Received April 26, 1982

DELANO P. CHONG. Can. J. Chem. **61**, 1 (1983).

Valence-electron shake-up satellite bands in the ionization spectra of carbon dioxide, nitrous oxide, and tetrafluoroethene have been calculated with a modified version of the HAM/3 program. The results are compared with experiment and with the computations based on two-particle-hole Tamm-Dancoff approximation Green's function method. Because of the limitation of such Green's function procedures for inner-valence electrons, the results can often be inferior to those from the present HAM/3 calculations.

DELANO P. CHONG. Can. J. Chem. **61**, 1 (1983).

Utilisant une version modifiée du programme HAM/3 on a calculé les bandes satellites d'agitation de l'électron de valence dans les spectres d'ionisation du bioxyde de carbone, de l'oxyde nitreux et du tétrafluoroéthène. On a comparé ces résultats avec ceux obtenus expérimentalement et avec ceux obtenus par les calculs basés sur l'approximation de Tamn-Dancoff de la particule à deux trous de la méthode de fonction de Green. A cause de la limitation de telles méthodes de fonction de Green pour les électrons de valence internes, les résultats peuvent être inférieurs à ceux obtenus actuellement par les calculs de HAM/3.

1. Introduction

Ionization processes have been studied extensively by photoelectron (PE) spectroscopy with ultraviolet photon sources, X-rays, and synchrotron radiation. Recently, both binary and dipole (e,2e) binding energy spectra have been obtained for a number of molecules. The importance of valence-electron shake-up (VESU) satellite bands in ionization spectra is well recognized, especially for inner-valence electrons. Such VESU structure will even dominate the ionization spectra of many larger molecules to such an extent that there is often a complete breakdown of the molecular orbital model.

In the past few years, Cederbaum and co-workers (1–4) have used the two-particle-hole Tamm-Dancoff approximation (2ph-TDA) in their Green's function (GF) calculation of inner-valence ionization spectra. Because of the large dimension of the matrices to be diagonalized, the atomic orbital basis set is usually limited to double-ζ quality and the molecular orbital space is often truncated. Consequently, the 2ph-TDA results thus far are not as accurate as those from the outer-valence Green's function method (5).

Another *ab initio* method used to analyze VESU in ionization spectra is limited configuration interaction (CI) (6, 7).

On the other hand, Lindholm and Åsbrink (8) simplified the complex problem of VESU, incorporating the treatment into the semi-empirical HAM method (9, 10) and obtaining reasonable agreement with the observed PE spectra of ethene and benzene. Unfortunately, minor errors were inadvertently allowed into their simple treatment. These errors have been corrected (11) and the HAM/3 program (12) has been modified in our laboratory to perform VESU calculations.

In this paper, we wish to report semiempirical HAM/3 computations of the VESU bands in the ionization spectra of CO_2, N_2O, and C_2F_4 and compare the results with those from 2ph-TDA GF calculations as well as with experiment. Experimental geometries (13) are used throughout. The method is reported elsewhere (11). Suffice it to say that the relative intensities are estimated by the sum of the squared amplitudes (multiplied by the degeneracy factor). In other words, we assume uniform in-phase non-interfering photoionization cross-section matrix elements (4).

2. Carbon dioxide

Experimental studies (4, 14–19) of the ionization of CO_2 were reviewed by Domcke *et al.* (4) in 1979. Since then, another binary (e,2e) spectrum has been recorded (20). These results are summarized in Table 1. In Fig. 1, we present some of them (4, 15, 20) to show the uncertainty in the locations of the VESU satellite bands.

The results of the present calculations are summarized in Table 2 and compared with those of 2ph-TDA GF (4) in Fig. 1. In the GF method, the low-energy region is more accurately calculated by the outer-valence GF procedure than by 2ph-TDA. For different reasons, the original HAM/3 method without VESU is in better agreement with experiment for the primary PE bands than the present inclusion of VESU. Consequently, only the inner-valence region of 20–45 eV is shown in Fig. 1 (*d*) and (*e*). There is qualitative agreement between the two sets of calculations, although there are some differences in the vertical ionization potentials (VIP) and the relative intensities. The first VESU band of appreciable intensity is due to a $^2\Pi_u$ state at 25.68 eV according to HAM/3. This VIP is closer to the binary (e,2e) value of 25 eV (20) and the dipole (e,2e) result of 26.5 eV (4). The 2ph-TDA GF result of 28.33 eV (4), on the other hand, agrees better with the HeII value of 27.2 eV (16) and the synchrotron VIP of 27.3 eV (18). That this state is a Π state has been confirmed by momentum distribution measurements (20). At higher energies, the most intense band is at 37 eV according to HAM/3 (35.3 eV by 2ph-TDA GF (4)), with a strong line also predicted at 38.8 eV. These results are in excellent agreement with the experimental ones summarized in Table 1.

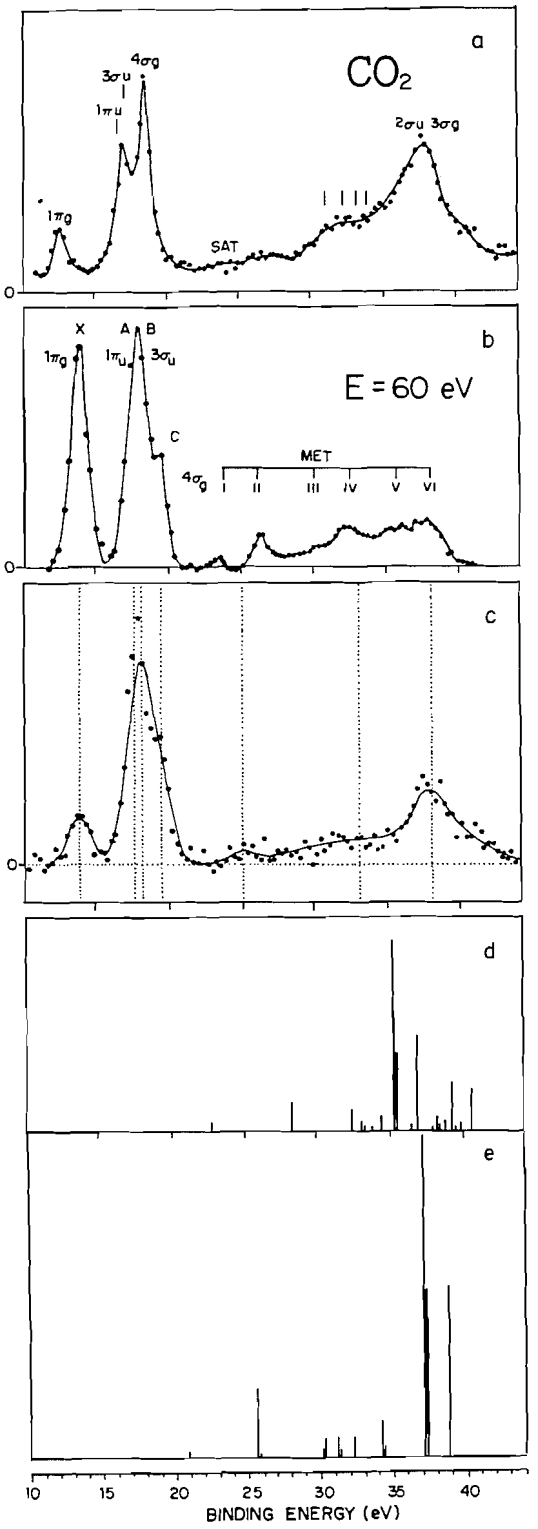

FIG. 1. Comparison of ionization spectra of CO_2: (*a*) ESCA (15), (*b*) dipole (e,2e) (4), (*c*) binary (e,2e) (20), (*d*) calculated by 2ph-TDA GF (4), (*e*) calculated by HAM/3.

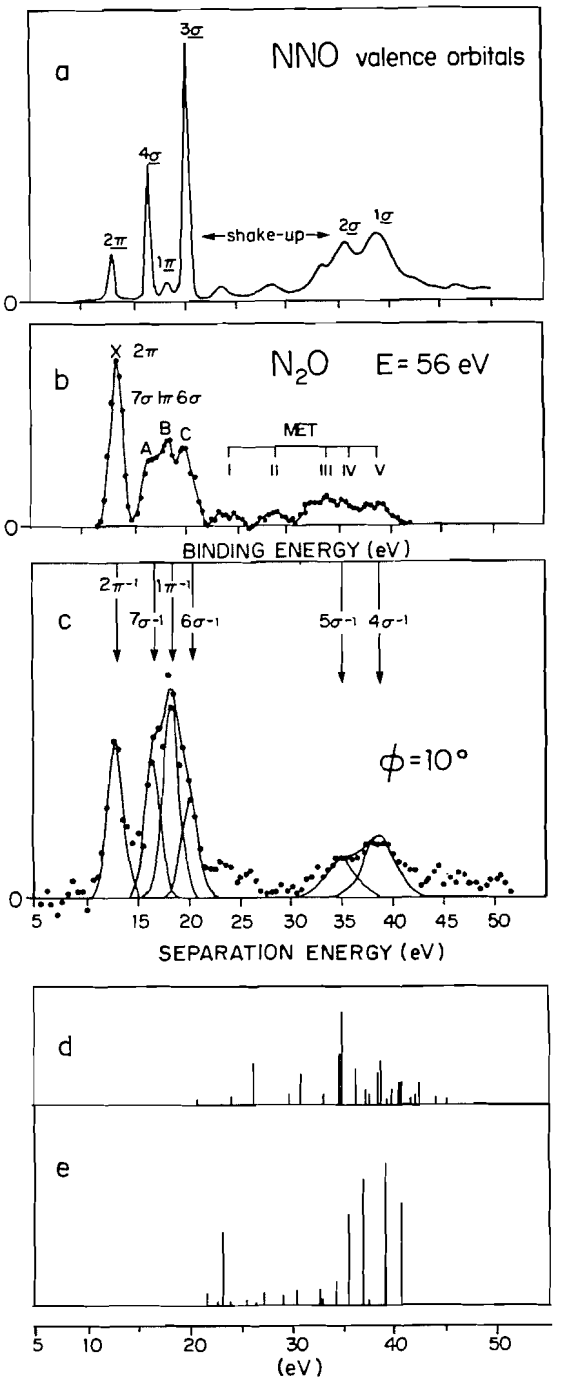

FIG. 2. Comparison of ionization spectra of N_2O: (*a*) ESCA (23), (*b*) dipole (e,2e) (4), (*c*) binary (e,2e) (24), (*d*) calculated by 2ph-TDA GF (4), (*e*) calculated by HAM/3.

3. Nitrous oxide

As in the case of CO_2, we first summarize the experimental results on N_2O in Table 3 and compare some of them (4, 23, 24) in Fig. 2. The uncertainty in the positions of the VESU bands is about 0.5 eV (4).

The results of our HAM/3 computations are displayed in Table 4 and compared with those of 2ph-TDA GF (4) in Fig. 2. Again, only the interesting region of 20–45 eV is displayed in Fig. 2 (*d*) and (*e*), and the agreement between the two sets of calculations is only qualitative. The VESU satellites calculated by HAM/3 to be at 21.6 and 23.2 eV agree better with the observed spectra in UPS (16), XPS (23), and dipole (e,2e) studies (4). The VIP of 23.8 and 26.2 eV from 2ph-TDA GF calculations (4), on the other hand, show better agreement with the recent binary (e,2e) experiment (24).

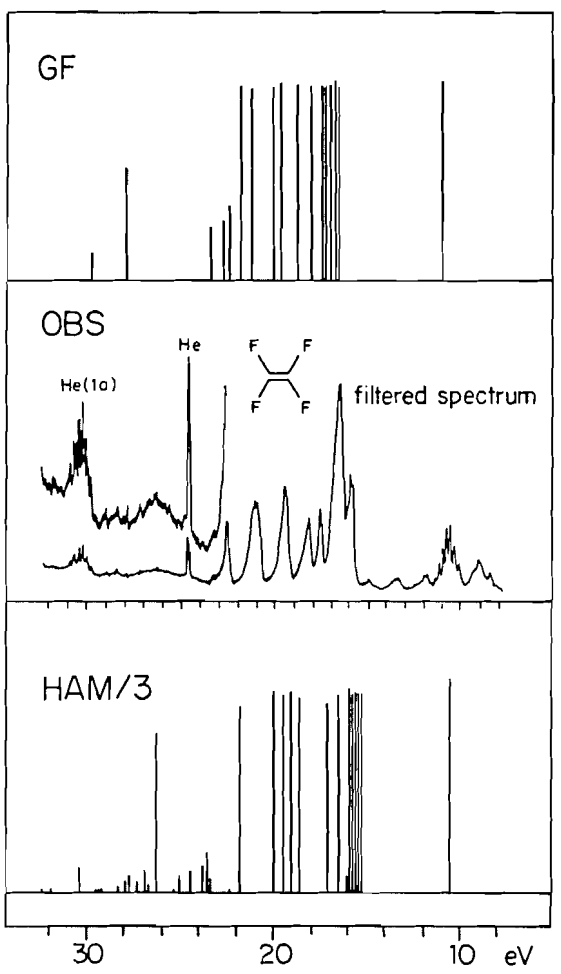

FIG. 3. Comparison of ionization spectra of C_2F_4.

4. Tetrafluoroethene

The VESU satellite bands of C_2F_4 have been studied both experimentally and theoretically (with 2ph-TDA GF method) by Bieri and co-workers (5, 25).

Our HAM/3 calculations are given in Table 5 and compared with the previous results (5, 25) in Fig. 3. The VESU band observed at 22.5 eV is very sharp. It corresponds to the intense band at 21.8 eV in the HAM/3 results. In contrast, the 2ph-TDA GF calculations predict three bands in this energy region, at 22.5, 22.7, and 23.4 eV, with relative intensities of 0.35, 0.28, and 0.25, respectively. The $(2a_g)^{-1}$ band at 26.3 eV is closer to the HAM/3 value of 26.25 eV than to the VIP of 27.94 eV predicted by 2ph-TDA GF (5, 25).

5. Discussions

From the examples given above, one sees that the HAM/3 program, after modifications to include VESU, is capable of producing results which can compete with those from 2ph-TDA GF calculations in terms of reliability at a small fraction of the computing cost. Results of similar quality have also been obtained for formamide (11), N_2O_4, CH_3NO (26), N_2, C_2H_2, CO, O_3, and other molecules (27).

Because the parameters in the HAM/3 program were obtained without considering VESU, the VIP of the outer-valence electrons are more reliably calculated excluding VESU than including. One could partially correct this deficiency by shifting the orbital energies so that the VIP for the primary hole states calculated with VESU match the experimental values. However, this procedure is completely empirical and the HAM/3 parameters used are not the best set. In principle, one should reoptimize the entire set of parameters in the HAM/3 method. In practice, the reoptimization will be carried out in Version 4 of the HAM method (28).

Synthesis of indeno[1,2,3-*ij*]isoquinolines

HEMANT A. PATEL AND DAVID B. MACLEAN[1]
Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received August 26, 1982

HEMANT A. PATEL and DAVID B. MACLEAN. Can. J. Chem. **61**, 7 (1983).

1-Methyl and 1-benzyl-1,2,3,10b-tetrahydro-5,6,8,9-tetramethoxyindeno[1,2,3-*ij*]isoquinoline have been synthesized from the corresponding 8-phenyl-3,4-dihydro-1(2*H*)isoquinolinones by treatment with $POCl_3$ under Vilsmeier conditions followed by borohydride reduction. The isoquinolinones were prepared in six steps from 2-(2,3,4-trimethoxyphenyl)-4,4-dimethyl-2-oxazoline. This sequence of reactions provides a new route to dihydro and tetrahydroindeno[1,2,3-*ij*]isoquinolines.

HEMANT A. PATEL et DAVID B. MACLEAN. Can. J. Chem. **61**, 7 (1983).

On a synthétisé la méthyl-1 et la benzyl-1 tétrahydro-1,2,3,10b tétraméthoxy-5,6,8,9 indéno[1,2,3-*ij*] isoquinoléine à partir des phényl-8 dihydro-3,4 (2*H*) isoquinolinones-1 que l'on traite par du $POCl_3$ dans les conditions de Vilsmeier suivi d'une réduction par un borohydrure. On a préparé les isoquinolinones en 6 étapes à partir de la (triméthoxy-2,3,4 phényl)-2 diméthyl-4,4 oxazoline-2. Cette suite de réactions fournit une nouvelle voie d'accès aux dihydro et aux tétrahydro-indénol[1,2,3-*ij*] isoquinoléines.

[Traduit par le journal]

Indeno[1,2,3-*ij*]isoquinoline (2-azafluoranthene) **1** was reported in 1948 as a constituent of coal tar and its structure established through degradation to known compounds (1). The synthesis of **1** from a fluorenone precursor was reported in 1958 by Campbell and Reid who, at the same time, described further physical properties and several reactions of this system (2). In 1972 Cava *et al.* (3) isolated the alkaloids, rufescine **2** and imeluteine **3**, from *Abuta rufescens* and *Abuta imene* and demonstrated, through spectral examination and by synthesis, that they were methoxylated derivatives of **1**. A few years later Huls *et al.* (4) isolated another alkaloid of this class from *Triclisia gilletii* to which they assigned structure **4** on spectral grounds and confirmed this structure through an unambiguous synthesis. More recently Menachery and Cava (5) isolated the alkaloids, norrufescine and telitoxine, from *Telitoxicum peruvianum* for which they proposed the structures **4***a* and **4***b*, respectively, on the basis of spectroscopic data.

Fluorenones (2, 6), 1-(2-aminophenyl)-3,4-dihydroisoquinolines (3, 4), and 1-(2-aminophenyl)-1,2,3,4-tetrahydroisoquinolines (7) have been used as starting materials to prepare the ring system present in **1**. In the synthesis beginning with the isoquinolines the five membered ring was generated by diazotization followed by Pschorr cyclization (3, 4, 7). This procedure worked well in the synthesis of rufescine and imeluteine (3) but gave low yields in the synthesis of **4** (4). In the third case (7) the ring system of **1** was formed in unspecified yield but products expected from a simple cyclization were not obtained. Here we report the synthesis of 1,2,3,10b-tetrahydro-5,6,8,9-tetramethoxy-1-methylindeno[1,2,3-*ij*]isoquinoline **5** and its 1-benzyl analogue **6** in which the ring system is generated by a new route from the corresponding 8-phenyl-1(2*H*)isoquinolinone. In the course of this work we have prepared some previously unreported 8-phenylisoquinoline derivatives.

Only a few syntheses of 8-phenylisoquinolines have been reported. The classical routes, namely the Bischler–Napieralski, Pictet–Spengler, and the Pomeranz–Fritsch cyclizations, when applied to this task have proved unrewarding. Our experience with the Pomeranz–Fritsch reac-

tion (*vide infra*) and its various modifications confirms the experience of earlier workers. The first successful synthesis of 8-phenylisoquinoline was reported by Ahmad and Hey (8) who prepared the parent compound and a few derivatives. In 1979 Dyall and Pullin (9) used a related phenylation procedure to prepare 8-phenylisoquinoline and its six isomers. In the same year Ellefson (10) published a method that promises to be generally applicable to the preparation of a range of substituted 8-phenylisoquinolines or 8-phenyl-1-(2*H*)isoquinolines. Pridgen (11) has shown that haloisoquinolines will couple with aryl magnesium halides in the presence of dichloro[1,3-bis(diphenylphosphino)propane]nickel II (Ni dppp) and has prepared two 8-phenylisoquinolines by this route, both in good yield. More recently Hara *et al.* (12) have shown that a *p*-quinolacetate derived from a 6,7-dioxygenated tetrahydroisoquinoline will react with aralkylethers in the presence of trifluoracetic acid to give 8-phenyltetrahydroquinolines.

We were interested, like earlier workers, in the 8-phenylisoquinolines as precursors of aporphine alkaloids and set out to prepare derivatives of 6,7-dimethoxy-8-(3,4-dimethoxyphenyl)isoquinoline. In the course of our work we made the related 1-(2*H*)isoquinolinones and observed that they underwent cyclization and reduction to indeno[1,2,3-*ij*]isoquinoline derivatives.

Our first approach to the 8-phenylisoquinolines was through the Pomeranz–Fritsch reaction. We expected that recent modifications of the reaction might be successful even though earlier attempts gave negative results. To this end we set out to prepare 3,4-dimethoxy-2-(3,4-dimethoxyphenyl)benzaldehyde. The Ullman reaction gave very poor yields but the route outlined in Scheme 1 was suitable. 2,3,4-Trimethoxybenzoic acid was converted by established procedures to the oxazoline **7** and that in turn in excellent yield to the biphenyl **8** by the method of Meyers and Mihelich (13). The aldehyde **9** was prepared from **8** by the procedure developed by Nordin (14) which involved quaternization at nitrogen, borohydride reduction, and hydrolysis. The aldehyde **9** was converted to the Schiff's base **10** and that in turn to its reduction product **11**, the two compounds required to test the various modifications of the Pomeranz–Fritsch ring closure reaction for the formation of the isoquinoline system. In the case of **10**, cyclization was attempted with polyphosphoric acid (15), 70% H_2SO_4 (16), and $BF_3 \cdot Et_2O/(CF_3CO)_2O$ (17) with a singular lack of success. The same was true when **11** was treated with 6 *M* HCl (18) or its tosyl derivative with 6 *M* HCl in dioxane (19). The reasons for the failure of this cyclization in this seemingly highly activated system are not apparent. A possible explanation may be that the oxonium ion generated from the acetal readily complexes with the π electrons of the *ortho* phenyl group and decomposes to products other than those of normal cyclization. Models show that the interaction would be favourable geometrically.

The next approach to our target molecule was based on the method of Pridgen (11). We prepared the previously unreported 8-bromo-6,7-dimethoxyisoquinoline **12** from 2-bromo-3,4-dimethoxybenzaldehyde (20, 21) via the modified Pomeranz–Fritsch procedure developed by Bewis *et al.* (17). Treatment of isoquinoline **12** with 3,4-dimethoxyphenylmagnesium bromide according to Pridgen's procedure in the presence of "Ni dppp" did not yield the expected 8-phenylisoquinoline.

Finally we turned to the method of Ellefson (10) (Scheme 2) which proved to be successful. The oxazoline **8** was lithiated with *n*-BuLi (22, 23) and treated with an excess of ethylene oxide to give compound **13** which was hydrolysed (24) in 3 *M* HCl to the isocoumarin **14**; the yield was found to be sensitive

both to the acid concentration and the time of reflux. The amide **15** was obtained by treating **14** with a mixture of benzylamine and benzylammonium chloride under reflux for 24 h. Esterification of the primary hydroxy group of **15** was effected with mesyl chloride in pyridine and the mesylate treated with sodium hydride in THF to afford the lactam **16**.

2-Methyl-3,4-dihydro-6,7-dimethoxy-8-(3,4-dimethoxyphenyl)-1(2*H*)isoquinolinone **18** was prepared in an analogous series of reactions by the sequence **14** → **17** → **18**.

The indeno[1,2,3-*ij*]isoquinolines were formed from the lactams **16** and **18** by treatment with $POCl_3$ as shown in Scheme 3. The tetrahydro compounds **5** and **6** were obtained in good yield by reduction of the isoquinolinium salts, **20** and **19**, respectively with sodium borohydride.

The structures of the compounds discussed above are based upon their composition and their spectroscopic properties, particularly the ^1H nmr spectra. It is not the intention to give a detailed analysis of the spectra but several features are noteworthy. In all the biphenyls and 8-phenylisoquinolines prepared in this study, one methoxy group appears in the vicinity of 3.5 + 0.1 ppm, in contrast to the other three which appear in the region 3.9 + 0.2 ppm. We assign the low field signal to the methoxy group *ortho* to the phenyl group by which it must be shielded because of the nonplanarity of the biphenyl system. In the indeno[1,2,3-*ij*]isoquinolines none of the four methoxy signals occurs near 3.5 ppm, presumably because the molecule is forced into near planarity by the constraints of the ring system. The chemical shifts of other protons in the indenoisoquinoline systems are more or less in accord with expectations based on analogy with the spectra of aporphine alkaloids (25).

It is noteworthy that compound **5** shows only three aromatic protons in its ^{1}H nmr spectrum and only three aromatic carbon atoms bound to hydrogen in its ^{13}C nmr spectrum. Both the ^{13}C and ^{1}H spectra indicate that there are only two methylene groups and one methine group in the molecule. Similar results are observed for **6** but the ^{1}H spectrum is more complex because of the presence of the *N*-benzyl group.

This study provides a new approach to the indeno-[1,2,3-*ij*]isoquinoline system. The precursor 8-phenyl-1-(2*H*)-isoquinolinones may be conveniently prepared from 2-(2-methoxyphenyl)-4,4-dimethyloxazolines by the method of Ellefson (10). Two key steps in this synthesis involve oxazoline chemistry, the first, directed displacement of the methoxy group *ortho* to the oxazoline by the method of Meyers and Mihelich (13), and the second, *ortho* lithiation of the oxazoline followed by alkylation with ethylene oxide (10, 22, 23).

Experimental

Apparatus, materials, and methods

The continuous wave ^{1}H nmr spectra were run on a Varian EM 390 or T-60 spectrometer. The Fourier transform spectra were run on either a Bruker WP 80 or WH 90 or WM 250 spectrometer. Unless otherwise specified, the samples were dissolved in chloroform-*d* using tetramethylsilane (TMS) as the internal standard. Chemical shifts, quoted as δ values, were measured in relation to TMS. The symbols s, singlet, d, doublet, t, triplet, q, quartet, bs, broad singlet, and m, multiplet are used in reporting spectra. The ^{13}C nmr spectra were run at 62.9 MHz on a Bruker WM 250 FT spectrometer at 22.7°C. Mass spectra were recorded on a V.G. Micromass 7070 F mass spectrometer, at 70 eV.

Infrared spectra were recorded on a Perkin–Elmer 283 spectrometer in chloroform solution. Melting points were determined on a Kofler micro hot stage and are uncorrected. The microanalyses were performed by the Guelph Chemical Laboratories Ltd., Guelph, Ontario.

Thin layer chromatography (tlc) was performed using polygram Sil G/UV$_{254}$ and Al_2O_3 N/UV$_{254}$ plates. Gravity columns were run using Merck SiO_2 60, and "flash" columns prepared as described in the literature (26).

THF was dried by distillation from Na in a N_2 atmosphere, just prior to use. The following compounds were prepared by standard methods and gave satisfactory physical and spectral data: 2-bromoisovanillin (20), 2-bromo-3,4-dimethoxybenzaldehyde (21), 4-iodoveratrole (27), triethyloxonium fluoroborate (28).

2-(2,3,4-Trimethoxyphenyl)-4,4-dimethyl-2-oxazoline 7

$SOCl_2$ (44 mL; 0.6 mol) was added in one lot to 2,3,4-trimethoxybenzoic acid (42.4 g; 0.2 mol) and the dark brown mixture was stirred at ambient temperature for 24 h. The excess $SOCl_2$ was distilled off leaving a dark brown oil which was dissolved in CH_2Cl_2 (150 mL). The resulting solution was added dropwise to a stirred solution of 2-amino-2-methyl-1-propanol (36.8 g; 0.4 mol) in CH_2Cl_2 (150 mL) at 0°C during 1 h and the reaction mixture was left to stir overnight. After filtration, the filtrate was washed with H_2O, 5% HCl, 5% NaOH, and H_2O and dried. Removal of the solvent furnished the trimethoxybenzamide as a white solid (42.5 g; 75%), which was pure enough for the next step. To the above amide (42.5 g; 0.15 mol), $SOCl_2$ (16 mL) was added and the mixture stirred. After the solid had dissolved, the yellow solution was further stirred for 25 min and poured into anhydrous ether (150 mL). The precipitated hydrochloride was washed with ether and dried (43.4 g; 96%). The solid hydrochloride was dissolved in a minimum of H_2O, neutralized with cold 50% NaOH, extracted with ether, washed, and dried. Removal of the solvent gave a pale yellow oil which was crystallized from a small amount of cold petroleum ether, giving the required oxazoline as colorless crystals (35.5 g; 93%), mp 43–44°C; ir ($CHCl_3$): 2935, 1650, 1602, 1461, 1392, 1358, 1320, 1112, 1090, 970 cm^{-1}; ^{1}H nmr: 1.35 (6H, s, CH_3), 3.87 (9H, s, OCH_3), 4.05 (2H, s, CH_2), 6.67 (1H, d, J = 9 Hz, Ar-H), 7.50 (1H, d, J = 9 Hz, Ar-H) ppm; ms m/z: 265 (M^+ 46%), 250 (75%), 222 (31%), 204 (25%), 192 (33%), 179 (61%), 178 (100%), 165 (20%), 151 (21%). *Anal.* calcd. for $C_{14}H_{19}NO_4$: C 63.38, H 7.10; found: C 63.42, H 7.10%. *Mol. Wt.* calcd. for $C_{14}H_{19}NO_4$: 265.131; found (hrms): 265.128.

2-[2-(3,4-Dimethoxyphenyl)-3,4-dimethoxyphenyl]-4,4-dimethyl-2-oxazoline 8

To the stirred solution of Grignard reagent (prepared from 4-bromoveratrole (26.04 g; 0.12 mol) and Mg (3.0 g; 0.12 mol) in refluxing THF (100 mL)) was added the oxazoline **7**, (26.5 g; 0.1 mol in THF (50 mL)) at 10°C during 10 min. The reaction mixture was allowed to stir at room temperature for 20 h, slowly decomposed with saturated NH_4Cl (50 mL), extracted with CH_2Cl_2, washed with brine, and dried. Evaporation of the solvent furnished a red viscous liquid which was triturated with petroleum ether to give yellow crystals of the required product (34.1 g; 92%), mp 97–99°C; ir ($CHCl_3$): 2940, 2840, 1650, 1600, 1572, 1488, 1462, 1355, 1320, 1300, 1120, 1010, 970, 940, 860 cm^{-1}; ^{1}H nmr: 1.22 (6H, s, C—CH_3), 3.52 (3H, s, OCH_3), 3.77 (2H, s, CH_2), 3.85 (3H, s, OCH_3), 3.92 (6H, s, OCH_3), 6.84–7.10, 7.27–7.45 (5H, m, Ar-H) ppm; ms m/z: 371 (M^+ 37%), 370 (100%), 356 (14%), 285 (13%). *Anal.* calcd. for $C_{21}H_{25}NO_5$: C 67.91, H 6.79; found: C 67.92, H 6.70%. *Mol. Wt*: calcd. for $C_{21}H_{25}NO_5$: 371.173; found (hrms): 371.174.

2-[2-(3,4-Dimethoxyphenyl)-3,4-dimethoxyphenyl]-3,4,4-trimethyl-2-oxazolinium iodide

A solution of the product **8**, prepared above (3.71 g; 0.01 mol) and MeI (1.9 g; 0.015 mol) in nitromethane (7 mL) was heated at 70°C overnight. The cooled red reaction mixture was diluted with an equal volume of ether, ice-cooled, and filtered to furnish yellow crystals of the required quarternary salt (4.9 g; ~96%), mp 190–192°C; ir ($CHCl_3$): 3310, 2937, 1632, 1580, 1480, 1360, 1280, 1108, 918 cm^{-1}; ^{1}H nmr: 1.53 (6H, s, C—CH_3), 2.88 (3H, s, $=\overset{+}{N}$—CH_3), 3.57 (3H, s, OCH_3), 3.90 (3H, s, OCH_3), 3.93 (3H, s, OCH_3), 4.00 (3H, s, OCH_3), 5.03 (2H, s, CH_2), 6.70–7.30 (4H, m, Ar-H), 8.29 (1H, d, J = 7.5 Hz, Ar-H). *Anal.* calcd. for $C_{22}H_{28}NO_5I$: C 51.47, H 5.50; found: C 51.54, H 5.41%.

2-(3,4-Dimethoxyphenyl)-3,4-dimethoxybenzaldehyde 9

(A) To a stirred solution of the quarternary salt prepared above (5.1 g; 0.01 mol) in EtOH (40 mL) was added $NaBH_4$ (0.378 g; 0.01 mol) in portions at 0°C, and the mixture was stirred at 0°C for 4 h. The yellow reaction mixture was then diluted with 2 *M* HCl (80 mL) to give a red solution that was extracted with CH_2Cl_2, washed with brine, and dried. Removal of the solvent yielded a red oil which was purified by flash chromatography giving the required aldehyde as a white solid (2.1 g; 66%). A portion was recrystallized from 95% EtOH to give colorless crystals, mp 119–120°C; ir ($CHCl_3$): 2840, 1680, 1582, 1460, 1322, 1122, 940, 900 cm^{-1}; ^{1}H nmr: 3.57 (3H, s, OCH_3), 3.89 (3H, s, OCH_3), 3.95 (3H, s, OCH_3), 3.99 (3H, s, OCH_3), 7.20–7.43 (4H, m, Ar-H), 7.85 (1H, d, J = 9 Hz, Ar-H), 9.74 (1H, s, CHO) ppm; ms m/z: 302 (M^+, 100%), 287 (11%), 259 (14%), 229 (14%). *Anal.* calcd. for $C_{17}H_{18}O_5$: C 67.54, H 6.00%; found: C 67.51, H 6.28%. *Mol. Wt.* calcd. for $C_{17}H_{18}O_5$: 302.114; found (hrms): 302.108.

(B) A mixture of 2-bromo-3,4-dimethoxybenzaldehyde (1.22 g; 0.05 mol) and 4-iodoveratrole (2.64 g; 0.01 mol) was warmed on a steam bath to form a homogenous solution to which copper powder (30 g) was added in several portions according to the procedure of Brown and Robin (29). After each addition, the reaction mixture was centrifuged to form a compact mass which was then heated at 220–230°C for 1 h. After cooling, it was thoroughly washed with CH_2Cl_2 and filtered. The filtrate on evaporation furnished a red oil which was purified by flash chromatography, giving the required aldehyde as a white solid (0.2 g; 13%), mp 119–120°C.

2-(3,4-Dimethoxyphenyl)-3,4-dimethoxybenzylideneaminoacetaldehyde diethyl acetal 10

A mixture of aminoacetaldehyde diethyl acetal (0.732 g; 0.055 mol) and the aldehyde **9** (1.51 g; 0.005 mol) in dry benzene (25 mL)

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

was refluxed under a Dean–Stark trap until no further water was separated (14 h); removal of the solvent under vacuum then gave the required Schiff's base **10** as an oil (2.0 g; ~96%) which was used without further purification for either cyclization or reduction; ^{1}H nmr: 1.17 (6H, t, J = 6 Hz, CH_3), 3.53 (3H, s, OCH_3), 3.47–3.73 (6H, m, CH_2), 3.85 (3H, s, OCH_3), 3.93 (6H, s, 2 × OCH_3), 4.73 (1H, t, J = 5 Hz, CH_2—C*H*—O), 6.67–7.06 (4H, m, Ar-H), 7.86 (1H, d, J = 9 Hz, Ar-H), 7.97 (1H, s, CH=N) ppm.

N-[2-(3,4-Dimethoxyphenyl)-3,4-dimethoxy]benzylaminoacetaldehyde diethyl acetal ***11***

The benzylideneaminoacetal **10** (2.09 g; 0.005 mol) was dissolved in absolute ethanol (25 mL) and platinum dioxide (30 mg) was added. The solution was hydrogenated at 45 psi and 25°C for 16 h. The catalyst was filtered and the solvent evaporated under vacuum to yield the required benzylamino acetal **11** as a viscous oil (2.0 g; ~98%) which was used without further purification for attempted cyclization reactions; ^{1}H nmr: 1.13 (6 H, t, J = 6 Hz, CH_2CH_3), 2.53 (2H, d, J = 6 Hz, CH_2), 2.75 (2H, s, CH_2), 3.23–3.70 (5H, m, 2 × CH_2—O, NH), 3.57 (3H, s, OCH_3), 3.87 (3H, s, OCH_3), 3.90 (3H, s, OCH_3), 3.93 (3H, s, OCH_3), 4.45 (1H, t, J = 6 Hz, C*H*—O), 6.70–7.18 (5H, m, Ar-H) ppm.

8-Bromo-6,7-dimethoxyisoquinoline ***12***

A mixture of aminoacetaldehydediethylacetal (2.39 g; 0.018 mol) and 2-bromo-3,4-dimethoxybenzaldehyde (4.0 g; 0.0163 mol) in C_6H_6 was refluxed under a Dean–Stark trap until no further H_2O separated (6 h). The solvent was removed and the oily Schiff base was treated at 5°C with trifluoroacetic anhydride (17 mL).

This solution was added to the stirred solution of $BF_3 \cdot AcOH$ complex (40% BF_3; 12.3 g; 3 mol) in trifluoroacetic anhydride (20 mL) at 5°C. The solution was stirred for 48 h at room temperature and the deep cherry red mixture was poured into ice-water, basified with aqueous NH_3, and extracted with $CHCl_3$. The combined $CHCl_3$ extract was extracted with 4 *M* HCl, basified with aqueous NH_3 and extracted with CH_2Cl_2, washed, and dried. Evaporation of the solvent gave the required isoquinoline as a solid (1.26 g; 29%), mp 135–137°C; ir ($CHCl_3$): 2944, 2840, 1620, 1550, 1480, 1460, 1390, 1335, 1142, 995, 870, 850, cm^{-1}; ^{1}H nmr: 3.97 (3H, s, OCH_3), 4.03 (3H, s, OCH_3), 7.03 (1H, s, H-5), 7.43, (1H, d, J = 5 Hz, H-4), 8.43 (1H, d, J = 5 Hz, H-3), 9.45 (1H, s, H-1) ppm; ms m/z: 269 (M^+, 98%), 267 (100%), 254 (24%), 252 (25%), 226 (28%), 224 (34%), 173 (11%), 117 (16%), 102 (15%), 75 (20%). *Anal.* calcd. for $C_{11}H_{10}NO_2Br$: C 49.27, H 3.76; found: C 49.25, H 3.74%. *Mol. Wt.* calcd. for $C_{11}H_{10}NO_2{}^{79}Br$: 266.989; found (hrms): 266.993.

2-[2-(3,4-Dimethoxyphenyl)-3,4-dimethoxy-6-(2-hydroxyethyl)-phenyl]-4,4-dimethyl-2-oxazooline ***13***

To the stirred solution of the oxazoline (11.13 g; 0.03 mol) in dry THF (125 mL) under argon at −10°C was added n-BuLi (30 mL of 1.5 *M* in hexane; 0.045 mol) and the mixture further stirred at −5 to −10°C for 6 h. The resulting deep red solution was treated with ethylene oxide (12 mL) at −10°C and immediately a balloon (5 L capacity) was fixed at the top of the reflux condenser to keep the ethylene oxide atmosphere under slight pressure throughout the reaction time. The mixture was stirred for 3 h at −5 to −10°C and allowed to warm up to room temperature overnight. Water (40 mL) was added, the THF evaporated, and the aqueous phase extracted with CH_2Cl_2, washed with brine, and dried. Distillation of the solvent gave a red oil which was purified by flash chromatography, giving a yellow oil (7.6 g; 61%) which was crystallized from ethyl acetate – petroleum ether to furnish the required alcohol as a white solid (5.5 g; 44%) mp 131–132°C; ir ($CHCl_3$): 3200, 2940, 2840, 1650, 1582, 1460, 1355, 1320, 1135, 1070, 1000, 965, 858 cm^{-1}; ^{1}H nmr: 1.23 (6H, s, C—CH_3), 2.91 (2H, t, J = 6 Hz, CH_2) 3.48 (3H, s, OCH_3), 3.63 (2H, s, CH_2), 3.85 (3H, s, OCH_3), 3.90 (6H, s, OCH_3), ca. 3.9 (2H, t, CH_2OH, obscured by OMe signal), 5.06 (1H, bs, OH), 6.83–6.93 (4H, m, Ar-H) ppm; ms m/z: 415 (M^+, 30%), 414 (30%), 397 (83%), 384 (100%), 369 (30%). *Anal.* calcd. for $C_{23}H_{29}NO_6$: C 66.49, H 7.04; found: C 66.52, H, 7.01%. *Mol. 3,4-Dihydro-6,7-dimethoxy-8-(3,4-dimethoxyphenyl)isocoumarin ***14***

A mixture of the oxazoline prepared above (8.3 g; 0.02 mol) and 3 *M* HCl (250 mL) was stirred under reflux for 20 min. The solid that separated from the hot red reaction mixture was filtered after cooling, washed with H_2O, and dried to furnish the required isocoumarin as a white solid (6.88 g; 79%), a portion of which was crystallized from 95% EtOH giving colorless, long needles, mp 194–195°C; ir ($CHCl_3$): 2940, 2840, 1725, 1585, 1455, 1386, 1352, 1260, 1136, 1090, 1010, 990 cm^{-1}; ^{1}H nmr: 3.00 (2H, t, J = 6 Hz, CH_2), 3.48 (3H, s, OCH_3), 3.85 (3H, s, OCH_3), 3.91 (3H, s, OCH_3), 3.95 (3H, s, OCH_3), 4.45 (2H, t, J = 6 Hz, CH_2O), 6.67–6.95 (4H, m, Ar-H) ppm; ms m/z: 344 (M^+, 100%), 329 (12%), 165 (12%). *Anal.* calcd. for $C_{19}H_{20}O_6$: C 66.27, H 5.86%; found: C 66.21, H 5.92%.

N-*Benzyl-6-(2-hydroxyethyl)-2-(3,4-dimethoxyphenyl)-3,4-dimethoxybenzamide* ***15***

A mixture of the isocoumarin (5.1 g; 0.0148 mol) and benzylamine hydrochloride (3.05 g; 0.0213 mol) in benzylamine (20 mL) was stirred at 120–125°C for 24 h. The red solution was cooled, poured into 5% HCl (200 mL), and extracted with CH_2Cl_2. The combined CH_2Cl_2 extract was washed with 5% HCl, H_2O, and dried. Removal of the solvent furnished a red oil which was purified by flash chromatography giving the required benzamide as a white solid (5.85 g; ~88%), mp 58–60°C; ir ($CHCl_3$): 3440, 3350, 2940, 2840, 1736, 1640, 1580, 1460, 1315, 1135, 1000 cm^{-1}; ^{1}H nmr: 2.83 (2H, t, J = 6 Hz, $PhCH_2$), 3.40 (3H, s, OCH_3), 3.73 (3H, s, OCH_3), 3.87 (6H, s, OCH_3), ca. 3.9 (2H, CH_2OH, obscured by OMe signal), 4.30 (2H, d, J = 6 Hz, CH_2—N), 5.22 (1H, s, OH), 5.69 (1H, t, J = 6 Hz, NH), 6.86–7.50 (9H, m, Ar-H) ppm, ms m/z: 451 (M^+, 30%), 433 (72%), 432 (42%), 342 (37%), 327 (23%), 315 (28%), 297 (33%), 91 (100%). *Mol. Wt*: calcd. for $C_{26}H_{29}NO_6$: 451.196; found (hrms): 451.200.

N-*Benzyl-6-[2-(methylsulfonyloxy)ethyl]-2-(3,4-dimethoxyphenyl)-3,4-dimethoxybenzamide*

A solution of the alcohol **15** (6.76 g; 0.015 mol) and mesyl chloride (3.44 g; 0.03 mol) in dry pyridine (50 mL) was left in the refrigerator overnight. The resulting yellow solution was poured into cold H_2O (100 mL) and extracted with CH_2Cl_2. The combined CH_2Cl_2 extract was washed with 5% HCl, H_2O, and dried. Removal of the solvent gave the required mesylate as a yellow oil (7.66 g; 97%), which was pure enough for the next step.

2-Benzyl-3,4-dihydro-6,7-dimethoxy-8-(3,4-dimethoxyphenyl)-1-(2H)isoquinolinone ***16***

A mixture of the above mesylate (7.66 g; 0.0145 mol) and NaH (50% suspension in oil; 1.738 g; 0.036 mol) in dry THF (150 mL) was stirred under reflux overnight. The mixture was cooled and the excess of NaH was decomposed with H_2O. The THF was removed and the residue was taken up in CH_2Cl_2, washed with H_2O, and dried. Evaporation of the solvent yielded a red viscous liquid which was thoroughly washed with petroleum ether (to remove paraffin oil) to give a yellow solid, which was crystallized from ethyl acetate – petroleum ether to furnish the required isoquinolinone as a white solid (3.82 g; 71%), mp 140–141°C; ir ($CHCl_3$): 2940, 2840, 1668, 1590, 1464, 1385, 1350, 1318, 1135, 1095, 1010 cm^{-1}; ^{1}H nmr: 2.92 (2H, t, J = 6 Hz, $PhCH_2$) 3.47 (3H, s, OCH_3), 3.79 (3H, s, OCH_3), 3.92 (6H, s, OCH_3), 4.30 (2H, t, J = 6 Hz, N—CH_2), 4.37 (2H, s, $PhCH_2$—N), 6.67–7.2 (9H, m, Ar-H) ppm; ms m/z: 433 (M^+, 49%), 432 (100%), 418 (13%), 341 (26%), 326 (10%), 91 (30%). *Anal.* calcd. for $C_{26}H_{27}O_5N$: C 72.04, H 6.28, N 3.23%; found: C 72.08, H 6.40, N 3.01%.

N-*Methyl-6-(2-hydroxyethyl)-2-(3,4-dimethoxyphenyl)-3,4-dimethoxybenzamide* ***17***

A mixture of the isocoumarin **14** (2.55 g; 0.074 mol) and methyl amine (40% aqueous solution; 10 mL) in CH_3OH (35 mL) in a round-bottom flask fitted with a reflux condenser and balloon (5 L capacity) at the top (to prevent the escape of methyl amine gas) was heated under reflux with stirring for 24 h. Upon cooling, the green reaction mixture was diluted with H_2O (10 mL), the CH_3OH evaporated, and the

2,3-Dihydro-5,6,8,9-tetramethoxy-1-methylindeno[1,2,3-ij]-isoquinolinium chloride ***20***

A mixture of *N*-methylisoquinolinone prepared above (1.5 g; 0.0042 mol) and $POCl_3$ (1.3 g; 0.0085 mol) in dry toluene (25 mL) was refluxed under argon for 4 h. The dark brown reaction mixture was cooled, diluted with an excess of petroleum ether, ice-cooled, and filtered to give brown crystals of the cyclized product (1.5 g; 96%), mp 117–120°C; ir ($CHCl_3$) 2940, 1670, 1594, 1464, 1402, 1280, 1100, 994 cm^{-1}; ^1H nmr: (CF_3COOH): 3.23 (2H, t, J = 7.5 Hz, CH_2), 3.97 (3H, s, $=\overset{+}{N}CH_3$), 4.08 (6H, s, OCH_3), 4.17 (6H, s, OCH_3), 4.33 (2H, t, J = 7.5 Hz, *CH*$_2$—N), 6.67 (1H, s, Ar-H), 7.50 (1H, s, Ar-H), 7.60 (1H, s, Ar-H) ppm.

1,2,3,10b-Tetrahydro-5,6,8,9-tetramethoxy-1-methylindeno-[1,2,3-ij]isoquinoline ***5***

To a stirred solution of the quarternary salt prepared above (0.751 g; 0.002 mol) in EtOH (20 mL) was added $NaBH_4$ (0.228 g; 0.006 mol) in small portions (10 min) and further stirred for 2 h at room temperature. During this time the deep brown reaction mixture became colorless. The excess of $NaBH_4$ was destroyed by adding glacial acetic acid, the CH_3OH evaporated, and the residue treated with H_2O (10 mL), basified to pH >10 with NaOH, and extracted with CH_2Cl_2. The combined CH_2Cl_2 extract was washed with brine and dried. Evaporation of the solvent furnished a gum (0.412 g; 61%). The base was recovered from the purified hydrochloride (*vide infra*) for spectroscopic analysis; ir ($CHCl_3$): 2940, 2840, 1605, 1580, 1462, 1400, 1320, 1290, 1260, 1100, 998 cm^{-1}; ^1H nmr (250 MHz): 2.30 (3H, s, NCH_3), 2.8 (2H, m, H's at C-3), 3.2 (2H, m, H's at C-2), 3.85 (3H, s, OCH_3), 3.90 (3H, s, OCH_3), 3.93 (3H, s, OCH_3), 3.96 (3H, s, OCH_3), 4.27 (1H, s, H-10b), 6.51 (1H, s, Ar-H), 7.18 (1H, s, Ar-H), 7.52 (1H, s, Ar-H) ppm; ^{13}C nmr: 24.03 (t, C-3), 38.74 (q, N—Me), 54.31 (t, C-2) 56.35 (q, 3 × OCH_3), 60.64 (q, 1 × OCH_3), 67.56 (d, C-10b) 107.17, 109.23, 109.57 (all d's, C-4, C-7, C-10) 127.53, 131.95, 133.27, 135.06, 137.51, 142.56, 148.66, 149.60, 153.82 (all s's, other aromatic C-atoms); ms *m/z*: 341 (M^+, 45%), 340 (68%), 326 (24%), 310 (100%), 296 (10%), 283 (25%). *Mol. Wt.* calcd. for $C_{20}H_{22}NO_4$ (M − 1): 340.155; found (hrms): 340.152.

The free base was dissolved in ethanol and treated with dry HCl. Upon addition of ether the hydrochloride crystallized as a white solid. Recrystallization from ethanol–ether gave colorless crystals, mp 207–209°C. The hydrochloride was highly solvated and failed to give satisfactory analysis even after prolonged drying at 70°C at 1.0 Torr. The ^1H nmr ($CDCl_3$, 250 MHz) of the hydrocloride showed that the crystals contained roughly 5 moles of water. The following signals were observed: −1.75 (ca. 10H, H_2O), 2.24 (d, N—Me, J = 5 Hz), 2.9–3.7 (m, 4H, H's at C-2 and C-3), 3.90, 3.96, 3.97, 3.98 (4s, 3H each, 4 × OCH_3), 5.20 (s, 1H, H-10b), 6.58, 7.47, 8.01 (3s, 1H each, 3 × Ar-H) ppm.

2,3-Dihydro-5,6,8,9-tetramethoxy-1-benzylindeno[1,2,3-ij]-isoquinolinium chloride ***19***

A mixture of *N*-benzylisoquinolinone **16** (0.866 g; 0.002 mol) and $POCl_3$ (0.616 g; 0.004 mol) in dry toluene (15 mL) was refluxed under argon for 4 h. The dark brown reaction mixture was cooled, diluted with an excess of petroleum ether, ice-cooled, and filtered to give brown crystals of the cyclized product (0.8 g; 92%) mp 134–136°C; ir ($CHCl_3$): 2940, 2840, 1660, 1610, 1595, 1500, 1464, 1408, 1350, 1282, 1164, 1086, 1005 cm^{-1}; ^1H nmr (CF_3COOH): 3.13 (2H, t, J = 7.5 Hz, CH_2), 3.75 (3H, s, OCH_3), 3.97 (3H, s, OCH_3), 4.05 (6H, s, OCH_3), 4.18 (2H, t, J = 7.5 Hz, CH_2), 5.35 (2H, s, CH_2), 6.55 (1H, s, Ar-H), 7.18–7.55 (7H, m, Ar-H) ppm.

1,2,3,10b-Tetrahydro-5,6,8,9,-tetramethoxy-1-benzylindeno-[1,2,3-ij]isoquinoline **6**

To a stirred solution of the quarternary salt **19** (0.451 g; 0.001 mol) in EtOH (10 mL) was added $NaBH_4$ (0.114 g; 0.003 mol) in small portions (10 min) and the solution further stirred for 2.5 h at room temperature. During this time the deep brown reaction mixture became faint yellow. The excess of $NaBH_4$ was destroyed by adding glacial acetic acid, the CH_3OH evaporated, and the residue treated with H_2O (5 mL), basified to pH >10 with NaOH, and extracted with CH_2Cl_2. The combined CH_2Cl_2 extract was washed with brine and dried. Removal of the solvent furnished the required indenotetrahydroisoquinoline as a gum (0.30 g; 74%). The base was recovered from the purified hydrochloride (*vide infra*) before spectroscopic analysis; ir ($CHCl_3$): 2940, 2840, 1610, 1500, 1468, 1400, 1290, 1108, 1090, 1002 cm^{-1}; ^1H nmr (250 MHz): 2.66–2.94 (2H, m, H's at C-3), 3.15–3.32 (2H, m, H's at C-2), 3.35 (2H, s, N—CH_2—Ph), 3.90 (3H, s, OCH_3), 3.93 (3H, s, OCH_3), 4.01 (3H, s, OCH_3), 4.02 (3H, s, OCH_3), 4.77 (1H, s, H-10b), 6.59 (1H, s, Ar-H), 7.17 (1H, s, Ar-H), 7.20–7.35 (5H, m, Ar-H), 7.59 (1H, s, Ar-H) ppm; ms *m/z*: 417 (M^+, 65%), 416 (52%), 402 (37%), 387 (29%), 386 (64%), 325 (11%), 298 (43%), 283 (15%), 91 (100%), 65 (47%). *Mol. Wt.* calcd. for $C_{26}H_{27}NO_4$: 417.194; found (hrms): 417.194. The free base was converted to its hydrochloride in ether solution and recrystallized from ethanol, mp 185–187°C. The hydrochloride was highly solvated and failed to give satisfactory elemental analysis even after prolonged drying at 70°C and 1.0 Torr. In the nmr (250 MHz) spectrum, peaks were present at 1.23 (t) and 3.72 (q) attributed to ethanol of solvation and at 1.58 (s) attributed to water of solvation. The signals attributed to the compound itself appeared as follows: 2.80–3.45 (4H, complex m, H's at C-2 and C-3), 3.7 (1H, underlying CH_2 of EtOH, one H from the N—*CH*$_2$—Ph), 3.94 (3H, s, OCH_3), 3.98 (3H, s, OCH_3), 4.02 (6H, s, 2 × OCH_3), 4.11–4.18 (1H, dd, one H from N—*CH*$_2$Ph), 5.41 (1H, s, H-10b), 6.61 (1H, s, Ar-H), 7.35 and 7.58 (5H, 2 multiplets, aromatic H's of benzyl group), 7.50 (1H, s, Ar-H), 8.31 (1H, s, Ar-H), 13.85 (1H, bs, NH) ppm.

Received April 27, 1982

L. V. HALEY and J. A. KONINGSTEIN. Can. J. Chem. **61**, 14 (1983).

We present a modification of a supermolecule model of a general chlorophyll dimer, and calculate the excited state electronic Raman selection rules between the various singlet states. The model utilizes the electronic part of the total wavefunction within the strong intermolecular coupling scheme. Under this condition and the neglect of underlying orbitals, the electronic wave function of the dimer is reduced to a four orbital function with each monomer contributing one HOMO and one LUMO. Using a Hückel type molecular orbital calculation, the one electron orbital energies and coefficients of the ground and excited state wavefunctions of the dimer are obtained and are shown to depend explicitly on the ground and excited state intermolecular interaction terms. The resulting Raman activity calculation between the various excited state configurations yields two types of tensor elements: (*1*) contains only coordinates of the individual monomer α_1 (molecule 1) and α_2 (molecule 2) and are called spatially localized elements and (*2*) labelled spatially delocalized and contains coordinates of both monomer molecules simultaneously (α_3 and α_4).

L. V. HALEY et J. A. KONINGSTEIN. Can. J. Chem. **61**, 14 (1983).

Nous présentons une modification d'un modèle de super molécule pour un dimère général de la chlorophylle et nous calculons les règles de sélection Raman électronique de l'état excité entre les divers états singulets. Le modèle utilise la partie électronique de la fonction d'onde globale à l'intérieur du schéma de couplage intermoléculaire fort. Dans ces conditions et en négligeant les orbitales soulignées, on réduit la fonction d'onde électronique du dimère à 4 fonctions d'orbitales; chaque monomère contribuant une fonction HOMO et une base vacante. Faisant appel à un calcul d'orbitale moléculaire de type Hückel, on a obtenu les énergies de l'orbitale à un électron et les coefficients des fonctions d'onde des états fondamental et excité du dimère et on montre qu'elles dépendent explicitement des termes de l'interaction intermoléculaire des états fondamental et excité. Le calcul de l'activité Raman résultant entre les diverses configurations de l'état excité donne deux types d'éléments de tension: (*1*) il contient uniquement les coordonnées du monomère individuel α_1 (molécule 1) et α_2 (molécule 2) et on les appelle des éléments localisés spatialement et (*2*) des éléments marqués délocalisés spatialement qui contiennent simultanément les coordonnées des deux monomères (α_3 et α_4).

[Traduit par le journal]

I. Introduction

In the past, laser-induced electronic Raman transitions have been induced and recorded from many types of systems like rare earth (1) or transition metal ions (2) in solids, of molecules (3) or molecular complexes (4) and recently also of optical-pumped excited electronic states (5). The selection rules — and in some cases the theory (6) for the intensity (3, 6) — of the electronic Raman effect are well understood and in this paper we consider the case of an electronic Raman effect between excited states of chlorophyll dimers. The structure of such dimers is dynamic and monomeric chlorophyll molecules assume the roles of donor and acceptors (7). The frequency associated with the change in roles is smaller than the duration of a Raman transition, hence one expects a well-defined light scattering spectrum. Using time-resolved fluorescence spectroscopy, an insight has been obtained of the excited state separation of a chlorophyll dimer in pyridine (8). An energy level diagram (9, 10) of the excited states of dimers has been published; however, in the present work a more complete analysis is made. The position of excited state discussed here is based on various excited state configurations which arise from the occupation of orbitals, related to the highest occupied and lowest unoccupied molecular orbital levels of monomeric chlorophyll molecules. A series of excited level electronic Raman transitions are predicted and an insight is obtained of the selection rules. The lifetime of these excited states is such that sufficient populations can be created during optical pumping with pulsed lasers. That part of the laser radiation not used for pumping may then be employed as a Raman probe to induce the electronic transitions, this method has been shown to yield good results for other systems (11–14).

II. Ground and excited state wavefunctions for chlorophyll dimers

Presently, there are several publications containing information on the process which governs the intensity of the fluorescence transitions of dimeric Chl *a* in solution (9, 10). These transitions originate from a number of excited states, and they are derived from various possible excited electronic configurations. In the present study, we are primarily concerned with Raman scattering between some of these excited states and the details of the electronic scattering process will be given in the next section.

Our starting point is centered around the occupation of the two sets of orbitals of a general dimer which are related to the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital levels (LUMO) of the monomer (see Fig. 1*a*) where the individual chromophor molecules 1 and 2 are not necessarily identical. The monomer levels for molecule 1 are separated by Δm cm^{-1}, and for molecule 2, the splitting is $\Delta m'$ cm^{-1}. In the dimer, the orbital splitting is δ_g for the ground state and δ_{ex}

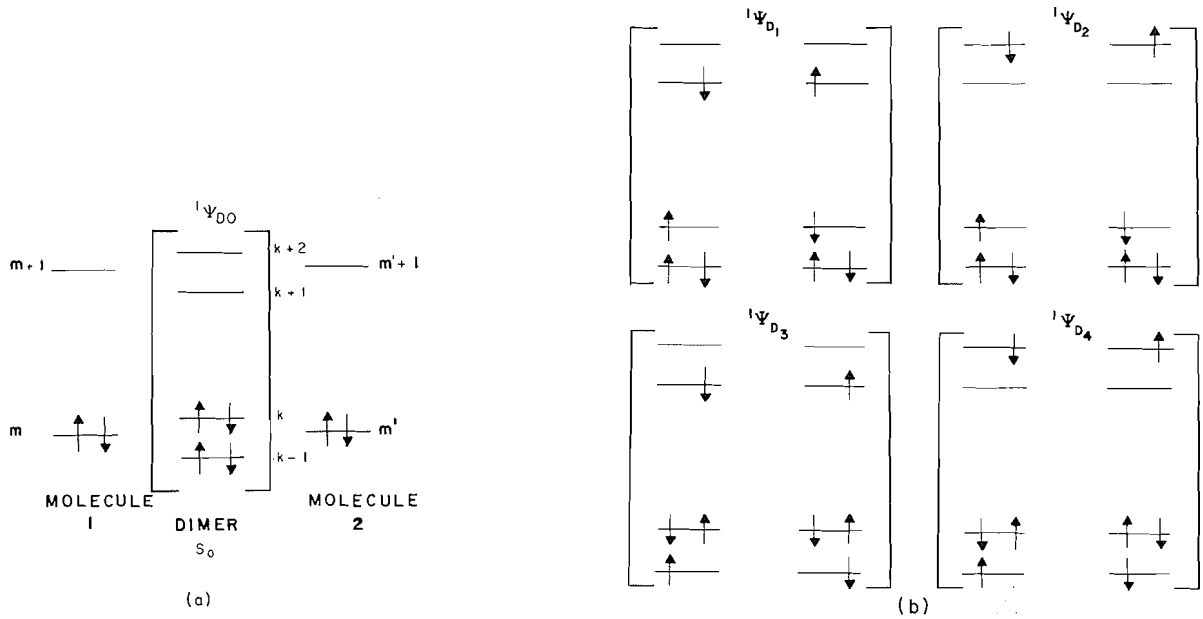

FIG. 1. (*a*) Ground state orbital schematic of a four orbital chlorophyll dimer model, (m, m') and (m + 1, m' + 1) are the monomer HOMO and LUMO respectively. $k-1$, k, k + 1, and k + 2 represent the HOMO − 1, HOMO, LUMO, and LUMO + 1 of the dimer respectively. (*b*) Configuration of the various excited states of the dimer. Orbital labelling is the same as in (*a*).

for the excited state (see below for definitions of δ_g and δ_{ex}). In general, the $S_1 \rightarrow S_0$ fluorescence of the monomer occurs in the 660–730 nm spectral region (8, 15), and with $\delta_g \neq \delta_{ex} \ll \Delta m, \Delta m'$ cm^{-1}, we expect the fluorescence of the dimer also to occur in this region. It is well known that dimeric Chl *a* units assume the role of donor and acceptor molecules with a dynamic structure (7), and we assume this phenomenon is also active in the general case. The frequency of this process is slower than the duration of the Raman transition between electronic levels of the dimer, consequently the dimer may be considered as an asymmetric donor–acceptor molecule.

In the theory of the transfer of electronic energy between two or more molecules (16), the amount of interaction between the molecules is characterized by an intermolecular potential energy term. The size of this term determines the strength of the coupling among the molecules. For chlorophyll molecules with an intermolecular distance less than or equal to the usual van der Waals contact distance (3.4–3.6 Å) (17), a supermolecule formation can be expected with a large interaction between the monomer molecules. In the exciton model theory (16), this situation would be the strong interaction or strong coupling limiting case. Under these conditions and within the Born–Oppenheimer approximation, the wave function for the singlet ground state of the dimer is

$$[1] \quad {}^1\Psi_{ev} = {}^1\Psi_{D0}\,\theta_v$$

where $^1\Psi_{D0}$ is the electronic wave function and θ_v the vibrational wave function. In the present study, we will only consider the electronic part of the total wave function for the derivation of the selection rules for the Raman transitions.

Recent *ab initio* calculations (18) predict a π type HOMO for chlorophyllide *a* and related molecules, therefore we can reduce the formal $2N_T$ electron description of the dimer where N_T is the total number of π electrons in a monomer molecule to a four π electron problem if we assume that neglected molecular orbitals are not significantly involved in the stabilization of the dimer. Under this condition, the electronic ground state wave function for the dimer is

$$[2] \quad {}^1\Psi_{D0} = N_0 \mid \psi_{k-1}\bar{\psi}_{k-1}\psi_k\bar{\psi}_k \mid$$

where N_0 is a normalization constant and the subscripts k and $k-1$ are the HOMO and HOMO − 1 respectively. Since the individual chlorophyll molecules of the dimer are highly conjugated systems of carbon, nitrogen, and oxygen atoms, a simple Hückel type model will be adequate for the present calculation.

The monomer HOMO's ϕ_m and $\phi_{m'}$, denoted as (m) and (m') in Fig. 1*a*, are taken to be Hückel-type molecular orbitals with $\langle\phi_m \mid \phi_{m'}\rangle = 0$. In order to calculate the dimer molecular orbitals ψ_k and ψ_{k-1} in a modification of a supermolecule model (19), the following effective one electron Hamiltonian is used:

$$[3] \quad \hat{\mathcal{H}} = \hat{\mathcal{H}}_1 + \hat{\mathcal{H}}_2$$

where $\hat{\mathcal{H}}_1$ and $\hat{\mathcal{H}}_2$ are the monomer Hamiltonians. Diagonalization of the appropriate secular equation yields the eigenvalue results

$$[4] \quad \epsilon'_D(\pm) = \left(\frac{\epsilon_m + \epsilon_{m'}}{2}\right) \pm \frac{1}{2}\sqrt{(\epsilon_m - \epsilon_{m'})^2 + 4H^2_{m,m'}}$$

where ϵ_m and $\epsilon_{m'}$ are the one electron orbital energies of molecules 1 and 2 respectively, and $H_{m,m'}$ is the one electron intermolecular interaction term. In terms of the notation given in eq. [2], the eigenvalue for the HOMO of the dimer is $\epsilon'_D(+) = \epsilon_k$ with the eigenvector

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

[5] $$\psi_k = \frac{1}{\sqrt{2}}[{}^gC_{11}\phi_m + {}^gC_{12}\phi_{m'}]$$

with

[6] $${}^gC_{11} = \left\{1 + \frac{(\epsilon_m - \epsilon_{m'})}{[(\epsilon_m - \epsilon_{m'})^2 + 4H^2_{m,m'}]^{1/2}}\right\}^{1/2}$$

[7] $${}^gC_{12} = \left\{1 - \frac{(\epsilon_m - \epsilon_{m'})}{[(\epsilon_m - \epsilon_{m'})^2 + 4H^2_{m,m'}]^{1/2}}\right\}^{1/2}$$

For the HOMO − 1, $\epsilon'_D(-) = \epsilon_{k-1}$ and the resulting eigenvector is

[8] $$\psi_{k-1} = \frac{1}{\sqrt{2}}[{}^gC_{21}\phi_m - {}^gC_{22}\phi_{m'}]$$

and

[9] $${}^gC_{21} = \left\{1 - \frac{(\epsilon_m - \epsilon_{m'})}{[(\epsilon_m - \epsilon_{m'})^2 + 4H^2_{m,m'}]^{1/2}}\right\}^{1/2}$$

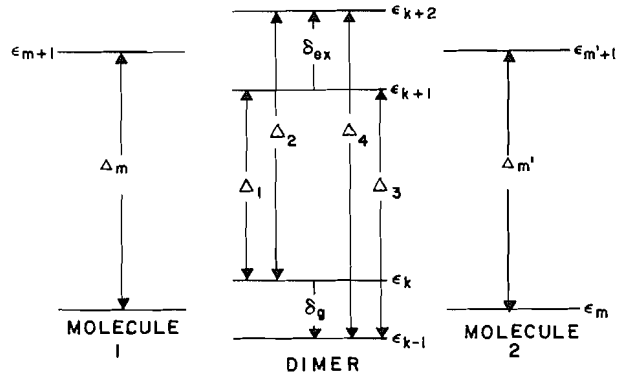

FIG. 2. One electron energy schematic for the monomer and dimer molecules. Terms are defined in the text.

[10] $${}^gC_{22} = \left\{1 + \frac{(\epsilon_m - \epsilon_{m'})}{[(\epsilon_m - \epsilon_{m'})^2 + 4H^2_{m,m'}]^{1/2}}\right\}^{1/2}$$

To obtain the LUMO and LUMO + 1 of the dimer, let the monomer levels $(m + 1)$ and $(m' + 1)$ in Fig. 1*a* be represented by the Hückel type wave functions ϕ_{m+1} and $\phi_{m'+1}$ respectively. Also, $\langle\phi_{m+1}|\phi_{m'+1}\rangle = 0$. Using eq. [3], the ϕ_{m+1} and $\phi_{m'+1}$ wave functions, and standard matrix algebra, we obtain the following eigenvalues:

[11] $$\epsilon''_D(\pm) = \left(\frac{\epsilon_{m+1} + \epsilon_{m'+1}}{2}\right) \pm \frac{1}{2}\sqrt{(\epsilon_{m+1} - \epsilon_{m'+1})^2 + 4H^2_{m+1,m'+1}}$$

The corresponding dimer wave functions of $\epsilon''_D(-) = \epsilon_{k+1}$ and $\epsilon''_D(+) = \epsilon_{k+2}$ (LUMO and LUMO + 1 respectively) are

[12] $$\psi_{k+1} = \frac{1}{\sqrt{2}}[{}^cC_{11}\phi_{m+1} - {}^cC_{12}\phi_{m'+1}]$$

[13] $$\psi_{k+2} = \frac{1}{\sqrt{2}}[{}^cC_{21}\phi_{m+1} + {}^cC_{22}\phi_{m'+1}]$$

with

[14] $${}^cC_{11} = {}^cC_{22} = \left\{1 - \frac{(\epsilon_{m+1} - \epsilon_{m'-1})}{[(\epsilon_{m+1} - \epsilon_{m'+1})^2 + 4H^2_{m+1,m'+1}]^{1/2}}\right\}^{1/2}$$

[15] $${}^cC_{12} = {}^cC_{21} = \left\{1 + \frac{(\epsilon_{m+1} - \epsilon_{m'+1})}{[(\epsilon_{m+1} - \epsilon_{m'+1})^2 + 4H^2_{m+1,m'+1}]^{1/2}}\right\}^{1/2}$$

Using the four electron model described in the above calculation, the expression for the orbital splitting between ψ_k and ψ_{k-1} is found to be

[16] $$\delta_g = \sqrt{(\epsilon_m - \epsilon_{m'})^2 + 4H^2_{m,m'}}$$

and

[17] $$\delta_{ex} = \sqrt{(\epsilon_{m+1} - \epsilon_{m'+1})^2 + 4H^2_{m+1,m'+1}}$$

for the ψ_{k+1} and ψ_{k+2} orbital splitting. In the present discussion, we assume that the $\delta_{ex} > \delta_g$ due to a geometry change of the chlorophyll molecules in their excited state. The above results are collected and shown in Fig. 2.

Within the four orbital model of chlorophyll dimers, four single excited state configurations can be derived from the orbitals shown in Fig. 1*a*. They give rise to four state functions:

[18] $${}^1\Psi_{D1} = N_1[\,|\,\psi_{k-1}\bar{\psi}_{k-1}\psi_k\bar{\psi}_{k+1}\,| - |\,\psi_{k-1}\bar{\psi}_{k-1}\bar{\psi}_k\psi_{k+1}\,|\,]$$

[19] $${}^1\Psi_{D2} = N_1[\,|\,\psi_{k-1}\bar{\psi}_{k-1}\psi_k\bar{\psi}_{k+2}\,| - |\,\psi_{k-1}\bar{\psi}_{k-1}\bar{\psi}_k\psi_{k+2}\,|\,]$$

[20] $${}^1\Psi_{D3} = N_1[\,|\,\psi_{k-1}\bar{\psi}_k\psi_k\bar{\psi}_{k+1}\,| - |\,\bar{\psi}_{k-1}\psi_k\bar{\psi}_k\psi_{k+1}\,|\,]$$

[21] $${}^1\Psi_{D4} = N_1[\,|\,\psi_{k-1}\bar{\psi}_k\psi_k\bar{\psi}_{k+2}\,| - |\,\bar{\psi}_{k-1}\psi_k\bar{\psi}_k\psi_{k+2}\,|\,]$$

Schematic representations of the excited singlet state configurations are shown in Fig. 1*b*.

Before discussing the selection rules for the Raman processes in the dimer system, the calculation of the excitation energies and energy differences among the excited state configurations will be necessary. Four excitation energies can be found to arise from

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

the ground state level to the levels described by the wave functions given in eqs. [18]–[21]. For the excitation energy between $^1\Psi_{D1}$ and $^1\Psi_{D0}$, we can use the following calculation

[22] $\langle {}^1\Psi_{D1} \mid \hat{\mathcal{H}} \mid {}^1\Psi_{D1}\rangle - \langle {}^1\Psi_{D0} \mid \hat{\mathcal{H}} \mid {}^1\Psi_{D0}\rangle = \epsilon_{k+1} - \epsilon_k = \Delta_1$

where $\epsilon_{k+1}$and ϵ_k are the one electron energies given by eqs. [4] and [11]. The analogous expressions for the remaining transitions are

[23] $\langle {}^1\Psi_{D2} \mid \hat{\mathcal{H}} \mid {}^1\Psi_{D2}\rangle - \langle {}^1\Psi_{D0} \mid \hat{\mathcal{H}} \mid {}^1\Psi_{D0}\rangle = \epsilon_{k+2} - \epsilon_k = \Delta_2$

[24] $\langle {}^1\Psi_{D3} \mid \hat{\mathcal{H}} \mid {}^1\Psi_{D3}\rangle - \langle {}^1\Psi_{D0} \mid \hat{\mathcal{H}} \mid {}^1\Psi_{D0}\rangle = \epsilon_{k+1} - \epsilon_{k-1} = \Delta_3$

and

[25] $\langle {}^1\Psi_{D4} \mid \hat{\mathcal{H}} \mid {}^1\Psi_{D4}\rangle - \langle {}^1\Psi_{D0} \mid \hat{\mathcal{H}} \mid {}^1\Psi_{D0}\rangle = \epsilon_{k+2} - \epsilon_{k-1} = \Delta_4$

If eqs. [4] and [11] are substituted into eqs. [22]–[25], the excitation energies can be obtained in terms of the individual monomer transition energies, ground and excited state interaction energy terms. We find that

[26] $\Delta_1 = \frac{1}{2}[\Delta m + \Delta m'] - \frac{1}{2}[\delta_{ex} + \delta_g]$

[27] $\Delta_2 = \frac{1}{2}[\Delta m + \Delta m'] + \frac{1}{2}[\delta_{ex} - \delta_g]$

[28] $\Delta_3 = \frac{1}{2}[\Delta m + \Delta m'] - \frac{1}{2}[\delta_{ex} - \delta_g]$

[29] $\Delta_4 = \frac{1}{2}[\Delta m + \Delta m'] + \frac{1}{2}[\delta_{ex} + \delta_g]$

where

[30] $\Delta m = \epsilon_{m+1} - \epsilon_m$

[31] $\Delta m' = \epsilon_{m'+1} - \epsilon_m$

The ϵ_{m+1}, $\epsilon_{m'+1}$, ϵ_m, and $\epsilon_{m'}$ are the one electron orbital energies of the LUMO and HOMO of the respective monomers. With the given condition of $\delta_{ex} > \delta_g$, the following order is found $\Delta_4 > \Delta_2 > \Delta_3 > \Delta_1$.

Using eqs. [26]–[31], the energy differences between the excited states can be calculated and the six differences are

[32] $\Delta_4 - \Delta_3 = \delta_{ex}$

[33] $\Delta_2 - \Delta_1 = \delta_{ex}$

[34] $\Delta_4 - \Delta_2 = \delta_g$

[35] $\Delta_3 - \Delta_1 = \delta_g$

[36] $\Delta_4 - \Delta_1 = \delta_{ex} + \delta_g$

[37] $\Delta_2 - \Delta_3 = \delta_{ex} - \delta_g$

The results shown in eqs. [32]–[37] predict four first order Raman transitions eqs. [32]–[35], with accidental degeneracies encountered in the difference pairs eqs. [32], [33] and eqs. [34], [35]. The sum and difference of the interaction energies in eqs. [36] and [37] will be observed as second order Raman transitions; consequently we will not consider this type of transition in the following discussions.

