound by cys 46, his 67, and cys 174. The fourth ligand site is occupied by the non-reducible DMSO oxygen as shown in Fig. 1 (1*g*) and the reducing agent (NADH) is positioned close to the Zn^{2+}-bound sulfoxide.

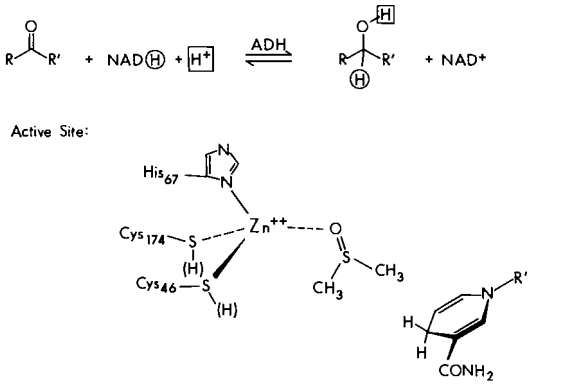

FIG. 1. The active site structure of a DMSO inhibited ternary complex of horse liver alcohol dehydrogenase depicting the Zn^{2+} binding site (1*g*).

The unusual "type 1" copper–blue proteins such as plastocyanin, stellacyanin, and azurin (2) contain a Cu^{2+} ion bound by cys, his, and/or met groups. The recently determined crystal structure of plastocyanin (2*a*) indicates that the Cu^{2+} ion is bound in a distorted tetrahedral geometry by two histidine imidazoles, a methionine SCH_3, and a cysteine SH. Stellacyanin (2*d*, *c*) contains no methionine so its copper binding site must differ from that of plastocyanin by at least one residue, but as yet no X-ray structure for the former is available. Several sulfur- and nitrogen-containing small molecules have been investigated as models for these proteins (3).

On the other hand, for the small molecules which have been investigated as models for NADH dependent oxido-reductases (4), no attempt has been made to approximate the known catalytic sites in the enzyme. It seemed to us that since the ADH's

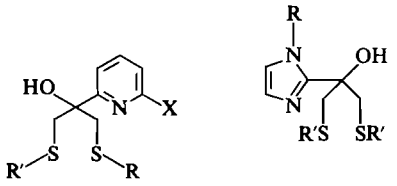
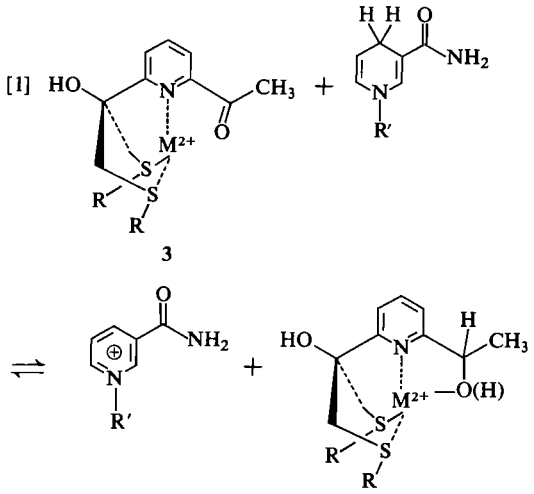
isolated from mammalian, yeast, or bacterial sources, while differing in their tertiary structures, have very similar catalytic sites (1*e*), that any model system for ADH should at least incorporate two thiols and an imidazole or pyridine nitrogen as a Zn^{2+} binding site. For this reason we have synthesized and studied a new class of S-, N-containing ligands of general structure **1** and **2**. Inspection of



1 **2**

molecular models indicates that the unique connectivity of **1** and **2** orients the metal-binding groups (S and N) to form a tridentate chelate which might be a reasonable model for the active site depicted in Fig. 1. In the cases where X is a carbonyl-containing moiety as in **3**, one might observe reduction of the (possibly) coordinated C=O by 1,4-dihydropyridines to form an alcohol(ate) (**4**) as in reaction [1].



3

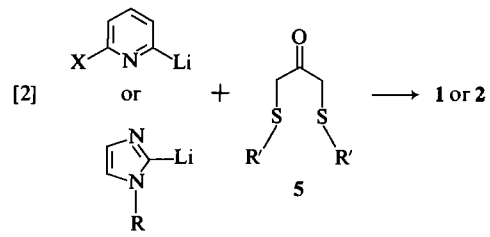
4

In this report we present the synthesis of the type **1** and **2** ligands, studies of their metal binding abilities, and some titration data of their 1:1 Zn^{2+} complexes. Subsequent publications will consider the kinetic and mechanistic aspects of the redox process.

Results

(A) Syntheses

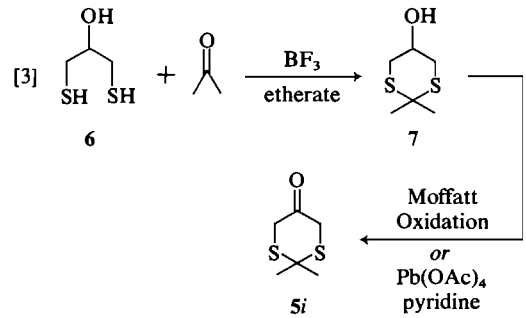
The basic approach to these unknown ligands involves the nucleophilic addition of the appropriate 2-pyridyl (5) or 2-imidazolyl anions to the bis-1,3-dithioethers of acetone (**5**) as in reaction [2].



While 1 equiv. of 2-pyridyl lithium adds to acetone to provide reasonable yields of **16** (*vide infra*) at least 2 equiv. of this anion must be used per equiv. of **5** to obtain product, and even with 3 equiv. of anion the yields are not high (≤42%). On the other hand, methyl magnesium chloride gave satisfactory yields (~50%) of the corresponding addition product with **5** at a 1:1 ratio. The dithio ketones themselves (**5***a*–*h*) can be made in 30 to 90% yields by the bis displacement on 1,3-dichloroacetone by the appropriate thiolate anion (6). In order to obtain the free thiols of **1** and **2** (R = R′ = H) two routes were considered which utilize a suitably protected derivative of **5**. The first of these utilizing ketone **5***i* (7) (produced by the route outlined in reaction [3]) was deemed inappropriate since the oxidation of alcohol **7** proceeded in low and variable yield.

An alternative ketone (**5***j*) can be prepared in 80% yield by the double displacement of the bis-lithio anion of "1,3-dimercapto acetone"[1] (8) on chloromethylethyl ether. Deprotection of the hemithioacetal group (9) was accomplished by stirring **1** or **2** (R = R′ = $CH_2OCH_2CH_3$) in a 4:1 mixture of CH_3CN:H_2O with $HgCl_2$ to give a thick precipitate (presumably **8**) from which the free thiol could be liberated by H_2S treatment as in reaction [4]. We believe **8** is deprotonated as shown since the reaction mixture becomes very acidic as soon as $HgCl_2$ is added to the mixture.

In order to produce the 2,6-disubstituted pyridines (**1** X = $\overset{O}{\overset{\|}{C}}CH_3$; X = $CHOHCH_3$ (**14** and **15**,

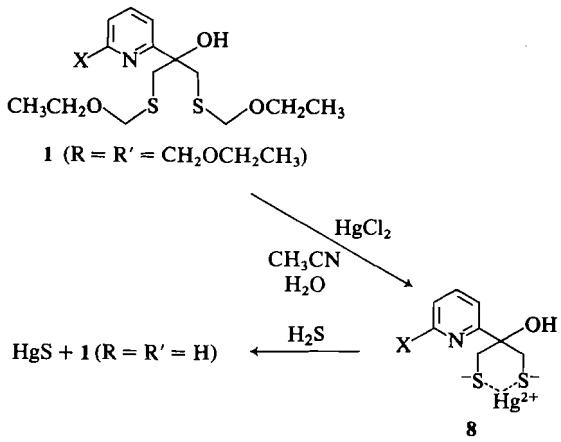


6 **7** **5***i*

[1] Schotte has proposed that this material exists as a dimer (8), a fact which is verified by mass spectral and infrared measurements.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/05/12
For personal use only.

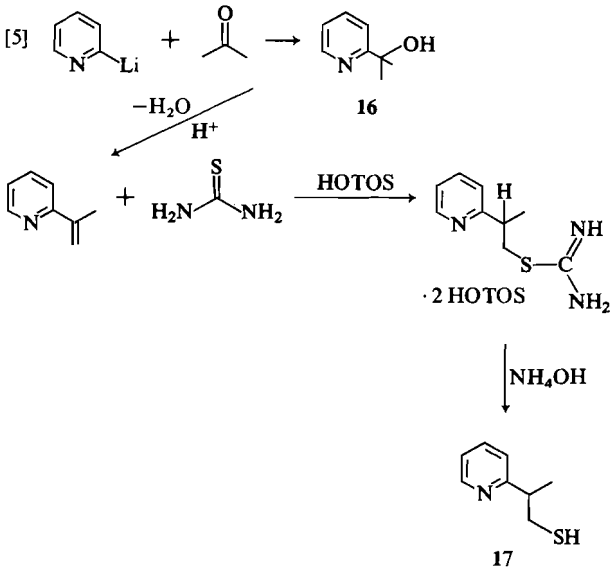
[4]



respectively)), the pathway shown in Scheme 1 was adopted. When the reaction mixture containing the fully protected material **9** was washed with 0.1 *N* HCl, debrominated residual unreacted starting pyridine was removed; further extraction of the reaction mixture with 3 *N* HCl gave **9** which on standing for 24 h in 3 *N* HCl at room temperature afforded the partially deblocked **1** (X = $COCH_3$, R = R′ = $CH_2OCH_2CH_3$). Deblocking of the thiol was accomplished as in reaction [4].

Finally compound **17** (*vide infra*) was produced by the route outlined in reaction [5].

[5]



2(2-Pyridyl)propene (ref. 10*a*, prepared by acid-catalysed dehydration of **16**) when treated with 2.1 equiv. of *p*-toluenesulfonic acid (HOTOS) and 1 equiv. of thiourea (10*b*) gives the corresponding thiouronium salt which analysed as the ditosylate. Deprotection of this material in 4:1 NH_4OH:H_2O for 1 h gave **17**.

Table 1 lists the yields and physical data for ketones **5***a*–*j*, and in Table 2 are listed the physical data for thioethers **1***a*–*i* (X = H). Table 3 lists the data for thiols **10**–**17**.

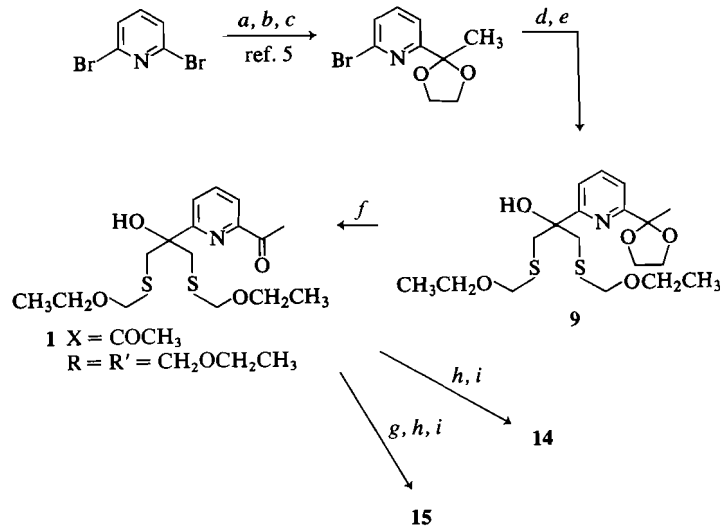
(B) Titration and Metal Stability Constants

(*i*) pK_a measurements (11) were performed on thioethers **1***a*–*i* and thiols **10**–**13**, **16**, and **17** at concentrations of 4×10^{-3} *M* in 50% (v/v) aqueous dioxane at 25°C and constant ionic strength of I = 0.3 *M* $NaNO_3$. The data were analysed by a modified computer version of Simms' method (12, 13) and are given in Table 4. A general trend emerges when one compares the pK_a's of the substituted aryl thioethers **1***d*–*h*; electron withdrawing groups on the phenyl ring reduce the pK_a's in this medium substantially. Since the sulfur atoms are each four atoms removed from the site of protonation, the pK_a change of 0.56 units in passing from the *p*-OCH_3 to *m*-CF_3 derivatives seems appropriate for a simple through bond inductive effect or field effect. It is shown in Table 4 that each of the pyridine-sulfur containing species is a weaker base than is **16**; **17** might be considered an exception, but the latter contains no electron withdrawing α-OH group so its basicity is higher.

(*ii*) *Metal stability constants*, $pK_{M^{2+}}$ values for weak binding ligands **1***a*–*i* and **16** were determined by potentiometric titration methods (14*a*) on roughly 5×10^{-3} *M* solutions of ligand containing a 20-fold excess of metal (I = 0.3 *M*, T = 25°C) and the results are compiled in Table 5. For the Cu^{2+} complexes where the $pK_{M^{2+}}$ values are larger, titration methods outlined in ref. 13 were used successfully.

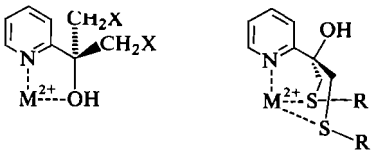
On the basis of the data given in Table 5 one can see that ligands **1***a*–*i* bind the divalent ions weaker than does **16**. Thus it appears that the thioether functionality does not contribute constructively to the complex formation, an observation noted by earlier workers (14*b*). Comparison of the data for **16** with those for pyridine (15) and α-picoline (16) (Table 5) shows that the former binds the divalent ion more tightly, probably by involvement of the α-OH group as in **18**. Since in general the thioethers bind more poorly than **16** but better than α-picoline; we cannot tell unambiguously whether their chelates resemble **18** or **19**, although one notes that the electron-withdrawing groups on the aryl ring decrease the binding ability as they do the pK_a's in Table 4. Thus probably a similar inductive mechanism is operative in both H^+ and M^{2+} binding.

The determination of the stability constants for the thiol containing ligands **10**–**15** and **17** is not as simple a task as for the thioethers since precipitation invariably accompanies the titration. Relatively few $pK_{M^{2+}}$ values for thiols have been re-



SCHEME 1. *a*, *n*BuLi, ether; *b*, dimethylacetamide; *c*, HOTOS, 2,2-dimethoxypropane, ethylene glycol; *d*, *n*BuLi, ether; *e*, **5***j*; *f*, HCl/H_2O; *g*, $NaBH_4$, ethanol; *h*, $HgCl_2$, CH_3CN/H_2O; *i*, H_2S.

ported (17). However, the reported values are large for 1,2-dithioethane (ref. 17*a*, $pK_{Ni^{2+}} = 20.7$) and 2,3-dimercapto-1-propanol (ref. 17*b*, $pK_{Zn^{2+}} = 13.5$). Utilizing the titration methods in ref. 12 one finds that the monothiol pyridine **13** also binds



18, X = H **19**

Zn^{2+}, Co^{2+}, and Ni^{2+} very strongly, the respective $pK_{M^{2+}}$ values being 10.8, 10.9, and 10.8. It is therefore expected that the remaining thiols will be strong chelators as well, and although we do not have reliable $pK_{M^{2+}}$ values we believe that they are bound strongly through sulfur.

(iii) Titration of ligands **1**a, *11, 12, and 17 in the presence and absence of* Zn^{2+}. Thiols undoubtedly bind metals strongly as deprotonated thiolate complexes (17, 18), which is supported by the observation that when the neutral thiols and metals are mixed, H^+ ion is released. Since most of the mechanisms postulated for the action of ADH (*vide infra*) require a strongly electrophilic metal (i.e., as a Lewis acid for polarizing the presumably coordinated carbonyl), we were concerned about the state of ionization of the thiols at various pH values in the presence of Zn^{2+}. As a control experiment, weakly binding thioether **1***a* was titrated in 50% aq. dioxane ($I = 0.3$ *M*, $T = 25$°C) both in the absence, and presence of 1 equiv. of Zn^{2+}. Figure 2 shows the titration curves and it is seen that the pyridine–H^+ ionization is perturbed only slightly when Zn^{2+} is added. It is important to note that for the latter titration only 1 equiv. of OH^- is consumed up to a pH ~ 6; further addition of OH^- resulted in precipitation of $Zn(OH)_2$.

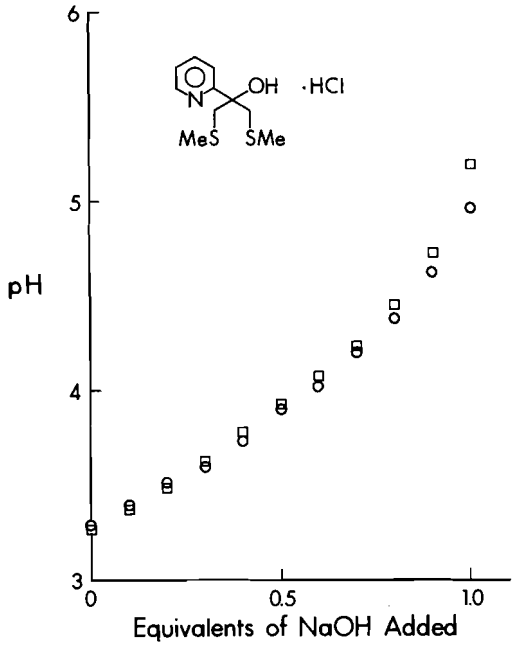


FIG. 2. A plot of the titration curve for **1***a* (pH vs. equivalents of NaOH added) in the absence (□) and presence (○) of 1 equiv. of Zn^{2+} in 50% aq. dioxane, $I = 0.3$, $T = 25$°C.

On the other hand, similar titration experiments performed on pyridine mono thiol **17** (Fig. 3) showed (in the absence of metal) a pK_a of 4.21 corresponding to the pyridinium → pyridine titra-

tion, and a thiol → thiolate ionization at pH ≈ 10. In the presence of Zn^{2+}, however, the titration curve is markedly displaced with 2 equiv. of OH^- being consumed by pH < 6. At pH's in excess of 6.5 visible precipitation occurred which was tied to the consumption of additional OH^-. For best comparison of the data, it is clearly desirable to perform the analogous titrations on pyridine dithiol **10**, but its metal complex precipitated even at low pH. How-

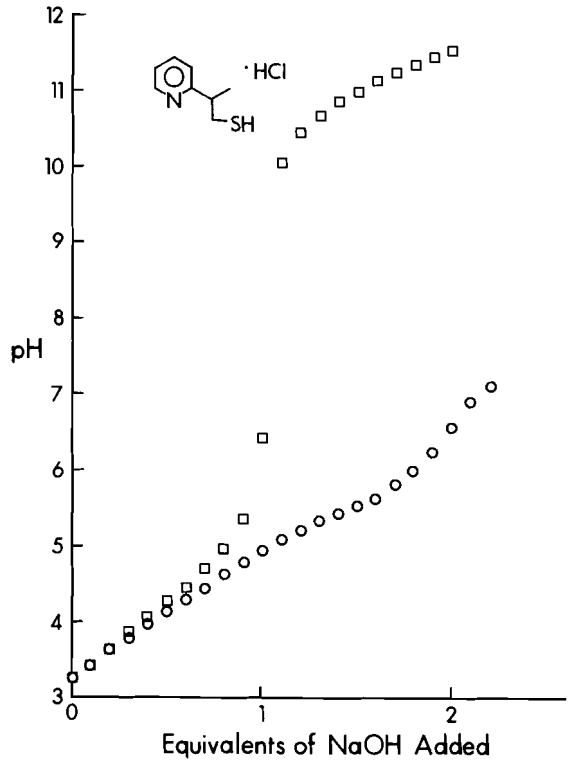

FIG. 3. A plot of the titration curve for **17** (pH vs. equivalents of NaOH added) in the absence (□) and presence of 1 equiv. of Zn^{2+} in 50% aq. dioxane, $I = 0.3$, $T = 25°C$. The deviation in the latter plot at pH > 6.5 is tied to visible precipitation of some species.

ever, the analogous imidazoles **11** and **12** proved more soluble, and their titration curves are shown in Fig. 4. For both species in the absence of metal one sees the imidazolium → imidazole pK_a of ~5.4, and a further titration of thiol at ~pH 9.4 (Table 4). In the presence of Zn^{2+}, however, the situation is very different, and in both cases one sees the consumption of 3 equiv. of OH^- at pH values less than 6. While no visible precipitation occurs up to pH 6, at higher values the complexes precipitated.

On the basis of the above, the additional consumption of 2 equiv. of OH^- can be most adequately explained as having arisen from the formation of stable thiolate complexes such as **20** which may neutralize the metal's charge sufficiently to render the complex insoluble.

12 R = H

Discussion

Mechanisms for the reduction of carbonyls by ADH involve the active site Zn^{2+} acting as a Lewis acid catalyst to activate the carbonyl for the reduction by NADH by inner sphere coordination of the carbonyl oxygen (1*e*, *g*, 19). Spectroscopic measurements on a chromophoric aldehyde support direct coordination of the aldehyde carbonyl (19*b*, *c*), and electronic substituent effects on the ADH catalysed reduction of substituted benzaldehydes have been used to support the Lewis acid mechanism (19*e*). Variations of this general mechanism which involve concerted H^- delivery from the NADH to the Zn^{2+} coordinated carbonyl and syncronous (20*a*) or stepwise (20*b*) delivery of H^+ from an additional Zn^{2+} coordinated H_2O. (For a recent review of other evidence for involvement of substrate and Zn^{2+} in the active site see ref. 21.)

An alternative role for the Zn^{2+} ion was proposed (22) based on nmr studies of the Co^{2+} substituted enzyme and involves a Zn^{2+} bound water molecule which functions as a protonic acid base catalyst in the facilitation of hydride transfer from the NADH to the C=O.

Additional mechansims involving electron transfer followed by H· transfer from the NADH to the metal-coordinated carbonyl have been proposed (23, 24). Recent work of van Eikeren *et al.* (25) has demonstrated the viability of the electron transfer mechanism in reductions of pyridyl ketones with *N*-propyl-1,4-dihydronicotinamides and supports this previously suggested mechanism. It is not clear, however, whether the metal-ion catalysed reductions proceed by a stepwise electron, H· transfer. Recent work by Ohno *et al.* (26) on the Mg^{2+} catalysed reduction of thiopivalophenone and methyl benzoyl formate by 1-benzyl-1,4-dihydronicotinamide (BNAH) leads these authors to propose that in some cases, a metal ion can lower the transition state for electron transfer from the dihydronicotinamide to the coordinated carbonyl; in other cases, the metal stabilizes the overall transition state for reduction. Additional workers (27) have reported on the basis of the discrepancy between kinetic isotope effects and product isotope yields, the existence of at least one intermediate in the reduction of α,α,α-trifluoroacetophenone (27) and 1,10-phenanthroline-2-carboxaldehyde (4*b*) by BNAH or its analogs.

It would appear that regardless of the exact mechanism which is adopted by the enzyme during reduction, the *positive* character of the metal must be involved either as a Lewis acid for C=O polarization, ketyl radical anion stabilization, or to re-

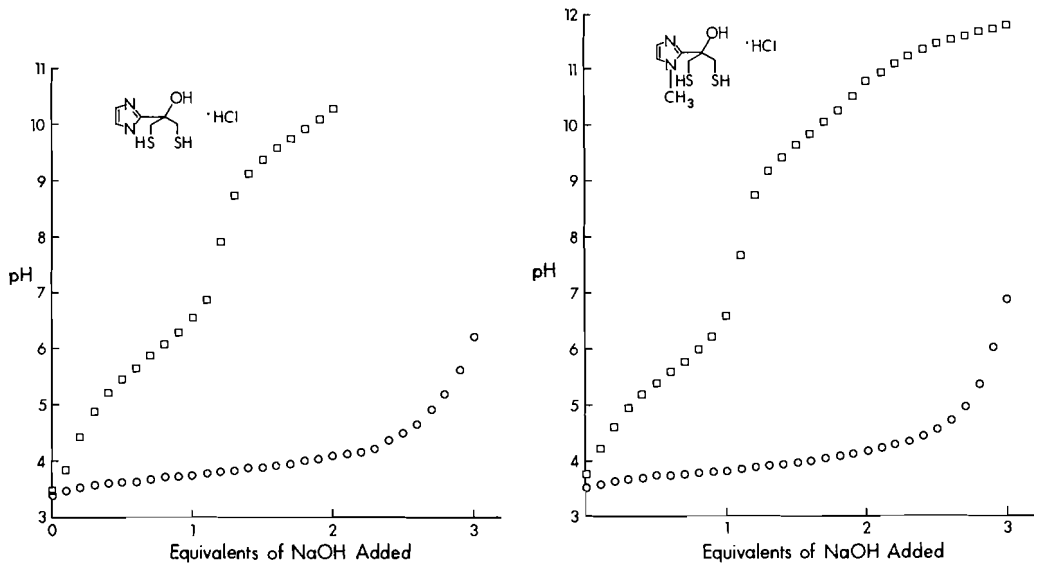

FIG. 4. A plot of the titration curves for imidazoles **11** and **12** (pH vs. equivalents of NaOH added) in the absence (□) and presence (○) of 1 equiv. of Zn^{2+} in 50% aq. dioxane, $I = 0.3$, $T = 25°C$. The similarity of both curves in the presence of Zn^{2+} indicates that the titration of an imidazole (N—H) proton is not occurring.

duce the pK_a of a Zn^{2+} bound H_2O enough to facilitate proton transfer reactions which accompany the reduction. It is expected then that inside the active site of the enzyme the net (+) charge of the metal at the time of C=O reduction should be an important factor. The titration data on the metal complexes of ligands **11** and **12**, however, indicate that at pH values in excess of 6 (where the enzyme operates), both thiols are completely deprotonated and therefore the Zn^{2+} charge is effectively neutralized. A hydrophobic environment in the active site would only serve to favor this charge neutralization.

In a preliminary form we have looked at the reduction of ligand **14** which contains an acetyl group at the 6-position of the pyridine. For reasons of solubility of the Zn^{2+} complex, the solvent system required to dissolve 3×10^{-3} *M* in each of **14**, $ZnCl_2$, and *N*-propyl-1,4-dihydronicotinamide (PNAH) was 90% (v/v) HMPA/H_2O. With 2 equiv. of added HCl (to make an acidic environment), a rapid loss of PNAH was observed by monitoring the absorbance at 350 nm. This was clearly tied to the acid catalysed hydration of PNAH (25, 28) as was evidenced by a characteristic isosbestic point at 310–315 nm. For **14**, PNAH, and $ZnCl_2$ in the same solvent system but with 1 equiv. of added NaOH, we observed a slow loss of PNAH (14% over 21 h) which again was tied to the formation of the hydrated product. Apparently in this medium we have no evidence to support a Zn^{2+} promoted reduction of **14** by PNAH. This seems disturbing in light of the considerable number of examples of 2-pyridyl aldehyde and ketone reduction by PNAH or BNAH which are catalysed by Zn^{2+} or Mg^{2+} (4, 26, 29). However, none of the latter examples utilizes a metal-binding site which contains an anionic ligand and therefore the electrophilicity of the metal in these cases was considerable. Metal coordinated acetyl acetonates also do not reduce under conditions where α-pyridyl ketones or α-keto esters do, presumably because the negatively charged acetylacetonate deadens the M^{2+} charge (26*b*). Although we do not know the detailed reasons for the lack of reducibility of Zn^{2+} bound **14**, we believe it is due to the fact that the deprotonated thiols reduce the electrophilicity of the metal sufficiently so that it either does not bind the pyridyl ketone, or does not interact sufficiently with the C=O group to promote reduction. While on the basis of the above one can only speculate about the analogous catalytic process in the enzyme, one might wonder about the Zn^{2+} electrophilicity if both the cysteine thiolates are coordinated to the metal during the reduction step. Similarly one might wonder about mechanisms which involve a $Zn^{2+}—OH_2 \rightleftarrows Zn^{2+}—OH$ ionization which facilitates proton transfers during the reduction (2) if Zn^{2+} already has two anionic groups attached to it. More work will be required to assess the importance of the state of ionization of the Zn^{2+}-bound sulfhydryl groups in the redox process, and further work is in progress in these laboratories to this end.

Experimental

Melting and boiling points are uncorrected. Routine ir and nmr spectra were respectively obtained using a Nicolet FTIR Spectrophotometer ($CHCl_3$ cast film) and either a Varian A-60 or Varian HA-100-15 (Fourier transform modifications provided by a Digilab FTS NMR-3 System). Titration data were obtained using equipment and methods outlined in ref. 12.

Ketones (5)

Syntheses of the thio ether containing ketones were accomplished by one of two methods outlined below for the preparation of bis-1,3-dithiomethyl acetone (**5***a*, method A) and bis-1,3-di(*p*-tolylthio)acetone (**5***e*, method B).

Method A

To a solution of 8.0 g (0.2 mol) NaOH in 100 mL of 95% ethanol held at −20°C was added 9.2 g (0.2 *m*) of CH_3SH which had previously been condensed in a cold trap. After warming to room temperature, this solution was added over 30 min to a stirred solution of 12.7 g (0.1 mol) of 1,3-dichloroacetone[2] in 100 mL of 95% ethanol. After stirring for 12 h, the resultant mixture was poured onto 100 g of ice and left for 30 min. After extraction of this mixture with CH_2Cl_2 (3 × 100 mL), the combined extracts were dried (Na_2SO_4), and stripped of solvent to yield an oil which was distilled to give 13.0 g (87%) of **5***a* (bp 53°C/0.55 Torr, lit. 106–109°C/9 Torr (Table 1)).

Method B

A solution of 8.0 g (0.2 mol) NaOH in 150 mL 98% EtOH was added over a 30 min period at room temperature to a stirred solution of 24.8 g (0.2 mol) *p*-methylthiophenol and 12.7 g (0.1 mol) 1,3-dichloroacetone.[2] After stirring for 12 h the mixture was poured onto 100 g ice, and the mixture left for 30 min. The resulting solid was filtered and recrystallized from methanol to give 20.6 g (68%) of **5***e* (mp 65–66°C; lit. 66–67°C, Table 1).

*Ketone 5*i

(3,5-Dithia-4,4-dimethylcyclohexanone (**5***i*)) was prepared from 3,5-dithia-4,4-dimethylcyclohexanol (**7**) as below.

To a solution of 24.8 g (0.2 mol) 1,3-dimercapto-2-propanol (**6**) and 11.8 g (0.2 mol) dry acetone in 200 mL $CHCl_3$ cooled to 0°C was cautiously added 10 mL BF_3:etherate. After 18 h at 5°C, the opaque mixture was washed with 100 mL aq. Na_2CO_3, water, and dried over Na_2SO_4. Following solvent removal, the residue was fractionally distilled to give 19.5 g (59%) of the alcohol (**7**) as a colorless oil (bp 58°C/0.08 Torr). Considerable decomposition of the material accompanies distillation but nmr analysis of the crude product indicates >90% yield. Nmr ($CDCl_3$) δ: 1.62 (s, 3H); 1.74 (s, 3H); 2.6–3.3 (m, 4H); 3.6 (d, 1H); 3.9 (m, 1H). *Anal.* calcd. for $C_6H_{12}S_2O$: C 43.87, H 7.36, S 39.03; found: C 43.61, H 7.38, S 38.86.

The ketone (**5***i*) (Table 1) was prepared from **7** in low and erratic yields by either pyridine/$Pb(OAc)_4$ oxidation (30*a*) or Moffatt oxidation (30*b*).

*Ketone 5*j

1,3-Dimercapto acetone[1] (12.2 g, 0.1 mol) in 300 mL dry THF was cooled to −5°C and 0.2 mol of *n*BuLi were added such that the temperature did not exceed 0°C. After stirring an additional 1 h, the cream-colored suspension was cooled to −65°C and 20.8 g (0.22 mol) of $ClCH_2OCH_2CH_3$ in 50 mL dry THF was added over 30 min. The mixture was left to warm up and stir overnight and then 200 mL H_2O were added, the THF layer separated, and the aqueous layer extracted with 2 × 100 mL ether. The combined organic extracts were dried and the solvent removed *in vacuo*. Distillation of the residue from a preheated oil bath (130°C) yielded 18.8 g (80%) of **5***j* as a pale yellow liquid; bp 115°C/0.1 Torr, nmr (Table 1). *Anal.* calcd. for $C_9H_{18}O_2S_2$: C 45.35, H 7.61, S 26.90; found: C 45.36, H 7.67, S 26.88.

*Ketone 5*k

This was prepared in a similar fashion to **5***j* by the sequential addition of 1 equiv. *n*BuLi (−50°C) 1 equiv. $ClCH_2OCH_2CH_3$ (−65°C), 1 equiv. *n*BuLi (−65°C) and 1.2 equiv. CH_3I to a stirred solution of 1,3-dimercaptoacetone in THF. After warming to room temperature overnight, 100 mL H_2O was added, and the mixture worked up as for **5***j*. Yield (after 3 fractional distillations) 4.7 g (24%) as a pale yellow liquid, bp 75°C/0.05 Torr. Satisfactory analyses could not be obtained for **5***j* so it was subjected to the pyridyl formation in an impure state (*vide infra*).

The alcohols in Table 2 were prepared by the general method outlined below.

*2-Lithiopyridine (5*a)

A solution of 14.2 g (0.09 mol) of 2-bromopyridine in 150 mL dry THF or ether was cooled to −65°C under N_2. Then 0.09 *m* of *n*BuLi (~2 *M* in hexane) was added via syringe at such a rate that the temperature did not rise above −55°C. After 15 min stirring at −50°C (not above −50°C to avoid decomposition) the red-brown solution was cooled to −65°C for subsequent use.

*Preparation of Alcohol 1*a

A solution of 4.50 g (0.03 mol) of ketone **5***a* in 50 mL of dry THF was added dropwise to 0.09 mol of 2-lithio pyridine (prepared as above) at −65 to −60°C. After stirring for 2 h at −65°C and having warmed to −40°C, the mixture was quenched by the addition of 50 mL water, and then brought to room temperature. Then 50 mL more H_2O were added, and the THF layer separated. The remaining aqueous layer was extracted with 2 × 100 mL ether, and the combined organic layers dried (Na_2SO_4), stripped, and the residue put on a vacuum line to remove pyridine. This residue was taken up in 200 mL ether, and dry HCl gas passed into the solution until no more precipitate appeared. The oily precipitate was triturated with acetone and recrystallized twice from $CHCl_3/CH_3OH$ to give 3.24 g (42%) of **1***a* as its HCl salt; mp 170–172°C. *Anal.* calcd. for $C_{10}H_{10}NOS_2Cl$: C 45.11, H 6.02, N 5.26; found: C 45.08, H 6.12, N 5.35. Spectral data are given in Table 2.

The alcohols which contain the free thiol functionality (Table 3) were prepared as follows.

Preparation of Alcohol 10

A solution of 0.09 mol of 2-pyridyl lithium was prepared as above (150 mL ether) and kept at −65°C. Ketone **5***j* (7.14 g, 0.03 mol) in 50 mL of ether was added over 30 min and the mixture stirred at −65°C. It was then warmed to −40°C and 50 mL saturated NH_4Cl added. After the solution had been brought to >0°C, 200 mL H_2O was added, the ether layer was separated, and the aqueous layer extracted with ether (2 × 100 mL). The combined ether extracts were dried (Na_2SO_4) and the volatiles removed *in vacuo*. The residue was then dissolved in ether (200 mL) and extracted with 6 × 50 mL of 3 *M* aq. HCl. Neutralization of the acid extracts with solid K_2CO_3 followed by $CHCl_3$ extraction (4 × 100 mL), drying and evaporation gave the addition product in reasonably pure form; nmr ($CDCl_3$) δ: 1.2 (t); 3.3 (ABq); 3.5 (q); 4.6 (s); 5.0 (s, Br); 7.0–7.7 (m); 8.4–8.6 (m).

This residue was then dissolved in 20 mL of 4:1 (v/v) CH_3CN/H_2O, and a solution of 16.3 g (0.06 mol) $HgCl_2$ in 130 mL of 20% aq. CH_3CN added which caused the rapid formation of a precipitate accompanied by H^+ release (solution became acidic). After 4 h stirring, the mixture was filtered and the precipitate washed with 200 mL H_2O. The solid was then slurried with 200 mL H_2O with rapid stirring and H_2S passed

[2]1,3-Dichloroacetone is a powerful lachrymator and vesicant and should be handled with due caution.

For personal use only.

through for 6 h after which the resultant black mixture was treated with solid K_2CO_3 to raise the pH to 8, and then continuously extracted with ether under a nitrogen atmosphere. The ether extract was dried, filtered, and dry HCl passed through. The resultant oil crystallized on standing, and the solid material vacuum dried to give 1.75 g (25%) of **10** as pale yellow crystals: mp 158–160°C. *Anal.* calcd. for $C_8H_{12}NOS_2Cl$: C 40.41, H 5.09, N 5.89, Cl 14.91; found: C 40.54, H 5.14, N 6.07, Cl 14.87.

Alcohol 13 was obtained similarly but using ketone **5***k* as a starting material; mp 162–164°C (HCl) (Table 3). *Anal.* calcd. for $C_9H_{14}NOS_2Cl$: C 42.93, H 5.60, N 5.60, S 25.47; found: C 42.96, H 5.64, N 5.51, S 25.34.

Alcohol 11

This was obtained by the addition of 2-lithio-*N*-methylimidazole (prepared analogously to 2-lithio pyridine but by H^+ abstraction from *N*-methylimidazole) to ketone **5***j*. Workup as for alcohol **10** with the exception of the final HCl salt formation with dry HCl gave **11**, mp 119–121°C. *Anal.* calcd. for $C_7H_{12}N_2OS_2$: C 41.15, H 5.92, N 13.71, S 31.39; found: C 41.28, H 5.90, N 13.70, S 31.55.

Alcohol 12

This was prepared by the addition of 2-lithio-1-(bisethoxy methyl)imidazole (31) to ketone **5***j*. Deprotection of the imidazole nitrogen was followed by a similar extraction and isolation procedure as for **11**, mp 106–107°C (Table 3). *Anal.* calcd. for $C_6H_{10}N_2S_2O$: C 37.87, H 5.30, N 14.72, O 8.41, S 33.70; found: C 38.21, H 5.24, N 14.51, O 8.64, S 34.03.

Alcohol 14

This was prepared by the addition of the ethylene ketal of 6-acetyl-2-lithiopyridine to ketone **5***j* analogously to the procedure for **10**. The reaction mixture after the addition of saturated aq. NH_4Cl was washed with 3 × 150 mL of 0.1 *M* HCl followed by 4 × 100 mL of 3 *M* HCl; the latter extracts contained the addition product. After standing for 24 h (to hydrolyse the ethylene ketal) the latter acid extract was neutralized with solid K_2CO_3 and extracted with $CHCl_3$ (3 × 100 mL). The cleavage of the ethoxymethylthio groups was effected as before, and the product was obtained as a colorless gel after column chromatography over SiO_2 ($CHCl_3$) of the material isolated from the continuous ether extract; mp (Table 3). *Anal.* calcd. for $C_{10}H_{13}NO_2S_2$: C 49.36, H 5.38, N 5.76, O 13.15; found: C 49.65, H 5.28, N 5.99, O 13.02.

Alcohol 15

This was prepared following the route described for **14** except that the 6-acetyl group on the pyridine (ethoxymethylthio) compound was reduced with 200 mol% $NaBH_4$ in absolute ethanol at room temperature. TLC analysis showed the reaction to be completed in less than 1 h. The product was prepared analogously to **14** except that it was isolated as its HCl salt without chromatography (Table 3). *Anal.* calcd. for $C_{10}H_{15}NO_2S_2 \cdot HCl$: C 42.62, H 5.72, N 4.97, O 11.35, S 22.75; found: C 42.65, H 5.60, N 4.78, O 11.63, S 22.70.

Photolysis of heptamethylbenzenonium cation in aqueous acids. Preparation of pentamethylcyclopentadiene

RONALD F. CHILDS, MAUNG ZEYA, AND ROBERT P. DAIN
Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received July 9, 1980

RONALD F. CHILDS, MAUNG ZEYA, and ROBERT P. DAIN. Can. J. Chem. **59**, 76 (1981).

Irradiation of heptamethylbenzenium ion in a variety of aqueous acids using light of wavelength greater than 350 nm leads to the formation of pentamethylcyclopentadiene and acetone. In 50% HBF_4 and 70% $HClO_4$ this photolysis is very clean and can be used as a convenient preparation of pentamethylcyclopentadiene. A mechanism is proposed for the reaction.

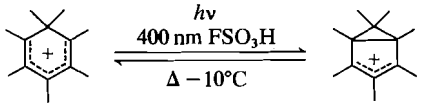
RONALD F. CHILDS, MAUNG ZEYA et ROBERT P. DAIN. Can. J. Chem. **59**, 76 (1981).

En irradiant l'ion heptaméthylbenzénium dans différentes solutions aqueuses d'acide, par une lumière dont la longueur d'onde est supérieure à 350 nm, on obtient le pentaméthylcyclopentadiène et l'acétone. Dans le HBF_4 à 50% et dans le $HClO_4$ à 70%, cette photolyse se fait proprement et peut être utilisée comme méthode convenable de préparation du pentaméthylcyclopentadiène. On propose un mécanisme pour cette réaction.

[Traduit par le journal]

Benzenonium ions undergo an efficient and very clean photoisomerization to give bicyclo[3.1.0]-hexenyl cations (1–3). This seemingly very general photoisomerization could be a synthetically useful route to derivatives of bicyclo[3.1.0]hexene. However, the usefulness of this reaction is curtailed by two factors. The first of these is the facile thermal valence isomerization of the bicyclohexenyl cations to the starting benzenonium ions which necessitates the use of low temperatures for the photoreaction. Secondly, the recovery of the photoproducts from large volumes of such strong acids as FSO_3H and H_2SO_4 which are generally used for these reactions becomes problematical as the reactions are scaled up.

In an attempt to overcome these difficulties we have examined the photoreactions (1, 2) of heptamethylbenzenonium ion, **1** (4, 5), in a variety of weaker acids. The intent of this study was to try and find an acid medium in which **1** was stable but its photoproduct **2** would react with a nucleophile

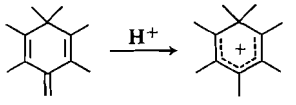


1 **2**

to give a kinetically stable material. This could allow the photoreaction to be carried out at room temperature and, if a weaker acid were used, facilitate product isolation Precedent for this type of approach comes from the early work of van Tamelen and co-workers on the tropylium, trityl, and cyclopropenium cations (6).

Results and Discussion

Cation **1** was obtained by protonation of **3** (4, 5). The triene **3** is a sufficiently basic hydrocarbon ($pK_a = 1.38$ (7)) to allow preparation of solutions of **1** in a variety of acids. Those used in this study included 96%, 24%, and 13% H_2SO_4, 5 *M* HCl, 70% $HClO_3$, 50% HBF_4, and CF_3COOH. ^1H nuclear magnetic resonance spectra of solutions of **3** in



3 **1**

these acids indicated complete protonation and the presence of **1**. Over the time span of the photochemical reactions these solutions of **1** were stable at room temperature. When left for extended periods of time, particularly with aqueous HCl, **1** slowly degraded to hexamethylbenzene (4).

Irradiations of **1** were carried out using light of wavelength greater than 350 nm to ensure that the cation was the only absorbing species. A series of qualitative irradiations were carried out in nmr tubes using the acids listed above. The extent of reaction was monitored by ^1H nmr spectroscopy. With the exception of 96% H_2SO_4, a photoreaction was observed in all the acid solutions as shown by the loss of the resonances attributable to **1**. In the case of 96% H_2SO_4 no reaction could be detected when the solution was irradiated for 20 times the length of time required for complete reaction in the other acids.

With 24 and 13% H_2SO_4 and 5 *M* HCl as solvents a precipitate was formed during the course of the

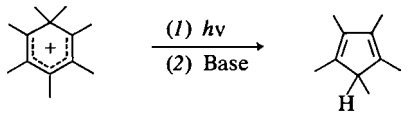
irradiation. The ^{1}H nmr spectrum of the solution obtained after all **1** had been photoreacted showed a sharp singlet at δ 2.2 and a broad signal at δ 1.4. Neutralization of the acid led to a high recovery of organic material (>90%) containing varying quantities of a volatile compound and an intractable "polymer". The volatile component was identified as pentamethylcyclopentadiene, **4**, by comparison

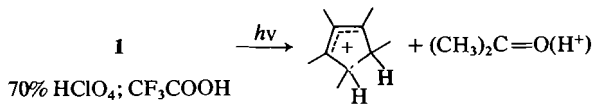


1 **4**

5 *M* HCl, 24 and 13% H_2SO_4

of its properties with an authentic sample (8). The yield of **4** was much higher in the H_2SO_4 solutions (78% in 24% H_2SO_4) than with the HCl solutions, Table 1.

When $HClO_4$ and CF_3COOH were used as solvents no precipitate was formed on irradiation of **1**. Instead the ^{1}H nmr spectrum indicated the presence of the *cis* and *trans* isomers of protonated pentamethylcyclopentadiene, **5** (9), together with a sharp singlet whose position varied according to the acid used (δ 2.67, $HClO_4$; δ 2.20, CF_3COOH). Addition of a small amount of acetone to each of these solutions caused these signals to be enhanced in intensity and it would appear that the other photoproduct of these reactions is acetone. The



5

cis/*trans* isomers

position of the signals due to the methyl-group resonances of acetone is very dependent on the acid medium used, reflecting different degrees of its protonation (10). Neutralization of these acid solutions led to the recovery of **4** in high yield.

Mechanistic Considerations

A likely sequence of events linking **1** with **4** and acetone is shown in Scheme 1. The photochemically induced isomerization of **1** to **3** is well established to occur in FSO_3H at low temperatures. The reverse thermal isomerization of **2** to **1** is symmetry forbidden and in practice involves a substantial activation energy, $\Delta G^{\ddagger} = 83$ kJ/mol in FSO_3H (1). Provided **2** remains ionic, this barrier appears to be essentially independent of medium and counter-ion changes. In the more nucleophilic, weak acids used in this study, **2** would be expected to either lose a proton or react with a nucleophile to form **6** (11), **7**, **8**, or **9** (12). Ring protonation of **9** would lead to **10** which could fragment to give **4** and protonated acetone. Comparable cleavage reactions have been reported on protonation of 5-acylpentamethylcyclopentadiene and other cyclopentenone derivatives (13).

Support for this scheme comes from the treatment of **8**, prepared by reaction of CH_3Li with 1,3,4,5,6,6 - hexamethylbicyclo[3.1.0]hex - 3 - en - 2-one (5), with 24% H_2SO_4. The ^{1}H nmr spectrum of the solution so obtained was the same as that produced photochemically from **1** in the same medium and neutralization of the acid led to the recovery of **4**.

Synthetic Considerations

Pentamethylcyclopentadiene has been widely used as a ligand in organometallic chemistry. There

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12

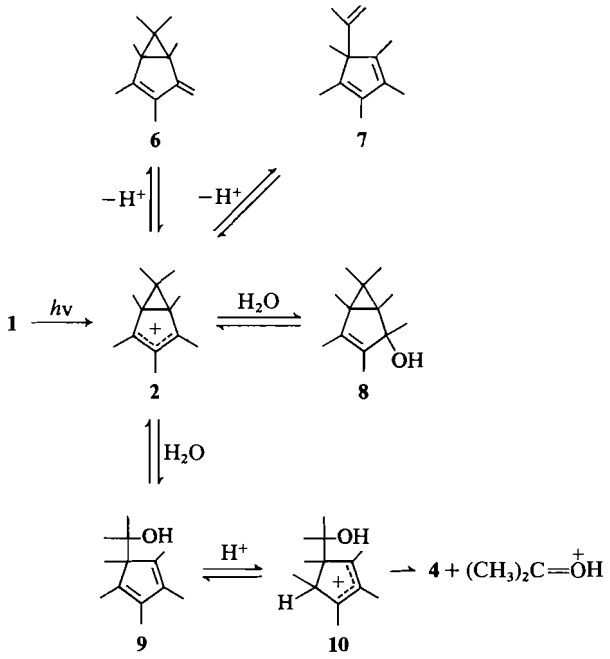

SCHEME 1

are several syntheses reported for this compound. These seem to fall into two main groups, those based on an elaboration of the five-membered ring from acyclic precursors and others based on hexamethyldewarbenzene (8, 14). The results described above suggested an alternative route starting from hexamethylbenzene.

Using a Friedel–Crafts reaction of hexamethylbenzene with $AlCl_3$ and methyl chloride it is possible to obtain the tetrachloroaluminate salt of **1** or the triene **3** in very high yields (4). Irradiation of a solution of **1** (1.5 g) in aqueous HBF_4 using a medium pressure mercury lamp and Pyrex filter led to the production of pentamethylcyclopentadiene in an 80% isolated yield. There seems to be no reason why the reaction could not be scaled up beyond this level and this two-step reaction sequence represents one of the easiest routes to **4**.

Experimental

The nmr spectra were recorded using a Varian EM-390 spectrometer. The chemical shifts of the samples in the aqueous acids were referenced to internal tetramethylammonium tetrafluoroborate taken as δ 3.10. Gas chromatographic analyses were performed using a Varian 3700 gas chromatograph coupled with a Varian CDS 111 integrator, and using a 5 ft × 1/8 in. column packed with 15% Carbowax on Chromasorb W.

Preparation of Acid Solutions of 1

The triene **3** (0.5 g) was dissolved in the appropriate acid by stirring at 0°C. With the aqueous H_2SO_4 solutions it was found to be more convenient to use a smaller amount of a stronger acid in the dissolution step and then add water to the resulting solution to give the appropriate concentration.

Photolyses were carried out using a Phillips SP 500 W super pressure mercury arc lamp. The light beam was arranged to pass through a water filter to remove infrared light and then through a Corning filter No. 3060 with a cutoff at 350 nm. Samples to be irradiated were placed in 10 mm Pyrex tubes and the reactions monitored by ^1H nmr to see when all **1** had been consumed. A typical reaction on the scale indicated above took some 3 h. Results obtained in a variety of acids are summarized in Table 1.

Recovery of photoproducts from the acid solutions was achieved by the slow addition of the acid to a stirred slurry of Na_2CO_3 (10 g) in ether (25 mL) at −78°C. The mixture was allowed to warm to room temperature and the ether layer separated, washed with water (1 × 20 mL), and dried. Removal of the ether *in vacuo* gave an oily residue which was weighed, vacuum transferred (160°C/15 Torr) nm, and analysed by glpc. Results are summarized in Table 1.

Preparative Scale Photolysis

The triene **3** (1.48 g) was added in small quantities to fluoroboric acid (120 mL, 50%) kept at 0°C. The resulting red solution was irradiated with a 125 W Hanovia medium pressure mercury lamp for 24 h at room temperature. (The photoreaction was monitored by ^1H nmr.) An oily liquid separated during the photolysis and this was subsequently extracted with ether (3 × 50 mL). The ether was washed with aqueous $NaHCO_3$ until neutral, with water (1 × 50 mL), and dried over $MgSO_4$. Removal of the ether *in vacuo* gave an oil (1.03 g) which consisted of **4** (90%), hexamethylbenzene (7%), and some minor unidentified components.

3-Methylene1,2,4,5,6,6-hexamethylcyclohex-1,4-diene 3 (4, 5)

Hexamethylbenzene (1.62 g) and $AlCl_3$ (2.0 g) were mixed and placed in a Parr pressure reactor. The reactor was cooled and CH_3Cl (25 g) was added and the mixture allowed to stand at room temperature for 16 h. The excess CH_3Cl was vented off, the remaining solid added to ice/water (80 mL)/ether (20 mL) mixture and the solution basified with NaOH. The ether layer was separated, the aqueous phase reextracted with ether (1 × 20 mL), and the combined ether extracts dried ($MgSO_4$). Removal of the ether *in vacuo* gave **3** (1.70 g, 96.5% yield) contaminated with less than 0.5% hexamethylbenzene.

1,2,3,4,5,6,6-Heptamethylbicyclo[3.1.0]hex-3-en-2-ol, 8

1,3,4,5,6,6-Hexamethylbicyclo[3.1.0]hex-3-en-2-one (0.77 g) in anhydrous ether (20 mL) was treated with methyllithium (6.7×10^{-3} mol in ether) at 25°C for 6 h. Saturated ammonium chloride solution (25 mL) was added and the ether layer separated, washed with water, and dried ($MgSO_4$). Removal of the ether gave **8** as an oil (0.81 g), bp 150°C at 0.5 Torr; ir (film): 3460, 2940, 2880, 1645 cm^{-1}; ^1H nmr δ: 1.85 (s, 1H), 1.55 (s, 6H), 1.20, 1.12, 1.05, and 1.02 (all s, 3H). *Anal.* calcd. for $C_{13}H_{22}O$: C 80.34, H 11.42; found: C 80.50, H 11.22%.

Rearrangement of 8 in 24% H_2SO_4

The alcohol **8** (1 g) was dissolved in 48% H_2SO_4 (20 mL) by stirring at 0°C. Water (20 mL) was added slowly with cooling and the resulting solution allowed to warm to room temperature for 0.5 h. The solution was cooled to 0°C and neutralized by the addition of Na_2CO_3. The organic material was extracted into ether (2 × 20 mL), the ether extract dried ($MgSO_4$), and the ether removed to give an oil (0.69 g). The oil was distilled at 160°C/15 Torr to give 0.65 g of a material which by its ^1H nmr spectrum consisted mainly of **4**. The glpc analysis showed 4 (91%) and hexamethylbenzene (9%) to be the only volatile constituents.

Received July 30, 1980

JOHN L. HOLMES, MERVIN FINGAS, and F. P. LOSSING. Can. J. Chem. **59**, 80 (1981).

It is shown that gas-phase heats of formation of homologous odd-electron organic cations can be well represented by an equation of the form $\Delta H_f[\text{ion}]^{+\cdot} = A - Bn + C/n$, where A, B, and C are constants and n is the total number of atoms in the molecule. Values for A, B, and C have been determined for the linear homologous series: alkanes, olefins, alkynes, alkanols, aliphatic ethers, aliphatic aldehydes, aliphatic ketones, alkanoic acids, alkyl chlorides, bromides, and iodides. For each of these series, correction terms for chain branching, double-bond position, and asymmetry effects are also given. These equations can be applied to molecules containing 40 or more atoms. The data base for this work is also presented.

JOHN L. HOLMES, MERVIN FINGAS et F. P. LOSSING. Can. J. Chem. **59**, 80 (1981).

On montre que les chaleurs de formation en phase gazeuse des électrons célibataires des cations organiques homologues, peuvent être représentées par une équation de la forme $\Delta H_f[\text{ion}]^{+\cdot} = A - Bn + C/n$ où A, B et C sont des constantes et n est le nombre total d'atomes de la molécule. On a déterminé les valeurs de A, B et C pour les séries homologues suivantes: alcanes, oléfines, alcynes, alcanols, éthers aliphatiques, aldéhydes aliphatiques, cétones aliphatiques, acides alcanoiques, chlorures, bromures et iodures d'alkyle. Pour chacune de ces séries, on rapporte les termes de correction pour les chaînes latérales, la position de doubles liaisons et les effets d'asymétrie. Ces équations peuvent être appliquées aux molécules contenant 40 atomes ou plus. On présente également les données de base de ce travail.

Introduction

Sufficient data for the heats of formation of neutral organic molecules have been accumulated to make possible the development of a general additivity scheme for calculating ΔH_f^{298} for a very wide range of simple organic compounds (1).

For ionised organic molecules no such scheme has so far been established even though there are now probably more accurate data for molecular ionisation energies than for heats of combustion. The latest collection of data for organic cations (2) contains some 1500 values but the literature covered extends only to the end of 1971. The compilation includes many observations of ionization energies (IE) and appearance energies (AE) from which no heat of formation was derived owing to the possible unreliability of the observations. For example, IE and AE values obtained by electron impact using a conventional mass spectrometer are generally unreliable; ambiguities can also arise in AE measurements where the structure of the neutral product of the fragmentation is uncertain. Such matters are discussed by Rosenstock in the introduction to the aforementioned data collection (2).

We have accumulated some 8000 IE and AE values from the post-1971 literature and from our own laboratories. These data have sufficed for the construction of the general correlation scheme described in this paper. The present equations have been determined empirically but their form corresponds to the fact that ΔH_f(molecular ion) = ΔH_f(neutral) + IE (i.e., the equations contain terms relating to these two components). In this paper we present results only for odd-electron (molecular) ions. Even-electron ions will be dealt with in a subsequent publication.

Equations such as those described here are not only useful for predicting new ΔH_f^{298} values but also for revealing misfits which could indicate incorrect values for ΔH_f(neutral) or IE, or, more interestingly, an ion structure having special stabilizing or destabilizing properties.

Method

Of several possible approaches we elected to devise relationships which would permit direct calculation of ionic heats of formation rather than ionisation energies. For homologous series of ions, the data clearly show that, unlike their neutral counterparts (1, 3), ionic heats of formation cannot be reproduced satisfactorily by any additivity sys-

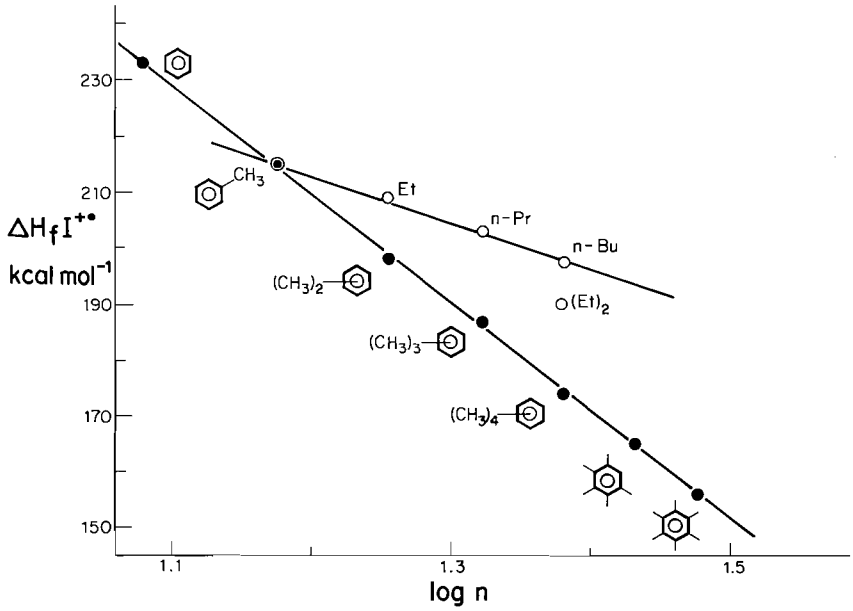

FIG. 1. Differentiation between a true homologous series and multiple substitution effects as discussed in the text. Data from refs. 2, 4, 5, and 6.

tem using constant atom and/or group equivalents. The reason for this is that whereas ΔH_f(neutral) for neighbouring homologues differ by a constant increment (1), the IE values decrease approximately exponentially with increasing homologue size. Thus ΔH_f(molecular ion) = ΔH_f(neutral) + IE cannot be incremental.

We will show here that ΔH_f for homologous series of odd electron organic cations can be calculated using as a basis empirical equations of the form $\Delta H_f[M]^{+\cdot} = A - Bn + C/n$ where A, B, and C are constants and n is the total number of atoms in the molecule. Such an equation, derived for a series of *unbranched homologous molecular ions*, will be referred to hereafter as the *generic* equation for that series. Once the generic equation for an homologous series had been derived, structural parameters for isomeric members of the series were established, for example, positional effects of chain branching, substituent size effects, double bond position, etc. The correction terms were found to be additive and characteristic of the particular homologous series but different from corresponding terms for their neutral counterparts.

These equations are valid up to ca. twenty C atoms and reproduce very satisfactorily the available experimental values to within 2 kcal mol^{-1}. Heats of formation of homologous series for which insufficient data are available to permit useful evaluation of A, B, and C, can be represented by a simple linear equation of the form $\Delta H_f[M]^{+\cdot} = \alpha - \beta \log n$, where α and β are constants and n again is the total number of atoms in the molecule; such equations hold only up to 8 to 10 carbon atoms. Indeed all series investigated can be fitted by the simpler equation over the above range but extension above ca. C_8 requires the three-term generic equation. As will be shown below, the simpler equation permits useful graphical representation of the data.

It is essential to note that for all homologous series with π-bonds, the smallest molecule to which the generic equation may be applied is not the member with *smallest n* but the first member containing a *methyl group* (e.g., $CH_3CH{=}CH_2$ not $CH_2{=}CH_2$). This characteristic of an homologous series is illustrated in Fig. 1, in which ΔH_f data for two series of aromatic ions are presented in simple graphical form as a function of log n. Both series fit simple linear equations $\Delta H_f[M]^+ = \alpha - \beta \log n$. The alkyl benzenes constitute a *true* homologous series, starting at toluene, whereas the series of multi-methyl substituted benzenes having benzene as its first member, illustrates the cumulative effect of multiple substitution by a functional group (in this case $CH_3^{\bullet}$) at a single atom or group of atoms. Note that this series is represented in the graph by the most stable positional isomers. The experimental value of ΔH_f for [diethylbenzene]$^{+\cdot}$ is also shown in Fig. 1; this point is co-linear with [benzene]$^{+\cdot}$ and [ethylbenzene]$^{+\cdot}$.

Our methods are readily applicable to other such

TABLE 1. Generic equations $\Delta H_f = A - Bn + C/n$ (kcal mol^{-1}) and correction terms

Series	A	B	C	Correction terms: Description	Correction terms: Magnitude
Alkanes	224	2.2	298	For each branch	−3
1-Olefins	231.6	1.61	110	For branch on carbon-2	−13
				For each remote branch	−2.5
x-Olefins (*trans*)	219.6 − x	1.61	110	(For $x \geq 2$)	
				For each branch on doubly-bonded carbon	−13
				For each branch elsewhere	−2.5
				cis corrections (same as for neutral compounds (1)):	
				For one *cis* correction	+1
				For two *cis* corrections around one double bond	+3
				When one group is *t*-butyl	+4
				When both groups are *t*-butyl	∼+10
1-Alkynes	278	1.57	110	For each branch (provisional)	−4
2-Alkynes	260	1.57	110	For each branch (provisional)	−4
3-Alkynes	257	1.57	110	For each branch (provisional)	−4
4-Alkynes	257	1.57	110	For each branch (provisional)	−4
5-Alkynes	256	1.57	110	For each branch (provisional)	−4
Alkanols	175	1.59	216	For each branch adjacent to —OH	−6
				For each branch elsewhere	−2
Aliphatic ethers	157	1.41	368	For each branch adjacent to —O—	−4.5
				For each branch elsewhere	−3
				Asymmetry correction, per carbon[a]	+1
Aliphatic aldehydes	188	1.65	135	For each branch adjacent to C=O	−5
				For each branch elsewhere	−3
Aliphatic ketones	166	1.78	252	For each branch adjacent to C=O	−3.5
				For each branch elsewhere	−1.5
				Asymmetry correction, per carbon[a]	+1.5
Alkanoic acids	142	1.90	112	For each branch adjacent to C=O	−3.5
				For each branch elsewhere	−1.5
Chloroalkanes	236	1.98	57	For each branch adjacent to halogen	−5
Bromoalkanes	219	1.40	115		
Iodoalkanes	222	1.69	44	For each branch elsewhere	−3

[a] The asymmetry correction, applicable to ethers and ketones having different numbers of C-atoms on either side of the functional group, refers to the smallest number of C-atoms which must be transferred to give the most symmetrical species, e.g. for methyl pentyl ketone the asymmetry correction is +3 kcal mol^{-1}.

substitutional series; these effects will be described in a forthcoming publication.

The Generic Equations

The function of the generic equations is to achieve a correct balance between the heats of formation of the neutral homologues, which become incrementally more negative with increasing molecular size, and the ionization energy, which falls approximately linearly with $1/n$. The three constants A, B, and C for a number of unbranched homologous series of odd-electron ions are given in Table 1. These have been fitted to the corresponding experimental ΔH_f(ion) values given in Tables 2 to 10, which we have selected as the most reliable and self-consistent. For many homologues, experimental heats of formation of the neutral species are not available; a few show irregular incremental changes along the series. Where such is the case, we have used heats of formation calculated by additivity. We have used spectroscopic or photon impact experimental values for the adiabatic ionization energies where these are available, supplemented where necessary by measurements made in this laboratory using mono-energetic electrons.

Structural Parameter Correction Terms

Having established the generic equation for an

unbranched series of homologues, it is then necessary to apply correction terms for structural effects. These are described below.

(*1*) Chain branching on or adjacent to a functional group generally has a larger stabilizing effect than a remote branch.

(*2*) For olefins, the effect of substitution (branching) on a doubly bonded C-atom has a much larger stabilizing influence and this special type of branching on a functional group can be treated by a constant correction term. For these homologues adjacent and remote branching have equal effects.

(*3*) For non-terminal olefins the equations are for the *trans*-isomers. The corrections for *cis*-isomers given in Table 1 are the same as those for the neutral molecules (1).

(*4*) For alkynes, generic equations are given for different triple bond positions; branching effects appear to be non-specific.

(*5*) In addition to the branching coefficients, asymmetry corrections are required for ethers and ketones; these are described in Table 1.

(*6*) Ring strain effects are discussed in detail below but it is important to note that the magnitude of such effects in ions appears to be closely similar to that for the neutral species.

Calculations

Calculation of an ionic heat of formation involves the following steps, using the data in Table 1:

(*1*) the appropriate *generic equation* is solved, using the total number of atoms n.

(*2*) the structural parameter corrections applicable to the ion are then added to or subtracted from the number derived in (*1*).

Ionic heats of formation calculated by our method are presented in Tables 2–10, together with the data base for this work. The agreement between the experimental and calculated ΔH_f(ion) values is excellent, generally within 2 kcal mol^{-1}.

It must be emphasized that the values of the coefficients in the generic equations are those which yield results closest to presently available experimental values of acceptable accuracy. When

[d]The IE values in parentheses in the earlier part of this table are from the work of Carlier et al. (32). Note that these ions are "hot" with respect to their fragmentation to yield the very abundant m/z 67, $[C_5H_7]^+$ ion and the given IE values correspond closely to those observed by ourselves (13) for the AE of m/z 67 in these compounds. The photoelectron values (d) did not include mass analysis and so could be subject to error. For this reason we have selected the results for ref. 13 for these ΔH_f values.

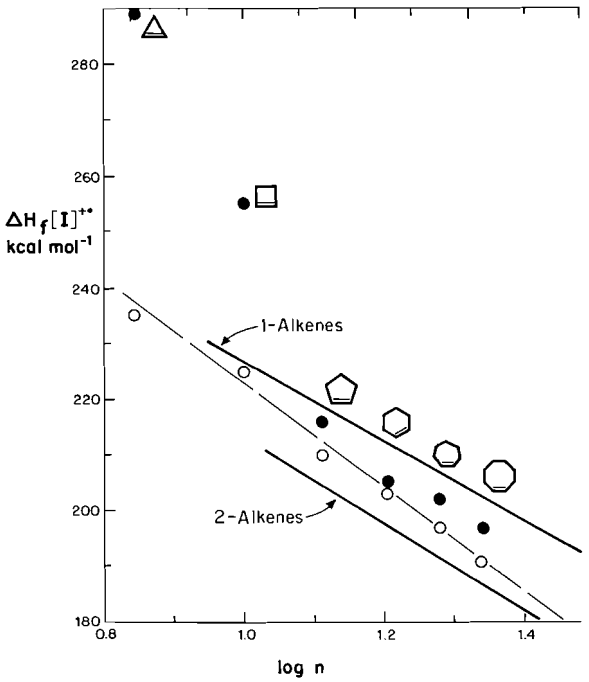

FIG. 3. Heats of formation of alkenes plotted against log n. Closed circles are experimental values for cyclo-alkenes (2), the designated lines for 1-alkenes and 2-alkenes are from data in Table 2. Open circles are the apparent ΔH_f values for the cyclic compounds obtained by subtraction from the closed circle values of the ring strain energy (1) for the neutral species.

experimental ionisation energy plus ΔH_f(neutral) calculated by additivity (1) but *omitting* the ring strain energy correction. All the points lie close to a common line. Thus for these ions, in which the ionised group is not within the ring, size (n) can be regarded as the major criterion affecting their heats of formation and that the ring strain energy in the cyclic ions is similar to that for the neutral cyclic compounds.

Figure 3 shows similar plots for cyclic olefins. Here the ionised π-system is within the ring and the ΔH_f values, again obtained from an experimental IE and omitting the neutral ring strain energy correction, lie between those for the 1-alkenes and 2-alkenes. Again it may be concluded that the ring strain energy in the ions is also similar to that obtained in the neutral cycloalkenes.

Synthesis and structure of *N,N'*-ethylenebis(salicylideneiminato)chlorogallium(III) and its methyl analog

KENNETH S. CHONG, STEVEN J. RETTIG, ALAN STORR, AND JAMES TROTTER

Department of Chemistry, University of British Columbia, Vancouver, B.C., Canada V6T 1Y6

Received June 20, 1980

KENNETH S. CHONG, STEVEN J. RETTIG, ALAN STORR, and JAMES TROTTER. Can. J. Chem. **59**, 94 (1981).

The synthesis and physical properties of *N,N'*-ethylenebis(salicylideneiminato)chlorogallium(III) and *N,N'*-ethylenebis-(salicylideneiminato)methylgallium(III) are described. Crystals of *N,N'*-ethylenebis(salicylideneiminato)chlorogallium(III) dichloromethane are monoclinic, $a = 13.049(1)$, $b = 9.525(1)$, $c = 15.459(2)$ Å, $\beta = 92.452(5)°$, $Z = 4$, space group $P2_1/a$. The structure was solved by Patterson and Fourier syntheses and was refined by full-matrix least-squares procedures to $R = 0.042$ and $R_w = 0.051$ for 1815 reflections with $I \geq 3\sigma(I)$. The gallium atom is bonded to one chlorine atom and to the tetradentate *N,N'*-ethylenebis(salicylideneiminato) ligand to give a coordination geometry which is intermediate between square pyramidal and trigonal bipyramidal. Important bond lengths (corrected for libration) are: Ga—Cl, 2.228(2), Ga—O, 1.868(4) and 1.883(4), Ga—N, 2.019(6) and 2.035(5) Å. The crystal structure consists of discrete $(C_{16}H_{14}N_2O_2)GaCl$ and CH_2Cl_2 molecules linked by a C—H···O hydrogen bond (O···H = 2.31, O···C = 3.295(9) Å, C—H—O = 176°) to form complex-solvate units.

KENNETH S. CHONG, STEVEN J. RETTIG, ALAN STORR et JAMES TROTTER. Can. J. Chem. **59**, 94 (1981).

On décrit la synthèse et les propriétés physiques du *N,N'*-éthylène bis(salicylidèneiminato)chlorogallium(III) et du *N,N'*-éthylène bis(salicylidèneiminato)méthylgallium(III). Les cristaux de *N,N'*-éthylène bis(salicylidèneiminato)chlorogallium(III) dichlorométhane sont monocliniques et appartiennent au groupe d'espace $P2_1/a$ avec $a = 13,049(1)$, $b = 9,525(1)$, $c = 15,459(2)$ Å, $\beta = 92,452(5)°$, $Z = 4$. On a résolu la structure par les synthèses de Fourier et de Patterson et on l'a affinée par la méthode des moindres carrés (matrice entière) jusqu'à une valeur de R de 0,042 et de R_w de 0,051 pour 1815 réflexions avec $I > 3\sigma(I)$. L'atome de gallium est lié à un atome de chlore et au ligand tétradentate *N,N'*-éthylène bis(salicylidèneiminato) pour donner une géométrie de coordination qui est intermédiaire entre la pyramide carrée et la bipyramide trigonale. Les longueurs de liaisons importantes (corrigées pour la libration) sont: Ga—Cl, 2,228(2), Ga—O, 1,868(4) et 1,883(4), Ga—N, 2,019(6) et 2,035(5) Å. La structure du cristal consite en des molécules individuelles de $(C_{16}H_{14}N_2O_2)$ GaCl et de CH_2Cl_2 liées par une liaison hydrogène C—H···O (O···H = 2,31, O···C = 3,295(9) Å, C—H—O = 176°) conduisant à la formation d'unités de complexes solvatés.

[Traduit par le journal]

Introduction

In a previous paper (1) we described the reaction of trimethyl gallium with *N,N'*-ethylenebis-(salicylideneimine) in which either one dimethyl gallium moiety was bound to the ligand system in a postulated six-coordinate gallium complex, or two dimethyl gallium moieties were incorporated in the product if an excess of the gallium alkyl starting material was employed. The present study was undertaken to determine if five-coordinate gallium complexes could be produced using this type of ligand system and thereby extend our previous investigations in this area (2–6) to include square-pyramidal gallium complexes. Two complexes, **1**, have been characterized and the crystal structure of the compound **1***a* has been determined.

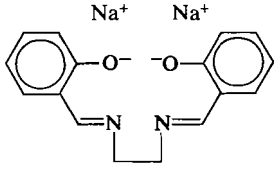
b X = Me



2

Experimental

Starting Materials

All solvents were dried and distilled before use and reactions were carried out in a glove box filled with dry nitrogen or in a nitrogen-blanketed apparatus. Methyl gallium dichloride was prepared by a standard procedure (7) from gallium trichloride (8) and tetramethylsilane. *N,N'*-Ethylenebis(salicylideneimine), prepared from ethylenediamine and salicylaldehyde by standard methods, was converted to its disodium salt, **2**, by reaction with sodium hydride in THF solvent. The disodium salt was isolated as a white solid.

N,N'-*Ethylenebis(salicylideneiminato)chlorogallium(III), 1*a

This compound was prepared by reacting the disodium salt, **2**, (2.713 g, 8.69 mmol) with gallium trichloride (1.530 g, 8.69 mmol) in THF at room temperature. The reaction mixture was stirred for several days to ensure complete reaction. It was then filtered and the crude product, obtained from the filtrate after removal of solvent under vacuum, was recrystallized from benzene (Soxhlet extraction) to give pale yellow crystals in ~ 50% yield. *Anal.* calcd. for **1***a*: C 51.6, H 3.8, N 7.5; found: C 51.1, H 3.9, N 7.7. The mass spectrum of **1***a* (recorded on a Varian MAT CH4B mass spectrometer at 70 eV with an ion source temerature of approximately 70°C) was dominated by two very strong signals due to the parent ion and to the parent ion minus the Cl group. ^1H nmr (d^6-acetone solution): $\tau_{-CH_2-CH_2-} = 6.10$ ppm singlet, $\tau_{HC=N} = 1.49$ ppm singlet, $\tau_{d^6\text{-acetone}} = 8.17$ ppm.

N,N'-*Ethylenebis(salicylideneiminato)methylgallium(III), 1*b

The methyl gallium derivative was prepared in a similar manner to that described above for the chloro compound. The di-

sodium salt, **2**, (1.110 g, 3.55 mmol) was reacted with methyl gallium dichloride (0.550 g, 3.55 mmol) in THF at room temperature for 12 h. The sodium chloride precipitated was then filtered off and the crude product isolated from the filtrate by removal of solvent under vacuum. This crude product was recrystallized from benzene/THF to yield a pale yellow solid in ~ 80% yield. *Anal.* calcd. for **1***b*: C 58.2, H 4.9, N 8.0; found: C 58.6, H 5.7, N 7.9. The mass spectrum of compound **1***b* shows a very weak parent ion signal and was dominated by the very strong signal due to the parent ion minus the Me group. In addition a weak signal due to the doubly charged parent minus Me group ion was also evident in this spectrum. ^{1}H nmr (d^6-acetone solution): τ_{GaMe} = 10.73 ppm singlet, $\tau_{\text{"}CH_2\text{—}CH_2\text{"}}$ = 6.25 ppm complex multiplet, $\tau_{HC=N}$ = 1.69 ppm singlet, $\tau_{d^6\text{-acetone}}$ = 8.17 ppm.

X-ray Crystallographic Analysis of N,N'-*Ethylenebis(salicylideneiminato)chlorogallium(III) Dichloromethane*

Crystals suitable for X-ray analysis were obtained by recrystallization from benzene/dichloromethane. The crystal chosen was mounted in a general orientation and had dimensions of ca. 0.50 × 0.42 × 0.10 mm. Unit-cell parameters were refined by least-squares on 2 sin θ/λ values for 25 reflections measured on a diffractometer with Mo K_α radiation (λ = 0.71073 Å). Crystal data (at 22°C) are:

$C_{17}H_{16}Cl_3GaN_2O_2$ fw = 456.1

Monoclinic, a = 13.049(1), b = 9.525(1), c = 15.459(2) Å, β = 92.452(5)°, V = 1919.6(4) Å^3, Z = 4, ρ_c = 1.285 g cm^{-3}, $F(000)$ = 920, μ(Mo K_α) = 19.38 cm^{-1}. Absent reflections: $h0l$, $h \neq 2n$ and $0k0$, $k \neq 2n$ define uniquely the space group $P2_1/a$ (non-standard setting of $P2_1/c$, C_{2h}^5, No. 14).

Intensities were measured with graphite monochromatized Mo K_α radiation on an Enraf-Nonius CAD4-F diffractometer. An ω–2θ scan at 1.18–10.06° min^{-1} over a range of (0.75 + 0.35 tan θ) degrees in ω (extended by 25% on both sides for background measurement) was employed. Data were measured to 2θ = 50°. The intensities of 3 check reflections, measured every 3600 s throughout the data collection, remained constant to within ±4%. After data reduction, an absorption correction was applied using the Gaussian integration method (9, 10). Transmission factors ranged from 0.439 to 0.836 for 208 sampling points. Of the 3379 independent reflections measured, 1815 (54%) had intensities greater than 3σ(I) above background where $\sigma^2(I) = S + 2B + (0.04(S - B))^2$ with S = scan count and B = background count.

The positions of the gallium and the chlorine bonded to it were determined from the Patterson function and those of the remaining non-hydrogen atoms from a subsequent Fourier synthesis. After full-matrix least-squares refinement of the non-hydrogen atoms with anisotropic thermal parameters to R = 0.053, a difference map gave positions for all hydrogen atoms except those associated with the solvate. The solvent hydrogen atom positions were calculated and kept fixed during subsequent cycles of refinement while the remaining hydrogen atoms were refined with isotropic thermal parameters. The scattering factors of ref. 11 were used for non-hydrogen atoms and those of ref. 12 for hydrogen atoms. Anomalous scattering factors from ref. 13 were used for the Ga and Cl atoms. The weighting scheme, $w = 1/\sigma^2(F)$ where $\sigma^2(F)$ is derived from the previously defined $\sigma^2(I)$ gave uniform average values of $w(|F_o| - |F_c|)^2$ over ranges of $|F_o|$ and was employed in the final stages of refinement. Convergence was reached at R = 0.042 and R_w = 0.051 for 1815 reflections with $I \geq 3\sigma(I)$. For all 3379 reflections R = 0.107 and R_w = 0.057. The function minimized was $\Sigma w(|F_o| - |F_c|)^2$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ and $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$.

On the final cycle of refinement the mean and maximum parameter shifts corresponded to 0.02 and 0.21σ respectively. The mean error in an observation of unit weight was 1.634. A final difference map showed maximum fluctuations of ±0.75 e Å^{-3} near the Ga and Cl atoms and ±0.20 e Å^{-3} elsewhere. The final positional and thermal parameters appear in Tables 1 and 2[1] respectively. Measured and calculated structure factors have been placed in the Depository of Unpublished Data.[1]

The ellipsoids of thermal motion for the non-hydrogen atoms are shown in Fig. 1. The thermal motion has been analysed in terms of the rigid-body modes of translation, libration, and screw motion (14) using the computer program MGTLS. The

[1]The structure factor table and Table 2 (thermal parameters) are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

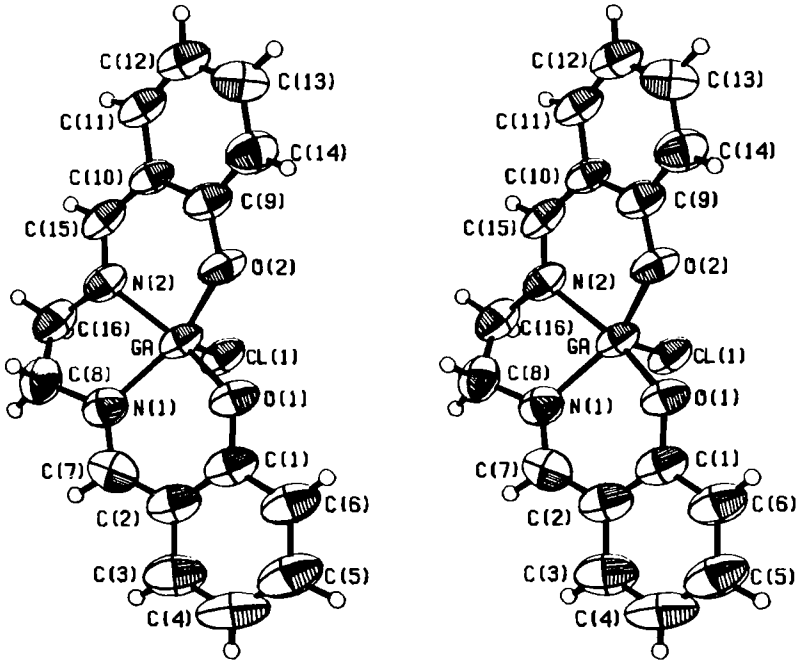

FIG. 1. Stereo view of the *N,N'*-ethylenebis(salicylideneiminato)chlorogallium(III) molecule, 50% thermal ellipsoids are shown for the non-hydrogen atoms.

rms standard error in the temperature factors σU_{ij} (derived from the least-squares analysis) is 0.0046 Å^2. Analysis of all non-hydrogen atoms except those of the solvent of crystallization gave rms $\Delta U_{ij} = 0.0070$ Å^2 and physically reasonable results. The appropriate bond distances have been corrected for libration (15), using shape parameters q^2 of 0.08 for all atoms involved. Corrected bond lengths are given along with the uncorrected values in Table 3 and the corrected bond angles do not differ from the uncorrected values listed in Table 4 by more than one standard deviation. Intra-annular torsion angles defining the conformations of the chelate rings are given in Table 5.

Results and Discussion

The two complexes reported here extend the series of five-coordinate gallium complexes structurally characterized to include an example of a severely distorted square-pyramidal geometry about the gallium atom. Thus the structure of the present chloro gallium complex, **1***a*, discussed below displays the gallium atom in a setting intermediate between square-pyramidal and trigonal bipyramidal in the mononuclear complex. Other five-coordinate gallium species which have been structurally characterized are better described as containing the gallium atom in a distorted trigonal bipyramidal environment and these compounds include a chain-like polymer (6), four binuclear gallium species (2, 3, 5), a cage structure involving eight gallium atoms two of which are five-coordinate (4), and a mononuclear species (16, 17).

The compounds **1***a* and **1***b* were easily prepared in good yield by reacting gallium trichloride or methyl gallium dichloride with a stoichiometric amount of the disodium salt of *N,N'*-ethylenebis-(salicylideneimine) in THF solvent. The compound **1***a* was obtained as an air-stable crystalline material suitable for X-ray investigations but numerous attempts to prepare similar quality crystals of the gallium methyl compound **1***b* were not successful. Interestingly the ^{1}H nmr in d^6-acetone solution of the chloro gallium compound, **1***a*, shows a singlet for the "CH_2—CH_2" protons whereas the compound **1***b* in d^6-acetone shows a very complex multiplet in the "CH_2—CH_2" region of the ^{1}H nmr spectrum. A rapidly fluxional process must occur for compound **1***a* in solution at room temperature since it is evident from the solid state structure that the four "CH_2—CH_2" protons are inequivalent. The compound **1***b*, on the other hand, must possess a more rigid structure in solution or undergo some interaction with the solvent which allows complex coupling to occur among the four "CH_2—CH_2" protons. Another notable difference between the two compounds **1***a* and **1***b* became evident from their mass spectra. The compound **1***a* displayed very strong signals for *both* the parent ion and the parent ion minus the Cl group. On the other hand the compound **1***b* displayed only a very weak signal due to the parent ion and its mass spectrum was dominated by the signal due to the parent ion minus

(salicylideneiminato)chlorogallium(III) dichloromethane consists of discrete $(C_{16}H_{14}N_2O_2)GaCl$ and CH_2Cl_2 molecules linked by a C—H···O hydrogen bond (O(2)···H(17b) = 2.31, O(2)···C(17) = 3.295(9) Å, C—H—O = 176°) to form complex-solvate units. All other intermolecular distances correspond to normal van der Waals contacts.

The gallium atom is coordinated to a chlorine and to the two nitrogen and two oxygen atoms of the tetradentate *N,N'*-ethylenebis(salicylideneiminato) ligand resulting in a coordination geometry which closely resembles the C_s "twisted wedge" described by King (18). This geometry is intermediate between square pyramidal in which the chlorine is apical and trigonal bipyramidal with N(2) and O(1) occupying the axial coordination sites (see Fig. 1). Neither the large differences between axial and equatorial bond lengths expected for trigonal bipyramidal coordination nor the equality of basal bond lengths expected for idealized square pyramidal geometry are observed. The Ga—O and Ga—N bond lengths are, however, consistent with the observed intermediate geometry. The "axial" distances are longer than their counterparts by 0.015 Å (2.7σ) for Ga—O and by 0.016 Å (2.1σ) for Ga—N.

The Ga—Cl(1) distance of 2.228(2) Å is slightly, but significantly, longer than the equatorial Ga—Cl distance (2.190(2) and 2.195(5) Å for two independent structure determinations) in the trigonal bipyramidal complex chlorobis(8-hydroxy-2-methylquinolinato)gallium(III) (16, 17). The mean[2] Ga—O and Ga—N bond lengths of 1.876(8) and 2.027(8) Å are similar to the corresponding values of 1.885(1) and 2.038(5) Å observed for the tetrahedrally coordinated gallium atoms in *N,N'*-ethylenebis(salicylideneiminato)bis(dimethylgallium) (1) and lie within the ranges observed for equatorially coordinated O and N in trigonal bipyramidal gallium complexes (1.845–1.967 and 1.949–2.035 Å respectively for Ga—O and Ga—N) (2–6, 16, 17).

The $(C_{16}H_{14}N_2O_2)GaCl$ molecule contains a system of five fused rings. Both of the terminal aromatic rings are slightly distorted from planarity (χ^2 = 9.0 and 8.9 respectively for the rings containing C(1) and C(9)), the maximum deviation of any atom from the mean planes being 0.017(8) Å. The intra-annular torsion angles for the chelate rings (Table 5) show that the two six-membered chelate rings are conformationally non-equivalent, that containing O(1) being significantly less planar than the other. The central five-membered chelate ring has an envelope conformation with C(16) displaced from the plane defined by the four other atoms. The internal geometry of the organic ligand is as expected (see Tables 3 and 4).

The overall geometry of the $(C_{16}H_{14}N_2O_2)GaCl$ molecule is very similar to that of the analogous Fe(III) complex $(C_{16}H_{14}N_2O_2)FeCl$ (19). The coordination about the metal atoms is nearly identical, corresponding valence angles being in excellent agreement. The M—Cl and M—O distances are equal within experimental error while the M—N distances are somewhat longer in the Fe complex (mean Fe—N = 2.082, mean Ga—N = 2.027 Å).

[2]Here and elsewhere in this report mean values refer to weighted means with rms deviations from the mean in parentheses.

Thermolysis of 5,5-dimethyl-4-aryl-Δ^1-1,2,4-triazolin-3-ones in solution. Products, kinetics, substituent effects, and solvent effects

LUBOMIRA M. CABELKOVA-TAGUCHI AND JOHN WARKENTIN
Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received June 23, 1980

LUBOMIRA M. CABELKOVA-TAGUCHI AND JOHN WARKENTIN. Can. J. Chem. **59**, 100 (1981).

A series of 5,5-dimethyl-4-aryl-Δ^1-1,2,4-triazolin-3-ones (Ar = C_6H_5, *p*-$C_6H_4CH_3$, *p*-$C_6H_4OCH_3$, *p*-C_6H_4Cl, and *p*-C_6H_4Br) were prepared from the corresponding 4-arylsemicarbazones of acetone by oxidative cyclization on alumina. The triazolinones decompose in solution to N_2, CO, and isopropylidene aryl amine, with first order kinetics, in the temperature range 148–200°C. Average activation parameters are $\Delta H^{\ddagger} = 35$ kcal mol^{-1} and $\Delta S^{\ddagger} = 8$ cal K^{-1} mol^{-1}. Substituent effects are correlated through σ-constants but the thermolyses are relatively insensitive to substituents, with $\rho = -0.17$ at 172.5°C. Solvent effects indicate a transition state that is less polar than the ground state.

It is tentatively concluded that the triazolinone fragmentation, like the analogous thermolysis of a Δ^3-1,3,4-oxadiazolin-2-one, may be a fully-concerted but nonsynchronous process with a transition state involving little, if any, charge separation. Other mechanisms, except for those involving highly polar (e.g. zwitterionic) transition states, have not been ruled out.

LUBOMIRA M. CABELKOVA-TAGUCHI et JOHN WARKENTIN. Can. J. Chem. **59**, 100 (1981).

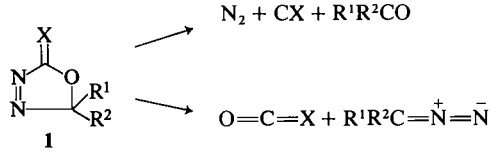
On a préparé une série de diméthyl-5,5 aryl-4 Δ^1-triazoline-1,2,4 ones-3 (Ar = C_6H_5, *p*-$C_6H_4CH_3$, *p*-$C_6H_4OCH_3$, *p*-C_6H_4Cl et *p*-C_6H_4Br) par une cyclisation oxydante sur l'alumine des aryl-4 semicarbazones de l'acétone appropriée. Dans l'intervalle de température de 148 à 200°C les triazolinones en solution se décomposent en N_2, CO et isopropylidène d'arylamine selon une cinétique d'un premier ordre. Les paramètres moyens d'activation sont: $\Delta H^{\ddagger} = 35$ kcal mol^{-1} et $\Delta S^{\ddagger} = 8$ cal K^{-1} mol^{-1}. On établi une corrélation entre les effets se substituants et les constantes σ, les substituants n'ont toutefois que peu d'effet sur les thermolyses puisque $\rho = 0{,}17$ à 172,5°C. Les effets de solvants indiquent un état de transition moins polaire que l'état fondamental.

On conclut d'une façon préliminaire que la fragmentation de la triazolinone, comme la thermolyse analogue de la Δ^3-oxadiazoline-1,3,4 one-2, peut être un processus pleinement concerté mais non synchrone avec un état de transition impliquant peu de séparation de charges. On n'a pas éliminé d'autres mécanismes, à l'exception de ceux mettant en jeu des états de transition fortement polaires (i.e. zwittérions).

[Traduit par le journal]

Introduction

The thermolysis chemistry of Δ^3-1,3,4-oxadiazoline systems (**1**) shows the interesting dichotomy represented by eq. [1]. Thus, compounds

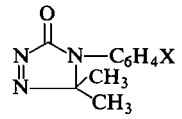


[1]

1

a $R^1 = R^2 =$ Ar; X = NAr
b $R^1 = R^2 =$ alkyl; X = NAr
c $R^1 = R^2 =$ alkyl; X = O
d $R^1 =$ alkyl, $R^2 =$ aryl; X = O
e $R^1 = R^2 =$ aryl; X = O
f $R^1 = R^2 =$ alkyl; X = N—N=$C(Ar)_2$
g $R^1 = R^2 =$ alkyl; X = N—N=CHAr

1*a* decompose to form aryl isocyanide and diaryl ketone as well as aryl isocyanate and diaryl diazomethane (1). Analogous fragmentations occur on thermolysis of **1***b* (2),[1] **1***c* (2–4), **1***d* (4), and **1***e* (3). The partitioning between the two thermolysis pathways is sensitive to the solvent polarity (3, 4), the substituents at C5 (1–4), and the exocyclic substituent (X) at C2 (2). In systems **1***f* and **1***g* the two piece fragmentation pathway can account for all of the observations and there may be little competition from the three-piece pathway (5).



2

a X = H
b X = *p*-CH_3
c X = *p*-OCH_3
d X = *p*-Cl
e X = *p*-Br

We have been interested also in the role that the ring oxygen plays in determining the fragmentation pathway of choice and we report here the thermolysis chemistry of 5,5-dimethyl-4-aryl-Δ^1-1,2,4-triazolin-3-ones, **2**, in solution.

Experimental

Syntheses

Triazolinones **2** were prepared by the method of Landquist (6) who cyclized 4-arylthiosemicarbazones and 4-arylsemicarbazones of ketones (**3**) on basic alumina, eq. [2]. Acetone-4-arylsemicarbazones, **3**, were prepared from acetone semicarbazone by transamidation with the appropriate *p*-substituted aniline, following the method of Borsche (7). In a typical preparation,

acetone semicarbazone (58 g, 0.5 mol) was heated at 145–165°C with aniline or p-substituted aniline (1.0 mol) in bis(2-methoxyethyl)ether (200 mL) to afford crude acetone-4-arylsemicarbazone in 25–35% yield. Purification by recrystallization (7) gave materials with the properties and spectral characteristics given in Table 1. A 5,5-dimethyl-4-aryl-Δ^1-1,2,4-triazolin-3-one, **2**, was prepared from the appropriate semicarbazone (**3**, ca.2 g) by stirring it at room temperature for 7 days with a slurry of alumina (Fisher Certified Reagent, Activity 1, 20–200 mesh, ca. 50 g) and dry chloroform (100 mL). Filtration, evaporation of the chloroform, and recrystallization of the crude solid residue from 95% ethanol yielded the triazolinone in 25–80% yield. Table 2 lists data for compounds **2**.

Solvents

Because of the high reactivities of isopropylidenearyl amines and of aryl isocyanates (the other potential products of thermolysis of **2**) carefully purified, dry solvents were used throughout.

Benzene and toluene (Mallinckrodt Analytical Reagent grade) were warmed with concentrated H_2SO_4. The hydrocarbon layers were separated, washed thoroughly with water, and dried over $CaCl_2$. The decanted liquids were then refluxed for 2 h in the presence of sodium wire before they were distilled. Fractions boiling at 80–81°C (benzene) and 110–111°C (toluene) were collected and stored over molecular sieves (5Å).

Chlorobenzene (Fisher Certified Reagent) was shaken repeatedly with portions of H_2SO_4 until the acid layer remained colourless. The chlorobenzene layer was washed with water and with potassium bicarbonate solution before it was dried over $CaCl_2$ and distilled. The fraction boiling at 130–131°C was redried over P_2O_5 and redistilled. Nitrobenzene (BDH, Analytical Reagent) was dried over P_2O_5 and distilled. It was stored over molecular sieves in a brown bottle.

Products of Thermolysis of 2a

A solution of **2*a*** (0.075 g, 4.0 × 10^{-4} mol) in 3 mL of dry benzene (see above) was degassed, sealed under vacuum, and heated at 175°C for 5 h. Quantitative analysis of the ^{1}H nmr spectrum (Varian HA-100 instrument) using a peak height calibration chart showed the presence of 0.052 g (98% yield) of acetone anil (isopropylidenephenyl amine). The ir spectrum contained a strong band at 1660 cm^{-1} ($\nu_{C=N}$) but none at 2270 cm^{-1} (ν_{ArNCO}). Gas chromatographic analysis (5 ft × $\frac{1}{4}$ in., 15% SE30 on 60–80 mesh Chromosorb P column) showed the presence of acetone, aniline, and acetone anil. Injection of freshly prepared acetone anil also led to acetone and aniline signals. These were therefore attributed to hydrolysis of the anil during handling or in the column.

The other triazolinones, **2*b*–*e***, gave analogous products as judged from the ^{1}H nmr and ir spectra of spent solutions. In no case were isocyanate bands near 2270 cm^{-1} evident in the ir spectra.

Kinetics

A stock solution of a triazolinone and internal standard toluene was loaded, in 0.3 mL portions, into Pyrex tubes which were sealed after at least three freeze–pump–thaw degassing cycles. Such tubes were mounted in a controlled temperature oil bath. Tubes withdrawn from time to time were cooled rapidly and stored cold. They were then warmed and opened, and the contents were transferred to an nmr tube for analysis. At least five scans of the reference signal and of the C-5 methyl signals from starting material were recorded. The average normalized peak height for starting material was converted to a concentration using a calibration chart and such concentrations were fitted to the first order rate law using a standard linear least-squares computer program. The program also gave the activation energies. Tables 3, 4, and 5 summarize the data for one of the compounds, **2*a***, while Table 6 summarizes the substituent effects. A typical Eyring plot is shown as Fig. 1 and the Hammett correlation is shown as Fig. 2.

Results and Discussion

Like oxadiazolinones (**1**) compounds **2** decompose in solution with first-order kinetics (Table 3). However, compounds **2** show no evidence for thermolysis by both of the competing pathways

characteristic of 1 (1–4). Only the three-piece fragmentation occurs, eq. [3]. The evidence against two-piece fragmentation rests on the absence of detectable concentrations of either aryl isocyanates or diazoalkanes from thermolysis of 2 in pure, dry solvents which do not react with either under the

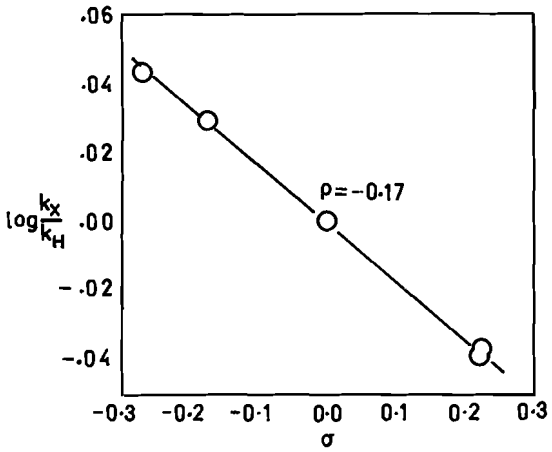

FIG. 2. Hammett correlation for thermolysis of **2** in nitrobenzene at 172.5°C.

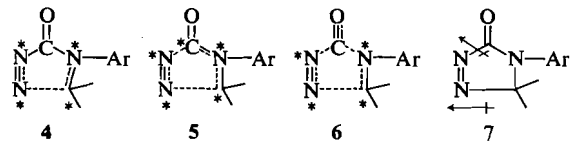
reaction conditions (Experimental). Moreover, neither acetone azine, the product of self destruction of 2-diazopropane (9), nor the known products[2] of reaction between arylisocyanates and 2-diazopropane were detected. It follows that the isopropylidene aryl amine, obtained in high yield, came from a unidirectional fragmentation. Specifically ruled out is a dual fragmentation pathway (eq. [3]) in which the two-piece component is reversible.

[3] 
The preference for three-piece fragmentation shown by **2** is not the consequence of a lowered free energy of activation, relative to that for three-piece fragmentation of **1***c*. For example, **1***c* ($R^1 = R^2 = CH_3$) fragments to N_2, CO, and acetone with $\Delta H^{\neq} = 30.3 \pm 0.3$ kcal mol^{-1} and $\Delta S^{\neq} = 7.4 \pm 0.9$ cal K^{-1} mol^{-1}, in toluene (4). Thus **2**, with $\Delta H^{\neq} \simeq 35$ kcal mol^{-1} and $\Delta S^{\neq} \simeq 8$ cal K^{-1} mol^{-1} (Tables 5, 6) are more stable, kinetically, and they are particularly stabilized against decomposition to aryl isocyanate and diazoalkane. Their isomers **1***b*, in sharp contrast, decompose by the dual pathways of eq. [1].[3] Such dependence of fragmentation modes on structure is not predictable on the basis of casual inspection. A rationale, based on the thermodynamics of the processes, will be offered in a forthcoming paper.

Many mechanisms need to be considered for a process involving the breaking of three bonds (4). For example, there are six ways of reaching the products by breaking the three bonds, one at a time, in successive, homolytic steps, and many more if heterolytic pathways, as well as combinations of homolytic and heterolytic steps, are considered. To these must be added a large number of two-bond and three-bond, concerted mechanisms with nonpolar or dipolar transition states.

Stepwise processes involving breaking of either bond to sp^2 carbon (C3), out of concert with another bond breaking process, seem unlikely because those bonds are expected to be shorter,[4] and stronger, than the bonds from sp^3 carbon to ring nitrogens. A consequence of this line of reasoning is that N1—C5 bond breaking should be part (or all) of what happens in the slow step, since N4—C5 bond breaking is ruled out on the basis of product identity. If the above postulate is accepted, only transition states with the gross features of **4**, **5**, and **6** need to be considered. Fine features include the



homolytic or heterolytic character of the bond ruptures and, for the latter character, the sense and the magnitude of the charge separation.[5] In the following paragraphs we examine the evidence in terms of those transition states. That evidence includes the solvent effects, the substituent effects, and the activation parameters.

The solvent effects on rate constants (Fig. 3) indicate that the transition state is less polar than the ground state as is the case for analogous fragmentation of **1***c* (4). An inverse relationship between rate and solvent polarity is a well-known feature of the thermolysis chemistry of *cis* azo compounds (11) and has been explained in terms of a large dipole moment for compounds having the *cis* azo function. We are therefore not restricted by the observed solvent effects to consideration of non-polar transition states. In fact, all types of

[2]Oxindoles, hydantoins, and oxazolidones. These compounds were prepared and studied concurrently in this laboratory by J. B. Fulton and their spectra and physical properties were known to us; J. B. Fulton and J. Warkentin, manuscript in preparation.

[3]Unpublished work of A. M. Cameron.

[4]An X-ray crystal structure (10) of **1***b* (Ar = *p*-C_6H_4Br) indicated that the oxadiazoline ring bonds to sp^2 carbon are shorter (N—C(sp^2) = 1.444 Å; O—C(sp^2) = 1.349 Å), than the ring bonds to sp^3 carbon (N—C(sp^3) = 1.472 Å; O—C(sp^3) = 1.458 Å).

[5]The sites at which radical or ionic character might develop are marked with an asterisk in **4**, **5**, and **6**.

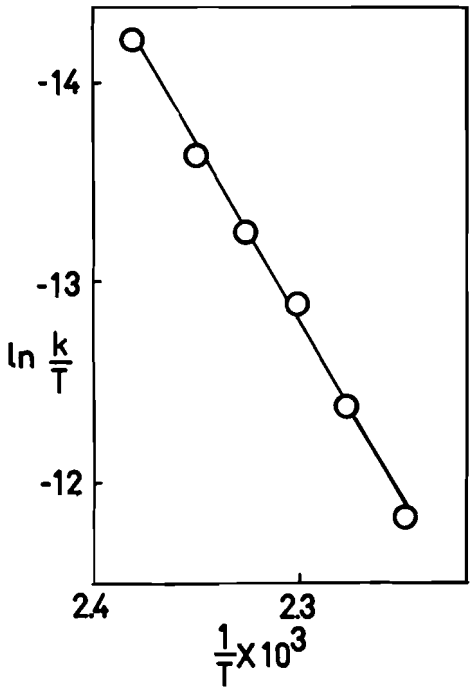

FIG. 3. Solvent effects on rate constants for thermolysis of **2***a*. The three solvents are, from left to right: benzene, chlorobenzene, and nitrobenzene and the average slope, including the other temperatures from Table 4, is -0.038 ± 0.012.

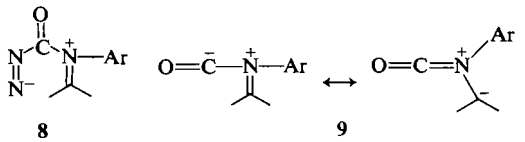
transition states (**4**, **5**, **6**) could be polar, but less polar than the ground state, because one or both of the major ground state dipole vectors (**7**) are partly lost. Thus, the solvent effect criterion is useful only for narrowing the choice of transition states, to exclude any with substantial charge separation, such as zwitterionic structures.

A Hammett rho (ρ) value of -0.17 at 172.5°C suggests that there is a small increase in electron demand at N4 in the transition state of the rate-determining step. This result was not expected, for N4 should already be depleted of electron density in the ground state by virtue of its attachment to the electron-withdrawing azocarbonyl group. Transition state **4** might accommodate both the small value and the solvent effects if it were essentially diradical-like with very limited charge separation, in the sense of **8**.

Transition state **5**, involving concerted breaking of two bonds, can not be excluded on the basis of the substituent and solvent effects. It could have some of the characteristics of a 1,3-dipole (**9**)[6] in which there is a formal positive charge on nitrogen. Thus, a negative ρ value of small magnitude could



8 **9**

be accommodated without requiring that transition state **5** should be more polar than the *cis* azo compound **2**. However, the absence of $M - 28$ peaks or M to $M - 28$ metastable peaks in the mass spectra of **2** suggests that **9** is not an intermediate in the mass spectral fragmentation of **2**. In view of that, **9** can be regarded as an unlikely intermediate from thermolysis of **2** in solvents of low polarity and the suitability of **5** to describe the transition state is put in doubt.

A fully concerted mechanism (transition state **6**) accommodates the solvent and substituent effects readily. In reaching transition state **6** the system has partly lost both of the major vectors (see **7**) contributing to the polarity of the ground state. If the fragmentation were nonsynchronous, with N1—C5 bond breaking running ahead of N2—C3 and N4—C3 bond-breaking motions,[7] then a small increase in electron demand at N4 would be expected. Insofar as N4 is concerned, the nonsynchronous but fully concerted fragmentation has the characteristics of **4**, which, it was pointed out earlier, also fits the polarity factors.

Interpretation of activation entropies requires caution and, preferably, support from other criteria of mechanism. The observed values of $\Delta S^{\ddagger}$ for **2** (8 cal K^{-1} mol^{-1}, Table 5) are compatible with either of the concerted processes, transition states **5** or **6**. Dissociative, concerted reactions do not show the large, positive values of $\Delta S^{\ddagger}$ that are expected on the basis of $\Delta S^{0}_{(reaction)}$. The reason for this is that the reaction fragments are still restricted at the transition state, with loosening of interfragment interactions partly compensated for by greater intrafragment rigidity as π-bonding in the fragments develops. For example the thermolyses of *cis*-3,5-diphenyl-1-pyrazoline (12) and those of *cis*- and *trans*-3,5-divinyl-1-pyrazoline (13) have $\Delta S^{\ddagger}$ values near zero.[8] Without conjugating substituents like phenyl or vinyl, whose rotations "freeze out" at the transition state, pyrazolines fragment with higher activation entropies. Nine methyl-substituted or unsubstituted pyrazolines (14) fragment with $\Delta S^{\ddagger}$ values between 2.9 and 11.2; the average being 8.7 cal K^{-1} mol^{-1} (14).[8] The

[6]The resonance depicted in **9** clearly requires a geometry that **5** can only approach if the transition state comes very late on the reaction coordinate.

[7]Nonsynchroneity, in the proposed sense, is in keeping with the qualitative order of bond strengths inferred from bond lengths of a model compound; footnote 4.

[8]For evidence that these are concerted reactions, see the appropriate references.

latter are fair models for **2** and two-bond, concerted fragmentation of **2**, via transition state **5**, would fit well with the observed $\Delta S^{\neq}$. However, the thermolysis of **1***c* to ketone, nitrogen, and carbon monoxide is probably a three-bond, concerted fragmentation (4). The value of $\Delta S^{\neq}$ (**1***c*, R = CH_3, 5.9 cal K^{-1} mol^{-1}, average for three solvents) is not significantly different from that observed for **2** and thus the $\Delta S^{\neq}$ criterion is also inconclusive.

Since a more exhaustive set of mechanistic criteria suggested that the three-piece fragmentation of compounds **1***c* involves concerted scission of three bonds (4), the weight of analogy is on the side of **6** as the most likely transition state for thermolysis of **2**.

Although concerted thermolyses of **1***c* and **2** into three products are thermally allowed, $\sigma 2s + \sigma 2s + \sigma 2s$, chelotropic processes, there is a subtle difference between the two systems. For the oxadiazolinone system, the geometric change required, other than bond breaking motions, is flattening at C5 (eq. [4]). The triazolinone system, however, can

[4] 
not reach the geometries of the products as economically. As eq. [5] shows, concerted fragmentation of **2** involving only flattening at C5 produces imine product with a 90° twist. The extra motion required to get to ground state product geometry in the latter case may be responsible, in part, for the higher activation enthalpy.

Biosynthesis of the quinolizidine alkaloids.[1] Incorporation of Δ^1-piperideine into matrine

FINIAN J. LEEPER,[2] GUNNAR GRUE-SØRENSEN, AND IAN D. SPENSER
Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received July 3, 1980

FINIAN J. LEEPER, GUNNAR GRUE-SØRENSEN, and IAN D. SPENSER. Can. J. Chem. **59**, 106 (1981).

Label from [6-^{14}C]-Δ^1-piperideine is incorporated nonrandomly into the carbon skeleton of the quinolizidine alkaloid, matrine, in *Sophora tetraptera* and *S. microphylla*. The distribution of radioactivity was determined by a new chemical degradation sequence. On the basis of the results, one of two previously postulated biogenetic schemes must be discarded. A modified biogenetic scheme is presented which is consistent with the present results and also leads to the correct stereochemistry of matrine.

FINIAN J. LEEPER, GUNNAR GRUE-SØRENSEN et IAN D. SPENSER. Can. J. Chem. **59**, 106 (1981).

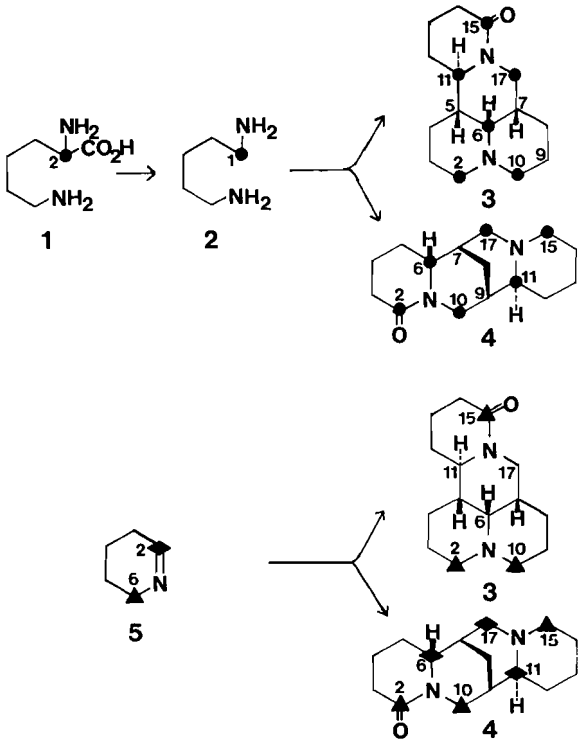
Dans la *Sophora tétraptera* et dans la *S. microphylla*, le ^{14}C en position 6 de la Δ^1-pipéridéine n'est pas incorporé au hasard dans le squelette carboné de la matrine, un alcaloïde du type quinolizidine. On a déterminé la distribution de la radioactivité à l'aide d'une nouvelle séquence pour la dégradation chimique. En se basant sur les résultats obtenus, on doit mettre de côté l'un des deux schémas biogénétiques proposé antérieurement. On présente un schéma biogénétique modifié qui est en accord avec nos résultats et qui conduit également à la stéréochimie appropriée de la matrine.

[Traduit par le journal]

Introduction

Matrine (**3**) is the major alkaloid of the genus *Sophora*. Its C_{15} skeleton, like that of its isomer, the lupine alkaloid lupanine (**4**)[3], is generated from three C_5 units which are derived from lysine (**1**) via cadaverine (**2**), a symmetrical (C_{2v}) molecule (Scheme 1). Thus, label from [2-^{14}C]lysine (2,3) and from [1-^{14}C]cadaverine (2–4) enters six carbon atoms of matrine, C-2, -6, -10, -11, -15, and -17. The evidence that activity is located at these six carbon atoms is conclusive for C-15 (2–4), adequate for C-2, C-10, (2, 3), and C-11 (2), circumstantial for C-17 (3), and inferred for C-6. It is assumed, but not rigorously demonstrated, that each of the labelled carbon atoms carries one sixth of the activity of intact matrine.

Δ^1-Piperideine (**5**) which has been shown to lie on the route from lysine and cadaverine into several lysine-derived alkaloids (anabasine (5), decodine (6), lycopodine (7), lupanine (1)) serves as a precursor of matrine (2). Label from [6-^{14}C]-Δ^1-piperideine was incorporated into C-15, and into C-2 and/or C-10. Significantly, the incorporation of label into C-15 (10% of the recovered specific activity) was much lower than the mean incorporation of label into C-2 and C-10 (45% of the recovered specific activity) (2). The reaction employed to gain access to C-2 and C-10 yielded degradation products which did not permit discrimination between these two carbon atoms. It is therefore unknown whether C-2 and C-10 were equally labelled (45% of recovered specific activity at each site) or not (e.g.



SCHEME 1. Incorporation of labelled precursors into matrine (**3**) and lupanine (**4**).

[1]This paper is dedicated to the memory of Léo Marion, on the anniversary of his death at the age of 80, on July 15th, 1979. It was in Léo Marion's laboratory, at the National Research Council of Canada Laboratories, Sussex Drive, Ottawa, that the very first tracer experiments, designed to test biogenetic hypotheses of the origin of natural products, were conducted during the period 1951–1954. One of us was privileged to participate in the design and execution of some of these pioneering studies.

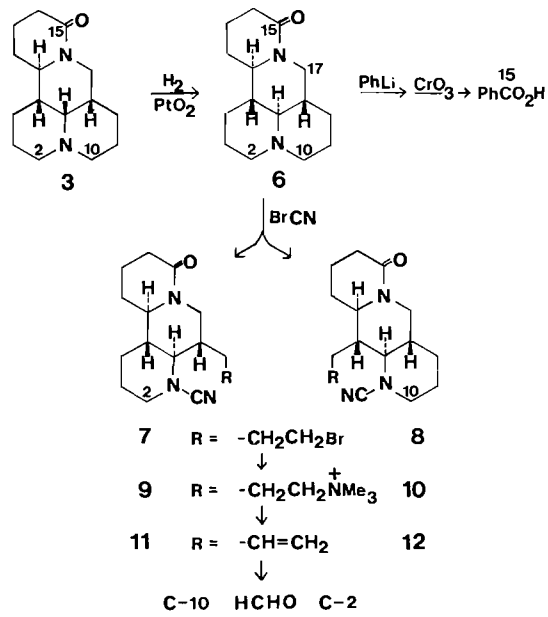
10% and 80% of recovered specific activity at one and at the other carbon atom, respectively, assuming equal yields of degradation product from each of the two sites).

We recently suggested that matrine should be regarded as a modified trimer of Δ^1-piperideine and advanced one of several possible biogenetic schemes based on this notion (1). As will be shown in the discussion that follows, and contrary to published statements (cf ref. 8), this idea is not inconsistent with the observed unequal incorporation of label from [6-^{14}C]-Δ^1-piperideine into different sites of matrine (2).

We have reinvestigated the incorporation of [6-^{14}C]-Δ^1-piperideine into matrine, in *Sophora tetraptera* and *S. microphylla*. Our results, based on a new degradation sequence which permits individual assay of the activity at each of the three crucial sites, C-2, -10, and -15, lead to a new biogenetic model of the origin of matrine, which is consistent with all experimental results and accounts for the stereochemistry of the alkaloid.



SCHEME 2. Degradation of matrine.

Methods and Results

[6-^{14}C]-Δ^1-Piperideine, prepared from [6-^{14}C]-lysine by oxidation with *N*-bromosuccinimide (7), was administered by the wick method, in separate experiments, to intact stocks of *Sophora tetraptera* (Experiment 1) and *S. microphylla* (Experiment 2). After three days in contact with the tracer, the plants were harvested and extracted. The alkaloid fraction of the extract yielded radioactive matrine (**3**). The matrine was diluted with inactive carrier and converted into allomatrine (**6**) (9) by heating with platinum oxide in an atmosphere of hydrogen. This isomerization under reducing conditions removed traces of a radioactive impurity, which was not removed by persistent chromatography and by repeated recrystallization of matrine. This impurity was probably a trimer of Δ^1-piperideine, e.g., α-tripiperideine, whose R_f value corresponds to that of matrine in a number of solvent systems, including those used in the purification of matrine. Hydrogenation of α-tripiperideine (10), under conditions used in the isomerization of matrine into allomatrine, yields piperidine which is volatile and would evaporate with solvent during work-up.

The three carbon atoms of matrine (**3**) (C-2, -10, -15) predicted to be the sites of label derived from [6-^{14}C]-Δ^1-piperideine, were obtained individually by degradation of allomatrine. The degradation sequence is shown in Scheme 2.

The carbonyl carbon (C-15) was extruded as benzoic acid, by reaction of allomatrine with phenyl lithium, followed by oxidation of the basic products of this reaction with Jones' reagent. A small amount of benzophenone, resulting from addition of two moles of phenyl lithium, was also isolated.

Carbon-2 and carbon-10 of matrine were obtained individually as formaldehyde (isolated as the dimedone derivative), as follows. Von Braun reaction of allomatrine (**6**) with cyanogen bromide (cf. ref. 11) yields two bromocyanamides, A (**7**) and B (**8**), which were separated and converted into the corresponding trimethylammonium salts (**9** and **10**) and then, by Hofmann elimination, into the alkenes (**11** and **12**). Oxidative cleavage with sodium metaperiodate in the presence of catalytic amounts of osmium tetroxide then yielded formaldehyde. The overall yield of formaldehyde dimethone was 58% and 43%, from bromocyanamide A and B, respectively.

The results of the degradation of the samples of matrine from the two experiments are shown in Table 1. In each case, the carbonyl carbon atom (C-15, benzoic acid) accounted for approximately one sixth of the total activity of matrine, whereas C-2 (formaldehyde dimethone) and C-10 (formaldehyde dimethone) each account for one quarter of the activity of the intact matrine. The three sites account for only two-thirds of the total activity of matrine.

TABLE 1. Incorporation of [6-^{14}C]-Δ^1-piperideine into matrine

[a]SA = Specific activity (dpm per mmol) × 10^{-4}.
[b]RSA = Relative specific activity (per cent) (allomatrine = 100).
[c]*This formaldehyde dimethone was obtained from a sample of bromocyanamide B which had been prepared from the original* bromocyanamide B, specific activity 1.26 (±0.01) × 10^4 dpm per mmol, by 2.64-fold dilution with inactive carrier. The result shown (0.33 (±0.02) × 10^4 dpm per mmol) is the corrected value.

Discussion

The Biosynthesis of Matrine

Radioactivity from [2-^{14}C]lysine (2, 3) and from [1-^{14}C]cadaverine (2–4) is incorporated nonrandomly into matrine (Scheme 1). Partial degradation of the radioactive matrine showed that in each case approximately one sixth of the radioactivity of the intact molecule was present at the carbonyl carbon (C-15) (2–4). Other degradation results were interpreted to indicate that each of five other carbon atoms, C-2, C-6, C-10, C-11, and C-17, also carried one sixth of the label. It was inferred that the carbon skeleton of matrine originates from three C_5 fragments which are derived from lysine via its decarboxylation product, cadaverine, and are incorporated in symmetrical fashion and with equal efficiency into each of the three C_5-segments of the alkaloid.

A number of biogenetic hypotheses have been advanced to rationalize this derivation of matrine. Each of these models finds a parallel in the schemes which have been proposed for the origin of lupanine from the same precursors.[3] The distribution of label from [^{14}C]lysine or [^{14}C]cadaverine, while serving to provide a general framework for the biogenetic models, has not yet provided a basis for discrimination between them.

The distribution of radioactivity from [2-^{14}C]- and [6-^{14}C]-Δ^1-piperideine within lupanine (**4**) is quite different from that of label from [2-^{14}C]- and [6-^{14}C]lysine, in that the individuality of C-2 and C-6 of Δ^1-piperideine is maintained on the route into the alkaloid and only three sites become labelled (1). Similarly, label from [6-^{14}C]-Δ^1-piperideine enters three sites of matrine (2). Thus, as in the case of the Lycopodium (7) and the Decodon (6) alkaloids, randomization of C-2 and C-6 of lysine occurs at some stage of the biosynthetic route between lysine (**1**) and Δ^1-piperideine (**5**), presumably during conversion of the decarboxylation product of lysine, i.e. cadaverine (**2**), into Δ^1-piperideine. Once the latter has been formed, equilibration of these carbon atoms does not occur. A study of the distribution of label within matrine derived from [6-^{14}C]-Δ^1-piperideine might serve to distinguish among the biogenetic models that have been proposed, particularly since activity from this source is not equally distributed among the three carbons of matrine which become labelled (2).

The biogenetic models that have been advanced to account for the origin of matrine differ from one another in the sequence in which the three C_5 units are assembled and in the intermediates that are invoked. In principle, each model envisages the formation of a C_{10} intermediate which, in a subsequent step, is converted into the C_{15} skeleton of the alkaloid by reaction with the third C_5 unit. Since label from [6-^{14}C]-Δ^1-piperideine enters one site only within each of the three C_5 units, C_5 compounds with C_{2v} symmetry (e.g., glutardialdehyde) cannot be relays between Δ^1-piperideine and the alkaloid. Several postulated biogenetic models (e.g. ref. 12) are thereby eliminated.

The C_{10} compounds ($C_{10}N$ or $C_{10}N_2$) that have been postulated as intermediates in the remaining models (1–3, 12–14) are derivable from tetrahydroanabasine (**13**), a dimer of Δ^1-piperideine. In aqueous solution at pH 6–8, Δ^1-piperideine dimerizes readily and within a few hours 80–90% of the compound has been converted into dimer (13). The labelling pattern of tetrahydroanabasine, derived from [6-^{14}C]-Δ^1-piperideine, is shown in Scheme 3. It is a necessary consequence of the dimerization process that the two labelled centres

[3]For a summary of the relevant literature see ref. 1.

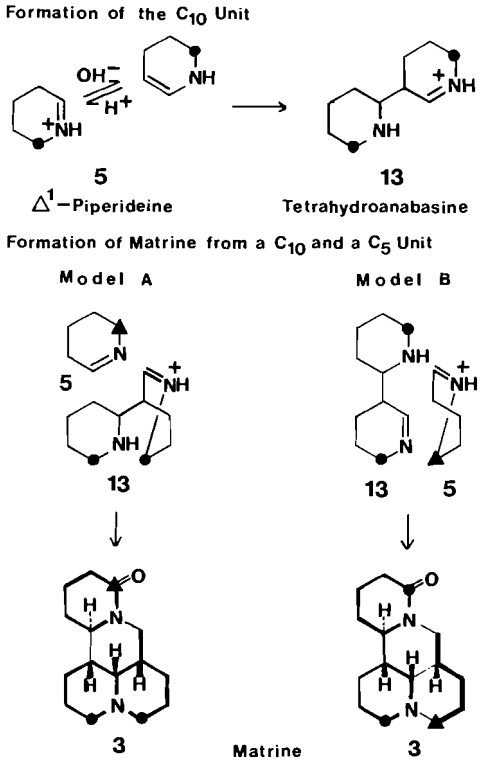

SCHEME 3. Two models for the derivation of matrine from tetrahydroanabasine (C_{10}) (**13**) and Δ^1-piperideine (C_5) (**5**).

of the dimer have the same molar specific activity, i.e. each of the labelled carbon atoms contains 50% of the activity of the intact molecule.

When [6-^{14}C]-Δ^1-piperideine is synthesized by oxidation of [6-^{14}C]lysine, the solution contains not only monomer, but also dimer. Entry of the mixture of labelled monomer and dimer into the plant will be followed by mixing of each component with the corresponding inactive material, if the latter is a normal component of the plant. Since it is unlikely that the two components will be diluted to the same extent, or that, after dilution, they will fully equilibrate with one another in the plant within the experimental period, it can be expected that the specific activity of the monomer unit present within the cell at any one time will not be the same as that of the two equally labelled centres of the dimer unit. As a consequence, the monomer-derived C_5-fragment of matrine will show a specific activity different (either higher or lower) from that of the two equally labelled centres within the dimer-derived C_{10} unit.[4]

[4]It is, of course, possible but not very likely that conditions may prevail which lead, quite fortuitously, to equal specific activity at the three labelled centres.

The variants of matrine biogenesis that have been proposed can all be accommodated by one or the other of two models (Scheme 3) which differ from one another in that different segments of matrine are derived from the C_{10} unit. An experiment with [6-^{14}C]-Δ^1-piperideine can serve as a critical test to distinguish between the two models, provided a degradation is available which permits individual assay of radioactivity at each of the three labelled carbon atoms, C-2, C-10, and C-15 of matrine. In such an experiment, the two labelled carbon atoms of matrine (**3**) supplied by the C_{10}-unit (●) must have the same specific activity. The labelled centre of matrine (▲) whose specific activity is different from that of the other two must be supplied by the C_5 unit.

Labelled matrine had been obtained from an experiment with [6-^{14}C]-Δ^1-piperideine in *Sophora flavescens* (2). Degradation showed that 10% of the recovered activity was located at the carbonyl carbon (C-15). The rest of the recovered activity was distributed over C-2 and C-10. Since the degradation that was employed did not permit individual assay of radioactivity at these two centres, the result that was obtained (2) cannot distinguish between the two models of Scheme 3 (Model A demands: C-2 of matrine, 45%; C-10, 45%; average 45%; model B demands: C-2 of matrine, 10%; C-10, 80%, average 45%; observed: average of C-2 and C-10, 45% (2)). By a new degradation sequence which was designed to recover C-2 and C-10 of matrine individually (see below), it is now shown (Table 1) that, in labelled matrine obtained from [6-^{14}C]-Δ^1-piperideine in each of two Sophora species, *S. tetraptera* (Experiment 1) and *S. microphylla* (Experiment 2), C-2 and C-10 show the same molar specific activity and are therefore supplied by the C_{10}-unit, whereas C-15 shows a different, lower, molar specific activity, and is therefore supplied by the C_5 unit. These results conclusively disprove all variants of model B, including the aldotripiperideine route of matrine biogenesis (1). The data are consistent with model A (Scheme 3).

It will be noted that in each case the three labelled centres that were recovered account for only two thirds of the activity of intact matrine (Table 1). A similar incomplete recovery of label within C-2, -10, and -15 of matrine derived from [6-^{14}C]-Δ^1-piperideine may have been encountered by Shibata and Sankawa (2). The remaining activity is presumably distributed over C-6, C-11, and C-17 of matrine, carbon atoms which would become labelled if [6-^{14}C]lysine or [1-^{14}C]cadaverine were available to the plant. Since [6-^{14}C]-Δ^1-piperideine was

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12

For personal use only.

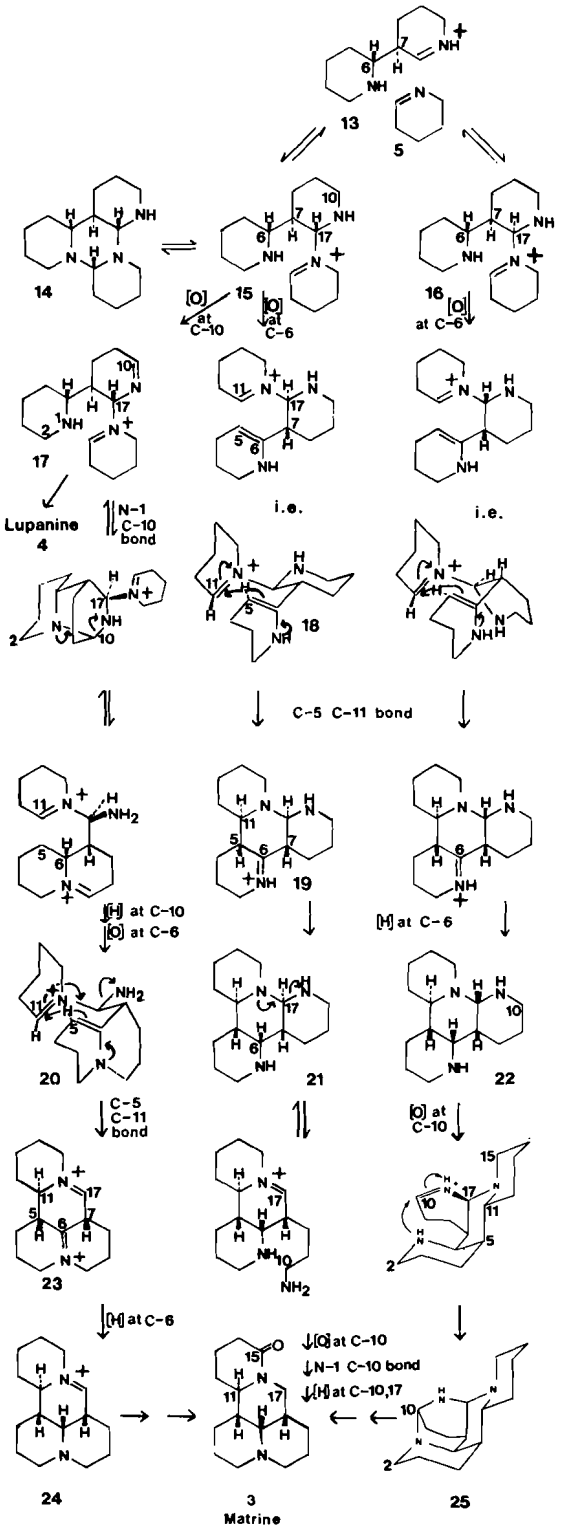
prepared by oxidation of [6-^{14}C]lysine, it is possible that traces of [6-^{14}C]lysine were present in the solution of Δ^1-piperideine that was fed to the plant. It has been reported that incorporation of lysine into matrine is more efficient than incorporation of Δ^1-piperideine (2). Residual [6-^{14}C]lysine in the feeding solution might then make a disproportionate contribution to the labelling of the product.

Another, more likely, explanation why the label is partially randomized may be that the conversion of cadaverine into Δ^1-piperideine in Sophora is reversible. It has recently been reported that the generation of lupine alkaloids from cadaverine in *Lupinus polyphyllus* is catalyzed by a cadaverine–pyruvate transaminase system, referred to as 17-oxosparteine synthase (15). Enzyme-bound 5-aminopentanal, i.e. Δ^1-piperideine, is postulated as the first intermediate. Transaminase-catalyzed reactions are, in general, readily reversible. The presence of an analogous enzyme system in Sophora would allow the partial reconversion of Δ^1-piperideine into cadaverine, and would thus account for the partial conversion of [6-^{14}C]- into [2-^{14}C]-Δ^1-piperideine, and the partial scrambling of label in matrine.

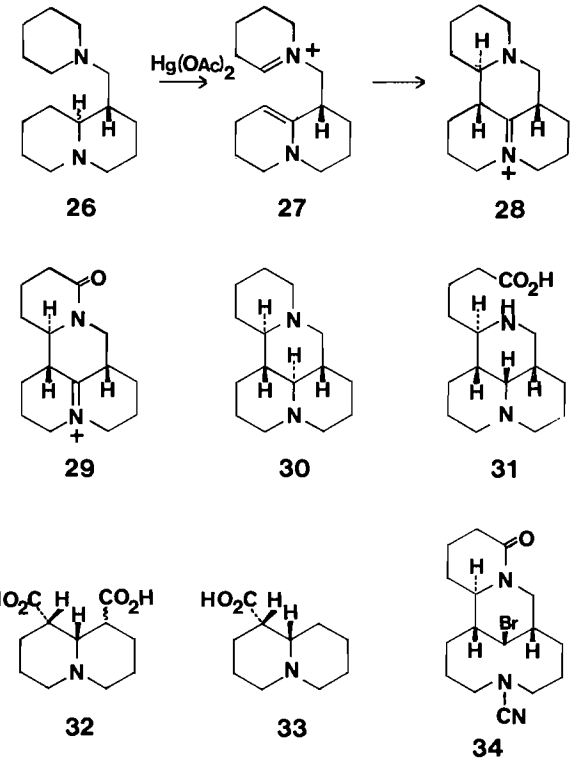
Many variations are possible for a route leading to matrine from a C_{10} unit, tetrahydroanabasine (**13**), and a C_5 unit, Δ^1-piperideine (**5**), which are consistent with model A (Scheme 3). Three of these variations are outlined in Scheme 4. They lead to the stereochemistry of matrine and relate its origin to that of the C_{15} lupine alkaloids. The starting point of two of these routes is the all-*trans* isomer of isotripiperideine (**14**), one of the trimers of Δ^1-piperideine. The same trimer was invoked also as the starting point for lupanine biogenesis (1). The scheme also includes another compound (**17**) which lies on the postulated route to lupanine.

Matrine (**3**) is generated in a series of unexceptional oxidation–reduction and cyclization steps. The stereochemistry of the four chiral centres of matrine is created in the course of bond-formation between C-5 and C-11,[5] and in the reduction at C-6. If ring-closure proceeds through a chair-like transition state (e.g. **18**, **20**) the hydrogen atoms at C-5 and C-11 of the newly formed ring in **19** and in **23**

[5]The numbering system for matrine which is adopted in this paper was introduced by Schütte *et al.* (3). It corresponds to the customary numbering system of the ring system of the $C_{15}N_2$ lupine alkaloids, and shows the biogenetic correspondence of the carbon atoms of the matrine and of the lupine skeleton. The difference between this numbering system and that used by Chemical Abstracts is minor but significant. Several other numbering systems for matrine have also been used.



SCHEME 4. Biogenesis of matrine.



will be *cis* and *trans*, respectively, to the hydrogen at C-7. There is chemical analogy for this postulate. Mercuric acetate oxidation (16) of **26** is reported to give, among other products, dehydromatridine (**28**), formed by spontaneous cyclization of **27**.

If in the reduction of the iminium salts **19** and **23**, generated in the above cyclization, the hydride approaches C-6 *trans* to the hydrogen atoms at C-5 and -7, the resulting product would have the favoured all-*trans* allomatridine (**30**) configuration. Inspection of a model shows, however, that the iminium salts are not planar, and that the less hindered approach to C-6 is *cis* to the adjacent hydrogen atoms. Thus, it is not the thermodynamically favoured allomatridine (**30**) configuration but the matridine configuration (**24**) which is likely to be kinetically favoured in this reduction. Indeed, chemical reduction of dehydromatrine (**29**) yields matrine (**3**) and not allomatrine (**6**) (17).

The 5*R*,6*S*,7*S*,11*R* stereochemistry of matrine (**3**) is not the only one found in the Sophora alkaloids. Other naturally occurring stereoisomers are accessible through the proposed biogenetic model. Thus, allomatrine (**6**) (5*R*,6*R*,7*S*,11*R*) could be generated in the reduction step at C-6. Epimers at C-7 (e.g. sophoridine, 5*R*,6*S*,7*R*,11*R*) and C-5 can result from equilibration of the appropriate iminium ion (e.g. **19** or **23**) with the corresponding enamine.

Our earlier scheme for the biogenesis of matrine (1) had invoked intermediacy of a "prematrine trimer" (**25**), generated in two steps from one of the stereoisomers (**22**) of aldotripiperideine, which was, in turn, derived as a variant of Model B (Scheme 3) in a single step from tetrahydroanabasine (**13**) and Δ^1-piperideine (**5**). The results now presented show that aldotripiperideine generated in this manner cannot serve as a precursor of matrine. Nevertheless, the notion that aldotripiperideine is implicated in matrine biogenesis remains attractive. Aldotripiperideine (of unknown stereochemistry) is converted into allomatridine (**30**) by treatment with Raney Nickel (18), conditions similar to those that convert matridine into allomatridine (19) and matrine into allomatrine (9). Furthermore, an aldotripiperideine of unknown stereochemistry occurs naturally (20). The aldotripiperideine (**22**) which yields the "prematrine trimer" by intramolecular cyclization is accessible from tetrahydroanabasine and Δ^1-piperideine not only by the route which is forbidden since it is a variant of Model B (1), but also by another route which is allowed since it is a variant of Model A. The first intermediate of this route is **16**, the C-17 epimer of **15**. The desired aldotripiperideine **22** is obtained from **16** by steps which parallel the route from **15** to the C-17 epimeric aldotripiperideine **21** (Scheme 4).

The Chemical Degradation of Matrine

For a complete investigation of the mode of incorporation into matrine of label from [2-^{14}C]- and [6-^{14}C]lysine and from [1-^{14}C]cadaverine, six carbon atoms, C-2, -6, -10, -11, -15, and -17 must be extruded for individual assay of radioactivity. Three of these, C-2, -10, and -15, must be obtained individually for an interpretation of the mode of incorporation of label from [6-^{14}C]-Δ^1-piperideine. Only one of these carbons, C-15, has been obtained directly, in the form of benzoic acid, by treatment of matrine with phenylmagnesium bromide (2) or phenyl lithium (3, 4), followed by chromic acid (2) or permanganate (3, 4) oxidation of the phenyldihydro derivative. Estimation of label at other centres was indirect, depending on the assay of products which were obtained by oxidative fragmentation of matrine and either contained more than one of the crucial carbon atoms or arose from two or more sites within the molecule.

These products were glutaric acid (2), succinic acid (2, 3), γ-aminobutyric acid (2, 3), β-alanine (2, 3), glycine (3), quinolizidine-5,7-dicarboxylic acid

(**32**) (3), and quinolizidine-5-carboxylic acid (**33**) (3). Glutaric acid, generated from the C_5 chain, C-11 to C-15, contains C-11 and -15, which cannot be differentiated from one another. Succinic acid can originate from four different C_4 units within the molecule. These are nonequivalent and would yield the compound at unequal rates.[6] These C_4 units contain C-2, -10, -11, and -15. Each of these carbon atoms would yield one of the carboxyl groups of succinic acid and cannot thus be assayed individually.[7] γ-Aminobutyric acid and β-alanine are each generated from two nonequivalent sites, encompassing C-2 and C-10, respectively, whose individual activity cannot therefore be determined. Similarly, glycine may be generated from three nonequivalent sites, embracing C-2, C-10, and C-17.

As far as the quinolizidine carboxylic acids **32** and **33** are concerned, we were unable to duplicate the oxidation of matrine which is reported (3, 22) to yield these products.[8] Under the conditions described in ref. 3 the sole reaction that occurs is hydrolysis, yielding matrinic acid (**31**) together with unreacted matrine. When more vigorous conditions were employed (22) γ-aminobutyric acid, β-alanine, and glycine were also obtained, in poor yield (5–15%).

Thus, reactions previously employed in the degradation of labelled matrine were unsuitable for gaining individual access to C-2 and C-10. A new degradation was developed for this purpose (Scheme 2).

The key to this degradation was the von Braun reaction with cyanogen bromide. Matrine does not undergo this reaction, but its conformationally stable all-*trans* stereoisomer, allomatrine (**6**), does (24), and isomerization of matrine into allomatrine proceeds in high yield (9). Reaction with cyanogen bromide converts allomatrine into two bromocyanamides, mp 126°C (24) and 166°C (24), 167–168°C (11), of which only the latter had been characterized (11). These two compounds were obtained in high yield and their separation proved possible. The ^{1}H nmr analysis of the neutral fraction from the reaction of allomatrine with cyanogen bromide revealed the presence of two compounds, in the ratio 3:2. The starting material, allomatrine (**6**), shows a double doublet δ 4.6 (J = 13 and 4 Hz), well separated from the rest of the spectrum, due to the equatorial 17-hydrogen atom which is coplanar with the carbonyl group and therefore significantly deshielded. The ^{1}H nmr spectrum of matrine shows a similar signal. The spectrum of the mixture of neutral reaction products showed two sets of double doublets, centered at δ 5.0 (major product A) and δ 4.7 (minor product B), respectively.

The two products resisted chromatographic separation (silica gel or reversed phase), but were eventually separated by repeated fractional crystallization from ethyl acetate/petroleum ether, by employing the double doublets at δ 5.0 and δ 4.7, respectively, as diagnostic indicators for the purity of the two products, mp 134–135°C, the major product (A), and mp 168–169°C, rising to 174–176°C after repeated recrystallization, the minor product (B). The structure of bromocyanamide B was determined by single crystal X-ray diffraction (25). It was shown to have structure **8**.

The two bromocyanamides, A and B, were each taken through a sequence of conventional steps which eventually led to the recovery of C-10 and C-2, respectively, as formaldehyde. Treatment with trimethylamine gave the quaternary ammonium salts, **9** and **10**, respectively. Hofmann elimination using potassium *tert*-butoxide yielded the alkenes, **11** and **12**. Their ^{1}H nmr spectra showed the pattern of signals characteristic for the protons of a terminal double bond, thus providing

---

[6]It had previously been assumed (3) that the sole source of succinic acid in the oxidation of matrine is the C_4 chain C-12, -13, -14, -15. That this assumption is in error is indicated by the report (21) that succinic acid is obtained in the oxidation of sophocarpine (i.e. 13,14-dehydromatrine).

[7]The uncertainty of the degradation is illustrated by the following. It is reported (3) that matrine, specific activity 13.7×10^4 cpm per mmol, gave succinic acid, specific activity 2.26×10^4 cpm per mmol, which was diluted with inactive carrier, to give a sample, specific activity 7.32×10^3 cpm per mmol. Whatever the source of this succinate from within the skeleton of matrine, only one of its carboxyl groups can be labelled. Yet, when this succinic acid was further degraded by a Schmidt reaction to yield inactive ethylene diamine and labelled carbon dioxide, the specific activity of the latter was 6.90×10^3 cpm per mmol, i.e. essentially identical with that of the succinic acid from which it was derived. This is clearly impossible, unless the degradation reaction is accompanied by a large reverse isotope effect.

[8]It is reported (22) that the quinolizidine mono- and dicarboxylic acids obtained by oxidation of matrine were optically active. This is surprising; the dicarboxylic acid thus apparently did not retain the stereochemistry of matrine. Furthermore, the physical constants reported for the monocarboxylic acid (referred to as *d*-lupininic acid) (mp 255°C; hydrochloride mp 275°C (dec.), $[\alpha]_D$ +37.78° (CH_3OH) (22)) correspond to those reported (23) for (+)epilupininic acid ((1*S*-*cis*)-2*H*-octahydroquinolizine-1-carboxylic acid) (mp 255°C, $[\alpha]_D^{15}$ +25.2° (*c* 1.6, H_2O); hydrochloride, mp 273°C, $[\alpha]_D^{15}$ +36.2° (*c* 1.9, H_2O)) rather than to those predicted for (+)lupininic acid (**33**) (reported (23) for (−)lupininic acid ((1*R*-*trans*)-2*H*-octahydroquinolizine-1-carboxylic acid), mp 172°C, $[\alpha]_D^{20}$ −7.2° (*c* 2.2, H_2O); hydrochloride, mp 258–259°C, $[\alpha]_D^{15}$ −9.5° (*c* 2.9, H_2O)).

early evidence that the two bromocyanamides were **7** and **8**, and that the third possible bromocyanamide (**34**) of allomatrine had not been produced. The alkene derived from bromocyanamide B was contaminated by the corresponding *tert*-butyl ether (ca. 20%). Formaldehyde, isolated as the dimethone, was obtained by oxidative cleavage of each alkene. Since the structures **7** and **8** are assigned to the bromocyanamides, A and B, respectively, the sample of formaldehyde from bromocyanamide B is derived from C-2, and that from bromocyanamide A from C-10 of matrine. It is of interest, however, that the interpretation of the tracer results did not depend on these assignments and was possible without them.

No more than 200 mg matrine was required to complete the degradation leading to assay of activity of C-15 (benzoic acid) and of each of C-2 and C-10 (formaldehyde dimethone). The sequence includes three compounds which retain all carbon atoms of matrine (allomatrine, bromocyanamides A and B) and must therefore show identical molar specific activity, serving as independent check of radiochemical purity.

Experimental

Administration of [6-^{14}C]-Δ^1-Piperideine to Sophora Spp.

Stocks of *Sophora microphylla* and *S. tetraptera* were obtained from Hillier Nurseries, Winchester, England. The stocks were planted in the greenhouse in April 1978, broke dormancy within two weeks and were allowed to grow normally for three months. The tracer experiments were conducted in July 1978.

The tracer, [6-^{14}C]-Δ^1-piperideine, was prepared (7) from a sample of DL-[6-^{14}C]lysine monohydrochloride (nominal specific activity 48 mCi per mmol, nominal total activity 0.3 mCi, Commissariat a l'Energie Atomique, France) to which had been added nonradioactive DL-lysine monohydrochloride (42 mg). The oxidation was carried out using *N*-bromosuccinimide (90 mg), yielding [6-^{14}C]-Δ^1-piperideine (nominal specific activity 1.3 mCi per mmol). A radioscan of a thin layer chromatogram of the product (silica gel; 1-butanol/acetic acid/water 2:1:1) showed the presence of a small amount of a second radioactive component, R_f 0.06, probably [2,10-^{14}C$_2$]tetrahydroanabasine, in addition to [6-^{14}C]-Δ^1-piperideine, R_f 0.28. Only traces of [6-^{14}C]lysine, R_f 0.09, could have been present. In each of two experiments, a solution of the radioactive product (0.07 mCi) was administered to 3 stocks of *S. tetraptera* (Experiment 1) and *S. microphylla* (Experiment 2) by infusion into the stems through cotton wicks. The plants were allowed to grow in contact with tracer for three days and were then harvested. The material, roots, stems, and leaves, was dried at 60°C.

Extraction of Matrine from Sophora microphylla

The dried plant material (34 g) was ground in a blender and extracted 10 h in a Soxhlet apparatus with acetic acid in ethanol (2% v/v, 250 mL). The extract was concentrated *in vacuo* to 50 mL, aqueous hydrochloric acid (2% v/v, 100 mL) was added, and concentration continued until all ethanol was removed. The mixture was then cooled in ice and filtered through Celite. The filtrate was extracted with chloroform (3 × 10 mL), neutralized with sodium carbonate, and made strongly alkaline with sodium hydroxide. The alkaline solution was extracted with chloroform (4 × 10 mL) and the extracts dried over sodium sulfate, filtered, and evaporated to dryness *in vacuo*. The residue was dissolved in chloroform and applied to a column of silica gel (Baker, 60–200 mesh, 15 × 1.5 cm) and eluted with $CHCl_3$/MeOH/0.880 NH_3 (97:3:0.3). The fractions containing matrine were identified by tlc (see below), concentrated, and then applied to a column of silica gel (Merck prepacked, size A) and eluted with $CHCl_3$/MeOH (97:3). The uv absorbance of the eluate was continuously monitored at 254 nm. The crude matrine (11 mg) which emerged (65–115 mL) was diluted with nonradioactive matrine (177 mg) and the carrier-diluted mixture was converted to allomatrine without further purification.

Extraction of Matrine from S. tetraptera

Labelled matrine (5 mg) was obtained from *S. tetraptera* (40 g dry weight) by essentially the same procedure. The crude product was diluted with nonradioactive matrine (270 mg) and converted into allomatrine.

The experimental details that follow are those used in the degradation of matrine from Experiment 2. The procedure followed in Experiment 1 differed only in minor details.

Conversion of Matrine (3) into Allomatrine (6)

Matrine (188 mg) was dissolved in acetic acid (8 mL), platinum dioxide (70 mg) was added, and the mixture was heated 15 h (bath temperature 105°C) with continuous stirring under an atmosphere of hydrogen. The composition of the mixture was monitored by tlc (silica gel; $CHCl_3$/MeOH/0.880 NH_3; 90:10:0.5) and the alkaloids visualized by spraying with Dragendorff's reagent (26) (matrine R_f 0.62, allomatrine R_f 0.50; R_f values are lower, 0.5 and 0.4 respectively, if the compounds are applied directly in acetic acid solution). If the conversion was not complete, the hydrogenation was continued after addition of fresh catalyst (70 mg, twice a day) until tlc showed that no matrine remained. When the reaction was complete, the catalyst was filtered off and washed with water and the filtrate was evaporated to dryness *in vacuo*. The residue was dissolved in 0.25 *M* sulfuric acid (10 mL) and the solution extracted with chloroform (2 × 3 mL). The acidic solution was neutralized with sodium carbonate and made strongly basic with sodium hydroxide. This alkaline solution was extracted with chloroform (5 × 3 mL) and the extract was dried over sodium sulfate, filtered, and evaporated to dryness *in vacuo*. The residue was dissolved in light petroleum (bp 30–60°C) and filtered through Celite, and the filtrate was concentrated. Upon cooling crystals appeared which were filtered off and recrystallized from light petroleum, yield 112 mg. Evaporation of the mother liquor yielded a residue from which further product was obtained by chromatography on a Merck prepacked silica gel column (size A) with $CHCl_3$/MeOH (96:4) as eluant. The total yield was 166 mg (88%).

This material was diluted with inactive allomatrine (85 mg) and recrystallized three times to constant radioactivity (mp 105–105.5°C; lit. (9) mp 103–105°C).

Degradation of Allomatrine

Carbon-15 as Benzoic Acid

Allomatrine (45.5 mg, 0.18 mmol) was dissolved in dry ether (2 mL) under an atmosphere of nitrogen. Phenyl lithium (2.7 *M*, in benzene/ether, 0.25 mL, 0.7 mmol) was injected and the solution stirred for 19 h. The solution was then cooled in an acetone/Dry Ice bath, methanol (0.5 mL) was injected, and the mixture was allowed to warm to room temperature. Sulfuric acid (0.25 *M*, 10 mL) was added and the mixture extracted with

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

chloroform (3 × 4 mL). The aqueous layer was neutralized with sodium carbonate and made strongly alkaline with sodium hydroxide. This alkaline solution was extracted with chloroform (4 × 4 mL) and the extract dried over sodium sulfate, filtered, and evaporated to dryness *in vacuo*. The residue was dissolved in ethanol (2 mL), concentrated hydrochloric acid (3 drops) was added, and the solution evaporated to dryness *in vacuo*. The residue was dissolved in sulfuric acid (2 *M*, 1.5 mL) and 2.7 *M* chromium trioxide in 4 *M* sulfuric acid (0.5 mL) was added. This mixture was heated 1 h at reflux in a bath at 125°C with stirring. The mixture was cooled, water (8 mL) was added, and the solution extracted with chloroform (4 × 4 mL). The chloroform extract was extracted with aqueous sodium bicarbonate (5% w/v, 2 × 5 mL) and the aqueous extract was acidified with concentrated hydrochloric acid and extracted with chloroform (4 × 3 mL). This chloroform extract was dried over sodium sulfate, filtered, and evaporated to dryness *in vacuo* to yield benzoic acid (15 mg, 67%) which was recrystallized twice from water, mp 121–122°C.

Carbon-2 and Carbon-10 as Formaldehyde

Bromocyanamides A and B (7 and 8). Allomatrine (166 mg, 0.67 mmol) was dissolved in a solution of cyanogen bromide in dry benzene (0.25 *M*, 5 mL, 1.25 mmol) which had been stored over anhydrous potassium carbonate. The solution was heated 1.5 h at reflux with stirring and was then evaporated to dryness *in vacuo*. Sulfuric acid (0.25 *M*, 10 mL) was added to the residue and the mixture extracted with chloroform (4 × 4 mL). The extract was dried over sodium sulfate, filtered, and evaporated to dryness. The product was a mixture of two isomeric bromocyanamides (A(**7**) and B(**8**)) in the ratio 3:2, as determined from the ^{1}H nmr spectrum. Each of these compounds shows a distinct double doublet (J = 13 and 4 Hz), centered at δ 5.00 and 4.73 ppm, respectively. The isomers were separated by fractional crystallization from ethyl acetate/light petroleum (bp 30–60°C). The ratio of products in each batch of crystals was determined by ^{1}H nmr. When seed crystals were available, the following procedure was employed. The mixture of products was dissolved in ethyl acetate (2 mL) at room temperature. Light petroleum was added until the solution turned cloudy. Seed crystals of bromocyanamide B were added and the mixture kept 1 h at 5°C. The crystals that appeared were pure or nearly pure bromocyanamide B (**8**). The mother liquor was evaporated to dryness *in vacuo* and the recrystallization procedure was repeated except that seed crystals of bromocyanamide A (**7**) were added. Pure or nearly pure bromocyanamide A was then obtained. The mother liquor of this second recrystallization yielded a further crop of bromocyanamide B. If impure crystals were obtained, a further recrystallization yielded pure product (^{1}H nmr). Each bromocyanamide was recrystallized from ethyl acetate/light petroleum.

Products: Bromocyanamide A (**7**): 90 mg (38%), mp 134–135°C (lit. (24) mp 126°C); $[\alpha]_D^{20}$ +153° (*c* 2.1, C_2H_5OH); ir ($CHCl_3$) ν: no *trans*-quinolizidine bands, 2210 (C≡N), 1660 (C=O) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 5.00 (dd, J = 4 and 13 Hz, 1H), 3.45 (t, J = 5 Hz, 2H), 3.6–0.9 (m, 21H) ppm; ^{13}C nmr ($CDCl_3$) δ: 169.0, 115.5, 66.1, 59.2, 51.6, 45.1, 44.7, 37.7, 33.6, 32.7, 29.7, 28.2, 26.5, (2C), 23.9, 18.9 ppm; ms *m/e*: 355, 353(M^+), 274, 248, 247, (100%). *Anal.* calcd. for $C_{16}H_{24}N_3OBr$: C 54.24, H 6.83, N 11.86, Br 22.56; found: C 54.42, H 6.92, N 11.74, Br 22.40.

Bromocyanamide B (**8**): 78 mg (33%), mp 174–176°C (lit. (11) mp 167–168°C); $[\alpha]_D^{20}$ +32° (*c* 2.0, C_2H_5OH); ir ($CHCl_3$) ν: no *trans*-quinolizidine bands, 2210 (C≡N), 1660 (C=O) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 4.73 (dd, J = 4 and 13 Hz, 1H), 3.45 (t, J = 5 Hz, 2H), 3.6–0.9 (m, 21H) ppm; ^{13}C nmr ($CDCl_3$) δ: 169.3, 115.5, 65.2, 59.0, 52.3, 45.8, 43.9, 38.0, 33.7, 32.6, 28.6, 27.8, 27.2, 25.9, 23.7, 18.9 ppm; ms *m/e*: 355, 353(M^+), 274, 248, 247 (100%). *Anal.* calcd. for $C_{16}H_{24}N_3OBr$: C 54.24, H 6.83, N 11.86; found: C 54.38, H 6.94, N 11.76.

Formaldehyde Dimethone. The bromocyanamide (A or B) (60 mg, 0.17 mmol) was dissolved in methanol (1 mL) and a solution of trimethylamine in methanol (25% w/w, 0.5 mL) was added. The solution was allowed to stand 3 days in a stoppered flask and was then evaporated to dryness and the residue dried *in vacuo*. Potassium metal (34 mg) was added to dry *tert*-butyl alcohol (2 mL) and, when it had all dissolved, a portion (1 mL, 0.43 mmol) of the solution was added to the above residue. The mixture was heated 3 h at reflux and then cooled. Water (10 mL) and sodium hydroxide (10% w/v, 2 mL) were added and the mixture extracted with chloroform (4 × 4 mL). The extract was dried over sodium sulfate, filtered, and evaporated to dryness *in vacuo*. The ^{1}H nmr of the residue indicated an almost quantitative yield of alkene from bromocyanamide A but only about 80% from B. Sodium metaperiodate (70 mg, 0.33 mmol for A; 58 mg, 0.27 mmol for B), water (1 mL), and a solution of osmium tetroxide in ethyl acetate (5 mg/mL, 0.5 mL, 0.01 mmol), was added to the residue. The mixture was vigorously stirred at room temperature for 2.5 h. Water (2 mL) was added and the mixture was extracted with chloroform (3 × 1 mL) to remove organic material other than formaldehyde. The chloroform extract was back-extracted with water (1 × 1 mL) and the combined aqueous extracts were then reextracted with light petroleum (bp 30–60°C) (1 × 2 mL) to remove traces of chloroform. Nitrogen was bubbled through the aqueous solution for a few minutes to remove the last traces of organic solvent and a solution of dimedone (48 mg, 0.34 mmol, for A; 39 mg, 0.27 mmol, for B) in 95% ethanol (0.5 mL) was then added. Formaldehyde dimethone started to precipitate almost immediately. After 1 h it was filtered off, washed with water, and dried *in vacuo*. Yield of formaldehyde dimethone: 29 mg (58%) from bromocyanamide A (**7**), (C-10); 21.5 mg (43%) from bromocyanamide B (**8**), (C-2). The product was recrystallized twice from ethanol/water, mp 190–191°C (lit. (ref. 26, p. 79) mp 189°C).

Determination of Radioactivity

Radioactivity was assayed by liquid scintillation counting (Mark 1 liquid scintillation computer, Model 6860, Nuclear Chicago). Samples were dissolved in toluene (4 drops) and the solution dispersed in A.C.S. (Amersham). Triplicate samples of each compound were counted under comparable conditions of quenching. Confidence limits shown in Table 1 are standard deviations from the mean.

Acknowledgments

This investigation was supported by a grant from the Natural Sciences and Engineering Research Council of Canada.

KUANG S. CHEN and JEFFREY K. S. WAN. Can. J. Chem. **59**, 116 (1981).

The primary processes in the photoreduction of 2-furaldehyde, 2-furyl methyl ketone, and 2-acetylthiophene by phenol, 2,6-di-*tert*-butylphenol, and pentachlorophenol, respectively, were studied by esr and time-resolved CIDEP techniques. These furan derivatives, in their excited triplet states, can abstract a hydrogen atom from phenol via either the carbonyl group or the carbon–carbon double bond. The present results suggest that they all behave in the primary processes predominantly as carbonyl compounds. The spin–lattice relaxation times of all transient and polarized radicals observed in these photochemical systems were estimated by the CIDEP technique. The photoreductions of furaldehyde and furyl methyl ketone were also examined by high-field CIDNP. The nuclear polarization is mainly due to the cage products and the results are consistent with triplet carbonyl abstraction mechanism. Secondary radical addition to the carbon–carbon double bond of the furan ring was also observed in the furaldehyde–phenol system.

KUANG S. CHEN et JEFFREY K. S. WAN. Can. J. Chem. **59**, 116 (1981).

On a étudié par la rpe et par les techniques de PEDIC à temps résolu le processus primaire de la photoréduction du furaldéhyde-2, de la furyl-2 méthylcétone et de l'acétyl-2 thiophène par le phénol, le di-*tert*-butyl-2,6 phénol et le pentachlorophénol respectivement. Ces dérivés furanniques, dans leurs états triplets excités, peuvent enlever un atome d'hydrogène du phénol par l'intermédiaire du carbonyle ou de la double liaison carbone–carbone. Les résultats obtenus suggèrent que dans le processus primaires ils se comportent tous principalement comme des composés carbonylés. Grâce à la technique PEDIC, on a évalué les temps de relaxation spin–réseau de tous les radicaux intermédiaires et polarisés observés dans ces systèmes photochimiques. On a également étudié les photoréductions du furaldéhyde et de la furylméthylcétone grâce à la PNDIC à haut champ. La polarisation nucléaire est due principalement aux produits encagés et les résultats sont en accord avec le mécanisme d'élimination par le triplet du carbonyle. On a également observé l'addition secondaire d'un radical sur la double liaison carbone–carbone du cycle furane dans le système furaldéhyde/phénol.

Introduction

The photoreductions of quinones by phenols have been used extensively in this laboratory as model systems for chemically induced magnetic polarization studies (1). While quinones contain both carbonyl groups and conjugated olefinic bonds, they behave essentially as carbonyl compounds in the photoreduction by phenols. Similarly, uranyl ions and organometals such as organotin and organomercury quench the excited triplet quinones mainly via the carbonyl moiety (2–4). Recently we began a systematic examination of the photoreductions of other diketones which contain also a reactive carbon–carbon double bond. Thus, the photoexcited "polarized" triplet malelic anhydride undergoes a primary hydrogen atom abstraction from the solvent molecule via its carbonyl oxygen. This is followed by a rapid rearrangement of the primary ketyl radical with the transfer of the hydroxylic proton to the neighboring C=C double bond (5). In general, it is much less obvious in the photoreactions of malelic anhydrides and maleimides (6) whether the triplet reacts exclusively via the carbonyl group or via the olefinic bond. In this report we examine another interesting class of compounds, the furan derivatives which contain a carbonyl group and adjacent olefinic bonds enclosed separately in a furan ring. Earlier we have developed the furilphenol system as a model to examine the detailed theory involved in low-field CIDNP studies (7–9). The esr and CIDEP results (10) show that two furil derived radicals were observed in the photoreduction: one is the "polarized" semidione radical and the other is an allyl radical formed by secondary radical addition to the furan ring. With 2-furaldehyde and 2-furyl methyl ketone, the present study shows that their excited triplet states behave mainly as a carbonyl compound in the primary processes of the photoreduction by phenol. To probe the effect of the heteroatom of the furan ring on the primary photochemical processes, the photoreduction of 2-acetylthiophene was examined and compared to that of 2-furyl methyl ketone.

Experimental

The chemicals were purchased from: MCB (2-furaldehyde and 2-furyl methyl ketone), Aldrich (2-acetylthiophene, phenol, 2,6-di-*tert*-butylphenol, and pentachlorophenol), and Canlab (2-propanol, toluene). The phenols and the furan derivatives were vacuum sublimed or distilled before use.

Sample solutions contained in suprasil tubings were degassed and the tubings were sealed off under vacuum. The concentrations of the reactants were adjusted to give the optimum CIDEP effect. Cw esr spectra were recorded while the samples were directly photolyzed (200 W super pressure Hg lamp) within the cavity of an X-band Varian E-3 spectrometer employing 100 kHz field modulation. The temperature of the sample in the cavity was controlled by flowing thermostatted nitrogen gas by the sample cell and the temperature was continuously monitored by a copper–constant thermocouple. For g-factor measurements, the magnetic field was measured by a Bruker nmr oscillator and the klystron frequency was determined with a Hewlett-Packard 5342 frequency counter.

CIDEP experiments were carried out using a Molectron UV24 pulsed N_2 megawatt laser and a time-resolved dc detection system described previously (11). The spin–lattice relaxation times of the "polarized" transient radicals were estimated by the time-resolved CIDEP technique (11), and the data were applied to determine the lower limits of the rate of the secondary radical addition reactions.

Results and Discussion

Photoreduction of 2-Furaldehyde by Phenols

Photolyses of 10% 2-propanol/90% toluene solutions of 2-furaldehyde (FHCO) and various phenols led to the observation of the primary "polarized" phenoxy radical (PhO*) and a furaldehye derived radical which was not polarized. Since phenols are much more efficient than 2-propanol in the quenching of the carbonyl triplets (10), the primary photochemical process which readily accounts for the initial polarization of the phenoxy radical, is the following:

$$[1]\quad \text{FHCO} + h\nu \xrightarrow{\text{ISC}} {}^3[\text{FHCO}]^* \xrightarrow[-80^\circ\text{C}]{\text{PhOH}} \text{PhO}^* + \text{FHCOH}^*$$

Despite the low temperature and the high sensitivity of CIDEP measurements, the primary radical FHCOH escaped experimental observation. Instead, the observed transient radical derived from furaldehyde was assigned to the adduct of a phenoxyl radical to ground state furaldehyde:

$$[2]\quad \text{PhO} + \text{FHCO} \xrightarrow[-56^\circ\text{C}]{k_a} \text{(I)}$$

(I)

At very low temperatures only the phenoxy radical was observed. As the temperature was gradually increased, the ratio of the signal intensity of the furan derived radical to that of the phenoxy radical also increased. When pentachlorophenol was used, the observed esr spectrum was simplified and all the hyperfine lines due to the protons in the radical adduct **I** could be resolved. These hyperfine coupling constants and their experimental assignments are: $a_1^H = 14.3$ G; $a_2^H = 8.2$ G; $a_3^H = 1.3$ G; and $a_4^H = 6.6$ G; $g = 2.0030 \pm 0.0001$. These assignments are consistent with a similar OH radical adduct to furaldehyde reported by Shiga and Isomoto (12). The magnitude of the coupling constants for protons 2 and 3 is characteristic of the allylic protons.

None of the hyperfine structure observed in the furan derived radical showed any temperature dependence. Along with the fact that this radical intensity increases relative to phenoxy radical at higher temperatures, we conclude that the esr spectrum observed cannot be due to the primary ketyl radical and therefore the assignment of the secondary radical adduct **I** is most reasonable. Since the primary phenoxy radical exhibited strong initial polarization, the fact that the adduct formed in reaction [2] did not retain any polarization can be used to estimate the *upper limit* of the rates of the secondary reactions, provided the spin–lattice relaxation times T_1s of the phenoxy radicals are known. Figure 1*a* shows a typical transient response of the unsubstituted phenoxy radical at a constant field with Fig. 1*b* showing the corresponding transient response of the 2,6-di-*tert*-butylphenoxy radical (DTB—PhO*) in the same furaldehyde photoreduction system, at −56°C. The estimated values of T_1 are 3.9 μs for the unsubstituted phenoxy radical and 6.5 μs for DTB—PhO, respectively. With these data and the knowledge of the approximate concentration of the furaldehyde in the sample concentration of the furaldehyde in the sample solutions, the upper limits of the rates of the secondary reactions at −56°C are found to be:

$$[2a]\quad \text{PhO}^* + \text{FHCO} \xrightarrow{k_a < 2.6 \times 10^5\ M^{-1}\ s^{-1}} \text{I}$$

$$[2b]\quad \text{DTB—PhO}^* + \text{FHCO} \xrightarrow{k_a < 1.5 \times 10^5\ M^{-1}\ s^{-1}} \text{I}$$

It is apparent that although DTB—PhO has a longer T_1 than PhO, its addition to furaldehyde would still be slower due to steric hindrance caused by the two bulky *t*-butyl groups. The results also suggest that the phenoxy radicals generally add slower to the olefinic bonds in furaldehyde than the corresponding additions to quinones and malelic anhydrides.

The failure of observing the primary furaldehyde radical cannot be used to argue that furaldehyde behaves as a carbonyl compound. Rather, it remains equally possible that the primary abstraction from the phenol is via the carbon–carbon double bond. In this regard we examined the high-field CIDNP effect in the photoreduction of furaldehyde

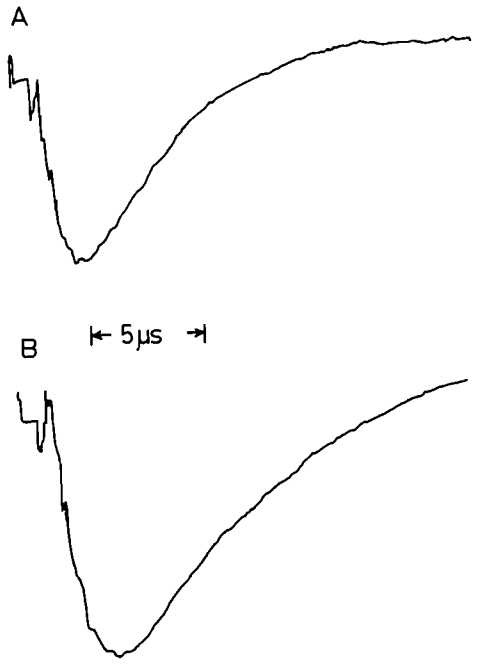

FIG. 1. The transient responses of (*a*) phenoxy radical and (*b*) 2,6-di-*tert*-butylphenoxy radical at −56°C observed in the laser flash photolysis of 2-furaldehyde in 10% 2-propanol/90% toluene containing the corresponding phenol. B_1 is 40 mG. The curve represents the difference between the on-resonance and off-resonance responses.

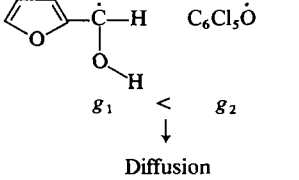
by pentachlorophenol in $CDCl_3$. The experiments were performed in a Bruker 60 MHz FT nmr spectrometer with a light pulsing device described by deBoer and Wan (13). Sample solutions containing furaldehyde and pentachlorophenol in $CDCl_3$ were vacuum degassed and sealed. The *net* CIDNP spectrum, i.e. the difference between dark and light observations, is presented in Fig. 2. At 14 kG (the spectrometer field), the net effect is predominant, although appreciable multiplet effects are shown by the furan proton H_3 which is adjacent to the carbonyl group.

The strong enhanced absorption of the aldehydic proton at δ 9.7 can be readily explained by the Kapteins's rules at high field (14) according to the following reaction scheme:

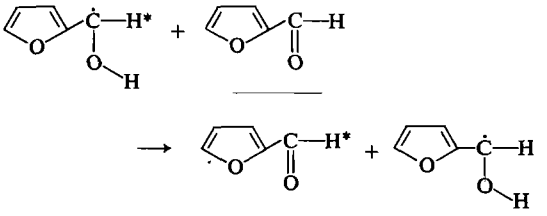
[1] $FHCO + h\nu \xrightarrow{ISC} {}^3[FHCO]$

[3] $^3[FHCO] + C_6Cl_5OH \rightleftharpoons$ T



In addition to the cage recombination process, an alternate mechanism involving the exchange reaction between the primary radical and the diamagnetic parent molecule could lead to the aldehydic proton polarization as well:

[3*a*]



Previous CIDNP studies (15, 16) have proposed such an exchange mechanism in the photoreduction of other aldehydes. These reactions can be very efficient in transferring nuclear spin polarization from the primary radicals to diamagnetic products. However, we have pointed out earlier (17) that if these exchange reactions are reversible, they can also convert an already polarized product to a radical with subsequent destruction of the polarization by relaxation.

By analogy of the furil and pentachlorophenol system (10), g_2 is expected to be larger than g_1 in the primary radical pair and the hyperfine coupling constant of the aldehydic proton would be negative. With these assumptions and the triplet furaldehyde as the precursor, the cage product would exhibit CIDNP with the aldehydic proton strongly enhanced absorptive. With the same transient furaldehyde "ketyl" radical, the furan proton H_3 adjacent to the carbon radical centre is expected to have the largest hyperfine coupling constant and thus showing appreciable multiplet effect. On the other hand, if the primary photochemical process involves the triplet FHCO abstracting a hydrogen atom via the carbon–carbon double bond giving an allylic type of radical similar to that of **I**, the esr parameters would change to a positive hyperfine coupling constant for the aldehydic proton with the proton H_1 having the largest hyperfine coupling constant. This reaction mechanism will lead to a cage product of the furaldehyde with the aldehydic proton in the emissive mode and with a lesser multiplet effect for the proton H_3.

The conclusion that the primary photochemical abstraction process of the triplet furaldehyde involves the carbonyl group is consistent with the CIDNP results. This is more than just a mere coincidence as the CIDNP results for the furyl methyl ketone described in the next section are consistently correlated with the same conclusion.

Photoreduction of 2-Furyl Methyl Ketone by Phenols

Two radicals were observed by esr when 2-furyl methyl ketone (FCOMe) was photoreduced by phenol at −60°C in a 10% 2-propanol/90% toluene solution. One of the radicals is the primary phenoxy radical and its esr spectrum changes to correspond to the particular substituted phenol used. CIDEP experiments show that both radicals exhibit initial polarization and that they have different values of T_1. In the 2,6-di-*tert*-butylphenol/ FCOMe system at −60°C, the values of T_1 are 6 μs for 2,6-di-*tert*-butylphenoxy radical and 4.3 μs for the other counter radical. Unlike the FHCO system, no new radicals were observed when the temperature was raised.

The results from both the esr and CIDEP observations support the following primary photochemical processes:

[4] FCOMe + $h\nu \xrightarrow{\text{ISC}}$ ^{3}[FCOMe]*

$$\xrightarrow[-80°C]{PhOH} \left[\text{2-furyl-C(OH)(}\dot{}\text{)-CH}_3\right]^* + \text{PhO}\dot{}\text{*}$$

II

The hyperfine coupling constants and their assignments to the ketyl radical II are: $a_1^H = 5.5$ G; $a_2^H = 1.3$ G; $a_3^H = 8.4$ G; $a_{CH_3}^H = 14.5$ G; and $a_{OH}^H = 1.29$ G (at −80°C). The last coupling constant is temperature dependent. These assignments are consistent with other ketyl radicals such as the furil ketyl radical (10) and the acetophenone ketyl radical (18). A *g*-factor of 2.0031 was measured for the ketyl radical II.

It is interesting to note that the addition of the primary phenoxy radical to the ground state FCOMe does not seem to be at all efficient. No esr spectrum could be observed for the adduct. On the other hand, it is not too surprising that the primary ketyl radical II is more stable (and thus observable) than the corresponding primary furaldehyde "ketyl" radical.

The mechanism of the primary photochemical reaction of FCOMe in reaction [4] was further supported by CIDNP results. Sample solutions containing FCOMe and pentachlorophenol in $CDCl_3$ exhibited a *net* CIDNP high field spectrum as shown in Fig. 3. Again the predominant polarization is underlined by the net effect and the strong emission of the methyl protons of the caged product FCOMe at δ 2.5 corresponds to a positive hyperfine coupling constant for the methyl protons which is expected in the ketyl radical II.

Thus, we conclude that both furaldehyde and furyl methyl ketone undergo primary photochemical abstraction reactions via their carbonyl group.

Photoreduction of 2-Acetylthiophene by Phenols

To study the effect of the heteroatom of the furan ring on the primary photochemical processes of furyl methyl ketone, we have carried out the photoreduction of 2-acetylthiophene by various phenols in 2-propanol and in 10% 2-propanol/90% toluene solvents. At −80°C, two radicals were observed; one was the phenoxy radical and the other counter radical was derived from the acetylthiophene. CIDEP experiments show that the phenoxy radical was polarized but the initial polarization magnitude was much weaker relative to that observed in the furyl methyl ketone/phenol system under identical conditions. Furthermore, repeated efforts failed to show positively the polarization from the acetylthiophene derived radical. These results can be discussed in terms of the following mechanism:

[5] $$\text{thienyl-C(=O)-CH}_3 + h\nu \xrightarrow{\text{ISC}} {}^3[\text{thienyl-C(=O)-CH}_3]^*$$

[6] $$^3[\text{thienyl-C(=O)-CH}_3]^* + \text{PhOH} \longrightarrow \text{PhO}\dot{}\text{*} + \text{thienyl-C(OH)(}\dot{}\text{)-CH}_3\text{*}$$

[7] $$\text{thienyl-C(OH)(}\dot{}\text{)-CH}_3 \longrightarrow \text{1,2,3-thienyl-C(O}^-\text{)(}\dot{}\text{)-CH}_3 + \text{H}^+$$

(III)

The totally emissive polarization observed in the phenoxy radical indicates the operation of the phototriplet CIDEP mechanism (19). However, the relatively much smaller magnitude of the initial polarization can be attributed to three different reasons. Firstly, the initial electron polarization of the acetylthiophene triplet in reaction [5] which arises from the unequal intersystem crossing rates to the three triplet sublevels may not be as large as that in the triplet furyl methyl ketone. The presence of the S atom may have influenced substantially the intersystem crossing processes and the characteristics of the triplet sublevels. Secondly, the initial polarization transferred to the phenoxy radical in reaction [6] depends heavily upon the rate of that chemical reaction, which must compete effectively with the spin depolarization rate of the polarized

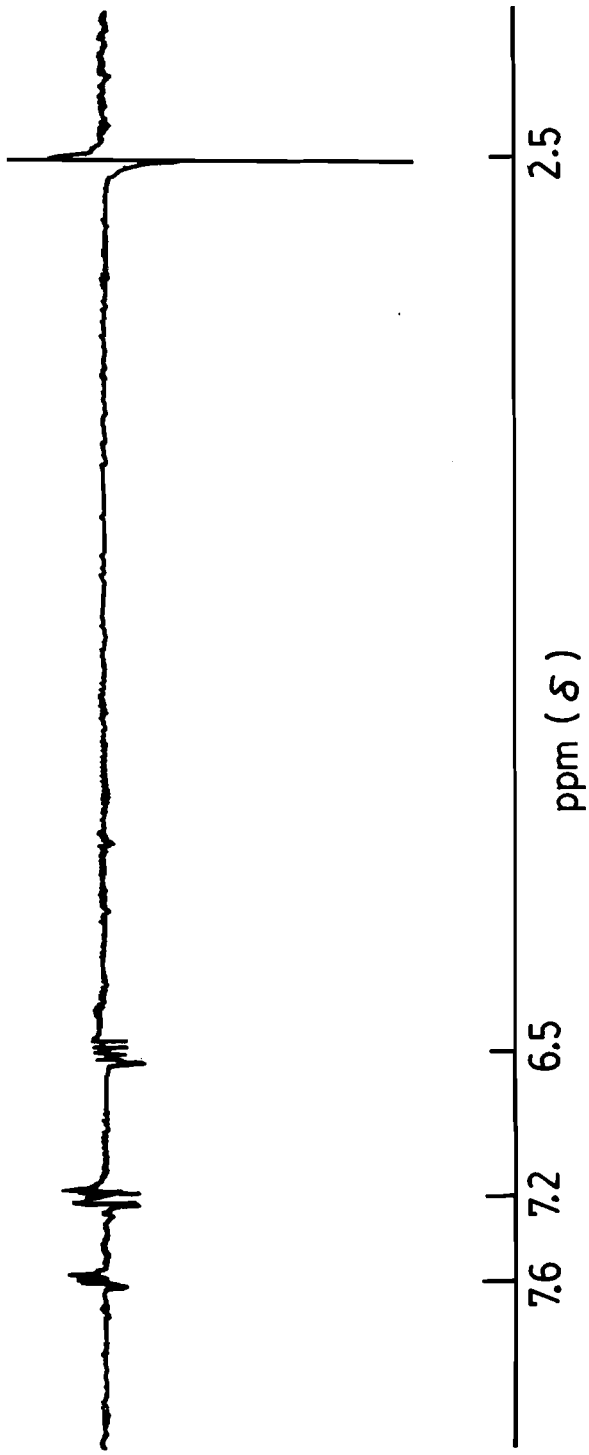

FIG. 3. The *net* proton-FT CIDNP spectrum of 2-furyl methyl ketone obtained in the photoreduction of the parent ketone by pentachlorophenol in $CDCl_3$.

triplet. In this regard, we have compared the cw signal intensity of the phenoxy radicals generated in both the acetylthiophene and the furyl methyl ketone systems under almost identical experimental conditions. The comparable intensity suggests that reaction [6] does not seem to be appreciably slower than reaction [4]. A third possible reason is that the spin–lattice relaxation rate of the polarized triplet acetylthiophene is faster than that of furyl methyl ketone, as the S atom has a larger spin–orbit coupling than the O atom. Indeed, the failure of observing polarization from the counter acetylthiophene derived radical can be partly attributed to the short T_1 of such radical.

The esr observation of the acetylthiophene radical during the photolysis is assigned to its radical anion **III**. The hyperfine coupling constants and their assignments are: $a_1^H = 7.40$ G; $a_2^H = 1.9$ G; $a_3^H = 7.6$ G; and $a_{CH_3}^H = 12.1$ G. These assignments are in good agreement with those observed by Hudson and Lewis (20) who generated the radical anions by the photolysis of acetylthiophene in methanol in the presence of sodium methoxide. In their systems they were able to observe the two conformers of the radical anion at equilibrium:

[8] 
In our photochemical system, the reduction proceeds via the triplet abstraction mechanism, reaction [6], and the radical anion **III** is subsequently formed by the ionization of the "ketyl" radical. The ionization is more favored in 2-propanol solution than in a 10% 2-propanol/90% toluene solution. It is interesting to note that no radical anion was observed when we photolysed a methanol solution of furyl methyl ketone in the presence of sodium methoxide, although with acetylthiophene we obtained essentially the same results as reported by Hudson and Lewis (20). This suggests that acetylthiophene is a much better electron acceptor than furyl methyl ketone and it accounts for the rapid ionization process in reaction [7] but not for the analogous ketyl radical of furyl methyl ketone.

Osmotic and activity coefficients of sodium sulphate in water from 50 to 150°C

OM. N. BHATNAGAR AND ALAN N. CAMPBELL
University of Manitoba, Department of Chemistry, Winnipeg, Man., Canada R3T 2N2

Received June 26, 1980

OM. N. BHATNAGAR and ALAN N. CAMPBELL. Can. J. Chem. **59**, 123 (1981).

The vapour pressure lowering, ΔP, of sodium sulphate solutions in water was measured in the concentration range 0.4 to 1.8 *m* and the temperature range 50 to 150°C by the use of a differential manometer. ΔP values were used to calculate the osmotic coefficient of sodium sulphate solutions. Pitzer's equation for osmotic coefficients was used to evaluate $\beta_{MX}^{(0)}$, $\beta_{MX}^{(1)}$, and C_{MX}^{ϕ} at each temperature. An attempt has been made to explain the changes in these constants in terms of the ion–ion and ion–solvent interactions. Using these constants, the mean activity coefficients, $\gamma_{\pm}$, of sodium sulphate were calculated at different temperatures and concentrations using Pitzer's equation.

OM. N. BHATNAGAR et ALAN N. CAMPBELL. Can. J. Chem. **59**, 123 (1981).

Faisant appel à un manomètre différentiel et opérant à des températures allant de 50 à 150°C, on a mesuré l'abaissement de la vapeur, ΔP, de solutions de sulfate de sodium dans l'eau à des concentrations allant de 0,4 à 1,8 *m*. On a utilisé les valeurs de ΔP pour calculer le coefficient osmotique des solutions de sulfate de sodium. On a utilisé l'équation de Pitzer relative aux coefficients osmotiques pour évaluer $\beta_{MX}^{(0)}$, $\beta_{MX}^{(1)}$ et C_{MX}^{ϕ} à chaque température. On a tenté d'expliquer les variations de ces constantes en fonction d'interactions ion–ion et ion–solvant. En utilisant ces constantes et l'équation de Pitzer, on a calculé les coefficients d'activité moyens, $\gamma_{\pm}$, du sulfate de sodium à différentes températures et à différentes concentrations.

[Traduit par le journal]

Introduction

Fundamental studies of electrolyte solutions at high temperatures have lagged behind those on pure gases and solids because experiments are difficult and their interpretation requires much sophistication. Until recently, the data available at high temperature lacked precision but recently some excellent work on thermodynamic properties of electrolyte solutions in water has been reported (1–7). In a previous paper (8) the authors reported the osmotic and activity coefficients of lithium chloride derived from measurements of the lowering of vapour pressure in the temperature range 50 to 150°C. In this paper the authors report the osmotic and activity coefficients of sodium sulphate in the concentration range 0.4 to 1.8 *m* and the temperature range 50 to 150°C.

Experimental

Analytical grade sodium sulphate was used without further purification. The concentrations of solution were determined after each experiment by gravimetric analysis of the solution as barium sulphate (9*a*). The experimental procedure was essentially the same as before (8). The only changes were that silicone oil was used in the bath, since it does not deteriorate at high temperatures. Also, four multijunction thermocouples were used to monitor the bath temperature constantly. These thermocouples were strategically located in the oil bath around the vapour pressure cell. The vapour pressure lowering was measured with a differential manometer as before (8).

Results and Discussion

The observed lowering of vapour pressure, ΔP, in Torr, was corrected to the density of mercury at 0°C. The size of the bulbs in the vapour pressure cell was reduced to minimize the vapour space and hence it was not necessary to make any temperature corrections to concentrations due to evaporation.

The possibility of HSO_4^- ion formation according to the reaction

$$SO_4^{2-} + H_2O \rightleftharpoons HSO_4^- + OH^-$$

was looked into. The second dissociation constant of sulphuric acid has been reported at high temperature by Marshall and Jones (9*b*). This was used to calculate the HSO_4^- ion concentration in the temperature and concentration range of present work. The HSO_4^- ion concentration was of the order of 10^{-5} *m* and was considered insignificant.

The osmotic coefficients were calculated from the following equation:

$$[1] \quad \phi = \frac{1000}{\nu m M_1 RT}\left[RT \ln (P^0/P) - \int_P^{P^0} \xi \mathrm{d}p - \overline{V}_1^{\,0}(\mathrm{l})\Delta P\right]$$

where ϕ is the osmotic coefficient, T the absolute temperature, R the gas constant, M_1 the molecular weight of water, m the molality, v the number of ions resulting from complete ionization of one molecule, P^0 and P are the vapour pressure of pure water and solution respectively, assuming the solute to be non-volatile.

The first term in the bracket gives the osmotic coefficient at low vapour pressures, the second term gives the corrections for the deviations of the vapour from the perfect gas law, and the third term is an

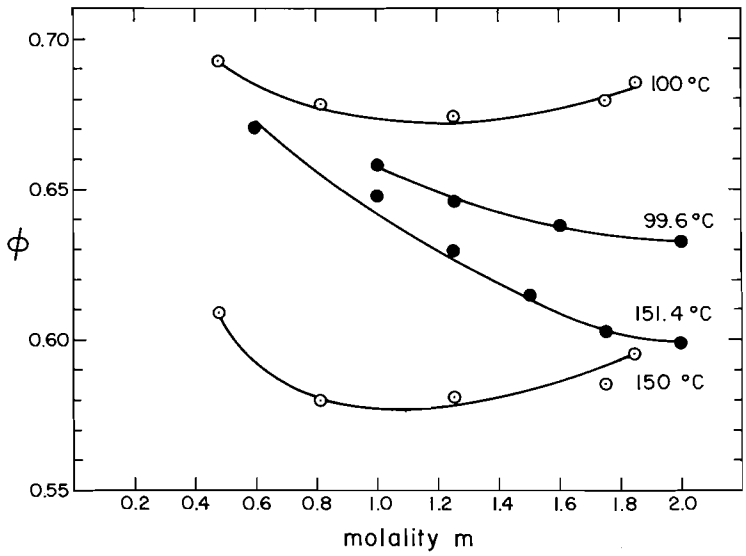

FIG. 1. Osmotic coefficient vs. molality m of sodium sulphate in water. ○ Data from present work, ● data from refs. 15 and 16.

adequate approximation for the isothermal compression of the solution from its own vapour pressure to that of pure water. The integrand ξ was calculated using the equation given by Smith, Keyes, and Gerry (10). $V^0(l)$ the molar volume of pure water and P^0 were calculated from the equations given in ref. 10. $\bar{V}_1{}^0(l)$ is used instead of $\bar{V}_1(l)$, the partial molar volume of water, because under these conditions the difference is negligibly small. Recently Pitzer (11) has developed a set of equations for thermodynamic properties of electrolyte solutions which are very general and can be applied to any valency type compounds. These equations are semi-empirical in nature but are quite successful in predicting the thermodynamic properties of electrolyte solutions up to 6 M (12–14). The relevant equations for osmotic and activity coefficients for a pure electrolyte are given as follows.

$$[2]\quad \phi - 1 = -|Z_M Z_X| A\phi \frac{I^{1/2}}{1 + bI^{1/2}} + \frac{m2\nu_M\nu_X}{\nu}[\beta_{MX}{}^{(0)} + \beta_{MX}{}^{(1)} \exp(-\alpha I^{1/2})] + \frac{m^2 2(\nu_M\nu_X)^{3/2} C_{MX}{}^{\phi}}{\nu}$$

$$[3]\quad \ln \gamma_{\pm} = -|Z_M Z_X| A\phi \left[\frac{I^{1/2}}{1 + bI^{1/2}} + \frac{2}{b}\ln(1 + bI^{1/2})\right] + \frac{m2\nu_M\nu_X}{\nu}\left\{2\beta_{MX}{}^{(0)} + \frac{2\beta_{MX}{}^{(1)}}{\alpha^2 I}\left[1 - \left(1 + \alpha I^{1/2} - \frac{\alpha^2 I}{2}\right)\exp(-\alpha I^{1/2})\right]\right\} + \frac{3m^2 2(\nu_M\nu_X)^{3/2} C_{MX}{}^{\phi}}{2\nu}$$

where Z_M and Z_X are the positive and negative ionic charges in electronic units. Likewise ν_M and ν_X are the number of ions of each type in the formulae and $\nu = \nu_M + \nu_X$. I is the ionic strength and $A\phi$ is the Debye–Hückel coefficient for the osmotic functions given by:

$$[4]\quad A\phi = 1/3\left(\frac{2\pi N_0 \rho\omega}{1000}\right)^{1/2}\left(\frac{e^2}{DkT}\right)^{3/2}$$

where all terms have the usual meaning and are explained elsewhere (14). The values of $A\phi$ in water at various temperatures for the present calculations were taken from ref. 14. The coefficients $\beta_{MX}{}^{(0)}$ and $\beta_{MX}{}^{(1)}$ account for the various short range interactions between M and X and for cosphere overlap effects, while $C_{MX}{}^{\phi}$ accounts for triple ion interaction and is important at high concentrations. The parameters α and b were given a value of 2 and 1.2 respectively for the present calculations, and were treated as independent of temperature. Pitzer and Mayorga (12) have used the same values of α and b for all different types of electrolytes and found them satisfactory. The experimental values of ϕ and m were used to evaluate the best values of $\beta_{MX}{}^{(0)}$, $\beta_{MX}{}^{(1)}$, and $C_{MX}{}^{\phi}$ which were in turn used to calculate the mean activity coefficient, $\gamma_{\pm}$, by eq. [3]. These activity coefficients were compared with those obtained by eq. [5] using graphical integration.

$$[5]\quad \ln \gamma_{\pm} = -(1 - \phi) - 2\int_0^{m^{1/2}} \frac{1 - \phi}{m^{1/2}}\, dm^{1/2}$$

The osmotic coefficients of sodium sulphate at various temperatures and concentrations are given in Table 1. For comparison the results have been plotted in Fig. 1 at 100 and 150°C and those reported by Soldano and co-workers (15, 16) at 99.6 and 151.4°C using the isopiestic method. There is a great difference in the two sets of data. Similar differences were observed for the LiCl data (8). Recently, Holmes, Baes, and Mesmer (7) determined the osmotic coefficients of KCl, $CaCl_2$, and $MgCl_2$ by the isopiestic method, and compared them with the earlier isopiestic results of Soldano and co-workers (16); they found the agreement to be fair to poor above 100°C.

Equation [2] uses experimental osmotic coefficients and concentrations to determine $\beta_{MX}^{(0)}$, $\beta_{MX}^{(1)}$, and C_{MX}^{ϕ}. Table 2 gives the values of $\beta_{MX}^{(0)}$, $\beta_{MX}^{(1)}$, and C_{MX}^{ϕ} at each temperature from 50 to 150°C. The second virial coefficient in Pitzer's equation (11) is a complicated function of many interactions and its physical interpretation in terms of molecular quantities is not simple. As has been discussed by Pitzer (11) the principal contributions to $\beta_{MX}^{(1)}$ will come from short range interactions of unlike charged ions while the interactions of like and unlike charged ions will both contribute to $\beta_{MX}^{(0)}$. Since the second virial coefficient is a weighted mean of the interactions of pairs of ions with signs $++$, $+-$, and $--$, it was shown by Pitzer and Mayorga (12) that the relative weighting of $+-$ interactions is greatest at low ionic strength and $++$ and $--$ terms become more important at higher ionic strength, but never equal to the weight of $+-$ interactions. The $\beta_{MX}^{(0)}$ in Table 2 increases with increasing temperature, reaches a maximum at around 125°C, and then decreases. Similar behaviour was observed for $\beta_{MX}^{(0)}$ values for NaCl (14). The $\beta_{MX}^{(1)}$ steadily decreases with increasing temperature, but this is not the case for NaCl (14). This would indicate that with increase in temperature the short range interactions between like and unlike charged ions, $+-$ type, become greater and the repulsive forces of the type $++$ and $--$ decrease with increase in temperature. The change of $\beta_{MX}^{(0)}$ and $\beta_{MX}^{(1)}$ for Na_2SO_4 with temperature is similar to that found for KCl and NaCl in water–methanol mixture (17). By addition of methanol to water the dielectric constant of the solvent mixture decreases and in the present work the same effect results by raising the temperature. However, it is interesting that $\beta_{MX}^{(1)}$ for NaCl (14) in water increases with increasing temperature while $\beta_{MX}^{(1)}$ for NaCl in methanol–water mixture (17) decreases with higher methanol content. In water sodium and sulphate ions are hydrated to a certain extent, and due to the difference in the ionic sizes and surface charge density

their hydrated sizes will be different. If the hydrated size of the ion decreases with increasing temperature, it will result in decrease of $\beta_{MX}^{(1)}$ and increase in $\beta_{MX}^{(0)}$ values. The mean activity coefficient, $\gamma_{\pm}$, calculated from Pitzer's eq. [3] and by eq. [5], are in good agreement if the inevitable errors of graphical integration are considered (Table 3). The activity coefficients show little change with temperature up to 100°C. Above this temperature the change is considerable. It is also interesting to note that the $\gamma_{\pm}$ values of Na_2SO_4 are much smaller as compared to NaCl at comparable concentrations and temperatures. Further measurements at higher concentrations and temperature are being carried out with greatly modified equipment in order to understand better the behaviour of Na_2SO_4 and other electrolytes in aqueous solutions.

Activity coefficients, densities, dipole moments, and surface tensions of the system triethylamine–methylethylketone–water

ALAN N. CAMPBELL

Department of Chemistry, University of Manitoba, Winnipeg, Man., Canada R3T 2N2

Received May 5, 1980

ALAN N. CAMPBELL. Can. J. Chem. **59**, 127 (1981).

The properties named in the title have been determined by standard methods. Viscosity, molar volume, and orientation polarisation all indicate abnormalities of the nature of association between the components.

The most interesting result is that of surface tension which indicates that, in the case of the binary system triethylamine–water, a surface layer of constant composition is formed over a wide range of total composition. When, by a rise in temperature of two or three degrees, this layer becomes unstable, it splits into two phases of different composition. The surface layer may then be instantaneously reformed and so on. A mechanism for the generation of a two-phase system is thus established. The data for the three-phase, isothermal, system are not so convincing, for reasons that are suggested.

ALAN N. CAMPBELL. Can. J. Chem. **59**, 127 (1981).

On a déterminé les propriétés mentionnées dans le titre en utilisant des méthodes normales. La viscosité, le volume molaire et l'orientation de la polarisation révèlent tous des anomalies dans la nature de l'association entre les composants.

Le résultat le plus intéressant est celui de la tension superficielle; il révèle que dans le cas du système binaire triéthylamine–eau, il se forme une couche de surface dont la composition est constante pour des compositions totales très variables. Quand cette surface devient instable, par suite d'une augmentation de la température de 2 à 3°C, elle se sépare en deux phases de compositions différentes. La couche de surface peut se reformer instantanément et ainsi de suite. On a donc établi un mécanisme de formation d'un système à deux phases. Pour les raisons invoquées les données relatives à un système isotherme à trois phases ne sont pas convaincantes.

[Traduit par le journal]

Introduction

A recent paper by the author (1) has defined the compositions of equilibrium liquid layers of the system triethylamine – methylethyl ketone – water, at constant temperatures lying between 0 and 160°C. The problem of why some liquid pairs (or triplets) separate into two layers, while others do not, has been approached via the different theories of solution. As an attempt to have a better description of the problem, the properties mentioned in the title have been studied. Some interesting results as to the mechanism of separation result from a study of surface tension.

Since the mere existence of two layers implies a large degree of non-ideality, it is to be expected that the activity coefficients in at least one layer should deviate widely from unity, and this was found to be so.

It seems obvious that there must be some connection between dielectric constant and partial miscibility though what that connection is, is not obvious. Nevertheless, the dielectric constants and refractive indices were determined, and the derived quantities, distortion polarisation, and orientation polarisation calculated.

The determination of surface tension at 16°C for the system triethylamine–water, at which temperature all mixtures are homogeneous and at 25°C for the ternary system triethylamine–methylethylketone–water was carried out as a matter of routine but the results were found to be very instructive.

Perhaps the best method, at least the one most free from approximations and assumptions, of obtaining activities and activity coefficients, is that of vapour pressure determination. Provided the pressures are low (not greater than 100 Torr) the vapours may be assumed to obey the ideal gas laws, and the simple relationship

$$[1] \quad a_1 = p_1/p_1^0$$

applies, where p_1 is the partial pressure of component 1, and p_1^0 the vapour pressure in the pure state. If the vapour pressures are higher, as in the determination of activity coefficients at higher temperatures (above 100°C) (2), the assumption of ideality can no longer be justified and a more complicated equation of state must be used. This usually requires the use of a computer programme. Worse still, no equation of state, except perhaps the virial equation with a sufficient number of terms, is entirely satisfactory. At room temperature, however, say 25°C, the simple relationship of eq. [1] is entirely satisfactory.

Since the compositions of congruent layers at 25°C (and other temperatures) have already been determined (1), it remained only to find the total vapour pressure (same for both layers) and the composition of the vapour from one or both layers.

Applications of Dalton's law then gives the partial pressures. Activity coefficients result from eq. [2]

[2] $a_1 = \gamma_1 N_1$

where N_1 is the mole fraction of component 1 in the liquid state. Since N_1 is very different in the two congruent layers, the activity coefficients of the same component are very different.

Experimental

For the investigation of equilibrium layers, a mixture of composition such as would give roughly equal volumes of each layer was stirred for 24 h at 25°C; samples of each (homogeneous) layer were then removed by suction.

Total vapour pressure was determined with a closed manometer and vapour composition by the air saturation method (error ±0.1 Torr). The latter method is not good for the determination of total vapour pressure because of the difficulty of ensuring complete saturation of the air and of knowing the exact volume of air (or nitrogen) passed through. The method, however, is very good for the determination of vapour composition, where it is not necessary to know the volume of gas passed through. The method has been frequently described by the author and by others (3). In this investigation, a presaturator at 30°C preceded the saturator at 25°C. The vapour was condensed in absorption tubes immersed in liquid nitrogen and analysed for triethylamine by conductimetric titration with standard hydrochloric acid. This figure, together with a determination of density, gave the total composition. The error in this analysis is ±1% of total content.

Densities were determined with large (50 cm^3) pyknometers and dielectric constants with a Sargent oscillometer. The error in density is not more than ±0.001 and in dielectric constant 0.1 unit.

Surface tension was determined at 16°C, a temperature at which all compositions of the triethylamine–water system are homogeneous. As the temperature of tap-water in Winnipeg in the winter is never above 10°C, it was easy to maintain a thermostat at 16°C by using a mercury–toluene regulator connected to a pumping system, so that the pump was activated whenever the temperature rose above 16°C. The capillary rise method, in the form of the two capillary method of Sugden (4), was used. The radii of cross-section of the capillaries were 9.800×10^{-3} cm and 2.260×10^{-2} cm respectively. With such fine capillaries, the capillary rise for water was 8.34 cm. Error of measurement equals ±0.01 cm.

Results

Vapour pressures, partial pressures, activities, and activity coefficients of TriE, MEK, H_2O are given in Table 1. Table 2 lists the dielectric constants, densities, refractive indices, distortion and orientation polarisations for the triethylamine–water system at 16°C. These results are shown graphically in Figs. 1 and 2.

The results of Campbell and Lam (5) show a pronounced viscosity maximum over the miscibility gap.

The surface tension of the triethylamine–water mixtures at 16°C is shown in Table 3.

In a recent investigation (1), the author studied

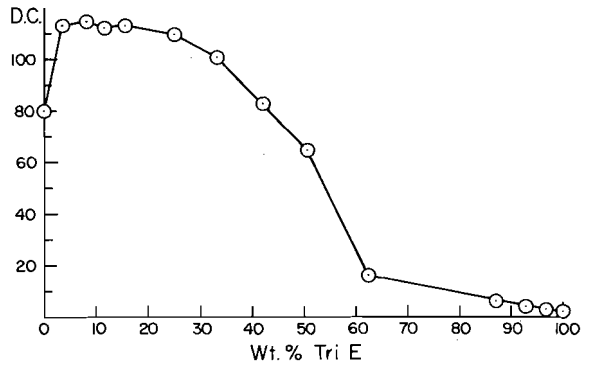

FIG. 1. Dielectric constant vs. wt.% triethylamine.

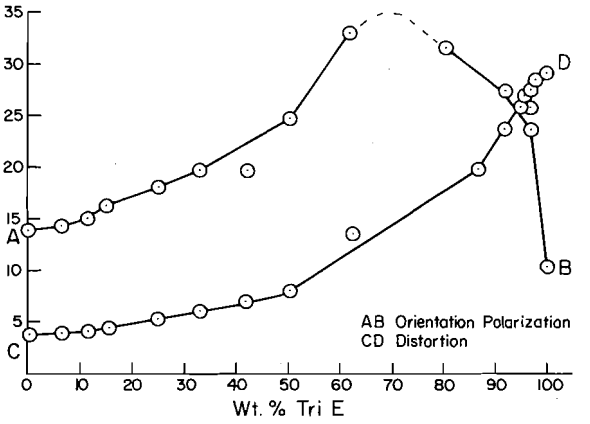

FIG. 2. Distortion and orientation polarisation vs. wt.% triethylamine.

the equilibrium conditions in the system triethylamine–methylethylketone–water and showed that at 25°C, there are two areas of heterogeneity: one, the larger, based on two layers containing water and triethylamine only. With addition of methylethylketone the area shrinks, giving rise to an isothermal critical composition (plait point). By analogy with the work just described on the triethylamine–water system it would seem that a series of compositions, tangential to the three-component system, should also show constant surface tension and constant composition of surface layer. Accordingly, eight mixtures were made up, lying on a straight line (in the triangular diagram) running from 12 wt.% methylethylketone – 88% water, to the point 37% triethylamine – 63% methylethylketone. The densities and surface tensions are given in Table 4.

Discussion

The densities, though crude, are sufficient to allow the showing of the trend in molar volume as shown in Fig. 3. In the system triethylamine–wa-

ter, the molar volume increases slowly and uniformly up to 60 wt.% triethylamine, but after this concentration, it increases much more rapidly to the value for pure triethylamine. This indicates that in solutions containing less than 60 wt.% (0.21 mole fraction triethylamine), the triethylamine is bound in some way to the water: further increases in triethylamine content leave the triethylamine more or less free to exhibit its own large molar volume. The viscosity results can be explained in the same way.

That the activity coefficients of triethylamine and of methylethylketone should be greater than unity is not surprising. That they should be so much greater than unity is not unknown. The activity coefficients of water are much smaller. The ratio of the activity coefficients of the same substance in the two layers is not constant, nor is there any reason why it should be. The deduction from the above that all the components of the homogeneous phases, when two liquid layers are found, are markedly non-ideal is to be expected.

In the binary system triethylamine–water, when dielectric constant is plotted against triethylamine content, it appears that the dielectric constant rises slowly up to 5% triethylamine, though there may be some doubt as to this because of the not inappreciable electric conductance of these weak solutions. After this apparent maximum, however, the dielectric constant falls rapidly up to 60 wt.% triethylamine (the same concentration as for molar volume) after which it decreases slowly and regularly to that of pure triethylamine. Much the same behaviour is shown by the distortion polarisation (obtained from the refractive index) and the orien-

68.42	—	31.58	0.7826	22.75

tation polarisation (from the dielectric constant and the distortion polarisation) (Fig. 2). Up to 50 wt.% triethylamine, both distortion and orientation polarisation increase slowly and regularly, but after this concentration, the rate of increase is much greater, leading, for the orientation polarisation, to a maximum at 70 wt.%.

If the (unlikely) assumption is made that water is acting merely as a diluent, and preserves its molar polarisation of 14.12, it is possible to calculate the molar polarisation of the triethylamine in solution. For example, a solution containing 74.14 wt.% triethylamine (mole fraction = 0.3378) has an experimental molar polarisation of 32.94.

$$32.94 = 0.3378x + (0.6625)(14.12)$$

$$x = 69.70$$

When this is done, however, and the results plotted, they appear very irregular: no obvious meaning can be attached to the curve.

When the surface tension results for the binary system are plotted (Fig. 4), it appears that the surface tension drops rapidly from that of water to a value of 21.30, which is below that of pure triethylamine, constant within the limits of experimental error. This value is reached with an addition of 16 wt.% triethylamine and continues constant up to 93% triethylamine: these are roughly the limits of the miscibility gap. In terms of the Gibbs adsorption theorem, this means that a surface layer of constant composition is formed by all mixtures lying within the gap. Since a rise in temperature of

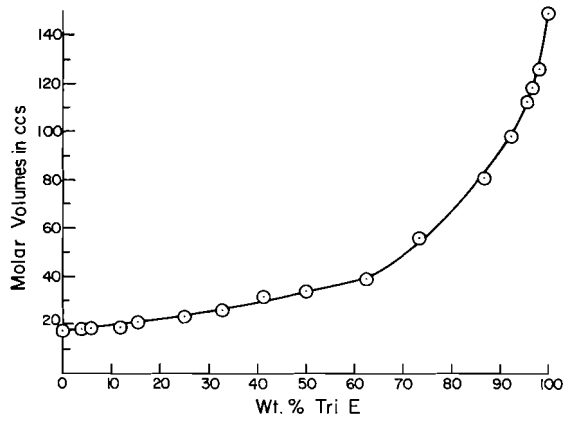

FIG. 3. Molar volume vs. wt.% triethylamine.

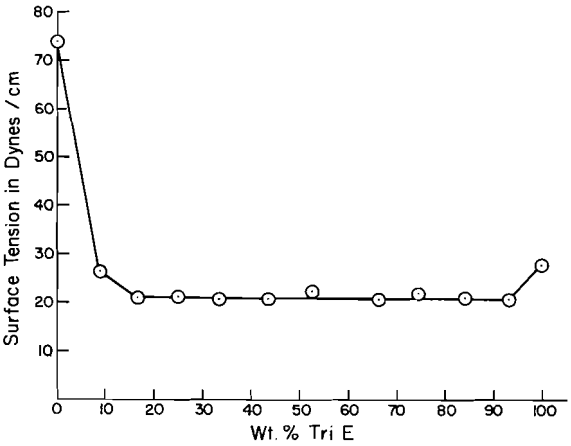

FIG. 4. Surface tension vs. wt.% triethylamine.

two or three degrees causes the mixtures to separate into two layers, it would seem that the surface layer becomes unstable and separates into two phases, only to be immediately reformed from the body of the liquid. The constancy of composition of the surface layer could easily be proved experimentally by means of a surface balance, but this seems unnecessary in view of the validity of the Gibbs theorem.

For the surface tension experiments on the three-component system, it is apparent that constancy cannot be claimed and indeed it should not be expected. The minimum on the temperature composition curve for the two-component system is very flat so that the tangential line is never very far from the heterogeneous region. The corresponding curve for the three-component system, however, shows high curvature, so that some compositions on the tangential line are far removed from heterogeneity. If the surface tension figures are plotted against triethylamine content, it appears that the surface tension drops from 36.52 dyn/cm at 12.48 wt.% MEK, 87.52% H_2O, to 27.07 dyn/cm at 20.39% MEK and 12.96% TriE, from which point the surface tension varies between 26 and 22 dyn/cm up to the binary system MEK–TriE. Probably if the mixtures had been chosen not on a straight line but so as to run parallel to the boundary of heterogeneity, a closer approach to constancy would have been found.

The outer-sphere oxidation of ascorbic acid by the thioureapentacyanoferrate(III) ion

DONAL H. MACARTNEY AND ALEXANDER MCAULEY[1]

The Department of Chemistry, University of Victoria, Victoria, B.C., Canada V8W 2Y2

Received July 25, 1980

DONAL H. MACARTNEY and ALEXANDER MCAULEY. Can. J. Chem. **59**, 132 (1981).

The oxidation of ascorbic acid by thioureapentacyanoferrate(III) has been investigated over the pH range 0.8–7.2 at an ionic strength of 1.0 *M* ($NaClO_4$). The variations in the rates of oxidation with hydrogen ion concentration are consistent with a reaction scheme involving three pH-related species; ascorbic acid (H_2A) ($k_1 = 0.111\ M^{-1}\ s^{-1}$, $\Delta H_1^{\ddagger} = 5.1$ kcal mol^{-1}, $\Delta S^{\ddagger} = -46$ cal deg^{-1} mol^{-1}), the ascorbic anion, (HA^-) ($k_2 = 66\ M^{-1}\ s^{-1}$, $\Delta H_2^{\ddagger} = 5.4$ kcal mol^{-1}, $\Delta S_2^{\ddagger} = -32$ cal deg^{-1} mol^{-1}) and the ascorbic dianion, (A^{2-}) ($k_3 = 8.78 \times 10^7\ M^{-1}\ s^{-1}$, $\Delta H_3^{\ddagger} = 3.1$ kcal mol^{-1}, $\Delta S_3^{\ddagger} = -12$ cal deg^{-1} mol^{-1}). The low reduction potential of $Fe(CN)_5TU^{2-}$ ($E^0 = 0.35$ V) permits the measurement of the rate of oxidation of the ascorbate dianion, not previously investigated with metal complexes. The second acid dissociation constant of ascorbic acid ($HA^- \rightleftharpoons A^{2-} + H^+$) has been measured in 1.0 *M* $NaClO_4$ over the temperature range studied. A relationship between the rate of oxidation and the reduction potentials of the ascorbic acid species is shown.

DONAL H. MACARTNEY et ALEXANDER MCAULEY. Can. J. Chem. **59**, 132 (1981).

On a étudié l'oxydation de l'acide ascorbique par le thiouréepentacyanoferrate(III) dans un intervalle de pH allant de 0,8 à 7,2 et à une force ionique de 1,0 *M* ($NaClO_4$). Les variations des vitesses d'oxydation avec la concentration en ions hydrogène sont en accord avec un processus réactionnel impliquant 3 espèces reliées au pH; l'acide ascorbique (AH_2) ($k_1 = 0{,}111\ M^{-1}\ s^{-1}$, $\Delta H_1^{\ddagger} = 5{,}1$ kcal mol^{-1}, $\Delta S^{\ddagger} = -46$ cal deg^{-1} mol^{-1}), l'anion ascorbate (AH^-) ($k_2 = 66\ M^{-1}\ s^{-1}$, $\Delta H_2^{\ddagger} = 5{,}4$ kcal mol^{-1}, $\Delta S_2^{\ddagger} = -32$ cal deg^{-1} mol^{-1}) et le dianion ascorbate (A^{2-}) ($k_3 = 8{,}78 \times 10^7\ M^{-1}\ s^{-1}$, $\Delta H_3^{\ddagger} = 3{,}1$ kcal mol^{-1}, $\Delta S_3^{\ddagger} = -12$ cal deg^{-1} mol^{-1}). Le faible potentiel de réduction du $Fe(CN)_5TU^{2-}$ ($E^0 = 0{,}35$ V) permet de mesurer la vitesse d'oxydation du dianion ascorbate dont l'oxydation par des complexes métalliques n'a pas été étudiée antérieurement. On a mesuré la deuxième constante de dissociation de l'acide ascorbique ($HA^- \rightleftharpoons A^{2-} + H^+$) dans une solution de $NaClO_4$ 1,0 *M* dans l'intervalle de température utilisée. On met en évidence une relation entre la vitesse d'oxydation et les potentiels de réduction de l'acide ascorbique et de ses deux anions.

[Traduit par le journal]

Introduction

The oxidation of ascorbic acid to dehydroascorbic acid has been investigated using a number of metal complexes as oxidizing agents (1–7). Among the various metal ions, complexes of iron(III) have frequently been used. The reactions of ascorbic acid with tris(1,10-phenanthroline)-iron(III) and its derivatives have been studied (2) with the differences in oxidation rates discussed in terms of free energy changes as related by the Marcus theory (8) to outer-sphere electron-transfer reactions.

These previous studies have involved primarily metal complexes with reduction potentials in the range 0.80–1.25 V. As a result, the rate constants for the acid-dependent pathway involving the ascorbate anion often approach the diffusion-controlled limit (3). In order to obtain the specific rates of oxidation of ascorbic acid (H_2A) and the ascorbate anion (HA^-) such kinetic studies were performed in solutions which were 0.01–1.0 *M* in acid. With thioureapentacyanoferrate(III) as the oxidizing agent the lower reduction potential (0.35 V) allows the measurement of rate constants in solutions up to pH 7. Under the latter conditions, a third species, the ascorbate dianion (A^{2-}), is involved in the reduction process. In this paper we present rate data on the various reactions, and using reduction potentials, correlate the rates of oxidation to the E^0 values for the ascorbic acid species.

Experimental Section

Reagents

Thioureapentacyanoferrate(III) solutions were prepared by adding a ten-fold excess of recrystallized thiourea (Fisher) to freshly prepared solutions of aquopentacyanoferrate(III) (1×10^{-4} *M*). Sodium pentacyanoammineferrate(II) was prepared by a standard procedure (ref. 9, p. 1511) from sodium nitroprusside, and recrystallized several times from concentrated ammonia. The pentacyanoammineferrate(III) may be formed by oxidation of the iron(II) complex with sodium nitrite (ref. 9, p. 1512). The corresponding aquo species was produced in solution by addition of NaOH (~pH 11) followed 15 min later by $HClO_4$ to ~pH 4. The concentration of $Fe(CN)_5OH_2^{2-}$ solutions was determined from absorbances in the visible spectrum (11) (λ340 nm; ε = 748 M^{-1} cm^{-1}, λ394 nm; ε = 743 M^{-1} cm^{-1}). The thiourea was then added, prior to the possible onset of any dimerization of the iron(III) species (11). Ascorbic acid (Sigma) solutions ($0.2–8.0 \times 10^{-2}$ *M*) were prepared in degassed buffered solutions just prior to their use.

Kinetic Measurements

The kinetic experiments were carried out using a stopped-flow apparatus described previously (12). Reactions were studied at temperatures between 10.4 and 32.5°C with thermostatting to ±0.05°C. The reduction of $Fe(CN)_5TU^{2-}$ was followed at 600 nm, its λ_{max} in the visible region. Perchloric acid was used to control the acidity of solutions in the 0.8–2.2 pH range, while phthalate, phosphate, or borate buffers were used

at higher pH levels. The ionic strength was maintained at 1.0 *M* in all cases using $NaClO_4$.

All kinetic measurements were made under pseudo-first-order conditions with ascorbate acid in at least a ten-fold excess. Data obtained from oscilloscope traces of photomultiplier output were collected by a PCM-12 minicomputer. Plots of $\ln (A_t - A_\infty)$ were linear for at least 3 half-lives.

Dissociation Constants

The second acid dissociation constant of ascorbic acid was measured at four temperatures between 10 and 34°C at 1.0 *M* ($NaClO_4$) ionic strength. A Radiometer 26 instrument with a GK2311C combination electrode, calibrated (13) at several pH values, was used. The ascorbic acid solutions were prepared in degassed distilled water and nitrogen was bubbled into the thermostatted (±0.1°C) cell throughout the titrations.

Spectra

A Varion Techtron 635 spectrophotometer was employed in the measurement of the visible spectra and in the determination of the stoichiometry of the redox reaction.

Cyclic Voltammetry

The reduction potential of $Fe(CN)_5TU^{2-/3-}$ was determined by cyclic voltammetry using a Princeton Applied Research Model 173 instrument with a PAR Model 175 Universal Programmer. Platinum wire working and counter electrodes and a saturated (NaCl) calomel reference electrode were employed.

Results[2] and Discussion

The complex $Fe(CN)_5TU^{2-}$ (TU = thiourea) is formed in the substitution reaction of aquopentacyanoferrate(III) with thiourea. This species is blue in aqueous solution with a maximum absorbance in the visible region at 600 nm ($\varepsilon = 2300\ M^{-1}\ cm^{-1}$). Reduction of the iron(III) complex by ascorbic acid yields a pale yellow–green solution with a visible maximum at 406 nm ($\varepsilon = 325\ M^{-1}\ cm^{-1}$). This peak is identical to that found for $Fe(CN)_5TU^{3-}$, formed in the reaction of aquopentacyanoiron(II) with thiourea (14). The visible spectra of the thioureapentacyanoferrate(II)/(III) species are shown in Fig. 1.

The stoichiometry of the reaction was determined by spectrophotometric (600 nm) titrations of a fixed concentration of $Fe(CN)_5TU^{2-}$ with varying amounts of ascorbic acid. The oxidant:reductant ratio was found to be 2.01 ± 0.05:1. The overall reaction may be written as

$$[1] \quad 2Fe(CN)_5TU^{2-} + H_2A \rightarrow 2Fe(CN)_5TU^{3-} + A + 2H^+$$

The first acid dissociation constant, K_1, for ascorbic acid ($H_2A \rightleftharpoons HA^- + H^+$) has been measured under various conditions of ionic strength and temperature (1–4, 15–17). The values used in this work

[2]Complete set of detailed rate data is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

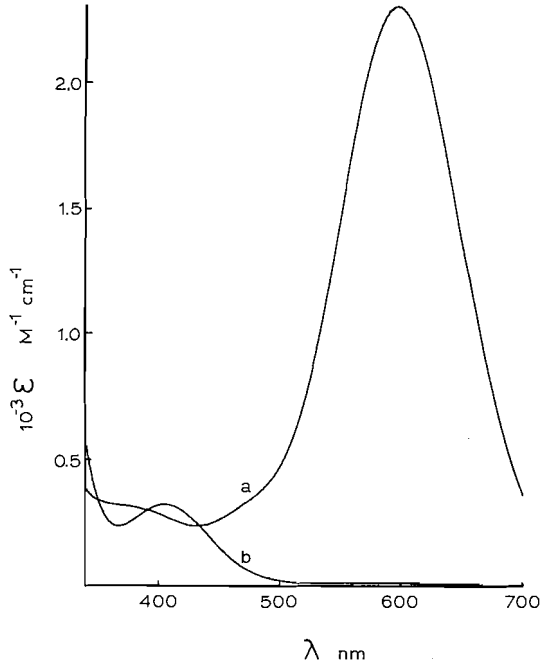

FIG. 1. Visible spectra of thioureapentacyano iron(III) and iron(II): (*a*) $Fe^{III}(CN)_5TU^{2-}$, (*b*) $Fe^{II}(CN)_5TU^{3-}$ formed upon addition of ascorbic acid.

(Table 2) are from interpolations of these literature values. The value of the second dissociation constants, K_2 ($HA^- \rightleftharpoons A^{2-} + H^+$), is less accurately known (4, 15, 16) for the temperature range and ionic strength used in this study and was therefore determined under the present conditions. At an ionic strength of 1.0 *M* ($NaClO_4$) the following values were found: at 10.0°C; $3.47 \pm 0.20 \times 10^{-12}\ M$, 16.2°C; $4.17 \pm 0.20 \times 10^{-12}\ M$, 25.4°C; $5.89 \pm 0.20 \times 10^{-12}\ M$, 34.0°C; $8.32 \pm 0.20 \times 10^{-12}\ M$.

Kinetics and Mechanism

The reaction between ascorbic acid and $Fe(CN)_5TU^{2-}$ was carried out under pseudo-first-order conditions with the reductant in excess. Plots of $\ln (A_t - A_\infty)$ against time were linear for at least three half-lives. The reaction is also first-order in ascorbic acid as shown in Fig. 2 where the rates have been measured at several acidities. The rate law may be expressed as

$$[2] \quad -d[Fe(CN)_5TU^{2-}]/dt = 2k_0[Fe(CN)_5TU^{2-}][H_2A]$$

Oxidations of ascorbic acid have been generally considered to take place in two one-electron steps with the formation of an ascorbate radical intermediate which is further oxidized to dehydroascorbic acid (A) (1–7). Previous studies (1–7) have

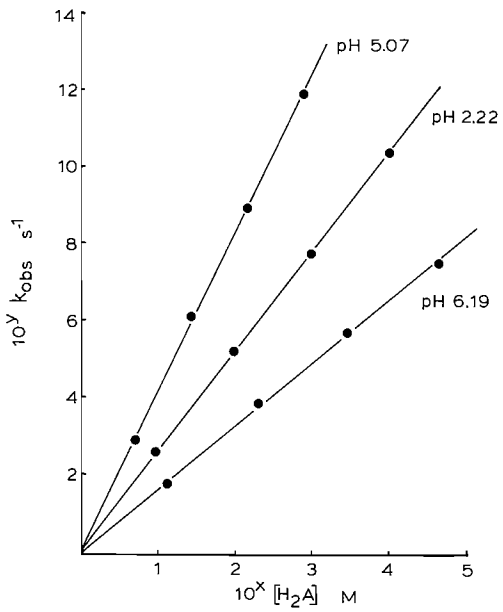

FIG. 2. Plots of k_{obs} against ascorbic acid concentration: pH 2.22; $x = 2, y = 2$, pH 5.07; $x = 3, y = 1$, pH 6.19; $x = 4, y = 1$.

demonstrated the dependence of the rate on the hydrogen ion concentration in the range $[H^+] = 0.01–1.0\ M$. This is attributed to two reacting forms of the reductant, the undissociated ascorbic acid (H_2A), and the ascorbate anion (HA^-). In the reduction of $Fe(CN)_5TU^{2-}$, where in the range pH 2–7.5 there is no change in the spectrum of the oxidant, the acid dependence continues as the acidity is decreased above pH 5. This can be attributed to a third reducing agent, the ascorbate dianion (A^{2-}).

The following reaction scheme is consistent with the data at pH 0.8–2.2:

$$[3] \quad H_2A \overset{K_1}{\rightleftharpoons} HA^- + H^+$$

$$[4] \quad HA^- \overset{K_2}{\rightleftharpoons} A^{2-} + H^+$$

$$[5] \quad Fe(CN)_5TU^{2-} + H_2A \xrightarrow{k_1} Fe(CN)_5TU^{3-} + HA^{\cdot} + H^+$$

$$[6] \quad Fe(CN)_5TU^{2-} + HA^- \xrightarrow{k_2} Fe(CN)_5TU^{3-} + A^{-\cdot} + H^+$$

$$[7] \quad HA^{\cdot} \overset{K_r}{\rightleftharpoons} A^{-\cdot} + H^+$$

Under the conditions used in this study the ascorbate intermediate is a radical anion. Only at high acid concentrations is the first pK_a of the $A^{-\cdot}$ species approached (18) ($pK_r = -0.45$).

At higher pH's (2.2–7.0) the additional reaction pathway is observed.

$$[8] \quad Fe(CN)_5TU^{2-} + A^{2-} \xrightarrow{k_3} Fe(CN)_5TU^{3-} + A^{-\cdot}$$

$$[9] \quad Fe(CN)_5TU^{2-} + A^{-\cdot} \xrightarrow{\text{fast}} Fe(CN)_5TU^{3-} + A$$

The reaction rates at various acidities at $T = 25°C$ are presented in Table 1. The observed second-order rate constant, k_0, may be expressed as:

$$[10] \quad k_0 = \frac{k_1[H^+]^2 + k_2K_1[H^+] + k_3K_1K_2}{[H^+]^2 + K_1[H^+] + K_1K_2}$$

It is of interest that over the pH range studied, k_0 increases by a factor of $> 3 \times 10^4$.

(i) $[H^+] > 0.01$ M

In this acidity range where there is no contribution from k_3 (eq. [8]), eq. [10] may be reduced to

$$[11] \quad k_0 = k_1 + k_2K_1/[H^+]$$

Treatment of the data from pH 0.8–2.2 according to eq. [11] is shown in Fig. 3 where the slope and intercept are equal to k_2K_1 and k_1 respectively. The values of k_1 and k_2 for the four temperatures studied are found in Table 2.

(ii) pH 4.8–7.2

Under these conditions the reaction pathway involving the undissociated ascorbic acid (eq. [5]) may be neglected, with the reduction of eq. [10] to the form

$$[12] \quad k_0 = k_2 + k_3K_2/[H^+]$$

Treatment of the data with eq. [12] is shown in Fig. 4, from which values of k_2 and k_3 are determined. Values of k_3 for the four temperatures are presented in Table 2. Values of k_2 determined from slopes using eq. [11] were used in calculating activation parameters. A much greater degree of uncertainty is associated with the values from the

32.5	13.1	12.2	84.4	7.94	10.3

$\Delta H_1^*(H_2A) = 5.1 \pm 1.0$ kcal mol^{-1}
$\Delta S_1^*(H_2A) = -46 \pm 5$ cal deg^{-1} mol^{-1}
$\Delta H_2^*(HA^-) = 5.4 \pm 0.5$ kcal mol^{-1}
$\Delta S_2^*(HA^-) = -32 \pm 2$ cal deg^{-1} mol^{-1}
$\Delta H_3^*(A^{2-}) = 3.1 \pm 0.5$ kcal mol^{-1}
$\Delta S_3^*(A^{2-}) = -12 \pm 2$ cal deg^{-1} mol^{-1}

intercepts in Fig. 4. Agreement between the two sets of data was, however, considered reasonable. For example, a slope of 66 ± 8 M^{-1} s^{-1} (Fig. 3) may be compared with the intercept 105 ± 25 M^{-1} s^{-1} (Fig. 4), T = 25°C.

From a knowledge of the specific rate constants and acid dissociation data, a pH profile may be constructed using eq. [10]. The calculated profile together with the experimental points at 25.0°C are shown in Fig. 5. Very good agreement was obtained for all four temperatures over the pH range 0.8–7.2.

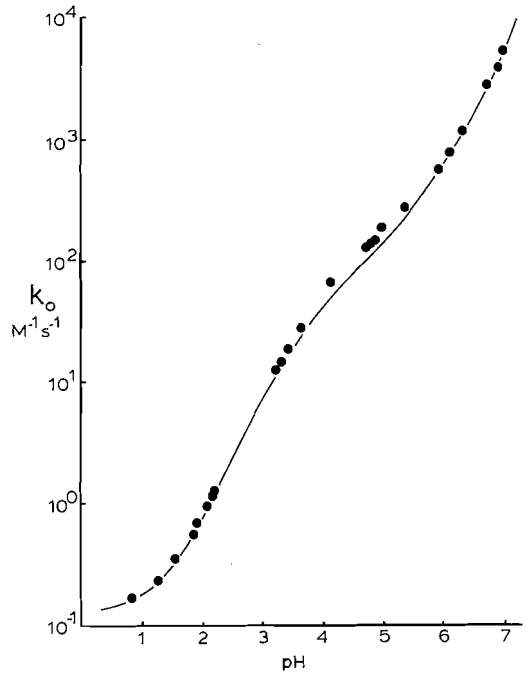

FIG. 5. pH profile of rates of oxidation of ascorbic acid by $Fe(CN)_5TU^{2-}$ at 25.0°C. The solid line is derived from eq. [10] using the values found in Table 2.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/05/12

The activation parameters corresponding to the specific rate constants of the three reaction pathways are shown in Table 2. In each case $\Delta H^{\ddagger}$ has a small positive value with $\Delta S^{\ddagger}$ being large and negative. The values of $\Delta H_1^{\ddagger}$ and $\Delta S_1^{\ddagger}$ are similar to those parameters ($\Delta H^{\ddagger} = 0$–5 kcal mol^{-1} and $\Delta S^{\ddagger} = -30$ to -40 cal deg^{-1} mol^{-1}) found for other metal complexes reacting with the undissociated ascorbic acid (1–3). Similarly $\Delta H_2^{\ddagger}$ and $\Delta S_2^{\ddagger}$ fall in the range ($\Delta H^{\ddagger} = 0$–5 kcal mol^{-1} and $\Delta S^{\ddagger} = -12$ to -32 cal deg^{-1} mol^{-1}) associated with the oxidation of the ascorbate anion (1–3). The values of $\Delta H_3^{\ddagger}$ and $\Delta S_3^{\ddagger}$ are consistent with trend to a smaller $\Delta H^{\ddagger}$ and less negative $\Delta S^{\ddagger}$ on going from H_2A to HA^- to A^{2-}. The trend in $\Delta G^{\ddagger}$ values; $\Delta G_1^{\ddagger}$ (18.8 kcal mol^{-1}) > $\Delta G_2^{\ddagger}$ (14.9 kcal mol^{-1}) > $\Delta G_3^{\ddagger}$ (6.6 kcal mol^{-1}), reflects the reactivity of the three species; $k_1 < k_2 < k_3$. The ratio $k_2{:}k_1$ ($T = 25$°C) for this system is about 6×10^2, fairly close to the value of 1.25×10^3 for the hexacyanoferrate(III) system (5).

For outer-sphere electron transfer reactions a relationship between the free energy of activation, ΔG_{12}^*, and the free energy of reaction ΔG_{12}^0, has been derived by Marcus (8). This correlation may be written in the form

$$[13] \quad \Delta G_{12}^* = W_{12} + \lambda(1 + G_{12}^0/\lambda)^2/4$$

where $\lambda = 2(\Delta G_{11}^* + \Delta G_{22}^*)$ with ΔG_{11}^* and ΔG_{22}^* referring to the self-exchange reactions of the reductant and oxidant. At the ionic strength used in this study the work term, W_{12}, is small, reducing eq. [13] to the form

$$[14] \quad \Delta G_{12}^* = 0.50\Delta G_{12}^0 + \text{constant}$$

This equation is equivalent to the linear correlation of the rate of electron transfer ($\log k_0$) with the standard reduction potentials of the ascorbate species if the reactions occur via an outer-sphere mechanism. Wong and Kochi (19) have presented this relationship in the equivalent form:

$$[15] \quad \log k_0 = 8.5E^0 + \text{constant}$$

Several estimates of the reduction potentials of the ascorbic acid/ascorbate radical and ascorbic anion/ascorbate radical have been reported. The estimated potentials vary depending on the extent of protonation postulated for the radical intermediate. If it is assumed that electron transfer occurs without simultaneous proton loss then the redox couples are $H_2A^{+\cdot}/H_2A$; $E^0 \simeq 1.35$ V (1, 3) and $HA^{\cdot}/HA^-$; $E^0 \simeq 0.93$ V (2). It can also be postulated that with the large acid dissociation constants of the ascorbate radical (18), pK_{r_2} ($H_2A^{+\cdot} \rightleftharpoons HA^{\cdot} + H^+$) $\ll -2$ and pK_{r_1} ($HA^{\cdot} \rightleftharpoons A^{-\cdot} + H^+$) = -0.45, proton loss occurs simultaneously with the electron transfer yielding a common intermediate, $A^{-\cdot}$ ($HA^{\cdot}$ at very high (> 1 M) acid concentrations). On this basis, the potential $E^0(pH_i)$ (at any pH value i) can be calculated using the expression (20)

$$[16] \quad E^0(pH_i) = E^0(pH_0) + 0.059 \log \frac{K_1K_2 + K_1[H^+] + [H^+]^2}{K_r + [H^+]}$$

where $E^0(pH_0)$ has been extrapolated from data at pH's 11 and 13.5 to be 0.99 V (21). This value is lower than that derived from kinetic data at $[H^+] = 1.0$ M. Using $E^0(pH_0) = 1.33$ V (3), however, yields a value for $E^0(A^{-\cdot}/HA^-)$ of 0.87 V, closely similar to that of 0.93 V derived earlier by Pelizzetti *et al.* (2). Using eq. [16] with this higher $E^0(pH_0)$ value we have calculated the potentials for the various species over the pH range studied.

Figure 6 shows a plot of $\log k_0$ against reduction potentials derived in this manner. The correlation is linear between pH 1 and pH 6 with a slope of 8.5 ± 0.1, in agreement with the form of the Marcus relationship in eq. [15]. This indicates that the three

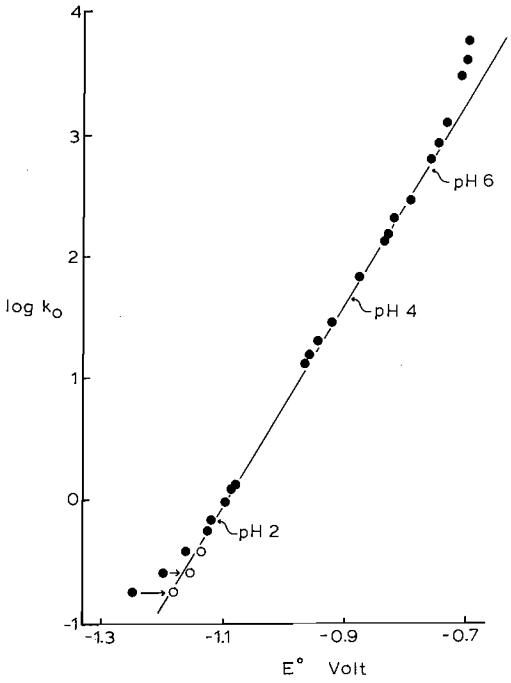

FIG. 6. Plot of $\log k_0$ against E^0, the reduction potential for the ascorbic acid/ascorbate radical couple. E^0 values are derived from eq. [16]. The unfilled circles show the corrections made for the protonation of $Fe(CN)_5TU^{2-}$ as discussed in the text.

ascorbate species, all contributing to the reaction rates in this pH range, react with thioureapentacyanoferrate(III) in an outer-sphere mechanism.

Using $E^0(pH_0) = 0.99$ V causes a shift of ~350 mV in the abscissa but produces no change in the slope of the line. There is some deviation in the fit (Fig. 6) below pH 2 and above pH 6. The derivation assumes a constant reduction potential of the Fe^{III}/Fe^{II} couple over the pH range studied. At low pH, however, there is likely to be some protonation of the iron(III) species, resulting in an increase in the potential. The following E^0 values at various acidities were measured by cyclic voltammetry: pH = 0.94, $E^0 = 0.41$ V; pH = 1.32, $E^0 = 0.39$ V; pH = 1.84, $E^0 = 0.37$ V; and pH = 5.80, $E^0 = 0.35$ V.

These potential changes suggest an estimated pK_a for $Fe(CN)_5TU^{2-}$ of ~1.8. Similar changes in E^0 with pH have been observed (22) in other $Fe(CN)_5L$ couples where L = H_2O, substituted thioureas and thioisonicotinamide. Insertion of the corrected E^0 values in Fig. 6 moves the experimental points (unfilled circles) closer to the observed line. At the higher pH's deviations may be due to the nature and concentration of added electrolytes (10) or possibly due to the uncertainty in the values chosen for $E^0(pH_0)$. Further studies in progress may help to clarify this situation.

LANGFORD BOOK, ARTHUR J. CARTY, and CHUNG CHIEH. Can. J. Chem. **59**, 138 (1981).

Reactions of L-tryptophan and D,L-homocysteine with mercury(II) halides in acidic ethanol/water solutions result in the formation of bis(L-tryptophanium) trichloromercurate(II) (TPTC) and bis(D,L-homocysteine thiolactonium) tetrabromomercurate(II) (HTTB) respectively. Their crystal structures consist of halide-bridged polymeric chains of quasi HgX_3^- units. The coordination geometry around Hg(II) in both anions is distorted trigonal bipyramidal. There are no chemical bonds between the amino acid cations and the mercury(II) ions. TPTC is monoclinic, space group $P2_1$ with a = 16.688(5), b = 5.626(1), c = 14.022(5) Å, β = 108.17(3)°. The structure was solved and refined from 2433 independent counter measured reflections to an R factor of 0.062. The two independent tryptophan molecules per asymmetric unit form a single cation via a strong hydrogen bond between the carboxylate groups. Thus the compound can be represented by $MHgCl_3$ where M is the cation. One of the three Cl^- ions is strongly bonded to one Hg(II) ion and weakly bonded to two other Hg(II) ions. In addition to the three short Hg—Cl distances of 2.403(3), 2.376(4), and 2.614(4) Å, there are two long Hg—Cl bonds of 2.833(4) and 2.888(4) Å to each Hg(II), from the weakly bridged chloride ions. HTTB is orthorhombic, space group *Pnma* with a = 8.068(3), b = 24.985(7), and c = 8.828(3) Å. The structure was refined to an R value of 0.066 for 819 observed reflections ($I \geq 3\sigma(I)$), however, inclusion of unobserved reflections did not change the parameters. The homocysteine free base used in the reaction was lactonised under the experimental conditions to a thiolactonium ion. There are three relatively short Hg—Br interactions (2.566(3) twice, 2.662(4) Å) within the distorted trigonal bipyramidal stereochemistry of each mercury atom and two longer Hg—Br bonds (2.917(6) and 3.087(5) Å). The polymeric, anion chains arrange in layers on the mirror planes ($y = \pm 1/4$) with these layers sandwiched by two layers of cations.

LANGFORD BOOK, ARTHUR J. CARTY et CHUNG CHIEH. Can. J. Chem. **59**, 138 (1981).

Les réactions du L-tryptophane et de la (D,L)-homocystéine avec les halogénures de mercure(II) dans des solutions acides d'éthanol/eau conduisent respectivement à la formation du trichloromercurate(II) de bis(L-tryptophanium) (TCTP) et de tétrabromomercurate(II) de bis(D,L-homocystéine thiolactonium) (TBHT). La structure de ces cristaux consiste en des chaînes polymérisées de quasi-unités HgX_3^- avec des halogènes en position de pont. La géométrie de coordination autour du Hg(II) dans les deux anions est déformée de façon trigonale bipyramidale. Il n'y a pas de liaisons chimiques entre les cations d'acides aminés et les ions mercure(II). Le TCTP est monoclinique avec a = 16,688(5), b = 5,626(1), c = 14,022(5) Å, β = 108,17(3)° groupe d'espace $P2_1$. On a résolu la structure à partir de mesures relatives à 2433 réflexions indépendantes et on l'a affinée jusqu'à une valeur conventionnelle R de 0,062. Les deux molécules indépendantes de triptophane par unité asymétrique forment un cation simple par l'intermédiaire de fortes liaisons hydrogènes entre les groupements carboxylates. Dans ce cas, le composé peut être représenté par la formule $MHgCl_3$ où M est le cation. L'un des trois ions chlorures est fortement lié à un ion Hg(II) et faiblement lié aux deux autres ions Hg(II). De plus, aux trois courtes liaisons HgCl de 2,403(3), 2,376(4) et 2,614(4) Å s'ajoutent deux longues liaisons de 2,833(4) et 2,088(4) Å dues aux ions halogénures liés faiblement aux ions Hg(II). Le THBT est orthorombique avec a = 8,068(3), b = 24,985(7) et c = 8,828(3) Å groupe d'espace *Pnma*. On a résolu la structure et on l'a affinée jusqu'à une valeur de R de 0,066 pour 819 réflexions observées ($I > 3\sigma(I)$). Cependant l'inclusion de réflexions non observées n'affecte nullement les paramètres. Dans les conditions expérimentales utilisées, l'homocystéine sous forme de base libre se transforme en ion thiolactum. Il y a trois interactions relativement courtes Hg—Br (deux mesurant 2,566(3) et une 2,662(4) Å) à l'intérieur de la stéréochimie déformée de façon trigonale bipyramidale de chaque atome de mercure et deux longues liaisons Hg—Br de (2,917(6) et 3,087(5) Å). La chaîne polymère d'anions s'arrange en couches dans les plans d'un miroir ($y = \pm\frac{1}{4}$). Ces couches sont comprimés entre deux couches de cations.

[Traduit par le journal]

Introduction

Mercury(II) ions interact with many biological sites through coordination with deprotonated thiol, imidazole, disulfide, thioether, amino, or carboxylate groups (1). A great deal of effort has been devoted to the characterisation and quantitation of these interactions in both model systems (1) and proteins (2). For obvious reasons much less attention has been focused on another important group of ligands, the halide ions. At physiological pH halide ion does not compete favourably with thiols or imidazole for primary coordination sites on Hg^{2+}, thus mercury–halide interactions are generally of secondary importance (3) unless there is an excess of Hg^{2+} over strong binding sites available. Nevertheless, there is a great deal of evidence pointing to the significance of mercury–halide complexation in biological systems. Thus, the reactivity of calf rennin towards mercurials is strongly modified in 2 *M* NaCl (2) and the uptake of methylmercury into the bloodstream via the stomach wall is influenced by the low pH and high

Cl^- concentration in this organ (4). Both neutral mercuric halides and halogeno anions have been extensively used as probes of biological activity in proteins; although displacement of halide ion or pseudohalide from the halogenomercurates(II) or pseudo-halomercurates(II) by anionic cysteine can occur as in lamprey haemoglobin (2, 5), numerous examples are known in which intact anionic mercurates interact electrostatically with the protein in a specific site. A notable illustration of the latter is the binding of HgI_3^- in myoglobin (6). The potential significance of Hg^{2+}/Cl^- binding in biological systems when covalent $HgCl_2$ is used as a reagent under acidic conditions is shown by the relatively strong Hg---Cl interactions in the model compounds $HgCl_2[SCH_2CH(NH_3)COOH]$ (3) and $Hg_2Cl_4[SCMe_2CH(NH_3)COOH]\cdot 2H_2O$ (7). For non-sulfhydryl containing proteins, there are frequently positively charged groups such as the guanidinium group of arginine and the terminal amino group of lysine. These groups are capable of interacting with mercurate anions via tight ion pair formation. While histidine imidazole will interact with mercurials via halide displacement at physiological pH, protonation at lower pH may effect a change to ionic binding between the positively charged histidine and an available anion.

As part of a more general program designed to prove certain aspects of mercury–halide binding in competition with other ligands under various conditions of salinity and pH we have investigated the reactions of two amino acids, one an important sulfhydryl containing amino acid homocysteine and the other a non-sulfhydryl molecule tryptophan with Hg^{2+}. In acidic solution protonation of the amino acids would be expected and we describe herein the synthesis and X-ray structures of two ionic complexes bis(D,L-homocysteine thiolactonium) tetrabromomercurate(II) and bis(L-tryptophanium) trichloromercurate(II) containing unusual mercury(II) anions formed under these conditions.

Experimental

Preparation of Compounds

Bis(L-tryptophanium) trichloromercurate(II) (TPTC) was prepared by mixing equal volumes of an aqueous solution of L-tryptophan (Sigma Chemical Co., St. Louis, MO) and an ethanol solution of mercury(II) chloride (BDH Chemicals, Toronto). Many attempts were made to crystallise products from solutions containing approximately 5 mmol of mercury chloride and 2.5 to 10 mmol of tryptophan. In all of the attempts, the small amounts of precipitate initially formed were removed by filtration and slow evaporation of the clear filtrates at 298 K gave bundles of very light brown but transparent crystals which were washed with a small amount of ethanol. The surface color of the dried crystals eventually turned brown on standing. *Anal.* calcd. for $C_{22}H_{25}Cl_3HgN_4O_4$: C 36.88, H 3.52, N 7.82, Cl 14.85; found: C 36.90, H 3.64, N 7.75, Cl 15.76.

Bis(D,L-homocysteine thiolactonium) tetrabromomercurate(II) (HTTB) was prepared by mixing an aqueous solution containing 4 mmol of D,L-homocysteine free base (Sigma) with an alcoholic solution containing 2 mmol of $HgBr_2$ (BDH). A large amount of white precipitate formed initially was redissolved by adding concentrated HBr thus changing the pH from ~4 to ~1. On evaporation rectangular colorless crystals were obtained. *Anal.* calcd. for $C_8H_{16}Br_4HgN_2O_2S_2$: C 12.70, H 2.13, N 3.70, Br 42.25; found: C 12.87, H 2.17, N 3.65, Br 40.82.

Elemental analyses were carried out by Galbraith Laboratories, Knoxville, TN.

X-ray Studies

Preliminary rotation, Weissenberg, and precession photographs were taken for space group determination and unit cell constant estimates. Suitable crystals were then selected for intensity measurements. The crystal sizes for TPTC and HTTB were 0.13 × 0.23 × 0.20 mm and 0.07 × 0.06 × 0.07 mm respectively, along the three crystallographic axes. These crystals were mounted on a Syntex $P2_1$ diffractomer. Unit cell parameters and orientation matrices were determined by least-squares fits of 15 low angle (10–25°) reflections for each compound. The crystal data are:

Bis(L-tryptophanium) Trichloromercurate(II)

$C_{22}H_{25}Cl_3HgN_4O_4$ fw = 716.20

Monoclinic, space group $P2_1(C_2^2$, No. 4, from systematic absences and structural analysis), $a = 16.688(5)$, $b = 5.626(1)$, $c = 14.022(5)$ Å, $\beta = 108.17(3)°$, $V = 1249.0(7)$ Å^3, $\rho_m = 1.90$ (by flotation in CCl_4/*s*-$C_2H_2Br_4$ mixtures), $Z = 2$, $\rho_c = 1.822$ (298 K; MoKα, $\lambda = 0.71069$ Å), μ(MoKα) = 66.4 cm^{-1}, $\mu R = 0.76$.

Bis(D,L-homocysteine Thiolactonium) Tetrabromomercurate(II)

$C_8H_{16}Br_4HgN_2O_2S_2$ fw = 756.58

Orthorhombic, space group *Pnma* (D_{2h}^{16}, No. 62, from systematic absences and structural analysis), $a = 8.068(3)$, $b = 24.985(7)$, $c = 8.828(3)$ Å, $V = 1780(1)$ Å^3, $\rho_m = 2.76$ (by flotation in CCl_4/*s*-$C_2H_2Br_4$ mixtures), $Z = 4$, $\rho_c = 2.822$ (298 K; MoKα, $\lambda = 0.71069$ Å), μ(MoKα) = 182.6 cm^{-1}, $\mu R = 0.64$.

All independent reflections with $2\theta \leq 50°$ were measured using the θ–2θ scan method with graphite monochromated MoKα radiation. The scan ranges were 0.8° below 2θ of MoKα_1 and above that of MoKα_2 and variable scan speeds in the range of 2–30° min^{-1} were used, to minimize counting errors for weak reflections. Background counts for half of the time used in the scan were measured at both extremes of the scan range.

Two strong reflections were repeatedly measured after every 50 reflections for monitoring purposes. No significant change in intensity with time was noted. The standard deviations, $\sigma(I)$, of intensities were calculated from counting statistics. Among 2433 reflections measured for TPTC, 2173 (89%) had $I > \sigma(I)$ and were considered observed. For HTTB, among 1614 reflections measured, 819 with $I > 3\sigma(I)$ and were considered as observed. The majority of unobserved reflections were in the reciprocal space with $2\theta > 40°$. Intensities were measured with a scintillation counter equipped with a pulse height analyzer. Lorentz-polarization corrections were applied in the derivation of structure amplitudes.

The coordinates of the mercury atoms were determined from three-dimensional Patterson maps. For TPTC, the indeterminable *y* coordinate was arbitrarily assigned a value of 1/4 and for

For personal use only.

HTTB, the mercury atom was situated on a mirror plane. Thus for TPTC Fourier maps based on the phase calculated from the mercury atom alone contained false mirror images and care was exercised in choosing peaks for other non-hydrogen atoms corresponding to the correct configuration of the amino acids. Atomic scattering factors from the International tables for X-ray crystallography (8) with anomalous dispersion corrected for Hg and Br atoms were used. When only observed reflections were included with isotropic temperature factors for all non-hydrogen atoms, the R $(=\Sigma||F_o| - |F_c||/\Sigma|F_o|)$ factors were 0.11 and 0.15 respectively for TPTC and HTTB, from full-matrix least-squares refinements. For TPTC, further refinement with unobserved reflections included and using anisotropic temperature parameters with a weighting scheme of $w = (30 - |F_o| + 0.013 \times F_o^2)^{-1}$ gave R and R_w $(= \{\Sigma w|F_o| - |F_c|)^2/\Sigma w|F_o|^2\}^{1/2}$ of 0.062 and 0.064 respectively. This scheme gave uniform values of $(\Sigma\omega|\Delta F|)/(n - p)$ for various ranges of F_o except the unobserved reflections. When unobserved reflections were excluded, R was 0.058. The shifts of parameters were less than 0.2σ in the last cycle of refinement and the final difference Fourier map showed only ripples (1.5 e/Å^3) around the mercury atom. The atomic coordinates are given in Table 1.[1]

For HTTB, the weighting function used was $w = (80 - |F_o| + 0.0063F_o^2)^{-1}$. The final R and R_w values were both 0.14 when all reflections were included. A final difference Fourier calculated using all measured reflections showed ripples (2.4 e/Å^3) around the Hg and Br atoms. The exclusion of unobserved reflections, however, gave much more satisfactory R and R_w values of 0.066 and 0.087 respectively. The shifts of parameters in the final cycle of refinement were less than 0.2σ. Atomic parameters obtained in refinements with or without weak reflections were not significantly different. Atomic coordinates are given in Table 2.[1] Computer programs used in the reduction, solution, and refinement of X-ray data have been described elsewhere (9).

Results and Discussion

Reaction of L-tryptophan with mercuric chloride in acidic aqueous alcohol solutions gives preferentially the ionic compound bis(L-tryptophanium) trichloromercurate(II) (TPTC) even when an excess amount of mercuric chloride was used. In contrast, bis(D,L-homocysteine thiolactonium) tetrabromomercurate(II) (HTTB) was obtained only when 2 mol of amino acid per mole of mercuric salt were used. Amorphous intractable solids were obtained for 1:1 molar ratios of reactants.

Both structures contain protonated amino acid cations and polymeric chains of halogenomercurates(II); the simple, monomeric ions HgX_3^- and HgX_4^{2-} found in other systems (10) are not present in TPTC and HTTB. However, in TPTC a cation consisting of two amino acid residues linked by a strong hydrogen bond (*vide infra*) is present whereas in HTTB the charge on the tetrabromomercurate(II) is balanced by two homocysteine thiolactone cations. Thus the formation of HTTB involves the lactonisation of homocysteine free base in acid solution.

In neither complex is there any evidence for close contact between ligating atoms on the amino acids and the metal ions. The immediate stereochemistry of the mercury atoms in both TPTC and HTTB is distorted trigonal bipyramidal, with two terminal and three triply bridging chloride

ions in the former and three terminal and two doubly bridging bromide ions in the latter (Figs. 1 and 2).

The five Hg—Cl bonds in TPTC, all of which are at distances less than the sum of the van der Waals radii (3.3 Å), can be divided into two groups. Amongst a group of three short Hg—Cl bonds defining an approximately trigonal $HgCl_3^-$ unit are two metal interactions with terminal halide ions and a third bond to a triply bridging chloride ion (Fig. 1). Two other halide ions Cl(3″) and Cl(3′) from neighbouring units at longer distances from Hg lie above and below this trigonal plane, thus defining the vertices of an approximate trigonal bipyramid. The angle Cl(3′)—Hg—Cl(3″) is 159.1(2)° and the angles between axial and equatorial bonds are in the range 79.1–96.1° (Table 3). The triply bridging chloride ion Cl(3) links the $HgCl_3^-$ units into a

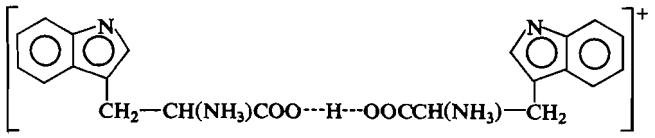
double chain extending along the 2_1 screw axis as shown in Fig. 3. The average Hg—Cl bond length within the quasi $HgCl_3^-$ unit (2.464 Å) compares favourably with the average equatorial distance of 2.415 Å in $(S_4N_3)HgCl_3$ (11) which consists of a structurally similar double chain of $HgCl_3^-$ units.

The atoms Hg, Br(2), and Br(3) in HTTB lie on the mirror plane at $y = 1/4$, but Br(1) occupies a general position. As in the case of TPTC the five Hg—X distances shown in Fig. 2 can be divided into two groups, with three short and two long bonds. It is interesting that while the stoichiometry is indicative of an $HgBr_4^{2-}$ ion, polymerisation via single Br^- bridges produces a structure containing quasi $HgBr_3^-$ units linked into elongated trigonal bipyramids via long axial Hg—Br interactions. As can be seen from a comparison of angles in Tables 3 for TPTC and HTTB, the polyhedron defined by the five bromide ions coordinated to Hg in the latter is considerably more distorted than in the chloride complex. As is the case for TPTC, the symmetry responsible for generating the polymeric linkage in HTTB is a 2_1 screw axis.

Although there are two amino acid residues in TPTC only a monovalent cation is required to balance the charge on the counterion. The X-ray data did not allow the location of hydrogen atoms on the amino acids but an analysis of intermolecular dis-

tances strongly suggested that the two tryptophan moieties were linked by a strong, possibly symmetrical hydrogen bond between carboxylate entities. Thus the O(2)---O(4) distance between the two independent tryptophan molecules is only 2.41(2) Å. This value lies at the lower end of the normal range of 2.40–2.45 Å for symmetrical O---H---O hydrogen bonds (12, 13) and compares for example with the value of 2.44(2) Å for the O---O distance in $Hg(SCH_2CH(NH_3)COO)(SCH_2CH(NH_3)COOH)Cl\cdot 0.5H_2O$ (3). We suggest therefore that the cation in TPTC is as shown below:



The remaining bond lengths and angles for the amino acid residues appear normal and have been deposited as supplementary data.[1] A packing diagram for TPTC is shown in Fig. 3. Tryptophan molecules can be divided into two parts: the hydrophobic ring and the hydrophilic amino-carboxylate tail. The tails arrange themselves around the double chain possibly due to N—H---Cl hydrogen bonding whereas the rings are packed back to back in the unit cell. Some of the shortest distances between the nitrogen atom of the amino group and Cl^- are: N(2)---Cl(1) (at $-x, 0.5+y, 1-z$), 3.27(1) Å; N(2)---Cl(3) (at $-x, 0.5+y, 1-z$), 3.28(1) Å; N(2)---Cl(2) (at $x, y, 1+z$), 3.39(2) Å; N(4)---Cl(1) (at $x, 1+y, z$), 3.41(2) Å. The shortest non-bonding distance between Cl^- and any oxygen atom is 3.50(2) Å.

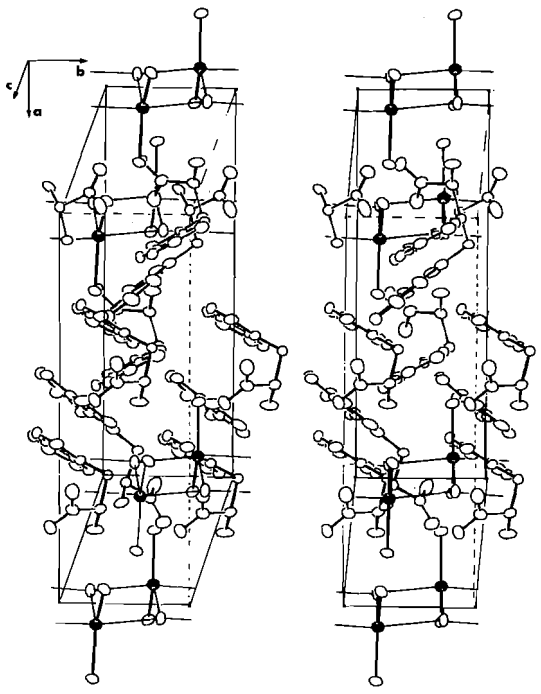


FIG. 3. Packing diagram of TPTC.

The puckered five-member ring of the thiolactonium ion in HTTB has the normal envelope conformation and the C(=O)—S bond length of 1.73(3) Å is shorter than the $C(H_2)$—S of 1.91(3) Å. The bond lengths and angles are normal[1] when compared to those in homocysteine thiolactone hydrochloride (14). The packing diagram (Fig. 4) illustrates $[Hg(Br_3)—Br]_n$ chains packed in layers on mirror planes with $y = \pm 1/4$. These layers are sandwiched between two layers, one as the mirror image of the other, of thiolactonium cations with the amino groups extended towards the bromide ions lying on the mirror planes. As a result, each nitrogen atom has five neighbouring Br^- ions within a range of 3.50 Å: N...Br(1), 3.39(2); N...Br(1) (at $0.5+x, y, 0.5+z$), 3.47(2); N...Br(2) (at $x, y, 1+z$), 3.50(2); N...Br(3), 3.33(2); N...Br(3) (at $0.5+x, 0.5-y, 0.5-z$), 3.20(2) Å. Some of these are probably due to the formation of N—H---Br hydrogen bonds. These three-layer sandwiches are stacked on top of each other alternating their orientations so that there are centers of symmetry between them.

In the two structures reported here, both Hg(II) ions have an effective coordination number of 5 with distorted trigonal bipyramidal stereochemistry. This coordination geometry is not particularly common for halogenomercurates(II), the only other examples of which we are aware being $[Me_3S][HgCl_3]$ (14), $[S_4N_3][HgCl_3]$ (11), $[Me_4N][HgBr_3]$ (15), $[Hg_3I_6(en)_2]$ (16), and $[Cr(NH_3)_6][HgCl_5]$ (17). It is interesting that the first four of these structures contain polymeric anions with axially elongated trigonal bipyramidal stereochemistry at mercury somewhat related to that in TPTC whereas $[Cr(NH_3)_6][HgCl_5]$ (17) has a more regular trigonal bipyramidal arrangement of halide ions around the metal with Hg—Cl(equatorial) of 2.640 Å and Hg—Cl(axial) of 2.518 Å. For halogenomercurates(II) of the HgX_3^- type, other com-

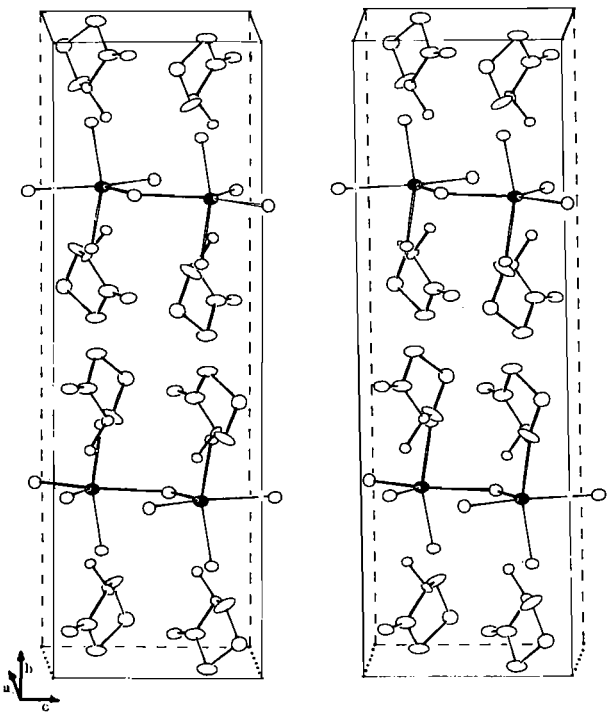

FIG. 4. Packing diagram of HTTB.

mon structures are the distorted octahedron with two long and four short bonds (18), the simple, unassociated three coordinate structure (19), and the distorted tetrahedron (20). By far the most frequently encountered structural unit in HgX_4^{2-} species is the tetrahedron (21). Clearly the structure of the ion is not necessarily indicated by the stoichiometry. In a biological sense the occurrence of structures containing polymeric $HgCl_3^-$ and $HgBr_4^{2-}$ ions, each having quasi HgX_3^- units present as structural units in conjunction with large organic cations may be significant since it suggests the possible appearance of such units in protein structures. The corresponding trigonal ion HgI_3^- has already been identified in myoglobin (6).

LANGFORD BOOK, ARTHUR J. CARTY, and CHUNG CHIEH. Can. J. Chem. **59**, 144 (1981).

Complexes $Hg[CH_3SCH_2CH(NH_2)COO]_2$ and $Hg[CH_3CH_2SCH_2CH_2CH(NH_3)COO]_2(ClO_4)_2$ obtained from reactions of yellow HgO with *S*-methyl-L-cysteine and ethionine respectively have been characterized by X-ray diffraction methods. The former is monoclinic, space group $P2_1$ with $a = 13.790(4)$, $b = 4.994(1)$, $c = 9.898(2)$ Å, and $\beta = 106.20(2)°$. The R and R_w factors were 0.063 and 0.075 respectively for 980 independent reflections. The *S*-methyl-L-cysteine complex is N,O bonded with two Hg—N bond lengths of 2.16(3) and 2.13(3) Å and ∠N—Hg—N=172(2)°. There are eight Hg···O distances within the range of 2.54–3.75 Å. The three shortest of these are distributed in an equatorial plane with respect to the N—Hg—N moiety. The Hg—O bond length of 2.54(2) Å is associated with the chelate ligand.

The ethionine complex is triclinic, space group $P\bar{1}$ with $a = 11.376(7)$, $b = 12.009(8)$, $c = 9.495(6)$ Å, $\alpha = 94.74(6)$, $\beta = 108.01(5)$, and $\gamma = 71.78(5)°$. The R and R_w values for all 3526 reflections were 0.083 and 0.10 respectively but R became 0.058 for only observed reflections ($I > 3\sigma(I)$). The Hg^{2+} is bonded to two sulfur, Hg—S = 2.436(5) and 2.537(4) Å, and two oxygen, Hg—O = 2.28(1) and 2.259(9) Å, atoms in a distorted tetrahedron. The Hg^{2+}–carboxylate interactions are stronger in the S-bonded than the N-bonded complex probably indicating a preference for Hg–amine coordination. At low pH when the amino group is protonated, Hg–thioether coordination becomes important for S-substituted amino acids.

LANGFORD BOOK, ARTHUR J. CARTY et CHUNG CHIEH. Can. J. Chem. **59**, 144 (1981).

On a caractérisé, par les méthodes de diffraction de rayons-X, les complexes $Hg[CH_3SCH_2CH(NH_2)COO]_2$ et $Hg[CH_3CH_2SCH_2CH_2CH(NH_3)COO]_2(ClO_4)_2$ obtenus respectivement par réaction du HgO jaune avec les *S*-méthyle L-cystéine et éthionine. Le premier est monoclinique et appartient au groupe d'espace $P2_1$ avec $a = 13,790(4)$, $b = 4,994(1)$, $c = 9,898(2)$ Å, et $\beta = 106,20(2)°$. Les facteurs R et R_w sont respectivement de 0,063 et 0,075 pour 980 réflexions indépendantes. Le complexe de *S*-méthyle L-cystéine est lié par N,O et comporte deux liaisons Hg—N de 2,16(3) et 2,13 Å et un angle ∠N—Hg—N de 172(2)°. Il y a huit distances Hg···O de l'ordre de 2,54 à 3,75 Å. Les trois distances les plus courtes sont distribuées dans un plan équatorial par rapport au fragment N—Hg—N. On attribue au ligand chélaté la liaison Hg—O de 2,54(2) Å.

Le complexe de l'éthionine est triclinique et appartient au groupe d'espace $P\bar{1}$ avec $a = 11,376(7)$, $b = 12,009(8)$, $c = 9,495(6)$ Å, $\alpha = 94,74(6)$, $\beta = 108,01(5)$, et $\gamma = 71,78(5)°$. Les valeurs de R et de R_w sont respectivement de 0,083 et 0,10 pour l'ensemble des 3526 réflexions mais la valeur de R devient égale à 0,058 pour les réflexions observées avec ($I > 3\sigma(I)$). L'ion Hg^{2+} est lié à deux atomes de soufre, Hg—S = 2,436(5) et 2,537(4) Å, et à deux atomes d'oxygène, Hg—O = 2,28(1) et 2,259(9) Å, selon un tétraèdre déformé. Les interactions Hg^{2+}–carboxylate sont plus fortes dans les complexes liés par le soufre que dans ceux liés par l'azote indiquant ainsi une préférence pour une coordination Hg–amine. Si le pH est faible, le groupe amine est protoné et la coordination Hg–thioéther devient importante pour les acides aminés ayant un substituant sur les soufre.

[Traduit par le journal]

Introduction

S-substituted amino acids have three possible binding sites towards metal ions, namely, the thioether, amino, and carboxylate groups. Towards mercuric ion (Hg^{2+}) the binding mode is pH dependent. Although early potentiometric work (1) suggested little or no involvement of thioether coordination to Hg^{2+} for methionine, ethionine, or *S*-methylcysteine, it later became apparent from ^1H (2–5) and ^{13}C nmr (4–6) studies of Hg^{2+}/methionine, ethionine, or *S*-methyl-L-cysteine solutions that under acidic conditions ($pD \leq 2$) Hg^{2+} was bound exclusively to the thioether sulfur atom.

This result thus parallels the behaviour of methionine towards CH_3Hg^+ (7). However, on raising the pH to 7.0 or above a reversal of binding site occurs; for methionine, Natusch and Porter (2) predicted N,O chelation at alkaline pH whereas in contrast the shorter alkyl chain of *S*-methyl-L-cysteine allowed S,N chelation under similar conditions (2). For isolated solids the paucity of sound structural information for methionine, ethionine, and *S*-methylcysteine complexes of Hg^{2+} gave rise to considerable speculation as to solid state structures. Livingston and Nolan (8) synthesised an ethionine complex $Hg(ethH)_2(ClO_4)_2$ from acidic solution and on the basis of ir measurements proposed a linear configuration at mercury with bonding localised at the amino group. On the other hand, the methionine derivative $Hg[CH_3SCH_2CH_2CH(NH_2)COO]_2$ prepared initially by McAuliffe *et al.* (9) and later by Birgersson, Drakenberg, and Neville (5) was formulated as an

N,O chelate in the solid state by the former workers (9) and as an amine-bonded species with weaker carboxylate bonding by Sze, Davis, and Neville (10). Thus despite abundant nmr evidence for thioether bonding in acid solution, none of the available spectroscopic data for solids pointed to sulfur bonding in isolated complexes. This apparent anomaly was recently resolved by an X-ray analysis of $Hg(CH_3SCH_2CH_2CH(NH_3)COO)_2(ClO_4)_2 \cdot 2H_2O$, isolated from acid solution, which demonstrated not only strong Hg^{2+}–thioether bonding but also additional important *intermolecular* interactions to carboxylate units of neighbouring molecules (11). This result and the remaining anomalies apparent in the literature concerning the solution and solid state structures of ethionine and *S*-methylcysteine complexes of Hg^{2+} prompted us to synthesise the ethionine complex $Hg(ethH)_2(ClO_4)_2$ by the method reported by Livingstone and Nolan (8) and a halide-free *S*-methylcysteine compound $Hg(S\text{-}Me\text{-}cyst)_2$ for X-ray analysis. We report the preparation and full structural characterisation of these species in this paper.

Experimental

Preparation of Compounds

$Hg(S\text{-}Me\text{-}cyst)_2$

Yellow mercuric oxide (5 mmol) was stirred in 200 mL water and a solution of *S*-methyl-L-cysteine (10 mmol in 50 mL water) was gradually added. The yellow HgO dissolved completely within 5 min of the addition of the *S*-methyl-L-cysteine solution. The resultant colourless solution had a pH of ~6. After stirring for 10 min, a white precipitate formed. Recrystallisation from hot aqueous solution by slow cooling and evaporation gave large thin triangular or rhomboidal crystals. The crystals were fragile and generally fragmented when attempts were made to cleave them. Considerable care was exercised in choosing an unflawed crystal for X-ray analysis. The data crystal produced good quality unstreaked Weissenberg photographs. *Anal.* calcd. for $C_8H_{16}HgN_2O_4S_2$: C 20.49, H 3.44, N 5.97; found: C 20.52, H 3.48, N 5.98.

$Hg(ethH)_2(ClO_4)_2$

Yellow mercuric oxide (5 mmol) was dissolved in a solution of D,L-ethionine (10 mmol in 50 mL water) with stirring. Concentrated perchloric acid (1 mL) was added to acidify the resultant solution to a pH of 1.0. The solution was then allowed to evaporate slowly at room temperature and flattened ellipsoidal crystals were isolated. *Anal.* calcd. for $C_{12}H_{26}Cl_2HgN_2O_{12}S_2$: C 19.85, H 3.61, N 3.86; found: C 19.61, H 3.62, N 3.86.

X-ray Structural Analysis

Weissenberg and precession photographs were taken for space group and cell constant determinations. The latter were refined by least-squares methods from the angles of 15 reflections for each crystal measured on a Syntex $P2_1$ diffractometer. Crystal data and information pertaining to structural analysis are listed in Table 1.

Intensities were collected at 298 ± 1 K using graphite monochromated MoKα radiation on a Syntex $P2_1$ diffractometer employing a θ–2θ scan mode. Two standard reflections were repeatedly measured at intervals of 25 reflections to monitor the stability during data collection. Their intensities decreased by 14% at the end of data collection owing to slow decomposition of the $Hg(S\text{-}Me\text{-}cyst)_2$ crystal in the X-ray beam. This decrease was used as a base for scaling the intensities of reflections collected after the standard reflections. For $Hg(ethH)_2(ClO_4)_2$ the intensities of standard reflections fluctuated within 4% during the course of data collection. Backgrounds were measured at both extremes of the scan. Lorentz and polarization corrections were applied to the derivation of structure amplitudes.

Both structures were solved by the heavy atom method. For $Hg(S\text{-}Me\text{-}cyst)_2$, the indeterminable *y* coordinate was arbitrarily assigned a value of 1/4. There were pseudo mirror planes at $y = \pm 1/4$ on the Fourier map based on the phase of the Hg atom alone. This pseudo symmetry was removed gradually by including initially one of the S atoms, then both S atoms in the phasing process for a Fourier synthesis. The L-configuration was chosen to agree with the amino acid used. Non-hydrogen atoms were located in successive Fourier or difference Fourier maps.

Least-squares refinements were carried out when all atoms were located and anisotropic temperature parameters were introduced at appropriate stages. Atomic scattering factors with anomalous dispersion coefficients were taken from ref. 12. Computer programs utilized in the solution and refinement of X-ray data have been described elsewhere (13).

Just before the conclusion of refinement, difference Fourier maps were synthesised; these indicated that the methyl groups in both structures were disordered. Two sites were given for the carbon atom of one of the methyl groups bonded to S in $Hg(S\text{-}Me\text{-}cyst)_2$ as C(24A) and C(24B). Similarly, C(12A) and C(12B) were due to the disorder of the terminal —CH_3 in one of the ethyl groups attached to the S atom in $Hg(ethH)_2(ClO_4)_2$. The ratios of occupancy factors were 3:1 and 2:1 respectively for the cysteine and ethionine compounds. Including these atoms in the refinement gave the *R* and R_w factors in Table 1. There were no significant peaks other than those in the vicinity of the Hg atom in the final difference Fourier maps. The refinement stopped when the shifts of parameters were less than 0.25 and the final difference Fourier maps showed only ripples (max. 1.0 e $Å^{-3}$) around the Hg atoms. Atomic parameters for the two crystal structures are given in Tables 2 and 3.[1]

Results and Discussion

In $Hg(S\text{-}Me\text{-}cyst)_2$ the Hg^{2+} ion is bonded to two amino groups with Hg—N bond lengths of 2.16(3) and 2.13(3) Å at an angle of 172(1)°. Short Hg—N bonds of this length are usually associated with two-coordinate, linear mercury complexes as in $(CH_3Hg)_2$(D,L-penicillamine)$\cdot 2H_2O$ (2.13 Å) (14), CH_3Hg(L-methionine) (2.06 Å) (15), CH_3Hg(L-tyrosine)$\cdot H_2O$ (2.17 Å) (16), $(PhHg)_2$(H-creatinine)(NO_3) (2.00 and 2.06 Å) (17), $(CH_3Hg)_2$(9-Me-adenine)(ClO_4) (2.08 and 2.09 Å) (18), $(CH_3Hg)_2$(adenine)$(NO_3)\cdot 2H_2O$ (2.08 and

2.09 Å) (18), and $Hg(1\text{-methylthymine})_2$ (2.04 Å) (19). Bonds of similar length are also found in mercuric chloride complexes of biologically important nitrogen bases such as $[HgCl_2(1\text{-Me-cytosine})]_2$ (2.17 Å) (20) and $[HgCl_2(guanosine)]$ (2.16 Å) (21) where the N—Hg—N bond system approaches linearity and other metal ligand interactions are weak. In addition to these strong Hg—N bonds, there are eight carboxylate oxygen atoms situated at distances less than 3.75 Å from the mercury atom, Table 4. Among these, three short Hg—O bonds (Hg—O(21) = 2.54(2) Å, Hg—O(12^{I}) = 2.60(4) Å, and Hg—O(22^{II}) = 2.82(3) Å) define an equatorial, trigonal plane with respect to the almost linear N—Hg—N moiety. Thus, N(1), N(2), O(21), O(12^{I}), and O(22^{II}) lie at the apices of a distorted trigonal bipyramid as shown in Fig. 1. A least-squares plane containing Hg and these three equatorial oxygen atoms has the equation $0.727X + 0.676Y - 0.121Z = 0.366$ referring to orthogonal axes X, Y, and Z. The displacements of the atoms Hg, O(21), O(12^{I}), O(22^{II}), N(1), and N(2) from this plane are −0.220, 0.040, 0.092, 0.088, −2.28, and 1.89 Å respectively. The shortest Hg—O bond length (Hg—O(21) of 2.54(2) Å) is from the same amino acid which is N-bonded to Hg^{2+}. Thus this amino acid is quite strongly N,O-chelated to the mercury atom. One of the carboxylate oxygen atoms of the other amino acid in the molecule is not coordinated since the Hg—O(11) distance (3.53(2) Å) is well outside the sum of Van der Waals radii for mercury and oxygen (~3.0 Å). Thus not only are

the two amino acids coordinated differently to mercury, but the presence of several additional marginal intermolecular carboxylate interactions gives rise to a rather complex coordination environment at the metal atom. Molecules of $Hg(S\text{-Me-cyst})_2$ are linked together by these intermolecular Hg^{2+}–carboxylate interactions forming polymeric chains along the 2_1 axes. Interactions between these chains are via Van der Waals forces. A packing diagram is shown in Fig. 2. It is interesting that Natusch and Porter (2) predicted an S,N bonding mode for the 1:2 Hg^{2+}/*S*-methyl-L-cysteine complex in basic solution, a result in obvious conflict with the present structural work unless there is a dramatic change in amino acid coordination to mercury on dissolution of $Hg(S\text{-Me-cyst})_2$. Although no X-ray data are yet available for the bis(methionine) complex $Hg[CH_3SCH_2CH_2CH(NH_2)COO]_2$ it is worth noting that the structural assignment for this molecule based on vibrational data (10), namely strong Hg^{2+}–amine and weaker Hg^{2+}–carboxylate bonding, compares reasonably with the structure of $Hg(S\text{-Me-cyst})_2$ prepared in the present work. From nmr measurements (2) it had been predicted that these two amino acids would bond differently to Hg^{2+} in neutral or basic solution due to the superior S,N chelating ability of *S*-methyl-L-cysteine.

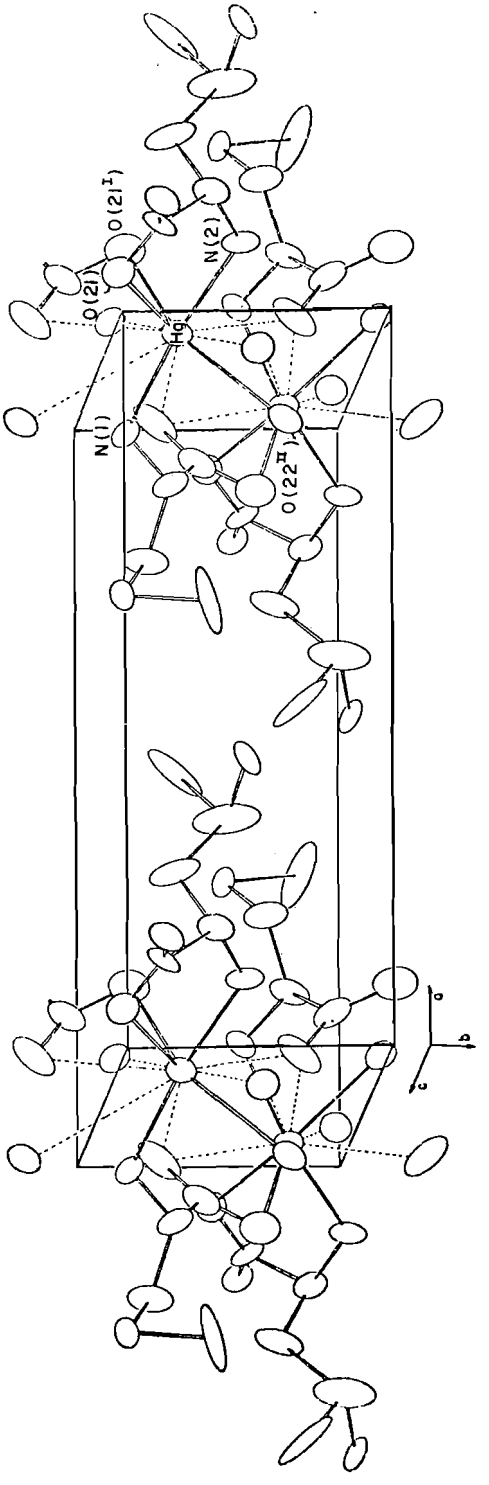

FIG. 2. Packing diagram for Hg(S-Me-cyst)$_2$.

In $Hg(ethH)_2(ClO_4)_2$ (Fig. 3) the Hg^{2+} ion is tetrahedrally bonded to two thioether sulfur and two carboxylate oxygen atoms as in the corresponding methionine complex (11). Previous conclusions regarding the aminoacid bonding in this complex (8) are thus erroneous. The principal structural features of the ethionine complex are the relatively strong Hg—S bonds of 2.436(5) and 2.537(4) Å, which are accompanied by two strong and two weak intermolecular Hg—O bonds. The two strong Hg—O bonds in $Hg(ethH)_2(ClO_4)_2$, 2.28(1) and 2.259(9) Å (and those for $Hg(methH)_2(ClO_4)_2 \cdot 2H_2O$: 2.27(1) and 2.32(1) Å (11)) are much stronger than the equatorial Hg—O bonds in Hg(S-Me-cyst)$_2$. Together with the other, weaker Hg—O interactions (3.00(1) and 3.03(1) Å) the coordination can be described as (4 + 2) to differentiate the primary coordination shell and the additional long range contacts (22). It is noteworthy that the Hg—S bond lengths in $Hg(ethH)_2(ClO_4)_2$ (ave. 2.487 Å) are significantly longer than those in the bis(cysteinato)mercury complex $Hg[SCH_2CH(NH_3)COO][SCH_2CH(NH_3)COOH]Cl \cdot 0.5H_2O$ (ave. 2.341 Å (23)) where coordination is to anionic sulfur.

Recognising that the shortest primary Hg—O contacts in Hg(S-Me-cyst)$_2$ (Hg—O(21) of 2.54(2) Å and Hg—O(12^{I}) of 2.60(4) Å) are considerably longer than the distances Hg—O(1^{I}) (2.28(1) Å) and Hg—O(3^{II}) (2.259(9) Å) in $Hg(ethH)_2(ClO_4)_2$ (Table 5) and also that the N—Hg—N angle (172(1)°) in the former is much closer to the ideal angle for digonal coordination than S(1)—Hg—S(2) of 123.2(1)° in the latter, it is tempting to suggest that amine coordination in Hg(S-Me-cyst)$_2$ is stronger than thioether bonding in $Hg(ethH)_2(ClO_4)_2$ or in $Hg(methH)_2(ClO_4)_2 \cdot 2H_2O$ (11). Greater *residual* Lewis acidity for mercury coordinated to two thioethers then promotes stronger carboxylate interactions.

Bonding sites of Hg^{2+} on S-substituted amino acids such as *S*-methylcysteine and ethionine are

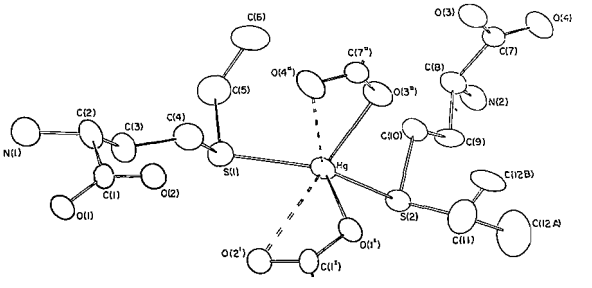

FIG. 3. Crystal structure of $Hg(ethH)_2(ClO_4)_2$.

pH dependent. In acid solutions, protonation of amino groups prevents their coordination to Hg^{2+} and S-coordination becomes important (2–6). Otherwise, amino-coordination is favourable and this is partly supported by the fact that the Hg—O(carboxylate) bonds are shorter in the S-bonded complex than in the N-bonded one. The strong Hg^{2+}–carboxylate interactions seen in these structures may extend beyond the solid state domain and play important roles in solution chemistry.

Finally we note that the use of HgO in reactions with amino acids has obvious significance for the synthesis of halide free mercury complexes.

Hydrogen bonding solvent effect on the basicity of primary amines CH_3NH_2, $C_2H_5NH_2$, and $CF_3CH_2NH_2$

YAN K. LAU AND P. KEBARLE

Chemistry Department, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received July 9, 1980

YAN K. LAU and P. KEBARLE. Can. J. Chem. **59**, 151 (1981).

The equilibria $RNH_3^+(H_2O)_{n-1} + H_2O = RNH_3^+(H_2O)_n$ were measured for R = CH_3, C_2H_5, and CF_3CH_2 from $n = 1$ to $n = 3$ with a pulsed electron beam high ion source pressure mass spectrometer. The proton and hydrate transfer equilibria $CH_3NH_3^+(H_2O)_n + C_2H_5NH_2 = CH_3NH_2 + C_2H_5NH_3^+(H_2O)_n$ were measured for $n = 0$ to $n = 3$. These data allow the evaluation of ΔH^0 and ΔG^0 for the reactions: $R_0NH_3^+(H_2O)_n + RNH_3^+ = R_0NH_3^+ + RNH_3^+(H_2O)_n$. $\Delta H^0 = \delta\Delta H^0_{0,n}(RNH_3^+)$, $\Delta G = \delta\Delta G^0_{0,n}(RNH_3^+)$. These data are compared with $\delta\Delta E_{0,3}$ (STO-3G) evaluated by Hehre and Taft. In general good agreement is observed at $n = 3$. The $\delta\Delta H^0_{0,3}(RNH_3^+) \approx \delta\Delta E_{0,3}(RNH_3^+)$ are also found close to the ion hydration free energy difference in aqueous solutions.

YAN K. LAU et P. KEBARLE. Can. J. Chem. **59**, 151 (1981).

Utilisant un spectromètre de masse ayant comme source d'ions à haute pression un faisceau pulsé d'électron, on a mesuré l'équilibre $RNH_3^+(H_2O)_{n-1} + H_2O = RNH_3^+(H_2O)$ où R = CH_3, C_2H_5 et CF_3CH_2 et n varie de 1 à 3. On a mesuré l'équilibre de transfert du proton et de l'hydrate: $CH_3NH_3^+(H_2O)_n + C_2H_5NH_2 = CH_3NH_2 + C_2H_5NH_3^+(H_2O)_n$ pour des valeurs de n allant de 0 à 3. Ces données permettent d'évaluer le ΔH^0 et le ΔG^0 des réactions: $R_0NH_3^+(H_2O)_n + RNH_3^+ = R_0NH_3^+ + RNH_3^+(H_2O)_n$. $\Delta H^0 = \delta\Delta H^0_{0,n}(RNH_3^+)$, $\Delta G = \delta\Delta G^0_{0,n}(RNH_3^+)$. On a comparé ces données avec la valeur de $\delta\Delta E_{0,3}$ (STO-3G) évaluée par Hehre et Taft. En général, on observe une bonne corrélation lorsque $n = 3$. On a également trouvé que les valeurs $\delta\Delta H^0_{0,3}(RNH_3^+) \approx \delta\Delta E_{0,3}(RNH_3^+)$ sont voisines de la différence d'énergie libre de l'hydratation de l'ion en solutions aqueuses.

[Traduit par le journal]

Introduction

"Understanding solvent effects" to the practicing non-specialist chemist really means having a qualitative description of the role of the solvent in terms of some easily recognizable properties of the ion and the solvent or solvent molecules. Early work on solvent effects was often based on the Born equation. The focus of such predictions was on the radius of the ion and the dielectric constant of the solvent. However, the models used were often over-simplified and at times amounted to using two variable parameters, the dielectric constant, variable because of the unknown extent of dielectric saturation, and the radius of the ion variable for reasons which become obvious when one considers the problem of describing an organic ion with charged functional group and some charge delocalization.

A continuing effort from this laboratory (1, 2) has been to try to show that some of the major features of ionic solvation in condensed media can be explained on basis of the interactions of the ion with a small number of solvent molecules. The pertinent experimental data are obtained from measurement of gas phase ion, $Ion^{\pm}$, solvent molecules, Sl, equilibria $(n - 1, n)$, as in reaction [1].

[1] $\quad Ion^{\pm}(Sl)_{n-1} + Sl = Ion^{\pm}(Sl)_n$

These provide $\Delta G^0_{n-1,n}$ and $\Delta H^0_{n-1,n}$. The key demonstration of the pertinence of the approach is given by plots of $\delta\Delta G^0_{0,n}$ (or $\delta\Delta H^0_{0,n}$) versus n, where $\Delta G^0_{0,n} = \Delta G^0_{0,1} + \Delta G^0_{1,2} + \cdots + \Delta G^0_{n-1,n}$. Consider two ions like B_0H^+ and BH^+, $\delta\Delta G^0_{0,n}$ is then given by $\delta\Delta G^0_{0,n} = \Delta G^0_{0,n}(BH^+) - \Delta G^0_{0,n}(B_0H^+)$. Plots of $\delta\Delta G^0_{0,n}$ versus n have shown, for a number of systems, that the $\delta\Delta G_{0,n}$ approaches the difference of the solvation energies of the ions in the liquid solvent already for some small n like $n =$ 5 or 6 or 7. (For examples of such plots see ref. 2 and Fig. 3 of this paper.) The success of this approach has a great attraction for the chemist since the formidable appearing problem of liquid solvent interactions is reduced to the familiar chemistry of ion–molecule, i.e. molecule–molecule interactions. An additional very important advantage is that the energetics, geometries, and even the thermodynamics (ΔH, ΔG, and ΔS) of an ion surrounded by a small number of molecules are amenable to theoretical calculations. The energetics and structures of small ion-molecule clusters — by quantum mechanical calculations (3), the energetics of large clusters — by pair potential calculations (4) and the thermodynamics with Monte Carlo calculations (4, 5). While such calculations can be executed with great computational input (large basis sets, large number of solvent molecules, periodic boundary conditions etc.) and the results can be of great significance, the effort may not be justified for a large number of different systems. Furthermore important qualitative insights may often be lost. It

is therefore desirable to have also more limited but skillfully applied calculations which provide qualitative insights. One such recent approach by Taagepera, DeFrees, Hehre, and Taft (6) is based on reactions [2]–[4].

[2] $R_0NH_3^+{}_{(g)} + RNH_{2(g)} = R_0NH_{2(g)} + RNH_3^+{}_{(g)}$

[3] $R_0NH_3^+{}_{(aq)} + RNH_{2(aq)} = R_0NH_3^+{}_{(aq)} + RNH_{2(aq)}$

[4] $R_0NH_3^+(H_2O)_3 + RNH_2(H_2O)_k = R_0NH_2(H_2O)_k + RNH_3^+(H_2O)_3$

Hehre and Taft (6) represent the aqueous medium effect $\delta\Delta G^0{}_{am}(exp)$ on the proton transfer between two primary amines as the difference between the energy for the proton transfer in the gas phase, reaction [2], and proton transfer in aqueous solution, reaction [3]. The medium effect is then given by eq. [5].

[5] $\delta\Delta G^0{}_{am}(exp) = \Delta G^0{}_2 - \Delta G^0{}_3$

Aqueous proton transfer [3] is then modelled by the process [4]. The aqueous ammonium ions are represented by the trihydrates involving the three strong primary hydrogen bonds, while the aqueous bases are variously modelled as containing zero, one, or three water molecules. One obtains a theoretical aqueous medium effect $\delta\Delta E_{am}$(STO-3G) by calculating the electronic energies of the

[6] $\delta\Delta E_{am}(STO\text{-}3G) = \Delta E_2 - \Delta E_4$

molecules entering reactions [2] and [4] with the minimal basis set STO-3G method. The authors (6) were able to show for several systems that $\delta\Delta E_{am}$ is very close to $\delta\Delta G^0{}_{am}$. For example, for $R_0 = C_2H_5$ and $R = CF_3CH_2$, $\delta\Delta G^0{}_{am}(exp) = -7.7$ kcal/mol, while $\delta\Delta E_{am}(STO\text{-}3G) = -7.3$ kcal/mol (for $k = 0$). Changes of $k = 0$ to $k = 1$ (one water molecule as proton donor to the nitrogen of the free base) and to $k = 3$ (additional two molecules as proton acceptors from the NH_2 group of the free base) did not improve the agreement with $\delta\Delta G_{am}(exp)$ significantly.

Since the accuracy of the STO-3G method can be questioned even when applied to an isodesmic process like [4], we were encouraged by Professor Taft to check the data by means of ion–molecule equilibria measurements. The outcome of these measurements is described in the following sections.

Experimental

The measurements were made with one of our pulsed electron beam high ion source pressure mass spectrometers using a quadrupole mass analyzer (7).

The clustering equilibria $(n - 1, n)$ (see reaction [7] and section on Results and Discussion) were measured in the presence of very small pressures of RNH_2 in order to avoid the formation of the protonated dimers $(RNH_2)_2H^+$. Typical gas mixtures were 0.1 mTorr RNH_2, 0.02–2 Torr H_2O, third gas CH_4 at ~4 Torr. Changes of water pressures by a factor of ~5 left the equilibrium constants $K_{n-1,n}$ invariant. The reaction sequence in the above mixture is: CH_5^+, $C_2H_5^+$ from CH_4 react very rapidly with H_2O leading to $H^+(H_2O)_n$. The proton hydrates react with RNH_2 forming $RNH_3(H_2O)_n^+$. The proton hydrates disappear completely as the $n - 1, n$ equilibria of the ammonium ions become established.

The proton and hydrate transfer equilibria (see reaction [8] and section on Results and Discussion) were measured with known mixtures of the two amines CH_3NH_2 and $C_2H_5NH_2$. The ratio methyl to ethyl amine was large in order to keep the methyl and ethylammonium intensities of similar magnitude. The constancy of the equilibrium constants was checked by varying the water pressure and the neutral amine concentration ratio.

Results and Discussion

As mentioned in the Experimental part, two types of equilibria measurements were made. The first kind were clustering equilibria $(n - 1, n)$ shown in reaction [7] for $R = CH_3$, C_2H_5, and CF_3CH_2 and $n = 1, 2, 3$.

[7] $RNH_3^+(H_2O)_{n-1} + H_2O = RNH_3^+(H_2O)_n$

The van't Hoff plots for these measurements are shown in Fig. 1. The thermochemical data resulting from the plots, $\Delta H^0{}_{n-1,n}$, $\Delta G^0{}_{n-1,n}$, and $\Delta S^0{}_{n-1,n}$ are shown in Table 1. A second set of experiments involved the measurement of equilibria [8] which involve proton and hydrate transfer.

[8] $R_0NH_3^+(H_2O)_n + RNH_2 = R_0NH_2 + RNH_3^+(H_2O)_n$

The van't Hoff plots for the equilibrium constants of reaction [8] for $R_0 = CH_3$ and $R = C_2H_5$ and $n = 0$ to 3 are shown in Fig. 2. The corresponding ΔG^0, ΔH^0, and ΔS^0 values are given in Table 1. Unfortunately equilibria [8] for $R_0 = C_2H_5$ and $R = CF_3CH_2$ could not be measured directly because of the large difference between the proton affinities of ethyl and trifluoroethyl amine.

The van't Hoff plots for reaction [8], Fig. 2, illustrate in a very graphic manner the attenuating effect of the aqueous medium on the proton transfer between methyl and ethyl amine. As n is increased from 0 to 3 there is a progressive decrease of slope, i.e. decrease of the exothermicity for the enthalpy change and a progressive lowering of the respective van't Hoff lines which signals a decrease of the exothermicity for the free energy change, with water addition. The corresponding numerical changes of ΔH^0 and ΔG^0 with n, in Table 1, permit a direct comparison with the $\Delta H^0{}_{(aq)}$ and $\Delta G^0{}_{(aq)}$ for proton transfer in the liquid aqueous medium (8) also given in Table 1. Increase of n leads to a progressive approach of the gas phase results to the aqueous values. At $n = 3$ the two sets of values come to within less than 1 kcal/mol.

The Taft–Hehre (6) measure of the aqueous medium effect: $\delta\Delta E_{am}$(STO-3G) (eq. [6]) corres-

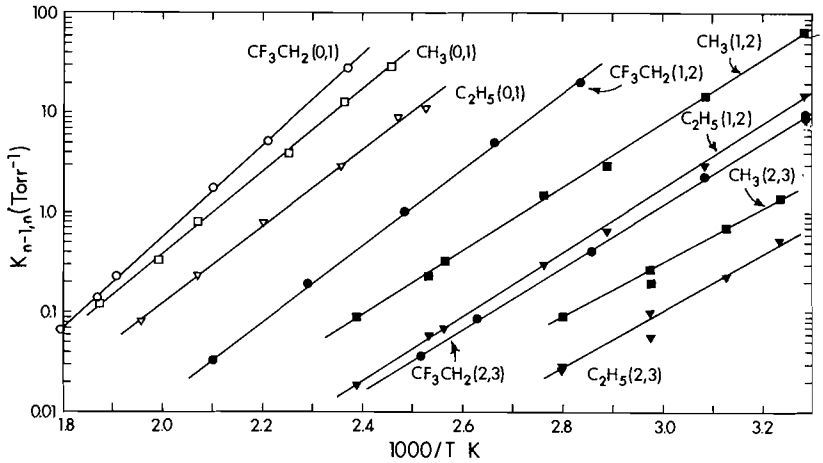

FIG. 1. van't Hoff plots of equilibrium constants $K_{n-1,n}$ for reactions $RNH_3^+(H_2O)_{n-1} + H_2O = RNH_3^+(H_2O)_n$. Numbers beside plots give value for $n-1,n$. The formulas give identity of R.

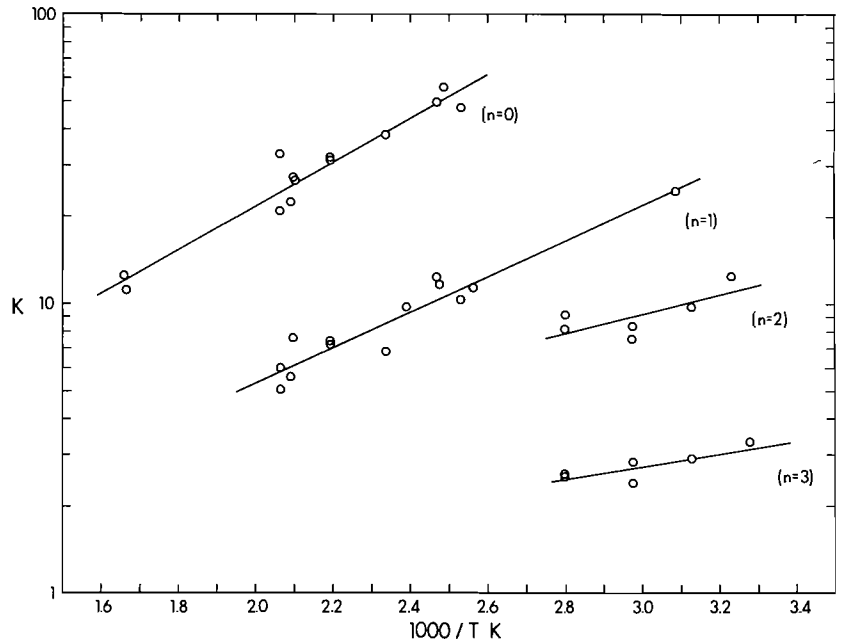

FIG. 2. van't Hoff plots of proton and hydrate transfer equilibria: $CH_3NH_3^+(H_2O)_n + C_2H_5NH_2 = CH_3NH_2 + C_2H_5NH_3^+(H_2O)_n$.

1 provide numerical values for eq. [10] with $n = 1$ to $n = 3$ for two base pairs: $R_0 = CH_3$, $R = C_2H_5$ and $R_0 = C_2H_5$, $R = CF_3CH_2$ dealt with by Hehre and Taft. For the pair CH_3, C_2H_5 a second set of $\delta\Delta H^0_{am}$(clust), and corresponding $\delta\Delta G^0$ can be obtained from the proton and hydrate transfer equilibra [8] by means of eq. [11], i.e. by subtracting the energy change for proton transfer in the absence of water

$$[11] \quad -\delta\Delta H^0_{0,n}(RNH_3^+) = \Delta H_8(n = n) - \Delta H_8(n = 0)$$

A summary of the data and a comparison with the STO-3G results is given in Fig. 3 which shows plots of $\delta\Delta H^0_{0,n}(RNH_3^+)$ and $\delta\Delta G^0_{0,n}(RNH_3^+)$ versus n. For the pair C_2H_5, CF_3CH_2 one finds very good agreement between the $\delta\Delta H^0_{0,3}$ and $\delta\Delta E_{0,3}$ results. The very close agreement is certainly fortuitous. Since the $\Delta H^0_{n-1,n}$ data have an error of some ± 1 kcal/mol, the cumulative error in the $\Delta H_{0,3}$ and $\delta\Delta H^0_{0,3}$ could easily be of the order of 2–3 kcal/mol.

Hehre and Taft (6) compared the $\delta\Delta E_{am}$(STO-3G) with the *free energy* $\delta\Delta G^0_{am}$(exp), see eq. [5]. The free energy rather than the enthalpy was chosen for the following reason. The $\delta\Delta E_{am}$ models only the hydrogen bonding solvent effect. In aqueous solution there are additional effects due to cavity formation CAV, structure making hydrophobic effects STR, van der Waals effects VDW, etc. (8). A partial cancellation of the $\delta\Delta H$ and $\delta(-T\Delta S)$ of the CAV, STR, VDW effects occurs so that the hydrgen bonding effect in the aqueous medium is quite well represented by the free energy difference $\delta\Delta G^0_{am}$(exp). Examination of Fig. 3 shows that for C_2H_5, CF_3CH_2 the gas phase hydrogen bonding data at $n = 3$ are in agreement with the corresponding $\delta\Delta G^0_{am}$, as was pointed out by Hehre and Taft (6) on the basis of $\delta\Delta E$(STO-3G).

As mentioned before, two sets of gas phase equilibria results are available for the pair $R_0 = CH_3$, $R = C_2H_5$, the data derived from the $(n-1, n)$ equilibria and the data from the proton and hydrate transfers, reaction [8]. For $\delta\Delta G^0_{0,n}(C_2H_5NH_3^+)$ the results from the two equilibrium determinations are in very good agreement. The $\delta\Delta G^0_{0,3}$ results are seen to be close to the $\delta\Delta G^0_{am}$(exp) and $\delta\Delta G^0_{aq}(C_2H_5NH_3^+)$ and the $\delta\Delta E_{am}$(STO-3G). Unfortunately the values obtained for $\delta\Delta H^0_{0,n}(C_2H_5NH_3^+)$ by the two different equilibrium measurements are not in good agreement. The largest differences ($\sim$2 kcal/mol) occurs for $n = 3$. The 0,3 value obtained from the $n-1, n$ equilibria (slopes of six van't Hoff plots) probably contains a larger accumulated error. Therefore these results are more suspect. If they are discounted, then one finds the $\delta\Delta E_{0,3}$(STO-3G) results of Hehre and Taft within less than 1 kcal/mol of the $\delta\Delta H_{0,3}$ results (equilibria [8]).

The present results fit into a more general trend, which is, that substituent effects on basicity and acidity are attenutaed in water due to hydrogen bonding to the ions, and particularly due to the

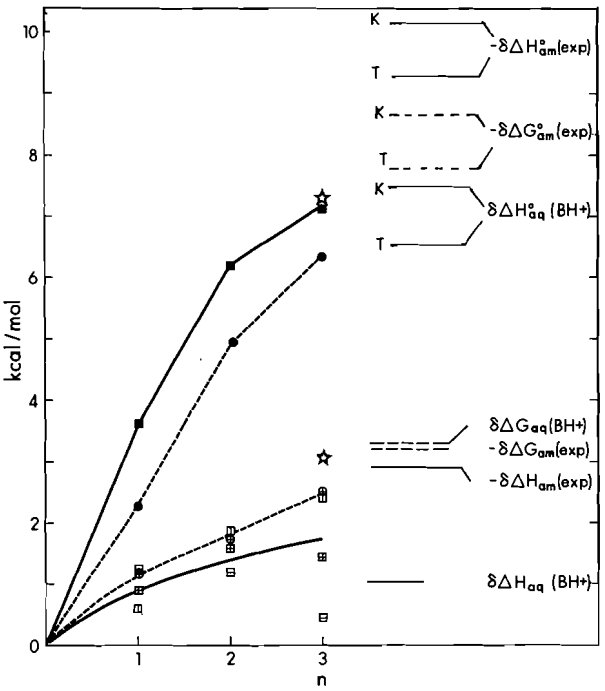

FIG. 3. Energy changes for hydrate transfer reactions:
[*a*] $C_2H_5NH_3(H_2O)_n^+ + CF_3CH_2NH_3^+ = C_2H_5NH_3^+ + CF_3CH_2NH_3(H_2O)_n^+$
■ $\Delta H^0 = \delta\Delta H^0_{0,n}(CF_3CH_2NH_3^+)$; ● $\Delta G = \delta\Delta G^0(CF_3CH_2NH_3^+)$; *$\Delta E$(STO-3G) Hehre and Taft (6). These data should be compared with $\delta\Delta H^0_{aq}(BH^+) = \Delta H^0_{aq}(CF_3CH_2NH_3^+) - \Delta H^0_{aq}(C_2H_5NH_3^+)$. Related quantities are also the aqueous medium effect: $\delta\Delta G^0_{am}$ and $\delta\Delta H^0_{am}$. Two sets of values: *K* and *T*, are shown for these data. This arises from differences in proton transfer in gas phase determinations (see footnotes *c* and *d* in Table 1). Read ordinate negative for reaction [*a*].
[*b*] $CH_3NH_3^+(H_2O)_n + C_2H_5NH_3^+ = CH_3NH_3^+ + C_2H_5NH_3^+(H_2O)_n$
$\Delta H^0 = \delta\Delta H^0_{0,n}(C_2H_5NH_3^+)$, ⊟ from $n-1,n$ equilibria Fig. 1, ◫ from equilibria [8] Fig. 2, ⊞ average of above, ⊕ $\Delta G^0 = \delta\Delta G^0_{0,n}(C_2H_5NH_3^+)$ average from $(n-1,n)$ equilibria and equilibria [8], results from the two types of equilibria are very close therefore only average is given in Table 1 and present figure. Read ordinate positive for reaction [*b*].

initial strong hydrogen bonds. Thus substituents that decrease the gas phase basicity of say RNH_2 increase the hydrogen bonding hydration of RNH_3^+. This automatic attenuation effect is simply expressed by the observation (9, 10) that hydrogen bonds in onium ions $BH^+...(OH_2)_n$ increase in strength as the acidity of BH^+ is increased, i.e., as the basicity of B is decreased. The operation of this rule is quite general and its important consequence on gas phase and aqueous substituent effects and the success of Hammet type plots based on aqueous acidities of benzoic acids has been discussed elsewhere (10). It may be pointed out that the van't Hoff plots in Fig. 1 provide one more illustration of the rule. The gas phase acidities of the onium ions RNH_3^+ increase in the order R = CF_3CH_2, CH_3, and C_2H_5. The van't Hoff lines for the (0, 1) interaction with water change slope and decrease in position in the same order. The interactions at higher $(n-1, n)$ follow the same trends, but the decreases of slope (ΔH) are somewhat less distinct than the decreases in height (ΔG).

Nitroxide derivatives of acetylacetone as spin-labelled ligands

D. PLANCHEREL[1] AND D. R. EATON

Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received July 7, 1980

D. PLANCHEREL and D. R. EATON. Can. J. Chem. **59**, 156 (1981).

Electron spin resonance spectra are reported from a number of radicals derived from 2,4-pentadione substituted at the 3 position with nitroxide-containing groups. If the substituent is *t*-butyl nitroxide no metal complexes are formed. This is attributed to steric factors which prevent the formation of the enol form of the β-diketone. If the substituent is trifluoromethyl nitroxide two types of metal complex have been observed. The esr spectra of the first type are very similar to that of the uncomplexed radical. Such complexes are formed with Co(III) and Al(III). The esr spectra of the second type show considerably increased ^{14}N and ^{19}F hyperfine coupling constants and in some cases large couplings to the metal nucleus. Complexes for the second type have been observed with Pd(II), Pt(II), and Rh(III). The possible structures of these radicals are discussed.

D. PLANCHEREL et D. R. EATON. Can. J. Chem. **59**, 156 (1981).

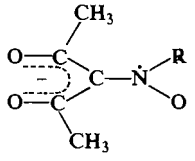
On rapporte les spectres de rpe d'un certain nombre de radicaux provenant de la pentadione-2,4 portant en position 3 un substituant contenant le groupe nitroxyde. Il ne se forme pas de complexes métalliques si le substituant est le *tert*-butylnitroxyde. On attribue ce fait à des facteurs stériques qui empêchent la formation de l'énol de la β-dicétone. Si le substituant est le trifluorométhylnitroxyde, on observe deux types de complexes métalliques. Le spectre de rpe du premier type est très semblable à celui du radical non complexé. De tels complexes se forment avec le Co(III) et le Al(III). Dans les spectres rpe du deuxième type, on note une augmentation considérable des constantes de couplage hyperfin du ^{14}N et du ^{19}F et dans certains cas de grands couplages avec le métal. On a observé des complexes du deuxième type avec le Pd(II), le Pt(II) et le Rh(III). On discute des structures possibles de ces radicaux.

[Traduit par le journal]

Introduction

Nitroxide radicals have been extensively used in chemistry and biochemistry as spin labels (1–3). The synthesis of a variety of compounds suitable for this purpose has been reported (4). Some years ago (5) we discussed the use of 4-pyridyl-*t*-butyl nitroxide as a spin-labelled ligand. The use of pyridine as the ligand moiety has some disadvantages. The complexes tend to be relatively labile, the esr spectra are fairly complex, and the nitroxide spin label is too far removed from the metal atom to make the observation of metal hyperfine coupling probable.

The intent of the present research was to investigate nitroxide substituted β-diketones as possible spin-labelled ligands. Specifically the potentialities of the anion radicals



R = *t*-butyl, CF_3

to serve as spin-labelled ligands have been explored. β-Diketone anions form very stable complexes with a wide variety of metal ions. The above radicals should give rather simple esr spectra — the *t*-butyl group does not give resolvable hyperfine splitting and at worst a small splitting can be anticipated from the methyl groups. At the same time, earlier nmr studies (6) have shown that relatively small modifications in metal–ligand bonding can give rise to large substituent effects at the γ position of β-diketone complexes.

Results

We report two sets of experiments, the first directed towards the synthesis of *t*-butyl nitroxide labelled metal complexes and the second towards the synthesis of trifluoromethyl nitroxide labelled complexes. The first set was unsuccessful as regards the primary objective. The results are nevertheless reported since they provide some interesting information on the stereochemistry of this class of radical. In the second set of experiments radicals containing metal ions are clearly formed but the chemistry is complex. Two different types of metal-containing radicals are involved, one with no hyperfine coupling to the metal and the other with large metal hyperfine coupling constants.

t-*Butyl Nitroxide Radicals*

The radicals are formed (7) by the reactions of *t*-butyl magnesium chloride with appropriate nitro compounds. There are two approaches to the formation of the spin-labelled acetylacetonate

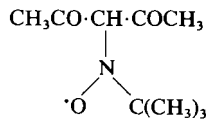
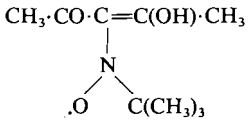
complexes — synthesis of the radical ligand followed by metal complex formation or nitration of acetylacetonate complexes followed by reaction with the Grignard reagent. Both approaches have been tried.

3-Nitro-2,4-pentanedione was prepared by literature methods (8, 9, 22) and reacted with *t*-butyl magnesium chloride in ether. The product could be extracted with other solvents. An esr spectrum in carbon tetrachloride is shown in Fig. 1(*a*) and the coupling constants are given in Table 1. The spectrum is entirely consistent with the radical **1***a*.



(**1***a*)

The coupling constants are within the range shown by similar nitroxides (10). 3-Nitro-2,4-pentanedione was deuterated by reaction with D_2O and after drying was reacted with *t*-butyl magnesium chloride. The esr spectrum shown in Fig. 1(*b*) results. Clearly the doublet splitting arises from the hydrogen at the 3 position. Treatment of the solution giving rise to spectrum 1*b* with water leads to no proton exchange. In another experiment an excess of base (cyclohexylamine) was added to a solution of the radical **1**, and again produced no change. It appears that this radical cannot exist in the enol form **1***b*.



(**1***b*)

Treatment of solutions of **1***a* with a variety of metal salts and complexes in several solvents leads to no new esr spectra.

Complexes of Co(III) 3-nitroactylacetone were prepared by the method of Collman *et al.* (8, 11) and separated by chromatography. No radicals were obtained by reaction with *t*-butyl magnesium chloride. Analogous Al(III) complexes are too labile to separate by chromatography. Reaction of a mixture of nitration products with *t*-butyl magnesium chloride leads to the formation of radical **1***a* and a second short-lived radical. The quality of the esr spectra of the latter species were inadequate for analysis. The nitration of Zn(II) acetylacetonate was unsuccessful, only Zn(II) acetate being isolated. We note that Statsko and co-workers (12) have reported the production of an anion radical of acetylacetone by the reaction of Grignard reagents with metal acetylacetonates. This radical was not observed in the present work.

All of the above results indicate that radical **I** can exist only in its keto form. It is difficult to rationalise this conclusion on the basis of electronic effects. The nitro compound is predominantly in the enol form (22) and there seems no good electronic reason why the nitroxide should be vastly different. A more likely explanation lies in steric effects. Molecular models indicate that the enolate is only possible if the π system of the acetylacetonate ring is perpendicular to the π N—O bond — the bulky *t*-butyl group prevents coplanarity. The keto isomer on the other hand is relatively sterically unhindered. The keto isomer though is only capable of forming weak complexes with metal ions (13). It appears that a less sterically hindered nitroxide is necessary to produce a good spin-labelled ligand (18).

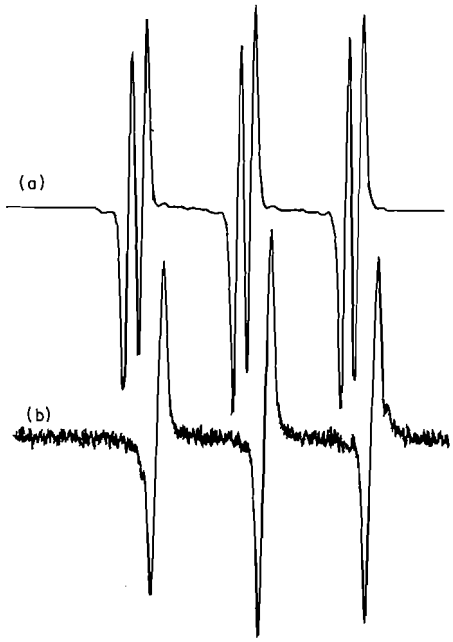


FIG. 1. (*a*) Electron spin resonance spectrum of 3 *t*-butyl nitroxide 2,4-pentanedione, in CCl_4; (*b*) esr spectum of this radical deuterated at the 3 positions in ether.

TABLE 1. Electron spin resonance data of *t*-butyl nitroxides

Molecule	a_N (G)	a_H (G)	ΔH (G)	g	Solvent
I	14.0_9	1.75	0.93	2.0066	CCl_4
	13.96	1.81		2.0064	Benzene
	13.88	1.72		2.0064	Et_2O
3-*d* **I**	13.88		1.04	2.0064	Et_2O

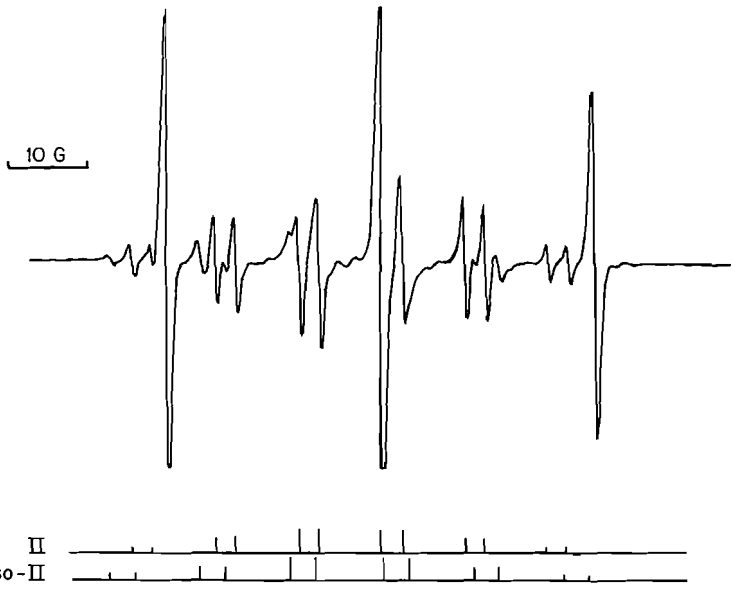

FIG. 2. Electron spin resonance spectrum from the reaction of equimolar acetylacetone and trifluoronitrosomethane, in CCl_4. The three intense lines are assigned to the iminoxy radical (**IV**) and the less intense lines arise from the diketo radicals (**II**) and (iso-**II**). The keto enol (**III**) is not visible in this spectrum.

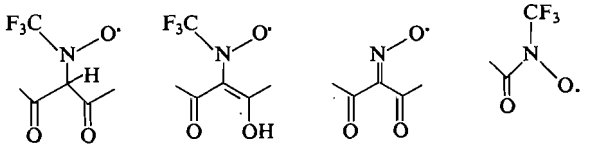
Trifluoromethyl Nitroxide Radicals

Booth *et al.* (14) have studied the reaction between trifluoronitrosomethane and acetylacetone and have reported the radical products **II** to **V**.



II **III** **IV** **V**

The occurrence of the enol radical **III** suggests that replacement of the *t*-butyl group by the trifluoromethyl group could circumvent the steric problems encountered above. We have therefore examined the reaction of trifluoronitrosomethane with both acetylacetone and with a variety of metal acetylacetonates.

Reaction of Trifluoronitrosomethane and Acetylacetone

The esr spectra obtained by this reaction are broadly in agreement with those reported by Booth *et al.* (14). A typical spectrum is shown in Fig. 2. The three most intense lines are assigned to the iminoxy radical **IV**. This radical decays relatively rapidly and after 30 min the main radical species present is the diketo radical **II** with smaller concentrations of the enol radical **III** and an unidentified species labelled iso-**II** in the figure. From the similarity of the coupling constants, we suspect that iso-**II** may be a geometric isomer of **II** possibly with the two keto group *trans*. We did not observe the radical **V**. Coupling constants are given in Table 2.

Reaction of Trifluoronitrosomethane with Aluminum Acetylacetonate

A spectrum obtained from this reaction is shown in Fig. 3. This spectrum represents the situation $2\frac{1}{2}$ h after the reaction was started. At earlier times radicals **II** and **IV** are present but appear to be less stable than in the case of the reaction with acetylacetone. The spectrum of Fig. 3 gives coupling constants and a *g* value similar to those reported for **III**. The differences, although small, are significant (see Table 2). The simplicity of the spectrum arises from the accidental equivalence of the ^{19}F and ^{14}N coupling constants. This radical is much more stable than those described above and can be easily detected 24 h after mixing the reactants. On the basis of the hyperfine coupling constants and the stability we assign it to the Al(III) complex of the anion of radical **III**. Note that no ^{27}Al hyperfine coupling can be detected.

Reaction of Trifluoronitrosomethane with Cobalt(III) Acetylacetonate

This reaction appears to be very similar to that with the aluminum complex. Again radicals **II** and **IV** appear in a transitory manner but the most stable species (remaining for more than 24 h) gives a spectrum very similar to the keto enol radical **III**. In this case (Table 2) the esr parameters are not significantly different. No ^{59}Co coupling is ob-

served. On the basis of the greatly enhanced stability (note that with acetylacetone we never observe the enol as more than a relatively minor component of the mixture) and by analogy with the Al(III) results we attribute the long-lived esr spectrum to a Co(III) complex of the anion of **III**.

Reaction of Trifluoronitrosomethane with Palladium(II) Acetylacetonate

This reaction gives quite different results to those described above. Initially radicals **II** and **IV** are observed with rather low intensities but these disappear completely after 12 h. There is also some indication of iso-**II**. After an induction period of 1 to 2 days two new radical species, labelled α and β in Fig. 4 appear. These spectra persist for 5 to 7 days with β being the longer-lived and predominating towards the end of this period. Both species can be analysed in terms of coupling to a ^{14}N atom and a CF_3 group, but both of these coupling constants are very much larger (12–14 G as opposed to 8–9 G) than those encountered previously. In addition the α radical has a further small coupling (2.5 G) with an $I = 1/2$ nucleus, presumably H. A typical spectrum, together with a computer simulation, is shown in Fig. 4. The agreement between the observed and simulated spectrum is sufficiently close to give confidence in the analysis. No ^{105}Pd coupling is observed but since the lines from the splitting due to this $I = 5/2$ nucleus would have only 3.5% of the main line intensities, this is not surprising. From the large changes in hyperfine coupling and the greatly enhanced stability it seems certain that the species responsible for these spectra contain

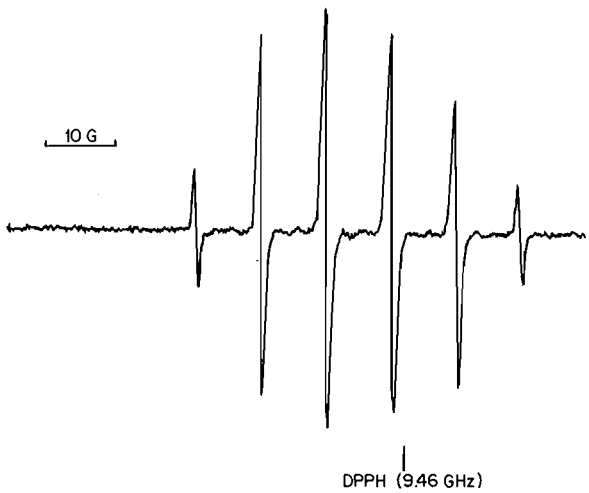

FIG. 3. Electron spin resonance spectrum from the reaction of $Al(acac)_3$ with trifluoronitrosomethane (1:3 mole ratio) in CCl_4. The only radical species present is the Al(III) complex of radical **III**.

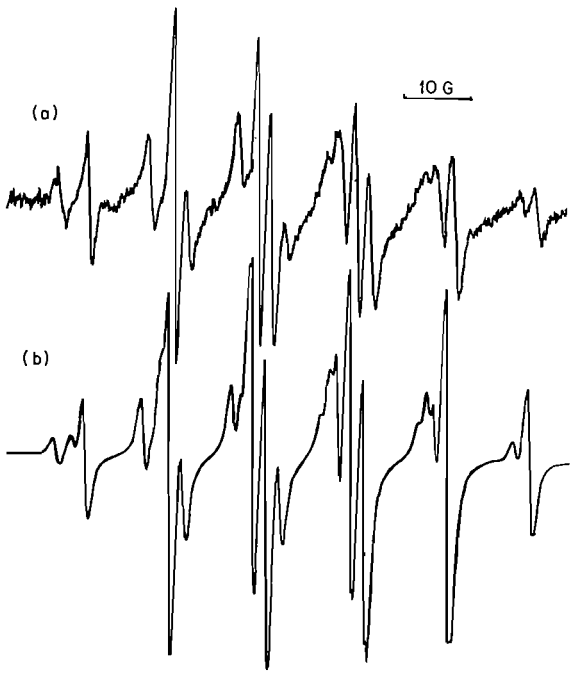

FIG. 4. (*a*) Electron spin resonance spectrum of the product from the reaction of $Pd(acac)_2$ with trifluoronitrosomethane (1:2 mole ratio) in CCl_4 after 6 days; (*b*) simulated spectrum using the parameters for the αPd and βPd radicals given in Table 2 and a Lorentzian line width of 1.0 G. The assumed concentration ratio of the αPd radical to the βPd radical is 0.3:1.0.

the metal ion. Electron spin resonance parameters are given in Table 2. Possible structures will be discussed below.

Reaction of Trifluoronitrosomethane with Platinum(II) Acetylacetonate

This reaction proceeds in a similar manner to that with the palladium analogue. There is only a single final product with ^{14}N and ^{19}F coupling constants quite similar to those of the β-palladium compound. In this case though there is an additional large coupling (63.2 G) ascribed to the 33.8% of ^{195}Pt with $I = 1/2$. A typical spectrum together with the computer simulation is shown in Fig. 5 and the measured parameters are given in Table 2. The final radical is stable for 8 to 12 days. In the early stages of the reaction there is some evidence for an additional "precursor" radical but the intensity was insufficient to allow analysis of the esr spectrum of this radical.

Reaction of Trifluoronitrosomethane with Rhodium(III) Acetylacetonate

This reaction shows some of the features of both the cobalt acetylacetonate and the palladium/platinum acetylacetonate reactions. Initially **II** and **IV** plus apparently some uncomplexed **III** are observed. After a few hours a new spectrum with large ^{14}N and ^{19}F couplings grows in intensity. This spectrum shows a ^{103}Rh coupling of 4.3 G (data in Table 2). However, this radical is much less stable than the Pd and Pt analogues and disappears after 5 or 6 h. Finally a weak spectrum (Fig. 6) remains. We do not believe that this represents a metal-containing species.

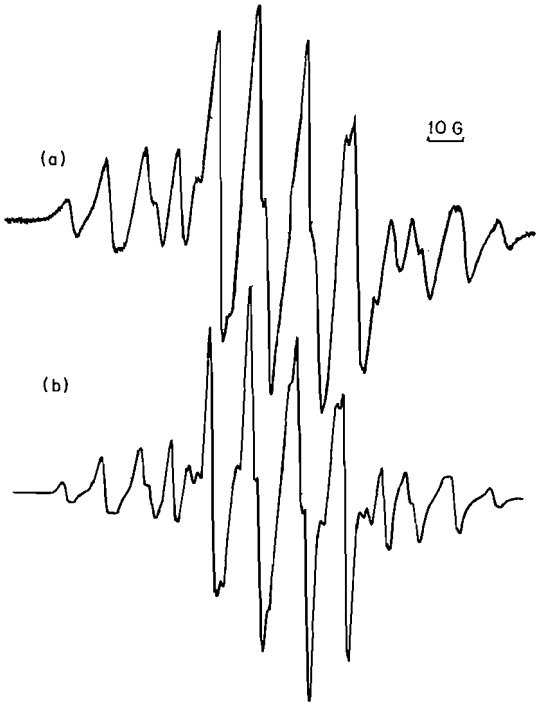

FIG. 5. (*a*) Electron spin resonance spectrum of the product from the reaction of $Pt(acac)_2$ with trifluoronitrosomethane (1:3 mole ratio) in CCl_4 after 1 day; (*b*) simulated spectrum using the parameters of Table 2 and a Lorentzian line width of 2.35 G.

Reaction of Trifluoronitrosomethane with Iridium(III) Acetylacetonate

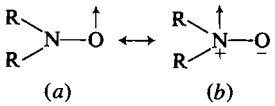
We have been unable to positively identify any metal-containing radical species in this reaction. Early in the reaction **II**, **IV**, and iso-**II** are all present as is the keto enol **III**. This latter radical shows very similar coupling constants to the version obtained from free acetylacetone and the stability is not significantly enhanced. There is therefore no real evidence for complex formation. After standing for several days the weak spectrum of Fig. 6 remains.

Discussion

The failure of the radical **I** to form metal complexes is almost certainly steric in origin. In its enol form the central carbon of the acetylacetone must be planar and this leads to steric hindrance between the methyl groups of the acetylacetone and the *t*-butyl substituent on the nitroxide. In the keto form the central carbon is tetrahedral and the steric hindrance is less. It has been reported elsewhere (15) that sterically hindered β-diketones exist exclusively in the keto form.

From the results of the reactions with aluminium (III) acetylacetonate and cobalt(III) acetylacetonate it seems very probable that the radical **III** does form metal complexes but that the effects of the metal are minimal. This is not therefore a satisfactory spin-labelled ligand. It is well established (5) that spin density from the nitroxide groups can be delocalized to neighbouring π systems when the stereochemistry is favourable. We must assume in this case that the π system of the nitroxide and that of the β diketone are fixed in mutually perpendicular planes to minimize steric interactions. We note that the ^{14}N and ^{19}F hyperfine coupling constants for radical **III** are not substantially different from those reported for the trifluoromethyl phenyl nitroxide (2).

The most interesting radicals are those formed in the reactions with Pd, Pt, and Rh acetylacetonates. Nitroxide radicals can be regarded as resonance hybrids of the two structures



(*a*) (*b*)

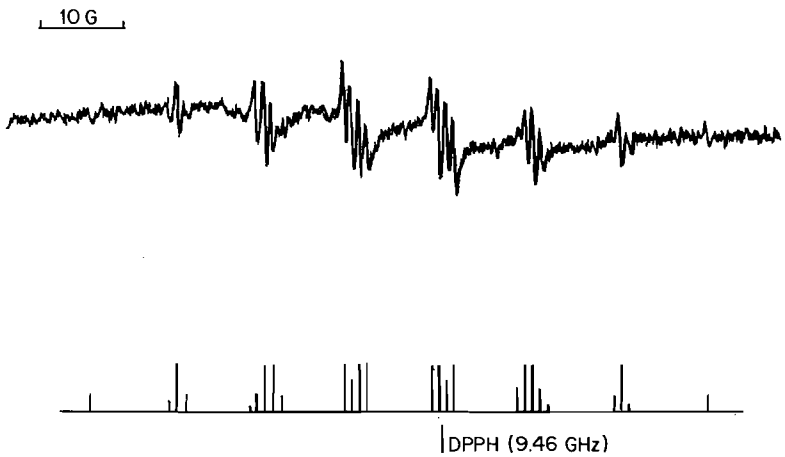


FIG. 6. Electron spin resonance spectrum of the final radical species from the reaction of $Rh(acac)_3$ or $Ir(acac)_3$ with trifluoronitrosomethane. Solvent CCl_4; 5 days reaction time. The analysis shown is for $H{\cdot}NO{\cdot}CF_3$ assuming the parameters given in the text.

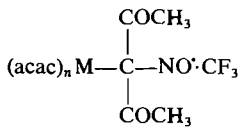
The greater the contribution of structure *b* the larger will be the ^{14}N hyperfine coupling since it is this structure which places the unpaired electron on the nitrogen. The large increase in ^{14}N hyperfine coupling for the Pd, Pt, and Rh radicals indicates that structure *b* is favoured. The observation of metal hyperfine coupling demands a radical which places the metal close to the nitroxide group. It may be noted that the numerical value of the ^{103}Rh coupling constant is much smaller than that of the ^{195}Pt coupling. Part of this difference arises from the smaller magnetic moment of ^{103}Rh.

We have considered three possible types of structure for these radicals.

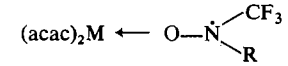
(*i*) One of the features of the chemistry of the β-diketonate complexes of the heavy transition metals in the formation of C bonded complexes in addition to O bonded complexes (16, 17).

Thus structures of the type



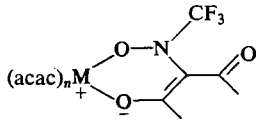
are possible.

(*ii*) The direct addition of nitroxide radicals to metal complexes with a vacant coordination site has been reported (1); i.e. structures of the type

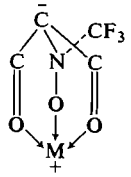


where R could be any of the groups corresponding to radicals **II**, **III**, or **V** or even a completely different group.

(*iii*) Formation of a metal nitroxide bond could be combined with bonding to the β-diketonate function. There are two modifications of this possibility. The ligand could remain bidentate in which case an NO bond replaces a CO bond, i.e.



Alternatively the ligand could become tridentate, i.e.



In this case the central carbon has become tetrahedral, with the resultant loss of aromaticity in the β-diketonate moiety, but with the added stability associated with a tridentate ligand. In either case there is the possibility of protonating the central carbon. A model indicates that the tridentate structure has very little strain.

The large ^{14}N coupling constant argues against alternative (*i*). It has been shown (19) that for phenyl nitroxide radicals electron withdrawing substituents favour resonance form (*a*) and decrease the ^{14}N coupling. Coordination of the carbon to a positive metal centre would be expected to have a similar effect. Neither does this structure provide a ready explanation of the additional ^{1}H coupling in the Pd α radical. Coordination of the nitroxide oxygen on the other hand would favour resonance structure (*b*) and increase the ^{14}N coupling. Alternative (*ii*) is satisfactory in this respect but cannot account for the additional ^{1}H coupling. Alternative (*iii*) is satisfactory in both respects. We favour the tridentate ligand since this will also ac-

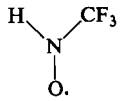
For personal use only.

count for the slow rate of formation of the radical (considerable molecular reorganization is necessary) and the high stability of the final product. It also provides a ready explanation of the greater stability of the Pd and Pt compounds compared with the Rh compound since in the former cases an additional coordination site is already available whereas in the latter case an acetylacetonate must be displaced. However, this assignment must remain tentative.

Booth *et al.* (14) have discussed possible mechanisms for the reaction of trifluoronitrosomethane with β-diketones and have rationalized the production of the various radicals observed. Their mechanisms are equally applicable to complexed β-diketones and we can add little to this discussion.

Finally we comment on the radical giving rise to the spectrum of Fig. 6. The esr spectrum can be fitted to that expected for the radical



with $a_F = 11.1 \pm 0.1$ G, $a_N = 12.0 \pm 0.1$ G, $a_H = 21.2 \pm 0.1$ G, and $g = 2.0069$. We have no ready explanation for the formation of this radical and the assignment must remain tentative. The radical anion CF_3NO^- has been reported (20) but the analysis of the spectrum is unclear.

Experimental

The majority of spectra were obtained using a JEOLCO-JES-3BS-X spectrometer operating at 9400 MHz. A few spectra were obtained with a Varian E-line spectrometer (University of Guelph) which has a higher sensitivity. Metal acetylacetonates were purchased from Research Organic/Inorganic Chemical Co.

Cobalt(III) [Bis(acetylacetonate)(3-nitroacetylacetonate)]

This complex was synthesized by analogy with the cobalt(III) [bis(3-nitroacetylacetonate)] (8) and the mixed ligand chromium(III) complexes (11). Finely ground $Cu(NO_3)_2 \cdot 3H_2O$ (1.6 g, 6.5 mmol) was dissolved in 100 mL acetic anhydride and stirred 30 min at 0°C. Cobalt(III) trisacetylacetonate (4.2 g, 1.8 mmol) was then added in 2–3 min. The mixture was stirred 3 h at 0°C and 1 h at room temperature, then poured into 1 L water/ice (1:1) and 11 g sodium acetate; this was again stirred 1 to 2 h. This solution (or suspension if any precipitate was present) was extracted three times with 300 mL chloroform. The chloroform solution was washed four times with 125 mL aqueous sodium acetate (5%) and twice with 200 mL water. The solution was dried over Na_2SO_4. The chloroform was then distilled off under vacuum and the dry residue was chromatographed on silica gel (60–120 mesh) with ethylacetate/benzene (1 to 2:100) as eluent. The column was approximately 30 cm long and 5 cm in diameter.

The products come in the order tri-, di-, mono-nitro derivatives; the separation of the di- and mono-nitro derivatives is reasonable and becomes excellent when a fractionator is used.

The purity was checked by thin layer chromatography and nmr (21). The complexes were recrystallized in chloroform/methanol. Yield: mono-nitro, 1.65 g (35%); di-nitro, 0.32 g (6%); unseparated ~ 1 g.

Copper(II) [Bis(3-nitroacetylacetonate)]

This was synthesized by the procedure of Collman and coworkers (8). It is interesting to note that the addition of copper nitrate must be carried out very slowly and carefully. There is an induction period of a few minutes before the very exothermic reaction starts.

3-Nitroacetylacetone

The procedure described by Yoshida *et al.* (22) was followed but 15 g of EDTA disodium salt were used instead of 150 g (probably a mistake) of EDTA diammonium salt.

3-d 3-Nitroacetylacetone

3-Nitroacetylacetone (0.1 mL) was dissolved in 5 mL $CDCl_3$ and shaken twice with 0.2 mL D_2O. The $CDCl_3$ solution was dried over Na_2SO_4 and then the $CDCl_3$ was removed under vacuum. The complete replacement of the methine and enol protons was checked by ^{1}H-nmr. The 3-*d* 3-nitroacetylacetone was used without further purification.

t-*Butylnitroxides*

General procedure: An approximately 0.2 *M* ethereal solution of *t*-butyl magnesium chloride was used in all cases.

Typically a 0.5 *M* to 3 *M* ethereal solution of the nitro derivative was slowly mixed with a stoichiometric excess of *t*-butyl magnesium chloride, and stirred 30 min at 0°C. After neutralization with ammonium chloride the mixture was extracted with ether and dried over sodium sulphate. If necessary, the ethereal solution was concentrated under vacuum.

3-(t-Butylnitroxyl)acetylacetone

The above general procedure was carried out with 0.65 g of 3-nitroacetylacetone (4.4 mmol) in 5 mL of dry ether. After neutralization and extraction, the ether was distilled off under vacuum, and the yellow product was chromatographed on a small column (Pasteur pipette; silica gel 60–200 mesh) with benzene as eluant. It was not possible to determine the purity of the obtained product but it was assumed to be between 50% and 80% as pure nitroxide.

3-d 3-(t-Butylnitroxyl)acetylacetone

The general procedure was used, starting with 3-*d* 3-nitroacetylacetone and using pure D_2O (without NH_4Cl) for the neutralization. The ethereal extract was concentrated or evaporated to dryness but not further purified. Experiments with this radical were mainly qualitative.

Some water (H_2O) was added to an ethereal solution of the deuterated nitroxide and no proton exchange was observed in the esr spectrum.

Trifluoronitrosomethane (CF_3NO) (14, 23, 24)

Silver trifluoroacetate was synthesized by reaction of trifluoroacetic acid with silver oxide (23). Then the procedure described by Taylor, Brice, and Wear (25) was followed. The obtained yield (23%) is lower than the value given in the literature (56%). The CF_3NO was distilled twice.

It is a blue compound as vapour (room temperature), liquid, or solid (77 K).

Trifluoronitroxyl Radicals (14)

Carbon tetrachloride was dried over molecular sieves (type 4A) and deoxygenated by bubbling dry nitrogen through it. Due to the different solubilities the solutions had the following concentration ranges: 0.05 *M* to 0.1 *M*: acacH; Co(III) and Al(III) acetylacetonates 0.01 *M* to 0.03 *M*: Rh(III), Ir(III), Pd(II), and Pt(II) acetylacetonates. The standard procedure was to make up a solution of the above mentioned concentration in carbon tet-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

rachloride. Dry nitrogen was bubbled a few minutes through this solution. Then 0.5 mL to 1 mL was transferred into an nmr tube and was degased using standard vacuum techniques. The required amount of trifluoronitrosomethane was then distilled into this tube from a vacuum system, before the tube was sealed under vacuum. The ratio of trifluoronitrosomethane and acetylacetone (free or complexed) was between 0.3:1 and 2:1. This means, e.g., a ratio $Co(acac)_3$:CF_3NO between 1:1 and 1:6 respectively.

The sealed tube was then warmed up from 77 K to room temperature in less than 2 min, and the esr spectra recorded.

With all metal complexes a precipitate was slowly formed. This was negligible in the case of $Al(acac)_3$ but was important with the other complexes, making any nmr measurement inaccurate (if the precipitate was suspended) or unreal (if it was centrifugated to the upper end of the tube, outside the measured solution). This precipitate was white (Al(III)) or brown to dark brown (Co, Rh, Ir, Pd, Pt).

Ouverture de dichlorocyclopropanes en présence d'un nucléophile interne. Absence de participation intramoléculaire. Réarrangement concerté en chlorures allyliques

LAURENT CHICHE, HENRI CHRISTOL, JACQUES COSTE, FRANCINE PIETRASANTA ET FRANÇOISE PLÉNAT
ERA No 610, Laboratoire de Chimie Organique, E.N.S. Chimie, 8, rue de l'Ecole Normale, 34075 Montpellier, France
Reçu le 25 avril 1980

LAURENT CHICHE, HENRI CHRISTOL, JACQUES COSTE, FRANCINE PIETRASANTA et FRANÇOISE PLÉNAT. Can. J. Chem. **59**, 164 (1981).

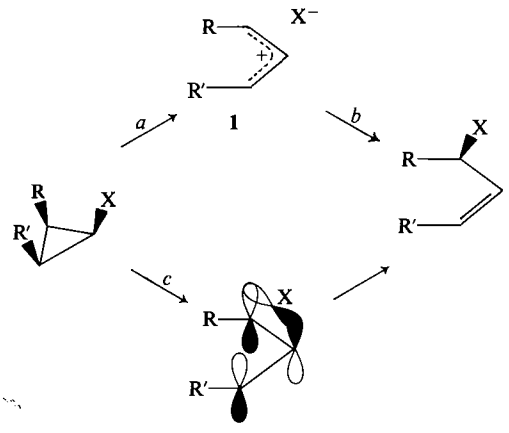
On montre qu'un nucléophile interne convenablement placé (groupement carboxylate), n'intervient pas au cours du réarrangement d'un dichlorocyclopropane en chlorures allyliques. Ce résultat paraît en faveur d'un mécanisme concerté, de type $\sigma_s^2 + \sigma_a^2$, pour ce réarrangement. Dans les composés obtenus, le chlore allylique peut ensuite être déplacé soit par le solvant (H_2O) pour conduire à des alcools, soit par le groupement carboxylique interne pour conduire à une lactone.[1]

LAURENT CHICHE, HENRI CHRISTOL, JACQUES COSTE, FRANCINE PIETRASANTA, and FRANÇOISE PLÉNAT. Can. J. Chem. **59**, 164 (1981).

It is shown that a conveniently placed internal nucleophile (carboxyl group) is not involved with the rearrangement of a dichlorocyclopropane into an allylic chloride. This result appears to support a concerted mechanism of a $\sigma_s^2 + \sigma_a^2$ type for this rearrangement. In the products obtained, the allylic chloride may undergo displacement either by solvent (H_2O), leading to alcohols, or by the internal carboxyl group, leading to a lactone.

[Journal translation]

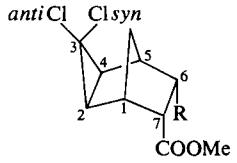
On sait que les halocyclopropanes conduisent par thermolyse à des halogénures d'allyle. L'ouverture du microcycle est presque toujours considérée comme concertée avec le départ de l'halogène et se conforme aux règles de Woodward–Hoffmann (schéma 1, étape a) (2). La paire d'ions intermédiaire **1** est suffisamment intime pour que le retour de l'halogène en position allylique se montre stéréospécifique (étape b) (2, 3). Jefford a proposé un autre mécanisme possible rendant bien compte de la stéréospécificité globale observée (2); il s'agirait d'une transposition 1,3 sigmatropique selon un processus $\sigma_s^2 + \sigma_a^2$, processus totalement concerté (étape c).



2

SCHÉMA 1

La distinction entre ces deux mécanismes s'est révélée délicate (3, 4). Toutefois, dans la première hypothèse, le développement d'une charge positive sur les carbones 2 et 3 devrait permettre à un nucléophile interne, convenablement placé et suffisamment puissant, d'intervenir pour conduire à des produits de cyclisation intramoléculaire. La participation d'un hydroxyle interne a ainsi déjà été suggérée (5); mais il n'a pas été démontré que l'éther cyclique obtenu dans ce cas ne résulte pas de la cyclisation, dans le milieu basique utilisé, de composés à chlore allylique qui auraient été primitivement formés par réarrangement thermique. De façon contradictoire, une absence de participation a été constatée pour le réarrangement des composés tricycliques **3** et **4** qui conduisent exclusivement aux esters à chlore allylique (4, 6):



3 R = H
4 R = COOMe

FIG. 1

Ce résultat pouvait être utilisé comme un argument en faveur d'un mécanisme totalement concerté. Cependant d'autres interprétations sont possibles; dans le cas d'un mécanisme ionique (schéma 1, étapes a et b), la participation d'un nucléophile interne peut entrer en jeu pendant ou après la formation de la paire d'ions **1**. Si elle est concomitante,

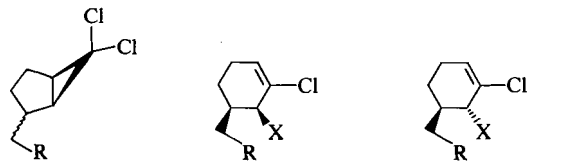
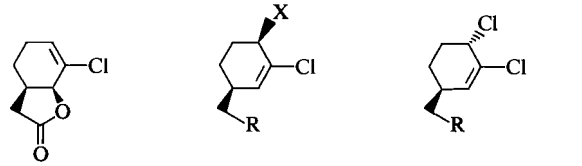
l'attaque du nucléophile interne est attendue avec inversion de configuration, comme l'était celle d'un nucléophile externe (3), ce qui n'est pas possible pour les composés **3** et **4**. D'un autre côté, une fois la paire d'ions **1** formée, cette contrainte stéréoélectronique n'existe plus, mais il y a alors possibilité de compétition entre le retour de l'halogène et l'attaque du nucléophile interne, et on peut craindre qu'à ce titre une fonction ester méthylique ne soit pas assez puissante.

Nous avons choisi pour notre part comme substrats les composés **5** qui présentent les avantages suivants. D'une part la souplesse relative de la molécule doit laisser au nucléophile interne la possibilité d'attaquer avec la stéréochimie requise, comme le suggèrent les résultats obtenus par Marshall et Ellison (7) dans la solvolyse de cyclopropyls–carbinols de même squelette. D'autre part, la tension de cycle, suffisamment faible pour que les composés dichlorocyclopropaniques puissent être isolés, demeure cependant assez forte pour que l'extension de cycle reste facile. Il sera dès lors possible de modifier le nucléophile interne (acide carboxylique ou carboxylate) et de faire varier les conditions de l'ouverture du noyau cyclopropanique, ce qui n'était pas le cas pour les composés **3** et **4**, ceux-ci se réarrangeant dans les conditions même de leur synthèse.

L'ouverture des composés **5** conduit, dans des proportions variables suivant les essais (Tableau 1), à la formation de la lactone **6**, des produits de réarrangement **7**, **9**, **11** et **13**, et de trois alcools **8**, **10** et **12**.



5a R = COOMe **7** X = Cl; **8** X = OH **9** X = Cl; **10** X = OH
b R = COOH
c R = COONa



6 **11** X = Cl; **12** X = OH **13**

SCHÉMA 2

Synthèses et structures

Composés bicycliques 5a *et* 5b

Les composés **5***a* ont été préparés par action du trichloracétate de méthyle, en présence de méthylate de sodium, sur le (cyclopenténYl-3)acétate de méthyle. Le spectre de rmn du produit d'addition, en présence d'$Eu(DPM)_3$, indique l'obtention des deux isomères *cis* et *trans* dans les proportions 25:75. L'hydrolyse basique de ce mélange conduit aux acides **5***b* dont l'isomère majoritaire a été isolé par l'intermédiaire du sel de dicyclohexylamine correspondant. Après régénération de l'acide, l'isomère **5***b* majoritaire est estérifié (CH_2N_2); l'identification a été faite à ce niveau et repose sur des corrélations chimiques (schéma 3): par réduction (Na/NH_3), puis régression de la chaîne latérale, on obtient le composé **15**-*trans*. L'isomère **15**-*cis* a été préparé par ailleurs (8) à partir du composé **16**-*cis* connu (9).

On démontre ainsi la stéréochimie *trans* de l'isomère **5** majoritaire. Par ailleurs, la réduction du mélange des isomères **5***a* (*cis*/*trans* = 25:75) conduit au mélange des isomères **14**-*cis* et *trans* connu (8), ce qui confirme la nature *cis* de l'isomère **5** minoritaire.

Composés d'extension de cycle

Les principales preuves chimiques utilisées dans les attributions de structure sont exposées sur le schéma **4**.

Le caractère γ-lactonique du composé **6** apparaît en ir ($\nu_{C=O}$ = 1780 cm^{-1}). Le spectre de rmn correspond bien à la structure proposée; la faible valeur de la constante de couplage entre H-2 et H-1 (J = 5,5 Hz) indique une jonction de cycle *cis* (10); en effet, les lactones de ce type à jonction de cycle *trans* présentent des constantes de couplage nettement supérieures ($J \geq$ 10 Hz (11)). La structure de ce composé a été confirmée par voie chimique par corrélation avec la lactone saturée **17** connue (fig. 2). La réduction en présence de palladium a été conduite sur le sel de sodium correspondant à la lactone **6**, en milieu basique fort, afin d'éviter l'hydrogénolyse de la liaison alkyle–oxygène (11*c*, 12).

L'hydrolyse basique de la lactone **6** conduit à l'hydroxyacide **8***b* qui est donc de stéréochimie *cis*; en effet, en présence d'une base suffisamment concentrée, l'hydrolyse des esters se fait uniquement par rupture de la liaison acyle–oxygène (13), donc ici avec rétention de configuration du carbone C-2. Pour confirmation, on constate que l'hydroxyacide **8***b* redonne la lactone **6** par cyclisation spontanée. En outre, l'hydroxy-ester **8***a* conduit, par réduction, à l'ester **18** qui, par cyclisation, donne la lactone saturée *cis* **17** connue. Les structures de la lactone **6** et des composés **8***b* et **8***a* (obtenu par estérification de l'acide **8***b*) sont ainsi établies sans ambiguité.

SCHÉMA 4

Les alcools **10***b* et **12***b* conduisent, par catalyse acide (benzène, acide *p*-toluènesulfonique) à la lactone **6**; cela indique un même squelette de base pour ces trois composés (et pour les esters dérivés **10***a* et **12***a*). Le composé **10***a* dont le spectre de rmn est voisin de celui du composé **8***a* (en particulier le proton éthylénique résonne sous la forme d'un triplet) est donc l'isomère *trans* indiqué. La structure de l'alcool **12***a*, en accord avec ses propriétés spectrographiques (en particulier le proton éthylénique résonne en rmn sous la forme d'un doublet), a été établie par réduction puis hydrolyse en hydroxy-acide **19**, connu (14).

FIG. 2

Les quatre isomères dichlorés **7**, **9**, **11** et **13**, obtenus en mélange par chauffage des composés **5**, n'ont pu être séparés directement, ni en tant qu'esters, ni en tant qu'acides. Cependant, par hydrolyse basique douce du mélange d'esters, les deux isomères **9***a* et **11***a* se cyclisent en lactone **6**, ce qui a permis d'isoler le mélange de **7***b* + **13***b*, dont la chromatographie sur colonne, permet d'isoler de très faibles quantités de chacun des deux isomères purs.

Les composés **9***a* et **11***a* ont du être préparés par d'autres voies, puis identifiés comme composants du mélange **7***a* + **9***a* + **11***a* + **13***a* par rmn. Le composé **9***a* a été obtenu à partir de l'alcool **8***a* par action du dichlorure de triphénylphosphine. Etant donné l'inversion de configuration généralement induite par l'utilisation de ce réactif (15, 3*b*), nous avons attribué la stéréochimie *trans* au composé **9***a*; le composé **7***a*, voisin de **9***a* en rmn, doit donc être l'isomère *cis*. Par isomérisation thermique, le composé **9***a* conduit, de façon majoritaire au composé **13***a*; étant donné que de tels réarrangements

de chlore allylique se font rapidement de façon synfaciale par un mécanisme de type S_Ni' (2, 13*b*), nous avons attribué la stéréochimie *trans* au composé **13***a*.

Le composé **11***a* n'a pu être obtenu pur, mais seulement comme composante majoritaire d'un mélange contenant les quatre isomères **7***a*, **9***a*, **11***a* et **13***a*, par action du chlorure de thionyle sur l'alcool **8***a*. La stéréochimie du composé **11***a* ainsi obtenu, qui doit être *cis* en accord avec le mécanisme S_Ni' souvent invoqué pour l'action du chlorure de thionyle (3*b*, 13*a*, 13*b*), a été confirmée de la même façon que ci-dessus par réarrangement allylique du composé **7***a*; ce dernier conduit en effet, par chauffage, à un mélange dans lequel le composé **11***a* est majoritaire.

La connaissance des signaux fournis en rmn par les composés **7**, **9**, **11** et **13**, a permis par la suite d'analyser qualitativement et quantitativement les mélanges de ces composés par rmn à 100 MHz.

Résultats et discussion

Le composé **5***a*-*trans* conduit, par chauffage, aux quatre composés à chlore allylique **7***a*, **9***a*, **11***a* et **13***a*, accompagnés de faibles quantités de la lactone **6** (cf. tableau 1, essai 1). Cependant, l'extrapolation, pour un avancement très faible de la réaction, des proportions relatives des isomères **7***a* et **11***a* et de la lactone **6** est proche de zéro, alors que les composés **9***a* et **13***a* sont présents en quantité importante. Il est donc très vraisemblable que les trois composés **7***a*, **11***a* et **6** ont été formés par réarrangement thermique de **9***a* et **13***a*. Dans les mêmes conditions, le mélange des isomères **5***a* conduit à une proportion notable des isomères *cis* **7***a* et **11***a*, et cela même pour un avancement réduit de la transposition (essai 2). Le réarrangement cyclopropyle–allyle observé est donc stéréospécifique: l'isomère **5***a*-*trans* conduit aux composés *trans* **9***a* et **13***a* avec une stéréospécificité proche de 100%, et l'isomère *cis* conduit aux composés *cis* **7***a* et **11***a* avec, toutefois, un degré de stéréospécificité qu'il ne nous a pas été possible de mesurer. La règle de Woodward–Hoffmann–De Puy implique que c'est le chlore disposé en *syn* qui quitte la molécule (2, 16): par conséquent la stéréospécificité observée montre que l'atome de chlore revient sur la molécule du côté où il est parti, conformément aux observations précédentes reportées en série tricyclique et bicyclique (2, 3).

En ce qui concerne la participation du groupement méthoxycarbonyle, on constate que le pourcentage de la lactone **6** est relativement faible, et que, par extrapolation pour un avancement très faible de la réaction il tend vers zéro (essais 1 et 2). Ce résultat traduit clairement l'absence de participation à l'ouverture du noyau cyclopropanique, le peu de lactone **6** observé provenant d'une cyclisation des composés d'extension de cycle initialement formés **7***a*, **9***a*, **11***a* et **13***a*. Dans les composés **5***a*, le groupement méthoxycarbonyle est en mesure d'attaquer le noyau cyclopropanique avec inversion de configuration (cf. plus haut); l'absence

de participation n'est donc pas due à des contraintes stéréoélectroniques: elle pourrait, par contre provenir d'une nucléophilie insuffisante de l'ester carboxylique.

L'ouverture des acides carboxyliques **5***b*, dans lesquels le nucléophile interne est plus puissant que précédemment (17), conduit en effet à un pourcentage supérieur de la lactone **6** (essais 3 et 4). Mais les résultats obtenus dans ce cas peuvent être interprétés de deux façons. *Voie 1*. Il y aurait réarrangement thermique préalable en composés à chlore allylique, puis cyclisation d'une partie du mélange obtenu en lactone **6**. *Voie 2*. Il y aurait formation initiale de la lactone **6** par participation de l'acide carboxylique interne; la lactonisation entraînant la présence d'HCl dans le milieu réactionnel, cet acide pourrait alors ouvrir la lactone **6** pour conduire aux composés à chlore allylique **7***b*, **9***b*, **11***b* et **13***b*.

Il est donc très difficile de déterminer, dans ce cas, l'origine exacte des produits formés. Tout au plus, la comparaison des résultats fournis par le mélange des isomères **5***b* (*cis*/*trans* = 25:75; essai 3) et par l'isomère **5***b*-*trans* seul, essai 4, montre que dans le cas du mélange, une partie au moins des composés dichlorés ne provient pas de la lactone **6**; en effet, les composés **7***b* et **11***b*, présents dans le premier cas, sont absents dans le second et proviennent donc directement de l'isomère **5***b*-*cis*. En conséquence, la participation directe de l'acide carboxylique (voie 2 du schéma 5), si elle existe, n'entre pas seule en jeu. Afin de mieux appréhender le mécanisme qui intervient, nous avons réalisé l'ouverture des composés **5** dans des conditions différentes; en effet, l'utilisation de températures plus basses pouvait modifier les rapports de vitesse entre ouverture puis lactonisation (voie 1), ou lactonisation par participation et ouverture de la lactone (voie 2), et ainsi permettre d'opter pour l'un ou l'autre mécanisme. L'ouverture ne pouvait alors être atteinte en des temps raisonnables qu'en présence d'un solvant de grande constante diélectrique dont la fonction est d'accélérer le processus (18).

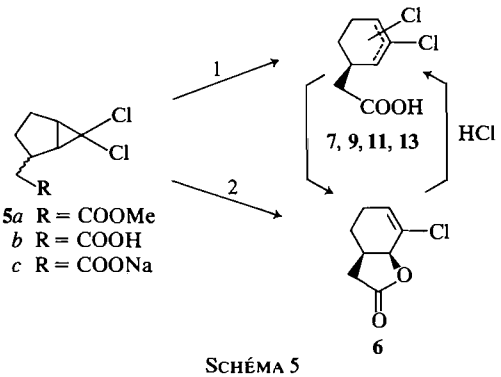

SCHÉMA 5

Nous avons choisi un solvant aqueux. Il fallait alors vérifier que l'emploi d'un tel solvant ne modifiait pas de façon notable le mécanisme, contrairement à ce qui est parfois proposé dans la littérature. En effet, l'ouverture dans de telles conditions des esters **5***a* (essai 5) conduit aux quatre composés à chlore allylique et à de faibles quantités de lactone **6**, comme c'était le cas lors de la thermolyse (essai 2); le caractère ionisant et dissociant du solvant utilisé n'implique donc pas, comme on pouvait le craindre, l'obtention directe d'un cation allylique dissocié, c'est à dire non impliqué dans une paire d'ions de type **1**, car celui-ci aurait conduit à des alcools par attaque du solvant (19*a*, *b*), et éventuellement à la lactone **6** par cyclisation intramoléculaire. Ce résultat mérite d'être souligné car l'obtention directe de cations allyliques à été invoquée (19), et récemment encore (20), lors d'ouverture d'halocyclopropanes en solution dans l'eau ou l'acide acétique. Après cette vérification, il était possible de poursuivre l'étude de l'ouverture des acides **5***b* en effectuant la réaction en présence de solvant polaire (essai 6); on obtient ici 47% de lactone **6** (dont nous avons vérifié la stabilité dans le milieu réactionnel) et 53% des composés à chlore allylique **7**, **11** et **13**; par conséquent, on met, ici en évidence que trois des composés à chlore allylique proviennent directement d'un réarrangement préalable en composés à chlore allylique (voie 1 du schéma 5). Les pourcentages relatifs observés pour ces composés sont alors très bien interprétés en fonction de leurs vitesses de lactonisation respectives, déterminées dans des conditions voisines, qui suivent l'ordre **9** > **11** ≫ **13** ≫ **7** (1); on comprend en effet aisément les taux très faible et nul des composés **11** et **9**, ceux-ci conduisant rapidement à la lactone **6**. Nous concluons donc, dans ce cas encore, à l'absence de participation du nucléophile interne à l'ouverture du noyau dichlorocyclopropanique; ce résultat paraît nettement en faveur d'un transfert de l'atome de chlore en position allylique totalement concerté (état de transition de type **2**), qui interdit la participation de tout nucléophile.

Nous avons enfin étudié le comportement des sels de sodium **5***c* dans lesquels le nucléophile interne est encore plus puissant. Ceux-ci conduisent (essais 7 et 8) à de fortes proportions de la lactone **6**, ce qui pouvait *a priori* faire penser à l'entrée en jeu d'une participation nucléophile interne. Mais nous savons que, dans des conditions semblables, les composés **9***c*, **11***c* et **13***c*, se lactonisent rapidement en composé **6** (1); nous avons

TABLEAU 2. Réactivité des composés **5***a*, **7***b* et **13***b* en milieu basique; produit réactionnel en % relatifs

Conditions[a]	Produit de départ	Avancement	Produit réactionnel[b]			
			5*b*	**8***b*	**10***b*	**12***b*
MeOH–H_2O (80:20)	**5***a*[c]	97	100	—	—	—
H_2O	**5***a*[c]	95	58[d]	27	2,5	12,5
	7*b*	100	—	25	4	71
	13*b*	100	—	82	2	16

[a]Les réactions sont menées en présence de 5 équivalents de soude.
[b]L'analyse a été réalisée dans tous les cas après estérification par le diazométhane.
[c]Mélange d'isomères *cis*/*trans* dans le rapport 25:75.
[d]Mélange d'isomères *cis*/*trans* dans le rapport 19:81.

également constaté que le composé **7***c*, pourtant le plus stable, évolue dans les conditions de l'ouverture (tableau 1, essai 9). On peut donc envisager, ici aussi, un réarrangement préalable en composés à chlore allylique, suivi d'une lactonisation rapide de trois d'entre eux (voie 1 du schéma 5). La présence du composé **7***c* en est révélatrice et cela d'autant plus que le pourcentage observé pour ce composé est inférieur au pourcentage réellement obtenu (le produit à réagi en partie) et que d'autre part ce pourcentage doit être rapporté à la proportion du composé **5***c*-*cis* dans le mélange d'isomères utilisé. On note également, lors de l'ouverture des composés **5***c*, la présence des alcools **10***c* et **12***c*; or leur formation directe par attaque des ions hydroxyles du solvant (rendu légèrement basique par la présence de sels de sodium d'acides carboxyliques) sur les composés **5***c* est improbable (3). Ces alcools peuvent donc résulter d'une attaque des ions hydroxyles, soit sur les composés **7***c*, **9***c*, **11***c* et **13***c* intermédiaires, soit sur la lactone **6**.[2] En milieu basique fort, on a vu que la lactone **6** conduit exclusivement à l'alcool **8**. Pourtant, dans ces conditions, l'ouverture des composés **5***c* donne également naissance aux alcools **10** et **12** (tableau 2, hydrolyse basique de **5***a*); par conséquent dans ce dernier cas au moins, et probablement dans le cas précédent, on peut conclure que les alcools observés résultent de l'hydrolyse des composés à chlore allylique et sont donc révélateurs de la formation intermédiaire de ces derniers (nous avons vérifié, cf. Tableau 2, que les composés **7***c* et **13***c*, issus des acides **7***b* et **13***b*, conduisent effectivement aux alcools **10***c* et **12***c* dans de telles conditions).

[2]On sait qu'en milieu faiblement basique, voire "neutre", l'hydrolyse d'esters peut se faire par rupture de la liaison alkyle–oxygène, ce qui permet, si le reste alkyle est un groupement allyle, l'entrée en jeu de réarrangements allyliques (21); la lactone **6** est donc théoriquement susceptible de conduire aux alcools **10** et **12**.

Conclusion

Malgré la présence d'un nucléophile interne puissant (groupement carboxylate), les composés **5***c* s'ouvrent donc eux aussi, comme les esters **5***a* et les acides **5***b*, en composés à chlore allylique selon la voie 1 du schéma 5. Ce résultat suggère, pour le réarrangement, un mécanisme concerté plutôt que par paire d'ions (schéma 1); en effet, nous avons montré par ailleurs (1) que pour les composés **9***c* et **11***c*, le groupement carboxylate interne déplace le chlore allylique très rapidement par participation intramoléculaire selon des processus S_N et S_N'; cette participation devrait donc se faire *à fortiori* sur une éventuelle paire d'ions intermédiaire de type **1** et conduire exclusivement à la lactone **6**.

Il faut donc remarquer que les résultats obtenus ici sont en désaccord avec ceux de Remy *et al.* qui concluent à l'existence de phénomènes de participation dans l'ouverture thermique d'halocyclopropanes (22).

Partie expérimentale

Indications générales

Les points de fusion, non corrigés, ont été déterminés en capillaire à l'aide de l'appareil du Dr. Tottoli. Les chromatographies en phase vapeur (cpv) ont été réalisées dans l'une des conditions suivantes précisée pour chaque cas; condition A: appareil Carlo Erba Fractovap GT série 200 à ionisation de flamme équipé d'une colonne de 2 m × 2 mm de remplissage 5% SE 30 sur CGLA 80/100 mesh; condition B: appareil Intersmat IGC 120 DFL à ionisation de flamme équipé d'une colonne de 1,5 m × 1/8 in. de remplissage 10% SE 30 sur PAW 80/100 mesh; on indiquera le temps de rétention (t_r), la température de colonne (T_c) et la pression de gaz vecteur (P). Les spectres ir ont été enregistrés sur spectrophotomètre Perkin Elmer 221 ou 377 en solution 0,2 *M* sauf indication contraire. Les spectres de rmn ont été enregistrés à 60 MHz et température ambiante sur appareil Varian modèle EM-360 ou A-60; pour les spectres enregistrés à 90 et 100 MHz (précisé dans chaque cas) nous avons utilisé les modèles EM-390 et HA-100; les déplacements chimiques sont donnés en ppm (référence interne TMS); les lettres s, d, t, q et m signifient respectivement singulet, doublet, triplet, quadruplet et multiplet. Les analyses centésimales ont été effectuées au laboratoire de Microanalyse du C.N.R.S. à l'E.N.S.C. de Montpellier.

(Dichloro-6,6 bicyclo[3.1.0]hexyl-2) acétates de méthyle cis *et* trans, *5*a

La cyclopropanation du (cyclopenténYl-3)acétate de méthyle est réalisée selon réf. 23, sous atmosphère d'azote sec. Pour 14 g d'oléfine, on utilise 18,5 g de MeONa et 59 g de CCl_3—COOMe. On obtient par distillation 2,7 g d'un mélange d'oléfine de départ et de composés d'addition **5***a*, puis 18,5 g (83%) de ces derniers: $Eb_{0,5}$ 100°C; cpv (conditions A) t_r 10 min 40 s, T_c 130 à 180°C (4°C/min), P 1,55 à 1,75 bar; ir ($CHCl_3$): 1735 (C=O) cm^{-1}; rmn ($CDCl_3$) δ: 3,71 (s, 3H, COOMe), 1,2 à 3,0 (m, 9H); rmn ($CDCl_3$ avec 0,1 mol d'Eu(DPM)$_3$ par mol de substrat) principaux signaux à δ: 4,26 (s, 0,75H, COOMe de **5***a-cis*), 4,05 (s, 2,25H, COOMe de **5***a-trans*).

Acides (dichloro-6,6 bicyclo[3.1.0]hexyl-2) acétiques cis *et* trans, *5*b

On agite 1 h à 20°C, 25 g des esters **5***a* dans 200 cm^3 de MeOH–H_2O (80:20) contenant 22,5 g de NaOH. On élimine le méthanol sous pression réduite sans chauffer. Les eaux sont lavées à l'éther et acidifiées à froid (HCl 50%). On extrait à l'éther; les éthers sont lavés (H_2O), séchés (Na_2SO_4), puis concentrés, ce qui laisse 22,8 g (97%) des acides **5***b* homogènes en ccm. Un échantillon très pur du mélange a été obtenu par filtration sur colonne de silice avec éther–éther de pétrole – acide formique (29,5:69,5:1); ir ($CHCl_3$): 1710 (C=O) cm^{-1}; rmn ($CDCl_3$) δ: 11,3 (s, large, 1H, COOH), 1,25 à 3,0 (9H). *Anal.* calc. pour $C_8H_{10}Cl_2O_2$: C 45,93, H 4,78, Cl 33,97; trouvée: C 46,1, H 5,0, Cl 34,2%.

Séparation de l'isomère 5b-trans

Selon la technique de Fouquey *et al.* (24), on ajoute à froid 21,8 g de dicyclohexylamine à 25 g d'acides **5***b*. Le sel formé cristallise rapidement en présence de quelques gouttes d'acétate d'éthyle; F 126–127°C (AcOEt). Celui-ci est dissous dans 50 cm^3 d'eau et 200 cm^3 de méthanol. On ajoute à froid une solution aqueuse de soude 0,5 *N* jusqu'à pH ≃ 10. Le méthanol est éliminé sous pression réduite à 20°C. Les eaux sont lavées (Et_2O), acidifiées (HCl 50%) et extraites à l'éther. Les éthers sont lavés (H_2O), séchés (Na_2SO_4) et concentrés. On recueille ainsi 5,2 g (20,8%) d'acide **5***b-trans* dont 2,0 g sont estérifiés par un excès de diazométhane en solution éthérée conduisant à 2,0 g (94%) d'ester **5***a-trans*: ir (film): 3030 C—H cyclopropyliques), 1740 C=O) cm^{-1}; rmn ($CDCl_3$) δ: 3,71 (s, 3H, COOMe), 1,2 à 3,00 (m, 9H); rmn ($CDCl_3$ avec 0,13 mol d'Eu(DPM)$_3$ par mol de substrat) principaux signaux à δ: 4,4 (s, 0,09H, COOMe de **5***a-cis*), 4,15 (s, 2,91H, COOMe de **5***a-trans*). *Anal.* calc. pour $C_9H_{12}Cl_2O_2$: C 48,43, H 5,38; trouvée: C 49,0, H 5,6%.

(Bicyclo[3.1.0]hexyl-2) acétate de méthyle-trans, ***14***a

On opère selon réf. 25; dans un ballon de 250 cm^3 balayé par de l'azote sec et muni d'une ampoule à égalisation de pression, on piège, en refroidissant à −70°C, 75 cm^3 d'ammoniac. On y additionne 1,8 g de sodium, puis goutte à goutte, 7 g d'ester **5***a-trans* en solution dans 35 cm^3 d'éther anhydre. Après 1/2 h d'agitation, on ajoute 4,2 g de chlorure d'ammonium, laisse évaporer l'excès d'ammoniac, ajoute un peu d'eau, puis extrait à l'éther. Les éthers sont séchés (Na_2SO_4) puis concentrés. Par chromatographie sur colonne de silice avec éther – éther de pétrole (10:90), on isole 1,24 g (18%) d'ester **5***a-trans* (ccm, rmn), et 1,65 g (34%) de composé **14***a-trans*. Infrarouge (CCl_4): 3070 et 3030 (C—H cyclopropylique), 1750 (C=O) cm^{-1}; rmn (CCl_4) δ: 3,60 (s, 3H, COOMe), 0,6 à 0,26 (m, 9H), 0,0 à 0,6 (m, 2H). Par addition d'Eu(DPM)$_3$ le singulet correspondant à COOMe se dédouble, laissant apparaître moins de 3% de **14***a-cis*.

Acide (bicyclo[3.1.0]hexyl-2)acétique trans, ***14***b

On agite 1,54 g d'ester **14***a* dans 25 cm^3 de MeOH–H_2O (80:20) contenant 2 g de soude pendant 2 h à 20°C. On élimine le méthanol sous pression réduite sans chauffer, puis lave à l'éther. On acidifie à froid (HCl 50%) et extrait à l'éther. Les éthers sont lavés (H_2O), séchés (Na_2SO_4) et concentrés sous pression réduite, ce qui laisse 1,25 g (89% d'acide **14***b-trans* homogène en ccm; ir (CCl_4): 1710 (C=O) cm^{-1}; rmn (CCl_4) δ: 11,5 (s large 1H, COOH), 2,1 à 2,7 (m, 3H), 1,0 à 2,1 (m, 6H) 0,0 à 0,6 (m, 2H). *Anal.* calc. pour $C_8H_{12}O_2$: C 68,57, H 8,57; trouvée: C 68,2, H 8,6%.

Chlorométhyl-2 bicyclo[3.1.0]hexane-trans, ***15***

On traite 1,12 g d'acide **14***b* selon la méthode de Kochi (26). On obtient ainsi 470 mg (45%) du composé **15***-trans* homogène en ccm; ir (film): 3070 et 3040 (C—H cyclopropylique) cm^{-1}; rmn (CCl_4, 100 MHz) δ: 3,35 et 3,26 (parties A et B de ABX, J_{AB} = 10,4 Hz, J_{AX} = 7,1 Hz, J_{BX} = 7,6 Hz, CH_2Cl), 2,28 (quatre raies, partie X de ABX dédoublée avec $J \simeq 7$, *CH*—CH_2Cl), 0,7 à 1,8 (m, 8H).

Chlorométhyl-2 bicyclo[3.1.0]hexane-cis, ***15***

A une suspension agitée de 1,52 g d'$AlLiH_4$ dans 30 cm^3 d'éther, on ajoute lentement 7 g d'ester **16***-cis* obtenu selon (9). On observe un reflux puis agite encore à température ambiante pendant 3 h. Après hydrolyse par le sel de Seignette, on décante la phase organique puis distille. On recueille 3,9 g (62%) d'hydroxyméthyl-2 bicyclo[3.1.0]hexane-*cis*; Eb = 87°C; ir (CCl_4): 3630 et 3100 à 3600 (O—H) cm^{-1}; rmn (CCl_4) δ: 4,12, (s, 1H, se déplace par dilution, O*H*), 3,50 (d, 2H, J = 7 Hz, CH_2OH), 2,0 à 2,7 (m, 1H, *CH*—CH_2OH), 0,5 à 2,0 (6H), 0,0 à 0,5 (m, 2H). *Anal.* calc. pour $C_7H_{12}O$: C 75,00, H 10,71; trouvée: C 75,0, H 10,5%.

Dans un ballon à deux tubulures équipé d'un réfrigérant avec garde à H_2SO_4 et ampoule à brome, on place 3,7 g de l'alcool précédent et 2,6 g de pyridine dans 40 cm^3 d'éther anhydre. On ajoute lentement à 0°C 4,28 g de $SOCl_2$; le chlorhydrate de pyridinium précipite immédiatement. Lorsque l'addition est terminée, on porte au reflux 2 h, filtre, concentre sous pression réduite et distille. On isole 1,5 g (35%) du composé **15** *cis* homogène en ccm; ir (film): 3072 et 3040 (C—H cyclopropyliques) cm^{-1}; rmn (CCl_4, 100 MHz) δ: 3,46 et 3,37 (parties A et B de ABX, J_{AB} = 10,5 Hz, J_{AX} = 7,4 Hz, J_{BX} = 6,9 Hz, 2H, CH_2Cl), 2,30 à 2,70 (m, 1H, *CH*—CH_2Cl), 0,5 à 2,0 (6H), 0,0 à 0,5 (m, 2H). *Anal.* calc. pour $C_7H_{11}Cl$: C 64,36, H 8,43; trouvée: C 64,5, H 8,4%.

Mélange des isomères cis *et* trans *du (bicyclo[3.1.0]hexyl-2)-acétate de méthyle,* ***14***a

La méthode utilisée ci-dessus pour l'obtention du composé **14***a-trans*, a été appliquée à 2,2 g de mélange des isomères **5***a* (*cis*/*trans* = 25:75). Après traitement identique, on obtient 0,33 g (15%) de mélange d'isomères **5***a* (ccm, rmn) et 0,48 g (32%) de mélange d'isomères **14***a*; ir (CCl_4): 3070 et 3030 (C—H cyclopropyliques), 1750 (C=O) cm^{-1}; rmn (CCl_4) δ: 3,60 (s, 3H, COO*M*e), 0,6 à 0,26 (m, 9H), 0,0 à 0,6 (m, 2H). Par addition d'Eu(DPM)$_3$ le singulet correspondant à COOMe se dédouble, indiquant la présence des isomères *cis* et *trans* dans les proportions respectives de 25:75.

(Dichloro-2,3 cyclohexényl-6)acétate de méthyle-cis, ***11***a

A 10 g d'alcool **8***a*, on additionne lentement à froid sous azote 11,9 g de chlorure de thionyle fraîchement distillé, puis agite 2 h à température ambiante (l'avancement est suivi par ccm). On étend à l'éther, basifie à froid (Na_2CO_3 10%) et décante la phase organique; celle-ci est lavée (H_2O/NaCl), séchée (Na_2SO_4) et concentrée. On recueille 9,3 g de mélange des produits **6** (60%) et **7***a*, **9***a*, **11***a* et **13***a* (40%) d'après la ccm et la rmn. Par chromatographie sur colonne de silice avec éther – éther de pétrole (20:80) de 5 g de mélange, on isole 132 mg (2,25%) de mélange possédant la composition suivante: **7***a* (3%), **9***a* (26%), **11***a* (61%), **13***a* (10%) et 2,03 g (33,4%) de mélange des mêmes produits dans les proportions respectives de 11%, 34%, 45% et

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

10%. La rmn du mélange contenant le composé **11***a* à 61% permet d'attribuer à ce dernier les signaux suivants ($CDCl_3$, 90 MHz) δ: 5,88 (dd, 1H, J = 2,3 et 0,9 Hz, H éthylénique), 4,48 (m, 1H, $W_{\frac{1}{2}}$ = 7,5 Hz, CHCl), 3,70 (s, 3H, COOMe).

(Dichloro-2,3 cyclohexényl-4)acétate de méthyle-trans-*9*a

Ce composé a été préparé à partir de 3,3 g de Ph_3P et 1,0 g d'alcool **8***a* selon la technique décrite par Fleming et Thomas (3). On récupère 3,8 g de produit brut contenant la lactone **6** et un mélange des composés dichlorés dans les proportions 30:70 (ccm, rmn). Par chromatographie sur colonne de silice avec éther – éther de pétrole (30:70), on isole les composés dichlorés: 649 mg (60%) de **9***a* (souillé toutefois par 15% de son isomère **11***a*); ir (CCl_4): 1742 (C=O), 1647 (C=C) cm^{-1}; rmn ($CDCl_3$, 100 MHz) δ: 6,04 (t, 1H, J = 3,9 Hz, H éthylénique), 4,3 (m à allure de d, $J \simeq 3,5$ Hz, CHCl), 3,69 (s, 3H, COOMe), 1,4 à 2,8 (m, 7H). *Anal.* calc. pour $C_9H_{12}Cl_2O_2$: C 48,43, H 5,38, Cl 31,83; trouvée: C 48,2, H 5,3, Cl 30,8%.

Acides (dichloro-2,3 cyclohexényl-4) et (dichloro-2,3 cyclohexényl-6)acétiques 7b *et* 13b. *Esters méthyliques correspondants* 7a *et* 13a

On prépare 9,3 g de mélange des isomères **7***a*, **9***a*, **11***a* et **13***a* et de la lactone **6** par action du chlorure de thionyle sur l'alcool **8***a* (cf. ci-dessus). Le mélange est enrichi en composés recherchés **7***a* et **13***a* par chauffage 5 h à 160°C (équilibrage thermodynamique), puis hydrolysé par agitation 1 h à 20°C avec une solution de 4 g de NaOH dans 80 cm^3 de méthanol et 20 cm^3 d'eau. On étend à l'eau, acidifie à froid (HCl 50%) et extrait par une quantité importante d'acétate d'éthyle. La phase organique est lavée (H_2O), séchée (Na_2SO_4) et concentrée, ce qui laisse 9 g de produit brut contenant les composés **7***b*, **13***b* et **6** (ccm, rmn). Par chromatographie sur colonne de silice avec éther – éther de pétrole – acide formique (29,5:69,5:1), on parvient à isoler avec difficulté 400 mg (3,9%) d'acide **7***b* et 300 mg (2,9%) d'acide **13***b*; 140 mg du premier et 125 mg du second ont été estérifiés par action d'un excès de diazométhane en solution éthérée pour conduire respectivement à 140 mg (94%) d'ester **7***a* et 126 mg (94%) d'ester **13***a*.

Acide **7***b*: F 156–158°C (éther – éther de pétrole); ir (KBr): 1700 (C=O) cm^{-1}; rmn ($CDCl_3$) δ: 9,44 (s, 1H, COOH), 6,05 (t élargi, 1H, J = 4 Hz, H éthylénique), 4,69 (s, 1H, $W_{\frac{1}{2}}$ = 4,6 Hz, CHCl), 1,5 à 2,9 (7H). *Anal.* calc. pour $C_8H_{10}Cl_2O_2$: C 45,93, H 4,78, Cl 33,97; trouvée C 46,2, H 4,8, Cl 33,8%.

Ester **7***a*: rmn ($CDCl_3$) δ: 5,97 (t, 1H, J = 3,8 Hz, H éthylénique), 4,61 (s, 1H, $W_{\frac{1}{2}}$ = 5 Hz, CHCl), 3,69 (s, 3H, COOMe), 2,1 à 2,9 (5H), 1,2 à 1,9 (2H).

Acide **13***b*: rmn (acétone-d_6) δ: 6,1 (d, 1H, J = 4,5 Hz, H éthylénique), 4,63 (t mal résolu, 1H, J = 4,2 Hz, CHCl), 1,0 à 3,0 (m, 7H).

Ester **13***a*: rmn ($CDCl_3$) δ: 5,97 (d, 1H, J = 4,5 Hz, H éthylénique), 4,47 (t, 1H, J = 3,5 Hz, CHCl), 3,70 (s, 3H, COOMe), 1,2 à 3,1 (7H).

Traitement basique des composés 5a, 7b *et* 13b: *obtention de la lactone* 6 *et des alcools* 10 *et* 12

(*a*) On agite 20 h à 20°C, 10 g de **5***a* (*cis*/*trans* = 25:75) dans 105 cm^3 d'une solution de soude à 8%. On lave à l'éther, acidifie à froid (HCl 50%) et extrait à AcOEt. La phase organique est lavée (H_2O/NaCl), séchée (Na_2SO_4), concentrée puis estérifiée immédiatement par action d'un excès de diazométhane en solution éthérée. On recueille un mélange composé des produits **5***a*, **8***a*, **10***a* et **12***a* (ccm, rmn); 4,3 g de ce mélange sont chromatographiés sur colonne de silice avec éther – éther de pétrole (25:75). L'alcool **8***a* se cyclise en lactone **6** sur la colonne et on recueille 100 mg d'alcool **10***a* souillé de lactone **6**, 360 mg d'alcool **12***a* souillé de lactone **6** et 780 mg (23,5%) de cette lactone. Deux nouvelles chromatographies permettent d'isoler 78 mg (1,8%) d'alcool **10***a* et 306 mg (7,9%) d'alcool **12***a*. L'analyse quantitative du produit de la réaction est indiquée ci-dessous en (*c*).

γ-*Lactone de l'acide (chloro-2 hydroxy-3 cyclohexényl-4)-acétique*-cis, *6*: F 76–77°C (ether–acétone); cpv (conditions B) t_r 15 min 50 s, T_c 130 à 170°C (4°C/min), P 1,2 à 1,3 bar; ir ($CHCl_3$): 1780 avec inflexion à 1755 (C=O), 1650 (C=C) cm^{-1}; rmn ($CDCl_3$, 100 MHz) δ: 6,21 (t, 1H, J = 4,2 Hz, H éthylénique), 4,76 (d, 1H, J = 5,5 Hz, CH—O—CO), 1,2 à 3,0 (m, 7H). *Anal.* calc. pour $C_8H_9ClO_2$: C 55,65, H 5,22, Cl 20,58; trouvée: C 55,5, H 5,2, Cl 20,5%.

(Chloro-2 hydroxy-3 cyclohexényl-4) acétate de méthyle-trans *10*a: F 48–53°C; ir ($CHCl_3$): 3596 et 3450 large (O—H), 1730 (C=O), 1650 (C=C) cm^{-1}; rmn ($CDCl_3$) δ: 5,97 (t, 1H, J = 3,8 Hz, H éthylénique), 3,97 (d, 1H, J = 5,5 Hz, CH—OH), 3,71 (s, 3H, COOMe), 3,60 (s, 1H, se déplace par dilution, H hydroxylique), 1,2 à 1,3 (m, 7H). *Anal.* calc. pour $C_9H_{13}ClO_3$: C 52,94, H 6,37, Cl 17,15; trouvée: C 53,4, H 6,4, Cl 16,4%.

(Chloro-2 hydroxy-3 cyclohexényl-6) acétate de méthyle-cis, *12*a: rmn ($CDCl_3$) δ: 5,84 (d, 1H, J = 2,5 Hz, éthylénique), 4,17 (t mal résolu, 1H, $J \simeq 5$ Hz, H carbinolique), 3,70 (s, 3H, COOMe), 3,45 (s large, se déplace par dilution, H hydroxylique), 1,2 à 2,8 (7H).

(*b*) *Obtention des acides* 10b *et* 12b

On agite 1 h, à 20°C, 440 mg de **10***a* dans 5 cm^3 de H_2O–MeOH (20:80) contenant 440 mg de NaOH; on étend à l'eau, lave à l'éther, acidifie à froid (HCl 50%) et extrait à l'éther. Les éthers, lavés (H_2O), séchés (Na_2SO_4) et concentrés conduisent à 350 mg (87%) d'acide **10***b* homogène en ccm: F 107–109°C; rmn (acétone-d_6) δ: 6,5 à 7,5 (m, 2H, —COOH et —OH), 5,93 (t, 1H, J = 4,0 Hz, H éthylénique), 3,93 (d, 1H, J = 6,0 Hz, H carbinolique), 1,2 à 3,0 (m, 7H). De la même façon, à partir de 592 mg de **12***a* on recueille 500 mg (90%) d'acide **12***b*: rmn ($CDCl_3$) δ: 7,51 (s large, 2H, COOH et OH), 5,92 (d, 1H, J = 2,0 Hz, H éthylénique), 4,18 (s, 1H, $W_{\frac{1}{2}}$ = 7,0 Hz, H carbinolique), 2,2 à 2,9 (m, 3H), 1,5 à 3,2 (m, 4H).

(*c*) La détermination des pourcentages des composants avant séparation a été réalisée en partie par rmn à 100 MHz; nous avons ensuite acétylé le produit brut précédent. Si les principaux signaux fournis en rmn par les composés **8***a* et **10***a* sont superposés, il n'en est pas de même au niveau des acétates correspondants. (La synthèse de ces derniers est indiquée ci-dessous en (*d*).) L'acétylation est menée sur 1 g de produit brut par 1,4 cm^3 d'anhydride acétique dans 14 cm^3 de pyridine; après 15 h d'abandon à 20°C, on ajoute de la glace et extrait à l'acétate d'éthyle. La pyridine est éliminée par lavage avec une solution saturée de $CuSO_4$ jusqu'à absence de changement de couleur. On lave à l'eau, au carbonate de sodium 10% et enfin avec une solution saturée de NaCl. On sèche (Na_2SO_4), concentre et chromatographie sur colonne de silice avec éther – éther de pétrole (10:90 varie graduellement jusqu'à 40:60) ce qui conduit à 410 mg (41%) de **5***a* (*cis*/*trans* = 19:81) et 525 mg de mélange des acétates correspondants à **8***a*, **10***a* et **12***a* (47,5%).

(*d*) Cent milligrammes de l'alcool **10***a* et 288 mg de l'alcool **12***a* sont acétylés séparément par la technique utilisée plus haut. On isole, par chromatographie sur colonne de silice avec éther – éther de pétrole (30:70), 37 mg (31%) d'acétate correspondant à **10***a*; rmn ($CDCl_3$) δ: 6,10 (t, 1H, J = 4,07 Hz, H éthylénique), 5,30 (signal large, 1H, $W_{\frac{1}{2}}$ = 8,3 Hz, CHOAc), 3,70 (s, 3H, COOMe), 1,3 à 2,7 (10H avec s à 2,11, $OCOCH_3$). On obtient par ailleurs 237 mg (68%) d'acétate correspondant à **12***a*; ir ($CHCl_3$): 1735 (C=O), 1650 (C=C) cm^{-1}; rmn ($CDCl_3$) δ: 6,05 (d, 1H, J = 2,2 Hz, H éthylénique), 5,36 (signal large, 1H, $W_{\frac{1}{2}}$ = 8 Hz, CHOAc), 3,70 (s, 3H, COOMe), 1,0 à 3,0 (m, 10H). *Anal.* calc. pour $C_{11}H_{15}ClO_4$: C 53,55, H 6,09; trouvée: C 53,8, H 6,3%.

(*e*) *Réactivité des composés* 7b *et* 13b

On place séparément 135 mg des composés **7***b* et **13***b* dans les conditions de l'hydrolyse des composés **5***a* (cf. plus haut en (*a*))

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

puis traite de façon identique. La composition des mélanges obtenus est déterminée comme paragraphe (*c*), mais l'absence de composés de type **5** a rendu inutile la chromatographie du mélange obtenu par acétylation. Les valeurs obtenues sont portées dans le tableau 2.

(Chloro-2 hydroxy-3 cyclohexényl-4)acétate de méthyle-cis, *8*a

On agite 20 h, à 20°C, 5 g de lactone **6** et 5,8 g de NaOH dans 67 cm³ d'eau. Puis on lave à l'éther, acidifie (HCl 50%) et extrait à l'acétate d'éthyle. La phase organique est lavée à l'eau, séchée (Na_2SO_4), concentrée sous pression réduite et immédiatement estérifiée par action d'un excès de diazométhane en solution éthérée. Après traitement on recueille 5,7 g (96%) de **8***a* contenant une trace de lactone **6** (ccm, rmn). Le composé a été purifié par filtration sur colonne de silice avec éther – éther de pétrole (70:30). Dans ces conditions le produit se cyclise intensivement en lactone **6**, mais on parvient à isoler 400 mg d'alcool **8***a* pur; ir ($CHCl_3$): 1729 (C=O), 1652 (C=C) cm^{-1}; rmn ($CDCl_3$) δ: 5,94 (t, 1H, J = 4,0 Hz, H éthylénique), 4,10 (dd, 1H, J = 5,5 et 3,5 Hz, H carbinolique), 3,65 (s, 3H, COOMe), 3,02 (d, 1H, J = 5,5 Hz, OH), 1,9 à 2,8 (m, 5H), 1,3 à 1,7 (m, 2H); par addition de CF_3COOH, le produit se lactonise rapidement en lactone **6**; on note auparavant les transformations suivantes: 4,1 (d, J = 3,5 Hz, H carbinolique), disparition du signal à 3,02. *Anal.* calc. pour $C_9H_{13}ClO_3$: C 52,94, H 6,37, Cl 17,15; trouvée: C 52,9, H 6,4, Cl 17,0%.

Ce composé a été acétylé selon la technique habituelle pour obtenir un composé présentant le spectre de rmn suivant, δ: 6,10 (t, 1H, J = 4,0 Hz, H éthylénique), 5,5 (signal large, 1H, $W_{\frac{1}{2}}$ = 6,0 Hz, CHOAc), 3,67 (s, 3H, COOMe), 0.7 à 2,8 (10H avec s à 2,1; O—$COCH_3$).

Réduction de la lactone 6; lactone de l'acide (hydroxy-2 cyclohexyl)acétique cis, *17*

Selon réf. 27, on agite 1 h, à 20°C, 400 mg de lactone **6** dans une solution THF–H_2O (30:70) 0,3 *M* en NaOH, puis hydrogène 2 h 30 min à 20°C, sous pression atmosphérique, en présence de 200 mg de Pd/C 10%. On filtre, acidifie à froid (HCl 50%) et extrait à l'acétate d'éthyle. La phase organique est lavée (H_2O), séchée (Na_2SO_4) et concentrée, puis chauffée 1/2 heure en présence de benzène et d'acide *p*-toluène sulfonique dans un ballon équipé d'un décanteur à eau. On étend à l'éther, lave rapidement ($NaHCO_3$ dilué), séche (Na_2SO_4) et concentre. Par chromatographie sur colonne de silice avec éther – éther de pétrole (20:80) on isole 80 mg (48%) de lactone **17** identique à un échantillon authentique (8).

*Réduction de l'alcool 8*a: *(hydroxy-2 cyclohexyl)acétate de méthyle* cis, *18*

On hydrogène 18 h à 20°C et sous pression atmosphèrique 1 g d'alcool **8***a* en présence de 430 mg de Pd/C 10% dans 50 cm³ de méthanol et 1 cm³ de pyridine. On étend à l'éther, filtre, extrait à AcOEt. La phase organique est lavée à l'eau, puis avec une solution saturée de sulfate de cuivre (jusqu'a absence de changement de coloration), enfin à l'eau, séchée (Na_2SO_4) et concentrée. Par chromatographie sur colonne de silice avec éther – éther de pétrole (30:70), on obtient 406 mg (48%) d'alcool **18** homogène en ccm; ir ($CHCl_3$): 3610 et 3460 large (O—H), 1729 (C=O) cm^{-1}; rmn ($CDCl_3$) δ: 3,9 (signal large, 1H, H carbinolique), 3,68 (s, 3H, COOMe), 1,1 à 2,7 (m, 12H avec pic à 2,53 qui se déplace par dilution, OH). *Anal.* calc. pour $C_9H_{16}O_3$: C 62,79, H 9,30; trouvée: C 63,3, H 9,2%.