III. Theory for excited state Raman scattering

Let us assume the following experimental conditions: (*1*) a chlorophyll dimer solution with a concentration of approximately 10^{-4} *M* is prepared for irradiation with a pulsed laser; (*2*) the laser radiation has a wavelength and sufficient power necessary to populate the first singlet state $^1\Psi_{D1}$; and (*3*) within the time of the laser pulse, there is the necessary energy remaining to produce a light scattering process among the excited states. Once the above conditions have been satisfied, the Raman spectrum of the chlorophyll dimer can be observed if the Raman activity between the excited states is allowed. To determine the electronic Raman activity, we start with an expression similar to that of the case for resonance enhancement of vibrational Raman scattering (20). The resulting expectation value of the dimer Raman operator α_D between the $^1\Psi_{D1}$ and $^1\Psi_{D2}$ states is

$$\langle {}^1\Psi_{D1} \mid \hat{\alpha}_D \mid {}^1\Psi_{D2}\rangle$$

where

[38] $$\hat{\alpha}_D = \frac{1}{h}\sum_{s_D}\left\{\frac{[\,\langle \hat{r}_\sigma(D) \mid s_D\rangle\langle s_D \mid \hat{r}_\rho(D)\,\rangle]}{\nu_{s_D} - \nu_0} + \frac{[\rho \leftrightarrow \sigma]}{\nu_{s_D} + \nu_0}\right.$$

for the non-resonant case. Here $\hat{r}_\sigma(D)$ and $\hat{r}_\rho(D)$ are the dimer dipole moment operators and s_D are the virtual state wave functions of the dimer. If we let

[39] $\hat{r}_\sigma(D) = \hat{r}_\sigma + \hat{r}'_\sigma$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

[40] $\hat{r}_\rho(D) = \hat{r}_\rho + \hat{r}'_\rho$

where the dipole moment operators $(\hat{r}_\sigma, \hat{r}_\rho)$ and $(\hat{r}'_\sigma, \hat{r}'_\rho)$ are defined with respect to the coordinates of molecule 1 and molecule 2 of the dimer respectively. Substitution of eqs. [39] and [40] into eq. [38] yields

$$[41]\quad \hat{\alpha}_D = \frac{1}{h}\sum_{s_D}\frac{1}{\nu_{s_D} - \nu_0}\Big\{[\,|\,\hat{r}_\sigma\,|\,s_D\rangle\langle s_D\,|\,\hat{r}_\rho\,|\; + \;|\,\hat{r}'_\sigma\,|\,s_D\rangle\langle s_D\,|\,\hat{r}'_\rho\,|\; + \;|\,\hat{r}_\sigma\,|\,s_D\rangle\langle s_D\,|\,\hat{r}'_\rho\,|$$

$$+\;|\,\hat{r}'_\sigma\,|\,s_D\rangle\langle s_D\,|\,\hat{r}_\rho\,|\,] + [\rho\leftrightarrow\sigma]\Big\}$$

therefore, using eqs. [18], [19], and [41],

$$[42]\quad \langle {}^1\Psi_{D1}\,|\,\hat{\alpha}_D\,|\,{}^1\Psi_{D2}\rangle = K_1[\langle\psi_{k+1}\,|\,\hat{\alpha}_1\,|\,\psi_{k+2}\rangle + \langle\psi_{k+1}\,|\,\hat{\alpha}_2\,|\,\psi_{k+2}\rangle + \langle\psi_{k+1}\,|\,\hat{\alpha}_3\,|\,\psi_{k+2}\rangle + \langle\psi_{k+1}\,|\,\hat{\alpha}_4\,|\,\psi_{k+2}\rangle]$$

where K_1 is a constant and

$$[43]\quad \langle\psi_{k+1}\,|\,\hat{\alpha}_1\,|\,\psi_{k+2}\rangle = \frac{1}{h}\sum_{s_D}\left\{\frac{[\langle k+1\,|\,\hat{r}_\sigma\,|\,s_D\rangle\langle s_D\,|\,\hat{r}_\rho\,|\,k+2\rangle]}{\nu_s - \nu_0} + \frac{[\rho\leftrightarrow\sigma]}{\nu_s + \nu_0}\right\}$$

$$[44]\quad \langle\psi_{k+1}\,|\,\hat{\alpha}_2\,|\,\psi_{k+2}\rangle = \frac{1}{h}\sum_{s_D}\left\{\frac{[\langle k+1\,|\,\hat{r}'_\sigma\,|\,s_D\rangle\langle s_D\,|\,\hat{r}'_\rho\,|\,k+2\rangle]}{\nu_s - \nu_0} + \frac{[\rho\leftrightarrow\sigma]}{\nu_s + \nu_0}\right\}$$

$$[45]\quad \langle\psi_{k+1}\,|\,\hat{\alpha}_3\,|\,\psi_{k+2}\rangle = \frac{1}{h}\sum_{s_D}\left\{\frac{[\langle k+1\,|\,\hat{r}_\sigma\,|\,s_D\rangle\langle s_D\,|\,\hat{r}'_\rho\,|\,k+2\rangle]}{\nu_s - \nu_0} + \frac{[\rho\leftrightarrow\sigma]}{\nu_s + \nu_0}\right\}$$

$$[46]\quad \langle\psi_{k+1}\,|\,\hat{\alpha}_4\,|\,\psi_{k+2}\rangle = \frac{1}{h}\sum_{s_D}\left\{\frac{[\langle k+1\,|\,\hat{r}'_\sigma\,|\,s_D\rangle\langle s_D\,|\,\hat{r}_\rho\,|\,k+2\rangle]}{\nu_s - \nu_0} + \frac{[\rho\leftrightarrow\sigma]}{\nu_s + \nu_0}\right\}$$

If the dimer orbitals ψ_{k+1} and ψ_{k+2} in eqs. [43]–[46] are replaced by their equivalent in terms of monomer orbitals (eqs. [12] and [13]), we obtain

$$[47]\quad \langle\psi_{k+1}\,|\,\hat{\alpha}_1\,|\,\psi_{k+2}\rangle = \frac{1}{2}\,{}^cC_{11}\,{}^cC_{21}\langle\phi_{m+1}\,|\,\hat{\alpha}_1\,|\,\phi_{m+1}\rangle$$

$$[48]\quad \langle\psi_{k+1}\,|\,\hat{\alpha}_2\,|\,\psi_{k+2}\rangle = -\frac{1}{2}\,{}^cC_{12}\,{}^cC_{22}\langle\phi_{m'+1}\,|\,\hat{\alpha}_2\,|\,\phi_{m'+1}\rangle$$

$$[49]\quad \langle\psi_{k+1}\,|\,\hat{\alpha}_3\,|\,\psi_{k+2}\rangle = \frac{1}{2}\,{}^cC_{11}\,{}^cC_{22}\langle\phi_{m+1}\,|\,\hat{\alpha}_3\,|\,\phi_{m'+1}\rangle$$

$$[50]\quad \langle\psi_{k+1}\,|\,\hat{\alpha}_4\,|\,\psi_{k+2}\rangle = -\frac{1}{2}\,{}^cC_{12}\,{}^cC_{21}\langle\phi_{m'+1}\,|\,\hat{\alpha}_4\,|\,\phi_{m+1}\rangle$$

Inspecting eqs. [41] and [47]–[50] reveals the following: (*1*) the operator $\hat{\alpha}_1$ and the monomer wave functions ϕ_{m+1} of eq. [47] are defined with respect to the coordinates of molecule 1; (*2*) similarly, the operator $\hat{\alpha}_2$ and monomer wave function $\phi_{m'+1}$ of eq. [48] contain only the coordinates of molecule 2, consequently we can identify these electronic Raman activity tensor elements as spatially localized elements; (*3*) in eqs. [49] and [50], both the operators $(\hat{\alpha}_3, \hat{\alpha}_4)$ and the wave functions $(\phi_{m'+1}, \phi_{m+1})$ contain the coordinates of molecule 1 and molecule 2 simultaneously. Hence, we can label such tensor elements as spatially delocalized. In a final form, eq. [42] is written as

$$[51]\quad \langle {}^1\Psi_{D1}\,|\,\hat{\alpha}_D\,|\,{}^1\Psi_{D2}\rangle = \frac{K_1}{2}\,[{}^cC_{11}\,{}^cC_{21}\langle\phi_{m+1}\,|\,\hat{\alpha}_1\,|\,\phi_{m+1}\rangle - {}^cC_{12}\,{}^cC_{22}\langle\phi_{m'+1}\,|\,\hat{\alpha}_2\,|\,\phi_{m'+1}\rangle + {}^cC_{11}\,{}^cC_{22}\langle\phi_{m+1}\,|\,\hat{\alpha}_3\,|\,\phi_{m'+1}\rangle$$

$$- {}^cC_{12}\,{}^cC_{21}\langle\phi_{m'+1}\,|\,\hat{\alpha}_4\,|\,\phi_{m+1}\rangle]$$

Thus eq. [51] contains four terms which contribute to the Raman activity of a general dimer and this result predicts a nonzero intensity at δ_{ex} cm^{-1} in the Raman spectrum. See Fig. 3*a* for the schematic representation of the process. Several general remarks can be made about the results of eq. [51]. First, the value of the individual coefficients ${}^cC_{11}$, ${}^cC_{21}$, ${}^cC_{12}$, and ${}^cC_{22}$ are different from unity because the individual molecules for the general case are different (i.e. Chl *a* – Chl *b*) but the products ${}^cC_{11}\,{}^cC_{21} = {}^cC_{12}\,{}^cC_{22}$ and ${}^cC_{11}\,{}^cC_{22} \neq {}^cC_{12}\,{}^cC_{21}$. Second, the most trivial case that can be encountered would be a dimer composed of identical molecules such as Chl *a* – Chl *a* and each component molecule would be placed in a mirror image configuration. Under these conditions, the coefficients ${}^cC_{11} = {}^cC_{21} = {}^cC_{12} = {}^cC_{22} = 1$ and the interaction terms $\delta_{ex} = \delta_g$. Since experimental data (7, 20) do not predict such a dimer configuration, we do not include this situation in our results in view of the fact that two of the excited states would be degenerate and configuration interaction calculations would be needed to eliminate the degeneracy. Third, the results of eq. [51] would be valid for skewed dimers as predicted from present data (7, 20), and this includes identical component molecules as well as hybrid dimers. The difference of δ_{ex} and δ_g can be expected from a geometry change in the excited state of the individual

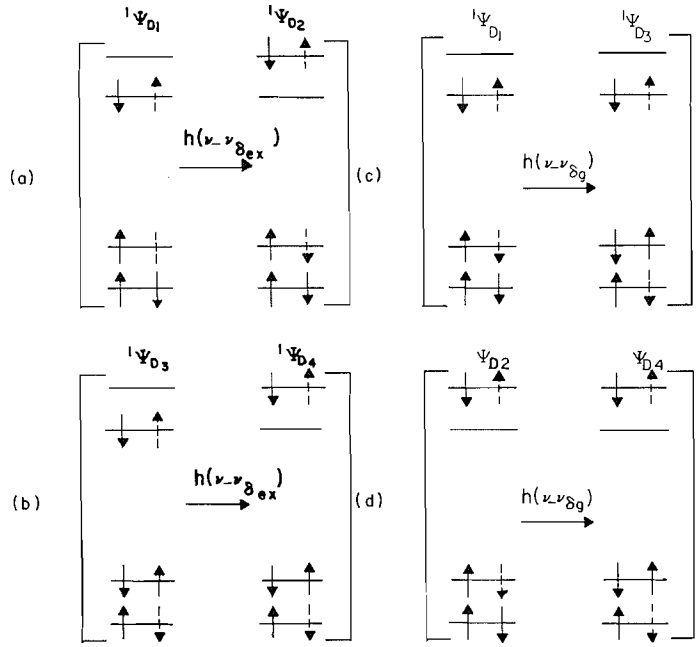

FIG. 3. (*a*, *b*) A representation of the Stokes excited state electronic Raman transitions which yield a transition at $h\nu_{\delta_{ex}}$ cm^{-1}. (*c*, *d*) Stokes transition at $h\nu_{\delta_g}$ cm^{-1}.

molecules of the dimer.

Finally, the Raman activity of the process described in eq. [51] originates from four terms: $\langle\phi_{m+1}|\hat{\alpha}_1|\phi_{m+1}\rangle$, $\langle\phi_{m'+1}|\hat{\alpha}_2|\phi_{m'+1}\rangle$, $\langle\phi_{m+1}|\hat{\alpha}_3|\phi_{m'+1}\rangle$, and $\langle\phi_{m'+1}|\hat{\alpha}_4|\phi_{m+1}\rangle$. Each of the terms is a Rayleigh-type process centered on either molecule 1 or molecule 2 (spatially localized) or between molecules 1 and 2 (spatially delocalized). In eq. [51] part of the expression for the activity is represented as a difference of the Rayleigh terms between molecule 1 and molecule 2. At first thought, these two terms would seem to cancel each other (at least for identical component molecules), but experimental data (7) show that a chlorophyll dimer exhibits an exchange of donor–acceptor roles at a frequency lower than the time scale of optical experiments. Therefore, at any point in time during the Raman experiment molecule 1 will be different from molecule 2 due to the donor–acceptor exchange, consequently $\langle\phi_{m+1}|\alpha_1|\phi_{m'+1}\rangle \neq \langle\phi_{m+1}|\alpha_2|\phi_{m'+1}\rangle$ and $\langle\phi_{m+1}|\alpha_3|\phi_{m'+1}\rangle \neq \langle\phi_{m'+1}|\alpha_4|\phi_{m+1}\rangle$. Also, a second transition $^1\Psi_{D3} \rightarrow {}^1\Psi_{D4}$ can give a Raman spectrum with a band at δ_{ex} cm^{-1} and $^1\Psi_{D3}|\alpha_D|{}^1\Psi_{D_4}\rangle$ yields the same results as eq. [51] for the selection rule. An orbital schematic for this process is shown in Fig. 3*b*.

In addition to the possibility of observing a Raman transition between states that are separated by δ_{ex} cm^{-1}, a similar calculation between the states $^1\Psi_{D1} \rightarrow {}^1\Psi_{D3}$ and $^1\Psi_{D2} \rightarrow {}^1\Psi_{D4}$ predicts a nonzero Raman activity at the frequency of δ_g cm^{-1}. Therefore,

$$[52]\quad \langle {}^1\Psi_{D1} \mid \hat{\alpha}_D \mid {}^1\Psi_{D3}\rangle = \langle {}^1\Psi_{D2} \mid \hat{\alpha}_D \mid {}^1\Psi_{D4}\rangle = \frac{K_2}{2}\,[{}^gC_{21}{}^gC_{11}\langle\phi_m \mid \hat{\alpha}_1 \mid \phi_m\rangle - {}^gC_{12}{}^gC_{22}\langle\phi_{m'} \mid \hat{\alpha}_2 \mid \phi_{m'}\rangle$$
$$+ {}^gC_{11}{}^gC_{22}\langle\phi_m \mid \hat{\alpha}_3 \mid \phi_{m'}\rangle - {}^gC_{12}{}^gC_{21}\langle\phi_{m'} \mid \hat{\alpha}_4 \mid \phi_m\rangle]$$

An inspection of the coefficients and Raman activity terms reveals that similar conditions are predicted from eq. [52] as in the above calculation of eq. [51]. Besides the obvious difference that the coefficients in eq. [52] contain the ground state interaction term, the results predict Raman activity based on Rayleigh terms which contain the HOMO's of the individual molecules. From the schematic representation of the transitions shown in Fig. 3*c* and *d*, the transitions predicted by eq. [52] can be seen to originate between the dimer orbitals ψ_{k-1} and ψ_k which have their parentage in the monomer HOMO's ϕ_m and $\phi_{m'}$. Thus, the calculation yields the expected results of depending on the spatially localized and delocalized terms.

IV. Conclusive remarks

In the present study, we have developed a model of a general chlorophyll dimer system within a modified supermolecule type of approximation. This model differs from the exciton theory model in that the present calculations yield explicitly the molecular orbitals of the dimer. The usual approach describes the dimer system only in terms of state functions. In addition, the calculations presented in sections II and III define and use the interaction energy δ_g between the HOMO and HOMO − 1 of the dimer. This specific formalism (supermolecule) was necessary to develop the selection rules for the Raman activity between excited states but it can also be used to obtain such rules governing the fluorescence transitions between all excited states and the ground state.

The inclusion of the ground state interaction energy δ_g besides the excited state interaction δ_{ex} terms results in a more complete prediction of excited state electronic (but also fluorescence) Raman transitions. The lifetime of these excited states is related to that of the monomers and for chlorophyll *in vitro* one finds that these lifetimes are in the order of nanoseconds. Such excited levels are readily populated using radiation of pulsed lasers and Raman probing can then take place with the part of the radiation not used for pumping or using another laser operating at a different wavelength. Such types of experiments may also yield information on

the position of absorption bands of the dimeric species and would allow one to distinguish a symmetric dimer from an asymmetric dimer.

Synthèse et étude chimique préliminaire des pentadiényl-2,4-phosphines

CATHERINE C. SANTINI ET FRANÇOIS MATHEY
Laboratoire CNRS–SNPE, 2–8 rue Henry Dunant, 94320 Thiais, France

Reçu le 9 juin 1982

CATHERINE C. SANTINI et FRANÇOIS MATHEY. Can. J. Chem. **61**, 21 (1983).

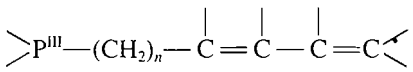
La réaction du magnésien de l'iodure de méthyle avec un oxa-1-phospha-2-cycloheptadiène-4,6 fournit facilement un oxyde de pentadiényl-2,4-phosphine après deux étapes intermédiaires conventionnelles. La phosphine correspondante peut être obtenue par réduction directe de l'oxyde au trichlorosilane ou par réduction–complexation du sulfure correspondant par le nickelocène. Elle ne semble pas pouvoir jouer le rôle de chélatant diène-phosphore pour un métal par suite de facteurs stériques. L'oxyde est un précurseur valable pour les triènes conjugués par réaction de Wittig–Horner avec un dérivé carbonylé.

CATHERINE C. SANTINI and FRANÇOIS MATHEY. Can. J. Chem. **61**, 21 (1983).

A penta-2,4-dienylphosphine oxide is easily obtained by reaction of methylmagnesium iodide with 1-oxa-2-phosphacyclohepta-4,6-diene followed by two more intermediate steps. The corresponding phosphine may be obtained either by trichlorosilane reduction of the oxide or nickelocene reduction–complexation of the sulfide. It seems that the dienic part of penta-2,4-dienylphosphines cannot be involved in a η^4-complexation for steric reasons. The oxides are valuable precursors for conjugated trienes through Wittig–Horner reactions with carbonyl compounds.

Introduction

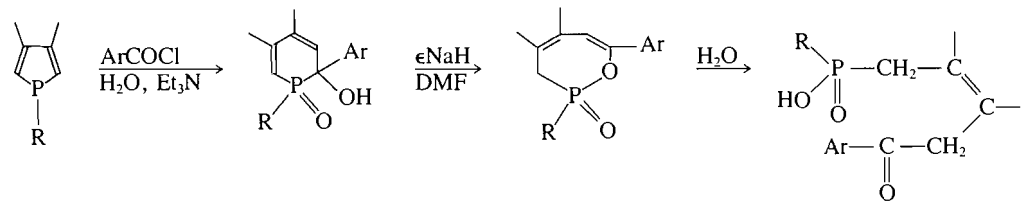
Depuis quelques années nous avons lancé un programme d'investigation systématique sur la synthèse et les propriétés coordinantes des diénylphosphines de structure générale



Nous avons ainsi préparé les butadiényl-1,3-phosphines de stéréochimie *E* (1) aptes à se coordonner sur deux centres métalliques disposés à une distance de l'ordre de 3,5 Å convenable pour l'activation bimétallique de petites molécules (2). Nous avons également préparé les hexadiényl-3,5-phosphines de stéréochimie *Z* (3) théoriquement capables de chélater un métal entre le phosphore trivalent et le diène. La longueur et la difficulté de cette dernière synthèse nous ont toutefois interdit l'étude systématique des propriétés coordinantes des phosphines correspondantes. Recherchant toujours un chélatant potentiel diène-phosphore trivalent, nous décrivons maintenant la préparation et quelques propriétés des pentadiényl-2,4-phosphines de stéréochimie *Z* d'accès beaucoup plus facile.

Synthèse des pentadiényl-2,4-phosphines

Nous avons découvert il y a quelques années (4) la double extension de cycle des phospholes par les chlorures d'acides aromatiques qui fournit facilement les cycles à 7 chaînons du type **2**. Ces cycles, par simple hydrolyse, donnent les cétones **3**

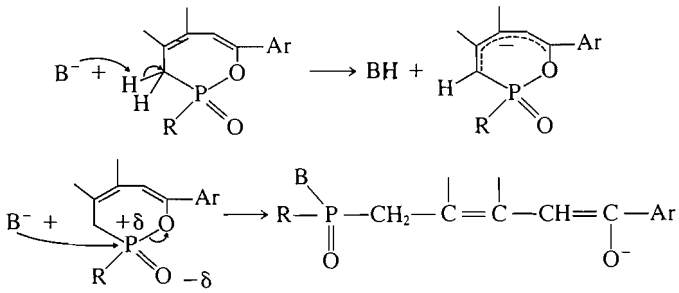


1 **2** **3**

présentant la stéréochimie *Z* désirée au niveau de la double liaison et offrant la possibilité de créer une seconde double liaison à partir du groupement carbonyle. Nous avons donc logiquement choisi d'utiliser les cycles du type **2** comme point de départ de nos synthèses.

Nous avons, tout d'abord, rencontré quelques difficultés dans la reproduction de la conversion **1** → **2**, la présence de traces d'eau dans le solvant utilisé ayant tendance à provoquer l'ouverture immédiate de **2** en **3**. Nous avons définitivement réglé ce problème en utilisant la triéthylamine au reflux du toluène comme catalyseur de l'extension de cycle; l'absence totale d'eau dans ce cas évitant toute ouverture malencontreuse de **2**, le rendement en **2** est alors quantitatif.

L'attaque d'un nucléophile B^- sur un cycle du type **2** peut, suivant les cas, se produire sur le CH_2 en α du P=O (métallation) ou sur le phosphore (ouverture) (5):



L'accroissement de la nucléophilie et de l'encombrement de B^- favorisent la métallation, leurs diminutions favorisent l'ouverture. En fonction de notre objectif, nous avons donc étudié l'action de MeMgI dans l'éther (nucléophile carboné peu encombré et peu basique) sur **2***a*.

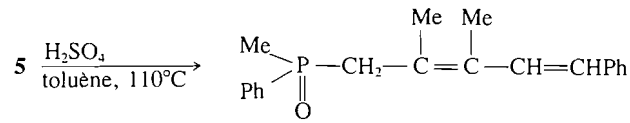
2a **4** **5**

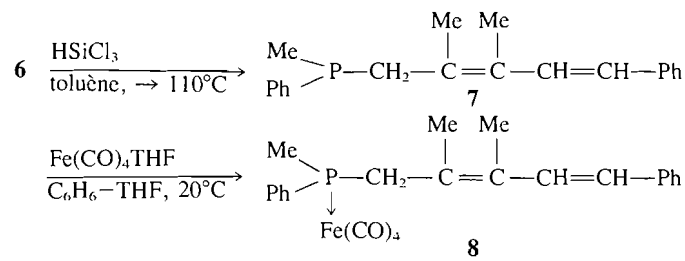
Nous avons ainsi obtenu l'oxyde de phosphine **4** avec un bon rendement. Sa réduction par le borohydrure de sodium dans le méthanol pour donner **5** ne pose aucun problème. L'alcool **5** est un mélange de deux diastéréoisomères comme l'indique le spectre de rmn ^{31}P. En ir, le groupe hydroxyle présente une fréquence très basse (3250 cm^{-1}) indépendante de la concentration et du solvant. D'un autre côté, **5** est élué plus facilement que **4** sur une colonne de gel de silice. Tout ceci suggère l'existence d'une liaison hydrogène intramoléculaire forte entre les groupes OH et PO. La déshydratation de **5** pour donner le diène **6** est classique dans son principe mais nécessite des précautions expérimentales car **6** est peu stable à haute température. Alors que la stéréochimie de la double liaison C(Me)=C(Me) est *Z* dans **6** comme dans **5** par suite du choix d'un précurseur cyclique, au contraire la nouvelle double liaison CH=CH de **6** est de stéréochimie *E* comme l'atteste la constante de couplage ^3J(H—H) observée (16 Hz). Ce résultat est logique pour une élimination E1. Le spectre de masse de **6** (70 eV, 180°C) indique comme schéma de décomposition pratiquement unique le clivage en oxyde de phosphine secondaire Ph(Me)P(O)H (*m/e* 140, 100%) et en hydrocarbure $C_{13}H_{15}$ (*m/e* 171, 100%). Nous avons effectivement constaté que **6** se décomposait par simple chauffage à partir de 170°C pour fournir un hydrocarbure non identifié (M = 196) et un résidu phosphoré pouvant être identifié comme $MePhPO_2H$ ($\delta^{31}P$ = 40 ppm dans l'eau).



(*Z*) (*E*)

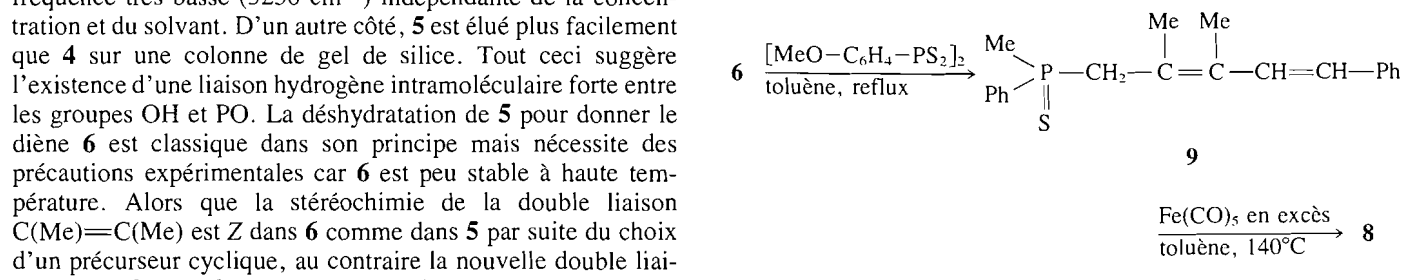
6

Malgré son instabilité à chaud, la préparation de **6** est assez satisfaisante puisque les produits de départ sont simples et accessibles et que le rendement global à partir du phosphole est supérieur à 30%. Le diène **6** est donc un synthon intéressant. En conséquence, nous avons étudié sa chimie de façon assez approfondie. Sa conversion en phosphine **7** a été réalisée de deux façons. Tout d'abord, nous avons utilisé une classique réduction au trichlorosilane. Dans ce cas on n'observe aucune hydrogénation du système diénique contrairement à ce qui est noté avec les oxydes de butadiényl-1,3-phosphines (1). L'éloignement du phosphoryle supprime la possibilité d'hydrogénation nucléophile du diène. La phosphine **7** ainsi obtenue a été caractérisée par son signal en rmn ^{31}P ($\delta^{31}P$(**7**) = −35,64 ppm dans C_6D_6) et complètement authentifiée par complexation à température ambiante par $Fe(CO)_4THF$.



7 **8**

Le rendement modeste de cette réduction (~30%) nous a incité à étudier une autre voie d'accès. La conversion de l'oxyde **6** en sulfure **9** est aisément réalisée par le réactif de Lawesson et coll. (6)[1] avec un rendement de 84%:



9 **8**

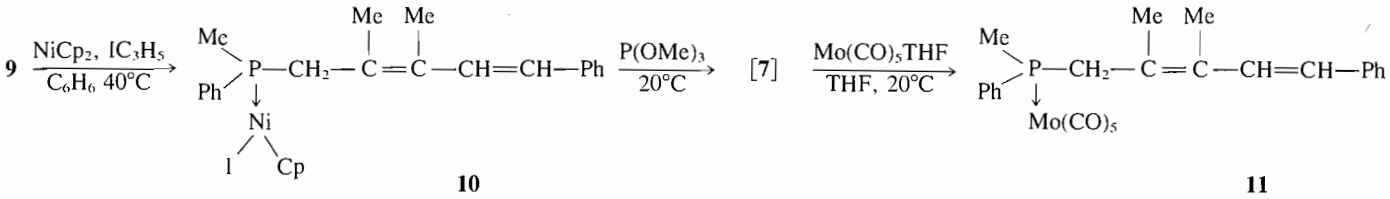
Ce sulfure **9** a été soumis à deux types de réductions—complexations. Tout d'abord chauffé en autoclave à 140°C avec un excès de fer pentacarbonyle, il conduit directement au complexe **8** avec un bon rendement (72%). Ce type de réduction—complexation des sulfures de phosphines a déjà été décrit dans la littérature (7). Il est à remarquer qu'il est plus simple et plus efficace de préparer **8** à partir de **6** en passant par le sulfure **9** que par la phosphine **7** (Rdt global 60% contre 15%). Mais le point le plus intéressant concerne l'absence de complexation de la partie diénique de **7** dans ces conditions énergiques. Cette absence jette un doute sur la capacité de **7** à jouer le rôle de coordinat chélatant et ce doute est confirmé par toute une série d'essais négatifs en ce sens sur les complexes **8** et **11**. A priori, cette incapacité peut être liée à deux causes: (1) une substitution inadaptée de la partie diénique de **7**; (2) un blocage stérique de la complexation du diène par le substituant phosphoré —CH_2P(Me)Ph dû à la géométrie *Z* de la double liaison en 2,3.

Une désactivation électronique du diène par le substituant phosphoré est exclue puisque nous avons montré que les butadiényl-1,3-phosphines avec une jonction directe P—diène sont capables de jouer le rôle de coordinats à 6 électrons (1). L'étude attentive du spectre de masse du complexe **8** apporte un élément de réponse à cette question. La perte de 4 carbonyles conduit à l'ion de *m/e* 350 (*I* = 100%). Cet ion perd classiquement son atome de fer pour donner la phosphine **7** (*m/e* 294, *I* = 7%). Mais le schéma de décomposition principal comporte une migration du fer du phosphore sur la partie diénique combinée avec une perte du substituant phosphoré analogue à celle observée sur l'oxyde **6**. Cette décomposition conduit à l'ion de *m/e* 226 ($C_{13}H_{14}Fe$, *I* = 56%) et est confirmée par la présence du métastable correspondant à *m/e* = 145.9. Il semble donc

[1]Nous avons déjà utilisé plusieurs fois ce réactif pour effectuer la conversion P=O → P=S dans des cas délicats, voir la référence 12: cas d'un phosphinate cyclique; la sulfuration s'effectue avec respect de la liaison P—O—C; Nief *et al.* (13): cas d'un oxyde d'hydroxy-2-dihydro-1,2-phosphorine; la sulfuration s'effectue avec respect de la fonction alcool; Santini *et al.* (14): cas d'un dimère d'oxyde de phosphole; la sulfuration s'effectue sans perte du pont phosphore. Récemment Horner et Lindel (15) ont décrit ce même type de conversion P=O → P=S sur des oxydes de phosphines plus simples.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

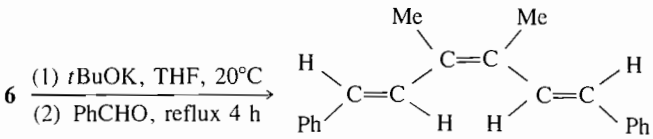
clair que la substitution de la partie diénique n'est pas en cause et que l'incapacité de **7** à jouer le rôle de coordinat à 6 électrons est liée à la géométrie *Z* de l'enchaînement P—CH_2—diène, ce que l'étude du modèle de Dreiding de **7** tend à confirmer.



10 **11**

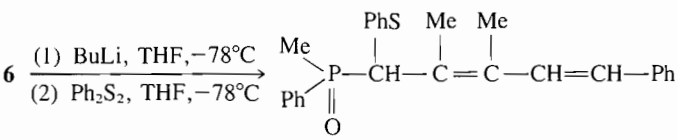
complexe du molybdène **11**. Cette séquence classique ne justifie aucun commentaire particulier. Comme annoncé précédemment, tous les essais de complexation de la partie diénique de **11** par $Fe(CO)_3$ ont échoué. Les phosphines du type **7** ne semblent donc pas présenter les possibilités attendues en chimie de coordination.

Disposant d'un accès commode à l'oxyde diénique **6**, nous avons voulu tester quelques possibilités synthétiques plus conventionnelles offertes par ce produit. La métallation de **6** par le tertiobutylate de potassium suivie d'un chauffage avec le benzaldéhyde conduit au triène attendu **12** de stéréochimie *E,Z,E* avec un rendement de 60%:



12

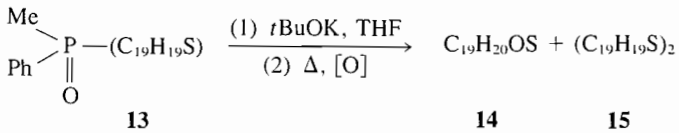
La structure symmétrique de **12** est confirmée par la présence d'un seul type de méthyle dans les spectres de rmn ^1H et ^{13}C de ce composé. Cette réaction est analogue à la dernière étape du mécanisme d'une synthèse des triènes à partir des sels de phospholéniums imaginée par Lednicer (9). Cependant, contrairement à Lednicer, nous pouvons ici obtenir des triènes dont les extrémités sont substituées différemment. Nous avons ensuite voulu transposer cette méthode pour obtenir des triènes fonctionnels. À titre d'exemple, nous avons donc préparé dans une première étape le produit phosphoré fonctionnel **13** par réaction de l'anion de **6** sur le diphényldisulfure:



13

Le composé **13** est un mélange de deux diastéréoisomères (rmn ^{31}P) dont l'un est fortement majoritaire et peut être obtenu à l'état quasiment pur. L'anion de **13**, préparé par réaction du tertiobutylate de potassium, ne réagit malheureusement pas avec le benzaldéhyde certainement à cause de son encombrement stérique. Au lieu du triène fonctionnel attendu, les seuls produits obtenus sont des hydrocarbures résultant de la décomposition thermique de l'anion. Ces hydrocarbures, préparés en petite quantité, n'ont pas pu être complètement identifiés. Cependent leur étude par spectrométrie de masse (ionisation chimique) semble montrer qu'ils résultent de l'oxydation et du couplage de la partie hydrocarbonée de **13**:

La réduction−complexation de **9** par le nickelocène suivant une technique maintenant bien rodée (8) conduit, quant à elle, au complexe **10** qui est détruit par le triméthylphosphite pour fournir la phosphine **7**. Cette dernière est convertie *in situ* en



13 **14** **15**

Ce type de dégradation oxydante d'anions α-phosphorylés a déjà été décrit dans la littérature (10).

Partie expérimentale

Toutes les réactions sont effectuées sous courant d'argon. Les points de fusion ont été déterminés au banc Kofler. Les spectres ir ont été enregistrés à l'aide d'un spectrophotomètre Perkin−Elmer 457; les spectres de masse ont été réalisés sur un appareil Nermag R10-10 par M. Charré de la S.N.P.E. (Vert-le-Petit) et sur un appareil AEI MS-30. Les spectres de rmn pour tous les noyaux ont été enregistrés sur un appareil Bruker WP−80. Les chromatographies sont effectuées sur colonne de gel de silice (70−230 mesh).

L'oxyde d'hydroxy-2-diméthyl-4,5-diphényl-1,2-dihydro-1,2-phosphorine **1***a* a été préparé à quelques modifications près comme décrit dans la littérature (4).

*Oxyde de diméthyl-4,5-diphényl-2,7-oxa-1-phospha-2-cycloheptadiène-4,6 (***2**a)

L'oxyde de phosphorine **1***a* (4 g, 3.7×10^{-2} *M*) et 25 cm^3 de Et_3N dans 250 cm^3 de toluène sont chauffés au reflux du solvant durant la nuit. Après refroidissement de la solution à la température ambiante le solvant est évaporé conduisant à 4 g de **2** (rendement quantitatif) qui cristallise lorsque 5 cm^3 d'éther éthylique sont ajoutés.

*Oxyde de (diméthyl-2,3-phényl-5-oxo-5-penténYl-2)méthylphénylphosphine (***4**)

On ajoute 15 cm^3 d'une solution de MeMgI (1.5 *N*) dans l'éther éthylique en 30 min à une solution de **2** (7 g, 2.6×10^{-3} *M*) dans l'éther. Un abondant précipité blanc apparaît. L'agitation est maintenue 2 heures à la température ambiante. Le milieu réactionnel est hydrolysé avec une solution diluée d'acide chlorhydrique, jusqu'à neutralisation du milieu. Les solvants sont évaporés, le résidu est repris au chloroforme (200 cm^3), puis lavé à l'eau. La phase organique est séchée, puis évaporée. Le résidu est chromatographié (éluant acétate d'éthyle) ce qui permet d'isoler 1.9 g de **2***a*, R_f 0.7, et **4** (5,3 g, ρ 72.6%), R_f 0.15. Le produit **4** ne cristallise pas; ir (film) ν(C=O): 1675, ν(C=C): 1590, 1572, ν(P=O): 1165 cm^{-1}; rmn ^1H ($CDCl_3$): 1.73 (d, $^2J_{PH}$ = 12 Hz, Me—P), 1.76 (s, CH_3—C), 2.8 (d, $^2J_{PH}$ = 14.5 Hz, CH_2—P), 3.7 (s, large, CH_2—C), 7.4 (m, Hmp Ph—P), 7.70 (m, Ho Ph—P); rmn ^{31}P ($CDCl_3$): 32.37 ppm.

Oxyde de (hydroxy-5-diméthyl-2,3-phényl-5-pentenyl-2)méthylphénylphosphine

À 5.3 g (1.62×10^{-2} M) de **4** dans 80 cm^3 de méthanol fraîchement distillé sur Mg sont ajoutés 0.2 g de $NaBH_4$ par portion. Le milieu réactionnel est agité 2 heures à la température ambiante. Le solvant est évaporé et le résidu est dissout dans du chloroforme, puis

lavé à l'eau jusqu'à neutralisation du milieu. La phase organique est sechée ($MgSO_4$), puis évaporée permettant d'isoler 5.0 g (ρ 93%) d'une huile jaune qui cristallise lorsque 5 cm^3 d'éther éthylique sont ajoutés; pf 163°C, R_f 0.45 ($MeCO_2Et$–MeOH 95:5); ir (KBr) ν (OH): 3240, ν (C=C): 1597 et 1585, ν (P=O): 1140 cm^{-1}; ir (CH_2Cl_2) ν (OH): 3250 cm^{-1} fréquence de vibration indépendante de la concentration; rmn ^1H ($CDCl_3$): 1.2 (s.large, Me—C), 1.77 (d, ^2J(H—P) = 12.6 Hz, Me—P), 1.82 (m, 2 isomères, Me—C), 2.15–3.5 (m, CH_2P + CH_2C—OH), 4.90 (dd, CH—OH), 7.2–7.9 (m, Ph); rmn ^{31}P ($CDCl_3$): 33.62 et 32.10 ppm (majoritaire); sm (70 eV, 130°C): 329 (M + 1, 1%), 310 (M − H_2O, 6%), 140 (PhMePOH, 100%).

Oxyde de (diméthyl-2,3-phényl-5-pentadiényl-2,4)méthylphénylphosphine (6)

Dix grammes de l'alcool **5** sont déshydratés par l'acide sulfurique en traces catalytiques dans le toluène anhydre au reflux en 2 heures. Après refroidissement à la température ambiante, le milieu réactionnel est lavé avec une solution saturée de carbonate, puis la phase organique est décantée, séchée conduisant à 6,5 g (ρ 68,7%) d'une huile incolore qui cristallise lorsque quelques gouttes d'éther sont ajoutées, pf 188°C, R_f = 0.27 ($MeCO_2Et$–MeOH 95:5); ir (KBr) ν(C=C): 1615, 1590 et 1570 faible, ν(P=O): 1160–1172 ep fort; rmn ^1H ($CDCl_3$): 1.73 (d, $^2J_{PH}$ = 12,7 Hz, Me—P), 1.86 (s, MeC=), 1.93 (s, MeC=), 3.07 (d, $^2J_{PH}$ = 16 Hz, CH_2—P), δ_A: 6.37 δ_B: 6.87 (J_{AB} = 16.02 Hz, HC=CH), rmn ^{31}P ($CDCl_3$): 32.7 ppm; sm (70 eV, 180°C): 310 (M, 77%), 171 ($C_{13}H_{15}$, 100%), 140 (PhMePH(O), 100%). *Anal.* calc. pour $C_{20}H_{23}OP$: C 77.39, H 7.47, P 9.98, trouvé: C 76.85, H 7.50, P 9.74.

(Diméthyl-2,3-phényl-5-pentadiényl-2,4)méthylphénylphosphine (7)

Dans un ballon monocol muni d'un réfrigérant à Carboglace, l'oxyde de phosphine **6** (0.8 g, 2.58 × 10^{-3} *M*) et le chlorosilane $HSiCl_3$ sont chauffés au reflux du toluène pendant 2 heures. Après évaporation du solvant et de l'excès de $HSiCl_3$, le résidu est repris au benzène et avec une solution saturée de bicarbonate. La phase organique est ensuite séchée et évaporée. L'huile incolore obtenue est étudiée en rmn ^{31}P (C_6D_6), δ: −35.64; +29.52 (oxyde de phosphine). Rendement environ 30% (déterminé par rmn). Tous les solvants utilisés sont dégazés.

Diméthyl-2,3-phényl-5-pentadiényl-2,4)méthylphénylphosphine fer tetracarbonyle (8)

La phosphine **7** (10^{-3} *M*) en solution dans 50 cm^3 de benzène est ajoutée à une solution de $Fe(CO)_4THF(Fe_2(CO)_9$, 0.4 g; THF, 100 cm^3, 25°C) après une heure d'agitation à la température ambiante, les solvants sont évaporés et le résidu chromatographié (éluant hexane–benzène 75:25) permettant d'isoler 0.25 g, ρ ≃ 50% du complexe **8**, R_f 0.33, pf 132°C; ir (hexane) ν(CO): 2050, F 1980 F, 1944, 1935 TF; rmn ^1H (C_6D_6): 1.28 (m, Me—C=), 1.47 (d, J_{PH} = 9.2 Hz, Me—P), 1.67 (deux massifs, Me—C=), 3.0 (d, J_{PH} = 10 Hz, CH_2—P), 6.3 et 6.5 (partie A de système AB, J_{AB} = 15.3 Hz); rmn ^{31}P (toluène): +56.24 ppm; sm (70 eV, 120°C): 462 (M, 1%), 434 (M—CO, 10%), 406 (M—2CO, 21%), 376 (M—3CO, 20%), 350 (M—4CO, 100%), 294 (L, 7%), 226 (350 − PhP(H)Me, 56%), 171 ($C_{13}H_{15}$, 24%).

Préparation de 8 à partir du sulfure de phosphine 9

Un mélange de 0.54 g (1.74 × 10^{-3} *M*) de sulfure de phosphine **9** et 2 g (10^{-2} *M*) de fer pentacarbonyle dans 100 cm^3 de toluène sont chauffés en autoclave à 140°C (*P* ≃ 5 bars) pendant 24 h. Après filtration du précipité noir sur Celite le filtrat est concentré, chromatographié sur silice (100 g, éluant toluène) conduisant à 0.45 g (ρ ≃ 72%) de complexe **8**; 0.1 g de sulfure de départ **9** élué avec le mélange toluène − acétate d'éthyle 90:10 sont recouvrés.

Sulfure de (diméthyl-2,3-phényl-5-pentadiényl-2,4)méthylphénylphosphine (9)

Un mélange de 1.24 g (4 × 10^{-3}*M*) d'oxyde de phosphine **6** et 0.88 g (2 × 10^{-3} *M*) de $[MeOC_6H_4PS_2]_2$ sont chauffés au reflux dans 100 cm^3 de toluène pendant 2 heures. Après refroidissement du milieu réactionnel à la température ambiante, le solvant est évaporé conduisant à une huile jaune-marron qui est chromatographiée (éluant toluène − acétate d'éthyle 95:5). Après le trimère $[MeOC_6H_4POS]_3$ R_f 0.7, 1.1 g (ρ 84%) de sulfure R_f 0.33 sont isolés sous forme d'une huile incolore qui cristallise lorsque 5 cm^3 d'éther éthylique sont ajoutés, pf (Et_2O) 135°C; R_f 0.57 dans CH_2Cl_2; ir (KBr) ν(C=C): 1625, 1600, 1580 cm^{-1}; rmn ^1H ($CDCl_3$): 1.6 (m, CH_3—C=), 1.73 (d, $^2J_{PH}$ = 12 Hz, CH_3P), 3.06 (d, $^2J_{PH}$ = 15Hz, CH_2—P), système AB δ_A: 6.08 δ_B: 6.52 (J_{AB} = 16 Hz, CH=CH); rmn ^{31}P: +34.8 ppm; sm (70 eV, 200°C): 326 (M, 10%), 171 ($C_{13}H_{15}$, 100%).

Iodure de (diméthyl-2,3-phényl-5-pentadiényl-2,4)méthylphénylphosphine cyclopentadiényl nickel (10)

Un mélange de 1.2 g (3.68 × 10^{-3} *M*) de sulfure de phosphine **9**, 2 g de nickelocène et 0.5 cm^3 d'iodure d'allyle sont chauffés à 40°C dans 100 cm^3 de benzène pendant 2 heures. Après filtration sur Célite des insolubles, le milieu réactionnel est concentré, puis chromatographié (éluant benzène), conduisant à 0.86 g (ρ 50%) d'une huile rouge sombre (R_f 0.7) qui cristallise lentement sous vide; rmn ^{31}P (C_6D_6): +13.8 ppm; sm (70 eV, 160°C, ^{58}Ni): 544 (M, 1%), 417 (M − I, 1%), 310 (LO, 35%), 294 (L, 20%), 171 ($C_{13}H_{14}$, 47%), 130 (100%).

(Diméthyl-2,3-phényl-5-pentadiényl-2,4)méthylphénylphosphine pentacarbonyl molybdène (11)

À 7 g (12.9 × 10^{-3} *M*) de complexe **10** dissous dans du benzène (100 cm^3) sont ajoutés 2 cm^3 de triméthylphosphite. La couleur du milieu réactionnel passe du rouge sombre au vert marron. L'agitation est maintenue 30 min. Puis le milieu réactionnel filtré sur silice (50 g) est ajouté à une solution de $Mo(CO)_5THF$ ($Mo(CO)_6$ 3.43 g; 1000 cm^3 de THF) à la température ambiante. L'agitation est maintenue 1 heure à cette température puis les solvants sont évaporés et le résidu est chromatographié (éluant hexane − toluène 80:20) ce qui permet d'isoler 3 g (ρ 53%) de complexe **11** (R_f 0.5) qui doit être recristallisé dans l'hexane (ρ 30%); ir (hexane) ν(CO): 2065 f, 1952 m, 1947 TF; rmn ^1H (C_6D_6): 1.21 (m, CH_3—C=), 1.37 (d, J_{PH} = 5.6 Hz, CH_3—P), 1.52 (m, CH_3—C=), 2.75 (d, J_{PH} = 7 Hz, CH_2—P), 6.3 et 6.57 (partie A du système AB, J_{AB} = 16 Hz, CH=CH); rmn ^{31}P: 6.87 ppm; sm (130°C, 70 eV, ^{98}Mo): 532 (M, 10%), 392 (*M* − 5CO, 47%), 294 (L, 53%), 171 ($C_{13}H_{15}$, 100%).

(E-Z-E) diméthyl-3,4-diphényl-1,6-hexatriène-1,3,5 (12)

On ajoute 0.23 g de tertiobutylate de potassium par portion à une solution d'oxyde de phosphine **6** (0.5 g, 1.6 × 10^{-3} *M*) dans 100 cm^3 de THF à la température ambiante. Dès l'addition de *t*BuOK il y a apparition d'une couleur rouge orangé sombre. L'agitation est maintenue 15 min après l'addition, puis 0.17 g (1.6 × 10^{-3} *M*) de benzaldéhyde sont ajoutés. Il y a décoloration spontanée du milieu réactionnel, puis ce dernier est chauffé pendant 4 heures à reflux du solvant. Après refroidissement à la température ambiante, 50 cm^3 d'eau sont ajoutés puis le milieu est extrait à l'éther éthylique (3 × 100 cm^3). La phase organique est décantée, séchée sur $MgSO_4$, puis concentrée conduisant à 0.25 g (ρ 60%) de **12**, solide jaune, F 175°C (pentane); rmn ^1H ($CDCl_3$): 2.2 (s, CH_3), 6.73 et 6.93 (partie A d'un système AB, J_{AB} = 16 Hz, CH=CH); rmn ^{13}C: 14.2 (s, CH—C=), 126.4–128.9 (m, Ph), 132.15 (s, C sec du phényl), 138.26 (s, $C(H)$=H); sm (70 eV, 150°C): 260 (M, 53%), 169 (M − $PhCH_2$, 66%), 91 ($PhCH_2$, 100%). D'après les points de fusion, **12** est différent du triène de même formule déjà décrit dans la littérature (11) qui est probablement de structure (*E,E,E*).

Oxyde de (diméthyl-2,3-phényl-5-phénylthio-1-pentadiényl-2,4)-méthylphénylphosphine (13)

On ajoute 3 cm^3 de BuLi (1.4 *N* dans l'hexane) goutte à goutte à une solution de 1 g (3.22 × 10^{-3} *M*) d'oxyde de phosphine **6** dans 50 cm^3 de THF refroidie à −78°C. Une coloration rouge sombre apparaît spontanément. En fin d'addition, l'agitation est maintenue 15 min à cette température, puis 0.7 g de diphényldisulfure dissous dans 25 cm^3 de THF sont ajoutés. En fin d'addition de ce réactif la couleur du milieu réactionnel est passée du rouge sombre à l'orange. L'agitation est maintenue 30 min à cette température, puis 50 cm^3 d'une solution

saturée en carbonate de sodium sont ajoutés et la température du milieu revient à l'ambiante. Le milieu réactionnel est extrait avec 4 × 25 cm^3 de CH_2Cl_2. Après décantation la phase organique est lavée avec 50 cm^3 d'acide chlorhydrique dilué, puis 50 cm^3 d'une solution aqueuse saturée en NaCl, puis est séchée sur $MgSO_4$. Après évaporation des solvants le résidu est chromatographié (éluant acétate d'éthyle) conduisant à 0.4 g (R_f 0.72) de $(PhS)_2$, 0.5 g (R_f 0.4, ρ 52%) de **13** et 0.3 g (R_f 0.1) de l'oxyde **6**. Composé **13**, solide blanc, pf 157−158°C; rmn ^1H ($CDCl_3$): 1.3 (s large, CH_3—C═), 2.01 (d, J_{PH} = 12.7 Hz, CH_3—P), 2.15 (s large, CH_3—C═), 4.5 (d, SPh | J_{PH} = 10.7 Hz, P—C*H*), 6.26 et 6.46 (partie A d'un système AB, J_{AB} = 16 Hz, CH═CH), 7.06 et 7.26 (partie B d'un système AB); rmn ^{31}P ($CDCl_3$): 34.51 (majoritaire) et 33.36 ppm; sm (IC): 419 (M + 1, 100%).

Décomposition thermique de l'anion de l'oxyde de phosphine 13

On ajoute 0.214 g de *t*BuOK par portion à une solution de **13** (0.8 g, 1.91 × 10^{-3} *M*) dans 50 cm^3 de THF à la température ambiante. Dès l'addition de *t*BuOK le milieu devient rouge sombre. En fin d'addition, le milieu réactionnel est chauffé pendant 2.5 h au reflux du solvant. Après refroidissement à la température ambiante, 50 cm^3 d'eau saturée en NH_4Cl sont ajoutés. Le milieu est extrait avec 3 × 25 cm^3 de CH_2Cl_2; la phase organique après décantation et lavage (50 cm^3 HCl 1 *N*, puis 50 cm^3 d'eau saturée en NaCl) est séchée sur $MgSO_4$. Après concentration le résidu est une première fois chromatographié sur silice (éluant CH_2Cl_2) conduisant à une huile jaune (0.46 g) éluant en tête. Cette huile est à nouveau chromatographiée (éluant hexane − CH_2Cl_2 80:20) permettant d'isoler 0.15 g (R_f 0.4) de **14** et 0.2 g (R_f 0.2) de **15**. Composé **14**: sm (ionisation chimique NH_3): 297 (M + 1, 100%), 279 (M − OH, 16%), 187 (M − PhS, 16%), 171 ($C_{13}H_{15}$, 22%). Composé **15**: sm (ionisation chimique NH_3): 560 (M + 2, 100%), 449 (M − PhS, 43%); 339 (449 − PhSH, 14%), 279 (M/2, 100%), 170 ($C_{13}H_{14}$, 20%). Les spectres rmn ^1H de **14** et **15** sont complexes et laissent supposer que **14** et **15** sont des mélanges de diastéréoisomères. On ne voit pas de bande OH sur le spectre ir de **14**.

The planar conformation of 2-methylthiobenzaldehyde in solution

TED SCHAEFER AND RUDY SEBASTIAN
Department of Chemistry, University of Manitoba, Winnipeg, Man., Canada R3T 2N2

Received June 30, 1982

TED SCHAEFER and RUDY SEBASTIAN. Can. J. Chem. **61**, 26 (1983).

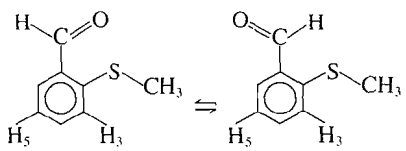
The ^{1}H nmr spectral parameters are extracted for a 4 mol% solution of 2-methylthiobenzaldehyde in CCl_4 at 305 K. The long-range spin–spin coupling constants involving the aldehydic and methyl protons are consistent only with a preferred conformation in which all heavy atoms are coplanar, as are the chemical shifts of the ring and methyl protons. This conclusion contradicts previous interpretations of the dipole moment, the nmr parameters, and of the infrared data for CCl_4 solutions. The present data show that the *O-syn* and *O-anti* forms of the compound are present in roughly equal proportions.

TED SCHAEFER et RUDY SEBASTIAN. Can. J. Chem. **61**, 26 (1983).

On a déduit les paramètres spectraux de la rmn du ^{1}H d'une solution à 4 mol% de méthyl-2 thiobenzaldéhyde à 305 K. Les constantes de couplages à longue distance impliquant les protons aldéhydiques et ceux du méthyle sont en accord uniquement avec une conformation préférentielle dans laquelle tous les atomes lourds sont coplanaires. Il en est de même pour les déplacements chimiques des protons du cycle et du méthyle. Cette conclusion contredit les interprétations antérieures du moment dipolaire, des paramètres de la rmn et des données infrarouges des solutions dans le CCl_4. Les données actuelles montrent que les formes *O-syn* et *O-anti* du composé sont présentes approximativement en proportions égales.

Introduction

The stereospecificity of the long-range coupling over five bonds, $^5J_m^{H,CHO}$, between the aldehydic proton and the ring proton in the *meta* position of benzaldehyde is documented (1–6). For example, in conformation **1***a* of 2-methylthiobenzaldehyde, **1**, the available evidence from a host of other *ortho* substituted benzaldehyde derivatives implies that ^5J vanishes for H-5 and may approach 1 Hz for H-3; with a corresponding reversal in **1***b*. In benzaldehyde itself, $^5J_m^{H,CHO}$ is 0.38 Hz (7), implying ^5J as 0.76 Hz to H-3 and 0.00 Hz to H-5 in the hypothetical rigid form **1***a*.



1*a* **1***b*

Small intrinsic substituent perturbations of $^5J_m^{H,CHO}$ may occur (5). Thus, in 2-methoxybenzaldehyde, $^5J_m^{H,CHO}$ to H-5 is 0.83 Hz (4), indicating also that the *O-anti* conformer is by far the most abundant in solution.

Because the barrier to internal rotation of the aldehyde group in benzaldehyde is at least 31 kJ/mol in solution (8), discussion in terms of a planar conformation is an adequate approximation. It follows that experimental values for $^5J_m^{H,CHO}$ in nonplanar conformations are not available. By analogy to other (9–11) $^5J_m^{H,XH}$ magnitudes and their theoretical conformational dependence, however, a finite $^5J_m^{H,CHO}$ is anticipated for all nonplanar aldehydic conformations.

If $^6J_p^{H,CHO}$ contains a substantial $\sigma-\pi$ component, then its magnitude will increase as $\sin^2\theta$ where θ is the angle by which the CHO plane twists out of the benzene plane. Indeed, significant magnitudes are observed for *ortho* disubstitution by chlorine or nitro moieties (12).

In view of these remarks, it is puzzling that no $^5J_m^{H,CHO}$ was observed for **1** in CCl_4 or acetone (13, 14) and that the apparent absence of the coupling was interpreted as evidence for a nonplanar conformation of **1**. A discussion (13) of the dipole moment and infrared spectrum of **1** came to the same conclusion.

It is shown below that **1** exists in CCl_4 solution in similar proportions of **1***a* and **1***b* and that *all* heavy atoms are effectively coplanar.

Experimental

Compound **1** was prepared from 2-methylthiobenzyl alcohol (Maybridge) by the method of Pratt and van de Castle (15) as adumbrated by Traynelis and Borgnaes (16). A 4 mol% solution of **1** in CCl_4, containing ca. 4 mol% of tetramethylsilane (TMS), was filtered into a 5 mm od nmr tube. The solution was thoroughly degassed by the freeze–pump–thaw procedure and was then flame-sealed into the nmr sample tube.

The ^{1}H nmr spectrum was calibrated in the frequency sweep mode on an HA100 spectrometer at a probe temperature of 305 K. The calibration procedure was recently described (17) and gave root-mean-square deviations of $\leq$0.02 Hz for the peak frequencies. Calibrations of the ring and aldehydic protons were carried out while decoupling the methyl protons, which couple to all ring protons.

Results and discussion

Spectral analysis

The LAME (18, 19) procedure, in which 80 of 84 calculated transitions with relative intensities above 0.05 were assigned to observed peaks, gave the spectral parameters in Table 1. As an example of the spectral quality, the observed and calculated spectrum of the aldehydic proton is displayed in Fig. 1. No coupling between the aldehydic and the methyl protons could be detected by double irradiation.

The conformation of the carbonyl group

The sum of the $^5J_m^{H,CHO}$ values in Table 1 is 0.82 Hz. If it is assumed that $^5J_m^{H,CHO}$ is solely determined by the stereospecificities discussed above, then the equilibrium constant for **1***b*/**1***a* is $^5J_5^{H,CHO}/^5J_3^{H,CHO}$ or 0.486/0.335. Hence, the population ratio is 59:41 to the advantage of **1***b*, the *O-anti* conformer.

An alternative, somewhat extreme, assumption has $^5J_3^{H,CHO}$ as the intrinsically perturbed parameter (the SCH_3 group is attached to the coupling pathway). That is, if **1** existed as **1***a*, $^5J_5^{H,CHO}$ would be 0.38 Hz, as in benzaldehyde; and if **1** were in

TABLE 1. The ^{1}H nmr spectral parameters for a 4 mol% solution of 2-methylthiobenzaldehyde in CCl_4 at 305 K

Parameter[a]	Value	Parameter[a]	Value
ν_{CHO}	1026.722(2)[b,c]	$^5J_3^{H,CHO}$	0.335(4)
ν_{CH_3}	245.025	$^5J_5^{H,CHO}$	0.486(3)
ν_3	727.620(3)	$^6J_p^{H,CHO}$	−0.032(4)
ν_4	743.104(3)	$^5J_o^{H,CH_3}$	−0.341
ν_5	720.149(3)	$^6J_4^{H,CH_3}$	±0.04 ± 0.01
ν_6	773.884(2)	$^7J_5^{H,CH_3}$	±0.05 ± 0.01
$^3J_{34}$	8.026(4)	$^6J_6^{H,CH_3}$	±0.06 ± 0.01
$^3J_{45}$	7.323(4)	Peaks observed	63
$^3J_{56}$	7.674(4)	Peaks calculated	84
$^3J_{35}$	1.078(3)	Peaks assigned	80
$^4J_{46}$	1.614(4)	Largest difference	0.02 Hz
$^5J_{36}$	0.476(4)	Root-mean-square	
$^4J_o^{H,CHO}$	−0.175(3)	deviation	0.008 Hz

[a]Chemical shifts are in Hz at 100.001 MHz to low field of internal TMS.
[b]The numbers in parentheses are the standard deviations in the last significant figures.
[c]An analysis based on peak positions obtained while decoupling the methyl protons.

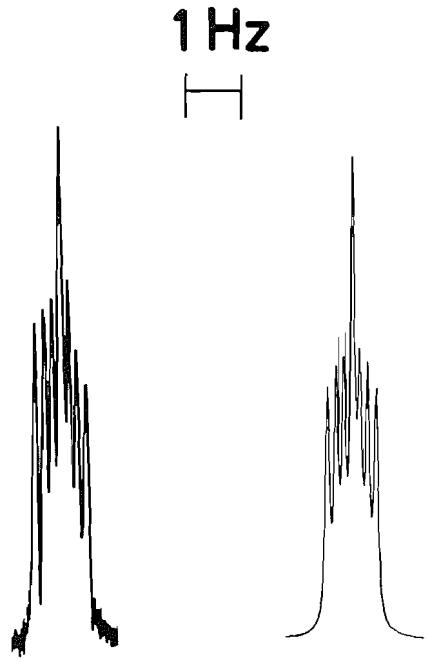

FIG. 1. The observed ^{1}H nmr spectrum at 100 MHz of the aldehydic proton of 2-methylthiobenzaldehyde is compared with that calculated with the parameters in Table 1. It is quite clear that the aldehydic proton couples to at least three ring protons. Decoupling experiments indicate very small or zero couplings between the methyl and aldehydic protons.

form **1***b*, $^5J_3^{H,CHO}$ would be 0.44 Hz. The sum of the two couplings would then equal 0.82 Hz as observed for **1**. In that event, one would write the equilibrium constant above as 0.38/0.335 or as 0.486/0.44, yielding the population ratio of **1***b* to **1***a* as 53:47.

The two approaches represent the limits of this ratio, suggesting an estimate of 56 ± 3:44 ± 3. The measurement errors themselves fall within the suggested range.

The question of the coplanarity of the carbonyl and benzene planes can be approached as follows. $^6J_p^{H,CHO}$ in **1** is apparently −0.03 Hz, the same as quoted for benzaldehyde (7). Whether these numbers are significant or not, if benzaldehyde is considered a planar molecule, then **1** must also have the aldehydic function in the benzene plane. As the carbonyl group takes on nonplanar conformations $^6J_p^{H,CHO}$ increases in magnitude, becoming −0.21(2) Hz in 2,6-dinitrobenzaldehyde and −0.15 (2) Hz in the 2,6-dichloro derivative (12). Whatever the twist angle in the latter two compounds, it is clear that **1** behaves more like benzaldehyde itself.

The conformation of the thiomethyl group

A detailed investigation of the long-range couplings of the methyl protons in 2,5-dichlorothioanisole (20) yields −0.35(1) Hz for the coupling to the *ortho* ring proton, $^5J_o^{H,CH_3}$. This coupling originates in a proximate manner, involving spin polarization via interactions of the electrons in the bonds containing the coupled nuclei. Its magnitude drops off rapidly as the SCH_3 group twists out of the benzene plane. In fact, in 2-hydroxythioanisole, where the C—S—C plane is held roughly perpendicular to the benzene plane by stereospecific hydrogen bonding to the 3*p* lone pair on sulfur, no $^5J_o^{H,CH_3}$ is observable (21). In **1**, $^4J_o^{H,CH_3}$ is −0.34(1) Hz, implying an effectively coplanar orientation of the benzene and SCH_3 skeletons.

Additional evidence comes from the ring proton shifts in **1**. The 3*p*. . .π conjugation in thioanisole and thiophenol is not very strong, the barrier to internal rotation about the C1—S bond being only about 3.3 kJ/mol (22, 23). The ring proton shifts reflect the extent of conjugation and are the same for the two compounds to within 0.02 ppm (24, 25). In **1**, the coplanar conformation of the SCH_3 group will be favored by the presence of the carbonyl function. Hence the π electron densities at C-3 and C-5 in **1** should increase, reflecting the increased π electron donation by SCH_3. On an additive basis, the observed shifts in benzaldehyde (26) and thioanisole (25), together with δ_H as 7.25 for benzene in CCl_4, imply δ_3, δ_4, δ_5, and δ_6 as 7.36, 7.43, 7.24, and 7.70 respectively. The observed shifts display excess high field shifts of 0.08 and 0.04 ppm at H-3 and H-5, respectively, consistent with increased π electron density at the sites *ortho* and *para* to SCH_3 and therefore with an increased tendency towards planarity of this substituent. The additive scheme predicts δ_4 as 7.43, observed as 7.43; and δ_6 as 7.70, whereas the observed value is 7.74. In view of concentration differences for the three compounds in CCl_4, it may be concluded that the ring proton shifts are consistent with a preferred coplanar conformation of the SCH_3 fragment.

The chemcial shift of the methyl protons in **1** is 2.45 ppm, is 2.44 ppm in thioanisole (25), and 2.43 ppm in 2,5-dichlorothioanisole (20). In contrast, it is 2.27 ppm in 2-hydroxythioanisole and, as shown previously (21), reflects the upfield shift caused by the magnetic anisotropy of the benzene nucleus in the perpendicular conformation. Accordingly, and allowing for small shifts caused by electronic perturbations by the substituent (21), δ_{CH_3} in **1** is consistent with a coplanar conformation of the SCH_3 group.

Other long-range couplings to methyl protons

In 2,5-dichlorothioanisole, in which the SCH_3 group prefers the benzene plane, the methyl protons couple significantly to all the ring protons. In 2-hydroxythioanisole, the SCH_3 fragment prefers a plane perpendicular to that of the ring and the methyl protons are appreciably coupled to H-3 and H-5 only (21). In **1**, the methyl protons do couple to all ring protons (Table 1), indicating a preferred planar conformation.

Carbonyl–sulfur interactions

The relative populations of the *O-syn* and *O-anti* conformers of **1** are very similar to those for 2-methylbenzaldehyde at the same temperature and in the same solvent (6). By way of contrast, there is no evidence for other than the *O-anti* conformation in 2-methoxybenzaldehyde, and 2-chlorobenzaldehyde appears to be at least 96% in the *O-anti* form (4). Considering the sizes of these substituents and the dipole moments of the C—Cl and C—O bonds in these two compounds, it appears reasonable that the significant population of the *O-syn* form of **1** can be attributed to a favorable dipole–dipole attraction of the C=O and C—S bonds which, to some extent, may overcome unfavorable steric repulsions. Because the sulfur atom is relatively polarizable, the favorable interaction may be predominantly of the dipole-induced dipole kind. In the corresponding tellurium compound, the *O-anti* form apparently predominates (14), suggesting steric repulsions as predominant.

Received July 5, 1982

TED SCHAEFER, RUDY SEBASTIAN, RICHARD P. VEREGIN, and REINO LAATIKAINEN. Can. J. Chem. **61**, 29 (1983).

A complete analysis of the ^{1}H nmr spectrum of 2-fluorotoluene yields $^4J_o^{F,CH_3}$, the spin–spin coupling constant between ^{19}F and the methyl protons, as 1.99 Hz. Analysis of nmr spectra of 21 other derivatives of 2-fluorotoluene shows that $^4J_o^{F,CH_3}$ can vary between 1.69 and 2.55 Hz. This strong dependence on substitution contrasts with the near invariance of other long-range couplings such as $^4J_o^{H,CH_3}$, $^6J_p^{H,CH_3}$, and $^5J_m^{F,CH_3}$. The substituent dependence is discussed in terms of coupling mechanisms. INDO MO FPT calculations of $^4J_o^{F,CH_3}$ are inadequate. By means of appropriate model compounds, an adequate empirical conformational dependence is deduced for $^4J_o^{F,CH_3}$, which can be used to reproduce some observed couplings. INDO MO FPT computations, in which certain off-diagonal Fock matrix elements are suppressed, are used to show that spin polarization via interacton of the methyl hydrogen orbitals is a major source of the discrepancy between theory and experiment. Some STO 3G MO calculations are reported for 2-fluorotoluene conformations.

TED SCHAEFER, RUDY SEBASTIAN, RICHARD P. VEREGIN et REINO LAATIKAINEN. Can. J. Chem. **61**, 29 (1983).

Une analyse complète du spectre de rmn du ^{1}H du fluoro-2 toluène fournit la constante de couplage spin–spin entre le ^{19}F et les protons du méthyle, $^4J_o^{F,CH_3}$ = 1,99 Hz. L'analyse des spectres de rmn de 21 autres dérivés du fluoro-2 toluène montre que $^4J_o^{F,CH_3}$ peut varier entre 1,69 et 2,55 Hz. Cette forte influence de la substitution contraste avec la quasi invariance des autres couplages à longue distance tels: $^4J_o^{H,CH_3}$, $^6J_p^{H,CH_3}$ et $^5J_m^{F,CH_3}$. On discute de l'influence des substituant en fonction des mécanismes de couplage. Les calculs INDO MO FPT de $^4J_o^{F,CH_3}$ ne sont pas adéquats. Au moyen d'un composé modèle approprié, on a déduit une influence conformationnelle empirique adéquate pour $^4J_o^{F,CH_3}$ qui peut être utilisée pour reproduire quelques-uns des couplages observés. On a utilisé des calculs INDO MO FPT dans lesquels on a supprimé certains éléments de la matrice de Fock hors diagonale pour montrer que cette polarisation de spin par l'intermédiaire des orbitales des hydrogènes du méthyle est la cause principale de cette différence entre la théorie et l'expérience. On rapporte quelques calculs d'OM STO 3G sur les conformations du fluoro-2 toluène.

[Traduit par le journal]

Introduction

Some of the spin–spin coupling constants between ring protons or ^{19}F nuclei and methyl protons are satisfactorily interpreted in terms of σ and σ–π electron coupling mechanisms (1–8). For example, $^6J_p^{H,CH_3}$ is a σ–π coupling, is insensitive to intrinsic (electronic) perturbations by ring substituents, and has a simple conformational dependence (1). In consequence, $^6J_p^{H,CH}$ has proved useful in deductions of conformational preferences, and of small barriers, about the exocyclic C—C bond in benzyl and benzal compounds (9). $^6J_p^{F,CH_3}$ can also be discussed in terms of a predominant σ–π mechanism (3), while $^5J_m^{F,CH_3}$ can be rationalized as a composite of σ and σ–π coupling mechanisms (8).

$^4J_o^{F,CH_3}$ is relatively large in magnitude (6), positive in sign (6), and may contain a third component, the so-called "through-space" contribution (10–14). Here this mechanism for the transmission of nuclear spin state information will be called the proximate component. INDO MO FPT computations (12), although in decent agreement with experiment for $^6J_p^{F,CH_3}$ (3) and $^5J_m^{F,CH_3}$ (8), apparently (14) overemphasize the proximate and/or σ mechanisms in 2-fluorotoluene.

In this paper, precise analyses of the ^{1}H nmr spectra of 2-fluorotoluene and 21 of its derivatives are reported. The results are examined for evidence concerning the relative importance of the three coupling mechanisms, the qualitative veracity of the INDO prediction of the conformational dependence of $^4J_o^{F,CH_3}$, and the reliability of some unexpected coupling magnitudes in the literature (15).

It turns out that, among the couplings mentioned above, $^4J_o^{F,CH_3}$ is unique in its large sensitivity to substituent perturbations and in that standard INDO MO FPT approaches fail in the reproduction of its conformational dependence. The latter is observed for defined dihedral angles by the use of 2,6-difluoroisopropylbenzene, 2-chloro-6-fluoroisopropylbenzene, and of 2,6-difluoroethylbenzene. The coupling mechanism is examined within the INDO MO approximation by the approach of Barfield (16), in which the development of spin polarization is repressed for certain nonbonded pathways.

Experimental

The compounds were mainly of commercial origin. The 3,5-dibromo, the 4,6-dibromo, and the 5-amino-4,6-diiodo derivatives of 2-fluorotoluene were prepared from the amino precursors in the obvious way. The deamination of the diiodo compound proved unsuccessful. The 4,5-dinitro and the 4,6-dinitro derivatives were made by nitration of 4-nitro-2-fluorotoluene. The synthesis of the 4-carbonyl fluoride derivative has been described (17). The 6-nitro and 6-amino derivatives were obtained via standard diazotization and reduction procedures from 2-amino-6-nitrotoluene. The 6-fluoro derivative appeared on reduction of 2,6-difluorobenzyl bromide with tri-n-butyl tin hydride. The 2,6-difluoroisopropylbenzene and 2-chloro-6-fluoroisopropylbenzene were synthesized from the corresponding carboxylic acids by methods recently described (18, 19), as was 2,6-difluoroethylbenzene from the acetophenone precursor (18). All compounds gave satisfactory mass spectra and characteristic ^{1}H nmr spectra.

The compounds were prepared as dilute solutions (see tabular data),

TABLE 1. Spectral parameters for a 9.9 mol% solution of 2-fluorotoluene, **1**, in CS_2 at 305 K

Parameter	Value[a]		Parameter	Value	
ν_{CH_3}[b]	—	220.205(2)	$^5J_{5F}$	−0.250(17)	−0.233(4)
ν_3	684.042(8)[c]	683.732(2)	$^4J_o^{H,CH_3}$	—	−0.779(2)
ν_4	701.940(9)	701.601(2)	$^5J_{m3}^{H,CH_3}$	—	0.401(2)
ν_5	689.940(10)	689.602(2)	$^5J_{m5}^{H,CH_3}$	—	0.352(2)
ν_6	703.917(9)	703.624(2)	$^6J_p^{H,CH_3}$	—	−0.603(2)
$^3J_{3F}$	9.748(14)	9.731(3)	$^4J_o^{F,CH_3}$	—	1.990(3)
$^3J_{34}$	8.188(13)	8.195(3)	$^3J_{45}$	7.423(13)	7.432(3)
$^4J_{35}$	1.226(11)	1.220(2)	$^3J_{56}$	7.529(13)	7.520(3)
$^4J_{46}$	1.782(10)	1.780(2)	Transitions		
$^4J_{4F}$	5.159(15)	5.186(4)	Calculated	86	646
$^4J_{6F}$	7.738(16)	7.723(4)	Assigned	76	581
$^5J_{36}$	0.344(13)	0.343(3)	rms deviation	0.028	0.017

[a]The first column refers to a calibration for which the CH_3 protons are decoupled.
[b]The shifts are in Hz at 100.001 MHz to low field of internal tetramethylsilane; the Bloch–Siegert shift is evident for the decoupled spectrum.
[c]The numbers in parentheses are the standard deviations in the least squares LAME analysis.

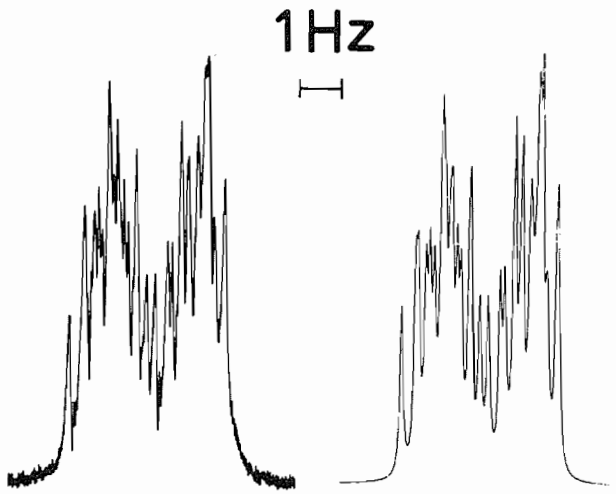

FIG. 1. The observed and calculated methyl proton ^{1}H nmr spectrum at 100 MHz of a 10 mol% solution of 2-fluorotoluene in CS_2 solution at 305 K. The calculated spectrum assumes the parameters in Table 1.

preferably in CS_2, containing ca. 4 mol% tetramethylsilane. The solutions were degassed by the freeze–pump–thaw technique and were flame-sealed into 5 mm od nmr tubes.

The ^{1}H nmr spectra were recorded in the frequency sweep mode on an HA100 spectrometer at a probe temperature of 305 K. Calibration procedures followed those described in detail recently (20). Interpolated peak frequences relative to TMS had standard deviations ≤0.02 Hz. Relative signs of coupling constants were found by weak multiple irradiation experiments (21). The spectral acquisitions for 2,6-difluoroisopropylbenzene and 2,6-difluoroethylbenzene have been described (18), those for 2-chloro-6-fluoroisopropylbenzene being done in the same way.

Calculations at the STO 3G (22) and INDO MO FPT (23) levels of molecular orbital theory were performed on an Amdahl 470/V7 system.

Results and discussion

Spectral analyses

Using the computer program LAME (24, 25), the spectral parameters for 2-fluorotoluene were extracted and are given in Table 1. Figure 1 displays the calculated and observed spectra for the methyl protons in 2-fluorotoluene. The program NUMARIT (26) was employed in the analysis of the spectra from the large spin systems, e.g., from the 6-methyl and 3-methyl derivatives and from 2,6-difluoroisopropylbenzene. The computer program MAOCON (27) was also utilized in some instances. The number of assigned transitions was as large as 1125 in one of these analyses.

In Table 2, the coupling constants of immediate interest in this paper are reported for 22 compounds. If an accuracy of 3 times the standard deviation in the parameters is assumed (99% confidence limits), the long-range couplings are known to an accuracy of at least 0.02 Hz and to 0.01 Hz in a substantial number of instances.

The couplings from ^{19}F to the methine and methylene protons in the isopropyl and ethyl compounds are quoted at the appropriate points in the text, and do not appear in Table 2.