Cyclisation de l'alcool 18: lactone 17

On agite 1 h 45 min, à 20°C, 400 mg de **18** dans 100 cm³ de MeOH–H_2O (80:20) contenant 0,48 g de soude. On étend à l'eau, élimine le méthanol sous pression réduite, lave à l'éther, acidifie à froid (HCl 50%) et extrait à l'acétate d'éthyle. La phase organique est lavée à l'eau, séchée (Na_2SO_4) et concentrée. Le produit brut est chauffé 1 h 15 min au reflux du benzène en présence d'acide *p*-toluène sulfonique dans un ballon muni d'un décanteur à eau. Puis on lave à l'eau, sèche (Na_2SO_4) et concentre. Par chromatographie sur colonne de silice avec éther – éther de pétrole (20:80), on recueille 229 mg (70%) de lactone **17** (ccm, rmn, ir).

*Réduction de l'alcool 12*a: *hydroxy acide 19*

Quatre cent dix milligrammes d'alcool **12***a* sont réduits comme ci-dessus (réduction de **8***a*). On isole 159 mg (50%) de (hydroxy-4 cyclohexyl)acétate de méthyle *cis*; ir (CCl_4): 3645 et 3480 large (O—H), 1750 (C=O) cm^{-1}; rmn ($CDCl_3$) δ: 3,96 (signal large, 1H, H carbinolique), 3,69 (s, 3H, COOMe), 3,3 (signal large, 1H, O—H), 2,1 à 2,4 (2H), 0.8 à 2,0 (9H). *Anal.* calc. pour $C_9H_{16}O_3$: C 62,79, H 9,30; trouvée: C 63,2, H 9,5%.

Cent trente-cinq milligrammes de cet ester sont agités 48 h à 20°C dans 3,7 cm³ de soude à 8% dans MeOH–H_2O (80:20). On étend à l'eau, élimine le méthanol sous pression réduite, lave (Et_2O), acidifie à froid (HCl 20%) et extrait AcOEt. La phase organique est séchée (Na_2SO_4), concentrée et chromatographiée sur colonne de silice avec éther – éther de pétrole – acide formique (69,5: 29,5:1). On récupère ainsi 27 mg du composé **19** identique à l'échantillon authentique préparé ci-dessous (F, ccm, ir).

Préparation de l'hydroxy-acide 19

On oxyde selon réf. 7 1,7 g de bicyclo [2.2.2] octanone-2 (14) par 3,1 g d'acide *m*-chloroperbenzoïque et 1,15 g de $NaHCO_3$ dans 100 cm³ de CH_2Cl_2. On lave par NaOH 5%, puis à l'eau saturée de NaCl, sèche (Na_2SO_4) et concentre sous pression réduite. Par chromatographie sur colonne de silice avec éther – éther de pétrole (60:40), on isole (*a*) 235 mg d'un composé de F 170°C; rmn ($CDCl_3$) δ: 4,30 (d, 2H, J = 3,6 Hz), 1,4 à 3,0 (10 H); (*b*) 1,1 g (57%) de lactone de l'acide (hydroxy-4 cyclohexyl)-acétique: F 146°C (litt. (14) F 145–148°C); rmn ($CDCl_3$) δ: 4,52 (signal large, 1H, $W_{\frac{1}{2}}$ = 4 Hz, CHOCO), 2,86 (d, 2H, J = 3,5 Hz, CH_2COO), 1,5 à 2,4 (9H).

On agite 2 h, à 20°C, 500 mg de la lactone de F 146°C obtenue ci-dessus dans 30 cm³ de soude aqueuse à 5%. On acidifie à froid (HCl 50%), puis extrait à l'acétate d'éthyle. La phase organique est séchée (Na_2SO_4) et concentrée. Après recristallisation on isole 385 mg (68%) d'acide **19**; F 139–140°C (AcOEt) (litt. (14) F 139–140°C); ir (KBr): 2400 à 3400 et 3440 (O—H), 1711 (C=O) cm^{-1}.

*Equilibrage thermique des composés 7*a, *9*a *et 11*a

Chacun des produits est chauffé, sous pression atmosphérique, à 160 ± 1°C. L'avancement est suivi par rmn à 60 MHz. Lorsque les pourcentages relatifs des quatre isomères ne varient plus que lentement, on enregistre le spectre de rmn à 100 MHz qui permet l'analyse du mélange obtenu (pour le réarrangement du composé **9***a*, la composition du produit obtenu a été évaluée à partir du spectre de rmn à 60 MHz). On obtient les résultats suivants:

		Produit de réarrangement en % relatifs				
Produit de départ	t_h	**6**	**7***a*	**9***a*	**11***a*	**13***a*
7*a* (140 mg)	2,5	9	28	14	38	11
9*a* (571 mg)	6	9	6	31	9	45
11*a* (126 mg)	5	17	12	18	19	34

For personal use only.

Lactonisation des composés 8b, *10*b *et 12*b

Dans un ballon de 250 cm³ équipé d'un décanteur à eau, on place 527 mg formés de 74% de **8***b*, 8% de **10***b* et 18% de **12***b*, 70 cm³ de benzène anhydre et 350 mg d'acide *p*-toluènesulfonique. On porte au reflux du benzène et suit l'avancement en ccm; après 2 h 30 min, on étend à l'éther, lave au carbonate de sodium 2% puis à l'eau. La phase organique, séchée (Na_2SO_4) puis concentrée, laisse 740 mg (98%) de lactone **6**. La phase aqueuse basique est acidifiée à froid (HCl 50%) puis extraite à l'acétate d'éthyle; après séchage (Na_2SO_4) et concentration, on obtient 70 mg de résidu contenant seulement des traces de lactone **6**.

Ouverture thermique des composés 5

Les produits sont placés en ampoules scellées (300 mg par ampoule) dans un bain d'huile à 130 ± 1°C. Les ampoules, prélevées une à une, sont refroidies par un bain de glace. L'avancement est déterminé, en rmn (60 MHz) par intégration des protons vinyliques apparus. La composition des mélanges réactionnels est déterminée par analyse du spectre de rmn à 100 MHz (après estérification par le diazométhane dans le cas des acides **5***b*, sauf pour l'acide **5***b-trans* pour lequel la composition est évaluée d'après le spectre de rmn à 60 MHz du mélange d'acides obtenu). Les résultats sont consignés dans le tableau 1.

Ouverture en solution des acides 5a *et* 5b

On agite 165 h, à 40°C, 2 g de mélange d'esters **5***a* (*cis*/*trans* = 25:75) dans 210 cm³ d'acétone et 91 cm³ d'eau. On prélève 75 cm³ que l'on étend à l'eau; l'acétone est éliminée sous pression réduite à 20°C puis on extrait à l'éther. Les éthers, lavés (H_2O/NaCl), séchés (Na_2SO_4) puis concentrés, laissent 498 mg de produit brut dont la composition est déterminée par analyse du spectre de rmn à 100 MHz. L'avancement de l'ouverture est mesuré, comme dans le cas de l'ouverture thermique, par l'intégration, en rmn, des signaux dus aux protons vinyliques des produits formés. On traite de la même façon 1,1 g de mélange d'acides **5***b* (*cis*/*trans* = 25:75). Ce produit brut est cependant estérifié par un excès de diazométhane en solution éthérée pour l'analyse par rmn à 100 MHz. La stabilité, dans ces conditions, de la lactone **6** a été établie ainsi: on agite 165 h, à 40°C, 330 mg de la lactone **6** dans 144 cm³ d'eau et 234 cm³ d'acétone contenant 2 mmol d'HCl (on travaille en présence d'HCl car la lactonisation des composés dichlorés **5***b* ou **7***b*, **9***b*, **11***b* et **13***b* libère une quantité stoechiométrique de cet acide). On élimine l'acétone sous pression réduite à 20°C puis extrait à l'éther; les éthers, séchés (Na_2SO_4) et concentrés mènent à 317 mg (96%) de lactone **6** inchangée.

Ouverture en solution des composés 5c *et réactivité du composé* 7c

A. A 4 g de **5***b* (*cis*/*trans* = 25:75) dissous dans 186 cm³ d'eau et 427 cm³ d'acétone, on ajoute 0,68 g de soude puis agite 165 h à 40°C. On élimine l'acétone sous pression réduite à 20°C. Par extraction à l'éther on isole 2,0 g de lactone **6** (rmn). La phase aqueuse est acidifiée par HCl 50% puis extraite à l'éther. Les éthers sont lavés (H_2O), séchés (Na_2SO_4), concentrés et immédiatement estérifiés par action d'un excès de diazométhane en solution éthérée. Après traitement on obtient un mélange présentant six taches en ccm. Par chromatographie sur colonne de silice avec éther – éther de pétrole (20:80, varie graduellement jusqu'à 50:50) on isole: (*1*) 631 mg d'esters **5***a* contenant d'après le spectre de rmn 28% du composé **7***a*. En présence d'Eu(DPM)$_3$ il est possible d'observer trois signaux dus aux COOMe des composés **5***a-cis*, **5***a-trans* et **7***a*. Les deux premiers ont pu être reconnus par ajout d'un mélange connu de **5***a cis* et *trans*; leur rapport d'intégration indique la proportion *cis*/*trans* de 7:93 pour **5***a*; (*2*) 108 mg (3,1%) d'alcool **10***a* (rmn); (*3*) 351 mg (10,1%) d'alcool **12***a* (rmn); (*4*) 60 mg de lactone **6** (rmn), ce qui, compte-tenu des 2 g isolés par extraction directe, conduit à un rendement de 70,4%.

B. Un gramme d'acide **5***b-trans*, soumis aux mêmes conditions, conduit à: (*1*) 590 mg (72%) de la lactone **6** (rmn) par extraction directe; (*2*) un produit brut présentant, après estérification, quatre taches en ccm et dont la composition précise a été déterminée par la méthode déjà utilisée pour l'analyse du produit de l'hydrolyse basique des composés **5***a*. Les résultats sont portés dans le tableau 1.

C. Réactivité du composé **7***c*: on place 140 mg d'acide **7***b* dans les conditions des réactions précédentes. On élimine ensuite l'acétone sous pression réduite à 20°C, puis acidifie à froid (HCl 20%) et extrait à l'éther. Les éthers sont lavés (H_2O), séchés (Na_2SO_4), concentrés et immédiatement soumis à l'action d'un excès de diazométhane en solution éthérée. Après traitement on récupère 150 mg d'un produit brut dont l'analyse est réalisée par rmn à 100 MHz, et rmn à 60 MHz du produit obtenu par acétylation. Le composé **7***a* est facilement mis en évidence et dosé en rmn à 100 MHz (signal à 4,61 Hz). Les résultats obtenus sont portés dans le tableau 1.

Action de l'hydroxyurée sur les esters α-acétyléniques

CHRISTIANE LASSALVY, CLÉMENT PETRUS[1] ET FRANÇOISE PETRUS

Laboratoire de Synthèse et d'Etudes Physicochimiques d'Hétérocycles Azotés, Université des Sciences et Techniques du Languedoc, Place E. Bataillon, 34060 Montpellier, France

Reçu le 2 avril 1980

CHRISTIANE LASSALVY, CLÉMENT PETRUS et FRANÇOISE PETRUS. Can. J. Chem. **59**, 175 (1981).

L'addition-1,4 de l'hydroxyurée sur les esters α-acétyléniques par l'oxanion $H_2N—CO—NHO^-$ conduit aux β-uréidoxy esters éthyléniques *E* et *Z*. Avec le tétrolate et le phényl propiolate d'éthyle, l'isomère *E* est isolé et identifié. L'isomère *Z* se cyclise *in situ* pour conduire, à partir du tétrolate, à la carboxamido-2 méthyl-5 isoxazolone-3. A partir du phényl propiolate, l'hydroxy-3 phényl-5 isoxazole est directement obtenu, le dérivé *N*-carboxamido intermédiaire n'étant pas isolé. Avec le propiolate d'éthyle, la cyclisation *in situ* de l'isomère *Z* conduit aussi à l'hydroxy-3 isoxazole. Le β-uréidoxy acrylate *E* n'est pas isolé; il réagit avec le solvant, dans une addition de Michaël, puis se cyclise en *N*-carboxamido-2 éthoxy-5 isoxazolidinone-3.

CHRISTIANE LASSALVY, CLÉMENT PETRUS, and FRANÇOISE PETRUS. Can. J. Chem. **59**, 175 (1981).

Hydroxyurea, in its oxanion form $NH_2—CO—NHO^-$, reacts in basic medium by a 1,4-addition to α-acetylenic esters leading to the *E* and *Z* ethylenic β-ureidoxy ester isomers. The *E* isomer can be isolated and identified from reaction with ethyl tetrolate and ethyl propiolate. The *Z* isomer undergoes cyclisation *in situ* to give the 2-carboxamido-5-methyl-3-isoxazolone. With phenyl propiolate, the 3-hydroxy-5-phenyl isoxazole is directly obtained without isolation of the intermediate *N*-carboxamido derivative. In the case of ethyl propiolate two cyclic compounds are obtained: 3-hydroxyisoxazole and 2-*N*-carboxamido-5-ethoxy-3-isoxazolidinone. The formation of the former is due to the *in situ* cyclisation of the *Z* isomer. The isolation of the latter compound can be explained by solvent addition to the *E* β-ureidoxyacrylate intermediate in a Michaël addition followed by cyclisation.

Introduction

L'hydroxyurée s'étant révélée une hydroxylamine *N*-protégée, ne réagissant que par son oxanion $NH_2—CO—NHO^-$, dans différentes réactions de substitutions nucléophiles (1) et additions de Michaël sur des dérivés éthyléniques (2), il nous a paru intéressant d'étudier le comportement de ce réactif avec les esters α-acétyléniques. Rappelons que Iwai et Nakamura (3) montrent que l'action de l'hydroxylamine sur les esters α-acétyléniques implique uniquement l'attaque par le doublet de l'azote qui peut conduire, suivant les conditions expérimentales, à une addition-1,4 pour donner des β-hydroxyaminoesters qui se cyclisent en isoxazolones-5, ou par action sur la fonction ester à des acides hydroxamiques qui se cyclisent en isoxazolones-3. D'où l'intérêt d'étudier l'action d'une hydroxylamine *N*-protégée, telle que l'hydroxyurée, sur les esters α-acétyléniques.

Nous avons donc réalisé cette étude en prenant comme esters de départ les propiolate, phényl propiolate et tétrolate d'éthyle en vue de comparer les effets de substituants.

Si dans tous les cas une addition-1,4 de l'hydroxyurée impliquant l'oxygène du réactif est observée, l'évolution des intermédiaires dans le milieu réactionnel est différente et nous expliciterons successivement les résultats obtenus à partir du tétrolate, phényl propiolate et propiolate d'éthyle.

[1]Auteur à qui toute correspondance sera adressée.

Résultats et discussion

Action de l'hydroxyurée sur le tétrolate d'éthyle

En milieu éthylate de sodium, on obtient un mélange de β-uréidoxy crotonate d'éthyle **1***a* et de carboxamido-2 méthyl-5 isoxazolone-3 **1***b*. Dans une première étape, l'addition-1,4 de l'hydroxyurée conduit aux deux β-uréidoxy crotonates d'éthyle *E* et *Z*, puis hétérocyclisation *in situ* de l'isomère *Z* par l'azote en α de l'oxygène (5-*exo*-trig), favorisée d'après les règles de Baldwin (4), pour donner le composé **1***b*. Le β-uréidoxy crotonate d'éthyle **1***a* obtenu, remis en présence d'éthylate de sodium, ne s'est pas cyclisé, la configuration *E* de ce composé ne permettant pas la cyclisation (schéma 1).

Action de l'hydroxyurée sur le phényl propiolate d'éthyle

Les résultats obtenus à partir de cet ester sont comparables à ceux observés précédemment. L'hydroxyurée réagit dans une addition-1,4 sur la triple liaison conjuguée au groupement ester, pour donner les β-uréidoxy cinnamates d'éthyle *E* et *Z*. Nous isolons l'isomère *E* non cyclisable **2***a* et l'hydroxy-3 phényl-5 isoxazole **2***c* à côté d'une petite quantité d'ester de départ non réagi. La formation du composé **2***c* est expliquée par le processus suivant: cyclisation 5-*exo*-trig de l'isomère *Z* par l'atome d'azote en α de l'oxygène conduisant à la carboxamido-2 phényl-5 isoxazolone-3 non isolée, qui évolue en hydroxy-3 phényl-5 isoxazole **2***c* (schéma 1).

SCHÉMA 1

Action de l'hydroxyurée sur le propiolate d'éthyle

Nous isolons l'hydroxy-3 isoxazole **3***c* et la carboxamido-2 éthoxy-5 isoxazolidinone-3 **3***d*. La formation de composés d'addition du solvant, β-éthoxy acrylate et β-diéthoxy propionate d'éthyle, abaisse le rendement de la réaction en produits cycliques.

Le processus de formation de **3***c* est comparable à celui donné plus haut pour le composé **2***c*: cyclisation 5-*exo*-trig du β-uréidoxy acrylate d'éthyle *Z*, formation de la carboxamido-2 isoxazolone-3 **3***b*, perte du groupement carboxamido pour donner l'hydroxy-3 isoxazole **3***c*.

Nous discutons maintenant la formation de **3***d* qui admet comme intermédiaire le β-uréidoxy acrylate d'éthyle *E* non isolé. En effet, en faisant réagir le propiolate d'éthyle avec un excès d'hydroxyurée (1 mol d'ester pour 2,5 mol de réactif) en présence d'éthylate de sodium, le diuréidoxy-3,3 propanoate d'éthyle **3***f* est obtenu à côté de l'hydroxy-3 isoxazole **3***c*. Il y a donc addition-1,4 de l'hydroxyurée sur la double liaison du β-uréidoxy acrylate d'éthyle *E*.

Sans excès d'hydroxyurée, l'éthylate s'additionne pour donner le β-uréidoxy β-éthoxy propionate dont l'hétérocyclisation 5-*exo*-trig conduit à l'isoxazolidinone **3***d*.

En l'absence d'hydroxyurée, nous observons l'addition de l'éthylate sur le propiolate conduisant à l'acide β-diéthoxy propionique.

Il apparaît ainsi que la cyclisation du β-uréidoxy acrylate d'éthyle *Z* est favorisée par rapport à l'addition de Michaël. D'autre part, nous notons une exaltation de la réactivité de la double liaison du β-uréidoxy acrylate *E* par rapport aux autres β-uréidoxy esters insaturés qui ne donnent pas d'addition de Michaël dans les mêmes conditions (schéma 2).

Identification des composés

Les uréidoxyesters sont identifiés par des méthodes spectrales ir et rmn (tableaux 1 et 2). Leurs spectres ir présentent les bandes d'un groupement carboxamide $H_2N—\underset{\underset{O}{\|}}{C}—NH$: $\nu_{C=O}$ à 1690–1700 cm^{-1}, ν_{NH_2} vers 3350–3500 cm^{-1}, δ_{NH_2} à 1600 cm^{-1} et en outre la bande ν_{CO} ester vers 1730–1750 cm^{-1} et la bande $\nu_{C=C}$ à 1640 cm^{-1} pour les esters éthyléniques. Ces données sont comparables à celles des spectres ir des uréidoxy esters (1*e*) et uréidoxy cétones cités dans la littérature (2*c*). Les spectres rmn corroborent les structures proposées.

Parmi les produits cycliques, l'hydroxy-3 isoxazole **3***c* et l'hydroxy-3 phényl-5 isoxazole **2***c* sont identifiés aisément par leur spectre rmn par comparaison avec les données de la littérature (3). Pour la carboxamido-2 méthyl-5 isoxazolone-3 **1***b*, nous notons les bandes à 1600 cm^{-1} dues à δ_{NH_2} et 3 bandes à 1630 cm^{-1}, 1690 cm^{-1} et 1750 cm^{-1}. Par comparaison avec les isoxazolones-3 *N*-substituées (5), les bandes à 1630 et 1690 cm^{-1} sont attribuées à $\nu_{C=C}$ et ν_{CO} cyclique; celle à 1750 cm^{-1} correspond à $\nu_{CO—NH_2}$, en accord avec Olive *et al.* (2*b*) qui notent la présence de $\nu_{N—CO—N}$ à 1735–1740 cm^{-1} pour des carboxamido-2 isoxazolidinones-3. Nous avons confirmé la structure de ce composé en synthétisant l'autre isomère, la carboxamido-2 méthyl-3 isoxazolone-5 par action du cyanate de potassium sur la méthyl-3 isoxazolone-5.

Son spectre présente les bandes à 1590 cm^{-1}, 1630 cm^{-1}, attribuées à δ_{NH_2} et $\nu_{C=C}$. La bande ν_{CO} à 1730 cm^{-1} est caractéristique des isoxazolones-5 *N*-substituées (6); celle à 1760 cm^{-1} correspond bien à $\nu_{CO—NH_2}$ confirmant les attributions précédentes.

Les spectres rmn confirment la structure isoxazolone-3 du composé (5*b*). Le spectre rmn de ce dernier est tout à fait comparable à celui de l'acétyl-2 méthyl-5 isoxazolone-3 donné dans la littérature (7) (tableau 3).

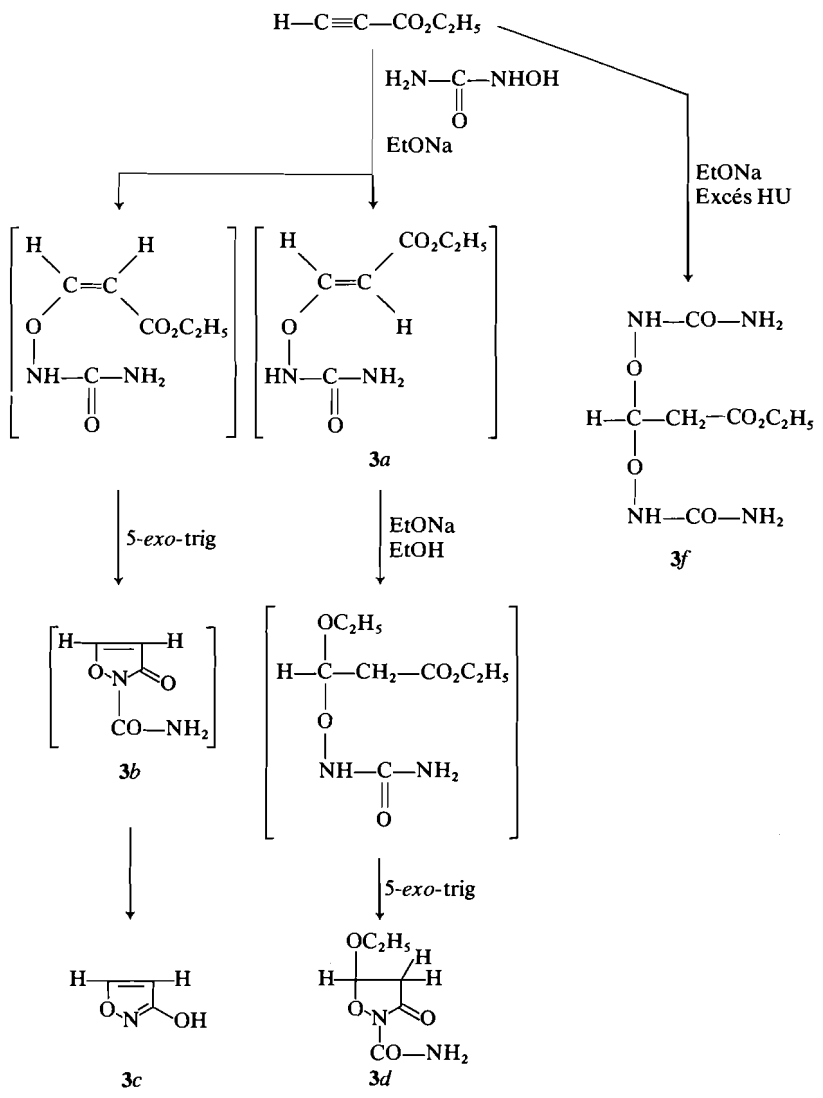

SCHÉMA 2

Le spectre ir de la carboxamido-2 éthoxy-5 isoxazolidinone-3 **3***d* présente les bandes du groupement carboxamido: δ_{NH_2} à 1600 cm^{-1}, ν_{CO-NH_2} à 1760 cm^{-1} et ν_{NH_2} à 3390 cm^{-1}. La bande à 1730 cm^{-1} correspondrait au CO du cycle.

Le spectre rmn dans le DMS-d_6 présente un système ABX dégénéré correspondant aux protons en 4 et 5 que nous avons résolu par double résonance, à côté des signaux du C_2H_5 et de NH_2; δ_{HA} = 2,6 ppm; δ_{HB} = 3,4 ppm; δ_{HX} = 5,63 ppm; J_{AB} = 17,4 Hz; J_{AX} = 0; J_{BX} = 5,6 Hz; δ_{CH_3} = 1,17 ppm; δ_{OCH_2} = 6 ppm; δ_{NH_2} = 7,25 ppm.

Conclusion

Nous avons montré que l'hydroxyurée réagissait sur les esters α-acétyléniques dans une addition-1,4 impliquant l'oxygène du réactif pour conduire à des β-uréidoxyesters éthyléniques *E* et *Z*. L'hétérocyclisation régiospécifique 5-*exo*-trig par l'azote en α de l'oxygène est une nouvelle voie de synthèse des isoxazolones-3.

Partie expérimentale

Mode opératoire général

A une solution de 0,1 mol de méthylate de sodium dans le méthanol (ou d'éthylate de sodium dans l'éthanol), on ajoute à température ambiante 0,1 mol d'hydroxyurée sous agitation; après dissolution de l'hydroxyurée, 0,1 mol d'ester acétylénique sont additionnés goutte à goutte à ce mélange.

L'agitation est maintenue suivant les cas durant une période de 24 à 48 h. Après évaporation du solvant à pression normale, le résidu réactionnel est repris par l'eau et extrait à l'éther.

La phase aqueuse est acidifiée par une solution d'acide chlorhydrique à 40% jusqu'à pH 3–4, constant.

(a) A partir du tétrolate d'éthyle

Le tétrolate d'éthyle est préparé suivant la méthode de

Nazarov *et al.* (8); Eb 60°C/25 Torr (litt. (9) Eb 163°C/752 Torr). Temps de réaction 4 jours.

A partir du résidu de la phase éthérée, le β-uréidoxy crotonate d'éthyle **1***a* est séparé par filtration, et purifié par recristallisation. La phase aqueuse est ensuite traitée comme précédemment; le solide est purifié par recristallisation dans l'éthanol. On obtient la carboxamido-2 méthyl-5 isoxazolone-3 **1***b*.

β-Uréidoxy crotonate d'éthyle **1***a*: F (éthanol) 138°C; Rdt 20%. *Anal.* calc. pour $C_7H_{12}N_2O_4$: C 44,68, H 6,43; trouvée: C 44,51, H, 6,25%.

Carboxamido-2 méthyl-5 isoxazolone-3 **1***b*: F (éthanol) 141°C; Rdt 50%. *Anal.* calc. pour $C_5H_6N_2O_3$: C 42,25, H 4,26; trouvée: C 42,17, H 4,28%.

(b) A partir du phényl propiolate d'éthyle

Temps de réaction 48 h. A partir du résidu de la phase éthérée, on sépare par filtration le β-uréidoxy cinnamate d'éthyle **2***a* et l'ester de départ non réagi (10%). Le précipité de la phase aqueuse est filtré. On isole ainsi l'hydroxy-3 phényl-5 isoxazole **2***c* qui est recristallisé dans l'éthanol.

β-Uréidoxy cinnamate d'éthyle **2***a*: F 130°C; Rdt 20%. *Anal.* calc. pour $C_{12}H_{14}N_2O_4$: C 57,59, H 5,64; trouvée: C 57,50, H 5,59%.

Hydroxy-3 phényl-5 isoxazole **2***c*: F 163–165°C (litt. (3) F 163–165°C); Rdt 50%; rmn (**5***b*) (DMS-d_6 à 60 MHz): 6,48 (s, H-4), 7,5 (m, C_6H_5), 11,4 (s, OH) ppm. *Anal.* calc. pour $C_9H_7NO_2$: C 67,07, H 4,38; trouvée: C 67,09, H 4,51%.

(c) A partir du propiolate d'éthyle

Temps de réaction 36 h. Le résidu de la phase éthérée est distillé; on obtient un mélange (50:50) de β-éthoxy acrylate d'éthyle et de β-diéthoxy propionate d'éthyle caractérisé par rmn avec un rendement global de 50%.

β-Éthoxy acrylate d'éthyle; rmn ($CDCl_3$ à 60 MHz): 7,56 (d, H_β), 5,13 (d, H_α, J = 12 Hz), 3,56 (m, O—CH_2), 4,13 (q,), 1,23 (m, CH_3) ppm.

β-Diéthoxy propionate d'éthyle; rmn: 4,87 (t, H), 2,63 (d, CH_2, J = 6 Hz), 3,56 (m, O—CH_2), 4,13 (q, ), 1,23 (m, CH_3) ppm.

La phase aqueuse est extraite plusieurs fois à l'acétate d'éthyle. Les extraits combinés sont séchés sur sulfate de sodium; l'acétate d'éthyle est évaporé sous pression réduite. Le solide récupéré est chromatographié sur colonne de silice (éluant: éther). On obtient l'hydroxy-3 isoxazole **3***c* et le carboxamido-2 éthoxy-5 isoxazolidinone-3 **3***d*.

Hydroxy-3 isoxazole **3***c*: F (hexane) 98–99°C (litt. (3) F 98–99°C); Rdt 25%; rmn (DMS-d_6 à 60 MHz): 6,13 (d, H-4), 8,57 (d, H-5, $J_{4,5}$ = 2 Hz), 11,1 (s large, OH) ppm. *Anal.* calc. pour $C_3H_3NO_2$: C 42,36, H 3,56; trouvée: C 42,57, H 3,56%.

Carboxamido-2 éthoxy-5 isoxazolidinone-3 **3***d*: F (éthanol) 126°C; Rdt 15%. *Anal.* calc. pour $C_6H_{10}N_2O_4$: C 41,38, H 5,79; trouvée: C 41,36, H 5,81%.

Cas particuliers

Action de l'hydroxyurée en excès

A une solution de 0,05 mol d'éthylate de sodium dans l'éthanol, on ajoute à température ambiante 0,125 mol d'hydroxyurée sous agitation et 0,05 mol de propiolate d'éthyle. L'agitation est maintenue pendant trois jours. Après évaporation du solvant, le résidu est repris par de l'eau; une petite quantité de diuréidoxy-3,3 propanoate d'éthyle précipite et est séparée par filtration. On acidifie jusqu'à pH ≃ 3–4. On extrait à l'acétate d'éthyle, on sèche sur sulfate de sodium. Cette phase est concentrée et le dérivé diuréidoxy qui précipite est séparé par filtration. En évaporant à sec le filtrat, on récupère l'hydroxy-3 isoxazole caractérisé par comparaison avec un échantillon authentique (3).

Diuréidoxy-3,3 propanoate d'éthyle: F (éthanol): 156–157°C. *Anal.* calc. pour $C_7H_{14}N_4O_6$: C 33,60, H 5,64, N 22,39; trouvée: C 33,60, H 5,76, N 22,30%.

En l'absence d'hydroxyurée

Le mode opératoire général est repris sans hydroxyurée. Temps de réaction 48 h. La phase aqueuse acidifiée est extraite à l'éther. La phase éthérée, séchée sur sulfate de sodium, est concentrée sous vide. On obtient l'acide β-diéthoxy propionique caractérisé par rmn et spectre de masse; rmn ($CDCl_3$ à 60 MHz): 2,66 (d, H), 4,90 (t, CH_2, J = 6 Hz), 7,00 (OH), 3,61 (m, OCH_2), 1,20 (t, CH_3, J = 6 Hz) ppm. Spectre de masse: pic moléculaire à *m/e* 162 (faible intensité); *m/e* 161, 117, 103 (forte intensité) caractéristiques d'un acétal (10).

Techniques utilisées

Les points de fusion non corrigés ont été mesurés en tube capillaire (appareil Büchi).

Les analyses ont été déterminées par le laboratoire Central de Microanalyse du CNRS.

Les spectres rmn ^1H ont été réalisés soit au moyen d'un appareil Varian modèle T60 ou Brucker WP 80. Les déplacements chimiques sont exprimés en ppm par rapport au TMS pris comme référence interne. Les spectres ir ont été enregistrés sur un appareil Perkin Elmer 297.

A kinetic method of analysis which distinguishes Fe(II) from Fe(III) and Fe(III) forms of various labilities from each other is based on spectrophotometric monitoring of the reaction of Fe(II) with ferrozine. Reduction of Fe(III) with hydroxylamine hydrochloride allows the single colourimetric reagent to detect all forms of Fe. The method is applied to study of the effects of a well characterized soluble soil organic acid sample, a fulvic acid, on the speciation of Fe(III) under conditions (pH = 6) where Fe(III) forms a colloidal hydrous oxide in the absence of fulvic acid, The effect of fulvic acid is to greatly increase the lability of Fe(III) compared to that in a hydrous oxide colloid. However, ultrafiltration and light scattering experiments indicate that the Fe(III) – fulvic acid species is larger than the hydrous ferric oxide colloid particles. Kinetic studies in the absence of hydroxylamine hydrochloride show that fulvic acid can act as a reducing agent for iron in the presence of an Fe(II) complexing agent like ferrozine but neither kinetic studies with an Fe(III) reagent nor Mössbauer spectra suggest significant initial presence of Fe(II) in the aged Fe(III) – fulvic acid samples.

COOPER H. LANGFORD, SHUI MUI WONG et ALAN W. UNDERDOWN. Can. J. Chem. **59**, 181 (1981).

Faisant appel à la détection spectrophotométrique de la réaction du Fe(II) avec la ferrozine, on a développé une méthode cinétique d'analyse qui permet de distinguer le Fe(II) du Fe(III) et des formes de Fe(III) de labilité variable. La réduction du Fe(III) par le chlorhydrate d'hydroxylamine permet de détecter toutes les formes de Fe à l'aide d'un seul réactif colorimétrique. On a appliqué cette méthode à l'étude des effets d'un échantillons d'un acide organique de sol soluble bien caractérisé, l'acide fulvique, sur la différenciation de Fe(III) dans des conditions (pH 6) où le Fe(III) forme un oxyde hydraté colloidal en l'absence d'acide fulvique. L'acide fulvique a comme effet d'augmenter fortement la labilité du Fe(III) par rappport à celle de l'oxyde hydraté colloidal. Cependant l'ultrafiltration et les expériences de diffraction lumineuse indiquent que l'entité Fe(III) – acide fulvique est plus volumineuse que les particules colloidals d'oxyde ferrique hydraté. Les études cinétiques, en l'absence du chlorhydrate d'hydroxylamine, montrent que l'acide fulvique peut agir comme agent réducteur du fer en présence d'un agent complexant du Fe(II) tel la ferrozine; toutefois ni les études cinétiques impliquant un réactif de Fe(III) ni le spectres Mossbauer ne suggèrent une présence initiale significative de Fe(II) dans les vieux échantillons de Fe(III) – acide fulvique.

[Traduit par le journal]

Introduction

Using sulfosalicylic acid (SSA) as a spectrophotometric reagent for kinetic analysis, we have studied complexation of Fe(III) by the well characterized soil fulvic acid sample which was derived from a Prince Edward Island Podzol Bh horizon by the Agriculture Canada group (1). In acid solution, a "1:1 complex" was found with conditional stability constant showing complex pH dependence (2). In solution at pH = 4, evidence was obtained for "dissolution" of colloidal hydrous ferric oxide by fulvic acid and some reduction of Fe(III) by fulvic acid was observed (3). Unfortunately, the spectrophotometric sensitivity of SSA is not adequate for analysis of true natural water models. The low solubility of Fe(III) at intermediate pH values (pH = 6–8) recommends study of quite dilute samples.

In this report a new kinetic reagent system which has good sensitivity for iron is described. It uses the sensitive Fe(II) spectrophotometric reagent ferrozine (the disodium salt of 3-(2-pyridyl)-5,6-bis(4-phenyl-sulfonic acid)-1,2,4-triazine) introduced by Stookey in 1970 (4). Determination of Fe(III) is accomplished by including the reducing agent hydroxylamine hydrochloride in the reagent solution. The new kinetic reagent is applied (as SSA was) to distinguishing species of different lability under pseudo first order kinetic conditions. Information about lability of iron species at pH = 6 is complimented with structural studies using light scattering, ultrafiltration, and Mössbauer spectroscopy.

The kinetic method of analysis depends upon the formation of a *common product* from one or more initial species present in the sample. Under first order or pseudo first order conditions, the kinetics of formation of the common product may be written:

$$[1] \quad P = A_0[1 - \exp(-k_A t)] + B_0[1 - \exp(-k_B t)] + \ldots + X$$

where P represents a concentration proportional parameter of the product, A_0 the concentration of species A initially present in the sample (expressed

in the same units as P), B_0 the initial concentration of species B, X a time-independent term including any concentrations of fast reacting species plus blank, and k_A, k_B the corresponding rate constants. In a sample containing two species with rate constants appropriate to the time scale of the experiment, the problem is to fit four parameters; A_0, B_0, k_A, and k_B. A_0 and B_0 are the "quantitative" parameters. k_A and k_B are the "qualitative" parameters which allow recognition of distinct species. In this work, the four parameters are obtained by a non-linear least-squares fitting procedure based on a library program using the Marquardt algorithm which has been extensively tested elsewhere (5). Tests in ref. 5 suggest that successful resolution of up to three components which differ in rate constant by a factor of three or more is achievable.

Experimental

Materials

Ferrozine was a generous gift of Diagnostic Chemicals, Ltd., Charlottetown, P.E.I. Fe(III) stock solutions were prepared by dissolution of A.R. grade iron wire in concentrated A.R. grade HNO_3. Fe(II) stocks were prepared from A.R. grade ferrous ammonium sulfate (used as a weighing form). Other reagent grade materials used as received were sulfosalicyclic acid, a TRIS buffer (2-amino-2-(hydroxymethyl)-1,3 propanediol), and trisodium phosphate. The sample of fulvic acid was prepared from a sample of the Armadale Bh horizon podzol described in ref. 1 according to the method cited there. Acidimetric titration curves agree with those for the sample described in ref. 1. Water for solutions was "tap" distilled water redistilled from permanganate in an all glass apparatus.

Solution Preparation

The kinetic reagent solution employed in most experiments was composed of 3.00×10^{-3} M ferrozine, 6.00×10^{-3} M $NH_2OH \cdot HCl$, and 1.0×10^{-2} M $HClO_4$. This solution determines final values of both the pH and ionic strength of all mixtures prepared from mixing equal quantities of it with the various sample solutions of this study. Consequently, rate constants are evaluated for constant solution conditions. Runs are also always pseudo first order in ferrozine and $NH_2OH \cdot HCl$. Iron-containing samples were prepared by diluting stock solutions, adjusting pH (as measured with an Orion 701A digital pH/mV meter) slowly by titration with TRIS, and finally aging for 27 h to provide for preliminary pseudo equilibration. That is, the solutions are equilibrated with respect to faster homogeneous processes, but probably not with respect to all heterogeneous processes. As before (3), 27 h was chosen as a common point for comparisons.

Kinetic Studies

Two types of experiments were conducted. For slower reactions equal volumes of reagent and sample were mixed and thermostated at 25.0°C. Aliquots were pipetted into 1 cm quartz cells in a Coleman 124 Spectrophotometer. The monitoring wavelength was 562 nm. The extinction coefficient of ferrozine at pH = 2.00 is $1.27 \pm 0.01 \times 10^4$ M^{-1} cm^{-1}. For faster reactions, kinetic data were collected using a Durrum–Gibson stopped flow spectrophotometer thermostated at 25.0°C.

Filtration, Light Scattering, and Mössbauer

The fraction of "larger" particles in each of solutions of Fe(III) equilibrated at pH = 6 and solutions of Fe(III) plus FA so equilibrated was estimated by filtration through 0.45 or 0.4 μm pore filters. Since such filters can have ion exchange properties, three types were compared (suppliers in parentheses); 0.45 μm cellulose acetate (Gelman), 0.45 μm cellulose acetate (Millipore), and 0.4 μm polycarbonate (Bio-Rad Laboratories). Two types of filter supports were used; glass and polycarbonate.

Light scattering studies were carried out using a Phoenix light scattering apparatus modified to accept the beam of a 5 mW He–Ne laser. Absorption corrections are based on data from the "straight through" orientation of the detector. Such experiments are more fully described elsewhere (6).

Mössbauer measurements were made using an instrument assembled in the laboratories of D. R. Wiles and described fully elsewhere (7). Briefly, it is a constant acceleration design operating in transmission geometry with a 0.2 mCu ^{57}Co(Pd) source. A 1024 channel multichannel analyzer collects count rates with a velocity increment of 0.03 mm s^{-1} per channel. Data analysis used a non-linear least-squares regression program (7).

Results

Fe(III) Hydrous Oxide Colloids

Solutions of initial Fe(III) concentrations of 5.00×10^{-5} M were adjusted to pH = 6.0 and aged. On mixing with the ferrozine/$NH_2OH \cdot HCl/HClO_4$ reagent the largest part of the Fe(III) reacted with a pseudo first order rate constant of $4.9 \pm 0.3 \times 10^{-3}$ s^{-1}. The concentration of this species yielded by the fitting routine was $4.8 \pm 0.1 \times 10^{-5}$ M. Mass balance considerations suggest the presence of a small quantity of a faster reacting component. This was detected on a sample subjected to filtration through a 0.45 μm filter and then run on the Durrum–Gibson stopped flow. The stopped flow data could be fitted kinetically as two components with pseudo first order rate constants of 1.5×10^{-1} s^{-1} and $4.8 \pm 0.2 \times 10^{-3}$ s^{-1} respectively. A large part of the total iron was removed by the filtration step. We conclude that about 4.8×10^{-5} M Fe(III) is present as a hydrous oxide colloid and about 2×10^{-6} M Fe(III) is present as small "dissolved" species.

Mixtures of Fe(II)/Fe(III)

The capacity of the system to discriminate Fe originally present in the 2+ oxidation state was tested on samples prepared by combining Fe(II) and Fe(III) stocks to give 2.5×10^{-5} M concentrations in each. The solution was titrated to pH = 6 with TRIS and aged for 27 h. A distinction between the initial Fe(II) and Fe(III) was clearly achieved. A quite rapid component appeared in the kinetics which is attributed to Fe(II). A slower component was fitted to a pseudo first order rate constant of 4.3 $\pm 0.5 \times 10^{-3}$ s^{-1}. The rate constant for this component is in satisfactory agreement with the value above. However, the concentrations of the fast (Fe(II)) component and the slower one do not add up to the original 5.0×10^{-5} M Fe concentration. In three runs, the concentrations found were: (*1*)

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

Fe(III), 2.4×10^{-5} *M*, Fe(II), 1.8×10^{-5} *M*, Fe(total), 4.2×10^{-5} *M*; (*2*) Fe(III), 2.6×10^{-5} *M*, Fe(II) 1.7×10^{-5} *M*, Fe(total), 4.3×10^{-5} *M*; (*3*) Fe(III), 2.6×10^{-5} *M*, Fe(II), 1.8×10^{-5} *M*, Fe(total), 4.4×10^{-5} *M*. Some ~13% of the total iron is not recovered. The loss was reproducible over 10 runs. The fate of this iron was traced by employing an ASTM Standard Method (8). Allowing a reaction time of over a month, 100 ± 5% of the total iron was recovered. Interestingly, it appears that Fe(II) (in solution *not* O_2-free) catalyzes formation of *insoluble* iron oxide precipitates. This phenomenon is reminiscent of the role of Cr^{2+} in dissolution of anhydrous $CrCl_3$.

Kinetics in Solutions of Fe(III) with Fulvic Acid

The fulvic acid sample used has the following functionality: 3.3 mequiv. g^{-1} phenolic-OH near carboxylates; 7.71 mequiv. g^{-1} of carboxylate; and 3.6 mequiv. g^{-1} of alcoholic-OH (1). It is assumed on the basis of "blocking experiments" (9) that all of the phenolic-OH is placed so that it can participate in salicylate like chelation and a "1:1 ratio with Fe(III)" is taken to be one phenolate group on FA to one Fe(III). The molecular weight was reported to be 951 (1). On this basis solutions were prepared to contain 1.50 mg mL^{-1} of FA. These are intended to be approximately 1.67×10^{-5} *M* and to provide an approximate 1:1 ratio of binding sites to the 5.00×10^{-5} *M* Fe(III) concentration prepared from Fe(III) stocks. Such 1:1 solutions were adjusted to pH = 6 with TRIS and aged for 27 h.

Kinetics on these samples were carried out with three reagent solutions. The first was the same as that used in the previous experiments, the second was the same except that the reducing agent $HONH_2 \cdot HCl$, was omitted, and the third was the less sensitive but direct Fe(III) reagent solution, based on sulfosalicyclic acid (SSA), which was described at length in ref. 3. Absorbance–time curves for a typical run in each of these cases are given in Fig. 1.

Non-linear regression yielded two components in the first case, a major one with a rate constant of 1.49 ± 0.03 s^{-1} and a minor one with a rate constant fast compared to the time scale of manual kinetics. The parameters are collected in Table 1. The first noteworthy observation is that both components found react faster than any component in the absence of FA. Clearly, FA affects all the Fe(III) hydrous oxide colloids. The second point is that one or both components *may* be an Fe(II) species prior to the addition of ferrozine reagent. This requires testing.

It is because of the second observation that kinetics were run with omission of $HONH_2 \cdot HCl$ and

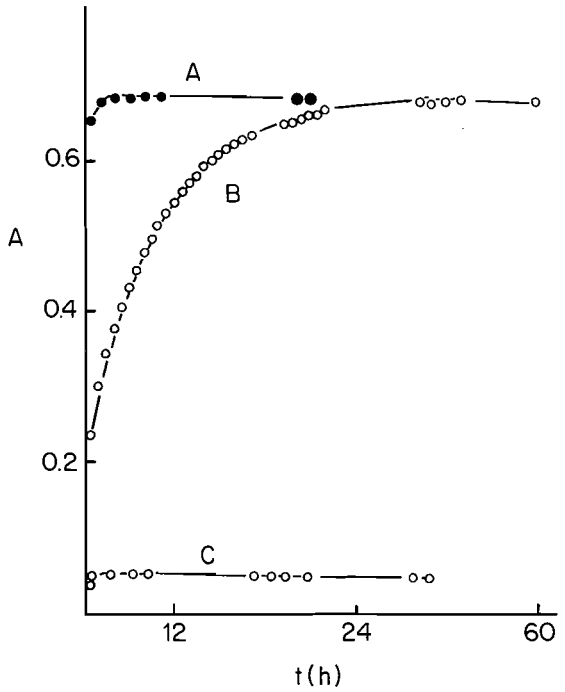

FIG. 1. Absorbance–time curves for reactions of samples containing fulvic acid. *A*, reagent contains ferrozine plus $NH_2OH \cdot HCl$; *B*, reagent contains ferrozine without an added reducing agent; *C*, reagent is SSA in acid, an Fe(III) reagent.

with the SSA reagent solution. The fifth and sixth entries in Table 1 show the results of using the Fe(III) reagent, SSA. SSA does not allow the low detection limit associated with ferrozine. Thus, results at total Fe equal to 5.00×10^{-5} are of low precision. However, there appears to be a single component. The SSA runs were repeated with total Fe raised to 1.00×10^{-4} *M*. In this case, the precision of the rate constant for three trials was quite good, supporting a single kinetic component. This component accounts for 100 ± 5% of the Fe at both concentration levels. The simplest interpretation is that all of the Fe is present in Fe(III) species.

However, the third and fourth entries in Table 1 show that 100% of the Fe can be delivered to the Fe(II) reagent, ferrozine in the absence of a reducing agent in the *reagent* solution. That is, FA can act as a reducing agent. Reduction by fulvic acid has *two* kinetic components as suggested by the apparent deviation of curve *B* of Fig. 1 from a single exponential; the figure does not clearly resolve the faster component (present in smaller quantity). The order of magnitude of the rate constant given in Table 1 for the fast component was adequately confirmed by five stopped-flow runs which yielded a rate constant from *initial rate* measurements of $1.13 \pm 0.13 \times 10^{-1}$ s^{-1}. (This value is not corrected for small contributions of the slower component.)

TABLE 1. Concentrations and rate constants for kinetically identified components present in samples prepared from Fe(III) and FA (all rate constants are averages of two or more runs; uncertainties are standard deviations from mean)

Sample	Reagent	Component	Rate constant (s^{-1})	Concentration (M)
Fe(III):FA	Fz:$NH_2OH \cdot HCl$[a]	Slow	1.49 ± 0.3	$4.27 \pm 0.08 \times 10^{-5}$
		Fast	—	$0.48 \pm 0.06 \times 10^{-5}$
	Fz[b]	Slow	$8.55 \pm 0.35 \times 10^{-3}$	3.50×10^{-5}
		Fast	$1.5 \pm 0.1 \times 10^{-1}$	$1.6 \pm 0.1 \times 10^{-5}$
	SSA[c]	Single	$3.2 \pm 0.8 \times 10^{-1}$	$4.9 \pm 0.1 \times 10^{-5}$
Fe(III):FA×2[d]	SSA	Single	$3.12 \pm 0.08 \times 10^{-1}$	$1.05 \pm 0.05 \times 10^{-4}$
Fe(III):FA:PO_4	Fz	Slow	$7.2 \pm 0.2 \times 10^{-3}$	$4.13 \pm 0.03 \times 10^{-5}$
		Fast	$1.2 \pm 0.1 \times 10^{-1}$	$0.91 \pm 0.01 \times 10^{-5}$

[a]This designates the reagent ferrozine plus $NH_2OH \cdot HCl$.
[b]This reagent omits $NH_2OH \cdot HCl$.
[c]This is the SSA reagent of ref. 3.
[d]"×2" indicates doubling of Fe(III) concentration.

TABLE 2. Filtration of samples through 0.45 μm cellulose acetate and 0.4 μm polycarbonate filters

	Cellulose acetate (Gelman)		Cellulose acetate (Millipore)		Polycarbonate (Bio-Rad Labs)	
Sample[a]	A[b]	B	A	B	A	B
Fe(III)	48.0%	—	0	0	58.5%	63.0%
Fe(III):FA	21.0%	—	25.0%	21.0%	22.3%	16.3%

[a]Samples are: Fe(III) = 5.00×10^{5} M Fe(III) stock adjusted to pH = 6; Fe(III): FA = 5.0×10^{-5} M from F(III) stock + 1.67×10^{-5} M from FA stock adjusted to pH = 6.
[b]A = glass filter support disc; B = polycarbonate filter support disc.

The observation that FA reduces Fe with at least two components in the kinetics confirms a preliminary observation reported in ref. 3 where phenanthroline was used as an Fe(II) reagent. There appear to be at least two distinguishable reducing sites on FA that must be used in the complete reduction of Fe(III) to Fe(II) by "one equivalent of FA chelate complexing sites". This illustrates once more the polydisperse mixture character (1) of even carefully purified FA.

Mössbauer Experiments

In order to provide support for the suggestion above that Fe in the presence of FA remains in the Fe(III) form until an Fe(II) reagent induces reduction, solid samples from the 27 h aged Fe:FA samples were obtained by freeze drying and Mössbauer spectra were recorded. A symmetric doublet was observed with an isomer shift of 0.440 mm/s and a quadrupole splitting of 0.770 mm/s. Half widths and areas of the two components of the doublet are very close. This is consistent with Fe(III). No Fe(II) signal was observable.

Filtration Studies

Since Fe(III) bound to FA is considerably more labile than Fe(III) in the hydrous oxide colloids at the same pH after the same period of aging, it is tempting to think of FA as a simple solubilizing complexing agent. But this may be a considerable oversimplification. Solutions of 5.00×10^{-5} M Fe(III) with and without "one equivalent" of FA, exactly, parallel to those used in kinetic experiments, were prepared and aged for 24 h. Aliquots were analyzed by atomic absorption to confirm 100% recovery of Fe then the samples were filtered through 0.45 μm cellulose acetate and 0.4 μm polycarbonate filters and Fe content of the *filtrate* was determined. Percentage Fe recovery in the filtrate is shown in Table 2. Making allowance for the known ion exchange properties of cellulose acetate, it seems clear that the Fe(III):FA sample has a *larger* fraction of particles of size greater than 0.4 μm than the Fe(III) hydrous oxide colloid. Fe(III) FA complexes would appear to be *aggregated despite* their *kinetic lability*.

Light Scattering

To confirm the aggregation effects in Fe(III):FA complexes from the opposite point of view. The Rayleigh scattering ratio at 90° (R_{90}) is shown in Fig. 2 as a function of added Fe(III) to a solution of 0.100 mg/mL of FA. Light scattering begins to increase rapidly above 1 mmol of Fe per mmol of FA. Under the above assumption this corresponds to

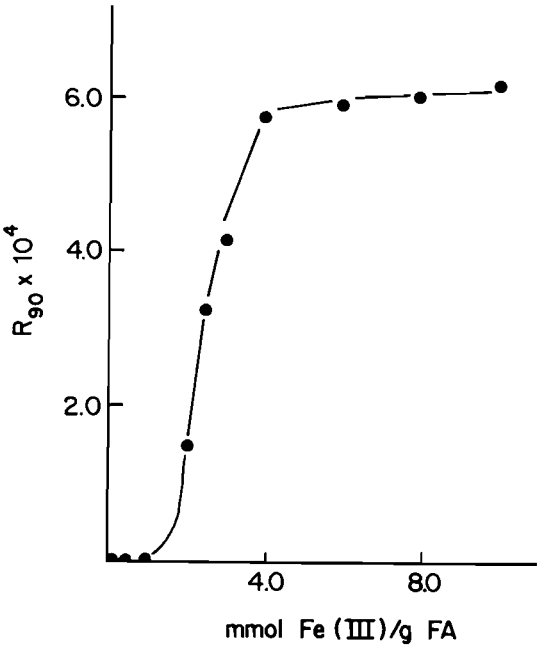

FIG. 2. Light scattering at 90° (R_{90}) as a function of added Fe(III) concentration for a solution of fulvic acid. It should be noted that the intercept at zero Fe(III) is *not* zero. The instrument has another order of magnitude of resolution.

one Fe to 3 mequiv. of fulvic acid. A limit is approached near 4 mequiv. of Fe to 3 mequiv. of FA. The figure suggests aggregation is extensive under the conditions of the kinetic studies.

Phosphate Effects

Another constituent of natural systems that interacts with iron is phosphate. Consequently, kinetic experiments on the Fe(III):FA system were repeated with the addition of 5.0×10^{-5} *M* Na_3PO_4. Solutions were still adjusted to pH = 6 and the ratio is 1:1:1 Fe(III):FA:PO_4. Again samples were aged 27 h. Phosphate effects are not large. The fact that phosphate has an effect is most clearly seen in the induced reduction of Fe(III) by FA. A typical pair of runs is illustrated in Fig. 3. Rate constants and concentrations are shown in the last two lines of Table 1. Phosphate retards the FA reduction reactions slightly. This probably implies the existence of a ternary complex.

Discussion

The concentration of FA used in these experiments corresponds to less than 10 mg per litre of "dissolved organic carbon". This is a value which realistically models natural waters. Moreover, titrations of lake water organic matter (10) and fractionated organic matter from a stream (11) suggest that our soil FA is a good model of a leading (often

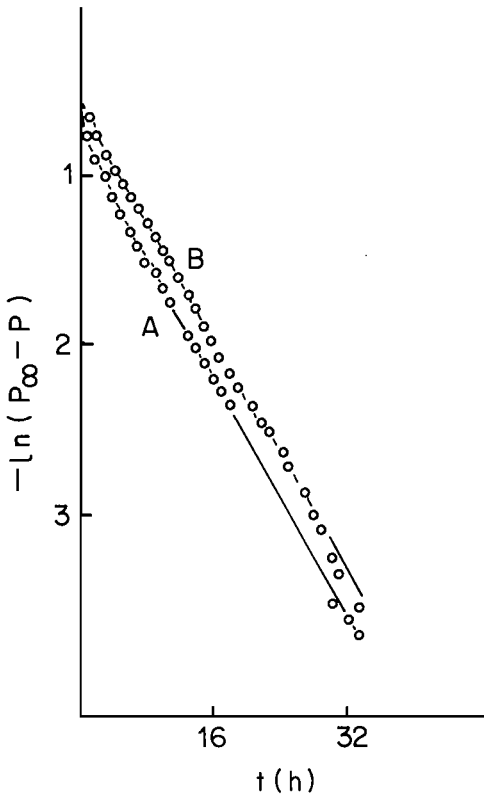

FIG. 3. The effect of added Na_3PO_4 on the kinetics of reduction of Fe(III) by fulvic acid. *A*, no phosphate; *B*, 1 equiv. of phosphate added (5×10^{-5} *M*).

dominant) component of natural water organic matter.

Recently, metal ion titrimetric studies (12) and light scattering as a function of pH (6) studies have confirmed the Schnitzer–Gamble (1) model of FA as a *polydisperse* mixture of predominantly phenol-polycarboxylate units with a limited degree of polymerization via covalent linkages but with extensive aggregation via hydrogen bonding and other labile interactions. This picture of FA can be used to construct a consistent interpretation of the *mechanism* by which FA "dissolves" hydrous ferric oxide colloids. Individual Fe ions or small fragments of hydroxo iron polymer are coordinated at FA sites analogous to the salicylic acid functionality. (A small fraction may be reduced to Fe(II) and, indeed, transient reduction *may* play a catalytic part in the "dissolution" mechanism as it does in a number of slow dissolutions known to inorganic chemistry.) The Fe ions coordinated to one fulvic acid unit bridge to other fulvic acid units to give the aggregates that are often of larger particle size than the hydrous oxide colloids. These aggregated complexes, however, remain comparatively labile.

The rate constant for reaction with SSA in a pH = 2 reagent solution is similar to that reported earlier for decomposition of a monomeric Fe(III)–FA complex that forms in strong acid media.

A recent field study of the organic ligands in the Indian River, Almonte, Ontario (13) emphasized a role for the reducing power of aquatic humic substances as well as their complexing power in metal ion mobilization. (Mobilization by dissolved organic acids appears to follow the order Fe > Mn > Ni ~ Cu.) The evidence of ease of ferrozine *induced* Fe reduction by fulvic acid suggests reductive steps in dissolution of metals from hydrous oxide sediments as a mechanism for the effect observed in the field.

The results on mixtures of Fe(II) and Fe(III) do illustrate the role of electron transfer steps in hydrolytic precipitate growth. Microscopic reversibility implies a role for electron transfer in the reverse process.

Acknowledgements

We thank Mr. Claude Bordeleau and Dr. D. R. Wiles for the Mössbauer spectra. Dr. J. R. Duffy suggested ferrozine and some of its homologs for our evaluation.

Received July 28, 1980

GREG MACLEAN, JACK PASSMORE, PETER S. WHITE, ARTHUR BANISTER, and JAMES A. DURRANT. Can. J. Chem. **59**, 187 (1981).

The crystal structure of $S_3N_2O_2$ has been redetermined and the structure refined to a final R of 0.057 and R_w of 0.076 for 550 reflections with $I \geq 2\sigma(I)$. $S_3N_2O_2$ is planar and of C_{2v} symmetry, as previously found by Weiss. The central S—N distances and angle are 1.647(3) Å, NŜN 97.3(2)°, with adjacent N—S distances and angles of 1.535(3) Å, SN̂S 124.3(2)°, and terminal S—O distances and angles of 1.446(4) Å, NŜO 118.0(2)°. The infrared and Raman spectra are reported and some assignments are made.

GREG MACLEAN, JACK PASSMORE, PETER S. WHITE, ARTHUR BANISTER et JAMES A. DURRANT. Can. J. Chem. **59**, 187 (1981).

On a déterminé de nouveau la structure cristalline du $S_3N_2O_2$ et on l'a affinée jusqu'à une valeur finale de $R = 0{,}057$ et $R_w = 0{,}076$ pour 550 réflexions avec $I \geq 2\sigma(I)$. Tel que Weiss l'avait établi antérieurement, la molécule de $S_3N_2O_2$ est planaire et possède une symétrie C_{2v}. Pour les S—N du centre, les distances et les angles sont respectivement de 1,647(3) Å et NŜN 97,3(2)°; pour les N—S adjacents les distances et les angles sont respectivement de 1,535(3) Å et SN̂S 124,3(2)° alors que les distances des S—O terminaux sont de 1,446(4) Å avec un NŜO de 118,0(2)°. On rapporte les spectres infrarouges et Raman; on a aussi procédé à quelques attributions de bandes.

[Traduit par le journal]

Introduction

In a recent survey (1) of structural data for inorganic and organic compounds containing two coordinate nitrogens attached to sulphur, it was shown that for unstrained S—N—S^{IV} compounds there is an inverse relationship between the nitrogen bond angle and the mean N—S distance, as given by eq. [1][1]

[1] $d_{NS} = 179.99 - 0.1599\hat{N}$

where $\hat{N}$ is the SNS bond angle in degrees, d_{NS} is the arithmetic mean (in pm) of the two adjacent NS distances. All available structural data were accommodated by eq. [1], except those for $S_3N_2O_2$ (3) and $N(SCl)_2^+$ in $N(SCl)_2BCl_4$ (4) (and recently $N(SCl)_2AlCl_4$ (5)). The published structure of $S_3N_2O_2$ (3) included a very short S^{IV}—O bond length of 1.37 Å, however standard deviations were not given. In the course of our work single crystals of $S_3N_2O_2$ were obtained and in view of the above, the crystal structure was redetermined.

Experimental

Preparation of $S_3N_2O_2$

Unless otherwise specified, the apparatus and techniques employed were the same as those described in refs. 6 and 7.

In a typical reaction SO_2 (3.69 g, 57.6 mmol) was condensed onto a mixture of $NS_2Br_2AsF_6$ (0.494 g, 1.56 mmol) (8) and CsF (0.421 g, 2.77 mmol) in one bulb of a two-bulb vessel incorporating a sintered glass frit. The mixture was stirred for 2 days at room temperature, the insoluble and soluble products were separated and the volatiles (SO_2, Br_2, and OSF_2) were slowly removed by evacuation. The insoluble portion (0.496 g) contained $CsAsF_6$ and a small amount of an unidentified species.

The orange soluble product (0.327 g) was held at 45°C for 30 min under a dynamic vacuum and a small quantity (ca. 0.1 g) of yellow plate-like crystals were formed above the heated zone. The crystals were identified as $S_3N_2O_2$.

The infrared spectrum of a Nujol mull using KBr plates was similar to that of an infrared spectrum of $S_3N_2O_2$ obtained by Chivers (9) and Durrant (10). Peaks were observed at 1185 vs, 1150 sh, 1086 mw, 1036 s, 1015 sh, 993 mw, 722 m (Nujol?), 684 ms, 656 w, 555 m, 503 m, 372 ms cm^{-1}. The Raman spectra of a sample of crystals in a melting point tube was obtained using a Ramalab Spex Spectrometer, with a slit width of 2 cm^{-1} and approximately 200 mW of power of the 5145 Å emitting laser line. Peaks were recorded at 1199 mw, 1165 vvw, 1039 vs, 1025 sh, 996 vvw, 806 vvw, 718 vvw, 687 mw, 656 vvw, 555 vvw, 515 mw, 385 vvw, 354 vvw, 236 mw, 166 vvw, 125 vvw, 108 w, 91 w, 59 m cm^{-1}.

Structure Determination

A crystal of dimensions 0.50 × 0.35 × 0.25 mm was mounted under nitrogen in a dried glass capillary as described previously (11) with the modification that crystals were examined and manipulated with the help of a Wild M3 microscope of long focal length mounted outside the dry box.

Preliminary precession photographs showed the space group to be $C2/c$ or Cc and cell parameters to be similar to those of Weiss (3). Accurate cell dimensions were obtained from a least-squares fit to the centered positions of 21 Friedel pairs of reflections on a Picker FACS-I diffractometer ($31° < 2\theta < 42°$). Graphite monochromated Mo $K_{\bar{\alpha}}$ radiation was used throughout

[1]Data giving rise to eqs. [1]–[4] have also been treated by a more sophisticated statistical model to give slightly different equations (2), but these changes do not affect the conclusions drawn here using eqs. [1]–[4] (which are based on a least-squares treatment).

the investigation. Relevant crystallographic data are:

$S_3N_2O_2$ f.w. = 156.20
Monoclinic, $C2/c$, $a = 16.389(3)$ Å, $b = 4.5719(6)$ Å, $c = 6.790(1)$ Å, $\beta = 96.64(2)°$, $V = 505.3$ Å^3, $Z = 4$, $\rho_c = 2.053$ Mg m^{-3}, $F(000) = 312$, μ(Mo $K_{\bar{\alpha}}$) = 1.27 mm^{-1}, $\lambda = 0.71069$ Å.

Intensity data were collected using an ω–2θ scan of 2 deg, corrected for dispersion of the K_α doublet. Backgrounds were estimated from standing counts at both ends of the scan and an analysis of the profile of the peak. Standards monitored throughout the data collection showed no significant deviation from their mean value. Data were collected for $2\theta \leq 60°$ which resulted in 741 unique reflections of which 550 were considered observed ($I \geq 2\sigma(I)$) and included in the subsequent refinement. After data reduction, the structure was refined by least squares using the positions of Weiss (3) as a starting point. The function minimized by the procedure was $\sum w(|F_o| - |F_c|)^2$ with $w = 1/(\sigma(F) + 0.005|F|^2)^2$, $\sigma(F)$ being derived from counter statistics and the factor 0.005 from an analysis of the statistics of the standards. Atomic scattering factors were those given in the International tables (12) and were corrected for anomalous dispersion. The final reliability indices were $R = 0.057$, $R_w = 0.076$ (0.077 and 0.081 respectively including unobserved reflections) and all shifts were zero in the final cycle of least squares. An attempt to refine the structure in the acentric space group Cc did not result in a significant improvement in the reliability factor indicating that $C2/c$ is the correct choice. Final positional parameters are given in Table 1.[2]

TABLE 1. Final positional parameters for $S_3N_2O_2$ with estimated standard deviations in parentheses

Atom	x	y	z
S(1)	0.5000(0)	0.1280(3)	0.2500(0)
S(2)	0.34669(5)	0.2826(3)	0.3676(2)
N(1)	0.4306(2)	0.3660(7)	0.3047(5)
O(1)	0.1728(2)	0.4752(9)	0.1194(6)

Results and Discussion

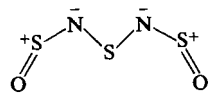
The reaction leading to $S_3N_2O_2$ and other products, described in the Experimental section, is complex and presumably involves participation of the solvent SO_2. The compound $S_3N_2O_2$ can be prepared more easily and in good yield by a variety of reported methods (13–15).

The packing of $S_3N_2O_2$ in the unit cell is shown in Fig. 1, and the structure of $S_3N_2O_2$ is depicted in Fig. 2, with bond distances and angles given in Table 2. The units of $S_3N_2O_2$ are planar with a perpendicular distance of 2.335 Å between the adjacent planes[2] (see Fig. 1).

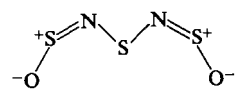
The overall geometry of $S_3N_2O_2$ is the same as that reported by Weiss (3). The NSO groups are *cis* with respect to the central sulphur atom. Similar *cis* configurations, and bond distances and angles within the NSO groups have been found in *cis*-HNSO (16), ClNSO (17), $PhSO_2NSO$ (18), and PhNHNSO (19). The S—O distance (1.446(4) Å) in $S_3N_2O_2$ is also similar to that found in these related molecules.

The overall bonding in $S_3N_2O_2$ may, to a first order of approximation, be depicted by valence bond structures **1**, **2**, and **3**.

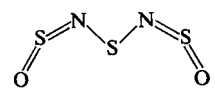
The central S—N bond distance 1.647(3) Å is somewhat less than that of other formally single S—N bonds (20) (cf. S_7NH, 1.73 Å (21) or H_3NSO_3, 1.775 Å (22)) and suggests that there is some delocalisation of the π system across the central suphur atom, thus, accounting for the planarity of the molecule. Using Pauling's (23) approach, the central SN, NS, and SO bonds have bond orders 1.37, 1.88, and 1.93 respectively. Similar SN bond orders are derived by Nyburg's relationship between bond order and bond distance for SN species (24). Planarity and a *cis–cis* configuration may also in part result as a consequence of weak bonding or electrostatic attraction between the central sulphur atom and terminal oxygen atoms. A related geometry has been found for the



1



2



3

NS_4^- (25, 26) and it has been suggested from calculations that the *cis* configuration arises from electrostatic attraction between a partially positively charged sulphur atom and negatively charged terminal sulphur.

Observed sulphur nitrogen bond distances and bond angles have been shown (1, 27) to be related by eqs. [1] and [2],

$$[2] \quad d_{SN} = 211.37 - 0.4661\hat{S}$$

where in eq. [2], d_{SN} is the average sulphur–nitrogen bond distance (in pm) adjacent to the $\hat{NSN}$ angle (in deg) (27). Table 3 shows that the new data are consistent with those obtained for other related unstrained sulphur nitrogen species.

The vibrational spectrum of $S_3N_2O_2$ is complex, however it seems reasonable to assign the 1185 (vs) cm^{-1} peak in the ir as the ν_{asym}(NSO) stretch, and the 1039 (vs) cm^{-1} peak in the Raman as the ν_{sym}(NSO) stretch. The relationship between these two stretching frequencies fits that found for other

[2]Tables of the structure factors, thermal parameters, and atomic deviations from the least-squares plane of $S_3N_2O_2$ may be obtained, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

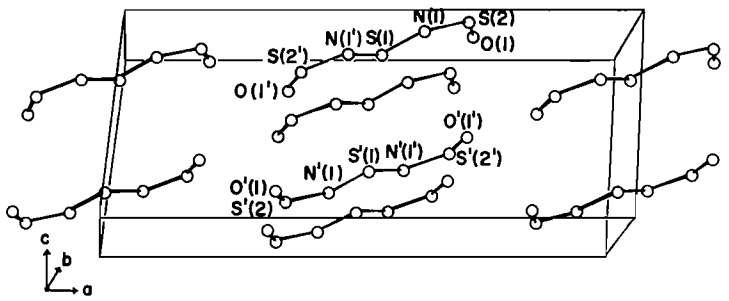


FIG. 1. The crystal packing in $S_3N_2O_2$.

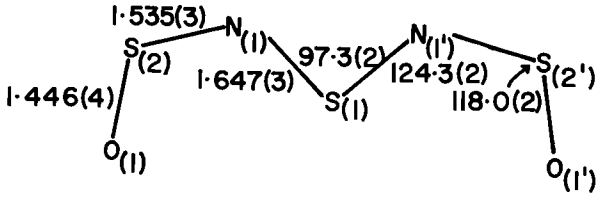

FIG. 2. Configuration of $S_3N_2O_2$, with distances in Å and angles in degrees.

TABLE 2. Bond distances (Å) and angles (deg) in $S_3N_2O_2$ with estimated standard deviations in parentheses that are not given in Fig. 2

Intramolecular contacts		Intermolecular contacts*	
Bond	Distance or angle	Bond	Distance
S(1)—S(2)	2.8132(9)	S(1)—S'(1)	3.5908(8)
S(1)—O(1)	3.142(4)	S(2)—O'(1')	3.185(4)
N(1)—S(1)—S(2)	26.8(1)		
N(1)—S(1)—O(1)	54.2(1)		
S(2')—S(1)—O(1)	178.28(9)		

*Includes all S—S distances ≤3.81 Å, and all S—O distances ≤3.24 Å.

NSO compounds (20, 28). It has been shown (28) that ν_{sym}(NSO) is largely associated with ν(NS) and ν_{asym}(NSO) with ν(SO). Therefore the 1185 cm^{-1} peak can also be assigned as ν_{SO}, and the 1039 cm^{-1} as ν_{SN}. The emprical relationship

[3] $\lambda_{SO}(\mu) = 0.251 d_{SO} - 27.809$

has been derived (10) relating λ_{SO} stretching wavelength with d_{SO} in pm. A d_{SO} value of 144.6 pm in eq. [3] gives a ν_{SO} of 1178 cm^{-1} which supports the assignment of the 1185 cm^{-1} peak in the ir as ν(SO). Similarly (10) eq. [4] has been found to relate $S^{(IV)}$—N distances to wavelengths.

[4] $d_{SN} = 4.672\lambda_{SN} + 110.12$

Consequently for d_{SN} = 153.5 pm, a ν(SN) of 1077 cm^{-1} is derived from eq. [4], again supporting the assignment of the very strong 1039 cm^{-1} peak in the Raman as ν(SN).

TABLE 3. Observed vs. calculated average SN bond length estimated by eqs. [1] and [2]

	Observed data		
Atom	Bond angle (deg)	Average d_{SN} (Å)	Calculated d_{SN} (Å)
N(1)	124.3(2)	1.591(7)	1.60 (eq. [1])
S(1)	97.3(2)	1.647(7)	1.66 (eq. [2])

Although one expects a strongly delocalised and vibrationally coupled system in $S_3N_2O_2$, the distance/wavelength correlations fit remarkably well; however, the assignments must be regarded as tentative.

NOTE ADDED IN PROOF:

An excellent paper reporting the X-ray structure of $S_3N_2O_2$ at −105°C, and an assignment of vibrational spectrum has now appeared, and is in essential agreement with our results (29).

Solvent effects on the visible absorption spectrum of crystal violet[1]

J. KORPPI-TOMMOLA[2] AND R. W. YIP
Division of Chemistry, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received July 28, 1980

J. KORPPI-TOMMOLA and R. W. YIP. Can. J. Chem. **59**, 191 (1981).

Addition of polar solvents to non-polar solutions of crystal violet results in dramatic changes in the visible absorption spectra. The observed changes are explained in terms of crystal violet existing as an ion-pair in non-polar solutions and as a solvated ion in polar solutions.

The spectrum of crystal violet in toluene and in acetone solution remains virtually unchanged over a wide temperature range. However in methanol, as was reported for ethanol (1), the short wavelength component of the absorption in the visible region disappears as the temperature is lowered. The spectral behaviour in alcoholic solutions suggests a decreasing solvent–solute interaction around the dye cation due to increased self-association of the solvent molecules as the temperature is decreased. Our observations have a direct application in interpreting some of the results of the photodynamics of crystal violet in solution.

J. KORPPI-TOMMOLA et R. W. YIP. Can. J. Chem. **59**, 191 (1981).

L'addition de solvants polaires aux solutions non polaires du cristal violet provoque des changements majeurs dans le spectre d'absorption visible. On explique les changements observés en fonction du fait que le cristal violet existe sous forme d'une paire d'ions dans les solutions non polaires et sous forme d'ion solvaté dans les solutions polaires.

Dans le toluène et dans une solution d'acétone, le spectre du cristal violet reste inchangé sur une large échelle de température. Cependant, dans le méthanol et tel que rapporté pour l'éthanol (1), la composante de courte longueur d'onde de l'absorption dans la région du visible, disparait lorsqu'on abaisse la température. Le comportement spectral dans les solutions alcooliques suggère une diminution de l'interaction solvant–soluté autour du cation colorant, provenant de l'augmentation de l'auto-association des molécules du solvant lorsque la température diminue. Nos observations trouvent une application directe dans l'interprétation de quelques résultats de la photodynamique du cristal violet en solution.

[Traduit par le journal]

Introduction

The phenyl rings of the dye cation crystal violet (CV) (tri-*p*-dimethylamino phenylcarbonium ion), like other triphenylmethane dyes, are forced out of the molecular plane by rotation about the central bonds because of steric hindrance between the rings (1). If all of the rings are rotated in the same sense over the same angle, then the cation resembles a propeller with D_3 symmetry. Within the Hückel approximation, this symmetry gives rise to a doubly degenerate lowest excited state (x, y polarized in the molecular plane) (2).

In dilute solution, crystal violet shows two overlapping absorption bands in the 550–600 nm region. These bands are not due to aggregation which has been observed in more concentrated solution (3). The presence of the two overlapping absorption bands can be due to a single species with a symmetry less than D_3 (giving rise to two non-degenerate states) or due to two species.

Early on, Lewis and co-workers (1) suggested that the bands are due to two rotamers; a symmetrical D_3 propeller-like species, and an unsymmetrical species with one of the phenyl rings rotated in the opposite sense with respect to the other two rings. This suggestion was based on the important observation that as the temperature is lowered, one of the bands (the one at short wavelength) tends to disappear while the other band increases in absorption. The observation clearly rules out the interpretation that the band structure represents a partially resolved vibrational structure of a single electronic state. Recent experiments on the picosecond recovery times of the two absorption bands on excitation with a single 530 nm picosecond pulse suggests the presence of two species in solution at room temperature (4). The recovery time proved to be dependent on the monitoring wavelength. A recent resonance Raman study suggests that CV exists as a single D_3 species in solution (5). Magnetic circular dichroism studies are also consistent with a single propeller-like species (either with symmetrical or unsymmetrical angles of twist of the phenyl group) with splitting of the degenerate E states (6).

The fluorescent properties of CV do not rule out the presence of two ground state species which can be rapidly transformed in the excited state. Independent of the exciting wavelength, CV shows only a single fluorescent band which mirrors the long wavelength absorption band (1, 2). The fluorescence polarized excitation spectrum shows a different polarization ratio for the two absorption

bands (2), indicating the presence of two electronic transitions.

To resolve the apparently conflicting results on CV, we have carried out a visible absorption study of CV in different solvents and solvent mixtures and a study of CV absorption at different temperatures. The results enable us to formulate a consistent picture of CV in solution which satisfactorily explains the visible absorption, fluorescence, and time-dependent recovery properties of CV in solution.

Results and Discussion

The visible absorption band of CV acetate in solution is a well resolved doublet in non-polar solvents but is a heavily overlapped doublet in polar solvents. The separation of the band maxima in non-polar solvents is about 65 nm while that in polar solvents is about 30 nm (Tables 1 and 2). The absorption spectrum of CV perchlorate in toluene (maxima at 535, 605 nm) is, within experimental error, identical with the spectrum of the acetate salt. To further investigate the two different band shapes, toluene solutions of CV were titrated with several polar and non-polar solvents. Results from the titrations are given in Fig. 1. The curves shown were obtained by measuring the peak height at 600 nm. Parallel behaviour is obtained for the short wavelength component in all titrations.

Adding benzene in toluene solution of the dye (2×10^{-5} *M*) left the molar absorption coefficient (ε) almost unchanged. Addition of acetonitrile and chloroform first decreases ε slightly and then increases it until the bulk is reached. Alcohol titrations result in most dramatic changes in the spectra (Fig. 1). Adding small amounts of alcohol reduces to less than one half of its initial value. Further addition of alcohol increases ε from its minimum value towards a final bulk ε in alcoholic solutions, the relative increase being over 400%. Saturation is reached by a mole fraction of 0.3. In *t*-butyl alcohol mixtures, ε remains low throughout the concentration region. Acetone titration shows an intermediate behaviour, which could be understood in terms of a keto–enol equilibrium in acidic acetone solutions. Beside changes in ε, addition of a polar solvent in toluene solutions of CV non-linearly shifts the wavelengths of the two absorption components. The short wavelength component (at 540 nm in toluene shifting to 560 nm in polar solvents) seems to be more sensitive to the addition of titrant than is the long wavelength component (Fig. 2). The wavelength shifts occur in the same concentration region as that observed for the sharp increase in ε (Fig. 1). Addition of non-polar solvent leaves the wavelengths of both absorption components unchanged.

TABLE 1. Absorption wavelengths of crystal violet in non-polar solvents

Solvent	λ_1 (nm)	λ_2 (nm)	$\Delta\lambda$ (nm)

Chloroform	587	560	27
Acetonitrile	587	558	29
Acetone	588	558	30
Fluorobenzene	593	560	33
Chlorobenzene	593	562	31
Benzonitrile	593	565	28

The results from our temperature measurements are shown in Fig. 3. Decreasing temperature decreases the intensity of the short wavelength component in the methanol spectra (Fig. 3*C*). The observation is similar to that reported by Lewis and co-workers (1) for ethanol solution. However in toluene solution (Fig. 3*A*), where the two components are well resolved, no significant relative intensity changes are observed over the temperature range from +50°C to −50°C. In acetone solutions, we observed some changes in the band shape as the sample was cooled, but disappearance of the short wavelength components does not occur as in methanol solutions (Fig. 3*B*). Overall increase in all spectra studied is partly due to narrower line widths and partly to solvent contraction at lower temperature.

To explain the doublet structure of the CV absorption band in the different solvents, we suggest that the "free" cation degeneracy (*E* state) is perturbed differently depending on the environment of the dye. In a non-polar solvent such as toluene, CV salt likely exists as ion pairs in solutions (1, 2), whereas in a polar solution such as methanol, all of the ions are solvated. The degenerate *E* state of the

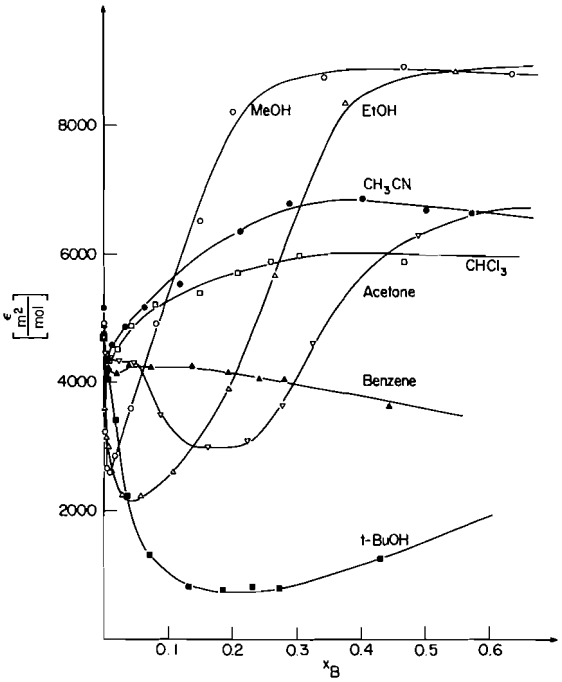

FIG. 1. Molar absorption coefficient ($\varepsilon_{600\,nm}$) as a function of molar fraction of titrant in toluene solutions of crystal violet acetate: ○ = methanol, △ = ethanol, ● = CH_3CN, □ = $CHCl_3$, ▲ = benzene, ▽ = acetone, and ■ = *t*-butyl alcohol.

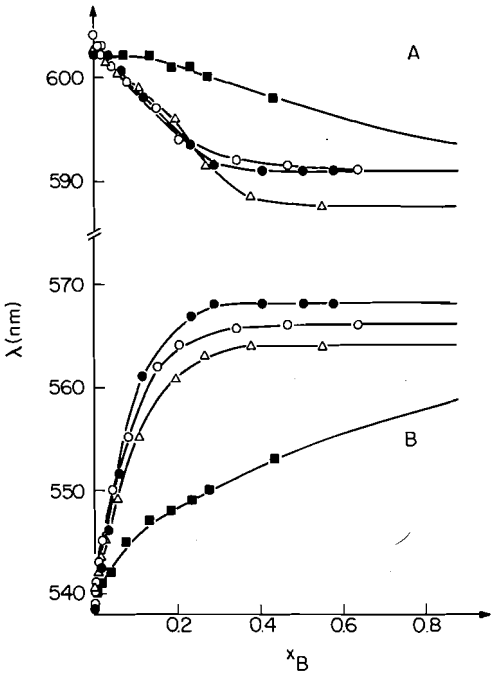

FIG. 2. Wavelengths of the two absorption components of crystal violet in toluene as a function of molar fraction of titrant: ○ = methanol, △ = ethanol, ● = chloroform, and ■ = *t*-butyl alcohol.

"free" cation will then be perturbed by dye cation–solvent interactions in polar solution and by the tightly bound counter anion in non-polar solution; the perturbation being larger in the latter case. The doublet structure does not appear to critically depend on the nature of the counter ion. The absorption spectrum of the perchlorate salt (more symmetric counter anion) was identical with that of the acetate salt in toluene. The sharp decrease in ε after adding small amounts of polar solvent in toluene solution of CV indicates one of the species in solution is disappearing, while the increase in ε with the further addition of titrant implies a new species is being formed. The initial decrease in ε could be explained by the disappearance of tight ion pairs in solution due to solvation of the counter ions. If the spectrum of CV in polar solvents is due to completely solvated dye cation, then further addition of polar solvent should increase the ε of the solution. Since solvated CV is assumed to have a more strongly overlapping band than does CV in an ion-pair, the further addition of polar solvent increases the overlap of the two absorbing components (Fig. 2) and increases the ε of the solution (Fig. 1). In acetonitrile and in chloroform titrations, the rising part of titration curve follows closely the above picture. In alcoholic titrations, the basic scheme is the same but the changes in ε are much more dramatic. Direct hydrogen bonding of alcohol monomers to the nitrogen atoms of the dye cation may be involved. Other phenomena such as self-association of the solvent and, in the case of *t*-butyl alcohol, steric hindrance may contribute to the overall behaviour of the titration curves.

The temperature dependence of the visible absorption spectrum of CV in alcoholic solutions (Fig. 3*C*) can be understood in terms of solvation changes with temperature. In addition to being a polar solvent, alcohols tend to self-associate. In dilute alcohol solution, dimer aggregates can be identified while in neat liquid only a few of the molecules remain in monomeric form (7). Reducing the temperature decreases the number of monomeric species in alcohols. Assuming that solvation is mainly due to the interaction of alcohol monomers and the dye cation, reducing the temperature decreases the number of solvent molecules capable of solvating the dye and finally trapping an almost "free" dye cation in a polymer matrix. Accordingly the degeneracy of the first excited state is returned and we see only one absorbing component in the spectra (Fig. 3*C*, ref. 1). It may be mentioned that in concentrated alcoholic dye solutions ($C > 5 \times 10^{-4}\,M$), the temperature behaviour is reversed to what we observed in dilute dye solutions, indicat-

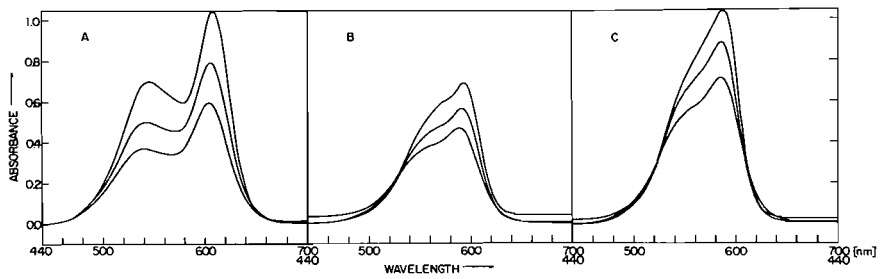

FIG. 3. Temperature dependence of crystal violet spectrum: (*A*) in toluene, temperatures from top to bottom $T = -50°C$, $+5°C$, and $+46°C$; (*B*) in acetone, $T = -87°C$, $-39°C$, and $+23°C$; (*C*) in methanol, $T = -70°C$, $-29°C$, and $+50°C$.

ing clustering of the dye molecules in the more concentrated solution (3).

The temperature dependence of the absorption spectrum of CV in ethanol was previously interpreted by Lewis and co-workers (1) in terms of an equilibrium between two rotamers (one absorbing at 500 nm and the other absorbing at 600 nm). Our results for the temperature studies of the absorption changes of CV in toluene suggests that this interpretation is incorrect and that the temperature behaviour of dilute CV in solution is best understood in terms of solvation changes. If there were two rotamers of the dye in alcohol solution, there is no reason why these should not be present in a solvent like toluene and give rise to a temperature dependence. Within experimental error, toluene spectra show no temperature dependence (Fig. 3*A*).

Our suggestion that the solvated and "free" CV in alcohol solution have different absorption spectra has a very important implication on the understanding of the excited state and recovery properties of triphenylmethane dyes in solution. If we assume that desolvation occurs in the excited state, the species which is undergoing non-radiative deactivation and fluorescence is the unsolvated dye cation having a single absorption band at 600 nm. This assumption is consistent with the observation of a single fluorescence band which mirrors the 600 nm absorption band (1, 2).

To explain our recovery kinetics (4), we propose a two-step mechanism, that is the decay of the unsolvated excited molecules is followed by resolvation of the ground state. If the first step is fast compared to the second solvation step, the first recovery monitored at 600 nm measures the decay of the unsolvated excited molecules. The slower recovery time observed at 550 nm would then be due to resolvation of the ground state. The exact kinetic picture depends on the relative magnitudes of the two rate constants and the kinetics has to be treated in terms of a two series first order reaction scheme. Our model implies a non-exponential recovery kinetics of CV in solution. Indeed, a poor single exponential fit particularly at 550 nm, was observed for the recovery of CV in glycerol (4). The important implication of the above model is that viscosity dependent radiationless decay rates cannot be obtained from recovery kinetics without considering solvation processes. Experiments on the photodynamics of CV in solution to test the above mechanism are in progress.

Experimental

Crystal violet carbinol was prepared by shaking methanol solution of the chloride (Baker Chemical) with excess of 1 *M* NaOH. The carbinol was then extracted from and recrystallized in hexane. Crystal violet acetate solutions (2×10^{-5} *M*) were made by dissolving the carbinol in the solvent and by adding acetic acid (0.05 *M*). Further addition of the acid did not increase the absorption of the solution. Crystal violet perchlorate was prepared from the carbinol and perchloric acid.

The spectra were recorded on a Cary 118 double beam spectrometer using 1 cm pathlength cells. Low temperatures were produced by boiling off liquid nitrogen through a cell holder. The temperature was measured right beside the sample cell using a copper–constantan thermocouple.

Received June 6, 1980

F. D. ROCHON, P. C. KONG, and R. MELANSON. Can. J. Chem. **59**, 195 (1981).

cis- and *trans*-[Pt(pm)$_2$X$_2$] where pm = pyrimidine and X = Cl, Br, have been synthesized. The *cis*-compounds were isolated from the reaction of K_2PtCl_4 and pm in water, while the *trans*-isomers were obtained by isomerization of *cis*-[Pt(pm$_2$X$_2$] in DMF in the presence of pm.

The crystal structures of the two compounds *trans*-[Pt(pm)$_2$X$_2$] have been determined by X-ray diffraction. The two compounds (X = Br and Cl) are isostructural. The crystals belong to the monoclinic $P2_1/c$ space group. The cell parameters are $a = 4.787(3)$, $b = 14.257(7)$, $c = 8.503(3)$ Å and $\beta = 99.33(4)°$ when X = Cl and $a = 4.826(3)$, $b = 14.822(5)$, $c = 8.516(5)$ Å and $\beta = 101.26(4)°$ when X = Br. The platinum atom is located on a centre of symmetry at the origin and $Z = 2$. The residual factors are $R = 0.029$ and $R_w = 0.036$ (X = Cl) and $R = 0.036$ and $R_w = 0.035$ (X = Br).

F. D. ROCHON, P. C. KONG et R. MELANSON. Can. J. Chem. **59**, 195 (1981).

Les complexes *cis* et *trans*-[Pt(pm)$_2$X$_2$] où pm = pyrimidine et X = Cl et Br ont été synthétisés. Les composés *cis* ont été isolés de la réaction de K_2PtCl_4 et pm dans l'eau, tandis que les isomères *trans* ont été obtenus par l'isomérisation de *cis*-[Pt(pm)$_2$X$_2$] dans le DMF en présence de pm.

La structure cristalline des deux composés *trans*-[Pt(pm)$_2$X$_2$] a été déterminée par diffraction des rayons X. Les deux composés (X = Cl et Br) sont isostructuraux. Les cristaux appartiennent au groupe spatial monoclinique $P2_1/c$. Les paramètres de maille sont $a = 4,787(3)$, $b = 14,257(7)$, $c = 8,503(3)$ Å et $\beta = 99,33(4)°$ pour X = Cl et $a = 4,826(3)$, $b = 14,822(5)$, $c = 8,516(5)$ Å et $\beta = 101,26(4)°$ pour X = Br. L'atome de platine se trouve sur un centre de symétrie à l'origine et $Z = 2$. Les facteurs résiduels sont $R = 0,029$ et $R_w = 0,036$ (X = Cl) et $R = 0,036$ et $R_w = 0,035$ (X = Br).

Introduction

Since the discovery of the antitumour properties of *cis*-[Pt(NH$_3$)$_2$Cl$_2$], a large research effort was made to synthesize complexes of the type *cis*-[Pt(L)$_2$Cl$_2$] (L = amine derivative) in order to extend the screening range of platinum complexes. In recent years, we have been involved in a program of synthesizing new platinum complexes and of studying their reactions and structures in solution and in the solid state. We have been studying the interaction between platinum compounds and amine ligands, since the antitumour properties of the platinum complexes were related to an interaction with the bases of cellular DNA. Since *trans*-[Pt(L)$_2$Cl$_2$] has no antitumour activity, and the *cis*-isomers may isomerize to the *trans*-isomers under certain conditions, the study of these isomerization reactions is important.

Platinum compounds of pyridine (py) and pyrimidine (pm) show some similar reactivity in non-aqueous solvents. For example, *cis*-[Pt(L)$_2$Cl$_2$] (L = py and pm) isomerise to the *trans*-isomers in dimethylsulphoxide (DMSO) or in dimethylformamide (DMF) in the presence of free L (1). In aqueous solution, the reactivities are different. In this paper, the chemical reactions of these compounds in aqueous solution are compared.

We have isolated *cis*- and *trans*-[Pt(pm)$_2$X$_2$] where pm = pyrimidine and X = Cl and Br. They were identified by infrared spectroscopy. The far infrared region was very similar to the spectra of *cis*- and *trans*-[Pt(pm)$_2$X$_2$] (where pm = 2-aminopyrimidine, 4-phenylpyrimidine, and 4-methylpyrimidine) reported earlier (1). In order to confirm the *cis* and *trans* configurations of the complexes, we decided to determine the crystal structures of the isomers. Unfortunately, only the *trans* isomers gave suitable crystals for X-ray diffraction. The crystal structures of both compounds *trans*-[Pt(pm)$_2$X$_2$] where X = Cl and Br are therefore reported below.

Experimental

cis-*[Pt(pm)$_2$Cl$_2$]*

Pyrimidine (0.2 g) is added to 0.415 g of K_2PtCl_4 dissolved in 10 mL of water. A yellow precipitate appears immediately. Two hours later, the precipitate is filtered off, washed with water, and dried under vacuum in the presence of P_2O_5 at room temperature. Yield: 85%. *Anal.* calcd.: C 22.54, H 1.88, Cl 16.67; found: C 22.22, H 1.91, Cl 17.06.

trans-*[Pt(pm)$_2$Cl$_2$]*

cis-[Pt(pm)$_2$Cl$_2$] (0.426 g) and 5 drops of pyrimidine are added to 5 mL of DMF. The mixture is left standing at room temperature for two weeks and yellow crystals appear slowly. The crystals are then collected by filtration and washed with a small amount of DMF and then with ether. Yield: 40%. The filtrate is diluted with ether and a precipitate appears immediately. Infrared spectroscopy has shown that the precipitate is the same as the crystals collected previously. Total yield: 75%. *Anal.* calcd.: C 22.54, H 1.88, N 13.15, Cl 16.67; found: C 22.59, H 1.85, N 12.83, Cl 16.89.

*$U_{eq} = \frac{1}{3}(U_{11} + U_{22} + U_{33} + 2U_{13}\cos\beta)$.

cis-[Pt(pm)$_2$Br$_2$] and trans-*[Pt(pm)$_2$Br$_2$]*

The same methods as the ones used for the chloro analogues were used. The solution of K_2PtBr_4 was prepared according to ref. 1.

The crystals *trans*-[Pt(pm)$_2$X$_2$] where X = Cl and Br used for X-ray diffraction were obtained as thin plates directly from the isomerization reaction of *cis*-[Pt(pm)$_2$X$_2$] and pm in DMF. After two weeks of standing in a stoppered flask, crystals started to appear.

A set of precession photographs for both crystals showed that the $h0l$, $l = 2n + 1$ and $0k0$, $k = 2n + 1$ reflections were systematic absences indicating the monoclinic space group $P2_1/c$. The cell parameters were obtained by least-squares refinement from the setting angles of 15 automatically centred reflections on a Syntex P$\bar{1}$ diffractometer using graphite-monochromatized MoKα radiation.

Crystal Data

$C_8H_8Cl_2N_4Pt$ $M_r = 426.17$

Monoclinic, $P2_1/c$, $a = 4.787(3)$, $b = 14.257(7)$, $c = 8.503(3)$ Å, $\beta = 99.33(4)°$, $V = 572.7(5)$ Å^3, $Z = 2$, $D_x = 2.471$, $D_m = 2.46(2)$ Mg m^{-3}, λ(MoKα) = 0.71069 Å, μ(MoKα) = 13.32 mm^{-1}, and T = 295 K.

$C_8H_8Br_2N_4Pt$ $M_r = 515.09$

Monoclinic $P2_1/c$, $a = 4.826(3)$, $b = 14.822(5)$, $c = 8.516(5)$ Å, $\beta = 101.26(4)°$, $V = 597.5(5)$ Å^3, $Z = 2$, $D_x = 2.863$, $D_m = 2.86(2)$ Mg m^{-3}, λ(MoKα) = 0.71069 Å, μ(MoKα) = 19.40 mm^{-1}, and T = 295 K.

Collection and Reduction of Intensity Data

The intensity data were collected from a crystal of *trans*-[Pt(pyrimidine)$_2$Cl$_2$] measuring 0.34 × 0.34 × 0.06 mm, the short dimension parallel to the a axis. The *trans*-[Pt(pyrimidine)$_2$Br$_2$] crystal measured 0.32 × 0.262 × 0.076 mm. A total of 1681 independent reflections (1747 for the bromo analogue) were measured in the region of $2\theta < 60°$ by the $2\theta/\theta$ scan technique using Mo Kα radiation. During the data collection three standard reflections were measured after every 47 reflections as a test of crystal and instrument stability. Their variations were less than 3% from their respective means. The 1108 reflections (1209 for the bromo analogue) for which the intensities were greater than $2.5\sigma(I)$ were considered observed. The standard deviation $\sigma(I)$ was calculated as already described (2). An absorption correction based on the equations of the crystal faces was applied to all the reflections of both crystals. The transmission factors varied from 0.061 to 0.452 for the chloro compound and from 0.018 to 0.224 for the bromo analogue. The data were corrected for the Lorentz and polarization effects. The scattering factors of Cromer and Waber (3) were used for platinum, bromine, chlorine, nitrogen, and carbon, those of Stewart, Davidson, and Simpson (4) were used for hydrogen. The anomalous dispersion terms (5) of platinum, bromine, and chlorine were included in the calculations.

Structure Determination

The position of the platinum atom in each structure determination was easily located on a centre of symmetry at the origin, from the three-dimensional Patterson map. The positions of all the other atoms, except the hydrogen atoms, were obtained by structure factor and Fourier map calculations. The refinement of the parameters was carried out by full-matrix least-squares methods. In the early stages of refinement, unit weight was assigned to all observed reflections. Later individual weights $w = 1/\sigma^2(F)$ (6) were applied. The hydrogen atoms on the pyrimidine ring were fixed at their calculated position and assigned isotropic thermal parameters of 6.0 Å^2. The refinement of the scale factor, the coordinates, and anisotropic temperature factors of all the non-hydrogen atoms converged to $R = \Sigma||F_o| - |F_c||/\Sigma|F_o| = 0.029$ (0.036 for the bromine compound) and $R_w = [\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2]^{1/2} = 0.036$ (0.035 for the bromine compound). The final difference Fourier map did not show peaks higher than ±0.8 e Å^{-3}.

The calculations were carried out with a Cyber 73 computer and the programs used have already been described (2). A table of observed and calculated structure factors is available from the Depository of Unpublished Data.[1]

Results and Discussion

The two analyzed compounds [Pt(pyrimidine)$_2$X$_2$] (X = Cl and Br) are isostructural. The refined atomic parameters for the two crystals are listed in Table 1. A list of the anisotropic temperature factors is available.[1] A labelled diagram of the two analyzed compounds is shown in Fig. 1. The bond lengths and the bond angles are shown in Table 2.

The platinum atom in the crystal lies on a centre of symmetry at the origin. The compounds have therefore the *trans* configuration as shown by infrared spectroscopy. The coordination around the platinum atom is square planar. The angles around platinum are close to the expected 90°. The Pt—Cl (2.296 Å) and the Pt—Br (2.427 Å) bonds

[1]Lists of structure factors and anisotropic thermal parameters are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

N(3)—C(4)—C(5)	123.3(8)	122.15(10)
C(4)—C(5)—C(6)	116.1(8)	118.6(10)

are normal and agree well with published values (2, 7–12).

The Pt—N distances (2.008 Å and 2.014 Å) are normal for bonds in position *trans* to nitrogen ligands which have a relatively low *trans* influence. The values agree well with the values found in other platinum–nitrogen base crystals (11, 13, 14).

The pyrimidine ring is planar in both compounds. The dihedral angles between the platinum coordination planes and the pyrimidine planes are 52.5° (chlorine compound) and 54.3° (bromine compound). The N—C bonds (1.29–1.35 Å are slightly shorter than the C—C bonds (1.35–1.40 Å). The values agree well with the values published for pyrimidine (15) and for pyrimidin-2-one (16). The pyrimidine ring angles vary from 116 to 126° for the chlorine compound and from 115 to 128° for the bromine compound. As Singh (17) has pointed out, the internal ring angle at a N atom is smaller if the N atom is not covalently bound to an extra-annular H atom. Here the internal angles at the N atoms are 117 and 115° at N(1) and 117 and 116° at N(3) for the chloro and the bromo analogues respectively. The binding of N(1) to the platinum atom does not change the internal angle at the nitrogen atom as it does in the hydrochlorides of pyrimidine and pyrimidin-2-one. The protonation at N(1) in both these compounds increases the ring angle at the nitrogen atom by about 6° (18). This effect shown by Singh (17) is not observed when platinum is the

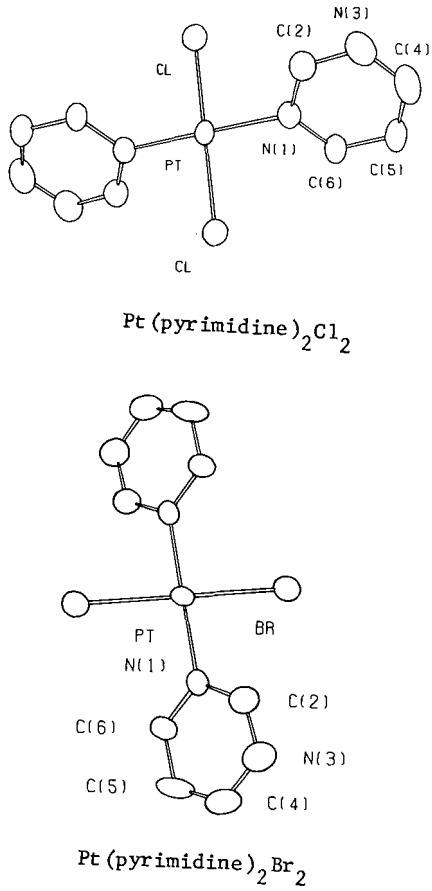

FIG. 1. Labelled diagrams of *trans*-[Pt(pyrimidine)$_2$Cl$_2$] and *trans*-[Pt(pyrimidine)$_2$Br$_2$].

exocyclic bonded group. Similar results have been observed in other platinum compounds (11, 19, 20). Therefore, coordination to the platinum atom does not affect the structure of the pyrimidine ligand.

Packing diagrams of the two crystals are shown on Fig. 2. The platinum coordination planes are almost parallel to the *bc* plane. All the pyrimidine rings are stacked in one direction parallel to the *c* axis and they are located approximately at $x = 0$ and at $x = \frac{1}{2}$. The packing therefore consists of alternate layers of pyrimidine rings and $PtCl_2$ moieties parallel to the *ac* plane. Since all the hydrogen atoms are located on carbon atoms, no strong hydrogen bonding was expected.

cis-[Pt(pm)X$_2$] were isolated from the reaction of K_2PtCl_4 and pm in water. The *trans*-isomers were prepared from the isomerization of the *cis*-isomers in DMF in the presence of pm. The reactivities of both isomers were compared to the reactivities of the pyridine analogues which we have studied in aqueous and non-aqueous solvents (1). Both *cis* and *trans*-[Pt(pm)$_2$Cl$_2$] are slowly soluble in 4 *M*

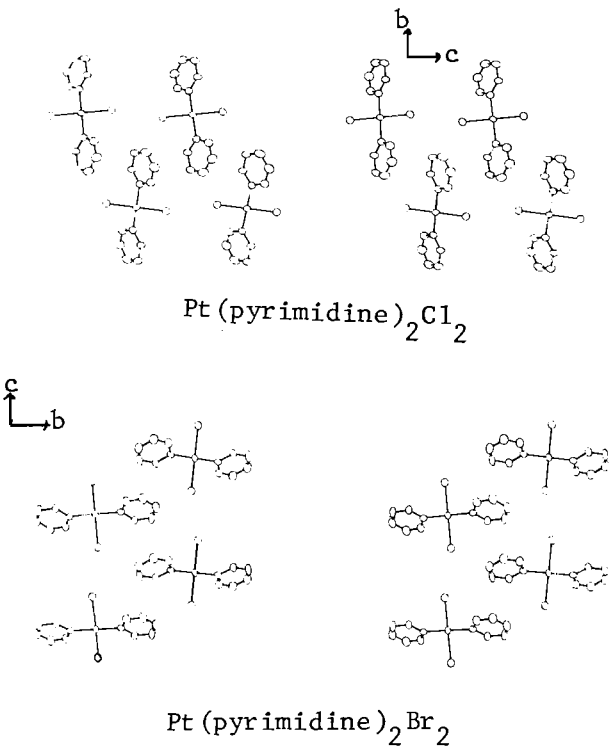

FIG. 2. Stereoscopic diagrams of the packing in the two crystals *trans*-[Pt(pyrimidine)$_2$Cl$_2$] and *trans*-[Pt(pyrimidine)$_2$Br$_2$].

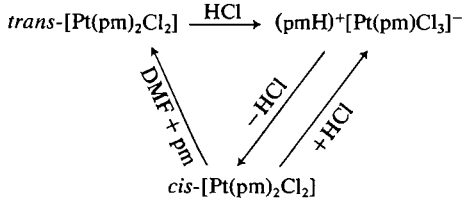
HCl solution at 80–100°C. After filtrating, the yellow solution can be cooled to room temperature without the appearance of any precipitate. The reaction is the following:

$$[Pt(pm)_2Cl_2] \xrightarrow{HCl} (pmH)^+[Pt(pm)Cl_3]^-$$

The solution can be evaporated to dryness and redissolved in water a few times. Then, the product is not soluble in water any more. It is also not soluble immediately in 4 *M* HCl solution at room temperature. Infrared spectroscopy has shown that the product is *cis*-[Pt(pm)$_2$Cl$_2$]. The same product was obtained no matter which isomer was used in the above reaction. The scheme in acid medium is therefore as follows:



In contrast, pyridine compounds, *trans*-[Pt(py)$_2$Cl$_2$], can be isolated from concentrated HCl solution on a steam bath (21). *trans*-[Pt(py)$_2$Cl$_2$] cannot be converted to the *cis*-isomer as the pyrimidine compound. The pyrimidine compounds dissolve easily in acid medium probably because the proton H^+ can easily approach the uncoordinated nitrogen atom of the pyrimidine ring, causing the coordinate bond to weaken and pyrimidine to dissociate from platinum.

The sulfoxides derived from 2,3-dihydro-4*H*-naphtho[1,2-*b*]thiopyran and its 4-phenyl and 4-oxo derivatives, as well as the analogous sulfoxides in the 2,3-dihydro-1*H*-naphtho[2,1-*b*]thiopyran series, have been synthesized and their structures established by spectroscopic methods, especially ^1H and ^{13}C nmr. On photolysis these sulfoxides have been found to react by a rather inefficient photochemical deoxygenation pathway.

On a synthétisé les sulfoxydes provenant du dihydro-2,3 4*H*-naphto[1,2-*b*] thiopyranne et ses dérivés phényl-4 et oxo-4 ainsi que les sulfoxydes analogues des séries dihydro-2,3 1*H*-naphto[2,1-*b*] thiopyranne et on a établi leurs structures en utilisant des méthodes spectroscopiques, plus particulièrement la rmn du ^1H et du ^{13}C. On a trouvé que la photolyse de ces sulfoxydes se produit par un processus de déoxygénation photochimique qui est relativement inefficace.

[Traduit par le journal]

Introduction

As an extension of our earlier photochemical studies of sulfoxides in the 4-thiochromanone series (1), we have undertaken the synthesis and examined the photochemistry of the analogous naphtho-fused 4-thiopyranone 1-oxides. Since we were interested in discovering whether the photochemical behavior of these sulfoxides was dependent on the location of the S=O group at the α- or β-positions in the naphthalene nucleus, we have prepared the two possible isomeric 4-oxo sulfoxides. We have also synthesized the analogous sulfoxides with the C=O group in the above sulfoxides replaced by a methylene unit, because we suspected that the carbonyl group may play a fundamental role in modifying the photochemical behavior of these sulfoxides. Finally, we have synthesized the sulfoxides in the above series where the carbonyl group is replaced by a $-CHC_6H_5-$ unit. Interest in this type of system arose from the report several years ago by Schultz and Schlessinger (2) of the photochemical dehydration of a naphtho-fused thiopyran oxide bearing the sulfinyl functionality at the 2-position in the naphthalene unit, and with phenyl substituents located both α- and γ- to the S=O group, in the hetero-ring. For comparative purposes, we have synthesized the *cis*- and *trans*-isomers, in both the 1-sulfinyl and the 2-sulfinyl naphthalene series.

The syntheses, the structural assignments for the various sulfoxides, and the photochemical results will be discussed in turn.

Results and Discussion

The syntheses of 2,3-dihydro-4*H*-naphtho[1,2-*b*]thiopyran **5** and its sulfoxide **6** and the analogous ketosulfide **7** and ketosulfoxide **8**, from 1-naphthalenethiol, via 3-(1-naphthylthio)propanoic acid **1**, were carried out essentially by literature procedures, as shown in Scheme 1. Neither of the sulfoxides had been reported previously. The syntheses of the phenyl-substituted sulfide **9** and its epimeric sulfoxides **10***a*,*b*, again starting from 1-naphthalenethiol, by way of the ketone **3** and the corresponding alcohol **4**, were also relatively straightforward, as outlined in Scheme 2. The total yield of the isomeric sulfoxides obtained by oxidation was 79%, the *trans*-isomer predominating, as expected from similar oxidations (3), in the ratio of almost 5:1. Evidence for the assignments of the *cis*- and *trans*-structures will be discussed in the next section. It is worth noting that, as an alternative route to **5**, an analogous attempt to cyclize the known alcohol 3-(1-naphthylthio)-1-propanol **2** by the stannic chloride procedure (Scheme 2) was unsuccessful, indicating that this reaction does not work for primary alcohols, at least in this series.

Starting from 2-naphthalenethiol, essentially similar synthetic routes led to the analogous sulfide **11** and ketosulfide **13** and their sulfoxides **12** and **14**, respectively. As observed in the 1-naphthyl series above, cyclization of the primary alcohol 3-(2-

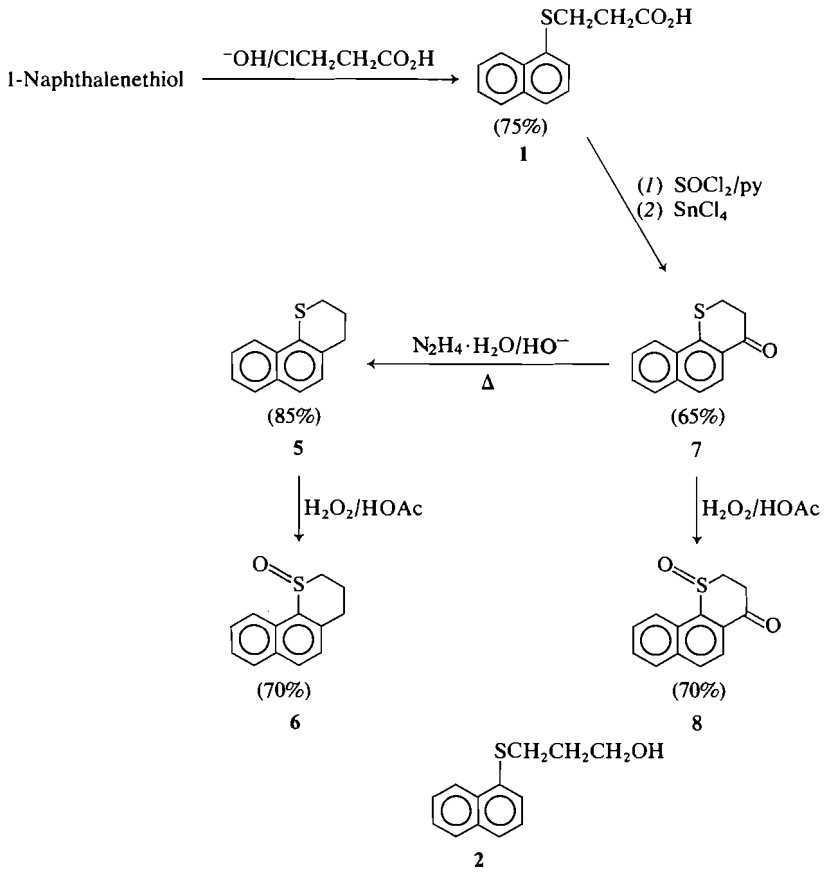

SCHEME 1

naphthylthio)-1-propanol, in an attempt to produce **11**, was unsuccessful. Oxidation of the phenyl derivative **15** produced a mixture of *cis*- and *trans*-sulfoxides **16***a*,*b* in 69% yield, the *trans*:*cis* ratio being slightly greater than 4:1.

Before proceeding to a discussion of the photochemical behavior of these sulfoxides we felt that it would be appropriate to examine their ^1H and ^{13}C nmr spectra, with the aim of assigning configurations to the *cis*- and *trans*-phenyl-substituted pairs of sulfoxides **10***a*,*b* and **16***a*,*b*, as it was felt initially that the photochemical behavior of these sulfoxides might show a stereochemical dependence. The 60 MHz ^1H nmr spectra for these compounds (see Experimental) look very complex and were rather uninformative. Somewhat better results, especially for compound **10***b*, were obtained with the 220 MHz spectra, the data from which are reported for the phenyl-substituted sulfoxides, as well as the parent-sulfoxides **6** and **12**, in Tables 1 and 2. Partial assignments could be made by analyzing those coupling constants which were obtained, by analogy with simple model systems, such as thiane 1-oxide (4), and also by running comparison spectra in C_6D_6, which had some effect in simplifying the spectra for first order analysis because of the greater spread of chemical shift values compared with those in $CDCl_3$. One interesting feature of the aromatic region in these spectra, allowing an immediate distinction to be made between the 1- and the 2-sulfinylnaphthalene series, is the fact that only in those sulfoxides where the sulfoxide group is at the 1-position (see numbering system in Tables) is a one-proton signal observed well downfield, at $\delta \approx 8.6$–8.8 (H-10). For the 4-sulfoxides (Table 2) with an adjacent *peri* aromatic proton at C-5, on the other hand, no aromatic proton downfield of $\delta \approx 8$ ppm is observed. (This is in accord with the fact that in the simple 4-thiochromanone 1-oxide system (1) only *one* aromatic proton is shifted well downfield, the one *peri* to the carbonyl group.) Even larger downfield shifts of the H-10 proton (to $\delta \approx 9.1$ ppm) were observed for the ketosulfide and ketosulfoxide **13** and **14**, due to analogous effects of the C-1 carbonyl group.

In terms of the immediate problem of assigning the *cis*- and *trans*-configurations to the sulfoxide mixtures **10** and **16**, however, the results in Tables 1

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12

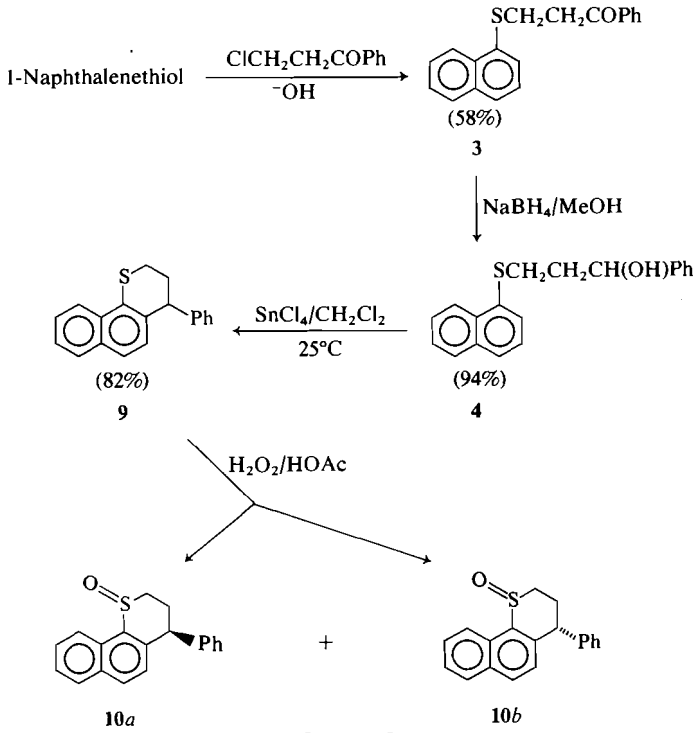
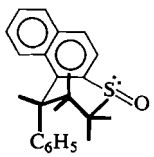


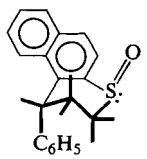
SCHEME 2

and 2 were not very helpful. Inspection of Dreiding models of both the 4-phenyl-2,3-dihydro-4*H*-naphtho[1,2-*b*]thiopyran 1-oxide **10** and 1-phenyl-2,3-dihydro-1*H*-naphtho[2,1-*b*]thiopyran 4-oxide **16** structures revealed an interesting clue in the latter case. (It has been shown (5) that benzo-fused thiopyrans prefer the "sofa" type conformation, but even if the "pseudo-chair" form is preferred here it does not invalidate the following discussion.) If the phenyl group is placed in an equatorial position in **16**, it is found that severe steric interaction with the H-10 proton would render free rotation of the phenyl ring virtually impossible. Since no evidence has been found in any of the nmr spectra (^1H or ^{13}C) for nonequivalent *ortho*- and *meta*-positions in the phenyl ring, we assume that in both **16***a* and **16***b* the phenyl substituent must be *axial* (strictly, pseudo-axial). Given the normal preference for the axial orientation in thiane oxides (4) and the preference for *trans*-sulfoxide formation in the oxidation of substituted cyclic sulfides (3) we can, with some confidence, assign the major isomer **16***b* the *trans*-diaxial conformation *B* and the minor *cis*-isomer **16***a* must therefore be assigned conformation *A*.

Attempts to substantiate this conclusion by carrying out a series of lanthanide-induced shift (LIS) studies, using gradually increasing amounts of the shift reagent ($Eu(fod)_3$) (6), were inconclusive, mainly because of the complexity of the ^1H nmr spectra already referred to. Qualitatively, however, one could observe that, as expected from coordination of the reagent with the sulfoxide oxygen atom, the H-1 proton was shifted by the smallest amount while, of the four remaining hetero-ring protons, two were clearly shifted by larger amounts.



A **16***a*



B **16***b*

If our proposal that the configurational isomerism in **16** can be ascribed to a change in the S=O bond orientation (axial vs. equatorial) is correct, then evidence in support of this should be available from the ^{13}C chemical shift of the β-carbon (C-2) in the two isomers. This can be seen readily from Table 4 where the much more upfield position ($\delta = 22.6$) observed for C-2 in **16***b* is consistent with the *gauche* relationship between the C-2/C-3 bond and the axial S=O bond. In contrast, the δ value for C-2 in the *cis*-isomer ($\delta = 27.1$) is much closer to the value observed ($\delta = 30.2$) in the analogous sulfide **15**. The $\Delta\delta$ of -7.6 ppm for C-2 between **16***b* and **15** in fact is in very good agree-

(*trans*)C_6H_5 **16***b*	5.02 dt (J = 4.5, 3.5)	—	2.31[c]	3.12[c] (3H)	3.12[c] (3H)		6.91 (2H), *ortho*-C_6H_5 protons 7.25 (3H), remaining C_6H_5 protons 7.40–7.88 (6H), H5, H6, H7, H8, H9, and H10

[a]Assignments were made from a study of the coupling constants (^2J and ^3J) and, in some cases, by using spin decoupling.
[b]Signals indicated appeared as multiplets, unless otherwise specified.
[c]Individual assignments for these protons must be regarded as tentative since, due to the complexity of the first-order spectra even at 220 MHz, individual coupling constants could not always be extracted.

ment with the Δδ of −9.5 ppm for C-2 between the parent sulfide and sulfoxides **11** and **12** and indicates that in **12** the S=O bond also adopts the axial arrangement. The Δδ values found for the same (β) carbon atom in thiane compared to thiane 1-oxide are −12.7 (S=O axial) and −4.9 (S=O equatorial) ppm (7).

Turning to the isomeric sulfoxides **10***a*,*b*, inspection of Dreiding models this time revealed no clear-cut preference for the orientation of the phenyl substituent. However, reference to the ^{13}C nmr data in Table 3, and analogy with the arguments used above for the other isomeric pair of sulfoxides, show again a (β)Δδ, this time for C-3, between **9** and **10***a* and **10***b* of −8.7 and −9.7 ppm, respectively. Between **5** and **6** the comparable Δδ value is −10.6 ppm, indicating that *all* of the sulfoxides in this series adopt the S=O axial orientation. Thus, in contrast to the *cis*/*trans* isomerism in the case of **16** where the phenyl substituent adopts an axial orientation in both isomers, in the case of the *cis*/*trans* isomers of **10**, the S=O bond adopts an axial orientation in both isomers, with the phenyl substituent also being axial in the predominant *trans*-isomer **10***b*, but equatorial in the minor *cis*-isomer **10***a* (in the 2,3-dihydro-4*H*-naphtho[1,2-*b*]thiopyran series an equatorial phenyl group is quite free to rotate). These assignments are in accord with the ^{1}H nmr data for **10***a*,*b* reported in Table 1. If our structural deductions from the ^{13}C nmr data, as well as the related evidence provided by Dreiding models and the oxidation results are correct, the only one of the two pairs of epimeric

[a]Chemical shifts in ppm downfield from TMS, in $CDCl_3$.
[b]Reference was made to the known pattern of chemical shifts in thiane and its oxide (axial and equatorial conformers) (7), as well as the peak multiplicities in arriving at these assignments.
[c]For a detailed discussion of the stereochemical assignment of these isomers, see text.

sulfoxides **10** and **16** which should possess an *axial* methine proton is the minor *cis*-isomer **10***a*, which might therefore be expected to reveal this distinction in its ^{1}H nmr spectrum. Indeed, this expectation is fulfilled, as reference to Table 1 shows δ = 4.28 ppm for the (H-4) methine signal, a value well upfield from those recorded for the methine protons (δ = 4.65–5.02 ppm) in the other three phenyl-substituted sulfoxides. Furthermore, although the methine signal at 4.28 ppm in **10***a* was not clearly resolved even in the 220 MHz spectrum, the line width ($W_{\frac{1}{2}} \approx$ 18 Hz) is clearly very much in accord with an axial conformation for this proton. This result provides valuable corroboration for the correctness of our stereochemical assignments.

12	CH_2	1	25.3	13.8	45.5
16*a*	CHC_6H_5	1 (*cis*-)[c]	41.3	27.1	42.3
16*b*	CHC_6H_5	1 (*trans*-)[c]	40.2	22.6	41.4

[a]Chemical shifts in ppm downfield from TMS, in $CDCl_3$.
[b]Reference was made to the known pattern of chemical shifts in thiane and its oxide (axial and equatorial conformers) (7), as well as the peak multiplicities, in arriving at these assignments.
[c]For a detailed discussion of the stereochemical assignment of these isomers, see text.

As in the case of the isomeric sulfoxides **16***a*,*b* an attempted LIS effect-analysis on **10***a*,*b* proved disappointing, although again it was clear that two of the C-2/C-3 protons, presumably those on the same side of the hetero-ring as the axial S=O bond, were being preferentially shifted.

The remaining effects observable from the ^{13}C nmr data in Tables 3 and 4 were reasonably in accordance with expectation. For example, the (α)-downfield shifts produced by converting the sulfide sulfur to sulfoxide lie in the range +17.5 → 21.3 ppm, compared with the average value of +19.7 ppm for thiane systems quoted by Lambert *et al.* (7). The β-effects have already been discussed and the γ-effects of converting sulfide into sulfoxide are very small (±2 ppm), as expected (7). The effects of introducing the phenyl substituent are in the range +12.1 → 16.9 ppm, for the α-effects and +6.9 → 9.6 ppm, for the β-effects (with one exception), well within the ranges expected (8). It is significant that the one exception is an apparent β(C_6H_5) effect of +13.3 ppm for the *cis*-sulfoxide, **16***a*. However, it will be noted that, according to our earlier arguments, **16***a* is the only one of the two isomeric pairs of sulfoxides with an S=O equatorial bond and it is thus much more likely that this is the correct explanation for the apparent anomaly, rather than an unusual β-effect of the phenyl substituent.

Rather surprisingly, given the variety of photochemical pathways observed in the 4-thiochromanone 1-oxide series (1), the sole photochemical reaction observed for the present sulfoxides in all experiments but one (see below), is a rather inefficient photochemical deoxygenation reaction to afford the corresponding sulfides. The

TABLE 5. Results of irradiation of sulfoxides[a,b]

Compound	Recovery of starting material (%)	Sulfide (%)[c]
6	57	Trace
12	84	8
8	—	57

[a]Irradiations were carried out for 24 h, in degassed benzene, unless otherwise stated (see Experimental).
[b]For relevant uv data, see Table 6 (Experimental).
[c]Corrected for recovered starting material.
[d]Irradiation for 5.5 h.

results of these irradiations,[4] carried out in benzene, are summarized in Table 5. Photochemical deoxygenation has been observed before (1, 9) but we have earlier characterized it as a reaction which normally occurs only when other photochemical processes (such as rearrangements via ring expansion to cyclic sulfenates, or reactions involving β- or γ-hydrogen abstraction processes) are disfavored (1). The deoxygenations observed here proceed more readily when the irradiation source is a medium-pressure mercury arc (115 or 400 W), emitting radiation mainly at 313 and 366 nm, essentially no reaction being observed when a low-pressure mercury source (4 W) was used, with the exception of the case discussed in detail below. Surprisingly, as is evident from Table 5, the keto-sulfoxides show little difference in behavior from the simpler sulfoxides, whereas they might have been expected to form products similar to those obtained in the thiochromanone series (1). However, the yields of sulfide obtained were somewhat better and relatively little starting material was recovered from the irradiation of compounds **8** and **14**. No major difference could be detected in the photochemical behavior of compounds **10** and **16**, whether single pure isomers were used or the *cis*/*trans* mixtures. In the latter case, however, significant changes in composition of the mixtures from *trans*:*cis* ratio's of ~4:1 to ~1:1 were observed, indicating that photo-epimerization of the sulfoxides was occurring to a significant extent.

The exceptional case referred to above was encountered when the mixture of *cis*- and *trans*-sulfoxides **16***a*,*b* was irradiated in benzene for a prolonged period (70 h) with the 4 W light source. In addition to recovered starting material (76%) and a small amount (12%) of the sulfide, a third product (4%) was obtained, in a very small quantity. The presence of a characteristic ^1H nmr signal at δ 9.75,

[4]Relevant uv spectral data are collected in the Experimental (Table 6).

as well as infrared bands at ν 2840, 2740 cm^{-1}, indicated that this product is an aldehyde. The apparent molecular ion at $m/e = 260$ and analogy with similar photochemical transformations already observed in the 4-thiochromanone 1-oxide series (1) lead us to propose structure **17** for this minor photoproduct. The structure of this photoproduct[5] was confirmed by a straightforward synthesis of **17** by the addition of bromoacetaldehyde diethyl acetal to 1-benzylnaphthalene **18**, in the presence of sodium amide, followed by acid hydrolysis. The photochemical rearrangement of **16***a*,*b* to **17** may be regarded as another example of the process which we have previously categorized (1) as a type B (sulfoxide) photoreaction. Thus, initial rearrangement of **16***a*,*b* to the corresponding seven-membered cyclic sulfenate, followed by S—O bond homolysis, loss of a sulfur atom, and (intramolecular) hydrogen atom transfer would lead to the observed aldehyde. The much lower yield encountered in the present case may be due to further photochemical degradation of the aldehyde, which is of a simple aliphatic type, unlike the β-ketoaldehydes produced from the thiochromanone sulfoxides (1).

The nature of the photochemical deoxygenation of sulfoxides is itself an interesting mechanistic question, touched upon by Gurria and Posner (9). Although we feel that this question is deserving of further study, the present sulfoxide systems are structurally not well suited for this purpose. We can, however, definitely rule out the possibility that the sulfoxides examined in this study (photochemically) disproportionate to equimolar amounts of sulfide and sulfone, since no traces of sulfone were ever found and since independent irradiation of the sulfone analogue of **8** (which gave the highest yield of sulfide in Table 5) under identical reaction conditions led to no change. We have also conducted an experiment involving the irradiation of **8** in the presence of cyclohexene in an attempt to trap any singlet oxygen, which may arise during the deoxygenation reaction, in the manner described by Gurria and Posner (9). No peroxide could be detected by spot tests, indicating that $^1O_2$ is not being formed and that the oxygen lost from the S=O group must be accounted for in some as yet unexplained fashion.

[5]The ^1H nmr spectrum of the authentic material (see Experimental) is much better resolved than that of the photoproduct, since the larger amount of material available allowed a greater degree of purification.

Experimental

The ir spectra were recorded on a Perkin-Elmer 257 grating spectrophotometer, uv spectra on a Unicam SP-8000 instrument, and ^1H nmr spectra on a Varian EM-360 spectrometer, with additional 220 MHz spectra being recorded for some of the sulfoxides studied. Natural abundance, proton decoupled ^{13}C nmr spectra were obtained on a Varian XL-100-15 spectrometer at 25.16 MHz, in the pulsed Fourier transform mode. The temperature of the probe was 32 ± 3°C. Spectral widths of 6000 Hz were routinely used, with acquisition times of 0.666 s and pulse widths of 12 μs. Mass spectra were routinely recorded with a Bell and Howell 21-490 instrument.

Elemental analyses were performed by the Scandinavian Micro-analytical Laboratory, Box 25 DK 2730, Herlev, Denmark. All melting points are uncorrected.

1-Naphthalenesulfonyl Chloride[6]

1-Naphthalenesulfonic acid (10.0 g, 0.040 mol) was dissolved in distilled water (75 mL). Sodium hydrogen carbonate (3.36 g, 0.040 mol) was slowly added to neutralize the solution. The solution was then brought to boiling and sodium chloride (7 g) added with stirring. Upon cooling, white crystals formed, which were collected and redissolved in a boiling solution of sodium chloride (10 g) in water (100 mL). Again, cooling and subsequent filtration gave sodium 1-naphthalenesulfonate as fine white crystals (5.8 g, 62%), after drying at 110°C.

Sodium 1-naphthalenesulfonate (9.00 g, 0.039 mol) was mixed with phosphorus pentachloride (8.13 g, 0.039 mol), and the mixture was heated at 170–180°C for 3 h (under anhydrous conditions), with intermittent shaking. Ice-cold water (~80 mL) was carefully poured onto the cooled solid mass with shaking and the aqueous phase was extracted with carbon tetrachloride (2 × 50 mL). The organic extracts were washed (H_2O, dried $MgSO_4$) and evaporated *in vacuo* to yield a brown oil, which crystallized on cooling. Recrystallization from hexane afforded pale tan needles of the title compound (6.0 g, 68%); mp 60–62°C (lit. (12) mp 67.5°C).

1-Naphthalenethiol[6]

1-Naphthalenesulfonyl chloride (5.48 g, 0.024 mol) was slowly added at −5°C to a mixture of crushed ice (60 g) and 98% sulfuric acid (11 mL) in a 250-mL 3-necked flask. Zinc dust (10.0 g), purified by stirring 3 min in 10% hydrochloric acid,

[6]An essentially identical procedure was used to make the analogous 2-naphthalene derivatives.

filtering, washing with H_2O/acetone, and then drying, was then added with vigorous stirring. After 1.5 h the mixture was brought to room temperature and then refluxed (90–100°C) for 5 h. On cooling, water (80 mL) was added and the mixture extracted with ether (2 × 100 mL). The organic layers were combined, dried ($MgSO_4$), and evaporated *in vacuo* to yield a pale yellow oil (3.3 g, 85%) of adequate purity, as indicated by tlc. Spectral properties of the oil were identical with those of an authentic sample.

3-(1-Naphthylthio)propanoic Acid, 1

1-Naphthalenethiol (1.74 g, 0.011 mol) was added to an aqueous solution of 1% sodium hydroxide (88 mL), followed by 3-chloropropanoic acid (1.18 g, 0.011 mol) in methanol (22 mL), with stirring. After refluxing for 4 h and subsequent cooling, 4 *M* hydrochloric acid was added until the solution reached pH 3. Extraction with dichloromethane (2 × 100 mL), combination and drying ($MgSO_4$) of the extracts, followed by evaporation *in vacuo* afforded a colorless solid which was digested with hexane and filtered. Recrystallization from benzene/hexane gave the title compound (2.0 g, 82%); mp 84–86°C (lit. (13) mp 89–90°C).

3-(2-Naphthylthio)propanoic Acid

This compound was prepared in 86% yield by essentially the same procedure, mp 101–102°C (lit. (13) mp 104–105°C).

*2,3-Dihydro-4*H*-naphtho[1,2-*b*]thiopyran-4-one, 7*

A mixture of 3-(1-naphthylthio)propanoic acid (0.5 g, 2.15 mmol), dry pyridine (0.015 mL), dry ether (5 mL), and thionyl chloride (0.54 g, 4.5 mmol), added in the above order, was refluxed for 45 min (14). The excess thionyl chloride was removed *in vacuo*, benzene (2 mL) was added, and again the solvent was removed *in vacuo*. The residual oil was dissolved in dry benzene (5 mL) and cooled to 2°C. Two precooled (2°C) solutions of stannic chloride (0.40 g) in dry benzene (0.5 mL) were added, separated by an interval of 20 min, and the mixture was left overnight under anhydrous conditions. The product was isolated by pouring the reaction mixture on to ice-water (80 mL) containing 11 *M* hydrochloric acid (10 mL), and extracting with dichloromethane (2 × 60 mL). The organic extracts were washed (10% $NaHCO_3$, H_2O), dried ($MgSO_4$), and evaporated to yield a pale yellow solid (0.4 g, 85%); mp (EtOH) 107–108°C (lit. (13) mp 107°C); ir ($CHCl_3$) ν: 1670 (CO) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.15–3.80 (4H, A_2B_2 system), 7.5–8.7 (6H, m).

*2,3-Dihydro-1*H*-naphtho[2,1-*b*]thiopyran-1-one, 13*

This compound was prepared by an essentially identical method, adapted from that of Young and Ohnmacht (15), in 81% yield; mp (EtOH) 64–66°C (lit. (13) mp 68–69°C); ir ($CHCl_3$) ν: 1667 (CO) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.2 (4H, A_2B_2 system), 7.1–7.8 (5H, m), 9.1 (1H, dd, J = 8.0, 2.0 Hz).

*2,3-Dihydro-4*H*-naphtho[1,2-*b*]thiopyran-4-one 1-Oxide, 8*

A solution of ketosulfide 7 (0.53 g, 2.5 mmol) in glacial acetic acid (5 mL) was cooled to a slush; 30% hydrogen peroxide (0.28 g, 2.5 mmol) was then added slowly with stirring. After 17 h at 25°C, the mixture was diluted with water (100 mL), neutralized with solid sodium hydrogen carbonate, extracted with dichloromethane (2 × 100 mL), dried ($MgSO_4$), and evaporated to yield an off-white solid (400 mg, 70%), recrystallized from hexane; mp 184–186°C; ir ($CHCl_3$) ν: 1675 (CO), 1025 (SO) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 2.7–4.0 (4H, m), 7.4–8.2 (5H, m), 8.45–8.90 (1H, m); ms *m/e*: 230 (21), 212 (91), 186 (100), 158 (49),

126 (22). *Anal.* calcd. for $C_{13}H_{10}O_2S$: C 67.82, H 4.38, S 13.90; found: C 67.44, H 4.35, S 13.91.

*2,3-Dihydro-1*H*-naphtho[2,1-*b*]thiopyran-1-one 4-Oxide, **14***

This compound was prepared by essentially the procedure described above for the isomeric sulfoxide and isolated in 45% yield; recrystallized from benzene–hexane; mp 109–110°C; ir ($CHCl_3$) ν: 1675 (CO), 1050 (SO) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 2.5–3.7 (4H, m), 7.4–8.3 (5H, m), 9.05 (1H, dd, J = 8.0, 3.0 Hz); ms *m/e*: 230 (20), 214 (12), 212 (11), 202 (100), 186 (28), 158 (18), 146 (37), 126 (18). *Anal.* calcd. for $C_{13}H_{10}O_2S$: C 67.82, H 4.38, S 13.90; found: C 67.82, H 4.43, S 13.89.

*2,3-Dihydro-1*H*-naphtho[2,1-*b*]thiopyran, **11***

This compound was readily obtained, although in a lower yield (37%) than previously reported in the literature (16), by the Wolff–Kishner reduction of the corresponding cyclic keto-sulfide; mp (*n*-hexane) 86–88°C (lit. (16) mp 91–92°C); ^1H nmr ($CDCl_3$) δ: 2.0–2.5 (2H, m), 2.9–3.2 (4H, m), 7.0–8.0 (6H, m); ms *m/e*: 200 (100). *Anal.* calcd. for $C_{13}H_{12}S$: C 77.98, H 6.04, S 15.98; found: C 78.09, H 6.07, S 15.84.

*2,3-Dihydro-4*H*-naphtho[1,2-*b*]thiopyran, 5*

As for the isomeric sulfide above, this compound was obtained in 74% yield (lit. (17) 82%) as a pale yellow oil; ^1H nmr ($CDCl_3$) δ: 1.9–3.2 (6H, m), 6.9–8.2 (6H, m); ms *m/e*: 200 (100).

*2,3-Dihydro-1*H*-naphtho[2,1-*b*]thiopyran 4-Oxide, **12***

A solution of the sulfide **11** (0.03 g, 1.5 mmol) in glacial acetic acid (4 mL) was cooled to a slush; hydrogen peroxide (30%) (0.17 g, 1.52 mmol) was added slowly with stirring. After 5 h at 25°C the mixture was diluted with water (100 mL), neutralized with solid $NaHCO_3$, and extracted with dichloromethane (2 × 100 mL). The organic extract was washed with water (1 × 100 mL), brine (1 × 100 mL), and dried ($MgSO_4$). Evaporation *in vacuo* afforded a pink solid (0.25 g, 77%); mp 125–127°C; ^1H nmr ($CDCl_3$) δ: 1.9–3.7 (6H, m), 7.3–8.7 (6H, m); ms *m/e*: 216 (32), 200 (35), 199 (100), 166 (54), 165 (29), 115 (22). *Anal.* calcd. for $C_{13}H_{12}OS$: C 72.21, H 5.59, S 14.81; found: C 72.05, H 5.61, S 14.53.

*2,3-Dihydro-4*H*-naphtho[1,2-*b*]thiopyran 1-Oxide, 6*

Essentially the same procedure was used as for the isomeric sulfoxide described above. Evaporation of the CH_2Cl_2 extracts *in vacuo* gave pale yellow needles (from dichloromethane–hexane) (0.62 g, 60%); mp 139–142°C; ^1H nmr ($CDCl_3$) δ: 1.9–3.9 (6H, m), 6.9–8.2 (5H, m), 8.7 (1H, dd, J = 8.5, 2.0 Hz). *Anal.* calcd. for $C_{13}H_{12}OS$: C 72.21, H 5.59, S 14.81; found: C 72.24, H 5.66, S 14.81.

3-(2-Naphthylthio)-1-phenyl-1-propanone

2-Naphthalenethiol (6.4 g, 0.04 mol) was added to a 1% aqueous sodium hydroxide solution (160 mL), followed by 3-chloro-1-phenyl-1-propanone (6.8 g, 0.04 mol) in methanol (80 mL), with stirring. After refluxing (4 h), the starting cloudy mixture had changed to two well-defined layers. After cooling, the crude product was extracted with methylene chloride. Washing the combined methylene chloride extracts (aqueous 10% NaOH, H_2O), drying ($MgSO_4$), and evaporation gave the crude product. This crude product was then recrystallized from 95% ethanol to give 3-(2-naphthylthio)-1-phenyl-1-propanone as a white solid (9.7 g, 83%), mp 70–72°C (dichloromethane – *n*-hexane) (lit. (18) mp 92°C); ir ($CHCl_3$) ν: 1690 (C=O) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.48 (4H, s), 7.3–8.15 (12H, m); ms *m/e*: 292 (16), 160 (100), 132 (29), 128 (21), 115 (32), 105 (76), 77 (46). *Anal.* calcd. for $C_{19}H_{16}OS$: C 78.06, H 5.52, S 10.95; found: C 77.81, H 5.55, S 11.14.

3-(2-Naphthylthio)-1-phenyl-1-propanol

3-(2-Naphthylthio)-1-phenyl-1-propanone (5.8 g, 0.02 mol) was dissolved in methanol (150 mL). Sodium borohydride (0.20 g, 0.0053 mol) was then added to the solution, and the mixture was stirred at 25°C for 3.5 h. Additional sodium borohydride (0.06 g) was then added and the mixture stirred for a further 1.5 h. The solution was poured into 2 *N* hydrochloric acid solution (180 mL) and the product extracted with dichloromethane. Washing (H_2O, 10% NaOH, H_2O), drying ($MgSO_4$), and evaporation of the solvent yielded 3-(2-naphthylthio)-1-phenyl-1-propanol (5.6 g, 96%) as a white solid; mp 64–66°C (dichloromethane – *n*-hexane); ^1H nmr ($CDCl_3$) δ: 1.97 (2H, q, J = 6.0 Hz), 2.21 (1H, s, exchanges with D_2O), 2.98 (2H, t, J = 7.0 Hz), 4.73 (1H, t, J = 6.0 Hz), 7.2–7.8 (12H, m); ms *m/e*: 294 (2), 276 (93), 247 (35), 199 (12), 117 (100), 105 (26), 91 (13). *Anal.* calcd. for $C_{19}H_{18}OS$: S 10.89; found: S 10.68.

*1-Phenyl-2,3-dihydro-1*H*-naphtho[2,1-*b*]thiopyran, 15*

3-(2-Naphthylthio)-1-phenyl-1-propanol (5.2 g, 0.018 mol) was dissolved in dichloromethane (180 mL). Stannic chloride (2.5 mL, 0.021 mol) was added dropwise during 10 min to the stirred solution. The color of the solution changed from colorless to yellow after the addition of stannic chloride. After stirring 2 h at 25°C, 2 *N* hydrochloric acid (180 mL) was added to the solution with disappearance of the yellow color. The organic layer separated, and the mixture was thoroughly extracted with dichloromethane. Washing the combined organic extracts (H_2O, 10% $NaHCO_3$), drying ($MgSO_4$), and evaporation gave 1-phenyl-2,3-dihydro-1*H*-naphtho[2,1-*b*]thiopyran as a pale grey solid (4.3 g, 88%); mp 131–133°C, on recrystallization from dichloromethane – *n*-hexane: ^1H nmr ($CDCl_3$) δ: 2.1–3.1 (4H, m), 4.87 (1H, t, J = 3.5 Hz), 7.0–7.8 (11H, m); ms *m/e*: 276 (100), 247 (38), 215 (11), 199 (13), 166 (9), 165 (8). *Anal.* calcd. for $C_{19}H_{16}S$: C 82.56, H 5.83, S 11.60; found: C 82.67, H 5.84, S 11.59.

cis- *and* trans-*1-Phenyl-2,3-dihydro-1*H*-naphtho[2,1-*b*]thiopyran 4-Oxide, **16a** and **16b***

1-Phenyl-2,3-dihydro-1*H*-naphtho[2,1-*b*]thiopyran (3.6 g, 0.013 mol) was dissolved in warm acetic acid (150 mL). After cooling to 10°C, 30% hydrogen peroxide (2.0 mL, 0.017 mol) was added dropwise to the cold solution during 10 min. The mixture was continuously stirred for 6 h at 25°C. The solution was then diluted with water (150 mL), and saturated with sodium acetate before extracting with dichloromethane. Washing the combined extracts (saturated NaCl, 10% $NaHCO_3$, saturated NaCl), drying ($MgSO_4$), and evaporation gave a milky white oil (3.6 g). After purification by chromatography on silica gel and elution with dichloromethane–acetone mixture (10:1), a mixture of *cis*- and *trans*-sulfoxides was obtained as a white solid (2.74 g, 69%); mp 155–160°C; ^1H nmr ($CDCl_3$) δ: 2.2–2.6 (2H, m), 2.8–3.3 (2H, m), 5.0 (1H, t), 6.8–7.9 (11H, m).

Separation of the *cis*- and *trans*-mixture (380 mg) by chromatography on silica gel (CH_2Cl_2:CH_3COCH_3 = 7:1) gave pure *cis*-isomer (65 mg); mp 207–209°C (dichloromethane – *n*-hexane) and pure *trans*-isomer (283 mg), mp 157–159°C (same solvent); ^1H nmr (*cis*) ($CDCl_3$) δ: 2.3–2.7 (2H, m), 3.0–3.3 (2H, m), 4.85 (1H, t), 6.8–7.9 (11H, m); ms *m/e*: 292 (18), 275 (100), 247 (19), 242 (30), 215 (20), 165 (12), 115 (14), 91 (88). *Anal.* calcd. for $C_{19}H_{16}OS$: C 78.06, H 5.52, S 10.95; found: C 77.80, H 5.53, S 10.90. ^1H nuclear magnetic resonance (*trans*) ($CDCl_3$) δ: 2.1–2.6 (2H, m), 2.75–3.15 (2H, m), 5.0 (1H, t), 6.8–8.0 (11H, m); ms *m/e*: 292 (6), 276 (100), 275 (36), 247 (37), 215 (15), 199 (13), 166 (10), 115 (12), 91 (44). *Anal.* calcd. for $C_{19}H_{16}OS$: C 78.06, H 5.52, S 10.95; found: C 77.64, H 5.56, S 10.79.

*4-Phenyl-2,3-dihydro-4*H*-naphtho[1,2-*b*]thiopyran, 9*

This compound was prepared by an analogous procedure to that described above for the isomeric naphtho[2,1-*b*] thiopyran derivative, starting from 1-naphthalenethiol, a comparable yield

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

(82%) being obtained in the cyclization step. The pale yellow oil had ^{1}H nmr ($CDCl_3$) δ: 1.9–3.2 (4H, m), 4.4 (1H, m), 6.9–8.1 (11H, m); ms *m/e*: 276 (100). *Anal.* calcd. for $C_{19}H_{16}S$: C 82.56, H 5.83, S 11.60; found: C 82.69, H 5.92, S 11.30.

cis- *and* trans-*4-Phenyl-2,3-dihydro-4*H-*naphtho[1,2-*b*]thiopyran 1-Oxide, 10*a *and 10*b

The thiopyran (3.1 g, 11.2 mmol) was dissolved in a mixture of glacial acetic acid (130 mL) and acetone (40 mL). At 25°C, 30% hydrogen peroxide (1.34 g, 11.76 mmol) was added dropwise, and after 4 h the solution was diluted with water (150 mL) and saturated with sodium acetate. It was then extracted with dichloromethane (2 × 100 mL), washed with NaOH solution (10%, 100 mL), water (2 × 100 mL), and dried ($MgSO_4$). Evaporation afforded a yellow oil (2.6 g, 79%), shown to be a mixture of isomers (approx. 5:1) by tlc. The mixture could not be separated by column chromatography since the isomers were so close in R_f value, but preparative tlc (run in dichloromethane–ethylacetate 3:1) afforded partial purification and a white solid (mixture); mp 186–192°C.

Further chromatographic separation of this mixture gave the two pure isomeric sulfoxides: *trans*-sulfoxide; mp 182–184°C, from dichloromethane–hexane; ^{1}H nmr ($CDCl_3$) δ: 1.9–3.5 (4H, m), 4.55 (1H, m), 6.7–8.0 (10H, m), 8.75 (1H, dd, J = 8.0, 2.0 Hz). *Anal.* calcd. for $C_{19}H_{16}OS \cdot \frac{1}{2}H_2O$: C 75.75, H 5.65, S 10.63; found: C 75.68, H 5.45, S 10.81; *cis*-sulfoxide; mp 201–202°C, from dichloromethane–hexane; ^{1}H nmr ($CDCl_3$) δ: 2.0–3.5 (4H, m), 3.9–4.3 (1H, m), 6.8–7.95 (10H, m), 8.75 (1H, dd, J= 8.0, 2.0 Hz). *Anal.* calcd. for $C_{19}H_{16}OS$: C 78.06, H 5.52, S 10.95; found: C 77.91, H 5.53, S 10.91.

3-(1-Naphthylthio)-1-propanol, 2

This alcohol was prepared in 68% yield as a pale yellow oil by the procedure of Cagniant and Cagniant (14) and showed the expected spectral characteristics. Attempted cyclization to **5** by the already described procedure using $SnCl_4$ was unsuccessful.

3-(2-Naphthylthio)-1-propanol

This alcohol was also prepared, in 90% yield, by the above procedure; mp 59–61°C (lit. (14) mp 63°C); ^{1}H nmr ($CDCl_3$) δ: 1.98 (2H, quintet, J = 7 Hz), 3.20 (2H, t, J = 7 Hz), 3.85 (2H, t, J = 7 Hz), 7.25–8.05 (8H, m, arom. and O*H*).

1-Methylsulfinylnaphthalene (Methyl 1-Naphthyl Sulfoxide)

To a solution of 1-methylthionaphthalene (19) (0.91 g, 5.23 mmol) in glacial acetic acid (15 mL) at 10–15°C, 30% hydrogen peroxide (0.593 g, 5.23 mmol) was added dropwise and the mixture stirred for 5 h. Work-up consisted of dilution with water (20 mL), extraction with dichloromethane (2 × 20 mL), washing (5% $NaHCO_3$ (4 × 20 mL), water (20 mL)), drying ($MgSO_4$), and evaporation to give a pale yellow solid (0.75 g, 75%); mp 64–66°C (lit. (10) mp 66–67°C); ir ($CHCl_3$) ν: 1065 cm^{-1}.

2-Methylsulfinylnaphthalene (Methyl 2-Naphthyl Sulfoxide)

Oxidation of 2-methylthionaphthalene (20) was carried out as for the 1-isomer above to give the sulfoxide in 70% yield; mp 104–106°C (lit. (21) mp 104–105°C); ir ($CHCl_3$) ν: 1060 cm^{-1}.

Irradiation of Sulfoxides

The irradiations were routinely conducted under nitrogen in degassed benzene as solvent, at concentrations around 0.2–0.5%, for varying periods of time. The ultraviolet source used was either a low-pressure (4 W) mercury arc, emitting mainly at 254 nm, or a medium-pressure arc (115 W or 400 W), emitting mainly at 313 and 366 nm. A typical example appears below.

*Irradiation of 1-Phenyl-2,3-dihydro-1*H-*naphtho[2,1-*b*]thiopyran 4-Oxide, 16*a,b

The *trans*/*cis* sulfoxide mixture (>4:1) (0.5 g) was irradiated in dry benzene in a quartz vessel for 70 h, using the low-pressure source. Evaporation of the solvent and chromatographic separation on silica gel gave three pure compounds: (*a*) a white solid (380 mg), shown to be a mixture of the starting sulfoxides. Further chromatography led to the isolation of almost equal amounts of the pure *cis*- (115 mg) and *trans*- (131 mg) isomers of the starting sulfoxide; (*b*) a solid of mp 122–125°C, shown to be identical with 1-phenyl-2,3-dihydro-1*H*-naphtho[2,1-*b*]thiopyran by mp, mmp, and spectral comparisons was obtained (14 mg, 12% based on starting material consumed); and (*c*) the final product (4 mg, 4%) was a pale yellow liquid (**17**); ir ($CHCl_3$) ν: 2840, 2740 (C*H*O), 1730 (CO) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 3.2 (2H, br d), 5.3 (1H, m), 6.8–8.2 (12H, m), 9.75 (1H, br s); ms *m/e*: 260 (53), 242 (16), 217 (100), 202 (47), 165 (11), 155 (84), 128 (21), 127 (63), 105 (42), 77 (58).

3-(1-Naphthyl)-3-phenylpropanal, 17

Following the general procedure of Kuznetsov and Libman (22), 1-benzylnaphthalene (23) **18** (2.31 g, 10.60 mmol) in dry ether (10 mL) was slowly dropped into a mixture of sodium amide (prepared from sodium) in liquid ammonia (0.45 g, 19.57 mmol and 20 mL liquid ammonia) cooled in a methanol – Dry Ice bath at −35°C.

After stirring for 1 h at −35°C, bromoacetaldehyde diethyl acetal (2.30 g, 11.68 mmol) was added over a period of 15 min. Ammonium chloride was added and the ammonia was allowed to evaporate. Water was added and the mixture was extracted with diethyl ether.

The ether layer was evaporated and the resulting oil was refluxed for 1 h in acetic acid (10 mL), water (5 mL), and hydrochloric acid (0.5 mL). Extraction with diethyl ether, washing with sodium carbonate solution, drying (Na_2SO_4), and evaporation of the ether gave an oil. Column chromatography (SiO_2, CH_2Cl_2) yielded 3-(1-naphthyl)-3-phenylpropanal, **17** (1.06 g, 25%). The infrared and mass spectral characteristics of this material were identical with those of the product of irradiation of **16***a,b*. The authentic material, however, after careful purification, afforded white crystals, mp 101–102°C (hexanes); ^{1}H nmr ($CDCl_3$) δ: 3.25 (2H, dd, J = 7 Hz, 2 Hz), 5.4 (1H, t, J = 7 Hz), 7.0–8.2 (12H, m), 9.75 (1H, t, J = 2 Hz).

Singlet Oxygen Trapping Experiment (9)

2,3-Dihydro-4*H*-naphtho[1,2-*b*]thiopyran-4-one 1-oxide **8** (0.14 g, 0.61 mmol) in degassed cyclohexene (10 mL) and glacial acetic acid (5 mL) was irradiated (medium-pressure arc, 400 W) for 22 h. Placing a drop of the solution on potassium iodide – starch paper did not leave a brown stain nor did a blue spot appear when a drop of water was added, indicating the absence of peroxide (24). A more sensitive spot test (from $FeSO_4 \cdot 7H_2O$ (0.90 g), 5 *M* hydrochloric acid (5 mL), zinc, and sodium thiocyanate (1.70 g)) also proved negative.

Selective transformations of secologanin: dihydroxylation

JOHN RICHARD PURDY, RAYMOND G. HAMILTON, LALARUKH AKHTER, AND STEWART MCLEAN
Department of Chemistry, University of Toronto, Toronto, Ont., Canada M5S 1A1

Received August 5, 1980

JOHN RICHARD PURDY, RAYMOND G. HAMILTON, LALARUKH AKHTER, and STEWART MCLEAN. Can. J. Chem. **59**, 210 (1981).

Sweroside tetraacetate (**2***b*) has been converted in high yield by osmylation to the epimeric glycols **3** and **4** (R = H) which have been separated. This reaction proceeds with high chemoselectivity for reaction at the vinyl side chain but with low stereoselectivity, leading to a small excess of the 3-*R* isomer. Secologanin derivatives appear to show a much lower chemoselectivity in this reaction, but the stereoselectivity is considerably higher, and opposite to that in the sweroside example. Conditions have been found for oxidizing the dimethylacetal **5***b* of secologanin tetraacetate in useful yields to the epimeric glycols **6** and **7** (R = H); in this reaction a large excess of the 3-*S* isomer is formed. The reasons for these differences in selectivity appear to be related to differences between the two series in conformational preference.

JOHN RICHARD PURDY, RAYMOND G. HAMILTON, LALARUKH AKHTER et STEWART MCLEAN. Can. J. Chem. **59**, 210 (1981).

La réaction du tétraacétate de sweroside avec le tétroxyde d'osmium conduit avec d'excellents rendements aux glycols épimères **3** et **4** (R = H) qu'on a pu séparer. Cette réaction se produit avec une haute régiosélectivité du côté de la chaîne latérale vinylique, mais avec une faible stéréosélectivité; elle conduit à un léger excès de l'isomère 3-*R*. Les dérivés de la sécologanine semblent exhiber une plus faible régiosélectivité au cours de cette réaction mais la stéréosélectivité est considérablement plus élevée et est à l'opposé de celle observée avec la sweroside. On a mis au point des conditions permettant d'oxyder du diméthylacétal (**5***b*) du tétraacétate de sécologanine en glycols épimères **6** et **7** (R = H) avec des rendements convenables; dans cette réaction, l'isomère 3-*S* est produit en grand excès. Les causes de ces différences de sélectivité semblent être reliées aux différences de préférence conformationnelle entre les deux séries.

[Traduit par le journal]

Secologanin (**1***a*) is an iridoid glycoside of considerable biosynthetic significance, particularly in the field of indole alkaloids (1), where it represents the common last nonnitrogenous precursor to a vast and diverse array of alkaloids. It appears to be established that it is after secologanin has been linked to a tryptophan-derived component that diversification takes place by further chemical modifications of the intermediate. Secologanin is of chemical interest itself as a molecule that incorporates a dense aggregation of sensitive functional groups and chiral centres. A study of the selective chemical transformations of secologanin could consequently afford results of synthetic and biosynthetic importance. We report here our studies of the dihydroxylation of the olefinic side chain.

Secologanin and its closely related congener sweroside (**2***a*) are readily available constituents of various *Lonicera* species. The osmium tetroxide oxidation of sweroside tetraacetate (**2***b*) has been described by Bock *et al.* (2) who isolated a modest yield of the diols resulting from a chemoselective oxidation of the vinyl side chain. Stereoselectivity was low, and they obtained an inseparable mixture of epimeric glycols. The acetylated glycols **3** and **4** (R = Ac) were, however, separated, and their configurations were assigned by correlation with secogalioside, the configuration of which was established by the nuclear Overhauser enhancement technique.

This reaction appeared to serve as an excellent model for our purpose, and in our hands optimization of the osmylation reaction, using the catalytic system with *N*-methylmorpholine *N*-oxide (3), has led to the conversion of sweroside tetraacetate to the epimeric mixture of glycols in over 80% yield. Furthermore, separation of the glycols themselves has been accomplished by chromatography, and each epimer has been isolated in a crystalline form; the ratio of **3** to **4** (R = H) produced in the reaction is 2:3. Each epimer has been acetylated to form the derivatives **3** and **4** (R = Ac) reported previously (2).

Despite the close similarity between secologanin and sweroside, the selective dihydroxylation of secologanin tetraacetate (**1***b*) proved to be a much more difficult task, even when the free aldehyde was protected as its dimethyl acetal (**5***b*). It appears probable that the cause of this difficulty is that the endocyclic double bond is more susceptible to oxidation in this series than in the sweroside series, and this oxidation leads to uncharacterizable products. It appears that the vinyl side chain is osmylated with some selectivity in the early stages of the reaction, but attempts to carry the reaction to completion inevitably lead to over-oxidation and diminished yields of the desired product. The best conversion of **5***b* to the glycols **6** and **7** (R = H) was achieved by carrying out the osmylation under carefully controlled conditions and stopping the reaction when somewhat less than half of the start-

(*a*) G = β-D-glucopyranosyl
(*b*) G = tetraacetyl-β-D-glucopyranosyl

ing material had reacted; after work-up, unchanged **5***b* could be conveniently recovered and the mixture of glycols could be isolated in yields of 40–45% based on unrecovered **5***b*. The nmr spectrum of the product shows that it contains the two epimeric glycols in a 10:1 ratio. The major epimer was isolated as a gum by chromatography, and samples enriched in the minor epimer were obtained, but these always contained some of the major epimer.

The configurations of the glycols were determined by converting the acetylated derivatives **6** and **7** (R = Ac) obtained from the glycol mixture to the corresponding derivatives **3** and **4** (R = Ac) in the sweroside series. The dimethyl acetal function was first hydrolyzed and the resulting aldehyde was reduced to the alcohol in high yield (86%) by sodium cyanoborohydride; acidic conditions caused the hydroxy esters to cyclize to the lactones **3** and **4** (R = Ac). Chromatography afforded the major epimer in crystalline form, isolated in 60% yield, and this was shown to be identical in every respect with **3** (R = Ac), the minor epimer obtained from sweroside. The minor epimer **4** (R = Ac) from secologanin was identical in chromatographic and spectroscopic characteristics with the major epimer from sweroside. Since the configurations of the glycols in the sweroside series appear secure (2), it follows that the glycols **6** and **7** (R = H) were obtained in the ratio of 10:1 in the secologanin series, and that the osmylation of **5***b* had taken place with a high degree of stereoselectivity to form the 3-*S* derivative.

The high stereoselectivity but low chemoselectivity in the secologanin series contrasts strikingly with the high chemoselectivity but low stereoselectivity in the sweroside series; furthermore, it is the 3-*R* isomer that is produced in small excess in the latter case. Another difference between the two series is in the conformational preferences of the molecules as revealed in their nmr spectra, and it seems probable that selectivity and conformational factors are interrelated. The conformation of the dihydropyran, ring A, that is common to all of these compounds could be judged from the coupling constant ($J_{1,2}$) between the configurationally *trans* protons at C-1 and C-2; other data, especially the magnitude of the allylic coupling between the protons at C-7 and C-9, were also of value. (Table 1 lists the key data).

In the sweroside series the conformational situation is uncomplicated. All of the derivatives examined show $J_{1,2}$ values characteristic of vicinal diequatorial protons, and relatively large values for allylic coupling with $J_{7,9}$ values in the range 2–2.5 Hz; values reported by others (4) for compounds in this series are in the same ranges. It follows that ring A retains the conformation depicted in **8** when the C-2 substituent is vinyl or a

Glycol **7** (R = H)	4.43	10.0	(2.67)	~0	Mixture with **6** (R = H); C-9 signals probably coincide

[a]Spectra obtained with $CDCl_3$ solutions, unless otherwise indicated.

more heavily substituted derivative and the C-1 substituent is a glucose residue or its tetraacetate, and the conformation is the same in aqueous or organic solvents. The presence of the fused lactone and the anomeric effect of the C-1 glycoside together appear sufficient to maintain ring A in the conformation **8** having an axial C-2 substituent in all of these compounds.

In the secologanin series, however, the conformational preference varies. Secologanin itself (*1a*) has been observed in aqueous (D_2O) solution (where the aldehyde exists largely in the hydrated form) and, in agreement with others (5), we have found $J_{1,2}$ = 7.0 Hz and $J_{7,9}$ = 1.0 Hz. In $CDCl_3$ solution, however, its tetraacetate *1b* exhibits $J_{1,2}$ = 3.0 Hz and $J_{7,9}$ = 1.5 Hz; the corresponding assignments of 2.5 and ~1 Hz for a carbon tetrachloride solution of its dimethyl acetal *5b* are made with less confidence because of interference from other signals. These results indicate that the equilibrium between the two conformations of ring A, **9** (corresponding to the sweroside conformation) and **10**, is more finely balanced; the effect of an aqueous medium leads to a preference for **10**, while in a nonaqueous solvent, **9** is preferred, and it is probable that the minor conformation is a significant component of the dynamic equilibrium in both media since the coupling constants do not correspond to the extreme values associated with either pure conformation. In the major glycol **6** (R = H) derived from *5b*, the values $J_{1,2}$ = 9.5 and $J_{7,9}$ ~ 0 Hz were observed, and the values for the minor glycol **7** (R = H) present in the reaction mixture were very similar. It seems clear that conformation **10** becomes strongly dominant when the bulk of the substituent R at C-2 increases and the preference of this group for an equatorial environment outweighs the combined effect of an axial C-7 substituent and an equatorial substituent at the anomeric centre C-1. The nmr spectra of intermediates in the conversion of **6** and **7** to **3** and **4** showed $J_{1,2}$ and $J_{7,9}$ values corresponding to conformation **10** until the lactone ring was closed.

These differences in conformational preference in the two series provide an explanation for the differences in the selectivity of the osmylation reaction. In the sweroside series the vinyl side chain is clearly axial and there is little difference in steric hindrance to approach by the reagent to either face. The C-2 substituent remains axial in the product glycol, as does the C-1 glycoside moiety; under these circumstances the internal 8,9 double bond appears to resist attack by osmium tetroxide. In the more conformationally mobile secologanin derivative, on the other hand, the osmylation shows a high degree of stereoselectivity for reaction at the vinyl side chain, and the C-2 substituent in the product glycol is equatorial. It is reasonable to propose that the steric environment of the vinyl side chain differs from that in the sweroside series during the osmylation process, and that reaction through conformation **10** is preferred as the bulky osmate develops (6), adopting an equatorial orientation in which there is more steric difference between the two faces of the side chain. The low chemoselectivity for reaction at the vinyl side chain may be attributed to the increased reactivity of the endocyclic double bond when the substituents at

C-1 and C-2 are both equatorial. This is the presumed conformation in the osmylated intermediate and the evidence presented above does indicate that over-oxidation increases as the concentration of osmylated material builds up. The possibility that some of the starting material **5***b* undergoes oxidation at the endocyclic double bond through the small amount of the reactive conformation present in the equilibrium can not be ruled out since no characterizable products of oxidation at this site in starting material or products have been isolated. The weight of the evidence indicates that osmylation in the secologanin series shows some chemoselectivity for the vinyl side chain and the reaction is stereoselective, but the product formed is susceptible to further oxidation at the endocyclic double bond. In any event, these studies have provided a useful route to secologanin derivatives carrying an oxidized C-2 side chain of established chirality; these are valuable synthetic intermediates.

Experimental

Melting points were determined on a calibrated Thomas-Kofler micro hot stage. Infrared spectra were measured on a Perkin-Elmer 337 spectrometer; the wavelengths (μ) of selected absorptions of solutions in chloroform are reported. Ultraviolet spectra were measured on a Unicam SP 1800 spectrometer; the λ_{max} values (nm) followed by the log ε values in parentheses for solutions in methanol are reported. Proton nmr data reported were measured at 220 MHz at the Canadian 220 MHz NMR Centre; unless otherwise indicated, solutions in $CDCl_3$ were used, and chemical shifts are reported on the τ scale followed by an indication of the multiplicity (initial letter) of the signal, the coupling constants (in Hz) when available, and the number of protons associated with the signal. (More detailed analyses than those reported are available in a number of cases.) A Waters Associates Prep LC/system 500 with PrepPak-500 cartridge (30 × 5.7 cm) was used for hplc separations.

Secologanin and sweroside were isolated from local *Lonicera* species (mainly *L. tatarica*).

Dihydroxylation of Sweroside Tetraacetate

Sweroside tetraacetate (13.05 g; 23.4 mmol), prepared by treatment of sweroside (**2***a*) with acetic anhydride in pyridine, was dissolved in a mixture of 80 mL of tetrahydrofuran and 50 mL of water containing *N*-methylmorpholine *N*-oxide dihydrate (5.36 g; 34.5 mmol) under argon, and a solution of osmium tetroxide (213 mg; 0.84 mmol) in 8 mL of *tert*-butyl alcohol was carefully added to the stirred reaction mixture (3). Stirring was continued at room temperature for 23 h, a slurry of 12 g of Florisil, 1 g of sodium hydrogen sulfite, and 80 mL of water was added, and the mixture was filtered. The filtrate was reduced in volume on a rotary evaporator until an aqueous slurry remained, and this was extracted with methylene chloride. The extract was thoroughly washed with 5% hydrochloric acid followed by 5% aqueous sodium bicarbonate and then brine, dried, and evaporated to dryness. A solid residue (10.89 g; 19.4 mmol) was obtained; its nmr spectrum showed that it was a 2:3 mixture of diols **3** and **4** (R = H). The diol mixture was separated by hplc on silica gel with elution by 1:9 methanol–ether. Isomer **3** (R = H) was isolated, after recrystallization from ether–methanol, as white crystals (2.5 g), mp 112–114°C; ir: 2.70, 2.77, 5.68, 5.84, 6.15; uv: 242 (3.68); nmr: 2.50 (d, J = 2.5; 1), 4.50 (d, J = 1.5; 1), 4.7–5.2 (complex; 4), 5.4–5.9 (complex; 4), 6.2–6.4 (complex; 4), 7.00 (m, 1), 7.45 (d, J = 4; 1; removed by D_2O), 7.76 (complex; 2; 1 after D_2O wash), 7.8–8.0 (complex; 2), 7.86 (s, 3), 7.91 (s, 3), 7.95 (s, 3), 8.02 (s, 3). *Anal.* calcd. for $C_{24}H_{32}O_{15}$: C 51.43, H 5.75; found: C 51.25, H 5.80. On acetylation this formed **3** (R = Ac), mp 172–173°C (lit. (2) mp 171–172°C), with spectroscopic characteristics corresponding to published values (2). Isomer **4** (R = H) was obtained in the same way as white crystals (4.1 g), mp 92–93°C; ir: 2.70, 2.77, 5.68, 5.84, 6.15; uv: 243 (3.79); nmr: 2.40 (d, J = 2; 1), 4.18 (d, J = 1.5; 1), 4.7–5.2 (complex; 4), 6.2–6.6 (complex; 4), 6.90 (m, 1), 6.94 (d, J = 4; 1; removed by D_2O), 7.32 (m, 1; removed by D_2O), 7.81 (m, 1), 7.82 (s, 3), 7.98 (s, 3), 8.00 (s, 3), 8.05 (s, 3), 8.15–8.3 (complex; 2). *Anal.* calcd. for $C_{24}H_{32}O_{15}$: C 51.43, H 5.75; found: C 51.31, H 5.81. On acetylation this formed **4** (R = Ac) with spectroscopic characteristics corresponding to published values but a somewhat higher mp, 150–151°C (lit. (2) mp 133.5–134.5°C).

*Dimethylacetal of Secologanin Tetraacetate (***5***b)*

A solution of secologanin (1.0 g) in 10 mL of methanol was stirred with Amberlite IR 120(H) ion-exchange resin (1.0 g) for one day. After filtration and evaporation of the solvent, the acetal **5***a* was isolated in essentially quantitative yield as a white amorphous solid; ir: 2.98 (broad), 5.90, 6.18; nmr complex, included: 2.58 (br. s, 1), 6.28 (s, 3), 6.68 (s, 6). *Anal.* calcd. for $C_{19}H_{30}O_{11}$: C 52.53, H 6.96; found: C 52.67, H 6.92. This was converted by treatment with acetic anhydride in pyridine to the tetraacetate **5***b*, an amorphous white solid; ir: 5.70, 5.87, 6.14; uv: 233 (3.97), 305 (shoulder); nmr (CCl_4): 2.76 (br. s, 1), 4.42 (ddd, J values 18, 10, 4; 1), 4.70 (dd, J values 18,2; 1), 4.74 (dd, J values 10,2; 1), 4.79 (d, J = 2.5; 1), 4.9–6.3 (complex; 8), 6.34 (s, 3), 6.75 (s, 3), 6.78 (s, 3), 7.31 (complex; 2), 7.8–8.2 (complex; 2), 7.94 (s, 3), 8.02 (s, 3), 8.04 (s, 3), 8.14 (s, 3).

Alternatively, the sequence could be reversed, producing first secologanin tetraacetate (**1***b*) and then **5***b*.

Dihydroxylation of the Secologanin Derivative **5**b

A solution of **5***b* (e.g. 2 g) and about a molar equivalent of osmium tetroxide in redistilled pyridine (e.g. 10 mL) was stirred at room temperature for 4 h. The black solution was stirred with aqueous sodium hydrogen sulfite (e.g. 3 g/150 mL) until its color had been discharged, and then it was thoroughly extracted with chloroform. The extract was washed with 5% aqueous sodium hydrogen carbonate and then brine, dried, and evaporated to dryness. A colorless residue was obtained, which was chromatographed on a silica gel column pretreated with water (3%); 3:7 hexane – ethyl acetate followed by 1:9 methanol – ethyl acetate were used for elution. (Solvents were pretreated with potassium carbonate.) Starting material (50–60%) was obtained from early fractions and the mixture of glycols **6** and **7** (R = H) was isolated from later fractions in yields corresponding to 40–45% of unrecovered **5***b*. The nmr spectrum showed the mixture to contain **6** and **7** in a 10:1 ratio. Repeated chromatography on the same system led to the isolation of the major epimer **6** (R = H) as a colorless oil; ir: 2.85 (broad), 5.75, 5.85; uv: 234 (3.94); nmr: 2.67 (s, 1), 4.61 (d, J = 10.0; 1), 4.7–6.3 (complex; 11), 6.35 (s, 3), 6.58 (s, 3), 6.72 (s, 3), 6.97 (m, 1), 7.80 (m, 1), 7.83 (s, 3), 7.89 (s, 6), 7.92 (s, 3), 8.01 (m, 1), 8.70 (m, 1). A homogeneous sample of the minor epimer was not isolated, but fractions enriched in this isomer were obtained and the signals characteristic of **7** (R = H) could be deduced from the nmr spectrum of the enriched mixture. *Anal.* calcd. for $C_{27}H_{40}O_{17}$: C 50.94, H 6.33; found: C 50.94, H 6.08.

The acetylated derivatives **6** and **7** (R = Ac) could be prepared from the glycols by standard procedures. They could be obtained more conveniently by treatment of the mixture obtained

from the osmylation reaction with acetic anhydride in pyridine for 12 h at room temperature. Chromatography of the product on silica gel with ether elution afforded unchanged **5***b* in the early fractions and the acetates **6** and **7** (R = Ac) in later fractions.

Conversion to the Sweroside Series

A solution of the mixture of **6** and **7** (R = Ac) (150 mg; 0.24 mmol) described above in a mixture of 3 mL of tetrahydrofuran and 5 mL of 0.1 *N* hydrochloric acid was stirred at room temperature for about 4 h to hydrolyze the dimethyl acetal function (monitored by tlc); sodium cyanoborohydride (15 mg; 0.24 mmol) was added and stirring was continued for about 10 min to reduce the aldehyde function (monitored by tlc). The solution was concentrated by evaporation under reduced pressure and then extracted with methylene chloride. The extract afforded the alcohol (120 mg; 0.20 mmol) which was dissolved in 10 mL of tetrahydrofuran containing 60 mg of concentrated hydrochloric acid. The solution was stirred at room temperature for about 7 h (monitored by tlc) and then worked up; tlc analysis of the residue (133 mg) showed two components with the same retention times as the sweroside derivatives **3** and **4** (R = Ac). The major component of the mixture was isolated after repeated preparative tlc as white crystals, mp 172–173°C, identical with the sample of **3** (R = Ac) obtained from sweroside (see above).

The conversion of sweroside to secologanin

RAYMOND G. HAMILTON AND STEWART MCLEAN
Department of Chemistry, University of Toronto, Toronto, Ont., Canada M5S 1A1

Received August 5, 1980

RAYMOND G. HAMILTON and STEWART MCLEAN. Can. J. Chem. **59**, 215 (1981).

A chemical route from sweroside (**2***a*) to secologanin (**1***a*) has been established. The lactone ring of sweroside tetraacetate (**2***b*) was opened by trimethylsilyl iodide. The unstable iodo carboxylic acid **3** (R = H; X = I) was then formed and immediately converted to its methyl ester. The iodo function was displaced by formate, and the formate was selectively methanolized under neutral conditions. The resulting alcohol **3** (R = Me; X = OH) was oxidized by pyridinium chlorochromate to the aldehyde, secologanin tetraacetate (**1***b*). With care, the conversion from the sweroside series to the secologanin series can be carried out in excellent yield. Secologanin can readily be recovered from its tetraacetate.

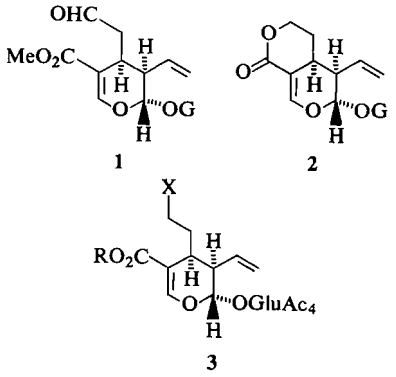
RAYMOND G. HAMILTON et STEWART MCLEAN. Can. J. Chem. **59**, 215 (1981).

On a établi une voie d'accès à la sécolaganine (**1***a*) à partir de la sweroside (**2***a*). On a ouvert le cycle lactonique du tétraacétate de sweroside (**2***b*) en utilisant l'iodure de triméthylsilyle. Il se forme alors l'acide iodocarboxylique **3** (R = H; X = I) qui est instable et qui se transforme immédiatement en son ester méthylique. L'iode est ensuite déplacé par un formate que l'on méthanolyse dans des conditions neutres. L'oxydation de l'alcool **3** (R = Me; X = OH) qui en résulte par le chlorochromate de pyridinium conduit à l'aldéhyde (**1***b*) le tétraacétate de sécologanine. En prenant des précautions, on peut, avec d'excellents rendements transformer des composés de la sweroside en composés de la série sécologanine. On peut récupérer facilement la sécologanine à partir de son tétraacétate.

[Traduit par le journal]

Secologanin (**1***a*), an iridoid of biosynthetic importance, is readily available as a constituent of various *Lonicera* species, where it occurs along with the related iridoid, sweroside (**2***a*). The chemical conversion of **1***a* to **2***a* can readily be carried out, and was used in the elucidation of the structure of secologanin (1). As part of one of our investigations we wished to demonstrate that the reverse process, the oxidative conversion of **2***a* to **1***a* could also be carried out chemically.

Sweroside tetraacetate (**2***b*) reacted rapidly with trimethylsilyl iodide (2) in chloroform at room temperature, and aqueous work-up produced a good yield of the unstable iodo carboxylic acid **3** (R = H; X = I), which was extremely prone to reclose to **2***b*. Immediate treatment of the intermediate acid with diazomethane converted it to its ester **3** (R = Me; X = I), which was obtained crystalline. Many attempts to replace the iodo function under oxidative or hydrolytic conditions failed, often because the intermediate recyclized. Conversion to the formate **3** (R = Me; X = OCHO) was successful when the iodide was treated with sodium formate in hexamethylphosphoric triamide, and selective methanolysis of the formate group was accomplished by prolonged treatment of **3** (R = Me; X = OCHO) with neutral methanol in refluxing tetrahydrofuran. The product alcohol **3** (R = Me; X = OH), which is also susceptible to lactonization, was successfully oxidized by pyridinium chlorochromate (3) to the aldehyde **1***b*, identical in every respect with a sample prepared by the acetylation of



(*a*) G = β-D-glucopyranosyl
(*b*) G = tetraacetyl-β-D-glucopyranosyl

secologanin. With care, all of these transformations can be carried out in very high yields. Problems arise principally from the ease with which intermediates relactonize to the sweroside derivatives. In the oxidation step our yield was only 80%, but the amount of sweroside tetraacetate recovered from the reaction corresponded to the undesired lactonization of 13% of the precursor **3** (R = Me; X = OH). With allowance made for recovered **2***b*, the series of reactions was carried out with 88% conversion of **2***b* to **1***b*. Secologanin (**1***a*) can readily be liberated from its tetraacetate by brief treatment with methanol containing a catalytic amount of potassium carbonate; it is preferable to protect the aldehyde group as its dimethyl acetal during this operation.

Experimental

Melting points were determined on a calibrated Thomas–Kofler micro hot stage. Infrared spectra were measured on a Unicam SP3-200 spectrometer; the wavelengths (μ) of selected absorptions of solutions in chloroform are reported. Ultraviolet spectra were measured on a Unicam SP800A spectrometer; the λ_{max} values (nm) followed by the log ε values in parentheses for solutions in methanol are reported. Proton nmr spectra were recorded on a Varian T-60 spectrometer or at the Canadian 220 MHz NMR Centre; the chemical shifts for solutions in $CDCl_3$ are reported on the τ scale followed in parentheses by an indication of the multiplicity (initial letter) of the signal, the coupling constants (in Hz) when available, and the number of protons associated with the signal.

Secologanin and sweroside were isolated from local *Lonicera* species (mainly *L. tatarica*).

Iodo Ester 3(R = Me; X = I)

Crystalline sweroside tetraacetate, **2***b*, (2.0 g; 3.8 mmol) was dissolved in 11 mL of freshly-distilled chloroform under argon and treated with trimethylsilyl iodide (0.9 g; 4.5 mmol). The solution was stirred for 1 h, further trimethylsilyl iodide (0.2 g) was added, and stirring was continued for 10 min. The solution was shaken with 50 mL of water, and the aqueous phase was thoroughly reextracted with chloroform. The combined organic solutions were concentrated under reduced pressure to a volume of about 25 mL, and treated with excess ethereal diazomethane. After the reaction was complete, acetic acid was added to remove the excess diazomethane, and the solution was evaporated under reduced pressure. The gummy residue was dissolved in methylene chloride, washed with 5% aqueous sodium thiosulfate and then brine, dried, and evaporated to dryness. The residue (2.4 g; 3.6 mmol) was substantially pure **3** (R = Me; X = I) which, on recrystallization from ether, formed needles, mp 156–159°C; ir: 5.70, 5.85, 6.13; uv: 230 (3.65); nmr (220 MHz): 2.65 (d, J = 1.5; 1), 4.38 (m, 1), 4.6–5.2 (complex; 7), 5.65–5.9 (complex; 2), 6.23 (m, 1), 6.27 (s, 3), 6.75–6.95 (complex; 2), 7.2–7.3 (complex; 2), 7.50 (m, 1), 7.89 (s, 3), 7.96 (s, 3), 7.99 (s, 3), 8.06 (s, 3), 8.17 (m, 1). *Anal.* calcd. for $C_{25}H_{33}O_{13}I$: C 44.93, H 4.97, I 18.98; found: C 44.81, H 4.86, I 19.29.

Formate 3(R = Me; X = OCHO)

The above iodo ester (102 mg; 0.15 mmol) and sodium formate (25 mg; 0.37 mmol) were dissolved together in 3 mL of hexamethylphosphoric triamide and stirred in a stoppered vessel at room temperature for 22 h. The solution was diluted with 60 mL of water and extracted with ether. The extract was washed with brine, dried, and evaporated to dryness. The residue, after recrystallization from ether, yielded **3** (R = Me; X = OCHO) (90 mg; 0.15 mmol) as needles, mp 152–154°C; ir: 5.70, 5.81, 6.13; uv: 230 (3.72); nmr (60 MHz): 2.09 (br.s, 1), 2.75 (br.s, 1), 4.4–5.25 (complex; 8), 5.6–6.3 (complex; 5), 6.33 (s, 3), 7.2–7.5 (complex; 2), 7.93 (s, 3), 8.00 (s, 3), 8.03 (s, 3), 8.10 (s, 3), 8.0–8.2 (complex; 2). *Anal.* calcd. for $C_{26}H_{34}O_{15}$: C 53.24, H 5.84; found: C 53.15, H 5.85.

Alcohol 3(R = Me; X = OH)

A solution of the above formate (45 mg; 0.075 mmol) in 3 mL of 1:1 methanol–tetrahydrofuran was refluxed for 1 week. Extraction with chloroform with standard work-up provided the alcohol **3** (R = Me; X = OH) as a residue (39 mg; 0.07 mmol) which after recrystallization from ether formed needles, mp 120–121°C; ir: 2.87 (broad), 5.70, 5.88, 6.13; uv: 233 (3.99); nmr (60 MHz): 2.70 (br.s, 1); 4.4–5.2 (complex; 8), 5.65–5.75 (complex; 2), 6.28 (s, 3), 6.3–6.6 (complex; 3), 7.1–7.7 (complex; 3), 7.97 (s, 3), 8.00 (s, 3), 8.02 (s, 3), 8.04 (s, 3), 8.1–8.4 (complex; 2). *Anal.* calcd. for $C_{25}H_{34}O_{14}$: C 53.76, H 6.14; found: C 53.77, H 6.16.

*Secologanin Tetraacetate 1*b

A solution of the above alcohol (125 mg; 0.224 mmol) in 11 mL of freshly distilled methylene chloride was transferred into a septum-capped flask that contained pyridinium chlorochromate (193 mg; 0.895 mmol), sodium acetate (15 mg; 0.179 mmol), and 1.1 g of Celite under argon (4). The reaction mixture was stirred at room temperature for 1 h, the solvent was pumped off, and the powder that remained was loaded onto a column of silica gel (15 g) and eluted with ether. Early fractions provided **1***b* (99 mg; 0.178 mmol) identical in the behavior, and ir, uv, and nmr spectroscopic characteristics with a sample prepared by acetylation of secologanin. Later fractions afforded sweroside tetraacetate (15 mg; 0.029 mmol).

*Secologanin 1*a

A solution of tetraacetate **1***b* (31 mg) in 5 mL of methanol was stirred with 240 mg of Amberlite 1R 120(H) ion exchange resin for 14 h at room temperature. The mixture was filtered, and the filtrate was stirred with 9 mg of potassium carbonate for 0.5 h at room temperature. The mixture was filtered, the filtrate was evaporated to dryness under reduced pressure, and the residue remaining was dissolved in a mixture of 1 mL of water and 4 mL of tetrahydrofuran to which 45 mg of concentrated hydrochloric acid was added. After 2 h, solid sodium hydrogen carbonate was added to neutralize the acid, and the mixture was stirred and then filtered. Removal of the solvent left secologanin as a residue; the conversion was essentially quantitative.

Stability of the 1,4-bis(2′-haloethyl)-1,4-diazabicyclo[2.2.1]heptane dication[1]

GEORGE R. PETTIT,[2] DONALD P. GIESCHEN, WILLIAM E. PETTIT, AND THOMAS E. RAWSON
Cancer Research Institute and Department of Chemistry, Arizona State University, Tempe, AZ 85281, U.S.A.

Received May 21, 1980

GEORGE R. PETTIT, DONALD P. GIESCHEN, WILLIAM E. PETTIT, and THOMAS E. RAWSON. Can. J. Chem. **59**, 217 (1981).

Certain derivatives of the 1,4-bis(2′-haloethyl)-1,4-diazabicyclo[2.2.1]heptane dication system ranging from dibromide **2***b* to ethanesulfonate **2***g* were found to be quite stable under essentially neutral conditions. A very convenient synthesis of 1,4-bis(2′-chloroethyl)-1,4-diazabicyclo [2.2.1]heptane dichloride (**2***d*) was developed in order to compare the relative stability of this system with that of dibromide **2***b*. While dichloride **2***d* was found to be less stable than dibromide **2***b*, it did prove very useful for rapid preparation of other anion derivatives such as dinitrate **2***e*, dihydrogen dimaleate **2***h*, diperiodate **2***i*, tetrachloroplatinate **2***j*, and tetrachloroaurate **2***k*. *At temperatures near 150°C, or upon ignition (in the open) or gentle shock, diperiodate* **2***i detonated violently*. The ethanesulfonate **2***g* was obtained from diperchlorate **2***a* employing an ion-exchange procedure. Stabilization of dication **2** provides an unusual heterocyclic system with exceptional anticancer properties.

GEORGE R. PETTIT, DONALD P. GIESCHEN, WILLIAM E. PETTIT et THOMAS E. RAWSON. Can. J. Chem. **59**, 217 (1981).

On a trouvé que certains dérivés du système dication bis(halo-2′ éthyl)-1,4 diaza-1,4 bicyclo[2.2.1] heptane allant du dibromure **2***b* à l'éthane sulfonate **2***g* sont tout à fait stables dans des conditions essentiellement neutres. On a mis au point une synthèse très pratique du dichlorure du bis(chloro-2′ éthyl)-1,4 diaza-1,4 bicyclo[2.2.1]heptane (**2***d*) dans le but de comparer la stabilité relative de ce système à celle du dibromure **2***b*. Bien que le dichlorure **2***d* soit moins stable que le dibromure **2***b*, il s'est révélé très utile pour une préparation rapide d'autres anions tels le dinitrate **2***e*, le dimaléate **2***h*, le diperiodate **2***i*, le tétrachloroplatinate **2***j* et le tétrachloroaurate **2***k*. *A des températures voisines de 150°C ou par allumage (à l'air libre) ou par un léger choc, le diperiodate* **2***i détonne violemment*. On a obtenu l'éthanesulfonate, **2***g*, à partir du diperchlorate, **2***a*, en utilisant un procédé d'échange d'ions. La stabilisation du dication **2** fournit un système hétérocyclique inhabituel qui a des propriétés anticancérigènes exceptionnelles.
[Traduit par le journal]

The unusual 1,4-diazabicyclo[2.2.1]heptane dication represents a chemically and theoretically interesting heterocyclic system. The methylene bridge carbon forms a relatively strained (96.8°) N—C—N bond and is derived from formaldehyde. Due to just these properties a substantial degree of reactivity can be anticipated. In 1964 we summarized discovery and preliminary antineoplastic activity of the 1,4-bis(2′-haloethyl)-1,4-diazabicyclo[2.2.1] heptane dication (2). Subsequently, detailed chemical (3*a*–*c*), structural (3*a*, 4), and biological (3*d*) studies of this novel ring system were described. The crystal structure of diperchlorate **2***a* was unequivocally confirmed by X-ray crystallographic analysis (4). Because of the broad spectrum anticancer properties displayed by 1,4-bis(2′-chloroethyl)-1,4-diazabicyclo[2.2.1]heptane diperchlorate (**1***a* → **2***a*) an evaluation of some selected anion derivatives was undertaken (3*d*). Since the methylene bridge carbon–nitrogen bond was found very susceptible to nucleophilic attack, preparation of salts derived from anions such as acetate was precluded. In contrast to the reaction of *N*,*N*-bis(2-chloroethyl)amine with formalin where the product required isolation as the diperchlorate derivative (**2***a*), the analogous diaminomethane formation and intramolecular cyclization (5) (**1***b* → **2***b*) with *N*,*N*-bis(2-bromoethyl)amine caused rapid separation of dibromide **2***b* from the reaction mixture and greatly simplified isolation. Interest in both the stability of dibromide **2***b* and in the preparation of other halide salts for biological evaluation led us to reexamine the structure and

stability of this substance, particularly in respect to intramolecular attack by bromide ion yielding an isomer such as **3**.

A specimen of dibromide **2***b* prepared in our laboratories approximately 16 years ago and stored at ambient temperatures was compared with a freshly prepared sample by potentiometric titration for bromide content and spectral techniques. The potentiometric titration established the presence of two bromide ions in each set of samples and the infrared spectra were identical. The ^{1}H and ^{13}C nmr spectra showed the expected methylene bridge protons and carbon at 5.64 and 82.8 δ respectively. Any remaining uncertainty about structure **2***b* was removed by observing the single natural abundance (6) ^{15}N nmr signal exhibited by both old and new specimens at −294 ppm. The preceding experiments established the reasonable stability of dibromide **2***b* under essentially neutral conditions and treatment with perchloric acid readily gave another useful derivative, diperchlorate **2***c*.

Establishment of the structure and stability behavior of dibromide **2***b* encouraged further efforts on the isolation of dichloride **2***d*. The amine **1***a* → **2***d* transformation was reexamined and eventually it was found that dichloride **2***d* could be selectively precipitated from the ethanol–water reaction mixture by employing 1,2-dimethoxyethane. By this means 54% yields of dichloride **2***d* were realized.[3] But interestingly, this halide derivative proved to be less stable than dibromide **2***b*. Dichloride **2***d* proved fairly unstable thermally and began to decompose (turn a straw color to brown) at temperatures above 60°C, while dibromide **2***b* appeared stable to ca. 160°C. Also, heating the dichloride (**2***d*) in refluxing ethanol for 6 h resulted in extensive degradation to *N*,*N*′-bis(2′-chloroethyl)piperazine hydrochloride. After similar treatment the corresponding diperchlorate (**2***a*) was recovered virtually unchanged.

Fortunately dichloride **2***d* did seem stable enough to serve as a very convenient intermediate for preparation of more useful derivatives. Our previous study (**3***d*) indicated that stabilization of dication **2** requires an anion of limited nucleophilicity. An anion corresponding to an acid with pK_a 2 or less seemed most desirable. Further evidence for this observation and its limitation with certain halide acids was provided by the following experiments. Reactions of silver nitrate or silver fluoride with a solution of dichloride **2***d* easily provided dinitrate **2***e* or difluoride **2***f*. Interestingly difluoride **2***f* proved to be very unstable, resisted purification and suggested a very real decrease in stability for the series bromide > chloride > fluoride. Therefore the sterically much larger iodide as anion should be superior to bromide ion and this possibility will be explored in the future. When the present evaluation of dication **2** stability was in progress a number of other possible anion derivatives seemed more attractive and the useful results uncovered will now be reviewed.

Dinitrate **2***e*, as predicted, proved to be quite stable and was routinely prepared as just described or by ion-exchange methods (3*d*) using diperchlorate **2***a*. With acids yielding silver salts of very limited solubility such as ethanesulfonic acid the latter ion-exchange procedure was best and the stable diethanesulfonate **2***g* was obtained in high yield. Except for eliminating trace amounts of silver from the product the reaction of dichloride **2***d* with a soluble silver salt was most simply performed. By this means reaction of dichloride **2***d* with silver hydrogen maleate provided an alternative (3*d*) synthesis of dihydrogen dimaleate **2***h*.

As soon as dichloride **2***d* became readily available many other potentially convenient and simple reactions leading to stabilization of dication **2** became practical. Illustrative was the facile preparation of diperiodate **2***i* and tetrachloroplatinate **2***j* using aqueous solutions of the dichloride (**2***d*) with sodium *meta*-periodate and chloroplatinic acid. The low thermal and shock stability of diperiodate **2***i* was surprising. *At temperatures approaching 150°C the diperiodate (***2***i) violently detonates*. The same result was obtained by gentle striking on a metal surface. Diperiodate **2***i* appears to be a potentially useful explosive and/or propellant.

The property of certain platinum–nitrogen bonded square planar complexes to inhibit tumor growth is well known (7).[4] Presumably the antineoplastic activity of such substances is due to DNA–platinum coordination. Since even gold chloride ($HAuCl_4$) forms a DNA complex (8) a selection of gold compounds should be evaluated (see also ref. 9). Here, for a beginning, tetrachloroaurate **2***k* was prepared from chloroauric acid trihydrate and dichloride **2***d* in hydrochloric acid.

Both dibromide **2***b* (102% life extension at 100 mg/kg) and tetrachloroplatinate **2***j* (87% life

[3]Dichloride **2***d* (melting at 174°C) was originally prepared in 4% yield by treating *N*,*N*,*N*′,*N*-tetrakis(2-chloroethyl)diaminomethane with diethyl ether (3*c*).

[4]The tetrachloroplatinate (**2***j*) was of special interest as a potentially useful cancer chemotherapeutic drug. Rationale was based on the observation that *cis*-platinum II diamine dichloride (the well-known platinum square planar coordination compound earlier found to have antibiotic effects) is now finding application in human cancer treatment, especially for testicular carcinoma.

extension at 50 mg/kg) were found to markedly inhibit growth of the National Cancer Institute's murine P388 lymphocytic leukemia (3*d*). The other derivatives of dication **2** reported herein are presently being evaluated.

Experimental

All solvents including water were redistilled (through glass). Melting points (capillary tube, oil bath) are uncorrected. Solvent extracts of aqueous solutions were dried over anhydrous magnesium sulfate. The infrared spectra were observed (Perkin-Elmer 299 Spectrophotometer) in potassium bromide and reported as ν_{max} in cm^{-1}. Nuclear magnetic resonance spectra were determined as follows: ^1H nmr (in ppm, δ) with respect to internal tetramethylsilane or sodium 2,2-dimethyl-2-silapentane-5-sulfonate using a Varian Associates T-60A or XL-100; ^{13}C nmr (at 22.6 MHz using a Bruker WH-90 nmr spectrometer) in ppm downfield from internal tetramethylsilane or, if observed in deuterium oxide solution, *p*-dioxane (67.4 ppm) was used as internal reference and chemical shifts were recalculated with respect to tetramethylsilane; and ^{15}N nmr in water with a 1 *M* solution of sodium nitrate (nitrogen-15) in deuterium oxide as external reference employing the same Bruker instrument. Unless otherwise noted the nmr spectra were determined in deuterium oxide solution. The potentiometric titrations were conducted using a digital millivoltmeter and Hewlett-Packard plotter to record volume vs. emf data. Element composition analyses were determined in the Spang Microanalytical Laboratory, Eagle Harbor, MI or the Mikroanalytisches Laboratorium, Fritz-Pregl-Strasse 14–16, West Germany.

1,4-Bis(2'-bromoethyl)-1,4-diazabicyclo[2.2.1]heptane Dibromide (2b)

Procedure A

The method we previously described (3*b* and *d*) was further developed (cf. **2***a*) and applied to the preparation of dibromide **2***b*. Immediately upon removal (rotary evaporation ice-bath) of solvent from the colorless oily *N,N*-bis(2-bromoethyl)amine (10, 11) (*caution, unstable and can vigorously decompose*) it was dissolved in absolute ethanol–formalin (37%).

Procedure B

To a solution of *N*-bis(2-bromoethyl)amine hydrochloride (**1***b*, ref. 10) (50.0 g) in 95% ethanol (300 mL) was added a solution prepared from water (45 mL), potassium hydroxide (10.7 g), and 95% ethanol (150 mL). The precipitate of potassium chloride was collected and 37% formalin (50 mL) was added to the filtrate. After remaining at room temperature overnight dibromide **2***b* (18.3 g) was collected. Addition of 70% perchloric acid (27 mL) to the reaction mixture filtrate and removal of the crystalline product 2 h later afforded 11.6 g of diperchlorate **2***c* (see below). By this means conversion of starting amine **1***b* to dibromide **2***b* and diperchlorate **2***c* amounted to 66% overall. Recrystallization from water–ethanol gave colorless plates of the monohydrate decomposing at 178.5–179.5°C as previously noted (3*b*); ir: 3600–3400, 3080–2980, 1460, 1370, 1120, 890, 660 (C—Br); ^1H nmr: 5.64 (s, 2H), 4.44 (s, 8H), 4.5–4.3 (t, 4H), 4.0–3.8 (t, 4H); ^{13}C nmr: 82.8, 60.0, 59.6, 59.4, 37.6, 22.8; and ^{15}N nmr δ: −294.6.[5] A specimen of dibromide **2***b* prepared 16 years earlier again showed only a single signal at −294.7 in the nitrogen-15 nmr spectrum.

A freshly prepared specimen of dibromide **2***b* and another sample prepared approximately 16 years earlier were found identical by spectral (ir and nmr) comparisons and by results of potentiometric titration experiments assessing bromide ion content. A 0.106 *M* solution of silver nitrate was employed to titrate, a 0.3531 g sample of the 1962 preparation of dibromide **2***b* and a 0.4370 g sample of the freshly prepared counterpart. The former specimen required 14.7 mL (14.8 calcd.) of silver nitrate solution and the latter required 17.8 mL (18.3 calcd.). Each set of titration curves (electrode/potential vs. calomel electrode) confirmed the presence of 2 bromide ions in each sample.

Three recrystallizations from 0.5% aqueous perchloric acid (recrystallization from water appeared to cause partial hydrolysis of the side chain carbon–bromine bond) afforded a pure specimen of *1,4-bis(2-bromoethyl)-1,4-diazabicyclo[2.2.1]-heptane diperchlorate* (**2***c*) as colorless prisms decomposing at 175–176°C; ir: 3080–2980, 1460, 1370, 1220–950 (ClO_4^-), 660 (C—Br); ^1H nmr: 5.65 (s, 2H), 4.5 (s, 8H), 4.5–4.3 (t, 4H), 4.1–3.9 (t, 4H); ^{13}C nmr (acetonitrile): 82.6, 60.0, 59.7, 59.2, 37.8, 22.7.[5] *Anal.* calcd. for $C_9H_{18}Br_2Cl_2N_2O_8$: C 21.07, H 3.54, Br 31.16, Cl 13.83, N 5.46; found: C 20.91, H 3.85, Br 31.12, Cl 13.75, N 5.39.

1,4-Bis(2'-chloroethyl)-1,4-diazabicyclo[2.2.1]heptane Dichloride (2d)

In a typical experiment 300 mL of 1,2-dimethoxyethane (glyme) was added to the reaction mixture resulting from condensation of *N*-bis(2-chloroethyl)amine (from 7.14 g of the hydrochloride) and 37% formalin (75 mL) in ethanol (125 mL) at room temperature for 24 h. Application of diglyme for this purpose also proved very useful. Upon cooling 32.0 g (54%) of dichloride **2***d* was collected and recrystallized from 10:3 ethanol–methanol to afford 18.6 g decomposing at 169–171°C; ir: 3060–2880, 1472, 1448–1436, 1118, 882, 670–668; ^1H nmr: 4.16–4.41 (m, 8H), 4.46 (s, 8H), 5.68 (s, 2H); ^{13}C nmr: 37.56 (—CH_2CH_2Cl), 59.63 (ring —CH_2CH_2—), 59.96 (—CH_2-CH_2Cl), 83.10 (ring —CH_2—).

After prolonged drying periods dichloride **2***d* was still found to retain some water. The following calculated elemental compositions were based on the results of careful Karl Fischer water determinations. *Anal.* calcd. for $C_9H_{18}Cl_4N_2 \cdot 0.31\ H_2O$: C 35.75, H 6.23, Cl 46.90; found: C 35.74, H 6.03, Cl 46.85, H_2O 2.09 (analytical specimen dried for 4 h at room temperature and at 0.1 Torr).

Anal. calcd. for $C_9H_{18}Cl_4N_2 \cdot 0.21\ H_2O$: C 36.05, H 6.19, Cl 47.29; found: C 36.10, H 6.03, Cl 47.05, H_2O 1.27 (analytical sample dried to constant weight at room temperature and at 0.1 Torr).

Substitution of tetrahydrofuran for glyme in this experiment caused separation of dichloride **2***d* as an oil that required separate crystallization from ethanol.

Stability of the 1,4-Bis(2'-chloroethyl)-1,4-diazabicyclo-[2.2.1] heptane Cation in Refluxing Ethanol–Water

Procedure A (With Dichloride 2d)

A solution of dichloride **2***d* (1.0 g) in 99% ethanol–water (25 mL) was heated at reflux for 6 h. Upon cooling 0.7 g of colorless crystalline material separated from the reaction mixture and was identified as *N,N'*-bis(2'-chloroethyl)piperazine hydrochloride by spectral comparison (ir and ^1H nmr) with an authentic sample

Procedure B (With Diperchlorate 2a)

A solution of diperchlorate **2***a* (1.0 g) in 83% ethanol–water (31 mL) was heated at reflux for 5.5 h. Upon cooling, 0.4 g of crystalline diperchlorate **2***a* separated from the reaction mixture. The filtrate was concentrated *in vacuo* and the residue was found to be mostly unchanged perchlorate **2***a*.

1,4-Bis(2-Chloroethyl)-1,4-diazabicyclo[2.2.1]heptane Dinitrate (2e)

Procedure A

Dichloride **2***d* (3.1 g) was dissolved in water (20 mL) and 10 mL (21 mmol) of 2.1 *M* aqueous silver nitrate was added. The

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

mixture was diluted to 150 mL with water and the solution was filtered through sintered glass and lyophilized to yield 3.3 g of colorless solid dinitrate **2***e*. Due to traces of silver impurities the product rapidly (ca. 1 h) darkened. Four recrystallizations from absolute methanol (sintered glass filtration) afforded colorless needles decomposing at 149–150°C (rapid heating).

Procedure B

Amberlite IRA-400 (170 mL, chloride form, ca. 2-fold excess) was placed in a chromatography column and converted to the resin hydroxide by washing with 8 L of 1 *N* sodium hydroxide. Excess sodium hydroxide was removed by elution with water and the resin was converted to the IRA-400 nitrate by elution with 400 mL of 1 *N* nitric acid. Excess nitric acid was removed with water until the eluate was neutral to Hydrion pH paper. A 1 L water solution of 1,4-bis(2′-chloroethyl)-1,4-diazabicyclo-[2.2.1]heptane diperchlorate (**2***a*, 21.2 g, 50 mmol) was passed slowly over the resin. Lyophilization of the resulting eluate afforded 16.2 g (93%) of dinitrate **2***e*. Three recrystallizations from methanol provided an analytical specimen decomposing at 149–150°C (rapid heating); ir: 3020 (H_2O), 2990, 1475, 1445, 1385, 1125, 895 (NO_3^-); ^1H nmr: 4.27–4.38 (m, 8H), 4.52 (s, 8H), 5.70 (s, 2H). *Anal.* calcd. for $C_9H_{18}N_4Cl_2O_6$: C 30.96, H 5.20, N 16.05, Cl 20.31, O 27.49; found: C 31.06, H 5.19, N 16.12, Cl 20.26, O 27.37.

Upon ignition (Bunsen burner flame) dinitrate **2***e* burned rapidly but not violently.

Decomposition of the 1,4-Bis(2′-chloroethyl)-1,4-diazabicyclo-[2.2.1]heptane Cation by Fluoride Ion

The hydroxide form of Amberlite IRA-400 (170 mL) was prepared as described above (Procedure B). The resin was converted to the fluoride form by transferring from the chromatography column to a plastic beaker and treating (twice) with 1 *N* hydrofluoric acid (250 mL). The resin fluoride was washed three times with water (250 mL), returned to the chromatography column, and washed with additional water (1 L). The column eluate at this stage was still acidic (ca. pH 3 using Hydrion pH paper). A solution of diperchlorate **2***a* (21.2 g, 0.05 mol) in 1 L of water was passed through the resin column. The resin was washed with additional water (200 mL) and both eluates were combined and lyophilized. The difluoride (**2***f*) remained colorless until lyophilization was nearly complete whereupon it darkened to an orange-brown tar-like mixture.

1,4-Bis(2′-chloroethyl)-1,4-diazabicyclo[2.2.1]heptane Diethanesulfonate (2g)

After conversion of Amberlite IRA-400 (170 mL chloride form) to the hydroxide form (cf. procedure B above) the resin was further converted to the ethanesulfonate form by elution with 1 *N* ethane sulfonic acid (300 mL). The resin was washed with water (400 mL) until a neutral (Hydrion pH paper) eluate was obtained. A solution of the diperchlorate **2***a* (10.6 g) in water (500 mL) was passed over the resin followed by 100 mL of water. The combined eluates were collected and lyophilized to yield colorless crystals. After dissolution in hot ethanol (15 mL) and reprecipitation by adding acetone 9.4 g (85%) of diethanesulfonate **2***g* were obtained as colorless crystalline plates. Recrystallization from isopropanol afforded a pure specimen: mp 195°C (dec.); ^1H nmr (XL-100) δ: 1.26 (triplet, 6H), 2.90 (quadruplet, 4H), 4.12–4.40 (complex, 8H), 4.46 (singlet, 8H), 5.67 (singlet, 2H). *Anal.* calcd. for $C_{13}H_{28}Cl_2N_2O_6S_2$: C 35.21, H 6.36, Cl 15.99, N 6.32, O 21.65, S 14.46; found: C 35.11, H 6.22, Cl 16.04, N 6.33, O 22.04, S 14.26.

1,4-Bis(2′-chloroethyl)-1,4-diazabicyclo[2.2.1]heptane Dihydrogen Dimaleate (2h)

To a solution of maleic acid (2.32 g, 0.02 mol) in water (10 mL) was added 6.21 mL (0.02 mol) of 3.22 *M* ammonium hydroxide followed by 10.0 mL of 2.10 *M* silver nitrate solution. The colorless silver salt, which precipitated immediately, was collected, washed (twice with cold water and once with acetone), and dried in a vacuum desiccator; yield, 2.85 g. The silver salt was dissolved in 500 mL of hot water and 1.95 g of dichloride **2***d* in water (10 mL) was added. After removal of precipitated silver chloride by filtering the solution through sintered glass, the filtrate was lyophilized to afford 2.68 g (46.0%) of a pinkish-gray solid. By comparison of infrared and proton magnetic resonance spectra the product was found identical with an authentic sample (3*d*).

1,4-Bis(2′-chloroethyl)-1,4-diazabicyclo[2.2.1]heptane Diperiodate (2i)

A solution of dichloride **2***d* (0.49 g), sodium metaperiodate (0.711 g, 0.0033 mol), and 4 mL of water was prepared by warming (steam bath). Upon cooling (ice bath) colorless needles of diperiodate **2***i* formed; yield, 0.56 g (55%). After recrystallization from water, the *diperiodate displayed an explosive decomposition temperature of 150°C and moderate shock sensitivity*; ir: 3040, 3020, 2985, 2970, 1468, 1438, 1360, 1110, 900, 835, and 667; ^1H nmr: 4.25 (4H), 4.33 (4H), 4.47 (8H), and 5.67 (2H). *Anal.* calcd. for $C_9H_{18}Cl_2I_2N_2O_8$: C 17.81, H 2.99, Cl 11.68, I 41.82, N 4.62; found: C 17.86, H 3.16, Cl 11.70, I 41.85, N 4.60.

When a few milligrams of diperiodate **2***i* were placed on an anvil and tapped with a hammer it consistently detonated with a loud report. Also, *when heated and/or ignited (in the open air) the diperiodate detonated with a vigorous report*. Great caution must be exercised when preparing and handling this substance.

1,4-Bis(2′-chloroethyl)-1,4-diazabicyclo[2.2.1]heptane Tetrachloroplatinate (2j)

A 0.7 g calculated amount (0.0017 mol) of potassium tetrachloroplatinate was prepared (12) (alternatively 0.7 g of commercial K_2PtCl_4 in 100 mL of 0.5 *N* hydrochloric acid may be used) by heating 0.82 g (0.0017 mol) of potassium hexachloroplatinate and 0.089 g (0.00085 mol) of hydrazine dihydrochloride in 20 mL of water at 55°C for 2.5 h. The resulting dark red solution was filtered and diluted to 90 mL with 0.5 *N* hydrochloric acid. At this point 0.5 g (0.0017 mol) of dichloride **2***d* was added and the mixture was heated at reflux to afford a light orange solution. Upon filtration (hot) and cooling, light orange needles of the tetrachloroplatinate (**2***j*) separated to yield 0.67 g (71%). Following recrystallization from 0.5 *N* hydrochloric acid the platinate decomposed at 235–243°C (without melting); ir: 3010, 1460, 1420, 1120, 910, and 655; ^1H nmr (dimethylsulfoxide-d_6): 4.27 (2H) and 4.30 (overlapping peaks 16H), and 5.71 (2H). *Anal.* calcd. for $C_9H_{18}Cl_6N_2Pt$: C 19.23, H 3.23, Cl 37.85, Pt 34.71; found: C 19.23, H 3.26, Cl 37.87, Pt 34.65.

1,4-Bis(2′-chloroethyl)-1,4-diazabicyclo[2.2.1]heptane Ditetrachloroaurate (2k)

To a solution of chloroauric acid trihydrate (0.97 g, 2.47 mmol) in 6 *N* hydrochloric acid was added dichloride **2***d* (0.37 g, 1.24 mmol) dissolved in 6 *N* hydrochloric acid. An immediate bright orange precipitate separated. The mixture was heated at reflux until the solid dissolved. The reaction mixture was cooled to room temperature and the orange crystalline product (plates and needles) collected. Yield, 0.58 g (52%); mp 185°C. An analytical specimen was obtained by three recrystallizations from 3 *N* hydrochloric acid; orange needles (mp 177°C (dec.)) and plates (mp 185°C (dec.)): ir: 3140, 2990, 1470, 1448, 1108, 1104, 892, 878, 696, 672; ^1H nmr δ: 4.22 (singlet, 16H) and 5.43 (singlet, 2H). *Anal.* calcd. for $C_9H_{18}Au_2Cl_{10}N_2$: C 11.97, H 2.01, Au 43.64, Cl 39.27, N 3.10; found: C 11.89, H 1.85, Au 43.58, Cl 39.50, N 3.22.

Adsorption of *N*-methylacetamide and L-arginine onto apatitic phosphates

J. V. GARCIA-RAMOS AND P. CARMONA
Instituto de Optica, C.S.I.C. Serrano, 121. Madrid-6. Spain
Received May 20, 1980

J. V. GARCIA-RAMOS and P. CARMONA. Can. J. Chem. **59**, 222 (1981).

The adsorption of *N*-methylacetamide and of L-arginine on apatitic phosphates has been studied by infrared spectroscopy. During the initial adsorption, the bands of adsorbed *N*-methylacetamide indicate the presence of the *trans* form attached to surface cations via the carbonyl group. The position of the amide I band is found to give a linear correlation with q/r for apatitic cations (where q is the charge and r the radius of a cation). At higher amounts of adsorbed amide, hydrogen bonding arises either from the self-association of amide molecules or from the binding of these to the surface phosphate anions. L-Arginine can be adsorbed through the groups containing NH bonds or through the carboxyl group. Infrared spectra of calcinated samples as well as the Ca/P ratio determinations point out that a substitution of L-arginine positive ions for surface cations takes place upon adsorption of this amino acid on apatitic calcium phosphate.

J. V. GARCIA-RAMOS et P. CARMONA. Can. J. Chem. **59**, 222 (1981).

On a étudié par la spectroscopie infrarouge l'adsorption de la *N*-méthylacétamide et de la L-arginine sur les phosphates apatitiques. Pendant l'adsorption initiale, les bandes de la *N*-méthylacétamide adsorbée indiquent la présence de la forme *trans* attachée à la surface des cations par l'intermédiaire du groupe carbonyle. On a trouvé que la position de la bande I de l'amide donne une corrélation linéaire avec le rapport q/r des cations apatitiques (où q est la charge et r le rayon du cation). Pour de plus grandes quantités d'amide, il se forme des liaisons hydrogènes soit à partir de l'auto-association des molécules d'amide soit à partir de leur point d'attache à la surface des anions phosphate. La L-arginine peut être adsorbée soit par le biais des groupes contenant les liaisons NH soit au moyen du groupe carboxylique. Les spectres infrarouges d'échantillons calcinés ainsi que les déterminations du rapport Ca/P révèlent qu'il se produit une substitution des ions positifs de la L-arginine à la surface du cation au lieu de l'adsorption de cet acide aminé sur le phosphate de calcium apatitique.

Introduction

Any investigation of conditions governing the formation and prevention of growth of hydroxyapatite is helpful for the treatment of urolithiasis (1). Apatitic calcium phosphate is a constituent of urinary calculi and frequently forms the nuclei of renal stones (2).

It has long been known that the addition of certain compounds to a crystallising medium can influence the growth rate of the crystals. Because renal stones consist predominantly of crystalline materials, prevention and retardation of their formation may be accomplished by the addition of compounds which are adsorbed onto certain crystal faces of some crystalline constituent. Elucidation of the adsorption mechanism of natural macromolecules onto apatitic calcium phosphate is hindered by the complexity of these molecules. In order to gain an insight into the prevention of stone formation, it is necessary to define the conditions that modify the crystal growth of the individual crystalline components. The effort in this work was to develop a model system in which each factor (individually and in combination) can be assessed. This model system overcomes the complexities encountered when a biological system is used as adsorbate where it is difficult to determine or isolate the factors or agents which promote or inhibit the growth of renal stone crystals. Therefore, it seems more convenient to use, as an initial step, smaller molecules with a low number of functional groups (e.g. *N*-methylacetamide, which contains the peptide group, L-arginine which bears a positively charged guanidinium group) as adsorbates.

Although the binding sites of amides for ions have been determined in solution (3) the present paper emphasizes spectroscopic aspects obtained from the adsorption of *N*-methylacetamide and of L-arginine onto apatitic calcium phosphate, with special reference to the form of the adsorbed species and the nature of its bonding to the surface.

Experimental

N-Methylacetamide (NMA) was prepared by Hofmann's procedure (4) and subjected to vacuum distillation (mp 28°C) several times. Its purity was checked by referring to its infrared spectrum. The deuteration of NMA was carried out by isotopic exchange in heavy water. The sample was dried over P_2O_5. This operation was repeated three times in a glovebox until it was concluded by infrared spectroscopy that deuteration was complete. The sample of L-arginine was purchased from Sigma Chemical Co. and was used as such.

The procedures for the preparation of apatitic calcium phosphate (ACP) and the determination of its specific surface have been described in a previous paper (5). Deuterated calcium, strontium, and barium apatite samples were obtained in the same way by using Na_2DPO_4 and $Ca(NO_3)_2$, $Sr(NO_3)_2$, and $Ba(NO_3)_2$ in heavy water solutions (pD = 10).

The adsorption of NMA was done in a glovebox. Finely

ground deuterated ACP on an agate mortar (30 mg) were placed in 0.5 mL of deuterium oxide. A few drops of this suspension were placed on a CaF_2 infrared window which was then dried in a vacuum desiccator over P_2O_5. This CaF_2 crystal containing the dried polycrystalline film of ACP was used as a window of the closed adsorption cell shown in Fig. 1, so that the ACP film was exposed to the vapor of the liquid NMA placed in the bottom of the cell (Fig. 1). The adsorption experiments were carried out this way at 35–37°C, and the infrared spectra were recorded every hour by using another cell containing liquid NMA and the adsorption cell pathlength to compensate for the NMA vapor not adsorbed onto the ACP polycrystalline film.

The procedure to determine the adsorption isotherm of L-arginine was as follows: aqueous solutions of 0.15, 1.50, 3.00, 4.50, and 7.50 m*M* L-arginine at pH 8 were prepared. Each solution (2 mL) was then added to 200 mg of apatitic calcium phosphate in test tubes. These were then placed in a water bath at 37°C for an hour and shaken every 10 min. The tubes were then centrifuged at 5000 g for 10 min and aliquots of supernatant were taken for chemical analysis according to the procedures of Moore and Stein (6) and Spies (7). The amounts adsorbed were obtained as differences between the initial and final amino acid concentrations. The amounts adsorbed per gram of calcium apatite (Q) versus equilibrium concentrations (C) constitute the adsorption isotherms for the amino acid considered.

Infrared spectra of the solid samples were studied using two Perkin-Elmer infrared spectrophotometers, models 457 and 225. Infrared spectra of aqueous solutions and films were recorded on the same instruments using CaF_2 cells with 0.1 mm pathlength.

About 2 g of calcium apatite containing adsorbed L-arginine, and the same weight of pure calcium apatite were heated at 800°C for 2 h. Infrared spectra of the calcinated products, in KBr, were then recorded.

The quantitative determinations of calcium were carried out by means of a double-beam Perkin-Elmer 305B atomic absorption spectrophotometer. Phosphorus was determined by the use of the conventional colorimetric procedures (8).

Results and Discussion

Vibrational spectroscopy has enabled us to identify the specific interactions between the peptide group and ACP by using hydrogen bond methods. According to literature (9), the *N*-methylacetamide molecule is stabilized by the resonance between the two structures

$$CH_3C{=}ONHCH_3 \leftrightarrow CH_3O^-C{=}N^+HCH_3$$

This resonance is affected by the formation of hydrogen bonds and by adsorption of the apatitic surface. We have compared the infrared spectra of this adsorbed substance with those of the liquid amide and in CCl_4 solution, in order to estimate the strength of the bonding between this amide group and apatitic phosphates (Table 1).

The infrared spectrum of a *N*-deuterated NMA liquid sample shows adsorption bands at 2480, 1635, and 1480 cm^{-1} which are observed at 2578, 1688, and 1406 cm^{-1}, respectively, in diluted CCl_4 solution (Table 1). These bands have been assigned to ν(N—D), amide I and amide II modes, respectively.

All these shifts in the frequencies can be explained by the nature of the vibrations as follows: the amide I band mainly arises from the ν(C=O) vibration and the amide II band from the δ(N—D) and ν(C—N) modes (10). Therefore, the frequency decrease of the amide I band indicates the decrease of the double bond character of the C=O bond, and the frequency increase of the amide II band may be explained considering that the N—D bond is fixed through the deuterium atom. In addition, part of the amide II band potential energy comes from the ν(C—N) vibration (10). Therefore, the frequency increase of the amide II band can also arise from the increase of the double bond character of the C—N group. In the same directions relative to this case, band shifts from the NMA spectrum in CCl_4 solution occur when NMA is adsorbed on the apatitic surface, as described below.

Figures 2 and 3 show the infrared spectra from adsorbed *N*-deuterated *N*-methylacetamide on ACP. Figures 2*a* and 3*a* are two background spectra from a dried polycrystalline film of ACP. During adsorption on this phosphate, the first detectable infrared bands (Figs. 2*b* and 3*b*) arise at 2569, 1563, and 1425 cm^{-1} (Table 1). The former can be assigned to the ν(N—D) vibration and its frequency is slightly lower than the one which corresponds to the same mode for this amide in diluted CCl_4 solution, 2578 cm^{-1} (Table 1). The band at 1563 cm^{-1} arises from carbonyl groups attached to the surface, and the 1425 cm^{-1} band can be assigned to the amide II mode, the frequency of which

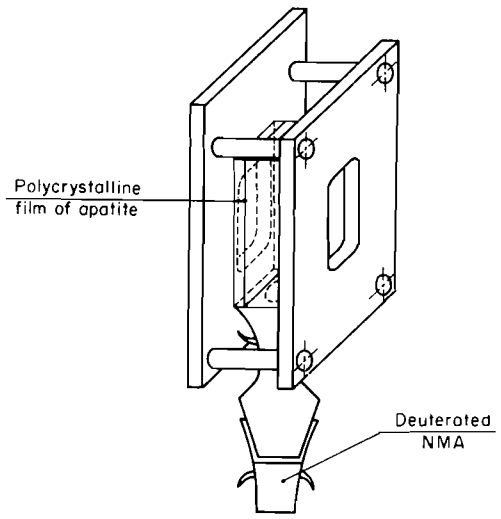

FIG. 1. Adsorption infrared cell.

TABLE 1. Positions of infrared bands of deuterated NMA in CCl_4 solution, in the liquid state and adsorbed on apatitic phosphates

NMA in CCl_4 solution (1.5%)	Liquid NMA	NMA adsorbed on apatitic surfaces*			Assignment
		ACP	ASP	ABP	
2578	2480	2569	2570	2571	ν(N—D)
1688	1635	1563	1568	1571	Amide I
1406	1480	1425	1424	1422	Amide II

*ACP: apatitic calcium phosphate, ASP apatitic strontium phosphate, and ABP apatitic barium phosphate.

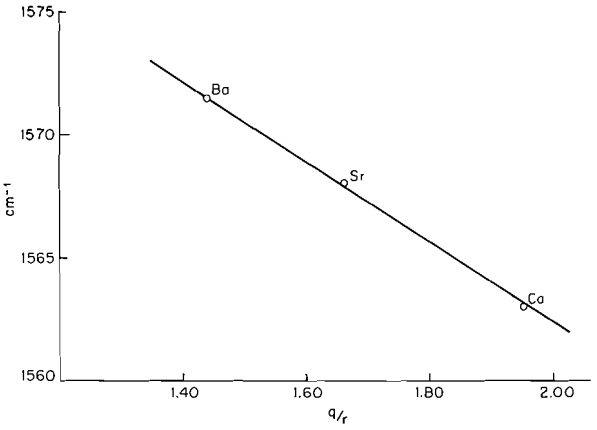

FIG. 4. The position of the amide I band of *N*-deuterated NMA adsorbed on different apatite phosphates as a function of q/r (eau $Å^{-1}$).

being higher than the one which arises from the same mode of *N*-deuterated NMA in the gaseous state (1385 cm^{-1}) (11) and from its isotopic species in CCl_4 solution (1406 cm^{-1}). As described above for liquid NMA, one could think that these band shifts from the NMA spectrum in CCl_4 solution are characteristic of adsorbed molecules being able to find phosphate anions (HPO_4^{2-}) to form hydrogen bonds (e.g. C=O...HPO_4^{2-}). However, the position of the amide I band is found to give a linear correlation with q/r for the apatitic cations (Fig. 4) where q is the cation charge and r its radius as taken from ref. 12, strongly suggesting that the main initial adsorption is at cation sites. In addition, the values for the amide I frequencies indicate that during the initial adsorption, the amide–apatite interactions can be described in terms of strongish ion–dipole binding between the carbonyl group and apatitic cations.

On the other hand, during the first stages of adsorption (Fig. 2*a*, 2*b*) the N—D groups are expected to be free of hydrogen-bonding. In fact, the ν(N—D) band is sharp and appears at a frequency near the corresponding value for the free NMA *trans* form in CCl_4 solution, 2578 cm^{-1} (9) (Table 1). The fact that the ν(N—D) frequency is slightly lower in the first case can be explained by considering that cation binding to the C=O group can increase the acidity of the N—D group (3). These results suggest that the adsorbed molecules probably take the *trans* form. Moreover, the wavenumber of the ν(N—D) vibration of the free *cis* form, 2540 cm^{-1} (9), would not be expected to move toward higher frequencies (2569 cm^{-1}) if adsorption of the NMA molecules had taken place keeping the *cis* conformation on the apatitic surface.

In the 1500–1400 cm^{-1} region, the strongest bands correspond to the amide II and $\delta_s N$ modes (10, 11) and therefore, only these bands are visible around 1420 and 1400 cm^{-1} during the initial adsorption (Fig. 3*b*). When the amount of adsorbate increases (Fig. 3*c*), C—H deformation modes appear at 1455 cm^{-1} these being posteriorly masked by the amide II band (Fig. 3*b*). This figure shows that the amide I and amide II bands become broader, increase in intensity, and shift to higher frequencies, 1610 and 1450 cm^{-1}, respectively. The same can be said for the ν(N—D) vibration, but this one varies in opposite direction, that is, toward lower values (about 2500 cm^{-1}). These changes arise from hydrogen bonding originated either in the self-association of NMA molecules or in the binding of these to the surface phosphate anions. This type of situation may be expected at high coverage due to the reduced availability of sites for cation binding to the carbonyl groups.

Infrared bands of L-arginine were assigned in a previous paper (13). Figure 5 includes the infrared spectrum of this substance adsorbed onto ACP showing a band at 1620 cm^{-1}, due to the ν_{as}(OCO)

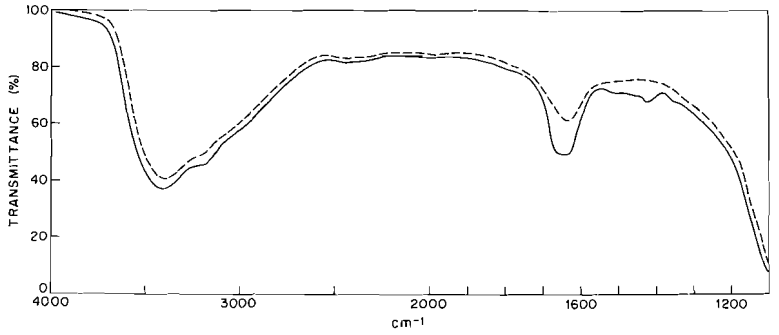

FIG. 5. Infrared spectra of ACP (dashed line) and of adsorbed L-arginine on ACP (full line), in KBr.

TABLE 2. Adsorption isotherm of L-arginine on ACP

$C_0 \times 10^6$ (mol/mL)	$C \times 10^6$ (mol/mL)	$Q \times 10^6$ (mol/g)	C/Q (g/mL)
1.00	0.74	2.56	0.29
1.50	1.02	4.80	0.21
2.00	1.59	4.10	0.39
2.50	1.93	5.75	0.34
3.00	2.21	7.93	0.28
4.00	2.87	11.13	0.26

vibration, superimposed on the apatitic water deformation band at 1635 cm^{-1}. In addition, the ν(N—H) and δ(N—H) bands appear at 3185 and 1515 cm^{-1}, respectively. The vibrations involving the NH groups in this substance appear at frequencies very near to those of the same modes for this amino acid in the solid state (13), which suggests that L-arginine is hydrogen bonded, via the guanidinium or amino groups, to surface anions on ACP. On the other hand, adsorption of L-arginine resulted in an upward shift of the ν_s(OCO) band (1420 cm^{-1}) with respect to the frequency of the same mode for L-arginine in aqueous solution (1395 cm^{-1}) (13). This occurs upon formation of calcium salts of carboxylic acids (14) where calcium ions are bound to carboxyl groups, and suggests that L-arginine can also bind to surface cations through the carboxyl group.

Table 2 gives the analytical figures used to obtain the adsorption isotherm. A Langmuir-type adsorption model did not fit the experimental results probably due to the fact that L-arginine can bind to ACP surface through several functional groups, as described above. Finally, calcium pyrophosphate is formed on calcination of ACP (15). Since the infrared spectra of calcinated samples show that the amount of pyrophosphate decreases when the adsorbate/adsorbent ratio increases, a substitution of L-arginine positive ions for surface cations will be expected. This is in agreement with the Ca/P ratio determinations showing that this ratio varies in the opposite direction to that of the adsorbate/adsorbent.

The addition of simple aromatic hydrocarbons to condensed aromatic thiophenes promoted by aluminum chloride. Part I. Naphtho[2,1-*b*]thiophene

PETER DAVID CLARK AND DAVID M. MCKINNON

Department of Chemistry, The University of Manitoba, Winnipeg, Man., Canada R3T 2N2

Received August 5, 1980

PETER DAVID CLARK and DAVID M. MCKINNON. Can. J. Chem. **59**, 227 (1981).

Naphtho[2,1-*b*]thiophene undergoes addition of aromatic hydrocarbons across the 1,2-bond in the presence of aluminum chloride. At 20°C 1-aryl-1,2-dihydronaphtho[2,1-*b*]thiophenes are the major products and at higher temperatures 2-arylnaphtho[2,1-*b*]thiophenes result. 1-Arylnaphtho[2,1-*b*]thiophenes may be prepared by treatment of the dihydro-addition products with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone thus giving a new synthesis of 1- and 2-arylnaphtho[2,1-*b*]thiophenes from the parent heterocycle.

PETER DAVID CLARK et DAVID M. MCKINNON. Can. J. Chem. **59**, 227 (1981).

En présence de chlorure d'aluminium, les hydrocarbures aromatiques s'additionnent au naphto[2,1-*b*]thiopène à travers la double liaison en 1,2. A 20°C, les aryl-1 dihydro-1,2 naphto[2,1-*b*]thiones sont les produits principaux et, à des températures plus élevées, il se forme des aryl-2 naphto[2,1-*b*]thiophènes. Les aryl-1 naphto[2,1-*b*]thiopènes peuvent être préparés par une réaction entre les produits d'addition dihydro et la dichloro-2,3 dicyano-5,6 benzoquinone-1,4; on a ainsi développé une nouvelle synthèse des aryl-1 et aryl-2 naphto[2,1-*b*]thiopènes à partir de l'hétérocycle apparenté.

Introduction

To date, only one synthesis of 1- and 2-arylnaphtho[2,1-*b*]thiophenes (**2***a*, *b*) has been described (1). This method involves the cyclodehydration of suitable (arylnaphthylthio)acetones (**1**) and, while satisfactory, it necessitates the individual preparation of these compounds. Also their cyclodehydration may give unwanted side products (2, 3). In recent work (4) it was shown that simple aromatic hydrocarbons add to the 2- or 3-positions of benzo[*b*]-thiophene (**3***a*) under very mild conditions. Either 2-arylbenzo[*b*]thiophenes (**3***b*) or 3-aryl-2,3-dihydrobenzo[*b*]thiophenes (**4***a*) were obtained by varying the reaction conditions. The dihydro products **4***a* readily dehydrogenated to 3-arylbenzo[*b*]thiophenes (**3***c*) thus giving a synthesis of either 2- or 3-arylbenzo[*b*]thiophenes from the parent heterocycle. In this paper we have investigated the reaction of naphtho[2,1-*b*]thiophene (**2***c*) with some aromatic hydrocarbons in the presence of aluminum chloride with a view to developing a general synthesis of 1- and 2-arylnaphtho[2,1-*b*]thiophenes (**2***a*, *b*).

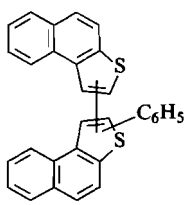
Results and Discussion

In a typical experiment naphtho[2,1-*b*]thiophene (**2***c*) was dissolved in excess of an aromatic hydrocarbon, two mol equivalents of aluminum chloride[1] were added, and the reaction mixtures were stirred either at 20°C or heated under reflux. An intense deep red color which always developed on addition of the aluminum chloride dissipated on addition of



6

[1]The reactions proceed more slowly with one mol equivalent of aluminum chloride.

[b]Phenol and polymeric material were isolated.
[c]Naphtho[2,1-*b*]thiophene was recovered.

dilute acid during the isolation of the products. The results of these reactions are summarized in Table 1.

A comparison of the results given in Table 1 with those obtained with benzo[*b*]thiophene (**3***a*) (4) reveals that, in general, the two systems react in a similar fashion. For example, treatment of a solution of naphtho[2,1-*b*]thiophene (**2***c*) in an aromatic hydrocarbon with aluminum chloride at 20°C results in good yields of 1-aryl-1,2-dihydronaphtho[2,1-*b*]-thiophenes (**5***b*). The isolation of these products was relatively simple and their further treatment with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone gave 1-arylnaphtho[2,1-*b*]thiophenes (**2***a*) in excellent yields (Table 4). Nevertheless, not all reactions at 20°C followed the results obtained with benzo[*b*]thiophene (**3***a*). For example, while the reaction of naphtho-[2,1-*b*]thiophene (**2***c*) with benzene gave 1-phenyl-1,2-dihydronaphtho[2,1-*b*]thiophene (**5***d*), under identical conditions benzo[*b*]thiophene (**3***a*) failed to react with benzene and self-addition occurred, resulting in a mixture of 2- and 3-(2′- and 3′-benzo[*b*]thienyl)-2,3-dihydrobenzo[*b*]thiophenes (4). It is significant that the reaction of naphtho[2,1-*b*]thiophene with benzene is very slow compared to other reactions (see Table 1). With benzo[*b*]thiophene the alternative pathway of self-addition is possible, but with naphtho[2,1-*b*]thiophene self-addition does not occur, possibly due to steric factors, and a slow reaction with benzene takes place. An attempt was made to force naphtho[2,1-*b*]thiophene to undergo self-addition by treatment of the solution in dichloromethane with aluminum chloride. Although the reaction mixture turned the usual deep red color no other reaction was apparent on work-up after 12 h. On prolonged reaction all naphtho[2,1-*b*]thiophene was consumed, but only polymeric products were obtained. Nevertheless, a mixture of products as a result of self-addition was isolated from the reaction of naphtho-[2,1-*b*]thiophene with benzene and aluminum chloride at 78°C. Although attempts to elucidate the precise structure of this mixture by hydrodesulfurization were unsuccessful, it is probable that it was a mixture of the compounds **6** (tlc, nmr, and mass spectra).

While the reaction mechanisms suggested (4) for benzo[*b*]thiophene almost certainly apply to naphtho[2,1-*b*]thiophene, Scheme 1 gives a brief outline of these. As was the case for benzo[*b*]thiophene (**3***a*), the formation of the aryl-1,2-dihydronaphtho-[2,1-*b*]thiophenes (**5***b*, *c*) was reversible (Scheme 1) since, when 1,2-dihydro-1-(4′-methylphenyl)naphtho-[2,1-*b*]thiophene (**5***e*) was treated with aluminum chloride in benzene solution at 20°C over 24 h, 1,2-dihydro-1-phenylnaphtho[2,1-*b*]thiophene (**5***d*) was isolated. Interestingly, the reactions of naphtho-[2,1-*b*]thiophene with 1,2- and 1,4-dimethylbenzene at 20°C resulted in reaction at C-2 rather than the usual reaction at C-1. This may be rationalized in terms of steric interference between the methyl groups of the hydrocarbons and the C—H bond at C-9 of the carbonium ion **8** so that products derived from carbonium ion **7** are observed.

Generally, when a mixture of naphtho[2,1-*b*]-thiophene and aluminum chloride in an aromatic hydrocarbon was heated, 2-arylnaphtho[2,1-*b*]thiophenes (**2***b*) were obtained (Table 1). This parallels the results with benzo[*b*]thiophene (4). 1,2-Dihydronaphtho[2,1-*b*]thiophene (**5***a*) was also obtained from the reaction in boiling ethylbenzene and probably results from hydride abstraction from ethylbenzene

[c]All values are ±0.2 Hz.

by the carbonium ions, **7** and **8**. Hydride abstractions from 1,2- and 1,4-dimethylbenzene have been observed previously (4, 5).

To summarize, it has been shown that it is possible to prepare either 1- or 2-arylnaphtho[2,1-*b*]thiophenes (**2***a*, *b*) as a result of the addition of aromatic compounds to the parent heterocycle **2***c*. This has given a more versatile synthesis of these compounds, and since naphtho[2,1-*b*]thiophene (**2***c*) shows little tendency for self-addition, it should be possible to extend the method to less reactive benzene derivatives. The method is limited to those benzene derivatives which do not coordinate strongly with aluminum chloride, as reactions with anisole and *N*-methylaniline failed to give addition products.

SCHEME 1. Mechanisms for the addition of aromatic compounds to naphtho[2,1-*b*]thiophene.

Product Analysis

Differentiation between 1- and 2-aryl-1,2-dihydronaphtho[2,1-*b*]thiophenes (**5***b*, *c*) was difficult, but could be accomplished by a combination of analysis of ^{1}H nmr signals of the dihydro protons and by desulfurization with Raney nickel. Similar difficulties were experienced during work with 2- and 3-aryl-2,3-dihydrobenzo[*b*]thiophenes (**4***a*, *b*) (4). There it was found that the geminal coupling J_{AB} in **4***b* (−15 Hz) is considerably larger than that in **4***a* (−11 Hz). Also oxidation of **4***b* to its *S*,*S*-dioxide leaves the value of J_{AB} relatively unchanged, while oxidation of **4***a* produces a much bigger change (−2.6 Hz) in J_{AB}. It seemed likely that the values of J_{AB} for the aryldihydronaphtho[2,1-*b*]thiophenes (**5***b*, *c*) should be similar to those for the benzo[*b*]thiophenes and so provide structural information. To test this, several hydrodesulfurizations were carried out (see Experimental) and in each case the spectral assignments were confirmed.[2] The ^{1}H nmr data for the aryldihydronaphtho[2,1-*b*]thiophenes (**5***b*, *c*) and their oxidized derivatives **9** are given in Table 2.

Experimental

The ^{1}H nmr spectra were obtained in deuteriochloroform solution, unless stated otherwise, on a Varian model EM360 spectrometer using tetramethylsilane as an internal standard. Melting points are uncorrected.

*Naphtho[2,1-*b*]thiophene (**2c**)*

This was prepared by the method of Tilak (6) and had mp 114–115°C (lit. (6) mp 114–115°C).

[2]Full characterization of products from Raney nickel hydrodesulfurizations was not carried out since analyses of the ^{1}H nmr spectra gave the necessary structural information.

Addition Reactions of Naphtho[2,1-b]thiophene at 20°C to Form 1- and 2-Aryl-1,2-dihydronaphtho[2,1-b]thiophenes (5)

(a) General Procedure

Aluminum chloride (Fisher, technical grade) (2.88 g, 0.020 mol) was added to a solution of naphtho[2,1-*b*]thiophene (2.0 g, 0.010 mol) in the appropriate aromatic hydrocarbon (100 mL). The organic material was isolated by extraction with ethyl acetate. Evaporation of the washed (H_2O) and dried ($MgSO_4$) organic extracts gave the products as oils which either yielded crystalline material from hexane solution or were purified further by chromatography on alumina and elution with hexane – ethyl acetate (20:1).

(b) With Benzene

The oily residue was dissolved in hexane (50 mL) and on keeping this solution at −5°C for 24 h 1,2-dihydro-1-phenylnaphtho[2,1-*b*]thiophene (**5***d*) was deposited as colorless needles (2.52 g, 88%), mp 129–130°C. The nmr spectrum δ: 6.9–7.9 (m, the aromatic protons).[3] The mass spectrum: M^+ 262; calcd.: 262. *Anal.* calcd. for $C_{18}H_{14}S$: C 82.45, H 5.35, S 12.20; found: C 82.05, H 5.30, S 12.15%.

(c) With Toluene

1,2-Dihydro-1-(4′-methylphenyl)naphtho[2,1-*b*]thiophene (**5***e*) was obtained as colorless prisms (2.2 g, 80%), mp 102–103°C from hexane solution. The nmr spectrum δ: 2.23 (s, Me) and 6.9–7.8 (m, the aromatic protons). The mass spectrum: M^+ 276; calcd.: 276. *Anal.* calcd. for $C_{19}H_{16}S$: C 82.60, H 5.80, S 11.60; found: C 82.50, H 5.75, S 11.55%.

The structure of this product was confirmed by hydrodesulfurization with Raney nickel. A mixture of the compound (0.5 g) and Raney nickel (1 g) in 95% aqueous ethanol was heated under reflux for 8 h. The reaction mixture was filtered and the filtrate was evaporated leaving an oily residue. Short path distillation (130°C at 0.2 Torr) of this oil gave 1-(4-methylphenyl)-1-(1′-naphthyl)ethane (92%) as a clear oil (8).[2] The nmr spectrum δ: 1.69 (d, CH—Me), 2.2 (s, Me), 4.88 (q, CH—Me), and 6.95–8.15 (m, the aromatic protons). The mass spectrum: M^+ 246; $C_{19}H_{18}$ requires M 246.

(d) With Ethylbenzene

1,2-Dihydro-1-(4′-ethylphenyl)naphtho[2,1-*b*]thiophene (**5***f*) was obtained as colorless needles (2.4 g, 76%), mp 94–95°C from hexane solution. The nmr spectrum δ: 1.15 (t, Me), 2.65 (q, CH_2), and 6.9–7.9 (m, the aromatic protons). The mass spectrum: M^+ 290; calcd.: 290. *Anal.* calcd. for $C_{20}H_{18}S$: C 82.75, H 6.20, S 11.05; found: C 82.50, H 6.30, S 11.25%.

(e) With 1,2-Dimethylbenzene

The semi-solid product was dissolved in hexane at 20°C and slowly 2-(3′,4′-dimethylphenyl)naphtho[2,1-*b*]thiophene (**2***j*) crystallized out as pale yellow needles (1.2 g, 38%), mp 229–230°C. The nmr spectrum δ: 2.0 (s, 2 Me) and 6.9–8.2 (m, the aromatic protons). The mass spectrum: M^+ 288; calcd.: 288. *Anal.* calcd. for $C_{20}H_{16}S$: C 83.35, H 5.55, S 11.10; found: C 83.50, H 5.45, S 11.25%.

Concentration of the mother liquors and cooling to −5°C gave 1,2-dihydro-2-(3′,4′-dimethylphenyl)naphtho[2,1-*b*]thiophene (**5***g*) (1.1 g, 35%), mp 62–64°C as colorless microcrystals. The nmr spectrum δ: 2.2 (s, 2 Me) and 7.0–8.2 (m, the aromatic protons). The mass spectrum: M^+ 290; calcd.: 290. *Anal.* calcd. for $C_{20}H_{18}S$: C 82.75, H 6.20, S 11.05; found: C 83.0, H 6.20, S 10.95%.

Raney nickel hydrodesulfurization of either of the foregoing products in hot ethanolic solution gave 1-(3′,4′-dimethylphenyl)-2-(1′-naphthyl)ethane as a colorless viscous oil.[2] The nmr spectrum δ: 2.25 (s, 2 Me), 2.7–3.4 (m, CH_2—CH_2), and 7.0–8.3 (m, the aromatic protons). The mass spectrum: M^+ 260; calcd. for $C_{20}H_{20}$: M 260.

(f) With 1,4-Dimethylbenzene

Chromatography of the crude product gave 1,2-dihydro-2-(2′,5′-dimethylphenyl)naphthol[2,1-*b*]thiophene (**5***h*) as a pale yellow oil (1.42 g, 45%).[4] The nmr spectrum δ: 2.28 (s, Me), 2.40 (s, Me), and 7.0–8.1 (m, the aromatic protons). The mass spectrum: M^+ 290; calcd. for $C_{20}H_{18}S$: M 290.

Aryl-1,2-dihydronaphtho[2,1-b]thiophene-S,S-dioxides (9)

The aryl-1,2-dihydronaphtho[2,1-*b*]thiophenes described were characterized as their *S,S*-dioxides (**9**) as an aid to structural elucidation (see Discussion). The relevant ^1H nmr data for these compounds are given in Table 2. They were prepared by oxidation with hydrogen peroxide in glacial acetic acid (see ref. 7) and crystallized from ethanol. Their properties are summarized in Table 3.

Addition Reaction of Naphtho[2,1-b]thiophene Above 20°C to Form 2-Arylnaphtho[2,1-b]thiophenes

(a) General Procedure

These reactions were carried out as described for the reactions at 20°C except that each experiment was carried out at the boiling point of the aromatic hydrocarbon.

(b) With Benzene

Chromatography of the dark residue gave a white solid which afforded colorless microcrystals of 2-phenylnaphtho[2,1-*b*]thiophene (**2***e*) (2.0 g, 71%), mp 107–108°C, lit. (1) mp 106–108°C. The nmr spectrum δ: 7.1–8.5 (m, the aromatic protons). The mass spectrum: M^+ 260; calcd.: 260. *Anal.* calcd. for $C_{18}H_{12}S$: C 83.10, H 4.60, S 12.30; found: C 82.80, H 4.50, S 12.20%.

Further elution of the column with hexane – ethyl acetate (1:1) gave a pale yellow solid (assigned as structure **6**) (0.25 g, 17%), mp 225–250°C. The nmr spectrum (DMSO-d_6) δ: 7.0–8.5 (m, the aromatic protons). The mass spectrum: M^+ 442.

Discussion of this product was given earlier.

(c) With Toluene

Chromatography of the crude product gave a pale yellow oil. This oil was dissolved in hexane and on cooling to −5°C, pale yellow microcrystals of 2-(4′-methylphenyl)naphtho[2,1-*b*]thiophene (**2***g*) (1.44 g, 48%), mp 110–112°C, were deposited. The nmr spectrum δ: 2.35 (s, Me), 7.0–8.5 (m, the aromatic protons). The mass spectrum: M^+ 274; calcd.: 274. *Anal.* calcd. for $C_{19}H_{14}S$: C 83.20, H 5.10, S 11.70; found: C 83.50, H 5.25, S 11.55%.

Hydrodesulfurization of this product with Raney nickel using the method described earlier gave 1-(4′-methylphenyl)-2-(1′-naphthyl)ethane (bp 150°C at 0.2 Torr) as a pale yellow oil (8).[2] The nmr spectrum δ: 2.35 (s, Me), 2.7–3.5 (m, CH_2—CH_2), and 7.0–8.5 (m, the aromatic protons). The mass spectrum: M^+ 246; $C_{19}H_{18}$ requires M 246.

(d) With 1,2-Dimethylbenzene

Chromatography of the crude product and crystallization of the resulting solid from hexane gave 2-(3′,4′-dimethylphenylnaphtho[2,1-*b*]thiophene (**2***j*) as pale yellow needles (1.28 g, 41%), mp 229–230°C. This product was identical (spectral properties, mixture melting point) to that obtained from the experiment with 1,2-dimethylbenzene at 20°C.

(e) With Ethylbenzene

Chromatography of the crude product gave a pale yellow oil. This was redissolved in hexane and on keeping this solution at

[3]Analysis of the dihydro signals for all aryl-1,2-dihydronaphtho[2,1-*b*]thiophenes is presented in Table 2.

[4]Complete purification of **5***h* was not possible, but this compound was characterized fully as its *S,S*-dioxide, **9***e*.

−10°C for 24 h, pale yellow microcrystals of 1,2-dihydronaphtho[2,1-*b*]thiophene (**5***a*) (0.70 g, 35%), mp 78–79°C were formed. The nmr spectrum δ: 3.5 (s, CH_2—CH_2) and 7.0–8.0 (m, the aromatic protons). The mass spectrum: M^+ 186, calcd. 186. *Anal.* calcd. for $C_{12}H_{10}S$: C 77.40, H 5.40, S 17.20; found: C 77.45, H 5.40, S 17.35%.

Evaporation of the mother liquors gave a pale yellow oil (1.6 g). Analysis of the mass and ^1H nmr spectra indicated compounds **2***h* or *i* and **2***k* or *l* were present, but resolution of the mixture could not be achieved. The nmr spectrum δ: 1.16 (t) and 2.60 (q) due to —CH_2CH_3 of **2***h* or *i*, 1.60 (d) and 4.14 (q) due to $CHCH_3$ of **2***k* or *l*, and 6.9–8.1 (m, the aromatic protons). The mass spectrum: M^+ 288.

*The Preparation of 1-Arylnaphtho[2,1-*b*]thiophenes*

General Procedure

A mixture of a 1-aryl-1,2-dihydronaphtho[2,1-*b*]thiophene (1 g) and 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (1.25 mol equiv.) in benzene (50 mL) was heated under reflux for 2 h. The reaction mixture was cooled and then was filtered through a short (ca. 5 cm) alumina (tlc grade) column. The colorless filtrate was evaporated to dryness and the residue was crystallized from hexane at −5°C. The results are summarized in Table 4.

Dielectric absorption of a few aromatic amines in a polystyrene matrix

S. P. TAY[1] AND S. WALKER

Department of Chemistry, Lakehead University, Thunder Bay, Ont., Canada P7B 5E1

Received April 10, 1980

S. P. TAY and S. WALKER. Can. J. Chem. **59**, 232 (1981).

Dielectric absorption studies in the ranges 77–373 K and 10^2–10^7 Hz have been made on aniline, poly(4-aminostyrene), *p*-toluidine, 4-chloroaniline, 1-aminopyrene, and 4-aminobiphenyl in a polystyrene matrix. An intramolecular process has been observed in poly(4-aminostyrene) and 1-aminopyrene with enthalpies of activation of 25 and 26 kJ mol^{-1} respectively. The enthalpy of activation of the intramolecular process is of the same order as that found for the torsional barrier in aniline and 4-fluoroaniline. The most likely candidate for the intramolecular process appears to be rotation of the amino group about the carbon–nitrogen bond.

S. P. TAY et S. WALKER. Can. J. Chem. **59**, 232 (1981).

On a étudié, dans les intervalles de 77 à 373 K et de 10^2 à 10^7 Hz, l'absorption diélectrique des composés suivants sur un support de polystyrène: aniline, poly(amino-4 styrène), *p*-toluidine, chloro-4 aniline, amino-1 pyrène et amino-4 biphényle. Dans les cas du poly(amino-4 styrène) et de l'amino-1 pyrène, on a observé une réaction intramoléculaire avec des enthalpies d'activation respectives de 25 et 26 kJ mol^{-1}. L'enthalpie d'activation des processus intramoléculaires est du même ordre de grandeur que celle qu'on a observé pour la barrière de torsion de l'aniline et de la fluoro-4 aniline. La rotation du groupe amino autour de la liaison carbon–azote semble être le phénomène le plus couramment observé lors des réactions intramoléculaires.

[Traduit par le journal]

Introduction

Numerous dielectric studies have been made in the microwave region on the intramolecular motion associated with aromatic amines in the pure liquid and solution (1–5). Internal rotation about the C—N bond of the non planar $C_{aromatic}$—NH_2 grouping or nitrogen inversion or both may be considered as the possible relaxation process(es) giving rise to dielectric absorption at higher frequencies in addition to the lower-frequency one for molecular rotation (6). Nevertheless, the dielectric data have not been sufficiently conclusive in the high frequency range to justify a clear-cut assignment of the intramolecular relaxation time, τ_2, which is, for example, 2.1×10^{-12} s for aniline in cyclohexane at 298 K (4). In addition, our previous work (7) has shown that little reliance can be placed on the τ_2 value from a Budó analysis (8) when the weight factor C_1 for the molecular relaxation time τ_1 is much larger than the weight factor C_2 for the intramolecular relaxation time τ_2, and also when $C_1 \simeq C_2$ for τ_2 values smaller than 4.3×10^{-12} s which seems to be the case in aniline. The angle (θ) of inclination of the dipole moment (μ) towards the principal axis of rotation in aniline is estimated from group moment calculations to be 48°. The perpendicular component (μ_2) and the parallel component (μ_1) of the dipole moment are $\mu \sin\theta$ and $\mu \cos\theta$. The relationship of $C_1/C_2 = \mu_1^2/\mu_2^2$ follows the Budó theory. By taking the dipole moments of aniline, chlorobenzene, and toluene as 1.51, 1.58, and 0.37 D respectively (9), we note that $C_1 = 1 - C_2 = 0.44$ in the case of aniline whereas in 4-chloroaniline $C_1 = 0.84$. In *p*-toluidine $C_1 = 0.25$ which is a condition for a good Budó analysis for τ_2. In the present work it has been anticipated that the rate of molecular relaxation would be more retarded in the medium of a polystyrene matrix than the intramolecular relaxation processes which could well be detected separately from the molecular one, and consequently accurate barriers could possibly be determined (10, 11).

Experimental and Results

Dielectric measurements on solutes dispersed in a polystyrene matrix and the evaluation of the results have been described previously (10–25). The polystyrene matrix was prepared in the way described by Davies and Swain (10). We have also adopted their experimental and analytical procedures for obtaining relaxation times and distribution parameters by means of the Fuoss–Kirkwood equation and the enthalpy of activation from the Eyring equation. All the solutes were purified before use. The polystyrene used here had a weight average molecular weight, $\bar{M}_W$, of 230 000. The dielectric data ε_m'', ν_m, β, and ε_∞ have been placed in the Depository of Unpublished Data and the results of Eyring equation analyses of these data are given in Table 1.[2]

Standard statistical techniques were employed to fit the function of temperature data to the Eyring equation. The 95% confidence intervals on ΔH_E were typically ±10% of the nominal values or ±3 kJ mol^{-1}, whichever is the greater, and in agreement with the work of Davies and Swain (10). For the ΔS_E term, these confidence intervals were of the order of ±50% of

the nominal values in some cases, since this term is often a small part of the intercept, $\{\ln (h/k_B) - \Delta S_E/R\}$, of the ln $(T\tau)$ versus $(1/T)$ plot (Figs. 1 and 2).

Discussion

Numerous dielectric absorption studies have now been made of solutes at low concentration in a polystyrene matrix (10–25). It should be noted that:

(*1*) For a single dielectric process the absorption curves are very broad and symmetrical and fit the Fuoss–Kirkwood curve well within the limits of experimental error (10, 11, 15). When asymmetrical absorption curves are obtained, this may suggest overlap of absorption (11, 22).

(*2*) From around room temperature to 95°C (the glass transition temperature of polystyrene), there is the possibility of observing a co-operative process involving both the polystyrene and the solute molecule since the latter lowers the glass transition temperature. Such a process is characterized by large ΔH_E (>100 kJ mol^{-1}) and ΔS_E values and is unlikely to be confused with an intramolecular process which has much smaller ΔH_E and ΔS_E values (26).

(*3*) The loss of the polystyrene itself is very small in the given frequency and the temperature region, and this is subtracted from the measured loss of the disk containing the solute (10, 11, 14). When the concentration of the solute in the polystyrene matrix is low (<5 to 7 mol%), the ΔH_E value for the molecular process is independent of concentration (27). For intramolecular processes this is also the case (15). As is apparent in the studies of Davies and Swain, the energy barrier for an intramolecular process is independent within experimental error of the polystyrene matrix (10). For example, an intramolecular process studied by the nmr technique in dilute liquid solution yields the same barrier as the dielectric study carried out in the polystyrene matrix (10). The latter work was extended by a most detailed study by Tay, Walker, and Wyn-Jones (11) where ΔH_E values obtained from the dielectric, ultrasonic and nmr techniques for a variety of intramolecular processes were compared. All three methods employed different solvent media but yielded intramolecular energy values in agreement well within experimental error. Furthermore, the results are readily repeatable. Numerous examples are now available where the polystyrene matrix approach enables the complete separation of group and molecular rotation and where the energy barrier for group rotation is similar in value to that obtained by other methods (10, 11, 15, 17, 19, 20).

(*4*) Electric dipole moment values deduced from the dispersion data agree only with literature values when the absorption occurs around room temperature (10, 23). At lower temperatures the moments

evaluated may be substantially smaller than the true value (10).

(5) The enthalpy of activation for the molecular relaxation of a solute in polystyrene is highly dependent on size for a particular type of solute molecule (14). Thus, for the series chlorobenzene, 4-chlorotoluene, and 4-chlorobiphenyl (see Table 1), the ΔH_E values are 11, 29, and 85 kJ mol^{-1} respectively. Hence, in the study of group relaxation the molecular and group processes may be sorted out by varying the size of the molecule to which the flexible group is attached.

We shall now discuss each of the solute molecules in turn and the first one to be considered is poly(4-aminostyrene) which from the dielectric point of view is the simplest since any absorption in our frequency and temperature ranges could not be attributable to relaxation of single molecules.

Poly(4-aminostyrene)

Previous work has indicated that it is feasible to study an intramolecular process by attachment of the molecular unit to the backbone of a polymer. For example, Heijboer (28) has shown that inversion of the cyclohexane ring can be readily detected in a dielectric study of poly(4-chlorocyclohexyl methacrylate). The activation enthalpy of 48 kJ mol^{-1} agrees within experimental error with that of 43 kJ mol^{-1} for ring inversion in cyclohexyl chloride from an nmr study (29), and with a value of 42.2 kJ mol^{-1} for the same process in cyclohexyl chloride in a polystyrene matrix determined by Davies and Swain (10) using a dielectric technique similar to that we currently employ. This work has also been repeated in this laboratory, and a value of 43 kJ mol^{-1} was obtained. Fielding-Russell and Wetton (30) studied the dielectric absorption of poly(4-ethoxystyrene) and observed a γ-relaxation in a temperature range of 93–163 K over a frequency range of 10^2–10^7 Hz in addition to the α- and β-relaxations which occurred above room temperature in the same frequency range. These authors suggest two motional possibilities to account for the γ-relaxation: (*a*) onset of rotation of the CH_2—CH_3 bond about the preceding O—CH_2 bond as axis; and (*b*) some form of large angle libration of the ethoxy group. They estimated an Arrhenius activation enthalpy of 21 kJ mol^{-1} for the γ-relaxation process. The clear separation of the γ-relaxation from the β-relaxation in poly(4-ethoxystyrene) suggests the possibility of an uncomplicated study of intramolecular motions of the amino group in poly(4-aminostyrene). The $\ln \tau T$ versus $1/T$ plot for poly(4-aminostyrene) in polystyrene is given in Fig. 1, and well within the limits of experimental error the data fit a straight line. The absorption occurs in the 125–198 K range and cannot be ascribed to α- and β-relaxation processes

which would occur at higher temperatures in the 10^2–10^6 Hz frequency range. It would seem that the relatively low ΔH_E value for poly(4-aminostyrene) in Table 1 can be attributed to an intramolecular process with an activation enthalpy of 25 kJ mol^{-1}.

Aniline, 4-Chloroaniline, and p-*Toluidine*

We have noted earlier that the Budó weight factors for molecular (C_1) and intramolecular (C_2) relaxations are approximately the same in the case of aniline. In *p*-toluidine the latter is larger whereas in 4-chloroaniline the reverse is true. Thus, it is expected that the intramolecular relaxation process would contribute more to the dielectric absorption in *p*-toluidine than the molecular one. On the contrary, dielectric loss arising from the molecular relaxation process would dominate the dielectric absorption in 4-chloroaniline. This is indeed observed in the present work. The ΔH_E value of 26 kJ mol^{-1} for 4-chloroaniline is very similar to that of 29 kJ mol^{-1} for the rigid molecule 4-chlorotoluene. Both molecules are of a similar size and shape with the latter molecule being just slightly larger which fits in with their relative ΔH_E values and also their ΔG_E values. Thus, as judged by the activation parameters for 4-chloroaniline, there is no indication of a contribution to the dielectric absorption from group rotation. This may be accounted for by the fact that $C_1 \gg C_2$.

The Eyring rate plot for *p*-toluidine in Fig. 1 indicates two limiting slopes from the low and high temperature data. The low frequency data yield ΔH_E and ΔS_E of 20 ± 1 kJ mol^{-1} and -32 ± 8 J K^{-1} mol^{-1} respectively, while the high frequency data yield the corresponding parameters of 32 ± 2 kJ mol^{-1} and 41 ± 8 J K^{-1} mol^{-1}, respectively. This is to be contrasted with the previously observed result that an Eyring rate plot for a single relaxation process is linear over the frequency range of 10^2–10^7 Hz regardless of the nature of the relaxation process. Some examples are 1-iodonaphthalene in polystyrene (14), 1,4-dinitrobenzene in polystyrene (16), furan-2-carbaldehyde in polystyrene (11), 1-fluoro-1,1,2,2-tetrachloroethane in polystyrene (11), and certainly, 4-chloroaniline in polystyrene in the present study (Fig. 1). The higher energy barrier of 32 kJ mol^{-1} for *p*-toluidine agrees better with the one of 29 kJ mol^{-1} for molecular relaxation in 4-chlorotoluene. Certainly, the lower barrier of 20 kJ mol^{-1} is much too low to be ascribed to the molecular relaxation of *p*-toluidine. When it is borne in mind that a value of 25 kJ mol^{-1} has been determined for the intramolecular process in poly(4-aminostyrene) and that in each case the absolute accuracy in ΔH_E is not better than ± 3 kJ mol^{-1}, then the lower barrier in *p*-toluidine would be in harmony with this. Certainly, it may be concluded that the dielectric absorption of *p*-toluidine indicates the presence of more than one relaxation process and most likely it is the overlap of the molecular and an intramolecular process.

Broad dielectric absorption is observed for aniline in polystyrene in the temperature range of 89.0–130.8 K which is about 40° lower than that for poly(4-aminostyrene). The loss curves (Fig. 3) are slightly asymmetrical, being somewhat steeper on the low frequency side. This is to be contrasted with the symmetrical curves observed for various rigid molecules where there is just one process (14). A reasonably linear Eyring plot yields ΔH_E and ΔS_E of 17 kJ mol^{-1} and 26 J K^{-1} mol^{-1} respectively which are to be compared with the corresponding values of 11 kJ mol^{-1} and -40 J K^{-1} mol^{-1} for chlorobenzene in polystyrene. In view of the asymmetry of the curves and the fact that the ΔH_E value does not match that for the molecular process, it would seem that overlap of intramolecular and molecular processes most likely occurs and that the Eyring parameters are not meaningful.

1-Aminopyrene and 4-Aminobiphenyl

The dielectric absorption in 1-aminopyrene is noteworthy. Such a large molecule with four fused rings would be expected to encounter a high energy barrier to molecular rotation, a lower limit of this being the 60 kJ mol^{-1} for 4-fluorobiphenyl in polystyrene (31). The barrier of 26 kJ mol^{-1} could not possibly be attributed to molecular relaxation and is best ascribed to an intramolecular process. This value agrees well with that for the intramolecular process in poly(4-aminostyrene). In

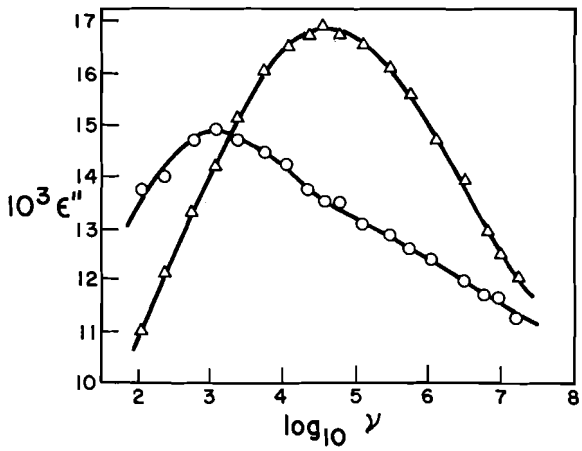

FIG. 3. Dielectric loss curves for aniline in polystyrene: ○, 94 K; △, 110.6 K.

contrast to 1-aminopyrene, 4-aminobiphenyl exhibits a broad dielectric absorption near room temperature, that is at about 120° higher than that for 1-aminopyrene. The ΔH_E value which emerges from the Eyring rate plot (Fig. 2) is 86 kJ mol^{-1}. By comparison with the ΔH_E value of 85 kJ mol^{-1} for 4-chlorobiphenyl (31) which is a rigid molecule of similar size and shape the relaxation process observed in 4-aminobiphenyl may be readily characterized as a molecular one. The presence of the molecular process in one case and its absence in the other could be accounted for by the molecular process of the much larger molecule, 1-aminopyrene, being at lower frequencies than we had available which would correspond with a higher free energy of activation than was the case for 4-aminobiphenyl. In fact, the temperature (330 K) used in the study of 4-aminobiphenyl is within about 20° of our upper limit. Thus, the absence of the molecular process for 1-aminopyrene may be accounted for.

Conclusions

Examination of poly(4-aminostyrene) and 1-aminopyrene in a polystyrene matrix has enabled a complete separation of an intramolecular process from that of a molecular one. Previous dielectric absorption studies of aniline (3), *m*-toluidine (4), and *p*-toluidine (4), in inert solvents in the microwave region revealed very little variation of the intramolecular relaxation time with temperatures over a 40, 25, and 35° range respectively and, consequently, a negligible enthalpy of activation. The present studies indicate a value of ~25 kJ mol^{-1} for an intramolecular process in 1-aminopyrene, and poly(4-aminostyrene). There are also signs of a similar process in *p*-toluidine. The two most likely candidates for the intramolecular process are nitrogen inversion or internal rotation of the amine group.

Relative intensity measurement of rotational transitions in the 0^+ and 0^- inversion states by the microwave spectroscopic technique has indicated that the inversion frequency for aniline itself is close to 46 cm^{-1} (32). An inversion barrier of 6.7 kJ mol^{-1} has been found for aniline from a vibrational analysis of the 294 nm band of its vapour (33). Semi-empirical calculations have yielded values between 2.9 and 14 kJ mol^{-1} for the barrier to pyramidal inversion in aniline (34). Recently, a far infrared investigation of aniline, aniline-ND_2, aniline-NHD, monohalosubstituted anilines, 2-aminopyrimidine, and 3-aminopyridine in the vapour phase has been reported (35–38), and an inversion barrier of 6.3 kJ mol^{-1} for aniline has been determined (35, 36). Inversion barriers for the nine *ortho*-, *meta*-, and *para*-substituted fluoro-, chloro-, and bromoanilines range between 4.6 and 7.2 kJ mol^{-1} for the extreme cases of *o*-bromoaniline and *p*-fluoroaniline respectively (37). For 3-aminopyridine the inversion barrier is 6.0 kJ mol^{-1}, whereas it is only 0.75 kJ mol^{-1} for 2-aminopyrimidine (38).

Thus, from the available physical evidence we note there is a small inversion barrier. Further it is improbable that the inversion will appreciably disturb the surrounding medium. Hence, it is unlikely that this inversion frequency would be shifted from the far infrared region to the radiofrequency range in our experiments by lowering the temperature or by changing to a more viscous medium. Thus, it would seem unlikely that nitrogen inversion is the candidate for the intramolecular process which we have observed. Far infrared studies of aniline and 4-fluoroaniline have resulted in rotational energy barriers of 24 and 18.8 kJ mol^{-1} (35). The value for aniline is almost coincident with that which we have found for the intramolecular process in poly(4-aminostyrene) and 1-aminopyrene. In the case of poly(4-aminostyrene), the ΔH_E value obtained is for an intramolecular process while in the case of 1-aminopyrene the value is much too small to be attributed to a molecular process. Altogether, it would seem that the most likely candidate for the intramolecular process observed for both these molecules is rotation of the amino group about the C—N bond.

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

MICHAEL L. POST, CAROL P. HUBER, GEORGE I. BIRNBAUM, and DAVID SHUGAR. Can. J. Chem. **59**, 238 (1981).

The structures of 1-α-D-xylofuranosylcytosine, $C_9H_{13}N_3O_5$ (**1**), and its hydrochloride salt, $C_9H_{13}N_3O_5$·HCl (**1**·HCl), have been determined by X-ray diffraction from diffractometer data, using direct method techniques. Both compounds crystallize in the orthorhombic system with $Z = 4$. Space group and cell parameters are, for **1**: $P2_12_12$, $a = 18.706$, $b = 8.127$, $c = 7.007$ Å; and for **1**·HCl: $P2_12_12_1$, $a = 16.800$, $b = 8.045$, $c = 8.897$ Å. Refinement by block-diagonal least-squares calculations gave a final R of 0.033 on 873 reflections and 0.034 on 914 reflections for **1** and **1**·HCl, respectively. The glycosyl torsion angles are in the *anti* domain, $\chi_{CN} = -25.1°$ (**1**) and $-28.6°$ (**1**·HCl), and the sugar puckers are nearly pure ${}_2^3T$ (**1**) and ${}^3E$ (**1**·HCl) forms. The C(4′)—C(5′) rotamer is *trans–gauche* in both cases. No intramolecular hydrogen bonding occurs in the xylofuranosyl rings. Lattice packing in the crystal structures occurs via intermolecular hydrogen bonding, with base stacking in pairs about one of the 2-fold axes for the neutral form, and with no base-stacking interactions for the protonated form. The biological implications of the structure and conformation of α-nucleosides are examined.

MICHAEL L. POST, CAROL P. HUBER, GEORGE I. BIRNBAUM et DAVID SHUGAR. Can. J. Chem. **59**, 238 (1981).

On a déterminé les structures de la 1-α-D-xylofurannosylcytosine $C_9H_{13}N_3O_5$ (**1**) et de son chlorhydrate par diffraction de rayons-X, en se basant sur des données obtenues par des méthodes directes. Les deux composés cristallisent dans le système orthorhombique avec $Z = 4$. Le groupe spatial et les dimensions de la maille sont pour le composé **1**: $P2_12_12$, $a = 18{,}706$, $b = 8{,}127$, $c = 7{,}007$ Å; et pour son chlorhydrate $P2_12_12_1$, $a = 16{,}800$, $b = 8{,}045$, $c = 8{,}897$ Å. On a affiné les structures par la méthode des moindres carrés (bloque diagonal) jusqu'à une valeur de $R = 0{,}033$ pour 873 réflexions et de 0,034 pour 914 réflexions respectivement pour le composé **1** et son chlorhydrate. Les angles de torsion glycosidiques sont dans le domaine *anti* $\chi_{CN} = -25{,}1°$ (**1**) et $-28{,}6°$ (**1**·HCl), et le plissement des cycles furannoses conduit à des formes presque parfaites ${}_2^3T$ (**1**) et ${}^3E$ (**1**·HCl). Dans les deux cas le rotamère C(4′)—C(5′) est *trans–gauche*. Il n'y a pas de liaison hydrogène intramoléculaire dans les cycles xylofurannosyles. L'organisation des molécules dans le cristal se fait par l'intermédiaire de liaisons hydrogène intermoléculaires; les bases s'entassent par paires le long de l'un des axes binaires de symétrie dans le cas de la forme neutre et sans interactions d'entassement des bases pour la forme protonée. On a examiné les implications biologiques de la structure et de la conformation des α-nucléosides.
[Traduit par le journal]

Introduction

Nucleotide residues hitherto found in natural nucleic acids occur exclusively in the β-anomeric configuration. There are, however, a number of examples of α-nucleosides and nucleotides, in the free state or as constituents of more complex molecules, such as the vitamin B_{12} group, in living cells (ref. 1, and references cited therein). Some α-nucleoside 5′-phosphates are substrates of 5′-nucleotidase (2, 3); α-5-formyluridine is sufficiently effective as a non-competitive inhibitor of *Escherichia coli* DNA-dependent RNA polymerase to permit the affinity labelling of the latter (4). Other α-nucleosides have also been found to be substrates for, and inhibitors of, a variety of enzymes (5, 6).

Increasingly widespread interest in the biological and physico-chemical properties of α-anomeric nucleosides and nucleotides derives largely from the unexpected findings that some are potent antimetabolites with antitumour and antiviral activities (7–11) which, in several instances, are comparable to, or even in excess of, those of the corresponding β-anomers (6, 10, 11). Undoubtedly the most striking illustration is α-2′-deoxy-6-thioguanosine, which is presently undergoing clinical trials (12). It is readily phosphorylated by kinase(s) in some tumour cells (13) and is incorporated into the terminal position of small oligodeoxynucleotides (14, 15), thus acting as a chain terminator. The foregoing has raised some questions as to the presumed gross structural dissimilarity between α- and β-anomeric nucleoside pairs, and led to the chemical synthesis of the two anomers of 3′-(hydroxymethyl)-branched 2′-deoxynucleosides of 6-thioguanine. *Both* of these, in agreement with expecta-

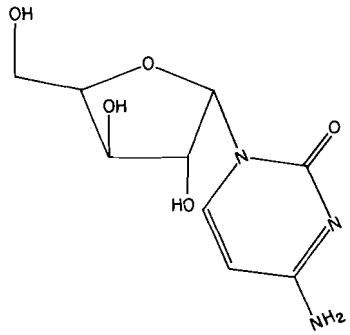
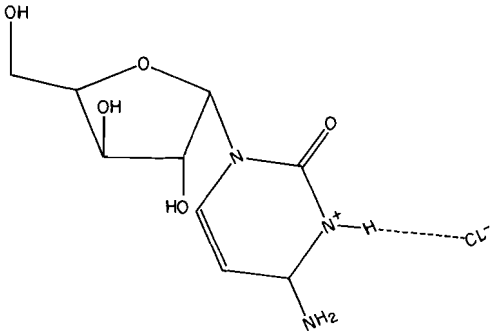
tions, were found to be not only *equally* effective as inhibitors of the growth of WI-L2 human lymphoblastoid cells, but to be even more effective in this regard than the parent α-2′-deoxy-6-thioguanosine (6).

It has also been found that the α-anomers of at least two arabinosyl nucleosides exhibit antiviral activities comparable to those of the corresponding β-anomers (10). Since substrate and/or inhibitor properties of a given class of compounds are dependent, amongst other factors, on conformational parameters, it is of obvious interest to compare the conformations of the two anomeric forms of nucleosides. However, only very limited structural and conformational solid state data are at present available for α-nucleosides (see ref. 1 and references cited therein). The utility of such solid state data in the interpretation of solution conformations obtained by nmr spectroscopy has already been admirably illustrated in the case of ribo- and deoxyribonucleosides (16, 17). We report here on the solid state structure and conformation of α-xylofuranosylcytosine (**1**) and of its hydrochloride salt



1

(**1**·HCl). The antimetabolic properties of some β-D-xylofuranosyl nucleosides have been well documented (18–21). It has been shown that 9-β-D-xylofuranosyladenine interferes with methylation of nuclear RNA (21) via inhibition of the synthesis of *S*-adenosyl-L-methionine (22). Insofar as we are aware, no attempts have yet been made to examine the possible antimetabolic properties of α-xylofuranosyl nucleosides, but their properties in some enzyme systems have received some attention as discussed below.



1·HCl

Experimental

Preparation of 1-α-D-Xylofuranosylcystosine (1) and 1·HCl

O^2,2′-anhydro-1-α-D-xylofuranosyluracil, obtained by the method of Holy (2), was heated under reflux with aqueous triethylamine (10% v/v) to produce 1-α-D-xylofuranosyluracil. The latter was then acetylated and treated with P_2S_5 in dioxane to give the 4-thio derivative (3) which, when aminated with methanolic ammonia in a sealed tube at 105°C, yielded **1**. Passage through a Dowex-50W (H^+) column followed by crystallization from anhydrous ethanol yielded pure **1**, mp 263–264°C (decomp.). The mother liquors from the crystallization were treated with excess HCl (2 *N*) and brought to dryness, to give the hydrochloride salt (**1**·HCl), which was then recrystallized several times from anhydrous ethanol to yield the pure product, mp 190–191°C (uncorr.).

X-ray Analysis of 1 and 1·HCl

Crystals of **1** and **1**·HCl were grown from anhydrous ethanol. Weissenberg and precession photographs were used to determine the space groups and preliminary cell constants. Accurate lattice parameters were obtained by least-squares treatment of the 2θ values of 19 and 14 (**1** and **1**·HCl, respectively) reflections centered on a diffractometer. Intensity data for both compounds were collected with Ni-filtered CuKα radiation (λ = 1.54178 Å) on a Picker diffractometer equipped with a scintillation detector and pulse height discriminator; θ–2θ scans were employed and background counts of 20 s were taken at each end of the scan range. Threshold levels for "unobserved" data were experimentally determined as the larger of 0.1 × total background *or* 50 counts (for **1**) and 48 counts (for **1**·HCl), and reflections with intensities lower than these values were excluded during structure refinement. Lorentz, polarization, and scaling factors (calculated with regard to frequently monitored check reflections) were applied to the raw data, but no corrections were made for absorption or secondary extinction. Crystal data and other pertinent details are as follows:

$C_9H_{13}N_3O_5$ (**1**) fw = 243.22
Orthorhombic, a = 18.706(4), b = 8.127(2), c = 7.007(1) Å, V = 1065.2 Å^3, Z = 4, ρ_{calcd} = 1.516, ρ_{meas} = 1.52 g cm^{-3} (20°C, CuKα Ni-filtered), μ = 10.8 cm^{-1}, crystal size 0.24 × 0.08 × 0.05 mm, $2\theta_{max}$ = 120°, scan speed 1° min^{-1} in 2θ, scan widths 1.7° for 2θ ≤ 90°; 2.0° for 90° < 2θ ≤ 120°, reflections observed/accessible = 873/947 (92%). Absences $h00$, $h = 2n + 1$; $0k0$, $k = 2n + 1$, space group $P2_12_12$.

$C_9H_{13}N_3O_5$·HCl (**1**·HCl) fw = 279.70
Orthorhombic, a = 16.800(3), b = 8.045(1), c = 8.897(1) Å, V = 1202.6 Å^3, Z = 4, ρ_{calcd} = 1.544, ρ_{meas} = 1.54 g cm^{-3} (20°C, CuKα Ni-filtered), μ = 30.4 cm^{-1}, crystal size 0.21 × 0.09 × 0.04 mm, $2\theta_{max}$ = 130°, scan speed 2° min^{-1} in 2θ, scan widths 1.4° for 2θ ≤ 80°, 1.6° for 80 < 2θ ≤ 105°, 1.8° for 105 < 2θ ≤ 130°, reflections observed/accessible = 914/1209 (76%). Absences $h00$, $h = 2n + 1$; $0k0$, $k = 2n + 1$; $00l$, $l = 2n + 1$, space group $P2_12_12_1$.

The structures were solved by direct methods using the symbolic addition procedure with tangent refinement and a multisolution approach. In each case, all nonhydrogen atoms were located in *E*-maps calculated with 119 and 144 phased *E*'s ≥ 1.45

and ≥ 1.50 for **1** and **1**·HCl, respectively. Refinement was carried out using block-diagonal least squares with the non-H atoms initially having isotropic, and then anisotropic, thermal motion. Hydrogen atoms were located in difference Fourier syntheses and their contribution was included in the refinement with isotropic thermal parameters. The function minimized throughout was $\Sigma w(|F_o| - |F_c|)^2$ with weights, w, in the form $\sqrt{w} = |F_o|/M$ for $|F_o| \leq M$; $\sqrt{w} = M/|F_o|$ for $|F_o| > M$ with $M = 12.4$ and 10.4 for **1** and **1**·HCl. These weighting schemes made the average values of $w(\Delta F^2)$ independent of $|F_o|$ and $\sin^2\theta$. Convergence was attained at an R of 0.033 and 0.034 for the observed data (0.043 and 0.061 for all data)[3] and an R_w of 0.034 and 0.040,[4] the figures for **1** being given first. Scattering factors were taken from ref. 23 and ref. 24 (for H) and those for O and Cl^- were corrected for the real and imaginary components of anomalous dispersion (23). The absolute configuration was chosen with respect to the known D-xylofuranosyl moiety in each structure. Programs used were from the NRC crystallographic set (25) and most figures are based on ORTEP II (26) plots. The final atomic parameters are given in Tables 1 and 2.

[3]Tables of observed and calculated structure factors, anisotropic thermal parameters, least-squares planes, and bond angles involving hydrogen atoms are available, at a nominal charge, from the Depository for Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

[4]$R_w = \Sigma\sqrt{w}(|F_o| - |F_c|)/\Sigma\sqrt{w}|F_o|$.

Results and Discussion

Views of the two molecules, together with the atom numbering scheme, are exhibited in Fig. 2. Bond lengths and bond angles for each structure are listed in Table 3, and conformational parameters, together with those for the related ribofuranoside, α-cytidine (data from ref. 1), are summarized in Table 4.

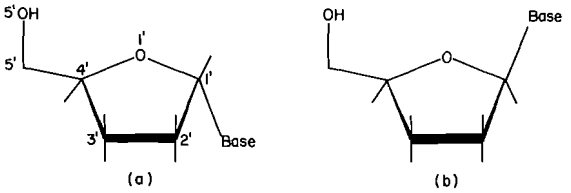

FIG. 1. The α (*a*) and β (*b*) anomeric configurations for a nucleoside.

Each structure exhibits the α-anomeric glycosyl linkage at C(1′) (see Fig. 1) with torsion angles, χ_{CN} (Table 5), of −25.1° and −28.6° for **1** and **1**·HCl, respectively, hence both in the *anti* domain. The glycosidic torsion angles are close to those reported for α-cytidine (1) and α-5-formyluridine (4), −28° and −22°, respectively, so that a χ_{CN} in this range appears reasonably typical for α-nucleosides with a 2′-hydroxyl *cis* to the aglycone.

Sugar Moieties

The pucker of the sugar rings is similar in the two structures: C(2′)*exo*—C(3′)*endo* in **1** and C(3′)*endo* in **1**·HCl. The former conformation is that observed in α-cytidine (1), and the latter in α-5-formyluridine (4), as well as in the α-nucleotide moiety of vitamin B_{12} (27). Furthermore, in the two crystallographically independent molecules of 9-α-D-arabinofuranosyladenine, the sugar moiety of one is C(2′)*exo*—C(3′)*endo*, and that of the other C(3′)*endo* (28). While it may be tempting to consider this narrow range of sugar conformations as preferred for nucleosides with the 2′-OH and the aglycone *cis* oriented, it should nonetheless be noted that a much broader range has been observed in the case of β-arabinofuranosyl nucleosides (29), as well as in other α-nucleosides (30).

This *cis* orientation of the 2′-OH and the aglycone results in a close approach between O(2′) and the ring N(1), which may be alleviated by various distortions. In **1** the $^{3}_{2}T$ pucker leads to the O(2′)—C(2′) and C(1′)—N(1) bonds being more staggered than in **1**·HCl, the difference in the torsion angle about C(1′)—C(2′) being 10° (Table 5). Furthermore, the N(1)—C(1′)—C(2′) bond angle is about 3° larger in **1** than in **1**·HCl. Consequently the N(1)···O(2′) contact in **1** is increased to 2.802 Å. On the other hand, the entire pyrimidine ring in **1**·HCl is displaced away from O(2′), as is clear from the large displacement (0.129 Å) of C(1′) from the ring plane. A similar, even larger, displacement (0.145 Å) was found in α-5-formyluridine (4). However, such distortion is not as effective in relieving the O(2)···N(1) interaction, this distance in **1**·HCl being a relatively short 2.674 Å. It follows that, in nucleosides in which the aglycone is *cis* to the O(2′), the sugar ring is unlikely to have ^{4}E or $_{4}E$ puckers, with the N(1)—C(1′)—C(2′)—O(2′) torsion angle approaching 0°, unless such a pucker is imposed by some structural features as, e.g. in the case of the cyclic O^{2},2′-anhydro-1-α-D-xylofuranosyluracil (31).

In both **1** and **1**·HCl, the conformation about the C(4′)—C(5′) bond is *trans–gauche*. In the case of ribonucleosides, the most commonly encountered conformation of the exocyclic 5′-CH_2OH is *gauche–gauche*. It is consequently of interest that

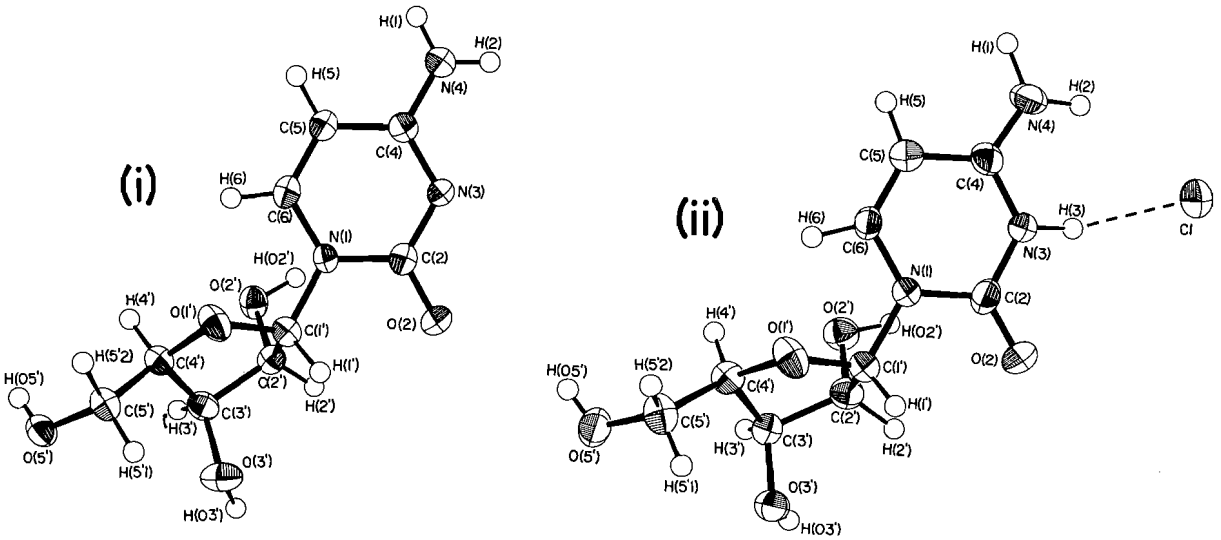

FIG. 2. Perspective views of (*i*) α-D-xylofuranosylcytosine (**1**), and (*ii*) α-D-xylofuranosylcytosine hydrochloride (**1**·HCl). Non-H atoms are represented by 50% probability thermal ellipsoids and H atoms by spheres of arbitrary radius.

solution studies on a series of analogues of 9-β-D-xylofuranosyladenine demonstrated a relatively low (< 30%) population of the *gauche–gauche* form (32). Furthermore, in the solid state structure of 1-β-D-lyxofuranosyluracil in which both the 2′-OH and 3′-OH are "up", i.e. *cis* to the 5′-CH_2OH, the conformation of the latter is *gauche–trans*, while in solution the *gauche–gauche* populations for the neutral form and for the neutral and protonated forms of 1-β-D-lyxofuranosylcytosine are exceptionally low, from 10% to 20% (33). Similarly low *gauche–gauche* populations of the exocyclic 5′-CH_2OH have been reported for the solution conformations of the α- and β-xylofuranosides of oxidized and reduced nicotinamides (34). This effect has been ascribed to steric and electrostatic effects of the "up" 3′-OH, which is *cis*, and adjacent, to the 5′-CH_2OH group (33).

Effects of Base Protonation

In the case of **1**·HCl, protonation occurs at the ring N(3), as might have been anticipated from previous X-ray studies (35), as well as from nmr solution data (36). Values of bond lengths in this portion of the cytosine ring are closely similar to those found in other protonated 1-substituted cytosines (35, 37–40). Thus, relative to the parent **1**, bonds C(2)—O(2) and C(4)—N(4) are shorter, and C(2)—N(3) and N(3)—C(4) slightly longer. This is accompanied by a decrease in bond angle at N(3)—C(4)—C(5) and N(1)—C(2)—N(3) of about 4°, with a similar increase at C(2)—N(3)—C(4). All of these changes are compatible with delocalization of the positive charge between the ring N(3) and the exocyclic N(4) (38, 39), as also observed in solution by ^{15}N nmr spectroscopy (36). In the neutral form, **1**, the heterocyclic ring atoms are planar within the limits of error, whereas in **1**·HCl N(3) is significantly displaced (0.012 Å) towards the chloride ion to which it is hydrogen bonded. The deviations of most of the hydrogen bond donor/acceptor atoms in the cytosine ring are in a direction such that a closer approach between H-bonded atom pairs occurs.

Hydrogen Bonding

All the hydrogen bonding in both structures is intermolecular (Table 6). In contrast to O^2,2′-1-α-D-xylofuranosyluracil, where *intra*molecular hydrogen bonding is observed between O(3′) and O(5′), viz. O(3′)—H···O(5′), in the solid state (31), no such intramolecular bonds are present in either **1** or **1**·HCl, where both the *trans–gauche* orientation at C(4′)—C(5′) and the C(3′)*endo* sugar pucker preclude its formation on purely geometrical grounds. Furthermore, for 9-β-D-xylofuranosyladenine in solution, where side chain and sugar ring conformations are not subject to crystal packing forces, no such hydrogen bonding occurs to any appreciable extent, if at all, for the neutral and protonated forms, or even in strongly alkaline medium where the sugar hydroxyl(s) ionize (32).

Crystal Packing

The modes of lattice packing are illustrated in Fig. 3, in which the hydrogen bonding interactions are also indicated. For the protonated form there is no overlap of bases in the solid state, the translational symmetry elements (see Fig. 3) ensuring, in this instance, the absence of close approaches of base atoms to symmetry-related molecules.

The situation is quite different for the neutral form, with mean base plane separations of 3.37 and 3.36 Å, these distances being between planes symmetrically related by the two unique 2-fold axes at $(\frac{1}{2}, 1)$ and $(\frac{1}{2}, \frac{1}{2})$, respectively, in the *ab* plane. The result is a base-stacking type of interaction (41) which is appreciable and occurs through the crystal lattice along a direction parallel to the *b*-axis. This is similar to the stacking pattern referred to as type III by Motherwell *et al.* (42), a pattern which is not the energetically preferred one and which is observed only infrequently. The perpendicularly projected overlap of bases amounts to approximately 30% in the case of the bases related by the $(\frac{1}{2}, 1)$ 2-fold axes, and approximately 0% for the $(\frac{1}{2}, \frac{1}{2})$ related bases. Consequently, extended base stacking is not predominant in the solid state. The

position of N(3), which is close to the centre of its "paired" base, when viewed in projection, is closely similar to the arrangement in the solid state structure of α-cytidine (1). Since protonation of N(3) usually precludes base stacking (38), this position may possibly be preferred for certain stacking modes (41), and is one which cannot be maintained on protonation, owing to the proximity of positive charges. It should, nonetheless, be noted that base stacking has been observed in the solid state structures of cytosine hydrochloride (38) and 1-methyl-N^4- hydroxycytosine hydrochloride (43).

Furthermore, in a study on the structure of the (1-methylcytosine)–(1-methylcytosine·H^+) complex, the two molecules were found to form asymmetrically hydrogen-bonded dimers, which were stacked in such a manner that molecular overlap was between charged and neutral bases (40). The mean stacking distance was 3.22 Å. The resulting base stacking mode, which is of obvious significance in relation to the solution conformation of protonated poly(rC), was considered to be favoured by overlapping of protonated with neutral species. It is, consequently, of interest to note that in the crystal structure of 1-methyl-N^4-hydroxycytosine·HCl, base overlapping is at least as extensive as in the foregoing complex, with an interplanar distance of about 3.25 Å (43); furthermore, the protonated N(3) atoms of the stacked molecules are even closer to each other in the latter structure than the protonated and non-protonated N(3) atoms in the (1-methylcytosine)–(1-methylcytosine·H^+) structure.

Biological Aspects

In the absence of data regarding antimetabolic

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12

activities of α-xylofuranosyl nucleosides, it is perhaps premature to discuss the conformational features of the present structures which may be of significance in various enzymatic systems. Model building studies do not reveal structural analogies between the α- and β-anomers of xylofuranosylcytosine as in the case of the anomers of 2′- deoxy-6-thioguanosine (6). However, some data of Bennett and Hill (44) are relevant to the foregoing. These authors examined the substrate properties towards adenosine kinase of a variety of anomeric nucleosides of adenine and 8-azaadenine in which the sugar moieties included arabinofuranose, xylofuranose, and lyxofuranose. Amongst these 9-β-D-xylofuranosyl-8-azaadenine and 9-α-L-lyxofuranosyladenine were good substrates. In general, it appeared that substrate activity required the presence of a 2′-hydroxyl *trans* to the aglycone, and a considerable degree of freedom about the glycosidic bond; with these conditions, it was irrelevant whether the 3′-hydroxyl or the exocyclic carbinol group are *cis* or *trans* relative to the aglycone. From these criteria it is obvious that the α-anomer of xylofuranosyladenine should not be a substrate, but this analogue was apparently not available. In view of the known importance of intracellular conversion of nucleoside analogues to their 5′-phosphates, which are the active analogues, it will obviously be of interest to examine the substrate properties towards pyrimidine nucleoside kinase(s) of the title compound of this study, the more so in that the α-anomers of a number of ribo-, deoxyribo-, and arabino-furanosyl nucleosides have been established as potent antimetabolites.

Acknowledgments

We are indebted to Dr. J. Giziewicz for synthesis of the title compounds. One of us (M.L.P.) is grateful to the National Research Council of Canada for the award of a Research Associateship (1975–1978) during the course of this investigation. The support of the Polish National Cancer Research Program (PR-6/1701, to D.S.) is also acknowledged.

Thione photochemistry. Dual pathways in aralkyl thione cyclizations[1]

S. Basu, Axel Couture, Kam W. Ho, Mikio Hoshino, Paul de Mayo, and R. Suau
Photochemistry Unit, Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received June 12, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

S. Basu, Axel Couture, Kam W. Ho, Mikio Hoshino, Paul de Mayo, and R. Suau. Can. J. Chem. **59**, 246 (1981).

It is shown that aralkyl thiones, which possess an oxygen atom at the δ position in the side chain, can therefore not undergo the preferred δ insertion, and insert at the γ and ε positions. Although ε insertion occurs only from the $^1(\pi,\pi^*)$ state, γ abstraction (followed by cyclization or cleavage) occurs from both $^1(\pi,\pi^*)$ and $^3(n,\pi^*)$ states. The quantum yields of photocyclization of **2***c*, **2***d*, and **2***g* change little with solvent polarity, which suggests that a thione–ether charge transfer interaction contributes little to the cyclization. Fluorescence and product quenching studies are reported which support this.

S. Basu, Axel Couture, Kam W. Ho, Mikio Hoshino, Paul de Mayo et R. Suau. Can. J. Chem. **59**, 246 (1981).

On montre que les aralkylthiones qui, dans la chaîne latérale, possèdent un atome d'oxygène en position δ ne peuvent pas subir une insertion privilégiée en position δ mais seulement en positions γ et ε. Quoique l'insertion ε se produise seulement à partir de l'état $^1(\pi,\pi^*)$, l'élimination en position γ (suivie d'une cyclisation ou d'une rupture) a lieu à partir des deux états $^1(\pi,\pi^*)$ et $^3(n,\pi^*)$. Les rendements quantiques de la photocyclisation de **2***c*, **2***d* et **2***g* qui changent à peine avec la polarité du solvant suggèrent que l'interaction de transfert de charge éther–thione contribuent faiblement à la cyclisation. On rapporte les études de fluorescence et de rupture des produits qui appuient cette suggestion.

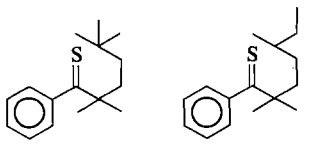
Introduction

In the previous papers of this series (1) we have shown that aralkyl thiones containing a hydrocarbon side chain, upon irradiation into the π,π^* band, cyclize to yield cyclopentane thiols. No such reaction was observed following excitation into the n,π^* state. In fact, the quantum yield of disappearance of such a thioketone is $\sim 10^{-2}$ upon π,π^* excitation and $\leq 10^{-5}$ upon n,π^* excitation.

Typically, in the thione **2***d*, ~40% of the thione molecules in the π,π^* state underwent δ-H abstraction, the remainder decaying radiationlessly. The hydrogen abstraction (Scheme 1) gave a 1,5-biradical whose lifetime was $< 10^{-8}$ s, and only one-tenth of these biradicals cyclized to product **3**, the remainder disproportionating to regenerate the thione.

No γ- or ε-cyclizations were observed in those thiones containing only hydrocarbon side chains, even when there were more ε-hydrogen atoms than δ-hydrogen atoms, as in 1-phenyl-2,2,5,5-tetramethylthiohexanone **6** and 1-phenyl-2-2-5-trimethylthiopentanone **7**.

We report here[2] that in those cases such as **2***g*, where the δ-carbon is replaced by an oxygen atom, S_2 excitation leads to the formation of both four-membered **4** and six-membered ring thiols **5**



6 **7**

(Scheme 2). Furthermore, Type II reaction products, i.e. ethyl vinyl ether and cyclobutanethiol, **4**, are now isolated upon n,π^* excitation and lead us to conclude that there are two routes to the Type II products.

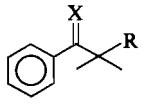
sponding ketones **1***g* and **1***j* which were, in turn, prepared by condensing the enolate anion of isobutyrophenone with the appropriate bromide. The ketone **1***h* was obtained by condensing the anion of isobutyrophenone with allyl bromide, followed by hydroxylation of the olefin with potassium permanganate to give the vicinal diol which was then methylated with methyl iodide. All thiones had closely similar absorption spectra, and this, together with the constant reduction potential (Table 2), suggested that there was insignificant interaction between the ground state thiocarbonyl function and any side chain, even when the latter was oxygenated.



1 X=O
2 X=S

a R = CH_2CH_3
b R = $CH_2CH_2CH_3$
c R = $CH_2CH(CH_3)_2$
d R = $CH_2CH_2CH_2CH_3$
e R = CH_3
f R = $CH_2CH_2CH(CH_3)_2$
g R = $CH_2CH_2OCH_2CH_3$
h R = $CH_2CH(OCH_3)(CH_2OCH_3)$
i R = CH_2OCH_3
j R = $CH_2CH_2CH_2OCH_3$

Preparative irradiations were conducted with benzene as solvent through Pyrex (excitation of S_1, S_2) and through a Corning filter 3-72 (S_1 only).

Irradiation of **2***g* through Pyrex gave **4** (45%), ethyl vinyl ether (5%), together with **5** (40%) (Scheme 2). Excitation of **2***g*, at $\lambda > 445$ nm slowly gave a complex mixture from which **4** (45%) and ethyl vinyl ether (10%) were isolated; no **5** could be detected. Irradiation of **2***h* gave **10** (32%) as a mixture of isomers and **11** (36%); at >450 nm **2***h* gave a mixture from which **10** and **11** were both absent. Both β-methoxy **2***i* and δ-methoxy **2***j* thiones underwent δ-cyclization in high yields to give thiols **12** (85%) and **13** (100%), respectively, when irradiated through Pyrex, but irradiation at $\lambda > 445$ nm did not lead to appreciable reaction; there was no change in the nmr spectrum after 2 weeks of using two 450 W lamps.

All the thiols were identified by the absorption at $\sim 2580\,cm^{-1}$ and the presence of an exchangeable (D_2O) uncoupled proton ~δ 2.0 in the ^1H nmr spectra. All five aromatic protons remained. No molecular ion peak was observed in the mass spectra, but M − H_2S and M − (H_2S + CH_3) were evident. Also, the thiols **10**, **11**, and **12**, were converted into olefins **14**, **15**, and **16**, respectively, in high yields, by the action of mercuric acetate.

Mechanistic Studies

The quantum yields of disappearance of **2***j* and formation of **13** were measured in benzene and acetic acid, both stereoisomers of **13** being estimated separately (Table 1). The ratios of the quantum yield of product formation and of disappearance in both solvents were ~0.85, consistent with the isolated yield of product. The drop in quantum yield from benzene to acetic acid is not attributed to solvent–thione interaction since there is no appreciable change in the π,π* band (297 nm); there is a blue shift (565 → 550 nm) in the *n*,π* absorption. The quantum yields of disappearance (2) of **2***j* and **2***i* were 2.7×10^{-2} and 4.9×10^{-2} at short wavelength (313 ± 5 nm), but at long wavelength were $\leq 10^{-4}$. The quenching of formation of **4** and **5** from **2***g* by biacetyl was possible at 313 nm with correction for quencher absorption; the plots of reciprocal quantum yield against biacetyl concentration are given in Fig. 1. The quantum yield of **5** ($7.4 \pm 0.5 \times 10^{-3}$) was unchanged in the presence of 1.7 *M* piperylene ($7.4 \pm 0.5 \times 10^{-3}$). Attempted

TABLE 1. Quantum yields of photocyclization of thioketone **2***j* at room temperature

	Concentration (M)	$\Phi_R{}^{1\,a}$	$\Phi_R{}^{2\,a}$	$\Phi_{dis}{}^{b}$	Conversion (%)
Benzene	7.2×10^{-3}	2.1×10^{-2}	2.1×10^{-2}	0.048	4.4
	9.7×10^{-3}	2.0×10^{-2}	2.1×10^{-2}	0.056	3.7
	1.7×10^{-2}	2.0×10^{-2}	2.1×10^{-2}		
Acetic acid	1.9×10^{-2}	1.0×10^{-2}	1.3×10^{-2}	0.028	1.6
	1.1×10^{-2}	1.1×10^{-2}	1.5×10^{-2}	0.026	2.8

[a]The quantum yields of formation of the cyclopentane thiols. The superscripts 1 and 2 indicate the different thiols in order of elution from the vpc column.
[b]The quantum yield of disappearance of the thioketone.

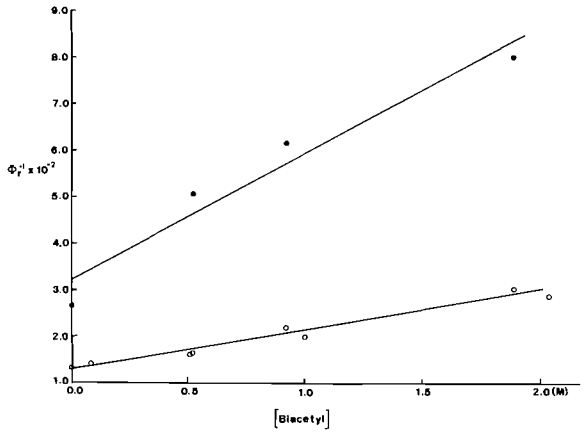

FIG. 1. The quantum yields of formation at **4** (●) and **5** (○) from the π,π^* excited thione **2***g* in the presence of biacetyl in benzene. The slope of **4** is $2.7 \times 10^{-2}\,M^{-1}$, intercept 320; the slope of **5** is $89\,M^{-1}$, intercept 125.

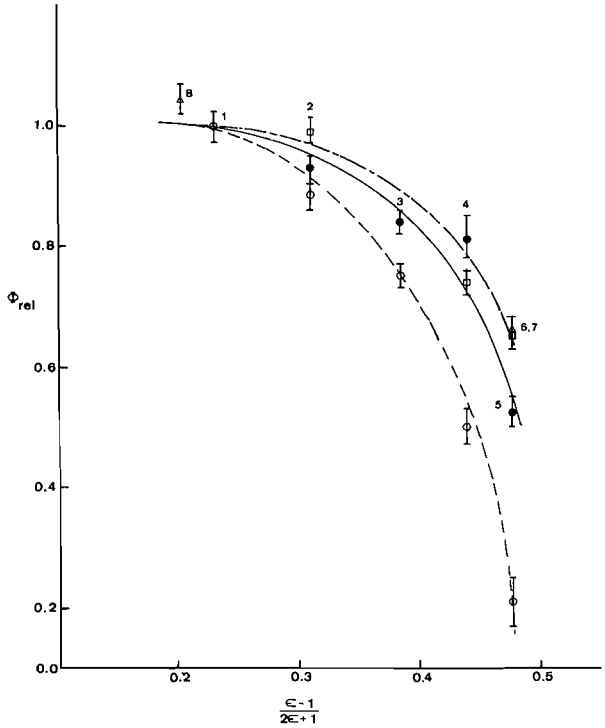

FIG. 2. Solvent effect on the quantum yield of photocyclization of π,π^* excited thiones at room temperature. The quantum yields (Φ_{rel}) are expressed relative to that in benzene. Solvents: 1, benzene; 2, 1,2-dimethoxyethane; 3, ethyl acetate; 4, *tert*-butyl alcohol; 5, ethanol; 6, acetic acid; 7, acetonitrile; 8, cyclohexane. Reactions studied are **2***g* → **4** (○), **2***g* → **5** (●), photocyclization of **2***c* (△) and **2***d* (□).

sensitization of the reaction with benzophenone, 2-acetonaphthone, and chrysene (E_T 69, 59.4, and 56.6 kcal/mol) was unsuccessful.

The photocyclization of **2***d* and **2***g* was studied at short wavelength in solvents of different polarities. The results, together with those observed previously for **2***c*, are given relative to that in benzene, and are plotted against the solvent polarity function $\{2(\varepsilon - 1)/2\varepsilon + 1\}$ (3) (Fig. 2). All efficiencies decrease with increasing polarity, **4** being most sensitive.

Charge Transfer Studies

The fluorescence of **2***a* was quenched by a variety of molecules whose excited states were higher than the π,π^* state of the thione. Using hexane and acetonitrile as solvents, the logarithms of the quenching rate constants were plotted against the ionization potential of the quenchers (Figs. 3 and 4). Two values for **2***b* (triethylamine and ethyl vinyl ether) are included in Fig. 3. The excited thiones appear to act as electron acceptors with regard to all species except acrylonitrile and fumaronitrile, towards which they act as donors. The photocyclization itself is also quenched by electron donors; the quenching of **2***c* and **2***d* by triethylamine has already been reported (1*c*); the quenching of the cyclization of **2***c* by di-*n*-butyl sulfide is shown in Fig. 5.

Reduction Potentials of Thiones

In Table 2 are presented the polarographic half-wave potentials of aromatic thioketones in dry acetonitrile containing 0.1 M tetraethylammonium perchlorate at 20°C. The potentials were measured against a silver – silver chloride electrode (aqueous) after removal of oxygen by purging with nitro-

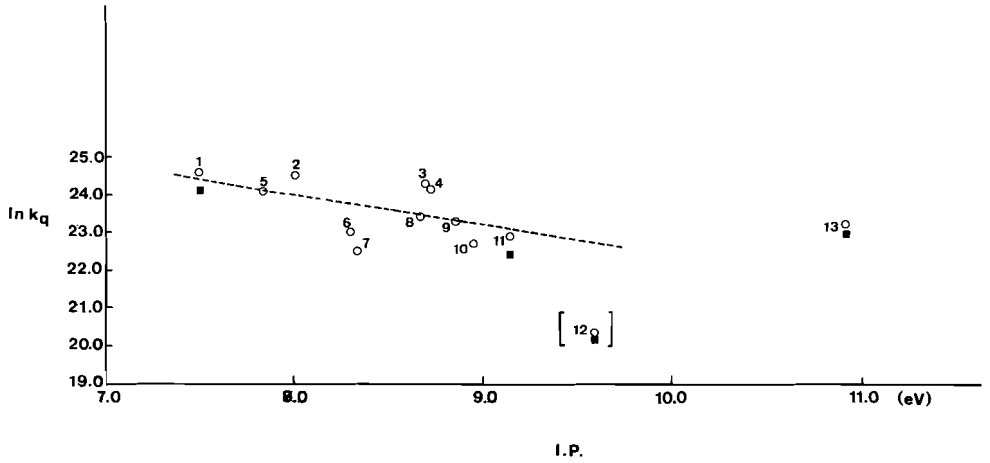

FIG. 3. Plot of the logarithm of fluorescence quenching rate constant against the ionization potential of quencher in hexane at 20°C. Thiones studied are **2***a* (○) and **2***b* (■). Quenchers: 1, triethylamine; 2, diethylamine; 3, 2-butylamine; 4, 2-propylamine; 5, 2,5-dimethyl-2,4-hexadiene; 6, di-*n*-butylsulfide; 7, 2,3-dihydropyran; 8, 2-methyl-2-butene; 9, isoprene; 10, cyclohexene; 11, ethyl vinyl ether; 12, diethyl ether (at the limit of detection; value may not be real); 13, acrylonitrile. The slope obtained by least-squares fitting method was $-0.86\,eV^{-1}$ (diethyl ether and acrylonitrile were excluded).

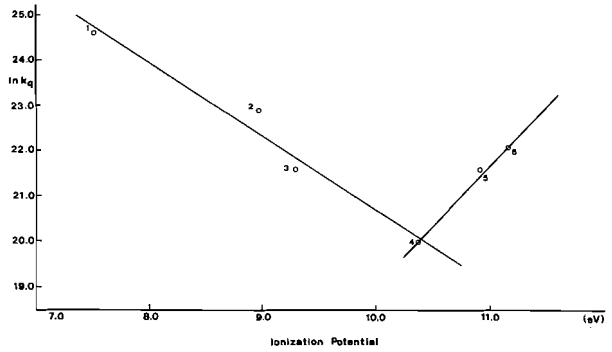

FIG. 4. Plot of logarithm of the fluorescence quenching rate constant against the ionization potential of quencher for thione **2***a* in acetonitrile at 20°C. Quenchers: 1, triethylamine; 2, cyclohexene; 3, pyridine; 4, acetic acid; 5, acrylonitrile; 6, fumaronitrile. The slopes of both lines obtained by least-squares fitting method were $-1.63\,eV^{-1}$ for donors and $2.7\,eV^{-1}$ for acceptors.

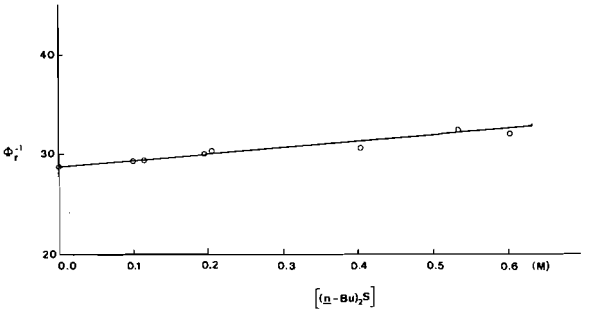

FIG. 5. Plot of the reciprocal of quantum yield of photocyclization of **2***c* against the concentration of di-*n*-butylsulfide in benzene. Slope and intercept obtained by least-squares fitting method were $6.1\,M^{-1}$ and 28.7.

gen. The polarographic current–voltage curves were obtained using a PAR model 170 system.

The reduction potentials of the thiones can also be estimated by the two following equations.

(*a*) Elofson's equation (4) (eq. [1]):

$$[1]\quad \text{Absorption maximum of the } {}^1n,\pi^* \text{ band (eV)} = (-0.59 \pm 0.04)E_{\frac{1}{2}}^{Red} + (1.46 \pm 0.11)$$

The $E_{\frac{1}{2}}^{Red}$ is the half-wave potential of the reduction of thioketone measured against the SCE. The energy of the maximum of the ${}^1n,\pi^*$ band of aralkyl thioketone is 2.14 eV. Therefore, the estimated reduction potential of aralkyl thioketone, against the SCE, is −1.17 V. Similarly, the reduction potential of thiobenzophenone is estimated to be −0.91 V.

(*b*) Loutfy's equation (5) (eq. [2]):

$$[2]\quad E_{\frac{1}{2}}^{Red}(C{=}S) = 1.06\,E_{\frac{1}{2}}^{Red}(C{=}O) - 0.79$$

vs. $(Ag/AgCl_s)$ electrode in acetonitrile.

Taking the reduction potential of acetophenone (−1.99 V in DMF) against the SCE (6) the thiones may be estimated as −1.32 V against $Ag/AgCl_s$ in acetonitrile (solvent correction −0.4 V (7)); correction for $Ag/AgCl_s$ in water against SCE at 20°C is

TABLE 2. Reduction potentials of aromatic thioketones in acetonitrile at 20°C

Thione	Concentration ($M \times 10^{-3}$)	$E_{\frac{1}{2}}^{red}$(V)
Thiobenzophenone	4.28	−1.03
2*e*	3.06	−1.35
2*f*	2.19	−1.30
2*g*	2.19	−1.35

For personal use only.

−0.04 V (7). The assumption is made that alkyl sidechains have no effect. The estimated potential of thiobenzophenone (−1.17 V vs. SCE in MeCN) is −1.13 V vs. $Ag/AgCl_s$.

Discussion

From the results reported a number of conclusions can be drawn: (*a*) in the absence of ethereal oxygen abstraction occurs only at the δ position; (*b*) with an ethereal oxygen at the δ position, and if no other δ hydrogen is available, abstraction occurs at ε and γ positions (the latter being accompanied by Type II cleavage); (*c*) when activated ε (primary) and δ (secondary) hydrogen is available (as in **2***h*) roughly equal amounts of δ and ε cyclization products are obtained. As might have been expected, the position of attack is the result of balanced stereochemical and energetic factors and the former is not, as was originally thought in the absence of results from the ethers, overwhelming.

Although the Type II process is observed in **2***g* (Scheme 2), following excitation into both upper and lower excited states, they follow essentially separate paths; that is, the product derived from excitation into the S_2 state is *not* in large measure obtained by preliminary internal conversion to the lower excited state. This follows because the quantum yield of formation of one of the stereoisomers of the cyclobutane thiols **4** was 3.5×10^{-3} from S_2 as against $< 10^{-4}$ upon excitation into the S_1 state. Further, this Type II reaction could not be sensitized with the higher efficiency with sensitizers of energy from 55–69 kcal/mol, nor could it, when initiated from S_2, be quenched with piperylene. There are, therefore, two distinct pathways for the Type II cleavage and closure, whereas the accompanying product from S_2 excitation, **5** ($\phi = 7 \times 10^{-3}$), is not formed on S_1 excitation and is derived by a single pathway.

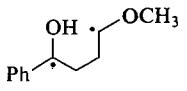
In the short wavelength excitation of **2***g* both **4** and **5** formation should, then, derive from a single intermediate. Both processes are quenched by biacetyl, and the Stern–Volmer plots (Fig. 1) indicate, within experimental error, the same lifetime for the common responsible excited state (170 and 140 ps respectively). The rates of formation of **4** and **5** are $2.1 \times 10^7\ s^{-1}$ and $5.2 \times 10^7\ s^{-1}$ respectively. The entropy required to freeze an internal C—C rotation in achieving the transition state is 4–5 gibbs (8) yet, despite the fact that two more rotations have to be frozen in its formation, **5** is generated faster than **4**. We attribute this to the difficulty the γ-hydrogen has in attaining the reactive volume of space (π) above and below the plane of the thione group (9).

In view of the efficient intersystem crossing in thiones the Type II products derived from S_1 excitation probably derive from the triplet (10). The difference in quantum yield obtained by this pathway to these products and that obtained from S_2 has at least three sources.

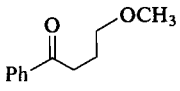
Firstly, the abstractions themselves differ in efficiency for energetic reasons. Good values are not available for the thiocarbonyl group, but a crude approximation using Benson's data (11) suggests that from the triplet (E_T = 46 kcal/mol) biradical formation might be close to thermoneutral, depending upon the value chosen for the conjugated thione and the weakening of S—H bond by an adjacent carbon-centered radical. Similarly, one may assume that the π bond energy of the C=S linkage is roughly equal to that of the triplet,[3] when the overall reaction involves the additional C—H cleavage and SH formation. Biradical formation, on the other hand, from the S_2 state is very exothermic (1*c*). Secondly, the geometry of the abstractions, as discussed elsewhere (9), is different. Since n,π^* and π,π^* abstractions occur in orthogonal planes, the conformational requirements in the transition state differ, γ abstraction from S_2 appearing markedly more difficult. Thirdly, the n,π^* pathway leads first to a triplet biradical. In its longer lifetime conformational change may occur to favour one or other of the chemical processes (elimination closure and disproportionation) open to it after spin relaxation to the singlet. The S_2 pathway presumably leads directly to the singlet.

It is interesting that the biradical **17***b* derived from **17***a* gives cyclobutanol and methyl vinyl ether in a ratio of 1:2.5 (13) whereas the biradical **18** derived from β-phenylethylthiobenzoate (14) gives only the elimination product. From **2***g* (Scheme 2) the ratio of cyclobutanethiol **4** to ethyl vinyl ether (n,π^*) was found to be 4:1. The lack of elimination from the biradical may be attributed to the presence of the two α-methyl substituents which in the transoid conformation for elimination are eclipsed with the thiol and phenyl groups **19**. This effect may also be observed in the ratio of cyclization and elimination of biradicals derived from thiobenzoate abstraction. As the β-substituent becomes larger the cyclization becomes more important, and becomes the major process when a *tert*-butyl group is present, as in **20**.

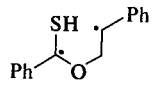
[3]This appears to be approximately true for carbonyl compounds. It is in approximate agreement with Benson's estimate of 55 kcal/mol for the π strength of thioformaldehyde (11). The energy of the $^3n,\pi^*$ state of thioformaldehyde was calculated to be 36–44 kcal/mol (12).



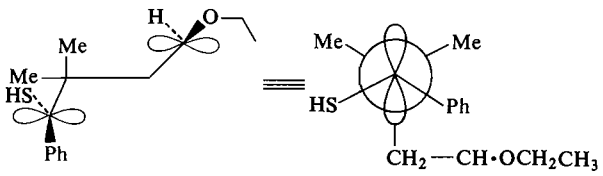
17*b*



17*a*

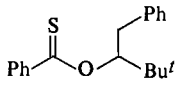


18



19

We have considered the possibility that intramolecular charge transfer occurs from the oxygen to the excited thione, followed by proton transfer. We believe this to be excluded both because of the poor quenching of the $^1\pi,\pi^*$ thione by ether and because of the decrease in the quantum yields of **4**, **5**, and other cyclopentane thiols with increasing solvent polarity (Fig. 2). The invariance of the π,π^* absorption band of **2***d* and **2***j* with solvent is also indicative of a lack of interaction. The small decrease in quantum yield observed may be because of different conformation populations in the various solvents, given that the conformers have different dipole moments.[4] Further, in protic solvents hydrogen bonding to the ethereal oxygen may also cause conformer population changes.



20

Charge Transfer in the $^1\pi,\pi^*$ Excited Thiones

The interactions of the π,π^* excited thioketone and some electron-donating and electron-accepting quenchers were studied in two ways: the change of the fluorescence quantum yield and the change of the quantum yield of photocyclization in the presence of charge transfer quenchers.

The free energy change for the formation of a charge transfer complex, ΔG_{CT}, in the excited state is given by eq. [3] (17).

$$[3] \quad \Delta G_{CT} = E(D/D^+) = E(A^-/A) = \Delta E_{o,o} + \Delta$$

where $E(D/D^+)$ is the oxidation potential of the donor, $E(A^-/A)$ is the reduction potential of the acceptor, $\Delta E_{o,o}$ is the excitation energy of the thioketone, Δ is the interaction term including the Coulombic term and entropy of interaction. Since the ionization potential, IP, and electron affinity, EA, of a molecule are linearly related to its oxidation potential and reduction potential, respectively, the above equation can be written as in eq. [4] (18).

$$[4] \quad \Delta G_{CT} \approx IP - EA - \Delta E_{o,o} + C$$

For the same chromophore, with a system of donors, ΔG_{CT} and the logarithm of the rate constant of fluorescence quenching, k_q, are linearly proportional to the ionization potential of the quencher (18). The relation for **2***a* and **2***b* is shown in hexane in Fig. 3 and for **2***a* in acetonitrile in Fig. 4. With the exception of acrylonitrile and fumaronitrile an approximately linear relationship is obtained. These substances have high ionization potentials and we conclude that here the excited thione is acting as a donor.

The slopes of these plots are for **2***a* and **2***b* $-0.86\,eV^{-1}$ (hexane) and for **2***a* $-1.63\,eV^{-1}$ and $2.7\,eV^{-1}$ for donors and acceptors respectively in acetonitrile. These values are far less than the value, $17.06\,eV^{-1}$ (18, 19), predicted for systems in which quenching of fluorescence occurs via complete electron transfer. A 3% charge transfer contribution in the exciplexes of aromatic thiones and olefins has been claimed by Turro and Ramamurthy (20).

This small charge-transfer interaction in the encounter complex was also observed in the variation of the quantum yield of photocyclization of **2***c* with the concentration of amine and sulfide: di-*n*-butyl sulfide, having a higher ionization potential, quenches the cyclization at a lower rate constant (Fig. 5, $k_q = 9 \times 10^8\,M^{-1}\,s^{-1}$) than triethylamine (1*c*). Although only these two quenchers were studied, their ionization potentials and quenching rate constants suggest also a small charge-transfer interaction between the excited thione and donor.

The processes of formation of **5** and the photocyclization of **2***c* and **2***d* appear very similar in solvents of various polarities, as shown in Fig. 2. Since there cannot be any intramolecular charge transfer in **2***c* and **2***d*, this parallel behaviour suggests that the formation of **5** should also involve only a neutral biradical intermediate with no charged species preceding it. This is consistent with the observed very small (if real) charge transfer interaction between the π,π^* thione and ether. The intramolecular charge transfer mechanism leading to **5** is thus excluded. Obviously, the formation of **4** cannot involve charged species either, for similar reasons. Such sensitivity to solvent as is shown in the formation of **4** may be attributed to solvent dependent conformational changes.

[4]See, for instance, ref. 15. The thiocarbonyl group has a similar dipole moment to that of the carbonyl group (16).

Experimental

General Procedures

The ^{1}H nmr spectra were obtained in carbon tetrachloride solution unless otherwise stated and are given in parts per million from internal Me_4Si. Mass spectra were obtained on an M-66 at 70 eV, relative intensities being given parenthetically. Melting points and boiling points are uncorrected; temperatures recorded for bulb-to-bulb distillation are external; petroleum ether (PE) refers to the fraction of boiling range 60–80°C. For vapor-phase chromatography (vpc) the following columns were used: (A) 15% FFAP on Chromosorb W, 80/100 (HP), $\frac{1}{4}$ in. × 6 ft; (B) 10% SE 30 on Chromosorb W, 80/100 (acid washed), $\frac{1}{4}$ in. × 6 ft.

Purifications of Solvents and Reagents

Commercial spectrograde benzene and cyclohexane were used without further treatment, while commercial spectrograde hexane was passed through a column of dry alumina; acetic acid was first distilled over chromium trioxide, and then fractionally distilled, after stirring with molecular sieve (4A) at 116°C, *tert*-butyl alcohol was fractionated twice over sodium after refluxing overnight; dimethoxyethane was obtained by distilling commercial product over calcium hydride (CaH_2). Acetonitrile was refluxed over CaH_2 for 12 h and fractionally distilled; cyclohexene was distilled over P_2O_5 at 83°C under nitrogen; isopropanol and ethyl benzene were fractionally distilled over sodium; 2,5-dimethyl-2,4-hexadiene was first distilled and then purified by vpc (5% DCC30). Acrylonitrile and ethyl vinyl ether were freshly distilled under nitrogen before use; commercial anhydrous analytical grade diethyl ether was distilled over molecular sieve (5A) before use; triethylamine, isopropyl amine, *sec*-butyl amine, diethyl amine, and pyridine were freshly distilled over sodium hydroxide pellets under nitrogen. Biacetyl was distilled under nitrogen and kept under reduced pressure; isoprene was distilled over lithium aluminium hydride; 2,3-dihydropyran was refluxed over CaH_2 and freshly distilled; diethyl maleate was fractionated through a spinning band column; fumaronitrile was sublimed. All thioketones were purified by vpc (Column B at 120°C); piperylene was freshly distilled.

Preparative Photochemistry

The reactions were carried out near room temperature using a 450-W Hanovia medium-pressure lamp.

Ketone Preparations

The ketones were prepared as described previously by condensing the enolate anion of isobutyrophenone and the appropriate bromide in boiling toluene or benzene.

1-Phenyl-3-methoxy-2,2-dimethylpropanone (1i)

This was prepared from isobutyrophenone (7.4 g, 0.05 mol), sodium amide (2 g), and chloromethyl methyl ether (8 g, 0.1 mol) in refluxing toluene (150 mL). The yield was 85% (8.3 g): bp 56°C (0.5 Torr); ^{1}H nmr δ: 7.35 (m, 5, arom), 3.39 (s, 2), 3.2 (s, 3), 1.2 (s, 6, CMe_2); mass spectrum *m/e*: 176 (M^+, 0.3), 148 (7), 105 (100), and 77 (54).

1-Phenyl-5-methoxy-2,2-dimethylpentanone (1j)

3-Methoxy propanol was prepared by the method of Smith and Sprung (21) in 71% yield. Phosphorus tribromide (6 g) was added to the alcohol (18 g, 0.2 mol) slowly with stirring at −15°C. The mixture was distilled after being stirred for 2 h at room temperature. The fraction boiling below 135°C was collected, washed with water, dried with $CaCl_2$, and redistilled to give 1-bromo-3-methoxypropane (6.1 g, 40%) bp 130–133°C (lit. (22) bp 132–133°C). Condensation of isobutyrophenone enolate anion (from 5.7 g of ketone and 1.8 g of sodium amide in 80 mL of toluene) with this bromide (6.1 g, 0.04 mol) gave the ketone **1o** in 59% yield (4.6 g): bp 105–106°C (0.25 Torr); ^{1}H nmr δ: 7.5–7.26 (m, 5, arom), 3.13 (m, 5), 1.7 (m, 4), 1.26 (s, 6, CMe_2); mass spectrum *m/e*: 220 (M^+, 2), 188 (8), 148 (3), 115 (38), 105 (100), and 77 (32). *Mol Wt.* calcd. for $C_{14}H_{20}O_2$: 220.1462; found (ms): 220.1468.

1-Phenyl-4-ethoxy-2,2-dimethylbutanone (1g)

This was prepared from 1-bromo-2-ethoxyethane and isobutyrophenone in 39% yield: bp 94–95°C (0.2 Torr); ^{1}H nmr δ: 7.13 (m, 5, arom), 3.34 (t, 2, J = 7 Hz), 3.26 (q, 2, J = 6.5 Hz), 2.0 (t, 2, J = 7.0 Hz), 1.26 (s, 6, CMe_2), 1.00 (t, 3, J = 6.5 Hz); mass spectrum *m/e*: 220 (M^+, 3) 148 (90), 105 (100). *Mol. Wt.* calcd. for $C_{14}H_{20}O_2$: 220.1462; found (ms): 220.1469.

1-Phenyl-2,2-dimethyl-pent-4-enone

This was prepared by condensing isobutyrophenone enolate anion (from 40 g of ketone and 10.7 g of sodium amide in 700 mL of toluene) with allyl bromide (36 g, 0.3 mol) in 87% yield (44 g): bp 68–72°C (0.1 Torr); ^{1}H nmr δ: 7.4 (m, 5, arom), 4.36–6.0 (m, 3), 2.46 (d, 2, J = 7 Hz), 1.26 (s, 6, CMe_2); mass spectrum *m/e*: 188 (M^+, 5), 105 (95), and 77 (100). *Mol. Wt.* calcd. for $C_{13}H_{16}O$: 188.1200; found (ms): 188.1201.

1-Phenyl-4,5-dimethoxy-2,2-dimethylpentanone (1h)

To a cooled solution (−10°C) of the ethylene ketal of the previous ketone (18.8 g, from the ketone ethylene glycol in benzene containing *p*-toluenesulfonic acid) in *tert*-butyl alcohol (800 mL) and ice-water (560 mL), $KMnO_4$ (19 g) and NaOH (4 g) in water (640 mL) at 0°C were added with vigorous stirring. After 5 min the mixture was bubbled with SO_2 until the manganese dioxide was dissolved. After isolation ($CHCl_3$) the diol was obtained as white crystals (21 g). The crude diol (mp 77–79°C) was then methylated with methyl iodide (18 mL) in 1,2-dimethoxyethane (125 mL, distilled from LAH) and sodium hydride (3 g) slowly added below 50°C. After 4 h the mixture was poured into water and the crude ketal isolated ($CHCl_3$). This was added to methanol–water (4:1, 300 mL) containing HCl (3 mL) and stirred at 60°C (12 h). After neutralization, isolation and distillation gave **1h** in 77% yield (15.5 g): bp 90–92°C (0.05 Torr); ^{1}H nmr δ: 7.3 and 7.6 (m, 5, arom), 3.36 (m, 3), 3.26 (s, 3), 3.16 (s, 3) 1.60–2.40 (m, 2), 1.23 (s, 6, CMe_2); mass spectrum *m/e*: 205 (100), 148 (9), 105 (85), and 89 (76). *Anal.* calcd. for $C_{15}H_{22}O_3$: C 71.97, H 8.86; found: C 72.04, H 8.91.

Thioketone Preparations

The thioketones were prepared from the corresponding ketones using previously reported methods (23).

1-Phenyl-3-methoxy-2,2-dimethylthiopropanone (2i)

The thione was prepared from **1i** and P_2S_5 in refluxing pyridine in 61% yield: λ_{max} (C_6H_{12}): 558, 296, and 226 nm (ε 110, 4980, and 13 600); ^{1}H nmr δ: 7.2 (m, 5, arom), 3.5 (s, 2), 3.28 (s, 3), 1.35 (s, 6, CMe_2); mass spectrum *m/e*: 208 (M^+, 15), 176 (25), 143 (34), 121 (55), 77 (30), and 45 (100). *Mol. Wt.* calcd. for $C_{12}H_{16}OS$: 208.0921; found (ms): 208.0914.

1-Phenyl-5-methoxy-2,2-dimethylthiopentanone (2j)

This compound was prepared from ketone **1j** with H_2S and HCl in absolute ethanol at −78°C in 45% yield, bulb-to-bulb distillation 82–90°C (0.2 Torr); λ_{max}(C_6H_{12}): 567, 297, and 229 (ε 105, 3850, and 9480; ^{1}H nmr δ: 7.13 (m, 5, arom), 3.18 (s, 3), 3.20 (m, 2), 1.70 (m, 4), 1.34 (s, 6, CMe_2); mass spectrum *m/e*: 236 (M^+, 37), 204 (12), 165 (52), 122 (100), 121 (58), and 113 (28). *Mol. Wt.* calcd. for $C_{14}H_{20}OS$: 236.1234; found (ms): 236.1215.

1-Phenyl-4-ethoxy-2,3-dimethylthiobutanone (2g)

The reaction of ketone **1g** and H_2S, HCl in absolute ethanol at −78°C gave thione **2g** in 55% yield, bulb-to-bulb distillation at 65–70°C (0.08 Torr); λ_{max}(C_6H_{12}): 566, 297, and 228 nm (ε 110,

For personal use only.

3830, and 8960); ^{1}H nmr δ: 7.13 (bs, 5, arom), 3.45 (t, 2, J = 7.0 Hz), 3.42 (q, 2, J = 6.5 Hz), 2.10 (t, 2, J = 7.0 Hz), 1.40 (s, 6, CMe_2), 1.09 (t, 3, J = 6.5 Hz); mass spectrum *m/e*: 236 (M^+, 2) 164 (100), 121 (92). *Mol. Wt.* calcd. for $C_{14}H_{20}OS$: 236.1234; found (ms): 236.1217.

*1-Phenyl-4,5-dimethoxy-2,2-dimethylthiopentanone (2*h)

This compound was prepared from the corresponding ketone with H_2S and HCl in absolute ethanol at −78°C in 45% yield, bulb-to-bulb distillation at 82–90°C (0.2 Torr); $\lambda_{max}(C_6H_{12})$: 558, 295, and 228 nm (ε 111, 3730, and 8570); ^{1}H nmr (CCl_4 + pyridine) δ: 3.30 (m, 3), 3.23 (s, 3), 3.15 (s, 3), 2.65 (m, 2), 1.42 (s, 3), 1.33 (s, 3); mass spectrum *m/e*: 234 (5), 221 (10), 164 (100), and 121 (50). *Anal.* calcd. for $C_{15}H_{22}O_2S$: C 67.64, H 8.33, S 12.01; found: C 68.39, H 8.32, S 11.68.

*Irradiation of 2*i

(a) Above 445 nm

The thione (156 mg) in benzene (150 mL) was irradiated through Corning filter 3-72 for 5 days. The ^{1}H nmr spectrum showed no change.

(b) Above 290 nm

The thione (210 mg) in benzene (200 mL) was irradiated through Pyrex to complete conversion (12 h). The solvent was evaporated *in vacuo*. The residue was dissolved in chloroform (3 mL) and glacial acetic acid (7 mL), and mercury acetate (400 mg) was added with stirring. After 2 h, the mixture was diluted with chloroform and filtered through Celite. The filtrate was washed with dilute sodium bicarbonate and dried over $MgSO_4$. Thin-layer chromatography gave 1,2-dihydrofuran **16** (148 mg, 85%) mp 32°C; ^{1}H nmr δ: 7.18 (m, 5, arom), 6.41 (s, 1), 4.05 (s, 2), 1.32 (s, 6, CMe_2); mass spectrum *m/e*: 174 (M^+, 55) 159 (73), 121 (30), 117 (100), and 47 (44). *Mol. Wt.* calcd. for $C_{12}H_{14}O$: 174.1044; found (ms): 174.1038.

*Irradiation of 2*j

The thione (153 mg) in bezene (10 mL) was irradiated (Pyrex) to complete conversion (8 h) to give **13** in virtually quantitative yield; bp 78–85°C (0.4 Torr). The ^{1}H nmr data indicated a 50:50 mixture of isomers, most clearly in the duplication of the methoxy peaks (3.33, 3.26), SH (2.31, 1.78), and geminal methyl groups (1.24, 1.17 (*trans* to phenyl); 0.82, 0.55 (*cis* to phenyl)); mass spectrum *m/e*: 202 (27), 187 (100), 129 (10), and 91 (9). *Anal.* calcd. for $C_{14}H_{20}OS$: C 71.16, H 8.53, S 13.54; found: C 71.24, H 8.70, S 13.52.

*Irradiation of 2*g

(a) Through Pyrex

A solution of thione (600 mg) in benzene (30 mL) was irradiated (Pyrex) for 40 h (>90% conversion). Preparative tlc (pet. ether/CH_2Cl_2, 5:2) afforded a partial separation into one stereoisomer, **4***a*, (112 mg, 19%, faster band) and a mixture of another isomer of **4***b* and **5** (396 mg, 60%). The thiol **4***a* (distilled 50–52°C/0.05 Torr); ^{1}H nmr δ: 7.96 and 7.32 (m, 5, arom), 4.41 (t, 1, X part of ABX, $J_{AX} = J_{BX}$ = 8 Hz), 3.62 (q, 2, J = 6.6 Hz), 2.2–1.85 (m, 2, AB part of ABX, J_{AB} = 11 Hz), 1.95 (s, 1, SH), 1.31, 0.67 (s, 3H each, CMe_2), 1.16 (t, 3, J = 6.6 Hz); mass spectrum *m/e*: 202 (100) and 187 (55). *Anal.* calcd. for $C_{14}H_{20}OS$: C 71.16, H 8.53, S 13.54; found: C 71.09, H 8.42, S 13.45.

The separation of **4***b* and **5** was achieved by vpc (column B, 165°C). The thiol **4***b* was eluted first (49 min, 29%), followed by **5** (70 min, 40%). The former (distilled 50–55°C/0.08 Torr) had ^{1}H nmr δ: 7.95 and 7.32 (m, 5, arom), 4.40 (t, X part of ABX, $J_{AX} = J_{BX}$ = 8 Hz), 3.55 (q, 2, J = 7 Hz), 2.12–1.79 (m, 2, AB part of ABX, J_{AB} = 11 Hz), 1.99 (s, 1, SH), 1.35 and 0.8 (s, 3H each, CMe_2), 1.23 (t, 3, J = 7 Hz); mass spectrum *m/e*: 236 (M^+, 2), 202 (100), and 187 (22). *Mol. Wt.* calcd. for $C_{14}H_{20}OS$: 236.1234; found (ms): 236.1218. The tetrahydropyran **5** was purified by tlc, distilled (61–65°C/0.04 Torr); ^{1}H nmr δ: 7.16 (m, 5, arom), 4.14 (q, 1, J = 6.5 Hz), 3.87 (m, 2), 1.70–2.24 (m, 2) (AA′BB′, J_{AB} = 14 Hz, $J_{AA'} = J_{AB'}$ = 2, $J_{BA'}$ = 10, $J_{BB'}$ = 7 Hz), 1.2 (s, 1, D_2O exchangeable), 1.38 (d, 3, J = 6.5 Hz), 1.12 and 0.67 (s, 3H each, CMe_2); mass spectrum *m/e*: 236 (M^+, 30), 202 (51), and 187 (100). *Mol. Wt.* calcd. for $C_{14}H_{20}OS$: 236.1234; found (ms): 236.1222.

Reaction of **5** (40 mg) with mercuric acetate in acetic acid gave the corresponding dihydropyran (27 mg, 77%) distilled at 50–53°C/0.05 Torr; $\lambda_{max}(C_6H_{12})$: 246 nm (ε 4500); ^{1}H nmr δ: 7.13 (m, 5, arom), 3.98 (m, 2), and 1.73 (m, 2) (AA′BB′: J_{AB} = 5, $J_{AB'}$ = 5.4, $J_{AB'} = J_{BA'}$ = 1.4, $J_{AA'} = J_{BB'}$ = 4 Hz), 1.38 (s, 3, vinyl methyl), 0.97 (s, 6, CMe_2); mass spectrum *m/e*: 202 (M^+, 25) and 187 (100). *Mol. Wt.* calcd. for $C_{14}H_{18}O$: 202.1357; found (ms): 202.1363.

(b) Above 445 nm

The thione (23 mg) in benzene (5 mL) was irradiated (two 450-W lamps, Corning filter 3-72, 6 days, 60% conversion); vpc analysis (Column A, 170°C) showed the presence of three major peaks: (20 min, 20%; 26 min, 25%), the two isomers of **4**, and (36 min) the thione. The thiols were collected and identified by ir spectra. The tetrahydropyran **5** was absent.

Identification of Ethyl Vinyl Ether

A solution of thione **2***g* (209 mg) in benzene (10 mL) was irradiated (Pyrex, 90% conversion, 24 h) and the product examined by vpc (Column B, 40°C).[5] A peak corresponding to ethyl vinyl ether (~5%) was observed, and the substance identified by collection and comparison of ir spectra. By irradiation at λ > 445 nm the yield of ether was ca. 10%.

*Irradiation of 2*h

The thione (500 mg) in benzene (45 mL) was irradiated to complete conversion (Pyrex, 24 h). Preparative tlc (pet. ether/ethyl acetate, 21:4) gave two major fractions A (slow) and B. Fraction A, after rechromatography, was recrystallized from ethanol to give **11** (180 mg, 36%); mp 60–61°C; ^{1}H nmr (C_6D_6) δ: 3.97, 4.22 (AB quartet, 2, J = 12 Hz), 3.85 (m, 1), 3.25 (m, 3), 3.14 (s, 3, OCH_3), 1.8 (dd, 1, J_1 = 10, J_2 = 14 Hz), 1.16 (s, 1, SH), 1.09, 0.84 (s, 3H each, CMe_2), 0.96 (dd, 1, J_1 = 2.5, J_2 = 14 Hz); (CCl_4): 4.05, 4.11 (AB quartet, 2H, J = 12 Hz), 3.9 (m, 1), 0.89 (s, 3); mass spectrum *m/e*: 232 (80), 217 (37), and 121 (100).

The thiol was dethiolated (200 mg) with mercuric acetate, purified by preparative tlc (CH_2Cl_2) to give **15** (111 mg, 70%), distilled at 76–80°C/0.08 Torr; $\lambda_{max}(C_6H_{12})$: 246 (ε 4600); ^{1}H nmr δ: 7.13 (s, 5, arom), 6.10 (s, 1, vinyl hydrogen), 4.05 (m, 1), 3.32 (s, 3, OCH_3), 2.88 (m, 2, AB part of ABX, J_{AB} = 10, $J_{AX} = J_{BX}$ = 5 Hz), 1.65 (m, 2, AB part of ABX, J_{AB} = 13.5, J_{AX} = 5, J_{BX} = 7 Hz), 1.20, 0.92 (s, 3H each, CMe_2); mass spectrum *m/e*: 232 (M^+, 100) and 217 (37). *Mol. Wt.* calcd. for $C_{15}H_{20}O$: 232.1462; found (ms): 232.1463.

Fraction B (200 mg) was rechromatographed using multi-development (pet. ether/ethyl acetate, 20:1, five developments) to give fractions C (80 mg) and D (110 mg). Fraction C, distilled 75–80°C (0.08 Torr), was **10**; ^{1}H nmr δ: 4.49 (d, 1H, J = 6 Hz), 3.9 (m, 1), 3.00, 2.78 (s, 3H each, OMe), 2.44 (s, 1, SH), 1.70–1.47 (m, 2, AB part of ABX, J_{AB} = 14, J_{AX} = 2.5, J_{BX} = 5 Hz), 1.13, 0.68 (s, 3H each, CMe_2); mass spectrum *m/e*: 232 (49) and 217 (100). This thiol was converted with mercuric acetate into the dimethoxy-dihydrofuran **14** (70 mg, 80%) described below.

The fraction D was treated with mercuric acetate and the olefin **14** (69 mg, 71%) was isolated by preparative tlc (pet. ether/ethyl acetate, 75:6), distilled (56–60°C/0.05 Torr); $\lambda_{max}(C_6H_{12})$: 254 (ε 4400); ^{1}H nmr δ: 7.34 (s, 5, arom), 4.22 (dd, 1,

[5]Care was taken to ensure the absence of the corresponding ketone. No isobutyrophenone was detected in the product.

$J_1 = 3.5$ Hz, $J_2 = 7$ Hz), 3.42, 3.36 (s, 3H each, OCH_3), 1.94 (dd, 1, $J_1 = 13.5$, $J_2 = 7$ Hz), 1.71 (dd, 1, $J_1 = 13.5$, $J_2 = 3.5$ Hz), 1.12, 0.98 (s, 3H each, CMe_2); mass spectrum *m/e*: 232 (M^+, 31) and 217 (100). *Mol. Wt.* calcd. for $C_{15}H_{20}O_2$: 232.1462; found (ms): 232.1460.

Irradiation of 2h *Above 445 nm*

A solution of **2***h* (190 mg) in benzene (40 mL) was irradiated to complete conversion (30 days). Vapor phase chromatographic analysis of the product (10% Carbowax 20M on Chromosorb P, 80/100, acid washed, ¼in. × 6 ft, 170°C) showed the presence of four main components (retention time 51, 54, 68, 77 minutes) but the above thiols (retention time **11**, 62, **10**, 64, and 70.5 min) were absent; column B at 175°C showed the absence of the tetrahydropyran.

Kinetic Studies

The samples were excited either with an Osram HBO 200 W high pressure mercury arc using an interference filter Schott #6672-02 (313 ± 5 nm) with ferrioxalate actinometry, or with an Ushio UXL-2003D Xenon ZKW discharge lamp in a calibrated Jasco Spectroirradiator at the appropriate wavelengths. Thiols were analyzed by vpc on a 6 ft glass column, using a flame detector (Aerograph 2400). Various conditions were used for different thiols.

Thiol	Calibration compound	Column temperature (°C)
13	*p*-Bromobiphenyl	140
4, 5	β-Acetonaphthalene	150

Fluorescence measurements were carried out on a Perkin Elmer MPF-4 spectrophotometer. The optical density of the samples was less than 0.1. The disappearance of thioketone was followed by the change of the optical density at the maximum of the n,π^* band.

Reduction Potentials

The half-wave potentials of the thioketones were measured in acetonitrile solution in a nitrogen atmosphere at room temperature with a PAR model 170 electroanalytical system. The potentials were measured with a dropping mercury electrode against the silver – silver chloride electrode. Each solution contained 0.1 *M* tetraethylammonium perchlorate and 10^{-3} *M* thioketone.

Received June 25, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

SHINKITI KOTO, SHIGERU INADA, TOYOSAKU YOSHIDA, MIYAKO TOYAMA, and SHONOSUKE ZEN. Can. J. Chem. **59**, 255 (1981).

The one-stage β-glucosylation of benzyl 3-*O*-acetyl-2,4-di-*O*-benzyl-α-D-glucopyranoside (**1**) with 2,3,4,6-tetra-*O*-benzyl-α-D-glucopyranose (**2**) using a mixture of *p*-nitrobenzenesulfonyl chloride, silver trifluoromethanesulfonate, and triethylamine, followed by deacetylation, gave benzyl *O*-(2,3,4,6-tetra-*O*-benzyl-β-D-glucopyranosyl)-(1→6)-2,4-di-*O*-benzyl-α-D-glucopyranoside (**3**). The disaccharide derivative **3** was then subjected to the β-glucosylation, followed by catalytic hydrogenation, to afford *O*-β-D-glucopyranosyl-(1→3)-*O*-[β-D-glucopyranosyl-(1→6)]-D-glucopyranose (**4**). The key intermediate **1** was prepared from D-glucose by way of a Fischer reaction, triphenylmethylation, a controlled benzylation, and detriphenylmethylation.

SHINKITI KOTO, SHIGERU INADA, TOYOSAKU YOSHIDA, MIYAKO TOYAMA et SHONOSUKE ZEN. Can. J. Chem. **59**, 255 (1981).

Un mélange de chlorure de *p*-nitrobenzènesulfonyle, de trifluorométhane sulfonate d'argent et de triéthylamine, provoque la β-glucosylation en une étape du *O*-acétyl-3 di-*O*-benzyl-2,4 α-D-glucopyrannoside de benzyle (**1**) par le tétra-*O*-benzyl-2,3,4,6 α-D-glucopyrannose (**2**) qui, suivie d'une déacétylation, donne le *O*-(tétra-*O*-benzyl-2,3,4,6 β-D-glucopyrannosyl)-(1→6)di-*O*-benzyl-2,4 α-D-glucopyrannoside de benzyle (**3**). La β-glucosylation du disaccharide **3**, suivie d'une hydrogénation catalytique, conduit au dérivé *O*-β-D-glucopyrannosyl-(1→3) *O*-[β-D-glucopyrannosyl-(1→6)]-D-glucopyrannose (**4**). On a préparé l'intermédiaire principal **1** à partir du D-glucose en le soumettant successivement à une réaction de Fischer, à une triphénylméthylation, à une benzylation contrôlée et finalement à une élimination du groupe triphénylméthyle.

[Traduit par le journal]

Introduction

In the past decade, various approaches to systematic synthesis of oligosaccharides have been reported (1). We ourselves have also presented a scheme for oligosaccharide synthesis systematically using a set of protecting groups (2). In all the approaches reported so far, however, building units have been coupled by modified Koenigs–Knorr reactions which always require the preparation of reactive intermediates such as glycosyl halides. Recently, we have found that an equimolar mixture of *p*-nitrobenzenesulfonyl chloride, silver trifluoromethanesulfonate, and triethylamine (3) is of use for activation of the hemiacetal hydroxyl groups of a stable intermediate, 2,3,4,6-tetra-*O*-benzyl-α-D-glucopyranose (**2**), even in the presence of alcohol (4). This enabled us to develop a one-stage β-glucosylation with **2** (5). In order to show the utility of our novel method, we attempted to synthesize *O*-β-D-glucopyranosyl-(1→3)-*O*-[β-D-glucopyranosyl-(1→6)]-D-glucopyranose (**4**), a branched-chain trisaccharide which builds the polyglucan, sclerotan, of the sclerotia of *Sclerotinia libertiana* (6) as well as the anti-tumor polyglucans, lentinan (7*a*) and schizophyllan (7*b*). This trisaccharide has been synthesized as a by-product of the condensation of 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranosyl bromide and benzyl 4,6-*O*-benzylidene-β-D-glucopyranoside (8).

Results and Discussion

Prior to preparing the key intermediate, benzyl 3-*O*-acetyl-2,4-di-*O*-benzyl-α-D-glucopyranoside (**1**), we investigated the controlled benzylation (9) of methyl 6-*O*-triphenylmethyl-α-D-glucopyranoside (**5**) (10). The benzylation of **5** by short heating in benzyl chloride containing a limited amount of potassium hydroxide gave the di-*O*-benzyl derivative **6** in a 62% yield. The structure of this compound was determined by measuring ^{1}H nmr of the acetate **7**; the spin system of H-1, H-2, and H-3 was analyzed by double resonance technique. The observed chemical shift value of H-3 shows that the acetyl group is at the C-3 position. The structure of **6** was alternatively confirmed as follows: **6** was detriphenylmethylated, methylated, and hydrogenated to give methyl 3,6-di-*O*-methyl-α-D-glucopyranoside (**9**) (11*a*) which was not oxidized by sodium periodate. The triphenylmethyl group of **7** was removed by mild acid hydrolysis to give the partially protected methyl glucoside **10** which has two kinds of protecting groups, benzyl (persistent) and acetyl (temporary) groups.

The preparation of **1** was then carried out. Benzyl α-D-glucopyranoside, conveniently prepared

by a Fischer reaction of D-glucose with benzyl alcohol in the presence of *p*-toluenesulfonic acid, was converted into the 6-*O*-triphenylmethyl derivative **11**. The controlled benzylation of **11** afforded the partially benzylated monosaccharide **12** in a 35% yield. The selectivity of the reaction became less prominent than in the case of **6** mentioned above. The structure of **12** was determined by ^{1}H nmr of the acetate **13**; again, the spin system of H-1, H-2, and H-3 was unequivocally assigned. The location of the signal of H-3 shows that the acetyl group is at the C-3 position. Mild hydrolysis of **13** removed the triphenylmethyl groups to furnish the desired intermediate **1**.

Compound **1** thus prepared was then glucosylated with **2** using our one-stage β-glucosylation. Treatment of an equimolar mixture of **1** and **2** in dichloromethane with the reagent mixture of *p*-nitrobenzenesulfonyl chloride, silver trifluoromethanesulfonate, and triethylamine (5), followed by deacetylation and subsequent chromatography, gave the partially protected benzyl α-gentiobioside **3** in a 69% yield; the isomaltose derivative **14** was also obtained in a 21% yield. Compound **3** was again glucosylated with **2** using the same reagent mixture to give the fully benzylated branched-chain trisaccharide **15** in a 29% yield; the α(1→3), β(1→6) trisaccharide derivative **16** (19%) was separated by chromatography. ^{13}C nuclear magnetic resonance of **15** in $CDCl_3$ shows that the compound has the β,β-configuration.

Catalytic hydrogenation of **15** over palladium black in moist acetic acid afforded the trisaccharide **4**; ^{13}C nmr of **4** in D_2O shows that the trisaccharide is an equilibrium mixture of the anomeric forms. A pair of the anomeric carbons (C-1) of the pyranose appears at δ 93.2 and 96.9. A pair of the signals of the C-3 are at δ 83.3 and 85.7, resembling the case of anomeric laminaribiose (12). The latter value is almost equal to that of the C-3 of laminaran (δ 85.5) and lentinan (δ 85.3) (13). The C-6 resonates at δ 69.9, agreeing with the case of anomeric gentiobiose (δ 70.2) (12) and the β(1→6) glucan (δ 70.0) (13). Acetylation of **4** with acetic anhydride and sodium acetate afforded the totally acetylated trisaccharide **17**.

It is noted that **1** with a primary hydroxyl group gives β-glucoside more selectively than does **3** with a secondary group. We interpreted this as follows. Compound **1** effectively consumes the glucosyl sulfonate immediately after its generation from **2** so that the ratio of alcohol to the sulfonate is kept high; this favors β-glucoside formation (14).

In conclusion, we have shown that our one-stage β-glucosylation with **2** using the reagent mixture is of use for oligosaccharide synthesis, employing benzyl (persistent) and acetyl (temporary) groups.

NOTE ADDED IN PROOF: one of the referees has

suggested that the glycosylation reaction could proceed via the protected glycosyl chloride.

Experimental

Melting points were determined by an MP-1 melting point apparatus (Yanagimoto); uncorrected values are given. Specific rotations were measured in a jacketed 1-dm cell by a DIP-180 automatic polarimeter (Japan Spectroscopic) at 20°C. Infrared spectra were measured with a JASCO IRA-1 grating infrared spectrophotometer. The ^{1}H nmr values were determined with a JEOL-PS-100 spectrometer; ^{13}C nmr values were observed with a JEOL-PS-100 spectrometer equipped with a JEOL-EC-100 computer. Column chromatography was done on silica gel (Kanto Kagaku); each fraction was examined by tlc on silica gel (Merck, No. 7731). Evaporation was done under reduced pressure using a rotary evaporator (Tokyo Rika-kikai) equipped with a WP-33 aspirator (Yamato) at 35–40°C, unless otherwise stated.

*Methyl 2,4-Di-*O*-benzyl-6-*O*-triphenylmethyl-α-*D*-glucopyranoside (6)*

A mixture of the triphenylmethyl derivative **5** (10) (1.0 g, 2.3 mmol), benzyl chloride (Tokyo Kasei, 15 mL, 130 mmol), and crushed potassium hydroxide (1.0 g, 18 mmol) was stirred at 95°C for 2 h. The cooled mixture was diluted with benzene, filtered, and evaporated *in vacuo* on a boiling water bath. The residue was chromatographed on a silica gel column with benzene–butanone (100:1→5:1, gradient) as solvent. This gave pure **6** (0.88 g, 62%), mp 63–66°C; $[\alpha]_D$ +49° (*c* 0.6, chloroform). *Anal.* calcd. for $C_{40}H_{40}O_6$: C 77.89, H 6.54; found: C 77.90, H 6.51.

*Methyl 3-*O*-Acetyl-2,4-di-*O*-benzyl-6-*O*-triphenylmethyl-α-*D*-glucopyranoside (7)*

The partially benzylated compound **6** (703 mg, 1.14 mmol) was treated with acetic anhydride (7 mL) in pyridine (7 mL) for 90 min. The mixture was diluted with cold methanol (70 mL), evaporated *in vacuo* at 60°C, and then purified on a silica gel column with benzene–butanone (30:1) as solvent. This afforded a pure sirup of **7** (750 mg, 100%); $[\alpha]_D$ +37° (*c* 0.8, chloroform); ^{1}H nmr ($CDCl_3$, TMS) δ: 1.94 (s, 3H, CH_3CO), 3.18 (dd, $J_{5,6}$ = 4.8 Hz, $J_{6,6'}$ = 10 Hz, 1H, H-6), 3.44 (s, 3H, CH_3O), 3.57 (dd, $J_{1,2}$ = 3.8 Hz, $J_{2,3}$ = 9.0 Hz, 1H, H-2), 3.64 (t, $J_{3,4}$ = $J_{4,5}$ = 9.0 Hz, 1H, H-4), 3.88 (m, $J_{4,5}$ = 9.0 Hz, $J_{5,6}$ = 4.8 Hz, $J_{5,6'}$ = 2.0 Hz, 1H, H-5), 4.25 and 4.35 (AB system, J_{AB} = 11 Hz, 2H, CH_2Ph-4), 4.66 (s, 2H, CH_2Ph-2), 4.84 (d, $J_{1,2}$ = 3.8 Hz, 1H, H-1), 5.54 (t, $J_{2,3}$ = $J_{3,4}$ = 9.0 Hz, 1H, H-3). *Anal.* calcd. for $C_{42}H_{42}O_7$: C 76.57, H 6.43; found: C 77.09, H 6.47.

*Methyl 3-*O*-Acetyl-2,4-di-*O*-benzyl-α-*D*-glucopyranoside (10)*

The acetate **7** (791 mg, 1.2 mmol) was dissolved in *p*-dioxane (8 mL) containing dilute sulfuric acid (3 *M*, 1.2 mL). The solution was heated at 82–92°C for 60 min. The cooled solution was neutralized carefully with powdered sodium hydrogen carbonate under stirring, evaporated, and chromatographed on a silica gel column with benzene–butanone (100:1→3:1, gradient). This afforded pure **10** (332 mg, 66%), mp 61–62°C; $[\alpha]_D$ +67° (*c* 1.0, chloroform); ir(film): 1750 (CH_3COO) cm^{-1}; ^{1}H nmr($CDCl_3$, TMS) δ: 1.87 (s, 1H, OH), 1.95 (s, 3H, CH_3CO), 3.35 (s, 3H, CH_3O), 4.60 (s, 4H, CH_2Ph-2 and -4), 4.65 (d, $J_{1,2}$ = 3.8 Hz, 1H, H-1), 5.55 (t, $J_{2,3}$ = $J_{3,4}$ = 9.5 Hz, 1H, H-3). *Anal.* calcd. for $C_{23}H_{28}O_7$: C 66.65, H 6.78; found: C 66.30, H 6.86.

*Methyl 2,4-Di-*O*-benzyl-α-*D*-glucopyranoside (8) and the Structural Proof*

A mixture of **6** (150 mg, 0.24 mmol), *p*-dioxane (1.5 mL), and dilute sulfuric acid (3 *M*, 0.23 mL) was heated at 85°C for 1 h. The mixture was diluted with benzene, extracted with aqueous sodium hydrogen carbonate (5%) and water, evaporated, and purified on a silica gel column with benzene–butanone (5:1) as solvent. This afforded pure **8** (75 mg, 83%), mp 74–75°C; $[\alpha]_D$ +88° (*c* 0.6, chloroform) (lit. (11*b*) mp 75°C; $[\alpha]_D^{23}$ +87°(*c* 1.18, chloroform)). *Anal.* calcd. for $C_{21}H_{26}O_6$: C 67.36, H 7.00; found: C 67.10, H 6.90.

Compound **8** (50 mg, 0.13 mmol) was reacted with methyl iodide (Tokyo Kasei, 0.3 mL) and powdered barium oxide (0.37 g) in *N*,*N*-dimethylformamide (1 mL) at 82°C for 3 h under vigorous stirring. The mixture was diluted with benzene, filtered, and evaporated *in vacuo* at 80°C. The residue was purified on a silica gel column with benzene–butanone (100:1→20:1, gradient) to give a homogeneous sirup of the dimethyl compound (52 mg, 97%); ^{1}H nmr ($CDCl_3$, TMS) spectrum contains three singlets of methoxyl group at δ 3.33, 3.36, and 3.69. This compound (49 mg, 0.12 mmol) was hydrogenated twice over palladium black (14 mg) in a mixture of methanol (3 mL), water (0.5 mL), and acetic acid (0.3 mL) at 340 kPa using a Paar hydrogenation apparatus to give methyl 3,6-di-*O*-methyl-α-D-glucopyranoside (**9**) (27 mg, 100%); $[\alpha]_D$ +145° (*c* 0.7 ethanol) (lit. (11) $[\alpha]_D$ +141.6° (*c* 1.22, ethanol)). *Anal.* calcd. for $C_9H_{18}O_6$: C 48.64, H 8.16; found: C 48.80, H 8.13. The ^{1}H nmr (D_2O, ext. TMS) spectrum has three singlets of methoxyl group at δ 3.84, 3.87, and 4.14. Monitoring tlc showed that compound **9** (2.2 mg, 0.01 mmol) did not react with sodium periodate (2.2 mg) in water (0.10 mL) at room temperature overnight, whereas methyl 4,6-di-*O*-methyl-α-D-glucopyranoside (15) was completely exhausted during the same reaction.

*Benzyl 6-*O*-Triphenylmethyl-α-*D*-glucopyranoside (11)*

Anhydrous D-glucose (Wako, 10 g, 55 mmol), benzyl alcohol (Wako, 10 mL), and *p*-toluenesulfonic acid monohydrate (Tokyo Kasei, 3 g, 16 mmol) were placed in a round-bottomed flask and the reaction was stirred well at 60–70°C for 4 h. Thin-layer chromatography of the reaction mixture showed that the main product was benzyl α-D-glucopyranoside (16); the β-anomer (17) was also detected. The mixture was diluted with chloroform (100 mL) containing triethylamine (Wako, 4.4 mL) and filtered. The filtrate was evaporated *in vacuo* on a boiling water bath and chromatographed on a silica gel column with chloroform–methanol (100:1→3:1, gradient) as solvent. This gave a sirup (5.7 g, 36%) of benzyl α-D-glucopyranoside; ^{13}C nmr (D_2O, ext. TMS) δ: 61.6 (C-6), 70.8 (C-4), 70.9 (CH_2Ph), 72.5 (C-2), 73.1 (C-5), 74.3 (C-3), 98.9 (C-1), 129.6, 129.9, 138.2 (phenyl). The slower-moving product was the β-anomer (0.6 g, 4%); ^{13}C nmr (D_2O, ext. TMS) δ: 62.0 (C-6), 70.8 (C-4), 72.6 (CH_2Ph), 74.3 (C-2), 77.0 (C-5), 77.1 (C-3), 102.4 (C-1), 129.6, 129.8, 137.1 (phenyl).

The α-glucoside (8.9 g, 31.5 mmol) was reacted with triphenylmethyl chloride (Tokyo Kasei, 9.2 g, 33 mmol) in pyridine (35 mL) at 60°C for 3 h. The mixture was diluted with chloroform and extracted with aqueous sodium hydrogen sulfate (5%) and water. After evaporation the residue was chromatographed on a silica gel column with benzene–butanone (10:1→1:1, gradient). This gave a pure solid of **11** (6.2 g, 36%), mp 75–77°C; $[\alpha]_D$ +25° (*c* 0.4, chloroform). *Anal.* calcd. for $C_{32}H_{32}O_6$: C 74.98, H 6.29; found: C 74.27, H 6.65.

*Benzyl 2,4-Di-*O*-benzyl-6-*O*-triphenylmethyl-α-*D*-glucopyranoside (12)*

A mixture of the triphenylmethyl compound **11** (6.1 g, 12 mmol), benzyl chloride (82 mL), and crushed potassium hydroxide (6.1 g) was stirred at 98°C for 2.5 h. The cooled mixture was processed as described for **6** and chromatographed on a

For personal use only.

column of silica gel. Gradient elution with benzene–butanone (100:1→10:1) gave pure **12** (2.9 g, 35%); $[\alpha]_D$ +72° (*c* 1.0, chloroform). *Anal.* calcd. for $C_{46}H_{44}O_6$: C 79.74, H 6.40; found: C 79.56, H 6.47.

Benzyl 3-O-Acetyl-2,4-di-O-benzyl-6-O-triphenylmethyl-α-D-glucopyranoside (13)

The partially benzylated product **12** (2.2 g, 32 mmol) was reacted with acetic anhydride (13 mL) and pyridine (6.5 mL) overnight. The cooled mixture was diluted with cold methanol (100 mL), evaporated *in vacuo* at 70°C, and purified on a silica gel column with benzene–butanone (100:1→20:1, gradient) as solvent. This gave pure **13** (2.4 g, 97%), mp 147–148°C; $[\alpha]_D$ +65°(*c* 1.0, chloroform); ^{1}H nmr ($CDCl_3$, TMS) δ: 1.95 (s, 3H, CH_3CO), 3.12 (dd, $J_{5,6}$ = 4.0 Hz, $J_{6,6'}$ = 10.0 Hz, 1H, H-6), 3.45 (dd, $J_{5,6'}$ = 2.0 Hz, $J_{6,6'}$ = 10.0 Hz, 1H, H-6'), 3.56 (dd, $J_{1,2}$ = 3.8 Hz, $J_{2,3}$ = 9.5 Hz, 1H, H-2), 3.65 (t, $J_{3,4} = J_{4,5}$ = 9.5 Hz, 1H, H-4), 3.91 (m, $J_{4,5}$ = 9.5 Hz, $J_{5,6}$ = 4.0 Hz, $J_{5,6'}$ = 2.0 Hz, 1H, H-5), 4.21 and 4.33 (AB system, J_{AB} = 10.0 Hz, 2H, CH_2Ph-4), 4.53 (s, 2H, CH_2Ph-2), 4.59 and 4.75 (AB system, J_{AB} = 12.0 Hz, 2H, CH_2Ph-1), 4.98 (d, $J_{1,2}$ = 3.8 Hz, 1H, H-1), 5.55 (t, $J_{2,3} = J_{3,4}$ = 9.5 Hz, 1H, H-3). *Anal.* calcd. for $C_{48}H_{46}O_7$: C 78.45, H 6.31; found: C 78.86, H 6.23.

Benzyl 3-O-Acetyl-2,4-di-O-benzyl-α-D-glucopyranoside (1)

The acetate **13** (625 mg, 0.85 mmol) was dissolved in *p*-dioxane (6 mL) containing dilute sulfuric acid (3 *M*, 0.4 mL). The reaction was stirred at 80°C for 60 min. The cooled mixture was diluted with benzene, then extracted with dilute sodium hydrogen carbonate (5%) and water. The solvent was evaporated and the residue was purified on a silica gel column with benzene–butanone (100:1→10:1, gradient) as solvent. This gave pure **1** as long needles (330 mg, 76%), mp 128–129°C; $[\alpha]_D$ +100°(*c* 0.3, chloroform); ir(KBr): 1740 (CH_3COO) cm^{-1}. *Anal.* calcd. for $C_{29}H_{32}O_7 \cdot H_2O$: C 68.22, H 6.71; found: C 68.03, H 6.22. Heating this at 105°C *in vacuo* gave the anhydrous form, mp 129–130°C. *Anal.* calcd. for $C_{29}H_{32}O_7$: C 70.71, H 6.55; found: C 70.96, H 6.62.

Benzyl O-(2,3,4,6-Tetra-O-benzyl-β-D-glucopyranosyl)-(1→6)-2,4-di-O-benzyl-α-D-glucopyranoside (3) and the α(1→6) Isomer (14)

Triethylamine (140 μL, 1.0 mmol) was added to a stirred mixture of **1** (492 mg, 1.0 mmol), **2** (18) (540 mg, 1.0 mmol), *p*-nitrobenzenesulfonyl chloride (222 mg, 1.0 mmol), and silver trifluoromethanesulfonate (257 mg, 1.0 mmol) in dichloromethane (5 mL) at −40°C. The bath temperature was allowed to rise to 0°C, at which temperature the reaction was agitated overnight. The reaction mixture showing a single main spot was diluted with benzene, filtered, and chromatographed on a silica gel column with benzene–butanone (100:1→5:1, gradient). This afforded a solid mixture (966 mg) of products giving the main spot. The solid was then dissolved in a mixture of methanol (10 mL), *p*-dioxane (2 mL), and acetone (6 mL). Dilute sodium methoxide (0.2 *M*, 5 mL) was added to the solution. After standing overnight, the solution showing two spots (R_f 0.38 and 0.31, benzene–butanone (10:1)) was neutralized with acetic acid, evaporated, and chromatographed on a silica gel column with benzene–butanone (100:1→10:1, gradient) as solvent. The faster-moving product was **14** (212 mg, 21%), mp 72–74°C; $[\alpha]_D$ +96°(*c* 1.0, chloroform); ^{13}C nmr ($CDCl_3$, TMS) showed two kinds of anomeric carbons at δ 94.4 (C-1) and 97.1 (C-1'). *Anal.* calcd. for $C_{61}H_{64}O_{11} \cdot H_2O$: C 73.92, H 6.71; found: C 73.66, H 6.62. Drying this at 105°C *in vacuo* gave anhydrous sirup. *Anal.* calcd. for $C_{61}H_{64}O_{11}$: C 75.29, H 6.63; found: C 74.97, H 6.58. The slower-moving product was **3** (683 mg, 69%), mp 88–91°C; $[\alpha]_D$ +82°(*c* 0.5, chloroform); ^{13}C nmr ($CDCl_3$, TMS) showed the presence of two anomeric carbons at δ 94.8 (C-1) and 103.8 (C-1'). *Anal.* calcd. for $C_{61}H_{64}O_{11} \cdot 0.5H_2O$: C 74.59, H 6.47; found: C 74.24, H 6.56. Dehydration of this at 105°C *in vacuo* gave an anhydrous sirup. *Anal.* calcd. for $C_{61}H_{64}O_{11}$: C 75.29, H 6.63; found: C 75.10, H 6.63.

Benzyl O-(2,3,4,6-Tetra-O-benzyl-β-D-glucopyranosyl)-(1→3)-O-[2,3,4,6-tetra-O-benzyl-β-D-glucopyranosyl-(1→6)]-2,4-di-O-benzyl α-D-glucopyranoside (15) and the α(1→3), β(1→6) Isomer (16)

To a stirred mixture of **2** (18) (147 mg, 0.27 mmol), **3** (251 mg, 0.26 mmol), *p*-nitrobenzenesulfonyl chloride (60 mg, 0.27 mmol), and silver trifluoromethanesulfonate (70 mg, 0.27 mmol) in dichloromethane (1.5 mL), triethylamine (38 μL, 0.27 mmol) was added at −40°C and the reaction was conducted as described above. The processed reaction mixture was chromatographed on a column of silica gel with benzene–butanone (100:1→10:1, gradient). This gave three fractions: fraction A (**15**, **16**, and octa-*O*-benzyl α,β-trehalose (19), 275.9 mg), fraction B (the self-condensation product and **3**, 96 mg), and fraction C (**2**, 20 mg). Rechromatography of fraction A gave fraction D (**15** and **16**, 133.2 mg) and then fraction E (**16** and the trehalose derivative, 122.3 mg). Fraction D was again chromatographed to give pure **15** (112.8 mg, 29%); $[\alpha]_D$ +38°(*c* 0.6, chloroform); ^{13}C nmr ($CDCl_3$, TMS) showed the presence of three anomeric carbons at δ 94.3 (C-1), 102.6 (C-1'), and 103.8 (C-1''). *Anal.* calcd. for $C_{95}H_{98}O_{16}$: C 76.28, H 6.60; found: C 76.15, H 6.54. Chromatography of fraction E gave pure **16** (73.7 mg, 19%); $[\alpha]_D$ +59°(*c* 1.4, chloroform); ^{13}C nmr ($CDCl_3$, TMS) showed the presence of three anomeric carbons at δ 94.6 (C-1), 97.3 (C-1'), and 103.6 (C-1''). *Anal.* calcd. for $C_{95}H_{98}O_{16}$: C 76.28, H 6.60; found: C 76.01, H 6.98.

O-β-D-Glucopyranosyl-(1→3)-O-[β-D-glucopyranosyl-(1→6)]-D-glucopyranose (4)

The fully benzylated trisaccharide **15** (100 mg, 0.067 mmol) was hydrogenated over palladium black (100 mg) in acetic acid (5 mL) containing water (0.05 mL) at 410 kPa overnight. The mixture was filtered, concentrated, and hydrogenated again over the catalyst (100 mg) in acetic acid (5 mL) containing water (3 mL). After repetition of a similar hydrogenation, the residual glass obtained was crystallized with ethanol to give **4** (30 mg, 89%), mp 183–188°C; $[\alpha]_D$ −1.1° (*c* 1.5, water) (lit. (8) mp 197–199°C; $[\alpha]_D$ −0.6° (*c* 1.15, water)); ^{13}C nmr (D_2O, ext. TMS) δ: 61.9 (73, C-6' and C-6), 69.2 (14, C-4), 69.9 (11, C-6), 70.8 (97, C-4' and C-4), 72.1 (29, C-2α and C-5α), 73.9 (23, C-2β), 74.3 (45, C-2), 74.6 (54, C-2'), 75.7 (11, C-5β), 76.8 (100, C-5' and C-5), 77.0 (66, C-3), 77.1 (65, C-3'), 83.3 (11, C-3α), 85.7 (10, C-3β), 93.2 (14, C-1α), 96.9 (15, C-1β), 104.0 (50, C-1), 104.3 (28, C-1'). *Anal.* calcd. for $C_{18}H_{32}O_{16}$: C 42.86, H 6.39; found: C 42.82, H 6.77.

O-(2,3,4,6-Tetra-O-acetyl-β-D-glucopyranosyl)-(1→3)-O-[2,3,4,6-tetra-O-acetyl-β-D-glucopyranosyl-(1→6)]-1,2,4-tri-O-acetyl-D-glucopyranose (17)

The trisaccharide **4** (20 mg, 0.04 mmol) was reacted with acetic anhydride (1 mL) and sodium acetate (100 mg) under stirring at 100°C for 6 h. After dilution with chloroform, filtration, and evaporation at 80°C *in vacuo*, the residue obtained was purified on a silica gel column with benzene–butanone (2:1) as solvent. This gave a pure glass of **17** (35 mg, 91%); ^{13}C nmr ($CDCl_3$, TMS) showed that the glass was an anomeric mixture (δ 88.9 (C-1α) and 91.6 (C-1β) (20)). The glass was crystallized with ethanol, mp 233–235°C; $[\alpha]_D$ −2.1° (*c* 0.7, chloroform) (lit. (6) mp 226–227°C; lit. (8) mp 237°C; $[\alpha]_D^{20}$ −2.56° (*c* 1.33, chloroform)). *Anal.* calcd. for $C_{40}H_{54}O_{27}$: C 49.69, H 5.63; found: C 49.81, H 6.05.

Received June 9, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

BERT FRASER-REID, KING MO SUN, RAYMOND Y-K. TSANG, PIERRE SINAŸ, and MARCK PIETRASZKIEWICZ. Can. J. Chem. **59**, 260 (1981).

Under some conditions deprotonation of various mixed disulfonate ester derivatives of carbohydrates leads to intramolecular displacement yielding a product in which a sultone is fused to the sugar ring. The procedure seems to work best when a mesylate and a benzenesulfonate are involved. Examples with both pyranose and furanose sugars are described.

BERT FRASER-REID, KING MO SUN, RAYMOND Y-K. TSANG, PIERRE SINAŸ et MARCK PIETRASZKIEWICZ. Can. J. Chem. **59**, 260 (1981).

Dans certaines conditions, la déprotonation de divers esters disulfoniques mixtes de carbohydrates donne lieu à un déplacement intramoléculaire conduisant à un produit dans lequel une sultone est fusionnée au cycle du sucre. La méthode semble mieux fonctionner quand on utilise un mésylate ou un benzènesulfonate. On décrit des exemples avec les sucres des types pyrannose et furannose.

[Traduit par le journal]

In a previous publication by one of us (1) it was shown that the reaction of methanesulfonyl chloride with a sugar α-keto-alcohol in the presence of sodium hydride caused efficient formation of a bicyclic system in which a sultone was fused to a pyranoside ring.[2] Bicyclic sultones are of interest in view of their potential for biological activity (3). In this communication we describe other routes from readily available sugars, which make these interesting, novel binuclear heterocyclic systems available for further use.

The present series of investigations began with the observation that a number of mixed disulfonates, upon treatment with organometal reagents, gave sultones in high yields. Thus the mesylate-tosylate **2** reacted with lithium acetylide – ethylenediamine complex to give the seven-membered sultone **3** in 98% yield as a crystalline substance. The structure of **3** follows from the elemental analysis, the nmr data indicating the retention of the isopropylidine group, and the ir data for the sulfonate (1170, 1345 cm^{-1}). A homologue was also prepared from the mesylate-tosylate **5** which gave the six-membered sultone **6** in 90% yield.

Analogous reactions in the pyranose series also occur. Thus the mesylate-tosylate **7***c* reacted with the dianion of ethyl acetoacetate, **8**, (4) to give **9** as a noncrystalline substance in 74% yield which was then hydrogenated over palladium to the saturated analogue **10**, as a crystalline substance.

A number of experiments were carried out to determine some of the requirements for the formation of sultones in these systems. The results in eqs. (a), (b), and (c), Scheme 1, indicate that in all cases the tosylate (or benzenesulfonate) was displaced, implying that the mesylate had been deprotonated and thereby producing a nucleophile. The pK_a data indicate that a mesylate group is eight times more acidic than a tosylate (5), hence under the reaction conditions the latter is the preferred leaving group.

With regard to compound **7***d*, even if one of the tosyl groups should be deprotonated, the planar aromatic ring would prevent the resulting anion from achieving an acceptable geometry to effect the displacement of the other tosyl group. It is therefore not surprising that when **7***d* was treated with the dianion **8**, the material was recovered unchanged. The same geometric constraints do not apply to the dimesylate **7***e*, which could conceivably give the analogues **9** and/or **11**. However, this substrate was also recovered unchanged after treatment with dianion **8**, even though a generous excess of base had been used.

Comparison of the results with **7***c* and **7***e* suggests that it is advantageous to have sulfonates of

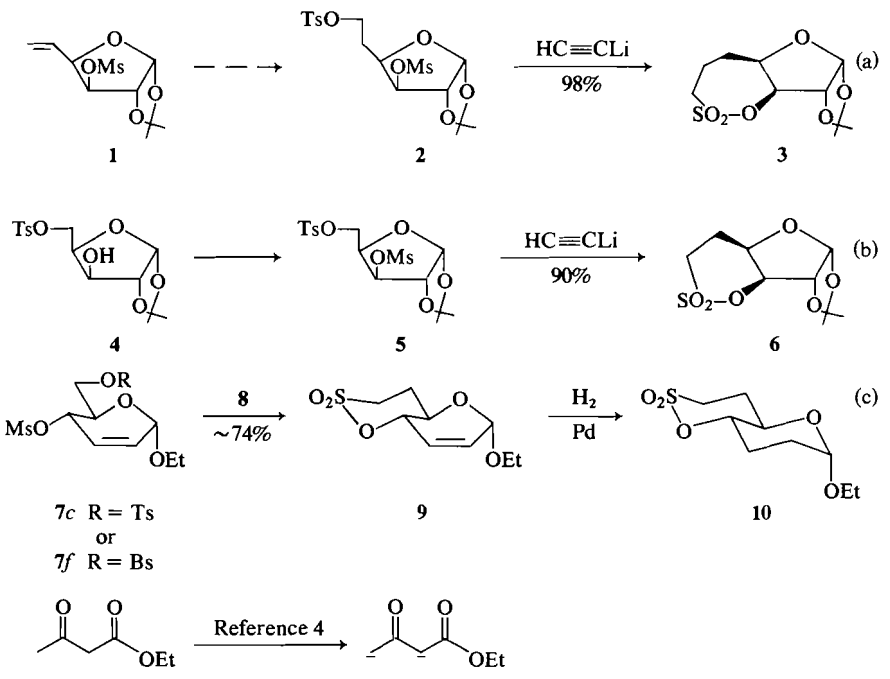

SCHEME 1

different reactivities so that one can be deprotonated preferentially while the other would be the favoured leaving group. These conditions are met with the mesylate-benzenesulfonate **7***f*. Although LDA in THF/HMPA did cause initial formation of **9** as detected by tlc, gross decomposition set in rapidly. However, some success was obtained with sodium hydride, and **9** was obtained in ~60% yield although an appreciable amount of starting material **7***f* was also recovered.

The properties and synthetic utility of these interesting sultones are being investigated in our laboratories and will be described in future publications.

Experimental

General

Melting points were determined on a Fisher-Johns heating stage or a Büchi apparatus, and are uncorrected. The nmr spectra were determined, unless otherwise stated, in deuteriochloroform containing 1% tetramethylsilane as internal standard with a Varian HR 220, Varian HA 100, Varian T-60, or a Perkin-Elmer R-32 (90 MHz) spectrometer. Coupling constants were obtained by measuring spacings of spectra judged to be first order.

Thin-layer chromatography (tlc) was performed on precoated 0.2 mm silica gel sheets (E. Merck, F-254) and developed with the solvent indicated. The chromatograms were first viewed under ultraviolet light, then sprayed with concentrated sulfuric acid and heated in an oven for complete visualization.

For column chromatography, E. Merck silica gel (0.05–0.20 mm, 70–325 mesh A.S.T.M.) was used.

Elemental analyses were carried out by Service Central d'Analyse, 69390 Vernaison, France, or Guelph Chemical Laboratories Ltd., Guelph, Ontario.

*5-Deoxy-1,2-*O*-isopropylidene-3-*O*-mesyl-6-*O*-tosyl-α-*D*-glucofuranose (2)*

A 1 *M* solution of diborane in tetrahydrofuran (1 mL) was added to a solution of the mesylate **1** (264 mg) (6) in tetrahydrofuran (5 mL). The mixture was stirred for 2 h at room temperature, then water (1 mL) was added, followed by a 30% hydrogen peroxide solution (0.7 mL) and a 30% sodium hydroxide solution (0.6 mL). The reaction was stirred for 1.5 h, evaporated, and the residue extracted with chloroform. The chloroform layer was evaporated and the residue was treated directly with tosyl chloride (280 mg) in dry pyridine (2 mL). After 12 h at room temperature, work-up gave a residue which was chromatographed on silica gel (5 g); elution with benzene – ethyl acetate (10:9) gave pure fractions of compound **2** (158 mg, 36%), mp 78–80°C; $[\alpha]_D^{20}$ −11° (*c* 0.86, $CHCl_3$); nmr data (acetone-d_6) δ: 1.30 and 1.43 (6H, 2s, Me), 1.90–2.20 (2H, m, CH_2), 2.45 (3H, s, Ts), 3.10 (3H, s, Ms), 3.90–4.40 (3H, m, CH_2 and H-4), 4.70–4.85 (2H, 2d, H-2 and H-3), 5.85 (2H, d, 4 Hz, H-1). *Anal.* calcd. for $C_{17}H_{24}O_9S_2$: C 46.78, H 5.54, S 14.69; found: C 46.83, H 5.52, S 14.74.

*5,6,7-Trideoxy-1,2,*O*-isopropylidene-α-*D*-xylo-heptofuranose-3,7-sultone (3)*

A solution of 5-deoxy-1,2-*O*-isopropylidene-3-*O*-mesyl-6-*O*-tosyl-α-D-glucofuranose (**2**, 87.2 mg) and lithium acetylide – ethylenediamine complex (46 mg) in dry dimethylsulfoxide (1 mL) was stirred for 20 min at room temperature. After addition of water (5 mL), the reaction mixture was extracted with ether (10 mL). The ether layer was distilled off and the residue was chromatographed on silica gel (3 g) to give the sultone **3** (57.1 mg, 98%), mp 148°C (chloroform–hexane); nmr data δ: 1.33 and 1.50 (6H, 2s, Me), 1.70–2.50 (4H, m, —CH_2—), 3.30–3.55 (2H, m, —CH_2SO_2—), 4.45–4.70 (1H, m, H-4), 4.80 (1H, d, 4 Hz, H-2), 5.07 (1H, d, 3 Hz, H-3), 6.00 (1H, d, H-1). *Anal.* calcd. for $C_{10}H_{16}O_6S$: C 45.45, H 6.10, S 12.11; found: C 45.20, H 5.74, S 11.94.

*1,2-*O*-Isopropylidene-3-*O*-mesyl-5-*O*-tosyl-α-*D*-xylofuranose (5)*

1,2-*O*-Isopropylidene-5-*O*-tosyl-α-D-xylofuranose (**4**, 6.88 g) was treated with mesyl chloride (1.7 mL) in pyridine (20 mL) during 12 h at 0°C. After work-up, compound **5** was obtained (7.88 g, 97%) mp 104–105°C (from ethyl acetate – hexane, 1:4); $[\alpha]_D^{20}$ −36° (*c* 0.43, $CHCl_3$); nmr data (acetone-d_6) δ: 1.30 and 1.40 (6H, 2s, Me), 2.45 (3H, s, Ts), 3.20 (3H, s, Ms), 4.15–4.60 (3H, m, H-4, H-5, H-5'), 4.85 (3H, d, 4 Hz, H-2), 5.07 (3H, d, 3 Hz, H-3 .), 6.00 (3H, d, H-1). *Anal.* calcd. for $C_{16}H_{22}O_9S_2$: C 45.49, H 5.25, S 15.18; found: C 45.63, H 5.22, S 14.91.

*5,6-Dideoxy-1,2-*O*-isopropylidene-α-*D*-xylo-hexofuranose-3,6-sultone (6)*

A solution of 1,2-*O*-isopropylidene-3-*O*-mesyl-5-*O*-tosyl-α-D-glucofuranose (**5**, 406 mg) and lithium acetylide – ethylenediamine complex (243 mg) in dry dimethylsulfoxide (7 mL) was stirred for 1 h at room temperature. After addition of water (20 mL), the reaction mixture was extracted with chloroform (3 × 20 mL). The chloroform layer was washed with water and run through a layer of silica gel. The solvent was distilled off and the residue dissolved in benzene (50 mL), washed with water (60 mL), and evaporated to give a white solid **6** (216 mg, 90%), only slightly soluble in many organic solvents at room temperature, mp 190–200°C (dec); nmr data ($CDCl_3$) δ: 1.32 and 1.50 (6H, 2s, Me), 2.50–2.70 (2H, m, CH_2), 3.05–3.25 (2H, m, CH_2SO_2), 4.25–4.40 (1H, m, H-4), 4.65 (1H, d, 4 Hz, H-2), 4.97 (1H, d, 1.5 Hz, H-3), 6.00 (1H, d, H-1). *Anal.* calcd. for $C_9H_{14}O_6S$: C 43.20, H 5.64, S 12.79; found: C 43.21, H 5.77, S 12.77.

*Ethyl 2,3-Dideoxy-4-*O*-mesyl-6-*O*-benzenesulfonyl-α-*D*-erythro-hex-2-enopyranoside (7*d*)*

A solution of ethyl 2,3-dideoxy-α-D-*erythro*-hex-2-enopyranoside (*7a*, 2.5 g) (7) in dry pyridine (100 mL) and methylene chloride (100 mL) was cooled to −40°C, and benzenesulfonyl chloride (2.5 g) dissolved in methylene chloride (20 mL) was added in small portions over 2 h. The reaction mixture was kept at −10°C for 3 days, and the residue after work-up was separated on a silica gel column. The monobenzenesulfonate *7b* (2.7 g; 60%) was then treated with mesyl chloride (2.0 mL) in pyridine (100 mL) at room temperature for 12 h giving *7d* (2.92 g; 87%). For *7d*, $[\alpha]_D^{20}$ +51.6° (*c* 5.44, $CHCl_3$); nmr data ($CDCl_3$) δ: 1.19 (3H, t, CH_3—CH_2O), 3.20 (3H, s, CH_3SO_3), 3.33–3.90 (2H, m, CH_3—CH_2—O), 4.00 (1H, m, H-5), 4.22 (2H, m, 2H-6), 4.96 (1H, bs, H-1), 5.01 (1H, bd, H-4), 5.62–6.12 (2H, q, H-2, H-3), 7.53–8.00 (5H, m, $PhSO_3$); ms *m/e* 347 (M^+ − OEt).

*Ethyl 2,3,6,7-Tetradeoxy-α-*D*-erythro-hept-2-enopyranosid-4,-7-sultone (9)*

(a) The dianion **8** was generated in the standard manner (4). Ethyl acetoacetate (5 g) was added dropwise to a suspension of 50% sodium hydride (1.5 g; 31 mmol) in ice-cold tetrahydrofuran. The solution became clear and after 10 min *n*-butyllithium (15 mL of 2.4 *M*; 36 mmol) was added dropwise whereupon the colour became orange-yellow. Hexamethylphosphoramide (20 mL) was then added and after stirring for another 20 min, the sugar *7c* (3) (1.0 g, 2.5 mmol) in tetrahydrofuran (5 mL) was added. Thin-layer chromatography in ethyl acetate – petroleum ether (1:4) showed the reaction to be complete after 15 min and water was added. After the extraction and washing with solutions of ammonium chloride and sodium bicarbonate, the material was chromatographed to give **9** (0.43 g, 74%) as a syrupy substance.