It may be noted that $^5J_p^{H,F}$ in 4-iodo-2-fluorotoluene is −0.66 Hz, not 0.46 Hz as previously (15) reported and that, in the 6-chloro derivative $^5J_m^{H,CH_3}$ is 0.45 Hz for H-3 and 0.40 Hz for H-5, while $^6J_p^{H,CH_3}$ is −0.62 Hz. These three numbers are unexceptional and quite different from those in the literature (15), where they are given as <0.06 Hz in magnitude.

The substituent dependence of $^4J_o^{F,CH_3}$

First, note that $^6J_p^{H,CH_3}$ for the compounds in Table 2 is essentially the same as the −0.62 Hz in toluene (28). This coupling is calculated (1) and observed (2, 7) to be proportional to $\langle\sin^2\theta\rangle$, the expectation value of $\sin^2\theta$, where θ is the angle by which the methyl C—H bond twists out of the ring plane. In other words, $^6J_p^{H,CH_3}$ is dominated by a σ−π mechanism which is insensitive to the presence of the ring substituents. Second, $^4J_o^{H,CH_3}$ for the compounds in Table 2 is also remarkably insensitive to the ring substituents and scarcely different from the −0.75 ± 0.03 Hz in toluene (28). $^4J_o^{H,CH_3}$ is also predominantly a σ−π coupling although a small σ component is likely (1).

The near invariance of these two couplings contrasts with $^4J_o^{F,CH_3}$, which ranges from 1.69 Hz in the 6-amino to 2.55 Hz in the 5-amino-4,6-diiodo dervative. In terms of the coupling model, there arises the question whether the variation in $^4J_o^{F,CH_3}$ can be attributed to a substituent perturbation of one or more of the three coupling mechanisms. In this paper, the aim is not the establishment of correlations between $^4J_o^{F,CH_3}$ and the plethora of

[a]Compound **1** is 2-fluorotoluene, positions of *additional* substituents being indicated for subsequent entries.

[b]The parentheses give the mol% concentration in CS_2 solution, also containing about 4 mol% of TMS.

[c]A 6 mol% solution in C_6D_{12} had δ_{CH_3} as 2.068 and $^4J^{F,CH_3}$ as 1.858(5) Hz.

[d]For a 5 mol% solution in C_6D_6, full analysis of ^{19}F nmr spectrum included.

[e]A 4.5 mol% solution CCl_4 gave the coupling parameters as listed and δ_{CH_3} as 2.146.

[f]For a 9.5 mol% solution in $CDCl_3$.

[g]11.7 mol% in CCl_4.

[h]5 mol% in CCl_4.

[i]Numbers in parentheses are standard deviations in the last significant figure.

[j]Because of the nature of the spin system, the sum of $^4J^{H,CH_3}$ and $^6J^{H,CH_3}$ is the reliable parameter.

[k]A 5 mol% solution in $CDCl_3$ gave 2.569(3) Hz. A 2 mol% solution in $CDCl_3$ gave 2.54 Hz at 400 MHz.

[l]$^5J_m^{F,CH_3}$ is −0.232(1) Hz. A full analysis of the ^{19}F spectrum for a 10 mol% solution in $(CD_3)_2C{=}O$ gave $^5J_m^{F,CH_3}$ as −0.212(1) Hz, $^4J_o^{F,CH_3}$ as 2.231(1) Hz, and $^5J_p^{H,CH_3}$ as −0.622(1) Hz.

[m]$^5J_m^{F,CH_3}$ is −0.251(5) Hz and $^5J_p^{F,CH_3}$ is 1.384(5) Hz. The ^{19}F nmr spectrum was not analyzed.

substituent parameters which have been used in many attempts at the interpretation of nmr chemical shifts (see, for example, refs. 29, 30, and 31). Rather, certain chemical shifts may be useful as indicators of an approach to the rationalization of the variation of $^4J_o^{F,CH_3}$ and to an eventual use of this coupling in conformational problems.

Now δ_{CH_3} in *para*, *meta*, and *ortho* derivatives of toluene is sensitive to the usual substituent parameters meant to describe the changes induced in σ and π electron distributions in benzene derivatives (32, 33), and is *not* sensitive to peculiar "ortho" or "heavy-atom" parameters (33). Figure 2 displays an illustrative plot[2] of $^4J_o^{F,CH_3}$ versus δ_{CH_3} for 18 of the compounds in Table 2.

Given that δ_{CH_3} is a rough measure of the electron density at the methyl site or at its contiguous carbon atom, the changes in δ_{CH_3} and $^4J_o^{F,CH_3}$ caused by *ortho* and *para* amino or nitro substituents are indicative of an electron density dependence of these parameters (points 2, 3, 11, 15, 16, 18, and Fig. 2). An amino group causes a negative shift in $^4J_o^{F,CH_3}$ and a nitro substituent causes a positive shift. Now, it is known that the hyperfine interaction parameter, Q_{CCH}, in radicals depends on the electron density (charge) on the contiguous carbon atom, decreasing as the electron density increases (34). The σ−π component of $^4J_o^{F,CH_3}$ is proportional to Q_{CCH} in the spin polarized molecule (1, 3). Because the amino group is a π electron donor, the decrease of $^4J_o^{F,CH_3}$ in the 4- and 6-amino derivatives (points 2 and 16) is consistent with the apparent properties of Q_{CCH}, as are the increases in the 4- and 6-nitro derivatives (points 3, 15, and 18).

However, the situation is really more complicated because $^4J_o^{H,CH_3}$ and $^6J_p^{H,CH_3}$ are also proportional to Q_{CCH} and would be expected to reflect the changes in Q_{CCH} suggested by the magnitudes of $^4J_o^{F,CH_3}$. As can be seen in Table 2, this expectation is not confirmed. Of course, the σ−π component of $^4J_o^{F,CH_3}$ is also proportional to the hyperfine parameter Q_{CF}, which may vary with the amount of formal double bond character in the C—F bond (6). The coupling is less sensitive to an amino substituent placed *para* to fluorine rather than *para* to methyl. However, 4-nitro and 5-nitro substituents cause the same increase in $^4J_o^{F,CH_3}$.

The σ−π contribution to $^4J_o^{F,CH_3}$ is also proportional to the reciprocal of a mean excitation energy to appropriate triplet states (35). Again, it is difficult to see why substituent-induced

[2]δ_{CH_3} should really be measured at infinite dilution, not at the roughly 10 mol% concentration in CS_2 of most of the compounds. For our purposes the present values are sufficiently accurate (see footnotes in Table 2).

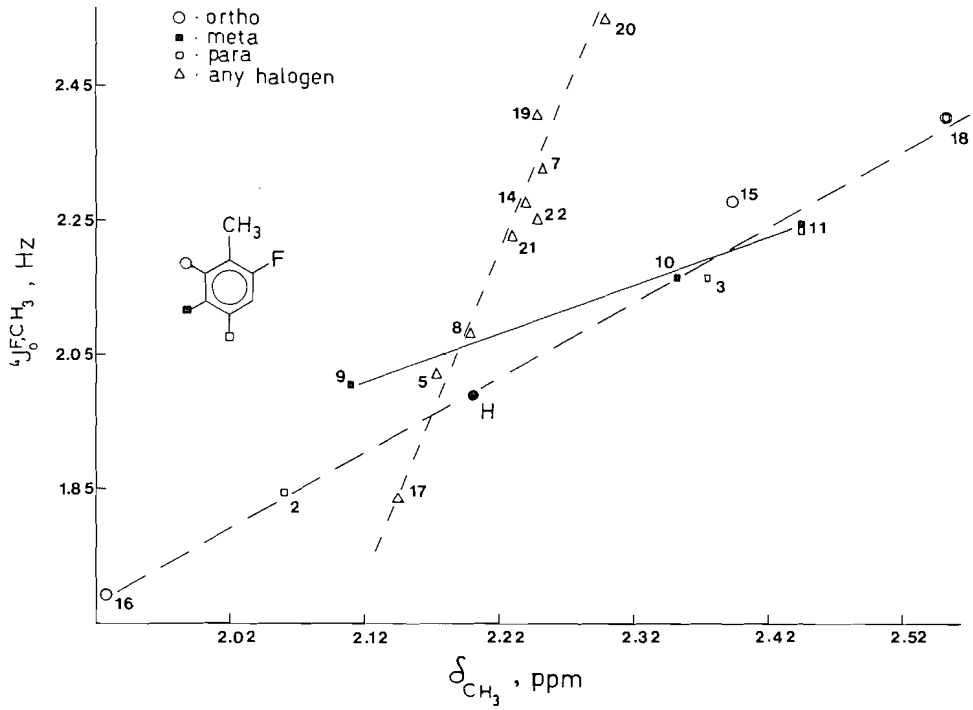

FIG. 2. $^4J_o^{F,CH_3}$ is plotted versus the chemical shift of the methyl protons for a series of 2-fluorotoluene derivatives. The substituents indicated as *ortho*, *meta*, or *para* are amino and nitro groups. The triangles identify *any* derivative containing one or more halogen substituents and may also contain other substituents. Note that a substituent placed *meta* to methyl is *para* to fluorine. Point 8 is for 5-Br, so that it could also be indicated as a solid square. The points are numbered as in Table 2.

changes in this excitation energy should leave $^6J_p^{H,CH_3}$ or $^4J_o^{H,CH_3}$ relatively constant, while perturbing $^4J_o^{F,CH_3}$ substantially.

The situation is further complicated by the trends in $^4J_o^{F,CH_3}$ for the halogen-substituted 2-fluorotoluene derivatives (Fig. 2). Over a range of only 0.15 ppm in δ_{CH_3}, $^4J_o^{F,CH_3}$ changes by 0.7 Hz. Part of this variation is probably conformationally determined (see below). Some of the variation must surely be an intrinsic electronic perturbation, unique to halogen substituents. Yet the perturbation is again such that Q_{CCH} and Q_{CH} and their associated triplet energies do not change much or do so in a compensatory manner. For example, $^6J_p^{H,CH_3}$ in symtetrafluorotoluene remains at -0.62 Hz, its value in toluene. However, in pentafluorotoluene (point 22 in Table 2) $^6J_p^{F,CH_3}$ is 1.38 Hz, about 0.25 Hz larger than in 4-fluorotoluene (3, 36), the amount by which $^4J_o^{F,CH_3}$ increases in the former compound relative to 2-fluorotoluene. These comparisons suggest variations in Q_{CF} as a cause of the changes in $^4J_o^{F,CH_3}$ in the halo derivatives.

No doubt $^4J_o^{F,CH_3}$ would correlate with other shift parameters for related molecules. For example, $^4J_o^{F,CH_3}$ for compounds **14**, **17**, **19**, and **20** (containing F, Cl, Br, and I *ortho* to CH_3) correlates well with $\delta_{C\text{-}1}$ in 2-halotoluenes (37). The latter also correlate well with "virtually all measureable liquid and/or vapor phase properties of halogen-containing molecules" (30). As indicated by Bailey and Wiberg (30), this fact may be related to the dominant role of the polarizability of the halogen containing molecules. Note that the largest $^4J_o^{F,CH_3}$ is found for compound **20**, containing two iodine substituents.

A partial resolution of these puzzles is provided by our previous data on methyl derivatives of the fluoropyridines (38). In these compounds $^6J_p^{H,CH_3}$ retains its value in toluene and the heteroatom also perturbs $^6J_p^{F,CH_3}$ only slightly. A good example among the eleven compounds is 2,6-dimethyl-3-fluoropyridine. Here $^6J_p^{H,CH_3}$ is $-0.59(2)$ Hz and $^6J_p^{F,CH_3}$ is 1.21(2) Hz. These two π electron dominated couplings are not appreciably perturbed by nitrogen. However, $^4J_o^{H,CH_3}$ is -0.52 Hz, substantially lower in magnitude than in toluene, and $^4J_o^{F,CH_3}$ is 3.03 Hz, 50% larger than in 2-fluorotoluene. The discussion in ref. 38 concluded that substantial polarization of the σ-core near C-2 and C-6 by the electronegative heteroatom caused changes in the σ electron contributions to $^4J_o^{H,CH_3}$ and $^4J_o^{F,CH_3}$.

With these facts in mind, comparison of all the long-range coupling data in Table 2 strongly suggests that much of the variation in $^4J_o^{F,CH_3}$ arises from changes in the σ electron contribution and/or in the proximate mechanism. It would be difficult and perhaps pointless to attempt a disentanglement of these two mechanisms. The data do indicate that changes in the π electron distribution will cause changes in, i.e. polarize, the σ-electron distribution. The latter are then reflected in changes in $^4J_o^{F,CH_3}$, as for the amino and nitro derivatives.[3]

In addition, $^4J_o^{F,CH_3}$ must also display a conformational dependence, unless the θ dependence of the σ electron/proximate component is independent of θ or behaves like the $\sigma-\pi$ component. The conformational dependence is now to be demonstrated. This will show that some of the changes in $^4J_o^{F,CH_3}$ for the 6-substituted derivatives very likely arise from the latter.

Empirical conformational dependence of $^4J_o^{F,CH_3}$

$^6J_p^{H,CH_3}$ in toluene is given by $-1.24\ \langle\sin^2\theta\rangle$ Hz (1, 9). Because the sixfold barrier is only 59 J/mol (41), the expectation value of $\sin^2\theta$ is 0.5 and $^6J_p^{H,CH_3}$ is observed and

[3]It appears that the nitro group withdraws "a constant amount of electron density from the ring regardless of what substituent is attached to the *meta* and *para* position" (39). Compare points 3 and 10 in Fig. 2, but see also ref. 40.

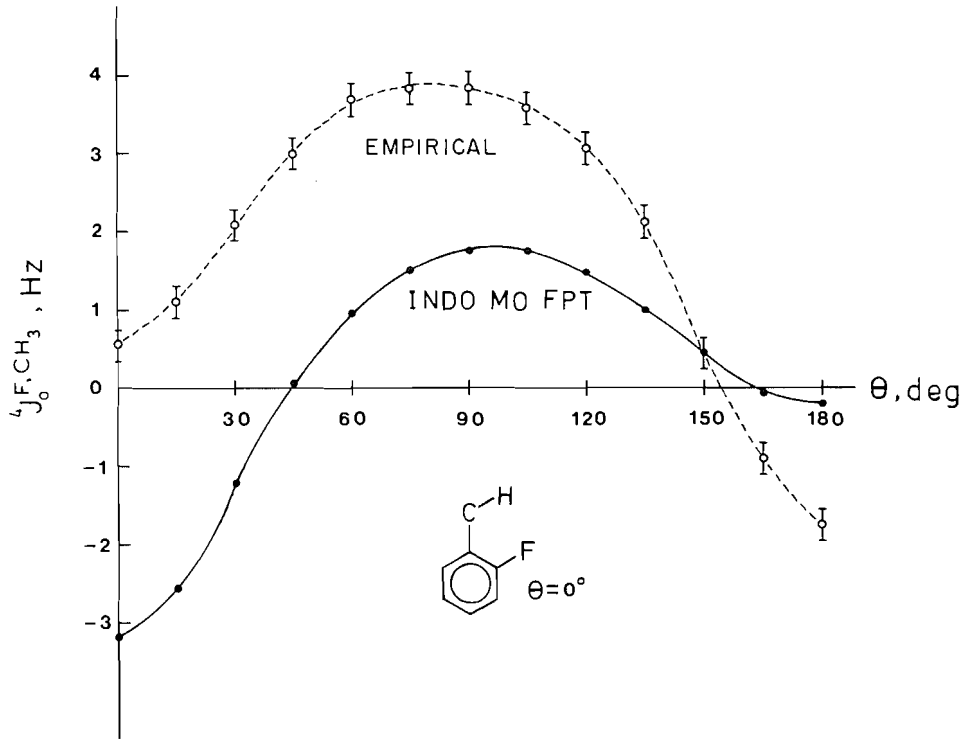

FIG. 3. The INDO MO FPT values for $^4J_o^{F,CH_3}$ in 2-fluorotoluene (14) are plotted versus the angle θ, as defined in the figure. At θ = 180° the C—H bond lies *trans* to the C—F bond and in the benzene plane. The upper curve shows the empirical couplings given in Table 3. This curve gives the correct "observed" couplings at θ = 0°, 30°, 150°, and 180° and also the experimental average value of $^4J_o^{F,CH_3}$. The error bars are meant to indicate that a coupling for a given conformation is reliable to about 0.2 Hz.

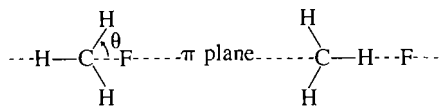
calculated by INDO MO FPT to be −0.62 Hz. The angle θ measures the out-of-plane twist of the C—H bond in the methyl group. This σ−π coupling mechanism yields $^6J_p^{H,CH_3}$ as −0.62 Hz, whatever the conformational preference of the methyl group, as follows from an average of $\sin^2\theta$ for the three C—H bonds in the methyl group. In 2-fluorotoluene, for example, **1**



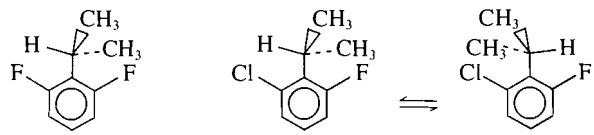
1 **2**

is favored over **2** (threefold barrier) by 2.7 ± 0.6 kJ/mol (42) but $^6J_p^{H,CH_3}$ remains the same as in toluene (Table 2).

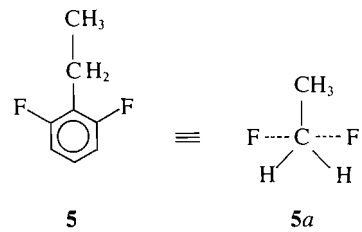
In 4-fluorotoluene, $^6J_p^{F,CH_3}$ is also dominated by a σ−π mechanism (1, 3). The INDO values (1) agree with this mechanism but underestimate its magnitude by about 0.2 Hz or 20%.

Now, the INDO MO FPT curve in Fig. 3 clearly suggests the presence of a σ−π component, varying as $\sin^2\theta$, but that other components cause a distortion. The average of the computed values is only 0.13 Hz. In 2,6-difluorotoluene, $^4J_o^{F,CH_3}$ is 1.84 Hz and, because the internal barrier is now sixfold and therefore very small, is near the number expected from a faithful theoretical value. Naturally, as follows from the discussion in the previous section, an intrinsic substituent perturbation from the good π donor fluorine (compare amino in Table 2) should reduce the average coupling somewhat (ca. 0.1 Hz) from its magnitude in a hypothetical 2-fluorotoluene with a vanishing internal rotational barrier.

An empirical approach to the θ dependence of $^4J_o^{F,CH_3}$ is provided by the measurement of $^4J_o^{F,CH}$ in **3**, **4**, and **5**. In **3** the twofold barrier to rotation about the sp^2-sp^3 carbon–



3 **4*a*** **4*b***



5 **5*a***

carbon bond is not less than 24 kJ/mol (18) and $^4J_o^{F,CH}$ is −0.60(1) Hz. At 180 K, rotation about the exocyclic carbon–carbon bond in **4** is slow enough so that two ^{19}F peaks can be observed. If it is assumed that there is no entropy difference between **4*a*** and **4*b***, admittedly somewhat unlikely, then the population of **4*a*** at 305 K can be extrapolated as 12%. If the stereospecific five-bond couplings, $^5J_m^{H,CH}$, in **4** at 305 K are used to obtain the populations of **4*a*** and **4*b*** as recently done for another molecule (43), then the population of **4*a*** is 24%. The latter is an overestimate, for reasons to be discussed in future. The free energy barrier to interconversion of **4*a*** and **4*b*** is not less than 41 kJ/mol (unpublished work in this laboratory). $^4J_o^{F,CH}$ in **4** is −1.33(1) Hz.

Because the internal barriers in both **3** and **4** are substantially larger than *kT* at 305 K, it is reasonable to derive $^4J_o^{F,CH}$ values for θ = 0° and 180° from the coupling data above. Assuming

For personal use only.

the population of **4***a* as 18%, yields $^4J^{F,CH}$ as 0.54 Hz at $\theta = 0°$ and as -1.74 Hz at $\theta = 180°$. The extremes in the population estimates suggest errors of ca. 0.25 Hz in these numbers.

Again, **5***a* is the preferred conformation of **5** to the extent of 25 ± 8 kJ/mol (18) and $^4J_o^{F,CH_2}$ is +1.29(1) Hz. Therefore, the latter can be taken as a reasonable estimate of the average of $^4J_o^{F,CH_2}$ at $\theta = 30°$ and 150°.

Unfortunately, there appears to be no clear procedure by which $^4J_o^{F,CH}$ can be measured for other angles θ, particularly at 90°. Nevertheless, the average value of $^4J_o^{F,CH_3}$ for essentially free rotation is known to within about 0.1 Hz and a $\sin^2\theta$ component is no doubt present. Accordingly, an empirical θ dependence of $^4J_o^{F,CH_3}$ is displayed in Fig. 3. The average value for this curve is 1.90 Hz, approximately midway between the values of 1.99 Hz for 2-fluorotoluene and 1.84 Hz for 2,6-difluorotoluene. The mean of the points at 30° and 150° is in fact within 0.01 Hz of the observed +1.29(1) Hz. The numbers at $\theta = 0°$ and 180° reproduce the experimental values. To allow for uncertainties in $^4J_o^{F,CH_3}$ introduced by, for example, distortions of bond angles caused by methyl substitution or by the bulky sidechain chlorine substituent in **4**, error bars are introduced into the empirical curve. Polarization of the α C—H bond by the methyl groups is apparently rather small (9, 44, 45). That $^4J_o^{F,CH}$ is indeed negative at $\theta = 180°$ is confirmed by previous work on the analogue of **4** in which the methyl groups are replaced by chlorine atoms (46).

Other tests of the empirical curve can be made as follows. A bulky substituent at position 6 should favor conformation **2** for the methyl group, although probably only by amounts comparable to *kT* (47). The mean of the couplings at $\theta = 0°$ and $\theta = 120°$ (weighted twice) is 2.22 Hz, an increase of 0.32 Hz over the value for free rotation. The data in Table 2, when allowance is made for the intrinsic electronic perturbations discussed above,[4] support this change in $^4J_o^{F,CH_3}$. In *cis* 1-fluoropropene $^4J_o^{F,CH_3}$ is +2.6 Hz (48). In this molecule the conformation analogous to **2** is favored rather strongly and, allowing for the difference in the nature of the intervening bonds, the curve in Fig. 3 can be said to be consistent with observation. The numbers defining this curve are given in Table 3.

It is clear that $^4J_o^{F,CH}$ has applications in the study of conformational preferences. It is also clear that the empirical curve in Fig. 3 should be used carefully with due attention being paid to nonconformational perturbations by substituents on the ring and/or sidechain. The latter may well amount to about 0.5 Hz in extreme cases and for certain conformations. For example, in 2,6-difluorobenzylbromide, $^4J_o^{F,CH_2}$ is 1.14(2) Hz (unpublished work in this laboratory). This value is 0.15 Hz smaller than in 2,6-difluoroethylbenzene. Part of this difference arises from the difference in electronegativity of the methyl and bromine substituents (9). Another part may be caused by the expected larger barrier to rotation about the sp^2-sp^3 carbon–carbon bond in the bromine compound. A larger barrier implies a sharper pair of θ values at 30° and 150°, implying in turn that the empirical values at these angles are in error by about 0.1 Hz.

One other test of the empirical curve in Fig. 3 is possible. The conformational dependence of four coupling constants in 2-fluorobenzyl alcohol is sufficiently well known for a comparison with conformational energy predictions from molecular orbital methods (48*a*). Such calculations were performed for 18 conformations and the prediction by STO-3G of these couplings is in good agreement with experiment. The same approach to $^4J_o^{F,CH_2}$ in 2-fluorobenzyl alcohol, observed to be 1.22(3) Hz in CS_2 solution (48*a*), yielded 1.51 Hz for the numbers in Table 3. It is very probable (48*b*) that the $\sigma-\pi$ parameter, Q_{CCH}, for a CH_2OH group lies between 85 and 90% of Q_{CCH} for a methyl group. Most of the significantly populated conformations have a significant $\sigma-\pi$ contribution to $^4J_o^{F,CH_2}$ so that a reduction of 0.1 to 0.2 Hz might well occur. Further, the weighting of coupling constants by "rigid" conformations is not rigorous (9). In any event, the present number is in much better agreement with experiment than the −0.16 Hz calculated in the same manner from the INDO curve in Fig. 3.

The empirical curve in Fig. 3 is well-defined at $\theta = 0$, 30, 150, and 180°. The area under the curve is also correct to within 0.2 Hz. The other points on the curve follow from the assumption that it be smooth and are *not* experimental points, except insofar as their average is constrained to an experimental value. The error bars are estimated by a consideration of intrinsic substituent effects, and possible distortions of geometry caused by substituents on the ring or on the methyl group. If considerations of this kind are made for a particular compound, it does seem that significant conformational deductions will be possible, but it should be noted that a referee has expressed doubts on this point.

TABLE 3. Some INDO MO FPT computations of $^4J_o^{F,CH_3}$ in Hz in 2-fluorotoluene

θ[a]	Emp[b]	INDO[c]	Fsp/CH_3[d]	Fsp/Csp[e]	Fs/CH_3[f]
0°	0.54	−3.15	0.08	−3.39	−0.07
15	1.14	−2.56	0.11	−2.77	−0.01

[a]The conformational angle θ is defined in Fig. 3 and is zero when the C—H and C—F bonds are *cis*.

[b]These define the empirical curve in Fig. 3.

[c]Taken from ref. 14 for a standard geometry.

[d]Here the off-diagonal Fock matrix elements involving the 2*s* and 2*p* orbitals of fluorine and the 1*s* orbital of the methyl protons are set to zero. The C—F bond length is 1.35(7) Å, the sp^2-sp^3 carbon–carbon length is 1.53(2) Å, and $\angle C_2C_1CH_3$ is 119° (see text).

[e]Fock matrix elements involving fluorine and carbon valence orbitals are set to zero.

[f]No interaction between 2*s* orbitals on fluorine and the methyl hydrogen 1*s* orbitals.

Modified INDO MO FPT calculations

Because the calculated values of $^4J_o^{F,CH_3}$ are clearly deficient, it is of interest to examine the origin of the large computed negative values near $\theta = 0°$. This examination involved the procedure of Barfield (16), in which off-diagonal elements of Fock matrices associated with orbitals centered on certain nonbonded atoms were set equal to zero. This approach prevented

[4]A reliable disentanglement of the conformational from the intrinsic electronic perturbations for the 6-substituted derivatives seems impossible at present.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

the transmission of spin–spin coupling via overlap of those orbitals. Some of these calculations are given in Table 3.

The numbers in Table 3 imply that it is the overlap of the hydrogen orbital with the 2*s* orbital on fluorine which is the primary interaction causing the large negative computed contributions to $^4J_o^{F,CH_3}$ near $\theta = 0°$. Furthermore, these calculations suggest that the observed negative value at $\theta = 180°$ arises via spin polarization of the orbitals on the methyl carbon. Finally, the computations clearly imply the expected $\sigma-\pi$ contributions to $^4J_o^{F,CH_3}$. If the Fock matrix elements involving direct overlap between the fluorine orbitals and the hydrogen orbitals are forced to vanish, then the computed curve qualitatively resembles the empirical curve in Fig. 2 but underestimates the average magnitude by a factor of about five.

It appears that the source of the qualitative discrepancy between calculated and observed couplings resides in the σ electron/proximate component of the computation. It is likely that 2-trifluoromethyl benzaldehyde is another example where a similar discrepancy occurs (11). Here $^5J_o^{CH,CF_3}$ is +2.2 Hz and is computed as negative (11). Yet, for the *cis* arrangement of the OH bond and the other substituent in 2-fluorophenol and 2-trifluoromethylphenol, $^4J_o^{OH,F}$ and $^5J_o^{OH,CF_3}$ lie near −4.5 Hz and are reproduced in a sensible way by INDO MO FPT approaches (49–51). Elucidation of these matters would be of interest; perhaps there exist other than contact mechanisms for some of these couplings (52).

Further MO calculations

The standard INDO MO FPT calculations assumed (14) a standard geometry (53). Because proximate coupling mechanisms are very sensitive to interatomic distances, a possible reason for discrepancies between theory and experiment lies in the difference between actual and standard geometries.

The geometry used by Schwoch and Rudolf (42) in their microwave work assumes a regular hexagon (r_{cc} = 1.391, r_{CH} = 1.084, r_{CF} = 1.348, r_{C-CH_3} = 1.520 Å) with tetrahedral angles at the methyl group. STO 3G MO calculations for such a geometry gave the eclipsed conformation, **2**, as 0.029 kJ/mol more stable than the staggered form, **1**. The latter is actually 2.7 ± 0.6 kJ/mol more stable than the former. INDO found 2.1 kJ/mol.

Partial optimization of bond angles and bond lengths at the STO 3G level yielded the following geometries (staggered, eclipsed):

$\angle C_2C_1C_7$(118.8°, 119.7), $\angle C_5C_6H_{12}$(120.4, 120.4)
$\angle C_1C_7H_{13}$(110.7, 110.7), $\angle C_1C_2F$(119.7, 120.1);
C_6—H_{12}(1.083 Å, 1.083), C_6—H(1.087, 1,087),
C—F(1.357, 1.357), C_1—C_7(1.532, 1.531).

All other bonds were kept at 120°, C—C lengths were 1.391 Å, and C—H lengths were 1.084 Å. For these geometries the staggered form was preferred by 0.10 kJ/mol.

For this partially optimized geometry, the INDO MO FPT calculations gave the staggered conformer a preference of 0.66 kJ/mol but did not encourage a belief that geometry accounts for the difficulties with the theoretical spin polarization mechanisms. Further STO 3G MO optimization procedures, in which all bond angles and bond lengths except for the regular hexagon were allowed to vary, did not alter the geometry or the conformational preferences in a significant way. It may be that optimization of the geometry of the benzene nucleus would lead to a more reliable result. It would also be very expensive (the details of the optimized structures are available from the authors).

INDO MO FPT calculations on derivatives of 2-fluorotoluene

Remarkably, the average over rotation for the calculated values of $^4J_o^{F,CH_3}$ in 2,6-difluorotoluene was 0.03 Hz and was 0.41 Hz in sym-tetrafluorotoluene. These *changes* from the calculated 0.13 Hz in 2-fluorotoluene reproduce the *trends* in Table 2 rather well. In addition, the average of $^6J_p^{H,CH_3}$ is calculated as -0.59_5 Hz, very close to the value in toluene and those observed (Table 2). Again, in the 4-nitro and 5-nitro derivatives an increase of 0.1 Hz is calculated for $^4J_o^{F,CH_3}$, roughly as observed. However, similar increases are also calculated for the corresponding amino compound, contrary to observation.

Summary and conclusions

In contrast to $^4J_o^{H,CH_3}$, $^6J_p^{H,CH_3}$, and $^6J_p^{F,CH_3}$, the magnitude of $^4J_o^{F,CH_3}$ in 2-fluorotoluene has a marked dependence on ring substituents. A large part of the substituent-induced changes in $^4J_o^{F,CH_3}$ is attributed to perturbations of the σ electron/proximate mechanisms, which are not easily distinguishable. The $\sigma-\pi$ contribution to $^4J_o^{F,CH_3}$ is relatively insensitive to intrinsic substituent perturbations. The conformational dependence of $^4J_o^{F,CH_3}$ is marked with a positive value for a planar *cis* orientation of the C—H and C—F bonds and a substantial negative value for a planar *trans* arrangement. These latter facts are not reproduced by standard INDO MO FPT computations. Further, examination of these calculations suggests that much of the disagreement with experiment originates in large negative contributions from 1*s*/2*s* overlaps between methyl hydrogens and fluorine. Judicious use of the empirical conformational dependence of $^4J_o^{F,CH}$ can be of value in stereochemical investigations.

Received July 20, 1982

WILLIAM A. ADAMS, PEETER KRUUS, and TIMOTHY J. PATRABOY. Can. J. Chem. **61**, 37 (1983).

Solubility and freezing point data are presented for the system sulfur dioxide – *N*-methyl-2-pyrrolidinone (NMP). The enthalpy and entropy of solution are determined as -33.7 kJ mol^{-1} and -94.6 J K^{-1} mol^{-1}, respectively. The freezing point diagram shows maxima at $X_{SO_2} = 0.33$ (-14.0°C) and $X_{SO_2} = 0.50$ ($+2.6$°C), suggesting the presence of 2:1 and 1:1 NMP:SO_2 complexes. The existence of such complexes in the liquid state is supported by viscosity and permittivity data. Nuclear magnetic resonance and Raman spectroscopic data suggest an overall shift of electron density from the nitrogen and the carbonyl carbon of NMP to the O of SO_2, with weakening of the CO bond of NMP.

WILLIAM A. ADAMS, PEETER KRUUS et TIMOTHY J. PATRABOY. Can. J. Chem. **61**, 37 (1983).

On présente les données relatives à la solubilité et au point de congélation du système bioxyde de soufre/*N*-méthylpyrrolidinone-2 (NMP). On a déterminé l'enthalpie et l'entropie de solution qui sont respectivement de $-33,7$ kJ mol^{-1} et $-94,6$ J K^{-1} mol^{-1}. Le diagramme du point de congélation montre des maxima à $X_{SO_2} = 0,33$ ($-14,0$°C) et $X_{SO_2} = 0.50$ ($+2,6$°C) suggérant ainsi la présence de complexes NMP:SO_2 du type 2:1 et 1:1. Les données de viscosité et de permitivité témoignent de l'existence de tels complexes à l'état liquide. Les données de la spectroscopie de la rmn et Raman suggèrent un glissement global de la densitè électronique de l'atome et du carbone du carbonyle du NMP vers l'oxygène du SO_2 avec un affaiblissement de la liaison CO du NMP.

[Traduit par le journal]

Introduction

Solutions of sulfur dioxide in organic solvents are of current interest for several reasons. Non-aqueous solvents can be effective absorbers of SO_2 for the purposes of pollution control (1), and are vital in lithium–SO_2 high energy density primary batteries (2).

The solvent *N*-methyl-2-pyrrolidinone (NMP) has several industrial uses such as in the extraction of various petroleum fractions and as a solvent in the plastics industry (3). It has also been proposed as a potential adsorbent for SO_2 and H_2S in pollution control systems (4). As seen in Table 1, it has many desirable properties. A thorough study of this system was undertaken in order to give background information needed to assess its usefulness for various applications. The nature of the SO_2–NMP molecular level interactions giving rise to the macroscopic properties was also investigated.

TABLE 1. Some properties of NMP and SO_2

Property	NMP (3)	SO_2 (5)
Molecular weight/g mol^{-1}	99.13	64.06
Freezing point/°C	−24	−75.5

Dipole moment/D	4.09	1.62
Relative permittivity	32.0	15.4 (0°C)
ΔH^{θ}_{vap}/ kJ mol^{-1}	52.8	24.9

Experimental

The NMP (Aldrich reagent grade or Fisher purified grade) was vacuum distilled (at 60 to 65°C) from a calcium hydride slurry. The infrared spectrum of the liquid showed no discernible peak at 3200 cm^{-1} corresponding to the OH stretch of water and gas chromatography showed water content to be less than 100 ppm. The purified liquid was stored under dried nitrogen and was degassed immediately before use on a vacuum line by at least three freeze–pump–thaw cycles. All manipulations were carried out under anhydrous conditions.

Matheson anhydrous SO_2 was used. For high pressure solubility experiments, it was not further purified, but for the remaining experiments it was subjected to a distillation.

Gas solubility measurements were made by introducing a known amount of SO_2 gas (up to 250 cm^3) to a known amount of NMP (typically of the order of 0.5 g) and noting the pressure above the solution after equilibration (typically 1 h). Constant stirring in the solubility flask was provided by a magnetic stirrer with temperatures maintained to better than ±0.05°C by a circulating bath. The pressure above the solution was measured by either a mercury manometer or an MKS Baratron pressure meter. Corrections to the mass of SO_2 dissolved were made assuming the gas in the space above the solution to follow the ideal gas equation of state.

Solubility measurements were made in sets with either the temperature or the total amount of SO_2 (in gas and solution phase) held constant. The latter method had to be used for solution temperatures greater than ambient. In such cases, only higher pressure solubility measurements were possible, as at low SO_2 content the NMP would have condensed out into the gas lines above the solution.

For some studies, e.g. viscosity, ultrasonics, relative permittivity, solutions were made up by diluting a concentrated solution of SO_2 in NMP with NMP. The SO_2 content was in such cases obtained by mixing the solution into standardized sodium hydroxide solution and then back titrating with hydrochloric acid, using bromcresol green as indicator. For other studies, e.g. freezing points, nmr, Raman, solutions were made up by weight.

Freezing point measurements were obtained from cooling and heating curves using apparatus similar to that in ref. 6, density using a pycnometer, viscosity using a Cannon Fenske viscometer, permittivity using a General Radio bridge operating at 2.5 to 10 kHz, and

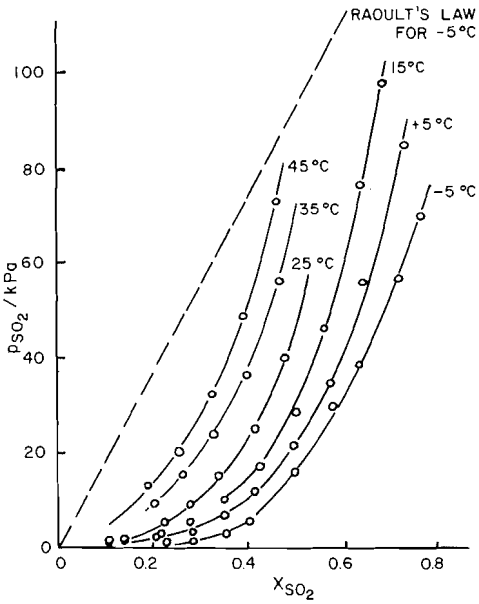

FIG. 1. Partial pressure of SO_2 above SO_2–NMP solutions.

ultrasonic absorption using the apparatus described in ref. 7.

Raman spectra were taken on a Jobin-Yvon HG2S spectrometer using the 514.5 nm line from a CR-12 argon ion laser at 300 mW power. Detection was by photon counting with a cooled R928 or R936 Hamamatsu PM tube with digital aquisition on a Nicolet 1180 computer. Curve resolution was done using the Nicolet 1180 CAP program with a Lorentzian–Gaussian distribution.

Nuclear magnetic resonance spectra were obtained on the following spectrometers: Varian T-60 for ^1H with tetramethylsilane as a reference, $T = 20 \pm 2°C$; Varian XL-100-12 with a Nicolet TT-100 Fourier transform data system for ^{13}C at 25.16 MHz with methanol-d_1 as reference, $T = 32 \pm 1°C$; Varian XL-200 for ^{17}O at 27.12 MHz with D_2O as reference, $T = 29°C$; Varian XL-200 for ^{15}N at 20.27 MHz with 2.9 *M* ammonium chloride in 1.0 *M* hydrochloric acid as reference, $T = 20.3°C$.

Results

(a) High pressure gas solubility

The high pressure solubility data are shown in Fig. 1.[1] There is a large negative deviation from Raoult's law ($p_{SO_2} = X_{SO_2} p^*_{SO_2}$) at all temperatures from −5 to 45°C, as illustrated by comparison of the −5°C curves. At the high X_{SO_2} values shown in Fig. 1, the partial pressure of NMP is negligible compared to the experimental uncertainty in the data.

Data displayed in Fig. 1 was used to calculate the excess free energy of mixing, ΔG^e_{mix}, of the solution. This quantity is defined as

$$[1]\quad \Delta G^e_{mix} = \Delta G_{mix} - \Delta G^{id}_{mix}$$
$$= \Delta G_{mix} - RT(X_{SO_2} \ln X_{SO_2} + X_{NMP} \ln X_{NMP})$$
$$= -RT(X_{SO_2} \ln \gamma_{SO_2} + X_{NMP} \ln \gamma_{NMP} \ln \gamma_{NMP})$$
$$= -RT\left\{X_{SO_2} \ln\left(\frac{p_{SO_2}}{X_{SO_2} p^*_{SO_2}}\right) + X_{NMP} \ln\left(\frac{p_{NMP}}{X_{NMP} p^*_{NMP}}\right)\right\}$$

For this calculation, the total measured pressure must be divided into the two partial pressures p_{SO_2} and p_{NMP}, even though p_{NMP} is very small.

[1]Tables of numerical data are available from P.K. at Carleton University.

*kPa.
†$\gamma_i \rightarrow 1$ as $X_i \rightarrow 1$.
‡ kJ mol^{-1}.

This was done by a method similar to that used in ref. 9. The ΔG^e_{mix} was assumed to be described by an equation

$$[2]\quad \Delta G^e_{mix} = RTX_{SO_2}X_{NMP} \sum_{r=1}^{4} c_r(X_{SO_2} - X_{NMP})^{r-1}$$

The activity coefficients and partial pressures are related to the coefficients c_r by the Gibbs–Duhem relation:

$$[3]\quad X_{SO_2} d \ln \gamma_{SO_2} + X_{NMP} d \ln \gamma_{NMP} = 0$$

This gives the relation:

$$[4]\quad \ln \gamma_{SO_2} = X^2_{NMP}\left\{c_1 + \sum_{r=2}^{4} c_r(2rX_{SO_2} - 1)(X_{SO_2} - X_{NMP})^{r-2}\right\}$$

A non-linear least-squares program was used to obtain the best values of the coefficients c_1 to c_4 using these relations and all the available experimental data. In the case of higher temperatures, only five data points were available.

Table 2 shows the results for the 25°C data, with Fig. 2 showing the ΔG^e_{mix} obtained. Table 3 gives a listing of the c_r for all temperatures studied. There is relatively little variation of the ΔG^e_{mix} curves with temperature, with the minimum varying only from −2.5 kJ mol^{-1} to −3.2 kJ mol^{-1}.

The data in Fig. 1 are well above the Henry's law region, where $p_{SO_2} = K_H X_{SO_2}$. A limiting value of K_H can be obtained by extrapolating p_{SO_2}/X_{SO_2} to $X_{SO_2} \rightarrow 0$, but this introduces considerable uncertainty.

(b) Low pressure gas solubility

Figure 3 shows the gas solubility data at low pressures.[1] Two methods were used to obtain the data: (*a*) series of measurements at constant temperature, varying the total SO_2 and

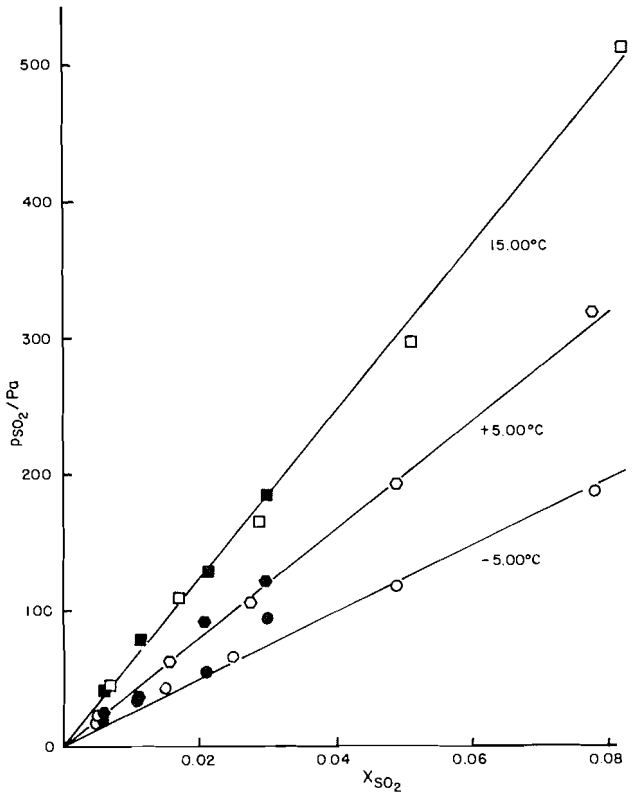

FIG. 3. Partial pressure of SO_2 above SO_2–NMP solutions in Henry's law range. Open symbols, method (*a*); closed symbols, method (*b*).

using the Baratron pressure meter, and (*b*) series of measurements at constant total SO_2, varying the temperature and obtaining pressure from a manometer aided by a cathetometer. These data are consistent with each other and are in the linear Henry's law region.

A free energy of solution can be obtained from such data. This is for the reaction:

[5] $SO_2(g) \rightleftharpoons SO_2(\text{NMP solution})$

The standard free energy of solution is defined as:

$$[6] \quad \Delta G^{\theta}_{sol} = -RT \ln K_a = -RT \ln \left(\frac{a_{SO_2(sol)}}{a_{SO_2(g)}} \right)$$

The activity equilibrium constant K_a approaches the ratio $X_{SO_2}/p_{SO_2} = 1/K_H$ as $X_{SO_2}, p_{SO_2} \rightarrow 0$ with the conventions

$$a_{SO_2(g)} = \gamma^{p}_{SO_2} p_{SO_2} \rightarrow p_{SO_2} \text{ as } p_{SO_2} \rightarrow 0$$

and

$$a_{SO_2(sol)} = \gamma^{l}_{SO_2} X_{SO_2} \rightarrow X_{SO_2} \text{ as } X_{SO_2} \rightarrow 0$$

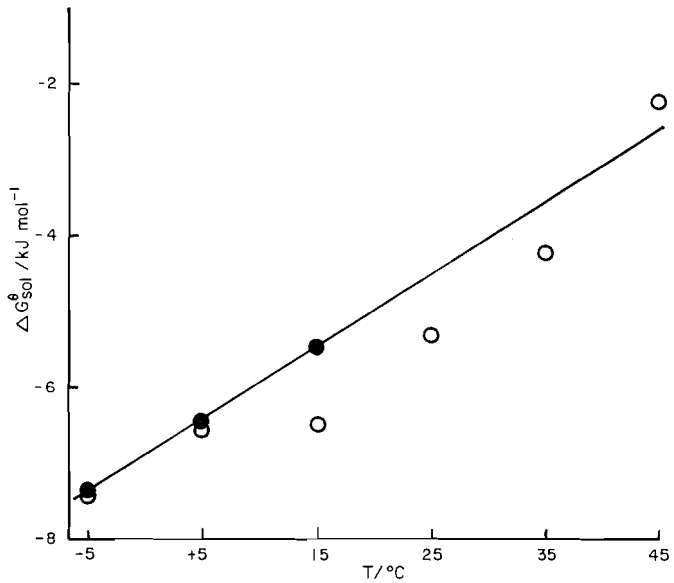

FIG. 4. ΔG^{θ}_{sol} for SO_2 in NMP ($X_{SO_2} \rightarrow 0$). ●, low pressure data (Fig. 3); ○, extrapolation from high pressure data (Fig. 1).

This latter convention commonly used in discussions of gas solubility differs from the convention in part (*a*), where $\gamma_{SO_2} \rightarrow 1$ as $X_{SO_2} \rightarrow 1$, even though composition is expressed in the same units (mol fraction).

Figure 4 shows the ΔG^{θ}_{sol} as a function of temperature. Points obtained from the extrapolation of high pressure data are also included, even though they are not considered very reliable. The entropy and enthalpy of solution can be obtained from such a plot as

$$[7] \quad \Delta S^{\theta}_{sol} = -\partial(\Delta G^{\theta}_{sol})/\partial T$$
$$\Delta H^{\theta}_{sol} = \Delta G^{\theta}_{sol} + T\Delta S^{\theta}_{sol}$$

The analysis using only low-pressure points gives values of

$$\Delta S^{\theta}_{sol} = -94.6 \pm 0.7 \text{ J K}^{-1} \text{ mol}^{-1}$$
$$\Delta H^{\theta}_{sol} = -33.7 \pm 0.2 \text{ kJ mol}^{-1}$$

(c) Freezing point diagram

The freezing point diagram for the system SO_2–NMP is shown in Fig. 5.[1] The accuracy of the data is estimated to be ±0.2°C, except for points near $X_{SO_2} \simeq 0.7$, where error limits are indicated. Eutectic temperatures of −29.6, −14.7, and −87.9°C are clearly present in some of the mixtures. The melting points of the pure components are close to, but somewhat higher, than literature values (Table 1), indicating that the NMP and SO_2 used were of high purity.

Both 1:1 and 1:2 complexes of SO_2 and NMP appear to be present in the solid, as indicated by the freezing point maxima at $X_{SO_2} = 0.33$ and $X_{SO_2} = 0.50$.

(d) Viscosity and density

The viscosity data[1] shown in Fig. 6 suggest that the 1:2 complex is also present in the liquid mixtures. The deviation of the actual viscosity from the ideal viscosity shows a maximum near $X_{SO_2} = 0.33$. The "ideal" viscosity η^{id} is taken here to be

$$[8] \quad \eta^{id} = \phi_{SO_2}\eta_{SO_2} + \phi_{NMP}\eta_{NMP}$$

where ϕ is the volume fraction. Values for the (hypothetical) viscosity of pure liquid SO_2 were obtained by extrapolation of data from ref. 10.

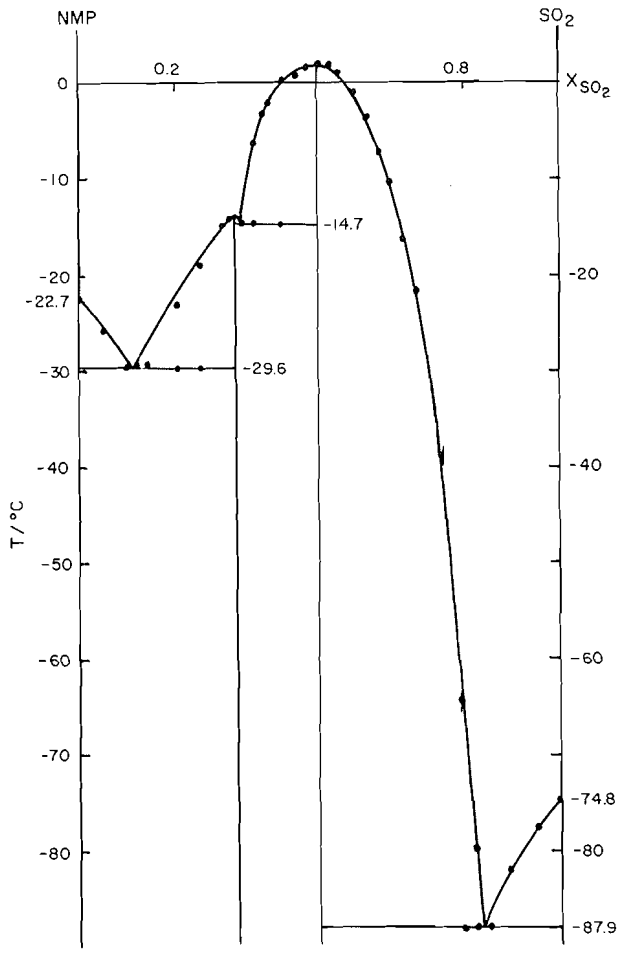

FIG. 5. Freezing point diagram for SO_2–NMP.

Density measurements were made of the solutions at 25°C. The results indicate negligible deviation from ideality, at least for the purpose of calculation of dynamic viscosity from flow times. The partial molar volume of the solutions is linear with X_{SO_2} (slope -55.5 cm^3 mol^{-1}, correlation coefficient 0.9997) in the experimentally investigated range ($X_{SO_2} < 0.5$). For pure NMP, the molar volume measured is 96.4 ± 0.1 cm^3 mol^{-1}, as compared to 96.5 cm^3 mol^{-1} obtained from data in Table 1. The corresponding values for pure (hypothetical) SO_2 are 40.9 ± 0.4 cm^3 mol^{-1} (from extrapolation of experimental data) and 43.9 cm^3 mol^{-1} (Table 1). The densities of the mixtures at 5°C were assumed to be ideal. The density of NMP was measured to be 1.044 g cm^{-3} and that of SO_2 was interpolated to be 1.42 g cm^{-3} (10).

(d) Relative permittivity

Reliable permittivity values could be obtained only for $X_{SO_2} < 0.25$. At 20 ± 2°C, ϵ increase approximately linearly from 33.4 (pure NMP) to 74 ± 1 ($X_{SO_2} = 0.248$).[1] At higher X_{SO_2} values, the conductivity was too high to make reasonably accurate permittivity measurements at the frequencies available. There was a considerable further increase of ϵ with X_{SO_2}; at $X_{SO_2} = 0.41$, the value of ϵ is estimated to be 170 ± 10.

(e) Ultrasonic absorption

NMP has ultrasonic absorption characteristic of associated liquids (11). In the frequency range 10.5 MHz to 52.5 MHz at 25°C it has a low absorption, $\alpha/\nu^2 = (40 \pm 5) \times 10^{-15}$ s^2 m^{-1}, with no consistent decrease with frequency. At 0°C, α/ν^2 increases to $(55 \pm 5) \times 10^{-15}$ s^2 m^{-1}.

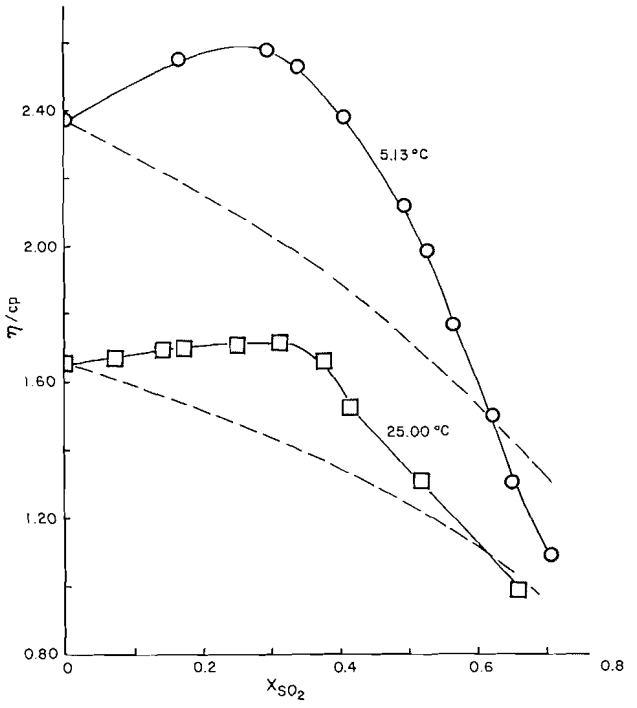

FIG. 6. Viscosity of SO_2–NMP solutions --- η^{id} (eq. [8]).

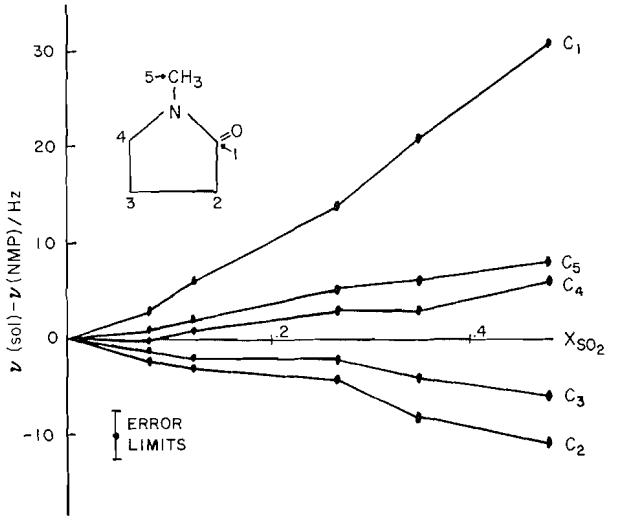

FIG. 7. Relative shifts of ^{13}C resonances in SO_2–NMP solutions, T = 32°C, 25.16 MHz.

When SO_2 is added to NMP at 25°C, the absorption follows the behaviour of the viscosity (Fig. 6). At 31.7 MHz, there is a small increase (from 40 to 50 units) to $X_{SO_2} \simeq 0.2$, and then a levelling off (data were taken to $X_{SO_2} = 0.47$). There is no evidence of any relaxation, i.e. decrease of α/ν^2 with ν, in the frequency range 10.5 to 52.5 MHz for a solution $X_{SO_2} = 0.27$ at 25°C or at 0°C.

(f) Nuclear magnetic resonance

Figure 7 shows the ^{13}C resonance shifts of the NMP carbons as SO_2 is added.[1] The resonances were assigned following ref. 12.

Similar data were taken using ^{1}H nmr.[1] The only identifiable shifts noted were for hydrogens on C_1 (methyl) and C_4; the frequency of both resonances decreased by 6 ± 2 Hz as X_{SO_2}

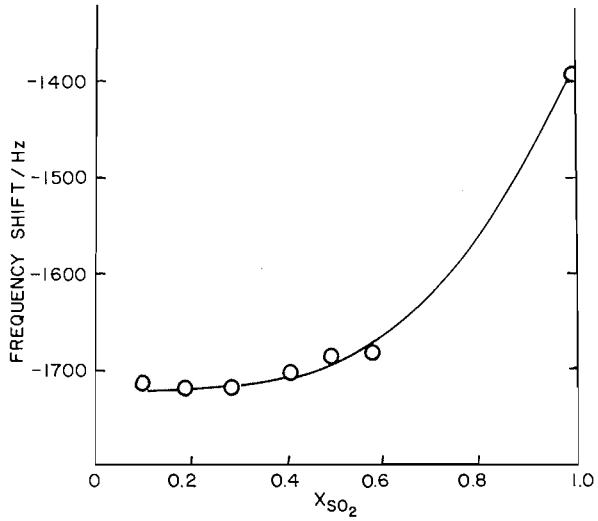

FIG. 8. Shifts of ^{17}O resonances of SO_2 oxygens in SO_2–NMP solutions relative to $D_2{}^{17}O$.

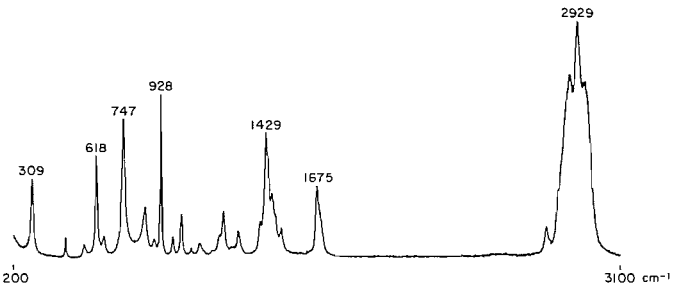

FIG. 9. Raman spectrum of NMP, 20°C. Slits 2, 4, 4, 2 cm^{-1}; one scan at 2 cm^{-1} s^{-1}. CH region at 2929 cm^{-1}, CO at 1675 cm^{-1}, CN at 1429 cm^{-1}.

increased from 0 to 0.45. The ^{15}N resonance frequency shifted from 1713 Hz (pure NMP) to 1834 Hz (X_{SO_2} = 0.58) on addition of SO_2. The frequencies quoted are relative to the reference (NH_4Cl in HCl solution). If this reference is assumed to be 29.43 ppm from ammonia, then pure NMP has its ^{15}N resonance at 113.9 ppm, somewhat different from the value 108.7 ppm previously reported (13).

Oxygen-17 nmr resonances were investigated for the oxygens both in the NMP and in SO_2. The NMP ^{17}O resonance showed no consistent trend in freqnency as SO_2 was added. The frequency was at +8240 Hz relative to D_2O, in reasonable agreement with the data for other amides such as dimethyl formamide (14). The ^{17}O resonance is broad, especially in NMP, so that its position is accurate to at best +20 Hz. This contrasts to the large shift of the NMP ^{17}O when water is added. The signal (at 24°C) shifts from 8257 Hz (X_{H_2O} = 0) to 7574 Hz (X_{H_2O} = 0.635) to 7184 Hz (X_{H_2O} = 0.792). Large ^{17}O shifts of oxygens in C=O bonds on adding water have been noted previously (14).

Figure 8 shows the shift in the SO_2 ^{17}O resonance as a function of X_{SO_2}.[1] There is considerable decrease in the ^{17}O resonance as NMP is initially added to SO_2, but at $X_{SO_2} < 0.33$, it no longer changes. The pure SO_2 value is taken from ref. 15; it is misquoted in ref. 16.

(g) Raman spectroscopy

Figure 9 shows the Raman spectrum of NMP from 200 to 1700 cm^{-1}, indicating the assignments of various modes. The

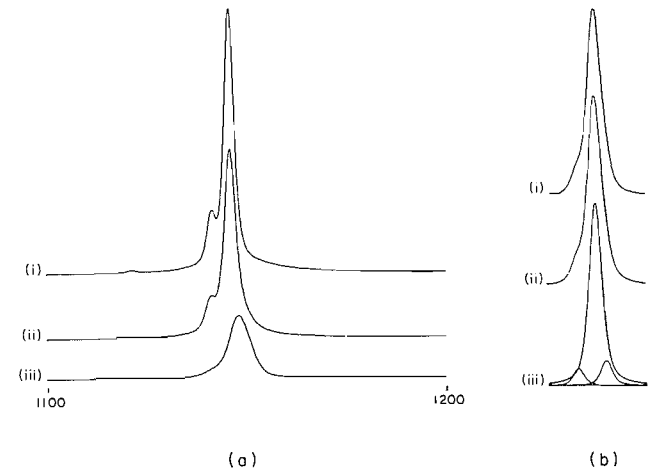

FIG. 10. (*a*) Raman spectra of the SO_2 stretch region, 25°C. Slits 2, 4, 4, 2 cm^{-1}; two scans at 1 cm^{-1} s^{-1}. (*i*) X_{SO_2} = 1, (*ii*) X_{SO_2} = 0.86, (*iii*) X_{SO_2} = 0.37. (*b*) Curve resolution of the SO_2 stretch region, X_{SO_2} = 0.51. (*i*) experimental, (*ii*) calculated, (*iii*) component bands (see Table 4). 40% Gaussian, 60% Lorentzian.

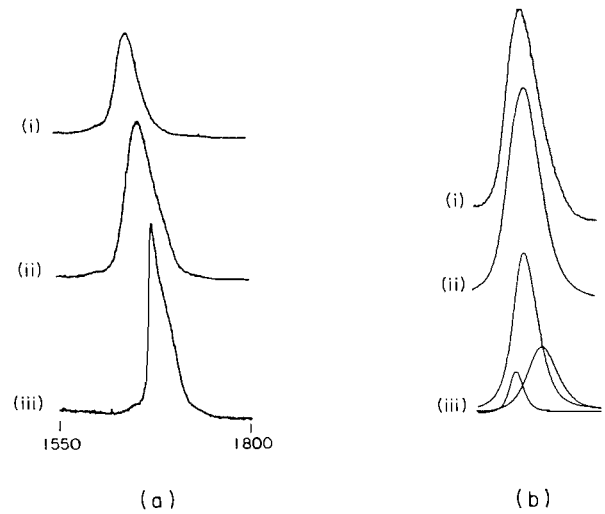

FIG. 11. (*a*) Raman spectra of the carbonyl region, 25°C. Slits 2, 4, 4, 2 cm^{-1}; four scans at 1 cm^{-1} s^{-1}. (*i*) X_{SO_2} = 0.86, (*ii*) X_{SO_2} = 0.37, (*iii*) X_{SO_2} = 0.00. (*b*) Curve resolution of the carbonyl region, X_{SO_2} = 0.51. (*i*) experimental, (*ii*) calculated, (*iii*) component bands (see Table 5). 40% Gaussian, 60% Lorentzian.

SO_2 bending (530 cm^{-1}) and asymmetric stretch (1320 cm^{-1}) regions overlap NMP bands, but the symmetric stretch (1148 cm^{-1}) can be seen without interference.

More detailed spectra of the NMP carbonyl and the SO_2 symmetric stretching regions are shown in Figs. 10 and 11. As can be seen there and in Tables 4 and 5 it is necessary to use at least two lines to resolve the carbonyl band properly, even for the pure NMP. Three lines are required for the SO_2 band. The low frequency shoulder (1140 cm^{-1}) is due to an isotopic shift (17). There are no significant changes in spectra recorded for the systems at 10°C and 5°C.[1]

Discussion

The system NMP–SO_2 contains several reasonably strong, specific interactions. The high Trouton constant (Table 1) and the C=O band shape (Fig. 10) suggest that NMP has a strong tendency to be in a dimer form as a liquid. There is consid-

erable evidence of dimerization in similar compounds (18). Sulfur dioxide is also believed to associate substantially, in spite of its low boiling point (9).

It is evident from the freezing point diagram (Fig. 5) that there is a strong 1:1 complex formed between NMP and SO_2. Several other organic compounds form such complexes with SO_2 (19, 20). There is also evidence of a complex $(NMP)_2:SO_2$ in the freezing point diagram. A diagram such as Fig. 5 is also obtained for the system dimethylsulfoxide–SO_2, except that in that case, a complex $DMSO:(SO_2)_2$ is apparent (21). The presence of such complexes gives an explanation for the viscosity and permittivity data obtained.

Viscosity data has been interpreted to give sizes of the aggregates present in solutions (22). The data in Fig. 6 can be used to estimate the activation energy for viscous flow. For pure NMP it is 12.4 kJ mol^{-1}, for X_{SO_2} = 0.33, 13.9 kJ mol^{-1}, and for X_{SO_2} = 0.50, 15.2 kJ mol^{-1}. An analysis following the suggestions in ref. 22 would suggest that pure NMP is to a large extent in a dimer form, and that at a mole fraction of 0.5, a 2:2 rather than a 1:1 complex could be present.

In principle, the equilibrium constants, K, for such complexation reaction can be obtained from thermodynamic and/or spectroscopic data. The ΔG^e_{mix} data can be fitted by various statistical-mechanical models, and the equilibrium constants obtained (9). The ΔH^θ of the equilibria can then be obtained from the temperature variation of the K's. Such an analysis of the ΔG^e_{mix} data (Table 3) was attempted using a model allowing for NMP dimers and NMP–SO_2 1:1 complexes. The results obtained showed no consistency. This may be because of an oversimplified model or because the experimental data are insufficiently extensive and accurate.

Spectroscopic evidence such as that in Figs. 10 and 11 is difficult to use for quantitative calculations of K values as resolution of such band into components is difficult and subjective. Tables 4 and 5 show no trends which could properly be used for such calculations. Molar scattering coefficients of the band components would also have to be estimated. Many additional Raman spectra would be required if "Job's method" (23) were to be attempted for an analysis.

The value ΔH^θ_{sol} = −33.7 kJ mol^{-1} obtained from the temperature dependence of Henry's law plots (Figs. 2, 3) refers to the enthalpy of solution of SO_2 at infinite dilution. The ΔH^θ_{sol} and ΔS^θ_{sol} values obtained for NMP are closest to the values for acetonitrile and propylene carbonate obtained by Benoit and Milanova (24), and considerably less negative than DMSO. There seems to be little correlation between the NMP ΔH^θ_{sol} and the Gutmann donor or acceptor numbers (25).

A simple classical calculation predicts an energy of this order of magnitude. The energy of two permanent, non-polarizable dipoles 4.1 D (NMP) and 1.6 D (S—O bond in SO_2) parallel and 0.3 nm apart is −15 kJ mol^{-1}. Attraction due to polarization and dispersion forces would lower this value, i.e. in-

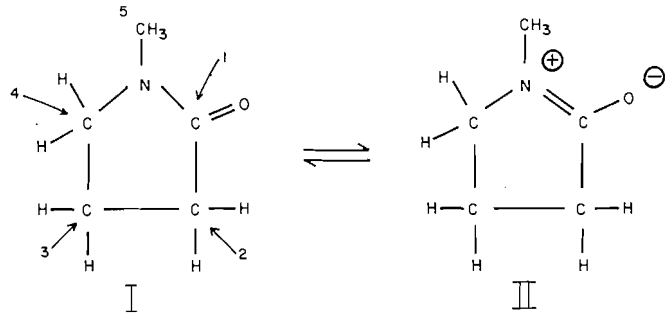

FIG. 12. Resonance structures of NMP.

crease the attraction. There is obviously a considerable distortion of the electronic distribution as indicated by the nmr and Raman results. The yellowish tinge of the solutions also suggests that some charge transfer is present.

An enthalpy value of -33 kJ mol^{-1} for complex formation gives an explanation for the kinetic effects observed. The kinetics are obviously more rapid than nmr time scales (10^{-2} s) as no new resonances are seen, only shifts. The lack of excess ultrasonic absorption at 10 MHz is likely due to the fact that the kinetics is slower than that time scale (10^{-7} s). An activation energy of 33 kJ mol^{-1} for a rate-controlling step in a reaction suggests a rate constant of the order of $10^{12} \exp[-33/(8.3 \times 0.3)] \simeq 10^6$ s^{-1} or a relaxation time τ of 10^{-6} s. This value of τ is a lower limit considering the nature of the assumptions made in this crude model.

The distortions of the electron distributions which occur on interactions of the SO_2 and the NMP can be inferred from the nmr and Raman spectra. The nmr results suggest that there is an overall electron shift from the carbonyl π system of NMP to the lowest unoccupied molecular orbital of SO_2. There seems to be little net change of the electon density near the O in NMP, but there is a decrease of electron density at the N and the carbonyl C. The C=O bond is weakened by these changes and shifts to lower frequencies (Fig. 11). Qualitatively this can be thought of as a shift of the NMP towards resonance structure **II** (Fig. 12), as in the case of other amides (14).

The SO_2 stretching frequency increases slightly as NMP is added. Any electron charge transferred to the SO_2 is thought to go into an orbital which is S—O antibonding but O—O bonding (26). Thus the first approximation would predict the opposite effect, i.e. a weakening of the S—O bond and a decrease in frequency. This is indeed what happens when Br^- ions interact with SO_2. Intense broad lines appear at 1135, 1120, and 1110 cm^{-1} (27). When pyridine is added to SO_2, both effects take place: the SO_2 frequency increases slightly from 1145 cm^{-1} and a broad intense absorption appears at 1130 cm^{-1} (8).

On the basis of the directions of the bond dipoles, it would be expected that the S of SO_2 is close to the O of NMP and the O of SO_2 close to the N of NMP (Fig. 12). X-ray diffraction experiments in the solid complex formed at $X_{SO_2} = 0.50$ would give a definitive structure for the complex.

Conclusion

Solubility and freezing point data for the system NMP–SO_2 shows that the large negative Raoult's law deviation is due to the formation of 1:1 and 2:1 NMP:SO_2 complexes. Viscosity and permittivity data support the existence of these complexes. The ΔH^{θ}_{sol} and ΔS^{θ}_{sol} for solution of SO_2 in NMP are -33.7 kJ mol^{-1} and -94.6 J K^{-1} mol^{-1} respectively, as determined from the temperature dependence of Henry's law constants.

The interaction of SO_2 with NMP seems to occur by electron density transferred from the nitrogen and the carbonyl carbon of NMP to the O of SO_2 by way of the —N—C=O π electron system of NMP. When complexed by SO_2, the NMP resembles more its resonance structure **II** (Fig. 12) with a reduced C—O bond order.

Acknowledgements

The authors are indebted to Dr. G. W. Buchanan and Ms. M. J. Bell (Carleton University) for providing ^{13}C, ^{15}N, and ^{17}O nmr spectra using the XL-100 and XL-200 machines; to Miss C. H. Hayes and Dr. C. L. Gardner (Defence Research Establishment, Ottawa) for providing Raman spectra and aid with permittivity, density, and viscosity measurements; and to Mr. L. Page for glassblowing. Molecular orbital treatment of substituent effects. I. Structures of some carbon acids and their conjugate bases

KENNETH E. EDGECOMBE AND RUSSELL J. BOYD
Department of Chemistry, Dalhousie University, Halifax, N.S., Canada B3J 4J3

Received April 30, 1982

KENNETH E. EDGECOMBE and RUSSELL J. BOYD. Can. J. Chem. **61**, 45 (1983).

The STO-3G optimized structures of three series of carbon acids, CH_nX_{4-n}, where n = 1, 2, or 3 and X = F, CN, or NO_2 and their corresponding conjugate bases are compared with the limited number of experimentally determined structures. The 6-31G* equilibrium geometries of CH_3^-, CH_2F^-, CHF_2^-, CF_3^-, CH_2CN^-, and $CH_2NO_2^-$ are included as a check on the reliability of the STO-3G structures of the anions. Although the effects of successive substitutions on the STO-3G structures are generally systematic, a few apparent anomalies are readily explained in terms of resonance stabilization. Calculations at the 3-21G level, on the STO-3G optimized structures, indicate that the stabilization energy associated with increasing the number of orbitals in the basis set is approximately additive. The stabilization energies are 0.865 ± 0.007 au per fluorine substituent, 0.661 ± 0.008 au per cyano substituent, and 1.561 ± 0.027 au per nitro substituent.

KENNETH E. EDGECOMBE et RUSSELL J. BOYD. Can. J. Chem. **61**, 45 (1983).

On a comparé les structures optimisées par des calculs STO-3G de trois séries d'acides carbonés CH_nX_{4-n} où n = 1, 2 ou 3 et X = CN ou NO_2 ainsi que les bases conjuguées correspondantes avec un nombre limité de structures déterminées expérimentalement. On a exclu les géométries d'équilibre 6-31G* de CH_3^-, CH_2F^-, $CF_3^-CH_2CN^-$ et $CH_2NO_2^-$ comme moyen de vérification des structures de STO-3G des anions. Bien que les effets des substitutions successives sur les structures de STO-3G sont généralement systématiques, on a expliqué facilement quelques anomalies apparentes en fonction de la stabilisation de la résonance. Les calculs au niveau 3-21G des structures améliorées en STO-3G indiquent que l'énergie de stabilisation associée à l'augmentation du nombre d'orbitales de l'ensemble de base est approximativement additive. Les énergies de stabilisation sont de 0,865 ± 0,007 ua par substituant fluor, de 0,661 ± 0,08 ua par substituant cyano et de 1,561 ± 0,027 par substituant nitro.

[Traduit par le journal]

Introduction

The effect of substituents on the properties of carbanions is usually based on thermodynamic and kinetic studies in solution (1). More recently gas-phase data have become available from flowing afterglow (2), high-pressure mass spectrometric (3) and ion cyclotron resonance experiments (4). As Hehre and co-workers (5) have stressed, the solution-phase results do not reflect the inherent properties of the anions so much as they reflect the effects of solvation. Alternatively *ab initio* molecular orbital (MO) theory may be used to obtain useful data appropriate to isolated molecules and ions in the gas phase (6). Although many *ab initio* MO calculations on monosubstituted methyl anions have been reported (5, 7), the effects of multiple substitutions have not been discussed. Accordingly, the results of a systematic study of three series of carbon acids, CH_nX_{4-n}, where n = 1, 2, or 3 and X = F, CN, or NO_2, and their corresponding conjugate bases, $CH_{n-1}X_{4-n}^-$, are presented in this paper.

Method and results

Standard single determinant *ab initio* MO calculations were carried out by use of the GAUSSIAN 76 program (8*a*) on a Control Data CYBER 170-720 system.[1] Complete geometry optimizations, subject only to specified symmetry constraints, were performed at the STO-3G level (9). Several of the anions have been optimized at the 6-31G* level. In order to improve energy calculations, charge distributions, and other properties, 3-21G calculations (10) were carried out on the STO-3G optimized structures.

The STO-3G equilibrium geometries of some carbon acids and their conjugate bases are compared with the available experimental structural data in Table 1. For each species the point group of the equilibrium geometry is listed. The equilibrium conformations of the nitromethanes and their conjugate bases are illustrated in Fig. 1. In all cases lower symmetries were included in the optimization procedure but only the data pertinent to the lowest energy structures are included in this paper. A few of the smaller molecules and ions which have been optimized at the STO-3G level by Pople's group (11) are listed for completeness.

Table 2 lists the STO-3G//STO-3G and 3-21G//STO-3G total energies. The stabilization of the total energy gained by replacing the minimal basis set by the small split-valence basis set is shown in the fourth column of Table 2.

Discussion

The point group symmetries of the STO-3G equilibrium conformations of the fluorine-containing species agree with the available experimental data. Where direct comparison of the geometries is possible, the agreement is quite typical for calculations at the STO-3G level (10, 19). Successive fluorination of CH_4 lengthens the C—H bond by 0.012 ± 0.002 Å at the STO-3G level. Within the carbanion series a similar but more pronounced effect is observed. Successive fluorination of CH_4 decreases the C—F bond by 0.007 Å at the STO-3G level.[2] The more pronounced shortening of the C—F bond at the 3-21G level: 1.404, 1.372, and 1.345 Å in CH_3F, CH_2F_2, and

[1] For a few of the larger calculations an expanded version of Gaussian 76 was used. The expanded version has been described in ref. 8*b*.

[2] See ref. 7*i* and references therein for further discussion of these effects.

$C(NO_2)_3^-$	−641.16189	−646.23324	−5.07135

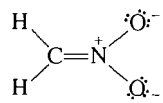
[a]All energies are in atomic units: 1 au = 27.2116 eV.

[b]According to the convention of Pople and co-workers (ref. 10) these results should be labelled as 3-21G//STO-3G since the calculations have been performed with the 3-21G basis set at the STO-3G optimum geometries.

CHF_3, respectively, is consistent with the 0.025 Å decrease observed experimentally (13). The 3-21G results for the C—H bond lengths are qualitatively opposed to the STO-3G results: 1.083, 1.080, 1.073, and 1.066 Å in CH_4, CH_3F, CH_2F_2, and CHF_3, respectively (11).

With two exceptions the point group symmetries of the cyano-substituted species match those of the fluorine analogues. The exceptions occur for $CH(CN)_2^-$ and $C(CN)_3^-$ which have higher symmetries than CHF_2^- and CF_3^-, respectively. These differences are readily explained in terms of resonance stabilization of the negative charge in the cyano cases. For CH_2CN^- resonance stabilization is not sufficient at the STO-3G level to produce the C_{2v} symmetry observed in the isoelectronic diazomethane, CH_2N_2 (20). At the 4-31G level, the planar C_{2v} structure is favoured (5). As observed in other compounds (21), the STO-3G C—N bond lengths agree extraordinarily well with experiment. This is due to cancellation of basis set and electron correlation errors (22). Successive CN substitutions lengthen the C—H bonds by about half as much as in the CH_nF_{4-n} series. In contrast to the $CH_{n-1}F_{4-n}^-$ series, the C—H bonds of the anions are predicted to be shortened by CN substitution. The C—C bond length increases with each additional CN substitution, except in $CH(CN)_2^-$ where there is a substantial shortening due to the resonance stabilization of the C_{2v} geometry. Once again the experimental data is too incomplete to test the reliability of these conclusions.

The symmetries of the equilibrium conformations of the nitromethanes are lower than those of the cyanomethanes. The effect of successive substituents on C—H bond lengths is systematic in the nitromethanes. For the anions the substituent effects are unique. The short C—H bond length in $CH_2NO_2^-$ is consistent with a principal resonance form which places a dou-



ble bond between C and N. This suggestion is consistent with the short C—N and long N—O bonds. Except for $CH_2NO_2^-$, the N—O bonds are remarkably constant. The C—N bond lengths of the nitromethanes appear to be overestimated by about 0.04 Å and are not strongly influenced by the number of nitro groups. In the anions, resonance stabilization leads to a large shortening of the C—N bond of $CH_2NO_2^-$, a smaller effect in $CH(NO_2)_2^-$, and a very small effect in $C(NO_2)_3^-$. Despite the scarcity of experimental structural data on the nitromethanes, we note that the observation that the NO_2 groups of $CH(NO_2)_3$ appear to be rotated by 26° around the CN bonds away from a coplanar HCNO arrangement (18) is consistent with the C_3 propeller structure obtained at the STO-3G level. In contrast to the cyanomethanes, loss of a proton from $CH(NO_2)_3$ does not lead to a more symmetrical anion. Thus $C(NO_2)_3^-$ has a C_3 propeller structure whereas $C(CN)_3^-$ has the planar D_{3h} structure at the STO-3G level. The latter is consistent with a resonance-stabilized structure and the substantial shortening of the C—C bond, in agreement with experiment (16). And finally to conclude this part of the discussion, we note that ∠CCN equals 180° in all of the cyano-substituted methanes and carbanions, whereas planar NO_2 groups are predicted only for CH_3NO_2, $CH_2NO_2^-$, $CH_2(NO_2)_2$, and $CH(NO_2)_3$.

It is well-known that one-electron properties calculated at the Hartree-Fock level are correct to first order (23–25) and that the equilibrium geometry may be regarded as a one-electron property (26). Although this does not imply any absolute accuracy, extensive calculations on neutral molecules and cations have shown that single-determinant molecular orbital theory produces geometries in close agreement with experimental val-

TABLE 3. Comparison of 4-31G and 6-31G* equilibrium geometries with the STO-3G results for selected anions

[a]At the STO-3G level, CH_2CN^- is predicted to have a C_s equilibrium conformation.

[b]All data from ref. 5, except CF_3^- which has been optimized at the 3-21G level (ref. 11).

[c]The results for CH_3^- are from ref. 11. The 6-31G* geometry optimizations are less extensive than the STO-3G results: the latter are believed to be within ±0.002 Å and ±0.2° of the true theoretical values whereas the former are estimated to be within ±0.005 Å and ±0.5° of the true 6-31G* values. The 6-31G* total energies are −39.44616, −138.32889, −237.21287, −336.11754, −131.28630, and −243.05770 au, respectively.

ues (27, 28). Even though anions have received less attention due to the lack of experimental data and to the problems associated with Hartree–Fock calculations on anions (6, 29), it appears that extended basis sets are necessary to obtain an accuracy comparable to the small basis set results for neutral molecules and cations (30). With this in mind we have carried out 6-31G* geometry optimizations for a few of the smaller anions included in this paper. The results are compared with the STO-3G and 4-31G geometries in Table 3. Relative to the 6-31G* basis set, the STO-3G basis set tends to overestimate the bond lengths between heavy atoms. We have noticed a similar effect in several electron-rich systems (31). CH_2F^- and, to a lesser extent, CHF_2^- are notable exceptions. Two major discrepancies between the STO-3G and 6-31G* angles are apparent: the extended basis set favours a nearly planar methyl anion and a planar cyanomethyl anion. With reference to the STO-3G results, the 4-31G angles are closer to the 6-31G* values, but the bond lengths are not consistently closer to the 6-31G* values. In the case of the C—F bond in CH_2F^-, the 4-31G basis set appears to over-correct the inadequacy of the STO-3G basis set. In general, the agreement between the STO-3G and 6-31G* anion geometries is only slightly poorer than comparable data for neutral species. On the basis of these calculations and previous studies of anion geometries (5, 32), we have carried out geometry optimizations for all anions and molecules at the STO-3G level and then for the calculation of properties we have carried out single point calculations at the 3-21G level. The size of some of the species included in this paper precludes geometry optimizations with extended basis sets for the entire set of molecules and anions. In a later paper we will show that the use of the STO-3G geometries has only a minor effect on our discussion of substituent effects.

The total energies (Table 2) obtained with the STO-3G and 3-21G basis sets at the STO-3G optimized geometries (Table 1) indicate that the stabilization associated with increasing the number of orbitals in the basis set is approximately additive. With reference to the differences between the 3-21G//STO-3G and STO-3G//STO-3G total energies, as listed in the fourth column of Table 2, successive differences of the stabilization energies within the series CH_4, CH_3F, CH_2F_2, CHF_3 and within the series CH_3^-, CH_2F^-, CHF_2^-, CF_3^- lead to an average value of 0.865 ± 0.007 au per fluorine substituent. This observation applies equally well to the neutral species and to the anions. The corresponding values are 0.661 ± 0.008 and 1.561 ± 0.027 au per cyano and nitro substituent, respectively. These stabilizations are not determined solely by the size of the substituent since the stabilization per fluorine atom is greater than that per cyano group.

The requirements for computer time were reduced by carrying out the 3-21G calculations at the STO-3G geometries. On the basis of the available data (11), the energy lowering associated with geometry optimization is expected to be small relative to the differences listed in Table 2. For CH_4 there is no change, while the lowering is 0.00092, 0.00205, 0.00406, and 0.00120 au for CH_3F, CH_2F_2, CHF_3, and CH_3CN, respectively. For properties such as proton affinities, which depend on differences between an acid and its conjugate base, there will be a substantial cancellation of errors. In such cases we believe that the 3-21G//STO-3G energies and wavefunctions provide a reliable indication of the consequences of extending a minimal basis set by increasing the number of orbitals while keeping the number of primitive Gaussians fixed.

In a later paper we will discuss the effect of substituents on the proton affinities and the charge distributions of the series of carbon acids included in this work and on the same properties of a number of simple carboxylic acids.

The structure and conformation of 1-phenyl-2-methylcyclopropene-3-carboxylic acid and *cis*-2-(*m*-nitrophenyl)cyclopropanecarboxylic acid

JAMES D. KORP, IVAN BERNAL, AND RICHARD FUCHS
Department of Chemistry, University of Houston, Houston, TX 77004, U.S.A.

Received July 6, 1982

JAMES D. KORP, IVAN BERNAL, and RICHARD FUCHS. Can. J. Chem. **61**, 50 (1983).

The structures of *cis*-2-(*m*-nitrophenyl)cyclopropanecarboxylic acid (**1**) and 1-phenyl-2-methylcyclopropene-3-carboxylic acid (**2**) have been determined by X-ray methods. Crystals of **1** are triclinic, space group $P\bar{1}$, with $a = 7.422$, $b = 8.615$, $c = 9.499$ Å, $\alpha = 60.24$, $\beta = 63.76$, $\gamma = 71.36°$, and two molecules in the unit cell. Crystals of **2** are monoclinic, space group $P2_1/c$, with four molecules in a unit cell of dimensions $a = 9.345$, $b = 13.286$, $c = 8.187$ Å, and $\beta = 98.22°$. The carboxyl group of **1** approaches the bisecting conformation. The phenyl group is 37° from this conformation, by contrast with the unhindered compound 2-(*p*-nitrophenyl) cyclopropyl methyl ketone. In **2** the carboxyl group bisects the three-membered ring, indicating that carbonyl-cyclopropene π interactions can occur if sterically allowed. The two rings are essentially coplanar, permitting maximum interaction of the phenyl group and the double bond. In both compounds, the carbonyl oxygen of the carboxyl is the nearer oxygen to the three-membered ring.

JAMES D. KORP, IVAN BERNAL et RICHARD FUCHS. Can. J. Chem. **61**, 50 (1983).

On a déterminé par cristallographie de rayons-X les structures de l'acide (*m*-nitrophényl)-2 cyclopropanecarboxylique (**1**) et de l'acide phényl-1 méthyl-2 cyclopropène-3 carboxylique (**2**). Les cristaux de l'acide (**1**) sont tricliniques et appartiennent au groupe d'espace $P\bar{1}$ avec $a = 7{,}422$, $b = 8{,}615$, $c = 9{,}499$ Å, $\alpha = 60{,}24$, $\beta = 63{,}76$, $\gamma = 71{,}36$. La maille élémentaire contient deux molécules. Les cristaux de l'acide (**2**) sont monocliniques et appartiennent au groupe d'espace $P2_1/c$ avec $a = 9{,}345$, $b = 13{,}286$, $c = 8{,}187$ Å, $\beta = 98{,}22°$ avec quatre molécules dans la maille élémentaire. Le groupe carboxyle de **1** s'approche de la conformation bisectrice. Le groupe phényle est à 37° de cette conformation contrairement à sa position dans le composé non encombré, (*p*-nitrophényl)-2 cyclopropyle méthyle cétone. Dans l'acide (**2**), le groupe carboxyle bisecte le cycle à trois chainons indiquant ainsi que des interactions entre le carboxyle et les électrons π du cyclopropène peuvent se produire si elles sont permises stériquement. Les deux cycles sont essentiellement coplanaires permettant ainsi une interaction maximale entre le groupe phényle et la double liaison. Dans les deux composés, l'oxygène du carbonyle du groupe carboxyle est celui qui est le plus près du cycle à trois chaisons.

[Traduit par le journal]

The presently available experimental thermochemical data on simple cyclopropane derivatives (1) (cyclopropane, 1,1-dimethylcyclopropane, cyclopropylamine, cyclopropyl cyanide, and cyclopropylbenzene) demonstrate appreciable stabilization only in the case of cyclopropylbenzene. This is surprising, in light of the well-established ability of π acceptor groups such as cyano and carbonyl to alter ring geometry (the substituent at C_1 shortens the distal C_2—C_3 bond, and lengthens the two vicinal bonds) (2), and the tendency of π donor groups to affect geometry in the opposite (F, Cl) or same (NH_2) direction. The phenyl group also appears to affect ring bond lengths (2). Crystal studies indicate the two rings are generally not in the bisected conformation required for electron release from cyclopropane to phenyl. As the inter-ring angle approaches 90° from the bisected conformation, electron donation from phenyl to the $4e'$ orbital of cyclopropane may be possible (3), but the interaction is not strong enough to require this conformation in the crystal of 1,1-dibromo-*trans*-2,3-diphenylcyclopropane (3). The carboxyl group of 2,2-diphenylcyclopropanecarboxylic acid bisects the cyclopropane ring, but the phenyl groups are at 87° and 71° to the bisected conformation (4). By contrast, *trans*-2-(*p*-nitrophenyl)cyclopropyl methyl ketone exists with both the aromatic ring and acetyl groups essentially bisecting the cyclopropane ring (5).

It is interesting to speculate whether the preferred conformation of the phenyl group is dependent on the electronic properties of other substituents, or on steric factors in the molecule. With this question in mind we have undertaken an X-ray study of the hindered compound *cis*-2-(*m*-nitrophenyl)cyclopropanecarboxylic acid (6), containing the same conjugating groups (phenyl, carbonyl) as the unhindered compound *trans*-2-(*p*-nitrophenyl)cyclopropyl methyl ketone.

From the sparse data on cyclopropene derivatives with phenyl and carbonyl substituents a somewhat different question arises. The structure of 3,3-dimethoxycarbonyl-1-methyl-2-phenylcyclopropene (7) has the two rings coplanar, for maximum interaction of phenyl with the cyclopropene double bond. However, the carbonyl groups deviate substantially from the ring-bisecting conformation, and conjugation is uncertain (8). This may result from mutual repulsion of the two carbomethoxy groups. 1-Phenyl-2-methylcyclopropene-3-carboxylic acid (9) has now been examined to determine whether the unhindered carbonyl substituent prefers the bisecting conformation.

Experimental

Synthesis

cis-*2-(*m*-Nitrophenyl)cyclopropanecarboxylic acid*

This compound was synthesized by the addition of ethyl diazoacetate to *m*-nitrostyrene, ester hydrolysis, and separation of the *cis*- and *trans*-acids by repeated fractional crystallization (6), mp 178.7−179.7°C. A crystal for X-ray study was formed by slow partial evaporation at room temperature of an acetonitrile solution.

1-Phenyl-2-methylcyclopropene-3-carboxylic acid

Ethyl diazoacetate was added to 1-phenylpropyne, and the resulting ester was hydrolyzed to the acid, mp 137.2−137.9°C (9). A crystal was grown from benzene solution by partial evaporation at room temperature.

X-ray structure determination

Data collections for the two different compounds were similar,

except as noted below. An Enraf-Nonius CAD-4 automatic diffractometer was used with MoKα radiation which was monochromatized by a dense graphite crystal, assumed for all purposes to be ideally imperfect. Final cell constants, as well as other pertinent data, are given in Table 1. For the monoclinic cyclopropene the data were collected from the quadrant of reciprocal space having k and l non-negative while h assumes all values, whereas for the triclinic cyclopropane the hemisphere of data having l non-negative was used. Intensities were measured using the $\theta-2\theta$ scan technique, with the scan rates depending directly on the net count obtained in rapid prescans of each reflection. The standard reflections monitored every 2 h during both experiments showed no unusual aberrations. In reducing the data, Lorentz and polarization factors were applied, but no corrections for absorption were made.

Both structures were solved using MULTAN (10), with the cyclopropane being a somewhat more difficult problem due to the lack of translational symmetry in the space group. The usual sequence of isotropic and anisotropic refinement was followed, after which all hydrogens were located in difference density Fourier maps. In the case of the cyclopropene, the hydrogen temperature factors refined poorly and thus were held fixed at reasonable values in the final refinement. After all shift/esd ratios were less than 0.1, the full-matrix least-squares refinement converged to the agreement factors listed in Table 1. The atomic scattering factors for C, O, and N were computed from numerical Hartree–Fock wave functions (11); for hydrogen those of Stewart, Davidson, and Simpson were used (12). All calculations were made with the SHELX-76 series of crystallographic programs (13). No unusually high correlations were noted in either refinement. Final positional and thermal parameters for the cyclopropene are listed in Table 2, while those for the cyclopropane are in Table 3. Bond lengths, angles, least-squares planes, and torsion angles are given in Tables 4–7 based on these positions. The numbering schemes for the molecules are shown in the stereoviews of Figs. 1 and 2.

Discussion

cis-2-(m-Nitrophenyl)cyclopropanecarboxylic acid

The bond lengths and angles in the two substituents are as expected based on previous structural determinations. The six phenyl ring distances average 1.383 Å, with the bond of attachment (C4—C5) = 1.494 Å. These values compare quite well with the averages of 1.387 Å and 1.502 Å reported in the survey by Allen (2). The nitro group is twisted less than 4° with respect to the phenyl ring and exhibits the characteristic deviation from trigonality caused by the nonbonded electron pair repulsions of the oxygens (14–16). The carboxyl group adopts the preferred (17, 18) conformation having the carbonyl oxygen near the cyclopropane center. The OH group is in the *syn*-planar conformation, and the overall geometry agrees quite well with the averages reported in the exhaustive study of carboxylic acids made by Leiserowitz (19). The C1—C2 length is shorter than would be expected for a C_{sp^2}—C_{sp^3} bond (1.505 Å) (20), and is indicative of conjugation between the cyclopropane and the C=O group. Both cyclopropane ring substituents are approximately in the *cis gauche* (cg3) position, according to the terminology of Allen (2), although the carboxyl is considerably closer to the *cis* bisecting (cb) position than is the phenyl (as shown by the torsion angles C3—C2—C1—O2 = 16°, C6—C5—C4—C3 = 6°).

The cyclopropane ring itself shows substantial bond asymmetry, having a maximum difference of 0.060 Å. Compared to the bond length of 1.510 Å found in unsubstituted cyclopropane (21), C3—C4 is seen to be somewhat shorter while C2—C4 is considerably longer. The variation of bond lengths with exocyclic substituents has been examined theoretically (22, 23) and experimentally (2, 4, 17, 24), and it is now well established that both carboxyl and phenyl substituents have the effect of shortening the distal cyclopropane bond while lengthening the vicinal ones. Furthermore, the absolute amount of the shortening is correlated with the positioning of the substituent group, with the maximum effect occurring at the bisecting position (2, 3) where the substituent π system has the greatest overlap with the occupied $3e'$ orbital of cyclopropane (3).

Although it would seem reasonable to expect some alteration of the bond shortening by adding substituents such as a nitro group to the phenyl ring, this can effectively be ruled out in light of the reported results of Jason and Ibers (3).

Our cyclopropane ring distance pattern is in complete accord with the above observations, and, in fact, provides additional evidence to support the "additivity principle" suggested for π-acceptor substituents (25). This proposes that "bond length asymmetry in multiply-substituted cyclopropanes should approximate a summation of the asymmetries induced by each individual substituent." Our ring values can be thought of as the composite of the following two effects: (*1*) The carboxyl group shortens the distal bond C3—C4 by an amount δ_c and lengthens each of C2—C3 and C2—C4 (by $\sim\delta_c/2$). (*2*) The phenyl ring shortens C2—C3 by δ_p and lengthens C2—C4 and C3—C4 (by $\sim\delta_p/2$).

According to Allen (2), reasonable values to expect for δ_c and δ_p are 0.023 Å and 0.018, and when applied to the value

of 1.510 Å for normal cyclopropane the predicted values of our ring bond distances would be:

$$\text{C2—C3} = 1.510 + \frac{0.023}{2} - 0.018 = 1.504 \text{ Å}$$

$$\text{C2—C4} = 1.510 + \frac{0.023}{2} + \frac{0.018}{2} = 1.531 \text{ Å}$$

$$\text{C3—C4} = 1.510 - 0.023 + \frac{0.018}{2} = 1.496 \text{ Å}$$

These predictions agree remarkably well with the observed values of 1.512, 1.550, and 1.490 Å, especially taking into account that the phenyl and carboxyl groups in our compound are not in the ideal bisecting conformations. Also, the application of $\delta/2$ to each vicinal bond is overly simplistic and has been shown to be the non-preferred case in the compilation by Allen (2). The overly long C2—C4 bond might also imply some synergy between the two exocyclic substituent effects.

The fact that the C2—C3 value is longer than predicted while the C3—C4 value is shorter fits in well with the earlier remark (*vide supra*) about the greater deviation of the phenyl ring from the bisecting position. It is not at all clear, however, why *both* the phenyl and the carboxyl groups deviate — the closest contact between the two groups is O2···H6 = 2.98 Å, which is longer than the O2···H8′ intermolecular contact (2.77 Å), and so steric hindrance alone does not seem to be the answer. In the unhindered *trans* methyl ketone analog investigated by Bordner *et al.* (5), both substituents are near the bisecting position, with the phenyl ring somewhat closer to ideal than the carbonyl. Their ring bond length pattern is the same as ours, although the values are much lower and subject to some suspicion due to the higher R value and standard deviations. Also, the maximum difference between ring bonds in the *trans* compound is only 0.030 Å, half of the value which we observe in the *cis* where less difference would be expected due to the angles of the substituents.

The packing of the molecules in the unit cell is shown in Fig. 3. Pairs of molecules are mutually hydrogen bonded across crystallographic inversion centers, while the π clouds of the phenyl ring are in staggered opposition in planes parallel to the b axis. The hydrogen bonding parameters are: O···O = 2.674(3) Å, O···H = 1.57(3) Å, and O—H···O = 172(3)°. These values agree well with those found in other cyclopropanecarboxylic acids having similar hydrogen bonding (4, 17, 26).

1-Phenyl-2-methylcyclopropene-3-carboxylic acid

In the cyclopropene compound, the bond lengths and angles of the substituents are not in such good agreement with literature values as are those in the cyclopropane. The six phenyl ring distances average 1.376 Å with a bond of attachment (C4—C5) = 1.446 Å. There is large variation among the individual bond lengths due to the high thermal motion of the more distant ring carbons, the magnitude of which can be clearly seen in Fig. 2. The carboxyl group shows a much smaller difference between C—O bond lengths, possibly due to more extensive conjugation with the three-membered ring. The bond of attachment (C1—C2) is again much shorter than that of a pure C_{sp^2}—C_{sp^3} (20), and the whole system may be somewhat more delocalized than in the cyclopropane case. The carboxyl group is in the preferred conformation (17, 18) having the carbonyl oxygen nearer the cyclopropene center, and with a *syn*-planar hydrogen. The orientation is *cis* bisecting with respect to the cyclopropene, while the phenyl ring, on the other hand, is practically co-planar with it.

The cyclopropene ring has an exceedingly short double bond, shorter than those found in ethylene (27) and in allene (28). The explanation for this is increased s character in the σ component of the bond, together with strong $p\pi$ overlap (8).

[a]The average esd is 0.3°.

The ring geometry is in reasonably good agreement with electron diffraction results for cyclopropene itself (29), although the strong conjugation with the exocyclic substituents tends to weaken the comparison. In fact, the only structural report in the literature which lends itself to close comparison is that of the 3,3-dimethoxycarbonyl analogue (7). Those values are in remarkably good agreement with ours, with the exception of the C—O bonds. The cyclopropene ring bond patterns are identical, with the longer of the two C_{sp^2}—C_{sp^3} bonds being opposite the phenyl substituent. Our double bond is slightly shorter, which could be due to the more favorable positioning of the carboxyl group with respect to orbital overlap of the π system. Obviously, the answer to the question that provided the impetus for this investigation is that the unhindered carbonyl substituent does indeed prefer the *cis* bisecting conformation, but it remains to be shown whether or not any perturbations to the cyclopropene caused by π-acceptor substituents can be quantified as in the case of the cyclopropanes.

The molecular packing in the unit cell is shown in Fig. 4. As in the case of the cyclopropane compound, pairs of molecules are mutually hydrogen bonded across inversion centers, although the arrangement of the pairs is completely different.

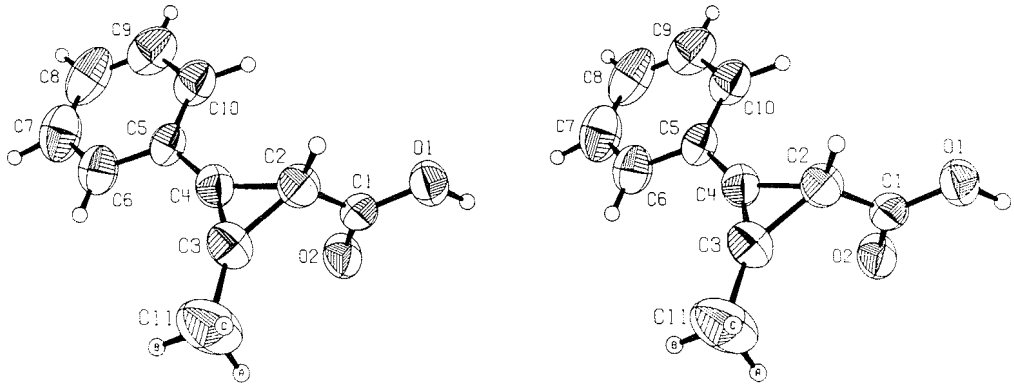

FIG. 2. Stereoscopic view of the atom-labeling scheme for 1-phenyl-2-methylcyclopropene-3-carboxylic acid. The thermal ellipsoids are 40% equiprobability envelopes, with hydrogens as spheres of arbitrary diameter.

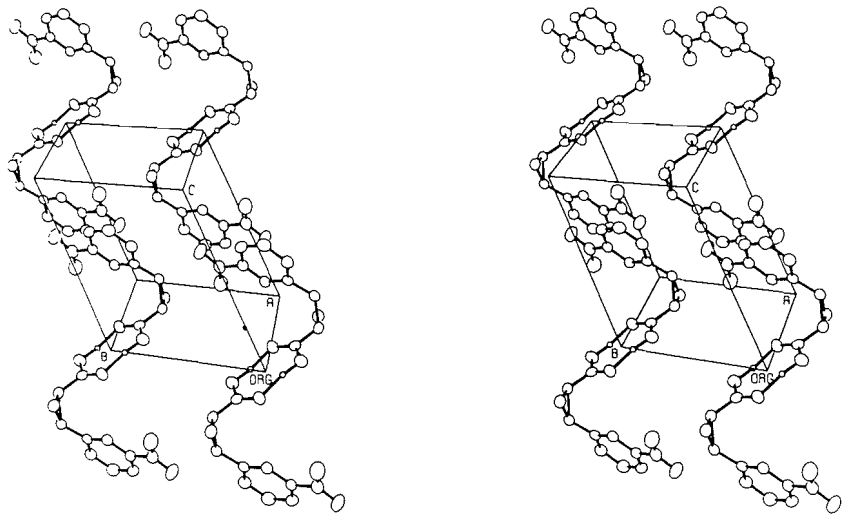

FIG. 3. Stereoscopic view of the molecular packing of the cyclopropane compound, as viewed along the *a* axis. Hydrogens are omitted for clarity, and the hydrogen bonds between pairs of molecules are included.

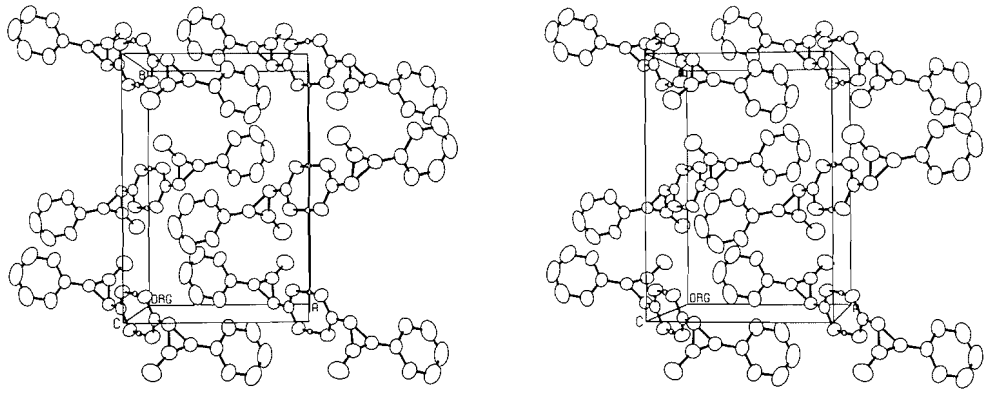

FIG. 4. Stereoscopic view of the molecular packing of the cyclopropene compound, as viewed into the *c* axis. Hydrogens are omitted, and hydrogen bonds between pairs of molecules across inversion centers are included.

The O···O separation is 2.609(3) Å, O···H = 1.63(3) Å, and the O—H···O angle is 173(3)°. There are no unusually close intermolecular contacts.

Mononuclear and binuclear copper(II) complexes of some polyfunctional pyridyl phthalazines

GRAHAM BULLOCK, FREDERICK W. HARTSTOCK, AND LAURENCE K. THOMPSON[1]
Department of Chemistry, Memorial University of Newfoundland, St. John's, Nfld., Canada A1B 3X7

Received June 24, 1982

GRAHAM BULLOCK, FREDERICK W. HARTSTOCK, and LAURENCE K. THOMPSON. Can. J. Chem. **61**, 57 (1983).

Mononuclear and binuclear copper(II) complexes of the potentially tetradentate binucleating ligands 1,4-di(3′-methyl-2′-pyridyl)aminophthalazine (PAP3Me) and 1,4-di(5′-methyl-2′-pyridyl)aminophthalazine (PAP5Me) are reported. In the case of the ligand 1,4-di(4′,6′-dimethyl-2′-pyridyl)aminophthalazine (PAP46DiMe) only binuclear derivatives were obtained. The mononuclear complexes, involving protonated ligand, result from the sensitivity of these ligands to mildly acidic conditions in aqueous solutions of certain copper salts. Binuclear, neutral ligand, complexes are also formed when the pH increases. Hydroxy bridged binuclear structures exist in all the binuclear complexes described with the exception of one acetate bridged derivative. Sub normal magnetic moments are observed for all the binuclear complexes (<1.74 BM) indicating spin coupled systems with very low values (<0.88 BM) for binuclear complexes of PAP46DiMe, indicating the possibility of strong antiferromagnetic exchange between the metal centres.

GRAHAM BULLOCK, FREDERICK W. HARTSTOCK et LAURENCE K. THOMPSON. Can. J. Chem. **61**, 57 (1983).

On rapporte les complexes mononucléaires et binucléaires de cuivre (II) des ligands binucléaires potentiellement tétradentates, di(méthyl-3′ pyridyl-2′)-1,4 aminophthalazine (PAP3Me) et di(méthyl-5′ pyridyl-2′)-1,4 aminophthalazine (PAP5Me). On a obtenu uniquement des dérivés binucléaires dans le cas du ligand di(diméthyl-4′,6′ pyridyl-2′) aminophthalazine (PAP4DiMe). Les complexes mononucléaires, impliquant un ligand protoné, proviennent du fait que ces ligands sont sensibles aux conditions acides douces des solutions aqueuses de certains sels de cuivre. Il se forme également des complexes binucléaires de ligand neutre, lorsque le pH augmente. Des structures binucléaires, ayant un hydroxy en position de pont, existent dans tous les complexes binucléaires décrits à l'exception d'un dérivé ayant un pont acétate. On a observé des moments magnétiques sub-normaux pour tous les complexes binucléaires (<1,74 BM) indiquant ainsi des systèmes à spin couplé avec de très faibles valeurs (<0,88 BM) pour les complexes binucléaires de PAP46DiMe et également la possibilité d'un fort échange antiferromagnétique entre les centres métalliques.

[Traduit par le journal]

Introduction

Binuclear copper centres are found in the oxygen breathing protein hemocyanin and in a number of enzymes which have oxidase or oxygenase function (Type III centres). Magnetic studies have shown that strong antiferromagnetic exchange exists between the two copper(II) centres in Megathura crenulata oxyhemocyanin ($-2J \geq 1250$ cm^{-1}) (1, 2) and Rhus vernicifera laccase ($-2J \geq 1000$ cm^{-1}) (2). Antiferromagnetic coupling is usually mediated by a superexchange pathway which would imply the presence of a bridging group or groups between the two copper atoms and that the metal centres would be in close proximity in the protein. Resonance Raman studies on oxyhemocyanins have indicated a peroxide bridge between the copper(II) centres (3, 4) and EXAFS studies by Spiro *et al.* on Busycon canaliculatum oxyhemocyanin have suggested a copper–copper separation of 3.67 Å in a proposed structure with three imidazoles bound to each copper centre, a peroxide bridge, and another endogenous protein ligand bridge (5). Hodgson *et al.* studied the oxyhemocyanin binuclear centres in Megathura crenulata and Helix pomatia and found the two copper atoms to be separated by 3.55 Å in a proposed structure involving two imidazoles per copper, a peroxide bridge and a protein ligand bridge in an approximately square planar structure (6). Further studies by Solomon *et al.* suggest two copper centres bridged by peroxide and some endogenous ligand with two imidazoles and a water molecule at each five-coordinate copper centre in various mollusc and arthropod oxyhemocyanins. They also point out the similarity, based on chemical and spectroscopic studies, of the Type III centre in tyrosinase with that in oxyhemocyanin (7, 8). Reporter probe studies involving substitution of copper(II) by cobalt(II) in squid (Sepioteuthis lessoniana) hemocyanin suggest that in the deoxy form, three histidine imidazoles are bound to each copper(I) centre in a structure involving one pseudo-tetrahedral copper site and a tetragonally distorted site with a possible endogenous bridge. A double bridged five-coordinate structure involving three imidazoles per copper, a bridging peroxide, and another bridge group was proposed for the oxy form (9).

In previous papers we have described the copper coordination chemistry of some polyfunctional binucleating pyridylphthalazines, which present the two copper centres with two nitrogen donor groups in multibridged structures involving, in many cases, hydroxy bridges between the metal centres (10–13). The ligands have included PAP(1,4-di(2′-pyridyl)-aminophthalazine) and PAP4Me and PAP6Me which have methyl substituents on the 4- and 6-positions of the pyridine rings respectively. X-ray structures have shown that the binuclear centre in a series of hydroxy bridged species can be tuned by varying a third bridging group (Fig. 1) (10, 12–14). In general, systems of this sort have low room temperature magnetic moments, signalling exchange-coupled copper centres and in cases where exchange integrals were measured the exchange was observed to increase with increasing oxygen bridge angle.

In this report we describe the copper coordination chemistry of three other related pyridyl phthalazines: 1,4-di(3′-methyl-2′-pyridyl)aminophthalazine (PAP3Me), 1,4-di(5′-methyl-2′-pyridyl)aminophthalazine (PAP5Me), and 1,4-di(4′,6′-di-

methyl-2′-pyridyl)aminophthalazine (PAP46DiMe) (Fig. 2). These ligands are previously unreported. Protonated ligand mononuclear complexes and neutral ligand binuclear complexes are obtained for PAP3Me and PAP5Me while for PAP46DiMe only binuclear complexes have been synthesized so far. In many cases low room temperature magnetic moments suggest antiferromagnetically-coupled copper(II) centres and in most of the binuclear complexes hydroxy bridges are implicated.

Experimental

Electronic spectra were recorded with a Cary 17 spectrometer and infrared spectra with a Perkin-Elmer Model 283 spectrometer. Magnetic susceptibilities were obtained at room temperature by the Faraday method using a Cahn Model #7600 Faraday Magnetic Susceptibility system, coupled to a Cahn gram electrobalance. Microanalyses were carried out by Canadian Microanalytical Service, Vancouver (C, H, N). Metal analyses were determined by atomic absorption with a Varian Techtron AA-5, after digestion of the samples in concentrated HNO_3 or aqua regia.

Ligands

PAP3Me (mp 257°C), PAP5Me (mp 114°C), and PAP46DiMe (mp 288–289°C) (Fig. 2) were prepared by the same methods used for the synthesis of other previously reported pyridylphthalazines (10, 12). Further details on their syntheses and the general properties of these and other pyridylphthalazines will be published elsewhere. Satisfactory elemental analyses were obtained for these three ligands (Table 1).[2]

Copper complexes (LH = protonated ligand)

$[Cu_2(PAP3Me)(OH)X_3]\cdot yH_2O$ (I) (X = Cl, y = 1.5), (II) (X = Br, y = 0); $[Cu_2(PAP5Me)(OH)X_3]$ (IX) (X = Cl), (X) (X = Br)

$CuCl_2\cdot 2H_2O$ (1.50 g, 8.80 mmol) was dissolved in water (50 mL), PAP3Me (1.50 g, 4.39 mmol) added, and the mixture refluxed until the ligand dissolved. After 10–15 min a green crystalline powder (**I**) formed which was filtered off, washed with water, and dried under vacuum. The other compounds were prepared similarly and obtained as green crystalline solids.

$[Cu_2(PAP46DiMe)(OH)Cl_3]\cdot EtOH$ (XVII)

$CuCl_2\cdot 2H_2O$ (0.920 g, 5.40 mmol) was dissolved in water (150 mL), PAP46DiMe (1.00 g, 2.70 mmol) added, and the mixture refluxed for 4 h. The hot solution was filtered to remove a small amount of orange impurity and the volume of the green solution reduced by half. Addition of ethanol (30 mL) led to the formation of dark green crystals (**XVII**) on standing.

$[Cu(PAP3MeH)_2](ClO_4)_4\cdot 2H_2O$ (IV), $[Cu_2(PAP3Me)(OH)(H_2O)_2](ClO_4)_3$ (V), $[Cu(PAP5MeH)_2](ClO_4)_4\cdot H_2O$ (XII)

$Cu(ClO_4)_2\cdot 6H_2O$ (1.50 g, 3.98 mmol) was dissolved in water (100 mL), PAP3Me (0.690 g, 2.01 mmol) added, and the mixture refluxed for $1\frac{1}{2}$ h. A brown precipitate (**IV**) was filtered off and the green mother liquor reduced in volume. On standing a green crystalline powder (**V**) was obtained. Compound **XII** was obtained similarly as a buff solid, but the corresponding binuclear complex could not be obtained in a pure enough state and so is not reported.

$[Cu(PAP3MeH)_2](NO_3)_4\cdot 3H_2O$ (VI), $[Cu_2(PAP3Me)(OH)(H_2O)_2(NO_3)_2]NO_3$ (VII), $[Cu_2(PAP3Me)(OH)(NO_3)_2](NO_3)$ (VIII), $[Cu(PAP5MeH)_2(H_2O)_2](NO_3)_4\cdot 5H_2O$ (XIII), $[Cu_2(PAP5Me)(OH)(H_2O)_2(NO_3)_2](NO_3)$ (XIV), $[Cu_2(PAP5Me)(OH)(NO_3)_2](NO_3)$ (XV)

$Cu(NO_3)_2\cdot 3H_2O$ (1.00 g, 4.14 mmol) was dissolved in water (100 mL), PAP3Me (0.680 g, 1.99 mmol) was added, and the mixture refluxed for 1 h. The green solution was filtered and allowed to stand. A light brown crystalline powder (**VI**) was obtained which was filtered off and the mother liquor reduced in volume. On standing blue crystals (**VII**) were obtained. Compounds **XII** (buff) and **XIV** (dark blue) were prepared similarly while **VIII** and **XV** (green) were obtained by heating **VII** and **XIV** respectively at 80°C under vacuum for several hours. Compound **XIX** was obtained as green crystals by a procedure similar to that of **VII**, using ethanol as solvent. No protonated complex was obtained in this case.

$[Cu(PAP3Me)(OH)(SO_4)(H_2O)_2](SO_4)_{0.5}\cdot 5H_2O$ (III), $[Cu_2(PAP5Me)(OH)(SO_4)(H_2O)](SO_4)_{0.5}$ (XI)

$CuSO_4\cdot 5H_2O$ (1.00 g, 4.00 mmol) was dissolved in warm water (100 mL), PAP3Me (0.680 g, 1.99 mmol) added, and the mixture refluxed for $1\frac{1}{2}$ h. The green product **III** was filtered off and recrystallized from water to given bright green crystals. Compound **XI** was prepared similarly and obtained as green crystals.

$[Cu_2(PAP5Me)(CH_3COO)_3]\cdot 0.5CHCl_3$ (XVI), $Cu_2(PAP46DiMe)(OH)(CH_3COO)_2]\cdot 1.5H_2O$ (XVIII)

$[Cu(CH_3COO)_2\cdot H_2O]_2$ (1.00 g, 2.51 mmol) was dissolved in methanol (100 mL), PAP5Me (0.800 g, 2.34 mmol) added, and the mixture refluxed for $1\frac{1}{2}$ h. A khaki-green powder formed (**XVI**) which was filtered off and recrystallized from chloroform/hexane. Compound **XVIII** was prepared similarly using ethanol as solvent and obtained as a sparingly soluble khaki-brown product which was used without further purification.

Satisfactory analytical data have been obtained for all the complexes and are reported in Table 1 which is available from the Depository of Unpublished data.[2]

Results and discussion

Characterization of the complexes

Tetradentate pyridylphthalazines (PAPR; R = H, 4Me, 6Me) (Fig. 2) have shown a preference for the formation of binuclear complexes in which two metals are bound to the same ligand in a multiple bridged structural arrangement (10–17). Polynuclear derivatives involving three copper centres have also been reported (11, 12) and in some cases protonated, mononuclear derivatives are found in which the formation of a protonated ligand is seen as the result of the sensitivity of these ligands to even mildly acidic conditions which are common in

[2]Photocopies may be obtained at a nominal charge, upon request, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Canada K1A 0S2.

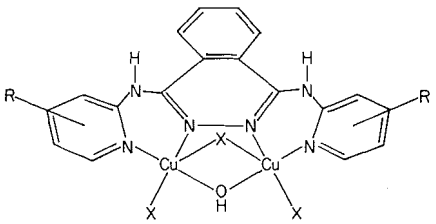

FIG. 3. Proposed structures for the complexes $[Cu_2(PAP3Me)(OH)X_3]$ (X = Cl, Br), $[Cu_2(PAP5Me)(OH)X_3]$ (X = Cl, Br), and $[Cu_2(PAP46DiMe)(OH)Cl_3]$.

aqueous solutions of transition metal salts (11, 12, 17).

Magnetic and X-ray structural studies have shown that in binuclear copper complexes of PAP (R = H), in which a constant structural feature involves the double bridge including a hydroxide and the phthalazine N—N group, variation in size of the third bridging group (e.g. $Cl \rightarrow IO_3$) can dramatically alter the spin exchange between the metal centres as a result of a concomitant increase in the oxygen bridge angle (13). This change is also reflected in the room temperature magnetic moments. While modifications in the bridging groups can tune the binuclear centre, structural variations in the ligand itself appear also to be capable of altering the geometry at the binuclear centre by imposing certain steric constraints. The complexes $[Cu_2(PAP6Me)(OH)X_3]$ (X = Cl, Br) (12) were shown to have very low room temperature magnetic moments (<0.7 BM) possibly indicating stronger exchange than that observed in the complex $[Cu_2(PAP)(OH)(IO_3)_3]\cdot 4H_2O$ (10, 13) and an increased oxygen bridge angle.

In this report we have examined the ligands PAP3Me, PAP5Me, and PAP46DiMe (Fig. 2) in which steric constraints imposed by the substituent methyl groups on the pyridine rings are likely to differ from those of the previously reported systems. Earlier studies indicate that the pK_a of PAP is close to 3.8 and that the ligand can behave as a neutral, anionic, or cationic entity (10–12). In its neutral form $\pi-\pi^*$ charge transfer absorptions were found to occur in the range 27400–29600 cm^{-1}, while for anionic systems the lowest energy charge transfer band was found to occur between 24000 and 25600 cm^{-1} (10). In the uncomplexed ligand this band occurs at 26200 cm^{-1}. Criteria of this sort will be used to assess the charged state of the methylated ligands. The nuetral ligands PAP3Me, PAP5Me, and PAP46DiMe have $\pi-\pi^*$ absorptions in methanol in the range 26700–27800 cm^{-1} (Table 2).

The chloro-complexes **I**, **IX**, and **XVII** and the bromo-complexes **II** and **X** appear to have similar five-coordinate structures, in which, as in the PAP analogues (10–12) the two metals are bridged by a phthalazine moiety, a hydroxide, and a halide (Fig. 3, X = Cl, Br). Reduced magnetic moments (Table 2) are observed for all the halide complexes indicating exchange coupled copper centres. However, the very low moment observed for the PAP46DiMe complex suggests strong exchange with the possibility of a quite large oxygen bridge angle. As in the case of the PAP6Me complexes (12) this may be attributable to steric effects associated with the 6-methyl substituents on the pyridine rings.

The sulfato-complexes of PAP3Me (**III**) and PAP5Me (**XI**) are both neutral ligand systems involving hydroxy bridges between the copper centres. Very rich infrared absorption is observed for both systems in the range 950–1200 cm^{-1} (Table 2) where the ν_1 and ν_3 vibrations associated with sulfate are observed. The sulfate ion (T_d) exhibits one broad band (ν_3) at about 1100 cm^{-1} but on reducing the symmetry through C_{3v} to C_{2v} two and three bands respectively associated with the ν_3 vibration are observed in the range 1000–1200 cm^{-1} (18). It seems likely that a bidentate sulfato bridge occurs in both systems and the most obvious place for it to occur would be as a bridge between the two copper centres. The other sulfate could be ionic or perhaps behave as a bidentate bridge between two binuclear centres.

An X-ray structural study (13) of the analogous system $[PAPCu_2(OH)Cl(SO_4)]\cdot 2H_2O$ reveals a sulfate bridge and a hydroxy bridge between two five-coordinate copper centres (Fig. 1, X = SO_4; Y = Cl). However, the sulfate group is in fact tridentate, bridging a third copper atom from the binuclear centre in an adjacent molecule. The Cu—O(H)—Cu bond angle was found to be 115.6° and the Cu—Cu separation 3.211 Å. A low magnetic moment (1.01 BM) was found, indicative of fairly strong magnetic exchange between the copper centres. Details of this structure will be published elsewhere. An immediate structural analogy between this compound and **III** and **XI** may not be reasonable because of the presence of an additional half sulfate in each case. However, these systems both clearly contain binuclear hydroxy bridged copper(II) centres. The magnetic moment for **III** is close to the spin-only value for copper(II), implying a small exchange, while the low moment for **XI** suggests significant spin exchange between the copper(II) centres and a much larger oxygen bridge angle.

As with other PAP-type ligands, protonated mononuclear complexes are formed with certain copper salts in addition to neutral ligand polynuclear derivatives (11, 12). PAP3Me reacts with copper perchlorate in aqueous solution to give a buff solid (**IV**) initially which appears to be a four-coordinate square planar derivative involving two bidentate protonated ligands. The high magnetic moment for this system is typical of a mononuclear copper(II) complex. A typical feature of these protonated complexes is a rich CN-stretching region of the infrared spectrum with, in some case, in excess of four distinguishable bands. The neutral systems usually only exhibit two such bands. The site of protonation is assumed to be the pyridine nitrogen (11). Compound **IV** exhibits just two CN-stretching bands which may indicate protonation at a different ligand nitrogen site.

The perchlorate complex **V** is a binuclear system involving neutral ligand and although a hydroxide absorption cannot be clearly seen in the infrared it is implied that such a group bridges the two metal centres. A rather broad perchlorate band is observed in the infrared at 1080 cm^{-1} but the lack of structure of this absorption suggests that the perchlorate group is ionic. However, a weakly associated perchlorate bridge between the two copper centres should not be ruled out. The low magnetic moment for **V** indicates significant spin exchange and a fairly large oxygen bridge angle, which can be associated with a bulky third bridge between the metal centres (e.g. ClO_4).

With PAP5Me only the protonated mononuclear perchlorate complex **XII** could be isolated satisfactorily and as with **IV** appears to have a speudo-square planar structure. Four CN-stretching bands are observed in the infrared, in general agreement with other such systems, suggesting protonation at the pyridine nitrogen sites.

As with copper perchlorate two pairs of complexes are obtained in each case in the reactions between PAP3Me and PAP5Me with copper nitrate in aqueous solution. The protonated mononuclear complex **VI** has a high energy $d-d$ absorption, perhaps more typical of a pseudo-square system,

TABLE 2. Electronic spectra (mull transmittance), infrared spectra, and magnetism

	Compound	$d-d$ (cm^{-1})	CT (cm^{-1})	Infrared (cm^{-1})	μ $(BM)_{Cu}$ (room temp.)

*Methanol solution.

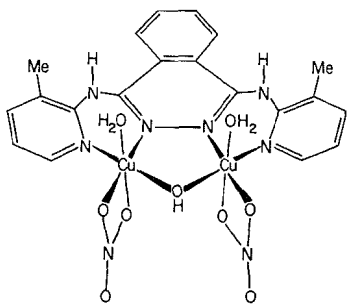

FIG. 4. Proposed structure for the cation in $[Cu(PAP3Me)(OH)(H_2O)_2(NO_3)_2](NO_3)$.

although a tetragonally distorted six-coordinate system involving loosely bound water should not be ruled out. A high magnetic moment for this complex typifies a mononuclear entity and, as with other protonated PAP3Me systems, only two CN-stretching bands are observed (1604, 1630 cm^{-1}). **XIII** exhibits five prominant CN-stretching bands, typical of a protonated ligand, and a high magnetic moment. A shoulder at 14900 cm^{-1} in the electronic spectrum suggests a tetragonally distorted six-coordinate system involving axially bound water molecules.

The binuclear dark blue nitrate complex **VII** has a hydroxy bridge and infrared absorption associated with coordinated water. Three nitrate combination bands ($\nu_1 + \nu_4$) are observed at 1728, 1744, and 1756 cm^{-1}. The absorption at 1744 cm^{-1} can be associated with ionic nitrate while the other two bands suggest the presence of bidentate chelating nitrate. There is no infrared evidence to support the presence of a bidentate bridging nitrate between the two copper centres (19), which was found to be the case in the blue six-coordinate complex $[Cu_2(PAP4Me)(OH)(H_2O)_2(NO_3)_2]NO_3$ according to X-ray studies (12, 13). The low magnetic moment for this system indicates significant exchange between the metal centres and a large oxygen bridge angle. The $d-d$ absorption at 15900 cm^{-1} is comparable with that observed for the PAP4Me analogue (16300 cm^{-1}) and so a six-coordinate structure is suggested for this system (Fig. 4).

On heating **VII** under vacuum a colour change from blue to green occurs (**VIII**). Two water molecules are clearly lost but the role of the nitrate groups appears to be the same. If the $\nu_1 + \nu_4$ nitrate band at 1743 cm^{-1} can be associated with ionic nitrate the other two bands suggest the presence of bidentate chelating nitrate. A five-coordinate structure involving a hydroxy bridge is suggested for this system (Fig. 4, water molecules removed from both copper centres). Since the magnetic moment does not change appreciably on dehydration the hydroxy bridge angle in both systems is presumed to be comparable.

The blue PAP5Me complex **XIV** has similar spectral and magnetic features to **VII** and a similar structure is proposed for this system (Fig. 4). On heating this compound under vacuum a colour change from blue to green also occurs (**XV**). A shift in the $d-d$ absorption of 1100 cm^{-1} to higher energy was

observed in addition to an increase in the magnetic moment from 1.18 to 1.60 BM. It is clear from the microanalysis that two water molecules are lost on heating and coupled with nitrate combination band data, indicating the presence of both ionic and chelating bidentate nitrate, a five-coordinate binuclear hydroxy bridged structure is again proposed (Fig. 4; water molecules removed from both copper centres). The increase in magnetic moment on dehydration can be interpreted in terms of a decrease in the oxygen bridge angle which may result from the steric constraints associated with the pyridine ring methyl substituents occupying different ring positions.

Copper acetate complexes have been obtained with PAP5Me (**XVII**) and PAP46DiMe (**XVIII**) and a comparison of their spectral and magnetic properties reveals some substantial structural differences. A low energy charge transfer absorption indicates the presence of anionic ligand in **XVI** and infrared absorptions due to carboxylate suggest the presence of both terminal and bridging acetate, although there is no significant absorption associated with the asymmetric vibration of a terminally bound carboxylate (10, 12). Structurally **XVI** appears to be similar to a series of copper carboxylate complexes of the pyridylphthalazine PAP (10) which were assumed to have a carboxylate bridge between the two copper centres and two terminally bound carboxylates. The absence of an asymmetric terminal carboxylate vibration was seen as a result of an intermolecular association where the terminal carboxylates form weak bridges to adjacent molecules thus forming effectively five-coordinate systems. The magnetic moment of 1.74 BM does not necessarily indicate a non-exchanged system but that the spin exchange is likely to be small. Low temperature magnetic studies by the Gouy method have shown an exchange integral $-2J = 114$ cm^{-1} for the analogous complex $[Cu_2(PAP)(CH_3COO)_3]$ (20) which has a room temperature moment of 1.66 BM (10).

The copper acetate complex of PAP46DiMe (**XVIII**) has a low energy charge transfer absorption implying the presence of anionic ligand and a very low room temperature magnetic moment indicating a strongly coupled system with a hydroxy bridge. A strong broad infrared absorption at 3400 cm^{-1} is associated with a hydroxide bridge which may be hydrogen bonded to either a neighbouring carboxylate or a water molecule. Infrared absorptions associated with both terminal and bridging carboxylate can be identified and suggest a carboxylate bridge between the two copper centres. Since the molecule contains just two acetate groups a terminal acetate is assigned to one copper atom with the possibility of a water molecule occupying the fifth coordination site at the other copper centre (Fig. 3, X = CH_3COO^-, one terminal X = H_2O). The $d-d$ absorption for this system is consistent with five-coordinate copper(II).

Binucleating pyridyl phthalazines (PAPR) present the two copper centres each with two nitrogen donor groups (mimetic of histidine imidazole) in mainly five-coordinate systems involving in most cases hydroxy bridges. Metal–metal separations have approached 3.2 Å with Cu—O—Cu bridge angles of up to around 115° (12–14) and very low room temperature magnetic moments have been observed, indicative of antiferromagnetic exchange. The largest exchange integral so far was found to be 335 cm^{-1} ($-2J$) for the complex $[Cu_2PAP(OH)(IO_3)_3]\cdot 4H_2O$ (10, 13) which has an oxygen bridge angle of 113.4°. It is expected that enhanced exchange will be observed for those systems with increased bridge angles. The maximum metal–metal separation, and hence Cu—O—Cu bridge angle in these binuclear phthalazine complexes, will perhaps be determined by the dimensions of the Cu_2N_2 (phthalazine) unit and assuming a limit of 120° in the Cu—N—N angle a limit of ~3.4 Å would be placed on this separation. However, in other pyridyl phthalazine and pyridyl pyridazine complexes involving nickel and copper, respectively, the M—N—N (diazine) angle has been shown to exceed 120° (21–23). In the complex $[Ni_2(dhph)_2(H_2O)_4]Cl_4\cdot 2H_2O$ (dhph = 1,4-dihydrazinophthalazine) Ni—N—N (phthalazine) angles of 124.8° and 125.6° are found with a metal–metal separation of 3.791 Å (21) while for the complex $[Cu_2LCl_3(OH)(H_2O)]$ (L = 3,6-bis(2′-pyridyl)pyridazine), Cu—N—N (pyridazine) angles of 120.7° and 120.9° are found with a metal–metal separation of 3.376 Å and a Cu—O—Cu bridge angle of 126.5° (no exchange data are quoted for this system) (23). Clearly, therefore, diazine systems, including phthalazines, pyridazines, and pyrazoles, should be capable of generating binuclear copper systems with metal–metal separations in the range anticipated for hemocyanin and the Type III centres. The implication of this and other studies (10, 12–14) involving binuclear phthalazine complexes is that the Cu—O(R)—Cu unit is a reasonable proposition for the exchange coupled part of the biological chromophore in these binuclear protein centres. The ubiquity of the $[Cu—O(H)—Cu]^{3+}$ unit suggests that the oxygen bridge may simply be a hydroxide and not part of a protein side chain.

Crystal structures of an α-cyclobutyl tricyclic enone and its *p*-bromobenzoate derivative

RICHARD A. PAUPTIT AND JAMES TROTTER

Department of Chemistry, University of British Columbia, Vancouver, B.C., Canada V6T 1Y6

Received April 20, 1982

RICHARD A. PAUPTIT and JAMES TROTTER. Can. J. Chem. **61**, 63 (1983).

Crystals of the enone, $C_{22}H_{32}O_3$, are monoclinic, $P2_1/n$, a = 15.722(4), b = 7.463(2), c = 17.213(1) Å, β = 104.67(1)°, Z = 4. The structure was solved by direct methods and was refined to R = 0.040 for 656 reflections with $I/\sigma(I) \geq 3.0$. Crystals of the *p*-bromobenzoate derivative are triclinic, $P\bar{1}$, a = 11.023(1), b = 11.877(1), c = 10.900(1) Å, α = 90.461(8), β = 111.57(1), γ = 80.51(1)°, Z = 2. The structure was solved by Patterson and Fourier methods and refined to R = 0.032 for 2715 reflections with $I/\sigma(I) \geq 3.0$. The X-ray studies were carried out in order to investigate a possible highly strained *trans*-fused 4- and 5-membered ring system in a photoadduct obtained as an intermediate in the projected syntheses of stemodin and aphidicolin. The ring system was, however, *cis*-fused.

RICHARD A. PAUPTIT et JAMES TROTTER. Can. J. Chem. **61**, 63 (1983).

Les cristaux de l'énone, $C_{22}H_{32}O_3$, sont monocliniques, $P2_1/n$, a = 15.722(4), b = 7.463(2), c = 17.213(1) Å, β = 104.67(1)°, Z = 4. On a résolu la structure par les méthodes directes et on a l'affinée jusqu'à une valeur de R = 0.040 pour 656 réflexions avec $I/\sigma(I) \geq 3.0$. Les cristaux de la derivée de *p*-bromobenzoate sont tricliniques, $P\bar{1}$, a = 11.023(1), b = 11.877(1), c = 10.900(1) Å, α = 90.461(8), β = 111.57(1), γ = 80.51(1)°, Z = 2. On a résolu la structure par les méthodes de Patterson et de Fourier et on l'a affinée jusqu'à une valeur de R = 0.032 pour 2715 réflexions avec $I/\sigma(I) \geq 3.0$. On a fait les études par X-rayon pour réchercher une système des cycles a 4 et 5 membres possiblement *trans*-fusée et très constraindu dans un photoproduit obtenu comme une intermediaire dans une synthèse projetée de stemodin et de aphidicolin. La système des cycles était, néanmoins, *cis*-fusée.

Introduction

Recent work by Piers and co-workers (1) directed towards the total synthesis of the tetracyclic diterpenoids aphidicolin (**1**, Scheme 1) and stemodin (**2**) included the photoaddition of allene to the tricyclic enone **3**. The latter reaction produced, as major products, two isomeric photoadducts which could be separated by column chromatography on silica gel. The isomer first eluted (39% yield) was shown by X-ray crystallography to possess structure **4** (2), and, therefore, the second product (42% yield) was presumed to be the isomeric photoadduct **5**. Subjection of the keto olefin 4 to ozonolysis (O_3, CH_2Cl_2/MeOH, −78°C; Me_2S) (see Scheme 2) followed by treatment of the resultant cyclobutanone with NaOMe/MeOH (room temperature, 2.5 h), produced the expected keto ester **6** (see Scheme 2), in 88% yield. However, surprisingly, when the second photoadduct (presumed to be **5**) was subjected to an identical sequence of reactions, the product (obtained in excellent yield) proved to be the *same* keto ester **6**, rather than the expected substance **7**. This unexpected result implied either (*a*) that the second photoaddition product was not **5** but possessed the (unlikely) *trans*-fused structure **8**, or (*b*) that a novel and facile rearrangement reaction had occurred in the transformation of **5** into **6**.

In order to provide conclusive evidence regarding the structure of the second photoadduct, an X-ray study was undertaken. Described herein are the results of this study, which unequivocally establishes that the second photoaddition product possesses structure **5**.[1]

X-ray crystal structure of compound 5

Unfortunately, compound **5** did not crystallize as easily as the isomeric substance **4**, and the quality of the crystals even after various recrystallizations was poor. Considerable effort was required in selecting a crystal which was suitable for analysis. Crystals that were apparently well-formed were shown to be multiple platelets by examination on a polarizing microscope, or if this failed, by X-ray photography. Eventually, by selecting a sufficiently thin platelet (0.05 × 0.42 × 0.35 mm^3), a single crystal was located.

Experimental

Crystal data are as follows:

$C_{22}H_{32}O_3$ fw = 344.5

Monoclinic, a = 15.722(4), b = 7.463(2), c = 17.213(1) Å, β = 104.67(1)°, V = 1953.8 Å^3, Z = 4, space group = $P2_1/n$, $F(000)$ = 752, λ = 0.71073 Å, D_c = 1.17 g/cm^3, μ = 0.7 cm^{-1}.

The intensity data were collected on an Enraf-Nonius CAD4 diffractometer using an ω–(1/3)θ scan technique and graphite-monochromatized MoKα radiation. The ω-scan angle was (1.2 + 0.35 tan θ)° and the aperture was (2.50 + tan θ) mm wide and 4 mm high. The intensities of three standard reflections were measured every hour and showed no variation. Another three reflections were checked every 100 reflections for orientation, and reorientation occurred if the difference between observed and calculated scattering vectors was greater than 0.06°.

Of the 3836 reflections collected within the range $0 < \theta \leq 25°$, only 749 (19.5%) had $I/\sigma(I) \geq 3.0$, and so all reflections with a θ value greater than 19.5° were removed from the data set. Of the remaining data, 656 out of 1708 (38%) reflections have $I/\sigma(I) \geq 3.0$ and were considered observed. The unit cell parameters were refined by least-squares methods with sin θ/λ values of 18 reflections in the θ range 9 to 18°, and they appear above with other crystal data. Absorption effects were negligible, and Lorentz and polarization corrections were applied.

The structure was solved by direct methods. 342 E's > 1.2 were obtained from a K-curve and, together with the 50 lowest E's, were input into the MULTAN (3) programme, and from the correct E-map

[1]Some of the details regarding the pathway via which **5** is converted into **6** have been elucidated (see ref. 1).

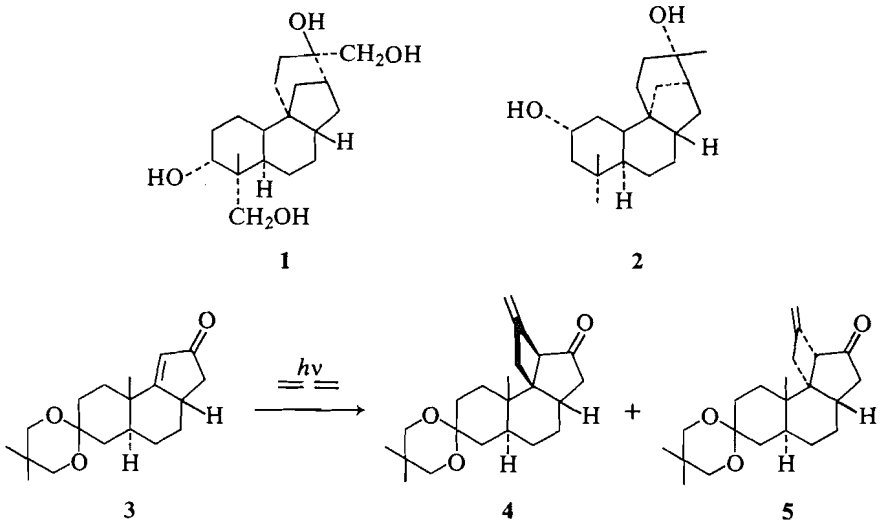
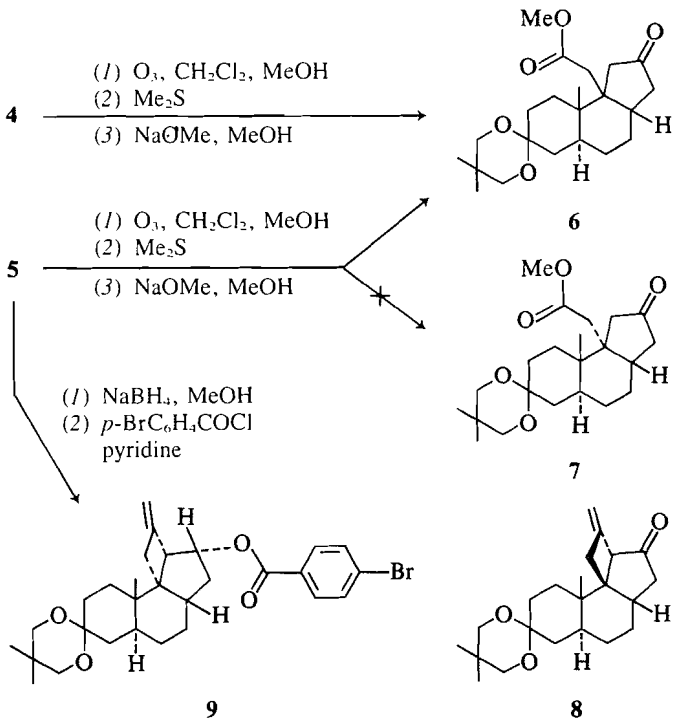


SCHEME 1



SCHEME 2

the positions of all 25 non-hydrogen atoms could be determined.

After three isotropic and seven anisotropic least-squares refinement cycles, all the hydrogen atoms could be located on a difference map; however, the use of calculated positions for the hydrogen atoms produced a significantly lower R value. Attempts to refine the hydrogen thermal parameters proved unsuccessful, and each hydrogen was assigned a temperature factor 10% greater than that of the carbon to which it is bound (25% for methyl hydrogens). The structure converged after three more least-squares cycles using a Hughes' weighting scheme (4) where $(w)^{1/2} = 1.0$ for $|F_o| < F^*$ and $(w)^{1/2} = F^*/|F_o|$ for $|F_o| > F^*$, and $F^* = 21.0$. The weighting scheme could be slightly improved so three more cycles were run with $F^* = 20.0$. The final R values are $R = 0.040$ (0.169 including the unobserved reflections to $\theta = 19.5$) and $R_w = 0.053$. The scattering factors of ref. 5 were used for non-hydrogen atoms and those of ref. 6 for the hydrogen atoms. Final positional and isotropic thermal parameters[2] appear in Table 1.

Results

It can be concluded from the X-ray study summarized above that the structure of the second photoadduct is as shown in structural formula **5**. A stereoview of the molecule with the atomic labelling is shown in Fig. 1. Bond lengths and angles[2] of the non-hydrogen atoms appear in Tables 2 and 3. There are no unusually short intermolecular distances.[2]

[2]Anisotropic thermal parameters, bond lengths and angles of the hydrogen atoms and the *p*-bromobenzoate group, mean plane calculations, packing diagrams, and the structure factor tables for both structures are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

X-ray crystal structure of compound 9

In view of the difficulty in selecting a suitable crystal of **5**, it seemed possible that the crystal chosen for examination might have been one of an impurity — a minor third product. The validity of such a suggestion is always difficult to establish. A structure determination on another crystal in the batch would be expensive, time consuming, and only conclusive if it produced different results. Also, the crystals were sufficiently poor that locating another single crystal of reasonable quality would have been a major task in itself.

An X-ray analysis of a derivative of the second eluted isomer that produces high quality crystals should solve this ambiguity. Therefore, compound **5** was reduced with sodium borohydride in methanol and the resultant alcohol was allowed to react with *p*-bromobenzoyl chloride in pyridine. The resultant *p*-bromobenzoate **9** yielded crystals of high quality (recrystallization from ethanol, 0.42 × 0.33 × 0.37 mm^3).

Experimental

Crystal data are as follows:

$C_{29}H_{37}BrO_4$ fw = 529.5

Triclinic, a = 11.023(1), b = 11.877(1), c = 10.900(1) Å, α = 90.461(8), β = 111.57(1), γ = 80.51(1)°, Z = 2, space group = $P\bar{1}$, $F(000)$ = 556, λ = 0.71073 Å, D_c = 1.32 g/cm^3, V = 1306.8 Å^3, μ = 15.86 cm^{-1}.

Preliminary photography showed that the crystal is triclinic and, as the derivative is a racemate, of the centrosymmetric space group $P\bar{1}$.

The data were collected on an Enraf-Nonius CAD4 diffractometer using an ω–(4/3)θ scan technique and graphite-monochromatized MoKα radiation. The ω-scan angle was (0.70 + 0.35 tan θ)° and the aperature was (2.50 + tan θ) mm wide and 4 mm high. The intensities of three standard reflections were meaured every hour and showed a linear decay of 2% over the data collection. The data were scaled accordingly. Three reflections out of every 100 were checked for orientation, and reorientation occurred if the difference between observed and calculated scattering vectors was greater than 0.05°.

Of the 4549 reflections collected in the range $0 < \theta \leq 25°$, 2715 (59.7%) had $I/\sigma(I) \geq 3.0$ and were considered observed. The cell parameters were refined by least-squares methods with the sin θ/λ values of 24 reflections in the θ range 15 to 19°, and appear together with other crystal data above. The large value of the linear absorption coefficient μ suggests that an absorption correction is in order. 144 sampling points were used with an average spacing of 0.076 mm for a crystal volume of 0.0568 mm^3, and the resulting transmission factors varied from 0.569 for the −12 −4 4 reflection to 0.631 for 5 −1 9. The intensities were thus corrected for absorption, as well as for Lorentz and polarization effects.

The structure was solved by Patterson techniques: the Patterson map contains one outstanding non-origin peak at (0.1542, 0.3450, 0.9215) which establishes the position of the bromines at ±(0.0771, 0.1725, 0.4608).

Other atomic positions (including hydrogens) were then located by Fourier methods, and the structure was refined by least-squares methods, with a polynomial weighting scheme (7) and an anomalous dispersion correction for Br (8), to final R and R_w values of 0.032 and 0.036 (0.083 and 0.076 including the unobserved reflections) respectively. The final coefficients used in the polynomial weighting scheme were A = 0.3074, B = 0.0464, C = −0.00511, and D = 0.000129. In the last cycle, the mean and maximum parameter shifts were 0.046 and 0.474σ, respectively. A final difference map was calculated and showed two peaks of 0.4 electrons/Å^3. One is in the vicinity of the bromine and could perhaps be due to a lone pair interaction, but the other is near the ring containing the two oxygens for no obvious reason. Interestingly enough, bond lengths and bond angles involving O(2) and C(18) show some slight deviations from normal values. Final positional and isotropic thermal parameters[2] are listed in Table 4.

Results

A stereoview of the molecule is presented in Fig. 2. With the exception of the *p*-bromobenzoate group, the atomic labelling is as before.

The *p*-bromobenzoate derivative contains the four-membered ring *cis*-fused to the cyclopentanone ring. Therefore the previous structure solved was not an impurity, but was indeed the second eluted isomer. Bond lengths and angles of the non-hydrogen atoms[2] for the bulk of the molecule[2] are listed in Tables 2 and 3. The crystal is held together by van der Waals forces.[2]

Discussion

Whenever the structures of three molecules (**4**, **5**, and **9**; ref. 2 plus this paper) as similar as those presented so far are solved, it is of interest to compare derived quantities, e.g. bond lengths, bond angles, and molecular geometry.

Those data for **5** are included for completeness, although this structure is less accurately determined.

Bond lengths for these three structures are compared in Table 2. Upon inspection of this table, it is immediately obvious that the estimated standard deviations in molecule **5** are about three times as great as those in molecules **4** and **9**. This is not surprising; the crystal structure of **5** is the least accurate of the three, mainly as the crystal was so poor that only 20% of the collected reflections could be considered observed (as opposed to 60% in the other two structures). Consistent with this, the *R* values for the structure of molecule **5** are slightly larger than those for **4** and **9**, especially when the unobserved reflections are included.

The bond lengths compare extremely well with each other. Only one pair shows a significant difference (i.e., has a difference greater than 3.0σ): O(2)—C(18) has lengths 1.428(3) (in **4**) and 1.406(4) Å (in **9**), a difference of only 0.022 Å (about 4.5σ) and so of little importance. The largest absolute difference is for C(18)—C(19), which has lengths 1.546(10) (in **5**) and 1.515(4) Å (in **9**), a difference of 0.031 Å, but this only corresponds to about 3.0σ.

More interesting trends may be found by comparing the bond angles (Table 3). Because of the larger esd's in **5**, the closest match is most often found between the values from **4** and **9**. However, bond angles involving O(2) and C(18) in **9** again show significant but most probably unimportant deviations. This might be related to the slight electron density (0.4 electrons/Å^3) located near this ring. Important deviations do occur when we examine bond angles in the vicinity of the four-membered ring. Angles involving atoms in the six-membered ring closest to the cyclobutyl ring are very similar in **5** and **9** but very different in **4**. It seems very likely that the magnitudes of these angles are affected by the orientation of the four-membered ring. This effect is especially pronounced in the angles marked with an asterisk (*) in Table 1. In examining the angles in the five-membered ring, one notices that this time

the odd angles seem to come from the *p*-bromobenzoate derivative, **9**. This is not too surprising as the hybridization of C(12) is different in **9**. The angles that are affected by this are marked with a plus sign (+) in Table 1. The cyclobutyl angles are all fairly similar and do not deviate greatly from the free cyclobutyl angle (9), 89.3°.

Mean plane calculations[2] were performed for planes in the vicinity of the cyclobutyl ring for all three structures. The envelope tip of the five-membered ring, C(13), is always oriented in the same direction as the cyclobutyl ring. The change of hybridization at C(12) in the *p*-bromobenzoate deriv-

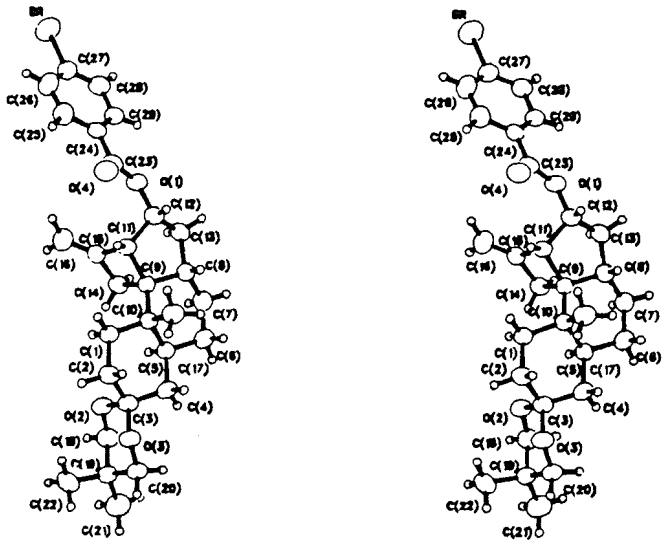

FIG. 2. A stereoview of molecule **9**.

ative affects the geometry of the five-membered ring only slightly — the envelope tip is bent down 35 and 36° in **4** and **5**, and 39° in **9**. When O(1) is doubly bound to C(12) it is on the opposite side of the five-membered ring to the envelope tip. The cyclobutyl ring is folded away from the envelope tip along the C(11)...C(14) axis in every structure, although the degree of folding varies — 14°, 4.3°, and 12.7° in **4**, **5**, and **9** respectively. The angle between the cyclobutyl and five-membered rings is about 109° for all three structures. For the *p*-bromobenzoate derivative, the phenyl group is oriented at 22° to the carboxyl moiety. The bromine lies in the phenyl plane. The other six-membered rings all have chair conformations.

Crystal structures of optically active naphthidine (4,4′-diamino-1,1′-binaphthyl) and 1,1′-binaphthyl

RICHARD A. PAUPTIT AND JAMES TROTTER
Department of Chemistry, University of British Columbia, Vancouver, B.C., Canada V6T 1Y6

Received August 3, 1982

RICHARD A. PAUPTIT and JAMES TROTTER. Can. J. Chem. **61**, 69 (1983).

Crystals of optically active naphthidine and of binaphthyl are tetragonal, $P4_12_12$ (or $P4_32_12$), a = 7.945(1), 7.164(2), c = 24.264(5), 27.70(1) Å, respectively, Z = 4. The structures were solved by direct methods and refined by full-matrix least-squares techniques to respective R = 0.068 and 0.030 for 548 and 562 reflexions. The dihedral angles between the planes of the naphthalene residues are 87 and 102°, respectively. Bond lengths and angles are normal.

RICHARD A. PAUPTIT et JAMES TROTTER. Can. J. Chem. **61**, 69 (1983).

Les cristaux de naphtidine et de binaphtyle actifs optiquement sont tetragonals, $P4_12_12$ (ou $P4_32_12$), a = 7.945(1), 7.164(2), c = 24.264(5), 27.70(1) Å, respectivement, Z = 4. On a résolu les structures par les méthodes directes et on les a affinées par la méthode des moindres carrés (matrice entière) jusqu'à des valeurs respectives de R = 0.068 et 0.030 pour 548 et 562 réflexions. Les angles dièdres entre les plans des residus naphtaléniques sont 87 et 102°, respectivement. Les longeurs de liaison et les angles sont normales.