(b) In a similar experiment to the foregoing, the mesylate-benzenesulfonate, *7f*, (1.0 g, 2.6 mmol) (8) afforded compound **9** (0.43 g) also in 74% yield.

(c) Sodium hydride (50 mg of 50%; 1.04 mmol) was suspended in dry tetrahydrofuran (5 mL) and compound *7f* (0.1 g, 0.26 mmol), dissolved in 5 mL of the same solvent and 5 mL of hexamethylphosphoramide, was added. After stirring at room temperature for 18 h, tlc in ethyl acetate – petroleum ether (1:4) still showed the presence of starting material. Work-up and separation by preparative layer chromatography afforded some starting material, *7f* (15 mg), and the title compound **9** (31 mg) in 60% yield based on unrecovered starting material. For **9**, $[\alpha]_D^{20}$ 3.4 (*c* 5.62, $CHCl_3$); nmr data ($CDCl_3$) δ: 1.10 (3H, t, CH_3—

CH_2O—), 2.00–2.20 (2H, m, CH_2—CH_2SO_2—), 3.12–3.46 (2H, m, CH_3—CH_2—O—), 3.50 (1H, m, H-5), 4.35 (1H, d, H-4), 4.46 (1H, s, H-1), 5.16–5.34 (2H, q, H-2, H-3); ms *m/e* 234 (M^+).

*Ethyl 2,3,6,7-Tetradeoxy-α-D-*erythro*-heptopyranosid-4,7-sultone (**10**)*

The sultone **9** (200 mg) was hydrogenated over 5% palladium on carbon in ethanol. Preparative layer chromatography using methanol – methylene chloride (1:24) afforded 150 mg (75%) of **10**, mp 119–120°C; $[\alpha]_D^{20}$ 57.2°(*c* 1.02, $CHCl_3$); nmr data ($CDCl_3$) δ: 1.20 (3H, t, CH_3—CH_2O—), 1.78–2.40 (6H, m, 2H-2, 2H-3, 2H-6), 3.10–3.41 (2H, m, CH_2—SO_3—), 3.78 (1H, m, H-5), 4.22 (1H, q, H-4), 4.70 (1H, t, H-1). *Anal.* calcd. for $C_9H_{16}O_5S$: C 45.75, H 6.83, S 13.57; found: C 45.75, H 6.98, S 13.46.

The formation of azoxyalkanes in reactions of some organometallic reagents with *N*-nitroso-*O*,*N*-dialkylhydroxylamines: the nonphotochemical synthesis of an acyclic (*E*)-azoxyalkane

A. C. M. MEESTERS, H. RÜEGER, K. RAJESWARI, AND M. H. BENN[1]

Chemistry Department, The University, Calgary, Alta., Canada T2N 1N4

Received July 10, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

A. C. M. MEESTERS, H. RÜEGER, K. RAJESWARI, and M. H. BENN. Can. J. Chem. **59**, 264 (1981).

Azoxyalkanes were found to be regiospecifically formed in the reactions of some alkyllithium and Grignard reagents with *N*-nitroso-*O*,*N*-dialkylhydroxylamines. Remarkably, although (*Z*)-stereomers were usually produced, in one case the (*E*)-isomer was predominant.

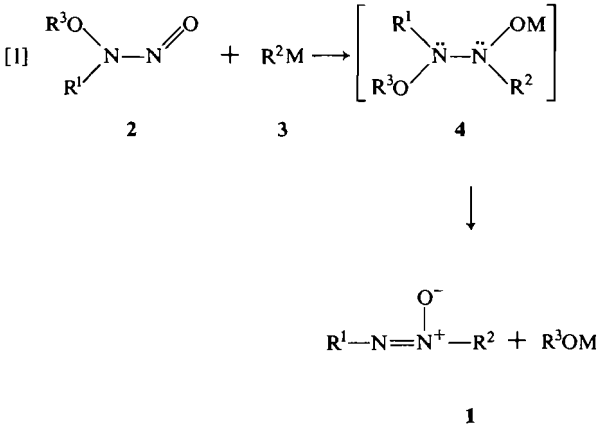
A. C. M. MEESTERS, H. RÜEGER, K. RAJESWARI et M. H. BENN. Can. J. Chem. **59**, 264 (1981).

On a trouvé que les azoxyalcanes se forment de façon régiospécifique dans les réactions des alkyllithium et des réactifs de Grignard avec les *N*-nitroso *O*,*N*-dialkylhydroxylamines. On a notamment trouvé un cas où l'isomère (*E*) est le produit principal en dépit du fait qu'il y a généralement formation des stéréoisomères (*Z*).

[Traduit par le journal]

Introduction

Faced with a need for some unsymmetrical azoxyalkanes (**1**, $R^1 \neq R^2$), it occurred to us that as an alternative to the existing methods (1), they might be prepared by the reaction of *N*-nitroso-*O*,*N*-dialkylhydroxylamines (**2**) with organometallic reagents (**3**), a process schematically portrayed by eq. [1], and apparently not previously investigated.



[1]

2 **3** **4**

1

We were encouraged to investigate this possibility by the report that alkyllithium reagents added to the nitroso function of *N*-nitrosoamines (2), and the observation that the *N*-alkoxy-*N'*-hydroxy intermediates **5***a* and *b*, closely related to **4**, regiospecifically eliminated methanol to afford the azoxyalkanes **6***a* and **6***b* (1*b*), eq. [2].

However, we anticipated problems arising as a result of such competing processes as α-metallation of the nitrosohydroxylamine, eq. [3], and further, "over-reaction" of the azoxyalkane products with the organometallic reagents, cf. eqs. [4] and [5] (3).

Results and Discussion

In fact, exploratory experiments in which methyllithium was allowed to react with *N*-nitroso-*O*,*N*-dimethylhydroxylamine, in ether, at ca. −65°C, gave (*Z*)-azoxymethane in 10–20% yield. Accordingly we decided to probe further.

Our experiences, summarized by the examples given in Table 1, and further illustrated in the Experimental (3), suggest that the reaction of *N*-nitroso-*O*,*N*-dialkylhydroxylamines with some organometallic reagents *can* result in the regiospecific formation of azoxyalkanes. Unfortunately, the synthesis is at present effectively restricted to primary alkyllithium reagents, and is of dubious preparative value on account of the low yields, the major products indeed being those corresponding to "over-reactions". However, during this work we made the following striking discovery.

The reaction of methyllithium with *N*-nitroso-*O*-methyl-*N*-*n*-butylhydroxylamine gave two isomeric ($C_5H_{12}N_2O$) products (*A* and *B*), both of which were obtained as liquids, homogeneous by glc analysis. Some spectroscopic properties of these two compounds are listed in Table 2.

The less polar, minor isomer *A* was thus identified as the expected (*Z*)-azoxyalkane (**7**). When *B* was heated (in boiling toluene solution) it was cleanly but slowly converted into *A* (the pro-

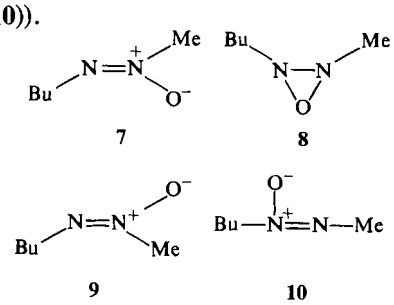
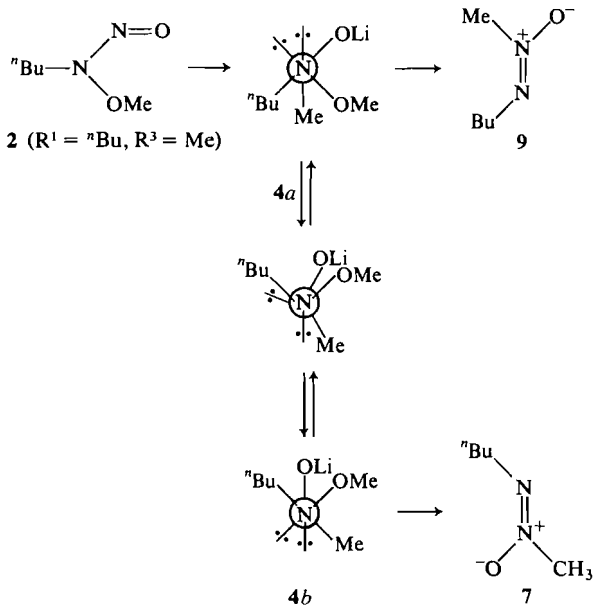
cess was almost complete after 24 h). The ir and uv spectra of *B* are inconsistent (4, 5) with it being the oxadiazirine (**8**), but are in accord (4, 5) with the (*E*)-azoxyalkane structure (**9**); as are the nmr data (which also exclude the regioisomeric (*E*)- and (*Z*)-(**10**)).



This finding surprised us, for in all the other cases the azoxyalkanes were isolated as (*Z*)-stereomers. To account for the formation of **9** we offer the following rationalization. The *N*-nitroso compound exists predominantly in the (*Z*)-conformation (as shown in **2**, Scheme 1) (6). Addition of methyllithium reagent then yields an intermediate (**4***a*) in which the barrier to inversion at nitrogen is sufficiently high that elimination of methoxide is faster, with the consequence that **9** is kinetically favoured over **7**.

If this were the case, why are (*E*)-azoxyalkanes not the usual isomers isolated? We suggest that as the steric bulk of either, or both, of the two alkyl substituents is increased, thermal isomerization to the more stable (*Z*)-stereomer becomes easy; and/or that in cases where there are more hydrogens attached to the distal (to oxidized nitrogen) α-carbon atom than on the proximal, isomerization via a distal anionic species becomes a facile process,[2] i.e. under our reaction conditions the process *E*-**1** ⇄ *E*-**11** ⇄ *Z*-**11** ⇄ *Z*-**1** may permit thermodynamic (equilibrium) control of azoxyalkane product-formation, with the consequence that *Z*-**1** is isolated (Scheme 2).

Of all the examples which we studied, only the reaction of methyllithium with *N*-nitroso-*N*-*n*-butyl-*O*-methylhydroxylamine would be expected



SCHEME 1. A suggestion for the reaction of methyllithium with *N*-nitroso-*N*-*n*-butyl-*O*-methylhydroxylamine.

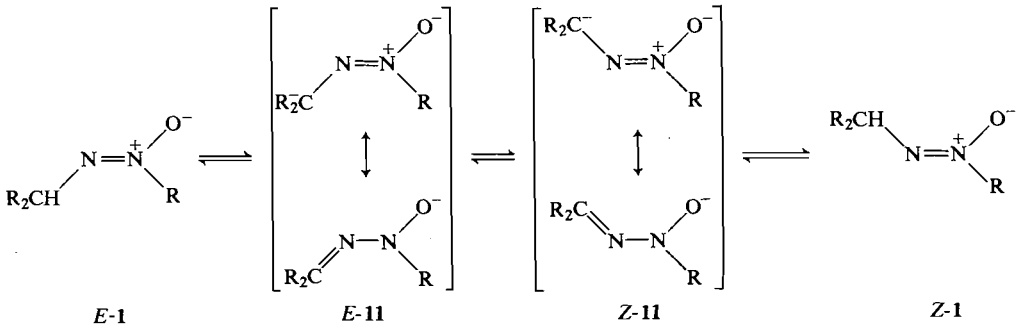
to yield an azoxyalkane which was relatively sterically unhindered, and possessed more proximal α-hydrogen atoms than distal, i.e. where the preferred anion would be the proximal one, with less of a tendency to undergo $E \rightarrow Z$ isomerization than the distal anion.

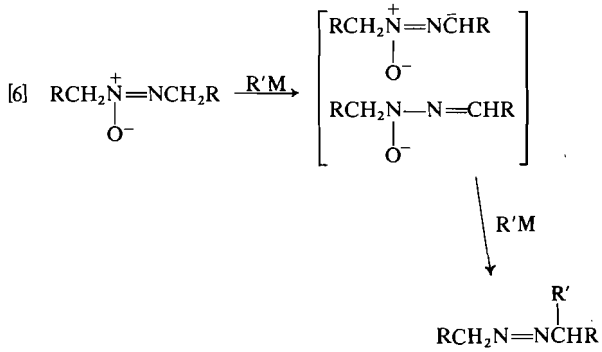
We also suspect that formation of the proximal carbanion may protect an azoxyalkane from "over-reactions" (i.e. prevent reactions such as that of eq. [6]), and so be responsible for the relatively good yields of **9** obtained under our reaction conditions.

We hoped that we might be able to supress reactions such as [6] by selecting an organometallic reagent which retained high nucleophilicity, but was less basic than an alkyllithium. However, the



E-1 *E*-11 *Z*-11 *Z*-1

SCHEME 2. The isomerism of (*E*)- and (*Z*)-azoxyalkanes via an anionic intermediate.



use of Grignard or cuprate reagents gave even lower yields of isolated azoxyalkanes (cf. Table 1), with concomitant increased production of reduction products.

As matters thus rest, the reaction of *N*-nitroso-*O*,*N*-dialkylhydroxylamines with organometallic reagents is seen to be a tantalizingly restricted route to azoxyalkanes.

Experimental

Physical Measurements

Boiling points are uncorrected.

Elemental analyses were performed by the Schwartzkopf Microanalytical Laboratory, Woodside, NY. The ^{1}H nmr spectra were measured on Hitachi Perkin-Elmer R24B, and Bruker WH-90 FT spectrometers, and ^{13}C nmr on the latter instrument. All samples were dissolved in $CDCl_3$, and shift values are quoted on the δ scale in ppm from a tetramethylsilane internal standard. Infrared spectra (ir) were recorded on Perkin-Elmer 337 or 467 grating spectrometers, liquids being examined as thin films. Mass spectra (ms) were measured on a Varian Associates MAT CH-5 spectrometer, while analyses involving ms of gas chromatographically separated samples (gc–ms) were made with a Hewlett-Packard 5992A system equipped with glass columns (17.0 cm × 0.75 (id) cm) packed with OV-101 or OV-17 (3%) on Chromosorb WHP 80/100.

Analytical gas chromatography (glc) was performed using a Bendix 2500 instrument, also using glass columns, packed with OV-1 or OV-17 liquid phases (3%). Preparative glc (pglc) was carried out with an Aerograph 90P unit, fitted with a 2 m × 3 mm column packed with SE-30 (10%) on Chromosorb W 60/80. Ultraviolet spectra (uv) were measured on a Cary 15 spectrophotometer, using 1 cm quartz cells.

Materials

Methyl- and *n*-butyllithium reagents were commercially available (Aldrich Chemical Co.) as solutions in diethyl ether and hexane respectively, and were used as received.

The *N*-nitroso-*O*,*N*-dialkylhydroxylamines were prepared by nitrosation (8) of the corresponding hydroxylamines, characterized spectroscopically, and used directly. (CAUTION! *N*-nitroso-*O*,*N*-diethylhydroxylamine is known (9) to cause cancer in rats, so it, and its homologues, should be handled with great care.) Of the hydroxylamines, *O*,*N*-dimethylhydroxylamine hydrochloride was obtained as a commercial product (Aldrich Chemical Co.), the others were synthesized by a standard procedure (10) or the sodium cyanoborohydride reduction (11) of the *O*-alkyl oximes (themselves obtained by condensing the appropriate *O*-alkylhydroxylamines and aldehydes). Exceptional was *O*,*N*-di-*tert*-butylhydroxylamine, for which we had to devise a special synthesis (12).

The Reaction of Organometallic Reagents with N-*Nitroso*-O,N-*dialkylhydroxylamines*

Typically, one or two equivalents of the organometallic reagent were added to one of the nitroso compounds dissolved in anhydrous diethyl ether, at ca. −75°C, under an atmosphere of dry argon. When optimizing conditions, aliquots of the reaction mixture were withdrawn periodically (with a syringe, via a serum-capped sampling port), quenched in aqueous ammonium chloride, and the solution analysed by glc. When the nitroso reactant was seen to have been consumed, the reaction mixture was stopped. Product isolation involved extracting the azoxyalkanes from the acidified reaction mixture, a procedure which facilitated their separation from basic, "over-reaction" products. However, it should be noted that (*E*)-azoxyalkanes are more polar than their (*Z*)-stereomers, and correspondingly more soluble in water, so continuous extraction may be required. Column chromatography (Merck Silica Gel 60 70/230 mesh), or pglc was also required. The examples given below provide details of these methods.

The Reaction of n-*Butyllithium with* N-*Nitroso*-O,N-*dimethylhydroxylamine: The Preparation of* (Z)-*1*-n-*Butyl-2-methyldiazene-1-oxide* (Z)-*1* (R^1 = *Me*, R^2 = ^{n}*Bu*)

A hexane solution of *n*-butyllithium (1.6 *M*, 35 mL, 56 mmol) was added dropwise over 30 min to a stirred solution of *N*-nitroso-*O*,*N*-dimethylhydroxylamine (3.6 g, 40 mmol) in diethyl ether (50 mL) maintained at −78°C, under an argon atmosphere. The light yellow suspension which formed was stirred for a further hour at −78°C, and then quenched at −60°C by the addition of saturated aqueous ammonium chloride solution (20 mL). When this mixture had warmed to 0°C, the yellow ether phase was separated from the colourless aqueous phase, washed with hydrochloric acid (3 *M*, 3 × 10 mL) and brine (1 × 10 mL), then dried ($MgSO_4$), and evaporated to yield a yellow oil (X-1) (1.5 g).

The aqueous phase from the quenched reaction was combined with the various aqueous washes, basified with aqueous ammonia,[3] and extracted with diethyl ether (3 × 100 mL). The combined ether extracts were then dried ($MgSO_4$) and evaporated to yield a second yellow oil (X-2) (1.6 g).

A gc–ms analysis of X-1 revealed three major products: X-1-*1* (ca. 20%, P^+ 99 amu); X-1-*2* (ca. 8%, P^+ 142 amu), and X-1-*3* (ca. 72%, P^+ 156 amu). Of these, X-1-*1* and X-1-*3* were isolated by pglc, and purified by bulb-to-bulb distillation (18 Torr pressure, bath ca. 80°C). X-1-*2* was recognized as identical with X-2-*1* (identical gc–ms data) and identified as described below.

As thus obtained X-1-*1* was a near colourless liquid; λ_{max} (EtOH) (log ε): 218 (ca. 3.7); ir ν_{max}: 1515, 1385, and 1328 cm^{-1}; ^{1}H nmr δ: 0.95 (3H, t, *J* = 7 Hz), 1.1–1.6 (2H, m), 1.97 (2H, p, *J* = 7 Hz), 3.20 (3H, s), and 4.20 (2H, t, *J* = 7 Hz); ^{13}C nmr δ: 13.5 (q), 19.7 (t), 29.8 (t), 39.4 (q), and 69.4 (t); ms: 99 (100) (*M* − 17), 61 (32), 60 (25), 57 (68), 43 (98), and 41 (98) amu, all consistent with this product being (*Z*)-1-*n*-butyl-2-methyldiazene-1-oxide ((*Z*)-**1**, R^1 = Me, R^2 = *n*-Bu). *Anal.* calcd. for $C_5H_{12}N_2O$: C 51.70, H 10.42, N 24.12%; found: C 52.10, H 10.35, N 24.23%.

Similarly X-1-*3* was obtained as a nearly colourless oil; ir ν_{max}: 2950, 2870, 1470, 1438, and 1382 cm^{-1}; ^{1}H nmr δ: 0.85 (3H, t, *J* = 7 Hz), 0.90 (3H, t, *J* = 7 Hz), 1.2–2.2 (10H, m), 3.80 (4H, t, *J* = 7 Hz); ^{13}C nmr δ: 14.0 (two coincident signals, q), 20.6 (t), 22.5

[3]If the acidic solution was extracted continuously with dichloromethane for 24 h and the dried ($MgSO_4$) extracts were evaporated, only a trace of yellow oil was obtained.

(t), 27.4 (t), 29.6 (t), 29.8 (t), 68.9 (t), and 69.2 (t); ms: 156 (14), 56 (62), 43 (100), and 41 (62) amu, all consistent with this being *N*-*n*-butyl-*N'*-*n*-pentyldiazene. *Anal.* calcd. for $C_9H_{20}N_2$: C 69.18, H 12.81%; found: C 69.00, H 13.05%.

Analysis of X-2 by gc–ms revealed the presence of two major products X-2-*1* (ca. 40%, P^+ 142 amu) and X-2-*2* (ca. 60%, P^+ 156 amu). These were isolated by pglc, and purified by bulb-to-bulb distillation as before.

As thus obtained, X-2-*1* was a colourless oil; ^{1}H nmr δ: 0.91 (3H, t, J = 7 Hz), 1.2–2.1 (4H, m), and 3.75 (2H, t, J = 7 Hz); ^{13}C nmr δ: 13.9 (q), 20.5 (t), 29.8 (t), and 69.0 (t); ms: 142 (15), 57 (95), and 41 (100) amu, all consistent with this being *N*,*N'*-di-*n*-butyldiazene. *Anal.* calcd. for $C_8H_{18}N_2$: C 67.49, H 12.74, N 19.76%; found: C 67.38, H 12.55, N 19.83%.

Similarly X-2-*2* was obtained as a near colourless oil; ^{1}H nmr δ: 0.92 (3H, t, J = 7 Hz), 0.94 (3H, t, J = 7 Hz), 1.2–1.6 (6H, m), 2.35 (2H, q, J = 7.5 Hz), 2.65 (3H, s), 3.07 (2H, t, J = 6.8 Hz), and 6.63 (1H, t, J = 5.5 Hz); ^{13}C nmr δ: 13.7 (q), 14.0 (q), 20.3 (t), 21.2 (t), 29.0 (t), 35.2 (t), 38.3 (q), 58.3 (t), and 138.2 (d); ms: 156 (16), 113 (100), and 44 (28) amu, all consistent with this being butanal *N*-*n*-butyl-*N*-methylhydrazone, and presumably the (*E*)-stereomer. *Anal.* calcd. for $C_9H_{20}N_2$: N 18.00%; found: N 17.43%.

The Preparation of (E)-, *and* (Z)-*1-Methyl-1-*n*-butyldiazene-1-oxides* (*(E)-9, and (Z)-9*)

A solution of methyllithium (1.9 *M* in diethyl ether, 12.9 mL, 21.6 mmol) was added, over the course of 10 min, to a stirred solution of *N*-nitroso-*N*-*n*-butyl-*O*-methylhydroxylamine (1.43 g, 10.8 mmol) in diethyl ether (60 mL), maintained at ca. −60°C, under an atmosphere of argon. After about 0.5 equiv. of the methyllithium had been added a yellow precipitate began to separate. After addition was complete, the reaction mixture was stirred at ca. −60°C for 30 min. A sample (0.5 mL) was then withdrawn, quenched in a saturated aqueous solution of ammonium chloride (1 mL), the ether phase separated, dried ($MgSO_4$), and analysed by glc. Little nitrosohydroxylamine remained, so the main bulk of the reaction mixture was allowed to warm up. At about 0°C the precipitate was almost completely dissolved, and the solution was orange coloured. The mixture was then shaken with saturated aqueous ammonium chloride solution (10 mL). The ether phase was separated, washed with dilute hydrochloric acid (3 *M*, 3 × 10 mL), and again with saturated aqueous ammonium chloride solution (1 × 10 mL), before being dried ($MgSO_4$) and concentrated (at atmospheric pressure) to a yellow oil (fraction X-1, 0.85 g), which still contained some ether.

The aqueous phase from the quenching of the reaction mixture was combined with the other aqueous washings and the whole (ca. 60 mL, pH ca. 1) was extracted continuously with dichloromethane, for 8 h. The organic extract was then dried ($MgSO_4$) and evaporated at atmospheric pressure to yield another yellow oil (X-2, 2.07 g).

The aqueous phase was brought to pH ca. 4 (indicator paper) with aqueous ammonia, and extracted continuously with dichloromethane for a further 24 h. Processing of the organic extract as before yielded a little more yellow oil (X-3, 0.19 g).

A glc analysis of X-1 (on 10% SE-30 at 80°C) revealed the presence of one major component. This was isolated after column chromatography (monitored by glc) as a nearly colourless oil (eluted with CH_2Cl_2), >98% pure by glc analysis (60 mg). This material, isomer *A*, was purified for analysis by bulb-to-bulb distillation under reduced pressure (80°C bath, at 20 Torr). *Anal.* calcd. for $C_5H_{12}N_2O$: C 51.70, H 10.42, N 24.12%; found: C 51.48, H 10.50, N 24.15%. The spectroscopic data collected from isomer *A* ((*Z*)-**9**) are presented in Table 2 (see text), and revealed this to be the (*Z*)-azoxyalkane (**7**).

The glc analyses of X-2 and X-3 revealed them to be very similar (containing small amounts of isomer *A*, and many other minor products, together with major amounts of a new component). Accordingly, these fractions were combined and subjected to column chromatography (as before, monitoring the separation by glc). Small amounts of isomer *A* (ca. 20 mg) were isolated from the initial (CH_2Cl_2) eluates, while a major component appeared in the later (CH_2Cl_2–Et_2O 1:1 (v/v)) fractions. Removal of the solvent afforded this second substance as a pale yellow oil (295 mg), >98% pure by glc. This material, isomer *B*, was also purified for analysis by bulb-to-bulb distillation. Found: C 51.76, H 10.41, N 23.90% cf. isomer *A*. The spectroscopic data collected for isomer *B* ((*E*)-**9**) are also presented in Table 2, and showed it to be the (*E*)-azoxyalkane (**9**).

Thermal Isomerization of B

A solution of *B* (30 mg) in toluene (5 mL) was boiled under reflux and the reaction mixture monitored by glc. After 24 h, *B* appeared to have been destroyed. After removal of toluene, under reduced pressure (ca. 20 Torr) at room temperature, an ^{1}H nmr spectrum of the residue (20 mg) revealed it to be the isomer *A* (**7**); together with traces of residual *B* and toluene.

A total synthesis of the enantiomer of anhydromyriocin (anhydrothermozymocidin)[1]

DANIEL R. PAYETTE[2] AND GEORGE JUST

Department of Chemistry, McGill University, Montreal, P.Q., Canada H3A 2K6

Received July 2, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

DANIEL R. PAYETTE and GEORGE JUST. Can. J. Chem. **59**, 269 (1981).

The optical antipode of anhydromyriocin, the γ-lactone derived from the antibiotic myriocin (thermozymocidin), was synthesized from L-arabinose, establishing the absolute configuration of myriocin as **47**. In contrast to its natural enantiomer, it showed but little antifungal activity.

DANIEL R. PAYETTE et GEORGE JUST. Can. J. Chem. **59**, 269 (1981).

L'antipode optique de l'anhydromyriocine, la γ-lactone obtenue à partir de l'antibiotique myriocine (thermozymocidine) a été synthétisé à partir du L-arabinose, établissant ainsi **47** comme étant la configuration absolue de la myriocine. Contrairement à son énantiomère naturel, ce produit ne montra que peu d'activité fungicide.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

In 1972, two antifungal agents, myriocin and thermozymocidin, were isolated from *Myriococcum albomyces NRRL 3858* (1) and *Albomyces 20,349* (2) respectively. They were both identified as 2-amino-2-hydroxymethyl-3,4-dihydroxy-14-oxo-eicos-6-enoic acid (3, 4). Some ambiguity remained concerning their identity and relative stereochemistries. Their absolute configuration was not reported. Bagli *et al.* (3) suggested the stereochemistry **1** for anhydromyriocin, whereas Kuo and Wendler (5) assigned the configuration **2**, based on spectral comparison of various synthetic racemic isomers of the lactonic ester **3** with Bagli's products. This was in accord with the relative stereochemistry obtained by X-ray diffraction for thermozymocidin.[3]

We decided to synthesize anhydrothermozymocidin from chiral precursors, and compare it to the γ-lactone derived from natural myriocin, thus (*a*) confirming the identity or nonidentity of the two compounds and (*b*) proving their absolute and relative configuration.

Synthetic Approach

The best candidate for a precursor seemed to be arabinose which already contains the desired *vic*-diol in a *threo* configuration and of which both D and L isomers are available. In the approach described, the two main problems were (*a*) elongation of the pentose at C-1 by at least one carbon atom permitting the introduction of a *trans* double bond and the hydrocarbon chain, and (*b*) selective protection of the 4-hydroxy function, allowing its conversion at a later stage to a ketone and hence to a cyanoamine and amino acid.

We first studied the use of phosphorus ylids on partially protected pentofuranoses, hoping to effect simultaneous homologation at C-1 and opening of the sugar, thus allowing subsequent protection of the free hydroxyl group. The use of stabilized ylids is limited by the ease with which the products cyclize via a Michael-type addition (6), restricting the choice of hydroxyl protecting groups. It was our experience that although nonstabilized ylids react sluggishly with closed sugars, others, of intermediate reactivity, such as thiomethylmethylenetriphenylphosphorane, did give the desired intermediate. However, we also found that hydrolysis of the resulting terminal vinyl sulfides to the free aldehydes presented major difficulties.

We then decided to use the sugar in the open form and concentrate on the homologation itself. We describe several approaches involving (*a*) attempted displacement of mesylate or iodide functions with an acetylenic anion (**6** → **7** → **8** → **9** →); (*b*) a two-carbon elongation via a stabilized ylid leading to a carboxylic acid, followed by oxidative decarboxylation and ultimately the formation of a terminal phosphonium salt (**6** → **11** → **12** → **13** → **19** →); (*c*) formation, via a Wittig reaction, of a model α,β-unsaturated ketone followed by reduction, with a borane reagent, of the corresponding tosylhydrazone accompanied by migration of the double bond (**6** → **14** → **15** → **16**); and finally, (*d*) the method which proved to be the most practical: a one carbon elongation using nitromethane addition with eventual transformation to a terminal bromide or an aldehyde, permitting the formation of the double bond by a Wittig reaction (**6** → **17** → **18** → **19** or **18** → **20** → **21**).

acetal **4** (8) was protected as its *tert*-butyldimethylsilyl ether **5** (9) and converted to the free aldehyde **6** (10). Reduction with sodium borohydride gave alcohol **7** which was transformed to the mesylate **8** (11) and then to the iodide **9** by refluxing **8** in 2-butanone with excess sodium iodide (12). Reaction of **8** or **9** with the lithium salt of a model acetylene (1-octyne) in 10% HMPT/THF gave exclusively, and regardless of temperature, elimination products. Furthermore, formation of iodide **9** from mesylate **8** was complicated by the competing formation of tetrahydrofuran derivative **10**, so that no more than 40% **9** could be isolated.

Next, aldehyde **6** was treated with carbomethoxymethylenetriphenylphosphorane in methanol to give a mixture of *E* and *Z* olefins **11**, which was reduced to the saturated methyl ester with sodium borohydride in the presence of nickelous chloride (13). Treatment with lithium *n*-propylmercaptide in HMPT (14) gave the free acid **13**, but all attempts to convert **13** through Hunsdiecker-type (15) reactions to bromide **19**

failed. However, this terminal bromide **19**, which we hoped to convert to the corresponding phosphonium salt, was produced by a different route as will be discussed later in the text.

The first successful formation of a *trans* double bond at the appropriate position (**16**) was accomplished by the catecholborane reduction (16) of tosylhydrazone **15**, obtained by reaction of aldehyde **6** with 1-triphenylphosphoranylidene-2-propanone in DMF, followed by reaction of the resulting *trans* α,β-unsaturated ketone **14** with tosylhydrazine (17) in ethanol at 20°C. However, the low yields, the relative instability of **15**, and the difficulties in obtaining it in a pure state prompted us to look for a more practical approach.

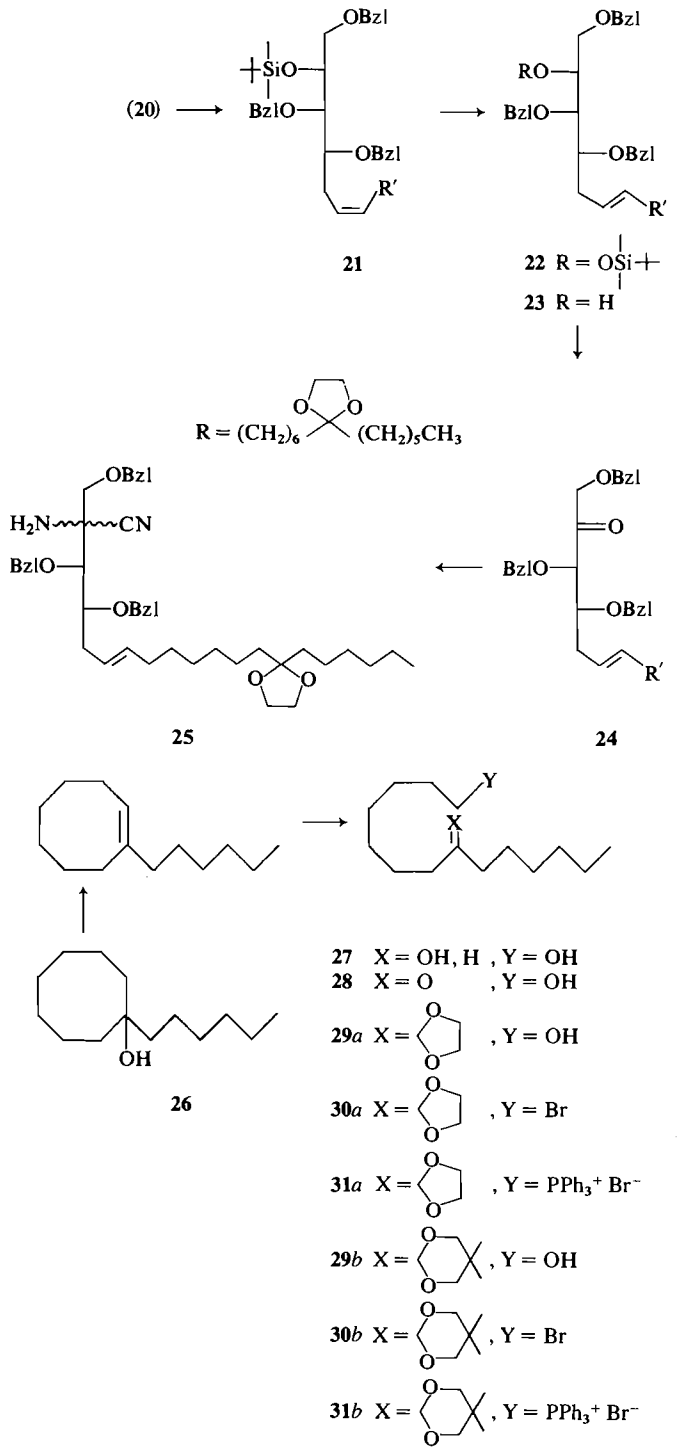
Wollenberg and Miller (18) reported a very efficient method of converting aldehydes into saturated nitro compounds having one more carbon atom by the addition of nitromethane, using fluoride ions as base, followed by acetylation and reduction with sodium borohydride. We found that, although this method failed on closed sugars, it could be applied successfully on aldehydo sugars such as **6**, giving the nitro compound **17** in 76% overall yield. Ozonolysis of the sodium nitronate salt (19) of **17** in ethanol, followed by reductive work-up with sodium borohydride, gave alcohol **18**, which could then be converted to bromide **19** by Hanessian's method (20). Attempts were made to form the corresponding phosphonium bromide by reaction with triphenylphosphine in various refluxing solvents such as toluene, ethanol, or dimethylformamide (21), but they resulted in either recovery of the starting material or its complete destruction.

Oxidation of **18** with pyridinium chlorochromate (22) gave the base sensitive aldehyde **20** which could, in principle, be submitted to the action of an appropriate Wittig reagent.

Wittig reactions involving nonstabilized ylids generally produce, in the absence of soluble lithium salts, predominately *cis* olefins (23). Schlosser and Christmann (24) reported recently a modification of this reaction, whereby the intermediate betaine is isomerized to its more stable *threo* form by adding a second equivalent of base. Conflicting reports have appeared concerning the generality of this procedure (25). When we treated aldehyde **6** with the ylid generated from a model *n*-alkyltriphenylphosphonium iodide, following exactly Schlosser's procedure using freshly prepared phenyl lithium as base and a 1:1 mixture of THF/diethyl ether as solvent, we obtained at best a nonseparable 1:1 mixture of *cis* and *trans* olefins as determined by ^{13}C nmr. We then decided to prepare the *cis*-olefin using the standard Wittig reaction conditions and isomerize it chemically to its *trans* isomer. For this, we needed the phosphonium bromide salt **31** which was prepared as follows.

Reaction of cyclooctanone with *n*-hexylmagnesium bromide in refluxing ether and dehydration of the resulting tertiary alcohol **26** with iodine in refluxing xylene (26) gave 1-hexylcyclooctene. Ozonolysis in ethanol at −70°C, followed by reductive work-up with sodium borohydride, gave the conveniently crystalline diol **27**. Selective oxidation of the secondary alcohol function with bromine–HMPT (27) afforded 1-hydroxy-8-tetradecanone **28** which was ketalized with either ethylene glycol or 2,2-dimethyl-1,3-propanediol in refluxing benzene with *p*-toluenesulfonic acid as catalyst to afford **29***a* or **29***b*. Alcohols **29** were then converted to the corresponding bromides **30** with *N*-bromosuccinimide and triphenylphosphine in DMF (20). Treatment of **30***a* with triphenylphosphine under argon at 140°C for 5.5 h gave **31***a* as a glassy material, which had to be purified by fractional precipitation. However, the infrared and nmr spectra of **31***a* showed partial hydrolysis of the ketal function (10 to 30%). This problem was later solved by using the less acid sensitive ketal **30***b* instead of **30***a*, and carrying out the reaction in acetonitrile in the presence of trimethyl orthoformate. The phosphonium salt **31***b* thus obtained was also purified by repeated precipitation.

Aldehyde **20** was submitted to the action of the ylid generated from **31***a* in THF at −70°C. *Cis*-olefin **21**, contaminated with less than 5% of its *trans* isomer, was obtained in 67% yield. The conditions of this reaction proved to be critical. Too rapid an addition of aldehyde to the cold ylid solution or higher reaction temperature resulted in the formation of elimination products. The isomerization of the *cis* to the *trans*-olefin **22** was carried out according to the method of Vedejs and Fuchs (28) which involves epoxidation, followed by reaction with lithium diphenylphosphide, quaternization with methyl iodide, and decomposition of the intermediate betaine. Desilylation of **22** with tetra-*n*-butylammonium fluoride in THF (9) and oxidation with dimethyl sulfoxide – acetic anhydride (29) gave ketone **24**. Treatment with sodium cyanide and ammonium chloride in methanolic ammonia for 4 days at 20–25°C produced the two isomeric cyanoamines **25** which were separated by high pressure liquid chromatography but could not be assigned definite structures. Debenzylation using published procedures (30) was unfortunately not



successful. Even hydrogenolysis over palladium on charcoal in ethanol – acetic acid, which, we hoped, would have given the saturated debenzylated product, failed, **25** acting, as could be demonstrated, as a very effective catalyst poison. The complete sequence was therefore repeated using acid labile protecting groups.

The L-arabinose derivative **32** (31) was tritylated and, without purification, silylated (9) to give the fully protected dithioacetal **33**, which was trans-

formed into the 2-deoxy aldehyde **37** (**33** → **34** → **35** → **36** → **37**) as described in the benzylated series (**5** to **20**). The Wittig reaction was performed with the phosphonium salt **31***b* rather than **31***a* giving a much improved yield of *Z*-olefin **38**. Epoxidation of **38** was best carried out in cyclohexane and gave a mixture of products, the two major components of which were assumed to be the two *erythro* epoxides and were therefore not separated. The use of more polar solvents, such as CH_2Cl_2 and dichloroethylene, or the addition of a buffer solution (32) resulted in more complex reaction mixtures.

Successive treatment of the epoxides with lithium diphenylphosphide and methyl iodide produced the *E*-olefin **39**[5] in 81% yield from **38**. Desilylation and oxidation as from **22** to **24** gave ketone **41** which, upon treatment with sodium cyanide and ammonium chloride for 8 days, gave cyanoamines **42** and **43** in a 4:5 ratio and 71% total yield. The reaction could easily be monitored by tlc which indicated, more clearly than with **25**, the rapid formation of the corresponding cyanohydrins, followed by their slow conversion to the more polar cyanoamines. Heating only resulted in a very modest increase in reaction rate and the formation of more impurities. Separation of the cyanoamines could this time be achieved by "flash" column chromatography (33).

The final step, consisting of the simultaneous acid hydrolysis of all protecting groups and acid catalyzed lactonization, was first attempted by treating **42** with 90% aqueous trifluoroacetic acid at 25°C for 10 min. Deprotection of the different functionalities seemed complete from the presence of ketone (1710 cm^{-1}) and hydroxyl (3200–3600 cm^{-1}) absorptions in the infrared spectrum of the major product, and also from its polarity on tlc, as compared with "natural" anhydromyriocin; but no lactone or carboxylic acid absorption could be detected. However, treatment of **42** with wet methanolic HCl for 3 h at 45°C, gave lactone **44**, in 56% yield, the ir, 200 MHz ^{1}Hmr, and ms spectra of which were superimposable with that of the γ-lactone derived from natural myriocin (3). This, and comparison of the optical rotation of **44** in methanol and methanolic HCl, with that reported for anhydromyriocin $[\alpha]_D^{24}$ + 33.4° (*c* 0.718, MeOH) (3) and for anhydrothermozymocidin hydrochloride $[\alpha]_D^{25}$ + 33° (*c* 1.0, MeOH) (4*b*), clearly demonstrated (*a*) the identity of myriocin and thermozymocidin, and (*b*) that **44** is the optical antipode of their γ-lactone, proving **46** to be their absolute configuration.

The other cyanoamine **43** was similarly transformed into lactone **45**, the different spectra of which, while confirming the structure, showed significant differences to that of **44**.

Biological Activity

Lactones **44** and **45** did not show any significant in vitro antimicrobial activity against Candida, Dermatophytes, and Trichomonads.

Experimental

General

Mass spectra (ms) were obtained on a HP 5984 or LKB-9000 mass spectrometer. Infrared (ir) spectra were obtained on a Perkin Elmer 297 spectrophotometer. Proton and carbon-13 magnetic resonance spectra were recorded on Varian T-60, T-60A, XL-200, and on Brucker FT 90 spectrometers. High pressure liquid chromatography separations were performed on an Altex 300 instrument, using "Spherisorb S10W" silica gel (Technical Marketing Associates). Chemical shifts were measured using tetramethylsilane as internal standard. Thin-layer chromatography was carried out using precoated Kieselgel 60 F_{254} silica gel plates. All column chromatography was performed using the "flash chromatography" technique described by Still *et al.* (33) and using 32–63 μ (400–230 mesh) silica gel (ICN).[6] Microanalyses were carried out by Mid-West Microlab Ltd., Indianapolis, IN. Melting points were determined on a Gallenkamp block and are uncorrected unless otherwise mentioned. The following abbreviations were used: rt (room temperature), tlc (thin layer chromatography), s (singlet), d (doublet), m (multiplet), etc., b (broad or badly defined), pe (petroleum ether 30–60°C), HMPT (hexamethylphosphoric triamide), EI (electron impact), and CI-IB (chemical ionization/isobutane).

*2,3,5-Tri-*O*-benzyl-4-*O*-*tert*-butyldimethylsilyl-*D*-arabinose Diethyl Dithioacetal (5)*

A solution of alcohol **4** (8) (9.4 g, 18 mmol) in dry DMF (100 mL) was treated with *tert*-butyldimethylsilyl chloride (3.5 g, 23 mmol) and imidazole (3.5 g, 51 mmol) under argon, for 3 days at ambient temperature. Water (200 mL) was added and the product was extracted with pe (6 × 100 mL). The combined extracts were washed with water (3 × 100 mL), dried ($MgSO_4$), and concentrated *in vacuo* to a colorless oil. Chromatography (by successive elution of a 55 mm column with 400 mL pe and 1000 mL 8% EtOAc/pe) gave 11.1 g of pure **5** (95%): $[\alpha]_D^{22}$ −13.0° (*c* 13.3, $CHCl_3$); ir (film) ν_{max}: 1250 and 830 (Si—C) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.09, 0.13 (2s, 6H, $Si(CH_3)_2$), 0.90 (s, 9H, $SiBu^t$), 1.11, 1.19 (2t, 6H, J = 7.5 Hz, SCH_2CH_3), 2.51, 2.75 (2q, 4H, J = 7.5 Hz, SCH_2CH_3), 3.3–5.0 (m's, 12H) and 7.23 (s, 15H, phenyls) ppm; ms (EI, 15 eV, 60°C) *m/e*: 640 (0.2, M^+), 583 (9), 579 (2), 505 (9), 267 (71), and 91 (100); *Anal.* calcd. for $C_{36}H_{52}O_4S_2Si$: C 67.45, H 8.18, S 10.00; found: C 67.26, H 8.07, S 9.89.

*2,3,5-Tri-*O*-benzyl-4-*O*-*tert*-butyldimethylsilyl-*aldehydo-*D*-arabinose (6)*

A solution of **5** (1.05 g, 1.64 mmol), $HgCl_2$ (0.90 g, 3.3 mmol), and HgO (0.90 g, 4.1 mmol) in 20 mL of 90% aqueous acetone

[5]The isomeric purity of the olefin was established by ^{13}C nmr of the final product **44**, which showed no detectable amount of *cis*-olefin carbons.

was stirred at rt for one hour. Hexane (50 mL) was added and the mixture was filtered through Celite. The filtrate was concentrated *in vacuo* to about 20 mL causing the precipitation of more mercuric salts which were filtered off. This filtrate, diluted with 30 mL hexane, was washed with 5% KI (2 × 60 mL) and water. Drying ($MgSO_4$) and evaporation of the solvent left 0.87 g (99%) of colorless aldehyde **6** which, as shown by tlc and ir spectroscopy, needed neither purification nor dehydration. An analytical sample was obtained by chromatography (8% EtOAc/hexane); $[\alpha]_D^{22}$ −12° (*c* 10.2, $CHCl_3$); ir (film)ν_{max}: 2895 and 1736 (aldehyde) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.07 (s, 6H, $Si(CH_3)_2$), 0.90 (s, 9H, $SiBu^t$), 3.40–4.32 (m's, 5H), 4.45 (s, 2H, CH_2Ph), 4.56 (s, 2H, CH_2Ph), 4.40, 4.60, 4.67, 4.87 (ABq, 2H, *J* = 11 Hz, CH_2Ph), 7.23, 7.26 (2s, 15H), and 9.8 (apparent s, 1H, CHO) ppm.

Alcohol 7

Aldehyde **6** (1.27 g, 2.38 mmol) was reduced by treatment with sodium borohydride (90 mg, 2.37 mmol) in 15 mL methanol for 30 min. The solvent was evaporated and replaced by hexane (50 mL), and the mixture was acidified with 10% aqueous acetic acid. The aqueous phase was extracted with hexane and the combined extracts were washed with saturated $NaHCO_3$ and water. Drying ($MgSO_4$) and evaporation of the solvent left 1.15 g (91%) of pure **7**; $[\alpha]_D^{22}$ −8° (*c* 17, $CHCl_3$); ir (film) ν_{max}: 3200–3600 (hydroxyl) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.08 (s, 6H, $Si(CH_3)_2$), 0.90 (s, 9H, $SiBu^t$), 2.68 (bs, 1H, OH), 3.40–3.95 (m's, 6H), 4.00–4.32 (m, 1H), 4.43, 4.59, 4.68 (3s, 2H each, CH_2Ph), and 7.23 (s, 15H) ppm; ms (EI, 15 eV, 20°C) *m/e*: 481 (0.4), 446 (2), 340 (24), and 181 (100); *Anal.* calcd. for $C_{32}H_{44}O_5Si$: C 71.60, H 8.26; found: C 71.44, H 8.49.

Mesylate 8 (ref. 11)

Methanesulfonyl chloride (0.41 mL, 5.26 mmol) was added dropwise to a cold solution (ice–salt bath) of alcohol **7** (1.99 g, 3.71 mmol) and triethylamine (1.04 mL, 7.43 mmol) in dry pentane. After 5 min, hexane (70 mL) was added and the mixture was washed successively with 1 *N* HCl (2 × 50 mL), water (50 mL), and saturated $NaHCO_3$. Drying ($MgSO_4$) and evaporation of the solvent left a colorless oil which was chromatographed (18% EtOAc/hexane) to give 2.04 g (89%) of mesylate **8**; $[\alpha]_D^{22}$ −5.5° (*c* 6.5, CCl_4); ir (film)ν_{max}: 1182 (—SO_2—O—)cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.06 (s, 6H, $Si(CH_3)_2$), 0.89 (s, 9H, $SiBu^t$), 2.78 (s, 3H, OSO_2CH_3), 3.36–4.16 (m's, 7H), 4.26–4.84 (m's, 6H, 3× CH_2Ph), and 7.25 (s, 15H) ppm; ms (CI-IB, 25–130°C) *m/e*: 615 (0.6, $M^+ + 1$), 211 (100).

Iodide 9 and Tetrahydrofuran 10 (ref. 12)

A solution of mesylate **8** (494 mg, 0.81 mmol) and anhydrous sodium iodide (1.2 g, 8.0 mmol) in 15 mL freshly distilled 2-butanone was refluxed for 80 min, at which time production of the desired iodide **9** had stopped as indicated by tlc (15% EtOAc/hexane). Hexane and water (20 mL each) were added. The aqueous phase was extracted with hexane (3 × 10 mL) and the combined extracts were washed successively with aqueous sodium thiosulfate, saturated $NaHCO_3$, and water. After drying ($MgSO_4$) and concentration *in vacuo*, chromatography (4%, EtOAc/hexane) afforded 188 mg (36%) of iodide **9**. When the reaction was allowed to continue, iodide **9** was all converted to a by-product, identified as **10**, after the same work-up as above and chromatography (14% EtOAc/hexane); iodide **9**: $[\alpha]_D^{22}$ −4.3° (*c* 9.0, CCl_4); ^{1}Hmr (CCl_4) δ: 0.09 (s, 6H, $Si(CH_3)_2$), 0.91 (s, 9H, $SiBu^t$), 3.26–4.16 (m's, 7H), 4,42, 4.61, 4.70 (3s, 2H each, CH_2Ph), and 7.24 (s, 15H) ppm; ms (CI-IB, 23–125°C) *m/e*: 647 (45, $M^+ + 1$), 181 (100); tetrahydrofuran **10**: $[\alpha]_D^{22}$ −10° (*c* 1.2, CCl_4); ^{1}Hmr (CCl_4) δ: 3.38–3.60 (m, 2H), 3.77–4.05 (m, 5H), 4.39 (s, 2H, CH_2Ph), 4.51 (s, 4H, CH_2Ph), and 7.23 (s, 15H) ppm; ms (CI-IB, 24–120°C) *m/e*: 405 (43, $M^+ + 1$), 181 (100).

Unsaturated Ester 11

A solution of aldehyde **6** (1.88 g, 3.52 mmol) and carbomethoxymethylenetriphenylphosphorane (1.41 g, 4.23 mmol) in 20 mL methanol was kept at rt for 18 h. The solvent was evaporated and replaced by 100 mL hexane. The precipitate was filtered off and washed with hexane. The filtrate was concentrated *in vacuo* to leave a colorless oil which appeared on tlc as a clean pair of spots, in a 3 to 2 ratio, the major component being the less polar one. It was possible, by flash chromatography (7% EtOAc/hexane), to obtain a small amount of the two components in sufficient purity to identify them as the *cis* (major) and *trans* (minor) isomers of **11**. The total yield of the purified mixture of isomers was 2.00 g (96%); *cis* isomer: ir (film) ν_{max}: 1738 (α,β-unsaturated ester) and 1652 (C=C) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.05 (s, 6H, $Si(CH_3)_2$), 0.91 (s, 9H, $SiBu^t$), 3.49–4.26 (m's, 7H, $COOCH_3$ singlet at 3.62), 4.48 (s, 4H, CH_2Ph), 4.67 (s, 2H, CH_2Ph), 5.29 (d of d, M part of an ABMX pattern, 1H, $J_{3,4}$ = 8.5 Hz, $J_{2,4}$ < 1 Hz, $J_{4,5}$ = 4 Hz, C-4), 5.73, 5.92, 6.10, 6.23, 6.28, 6.41 (AB part of the ABMX, 2H, $J_{2,3}$ = 11 Hz, C-2,3), and 7.24 (s, 15H) ppm; ms (EI, 70 eV, 105°C) *m/e*: 577 (0.1), 533 (0.3), 482 (0.1), 425 (1), 181 (12), and 91 (100); *trans* isomer: ir (film) ν_{max}: 1742 (α,β-unsaturated ester), 1655 (C=C) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.05 (s, 6H, $Si(CH_3)_2$), 0.95 (s, 9H, $SiBu^t$), 3.43–3.89 (m's, 6H, $COOCH_3$ singlet at 3.70), 3.97–4.76 (m's, 8H), 5.90, 6.16 (B part of an apparent ABX pattern, 1H, $J_{2,3}$ = 17 Hz, $J_{3,4}$ = 6 Hz, $J_{2,4}$ < 1Hz, C-2), 6.79, 6.89, 7.06, 7.16 (A part of the ABX, 1H, C-3), and 7.24 (s, 15H) ppm; ms (EI, 70 eV, 85°C) *m/e*: 533 (0.1), 482 (0.2), 425 (0.3), 181 (15), and 91 (100).

Methyl Ester 12 (ref. 13)

To a solution of unsaturated esters **11** (2.00 g, 3.39 mmol) in 25 mL methanol cooled in an ice bath, nickelous chloride hexahydrate (0.081 g, 0.34 mmol) was added and the mixture was stirred until dissolution was complete. Then, sodium borohydride (0.259 g, 6.79 mmol) was added slowly, followed, after five minutes, by 5 mL water. Most of the methanol was evaporated off and replaced by hexane (50 mL), and the mixture was acidified with 10% aqueous acetic acid. The aqueous phase was separated and extracted with hexane (3 × 50 mL). The combined organic phases were washed with saturated $NaHCO_3$ and water, dried over $MgSO_4$, and concentrated *in vacuo* to give, after chromatography (10% EtOAc/hexane), 1.80 g (90%) of **12**; $[\alpha]_D^{22}$ +2.5° (*c* 9.1, $CHCl_3$); ir (film) ν_{max}: 1735 (ester) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.07 (s, 6H, $Si(CH_3)_2$), 0.89 (s, 9H, $SiBu^t$), 1.72–2.51 (m's, 4H, CH_2CH_2COOR), 3.53–4.25 (m's, 8H, $COOCH_3$ singlet at 3.57), 4.49 (s, 2H, CH_2Ph), 4.35, 4.55, 4.61, 4.81 and 4.52, 4.71, 4.76, 4.95 (2 ABq, 2H each, *J* = 11 Hz, CH_2Ph), and 7.25 (s, 15H) ppm; ms (EI, 15 eV, 22°C) *m/e*: 536 (0.3), 502 (0.3), 337 (11), 245 (25), and 181 (100); *Anal.* calcd. for $C_{35}H_{48}O_6Si$: C 70.91, H 8.16; found: C 70.76, H 8.34.

Carboxylic Acid 13 (ref. 14)

A solution of 1-propanethiol (1.26 mL, 14 mmol) in 10 mL dry THF, was treated under argon with *n*-butyl lithium (6.9 mL, 1.6 *M* solution in hexane, 11 mmol) for 5 min at room temperature. Then, 10 mL HMPT was added, followed after 5 min by a solution of methyl ester **12** (1.65 g, 2.79 mmol) in 25 mL HMPT. After 2.5 h, the mixture was poured in 200 mL 5% aqueous acetic acid and several extractions with diethyl ether (4 × 60 mL) were performed. The combined ether extracts were shaken with 100 mL 10% aqueous silver nitrate and the solids were filtered off before the organic phase could be separated. Drying ($MgSO_4$) and evaporation of the solvent gave an oil still containing some HMPT and acetic acid. This oil was then taken up in hexane (100 mL), washed with water (5 × 50 mL), dried, and concentrated again. Chromatography of the residue (a 55 mm column was eluted with successive 500 mL portions of 20%, 50%

EtOAc in hexane, and pure EtOAc) gave 1.40 g of pure **13** (88%); $[\alpha]_D^{22}$ +1.2° (*c* 6.9, $CHCl_3$); ir (film) ν_{max}: 3400–2500 and 1710 (carboxylic acid) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.08 (s, 6H, $Si(CH_3)_2$), 0.90 (s, 9H, $SiBu^t$), 1.96 (m, 2H, C-3), 2.30 (m, 2H, C-2), 3.40–4.22 (m's, 5H), 4.47 (s, 2H, CH_2Ph), 4.34, 4.53, 4.62, 4.80 and 4.51, 4.69, 4.75, 4.93 (2 ABq, 2H each, J = 11 Hz, CH_2Ph), 7.24 (s, 15H), and 11.15 (bs, 1H, COOH) ppm; ms (EI, 15 eV, 20–100°C) *m/e*: 523 (0.2), 521 (0.6), 489 (1.2), 381 (3), and 91 (100); *Anal.* calcd. for $C_{34}H_{46}O_6Si$: C 70.54, H 8.01; found: C 70.71, H 8.25.

Unsaturated Ketone 14

Aldehyde **6** (1.26 g, 2.36 mmol), in 15 mL dry DMF, was treated with 1-triphenylphosphoranylidene-2-propanone (900 mg, 2.83 mmol) in the presence of benzoic acid (14 mg, 0.11 mmol) for 16 h at rt and 2.5 h at 80°C. Water (100 mL) was added and the mixture was extracted with hexane (6 × 50 mL). The combined extracts were washed with saturated $NaHCO_3$ and water (3 × 50 mL), dried over $MgSO_4$, and concentrated *in vacuo*. Chromatography (7% EtOAc/hexane) afforded 0.95 g (70%) of ketone **14**; $[\alpha]_D^{22}$ −13° (*c* 6.5, $CHCl_3$); ir (film) ν_{max}: 1691 (α,β-unsaturated ketone) and 1630 (C=C) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.06 (s, 6H, $Si(CH_3)_2$), 0.89 (s, 9H, $SiBu^t$), 2.11 (s, 3H, $COCH_3$), 3.41–3.86 (m's, 3H), 3.96–4.46 (m's, 2H), 4.49, 4.70 (2s, 4H and 2H, CH_2Ph), 6.08, 6.35, 6.59, 6.69, 6.86, 6.96 (AB part of an apparent ABX pattern, 2H, J_{AB} = 17 Hz, J_{AX} = 6 Hz, J_{BX} < 1 Hz, CH=CH), and 7.26 (s, 15H) ppm; ms (CI-IB, 27–130°C) *m/e*: 575 (2.4, M^+ +1), 107 (100); *Anal.* calcd. for $C_{35}H_{46}O_5Si$: C 73.13, H 8.07; found: C 73.25, H 8.29.

Tosylhydrazone 15 (ref. 17)

A solution of ketone **14** (574 mg, 1.65 mmol) and *p*-toluenesulfonylhydrazine (338 mg, 1.82 mmol) in 15 mL absolute ethanol was stirred at rt for 3 h. The solvent was evaporated off at rt and the residue chromatographed (22% EtOAc/hexane) to yield 0.51 g (42%) of unstable hydrazone **15** as a yellow oil; $[\alpha]_D^{22}$ +3° (*c* 13, $CHCl_3$); ir (film) ν_{max}: 3220 (N—H), 1603 (olefin), and 1172 (SO_2—N) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.02, 0.04 (2s, 6H, $Si(CH_3)_2$), 0.87 (s, 9H, $SiBu^t$), 1.77 (s, 3H, C-1), 2.40 (s, 3H, $PhCH_3$), 3.33–4.72 (m's, 11H), 5.73, 5.83, 6.00, 6.10, 6.23, 6.50 (AB part of an ABX, 2H, J_{AB} = 16 Hz, J_{AX} < 1 Hz, J_{BX} = 6 Hz, CH=CH), 7.17–7.38, 7.76–7.99 (m's, 19H), and 8.24 (bs, 1H, NH) ppm.

Olefin 16 (ref. 16)

Catecholborane (0.1 mL, 0.9 mmol) was added to a solution of tosylhydrazone **15** (500 mg, 0.67 mmol) in chloroform (5 mL) under argon. After one hour at 0°C and one more hour at rt, sodium acetate trihydrate (300 mg, 2.2 mmol) was added and the mixture was refluxed for 3 h. Most of the chloroform was evaporated and replaced by 50 mL hexane. This solution was washed twice with water and the aqueous phases were extracted with hexane (30 mL). The combined organic phases were dried ($MgSO_4$) and concentrated to give a yellow oil which was chromatographed (4% EtOAc/hexane) yielding 220 mg (58%) of olefin **16**; $[\alpha]_D^{22}$ −11° (*c* 2.6, CCl_4); ir (film) ν_{max}: 970 (*trans* olefin) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.06 (s, 6H, $Si(CH_3)_2$), 0.89 (s, 9H, $SiBu^t$), 1.63 (d, 3H, J = 4 Hz, allylic CH_3), 2.32 (m, 2H, allylic CH_2), 3.40–4.26 (m's, 5H), 4.47, 4.57 (2s, 2H each, CH_2Ph), 4.52, 4.70, 4.75, 4.93 (ABq, 2H, J = 11 Hz, CH_2Ph), 5.42 (m, 2H, CH=CH), and 7.26 (s, 15H) ppm; *Anal.* calcd. for $C_{35}H_{48}O_4Si$: C 74.95, H 8.63; found: C 75.15, H 8.80.

Nitrosugar 17 → Cyanoamine 25

Most compounds in the **17** to **25** series were prepared using similar or identical procedures and work-up as compounds **35** to **43**. For additional details, the reader is referred to the procedures of the latter series.

3,4,6-Tri-O-benzyl-5-O-tert-butyldimethylsilyl-1,2-dideoxy-1-nitro-D-arabino-hexitol (17)

Similarly to the preparation of **35**, aldehyde **6** (500 mg, 0.90 mmol) was treated successively with (*a*) nitromethane (0.14 mL, 2.6 mmol), anhydrous KF (3 mg, 0.05 mmol), and 18-crown-6 (12 mg, 0.05 mmol) in isopropanol for 3 h at rt; (*b*) acetic anhydride (0.12 mL, 1.3 mmol) and 4-dimethylaminopyridine (10 mg, 0.09 mmol) in anhydrous Et_2O for 18 h; and (*c*) $NaBH_4$ (100 mg, 2.8 mmol) in absolute EtOH (5 mL) in an ice bath. The same tlc solvent (9% EtOAc/pe) was used for each step. After work-up and chromatography (7% EtOAc/pe), 411 mg of nitro compound **17** (76%) was obtained; $[\alpha]_D^{22}$ +2.0° (*c* 13.5, $CHCl_3$); ir (film) ν_{max}: 1548 (RNO_2) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.08 (s, 6H, $Si(CH_3)_2$), 0.90 (s, 9H, $SiBu^t$), 1.85–2.45 (m, 2H, $CH_2CH_2NO_2$), 3.39–3.9 (m's, 4H), 3.9–4.45 (m's, 3H, including a triplet at 4.28 for CH_2NO_2, J = 7 Hz), 4.47–4.92 (m's, 6H, CH_2Ph), 7.23 and 7.27 (2s, 15H) ppm; ms (CI-IB, 135°C) *m/e*: 580 (2.5, M^+ +1), 181 (100); *Anal.* calcd. for $C_{33}H_{45}NO_6Si$: C 68.36, H 7.82, N 2.41; found: C 68.21, H 7.75, N 2.46.

3,4,6-Tri-O-benzyl-5-O-tert-butyldimethylsilyl-2-deoxy-D-arabino-hexitol (18)

As for **36**, alcohol **18** was prepared by ozonolysis of the sodium nitronate salt of **17** in EtOH followed by reductive work-up with $NaBH_4$. The yield after chromatography (25% EtOAc/pe) amounted to 83%; $[\alpha]_D^{22}$ +3.4° (*c* 17.6, $CHCl_3$); ir (film) ν_{max}: 3450 (hydroxyl) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.08 (s, 6H, $Si(CH_3)_2$), 0.90 (s, 9H, $SiBu^t$), 1.83 (t, 2H, J = 6 Hz, CH_2CH_2OH), 2.28 (s, 1H, OH), 3.40–4.28 (m's, 7H), 4.48 (s, 2H, CH_2Ph), 4.38, 4.57, 4.64, 4.83 (ABq, 2H, J = 11 Hz, CH_2Ph), 4.52, 4.71, 4.78, 4.96 (ABq, 2H, J = 11 Hz, CH_2Ph), 7.23 and 7.27 (2s, 15H) ppm; ms (CI-IB, 55°C) *m/e*: 551 (17, M^+ +1), 181 (100); *Anal.* calcd. for $C_{33}H_{46}O_5Si$: C 71.96, H 8.42; found: C 71.78, H 8.51.

3,4,6-Tri-O-benzyl-1-bromo-5-O-tert-butyldimethylsilyl-1,2-dideoxy-D-arabino-hexitol (19) (ref. 20)

To a solution of alcohol **18** (272 mg, 0.49 mmol) and triphenylphosphine (142 mg, 0.54 mmol) in dry DMF (1.0 mL), was slowly added *N*-bromosuccinimide (97 mg, 0.54 mmol). After 15 min, methanol (0.2 mL) was added followed after 5 min by water (5 mL). This mixture was extracted with hexane (4 × 10 mL) and the combined extracts washed with water (3 × 20 mL). Drying ($MgSO_4$) and evaporation of the solvent left a semi-crystalline residue containing some triphenylphosphine oxide. Chromatography (9% EtOAc/pe) afforded 211 mg (70%) of bromide **19** as a colorless oil; $[\alpha]_D^{22}$ +16° (*c* 2.65, $CHCl_3$); ^{1}Hmr ($CDCl_3$) δ: 0.05 (s, 6H, $Si(CH_3)_2$), 0.90 (s, 9H, $SiBu^t$), 2.04 (q, 2H, J = 7 Hz, C-2), 3.36 (t, 2H, J = 7 Hz, CH_2Br), 3.50–4.18 (m's, 5H), 4.47 (s, 2H, CH_2Ph), 4.37, 4.56, 4.63, 4.82 (ABq, 2H, J = 11 Hz, CH_2Ph), 4.48, 4.67, 4.72, 4.90 (ABq, 2H, J = 11 Hz, CH_2Ph), and 7.26 (s, 15H) ppm; ms (CI-IB, 10–100°C) *m/e*: 615, 613 (4.9, 4.5, M^+ +1), 181 (100); *Anal.* calcd. for $C_{33}H_{45}BrO_4Si$: C 64.58, H 7.39, Br 13.02; found: C 64.43, H 7.39, Br 13.31.

3,4,6-Tri-O-benzyl-5-O-tert-butyldimethylsilyl-2-deoxy-aldehydo-D-glucose (20)

A solution of alcohol **18** (618 mg, 1.12 mmol) in 5 mL dry CH_2Cl_2 was treated at rt with pyridinium chlorochromate (22) (360 mg, 1.67 mmol) in the presence of Celite (360 mg) and anhydrous sodium acetate (45 mg, 0.55 mmol). The reaction was in general complete in less than two hours. Hexane (15 mL) was added and the mixture was stirred for another 15 min, until the precipitate took a granular aspect. The mixture was filtered through Celite and the solids washed with several portions of hexane. The combined filtrates were concentrated *in vacuo* at rt to a colorless oil which was chromatographed (17% EtOAc/hexane) giving 474 mg (77%) of pure aldehyde **20**. This

For personal use only.

product was always used immediately because of its relative instability; $[\alpha]_D^{22}$ −6.4° (*c* 7.85, $CHCl_3$); ir (film) ν_{max}: 1722, 2720 (aldehyde) cm^{-1}; ^{1}Hmr($CDCl_3$) δ: 0.07 (s, 6H, $Si(CH_3)_2$), 0.89 (s, 9H, SiBu^t), 2.67 (d of d, 2H, *J* = 2, 6 Hz, CH_2CHO), 3.40–4.33 (m's, 5H), 4.47 (s, 2H, CH_2Ph), 4.59 (s, 2H, CH_2Ph), 4.45, 4.64, 4.70, 4.89 (ABq, 2H, *J* = 11 Hz, CH_2Ph), 7.24, 7.28 (2s, 15H), and 9.64 (t, 1H, *J* = 2 Hz, CHO) ppm.

Z-Olefin 21

In a procedure similar to the preparation of **38**, the freshly prepared aldehyde **20** (490 mg, 0.89 mmol) was added to a solution at −70°C of the ylid previously prepared by the action of *n*-butyl lithium (0.60 mL, 1.6 *M* in hexane, 0.95 mmol) on phosphonium salt **30***a* (660 mg, 1.1 mmol). The same work-up and purification by chromatography (7% EtOAc/hexane) yielded 472 mg (67%) of olefin **21**, the isomeric purity of which, as determined by ^{13}C nmr, was approximately 95% (*cis*); $[\alpha]_D^{22}$ −4.4° (*c* 10, $CHCl_3$); ir (film): no detectable absorption at 973 cm^{-1} (*trans* olefin); ^{1}Hmr ($CDCl_3$) δ: 0.08 (s, 6H, $Si(CH_3)_2$), 0.91 (apparent s, 12H, SiBu^t and CH_2CH_3), 1.10–1.80 (m's, 20H), 1.80–2.22 (m, 2H, C-8), 2.39 (m, 2H, C-5), 3.41–3.78 (m, 4H), 3.86 (s, 4H, dioxolane CH_2's), 3.93–4.27 (m, 1H), 4.48, 4.57 (2s, 2H each, CH_2Ph), 4.50, 4.69, 4.74, 4.93 (ABq, 2H, *J* = 11 Hz, CH_2Ph), 5.42 (m, 2H, CH=CH), and 7.24 (s, 15H); ^{13}C nmr ($CDCl_3$) δ: 132.03, 125.39 (C-7, C-6), 29.58, and 27.53 (C-5,8) ppm; the corresponding carbons of the *trans* isomer at 133.21, 125.93, 34.44, and 32.66 ppm were barely detectable (approximately 5%); ms (EI, 15 eV, 86°C) *m/e*: 786 (1.4, M^+), 731 (2), 701 (16), and 157 (100); *Anal.* calcd. for $C_{50}H_{76}O_6Si$: C 74.86, H 9.36; found: C 75.12, H 9.44.

E-*Olefin 22*

The *Z*-olefin **21** (957 mg, 1.22 mmol) in CH_2Cl_2 (20 mL) was treated at rt with *m*-chloroperbenzoic acid (283 mg, approximately 85% peroxyacid, 1.40 ± 0.07 mmol) for 3 h. More peroxyacid (25 mg, 0.12 mmol) was then added and the stirring continued for 1.5 h. Hexane (30 mL) was added and this mixture was washed successively with 5% aqueous Na_2SO_3 (50 mL), saturated $NaHCO_3$, and water. Drying ($MgSO_4$), concentration *in vacuo*, and chromatography (11% EtOAc/hexane) gave 884 mg (90%) of epoxide, presumably a mixture of *erythro* isomers not separated on tlc; ^{1}Hmr ($CDCl_3$) δ: 0.08 (s, 6H, $Si(CH_3)_2$), 0.91 (apparent s, 12H, SiBu^t and C-20), 1.10–2.01 (m's, 24H), 2.91 (m, 2H, C-6,7), 3.30–3.82 (m's, 3H), 3.82–4.24 (m's, 6H), 4.39–4.90 (m's, 6H, CH_2Ph), and 7.24 (s, 15H) ppm; ms (EI, 70eV, 93°C) *m/e*: 746 (0.2), 745 (0.3), 717 (1.3), 91 (100).

As in the preparation of **39**, the epoxides derived from **21** (884 mg, 1.10 mmol) were treated, in dry THF and under argon, with lithium diphenylphosphide (28) (2.3 mL of a 0.50 *M* solution in THF, 1.15 mmol) for 30 min followed by methyl iodide (0.1 mL, 1.6 mmol) for another 30 min. Chromatography (7% EtOAc/hexane) afforded 708 mg (74% from **21**) of *E*-olefin **22**. The ^{13}C nmr spectrum showed this olefin to be at least 95% *trans*; $[\alpha]_D^{22}$ −4.4° (*c* 10.6, $CHCl_3$); ir (film) ν_{max}: 973 (*trans* olefin) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: essentially identical to that of **21**; ^{13}C nmr ($CDCl_3$) δ: 133.21, 125.93 (C-7, C-6), 34.44, and 32.66 (C-5,8) ppm, all four carbons showing the characteristic downfield shift (34) from the *cis* isomer; *Anal.* calcd. for $C_{50}H_{76}O_6Si$: C 74.86, H 9.36; found: C 75.01, H 9.64.

Alcohol 23

To a solution of silyl ether **22** (818 mg, 1.04 mmol) in dry THF (7 mL) under argon, was added 1.75 mL of 0.65 *N* tetra-*n*-butylammonium fluoride (9) (1.13 mmol) in THF. After 7 h at rt, hexane (30 mL) was added, the solution was washed with water (2 × 50 mL), dried ($MgSO_4$), and concentrated *in vacuo*. The residue was chromatographed (28% EtOAc/hexane) to give 590 mg (84%) of pure **23**; $[\alpha]_D^{22}$ −1° (*c* 7.4, $CHCl_3$); ir (film) ν_{max}: 3300–3600 (hydroxyl) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.90 (bt, 3H, *J* = 6 Hz, C-20), 1.10–1.75 (m's, 20H), 1.93 (m, 2H, C-8), 2.41 (bt, 2H, *J* = 6 Hz, C-5), 3.09 (bs, 1H, OH), 3.32–3.75 (m, 4H), 3.86 (s, 4H, dioxolane CH_2's), 3.88–4.25 (m, 1H), 4.50 (s, 2H, CH_2Ph), 4.57 (s, 4H, CH_2Ph), 5.39 (m, 2H, CH=CH), 7.23 and 7.25 (2s, 15H, phenyls) ppm; *Anal.* calcd. for $C_{43}H_{60}O_6$: C 76.75, H 8.99; found: C 76.52, H 9.11.

Ketone 24

Alcohol **23** was oxidized with a 3:2 mixture of dimethylsulfoxide and acetic anhydride, exactly as described in the preparation of **41**, to give a 74% yield of ketone **24** after chromatography (20% EtOAc/hexane); $[\alpha]_D^{22}$ −26° (*c* 9.4, $CHCl_3$); ir (film) ν_{max}: 1732 (ketone) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.90 (bt, 3H, *J* = 6 Hz, C-20), 1.08–1.73 (m's, 20H), 1.87 (m, 2H, C-8), 2.35 (bt, 2H, *J* = 6 Hz, C-5), 3.64–4.07 (m's, 6H, dioxolane CH_2's singlet at 3.86), 4.27–4.71 (m's, 8H), 5.27 (m, 2H, CH=CH), and 7.25 (s, 15H) ppm.

Cyanoamines 25

Ketone **24** (411 mg, 0.61 mmol) was dissolved in 12 mL methanol previously saturated with ammonia. Sodium cyanide (60 mg, 1.2 mmol) and ammonium chloride (60 mg, 1.1 mmol) were added and the mixture was stirred at rt for 4 days. Ammonia gas was occasionally bubbled in to insure saturation. The reaction was monitored by tlc (25% EtOAc/hexane). The solvent was evaporated off and the residue was taken up in Et_2O (30 mL) and water (30 mL). The separated aqueous phase was extracted with ether (10 mL) and the combined organic phases were washed with saturated $NaHCO_3$ and water. Drying ($MgSO_4$) and evaporation of the solvent left a yellow oil which was filtered on a short silica gel column (10 g, eluted with 30% EtOAc/hexane) to remove polar impurities. The two cyanoamines, separated by high pressure liquid chromatography (230 psi, 20% EtOAc and 0.1% MeOH in hexanes), amounted to 155 mg (37%) of the less polar isomer and 137 mg (32%) of the more polar one; *less polar isomer*: $[\alpha]_D^{22}$ +2° (*c* 5.4, $CHCl_3$); ir (film) ν_{max}: 3390, 3320 (R—NH_2), 2220 (nitrile), and 972 (*trans* olefin) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.90 (bt, 3H, *J* = 6 Hz, C-20), 1.04–2.22 (m's, 24H), 2.51 (bt, 2H, *J* = 6 Hz, C-5), 3.29–3.79 (m's, 4H), 3.86 (s, 4H, dioxolane CH_2's), 4.31, 4.49, 4.56, 4.74 (ABq, 2H, *J* = 11 Hz, CH_2Ph), 4.49, 4.69 (2s, 2H each, CH_2Ph), 5.39 (m, 2H, CH=CH), and 7.24 (s, 15H, phenyls) ppm; ms (EI, 70 eV, 89°C) *m/e*: 641 (0.3), 584 (5), 476 (5), 240 (30), 157 (49), and 91 (100); *Anal.* calcd. for $C_{44}H_{60}N_2O_5$: C 75.83, H 8.68, N 4.02; found: C 75.55, H 8.69, N 4.07; *more polar isomer*: $[\alpha]_D^{22}$ +5° (*c* 5.4, $CHCl_3$); ir (film): identical to that of the other isomer; ^{1}Hmr ($CDCl_3$) δ: differs from the spectrum of the other isomer only in the 3.3–4.7 ppm region: 3.33–3.96 (m's, 8H, dioxolane CH_2's singlet at 3.86), 4.41, 4.61, 4.68, 4.87 (ABq, 2H, *J* = 11 Hz, CH_2Ph), 4.51, and 4.56 (2s, 2H each, CH_2Ph) ppm; ms (EI, 70 eV, 73°C) *m/e*; 669 (0.2), 584 (2), 476 (11), 240 (10), 157 (52), and 91 (100); *Anal.* calcd. for $C_{44}H_{60}N_2O_5$: C 75.83, H 8.68, N 4.02; found: C 75.54, H 8.61, N 4.25.

1-n-Hexylcyclooctanol (26)

A solution of 1-bromohexane (42 mL, 0.3 mol, in 50 mL dry Et_2O) was added to a stirred suspension of 14 g magnesium turnings (0.6 mol) in 400 mL dry Et_2O (under an argon atmosphere) at a rate which maintained a gentle reflux. After the addition was complete, the reflux was continued for 30 min. Then, a solution of cyclooctanone (40 g, 0.32 mol) in 50 mL Et_2O was added dropwise, again at a rate sufficient to maintain reflux which was continued for 30 min after the addition.

The cooled mixture was poured into 800 mL ice-water containing 80 mL concentrated H_2SO_4. After separation, the aqueous phase was extracted twice with ether and the combined organic phases were washed twice with water. Neutralization

(saturated $NaHCO_3$), drying ($MgSO_4$), and evaporation of the solvent left a yellow liquid. Distillation gave 24.9 g of product, bp 100–115°C/0.03 Torr, which still contained about 23% unreacted cyclooctanone as determined by glc (3 ft column, 3% OV-101, 250°C). Further purification was found unnecessary before the following reaction. Nevertheless, a small sample was later redistilled and a fraction collected at 104°C/0.005 Torr (found to be 96% pure by gc) was used for characterization; ir (film) ν_{max}: 3200–3600 (hydroxyl) cm^{-1}; ms (EI, 70 eV, 25°C) *m/e*: 194 (0.6, $M^+ - 18$), 183 (0.4), 169 (1.2), 155 (5.3), 141 (16), and 127 (100, $M^+ - 85$).

1,8-Tetradecanediol (27)

The mixture obtained previously (containing about 77% of alcohol **26** (90 mmol) and 23% cyclooctanone) was refluxed in 250 mL xylene in the presence of 150 mg iodine (0.6 mmol) (26) using a Dean-Stark trap, and the progress of the reaction was followed by glc (3% OV-101, 230°C). After 30 min, the solvent was distilled off and the residue taken up in 100 mL hexane. This solution was washed with 1.5% $Na_2S_2O_3$ (5 × 50 mL) and once with water. Drying ($MgSO_4$) and evaporation of the solvent gave a yellow liquid which was dissolved in absolute ethanol and treated with excess ozone at −70°C. After purging with a stream of nitrogen, $NaBH_4$ (10 g, 263 mmol) was added and the stirred solution allowed to warm up to rt (2 h). Most of the solvent was evaporated off and replaced by $CHCl_3$ (100 mL). The mixture was acidified with 10% aqueous AcOH and the aqueous phase extracted with $CHCl_3$. The $CHCl_3$ extracts were washed twice with water and neutralized with saturated $NaHCO_3$. Drying ($MgSO_4$) and evaporation to dryness gave a colorless oil which was crystallized from cold hexane (−50°C). After recrystallization, a 17.1 g yield (25% from bromohexane) of diol **27** was obtained; mp: 47.5–48.5°C; ir ($CHCl_3$) ν_{max}: 3300–3550 and 3610 (hydroxyls) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.7–2.0 (m, 25H), 2.44 (s, 2H, OH), and 3.45–3.70 (m, 3H, CH_xOH) ppm; ms (EI, 70 eV, 21°C) *m/e*: 213 (0.2), 211 (0.2), 194 (0.4), 166 (0.5), 145 (19), 127 (19), 109 (90), and 55 (100); *Anal.* calcd. for $C_{14}H_{30}O_2$: C 72.98, H 13.13; found: C 73.12, H 13.17.

1-Hydroxy-8-tetradecanone 28 (ref. 27)

To a mixture of diol **27** (9.9 g, 43 mmol) and hexamethyl phosphoric triamide (1.62 g, 9.1 mmol), in 350 mL CH_2Cl_2 and 250 mL of 8% $NaHCO_3$ at 5°C, was added dropwise a solution of Br_2 (7.9 g, 49 mmol) in 90 mL CH_2Cl_2 with vigorous stirring. The reaction, monitored by tlc (Et_2O) during and after the addition, was not allowed to go to completion since significant amounts of impurities, that proved difficult to remove, started to appear towards the end. The reaction was stopped by adding "reagent" hexane, which contains small amounts of olefins, until the orange color disappeared. The CH_2Cl_2 phase was separated and concentrated *in vacuo*, and replaced by hexane/Et_2O (1:1, 200 mL). After washing this solution several times with water to remove the HMPT, drying ($MgSO_4$) and evaporation of the solvent afforded a white crystalline mass, which could not be purified by crystallization. Chromatography (45% EtOAc/hexane) gave 7.1 g (72%) of colorless crystals. A sample recrystallized from cold hexane was used for characterization; mp 52.0–53.0°C; ir ($CHCl_3$) ν_{max}: 1710 (ketone), 3300–3550 and 3620 (hydroxyl) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.65–1.8 (m, 21H), 2.36 (t, 4H, J = 6.5 Hz, —CH_2CO—), 2.73 (s, 1H, OH), and 3.54 (t, 2H, J = 6 Hz, —CH_2OH) ppm; ms (EI, 70 eV, 35°C) *m/e*: 228 (0.5, M^+), 227 (0.3), 211 (0.6), 210 (0.4), 158 (6.7), 143 (7.6), 128 (27), 113 (40), and 43 (100); *Anal.* calcd. for $C_{14}H_{28}O_2$: C 73.63, H 12.36; found: C 73.27, H 12.68.

2-(7-Hydroxy-n-heptyl)-2-n-hexyl-1-3-dioxolane (29a)

A solution of ketone **28** (6.6 g, 29 mmol) in 1800 mL benzene was refluxed in the presence of $TsOH \cdot H_2O$ (900 mg, 5 mmol) and ethylene glycol (50 mL) using a Dean-Stark trap. The reaction was monitored by glc (OV-101, 200–280°C), product and starting material having the same R_f on tlc. After 4.5 h the mixture was concentrated *in vacuo* to about half its volume. The benzene phase was separated, washed with saturated $NaHCO_3$ (2 × 100 mL), and dried over $MgSO_4$. Evaporation of the solvent left a yellow liquid which was treated with $NaBH_4$ (0.4 g, 11 mmol) in 70 mL EtOH for 0.5 h to reduce any residual ketone to the more polar diol **27**. The solvent was evaporated *in vacuo*, replaced by hexanes (200 mL), and the mixture was acidified with 10% aqueous AcOH. Neutralization (saturated $NaHCO_3$), drying ($MgSO_4$), evaporation of the solvent, and purification by chromatography (45% EtOAc/hexane) gave 6.75 g pure **29*a*** (86%); ir (film) ν_{max}: 3200–3600 (hydroxyl) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.7–2.0 (m, 25H), 2.90 (s, 1H, OH), 3.50 (t, 2H, J = 6.5 Hz, CH_2OH), and 3.85 (s, 4H,dioxolane CH_2's) ppm; ms (CI-IB, 34°C) *m/e*: 273 (100, $M^+ + 1$); *Anal.* calcd. for $C_{16}H_{32}O_3$: C 70.54, H 11.84; found: C 70.30, H 11.93.

5,5-Dimethyl-2-(7-hydroxy-n-heptyl)-2-n-hexyl-1,3-dioxane (29b)

A solution of the hydroxyketone **28** (7.6 g, 31 mmol), 2,2-dimethyl-1,3-propanediol (13 g, 125 mmol), and $TsOH \cdot H_2O$ (150 mg, 0.8 mmol) in one liter of benzene was refluxed overnight using a Dean-Stark trap. The solvent was evaporated off *in vacuo* and the residue was treated with $NaBH_4$ (150 mg, 3.9 mmol) in 50 mL EtOH for 0.5 h to reduce any residual ketone to the more polar diol **27**. The ethanol was evaporated off, replaced with 100 mL hexanes, and the mixture was acidified with 10% aqueous AcOH. After neutralization with saturated $NaHCO_3$ and drying ($MgSO_4$), the solvent was removed *in vacuo* to give a yellowish liquid which was chromatographed (35% EtOAc/hexane) to give 9.5 g of pure ketal **29*b*** (97%); ir (film) ν_{max}: 3100–3600 (hydroxyl) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.7–2.0 (m, 31H, including a singlet at 0.90 for $C(CH_3)_2$), 2.8 (bs, 1H, OH), and 3.25–3.70 (m, 6H, dioxane ring CH_2's and CH_2OH) ppm; ms (EI, 15 eV, 80°C) *m/e*: 231 (1.3), 230 (13), 229 (100), and 199 (91).

2-(7-Bromo-n-heptyl)-2-n-hexyl-1,3-dioxolane (30a)

This material was prepared in 86% yield from alcohol **29*a*** by the same procedure used for **30*b***, and was purified by flash chromatography using 5% EtOAc/hexane as eluent; ^{1}Hmr ($CDCl_3$) δ: 0.7–2.1 (m, 25H), 3.38 (t, 2H, J = 6.5 Hz, CH_2Br), and 3.87 (s, 4H, dioxolane CH_2's) ppm; ms (CI-IB, 30°C) *m/e*: 337 (100, $M^+ + 1$) and 335 (95, $M^+ + 1$); *Anal.* calcd. for $C_{16}H_{31}BrO_2$: C 57.31, H 9.32, Br 23.83; found: C 57.22, H 9.33, Br 24.00.

2-(7-Bromo-n-heptyl)-5,5-dimethyl-2-n-hexyl-1,3-dioxane (30b) (ref. 20)

To a solution of alcohol **29*b*** (9.5 g, 30 mmol) and triphenylphosphine (9.50 g, 36.3 mmol) in 50 mL dry DMF was added slowly *N*-bromosuccinimide (6.50 g, 36.5 mmol) at 10°C. The reaction followed by tlc (20% EtOAc/hexane), was generally complete in less than 30 min. This mixture was then extracted with hexanes (80 mL). Water was added to the DMF phase until triphenylphosphine oxide started precipitating out and 6 more hexane extractions (80 mL) were performed. The combined hexane phases were washed twice with water, dried ($MgSO_4$), and evaporated to dryness. The residue was purified by flash chromatography (2% EtOAc/hexane) affording 9.92 g pure **30*b*** (87%) as a colorless liquid; ^{1}Hmr ($CDCl_3$) δ: 0.6–2.2 (m, 31H, including a singlet at 0.90 for $C(CH_3)_2$), 3.30 and 3.32 ((t, J = 6.3 Hz, CH_2Br) and (s, dioxane ring CH_2's), total integration 6H) ppm; ms (EI, 15 eV, 85°C) *m/e*: 294 (5), 293 (44), 292 (6), 291

For personal use only.

(42), 200 (13), and 199 (100); *Anal.* calcd. for $C_{19}H_{37}BrO_2$: C 60.47, H 9.88, Br 21.17; found: C 60.49, H 10.17, Br 21.21.

*7-(2-*n*-Hexyl-1,3-dioxolan-2-yl)-*n*-heptyl-triphenylphosphonium Bromide (31a)*

A mixture of bromide **30***a* (4.25 g, 12.7 mmol) and triphenylphosphine (3.80 g, 14.5 mmol) was heated at 140°C under argon for 5.5 h. The glassy material obtained was dissolved in a minimum of acetone and the phosphonium salt was precipitated by adding (slowly at first) anhydrous Et_2O (400 mL). The precipitate was allowed to settle overnight and the clear solution decanted. The residue was pumped dry (2 h) leaving 5.3 g (70%) of phosphonium salt **31***a* as a thick foam. This method of preparation of phosphonium salts containing a ketal function proved unreliable since a variable amount (10–30%) of ketone, resulting from partial hydrolysis of the ketal function, could be detected in the ir spectrum: ir (film) ν_{max}: 1590 (C=C) and 1710 (variable intensity) (ketone) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.7–2.0 (m, 25H), 3.5–3.85 (bs, 2H, CH_2—P^+), 3.87 (s, 4H, dioxolane CH_2's), and 7.2–8.0 (m, 15H, phenyls) ppm.

*7-(5,5-Dimethyl-2-*n*-hexyl-1-3-dioxan-2-yl)-*n*-heptyl-triphenylphosphonium Bromide (31b)*

In a flask stoppered with a septum, a mixture of bromide **30***b* (3.06 g, 8.12 mmol), triphenylphosphine (3.22 g, 12.3 mmol), and trimethyl orthoformate (1.8 mL) in dry acetonitrile (7.0 mL) was heated under argon, in an oil bath kept at 90°C, for 14 h. The solvents were evaporated *in vacuo* and the residue was dissolved in a minimum of dry tetrahydrofuran. The phosphonium salt was precipitated out by adding (slowly at first) anhydrous Et_2O (250 mL). The precipitate was allowed to settle overnight (under an argon atmosphere) and the ether solution decanted. Another precipitation from THF with Et_2O was performed and the residue was dried on a pump for 2 h to yield 4.4 g (85%) of a very thick foam.

When the precipitate was kept under an ether layer and under a dry atmosphere (argon) for a few days, partial crystallization occurred, but collection and storage of the crystals was complicated by their highly hygroscopic nature which caused them to turn back into an oil; ir (film) ν_{max}: 1590 (C=C) cm^{-1}, no trace of carbonyl absorption; ^{1}Hmr (CCl_4) δ: 0.6–2.0 (m, 31H), 3.35 (s, 4H, dioxane ring CH_2's), 3.9–4.5 (bs, 2H, CH_2—P^+), and 7.1–8.3 (m, 15H, phenyls) ppm.

*4-*O*-tert-Butyldimethylsilyl-2,3-*O*-isopropylidene-5-*O*-triphenylmethyl-*L*-arabinose Diethyl Dithioacetal (33)*

A solution of 2,3-*O*-isopropylidene-L-arabinose diethyl dithioacetal **32** (31) (14.3 g, 48.3 mmol), triphenylmethyl chloride (16.2 g, 58.2 mmol), and 4-dimethylaminopyridine (0.3 g, 2.45 mmol) in 25 mL dry pyridine was stirred at room temperature for two days. Then 50 mL dry DMF was added, followed by *tert*-butyldimethylsilyl chloride (11.0 g, 73.1 mmol) and imidazole (11.0 g, 162 mmol). After stirring at rt for 24 h, water (100 mL) was added and the mixture was extracted with hexanes (6 × 100 mL). The combined hexane phases were washed successively with 1*N* HCl, saturated $NaHCO_3$, and water. Drying over $MgSO_4$ and evaporation of the solvent afforded a colorless oil which partially crystallized. Recrystallization from absolute ethanol and purification of the residue by chromatography (2% EtOAc/petroleum ether) gave a total yield of 27.0 g (86% from **33**); mp 92–93°C; $[\alpha]_D^{22}$ −33° (*c* 12, $CHCl_3$); ir (film) ν_{max}: 1590 (aromatic) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: −0.09, 0.07 (2s, 6H, $Si(CH_3)_2$), 0.83 (s, 9H, SiBu^t), 1.27, 1.29 (2t, 6H, J = 7.5 Hz, CH_3CH_2S—), 1.33, 1.47 (2s, 6H, $C(CH_3)_2$), 2.67 (q, 4H, J = 7.5 Hz, CH_3CH_2S—), 3.05–3.4 (m, 2H), 3.8–4.6 (m, 4H), and 7.05–7.55 (m, 15H, trityl) ppm; *Anal.* calcd. for $C_{37}H_{52}O_4S_2Si$: C 68.05, H 8.02, S 9.82; found: C 68.29, H 7.88, S 10.10.

*4-*O*-tert-Butyldimethylsilyl-2,3-*O*-isopropylidene-5-*O*-triphenylmethyl-aldehydo-*L*-arabinose (34)*

The dithioacetal **33** (5.0 g, 7.7 mmol) was dissolved in 90 mL acetone, and 5 mL water was added followed by HgO (3.7 g, 17 mmol) and $HgCl_2$ (4.6 g, 17 mmol). The mixture was refluxed until no starting material could be detected by tlc (15% EtOAc/hexanes, 1.5 h). Hexane (200 mL) was added to the cooled suspension and a vigorous stirring maintained for 10 min. After filtration through Celite, the solids were washed with several portions of hexane and the combined filtrates concentrated *in vacuo* to about half their volume. The solution was decanted from the precipitated mercuric salts, washed with 5% aqueous KI (5 × 100 mL), and washed once with water. Drying over $MgSO_4$ and evaporation of the solvent left a colorless oil which was purified by flash chromatography (12% EtOAc/hexanes). The ^{1}Hmr and ir spectra showed that the aldehyde group was at least 50% hydrated. Therefore, the product was refluxed for 30 min, in 100 mL benzene using a Dean-Stark trap. Evaporation of the solvent left 4.6 g of a viscous oil which still contained some mercuric salts (as demonstrated by the immediate appearance of elemental mercury when a small amount of this aldehyde was treated with $NaBH_4$ in methanol). In general, no further purification was performed and this material was used directly in the following step.

In a subsequent run, an analytical sample was obtained by repeating the same sequence (treatment with KI and chromatography) until no mercuric salts could be detected. After dehydration in refluxing benzene, the following data could be obtained: $[\alpha]_D^{22}$ +3° (*c* 8, $CHCl_3$); ir (film) ν_{max}: 2800, 2710, 1735 (aldehyde) cm^{-1}; ^{1}Hmr (CCl_4) δ: −0.12, 0.02 (2s, 6H, $Si(CH_3)_2$), 0.83 (s, 9H, SiBu^t), 1.30, 1.40 (2s, 6H, $C(CH_3)_2$), 3.1 (apparent d, 2H), 3.7–4.0 (m, 1H), 4.25 (bs, 2H), 7.03–7.45 (m, 15H, trityl), and 9.55 (bs, 1H, CHO) ppm.

*5-*O*-tert-Butyldimethylsilyl-1,2-dideoxy-3,4-*O*-isopropylidene-1-nitro-6-*O*-triphenylmethyl-*L*-arabino-hexitol (35) (ref. 18)*

The aldehyde **34**, freshly prepared from 5.0 g of the dithioacetal **33** (7.7 mmol), was dissolved in 25 mL dry isopropanol. Nitromethane (2.0 mL, 37 mmol), anhydrous KF (50 mg, 0.86 mmol), and 18-crown-6 (120 mg, 0.45 mmol) were added and the mixture was stirred at room temperature for 3 h. The course of the reaction was followed by tlc (10% Et_2O/benzene).

The isopropanol was removed *in vacuo* at rt. The foamy material obtained was dissolved in 30 mL dry Et_2O and treated with acetic anhydride (2.0 mL, 21 mmol) and 4-dimethyl-aminopyridine (60 mg, 0.50 mmol). Thin-layer chromatography (2.5% Et_2O/benzene) indicated that after 50 min, all the β-hydroxynitro compound had been replaced by two less polar spots. The ether was evaporated off and replaced by 100 mL absolute EtOH. This solution was cooled in an ice bath and $NaBH_4$ (2.2 g, 58 mmol) was added very slowly. After one hour, a new spot on tlc (benzene), which had gradually appeared between the two original ones, had completely replaced them. The solvent was evaporated *in vacuo*, hexanes (100 mL) and water (50 mL) were added to the residue, and this mixture, in an ice bath, was slowly acidified with 10% aqueous AcOH. The aqueous phase was separated and washed twice with hexanes (100 mL). The combined organic phases were washed with water (3 × 100 mL), neutralized with saturated $NaHCO_3$, washed with water again, dried over $MgSO_4$, and concentrated *in vacuo* to a very thick syrup. Chromatography (8% EtOAc/hexanes) yielded 3.8 g of pure **35** (83% from **33**); $[\alpha)_D^{22}$ −1.1° (*c* 10,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

$CHCl_3$); ir (film) ν_{max}: 1553 (NO_2) cm^{-1}; ^{1}Hmr (CCl_4) δ: −0.08, 0.03 (2s, 6H, $Si(CH_3)_2$), 0.83 (s, 9H, $SiBu^t$), 1.29, 1.35 (2s, 6H, $C(CH_3)_2$), 2.05 (bt, 2H, J = 7.5 Hz, $—CH_2CH_2NO_2$), 2.75–3.4 (m, 2H), 3.75–4.05 (m, 3H), 4.28 (t, 2H, J = 7.5 Hz, $—CH_2NO_2$), and 7.03–7.42 (m, 15H, trityl) ppm; *Anal.* calcd. for $C_{34}H_{45}NO_6Si$: C 69.00, H 7.66, N 2.36; found: C 69.21, H 7.93, N 2.55.

*5-O-tert-Butyldimethylsilyl-2-deoxy-3,4-O-isopropylidene-6-O-triphenylmethyl-*L*-arabino-hexitol (36) (ref. 19)*

A solution of nitro compound **35** (3.8 g, 6.4 mmol) in absolute EtOH was treated with 13 mL of freshly prepared 0.59*N* EtONa/EtOH and the solution was kept stirring under nitrogen for 15 min. O_3 (36 mmol/h) was bubbled through the solution at −70°C for 17 mins (10 mmol). After purging the excess ozone with a stream of nitrogen, $NaBH_4$ (500 mg) was added, and the stirred solution was allowed to warm up to room temperature (2 h). Most of the solvent was evaporated off and replaced with hexanes (50 mL) and water (20 mL). The mixture was acidified with 10% aqueous AcOH and the separated aqueous phase washed with hexanes (2 × 50 mL). The combined organic phases were washed twice with water, neutralized with saturated $NaHCO_3$, and washed again with water. Drying ($MgSO_4$) and evaporation of the solvent gave a colorless oil which was chromatographed (27% EtOAc/hexanes) giving 3.3 g of pure **36** (92%); $[\alpha]_D^{22}$ +1.4° (*c* 11, $CHCl_3$); ir (film) ν_{max}: 3200–3600 (alcohol hydrogen bonding) cm^{-1}; ^{1}Hmr (CCl_4) δ: −0.10, 0.02 (2s, 6H, $Si(CH_3)_2$), 0.83 (s, 9H, $SiBu^t$), 1.30, 1.37 (2s, 6H, $C(CH_3)_2$), 1.68 (bt, 2H, J = 5.5 Hz, $—CH_2CH_2OH$), 2.0 (bs, 1H, OH), 2.9–3.3 (m, 2H), 3.56 (t, 2H, J = 5.5 Hz, $—CH_2OH$), 4.9 (bs, 3H), and 7.05–7.45 (m, 15H, trityl) ppm; *Anal.* calcd. for $C_{34}H_{46}O_5Si$: C 72.56, H 8.24; found: C 72.30, H 8.04.

*5-O-tert-Butyldimethylsilyl-2-deoxy-3,4-O-isopropylidene-6-O-triphenylmethyl-*aldehydo-L-*glucose (37)*

A solution of **36** (3.3 g, 5.9 mmol) in 180 mL dry methylene chloride was treated with pyridinium chlorochromate (2.5 g, 11.6 mmol) (22) in the presence of Celite (2.5 g) and anhydrous NaOAc (500 mg, 6.1 mmol) for 4 h, at ambient temperature, with vigorous stirring. Hexane (300 mL) was added and stirring was continued for a few minutes, until the precipitate had taken a granular aspect. The suspension was then filtered through Celite and the solids washed several times with hexane. The combined filtrates were concentrated *in vacuo* (water bath at 25°C) to about 100 mL and filtered again through Celite. The solvent was evaporated and the residue chromatographed (flash, 13% EtOAc/hexane) to yield 2.8 g (85%) of pure aldehyde. This product was always prepared just prior to use; $[\alpha]_D^{22}$ −1.1° (*c* 8.6, $CHCl_3$); ir (film) ν_{max}: 2820, 2720, and 1728 (aldehyde) cm^{-1}; ^{1}Hmr (CCl_4) δ: −0.10, 0.01 (2s, 6H, $Si(CH_3)_2$), 0.83 (s, 9H, $SiBu^t$), 1.33 (bs, 6H, $C(CH_3)_2$), 2.42 (d of d, 2H, J = 2, 5.5 Hz, CH_2CHO), 2.8–3.4 (m, 2H), 3.8–4.6 (m, 3H), 7.1–7.5 (m, 15H, trityl), and 9.65 (t, 1H, J = 2 Hz, CHO) ppm.

Z-Olefin 38

A solution of the phosphonium salt **31***b* (4.4 g, 6.9 mmol) in dry THF (30 mL) under argon was treated with 1.6*N* *n*-BuLi in hexane (3.5 mL, 5.6 mmol) at 25°C for 10 min, then cooled to −70°C. A solution of the freshly prepared aldehyde **37** (2.8 g, 5.0 mmol) in 20 mL dry THF was added dropwise (one drop per second). After stirring at −70°C for 5 min, 1 mL *t*-BuOH in 5 mL THF was added, the mixture was warmed up to 20°C, and stirred for 20 min. Et_2O (50 mL) was added and the mixture was washed with water (4 × 50 mL), dried ($MgSO_4$), and concentrated *in vacuo* to a volume of about 10 mL. Hexane (100 mL) was added, causing precipitation of Ph_3PO which was filtered off. The filtrate was concentrated again *in vacuo* to half its volume, cooled in an ice bath, and Ph_3PO filtered again. Evaporation of the solvent to dryness left a yellow oil which was purified by flash chromatography as follows. Half of the crude material was applied on a 55 mm id column as a 30% (approx.) solution in 2% EtOAc/hexane and the column was eluted successively with 2% and 3% EtOAc/hexane (1000 mL each); 50 mL fractions were collected. Fractions 16–34 contained pure olefin **38**; total yield: 3.6 g (86%); $[\alpha]_D^{22}$ −4° (*c* 10, $CHCl_3$); ir (film) ν_{max}: 3000–3100 (aromatic C—H), 2800–3000 (aliphatic C—H, large), 1601 (C=C), and no detectable absorption at 971 cm^{-1} (*trans* olefin) which was present in the spectrum of the *trans* isomer **38**; ^{1}Hmr (CCl_4) δ: −0.11, 0.02 (2s, 6H, $Si(CH_3)_2$), 0.6–2.5 (m's, 48H), 3.0–3.25 (m, 2H), 3.33 (s, 4H, dioxane ring CH_2's), 3.86 (m, 3H), 5.2–5.8 (m, 2H, CH=CH), and 7.05–7.55 (m, 15H, trityl) ppm; *Anal.* calcd. for $C_{53}H_{80}O_6Si$: C 75.67, H 9.59; found: C 75.60, H 9.85.

E-Olefin 39

A solution of *Z*-olefin **38** (3.1 g, 3.7 mmol) in 80 mL cyclohexane was treated with *m*-chloroperbenzoic acid (0.95 g, approximately 85% peroxyacid, 4.7 ± 0.3 mmol) for 30 min at 5°C and 90 min at ambient temperature. More peroxyacid (0.30 g, 1.4 ± 0.1 mmol) was added. After one hour, hexane (70 mL) was added and the solution was washed successively with 5% aqueous Na_2SO_3 (2 × 50 mL), saturated $NaHCO_3$, and water. Drying ($MgSO_4$) and evaporation of the solvent *in vacuo* left a crude material which appeared on tlc (15% EtOAc/hexane) as three very close spots. The two major components presumed to be the two possible *erythro* epoxides were separated from the minor (least polar) one by repeated flash chromatography, each time using successively 5 and 10% EtOAc/hexane. A total yield of 3.0 g (95%) of *erythro* epoxides was obtained; ^{1}Hmr (CCl_4) δ: −0.07 and 0.02, −0.05 and 0.02 (two pairs of s, 6H, $Si(CH_3)_2$), 0.6–2.3 (m's, 48H), 2.5–3.5 (m's, 8H, with a singlet at 3.33 for dioxane CH_2's), 3.7–4.2 (m, 3H), and 7.02–7.55 (m, 15H, trityl) ppm.

A 0.45*M* solution of lithium diphenylphosphide (28) was prepared by treating chlorodiphenylphosphine (0.18 mL, 1.0 mmol) in 20 mL dry tetrahydrofuran with excess lithium (28 mg) for 3 h at room temperature, under an argon atmosphere; 8.3 mL of this solution (3.7 mmol) was added with a syringe to a solution of the epoxides (3.0 g, 3.5 mmol) in 20 mL dry THF under argon. After 25 min at 20°C, methyl iodide (0.5 mL, 8.1 mmol) was added and stirring was continued for 90 min. The mixture was then poured in 100 mL saturated $NaHCO_3$ and the separated aqueous phase was extracted with hexane (4 × 50 mL). The combined organic phases were washed with water (3 × 50 mL), dried over $MgSO_4$, and concentrated *in vacuo*. Purification by chromatography (4% EtOAc/hexane) afforded 2.5 g (85%) of pure olefin **39** (81% from **38**); $[\alpha]_D^{22}$ −6.7° (*c* 5.5, $CHCl_3$); ir (film) ν_{max}: identical with that of *Z*-olefin **37** plus a 970 cm^{-1} absorption for *trans* olefin; ^{1}Hmr (CCl_4) δ: −0.11, 0.01 (2s, 6H, $Si(CH_3)_2$), 0.6–2.3 (m's, 48H), 3.0–3.25 (m, 2H), 3.33 (s, 4H, dioxane ring CH_2's), 3.83 (m, 3H), 5.25–5.50 (m, 2H, —CH=CH—), and 7.05–7.55 (m, 15H, trityl) ppm.

Alcohol 40

Tetra-*n*-butylammonium fluoride trihydrate (1.8 g, 5.7 mmol) was azeotroped with benzene, the benzene evaporated, and dry THF (40 mL) was added. A solution of the silyl ether **39** (2.5 g, 3.0 mmol) in dry THF (20 mL) was then introduced and the mixture was refluxed until the reaction appeared complete on tlc (14% EtOAc/hexane, 2 to 3 h), the reaction being carried out under argon. Hexane (50 mL) was added, the solution was washed with water (2 × 50 mL), dried ($MgSO_4$), and concentrated *in vacuo*. Chromatography of the residue (14% EtOAc/hexane) gave 1.9 g of alcohol **40** (88%); $[\alpha]_D^{22}$ −6° (*c* 13, CCl_4); ir (film) ν_{max}: 3300–3600 (hydroxyl) cm^{-1}; ^{1}Hmr (CCl_4) δ: 0.90 (apparent s, 9H, dioxane $C(CH_3)_2$ and CH_2CH_3), 1.05–2.40

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

(m, 30H), 2.4–2.7 (bs, 1H, OH), 3.1–4.1 (m's, 9H, dioxane CH_2's singlet at 3.33), 5.30–5.55 (m, 2H, CH=CH), and 7.1–7.55 (m, 15H, trityl) ppm.

Ketone 41

Alcohol **40** (1.9 g, 2.6 mmol) was dissolved in 10 mL of a 3:2 mixture of dry dimethyl sulfoxide and acetic anhydride. The solution was stirred at room temperature under argon for 18 h. Water (50 mL) was added and the mixture was extracted with hexane (6 × 50 mL). The combined hexane solutions were washed with water (2 × 50 mL), dried over $MgSO_4$, and stripped of solvent *in vacuo* at rt. The residue was chromatographed by the successive elution of a 55 mm column with 5% and 10% EtOAc/hexane (1000 mL each) which yielded 1.65 g of pure ketone **41** (87%); $[\alpha]_D^{22}$ +8° (*c* 9.5, CCl_4); ir (film) ν_{max}: 1737 (ketone) cm^{-1}; ^{1}Hmr (CCl_4) δ: 0.7–2.4 (m's, 39H), 3.33 (s, 4H, dioxane CH_2's), 3.70–3.90 (m, 2H), 4.00 (m, 2H), 5.25–5.50 (m, 2H, CH=CH), and 7.0–7.55 (m, 15H, trityl) ppm.

Cyanoamines 42 and 43

Ketone **41** (1.60 g, 2.21 mmol) was dissolved in 80 mL methanol previously saturated with ammonia. Sodium cyanide (350 mg, 7.1 mmol) and ammonium chloride (350 mg, 6.5 mmol) were added and the mixture was stirred at 20–25°C for 8 days with daily bubbling in of ammonia to ensure saturation. As shown by tlc (20% EtOAc/hexane), the ketone was rapidly converted into two more polar compounds, identical in R_f's with the products obtained by treating **41** with sodium cyanide and sodium bisulfite in methanol, and therefore probably the cyanohydrins. In the following days, the cyanohydrins were slowly replaced by the even more polar cyanoamines. The solvent was removed *in vacuo* and replaced with hexane (100 mL). This solution was washed with water, dried ($MgSO_4$), and concentrated to a yellow oil. Repeated flash chromatography on a 55 mm column (15% EtOAc/hexane) allowed the isolation of cyanoamines **42** (more polar) and **43** (less polar) in respective yields of 0.51 g (31%) and 0.66 g (40%); cyanoamine **42**: $[\alpha]_D^{22}$ −4° (*c* 6, $CHCl_3$); ir (film) ν_{max}: 3320 and 3390 (R—NH_2), 973 (*trans* olefin) cm^{-1}, nitrile absorption too small to be observed; ^{1}Hmr (CCl_4) δ: 0.7–2.4 (m's, 41H), 3.07 (bs, 2H), 3.20–3.75 (m, 6H, dioxane CH_2's singlet at 3.33), 3.80–4.25 (m, 2H), 5.10–5.40 (m, 2H, CH=CH), and 7.05–7.55 (m, 15H, trityl) ppm; *Anal.* calcd. for $C_{48}H_{66}N_2O_5$: C 76.76, H 8.86, N 3.73; found: C 76.61, H 9.04, N 3.58; cyanoamine **43**: $[\alpha]_D^{22}$ −26° (*c* 8.0, $CHCl_3$); ir (film) ν_{max}: 3330 and 3400 (R—NH_2), 975 (*trans* olefin) cm^{-1}, nitrile absorption too small to be observed; ^{1}Hmr (CCl_4) δ: essentially identical to that of **41**, apparent broad singlet at 3.07 ppm replaced by a multiplet: 2.85–3.20 (2H) ppm; *Anal.* calcd. for $C_{48}H_{66}N_2O_5$: C 76.76, H 8.86, N 3.73; found: C 76.90, H 8.97, N 3.55.

Lactone 44

To a solution of cyanoamine **42** (430 mg, 0.57 mmol) in 2.0 mL methanol was added 8.0 mL of 3% water in methanol previously saturated with HCl gas. The mixture was kept in a water bath at 45°C for 3 h. The solvent was then removed *in vacuo* and replaced by 30 mL chloroform. This solution was washed several times with saturated K_2CO_3, then with water (until neutrality), dried over $MgSO_4$, and concentrated *in vacuo*. Chromatography (flash, on a 10 mm column, 11% methanol in chloroform) followed by recrystallization from diethyl ether/hexane gave 125 mg (56%) of crystalline **44**. An analytical sample was obtained by further recrystallization from the same solvents until a constant melting point of 79.5–80.0°C (corrected) was recorded; $[\alpha]_D^{22}$ −24° (*c* 3.0, methanol) and −38° (*c* 0.55, 0.037 *N* HCl in methanol); ir (CH_2Cl_2) ν_{max}: 3100–3650 with maxima at 3310, 3390, and 3605 (R—NH_2 and R—OH), 1774 (γ-lactone), 1709 (ketone) and 970 (*trans* olefin) cm^{-1}; ^{1}Hmr, 200 MHz, ($CDCl_3$) δ: 0.86 (t, 3H, J = 7 Hz, C-20), 1.00–1.42 (m's, 12H), 1.54 (p, 4H, J = 7 Hz, C-12,16), 2.00 (q, 2H, J = 6.5 Hz, C-8), 2.38 (t, 4H, J = 7 Hz, C-13,15), 2.56 (t, 2H, J = 6.5 Hz, C-5), 3.62, 3.67, 3.74, 3.79 (ABq, 2H, J = 11 Hz, CH_2OH), 4.11 (d, 1H, J = 3.5 Hz, C-3), 4.46 (t of d, 1H, J = 3.5, 6.5 Hz, C-4), and 5.52 (m, 2H, $J_{6,7}$ = 16 Hz, $J_{5,6}$ = $J_{7,8}$ = 6.5 Hz, δ_6 = 5.43, δ_7 = 5.61) ppm, exchangeable protons not included; ^{13}C nmr ($CDCl_3$): the olefinic carbons C-6 and C-7 appear at 123.72 and 134.78 ppm respectively, with no detectable amount of the carbons from the corresponding *cis*-olefin which would normally appear at slightly higher field (34); ms (EI, 70 eV, 22–130°C) *m/e*: 383 (M^+, 0.5), 256 (60), 200 (12), 113 (17), 104 (35), and 102 (100); all spectra were superimposable with that of anhydromyriocin, prepared as described by Bagli *et al.* (3) from natural myriocin.

Lactone 45

Cyanoamine **43** (450 mg, 0.60 mmol) was treated as described above with wet methanolic HCl for 3 h at 45°C. After work-up, the crude product was purified by chromatography (10 mm column, 5% MeOH/$CHCl_3$) and recrystallized from Et_2O/hexane to give 140 mg (60%) of pure **45**, melting at 76.0–76.5°C (corrected); $[\alpha]_D^{22}$ −54° (*c* 2.7, methanol); ir (CH_2Cl_2) ν_{max}: 3200–3650 with maxima at 3310, 3380, and 3590 (R—NH_2 and R—OH), 1772 (γ-lactone), 1709 (ketone) and 970 (*trans* olefin) cm^{-1}; ^{1}Hmr, 200 MHz, ($CDCl_3$) δ: 0.86 (t, 3H, J = 7 Hz, C-20), 1.00–1.44 (m's, 12H), 1.54 (p, 4H, J = 7 Hz, C-12, 16), 2.00 (q, 2H, J = 6.5 Hz, C-8), 2.38 (t, 4H, J = 7 Hz, C-13,15), 2.54 (m, 2H, C-5), 3.78, 3.83, 3.94, 3.99 (ABq, 2H, J = 11 Hz, CH_2OH), 4.11 (d, 1H, J = 3.5 Hz, C-3), 4.70 (t of d, 1H, J = 3.5, 6.5 Hz, C-4), and 5.52 (m, 2H, $J_{6,7}$ = 16 Hz, $J_{5,6}$ = $J_{7,8}$ = 6.5 Hz, δ_6 = 5.41, δ_7 = 5.62 ppm) ppm, exchangeable protons not included; ms (EI, 70 eV, 23–135°C) *m/e*: 383 (M^+, 0.2), 256 (13), 200 (2), 113 (17), 104 (48), and 102 (100).

Acknowledgements

We are grateful to the Natural Sciences and Engineering Research Council of Canada for financial support. We also thank Mr. A. Ugolini, Dr. W. Dawson, Dr. J. Everett, and Ms. L. Ayotte for ^{13}C and 200 MHz ^{1}Hmr spectra; Dr. O. A. Mamer, Dr. V. Taguchi, and Ms. J. Montgomery for the mass spectra; and Dr. N. Elmore, Imperial Chemical Industries, Macclesfield, for making available the biological testing results. The gift of an authentic sample of myriocin from Dr. J. Bagli, Ayerst Laboratories, Montreal, Canada, is gratefully acknowledged.

Synthesis of colchifoline from deacetylcolchiceine

MARIA A. IORIO AND MARISA MOLINARI

Laboratory of Pharmaceutical Chemistry, Istituto Superiore di Sanità, 00161 Rome Italy

AND

ARNOLD BROSSI

Medicinal Chemistry Section, Laboratory of Chemistry, NIAMDD, National Institutes of Health, Bethesda, MD 20205, U.S.A.

Received June 23, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

MARIA A. IORIO, MARISA MOLINARI, and ARNOLD BROSSI. Can. J. Chem. **59**, 283 (1981).

Treatment of a mixture of deacetylcolchicine and deacetylisocolchicine, obtained by diazomethane methylation of deacetylcolchiceine, with trifluoroacetylglycolyl chloride in pyridine, afforded directly colchifoline and isocolchifoline. The two ether isomers could be separated by chromatography and the material eluted first proved to be identical with colchifoline isolated from commercial samples of colchicine.

MARIA A. IORIO, MARISA MOLINARI et ARNOLD BROSSI. Can. J. Chem. **59**, 283 (1981).

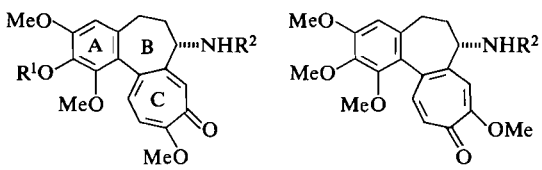
Un mélange de déacétylcolchicine et de déacétylisocolchicine, obtenu par la méthylation de la déacétylcolchicéine par le diazométhane, réagit avec le chlorure de trifluoroacétylglycolyle dans la pyridine et conduit directement à la colchifoline et à l'isocolchifoline. On peut séparer les deux éthers isomères par chromatographie. Le premier produit élué est identique à la colchifoline que l'on a isolé à partir d'un échantillon commercial de colchicine.

[Traduit par le journal]

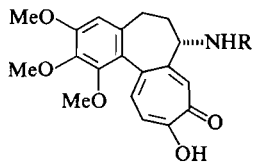
Colchifoline (**5**) is a novel congener of colchicine (**3**), recently detected and isolated from commercial samples of colchicine (1). It is chemically the *O*-methyl ether of 2-demethylcolchifoline (**7**), an alkaloid isolated by Šantavý and co-workers (2) from the leaves of *Colchicum autumnale L.* The finding of hydroxyacetylated alkaloids besides colchicine and *N*-formyl congeners is interesting, and suggests that these alkaloids are possibly related to each other through a biooxidative degradation of the *N*-acetyl group of colchicine.

We now would like to report a synthesis of colchifoline (**5**) from deacetylcolchiceine (**8**), readily available from colchicine (**3**) (3).

A mixture of **1** and **2** was obtained from deacetylcolchiceine (**8**) by the procedure of Raffauf *et al.* (4). This mixture, when treated with trifluoroacetylglycolyl chloride in pyridine, afforded, judged by tlc, a mixture of the two hydroxyacetylated derivatives **5** and **6**. Trifluoroacetylglycolyl chloride, a novel hydroxyacetylating agent, was prepared from glycolic acid by treatment with trifluoroacetic anhydride and treatment of the acid with refluxing thionyl chloride in the form of a colorless liquid (see Experimental). The reaction mixture obtained after usual work-up was separated by chromatography over silica gel. The first eluted material was identical with colchifoline (**5**), a minor contaminant of commercial colchicine (1). The second compound, obtained in at least equal amounts, was assigned the structure of isocolchifoline (**6**). The two ethers **5** and **6** are converted by refluxing 0.1 *N* HCl into colchifoleine (**9**), illustrated with the same arrangements of the oxygen functionalities in ring C as in colchiceine (**10**) (5).



1 R^1 = Me, R^2 = H **2**
3 R^1 = Me, R^2 = COMe **4**
5 R^1 = Me, R^2 = $COCH_2OH$ **6**
7 R^1 = H, R^2 = $COCH_2OH$



8 R = H
9 R = $COCH_2OH$
10 R = COMe

Structure Assignments

The colchicine-like nature of ring C in colchifoline (**5**) and the *iso* structure of isocolchifoline (**6**) were evident from a comparison of their ^1H nmr spectra (aromatic protons) with those of reference substances (**3**, **4**) reported recently (6–8). Mass spectra of colchifoline (**5**) and isocolchifoline (**6**) showed the same fragmentation pattern with the

same base peak, *m/z* 312, but varied somewhat in peak intensity. In the mass spectrum of **6** the fragment ions corresponding to $(M - COCH_2OH)^+$, *m/z* 356 (13%); $(M - NH_2COCH_2OH)^{+\cdot}$, *m/z* 340 (35%); and $(M - (CO + COCH_2OH))^+$, *m/z* 328 (18%), are of much higher intensity than the same fragments in colchifoline (**5**) (1).

Experimental

Melting points (uncorrected) were determined in open glass capillaries on a Büchi-Tottoli apparatus. Microanalyses were performed by the Microanalytical Section (ISS) under the direction of Dr. A. Mazzeo-Farina. Optical rotations were measured with a Perkin-Elmer model 141. Fourier transform ^{1}H nmr spectra were recorded at 100 MHz with a Varian XL 100 spectrometer at 29°C and mass spectra with a LKB 2091 spectrometer (70 eV) equipped with a Digital PDP 11 data processing system, samples applied by direct inlet, and probe usually heated from 25 to 200°C. Thin-layer chromatography utilized silica gel plates (Stratocrom SI F254, C. Erba).

Trifluoroacetylglycolic Acid

To a stirred and ice-cooled suspension of glycolic acid (5 g, 66 mmol) in 100 mL dichloromethane a solution of trifluoroacetic anhydride (12 mL, 86 mmol) in 50 mL dichloromethane was added dropwise during 2 h. The homogeneous solution was then stirred at room temperature for two days, evaporated under vacuum, and distilled at 95–98°C (10 Torr) to afford 9.3 g (82%) of the title compound in the form of a colorless liquid: $n_D^{24} = 1.3690$; nmr ($CDCl_3$) δ: 4.93 (s, 2H, CH_2), 10.3 (s, 1H, OH). *Anal.* calcd. for $C_4H_3F_3O_4$ (172.07): C 27.92, H 1.76; found: C 27.68, H 1.99.

Trifluoroacetylglycolyl Chloride

Trifluoroacetylglycolic acid (9 g, 52 mmol) was refluxed for 6 h in 10 mL of thionyl chloride. After this period excess thionyl chloride was removed under vacuum at room temperature and the residue distilled to afford 7.8 g (78%) of the acid chloride: bp 30–32°C (10 Torr); $d^{18} = 1.505$; nmr ($CDCl_3$) δ: 5.18 (s, CH_2). *Anal.* calcd. for $C_4H_2ClF_3O_3$ (190.51): C 25.22, H 1.06; found: C 24.94, H 1.14.

Colchifoline (5) and Isocolchifoline (6) from a Mixture of 1 and 2

To a crude mixture of **1** and **2**, prepared from 2 g of **8**, dissolved in 30 mL dichloromethane and 1.50 mL of pyridine, and cooled in an ice-bath, was carefully added dropwise, under stirring and under anhydrous conditions, 1.2 mL (9.5 mmol) of trifluoroacetylglycolyl chloride. After each drop a red color developed but disappeared quickly on stirring. After standing overnight the solution contained two new major products by tlc (SiO_2 F254, $CHCl_3$–MeOH–NH_4OH 90:9:1) with R_f 0.49 and 0.31 and identical with the isolated products **5** and **6**. The solution was washed twice with water (2 × 3 mL) before drying (Na_2SO_4). The reaction products obtained after evaporation were dissolved in chloroform and chromatographed on a column (2.5 × 80 cm) of silica gel-60 (0.04–0.06 mm) packed in $CHCl_3$, and eluted with $CHCl_3$ containing 5% MeOH and 0.5% NH_4OH. The first compound isolated was colchifoline **5** (500 mg), which crystallized from ethyl acetate. This compound retains solvent firmly and loses it after prolonged heating at 100°C (0.5 Torr). The melting point rises to 151–152°C; $[\alpha]_D^{22}$ −149° (*c* 0.94, $CHCl_3$). *Anal.* calcd. for $C_{22}H_{25}NO_7$ (415.44): C 63.60, H 6.07, N 3.37; found: C 63.47, H 5.91, N 3.17.

This compound was identical with a sample isolated from commercial colchicine (1) by tlc, mixture mp, and spectral data. The second component (660 mg) was isocolchifoline (**6**) which was crystallized from ethyl acetate – dichloromethane: mp 220–221°C; $[\alpha]_D^{22}$ −297° (*c* 1, $CHCl_3$). *Anal.* calcd. for $C_{22}H_{25}NO_7$ (415.44): C 63.60, H 6.07, N 3.37; found: C 63.40, H 6.12, N 3.33.

Colchifoleine (9)

This enol was obtained by refluxing **5** or **6** during 1 h (100 mg) in 0.1 *N* HCl (6 mL). The crystalline precipitate was filtered, washed with cold water, and crystallized from H_2O–MeOH: mp 227–228°C, $[\alpha]_D^{22}$ −254° (*c* 0.65, $CHCl_3$). *Anal.* calcd. for $C_{21}H_{23}NO_7$ (401.41): C 62.83, H 5.78, N 3.49; found: C 62.52, H 5.86, N 3.60.

The leaf oil terpene composition of incense cedar and coast redwood[1,2]

E. VON RUDLOFF

Prairie Regional Laboratory, National Research Council of Canada, Saskatoon, Sask., Canada S7N 0W9

Received June 17, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

E. VON RUDLOFF. Can. J. Chem. **59**, 285 (1981).

Analysis by an on-line computerized gas chromatographic – mass spectral method of the volatile leaf oils of the North American incense cedar and coast redwood revealed unusual percentage compositions of the major terpenes and presence of unique minor components. The chemosystematic implications are discussed briefly.

E. VON RUDLOFF. Can. J. Chem. **59**, 285 (1981).

L'analyse, par chromatographie en phase gazeuse couplée à une spectromètre de masse relié à un ordinateur, des huiles volatiles des feuilles du cèdre aromatique nord américain et du séquoia de mer révèle la présence de pourcentages inhabituels des principaux terpènes ainsi que la présence de constituants secondaires uniques. On discute brièvement des implications chimiosystématiques.
[Traduit par le journal]

Introduction

Recently, we reported on a gas chromatographic (gc) – mass spectrographic method for the identification of known terpenes in complex essential oils, such as the volatile conifer leaf oils (1). On-line computerized comparisons of mass spectra (ms) and relative retention times (rrt) facilitate quick and reliable assignment of peak identities even with the many terpenes that have similar ms. Of course the problem with unknown components, for which no reference spectra are available, remains. However, this is not a major drawback in chemosystematic studies because similarity or dissimilarity of unknowns with the same rrt in different or related species, varieties, hybrids, etc. can be established quite readily. We have improved this method by use of high efficiency glass capillary columns and although not all separation problems were solved, most components of several complex juniper leaf oils could be identified (2–4). The present communication deals with a similar analysis of the volatile leaf oils of incense cedar, *Calocedrus decurrens* (Torr.) Florin (syn. *Libocedrus decurrens* Torr.; fam. *Cupressaceae*) and for comparison also coast redwood, *Sequoia sempervirens* (D. Don) Endl. (fam. *Taxodiaceae*). Both sets of leaf samples were collected in the dormant season in northern California. The oil of incense cedar does not appear to have been analyzed by modern methods, whereas that of coast redwood was analyzed by gc and infrared (ir) spectroscopy by Levinson and co-workers in 1968 (5). Hilal *et al.* (6) reported on some bactericidal properties of redwood leaf oil components and the terpenoids of the pocket resin were investigated by Anderson and co-workers (7).

Results and Discussion

The mean relative percentage composition from 5 trees each of incense cedar and coast redwood is shown in Table 1. The terpene pattern of incense cedar is unusual among North American conifers, having relatively large amounts of limonene, car-3-ene, α-pinene, myrcene, and α-terpinyl acetate and low amounts of β-pinene, β-phellandrene, and the camphene group of terpenes (8). The presence of small amounts of 3-methylenebicyclo[3.2.1.]oct-2-ene, two possible isomers (rrt 0.252 and 0.394), and at least some of the 11 unknown minor components in the oxygenated monoterpene range is unique. The paucity of sesquiterpenes (no sesquiterpene hydrocarbon that may be correlated with Schorger's "libocedrene" (9) was found), but the presence of cedrol, as well as the absence of allyl phenyl ethers are also noteworthy. Trace components that could be identified were: tetrahydrofuran, oct-1-en-3-ol, *cis*- and *trans*-sabinene hydrate, borneol, *trans*-carveol, and methyl thymol. The quantitative variation from one tree to another was relatively small (8), although car-3-ene varied from 10 to 30%.

The major components of the leaf oil of coast redwood from northern California (α-pinene, limonene, β-phellandrene, γ-terpinene, myrcene, terpinolene, terpinen-4-ol, and eudesmol isomers) are the same as those reported by Levinson and co-workers (5). However, we found more sabinene than β-pinene, less α-terpineol and its acetate, and only traces of citronellol and geraniol. These dif-

ferences may be the result of variation from one population to another. In addition to the compounds listed in the table, we also identified trace amounts of isopentenyl isovalerate (an unusual hemiterpenoid ester found in yellow cedar, *Chamaecyparis nootkatensis* (D. Don) Spach (10) and Sitka Spruce, *Picea sitchensis* (Bong.) Carr. (11) leaf oils), hex-3-en-1-ol, tetrahydrofuran, oct-1-en-3-ol, 2-nonanone, 2-undecanone, *cis*-ocimene, *cis*- and *trans*-sabinene hydrate, camphene hydrate, borneol, neryl and geranyl acetate (but no citronellyl acetate), α-cubebene, β-bourbonene (like some of the cadinene–muurolene isomers a possible rearrangement product of germacrene-D (12)), thujopsene, β-selinene, β-cubebene, as well as several elemene, germacrene, cadinene and muurolene isomers, calamenene, 4:10-dimethyl-7-isopropylbicyclo[4.4.0]deca-1:4-diene (13), three cadinol isomers, torreyol, and possibly bisabolol. The elemol isomer with rrt 1.466 is not hedycaryol, the potential precursor of elemol and eudesmol isomers (14, 15), nor did its ms correspond to that of δ-elemol. At least 8 trace components in the monoterpene range and 15 in the sesquiterpene range remain to be identified. The great diversity of sesquiterpenes contrasts strongly with their paucity in incense cedar leaf oil and is, together with the relatively large amounts of the terpinene isomers, terpinen-4-ol, germacrene-D, and the elemol and eudesmol isomers, of chemosystematic value (8). Also, it is unusual in conifer leaf oils to find α-pinene as the main component, the only other North American species with this trait being the common juniper, *Juniperus communis* L. and yellow cedar (some trees only) (8).

Although not all of the leaf oil components of incense cedar and coast redwood could be identified, much data that are of chemosystematic value were readily obtained by the improved gc–ms

method. Presence or absence of compounds of interest (even those with unknown ms) can be established without having to resort to more time-consuming separation techniques that require larger amounts of oil. By using the total ion count for each gc peak, relative percentages can be obtained simultaneously. These percentages correspond fairly well with those obtained with a thermal conductivity detector.

Incense cedar and coast redwood are monotypic species of the order *Cupressales* and their leaf oil patterns reflect their separate taxonomic classification. Whereas there is some similarity of the monoterpene hydrocarbon patterns with that of yellow cedar, the oxygenated monoterpenes and sesquiterpenes differ greatly (8, 10). Gough and Mills (16) have found unusual diterpenes in the wood of incense cedar.

Experimental

The leaves and twigs from 5 trees each of incense cedar near Gasquet and coast redwood east of Crescent City, northern California, were collected in the fall of 1977. These were transported and stored in the cold and dark. The leaves were separated from the twigs and steam-distilled for 6 h (4, 8, 17, 18). Whereas the recovery of volatile oil from coast redwood leaves was complete (0.4–0.7%, based on fresh weight), that of the incense cedar was incomplete and distillation was continued for a further 18 h (yield 0.6–0.9%). The relative percentages of the individual components were determined by analysis on four different packed gc columns (Apiezon-L, PEG 20M-OV 17, PEG 20M-QFI, and EGPN (17, 18); helium as carrier gas, TCD) (17–19). Aliquots (1 μL) of the leaf oils in ether (1:20 v/v) were analyzed by gc–ms on a deactivated 30 m SP 2100 glass capillary column (J + W Scientific) (1:30 split ratio, helium as carrier gas) on a Finnigan model 4000 quadropole gc – mass spectrometer (2), temperature-programming from 55°C (held for 6 min after injection) to 220°C (held for 15 min) at 3°/min. Mass spectral scans were taken every second. The recorded ms were compared by the computerized method (1) with those in our own file as well as the Finnigan Library of the National Bureau of Standards. Spectra of unknown compounds were also compared with those in the literature (e.g. ref. 13). The ms of peak 2 of incense cedar showed a "purity" of 900 (max. 1000) for 3-methylenebicyclo[3.2.1]oct-2-ene in the Finnigan NBS library, which represents a high degree of similarity. Mass spectrum of the elemol isomer: 121(100), 93(78), 41(71), 105(64), 67(61), 107(56), 91(52), 81(49), 79(44), 119(42) (just as with elemol, the parent ion peak mass 220 was not recorded); ms of sesquiterpene alcohol, rrt 1.530, *m/e*: 222(2), 95(100), 150(72), 43(63), 151(58), 41(51), 81(40), 93(35), 69(35), 107(33), 55(28). The ir and ^{1}Hmr spectra of the main components of incense cedar leaf oil were recorded for the fractions isolated in preparative gc (17–19).

Atlantic Research Laboratory, National Research Council of Canada, 1411 Oxford Street, Halifax, N.S., Canada B3H 3Z1

Received July 7, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

ALFRED W. HANSON, ARCHIBALD W. MCCULLOCH, and A. GAVIN MCINNES. Can. J. Chem. **59**, 288 (1981).

Substituted dimethyl 1,4-pentadiene-1,2-dicarboxylates (**1** or **3**) may be prepared by $AlCl_3$-promoted or thermal ene reaction of olefins with dimethyl acetylenedicarboxylate. Lactonization of these adducts is catalyzed by acid. In the presence of 80% H_2SO_4 the predominant product (ca. 80%) is a (*Z*)-dihydro-3-carbomethoxymethylene-2(3*H*)-furanone (**2** or **4**). Cyclization with anhydrous HCl affords a mixture of products, the composition of which depends on the starting material; major products include the corresponding (*E*)- and δ-lactone isomers (**6** and **7**). Detailed ^1H and ^{13}C nmr data are reported for all compounds. The structures of the (*E*)-4,5,5-trimethyl-, (*Z*)-4,5,5-trimethyl-, and (*Z*)-4,4,5,5-tetramethyl furanone derivatives (**6***a*, **2***a*, and **2***b*) have been established by X-ray crystallography. The properties of some of these lactones are discussed, as are possible methods of removal of the carbomethoxyl from **2**.

ALFRED W. HANSON, ARCHIBALD W. MCCULLOCH et A. GAVIN MCINNES. Can. J. Chem. **59**, 288 (1981).

Les pentadiène-1,4 dicarboxylates-1,2 de diméthyle substitués (**1** ou **3**) peuvent être préparés par une réaction ène favorisée par $AlCl_3$ ou par une réaction thermique des oléfines avec l'acétylènedicarboxylate de diméthyle. L'acide catalyse la lactonisation de ces adduits. En présence de H_2SO_4 à 80%, les produits majoritaires (ca. 80%) sont les (*Z*) dihydrocarbométhoxyméthylène-3 (3*H*)-furannones-2 (**2** ou **4**). La cyclisation par du HCl anhydre conduit à un mélange de produits dont la composition dépend du produit de départ; les produits principaux comprennent les isomères (*E*) et les δ-lactones correspondants (**6** et **7**). On rapporte les données détaillées de la rmn du ^1H et du ^{13}C de tous les composés. Utilisant la diffraction des rayons-X, on a déterminé les structures des dérivés des (*E*)-triméthyl-4,5,5, (*Z*)-triméthyl-4,5,5 et (*Z*)-tétraméthyl-4,4,5,5 furannones (**6***a*, **2***a* et **2***b*). On discute des propriétés de quelques-unes de ces lactones ainsi que des méthodes possibles d'élimination du groupe carbométhoxyle du composé **2**.

[Traduit par le journal]

Introduction

As an extension of our studies on the effect of Lewis acids on Diels–Alder additions of dimethyl acetylenedicarboxylate (DMAD) (2), we have investigated the effect of $AlCl_3$ on ene reactions involving this compound. As anticipated, the Lewis acid causes dramatic acceleration of the reactions of DMAD with various olefins, and is particularly useful in the case of volatile olefins (see below). The adducts **1** are structurally suited as intermediates for the synthesis of substituted α-methylene-γ-lactones, which are potential antitumor agents (refs. 3, 4, and references therein) and in which there has thus been considerable recent synthetic interest (5, 6). Our observation of such compounds as by-products of certain $AlCl_3$-promoted reactions encouraged us to undertake a detailed study of the effect of acids on adducts **1**.

Results and Discussion

Ene Reactions

Adducts **1***a*, *b*, and **3** were prepared by $AlCl_3$-promoted reactions of 2-methyl-2-butene, 2,3-dimethyl-2-butene, and 1-methylcyclohexene with DMAD. No reaction occurred in the absence of the Lewis acid, even on extended reflux. The $AlCl_3$-promoted ene reaction with DMAD appears to be limited to 1,1-di-, tri-, and tetrasubstituted olefins, since similar reactions involving mono- or 1,2-disubstituted olefins afford chiefly cyclobu-

tenes (1).[3] Similar results have been reported by Snider *et al.* using propiolate esters as enophiles (7); since our submission of this manuscript they have also published an account of related work using DMAD (8). Although we obtained **1***a* and **3** in 55–60% yield our isolated yield of pure **1***b* was low (28%) and by-products included **2***b* (17%) and **6***b* (8%).

Adducts **1***c–e* were most conveniently prepared by thermal reaction of methylenecyclohexane, ethylidenecyclohexane, and β-pinene with DMAD.

Lactonization

Cyclization of **1** was catalyzed by acid, the product composition being dependent upon the type of acid used. The reagent of choice for the conversion of **1***a–d* to **2***a–d* (or of **3** to **4**) was 80% sulfuric acid. The products were obtained in 80–85% yield after only a few minutes at room temperature. Similar conditions have been reported for cyclization of *cis* 2,5-dienoic acids and esters to δ-lactones (9). As expected, strongly acidic conditions caused rearrangement of the α-pinene derivative **1***e*.

In contrast to the behavior with H_2SO_4, treatment of **1***a* with anhydrous HCl over a period of 5 days led to a mixture of products, the chief of which was **6***a* (37%). The isomers **7***a* (3%) and **8***a* (6%) were also obtained, as were the chlorinated derivatives **9***a* (5%) and **9***b* (6%). Compound **2***a* was shown to isomerize readily to **8***a* under the same conditions. Similar reaction of **1***b* with anhydrous HCl afforded a 3:1 mixture of **6***b* and **2***b*. In contrast, although **6***c* was formed in the HCl-catalyzed reaction of **3** it was obtained only as a minor product (3%), as was **8***b* (6%) resulting from isomerization of **4**. The predominant product in this case was **7***b* (35%).

Properties

Although reaction of **2***a* with anhydrous HCl rapidly afforded **8***a* (together with a small amount of **9***a*), **6***a* was unaffected under similar conditions. Overnight treatment of either **2***a* or **6***a* with refluxing triethylamine, however, caused conversion to **8***a*.

With refluxing 50% H_2SO_4 the hydrolysis product from **2***a* was **8***c*. Hydrolysis without migration of the double bond, to give **5***a*, was achieved using 65% H_2SO_4 at 25°C (slow) or refluxing 10% NaOH.

Catalytic reduction of either **2***b* or **6***b* over 5% Pd/C proceeded smoothly to give **10***c*. Reduction of **6***a* gave **10***a* as the only product. Hydrogenation of **2***a* under identical conditions yielded **10***a* (15%) and **10***b* (22%), as well as the unexpected **8***a* (54%).[4]

[3]This work will be detailed elsewhere.

[4]Although not separated and characterized, a similar mixture of products was obtained on catalytic reduction of **2***d*; in contrast, no olefinic material was detected in the product of hydrogenation of **2***c*.

We have investigated removal of the carbomethoxyl group to give the parent α-methylene lactones. Our first attempts utilized the reported oxidative decarboxylation of lactone acetic acids (10, 11). Thus, **10***d*, obtained by saponification of **10***c*, afforded **11** in 15% yield. Significantly improved product quality and yield (79%) resulted when direct copper/quinoline decarboxylation of **5***b* was employed. Our preliminary evidence suggests that the direct decarboxylation is limited to lactone acids of type **5** in which C-4 is fully substituted.

d $R^1 = R^2 = CH_3$; $R^3 = H$

Antitumor screening of **2***a*, **2***b*, **4**, **6***a*, and **11** has revealed no activity against P388 lymphocytic leukemia.

Structures

The structures of all new compounds were established largely from spectral considerations. Mass spectra (including accurate mass determinations) and infrared absorptions are given in the experimental section. Full ^1H nmr data are presented in Tables 1 (adducts) and 2 (lactones). Detailed high-resolution ^{13}C nmr data are given in Tables 3 (adducts), 4, and 5 (lactones).

Adducts

The ^1H and ^{13}C nmr spectra of **1***a–e* are entirely consistent with the structure and stereochemistry anticipated from consideration of the ene reaction mechanism (12). The *cis* relationship of the two ester groups is established both from the high-field chemical shift (ca. δ 5.8) of H-1, and the characteristic *trans* coupling ($^3J_{CH} \sim$ 12 Hz) between the ester carbonyl carbon (at C-2) and H-1 (13). The endocyclic double bond of **3** results from isomerization of the initially formed adduct. Analogous adducts with propiolate esters have been reported by Snider *et al.* (7).

Lactones 2a, 2b, *and* 6a

The structures of these three compounds were determined from their spectral properties (see below). X-ray crystal structure analyses, which were performed to obtain conformations in the solid state, served also to confirm these structures. Comparable views of the molecules are given in Fig. 1. Some torsion angles and, for the lactone rings, the equivalent conformation parameters (14) are given in Table 8; these data, together with the final atomic positions (Table 6) have been placed in the Depository of Unpublished Data.[5] The ring conformations are intermediate between the extremes of envelope and "half-chair". The methyl substituents at C-4 are unequivocally "equatorial" or "axial". In **2***b* (with two substituents at C-4) the axial bond is significantly longer than the equatorial (1.560 (3)Å, compared to 1.510 (3)Å). In **2***a* the lone substituent at C-4 is in the equatorial position. The molecule is otherwise similar to **2***b* except that the carbomethoxyl group is (perhaps because of packing forces) rotated by about 180°. In **6***a* the carbomethoxyl group is *trans* to the ring carbonyl, and this configuration brings O-7′ quite close to the position which would be occupied by an equatorial substituent (H-4 is 2.67Å from O-7′; other things being equal, the corresponding methyl substituent would be even closer). It is presumably for this reason that the substituent at C-4 is found in the axial position.

Other Lactones

The combined nmr evidence limited the structural possibilities for the three isomers **2***a*, **6***a*, and **7***a*. The latter, not identified by X-ray analysis, shows characteristic ir absorption centered at 1718 cm^{-1}, in contrast to the γ-lactones which show carbonyl absorptions near 1760 cm^{-1}.

Couplings ($^3J_{CH}$) involving α,β-unsaturated carbonyl systems depend on the double bond stereochemistry, being significantly larger when the coupled hydrogen is *trans* to the carbonyl carbon (13). In the case of **2***a* and **6***a* the *trans*- and *cis*-orientations of the lactone carbonyl carbon and the olefinic hydrogen are reflected by $^3J_{CH}$ values of 12.5 and 6.4 Hz respectively. In **7***a* the lactone carbonyl carbon is coupled only to the geminal olefinic hydrogen (^2J = 3.7 Hz), while the ester carbonyl carbon shows a characteristic *cis* $^3J_{CH}$ of 6.0 Hz with this hydrogen.

The nmr spectra of **4**, **6***c*, and **7***b* are very similar to those of the analogues **2***a*, **6***a*, and **7***a*, with the obvious exceptions due to replacement of two methyl groups by a cyclohexane ring. Similarly, the spectra of **2***b* and **6***b* are closely comparable to those of **2***a* and **6***a*. The structures of the spirocyclic derivatives **2***c* and **2***d* also followed from their obvious spectral similarities to **2***a*.

That **8***a* and **8***b* were isomeric with **2***a* and **2***b* respectively was established by accurate mass

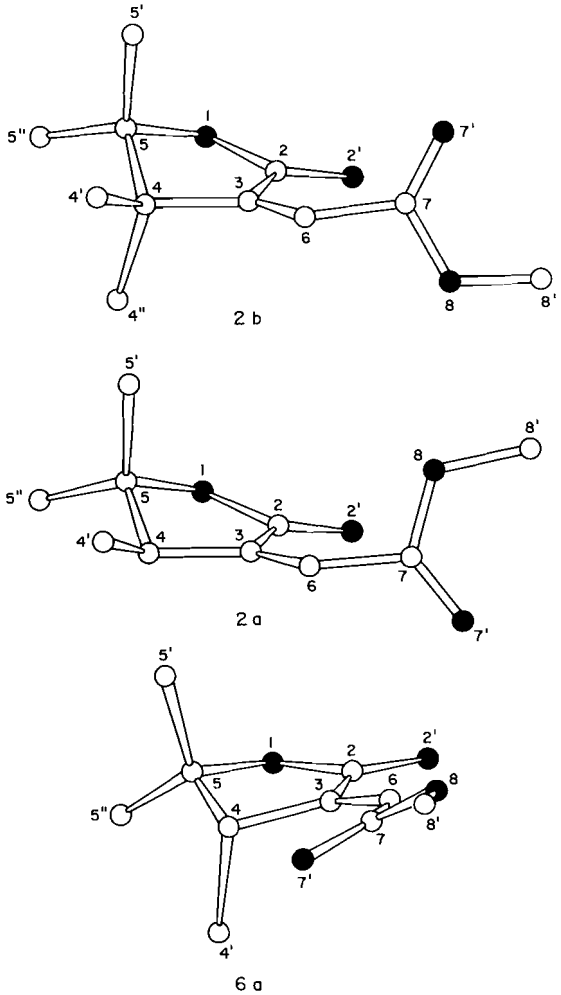

FIG. 1. Equivalent views of the three molecules studied by X-ray crystallography. Solid circles O, open circles C.

measurements. The presence of the endocyclic double bond in these compounds was shown by the appearance of nmr signals for allylic methyl (**8***a*; δ_H 2.00; δ_C 11.33 ppm) and methylene (**8***a* and **8***b*; $\delta_H \sim$ 3.3; $\delta_C \sim$ 28 ppm) groupings and for two quaternary olefinic carbons (116–120 and 167–170 ppm).

The mass spectra of the reduction products **10***a–c* showed that these compounds were derived by addition of one mole of hydrogen to the appropriate lactones (see above). This was confirmed by their nmr spectra which showed that the products possessed saturated rings carrying a $-CH_2CO_2CH_3$ grouping. Differentiation of isomers **10***a* and **10***b* was based on the observed vicinal couplings of 10.9 and 7.8 Hz between the two ring hydrogens, indicative of *trans* and *cis* relationships respectively (15).

The structures of the four acids **5***a*, **5***b*, **8***c*, and **10***d* followed from their characteristic ir and ^{1}H nmr

[a]Values of $^{n}J_{CH}$ were obtained from first-order spectral analysis.

[b](*i*) All C-methyl resonances were q (^{1}J 126.3–129.4) and in addition were coupled to geminal and vicinal hydrogens; (*ii*) C-5 was a m (showing geminal and vicinal couplings), except in **7***a* and **7***b* where it was a dm (^{1}J 130–133); (*iii*) each OCH_3 carbon was a q (^{1}J 147.0–148.3); (*iv*) all cyclohexane methylenes were btm (^{1}J 128–130).

signals for carboxyl groups and from the very close similarity of their remaining spectral properties to those of the corresponding esters **2***a*, **2***b*, **8***a*, and **10***c*.

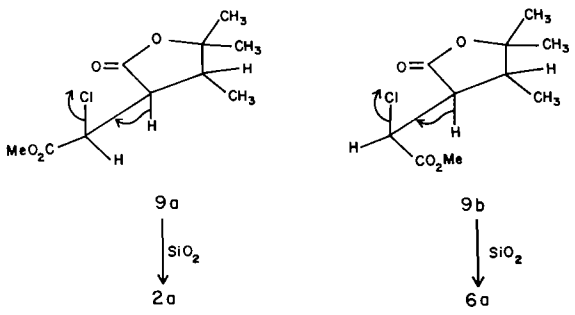
In the case of the chloro compounds **9***a* and **9***b* the structure followed from their mass spectra, which indicated a molecular formula $C_{10}H_{15}O_4Cl$ and a close structural resemblance to **10***a* and **10***b*, and from their combined ^1H and ^{13}C nmr spectra. The ^1H nmr spectrum of each compound was characterized by *trans* couplings (J = 11.7 and 12.1 Hz respectively) between the two ring hydrogens (15). Finally, stereospecific dehydrochlorination of **9***a* to **2***a* and of **9***b* to **6***a* on silica gel (see Experimental) can only be explained on the basis of **9***a* and **9***b* being diastereoisomers, epimeric at the chloro-substituted carbon C-6 (Scheme 1).

The presence of the unsubstituted *exo* methylene group in **11** was established by ^1H nmr (single proton resonances at 5.43 and 6.13 ppm, with characteristically small geminal coupling (16)) and ^{13}C nmr (in which C-6 appeared as the X part of an ABX, with outer spacing = $J_{AX} + J_{BX}$ = 322.7 Hz). As expected, the carbonyl carbon showed both *cis* (^3J = 7.0 Hz) and *trans* (^3J = 13.7 Hz) couplings to the olefinic hydrogens (13).

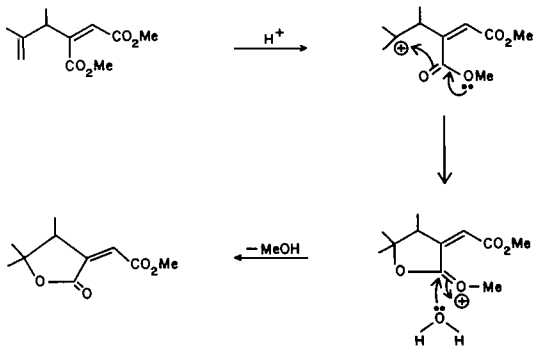
Mechanisms

The mechanistic alternatives for the $AlCl_3$-promoted ene reaction have been reviewed by Snider *et al.* (7, 8).

Protonation of **1** and subsequent cyclization and hydrolysis (Scheme 2) gives **2** (or **4**), the original stereochemistry of the ester-substituted double bond being retained. Pathways explaining the formation of all major products isolated from the HCl-catalyzed reaction of **1***a* are illustrated in Scheme 3. Protonation of the double bond and cyclization can occur as above (a); the product in this case is the (*Z*)-isomer **2***a*, which immediately isomerizes to **8***a*. Isolation of the (*E*)-lactone **6***a* and δ-lactone **7***a* suggests that there is appreciable



SCHEME 1



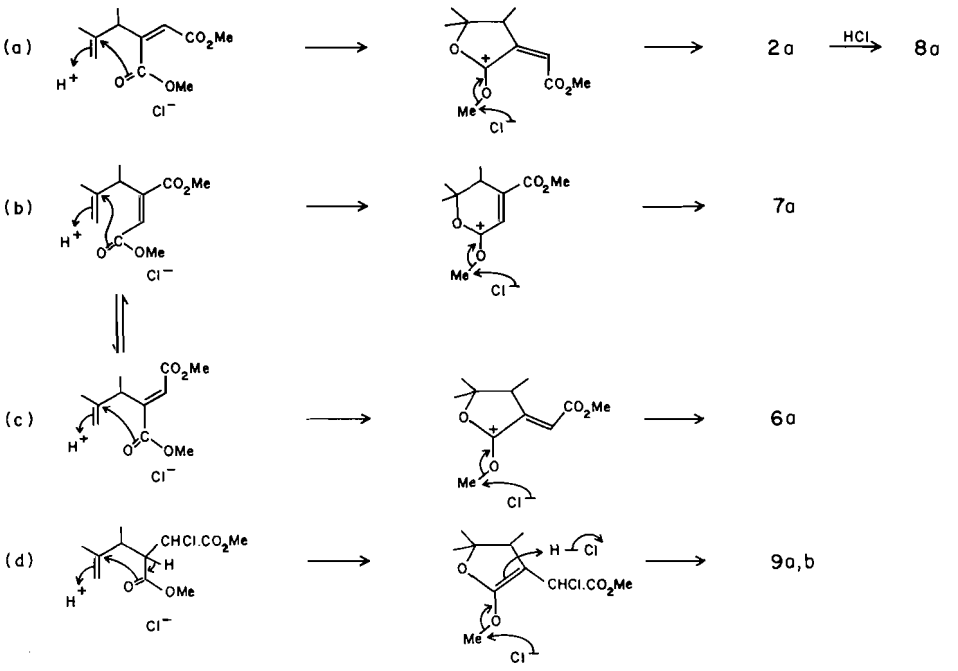
SCHEME 2

isomerization of the ester-substituted double bond of **1***a*, possibly through an HCl addition/elimination pathway. Cyclization can then proceed in either conformer as shown (b or c). Finally, addition of HCl to the ester-bearing double bond of **1***a* could also result in a chlorine-containing intermediate which could cyclize in such a way (d) as to produce the two chloro-lactones **9***a* and **9***b*, both having the more favorable *trans* orientation of the bulky side-chain at C-3 and the methyl substituent at C-4. Similar mechanisms must operate in the HCl-promoted cyclizations of **1***b* to **2***b* and **6***b*, and of **3** to **4** (which isomerizes to **8***b*), **6***c*, and **7***b*.

The properties of the lactones are for the most part unexceptional. The behavior of **2***a* and **6***a* during catalytic reduction is of interest. The product of reduction of **6***a* does not correspond to that predicted from classical theory, but can be explained on the basis of steric interaction in the diadsorbed substrate (17). Thus, although classical theory would predict approach of the catalyst on the less sterically hindered side of the molecule (opposite to the methyl at C-4), such attachment would introduce severe steric interaction between the methyl at C-4 and the carbomethoxyl group. Thus, the net result is preferred approach on the same side as the methyl at C-4 and consequently hydrogenation to give **10***a*. In the case of **2***a* much less steric strain is introduced by adsorption on the side opposite the methyl group. Such "classical" approach leads to **10***b*. Sterically favored catalyst abstraction of H-4 in the diadsorbed intermediate, followed by desorption, affords the dominant product **8***a*. The isolation of small amounts of **10***a* from the reduction of **2***a* indicates that the catalyst may also approach from the same side as the C-4 methyl.

Although the cyclization of substituted 1,4-pentadiene-1,2-dicarboxylates offers a useful synthetic route to γ-lactones of type **2**, it is limited at present to adducts **1** in which R^3 is an alkyl group.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/05/12
For personal use only.



SCHEME 3

Procedures for lactonization of **1** (R^3 = H) are currently being explored, as are alternative methods of removing the ester group from **2**. Since it has been suggested that antitumor activity may require not only an α-methylene-γ-lactone moiety, but also a second α,β-unsaturated carbonyl system elsewhere in the molecule (4), work is in progress to extend our approach to more complex compounds.

Experimental

All nmr spectra were measured in $CDCl_3$ unless stated otherwise. Standard abbreviations used in the tabulated data are as follows: b broad, s singlet, d doublet, t triplet, q quartet, qu quintet, m multiplet. All ^1H nmr spectra were recorded on a Varian HA-100D spectrometer. The ^{13}C nmr spectra were recorded on a Varian XL-100-15 spectrometer under the following conditions; frequency 25.16 MHz; acquisition time 0.8 or 1.6 s (data accuracy ±0.6 or ±0.3 Hz); spectral width 5120 Hz; flip angle 30°; internal ^2H lock to solvent; temperature about 30°C. ^1H irradiation at 100 MHz: (*a*) $\gamma H_2/2\pi$ ca. 3800 Hz, broadband irradiation by 0–180° phase modulation at 150 Hz; (*b*) as for (*a*), but irradiation only applied for 1.6 s between data acquisition periods (high-resolution spectrum with retained nOe).

High-resolution mass spectral measurements were made with a Dupont-CEC 21-110B double-focussing mass spectrometer, using electrical detection for mass measurements. Infrared absorptions were measured on Perkin-Elmer 521 or 180 spectrometers. Column chromatographic separations were carried out on Mallinckrodt silicic acid (100 mesh) and preparative thin-layer chromatography (plc) on 2.0 mm Merck silica gel F-254 precoated plates.

$AlCl_3$-promoted Ene Reactions

*Preparation of 1*a

A solution of DMAD (14.2 g, 0.1 mol) in CH_2Cl_2 (150 mL) was added to an ice-cooled, vigorously stirred suspension of $AlCl_3$ (13.3 g, 0.1 mol) in CH_2Cl_2 (250 mL). To this was then added 2-methyl-2-butene (14.0 g, 0.2 mol). There was a vigorous exothermic reaction. After 1 h at room temperature the reaction mixture was poured into ice-water/CH_2Cl_2. The organic phase and CH_2Cl_2 extracts of the aqueous phase were combined, dried, and evaporated. Column chromatography (50% benzene/chloroform) of the orange oily residue afforded pure *(Z)-dimethyl-3,4-dimethyl-1,4-pentadiene-1,2-dicarboxylate* **1***a* as a straw-colored oil (12.74 g, 60%) n_D^{22} = 1.4669; ν_{max} (liq. film) 1729, 1641 cm^{-1}. Molecular ion (2%) at *m/e* 212.1049 ($C_{11}H_{16}O_4$ requires 212.10486); base peak at *m/e* 152.0834 ($C_9H_{12}O_2$ requires 152.08373); ions at *m/e* 197.0819 (8%) ($C_{10}H_{13}O_4$ requires 197.08139) and *m/e* 93.0703 (74%) (C_7H_9 requires 93.07043).

Other column fractions contained **1***a* with unreacted DMAD as a contaminant.

*Preparation of 1*b

A reaction employing $AlCl_3$ (15.96 g, 0.12 mol), DMAD (17.04 g, 0.12 mol), and 2,3-dimethyl-2-butene (20.16 g, 0.24 mol) in CH_2Cl_2 (480 mL), for 90 min at room temperature, was worked up as before to give a reddish oil. Chromatography (50% benzene/$CHCl_3$) gave (*i*) unreacted DMAD (2.902 g); (*ii*) a yellow oil (0.597 g), composed of **1***b* (see below) heavily contaminated by dimethyl chloromaleate (δ_H 6.33) and dimethyl chlorofumarate (δ_H 7.17); (*iii*) a yellow oil (2.745 g), composed of **1***b* slightly contaminated by the two chloro olefins; (*iv*) *dimethyl 3,3,4-trimethyl-1,4-pentadiene-1,2-dicarboxylate* **1***b* which was obtained as a pale yellow oil (7.59 g, 28%) n_D^{25} = 1.4552; ν_{max} (liq. film) 1731, 1637 cm^{-1}. Molecular ion (6%) at *m/e* 226.1211 ($C_{12}H_{18}O_4$ requires 226.12051); base peak at *m/e* 170; (*v*) **6***b* (1.92 g, 8%) (see below); (*vi*) dimethyl ethoxymaleate (contaminant from DMAD?), which was obtained as a pale yellow oil (0.442 g); ν_{max} (liq. film) 1749, 1715, 1621 cm^{-1}. Molecular ion (66%) at *m/e* 188.0675 ($C_8H_{12}O_5$ requires 188.06848); base peak at *m/e* 101; ions at *m/e* 173.0454 (73%) ($C_7H_9O_5$ requires 173.04500) and *m/e* 157.0500 (87%) ($C_7H_9O_4$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/05/12
For personal use only.

requires 157.05009); (*vii*) pure **2***b*, obtained as a colorless solid (4.418 g, 17%) (see below).

Preparation of **3**

A solution of DMAD (14.20 g, 0.1 mol) in CH_2Cl_2 (100 mL) was added to a stirred suspension of $AlCl_3$ (13.3 g, 0.1 mol) in CH_2Cl_2 (150 mL). To this was added 1-methylcyclohexene (10.56 g, 0.11 mol) at a rate such that the temperature did not rise above 30°C. After 1 h at room temperature, work-up as above followed by column chromatography (50% benzene/chloroform) gave **3** as a pale yellow oil (13.33 g, 56%) n_D^{25} = 1.4940; ν_{max} (liq. film) 1735 (sh), 1726, 1642 cm^{-1}. Molecular ion (7%) at *m/e* 238.1213 ($C_{13}H_{18}O_4$ requires 238.12051); base peak at *m/e* 206.0941 ($C_{12}H_{14}O_3$ requires 206.09430); ion at *m/e* 178.0995 (93%) ($C_{11}H_{14}O_2$ requires 178.09938).

Thermal Ene Reactions

Preparation of **1**c

A mixture of methylenecyclohexane (5.00 g, 0.052 mol) and DMAD (6.66 g, 0.047 mol) was heated at 110°C for 6 days; ^1H nmr analysis indicated 70% conversion to **1***c*. Repeated column chromatography ($CHCl_3$) and plc (10% acetone/petroleum ether) afforded **1***c* as an almost colorless oil, n_D^{21} = 1.4873; ν_{max} (liq. film) 1725 cm^{-1}. Molecular ion (7%) at *m/e* 238.1196 ($C_{13}H_{18}O_4$ requires 238.12051); base peak at *m/e* 119.

Preparation of **1**d

A mixture of ethylidenecyclohexane (12.12 g, 0.110 mol) and DMAD (14.21 g, 0.100 mol) was heated at 120°C for 72 h. Chromatography ($CHCl_3$) of the crude product afforded (*a*) unreacted ethylidenecyclohexane (0.812 g); (*b*) a mixture (3:2) of DMAD and **1***d* (1.890 g); (*c*) pure **1***d* as an almost colorless oil (12.47 g, 50%), n_D^{25} = 1.4898; ν_{max} (liq. film) 1737 cm^{-1}. Molecular ion (6%) at *m/e* 252.1350 ($C_{14}H_{20}O_4$ requires 252.13616); base peak at *m/e* 133.1020 ($C_{10}H_{13}$ requires 133.10173).

Preparation of **1**e

A mixture of β-pinene (5.44 g, 0.04 mol) and DMAD (6.24 g, 0.044 mol) was heated at 130°C for 5 h. Chromatography (50% benzene/$CHCl_3$) of the yellow oil obtained gave (*a*) colorless oil (3.693 g), consisting of **1***e* and about 10% DMAD, and (*b*) pure **1***e* as a colorless oil (5.033 g, 45%), n_D^{21} = 1.4952; ν_{max} (liq. film) 1736 cm^{-1}. Molecular ion (34%) at *m/e* 278.1517 ($C_{16}H_{22}O_4$ requires 278.15181); base peak at *m/e* 203.0710 ($C_{12}H_{11}O_3$ requires 203.07082).

Cyclizations Catalyzed by 80% Sulfuric Acid

Conversion of **1**a *to* **2**a

Diene **1***a* (212 mg) was dissolved in 80% sulfuric acid (1 mL). After 2 min the mixture was poured into ice-water/CH_2Cl_2. The organic phase and CH_2Cl_2 extracts of the aqueous phase were combined, dried, and evaporated to give a pale yellow oil (188 mg), plc (25% acetone/petroleum ether) of which afforded pure (Z)-*dihydro-3-carbomethoxymethylene-4,5,5-trimethyl-2(3H)-furanone* **2***a* (167 mg, 84%). Recrystallization from petroleum ether gave colorless prisms, mp 51–51.5°C; ν_{max} (KBr) 1762, 1737, 1677 cm^{-1}. Molecular ion (2%) at *m/e* 198.0893 ($C_{10}H_{14}O_4$ requires 198.08921); base peak at *m/e* 140.0471 ($C_7H_8O_3$ requires 140.04735).

Cyclization of **1***a* to **2***a* did not occur using 50% H_2SO_4; with 65% H_2SO_4 reaction occurred slowly, but gave mainly the hydrolyzed product **5***a*.

Conversion of **1**b *to* **2**b

Diene **1***b* (1.00 g) was dissolved in 80% H_2SO_4 (5 mL). After 20 min at room temperature the mixture was worked up as above. The residue on plc ($CHCl_3$) gave (Z)-*dihydro-3-carbomethoxymethylene-4,4,5,5-tetramethyl-2(3H)-furanone* **2***b* (746 mg, 80%). Recrystallization from petroleum ether/ethyl acetate gave colorless prisms, mp 73.5–74.5°C; ν_{max} (KBr) 1760, 1733 cm^{-1}. Molecular ion not observed ($C_{11}H_{16}O_4$ requires 212); base peak at *m/e* 154.0630 ($C_8H_{10}O_3$ requires 154.06300); ions at *m/e* 197.0806 (2%) ($C_{10}H_{13}O_4$ requires 197.08139), 181.0865 (8%) ($C_{10}H_{13}O_3$ requires 181.08647), and 126.0687 (76%) ($C_7H_{10}O_2$ requires 126.06801).

Conversion of **1**c *to* **2**c

Treatment of **1***c* (750 mg) with 80% H_2SO_4 (3 mL) for 10 min at room temperature gave an orange oil. Chromatography (50% benzene/$CHCl_3$) afforded **2***c* as an almost colorless oil (586 mg, 83%), n_D^{22} = 1.5014; ν_{max} (liq. film) 1766, 1742, 1680 cm^{-1}. Molecular ion (18%) at *m/e* 224.1051 ($C_{12}H_{16}O_4$ requires 224.10486); base peak at *m/e* 126.0318 ($C_6H_6O_3$ requires 126.03170).

Conversion of **1**d *to* **2**d

Reaction of **1***d* (2.00 g) with 80% H_2SO_4 (6 mL) for 10 min at room temperature afforded a yellow oil which crystallized. Recrystallization from petroleum ether gave **2***d* as cream-colored prisms (1.47 g, 78%), mp 81–82.5°C; ν_{max} (liq. film) 1758, 1738 cm^{-1}. Molecular ion (5%) at *m/e* 238.1203 ($C_{13}H_{18}O_4$ requires 238.12051); base peak at *m/e* 140.0472 ($C_7H_8O_3$ requires 140.04735).

Conversion of **3** *to* **4**

Reaction of **3** (714 mg) with 80% H_2SO_4 (3 mL) for 10 min at room temperature followed by plc (25% acetone/petroleum ether) gave **4** as a colorless crystalline solid (535 mg, 79%), mp 60–61°C; ν_{max} (KBr) 1760, 1742, 1675 cm^{-1}. Molecular ion (65%) at *m/e* 224.1051 ($C_{12}H_{16}O_4$ requires 224.10486); base peak at *m/e* 93.0703 (C_7H_9 requires 93.07043).

Cyclizations Catalyzed by HCl

Conversion of **1**a *to* **6**a, **7**a, **8**a, **9**a, *and* **9**b

A solution of **1***a* (7.20 g) in CH_2Cl_2 (175 mL) was saturated with HCl(gaseous). The solution was allowed to stand at room temperature, with periodic addition of HCl(gaseous) for 5 days. The residue obtained on evaporation was chromatographed (2% acetone/petroleum ether) to give a solid (2.78 g), crystallization of which from petroleum ether gave (E)-*dihydro-3-carbomethoxymethylene-4,5,5-trimethyl-2(3H)-furanone* **6***a* as colorless prisms (2.49 g, 37%), mp 54–55°C; ν_{max} (KBr) 1759, 1726 cm^{-1}. Molecular ion (< 1%) at *m/e* 198.0895 ($C_{10}H_{14}O_4$ requires 198.08921); base peak at *m/e* 112; ion (82%) at *m/e* 140.0470 ($C_7H_8O_3$ requires 140.04735). Continued elution with 5% acetone/petroleum ether gave (*a*) a solid, crystallization of which from petroleum ether gave the pyranone **7***a* as colorless prisms (223 mg, 3.3%), mp 54–55.5°C; ν_{max} (KBr) 1718 (br) cm^{-1}. Molecular ion (1%) at *m/e* 198.0895 ($C_{10}H_{14}O_4$ requires 198.08921); base peak at *m/e* 140.0467 ($C_7H_8O_3$ requires 140.04735); (*b*) a solid (628 mg); crystallization from petroleum ether gave **9***b* as colorless prisms (472 mg, 5.9%), mp 70–71°C; ν_{max} (CCl_4) 1772, 1740 (sh) cm^{-1}. Very weak (< 1%) molecular ions at *m/e* 236 and 234 ($C_{10}H_{15}O_4$ ^{37}Cl and $C_{10}H_{15}O_4$ ^{35}Cl require 236 and 234); base peak at *m/e* 113.0606 ($C_6H_9O_2$ requires 113.06026); ions at *m/e* 221.0401 (4%) ($C_9H_{12}O_4$ ^{37}Cl requires 221.03946) and *m/e* 219.0430 (13%) ($C_9H_{12}O_4$ ^{35}Cl requires 219.04236); (*c*) a solid (500 mg); crystallization from petroleum ether/ethyl acetate gave **9***a* as colorless prisms (403 mg, 5.1%), mp 67–68°C: ν_{max} (CCl_4) 1775, 1745 (sh) cm^{-1}. Very weak (< 1%) molecular ions at *m/e* 236 and 234 ($C_{10}H_{15}O_4$ ^{37}Cl and $C_{10}H_{15}O_4$ ^{35}Cl require 236 and 234); base peak at *m/e* 113.0605 ($C_6H_9O_2$ requires 113.06026); ions at *m/e* 221.0401 (4%) ($C_9H_{12}O_4$ ^{37}Cl requires 221.03946) and *m/e* 219.0425 (10%) ($C_9H_{12}O_4$ ^{35}Cl requires 219.04236).

The column was now eluted with 50% acetone/petroleum ether. This gave **8***a* as an almost colorless oil (399 mg, 5.9%), n_D^{24} = 1.4689. On standing at 0°C this solidified, mp 36–38°C; ν_{max} (liq. film) 1760 (sh), 1741, 1685 cm^{-1}. Molecular ion (73%) at

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/05/12
For personal use only.

m/e 198.0899 ($C_{10}H_{14}O_4$ requires 198.08921); base peak at *m/e* 155.0711 ($C_8H_{11}O_3$ requires 155.07082).

NOTE: On prolonged (>72 h) exposure to silica gel, either on stirring in $CHCl_3$ or adsorbed to plc plates, **9***a* was quantitatively converted to **2***a*, while **9***b* was quantitatively converted to **6***a*.

Conversion of **1**b *to* **2**b *and* **6**b

A solution of **1***b* (0.450 g) in CH_2Cl_2 (15 mL) was saturated with HCl(gas) and allowed to stand at room temperature for 24 h. The product was shown by ^1H nmr to be a 3:1 mixture of **6***b* and **2***b*. These isomers were readily separated by plc ($CHCl_3$). *(E)-Dihydro-3-carbomethoxymethylene-4,4,5,5-tetramethyl-2(3H)-furanone* **6***b* was obtained as a pale yellow oil, n_D^{25} = 1.4760, which could not be induced to crystallize; ν_{max} (liq. film) 1762, 1728 cm^{-1}. Molecular ion not observed ($C_{11}H_{16}O_4$ requires 212); base peak at *m/e* 126.0685 ($C_7H_{10}O_2$ requires 126.06801); ion at *m/e* 154.0632 (67%) ($C_8H_{10}O_3$ requires 154.06300).

Conversion of **3** *to* **6**c, **7**b, *and* **8**b

Crude **3** derived from reaction of 1-methylcyclohexene (3.664 g, 0.038 mol) with dimethyl acetylenedicarboxylate (4.927 g, 0.035 mol) and $AlCl_3$ (4.614 g, 0.035 mol) was dissolved in CH_2Cl_2 (200 mL) and the solution saturated with HCl(gas). The mixture was allowed to stand at room temperature, with periodic addition of HCl(gas), for 11 days. The residue obtained on evaporation was chromatographed ($CHCl_3$) to give (*a*) an initial fraction (599 mg), containing some unreacted acetylenic ester; (*b*) a yellow oil (2.8 g). Column chromatography (10% acetone/petroleum ether) of this gave (*i*) an oil (718 mg), repeated plc (75% benzene/$CHCl_3$) of which afforded pure **6***c* as a pale yellow oil (225 mg, 3%), which crystallized, mp 27–30°C; ν_{max} (liq. film) 1761, 1723 cm^{-1}. Molecular ion (7%) at *m/e* 224.1048 ($C_{12}H_{16}O_4$ requires 224.10486); base peak at *m/e* 177.0545 ($C_{10}H_9O_3$ requires 177.05517); and (*ii*) compound **7***b* (773 mg) (see below); (*c*) pure **7***b* as a colorless solid (2.003 g, total yield 35%), mp 81–82°C; ν_{max} (KBr) 1715 (br) cm^{-1}. Molecular ion (100%) at *m/e* 224.1048 ($C_{12}H_{16}O_4$ requires 224.10486); (*d*) a yellow oil (950 mg), half of which (estimated yield 5–6%) was **8***b*. Pure **8***b* was obtained from this fraction only after repeated plc ($CHCl_3$) as a colorless crystalline solid, mp 80.5–82°C; ν_{max} (KBr) 1731, 1675 cm^{-1}. Molecular ion (19%) at *m/e* 224.1040 ($C_{12}H_{16}O_4$ requires 224.10486); base peak at *m/e* 181.0862 ($C_{10}H_{13}O_3$ requires 181.08647).

Reactions of Lactones

Conversion of **2**a *to* **8**a

A solution of **2***a* (260 mg) in CH_2Cl_2 (25 mL) was saturated with HCl(gas) and the mixture stirred at room temperature for 24 h. The residue obtained on evaporation was subjected to plc ($CHCl_3$; 10% acetone/petroleum ether), which gave **8***a* as an almost colorless oil (156 mg, 60%) (see above). Signals for **9***a* were present in the ^1H nmr spectrum of the crude product, but this compound did not survive plc. A quantitative yield of **8***a* was also obtained when a solution of **2***a* (100 mg) in triethylamine (15 mL) was refluxed for 17 h.

Conversion of **6**a *to* **8**a

A solution of **6***a* (133 mg) in CH_2Cl_2 (20 mL) was saturated with HCl(gas) and the mixture stirred at room temperature for 42 h. Evaporation gave an oil (135 mg), ^1H nmr of which indicated unchanged **6***a*. However, an almost quantitative conversion of **6***a* to **8***a* was observed when the former (100 mg) was refluxed in triethylamine (15 mL) for 20 h.

Conversion of **4** *to* **8**b

A solution of **4** (240 mg) in CH_2Cl_2 (15 mL) was saturated with HCl(gas) and stirred at room temperature for 24 h. Evaporation gave an oily residue, plc ($CHCl_3$) of which afforded **8***b* as a colorless crystalline solid (197 mg, 82%).

Conversion of **2**a *to* **8**c

Lactone **2***a* (200 mg) was refluxed in 50% H_2SO_4 (10 mL) for 1 h, and the cooled solution then extracted with ether. Drying and evaporation gave the acid **8***c* as cream-colored rosettes (164 mg, 88%), mp 113–115°C; ν_{max} (KBr) 3700–2400 (br. env., with maxima at 3530 and 3410), 1726, 1712, 1685 cm^{-1}. Molecular ion (15%) at *m/e* 184.0740 ($C_9H_{12}O_4$ requires 184.07356); base peak at *m/e* 141.0549 ($C_7H_9O_3$ requires 141.05517); ion at *m/e* 169.0502 (45%) ($C_8H_9O_4$ requires 169.05009).

Conversion of **2**a *to* **5**a

Lactone **2***a* (200 mg) was refluxed for 1 h in 10% NaOH (10 mL). After cooling the solution was extracted with ether, then acidified. Ether extraction of the acid solution afforded acid **5***a* as a pale yellow oil (153 mg, 82%), n_D^{25} = 1.4920; ν_{max} (liq. film) 3700–2400 (br. env. with maxima at 2760 and 2660 cm^{-1}), 1759 (sh), 1730 (br.) cm^{-1}. Molecular ion (22%) at *m/e* 184.0740 ($C_9H_{12}O_4$ requires 184.07356); base peak at *m/e* 141; ion at *m/e* 169.0495 (48%) ($C_8H_9O_4$ requires 169.05009).

Conversion of **2**b *to* **5**b

A solution of **2***b* (1.00 g) in 10% NaOH (30 mL) was heated at 100°C for 3 h. Similar work-up to that used for **5***a* above gave a virtually quantitative yield of **5***b*. The latter crystallized from petroleum ether/ethyl acetate as colorless needles, mp 75.5–77°C; ν_{max} (KBr) 3500–2500 (br. env.), 1730 (br), 1640 (br) cm^{-1}. Molecular ion not observed ($C_{11}H_{16}O_4$ requires 212); base peak at *m/e* 140.0468 ($C_7H_8O_3$ requires 140.04735).

Catalytic Reduction of **6**a

The unsaturated lactone **6***a* (212 mg) in methanol (20 mL) was hydrogenated over 5% Pd/C (70 mg). After uptake of H_2 had ceased (30 min) the normal work-up gave **10***a* as a colorless oil (205 mg, 96%) n_D^{24} = 1.4529; ν_{max} (liq. film) 1764, 1737 cm^{-1}. Molecular ion not detected ($C_{10}H_{16}O_4$ requires 200); base peak at *m/e* 114.0685 ($C_6H_{10}O_2$ requires 114.06808); ion at *m/e* 185.0808 (24%) ($C_9H_{13}O_4$ requires 185.08139).

Catalytic Reduction of **2**a

A solution of **2***a* (756 mg) in methanol (40 mL) was hydrogenated over 5% Pd/C (230 mg). When uptake of H_2 abruptly ceased (10 min) the solution was filtered and evaporated to give a pale yellow oil (750 mg), plc ($CHCl_3$) of which afforded (*a*) a pale yellow oil (283 mg), ^1H nmr of which showed a mixture of **10***a* and **10***b* in an approximate ratio of 2:3. Repeated plc (25% acetone/petroleum ether; $CHCl_3$) gave **10***b* as a pale yellow oil (90 mg), n_D^{24} = 1.4546; ν_{max} (liq. film) 1762, 1736 cm^{-1}. Molecular ion (< 1%) at *m/e* 200.1047 ($C_{10}H_{16}O_4$ requires 200.10486); base peak at *m/e* 114; ion at *m/e* 185.0811 (46%) ($C_9H_{13}O_4$ requires 185.08139); (*b*) a pale orange oil, further plc ($CHCl_3$) of which gave **8***a* (408 mg, 54%).

Similar results were obtained using Adams' catalyst in place of 5% Pd/C, or EtOAc as solvent.

No conversion of **2***a* to **8***a* was observed on treatment with methanol and 5% Pd/C. No **8***a* was formed upon "hydrogenation" of a mixture of **10***a* and **10***b* for 3 h over 5% Pd/C. In addition **8***a* could not be reduced under these conditions.

When the reduction of **2***a* was carried out with deuterium the **8***a* isolated was shown by ^1H nmr to have a single deuterium located at C-6.

Conversion of **2**b *(or* **6**b*) to* **10**d

(*a*) The unsaturated lactone **2***b* or **6***b* (400 mg) in methanol (35 mL) was hydrogenated over 5% Pd/C (60 mg). When uptake of H_2 ceased (2–4 h) the usual work-up gave **10***c* in almost quantitative yield as a colorless oil.

(*b*) The saturated lactone **10***c* (3.10 g) obtained as in (*a*) was dissolved in 10% NaOH (50 mL) and refluxed for 1 h. The cooled solution was extracted with ether, then acidified. Ether extraction of the acid solution gave **10***d* as a colorless solid (2.638 g, 91%). Recrystallization from petroleum ether/ethyl acetate af-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/05/12
For personal use only.

forded prisms, mp 137–139°C; ν_{max} (KBr) 3650–2500 (br. env. with max. at 3450), 1749, 1700 cm^{-1}. Molecular ion (< 1%) at *m/e* 200.1049 ($C_{10}H_{16}O_4$ requires 200.10486); base peak at *m/e* 114.0685 ($C_6H_{10}O_2$ requires 114.06808); ion at *m/e* 185.0812 (30%) ($C_9H_{13}O_4$ requires 185.08139).

Preparation of **11**

(a) Oxidative Decarboxylation of **10***d* (cf. ref. 18)

A mixture of **10***d* (400 mg), $Cu(OAc)_2 \cdot H_2O$ (87 mg), and pyridine (53 mg) in benzene (20 mL) was stirred at room temperature for 45 min. Lead tetraacetate (2.96 g) in benzene (30 mL) was then added. The resulting mixture was stirred in the dark for 2 h and was then refluxed under N_2 for 19 h. The green solution was washed twice with water, dried, and evaporated. The residue (192 mg) was shown by ^1H nmr to be a mixture of **10***d* and **11** (see below) in a molar ratio of 2.4:1 (estimated conversion to **11**, 15%).

(b) Decarboxylation of **5***b*

A stirred mixture of **5***b* (5.40 g), copper powder (530 mg) and quinoline (120 mL) was heated at 200°C for 6 h. The mixture was cooled, washed with 2 *N* HCl, filtered, and extracted with ether. Evaporation of solvent from the dried extract yielded a yellow oil. Column chromatography afforded **11** (3.309 g, 79%) as an apparently volatile colorless oil which crystallized at low temperature, with mp 14–17°C; ν_{max} ($CHCl_3$) 1753 cm^{-1}. Molecular ion (< 1%) at *m/e* 154.0995 ($C_9H_{14}O_2$ requires 154.09938); base peak at *m/e* 96.0580 (C_6H_8O requires 96.05752).

The above decarboxylation can also be achieved using Cu powder and pyridine. However, the reaction is slower and the quality of the product inferior to that obtained using quinoline.

Crystallography

The several space groups were determined from single-crystal photographs. The unit cell constants were derived from least-squares analyses of the settings of a Picker four-circle diffractometer for twelve or more reflections in the range $98 < 2\theta < 130°$. The intensities of all independent reflections with $2\theta < 130°$ were measured with θ–2θ scans, using Ni-filtered CuKα radiation ($\lambda\alpha_1$ = 1.5405 Å). Individual reflection profiles were analysed as described by Grant and Gabe (19). The standard deviations of the measured intensities were evaluated from counting statistics, and reflections for which $I(\text{net}) < 2\sigma(I(\text{net}))$ were treated as unobserved.

All structures were solved uneventfully with the aid of MULTAN (20). Refinement was by block-diagonal least squares, minimizing $\Sigma w\Delta F^2$, where $1/w = \sigma^2(F_o) + kwF_o^2$. Hydrogen atoms were included in the refinement, with initial positions reasonably assumed, or inferred from difference-Fourier syntheses. The parameters refined were atomic coordinates, temperature factors (anisotropic for C and O), scale factor, and secondary extinction coefficient *g* (21). The computer programs used are identified in ref. 22. The atomic scattering factors were taken from ref. 23. The final atomic coordinates are given in Table 6. (Tables of final atomic positions, bond lengths, torsion angles, thermal parameters, and F_o and F_c have been placed in the Depository of Unpublished Data.[5])

Crystal Data and Refinement Details

Compound **2**b

Monoclinic, $P2_1/a$, (systematic absences: $0k0$ for k odd; $h0l$ for h odd) a = 11.585 (1), b = 15.884 (1), c = 6.7238 (5) Å, β = 111.61 (3)°, V = 1150.3 Å^3, ρc = 1.225, Z = 4, specimen dimensions 0.2 × 0.3 × 0.6 mm, no absorption corrections (μ = 0.78 mm^{-1}), g for secondary extinction 4.36 × 10^4 Å, kw in weighting scheme, 0.0002. 1955 reflections were scanned, and of these 1658 were observed. For the latter only, the final R index was 0.049 (Rw = 0.074). The esd's of bond lengths and angles (C and O only) are 0.002 to 0.003 Å and 0.1 to 0.2°.

Compound **2**a

(Because of severe decomposition problems, the specimen was maintained at −150°C with the use of a modified Syntex cryostat.) Triclinic, $P\bar{1}$, a = 8.518 (1), b = 9.554 (1), c = 6.723 (1)Å, α = 101.34 (1), β = 88.20 (1), γ = 109.29 (1)°, V = 506.0 Å^3, ρc = 1.301 g cm^{-3}, Z = 2, specimen dimensions 0.05 × 0.3 × 0.3 mm, no absorption corrections (μ = 0.83 mm^{-1}), g for secondary extinction 2.6 × 10^4Å, kw in weighting scheme, 0.0004. 1714 reflections were scanned, and of these 1506 were observed. For the latter only, the final R index was 0.037 (Rw = 0.052). The esd's of bond lengths and angles are 0.002 Å and 0.1°.

Compound **6**a

(To prevent rapid decomposition in air, the specimen was sealed in a thin-walled glass tube). Monoclinic, $P2_1/n$, (systematic absences: $0k0$ for k odd; $h0l$ for $h + l$ odd), a = 9.061 (1), b = 18.630 (2), c = 6.292 (1)Å, β = 96.77 (1)°, V = 1054.7 Å^3, ρc = 1.248 g cm^{-3}, Z = 4, specimen dimensions 0.3 × 0.5 × 0.7 mm, no absorption corrections (μ = 0.79 mm^{-1}), g for secondary extinction, 6.5 × 10^3Å, kw in weighting scheme, 0.0005. 1801 reflections were scanned, and of these 1398 were observed. For the latter only, the final R index was 0.041 (Rw = 0.066). The esd's of bond lengths and angles are 0.002 to 0.003 Å, and 0.1 to 0.2°.

Acknowledgments

We wish to thank Mrs. M. G. Flack for her excellent technical assistance and J. Hiltz (NRCC summer student, 1976) for his contribution to this work. Our thanks go also to J. Van Ingen for ^1H nmr data, P. F. Seto for ir data, and D. J. Embree for accurate mass determinations. We thank the Drug Evaluation Branch, National Cancer Institute, Bethesda, MD for conducting antitumor screening.

Received July 21, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

ALEX NICKON, RAYMOND C. WEGLEIN, and C. THOMAS MATHEW. Can. J. Chem. **59**, 302 (1981).

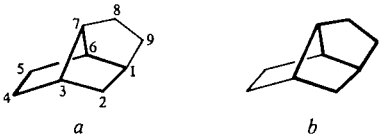
The brexane skeleton functionalized at C-5 is perceived as potentially useful for various mechanistic studies. Our present objective was to prepare and characterize brex-5-yl derivatives and to seek spectroscopic evidence for geometric distortion in the skeleton. The structures synthesized include brex-4-ene, brexan-5-one, both of the epimeric brexan-5-ols, and various derivatives of these compounds. Spectroscopic data (ir, ^{1}H nmr, and uv) are compared with those from relevant model compounds and are most simply interpreted on the basis of a twist in the brexyl skeleton. This distortion imparts more *exo* character to the C—H bonds at C-4 and more *endo* character to the C—H bonds at C-5. As an extension of the useful terms geminal and vicinal, we propose the word *hominal* to represent a 1,3-relationship between two groups.

ALEX NICKON, RAYMOND C. WEGLEIN et C. THOMAS MATHEW. Can. J. Chem. **59**, 302 (1981).

On croit que le squelette brexane ayant une fonction en C-5 pourrait s'avérer utile pour diverses études de mécanisme. Notre objectif est de préparer et de caractériser des brexanes substitués en position 5 et de chercher les preuves spectroscopiques de la déformation géométrique du squelette. Parmi les composés synthétisés on note le brexène-4, la brexanone-5, les deux brexanols-5 épimères et plusieurs dérivés de ces composés. On a comparé les données spectroscopiques ir, rmn du ^{1}H et uv de ces composés avec celles de composés modèles appropriés et on les a interprété uniquement en fonction d'une torsion du squelette brexyle. Cette déformation donne aux liaisons C—H en position 4 un caractère fortement *exo* et à celles en C-5 un caractère fortement *endo*. Comme extension des termes géminal et vicinal très utilisés nous proposons le mot *hominal* pour représenter la relation 1,3 entre deux groupes.

[Traduit par le journal]

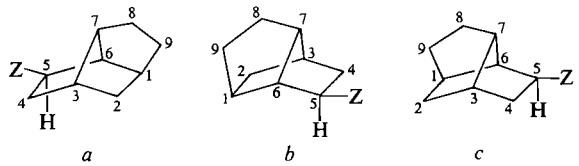
Tricyclo[4.3.0.0^{3,7}]nonane (**1**), trivially named brexane, is an intriguing homolog of bicyclo-[2.2.1]heptane because it is comprised of two partially superposed norbornyl units with one cyclopentyl ring in common. The norbornyl moieties are revealed in **1***a* and **1***b* by bold lines, and the common ring is numbered **1**, **2**, **3**, **7**, and **6**. Previ-



a *b*

1

ously, we prepared and characterized this tricyclic hydrocarbon and its C-2 and C-4 monofunctional derivatives (1). In this paper we draw attention to some potentially useful aspects of C-5 functionalized brexanes and describe their syntheses, characterization, and some transformations. As illustrated in the *exo* derivative **2** (shown in two perspectives, **2***a* and **2***b*, and also in a mirror image perspective, **2***c*), a departing group Z at C-5 apparently has "norbornyl-like" surroundings. However, the remote two-carbon bridge (C-8, C-9) restricts the skeletal changes that might accompany (or follow) ionization of Z. To illustrate, let us consider the three general types of rearrangements observed in norbornyl cations. With conventional norbornyl numbering, these rearrangements are termed 3,2-hydrogen shifts, 6,2-hydrogen shifts, and Wagner–Meerwein ring-bond shift (2). Of these processes the 3,2-H shift (i.e. the *vicinal* H shift) is by far the slowest (2*d*). It is barely detectable in acetolysis of *exo*-norbornyl brosylate (3, 4) but was observed in formolysis (3) and in a low temperature ^{1}H nmr study of the norbornyl cation in $SbF_5/SO_2/SO_2F_2$ (5). For the vicinal shift in substituted norbornyl cations, an *exo*-H rearranges much faster than does an *endo*-H, and some researchers relate this stereochemical preference to structural peculiarities of norbornyl cations (6). By analogy a vicinal H shift in the brex-5-yl cation to



a *b* *c*

2

produce **4** appears possible and would be easily detected from a product study.[1] In contrast, cation **3** should resist the other two types of "norbornyl"

[1]The rearranged cation **4** has been generated other ways in HOAc, and its fate is known (refs. 1, 7, 8). For example, prior to capture, much of it undergoes Wagner–Meerwein shift to the brendyl cation **6**.

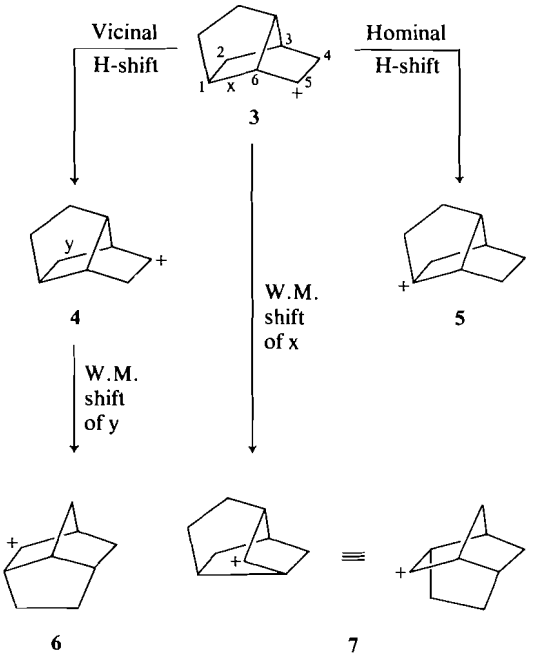
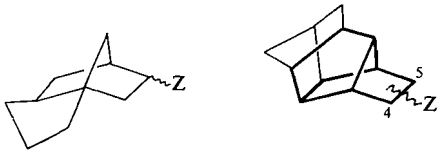
rearrangements. Thus, hydride transfer from C-1 to C-5 (analogous to the norbornyl 6,2-H shift and which we term a *hominal*[2] shift) is unlikely because it produces the bridgehead cation **5**, whose instability should parallel that of the bridgehead 1-norbornyl cation (9). A conventional Wagner–Meerwein shift (**3** → **7**) is also unfavourable, because it would produce the twist-brendyl skeleton **7**, which is considerably more strained than the initial skeleton (10).[3] Clearly, if the brex-5-yl system is denied this Wagner–Meerwein shift capability, then a complete mechanistic study of its ionization behavior becomes important because the "nonclassical" ion interpretation of norbornyl chemistry requires onset of such a shift during ionization of *exo*-derivatives (2), whereas other interpretations do not (11). Other workers have independently recognized the potential value of constrained skeletons for mechanistic study and have prepared tricyclic and pentacyclic structures like **8***a* (12*a*) and **8***b* (12*b*, *c*). Although **8***b* contains a brexyl unit within its skeleton (see heavy lines), this pentacycle has extra nonbonded interactions and other complicating features that would preclude direct comparison with the norbornyl system.



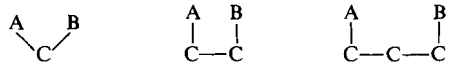
3 4 5 6 7



8*a* 8*b*

Another worthwhile mechanistic study would compare brex-5-yl (**3**) and brex-4-yl (**4**) behavior, because the latter cation generated solvolytically does rearrange via Wagner–Meerwein shift to the brend-2-yl system **6** (7, 8). Such comparison is especially meaningful if the surroundings of a substituent at C-5 and C-4 are similar enough so that differences in kinetic behavior could not be attributed to differences in nonbonded interactions. Because molecular models of brexane suggest that the ethano bridge twists[4] the "norbornyl" portion somewhat, it becomes essential to learn experimentally how this twist affects the local environ-

[2]Chemists use *geminal* and *vicinal* to designate, respectively, attachment to the same atom (i) and to adjacent atoms (ii). However, no convenient word serves for iii, the next stage in



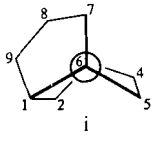
i ii iii

geminal *vicinal* *hominal*

this progression; and clarity sometimes suffers. For example, a 1,5-H shift in the brexyl cation **3** corresponds structurally to a 6,2-H shift in the norbornyl cation; and both represent 1,3-H shifts in the generalized sense. To avoid possible misinterpretation of the numerals, chemists frequently resort to awkward terms such as "6,2-norbornyl type" or "1,3-type" to describe this general class of H-shift. Since "homo" is widely used to denote a homologous counterpart (cf. homoenolate ion, homoconjugation, homoaromaticity, etc.), we propose "hominal" to signify a 1,3-relationship between two groups. (The ending *inal* rather than *onal* keeps its spelling and pronunciation as in gem*inal* and vic*inal*.) Thus, a hominal elimination is a 1,3- or γ-elimination. And, we may speak of hominal proton coupling in nmr (J_{hom}), of hominal orbital overlap, of hominal insertions by carbenes, of *hom*-dihalides, of hominal H-loss from a cation, of hominal axial interactions in a cyclohexane chair, etc.

[3]The strain in twist-brendane has been estimated (ref. 10*b*) to exceed that in brexane by 5.2–8.7 kcal/mol (21.8–36.4 kJ/mol).

[4]Altona and Sundaralingham (13) would describe this distortion as a *synchro*-twist. Thus, if perspective **2***b* of brexane is viewed along the C-6 · · · C-3 vector, the *rear* atoms (C-2 and C-4) of the *norbornyl unit* are both displaced in the *same twist sense* (i.e. both counterclockwise or both clockwise) relative to the front atoms (C-1 and C-5). For the enantiomer depicted in **2***b*, the *synchro* twist is counterclockwise (as shown in i), whereas



i

for the mirror image **2***c* the *synchro* twist is clockwise. When the rear atoms of a substituted norbornyl unit are displaced in opposite twist senses (i.e. one clockwise and one counterclockwise), the twist is termed *contra*.

ments at C-4 and C-5 relative to each other and relative to their norbornyl counterparts. We shall first outline our syntheses and characterization of brexanes functionalized at C-5. Then we shall describe relevant spectral features of the C-5 and C-4 derivatives as probes for geometric distortion in the brexyl skeleton. These studies provide a necessary foundation for later interpretation of kinetic behavior.

Our starting point was deltacyclane (**10**) (1), obtained by Wolff–Kishner reduction of deltacyclan-8-one (**9**) (1, 14) and also by hydrogenation of deltacyclene (15). In this work we improved considerably the reported (14) two-step synthesis of ketone **9** from norbornadiene and α-chloroacrylonitrile. Then, by a known three-step sequence, we converted hydrocarbon **10** to a mixture of brexan-4-one (**11**) and brendan-2-one (**12**), readily separated by gas chromatography (1). We tried, unsuccessfully, to convert **11** to brex-4-ene (14) by the Shapiro–Heath (16) modification of the Bamford–Stevens reaction, but we satisfactorily accomplished this change by bromination, reduction with $NaBH_4$, and reductive elimination of the bromohydrins with zinc. This sequence was carried through without characterization of intermediates and has the added advantage that it can be applied to a mixture of **11** and **12**. The latter ketone, being nonenolizable, is not brominated and ends up as alcohols, from which we separated liquid olefin **14** by column chromatography. A different route to brex-4-ene is now available through discovery by Brieger and Anderson (17) that 1-(3′-butenyl)-1,3-cyclopentadiene (**13**) at 180°C undergoes diene isomerization followed by intramolecular Diels–Alder addition to give an olefin identical with our brex-4-ene.[5]

Osmium tetroxide converted olefin **14** to the *exo*–*cis*-diol **15**, for ir and ^1H nmr studies. Although we have no rigorous proof, the *exo* stereochemistry for **15** is indicated by the lack of nmr coupling between each of the carbinyl protons at C-4 and C-5 and its adjacent bridgehead proton. Furthermore, as will soon become evident, *exo* attack is highly favored in other additions to brex-4-ene.

Hydroboration of olefin **14** produced virtually only two alcohols, in ca. 72:28 ratio. The minor component corresponded to the known *exo*-brexan-4-ol (**16**) (1). Acetylation of the mixture and separation by preparative gas chromatography afforded the known *exo*-brexan-4-ol acetate (**17**) (1) and the major product, *exo*-brexan-5-ol acetate (**19**). This new, liquid acetate was fully characterized and was reduced with $LiAlH_4$ to crystalline *exo*-brexan-5-ol (**18**), which gave a solid brosylate **20** by treatment with brosyl chloride in pyridine. The *exo* stereochemistry in compounds **18**–**20** follows from several spectral correlations to be discussed later.

In contrast to hydroboration, which gave *exo* products almost exclusively, oxymercuration of brex-4-ene (**14**) followed by acetylation produced ca. 35 rel.% of *endo*-brexan-5-ol acetate (**22**) together with *exo*-4-OAc **17** (54%) and *exo*-5-OAc **19** (11%). The pure, liquid *endo*-5-OAc **22** was separated by gas chromatography and was reduced with $LiAlH_4$ to solid *endo*-brexan-5-ol (**21**). This alcohol gave a crystalline brosylate (**23**) by action of methyl lithium and brosyl chloride. Each of the epimeric alcohols **18** and **21** was oxidized to brexan-5-one (**24**), but we used the (more plentiful) *exo*-alcohol to get this liquid ketone in quantity. We reconverted brexan-5-one to brex-4-ene (**14**) by a Bamford–Stevens sequence (18) and so proved that the brexane skeleton remains intact in ketone **24**. Let us now compare spectral properties of our tricyclic molecules with their norbornyl counterparts to probe for distortions in the brexane skeleton (19).[6]

Spectral Characteristics

Infrared carbonyl stretching frequencies in cyclic ketones have been used to estimate C—CO—C bond angles (20) and to assess strain in secondary, cycloalkyl cations (21). In carbon tetrachloride the ketone bands (cm^{-1}) in brexan-5-one (1749), brexan-4-one (1751) (7), and brexan-2-one (1751) (7) are very close to that in norbornan-2-one (1751) (7, 20*b*, *d*). In this respect, therefore, the brexyl skeleton is clearly "norbornyl-like."[7]

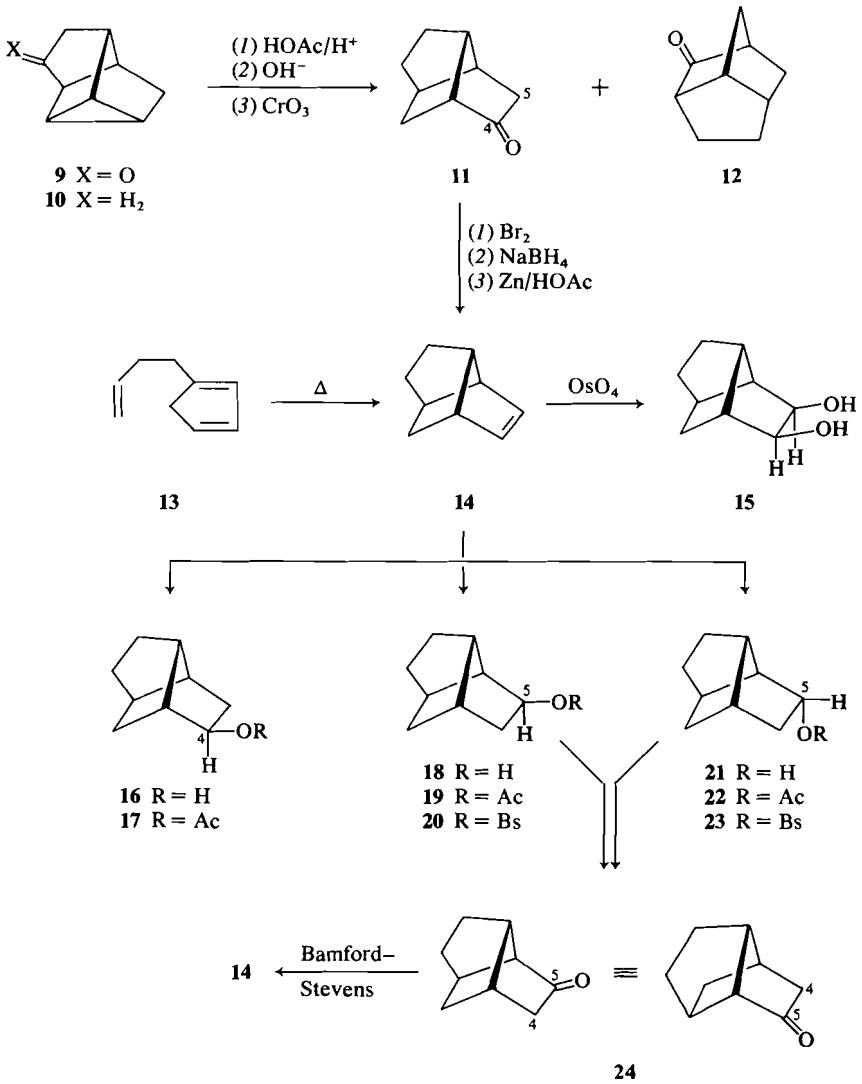
From studies of the near infrared spectral region, Gassman and Hooker (23) found that norbornenes show an overtone of the olefinic C—H stretch between 6083–5977 cm^{-1}. The band position depends on skeletal structure, and on the number of substituents and their electronic and stereochemical nature. Norbornene itself absorbs at 6013 cm^{-1}, and we find that brex-4-ene is very similar, with absorption at 6010 cm^{-1}.

Another infrared spectral comparison involves

[5]We thank Dr. G. Brieger for helpful exchange of information.

[6]For extensive tables that also include other polycyclic systems in these comparisons, see ref. 19.

[7]In contrast, the pentacyclic ketones related to **8***b* represent distorted norbornyl homologs because the 4-one absorbs at 1746 and the 5-one at 1744 (22). For a stretching frequency of 1751 the C—CO—C angle is estimated at 101.5° (20*d*); and 1744 corresponds to 104.8°. Note, however, that similarity to norbornan-2-one, and not absolute value, is the relevant aspect. The tricyclic ketone related to **8***a* has a "norbornyl-type" carbonyl at 1749 (12*a*).



intramolecular H-bonding in vicinal diols recorded at high dilution. An important factor determining the difference (Δν) in O—H stretching frequency between the "bonded" and "nonbonded" OH bands is the dihedral angle between the adjacent oxygens; the larger the dihedral angle the smaller the Δν (24).

Our *exo–cis*-brexane-4,5-diol (**15**) in carbon tetrachloride has Δν 92.4 cm^{-1} (Table 1, Entry 1), which is somewhat less than the values (Δν 103 and 102) for *cis*-norbornanediols (Entry 2). In this respect, therefore, the brexanediol differs from its norbornyl counterparts. Viewed most simply this smaller Δν indicates a skeletal twist, which increases the dihedral angle between the two C—O bonds relative to that in norbornanediol.

However, several selected known *cis* diols shown in Table 1 reveal that factors other than dihedral angle can influence Δν. For example, although the vicinal C—O bonds in camphane (Entry 3) seem as rigidly eclipsed as those in norbornane, the Δν's for the camphanediols (90–96 cm^{-1}) are lower and more like that in brexanediol. Also, the homoadamantanediol (Entry 4) exhibits a still smaller Δν (89 cm^{-1}), and yet molecular mechanics calculations for the parent hydrocarbon favour C_{2v} symmetry, i.e. a nontwisted ethano bridge, with a near 0° dihedral angle for vicinal bonds (25). Finally, noradamantane-3,7-diol (Entry 5) has a surprisingly low Δν (37 cm^{-1}) despite its locked framework, and a dihedral angle of 0° imposed by symmetry (26). Evidently, other factors (such as H—O—C and C—C—O angles) also influence Δν, and these factors might also help explain why Δν for

4		89	25
5		37	26

brexan-4,5-diol (Entry 1) is lower (by ca. 10 cm^{-1}) than that for the norbornanediols. However, because molecular models clearly suggest a synchro twist (13) in the norbornyl units of brexane, and because this tricyclic skeleton has no steric interactions that might impose unusual H—O—C or C—C—O angles, we are inclined to accept a noneclipsed arrangement (i.e. dihedral angle > 0°) for the vicinal bonds in brexanediol.

Proton nmr also provides clues about distortions in brexyl derivatives. We shall first examine olefinic analogs and then derivatives containing only sp^3 carbons. Table 2 summarizes chemical shifts and coupling constants for the olefinic hydrogens in norbornene, brex-4-ene, and pertinent model compounds. In norbornene (Entry 1), our reference model (27, 28), the olefinic hydrogens are equivalent (δ 5.94), but their mutual coupling (J = 5.8 Hz) has been determined indirectly from ^{13}C nmr (28*c*). This equivalence is lost and the skeleton is distorted when a *trans*-fused, five-membered ring is attached as shown in Entry 2 (29). In this tricycle the vinyl hydrogens H-2 and H-3 differ appreciably in location (Δδ = 0.75), and each hydrogen couples differently (ΔJ = 0.50) with its vicinal bridgehead proton. These differences may arise in part from changes in ring angles at each trigonal carbon (i.e. rehybridization) (29) and in part from skeletal twisting. A synchro twist induced by the remote *trans*-fused ring swings H-2 slightly downward (*endo* direction) and H-3 slightly upward (*exo* direction). The dihedral angles change such that the coupling constant $J_{3,4}$ should be greater than $J_{1,2}$ as was observed. Also, relative to norbornene, the chemical shifts for H-2 and H-3 are displaced in opposite directions, and this feature is expected based on published ^1H nmr studies of saturated and unsaturated norbornyl compounds (30). Those studies showed that *exo* hydrogens appear generally at lower field (larger δ) than do *endo* hydrogens. Whatever the theoretical basis for these *exo–endo* differences,[8] olefinic H's that acquire *endo* or *exo* character due to ring-twist might be expected to change their chemical shifts correspondingly. Interestingly, the vinyl–vinyl coupling constant $J_{2,3}$ in this distorted molecule (Entry 2) and in norbornene are virtually the same. Probably this coupling is simply not sensitive enough to reveal a skeletal twist. Alternatively, a compensating effect on $J_{2,3}$ might be produced by changes in olefin-carbon hybridization, because the magnitude of vinyl–vinyl coupling is known to depend on the H—C=C angles (31).

In the pentacyclic brexyl homolog, Entry 3, the olefinic H's were not dissimilar enough[9] to show distinct signals with discernible couplings (22, 32). Therefore, unlike the case in Entry 2, ^1H nmr gives no information about distortion in the pentacyclic olefin.

Brex-4-ene (Entry 4) represents a situation between those of Entries 2 and 3. Thus, the vinyl H's have distinctly different chemical shifts and these accord with a synchro twist that increases the *exo* character of H-4 (larger δ) and increases the *endo* character of H-5 (smaller δ). But, the difference (Δδ = 0.24) is less than that in Entry 2 (Δδ = 0.75), and this smaller change might reflect a smaller distortion. The coupling constants, $J_{3,4}$ and $J_{5,6}$, in Entry 4 give no structural clues, because they are equal to each other and comparable to the corresponding couplings in norbornene (Entry 1).

In 9-oxo-brex-4-ene (Entry 5), the remote polar carbonyl group slightly perturbs the olefinic chemical shifts. But, relative to norbornene, the Δδ's and ΔJ's follow the same trends as in brex-4-ene (19).[6] In summary, the chemical shift differences for the olefinic hydrogens in brex-4-ene support a synchro twist in which H-4 becomes more *exo*-like and H-5 becomes more *endo*-like, with the practical consequence that *exo* approach by reagents should be easier at C-5 than at C-4. *Endo*-approach might also be partly influenced by this twist, but could be

[8]Musher (ref. 30*a*) suggested that the bicyclo[2.2.1]heptane ring skeleton has an inherent magnetic anisotropy that deshields *exo* hydrogens relative to *endo* hydrogens.

[g]We are grateful to Adams and Trecker (ref. 33) for privately informing us of their synthesis of 9-oxo-brex-4-ene (Table 2, Entry 5) and for providing a sample. We confirmed their proposed structure by catalytic hydrogenation of the double bond to give authentic brexan-4-one, and not (as reported in ref. 33) by Wolff–Kishner reduction to give brex-4-ene.

dominated by interactions with the transannular *endo* hydrogens at C-1 and C-2.

We now turn to our saturated brexyl systems to seek evidence for skeletal twist relative to their norbornyl counterparts (34). Electron diffraction studies (35) on norbornane reveal a skeleton with C_{2v} symmetry and, therefore, virtually eclipsed vicinal hydrogens at the sides of the boat-shaped ring, i.e. C—H dihedral angles of 0° and 120°. X-ray studies on a small number of norbornanes show that substitution can distort the ring slightly in a *synchro* or *contra* manner to change these dihedral angles (13).[10] Therefore the reported ranges for ^{1}H nmr shifts and for coupling constants (derived from a large number of substituted norbornanes) already embrace molecules slightly distorted from true C_{2v} symmetry and from the corresponding true dihedral angles. Marchand *et al.* (36) have pointed out that even for norbornane itself and for its non-distorted analogs, *exo–exo* vicinal coupling exceeds *endo–endo* coupling, and they proposed a theoretical interpretation involving transannular interactions of the C-2 and C-3 bonds with the C-7 methylene bridge (37). Therefore, an in-depth understanding of couplings in our brexanes relative to those in norbornanes should take into account these hominal interactions as well as vicinal ones. Qualitatively, however, we might probe for distortion in the brexyl skeleton through the Karplus relationship between vicinal dihedral angle and J_{HH} (38). Although the literature is replete with accurate *J*'s for unsaturated norbornyl derivatives (34, 36, 37), the data for saturated norbornanes are meagre. Table 3 lists the available information (Entries 1 and 2) and also summarizes the chemical shifts and coupling constants for our monofunctional brexanes (Entries 3 through 7). Although the norbornyl analogs are of little help, we can infer a twist in the saturated brexyl skeleton from the following

[10]Although calculations suggest that *synchro* twist should prevail when substituents are at C-2 and/or C-3, one example of *contra* twist has been observed, namely, in *exo*-norbornan-2-ol tosylate, where the O—S bond and the aryl ring may exert their own special influence (ref. 13).

[a]When J's are not extractable from multiplets owing to poor resolution, we report $W_{1/2}$, i.e. the width (Hz) of the multiplet at half-height. Subscripts x = *exo*, n = *endo*.
[b]Recorded in $CDCl_3$.
[c]Recorded in CCl_4.
[d]Couplings in these specific compounds do not appear to be reported. However, for various bicyclo[2.2.1]heptane derivatives (saturated and unsaturated), typical J ranges are as follows: $J_{x,x} = 7.4–11.6$; $J_{x,n} = 2.1–4.6$; $J_{1,2x} = 2.9–4.3$; $J_{1,2n} = 0$; $J_{2x,6x} = 1.0–1.8$; $J_{2n,7anti} = 2–4$. See refs. 19 and 34.
[e]This value (±0.5 Hz) was confirmed by stereospecific preparation of monodeuterated analogs (ref. 18).
[f]Coupling constants not recorded.
[g]Note in the formula as written and numbered in entry 7, if the H and Z at C-2 were interchanged, then this coupling would be $J_{1,2}$.

line of reasoning. For the eclipsed, i.e. norbornyl-type, geometry (see **25**), the vicinal couplings, $J_{2x,3n}$ and $J_{3x,2n}$, both correspond to a dihedral angle of ca. 120° because of symmetry; and, therefore, whether an *exo* substituent (for example) is at C-2 or C-3 makes no difference in the *exo–endo* coupling of the remaining hydrogens. In contrast, for a brexane that is synchro-twisted by θ° (see **26**), an *exo* substituent at C-4 should leave the $J_{4n,5x}$ with a decreased coupling (i.e. dihedral angle 120 − θ°), whereas an *exo* substituent at C-5 should leave $J_{5n,4x}$ with an increased coupling (i.e. dihedral angle ca. 120 ± θ°).

The $J_{n,x}$ couplings in three brexyl compounds in Table 3 were identifiable, and those in Entries 4 and 6 constitute a relevant pair for comparison. The 1.5 Hz for $J_{4n,5x}$ in Entry 4 (Z = OAc) is appreciably smaller than the 4.0 Hz for $J_{5n,4x}$ in Entry 6, in accord with a synchro twist.

As a final nmr indication of geometric distortion, we note that the observed couplings ($J \sim 5–6$ Hz) involving an *exo*-H and a vicinal bridgehead hydrogen in two brexyl derivatives (viz. $J_{5x,6}$ in Entry

5, and $J_{2,3}$ in Entry 7) are markedly higher than those in saturated norbornanes (ca. 3.5 Hz, ref. 39).

In ultraviolet excitation of alkenes, a rotation around the double bond increases the wave length of absorption, and Coulson and Stewart have shown theoretically for ethylene how the angle of twist alters the ground state and excited states (40). Our gas phase ultraviolet measurements gave λ_{max} 200 nm for brex-4-ene and λ_{max} 195 nm for norbornene. This difference is consistent with a twist in the tricyclic olefin although by itself is not persuasive, because factors other than olefinic twist could also affect the absorption. Interestingly, 9-oxo-brex-4-ene (Table 2, Entry 5) gave λ_{max} 195 nm. The carbonyl group should widen the ring angle at C-9 and thus lessen the twist. This expectation agrees with the shorter wave length absorbed by the keto-olefin relative to that in brex-4-ene. Thus, the combined evidence from ir, ^{1}H nmr and uv qualitatively supports a synchro twist in the brexyl skeleton, although it cannot define the atomic positions quantitatively. We have previously used computer calculations to estimate dihedral angles in other bridged molecules (10). Now applied to brexane, these calculations lead to a twist of 12.1° for the *exo* bonds and 13.1° for the *endo* bonds, away from the eclipsed array (see **26**). We emphasize, however, that these estimates pertain to the saturated hydrocarbon, and not necessarily to substituted or unsaturated derivatives (41).

Experimental

General

Unless stated otherwise, the following applies. Melting points were determined in sealed Pyrex capillaries, are corrected, and are rounded to the nearer half degree. For distillations we used a 20–30 cm Vigreux column equipped with a cold-finger condenser and a fraction cutter. Reduced pressures refer to millimeters of Hg (Torr). Elemental analyses were by M—H—W Laboratories, Garden City, MI. Routine infrared spectra were run on a Perkin-Elmer Model 337 grating instrument; special spectra (e.g. for H-bonding) were obtained with Perkin-Elmer Model 521 (grating), and near-infrared were recorded with Cary Model 14 spectrometers. Band positions refer to cm^{-1} and the letters sh, w, m, s, and br refer to shoulder, weak, medium, strong, and broad. Ultraviolet spectra refer to the gas phase and were recorded at atmospheric pressure in 1 cm quartz cells on Cary Model 14 and Model 15 spectrometers equipped with a nitrogen flush.

^{1}H nuclear magnetic resonance spectra were run on Varian Associates, Inc., A-60 and HA-100 instruments. The 100 MHz instruments were used in most cases where J values were measured and were operated by Mr. William Ellis, by Dr. James Alderfer (Johns Hopkins School of Hygiene and Public Health, courtesy of Professor Paul O. P. Ts'o), by Dr. Haruhiko Yagi (National Institutes of Health, courtesy of Dr. B. Witkop), and by Mr. Robert Confer (Pennsylvania State University, courtesy of Professor L. M. Jackman), whom we thank.

Analytical gas chromatography (glc) was conducted on a Perkin-Elmer Model 900 analytical instrument equipped with a hydrogen flame ionization detector linked to a Model 16 Honeywell recorder and disc integrator. Preparative glc was done with a Wilkins Aerograph "Autoprep" Model A-700 fitted with a thermal conductivity detector and Honeywell recorder. Temperatures were routinely 180 ± 10°C for the injector and 230 ± 10°C for the detector. The carrier gas was always helium. Retention times (t_R) are in minutes, and relative percentages were determined from disc integration data and represent the average of at least two determinations. Column designation, column temperature, and column inlet pressure are included for each case.

Analytical Columns

A-1: Golay R 300 ft (0.01 in. id) with polypropylene glycol liquid phase (UCON-oil LB-550-X). A-2: Golay FFAP, 100 ft (0.02 in. id) with Varian's Free Fatty Acid Phase. A-3: 9 ft (1/8 in. od) 15% Carbowax 20M on 80/100 Chromosorb W. A-4: 9 ft (1/8 in. od) 20% Reoplex 400 on 80/100 Chromosorb W. A-5: 9 ft (1/8 in. od) 10% Carbowax 20M on 80/100 Chromosorb W. A-6: 9 ft (1/8 in. od) 20% MBMA (*m*-bis-(*m*-phenoxy)benzene + Apiezon L Grease) on Chromosorb W 80/100. A-7: Golay Reoplex 400, 300 ft (0.01 in. id).

Preparative Columns

P-1: 50 ft (1/4 in. od) 20% Reoplex 400 on 80/100 Chromosorb W. P-2: 20 ft (3/8 in. od) 30% Carbowax 20M on 40/60 Chromosorb W. P-3: 18 ft (3/8 in od) 27% diethylene glycol succinate (DEGS) on 80/100 Chromosorb W.

Solvents and Reagents

Brown's oxidation reagent containing two oxygen milliequivalents per milliliter consisted of a solution of sodium dichromate (50 g, 0.168 mol) in 96% sulfuric acid (37.5 mL) and distilled water (150 mL), made up to a final volume of 253 mL with more distilled water (42). *Preoxidized ether*: twice the volume of diethyl ether necessary for an oxidation was stirred with one-tenth of its volume of Brown's reagent for 1 h. The ether layer was washed successively with 1/10 volume proportions of water, saturated sodium bicarbonate, and brine. The ether was dried over $MgSO_4$. *Dry ether* was obtained by distillation from lithium aluminum hydride. To purify n-*pentane* we stirred commercial pentane for 24 h with 1/4 its volume of a 1:1 solution of concentrated and fuming sulfuric acids. The pentane layer was washed repeatedly with water and saturated sodium bicarbonate. It was dried over $MgSO_4$ and finally was distilled (bp 35–36°C) from sodium wire. *Methylene chloride* was stirred (24 h) with concentrated sulfuric acid, was washed repeatedly with water, then with saturated sodium carbonate. It was dried over calcium chloride and finally distilled (bp 39–40°C) from phosphorous pentoxide. *Chromium trioxide – pyridine complex* was obtained by addition of CrO_3 (6 molar equivalent, vacuum dried before use) to a magnetically stirred solution of pyridine (12 molar equivalent) in purified methylene chloride (ca. 15 mL per 1.0 mmol of alcohol to be oxidized) protected with a calcium chloride drying tube. After 1–2 h stirring at room temperature, we added the alcohol to be oxidized.

Deltacyclan-8-one (9)

(a) Diels–Alder Reaction

A degassed mixture of freshly distilled norbornadiene (44.0 g, 0.48 mol), freshly distilled α-chloroacrylonitrile (40.3 g, 0.46 mol, Marbon Chemical Division of Borg-Warner), and hydroquinone (0.3 g) was heated 14 h at 200°C in a thick, vacuum-sealed Pyrex tube. The cooled mixture was poured into pentane (1 L), was filtered to remove polymer, and was concentrated on a rotary evaporator. Distillation of the residue gave 56.3 g (68%) of *8-cyano-8-chlorodeltacyclane*; bp 73–75°C at 1 Torr (lit. (14) bp 89–94°C at 0.1 Torr). The characteristic ir (neat) and ^{1}H nmr bands agreed with those reported (14).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

(b) Hydrolysis

The adduct (43 g) was hydrolyzed in dimethyl sulfoxide – aqueous KOH essentially as reported (14). The residue from work-up gave 18.7 g (58%) of deltacyclan-8-one (bp 104°C, 21 Torr), whose ir, ^{1}H nmr, and glc were identical to those of an authentic sample (1).

Deltacyclane (10)

Wolff–Kishner reduction of ketone **9** as reported gave this hydrocarbon, whose ir and glc (A-6, 100°C, 40 psi) were identical to those of an authentic sample (1). We also obtained deltacyclane by hydrogenation (10 h at 50 psi) of deltacyclene (15) (33.4 g) in pentane (80 mL) over prereduced PtO_2 (0.06 g in 20 mL pentane). Filtration and evaporation left 33.5 g of pure deltacyclane. Near ir (not previously reported in ref. 1) (CCl_4): 5992 cm^{-1}, ε 0.960.

Brexan-4-one (11) and Brendan-2-one (12)

The cyclopropyl ring in deltacyclane was opened with $HOAc/H_2SO_4$, and the derived mixture of *exo*-4-brexyl and *exo*-2-brendyl acetates was saponified to an alcohol mixture, which was directly oxidized to a mixture of ketones **11** and **12** (ratio typically ~ 1:1.2) as described (1*b*). Preparative glc (P-2, 185°C, 60 psi) of 200 μL batches of neat, liquid mixture separated the ketones with collection efficiency of 65% and a purity for each of > 99% (A-3, 170°C, 40 psi). However, for routine preparation of brex-4-ene, we were able to use the ketone mixture rather than pure brexan-4-one because brendan-2-one has no readily enolizable hydrogens.

Brex-4-ene (14)

(a) Halohydrin Route

A mixture (typically 1:1.2) of ketones **11** and **12** (4.63 g, 34 mmol) was treated with pyridinium hydrobromide perbromide (43*a*) (5.43 g, 17 mmol) in glacial acetic acid (35 mL) for 40 min at 55°C. The solution was added to water (450 mL) and extracted with methylene chloride (3 × 30 mL), which was then washed successively with 0.1 *N* sodium thiosulfate (50 mL) and saturated sodium bicarbonate (100 mL). The organic layer was dried over $MgSO_4$ and evaporated to leave 5-bromobrexan-4-one and brendan-2-one as a mixture (5.5 g), which was reduced directly with $NaBH_4$ (0.322 g, 8.5 mmol) in ethanol (15 mL). After 1 h at room temperature the reaction mixture was added to water (350 mL) and extracted with ether (5 × 20 mL), which was then washed with brine (50 mL), dried over $MgSO_4$, and evaporated to leave a mixture (5.45 g) of bromohydrins and brendan-2-ol.[11] This mixture in glacial acetic acid (10 mL) containing water (1 mL) was stirred 30 min at room temperature with zinc (2.2 g). After addition of water (200 mL) and extraction with pentane (3 × 20 mL) the extract was washed with saturated sodium bicarbonate and dried over anhydrous sodium carbonate. The residue (3.06 g) from evaporation was chromatographed on Alcoa F-20 alumina (100 g). Elution with pentane (100 mL) gave liquid brex-4-ene (0.71 g, 36% based on ketone **11**), which was > 98% pure by glc (A-6, 100°C, 40 psi). Ultraviolet λ_{max}: 200 ± 0.2 nm (gas phase, atmospheric pressure). Under the same conditions norbornene had λ_{max} 195 nm. Infrared ν (CCl_4): 6010 cm^{-1}, ε 0.724; ν (CS_2): 3050 (m), 1340 (m), 702 (s, *cis* olefin CH) cm^{-1}; ν (neat): 1615 cm^{-1}; ^{1}H nmr (CCl_4) δ: 6.01 and 5.77 (olefinic hydrogens at C-4 and C-5, respectively, each signal is a double doublet, $J_{4,5}$ = 5.7 Hz, $J_{3,4}$ = $J_{5,6}$ = 3.0 Hz), 2.53 (broad s, 1), 2.38 (broad s, 1), 2.10 (broad s, 1), 1.83–1.49 (m, 3), 1.49–1.03 (m, 3), 0.86 (m, 1).[12]

Anal. calcd. for C_9H_{12}: C 89.94, H 10.06; found: C 89.72, H. 10.18.

(b) Intramolecular Diels–Alder Route

Sodium (4.82 g, 0.21 mol) was finely dispersed in boiling xylene. The bulk of the xylene was decanted from the cooled mixture, and dry tetrahydrofuran (50 mL) was added, then decanted. Addition and decantation of tetrahydrofuran was repeated three times to remove xylene, which is difficult to separate from brex-4-ene. Finally, dry tetrahydrofuran (100 mL) was added, and the ice-cooled mixture was stirred in a nitrogen atmosphere as cyclopentadiene (20 mL) from pyrolysis of dicyclopentadiene (43*b*) was added over 30 min. After an additional 45 min, 4-bromobutene (27 g, 0.2 mol, Columbia Organic Chemicals Co.) was added over 45 min, and the mixture was stirred an additional 2.5 h. Work-up as described by Brieger and Anderson (17) gave crude 1-(3′-butenyl)-1,3-cyclopentadiene (**13**, 20.2 g, 84%), with ir and ^{1}H nmr absorption as reported (17). The crude triene was immediately dissolved in benzene (50 mL) and heated in a sealed tube for 4 h at 180°C. Removal of the benzene on a rotary evaporator and vacuum distillation of the residue gave 17.3 g (72%) of brex-4-ene; bp 84–86°C (100 Torr), > 99% pure by glc (A-6, 100°C, 40 psi), and identical in all respects to olefin from the bromohydrin route.

exo–cis-*Brexane-4,5-diol (15)*

Osmium tetroxide (0.5 g, 1.97 mmol) in ether (6 mL) was added at once to a stirred, carbon tetrachloride (3 mL) solution of brex-4-ene (0.25 g, 2.08 mmol), which was freshly purified by preparative glc (P-2, 100°C, 18 psi). Though exothermic, the reaction did not require cooling. After 84 h pyridine (10 mL), water (10 mL), and sodium bisulfite (0.5 g, 4.8 mmol) were added and stirring was continued 1 h to reduce the osmate ester. Water (25 mL) was added, the mixture was extracted with methylene chloride (5 × 20 mL), which was then washed with 5% hydrochloric acid (10 mL) and with saturated sodium bicarbonate (10 mL), and dried ($MgSO_4$). Evaporation left 0.072 g (24%) of diol, which was recrystallized twice from hexane, mp 98–99°C (0.049 g). Infrared ν (CCl_4): 3620 (m), 3550–3340 (m), 1080 (m), 1060 (s). At high dilution (5 × 10^{-3} *M* in CCl_4), a spectrum recorded with scale expansion on a Perkin-Elmer Model 521 showed a sharp "free" OH at 3631.0 and a broader "bonded" OH at 3538.6 (Δν 92.4 cm^{-1}). ^{1}H nuclear magnetic resonance (CCl_4) δ: 3.95 (d, 1, C-5 H, $J_{4,5}$ = 6.0 Hz), 3.66 (d, 1, C-4 H, $J_{4,5}$ = 6.0 Hz), 2.99 (broad s, 2, OH), 2.46 (broad s, 1), 2.08–1.78 (m, 3), 1.77–1.05 (m, 4), 1.01–0.78 (m, 2). *Anal.* calcd. for $C_9H_{14}O_2$: C 70.10, H 9.15; found: C 70.04, H 9.02.

exo-*Brexan-5-ol Acetate (19)*

Dropwise (75 min) addition of a solution of sodium borohydride (0.34 g, 8.98 mmol) in dry diglyme (9 mL) to freshly distilled boron trifluoride etherate (2.3 mL, 16.2 mmol) in dry diglyme (2 mL) generated diborane, which was continuously passed into a stirred solution of brex-4-ene (3.61 g, 30 mmol) by a stream of nitrogen. The reaction flask was vented to a scrubber containing acetone. The diborane generator was heated 3 h with an air gun and then was recharged with the same amounts of reactants, and the whole cycle was repeated. After the diborane generator was finally heated for an extra 3 h, water (2 mL) was slowly added to the stirred reaction flask to decompose the excess of diborane. After 15 min sodium hydroxide solution (3.2 mL, 3 *N*) was added, followed by hydrogen peroxide (3.2 mL, 30%). The mixture was warmed to 50°C, held there for 1 h, and then poured into a solution of saturated sodium chloride (20 mL) that contained an excess of solid sodium chloride to ensure saturation. The tetrahydrofuran layer was separated, and the aqueous layer was extracted with ether (3 × 15 mL). The combined organic extracts were dried (Na_2SO_4) and evaporated under vacuum. The solid (2.95 g) was almost entirely a mixture of *exo*-brexan-5-ol (18) and *exo*-brexan-4-ol (16) whose approximate ratio (ca.

[11]The brendan-2-ol is largely *endo*. Compare $LiAlH_4$ reduction of brendan-2-one (ref. 1*b*).

[12]Proton assignments at C-4 and C-5 are unambiguous, because we also had 4-deuteriobrex-4-ene from another project (ref. 18).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

3:1) was estimated from their C*H*—O nmr signals in CCl_4 at δ 3.95 and 3.58,[13] respectively. More accurate analysis (glc, A-1, 110°C, 50 psi) revealed a ratio of 72:28 (t_R 110.0 and 112.4 min, respectively). The latter retention time was identical to that of an authentic sample of *exo*-brexan-4-ol (1).

The alcohol mixture (2.45 g) was acetylated with acetic anhydride (5.2 g) in pyridine (10 mL) for 6 h at 25°C and then 10 min on the steam bath. Ether (125 mL) was added and the solution was washed successively with 5% hydrochloric acid (2 × 100 mL), saturated sodium bicarbonate (2 × 50 mL), and saturated sodium chloride (50 mL), and was dried ($MgSO_4$). Evaporation left the acetates as a 72:28 mixture with t_R 30 and 32 min, respectively, (A-4, 125°C, 50 psi). These acetates were separated by preparative glc (P-2, 180°C, 30 psi, t_R 77 min and 90 min). The liquid *exo*-brexan-5-ol acetate (**19**) was rechromatographed on a Reoplex column (P-1, 155°C, 30 psi) and was 99.9% pure. Infrared ν (CCl_4): 1740 (s), 1250 (vs), 1230 (m), 1062 (m), 1045 (w), 1025 (m) cm^{-1}; ^1H nmr (CCl_4) δ: 4.79 (doublet of doublets, 1, CH—O, $J_{4x,5n}$ = 4 Hz, $J_{4n,5n}$ = 7.2 Hz), 2.12 (broad s, 1), 2.07–1.15 (m, 12), 1.01 (broad s, 2). A $OCOCH_3$ singlet at 1.92 protrudes sharply from its surrounding multiplets.[14] *Anal.* calcd. for $C_{11}H_{16}O_2$: C 73.30, H 8.94; found: C 73.23, H 8.96.

exo-*Brexan-5-ol (18)*

exo-Brexan-5-ol acetate (0.36 g) was reduced with lithium aluminum hydride (0.15 g) in ether (50 mL) for 12 h at room temperature and 30 min at reflux. After cautious addition of a little saturated ammonium chloride, the ether was decanted and the residual salts were washed with ether. After being dried ($MgSO_4$) and evaporated, the ether left 0.25 g (90%) of liquid *exo*-brexan-5-ol, which gave the analytical sample (0.21 g) after one bulb-to-bulb distillation at 0.9 Torr at a bath temperature of 90–110°C. Infrared ν (CCl_4): 3605 (m), 1068 (m), 1012 (m) cm^{-1}; ^1H nmr (CCl_4) δ: 3.95 (double doublet, 1, CH—O, $J_{4x,5n}$ = 4.0 Hz, $J_{4n,5n}$ = 7.0 Hz), 2.60 (s, 1), 2.19 (broad s, 1), 2.0–1.05 (m, 9), 0.95 (broad s, 2). *Anal.* calcd. for $C_9H_{14}O_2$: C 78.21, H 10.21; found: C 78.37, H 10.39.

exo-*Brexan-5-ol* p-*Bromobenzenesulfonate (20)*

Brosyl chloride (0.50 g) and *exo*-brexan-5-ol (0.13 g) in benzene (1 mL) and dry pyridine (2 mL) stood three days in the freezer. The precipitated pyridine hydrochloride was removed and washed with ether. The combined ether–benzene solution was washed with cold 5% hydrochloric acid (3 × 10 mL), with saturated sodium bicarbonate (2 × 10 mL), and with 10 mL of saturated sodium chloride, and was dried over $MgSO_4$. Evaporation left 0.35 g of oil, which was taken up in pentane and treated for 30 min with Norite. Filtration through Celite followed by concentration and cooling to −78°C gave a solid, which was collected and recrystallized twice from ether–pentane; 0.13 g, mp 72–73.5°C (remelts at 71–73°C); ir ν (CCl_4): 1190 (s), 1180 (m), 1100 (m), 1075 (m), 1015 (m), 970 (m), 948 (m), 932 (m), 895 (m), 882 (m), 606 (m), 550 (m) cm^{-1}; ^1H nmr (CCl_4) δ: 7.83 (s, 4), 4.67 (double doublet, 1, C*H*—O), 2.3–0.8 (m, 12). *Anal.* calcd. for $C_{15}H_{17}BrO_3S$: C 50.42, H 4.76; found: C 50.15, H 4.82.

endo-*Brexan-5-ol Acetate (22)*

Brex-4-ene (**14**, 12.01 g, 0.1 mol) in tetrahydrofuran (5 mL) was oxymercurated–demercurated with mercuric acetate (35.05 g, 0.11 mol) in water (100 mL) – tetrahydrofuran (100 mL) by a reported general procedure (44). Work-up left an oil (12.3 g, 89%) that contained the following mixture of brexyl alcohols and acetates as revealed by glc (A-1, 110°C, 50 psi): *endo*-5-ol (33%), *exo*-5-ol (10%), *exo*-4-ol (48%), *endo*-5-OAc (2.8%), *exo*-5-OAc (1.3%), *exo*-4-OAc (5.3%). This mixture was combined with acetic anhydride (65 mL) and pyridine (10 mL) and, after 8 h at room temperature, ice was added, the mixture was stirred 30 min, and then combined with water (500 mL) and ether (100 mL). Work-up as described earlier for acetylation left 12.5 g (78.5%) of oil, shown by glc (A-1, 110°C, 50 psi) to consist of: *endo*-5-OAc (35%), *exo*-5-OAc (11%), and *exo*-4-OAc (54%) in that order of elution. Separation by preparative glc (P-1, 158°C, 30 psi) gave pure, liquid *endo*-brexan-5-ol acetate; ir ν (CCl_4): 1740 (s), 1375 (m), 1365 (m), 1248 (s), 1148 (m), 1132 (m), 1036 (m) cm^{-1}; ^1H nmr (CCl_4) δ: 5.05 (double doublet and fine structure, 1, J = 8.5, 5.0, 1.5 Hz, CH—O), 2.3–0.95 (m, 15). *Anal.* calcd. for $C_{11}H_{16}O_2$: C 73.20, H 8.94; found: C 73.36, H 9.06.

endo-*Brexan-5-ol (21)*

Reduction of *endo*-brexan-5-ol acetate (0.133 g) in ether (20 mL) with lithium aluminum hydride (0.056 g) for 13 h at room temperature left 0.106 g of solid on normal work-up; mp 65–66°C. Recrystallization from pentane gave the analytical sample (0.092 g, 90%), mp 68–69.5°C; ir ν (CCl_4): 3601 (m), 1148 (w), 1128 (w), 1078 (m), 1040 (m,), 992 (m); ^1H nmr (CCl_4) δ: 4.30 (m, 1, CH—O), 2.23 (broad d, 1), 2.08–1.75 (m, 4), 1.62–1.18 (m, 6), 1.18–0.92 (m, 2). *Anal.* calcd. for $C_9H_{14}O$: C 78.21, H 10.21; found: C 78.09, H 10.03.

endo-*Brexan-5-ol* p-*Bromobenzenesulfonate (23)*

Methyl lithium (100 μL, 1.8 *M*, Alpha Inorganics, Inc.) was added by syringe to a stirred solution of *endo*-brexan-5-ol (0.023 g, 0.168 mmol, mp 65–66.5°C) in dry ether (1 mL). After 10 min, brosyl chloride (0.045 g, 0.174 mmol) in ether (2 mL) was added by syringe. After 1 h the mixture was diluted with ether and was washed successively with water (20 mL), saturated sodium bicarbonate (20 mL), and saturated sodium chloride (20 mL), and was dried over sodium sulfate and potassium carbonate. Evaporation left 0.060 g (99%) of oil, which was crystallized from pentane at −78°C; 0.012 g, mp 71.5–72.5°C (remelts at 71–71.5°C); ir ν (CCl_4): 1401 (m), 1385 (m), 1190 (s), 1100 (w), 1070 (m), 950 (w), 880 (m) cm^{-1}; ^1H nmr (CCl_4) δ: 7.65 (m, 4, aromatic), 4.96 (double doublet with extra splitting, 1, J = 5.0, 9.0, 1.5 Hz, CH—O), 2.20 (m, 2), 2.0–1.0 (m, 10). *Anal.* calcd. for $C_{15}H_{17}BrO_3S$: C 50.42, H 4.76; found: C 50.42, H 5.00.

Brexan-5-one (24)

exo-Brexan-5-ol (0.54 g, 0.39 mmol) was treated with chromium trioxide – pyridine complex (5.98 mmol) in methylene chloride (45). After 45 min the reaction mixture was taken up in ether (100 mL) and washed with 5% hydrochloric acid (2 × 50 mL), saturated sodium bicarbonate solution (2 × 50 mL), and with saturated sodium chloride. The dried ($MgSO_4$) ether gave 0.049 g (93%) of liquid ketone, which was distilled bulb-to-bulb (90–100°C at 0.9 Torr) to give the analytical sample. Infrared ν (CCl_4): 1749 (s), 1460 (w), 1415 (m), 1320 (m), 1275 (m), 1160 (m), 1145 (m), 1060 (m) cm^{-1}; ^1H nmr (CCl_4) δ: 2.5–2.1 (m, 3), 1.98 (broad s, 1), 1.85 (s, 1), 1.80–1.35 (m, 5), 1.26 (broad s, 2). *Anal.* calcd. for $C_9H_{12}O$: C 79.37, H 8.88; found: C 79.21, H 9.01.

We have reconverted brexan-5-one to brex-4-ene by a Bamford–Stevens sequence (18) as extra proof of skeletal integrity.

9-Oxo-brex-4-ene (Table 2, Entry 5)

Adams and Trecker isolated this compound in low yield from dye-sensitized photooxygenation of 2-ethylidenebicyclo-[2.2.1]hept-4-ene (33). The enone is liquid but gives a crystalline 2,4-dinitrophenylhydrazone (mp 165–166°C), and also a pyrrolidine iminium perchlorate (mp 164–165°C), from which the pure enone is regenerated by alkaline hydrolysis. Dr. Adams kindly provided a sample of his enone, the following infrared and ^1H nmr data, and experimental details. Infrared ν: 3051 (w, olefin CH), 1748 (s, C=O), 1570 (w, C=C), 1404 (m, CH_2CO),

[13]In $CDCl_3$, the CH—O doublet in *exo*-brexan- 4-ol is at δ 3.71 (ref. 1*b*).

[14]Assignment of coupling constants was straightforward, because we had on hand 4-*exo*-deuterio-*exo*-brexan-5-ol acetate and 4-*endo*-deuterio-*exo*-brexan-5-ol acetate (ref. 18).

703, 722 (s, *cis* olefin CH) cm^{-1}; ^1H nmr δ: 1.25 (m, 1, 2-*endo*), 1.65 (m, 1, 2-*exo*), 2.05 (m, 2, C-8 CH_2), 2.35 (m, 1, C-7 H), 2.67 (m, 1, C-3 H), 2.93 (m, 1, C-6 H), 5.88 (m, 1, C-5 H), 6.37 (m, 1, C-4 H). Adams and Trecker derived these nmr assignments and the following coupling constants by appropriate double irradiation techniques: $J_{2n,2x} = 12.9, J_{1,2n} = 6.2, J_{4,5} = 5.5, J_{2x,3} = 5.0, J_{3,4} \sim J_{5,6} = 3.2, J_{1,2x} \sim J_{2n,3} = 0$ Hz. We duplicated their synthesis and also confirmed the structure of the enone by catalytically hydrogenating the double bond to give brexan-4-one, identical in all respects with an authentic sample (1). We measured the near-infrared spectrum of 9-oxo-brex-4-ene in CCl_4: λ: 6031 cm^{-1} (ε 1.044). The gas-phase uv had λ_{max} 195 nm.

Stereoselective syntheses of *O*- and *S*-nitrophenyl glycosides. Part III.[1] Syntheses in the α-D-galactopyranose and α-maltose series

MARCEL APPARU,[2] MICHÈLE BLANC-MUESSER, JACQUES DEFAYE, AND HUGUES DRIGUEZ

Centre de Recherches sur les Macromolécules Végétales, Centre National de la Recherche Scientifique,[3] 53 X, 38041 Grenoble, France

Received June 19, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

MARCEL APPARU, MICHÈLE BLANC-MUESSER, JACQUES DEFAYE, and HUGUES DRIGUEZ. Can. J. Chem. **59**, 314 (1981).

The action of *p*-nitrophenol on penta-*O*-acetyl-β-D-galactopyranose in dichloromethane, in the presence of stannic tetrachloride, gave *p*-nitrophenyl α-D-galactoside in fair yield. This technique failed when *o*-nitrophenol was used. Tetra-*O*-acetyl-β-D-galactopyranosyl and hepta-*O*-acetyl-β-maltosyl chlorides were converted to *p*- or *o*-nitrophenyl α-D-glycosides and *p*-nitrophenyl α-D-1-thioglycosides in good yield using hexamethylphosphoramide as a solvent and the sodium salt of the phenols as nucleophiles. The galactosides have been functionalized for further condensation at the C-4 position by selective benzoylation.

MARCEL APPARU, MICHÈLE BLANC-MUESSER, JACQUES DEFAYE et HUGUES DRIGUEZ. Can. J. Chem. **59**, 314 (1981).

L'action du *p*-nitrophénol en présence de chlorure stannique sur le penta-*O*-acetyl-β-D-galactopyranose dissous dans du dichlorométhane conduit au *p*-nitrophényl-α-D-galactoside. Cette technique n'aboutit pas à la formation de galactoside lorsque l'*o*-nitrophénol est utilisé. Les chlorures de tétra-*O*-acétyl-β-D-galactopyranosyle et d'hepta-*O*-acétyl-β-maltosyle dissous dans l'hexaméthylphosphoramide et traités par le sel de sodium des *p*- ou *o*-nitrophénol ou du *p*-nitrothiophénol, conduisent avec de bons rendements aux glycosides correspondants. Les galactosides ont été fonctionnalisés par benzoylation sélective pour des condensations ultérieures impliquant la position C-4.

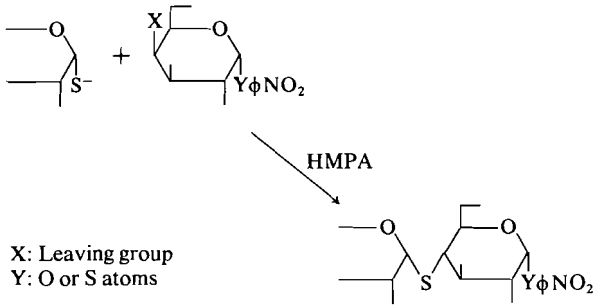
Introduction

Within the framework of a program on the mechanism of action of α-amylase using the substrate analogs approach we have undertaken the synthesis of some derivatives of nitrophenyl maltosides and maltotriosides in which the oxygen atoms at C-1, C′-1 and/or C″-1 might be replaced by a sulfur atom.

In former articles in this series (1) the steric control in 1-thioglycosylation was achieved by a S_N2 type of reaction involving the action of a thiolate anion on glycosyl halides. The reverse displacement of a leaving group by a 1-thioglycose is an alternative approach (2), Scheme 1. The present paper deals with the application of this method to derivatives of D-galactose and maltose suitable for the above purpose.

Results and Discussion

Nitrophenyl α-D-galactopyranosides and α-maltosides are well known and even commercially available. However, their preparation has been found cumbersome by us, as well as by others (3, 4), leading to much poorer yields than those reported (5, 6).



SCHEME 1

In 1953 Lemieux and Shyluk (7) pointed out that the reaction between phenol and penta-*O*-acetyl-β-D-glucopyranose in benzene solution for short periods at reflux temperature, in the presence of anhydrous stannic chloride as a catalyst, gave phenyl β-D-glucopyranoside. This work was reinvestigated ten years ago by Ingle and Bose (8) and more recently this method was used for the synthesis of alkyl β-D-glycosides (9) and their α-anomers through *in situ* anomerization of the former compounds.

Since 1,2-*cis* aryl glycosides with electron withdrawing groups on the aglycon have not yet been prepared extensively by the application of the above method, we have investigated the possible synthesis of *p*- and *o*-nitrophenyl α-D-galactopyranosides and maltosides, starting from their corresponding β-acetates and using stannic chloride as a catalyst.

[a]Abbreviations: d doublet, dd doublet of doublets, t triplet, m multiplet, l large (splitting < 1.5 Hz).

The reaction of 1,2-*trans* per-*O*-acetylated sugars in dichloromethane was monitored by tlc and the crude product, after work-up, was examined by ^{13}C nmr. Several experimental conditions (temperature, variable ratio of stannic chloride – sugar, delayed addition of the phenol) were tried. Glycoside formation was invariably complete within 6 h at 60°C when 2 mol/equiv. of stannic tetrachloride were added to a dichloromethane solution of 1,2,3,4,6-penta-*O*-acetyl-β-D-galactopyranose (**1**) containing 1.5 mol/equiv. of *p*-nitrophenol.

A substantial part (30–40%) of the more abundant α-anomer **2** was easily isolated by crystallization and the two anomeric acetylated glycosides remaining in the mother liquor were separated by column chromatography.

In contrast with the results obtained in the synthesis of alkyl α-D-glycosides (9), it appears that the *p*-nitrophenyl α-D-galactoside **2** formed did not result from anomerization. Indeed, when pure β-anomer **3** was treated with stannic chloride under dichloromethane in the above conditions, tlc or ^{13}C nmr spectroscopy showed no α-galactoside formation, in good agreement with the known fact that phenyl β-D-glycosides are not easily subject to anomerization (3, 10). This would suggest that pathways alternative to those proposed by Banoub and Bundle (9) are possible.

From the preceding result, it could be expected that *o*-nitrophenyl α-D-galactoside **4** would be formed from the condensation of penta-*O*-acetyl-β-D-galactopyranose **1** with *o*-nitrophenol using the

same technique. Unexpectedly, under similar conditions no glycoside formation was detected and the major product isolated from the reaction was penta-*O*-acetyl-α-D-galactopyranose **5**. Lemieux and Brice (11) have shown that the treatment of **1** with stannic chloride in chloroform led to its α-anomer **5** in the absence of an alcohol. Thus, under the conditions used, one can postulate that an interaction occurred between stannic chloride and the vicinal nitro and hydroxyl groups on the benzene ring which hindered the ability of the hydroxyl function to participate in the formation of a glycosidic linkage.

This above disappointing experiment led us to investigate, for these syntheses, the application of a method earlier developed in the *manno* and *gluco* series (1*a*, *b*). The technique involves a strong dipolar aprotic solvent, hexamethylphosphoramide (HMPA) and the *in situ* activation of the nucleophile as its sodium salt. An inversion occurs at C-1 of the per-*O*-acetyl halides notwithstanding the presence of vicinal *O*-acyl participating groups.

Addition of tetra-*O*-acetyl-β-D-galactopyranosyl chloride (12) **6** to a solution of the sodium salt of *p*- or *o*-nitrophenol in HMPA gave, by direct crystallization after work-up, the expected products in 40 and 51% yield respectively. The advantage of this method was further demonstrated by the specific

syntheses of *p*- and *o*-nitrophenyl maltoside derivatives **7** and **8**; these two compounds were obtained with 45 and 37% yield respectively from **9** by direct crystallization via the hepta-*O*-acetyl-β-maltosyl chloride **10**. It is worthwhile to note that, in our hands, application of the stannic chloride procedure did not give pure **7** without chromatographic purification, the β-anomer **11** being always present as a side product.

In the same way, addition of glycosyl halides **6** or **10** to a solution of the sodium salt of *p*-nitrothiophenol gave after chromatography the 1,2-*cis*-thioglycosides **12** and **13** in 73 and 60% yields respectively. These compounds, potential inhibitors of glycosidases, are usually obtained in low yield together with their 1,2-*trans* anomers by reaction of an aldose with a thiol under strongly acidic conditions, or by fusion of a fully acetylated sugar with thiols in the presence of a Lewis acid.[4]

The de-*O*-acetylated compounds **14–19** were obtained by careful addition of sodium methoxide. In the presence of an excess of this reagent a mixture of *O*-phenyl isomers was obtained which probably arose from migration of the *O*-phenyl group from the anomeric to the C-2 or C-3 position as demonstrated by Horton and Luetzow (14) using aqueous alkali.

The hydroxyl free *galacto* compounds **14–16** were converted to suitable derivatives for further condensation (see Scheme 1) by selective benzoylation with benzoyl chloride in pyridine at −20°C. A difference in selectivity was observed between the *O*- and *S*-compounds. Partial benzoylation of *p*-nitrophenyl 1-thio-α-D-galactoside **16** with 3.3 mol/equiv. of the acylating reagent afforded mainly the 2,3,6-tri-*O*-benzoyl derivative **20** (57% yield) together with several minor compounds such as the 3,4,6- and 2,4,6-tribenzoates **21** and **22** (3 and 2% yield respectively), the tetrabenzoate **23**, and the 3,6-di-*O*-benzoyl derivative **24** (15 and 2% yield respectively). However, with the *p*- and *o*-nitrophenyl compounds **14** and **15**, the 2,3,6-tri-*O*-benzoates **25** and **26** were the only partially substituted products isolated (70 and 79% yield respectively), together with about 5–10% yield of the perbenzoylated products **27** and **28**.

[4]For a review see refs. 1 and 13.

9 R = X = OAc
10 R = OAc; X = Cl
11 R = OAc; X = $OC_6H_4NO_2p$

This decreasing of the selectivity from the *O*-glycosyl to *S*-glycosyl series may be due either to a lack of hydrogen bonding between acyl pyridinium ions and the aglycon (15) or to a steric hindrance of the bulky sulfur atom which may lead to a distorted chair conformation. In this last eventuality, it is well known that a preferential acylation may be related to the orientation of vicinal groups, since high yields of substitution at the equatorial hydroxyl vicinal to the axial hydroxyl are usually obtained (16, 17).

All the compounds showed the expected proton magnetic resonance spectra (Tables 1 and 2), but for the aryl 1-thio-α-D-glycosides the anomeric coupling constants had a value of 5.5–6 Hz versus 4 Hz found for their *O*-analogs, and H-1 was deshielded by about 0.3 ppm. The ^{13}C nmr parameters are recorded in Table 3.

Conclusion

The results presented in this paper show that *p*-nitrophenyl α-D-galactopyranosides and maltosides can be obtained by both stannic chloride or HMPA methods. However, stannic chloride can-

[c]From the hydroxyl free glycoside.

not be applied for the syntheses of *o*-nitrophenyl derivatives nor 1-thio-α-D-glycosides. The simplicity of the HMPA procedure, together with its versatility, suggest that this method may have considerable potential for this type of synthesis, and constitutes a useful alternative to other methods.

Experimental

Solutions were dried (sodium sulfate) and evaporated *in vacuo* at temperatures below 45°C. Thin layer chromatography (tlc) was performed on silica gel (Merck F 254, Merck, Darmstadt, Germany). Preparative chromatography used silica gel (Merck 60, 70–230 mesh). Optical rotations were determined with a Quick polarimeter (Roussel et Jouan) at room temperature. The ^{1}H nmr spectra were recorded at 250 MHz with a Cameca spectrometer. Assignments were confirmed by double irradiation or the INDOR technique. The ^{13}C nmr spectra at 25.18 MHz were recorded with a Bruker WP 100 instrument. The chemical shifts are reported in δ (ppm) relative to internal TMS and the coupling constants (in brackets) in Hz.

General Procedure for the Preparation of Nitrophenyl Glycosides 2, 4, 7, 8, 12, and 13 in HMPA

Chlorides **6** or **10** prepared from their per-*O*-acetylated precursors (10 g) by using dichloromethyl methyl ether and boron trifluoride as described (12), were added to a solution of HMPA (40 mL for **6** or 25 mL for **10**) containing the sodium salt of nitrophenol (1.6 mol/equiv.) or nitrothiophenol (2.0 mol/equiv.) prepared from the phenol or thiophenol and sodium hydride (1*b*). The mixture was stirred at 40°C for 6 h, then overnight at room temperature. An ice-water mixture (150 mL) was added and the precipitate filtered on a Celite bed, washed with water, then dissolved in dichloromethane (150 mL). The organic layer was poured into water (100 mL), which was then extracted with dichloromethane (2 × 150 mL), and each portion washed with water (2 × 100 mL). After solvent removal, crystallization from ethanol or purification by column chromatography for the thioderivatives **12** and **13**, yielded the pure glycosides **2**, **4**, **7**, **8**, **12**, and **13**. The yields, physical constants, and migration solvents for these compounds are reported in Table 4.

p-*Nitrophenyl 2,3,4,6-Tetra-*O*-acetyl-α-D-galactopyranoside (2) (by the Stannic Chloride Method)*

Stannic tetrachloride (6 mL, 55 mmol) was added to a solution of penta-*O*-acetyl-β-D-galactose **1** (10 g, 25 mmol) and *p*-nitrophenol (5.2 g, 37 mmol) in dichloromethane (50 mL). After 5 h at 60°C, dichloromethane (50 mL) was added and the reaction mixture was poured into an ice-cold saturated bicarbonate solution, then neutralized with solid sodium bicarbonate, filtered on Celite bed, and extracted with chloroform (2 × 100 mL). The organic phase was washed again with ice-cold saturated bicarbonate solution and water (100 mL). Crystallization of the crude product afforded pure **2** (3.9 g, 33%, Table 4). Column chromatography of the mother liquor provided an additional 1.2 g of **2** and its β-anomer **3** (0.35 g, 3%), identical with an authentic sample (18) by ^{1}H and ^{13}C nmr spectra and its melting point 141–143°C, lit. (18) mp 145–146°C.

*De-*O*-acetylation of Nitrophenyl Glycosides 2, 4, 7, 8, 12, and 13*

In a typical experiment the acetylated glycoside (**8**, 1 mmol) was suspended in methanol (150 mL), 0.4 mL of 1 *M* sodium methoxide was added, and the reaction mixture stirred overnight. The clear solution was neutralized with Amberlite IR 120 (H^+), filtered, concentrated to dryness, and freeze-dried. The solid foam obtained in quantitative yield can be recrystallized from ethanol or used without crystallization. Confirmation of the expected structure was obtained by ^{13}C nmr spectroscopy (Table 3). Physical constants and analytical data are recorded in Table 4.

Selective O*-Benzoylation of Glycosides 14–16*

Compounds **14**, **15**, or **16** (9 mmol) were dissolved in anhydrous pyridine (45 mL), cooled to −20°C, and then benzoyl chloride (3.78 mL, 30.4 mmol) in pyridine (4 mL) was added slowly. After 18 h, methanol (20 mL) was poured into the flask and the solution was evaporated to dryness. The reaction mixture of compounds **14** or **15** was dissolved in dichloromethane (100 mL) and washed with water (2 × 100 mL). The aqueous layer was back-extracted with dichloromethane (2 × 100 mL). The crude product showed only two spots on tlc corresponding to perbenzoylated glycosides and the expected compounds **25** and **26**, which were obtained pure after chromatography (Table 4). The solid obtained from **16**, insoluble in dichloromethane, was dissolved in methanol (100 mL); silica gel (10 g) was added and the suspension evaporated to dryness, the powder was applied to the top of a wet chromatography column (100 g), and eluted. The first fraction was characterized as *p*-nitrophenyl 2,3,4,6-tetra-*O*-benzoyl-1-thio-α-D-galactopyranoside (**23**), then the 3,4,6-tri-*O*-benzoyl derivative **21**, followed by its 2,4,6-tri-*O*-benzoyl isomer **22**, appeared. The main fraction to be eluted from the column was pure *p*-nitrophenyl 2,3,6-tri-*O*-benzoyl-1-thio-α-D-galactopyranoside (**20**).

Received July 2, 1980

This paper is dedicated to Prof. Raymond U. Lémieux on the occasion of his 60th birthday

GERRY KAVADIAS and STEPHAN VELKOF. Can. J. Chem. **59**, 321 (1981).

The syntheses of 9-oxobenzomorphans **10** and **12** are described. Both products exist in the cyclic forms **11** and **13** respectively. Hydrobromide and oxalate salts of the 9-oxobenzomorphan **1** when crystallized from methanol form stable methylhemiketals **4** and **5**. Bromination of **5** yielded benzomorphan **8** which on treatment with sodium hydroxide produced, via **10**, the cyclic hemiketal **11**. Reaction of **8** with sodium hydrogen sulfide afforded, via **12**, the cyclic hemithioketals **13**.

GERRY KAVADIAS et STEPHAN VELKOF. Can. J. Chem. **59**, 321 (1981).

On décrit les synthèses des oxo-9 benzomorphanes **10** et **12**. Les deux produits existent respectivement sous les formes cycliques **11** et **13**. Si l'on recristallise le bromhydrate et l'oxalate de l'oxo-9 benzomorphane **1** dans le méthanol, il y a formation des méthylhémicétals stables **4** et **5**. La bromation de **5** donne le benzomorphane **8** qui réagit avec l'hydroxyde de sodium pour conduire à l'hémicétal cyclique **11** par l'intermédiaire du composé **10**. Le composé **8** réagit avec le sulfure acide de sodium et conduit, par l'intermédiaire du dérivé **12**, aux hémithioacétals cycliques **13**.

[Traduit par le journal]

In our search for new structures as medicinally useful analgesics, the benzomorphans of the general structure I (Fig. 1, X = O, S) appeared as promising candidates. Interest in these classes of compounds has been generated from the anticipation that these products would exist predominantly or entirely in the cyclic hemiketalic form II, thus resembling known structures which have important analgesic activity. It was recently reported that several 14-hydroxymorphinans (III) (1) and 8-oxomorphinans (IV) (2) possess valuable pharmacological activities as analgesics and narcotic antagonists. Compounds of formula II combine in a single structure both the structural elements which appear to be associated with the biological properties of III and IV, i.e. the hydroxy group and the heteroatom at the 14- and 8-positions, respectively.

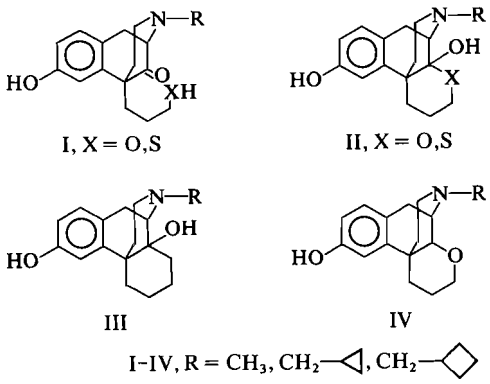

FIG. 1.

The present paper describes the preparation of the cyclic hemiketal **11** and the cyclic hemithioketals **13***a* and **13***c* (Scheme 3). We have previously presented the syntheses of 9-oxobenzomorphans **1***a*, *b* (3–5) and these compounds served as starting materials in the present syntheses.

The first goal was to prepare the bromides **8***a–c*, the key intermediates of our synthetic scheme. Initially, an attempt was made to synthesize **8***a*,*b* by bromination of 5-allyl-9-oxobenzomorphans **1***a*,*b* but this approach was unsuccessful. Thus, reaction of **1***a* with bromine in methanol solution and in the presence of silver acetate (6) failed to produce the desired **8***a* but instead yielded a product mixture (4 components) from which the tetrahydrofurano compound **3** was isolated (Scheme 1).

The preparation of **8***a*,*b* was accomplished by bromination of **5***a*,*b* (Scheme 2) as will be discussed later. It is appropriate at this point to describe briefly the syntheses and properties of the methyl hemiketals **4***a*,*b* and **5***a*,*b*. When the oxalate or hydrobromide salts of **1***a*,*b* were dissolved in methanol and the solution permitted to stand for sufficient time (6–10 h) before crystallization was induced, the respective hemiketals **4***a*,*b* and **5***a*,*b* were formed in good yields. Two isomers were predicted for each individual hemiketal salt and apparently both were formed. Separation of the isomers was readily accomplished by fractional crystallization. Interestingly, the hemiketal salts **4***a*

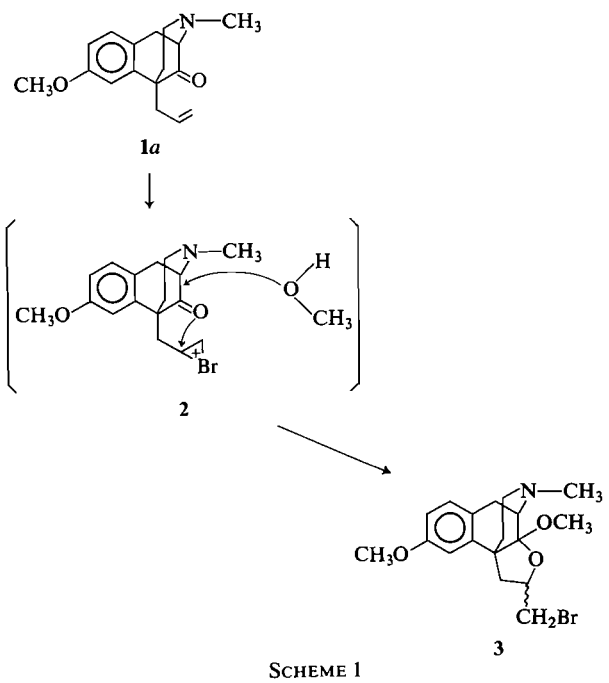

SCHEME 1

and **5***a* when treated with base did not generate the precursor ketone **1***a* as might have been expected but instead provided the methyl hemiketal free base **6** as a stable crystalline product (mp 107–111°C). Compound **6** was stable both in the crystalline form and in solution and could be recrystallized from ethanol without appreciable decomposition. Regeneration of the precursor ketone **1***a* could be effected by treatment of **6** with aluminum oxide or by refluxing of **6** in methanol solution. Structural assignment to **6** as the methyl hemiketal was based on elemental analysis, ir and ^{1}Hmr spectroscopy, and by the fact that it could be converted to **1***a* as mentioned above. The ir spectrum of **6** showed strong absorption at 3380 cm^{-1} (OH) and lacked the carbonyl absorption band (~1700 cm^{-1}) and the ^{1}Hmr spectrum was in accord with the proposed structure (see Experimental). Base treatment of the methyl hemiketal hydrobromide **5***b* generated the ketone **1***b*, not the hemiketal free base as might have been anticipated from the above discussion.

Bromination of the methyl hemiketal **6** or its hydrobromide salt **5***a* in chloroform at 0°C produced in quantitative yield **8***a* hydrobromide as a mixture of two stereoisomers. One isomer was predominant in the mixture and was isolated in 70% yield by crystallization. The structure of **8***a* was established by analytical and spectroscopic data (see Experimental) and further confirmed by chemical transformation to the ketone **9**. Treatment of **8***a* with sodium hydride in DMF followed by acid hydrolysis yielded the ketone **9**, thus establishing the relative positions of bromine and methoxy group on the side chain of the molecule.

Bromination of the hemiketal hydrobromide **5***b* in chloroform yielded **8***b* hydrobromide (100%) as a mixture of two stereoisomers (isomerism at C—OCH_3) in a ratio of approximately 1:1, separated by fractional crystallization. The configuration of the carbon attached to the methoxy group in **8***b* was not

12,13 *a* R = CH_3
b R = $CH_2C_6H_5$
c R = H

SCHEME 3

established and for classification purposes the two isomers were designated as A- and B-isomers.

The mechanism of the reaction of the methyl-hemiketals **5***a,b* and **6** with bromine can be envisioned as occurring with initial formation of the bromonium ion **7***a,b* followed by migration of the methoxy group to form **8***a–c*.

Treatment of each isomer of **8***b* with trifluoroacetic acid (7) removed the benzyl group and afforded the respective isomers of **8***c*.

Treatment of **8***a* with sodium hydroxide in aqueous ethanol at room temperature produced, via **10**, the cyclic hemiketal **11** in 53% yield (Scheme 3). The ir spectrum of **11** lacked carbonyl absorption in the area of 1700 cm^{-1} thus indicating that the compound existed entirely in the cyclic form.

Reaction of **8***a* with sodium hydrogen sulfide in aqueous ethanol at reflux temperature gave, via **12***a*, the cyclic product **13***a* in 75% yield. In a similar manner, each isomer of **8***c* upon treatment with sodium hydrogen sulfide produced respective isomers of **13***c* in 75–80% yield. Lack of carbonyl absorption on the ir spectra of **13***a,c* was taken as evidence for the cyclic nature of these products.

Compound **11** did not exhibit significant analgesic activity whereas compounds **13***a,c* were moderately active (see Table 1).

Experimental

The melting points were determined on a Mel-Temp melting point apparatus and are not corrected. The ir spectra were recorded on a Unicam SP-200G grating ir spectrometer. The

[a]Subcutaneous administration.

^{1}Hmr spectra were taken with a Varian A-60A spectrometer. Tetramethylsilane (for solutions other than deuterium oxide) and sodium 4,4-dimethyl-4-silapentane-1-sulfonate (for solutions of deuterium oxide) were used as internal standards. Thin-layer chromatography (tlc) was carried out on microscope slides coated with silica gel G (E. Merck, A. G., Darmstadt) and the spots were visualized with sulfuric acid. The analysis were performed by Micro-Tech Laboratories, Skokie, IL.

*Tetrahydrofuranobenzomorphan 3. Bromination of 5-Allyl-9-oxo-6,7-benzomorphan 1*a

A solution of bromine (4.9 g, 30.5 mmol) in methylene chloride (10 mL) was added dropwise during 15 min to a stirred mixture of **1***a* (3–5) (7.32 g, 27 mmol) and silver acetate (5.09 g, 30.5 mmol) in methanol (100 mL) at 0°C. After stirring for 1 h at 0°C, the reaction mixture was filtered. The filtrate was evaporated and the residue was partitioned between a saturated solution of sodium bicarbonate (100 mL) and ether (100 mL). The ether solution, after drying, was evaporated to give 8.0 g of a syrup which on tlc (silica, 5% ethanol in ether) showed four spots. This product was dissolved in ethanol (20 mL), treated with a hot solution of picric acid (7.2 g) in ethanol (120 mL), and the precipitate was collected to give 5.0 g of the picrate salt of **3**, mp 170–179°C. The mp of this salt was unchanged after two more recrystallizations from ethanol. Treatment of the picrate salt of **3** with sodium bicarbonate and extraction with ether afforded the free base (**3**) as a syrup; ir ($CHCl_3$): 1610, 1505 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 2.41 (s, 3H, NCH_3), 3.20 (s, 3H, OCH_3), 3.73 (s, 3H, Ar—OCH_3), 3.66–3.86 (m, 2H, CH_2Br), 4.20–4.80 (m, 1H, O—C—H), 6.5–7.0 (m, 3H, ArH).

The oxalate salt of **3** had mp 164–169°C (ethanol–ether, 1:1). *Anal.* calcd. for $C_{18}H_{24}BrNO_3 \cdot C_2H_2O_4$: C 50.85, H 5.54, Br 16.91; found: C 50.48, H 5.51, Br 17.21.

5-Allyl-2′,9-dimethoxy-9-hydroxy-2-methyl-6,7-benzomorphan Oxalate (4a)

A mixture of 19.8 g of 5-allyl-2′-methoxy-2-methyl-9-oxo-6,7-benzomorphan (**1***a*) oxalate (anhydrous salt) and 250 mL of dry methanol was heated under reflux until all the solids had dissolved and then the solution was allowed to cool gradually to room temperature. Crystallization usually commenced after 4–5 h; if solids were formed prior to this time, they were redissolved by heating the mixture. After standing at room temperature for 18 h, the crystalline precipitate was collected by filtration to give 11.0 g of methyl hemiketal oxalate **4***a*, mp 158–160°C. Concentration of the filtrate under reduced pressure and trituration of the residue with methanol (50 mL) afforded another 1.6 g of **4***a*, mp 156–160°C. The two crops were combined to a total of 12.6 g (59%). *Anal.* calcd. for $C_{20}H_{27}NO_7$: C 61.06, H 6.91, N 3.55; found: C 60.95, H 6.90, N 3.52.

*5-Allyl-2′,9-dimethoxy-9-hydroxy-2-methyl-6,7-benzomorphan Hydrobromide (5*a)

A solution of 10.5 g of 5-allyl-2′-methoxy-2-methyl-9-oxo-6,7-benzomorphan (**1***a*) in dry ether (50 mL) was mixed with a solution of hydrogen bromide in ether and the precipitated **1***a* hydrobromide collected by filtration. A mixture of this salt and

dry methanol (50 mL) was heated under reflux until all the solids had dissolved and then the solution was left to stand at room temperature. Samples of the reaction mixture were taken at intervals, diluted with chloroform, and examined by ir; the carbonyl band of **1***a* hydrobromide slowly decreased and completely disappeared after 6 h indicating that the formation of **5***a* was completed. At this point, the solution was diluted with anhydrous ether (50 mL) and the resulting solution was allowed to slowly crystallize at room temperature overnight. The crystalline precipitate was collected by filtration to provide 10.7 g (72%) of methyl hemiketal hydrobromide **5***a*, mp 165–167°C, resolidified and melted at 195–200°C (dec.); ir (Nujol): 3300, 2600, 1605, 1505 cm^{-1}. *Anal.* calcd. for $C_{18}H_{25}NO_3 \cdot HBr$: C 56.26, H 6.81, N 3.64; found: C 56.20, H 6.79, N 3.62.

When a solution of **1***a* hydrobromide in methanol, soon after it was prepared, was induced to crystallize by the addition of ether, unchanged starting material was recovered.

A solution of **1***a* hydrobromide in methanol allowed to stay at room temperature for 1 h and then evaporated gave a mixture of starting material and **5***a* (OH and CO bands on ir).

5-Allyl-2',9-dimethoxy-9-hydroxy-2-methyl-6,7-benzomorphan (6)

Into a separatory funnel were added 100 mL of water, 7 mL of concentrated ammonium hydroxide, 12.65 g of methyl hemiketal oxalate **4***a*, and 50 mL of methylene chloride and the mixture was shaken until the solids had dissolved. The organic layer was separated and the aqueous phase extracted with methylene chloride (50 mL). Evaporation of the combined extracts at 30°C and crystallization of the residue from ether (25 mL) gave 7.1 g of **6**, mp 107–111°C. Another 0.5 g of **6** was obtained by evaporation of the mother liquor and crystallization of the residue from ether (10 mL). The two crops were combined to give a total yield of 7.6 g (77.5%) of **6**; ir ($CHCl_3$): 3380, 1610, 1505 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 2.35 (s, 3H, NCH_3), 3.25 (s, 3H, OCH_3), 3.68 (s, 3H, Ar—OCH_3), 4.23 (s, 1H, OH), 4.83–5.25 (m, 2H, C=CH_2), 5.8–6.43 (m, 1H, CH=C), 6.5–7.0 (m, 3H, ArH). *Anal.* calcd. for $C_{18}H_{25}NO_3$: C 71.25, H 8.30, N 4.61; found: C 71.45, H 8.42, N 4.58.

A sample of **6** was dissolved in boiling ethanol and the solution allowed to crystallize. The crystalline product, mp 105–110°C was identical in all respects (ir, ^{1}Hmr) with **6**, thus indicating the stability of the compound in this solvent.

Compound **6** when dissolved in boiling methanol and the solution evaporated was converted quantitatively to the ketone **1***a*.

Treatment of a solution of **6** in chloroform with aluminum oxide gave the ketone **1***a* (100%).

5-Allyl-2'-benzyloxy-9-hydroxy-9-methoxy-2-methyl-6,7-benzomorphan Hydrobromide (5b)

To a solution of 6.0 g of 5-allyl-2'-benzyloxy-2-methyl-9-oxo-6,7-benzomorphan (**1***b*) (3–5) in dry ether was added an ethereal solution of hydrogen bromide and the precipitated **1***b* hydrobromide collected by filtration (7.4 g). A mixture of this salt and 40 mL of dry methanol was heated under reflux and, after the solids had dissolved, the solution was allowed to stay at room temperature. Crystallization usually commenced after 6–7 h; when solids were formed before this period of time, they were redissolved by heating the mixture. After standing at room temperature for 24 h, the crystalline precipitate that was formed was collected by filtration to give 4.4 g (55%) of methyl hemiketal hydrobromide **5***b*, mp 115–120°C; ir (Nujol): 3300, 2650, 1605, 1505 cm^{-1}. *Anal.* calcd. for $C_{24}H_{29}NO_3HBr$: C 62.64, H 6.56; found: C 62.45, H 6.53.

The mother liquor was evaporated and the residue was crystallized from methanol (5 mL) to give 2.6 g (32%) of the other isomer of **5***b*, mp 150–160°C; ir (Nujol): 3300, 2650, 1605, 1505 cm^{-1}. *Anal.* found: C 62.55, H 6.55.

Treatment of **5***b* (either isomer) with a base and extraction with ether produced the ketone **1***b*.

In another experiment, 6.0 g of **1***b* hydrobromide was dissolved with an excess of methanol (150 mL) and the solution was let stand 48 h at room temperature. Removal of the solvent under reduced pressure and trituration of the residue with ether gave 6.45 g (100%) of crystalline **5***b*, as a mixture of two isomers. This material was used in the bromination reaction.

2'-Methoxy-2-methyl-9-oxo-5-[3"-(1"-bromo-2"-methoxypropyl)]6,7-benzomorphan (8a)

A. Bromination of the Methyl Hemiketal 6

To a stirred solution of 2.24 g (14 mmol) of bromine in 150 mL chloroform at 0°C was quickly added a solution of 4.23 g (14 mmol) of **6** in 70 mL chloroform and the reaction mixture stirred at 0°C for 15 min. Removal of the solvent *in vacuo* gave 6.5 g (100%) of **8***a* hydrobromide as a mixture of two isomers. A sample of this salt was converted to the free base and examined by tlc on alumina plates using 1% methanol in chloroform as eluent; it showed two spots of R_f 0.28 (major) and 0.49 (minor) for the two isomers of **8***a*. Recrystallization of the crude salt from dry acetone afforded 4.5 g (70%) of **8***a* hydrobromide as a single isomer, mp 132–134°C; ir (Nujol): 2500, 1740, 1610, 1505 cm^{-1}. *Anal.* calcd. for $C_{18}H_{24}BrNO_3 \cdot HBr$: C 46.67, H 5.44, Br 34.50; found: C 46.40, H 5.36, Br 34.32.

The free base **8***a* was regenerated from its hydrobromide salt by treatment with ammonium hydroxide followed by extraction with chloroform. Compound **8***a* thus obtained showed a single spot on tlc of R_f 0.28; ir ($CHCl_3$): 1725, 1610, 1505 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 2.43 (s, 3H, CH_3), 3.25 (s, 3H, OCH_3), 3.76 (s, 3H, Ar—OCH_3), 6.6–7.1 (m, 3H, ArH).

B. Bromination of Methyl Hemiketal Hydrobromide 5a

To a stirred solution of bromine (3.87 g, 24.2 mmol) in chloroform (240 mL) at 0°C was quickly added a solution of **5***a* (9.3 g, 24.2 mmol) in methanol–chloroform mixture (60 mL, 1:3) and the reaction mixture stirred at 0°C for 15 min. Removal of the solvent by evaporation left a residue which was basified with 1 *N* sodium hydroxide and extracted with ether. The ether extract, after drying ($MgSO_4$), was treated with a solution of hydrogen bromide in dry ether and the mixture evaporated to dryness. The residual oil crystallized from acetone to give 7.3 g (65%) of **8***a* hydrobromide, mp 132–134°C, identical in all respects (mixture mp, ir, ^{1}Hmr) with that from the previous preparation.

2'-Benzyloxy-2-methyl-9-oxo-5-[3"-(1"-bromo-2"-methoxypropyl)]-6,7-benzomorphan (8b) (A- and B-Isomers)

A solution of the hemiketal hydrobromide **5***b* (5.08 g, 11 mmol) in chloroform (120 mL) was added in one lot to a stirred solution of bromine (1.76 g, 11 mmol) in chloroform (140 mL) at 0°C. After stirring for 15 min, the reaction mixture was evaporated under reduced pressure to give 5.9 g (100%) of **8***b* hydrobromide (mixture of two isomers) as a syrup. The syrupy product was dissolved in dry acetone (20 mL), the solution diluted with dry ether (10 mL), and the resulting solution allowed to crystallize at room temperature. The crystalline precipitate was collected by filtration to give 2.7 g, mp 100–110°C. This product was suspended in dry acetone (20 mL), the mixture was heated under reflux with stirring, and then cooled to room temperature. The solids were collected by filtration to give 1.8 g of one isomer of **8***b* hydrobromide (A-isomer), mp 132–135°C. *Anal.* calcd. for $C_{24}H_{28}BrNO_3 \cdot HBr$: C 53.45, H 5.42, Br 29.63; found: C 52.98, H 5.28, Br 30.12.

The free base **8***b* (A-isomer) was quantitatively regenerated from the above salt by treatment with sodium bicarbonate and extraction with chloroform. Thin-layer chromatography (Al_2O_3, 1% MeOH–$CHCl_3$) showed one major spot of R_f 0.40 and a trace of a spot of R_f 0.61 (the other isomer); ir (neat): 1725, 1605,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/05/12
For personal use only.

1500 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 2.33 (s, 3H, NCH_3), 3.13 (s, 3H, OCH_3), 3.55 (m, 2H, CH_2Br), 5.0 (s, 2H, CH_2Ar), 6.7–7.4 (m, 8H, ArH).

The mother liquor and the acetone extract were combined and evaporated. The residue crystallized from an acetone–ether mixture (40 mL, 1:1) to give 1.9 g, mp 148–158°C. This product contained mainly (~85%) the hydrobromide salt of the other isomer **8***b* (B-isomer). *Anal.* calcd. for $C_{24}H_{28}BrNO_3 \cdot HBr$: C 53.45, H 5.42, Br 29.63; found: C 52.81, H 5.42, Br 30.08.

The above salt was converted to the free base **8***b* (B-isomer) by treatment with sodium bicarbonate and extraction with chloroform. The free base **8***b* thus obtained showed on tlc (Al_2O_3, 1% MeOH–$CHCl_3$) one major spot of R_f 0.61 (B-isomer) and a minor of R_f 0.40 (A-isomer); ir (neat): 1725, 1605, 1500 cm^{-1}, ^{1}Hmr ($CDCl_3$) δ: 2.43 (s, 3H, NCH_3), 3.03 (s, 3H, OCH_3), 3.81 (m, 2H, CH_2Br), 5.0 (s, 2H, CH_2Ar), 6.7–7.4 (m, 8H, ArH).

*2'-Hydroxy-2-methyl-9-oxo-5-[3"-(1"-bromo-2"-methoxypropyl)]-6,7-benzomorphan (**8***c*) *(A- and B-Isomers)*

A-Isomer

To 1.2 g (2.6 mmol) of compound **8***b* (A-isomer) was added 19 mL of trifluoroacetic acid (7) at 25°C. The solution was let stand at 25°C for 72 h and then evaporated. The residue was chromatographed on alumina (130 g, Activity II) with 2% methanol in methylene chloride as eluent to yield 0.7 g (72.5%) of **8***c* (A-isomer), mp 166–168°C (dec.); ir ($CHCl_3$): 3300, 1730, 1605, 1505 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 2.38 (s, 3H, NCH_3), 3.21 (s, 3H, OCH_3), 6.6–7.2 (m, 3H, ArH). *Anal.* calcd. for $C_{17}H_{22}NBrO_3$: C 55.44, H 6.02, Br 21.69; found: C 55.38, H 6.05, Br 21.62.

B-Isomer

In a manner analogous to that given above for the preparation of the A-isomer, 1.06 g of **8***b* (B-isomer) was treated with trifluoroacetic acid (7) and the product purified by chromatography on alumina to give 0.72 g (85%) of the B-isomer of **8***c*; ir ($CHCl_3$): 3300, 1730, 1605, 1505 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 2.44 (s, 3H, NCH_3), 3.05 (s, 3H, OCH_3), 6.6–7.2 (m, 3H, ArH). *Anal.* found: C 55.28, H 5.98, Br 21.65.

*2'-Methoxy-2-methyl-9-oxo-5-[3"-(2"-oxopropyl)]-6,7-benzomorphan (**9**)*

To a suspension of 0.85 g of sodium hydride (from a 55% mineral oil dispersion washed three times with benzene) in 20 mL of dry DMF was added a solution of 10.2 g (26.4 mmol) of **8***a* in 15 mL of DMF and the mixture was stirred at 70°C for 6 h and at room temperature for 18 h. The reaction mixture was diluted with water (100 mL) and extracted with ether (3 × 100 mL). The combined extracts, after being washed with water and dried, were evaporated to dryness. The residue (5.8 g) was dissolved in 1 *N* aqueous hydrochloric acid (40 mL) and the solution was allowed to stand at room temperature for 1 h. The reaction mixture was then neutralized with 10% sodium bicarbonate solution and extracted with ether. The ether extract, after drying, was evaporated and the residue chromatographed on silica with 3% methanol in chloroform as eluent, to give 3.0 g (40%) of **9**; ir ($CHCl_3$): 1730, 1610, 1510 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 2.18 (s, 3H, C(=O)—CH_3), 2.45 (s, 3H, NCH_3), 3.05 (s, 2H, CH_2CO), 3.73 (s, 3H, OCH_3), 6.5–7.2 (m, 3H, ArH). *Anal.* calcd. for $C_{17}H_{21}NO_3$: C 71.05, H 7.36, N 4.87; found: C 70.82, H 7.48, N 4.81.

*3,6-Dimethoxy-14-hydroxy-17-methyl-8-oxomorphinan (**11**)*

A solution of **8***a* (3.0 g, 6.5 mmol) and sodium hydroxide (0.64 g, 16 mmol) in 65% ethanol–water mixture (12 mL) was stirred at room temperature for 48 h. The reaction mixture was concentrated under reduced pressure and the residue partitioned between water and chloroform. The chloroform and the organic extracts were combined, dried, and evaporated. The residue was chromatographed on 80 g of alumina (activity II) with 2% methanol in methylene chloride to give 1.1 g (53%) of **11**, mp 141–142°C; ir ($CHCl_3$): 3300, 1610, 1505 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 2.38 (s, 3H, NCH_3), 3.43 (s, 3H, OCH_3), 3.78 (s, 3H, $ArOCH_3$), 6.6–7.2 (m, 3H, ArH). *Anal.* calcd. for $C_{18}H_{25}NO_4$: C 67.68, H 7.88, N 4.38; found: C 67.58, H 7.92, N 4.35.

*3,6-Dimethoxy-14-hydroxy-17-methyl-8-thiomorphinan (**13**a)*

Hydrogen sulfide was bubbled for 15 min into a solution of potassium hydroxide (0.7 g, 12.5 milliequiv.) in 90% ethanol (15 mL). To the resulting solution of potassium hydrosulfide was added a solution of **8***a* (1.15 g, 3 mmol) in 90% ethanol (5 mL) and the reaction mixture was heated under reflux for 1.5 h while hydrogen sulfide was bubbled into the solution. The reaction mixture, after cooling to room temperature, was diluted with water (50 mL) and extracted twice with 50 mL portions of chloroform. The combined chloroform extracts were washed with water (60 mL), dried over sodium sulfate, and filtered. Evaporation of the filtrate gave 1.0 g of crystalline product which showed on tlc (alumina, 2% MeOH–CH_2Cl_2) a single spot of R_f 0.59. Recrystallization from ethanol afforded 0.75 g (75%) of **13***a*, mp 176–177°C; ir ($CHCl_3$): 3600, 3400, 1610, 1505 cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 2.32 (s, 3H, NCH_3), 3.40 (s, 3H, OCH_3), 3.70 (s, 3H, $ArOCH_3$), 4.90 (s, 1H, OH), 6.4–7.0 (m, 3H, ArH). *Anal.* calcd. for $C_{18}H_{25}NO_3S$: C 64.44, H 7.51, S 9.56; found: C 64.54, H 7.58, S 9.39.

*3,14-Dihydroxy-6-methoxy-17-methyl-8-thiomorphinal (**13**c)*

A-Isomer

A mixture of 0.5 g (1.35 mmol) of **8***c* (A-isomer) and 0.47 g (6.5 mmol) of potassium hydrosulfide in 14 mL of 90% ethanol was heated under reflux for 3 h while hydrogen sulfide was bubbled into the solution. The reaction mixture was evaporated to dryness and the residue partitioned between chloroform (80 mL) and water (10 mL). The organic phase was separated and the aqueous phase extracted with chloroform (2 × 15 mL). The combined chloroform extracts, after drying, were evaporated and the residue was chromatographed over silica gel (50 g) with 3% methanol in chloroform as eluting solvent to give 0.35 g (80%) of **13***c* (A-isomer), mp 227–229°C. Thin layer chromatography (silica, 5% MeOH–ether) showed a single spot of R_f 0.38; ir (Nujol): 3300, 1605, 1505 cm^{-1}. *Anal.* calcd. for $C_{17}H_{23}NO_3S$: C 63.52, H 7.21, S 9.97; found: C 63.48, H 7.09, S 9.88.

B-Isomer

Using the procedure described above for the preparation of the A-isomer, 0.7 g (1.9 mmol) of **8***c* (B-isomer) were reacted with potassium hydrosulfide (9 mmol) in 90% ethanol (20 mL) to provide 0.48 g (78%) of the B-isomer of **13***c*, mp 245–246°C (ethanol); ir (Nujol): 3300, 1605, 1505 cm^{-1}. *Anal.* calcd. for $C_{17}H_{23}NO_3S$: C 63.52, H 7.21, N 4.35, S 9.97; found: C 63.29, H 7.73, N 4.40, S 7.92.

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

J. STUART GROSSERT, DONALD L. HOOPER, and WILLIAM M. NEAVES. Can. J. Chem. **59**, 326 (1981).

2,4,6-Trithiaheptane (**1***a*) has been prepared by lithium tetrahydridoaluminate reduction of the methiodide of 1,3,5-trithiane (**2**). Treatment of **1***a* with strong bases permitted formation of 3-alkylated derivatives (**3**) which could in turn be converted into diastereomeric mixtures of 3,5-dialkyl derivatives (**4**). A two-step alkylation of **1***a* with 1-bromo-3-chloropropane led to the formation of 2,6-bis(methylthio)thiane (**5**). Proton and ^{13}C nmr spectral studies on these compounds, including the measurement of long-range carbon–proton coupling constants, are described; their mass spectra showed elimination of methanethiol as a characteristic major fragmentation pathway.

J. STUART GROSSERT, DONALD L. HOOPER et WILLIAM M. NEAVES. Can. J. Chem. **59**, 326 (1981).

On a préparé le trithia-2,4,6 heptane (**1***a*) en réduisant le méthyliodure du trithianne-1,3,5 (**2**) par le tétrahydroaluminate de lithium. La réaction du composé **1***a* avec des bases fortes conduit à la formation de dérivés alkylés (**3**) qui peuvent être ensuite transformés en des mélanges diastéréoisomères de dérivés (**4**) dialkylés en 3 et 5. Une alkylation en deux étapes de **1***a* par le bromo-1 chloro-3 propane conduit à la formation du bis(méthylthio)-2,6 thianne (**5**). On décrit les études spectrales de ces composés en rmn du ^1H et du ^{13}C, y compris les mesures des constantes de couplage à longue distance carbon–proton; leurs spectres de masse indiquent que l'élimination de méthanethiol est une caractéristique du processus principal de fragmentation.

Introduction

As part of a continuing interest in the preparation and properties of sulfur-containing organic molecules (1), we wished to explore the preparation and spectral properties of compounds derived from 2,4,6-trithiaheptane, **1***a* (2). In particular, we were interested in examining whether **1***a* would form a sulfur-stabilized carbanion which could be usefully alkylated, especially since it was known that alkylation of simple, acyclic mercaptals is not generally a synthetically useful reaction (3).

Preparative Results

Fehér and Vogelbruch first prepared 2,4,6-trithiaheptane, **1***a*, using a classical condensation of chloromethyl methyl sulfide with sodium sulfide (2). It seemed possible that **1***a* could be derived also by hydride reduction of an *S*-methyl sulfonium salt of *s*-trithiane, e.g. **2***a*. Such a reduction is precedented, although it does not appear to have been used widely (4). The preparation of **2***a* has been reported (5). We found it to be rather unstable both in solution and in the crystalline state, especially if it had not been carefully recrystallized; however, the pure solid was adequately stable if stored in a freezer. Attempts to record an ^1H nmr spectrum of **2***a* were frustrated by its insolubility in solvents such as chloroform and by its rapid decomposition in solvents such as DMSO-d_6. Spectra obtained showed peaks that could be attributed to **1***b*, **2***a*, *s*-trithiane, and iodomethane. However, **2***a* dissolved in trifluoroacetic acid and when treated with an equimolar amount of silver trifluoroacetate gave a

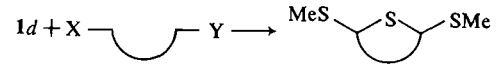
solution which had the expected ^{1}H nmr spectrum of **2***b*. As might be expected **2***a* decomposed over a wide temperature range when heated. Obviously, a less nucleophilic counterion than iodide was required if **2***a* was to be studied further. Nevertheless, reduction of **2***a* was successfully achieved in reasonable yield with lithium tetrahydridoaluminate in THF, to give **1***a* identical by glc, tlc, spectra, and odor with the material prepared by Fehér and Vogelbruch's method.

As a bis-thioacetal, **1***a* could be expected to form a monolithio derivative, **1***c*, (3) or perhaps even a dilithio derivative (**1***d*); this latter might have been susceptible to oxidation (6) or to dialkylation with ring formation (7), as below:



We have found that **1***c* could be generated readily under standard conditions (3) and that it reacted efficiently with standard electrophiles, such as iodomethane to give 3-methyl-2,4,6-trithiaheptane, **3***a*, or with 1-bromobutane to yield the *n*-butyl derivative, **3***b*. Quenching **1***c* with deuteroacetic acid gave **3***c*, but of more interest was the reaction of **1***c* with 1-bromo-3-chloropropane which gave **3***d*, a compound that had potential for ring closure by a two-step reaction. Possibility of direct ring formation via an ambident electrophile and **1***d* as outlined above was ruled out when we found that several reactions of **1***a* with two equivalents of *n*-butyllithium followed by quenching with different proton donors failed to regenerate **1***a*. It appears therefore that **1***d* is quite unstable.

Compounds **3***a–c* were foul-smelling oils which could be distilled and were subjected to spectral studies that are detailed presently. As might be expected, **3***d* was less stable and decomposed on standing or on attempted distillation.

Before attempting ring closure of **3***d*, we explored further alkylation of **3***a* and **3***b* by metallation with lithium diisopropylamide (LDA) and alkylation with iodomethane, which resulted in the rapid formation of 3,5-dialkylated 2,4,6-trithiaheptanes, **4***a* and **4***b*, as mixtures of two diastereomers. It is not apparent from the data we have obtained which is the predominant diastereomer although it can be argued[2] that the *erythro* diastereomer should be formed more readily than the *threo* (*dl* pair) isomer. We are investigating this point further. The nmr spectra and glc analyses showed no significant amounts of 3,3-dialkylation products.

Overnight reaction of **3***d* with LDA gave **5** as a thick foul-smelling oil, that was a ca. 5:1 diastereomeric mixture. Formation of this bis-substituted thiane was confirmed when it was oxidized by H_2O_2–HOAc to a tris-sulfone, **6**, that had a correct combustion analysis for $C_7H_{14}O_6S_2$ and an ir spectrum which indicated sulfone groups. The ^{1}H and ^{13}C nmr spectra of **6** were consistent with its structure and with it being a mixture of two components. The mass spectrum showed a molecular ion corresponding to the molecular weight of **6**, as well as peaks at $M^+ \cdot - 79$ and *m/z* 79, indicative of an $MeSO_2$— group.

Mass Spectra

The mass spectra of the trithiaheptanes (**1***a*, **3***a–d*, **4***a*, *b*) all showed loss of MeSH as a major initial fragmentation (cf. Table 1[3] and Scheme 1, **A** → **D**). This fragmentation was supported in all cases by a metastable ion and it has been observed previously in bis(alkylthio) alkanes (10, 11).[4] Ions **B** and **C** can be formed by standard fragmentations of thioethers (10); **G** and **H** are readily explicable as arising from **D** although it is conceivable that they could derive from **C** or **B** respectively. Thiane **5** also showed loss of CH_3SH as the initial fragmentation process (for spectrum, see Experimental), although in this case subsequent fragmentation appeared to occur chiefly by loss of MeS· since *m/z* 99 is the base peak of the spectrum. Presumably the ion at *m/z* 97 is the thiacyclohexatriene cation derived from *m/z* 99. There is some precedent for this type of fragmentation pattern from the mass spectra of methylthianes (10, 12).

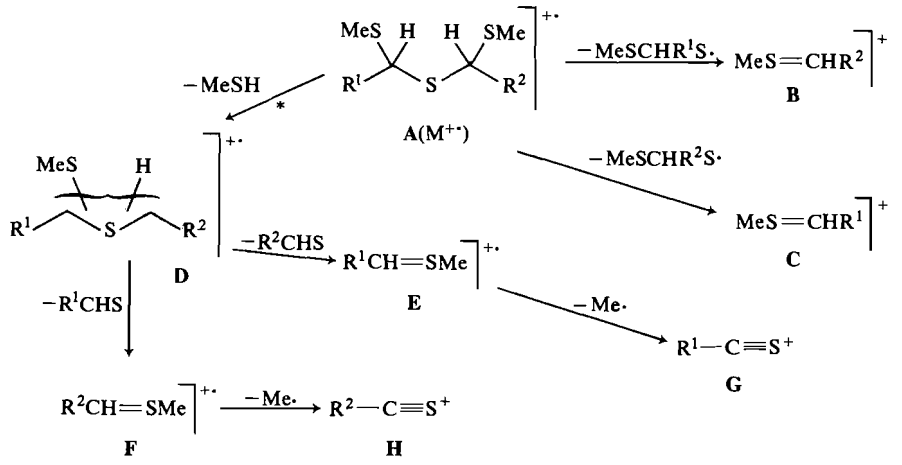
Nuclear Magnetic Resonance Spectra

The nmr spectra of the trithiaheptanes (Tables 2–4) showed a number of interesting features. The "gated" ^{13}C nmr spectra of **1***a* and **3***a* were especially informative due to very clearly defined three-bond ^{13}C—^{1}H couplings across sulfenyl sulfur which permitted unambiguous assignment of all the resonances in the spectrum of **3***a*. In fact, the particular structures of **1***a* and **3***a* make them ideal

[2]This argument derives from the assumption (8, 9) that the most stable configuration and conformation of the carbanions derived from **3***a*, *b*, or *d* would have the anion orbital *trans*, antiparallel to both adjacent C—S bonds, cf. **7**.

[3]Table 1 is available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

[4]This type of fragmentation has subsequently proved valuable in structure determination of substituted 2,4,6-trithiaheptanes, J. S. Grossert and M. Langman, to be published.



SCHEME I

molecules for observing high-resolution ^{13}C nmr spectra without wide-band ^{1}H decoupling (13).

The assignment of the ^{1}H nmr spectra (Table 2) is straightforward, save for the assignment of the SMe groups. This was carried out by a combination of heteronuclear decoupling methods and is reported elsewhere[5] as an example of a general method of assigning XCH_3 signals. The transmission of chirality effects through sulfenyl sulfur as evidenced by the appearance of methylene AB quartets in **3** is noteworthy. This type of observation is precedented, albeit uncommonly (14).

The ^{13}C nmr assignments (Table 3) are the result of spectra measured under conditions of full ^{1}H decoupling, single-frequency off-resonance decoupling (SFORD) (15) and "gated" ^{1}H decoupling (16). The SFORD spectra were used to distinguish methyl, methylene, and methine carbon signals and to assign the signals of the *n*-butyl carbons of **3***b* and **4***b*. In these SFORD spectra each methylene resonance for a carbon of the *n*-butyl chain showed second-order lines between the components of the first-order triplet, as expected (17) for the SFORD signals of carbons coupled to a tightly-coupled proton spin system. For each of **3***a* and **3***b* the C(1) and C(7) SMe signals were distinguished by the distinctive patterns observed in gated decoupling experiments. In each case, C(1) was a quartet of doublets and C(7) was a quartet of triplets, with the fine doublet or triplet splitting arising from three-bond coupling through sulfenyl sulfur to the methine proton at C(3) or to the methylene protons at C(5). Similarly, in **4***a* and **4***b* the CMe and SMe signals were distinguished by the splitting patterns observed under gated decoupling conditions. The two SMe signals of an individual diastereomer could not be differentiated in this way and the assignments of C(1) and C(7) for **4***a* and **4***b* in Table 3 may have to be reversed. The signals of the two diastereomers could, of course, be distinguished by their different integrals in the fully decoupled spectrum of a mixture.

The coupling across sulfenyl sulfur atoms, which we have exploited in making some of the above assignments, proved to be a considerable complication in extracting values of $^{2}J_{CH}$ and $^{3}J_{CH}$ for C(3) and C(5). The coupling constants reported in Table 4 were extracted from the gated decoupling spectra by first-order analysis. Cases for which $^{3}J_{CH}$ values are not reported in Table 4 were those in which C(3) and C(5) are subject to so many 2- and 3-bond couplings with protons that the first-order patterns could not be distinguished within the resolution of the experiment.

The parameters reported in Tables 3 and 4 usefully supplement data available (18–23) for open-chain organosulfur compounds. For example, it is known (18) that the α, β, γ, and δ substituent effects of a sulfenyl sulfur atom in simple sulfides are little different from those of a carbon atom. The ^{13}C chemical shifts of the trithiaheptanes reported in Table 3 confirm this. For C(1), the terminal methyl group of heptane, δ (^{13}C) = 13.9 which changes to δ 13.7 for the corresponding carbon of di-*n*-propyl sulfide (18) and to δ 14.2 in **1***a*, where heptane carbons C(2), C(4), and C(6) are all replaced by sulfur atoms. The change in chemical shift for C(3) in the same series is from δ 32.4 to δ 34.6 to δ 35.8. The greatest experimental chemical shift changes for the trithiaheptanes are the result of 3- and/or 5-alkyl substitution. These chemical shift changes,

referred to trithiaheptane **1***a* as a base, are listed as Δ^{exp} in Table 3. The values Δ^{calc} in this table are the calculated substituent effects for the corresponding carbons of heptane, using the substituent parameters of Lindeman and Adams (ref. 24; see also ref. 25). The agreement between Δ^{exp} and Δ^{calc} is such that it appears quite acceptable to use the hydrocarbon substituent parameters to predict chemical shifts in acyclic compounds containing sulfenyl sulfur, once again emphasizing the similarity of carbon and sulfur for this particular aspect of ^{13}C spectroscopy.

The directly bonded carbon—proton coupling constants (Table 4) were almost invariant for a particular carbon throughout the series **1***a*–**4***b*. This is the expected result, as the dominant factor for $^1J_{CH}$ is known (26) to be the electronegativity of the atoms bonded to the carbon of the ^{13}C—H fragment. A calculation using Malinowski's ζ values (27) gave $^1J_{CH}$ = 138.0 Hz for C(1) and C(7), $^1J_{CH}$ = 150.9 for a C(3) or C(5) methylene group, and $^1J_{CH}$ = 151.8 for a C(3) or C(5) methine group.

In discussing the experimental $^3J_{CH}$ values for the series, reference must be made to the work of Dorman, Bauer, and Roberts (28) on "long-range" carbon—proton coupling in methyl ethers. They observed a strong decrease in the coupling $^3J_{CH}$ of the methoxyl carbon to the α-proton(s) with increasing bulk of the α-substituents, and a less striking decrease in the three-bond coupling of the methoxyl protons to the α-carbon. The $^3J_{CH}$ values in Table 4 are in general agreement with these trends and with similar values reported by Dauphin and Cuer (23). In **1***a*, **3***a*, and **3***b* the splitting patterns of C(3) and C(5) showed $^3J_{C(3),H(5)}$ and $^3J_{C(5),H(3)}$ to be somewhat smaller than $^3J_{C(3),H(1)}$ and $^3J_{C(5),H(7)}$ which indicates the effect of sulfenyl sulfur as a substituent to the coupling fragment C—S—C—H. We are not aware of any published data on the effect of sulfenyl sulfur as a substituent on the corresponding fragment C—C—C—H, but a similar effect would be predicted.

The smaller values 3.5 Hz and 3.8 Hz for $^3J_{C(1),H(5)}$ in the spectra of the major diastereomers of **4***a* and **4***b* indicated a larger contribution of *gauche* $^3J_{CH}$ values in comparison with the contribution to $^3J_{CH}$ in the minor diastereomer, and hence a greater population of conformers with either the —CHRS— chain or an alkyl group *anti* to the terminal S-methyl group.

The ^{13}C nmr spectrum of **5** showed 4 lines, with appropriate chemical shifts and off-resonance multiplicities, for the major diastereomer. This was presumed to have a *cis* configuration, support for which came from the ^{1}H nmr spectrum which showed a single intense S-methyl peak. The minor component (ca. 15%) showed two methylene, one methine, and two S-methyl ^{13}C resonances, as would be expected from the *trans* compound. The two methyl peaks were not sufficiently intense to enable both to be seen clearly in either the off-resonance ^{13}C spectrum or in the ^{1}H spectrum, in this latter case, due to overlapping methylene resonances.

Conclusions

The alkylation reactions discussed in this paper represent a further development in methods for the

umpolung of carbonyl reactivity (3, 29). Of particular interest in this case is the availability of a second acidic proton for cyclization reactions to produce compounds such as **5**, a masked glutaraldehyde. We are actively exploring ways to extend the synthetic versatility of these reactions and to explore stereochemical consequences that arise from the particular geometry that molecules such as **1***e* adopt in the formation of **4** and **5**.

Experimental

General

Proton nmr spectra were measured on either a T-60 or a CFT-20 spectrometer and the chemical shifts are reported with respect to internal TMS. Carbon nmr spectra were recorded (CFT-20) in $CDCl_3$ which served as solvent, lock signal, and internal reference. The ^{13}C chemical shifts are reported with respect to TMS, δ ($^{13}CDCl_3$) = 76.90 (30). All gated decoupling experiments used the maximal acquisition time allowed for the minimum spectral width which could avoid "foldover" of spectral lines. These experiments used 90° pulses with 2–5 s delay between pulses. Typically, 20 000 pulses were required for the 50–75% solutions of trithiaheptanes in $CDCl_3$. The carbon—proton coupling constants reported were extracted from the experimental splitting of resonance signals in the gated decoupling experiments. Cases showing obvious second-order characteristics are not reported here.

Mass spectra were obtained from a DuPont-CEC 21-104 spectrometer with a glass probe inserted directly into the source, which operated at 70 eV and ca. 150°C. Gas–liquid chromatographic analyses were run on an H-P 5750 f.i.d. instrument using an SE30 column (5% on Chromosorb W) at 140–160°C, with N_2 carrier gas. Thin-layer chromatographic analyses were on Merck HF-254 silica gel, developed with 1.5–3.0% EtOAc in isooctane and visualized by uv light or by cerate spray (31). Tetrahydrofuran (THF) was distilled first from P_2O_5 and then, immediately before use, from $NaAlH_4$ under dry N_2. Diisopropylamine (iPr$_2$NH), hexamethylphosphoric-triamide (HMPTA), and *N,N,N,N*-tetramethylethylenediamine (TMEDA) were distilled at the appropriate pressure from CaH_2. *n*-Butyllithium (*n*BuLi) was 2.4 *M* in hexane (Alfa Inorganics) and its molarity was checked by the method of Watson and Eastham (32). Other chemicals were obtained from Fisher Scientific, Eastman Organic, or Aldrich and were purified only if necessary. Bulb-to-bulb distillations were carried out using a set of bulbs which rotated on a Chemquip rotary evaporator and which were heated by an oven fashioned from a pair of concentric glass tubes, Nichrome heating wire, and Transite ends. Combustion analyses were by Dr. F. Pascher, Bonn, West Germany.

*Preparation of Methylthionia-3,5-dithiacyclohexane Iodide, 2*a

s-Trithiane was treated with $(MeO)_2SO_2$, followed by KI, according to the method of Lee and Dougherty (5) to give the sulfonium iodide **2***a*, which was thrice rapidly recrystallized from DMSO–CH_2Cl_2. The colorless crystals of **2***a* were washed with cold CH_2Cl_2, dried *in vacuo* and stored at −15°C.

Reduction of **2**a *to 2,4,6-Trithiaheptane, 1*a

A stirred suspension of **2***a* (3.62 g, 12.9 mmol) in dry THF (150 mL) was cooled (ice bath) and treated cautiously with $LiAlH_4$ (0.5 g). The reaction was stirred overnight at room temperature, the excess hydride was destroyed with acetone, and the slurry filtered through Celite, which was Soxhlet extracted with CH_2Cl_2. The filtrate and CH_2Cl_2 extracts gave on evaporation a yellow oil which was chromatographed (CH_2Cl_2, silica gel) to give **1***a* as a pale yellow oil (1.26 g, 63%) that on distillation gave **1***a* as a colorless oil, identical in all respects to material prepared by Fehér and Vogelbruch's method (2), bp 52–54°C, 0.05 Torr; for ms see Table 1; for nmr see Tables 2–4.

Preparation of 3-Substituted 2,4,6-Trithiaheptanes, 3

(a) General Procedure and Preparation of **3**a

A solution of 2,4,6-trithiaheptane (**1***a*, 2.46 mL, 19.0 mmol) in THF (25 mL) was cooled by a ca −80°C bath (liquid N_2 – acetone slush) in an N_2 atmosphere with magnetic stirring. *n*-Butyllithium (7.9 mL, 19.0 mmol) was added by syringe, followed after 30 min by iodomethane (1.5 mL, 24.1 mmol). After 15–30 min a precipitate was observed, and the reaction was allowed to warm to room temperature (ca. 60 min), after which it was poured into an aqueous buffer solution (10% NH_4Cl, 10% NaOAc, 100 mL). This was extracted with CH_2Cl_2 (1 × 25, 3 × 15 mL) which was washed with water, dried ($MgSO_4$), and rotary evaporated to a pale yellow oil which was distilled to give 3-methyl-2,4,6-trithiaheptane, **3***a*, as a colorless oil (2.7 g, 85%), bp 54–56°C/0.05 Torr.

(b) Preparation of Butyl Derivative, **3**b

Compound **1***a* (3.11 mL, 23.8 mmol) was reacted as in (*a*) with *n*BuLi (9.9 mL, 23.8 mmol) and 1-bromobutane (2.8 mL, 26.2 mmol). The reaction warmed slowly and was stirred overnight at room temperature. It gave **3***b* as a colorless oil (4.37 g, 87%), bp 75°C/0.08 Torr.

(c) Preparation of Deuterioderivative, **3**c

The reaction as under (*a*) was quenched with DOAc to give **3***c* as a colorless oil. Compounds **3***a–c* were homogeneous by tlc and glc.

(d) Preparation of γ-Chloropropyl Derivative, **3**d

Compound **1***a* (5.1 mL, 39 mmol) was reacted as in (*b*) with *n*BuLi (17.0 mL, 40 mmol) and 1-bromo-3-chloropropane (8.0 mL, 75 mmol) to give **3***d* which was not distilled since it was essentially clean (^1H nmr), yield 8.18 g (91%), ms: 232, 230 (0.3, 0.8, $M^{+\cdot}$), 184 (0.6), 182 (1.4), 171 (0.3), 169 (0.8), 153 (25), 105 (29), 87 (24), 61 (100), 45 (89); nmr see Table 2.

Preparation of 3,5-Disubstituted 2,4,6-Trithiaheptanes, 4

(a) Preparation of Dimethyl Compound, **4**a

Lithium diisopropylamide (LDA) was prepared at ca. −80°C in THF from iPr$_2$NH (0.43 mL, 3.1 mmol) and *n*BuLi (1.3 mL, 3.1 mmol) and to this was added a solution of **3***a* (521 mg, 3.1 mmol) in THF (20 mL). Procedures as for **3***a* gave **4***a* as a yellow oil (427 mg, 76%) which was distilled (0.01 Torr, bulb-to-bulb) to give a colorless oil (250 mg), ratio of two components (glc) 2.38:1. A repeat experiment on **3***a* (644 mg, 3.8 mmol) with only *n*BuLi (not LDA) as base gave **4***a* (580 mg, 83%) which was distilled to give a colorless oil (446 mg), ratio of components 2.35:1.

(b) Preparation of n*-Butylmethyl Compound,* **4**b

Compound **3***b* (1.00 g, 4.76 mmol) was treated with LDA as for the preparation of **4***a*, to give a pale yellow oil, **4***b* (729 mg, 74%), which was distilled (0.01 Torr, bulb-to-bulb) to give a colorless semisolid oil, diastereomer ratio (glc) 3.6:1.

Preparation of 2,6-Bis(methylthio)thiane, 5

LDA was prepared from iPr$_2$NH (5.4 mL, 38.4 mmol) and *n*BuLi (16.0 mL, 3.84 mmol) in THF (50 mL). To this was added HMPTA (3.8 mL) and **3***d* (8.81 g, 35.6 mmol). The mixture was allowed to warm to room temperature at which it was stirred for 20 h. After work-up, the crude product was chromatographed on silica gel, with toluene–isooctane (2:3, 500 mL) as eluant, which gave **5** as a pale yellow oil (3.29 g, 48%) that appeared to be clean by nmr and mass spectrometry, but which decomposed on attempted distillation; ^1H nmr ($CDCl_3$) δ: 4.05 (m, major, CH), 3.80 (m, minor, CH), 2.5–1.8 (m, CH_2 envelope), 2.20 (s, minor, SMe), 2.18 (s, major, SMe); ^{13}C

nmr, major δ: 47.19 C(2, 6), 32.66 C(3, 5), 21.89 C(4), 14.09 (SMe); minor δ: 47.91 C(2, 6), 32.87 C(3, 5), 26.73 C(4), 14.60, 12.82 (SMe); ms: 194 (9, $M^{+\cdot}$), 147 (11), 146 (43), 99 (100), 98 (26), 97 (42), 87 (40), 76 (61), 65 (18), 47 (54), 45 (82).

*Preparation of 2,6-Bis(methanesulfonyl)thiane-*S,S*-dioxide, 6*

A stirred, cooled solution of **5** (490 mg, 2.5 mmol) in glacial acetic acid (10 mL) was treated with 50% H_2O_2 (3 mL). After 10 min, the ice bath was removed and the reaction was stirred at room temperature for 65 h. The mixture was poured into 10% $NaHSO_3$ solution (100 mL) which was extracted with ethyl acetate (3 × 50 mL), from which **6** (300 mg, 41%) was obtained as a pale yellow solid. Two recrystallizations from acetone and a sublimation (130°C, 0.3 Torr) gave pure **6**, mp 253–254°C; ir: 1340, 1325, 1168, 1158, 790 cm^{-1}; ^1H nmr (DMSO-d_6) δ: 1.4–2.7 (m, CH_2 + DMSO), 3.30, 3.33 (2 × s, $MeSO_2$—), 4.9–5.4 (m, CH); ^{13}C nmr (DMSO-d_6), major component δ: 19.50 C(4), 24.79 C(3, 5), 42.78 (SO_2Me), 76.97 C(2, 6); minor component: δ: 21.93, 25.09, 43.02, 78.39; *Anal.* calcd. for $C_7H_{14}O_6S_3$: C 28.95, H 4.86, S 33.13%; found: C 29.00, H 4.90, S 32.86%.

Regioselective eliminations in reactions of carbohydrate derivatives with superoxide, or with borohydride in 2-propanol

VANGA S. RAO AND ARTHUR S. PERLIN

Department of Chemistry, McGill University, Montreal, P.Q., Canada H3C 3G1

Received July 9, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

VANGA S. RAO and ARTHUR S. PERLIN. Can. J. Chem. **59**, 333 (1981).

The reaction between 2,3,4,6-tetra-*O*-benzyl-1,5-di-*O*-mesyl-D-glucitol (**2**) and potassium superoxide resulted in the loss of H-4 and the 5-mesyloxy (as well as 1-mesyloxy) substituent, and an almost quantitative conversion into enol ether **4**, i.e., 1,3,4,5-tetra-*O*-benzyl-3-dehydro-2-deoxy-L-*threo*-hex-2-enitol. When the reaction was performed with **8**, in which the 1-*O*-mesyl group (of **2**) is replaced by *O*-(methoxy)trityl, the outcome was wholly different: an olefin was formed through the removal of a primary (H-6) rather than a secondary (H-4) proton, and nucleophilic displacement also took place. Results similar to those for **8** were obtained with the 2-epimer of **2**, i.e., 2,3,4,6-tetra-*O*-benzyl-1,5-di-*O*-mesyl-D-mannitol (**12**). It is suggested that selective displacement of the 1-*O*-mesyl group of **2** by superoxide generates a 1-peroxy anion (**6**) that abstracts H-4 intramolecularly, promoting concomitant loss of the 5-mesyloxy group. The transition state for proton abstraction within anion **6** appears to be more stable than that of the corresponding anion in the *manno* series, accounting for the different reaction routes for **2** and **12**. Elimination occurred also in the reduction of 2,3,4,6-tetra-*O*-benzyl-D-glucopyranose with sodium borohydride in 2-propanol, en route to **2**, affording 2,4,6-tri-*O*-benzyl-2-dehydro-3-deoxy-D-*threo*-hex-2-enitol (**21**). The ^{1}H nmr spectra of alditol derivatives **2**, **8**, and **12** show that these molecules depart substantially from extended zigzag conformations, in contrast to configurationally related peracetylated acyclic derivatives.

VANGA S. RAO et ARTHUR S. PERLIN. Can. J. Chem. **59**, 333 (1981).

Par réaction avec le superoxyde de potassium le tétra-*O*-benzyl-2,3,4,6 di-*O*-mésyl-1,5 D-glucitol (**2**) perd le proton en H-4 et le groupe mésyloxy-5 (ainsi que le mésyloxy-1) et se transforme presque quantitativement en éther énolique **4** soit le tétra-*O*-benzyl-1,3,4,5 déhydro-3 déoxy-2 L-*thréo*-hexène-2 itol. Si l'on effectue la même réaction sur le composé **8** qui correspond au remplacement du groupe *O*-mésyl-1 (de **2**) par un groupe *O*-(méthoxy)trityl, la réaction est très différente. Il se forme une oléfine par l'intermédiaire d'une élimination de l'hydrogène primaire (H-6) plutôt que par celle du proton (H-4) et il se produit ainsi un déplacement nucléophile. Avec l'épimère du composé **2**, soit le tétra-*O*-benzyl-2,3,4,6 di-*O*-mésyl-1,5 D-mannitol (**12**), on obtient des résultats semblables à ceux que donne le composé **8**. On suggère que le déplacement sélectif du groupe *O*-mésyl-1 du composé **2** par le superoxyde, engendre un anion péroxy (**6**) qui enlève intramoléculairement H-4 en favorisant la perte concomitante du groupe mésyloxy en position 5. L'état de transition lors de l'élimination du proton dans l'anion (**6**) semble être plus stable que celui dérivant de l'anion correspondant des séries *manno*; ceci explique les réactions différentes de **2** et **12**. Lors de la réduction du tétra-*O*-benzyl-2,3,4,6 D-glucopyranose par le borohydrure de sodium dans le propanol-2, il se produit également une élimination qui conduit au tri-*O*-benzyl-2,4,6 déhydro-2 déoxy-3 D-*thréo*-hexène-2 itol (**21**) plutôt qu'au composé **2** attendu. Les spectres rmn du ^{1}H des dérivés alditol **2**, **8**, et **12** indiquent que ces molécules s'éloignent de façon marquées des conformations en zig zag en contradiction avec les configurations des dérivés acycliques peracétylés apparentés.

[Traduit par le journal]

Introduction

In examining possibilities for a novel synthesis of L-idose, 2,3,4,6-tetra-*O*-benzyl-1,5-di-*O*-mesyl-D-glucitol (**2**) was prepared[1] by hydride reduction of 2,3,4,6-tetra-*O*-benzyl-D-glucopyranose (**1**), followed by mesylation. It was anticipated that the use of potassium superoxide (KO_2) to displace the mesyloxy substituents of **2**, by analogy with corresponding S_N2 reactions in the acyclic and alicyclic series (1, 2) would yield 1,3,4,5-tetra-*O*-benzyl-L-iditol (**3**), potentially a suitable precursor to L-idose. Instead, an uncommon type of elimination process ensued. Another unexpected elimination reaction was encountered during the reduction of **1** with sodium borohydride in 2-propanol. These, and related, observations form the subject of the present article.

Results and Discussion

Reaction between 2,3,4,6-Tetra-O-benzyl-1,5-di-O-mesyl-D-glucitol and Potassium Superoxide

When alditol **2** was subjected to reaction with KO_2, in 1:1 methyl sulfoxide – dimethylformamide containing 18-crown-6 (1, 2) an almost quantitative yield was obtained of an unstable monohydroxy compound, characterized as **4**. That is, the ^{1}H nmr spectrum of **4** contained an appropriate downfield triplet (δ 5.20) attributable to H-2, as well as an OH-6 doublet of doublets (δ 2.77, eliminated by deuterium exchange). Moreover the acetylation of **4** with acetic anhydride – pyridine produced a syrupy monoacetate (**5**), characterized by ^{13}C resonance signals attributable to the enol ether moiety

(C-3 at δ 154.2 and C-2 at δ 101.3), as well as by a simple A_2X spin system anticipated for H-1,1′ (δ 4.17) and olefinic H-2 (δ 5.18).[2]

To account for the high degree of regioselectivity observed in this reaction[3] it is suggested that, initially, only the 1-*O*-mesyl group of **2** is displaced by O_2^-, and subsequent electron transfer (2) generates an intermediate peroxy monomesylate (**6**). A large difference in reactivity of this magnitude between the 1-*O*-mesyl substituent and that at position 5 is to be expected, in the light of comparative rates of displacement of primary vs. secondary sulfonyloxy groups in alditol derivatives (3–5). Intramolecular abstraction[4] of H-4 by the anion and extrusion of the sulfonyloxy group at C-5 then follow, as in **7**, giving rise to the enol ether (**4**). The stereochemistry of the elimination process is not known, however, as the configuration of the enol moiety in **4** has yet to be determined.

Support for the requirement of such an intermediate as **6** is furnished by the fact that the reaction characteristics of **8**, the 1-*O*-(methoxy)trityl analog of **2**, are markedly different. That is, although several products were formed in the reaction of **8** with superoxide under the same conditions, an olefin corresponding to **4** was not among those detected. According to the ^{1}H nmr spectrum of the peracetylated reaction mixture, the main products (about 40% each) were an L-iditol derivative (**9**; based on close similarities to the spectrum of 1,5-di-*O*-acetyl-2,3,4,6-tetra-*O*-benzyl-L-iditol

[2]Catalytic de-*O*-benzylation of **5** gave a mixture of products that was not separated. However, a major signal in the ^{1}H nmr spectrum of the mixture was a triplet at δ 2.99 (J = 6.0 Hz), attributable to the 2-methylene group of a 2-deoxy-3-keto structure (—CO—CH_2—CH_2OH) expected when the enolic ether substituent of **5** is removed.

[3]The isolation of a single product precludes the possibility that a 1-enolate was formed originally, and then isomerized to **4**, as a mixture of *cis* and *trans* isomers of **4** should have been encountered (6).

[4]An intramolecular elimination process involving superoxide has been cited (7), although details are as yet unavailable.

(**10**)), and a 1-hexenitol (**11**) (δ 6.42 (1 H, d, H-1); $J_{1,2}$ = 13.0 Hz).[5] The latter olefin, in fact, should be one product ordinarily formed in an E_2 process (8), as its formation is initiated by the abstraction of a primary proton. For the same reason, a product analogous to **11** is to be expected in an elimination reaction of **2** whereas, by contrast, the formation of **4** requires the exclusive removal of a secondary proton (H-4).

The proton–proton coupling constants (Table 1), obtained from 200 MHz spectra of **2** and **8**, show that these two alditols are closely similar in conformation. Furthermore, it is evident from the discussion to be presented later that the molecules are not primarily in an extended zigzag conformation. As **8** cannot give rise to an anionic intermediate analogous to **6**, its reaction with superoxide is unexceptional. For alditol **2**, however, molecular models suggest that in rotamers commensurate with the coupling constants of protons 2–5, the introduction of a peroxy anion moiety at C-1 could allow for a facile intramolecular attack by this anion on H-4, and lead to the formation of the regioselective elimination product (**4**). Moreover, the transition state envisaged for this route appears to be favorable, especially when the result obtained from **2** is compared with that from its *manno* epimer.

That is, in the reaction of 2,3,4,6-tetra-*O*-benzyl-1,5-di-*O*-mesyl-D-mannitol (**12**) with potassium superoxide, a mixture of displacement and elimination products was formed comparable to that described for the *O*-mesyl-*O*-(methoxy)trityl derivative (**8**), and there was no indication whatever that an enol ether corresponding to **4** had been produced. Hence, the ^{1}H nmr spectrum of the peracetylated reaction mixture, which showed that the *O*-mesyl substituents had been completely removed, contained a prominent doublet (δ 6.42, $J_{1,2}$ = 13.0 Hz) commensurate with a 1-hexenitol structure (**13**) analogous to **11**. By contrast, there was no signal in the vicinity of δ 5.2, as would be expected for **14**, an enol ether analogous to **5**. Therefore, the elimination product from **12** is the normal one, due to abstraction of a primary proton (H-6 or H-6′).

Although the extended zigzag conformation should be more readily favored (9) by **12** than by **2**, because in this conformation the substituents on C-2 to -5 are staggered, coupling data (Table 1) show that there must be a substantial population of other rotameric states, as discussed below. However, as $J_{2,3}$ could not be determined, it is unclear if the anionic function of the 1-peroxy intermediate (**15**) expected from **12** would be in close proximity to H-4, as already proposed for **6**. Nevertheless, intramolecular proton abstraction within **15** should involve a less favorable transition state than one for **6**. That is, in comparing transition states **16** and **17**, corresponding to **6** and **15**, respectively, it is found that the 2- and 4-benzyloxy substituents of **17** are eclipsed, whereas there are no comparable destabilizing interactions in **16**. Differences such as these help to account for the fact that the *manno* isomer (**12**) follows a conventional reaction course with superoxide, whereas the *gluco* isomer (**2**) undergoes the highly regioselective, unusual, elimination reaction described.

*Elimination Accompanying the Reduction of 2,3,4,5-Tetra-*O*-benzyl-*D*-glucopyranose (1) with Borohydride in 2-Propanol*

For the preparation of **2**, described at the outset, 2,3,4,6-tetra-*O*-benzyl-D-glucopyranose (**1**) was reduced to the corresponding D-glucitol derivative (**18**) with sodium borohydride in 7:3 tetrahydrofuran–water. In a separate attempt to prepare **18**, employing 2-propanol under reflux as the solvent, a mixture of two products was formed. The mixture was acetylated and separated by column chromatography on silica gel. About half of the material consisted of the diacetate of the reduction product anticipated, i.e., 1,5-di-*O*-acetyl-2,3,4,6-tetra-*O*-benzyl-D-glucitol (**19**), prepared also by acetylation of **18**. The second component was shown by ^{1}H nmr spectroscopy to be a 2-enitol (**20**); it contains two *O*-acetyl groups, three *O*-benzyl substituents, and an olefinic proton on C-3 (δ 4.97, d, $J_{3,4}$ = 9.2 Hz). H-1 and -1′ of **20** give rise to an AB pair of signals (J = 12.0 Hz), and these two signals were replaced by two broad singlets when sodium borodeuteride was used in the reduction. These data received support from the ^{13}C spectrum, which exhibited signals at δ 153.2 (C-2) and 111.4 (C-3) commensurate with the enol ether structure proposed for **20**. Consequently, the formation of diol **21** (from which **20** was derived by acetylation) involved not only the reduction of the hemiacetal moiety of **1**, but also the elimination of H-2 and the 3-benzyloxy substituent.

Although 2-propanol is widely employed (10) as a solvent for reductions with sodium borohydride, it leads (11) to formation of the corresponding tetraboronate ion and, on dissociation of the latter, of a strong base:

$$B(OiPr)_4^- \rightleftharpoons B(OiPr)_3 + OiPr^-$$

[5] A minor product was the corresponding D-glucitol derivative. The latter could have arisen through hydrolysis, due to a trace of moisture present, or possibly also due to limited attack of O_2^- on sulfur.

For personal use only.

Accordingly, is has been reported (12) that some carbonyl reductions in 2-propanol are accompanied by extensive enolization, leading to epimeric or racemic products. The formation of **21** also may be accounted for by an initial enolization (**22**), which then is followed by migration of the double bond and concomitant elimination of the benzyloxy group on C-3 (**23**),[6] and hydride reduction. However, as there was no trace of the D-mannitol derivative (**24**) that would be obtained through prior epimerization of **1**, the rate of the migration–elimination step (**23**) likely exceeds that of enolization (**22**). It is worth noting that the C-2 epimer of **1**, namely 2,3,4,6-tetra-*O*-benzyl-D-mannose was largely reduced to the corresponding alditol under the same reaction conditions. That is, ^{1}H nmr analysis of the product, after acetylation, indicated that a 9:1 mixture of alditol **24** and olefin **20** was obtained (the *gluco* isomer **19** was not detected). However, the mannose derivative may well be expected to undergo elimination less extensively than **1**, because the rate of base-catalysed enolization is more rapid in the *gluco* than in the *manno* series (13), whereas the relative rates of reduction with diborane are reversed (14).

Conformations of Alditol Derivatives

Reference has been made above to proton–proton couplings (Table 1) obtained at 200 MHz for the alditol derivatives. As coupling data are available from a number of studies (9) dealing with the conformations of acyclic carbohydrate derivatives, it was of interest to compare the present results with those obtained with configurationally-related compounds. For this purpose, coupling parameters (15) for the hexaacetates of D-glucitol (**25**) and D-mannitol (**26**) are included in Table 1.

There are some substantial differences between our results and those for the hexaacetates. Particularly noteworthy are the much larger values of $J_{4,5}$ exhibited by the latter compounds, which are characterized (9) by conformations in which protons -4 and -5 are mainly *trans*. Other acyclic derivatives in the *gluco* and *manno* series show analogous properties; e.g. a recent study (16) on hexononitrile pentaacetates reports $J_{4,5}$ values of 8.4 Hz (*gluco*) and 9.2 Hz (*manno*). Consequently, the alditols described here are unusual in being represented prominently by arrangements of chain carbon atoms in which H-4 and H-5 are *gauche*, and thus depart from extended zigzag conformations. As $J_{3,4}$, $J_{4,5}$, and $J_{5,6}$ are essentially constant ($J_{5,6'}$ is altered noticeably) for alditols **2**, **8**, and **19**, as well as **12** and **24**, a change in the C-5 substituent from *O*-acetyl to *O*-mesyl has only a minor influence on conformation. Hence differences observed with respect to the peracetylated alditols may be attributed to the *O*-benzyl substituents, although molecular models have provided little insight as to possible steric causes for these changes.

Experimental

General Methods

Solutions were usually evaporated below 40°C under diminished pressure. Solvents were dried by conventional procedures, distilled, and stored over molecular sieves (Type 4A). Potassium superoxide was obtained from Ventron Corp., 18-crown-6 from Aldrich Chemicals, and 2,3,4,6-tetra-*O*-benzyl-D-glucose from Pfanstiehl Laboratories (Waukegan, IL). Silica gel for column chromatography was obtained from Macherey Nagel and Co. (Germany). Microanalyses were performed by Guelph Chemical Laboratories, Ltd. (Guelph, Ont.). Proton magnetic resonances were recorded with a Varian T-60, HA-100, or XL-200 spectrometer, using $CDCl_3$ as the solvent. Chemical shifts (δ) are reported with reference to tetramethylsilane and, together with the coupling constants given, were obtained by first-order analysis of 200 MHz spectra with the aid of homonuclear decoupling experiments. Carbon-13 nmr spectra were recorded with a Bruker WH-90 spectrometer. Mass spectra were obtained with an LKB 9000 spectrometer at an ion source of 70 eV.[7]

*1,3,4,5-Tetra-*O*-benzyl-L-gulitol (18)*

Sodium borohydride (5 g) was added to a stirred solution of 2,3,4,6-tetra-*O*-benzyl-D-glucopyranose (**1**) (5.0 g) in 7:3 tetrahydrofuran–water (70 mL), the solution was heated under reflux for 18 h, and then evaporated. Water was introduced, followed by chloroform, and the chloroform layer was washed successively with 5% hydrochloric acid, saturated sodium hydrogen carbonate, and water, dried (anhydrous sodium sulfate), and evaporated, to give a colorless, viscous syrup (5.12 g); $[\alpha]_D$ +8.2 (*c* 5.1, $CHCl_3$); ^{1}H nmr data for **18**: δ: 2.15 (1H, t, OH-6, J = 6.0), 2.85 (1H, d, OH-2, J = 6.0), 3.3–4.0 (8H, overlapped m, H-1 to -6′), 4.20, 4.30, 4.36, 4.40 (8H, s, OCH_2), 6.8–6.9 (20H, overlapped m, C_6H_5).

[6]As kindly pointed out by a referee, an *intramolecular* elimination of the 3-benzyloxy group of **22** is a plausible alternative.

[7]Chemical ionization (isobutane; HP 5980 A spectrometer) was also used for most of the compounds described. In general, with both electron impact and chemical ionization, parent ions were not detected and only fragments of relatively low molecular weight were observed.

*2,3,4,6-Tetra-*O*-benzyl-1,5-di-*O*-mesyl-*D*-glucitol (2)*

A solution of methanesulfonyl chloride (1.4 g) in pyridine (10 mL) was added through a septum to a solution of **18** (2.7 g) in pyridine (20 mL) cooled in an ice-bath. After 48 h in the cold, the reaction mixture was poured into ice-water, and a thick syrupy deposit that formed was extracted with chloroform. The extract was washed successively with 5% hydrochloric acid, saturated sodium hydrogen carbonate, and water, dried (anhydrous sodium sulfate), and evaporated, affording a colorless, viscous syrup (3.0 g); $[\alpha]_D$ +7.6 (*c* 9.1, $CHCl_3$); ^1H nmr data for **2**: δ: 2.96 and 3.08 (2 × 3H, s, CH_3), 3.84 (1H, t, H-3), 3.9 (1H, dd, H-6′), 4.0 (1H, dd, H-6), 4.04 (1H, m, H-2), 4.18 (1H, dd, H-4), 4.39 (1H, dd, H-1′), 4.61 (1H, dd, H-1), 5.17 (1H, dt, H-5), 4.60 (2H, s, OCH_2), 4.69 (2H, s, OCH_2), 4.70 and 4.81 (2H, AB, *J* = 11.4, OCH_2), 4.76 and 4.89 (2H, AB, *J* = 11.4, OCH_2), 7.36–7.64 (20H, m, C_6H_5). Other coupling data are given in Table 1. *Anal.* calcd. for $C_{36}H_{42}O_{10}S_2$: S 9.18; found: S 8.74.

*1,3,4,5-Tetra-*O*-benzyl-3-dehydro-2-deoxy-*L*-threo-hex-2-enitol (4)*

To a vigorously stirred solution of potassium superoxide (0.51 g, 7.15 mmol; finely ground and weighed under dry nitrogen) and 18-crown-6 (0.95 g, 3.57 mmol) in 1:1 methylsulfoxide–dimethylformamide (5 mL), cooled in an ice-bath and under dry nitrogen, was added a solution of **2** (0.5 g, 0.71 mM) in the same solvent mixture (5 mL). An orange-yellow color developed briefly, and then the original yellow color returned, the coolant was removed, and 24 h later additional 18-crown-6 (0.95 g in 4 mL of the solvent mixture) was introduced. Following a further period of 3 h, the reaction mixture was poured into ice-water saturated with sodium chloride, extracted with chloroform, and the extract was washed successively with cold 10% hydrochloric acid, sodium hydrogen carbonate, and water, dried (anhydrous sodium sulfate), and evaporated. The syrupy residue was freed from 18-crown-6 by passage through a column of silica gel using 1:1 chloroform – ethyl acetate as eluant, and recovered by evaporation; yield, 0.23 g. ^1H nuclear magnetic resonance data for **4**: δ: 2.77 (1H, dd, OH-6, $J_{OH\text{-}6,H\text{-}6}$ = 7.8, $J_{OH\text{-}6,H\text{-}6'}$ = 4.2), 3.64 (1H, m, H-6′, $J_{5,6'}$ = 4.5, $J_{6,6'}$ = 12.5), 3.80 (1H, m, H-6, $J_{5,6}$ = 3.5, $J_{6,6'}$ = 12.5), 4.0 (1H, m, H-5, $J_{4,5}$ = 7.8, $J_{5,6} \simeq J_{5,6'} \simeq 4$), 4.09 (2H, d, H-1, 1′, $J_{1,2}$ = 7.8), 4.51 and 4.59 (2H, AB, OCH_2, *J* = 11.4), 4.58 and 4.78 (2H, AB, OCH_2, *J* = 11.4), 4.61 (1H, d, H-4, $J_{4,5}$ = 7.8), 4.81 and 5.01 (2H, AB, OCH_2, *J* = 11.4), 4.93 (2H, s, OCH_2), 5.20 (1H, t, H-2, $J_{1,2}$ = $J_{1',2}$ = 7.8), 7.35–7.65 (20H, m, C_6H_5).

*6-O-Acetyl-1,3,4,5-tetra-*O*-benzyl-3-dehydro-3-deoxy-*L*-threo-hex-2-enitol (5)*

The title compound was prepared in quantitative yield by acetylation of **4** with 1:2 acetic anhydride – pyridine. The ^1H nmr data for **5** were δ: 2.04 (3H, s, CH_3), 4.09–4.19 (3H, overlapping m, H-5, 6,6′), 4.17 (2H, d, H-1, 1′, $J_{1,2}$ = 7.25), 4.49 (1H, d, H-4, $J_{4,5}$ = 7.0), 4.53 (2H, s, OCH_2), 4.56 and 4.78 (2H, AB, OCH_2, *J* = 11.8), 4.78 and 4.89 (2H, AB, OCH_2, *J* = 11.8), 4.90 (2H, s, OCH_2), 5.18 (1H, t, H-2, $J_{1,2}$ = $J_{1',2}$ = 7.25), 7.35–7.61 (20H, m, C_6H_5); ^{13}C nmr data: δ: 20.8 (CH_3), 64.1, 65.1 (2×), 69.6, 70.9, 72.4, 74.1 (2×) (4 CH_2, C-1, -4, -5, -6), 101.3 (C-2), 128.5–127.7 (C-2′ to C-6′ of C_6H_5), 138.2, 138.8 (3×) (C-1′ of C_6H_5), 154.2 (C-3), 170.8 (C=O). *Mol. wt.* calcd. for $C_{36}H_{38}O_6$: 566.7; found: M^+ 566.

*5-O-Mesyl-1-O-(methoxy)trityl-2,3,4,6-tetra-O-benzyl-*D*-glucitol (8)*

A solution of **18** (7.8 g) and (methoxy)trityl chloride (5.0 g) in dry pyridine (50 mL) was stirred for 48 h at 5°C, ice-water was introduced, the mixture was extracted with chloroform, and the extract was washed successively with 5% hydrochloric acid, sodium hydrogen carbonate, and water, dried (anhydrous sodium sulfate), and evaporated. The syrupy residue (12.1 g) was treated with methanesulfonyl chloride as described above under **2**, affording **8** as a hygroscopic foam; $[\alpha]_D$ +12.6 (*c* 5.0, $CHCl_3$); ^1H nmr data for **8**: δ: 2.95 (3H, s, CH_3SO_2), 3.29 (1H, dd, H-1′), 3.85 (3H, s, OCH_3), 3.59 (1H, dd, H-1), 3.81 (1H, dd, H-6′), 3.93–4.02 (3H, overlapping m, H-2, 4, 6), 4.06 (1H, t, H-3), 4.22 and 4.65 (2H, AB, OCH_2, *J* = 11.2), 4.51 and 4.53 (2H, AB, OCH_2, *J* = 11.2), 4.71 and 4.80 (2H, AB, OCH_2, *J* = 11.2), 4.72 and 4.83 (2H, AB, OCH_2, *J* = 11.2), 5.01 (1H, m, H-5), 7.11–7.71 (20H, m, C_6H_5). Other coupling data are given in Table 1. *Anal.* calcd. for $C_{55}H_{56}O_9S$: C 73.97, H 6.32; found: C 73.88, H 6.41.

*2,3,4,6-Tetra-*O*-benzyl-1,5-di-*O*-mesyl-*D*-mannitol (12)*

2,3,4,6-Tetra-*O*-benzyl-D-mannopyranose[8] was reduced with sodium borohydride in aqueous tetrahydrofuran, as described above under **18**, and then methanesulfonated, as described under **2**. The product was a viscous syrup; $[\alpha]_D$ +12.1 (*c* 3.0, $CHCl_3$); ^1H nmr data for **12**: δ: 2.89, 2.94 (2 × 3H, s, CH_3), 3.77–3.86 (2H, overlapping m, H-2, 3), 3.78 (1H, dd, H-6′), 3.89 (1H, dd, H-6), 4.04 (1H, dd, H-4), 4.39 (1H, dd, H-1′), 4.41 and 4.64 (2H, AB, OCH_2, *J* = 11.4), 4.46 (2H, s, OCH_2), 4.55 and 4.75 (2H, AB, OCH_2, *J* = 11.4), 4.71 (2H, s, OCH_2), 4.69 (1H, dd, H-1), 4.99 (1H, m, H-5). Other coupling data are presented in Table 1. The mass spectrum was closely similar to that of **2**.

1,5-di-O-Acetyl-2,4,6-tri-O-benzyl-2-dehydro-3-deoxy-D-threo-hex-2-enitol (20) and 1,5-Di-O-acetyl-2,3,4,6-tetra-O-benzyl-D-glucitol (19)

2,3,4,6-Tetra-*O*-benzyl-D-glucopyranose (5.0 g) was dis-

[8]Kindly furnished by R. G. S. Ritchie.

solved in boiling 2-propanol, sodium borohydride (5.0 g) was introduced, refluxing was continued for 24 h, and the solution was evaporated. Water was added to the residue, followed by chloroform, and the chloroform layer was washed successively with 1% hydrochloric acid, sodium hydrogen carbonate, and water, dried (anhydrous sodium sulfate), and evaporated (yield, 4.9 g). The syrupy residue was acetylated with 1:2 acetic anhydride – pyridine (yield, 5.4 g), and the acetylation product (1.0 g) was chromatographed on a column of silica gel packed in petroleum ether, using gradient elution with mixtures of petroleum ether – chloroform. Compound **19** emerged first (yield, 0.4 g); $[\alpha]_D$ +6.6 (*c* 3.9, $CHCl_3$); its ^1H nmr spectrum was indistinguishable from the diacetate prepared from **18**. The ^1H nmr data for **19** were δ: 1.96 and 2.01 (2 × 3H, s, CH_3), 3.72 (1H, dd, H-3), 3.74 (1H, dd, H-6′), 3.81–3.91 (1H, m, H-2), 3.86 (1H, dd, H-6), 3.97 (1H, dd, H-4), 4.17 (1H, dd, H-1′), 4.29 (1H, dd, H-1), 4.15 and 4.51 (2H, AB, OCH_2, J = 12), 4.62 and 4.65 (2H, AB, OCH_2, J = 12), 4.63 (2H, s, OCH_2), 4.68 (2H, s, OCH_2), 5.3 (1H, m, H-5), 7.27–7.41 (20H, m, C_6H_5); other coupling data are given in Table 1. Continued elution of the column afforded **20** (yield, 0.35 g); $[\alpha]_D$ +15.6 (*c* 2.8, $CHCl_3$); ^1H nmr data for **20**: δ: 2.08 and 2.11 (2 × 3H, s, CH_3), 3.68 (2H, d, H-6,6′, $J_{5,6}$ = 5.2), 4.34 and 4.50 (2H, AB, OCH_2, J = 12), 4.48 and 4.58 (2H, AB, OCH_2, J = 12), 4.87 (2H, s, OCH_2), 4.65 and 4.72 (2H, AB, H-1,1′, J = 13.6), 4.69 (1H, dd, H-4, $J_{3,4}$ = 9.2, $J_{4,5}$ = 5.6), 4.97 (1H, d, H-3, $J_{3,4}$ = 9.2), 5.26 (1H, dd, H-5, $J_{4,5}$ = $J_{5,6}$ = 5.2), 7.27–7.43 (15H, m, C_6H_5). The ^{13}C nmr data were δ: 20.9, 21.1 (2 CH_3), 62.3, 68.7, 70.5, 71.3, 71.6, 73.0, 73.3 (3 CH_2, C-1, -4, -5, -6), 111.4 (C-3), 127.7–128.3 (C-2′ to C-6′ of C_6H_5), 137.0, 138.2, 138.5 (C-1′ of C_6H_5), 153.2 (C-2), 170.3 (C=O).

Conversion of hydroxyl groups into bromo groups in carbohydrates with inversion of configuration

BJÖRN CLASSON, PER J. GAREGG, AND BERTIL SAMUELSSON

Department of Organic Chemistry, Arrhenius Laboratory, University of Stockholm, S-106 91 Stockholm, Sweden

Received August 6, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

BJÖRN CLASSON, PER J. GAREGG, and BERTIL SAMUELSSON. Can. J. Chem. **59**, 339 (1981).

A novel reagent system is described for the efficient, one-step transformation of hydroxyl groups in carbohydrates to bromodeoxy groups. The reaction proceeds with inversion of configuration. The reagent system consists of triphenylphosphine, tribromoimidazole, and imidazole in toluene at elevated temperature. The carbohydrate need not be soluble in toluene. The examples given include substitution of isolated primary and secondary hydroxyl groups in otherwise protected carbohydrates as well as disubstitution involving one primary and one secondary position in hexopyranosides. High yields are obtained in the replacement of hydroxyl by bromine in the 2-position of 3,4,6-protected methyl α-D-gluco- and -mannopyranosides.

BJÖRN CLASSON, PER J. GAREGG et BERTIL SAMUELSSON. Can. J. Chem. **59**, 339 (1981).

On décrit un nouveau système de réactif qui permet de transformer efficacement une seule étape les groupes hydroxyles des carbohydrates en groupes bromodéoxy. La réaction se fait avec inversion de configuration. Le système de réactif est constitué de triphénylphosphine, de tribromoimidazole et de l'imidazole dans le toluène à haute température. Il n'est pas nécessaire que le carbohydrate soit soluble dans le toluène. Les exemples donnés comprennent la substitution de groupe hydroxyle primaire et secondaire de carbohydrates par ailleurs protégés ainsi que la disubstitution impliquant une position primaire et une position secondaire des hexopyrannosides. On a obtenu des rendements élevés en remplaçant l'hydroxyle par le brome en position 2 des α-D-gluco- et mannopyrannosides de méthyle protégés en positions 3,4,6.

[Traduit par le journal]

Introduction

Replacements of hydroxyl groups in carbohydrates by halogen, giving rise to halogeno sugars, represent important synthetic transformations. Halogeno sugars are useful intermediates for obtaining *inter alia* amino sugars and deoxy sugars.

We have previously reported transformations using novel reaction systems consisting of triphenylphosphine together with either iodine and imidazole or triiodoimidazole **1** and imidazole in toluene at elevated temperature (1–4). These reagent systems convert vicinal hydroxyl groups in hexopyranosides into the corresponding dideoxyhexenopyranosides (1, 2). Single hydroxyl groups are converted, with inversion of configuration, into the corresponding deoxyiodo compounds including the 2-position in hexopyranosides. Partial iodinations, at primary positions in unprotected hexopyranosides, are possible in good yields (3, 4). An obvious extension of this work is the use of this type of reaction for obtaining bromodeoxy sugars. Some of our work in this area is the subject of this paper. The examples include the disubstitutions of methyl hexopyranosides and a facile synthesis of methyl 3,6-dideoxy-α-D-*ribo*-hexopyranoside ("methyl α-paratoside") from methyl α-D-glucopyranoside. Previous work on the synthesis of bromodeoxy sugars has been reviewed (5).

Results and Discussion

The reagent system used consists of triphenylphosphine, tribromoimidazole, and (usually) imidazole in toluene at elevated temperature. In the various brominations described below, we found that the addition of a few equivalents of imidazole sometimes resulted in improved yields and cleaner reactions. The reason for this is not obvious, although we have noted that whenever a hard precipitate is formed in the reaction mixture no further reaction takes place. The addition of imidazole, however, dissolves this complex and the reaction then proceeds. Yields of products thus obtained are given in brackets in Scheme 1, which shows the various compounds obtained in the present work.

Reactions at Single Hydroxylated Positions

The examples include the methyl 3,4,6-tri-*O*-benzyl-D-hexopyranosides with the α-D-*manno*- (**3**), α-D-*gluco*- (**5**), and β-D-*gluco*- (**7**) configurations as well as methyl 2,3-*O*-isopropylidene-β-D-ribofuranoside (**9**) and 1,2:3,4-di-*O*-isopropylidene-α-D-galactopyranose (**11**). Of the various substrates examined in the present reaction system, serious difficulty was encountered with 1,2:5,6-di-*O*-isopropylidene-α-D-glucofuranose only. In the corresponding iodination (3, 4) 3-deoxy-3-iodo-1,2:5,6-di-*O*-isopropylidene-α-D-allofuranose was

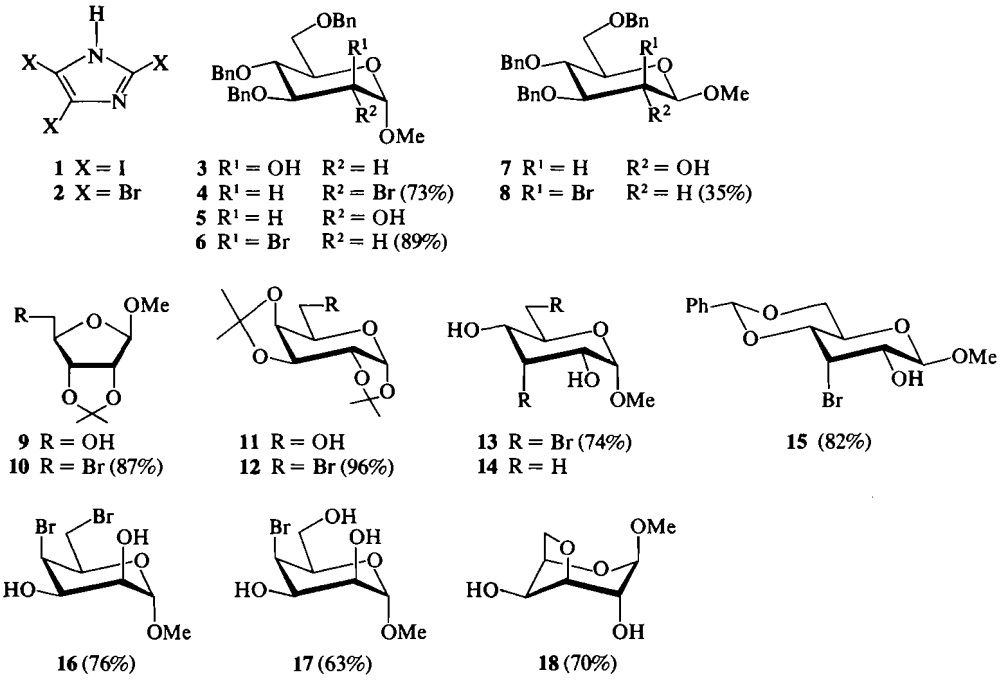
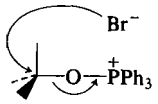


SCHEME 1

obtained in a 78% yield. The bromination, however, yielded mainly olefin and only about 30% of 3-bromo-3-deoxy-1,2:5,6-di-*O*-isopropylidene-α-D-allofuranose. Nuclear magnetic resonance data were obtained showing the corresponding characteristic H-2 triplet previously observed for the corresponding iodide (6, 7), ^{1}H nmr (100 MHz, $CDCl_3$) δ: 4.70 (t, $J_{1,2} \sim J_{2,3} \sim 3.7$ Hz, H-2). We find the ease by which bromination in the 2-position occurs particularly significant. A plausible mechanism for the product-forming reaction in these substitutions could be of a "push–pull" type:



Reactions of Methyl Hexopyranosides

Dibromination of methyl α-D-glucopyranoside produced the dibromide **13**. The *allo* configuration was established by ^{1}H nmr spin decoupling experiments. Catalytic hydrogenation yielded methyl α-paratoside **14** (8). This constitutes an excellent route to **14** from methyl α-D-glucopyranoside.

The factors determining the substitution pattern in **13** are not obvious. Jennings and Jones (9) have shown that methyl α-D-glucopyranoside reacts with sulfuryl chloride in pyridine–chloroform to give methyl 4,6-dichloro-4,6-dideoxy-α-D-galactopyranoside 2,3-di(chlorosulfate) in 84% yield. The corresponding β-anomer, however, gave the 3,6-dichloro-3,6-dideoxy as well as the 4,6-dichloro-4,6-dideoxy compound. Similar substitution patterns were observed with the methanesulfonyl chloride – dimethyl formamide reagent (10). The lack of reactivity at C-3 in methyl α-D-glucopyranoside in these chlorination reactions was ascribed to steric interference by a 1,3-diaxial interaction between the α-methoxyl group in the $^4C_1$ conformation and the incoming nucleophile. In the present bromination reactions this might be overcome by conformational inversion at the elevated temperatures through cyclic phosphonium diester formation bridging *O*-2 and *O*-4 in the $^1C_4$ conformation in the reaction intermediates. No such intermediates have, however, been isolated and this explanation is therefore highly tentative. In the product obtained (**13**) the *cis*-relationship between OH-2, Br-3, and OH-4 makes epoxide formation from **13** impossible, contributing to the high yield obtained.

Monobromination of methyl 4,6-*O*-benzylidene-α-D-glucopyranoside gave a mixture of products in low yields in agreement with the above considerations. The corresponding β-anomer, however, for which no 1,3-diaxial hindrance to 3-substitution in the $^4C_1$ conformation exists, yielded the bromodeoxy glycoside **15** in 82% yield. Bundle (11) chlorosulfated the same starting material to obtain crystalline methyl 4,6-*O*-benzylidene-β-D-glucopy-

ranoside 2,3-bis(chlorosulfate) in 77% yield. This, upon reaction with tetraethylammonium bromide in chloroform, gave **15** as the 2-(chlorosulfate) in 84% yield (11).

Dibromination of methyl α-D-mannopyranoside gave **16** in 76% yield. The structure of **16** was ascertained by ^{1}H nmr spin decoupling experiments performed with the derived 2,3-acetate of **16**. Monobromination of methyl 6-*O*-(triphenylmethyl)-α-D-mannopyranoside followed by detritylation similarly gave **17**. Jennings and Jones obtained only methyl 6-chloro-6-deoxy-α-D-mannopyranoside 2,3,4-tri(chlorosulfate) from the reaction of methyl α-D-mannopyranoside with sulfuryl chloride (9). This was attributed to a 1,3-diaxial interaction between OH-2 and incoming nucleophile approaching the 4-position (12) in the $^4C_1$ conformation rendering 4-substitution unlikely, similarly nucleophilic substitution at C-3 would be hindered by axial OCH_3. Forced reaction conditions towards nucleophilic displacement at C-4 have resulted in ring contraction and substitution at C-5, presumably via *O*-5 participation. Thus, methyl 6-deoxy-2,3-*O*-isopropylidene-α-D- and α-L-mannopyranoside carrying a sulfonyloxy substituent at C-4 upon treatment with azide anion gave methyl 5-azido-5,6-dideoxy-2,3-*O*-isopropylidene-α-D- and α-L-talofuranosides together with smaller amounts of the corresponding allofuranosides (13, 14). The reactivity at C-4 in the present brominations therefore seems surprising. A tentative explanation, analogous to the one given above for the results obtained with methyl α-D-glucopyranoside might be that methyl α-D-mannopyranoside forms a cyclic phosphonium diester across *O*-2 and *O*-3.

In contrast to the results described above, attempted dibrominations of methyl α-D- and β-D-galactopyranosides gave low yields of reaction products and no dibromodideoxy compounds. Attempted monobromination of methyl β-D-galactopyranoside gave a 70% yield of the 3,6-anhydrosugar **18** and this is a convenient route to **18**.

Experimental

General Methods

Melting points are corrected. Concentrations were performed at reduced pressure and a bath temperature below 40°C. Optical rotations were obtained using a Perkin-Elmer 241 polarimeter. The nmr spectra were recorded using a Jeol JNM FX 100 instrument. Chemical shifts are given in ppm downfield from tetramethylsilane. The nmr spectra which were recorded for all new compounds were invariably in agreement with the postulated structures. Only selected nmr data are given below. Thin layer chromatography was carried out using precoated silica gel plates (F_{250} Merck) and the spots were detected by charring with 8% aqueous sulfuric acid. All reactions were monitored by tlc. The yields given below are for purified products. Column chromatography was performed using silica gel 60 (0.040–0.063 mm, Merck).

Tribromoimidazole 2 (15)

Compound **2** was prepared by adding bromine (3 equivalents) to imidazole (4 equivalents) in water, filtering off the product, and recrystallizing from ethanol–water.

Work-up Procedure A (for water-insoluble products)

After cooling to room temperature the product was stirred for 5 min with an equal volume of saturated aqueous sodium hydrogen carbonate. Iodine was added portion-wise. When the organic phase remained iodine-coloured it was stirred for another 10 min. Aqueous sodium thiosulfate was added to remove the excess iodine. The mixture was then transferred to a separating funnel. Any material remaining in the reaction vessel was dissolved in the minimum amount of acetone and added to the main bulk of material. After diluting with toluene, the organic phase was extracted with water, dried ($MgSO_4$), filtered, and concentrated. In small-scale preparations the residue was subjected to column chromatography directly; in larger-scale preparations it was found to be advantageous to precipitate triphenylphosphine oxide with diethyl ether, filtering and concentrating before proceeding to purification by means of column chromatography (toluene – ethyl acetate 4:1).

Work-up Procedure B (for products soluble in both water and organic solvents)

The procedure was the same as that described above until after the transfer of the product to a separating funnel. The organic phase was then separated and the aqueous phase was extracted four times with dichloromethane. The combined organic phases were dried ($MgSO_4$), concentrated, and then subjected to column chromatography (toluene – ethyl acetate 1:1).

Reaction Conditions

The conditions used in individual preparations are described below. The reaction is normally completed in a few hours at elevated temperatures and results in a high-density *liquid phase* immiscible with toluene. If a hard precipitate is formed, a few molar equivalents of imidazole should be added to the reaction mixture.

Methyl 3,4,6-Tri-O-benzyl-2-bromo-2-deoxy-α-D-glucopyranoside (4)

A mixture of **3** (16) (0.30 g, 0.64 mmol), triphenylphosphine (0.93 g, 3.54 mmol), tribromoimidazole (0.54 g, 1.77 mmol), and imidazole (0.12 g, 1.77 mmol) in toluene (50 mL) was stirred for 1 h at 80°C and then under reflux at a bath temperature of 120°C overnight. Work-up (procedure A) yielded **4** (0.25 g, 73%), $[\alpha]_D^{22}$ +85° (*c* 1.0, $CHCl_3$); ^{13}C nmr (25 MHz, $CDCl_3$) δ: 51.16 (C-2), 55.74 (OCH_3), 68.38 (C-6), 99.77 (C-1). *Anal.* calcd. for $C_{28}H_{31}O_5Br$: C 63.8, H 5.92, Br 15.2; found: C 63.9, H 5.99, Br 15.3.

Methyl 3,4,6-Tri-O-benzyl-2-bromo-2-deoxy-α-D-mannopyranoside (6)

A mixture of **5** (17) (0.37 g, 0.80 mmol), triphenylphosphine (0.92 g, 3.51 mmol), **2** (0.54 g, 1.77 mmol), and imidazole (0.12 g, 1.76 mmol) in toluene (35 mL) was stirred under reflux at a bath temperature of 120°C for 6 h. Work-up (procedure A) yielded **6** (0.39 g, 89%), $[\alpha]_D^{22}$ +21° (*c* 1.0, $CHCl_3$); ^{13}C nmr (25 MHz, $CDCl_3$) δ: 51.38 (C-2), 55.26 (OCH_3), 69.02 (C-6), 101.16 (C-1). *Anal.* calcd. for $C_{28}H_{31}O_5Br$: C 63.8, H 5.92, Br 15.2; found: C 63.7, H 5.84, Br 15.2.

Methyl 3,4,6-Tri-O-benzyl-2-bromo-2-deoxy-β-D-mannopyranoside (8)

A mixture of **7** (17) (0.25 g, 0.54 mmol), triphenylphosphine

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

(0.565 g, 2.15 mmol), **2** (0.328 g, 1.08 mmol), and imidazole (0.148 g, 2.15 mmol) in toluene (25 mL) was stirred under reflux at a bath temperature of 120°C for 5 h. Work-up (procedure A) yielded **8** (0.10 g, 35%), $[\alpha]_D^{22}$ −43° (*c* 1.25, $CHCl_3$); ^{13}C nmr (25 MHz, $CDCl_3$) δ: 53.6 (C-2), 57.0 (OCH_3), 99.2 (C-1). Due to instability a satisfactory analysis could not be obtained for this compound.

*Methyl 5-Bromo-5-deoxy-2,3-*O*-isopropylidene-β-*D*-ribofuranoside (10)*

A mixture of **9** (18) (0.50 g, 2.45 mmol), triphenylphosphine (1.28 g, 4.88 mmol), **2** (0.91 g, 2.98 mmol), and imidazole (0.20 g, 2.98 mmol) in toluene (50 mL) was stirred for 1 h at 70°C and then for 2 h at 90°C. Work-up (procedure A) yielded **10** (0.57 g, 87%), $[\alpha]_D^{22}$ −79° (*c* 1.0, $CHCl_3$) (lit. (19) $[\alpha]_D^{25}$ −80° (*c* 2.61, $CHCl_3$)). The ^1H nmr shifts and coupling constants were in agreement with those published (19).

*6-Bromo-6-deoxy-1,2:3,4-di-*O*-isopropylidene-α-*D*-galactopyranose (12)*

A mixture of **11** (20) (1.00 g, 3.84 mmol), triphenylphosphine (2.02 g, 7.70 mmol), **2** (1.17 g, 3.84 mmol), and imidazole (0.26 g, 3.82 mmol) in toluene (50 mL) was stirred for 1 h at 70°C and then for 2 h at 95°C. Additional tribromoimidazole (0.58 g, 1.90 mmol) was added and the mixture was stirred for 2 h at 95°C. Work-up (procedure A) yielded **12** (1.19 g, 96%), $[\alpha]_D^{22}$ −47° (*c* 1.0, $CHCl_3$) (lit. (11) $[\alpha]_D$ −58.9° (*c* 1.15, $CHCl_3$)); ^1H nmr (100 MHz, $CDCl_3$) δ: 1.35 (2 × s, 6H), 1.44 (s, 3H), 1.54 (s, 3H, isopropylidene H), 3.46 (dd, 2H, H-6, H-6′), 4.10 (dt, H-5), 4.28–4.42 (m, H-2, H-4), 4.64 (dd, 1H, H-3), 5.54 (d, 1H, H-1), $J_{1,2}$ = 5.2 Hz, $J_{2,3}$ = 7.8 Hz, $J_{3,4}$ = 2.4 Hz, $J_{4,5}$ = 2.0 Hz, $J_{5,6}$ = 3.7 Hz, $J_{5,6}$ = 4.1 Hz.

*Methyl 3,6-Dibromo-3,6-dideoxy-α-*D*-allopyranoside (13)*

A mixture of methyl α-D-glucopyranoside (0.50 g, 2.57 mmol, finely ground), **2** (1.57 g, 5.15 mmol), and triphenylphosphine (2.70 g, 10.3 mmol) in toluene (50 mL) was stirred for 1 h at 75°C and then at a bath temperature of 110°C for 4 h. Work-up (procedure B) yielded **13** (0.613 g, 74%), $[\alpha]_D^{22}$ +86° (*c* 1.0, $CHCl_3$). Material crystallized from ethanol decomposed at 150°C; ^{13}C nmr (25 MHz, $CDCl_3$) δ: 32.8 (C-6), 56.0 (OCH_3), 62.6 (C-3), 98.8 (C-1). *Anal.* calcd. for $C_7H_{12}O_4Br_2$: C 26.3, H 3.78, Br 50.0; found: C 26.3, H 3.64, Br 50.0. For the 2,4-di-*O*-acetyl derivative of **13**, ^1H nmr (100 MHz, $CDCl_3$) δ: 4.73 (dd, 1H, H-4), $J_{3,4}$ = 3.7 Hz, $J_{4,5}$ = 9.5 Hz.

*Methyl 3,6-Dideoxy-α-*D*-ribo-hexopyranoside (14)*

Catalytic hydrogenation of **13** (0.10 g, 0.31 mmol) in ethanol (10 mL) containing triethylamine (1 mL) was hydrogenated over 10% palladium on carbon at atmospheric pressure for 24 h. The mixture was filtered (Celite), concentrated, diluted with water, passed through an anion exchanger, and concentrated to yield **14** (0.043 g, 85%), $[\alpha]_D^{22}$ +169° (*c* 1.0, $CHCl_3$) (lit. (8) $[\alpha]_{578}^{33}$ +170° ($CHCl_3$)). A ^{13}C nmr spectrum of **14** was superimposable on that given by an authentic sample (8).

*Methyl 4,6-*O*-Benzylidene-3-bromo-3-deoxy-β-*D*-allopyranoside (15)*

A mixture of methyl 4,6-*O*-benzylidene-β-D-glucopyranoside (0.25 g, 0.886 mmol), **2** (0.81, 2.66 mmol), triphenylphosphine (1.39 g, 5.32 mmol), and imidazole (0.181 g, 2.66 mmol) in toluene (25 mL) was stirred for 4 h at 75°C. Work-up (procedure B, but using isooctane – ethyl acetate 1:2 for column chromatography instead of toluene – ethyl acetate) yielded **15** (0.25 g, 82%), which crystallized from ethyl acetate – light petroleum, mp 118–120°C; $[\alpha]_D^{22}$ −9° (*c* 1.5, $CHCL_3$) (lit. (11) mp 97–99°C, $[\alpha]_D^{22}$ −23° ($CHCl_3$)). The ^1H nmr data corresponded to those published (11).

*Methyl 4,6-Dibromo-4,6-dideoxy-α-*D*-talopyranoside (16)*

A mixture of methyl α-D-mannopyranoside (0.50 g, 2.57 mmol, finely ground), **2** (1.57 g, 5.15 mmol), and triphenylphosphine (2.70 g, 10.3 mmol) in toluene (50 mL) was reacted and worked up as described for **13**, to yield **16** (0.624 g, 76%) which crystallized from toluene, mp 106–110°C; $[\alpha]_D^{22}$ +77° (*c* 1.0, $CHCl_3$); ^{13}C nmr (25 MHz, $CDCl_3$) δ: 32.4 (C-6), 55.6 (OCH_3), 57.6 (C-4), 65.1, 68.8, and 70.5 (C-2, C-3, and C-5), 102.0 (C-1). *Anal.* calcd. for $C_7H_{12}O_4Br_2$: C 26.3, H 3.78, Br 50.0; found: C 26.2, H 3.63, Br 50.1. Compound **16** was acetylated to give methyl 2,6-di-*O*-acetyl-4,6-dibromo-4,6-dideoxy-α-D-talopyranoside which had ^1H nmr (100 MHz, $CDCl_3$) δ: 2.10 (s, 3H, CH_3CO), 2.15 (s, 3H, CH_3CO), 3.46 (s, 3H, OCH_3), 3.58 (dd, 2H, H-6, H-6′), 4.13 (dt, 1H, H-5), 4.53 (dd, 1H, H-4), 4.77 (d, 1H, H-1), 5.10 (m, 1H, H-2), 5.26 (dd, 1H, H-3), $J_{1,2}$ = 1.3 Hz, $J_{2,3}$ = 4.1 Hz, $J_{3,4}$ = 4.2 Hz, $J_{4,5}$ = 2.0 Hz.

*Methyl 4-Bromo-4-deoxy-α-*D*-talopyranoside (17)*

A mixture of methyl 6-*O*-(triphenylmethyl)-α-D-mannopyranoside (0.40 g, 0.92 mmol), **2** (0.59 g, 1.83 mmol), triphenylphosphine (0.48 g, 1.83 mmol), and imidazole (0.124 g, 1.82 mmol) in toluene (40 mL) was stirred for 1 h at 80°C and then for 4 h at 100°C. Work-up (procedure B) excluding column chromatography yielded presumed methyl 4-bromo-4-deoxy-6-*O*-(triphenylmethyl)-α-D-talopyranoside which was detritylated by treatment with 80% aqueous acetic acid for 4 h at 65°C. The reaction mixture was concentrated and partitioned between water and dichloromethane. The aqueous phase was concentrated and the product purified by column chromatography (water-saturated ethyl acetate) to yield **17** (0.15 g, 63%) which crystallized from ethyl acetate – light petroleum, mp 105°C; $[\alpha]_D^{22}$ +102° (*c* 1.0, H_2O). *Anal.* calcd. for $C_7H_{13}O_5Br$: C 32.7, H 5.10, Br 31.1; found: C 32.7, H 4.99, Br 31.0. Compound **17** was acetylated to give methyl 2,3,6-tri-*O*-acetyl-4-bromo-4-deoxy-α-D-talopyranoside; ^1H nmr (100 MHz, $CDCl_3$) δ: 2.06 (s, 3H, CH_3CO), 2.08 (s, 3H, CH_3CO), 2.12 (s, CH_3CO), 3.38 (s, OCH_3), 4.08–4.32 (m, 3H, H-5, H-6, H-6′), 4.40 (d, 1H, H-4), 4.75 (s, 1H, H-1), 5.12 (dd, 1H, H-2), 5.23 (t, 1H, H-3), $J_{1,2}$ = 0.2 Hz, $J_{2,3}$ = 4 Hz, $J_{3,4}$ = 4 Hz, $J_{4,5} \sim 0$ Hz; ^{13}C nmr (25 MHz, $CDCl_3$) δ: 20.8 (CH_3CO), 47.3 (C-4), 55.2 (OCH_3), 65.4, 66.0, 66.5, 67.1 (C-2, C-3, C-5, C-6), 99.4 (C-1), 169.9 (CH_3CO).

*Methyl 3,6-Anhydro-β-*D*-galactopyranoside (18)*

A mixture of methyl β-D-galactopyranoside (0.50 g, 2.57 mmol, finely ground), **2** (1.15 g, 3.79 mmol), triphenylphosphine (1.99 g, 7.57 mmol), and imidazole (0.860 g, 12.6 mmol) in toluene (50 mL) was stirred at 100°C for 2.5 h. The reaction mixture was extracted with water. The combined aqueous extracts were concentrated and the residue acetylated. The product was purified by column chromatography (toluene – ethyl acetate 2:1) to yield **18** as the diacetate (0.438 g, 70%). Deacetylation and crystallization from ethyl acetate yielded **18**, mp 117°C; $[\alpha]_D^{22}$ −112° (*c* 1.0, H_2O) (lit. (21) mp 119°C, $[\alpha]_D^{18}$ −115° (H_2O)).

Synthesis of some bicyclo[2.2.2]oct-5-en-2-ones and bicyclo[2.2.2]octan-2-ones. Rearrangements accompanying oxidative decarboxylation with lead tetraacetate

PETER YATES AND GORDON E. LANGFORD[1]

Lash Miller Chemical Laboratories, University of Toronto, Toronto, Ont., Canada M5S 1A1

Received June 25, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

PETER YATES and GORDON E. LANGFORD. Can. J. Chem. **59**, 344 (1981).

1-Methoxy-2-methyl-1,4-cyclohexadiene (**3**), 2-methoxy-1-methyl-1,3-cyclohexadiene (**2**), and 2-methoxy-1,5,5-trimethyl-1,3-cyclohexadiene (**14**) on heating with maleic anhydride give 1-methoxy-*endo*-7-methylbicyclo[2.2.2]oct-5-ene-*syn*-2,3-dicarboxylic acid anhydride (**7**) and its 6-methoxy-1-methyl (**16***a*) and 6-methoxy-1,8,8-trimethyl (**16***b*) analogues, respectively. On hydrolysis **16***a* and **16***b* give the corresponding keto dicarboxylic acids, **18***a* and **18***b*, via keto anhydrides **17***a* and **17***b*. Treatment of **18***b* with lead tetraacetate gives 1,8,8-trimethylbicyclo[2.2.2]oct-5-en-2-one (**19**) together with products in which rearrangement to a bicyclo[3.2.1]octane system has occurred. Treatment of **17***b* with bis(triphenylphosphino)nickel dicarbonyl gives only **19**; similar treatment of **17***a* gives 1-methylbicyclo[2.2.2]oct-5-en-2-one (**1**). Reaction of bicyclo[2.2.2]octane-2,3-dione (**27**) with methyllithium gives 3-hydroxy-3-methylbicyclo[2.2.2]octan-2-one (**28**), its dimer **31**, and a diol **30**. Treatment of 5-*exo*-acetoxy-1, 5-*endo*-dimethyl-6-oxobicyclo[2.2.2]octane-*anti*-2,3-dicarboxylic acid (**37**) with lead tetraacetate gives 3-*endo*-acetoxy-1,3-*exo*-dimethylbicyclo[2.2.2]oct-5-en-2-one (**33**) as a minor product; the major product is derived by rearrangement to a bicyclo[3.2.1]octane system. It is proposed that this rearrangement, like that of **18***b*, involves oxidative decarboxylation of a single carboxylic acid group to give a carbonium ion that undergoes rearrangement via a 1,2-acyl migration.

PETER YATES et GORDON E. LANGFORD. Can. J. Chem. **59**, 344 (1981).

Par chauffage avec l'anhydride maléique, le méthoxy-1 méthyl-2 cyclohexadiène-1,4 (**3**), le méthoxy-2 méthyl-1 cyclohexadiène-1,3 (**2**) et le méthoxy-2 triméthyl-1,5,5 cyclohexadiène-1,3 (**14**) donnent respectivement l'anhydride de l'acide méthoxy-1 méthyl-7-*endo* bicyclo[2.2.2] octène-5 dicarboxylique-2,3-*syn* (**7**) et ses analogues méthoxy-6 méthyl-1 (**16***a*) et méthoxy-6 triméthyl-1,8,8 (**16***b*). Par hydrolyse, les composés **16***a* et **16***b* donnent les acides céto dicarboxyliques **18***a* et **18***b* correspondants par l'intermédiaire des anhydrides cétoniques **17***a* et **17***b*. Le composé **18***b* réagit avec le tétraacétate de plomb et donne la triméthyl-1,8,8 bicyclo[2.2.2] octène-5 one-2 (**19**) aux côtés de produits qui se sont transposés en des dérivés du bicyclo[3.2.1]octane. La réaction du composé **17***b* avec le bis(triphénylphosphino) nickel dicarbonyle donne seulement le dérivé **19**; par une réaction analogue, **17***a* fournit le méthyl-1 bicyclo[2.2.2] octène-5 one-2 (**1**). La réaction de la bicyclo[2.2.2] octadione-2,3 (**27**) avec le méthylithium fournit l'hydroxy-3 méthyl-3 bicyclo[2.2.2] octanone-2 (**28**), son dimère **31** et un diol **30**. L'acide acétoxy-5-*exo* diméthyl-1,5-*endo* oxo-6 bicyclo[2.2.2] octanedicarboxylique-2,3-*anti* (**37**) réagit avec le tétraacétate de plomb pour fournir l'acétoxy-3-*endo* diméthyl-1,3-*exo* bicyclo[2.2.2] octène-5 one-2 (**33**) comme produit secondaire; le produit principal provient d'une transposition en un système bicyclo[3.2.1]octane. On suggère que cette transposition, comme celle du composé **18***b*, implique une décarboxylation oxydante d'un seul groupement carboxyle conduisant à un carbocation qui subit une transposition par l'intermédiaire d'une migration acyle-1,2.

[Traduit par le journal]

During the course of ^{13}C nmr spectroscopic studies (1) and other work (2, 3) on bicyclo[2.2.2]oct-5-en-2-ones and bicyclo[2.2.2]octan-2-ones we had occasion to synthesize several members of these series. We report this work here because we consider that it includes several features of intrinsic interest.

1-Methylbicyclo[2.2.2]oct-5-en-2-one and Related Compounds

1-Methylbicyclo[2.2.2]oct-5-en-2-one (**1**) was first obtained by routes *A* and *B* in Scheme 1 (4). In each case **1** was formed as a component of a complex mixture of products and it was isolated by preparative gas–liquid chromatography. Subsequently **1** was prepared in good yield by route *C* in Scheme 1 (5). Although the "ortho effect" greatly favours the desired regiochemistry of the Diels–Alder reaction in route *C*, alkyl substitution is rarely found to lead to regiospecific addition (6), and indeed it was observed (4) that the product mixture from route *A* contained a small amount of 4-methylbicyclo[2.2.2]oct-5-en-2-one, the regioisomer of **1**. We therefore thought it worthwhile to investigate an alternative route for the preparation of the latter, and chose 1-methyl-2-methoxy-1,3-hexadiene (**2**) as the diene component of a Diels–Alder reaction pathway to the desired product.

It has been reported (7) that Birch reduction of *o*-methylanisole gives a mixture of the 1,4-dienes **3** and **4**, which is converted on treatment with potassium amide in liquid ammonia to a mixture of the 1,3-dienes **2** and **5**, in which the former is the major component; the structures of the conjugated dienes were inferred from the Diels–Alder adducts that they formed. However, although the Birch reduc-

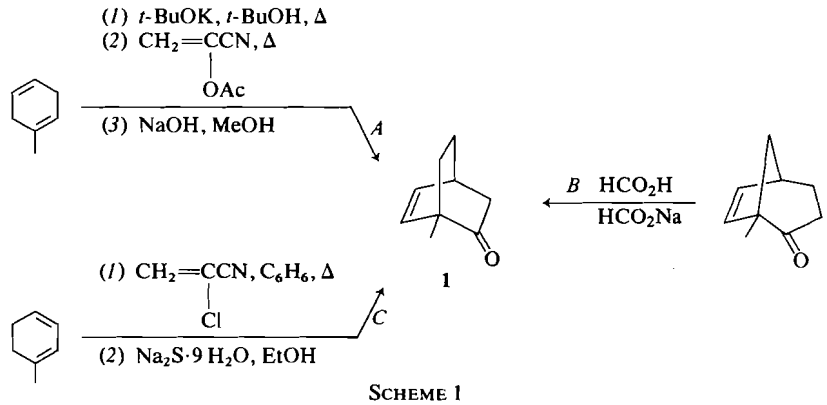
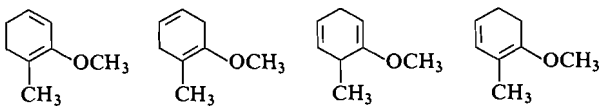


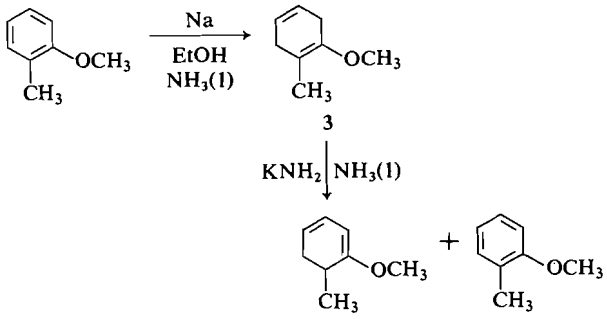
SCHEME 1

tion gave the expected unconjugated diene **3**, identified by ^1H and ^{13}C nmr spectroscopy, treatment of this with potassium amide in liquid ammonia gave in our hands a conjugated diene as the major product together with a substantial amount of the rearomatization product, *o*-methylanisole



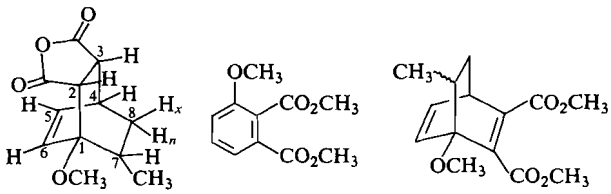
2 **3** **4** **5**

(Scheme 2). The ^1H nmr spectrum of the crude reaction product (signals at δ 1.03 (d, $J = 7$ Hz, 3H), 3.57 (s, 3H), 4.88 (d, $J = 6$ Hz, 1H), 5.2–5.5 (m, 1H), 5.7–6.0 (m, 1H)) clearly established that the conjugated diene has structure **6** and showed, furthermore, none of the signals observed for an authentic sample of **2** (*vide infra*). The preferential formation of **6** from **3** can be interpreted in terms of thermodynamic control of the reaction, in which catalytic quantities of base are used. Of the conjugated dienes that can be formed **6** is expected to be the most stable because an oxygen lone pair of electrons is in linear, rather than cross, conjugation with the conjugated diene system, and steric interaction between the methoxyl and methyl groups is minimized.



SCHEME 2

The product of the Birch reduction was further characterized by the preparation of Diels–Alder adducts of its conjugated isomer. Because of the instability of the conjugated diene and the difficulty of preparing it free from *o*-methylanisole, the isomerization and addition were performed simply by heating **3** in the presence of the dienophile (8).



7 **8** **9**

Reaction with maleic anhydride at 140°C gave the adduct **7**,[2] whose gross structure is assigned on the basis of its ir and ^1H and ^{13}C nmr spectra (Table 1). Although no first order analysis of the coupling constants was possible in the ^1H nmr spectrum in deuteriochloroform, several coupling constants could be derived from the spectrum in hexadeuterioacetone. In particular H(3) is observed to be vicinally coupled to H(2) ($J = 9$ Hz) and H(4) ($J = 3$ Hz) but has no long-range coupling. This leads to the assignment of the endo stereochemistry of the anhydride ring with respect to the double bond as in **7**, since if the anhydride ring were exo a longe-range "W" coupling of ~2 Hz would be expected between H(3) and *endo*-H(8) (9). The methyl group is assigned the endo configuration as in **7** because it and one of the methylene protons (*endo*-H(8)) are strongly shielded (10); the exo protons at C(7) and C(8) are both ~1 ppm less shielded than *endo*-H(8).

[2]All chiral compounds were obtained as racemates and their structural representations do not imply absolute configurations.

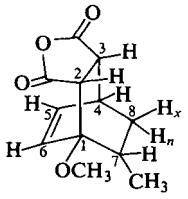
TABLE 1. ^1H and ^{13}C nuclear magnetic resonance spectra of compound **7**[a,b]



7

	$^H\delta(CDCl_3)$	$^H\delta(CD_3COCD_3)$		$^C\delta(CDCl_3)$
H(2)	2.9–3.6 (m)	3.75 (d, 9 Hz)	C(1)	80.3
H(3)		3.48 (dd, 9, 3 Hz)	C(2)	46.3
H(4)		2.8–3.15 (m)	C(3)	44.2
H(5)	5.9–6.4 (m)	6.25 (dd, 9, 6 Hz)	C(4)	31.2*
H(6)		6.00 (br d, 9, ~2 Hz)	C(5)	130.3
H(7)	1.8–2.4 (m)	1.9–2.2 (m)	C(6)	134.5
H(8x)		2.2–2.5 (m)	C(7)	31.8*
H(8n)	0.8–1.3 (m)	0.8–1.2 (m)	C(8)	33.9
$CH_3(7)$	0.83 (d, 7 Hz)	0.77 (d, 7 Hz)	$CH_3(7)$	17.4
CH_3O	3.48 (s)	3.47 (s)	CH_3O	49.8
			CO	169.0, 172.3

[a] The intensities of the proton signals are in accord with the assignments; signal multiplicities and coupling constants are given in parentheses.
[b] The multiplicities of the ^{13}C signals in the single frequency off-resonance decoupled spectrum are in accord with assignments; the individual assignments of ^{13}C signals marked with asterisks are uncertain.

This assignment is in accord with the similarity of the chemical shifts of H(2) and H(3); if the methyl group had the exo configuration, it would be anticipated that it would exert a deshielding steric repulsion effect on H(2) (11).

Reaction of **3** with dimethyl acetylenedicarboxylate at 180–195°C gave dimethyl 3-methoxyphthalate (**8**), which must be formed by loss of propene from the adduct **9** (Alder–Rickert reaction (12)). Thus in the case of the thermal as in the base-catalyzed isomerization of **3** the conjugated diene formed is **6** not **2**.

The alternative route to **2** from 3-methyl-2-cyclohexenone (**10**) shown in Scheme 3 was therefore adopted. This is based on the synthesis of the closely related diene **14** from isophorone (**10***b*) (13). The latter synthesis was first repeated to determine optimum conditions for each step and to obtain **14** as a precursor to the corresponding bicyclo[2.2.2]octenone. It was found that the compounds in the monomethyl series are much more reactive than their trimethyl analogues and that reaction conditions had to be controlled carefully. Whereas **10***b* is epoxidized smoothly at 15–20°C and is unreactive at lower temperatures, the yield of epoxide **11***a* from **10***a* increased from 35 to 92% when the reaction temperature was lowered to 0–5°C; this is considered to be due to hydrolytic

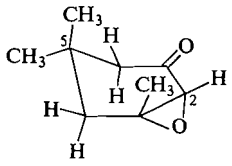
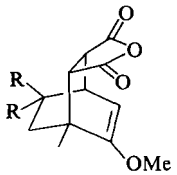
opening of the epoxide ring of **11***a* at the higher temperature. The reaction temperature is also critical for the conversion of **11***a* to **12***a*. Curiously, although **11***a* reacts rapidly with methanolic sodium methoxide at 0–5°C, the best yields of **12***a* were obtained when the epoxide was added dropwise to boiling methanolic sodium methoxide; competing reactions leading to polymer formation appear to predominate at low temperatures. The corresponding reaction occurs much more slowly in the case of **11***b*, analysis of whose ^{1}H nmr spectrum shows it to have the conformation **15** in which the axial methyl group at C(5) hinders rearside attack by methoxide on the epoxide at C(2). In both series formation of the tosylhydrazones **13***a* and **13***b* and conversion of these to the dienes **2** and **14** could be effected in high yield under appropriate conditions (see Experimental) and the overall yields of the dienes from **10***a* and **10***b*, respectively, were ~50 and 63%.

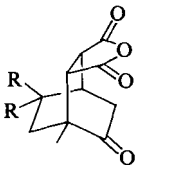


15

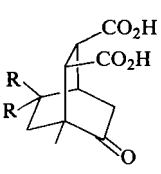
Diene **2** was identified by its ^{1}H nmr spectrum and the relationship of this spectrum to that of **14** (Table 2). Both dienes decomposed on standing and it was found to be best to convert them immediately to their adducts with maleic anhydride. Gross structures corresponding to **16***a* and **16***b* are assigned to these adducts based on their ir, ^{1}H nmr (Table 3), and ^{13}C nmr (1) spectra. Acid-catalyzed hydrolysis of **16***a* and **16***b* with one equivalent of water gave the keto anhydrides **17***a* and **17***b*, respectively; in the presence of excess water the keto dicarboxylic acids **18***a* and **18***b*, respectively, were formed. The stereochemistry of **17***b*, and thus of **16***b* and **18***b*, is assigned on the basis of an analysis of its



16*a* R = H
16*b* R = Me



17*a* R = H
17*b* R = Me



18*a* R = H
18*b* R = Me

^{1}H nmr spectrum (Table 3). The long-range "W" coupling of ~2 Hz observed between H(3) and H(5n) is only possible with the stereochemistry shown (9), demonstrating that maleic anhydride added in the normal endo fashion. Corroboration for this stereochemical assignment derives from the large downfield shifts of H(3) and H(5n) relative to H(2) and H(5x), respectively, which can be attributed to the deshielding steric compression effects of the *gem*-dimethyl groups (11). Independent evidence for the stereochemistry of **16***b* is provided by the absence of long-range coupling between H(2) and H(7n), since in the exo stereoisomer the corresponding protons would have a "W" relationship. Although the spectrum of the keto anhydride **17***a* could not be analyzed in detail, the absence of long-range coupling in the spectrum of **16***a* between H(2) and H(7n) and between H(3) and H(8n) demonstrates that this, and thus **17***a* and **18***a*, have the endo stereochemistry shown.

The keto acid **18***b* has been prepared previously by hydrolysis of the Diels–Alder adduct of the enol acetate of **10***b* and maleic anhydride and converted to 1,8,8-trimethylbicyclo[2.2.2]oct-5-en-2-one (**19**) in undisclosed yield by oxidative bisdecarboxylation with lead tetraacetate in pyridine (14). In our hands such treatment of **18***b* gave a mixture containing **19** (30–40%) and three other compounds that are considered to be the rearrangement products **20–22** (Scheme 4). Compound **19** was identified by its ir, ^{1}H nmr (Table 4), and ^{13}C nmr (1) spectra. Compound **20** was obtained as a crystalline solid, but **21** and **22** were not separated from each other. The structures **20–22** are assigned on the basis of spectroscopic (see Experimental) and mechanistic considerations (Scheme 5), and although they have not been established rigorously they gain authentication from their relationship to the structure of the rearrangement product formed in a related reaction (*vide infra*).