Introduction

When maintained at temperatures just below the melting point, racemic 1,1′-binaphthyl undergoes spontaneous resolution to the higher-melting optically active form (1–4). In contrast, for the 4,4′dimethyl derivative rapid racemization of the active form is observed (5, 6). 4,4′-Diamino-1,1′-binaphthyl (naphthidine) also exhibits racemization, although in a narrow temperature range (197–202°C) just below the melting point active naphthidine has been obtained from the racemate by seeding (7). In a continuing study of these phenomena the crystal structure of optically active naphthidine has now been investigated. Since the crystal structure of optically active 1,1′-binaphthyl was unknown, its structure has also been determined; after completion of the work two other independent studies of binaphthyl appeared (8, 9), and our results are presented briefly for completeness and for comparison.

Experimental

Crystal and intensity data for both compounds were measured on an Enraf-Nonius CAD4 diffractometer.

I. 4,4′-Diamino-1,1′-binaphthyl, naphthidine (optically active form)
Crystal data:
$C_{20}H_{16}N_2$, mp = 204°C fw = 284.4
Tetragonal, $P4_12_12$ (or $P4_32_12$), a = 7.945(1), c = 24.264(5) Å, V = 1532 Å^3, Z = 4, ρ_c = 1.23 g cm^{-3}, CuKα, λ = 1.5418 Å, μ = 5.3 cm^{-1}.

The crystals were well-formed brown tetragonal bipyramids, but they were weakly diffracting and appeared to decompose (or racemize (7)), becoming opaque, often with liquified surfaces. Three separate data sets were collected. An initial set with MoKα radiation had too small a proportion of observed reflections, a second set with CuKα radiation and $\theta \leq 45°$ was used to solve the structure, and a final set, CuKα and $\theta \leq 65°$, was used in the refinement. In the final set an $\omega - (2/3)\theta$ scan was used, with an ω scan angle of (0.7 + 0.14 tan θ) deg extended by 25% on either side for background counts, and an aperture (2.5 + tan θ) mm wide and 4 mm high. Three check reflections were used for orientation control and scaling. 548 of 826 reflections (66%) with $\theta \leq 65°$ had $I/\sigma(I) \geq 3.0$, where $\sigma^2(I) = S + B + (0.04S)^2$, S and B being the scan and background counts, and were used in the analysis.

The structure was solved by direct methods with use of MULTAN (10) and refined by full-matrix least-squares techniques. Difficulty was encountered in locating the hydrogen atoms; the ring H atoms were placed in ideal calculated positions, and the two amino hydrogen atoms were assigned to the most chemically plausible peaks near the nitrogen atom on a difference map. Refinement of C and N parameters was then completed to final R = 0.068 and R_w = 0.075 for 548 reflections. Scattering factors of refs. 11 and 12 were used, with the weighting scheme $\sqrt{w} = 1$ for $|F_o| \leq 19$, $\sqrt{w} = 19/|F_o|$ for $|F_o| > 19$.

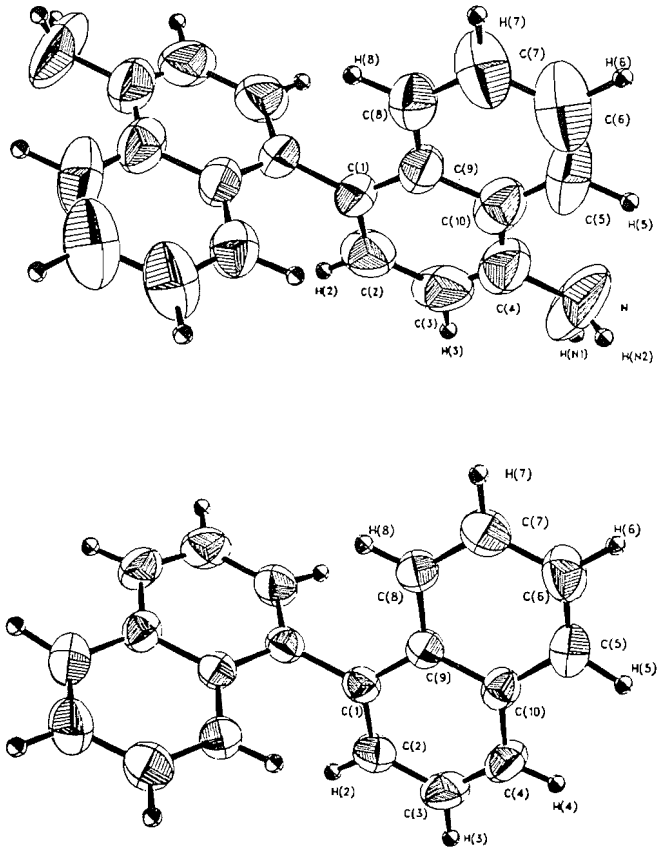

FIG. 1. Views of optically active naphthidine (top) and 1,1′-binaphthyl (bottom).

The intensity data were collected with MoKα radiation, ω−θ scan, ω scan angle (1.0 + 0.35 tan θ) deg, aperture (2.75 + tan θ) × 4 mm, and 562 of 812 reflexions (69%) with $\theta \leq 25°$ had $I \geq 3\sigma(I)$. The structure was solved by direct methods, the hydrogen atoms being located from a difference map and included in the refinement. A polynomial weighting scheme was used (13), with $A = -0.0201$, $B = 0.0372$, $C = -0.004211$, and $D = 0.000169$, and final R and R_w were 0.030 and 0.037, respectively, for 562 reflections.

The atomic positional parameters for the two structures are given in Table 1.[1]

Results and discussion

For each structure the asymmetric unit is one half of the molecule, the other half being generated by rotation about a crystallographic twofold axis which bisects the C(1)—C(1′) bond (Fig. 1). The naphthalene residues are approximately at right angles to each other in both molecules, although the arrangement in naphthidine is slightly "*cis*" (dihedral angle 87°) while in binaphthyl it is slightly "*trans*" (102°). The naphthalene residues show small folds along C(9)—C(10), 2.5° in naphthidine and 1.6° in binaphthyl.[1] The positions derived from the difference map for the amino hydrogen atoms suggest a pyramidal NH_2 group about 60° out of the naphthalene plane (Fig. 1); however, the positions should not be considered too reliable, in view of the difficulty in locating these atoms. Bond lengths and valency angles (Table 2[1]) are normal.

TABLE 2. Bond lengths (Å) and valency angles (degrees) in optically active naphthidine and 1,1′binaphthyl

C(5)—C(10)—C(9)	118.9(7)	118.9(2)

In both structures the molecules spiral around the fourfold screw axes along c, and packing forces are of van der Waals type. In naphthidine the closest intermolecular N . . . N distance is 3.48(2) Å, considerably longer than the N . . . N range of 2.9−3.3 Å normally found in N—H . . . N type hydrogen bonds.

Five binaphthyls have been the subjects of recent crystal structure studies, two racemates (binaphthyl and the 4,4′-dimethyl derivative) and three optically active forms (binaphthyl, the 4,4′-dimethyl, and 4,4′-diamino derivatives) (present paper and refs. 6, 8, 9, 14). The molecules in the racemic forms have dihedral angles between the two naphthalene residues of about 68° (i.e. a *cis* conformation); in the optically active forms this dihedral angle is 80−102°. The molecules in the racemic forms are thus slightly more compact and pack to give a higher density for the racemic form in each case. Both racemates crystallize in space group $C2/c$, although the unit cells are not of similar shape. All three chiral forms crystallize in space group $P4_12_12$, with $a = 7-8$, $c = 24-27$ Å. The crystallographic results shed little light on the dif-

[1]Anisotropic thermal parameters, hydrogen atom positional and thermal parameters, bond lengths and angles involving hydrogen atoms, details of mean planes, packing diagrams, and structure factors are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

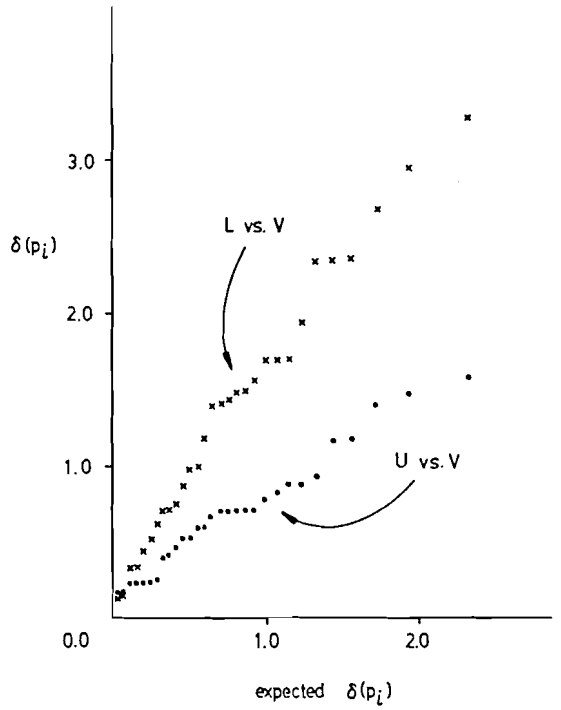

FIG. 2. Half-normal probability plots comparing the carbon positional parameters for 1,1′-binaphthyl from three studies: U = ref. 8, L = ref. 9, V = present paper.

ferences in stereochemical behaviour (resolution vs. racemization), which appear to arise from the different ranges in temperature in which racemic and eutectic phases are stable (7); and, as ref. 7 comments, "a crystallographically based explanation of relative stabilities of polymorphic phases does not seem possible as yet". In addition, under the conditions of ref. 8, the major reaction pathway in the spontaneous resolution of binaphthyl appears to be a solid−vapour−solid process and not a solid−solid transformation.

The bond distances in the five structures generally do not differ much from the lengths of the corresponding bonds in naphthalene. The shortest bonds are those of type C(1)—C(2) (and 3—4, 5—6, 7—8) with mean values in the range 1.360−1.369 (σ = 0.003−0.009 Å), the value in naphthalene being 1.357(4) Å (15). Mean values for the other types of bond are all in the range 1.40−1.44 Å. The central C(1)—C(1′) bonds are in the range 1.481−1.511 Å, the differences probably not being significant.

Finally a comparison may be made between the three independent sets of results for optically active 1,1′-binaphthyl (present paper and refs. 8 and 9). The present (V = Vancouver) and ref. 8 (U = Urbana) results agree very closely. The *a* cell parameters (7.164(2) and 7.181(2) Å) differ by about 6σ, which probably indicates slightly optimistic estimates of the standard deviations. A more detailed comparison by use of half-normal probability plots (16) confirms the good agreement. For example, a plot of differences between the two sets of positional parameters for the ten carbon atoms (Fig. 2, U vs. V) is approximately linear, with close-to-zero intercept, and slope slightly less than unity, suggesting that the estimated standard deviations are slightly too large (by about 30%). The agreement with the ref. 9 (L = London) results is not quite so close, with differences in cell parameters of about 20σ, and half-normal probability plot with slope of about 1.5 (Fig. 2, L vs. V).

Phthalocyanines: electrolyte Schottky-junction devices

R. O. LOUTFY AND L. F. MCINTYRE

Xerox Research Centre of Canada, 2480 Dunwin Drive, Mississauga, Ont., Canada L5L 1J9

Received April 20, 1982

R. O. LOUTFY and L. F. MCINTYRE. Can. J. Chem. **61**, 72 (1983).

The photoelectrochemical properties of phthalocyanine coated tin-oxide (SnO_2) electrodes in the presence of several redox couples were investigated. The photovoltaic performances were optimized for $Fe(CN)_6^{4-/3-}$ and I_2/I_3^- redox couples with respect to concentration, pH, counter electrode, and back contact. Under AM2 solar illumination the SnO_2/x-H_2Pc $Fe(CN)_6^{4-/3-}$ cells developed a photocurrent of 0.63 mA/cm^2, photovoltage of 0.33 volts, fill factor of 0.25, and a power conversion efficiency of 0.07% to white light irradiation of 75 mW/cm^2. The low efficiency of carrier collection was attributed to the high series resistance, surface recombination of carriers, and slow charge exchange at the counter electrode.

R. O. LOUTFY et L. F. MCINTYRE. Can. J. Chem. **61**, 72 (1983).

On a étudié les propriétés photoélectrochimiques d'une électrode de phtalocyamine recouverte d'oxyde d'étain (SnO_2) en présence de plusieurs couples rédox. On a maximisé les performances photovoltaiques des couples redox $Fe(CN)_6^{4-/3-}$ et I_2/I_3^- en ce qui a trait à la concentration, au pH, à l'électrode opposé et au contact de retour. Sous la lumière solaire de type AM2, les cellules de SNO_2/x-H_2Pc $Fe(CN)_6^{4-/3-}$ développement un courant photoélectrique de 0,63 mA/cm^{-2}, un photovoltage de 0,33 volt, un facteur de remplissage de 0,25 et un pouvoir de conversion efficace de 0,07% en irradiation de lumière blanche de 75 mW/cm^{-2}. On attribue la faible efficacité du transporteur de réception à une grande série résistance, à la surface de recombinaison des transporteurs et à un échange lent à l'électrode opposé.

[Traduit par le journal]

1. Introduction

Photoelectrochemical solar cells are the analog of a metal–semiconductor junction, with the metal replaced by an electrolyte. The junction formed at the interface between the semiconductor and the electrolyte serves in the photoconversion. Many of the electrochemical photovoltaic cells can convert light energy directly to electricity as well as store the energy internally as chemical products. In electrochemical cells the conductivity and charge injection characteristics of the space charge layer are easily altered by the use of surfactants and by adjusting the chemical potential and composition of the electrolyte. These features make electrochemical photovoltaic cells an attractive alternative to the expensive solid state solar cells. The major problem with photoelectrochemical cells has been photocorrosion processes which are observed with most inorganic semiconductors in aqueous electrolyte. However, recently Heller and Vadimsky (1) have shown that a stable and efficient semiconductor–electrolyte solar cell based on *p*-type InP can be made. The resistance of the *p*-type semiconductor to photocorrosion was attributed to cathodic protection of the semiconductor against surface oxidation.

The goal of this work is to evaluate the feasibility and practicality of solar cells consisting of organic semiconductors in contact with an electrolyte. Two organic semiconductors, x-metal free phthalocyanine (x-H_2Pc) and vanadyl phthalocyanine (VOPc), which are well matched to the solar spectrum were investigated. Several redox couples were used; the performance of $Fe(CN)_6^{4-/3-}$ and I_2/I_3^-, in particular, was optimized. The principle element of the photoelectrochemical cell is a thin organic film of microcrystalline particles of phthalocyanines (x-H_2Pc or VOPc) dispersed in a polymer binder coated onto a conductive tin-oxide (SnO_2) substrate. These films functioned as photocathodes in electrochemical cells in contact with aqueous electrolyte containing the $Fe(CN)_6^{4-/3-}$ or I_2/I_3^-. The effects of electrolyte, pH, redox couple concentration, counter electrodes, and back electrodes are discussed. The action spectra and capacitance–voltage behaviour are presented. The stability of these systems both in the dark and under illumination is also described.

2. Experimental

Materials

x-H_2Pc was prepared as described before (2). The process involves dissolving commercial H_2Pc in concentrated sulfuric acid kept at 5°C, then pouring the mixture, while stirring, into ice-water. The blue flaky precipitation (α-H_2Pc) is then filter washed with ammonia solution, water, acetone, then methanol, and dried. The solid α-H_2Pc is then dry milled for three weeks in a plastic bottle using flint stones; this process induces the conversion of α-H_2Pc to x-H_2Pc. Finally, methyl ethyl ketone is added and milling is continued for 16 h to form a slurry before filtering, then washing with acetone and methanol. Vanadyl phthalocyanine (VOPc) was obtained from the reaction of phthalonitrile and vanadium tetrachloride. The deep blue product was acid pasted in sulfuric acid to give submicron (25 nm) particles. The x-H_2Pc pigment particle size, determined by scanning electron microscopy, averaged 80 nm in diameter. All other matierals were from common commercial sources, used without further purification. The polymer used throughout this study was Makrolon 5705 (MK), a polycarbonate from Bayer. Other polymers used were polyester PE-200 and polyvinylacetate (PVA).

The phthalocyanine films were prepared as described previously (3). All films contained approximately 60 weight percent of the phthalocyanine dispersed in polymer binder coated onto precleaned heavily doped SnO_2 (NESA glass, PPG Company, Pittsburg Pennsylvania). The thickness of the pigmented films was measured using a Talystep and on average was 1 μm.

Apparatus

The experimental setup of a typical electrochemical cell was described previously (4). The cell body was made of Plexiglas. The phthalocyanine-coated SnO_2 electrodes were pressure sealed to the cell body using a rubber gasket. The electrolyte was contained in a cylindrical cavity made in the cell, with a thin window on one side and the phthalocyanine electrode on the other. A platinum or ruthenized titanium ring was used as counter electrode. The sample electrode was

illuminated through the electrolyte with an Oriel 1 KW Xenon Solar simulator. Monochromatic light was obtained through a set of narrow band pass filters, each of which had a transmitting band of half width of 8–10 nm. The radiant intensity was measured with a Karl Lambrecht calibrated light probe. The photoelectrochemical current and voltage were measured using a Keithley electrometer (model 616). The dark and light current–voltage characteristics of the electrochemical cells were determined using Polarographic analyser EG&G, model 174A.

In preliminary experiments it was shown that the same photovoltage and current were observed using either the two-electrode arrangement or by measuring potential relative to a reference electrode (which was $Ag/AgNO_3$ or calomel reference electrode). For this reason the simpler arrangement was used, involving only two electrodes. The light source for action spectrum measurements consisted of a 150-W Xe lamp and a $\frac{1}{4}$-m Jarrel Ash monochromator. All photocurrent action spectra have been normalized against the photon flux of the lamp and monochromator (3).

The capacitance of the cells was measured using the low frequency oscillographic technique described in ref. 5 at 10 Hz.

3. Results

3.1 Current–voltage behaviour of the phthalocyanine coated SnO_2 electrode

The current–voltage characteristics of all films investigated showed strong rectifying behaviour (Fig. 1(a)) with large anodic current arising in the positive potential region, typical of *p*-conducting material. In the presence of oxidizing agents, e.g. $Fe(CN)_6^{3-}$ or I_2, a large cathodic photocurrent was observed. The electrochemical current–voltage behaviour of SnO_2/x-H_2Pc electrodes in the presence of 0.1 *M* $K_4Fe(CN)_6$/0.01 *M* $K_3Fe(CN)_6$ in solution at pH 8 is shown in Fig. 1(b) under solar illumination (85 mW/cm^2). The cell generated a V_{oc} of 0.2 volts while J_{sc} was 135 μA/cm^2. The fill factor had a value of 0.28. The power conversion efficiency for solar light is 0.01%. Using 620 nm light at a power density of 2.5 mW/cm^2, the quantum efficiency in terms of incident radiation is 10^{-2}. The efficiency in terms of absorbed photon is about 10^{-1}. This low efficiency is due to considerable recombination of carriers in the junction as indicated by the high reverse saturation current, J_0, (1.7×10^{-6} A/cm^2) and to the high series resistance. The performance characteristics of SnO_2/x-H_2Pc electrodes in the presence of 0.1 *M* KI/0.003 *M* I_2 at pH 7 was quite similar and is shown in Fig. 1(c). The V_{oc} = 0.15 volts, J_{sc} = 84 μA/cm^2, ff = 0.26, and the power conversion efficiency = 0.0035%.

The photoelectrochemical behaviour of the SnO_2/VOPc electrode in the presence of $Fe(CN)_6^{4-/3-}$ at pH 8.0 under solar illumination was quite similar to that of SnO_2/x-H_2Pc. The V_{oc} = 0.22 volts, J_{sc} = 270 μA/cm^2, and ff = 0.28.

3.2 Effect of redox couples concentration

The output power of the SnO_2/x-H_2Pc photocathodes was found to depend strongly on the concentration of the redox couples. Figure 2 shows the dependence of the short circuit photocurrent, J_{sc}, and open circuit photovoltage, V_{oc}, on the concentration of $Fe(CN)_6^{4-/3-}$ and I_2/I_3^-. The addition of a small amount of $K_4Fe(CN)_6$ to the $K_3Fe(CN)_6$ solution or I_2 to KI solution sharply increases the cathodic photocurrent of SnO_2/x-H_2Pc electrodes as shown in Figs. 2(a) and (b), respectively. After the initial sharp increase at low concentration, the current tends to level off, then drop at high concentration, suggesting that internal electron–hole pair recombination, rather than the solution reduction, is governing the current. The open circuit voltage monotonically decreases with increasing the concentration of $K_4Fe(CN)_6$ or I_2. The optimum redox

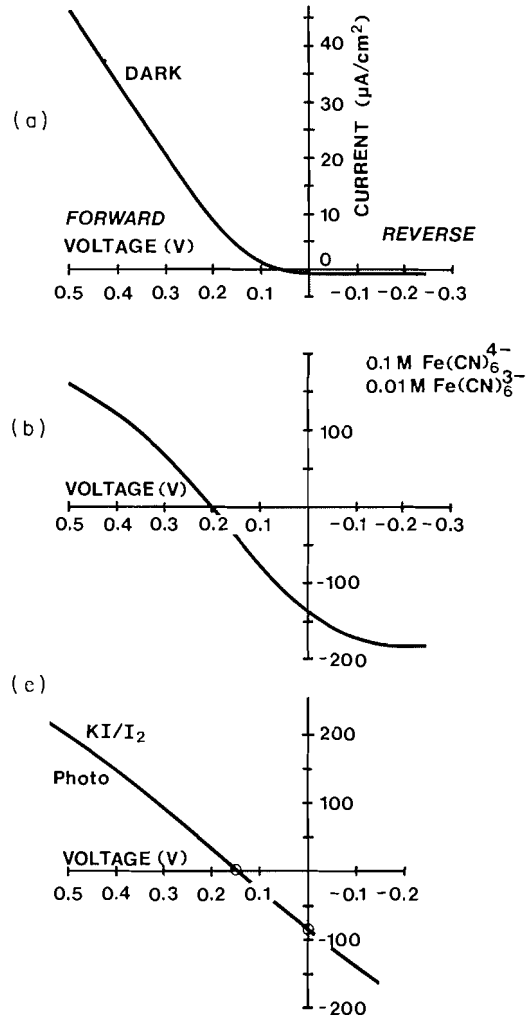

FIG. 1. Current–voltage characteristics of the SnO_2/x-H_2Pc electrode (a) in the dark; and under illumination (150 mW/cm^2) in presence of (b) 0.1 *M* $Fe(CN)_6^{4-}$/0.01 *M* $Fe(CN)_6^{3-}$ (pH 8) and (c) 0.1 *M* KI/0.003 *M* I_2 (pH 7). The sign of the potential is that applied to the SnO_2/Pc.

couple concentrations were found to be: 0.1 *M* $K_4Fe(CN)_6$/0.01 *M* $K_3Fe(CN)_6$ and 1 *M* KI/0.003 *M* I_2.

3.3 Effect of pH

Figures 3(a) and (b) show the influence of pH of the electrolyte on the magnitude of short circuit current and open circuit voltage for the 0.1 *M* $Fe(CN)_6^{4-}$/0.01 *M* $Fe(CN)_6^{3-}$ and 1 *M* KI/0.003 *M* I_2 solutions using platinum as counter electrode. The photocurrent and voltage reach a maximum at pH 8 for the $Fe(CN)_6^{4-/3-}$ and at pH 7 for the I_2/I_3^- redox system. The electrochemical redox potential of these couples at that pH is +0.2 volts vs. SCE (6).

3.4 Dependence of photocurrent and voltage on light intensity

The photocurrent of the system SnO_2/x-H_2Pc/$Fe(CN)_6^{4-/3-}$ pH 8/Pt varied linearly with light intensity with a light intensity exponent near unity. Similar results were obtained for the I_2/I_3^- system, however, the light intensity exponent was 0.56. Information on the junction parameters *n* and J_0, diode quality factor and reverse saturation current, respectively, can be obtained using the simple diode equation:

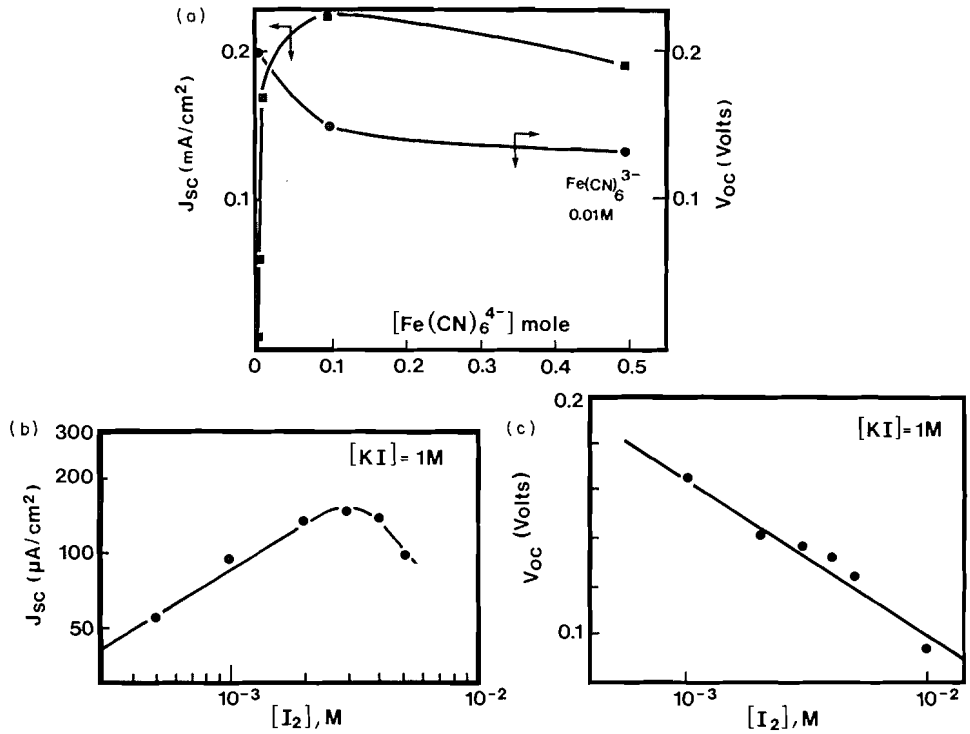

FIG. 2. The dependence of short circuit current, J_{sc} and open circuit voltage, V_{oc} on the concentration of (a) $K_4Fe(CN)_6$ (pH 8) and (b, c) I_2 (pH 7).

$$V_{oc} = \left(\frac{nRT}{e}\right) \ln\left[\frac{J_{sc}}{J_0} + 1\right]$$

Plots of V_{oc} against $\ln J_{sc}$ determined at different light intensities give a straight line, the slope is nkT/e and the intercept is $\ln J_0$. Values of 1.2 and 1.7×10^{-6} A/cm^2 for n and J_0, respectively, were obtained for the $Fe(CN)_6^{4-/3-}$ redox couples. Similar n and J_0 values of 1.3 and 8.6×10^{-7} A/cm^2 were obtained for the I_2/I_3^- system. The relatively large reverse saturation current indicates that surface recombination of carrier is a significant energy wasting process.

3.5 *Action spectrum*

The spectral dependence of the cathodic photocurrent of SnO_2/x-H_2Pc/$Fe(CN)_6^{4-/3-}$ system is shown in Fig. 4, which is essentially the same as the absorption spectrum of x-H_2Pc film if the light is incident through the electrolyte side. For light incident on the SnO_2 electrode, the action spectrum resembled the transmission spectrum of x-H_2Pc film. This behaviour indicates the presence of a Schottky junction at the semiconductor–electrolyte interface.

3.6 *Dependence of photocurrent and voltage on electrode materials*

The back contact has a significant effect on the performance of the device. We varied the back electrode using Pt, Au, Ag, ITO, Cr, Cu, and In and compared the device performance to that of the standard SnO_2 electrode. The photocurrent, J_{sc}, increased with the increase of the work function of the back electrode, see Table 1. The function of the back electrode is to provide an ohmic contact to the *p*-type x-H_2Pc. The results indicate that the contact between x-H_2Pc and the back electrode becomes more ohmic as the work function increases. The performance characteristics of SnO_2/x-H_2Pc/$Fe(CN)_6^{4-/3-}$ cells were found to depend strongly on the counter electrode. Table

Au	0.03	0.22

2 lists the photocurrent and voltage for the above cell as a function of the counter electrode. Cathodic photocurrent as high as 0.63 mA/cm^2 and photovoltage of 330 mV were observed with aluminum counter electrodes. The power conversion efficiency of this device approaches 0.1%. In these cells the dark current was in the order of a few nanoamps. The strong dependence of the photocurrent on the counter electrode materials could be due to oxidation of the metal electrode by a photoassisted electrochemical catalytic mechanism.

3.7 Capacitance measurements

Application of a sinusoidal voltage across the space charge region of a semiconductor electrode leads to a periodic redistribution of charge, which manifests itself as a capacitance. Figure 5 shows the current−voltage curve of the SnO_2/x-H_2Pc

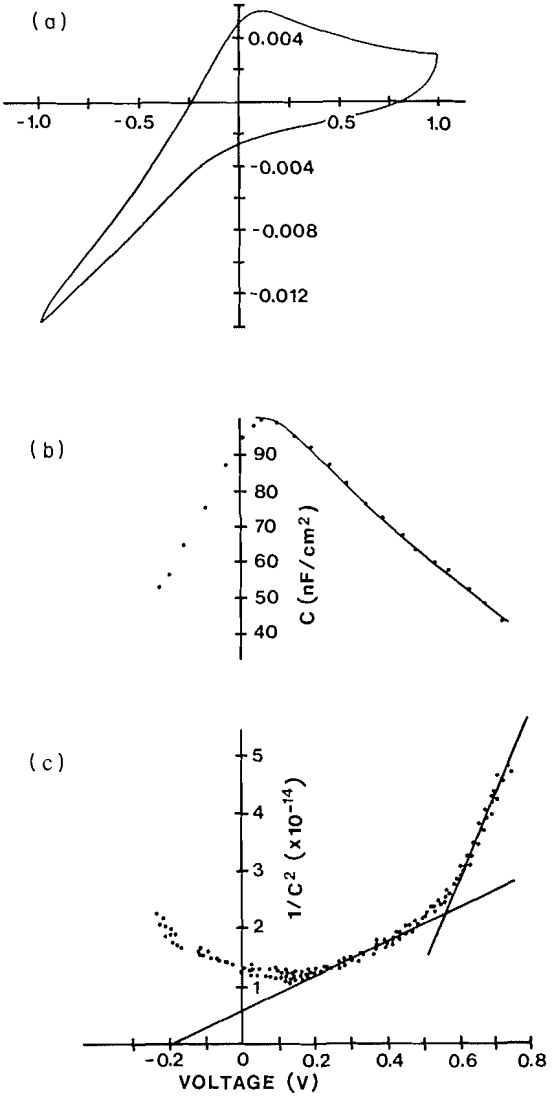

FIG. 5. Low frequency oscillogram of the SnO_2/x-H_2Pc/ $Fe(CN)_6^{4-/3-}$ (pH 8)/Pt cell (a); capacitance vs. voltage (b); and $1/C^2$ vs. *V* plot (c).

electrode immersed in a phosphate buffer solution (pH 8) containing $Fe(CN)_6^{4-/3-}$. The observed hysteresis gives the junction capacitance (5). The zero bias capacitance is 110 nF/cm^2 which gives a barrier width ($C = \epsilon\epsilon_0/W$) of 300 Å. A plot of $1/C^2$ vs. *V* is shown in Fig. 5. The plot can be fitted to two straight lines intersecting at +0.50 volts. The discontinuity in the $C-V$ plot is due to interfacial states localized 0.7 eV above the Fermi level (4). The slope of the $1/C^2$ vs. *V* plot at low bias gives the density of hole traps and ionized states which approached 1×10^{17} cm^{-3}; the intercept gives the barrier potential V_b which is 0.2 volts.

3.8 Time dependence

The stability of the SnO_2/x-H_2Pc electrode in solution is quite remarkable. The photocurrent−time and photovoltage−time dependence for SnO_2/x-H_2Pc in the presence of $Fe(CN)_6^{4-/3-}$ at pH 8 and I_2/I_3^- and pH 7 were found to be stable for hours.

4. Discussion

Results presented here (particularly the action spectrum and

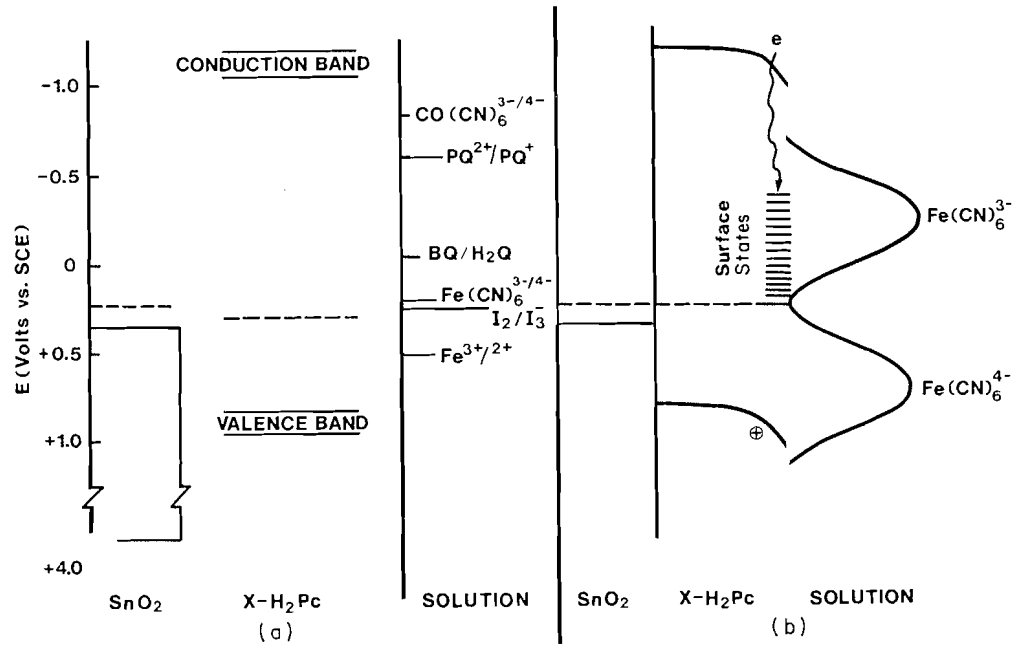

FIG. 6. Energy level diagram of SnO_2, x-H_2Pc, and redox couple potentials (a) and energy scheme of x--$H_2Pc/Fe(CN)_6^{4-/3-}$ at pH 8 (b).

capacitance−voltage data) give considerable support to the idea that phthalocyanine pigment is capable of forming a Schottky junction with various electrolyte containing redox couples. The Schottky barrier width determined from the $C-V$ data is about 300 Å. This value gives a solar light collection efficiency of x-H_2Pc/electrolyte devices of 29% (3). If the photogeneration efficiency within the barrier region is 100%, the 75 mW/cm^2 light would generate a short circuit current of 11 mA/cm^2. We obtained instead between 0.11 to 0.63 mA/cm^2 depending on the back and counter electrodes, indicating that the generation efficiency for x-H_2Pc is 1 to 6×10^{-2}. Recently Bard and co-workers (7) reported on the spectral sensitization of several single-crystal n-type semiconductors by various phthalocyanine thin films in photoelectrochemical cells using hydroquinone/benzoquinone (H_2Q/BQ) redox couples. Both anodic and cathodic sensitized photocurrent could be observed depending upon the applied potential. The photoelectrochemical efficencies of these systems ranged from 1.3×10^{-5} to 1.1×10^{-3} per absorbed photon and under external potential bias. Similarly, Armstrong and co-workers (8) reported on the sensitization of SnO_2 electrodes by thin films of phthalocyanines (GaPcCl, GaPcF, AlPcF, AlPcCl, and silicon phthalocyanine) in PEC using H_2Q. Efficiencies for the dye-sensitized photoelectrolysis of H_2Q of 10^{-2} per absorbed photon (monochromatic) and under potential bias were reported (8). In our systems the cathodic photocurrents reported above were obtained under short circuit conditions. A much larger anodic and cathodic photocurrent can be obtained under forward and reverse bias potenital, respectively. However, for solar energy applications, interest lies in cells which can operate without external bias.

In Fig. 2 the dependence of SnO_2/x-H_2Pc photocurrent and voltage on the concentration of the $Fe(CN)_6^{4-/3-}$ and I_2/I_3^- redox couples is shown. The open circuit voltage (V_{oc}) changes by the expected 60 mV due to a 10-fold change in the ratio of oxydant/reductant. However, the dependence of the photoreduction current on the redox couples concentration is quite surprising. The highest photoreduction currents were obtained at relatively low concentration of oxydant and very high concentration of reductant. These results suggest that the performance of these cells is limited by the discharge rate of the reductant at the counter electrode.This hypothesis is corroborated by the strong dependence of the photocurrent on the counter electrode materials (Table 2). In these cases the discharge at the counter electrode might involve, in addition to the oxidation of the reductant, an oxidation of the metal electrode by photoassisted electrochemical catalytic mechanism. It should be noted that in these cells the dark current was very small, in the order of a few nanoamps. We found, however, platinum, gold, and ruthenized titanium to be sufficiently inert under our experimental conditions.

TABLE 3. Effect of redox couples formal potential on the performance of SnO_2/x-H_2Pc cathodes

Redox system	E^0 (volts vs. SCE)	V_{ph} (volts)	J_{sc} (A/cm^2)
$Co(CN)_6^{4-/3-}$	−0.83	0.44	80

$Co(CH_3COCHCOCH_3)_3^{3+/2+}$	1.84	0.24	8

Surface state model

When a photon of light is absorbed at the semiconductor electrode, an electron−hole pair is created. The electron and hole separate under the influence of the junction field. The electrons (minority carriers) are driven to the surface and reduce an acceptor in solution. The holes are conducted through the bulk of the material and the back electrode to the anode where they oxidize a donor (reductant) in solution. Electron transfer from the semiconductor to an electroactive species in the electrolyte theoretically is feasible if the Gaussian energy

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

distribution of the solution redox species overlaps the conductance band of the *p*-type semiconductor (9).

It is usual to determine the potential of the band edges of a semiconductor in a particular electrolyte experimentally and then select an appropriate redox system. Energy band models can be a useful starting point to indicate the potential region for a practical choice of redox couple. Figure 6 shows the energy-band diagram for the interface between x-H_2Pc and electrolyte solution. The upper edge of the valence band of x-H_2Pc lies at $+0.9 \mp 0.1$ volts vs. SCE and the lower edge of the conduction band lies at -1.1 ∓ 0.1 volts vs. SCE (10). The Fermi level is 0.6 eV from the valence band (11) and, therefore, the flat band potential, V_{fb}, for x-H_2Pc is near +0.3 volts vs. SCE. In order to realize the maximum open circuit voltage V_{max} ($V_{max} = V_{fb} - E^0$), where E^0 is the equilibrium redox potential, one should select in our case a redox couple with sufficient negative potential ($E^0 \leq -0.8$ volts vs. SCE). Table 3 shows the dependence of the open circuit voltage and short circuit photocurrent of SnO_2/x-H_2Pc electrodes on the standard potential of a series of redox couples. One notes a weak dependence of V_{oc} on E^0 and strong dependence of photocurrent on E^0. Surprisingly, the highest photoactivity was observed with redox couples with energies located within the x-H_2Pc forbidden gap region (E^0 between -0.1 to $+0.3$ volts vs. SCE). These results suggest that the simple idealized model for a semiconductor–electrolyte interface must be modified. It has been shown previously that surface states present in sufficient density in the forbidden band gap of a semiconductor can mediate electron transfer processes across the interphase (6, 12), even for couples with energies located within the forbidden gap. The experimental results presented here lead to the conclusion that charge exchange between x-H_2Pc and $Fe(CN)_6^{4-/3-}$ or I_2/I_3^- must occur via surface states as shown in Fig. 6b.

This surface-controlled model is consistent with recent results by Fan and Faulkner (10) who studied charge transfer between *p*-type phthalocyanine electrodes and various iron complexes.

Although interfacial states were important in mediating electron transfer from x-H_2Pc to $Fe(CN)_6^{4-/3-}$ and I_2/I_3^- systems, they limit the open circuit voltage. They also constitute a path for loss of the photogenerated carriers by surface recombination. The nature of surface states in phthalocyanines is not clear at the present time, however, adsorbed oxygen or surface dislocation are very likely candidates. Attempts to eliminate or influence the energetics of the surface state by adsorption of ionic species or by surfactants is under way. The behaviour of SnO_2/x-H_2Pc as a photocathode makes possible the use of a photoanode as the counter electrode to increase power output. Cadmium sulfide was successfully used as counter electrode, increasing the photovoltage of the SnO_2/x-H_2Pc/$Fe(CN)_6^{4-/3-}$/CdS cell to 0.95 volts and photocurrent to 0.5 mA/cm^2.

In summary, we feel that the phthalocyanine coated tin-oxide electrode is a good candidate for future investigation as photocathode. Reduction of surface recombination of photogenerated carriers should be the major focus of future development.

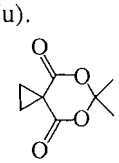
Treatment of isophorone (**8**) with sodium amide and 1,2-dibromomethane gives 6,6-dimethyl-8-methylenespiro[2.5]octan-4-one (**9**) and 6,6,8-trimethylspiro[2.5]oct-7-en-4-one (**10**); similar treatment of 3-methylcyclohex-2-en-1-one (**5**) gives analogous spiro compounds **6** and **7** together with 8-methylenedispiro[2.1.2.3]decan-4-one (**11**) and 8-methyldispiro[2.1.2.3]dec-8-en-4-one (**12**). The spiro ketones **6**, **7**, **9**, and **10** undergo homoconjugate nucleophilic addition on being heated in morpholine with cleavage of the cyclopropane rings to give 2-[2-(4-morpholinyl)ethyl]cyclohex-2-en-1-ones. The rates of reaction are much greater for the *exo* methylene compounds **6** and **9** than for their *endo* isomers **7** and **10**, but the rate of reaction of **10** is only slightly greater than that of the corresponding saturated compound, 6,6,8-trimethylspiro[2.5]octan-4-one (**15**). A corresponding rate differential between **9** and **10** is observed in their reactions with isophorone (**8**) and sodium hydride to give 2,2′-(ethanediyl)bis[3,5,5-trimethylcyclohex-2-en-1-one] (**18**). The acceleration in the cases of **6** and **9** relative to that of **15** is attributed to spiroactivation by both the carbonyl and exocyclic ethylenic groups; the much smaller effect of the endocyclic ethylenic groups in the cases of **7** and **10** is ascribed to torsional strain in the transition states for ring opening. The spiro ketones **6**, **7**, **9**, and **10** also undergo acid-catalyzed cyclopropane ring cleavage in ethanol, giving 2-(2-ethoxyethyl)cyclohex-2-en-1-ones. Again the *exo* methylene compounds **6** and **9** react much more rapidly than their *endo* isomers **7** and **10**; this is considered to be due to factors analogous to those operative in the nucleophilic addition reactions and/or the more rapid protonation of the *exo* methylene compounds.

PETER YATES, PATRICK HUGH HELFERTY et PAUL MAHLER. Can. J. Chem. **61**, 78 (1983).

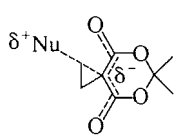
L'isophorone (**8**) réagit avec l'amidure de sodium et le dibromo-1,2 éthane en donnant la diméthyl-6,6 méthylène-8 spiro[2.5] octanone-4 (**9**) et la triméthyl-6,6,8 spiro[2.5] octène-7 one-4 (**10**). Dans les mêmes conditions, la méthyl-3 cyclohexène-2 one-1 (**5**) donne les composés spiro analogues **6** et **7** ainsi que la méthylène-8 dispiro[2.1.2.3] décanone-4 (**11**) et la méthyl-8 dispiro[2.1.2.3] décène-8 one-4 (**12**). Lorsqu'on les chauffe dans la morpholine, les spiro cétones **6**, **7**, **9** et **10** subissent une addition nucléophile homoconjuguée avec une rupture des cycles cyclopropane en donnant des [(morpholinyl-4)-2 éthyl]-2 cyclohexène-2 ones-1. Les vitesses de réaction sont plus élevées pour les composés ayant une méthylène *exo* (**6** et **9**) que pour le cas des isomères *endo* (**7** et **10**); la vitesse de réaction du composé **10** est légèrement plus grande que celle du composé saturé correspondant: la triméthyl-6,6,8 spiro[2.5] octanone-4 (**15**). On a observé une différence de vitesse correspondante entre les composés **9** et **10** lorsqu'ils réagissent avec l'isophorone (**8**) et l'hydrure de sodium en donnant la (éthanediyl)-2,2′ bis(triméthyl-3,5,5 cyclohexène-2 one-1) (**18**). On attribue l'accélération dans le cas des composés **6** et **9** par rapport à celle du composé **15** a une spiro-activation à la fois par le groupe carbonyle et les groupes éthylèniques *exo*-cycliques; on attribue l'effet beaucoup plus faible du groupe éthylénique *endo*-cyclique, dans le cas des composés **7** et **10**, à une contrainte de torsion dans l'état de transition de l'ouverture du cycle. Les cétones **6**, **7**, **9** et **10** subissent également un clivage acido-catalysé du cyclopropane dans l'éthanol en donnant les (éthoxy-2 éthyl)-2 cyclohexène-2 ones-1. Là encore les composés ayant un méthylène *exo*-cyclique **6** et **9** réagissent plus rapidement que leurs isomères *endo*-cycliques **7** et **10**. On considère que ce fait est dû à des facteurs semblables à ceux que l'on rencontre dans les réaction d'addition nucléophile et/ou la protonation plus rapide des composés à méthylène *exo*.

[Traduit par le journal]

The term "spiroactivation" has been coined by Danishefsky and Singh (2) to describe the remarkable facilitation of homoconjugate addition of nucleophiles to cyclopropanes with geminal activating groups when these groups are incorporated into a spirocyclic system as in **1**. They have proposed that in such spiro compounds the carbonyl groups are held in an optimal orientation for delocalization of the developing carbanion in the transition state (**2**) for opening of the cyclopropyl ring by a nucleophile (Nu).



1



2

We have investigated the homoconjugate addition of nucleophiles to β,γ-unsaturated α-spirocyclopropyl ketones of types **3** and **4** to determine whether spiroactivation is involved in these cases and, if so, whether its magnitude is dependent on the relative disposition of the carbonyl and ethylenic double bonds, *exo*–*exo* in **3** and *exo*–*endo* in **4**. We have also investigated the acid-catalyzed fission of the cyclopropane ring of such spiro ketones.

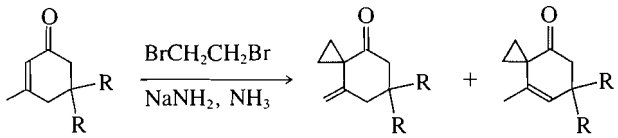
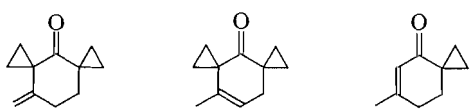


SCHEME 1

in liquid ammonia gave a mixture of 8-methylenespiro[2.5]-octan-4-one (**6**, 26%) and 8-methylspiro[2.5]oct-7-en-4-one (**7**, 15%) together with unconsumed **5** (47%) and 1,2-dibromoethane (12%). The mixture was separated by preparative gas chromatography since distillation failed to separate **6** and **7** from **5**. We have found that treatment of isophorone (**8**) under analogous conditions gave a mixture of 6,6-dimethyl-8-methylenespiro[2.5]octan-4-one (**9**, 35%) and 6,6,8-trimethylspiro-[2.5]oct-7-en-4-one (**10**, 19%) together with **8** (46%) (Scheme 1).[3] Again the starting ketone could not be separated from the spiro ketones by distillation. However, it was found possible to free the spiro ketones from **8** by treatment of the mixture with alkaline hydrogen peroxide, which oxidized **8** to an acidic product (5) that was removed as its salt. This procedure led to an 83% recovery of a mixture of **9** and **10** from which a pure sample of **9** was obtained by column chromatography. Heating a mixture of **9** and **10** in dioxane containing *p*-toluenesulfonic acid completely converted the *exo* compound **9** to the more stable *endo* compound **10** (*vide infra*) and permitted the isolation of the latter in pure form. The assignments of structures **9** and **10**, like those of the other reaction products discussed in the sequel, are based on spectroscopic data. The ir and ^{1}H nmr spectra of **10** corresponded to those previously reported by Ofune *et al.* (6). These workers prepared **10** from the photoadduct of **8** and ethylene in an overall yield of 48% from **8**, whereas our yield was 27%; however, their route did not provide **9**.

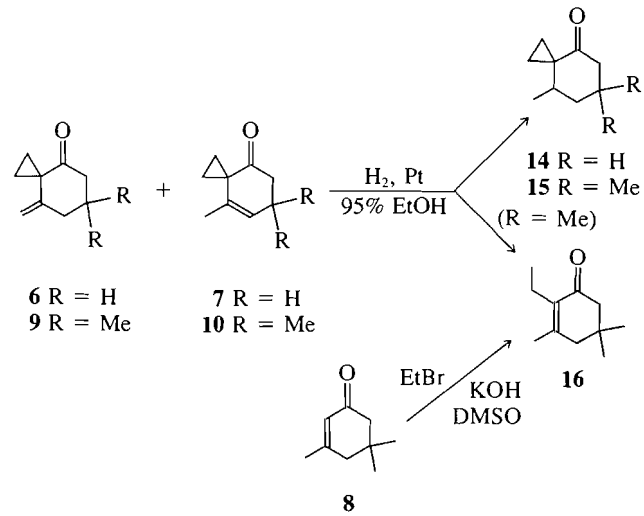
Having prepared **9** and **10** from **8**, we reinvestigated the preparation of the analogous spiro ketones **6** and **7** from **5**. Alkylation of **5** with 1,2-dibromoethane as before gave a mixture of **6** (19%) and **7** (19%) together with unconsumed **5** (54%) and the dispiro ketones **11** (2%) and **12** (6%). Unfortunately, attempted removal of **5** by treatment of the product mixture with alkaline hydrogen peroxide resulted in concomitant destruction of **6** and **7**, although the dispiro ketones **11** and **12** were stable under the reaction conditions; the survival of the



11 **12** **13**

latter and of **9** and **10** is ascribed to steric hindrance to attack of hydroperoxide anion at the carbonyl group in these compounds. Chromatography of the product mixture allowed the separation of unconsumed **5** and provided a mixture of the dispiro ketones **11** and **12**, a mixture of the spiro ketones **6** and

[3]Resubmission of mixtures of this type to the original alkylation conditions led to a product mixture containing an increased proportion of **9** and **10**, but this was offset by reduction in overall recovery. Alkylation with the use of powdered potassium hydroxide in dimethyl sulfoxide (4) returned 81% of **8** and gave only 19% of **9** and **10**.



SCHEME 2

7, and pure 8-methylenespiro[2.5]octan-4-one (**6**). Treatment of the mixtures of spiro ketones and of dispiro ketones with *p*-toluenesulfonic acid in dioxane gave pure samples of 8-methylspiro[2.5]dec-7-en-4-one (**7**) and 8-methyldispiro-[2.1.2.3]dec-8-en-4-one (**12**), respectively. The other dispiro ketone, **11**, could not be separated from its mixture with **12**. Compounds **6** and **7** were identified by comparison of their ir and ^{1}H nmr spectra with those reported by Newman *et al.* (3)[4] and the structural assignments were confirmed by these and other spectroscopic data. The assignment of structure **12** is based on spectroscopic data and that of **11** on comparison of the spectra of the mixture of **11** and **12** with the corresponding spectra of **12**.

The dispiro compounds are considered to be formed via alkylation of **6** and **7** rather than of **13**, since none of the latter was detected in the product mixture and its formation would be expected to involve the kinetic enolate while the reaction conditions favor formation of the thermodynamic enolates (7). There was no evidence for the formation of the analogous dispiro compounds from **8**. While **8** has been methylated at C-6 with lithium isopropylcyclohexylamide and methyl iodide (8), unfavorable steric interaction between the more bulky 1,2-dibromoethane and one of the geminal methyl groups must prevent the introduction of a bromoethyl group at C-5 in **9** and **10**.

Newman *et al.* (3) reported that hydrogenation of a mixture of **6** and **7** in 95% ethanol over platinum gave 8-methylspiro-[2.5]octan-4-one (**14**) (Scheme 2). Similar treatment of a 4:1 mixture of **9** and **10** resulted in the rapid uptake of 0.8 molar equivalent of hydrogen, after which the rate of uptake slowed considerably. Analysis of the product mixture by ^{1}H nmr spectroscopy and gas chromatography showed that it consisted mainly of 6,6,8-trimethylspiro[2.5]octan-4-one (**15**) together with 2-ethyl-3,5,5-trimethylcyclohex-2-en-1-one (**16**) and unconsumed **10**. Further hydrogenation of the mixture under analogous conditions gave a mixture of **15** (85%) and **16** (15%) (Scheme 2), which was separated by column chromatography. The structural assignment for **15** is based on spectroscopic data and that for **16** on direct comparison with an authentic sample prepared by ethylation of **8** with ethyl bromide and potassium hydroxide in dimethyl sulfoxide (cf. ref. 4).

[4]Compound **7** has also been obtained from the photoadduct of **5** and ethylene in an overall yield of 12% (6).

1 17

SCHEME 3

The persistence of **10** after uptake of 0.8 molar equivalent of hydrogen, although it represents only 20% of the mixture of **9** and **10**, reveals that hydrogenation of the *endo* isomer proceeds much more slowly than that of the *exo* isomer, presumably because of increased steric hindrance. The hydrogenolysis of the cyclopropane ring to give **16**, which may involve 1,4 addition to **9**, finds analogy in the reduction of **1** to **17** (2*a*) (Scheme 3). The fact that such hydrogenolysis was not observed in the case of **6** and **7** (3) is attributable to more ready hydrogenation of the ethylenic double bond in the absence of the geminal dimethyl group.

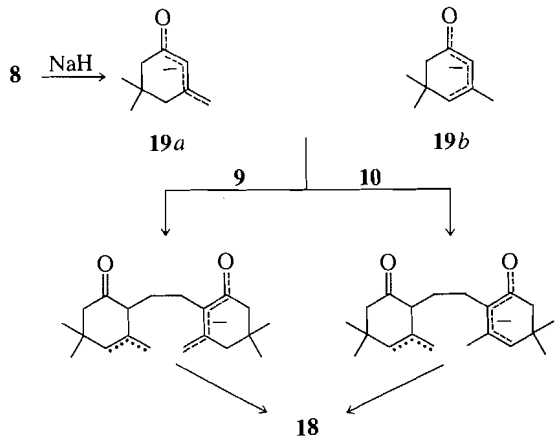
18

SCHEME 4

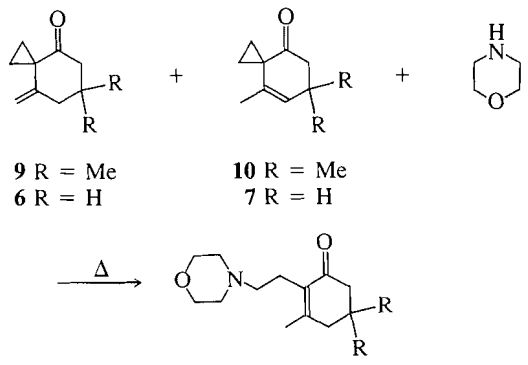


18

SCHEME 5

Homoconjugate nucleophilic addition

Heating of a 3.5:1 mixture of **9** and **10** with **8** and sodium hydride in toluene for 10 h gave 2,2′-(ethanediyl)bis[3,5,5-trimethyl-2-cyclohexen-1-one] (**18**) together with unconsumed **8** and **10**. Similar treatment of pure **10** and **8** again gave **18**, together with unconsumed **8** and **10** (Scheme 4). Heating of a 3:1 mixture of **9** and **10** in toluene with sodium hydride did not result in any change in the isomer ratio. The fact that interconversion of **9** and **10** does not occur under the reaction conditions establishes that **18** must be formed by attack of the anions **19***a* and **19***b* on both **9** and **10** (Scheme 5). That all of



9 R = Me
6 R = H

10 R = Me
7 R = H

20 R = Me
21 R = H

SCHEME 6

9 but not all of **10** was consumed after 10 h when the 3.5:1 mixture of these compounds was subjected to the reaction demonstrates that the rate of ring opening of **9** is significantly greater than that of **10**.

Heating of a mixture of **9** and **10** in morpholine gave 3,5,5-trimethyl-2-[2-(4-morpholinyl)ethyl]cyclohex-2-en-1-one (**20**) (Scheme 6), which was also formed when **10** alone was heated in morpholine. Again the rate of ring opening of **9** was greater than that of **10**: while 95% conversion of **10** into **20** required 110 h, conversion of **9** into **20** was complete within 3 hours under similar conditions. An analogous difference in reaction rates was observed when a mixture of **6** and **7** was heated in morpholine: both gave 3-methyl-2-[2-(4-morpholinyl)ethyl]-cyclohex-2-en-1-one (**21**) (Scheme 6), but while the *exo* isomer **6** was completely consumed in 3 hours, reaction of the *endo* isomer **7** was incomplete after 80 h. Heating of a mixture of the two *endo* isomers **7** and **10** in morpholine gave a mixture of **20** and **21** and revealed that the rate of consumption of **10** was slower than that of **7**.

Heating of **15**, the saturated analogue of **9** and **10**, with morpholine gave *trans*-3,5,5-trimethyl-2-[2-(4-morpholinyl)-ethyl]cyclohexan-1-one (**22**) (Scheme 7). The gross structure of **22** is assigned on the basis of spectroscopic data and its independent synthesis by hydrogenation of **20**. The relative configuration is assigned on the basis of the observations that the compound is unchanged on being heated for 18 h with methanolic sodium methoxide and that, on treatment with sodium methoxide in methanol-*O*-*d*, deuterium is introduced into both the C-2 and C-6 positions; these observations taken together show that it has the more stable *trans* configuration as in **22**. The formation of the *trans* product via the hydrogenation

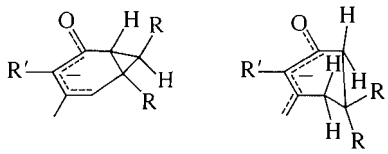
of **21** is attributable to either 1,4-addition followed by ketonization of the resulting enol or to 1,2-addition to give the *cis* isomer of **22** followed by self-catalyzed epimerization of this to **22**.

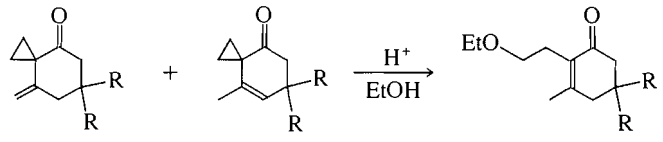
In its reaction with morpholine, consumption of **15** required ~240 h, whereas that of **10** required 110 h and that of **9** <3 hours. In summary, the order of rates of nucleophilic ring opening of the spiro compounds studied is **6** ≃ **9** ≫ **7** > **10** > **15**. The very much greater rates for the β,γ-unsaturated ketones **6** and **9** relative to the rate for the saturated ketone **15** are attributed to spiroactivation involving both the *exo* ethylenic double bond and the carbonyl group, although the conditions required for homoconjugate addition are still much more vigorous than in the case of the spiro acylal **1** since only one of the activating groups is a carbonyl group and the other is the much more weakly activating ethylenic double bond.

Of considerable interest is the observation that the β,γ-unsaturated ketones **7** and **10** are considerably less reactive than **6** and **9** and only slightly more reactive than the saturated ketone **15**. It seems unlikely that this is simply related to a variation of spiroactivation resulting from the change from an *exo*–*exo* disposition of the carbonyl and ethylenic double bonds to an *exo*–*endo* disposition and we propose the following interpretation. Full delocalization of the anions formed from the *endo* compounds **7** and **10** requires coplanarity of all of the six-membered ring atoms with concomitant angle strain at C-5 and C-6 and eclipsing of the C-5 hydrogen atoms or methyl groups with the C-6 hydrogen atoms (cf. **23**). In contrast, full delocalization of the anions formed from the *exo*-methylene compounds **6** and **9** requires coplanarity of only five of the six-membered ring atoms with C-5 out of plane (cf. **24**). While this difference will only be partially developed in the transition states it seems likely that it can account for the very much more rapid reaction of the *exo*-methylene compounds. In these terms the greater reactivity of **7** in comparison with **10** can be attributed to the smaller torsional strain in a transition state related to **23** when R = H than when R = CH_3.



23 **24**

R = H, Me



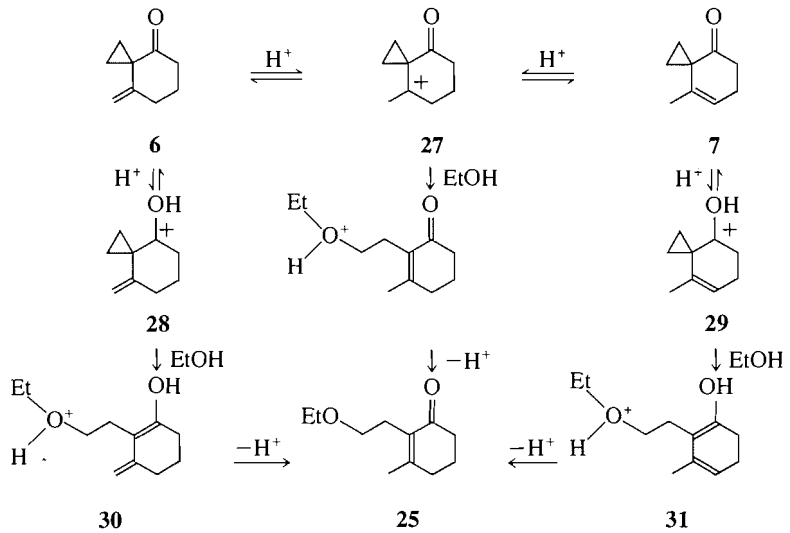
6 R = H, **9** R = Me **7** R = H, **10** R = Me **25** R = H, **26** R = Me

SCHEME 8

Acid-catalyzed cyclopropane ring cleavage

Newman *et al.* (3) have reported that the *exo*-methylene spiro ketone **6** was cleanly isomerized to its *endo* isomer **7** when a mixture containing both **6** and **7** was heated in ethanol containing *p*-toluenesulfonic acid. Although we were able to effect such a clean isomerization when the reaction was carried out in dioxane (*vide supra*), we found that when a 1:1 mixture of **6** and **7** was heated in boiling ethanol containing *p*-toluenesulfonic acid for 6 hours a 3:1 mixture of **7** and 2-(2-ethoxyethyl)-3-methylcyclohex-2-en-1-one (**25**) was formed with almost complete consumption of **6**. Further treatment of this mixture under the same conditions led to its complete conversion to **25** after 109 h (Scheme 8). These results show clearly that acid-catalyzed fission of the cyclopropane ring occurs much more rapidly in the *exo* compound **6** than in the *endo* compound **7**. Analogous observations were made in the cases of **9** and **10**. Treatment of a 3:1 mixture of these compounds under the same reaction conditions led to complete conversion to 2-(2-ethoxyethyl)-3,5,5-trimethylcyclohex-2-en-1-one (**26**) after 150 h (Scheme 8). Again, examination of the reaction mixture at earlier stages of the reaction showed that conversion of the *exo* compound **9** to **26** was much more rapid than that of the *endo* compound **10**.

The formation of **25** and **26** from the spiro compounds can be interpreted in the terms depicted for **25** in Scheme 9. One pathway could involve protonation of the ethylenic double bond to give **27**. Alternatively, the transformations could be initiated by protonation of the carbonyl group to give **28** or **29**.



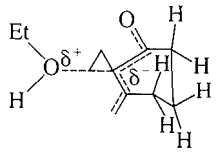
6 **27** **7**

28 **29**

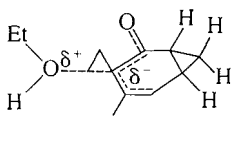
30 **25** **31**

SCHEME 9

The more rapid ring fission of the *exo* compounds relative to the *endo* compounds may involve two factors. First, formation of ions of type **27** from the *exo* compounds is more ready than from the *endo* compounds because of the greater stability of the latter. Second, in analogy with our previous proposal to account for the rate differences in the corresponding homoconjugate nucleophilic addition reactions, we suggest that the rate differences here may reflect that planarity, and therefore maximum delocalization of the developing diene system in the transition states leading to **30** or **31** can be more readily achieved by the *exo* isomer (cf. **32**) than the *endo* isomer (cf. **33**).



32



33

Experimental

Melting points were determined on a Fisher–Johns apparatus and are uncorrected. The ir spectra were taken in $CHCl_3$ solution and the ^1H and ^{13}C nmr spectra in $CDCl_3$ solution unless otherwise specified. The uv spectra were taken in 95% ethanol and/or hexane solution as indicated. Gas chromatography (gc) analyses were carried out on a Varian 2700 gas chromatograph, equipped with a flame ionization detector. The temperatures of the in-column injector and detector were set at 260°C and 335°C, respectively; oven temperatures of 90–120°C were used, unless otherwise noted. The flow rate of the carrier gas (nitrogen) was maintained at 30 mL/min. Unless otherwise indicated, a 6-ft glass column (od 1/8 in., id 2 mm) packed with 3% OV-101 on Chromosorb G(HP), 80/100 was utilized. The only other column used was a 6-ft glass column (od 1/8 in., id 2 mm) packed with 3% OV-17 on Chromosorb W(HP), 80/100. The relative intensities and retention times were determined with a Varian Chromatography Data System 111C; since in some cases there was peak overlap and the relative intensities are uncorrected for variation in the response factors the relative product yields given are approximate only. Analytical thin-layer chromatography (tlc) was carried out on 70 × 20 × 0.25 mm silica gel LK6F plates from Whatman Inc. Preparative tlc was carried out on 20 × 20 cm plates coated with a 1-mm or 2-mm layer of silica gel and activated at 150°C for 30 min prior to use. Column chromatography was performed on silica gel (Grace–Davison, grade 923, 100/200). Organic solutions were dried over anhydrous $MgSO_4$ and concentrated on a rotary evaporator under water aspirator pressure.

*Alkylation of isophorone (**8**) with 1,2-dibromoethane. Formation of **9** and **10***

Liquid ammonia (~50 mL) was distilled into a 100-mL three-necked flask containing sodium amide (4.00 g, 108 mmol) and a magnetic stirring bar and fitted with a Dry-Ice condenser with a soda-lime guard tube. Isophorone (**8**) (4.98 g, 36.0 mmol) was added and the solution was boiled under reflux for 1 h after which 1,2-dibromoethane (20.3 g, 108 mmol) was added dropwise over 30 min. The solution was boiled under reflux for 4 h, ammonium chloride (5.5 g) was added, and the ammonia was allowed to evaporate. The products were taken up in methylene chloride (150 mL) and the solution was washed with water (100 mL) and aqueous 20% ammonium chloride (75 mL). The organic layer was dried, evaporated, and fractionally distilled to give a mixture of **8** (46%), 6,6-dimethyl-8-methylenespiro[2.5]octan-4-one (**9**, 35%), and 6,6,8-trimethylspiro-[2.5]oct-7-en-4-one (**10**, 19%), bp 80–89°C (12 Torr), as shown by gc analysis. The yields of **9** and **10** based on consumed starting material were 55% and 30%, respectively. Attempted separation of **8** from **9** and **10** by spinning band distillation was unsuccessful.

*Oxidative removal of isophorone (**8**) from a mixture of **8**, **9**, and **10**. Isolation of 6,6-dimethyl-8-methylenespiro[2.5]octan-4-one (**9**)*

To an ice-cooled solution of a mixture of **8**, **9**, and **10** (21.3 g; 26% **9** and 9% **10**), prepared as above, in methanol (785 mL), was added 1 *N* aqueous sodium hydroxide (440 mL). Over 30 min 30% hydrogen peroxide (200 mL) was added at a rate such that the solution temperature did not exceed 20°C. The solution was stirred overnight at room temperature, poured into water (500 mL), and extracted with methylene chloride (3 × 500 mL). The extracts were washed with saturated aqueous ferrous sulfate (400 mL) and water (400 mL), dried, and evaporated. Distillation through a Vigreux column gave a 3:1 mixture of **9** and **10** (6.20 g, 83%), bp 87–89°C (12 Torr). This mixture (1.25 g) was chromatographed on silica gel (130 g) with 5% ether in hexanes. The eluate was analyzed by gc. Initially a mixture of **9** and **10** was eluted, but the proportion of **10** decreased in later fractions until only **9** was present. Combination of the fractions containing both **9** and **10** followed by solvent removal gave 1.08 g of the isomer mixture. Evaporation of the solvent from the fractions containing only **9** yielded a pale yellow oil (156 mg) which was molecularly distilled at 105°C (12 Torr) to give pure **9** (124 mg); ir λ_{max}: 3.43 (m), 5.95, 6.10 (m) μm; uv λ_{max} (ε) (hexanes): 214 (2220), 218 (2200), 278 (37), 287 (37) nm; ^1H nmr δ: 1.05 (s, 6H), 1.12 (m, 2H), 1.50 (m, 2H), 2.30 (s, 2H), 2.40 (br s, 2H), 4.52 (m, 1H), 4.63 (m, 1H); ^{13}C nmr δ: 209.1, 146.5, 105.8, 53.4, 47.6, 32.9, 31.7, 28.4, 22.1; *m/e*: 164 (100). *Anal.* calcd. for $C_{11}H_{16}O$: C 80.44, H 9.82; found: C 80.21, H 9.85.

*Isomerization of **9** to **10**. Isolation of 6,6,8-trimethylspiro[2.5]oct-7-en-4-one (**10**)*

A mixture of **9** and **10** (250 mg, 1.52 mmol) obtained as above was dissolved in dioxane (5.0 mL) containing *p*-toluenesulfonic acid (25 mg) and the solution was boiled under reflux for 1 h. After cooling, the solution was poured into saturated aqueous sodium bicarbonate (25 mL) and the mixture was extracted with methylene chloride (4 × 15 mL). The combined organic extracts were dried and filtered and the solvent was removed. Molecular distillation at 110°C (12 Torr) gave 6,6,8-trimethylspiro[2.5]oct-7-en-4-one (**10**) (208 mg, 84%); ir λ_{max}: 3.40 (m), 5.91, 6.03 (w) μm; uv λ_{max} (ε) (95% ethanol): 214 (3230), 239 (766) nm; uv λ_{max} (ε) (hexanes): 217 (2170), 232 (sh, 1070), 284 (43) nm; ^1H nmr δ: 1.08 (s, 6H), 1.13 (m, 2H), 1.35 (m, 2H), 1.48 (d, J = 2 Hz, 3H), 2.37 (s, 2H), 5.55 (m, 1H), ^{13}C nmr δ: 210.5 (s), 133.5 (d), 131.2 (s), 53.3 (t), 33.4 (s), 31.1 (s), 29.2 (q), 17.6 (q), 16.8 (t); *m/e*: 164 (14), 149 (100). *Mol. Wt.* calcd. for $C_{11}H_{16}O$: 164.1201; found (ms): 164.1194. *Anal.* calcd. for $C_{11}H_{16}O$: C 80.44, H 9.82; found: C 80.17, H 9.89.

*Alkylation of 3-methylcyclohex-2-en-1-one (**5**) with 1,2-dibromoethane. Formation of **6**, **7**, **11**, and **12** and isolation of 8-methylenespiro[2.5]octan-4-one (**6**)*

Liquid ammonia (~1500 mL) was distilled into a 3-L three-necked flask containing sodium amide (117 g, 3.00 mol) and a magnetic stirring bar and fitted with a soda-lime guard tube. 3-Methylcyclohex-2-en-1-one (**5**) (110 g, 1.00 mol) was added and the solution was boiled under reflux for 1 h after which 1,2-dibromoethane (564 g, 3.00 mol) was added dropwise over 30 min. The solution was boiled under reflux for 4 h, ammonium chloride (161 g) was added, and the ammonia was allowed to evaporate. The products were taken up in methylene chloride (500 mL) and the solution was washed with water (500 mL) and aqueous 20% ammonium chloride (250 mL). The organic layer was dried, evaporated, and fractionally distilled to give a mixture of **5** (54%), 8-methylenespiro[2.5]octan-4-one (**6**; 19%), 8-methylspiro[2.5]oct-7-en-4-one (**7**; 19%), 8-methylenedispiro-[2.1.2.3]decan-4-one (**11**; 2%), and 8-methyldispiro[2.1.2.3]dec-8-en-4-one (**12**; 6%) (46 g), bp 35–60°C (0.25 Torr). The yields of **6**, **7**, **11**, and **12** based on consumed starting material were 8.3%, 8.3%, 0.73%, and 2.2%, respectively.

Attempted oxidative removal of **5** from the spiro compounds (as in the case of isophorone) resulted in concomitant consumption of **6** and **7**. Chromatography of the distillate (9.0 g; Waters Associates Prep. LC/System 500, silica gel) with 2% ether in hexanes gave a 1:3

For personal use only.

mixture of dispiro ketones **11** and **12** (0.66 g) followed by a 1:1 mixture of spiro ketones **6** and **7** (3.2 g); **5** (4.60 g) was recovered by elution with ethyl acetate. Compound **11** could not be separated from its isomer **12** by column chromatography on silica gel or by analytical hplc on μ Porasil or μ Bondapak C_{18}. Comparison of the ^{1}H nmr spectrum of the mixture of **11** and **12** with that of pure **12** (*vide infra*) revealed multiplets at δ 2.47, 4.43, and 4.63, assigned to **11**.

The mixture of spiro compounds **6** and **7** (2.00 g) was chromatographed on silica gel (250 g) with 10% ether in hexanes. The eluate was analyzed by gc. Initially a mixture of **6** and **7** was eluted, but the proportion of **7** decreased in later fractions until only **6** was present. Combination of the fractions containing **6** and **7** followed by solvent removal gave 1.82 g of the isomer mixture. Evaporation of the solvent from the fractions containing only **6** yielded an oil (158 mg) which was molecularly distilled at 85°C (12 Torr) to give pure **6** (145 mg); ir λ_{max}: 3.41 (m), 5.92, 6.10 μm; uv λ_{max} (ε) (hexanes): 217 (1730), 284 (58.2) nm; ^{1}H nmr δ: 1.12 (m, 2H), 1.48 (m, 2H), 1.7−2.2 (m, 2H), 2.3−2.8 (m, 4H), 4.50 (s, 1H), 4.67 (s, 1H); ^{13}C nmr δ: 209.3 (s), 147.8 (s), 105.0 (t), 39.7 (s), 34.1 (t), 33.6 (t), 22.3 (t), 22.0 (t). The ir and ^{1}H nmr spectra corresponded with those previously reported for **6** (3).

*Isomerization of **6** to **7**. Isolation of 8-methylspiro[2.5]oct-7-en-4-one (**7**)*

A mixture of **6** and **7** (285 mg, 2.10 mmol) obtained as above was dissolved in dioxane (6.0 mL) containing *p*-toluenesulfonic acid (29 mg) and the solution was boiled under reflux for 1 h. After cooling, the solution was poured into saturated aqueous sodium bicarbonate (25 mL) and the mixture was extracted with methylene chloride (4 × 15 mL). The combined organic extracts were dried and filtered and the solvent was removed. Molecular distillation at 90°C (12 Torr) gave 8-methylspiro[2.5]oct-7-en-4-one (**7**) (202 mg, 71%); ir λ_{max}: 3.44 (m), 5.88 μm; uv λ_{max} (ε) (hexanes): 222 (1150), 232 (sh, 941), 275 (78) nm; uv λ_{max} (ε) (95% ethanol): 218 (1130), 235 (576), 285 (sh, 79) nm; ^{1}H nmr δ: 1.15 (m, 2H), 1.36 (m, 2H), 1.53 (m, 3H), 2.48 (m, 4H), 5.73 (m, 1H); ^{13}C nmr δ: 210.5, 133.9, 122.0, 38.5, 31.9, 22.7, 17.8, 16.8. The ir and ^{1}H nmr spectra corresponded with those previously reported for **7** (3).

*Isomerization of **11** to **12**. Isolation of 8-methyldispiro[2.1.2.3]dec-8-en-4-one (**12**)*

A 1:3 mixture of **11** and **12** (1.16 g, 7.16 mmol) obtained as above was dissolved in dioxane (25 mL) containing *p*-toluenesulfonic acid (40 mg) and the solution was boiled under reflux for 4 h. After cooling, the solution was poured into saturated aqueous sodium bicarbonate (100 mL) and the mixture was extracted with methylene chloride (4 × 70 mL). The combined organic extracts were dried and filtered and the solvent was removed. Molecular distillation at 105°C (12 Torr) gave 8-methyldispiro[2.1.2.3]dec-8-en-4-one (**12**) (1.05 g, 91%); ir λ_{max}: 3.46 (w), 5.98 μm; uv λ_{max} (ε) (hexanes): 221 (1470), 230 (sh, 1150), 280 (75) nm; ^{1}H nmr δ: 0.68 (m, 2H), 0.9−1.5 (m, 6H), 1.53 (m, 3H), 2.35 (m, 2H), 5.72 (m, 1H); ^{13}C nmr δ: 210.4 (s), 133.0 (s), 121.0 (d), 32.6 (t), 31.8 (s), 26.4 (s), 18.9 (t), 18.5 (q), 17.2 (t); *m/e*: 162 (31), 134 (100). *Anal.* calcd. for $C_{11}H_{14}O$: C 81.44, H 8.70; found: C 81.44, H 8.73.

*Reduction of **9** and **10**. Preparation of 6,6,8-trimethylspiro[2.5]-octan-4-one (**15**) and formation of **16***

A 4:1 mixture of **9** and **10** (504 mg, 3.07 mmol) in 95% ethanol (20 mL) was stirred with platinum oxide (30.6 mg) under hydrogen (1 atm) for 14 h. The catalyst was allowed to settle and the supernatant solution was transferred to a flask containing fresh platinum oxide (2.10 mg) in 95% ethanol (5.0 mL). The spent catalyst was washed with 95% ethanol (2 × 30 mL) and the washings were combined with the solution containing fresh catalyst, which was stirred under hydrogen for 11 h. The catalyst was filtered and washed with ethanol and ether and the solvent was evaporated from the combined filtrate and washings. Gas chromatographic analysis (OV-17) showed that the crude product (441 mg, 86%) was a mixture of **15** (85%) and **16** (15%). This material was chromatographed on silica gel (80 g) with 10% ether in hexanes. The second band eluted (48.1 mg, 9%) was shown to be **16** by comparison of its ^{1}H nmr and ir spectra with those of an authentic sample (*vide infra*). The first fraction was molecularly distilled at 90°C (12 Torr) to provide 6,6,8-trimethylspiro[2.5]octan-4-one (**15**; 345 mg, 68%); ir λ_{max}: 3.42 (m), 5.91 μm; ^{1}H nmr δ: 0.4−0.9 (m) and 0.73 (d, J = 5 Hz) (5H), 0.9−1.3 (m) and 1.05 (s) (8H), 1.3−1.7 (m, 3H), 2.1−2.3 (m, 2H); ^{13}C nmr δ: 211.8 (s), 53.3 (t), 46.7 (t), 32.3 (s), 32.0 (d), 31.9 (s), 29.3 (q), 27.2 (q), 16.4 (q), 13.6 (t), 10.0 (t); *m/e*: 166 (20), 82 (100). *Anal.* calcd. for $C_{11}H_{18}O$: C 79.46, H 10.91; found: C 79.30, H 10.84.

*Preparation of 2-ethyl-3,5,5-trimethylcyclohex-2-en-1-one (**16**) (4)*

To a stirred solution of isophorone (**8**) (1.38 g, 10.0 mmol) and ethyl bromide (1.09 g, 10.0 mmol) in dimethyl sulfoxide (15 mL) was added over 3 h powdered potassium hydroxide (840 mg, 15.0 mmol). The mixture was stirred for a further 8 h at room temperature, poured into water, neutralized with 0.1 *N* hydrochloric acid, and extracted with ether. The combined organic solutions were washed with water, dried, and evaporated to provide a reddish oil (1.95 g). Gas chromatographic analysis of this oil revealed the presence of **8** (25%), **16** (45%), and three other components (8−12% each). Preparative tlc of this material (259 mg) with 50% ether in hexanes gave pure 2-ethyl-3,5,5-trimethylcyclohex-2-en-1-one (**16**; 110 mg); ir λ_{max}: 3.41 (m), 6.03, 6.14 (m) μm; uv λ_{max} (ε) (95% ethanol): 244 (9040) nm (lit. (9) 246 (9400) nm): ^{1}H nmr δ: 0.92 (t, J = 8 Hz) and 1.02 (s) (9H), 1.92 (s, 3H), 2.22 (s) and 2.28 (br q, J = 9 Hz) (6H); ^{1}H nmr δ (C_6D_6): 0.77 (s, 6H), 0.98 (t, J = 7 Hz, 3H), 1.52 (s, 3H), 1.73 (br s, 2H), 2.07 (s, 2H), 2.36 (br q, J = 7 Hz, 2H); ^{13}C nmr δ: 198.7 (s), 151.9 (s), 136.1 (s), 51.4 (t), 47.0 (t), 32.7 (s), 28.2 (q), 21.0 (q), 18.2 (t), 13.4 (q); *m/e*: 166 (48), 110 (100).

*Reaction of isophorone (**8**) with sodium hydride and a mixture of **9** and **10**. Preparation of 2,2′-(ethanediyl)bis[3,5,5-trimethylcyclohex-2-en-1-one] (**18**)*

To a mixture of isophorone **8** (67%) and spiro ketones **9** (26%) and **10** (7%) (5.00 g, 10.1 mmol) in toluene (15 mL) was added a 50% dispersion of sodium hydride in mineral oil (870 mg, 18.1 mmol). The resulting mixture was boiled under reflux under nitrogen for 10 h, allowed to cool to room temperature,and quenched with 0.5 *N* hydrochloric acid (40 mL). The two layers were separated and the aqueous layer was extracted with methylene chloride (3 × 25 mL). The combined organic solutions were washed with saturated aqueous sodium bicarbonate, dried, and evaporated. The remaining solid, dispersed in oil, was collected by vacuum filtration and washed with the minimum volume of petroleum ether (bp 30°−60°C). The ^{1}H nmr and gc analyses of the oil obtained on evaporation of the solvent from the washings revealed the presence of unconsumed **8** and **10**. None of the *exo* isomer **9** was present. The solid, 2,2′-(ethanediyl)bis[3,5,5-trimethylcyclohex-2-en-1-one] (**18**; 1.37 g, 45%), was ~99% pure by gc analysis.[5] A sample for elemental analysis was obtained by recrystallization from acetone; mp 181°−182.5°C; ir λ_{max}: 3.40 (m), 6.03, 6.11 (sh) μm; uv λ_{max} (ε) (95% ethanol): 244.5 (16600) nm; ^{1}H nmr δ: 1.02 (s, 12H), 2.02 (s, 6H), 2.22 (s) and 2.27 (s) (12H); ^{1}H nmr δ (C_6H_6): 0.80 (s, 12H), 1.68 (s, 4H), 1.88 (s, 6H), 2.08 (s, 4H), 2.58 (s, 4H); ^{13}C nmr δ: 199.0 (s), 153.5 (s), 134.0 (s), 51.5 (t), 47.1 (t), 32.8 (s), 28.3 (q), 24.6 (t), 21.3 (q); *m/e*: 302 (78), 152 (100), 96 (100). *Anal.* calcd. for $C_{20}H_{30}O_2$: C 79.42, H 10.00; found: C 79.16, H 9.89.

*Reaction of isophorone (**8**) with sodium hydride and **10**. Formation of **18***

To a mixture of isophorone **8** (78%) and **10** (22%) (2.50 g, 3.35 mmol of **10**) in toluene (7.5 mL) was added a 50% dispersion of sodium hydride in mineral oil (433 mg, 9.02 mmol). The resulting mixture was boiled under reflux under nitrogen for 10 h and poured into water (13 mL), and the basic solution was neutralized with dilute hydrochloric acid. The layers were separated and the aqueous phase

[5]The oven temperature for the gc analysis was 240°C.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

was extracted with methylene chloride (3 × 16 mL). The combined organic solutions were washed with saturated aqueous sodium bicarbonate and dried, and the solvent was evaporated to give a suspension of a solid in oil. The solid was collected by vacuum filtration and washed with a minimum volume of petroleum ether (bp 30°−60°C). The ^{1}H nmr and gc analyses[5] of the oil obtained on evaporation of the solvent from the washings revealed the presence of unconsumed **8** and **10**. The solid (403 mg, 40%) was shown by ^{1}H nmr, ir, and gc analyses to be **18**.

*Treatment of a mixture of **9** and **10** with sodium hydride in toluene*

To a 1:2 mixture of **9** and **10** (150 mg, 0.915 mmol) in toluene (1.5 mL) was added a 50% dispersion of sodium hydride in mineral oil (43.5 mg, 0.906 mmol). The resulting mixture was boiled under reflux under nitrogen for 10 h and poured into water (5.0 mL), and the basic solution was neutralized with dilute hydrochloric acid. The layers were separated and the aqueous phase was extracted with methylene chloride (3 × 15 mL). The combined organic solutions were washed with saturated aqueous sodium bicarbonate and dried, and the solvent was evaporated. The oil thus obtained (126 mg) consisted of **9** and **10** in a 1:2 ratio and a small amount of mineral oil.

*Reaction of a mixture of **9** and **10** with morpholine. Preparation of 3,5,5-trimethyl-2-[2-(4-morpholinyl)ethyl]cyclohex-2-en-1-one (**20**)*

A mixture of spiro ketones **9** (79%) and **10** (21%) (549 mg, 3.34 mmol) was dissolved in morpholine (distilled from calcium hydride; 6.0 mL) and the solution was boiled under reflux under nitrogen for 28 h. Gas chromatographic analysis of aliquots showed that while all of **9** was consumed within 3 h, **10** was still present when the reaction was stopped after 28 h. Evaporation of the morpholine gave a viscous oil which was molecularly distilled at 55°C (0.025 Torr) to provide a liquid which was shown by ^{1}H nmr spectroscopy to be a mixture of **20** and unconsumed **10**. Further molecular distillation at 100°C (0.025 Torr) yielded 3,5,5-trimethyl-2-[2-(4-morpholinyl)-ethyl]cyclohex-2-en-1-one (**20**; 520 mg, 62%) as a colorless liquid; ir λ_{max}: 3.47 (m), 3.53 (m), 6.07, 6.14 (sh), 8.97 (m) μm; uv λ_{max} (ϵ) (95% ethanol): 245.5 (9400) nm; ^{1}H nmr δ: 1.00 (s, 6H), 1.93 (s, 3H), 2.22 (s, 4H), 2.3−2.6 (m, 8H), 3.70 (m, 4H); ^{1}H nmr δ (C_6D_6): 0.80 (s, 6H), 1.53 (s, 3H), 1.72 (s, 2H), 2.07 (s, 2H), 2.2−2.8 (m, 8H), 3.57 (m, 4H); ^{13}C nmr δ: 198.5 (s), 153.3 (s), 132.5 (s), 67.1 (t), 57.7 (t), 53.7 (t), 51.2 (t), 47.1 (t), 32.7 (s), 28.2 (q), 22.4 (t), 21.3 (q); *m/e*: 251 (0.6), 100 (100). *Mol. Wt.* calcd. for $C_{15}H_{25}NO_2$: 251.1885; found (ms): 251.1891. *Anal.* calcd. for $C_{15}H_{25}NO_2$: C 71.67, H 10.02, N 5.57; found: C 71.62, H 10.12, N 5.65.

*Reaction of **10** with morpholine. Formation of **20***

Spirooctenone **10** (300 mg, 1.83 mmol) was dissolved in morpholine (3.0 mL) and the solution was boiled under reflux. After 43, 64, 88, and 110 h the ^{1}H nmr spectrum of the crude product mixture was obtained. Integration of the first spectrum indicated 72% conversion of **10** to amine **20**. After 88 h, ~10% of **10** was observed, but none was detected after 110 h. The crude product was dissolved in ether (30 mL) and extracted with 0.6 *N* hydrochloric acid (3 × 25 mL). The organic solution was washed with saturated aqueous sodium bicarbonate (15 mL) and water (15 mL), dried, and evaporated, leaving a yellow oil (18 mg) which was <50% **10** (by ^{1}H nmr analysis). The combined aqueous extracts were basified with potassium hydroxide and extracted with ether (3 × 40 mL). The combined organic extracts were washed with water (50 mL), dried, and evaporated to give **20** (268 mg, 58%).

*Reaction of a mixture of **6** and **7** with morpholine. Preparation of 2-methyl-2-[2-(4-morpholinyl)ethyl]cyclohex-2-en-1-one (**21**)*

A 1:1 mixture of spiro ketones **6** and **7** (302 mg, 2.22 mmol) in morpholine (5.0 mL) was boiled under reflux under nitrogen for 80 h. Gas chromatographic analysis of aliquots revealed that while all of **6** was consumed within 3 h, **7** was still present after 80 h. Evaporation of the morpholine gave a viscous oil which was molecularly distilled at 55°−95°C (0.05 Torr) to give a mixture of **21** and unconsumed **7** (38 mg). Further molecular distillation at 105°C (0.05 Torr) gave 3-methyl-2-[2-(4-morpholinyl)ethyl]cyclohex-2-en-1-one (**21**; 277 mg, 56%); ir λ_{max}: 3.44 (m), 6.03, 6.15 (m) μm; uv λ_{max} (ϵ) (95% ethanol): 243 (9300) nm; ^{1}H nmr δ: 1.97 (s) and 1.8−2.2 (m) (5H), 2.2−2.6 (m, 12H), 3.72 (m, 4H); ^{13}C nmr δ: 198.3, 156.1, 133.4, 67.0, 57.7, 53.6, 37.7, 32.8, 22.5, 22.2, 21.1; *m/e*: 223 (13), 100 (27), 99 (100). *Anal.* calcd. for $C_{13}H_{21}NO_2$: C 69.92, H 9.48, N 6.27; found: C 69.79, H 9.46, N 6.41.

*Reaction of a mixture of **7** and **10** with morpholine*

A 1.5:1 mixture of **7** and **10** in morpholine was boiled under reflux for 90 h. Gas chromatographic analysis revealed that after 24, 38, and 64 h the ratios of **10**:**7** were 1.9:1, 2.2:1, and 3.0:1, respectively. While some of **10** was present after 90 h, **7** was not detected. Evaporation of the morpholine followed by ^{1}H nmr and ir analyses showed that **7** and **10** had been converted to **21** and **20**.

*Hydrogenation of **20**. Preparation of 3,5,5-trimethyl-2-[2-(4-morpholinyl)ethyl]cyclohexan-1-one (**22**)*

Amine **20** (230 mg, 0.916 mmol) in 95% ethanol (10 mL) was stirred with 10% palladium on carbon (30 mg) under hydrogen (1 atm). The catalyst was filtered and washed with ethanol and ether and the solvent was evaporated from the combined filtrate and washings. Molecular distillation at 110°C (0.05 Torr) gave 3,5,5-trimethyl-2-[2-(4-morpholinyl)ethyl]cyclohexan-1-one (**22**; 193 mg, 83%); ir λ_{max}: 3.52 (m), 5.88 μm; ^{1}H nmr δ: 0.87 (s) and 1.05 (s) (9H), 1.53 (br s, 2H), 1.6−2.0 (m, 3H), 2.07−2.25 (m, 3H), 2.25−2.63 (m, 6H), 3.67 (t, J = 4.5 Hz, 4H); ^{13}C nmr δ: 211.8 (s), 67.0 (t), 57.0 (t), 54.9 (t), 54.4 (d), 53.8 (t), 48.3 (t), 35.5 (s), 34.4 (d), 32.1 (q), 25.6 (q), 22.5 (t), 20.9 (q); *m/e*: 253 (5), 100 (100). *Anal.* calcd. for $C_{15}H_{27}NO_2$: C 71.10, H 10.74, N 5.53; found: C 70.67, H 10.65, N 5.72.

*Reaction of **15** with morpholine. Formation of **22***

Spirooctanone **15** (165 mg, 0.994 mmol) was dissolved in morpholine (3.0 mL) and the solution was boiled under reflux. After 47, 89, 137, 200, and 240 h the ^{1}H nmr spectrum of the crude product mixture was obtained. While peaks attributable to unconsumed **15** were observed in the first four spectra, no evidence for its presence was detected in that taken after 240 h. A solution of the crude product in ether (20 mL) was washed with 0.6 *N* hydrochloric acid (3 × 15 mL) and water (15 mL), dried, and evaporated to provide an oil (17 mg), which was shown by ^{1}H nmr spectroscopy to be primarily **15**. The combined acidic washings were neutralized with potassium hydroxide and extracted with ether (3 × 20 mL). The combined organic extracts were washed with water, dried, and evaporated to give amine **22** (53 mg, 21%) having ir, ^{1}H nmr, and ^{13}C nmr spectra identical to those described above.

*Treatment of **22** with methanolic sodium methoxide*

Amine **22** (66 mg, 0.261 mmol) in methanol (3.0 mL) containing sodium methoxide (340 mg) was boiled under reflux for 18 h. After cooling, the mixture was poured into water and extracted with ether. The combined organic extracts were washed with water, dried, and evaporated to return **22** (64 mg, 97% recovery) which was shown by ir and ^{1}H nmr spectroscopy to be identical to the starting material.

*Treatment of **22** with sodium methoxide in methanol*-O-d. *Formation of deuterated **22***

A solution of amine **22** (193 mg, 0.763 mmol) in methanol-*O-d* (5.0 mL) containing sodium methoxide (200 mg) was boiled under reflux for 18 h. After cooling, the mixture was poured into ether (25 mL) and extracted with water (2 × 10 mL). The organic layer was dried and evaporated to give an oil (135 mg, 70% recovery), the ir spectrum of which was very similar to that of the starting material. In its ^{1}H nmr spectrum the relative area of the multiplets at δ 2.07−2.25 and 3.54 was 1.1:4.0; in unlabelled **22** it was 3.0:4.0. Its fully decoupled ^{13}C nmr spectrum corresponded to that of unlabelled **22** except for the absence of the peaks at δ 54.9 and 54.4 and the presence of several very weak peaks at δ ~54.5. Its mass spectrum had peaks at *m/e*: 256 (1.6), 255 (2.9), 254 (2.3), 253 (1.1), and 100 (100).

Reaction of a mixture of ***6*** *and* ***7*** *with acidic ethanol. Preparation of 2-(2-ethoxyethyl)-3-methylcyclohex-2-en-1-one (****25****)*

A 1:1 mixture of **6** and **7** (219 mg, 1.61 mmol) in ethanol (3.0 mL) containing *p*-toluenesulfonic acid (25 mg) was boiled under reflux. After 6 h, gc analysis showed that the ratio of **7** to **6** was 45:1. The reaction mixture was poured into water (15 mL) and extracted with methylene chloride (3 × 15 mL). The combined organic extracts were dried and evaporated. ^{1}H nuclear magnetic resonance spectroscopy showed that the crude material was a 3:1 mixture of **7** and the product **25**. This mixture was dissolved in ethanol containing *p*-toluenesulfonic acid as above and the solution was boiled under reflux for 63 h (total = 69 h). ^{1}H nuclear magnetic resonance spectroscopy of the material obtained after work-up as above revealed that the ratio of **7** to **25** was 1:7. Further treatment of this mixture with boiling acidic ethanol for 46 h (total = 115 h), followed by work-up as above and molecular distillation at 100°C (12 Torr), gave 2-(2-ethoxyethyl)-3-methylcyclohex-2-en-1-one (**25**; 166 mg); ir λ_{max}: 3.40 (m), 6.02, 6.13 (m) μm; uv λ_{max} (ϵ) (95% ethanol): 244 (10 900), 310 (64) nm; ^{1}H nmr δ: 1.17 (t, J = 7 Hz, 3H), 2.00 (s) and 1.7–2.2 (m) (5H), 2.37 (br t, J = 6 Hz) and 2.58 (t, J = 7 Hz) (6H), 3.36 (t, J = 7 Hz) and 3.45 (q, J = 7 Hz) (4H); ^{13}C nmr δ: 198.5, 157.3, 132.2, 69.3, 66.0, 37.8, 33.0, 26.0, 22.3, 21.4, 15.3; *m/e*: 182 (42), 136 (100). *Anal.* calcd. for $C_{11}H_{18}O_2$: C 72.49, H 9.95; found C 72.31, H 9.86.

Reaction of a mixture of ***9*** *and* ***10*** *with acidic ethanol. Preparation of 2-(2-ethoxyethyl)-3,5,5-trimethylcyclohex-2-en-1-one (****26****)*

A 3:1 mixture of **9** and **10** (500 mg, 3.05 mmol) in ethanol (7.0 mL) containing *p*-toluenesulfonic acid (50 mg) was boiled under reflux. Gas chromatographic analysis showed that **9** was consumed within 10 h. However, complete consumption of **10** required 150 h. After 150 h the reaction mixture was poured into saturated aqueous sodium bicarbonate (40 mL) and extracted with methylene chloride (3 × 40 mL). The combined organic extracts were dried, evaporated, and molecularly distilled at 135°C (12 Torr) to give 2-(2-ethoxyethyl)-3,5,5-trimethylcyclohex-2-en-1-one (**25**; 412 mg, 64%); ir λ_{max}: 6.06, 6.16 (m) μm; uv λ_{max} (ϵ) (95% ethanol): 245 (10 500), 310 (69) nm; ^{1}H nmr δ: 1.03 (s, 6H), 1.17 (t, J = 7 Hz, 3H), 1.97 (s, 3H), 2.24 (s, 4H), 2.60 (br t, J = 7 Hz, 2H), 3.37 (t, J = 7 Hz) and 3.46 (q, J = 7 Hz) (4H); ^{1}H nmr δ (C_6H_6): 0.82 (s, 6H), 1.12 (t, J = 7 Hz, 3H), 1.67 (br s, 3H), 1.80 (m, 2H), 2.12 (s, 2H), 2.75 (br t, J = 7 Hz, 2H), 3.30 (t, J = 7 Hz) and 3.43 (q, J = 7 Hz) (4H); ^{13}C nmr δ: 198.7, 154.6, 131.1, 69.3, 66.0, 51.3, 47.2, 32.7, 28.2, 25.8, 21.6, 15.3; *m/e*: 210 (21), 164 (100). *Anal.* calcd. for $C_{13}H_{22}O_2$: C 74.24, H 10.54; found: C 74.10, H 10.42.

Ullmann condensation using copper or copper oxide as the reactant. Arylation of active hydrogen compounds (imides, amides, amines, phenol, benzoic acid, and phenylacetylene)

TAKAKAZU YAMAMOTO[1] AND YASUNDO KURATA

Research Laboratory of Resources Utilization, Tokyo Institute of Technology, 4259 Nagatsuta, Midori-ku, Yokohama 227, Japan

Received April 26, 1982

TAKAKAZU YAMAMOTO and YASUNDO KURATA. Can. J. Chem. **61**, 86 (1983).

Ullmann condensation using Cu or copper oxide as the reactant and using no base has been studied. Reactions of active N—H, O—H, and C—H compounds, RZH (imides, amides, amines, phenol, benzoic acid, and phenylacetylene), with mixtures of aryl halides and more than a stoichiometric amount of Cu or copper oxide (Cu_2O or CuO) without addition of base lead to facile arylation of the active hydrogen compounds. In the arylation reaction Cu and copper oxides serve not only as the catalyst but also as the acceptor of halogen from aryl halide. The reactivity of phenyl halide, PhX, increases in the order PhCl < PhBr < PhI. Cu generally gives higher yields than Cu_2O and CuO and, of the two copper oxides, Cu_2O has the higher activity. The stronger the acidity of the active hydrogen compound (RZH), the more easily the compound is phenylated by the mixture of PhX and Cu; a roughly linear correlation between T_i, the temperature where the phenylation starts, and the pK_a value of the active hydrogen compound has been observed. A mechanism involving initial formation of an RZ—Cu species by the reaction between RZH and Cu or copper oxide and ensuing attack of organic halide at the RZ—Cu species is proposed.

TAKAKAZU YAMAMOTO et YASUNDO KURATA. Can. J. Chem. **61**, 86 (1983).

On a étudié la condensation de Ullman qui utilise le cuivre ou l'oxyde de cuivre comme réactif en l'absence de base. Les réactions des composés ayant des hydrogènes actifs N—H, O—H et C—H, RZH (imides, amides, amines, phénol, acide benzoique et phénylacétylène) avec des mélanges d'halogénures aryliques en présence d'un excès de cuivre ou d'oxyde de cuivre (Cu_2O ou CuO) et en l'absence de base conduit à une arylation facile des composés ayant un hydrogène actif. Dans les réactions d'arylation le Cu et les oxydes de cuivre servent non seulement de catalyseur mais également d'accepteur d'halogène des halogénures aryliques. La réactivité de l'halogénure de phényle PhX augmente dans l'ordre: PhCl < PhBr < PhI. Le cuivre donne généralement de meilleurs rendements que le Cu_2O ou le CuO et des deux oxydes de cuivre le CuO_2 est le plus actif. Si l'acidité du composé hydrogène actif (RZH) est élevée il est plus facile de le phényler avec le mélange de PhX et de Cu; on a observé une corrélation linéaire approximatique entre T_i, la température de départ de la phénylation, et la valeur de pK_a du composé à hydrogène actif. On propose un mécanisme impliquant la formation initiale d'espèces du type RZ—Cu par suite de la réaction entre RZH et le cuivre ou l'oxyde de cuivre et l'attaque subséquente de l'halogénure organique sur RZ—Cu.
[Traduit par le journal]

Introduction

Copper promoted arylation of O—H (e.g., phenol) and N—H (e.g., diphenylamine) compounds by aryl halides (Ullmann condensation) has been widely applied to the preparation of aromatic compounds (1).

$$[1]\quad RZH + ArX \xrightarrow{Cu} RZ—Ar$$

ZH = OH, NH

Addition of bases such as K_2CO_3 and KOH as the acceptor of HX released is necessary for the reaction to proceed, and sometimes, instead of the O—H and N—H compounds, use of their salts (e.g., C_6H_5OK) as the starting material is required. In almost 80 years of study of the Ullmann condensation, reactions using copper metal (2*a*) or copper oxide (2) catalyst themselves as the acceptor of halogen, and thus using no base,

$$[2]\quad RZH + ArX + Cu \text{ (or Cu oxide)} \longrightarrow RZ—Ar + CuX$$

have also been reported, but the reported examples of this type of reaction (especially reactions using Cu metal as the reactant) are limited and no systematic study of the reaction has been reported. We have made a systematic study of the reactions expressed by eq. [2], and in this paper we wish to report several features of the reactions, including some advantages of the reaction over the usual Ullmann condensation using base. Part of the results were briefly reported previously in communication form (3).

Results and discussion

Table 1 shows typical data of the present Ullmann condensation using Cu or copper oxide as the reactant. As shown in Table 1, a variety of active hydrogen compounds are arylated by simply heating them with mixtures of the aryl halides and Cu metal or copper oxide. Thus, the condensation reaction proceeds smoothly without addition of solvent, and this is regarded as one of the merits of the present condensation reaction since removal of solvent from the reaction mixture is not necessitated in the present reaction and consequently isolation of products becomes easy. It is known that the yield of the usual Ullmann condensation using base depends on the solvent, and employment of special solvents (usually polar solvents) such as 2,4,6-collidine and quinoline is required in order to get a reasonably good yield. Good miscibility of RZH with ArX in the present system seems to account for the occurrence of the facile condensation reaction in the absence of solvent; in the usual Ullmann condensation only ArX is a liquid material and both the salt of RZH or base and the copper catalyst are generally

insoluble in ArX, whereas in the present reaction system RZH and ArX mix well with each other and Cu or copper oxide is the only insoluble material.

Yields of the arylation reactions of phthalimide (4), succinimide (4), diphenylamine (5), phenol (1, 2), and benzamide (6) are comparable to, or higher than, those attained by the usual Ullmann condensation. For 2-pyrrolidinone, acetamide, and phenylacetylene, arylation of these compounds by the usual Ullmann condensation has no precedents. As for aniline, its arylation by active aryl halides such as halobenzoic acid (6) has some precedents, but phenylation of aniline by simple phenyl halides, PhX, has not been reported. Details of the arylation reactions of each class of active hydrogen compounds are described below.

Imides

Among the active hydrogen compounds tested, imides (phthalimide and succinimide) are most easily phenylated by phenyl halides. In the phenylation of phthalimide, substitution of the p-hydrogen of phenyl bromide by an electron-donating group (CH_3, OCH_3) or electron-withdrawing element (F) has only a minor effect on the yield (Expts. 2–4 in Table 1). Figure 1 shows the temperature dependence of the yield in the phenylation reaction of phthalimide by the mixture of PhBr and Cu or copper oxide.

As shown in Fig. 1, the reaction starts at about 145°C when Cu or Cu_2O is employed as the reactant. The yield increases on raising the temperature and almost a quantitative yield is attained at about 210°C but, when Cu_2O is employed, further raising of the temperature causes degradation of the product and thus the yield decreases. In contrast to the high yield attained by using the mixture of PhBr and Cu or Cu_2O, only a poor yield was obtained in the arylation reaction of phthalimide by a mixture of PhBr and CuO.

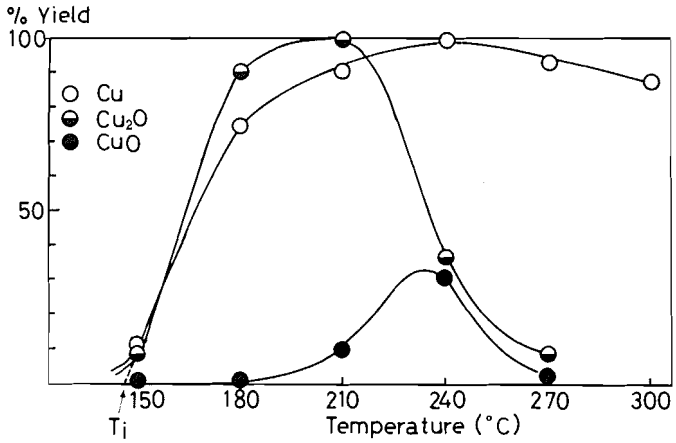

FIG. 1. Temperature dependence of the yield of *N*-phenylphthalimide in the phenylation reaction of phthalimide by the mixture of PhBr (2 mol/mol of phthalimide) and Cu (4.7 mol/mol of phthalimide, ○), Cu_2O (2.4 mol/mol of phthalimide, ◒), or CuO (4.7 mol/mol of phthalimide, ●). Time = 12 h.

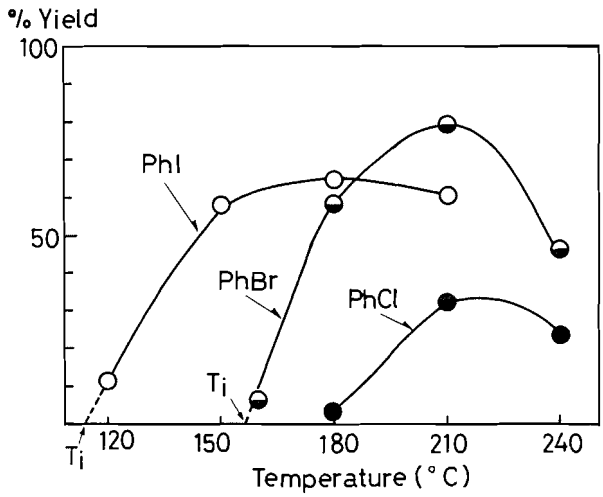

FIG. 2. Temperature dependence of the yield of PhCONHPh in the phenylation reaction of benzamide by the mixture of Cu (4.7 mol/mol of benzamide) and PhI (○), PhBr (◒), or PhCl (●). PhX = 2 mol/mol of benzamide. Time = 12 h.

The trends (temperature dependence of yield and relative activities of Cu, Cu_2O, and CuO) observed for the phenylation of phthalimide are also observed for the phenylation of succinimide. It is reported that PhCl is inactive for phenylation of imides in the usual Ullmann condensation (4), but in the present condensation reaction PhCl is also active if it is used in combination with Cu metal, and thus *N*-phenylsuccinimide is obtained in a medium yield (Expt. 10). Since *N*-arylimides are easily converted into arylamines, the present method seems to be applicable to the preparation of arylamines from imides and aryl halides.

Amides

Amides of both aromatic and aliphatic acids (benzamide and acetamide) are phenylated by mixtures of PhX and Cu or copper oxide, and the present method is also applicable to the phenylation of the cyclic amide, 2-pyrrolidinone.

Figure 2 shows the temperature dependence of the yield of the phenylation reaction of benzamide by PhX and Cu. When

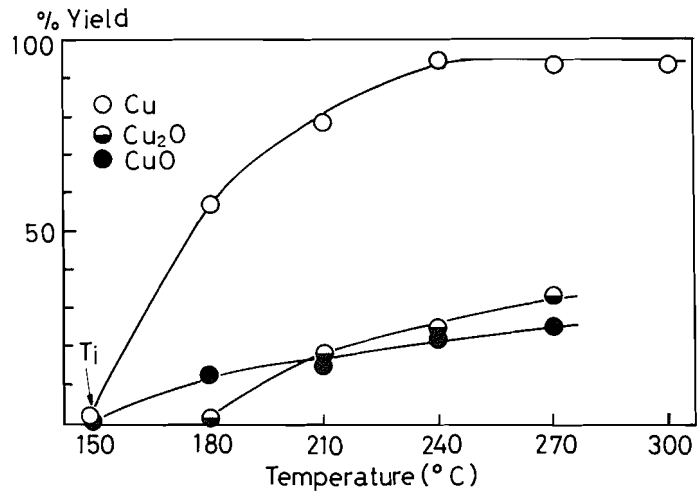

FIG. 3. Temperature dependence of the yield of PhOPh in the phenylation reaction of PhOH by the mixture of PhBr (2 mol/mol of PhOH) and Cu (4.7 mol/mol of PhOH, ○), Cu_2O (2.4 mol/mol of PhOH, ◒), or CuO (4.7 mol/mol of PhOH, ●). Time = 12 h.

a mixture of PhBr and Cu is employed, the coupling reaction starts at about 160°C and the yield of PhCONHPh reaches 79% at 210°C, but the yield decreases at higher temperature due to occurrence of a perphenylation reaction to give $PhCONPh_2$ and a deamination reaction from $PhCONPh_2$ to give $HNPh_2$ (cf. Table 1). A similar dependence of the yield on temperature was observed for phenylation of acetamide by PhX and Cu; the yield of the reaction using PhBr reaches a maximum at 180°C and decreases due to the perphenylation and deamination reactions. Formation of $HNPh_2$ in the usual Ullmann condensation between $CH_3CONHPh$ and PhX has been reported (1*d*). At lower temperatures (below 150°C, 170°C, and 210°C for PhI, PhBr, and PhCl, respectively), perphenylation and deamination are negligible.

The phenylation of 2-pyrrolidinone by the mixture of PhBr and Cu proceeds quantitatively in a temperature range of 180–210°C. A mixture of Cu_2O and PhBr needs somewhat higher temperature to provide a quantitative yield. The yield of the phenylation reaction of 2-pyrrolidinone by a mixture of PhBr and Cu or Cu_2O decreases to ca. 70% at 240°C, presumably due to a deamination reaction similar to that observed in the phenylation reaction of benzamide and acetamide, although in this case products of the deamination reaction have not been identified. CuO gives only a low yield.

Amines

In the phenylation of Ph_2NH, the reactivity of PhX increases in the order PhCl < PhBr < PhI; PhCl gives only a low yield even at 270°C. Among the copper species, only Cu gives a reasonably high yield and copper oxides give only poor yields (e.g., a mixture of Cu_2O and PhBr phenylates Ph_2NH in only 1% yield at 210°C). As shown in Table 1 (Expts. 20–22) phenylation of aniline gives a mixture of Ph_2NH and Ph_3N, but in the presence of excess PhI the reaction gives Ph_3N exclusively. An aralkyl amine, $(PhCH_2)_2NH$, was also phenylated by the mixture of PhX and Cu or copper oxide, but the yield (e.g., 38% by a mixture of PhBr and CuO, which has the highest activity among the copper species in this phenylation reaction, in contrast to the other phenylation reaction where CuO generally has the lowest activity) was low.

The phenylation reactions of amines were retarded by addi-

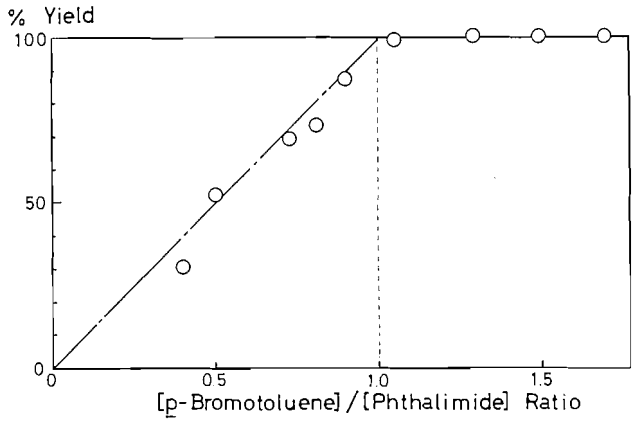

FIG. 4. Effect of the amount of *p*-bromotoluene on the yield of the arylation reaction of phthalimide at 240°C. Cu = 4.7 mol/mol of phthalimide. Time = 12 h.

tion of basic ligand such as pyridine and *o*-phenanthroline.

Phenol

Figure 3 shows the temperature dependence of the yield of the arylation reaction. As shown in Fig. 3, the phenylation of PhOH by the mixture of PhBr and Cu starts at ca. 150°C and the yield increases on raising the temperature. Phenylation by the mixture of PhI and Cu starts at a lower temperature and among the copper species only Cu gives good yields in the phenylation reactions of phenol.

Benzoic acid

Phenylation of PhCOOH by the mixture of PhBr and Cu starts at 130°C, and among the copper species only Cu gives good yields. Formation of biphenyl (Expts. 25 and 26) seems to be due to an Ullmann coupling reaction of PhX or to a copper catalyzed decarbonylative coupling between PhCOOH and PhX as reported by Nilsson (7).

Besides the phenylation reaction of PhCOOH by the mixture of PhX and Cu, alkylation reactions of PhCOOH by mixtures of alkyl halides and Cu also proceed to give the corresponding esters in good yields (e.g., 83% by a mixture of EtBr and Cu at 210°C). In this alkylation reaction, in contrast to the phenylation reaction, Cu_2O and CuO also have high activities, and yields comparable to those attained by Cu are obtained.

Compounds having active C—H bond

The present method is applicable to the phenylation of phenylacetylene, a compound having an active C—H bond. Attempts to arylate other active C—H compounds such as diethyl malonate and acetophenone, however, have not been successful. Heating of diethyl malonate with a mixture of PhX and Cu led to the evolution of CO_2. Bjorklund and Nilsson (8) reported arylation of 1,3,5-trinitrobenzene, having the active C—H bond, by aryl iodide and Cu_2O. Hagihara and coworkers (9) reported substitution of the acetylenic hydrogen by reaction with aryl halides and Et_3N in the presence of catalytic amounts of Pd–phosphine complex and CuI.

Reaction conditions and relative reactivities of the reactants

Amount of aryl halide

Among the arylation reactions tested, the arylation of imides by a mixture of aryl halide and Cu proceeds most cleanly and the yield of the reaction between phthalimide and the mixture of *p*-bromotoluene and Cu (3.0 mol/mol of phthalimide) increases linearly with increase in the amount of

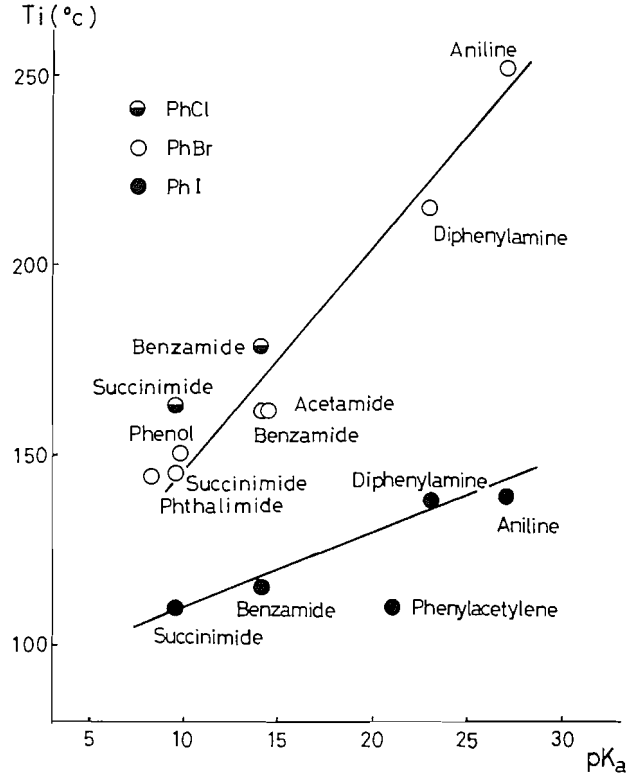

FIG. 5. Plots of the initiation temperature, T_i, against pK_a value of the active hydrogen compound.

p-bromotoluene (Fig. 4). The data shown in Fig. 4 indicate that 1 mol of *p*-bromotoluene arylates 1 mol of phthalimide. Although similar increases in the yield with increase in the amount of organic halide are observed in the other arylation reactions described above, such a clean 1:1 correlation between the amount of aryl halide and the yield as shown in Fig. 4 was not obtained, and generally addition of more than ca. 1.5 mol of ArX per mol of RZH is necessitated in order to get maximum yields. When the acidity of the active hydrogen compound is weak, as in the case of aniline, addition of a large excess of organic halide is desirable.

Amount of Cu and relative reactivities of Cu species

In the 1:1 reaction between phthalimide and *p*-bromotoluene the yield of the reaction increases with an increase in the amount of Cu (yield = 58%, 86%, and 100% at 1.0, 2.0, and 3.0 mol of Cu per mol of phthalimide, respectively). Generally, addition of 3 mol of Cu is sufficient for the phenylation of RZH employed in the present study.

Among the copper species, Cu metal gives higher yields than Cu_2O and CuO in most cases and, of the two copper oxides, Cu_2O usually has the higher activity.

Relative activities of ArX and RZH

The reactivity of PhX increases in the order PhCl < PhBr < PhI as judged from the reaction temperature and the yield. PhF has no activity in the phenylation reaction. Weingarten (10) reported a similar trend concerning the usual $CuCl_2$-catalyzed Ullmann condensation between PhOK and PhX.

Since the present condensation reaction is applicable to various RZH compounds under simple common reaction conditions using neither solvent nor base, a direct comparison of the reactivity of RZH is possible. Figure 5 shows plots of initiation temperature, T_i, where the phenylation of the RZH starts (for

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

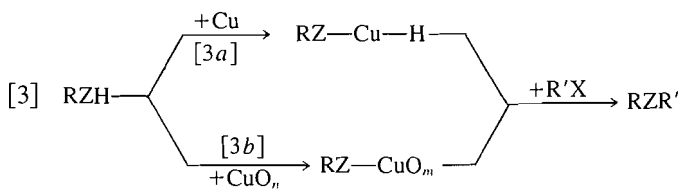
some examples, see Figs. 1–3), against the pK_a value of RZH. As shown in Fig. 5, a roughly linear correlation between pK_a value and T_i holds for the phenylation of phenol and N—H compounds (imides, amides, and amines). The data point for phenylacetylene, however, deviates from the linearity, indicating that the acetylenic compound has a higher reactivity against Cu than expected from its pK_a value.

Although it has been recognized (1) that phenol and aryl amine having more acidic O—H and N—H bonds generally have higher reactivities in the usual Ullmann condensation, such a relationship as shown in Fig. 5 has not been demonstrated, since each of the usual Ullmann condensation reactions has been carried out under different reaction conditions (different solvent and catalyst).

Usually the yield of the reaction exceeds 70–80% at a temperature higher than T_i by 50°C.

Reaction mechanism

One of the conceivable reaction mechanisms of the present condensation reaction includes initial formation of a Cu—N, Cu—O, or Cu—C intermediate by the reaction of the active hydrogen compound with Cu or copper oxide; the ensuing coupling reaction between the Cu—N, Cu—O, or Cu—C intermediate and the organic halide gives the product



It is reported that isolated Cu—N (11*a*), Cu—O (11*b*, *c*), and Cu—C (12) species give corresponding N-, O-, and C-aryl compounds on treating them with aryl halides. In the case of PhCOOH, $Cu(OCOPh)_2(PhCOOH)$ (13) was actually isolated from a mixture of PhCOOH and CuO heated at 240°C, and reactions of Cu(II) benzoates such as $Cu(OCOPh)_2(PhCOOH)$ and Cu(OH)(OCOPh) (14) with aryl halides afforded the corresponding esters. The reaction mechanism expressed by eq. [3] is consistent with the trend that the O—H and N—H compound having higher acidity has a higher reactivity, since a more acidic compound is expected to react with Cu more easily.

Experimental

Material

Cu was prepared by reducing Cu^{2+} with Zn (15). The powder X-ray diffraction spectrum of the copper showed contamination with a small amount of Cu_2O. Use of commercially available Cu gave a somewhat lower yield. Copper oxide (Cu_2O and CuO), active hydrogen compounds, and organic halides were used as purchased from Tokyo Kasei or Wako Co., Ltd.

Condensation reactions

Phthalimide (1.5 g, 10 mmol), phenyl bromide (3.0 g, 19 mmol), and Cu (1.9 g, 30 mmol) were placed in a 50 cm^3 simple type stainless steel autoclave purchased from Taiatsu Glass Co., Ltd. (Type VS-1). The autoclave was heated at 240°C (temperature at the outside of the autoclave) for 12 h. Gas chromatographic analysis of the gas phase showed evolution of a small amount of H_2 during the reaction. Most of the *N*-phenylphthalimide formed was obtained as white needles which were scraped up from the reaction vessel by a spatula. After extracting products further with ethyl alcohol, the needles of *N*-phenylphthalimide and 1 mmol of *p*-methylbiphenyl (standard for glc) were dissolved in the extract. The glc analysis using a Shimadzu GC-3BT gas chromatograph (column SDC-410, 300°C, carrier gas = He) indicated consumption of all phthalimide and formation of 10 mmol (100%) of *N*-phenylphthalimide (cf. Expt. 1). Use of a glass autoclave instead of the stainless steel autoclave gave almost the same results. When the reaction temperature is not high, use of the usual glass tube is also possible.

Other condensation reactions were carried out analogously in the simple type autoclave. Throughout the text, Table 1, and Figs. 1–5 the reaction temperature indicates the temperature at the outside of the autoclave. The temperature at the inside of the autoclave was found to be lower by 10–15°C than the temperature outside the autoclave. All the reactions listed in Table 1, including the reactions using Cu, were carried out in the stainless steel autoclave filled with air (1 atm) containing ca. 0.5 mmol of O_2. For the phenylation of phthalimide, 2-pyrrolidinone, and phenol with the mixture of Cu and PhBr (Expts. 1, 15, and 24, respectively), carrying out the phenylation reactions under N_2 gave almost the same yields but, in the case of the phenylation of less acidic Ph_2NH (Expt. 19) with the mixture of Cu and PhBr (Expt. 19), carrying out the reaction under N_2 gave a considerably lower yield (ca. 40%) than that given in Table 1, indicating the importance of the activation of Ph_2NH and/or Cu by O_2 in the phenylation reaction of Ph_2NH.

Isolation of $Cu(OCOPh)_2(PhCOOH)$ and reactions of Cu(II) benzoates with aryl halides

Heating a mixture of PhCOOH (1.8 g, 15 mmol) and CuO (3.7 g, 47 mmol) in the simple type autoclave at 240°C for 12 h gave H_2O and a solid containing a blue material. Extraction of the blue material with acetone gave a blue solution. Acetone was evaporated in vacuum and the remaining blue material was washed with ether repeatedly to obtain a blue complex, which was characterized as $Cu(OCOPh)_2(PhCOOH)$ (13) by comparing its ir spectrum with that of an authentic sample.

Heating a mixture of $Cu(OCOPh)_2(PhCOOH)$ (1.0 g, 2.3 mmol) and PhBr (0.74 g, 4.7 mmol) in the simple type stainless steel autoclave at 240°C for 12 h gave 1.7 mmol of PhCOOPh, and heating 0.06 mmol of Cu(OH)(OCOPh) (14) with aryl halides gave PhCOOAr in medium yields.

Experimental study of the structure I clathrate hydrate of trimethylene oxide by adiabatic calorimetry

JOHN COMPER, ANDRÉ QUESNEL, COLIN A. FYFE, AND ROBERT K. BOYD
Department of Chemistry, University of Guelph, Guelph, Ont., Canada N1G 2W1
Received October 14, 1981[1]

JOHN COMPER, ANDRÉ QUESNEL, COLIN A. FYFE, and ROBERT K. BOYD. Can. J. Chem. **61**, 92 (1983).

The structure I clathrate hydrate of trimethylene oxide (TMO), of composition $6TMO:46H_2O$, has been studied by adiabatic calorimetry over the temperature range 85–270 K. A thermal anomaly, with the appearance of a classical λ-transition, was observed between about 140–170 K. This anomaly was reproducible, provided precautions were taken against supercooling. No evidence for such a transition has been observed in previous studies using dynamic relaxation techniques (dielectric and nmr relaxation). The temperature range of this anomaly is close to the melting point of a known TMO-rich eutectic, but evidence is presented which argues against interpretation of the present observations in these terms. The previous relaxation measurements indicated a transition involving mobility of the TMO guest, centred at about 100 K. In the present work, the only evidence of this transition consisted of a much worse (order of magnitude) precision in the measured heat capacities in this temperature range. Thermal equilibration is known to be extremely slow in this system. The transition observed in the present work at higher temperatures must therefore correspond to some restructuring of the water host, and this may be connected with anomalous results obtained previously for the far infrared absorptions of water in the TMO clathrate hydrate.

JOHN COMPER, ANDRÉ QUESNEL, COLIN A. FYFE et ROBERT K. BOYD. Can. J. Chem. **61**, 92 (1983).

On a étudié la structure I du clathrate de l'hydrate de l'oxyde de triméthylène (OTM) de composition $6(OTM):46(H_2O)$, par calorimétrie adiabatique dans un intervalle de température allant de 85 à 270 K. On a observé une anomalie thermique avec l'apparition d'une transition λ classique environ entre 140–170 K. Cette anomalie est reproductible et on a pris de précautions pour prévenir la surfusion. On n'a pas obtenu la preuve de l'existence d'une telle transition dans les études antérieures utilisant les techniques de relaxation dynamique (relaxation rmn et diélectrique). Le domaine de température de cette anomalie est voisin du point de fusion d'un eutectique connu riche en OTM, mais on présente des preuves qui vont à l'encontre de l'interprétation des observations actuelles dans ces termes. Les mesures antérieures de relaxation suggèrent la présence d'une transition centrée autour de 100 K impliquant la mobilité du OTM hôte. Dans ce travail, la seule preuve de cette transition consiste en une très mauvaise précision (un ordre de grandeur) dans les capacités calorifiques mesurées dans ce domaine de température. On sait que l'équilibration thermique est très lente dans ce système. La transition que l'on observe dans ce travail à température plus élevée doit cependant correspondre à une certaine restructuration de l'eau hôte et ceci doit être relié aux résultats anormaux obtenus antérieurement par les absorptions, dans l'infrarouge lointain, de l'eau dans le clathrate de l'hydrate du OTM.
[Traduit par le journal]

Introduction

Molecular clathrate solids are crystals in which one species, the "host", forms a strongly-bonded structure which provides cages for individual molecules of a second "guest" species. The guests are firmly held in these cages, although there is seldom anything resembling a chemical bond formed between host and guest. A clathrate hydrate is a special case in which the host consists of an ice-like hydrogen-bonded structure (1) of water molecules. Current understanding of the structures of clathrate hydrates relies upon the work of von Stackelberg (2, 3). Apart from their inherent chemical interest, the practical importance of clathrate hydrates lies in the existence of large natural deposits of clathrate hydrates of methane (1). For the present calorimetric study, however, we chose to work with a system which is more readily handled than the methane case.

Trimethylene oxide (TMO) forms two distinct hydrates. That melting incongruently at about 264 K has been identified (4–6) as a clathrate hydrate of von Stackelberg's structure II (2) with a composition close to $TMO:17H_2O$. The hydrate melting incongruently near 252 K was identified as having von Stackelberg's structure I (3) by dielectric and proton nmr linewidth studies (4, 7) and X-ray powder diffraction measurements.[2] These studies (4,7)[2] suggested a composition, for this structure I hydrate, of $TMO:7\frac{2}{3}H_2O$, i.e. $6TMO:46H_2O$. This composition is consistent with a structure I hydrate in which each of the six larger tetrakaidecahedral cages, in the unit cell, is occupied by a TMO guest, while the two smaller dodecahedral cages are empty. As emphasised previously (7, 9), such a conclusion is reasonable in view of the fairly large size of the TMO molecule (van der Waals diameters of 0.55 nm, and 0.62 nm through the diagonally opposed methylene groups) compared with the mean free diameter (0.51 nm) of the dodecahedral cages. The cubic cell lattice parameter of the TMO structure I hydrate was found[2] to be slightly larger than the range of values found for a range of other structure I hydrates (3), as expected from the anticipated tight fit of TMO guest into even the larger cages (mean free diameter 0.58 nm).

However, a study (6, 10) of the TMO–water phase diagram, using thermal analysis, suggested a composition $TMO:6\frac{1}{2}H_2O$ for the structure I hydrate. Such a composition implies that more than 50% of the smaller cages are occupied by TMO guests. It was emphasised previously (7) that equilibration in the TMO–water system is extremely slow, so that erroneous results could easily arise if insufficient equilibration time were allowed. This discrepancy in the literature was one reason for undertaking the present work. In addition, comparison (9) of the far infrared spectra of structure I hydrates of ethylene oxide, cyclopropane, and TMO, between about 100 and 200 cm^{-1} at 4.3 K, indicates that TMO modifies the absorption by the water

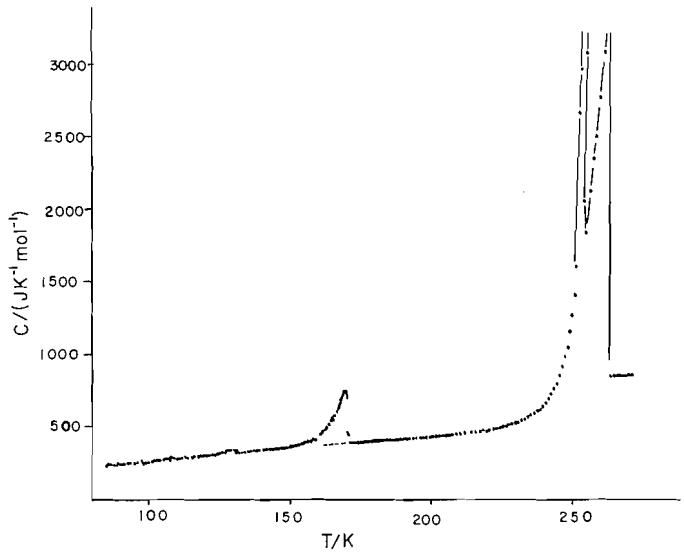

FIG. 1. Heat capacities (C/J K^{-1} mol^{-1}) obtained for structure I hydrate of trimethylene oxide. On this scale, most individual data points cannot be resolved (average temperature rise per determination ~0.5 K). Dashed curve between 162 and 170 K represents supercooling (Series 5 experiments).

molecules in a fashion qualitatively different from that of either of the other two guest species. There appeared (9) to be no unambiguous explanation for this discrepancy. It was hoped that the present work might shed some light on this problem also.

Experimental

The TMO used in these experiments was a product of Columbia Organic Chemicals Co., and was used without further purification other than a single distillation from which the middle third of the distillate was used for the work described here. Analysis by gc/ms (10% SE 30 on 80/100 mesh Chromosorb W-HMDS, 6 foot column, 2 mm id, in Perkin-Elmer Sigma III GC, interfaced to VG Analytical 7070F mass spectrometer with VG 2025 datasystem) revealed *no* impurities attributable to the distilled TMO sample. Several sets of temperature programming/carrier flow-rate conditions were tried, but all yielded a single gc peak corresponding to TMO. This procedure should easily have detected impurities at the 0.1% level, and probably at even lower levels. The calorimeter vessel was loaded by weighing out 20.3955 g of TMO plus 48.5024 g of triply distilled water, a molar ratio of 1:7.664. Both liquids were de-aerated immediately before weighing by bubbling helium gas through them for 1 h. Following loading of the calorimeter via syringes through small tubes of solder attached to the lid, the residual air was flushed out by a stream of helium which was first bubbled through a TMO–water mixture of the same composition. The calorimeter vessel was then sealed off by fusing closed the solder tubes. The vessel was reweighed, and the residual solder was weighed separately. No discrepancy attributable to loss or gain of sample was detected. The calorimeter and peripheral equipment have been described previously (11). After mounting the cryostat, the calorimeter vessel was maintained at 240 ± 2 K continuously for 17 days, in an attempt to ensure complete transformation to structure I solid from structure II plus TMO-rich liquid (7). The vessel was then maintained at 130 ± 5 K for a further 28 days. This conditioning temperature was chosen in the light of the findings (7) of long-term drift in the dielectric properties at temperatures between 40 and 100 K. The subsequent thermal history of the present sample is described with the experimental results.

Results and discussion

In all, 300 independent determinations of heat capacity were made, in the temperature range 85 to 272 K. It is neither convenient nor necessary to tabulate this large quantity of data in detail here,[3] since most of it falls in regions of little interest with no thermal anomalies. Accordingly, a gross overview of the results obtained is shown in Fig. 1, while regions of more immediate interest are plotted in more detail in Fig. 2. A summary of the thermal history of the sample, following its original conditioning (see Experimental section), is shown in Table 1. Following Series 19 (Table 1), the sample was again conditioned at 240 ± 2 K for 14 days, then at 135 ± 5 K for 7 days, and finally at 85 ± 5 K for 16 days. The experiments of Series 20 (Table 1) were then begun. The heat capacities, obtained under pressure of helium of ~1 atm at room temperature, were corrected for the empty calorimeter vessel plus solder and grease, but the precision was such that helium correction was not justifiable.

It is clear from Fig. 2(*b*) that the quality of the data obtained between 85 and 130 K, in Series 20–28 (Table 1), is signifi-

cantly worse than that of any other Series in the present work. The importance of this temperature range lies in the fact that the dielectric and nmr linewidth studies (7) indicate that an ordering transition, in which TMO dipoles assume parallel alignment along the $\bar{4}$ axes of the large cages, occurs below about 105 K. On the other hand, no evidence for such a transition was found in the thermal analysis experiments (6, 10), which covered the range from 77 K to room temperature. Unfortunately, the present work does not significantly clarify the situation in the temperature range 80–120 K. The unexpectedly large scatter in the data of Fig. 2(*b*) might possibly reflect an order–disorder transition of the type proposed (7) if the preconditioning period of 16 days at 85 K (see above) were insufficient. It is known (7) that the dielectric behaviour below 100 K changes on a timescale of weeks, though the present conditioning period was chosen with this in mind. Alternatively, it is possible that the present conditioning *did* suffice to establish the ordered phase at 85 K, but the disordering process is sufficiently slow that thermal equilibrium was not, in fact, established thereafter in our experiments. The experiments of Series 24 (Table 1) were conducted to test whether waiting a longer time for the final temperature measurement, after the heat input, would make any difference to the quality of the data. This was found to not be the case. Thus the outcome of those of the present experiments conducted between 85 and 130 K is disappointing, and merely indicates that some thermal process was not fully equilibrated.

The results obtained between about 240 and 265 K appear to be generally consistent with the published phase diagram (6). The maximum in the heat capacity curve (Fig. 1) observed near 253 K corresponds to the peritectic temperature of 252.5 K observed (6) for the transition (structure I hydrate → structure II hydrate plus TMO-rich liquid). Above this temperature the structure II hydrate progressively melts; a mixture of composition 1TMO:$7\frac{2}{3}H_2O$ should be completely melted (6) at temperatures above about 262 K, in good agreement with the present observations (Fig. 1). Thus, the present work appears to be entirely consistent with the earlier thermal analysis data (6) in this temperature range.

The results obtained in the temperature range 140–175 K (Fig. 2(*a*)) have the appearance of a classical λ-transition. The results of Series 5 (Table 1) show that it is possible to supercool the system below this transition. The baselines above and below the transition extrapolate well into one another, and through the data of Series 5. If the measured heat capacities are taken to be C_P values, the excess enthalpy of the transition ΔH_{excess} is 2360 J mol^{-1}, while the excess enthropy ΔS_{excess} is 13.9 J K^{-1} mol^{-1}. If the transition does, in fact, correspond to a simple order–disorder transition, so that ΔS_{excess} can be interpreted (12) as $R \ln (W_a/W_b)$ where W_a and W_b are the numbers of distinguishable configurations above and below the transition, respectively, then $(W_a/W_b) = 5.3$. If such an interpretation is valid, it is pertinent to note here that the nmr linewidth results (7) indicate that, at the temperature of the thermal transition (169 K at peak), the TMO guest molecules are already reorienting extremely fast, indicated by the closeness of the second moments to the limiting value calculated on the assumption of isotropic rotation of the TMO molecules (7). Thus, if the thermal transition observed here is indeed of this type, it cannot correspond to an ordering of the TMO guests within the cages, but must involve the host lattice in some way.

However, it remains to be established that the observed

transition (Fig. 2 (*a*)) is genuine. In particular, it is disturbing that the temperature of this transition is close to that of an eutectic point observed (6) at 172 K. While it is true that the thermal analysis results (6) are somewhat suspect due to insufficient thermal conditioning (for example, only 1 h at 248 K (6), with no other conditioning process), the establishment of this eutectic point from the TMO-rich side should be relatively unambiguous. Temperature measurements in the present work were made using a Leeds and Northrup platinum resistance thermometer calibrated by the National Research Council of Canada. The discrepancy between 172 K (6) and 169 K (present work) could represent uncertainties in the thermal analysis results (6).

The composition of the TMO–water mixture used in the present work was almost exactly that for the structure I hydrate. In principle, therefore, there should be *no* observable effect from this eutectic. However, the well-documented difficulties (7) in equilibrating this system do raise the possibility of localised inhomogeneities within the sample used in this work. At the simplest conceptual level, there might possibly have existed one region which was TMO-rich, relative to the structure I hydrate composition. (Of course, this would imply the existence of a corresponding water-rich region elsewhere.)

We now examine in more detail the possible interpretation of the thermal transition, observed in the present work (Fig. 2 (*a*)), in terms of eutectic melting. The eutectic point at 172 K involves (6) co-equilibrium of almost pure solid TMO, a liquid phase containing 93% (by mass) of TMO, and solid structure I hydrate. If such an eutectic did in fact occur in the present experiments, the postulated TMO-rich region buried within the structure I hydrate must have given rise to the first two phases mentioned in the preceding sentence, i.e., must have been >93% TMO. This conclusion permits the following rough estimate of the amount of TMO locked up in this postulated inhomogeneity. The enthalpy of fusion of TMO does not appear to have been measured, but that of the homologue ethylene oxide has been found (13) to be 5173 J mol^{-1}. On this basis, the enthalpy of fusion of TMO is estimated to be 5500 J mol^{-1}. The observed eutectic is 80 mol% of TMO, so that 1 mol of TMO in the liquid eutectic is associated with 0.24 mol of H_2O; for this liquid to have been formed by the postulated eutectic melting, 0.97 mol of solid TMO plus 0.03 mol of structure I hydrate must have melted. The enthalpy of fusion of the structure I hydrate, under these conditions, is not known. We estimate this quantity as the sum of the values for the separate components; this should not give rise to gross error, in view of the small amount (3%) of the hydrate involved in the eutectic melt. Thus, finally, our rough estimate for the enthalpy of fusion of 0.97 mol solid TMO plus 0.03 mol structure I hydrate, to form the postulated eutectic liquid containing 1 mol TMO (at 172 K), is $(\Delta H_{fusion}(TMO) + 0.24x\Delta H_{fusion}(H_2O)) =$ 6950 J/(mol of TMO in liquid eutectic). The observed excess enthalpy associated with the observed transition (Fig. 2(*a*)) was 2360 J/(mol of TMO assumed to be present as TMO: $7\frac{2}{3}H_2O$), and 0.3512 mol of TMO were present. The *actual* observed excess enthalpy was thus 829 J. If this observation is interpreted as eutectic melting, approximately 0.12 mol of TMO, or 34% of the TMO in the sample, must have melted to eutectic. This estimate is somewhat crude but the implication, that 30–40% of the TMO in the present sample existed as essentially pure solid TMO, seems unlikely in view of the precautions taken in conditioning the sample. Such an interpretation also implies that a corresponding proportion of the water was present as essentially pure ice, a proposal not borne out by Fig. 1 which shows that melting was complete at temperatures above 263 K or so.

A further consideration which supports this view concerns the baseline values for the heat capacities immediately above and below the transition (Fig. 2(*a*)). As noted above, these extrapolate well into one another, and through the data of Series 5. If, immediately above the transition, the sample did indeed contain a large proportion of liquid as required by the interpretation in terms of eutectic melting, the heat capacity above the transition would be expected to be appreciably higher than predicted by extrapolation of the low-temperature data. The undercooled system investigated in Series 5 was the result (Table 1) of only one hour's equilibration after cooling below the transition; these data are in excellent agreement with the extrapolated baseline. Much more extreme examples of undercooling below higher-order transitions are known (14). On the other hand, the fact that undercooling occurs so readily also presents some difficulties for the eutectic melting theory. It is, of course, possible to undercool a liquid below its freezing point in the absence of nuclei for crystallisation. However, the eutectic interpretation of the observed transition requires that above the transition the liquid eutectic exists in intimate contact, and in equilibrium, with large amounts of one of the solids which solidify out on cooling (structure I hydrate). There should thus have been no shortage of sites to initiate solidification on cooling the sample. An interpretation in terms of host lattice reorganisation meets no such difficulties.

If it is tentatively accepted that the transition near 169 K is indeed a genuine effect, reflecting some change in the host lattice of the structure I hydrate, the earlier data must be re-examined. First, the dynamic relaxation studies (dielectric and nmr) (7) are not always sensitive to minor structural changes. It is conceivable that, if genuine, the transition near 169 K did not show up in these results (7). The X-ray powder diffraction patterns were obtained[2] both at 240 K and at 140 K. In both cases, the cubic lattice characteristic of structure I hydrates was observed, with a slight decrease in the unit cell dimension at the lower temperature.[2] Assuming that the sample used in the X-ray work[2] was not supercooled through the transition near 169 K, although our experience indicates that this is easily done, these results indicate that only a minor structural change can be involved. This is consistent with the fairly small excess enthalpy and entropy changes associated with the transition. It is conceivable that this transition is connected in some way with the anomalous water vibrations in the far infrared, observed (9) for the structure I TMO clathrate hydrate.

Finally the implications, of accepting the thermal anomaly near 169 K as a genuine transition, for the TMO–water phase diagram obtained (6) by thermal analysis must be investigated. As pointed out previously (7), this phase diagram is almost certainly in error, at least in part, in view of the composition TMO:$6\frac{1}{2}H_2O$ deduced (6, 10) for the structure I hydrate. The compositions of the incongruently melting compounds were determined (6, 10) as the compositions giving maximum duration of thermal arrest during the conversion of one solid to another while in equilibrium with a liquid phase (8). As noted previously (7), erroneous analysis may have resulted (6, 10) from the lack of proper equilibration. It is also signifcant that interpretation of the durations of thermal arrest as a function of composition assumed (6, 10) that these plots are triangular, with the composition of the incongruently melting compound given by the apex. Clearly this is not necessarily so (8), and

indeed the plots for the TMO–water system (6, 10) are quite poorly defined near the structure I hydrate composition, being fairly flat there. Since a composition TMO:$7\frac{2}{3}H_2O$ corresponds to 29.6% of TMO by mass, not too different from 33.1% for TMO:$6\frac{1}{2}H_2O$, the possibility of erroneous interpretation from this cause is also real.

Also significant, from the point of view of the present work, is the earlier finding (6, 10) of a "thermal arrest" at 165 K. This thermal arrest was not reproducible, in accord with the present finding of ready supercooling through the transition near 169 K. The original authors (6, 10) interpreted their findings in terms of an eutectic point involving solid TMO, structure II hydrate, and liquid containing about 81% by mass of TMO. Such an eutectic point would be observable only in mixtures in which lack of proper equilibration at ~240 K had prevented structure I hydrate from being formed. In view of the very long equilibration times used in the present work (about three times longer than that used in the dielectrics and nmr work (4)), we do not consider it likely that structure II hydrate played any significant role in the present work at these temperatures. However, an alternative explanation of these earlier observations (6, 10) would involve a real higher-order transition in the structure I hydrate, as postulated here. In the absence of more experimental details of the thermal arrest studies, it does not seem possible to examine this proposal further.

In summary, the most suggestive finding of the present calorimetry studies is the proposed existence of a λ-transition in the structure I hydrate of TMO, peaking near 169 K. The most likely interpretation of such a transition appears to involve changes in the host lattice. While it is not possible to entirely rule out an interpretation of the observations in terms of eutectic melting in localised TMO-rich inhomogeneities, the evidence does appear, on balance, to oppose such a view. If genuine, the observed transition might be connected with anomalous results obtained (9) for the far infrared absorptions of the water in this system, and with a non-reproducible thermal arrest observed (6, 10) near 165 K. On the other hand, it is disturbing that dielectric and nmr measurements (7) did not find any evidence for this transition. At the very least, the present work re-emphasises the necessity for extreme care in the preparation and conditioning of this system.

A comparison of methyl and phenyl substituent effects on the gas phase basicities of amines and phosphines

S. IKUTA[1] AND P. KEBARLE[2]

Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received June 2, 1982

S. IKUTA and P. KEBARLE. Can. J. Chem. **61**, 97 (1983).

The proton affinities of phenyl phosphine and cyclohexylphosphine were measured by determining the equilibrium constants of proton transfer equilibria with a pulsed electron beam high ion source pressure mass spectrometer. These proton affinities combined with values for methyl and phenyl phosphines and the analogous amines provide an interesting comparison of the methyl and phenyl substituent effects on the basicities of phosphine and ammonia. Methyl substitution increases the basicity of both ammonia and phosphine; however, the increase is significantly larger for the phosphine. Phenyl substitution increases the basicity of ammonia and phosphine and the increase for phosphine is very much larger. Calculations at the STO-3G, 4-31G, STO-3G*, and 4-31G* (* with *d* orbitals) for PH_3, $MePH_2$, $PhPH_2$, the protonated species, and the nitrogen analogues predict proton transfer reaction energies in good agreement with the experimental results. A shortening of the C—P bond is predicted for protonation of $MePH_2$ and particularly $PhPH_2$, while a lengthening of the C—N bond is predicted for the corresponding nitrogen compounds. The much stronger increase in proton affinity of the phosphines caused by phenyl substitution is due to the stabilization of the phenyl phosphonium ion by π donation from the phenyl group to the empty orbitals of phosphorus in the PH_3^+ group; in contrast, in the amines, it is the free base aniline which is stabilized by conjugation of the nitrogen lone pair with the aromatic ring. This stabilization of the free base is less important in phenyl phosphine. The participating empty orbitals of phosphorus in the conjugation of phenyl with PH_3^+ in phenyl phosphonium are mostly π^* with some πd participation. The stabilization of the aniline free base contributes considerably more than the conjugation in the phosphonium ion, to the phenyl substituent difference for the amines and phosphines. The factors involved in the bigger substituent effect of methyl in the phosphines are somewhat similar to those for phenyl: stabilization of the methyl amine by conjugation of the nitrogen lone pair with empty orbitals of CH_3 and stabilization of the $CH_3PH_3^+$ by hyperconjugation. An alternate description can be given in terms of hybridization changes.

S. IKUTA et P. KEBARLE. Can. J. Chem. **61**, 97 (1983).

On a mesuré les affinités pour le proton de la phénylphosphine et de la cyclophosphine en déterminant les constantes des équilibres de transfert du proton à l'aide d'un spectromètre de masse à faisceau d'électrons pulsés avec une source d'ions à haute pression. Ces affinités pour le proton combinées aux valeurs des méthyl- et phényl-phosphines et des amines analogues fournissent une comparaison intéressante des effets des substituants méthyle et phényle sur les basicités de la phosphine et de l'ammoniac. La substitution du méthyle augmente la basicité de la phosphine et de l'ammoniac; l'augmentation est plus forte pour la phosphine. La substitution du phényle augmente la basicité de l'ammoniac et de la phosphine et l'augmentation dans le cas de la phosphine est de beaucoup plus forte. Les calculs aux niveaux STO-3G, 4-31G, STO-3G* (avec les orbitales *d*) pour le PH_3, le $MePH_2$, le $PhPH_2$, les espèces protonées et les analogues azotés prédisent des énergies de réaction de transfert du proton en parfait accord avec les résultats expérimentaux. On a prédit un racourcissement de la liaison C—P pour la protonation de $MePH_2$ et particulièrement celle du $PhPH_2$ tandis que l'on prédit un élongation de la liaison C—N dans le cas des composés azotés correspondants. L'augmentation beaucoup plus forte de l'affinité des phosphines pour le proton provoquée par le substituant phényle est due à la stabilisation de l'ion phénylphosphonium par transfert π du phényle aux orbitales vacantes du phosphore du groupe PH_3^+; au contraire dans le cas des amines, c'est la base libre aniline qui est stabilisée par la conjugaison du doublet libre de l'azote avec le noyau aromatique. Cette stabilisation de la base libre est moins importante dans le cas de la phénylphosphine. Les orbitales vacantes du phosphore participant dans la conjugaison du phényle avec PH_3^+ du phénylphosphonium sont principalement du type π^* avec une participation occasionnelle des orbitales πd. La stabilisation de l'aniline sous forme de base libre contribue d'avantage que la conjugaison dans l'ion phosphonium à la différence du substituant phényle pour les amines et les phosphines. Les facteurs impliqués dans le plus grand effet de substituant du méthyle dans les phosphines sont quelque peu semblables à ceux du phényle. Ce sont la stabilisation de la méthylamine par conjugaison du doublet libre de l'azote avec les orbitales vides du CH_3 et la stabilisation du $Ch_3PH_3^+$ par hyperconjugaison. On peut faire alterner une description en fonction des changements d'hybridation.

[Traduit par le journal]

Introduction

We reported recently (1) measurements of the gas phase basicities of Me_2PhP, $MePh_2P$, and Ph_3P. The present work gives experimental determinations of the basicities of phenyl phosphine $PhPH_2$ and cyclohexyl phosphine. The basicities of PH_3, $MePH_2$, Me_2PH, and Me_3P (2–4) as well as the basicities of almost all analogously substituted amines (3) are available in the literature. On the basis of these data it is possible to make an interesting comparison between the methyl and phenyl substituent effects in ammonia and phosphine. In order to obtain additional insights, molecular orbital calculations for some key bases and their onium ions were also performed.

Experimental

The gas phase basicity measurements were performed with a pulsed electron beam high ion source pressure mass spectrometer. The measurements of the proton transfer equilibria were similar to those described in the preceding publication (1).

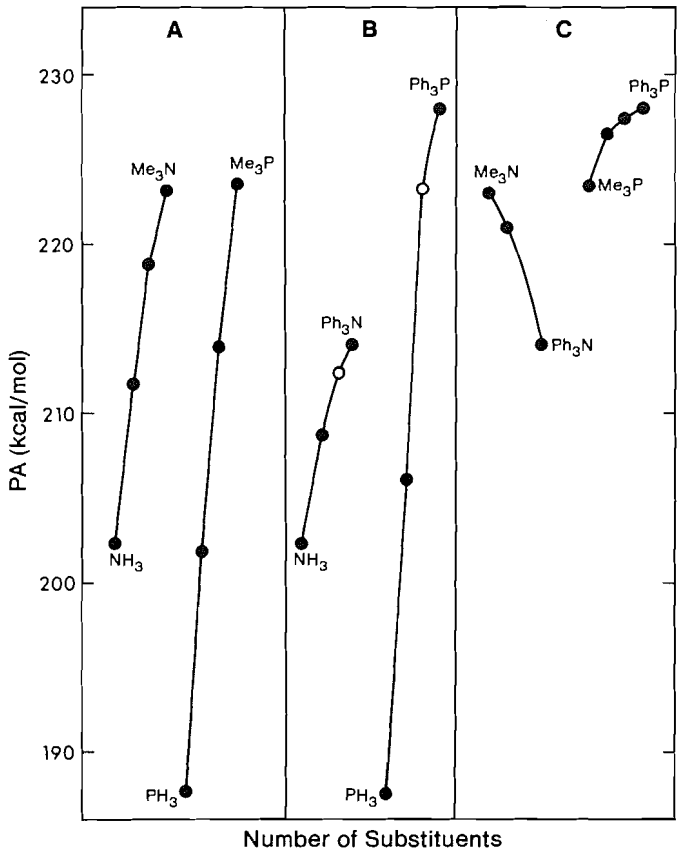

FIG. 1. Changes of proton affinities of amines and phosphines with methyl and phenyl substitution. (*A*) Methyl increases the proton affinity of both ammonia and phosphine but the increase for the phosphine is larger. (*B*) Phenyl increases the proton affinity of ammonia and phosphine but the increase for the phosphine is much larger. (*C*) Progressive replacement of methyl by phenyl decreases the proton affinity of trimethylamine while an increase for trimethylphosphine is observed. ●, experimental results from Table 1. ○, interpolated values.