Because of these complications associated with the preparation of **19** by reaction of **18***b* with lead

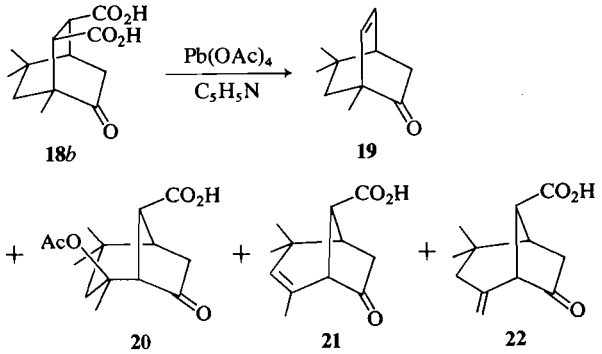
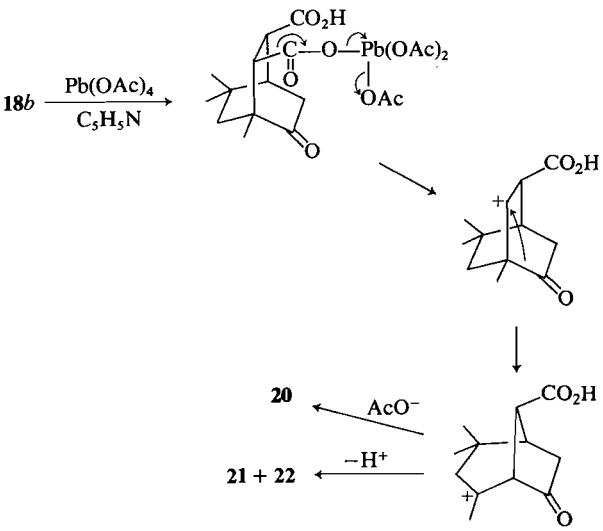
tetraacetate, its preparation by treatment of the keto anhydride **17***b* with bis(triphenylphosphino)nickel dicarbonyl[3] was investigated (15). This procedure gave **19** in essentially quantitative yield and the formation of rearrangement products was not observed. It is of interest that application of the procedure to the enol ether **16***b* gave only *o*-methylanisole in addition to recovered **16***b*. The preparation of the original target molecule, 1-methylbicyclo[2.2.2]oct-5-en-2-one (**1**) from the keto anhydride **17***a* was also accomplished by this method (Scheme 6). The weight and ^{1}H nmr spectra of the crude product indicated that again the bicyclo[2.2.2]octenone was formed in essentially quantitative yield; however, losses during chromatography attributable to its very high volatility reduced the yield of isolated product to 52%. Its



SCHEME 4

[3]We thank Professor D. N. Butler, York University, for a generous supply of this compound.



SCHEME 5

structure was established by its ir, ^{1}H nmr (Table 4), and ^{13}C nmr (1) spectra.

Catalytic hydrogenation of **1** and **19** gave the corresponding bicyclo[2.2.2]octanones **23** and **24**, respectively (Scheme 6). The former has been obtained previously by other routes (16, 17). Their ir, ^{1}H nmr (Table 4), and ^{13}C nmr (1) spectra are in accord with expectation.

Compounds Related to 3-Hydroxybicyclo[2.2.2]-octan-2-one

3-Hydroxybicyclo[2.2.2]octan-2-one (**25**) (18) and its *O*-acetyl derivative (**26**) (19) have been prepared previously from bicyclo[2.2.2]octane-2,3-dione

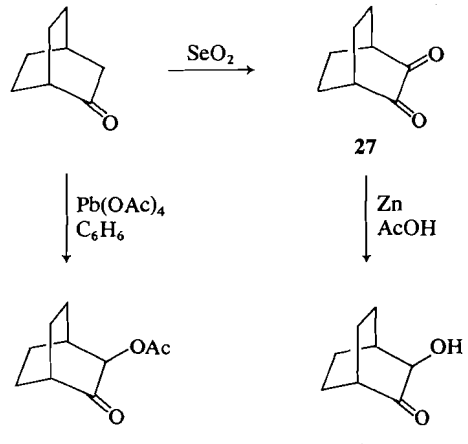
SCHEME 6

(**27**) and bicyclo[2.2.2]octanone by the routes shown in Scheme 7. We wished to prepare the corresponding 3-methyl compound, 3-hydroxy-3-methylbicyclo[2.2.2]octan-2-one (**28**). Preparation of **28** was approached by reaction of methyllithium with dione **27**. Slow dropwise addition of methyllithium to **27** in ether led to decolorization after the addition of 0.5 equivalent. Work-up of the reaction mixture at this stage gave a product $C_{17}H_{24}O_4$, whose spectra showed it to be one of the stereoisomers **29**, derived by reaction of **28** with unconsumed **27** (Scheme 8).[4] When a slight excess (~1.1 equiv.) of methyllithium was added to **27** a complex product mixture was obtained from which three major components were isolated by chromatography. These were identified spectroscopically as the desired ketol **28**, a diol of type **30**,[5] and a dimer **31** of **28**. The facile formation of dimers from α-ketols is well known (20); in the present case the dimer may have a structure of type **31***a* or **31***b*. It seems likely that dimers of the latter type will have, as a result of equilibration, *cis* fusions of the dioxane ring with the bicyclo[2.2.2]octane rings. In this event they will have a symmetry element absent in dimers of type **31***a*. Since the ^{13}C nmr spectrum of the dimer showed sixteen discrete signals



27

26

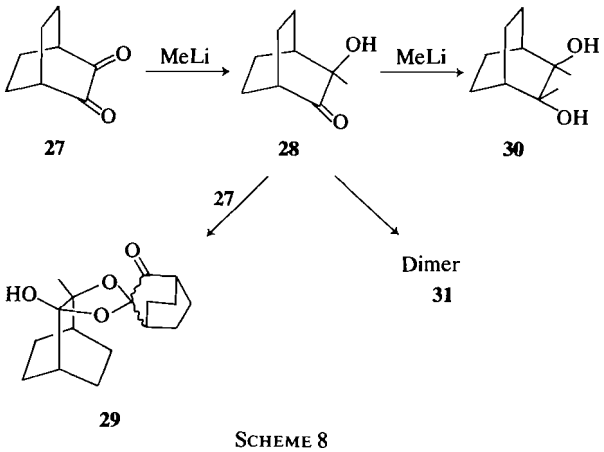
25

SCHEME 7

[4]It is probable that both stereoisomers were formed, but only one was isolated on crystallization of the crude reaction product.

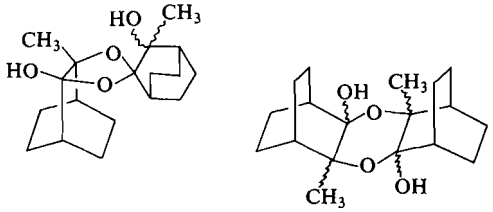
[5]In an earlier investigation,[6] two such diols were isolated; the diol isolated in the present work corresponds to the major product isolated previously, which was tentatively assigned structure **30** on the basis of ir spectroscopic comparison.

[6]P. Yates and K. E. Stevens, unpublished results.



SCHEME 8

(including two methyl signals), it is concluded that the structure of the dimer isolated is of type **31***a*.



31*a* **31***b*

The final synthetic objectives in this work were the compounds **32–34**. These could be obtained from the known compounds **35** and **36** (19) by the routes shown in Scheme 9. However, in contrast to the cases of compounds **17***a* and **17***b*, the yields in the reactions of **35** and **36** with bis(triphenylphosphino)nickel dicarbonyl were abysmal (5–10%) and insufficient **32** and **33** could be isolated from these routes for full characterization. Interestingly, **32** was accompanied by 2,6-dimethylphenol, a plausible route for whose formation is shown in Scheme 10. Oxidative bisdecarboxylation with lead tetraacetate and pyridine of **37**, the dicarboxylic acid derived from mild hydrolysis of **36** also gave **33** in very low yield, but sufficient material was obtained for characterization of this and its hydrogenation product **34** (Table 5).

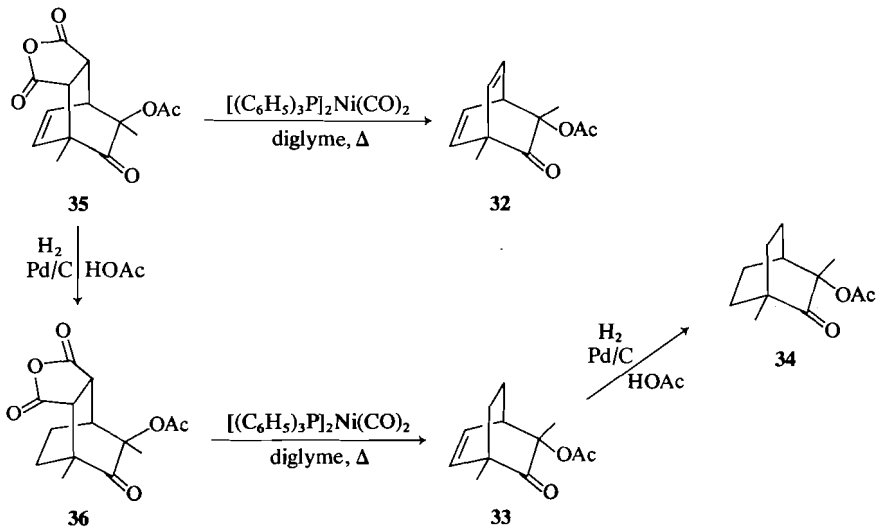
[a]See footnote *a* in Table 1.

The major product from the reaction of **37** with lead tetraacetate and pyridine was a compound $C_{13}H_{16}O_5$ that is assigned structure **38**; this undergoes ready hydrolysis of the acetate group to give **39**. These structural assignments are based on spectroscopic data (see Experimental). Compound **38** is thought to be formed as in Scheme 11. The rearrangement of the bicyclo[2.2.2]octane to a bicyclo[3.2.1]octane system in the course of this



SCHEME 9

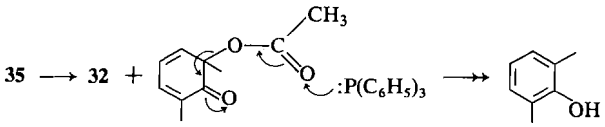


SCHEME 10

reaction and the analogous rearrangement when **18*b*** is treated with lead tetraacetate and pyridine (*vide supra*) is of considerable interest. Carbonium ions of type **40** have been previously implicated as intermediates in the oxidative bisdecarboxylation reaction (21), and the unusual competition between rearrangement and decarboxylation of such intermediates in the present cases is attributable to the high migratory aptitude of the acyl group and the formation of a tertiary carbonium ion. The final formation of a lactone from this ion in the case of **37**, but of products derived by deprotonation and attack of acetate ion in the case of **18*b***, reflects the difference in the stereochemical relationship between the carboxylic acid groups and the ketone group in the two series.

Experimental

Unless otherwise specified, melting points are uncorrected, ir spectra were recorded for $CHCl_3$ solutions, ^1H and ^{13}C nmr spectra were recorded for $CDCl_3$ solutions, and solutions in organic solvents were dried over anhydrous $MgSO_4$.

Birch Reduction of 2-Methylanisole. Formation of 1-Methoxy-2-methyl-1,4-cyclohexadiene (3)

2-Methylanisole was prepared by methylation of *o*-cresol with dimethyl sulfate (22). It was reduced by the method of Birch (7, 23) to the 1,4-diene **3**; ^1H nmr δ: 1.65 (br s, 3H), 2.6–2.9 (m, 4H), 3.54 (s, 3H), 5.6–5.8 (m, 2H); ^{13}C nmr δ: 145.6 (s), 124.6 (d), 123.7 (d), 111.4 (s), 55.9 (q), 33.0 (t), 26.2 (t), 14.9 (q).

Treatment of 3 with Potassium Amide. Formation of 1-Methoxy-6-methyl-1,3-cyclohexadiene (6) and o-Methylanisole

Liquid ammonia (~50 mL) was distilled into a 100-mL three-necked flask containing a polyethylene-covered magnetic stirring bar and fitted with a dry-ice condenser with a soda-lime guard tube. Potassium (0.17 g, 4.4 mg-atom) was added with stirring, forming a dark blue solution. After a few minutes, ferric nitrate nonahydrate (42 mg) was added and 10 min later more potassium (0.09 g, 2.3 mg-atom) was added. The solution was stirred for 40 min and then the 1,4-diene **3** (1.28 g, 10.3 mmol) was added dropwise. The mixture was stirred for a further 30 min and water (20 mL) was carefully added dropwise. The condenser was removed and stirring was continued for 2.5 h. The residue was extracted with dichloromethane (3 × 50 mL). The extracts were dried (K_2CO_3) and evaporated to give an oil whose ^1H nmr spectrum showed two major components, *o*-methylanisole (~30%) and **6** (~60%); ^1H nmr δ: 1.03 (d, J = 7 Hz, 3H), 3.57 (s, 3H), 4.88 (d, J = 6 Hz, 1H), 5.2–5.5 (m, 1H), 5.7–6.0 (m, 1H), a broad, unresolved absorption at δ 1.5–3.0 includes the signals of the other three aliphatic protons. Increased proportions of *o*-methylanisole were isolated with longer reaction times.

*Reaction of 3 with Maleic Anhydride. Formation of 1-Methoxy-7-*endo*-methylbicyclo[2.2.2]oct-5-ene-*syn*-2,3-dicarboxylic Acid Anhydride (7)*

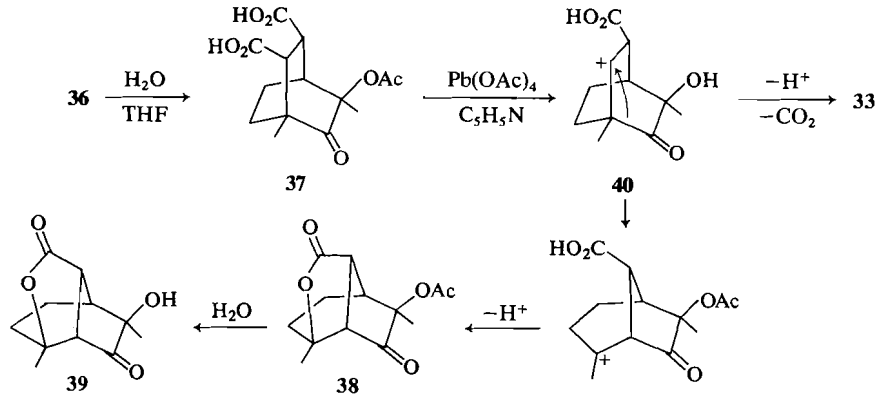
A sample of crude diene **3** (1.71 g, ~75% pure), obtained as above, and maleic anhydride (1.9 g) were stirred together. In a few minutes the mixture became warm and the anhydride dissolved, forming a clear red solution. The solution was heated under nitrogen in an oil bath at 140°C overnight and then volatile material was removed on a vacuum line starting at 20°C (10 Torr) and going to 65°C (0.05 Torr). The residue was a dark brown viscous oil (2.39 g). It was chromatographed on silica gel (60 g) with 2:1 hexanes – ethyl acetate and the major fraction (R_f 0.26) was recrystallized from chloroform–hexanes to give white crystalline **7**, mp 136–138°C; ir λ_{max}: 5.40 (w), 5.67 μm; ^1H and ^{13}C nmr: see Table 1; *m/e*: 180.0422 ((M − C_3H_6)$^+$ 180.0422). *Anal.* calcd. for $C_{12}H_{14}O_4$: C 64.85, H 6.35; found: C 64.55, H 6.43.

Reaction of 3 with Dimethyl Acetylenedicarboxylate. Formation of Dimethyl 3-Methoxyphthalate (8)

A sample of crude diene **3** (2.08 g, ~75% pure) obtained as above was heated with dimethyl acetylenedicarboxylate (2.38 g, ~33% excess) in an oil bath with stirring under reflux. The bath temperature was raised to 180°C over 30 min and then maintained at 180–195°C for 90 min. Distillation of the residue yielded crude **8** (1.86, ~66%), bp 135–142°C (0.9 Torr). A portion of the distillate was chromatographed on silica gel with 3:1 hexanes – ethyl acetate, and the material thus obtained was recrystallized from 95% ethanol to give pure, crystalline **8**, mp 75–76°C (lit. (24) mp 72–72.5°C, (7) mp 77–77.5°C); ir λ_{max}: 5.82 (br), 6.32 (m) μm; ^1H nmr δ: 3.85 (s, 3H), 3.88 (s, 3H), 3.95 (s, 3H), 7.0–7.7 (m, 3H); *m/e*: 224.0685 (M$^+$ 224.0685).

2-Methoxy-1,5,5-trimethyl-1,3-cyclohexadiene (14) (13)

Isophorone oxide (**11*b***) was prepared by treatment of isophorone with alkaline hydrogen peroxide in methanol (25).



SCHEME 11

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

A solution of **11***b* (36.0 g, 0.214 mol) in methanol (25 mL) was added dropwise with stirring to a solution of sodium (9.0 g, 0.39 g-atom) in methanol (175 mL) at room temperature under nitrogen. The mixture was boiled under reflux for 2 h, cooled, and poured into ice water (500 mL). After extraction with dichloromethane (4 × 150 mL) the organic phase was washed with saturated brine, dried, and evaporated to give a brown liquid. Distillation of the crude product yielded **12***b* (35.3 g, 90%) as a colorless liquid, bp 78–80°C (2.8 Torr); ^{1}H nmr δ: 1.06 (s, 6H), 1.90 (s, 3H), 2.2–2.4 (m, 4H), 3.65 (s, 3H).

Ketone **12***b* (2.84 g, 16.9 mmol) was heated with *p*-toluenesulfonylhydrazine (3.15 g, 16.9 mmol) in 60% aqueous methanol at ~65°C for 2 h. The hot solution separated into two phases, and on cooling the lower phase solidified. The solid was filtered and recrystallized from 95% ethanol to give crystalline tosylhydrazone **13***b* (5.02 g, 88%), mp 123–124.5°C; ^{1}H nmr δ: 0.96 (s, 6H), 1.76 (s, 3H), 2.04 (s, 2H), 2.15 (s, 2H), 2.41 (s, 3H), 3.53 (s, 3H), 7.2–7.5 (m, 2H), 7.8–8.1 (m, 2H) ppm. *Anal.* calcd. for $C_{17}H_{24}N_2O_3S$: C 60.69, H 7.19, N 8.33; found: C 60.41, H 7.09, N 8.29.

Tosylhydrazone **13***b* (10.27 g, 30.6 mmol) in dry ether (100 mL) was stirred under nitrogen in a three-necked flask fitted with a reflux condenser and dropping funnel. A solution of methyllithium in ether (1.23 *M*; 53 mL, 65 mmol) was added dropwise at room temperature over 1 h. The mixture was boiled under reflux for 1 h and cooled in an ice bath, and water (50 mL) was added dropwise. The aqueous phase was washed twice with ether (400 mL total), and the combined ether extracts were washed with saturated brine, dried, and evaporated to give **14** as an oil; ^{1}H nmr δ: 1.00 (s, 6H), 1.68 (br s, 3H), 2.0–2.1 (m, 2H), 3.54 (s, 3H), 5.46 (d, J = 10 Hz, 1H), 5.80 (d, J = 10 Hz, 1H). This was treated immediately with maleic anhydride to give **16***b* (*vide infra*).

2-Methoxy-1-methyl-1,3-cyclohexadiene (2)

A solution of 30% hydrogen peroxide (11.8 *M* by iodometric titration; 20 mL, 0.33 mol) in methanol (100 mL) was stirred in an ice bath and 3-methyl-2-cyclohexen-1-one (11.0 g, 0.100 mol) was added. A solution of 6 *N* aqueous sodium hydroxide (8.4 mL, 0.05 mol) was placed in a dropping funnel. When the solution in the flask had cooled to 0°C, a few drops of aqueous sodium hydroxide were added cautiously with monitoring of the temperature. The temperature rose slowly to 5°C and remained there for about 15 min. When the temperature fell to 3.5°C, a few more drops of aqueous sodium hydroxide were added, and the temperature again rose to 5°C. After 15 min the temperature had fallen below 2°C, and the remainder of the aqueous sodium hydroxide was added more rapidly over about 10 min while keeping the temperature below 5°C. The mixture was stirred for a further 45 min in the ice bath, and then poured onto ice (100 g) and extracted quickly with dichloromethane (4 × 60 mL). The extracts were dried and evaporated, and the residue was distilled to give the epoxide **11***a* (11.60 g, 92%), bp 66–68°C (5.5 Torr); ^{1}H nmr δ: 1.45 (s, 3H), 1.4–2.7 (m, 6H), 3.08 (s, 1H); *m/e*: 126.0681 (M^+ 126.0680). *Anal.* calcd. for $C_7H_{10}O_2$: C 66.65, H 7.99; found: C 66.17, H 8.04.

A solution of epoxide **11***a* (12.8 g, 0.101 mol) in methanol (10 mL) was added dropwise over 10 min with stirring under reflux to a boiling solution obtained by reaction of sodium (3.4 g, 0.15 g-atom) with methanol (65 mL). After 5 min the mixture was cooled in an ice bath and poured onto crushed ice (100 g), and the mixture was extracted with dichloromethane (4 × 50 mL). The combined extracts were washed with saturated brine, dried, and evaporated to give enol ether **12***a* (12.9 g, 91%) as a brown oil, which was used for conversion to the tosylhydrazone **13***a*. Pure **12**a was obtained by distillation; bp 73–75°C (3.0 Torr); ^{1}H nmr δ: 1.8–2.2 (m, 2H), 1.93 (br s, 3H), 2.3–2.6 (m, 4H), 3.65 (s, 3H); *m/e*: 140.0836 (M^+ 140.0836). *Anal.* calcd. for $C_8H_{12}O_2$: C 68.55, H 8.63; found: C 68.14, H 8.58.

Compound **12***a* (7.90 g, 56 mmol) and *p*-toluenesulfonylhydrazine (10.60 g, 57 mmol) were warmed gently together in 95% ethanol (25 mL) until they dissolved, and the solution was allowed to cool slowly to room temperature and stand overnight. Yellow crystals of tosylhydrazone **13***a* separated and the mother liquor assumed a dark red-brown color. The yellow product was filtered, washed with ethanol, and recrystallized from 95% ethanol to give **13***a* (15.65 g, 90%), as pale yellow needles, mp 160–162°C; ^{1}H nmr δ: 1.5–2.5 (m, ~6H), 1.81 (s, 3H), 2.41 (s, 3H), 3.60 (s, 3H), 7.30 (m, 2H), 7.90 (m, 2H); *m/e*: 308.1203 (M^+ 308.1188). *Anal.* calcd. for $C_{15}H_{20}N_2O_3S$: C 58.42, H 6.54, N 9.08; found: C 58.32, H 6.55, N 8.91.

Tosylhydrazone **13***a* (0.346 g, 1.12 mmol) was stirred in dry ether (10 mL) and a solution of methyllithium in ether (1.2 *M*; 2.7 mL, 3.2 mmol) was added dropwise under nitrogen. The mixture was boiled under reflux for 15 min, allowed to stand for 45 min, and then cooled in an ice bath. Aqueous 5% sodium carbonate (10 mL) was added dropwise and the mixture was extracted with dichloromethane (4 × 20 mL). The combined extracts were dried and evaporated to give **2** (0.117 g, 84%) as an oil; ^{1}H nmr δ: 1.72 (s, 3H), 1.8–2.4 (m, 4H), 3.54 (s, 3H), 5.6–6.1 (m, 2H). This was treated immediately with maleic anhydride to give **16***a* (*vide infra*).

*Reaction of 2 with Maleic Anhydride. Formation of 6-Methoxy-1-methylbicyclo[2.2.2]oct-5-ene-*syn*-2,3-dicarboxylic Acid Anhydride (16a)*

Crude diene **2** freshly prepared from tosylhydrazone **13***a* (5.09 g, 16.5 mmol) was dissolved in dry benzene (20 mL) under nitrogen, and the solution was cooled in an ice bath. A solution of maleic anhydride (1.6 g, 16.3 mmol) in dry benzene (20 mL) was added slowly with stirring. The solution was stored overnight at 8°C. The solvent was evaporated and the solid residue (3.23 g) was sublimed at 0.005 Torr (at this pressure, excess maleic anhydride does not condense on the cold finger, but sublimes into the liquid nitrogen trap). A viscous oil condensed on the cold finger and then crystallized to a pale yellow solid (2.56 g). Recrystallization of the sublimate from chloroform–hexanes gave the Diels–Alder adduct **16***a* (2.37 g, 65%), as white crystals, mp 103–106°C. An analytical sample was obtained by a second recrystallization, mp 105–107°C; ir λ_{max}: 5.42 (w), 5.50 (w), 5.68, 6.17 (m) μm; ^{1}H nmr: see Table 3: ^{13}C nmr δ: 173.1 (s), 172.2 (s), 160.6 (s), 93.0 (d), 55.0 (q), 50.1 (d), 46.4 (d), 39.3 (s), 32.9 (t), 32.5 (d), 25.8 (t), 17.8 (q). *Anal.* calcd. for $C_{12}H_{14}O_4$: C 64.85, H 6.35; found: C 64.48, H 6.39.

*Reaction of 14 with Maleic Anhydride. Formation of 6-Methoxy-1,8,8-trimethylbicyclo[2.2.2]oct-5-ene-*syn*-2,3-dicarboxylic Acid Anhydride (16b)*

Crude diene **14**, freshly prepared from tosylhydrazone **13***b* (10.27 g, 30.6 mmol), was dissolved in benzene (10 mL) and maleic anhydride (50 g, 51 mmol) was added. The solution was stirred at room temperature overnight. The solvent was evaporated, and the residue was heated on a vacuum line at 50–65°C for 1 h. Recrystallization of the brown residue from dichloromethane–hexanes yielded needles of adduct **16***b*. A further small crop was obtained by recrystallization from ether of the residue obtained by concentration of the mother liquors. The yield of **16***b* was 5.83 g, (76% based on tosylhydrazone **13***b*). An analytical sample was prepared by recrystallization from ether; mp 138–139°C; ir λ_{max}: 5.40 (w), 5.66, 6.15 (m) μm; ^{1}H nmr: see Table 3; ^{13}C nmr δ: 173.8 (s), 171.1 (s), 159.2 (s), 93.7 (d), 55.2 (q), 49.5 (t), 48.8 (d), 43.9 (d), 43.7 (d), 41.3 (s), 34.6 (s), 30.5 (q), 29.3 (q), 17.8 (q); *m/e*: 250.1202 (M^+ 250.1205). *Anal.* calcd. for $C_{14}H_{18}O_4$: C 67.18, H 7.25; found: C 67.11, H 7.19.

Hydrolysis of **16**a. *Formation of 1-Methyl-6-oxobicyclo[2.2.2]octane*-syn-*2,3-dicarboxylic Acid Anhydride (***17***a) and Acid (***18***a)*

Enol ether **16***a* (2.00 g, 9.0 mmol) was dissolved in warm tetrahydrofuran (10 mL). Concentrated hydrochloric acid (0.15 mL) was added dropwise with stirring. Crystals began to separate immediately. After standing for 30 min at room temperature the mixture was evaporated to dryness, and the white crystalline residue was washed with dry ether. The crystals, which were insoluble in ether, were pure keto anhydride **17***a* (1.76 g, 94%). By concentration of the ether washings a further crop of **17***a* was obtained, 0.059 g (3%). An analytical sample was prepared by recrystallization from chloroform; mp 216–215°C; ir λ_{max}: 5.32 (w), 5.62, 5.76 μm; ^{1}H nmr: see Table 3. *Anal.* calcd. for $C_{11}H_{12}O_4$: C 63.45, H 5.81; found: C 63.37, H 5.85.

If, after a few minutes, water was added to the reaction mixture, and the mixture was boiled under reflux for 1 h, a mixture of **17***a* and the corresponding dicarboxylic acid **18***a* was formed; ir λ_{max}: 2.9–4.2, 5.2 (w), 5.80 (br) μm. The latter was not obtained in pure form.

Hydrolysis of **16**b. *Formation of 1,8,8-Trimethyl-6-oxobicyclo[2.2.2]octane*-syn-*2,3-dicarboxylic Acid Anhydride (***17***b) and Acid (***18***b)*

Enol ether **16***b* (2.2 g, 8.8 mmol) was stirred in tetrahydrofuran (20 mL) with 3 *N* hydrochloric acid (2 mL) for 1 h. Evaporation gave an oil, shown by ^{1}H nmr spectroscopy to be a mixture of **16***b* (30%) and **17***b* (70%). The mixture was redissolved in tetrahydrofuran (20 mL), stirred with 6 *N* hydrochloric acid (2.0 mL) for 2 h, and evaporated to give an oil. Dichloromethane was added and the white precipitate of **18***b* was filtered. The filtrate was evaporated to give a solid, which was washed with ether, leaving **17***b* as an amorphous white solid (1.82 g, 87%), mp 133.5–134°C; ir λ_{max}: 5.36 (w), 5.62, 5.78 μm; ^{1}H nmr: see Table 3; *m/e*: 236.1050 (M^+ 236.1048). *Anal.* calcd. for $C_{13}H_{16}O_4$: C 66.09, H 6.83; found: C 65.93, H 6.89.

The fraction from the hydrolysis of **16***b* that was insoluble in dichloromethane was crystallized from aqueous acetone to give diacid **18***b* (0.123 g, 5.5%) as white needles, mp 199–201°C; ir λ_{max} (KBr): 3.0–4.0, 5.80, 5.87 μm; ^{1}H nmr δ (acetone-d_6 + D_2O): 0.94 (s, 3H), 0.97 (s, 3H), 1.15 (s, 3H), 1.32 (d, J = 14 Hz, 1H), 1.63 (d, J = 14 Hz, 1H), ~2.15 (m, under acetone-d_5 signal, 1H) 2.41 (ddd, J = 19, 3.5, 2 Hz, 1H), 2.94 (dd, J = 19, 2.2 Hz, 1H), 3.15 (d, J = 12 Hz, 1H), 3.58 (ddd, J = 12, 2, 2 Hz, 1H). *Anal.* calcd. for $C_{13}H_{18}O_5$: C 61.41, H 7.14; found: C 61.31, H 7.10.

Lead Tetraacetate Oxidation of **18**b. *Formation of 1,8,8-Trimethylbicyclo[2.2.2]oct-5-en-2-one (***19***) and Compounds 20–22*

Diacid **18***b* (427 mg, 1.68 mmol) and dry lead tetraacetate (930 mg, 2.15 mmol) were combined in a small flask and then dried on a vacuum line (0.005 Torr) for 2 h at room temperature. Pyridine (dried by distillation from calcium hydride onto freshly activated molecular sieves; 5 mL) was syringed into the flask under nitrogen and the mixture was heated with stirring for 5 min in an oil bath at 60–64°C. Gas was evolved and the mixture darkened. The mixture was then cooled in an ice bath and slowly added to ice-cold 2 *N* nitric acid (40 mL). The solution was extracted with dichloromethane (5 × 12 mL) and the combined extracts were washed with 2 *N* nitric acid (5 mL) and saturated brine (5 mL), dried, and evaporated to give an orange oil (300 mg).

The oil was chromatographed on silica gel with 10:1 hexanes – ethyl acetate to give enone **19** (92 mg, 33%), which had a distinctive, camphor-like odor; sublimation gave colorless crystals, mp 42–44°C; ir λ_{max} 5.85 μm; ^{1}H nmr: see Table 4; *m/e*: 164.1180 (M^+ 164.1201).

On further elution of the silica gel column with 2:1 hexanes – ethyl acetate two further fractions were isolated. The first (79 mg) was an oil, considered to be a mixture of **21** and **22**; ^{1}H nmr: signals (~1:1:2) at δ 4.75 (br s), 4.85 (br s), and 5.2 (br s); ^{13}C nmr: two strong signals at 133.2 (d) and 129.3 (s), and two weaker signals at 142.0 (s) and 111.9 (t) and signals at δ 208.3 (s) and 179.5 (s). The second (35 mg) was a crystalline solid, mp 170–172°C, considered to be **20**; ir λ_{max}: 3.0–3.7, 5.70 (br) μm; ^{1}H nmr: δ 2.00 (s), no vinyl proton signals; *m/e*: 268.1359 (M^+ 268.1311).

Treatment of **17**b *with bis(Triphenylphosphino)nickel Dicarbonyl. Formation of 1,8,8-Trimethylbicyclo[2.2.2]oct-5-en-2-one (***19***)*

Anhydride **17***b* (0.123 g, 0.52 mmol), bis(triphenylphosphino)nickel dicarbonyl (0.327 g, 0.51 mmol), and a small magnetic stirring bar were placed in a small two-necked flask fitted with a rubber septum and dried on a vacuum line with gentle warming from a heat gun. Diglyme (dried by distillation from sodium and stored over molecular sieves under nitrogen; 2.0 mL) was syringed into the flask under nitrogen. The mixture was boiled under reflux under nitrogen for 3 h with stirring. The diglyme was distilled from the mixture under high vacuum into a liquid nitrogen trap; additional diglyme (~3 mL) was added to the residue, and the distillation was repeated. The distillates were combined and added to water (100 mL), and the mixture was extracted with pentane (4 × 50 mL). The pentane extracts were washed repeatedly with water (5 × 100 mL) with very vigorous shaking to remove diglyme and with saturated brine (50 mL) and dried. The pentane was carefully distilled at 0.5–1.0 atm to give **19** in essentially quantitative yield. Chromatography on silica gel with 10:1 pentane – ethyl acetate yielded pure **19**, identical in spectroscopic properties with the sample prepared by lead tetraacetate oxidation of **18***b* (*vide supra*).

Treatment of **16**b *with bis(Triphenylphosphino)nickel Dicarbonyl. Formation of* o-*Methylanisole*

Treatment of anhydride **16***b* with bis(triphenylphosphino)-nickel dicarbonyl following the procedure described above for the preparation of **19** gave a crude product that was shown by ^{1}H nmr spectroscopy to contain *o*-methylanisole together with unconsumed **16***b*.

*1-Methylbicyclo[2.2.2]oct-5-ene-2-one (***1***)*

Enone **1** was prepared by treatment of anhydride **17***a* with bis(triphenylphosphino)nickel dicarbonyl, following the procedure described above for the preparation of **19**. The conversion appeared to be quantitative by ^{1}H nmr spectroscopy but, due to the volatility of **1**, the isolated yield was only 52% after chromatography; **1** was obtained as a colorless oil; ir λ_{max}: 5.86 μm; ^{1}H nmr: see Table 4; *m/e*: 136.0892 (M^+ 136.0888).

*1-Methylbicyclo[2.2.2]octan-2-one (***23***)*

Enone **1** (87 mg, 0.64 mmol) was dissolved in glacial acetic acid (5 mL) and the solution was stirred with 5% palladium on carbon (50 mg) under hydrogen (1 atm) for 3 h. The catalyst was filtered and washed with dichloromethane, and the filtrate and washings were basified by addition to a cold solution of potassium hydroxide (10 g) in water (50 mL). The mixture was extracted with dichloromethane (4 × 15 mL), and the organic phase was dried and evaporated to yield **23** (64 mg, 73%) as a colorless oil (lit. (16) mp 36–37°C, (17) 30–31°C); ir λ_{max}: 5.83 μm; ^{1}H nmr: see Table 4; *m/e*: 138.1043 (M^+ 138.1044).

*1,5,5-Trimethylbicyclo[2.2.2]octan-2-one (***24***)*

Enone **19** (100 mg, 0.61 mmol) was dissolved in glacial acetic acid (2.0 mL) and 5% palladium on carbon catalyst (50 mg) was added. The mixture was stirred overnight under hydrogen

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

(1 atm), although gas uptake appeared to be complete within 10 min. The catalyst was removed by filtration through Celite and washed with dichloromethane. The combined filtrate and washings were added to aqueous 5% sodium carbonate (50 mL), and the mixture was extracted with dichloromethane (4 × 12 mL). The extracts were washed with aqueous sodium carbonate (5 mL), dried, and evaporated to give **24** (90 mg, 89%) as a colorless oil with a camphor-like odour. Chromatography on silica gel with 15:1 hexanes – ethyl acetate yielded pure **24**; ir λ_{max}: 5.80 μm; ^{1}H nmr: see Table 4; *m/e*: 166.1357 (M^+ 166.1357).

Reaction of Bicyclo[2.2.2]octane-2,3-dione (27) with 0.5 Equivalent of Methyllithium. Formation of Compound 29

Bicyclo[2.2.2]octane-2,3-dione (**27**; 0.46 g, 3.3 mmol) was stirred in dry ether (40 mL) under nitrogen; the yellow crystals did not dissolve completely. A solution of methyllithium in ether (1.67 *M*) was slowly added by syringe. The yellow solution abruptly turned white when 1.0 mL (1.67 mmol) of methyllithium had been added. After standing overnight the reaction mixture was treated with a little isopropyl alcohol and then water. The aqueous phase was saturated with sodium chloride, separated, and washed with chloroform (4 × 40 mL). The combined organic solution and extracts were dried and evaporated to give oily pale yellow needles. After one recrystallization from hexanes and two from diethyl ether, **29** (0.10 g) was obtained as white needle-shaped crystals, mp 161.5–162°C (corr); ir λ_{max}: 2.96 (w), 5.78 μm; ^{1}H nmr δ 1.0–2.6 (m, ~20H), 1.33 (s, 3H), 5.30 (s, 1H); ^{13}C nmr δ: 218.8, 106.6, 104.0, 87.1, 42.9, 38.5, 36.8, 35.5, 24.5, 22.1, 22.0, 21.1, 21.0, 20.9, 20.5, 20.4, 20.2 (17 lines); *m/e*: 264.1729 ($M - CO)^+$ 264.1725). *Anal.* calcd. for $C_{17}H_{24}O_4$: C 69.84, H 8.27; found: C 69.63, H 8.28.

Reaction of Bicyclo[2.2.2]octane-2,3-dione (27) with 1.1 Equivalents of Methyllithium. Formation of 3-Hydroxy-3-methylbicyclo[2.2.2]octan-2-one (28) and Compounds 30 and 31

Dione **27** (0.559, 4.0 mmol) was treated in dry ether (50 mL) with methyllithium (4.4 mmol) and the reaction mixture was worked up as above. Three major components were identified in the crude product mixture by tlc (silica gel, 4:1 hexanes – ethyl acetate) and isolated by column chromatography: **31** (R_f 0.33; 0.11 g, 18%), **28** (R_f 0.25; 0.20 g, 32%) and **30** (R_f 0.17; 0.19 g, 28%). The relative yields of the products were found to vary.

Compound **31** was a white powder sparingly soluble in hexane. It was purified by washing with hexanes; mp 195–197°C (corr, sealed cap); ir λ_{max}: 2.85–2.95 μm; ^{1}H nmr δ: 1.2–2.0 (m, ~20H), 1.4 (s, 6H); ^{13}C nmr δ: 111.4 (s), 104.8 (s), 86.2 (s), 76.4 (s), 40.1 (d), 37.9 (d), 37.3 (d), 36.3 (d) 25.3 (q), 23.0 (t), 22.5 (t), 21.6, 21.1, 21.0, 20.8, 20.3;[7] *m/e*: 308.1992 (M^+ 308.1988). *Anal.* calcd. for $C_{18}H_{28}O_4$: C 70.10, H 9.15; found: C 70.11, H 9.08.

Compound **28** was recrystallized from hexanes; mp 116–121°C; ir λ_{max}: 2.84 (w), 5.78 μm; ^{1}H nmr δ: 1.2–2.1 (m, 9H), 1.33 (s, 3H), 2.2–2.4 (m, 1H), 2.7 (br s, 1H, exchanges with D_2O); ^{13}C nmr δ: 220.7 (s), 75.6 (s), 41.8 (d), 38.2 (d), 25.4 (t), 23.3 (q), 22.1 (t), 21.9 (t), 20.6 (t); *m/e*: 154.1033 (M^+ 154.0993). *Anal.* calcd. for $C_9H_{14}O_2$: C 70.10, H 9.15; found: C 69.98, H 9.13.

Compound **30** was recrystallized from hexanes; mp 190–192°C; ir λ_{max}: 2.88, 2.95 μm; ^{1}H nmr δ: 1.27 (s, 6H), 1.3–1.8 (m, 8H), 1.8–2.1 (m, 2H), 2.8 (br s, 2H, exchanges with D_2O); ^{13}C nmr δ: 73.4 (s), 38.8 (d), 24.7 (q), 22.8 (t), 20.7 (t); *m/e*: 170.1313 (M^+ 170.1307). *Anal.* calcd. for $C_{10}H_{18}O_2$: C 70.55, H 10.66; found: C 70.49, H 10.63.

Treatment of 35 and 36 with bis(Triphenylphosphino)nickel Dicarbonyl. Formation of Compounds 32 and 33

Treatment of the anhydrides **35** and **36** (19) with bis(triphenylphosphino)nickel dicarbonyl following the procedure described above for the preparation of **19** gave mixtures whose ^{1}H nmr spectra indicated the presence of **32** and **33**, respectively. However, the very low yields (5–10%) of these products and difficulties in their purification precluded their full characterization. The formation of **33** was established by comparison of the ^{1}H nmr spectrum of the crude product with that of **33** obtained by treatment of **37** with lead tetraacetate (*vide infra*). Compound **32** was isolated by preparative tlc (silica, dichloromethane) as an amorphous solid (R_f 0.2–0.4); ^{1}H nmr δ: 1.58 (s, 6H), 1.96 (s, 3H), 4.7 (m, 1H), 6.08 (dd, J = 6.5, 2 Hz, 2H), 6.35 (t, J = 6.5 Hz, 1H), 6.42 (t, J = 6.5 Hz, 1H). A second product isolated from the chromatogram (R_f 0.5–0.7) was shown to be 2,6-dimethylphenol by ^{1}H and ^{13}C nmr spectroscopic comparison with an authentic sample.

Lead Tetraacetate Oxidation of 37. Formation of 3-endo-Acetoxy-1,3-exo-dimethylbicyclo[2.2.2]oct-5-en-2-one (33) and Compounds 38 and 39

Anhydride **36** (1.20 g) was dissolved in tetrahydrofuran (20 mL), water (20 mL) was added, and the mixture was stirred overnight. Evaporation of the clear solution yielded crude **37** as a white solid; ir λ_{max}: 2.9–4.2, 5.76 (br) μm; ^{1}H nmr δ: 1.13 (s, 3H), 1.65 (s, 3H), 2.10 (s, 3H).

Crude diacid **37** (1.09 g, 3.7 mmol) was dried in vacuum and dissolved under nitrogen in pyridine that had been dried by distillation from barium oxide and saturated with oxygen. Lead tetraacetate (recrystallized from glacial acetic acid and dried in vacuum; 2.42 g, 5.5 mmol) was added to the solution, which became warm. When the nitrogen stream from the reaction flask was bubbled through fresh limewater, the latter rapidly turned milky. The reaction mixture was heated for 8 min in an oil bath at 67 ± 2°C, cooled, and slowly added dropwise with stirring to dilute nitric acid at 6–7°C (ice bath). The clear yellow solution was extracted with ether and the organic phase was washed with aqueous sodium bicarbonate followed by saturated brine, and dried. Evaporation yielded an oil from which compounds **33** and **38** were isolated by column chromatography with 4:1 hexanes – ethyl acetate on silica gel (50 g).

The first compound eluted (R_f 0.45) was **33** (42 mg, 5.5%), which was obtained as needles; ^{1}H nmr: see Table 5; *m/e*: 166.0997 ($(M - C_2H_2O)^+$ 166.0994).

The major fraction (R_f 0.18) from the chromatogram was compound **38**, which was obtained as an oil that could not be crystallized; ir λ_{max}: 5.62–5.78 μm; ^{1}H nmr δ: 1.1–2.1 (m, 4H), 1.53 (s, 6H), 2.04 (s, 3H), 3.1–3.4 (m, 3H) (in C_6D_6 the 6H singlet at δ 1.53 was resolved into two 3H singlets); ^{13}C nmr (C_6D_6) δ: 206.3 (s), 174.3 (s), 169.3 (s), 86.7 (s), 86.0 (s), 60.2 (d), 47.9 (d), 43.2 (d), 30.8 (t), 24.0 (q), 22.2 (t), 20.8 (q), 16.2 (q); *m/e*: 252 (M^+ 252).

After storage for 6 months at room temperature, the oil **38** had changed into a new, solid product. Recrystallization of this solid from dichloromethane yielded a crystalline compound **39**. The same substance had been isolated as a minor product (R_f 0.09) in the chromatographic separation of the original crude product from the lead tetraacetate reaction. Compound **39** had mp 167–168°C; ir λ_{max}: 2.87 (w), 5.62, 5.73 μm; ^{1}H nmr δ: 1.2–2.1 (m, 4H), 1.38 (s, 3H), 1.52 (s, 3H), 2.08 (s, 1H, absent after D_2O treatment), 2.5–2.8 (m, 1H), 3.17 (dt, J = 5.5, 1.8 Hz, 1H), 3.58 (t, J = 5.5 Hz, 1H); ^{13}C nmr δ: 210.9, 175.8 (or 176.8),[8] 86.5,

[7]The sample was not sufficiently soluble in $CDCl_3$ to determine the multiplicities of the signals in the δ 21.6–20.3 range; in $CDCl_3$ – pyridine-d_5 one of these signals is a quartet (δ 21.0) and the others are triplets. Two of the signals in the δ 20–23 range must each correspond to two different carbon atoms, since only 16 signals were observed.

[8]Owing to the low solubility of **39**, this signal could not be identified unambiguously.

78.9, 59.8, 47.6, 44.3, 30.8, 24.3, 21.9, 18.2; *m/e*: 210.0884 (M^+ 210.0892). *Anal.* calcd. for $C_{11}H_{14}O_4$: C 62.85, H 6.71; found: C 62.74, H 6.60.

3-Acetoxy-1,3-dimethylbicyclo[2.2.2]oct-2-anone (34)

Enone **33** was hydrogenated in glacial acetic acid over 5% Pd/C at 1 atm and 20°C for 43 h. The catalyst was filtered. The filtrate was evaporated, and the residue was dissolved in dichloromethane, washed with aqueous sodium bicarbonate, and dried. Evaporation yielded an oil whose ^1H nmr spectrum showed no vinyl proton signals. The crude product was chromatographed on silica gel with 5:1 hexanes–ethyl acetate to give **34** as an oil; ^1H nmr: see Table 5; *m/e*: 168.1142 ($(M - C_2H_2O)^+$ 168.1150).

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

JAMES FREDERICK KING and TERESA MEE-LING LEE. Can. J. Chem. **59**, 356 (1981).

Phenyl [0]betylate fluorosulfate (**2**), the first example of a "[0]betylate" (trialkylammoniosulfate ester), has been prepared by methylation of phenyl *N,N*-dimethylsulfamate with methyl fluorosulfate. Nucleophiles react with **2** either by attack on the sulfur or methyl carbon atoms, but with no sign of any products derived from benzyne or the phenyl cation. A synthesis of enol *N,N*-dimethylsulfamates has been devised using a reagent, $Me_2NSO_2\overset{+}{N}Me_3\ FSO_3^-$, prepared from tetramethylsulfamide and methyl fluorosulfate, but no satisfactory method was found for converting the sulfamic ester to the [0]betylate. Evidence is presented that phenyl chlorosulfate reacts with trimethylamine to give the phenyl [0]betylate which then undergoes further reaction.

JAMES FREDERICK KING et TERESA MEE-LING LEE. Can. J. Chem. **59**, 356 (1981).

On a préparé le fluorosulfate de [0]bétylate de phényle (**2**) le premier exemple d'un "[0]bétylate" (ester de trialkylammoniosulfate) par la méthylation du *N,N*-diméthylsulfamate de phényle à l'aide du fluorosulfate de méthyle. Les nucléophiles réagissent avec le composé **2** par attaque sur les atomes de soufre ou de carbone du méthyle; on n'a toutefois isolé aucun composé pouvant provenir du benzyne ou du cation phényle. On a mis au point une synthèse de *N,N*-diméthylsulfamates d'énol en utilisant le réactif $Me_2NSO_2\overset{+}{N}Me_3\ FSO_3^-$, préparé à partir de la tétraméthylsulfamide et du fluorosulfate de méthyle; on n'a toutefois pas trouvé de méthode satisfaisante permettant de transformer l'ester sulfamique en [0]bétylate. On rapporte des données indiquant que le chlorosulfate de phényle réagit avec la triéthylamine pour conduire au [0]bétylate de phényle qui subit alors d'autres réactions.

[Traduit par le journal]

Introduction

We have recently pointed to the synthetic utility of "betylates", i.e. esters of the general formula $R_3\overset{+}{N}(CH_2)_nSO_2OR'X^-$, especially those in which $n = 2$ or 3, which we refer to as [2]- or [3]betylates (1–3).[2] As an extension of this work it was natural to consider the properties to be expected in the lowest member of this series, the [0]betylates or trialkylammoniosulfates, $R_3\overset{+}{N}SO_2OR'X^-$. The direct attachment to the sulfonyl group of a function as electron withdrawing as a trialkylammonio group would be expected to lead to a total grouping $R_3\overset{+}{N}SO_2O$ with very high nucleofugality[3] indeed. One difficulty with the synthesis of a highly reactive functional group is that many species containing the grouping may be too short-lived for isolation and characterization. Because phenyl derivatives are commonly the most readily obtained of the isolable compounds containing a powerfully nucleofugal group, we chose to explore first the preparation of a phenyl [0]betylate salt.

Accordingly this paper describes the preparation, characterization, and some reactions of the first [0]betylate or ammoniosulfate ester, *N,N,*-dimethyl-*N*-(phenoxysulfonyl)methanaminium fluorosulfate (**2**). The accompanying paper reports analogous experiments aimed at providing *alkyl* [0]betylates; as is described there, these reactions gave substitution, elimination, or rearrangement products derived in all likelihood from highly reactive alkyl [0]betylate intermediates.[4]

Results and Discussion

A Stable [0]Betylate, N,N-*Dimethyl*-N-*(phenoxysulfonyl)methanaminium Fluorosulfate*

The synthesis of the first isolated and characterized [0]betylate was achieved very simply. Recalling that sulfonamides react with powerful alkylating reagents to form sulfonylammonium salts (6–8), we treated phenyl *N,N*-dimethylsulfamate (**1**) with an excess of neat methyl fluorosulfate.

[1]Part 22 in the series Organic Sulfur Mechanisms. Part 21: Can. J. Chem. **57**, 3278 (1979).

[2]We have proposed the trivial name "betylates" (which originates from their formation of betaines by simple nucleophilic substitution) to encompass those compounds which in current Chemical Abstracts usage might be called ω-alkoxysulfonyl-*N,N,N*-trialkyl-1-alkanaminium (or ω-aryloxysulfonyl-*N,N,N*-trialkyl-1-alkanaminium) salts and *N*-alkoxysulfonyl-*N,N*-dimethylmethanaminium (or *N*-aryloxysulfonyl-*N,N*-dimethylmethanaminium) salts. The name betylate, with or without a numerical descriptor, has the advantage of very simply denoting a class of structurally similar species in a manner easily conveyed in both spoken and written form. It is neither suited to be nor intended as a formal substitute for official nomenclature in naming individual chemical species.

[3]In this and the following paper we use "nucleofuge" as a synonym for the more familiar "leaving group", along with "nucleofugal" and "nucleofugality" as the most felicitous derived forms (4).

[4]A preliminary account of both aspects of this work has appeared elsewhere (5).

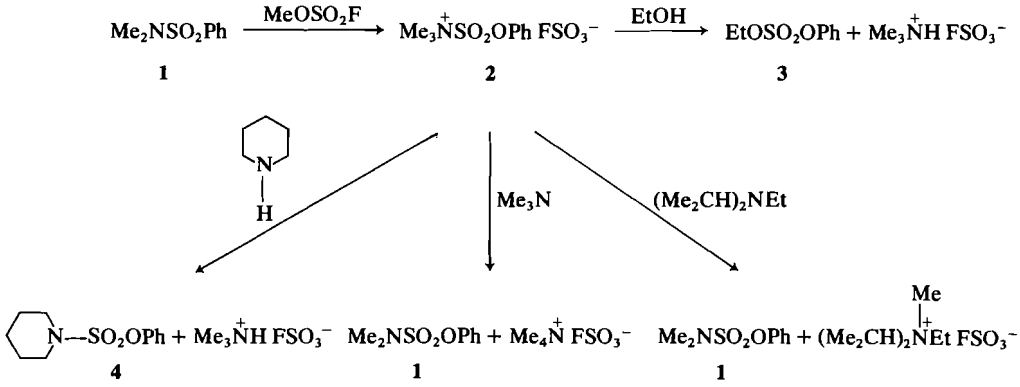

SCHEME 1

Reaction for 18 h at 50°C gave an 88% yield of the [0]betylate (**2**) as a white crystalline solid which gave correct element analyses. The proton nmr spectrum showed only a methyl singlet at 3.70 (9H) and the aromatic protons at 7.56 ppm (5H). Strong bands at 1445 and 1210 cm^{-1} were found in the infrared spectrum, as expected for a sulfonyl group flanked by strongly electron withdrawing groups (9).

The further reactions in Scheme 1 serve both to confirm the assigned structure and to illustrate some of the reactions of the new functional group. Displacement at sulfur occurs very readily at room temperature with either alcohol or piperidine, forming trimethylammonium ion and, respectively, ethyl phenyl sulfate (**3**) and the sulfamic ester **4**.

Simple displacement at sulfur of trimethylamine by trimethylamine must of course simply give back **2**, and so reaction with this amine was tried with the possibility in mind that we might see a different, and more interesting, reaction course such as cleavage of the Ph—O bond, possibly with formation of benzyne. What we observed, however, was a rapid, slightly exothermic methyl transfer giving **1** and tetramethylammonium fluorosulfate. Use of hindered amines did not help. Diisopropylethylamine reacted more slowly than trimethylamine, but by essentially the same route, to give **1** and the quaternary ammonium salt. 2,6-Di-*tert*-butylpyridine probably did not react directly with **2** at all; the reaction mixture after one week at 60°C appeared to consist, in addition to unreacted **2**, of **1** and the tetramethylammonium cation, suggesting that the products were formed via slow hydrolysis followed by reaction of the trimethylamine as above. Other workers have encountered a similar failure to detect either phenyl cations or benzyne with so-called "super sulfonate" esters (10).

Preparation of Enol N,N-*Dimethylsulfamates and Attempted Formation of the Corresponding [0]Betylates*

Enol trifluoromethanesulfonates (triflates) are well known as useful precursors of vinyl cations (11), although ionization even of such a strongly nucleofugal group as triflate can be slow. It therefore seemed worthwhile to determine if [0]betylates could be used to form vinyl cations, especially those not readily obtained in other ways. Difficulties, unfortunately, arose.

The first problem appeared in the preparation of enol *N,N*-dimethylsulfamate esters. Whereas the procedure of Binkley and Degering (12), involving reaction of a sodium alkoxide or aryloxide with *N,N*-dimethylsulfamoyl chloride, had worked well for aryl and alkyl *N,N*-dimethylsulfamates (see Table 1 and the accompanying paper), the corresponding reaction of sodium or lithium cyclohexenoxide, for example, gave no sign of the sulfamate ester. The only identified product from this reaction was tetramethylsulfamide (**5**). Since sulfamoyl chlorides appear to show the usual tendency for the chlorosulfonyl group to undergo reduction (13), and since enolates react with arenesulfonyl chlorides to give the α-chlorinated carbonyl compound and the arenesulfinate anion (14), it seems likely that alkali cyclohexenoxides attacked the chlorine rather than the sulfur atom of the sulfamoyl chloride to form 2-chlorocyclohexanone and the sulfinimidate anion, $Me_2NSO_2^-$, which then reacted with more sulfamoyl chloride to give tetramethylsulfamide (**5**) and sulfur dioxide.

The behaviour of the chlorosulfonyl group is readily systematized in hard–soft acid–base terms (15), i.e. "hard" nucleophiles attack preferentially at the sulfonyl sulfur, the "hard" electrophile, whereas "soft" nucleophiles attack at chlorine, the

[c]Determined on the Varian T-60 instrument.

"soft" electrophile. What is therefore required in the present instance is a reagent Me_2NSO_2Z in which Z is a good nucleofuge but a poor electrophile (especially not "soft"), so that the preferred reaction would then be simply the reaction of the "hard" oxygen atom of the enolate with the "hard" sulfur atom. Such a reagent was found in *N,N*-dimethyl-*N*-dimethylsulfamoylmethanaminium fluorosulfate (**6**), which was readily prepared by reaction of tetramethylsulfamide (**5**) with methyl fluorosulfate. Reaction of **6** with the appropriate lithium enolates gave the enol sulfamic esters **7** and **8** (see Table 1). We have not explored the generality of the reaction nor made any serious attempt to optimize yields, but the procedure appears to provide a serviceable route to enol (and presumably other) dialkylsulfamate esters. The method provides an illustration of the usefulness of the strongly nucleofugal properties of a trialkylammonio group when attached to sulfonyl sulfur, already encountered above in the reactions of **2** (see Scheme 1).

We did not, however, succeed in making the [0]betylates from the enol sulfamates. The products from reaction with methyl fluorosulfate were typically dark purple-brown mixtures from which we isolate nothing except (from **7**) a small amount of the betaine, $Me_3\overset{+}{N}SO_3^-$; suggesting formation of perhaps a small amount of the [0]betylate; further work is clearly in order.

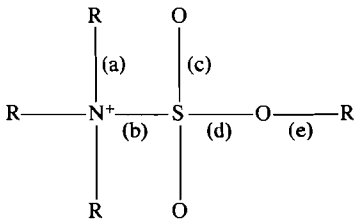
Before we had found the method for making enol sulfamates via **6**, we examined other possible candidates for the reagent Me_2NSO_2Z specified above. We readily obtained compounds in which Z was *p*-nitrophenyl and 1-imidazolyl, respectively, but both proved unreactive to lithium cyclohexenoxide. An attempt at making 2,4-dinitrophenyl *N,N*-dimethylsulfamate by reaction of sodium 2,4-dinitrophenoxide with *N,N*-dimethylsulfamoyl chloride gave no sign of the desired ester.

Other Possible Routes to [0]Betylates

If we examine the general structural formula of the [0]betylate cation below, we can readily see five potential routes to its synthesis, labelled (a) to (e), according to which bond is formed in the final step.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

Route (a), i.e. final formation of the bond labelled (a), is of course the method used in this study. Alkylation with reagents other than methyl fluorosulfate is an obvious variation. Methyl triflate was tried and found to give exactly analogous results with phenyl *N*,*N*-dimethylsulfamate; an nmr experiment showed the peaks expected of the triflate salt of **2**.



Route (b) is embodied in a suggestion by Charalambous *et al.* (16) to account for formation of alkyl chlorides on treatment of alkyl chlorosulfates with pyridine or triethylamine.

$$ROSO_2Cl + C_5H_5N \rightarrow [ROSO_2\overset{+}{N}C_5H_5] + Cl^- \rightarrow RCl + C_5H_5\overset{+}{N}SO_3^-$$

To test this idea and explore the synthetic value of this route, we treated phenyl chlorosulfate with excess trimethylamine and obtained phenyl *N*,*N*-dimethylsulfamate (**1**) and tetramethylammonium chloride, precisely what would be expected from initial formation of the [0]betylate (**2**) followed by its rapid reaction with trimethylamine as shown in Scheme 1. Use of a limited amount of the amine gave the same products plus unreacted starting material, with no sign of the intermediate (**2**) visible in the nmr spectrum. We had already observed that **2** on reaction with tetraethylammonium chloride for 1 min at room temperature gave a roughly 2:1 mixture of phenyl chlorosulfate and phenyl *N*,*N*-dimethylsulfamate (**1**), the latter, as before, being derived from reaction of **2** with trimethylamine, the coproduct of the initial reaction. It is evident that both displacement of chloride ion from phenyl chlorosulfate by trimethylamine to form **2**, and the reverse process, are rapid reactions. In the hope of obtaining direct spectroscopic evidence for formation of **2**, we treated phenyl chlorosulfate with a mixture of trimethylamine and silver hexafluoroantimonate. A limited amount of the amine gave a product showing mostly unreacted phenyl chlorosulfate in the nmr spectrum, but characteristic signals due to **2** at 3.70 and 7.56 ppm (in roughly 10% yield) were clearly in evidence. In another experiment with more trimethylamine the proportion of **2** did not appear to increase but rather the starting material diminished and peaks showing the presence of **1** and tetramethylammonium cation appeared. Route (b) is probably of limited use as a procedure for isolating [0]betylates, but these experiments serve to confirm the original suggestion of Charalambous *et al.* (16) that reaction of chlorosulfate esters with tertiary amines proceeds by way of a transitory [0]betylate. The reaction may well prove of value as an easy method of making a highly reactive, short-lived [0]betylate in the presence of chloride ion (or, with the use of silver salts, in the presence of any of a considerable choice of other ions as well).

Charalambous *et al.* (16) used pyridine for most of these experiments and it might be momentarily surprising to note that we saw little or no reaction in an nmr experiment with phenyl chlorosulfate and pyridine in carbon tetrachloride. This observation does not preclude reaction of pyridine with phenyl chlorosulfate, but does require that if such reaction occurs, the equilibrium constant must strongly favour the starting materials. The speed of the reaction of phenyl [0]betylates (e.g. **2**) with chloride ion, as discussed above, is entirely consistent with this conclusion.

The other routes indicated in the above structure need only brief comment. Route (c) we have not tried at all; possible precursors such as the sulfinic analogue of a [0]betylate do not appear to be readily available. Route (d) might be practicable if one could obtain a compound of the type $R_3\overset{+}{N}SO_2\overset{+}{N}R_3$, but in our preparation of the monocation **6** we saw no sign of further alkylation to the dication. One version of route (e) would be alkylation of the betaine $Me_3\overset{+}{N}SO_3^-$, but it is evident that a much less nucleophilic anion than fluorosulfate or triflate is required as the counterion of the potential [0]-betylate, since the experiments in the accompanying paper clearly show that with these anions the equilibrium lies far on the side of betaine and ester rather than that of the betylate. Whether or not such reagents as trimethyloxonium fluoroborate or methyl fluoride–antimony pentafluoride would alkylate the betaine remains to be demonstrated.

It is evident that much more work is required to find all of the possible pathways to [0]betylates and to assess their merits. The present paper describes only the beginning: we have found a preparative route leading to this class of compounds and thereby demonstrated its existence by actual isolation and characterization. The accompanying paper explores the application of this route to alkyl derivatives, in which the exclusive, and very rapid, mode of reaction is C—O cleavage with formation of the betaine $Me_3\overset{+}{N}SO_3^-$, a reaction which displays the extraordinary leaving-group ability of the [0]betylate grouping.

Experimental

Infrared spectra were determined using a Beckman IR-20A instrument and NaCl cells. Routine ^{1}Hmr spectra were obtained with a Varian T-60 instrument unless otherwise indicated; ^{1}Hmr spectra of pure compounds (except where otherwise specified) and ^{13}Cmr spectra were determined using Varian XL-100 spectrometers. Mass spectra were run on a Varian MAT-311A instrument. Normal reaction work-up procedure included drying with anhydrous sodium sulfate and evaporation of the solvent under reduced pressure using a rotary evaporator. Methyl fluorosulfate, as supplied (labelled "Magic Methyl") by Aldrich Chemical Co., Milwaukee, WI, U.S.A., was distilled before use.

Phenyl N,N-*Dimethylsulfamate (1)*

Phenol (4.7 g, 50 mmol) was added to a suspension of sodium hydride (1.2 g, 50 mmol, oil-free, obtained by washing 2.4 g of the 50% suspension with hexanes) in 1,2-dimethoxyethane (50 mL). After hydrogen evolution had slowed, *N,N*-dimethylsulfamoyl chloride (12) (7.9 g, 55 mmol) was added; the temperature of the reaction mixture rose to 40–50°C. The mixture was stirred without heating overnight, and most of the solvent then removed on the rotary evaporator. The residue was worked up by extraction with a mixture of chloroform and water. The organic layer was dried and evaporated. Distillation of the crude product gave **1** (9.39, 93%); ms: M^+ calcd. 201.0459; found 201.0456; other properties are given in Table 1.

N,N-*Dimethyl*-N-*phenoxysulfonylmethanaminium Fluorosulfate (Phenyl[0]Betylate Fluorosulfate, 2)*

A solution of phenyl *N,N*-dimethylsulfamate (**1**) (2 g, 10 mmol) in methyl fluorosulfate (3 mL) was heated at 50°C for 18 h, after which time the mixture had solidified. Dry CH_2Cl_2 (20 mL) was added, the solid mass broken up, and the supernatant liquid decanted; three further washes with CH_2Cl_2 gave a white solid (2.76 g, 88%) which was dried under vacuum; mp 122–125°C; ir ν_{max} (Nujol): 1575 (m), 1445 (vs), 1280 (vs), 1210 (s), 1115 (s), 1070 (s), 910 (s), 770 (s), 705 (s), 650 (s) cm^{-1}; ^{1}Hmr δ: 7.56 (5H, broad s), 3.70 (9H, s) ppm. *Anal.* calcd. for $C_9H_{14}NO_6S_2F$: C 34.29, H 4.44, N 4.44, S 20.32; found: C 34.37, H 4.49, N 4.36, S 20.21.

Reactions of Phenyl [0]Betylate Fluorosulfate (2) with Nucleophiles

(a) Ethanol

Just enough ethanol was added to **2** (254 mg, 0.81 mmol) to give a solution, which was allowed to stand for 1 h. It was then taken up in water and extracted twice with $CHCl_3$. The organic layer was dried and the solvent evaporated. The residue after distillation (0.6 Torr, bath 110°C) gave **3** as a colorless oil (100 mg, 61%); ir ν_{max}: 1595 (m), 1400 (vs), 1210 (vs), 1000 (s) cm^{-1}; ^{1}Hmr δ: 7.16 (5H, m) 4.38 (2H, q, J = 7 Hz), 1.40 (3H, t) ppm; ms *m/e*: calcd. M^+ 202.0300; found 202.0297.

(b) Piperidine

Piperidine (85 mg, 1 mmol) was added to a solution of **2** (315 mg, 1 mmol) in acetonitrile (4 mL). A mildly exothermic reaction ensued and the mixture turned yellow-green; after ½ h the mixture was diluted with $CHCl_3$ and the solution extracted six times with water. The $CHCl_3$ layer was dried and the solvent removed; the residue (209 mg) was distilled (0.6 Torr, bath 125°C) to give **4** as a colorless oil which subsequently solidified, mp 57–59°C; ir ν_{max}: 1585 (m), 1380 (vs), 1190 (vs), 950 (s) cm^{-1}; ^{1}Hmr δ: 7.2 (5H, m), 3.2–3.4 (4H, br t), 1.5–1.7 (6H br s) ppm; ms *m/e*: calcd. M^+ 241.0772; found 241.0772.

The combined aqueous layers were made strongly basic with NaOH and nitrogen passed over the solution and into a solution of picric acid in absolute ethanol. The yellow precipitate was collected and washed with ether; yield 109 mg (38%) melting at 212–216°C; reported mp for trimethylammonium picrate 216°C (17).

(c) Trimethylamine

Excess gaseous trimethylamine was added (from a syringe) to **2** (88 mg, 28 mmol) dissolved in acetonitrile-d_3 (0.5 mL); mild evolution of heat and formation of a precipitate were observed as the amine was added. The liquid phase was decanted, diluted with water, and extracted twice with $CHCl_3$. The organic layer was dried and concentrated by evaporation; dry ether was added and the ethereal solution decanted from insoluble material and evaporated. The nmr and ir spectra of the residue (39 mg) were identical to those of an authentic sample of phenyl *N,N*-dimethylsulfamate; yield 70%.

The precipitate formed in the reaction was washed with dry ether and dried; the nmr spectrum (D_2O) was identical to that of an authentic specimen (mp > 360°C) of tetramethylammonium fluorosulfate prepared by reaction of trimethylamine with methylfluorosulfate.

(d) N,N-*Diisopropyl*-N-*ethylamine*

N,N-Diisopropyl-*N*-ethylamine (193 mg, 1.5 mmol) and **2** (472 mg, 1.5 mmol) were dissolved in dry acetonitrile (2 mL); the mixture gradually turned brown. After one day at room temperature the mixture was diluted with water and extracted twice with $CHCl_3$. Evaporation of the solvent gave an oil (245 mg, 81%) which was distilled (139 mg, 46%) and which showed nmr and ir spectra identical to those of authentic phenyl *N,N*-dimethylsulfamate (**1**).

The aqueous layer was evaporated to dryness and the residue taken up in isopropyl alcohol and the solution filtered. Evaporation of the filtrate gave a white solid (163 mg, 45%), mp 289–292°C (dec.); the nmr spectrum was identical with that of an authentic specimen of *N,N*-diisopropyl-*N*-ethyl-*N*-methylammonium fluorosulfate (mp 292°C with decomposition) prepared by reaction of the amine with methyl fluorosulfate.

(e) 2,6-Di-tert-*butylpyridine*

The amine (290 mg, 1.5 mmol) and **2** (478 mg, 1.5 mmol) in CD_3CN (1.5 mL) appeared from nmr spectra to react only very slowly. After one week about 55% of the initial amount of **2** was consumed. Peaks at 7.2 and 2.9 ppm in the nmr were assigned to phenyl *N,N*-dimethylsulfamate (**1**) (and confirmed by addition of authentic **1**), and a peak at 3.1 ppm to tetramethylammonium fluorosulfate; a strong peak at 1.5 ppm, presumably due to either di-*tert*-butyl pyridinium or di-*tert*-butyl-*N*-methylpyridinium cation, was also present.

(f) Tetraethylammonium Chloride

To a solution of **2** (139 mg, 0.44 mmol) in dry acetonitrile (1 mL), carefully dried tetraethylammonium chloride (241 mg, 1.45 mmol) also in dry acetonitrile (0.5 mL) was added. After 1 min the mixture was diluted with water and the solution extracted twice with $CHCl_3$. The solvent was evaporated to yield a clear liquid (64 mg), shown by peaks at 7.3, 7.2, and 3.9 ppm to consist almost entirely of a roughly 2:1 mixture of phenyl chlorosulfate and phenyl *N,N*-dimethylsulfamate.

N,N-*Dimethyl*-N-*Dimethylsulfamoylmethanaminium Fluorosulfate (6)*

Tetramethylsulfamide (**5**) (0.4 g, 2.6 mmol), prepared from dimethylamine and *N,N*-dimethylsulfamoyl chloride as described by Behrend (18), was dissolved in dry CH_2Cl_2 and allowed to react with methyl fluorosulfate (0.5 mL, 6.2 mmol) for 1 day, whereupon dry CH_2Cl_2 (20 mL) was added and the crystalline product collected by filtration, washed twice with CH_2Cl_2, and dried under reduced pressure. The product (5.2 g, 74%) was a white solid, mp 163–164°C; ^{1}Hmr δ: 3.26 (6H, s), 3.30 (9H, s). *Anal.* calcd. for $C_5H_{15}FN_2O_5S_2$: C 22.55, H 5.63, N 10.52, S 24.06; found: C 22.68, H 5.67, N 10.39, S 23.98.

2-Methylpropenyl N,N-*Dimethylsulfamate (7)*

Lithium 2-methylpropenoxide was generated in DME from methyllithium (15 mmol) and trimethylsilyl 2-methylpropenyl

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

ether (2.16 g, 15 mmol) as described by Stang *et al.* (19). To the solution of the enolate at −70°C, **6** (1.33 g, 5 mmol) was added in portions. The mixture was then allowed to warm to room temperature and stirred overnight. The volatile components were removed on the rotary evaporator, water was added to the residue, and the mixture extracted twice with $CHCl_3$. The organic extract was dried and the solvent evaporated and the residue distilled to give a colourless liquid (0.53 g, 59%) which solidified to needles on cooling; ms: M^+ calcd. 179.0616; found 179.0615; other properties are listed in Table 1.

1-Cyclohexenyl N,N-*Dimethylsulfamate (8)*

Redistilled cyclohexanone (1.67 g, 17 mmol) and oil-free sodium hydride (20 mmol, from the 50% suspension in mineral oil, 1 g) in dry 1,2-dimethoxyethane (DME) (30 mL) were heated under N_2 at 70°C for 3 h. The reaction mixture was cooled in ice and **6** (4.79 g, 18 mmol) added in portions via a solid-addition tube. After 1 h at room temperature water was added and the mixture extracted with three portions of $CHCl_3$. The combined $CHCl_3$ extracts were dried and the solvent evaporated to give an orange oil which was distilled to give **8** as a colourless liquid (2.63 g, 75%) with the properties summarized in Table 1.

p-*Nitrophenyl* N,N-*Dimethylsulfamate*

p-Nitrophenol (7.0 g, 50 mmol) was added in portions to a suspension of oil-free sodium hydride (50 mmol, from 2.4 g of 50% suspension in mineral oil) in DME. After hydrogen evolution had slowed, *N,N*-dimethylsulfamoyl chloride (6.46 g, 45 mmol) was added to the bright orange suspension. The mixture was heated at 70°C overnight and then cooled and worked up by distribution in water–benzene. The benzene layer was washed with dilute NaOH and water and dried, and the solvent evaporated to give a light-yellow solid. On recrystallization from benzene–hexanes this yielded a very pale yellow solid (8.6 g, 78% yield), mp 124–127°C; ms: M^+ calcd. 246.0310; found 246.0313; other properties are recorded in Table 1.

Dimethylsulfamoyl-1-imidazole

N,N-Dimethylsulfamoyl chloride (4.3 g, 30 mmol) and imidazole (4.1 g, 60 mmol) in $CHCl_3$ (50 mL) were allowed to react at 25°C for 30 min. The mixture was then taken up in water and extracted with benzene. The organic layer was washed with water, dried, and the solvent evaporated leaving a colourless liquid, which on distillation gave a solid (mp 45–48°C, 3.3 g, 63%); ms: M^+ calcd. 175.0415; found 175.0415; other properties are listed in Table 1.

Reaction of Phenyl Chlorosulfate with Trimethylamine

To a solution of phenyl chlorosulfate (216 mg, 1.1 mmol) (20) in $CDCl_3$ (0.5 mL) excess trimethylamine (80 to 90 mL vapour) was added from a syringe. After 15 min the mixture was partitioned between CCl_4 and water. The CCl_4 layer was dried and the solvent evaporated leaving a pale yellow oil (170 mg, 75%), the nmr and ir spectra of which were identical to those of authentic phenyl *N,N*-dimethylsulfamate (**1**). In a separate experiment the solid precipitate was shown to be tetramethylammonium chloride; addition of authentic tetramethylammonium fluorosulfate enhanced the nmr signal (in D_2O solution).

In another experiment silver hexafluoroantimonate (276 mg of the complex with two benzene molecules, 0.55 mmol) was dissolved in dry acetonitrile (0.3 mL) and dry trimethylamine gas (4 mL) added. Another flask containing phenyl chlorosulfate (109 mg, 0.57 mmol) in dry acetonitrile (0.2 mL) was cooled to −40°C and kept cold while the Me_3N–$AgSbF_6$ solution was added dropwise. The nmr spectrum of the solution (after it had come to room temperature) showed a singlet at 3.7 ppm characteristic of the $Me_3\overset{+}{N}SO_2OPh$ cation; addition of authentic **2** enhanced the signal. Other signals in the same spectrum corresponded to unreacted phenyl chlorosulfate, benzene, acetonitrile, and perhaps a small amount of trimethylammonium ion. In another experiment using different quantities, phenyl chlorosulfate (41 mg, 0.21 mmol), silver hexafluoroantimonate – benzene complex (119 mg, 0.24 mmol), and trimethylamine (5 mL of gas) in CH_3CN, the size of the peak at 3.7 ppm ascribed to the $Me_3\overset{+}{N}SO_2OPh$ cation was about the same but additional peaks at 3.1 and 2.9 ppm, probably due to Me_4N^+ cation and **1**, respectively, were observed; the peak at 7.5 ppm due to phenyl chlorosulfate was diminished relative to the peak at 7.35 ppm due to benzene.

Reaction of Phenyl N,N-*Dimethylsulfamate (1) with Methyl Trifluoromethanesulfonate*

The nmr spectrum of a solution of **1** in excess methyl trifluoromethanesulfonate (triflate) kept at room temperature, was observed at intervals. The reaction was characterized by replacement of the signals at 2.9 and 7.3 ppm due to **1** by peaks at 3.7 and 7.5 ascribed to phenyl [0]betylate triflate, and was about half complete in 6 h and about 95% complete after 24 h. Only trace amounts of materials other than starting materials and the [0]betylate product were visible in the nmr spectrum.

Betylates. 2. The formation and high reactivity of alkyl [0]betylates[1]

JAMES FREDERICK KING AND TERESA MEE-LING LEE

Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received July 21, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

JAMES FREDERICK KING and TERESA MEE-LING LEE. Can. J. Chem. **59**, 362 (1981).

Unhindered primary alkyl *N*,*N*-dimethylsulfamates (**1**) react with methyl fluorosulfate to give the corresponding alkyl fluorosulfates (**3**) and the betaine, $Me_3\overset{+}{N}SO_3^-$ (**4**), evidently by way of the intermediate alkyl [0]betylate fluorosulfate (**2**); with certain other alkyl esters (**1**) products of substitution, elimination, and rearrangement are formed. The reaction not only provides a potentially useful route to simple alkyl fluorosulfates, but serves to demonstrate the powerful nucleofugality of the [0]betylate group. To obtain a method for predicting the reactivity of [0]betylates, we have compared substituent parameters with rate constants in four series of nucleophilic displacements involving esters of the general structure $ROSO_2Z$; correlation (of log *k*) with σ^* is mediocre but a new parameter, σ^*_{15} with a "15% resonance" contribution as defined by Swain and Lupton, gives good to excellent agreement in the four reaction series. Evidence is presented for formation of the 7-norbornyl cation via the [0]betylate from 7-norbornyl *N*,*N*-dimethylsulfamate and methyl fluorosulfate. Comparison with what is known of the reactivities of 7-norbornyl *p*-toluenesulfonate and trifluoromethanesulfonate esters serves to confirm that [0]betylates are among the most nucleofugal functions of which a derivative has been fully characterized.

JAMES FREDERICK KING et TERESA MEE-LING LEE. Can. J. Chem. **59**, 362 (1981).

Les *N*,*N*-diméthylsulfamates d'alkyles (**1**) primaires non encombrées réagissent avec le fluorosulfate de méthyle pour donner les fluorosulfates d'alkyles correspondants (**3**) et la bétaine $Me_3\overset{+}{N}SO_3^-$ (**4**), manifestement par l'intermédiaire du fluorosulfate de [0]bétylate d'alkyle (**2**). Il se forme des produits de substitutions, d'élimination et de transposition avec d'autres esters d'alkyles (**1**). La réaction ne fournit pas seulement une voie d'accès très pratique aux fluorosulfates d'alkyle, mais sert également à démontrer le puissant caractère nucléofuge du groupe [0]bétylate. Dans le but d'obtenir une méthode permettant de prédire la réactivité des [0]bétylate nous avons comparé les paramètres des substituants avec les constantes de vitesse de quatre séries de déplacements nucléophiles impliquant des esters de structure générale $ROSO_2Z$. La corrélation entre le log de *k* et σ^* est médiocre, mais un nouveau paramètre, σ^*_{15} comprenant une contribution de "résonance de 15%" telle que définie par Swain et Lupton, fournit une bonne corrélation avec les 4 séries de réactions. On prouve la formation du cation norbornyle-7 par l'intermédiaire du [0]bétylate à partir du *N*,*N*-diméthylsulfamate de norbornyle-7 et du fluorosulfate de méthyle. En se basant sur les données connues au sujet des réactivités des *p*-toluènesulfonates et trifluorométhanesulfonate de norbornyle-7, on a pu confirmer le fait que les [0]bétylates font partie des fonctions les plus nucléofuges dont on a pu caractériser complètement un dérivé.

[Traduit par le journal]

Introduction

In the accompanying paper (1) we have reported that phenyl *N*,*N*-dimethylsulfamate reacts with methyl fluorosulfate to yield the first example of an isolable "[0]betylate" (i.e. trialkylammoniosulfate) ester.[2]

$$Me_2NSO_2OPh + MeOSO_2F \rightarrow Me_3\overset{+}{N}SO_2OPh\ FSO_3^-$$

The [0]betylate group, $R_3\overset{+}{N}SO_2O$, would be predicted to be highly nucleofugal, i.e. to be a powerful leaving group, since the attachment of such strongly electron-withdrawing functions as the fluoro or trifluoromethyl groups directly to the sulfonyl sulfur has led to sulfonic esters of high reactivity, the so-called "super sulfonates". In fact, by a quantitative method of assessment described in detail later in this paper, we estimate that [0]betylates should be a number of orders of magnitude more reactive than even the "super sulfonates". Accordingly when we had determined that an aryl [0]betylate could be prepared from an aryl *N*,*N*-dimethylsulfamate, we quickly turned our attention to the corresponding reaction of *alkyl N*,*N*-dimethylsulfamates. This paper describes our study of this reaction and our observation of the remarkable nucleofugality (leaving group activity) of the [0]betylate function.[3] In addition, as is described in the final part of this paper, the latter point has led to the development of a simple linear free energy relationship based on the Swain–Lupton treatment of electronic effects of substituents (3), which enables prediction of the variation in reactivity of compounds of the type $ROSO_2Z$ with change in Z.

Results and Discussion

with methyl fluorosulfate has not in our hands led to the isolation of an alkyl [0]betylate (**2**), though from the results given in this section it will become evident that this is indeed the usual first step and that the [0]betylate simply undergoes further reaction. With simple primary alkyl *N*,*N*-dimethylsulfamates the isolated products are the alkyl fluorosulfate (**3**) and the betaine (**4**). The yields and spectroscopic properties of a number of alkyl fluorosulfates produced in this manner are given in Table 1. No attempt has been made to optimize these yields but it would appear that this is a serviceable general procedure for converting unhindered primary alcohols into their fluorosulfate esters.[4] Some of the limitations of this route are displayed by the reactions of isobutyl and neopentyl *N*,*N*-dimethylsulfamates, which gave respectively isobutene and *tert*-butyl fluoride, and 2-methyl-2-butene. Reaction of isopropyl *N*,*N*-dimethylsulfamate appeared to give the fluorosulfate ester which was evidently unstable under the reaction conditions. Because the procedure of Ahmed *et al.* (4) for specifically making ethyl fluorosulfate is easier we did not try to make it by our route on a preparative scale, but an nmr experiment showed that the reaction in fact gives ethyl fluorosulfate and the betaine efficiently. Similarly the reaction of methyl *N*,*N*-dimethylsulfamate with methyl fluorosulfate appears, at least in part, to give **4** plus another molecule of methyl fluorosulfate; a fuller discussion of this reaction is given later in this section.

The available evidence is nicely consistent with the route shown in Scheme 1, i.e. initial formation of the [0]betylate, a process which is exactly parallel to the formation of the phenyl derivative (**1**), and then, as the second step, conversion of the ion-pair (**2**) into the alkyl fluorosulfate (**3**) and the betaine (**4**). The latter conversion may be regarded as a "substrate–reagent ion-pair" (SRIP) reaction (6), a process we have found in the reactions of [2]- and [3]betylates to be a surprisingly facile process, even for anions of very low nucleophilicity. The perchlorate or trifluoromethanesulfonate (triflate) salts of 1-hexadecyl [2]betylate, for example, are converted almost quantitatively into 1-hexadecyl perchlorate or 1-hexadecyl triflate, respectively, by refluxing in toluene for one hour (6). In this context rapid formation of the primary alkyl fluorosulfates (**3**) from the ion-pair (**2**) is entirely expected in view of the high nucleofugality predicted for the

$$\underset{\mathbf{1}}{Me_2NSO_2OR} + MeOSO_2F \longrightarrow \underset{\mathbf{2}}{[Me_3\overset{+}{N}SO_2OR\ FSO_3^-]}$$

$$\downarrow$$

$$\underset{\mathbf{3}}{ROSO_2F} + \underset{\mathbf{4}}{Me_3\overset{+}{N}SO_3^-}$$

SCHEME 1

[0]betylate grouping. It should perhaps be pointed out, however, that the fluorosulfate salts of 1-alkyl [2]betylates have not, in our hands, given 1-alkyl fluorosulfates, but rather the di-1-alkyl sulfates (6). These are believed to arise via the comparatively rapid hydrolysis of the fluorosulfate anion by adventitious moisture, followed by SRIP reactions with the bisulfate and alkylsulfate betylate ion-pairs. With the present scheme, however, this complication does not arise, perhaps because the nucleofugality of the [0]betylate group is such that displacement is readily effected at temperatures at which fluorosulfate is stable, or possibly simply because any water entering the system is rapidly scavenged by reaction with methyl fluorosulfate. It may be noted here that use of methyl trifluoromethanesulfonate (triflate) instead of the fluorosulfate gave the analogous result; the nmr spectrum of a mixture of excess methyl triflate with 3-phenyl-1-propyl *N*,*N*-dimethylsulfamate (**1**, R = $PhCH_2CH_2CH_2$) showed, after an interval, peaks identical to those of an authentic specimen of 3-phenyl-1-propyl triflate.

In the hope of finding at least an occasional isolable alkyl [0]betylate, we gave especial attention to those alkyl groups which are particularly reluctant to undergo nucleophilic substitution (or elimination) reactions. Recalling the low reactivity of 2,2,2-trifluoroethyl sulfonic esters (7), we synthesized 2,2,2-trifluoroethyl *N*,*N*-dimethylsulfamate (**1**, R = CF_3CH_2). Its reaction with methyl fluorosulfate was very slow, presumably because of the effect of the strongly electron-withdrawing trifluoromethyl group on the reactivity of the free electron pair of the nitrogen atom. The course of the reaction, however, was the same as that found with other alkyl groups, giving the fluorosulfate ester (**3**) in moderate yield. Extending the substitution by a trifluoromethyl group one step further led to complete deactivation of the nitrogen atom; 1,1,1,3,3,3-hexafluoro-2-propyl *N*,*N*-dimethylsulfamate (**1**, R = $(CF_3)_2CH$) showed little or no reaction with neat methyl fluorosulfate even after five weeks at 50°C.

It would appear that the inhibition of [0]betylate

[4]Previous methods have been conveniently summarized by Olah *et al.* (5).

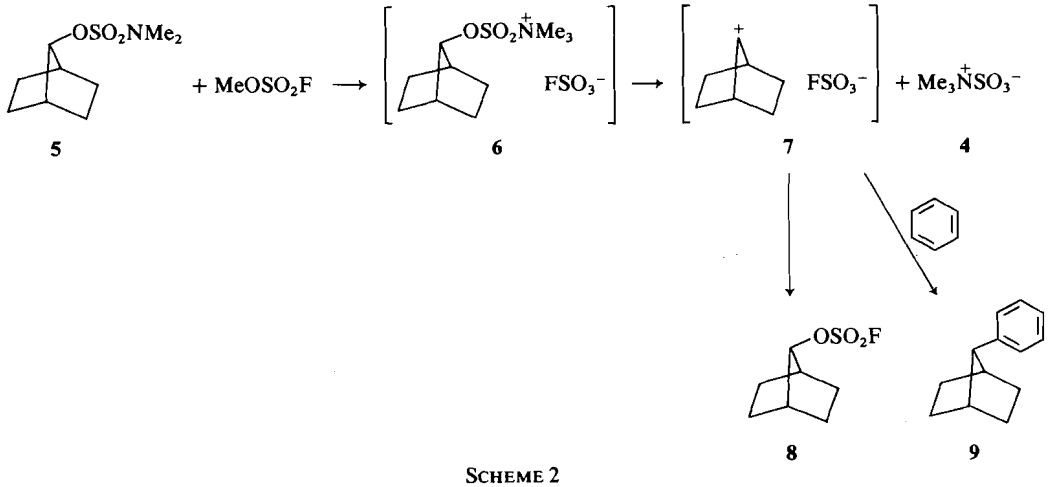
TABLE 1. Alkyl fluorosulfates: yield from the alkyl *N,N*-dimethylsulfamate and spectroscopic properties

Alkyl group	Percentage yield[a]	Nuclear magnetic resonance absorption			Major peaks in the infrared spectrum (in cm^{-1})
		^{19}F in ppm from $CFCl_3$	^{1}H in ppm from Me_4Si	^{13}C in ppm from Me_4Si[b]	
Methyl[c]	—	−31.4	4.20	62.5(CH_3)	1455, 1430, 1230, 1000, 840, 745
Ethyl[c]	—	−35.2 (J_{HF}0.9)	1.52(3H, t of d), 4.62(2H, q, J = 3.5)	14.5(CH_3), 74.8(CH_2)	1435, 1230, 990, 955, 825
1-Propyl	45	−34.6	1.04(3H, t, J = 7, 1.89(2H, sextet), 4.44(2H, t)	9.7(CH_3), 22.4(CH_2), 79.8(CH_2)	1440, 1230, 970
1-Butyl	68	−34.6	0.97(3H, t), 1.46(2H, sextet), 1.82(2H, quintet), 4.53(2H, t, J = 7)	13.3(CH_3), 18.5(CH_2) 30.7(CH_2), 77.9(CH_2)	1440, 1230, 965
2,2,2-Trifluoroethyl	36	−38.3(q, J_{FF}2.6) 74.6(t of d, J_{HF}7.4)	4.74(quartet)	69.5(CH_2, q, J_{CF} = 39.8)[d]	1460, 1446(sh), 1293, 1231, 1184, 1042, 962, 855, 810
3-Phenyl-1-propyl	52(86)	−34.7	1.95–2.30(2H, quintet), 2.76(2H, t) 4.49(2H, t, J = 7), 7.18(5H, d)	30.1(CH_2), 31.1(CH_2), 76.8(CH_2) 126.6(CH), 128.5(CH), 128.8(CH), 139.6(C)	1438, 1226, 963
7-Norbornyl	32(60)	−36.9	1.2–2.0(8H, m), 2.41(2H, s), 4.88(1H, s)	25.5(CH_2), 26.5(CH_2), 39.0(CH) 95.1(CH)	1440, 1230, 975 934, 792

[a]Yields with parentheses refer to crude products, those without to distilled products.
[b]^{13}C chemical shifts were obtained from ^{1}H noise-decoupled spectra. The number of hydrogens on each carbon was deduced from off-resonance spectra.
[c]The spectrum of methyl fluorosulfate was obtained from a redistilled sample of the commercial material, that of ethyl fluorosulfate from a sample prepared by the method of Ahmed *et al.* (4).
[d]No signal was observed for the CF_3 carbon.

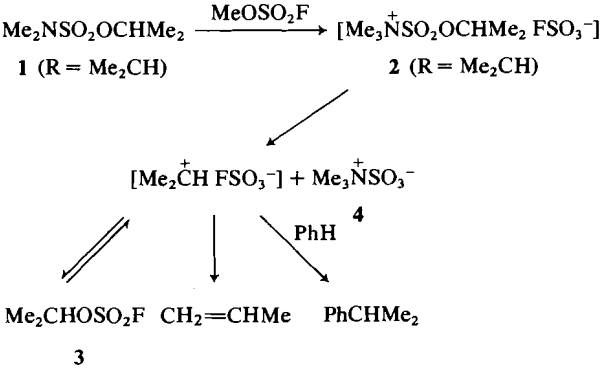


5 6 7 4 8 9

SCHEME 2

formation outweighs the possible benefits of having trifluoromethyl groups present, and we turned to another quarter in our attempts to find an isolable alkyl[0]betylate. 7-Norbornyl derivatives are known to be very slow to solvolyze (8). This has been ascribed by Schleyer and Nicholas (9) principally to the added angle strain required by carbonium ion formation. Bimolecular displacement in this system would be expected to show the same increase in angle strain, and, in addition, to have nonbonding repulsions of nucleophile and nucleofuge with the *exo*-hydrogens,[5] in the fashion suggested by Schleyer and co-workers (10) as one of the factors contributing to "limiting" (S_N1) character in the solvolysis of 2-adamantyl derivatives. We found that 7-norbornyl *N*,*N*-dimethylsulfamate (**5**) with methyl fluorosulfate formed the betaine (**4**) and 7-norbornyl fluorosulfate (**8**) in about 60% yield. Clearly the [0]betylate (**6**) had again been formed and had reacted further. Further insight was provided by reaction in the presence of benzene (three equivalents with respect to **5**), which gave 7-phenylnorbornane (**9**) as the major product (58% yield) in addition to a 17% yield of the fluorosulfate ester (**8**). The structure of **9** followed readily from elemental analysis and spectra, especially the ^{13}Cmr spectrum which showed in the saturated carbon region only the characteristic four signal pattern appropriate to the symmetrical 7-norbornyl skeleton. The formation of **9** is simply explained as a Friedel–Crafts reaction involving the norbornyl cation (**7**) as in Scheme 2. Since 7-norbornyl fluorosulfate gave no reaction with benzene under these conditions, the [0]betylate (**6**) is presumably the immediate precursor of the cation (**7**). The formation of the Friedel–Crafts product from the 7-norbornyl *N*,*N*-dimethylsulfamate (**5**), is to be contrasted with the reactions of the ethyl and 2,2,2-trifluoroethyl esters (**1**), which, as expected for a simple concerted (S_N2) displacement, gave no sign of the alkylbenzene when benzene was included in the reaction mixture. An even clearer indication of the same point is the reaction of 3-phenyl-1-propyl *N*,*N*-dimethylsulfamate; there was no sign in the nmr spectrum of the crude product of any indane, the intramolecular Friedel–Crafts product.

Reaction of isopropyl *N*,*N*-dimethylsulfamate (**1**, R = Me_2CH), on the other hand, gave some cumene, pointing to the presence of isopropyl cation in the reaction mixture. The known ability of isopropyl fluorosulfate to form cumene with benzene (5), taken with the presence in the nmr spectrum as the reaction proceeds of peaks ascribable to isopropyl fluorosulfate, points to the following sequence.



Still pursuing the goal of isolating an alkyl [0]betylate we attempted to prepare 1-apocamphyl

[5]Gassman *et al.* (11) report that sodium methoxide in methanol reacts with 7-norbornyl tosylate by way of S—O cleavage to form 7-norbornanol with no trace of the products of S_N2 attack on C-7 with C—O cleavage.

and 1-norbornyl[6] [0]betylates, but were thwarted by difficulties in obtaining the *N*,*N*-dimethylsulfamate ester from the alcohol.

As was mentioned, the reaction of methyl *N*,*N*-dimethylsulfamate (**1**, R = Me) is different in one important respect from that of all of the other *N*,*N*-dimethylsulfamate esters: methyl fluorosulfate is a product of the reaction as well as a reagent. The picture is further complicated by the fact that the methyl ester (**1**, R = Me) rearranges to the betaine (**4**) merely on standing at room temperature for an extended period (12, 13), and the question then arises, does the betaine (**4**) which is produced when the methyl ester (**1**, R = Me) is mixed with methyl fluorosulfate come from the previously known uncatalyzed rearrangement, or is it formed as in Scheme 1? Our limited observations indicate that the latter route accounts for at least part of the product. Whereas "a period of several weeks" is reported (14) as the time required for complete rearrangement of neat methyl *N*,*N*-dimethylsulfamate (**1**, R = Me) at room temperature, we found that in the presence of methyl fluorosulfate (about 30 mol%) the ester (**1**, R = Me) was converted to **4** in seven days. The roughly first order disappearance of **1** (R = Me) as followed by nmr spectra gave $k \approx 6 \times 10^{-5}\ s^{-1}$, or $t_{1/2} = 21$ h; the amount of methyl fluorosulfate remained constant. In another nmr experiment using methyl-d_3 fluorosulfate, a peak at 4.20 ppm characteristic of methyl fluorosulfate (and which was initially absent) gradually developed; this is precisely what would be expected from the Scheme 1 route, but not from a reaction in which methyl fluorosulfate is merely a spectator. The rate of the rather slow reaction of a solution (1.8 *M*) of **1** (R = Me) in chloroform-*d* containing methyl fluorosulfate (0.8 *M*) was also followed by nmr. The amount of methyl fluorosulfate remained constant while that of **1** (R = Me) decreased steadily. The reaction was more than 90% complete after six weeks at 40°C, but neither first nor second order plots showed acceptable linearity. The data suggested rather a mixed order reaction such as might arise if the reaction were proceeding in part as in Scheme 1 and in part by a second order process. The nature of the latter is uncertain but it could be alkylation of the ester (**1**) by the intermediate ion pair (**2** FSO_3^-) to form the betaine (**4**) plus another ion pair (**2** FSO_3^-). With the aid of the steady state assumption (which is justified by the absence of any peaks ascribable to **2** in the nmr spectra), one may readily show that such a chain propagation step, **2** $FSO_3^- + \mathbf{1} \rightarrow \mathbf{4} + \mathbf{2}\ FSO_3^-$, would lead to a second order dependence on the ester (**1**, R = Me).

Another possibility is that the putative second order reaction is simply the uncatalyzed rearrangement that occurs in the absence of methyl fluorosulfate. The mechanism of this reaction has in fact been studied by Ziegler and Orchin (13) who report a first order rate constant for the rearrangement in 1,2,4-trichlorobenzene at 130–132°C. They also observed, however, the formation of crossed products from reaction of a mixture of two sulfamic esters and concluded that their "experiments suggest that the rearrangement proceeds through some type of ion pair", which they represent as a methyl cation – *N*,*N*-dimethylsulfamate ion pair. This route, however, appears highly improbable in the light of recent information on the difficulty of intramolecular transfer of a methyl group between nucleophilic centres (15, 16). It is evident on examination of a fuller description of this work (14) that the experimental difficulties were such that a reaction order of greater than unity for the rearrangement of **1** (R = Me) is not precluded.[7] In the context of the present paper it is tempting to suggest that the first step of the reaction is a bimolecular methyl transfer to form the [0]betylate sulfamate ion pair, $Me_3\overset{+}{N}SO_2OMe\ Me_2NSO_3^-$, and that this may then either collapse to form two molecules of the betaine (**4**), or else undergo methyl transfer chain propagation steps with unreacted ester (**1**, R = Me); such a scheme would lead to second or higher order dependence on the ester (**1**, R = Me).[8] If the first step in the uncatalyzed rearrangement is indeed methylation of the ester (**1**, R = Me) by another molecule of the same ester, it is highly unlikely that such a process would compete with methylation by methyl fluorosulfate, a far more powerful methylating agent.[9] This would suggest that the uncatalyzed rearrangement is not the second (or higher) order process which appears to be present in the reaction of the ester (**1**, R = Me) with methyl fluorosulfate, but it is evident that further work is required to make any definite pronounce-

[6]We are grateful to Dr. D. F. Tavares (University of Calgary) for his patient efforts in this frustrating endeavour.

[7]NOTE ADDED IN PROOF: Recent crossing experiments with a mixture of deuterium-labelled and unlabelled **1** (R = Me) show the rearrangement to **4** to be entirely *intermolecular* in acetonitrile solution starting with total concentrations of either 0.08 *M* or 2.0 *M* (see ref. 34).

[8]Kinetic analysis of an exactly analogous scheme is given in a discussion of the closely related intramolecular rearrangement of $Me_2N(CH_2)_4SO_2OMe$ to the corresponding betaine (16).

[9]The quantitative relationships developed in the next section predict that methyl fluorosulfate methylates water and triethylamine respectively 10^5 and 10^8 times faster than does methyl *N*,*N*-dimethylsulfamate (**1**, R = Me).

TABLE 2. Rate constants for nucleophilic substitution reactions of ZSO_2OR

	R = Methyl		R = Ethyl	
Z	H_2O[a] (s^{-1})	Sodium *p*-nitrophenoxide[b] ($M^{-1}s^{-1}$)	Triethylamine[c] ($M^{-1}s^{-1}$)	Sodium ethyl acetoacetate[d] ($M^{-1}s^{-1}$)
Methyl	1.66×10^{-7}	—	3.6×10^{-7}	—
Phenyl	3.78×10^{-7}	—	—	—
p-Tolyl	—	0.0196	1.2×10^{-6}	1.3×10^{-5}

[e]Statistically corrected (i.e. *k*/2).

ment on the formation of the betaine (**4**) from the ester (**1**, R = Me) other than that Scheme 1 is followed for at least part of the reaction in the presence of methyl fluorosulfate.

Prediction of the Rates of Reaction of [0]Betylates and Other Alkyl Esters of General Formula $ROSO_2Z$

It is evident from both this and earlier work that change of Z in compounds of the general formula $ROSO_2Z$ can have a very large effect on the ease of nucleophilic displacement of the R group. In this section we examine previously reported data with an eye to finding a useful predictive relationship, and then check to see if this and our admittedly limited information on [0]betylate reactivity are consistent.

Previous rate data on compounds of the general formula $ROSO_2Z$ having quite different substituent groups, Z, are summarized in Table 2. One may see immediately that electron-withdrawing substituents accelerate these reactions, but closer inspection shows that this is not a direct function of a simple inductive (or field) effect. Log *k* values for these reactions correlate only indifferently with the Taft σ^* values, for example, with correlation coefficients (*r*) ranging from 0.88 to 0.94. Note particularly the two series having both Z = CF_3 and F; in both cases the triflate reacts faster than the fluorosulfate even though σ^* (or σ_I) is greater for a fluoro than a trifluoromethyl substituent. The data are not without pattern, however; a least-squares linear regression analysis of each of the three other reactions with respect to the hydrolysis at 0.3°C yields correlation coefficients that are all greater than 0.997.

Perhaps the simplest solution to the problem is to postulate resonance:

$$ROSO_2\text{—}\ddot{Z} \leftrightarrow RO\bar{S}O_2{=}Z^+$$

This hypothesis is, of course, not new, an excellent case for electron donation into the sulfonyl group having been made some time ago by Bordwell *et al.* (21). Such electron delocalization would be expected to be important in stabilizing the ground state (as shown) and also in inhibiting the development of a partial negative charge on the dicoordinated oxygen atom in the transition state. We find, in fact, that the use of a modified σ^* parameter which specifically includes a resonance component gives quantitative support for this idea. The new parameter, which we call σ_x^*, is derived directly from the field and resonance parameters of Swain and Lupton (3) with scaling to facilitate comparison with conventional σ^* and ρ^* values.[10] In particular, σ_{15}^* and σ_{20}^* values, i.e. σ^* values with respectively "15% resonance" and "20% resonance" components (3), yield quite acceptable correlations having *r* values ranging from 0.969 to 1.000. Tables 3 and 4 list the results obtained on the basis of "15% resonance"; correlations with σ_{20}^* values are not very different, being slightly better with the hydrolysis and triethylamine reactions and rather poorer with the *p*-nitrophenoxide and enolate displacements. Table 4 also reports, in parentheses,

[10]We define σ_x^* from the Swain-Lupton relation $\sigma = f\mathcal{F} + r\mathcal{R}$, as follows:

(*i*) $(\sigma_x^*)_z = 2.60\,[\mathcal{F}_z + 1.6\mathcal{R}_z x/(100 - x)] + 0.49$

where $x = \%\mathcal{R}$ the "percent resonance" or "sensitivity to resonance effects", and $\mathcal{F}_z$ and $\mathcal{R}_z$ are the field and resonance parameters for substituent Z, all as defined by Swain and Lupton (3). The constants 2.60 and 0.49 (which were obtained from $\sigma_H^* = 0.49$ and $\sigma^*_{Me_3N^+} = 4.29$[11]) give σ_x^* values such that in the absence of resonance effects (i.e. either $x = 0$ for a reaction or $\mathcal{R} = 0$ for a substituent) then $(\sigma_x^*)_z \equiv \sigma_z^*$ (if calculated from $\mathcal{F}$ and $\mathcal{R}$).

[11]The value $\sigma^*_{Me_3N^+} = 4.29$ was obtained from the expression $pK_a = 4.81 - 0.69\sigma^*$ relating pK_a values of acids of the type ZCH_2COOH to the calculated σ^* values of Takahashi *et al.* (22) (J. P. Guthrie, private communication).

TABLE 3. σ^*_{15} values[a]

Z	$\mathscr{F}$	$\mathscr{R}$	σ^*_{15}
CH_3	−0.052	−0.141	0.25
C_6H_5[b]	0.139	−0.088	0.79
C_2H_5O	0.363	−0.444	1.11
CH_3O	0.413	−0.500	1.20
F	0.708	−0.336	2.08
CF_3	0.631	0.181	2.26

[a]$\mathscr{F}$ and $\mathscr{R}$ values are from Swain and Lupton (3), the σ^*_{15} values are calculated from $\sigma^*_{15} = 2.60\,(\mathscr{F} + 0.282\,\mathscr{R}) + 0.49$.
[b]The same values were assigned to *p*-tolyl.

results obtained assuming $\sigma^*_{15} = \sigma^*_0 = 2.13$ for the CF_3 group, i.e. that there is no resonance contribution with this substituent. The proposed resonance involves electron donation from the Z group, whereas the positive value of the $\mathscr{R}$ parameter of the CF_3 group signifies electron withdrawal. It is at least arguable that no such electron withdrawal will occur between sulfonyl and trifluoromethyl groups and hence that a different substituent parameter is appropriate. It is evident, however, from Table 4 that the results are much the same with or without a trifluoromethyl resonance component.

The addition of an adjustable parameter can be expected, of course, to improve any correlation, but it should be specifically noted in the present discussion that the *same* value, i.e. "15% resonance", gives a good fit for *four* separate reaction series. When this is taken with the considerable body of other evidence supporting electron donation into a sulfonyl group (21), the present treatment is in our view eminently sensible; it is clearly capable of direct application not only to reactions of other sulfonyl compounds but, in principle, also to reactions of any system in which resonance occurs between the substituent and the reacting centre.

From the final column in Table 4 we note that the rate constants predicted for the corresponding reactions of [0]betylate are indeed high, and that our failure to isolate or even in most instances to see any direct sign of an alkyl [0]betylate is therefore not surprising.

The one reaction which may have given such a sign was that of 7-norbornyl *N,N*-dimethylsulfamate (**5**), which showed a small peak at 3.75 ppm as the reaction proceeded. The position of this signal was close to that for the methyl group in phenyl [0]betylate fluorosulfate, i.e. 3.70 ppm (**1**); if it was indeed due to **6** then the size of the peak would indicate a maximum of about 10% of **6** during the reaction. From this value plus a rough estimate of the rate constant of about $6 \times 10^{-5}\,s^{-1}$ for disappearance of **5**, we may arrive at a first order rate constant of about $4 \times 10^{-4}\,s^{-1}$ for the reaction **6** → **7** in methyl fluorosulfate; this number is a minimum value since if the peak in question is not due to **6**, then in the absence of any larger appropriate peaks to assign to **6**, we must assume that **6** reacts even more quickly.

For comparison, the reported rate constants for the acetolyses of 7-norbornyl *p*-tosylate and triflate at 25°C are respectively $6.36 \times 10^{-15}\,s^{-1}$ (8) and $1.37 \times 10^{-9}\,s^{-1}$ (23). We have no direct information on the relative ease of ionization reactions in methyl fluorosulfate vs. acetic acid, but we may hazard a guess via the Hildebrand solubility parameter δ, which has been correlated by Herbrandson and Neufeld (24) with the Winstein–Grunwald solvent parameter **Y**. The relation $\mathbf{Y} = 0.524\,\delta_{25} - 8.25$ and $\delta_{25} = 9.9$ gives a **Y** value of −3.6 for methyl fluorosulfate.[12] For acetic acid **Y** = −1.639 (27), and hence the rate of ionization of *tert*-butyl chloride is estimated to be about 100 times faster in acetic acid than in methyl fluorosulfate. If we may apply the same factor to the ionization of **6** then we obtain $4 \times 10^{-2}\,s^{-1}$ for acetolysis of **6** at 25°C. This estimate, though very rough, is remarkably close to the rate constant, $3 \times 10^{-2}\,s^{-1}$, that we may calculate from the acetolysis rates of the tosylate and triflate taken with σ^*_{15} values given in Table 3; using $\sigma^*_{15} = 2.13$ for trifluoromethyl (as discussed) gives $5 \times 10^{-1}\,s^{-1}$ for the acetolysis of the [0]betylate (**6**). Though the approximations made in this analysis are both many and crude, the results are in full agreement with the mechanism in Scheme 2.

It should perhaps be explicitly noted that although the modified Taft equation gives us a quantitative picture of the reactivity of [0]betylates, the simple qualitative conclusion that [0]betylates are highly nucleofugal is quite independent of any such treatment. Whereas the rate constant for acetolysis of 7-norbornyl triflate at room temperature is about $10^{-9}\,s^{-1}$, the lower limit for the specific rate of the reaction **6** → **7** in methyl fluorosulfate, which is in all likelihood a less polar medium, is about $10^{-4}\,s^{-1}$. A [0]betylate is therefore more nucleofugal than a triflate, itself a "super sulfonate", by at least five orders of magnitude, and must be one of the most powerful nucleofuges for which a derivative has been isolated and characterized. This conclusion invites comparison of [0]betylates with diazonium ions, the simple alkyl derivatives of which are highly reactive transient species whereas aryl and certain specially constructed alkyl derivatives

[12]The value of δ_{25} was calculated from $d = 1.424$ and bp 92°C (25) as described by Hildebrand and Scott (26).

TABLE 4. Correlation of the reactions of ZSO_2OR with σ_{15}^*

Reagent[a]	ρ_{15}^{*}[b]	log k_0[b]	r[b]	Estimated[c] $k_{Me_3N}^{+}$
Water (R = Me)	2.36 (2.45)[d]	−7.90 (−7.95)	0.978 (0.973)	$2 \times 10^2\ s^{-1}$ $(4 \times 10^2\ s^{-1})$
Sodium nitrophenoxide (R = Me)	3.28 (3.62)[d]	−4.30 (−4.63)	1.000 (1.000)	$6 \times 10^9\ M^{-1}\ s^{-1}$ $(8 \times 10^{10}\ M^{-1}\ s^{-1})$
Triethylamine (R = Et)	3.25	−7.93	0.969	$1 \times 10^6\ M^{-1}\ s^{-1}$
Sodium ethylacetoacetate (R = Et)	4.23 (4.48)[d]	−9.93 (−10.18)	0.999 (0.999)	$2 \times 10^8\ M^{-1}\ s^{-1}$ $(1 \times 10^9\ M^{-1}\ s^{-1})$

[a]In the reactions described in Table 2.
[b]Slope (ρ_{15}^{*}), intercept (log k_0), and correlation coefficient (r) obtained by least-squares linear regression.
[c]Rate constant estimated for $Me_3\overset{+}{N}SO_2OR$ using $\sigma_{15}^{*} = \sigma^{*} = 4.29$[10] and the linear regression parameters.
[d]Values in parentheses are calculated using $\sigma_{15}^{*} = \sigma_0^{*} = 2.13$ for CF_3, i.e. assuming no electron-withdrawing resonance (see text).

are isolable. The evidence for formation of phenyl cations from aryldiazonium salts (28), taken with our failure to observe any analogous reactions from phenyl [0]betylate (1), would suggest that, in this particular system, at least, the diazonium ion is probably the more nucleofugal group.

It seems likely that the high reactivity of the [0]betylate function and its ease of formation from a hydroxylic precursor will combine to make it a synthetically useful as well as mechanistically interesting group. The present papers, however, constitute only the initial survey of the chemistry of [0]betylates and the numerous unanswered questions raised here, and many others as well, must await further experimentation.

Experimental

Spectrometers and general procedures are the same as those given in the accompanying paper (1). The ^{19}Fmr spectra were also determined on a Varian XL-100 instrument. Vapour phase chromatography was carried out with a F + M 700 Chromatograph using 6 ft × 1/4 in. columns containing silicone rubber SE 30 on Chromosorb W. The alcohols used in the preparation of **1** were commercial materials except for 7-norbornanol which was made from norbornene by a known route (29).

Preparation of Alkyl N,N-*Dimethylsulfamates (1)*

A suspension in 1,2-dimethoxyethane of the sodium alkoxide, generated by reaction of the alcohol with oil-free sodium hydride, was treated with *N,N*-dimethylsulfamoyl chloride (30). The scale of the preparations varied from 1 to 50 mmol; the limiting reagent with low boiling alcohols was the sulfamoyl chloride but with the others was the hydroxylic starting material. The properties and yields are summarized in Table 5. The methyl ester (**1**, R = Me) was used in further experiments without any attempt at purification by distillation; this ester rearranges readily to **4** on heating and is reported to be undistillable (12).

Reaction of Methyl Fluorosulfate with Alkyl N,N-*Dimethylsulfamate Esters (1)*

A preliminary examination of each reaction was carried out by observing the proton nmr spectrum (T-60) after standing for intervals (with or without heating) of a solution of the sulfamic ester (**1**) (about 0.3 mmol) in methyl fluorosulfate (0.3 mL) in a sealed nmr tube. Yields and spectra of products from preparative runs are given in Table 1.

(a) Ethyl N,N-*Dimethylsulfamate (1, R = Et)*

After one day at room temperature the proton nmr spectrum (XL-100) of a mixture of ethyl *N,N*-dimethylsulfamate (53 mmol) and benzene (80 mmol) in excess methyl fluorosulfate showed peaks at 1.55 (t), 4.61 (q), and 7.43 (s) (all relative to the singlet at 4.20 ppm due to $MeOSO_2F$); no sign of any signals appropriate to the ethyl group of ethyl benzene was observed; the ^{19}F spectrum showed a peak at −35.0 relative to the peak due to methyl fluorosulfate at −31.42 ppm.

(b) 1-Butyl N,N-*Dimethylsulfamate (1, R = $CH_3CH_2CH_2CH_2$)*

The nmr tube experiment indicated the reaction to be about half complete after 6 h, and complete after 5 days at room temperature.

The butyl ester (**1**, R = $CH_3CH_2CH_2CH_2$) (6.2 g, 34 mmol) and methyl fluorosulfate (3.1 g, 27 mmol) were allowed to stand at room temperature in a sealed ampoule for 6 days, whereupon the brown supernatant liquid was decanted from the white deposit of the betaine (**4**). The solid was washed with dry CH_2Cl_2 and the combined liquid phases distilled. The initial distillate at atmospheric pressure was mostly CH_2Cl_2 and was discarded. Distillation under reduced pressure (about 25 Torr) gave 1-butyl fluorosulfate (bp 57°C, 2.9 g, 68%).

(c) Propyl N,N-*Dimethylsulfamate (1, R = $CH_3CH_2CH_2$)*

The nmr experiment showed roughly 80% reaction after 24 h at room temperature. In the preparative experiment a mixture of methyl fluorosulfate (3.3 g, 29 mmol) and the propyl ester (6 g, 36 mmol) were allowed to stand at room temperature and then worked up in the same way as the product from the 1-butyl ester, to give propyl fluorosulfate (1.85 g, 45%).

(d) 2,2,2-Trifluoroethyl N,N-*Dimethylsulfamate (1, R = CF_3CH_2)*

The nmr experiment (with added benzene) after 3 days at 60°C showed about 80% conversion to 2,2,2-trifluoroethyl fluorosulfate, which gave a quartet at 4.8 ppm (i.e. 0.6 ppm downfield from the singlet of methyl fluorosulfate); there was no sign of any product derived from alkylation of the benzene. The white precipitate showed a peak at 3.1 ppm (CD_3CN) appropriate to the betaine (**4**).

A mixture of the sulfamic ester (**1**, R = CF_3CH_2) (5.8 g, 28 mmol) and methyl fluorosulfate (2.51 g, 22 mmol) was heated in a sealed ampoule at 70°C for 12 days. Work-up and distillation (at atmospheric pressure) as with the butyl ester gave a sample

of 2,2,2-trifluoroethyl fluorosulfate (1.46 g, 36%) which appeared to contain a minor amount of impurity; the purest fraction boiled at 82–83°C. *Anal.* calcd. for $C_2H_2F_4O_3S$: C 13.19, H 1.10; found: C 12.94, H 1.23.

(e) 3-Phenyl-1-propyl N,N-*Dimethylsulfamate (1, R = $PhCH_2CH_2CH_2$)*

The nmr experiment indicated that reaction was complete in 2 h at 60°C. Reaction of the ester (**1**, R = $PhCH_2CH_2CH_2$) (3 g, 12 mmol) and methyl fluorosulfate (4 mL, 50 mmol) at 60°C for 5 h, followed by work-up as above, gave a brown liquid (2.3 g, 86% crude yield) the nmr spectrum of which indicated the product to be >90% 3-phenyl-1-propyl fluorosulfate with no sign of any peaks ascribable to indane. Distillation gave a colorless oil (1.4 g, 52%) boiling at 75–77°C/0.8 Torr. Mass spectrum: M^+ calcd. 218.0409; found 218.0413.

(f) 7-Norbornyl N,N-*Dimethylsulfamate (5)*

The nmr experiment (with added benzene) showed 30% reaction (as measured by the shrinkage of the signal at 2.9 ppm) after 75 min and 50% reaction after 210 min corresponding to a rate constant for disappearance of **5** of about 6×10^{-5} s^{-1}. An extra signal about 0.1 ppm upfield from that of benzene pointed to formation of an aromatic product, and a small peak at 3.75 ppm consistent with the intermediacy of **6** (~10%) was present in the spectra observed after 75 and 210 min of reaction.

In a preparative run the ester (**5**, 0.6 g, 2.7 mmol) and methyl fluorosulfate (1.5 mL, 18.5 mmol) were allowed to react for 60 h at room temperature. Carbon tetrachloride was added to the reaction mixture and the liquid phase separated from the solid; the latter was washed twice with more CCl_4 and the CCl_4 solutions combined and the solvent evaporated leaving a crude product (0.32 g, 60%) which appeared from its nmr spectrum to consist of the fluorosulfate ester (**8**) containing a small amount (<10%) of starting sulfamate (**5**). Two distillations under reduced pressure (20 Torr, bath 115°C) gave the pure product (0.17 g, 32%). *Anal.* calcd. for $C_7H_{11}FO_3S$: C 43.30, H 5.67, S 16.50; found: C 43.22, H 5.82, S 16.32.

In another reaction a mixture of **5** (0.28 g, 1.3 mmol) and methyl fluorosulfate (0.3 mL, 3.7 mmol) with benzene (0.3 g, 3.9 mmol) was allowed to stand at room temperature for 20 h, after which time the mixture consisted of a dark purple liquid and a white solid. The volatile constituents were evaporated and the residue mixed with ether; the ether solution was separated from the solid (**4**), and the solvent evaporated. The residue was then mixed with hexanes, the solution separated from the small amount of coloured oil, and the solvent evaporated. The crude product (0.17 g) appeared from its nmr spectrum to consist almost entirely of 7-phenylnorbornane (**9**) and 7-norbornyl fluorosulfate (**8**); the relative areas of the peaks at 2.9 and 4.9 ppm indicated a 3:1 ratio of **9** to **8**, or yields of about 58% and 17%, respectively. The product from five similar small scale runs was chromatographed on a column of silica gel. 7-Phenylnorbornane (**9**) was eluted with hexanes and distilled (bath 105°C/6 Torr). Infrared ν_{max}: 2955 (vs), 1600 (m), 1495 (s), 1450 (s), 720 (s), 695 (s) cm^{-1}; ^{1}Hmr δ: 7.18 (5H, m), 2.86 (1H, br s), 2.53 (2H, br s), 1.0–1.8 (8H, m) ppm; ^{13}Cmr δ: 23.9 (CH_2), 26.8 (CH_2), 35.9 (CH), 50.0 (CH), 122.0 (CH), 124.3 (CH), 124.6 (CH), 138.2 (C) ppm. *Anal.* calcd. for $C_{13}H_{16}$: C 90.70, H 9.31; found: C 90.47, H 9.51.

When a small sample of the crude reaction product (i.e. before any work-up), derived from reaction of **5** with methyl fluorosulfate without benzene, was treated with excess benzene and allowed to stand for 19 h at room temperature, the nmr spectrum showed no sign of any 7-phenylnorbornane (**9**).

(g) Isobutyl N,N-*Dimethylsulfamate (1, R = Me_2CHCH_2)*

The nmr experiment showed the reaction to be complete after about 18 h at room temperature (as judged by the virtual disappearance of the original peak at 2.9 ppm); extensive signal broadening perhaps due to the presence of a solid phase (**4**) made interpretation difficult, but strong peaks at 0.9 to 1.1 and 1.2 to 1.3 ppm suggested dimeric and perhaps oligomeric products from isobutene.

In a preparative experiment nitrogen was passed over a mixture of isobutyl *N,N*-dimethylsulfamate (2 g, 11 mmol) and methyl fluorosulfate (4 mL, 49.5 mmol) and the gas stream passed through a trap cooled in a Dry Ice – acetone bath. After 4 h a visible condensate had collected in the trap. The nmr spectrum of this material ($CDCl_3$) showed broad "singlets" at 1.7 and 4.6 ppm identical with those of an authentic sample of isobutene, and, in addition two peaks of equal intensity ascribable to *tert*-butyl fluoride, δ 1.33 ppm, J_{HF} = 20.4 Hz; reported: 1.30 ppm, J_{HF} = 20 Hz (neat) (31) and 1.33 ppm, J_{HF} = 20.5 Hz (CCl_4) (32). The infrared spectrum (gas phase) showed peaks at 2970, 1770, 1655, 1455, and 890 cm^{-1} as shown by authentic isobutene, plus additional strong peaks at 1380, 1260, and 1200 cm^{-1}; the gas phase ir spectrum of *tert*-butyl fluoride is reported to show strong bands at 1380, 1260, 1205, and 890 cm^{-1} (33).

In another experiment nitrogen was passed over a mixture of the sulfamic ester (1 g, 5.5 mmol), methyl fluorosulfate (1.5 mL, 18.6 mmol), and calcium carbonate (1 g) at room temperature for 2.5 h while the gas stream passed through a trap cooled in a Dry Ice – isopropyl alcohol mixture. Pentane (0.34 g) was added to the trap and the solution analyzed by vpc; the quantity of isobutene in the trap was thereby estimated to be about 50 mg (16% yield).

(h) Neopentyl N,N-*Dimethylsulfamate (1, R = Me_3CCH_2)*

A mixture of the sulfamate ester (**1**, R = Me_3CCH_2) (1.8 g, 9.2 mmol) and methyl fluorosulfate (3 mL, 37 mmol) was allowed to stand at room temperature for 1.5 h. Nitrogen was passed through the mixture of liquid and solid (**4**) and then through a trap cooled in Dry Ice. The nmr spectrum of the product was found by comparison with authentic spectra to correspond to a 2:1 mixture of methyl fluorosulfate and 2-methyl-2-butene. In another experiment the volatile products were analyzed by vpc; addition of an authentic specimen of 2-methyl-2-butene enhanced the signal of the major volatile product.

(i) Isopropyl N,N-*Dimethylsulfamate (1, R = Me_2CH)*

The nmr experiment showed new peaks at 1.6 (d) and 5.2 (m) ppm strongly suggestive of isopropyl fluorosulfate. These peaks reached maximum intensity around 2 to 3 h after start of the reaction and then gradually disappeared. A mixture of the sulfamate ester (43 mg, 0.3 mmol), methyl fluorosulfate (0.2 mL, 2.5 mmol), and benzene (182 mg, 2.3 mmol) was observed by nmr; the starting material had virtually disappeared after 7 h at room temperature. Signals in both the nmr spectrum and vpc assigned to cumene were enhanced on addition of authentic cumene.

(j) Methyl N,N-*Dimethylsulfamate (1, R = Me)*

A mixture of the methyl ester (**1**, R = Me), methyl fluorosulfate, and benzene (added as the nmr integration standard) in a molar ratio of 8:3:1 a sealed nmr tube was allowed to stand at room temperature. After an initial drop (in the first 3 h) perhaps due to adventitious hydrolysis, the methyl fluorosulfate signal stayed constant while the disappearance of the methoxy methyl signal (at 3.8 ppm) followed a first order rate law to >90% reaction, $k = 9.6 \times 10^{-6}$ s^{-1} ($r = 0.995$).

In another experiment a solution of the ester (**1**, R = Me) (94 mg, 0.68 mmol, 1.8 *M*), methyl fluorosulfate (34 mg, 0.3 mmol, 0.8 *M*), and benzene (24 mg, 0.3 mmol, 0.8 *M*) in $CDCl_3$ (364 g, 243 μL) in a sealed nmr tube was heated in an oil bath at 40.2°C. The nmr spectrum was determined at intervals over a period of about 6 weeks at the end of which time the concentration of the ester was <30% of the initial concentration; the methyl fluorosulfate concentration was unaltered. The ester was half consumed after about 240 h. A plot of ln[ester] vs. time was distinctly curved, the slope diminishing at longer times;

plots of 1/[ester] and 1/[ester]$^{1/2}$ vs. time were also curved with the slopes increasing at longer times.

Reaction of 3-Phenyl-1-propyl N,N-*Dimethylsulfamate (1, R = $PhCH_2CH_2CH_2$) with Methyl Trifluoromethanesulfonate*

The nmr spectrum of a mixture of the sulfamic ester and excess methyl triflate held at room temperature was observed at intervals. The triplet at 4.1 ppm due to the sulfamic ester (and which was partly obscured by the singlet at 4.1 of the methyl triflate) gradually disappeared while a new triplet appeared at 4.5 ppm. Other peaks were observed at 7.1 (s), 2.6–3.0 (m), and 1.9–2.4 (m). The reaction appeared complete after about 24 h; the product consisted of a white solid (presumed to be **4**) and a light brown liquid. Addition of a sample of 3-phenyl-1-propyl triflate prepared by reaction of sodium 3-phenyl-1-propoxide with triflic anhydride enhanced the above signals.

Acknowledgements

We thank Professor J. B. Stothers for the ^{13}Cmr spectra, Mrs. Heather Schroeder for the ^{19}F and the XL-100 ^{1}Hmr spectra, and Mr. Doug Hairsine for the mass spectra. This work was supported by a grant from the National Research Council of Canada.

Reaction des glycosyl isonitriles avec les amines et les alcools

DANIELLE MARMET, PAUL BOULLANGER ET GÉRARD DESCOTES

Université Claude Bernard Lyon I, Ecole Supérieure de Chimie Industrielle de Lyon, ERA 689 du C.N.R.S., 69622 Villeurbanne, France

Reçu le 28 mai 1980

Ce papier est dédié au Prof. Raymond U. Lemieux pour son 60ème anniversaire

DANIELLE MARMET, PAUL BOULLANGER et GÉRARD DESCOTES. Can. J. Chem. **59**, 373 (1981).

Après complexation par les métaux, les glycosylisonitriles **1** peuvent réagir avec les alcools pour conduire principalement à des orthoesters si le carbone C-2 porte un groupe participant et (ou) à des alkyl glycosides sans stéréosélectivité particulière. Avec les amines, l'α-addition sur **1** conduit à des formamidines avec de bons rendements. La synthèse stéréospécifique d'une glucosyl quinazolinone **15** est décrite par hétérocyclisation ultérieure de la formamidine obtenue avec l'anthranilate de méthyle.

DANIELLE MARMET, PAUL BOULLANGER, and GÉRARD DESCOTES. Can. J. Chem. **59**, 373 (1981).

After complexation with metals, glycosylisonitriles **1** react with alcohols to give mainly orthoesters, if C-2 bears a participating group, and/or alkyl glycosides without particular stereoselectivity. In the case of amines, formamidines are obtained by α-addition to **1** in good yields. An example of further heterocyclisation is given with the stereospecific synthesis of the glucosyl-quinazolinone **15**.

Introduction

Notre récente synthèse de glycosylisonitriles (1) nous a permis d'étudier leur réactivité comme synthons et de la comparer avec celle d'isonitriles non glucidiques.

De nombreuses données de la littérature en série aliphatique permettaient d'envisager des réactions d'α-métallation à l'aide de bases fortes (2) ou d'α-additions de composés à hydrogène mobile par complexation avec divers métaux ou sels métalliques (3) (Schéma 1).

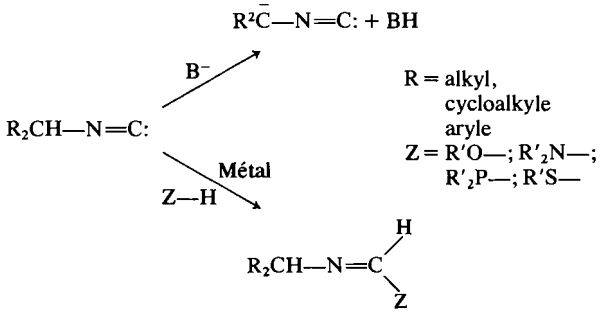

SCHÉMA 1

Nos essais d'arrachement du proton anomère par métallation se sont révélés négatifs quels que soient la base ou le glycosylisonitrile utilisés. Ce manque de réactivité, qui peut être raisonnablement attribué à l'effet mésomère donneur défavorable de l'oxygène du cycle, peut être rapproché des récents échecs de Nolte *et al.* (4) au cours d'essais d'anomérisation par diverses bases fortes d'un glucosylisonitrile de configuration β.

Par contre, l'étude de la réactivité, vis-à-vis de composés à hydrogène mobile, des glucosylisonitriles complexés par des sels métalliques a permis de mettre en évidence une différence importante entre les amines qui donnent une réaction d'α-addition (5) et les alcools qui ne donnent lieu qu'à une réaction de substitution non observée en série aliphatique.

La complexation des glucosylisonitriles avec des métaux et sels métalliques et la réactivité des complexes ainsi obtenus avec quelques alcools et amines font l'objet de cette publication.

Résultats et discussion

Complexation de glucosylisonitriles avec divers métaux et sels métalliques

Comme l'ont montré Saegusa *et al.* les α-additions d'alcools (6) et d'amines (5) sur les isonitriles ne peuvent être réalisées que par la formation de complexes intermédiaires σ entre les isonitriles et des sels métalliques ou métaux des groupes IB (Cu, Ag, Au) ou IIB (Zn, Cd, Hg) (Schéma 2). Les métaux et leurs chlorures peuvent catalyser l'addition des amines aliphatiques à température ambiante (6); les métaux et leurs oxydes celle des alcools à 120°C (6).

La formation de ces complexes peut être mise en évidence en spectroscopie infrarouge par l'observation d'un déplacement vers les courtes longueurs d'onde de la bande isonitrile après complexation (7). La valeur absolue du déplacement ν N=C :) complexé − ν (N=C :) libre donne une

indication sur la stabilité du complexe formé puisqu'un grand déplacement de bande indique un complexe stable et peu réactif et un déplacement faible, un complexe moins stable et plus réactif (3).

La complexation du tétra-*O*-acétyl-2,3,4,6-β-D-glucopyranosylisonitrile **1** avec divers métaux et sels métalliques, étudiée dans divers solvants a montré que la valeur ν (N≡C :) complexé − ν (N≡C:) libre était indépendante du solvant (éther, dichlorométhane, acétonitrile) excepté dans le cas du chlorure d'argent. En spectroscopie infrarouge on observe à côté de la bande isonitrile libre à 2145 cm^{-1} une faible bande due à l'isonitrile complexé et correspondant à un déplacement moyen de 40 à 50 cm^{-1} en accord avec ceux précédemment décrits par Saegusa et Ito (3).

Les résultats de ces complexations sont résumés dans le Tableau 1.

Les résultats du Tableau 1 montrent que deux systèmes catalytiques provoquent la formation de complexes de plus faible stabilité dont la stoechiométrie n'a pas été étudiée: le chlorure d'argent dans l'acétonitrile et le chlorure mercurique dans le dichlorométhane ou l'acétonitrile (δ:ν (N≡C:) = 39 cm^{-1} et 33 cm^{-1} respectivement). Leur utilisation ultérieure a confirmé leur meilleure réactivité dans la réaction avec les alcools pour le chlorure d'argent et dans l'α-addition des amines aromatiques pour le chlorure mercurique.

Réactivité des alcools avec les glucosylisonitriles complexés

Le manque de réactivité des alcools sur les glucosylisonitriles libres, indépendemment de la température, ou complexés à température ambiante, quels que soient le sel métallique ou l'alcool saturé utilisés est en accord avec les résultats obtenus en série aliphatique par Saegusa *et al.* (5).

A température plus élevée cependant (≥ 70°C), deux types de réactions sont observés en fonction de l'agent complexant utilisé. Les complexes formés avec les oxydes cuivreux ou cuivriques (meilleurs catalyseurs d'α-addition d'alcools selon Saegusa (6)) subissent une décomposition, suivie en spectroscopie infrarouge, pour régénérer l'isonitrile libre initial.

Avec le cuivre, le chlorure cuivreux et principalement avec le chlorure d'argent dans l'acétonitrile (complexe le moins stable d'après l'étude infrarouge), l'alcool réagit sur le glycosylisonitrile pour conduire à un mélange d'orthoesters *endo* et *exo* (**3***a*, **4***a*, **5***a*, **6***a*) majoritaires et de glucosides (**3***b*, **4***b*, **5***b*, **6***b*). Dans chaque cas, l'isomère *exo* de **3***a* à **6***a* est formé très majoritairement (≥ 90%) par rapport à l'isomère *endo* comme le montrent les paramètres rmn ^1H (en particulier le déplacement chimique du groupement méthyle *endo* de l'orthoester) par référence aux résultats de la littérature (8, 9). En l'absence de groupe participant en position C-2 (cas du tétra-*O*-méthyl-2,3,4,6-β-D-glucopyranosyl isonitrile **2**) (1), seuls les glycosides **7** de configuration α (57%) et β (35%) sont formés dans cette réaction. Le formimidate attendu **8** n'est jamais observé dans les produits de réaction (Schéma 3).

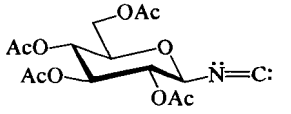
Le complexe isonitrile – chlorure d'argent peu stable dans l'acétonitrile (Tableau 1) semble réagir comme groupe partant en présence d'alcool à haute température; la formation d'un ion oxocarbenium suggérée par la participation de l'acétate en C-2 dans le cas de **1** et par le manque de stéréospécificité de la réaction dans le cas de **2** pourrait expliquer la formation des produits observés (**4** à **7**) par un mécanisme inverse de celui avancé pour la formation des glycosylisonitriles par substitution nucléophile (1) (Schéma 3).

La fragilité de la liaison C—N anomère dans les glycosylisonitriles due à la facilité de formation d'un ion oxocarbénium assistée par la participation de l'oxygène du cycle pyrannique peut donc expliquer la différence de réactivité de ceux-ci vis-à-vis des alcools par rapport à leurs homologues aliphatiques.

Réactivité des amines sur les glucosylisonitriles complexés

Comme précédemment observé en série aliphatique (5), les amines aliphatiques réagissent

TABLEAU 1. Complexation du glucosylisonitrile **1** avec quelques sels métalliques



1

Métal ou sel métallique[a]	ν (N≡C) complexé cm^{-1}[b]
Cu	2192
CuO	2191
Cu_2O	2192
CuCl	2192
$HgCl_2$	2178
Ag_2O	2195
AgCl[c]	2194

[a]Isonitrile (40 μmol); solvant (acétonitrile ou dichlorométhane) (1,5 mL); sel métallique (4 μmol); température ambiante; 24 h de complexation.
[b]Mesures infrarouge réalisées avec un appareil Perkin–Elmer 225.
[c]Valeur obtenue dans le dichlorométhane; dans ce cas seulement, une différence importante est observée dans l'acétonitrile (ν (N≡C): 2184).

SCHÉMA 3

TABLEAU 2. Synthèse de glucosylformamidines[a] obtenues à partir du tétra-*O*-acétyl-2,3,4,6-β-D-glucopyranosylisonitrile **1**

Amine	Temps de réaction (min)	Rendement (%)	Produit obtenu	
Pipéridine	15	90	RR′ = —$CH_2(CH_2)_3CH_2$—	**9**
Diéthylamine	20	92	R = R′ = Et	**10**
Dibutylamine	20	93	R = R′ = *n*-Bu	**11**
Isobutylamine	30	98	R = *iso*-Bu; R′ = H	**12**
Aniline	20[b]	99	R = Ph; R′ = H	**13**

[a]Formamidines obtenues par réaction d'une amine (3,3 mmol) sur l'isonitrile 1 (1 mmol) en présence de chlorure d'argent (0,07 mmol) dans le dichlorométhane (0,8 mL) à 0°C.
[b]Catalyseur utilisé: chlorure mercurique.

sur les glucosylisonitriles complexés par les chlorures métalliques, à température ambiante, pour conduire par α-addition à des formamidines (**9** à **13**) (Tableau 2) (10). Cette addition semble être stéréospécifique, excepté dans le cas de **13**, puisqu'un seul des isomères *Z* ou *E* de **9** à **12** est isolé comme le montrent les spectres de résonance magnétique nucléaire ^1H et ^{13}C. Les conditions opératoires utilisées, la stabilité des formamidines obtenues au cours de chauffage à des températures voisines de 50°C et la facilité de cyclisation de la formamidine **14** en quinazolinone **15** semblent indiquer que seul l'isomère thermodynamique de configuration *E* est isolé au cours de cette addition. Ces résultats sont en accord avec les récents travaux de Hegarty et Chandler (11, 12) qui indiquent que le produit cinétique *Z* d'addition d'une amine secondaire sur un isonitrile s'isomérise à température ambiante en produit thermodynamique de configuration *E*.

Les meilleurs rendements sont obtenus par complexation avec le chlorure d'argent dans le dichlorométhane ou l'acétonitrile. Dans le cas des amines aromatiques (aniline ou anthranilate de méthyle) de bons résultats ont été obtenus en utilisant comme agent complexant le chlorure mercurique à température ambiante. Ces données sont en accord avec la stabilité présumée des complexes étudiés en spectroscopie infrarouge (Tableau 1).

Utilisés à température ambiante ou à 0°C, les glucosylisonitriles complexés sont donc susceptibles de conduire à des réactions d'α-addition comme leurs homologues aliphatiques; ce n'est qu'à température plus élevée que le groupement isonitrile complexé peut se comporter comme groupe partant et conduire à une substitution nucléophile en position anomère avec les alcools; cette dualité de réactivité n'a pas, à notre connaissance, été signalée en série aliphatique.

Les résultats satisfaisants obtenus dans la synthèse des formamidines ont permis d'envisager une application de cette α-addition à la préparation de nucléosides de configuration définie. Dans ce but, l'anthranilate de méthyle a été condensé sur le glucosylisonitrile **1** complexé par le chlorure d'argent ou le chlorure mercurique.

Dans le premier cas, la formamidine **14** obtenue reste complexée au chlorure d'argent même après un chauffage prolongé. La catalyse par le chlorure mercurique, complexant plus faible (Tableau 1), permet de réaliser une hétérocyclisation directe en quinazolinone **15** précédemment préparée par une autre voie (13), par simple reflux dans le dichloroéthane (Schéma 4). Une telle hétérocyclisation directe a déjà été mentionnée dans la synthèse des 1 *N*-(ribofuranosyl) adénines par Imbach et coll. (14).

Cet exemple de synthèse stéréospécifique de la quinazolinone **15** permet d'éviter la non régio- et stéréosélectivité observées lors de la substitution d'halogénures de glycosyles par l'hydroxy-4 quinazoline (formation de dérivés d'O- et C-substitution (13) et des anomères α et β (15)). Les glycosylisonitriles acétylés représentent donc de nouveaux synthons osidiques (16) à configuration anomérique définie utilisables en synthèse

Partie expérimentale

Les points de fusion sont déterminés en tube capillaire sur un appareil Buchi et ne sont pas corrigés. Les pouvoirs rotatoires sont mesurés sur un polarimètre Perkin Elmer 141 dans des cellules de 1 dm. Les spectres infrarouge sont enregistrés sur spectromètres Perkin Elmer 225 et 237. Les spectres de rmn ^1H sont enregistrés sur appareil Varian A 60 et Varian HA 100 (référence: Me_4Si interne); les spectres de rmn ^{13}C sur appareil Varian XL 100 opérant à 25.2 MHz (référence Me_4Si interne). Les chromatographies sont réalisées sur gel de silice Merck (230–400 mesh).

Tétra-O-acétyl-2,3,4,6-β-D-glucopyranosylisonitrile 1

Préparé selon le mode opératoire de Nolte *et al* (4) à partir du bromure de tétra-*O*-acétyl-2,3,4,6-α-D-glucopyranosyle (17), les

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/05/12
For personal use only.

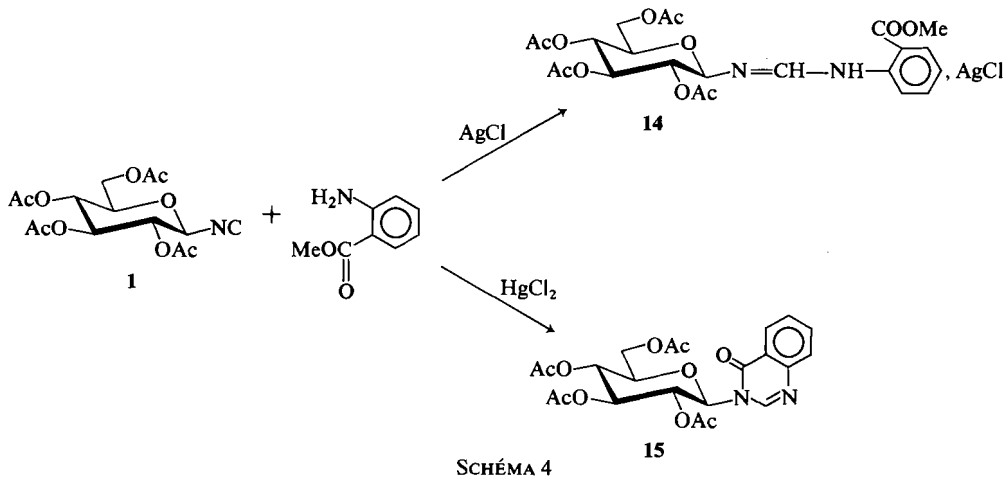

SCHÉMA 4

propriétés physiques et spectrales de **1** sont en accord avec celles décrites par Martin-Lomas et Chacon-Fuertes (18).

Tétra-O-méthyl-2,3,4,6-β-D-glucopyranosylisonitrile 2
Préparé selon le mode opératoire précédemment publié (1).

Réaction du glucopyranosylisonitrile complexé 1 avec les alcools

A l'isonitrile **1** (357 mg, 1 mmol) en solution dans l'acétonitrile (1 mL) est ajouté du chlorure d'argent anhydre (10 mg, 7×10^{-2} mmol). Après solubilisation, l'alcool (2 mmol) est ajouté à la solution qui est portée à reflux jusqu'à disparition complète de la bande infrarouge ν (N=C:) du groupement isonitrile.

Après précipitation du chlorure d'argent par dilution dans le solvant réactionnel et évaporation du solvant, les mélanges obtenus sont chromatographiés sur gel de silice (éluant acétate d'éthyle – hexane 1:1). Les produits principaux ainsi récupérés sont les orthoesters *exo* **3***a* à **6***a*, identifiés par référence aux produits décrits dans la littérature et par les spectres rmn ^1H caractéristiques de ces composés (8, 9).

*Tri-O-acétyl-3,4,6-(1-méthoxyéthylidène)-1,2-O-α-D-glucopyranose 3*a
Obtenu après 3 h de reflux avec un rendement de 84%. Huile incolore, $[\alpha]_D^{20}$ +50,6° (*c*, 1,6, $CHCl_3$) (litt. (19) $[\alpha]_D$ +48,3° ($CHCl_3$)). Spectre rmn ^1H en accord avec celui décrit dans la littérature (8).

*Tri-O-acétyl-3,4,6-[1-(méthyl-1-propyloxyéthylidène)]-1,2-O-α-D-glucopyranose 4*a
Obtenu après 3 h de reflux avec un rendement de 52%. Solide blanc, F = 67°C (alcool 95°C); $[\alpha]_D^{20}$ +39° (*c* 2,4, $CHCl_3$); rmn ^1H (CD_3CN) δ ppm: 5,60 (d, 1H, H-1, $J_{1,2}$ = 5,2 Hz); 5,03 (t, 1H, H-3, $J_{2,3}$ = 2,7 Hz, $J_{3,4}$ = 2,7 Hz); 4,90–4,65 (m, 1H, H-4, $J_{4,5}$ = 8,8 Hz); 4,40–4,0 (m, 3H, H-2, H-6, H-6′); 3,90–3,50 (m, 1H, H-5); 1,67 (s, 3H, CH_3 orthoester): 1,50–0,80 (m, 9H, *n*-butyl). *Anal.* calc. pour $C_{18}H_{28}O_{10}$: C 53,46, H 6,98, O 39,56; trouvé: C 53,33, H 6,76, O 39,73.

*Tri-O-acétyl-3,4,6-(1-n-butoxyéthylidène)-1,2-O-α-D-glucopyranose 5*a
Préparé dans le butanol comme solvant et avec le cuivre métallique comme catalyseur le produit est obtenu après 10 h de reflux avec un rendement de 35%. Les constantes physiques de **5***a* sont en accord avec celles décrites dans la littérature (20). Huile incolore, $[\alpha]_D^{20}$ +41° (*c* 1,5, $CHCl_3$) (litt. (20) $[\alpha]_D$ +33,8° ($CHCl_3$)).

*Tri-O-acétyl-3,4,6-[1-(propyl-1-butyloxyéthylidène)]-1,2-O-α-D-glucopyranose 6*a
Obtenu après 6 h de reflux avec une rendement de 47%. Huile incolore, $[\alpha]_D^{20}$ +22° (*c* 4,4, $CHCl_3$); rmn ^1H (CD_3CN) δ ppm: 5,70 (d, 1H, H-1, $J_{1,2}$ = 5,0 Hz); 5,15–4,65 (m, 2H, H-3, H-4); 4,43–4,23 (m, 1H, H-2); 4,20–3,50 (m, 3H, H-6, H-6′, H-5); 1,63 (s, 3H, CH_3 orthoester); 1,50–0,60 (m, 15H, heptyl). *Anal.* calc. pour $C_{21}H_{34}O_{10}$: C 56,49, H 7,68; trouvé: C 56,35, H 7,62.

Réaction du glucopyranosylisonitrile 1 complexé avec les amines

A l'isonitrile **1** (357 mg, 1 mmol) dans le dichlorométhane (0,8 mL) à 0°C est ajouté le chlorure d'argent (10 mg, 7×10^{-2} mmol) pour les amines aliphatiques ou le chlorure mercurique (19 mg, 7×10^{-2} mmol) pour les amines aromatiques. Après solubilisation, l'amine (3,3 mmol, Tableau 2) est ajoutée à la solution et l'agitation poursuivie pendant 30 min jusqu'à disparition de la bande infrarouge du groupement isonitrile ν(N=C:). Après concentration et filtration, de l'hexane (2 × 2 mL) est ajouté à la solution pour précipiter le sel métallique; le filtrat est alors concentré et repris avec un mélange éther – éther de pétrole (45–60°C) pour cristallisation éventuelle du produit d'α-addition. Les formamidines de configuration probable *E*, excepté dans le cas de **13** (*Z* + *E*) sont caractérisées par rmn ^1H (proton —N=C*H*—N< très déblindé 7,3–7,5 ppm) et infrarouge (ν(—N=C<) 1630 cm^{-1}).

N-*(Tétra-O-acétyl-2,3,4,6-β-D-glucopyranosyl)-N′,N′-pentaméthylène formamidine 9*
Obtenue avec un rendement de 90%. Solide blanc, pf 107–108°C (éther); $[\alpha]_D^{20}$ = +2,3° (*c* 2,4, $CHCl_3$); ir (KBr) ν_{max}: 1620 cm^{-1} (>C=N—); rmn ^1H (CD_3COCD_3) δ ppm: 7,48 (s, 1H, —N=C*H*—N<); 5,30–4,70 (m, 3H, H-2, H-3, H-4); 4,50 (d, 1H, H-1, $J_{1,2}$ = 8,2 Hz); 4,25–3,90 (m, 3H, H-5, H-6, H-6′); 3,50–3,20 (m, 4H, H αα′pipéridine); 1,75–1,40 (m, 6H, Hββ′γ pipéridine); rmn ^{13}C (CD_3COCD_3) δ ppm: 156,2 (>*C*=N); 94,4 (C-1); 74,2–74,0–73,7 (C-2, C-3, C-5); 69,8 (C-4); 63,2 (C-6). *Anal.* calc. pour $C_{20}H_{30}O_9N_2$: C 54,29, H 6,83, N 6,33; trouvé: C 54,28, H 6,86, N 6,28.

N-*(Tétra-O-acétyl-2,3,4,6-β-D-glucopyranosyl)-N′,N′-éthyl formamidine 10*
Obtenue avec un rendement de 92%. Solide blanc, pf 83–85°C (éther – éther de pétrole); $[\alpha]_D^{20}$ = +1,6° (*c* 3,1, $CHCl_3$); ir (KBr) ν_{max}: 1620 cm^{-1} (>C=N—); rmn ^1H (CD_3COCD_3) δ

Conformational analysis in carbohydrate chemistry. V.[1] Formation of glycosidic anhydrides from heptoses

STEPHEN JOHN ANGYAL AND TRUNG QUANG TRAN

School of Chemistry, University of New South Wales, Kensington, N.S.W. 2033, Australia

Received July 11, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

STEPHEN JOHN ANGYAL and TRUNG QUANG TRAN. Can. J. Chem. **59**, 379 (1981).

The position of the equilibrium between aldoheptoses and their glycosidic anhydrides depends crucially on the configuration of the heptose. Depending on that configuration, the 1,6-anhydropyranose, the 1,7-anhydropyranose, or the 1,6-anhydrofuranose is the major product, its proportion varying from 99% to less than 1%. The position of the equilibrium is predictable from conformational considerations. 1,7-Anhydrofuranoses have not been encountered. The 1,3-dioxane ring of the 1,7-anhydropyranoses was found to assume a skew form.

STEPHEN JOHN ANGYAL et TRUNG QUANG TRAN. Can. J. Chem. **59**, 379 (1981).

La position de l'équilibre entre les aldoheptoses et leurs anhydrides glycosidiques dépend fondamentalement de la configuration de l'heptose. Dépendant de la configuration, le produit majoritaire est soit l'anhydro-1,6 pyrannose, soit l'anhydro-1,7 pyrannose ou soit l'anhydro-1,6 furannose et ses proportions varient de 99% à moins de 1%. On peut prédire la position de l'équilibre à partir des considérations conformationnelles. On n'a pas mis en évidence la présence de l'anhydro-1,7 furannose. On a trouvé que le cycle dioxanne des anhydro-1,7 pyrannoses présente une forme décalée.

[Traduit par le journal]

Introduction

Although the 1,6-anhydrides of the aldohexoses have been extensively studied and widely used as synthetic intermediates (2), very little was known until recently about the glycosidic anhydrides of the aldoheptoses. These anhydrides are formed from, and are in equilibrium with, the parent aldoses in boiling aqueous solutions containing a strong acid. In this way, Richtmyer and his coworkers obtained the 1,6-anhydropyranose (3) from D-*glycero*-D-*ido*-heptose, and the 1,6- and 1,7-anhydropyranoses (4) from D-*glycero*-D-*gulo*-heptose. Recently, Angyal and Beveridge (1) prepared the 1,6-anhydropyranoses of D-*glycero*-L-*manno*-, D-*glycero*-L-*allo*-, and D-*glycero*-L-*altro*-heptoses. These anhydrides were found to be present in the equilibrium mixtures in much higher proportion than were the 1,6-anhydrides in the equilibria with the respective aldohexoses. The higher stability of the heptose anhydrides, compared with the hexose anhydrides, was attributed (1) to the ring closure occurring through a secondary, rather than through a primary, hydroxyl group.

The proportion of 1,6-anhydropyranose in equilibrium with an aldohexose ranges from 0.2% for glucose to 76% for idose (5). These proportions have been explained in terms of nonbonded interactions (5). With the recognition that the tendency for ring formation through primary hydroxyl groups is different from that through secondary hydroxyl groups, it is possible now to discuss the conformational analysis of anhydroheptoses by analogy to that of the anhydrohexoses, and to make predictions about the proportion of the anhydroheptoses at equilibrium. Some of these predictions have now been tested.

For the aldoheptoses, three different types of glycosidic anhydrides are significant: the 1,6- and 1,7-anhydro-pyranoses and the 1,6-anhydrofuranoses. The 1,7-anhydrofuranoses, which contain fused five- and seven-membered rings, would have low stability and have, in fact, not been encountered in our work. Other types of anhydrides, such as the 1,4-anhydropyranoses (6), would occur in very small amounts only.

There are sixteen possible diastereomeric aldoheptoses (counting each pair of enantiomers only once); we have not investigated all of them. The synthesis of some of the aldoheptoses is quite cumbersome and it was felt that not all of them would yield worthwhile information. Thus, the discussion which follows will allow us to predict with confidence, even though we were not able to test our prediction, that D-*glycero*-L-*ido*-heptose would be converted to an extent of over 99% into the 1,6-anhydropyranose, and that D-*glycero*-D-*gluco*-heptose would yield no anhydride in a proportion over 0.1%.

Results and Discussion

1,6-Anhydropyranoses

The proportions of 1,6-anhydropyranose in equilibrium with each aldohexose are (5): glucose,

0.2; mannose, 0.8; galactose, 0.8; talose, ≧2.8; allose, ≧14; altrose, 65; gulose, 65; and idose, 76%. When the additional hydroxymethyl group in the 1,6-anhydroheptoses is *exo*, the proportion of the anhydride in equilibrium was found to be considerably higher (1), namely, 15% for D-*glycero*-L-*manno*-heptose, 54% for D-*glycero*-L-*allo*-heptose, and 98% for D-*glycero*-L-*altro*-heptose. It is reasonable to assume that similar increases would occur in going from the other hexoses to the homomorphous D-*glycero*-L-heptoses (and their L-*glycero*-D-heptose enantiomers), the anhydrides of which all have *exo* hydroxymethyl groups. In fact, we found that on equilibration D-*glycero*-L-*gluco*-heptose gave 7.5%, D-*glycero*-L-*galacto*-heptose 18%, and D-*glycero*-L-*talo*-heptose 31% of the 1,6-anhydropyranose. The structures of these anhydrides were not proven because we had insufficient material for their isolation but, by analogy with the other heptoses, it is very likely that they are 1,6-anhydropyranoses. The other anhydrides of these heptoses would have very unfavourable interactions. The remaining heptoses of this group, D-*glycero*-L-*gulo*- and D-*glycero*-L-*ido*-heptose, were not available but, by analogy with D-*glycero*-L-*altro*-heptose, one can confidently predict that they would be converted into the 1,6-anhydropyranoses to the extent of at least 98%.

The 1,6-anhydropyranoses of the D-*glycero*-D-heptoses (and their L-*glycero*-L-heptose enantiomers) have the hydroxymethyl group in the *endo* configuration (**1**) and are therefore less stable than the homomorphous hexose derivatives. Thus we found that D-*glycero*-D-*gulo*-heptose yields only 11%, and D-*glycero*-D-*ido*-heptose 35%, of the 1,6-anhydropyranose (compared with 65 and 76% for the hexoses). One would then predict that D-*glycero*-D-*altro*-heptose would give the 1,6-anhydride in a proportion similar to that of the *gulo* compound, and that D-*glycero*-D-*gluco*-, -D-*manno*-, -D-*galacto*-, and -D-*talo*-heptose would yield only traces of the anhydride. In fact, on equilibration of the *galacto* and *talo* isomers we found (by glc) only very small amounts (<0.5%) of compounds which could be the 1,6-anhydropyranoses. D-*glycero*-D-*allo*-Heptose yielded approximately 3% of the 1,6-anhydride; this is about the proportion one would have predicted by comparison with allose (14%).

1,7-Anhydropyranoses

Only one anhydride of this type has been described, 1,7-anhydro-D-*glycero*-β-D-*gulo*-heptopyranose, obtained in about 10% yield[2] from the heptose on equilibration (4). We found that D-*glycero*-D-*ido*-heptose gave 40% of the 1,7-anhydride. The ring system contained in these anhydrides (analogous to the bicyclo[3,3,1]nonane system) is inherently unstable owing to the interaction, in the twin-chair form (**2**), between the *endo* hydrogen atoms on C-3 and C-7. The strain in bicyclo[3,3,1]nonane has been estimated (7) to be ~42 kJ mol^{-1}. The 1,7-anhydrides appear to be about equal in stability to the 1,6-anhydrides with an *endo* hydroxymethyl group; judging by models, the configuration of C-6 does not appear to affect the stability to any significant extent, except in those cases when O-4 is equatorial: the 1,7-anhydride of a D-*glycero*-L-heptose would then have a parallel 1,3-interaction between O-4 and O-6.

These considerations indicate that D-*glycero*-D-*altro*-heptose (which we did not have) would give about 10% of the 1,7-anhydride, and D-*glycero*-D-*allo*-heptose, about 4%. In fact, equilibration of the latter compound produced an anhydride in 4.3% yield; this we believe to be the 1,7-anhydride. The 1,7-anhydride of D-*glycero*-L-*altro*-heptose would have a stability similar to that of the D-*glycero*-D-*altro* compound but would hardly be detectable in the presence of the overwhelming proportion (98%) of the 1,6-anhydride. None of the other heptoses would yield a substantial proportion of the 1,7-anhydropyranose.

In fact, the other heptoses we investigated did not yield any compound that we could recognize as the 1,7-anhydropyranose. D-*glycero*-L-*allo*-Heptose gave two minor components (beside the 1,6-anhydropyranose); one of these is probably the 1,7-anhydropyranose.

In order to identify the anhydride obtained from D-*glycero*-D-*ido*-heptose as the 1,7-anhydride, we studied its nmr spectrum and, for comparison, also

[2]Angyal and Dawes (5) reported a much higher conversion (66%) but we were unable to repeat their results. Even after 72 h boiling with 5% sulfuric acid, only 11.4% of the 1,7-anhydride was found to be present, and the amount no longer increased with time.

those of 1,7-anhydro-D-*glycero*-D-*gulo*-heptopyranose and of the 1,6-anhydrides of these two heptoses. In all of these spectra, only the signal of H-1 could be distinguished, the other signals overlapping extensively. However, when these compounds were acetylated, the signals of H-2, H-3, H-4, and either H-6 or H-7 and H-7′ shifted downfield, and all the spectra could be fully analysed. In the spectra of the acetylated 1,6-anhydrides, the signals of H-5 and H-6 were at highest field, showing thereby that C-5 and C-6 do not carry acetoxy groups. On the other hand, in the spectra of the acetylated 1,7-anhydrides, the signals of H-5, H-7, and H-7′ were at highest field.

The conformations of these 1,7-anhydrides are of interest. Bicyclo[3,3,1]nonane, in the absence of *endo* substituents which would cause steric interaction, is predominantly in the twin-chair form, with the chairs somewhat flattened (8). It has been suggested, however, that in the 1,7-anhydropyranoses the interaction between H-3 and H-7 may be sufficiently large to encourage the 1,3-dioxan ring to exist, at least partially, in a boat conformation (9). In fact, the nmr spectra of the acetates clearly show that the anhydride ring is not in the chair form (**2**): in that form, $J_{5,6}$, $J_{6,7}$, and $J_{6,7'}$ would all have values of ~3.5 Hz. In the spectrum of tetraacetyl-1,7-anhydro-D-*glycero*-β-D-*gulo*-heptose these values are 1.2, 7.1, and 9.0 Hz, respectively, which seems to indicate that the 1,3-dioxan ring is in the $^{a6}S_{a2}$ skew form (**3**). The *ido* anhydride has somewhat smaller coupling constants (1.0, 5.3, 5.1 Hz); there seems to be more of the twin-chair form in equilibrium with the skew form. Accordingly, the pyranose ring is somewhat flattened ($J_{2,3}$ and $J_{3,4}$ are less than 10 Hz).

1,6-Anhydrofuranoses

No anhydrofuranose derivative of an aldoheptose has so far been reported. From the aldohexoses, small amounts (0.04–2.5%) of the 1,6-anhydrofuranoses are produced on equilibration in acid solution (5, 6, 10), in addition to the predominant 1,6-anhydropyranoses. The anhydrofuranoses of talose and altrose occur in the highest proportion (2.5 and 1.6%), followed by those of allose (1.0%) and galactose (0.95%). Since the formation of the 1,6-anhydrofuranose from an aldoheptose would involve ring formation through a secondary hydroxyl group, it is predictable that the anhydride will be formed in a considerably higher proportion than it is from the homologous hexose, provided that the additional hydroxymethyl group is *exo* and therefore its presence does not introduce an unfavourable steric interaction.

Of all the diastereomers, the 1,6-anhydrofuranose of D-*glycero*-D-*talo*-heptose would be the energetically most favourable one: O-2, O-3, and C-7 are *exo* and O-5 is equatorial. It was found that this heptose gave one anhydride in 11.2% yield. The nmr spectrum of its acetate proved that this is, indeed, the anhydrofuranose (**4**): $J_{1,2}$ and $J_{3,4}$ are smaller than 0.5 Hz and $J_{2,3}$ is 6.7 Hz. The spectrum is similar to that of the acetate of 1,6-anhydro-α-D-talofuranose (5). The six-membered anhydro-ring is in the chair form ($J_{5,6}$ is 10.0 Hz).

The 1,6-anhydrofuranoses of D-*glycero*-D-*galacto*- and D-*ido*-heptose would differ from the preceding anhydride only in having an *endo* hydroxyl group on C-2 and C-3, respectively, and would therefore also be energetically favourable. D-*glycero*-D-*galacto*-Heptose produced, on equilibration, 7.5% of an anhydride, which was shown to be the 1,6-anhydrofuranose by the nmr spectrum of its acetate; this is closely similar to the spectrum of the acetate of 1,6-anhydro-α-D-*galacto*-furanose (11). Although D-*glycero*-D-*ido*-heptose is converted into the two anhydropyranoses in a yield of nearly 75%, glc shows the presence of another anhydride (1.3%) which presumably is the anhydrofuranose.

In the D-*glycero*-L-heptose series, the 1,6-anhydrofuranoses of the *gluco*, *allo*, and *altro* configuration have the most favourable structures (C-7 *exo* and no, or only one, *endo* hydroxyl group). In the equilibrium mixtures formed from the *gluco* and *allo* isomers, glc shows the presence of an anhydride in a proportion higher than that of the anhydrofuranose of glucose and allose, respectively; these we presume to be the 1,6-anhydrofuranoses though we have not isolated them. Since D-*glycero*-L-*altro*-heptose is converted to the 1,6-anhydropyranose to the extent of 98%, the anhydrofuranose was not detected. Additional small peaks are also seen in the glc curves of the equilibrium mixtures from D-*glycero*-L-*galacto*- and D-*glycero*-L-*talo*-heptoses. These are also believed to represent anhydrofuranoses; although they would have *endo* hydroxymethyl groups, ring closure through a secondary hydroxyl group would compensate for this steric effect; the proportion of 1,6-anhydrofuranose is about the same as that formed from the homologous hexoses. From D-*glycero*-L-*talo*-heptose, yet another anhydride appears to be produced; since the 1,7-anhydropyranose would be energetically unfavourable, we cannot guess its structure.

Chaby and Szabó (12) distinguished the 1,6- and 1,7-anhydroheptopyranoses from each other by the mass spectra of their acetates. The spectra show the same peaks but in different proportions. We recorded the mass spectra of the acetates of the two

*NOTE: figures in parentheses are estimates based on analogy.
†The structure of this compound has not been unequivocally determined.
‡Reference 1.

1,6-anhydrofuranoses and again found the same peaks in proportions somewhat similar to those in the spectra of the 1,7-anhydrides. The proportions were not the same in the spectra of the *galacto* and the *talo* isomer. In view of these results we are disinclined to rely on mass spectra for the determination of the structures of the anhydroheptoses.

The results obtained are summarized in Table 1. For those heptoses which we did not investigate, we estimated the proportion of the anhydrides in equilibrium by analogy with the homologous hexoses and the other heptoses; these estimates are shown in parentheses. Those components whose structures we have not determined are also indicated.

Experimental

General

Solvents were evaporated under diminished pressure in rotary evaporators. All solvents used for chromatography were distilled. "Light petroleum" refers to the fraction boiling between 60 and 80°C; "ethanol" refers to 95% ethanol; mixed solvents were prepared on a v/v basis.

Column chromatography was performed on Merck Silica Gel H (Type 60). Gas–liquid chromatography (glc) was carried out with a custom-built instrument, using nitrogen as carrier gas with a flow-rate of 60–80 mL per min, and a hydrogen flame-ionization detector. The 1.5 m coiled glass column was filled with 3% SP-2401 on Chromosorb W (AW-DMCS) and was kept at 210 or 215°C. Peaks were cut out and weighed; it was assumed that all compounds gave equal detector responses. The compounds were analysed by glc as their acetates. Most reaction mixtures showed small amounts of very volatile compounds (R_t < 1 min) which could be dianhydrides or decomposition products. The pure heptoses gave up to four peaks after acetylation: those of the two pyranoses and of the two furanoses.

Thin-layer chromatograms (tlc) were run on Merck Silica Gel G (Type 60), supported on microscope slides, without activation. The compounds were detected by spraying with 20% sulfuric acid in ethanol and then heating on a hot-plate.

Proton magnetic resonance spectra were recorded with JEOL JNM-4H-100 and JNM-FX-100 spectrometers. The spectra described here were run in deuteriated benzene, using Me_4Si as internal standard; most of the spectra were also run in deuteriochloroform but those spectra could not be fully analysed. Mass spectra were recorded with an AEI MS-12 spectrometer by electron impact at 70 eV from a direct insertion probe at 25°C and a source temperature of 230°C. Optical rotations were determined with a Bendix NPL Automatic Polarimeter 143C, equipped with a JANUS digital readout, in a 2 cm cell. Microanalyses were carried out by Mr. J. Sussman in the School's microanalytical laboratory.

Establishment of Equilibria

A solution containing the heptose in 5% aqueous sulfuric acid (20 parts) was heated on a steam-bath for 48 h. Samples removed from time to time, and analysed by glc after acetylation, showed that in every case equilibrium had been reached by that time. The acid was removed by stirring with Amberlite IRA 400 resin in the hydrogen carbonate form until the solution was neutral. Evaporation gave a syrup. In those cases where a large proportion of the heptose remained unchanged, some of it was recovered by crystallization at this stage. The mixture was then treated with acetic anhydride–pyridine (1:1) on a steam-bath for 2 h, evaporated, the residue dissolved in chloroform, and washed first with *M* sulfuric acid, then with saturated sodium hydrogencarbonate solution. After evaporation, the residue was chromatographed on a column of silica gel; the acetates of the anhydrides emerged before those of the heptoses. Some of the acetates crystallized; those that did not, were distilled at a pressure of 0.2–0.3 Torr.

Equilibration of D-glycero-L-gluco-*Heptose (13)*

The glc peaks (215°C): 0.7% (R_t 2.1 min), 8.5% 1,6-anhydropyranose (2.7 min), 51% β-pyranose (6.0 min), and 40% α-pyranose (7.2 min).

Equilibration of D-glycero-L-galacto-*Heptose (14)*

The glc peaks (215°C): 0.6% (2.2 min), 18% 1,6-anhydropyranose (3.2 min), 40% β-pyranose (6.7 min), 13.6% furanose (?) (7.5 min), and 29% α-pyranose (8.3 min).

Equilibration of D-glycero-L-talo-*Heptose (14)*

The glc peaks (210°C): 2.8% (3.5 min), 2.5% (4.2 min), 31% 1,6-anhydropyranose (5.1 min), 37% heptose (15.0 min), and 26% heptose (17.8 min). The substance appearing at 4.2 min is formed more slowly than the other products; after 24 h it amounts to only 1.4%.

Equilibration of D-glycero-D-gulo-*Heptose (15)*

The glc peaks (210°C): 11.4% 1,7-anhydropyranose (4.8 min), 10.8% 1,6-anhydropyranose (6.2 min), and four heptose peaks: 68.5% (12.6 min), 2.5% (17 min), 3.6% (19.5 min), 3.2% (22.5 min). The 1,7-anhydride is formed at a slower rate than the 1,6-anhydride; after 24 h the composition was 5.0, 9.0, 73.9, 2.1, 4.6, and 5.4%, respectively.

Column chromatography with ether – petroleum ether (1:3) as eluant gave, in fractions 7–12, 2,3,4,6-tetra-*O*-acetyl-1,7-anhydro-D-*glycero*-β-D-*gulo*-heptopyranose, $[\alpha]_D^{22}$ +48.9° (*c* 1.43, $CHCl_3$); nmr δ: 1.44, 1.62, 1.71, 1.91 (Ac), 3.59 (dd, H-7′, $J_{6,7'}$ = 9.0, $J_{7,7'}$ = −10.8), 3.71 (H-7, $J_{6,7}$ = 7.1), 4.59 (dd, H-5, $J_{4,5}$ = 6.3, $J_{5,6}$ = 1.2), 5.06 (d, H-1, $J_{1,2}$ = 1.8), 5.14 (ddd, H-6),

5.57 (dd, H-2, $J_{2,3}$ = 3.8), 5.59 (dd, H-4, $J_{3,4}$ = 10.3), 5.85 (dd, H-3). *Anal.* calcd. for $C_{15}H_{20}O_{10}$: C 50.00, H 5.59; found: C 50.23, H 5.56.

Fractions 21–39 gave 2,3,4,7-tetra-*O*-acetyl-1,6-anhydro-D-*glycero*-β-D-*gulo*-heptopyranose, $[\alpha]_D^{22}$ +20.1° (*c* 1.61, $CHCl_3$); nmr δ: 1.59 (Ac), 1.64 (Ac), 1.68 (2Ac), 3.99 (quin, H-6), 4.27 (t, H-5, $J_{4,5} = J_{5,6}$ = 4.1), 4.35 (dd, H-7′, $J_{6,7'}$ = 4.2, $J_{7,7'}$ = −12), 4.49 (dd, H-7, $J_{6,7}$ = 7.5), 5.30 (d, H-1, $J_{1,2}$ = 2.3), 5.44 (dd, H-2, $J_{2,3}$ = 5.0), 5.52 (dd, H-4, $J_{3,4}$ = 9.6), 5.84 (dd, H-3). *Anal.* calcd. for $C_{15}H_{20}O_{10}$: C 50.00, H 5.59; found: C 49.90, H 5.37.

Equilibration of D-glycero-D-ido-*Heptose (15)*

The glc peaks (210°C): 39% 1,7-anhydropyranose (2.5 min), 33.5% 1,6-anhydropyranose (2.8 min), 1.3% anhydrofuranose (?) (4.4 min), and four peaks of the heptose: 3.2% (7.7 min), 4.2% (10.6 min), 15.4 (11.8 min), 3.4% (14.5 min).

Column chromatography with ethyl acetate – light petroleum (1:4) as eluant gave, in fractions 28–40, 2,3,4,6-tetra-*O*-acetyl-1,7-anhydro-D-*glycero*-β-D-*ido*-heptopyranose which crystallized from benzene – light petroleum as needles, mp 74–76°C; $[\alpha]_D^{26}$ −34.5° (*c* 1.48, $CHCl_3$); nmr δ: 1.51, 1.66, 1.73, 1.85 (Ac), 3.60 (dd, H-7′, $J_{6,7'}$ = 5.1, $J_{7,7'}$ = −12.7), 3.80 (dd, H-7, $J_{6,7}$ = 5.3), 4.36 (broad d, H-5), 4.93 (dt, H-6, $J_{5,6}$ = 1.0), 5.11 (dd, H-2, $J_{1,2}$ = 3.7, $J_{2,3}$ = 9.0), 5.28 (broad d, H-1), 5.32 (dd, H-4, $J_{3,4}$ = 9.5, $J_{4,5}$ = 6.6), 5.99 (t, H-3). There appears to be long-range coupling between H-1 and H-5. *Anal.* calcd. for $C_{15}H_{20}O_{10}$: C 50.00, H 5.59; found: C 50.92, H 5.80.

Fractions 46–56 gave 2,3,4,7-tetra-*O*-acetyl-1,6-anhydro-D-*glycero*-β-D-*ido*-heptopyranose, $[\alpha]_D^{23}$ −53° (*c* 1.15, $CHCl_3$); nmr δ: 1.59, 1.60, 1.65, 1.70 (Ac), 4.03 (quin, H-6), 4.14 (t, H-5, $J_{5,6}$ = 4.2), 4.34 (dd, H-7′, $J_{6,7'}$ = 6.2, $J_{7,7'}$ = −12.1), 4.50 (dd, H-7, $J_{6,7}$ = 7.6), 5.05 (d, H-2, $J_{1,2}$ = 1.7, $J_{2,3}$ = 8.0), 5.28 (ddd, H-4, $J_{3,4}$ = 9.0, $J_{4,5}$ = 4.5, $J_{4,6}$ = 1.1), 5.43 (d, H-1), 5.87 (dd, H-3). *Anal.* calcd. for $C_{15}H_{20}O_{10}$: C 50.00, H 5.59; found: C 50.79, H 5.84.

Equilibration of D-glycero-D-allo-*Heptose (16)*

The glc peaks (215°C): 4.3% 1,7-anhydropyranose (?) (3.0 min), 2.9% 1,6-anhydropyranose (?) (3.8 min), 71.6% β-pyranose (8.3 min), and three other forms of the heptose: 10.8% (10.5 min), 4.2% (11.6 min), 6.1% (13.5 min).

Equilibration of D-glycero-D-galacto-*Heptose (17)*

The glc peaks (210°C): 8.5% 1,6-anhydrofuranose (6.8 min), 0.5% (9.3 min), 0.5% (10.1 min), 47.5% heptose (16.5 min) and 43.5% (23.3 min). Column chromatography over silica gel (10 parts) with ether – petroleum ether (1:2) (10 mL fractions) gave, in fractions 14–21, 2,3,5,7-tetra-*O*-acetyl-1,6-anhydro-D-*glycero*-β-D-*galacto*-heptofuranose, $[\alpha]_D^{22}$ +151.3° (*c* 1.25, $CHCl_3$); nmr δ: 1.51 (Ac), 1.62 (Ac), 1.82 (2Ac), 4.0–4.35 (m, 3H, H-6, 7, 7′), 4.67 (d, H-4, $J_{4,5}$ = 4.6), 5.09 (dd, H-5, $J_{5,6}$ = 9.1), 5.18 (ddd, H-2, $J_{1,2}$ = 4.8, $J_{2,3}$ = 2.5, $J_{2,5}$ = 0.6), 5.40 (d, H-3, $J_{3,4}$ = 0), 5.63 (d, H-1). Mass spectrum *m/e* (relative abundance): 43 (100), 81 (8), 82(8), 110 (10), 111 (11), 115 (15), 153 (8), 157 (11). *Anal.* calcd. for $C_{15}H_{20}O_{10}$: C 50.00, H 5.59; found: C 50.47, H 5.64.

Equilibration of D-glycero-D-talo-*Heptose (17)*

The glc peaks (210°C): 12.2% 1,6-anhydrofuranose (5.7 min), trace (7.8 min), and three peaks of the heptose: 22.5% (11.6 min), 58% (15.5 min), 7.5% (17.7 min). Column chromatography, as above, gave in fractions 11–18, 2,3,5,7-tetra-*O*-acetyl-D-*glycero*-α-D-*talo*-heptofuranose, $[\alpha]_D^{23}$ +106.5° (*c* 1.3, $CHCl_3$); nmr δ: 1.60, 1.64, 1.71, 1.81 (Ac), 3.29 (dt, H-6, $J_{5,6}$ = 10.0, $J_{6,7} + J_{6,7'}$ = 7.0), 4.10 (dd, H-7′, $J_{7,7'}$ = −12.1), 4.11 (dd, H-7), 4.76 (d, H-4, $J_{4,5}$ = 4.6), 5.04 (dd, H-5), 5.33 (d, H-3, $J_{2,3}$ = 6.7, $J_{3,4}$ = < 0.5), 5.39 (s, H-1, $J_{1,2}$ = 0), 5.43 (d, H-2). Mass spectrum *m/e* (relative abundance): 43 (100), 63 (6), 81 (8), 82 (7), 97 (6), 110 (15), 111 (12), 115 (20), 153 (8), 157 (11). *Anal.* calcd. for $C_{15}H_{20}O_{10}$: C 50.00, H 5.59; found: C 51.38, H 5.70.

Acknowledgments

This work was supported by a grant from the Australian Research Grants Committee. The authors are grateful to Mrs. Donna Range for carrying out some of the preliminary experiments and to Dr. V. Bílik (Bratislava) for a gift of samples of D-*glycero*-L-*galacto*- and D-*glycero*-L-*talo*-heptoses.

Received June 27, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

N. Leo Benoiton and Francis M. F. Chen. Can. J. Chem. **59**, 384 (1981).

Reaction of N-ethyl,N′-(γ-dimethylaminopropyl)-carbodiimide·HCl with one equiv. of *N*-*tert*-butoxycarbonyl-L-valine (**3***a*) in dichloromethane at 23°C gives, besides the symmetrical anhydride (**5***a*), the optically pure 2-*tert*-butoxy-4-isopropyl-5(4*H*)-oxazolone (**4***a*) which can be obtained in 50% yield under selected conditions. The 2-benzyloxycarbonyl-4-isopropyl-5(4*H*)-oxazolone (**4***b*) is similarly obtainable from *N*-benzyloxycarbonyl-L-valine (**3***b*). Anhydrous acid converts **4***a* to the oxazolidinedione. Simple preparations of the *N*-carboxyanhydrides of valine and isoleucine have been devised from these reactions. Compound **4** reacts with **3** to give **5**. Compound **4** reacts with an amino acid ester to give the optically pure peptide even in the presence of salts, but partial racemization occurs for reactions in the presence of a tertiary amine. Evidence for the implication of 2-alkoxy-5(4*H*)-oxazolones in the couplings of *N*-alkoxycarbonylamino acids is presented. Compound **4***a* has been isolated in 6–11% yield from carbodiimide-mediated reactions of **3***a* with itself or amino acid methyl esters which have been terminated before completion.

N. Leo Benoiton et Francis M. F. Chen. Can. J. Chem. **59**, 384 (1981).

La réaction du chlorohydrate de *N*-éthyl,*N*′(γ-diméthylaminopropyl)carbodiimide avec un équivalent de *N*-*tert*-butoxycarbonyl-L-valine (**3***a*) dans le dichlorométhane à 23°C donne en plus de l'anhydride symétrique (**5***a*), le composé *tert*-butoxy-2 isopropyl-4 (4*H*)oxazolone-5 (**4***a*) que l'on peut obtenir dans des conditions choisies avec un rendement de 50%. D'une façon analogue, on obtient le benzyloxycarbonyl-2 isopropyl-4 (4*H*)oxazolone-5 (**4***b*) à partir de la *N*-benzyloxycarbonyl-L-valine (**3***b*). L'acide anhydre transforme le composé **4***a* en oxazolidinedione. A partir de ces réactions, on a mis au point des préparations simples de *N*-carboxyanhydrides de la valine et de l'isoleucine. Le composé **4** réagit avec **3** et donne le composé **5**. Le produit **4** réagit avec un ester d'acide aminé pour conduire au peptide optimiquement pur même en présence de sels, mais il se produit une racémisation partielle au cours des réactions conduites en présence d'une amine tertiaire. On présente la preuve de l'implication des alkoxy-2 (4*H*)oxazolones-5 dans les couplages des acides aminés *N*-alkoxycarbonylés. On a isolé le composé **4***a* à partir des réactions d'autocondensation du composé **3***a* ou de sa condentation sur les esters méthyliques d'acides aminés en présence de carbodiimide qui s'arrêtent avant d'avoir totalement réagi.

[Traduit par le journal]

When an acylamino acid or a protected peptide (**1**) is coupled with a nucleophile (amine or phenol), racemization frequently occurs. The change in stereochemistry is the result of the formation of the 2-alkyl-5(4*H*)-oxazolone (**2**) by cyclization of the activated *N*-substituted amino acid moiety. Compound **2** racemizes faster than it couples with the nucleophile. However, no racemization occurs when an *N*-alkoxycarbonylamino acid (**3**) is coupled, as is done successively during the build-up of a peptide chain starting from the *C*-terminus. The reason accepted to explain the preservation of stereochemistry has been that the corresponding 2-alkoxy-5(4*H*)oxazolones (**4**) are not formed because of the unique nature of the urethane carbonyl group (1). We describe here results which are incompatible with this basic tenet of peptide chemistry. As a follow-up on our work on the synthesis of symmetrical anhydrides (**5**) of *N*-alkoxycarbonylamino acids (2), we describe the preparation and characterization of the 2-alkoxy-5(4*H*)-oxazolones **4***a* and **4***b* derived from Boc-Val (**3***a*) and Z-Val (**3***b*) respectively,[1] as well as their isolation from reaction mixtures similar to those used in peptide synthesis.[2]

Reaction of the soluble carbodiimide EDC (**6**) with two equiv. of **3** in dichloromethane followed by washing with aqueous citric acid and sodium hydrogen carbonate gave 70–80% yields of symmetrical anhydride (**5**) for several Boc- and Z-amino acids but lower yields for Boc-Val and Boc-Ile (2). Attempts to increase the yield of **5** by using more EDC (1 equiv.) produced a second stable neutral product which could be obtained pure (yield, 20% by weight) after removal of solvent by precipitating out the anhydride with light petro-

leum. ^{1}H nuclear magnetic resonance spectroscopy indicated it to be a derivative of valine with a *tert*-butyl group displaced 0.13 ppm downfield from that of a Boc or *tert*-butyl ester group, and which had lost its —N—H proton, as evidenced by the sharp α-proton doublet (4.13 ppm). Reaction with anhydrous methylamine gave a quantitative yield of Boc-Val-$NHCH_3$ thus establishing it to be an activated form of Boc-Val. Elemental analysis corresponded with Boc-Val which had lost one mole of water. Infrared absorption at 1845 and 1700 cm^{-1} combined with the absence of absorption at 3400 (—N—H) and 1770 (urethane carbonyl) cm^{-1} indicated the 5(4*H*)-oxazolone structure (4, 5). The compound is therefore 2-*tert*-butoxy-4-isopropyl-5(4*H*)-oxazolone (**4***a*). The aziridinone structure is excluded on the basis of the mass spectrum and the absence of absorption for a urethane carbonyl group (4) in the ir spectrum. The high specific rotation (−49.6° in $CHCl_3$) indicated that the compound was not appreciably racemized. A test for optical purity (see below) established it to be optically pure (<0.1% D-isomer).

Compound **4***a* could be detected and quantitated in the presence of other derivatives of Boc-Val by integration of the *tert*-butyl peaks of nmr spectra. No **4***a* could be detected after reaction of EDC with two equiv. of Boc-Val, or after a reaction carried out in dimethylformamide. More **4***a* was formed at 23°C (35%) than at 0°C (30%); the yield of **5***a* was greater at 0°C (55%) than 23°C (40%). Other factors increased the yield of **4***a*. Maximum yield (55%; isolated) was achieved by adding the Boc-Val dropwise to a dilute solution containing excess EDC and some triethylamine·HCl. Compound **4***a* was stable in deuterochloroform at −5°C for 5 days, in dimethylformamide at 23°C for 2 h, and in dichloromethane–ethanol (20:1) at 23°C for 20 h. It slowly decomposes in solutions containing water giving rise to *tert*-butanol, and is converted to valine *N*-carboxyanhydride (**7***a*) on standing in *tert*-butanol, anhydrous acid, or *in vacuo*. Since **5***a* is also converted to **7***a* by dry HCl, the mixture of **4***a* and **5***a* obtained from the reaction of Boc-Val and EDC serves as a convenient source for the preparation of **7***a*.[3] The valine hydrochloride liberated from **5***a* can be eliminated by simple filtration of the solution of **7***a* in dichloromethane.

Evidence for the formation of the 2-*tert*-butoxy-5(4*H*)-oxazolones (**4**) from the following Boc-amino acids, using one equiv. of EDC, was also obtained (% yield): alanine, 15; leucine, 5; isoleucine, 45; phenylalanine, 15. But in no case could the product be isolated pure because the symmetrical anhydride could not be precipitated out completely. The best product from Boc-Ile contained 5% of anhydride. The mixture of **4***c* and **5***c* obtained from Boc-Ile and EDC could be used to prepare **7***c* in good yield.[3]

When EDC was reacted with Z-Val (**3***b*) as described for reactions with Boc-Val, the analogous 2-benzyloxy-5(4*H*)-oxazolone (**4***b*), $[\alpha]_D$ −55.8° ($CHCl_3$), was obtained in 20% yield using one equiv. of EDC, and in 55% yield using the conditions giving maximum yield. Elemental analysis, nmr, ir, and mass spectra were in accord with this structure. The compound is readily detected and quantitated in a mixture on the basis of the methyleneoxy protons of the nmr spectrum which are 0.20 ppm downfield from those of a Z-group. Compound **4***b* is more stable than **4***a*, not decomposing *in vacuo*, or on standing in *tert*-butanol or wet dichloromethane for 24 h. After 36 h in ethanol, it had been completely converted to the ethyl ester. It reacted with *p*-nitrophenol to give the ester, and with Z-Val to give the symmetrical anhydride (**5***b*), but did not react with *p*-nitroaniline. Catalytic hydrogenation of **4***b* gave **7***a*.

Compound **4***a* reacted with an equiv. of Z-Val and **4***b* with an equiv. of Boc-Val to give quantitative yields of identical products whose nmr and ir curves were consistent with the anhydride structure BocNH—$((CH_3)_2CH)$CH—CO—O—CO—$CH(CH(CH_3)_2)$—NHZ.[4] Unequivocal proof of the absence of the anhydrides **5***a* or **5***b* in the product cannot be provided.

Other 2-benzyloxy-5(4*H*)-oxazolones isolated from reactions using conditions giving maximum yields were those from Z-Phe (**4***d*; 25%), Z-Gly (5%), and Z-Cys(Bzl) (3%). All were pure as evidenced by nmr spectroscopy, but only **4***d* was completely characterized.

When EDC was reacted with two equiv. of **3***a* for 30 min as for the preparation of **5***a*, after work-up the sole product was **5***a*. However, when such a synthesis was terminated at 3 min by the addition of aqueous sodium bicarbonate, and the products were examined after removal of the water-soluble side-products, a 37% yield of an equimolar mixture of **4***a* and **5***a* was found. This corresponds to a 12% yield of **4***a*. An additional experiment established that **4***a* is present in the reaction mixture before

[3]The generality of this approach for the preparation of *N*-carboxyanhydrides is under investigation.

[4]The mp previously reported for this compound which is an oil is an error (3).

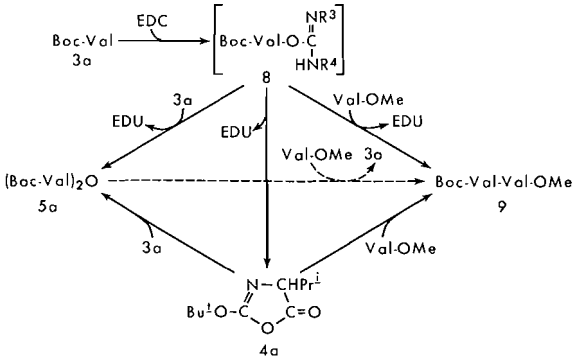
contact with water. Compound **4***a* does not decompose upon standing in dichloromethane at 23°C, and reacts within minutes with **3***a* to give **5***a*. Compound **5***a* did not give rise to any **4***a* when it was left several hours in dichloromethane, even in the presence of triethylamine·HCl. We therefore conclude that **4***a* is an intermediate in the reaction of EDC with **3***a* to give **5***a*. When **3***a* is not present in amount sufficient to react with all of the activated **3***a*, **4***a* accumulates, to the extent of >25%. The initial product of the reaction of EDC with **3***a* is the *O*-acylisourea (**8**);[5] **8** then reacts with **3***a* to give **5***a*. But some of **8** must cyclize to form **4***a* which then reacts with **3***a* to give **5***a* (Scheme 1).

Having succeeded in isolating **4***a* from a reaction mixture containing an oxygen nucleophile, an attempt was made to isolate it from a mixture containing a nitrogen nucleophile. A normal coupling of Boc-Val with Val-OMe·HCl (NMM) mediated by EDC (3 mmol of each) was terminated after 3 min by the addition of aqueous citric acid. Work-up as usual followed by precipitation of the protected dipeptide with light petroleum and removal of solvent by evaporation gave 45 mg (7.5% yield) of pure **4***a*. A similar experiment using DCC gave essentially the same results except that the product was contaminated with an equal amount of non-peptide Boc-derivative (*N*-acylurea). Since **4***a* is known to react with amines to give amides, and since there is no **4***a* in the above reaction mixtures if they are left for 30 min, we conclude that **4***a* is an intermediate in the carbodiimide-mediated coupling of Boc-Val with Val-OMe. As in the previous case, some *O*-acylisourea must cyclize to form **4***a* which then reacts with Val-OMe to give the protected peptide **9** (Scheme 1). An additional possibility is that some of the **4***a* reacts with **3***a* to form **5***a* which then reacts with Val-OMe to give the peptide. Evidence pointing to this comes from the following competitive experiment. When **4***a* was added to a mixture of Z-Val and Val-OMe (1 equiv. of each), the product consisted of Z-Val-Val-OMe (15%) in addition to Boc-Val-Val-OMe. Formation of the anhydride (or **4***b*) must be invoked to account for the appearance of Z-Val-Val-OMe. Implication of the anhydride in these couplings, however, would run contrary to the contention that the *O*-acylisourea and not the symmetrical anhydride is the activated intermediate for synthesis in solution (6). Other competitive experiments were carried out, but these could not be rationalized because of the complexity of the system examined.



SCHEME 1

The question which immediately arises with respect to the implication of 2-alkoxy-5(4*H*)-oxazolones in couplings is whether it is a phenomenon general to carbodiimide-mediated couplings. The results of an attempt to answer this question are given in Table 1. The 2-alkoxy-5(4*H*)-oxazolone was detectable in most of the reaction mixtures examined, the amount being independent of the nature of the carbodiimide or the side-chain of the amino acid ester nucleophile involved. Three factors had an important bearing on the amounts isolated: temperature, *N*-protecting group, and residue activated. The amount was 6–11% for Boc-Val and Boc-Ile at 23°C. It dropped to 0.3–1% at 0°C, or for Boc-Leu and Z-Val at 23°C; No 5(4*H*)-oxazolone was detectable for Z-Val or Boc-Leu at 0°C. The amount detected represents the balance between the rate of formation of the 5(4*H*)-oxazolone and its rate of reaction with the ester. Failure to detect the 5(4*H*)-oxazolone in the latter cases can-

[a]Couplings (3 mmol) in dichloromethane were terminated after 3 min. Yields represent neutral product remaining in mother liquor after normal work-up followed by precipitation of peptide and *N*-acylurea with light petroleum.
[b]Used as hydrochloride, neutralized with *N*-methylmorpholine.
[c]Isolated pure (40–45 mg).
[d]Mixed with an equal amount of inert unesterified Boc-derivative (*N*-acylurea).
[e]Mixed with 1/5 of its weight of peptide.
[f]Not pure. Addition of methylamine eliminated the α-hydrogen doublet in the nmr spectrum producing the CH_3NH doublet of the methylamide.

not be taken as proof that it was not formed. Kinetic data are required before the results can be completely rationalized. We nevertheless conclude that the data in Table 1 provide compelling evidence in favor of the tenet that the 2-alkoxy-5(4*H*)-oxazolone is implicated generally in the carbodiimide-mediated couplings of **3**.

Both **4***a* and **4***b* were shown to be optically pure when assessed by a procedure used routinely in our laboratory. The method consists in coupling the Boc-amino acid, in this case the 5(4*H*)-oxazolone, with L-Lys(Z)-OBzl followed by deprotection and analysis for the diastereomeric peptides with an amino acid analyzer (7). The ester is used as the hydrochloride salt, which is neutralized by adding NMM. Besides demonstrating the optical integrity of the 2-alkoxy-5(4*H*)-oxazolones, the test also demonstrated that they couple without racemization, even in the presence of salt. These results were mandatory if the 2-alkoxy-5(4*H*)-oxazolones are to be implicated in coupling reactions which are known to proceed without racemization. So there is no inconsistency between the results and the proposals. The chiral stability of the 2-alkoxy-5(4*H*)-oxazolones (**4**) contrasts with that of the 2-alkyl-5(4*H*)-oxazolones (**2**) which cannot be coupled without extensive racemization (1, 8). When **4***a* and **4***b* were coupled in the presence of a tertiary amine base, however, some racemization did occur, 6 and 15%, respectively, in the presence of 0.2 equiv. of triethylamine. As much as 50% of **4***b* was racemized when it was coupled in the presence of 1.0 equiv. of triethylamine. The difference in the chiral stabilities of the two types of 5(4*H*)-oxazolones is therefore one of degree.

In view of the above, we submit that the tenet that **3** does not racemize when it is coupled because it does not form the 5(4*H*)-oxazolone must now be rejected. The 5(4*H*)-oxazolone can and does form in some cases. The reason no racemization obtains is that even if the 2-alkoxy-5(4*H*)-oxazolone does form, it is chirally stable under normal conditions of coupling. Caution with technique should be exercised, however, because **4** can racemize in the presence of excess base.

When **4***a* was first encountered by us, the only reference in the literature to the existence of a 2-alkoxy-5(4*H*)-oxazolone was a communication by Jones and Witty (9). They reported that the cyclic compound derived from Z-Phe and phosgene or thionyl chloride followed by triethylamine, which had been described as the *N*-benzyloxycarbonyl-3-benzylaziridin-2-one (10), was in fact the 2-benzyloxy-5(4*H*)-oxazolone **4***d*. The so-called *N*-acylaziridinones had been suggested for use in peptide synthesis since they reacted with amino acid esters to give unracemized products (10). The full paper by Jones and Witty (11) became available to us shortly after our presentation at the Washington Symposium. They have shown with kinetic data that **4***d* reacts with amine nucleophiles (anilines) more quickly, and racemizes in the presence of a tertiary amine base more slowly, than the corresponding 2-phenyl-5(4*H*)-oxazolone. Our results are in complete harmony with those of Jones and Witty as well as with the observations of Miyoshi (10).