The proton equilibria measured were:

[1] $PhPH_3^+ + PhNH_2 = PhPH_2 + PhNH_3^+$
$\Delta G_1^0 = -2.7 \pm 0.2$ kcal/mol

[2] $PhPH_3^+ + cyclo\text{-}C_6H_{11}PH_2 = PhPH_2 + cyclo\text{-}C_6H_{11}PH_3^+$
$\Delta G_2^0 = -2.5 \pm 0.5$ kcal/mol

Measurements were made at temperatures between 70 and 300°C. The free energy changes observed at different temperatures were fairly close and showed no consistent trend with temperature which indicates that the entropy change in both reactions is small, i.e. $\Delta G^0 \approx \Delta H^0$. Equilibrium [2] showed some dependence of the equilibrium constant on the ratio of the neutral bases. The cause for this was not discovered. The larger error limit for that determination was selected in order to given an indication of that problem.

Calculations

The total energies of the various compounds were obtained after geometry optimizations. The PH_3 and PH_4^+ geometries were completely optimized using the energy gradient method (6) with the STO-3G (7), STO-3G* (8), 4-31G (9), and 4-31G* basis set. A *d* polarization function with $\zeta = 0.43$ (10) was added to obtain 4-31G*. The CH_3PH_2 and $CH_3PH_3^+$ were fully optimized with the energy gradient method in the STO-3G and STO-3G* calculations. Parabolic 3 point fitting was used in the optimized geometry in the 4-31G calculation. For 4-31G* the 4-31G geometry was used.

TABLE 1. Proton affinities of methyl and phenyl phosphines and the corresponding amines

Compound	PA (kcal/mol) P	PA (kcal/mol) N

[a]Proton affinities based on $PA(NH_3) = 202.3$ kcal/mol Kebarle (5) Beauchamp (3). This values is not well established; however, only the relative proton affinities are of interest in this work.
[b]Staley and Beauchamp (2, 3).
[c]This work.
[d]Kebarle (5), see also Beauchamp (3).
[e]Munson (4).

The energy gradient method was used in $C_6H_5PH_2$ and $C_6H_5PH_3^+$ optimizations to obtain the STO-3G geometries; however, the benzene ring was taken as invariant with r(C—C) = 1.397 Å, r(C—H) = 1.084 Å.

NH_3 and NH_4^+ were optimized completely with the energy gradient method, CH_3NH_2 and $CH_3NH_3^+$ were optimized by the energy gradient method when STO-3G was used while parabolic fitting was used with 4-31G. $C_6H_5NH_2$ and $C_6H_5NH_3^+$ were optimized in the same manner as the corresponding phosphorus compounds.

The calculations were performed with the Gaussian 70 (11), HONDO 5 (12), and Monster Gauss 81 (13) programs.

Results and discussion

The effect of methyl and phenyl substitution on the basicities of ammonia and phosphine is shown in Fig. 1. The proton affinity of phosphine is some 15 kcal/mol lower than that of ammonia. Methyl substitution increases the basicities of both compounds (see Fig. 1*A*); however, the effect of methyl is much larger for the phosphines. Thus, while the proton affinity of phosphine is 15 kcal/mol lower than the proton affinity of ammonia, after triple methyl substitution, the proton affinity of trimethylphosphine has caught up with and even slightly surpassed the proton affinity of trimethylamine. The difference between the substituent effects in ammonia and phosphine is even more dramatic for the phenyl substituent. Substitution with phenyl increases the basicities of both ammonia and phosphine; however, the increase for the proton affinity of phosphine is so much larger that the proton affinity of the phosphine almost catches up with the proton affinity of the amine after the first phenyl substitution. By the time the third phenyl has been put on, the proton affinity of the phosphines is found to exceed that of the amine by some 14 kcal/mol (Fig. 1*B*). A comparison of the replacement of methyl by phenyl is shown in Fig. 1*C*. In the amines, replacement of methyl by phenyl lowers the basicity, for the phosphines the opposite is true. Thus, tri-

[a]To calculate the total energies fully optimized geometries were used except for the systems whose energies are shown in parentheses. The total energies are given in atomic units 1 au = 627.2 kcal/mol.
[b]The geometry except that of the benzene ring was optimized.
[c]STO-3G geometries were used.
[d]The exponent for the polarization function was 0.39.
[e]The exponent for the polarization function was 0.43.
[f]4-31G geometries were used.
[g]Optimized geometry parameters given in Table 3.

methylamine and trimethylphosphine have about the same proton affinity, while the proton affinity of triphenylphosphine is very much larger than that of triphenylamine.

The proton affinities used in Fig. 1 were obtained from Table 1, some are literature values (1−4), others are results of the present work (see Experimental). The proton affinity of cyclohexylphosphine (Table 1) can be compared with that of the corresponding amine. The cyclohexyl substituent increases the basicities of NH_3 and PH_3, the increase being larger for the phosphine. The effect is similar to that observed for methyl substitution.

In order to obtain additional insights on the differences between the amine and phosphine basicities described above, we performed *ab initio* calculations for the neutral and protonated bases: ammonia, methylamine, aniline, and the corresponding phosphines. Some details about the calculations are given in the Calculations section. The total energies $E(B)$ and $E(BH^+)$ obtained from the calculations are shown in Table 2. The geometries are given in Table 3. The proton affinities predicted by the calculation can be obtained from the difference: $E(B) - E(BH^+)$. The resulting proton affinities are not very close to the experimental values, even for the best basis set used (4-31G, 4-31G*). The major source of error, when a good basis set is used, is the neglect of zero point energy, which can be as large as 10 kcal/mol (14). Much more useful are the energy changes ΔE for the (isodesmic) proton transfer reactions, shown in Table 4. Fairly good agreement with the experimental enthalpy change is observed with nearly all basis sets. For the phosphines, use of the more extensive 4-31G and 4-31G* leads to a small improvement of the agreement between theory and experiment. One important benefit from the data in Table 4 is the clarification of the site of protonation that they provide. It has been shown that protonation of the nitrogen in aniline is more favorable (by ~1 kcal/mol) than protonation of the ring (15, 16). Without the present calculations for the phenyl phosphine it would not have been completely straightforward to decide whether ring or substituent protonation is more favorable. The agreement of the calculated ΔE with the experimental result demonstrates that phosphorus protonation has occurred.

There has been considerable discussion in the literature (3, 17) of the methyl and phenyl substituent effects in ammonia. Thus, it has been recognized that the dominant effect causing the increase of basicity with methyl substitution is the stabilization of the onium ion by the polarizability due to methyl. Probably the most satisfactory proof of that effect is given by the protonation energy decomposition method of Morokuma (18). Interestingly, the polarizability contribution in the series $NH_3 \rightarrow Me_3N$ was properly assessed only at the 4-31G level of calculation, STO-3G did not adequately predict this effect.

The fact that methyl provides an increase of basicity in the $PH_3 \rightarrow Me_3P$ series that is larger than the increase in the ammonia series can not be explained by larger polarizability increases in the phosphine series since these changes, if anything, should be smaller. Beauchamp (2) has pointed out the essential factors responsible for the stronger methyl effect in the phosphines. Conversion of the H—N bonds of ammonia to C—N bonds requires an increase of the bond length and this is achieved by an increase of the p character of the C—N bond(s) at the expense of the p character of the lone pair. The latter corresponds to a shrinkage of the lone pair and leads to a decrease of the dipole moment in the series NH_3-Me_3N. The lone pair becomes less suited for protonation and a partial rehybridization to increase the p character of the lone pair occurs on protonation. This has an adverse effect on the proton affinity of the methylated species. The situation is different for the phosphines, since already in PH_3 rather long bonds are required, these have strong p character which leaves the lone pair with strong s character. Therefore, methylation can induce only a very minor decrease of the p character of the lone pair. Thus, the differential effect of larger and larger increases of p character on protonation is mostly absent in the series PH_3, Me_3P.

Calculated p/s ratios of the lone pair orbital obtained with localized orbital analysis by Boys (19) method using the STO-3G basis set are shown below. They follow all the qualitatively

predicted changes of the rehybridization argument. An approximate estimate of the energy cost of the rehybridization can be made from Morokuma's (18) energy decomposition scheme, by assuming that the lone pair hybridization change will show up mostly in the term ES corresponding to the electrostatic energy of attraction between the proton and the base. The change of this term from NH_3 to $MeNH_2$ is found (18) to be ~+3 kcal/mol while for the corresponding phosphines the change should be much less, i.e. ~0.5 kcal/mol. The difference of ~2.5 kcal/mol is close to the experimentally and theoretically calculated differences of the proton transfer reactions, see Table 4. This suggests that rehybridization changes are the major cause for the smaller methyl effect on the basicity of the amines as compared to the phosphines.

The large difference in the phenyl substituent effect for NH_3

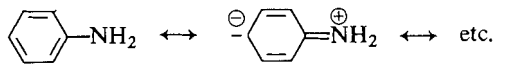
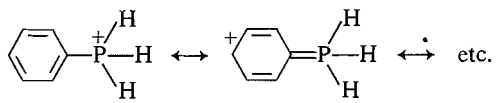
and PH_3 can arise mostly from two factors. It has long been recognized that aniline is stabilized by conjugation as shown below (structure **I**). Since this stabilization of the base does not



I

occur in the protonated onium ion, a reduction of basicity results. Due to a mismatch between the bonding orbitals of the phosphorus and the π orbitals of the aromatic ring the stabilization in **I** is expected to be much less in phenyl phosphine. A second factor is conjugation which stabilizes specifically the phosphonium ion as shown in structure **II**. This conjugation



II

will not be important in the anilinium ion, since nitrogen does not have suitable empty orbitals to accept π donation from the aromatic system.

Results pertinent to the discussion above are given in Table 5, which gives the calculated electron transfer between occupied and unoccupied orbitals in RX where R is either methyl or phenyl and X is NH_2, NH_3^+ or PH_2, PH_3^+. Examining first aniline, we find a large electron transfer (0.088) from NH_2 to phenyl which should correspond to the conjugation **I**. The corresponding transfer in phenyl phosphine is much smaller, i.e., only about one third the aniline effect. The transfer of electrons from phenyl to PH_3^+ corresponding to conjugation **II** is also a relatively large effect, the analogous transfer from phenyl to NH_3^+ is predicted to be only half as big. Thus, the results in Table 5 are supportive of the differential effect of conjugation **I** in reducing the basicity of aniline but not of phenyl phosphine and conjugation **II** in selectively increasing the stability of the phenyl phosphonium ion. The numbers in Table 5, if taken at face value, indicate that the difference of the phenyl substituent effect between ammonia and phosphine is much more due to the selective stabilization of aniline by conjugation **I** than to the selective stabilization of the phenyl phosphonium ion by conjugation **II**.

The conjugative stabilization **II** of the phenyl phosphonium ion may be thought to involve significant phosphorus *d* orbital participation. Since the STO-3G basis set does not include *d* orbitals for phosphorus, the importance of conjugation **II** in Table 5 may be thought to be grossly underestimated. Very probably this is not the case. We saw earlier in Table 4 that the 4-31G calculation gives very good agreement with the experimentally measured enthalpy change for reaction [2]. The 4-31G also does not contain *d* orbitals. It is true that in Table 4, STO-3G*, with *d* orbitals, gives better agreement with the ΔH than STO-3G, but in the case of STO-3G, addition of *d* orbitals provides an important increase of the flexibility of the basis set and needs not to mean true *d* orbital participation. The conjugation **II** seems to be due mostly to the empty π^* orbitals of the phosphorus which happen to match somewhat with the π orbitals of benzene.

The results in Table 5 for methyl substitution in NH_3 and PH_3 run parallel to the discussed effects for phenyl substitution. Thus, there is a significant stabilization of the neutral base, methyl amine, by conjugation of empty orbitals on methyl with occupied orbitals on NH_2, just as was the case for aniline, and there is a noticeable stabilization by conjugation of occupied orbitals of methyl with unoccupied orbitals in PH_3^+, for the methyl phosphonium ion, just as was the case for phenyl phosphonium, only the effects for methyl are considerably smaller than those for phenyl. The respective C—N and C—P bond length changes with protonation are also parallel for methyl and phenyl. The C—N bonds for both methyl and phenyl increase in length, while the C—P bonds decrease in length, with pro-

$PhNH_2$	0.246	0.080
$PhPH_2$	0.184	0.228

tonation. Table 6 summarizes these bond lengths as predicted by STO-3G. The bond length changes predicted by 4-31G, where available (Table 3), support the same trends. The Mulliken electron populations between C—N resp. C—P are also given in Table 6. Comparing the changes in these bond populations with the changes in Table 5 one finds that the changes of Table 5, outlined in the discussion above, make an important contribution also to the total Mulliken bond population changes. This indicates that the dominant conjugations of Table 5 are largely responsible for the opposite C—N resp. C—P bond length changes on protonation of the bases.

Earlier in this discussion, the smaller basicity increasing effect of methyl on ammonia, as compared to phosphine, was explained on the basis of rehybridization, i.e. a decrease of *p* character of the lone pair in methyl amine. The data in Table 5 for methyl amine predict conjugation between the NH_2 group as electron donor and CH_3 as acceptor. The two explanations appear different only because they are cast in the different language of two bonding models that chemists use. The situation is analogous regarding the stabilization of the methyl phosphonium ion. There is (a small) stabilization by conjugation with CH_3 acting as electron donor and PH_3^+ as the acceptor (Table 5). This is recognized as hyperconjugation, but it can also be described as a rehybridization.

The oxidation of a nickel(II) oxime complex by polypyridine iron(III) ions in acidic aqueous media. Formation of a Ni(IV) species

D. H. MACARTNEY[1] AND A. MCAULEY[2]
Department of Chemistry, University of Victoria, Victoria, B.C., Canada V8W 2Y2

Received December 29, 1981

D. H. MACARTNEY and A. MCAULEY. Can. J. Chem. **61**, 103 (1983).

The kinetics of the oxidation of a nickel(II) oxime complex by a series of iron(III) phenanthroline and bipyridine cations, $Fe(LL)_3^{3+}$, have been investigated. The overall reaction

$$Ni(II)(H_2L)^{2+} + 2Fe(LL)_3^{3+} \rightarrow Ni(IV)L^{2+} + 2Fe(LL)_3^{2+} + 2H^+$$

is considered to take place via two one-electron steps, the first (rate-determining) process yielding $Ni(III)(H_2L)^{3+}$ being followed by very rapid oxidation to the nickel(IV) product. The second order rate constants at 25°C in 0.50 *M* *p*-toluenesulphonic acid are: $Fe(dmbpy)_3^{3+}$, $1.32 \times 10^3\ M^{-1}\ s^{-1}$; $Fe(dmphen)_3^{3+}$, $3.73 \times 10^3\ M^{-1}\ s^{-1}$; $Fe(bpy)_3^{3+}$, $3.20 \times 10^4\ M^{-1}\ s^{-1}$; $Fe(mphen)_3^{3+}$, $6.83 \times 10^4\ M^{-1}\ s^{-1}$; $Fe(phen)_3^{3+}$, $9.16 \times 10^4\ M^{-1}\ s^{-1}$; and $Fe(cphen)_3^{3+}$, $5.6 \times 10^5\ M^{-1}\ s^{-1}$. The reactions are outer-sphere in character. The rate of the corresponding cross reaction of nickel(II) species with $Ru(bipy)_3^{3+}$ ($k_{12} = 1.1 \times 10^6\ M^{-1}\ s^{-1}$) has also been measured. Activation parameters have been incorporated in a Marcus theory correlation to yield information ($k_{11} \sim 3 \times 10^3\ M^{-1}\ s^{-1}$) for the $Ni^{II}(H_2L)^{2+}/Ni^{III}(H_2L)^{3+}$ electron exchange reaction. This value is compared with exchange parameters for Ni^{II}/Ni^{III} tetraaza-macrocycle and other similar systems.

D. H. MACARTNEY et A. MCAULEY. Can. J. Chem. **61**, 103 (1983).

On a étudié la cinétique de l'oxydation d'un complexe oxime de nickel(II) par une série de cations phénanthroline et bipyridine de fer(III), $Fe(LL)_3^{3+}$. On considère que la réaction globale suivante:

$$Ni(II)(H_2L)^{2+} + 2Fe(LL)_3^{3+} \rightarrow Ni(IV)L^{2+} + 2Fe(LL)_3^{2+} + 2H^+$$

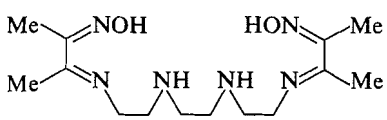
se fait par l'intermédiaire de deux étapes à un électron, la première (qui est l'étape déterminante) donne le Ni(III) $(H_2L)^{3+}$ est suivie de l'oxydation rapide en un composé de nickel(IV). Les constantes de vitesse d'ordre deux à 25°C dans l'acide *p*-toluènesulfonique 0,50 *M* sont de $Fe(dmphen)_3^{3+}$, $1,32 \times 10^3\ M^{-1}\ s^{-1}$; $Fe(dmphen)_3^{3+}$, $3,73 \times 10^3\ M^{-1}\ s^{-1}$; $Fe(bpy)_3^{3+}$, $3,20 \times 10^4\ M^{-1}\ s^{-1}$; $Fe(mphen)_3^{3+}$, $6,83 \times 10^4\ M^{-1}\ s^{-1}$; $Fe(phen)_3^{3+}$, $9,16 \times 10^4\ M^{-1}\ s^{-1}$ et $Fe(cphen)_3^{3+}$, $5,6 \times 10^5\ M^{-1}\ s^{-1}$. Les réactions ont un caractère périférique. On a également mesuré la vitesse de la réaction croisée des espèces de nickel(II) avec le $Ru(bipy)_3^{3+}$ ($k_{12} = 1,1 \times 10^6\ M^{-1}\ s^{-1}$). On a incorporé les paramètres d'activation dans une corrélation de la théorie de Marcus pour obtenir l'information sur la réaction d'échange d'électron du $Ni^{II}(H_2L)^{2+}/Ni^{III}(H_2L)^{3+}$ ($k_{11} \sim 3 \times 10^3\ M^{-1}\ s^{-1}$). On a comparé cette valeur avec les paramètres d'échange du tétraazamacrocycle Ni^{II}/Ni^{III} et d'autres systèmes semblables.

[Traduit par le journal]

Introduction

Investigations of metal complexes containing nickel in oxidation states greater than +2 have been of considerable interest recently (1–4). Significant progress has been made in the stabilisation and description of nickel(III) complexes, with primary attention being paid to compounds containing tetraaza-macrocyclic ligands (5–7). In the case of nickel(IV) there are fewer reported complexes (8). However, compounds containing dioxime ligands have been prepared and studied (3, 8–11).

For the stabilisation of nickel(IV), a hexadentate dioxime ligand of type **I** has been employed (9). This ligand,



I

3,14-dimethyl-4,7,10,13-tetraazahexadeca-3,13-diene-2,15-dioxime (H_2L), forms pseudo-octahedral NiN_6 complexes with nickel(II), (III), and (IV). The preparative oxidation of the nickel(II) oxime complex, $Ni(H_2L)^{2+}$, to the nickel(IV) species has been accomplished both electrochemically ($E°(Ni^{IV}/Ni^{II}) = 0.95$ V) (10) or chemically with nitric acid (9).

With the exception of a recent study (12) in these laboratories of the oxidation of $Ni(H_2L)^{2+}$ by Co^{3+}, no kinetic data on the oxidation of nickel(II) oximes in aqueous solution have been reported previously.

In the present investigation the kinetics of the oxidation of $Ni^{II}(H_2L)^{2+}$ by a series of substituted polypyridine (1,10-phenanthroline and 2,2′-bipyridine) complexes of iron(III), $Fe(LL)_3^{3+}$, were examined. These complexes have been used in a number of rate studies with a variety of reductants, including Fe^{2+} (13), I^- (14), and ascorbic acid (15). The insolubility of the $Fe(LL)_3^{3+}$ species in non-coordinating perchlorate media prevents their use with a number of reductants. In the present study, however, both the reductant, $Ni(H_2L)^{2+}$, and the oxidants are soluble in the *p*-toluenesulphonate medium employed.

The activation parameters for this reaction system may be used in an estimation of the self-exchange parameters of the Ni^{II}/Ni^{III} oxime couple by means of Marcus theory correlations. These parameters are of interest for comparison with the values determined for the Ni^{II}/Ni^{III} tetraaza-macrocycle exchange reactions (16, 17), where there is an increase in coor-

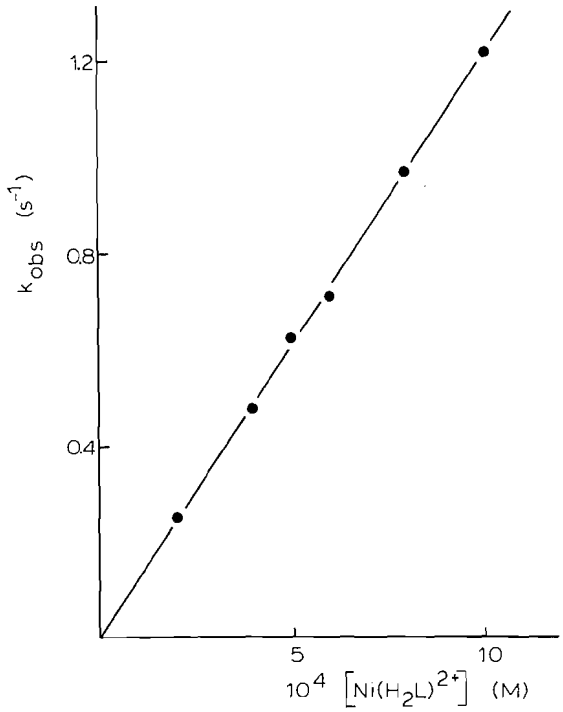

FIG. 1. Dependence of k_{obs} on $[Ni(H_2L)^{2+}]$ in the reaction with $Fe(dmbpy)_3^{3+}$ at 25°C, $[H^+] = 0.50\ M$, $I = 1.00\ M$ (H^+/Li^+ *p*-toluenesulphonate).

dination number on oxidation similar to the axial solvent interactions seen to be of importance in the attainment of nickel(III) for deprotonated peptide complexes (18).

Experimental

Reagents

The nickel(II) oxime complex $Ni(H_2L)(ClO_4)_2$, was prepared (9) by the addition of the ligand H_2L (H_2L = 3,14-dimethyl-4,7,10,13-diene-2,15-dione dioxime (19) to a methanol solution of nickel(II) perchlorate, followed by recrystallization from water. Analysis of the product, performed by the Canadian Microanalytical Service, was satisfactory; obsd. (calcd.) C 29.71 (29.49), H 5.02 (4.91), N 14.75 (14.70).

The iron(II) complexes, $[Fe(LL)_3](ClO_4)_2$, containing substituted 1,10-phenanthroline and 2,2′-bipyridine ligands (LL) were prepared by mixing solutions of ammonium ferrous sulphate and the polypyridine ligands (G. F. Smith) in methanol. The perchlorate salts of the iron(II) complexes were precipitated by the addition of an excess of sodium perchlorate. The iron(III) species, $Fe(LL)_3^{3+}$, were prepared in situ by the addition of 0.75 equivalents of Co^{3+} (in 4 *M* $HClO_4$) to acidic aqueous solutions of $Fe(LL)_3^{2+}$ ($2-4 \times 10^{-5}\ M$).

The reactions were studied in *p*-toluenesulphonate media, in which both the reductant and oxidants are soluble. The acid concentration was maintained at 0.50 *M* with recrystallized *p*-toluenesulphonic acid (Fisher). The ionic strength was constant at 1.00 *M* using lithium *p*-toluenesulphonate, prepared by neutralisation of the acid with lithium carbonate.

Kinetic studies

The kinetic experiments were carried out using a stopped-flow apparatus described previously (20). Reactions were studied at temperatures between 16.4 and 31.0°C with thermostating to ±0.05°C. Pseudo-first-order conditions of excess $[Ni(H_2L)^{2+}]$ were employed and the reactions were monitored at 500 nm where both $Ni^{IV}L^{2+}$ and $Fe(LL)_3^{2+}$ absorb strongly. Absorbance data derived from photomultiplier output were collected by a PCM-12 mini-computer. Plots of ln $(A_\infty - A_t)$ against time were linear for three or more half-lives.

Cyclic voltammetry

The reduction potentials of the $Fe(LL)_3^{2+}$ complexes in 1.00 *M* *p*-toluenesulphonic acid were determined by cyclic voltammetry. A Princeton Applied Research Model 173 instrument with a PAR Model 175 Universal Programmer were employed in conjunction with platinum working and counter electrodes and a saturated calomel electrode. Similar measurements were also made on the nickel(II) and nickel(IV) species. In this case the cyclic voltammograms observed were dependent on the pH of the solution. For runs at high acidity the Ni(IV) complex was used owing to possible hydrolysis of the nickel(II) species under these conditions. At higher pH's where two one-electron transfer reactions were observed, acetate and phosphate buffered solutions were employed.

Results

Reaction in solution of nickel(II) complex with the oxidants studied produced an immediate change in spectrum consistent with the formation of the nickel(IV) cation. In solutions of 0.5 *M* $[H^+]$, the products were stable for at least several hours. The stoichiometry of the oxidation is represented (to ±4%) by the reaction

$$[1]\quad Ni(II)(H_2L)^{2+} + 2Fe(LL)_3^{3+} \rightarrow Ni(IV)L^{2+} + 2Fe(LL)_3^{2+} + 2H^+$$

Oxidants used in this study may be represented by the following: $Fe(dmbpy)_3^{3+}$, (dmbpy) = 4,4′-dimethyl-2,2′-bipyridine; $Fe(dmphen)_3^{3+}$, (dmphen) = 4,7-dimethyl-1,10-phenanthroline; $Fe(bpy)_3^{3+}$, (bpy) = 2,2′-bipyridine; $Fe(mphen)_3^{3+}$, (mphen) = 5-methyl-1,10-phenanthroline; $Fe(phen)_3^{3+}$, (phen) = 1,10-phenanthroline; and $Fe(cphen)_3^{3+}$, (cphen) = 5-chloro-1,10-phenanthroline.

Owing to the insolubility of the reactants in perchlorate media, the investigation was carried out using $I = 1.0\ M$ *p*-toluenesulphonate, pts^-, with Lipts = Hpts = 0.50 *M*. Under the pseudo-first-order conditions of excess reductant, the order of reaction was established as unity with respect to each reagent. In Fig. 1 is shown the first-order dependence of k_{obs}, the observed rate constant, on the concentration of $Ni(H_2L)^{2+}$ for the reaction of $Fe(dmbpy)_3^{3+}$ at 25°C. Although solid samples of some of the iron(III) complexes were prepared and used, it was found more convenient to prepare $Fe(LL)_3^{3+}$ ions in situ in most cases by oxidation of the corresponding $Fe(LL)_3^{2+}$ complex by a stoichiometric deficiency of Co_{aq}^{3+}. No dependence of k_{obs} on either Co^{2+} or $Fe(LL)_3^{2+}$ concentrations was observed. In the reaction with $Fe(phen)_3^{3+}$, for example, the rate constant for the $Fe(phen)_3^{3+}$ solution prepared by Co^{3+} oxidation ($9.16 \times 10^4\ M^{-1}\ s^{-1}$) is in agreement with the value obtained with a solution prepared from solid $[Fe(phen)_3](ClO_4)_3$ ($8.95 \times 10^4\ M^{-1}\ s^{-1}$).

There was also no hydrogen ion dependence observed in this reaction system. The rate constant measured for $Fe(dmbpy)_3^{3+}$ at $[H^+] = 0.10\ M$ ($1.32 \times 10^3\ M^{-1}\ s^{-1}$) agrees with the value obtained at $[H^+] = 0.50\ M$ ($1.25 \times 10^3\ M^{-1}\ s^{-1}$). The rate expression may therefore be written as

$$[2]\quad d[Ni^{IV}L^{2+}]/dt = k[Ni(H_2L)^{2+}][Fe(LL)_3^{3+}]$$

The second-order rate constants for the six oxidants, measured at several temperatures together with the corresponding activation parameters are presented in Table 1.

Cyclic voltammetry of $Fe(LL)_3^{2+/3+}$

The reduction potentials of the $Fe(LL)_3^{3+}$ complexes in 1.00 *M* *p*-toluenesulphonic acid were measured using cyclic voltammetry. Reversible one-electron traces were observed in

[a] Measured in 1.0 *M* *p*-toluenesulphonic acid.
[b] In kcal mol^{-1}.
[c] Derived using eq. [17], $\Delta G^*_{22} = 3.5$ kcal mol^{-1} and work terms quoted in text. Average $\Delta G^{**}_{11} = 9.88 \pm 0.19$ kcal mol^{-1}.

each case, with separations between cathodic and anodic peaks in the range 60−70 mV at a scan rate of 50 mV s^{-1}. The E° values (vs. NHE) are listed in Table 2. These reduction potentials are about 60−100 mV more positive than the values measured in 0.50 *M* H_2SO_4 (e.g. $Fe(phen)_3^{2+/3+}$, $E^\circ = 1.14$ V in *p*-toluenesulphonic acid and $E^\circ = 1.06$ V in H_2SO_4) (13).

One inference from the lower value of E° in sulphate media compared to the much more weakly coordinating pts^- ion is that ion-pairing $[Fe(LL)_3^{3+} \cdot SO_4^{2-}]$ takes place in solution. From the ΔE° values obtained, assuming no outer-sphere interaction with pts^-, an estimate of K_{ip} $(Fe(LL)_3^{3+} \cdot SO_4^{2-})$ ~10−15 *M* may be derived dependent on the individual complexes. If such is the case, then for many previous studies, normally carried out in 0.5 *M* SO_4^{2-}, there is a reasonable concentration (40−50%) of the ion-pair present in the solution.

[a] Scan rates 2−5 mV/s. Using higher scan rates (50−100 mV/s) peak separations of 50−60 mV were observed.
[b] Peaks overlapping.
[c] Scan rates 5−20 mV/s.
[d] At $[H^+] = 1.00$ *M*, $E^\circ_{obs} = 0.94$ V.

Previous authors (14) have attempted to take effects of such interactions into account and have estimated (21) a value of K_{ip} $[Fe(LL)_3^{3+} \cdot I] = 4.1$ *M* for the iodide complex, in reasonable agreement with the present data. More information on these interactions is needed before any differences in reactivities can be ascribed.

Cyclic voltammetry of the Ni(IV)/Ni(II) complexes

The observed redox potentials of the nickel species were found to be significantly pH-dependent (Table 3). At higher

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

acid concentrations ($I = 0.1\ M$ pts^-) only a single two-electron wave (peak-to-peak separation ~45 mV) was observed at scan rates of 2–5 mV/s. The potentials observed are similar to those observed in chloride media (8) although in that study a 30 mV separation was observed. Above pH ≈ 4 (Table 3), two processes were discernible, each of which at pH > 7 showed separations of 60 mV. The higher potential was acid independent whereas the position of the lower moved, up to pH ~ 7.8, where pH independence was noted. These findings, including a marked departure from 60 mV reversible separation at higher pHs, are in excellent agreement with extensive studies in nitrate media completed by Lappin (22).

At pH = 0, the data are consistent with a single process (E° vs. NHE)

[3] $Ni(IV)L^{2+} + 2H^+ + 2e \leftrightharpoons Ni(H_2L)^{2+}$ $\quad E^\circ = 0.94$ V

where the product formed is the (oxime-) protonated nickel(II) species. Above pH ~ 5, the Ni(III)/(II) couple is acid dependent, owing to the protonation (10) of the nickel(II) species ($pK_1 = 7.69$, $pK_2 = 5.91$) and of the nickel(III) complex ($pK_3 = 3.91$) (22) where only a single acid–base equilibrium is observed.

[4] $Ni(III)L^+ + 2H^+ + e \rightleftharpoons Ni(II)(H_2L)^{2+}$ $\quad E^\circ = 1.23$ V

[5] $Ni(III)L^+ + H^+ + e \rightleftharpoons Ni(HL)^+$ $\quad E^\circ = 0.87$ V

[6] $Ni(III)L^+ + e \rightleftharpoons Ni(II)L^+$ $\quad E^\circ = 0.41$ V

[7] $Ni(III)HL^{2+} + e \rightleftharpoons Ni(HL)^+$ $\quad E^\circ = 0.64$ V (22)

The redox process for the nickel(IV) ion is independent of acidity.

[8] $Ni(IV)L^2 + e \rightleftharpoons Ni(III)L^+$ $\quad E^\circ = 0.65$ V

Discussion

The results of the kinetic study are consistent with a mechanism of the form

[9] $Ni(II)(H_2L)^{2+} + Fe(LL)_3^{3+} \xrightarrow{k} Ni(III)(H_2L)^{3+} + Fe(LL)_3^{2+}$

[10] $Ni(III)L + Fe(LL)_3^{3+} \xrightarrow{\text{fast}} Ni(IV)L + Fe(LL)_3^{2+}$

where a rate-determining one-electron outer-sphere reaction is proposed. Both $Fe(LL)_3^{3+}$ and $Ni(H_2L)^{2+}$ are relatively substitution-inert, and the large rate constants (10^3–10^5 $M^{-1}\ s^{-1}$) observed are considered to preclude any inner-sphere mechanism.

Since, under the reaction conditions, the reductant is in the form $Ni(II)(H_2L)^{2+}$ and the electron transfer rate is independent of acidity, the appropriate reductant redox couple is $Ni(II)(H_2L)^{2+}/Ni(III)(H_2L)^{3+}$. There is preliminary X-ray crystal (23) and solution (22) evidence for protonation of only one of the oxime groups in the nickel(III) complex. If, for the reaction

$$Ni(III)HL^{2+} + H^+ \rightleftharpoons Ni(III)(H_2L)^{3+}$$

$pK_4 < 0$ then $E^\circ(Ni(III)(H_2L)^{3+}/Ni(II)(H_2L)^{2+} \geq 0.98$ V. We have attempted to derive a more accurate assessment of this reduction potential by reaction in similar conditions with $Ru(bipy)_3^{3+}$. The overall process exhibits the same second order dependence (first with respect to both [Ni(II)] and [Ru(III)]). For nickel(III)/(II) complexes of this type the self-exchange rate (k_{11}) is ~1–3 × 10^3 $M^{-1}\ s^{-1}$. Combination of this parameter with that k_{22} for the $Ru(bipy)_3^{3+/2+}$ couple ($10^9\ M^{-1}\ s^{-1}$) (21) and the observed second order rate constant for the cross reaction, $k_{12} = 1.1 \times 10^6\ M^{-1}\ s^{-1}$ leads to a reduction potential $E^\circ(Ni(III)/(II)(H_2L)) \sim 1.23$ V. We have used this value in free-energy calculations. A consequence of this value is that pK_4 may be computed as −3 to −4 in keeping with only one observed protonation of the nickel(III) complex.

Although in most instances the net free energy changes for the first step are unfavourable, there is no evidence for any reaction reversibility. This is, in part, the result of reaction conditions where a large excess of reductant nickel(II) (15–80-fold over the iron(III) present) was used and also from a very favourable second step ($E^\circ(Ni(IV)/(III)) = 0.65$ V). In the case of $Fe(bipy)_3^{3+}$, for example, the free energy change leads to an equilibrium constant $K = 4 \times 10^{-3}$ and hence a reverse rate of $7 \times 10^6\ M^{-1}\ s^{-1}$. The subsequent reaction to yield $Ni(IV)L^{2+}$, however, has a rate calculated as $6 \times 10^8\ M^{-1}\ s^{-1}$. Even in the least favourable system, $Fe(dmbpy)_3^{3+}$, no evidence was found for reversibility, with a first-order dependence on [Ni(II)] confirmed over a wide concentration range (See Fig. 1).

The Marcus theory (24) for outer-sphere electron transfer reactions predicts a relationship between the free energy of reaction (ΔG°_{12}), the free energy of activation for the cross reaction (ΔG^*_{12}), and the free energies of activation for the reductant and oxidant self-exchange reactions (ΔG^*_{11} and ΔG^*_{22}). The relationship may be expressed in the form

[11] $$\Delta G^*_{12} = w + \lambda_{12}/4 + \Delta G^\circ_{12}/2 + (\Delta G^\circ_{12})^2/4\lambda_{12}$$

where $\lambda_{12} = 2(\Delta G^*_{11} + \Delta G^*_{22})$ and w is a parameter encompassing work terms associated with each of the free energy parameters.

Consideration has recently been given to the work term contributions in systems analysed using this approach (25–27). The relationship [11] may be rewritten in a modified form

[12] $$\Delta G^{**}_{12} = 0.5(\Delta G^{**}_{11} + \Delta G^{**}_{22}) + 0.5\Delta G^\circ_c(1 + \alpha)$$

where

[13] $$\Delta G^{**}_{12} = \Delta G^*_{12} - w_{12}$$

[14] $$\Delta G^{**}_{11} = \Delta G^*_{11} - w_{11}$$

[15] $$\Delta G^{**}_{22} = \Delta G^*_{22} - w_{22}$$

and

[16] $$\Delta G^\circ_c = \Delta G^\circ_{12} + w_{21} - w_{12}$$

The single and double asterisks refer to measured and corrected free energies of activation, the subscripts 1 and 2 relate to the nickel and iron couples, and w represents the corresponding Coulombic term. ΔG° and ΔG°_c are the measured and corrected reaction free energies.

In these systems, the distance between the centres in the activated complex is taken as 12 Å. Within the error of measurement, there is no detectable difference in the Fe—N bond lengths between $Fe(phen)_3^{2+}$ and $Fe(phen)_3^{3+}$ (26, 28). In the case of the nickel complexes, a recent study has compared the Ni—N, oxime, imine, and amine bond lengths in a similar species (11) where the ligand is a tridentate "half" of that considered here. For bis-2-(2-aminoethyl)imino-3-butanone oximato nickel(IV), the metal ion coordination geometry is distorted octahedral with the two tridentate ligands in a meridional arrangement, no significant changes in stereochemistry having occurred during oxidation from the nickel(II) ion. Val-

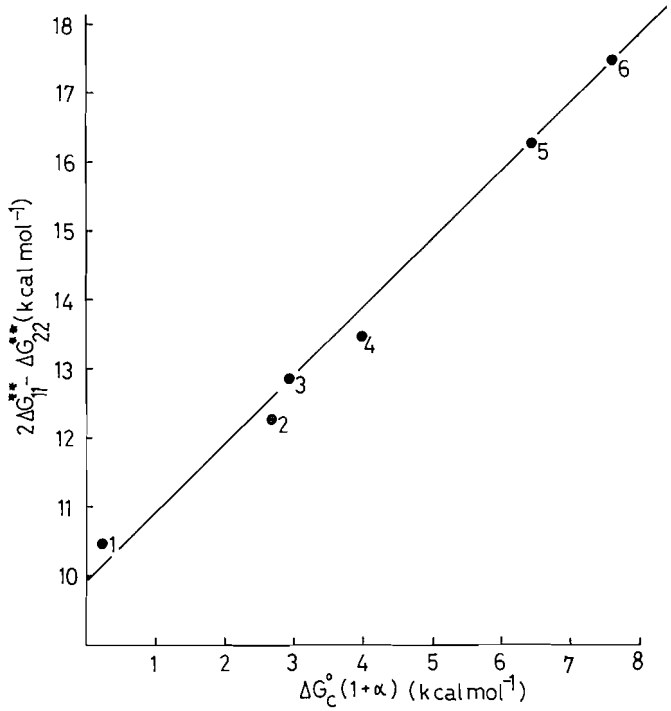

FIG. 2. Marcus plot for the oxidation of $Ni^{II}(H_2L)^{2+}$ with various $Fe(LL)_3^{3+}$ complexes: $Fe(cphen)_3^{3+}$ (*1*), $Fe(phen)_3^{3+}$ (*2*), $Fe(mphen)_3^{3+}$ (*3*), $Fe(bpy)_3^{3+}$ (*4*), $Fe(dmphen)_3^{3+}$ (*5*), and $Fe(dmbpy)_3^{3+}$ (*6*). Line drawn is of slope 0.96 (eq. [17]).

ues for the Ni(III)—N (oxime, imine, and amine) bond lengths were derived by averaging the appropriate Ni(IV)—N and Ni(II)—N distances (11).

In order to estimate the self-exchange rate constants for the $Ni(II)(H_2L)^{2+}/Ni(III)(H_2L)^{3+}$ electron exchange reaction, a Marcus plot was made according to the equation

$$[17] \quad (2\Delta G_{12}^{**} - \Delta G_{22}^{**}) = \Delta G_{11}^{**} + \Delta G_c^{\circ}(1 + \alpha)$$

where

$$[18] \quad \alpha = \Delta G_c^{\circ}/4(\Delta G_{11}^{**} + \Delta G_{22}^{**} - w_{11} - w_{22})$$

Initial values of ΔG_{11}^{**} were calculated using $\alpha = 0$ and using these in [18] an iterative approach led to limiting values of α. Thermodynamic data used are presented in Table 2. The reported value ($k_{22} = 3 \times 10^8\ M^{-1}\ s^{-1}$) (29) was used for the rate of $Fe(LL)_3^{2+/3+}$ self exchange. In Fig. 2 is shown a plot of $(2\Delta G_{12}^{**} - \Delta G_{22}^{**})$ against $\Delta G_c^{\circ}(1 + \alpha)$. The line drawn is of unit slope (eq. [17]) and the intercept yields a value of $\Delta G_{11}^{**} = 9.88 \pm 0.2$ kcal mol^{-1} ($k_{11} \sim 2.7 \times 10^3\ M^{-1}\ s^{-1}$). This value is very similar to those derived recently by Lappin (22). In the reactions (pH = 4–7) of $Ni(III)HL^{2+}$ and $Ni(III)L^{+}$ with $Co(phen)_3^{2+}$, rates of $10^3\ M^{-1}\ s^{-1}$ and $2 \times 10^3\ M^{-1}\ s^{-1}$) respectively were found for the nickel(II)/(III) exchanges.

Although complete structural and vibrational spectroscopic data are not yet available, the exchange rate derived in the present study is consistent with relatively small changes in bond lengths within the Ni complexes on electron transfer. The rate-determining process involves exchange between d^8 and d^7 octahedral species, the latter with an unpaired electron likely residing in the d_z^2 orbital. Where large structural changes are involved in outer-sphere reactions, exchange is generally slow, e.g. in the $Co(phen)^{2+/3+}$ (30) or $Co(sepulchrate)^{2+/3+}$ (31) systems the rates are 45 and 5 $M^{-1}\ s^{-1}$ respectively, and Co(II)/Co(III)–nitrogen bond length differences are of the order of 0.19 Å respectively (31). For the $Fe(phen)^{3+/2+}$ exchange where the M—N bond lengths are essentially the same, rates are $\sim 10^8\ M^{-1}\ s^{-1}$ (26–28). It would appear that for the octahedral Ni(II)/(III) complexes under consideration, the Ni—N distances change by ≤ 0.1 Å on electron transfer. Structural studies currently being undertaken will hopefully confirm this suggestion.

Unfortunately attempts to prove the existence of Ni(III)L species as intermediates were unsuccessful. Both uv–visible and esr methods were used but no firm evidence of any transient species was obtained.

The Ni(II)/Ni(III) oxime self-exchange parameters are similar to those found for Ni(II)/(III) cyclam complexes. Recent measurements of the $Ni(cyclam)^{2+/3+}$ exchange rate constant using ^{61}Ni esr (16) in 1.0 M $HClO_4$ yielded a $k_{11} = 1 \pm 0.3 \times 10^3\ M^{-1}\ s^{-1}$. Some variation might be expected for other macrocyclic systems, however, as is shown in the range of rates observed for cobalt(II)/(III) systems (32).

The oxime complexes have an octahedral configuration in both the Ni(II) and Ni(III) species, whereas a change from square-planar $Ni^{II}L^{2+}$ to octahedral $Ni^{III}L(H_2O)_2^{3+}$ occurs when L is a tetraaza-macrocycle.The similarity in the self-exchange parameters suggests there is only a small reorganisational energy associated with the change in geometry. Kinetic studies on the oxidation of other nickel(II) complexes with cyclic and non-cyclic ligands will be useful in further determining the effect of ring size, substituents, and geometry on thermodynamics of electron exchange.

Nuclear magnetic resonance characterization of the ring conformations of monosubstituted derivatives of 1,3-dioxa-5,6-benzocycloheptene

R. ST-AMOUR AND M. ST-JACQUES

Département de Chimie, Université de Montréal, C.P. 6210, Succ. A, Montreal (Que.), Canada H3C 3V1

Received May 21, 1982

R. ST-AMOUR and M. ST-JACQUES. Can. J. Chem. **61**, 109 (1983).

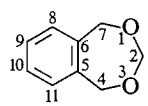
The conformational properties of 2-alkyl (Me, Et, i-Pr, and *t*-Bu) and 2-phenyl derivatives of 1,3-dioxa-5,6-benzocycloheptene (**1**) were studied by ^{13}C dnmr. Analysis of slow exchange spectra at 100.6 MHz indicates that all derivatives except *tert*-butyl exist in an equilibrium of chair (major) and twist-boat (minor) conformations. Substituent effects on the position of the equilibrium are rationalized in terms of steric effects.

R. ST-AMOUR et M. ST-JACQUES. Can. J. Chem. **61**, 109 (1983).

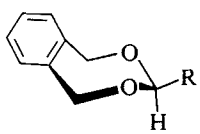
Faisant appel à la rmn du ^{13}C, on a étudié les propriétés conformationnelles des dérivés alkyl-2 (Me, Et, i-Pr et *t*-Bu) et phényl-2 du dioxa-1,3 benzo-5,6 cycloheptène (**1**). L'analyse des spectres d'échange lent à 100,6 MHz indique que tous les dérivés, à l'exception du *tert*-butyl, existent dans des conformations à l'équilibre de la forme chaise (majoritaire) et de la forme bateau croisé (minoritaire). On rationalise les effets des substituants sur la position de l'équilibre en fonction des effets stériques.

[Traduit par le journal]

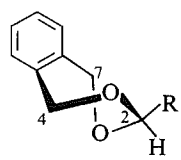
Present knowledge of the conformational properties of derivatives of 1,3-dioxa-5,6-benzocycloheptene (**1**; also called 2,4-benzodioxepin) indicates that they can exist either in the chair conformation (C) the twist-boat form (TB), or as a mixture of both. For example, ^1H and ^{13}C dnmr results have shown that **1** exists as a mixture of C (79%) and TB (21%) forms in CHF_2Cl at $-130°C$. Furthermore, whereas the low temperature ^{13}C nmr spectra of the 2-methyl derivative (**4**) were interpreted in terms of a highly dominant chair conformation (**2**; R = CH_3), the 2-methoxy derivative was shown (1) to adopt the TB form exclusively (**3**; R = OCH_3).



1

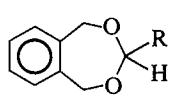


2



3

More recently, infrared and dipole moment studies on compound **1** and the series of 2-substituted derivatives **4** to **11** suggested that most of these derivatives adopt two conformations in solution at room temperature (2, 3). Quantitative determinations were not made for all compounds because of the inherent limitations of the experimental techniques used, although it was possible to suggest that the *tert*-butyl derivative (**8**) exists solely in the C form (2) and that the aryl derivatives (**9**–**11**) exist as a mixture with a C/TB ratio approximately 2:3 (3).



4

4	R = CH_3	**9**	R = C_6H_5
5	CH_2CH_3	**10**	C_6H_4Cl
6	$CH(CH_3)_2$	**11**	$C_6H_4NO_2$
7	$CH_2CH_2CH_3$	**12**	OCH_3
8	$C(CH_3)_3$		

Our continuing work on this system had led us to investigate compounds **4**, **5**, **6**, **8**, and **9** by ^{13}C nmr at high field (100.6 MHz) which, because of increased sensitivity, clearly reveals signals for the less populated conformation thus permitting a complete and quantitative conformational characterization of the 2-monosubstituted derivatives. Furthermore, the ^{13}C nmr parameters obtained for the various forms provide useful parameters for conformational and stereochemical diagnostic purposes.

Results

Compounds **4**, **5**, **6**, and **9** were found to give pertinent temperature dependent ^{13}C nmr spectra. For example, the 100.6 MHz ^{13}C nmr spectra of **4** (2-CH_3 derivative) are shown in Fig. 1 where it is seen that each of the various lines splits into two lines of unequal intensity, the more intense one is labelled c and the less intense one is labelled b in the spectrum recorded at $-115°C$. The spectrum at $-83°C$ shows the characteristic line broadening. Table 1 contains a summary of the chemical shifts for all the pertinent signals at high and low temperatures. Integration of the two lines for the various signals in the low temperature spectra reveals that the ratios of c/b are 87:13 for a CH_3OCH_3 solution and 96:4 in the more polar CHF_2Cl solvent. Published data (1, 2) indicate that the c lines are associated with the chair form and the b lines with the TB form; this assignment is confirmed in the next section. Consequently the free energy difference (ΔG^0) between these two conformations can be calculated in a straightforward manner taking into account the existence of two equivalent TB forms (see discussion in the next section). Table 2 contains a summary of the thermodynamic data obtained for all the compounds studied in both solvents.

Free energies of activation ($\Delta G^{\ddagger}$) can most easily be obtained from the changing spectra of compound **9** (2-phenyl) for which the 2-site approximation yields 7.9 kcal/mol (33.4 kJ/mol) at $-98°C$, the coalescence temperature determined at 20.15 MHz for a solution in CHF_2Cl; because of the appreciable intensity of both lines, this value is a reasonable approximation for $\Delta G^{\ddagger}$ which turns out to be similar to the reported

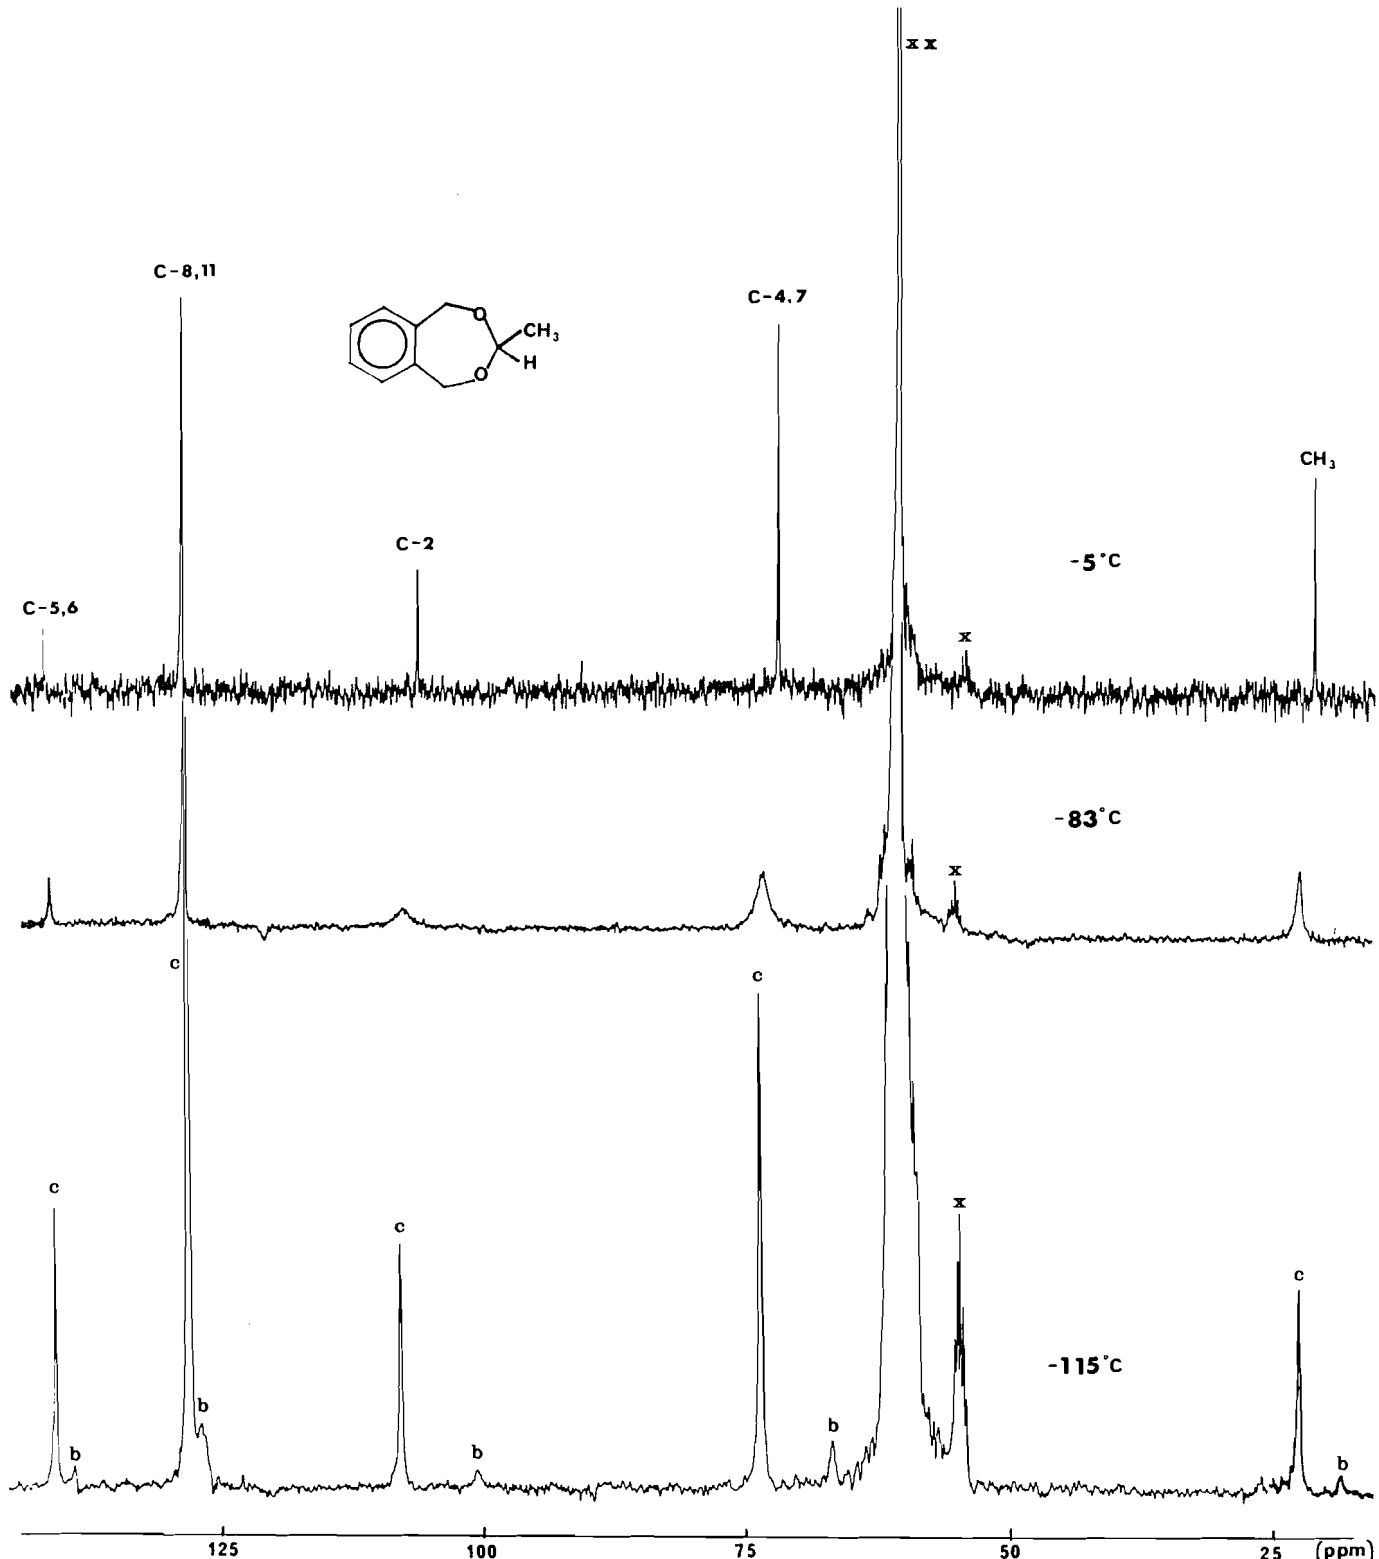

FIG. 1. The 100.6 MHz ^{13}C nmr spectra of **4** (2-CH_3 derivative) in CH_3OCH_3 solution at several temperatures. The lock (CD_2Cl_2) and solvent signals are labelled × and ×× respectively.

value for **1** (1).

Finally, compound **8** (2-*tert*-butyl) does not show a spectral change for the seven-membered ring carbon-13 signals but instead shows a spectral change of the methyl signal which splits into a characteristic doublet owing to slowing down of the C—C bond rotation at low temperatures. A similar observation was noted for 2-*tert*-butyl-1,3-dioxa-5,6-cycloheptene (4).

Discussion

Ring conformations

The data reported in Table 1 provide direct evidence for the existence of a mixture of two ring conformations for compounds **4**, **5**, **6**, and **9** whereas for **8** (2-*tert*-butyl) the signals of only one conformation are detected at low temperatures. Earlier work (1) on **4** had shown that the predominant con-

[a]In kcal/mol, calculated from measurements on the C-4,7 signals and using the equation $\Delta G^{0} = -RT \ln K$ where $K = [C]/[TB]$.
[b]In kcal/mol calculated from $\Delta G^{0}_{corr} = \Delta G^{0} + RT \ln 2$ for the monosubstituted derivative.

former is the equatorially substituted chair (C-e) and the dynamic spectral results shown in Fig. 1 clearly reveal the existence of a minor conformer whose chemical shift parameters are labelled (b) in Table 1.

Although it appears most probable that this second conformer is the TB form (1−4), the ^{13}C chemical shifts determined at −115°C confirm this identification. In fact it has been reported (1) that the C and TB forms of the parent compound **1** show characteristic chemical shift differences for the C-5,6 (1.1 ppm) and C-8,11 (1.5 ppm) signals which are relatively insensitive to the substitution pattern on C-2 for several alkyl substituents. The observations that the less intense C-5,6 signal of **4** is 1.2 ppm upfield from the more intense one and that the C-8,11 signal is 1.3 ppm upfield for the minor conformer are in accord with the expectation that the TB form is less abundant.

Supporting arguments are also provided from the analysis of the C-4,7 chemical shifts in terms of the so-called γ-effect of the substituents (7), which is discussed in detail later in the text.

Similar arguments for compounds **5** and **6** lead to the conclusion that the minor conformer ((b) signals in Table 1) is also the TB form.

The low temperature spectrum for **8** shows that the *tert*-butyl group has a stronger conformational preference than the methyl (**4**), ethyl (**5**), and isopropyl (**6**) groups. Indeed the ^{13}C chemical shifts show that for **8** only the C-e form is detected in the low temperature ^{13}C nmr spectrum. A similarly strong C-e preference was noted previously for the analogous 2-*tert*-butyl derivative of 1,3-dioxacycloheptene (4).

Finally, a similar analysis of the C-5,6, C-8,11, and C-4,7 signals of each of the two forms observed for **9** leads to the association of the (c) lines of Table 1 with the C-e conformation and the (b) lines with the TB form. Interestingly, the phenyl group favours the TB form to a greater extent than the alkyl groups as the data in Table 2 show.

It is also important to point out that while the C-e ⇌ TB interconversion in Scheme 1 has been slowed down sufficiently on the nmr time scale to lead to distinct signals for each form, the inversion process of the minor TB form (TB ⇌ TB*,

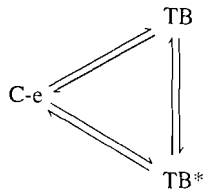


SCHEME 1

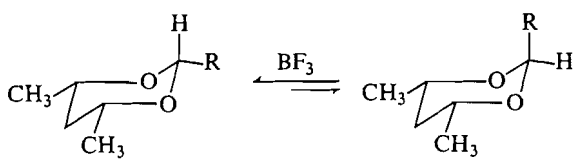
where the * indicated mirror image conformations) of **4**, **5**, **6**, and **9** has not been slowed down. If it had been, then the benzylic C-4 and C-7 would give distinct signals as was found to be the case for the 2-methoxy derivative (1).

The conformational effect of the 2-substituents

The low temperature conformational populations determined in two solvents are summarized in Table 2. Coupled with the results for the 2-methoxy group (1), it is seen that the conformational preference for the TB form in the more polar solvent (CHF_2Cl) is OCH_3(~100%), C_6H_5 (23%), $(CH_3)_2CH$ (9%), CH_3CH_2 (6%), and CH_3 (4%). Comparison with the parent compound **1** for which 21% of TB exist, however, indicates that alkyl substitution actually destabilized the TB form relative to C-e while phenyl substitution has relatively little overall effect. The distinct behaviour of the 2-methoxy derivative was ascribed to stereoelectronic effects (1) and for this reason this compound will not be compared further with the other monosubstituted derivatives in Table 2.

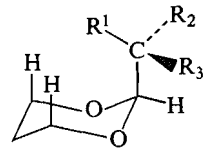
The solvent change to the less polar dimethyl ether increases the amount of TB for all compounds except for **6** (2-isopropyl). Nevertheless the overall qualitative picture is still retained.

In order to express the measured conformer populations in terms of thermodynamic parameters, consideration must be given to the statistical weight (or symmetry number) of the C and TB forms for the parent compound and for the monosubstituted derivatives. Differences in symmetry numbers for the C and TB forms are important when one wishes to use the approximation $\Delta H^0 \approx \Delta G^0$. In Table 2, the statistical contribution to entropy, namely R ln 2, must then be taken into account for the monosubstituted derivatives by means of the equation $\Delta G^0_{corr} = \Delta G^0 + RT$ ln 2. This effectively corresponds to the removal of entropic contributions from purely statistical effects, which is required prior to any attempt to relate thermodynamic data to structural parameters such as steric effects, nonbonded interactions, etc. (8, 9).

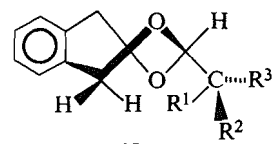


13	R = CH_3	ΔG^0 = 3.98 kcal/mol
14	= CH_3CH_2	= 4.04
15	= $(CH_3)_2CH$	= 4.17
16	= $(CH_3)_3C$	> 4.9
17	= C_6H_5	= 3.12

It is interesting to compare the trends for ΔG^0_{corr} in Table 2 with ΔG^0 values obtained for BF_3 catalysed equilibrations of derivatives **13** to **17** of 4,6-dimethyl-1,3-dioxane in diethyl ether at 25°C (10). Although these values correspond to the C-e ⇌ C-a process, there exists a remarkable parallel to the trend of ΔG^0_{corr} listed in Table 2 for solutions in dimethyl ether for the C-e ⇌ TB process of the analogously 2-substituted seven-membered acetals. Such an observation suggests that similar factors could be responsible in large part for the shifts in equilibria. Thus it is pertinent to point out that steric (nonbonded) interactions between the 2-alkyl substituent of the dioxanes with the two *syn*-axial protons on C-4 and C-6 (as in **18** where the R groups are either H or CH_3) were deemed responsible for the observed ΔG^0 values.

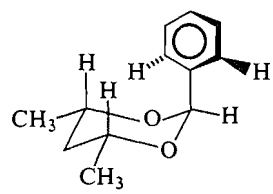


18

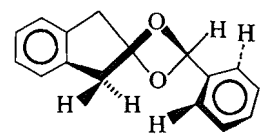


19

Structure **19** shows that a similar nonbonded interaction can exist in the TB form of the seven-membered acetals between only one of the benzylic protons and the alkyl substituent. Furthermore, for **4**, **5**, and **6** repulsive CH_3---H nonbonding interaction is avoided in the conformation with R^1 = H whereas for the *tert*-butyl derivative (**8**) R^1 = CH_3 and nonbonding CH_3---H repulsion is present. Consequently greater destabilization of conformation **19** occurs for **8** so that only the C-e form is effectively detected by the nmr methods.



20



21

The conformational effect of the phenyl group in **9** and **17** is more subtle and for **17** was found to reflect a substantial difference in the freedom of internal rotation about the C-2 to phenyl bond in the axial and equatorial isomers (11, 12). In fact, it was shown that the equatorial phenyl is an effectively free rotor whereas the axial phenyl librates about an average perpendicular orientation which is illustrated by structure **20**. An unusually large conformational entropy results (ΔS^0 = 3.9 eu) so that ΔH^0 = −2.0 kcal/mol, a value significantly smaller than ΔG^0 = −3.12 kcal/mol.

It therefore appears that the phenyl group in the TB form can take up a position which effectively minimizes nonbonded interaction with the axial-like benzylic proton. Structure **21** represents a possible favored orientation. Thus, the phenyl group would not significantly destabilize the TB form as the results in Table 2 seem to indicate. Alternatively, if a significant stereoelectronic (or anomeric) effect were operational, it would most likely perturb the C ⇌ TB equilibrium which ought to be a probe for this kind of stabilizing effect as indicated by the fact that the 2-methoxy derivative exists exclusively in the TB form (1).

The nmr results reported in Table 2 therefore constitute reliable quantitative conformational information at the temperatures of measurement which are relatively low. But in order to compare them with results obtained from other methods (albeit less precise than nmr) such as the interpretation of

			γ_a −2.59	

[a]Calculated as the difference between the chemical shift of each signal with the corresponding one in the parent compound **1**. A negative sign means an upfield shift.
[b]Values taken from ref. 1. Here $\gamma_g = \gamma_{gauche}$ and $\gamma_a = \gamma_{anti}$ effects.

dipole moments and ir studies (2, 3), at significantly higher temperatures, it is necessary to extrapolate from the data obtained at low temperatures (13).

Firstly, it is possible to obtain approximate conformer populations at about +25°C from the analysis of averaged chemical shifts at room temperature which actually represent a weighted average of the individual chemical shifts observed below the coalescence temperature. Mole fractions of the C and TB forms for the compounds listed in Table 2 can easily be calculated (14, 15).

It is well known that the accuracy of this averaged chemical shift method is reduced when the temperature dependences of the chemical shifts are not taken into account. Although this question was not resolved through chemical shift measurements below coalescence for an appreciable temperature range, the data for the *tert*-butyl derivative **8**, which exists only in the C-e form, may be pertinent. Table 1 shows that C-2 and C-4,7 signals of the C-e form of **8** have the same chemical shift at 25° and −115°C, whereas the published data for the 2,2-dimethyl derivative (1) shows that the C-2 and C-4,7 TB signals undergo very little change from 25° to −120°C, namely 0.1 and 0.6 ppm respectively. But because it has been shown that the chemical shift of TMS exhibits a temperature gradient (16), this method must be considered as very approximative. For example, the C/TB ratios are calculated as 61:39 for **1**, 51:49 for **9** in CHF_2Cl and 57:43 for **1**, 45:55 for **9** in CH_3OCH_3.

Secondly, it is interesting to note that a simple extrapolation of the experimentally determined K values (Table 2) to higher temperature using the equation $\Delta G^0 = -RT \ln K$, while assuming that $\Delta S^0 \approx 0$ and that ΔH^0 is temperature independent, yields relative amounts for the two conformers which are quite similar to those obtained by the chemical shift method. For example, the C/TB ratio is 65:35 for **1**, 58:42 for **9** in CHF_2Cl and 59:41 for **1**, 45:55 for **9** in CH_3OCH_3. Of course, such closeness could be fortuitous since the ΔS^0 and ΔH^0 effects could cancel each other in large part. The uncertainty associated with this second method can be appreciated from a consideration of results published for six-membered cyclic acetals where it is seen that the ΔS^0 measured are small (17, 18). On the other hand, the case of the phenyl derivative (**9**) is different because a large ΔS^0 value exists, as was pointed out earlier (11).

It is therefore interesting to compare the extrapolated nmr results with those obtained from dipole moment studies (2) which gave a C/TB ratio of 44:56 in CCl_4 at room temperature for the parent compound **1**. The nmr value in CH_3OCH_3 is 57:43 and the difference in polarity between these two solvents might not be sufficient to account for the observed difference between the two sets of values. Nevertheless, it is significant that both methods converge in indicating nearly equal amounts for both conformers.

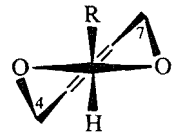
For the 2-phenyl derivative (**9**), dipole moments (3) yielded a C/TB ratio of 40:60 while the nmr results indicate a 45:55 ratio. Agreement is therefore quite good. Unfortunately, the dipole moment approach did not permit quantification for **4**, **5**, and **6** (2-alkyl derivatives) so that the nmr results constitute the sole source of quantitative information.

Carbon-13 chemical shifts

The observation of individual ^{13}C nmr signals for the C-e and TB forms, as given in Table 1, permits the determination of the stereodependent effect of substituent on the chemical shifts of carbons C-2, C-4,7, and C-5,6 which are commonly termed α, γ, and δ effects respectively (7). These parameters are summarized in Table 3.

Whereas for six-membered cyclic acetals it is difficult to obtain reference parameters for the TB form, in this family of seven-membered rings it is the C-a form which has not yet been observed. Accordingly, only the C-e form is common to similar derivatives of both ring sizes.

Furthermore, it must be recognized that the seven-membered TB form is still undergoing rapid inversion through a pseudorotation process. Hence, some of the ^{13}C nmr signals represent averages at −115°C as was clearly demonstrated previously (1) for **12**, whose ^{13}C nmr spectrum at −150°C shows two benzylic carbon signals (i.e. C-4 and C-7 are no longer made equivalent by rapid inversion as shown in structure **22**). Unfortunately, the inversion barrier is lower when the substituent is nonpolar so that TB averaging is still rapid even at −150°C for the compounds listed in Table 1.



22

The α and δ effects in Table 3 reveal similar magnitudes for C-e and TB for a given substituent. By comparison, methyl

For personal use only.

substitution on C-2 of 1,3-dioxane produced α_e and α_a parameters of 5.06 and −1.02 ppm respectively (5).

The γ effect is most interesting since it is this parameter which is most useful for stereochemical and conformational assignments. Whereas γ_e for 2-methyl substitution of 1,3-dioxane is −0.14 (5), a significant difference is found for **4** for which γ_e is −1.54 ppm, possibly because of differences in ring puckering as will be discussed shortly. Part of the difference may also originate from temperature effects on chemical shifts. It is therefore pertinent to compare the above value of −1.54 ppm for **4** with the −1.63 ppm at 25°C and −1.24 ppm at −85°C for 5-methylbenzocycloheptene (19). Finally, the trend for γ_e values observed for **4**, **5**, **6**, and **8** may be indicative of some ring deformation as the substituent size increases.

The γ_{TB} upfield shifts in Table 3 are also fairly constant, being −2.83 ppm for methyl substitution in **4**. This value actually represents the average of a small γ_{anti} effect (C-4 in **22**) and a larger γ_{gauche} effect (C-7 in **22**). Here again differences in ring puckering prevent simple comparison with six-membered ring parameters for γ_{anti} and γ_{gauche}.

Recently, a successful attempt to correlate the γ effect with dihedral angles has been reported (20) and it is useful to consider our results from that point of view. Although both steric and electronic factors have been considered in the past to explain the γ effect, it now appears acceptable to consider that a linear relationship with dihedral angles exists for CH_2 groups in substituted cycloalkanes.

Assuming that a similar linear relationship also existed for CH_2 carbons of acetals, the γ_e and γ_a effects of six-membered acetals substituted at C-2 with a methyl group then should provide useful reference values for dihedral angles of ~180° and ~60°. The average of two sets of published γ_e and γ_a values are used for this purpose, −0.14 and −7.76 ppm (5) and 0.1 and −7.3 ppm (6). Now, if we consider that the γ_e effect for **4** corresponds to a dihedral angle of about 160° (as measured from Dreiding models of the C-e form), we find that these three reference points on a γ vs. angle plot fall on a straight line. Therefore, the existence of a linear relationship for CH_2 carbons next to oxygen in acetals appears verified.

Examination of the TB form (**22**) for **4** shows that the measured dihedral angles for the C(4)—O—CH—CH_3 and C(7)—O—CH—CH_3 moities depend on the exact geometry of the ring conformation. Because the TB conformation is rather flexible, it is a priori impossible to select the minima on the energy profile of the pseudorotation cycle. Nevertheless, it appears reasonable to assume that the C(4)—O—CH—CH_3 dihedral angle is close to 180°; molecular models then show that the C(7)—O—CH—CH_3 angle is about 85 ± 5°. Using the straight line obtained above for acetals, γ effects of about 0.0 and −6.0 ppm are found to correspond to these two dihedral angles (i.e. 180° and 85°) so that their average (−3.0 ppm) is reasonably close to the value of −2.8 ppm determined experimentally for the TB form of **4**. Even though the quality of such linear relationships is not sufficient to permit the determination of accurate dihedral angles (20), it appears adequate to rationalize the γ parameters summarized in Table 3. Hence the differences between six and seven-membered acetals are due mainly to different ring geometries.

The γ_{TB} parameter (−2.8 ppm) determined for **4** is most useful to reassess the conformational situation of 2-methyl-1,3-dioxa-5,6-cycloheptene (**4***a*) for which the benzo group of **4** is replaced by a double bond. The reported upfield shift for the C-4,7 signal of **4***a* relative to the parent compound is −1.68 ppm (4); this value is significantly less than the −2.8 ppm determined for **4**. It would therefore appear that the predominant conformation of **4***a* is TB, as previously concluded (4), but that a significant amount of the C-e form does exist in rapid equilibrium even at −150°C.

Experimental

Melting points are uncorrected and were determined using a Buchi melting point apparatus.

Routine ^1H nmr spectra were recorded at 90 MHz on a Bruker WH-90 spectrometer. The room temperature ^{13}C nmr spectra were recorded at 20.15 MHz on a Bruker WP-80 spectrometer as were the variable temperature spectra of **9**. The lower temperature ^{13}C nmr spectra used for population determination were taken at 100.6 MHz using a Bruker WH-400 spectrometer equipped with a variable temperature unit (B-VT-1000) and located at the "Laboratoire Régional de rmn à haut champ" in Montreal.

The ^{13}C nmr spectra were recorded with proton decoupling for solutions in CHF_2Cl or CH_3OCH_3 using from 75 to 150 mg of sample in about 2.5 mL of solvent containing a little Me_4Si and about 15% of CD_2Cl_2 (for locking purposes) in standard 10 mm tubes which had been degassed and sealed. The temperatures of the spectra recorded at 20.15 MHz were determined after calibration with a thermocouple and are believed to be accurate to at least ±3°C.

The following instrumental conditions are typical for the low temperature ^{13}C nmr spectra at 100.6 MHz: flip angle: 65−70°; SW = 17 000−25 000 Hz; data size: 16K; acquisition time = 0.328 s or 0.482 s; pulse repetition time = 0.428 or 0.582 s. Temperatures were determined directly using the B-VT-100 unit. Calibration using a thermocouple inside a solvent-containing nmr tube indicates that the low temperatures reported are known within ±3°C. Results published by Booth and Jozefowicz (21) indicate that integrations of the c and b signals for a given carbon should not suffer from differential T_1 and nOe effects at −115°C. In fact, a check was carried out for compound **9** at −115°C and the T_1 values obtained are: 0.19 s for C-4,7 of C, 0.18 for C-4,7 of TB, 0.38 for C-2 of C, and 0.35 for C-2 of TB. Furthermore, variations in the flip angle did not significantly change the results for conformer populations.

Compound preparation

All compounds were prepared from recrystallized 1,2-benzenedimethanol (Aldrich) using a published procedure (22). In all cases, the work-up included removal of most of the benzene solvent by distillation at atmospheric pressure and distillation of the compounds at reduced pressure (~1 Torr). Yields varied from 45% to 75%. All melting points agreed with those reported in the literature (2, 3).

The ^1H nmr spectra of compounds **4** and **9** were identical to those reported previously (1, 2) while those for compounds **5**, **6**, and **8** show the following characteristics for $CDCl_3$ solutions. Compound **5**: 7.2 (s, 4H), 4.9 (s, 4H), 4.8 (t, 1H), 1.7 (m, 2H), 1.0 (t, 3H). Compound **6**: 7.2 (s, 4H), 4.9 (s, 4H), 4.5 (d, 1H), 1.9 (m, 1H), 1.0 (d, 6H). Compound **8**: 7.2 (s, 4H), 4.9 (s, 4H), 4.4 (s, 1H), 1.0 (s, 9H).