Our conclusion on the chiral stability of 2-alkoxy-5(4*H*)-oxazolones is the same as that of Jones and Witty (11). As pointed out by them, it has already been clearly demonstrated that the 4-proton in the analogous 2-alkoxy- 5(4*H*)-thiazolone is much less acidic than that in the corresponding 2-alkyl-5(4*H*)-thiazolone (12), so the observations are as expected.

Explanations invoked to account for the apparent reluctance of **3** to form **4** have been the lower acidity of the —N—H (11, 13) and the lower nucleophilicity of the carbonyl (14) of the urethane group. Cyclization of **3** is considered to require an exceptionally good leaving group such as chloride at the carboxyl group (1, 11) and, until the report of Jones and Witty, was considered to be accompanied by expulsion of the alkyl group giving rise to the *N*-carboxyanhydride **7** (1). Cyclization without loss of the alkyl group obviously does occur, and it occurs under conditions less forcing than previously thought. In fact, the conditions used to make

For personal use only.

2-alkyl-5(4*H*)-oxazolones (**2**) using EDC (15) are identical with those used here to make the 2-alkoxy-5(4*H*)-oxazolones (**4**) except that 0°C is used in the former case, to avoid racemization. The differences in nature between the amide and urethane groups of the two substrates are therefore of little consequence in the cyclization. A more important difference resides in the fate of the products once formed. Compound **2** undergoes no apparent reaction with the substrate, while **4** reacts to form **5**. This can account in part for the much higher yields of **2** than **4** from the reactions.

Our results on the racemization attending couplings of **4** in the presence of base indicate that the 2-*tert*-butoxy group allowed less racemization than the 2-benzyloxy group. This is consistent with the report that the racemizing tendency of the *tert*-butoxycarbonyl group is four times lower than that of the benzyloxycarbonyl group (16). It suggests also that the lability of the 4-proton in **4** is affected by the electron donating property of the 2-alkoxy substituent. Inspection of molecular models indicates that steric effects cannot be invoked to explain the different ionizing tendencies of the 4-proton in 5(4*H*)-oxazolones. The electronic effects of the 2-alkoxy substituent must also be responsible for the unusually low acidity of the 4-proton in **4** relative to that in **2**.

Experimental

General

EDC (17) was purchased from Sigma Chemical Co., St. Louis. Light petroleum refers to the 30–60°C fraction, from Baker (Canlab). Magnesium sulfate was used as drying agent. Solvents were removed at room temperature using a rotary evaporator. Melting points were taken by the capillary method and are uncorrected. Optical rotations were measured with a Perkin-Elmer model 141 polarimeter using a 1-dm tube. The ir spectra were taken on a Unicam SP1100 spectrometer. Proton and carbon-13 nmr spectra were taken on Varian T60 and FT80 instruments, respectively. Chemical shifts are given in ppm relative to tetramethylsilane as internal standard for solutions in deuterochloroform. Elemental analyses were done by Mr. H. Seguin, National Research Council, Ottawa. The stereochemical purities of **4** and **7** were established by adding the products (0.5 mmol) to a solution of L-Lys(Z)-OBzl·HCl (NMM) in dichloromethane. Peptide products were isolated, deprotected, and analyzed for the diastereomers as previously described (7). For assessing the racemization of **4***a* and **4***b* during couplings in the presence of base, the base was added to the solution of the ester.

2-tert-*Butoxy-4-isopropyl-L-5(4*H*)-oxazolone* (**4***a*)

(i) Using Reactants in Equimolar Amounts

A solution of Boc-Val (434 mg; 2 mmol) and EDC (384 mg; 2 mmol) in 20 mL of CH_2Cl_2 was stirred at 0°C for 30 min. The solution was washed with cold 10% aqueous citric acid (20 mL), saturated aqueous $NaHCO_3$ (20 mL), and water (20 mL) and dried. The solvent was removed and light petroleum was added to the residue. After 18 h at −5°C, the crystalline symmetrical anhydride (**5***a*) (207 mg; 50%) mp 84–85°C was filtered off and the solvent was removed to leave a clear oil (80 mg; 20%); $[\alpha]_D^{23}$ −49.6° (*c* 2.0, $CHCl_3$); ir (liquid film): 1845, 1700 cm^{-1}; ^1H nmr δ: 0.94 (d, 3, *J* = 7 Hz), 1.06 (d, 3, *J* = 7 Hz), 1.60 (s, 9), 2.18 (m, 1), 4.13 (d, 1, *J* = 4 Hz); ^{13}C nmr δ: 175.7 (s, C=O), 155.9 (s, C=N), 85.4 (s, $C(CH_3)_3$), 71.0 (d, C—N), 31.1 (d, $C(CH_3)_2$), 27.5 (q, $C(CH_3)_3$), 18.8 and 17.3 (q, $C(CH_3)_2$); ms *m/e*: 199 (M^+ absent), 184 (2, $M^+ - CH_3$), 144 (2, **7***a*H^+), 116 (5, **7***a*H^+ − CO), 101 (20, $(CH_3)_3COCO^+$), 57 (100, $(CH_3)_3C^+$), 41 (90, $C_3H_5^+$). *Anal.* calcd. for $C_{10}H_{17}NO_3$ (Boc-Val − H_2O): C 60.28, H 8.60, N 7.03; found: C 60.04, H 8.47, N 7.02; optical purity >99.8%.

(ii) Conditions Giving Maximum Yield

Boc-Val (2 mmol) in 20 mL of CH_2Cl_2 was added dropwise over 20 min to a stirred solution of EDC (3 mmol) and $Et_3N \cdot HCl$ (3 mmol) in 100 mL of CH_2Cl_2. Work-up as in (*i*) gave a 20% yield of **5***a* and a 50% yield (200 mg) of **4***a*.

(iii) From a Prematurely Terminated Synthesis of **5**a

A solution of Boc-Val (2 mmol) and EDC (1 mmol) in 20 mL of CH_2Cl_2 was stirred at 23°C for 3 min. The mixture was washed with acid and aqueous bicarbonate as in (*i*), and the solvent was removed. Analysis showed the residue (160 mg; ≈37%) was an equimolar mixture of **4***a* and **5***a*. Removal of **5***a* by precipitation (−5°C) with light petroleum and elimination of solvent gave pure **4***a* (40 mg, 10%). When the reactants were stirred for 20 min before work-up, no **4***a* could be detected in the product.

(iv) From a Prematurely Terminated Coupling

To a stirred solution of Boc-Val, Val-OMe·HCl, and NMM (3 mmol of each) in 60 mL of CH_2Cl_2 at 23°C was added EDC (3 mmol). After 3 min the solution was washed and dried as in (*i*), the solvent was removed, and light petroleum was added. After 15 h at −5°C, the Boc-Val-Val-OMe and any **5***a* were filtered off. Elimination of the solvent gave **4***a* (45 mg; 7.5%).

Similar work-up after 3 min of a coupling mixture containing DCC instead of EDC gave a 6% yield of **4***a* mixed with an equiv. of inert Boc-derivative (see Table 1). The presence of **5***a* in the mixture is excluded on the basis of reaction of the mixture with CH_3NH_2 in ether. Extraction of the solution with *N* hydrochloric acid, and analysis of the aqueous extract (nmr) showed the presence of Val-$NHCH_3$ but no valine.

*2-Benzyloxy-4-isopropyl-L-5(4*H*)-oxazolone* (**4***b*)

A synthesis starting with Z-Val (2 mol) and EDC (2 mmol) carried out as described in (*i*) for the preparation of **4***a* gave crystalline **5***b* (243 mg; 50%) mp 99–101°C, followed by **4***b* as an oil (93 mg; 20%); $[\alpha]_D^{23}$ −55.8° (*c* 1.0, $CHCl_3$); ir (liquid film): 1845, 1700 cm^{-1}; ^1H nmr δ: 0.93 (d, 3, *J* = 8 Hz), 1.07 (d, 3, *J* = 8 Hz), 4.20 (d, 1, *J* = 4 Hz), 5.40 (s, 2), 7.48 (s, 5); ^{13}C nmr δ: 175.3 (s, C=O), 158.3 (s, C=N), 134.4–128.6 (aryl carbons), 71.6 (t, Ph*C*), 71.0 (d, C—N), 31.0 (d, $C(CH_3)_2$), 18.6 and 17.2 (q, $C(CH_3)_2$); ms *m/e*: 233 (3, M^+), 205 (8, M^+ − CO), 152 (17, $PhCH_2OCONH_3^+$), 107 (20, $PhCH_2O^+$), 91 (100, $PhCH_2^+$). *Anal.* calcd. for $C_{13}H_{15}NO_3$: C 66.93, H 6.48, N 6.01; found: C 67.10, H 6.65, N 6.15; optical purity >99.8%.

Under conditions giving maximum yield as in (*ii*) Z-Val (2 mmol) gave 160 mg of **5***b*, followed by 253 mg (54%) of **4***b*.

*2-Benzyloxy-4-benzyl-L-5(4*H*)-oxazolone* (**4***d*)

Using the conditions giving maximum yield as in (*ii*) Z-Phe (2 mmol) gave 140 mg (25%) of **4***d* which could be crystallized from ether – light petroleum. Melting point 65–66°C; $[\alpha]_D^{23}$ −36.5° (*c*, 1.5, tetrahydrofuran) (lit. (11) mp 73–73.5°C; $[\alpha]_D$ −36.0°); ^1H nmr δ: 3.14 (d, 1, *J* = 6 Hz), 3.16 (d, 1, *J* = 5 Hz), 4.60 (2d, 1, *J* = 5 and 6 Hz), 5.33 (s, 2), 7.22 (s, 5), 7.40 (s, 5). *Anal.* calcd. for $C_{17}H_{15}NO_3$: C 72.58, H 5.36, N 4.98; found: C 72.32, H 5.52, N 4.89.

Reaction of **4a** *with Methylamine*

To **4***a* (153 mg) was added excess CH_3NH_2 in anhydrous ether, obtained by extraction from an aqueous solution saturated with NaCl, and the solvent was removed after 10 min. The residue was dissolved in ether, and the solution was washed with 5% aqueous citric acid and aqueous $NaHCO_3$, dried, and the solvent was removed. The residue (mp 98–102°C) was recrystallized from CH_2Cl_2 – petroleum ether to give 165 mg (94%) of Boc-Val-$NHCH_3$, mp 113–114°C; ^{1}H nmr δ: 0.95 (d, 6), 1.42 (s, 9), 2.10 (m, 1), 2.82 (d, 3, J = 5 Hz), 3.90 (dd, 1, J = 9 and 5 Hz), 5.10 (br, 1), 6.1 (br, 1). *Anal.* calcd. for $C_{11}H_{22}N_2O_3$: C 57.4, H 9.6, N 12.2; found: C 57.2, H 9.5, N 12.1.

Reactions of **4** *with* **3** *to give* **5**

To **4***a* in CH_2Cl_2 was added an equiv. of **3***a*. After 15 min, the solution was washed with aqueous $NaHCO_3$, dried, and the solvent was removed. Addition of light petroleum gave **5***a* (>90% yield). Compound **5***b* was obtained similarly from **4***b* and **3***b*. Reaction of **4***a* with **3***b*, or **4***b* with **3***a*, gave the same product (oil) whose nmr spectrum indicated one Boc-group and one Z-group per two isopropyl side-chain groups of valine.[4]

*L-Valine-N-carboxyanhydride (***7a***)*

(i) Synthesis from Boc-Val

A solution of Boc-Val (2 mmol) was treated with EDC under conditions giving a maximum yield of **4***a*. After work-up and removal of solvent, the residue (0.36 g) containing **5***a* (34%) and **4***a* (50%) was left in 20 mL of CH_2Cl_2 saturated with dry HCl at 0°C for 2 h. The solvent was removed by evaporation, more was added, and evaporation was repeated. CH_2Cl_2 was added and the mixture was filtered. The solvent was removed, and the residue was recrystallized from $CHCl_3$ – light petroleum to give 185 mg (65%) of *N*-carboxyanhydride **7***a*, mp 57–58°C; $[\alpha]_D^{24}$ −45.0° (*c* 1.0, acetone) (lit. (18) mp 71°C; $[\alpha]_D$ −43°; lit. (19) mp 67–69°C, $[\alpha]_D$ −44.4°); ir ($CHCl_3$): 3345, 1860, and 1795 cm^{-1}; ^{1}H nmr δ: 1.06 (d, 3, J = 6 Hz), 1.10 (d, 3, J = 6 Hz), 2.30 (m, 1), 4.28 (d, 1, J = 4 Hz), and 7.15 (br, 1). *Anal.* calcd. for $C_6H_9NO_3$: C 50.34, H 6.34, N 9.79; found: C 50.36, H 6.49, N 9.77; optical purity >99.8%. The product is completely soluble in $CHCl_3$ indicating the absence of polymer.[6]

(ii) Reaction of **4a** *with Hydrogen Chloride*

When **4***a* was left in CH_2Cl_2 containing dry HCl at 0°C, a 90% yield of **7***a* was obtained.

(iii) Catalytic Hydrogenation of **4b**

When **4***b* was hydrogenated in *tert*-butanol in the presence of 5% palladium-on-charcoal catalyst, a quantitative yield of **7***a* was obtained.

*L-Isoleucine-N-carboxyanhydride (***7c***)*

This compound was obtained from Boc-Ile as described for the preparation of **7***a*. Yield: 65%; mp 65–66°C;[6] $[\alpha]_D^{24}$ −27.0° (*c* 2.0, acetone) (no data reported (19, 20)); ir ($CHCl_3$): 3360, 1860, and 1795 cm^{-1}; ^{1}H nmr δ: 1.05 (m, 6), 1.45 (m, 2), 2.00 (br, 1), 4.25 (d, 1, J = 4 Hz), and 7.10 (br, 1). *Anal.* calcd. for $C_7H_{11}NO_3$: C 53.49, H 7.06, N 9.91; found: C 53.66, H 7.18, N 8.89; optical purity >99.8%.

Isolation of **4** *from Prematurely Terminated Couplings (Table 1)*

Reactions and work-up were as described for the isolation of **4***a* according to (*iv*). The identity of the products was confirmed by adding anhydrous methylamine and noting the change in the nmr spectrum.

[6]The mp gradually increases after storage of the *N*-carboxyanhydride at −5°C (4° in four days). Removal of polymerized material by taking up the mixture in chloroform and filtering, gives product (80% recovery) with the original mp.

J. WILLIAM LOWN and HSIAO-HSIUNG CHEN. Can. J. Chem. **59**, 390 (1981).

The nature of the reactive oxygen species generated from certain quinone antitumor antibiotics upon reductive activation in aqueous solution was investigated. A kinetic criterion was employed involving the relative rate of trapping of hydroxyl and formate radicals by the spin-trap 5,5-dimethyl-1-pyrroline-*N*-oxide (DMPO) in conjunction with epr spectroscopy. By comparison with a system involving the photolysis of hydrogen peroxide as a standard free hydroxyl system it was concluded that at pH 7 and at 37°C reductive activation of adriamycin, daunorubicin, mitomycin B, mitomycin C, and streptonigrin gives rise to free hydroxyl radicals in direct contrast with, for example, the photolysis of quinones in solution.

J. WILLIAM LOWN et HSIAO-HSIUNG CHEN. Can. J. Chem. **59**, 390 (1981).

On a étudié la nature des espèces réactives d'oxygène produites à partir de certaines quinones antibiotiques antitumescentes par une activation réductrice en solution aqueuse. On a utilisé un critère cinétique faisant intervenir la vitesse de piégeage des radicaux hydroxyle et formate par le capteur de spin, *N*-oxyde de diméthyl-5,5 pyrroline-1 (ODMP), conjointement avec la spectroscopie de rpe. Par comparaison avec un système impliquant la photolyse du peroxyde d'hydrogène en tant que système de référence pour le groupe hydroxyle libre, on a conclu qu'à un pH de 7 à 37°C l'activation réductrice de l'adriamycine, de la daunorubicine, de la mitomycine B, de la mitomycine C et de la streptonigrine produit des radicaux hydroxyles libres contrairement à ce qui se produit lors de la photolyse des quinones en solution.

[Traduit par le journal]

Introduction

There is accumulating evidence that reactive oxygen species, including the superoxide anion radical, hydrogen peroxide, and the hydroxyl radical are generated in vivo during the metabolism and/or molecular mechanism of cytotoxic action of certain antitumor antibiotics, especially those containing quinone moieties (see Fig. 1) (1–9). Oxidizing agents have many deleterious effects on cells including lipid peroxidation, macromolecule depolymerization, and membrane damage (2, 10–12). Many of these effects have been directly attributed to the hydroxyl radical owing to its high reactivity (13–17). Thus it became important from the viewpoint of elucidating the mechanism of action of antibiotics to determine the exact nature of the oxygen species produced. In a previous paper we reported the detection of superoxide and hydrogen peroxide formed in solution from a group of reductively activated quinone antibiotics (7). The formation of hydroxyl radicals was strongly implicated but not unambiguously proven. In the present work we provide evidence using kinetic criteria in conjunction with epr spectroscopy for the generation of hydroxyl radicals from certain quinone antibiotics, some of which are of clinical use in the treatment of cancer.

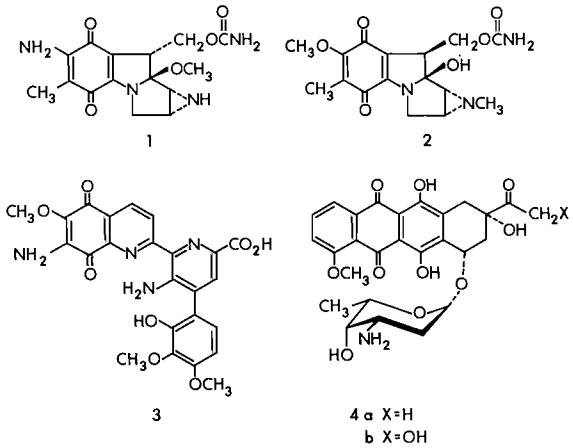

FIG. 1. Structures of quinone antitumor antibiotics. 1, Mitomycin C; 2, mitomycin B; 3, streptonigrin; 4a, daunorubicin; and 4b, adriamycin.

Results

Ultraviolet photolysis of dilute hydrogen peroxide solutions is known to generate OH· radicals (18). Whereas the OH radical itself is too short lived to permit a steady state epr signal, added DMPO (19), however, produces a steady state DMPO·OH spin-adduct spectrum (Fig. 2A) with its characteristic four-line pattern (19, 20). Addition of sodium formate also introduced the typical six-line epr spectrum of the DMPO·formyl spin-adduct (21,

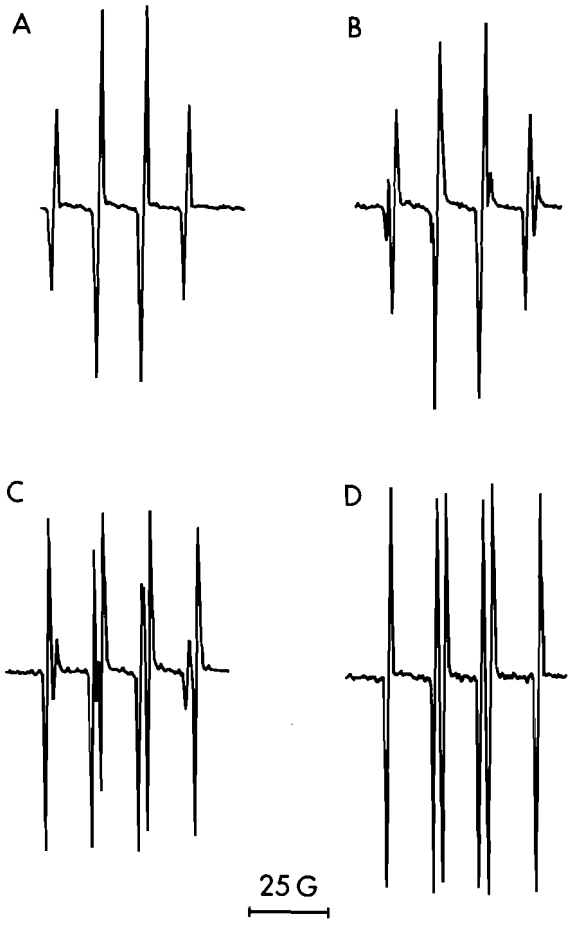

FIG. 2. Electron paramagnetic resonance spectra (microwave power 4 mW, modulation amplitude 0.05 G, scan time 1000 s) of DMPO spin-trapped radicals obtained by incubating 1×10^{-2} *M* mitomycin C reduced with 3×10^{-2} *M* sodium borohydride in the presence of different concentrations of sodium formate at pH 7.0. A(none); B, 7.5 m*M*; C, 62.5 m*M*; D, 100 m*M*. Spectrum A shows only the DMPO·OH spin adduct, hfs $a^N = 15.0$ G, $a^H = 15.0$ G. Spectrum D shows only the formyl DMPO spin adducts, hfs $a^N = 15.6$ G, $a^H = 18.8$ G. Spectra C and B show a superimposition of the spectra of the two spin adducts.

22) (Fig. 2D). As the concentration of the sodium formate increased, the signal strength of the DMPO·formyl species increased at the expense of the DMPO·OH adduct (e.g. Figs. 2B, C). The peroxide solution under uv photolysis was used as the free OH radical system (18) against which the antibiotics systems were compared.

Mitomycin C, when reduced with slightly in excess of one equivalent of sodium borohydride in aqueous solution and exposed to oxidation by air, gives rise to a semiquinone species which was identified by its epr hyperfine spectrum which in turn had been subject to computer simulation analysis (7). Care was taken to ensure that the excess of the sodium borohydride was removed before addition of the DMPO to prevent its reduction (*vide infra*). Addition of DMPO and incubation at pH 7 in phosphate buffer and at 37°C gave rise to the superimposition of the epr signals due to the semiquinone together with the characteristic 1:2:2:1 DMPO·OH pattern.

It was established in control experiments that the spin-trapping agent DMPO in the pH 7.0 buffer solution did not give rise to radical species in the absence of the antibiotics. The reason why it was essential to remove excess of the reducing agent sodium borohydride before addition of the DMPO is that we had observed that phenyl *N-tert*-butylnitrone (PBN) in the presence of sodium borohydride is reduced to benzyl *tert*-butyl hydroxylamine, subsequent air oxidation of which gives rise to the benzyl *tert*-butyl nitroxide which affords a 9-line epr spectrum with hyperfine couplings $a^N = 16.2$ G, $a^H = 10.5$ G (7). Therefore DMPO was reduced with sodium borohydride in solution and the product exposed to air oxidation in order that the corresponding radical species produced from DMPO could be recognized if it was formed. Electron paramagnetic resonance examination shows a well-resolved 9-line spectrum with $a^N = 16.0$ G, $a^H_{CH_2} = 21.5$ G (Fig. 3).

As the concentration of the added sodium formate increased, the epr signal strength of the DMPO·formyl species increased at the expense of the DMPO·OH adduct. The ratio of the DMPO·OH peak height to the sum of the OH and formyl adduct

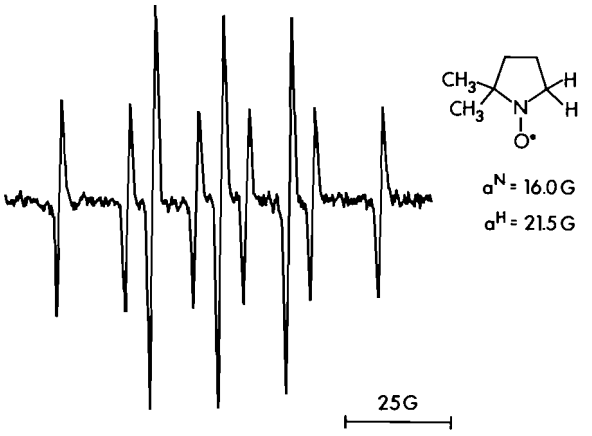

FIG. 3. Electron paramagnetic resonance spectrum (microwave power 8 mW, modulation amplitude 0.1 G, scan time 1000 s) of 2,2-dimethyltetrahydropyrrole *N*-oxide radical obtained from the reduction of DMPO with sodium borohydride followed by air oxidation; hfs $a^N = 16.0$ G, $a^H_{CH_2} = 21.5$ G.

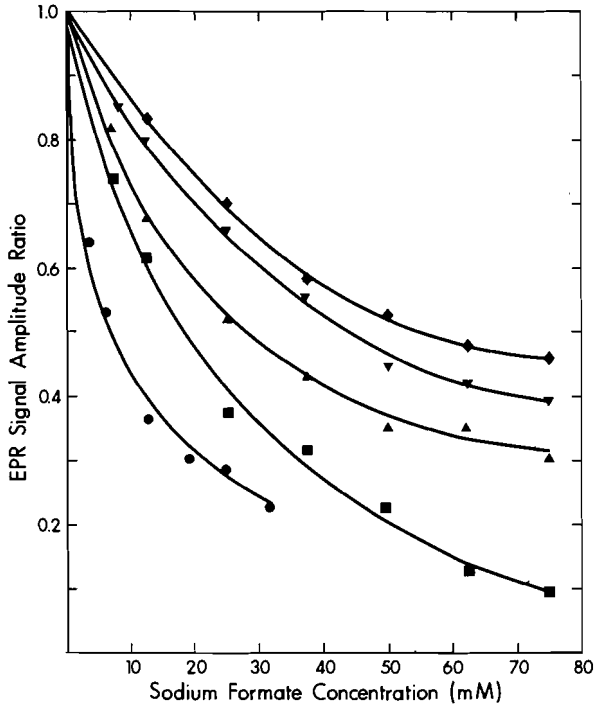

FIG. 4. Plot of the ratio (amplitude DMPO·OH adduct epr signal):(amplitude DMPO·formyl adduct + amplitude DMPO·OH adduct epr signals) versus concentration of added sodium formate for different antibiotics: ◆ mitomycin B; ▼ adriamycin; ▲ daunorubicin; ■ mitomycin C; ● streptonigrin.

peak heights was determined and plotted against formate concentration. The sodium formate concentration at which the DMPO·OH and DMPO·CO_2^- spin-adduct concentrations are equal was thus determined (Fig. 4).

Similar procedures were adopted to investigate the behavior of mitomycin B, daunorubicin, adriamycin, and streptonigrin. In the case of daunorubicin the radical generation, spin-trapping, and the epr analysis were performed at the three buffered pH's of 6, 7, and 8. The results of the determinations in each case of the formate concentration at which the DMPO·OH and DMPO·CO_2 spin adduct concentrations are equal are summarized in Table 1.

TABLE 1. Ratios of rate constants for reaction of hydroxyl species with formate anion and DMPO for quinone antibiotics at pH 7

Antibiotic	(k_9/k_{10})†	
Adriamycin	0.28 ± 0.15	
Daunorubicin*	0.18 ± 0.09	
Mitomycin B	0.37 ± 0.19	
Mitomycin C	0.11 ± 0.06	
Streptonigrin	0.05 ± 0.03	
H_2O_2 system	0.23 ± 0.12	
Benzoquinone	4.8 ± 0.4	(ref. 42)

*Value of (k_9/k_{10}) at pH $6.0 = 0.18 \pm 0.09$, and at pH $8.0 = 0.15 \pm 0.08$.
†Values of (k_9/k_{10}) were calculated for the antibiotics when the concentrations of the DMPO·OH and DMPO·formyl radicals were equal (see text).

Discussion

There is growing evidence that the generation of reactive oxygen species is intimately associated with the primary cytotoxic and, in some cases, secondary toxic effects of certain antitumor antibiotics. For example it has been shown that the glycopeptide antitumor antibiotics bleomycin and tallysomycin bind to DNA and through the intermediacy of an iron complex undergo redox cycling in vivo to generate reactive oxygen species (most probably O_2^- and OH·) which cleave DNA (23–26). Since these antibiotics bind at particular sequences in the genome they have been characterized as site-specific radical generators (3). Also, the anthracyclines daunorubicin and adriamycin exhibit many effects in vivo including interference with cell respiration and lipid peroxidation especially in heart tissue (27). There is evidence that these effects are associated with the generation of reactive oxygen radicals and may be causally related to the severe dose-related cardiotoxicity (1–3, 28–32). The surveillance system that ordinarily protects the cell against damage by oxygen species consists of superoxide dismutase which removes O_2^- and functions in tandem with the enzymes glutathione peroxidase and catalase (which remove H_2O_2) (33). Part of the selectivity expressed by antitumor agents such as bleomycin and mitomycin C which generate reactive oxygen species may therefore be attributed to the suppressed levels of superoxide dismutase and of catalase in neoplastic tissue (34). Because of the existence of these enzymes the intermediacy of superoxide and hydrogen peroxide in the action of quinone antitumor antibiotics is unambiguously established by their selective enzymatic removal (with consequent protection of macromolecules against damage), by superoxide dismutase and by catalase, respectively (4, 7, 25, 26).

By contrast, there appears to be no specific cell surveillance enzyme to remove OH·. The cell seems to rely on the removal of the precursor components O_2^- and H_2O_2 (from which OH· may arise) to prevent formation of hydroxyl radicals. The intermediacy of OH· and its role in antibiotic action has had to be inferred by indirect means, e.g. suppression of DNA scission by free radical scavengers like mannitol or sodium benzoate (7). In view of the high reactivity of OH· (which is arguably the most powerful oxidant encountered in biological

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

systems) it becomes essential to establish whether or not free OH· radicals are generated.

Alternative mechanisms may be envisaged for the formation of the hydroxyl radical from quinone antibiotics.

[1] $AB + [2H] \rightarrow ABH_2$

[2] $ABH_2 + O_2 \rightarrow ABH^{\cdot} + HO_2^{\cdot}$

[3] $HO_2^{\cdot} \rightarrow H^+ + O_2^{-}$

[4] $2O^{-} + 2H^+ \xrightarrow{SOD} H_2O_2 + O_2$

[5] $2H_2O_2 \xrightarrow{catalase} 2H_2O + O_2$

[6] $CMX{\cdot}Fe^{3+} + O_2^{-} \rightarrow CMXFe^{2+} + O_2$

[7] $CMX{\cdot}Fe^{2+} + H_2O_2 \rightarrow CMXFe^{3+} + OH^{\cdot} + OH^{-}$

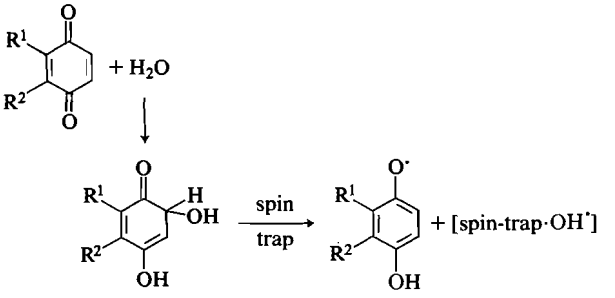
In the above scheme AB represents a reducible antibiotic. SOD represents superoxide dismutase. *CMX*· Fe signifies iron complexed in vivo to either protein or ATP, or in the case of the glycopeptide antibiotics bleomycin and tallysomycin to the antibiotics themselves. This scheme gains support from (*a*) electrochemical measurements that show the redox potentials of the antibiotics to be compatible with reductants available in vivo (35, 36), (*b*) from the unambiguous identification of the semiquinone species ABH· by epr (7) and of O_2^{-} and H_2O_2 by employing SOD and catalase, respectively (4, 7, 25, 26).

Although hitherto the generation of OH· species in vivo had been attributed to the Haber–Weiss reaction [8] this is improbable since it has recently

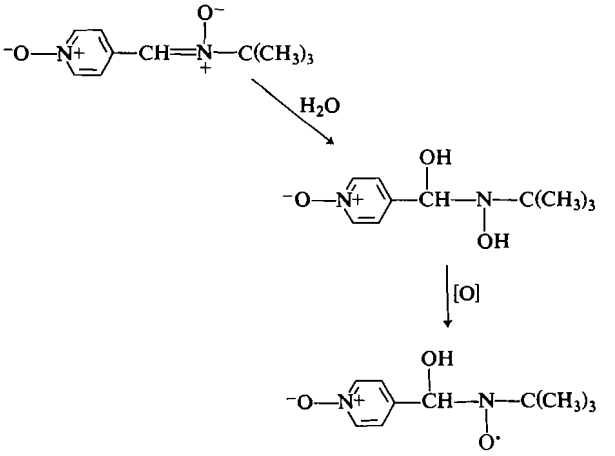
[8] $H_2O_2 + O_2^{-} \rightarrow OH^{\cdot} + OH^{-} + O_2$

been shown to be quite slow ($k < 0.3\ M^{-1}\ s^{-1}$) (37–39) and therefore is unlikely to represent the source of OH· species. Instead it has been suggested that the OH· radical is produced by reaction of O_2^{-} with Fe(III) complexed with protein or ATP since traces of iron are present in most biological systems (40). The release of free radicals in close proximity to DNA in the case of "site-specific free radical generators" e.g. bleomycin, adriamycin, daunorubicin, is necessary because of the high reactivity of OH·. Its rate constants are so large for most compounds that it will react with the first molecule it encounters. Thus, in order to damage DNA, OH must be released close to it.

A number of alternative mechanisms may be envisaged for the formation of "bound" hydroxyl radicals, i.e., via a species which is capable of donating a hydroxyl group to the spin-trap. In the case of quinone-containing antibiotics these could include for example a hydration pathway e.g.



The intermediate hydrated form of the activated antibiotic could serve, in effect, as an hydroxyl radical donor or a "bound hydroxyl radical". A mechanism such as this has precedence in the known photoinduced hydration of *p*-benzoquinone which is able to transfer a hydroxyl group to a spin-trap such as DMPO (41, 42). Another related reaction is the observed hydration of certain spin-traps in solution to give a hydroxylamine which is readily oxidizable to a stable nitroxide giving rise to a "false spin adduct", as observed by Janzen *et al.* in the case of the α-4-pyridyl-1-oxide *N-tert*-butyl nitrone (43).



In view of these mechanistic alternatives the kinetic criteria implicit in the formate procedure of Harbour and co-workers (21, 22) were applied to discriminate between a true free hydroxyl species and a "bound" hydroxyl species (hereafter referred to as X) generated from these antibiotics.[2] The basis of the method is as follows. Formate ion reacts rapidly with OH radicals to generate the formyl radical (44) with a rate constant of $2.7 \times 10^9\ M^{-1}\ s^{-1}$ at pH 7.0 (45).

$$HCOO^{-} + OH^{\cdot} \rightarrow CO_2^{-} + H_2O$$

The formyl radical thus produced can react with the

[2]The authors are indebted to Dr. J. R. Bolton for suggesting the application of their procedure to the present problem.

For personal use only.

spin-trap to produce a superposition of the OH and formyl radical spin-adduct spectra. At low formate concentrations most of the X will react directly with DMPO. At higher concentrations of formate, however, X will react to generate more of the formyl radical with a resultant increase in formyl adduct spectrum intensity. If X represents the free OH radical, the benzoquinone system should react identically with a system known to involve free OH, e.g. the kinetics of the two systems should be identical. If X is an intermediate other than OH, the systems are expected to behave differently.

Czapski and Bielski have established that uv photolysis of dilute hydrogen peroxide solutions produces free OH radicals (18) and for this reason it was chosen as the free OH radical system against which the antibiotic systems were compared. The relative concentrations of the OH and formyl spin-adducts were determined as a function of formate concentration for each system. This was done by measuring the amplitude of the low field peak of each spin-adduct signal. A correction for linewidth was made where necessary

$$I \propto \gamma'_{max}(\Delta H_{pp})^2$$

where I = approximate relative intensity, $2\gamma'$ = peak to peak amplitude, and ΔH_{pp} = peak to peak linewidth. Thus, corrected peak amplitude is proportional to peak area and radical concentration.

The competing reactions may be represented as follows

[9] $X + DMPO \xrightarrow{k_9}$ 
[10] $X + HCOO^- \xrightarrow{k_{10}} CO_2^{\cdot-} + H_2O$

[11] $CO_2^{\cdot-} + DMPO \xrightarrow{k_{11}}$ 
Reaction [11] is common for the antibiotics and hydrogen peroxide systems regardless of the nature of X. The two competing reactions are [9] and [10]

$$\text{Rate [9]} = k_9[X][DMPO]$$

$$\text{Rate [10]} = k_{10}[X][HCOO^-]$$

When the concentrations of OH and formyl spin-adducts are equal, then Rate [9] = Rate [10]. Then, assuming that reaction [11] goes to completion:

$$k_9[X][DMPO] = k_{10}[X][HCOO^-]$$

$$[HCOO^-]/[DMPO] = k_9/k_{10}$$

The concentrations of formate and DMPO under these conditions are known. If a particular antibiotic system involves a free OH radical, the ratio of the rate constants must be similar to that for the hydrogen peroxide system. It may be seen from the table that the ratios of (k_9/k_{10}) at pH 7 for adriamycin, daunorubicin, mitomycin B, mitomycin C, and streptonigrin are quite similar to that recorded for the hydrogen peroxide systems. In the example of daunorubicin (k_9/k_{10}) does not vary significantly over the pH range 6.0 to 8.0. By contrast the system involving the photolysis of *p*-benzoquinone, from which the stable products are hydroquinone and 2-hydroxy-1,4-benzoquinone, gives a very different value for (k_9/k_{10}) of 4.8 indicative of the intermediacy of a "bound" hydroxyl radical donor (42).

It has been suggested by a referee that owing to the high reactivity of the OH· radical some attack of this species on susceptible groups in the antibiotics (e.g. CH_3O, $\diagdown CH—OH$, $\diagdown CH—OR$) may be anticipated to compete with trapping of the OH· by formate anion. The radicals produced from such reactions should also be trapped by DMPO but since there was no evidence of addition epr signals in addition to the primary spin-adducts one may conclude such processes do not occur to a detectable extent.

The results demonstrate that these antibiotics are giving rise to the hydroxy radical by a mechanism similar to that given in reactions [1] to [7] and that it is free in solution. The results should assist in the understanding of the molecular mechanism of anticancer action and of the cytotoxicity of these antibiotics.

Experimental

Materials

Mitomycin C was purchased from Calbiochem. Mitomycin B was a gift from Dr. K. Shirahata, Kyoway Hakko Kogyo Co. Ltd., Tokyo, Japan. Streptonigrin was supplied by Dr. H. R. Wood, Jr., National Cancer Institute, Washington, DC. Daunorubicin and adriamycin were generous gifts from Dr. F. Arcamone, Farmitalia, Milan.

5,5-Dimethyl-1-pyrroline-*N*-oxide (DMPO) was purchased from Aldrich Chemical Co. and was purified by charcoal decolorization just before use. A standard solution of DMPO, 0.64 *M* was prepared in 0.1 *M* phosphate buffer, pH = 7.0.

Electron Paramagnetic Resonance Spectroscopy

The epr spectra were obtained on a Bruker ER-400 EPR spectrometer fitted with a Varian V3601 12-inch magnet with VFR Hall effect controller. Hyperfine couplings were obtained by comparison with peroxylamine disulfonate (triplet, spacing 13.0 G) and *g* values were obtained by direct Fieldial measurements.

Spin Trapping and EPR Detection of Radical Species from Reduced Quinone Antibiotics

A standard reaction solution was prepared for each run on a 400 μL scale with deionized water containing 5 mmol of EDTA, 25 mmol phosphate buffer pH 7.0, 0.16 mol DMPO, and either 0, 7.5 m*M*, 12.5 m*M*, 25 m*M*, 37.5 m*M*, 50 m*M*, 62.5 m*M*, or 75 m*M* sodium formate.

Separately, the semiquinone of each antibiotic was prepared

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

by treating 1000 μL of a 1×10^{-2} *M* solution of the antibiotic with 300 μL of 3×10^{-2} *M* sodium borohydride, incubated at room temperature and protected from the light in the presence of atmospheric oxygen for different periods of time depending on the redox potential of the antibiotics; ca. 3 min for mitomycin B, 6 min for streptonigrin, 10 min for daunorubicin, 15 min for mitomycin C, and 25 min for adriamycin. Care was taken to ensure that the excess of sodium borohydride was discharged before addition of the spin-trap to avoid the reduction of DMPO and its reoxidation to form the nitroxide which would have given rise to the 9-line epr spectrum shown in Fig. 3. After the room temperature incubation, 200 μL of the semiquinone solution was added into the prepared DMPO – sodium formate solution and incubated at 37°C for 2.5 h before the epr study.

The addition of sodium formate permits the detection of the hydroxyl radical which thereby gives rise to the formyl spin-trapped nitroxide according to the method of Harbour and Bolton (22). In the present study, however, the formate concentration was systematically varied. A plot of the relative peak heights of spin-adduct spectra versus formate concentration was made for each antibiotic. The relative concentrations of the OH and formyl spin adducts were determined by measuring the amplitude of the low field peak of each spin-adduct signal. Some decay of the signals occurred during the 1000 s scan time. Therefore, the spectrometer scans from low to high field, using the low field peaks, to minimize any error introduced by signal decay.

In control experiments it was established that in the presence of sodium formate and buffer the spin-trapping agent DMPO did not give rise to radicals in the absence of sodium borohydride treated antibiotics.

Synthesis of fluoro derivatives of 2-amino-2-deoxy-D-galactose and -D-glucose

LESLIE HOUGH, ANNA A. E. PENGLIS, AND ANTHONY C. RICHARDSON
Department of Chemistry, Queen Elizabeth College, London W8 7AH, Great Britain

Received July 2, 1980

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

LESLIE HOUGH, ANNA A. E. PENGLIS, and ANTHONY C. RICHARDSON. Can. J. Chem. **59**, 396 (1981).

Selective fluoride displacement of the 6-mesyloxy group of methyl 2-benzamido-3-*O*-benzyl-2-deoxy-4,6-di-*O*-mesyl-α-D-glucopyranoside **4** gave the 6-fluoride **5**. Subsequent removal of the blocking substituents afforded 2-amino-2,6-dideoxy-6-fluoro-D-glucose, isolated as its hydrochloride **11** and its *N*-acetyl derivative **12**. Nucleophilic displacement of the remaining 4-mesyloxy group of the intermediary 6-fluoro-4-mesylate **5**, by benzoate anion afforded derivatives of 2-amino-2,6-deoxy-6-fluoro-D-galactose (**18**). An interplay of similar substitutions on **4** gave, after deprotection, methyl 2-acetamido-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside (**22**), methyl 2-acetamido-3-*O*-acetyl-4,6-difluoro-2,4,6-trideoxy-α-D-glucopyranoside (**27**), and methyl 2-benzamido-3-*O*-benzyl-6-fluoro-2,4,6-trideoxy-β-L-*threo*-hex-4-enopyranoside (**28**).

Methyl 2-acetamido-2,4-dideoxy-4-fluoro-α-D-glucopyranoside diacetate (**31**) was synthesized from the 4-*O*-mesyl-6-*O*-trityl-galactopyranoside **29**.

LESLIE HOUGH, ANNA A. E. PENGLIS et ANTHONY C. RICHARDSON. Can. J. Chem. **59**, 396 (1981).

Le déplacement sélectif du groupe mésyloxy-6 du benzamido-2 *O*-benzyl-3 déoxy-2 di-*O*-mésyl-4,6 α-D-glucopyrannoside de méthyle (**4**) par un fluorure donne le dérivé fluoré en 6 (**5**). L'élimination subséquente des substituants protecteurs conduit à l'amino-2 didéoxy-2,6 fluoro-6 D-glucose que l'on a isolé sous forme de chlorhydrate (**11**) et de dérivé *N*-acétylé (**12**). Le déplacement nucléophile du groupe mésyloxy-4 du fluoro-6 mésylate-4 intermédiaire (**5**) par l'anion benzoate conduit aux dérivés de l'amino-2 déoxy-2,6 fluoro-6 D-galactose (**18**). Une séquence analogue de substitutions sur le composé **4** conduit, après déprotection, à l'acétamido-2 difluoro-4,6 tridéoxy-2,4,6 α-D-galactopyrannoside de méthyle (**22**), à l'acétamido-2 *O*-acétyl-3 difluoro-4,6 tridéoxy-2,4,6 α-D-glucopyrannoside de méthyle (**27**) et au benzamido-2 *O*-benzyl-3 fluoro-6 tridéoxy-2,4,6 β-L-*thréo*-hexéno-4 pyrannoside de méthyle (**28**).

On a synthétisé le diacétate de l'acétamido-2 didéoxy-2,4 fluoro-4 α-D-glucopyrannoside de méthyle (**31**) à partir du *O*-mésyl-4 *O*-trityl-6 galactopyrannoside (**29**).

[Traduit par le journal]

Substitution of fluorine into certain natural products, notably steroids, has sometimes markedly enhanced their biological activities. These effects have been explained in terms of the greater electronegativity of fluorine, which affects the acidity of neighbouring protons, coupled with the ability of fluorine to accept a hydrogen bond in the same way as oxygen. The latter property has motivated a considerable effort into the synthesis of carbohydrate derivatives in which one or more hydroxyl groups have been replaced by fluorine. For example, fluorinated analogues of D-glucose and D-galactose have been synthesized (1–3) for biochemical studies and the probing of molecular conformation by the use of ^{19}F nmr spectroscopy has added a new dimension to structural studies of carbohydrates in solution (3, 4). However, the anticipation that such fluorinated sugars would function as highly effective inhibitors of various enzymes (cf. fluorocitric acid (5) formed from fluoroacetic acid in vivo) has not been realized, although some do act as weak reversible inhibitors. For example, we have shown that 6-deoxy-6-fluorotrehalose is a good reversible inhibitor of insect trehalase (6).

In view of the wide distribution of D-glucosamine and D-galactosamine in the animal kingdom, the synthesis of specifically fluorinated analogues was investigated. Meanwhile the syntheses of derivatives of 2-amino-2,6-dideoxy-6-fluoro-D-glucose (**11**) and -D-galactose and 2-amino-2,4-dideoxy-4-fluoro-D-glucose have been reported (7–9), but by different and less convenient routes than those described herein, although the method described by Sharma and Korytnyk (8), in which primary hydroxyl groups could be displaced directly with fluorine by treatment with diethylaminosulphur trifluoride, was particularly convenient for the preparation of 6-deoxy-6-fluorohexosamine derivatives.

The most rational approach for the introduction of fluorine into 2-amino-2-deoxy-D-glucose and -D-galactose is by nucleophilic fluoride displacement of a sulphonyloxy group in a suitably blocked but readily available *gluco*-analogue. Thus, for the synthesis of the 6-fluorides, methyl 2-benzamido-3-*O*-benzyl-2-deoxy-4,6-di-*O*-mesyl-α-D-glucopyranoside (**4**) was considered appropriate. It was prepared from methyl 2-benzamido-4,6-*O*-benzylidene-2-deoxy-α-D-glucopyranoside (10) by sequential benzylation, mild acid hydrolysis, and mesylation in an overall yield of 55%. Selective

nucleophilic displacement of the primary ester of the 4,6-dimesylate **4** was readily achieved by reaction with tetrabutylammonium fluoride in acetonitrile (2, 3) for 1 h at reflux. The 6-fluoride **5** was isolated in 87% yield, and its structure confirmed by the ^{19}F nmr spectrum (Table 2) which displayed a triplet of doublets ($J_{H\text{-}6a,6\text{-}F} = J_{H\text{-}6b,6\text{-}F} = 47.5$, $J_{H\text{-}5,6F} = 22.5$ Hz) typical of a 6-deoxy-6-fluoroglucopyranoside (3, 11). Removal of the remaining mesyl group was accomplished by boiling methanolic sodium hydroxide, which gave methyl 2-benzamido-3-*O*-benzyl-2,6-dideoxy-6-fluoro-α-D-glucopyranoside (**6**), crystalline in 93% yield. Hydrogenolysis of the 3-*O*-benzyl-6-fluoride **6** in the presence of acid then gave crystalline methyl 2-benzamido-2,6-dideoxy-6-fluoro-α-D-glucopyranoside (**7**), which was also characterized as its diacetate **8**, the ^1H and ^{19}F nmr parameters of which were in complete accord with the structure (Tables 1 and 2). Hydrolysis of the diacetate **8** with hydrochloric acid afforded crystalline 2-amino-2,6-dideoxy-6-fluoro-α-D-glucose hydrochloride (**11**) in 90% yield. *N*-Acetylation of the amine salt **11** was accomplished by deionization of a solution of **11** followed by treatment with acetic anhydride (12) to give crystalline 2-acetamido-2,6-dideoxy-6-fluoro-α-D-glucose (**12**).

An alternative route to the *N*-acetyl derivative (**12**) involved treatment of methyl 3,4-di-*O*-acetyl-2-benzamido-2,6-dideoxy-6-fluoro-α-D-glucopyranoside (**8**) with a boiling mixture of acetic acid and acetic anhydride (13), thereby replacing the *N*-benzoyl substituent with *N*-acetyl. The reaction mixture was either processed directly to give methyl 2-acetamido-3,4-di-*O*-acetyl-2,6-dideoxy-6-fluoro-α-D-glucopyranoside (**9**) in 65% yield, or cooled and treated with a little sulphuric acid in order to acetolyze the glycosidic group. This latter treatment afforded a crystalline mixture of triacetates of 2-acetamido-2,6-dideoxy-6-fluoro-D-glucose which was mainly the α-pyranose, but which could not be resolved into a pure anomer by recrystallization. The pure α-pyranose tri-*O*-acetate (**10**) was, however, obtained from the 2-acetamido sugar (**12**) by acetylation with acetic anhydride in pyridine.

For the synthesis of the *galacto* isomer (**18**), the 6-fluoro-4-mesylate (**5**) was readily available. Nucleophilic displacement of the sulphonyloxy group by benzoate anion in hexamethylphosphoric triamide afforded the 4-*O*-benzoyl-galactoside (**13**) crystalline in 80% yield. Its ^1H nmr spectrum was indicative of the *galacto* configuration showing the H-3 and H-4 resonances as double doublets ($J_{2,3}$ 10.5 Hz, $J_{3,4}$ 3.2 Hz, $J_{4,5}$ 1.3 Hz) (14). On the other hand, the ^{19}F nmr spectrum was highly second order, as found with other 6-deoxy-6-fluorogalactopyranosides (6, 15).

The 4-*O*-benzoyl group was removed from the 6-fluoride (**13**) by transesterification with methanolic sodium methoxide, giving methyl 2-benzamido-3-*O*-benzyl-2,6-dideoxy-6-fluoro-α-D-galactopyranoside (**14**) in 80% yield. The ^{19}F nmr spectrum of **14** (Table 2), was first order and showed $J_{6F,5H} = 14.6$ Hz which was within the expected range for a galactoside (3, 11). Hydrogenolysis of the benzyl group of **14** in the usual manner yielded methyl 2-benzamido-2,6-dideoxy-6-fluoro-α-D-galactopyranoside (**15**), which was isolated as its crystalline diacetate (**16**). Acetolysis of the *N*-benzoyl group in **16** with a boiling mixture of acetic anhydride and acetic acid afforded methyl 2-acetamido-3,4-di-*O*-acetyl-2,6-dideoxy-6-fluoro-α-D-galactopyranoside (**17**) in 74% yield, de-*O*-acetylation of

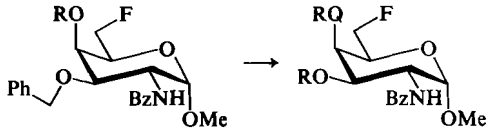
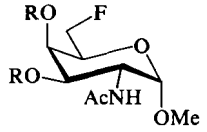
which gave the crystalline methyl 2-acetamido-2,6-dideoxy-α-D-galactopyranoside (**18**).



13 R = COPh
14 R = H

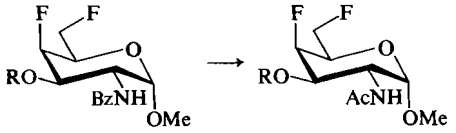
15 R = H
16 R = Ac



17 R = Ac
18 R = H

The 4,6-di-*O*-mesylglucopyranoside (**4**) was a suitable precursor of 2-amino-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside derivatives by prolonged treatment with tetrabutylammonium fluoride in acetonitrile for several days. The ^{19}F nmr spectrum of the crude concentrated reaction mixture showed the expected triplet of doublets due to F-6 at 73.3 ppm and a doublet of triplets due to F-4 at 61.7 ppm above external C_6F_6. The observed coupling constants of the F-6 signal were: $J_{H\text{-}6a,6F} = J_{H\text{-}6b,6F} = 45$ Hz, $J_{F,5H}$ 15.8 Hz. The corresponding parameters of the F-4 signal were $J_{F,4H}$ 53.5 Hz, $J_{F,3H} = J_{F,5H} = 31.5$ Hz. These were in complete accord with those expected for **19** with a primary fluorine substituent at C-6 and an axial secondary fluorine substituent at C-4 of a galactopyranoside (3, 4); the product **19** was subsequently isolated in 77% yield. However, the 4,6-difluoride **19** could be conveniently prepared in 62% yield by refluxing a solution of the 4,6-dimesylate (**4**) and anhydrous potassium fluoride in dry ethane-1,2-diol for 15–20 min. In general, the displacement of secondary esters on pyranosides by potassium fluoride has not been successful (3). There was no reason to suspect extensive introduction of the —OCH_2CH_2OH group in the molecule as previously reported (*4a*, 16) or any interference by the benzyloxy group at C-3 (17), although some nonspecific decomposition was observed.

The 4,6-difluorogalactoside (**19**) was hydrogenolyzed to give methyl 2-benzamido-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside which was acetylated immediately after work-up, to give the acetate (**20**). The ^1H nmr spectrum was complex due to extensive ^{19}F–^1H coupling; however, the ^{19}F nmr spectrum showed clearly the two expected resonances and both were first-order. The coupling constants (Table 1) were consistent with the *galacto* configuration.



19 R = CH_2Ph
20 R = Ac

21 R = Ac
22 R = H

Treatment of the *N*-benzoate **20** with acetic anhydride – acetic acid gave methyl 2-acetamido-3-*O*-acetyl-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside (**21**). The ^1H nmr spectrum of the *N*-acetate (**21**) was not amenable to first-order analysis, but the ^{19}F nmr spectrum (Table 2) was readily interpreted. A triplet of doublets was observed for F-6 at 74.80 ppm, $J_{F,6H} = J_{F,6'H} = 45.0$ Hz, $J_{F,5H}$ 13.5 Hz, and a triplet of doublets (with the two middle lines coalescing) corresponding to the F-4 signal, at 60.0 ppm above external C_6F_6; $J_{F,5H}$ 28.1 Hz, $J_{F,4H}$ 54.0 Hz, $J_{F,3H}$ 28.1 Hz. De-*O*-acetylation of **21** with sodium methoxide in methanol gave methyl 2-acetamido-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside (**22**).

The synthesis of fluorinated analogues of 2-amino-2-deoxy-D-glucose from **4** was then investigated by nucleophilic displacements involving double inversion at C-4, as employed in the synthesis of 4-deoxy-4-fluoro-D-glucose (18), 4,4′-dideoxy-4,4′-difluoro-α,α-trehalose and 4,6,4′,6′-tetrafluoro-α,α-trehalose (19) from suitable *gluco*-derivatives. Thus the dimesylate **4** was treated with lithium benzoate in hexamethylphosphoric triamide to give the syrupy 4,6-di-*O*-benzoylgalactopyranoside which, after de-*O*-acylation followed by mesylation, afforded crystalline methyl 2-benzamido-3-*O*-benzyl-2-deoxy-4,6-di-*O*-mesyl-α-D-galactopyranoside (**24**). The ^1H nmr spectrum confirmed the assigned structure (Table 1). The dimesylate existed in the $^4C_1$ conformation with the lowest field ring proton signal (H-4) at τ 4.63; $J_{1,2}$ 3.7 Hz, $J_{2,3}$ 11.4 Hz, $J_{3,4}$ 2.7 Hz, $J_{4,5}$ 0.5 Hz, (Table 1) were indicative of the *galacto* configuration.

Reaction of the 4,6-di-*O*-mesylgalactopyranoside (**24**) with potassium fluoride in boiling ethane-1,2-diol gave a mixture of the 4,6-difluoride (**25**) and the unsaturated 6-fluoride (**28**), separated by silica gel column chromatography in the ratio of 3:2 and in 65% overall yield. The ^{19}F nmr spectrum of **28** showed the expected triplet at 61.15 ppm (above external C_6F_6), $J_{F,6H} = J_{F,6'H} = 48.1$ Hz (Table 2). The 4,6-difluoride (**25**) was obtained in 39% yield, which was de-*O*-benzylated and then

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

acetylated to give methyl 3-*O*-acetyl-2-benzamido-4,6-difluoro-2,4,6-trideoxy-α-D-glucopyranoside (**26**). The *N*-benzoate **26** was then converted to the *N*-acetate **27**. The ^{19}F nmr spectra of **26** and **27** were first-order (Table 1), the coupling constants being indicative of the glucopyranoside in the $^4C_1$ conformation.

In an attempt to improve the proportion of substitution product, attempts were made to fluorinate the 4,6-di-*O*-mesylgalactopyranoside (**24**) with potassium fluoride in ethane-1,2-diol at lower temperatures (100°C) but the reaction failed to proceed. Elimination reactions usually accompany substitution at C-4 of galactopyranosides because of the favourable *trans*–diaxial relationship between the substituent at C-4 and H-3 and H-5, enhanced in this case by the high basicity of the fluoride anion.

Treatment of **24** with tetrabutylammonium fluoride in boiling acetonitrile for 24 h gave three products; ^{19}F nmr spectroscopic examination of the reaction mixture indicated the presence of the unsaturated 6-fluoride (**28**) (F-6, 60.60 ppm, above external C_6F_6), and the 4,6-difluoride **25**, (F-6, 77.70 ppm); the yields of the latter were variable (0–40%). The third product (5%) was separated by column chromatography but it gave no ^{19}F nmr signal.

The synthesis of methyl 2-acetamido-3,6-di-*O*-acetyl-2,4-dideoxy-4-fluoro-α-D-glucopyranoside (**31**) utilized a similar sequence involving double inversion at C-4. Thus, the 4,6-*galacto*-diol (**23**) was selectively and sequentially tritylated and mesylated to give methyl 2-benzamido-3-*O*-benzyl-2-deoxy-4-*O*-mesyl-6-*O*-trityl-α-D-galactopyranoside (**29**). The 4-mesylate **29** was fluorinated using tetrabutylammonium fluoride in acetonitrile for 24 h when tlc examination indicated the presence of one major compound. ^{19}F nuclear magnetic resonance spectroscopy confirmed that inversion of configuration had taken place at C-4 since the signal obtained was that expected for equatorial fluorine (3, 11), namely a double doublet at 34.0 ppm (above external C_6F_6), $J_{F,4}$ 50.8 Hz, $J_{F,3}$ 15.8 Hz, $J_{F,5}$ 2.5 Hz. No fluorination was observed on treatment of **29** with potassium fluoride in boiling ethane-1,2-diol, as evidenced by ^{19}F nmr spectroscopic examination. This result is not surprising, in view of the fact that in a parallel synthesis of 4-deoxy-4-fluoro-D-glucose (18), methyl 4-*O*-mesyl-2,3-di-*O*-methyl-6-*O*-trityl-α-D-galactopyranoside failed to react with caesium fluoride in ethane-1,2-diol, whereas the 4-*O*-mesyl group was displaced in the absence of the trityl ether group. Likewise, removal of the trityl group from **29** gave the 4-mesylate which reacted with potassium fluoride in ethane-1,2-diol to give methyl 2-benzamido-3-*O*-benzyl-2,4-dideoxy-4-fluoro-α-D-glucopyranoside in 25–40% yield.

After removal of the trityl group from the 4-fluoride by methanolysis, followed by hydrogenolysis of the 3-*O*-benzyl group, the resultant 3,6-diol was acetylated to give the crystalline methyl 2-benzamido-3,6-di-*O*-acetyl-2,4-dideoxy-4-fluoro-α-D-glucopyranoside (**30**).

The ^1H nmr spectrum of the 3,6-diacetate **30** (Table 1) was characteristic of a glucopyranoside structure in the $^4C_1$ conformation, with a typical long range coupling (3, 11) between H-1e and F-4e, as observed, for example, in the spectra of 4-deoxy-4-fluoro-D-glucopyranose (18). Methyl 2-acetamido-3,6-di-*O*-acetyl-2,4-dideoxy-4-fluoro-α-D-glucopyranoside (**31**) was then prepared from the *N*-benzoate **30** by treatment with acetic anhydride and acetic acid.

Experimental

Optical rotations are quoted for chloroform solutions at 20°C unless otherwise stated. Light petroleum refers to the fraction boiling at 60–80°C. For general experimental procedures see ref. 6.

Anhydrous Tetrabutylammonium Fluoride (TBAF) (20)

To a stirred solution of hydrogen fluoride (5.8 g) in water (60 mL) was slowly added 40% aqueous tetrabutylammonium hydroxide. The pH of the mixture was then adjusted to approximate neutrality by the addition of either further acid or base and the solution then diluted to ca. 800 mL. Upon storage at 0–5°C the clatherate $(4Bu_4NF \cdot H_2O)_8$ crystallized and was filtered off and washed with ice-cold water. It was then dried *in vacuo* over phosphorus pentoxide over the course of about two weeks with regular changes of desiccant. Yield 53 g (80%).

Methyl 2-Benzamido-3-O-benzyl-4,6-O-benzylidene-2-deoxy-α-D-glucopyranoside (2)

To a vigorously stirred solution of the 4,6-*O*-benzylidene acetal (**1**, 10) (19.3 g, 50 mmol) in dry *N*,*N*-dimethylformamide (100 mL) was added benzyl chloride (55 mL) followed by sodium hydride (2.4 g of 50% oil dispersion, 50 mmol). Further small quantities of sodium hydride (5 × 0.24 g) were added over a period of 2–3 h. Benzylation appeared to be rapid (tlc) and some of the product crystallized out of the reaction mixture. The reaction mixture was stirred overnight at room temperature and decomposed by the addition of ethanol (20 mL) and the resulting solid product filtered off. A further crop of product was obtained by concentration of the filtrate to smaller bulk. The combined crops were extracted with dichloromethane, and inorganic matter removed by filtration (Hyflo Supercel). Addition of diethyl ether to the extract yielded the crude benzyl ether (19.5 g, 82%). Recrystallization from dichloromethane–ethanol gave the 3-*O*-benzyl ether **2**, mp 254–255°C, $[\alpha]_D$ +143.5° (*c* 0.4). *Anal.* calcd. for $C_{28}H_{29}NO_6$ (475): C 70.7, H 6.15, N 2.95; found: C 70.8, H 6.0, N 2.9.

Methyl 2-Benzamido-3-O-benzyl-2-deoxy-α-D-glucopyranoside (3)

A suspension of the 3-*O*-benzyl ether (**2**) (20 g, 421 mmol) in glacial acetic acid – water (400 mL, 3:1 v/v) was heated under reflux for 20–30 min and the resulting clear solution evaporated to dryness. The residue was codistilled with water and toluene at 40–50°C to remove the last traces of acetic acid and dried *in vacuo* over P_2O_5 and sodium hydroxide pellets at 40–50°C. The crude solid so obtained (13 g, 79%) was sufficiently pure for the following stages, but an analytical sample was obtained by recrystallization from methanol – diethyl ether, mp 202.5–204°C, $[\alpha]_D$ +145° (*c* 0.5, methanol). *Anal.* calcd. for $C_{21}H_{25}NO_6$ (387): C 65.1, H 6.5, N 3.6; found: C 64.9, H 6.5, N 3.6.

Methyl 2-Benzamido-3-O-benzyl-2-deoxy-4,6-di-O-mesyl-α-D-glucopyranoside (4)

To an ice-cold solution of the 4,6-diol (**3**) (8 g, 20.7 mmol) in dry pyridine (50 mL) was added dropwise mesyl chloride (2 mL, 25 mmol). The reaction mixture was kept at ca. 5°C overnight and then poured slowly into vigorously stirred ice-water. The resulting solid was filtered off and extracted with dichloromethane. The extract was dried ($MgSO_4$), decolourized (charcoal), filtered (Hyflo Supercel), and evaporated to a small volume. Addition of ether gave the crystalline *dimesylate* (9.5 g, 85%), mp 196–197°C, $[\alpha]_D$ +115.5° (*c* 0.65). *Anal.* calcd. for $C_{23}H_{29}NO_{10}S_2$ (543): C 50.8, H 5.4, N 2.6; found: C 51.1, H 5.6, N 2.9.

Methyl 2-Benzamido-3-O-benzyl-2,6-dideoxy-6-fluoro-4-O-mesyl-α-D-glucopyranoside (5)

To a solution of the dry 4,6-dimesylate (**4**) (6 g, 11 mmol) in dry acetonitrile (30 mL) was added dry tetrabutylammonium fluoride (26 g, 100 mmol) and the mixture heated under reflux for 1 h. Thin-layer chromatography indicated complete conversion of the starting material to a single product. The reaction mixture was then cooled and slowly poured into ice-water. The solid, which separated, was filtered off and extracted with dichloromethane. The extract was washed with water, dried ($MgSO_4$), and evaporated to dryness to give the crude crystalline 6-fluoride (5.2 g, 87%) which was suitable for subsequent reactions. An analytically pure sample of the *6-fluoride* (**5**) was obtained from dichloromethane–ethanol, mp 187.5–189.5°C, $[\alpha]_D$ +136.5° (*c* 0.72). *Anal.* calcd. for $C_{22}H_{26}FNO_7S$ (467): C 56.5, H 5.6, N 3.0; found: C 56.7, H 5.5, N 2.95.

Methyl 2-Benzamido-3-O-benzyl-2,6-dideoxy-6-fluoro-α-D-glucopyranoside (6)

To a solution of the 4-mesylate (**5**) (4.8 g, 10.3 mmol) in dry methanol (50 mL) was added sodium hydroxide (4.4 g) and the mixture heated under reflux for 1 h. After cooling and dilution with water, the mixture was extracted three times with chloroform and the combined extracts then washed with water, dried ($MgSO_4$), and evaporated to dryness. Recrystallization of the solid residue from chloroform – diethyl ether gave the 6-fluoride (3.7 g, 93%), mp 162.5–165°C, $[\alpha]_D$ +105° (*c*, 1). *Anal.* calcd. for $C_{21}H_{24}FNO_5$ (389): C 64.8, H 6.2, N 3.6; found: C 64.5, H 6.15, N 3.5.

Methyl 2-Benzamido-2,6-dideoxy-6-fluoro-α-D-glucopyranoside (7)

A solution of the 3-*O*-benzyl ether (**6**) (0.5 g, 1.29 mmol) in methanol (50 mL) was hydrogenated at room temperature at 50 psi over 5% palladium-on-charcoal (0.1 g) in the presence of concentrated hydrochloric acid (2 mL). The reaction time varied from 1.5–18 h, depending on the particular batch of catalyst used. On completion of the reaction, the mixture was neutralized ($BaCO_3$) and, after removal of most of the inorganic salts, the filtrate was evaporated to dryness with a little silica gel (0.20 g) which was then applied to the top of a short column of silica gel (15 g). Elution with acetone gave the required 3,4-diol, free of inorganic material. Recrystallization from methanol gave **7** (0.3 g, 78%), mp 178.5–180°C, $[\alpha]_D$ +127° (*c* 0.44, methanol). *Anal.* calcd. for $C_{14}H_{18}FNO_5$ (299): C 56.2, H 6.05, N 4.7, F 6.35; found: C 56.1, H 6.0, N 4.6, F 6.6.

Methyl 3,4-Di-O-acetyl-2-benzamido-2,6-dideoxy-6-fluoro-α-D-glucopyranoside (8)

To a solution of **7** (0.25 g, 0.836 mmol) in pyridine (30 mL) was added acetic anhydride (5 mL) and the reaction mixture was allowed to stand at room temperature overnight. The mixture was evaporated to dryness and the residue was dissolved in dichloromethane and washed with saturated sodium bicarbonate, dried ($MgSO_4$), and then evaporated to dryness. The resulting crystalline diacetate (0.3 g, 91%) was sufficiently pure for subsequent reactions, but an analytical sample from ethyl acetate – cyclohexane had mp 120–122.5°C, $[\alpha]_D$ +139.5° (*c* 1.13).

Anal. calcd. for $C_{18}H_{22}FNO_7$ (383): C 56.4, H 5.8, N 3.7; found: C 56.4, H 5.9, N 3.8.

*Methyl 2-Acetamido-3,4-di-*O*-acetyl-2,6-dideoxy-6-fluoro-α-*D*-glucopyranoside (9)*

A solution of the *N*-benzoate (**8**) (1 g, 2.6 mmol) in acetic anhydride – acetic acid (250 mL, 4:1 v/v) was heated under reflux for 24 h. The reaction mixture was then cooled and slowly poured into an ice-cold mixture of dichloromethane and saturated aqueous sodium hydrogen carbonate mixture with vigorous stirring. The dichloromethane layer was separated, washed with water, dried ($MgSO_4$), evaporated to dryness, and the product recrystallized from acetone – light petroleum to give the *N*-*acetate* (0.55 g, 65%), mp 143.5–145.5°C, $[\alpha]_D$ +110° (*c* 1.05). *Anal.* calcd. for $C_{13}H_{20}FNO_7$ (321): C 48.6, H 6.2, N 4.35; found: C 48.8, H 6.2, N 4.3.

*2-Acetamido-1,3,4-tri-*O*-acetyl-2,6-dideoxy-6-fluoro-α,β-*D*-glucopyranose*

The above reaction was repeated but after the reflux the reaction mixture was cooled (5°C), concentrated sulphuric acid (3 mL) was added dropwise, and the mixture stored at room temperature for 24 h. It was then processed as above to give a crystalline mixture of anomeric 1,3,4-triacetates (0.3 g, 33%) which was mainly the α-anomer (nmr), mp 163.5–169.5°C (dichloromethane – diethyl ether – light petroleum); mixture mp with the pure α-anomer (**10**), 156–157°C, $[\alpha]_D$ +118.5° (*c* 0.6).

*2-Acetamido-2,6-dideoxy-6-fluoro-α-*D*-glucopyranose (12)*

A solution of either methyl 2-benzamido-2,6-dideoxy-6-fluoro-α-D-glucopyranoside (**7**) (0.5 g, 1.67 mmol) or its 3,4-diacetate (**8**) (0.64 g, 1.67 mmol) in 2 *M* hydrochloric acid (50 mL) and tetrahydrofuran (5 mL) was heated under reflux for 2.5 h when tlc (8:2 ether–methanol and 5:1:3:1 2-propanol – ethyl acetate – water – concentrated ammonia) showed the presence of one spot which gave a positive reaction with the ninhydrin and *p*-anisidine phthalate spray. The reaction mixture was evaporated to dryness and the residue codistilled twice with absolute ethanol to give the crude crystalline hydrochloride (**11**) (0.29 g, 90%). A solution of the hydrochloride in water–methanol (22 mL, 10:1) was added to Dowex-1(CO_3^{2-}) ion exchange resin (24 mL) and acetic anhydride (0.5 mL). The mixture was then stirred vigorously at 0–5°C for 90 min and filtered. The filtrate and washings were then passed through a column of Amberlite IR-120(H^+) (5 mL) and the eluate evaporated to dryness. Recrystallization from methanol gave the acetamide (0.3 g, 79%), mp 188–190°C (dec.), $[\alpha]_D$ +62.5° (5 min) → +33.2° (18 h) (*c* 0.28, water) (lit. (7) mp 209–210°C (dec.), $[\alpha]_D$ +64° → +33°). *Anal.* calcd. for $C_8H_{14}FNO_5$ (223): C 43.05, H 6.3, N 6.3; found: C 43.25, H 6.7, N 5.9.

*2-Acetamido-1,3,4-tri-*O*-acetyl-2,6-dideoxy-6-fluoro-α-*D*-glucopyranose (10)*

Acetylation in the usual way with acetic anhydride (3 mL) and pyridine (12 mL) of the *N*-acetate (**12**), (0.2 g, 0.9 mmol) gave **10** (0.2 g, 90%), mp 171–173°C after crystallisation from dichloromethane–ether – light petroleum, $[\alpha]_D$ +106.5° (*c* 0.61). *Anal.* calcd. for $C_{14}H_{20}FNO_8$ (349): C 48.1, H 5.7, N 4.0; found: C 48.1, H 5.8, N 4.15.

*Methyl 2-Acetamido-2,6-dideoxy-6-fluoro-α-*D*-glucopyranoside*

A solution of the 3,4-diacetate (**9**) (0.2 g, 0.62 mmol) in dry methanol (25 mL) which contained a catalytic amount of sodium methoxide was stored at room temperature overnight. Neutralization with Amberlite IR-120 (H^+) and evaporation to dryness gave the crystalline 3,4-diol (0.1 g, 67%) which was recrystallized from methanol–ether–cyclohexane, mp 163–165°C, $[\alpha]_D$ +120° (*c* 0.14, methanol). *Anal.* calcd. for $C_9H_{16}FNO_5$ (237): C 45.55, H 6.8, N 5.9; found: C 45.7, H 6.75, N 6.05.

*Methyl 2-Benzamido-4-*O*-benzoyl-3-*O*-benzyl-2,6-dideoxy-6-fluoro-α-*D*-galactopyranoside (13)*

To a suspension of the 4-mesylate (**5**) (4.6 g, 9.85 mmol) in hexamethylphosphoric triamide (10 mL) was added lithium benzoate (8 g) and the reaction mixture was stirred at 140°C for 24 h. After completion of the reaction, the mixture was cooled and slowly poured into vigorously stirred ice-water, and the resulting solid was filtered off. A solution of the solid in dichloromethane was washed once with water, dried ($MgSO_4$), and evaporated to give the 4-benzoate (3.9 g, 80%), mp 128–130°C when crystallized from dichloromethane – light petroleum, $[\alpha]_D$ +202° (*c* 0.68). *Anal.* calcd. for $C_{28}H_{28}FNO_6$ (493): C 68.15, H 5.7, N 2.85; found: C 67.9, H 5.65, N 2.9.

*Methyl 2-Benzamido-3-*O*-benzyl-2,6-dideoxy-6-fluoro-α-*D*-galactopyranoside (14)*

To a solution of the 4-benzoate (**13**) (3.5 g, 7.1 mmol) in anhydrous methanol (60 mL) was added *M* sodium methoxide (50 mL) and the mixture kept at room temperature overnight. The solution was then neutralized (Amberlite IR-120(H^+) resin) and evaporated to give a crystalline residue. The product **14** so obtained (2.5 g, 90%) was sufficiently pure for the next stage, but a small portion was recrystallized from chloroform–ether – light petroleum to give **14** mp 165–169.5°C, $[\alpha]_D$ +122.5° (*c* 0.67). *Anal.* calcd. for $C_{21}H_{24}FNO_5$ (389): C 64.8, H 6.2, N 3.6; found: C 64.9, H 6.2, N 3.5.

*Methyl 3,4-Di-*O*-acetyl-2-benzamido-2,6-dideoxy-6-fluoro-α-*D*-galactopyranoside (16)*

A solution of the 3-*O*-benzyl ether **14** (1.5 g, 3.85 mmol) in methanol (120 mL) was hydrogenated at room temperature at 50 psi over 5% palladium-on-charcoal (0.3 g) in the presence of concentrated hydrochloric acid (2 mL) as before. After completion (tlc) the reaction mixture was neutralized ($PbCO_3$) and evaporated to dryness, to give syrupy methyl 2-benzamido-2,6-dideoxy-6-fluoro-α-D-galactopyranoside (**15**). The diol (**15**) was acetylated immediately with acetic anhydride (5 mL) in pyridine (40 mL) at room temperature in the usual way. After 12 h the reaction mixture was evaporated to dryness and the residue dissolved in dichloromethane and washed successively with dilute hydrochloric acid, water, saturated sodium hydrogen carbonate, and water. The organic layer was dried ($MgSO_4$) and evaporated to dryness. The crystalline 3,4-diacetate (1.2 g, 80%) was sufficiently pure for the next stage, but recrystallization from chloroform–ether – light petroleum gave **16**, mp 141–143°C, $[\alpha]_D$ +111.5° (*c* 0.77). *Anal.* calcd. for $C_{18}H_{22}FNO_7$ (383): C 56.4, H 5.75, N 3.65, F 4.95; found: C 56.1, H 5.75, N 3.7, F 4.7.

*Methyl 2-Acetamido-3,4-di-*O*-acetyl-2,6-dideoxy-6-fluoro-α-*D*-galactopyranoside (17)*

A solution of the *N*-benzoate (**16**) (0.5 g, 1.3 mmol) in acetic anhydride – acetic acid (25 mL, 4:1 v/v) was heated under reflux for 24 h when tlc indicated the presence of one product. The reaction mixture was poured slowly into an ice-cold mixture of dichloromethane and aqueous sodium hydrogen carbonate with vigorous stirring. The organic layer was separated, washed with water, dried ($MgSO_4$), and evaporated to dryness, to give the syrupy *N*-acetate (0.31 g, 74%) which was recrystallized from dichloromethane–ether–cyclohexane, mp 122–126°C (sublim. and dec. from 115°C), $[\alpha]_D$ +105° (*c* 0.73). *Anal.* calcd. for $C_{13}H_{20}FNO_7$ (321): C 48.75, H 6.00, N 4.35; found: C 48.5, H 6.3, N 4.1.

Methyl 2-Acetamido-2,6-dideoxy-6-fluoro-α-D-galactopyranoside (18)

A solution of the diacetate **17** (0.2 g, 0.62 mmol) in dry methanol (25 mL), containing a catalytic amount of sodium

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

methoxide was kept at room temperature overnight, neutralized (Amberlite resin IR-120 (H^+)), and evaporated to dryness to give a crystalline residue. Recrystallization from ethanol–ether gave needles (0.11 g, 73%), mp 201–206°C (sublim. and dec.) with change in crystalline form at ca. 140°C, $[\alpha]_D$ +200° (*c* 0.53). *Anal.* calcd. for $C_9H_{16}FNO_5$ (237): C 45.6, H 6.75, N 5.9; found: C 45.2, H 6.65, N 5.7.

Methyl 2-Benzamido-3-O-benzyl-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside (19)

(*a*) A solution of the 4,6-dimesylate (**4**) (2 g, 3.68 mmol) and tetrabutylammonium fluoride (10 g) in dry acetonitrile (5 mL) was heated under reflux for 4–5 days. The reaction mixture was cooled, poured into ice-water, and the resultant solid filtered off. The solid was extracted with dichloromethane and the organic extract washed with water, dried (sodium sulphate), and decolourized (charcoal). Evaporation of the filtrate gave a semi-solid residue which was recrystallized from chloroform – diethyl ether – light petroleum to give the 4,6-difluoride **19** (1.1 g, 77%), mp 199–201°C, $[\alpha]_D$ +131.5° (*c* 0.40). *Anal.* calcd. for $C_{21}H_{23}F_2NO_4$ (391): C 64.45, H 5.9, N 3.6; found: C 64.15, H 5.85, N 3.7.

(*b*) A solution of the dimesylate **4** (4 g, 7.37 mmol) and dry potassium fluoride (4 g) in dry ethane-1,2-diol (4 mL) was heated under reflux for 25–30 min. The reaction mixture was cooled, poured into water, and the solid material filtered off. A solution of the solid in dichloromethane was washed with water, dried (magnesium sulphate), then decolourized (charcoal), and evaporated to dryness to give a solid (1.8 g, 62%) with identical ^1H nmr and ^{19}F nmr to that obtained above.

Methyl 3-O-Acetyl-2-benzamido-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside (20)

De-*O*-benzylation of the crude 4,6-difluoro-3-*O*-benzyl ether **19** (1.8 g, 4.6 mmol) was carried out in the presence of 5% palladium-on-charcoal in methanol and hydrochloric acid (2 mL) to give methyl 2-benzamido-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside which, without further purification, was acetylated in the usual way (acetic anhydride – pyridine) to give the 3-acetate **20** (1.1 g, 70%), mp 124.5–129°C from chloroform – diethyl ether – light petroleum, $[\alpha]_D$ +120° (*c* 0.62). *Anal.* calcd. for $C_{16}H_{19}F_2NO_5$ (343): C 56.0, H 5.55, N 4.1; found: C 56.05, H 5.8, N 4.2.

Methyl 2-Acetamido-3-O-acetyl-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside (21)

A solution of the *N*-benzoate **20** (0.8 g, 2.33 mmol) in acetic anhydride – acetic acid (200 mL, 4:1 v/v) was heated under reflux for 24 h. The reaction mixture was then cooled and slowly poured with vigorous stirring into an ice-cold mixture of dichloromethane and saturated sodium hydrogen carbonate. The dichloromethane layer was washed with water, dried (magnesium sulphate), and then evaporated to give a crystalline compound. Recrystallization from acetone–dichloromethane – light petroleum gave the *N*-acetate **21** (0.42 g, 64%), mp 203–205.5°C (sublimation and pre-softening at 198°C), $[\alpha]_D$ +142° (*c* 0.5). *Anal.* calcd. for $C_{11}H_{17}F_2NO_5$ (281): C 47.0, H 6.05, N 5.0; found: C 47.15, H 6.1, N 5.05.

Methyl 2-Acetamido-4,6-difluoro-2,4,6-trideoxy-α-D-galactopyranoside (22)

A solution of the 3-acetate **21** (0.3 g, 1.07 mmol) in methanol (30 mL) was treated as previously described with a catalytic amount of sodium methoxide in methanol to give, after neutralization, the title compound **22** (0.27 g, 87%) which was recrystallized from methanol, mp 211–214°C, crystalline change from dense plates to fine needles, 172–185°C, $[\alpha]_D$ +196° (*c* 0.71, methanol). *Anal.* calcd. for $C_9H_{15}F_2NO_4$ (239): C 45.2, H 6.25, N 5.9; found: C 45.05, H 6.3, N 6.0.

Methyl 2-Benzamido-3-O-benzyl-2-deoxy-α-D-galactopyranoside (23)

To a suspension of methyl 2-benzamido-3-*O*-benzyl-2-deoxy-4,6-di-*O*-mesyl-α-D-glucopyranoside **4** (15 g, 27.6 mmol) in hexamethylphosphoric triamide (60 mL) was added lithium benzoate (10 g) and the reaction mixture stirred at 140°C for 24–36 h. After completion of the reaction, the mixture was cooled and slowly poured into vigorously stirred ice-water. The solid so obtained was filtered off, dissolved in dichloromethane and washed with water, dried (magnesium sulphate), and evaporated to dryness to give the syrupy 4,6-dibenzoate (13.5 g, 70%). A solution of the syrup in methanol (150 mL) containing a catalytic amount of sodium methoxide was heated under reflux for 15 min. After cooling the mixture was neutralized with Amberlite IR-120 (H^+), the resin was filtered off and the filtrate was evaporated to dryness and recrystallized from dichloromethane–ethanol to give the 4,6-*galacto*-diol **23** (5.5 g, 52%), mp 167–168.5°C, $[\alpha]_D$ +141° (*c* 1.29, methanol). *Anal.* calcd. for $C_{21}H_{25}NO_6$ (387): C 65.1, H 6.5, N 3.6; found: C 65.2, H 6.55, N 3.8.

Methyl 2-Benzamido-3-O-benzyl-2-deoxy-4,6-di-O-mesyl-α-D-galactopyranoside (24)

The 4,6-dimesylate **24** was prepared as above from the diol **23** (4.7 g) in 90% yield. Recrystallization from dichloromethane–ethanol gave **24**, mp 213–215°C, $[\alpha]_D$ +118° (*c* 0.64). *Anal.* calcd. for $C_{23}H_{29}NO_{10}S_2$ (543): C 50.8, H 5.4, N 2.6, S 11.8; found: C 50.7, H 5.65, N 2.75, S 11.8.

Methyl 2-Benzamido-3-O-benzyl-4,6-difluoro-2,4,6-trideoxy-α-D-glucopyranoside (25) and Methyl 2-Benzamido-3-O-benzyl-6-fluoro-2,4,6-trideoxy-β-L-threo-hex-4-enopyranoside (28)

(*a*) A solution of the 4,6-dimesylate **24** (5 g, 9.2 mmol) and dry potassium fluoride (5 g) in dry ethanediol (4 mL) was heated under reflux for 20–30 min. Thin-layer chromatography (ethyl acetate – cyclohexane, 3:7) indicated two products in the ratio 2:3. The reaction mixture was poured into water; the solid material so obtained was filtered and extracted into dichloromethane. After washing once with water, drying (magnesium sulphate), and decolourizing (charcoal), the organic layer was evaporated to dryness. Silica gel chromatography (ethyl acetate – cyclohexane 1:4) effected separation of the two compounds. The unsaturated 6-fluoride (**28**) was eluted first and was recrystallized from dichloromethane – diethyl ether – light petroleum (0.87 g, 25%), mp 108.5–113.5°C (repeated crystallizations resulted in a wider melting range), $[\alpha]_D$ +154° (*c* 0.53). *Anal.* calcd. for $C_{21}H_{22}FNO_4$ (371): C 67.9, H 5.9, N 3.8; found: C 68.0, H 5.8, N 3.6. The second fraction contained the crystalline 4,6-difluoride (**25**), (1.4 g, 39%), mp 208.5–209.5 (from methanol), $[\alpha]_D$ +122.5° (*c* 0.5). *Anal.* calcd. for $C_{21}H_{23}F_2NO_4$ (391): C 64.4, H 5.9, N 3.6; found: C 64.0, H 5.8, N 3.6.

(*b*) To a solution of the 4,6-dimesylate (**24**) (0.5 g, 0.92 mmol) in dry acetonitrile (5 mL) was added tetrabutylammonium fluoride (2.5 g) and the mixture was heated under reflux. Thin-layer chromatography showed that after 2 h no starting material remained, with the formation of two faster moving compounds. Silica column chromatography (ethyl acetate – cyclohexane, 1:4) gave a fastest moving compound (0.08 g), which contained no fluorine as indicated by ^{19}F nmr ($CDCl_3$) spectroscopy, and a slower moving compound which corresponded to the unsaturated 6-fluoride **28** (0.3 g), which gave a triplet at 60 ppm upfield from external C_6F_6, with $J_{F,6}$ 48 Hz.

Methyl 3-O-Acetyl-2-benzamido-4,6-difluoro-2,4,6-trideoxy-α-D-glucopyranoside (26)

Hydrogenolysis of the 4,6-difluoride **25** (1.2 g, 3.07 mmol) was carried out as described previously to give methyl 2-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/05/12
For personal use only.

benzamido-4,6-difluoro-2,4,6-trideoxy-α-D-glucopyranoside (0.77 g, 83%) which, without further purification, was treated with acetic anhydride (3 mL) in pyridine (12 mL) to give the crystalline 3-acetate **26** (0.72 g, 83%), mp 159–160.5°C (dichloromethane–ethanol), $[\alpha]_D$ +73.5° (*c* 0.95). *Anal.* calcd. for $C_{16}H_{19}F_2NO_5$ (343): C 56.0, H 5.55, N 4.1; found: C 56.2, H 5.5, N 4.2.

Methyl 2-Acetamido-3-O-acetyl-4,6-difluoro-2,4,6-trideoxy-α-D-glucopyranoside (27)

The *N*-benzoate (**26**) (0.6 g, 1.75 mmol) was treated as previously described for **20** and the resultant *N*-acetate **27** (0.4 g, 83%) recrystallized from dichloromethane – light petroleum, mp 179–180°C (plates → needles at 142–152°C), $[\alpha]_D$ +50° (*c* 0.35). *Anal.* calcd. for $C_{11}H_{17}F_2NO_5$ (281): C 47.0, H 6.05, N 5.0; found: C 47.2, H 6.05, N 5.1.

Methyl 2-Benzamido-3-O-benzyl-2-deoxy-4-O-mesyl-6-O-trityl-α-D-galactopyranoside (29)

To a stirred solution of methyl 2-benzamido-3-*O*-benzyl-2-deoxy-α-D-galactopyranoside (**23**) (5.5 g, 14.2 mmol) in pyridine (50 mL) was added trityl chloride (6 g, 19.75 mmol). The reaction mixture was left at room temperature for 2–3 days, when tlc showed complete reaction. It was then cooled to 0°C and mesyl chloride (3 mL) was added dropwise. The reaction mixture was then kept at 0–5°C overnight, then slowly poured into water, and after standing for 1 h the resulting solid was filtered off and dissolved in dichloromethane. The solution was then decolourized by filtration through a Hyflo Supercel charcoal pad. The filtrate was concentrated to dryness and the residue was codistilled with small quantities of toluene, followed by carbon tetrachloride to remove the last traces of pyridine. On evaporation to dryness it gave a solid residue. The material was dissolved in dichloromethane and addition of ethanol effected crystallization (6 g, 60%). The material so obtained was sufficiently pure for subsequent reaction. The crystalline, analytically pure, 4-mesylate **29** was obtained after several recrystallizations from dichloromethane–ethanol, mp 193–196.5°C, $[\alpha]_D$ +72° (*c* 0.045). *Anal.* calcd. for $C_{41}H_{41}NO_8S$ (707): C 69.55, H 5.8, N 2.0; found: C 69.15, H 5.75, N 1.9.

Methyl 3,6-Di-O-acetyl-2-benzamido-2,4-dideoxy-4-fluoro-α-D-glucopyranoside (30)

To a solution of the 4-mesylate **29** (0.5 g, 0.71 mmol) in dry acetonitrile (10 mL) was added tetrabutylammonium fluoride (2.5 g) and the reaction mixture refluxed for 18 h when tlc indicated the formation of one major product. The reaction mixture was cooled and poured into ice-water and the solid so obtained was filtered and dissolved in dichloromethane. The solution was washed once with water, dried (sodium sulphate), and evaporated to dryness to give the 4-fluoride (0.3 g, 67%). The ^{19}F nmr spectrum (CD_3COCD_3/CH_2Cl_2) gave the characteristic low field quartet at 37 ppm above external C_6F_6; $J_{F,4}$ 50.8 Hz, $J_{F,3}$ 15.8 Hz, $J_{F,5}$ 2.5 Hz. The 4-fluoride (0.2 g) was then dissolved in methanol–chloroform (30 mL, 1:1 v/v), concentrated hydrochloric acid (0.2 mL) was added, and the solution stirred at room temperature for 3 h. Thin-layer chromatography indicated complete cleavage of the trityl group. The mixture was neutralized (lead carbonate), filtered, and the filtrate and washings (together with silica gel (0.5 g)) were evaporated to dryness. This material was loaded on a silica gel column (25 g). Elution with toluene removed the triphenylmethanol completely, and elution with toluene–acetone (1:4) gave methyl 2-benzamido-3-*O*-benzyl-2,4-dideoxy-4-fluoro-α-D-glucopyranoside (0.17 g, 94%). The material so obtained was suspended in methanol (50 mL) containing 5% Pd/C and concentrated hydrochloric acid (2 mL). The suspension was hydrogenated at room temperature at 50 psi. The mixture was neutralized (lead carbonate) and the catalyst and inorganic salts were filtered off. The filtrate and washings were evaporated to dryness and the solid so obtained, methyl 2-benzamido-2,4-dideoxy-4-fluoro-α-D-glucopyranoside (0.11 g, 85%), was dissolved in pyridine (30 mL). Acetic anhydride (8 mL) was added and the reaction mixture kept at room temperature overnight. Evaporation of the reagent and solvent was followed by dissolution of the residue in dichloromethane. The dichloromethane layer was washed with dilute hydrochloric acid, water, saturated sodium hydrogen carbonate, and water. It was then dried (magnesium sulphate), filtered (Hyflo Supercel), and concentrated to dryness. The crystalline 3,6-diacetate (**30**) (0.12 g, 85%) was obtained from dichloromethane – diethyl ether – light petroleum, mp 148.5–150.5°C, $[\alpha]_D$ +88 ± 10° (*c* 0.01). Mass spectrum *m/e*: 383 (M^+); 340 ($M^+ - CH_3CO$); 323 ($M^+ - HOAc$); 310 ($M^+ - OCH_3 - CH_2CO$). *Anal.* calcd. for $C_{18}H_{22}FNO_7$ (383): C 56.4, H 5.75, N 3.65; found: C 57.3, H 6.25, N 3.7.

Methyl 2-Acetamido-3,6-di-O-acetyl-2,4-dideoxy-4-fluoro-α-D-glucopyranoside (31)

The *N*-benzoate **30** (0.09 g, 0.24 mmol) was treated with a boiling mixture of acetic anhydride – acetic acid, as previously described, to give the *N*-acetate **31** (0.05 g, 69%), which was recrystallized from chloroform – light petroleum, mp 116–118°C, $[\alpha]_D$ +57.2 ± 10° (*c* 0.028). Mass spectrum *m/e*: 321 (M^+), 290 ($M^+ - OCH_3$), 278 ($M^+ - HOAc$), 261 ($M^+ - OCH_3 - CH_2CO$). *Anal.* calcd. for $C_{13}H_{20}FNO_7$ (321): C 48.60, H 6.25, N 4.35; found: C 49.7, H 6.4, N 4.5.

Acknowledgments

This paper is dedicated to Prof. Raymond U. Lemieux, on the occasion of his 60th birthday

SAUL WOLFE, RAYMOND JOHN BOWERS, SYED KHAQAN HASAN, and PETER MICHAEL KAZMAIER. Can. J. Chem. **59**, 406 (1981).

The title compounds, having the *R*-absolute configurations at sulfur, and labelled with ^{14}C at carbons 5, 6, and 7 of the seven-membered ring, have been synthesized by condensation of isotopically labelled 3D-benzhydryloxycarbonyl-6L-amino-2,2-dimethyl-5-oxoperhydro-1,4-thiazepine with *N*-Boc- and α-benzhydryl-protected L-α-aminoadipic acid and glycyl-L-α-aminoadipic acid, followed by oxidation with *m*-chloroperoxybenzoic acid and complete deprotection with formic acid. The conformations of the sulfoxides, and related thiazepines and thiazepine sulfoxides, have been examined by ^{1}Hmr spectroscopy. All thiazepines, and the two title sulfoxides, appear to exist in a twist boat conformation. Most other sulfoxides exist in a chair conformation, which is stabilized by an internal hydrogen bond between the sulfinyl oxygen and the amide proton at C6; when this hydrogen bond is not present, both chair and twist boat conformations may be observable. The title compounds are of interest as possible intermediates in penicillin biosynthesis from glycyl-δ-(L-α-aminoadipyl)-L-cysteinyl-D-valine (GACV) or ACV, according to a new theory, which deals, in particular, with the stereochemical course of the biosynthesis at the beta (β) carbon atom of valine.

SAUL WOLFE, RAYMOND JOHN BOWERS, SYED KHAQAN HASAN et PETER MICHAEL KAZMAIER. Can. J. Chem. **59**, 406 (1981).

On a synthétisé les composés mentionné dans le titre, ayant des configurations absolues *R* au niveau du soufre et marqués au carbone-14 en positions 5, 6 et 7 du cycle à 7, en condensant le produit marqué benzhydryloxycarbonyl-3D amino-6L diméthyl-2,2 oxo-5 perhydrothiazépine-1,4 sur les acides L-α-aminoadipique et glycyl-L-α-aminoadipique portant des groupes protecteurs *N*-Boc et α-benzhydryle. Cette étape est suivie d'une oxydation par l'acide *m*-chloroperoxybenzoique puis d'une déprotection complète par l'acide formique. On a étudié, par la spectroscopie de rmn du ^{1}H les conformations des sulfoxydes, des thiazépines apparentées et des sulfoxydes de diazépines. Toutes les thiazépines et les deux sulfoxydes mentionnés dans le titre semblent exister selon une conformation bateau-croisé. La plupart des autres sulfoxydes ont une conformation chaise qui est stabilisée par une liaison hydrogène intramoléculaire entre l'oxygène du sulfinyle et le proton de l'amide en position C-6. En l'absence de cette liaison hydrogène, on peut observer les deux conformations chaise et bateau-croisé. Les composés mentionnés dans le titre sont intéressants en tant qu'intermédiaires éventuels dans la biosynthèse de la pénicilline à partir de la glycyl-δ-(L-α-aminoadipyl)-L-cystéinyl)-D-valine (GACV) ou ACV selon une nouvelle théorie, qui traite, en particulier de l'aspect stéréochimique de la biosynthèse au niveau du carbone beta (β) de la valine.

[Traduit par le journal]

Introduction

The biosynthesis of Isopenicillin N (**1**) proceeds via the tripeptide δ-(L-α-aminoadipyl)-L-cysteinyl-D-valine (**2**) (ACV). This conversion has been established using cell-free extracts of the eukaryotic organisms *Penicillium chrysogenum* and *Cephalosporium acremonium* (1, 2), and also the prokaryotic organism *Streptomyces clavuligerus*.[1] A tetrapeptide containing glycine in addition to the elements of ACV has been isolated from the mycelium of *C. acremonium* (3) and also from *Paecilomyces persicinus P-10* (4) and found, in the latter case, to have the constitution Gly-Aad-Cys-Val (**3**) (GACV). The role of this tetrapeptide is not known.

The oxidative cyclization of **2** to **1** occurs with loss of only two carbon-bound hydrogens, viz., the β hydrogen of the valinyl moiety (5),[2] and the pro-*S* hydrogen of the cysteinyl moiety (6). Loss of these hydrogens accompanies the formation of the C2—S and C5—N bonds of the penicillin nucleus, and both of these bonds are formed with retention of configuration at carbon (7).

Although little is known concerning the nature of the species which lie between ACV (or GACV) and penicillin (2, 8), thiazepines have often been considered as possible penicillin precursors (9). The early work of Arnstein and Crawhall (*9a*), which established that L-valine is incorporated into penicillin with loss of the α hydrogen, led to the proposal that a cysteinyl-α,β-dehydrovalinyl peptide **4** is cyclized, initially to the 3D,6L-thiazepine **5**, and then to penicillin. This pathway was tested some years ago (*9b,c*), with negative results.

It was recognized only later that examination of the post-peptide stages of penicillin biosynthesis requires a cell-free system, and that the presence of an L-α-aminoadipyl side chain may be essential. It has also become clear that a thiazepine intermediate cannot arise via a dehydropeptide precursor, since the L- to D-isomerization of valine occurs

during the incorporation of this amino acid into ACV, and the α hydrogen of this amino acid is then retained during the late stages of the biosynthesis (2, 10).

The present work was founded on the following considerations. First, syntheses of the thiazepines **5***a* and **5***b* have not yet appeared in the literature. Secondly, oxidative cyclization of **5** to penicillin can be envisaged to occur via an intramolecular Pummerer reaction (11) of the derived sulfoxides **6**. As discussed elsewhere (12), such a process can account for the stereochemical course of penicillin biosynthesis at the β carbon of the cysteinyl moiety. Thirdly, a pathway to sulfoxides **6** exists that does not involve oxidation of a thiazepine precursor or loss of the α hydrogen of the valinyl moiety. This is the rearrangement of a sulfenate to a sulfoxide (**7** → **8**), which takes place with retention of configuration at carbon (13, 14). The required sulfenate in the present case is **9**, which could arise from the known β-hydroxyvaline-containing peptides **10** (3, 4) or their derived disulfides **11** (15). Since oxygenation at the β carbon of the valinyl moiety is expected to proceed with retention of configuration (16), a sequence **10** → **11** → **9** → **6** can account for the stereochemical course of penicillin biosynthesis at the β carbon of the valinyl moiety, and for the retention of the α hydrogen of this amino acid. It should be noted that the thermal sulfenate → sulfoxide rearrangement is slow in nonpolar media, although there is some evidence (13) of rate enhancement in polar solvents; the reaction is not known to occur in aqueous solution.

On the basis of these considerations, we have become interested in the syntheses of the thiazepines **5***a* and **5***b*, and the thiazepine sulfoxides **6***a* and **6***b*. These syntheses form part of a more general interest in the substrate specificities

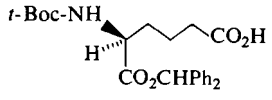
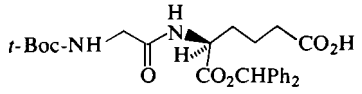
of cell-free systems derived from both eukaryotic and prokaryotic organisms. A synthesis of ACV, necessary for a demonstration of the efficacy of the systems to be employed, has already been published (17). The synthesis of GACV has also been achieved, and will be reported separately.[3]

Synthetic Studies

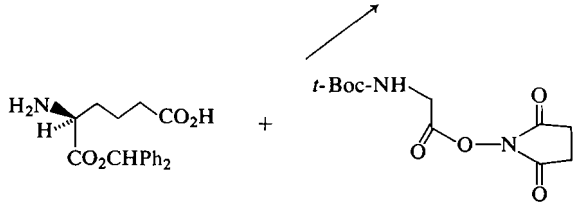
The syntheses were based on the successful strategy devised for ACV (17), which employed benzhydryl ester protection for carboxyl groups and *tert*-butoxycarbonyl (Boc) protection for amino groups. The syntheses of **5***a* and **6***a* therefore required the aminoadipic acid derivative **12**, already described (17). The syntheses of **5***b* and **6***b* required the glycylaminoadipic acid derivative **13**, which was prepared without difficulty from the α-benzhydryl ester **14** (17), by coupling with the *N*-hydroxysuccinimide ester of Boc-glycine (**15**). An alternative route to **5***b* was also worked out, as described below.



12

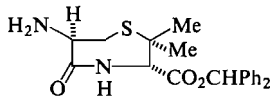


13

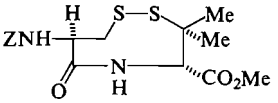


14 **15**

The syntheses also required the carboxyl-protected thiazepine **16**. Several routes to this compound were examined. Initially, it was considered that a stereospecific route might be feasible, by aminophosphine-promoted extrusion of a sulfur atom from the cyclic disulfide **17** (18). As summarized in Scheme 1, carbobenzoxy-*S*-trityl-L-cysteine (**18**) was condensed with the methyl ester of D-penicillamine, using *N*-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) (21). The resulting peptide (**19**), obtained in quantitative yield, was converted to the crystalline disulfide **17** in 65–70% yield upon exposure to a solution of iodine



16



17 Z = $PhCH_2OCO$—

in methanol at low temperature. Treatment of the disulfide with aminophosphines did not afford the desired thiazepine **20** under a variety of reaction conditions.[4]

Eventually it was found that **20** was formed in approximately 10% yield upon reaction of **17** with sodium cyanide in dimethylformamide (22), but the compound could not be isolated in pure form. This route was, therefore, abandoned.

The nonstereospecific synthesis of Leonard and Ning (23) was examined next. As shown in Scheme 2, methyl carbobenzoxyaminoacrylate (**21**) was allowed to react under a hydrogen atmosphere for six days with D-penicillamine in absolute methanol containing triethylamine. Trituration of the crude product with chloroform gave the crystalline 3D,-6L-thiazepine **22** in 18–22% yield. The 3D,6D-epimer of this compound could be crystallized from the chloroform filtrates in ca. 15% yield.

The dehydroalanine derivative **21** was prepared in two ways. The more efficient procedure, which was employed for the synthesis of unlabelled thiazepines, involved treatment of the methyl ester of carbobenzoxycysteine (**23**) with silver carbonate (24) or with Fetizon's reagent (25). This sequence afforded **21** in 77% overall yield from L-cystine. Alternatively, alanine was converted to the carbobenzoxy methyl ester **24**; successive treatment with freshly prepared *tert*-butyl hypochlorite and 1,5-diazabicyclo[5.4.0]undec-5-ene (DBU) produced a 1:1 mixture of **21** and **24** (26). The recovery of **24** from this two-step procedure is unexplained, since it could be demonstrated that the *N*-chloro compound **25** is formed in the first step in quantitative yield. The 1:1 mixture of **21** and **24** did not require purification. Reaction with D-penicillamine, as described above, led to crystalline thiazepine **22** and recovered crystalline **24**, which could be recycled. This latter sequence, beginning with L-[^{14}C(U)]-alanine, was used to prepare **22**, ^{14}C-labelled at C5, C6, and C7.

The conversion of **22** to the benzhydryl ester salt **26** is summarized in Scheme 3. Treatment with a solution of hydrogen bromide in glacial acetic acid gave the salt **27** in 91% yield (23), which could be neutralized with pyridine (23) to the amino acid **28** and then converted to **26** as a foam, following successive reactions with *p*-toluenesulfonic acid (*p*-

TsOH) and diphenyldiazomethane (DDM) (26). The overall yield of **26** from **27** in this manner was 53%. Alternatively, **27** was converted to the ammonium salt **29**, by successive treatment with Amberlite 120/H^+ and *N* ammonium hydroxide. Successive treatment with DDM, *followed* by *p*-TsOH, afforded *crystalline* **26**, in 74% overall yield from **27**.

Neutralization of **26**, and coupling with **12** and **13** using EEDQ, led to crystalline **30** (84%) and to **31** (78%) as a foam, respectively. The Boc-protected aminoadipylthiazepine **30** could also be converted to **31**, in an overall 50% yield, by selective removal of Boc (*p*-TsOH, Et_2O, CH_2Cl_2, reflux, 12 h (27)), followed by neutralization and condensation with **15**. Complete deprotection of **30** and **31** was achieved initially using a mixture of trifluoroacetic acid and anisole, as described previously (17). Subsequently, overnight treatment with formic acid was found to be equally effective.[5]

The oxidation of the thiazepines was examined at several stages in the sequence, and using a variety of reagents. These studies indicated that the introduction of the sulfoxide moiety was best accomplished following protection of the amino and

As a preliminary to the deprotection of the sulfoxides, optically active benzyl methyl sulfoxide and benzyl *o*-carboxyphenyl sulfoxide were exposed to a mixture of trifluoroacetic acid and anisole. This treatment led to rapid racemization at sulfur (28). Use of these conditions for the removal of Boc and benzhydryl protecting groups from the sulfoxides **32***d* and **32***e* was, therefore, considered to be inappropriate. A single experiment with **32***a* confirmed this conclusion; at −20°C the sulfoxide was converted to a complex mixture within 5 min. Deprotection via overnight treatment with 98–100% formic acid[5] was then found to be completely satisfactory and application of these conditions to **32***d* and **32***e* led to the fully deprotected thiazepine sulfoxides **32***f* (≡ **6***a*) and **32***g* (≡ **6***b*), respectively.

^{1}H Nuclear Magnetic Resonance Data and Conformational Analysis of the Thiazepines and Thiazepine Sulfoxides

Table 1 summarizes salient features of the ^{1}Hmr spectra of thirteen 3D,6L-thiazepines **33***a*–*m* and four 3D,6D-thiazepines **33***n*–*q* prepared during the present work. The following points can be made: (*i*) the vicinal H3–C3–N4–H4 coupling constants are in the range 7–8 Hz, suggesting that H3 and H4 have dihedral angles in the range 0–20° (*syn*) or 130–150° (*anti*) (29). In each case the seven-membered ring may adopt a chair or a twist-boat conformation (30), so that four conformations may, in principle, be considered, viz., the *syn*-chair (**A**), the *syn*-boat (**B**), the *anti*-chair (**C**) and the *anti*-boat (**D**); (*ii*) the chemical shift of H6 does not change significantly in the 3D,6L-isomers upon the introduction of benzhydryl or *p*-nitrobenzyl ester substituents on the C3-carboxyl group. This suggests that H6 does not lie in the shielding region of the carboxyl group, and that conformations **C** and/or **D** are preferred; (*iii*) in the 3D,6L-epimers, the two H6–H7 coupling constants range from 2.5–6.2 and 8.0–11.5 Hz; in the 3D,6D-epimers, these coupling constants are nearly equal, ca. 6 Hz. The vicinal coupling constants of the 3D,6L-epimers are close to the values expected (29) for 60° and 180° dihedral angles. In the cyclic disulfide L-cysteinyl-L-cysteine (**34**), whose crystal struc-

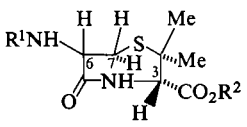
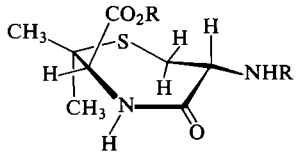
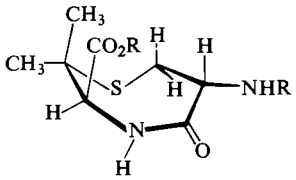
ture (**35**) is known (31), the dihedral angles with H6 are 71° and 196°, respectively, for the pro-*S* and pro-*R* hydrogens of the *N*-terminus, and the observed coupling constants are 3.5 and 12.1 Hz, respectively (32).



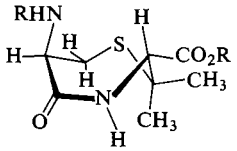
33



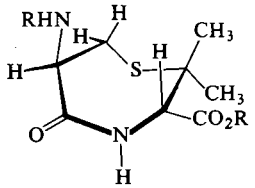
Chair **A**



Boat **B**

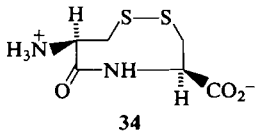


Chair C

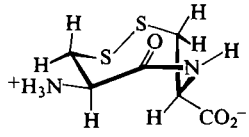


Boat **D**

In the chair conformation **C**, the estimated dihedral angles with H6 are ca. 20° (for the pro-*R* hydrogen) and ca. 100° (for the pro-*S* hydrogen). On the other hand, dihedral angles of ca. 60° and 180°



34



35

can be achieved in the flexible boat conformation **D**. It can be concluded, tentatively, that the 3D,6L-thiazepines exist in conformation **D**. As will be seen, most of the 1*R*,3D,6L-thiazepine sulfoxides adopt conformation **C**. An analogous conformational change has been observed during the transformation of penicillins to penicillin-*S*-sulfoxides (33). It must also be pointed out that **C** and **D** were earlier considered by Leonard and Wilson (9) (see also ref. 30) to be the most probable conformations of the 3D,6D-thiazepine **33** having $R^1 = PhCH_2CO$ and $R^2 = CH_3$.

Table 2 summarizes a variety of data concerning the seven thiazepine sulfoxides **32***a–g*. A first point of interest is the dextrorotatory change in $[\alpha]_D$ (+25 to +30°) following oxidation of the thiazepines. Since penicillin esters exhibit a dextrorotatory change in $[\alpha]_D$ of ca. +50 to +60° upon conversion to β-sulfoxides **36**, and a levorotatory change of ca. −150° upon conversion to α-sulfoxides **37** (34), this is a first indication that all sulfoxides prepared in this work have the *R*-configuration at sulfur. It is especially noteworthy that the 6D-isomer **32***d* also has the *R*-configuration at sulfur since, by analogy

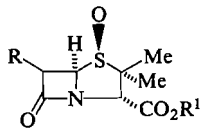
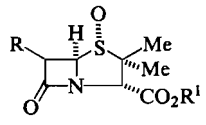
with penicillin chemistry (34), the *S*-configuration might have been expected in this case.

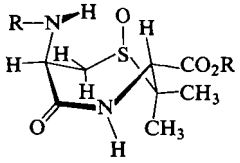
The ^{1}Hmr data confirm these configurational assignments, and indicate that conformation **C** (see **38**) is adopted by sulfoxides **32***a*,*b*,*d*, and *e*. Thus, in these compounds, oxidation results in a large (1.0–1.7 ppm) shift to lower field of the N—H6 proton, indicative of hydrogen bonding of this proton to the sulfoxide oxygen, a ca. 0.9 ppm shift to lower field of H3, indicative of a *syn*-axial effect (35), and only a small downfield shift of H6. In addition, the H6–H7 coupling constants, ca. 7–8 Hz for H6–H7*R* and ca. 1–3 Hz for H6–H7*S*, are consistent with the ca. 20° and 100° dihedral angles estimated earlier for conformation **C**. These various observations are those expected for **38**, in which H3, the β-substituent at C6, and the S—O bond all point in the same direction.



36



37

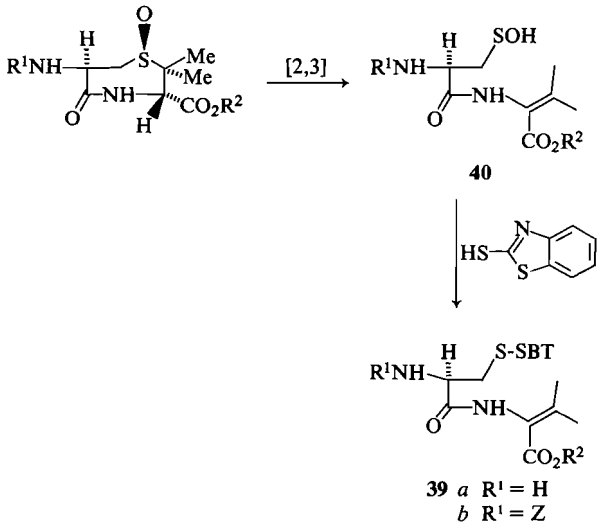


38

In the 6D-isomer **32***c*, both H3 and H6 exhibit shifts to lower field, and the N—H6 proton shows a small *upfield* shift, indicating absence of the internal hydrogen bond. The small downfield shifts of H3 and H6 in this compound, compared to those observed for H3 in **32***a*,*b*,*d*, and *e*, suggest that when this hydrogen bond is not present both conformations **C** and **D** may be significantly populated.

The data for the Aad- and Gly-Aad-sulfoxides indicate that these compounds exist mainly in conformation **D** in aqueous solution. Thus both H3 and H6 show small downfield shifts, consistent with an electrostatic (but not *syn*-axial) effect of the sulfoxide moiety (35), and the H6–H7 coupling constants have values close to those found in the thiazepines.[6]

The chemical properties of the thiazepine sulfoxides provide further support for the configurational assignments. Oxidation of **33***k* afforded a product whose ^{1}Hmr spectrum revealed the presence of a dehydrovaline moiety. Oxidation of **33***j*



39 *a* R^1 = H
b R^1 = Z

[6] An alternative interpretation of these latter observations is that *R*- to *S*-epimerization of the sulfoxides occurs under the formic acid deprotection conditions. However, this could be ruled out on the basis of the optical activity data for the protected and deprotected α-aminoadiphylthiazepine sulfoxides, together with the finding that optically active benzyl 2-carboxyphenyl sulfoxide is configurationally stable in formic acid solvent.

gave a product which appeared to be sulfoxide; however, neutralization again led to decomposition, with appearance of a dehydrovaline moiety in the ^{1}Hmr spectrum. Addition of mercaptobenzothiazole yielded the disulfide **39***a* (15*c*,*d*), characterized further as its carbobenzoxy derivative **39***b*. These observations are consistent with the occurrence of a [2,3] sigmatropic rearrangement of an *R*-sulfoxide to the sulfenic acid **40**. Such a reaction necessarily requires a *syn*-diaxial relationship between H3 and the sulfoxide oxygen, the rearrangement being facilitated by the *syn*-amino group at C6.

Experimental

General

Melting points were determined on a Mel-Temp apparatus, and are uncorrected. Optical rotations were obtained on a Perkin Elmer 141 polarimeter. Infrared spectra were recorded on either Perkin Elmer 180 or Acculab 6 instruments. Proton nmr spectra were recorded on Varian EM360, Bruker HX60, or Nicolet NT-360 spectrometers. Chemical shifts are reported in δ values relative to tetramethylsilane, acetone (δ 2.225 ppm), or 2,2-dimethyl-2-sila-pentane-5-sulfonate as internal standards. Mass spectra were obtained on a Jeol JMS-OISC instrument under electron impact conditions at 76 eV. Chemical ionization mass spectra were obtained on a Dupont 21-491B mass spectrometer by Mr. P. R. Gordon, whom we thank. Radioactive samples were counted in a toluene–cellosolve (2:1) scintillation solution on a Searle Delta 300 Model 6891 liquid scintillation counter. Analytical thin-layer chromatography (tlc) was performed on precoated Merck silica gel 60 F-254 plates, with aluminium or glass backing. Spots were observed under short wave ultraviolet light, or were visualized with iodine vapour, ninhydrin (Boc-derivatives were detected by spraying initially with 3:1 formic acid – concentrated hydrochloric acid, followed by ninhydrin), or with palladium chloride (for sulfur containing compounds). Preparative thin-layer chromatography (plc) was performed on Merck silica gel 60 F-254 precoated 20 × 20 cm plates (layer thickness 2 mm) or, alternatively, glass plates were coated with a slurry of Macherey Nagel silica gel G-HR and calcium sulfate. Lumilux green ZS was used as a fluorescent indicator. Merck 60 mesh silica gel was used for column chromatography. High performance liquid chromatography (hplc) utilized Merck prepacked Lobar columns, a Fluid Metering Inc. model RP-SY pump, and model PD-60-LF pulse dampener. Solvents were distilled before use and were dried, as necessary, by literature procedures. Unless stated, magnesium sulfate was used routinely as a drying agent. Microanalyses were carried out by Galbraith Laboratories, Knoxville, TN.

S-*Trityl-L-cysteine (19)*

L-Cysteine hydrochloride monohydrate (7.0 g, 40 mmol) was dissolved in a mixture of absolute methanol (15 mL) and chloroform (10 mL) and the solution was evaporated to dryness. This process was repeated twice and the resultant amorphous solid was finally treated with chloroform (15 mL) and again evaporated to dryness. The solid was dried overnight under high vacuum. To the anhydrous L-cysteine hydrochloride were added successively trityl alcohol (10.4 g, 40 mmol), freshly distilled acetic acid (40 mL), and boron trifluoride etherate (5.6 mL). The orange mixture was then placed in a preheated oil bath (40°C) and heated with stirring to 100°C over a period of 25 min. During this time most of the trityl alcohol dissolved and, after a further 15 min at 100°C, a clear amber-coloured solution resulted. Heating was discontinued and the solution was allowed to cool to room temperature (45 min), during which time a white precipitate formed. The reaction was quenched by addition of ethanol (60 mL), which discharged the amber colour, and the solid dissolved. Water (40 mL) was added, followed by anhydrous sodium acetate (12 g). The mixture was stirred until all of the solid had dissolved and was then diluted with water (140 mL). The product precipitated as a colourless oil, which rapidly crystallized as a fluffy white solid. This was collected the next day, washed well with water and acetone, and dried, finally under high vacuum to give a white amorphous solid, 13.06 g (90%) mp 150–155°C (lit. (19) mp 181–182°C), which was used without purification for the next step.

N-*Benzyloxycarbonyl*-S-*trityl-L-cysteine (18)*

A vigorously stirred solution of *S*-trityl-L-cysteine (7.2 g, 20 mmol), in 1 *N* sodium hydroxide (20 mL) and freshly distilled dioxane (20 mL), was cooled to 0°C in an ice-salt bath, and two drops of phenolphthalein indicator were added. Benzyl chloroformate (4.0 mL, 4.8 g, 28 mmol) and 1 *N* sodium hydroxide (30 mL) were then added dropwise from separate syringes, at such a rate that the solution remained slightly alkaline. Towards the end of the addition a white solid precipitated which masked the colour of the indicator, but the addition of the reagents was maintained at approximately the same rate. The addition was complete within 10 min and, after stirring for an additional 15 min at room temperature, the mixture was diluted with water (50 mL). The solid did not dissolve, and dioxane (10 mL) was added. To the resulting solution (pH 7.5) was added 2 *N* hydrochloric acid (10 mL), whereupon the product precipitated as a finely divided oil. The dioxane was evaporated rapidly under reduced pressure, and the residual white gum was extracted into ethyl acetate (4 × 50 mL). The organic extract was washed with dilute brine (2 × 50 mL), followed by saturated brine (30 mL), and was then dried and evaporated to leave a light, golden syrup. This was dissolved in methylene chloride (50 mL) and the solvent was reevaporated. Upon removal of the last traces of solvent, under high vacuum, the product became a white foam (10.57 g). The crude product was dissolved in ether (70 mL) and treated with dicyclohexylamine (4.0 mL, 20 mmol). A gelatinous precipitate formed rapidly, and the mixture soon became solid. Additional ether (50 mL) was added, and the mixture was left for 3 h at 5°C with occasional scratching. The crystals were collected, washed with cold ether, and dried under vacuum to give a white, microcrystalline solid, 11.90 g (88%). A portion of this solid was recrystallized twice from ethanol to give fine colourless needles mp 189–190°C (lit. (36*b*) mp 140–142°C); $[\alpha]_D^{24}$ +18.65 (*c* 2.0, CH_3OH) (lit. (36*b*) $[\alpha]_D^{20}$ +1.0 (*c* 2.0, CH_3OH)); ir (Nujol): 3430 (s, NH), 3062 (s, ArH), 2370 (br, m, NH_2^+), 1725 (s, urethane C=O), 1621 (s, CO_2^-), 1566 (s, amide II) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 0.66–2.16 (20H, m, cyclohexyl methylene protons), 2.66 (2H, m, C3 methylene protons), overlapping with 2.88 (2H, m, cyclohexyl methine protons), 4.15 (1H, m, C2 methine), 5.05 (2H, s, $PhCH_2$), 5.72 (1H, d, $J = 7$ Hz, slow exchange with D_2O, urethane N*H*), 6.75–7.8 (20H, m, Ar*H*), overlapping with 7.8–9.0 (2H, br, exchange with D_2O, NH_2^+). *Anal.* calcd. for $C_{42}H_{50}N_2O_4S$: C 74.30, H 7.42, N 4.12, S 4.72; found: C 74.00, H 7.27, N 4.37, S 5.15.

A suspension of the dicyclohexylammonium salt (3.0 g) in ether (75 mL) was shaken with 20% aqueous citric acid (40 mL) until all of the solid had dissolved. The ether layer was then washed with water (4 × 50 mL), followed by saturated brine (25 mL), dried, and evaporated to leave a white foam, 2.22 g (100%) mp 56–65°C (lit. (36*a*) mp 114–115°C); $[\alpha]_D^{24}$ +7.1° (*c* 0.45, CH_3OH) (lit. (36*a*) $[\alpha]_D^{25}$ +17° (*c* 1.41, CH_3OH)); ir ($CHCl_3$): 3700–2300 (br), 2630 (br, CO_2H), 1715 (s, urethane and carboxylic acid (C=O), 1495 (s, amide II) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ:

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

2.67 (2H, br d, C3 methylene), 4.23 (1H, m, C2 methine), 5.05 (2H, s, PhCH_2), 5.22 (1H, br d, J = 8 Hz, NH), 7.05–7.50 (20H, m, ArH), 8.42 (1H, s, CO_2H).

In view of the large difference between the melting point and rotation of the dicyclohexylamine salt observed in the present work and those of ref. 36*b*, the diethylamine salt was also prepared; mp (ethanol) 166–170°C (lit. (36*a*) 169°C); $[\alpha]_D^{26}$ +21.1 (*c* 2.15, CH_3OH) (lit. (36*a*) $[\alpha]_D$ +21.4 (*c* 5, CH_3OH)). It appears that the literature data for the dicyclohexylamine salt are in error.

D-Penicillamine Methyl Ester Hydrochloride

A solution of D-4-carboxy-2,2,5,5-tetramethylthiazolidine hydrochloride (4.45 g, 20 mmol) in water (100 mL) was treated with concentrated hydrochloric acid (1.0 mL) and refluxed for 9 min. The solution was cooled and evaporated to dryness. The crystalline residue was dissolved in methanol (30 mL) and benzene (10 mL), and the solvent was evaporated. This process was repeated once more, the product was suspended in benzene (30 mL), and the solvent was again evaporated to leave white platelets. The resultant anhydrous D-penicillamine hydrochloride was dissolved in anhydrous methanol (70 mL) and the solution was cooled to 0°C in a ice-salt bath, saturated with hydrogen chloride, warmed to room temperature (10 h), and then again recooled to 0°C and resaturated with hydrogen chloride. The mixture was again warmed slowly to room temperature (6 h) and then refluxed for 2.5 h, cooled, and evaporated to dryness. The crystalline residue was dissolved in methanol (40 mL) and the solvent was evaporated. This process was repeated, first with methanol (40 mL), and then with benzene (2 × 40 mL). The residual solid was dried under high vacuum for 1 h and then crystallized from dry *tert*-butanol (100 mL) to give fine, colourless needles, 2.42 g, (60%) mp 188–189.5°C (lit. (37) mp 180–182°C; lit (38) mp 186–188°C); $[\alpha]_D^{23.4}$ −10.82° (*c* 10, H_2O) (lit. (38) $[\alpha]_D$ −7.4° (H_2O)); ir (KBr): 3260–2520 (br, s, NH_3^+), 2480 (m, NH_3^+), 1744, 1734 (s, C=O), 1520, 1500 (s, NH_3^+) cm^{-1}; ^{1}Hmr ($CDCl_3$, trace CF_3CO_2H) δ: 1.50 (3H, s, CH_3), 1.67 (3H, s, CH_3), 2.18 (1H, s, exchange with D_2O, —SH), 3.90 (3H, s, CO_2CH_3), 4.17 (1H, m, collapses to singlet with D_2O exchange, CH), 7.65 (3H, br, exchange with D_2O, NH_3^+).

N-*Benzyloxycarbonyl*-S-*trityl*-L-*cysteinyl*-D-*penicillamine Methyl Ester* (*19*)

A solution of *N*-benzyloxycarbonyl-*S*-trityl-L-cysteine (497 mg, 1.0 mmol), in chloroform (6.0 mL), was stirred at room temperature and treated with EEDQ (247.3 mg, 1.0 mmol). After 5 min, D-penicillamine methyl ester hydrochloride (200 mg, 1.0 mmol) was added in one portion, followed by triethylamine (0.15 mL, 1.1 mmol). The resulting solution was stirred at room temperature for 24 h, and then diluted with chloroform (15 mL) and washed successively with 20% aqueous citric acid (3 × 10 mL), saturated sodium bicarbonate (2 × 10 mL), and saturated brine (10 mL). The organic layer was dried and evaporated to give a pale golden syrup, which, upon removal of the last traces of solvent under high vacuum, gave a white foam, 611.9 mg (100% yield); $[\alpha]_D^{25.6}$ +9.38° (*c* 4.0, CH_3OH); ir ($CDCl_3$): 3415 (m, NH), 3090, 3065 (w, ArH), 1736, 1718, 1686 (s, ester, urethane, amide C=O), 1595 (w, C=C), 1495 (s, amide II) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.29 (3H, s, CH_3), 1.45 (3H, s, CH_3), 1.95 (1H, s, exchange with D_2O, SH), 2.70 (2H, d, J = 7.5 Hz, cysteinyl CH_2—), 3.68 (3H, s, —CO_2CH_3), 3.99 (1H, m, cysteinyl —CH—), 4.60 (1H, d, J = 10 Hz, collapses to a singlet on exchange with D_2O/CF_3CO_2H, penicillamine CH—), 5.10 (2H, s, PhCH_2—), 5.28 (1H, d, J = 7.5 Hz, exchange with D_2O/CF_3CO_2H, urethane NH—), 6.90 (1H, d, J = 10 Hz, slow exchange with D_2O/CF_3CO_2H, amide NH), 7.09–7.66 (20H, m, ArH).

L-*Carbobenzoxyamino*-4D-*carbomethoxy*-3,3-*dimethyl*-6-*oxoperhydro*-1,2,5-*dithiazocine* (*17*) (*39*)

A solution of iodine (317 mg, 1.25 mmol) in methanol (14 mL) was stirred at room temperature and a solution of the dipeptide **19** (306 mg, 0.5 mmol) in methanol (8.0 mL) was added dropwise during 1 h. The reaction mixture was stirred for an additional 15 min, and the solution was then cooled to 0°C and the excess iodine destroyed by addition of 5% sodium thiosulfate solution (5.2 mL). The mixture was neutralized with saturated sodium bicarbonate (1.3 mL) and then evaporated to dryness. The residual solid was partitioned between ethyl acetate (25 mL) and water (25 mL). The organic layer was washed with brine (15 mL), dried, and evaporated to leave an amber gum. Trituration with hexane (2 × 10 mL) afforded a creamy white solid, which was collected by filtration and dried under high vacuum. The crude product (170 mg) was purified by plc on two plates (methylene chloride – ethyl acetate, 5:1). One major band (R_f 0.57–0.80) was isolated as a white foam, 113 mg (58% yield). Recrystallization from acetone–hexane gave colourless prisms, mp 123–124.5°C; $[\alpha]_D$ +284° (*c* 1.77, $CHCl_3$); ir (KBr): 3330, 3280 (s, NH), 1738, 1710, 1664 (s, ester, urethane, amide C=O), 1515 (s, amide II) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.48 (6H, s, CH_3), 2.80–3.60 (2H, A and B of ABX, J_{AB} = 14 Hz, J_{AX} = 10.5 Hz, J_{BX} = 5.0 Hz, C8 methylene), 3.75 (3H, s, CO_2CH_3), 4.28–4.83 (1H, m, C7 methine), 4.98 (1H, d, J = 11 Hz, C4 methine), 5.17 (2H, s, PhCH_2), 5.90 (1H, d, J = 8 Hz, urethane NH), 7.38 (1H, br d, J = 11 Hz, ring NH) overlapping with 7.42 (5H, s, Ph); ms (350°C, 76 eV) *m/e* (relative intensity > 20%): 399 (*M* + 1, 100), 334 (32), 91 (50); CIMS (isobutane): 457 (*M* + 57). *Anal.* calcd. for $C_{17}H_{22}N_2O_5S_2$: C 51.24, H 5.57, N 7.03, S 16.09; found: C 51.53, H 5.82, N 7.24, S 16.01.

Higher yields (65–70%) of **17** were obtained by addition of the peptide **19** to the iodine solution at 0°C. After the addition was complete the reaction mixture was warmed to 10°C over 20 min and then recooled, quenched with 5% sodium thiosulfate solution, and worked up as described above. A similar reaction involving addition of the dipeptide to the iodine solution at 10°C gave a 58% yield of **17**. A further reaction, maintained at 0°C throughout, failed to cleave the *S*-trityl group.

Reaction of 17 with Sodium Cyanide (*22*)

A solution of **17** (117 mg, 0.295 mmol) in freshly distilled dimethylformamide (5.0 mL) was stirred at room temperature under dry nitrogen and sodium cyanide (14.7 mg, 0.30 mmol) was added. The solid dissolved slowly to form a yellow solution. After 16 h, the reaction mixture was poured into water (40 mL), and the resultant fine white precipitate was extracted into ethyl acetate (2 × 40 mL). Saturated brine was added during the extraction to minimize emulsion formation. The combined extracts were washed with dilute brine (3 × 50 mL), saturated brine (15 mL), dried, and evaporated to leave a pale yellow solid (90 mg). Purification by plc (methylene chloride – ethyl acetate, 2:1) afforded two major bands, at R_f 0.68 (22.4 mg) and R_f 0.48 (24.4 mg). Analysis of the less polar band by ^{1}Hmr revealed it to be a 1:3 mixture of the cyclic disulfide **17** and the 3D,6D-thiazepine **33***p*. The more polar band contained an approximately 1:1 mixture of a dehydrovalinyl dipeptide and the 3D, 6L-thiazepine **33***g*.

N,N′-*Dibenzyloxycarbonyl*-L-*cystine*

A solution of L-cystine (9.6 g, 40 mmol) in 1 *N* sodium hydroxide (80 mL) was cooled below 5°C, and benzyl chloroformate (20.4 g, 120 mmol) and 1 *N* sodium hydroxide (160 mL) were added separately in portions, with vigorous stirring, at such a rate that the pH remained between 10 and 12. Addition of the reagents required 2 h, and a white precipitate formed as the reaction progressed. The cooling bath was then removed and the mixture was allowed to warm to room temperature, with con-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

tinued stirring. Most of the solid dissolved to give a slightly cloudy solution (pH 9.2), which was transferred to a separatory funnel and washed with ether (2 × 50 mL). The aqueous layer was then quickly added to 4 *N* hydrochloric acid (40 mL) and the resultant gummy precipitate extracted into ethyl acetate (3 × 100 mL). The combined extracts were dried and evaporated to leave a pale amber syrup, which became a white foam (22.65 g) upon removal of the last traces of solvent under high vacuum. The product was dried *in vacuo* for 8 h and then triturated with chloroform (100 mL). The foam dissolved initially, and the product rapidly crystallized out. The mixture was cooled at 5°C overnight and the crystals were then collected. The product was washed well with cold chloroform and dried (21.86 g, mp 102–117°C). A portion was recrystallized from chloroform containing a small amount of ethanol to give microneedles, mp 118–122°C (lit. (40) mp 113–114°C; lit. (41) mp 123°C); ir (Nujol): 3335 (s, NH), 3500–2200 (br, CO_2H), 1715 (s, urethane C=O), 1680 (s, CO_2H), 1530 (s, amide II).

N,N′-*Dibenzyloxycarbonyl-L-cystine Dimethyl Ester*

A solution of *N,N′*-dibenzyloxycarbonyl-L-cystine (508 mg, 1.0 mmol), in ethyl acetate (25 mL), was stirred at 0°C and treated with a slight excess of ethereal diazomethane. After 15 min, the excess diazomethane was destroyed by addition of a few drops of glacial acetic acid, and the mixture was evaporated to dryness. The syrupy residue was dissolved in methylene chloride (25 mL) and washed with saturated sodium bicarbonate (10 mL). The organic layer was dried and evaporated to leave a colourless syrup (531 mg, 99%). The product solidified, on standing, to a white solid, mp 67–72°C (lit. (36*a*) mp 73–75°C); ir (neat): 3330 (s, NH), 1720 (s, br, C=O), 1510 (s, amide II); ^{1}Hmr ($CDCl_3$) δ: 3.14 (4H, d, J = 5 Hz, —S—CH_2—), 3.71 (6H, s, CO_2CH_3), 4.38–4.78 (2H, m, —C*H*—), 5.08 (4H, s, Ph—CH_2—), 5.67 (2H, br d, J = 8 Hz, N*H*), 7.30 (10H, s, Ph).

N-Benzyloxycarbonyl-L-cysteine Methyl Ester (23)

A solution of *N,N′*-dibenzyloxycarbonyl-L-cystine dimethyl ester (10.78 g, 20.1 mmol) was stirred in methanol (150 mL) at 0°C. Ice-cold concentrated hydrochloric acid (13.0 mL) was then added dropwise at such a rate that the temperature remained below 5°C. The solution was then cooled to 0°C and zinc dust (6.0 g) was added in small portions over a 15 min period. When the addition was complete the mixture was stirred for a further 15 min at 0°C and then filtered into ice-cold saturated sodium bicarbonate (100 mL). The resultant mixture was concentrated under reduced pressure at 30°C until all of the methanol had been removed, and the residual slush was partitioned between ethyl acetate (150 mL) and water (200 mL). The aqueous layer was further extracted with ethyl acetate (2 × 100 mL) and the combined organic layers were washed successively with 2.5 *N* hydrochloric acid (2 × 30 mL), water (50 mL), saturated bicarbonate (30 mL), water (30 mL), and saturated brine (30 mL), and evaporated to a colourless syrup (10.53 g, 97%), which solidified on freezing. Infrared (film): 3350 (m, br, NH), 2578 (w, SH), 1735, 1718 (s, C=O), 1516 (s, amide II), 1211 (s, C—O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.42 (1H, t, J = 9 Hz, S*H*, exchange with D_2O), 3.01 (2H, q, J = 9 Hz, 5 Hz, S—CH_2, collapses to doublet J = 5 Hz on shaking with D_2O), 3.79 (3H, s, CO_2CH_3), 4.62 (1H, quintet, J = 5 Hz, 10 Hz, C*H*, collapses to triplet, J = 5 Hz on shaking with CF_3CO_2D/D_2O), 5.13 (2H, s, PhCH_2—), 5.77 (1H, br d, J = 10 Hz, N*H* exchange with CF_3CO_2D/D_2O), 7.38 (5H, s, *Ph*).

N-*Benzyloxycarbonyl Dehydroalanine Methyl Ester (21)*

Using Silver Carbonate (24)

N-Benzyloxycarbonyl-L-cysteine methyl ester (360 mg, 1.34 mmol) was treated with silver carbonate (555 mg, 1.5 equiv.). After a few min the mixture became hot and began to effervesce. The vigorous reaction was quenched by the addition of methanol (25 mL), and the resulting mixture was refluxed, with stirring, for 9 h. During this time the green suspension of silver carbonate became brown and then black. The mixture was cooled, filtered, the black filter cake washed well with ethyl acetate, and the combined filtrates were evaporated to dryness. The residue, which contained a trace of black solid, was dissolved in methylene chloride (20 mL) and filtered. A few crystals of hydroquinone were added to the filtrate and the solvent was then removed *in vacuo*. The unstable product was dried briefly under high vacuum to give a colourless syrup, 299 mg (95% crude yield) which was stored at −15°C (lit. (9*b*) mp 34–35°C); ir (film): 3420, 3360 (m, NH), 1740, 1720 (s, C=O), 1640 (m, C=C), 1525 (s, amide II) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 3.77 (3H, s, CO_2CH_3), 5.10 (2H, s, PhCH_2), 5.72 (1H, d, J = 1 Hz, H_E), 6.19 (1H, d, J = 1 Hz), 7.30 (6H, s, overlapping *Ph*CH$_2$ and N*H*). In a later experiment, which employed absolute methanol as the solvent, the reaction was incomplete after 9 h and, on washing the black filter cake with ethyl acetate, the washings became rich brown in colour. After evaporation of the solvent, the brown residue was extracted with warm hexane. Evaporation of these extracts afforded the dehydroalanine derivative in 68% yield.

Using Fetizon's Reagent (25)

A solution of *N*-carbobenzoxy-L-cysteine methyl ester (10.53 g, 39 mmol) in dry methanol (160 mL) was treated with water (1.0 mL), followed by Fetizon's reagent (23.4 g). The resulting mixture was stirred and heated to reflux at 75–80°C for 8.5 h. After this time, the colour of the reagent had changed from green to black, and an aliquot of the reaction mixture, swirled with ethyl acetate, did not impart any colour to the solvent. The black suspension was filtered and the solids washed with methanol. The combined filtrates were evaporated to leave an amber syrup containing some fine black particles, which were removed by dissolution of the product in methylene chloride (100 mL) and passage of this solution through two short columns (1 in. × 1 in.) of Celite with the aid of additional methylene chloride. A trace of hydroquinone was added to the filtered solution and the solvent was evaporated to leave an amber syrup that was dried briefly under high vacuum (8.50 g, 92%). The ir and nmr spectra of this syrup were identical to those of the material described above.

6L-Carbobenzyloxyamino-3D-carboxy-2,2-dimethyl-5-oxoperhydro-1,4-thiazepine (22) (23)

A solution of *N*-carbobenzoxydehydroalanine methyl ester (7.0 g, 30 mmol) in dry methanol (150 mL) was stirred under hydrogen at room temperature. D-Penicillamine (4.46 g, 30 mmol) was then added, followed by triethylamine (5.0 mL, 3.64 g, 36 mmol). Most of the solid dissolved to give a slightly cloudy solution, which cleared within 1 h. After eight days, the resultant amber solution was evaporated to dryness to leave a light golden foam. The product was dissolved in water (60 mL), layered with ethyl acetate (75 mL), and acidified to pH 2 with 2.5 *N* hydrochloric acid (13 mL). The layers were separated and the aqueous layer was extracted with ethyl acetate (2 × 50 mL). The combined organic layers were washed with saturated brine (25 mL) and dried. Evaporation of the solvent gave an off-white solid, which was triturated with chloroform (50 mL) and allowed to stand at room temperature for 24 h. The 3D,6L-thiazepine **22** was collected by filtration, washed with chloroform, and dried under high vacuum to give a white solid 2.28 g (22%) mp 203–206°C. Recrystallization from *n*-butanol (20 mL) gave a white, microcrystalline solid (1.62 g) mp 211–213°C (lit. (23) mp 222–222.5°C); $[\alpha]_D$ −12.6° (*c* 1.0, 7% $NaHCO_3$) (lit. (23) $[\alpha]_D$ −16° (*c* 1.0, 5% $NaHCO_3$)); ir (KBr): 3410 (m) and 3280 (m) (NH), 3600–2200 (br, OH), 1700 (sh) and 1693 (s) (CO_2H and

urethane C=O), 1615 (s, amide C=O); ^{1}Hmr (D_2O/K_2CO_3) δ: 1.30 (3H, s, CH_3), 1.57 (3H, s, CH_3), 2.88 (2H, br m, C7 methylene protons), 4.33 (1H, s, C3 methine), overlapping with 4.87 (1H, m, C6 methine), 5.16 (2H, s, PhCH_2), 7.44 (5H, s, Ar). Evaporation of the chloroform filtrate gave a pale golden foam (6.51 g) which was dissolved in ethyl acetate (75 mL) and extracted with saturated bicarbonate (3 × 30 mL). The combined aqueous extracts were washed with ethyl acetate (15 mL), layered with ethyl acetate (50 mL), and acidified to pH 2.4 with 2.5 *N* hydrochloric acid. The layers were separated and the aqueous layer was extracted with ethyl acetate (20 mL). The combined organic layers were washed with saturated brine (2 × 10 mL) and dried. Evaporation of the solvent gave a gummy foam which was dissolved in methylene chloride (40 mL) and again evaporated to dryness and dried under high vacuum to leave a pinkish yellow foam (5.21 g). When this was dissolved in benzene (25 mL) and the solution seeded with **22**, a second crop of material (1.0 g) mp 175–195°C (sealed tube) was obtained. The benzene mother liquor was evaporated to dryness and dissolved in ethanol (10 mL). Water was added to this solution until it became cloudy, and the 3D,6D-isomer crystallized slowly as an off-white solid (2.0 g). Recrystallization from *n*-butanol gave a white microcrystalline solid (1.4 g) mp 130–150°C (lit. (23) mp 125–150°C; $[\alpha]_D^{25}$ −10, $[\alpha]_{365}^{25}$ −34.5 (*c* 1.0, saturated $NaHCO_3$) (lit. (23) $[\alpha]_D$ −11° (*c* 1.0, 5% $NaHCO_3$)); ir (Nujol): 3400, 3300 (m, NH), 1725, 1698, 1615 (s, urethane, carboxyl, amide C=O); ^{1}Hmr (D_2O/K_2CO_3) δ: 1.21 (3H, s, CH_3), 1.44 (3H, s, CH_3), 2.71 (2H, br m, C7 methylene protons), 4.13 (1H, s, C3 methine proton), 4.64 (1H, m, C6 methine proton), 4.99 (2H, s, PhCH_2), 7.23 (5H, s, Ar).

6L-Carbobenzoxyamino-3D-carboxy-2,2-dimethyl-5-oxoperhydro-1,4-thiazepine Benzhydryl Ester (33h)

A suspension of **22** (176 mg, 0.5 mmol), in methylene chloride (3.0 mL), was treated during 5 min with a solution of diphenyldiazomethane (97 mg, 0.5 mmol) in methylene chloride (3.0 mL). The resulting pink solution was treated with formic acid (1 drop), the solvent was then evaporated, and the residue was dried under high vacuum, to leave a light yellow foam (269.5 mg). This crystallized upon addition of ether to give 199 mg, (79%) mp 162–163°C, $[\alpha]_D$ −24°, $[\alpha]_{365}$ −115°(*c* 1.0, CH_3OH); ir ($CHCl_3$): 3400 (m, NH), 1714, 1660 (s, amide, ester, urethane C=O), 1488, 1450 (s, amide II) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.38 (6H, s, CH_3), 2.83 (2H, m, C7 methylene protons), 4.27 (1H, d, J = 8 Hz, C3 methine), 4.68 (1H, m, C6 methine), 5.03 (2H, s, PhCH_2), 6.23 (1H, d, J = 5 Hz, urethane NH), 6.78 (1H, d, J = 8 Hz, amide NH), 6.97 (1H, s, benzhydryl methine), 7.33 (5H, s, Ar). *Anal.* calcd. for $C_{29}H_{30}N_2O_5S$: C 67.16, H 5.83, N 5.40; found: C 66.95, 67.20, H 6.00, 5.87, N 5.34, 5.34.

6L-Amino-3D-benzhydryloxycarbonyl-2,2-dimethyl-5-oxoperoxoperhydro-1,4-thiazepine p-*Nitrobenzyl Ester (33i)*

A solution of **22** (176 mg, 0.5 mmol) and *p*-nitrobenzyl bromide (119 mg, 0.55 mmol), in DMF (6.0 mL), was treated with anhydrous potassium carbonate (42 mg, 0.3 mmol) and stirred at room temperature for 21 h. During this period the crystalline potassium carbonate dissolved and was replaced by a fine white precipitate. The reaction mixture was poured into water (50 mL) and the product was extracted with ethyl acetate (2 × 20 mL). The combined organic layers were washed sequentially with water (4 × 25 mL), saturated sodium bicarbonate (20 mL), again with water (25 mL), and then dried. Evaporation of the solvent gave a white solid (249 mg), which was crystallized from acetone as white microneedles (188 mg, 77% yield), mp 191–192°C; $[\alpha]_D$ −26.4°, $[\alpha]_{436}$ −69.0° (*c* 2.0, CH_2Cl_2); ir (KBr): 3300, 3270 (m, NH), 1735, 1710, 1660 (s, ester, urethane, amide C=O), 1514 (s, $ArNO_2$), 1335 (s, $ArNO_2$) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.47 (6H, s, CH_3), 2.90 (2H, m, C7 methylene), 4.27 (1H, d, J = 8 Hz, C3 methine), 4.77 (1H, m, C6 methine), 5.10 (2H, s, ArCH_2), 5.30 (2H, s, ArCH_2), 6.17 (1H, br s, urethane NH), 6.63 (1H, d, J = 8 Hz, amide NH), 7.35 (5H, s, Ph), 7.57 (2H, d, J = 8 Hz, *p*-nitrobenzyl *H2* and *H6*, 8.25 (2H, d, J = 8 Hz, *p*-nitrobenzyl *H3* and *H5*). *Anal.* calcd. for $C_{23}H_{25}N_3O_7S$: C 56.66, H 5.17, N 8.62; found: C 56.54, 56.76, H 5.36, 5.25, N 8.57, 8.52.

6L-Amino-3D-carboxy-2,2-dimethyl-5-oxoperhydro-1,4-thiazepine Hydrobromide Salt (27) (23)

To a solution of 1 *M* hydrogen bromide in anhydrous acetic acid (10 mL) was added **22** (704 mg, 2.0 mmol). After 30 min stirring, most of the solid had dissolved and the mixture was allowed to stand while the product crystallized from solution. After a total of 4 h at room temperature, the product was collected by filtration, washed well with ether, and dried under high vacuum overnight to yield a white microcrystalline solid, 484 mg (81%), mp 229–232°C (dec.) sealed tube (lit. (23) mp 241–243°C (dec.)); $[\alpha]_D$ −65.0°, $[\alpha]_{365}$ −245° (*c* 2.0, CH_3OH); ir (KBr): 3700–2400 (s, br, CO_2H), 3582 (m), 3515 (m, NH_3^+), 1718 (s, CO_2H), 1650 (s, amide I) cm^{-1}; ^{1}Hmr (D_2O) δ: 1.62 (3H, s, CH_3), 1.67 (3H, s, CH_3), 2.82 (1H, q, J_{AB} = 14.9, J_{AX} = 2.5 Hz), 3.29 (1H, q, J_{AB} = 14.9, J_{BX} = 11.5 Hz) (A and B quartets for C7 geminal protons), 4.27 (1H, s, C3 methine), 5.02 (1H, q, J_{AX} = 2.5, J_{BX} = 11.5 Hz, X-quartet for C6 methine).

6L-Amino-3D-benzhydryloxycarbonyl-2,2-dimethyl-5-oxoperhydro-1,4-thiazepine p-*Toluenesulfonic Acid Salt (26)*

A slurry of Amberlite 1R 120 (H) (6 g) in water was added to a small glass column and the resin was washed with 2.5 *N* hydrochloric acid (30 mL) followed by deionized water (2 × 30 mL) until the column was neutral. A solution of **27** (273 mg, 0.91 mmol), in water (3.0 mL), was added to the column. The column was washed with deionized water (60 mL) until the washings were neutral and the thiazepine was then eluted with 1 *N* ammonium hydroxide (200 mL). Evaporation of the eluate gave a white solid, which was dissolved in water (20 mL) and reevaporated. Drying under high vacuum gave a mixture of the free thiazepine and its ammonium salt (194.3 mg) mp > 260°C; ir (KBr): 3320, 3100, 2600 (br, NH_3^+), 3230 (s, br, NH_4^+), 1652 (s, amide I), 1550 (s, br, CO_2^-), 1390 (s, NH_4^+ and CO_2^-); analytical tlc (Silica Gel): R_f 0.43 (2-butanone – acetic acid – water 4:1:1), ninhydrin yellow. The crude thiazepine (194 mg) was stirred for 18 h at 24°C with methylene chloride (3.6 mL), methanol (4.8 mL), and diphenyldiazomethane (345 mg, 1.8 mmol). The resulting red solution was filtered to remove a trace of suspended solid and evaporated to dryness. The residue was treated with acetone (2.5 mL), followed by anhydrous *p*-toluenesulfonic acid (155 mg, 0.9 mmol), to give a clear red solution. Dilution with dry ether (40 mL) precipitated the product as a white solid, which was collected after cooling overnight at 4°C. The product was washed with ether and air dried to give 374 mg (74% from the hydrobromide), mp 172–177°C (sealed tube). Recrystallization from boiling acetonitrile (4.5 mL) gave white microneedles (278 mg), mp 181–183°C (sealed tube) (an analytical sample had mp 187–189°C (sealed tube)); $[\alpha]_D^{24}$ −24.7°, $[\alpha]_{365}^{24}$ −117.3° (*c* 1.5, CH_3OH); ir (KBr): 3670–2400 (br, NH_3^+), 1735 (s, ester C=O), 1667 (s, amide I), 1160 (s, br, SO_3^-) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.26 (6H, s, CH_3), 2.34 (3H, s, ArCH_3), 2.5–3.47 (2H, m, C7 methylene), 3.98 (1H, d, J = 7 Hz, collapses to singlet with D_2O exchange, C3 methine), 4.69 (1H, m, C6 methine), 6.87 (1H, s, ester methine), 6.95 (2H, d, J = 8 Hz, tosyl *H3* and *H5*), 7.20 (5H, s, Ph) overlapping with 7.26 (5H, s, Ph), overlapping with 7.62 (2H, d, J = 8 Hz, tosyl *H2* and *H6*, overlapping with 7.5–8.37 (4H, br s, exchange with D_2O, NH_3^+ and amide NH). *Anal.* calcd. for $C_{28}H_{32}N_2O_6S_2$: C 60.41, H 5.79, N 5.03; found: C 60.19, H 5.98, N 4.92.

3D-Carboxy-6L-carbobenzoxyamino-2,2-dimethyl-5-oxoperhydro-1,4-thiazepine Methyl Ester (33g)

A suspension of **22** (102.4 mg) in ethyl acetate (10 mL) was stirred, cooled to 0°C, and a slight excess of ethereal diazomethane (8 mL) was added in portions. The solid dissolved to form a clear yellow solution, which was allowed to warm to room temperature during 1 h. The excess diazomethane was destroyed by the dropwise addition of acetic acid and the solvent was evaporated to give colourless microneedles, which were dried under high vacuum, mp 142–143.5°C. Recrystallization from chloroform–hexane gave colourless microprisms, mp 144–145°C; ir ($CHCl_3$): 3400 (m, NH) 1725, 1710, 1655 (s, urethane, ester, amide C=O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.42 (6H, s, CH_3), 2.87 (2H, br d, C7 methylene), 3.75 (3H, s, CO_2CH_3), 4.22 (1H, d, J = 7.5 Hz, C3 methine), 4.73 (1H, m, C6 methine), 5.03 (2H, s, PhCH_2), 6.28 (1H, d, J = 5 Hz, urethane NH), 6.93 (1H, d, J = 7.5 Hz, amide NH), 7.27 (5H, s, Ph).

The 6D-epimer **33***p* was prepared analogously to give colourless microprisms from chloroform–hexane, mp 142.5–143°C; ir ($CHCl_3$); 3390, 3370 (m, NH), 1730, 1710, 1670 (s, urethane, ester, amide C=O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.32 (6H, s, CH_3), 2.90 (2H, m, C7 methylene), 3.77 (3H, s, CO_2CH_3), 4.58 (1H, d, J = 7 Hz, C3 methine), overlapping with 4.70 (1H, m, C6 methine), 5.05 (2H, s, PhCH_2), 6.28 (2H, m, overlapping urethane and amide NH), 7.32 (5H, s, Ph).

3D-Benzhydryloxycarbonyl-6L-carbobenzoxyamino-2,2-dimethyl-5-oxoperhydro-1,4-thiazepine-1-oxide (32a)

A solution of **33***h* (259.0 mg, 0.5 mmol) in methylene chloride (10 mL) was stirred at 4°C and an ice-cold solution of 85% *m*-chloroperoxybenzoic acid (102.0 mg, 0.5 mmol), in methylene chloride (10 mL), was added dropwise during 25 min. The resultant solution was stirred at 4°C for an additional 2.5 h and then washed sequentially with 3.5% sodium bicarbonate (10 mL), 2% sodium thiosulfate (10 mL), 3.5% sodium bicarbonate (10 mL), and saturated brine (10 mL). The organic layer was then dried and evaporated to leave a white foam (262 mg, 98%), $[\alpha]_D$ 0.0°, $[\alpha]_{365}$ 0.0° (*c* 1.0, CH_2Cl_2); ir ($CHCl_3$): 3350 (m, NH), 1715, 1670 (s, urethane, ester, amide C=O), 1042 (s, sulfoxide) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.17 (3H, s, CH_3), 1.25 (3H, s, CH_3), 2.93 (1H, q, J = 1.6, 15.1 Hz, *H7S*), 3.18 (1H, q, J = 7.2, 15.1 Hz, *H7R*), 4.67 (1H, m, C6 methine), 5.09 (2H, s, CH_2), 5.22 (1H, d, J = 8 Hz, C3 methine), 6.66 (1H, d, J = 8 Hz, NH), 7.32 (6H, Ar and urethane NH). *Anal.* calcd. for $C_{29}H_{30}N_2O_6S$: C 65.15, H 5.66, N 5.24; found: C 65.29, H 6.01, N 5.12.

Sulfoxide **32***c*: white foam, $[\alpha]_D$ +18°, $[\alpha]_{365}$ +73° (*c* 2.02, CH_2Cl_2); ir ($CHCl_3$): 3400, 3375 (m, NH), 1725, 1670 (s, ester, urethane, amide C=O), 1045 (s, sulfoxide) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.12 (6H, s, CH_3), 2.6–3.5 (2H, m, C7 methylene), 5.02 (2H, s, PhCH_2), overlapping with 5.15 (1H, d, J = 7 Hz, C3 methine) and 5.37 (1H, m, C6 methine), 6.20 (1H, d, J = 8 Hz, urethane NH), 6.57 (1H, d, J = 7 Hz, amide NH), 6.92 (1H, s, benzhydryl methine), 7.27 (15H, s, Ph).

Sulfoxide **32***b*: pale yellow foam, $[\alpha]_D$ −23.0°, $[\alpha]_{436}$ −51° (*c* 2.2, methylene chloride); ir ($CHCl_3$): 3390, 3350 (m, NH), 1725, 1715, 1673 (s, ester, urethane, amide C=O), 1343 (s, $ArNO_2$), 1040 (m, sulfoxide) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.32 (6H, s, CH_3), 2.98 (1H, q, J = 2.2, 15.0 Hz, *H7S*), 3.33 (1H, q, J = 5.9, 15.0 Hz, *H7R*), 4.75 (1H, m, C6 methine), 5.05 (2H, s, ArCH_2), 5.25 (2H, s, ArCH_2), overlapping with 5.22 (1H, d, C3 methine), 6.55 (1H, d, J = 8 Hz, NH), 7.28 (5H, s, Ph), 7.52 (2H, m), overlapping with 7.57 (1H, br, NH), 8.22 (2H, m).

Preparation of N-tert-*Butoxycarbonylglycyl-L-α-aminoadipic Acid α-Benzhydryl Ester (13)*

A suspension of L-α-aminoadipic acid α-benzhydryl ester (596.6 mg, 1.82 mmol), in dry methanol (28 mL) and dimethoxyethane (8 mL), was treated with dicyclohexylamine (0.37 mL, 1.82 mmol) and the mixture was stirred for 5 min to give a slightly cloudy solution. Then the succinimidyl ester **15** (495.5 mg, 1.82 mmol) was added and stirring was continued for 30 min, at which time additional dicyclohexylamine (0.37 mL, 1.82 mmol) was added. The stirring was then continued for 24 h. Removal of the solvent gave a gummy yellow solid which was dissolved in methylene chloride (50 mL) and washed with 10% potassium bisulfate (3 × 25 mL) and saturated brine (25 mL) and dried over sodium sulfate. Evaporation of the solvent gave a sticky yellow foam (823 mg), which was purified on silica gel (50 g), (ethyl acetate – methanol, 10:1) to give a colourless foam (786.3 mg, 90%) $[\alpha]_D^{26}$ −20.8 (*c* 2.0, CH_3OH); ir ($CHCl_3$): 3580–2440 (br, CO_2H), 3410, 3360 (m, NH), 1710, 1680 (s, urethane, ester, carboxylic acid C=O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.40 (9H, s, *t*-Bu), overlapping with 1.17–2.50 (6H, m, α-aminoadipyl methylene), 3.80 (2H, d, J = 5.5 Hz, glycyl methylene), 4.70 (1H, m, α-aminoadipyl methine), 5.53 (1H, br, urethane NH), 6.90 (1H, s, benzhydryl methine), 7.13 (1H, d, J = 8 Hz, amide NH), overlapping with 7.32 (10H, s, Ph), 8.30 (1H, br, CO_2H).

3D-Benzhydryloxycarbonyl-6L-amino-2,2-dimethyl-5-oxoperhydro-1,4-thiazepine (16 ≡ 33k)

A suspension of the thiazepine benzhydryl ester *p*-toluenesulfonic acid salt **26** (270 mg, 0.485 mmol) in ethyl acetate (10 mL) was stirred with saturated sodium bicarbonate (5 mL) until all of the solid had dissolved. The organic layer was washed with sodium bicarbonate (5 mL), dried, and evaporated to leave a colourless syrup. This was dissolved in methylene chloride (15 mL) and the solvent was evaporated to leave a colourless foam, which was dried under high vacuum (178.5 mg, 96%). The product crystallized as colourless needles by slow evaporation from chloroform; mp 137–138.5°C; ir ($CHCl_3$): 3400, 3380 (m, NH, NH_2), 1740 (s, ester C=O), 1665 (s, amide C=O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.27 (3H, s, CH_3), 1.35 (3H, s, CH_3), 1.90 (2H, s, NH_2), 2.62 (1H, q, J_{AB} = 15.5 Hz, J_{BX} = 8.0 Hz), 2.92 (1H, q, J_{AB} = 15.5 Hz, J_{AX} = 4.0 Hz, AB quartet of ABX for C7 methylene), 3.95 (1H, q, J_{AX} = 8.0, J_{BX} = 4.0 Hz, C6 methine), 4.63 (1H, d, J = 7.5 Hz, C3 methine), 6.60 (1H, d, J = 7.5 Hz, amide NH), 6.92 (1H, s, benzhydryl methine), 7.28 (10H, s, Ph).

Fully Protected α-Aminoadipylthiazepine (30)

A solution of **12** (195.7 mg, 0.458 mmol) and EEDQ (116.1 mg, 0.47 mmol) in ethyl acetate (8.0 mL) was stirred for 5 min. To this was added the benzhydryl ester **33***k* (176.0 mg, 0.458 mmol), and the resultant solution was stirred for 72 h. The reaction mixture was then diluted to 25 mL with ethyl acetate and washed with 10% potassium bisulfate (2 × 10 mL), saturated brine (10 mL), dried, and evaporated to leave a syrup, which was dissolved in methylene chloride (15 mL) and again evaporated. Repetition of this process with more methylene chloride (15 mL) afforded an off-white foam (335.8 mg). Purification of a portion (172 mg) by plc, 2 plates, (chloroform – ethyl acetate, 1:1) gave one major band, R_f 0.38–0.60, which yielded a white foam (94 mg). This crystallized upon slow evaporation from ethyl acetate to give white microneedles, mp 193–197°C; $[\alpha]_D$ −41.5°, $[\alpha]_{365}$ −159° (*c* 1.2, CH_3OH); $[\alpha]_D$ −30.0°, $[\alpha]_{365}$ −114° (*c* 1.18, CH_2Cl_2); ir (KBr): 3320 (m, br, NH), 1735, 1700, 1657 (s, ester, urethane, amide C=O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.39 (3H, s, CH_3), 1.43 (9H, s, Boc), 1.46 (3H, s, CH_3), 1.57–1.93 (4H, m, CH_2CH_2), 2.16 (2H, m, CH_2CO), 2.77 (1H, q, J_{BX} = 10.2, J_{AB} = 15.0, *H7R*), 2.84 (1H, q, J_{AX} = 2.8, J_{AB} = 15.0, *H7S*), 4.25 (1H, d, J = 8 Hz, C3 methine), 4.41 (1H, m, Aad methine), 4.78 (1H, m, C6 methine), 5.12 (1H, d, J = 9 Hz, urethane NH), 6.24 (1H, d, J = 8 Hz, N4H), 6.78 (1H, d, J = 5 Hz, NH at C6), 6.88 (1H, s, benzhydryl CH), 6.99 (1H, s, benzhydryl CH), 7.32 (20H, m, Ar). *Anal.* calcd. for $C_{45}H_{51}N_3O_8S$: C 68.07, H 6.48, N 5.29; found: C 68.26, H 6.64, N 5.29.

Fully Protected Glycyl α-Aminoadipylthiazepine (31)

*A. From the Thiazepine 33*k

A solution of **13** (28.5 mg, 0.0588 mmol), in methylene chloride (0.3 mL), was stirred at room temperature with EEDQ (16.8 mg, 0.068 mmol). After 5 min the thiazepine **33***k* (22.6 mg, 0.0588 mmol), in methylene chloride (1 mL), was added. The volume was reduced by passing a stream of dry nitrogen over the surface of the solution, and was then adjusted to 0.5 mL. After 48 h the solvent was evaporated and the residual syrup was dissolved in ethyl acetate (2 mL) and washed with 10% potassium bisulfate (2 × 1 mL), saturated brine (1 mL), and dried over sodium sulfate. Evaporation gave a syrup, which was dissolved in methylene chloride (4 mL) and evaporated. Repetition of this process with more methylene chloride (4 mL) gave a creamy white foam, 47.6 mg. Purification by plc (methylene chloride – methanol, 9:1) gave one major band, R_f 0.48–0.65, as a white foam 39.2 mg (78% yield); $[\alpha]_D$ −23.3°, $[\alpha]_{365}$ −82.7° (*c* 1.74, CH_2Cl_2); ir ($CHCl_3$): 3390 (m, NH), 1725, 1660 (s, urethane, amide, ester C=O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.34 (3H, s, C*H*$_3$), 1.42 (9H, s, Boc), 1.49 (3H, s, C*H*$_3$), 1.52–1.95 (4H, m, C*H*$_2$C*H*$_2$), 2.18 (2H, m, C*H*$_2$CO), 2.78 (1H, q, J_{BX} = 6.2, J_{AB} = 15 Hz, *H7S*), 2.81 (1H, q, J_{AX} = 8.5, J_{BX} = 15 Hz, *H7R*), 3.75 (1H, octet, J_{AB} = 16 Hz, J_{AX} = 5.5, 6.0 Hz, glycyl CH_2), 4.32 (1H, br s, C3 methine), 4.69 (1H, sextet, Aad methine), 4.83 (1H, br s, C6 methine), 5.30 (1H, br s, urethane N*H*), 6.54 (1H, br d, *J* ~ 6 Hz, N4*H*), 6.87 (1H, s, benzhydryl C*H*), 6.98 (1H, s, benzhydryl C*H*), overlapping with 7.01 (1H, br d, *J* ~ 7.5 Hz, N*H*), 7.14 (1H, br s, N*H*), 7.24–7.40 (20H, m, Ar). *Anal.* calcd. for $C_{47}H_{54}N_4O_9S$: C 66.33, H 6.40, N 6.58; found: C 65.88, H 6.42, N 6.44.

B. Via the Fully Protected α-Aminoadipylthiazepine 30

The fully protected thiazepine **30** (81.0 mg, 0.102 mmol) was dissolved in methylene chloride (2 mL), and the solution was evaporated to a golden oil, which dissolved readily in dry ether (6.0 mL). Anhydrous *p*-TsOH (17.6 mg, 0.102 mmol) was added, and the mixture was refluxed for 5 h. A gum precipitated during this time but tlc analysis (ethyl acetate) of the ether soluble material indicated that starting material was still present. Reflux was continued for an additional 5 h and the solvent was then evaporated to leave an amber, gummy solid, which was triturated with ether (5 mL) to give an off-white solid 81.1 mg. Analysis by tlc (ethyl acetate) showed the presence of one major ninhydrin-positive spot, R_f 0.8, a very minor ninhydrin-positive impurity at R_f 0.65, and a trace of starting material, R_f 0.95, which was ninhydrin-negative. The crude salt was dissolved in methylene chloride (2 mL) and stirred with saturated sodium bicarbonate (1 mL). The organic layer was removed and the aqueous layer was extracted with methylene chloride (1 mL). The combined organic layers were dried over sodium sulfate, filtered, and stirred for 20 h at room temperature with **15** (27.2 mg, 0.10 mmol). The reaction mixture was then washed with water (2 × 2 mL), saturated brine (1 mL), and dried over sodium sulfate. Evaporation of the solvent gave an amber syrup, which was partially purified by precipitation from ethyl acetate (0.5 mL) with hexane to give an oil (69.3 mg). Further purification by rapid chromatography on silica gel (5 g) (ethyl acetate – methylene chloride, 1:2 then 1:1) gave a white foam (43.3 mg, 50% from **30**) which was identical by tlc and ^{1}Hmr with the material prepared above.

*Oxidation of the Fully Protected α-Aminoadipylthiazepine 30 to the Sulfoxide 32*d

A solution of the fully protected α-aminoadipyl thiazepine **30** (28.1 mg, 0.0354 mmol), in methylene chloride (0.5 mL), was stirred at 2°C and an ice-cold solution of 85% *m*-chloroperoxybenzoic acid (0.071 *M*, 0.5 mL) was added during 2 h. After stirring an additional 0.5 h at 0°C, the solution was washed with saturated sodium bicarbonate (2 × 1 mL), saturated brine (1 mL), dried, and evaporated to leave a colourless foam (28.2 mg, 98%) $[\alpha]_D$ −12.9, $[\alpha]_{365}$ −48.8 (*c* 4.12, CH_2Cl_2); ir (KBr): 3300 (m, br, NH), 1735, 1700, 1685, 1660 (s, urethane, ester, amide C=O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.20 (3H, s, C*H*$_3$), 1.25 (3H, s, C*H*$_3$), 1.68 (4H, m, C*H*$_2$C*H*$_2$), 2.10 (2H, m, C*H*$_2$CO), 2.94 (1H, q, *J* = 2.8, 15 Hz, *H7S*), 3.38 (1H, q, *J* = 7.0, 15 Hz, *H7R*), 4.38 (1H, m, Aad methine), 4.83 (1H, m, C6 methine), 5.18 (1H, d, *J* = 8 Hz, C3 methine), 5.18 (1H, d, *J* = 10 Hz, urethane N*H*), 6.45 (1H, d, *J* = 8 Hz, ring N*H*), 6.87 (1H, s, benzhydryl methine), 6.98 (1H, s, benzhydryl methine), 7.28 (20H, s, Ar), 8.33 (1H, br d, amide N*H*).

*Oxidation of the Fully Protected Glycyl α-Aminoadipylthiazepine 31 to the Sulfoxide 32*e

A solution of the fully protected glycyl α-aminoadipylthiazepine (34.7 mg, 0.041 mmol), in methylene chloride (0.5 mL), was stirred at 2°C and an ice-cold solution of 85% *m*-chloroperoxybenzoic acid (0.082 *M*, 0.5 mL) was added over 20 min. The solution was stirred at 2°C for an additional 20 min and was then washed with sodium thiosulfate (1 mL), saturated sodium bicarbonate (2 × 1 mL), saturated brine (1 mL), and dried over sodium sulfate. Evaporation of the solvent gave a white foam 32.3 mg, 91% yield $[\alpha]_D$ −6.16, $[\alpha]_{365}$ −61.6 (*c* 3.6, CH_2Cl_2); ir ($CHCl_3$): 3390, 3330 (m, NH), 1730, 1680, 1675 (s, ester, urethane, amide C=O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.20 (3H, s, C*H*$_3$), 1.23 (3H, s, C*H*$_3$), 1.42 (9H, s, *t*-Bu), 1.45–1.96 (4H, m, C*H*$_2$C*H*$_2$), 2.25 (2H, m, C*H*$_2$CO), 2.91 (1H, d, *J* = 15 Hz, *H7S*), 3.30 (1H, q, *J* = 8.7, 15 Hz, *H7R*), 3.78 (2H, br octet, J_{AB} = 17.0, J_{AX} = J_{BX} = 5 Hz, glycyl C*H*$_2$), 4.66 (1H, m, Aad methine), 4.87 (1H, m, C6 methine), 5.35 (1H, br, C3 methine), 6.40 (1H, br, urethane N*H*), 6.84 (1H, d, *J* = 7.5 Hz, ring N*H*), 6.86 (1H, s, benzhydryl methine), 6.98 (1H, s, benzhydryl methine), 7.33 (20 H, m, Ar), 8.28 (1H, br, N*H*). *Anal.* calcd. for $C_{47}H_{54}N_4O_{10}S$: C 65.11, H 6.28, N 6.46; found: C 65.04, H 6.68, N 6.29.

*Deprotection of the Fully Protected α-Aminoadipylthiazepine 30. Preparation of 5*a

A solution of the fully protected α-aminoadipylthiazepine (38.1 mg, 0.048 mmol), in anhydrous formic acid (3.0 mL), was stirred at room temperature for 18 h, and then evaporated to dryness. The residue was partitioned between water (5 mL) and ether (5 mL). The ether layer was extracted with water and the combined aqueous layers were evaporated to leave a glass (20.4 mg). Analytical tlc (silica gel): R_f 0.26 (2-butanone – acetic acid – water, 4:1:1), visible as a salmon-pink spot with ninhydrin, or yellow spot with palladium chloride. Very minor ninhydrin positive impurities were detected at R_f 0.50 and 0.63; $[\alpha]_D^{25}$ −48.8, $[\alpha]_{365}^{25}$ −172.4 (*c* 1.7, H_2O); ^{1}Hmr (D_2O) δ: 1.32 (3H, s, C*H*$_3$), 1.47 (3H, s, C*H*$_3$), 1.80 (4H, br m, C*H*$_2$C*H*$_2$), 2.35 (2H, m, C*H*$_2$CO), 2.78 (1H, q, *J* = 6.1, 15 Hz, *H7S*), 2.94 (1H, q, *J* = 9.0, 15 Hz, *H7R*), 3.82 (1H, br q, Aad methine), 4.30 (1H, s, C3 methine), 4.77 (1H, q, *J* = 6.1, 9.0, C6 methine). *Anal.* calcd. for $C_{14}H_{23}N_3O_6S{\cdot}H_2O$: C 44.32, H 6.64, N 11.07; found: C 43.89, H 6.77, N 11.01.

*Deprotection of the Fully Protected Glycyl-α-aminoadipylthiazepine 31. Preparation of 5*b

A solution of the fully protected glycyl-α-aminoadipylthiazepine (41.4 mg, 0.0486 mmol) in 97% formic acid (4.0 mL) was stirred at room temperature for 14 h. The formic acid was then evaporated and the residual syrup dissolved in methylene chloride (5 mL) and again evaporated. This process was repeated with more methylene chloride (5 mL) to leave a solid residue, which was partitioned between water (5 mL) and ether (2 mL). The aqueous layer was washed with more ether (2 mL) and then evaporated to leave a whitish glass (21.0 mg). Analytical tlc (silica gel): R_f 0.26 (2-butanone – acetic acid – water,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/05/12
For personal use only.

4:1:1), visible as an orange-yellow spot with ninhydrin or yellow spot with palladium chloride; ^{1}Hmr (D_2O) δ: 1.30 (3H, s, CH_3), 1.54 (3H, s, CH_3), 1.76 (4H, br m, CH_2CH_2), 2.36 (2H, m, CH_2CO), 2.85 (1H, q, J = 15.3, 3.3 Hz, C7 proton), 2.96 (1H, q, J = 15.3, 10.4 Hz, C7 proton), 3.88 (2H, s, glycyl CH_2), 4.32 (1H, s, C3 methine), 4.63 (1H, m, Aad methine), 4.77 (1H, m, C6 methine).

Deprotection of the Fully Protected α-Aminoadipylthiazepine Sulfoxide **32**d. *Preparation of* **6**a

A solution of the fully protected α-aminoadipylthiazepine sulfoxide (3.9 mg, 0.0048 mmol) in anhydrous formic acid (0.30 mL) was stirred at room temperature for 19 h. The formic acid was then evaporated and the residual oil partitioned between water (2 mL) and ether (2 mL). The ether layer was extracted with water (2 × 2 mL) and the combined aqueous layers were evaporated to leave a colourless glass (0.8 mg). Analytical tlc (silica gel): R_f 0.12 (2-butanone – acetic acid – water, 4:1:1), visible as an orange spot with ninhydrin or as a grey spot with palladium chloride and heating. Very minor, ninhydrin-positive impurities were present at R_f 0.23 and 0.53; $[\alpha]_D^{27}$ −7.6, $[\alpha]_{365}^{27}$ −28.5 (*c* 1.65, H_2O); ^{1}Hmr (D_2O) δ: 1.32 (2H, m, CH_3), 1.53 (3H, s, CH_3), 1.83 (4H, m, CH_2CH_2), 2.41 (2H, m, $COCH_2$), 3.29 (1H, q, J = 2.4, 13.7 Hz, *H7S*), 3.36 (1H, q, J = 10.2, 13.7 Hz, *H7R*), 3.85 (1H, m, Aad methine), 4.38 (1H, s, *H3*), 5.05 (1H, q, J = 2.4, 10.2 Hz, *H6*).

Deprotection of the Fully Protected Glycyl α-Aminoadipylthiazepine Sulfoxide **32**e. *Preparation of* **6**b

A solution of the fully protected glycyl α-aminoadipylthiazepine sulfoxide (43.2 mg, 0.0498 mmol), in 97% formic acid (4.0 mL), was stirred at room temperature for 14 h. The formic acid was then evaporated and the residue was dissolved in methylene chloride (5 mL) and again evaporated. Repetition of this process with more methylene chloride (5 mL) gave a solid residue, which was partitioned between water (4 mL) and ether (2 mL). The aqueous phase was washed again with ether (2 mL) and evaporated to leave a white glass (20.3 mg, 85%). Analytical tlc (silica gel): R_f 0.13 (2-butanone – acetic acid – water, 4:1:1) visualized as a yellow spot with ninhydrin and brown spot with palladium chloride and heating. A minor, ninhydrin-negative, palladium chloride-positive impurity was detected at R_f 0.34; ^{1}Hmr (D_2O) δ: 1.36 (3H, s, CH_3), 1.56 (3H, s, CH_3), 1.64–1.94 (4H, m, CH_2CH_2), 2.38 (2H, m, CH_2CO), 3.26 (1H, q, J = 2.6, 13.8 Hz, *H7S*), 3.36 (1H, q, J = 10.3, 13.8 Hz, *H7R*), 3.89 (1H, s, glycyl CH_2), 4.40 (2H, m, Aad methine and C3 methine), 5.02 (1H, br d, C6 methine).

Synthesis of Isotopically Labelled Thiazepines

To DL-alanine (800.2 mg, 8.98 mmol) was added a 2% ethanolic solution of L-[U-^{14}C]alanine (500 μCi, 171 mCi/mmol) and the resulting solution was evaporated to dryness. The residue was dissolved in water (10 mL) containing sodium bicarbonate (1.9 g, 22.5 mmol), and benzyl chloroformate (1.6 mL, 2.01 g, 11.8 mmol) was added dropwise, with stirring at room temperature during 5 min. The mixture was stirred for an additional 2 h and was then extracted with ether (3 × 20 mL). The aqueous phase was acidified to pH 2, whereupon an oil precipitated, which crystallized rapidly on cooling to give labelled carbobenzoxyalanine (1.525 g, 76%), mp 104–106°C. This was treated at 0°C with excess ethereal diazomethane, and the mixture was allowed to stand overnight and then filtered and evaporated to dryness to give labelled **24** (1.53 g, 95%) as a colourless syrup, which crystallized on scratching, mp 38–40°C. To this material (1.33 g, 5.96 mmol), in anhydrous methanol at 0°C, were added freshly prepared *tert*-butyl hypochlorite (42) (1.1 mL, 1.0 g, 9.2 mmol) and 0.17 mL of a 1% solution of sodium methoxide in dry methanol. The mixture was stirred for 2.5 h at 0°C and then evaporated and the residue dissolved in methylene chloride (20 mL). This solution was washed with saturated brine (10 mL), dried and evaporated to give labelled **25** as a colourless syrup (1.39 g, 90%); ^{1}Hmr ($CDCl_3$) δ: 1.5 (3H, d, J = 7.0 Hz), 3.7 (3H, s), 5.0 (1H, q, J = 7.0 Hz), 5.2 (2H, s), 7.36 (5H, s). A solution of the labelled **25** in methylene chloride (10 mL) was placed in a 50 mL three-necked flask equipped with a magnetic stirrer and fitted with two serum caps and a condenser topped with a drying tube. The flask was placed in a water bath maintained at 45°C, and DBU (775 mg, 5.1 mmol) was added, followed by additional methylene chloride (5 mL). The mixture was refluxed for 20 min, cooled, and extracted successively with water (10 mL), 3 *N* hydrochloric acid (10 mL), saturated sodium bicarbonate (10 mL), and water (10 mL). To the dried solution was added one crystal of 2,6-di-*tert*-butyl-4-methylphenol, and the solvent was then removed to yield a light brown syrup (1.26 g). Although the ^{1}Hmr spectrum of this material indicated that it was a 1:1 mixture of **21** and **24**, it was used without purification in the next step, reaction with D-penicillamine (822 mg, 5.5 mmol) in dry methanol (15 mL) containing triethylamine (0.85 mL, 6.0 mmol), as described earlier for the preparation of unlabelled **22**. Work-up in the same manner afforded 135.6 mg of **22**, 610 mg of the 3D,6D-epimer and, from the ethyl acetate extracts, 524 mg of recovered **24**, specific activity 30 μCi/mmol.

The crude **22** was recrystallized from hot *n*-butanol (1.1 mL) to give 120.5 mg, mp 203.5–204°C (dec.) (sealed tube), $[\alpha]_D^{29}$ −13° (*c* 0.5, $NaHCO_3$), specific activity 30 μCi/mmol. This material, ^{14}C-labelled at C5, C6, and C7, was used to prepare radioactive samples of the four thiazepines **5***a*, **5***b*, **6***a*, and **6***b*.

Conversion of **33**j *to* **39**a *and* **39**b

A solution of **33***j* (157.0 mg, 0.3 mmol) in methylene chloride (10 mL) was stirred at 2°C. An ice-cold solution of 85% *m*-chloroperoxybenzoic acid (60.9 mg, 0.3 mmol) in methylene chloride (5 mL) was added in small portions during 25 min. Stirring was continued for a further 1 h at 2°C and, during this time, a white precipitate formed which was collected by filtration and dried under high vacuum to give 51.8 mg, mp 144–150°C. The filtrate was stirred with 5% sodium thiosulfate (5 mL) followed by water (5 mL). Solid 2-mercaptobenzothiazole (50.1 mg, 0.3 mmol) was next added and the mixture was stirred at room temperature until this solid had dissolved. Saturated aqueous sodium bicarbonate (5 mL) was then added and the mixture was stirred for 10 h. After this time a solution of saturated brine (5 mL) was added to facilitate separation of the organic layer, which was then washed with saturated brine (5 mL), dried over sodium sulfate, and evaporated to leave a cloudy gum. The product was redissolved in methylene chloride, filtered to remove a fine suspension, and reconcentrated to a white foam (98.2 mg). Analysis by tlc (methylene chloride – ethyl acetate, 4:1) indicated the presence of two major components, at R_f 0.76 (2-mercaptobenzothiazole) and R_f 0.15, ninhydrin:yellow, palladium chloride:orange. This latter component was unstable on silica gel.

The mixture was subjected to flash chromatography on silica gel H (2 g) using methylene chloride (80 mL) to elute the 2-mercaptobenzothiazole (31.5 mg), and ethyl acetate (120 mL) to elute the polar component. The ethyl acetate eluent was evaporated and the gummy product was dissolved in methylene chloride (5 mL), filtered, and concentrated to give **39***a* as a white foam (56.0 mg, 48.7%). Infrared (CCl_4): 3335 (br, m, amide NH and NH_2), 1716 (s, ester C=O), 1682 (s, amide C=O) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.83 (3H, s, vinyl CH_3), overlapping with 1.95 (2H, s, rapid exchange with D_2O, NH_2), 2.15 (3H, s, vinyl CH_3), 2.68–3.95 (3H, m, cysteinyl methylene and methine protons), 6.82 (1H, s, benzhydryl methine), 7.02–7.95 (~14H, ArH), 8.72 (1H, br s, rapid exchange with D_2O, amide NH).

For personal use only.

The amine **39***a* (44.0 mg, 0.08 mmol) was treated with a solution of 0.096 *M* dicyclohexylamine in methylene chloride (1.0 mL, 1.2 equiv.) and stirred at 0°C. To this solution was added, during 1 min, a solution of benzyl chloroformate (19 mg, 0.11 mmol) in methylene chloride (1 mL). The resulting solution was stirred for 3 h at 0°C, and the solvent was evaporated and the residue partitioned between ethyl acetate (10 mL) and saturated sodium bicarbonate (10 mL). The organic layer was washed successively with saturated bicarbonate (10 mL), 10% potassium bisulfate (2 × 10 mL), saturated brine (10 mL), dried over sodium sulfate, and evaporated to leave a gummy foam (53.1 mg). The product was purified by plc (methylene chloride – ethyl acetate, 9:1) and the band R_f 0.45–0.65 was isolated (36 mg). Crystallization from chloroform–hexane gave **39***b* as an off-white solid (16.6 mg, 30%) mp 124–127°C; ir (Nujol): 3290 (s, amide and urethane NH), 1722, 1696, 1655 (s, ester, urethane, amide C=O), 1527 (s, amide II) cm^{-1}; ^{1}Hmr ($CDCl_3$) δ: 1.87 (3H, s, vinyl CH_3), 2.18 (3H, s, vinyl CH_3), 3.04 (1H, q, J_{AX} = 7.3, J_{AB} = 14.6 Hz), 3.43 (1H, q, J_{BX} = 4.5, J_{AB} = 14.6 Hz, cysteinyl CH_2), 4.78 (1H, m, cysteinyl C*H*) overlapping with 5.08 (2H, s, PhCH_2O), 6.59 (1H, br d, J = 7 Hz, urethane N*H*), 6.92 (1H, s, benzhydryl methine), 7.02–8.00 (20H, m, ArH), 9.19 (1H, br s, amide NH).

This paper is dedicated to Prof. Raymond U. Lemieux on the occasion of his 60th birthday

ITSUO KUROBANE, LEO C. VINING, A. GAVIN MCINNES, DONALD G. SMITH, and JOHN A. WALTER. Can. J. Chem. **59**, 422 (1981).

Elsinochromes C and D have been isotopically labelled by supplementing cultures of the producing fungus with sodium [1-^{13}C]-, [2-^{13}C]-, [1,2-^{13}C]-, or [2-^{13}C, 2-$^{2}H_3$]acetate and the distribution of isotope has been determined by ^{13}C and ^{2}H nuclear magnetic resonance spectroscopy. The pattern of ^{13}C labelling is consistent with assembly of the elsinochrome carbon skeleton from two heptaketide chains with loss of the terminal carboxyl groups, and dimerization to generate the 1,2-dihydrobenzo (*ghi*)-perylene ring system. Elsinochrome D was converted to the more soluble triacetate to examine the fate of ^{2}H presented to the culture as [2-^{13}C, 2-$^{2}H_3$]acetate. Deuterium labelling was restricted to the C-14 and C-16 methyl groups, a result consistent with these belonging to the "starter" C_2 units of polyketide intermediates. Carbon-13 enrichment data for elsinochromes labelled from [1,2-^{13}C]acetate indicated that the polyketide chains were formed from a highly enriched precursor pool with subsequent dilution accounting for a much lower average incorporation. Presence of spin–spin coupling between linked carbons derived from separate polyketide precursors implies that dilution occurs after the dimerization step. From the combined evidence a plausible pathway for elsinochrome biosynthesis is deduced.

ITSUO KUROBANE, LEO C. VINING, A. GAVIN MCINNES, DONALD G. SMITH et JOHN A. WALTER. Can. J. Chem. **59**, 422 (1981).

On a marqué isotopiquement les elsinochromes C et D en additionnant, aux milieux de cultures du champignon producteur, de l'acétate de sodium[^{13}C-1], [^{13}C-2], [^{13}C-1,2] ou [^{13}C-2, $^{2}H_3$-2]; on a déterminé la distribution des isotopes par la rmn du ^{13}C et du ^{2}H. Le modèle de marquage en ^{13}C est en accord avec l'élaboration du squelette carboné de l'elsinochrome à partir de deux chaînes d'heptacétide avec la perte des groupes carbonyles terminaux et une dimérisation qui produisent le système cyclique dihydro-1,2 benzo(*ghi*)-pérylène. On a transformé l'elsinochrome D en son triacétate plus soluble pour étudier le sort du ^{2}H introduit dans le milieu de la culture sous forme d'acétate [^{13}C-2, $^{2}H_3$-2]. Le marquage au deutérium est limité aux carbones C-14 et C-16 des groupes méthyles; ce résultat est en accord avec le fait que ces groupes appartiennent aux unités C_2 de départ des polycétides intermédiaires. Les données d'enrichissement au ^{13}C des elsinochromes marqués à partir de l'acétate [^{13}C-1,2] indiquent que les chaînes polycétides se forment à partir d'un ensemble de précurseurs fortement enrichis et dont la dilution subséquente est responsable du faible taux d'incorporation. La présence d'un couplage spin–spin entre les carbones liés provenant de précurseurs isolés de polycétide implique que la dilution se produit après l'étape de dimérisation. On a déduit, à partir de l'ensemble des données un cheminement possible pour la biosynthèse de l'elsinochrome.

Introduction

Fungi of the phytopathogenic genus *Elsinoë* and its imperfect stage *Sphaceloma*, produce the bright-red photosensitizing elsinochromes A (**1**), B (**2**), C (**3**), and D (**4**). Their structures, except for the absolute configuration of the chiral centers which remains undetermined, were deduced from chemical spectroscopic evidence (1–6). These pigments have, so far, been described only from *Elsinoë* or *Sphaceloma* strains. An earlier report of their formation by *Phyllosticta caryae* was withdrawn when this organism proved to be a misidentified strain of *Elsinoë randii* (3). While working with strains of the onion pink-root-disease fungus, *Pyrenochaeta terrestris*, we observed that one culture was exceptional and produced a mixture of red pigments subsequently recognized as elsinochromes. The main components were identified as **3** and **4**. Although **4** has been reported as only a minor component of *Elsinoë* species, where either **1** or a mixture of **2** and **3** usually predominate, it is possible that our culture of *P. terrestris* represents another example of a misidentified species. Unfortunately, this fungus no longer produces sexual structures so its true identity cannot be established.

Biosynthetic enrichment of **1** with [^{14}C]formate has shown that the methoxyl groups originate from the one-carbon pool of *Elsinoë araliae* (7). Partial chemical degradation of material labelled with [1-^{14}C]acetate gave results which suggested (5, 7) that the remaining carbons were derived from acetate and which were consistent with the involvement of two polyketide chains as depicted in Fig. 1A. Similar

1 $R^1 = R^5 = H$, $R^2 = \underset{13}{COCH_3}$, $R^3 = \underset{15}{COCH_3}$, $R^4 = \underset{17}{CH_3}$

2 $R^1 = R^5 = H$, $R^2 = \underset{13}{COCH_3}$, $R^3 = \underset{15}{CH(OH)}\underset{16}{CH_3}$, $R^4 = \underset{17}{CH_3}$

3 $R^1 = R^5 = H$, $R^2 = \underset{13}{CH(OH)}\underset{14}{CH_3}$, $R^3 = \underset{15}{CH(OH)}\underset{16}{CH_3}$, $R^4 = \underset{17}{CH_3}$

4 $R^1 = H$, $R^2 = \underset{13}{CH(OH)}\underset{14}{CH_3}$, $R^3 = \underset{15}{CH(OH)}\underset{16}{CH_3}$, $R^4 + R^5 = \underset{17}{CH_2}$

6 $R^1 = COCH_3$, $R^2 = \underset{13}{CH(OCOCH_3)}\underset{14}{CH_3}$, $R^3 = \underset{15}{CH(OCOCH_3)}\underset{16}{CH_3}$, $R^4 + R^5 = \underset{17}{CH_2}$

conclusions (5, 7, 9) have been drawn from a ^{13}C nmr investigation of ^{13}C-enriched samples of cercosporin (**5**), a closely related perylenequinone produced by the fungus, *Cercospora kikuchii*, which causes purple-speck disease of soybeans (8). The aromatic and side-chain carbon atoms of cercosporin were alternately labelled by [1-^{13}C]- and [2-^{13}C]acetate while the methoxy and methylenedioxy carbon atoms were derived from [^{13}C]formate (9).

However, none of this evidence strictly excludes the possibility that **1** and **5** are constructed from a single polyketide chain. An intermediate of the kind shown in Fig. 1B, where n may be any number including zero, might be processed by excising $n + 1$ internal carbon atoms and the carboxyl terminal group to give a product with the same distribution of isotopically labelled acetate carbon atoms as would be obtained from two chains originating as in Fig. 1A. To distinguish between these two possibilities it is necessary to determine the arrangement of intact two-carbon units derived from[1-$^{13}C_{0;1;1}$, 2-$^{13}C_{1;0;1}$]acetate (abbreviated in this paper to [1,2-^{13}C]acetate). However, an initial single-chain polyketide intermediate processed as shown in Fig. 1C would, by appropriate fusion of the fragments, give a product indistinguishable in labelling pattern from that of Fig. 1A. Thus the number of *de novo* polyketide chains used in the construction of these molecules can be firmly established only by identifying the chain-initiating units. This is difficult for symmetrical molecules like **1** and **5** and was not attempted in the preceding investigations.

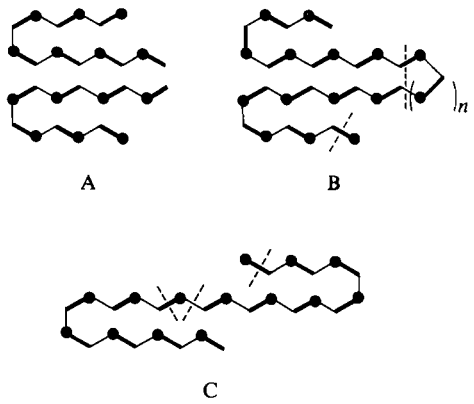

FIG. 1. Possible polyketide intermediates en route to elsinochromes and cercosporin.

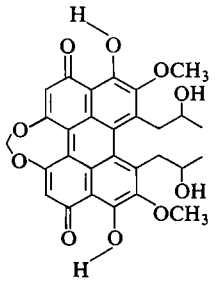

5

In this communication we provide the necessary evidence that the biosynthesis of elsinochromes involves two polyketide chains. Evidence of their polyketide origin was obtained by labelling **3** and the unsymmetrical **4** from [1-^{13}C]-, [2-^{13}C]-, and [1,2-^{13}C]acetate and determining the enrichment patterns by ^{13}C nmr spectrometry. The pressure of two chain-initiating units was established by enriching **4** with [2-$^{13}C_{0;1}$, 2-$^{2}H_{3;3}$]acetate (abbreviated to [2-^{13}C, 2-$^{2}H_3$]acetate throughout) and using ^{13}C and ^{2}H nmr to pinpoint the carbons bonded to ^{2}H in the metabolite.

Materials and Methods

Culture

Pyrenochaeta terrestris was obtained from the Centraalbureau voor Schimmelcultures, Baarn, where it is catalogued as CBS 322.62. It was maintained on Sabouraud-dextrose agar. Three substrains were isolated from the stock culture and CBS 322.62B, which produced the highest yields of elsinochromes C and D, was used in the study. To obtain a uniform vegetative inoculum, spores and mycelium from a slant were incubated for 4 days in a D-glucose (1%) – neopeptone (0.5%) – corn steep liquor (0.5%) medium. These and all subsequent liquid cultures were grown in 250 mL Erlenmeyer flasks containing 50 mL of medium and incubated at 25°C on a rotary shaker (220 rpm, 3.8 cm eccentricity). The vegetative inoculum was homogenized in a Waring blender and added in 2.5 mL portions to 50 mL of soluble starch (5%) – neopeptone (1%) production medium.

To establish the most efficient feeding regimen sterile solutions of [1-^{14}C]acetate (20 μCi/L) were added to cultures on the first, second, or third day of fermentation and incubation was continued until the tenth day before harvesting. The precursor concentration in the culture was 2 or 5 m*M*. Solutions of sodium [1-^{13}C]-, [2-^{13}C]-, [1,2-^{13}C]-, and [2-^{13}C, 2-^{2}H$_3$]-acetate were fed on the third day at final concentrations 5 m*M*. In all experiments the pigments were isolated on the tenth day from 1 L of culture broth.

Labelled Precursors