Finally, the ^{13}C nmr spectra reported in Table 1 confirmed the identity of each of the compounds prepared.

ROSS ELMORE ROBERTSON, EDWARD WONG, JOHN MARSHALL WILLIAM SCOTT, MICHAEL JESSE BLANDAMER, REHMAT KHAN, and CLIVE JOHNSON. Can. J. Chem. **61**, 116 (1983).

Kinetic data are reported for the solvolysis of 1-methyl cyclopentyl chloride in a 50% by volume ethanol + water mixture. These data are combined with kinetic data for solvolysis of three deuterated analogues; 1-methyl-d_3 cyclopentyl chloride, 1-methyl-2,2,5,5-d_4 cyclopentyl chloride, and 1-methyl-d_3-2,2,5,5-d_4 cyclopentyl chloride, being the d_3, d_4, and d_7 derivatives respectively. The kinetic data are used to calculate the kinetic deuterium isotope effect, k_H/k_D. For these systems, the d_7-isotope effect is close to the product of the d_3 and d_4 effects.

ROSS ELMORE ROBERTSON, EDWARD WONG, JOHN MARSHALL WILLIAM SCOTT, MICHAEL JESSE BLANDAMER, REHMAT KHAN et CLIVE JOHNSON. Can. J. Chem. **61**, 116 (1983).

On rapporte les données cinétiques de la solvolyse du chlorure de méthyl-1 cyclopentyle dans un mélange à 50% en volume d'éthanol et d'eau. On a combiné ces données aux données cinétiques de la solvolyse de trois analogues deutérés: le chlorure de méthyl-1-d_3 cyclopentyle, le chlorure de méthyl-1 cyclopentyl-2,2,5,5-d_4 et le chlorure de méthyl-1-d_3 cyclopentyl-2,2,5,5-d_4, ces composés ayant respectivement 3,4 et 7 atomes de deutérium. On a utilisé les données cinétiques pour calculer l'effet isotopique du deutérium, k_H/k_D. Pour ces systèmes, l'effet isotopique-d_7 est voisin du produit des effets d_3 et d_4.
[Traduit par le journal]

Quite generally, β-deuterium substitution leads to a decrease in rate constant for a solvolytic S_N reaction (1). We have measured the kinetic deuterium isotope effects for solvolysis of 1-methyl cyclopentyl chloride deuterated at the 1-methyl group, d_3, at the methylene groups in the 2 and 5 positions, d_4, and at both methyl and 2- and 5-methylene groups, d_7.

Results

The solvent was a 50% mixture of ethyl alcohol and water. The kinetics of solvolysis, followed by measuring the change in electrical conductance (2), obeyed first order kinetics (Table 1).

Discussion

In the solvolysis of 1-methyl cyclopentyl chloride, nucleophilic displacement of chloride occurs at a tertiary carbon centre and the most obvious comparison is with the kinetic data for *tert*-butyl chloride in the same solvent mixture (3). Indeed the isotope effect per *d*-atom on the 1-methyl(d_3) cyclopentyl compound is 1.099 at 283 K (i.e. $\sqrt[3]{1.329}$), which is close to that calculated for *tert*-butyl chloride, 1.11 (i.e. $\sqrt[9]{2.505}$). The corresponding value for the *d*-atoms at the 2 and 5 positions is quite different, 1.23, and must reflect the constraint imposed by the cyclopentyl ring on the conformational changes during the displacement process. It is noteworthy, however, that the overall isotope effect in the d_7-derivative is, over the measured temperature range, within 4% of that predicted by the products of the d_3 and d_4 kinetic isotope effects. In other words, the isotope effects are additive with respect to their contributions to the activation Gibbs function, $\Delta G^{\neq}$ (see Fig. 1).

Experimental

1-Methylcyclopentanol was prepared from cyclopentanone using the Grignard reaction. The chloride was prepared by passing dry HCl through the solution at 263 K. The 2,2,5,5-d_4 derivatives were prepared from cyclopentanone-d_4. The latter was prepared by warming together cyclopentanone and D_2O in the presence of a trace amount of K_2CO_3. The deuterated cyclopentanone was reduced to the alcohol (4) with 82% yield and better than 93% isotopic substitution. The 1-methyl(d_3) derivatives were prepared by well-established modifications to the above synthetic methods.

Alkylation of ambident ions derived from phosphoric–carboxylic imides. *N*-Benzoyl-*O*,*O*-dimethyl-*O*-ethylphosphorimidate and *E*/*Z* *O*-ethyl-*N*-(dimethylphosphoryl)benzimidate

VALERIE MIZRAHI, THEODORE HENDRICKSE, AND TOMASZ A. MODRO
Department of Organic Chemistry, University of Cape Town, Rondebosch, South Africa

Received April 16, 1982

VALERIE MIZRAHI, THEODORE HENDRICKSE, and TOMASZ A. MODRO. Can. J. Chem. **61**, 118 (1983).

The sodium salt of *N*-benzoyldimethylphosphoramidate was ethylated using triethyloxonium ion or ethyl iodide as alkylating agents. The former reaction gave two oxygen-alkylated products: *N*-benzoyldimethylethylphosphorimidate and *O*-ethyl-*N*-(dimethylphosphoryl)benzimidate. The latter reaction yielded only the carbonyl oxygen ethylation product as a pair of the geometrical (*E*/*Z*) isomers. The nmr spectra and fragmentation patterns of the obtained products are discussed.

VALERIE MIZRAHI, THEODORE HENDRICKSE et TOMASZ A. MODRO. Can. J. Chem. **61**, 118 (1983).

Utilisant l'ion triéthyloxonium ou l'iodure d'éthyle comme agent alkylant, on a éthylé le sel de sodium du *N*-benzoyl-diméthylphosphoramidate. La première réaction a donné deux produits alkylés contenant de l'oxygène; le *N*-benzoyl-diméthyléthylphosphorimidate et le O-éthyl-*N*-(diméthylphosphoyl)benzimidate. La dernière réaction a donné uniquement les isomères géométriques (*E*/*Z*) du produit d'éthylation de l'oxygène du carbonyle. On discute des spectres de rmn et des modes de fragmentation des produits obtenus.

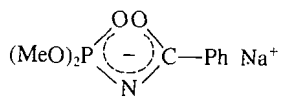
The Gabriel synthesis of primary amines is based on the nucleophilicity of the nitrogen of the imide salt. Following our interest in the reactivity of *N*-acylphosphoramidates,[1] we have investigated the nucleophilicity of the sodium salt of *N*-benzoyldimethylphosphoramidate (**1**) in alkylation reactions. The detailed charge distribution in the ion **1** is not known

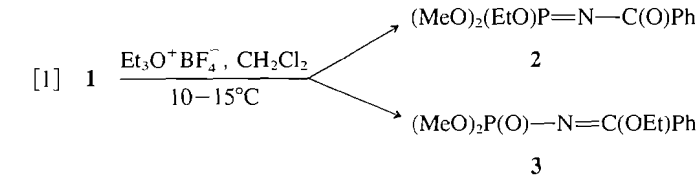


1

and the system can, in principle, give rise to the *N*-alkylated and two *O*-alkylated products. Zwierzak (1) recently reported the synthetic utility of *N*-alkylation of the similar salt $(EtO)_2P(O)NNaC(O)OBu^t$ under conditions of phase transfer catalysis. In this work, we report our results on the ethylation of **1** and the structural characteristics of the products formed.

Results and discussion

Ethylation of **1** with triethyloxonium tetrafluoroborate in methylene chloride gives two products which were identified by ^{1}H nmr and ir spectroscopy as the phosphoryl oxygen-ethylated (**2**) and carbonyl oxygen-ethylated (**3**) derivatives:



Products **2** and **3** are initially formed in about equimolar proportions, which probably corresponds to the kinetic control of the reaction. The concentration of **2** diminishes from 50% to zero between 5 and 20 h of the reaction, indicating greater stability of the benzimidate structure (**3**). The structure of *N*-benzoyl-*O*,*O*-dimethyl-*O*-ethylphosphorimidate (**2**) was established according to the following spectroscopic data. The methylene protons of the ethyl group resonate in the ^{1}H nmr spectrum as a low field quintet ($J_{H,H} = J_{H,P} = 7.5$ Hz), characteristic of the P^{IV}—OCH_2CH_3 function and indicate unambiguously the location of the ethyl moiety.

The ir spectrum of **2** showed a band for the carbonyl group at 1611 cm^{-1} and a new band at 1347 cm^{-1} due to the presence of a P=N bond. The positions of these bands remain in excellent agreement with the positions of the C=O (str.) and P=N (str.) bands of the trialkyl-*N*-acylphosphorimidates observed by other authors (1608–1620 cm^{-1} and 1346–1380 cm^{-1}, respectively) (2, 3).

In contrast to **2**, the methylene protons in **3** resonate as a quartet ($J_{H,H} = 7.5$ Hz), indicating no coupling with the ^{31}P nucleus. The ir spectrum of **3** showed the disappearance of the C=O band and retention of the band at 1271 cm^{-1} (P=O str.), as well as the appearance of a new band at 1657 cm^{-1}, characteristic of a C=N bond.[2]

In an attempt to prepare the *N*-alkylated derivative of **1**, this substrate was alkylated under similar conditions to those described by Zwierzak (1). However, we observed no alkylation at nitrogen, as indicated by the absence of a signal expected for the P(O)NEt group in the ^{1}H nmr spectrum of the product mixture. The reaction mixture consisted of two products having very similar R_f values on a tlc plate. The ^{1}H nmr spectrum of the reaction mixture also indicated the presence of two closely related compounds (Fig. 1). Both compounds exhibit a quartet at δ 4.0–4.5, characteristic of the methylene protons of the Et group, *not* coupled with the ^{31}P nucleus. In fact the spectrum of product A was found to be identical with that of the benzimidate (**3**) prepared above. The great similarity in the ^{1}H nmr spectra of these two compounds led us to believe that

[1]Papers concerning our results on the molecular structure, fragmentation patterns, and solvolytic behavior of *N*-acylphosphoramidates are being submitted for publication.

[2]Kabachnik *et al.* (4) report C=N (str.) at 1642–1644 cm^{-1} for *O*-methyl-*N*-(diethylphosphoryl)acetimidate.

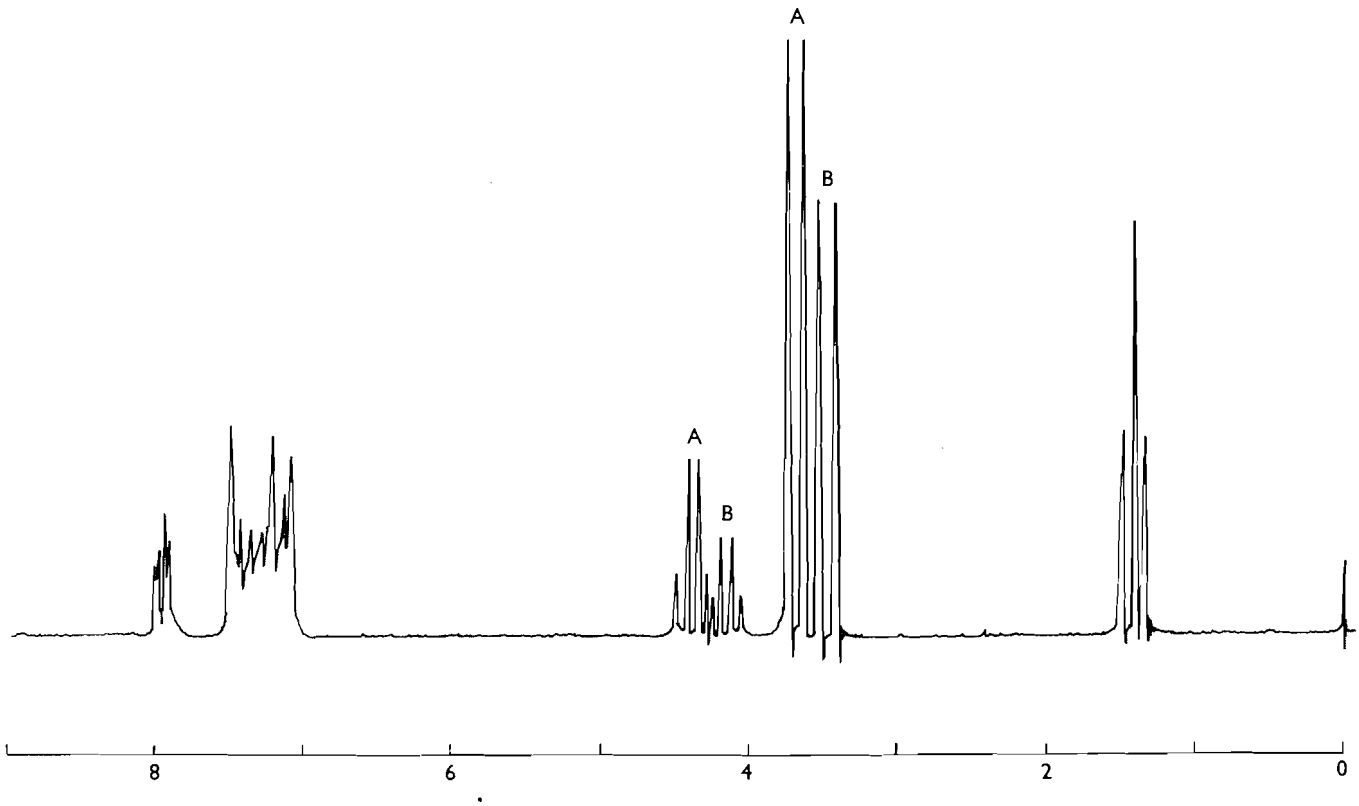

FIG. 1. The ^1H nmr spectrum ($CDCl_3$) of the reaction mixture obtained by ethylation of **1** with ethyl iodide.

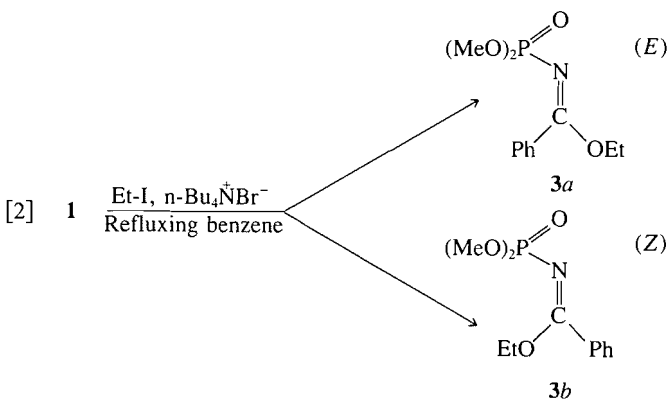
they are the geometrical isomers of *O*-ethyl-*N*-(dimethylphosphoryl)-benzimidate, **3***a* and **3***b*:



The benzimidates (**3**) were separated by column chromatography, and their structures determined by ^1H and ^{13}C nmr, ir, and mass spectrometry. The ^{13}C nmr spectra of the individual compounds are very similar, both showing five low field signals of the sp^2 carbon atoms (four aromatic and one of the C=N group), one high field signal of the β-methyl carbon of the ethyl group, and two midfield signals: a doublet ($J_{C,P}$ = 7.0 Hz) of the dimethylphosphoryl Me groups, and a singlet of the OCH_2 carbon of the *O*-imidate function. The most obvious difference between the ^{13}C nmr spectra of the two compounds lies in the chemical shift of the latter signal; the δ_{OCH_2} value of compound A is ca. 20 Hz more positive (more deshielded) than the δ_{OCH_2} value of the other isomer. Since the α-methylene carbons of **3***a* and **3***b* differ significantly in through-space distance to the phosphoryl group and to the pair of nonbonding electrons on nitrogen (*E*/*Z* relation), large differences in the shielding parameters of these atoms are expected. The infrared spectra of the alkylation products are extremely similar; both contain a prominent P=O (str.) band and a characteristic C=N (str.) band of frequency 1654–1657 cm^{-1}, in good agreement with literature values.

Although the nmr and ir spectroscopic results fully confirmed the postulated structures of the geometrical isomers **3***a* and **3***b*, the assignment of absolute configuration to the individual compounds was possible by analyzing and comparing their mass spectra. The ms of the ethylation products of **1** were recorded and fragmentation patterns of each of the isomeric compounds are proposed. The ions observed in the ms of compounds **2**, **3***a*, and **3***b* are given in Table 1.

The principal fragmentation pathway in the ms of **2** involves loss of a phenyl radical to give the resonance stabilized ion of *m*/*e* 180 (Scheme 1). Subsequent loss of ethylene via a MacLafferty rearrangement gives rise to the base peak of *m*/*e* 152, which can then fragment as indicated. It is unlikely that the loss of 28 mass units in going from *m*/*e* 180 to *m*/*e* 152 is due to CO expulsion since the resulting ion would be of much lower stability. The molecular ion also undergoes homolytic N—C bond fission to give the stable benzoylium ion of *m*/*e* 105 which further fragments in the characteristic way. Two pathways of minor importance but supported by metastable peaks involve loss of ethylene and water from the molecular ion to give fragments of *m*/*e* 229 and *m*/*e* 239 respectively. The fragments of *m*/*e* 212, *m*/*e* 154, *m*/*e* 127, and *m*/*e* 103 can be accounted for by an initial rearrangement of the parent ion, in which intramolecular nucleophilic attack by carbonyl oxygen at tetrahedral phosphorus occurs to give a tbp intermediate, which may collapse by loss of ethoxy radical to *m*/*e* 212, by loss of benzonitrile to the mixed phosphate ester of *m*/*e* 154, or by loss of ethyldimethylphosphate to benzonitrile radical ion of *m*/*e*

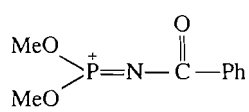
103. Loss of $C_2H_3\cdot$ from *m/e* 154 (via a double hydrogen shift mechanism (5)) yields the stable quasi-phosphonium ion of *m/e* 127. An alternative explanation of the presence of fragments of *m/e* 154 and 127 is based on the observation by Kirsanov *et al.* (6) that *N*-acyltriarylphosphorimidates (**4**) release nitriles when heated:

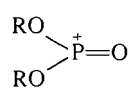
[3] $(ArO)_3P{=}N{-}\overset{\overset{O}{\|}}{C}{-}R \xrightarrow{\Delta} O{=}P(OAr)_3 + RCN$

4

No mechanism was proposed for reaction [3], but the most likely intermediate is identical to that shown in Scheme 1. In light of the above, it is conceivable that ethyldimethylphosphate and benzonitrile are formed prior to entering the ionization chamber. Direct loss of EtO· from the parent ion would yield fragment **5** of *m/e* 212, a nitrogen analogue of the commonly observed phosphorylium ions (**6**).



5



6

Very little information is available on the mass spectral characteristics of *N*-substituted phosphorimidates. Goldwhite *et al.* (7) discussed the possible origin of the most significant ions in the mass spectra of $(RO)_3PNEt$ (R = Me, Et); comparison with the ms of **2** shows that the nature of the fragment ions is determined exclusively by the substituent on nitrogen (ethyl vs. benzoyl) rather than by the substituents on phosphorus.

The most important fragmentation pathways available to the geometrical isomers **3***a* and **3***b* are given in Scheme 2. As can be seen from Table 1, the mass spectra of the isomers are specific for the type of isomer (*E* vs. *Z*), not in the nature of the ions, but in their abundance.

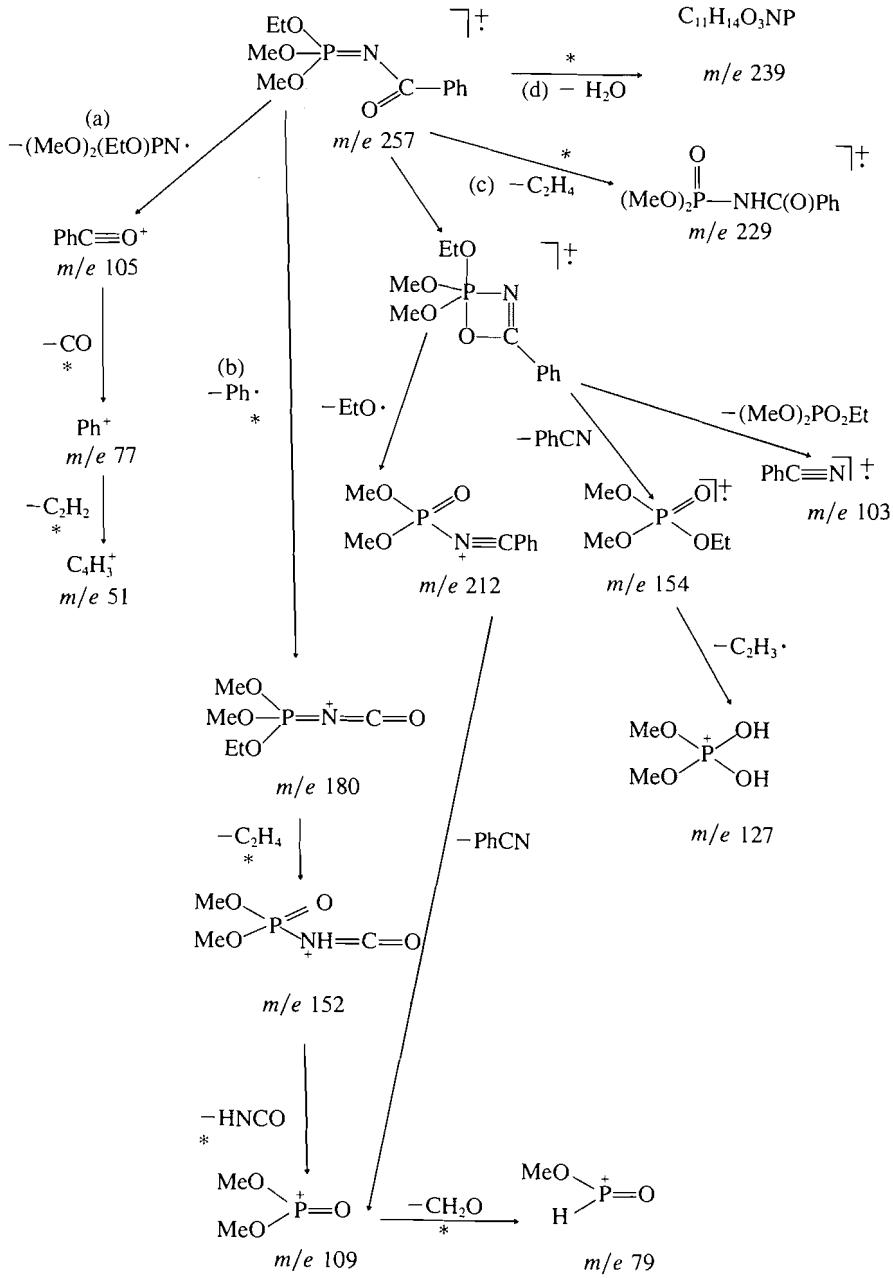
The two principal fragmentation pathways both involve the migration of a hydrogen from either the methoxyl or ethoxyl group to the nitrogen atom (pathways a, b). In the *E* isomer (**3***a*), loss of ethylene via a MacLafferty rearrangement is the most favoured pathway yielding the radical ion of *m/e* 229 (pathway a). This species is *N*-benzoyldimethylphosphoramidate, the precursor to the sodium salt (**1**), and its ms has recently been recorded (5). The second important H-migration fragmentation involves expulsion of a molecule of $C_2H_5O_3P$ and formation of *O*-ethylbenzimidate radical ion *m/e* 149 (pathway b). We have recently observed expulsion of the same neutral species in the ms of $(MeO)_2P(O)NHPh$ (5) and believe its structure is that of methyl methylene phosphite. This constitutes the principal fragmentation route of **3***b* (base peak *m/e* 149); it is also operative in the fragmentation of **3***a*, although to a lesser degree. The ms of independently synthesized ethylbenzimidate was recorded and we found the molecular ion to be remarkably stable (base peak). However, isomerization to *N*-ethyl benzamide does take place and subsequent fragmentation occurs as expected (8).

Loss of ethoxy radical from the molecular ion to yield *N*-dimethylphosphoryl benzonitrilium ion *m/e* 212 is a third minor pathway common to both isomers (pathway e). Loss of hydrogen from the molecular ion to yield the *O*-vinyl derivative *m/e* 255 is another minor pathway, again common to both isomers (pathway c). However, loss of benzonitrile from the molecular ion and from *m/e* 255 to yield the mixed phosphate esters *m/e* 154 and 152, respectively (pathways d, f), is more predominant in the fragmentation pattern of the *Z* isomer (**3***b*) than the *E* isomer (**3***a*). This is reasonable, since loss of benzonitrile from such a parent ion requires a *cis* orientation of the *N*-dimethylphosphoryl substituent and the migrating *O*-alkyl group (eq. [4]).

[4] 
R = Et (*m/e* 257)
R = $CH_2{=}CH$ (*m/e* 255)

Mixed phosphate ester formation appears to be the best explanation for the peaks observed at *m/e* 110, *m/e* 121, and *m/e* 127.

The main difference in the mass spectra of the geometrical isomers is a consequence of the stereospecificity of pathways a, d, and f, the former requiring a *trans* orientation and the latter two requiring a *cis* orientation of the *N*-dimethylphosphoryl and *O*-alkyl groups. The observation that all peaks are common to both spectra, but the peaks arising from initial loss of ethylene from the molecular ion (*m/e* 229, 228, 201, 105, 77, and 51) are noticeably more abundant in the ms of **3***a* than **3***b*, indicates a certain degree of interconversion of the



SCHEME 1. Proposed fragmentation pattern of **2**. NOTE: Pathways supported by metastable peaks are indicated by an asterisk.

isomers prior to fragmentation. The ion source temperature of 200°C thus appears to be sufficiently high to cause rotation about the carbon−nitrogen bond. The value of the C—N rotational barrier in benzimidates **3** is not known; however, it should not differ significantly from that determined for other N-substituted *O*-alkyl imidates. For a number of imidates R(R′O)CNR″, the inversion barrier has been found (9) to be of the order of 16−21 kcal mol^{-1}, sufficiently low to enable $E \rightleftharpoons Z$ interconversion at the ion source temperature.[3]

In conclusion, mass spectrometry is clearly a useful tool for distinguishing positional isomers. However, in accordance with the observation made by Natalis (10), a more detailed analysis of comparative ion peak intensities is required when using ms to differentiate geometrical isomers.

It is worthwhile to point out that in contrast to the literature report concerning a similar system (1), we were never able to detect any ethylation occuring at the nitrogen atom of ion **1**. This selectivity indicates that the kinetic and thermodynamic factors governing the nucleophilic behaviour of the carboxylic/phosphoric imide system are a sensitive function of the substrate and alkylating agent structures, as well as of the reaction conditions.

Experimental

The ^{1}H nmr spectra were recorded on a 100 MHz Varian XL100 spectrometer with TMS as internal standard. The ^{13}C nmr spectra were recorded on a WH90 Bruker spectrometer operating in the FT mode with TMS as internal standard. Infrared spectra were recorded on a Model 180 Perkin−Elmer ir spectrometer. Mass spectra were recorded on a VG Micromass 16F spectrometer operating at 70 eV and

[3]For all imidates reported in ref. 9, the coalescence temperature necessary to determine $\Delta G^{\neq}$ (E/Z) values by dynamic nmr spectroscopy was 90−150°C.

an ion source temperature of 200°C. Silica gel plates were used for thin-layer chromatography and Silica gel 60 (Merck, Art. 9385, 230–400 mesh) was used for column chromatography.

Ethylation of ***1*** *with triethyloxonium tetrafluoroborate*

A solution of 2.3 g (10 mmol) of *N*-benzoyldimethylphosphoramidate in 50 cm^3 dry benzene was added dropwise to a stirred suspension of 0.3 g (10 mmol) sodium hydride, forming a white jelly-like suspension of the sodium salt. The benzene was removed under reduced pressure leaving a white solid; ir (5% CCl_4 soln): 1205 (m, s), 1370 (s, s), 1550 (s, s), 1595 (m, s) cm^{-1}; ^1H nmr (DMSO-d_6), δ: 3.55 (6H, d, OCH_3, $J_{H,P}$ = 11 Hz), 7.4–7.5 (3H, m, *m*-, *p*-aryl H), 8.0–8.15 (2H, m, *o*-aryl H).

To a stirred suspension of 2.5 g (10 mmol) of the sodium salt in 50 cm^3 dry dichloromethane was added a solution of 1.9 g (10 mmol) triethyloxonium tetrafluoroborate in 10 cm^3 dry dichloromethane, maintaining the temperature at 10–15°C. The mixture was stirred for a fixed length of time (5–20 h), transferred to a separating funnel, and washed with 25 cm^3 water. The solution was dried over anhydrous magnesium sulfate and the solvent removed under reduced pressure, leaving a yellow oily product (1.82 g; 71% yield). Thin-layer chromatography (10% acetone in chloroform (v/v)) revealed two products of R_f values 0.40 and 0.56 respectively. After a reaction time of 5 h, the nmr spectrum of the product showed the formation of two compounds in 1 : 1 proportion (as measured from the integrated areas of the individual signals). The mixture was separated by column chromatography, eluting with the same solvent system, giving the following products.

First fraction

The pale yellow oil collected (**2**) showed the following spectral characteristics: ir (5% CCl_4 soln): 1187 (m, s, δ CH_3 of P—O—CH_3), 1347 (s, s, ν P=N), 1611 cm^{-1} with shoulder at 1624 (s, s, ν C=O) cm^{-1}; ^1H nmr ($CDCl_3$), δ: 1.39 (3H, t, CH_3, $J_{H,H}$ = 7 Hz), 3.92 (6H,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12

d, CH_3O, $J_{H,P}$ = 11 Hz), 4.30 (2H, quint., CH_2, $J_{H,H} = J_{H,P}$ = 7 Hz), 7.20–7.50 (3H, m, *m*-, *p*-aryl H), 8.12–8.24 (2H, pair of doublets, *o*-aryl H).

Second fraction

The yellow waxy solid (**3***a*) showed the following spectral characteristics: ir (5% CCl_4 soln): 1187 (m, s, δ CH_3 of P—O—CH_3), 1271 (s, s, ν P=O), 1657 (s, s, ν C=N) cm^{-1}; ^1H nmr ($CDCl_3$), δ: 1.42 (3H, t, CH_3, $J_{H,H}$ = 7.5 Hz), 3.67 (6H, d, CH_3O, $J_{H,P}$ = 11 Hz), 4.42 (2H, quart., $J_{H,H}$ = 7.5 Hz), 7.40–7.50 (3H, m, *m*-, *p*-aryl H), 7.87–7.98 (2H, pair of doublets, *o*-aryl H); ^{13}C nmr ($CDCl_3$, Hz downfield from TMS): 14.2 (s, β-CH_3 of the Et group), 53.2 (d, OCH_3, $J_{C,P}$ = 7.0 Hz), 64.0 (s, α-methylene of the OEt group), 125–135 (m, aromatic C and imidate C).

*Ethylation of **1** with ethyl iodide*

To a mixture of 0.02 mol of the sodium salt **1** (prepared as above) in 100 cm^3 dry benzene, was added a 10-fold excess of ethyl iodide (16.3 cm^3) together with a catalytic amount of tetra-n-butylammonium bromide (0.34 g, 5 mol%). The mixture was refluxed with stirring for 21 h. The supernatant benzene solution was decanted off and the solid white residue washed with 20 cm^3 benzene. The benzene was evaporated under reduced pressure to yield 3.00 g (58%) of crude product. This product was dissolved in 20 cm^3 chloroform and the solution was washed with water (2 × 5 cm^3). The organic layer was dried ($MgSO_4$) and the chloroform removed under reduced pressure, leaving a clear yellow oil. The product was subjected to column chromatography and eluted with 33% ethyl acetate in dichloromethane to yield the following compounds.

First fraction

The yellow waxy solid showed the same spectral characteristics as **3***a*.

Second fraction

The yellow oil (**3***b*) showed the following spectral characteristics: ir (5% CCl_4 soln): 1187 (m, s, δ CH_3 of P—O—CH_3), 1268 (s, s, ν P=O), 1654 (s, s, ν C=N) cm^{-1}; ^1H nmr ($CDCl_3$), δ: 1.42 (3H, t, CH_3, $J_{H,H}$ = 7.5 Hz), 3.48 (6H, d, OCH_3, $J_{H,P}$ = 11 Hz), 4.16 (2H, quart., CH_2, $J_{H,H}$ = 7.5 Hz), 7.10–7.30 (5H, m, aryl H), ^{13}C nmr ($CDCl_3$, Hz downfield from TMS): 14.0 (s, β-CH_3 of the OEt group), 44.2 (s, α-methylene of the OEt group), 53.2 (d, OCH_3, $J_{C,P}$ = 7.0 Hz), 125–135 (m, aromatic C, imidate C).

Received August 20, 1982

BRIAN K. HUNTER, KENNETH E. RUSSELL, and ATAA K. ZAGHLOUL. Can. J. Chem. **61**, 124 (1983).

Polystyrenes with 4-methoxyphenol end groups have been prepared by the cationic polymerization of styrene in the presence of the phenol. The products range from 1:1 adduct to polymer of number-average molecular weight close to 3000. The 1:1 adduct separated from the reaction mixture was shown by nuclear Overhauser effect studies to be 2-(1-methylbenzyl)-4-methoxyphenol. Only about half of the polymer molecules have 4-methoxyphenol end groups. ^{13}C nmr studies indicate that the polystyrene chains are attached principally at the 2-position of the phenol. The activity of the polymer as an antioxidant is comparable to that of corresponding low molecular weight methoxyphenols including butylated hydroxyanisole.

BRIAN K. HUNTER, KENNETH E. RUSSELL et ATAA K. ZAGHLOUL. Can. J. Chem. **61**, 124 (1983).

On a préparé des polystyrènes ayant le méthoxy-4 phénol-4 comme groupe terminal par polymérisation cationique du styrène en présence du phénol. Les produits vont de l'adduit 1:1 à un polymère d'un poids moléculaire moyen voisin de 3000. L'adduit 1:1 isolé du mélange réactionnel se révèle être le (méthyl-1 benzyl)-2 méthoxy-4 phénol d'après les études de eOn. Seulement la moitié des molécules de polymère aurait le méthoxy-4 phénol en position terminal. Les études de la rmn du ^{13}C indiquent que les chaînes de polystyrène sont attachées principalement en position 2 du phénol. L'activité du polymère comme antioxydant est comparable à celle des méthoxyphénols correspondants de faibles poids moléculaires incluant l'hydroxyanisole butylé.

[Traduit par le journal]

Introduction

Cationic polymerization of styrene in the presence of alkylphenols leads to polystyrenes with alkylphenols incorporated as a significant fraction of the end groups (1, 2). The growing polystyrene carbenium ion attacks the 4-position of the phenol if it is free, or the 6-position if there is an alkyl substituent at the 4-position. Products such as 2-*t*-butyl-4-methylphenol with a polystyrene chain attached at the 6-position show antioxidant activity comparable to that of 2,6-di-*t*-butyl-4-methylphenol, BHT.

Butylated hydroxyanisole, BHA, a mixture of 2- and 3-butyl-4-methoxyphenol, is a more reactive antioxidant than BHT. Replacement of the butyl group by a polystyrene chain should yield a phenol with comparable antioxidant activity to BHA but with different physical properties. The volatility of the phenol would be reduced, enabling the antioxidant to be used at higher temperatures without loss through vaporization. The compatibility of the antioxidant with polymers and with fats would be affected. The objectives of this research were thus to prepare polystyrenes with 4-methoxyphenol end groups, to characterize materials ranging from a 1:1 adduct to 4-methoxyphenols with attached polymer chains, and to determine whether these products had the anticipated high antioxidant activity.

Experimental

Styrene (Dow Chemical of Canada) was distilled under reduced pressure and dried over molecular sieves. 4-Methoxyphenol was recrystallized from benzene – petroleum ether. Dichloromethane was dried over molecular sieves. Aluminum chloride solutions were prepared in dichloromethane and allowed to stand in the dark for at least one day. *N*,*N*-Dimethylformamide was vacuum distilled from phosphorus pentoxide.

Polymerization mixtures were prepared containing styrene (3.7 *M*) and 4-methoxyphenol (0.1–0.5 *M*) in dichloromethane at the reaction temperature (−78°C to 20°C). Polymerization was initiated by the slow addition of aluminum chloride solution to the reaction mixture and terminated with methanol (1 mL) after a sufficient yield of polystyrene had been obtained. Polystyrene was precipitated by the dropwise addition of the solution to stirred methanol. It was reprecipitated twice from dichloromethane–methanol solutions and dried in a vacuum oven at 40°C.

The solution remaining after the first precipitation contained free 4-methoxyphenol and a number of low molecular weight derivatives. Dichloromethane and methanol were removed by means of a rotary evaporator and the residue distilled at reduced pressure. The fraction boiling in the range 40–60°C (at approximately 1 Torr) consisted mainly of 4-methoxyphenol and residual styrene monomer. The fraction boiling from 90–100°C was recrystallized from petroleum ether to give a white solid, mp 61–61.5°C. Mol. wt. (vapor pressure osmometry), 241 (calcd. for $C_{15}H_{16}O_2$, 228). *Anal.* calcd. for $C_{15}H_{16}O_2$: C 78.95, H 7.02; found: C 79.46, H 7.02. ^1H nmr ($CDCl_3$) δ: 1.56 (d, 3H, CH_3), 3.69 (s, 3H, OCH_3), 4.35 (q, 1H, CH), 4.92 (s, 1H, OH), 6.77 (s, 2H, aryl), 6.93 (s, 1H, aryl), and 7.35 (m, 5H, aryl).

The fraction boiling from 150–170°C in the low pressure distillation consisted largely of 1:2 4-methoxyphenol–styrene adducts together with some unsaturated oligomer. Two 1:2 adducts were separated by means of hplc (either a C_{18} analytical column with a 65:35 methanol–water as solvent, or a C_8 preparative column with 80:20 methanol–water as solvent). The main component appears to contain styryl groups at both the 2- and 6-positions.

Polymer characterization

Number-average molecular weights were determined by means of a Wescan vapor pressure osmometer with chloroform as solvent. Molecular weight distributions were obtained using a Waters 244 chromatograph with μ-styragel columns (100, 500, 1000, and 10 000 Å). The ratio of weight-average to number-average molecular weight is typically 1.5 for polymers prepared at 0–20°C but this is a minimum value because some low molecular weight polymer is lost during isolation. The presence of phenolic end groups over the whole range of polymer molecular weights is demonstrated through the use

of simultaneous refractive index and uv (280 nm) detection (1). The absorbance is a measure of phenol end group content because the polystyrene absorbs only weakly at 280 nm, and the change in refractive index is a measure of polymer concentration except at very low molecular weights. Removal of monomer, free phenol, and 1:1 adduct from the polymer is readily monitored by size exclusion chromatography since these materials are well resolved by the low porosity μ-styragel columns.

The fraction of polystyrene molecules with 4-methoxyphenol end groups was first estimated by uv analysis. The phenol-terminated polymer shows an absorbance maximum at 294 nm in chloroform solution as compared with 291 nm (ε, 3100 L mol^{-1} cm^{-1}) for 4-methoxyphenol and 292 nm (ε, 3700 L mol^{-1} cm^{-1}) for the 1:1 adduct. The molar absorptivity for the phenolic end groups was assumed to be equal to that for the 1:1 adduct in calculations of the phenol content of polymer samples. A direct estimate of the acidic OH groups in the polymer was obtained by potentiometric titration (3). The solvent was *N*,*N*-dimethylformamide and the base tetra-*n*-butyl ammonium hydroxide diluted with anhydrous isopropanol; titrations were performed under dry N_2.

The nmr spectra were obtained on a Bruker CXP-200 spectrometer (200 MHz for ^1H and 50.3 MHz for ^{13}C). With the exception of the nuclear Overhauser effect (nOe) difference spectra of the 1:1 adduct, samples were dissolved in $CDCl_3$ and run with pulse times and relaxation delays which give reliable intensity data for similar compounds. The nOe difference spectra were run in acetone-d_6 in which the spectrum of the aromatic protons of the phenol is well dispersed and easily analysed. Three spectra were run under identical conditions with a 1 s irradiation to establish the nOe, followed by a 5 ms delay and then by data acquisition. In one case, the irradiation was "off resonance" in order to provide a blank and in the other two cases the OH or the OCH_3 protons were irradiated. The spectra were Fourier transformed, phase corrected using the same phase parameters, and the difference taken between the blank and each of the specific irradiations.

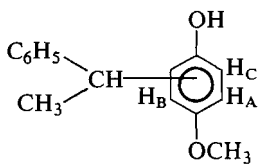
Antioxidant studies were conducted with styrene (10 mL) as substrate and azobisisobutyronitrile (0.010 *M*) as initiator (4). The volume of oxygen absorbed was determined as a function of time at a reaction temperature of 65°C.

Results and discussion

Polymerization of styrene by aluminum chloride at 20°C in the presence of 0.3 *M* 4-methoxyphenol leads to polymer of $\bar{M}_n \sim 2800$ and to significant amounts of 1:1 and 1:2 phenol–styrene adducts. An increase of 4-methoxyphenol concentration from 0.1 *M* to 0.3 *M* causes a decrease in $\bar{M}_n$ of the isolated polystyrene from about 3600 to 2800 and an increase in phenolic end groups from 23% to 45%. Increasing the temperature from −78°C to 20°C results in a decrease in $\bar{M}_n$ and an increase in the fraction of phenolic end groups from about 16% to 46%. Typical conditions of 0.3 *M* methoxyphenol and 20°C were chosen to yield a relatively high fraction of 4-methoxyphenol end groups.

The 1:1 adduct

Size exclusion chromatography of the precipitated polymer and of the mixture isolated from the remaining solution suggests the presence of 1:1 adduct in the reaction product. The material isolated by distillation is not a single compound but recrystallization yields a solid whose molecular weight and ^1H nmr spectrum correspond to the structure:



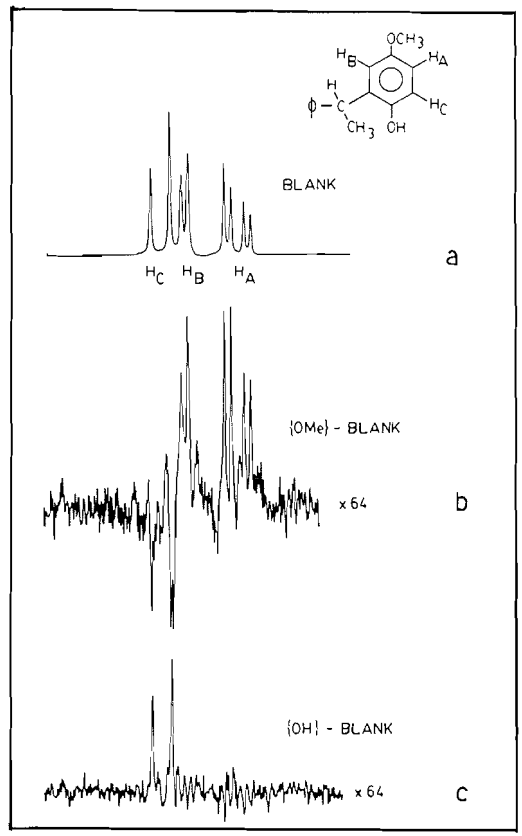


FIG. 1. Nuclear Overhauser effect study of the three protons of the phenolic ring of the 1:1 phenol–styrene adduct. Solvent: $(CD_3)_2CO$.

In particular the doublet at 1.56 ppm and the quartet at 4.35 ppm confirm the presence of the $CH_3CH\langle$ segment in the adduct. As anticipated, the resonance at 4.92 ppm almost disappears when D_2O is added, confirming the assignment to OH in chloroform-*d* solution. The ^1H nmr spectrum of the 1:1 compound in acetone-d_6 is similar to that obtained in chloroform-*d* solution except that the aromatic protons are well resolved and the OH resonance has moved upfield to 2.93 ppm.

The ^1H and ^{13}C nmr spectra of the adduct indicate that it is a single isomer. The preferred position of attack of the styryl carbenium ion on the phenol was investigated by means of nOe studies. Figure 1(*a*) shows the ^1H nmr spectrum in acetone-d_6 solution of the three protons of the aromatic ring of the phenol; (*b*) is a difference spectrum giving the effect of irradiating the methoxy resonance at 3.69 ppm and (*c*) the difference spectrum obtained on irradiating the hydroxy resonance at 2.93 ppm. Irradiation at OCH_3 increases the intensities of the resonances of two protons (H_A and H_B) whereas irradiation at OH increases the intensity of the resonance of one proton (H_C). The styryl group in the 1:1 adduct isolated in this work is consequently *ortho* to the OH rather than the OCH_3. The compound is therefore 2-(1-methylbenzyl)-4-methoxyphenol.

It is notable that in addition to the expected positive nOe's to the protons *ortho* to the methoxyl group, there is a large negative nOe to the proton *meta* to the methoxyl. This indirect negative nOe is transmitted via the intervening *ortho* proton and has been described in detail by Mersh and Sanders (5, 6).

^{13}C chemical shifts for the aromatic carbon atoms of 4-methoxyphenol are given in Table 1, together with those of the corresponding carbon atoms in the 1:1 adduct and

TABLE 1. ^{13}C nmr chemical shifts for derivatives of 4-methoxyphenol

				C-1	149.8	149.3*	147.4	147.8
C-2	116.4	129.4	133.4	133.3

C-5	115.3	112.4	111.9	111.6
C-6	116.4	116.9	116.7	116.2

*Solvent, $(CD_3)_2CO$ (7).

2-benzyl-4-methoxyphenol. In a general study of derivatives of benzylphenols (7) it was shown that introduction of a benzyl group at C-2 causes a 13 ppm downfield shift at C-2 and a 2.7 ppm upfield shift at C-5. The main effects of 1-methylbenzyl substitution are quite comparable — a 17 ppm downfield shift at C-2, and a 3.4 ppm upfield shift at C-5. Similar results are anticipated if a polystyrene chain is attached to C-2 of the 4-methoxyphenol.

Polystyrene with 4-methoxyphenol end groups

The main samples of polystyrenes prepared at 0°C in the presence of 0.3 *M* 4-methoxyphenol possess number-average molecular weights ($\bar{M}_n$) close to 3000. Simultaneous monitoring by uv (280 nm) and refractive index detectors showed that 4-methoxyphenol end groups are present in these samples over the whole range of molecular weights (approximately 500−8000). There is a maximum in the uv spectrum of the polymer at 294 nm compared with 292 nm for the 1:1 compound. The molar absorptivity of the 1:1 compound is 3700 L mol^{-1} cm^{-1} at λ_{max}, and if the phenolic end groups in the polymer possess the same molar absorptivity, the fraction of such end groups in the polystyrene samples is estimated to be at least 60%. Potentiometric titration yields a value of only 45%. The assumed molar absorptivity of the phenolic end groups in the polymer may be low and some of the polystyrene chains may be attached to the phenol at C-1 instead of C-2 or C-3.

The position on the phenol at which substitution occurs was investigated by means of ^{13}C nmr. The weaker resonances associated with the end groups do not overlap appreciably with the resonances arising from the phenyl groups in the polystyrene chain. Chemical shifts of the larger peaks originating from phenolic end groups are recorded in Table 1. The signal from the C-1 carbon bearing the OH group undergoes an upfield shift of about 2 ppm while the signal from the C-4 carbon bearing the OCH_3 group is unchanged. This implies that the preferred position of attachment of the polystyrene chain is at C-2 of the phenol. Such substitution leads to a 3.7 ppm upfield shift at C-5; the assignments at C-3 and C-6 are possibly interchanged.

The ^{13}C spectrum shows additional resonances close to 152 and 150 ppm and these indicate that attack can also occur at C-3 of the phenol. A fair proportion of the phenol is converted to the 1:1 adduct and some of it is incorporated as an end group, particularly if the yield of polymer is not kept low. The polystyrene thus contains a mixture of phenolic end groups and attachment at C-2 is merely a preferred rather than an exclusive chain-breaking process.

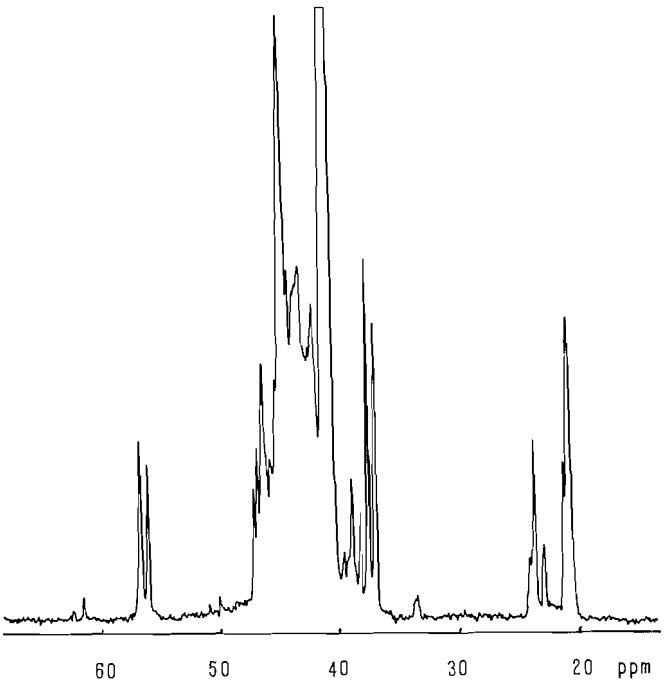

FIG. 2. Aliphatic region of ^{13}C nmr spectrum of polystyrene prepared in presence of 0.3 *M* 4-methoxyphenol. Solvent: $CDCl_3$.

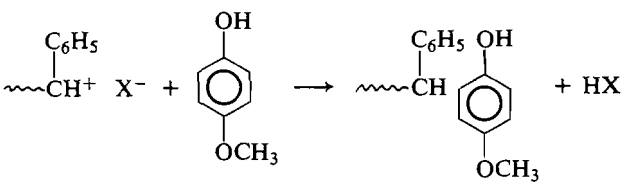
Some of the aromatic carbon atoms in the phenolic end groups, e.g. C-2, give rise to more than one peak in the ^{13}C spectrum. This is presumably the result of variations in tacticity in the polymer chain, since model compounds of polystyrene show effects of similar magnitude (8). The effect is more striking in the aliphatic region of the spectrum (see Fig. 2). A pattern of peaks at 20.9, 21.3, 23.0, and 23.5 ppm is similar to that observed with other low molecular weight styrenes prepared in the presence of alkylphenols. These resonances are found in the spectra of model compounds and have been assigned to a terminal methyl group in the polymer chain (8); the methyl group may be formed either by proton transfer (e.g. from a co-initiator in the initiation step) or as a result of hydrolysis of a Cl_2AlCH_2-group introduced in an alternative mode of initiation. Tacticity effects are probably also the cause of there being two methine peaks at 36.9 and 37.5 ppm. These are present in spectra of alkylphenol-terminated polystyrenes and are assigned to the CH carbon of the methylbenzyl end group. The strong resonances in the 40−46 ppm region arise from backbone CH and CH_2 groups in the polystyrene chain.

Incorporation of 4-methoxyphenol into polystyrene can be represented by the equation



Alternatively, chain breaking may occur by proton transfer from the carbenium ion to the negative ion or to monomer. The resulting end groups may be unsaturated (—CH=CHC_6H_5) or saturated indane derivatives (9, 10). A weak band at 965 cm^{-1} in the infrared spectrum of the polymer suggests the presence of some unsaturated end groups. It is also possible that some

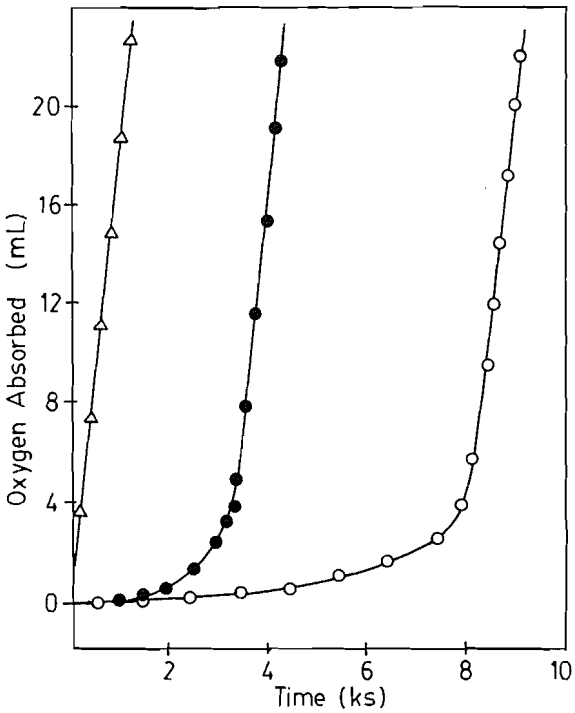

FIG. 3. Autoxidation of styrene at 65°C in the presence of various phenols. Δ, in the absence of phenol; ●, with 0.001 *M* polystyrene with phenol end groups; ○, with 0.001 *M* 1:1 adduct.

isomerization of unsaturated end groups may have occurred (11), resulting in methyl and methine groups in cyclic isomers which contribute to the patterns noted above. In each case, however, firm quantitative evidence has not been obtained.

Antioxidant activity of the phenol-terminated polystyrene

The 1:1 adduct and the phenol-terminated polymer were used as antioxidants for the autoxidation of styrene initiated by azobisisobutyronitrile at 65°C. Figure 3 shows the volume of oxygen absorbed as a function of time in the absence of phenol and in the presence of phenol-terminated polymer and of 1:1 phenol–styrene adduct at concentrations close to 0.001 *M*. In other experiments it was shown that the induction period is proportional to the concentration of phenol-terminated polymer in the range 0.00068 *M* to 0.0020 *M*. Assuming that the 1:1 adduct is pure, the fraction of phenolic end groups in the polystyrene sample was found to be 41%.

The behaviour of these materials as antioxidants is quite comparable to that of BHA under similar experimental conditions. At a concentration of 0.001 *M*, BHT reduces the initial rate of autoxidation of styrene to a much less extent than the 4-methoxyphenol derivatives. The rates of absorption of oxygen allow a rough estimate to be made of the ratio of rate constants for hydrogen abstraction by the peroxy radical from these phenols to that for its reaction with styrene. This ratio is close to 1000 at 65°C, confirming that the activity of these phenols is comparable to that of the more conventional antioxidant, 2-*t*-butyl-4-methoxyphenol (4, 12).

A constrained Roothaan–Hartree–Fock method

G. D. ZEISS AND M. A. WHITEHEAD

Chemistry Department, McGill University, 801 Sherbrooke Street West, Montreal, P.Q., Canada H3A 2K6

Received May 12, 1982

G. D. ZEISS and M. A. WHITEHEAD. Can. J. Chem. **61**, 128 (1983).

Nonperturbational and perturbation–iteration procedures for determining constrained Roothaan–Hartree–Fock wavefunctions are described and compared. The perturbation–iteration procedure most rapidly converges, the secant-parameterization method requires less computation and is less sensitive to numerical errors.

G. D. Zeiss et M. A. WHITEHEAD. Can. J. Chem. **61**, 128 (1983).

On décrit et on compare les procédés de non perturbation et de perturbation–répétition pour la détermination des fonctions d'onde de contrainte de Roothaan–Hartree–Fock. La méthode de perturbation–répétition converge plus rapidement alors que la méthode de mise en paramètre séquentielle requiert moins de calcul et elle est moins sensible aux erreurs numériques.

Introduction

The constrained variational Roothaan–Hartree–Fock (RHF) method (1–6) requires the wavefunction to satisfy one or more one-electron expectation value constraints (7–10). Non-variational calculations (11–19) used sufficient constraints to determine the wavefunction without the minimum energy principle.

Some of the constrained variational procedures considered here are applicable to this type of calculation. The variational calculations use several different procedures based on the parameterization (7), perturbation, perturbation–iteration methods (9), and pattern-search techniques in conjunction with the constrained density matrix methods (16). No calculation involved more than two free variational parameters. For larger systems computing the constrained RHF equations becomes significant, therefore several constraint procedures, with particular reference to computation, are developed. A rapid parameterization procedure, the *secant-parameterization method*, applicable to both singly and multiply constrained calculations, is described, and compared with several nonperturbational numerical methods, and perturbation theory methods. Computational difficulties, specific to multiply constrained calculations, are discussed.

Two questions arise: (*1*) how do constraints affect approximate wavefunctions, and (*2*) to what extent is a constrained wavefunction improved over a free variational wavefunction? Previous studies (7–9, 20–26) considered the effect of constraints on property expectation values, populations (27), and electron density distribution maps (7, 27, 28). In a constrained RHF calculation on HF (7), the expectation values of the dipole moment and the proton (deuteron) electric field gradient were constrained to experimental values; the constrained wavefunction significantly improved the expectation values of the diamagnetic shielding constant and the electric field at the proton and worsened the expectation values of the diamagnetic susceptibility and the electric field at the fluorine. The electron density distributions derived from the free variational and constrained wavefunctions compared with a distribution obtained from Nesbet's extended basis set RHF wavefunction (29) showed the gross characteristics of the exact wavefunction to be better represented by the constrained wavefunction. Two constrained RHF calculations using the N_2 wavefunction of Scherr (30), satisfied the molecular virial theorem (31) or yielded the experimental value (32) of the molecular quadrupole moment, the latter impaired the wavefunction, giving poorer expectation values for several one-electron properties, but (28) the virial theorem constraint improved the wavefunction.

The constrained Roothaan–Hartree–Fock equation for a closed shell system

The constrained Hartree–Fock method is a special case of the constrained variational theory in which, for a closed shell system, the wavefunction is required to have the form of an equivalence restricted (33) Slater determinant with $2n$ electrons and ϕ_ν linearly independent spatial one-electron functions to be determined. Each Hartree–Fock one-electron function ϕ_ν is expanded in terms of a finite number of known one-electron functions χ_i where $m > n$, and the coefficients $c_{i\nu}$ are to be

$$[1] \quad \phi_\nu = \sum_i^m \chi_i c_{i\nu}$$

determined. Substituting ϕ_ν into the free variational principle gives the constrained Roothaan–Hartree–Fock equations, which in canonical form are represented by the pseudo-eigenvalue equation

$$[2] \quad \sum_j^m F'_{ij} c_{j\nu} = \sum_j^m S_{ij} c_{j\nu} \epsilon'_\nu$$

and the associated constraint conditions

$$[3] \quad 2 \sum_\nu^n \sum_{ij}^m \langle \chi_i | M_q - \mu_q/2n | \chi_j \rangle c_{i\nu} c_{j\nu} = 0; \quad q = 1, \ldots, s$$

where M_q is a Hermitian operator and μ_q is the known expectation value of the operator, hence

$$[4] \quad F'_{ij} = F_{ij} + \sum_q^s \lambda_q \langle \chi_i | M_q - \mu_q/2n | \chi_j \rangle$$

and S_{ij} and F_{ij} are elements of the overlap matrix and Fock matrix, respectively. The quantities ϵ'_ν, $\nu = 1, \ldots, m$ are the roots of the secular equation

$$[5] \quad |F'_{ij} - \epsilon'_\nu S_{ij}| = 0$$

In the absence of constraints, when all $\lambda_q = 0$, eq. [3] reduces to the free variational RHF equation (3).

Equations analogous to [3]–[5] for open shell systems in either the unrestricted (34) or restricted (35) formulations are easily formulated.

Procedures for solving the constrained variational RHF equations

Solving the constrained RHF equations [3] and [4] requires simultaneous determination of the s Lagrange multipliers λ_q, and the nm variational parameters c_i of the trial wavefunction.

The secant-parameterization procedure (36)

In the parameterization method (22), the constraint conditions (4) are treated as a system of nonlinear equations in the independent variables λ_q, obtained by iteration. After each iteration a set of λ_q values is estimated and substituted into eq. [3], which is solved in the usual iterative self-consistent manner. The coefficients evaluate the expectation value of each constraint operator. The process is continued until each of the constraint conditions is satisfied to within a predetermined tolerance.

The secant-parameterization procedure requires two initial estimates of the Lagrange multiplier, $\lambda^{(0)}$ and $\lambda^{(1)}$, and the corresponding expectation values of the constraint operator, $\Delta\mu^{(0)}$ and $\Delta\mu^{(1)}$, where

$$[6] \quad \Delta\mu^{(i)} = \langle\psi^{(i)}|M - \mu|\psi^{(i)}\rangle$$

and $\psi^{(i)}$ is obtained by solving eq. [3] for $\lambda = \lambda^{(i)}$. $\lambda^{(0)}$ is chosen zero, and $\psi^{(0)}$ is the free variational RHF wavefunction: $\lambda^{(1)}$ is $\lambda^{(0)} \pm h$ (the sign is the sign of $\Delta\mu^{(0)}$), where h is a positive number sufficiently large that ($\Delta\mu^{(1)} = \Delta\mu^{(0)}$) possesses at least two or three significant digits, but small enough that only a few iterations are required for self-consistency when the coefficients $c_{i\nu}^{(0)}$ are used as an initial approximation to the $c_{i\nu}^{(1)}$. A new estimate $\lambda^{(2)}$ is

$$[7] \quad \lambda^{(i+1)} = \lambda^{(i)} - \frac{\lambda^{(i)} - \lambda^{(i-1)}}{\Delta\mu^{(i)} - \Delta\mu^{(i-1)}}\Delta\mu^{(i)}$$

Equation [3] is solved for $\lambda = \lambda^{(2)}$ and the process is repeated using $\lambda^{(1)}$ and $\lambda^{(2)}$. The coefficients determined for the previous value of λ initiate the iterative self-consistence procedure for solving eq. [3]. The iterative process terminates if (a)

$$[8] \quad |\delta\mu^{(i)}| < \epsilon_M$$

where ϵ_M is a predetermined tolerance; the procedure has converged, if (b)

$$[9] \quad |\Delta\mu^{(i)}| < \epsilon\Delta P_{\max}|M|$$

and the process is terminated. Here $\Delta P_{\max}$ is the largest absolute change in any element of the first order density matrix in the last iteration of the preceding self-consistency procedure, $|M| = \sum_{ij}|\langle\chi_i|M|\chi_j\rangle|$, and ϵ is a positive number ~1. This criterion terminates the process when the number of significant digits in ($\Delta\mu^{(i)} - \Delta\mu^{(i-1)}$) in eq. [7] becomes so small that the λ values estimated using eq. [7] become erratic, and if (c) after a pre-selected maximum allowed number of iterations, neither criterion (a) nor (b) is satisfied, the process is terminated.

For multiple constraints there are s constraint conditions, eq. [4] to be satisfied and s Lagrange multipliers λ_q to be determined. The cyclic procedure treats each constraint independently (25), while the remaining Lagrange multipliers are held constant. This procedure converges most rapidly when the constraint conditions are weakly coupled (37).

Nonperturbational procedures for determining constrained RHF wavefunctions

The approaches are: (*1*) direct energy minimization with respect to the variational parameters of the wavefunction subject to one or more nonlinear constraints, (*2*) solution of a system of nonlinear equations in the variables λ_q, (*3*) maximization of the expectation value of the fictitious Hamiltonian H' with respect to the parameters λ_q, and (*4*) application of the perturbation theory.

(1) Direct energy minimization (38–41) procedures for determining (unconstrained) RHF wavefunctions converge slowly.

(2) Two procedures (9, 22, 25, 42–44) are (a) the secant-parameterization method, and (b) a numerical procedure (45–47) for solving nonlinear equations.

(3) The derivative of the expectation value of the fictitious Hamiltonian H' with respect to the Lagrange multiplier λ_q is the expectation (22) value eq. [6] of the qth constraint operator, and this approach is well-suited to extremalization requiring the gradient of the function being extremalized (48).

The three numerical methods iterate to give a new set of λ_q values. Solve eq. [3] and use the wavefunction to calculate new expectation values of H' and the constraint operators. These expectation values determine new estimates of the λ_q's. The time-consuming part is the iterative SCF solution of the RHF equations. Therefore, a good comparative measure of the computation to solve the constrained RHF equations is the sum $\sum_i{}' N_{\text{SCF}}^{(i)}$ (the prime indicates that the iterations required initially to solve the unconstrained RHF equations are not included) of the number of iterations $N_{\text{SCF}}^{(i)}$ to achieve self-consistency in the ith step of the constraint procedure. The number of SCF iterations at each step depends on the SCF convergence criterion. The SCF procedure terminates if the energy change between SCF iterations is less than a predetermined value ϵ_E; for large ϵ_E, the number of SCF iterations is small, but ϵ_E must be small enough that the expectation values eq. [6] of the constraint operators are computed with sufficient precision for rapid convergence of the constraint procedure. Since the maximum change in any first order density matrix element between iterations is proportional to the square root of the corresponding energy change, this can be used to estimate an appropriate value of ϵ_E.

LiH constrained RHF calculations (Table 1) used these three numerical constraint procedures. The basis set was a minimum set of STO-4G functions (49) with Ransil's BLMO exponents (50). The constraints were the kinetic energy T, the diple moment x_n, and the electric field, E_{Li}^{c} and E_{H}^{c}, at the lithium and hydrogen nuclei, respectively, due to the electronic charge distribution. The SCF convergence criterion used was $\epsilon_E = 10^{-8}$ hartrees. For each constraint or combination of constraints the final values of the Lagrange multipliers from the three procedures agree to four significant figures. The secant procedure converges with much less computation (measured by $\Sigma' N_{\text{SCF}}^{(i)}$). The kinetic energy constraint calculations, Table 2, reveal that for the Fletcher–Powell method the initial rapid convergence rate becomes slow and erratic as the maximum is approached, because the E' hypersurface is very flat.

Rapid convergence requires a high precision in E' and in the expectation values of the constraint operators, achieved by making the SCF convergence criterion more stringent but thereby increasing the amount of computation. Brown's (45–47) method requires precise partial derivatives of the ex-

pectation values of the constraint operators with respect to the Lagrange multipliers λ_q, but the partial derivatives are evaluated numerically, and the method is very sensitive to imprecision in the calculated expectation values of constraint operators. The secant method is relatively *insensitive* to numerical errors in the calculated expectation values of constraint operators, and this is responsible for the rapid convergence.

The convergence criterion, $\epsilon_E = 10^{-8}$ hartrees, ensures convergence to 9–10 significant figures in the energy and about 5 significant figures in property expectation values. The computation is reduced by choosing a more lenient SCF convergence criterion; Table 3 contains results where ϵ_E was 10^{-5} hartrees: property expectation values are correct to at least 3–4 significant figures. Tables 1 and 3 show the Lagrange multipliers to agree to three significant figures. Table 4 shows the rate of convergence to be very rapid. The total number of SCF iterations in the constraint procedure is less than the number of iterations to solve the initial unconstrained RHF equations.

Sometimes no reasonable wavefunction satisfies a particular constraint condition (11–13, 25); the electric field or electric field gradient constraint at the proton on a minimum basis set LiH wavefunction with Slater exponents were unsuccessful, since the wavefunction lacks flexibility in regions weighted by the constraint operator (25, 27): a minimum basis set for LiH does not include a polarization function on the proton and cannot satisfy constraints of properties depending on the wavefunction near the proton.

Perturbation–iteration methods to determine constrained RHF wavefunctions

Three approximate forms of the first order RHF perturbation theory (8, 9, 20–24) are now applied to the constrained RHF method, and compared with calculations using the secant-parameterization procedure.

Perturbation theory (51–58) directly determines constrained variational wavefunctions, or is combined with a finite difference procedure (59–64), since for small basis set wavefunctions the perturbation expansion converges slowly (9, 22, 23, 65). In the iterative approach (66–74) each new estimate of the Lagrange multiplier is obtained using only the first term in the perturbation expansion. Both procedures were applied (8, 9) in the fully coupled CRHF form to a minimum basis set RHF calculation on N_2 in which the wavefunction was constrained to give the experimental molecular quadrupole mo-

ment (32). The convergence of the perturbation expansion was fast in the iterative perturbation procedure. The computation difficulties with solving the CRHF equations are not apparent for a minimum basis set N_2 wavefunction because of symmetry; less symmetrical systems and larger basis sets show the computational disadvantages of the CRHF method.

Three computationally less time-consuming first order RHF perturbation methods are examined in the context of the iterative perturbation procedure; the finite perturbation, FPT, and two uncoupled RHF methods.

To first order the Lagrange multiplier is

$$[10]\quad \lambda = \frac{\Delta\mu}{2E^{(2)}} + O(\Delta\mu^2)$$

where

$$[11]\quad E^{(2)} = \frac{d^2E}{d\lambda^2}$$

Using the generalized Hellman–Feynman theorem, $E^{(2)}$ is

$$[12]\quad E^{(2)} = \frac{d}{d\lambda}\langle\phi|\hat{M} - \mu|\phi\rangle$$

In the FPT method $E^{(2)}$ is evaluated using the finite difference analogue of eq. [12]. The "zeroeth order" RHF equations are solved for two values of λ where the difference h between them is small (64), and the method is capable of reproducing the exact CRHF value of $E^{(2)}$ to any desired accuracy.

The singly excited configuration obtained by replacing occupied ϕ_κ by virtual RHF orbitals ϕ_σ in the ground state RHF wavefunction are used as the zeroeth order wavefunction and the Rayleigh–Schrodinger perturbation theory applied giving an approximate sum-over-states expression for $E^{(2)}$

$$[13]\quad E^{(2)} \simeq -2\sum_{\kappa\phi}\frac{|\langle\phi_\kappa|M|\phi_\sigma\rangle|^2}{\epsilon_\sigma - \epsilon_\kappa - (\sigma\sigma|\kappa\kappa) + 2(\sigma\kappa|\sigma\kappa)}$$

ϵ_κ and ϵ_σ are the eigenvalues, and $(\sigma\sigma|\kappa\kappa)$ and $(\sigma\kappa|\sigma\kappa)$ are electron repulsion and exchange integrals. Neglecting these, a simple approximate expression is (71, 72)

$$[14]\quad E^{(2)} = 2\sum_{\kappa\sigma}\frac{|\langle\phi_\kappa|M|\phi_\sigma\rangle|^2}{\epsilon_\sigma - \epsilon_\kappa}$$

Equations [13] and [14] give different variants of the uncoupled RHF theory, I and II. Method I closely resembles the uncoupled RHF method of Langhoff *et al.* (57).

Constrained RHF calculations using these three perturbation methods, in conjunction with an iterative procedure, were perfomed on N_2, using a minimum basis set STO-4G function with Slater exponents (9). The constraint is the experimental molecular quadrupole moment (32). The SCF convergence criterion is $\epsilon_E = 1\times10^{-8}$ hartrees, and the corresponding value of ΔP_{max} is $\sim1\times10^{-4}$. The increment h in the finite perturbation theory was 1×10^{-3} to give $E^{(2)}$ to three significant figures, and was used to obtain the initial Lagrange multiplier in the secant-parameterization calculation. The Lagrange multiplier converged to five significant figures, Table 5 (the difference between the value of λ, 0.14148, and Bjørn's (9) value 0.14167, is because of different basis sets and the remaining errors in the quadrupole moment are all $\sim1\times10^{-4}$). The most rapid convergence is the finite perturbation method, the secant-parameterization and UCRHF method I are poorer, and UCRHF method II requires twice as many iterations, due to the poor estimates of $E^{(2)}$ obtained by the UCRHF method II (57, 75); the initial estimate of $E^{(2)}$ differs from the FPT value by 22% compared to a 5% discrepancy for the UCRHF method I

estimate. The errors in $E^{(2)}$ using the approximate UCRHF methods varies with the property constrained. The secant-parameterization procedure requires the least computation per iteration.

A disadvantage of the finite perturbation method is that eq. [3] must be solved for two values of λ at each step. In the secant-parameterization procedure eq. [3] is solved once per iteration after the initial step. In UCRHF method I $n(m-n)$ electron repulsion integrals are evaluated at each step and the same number of exchange integrals between RHF orbitals, significantly increasing the computation time per iteration. The UCRHF method II involves the least computation per iteration. Unfortunately, it also gives the slowest convergence. The secant-parameterization calculation required ~30 s on an IBM 360/75; the other calculations required 35–40 s.

The finite perturbation method uses numerical derivatives and is sensitive to calculated expectation value errors due to the SCF convergence criterion; values of $E^{(2)}$ calculated using eq. [3] or [4] are insensitive to the SCF convergence criterion. The secant-parameterization method is not sensitive to errors in constraint operator expectation values. Near convergence, when $(\lambda^{(i)} - \lambda^{(i-1)})$ becomes small, the correction $\Delta\lambda = (\lambda^{(i+1)} - \lambda^{(i)})$ to $\lambda^{(i)}$ obtained using eq. [7] is also small and very few significant digits are required (36).

Constrained RHF calculations with multiple constraints

The constrained RHF calculations on LiH in Tables 1 and 3 show the computation required to solve the constrained RHF equations increases dramatically with the number of constraints and hence the present calculations involve only two, or three, constraints. The combination of constraints influences the labour to determine multiple constrained wavefunctions.

A double constraint RHF calculation on LiH, in which the Hellman–Feynman electric field, E_A^e, at each nucleus is required to vanish, is given in Table 6. The expectation value of each constraint operator is independent of the Lagrange multiplier associated with the other constraint operator, the two constraint operators are only weakly coupled, and a cyclic multiple constraint procedure converges (37); the final Lagrange multipliers do not differ greatly from the values, 0.2411 and 0.7050, determined in singly constrained RHF calculations. An appropriate choice of the initial estimate $\lambda_q^{(0)}$ is the value in the corresponding singly constrained calculation (25, 37).

Table 7 contains results of a doubly constrained RHF calculation to CO; the wavefunction is constrained to give the experimental and theoretical values of the electric field gradient,

TABLE 6. LiH. *Determination of a doubly constrained RHF wavefunction using the cyclic secant-parameterization procedure.* The constrained properties are E_{Li}^e and E_H^e. Values of the Lagrange multipliers, the remaining errors in E_{Li}^e and E_H^e, and the total electronic energy are given for each cycle. The calculation was performed using BLMO exponents. The SCF convergence criterion was 10^{-5} *hartrees*

	Lagrange multipliers		Remaining errors in E_{Li}^e and E_H^e		
Cycle	$\lambda_1^{(i)}$	$\lambda_2^{(i)}$	$\Delta_1^{(i)}$	$\Delta_2^{(i)}$	$E^{(i)}$
0	0.0	0.0	0.0504	0.0298	−8.93653
1	0.2411	0.7449	0.0030	−0.0021	−8.91973
2	0.2574	0.6873	−0.0002	0.0001	−8.92054
3	0.2564	0.6919	7×10^{-6}	3×10^{-5}	−8.92052

TABLE 7. CO. *Determination of a doubly constrained RHF wavefunction using the cyclic secant-parameterization procedure.* The constrained properties are $-q_C^e$ and $-q_O^e$. Values of the Lagrange multipliers, the remaining errors in $-q_C^e$ and $-q_O^e$, and the total electronic energy are given for each cycle. The calculation was performed using a PL-4G (r^{-1}) basis set with Clementi and Raimondi's best atom exponents. The SCF convergence criterion was 10^{-6} *hartrees*

	Lagrange multipliers		Remaining errors in $-q_C^e$ and $-q_O^e$		
Cycle	$\lambda_1^{(i)}$	$\lambda_2^{(i)}$	$\Delta_1^{(i)}$	$\Delta_2^{(i)}$	$E^{(i)}$

$-q_A^e$, at each nucleus. The initial $\lambda_q^{(0)}$ were the values obtained in singly constrained RHF calculations. The expectation value of each constraint operator is strongly dependent on the value of the Lagrange multiplier of the other constraint operator, Table 7. This coupling between the constraint operators is stronger than in LiH, convergence is slower, and the final Lagrange multipliers values are quite different from the singly constrained values.

Constrained calculations with large basis sets show (24) the coupling between property operators to be greatest when the operators weight the same region, particularly if the basis set is relatively inflexible in these regions. In constrained minimum basis set calculations there is considerable coupling between

For personal use only.

constraint operators, even when they weight different regions of space. In some cases the wavefunction is unable to simultaneously satisfy two or more constraint conditions involving strongly coupled constraint operators (25), as in N_2, where the minimum basis set wavefunction posesses only two free variational degrees of freedom.

The expectation values of four of the seven properties of N_2, namely the molecular quadrupole moment, $-\theta_n^c$, the diamagnetic contribution to the diamagnetic susceptibility r_n^2, the total one-electron energy $T + V_{ne}$, and the electric field gradient $-q_N^c$, all depend on one of the two variational parameters, and it is impossible for the wavefunction to simultaneously satisfy two constraint conditions involving any two of these four properties.

Conclusion

Of the several procedures to determine constrained RHF wavefunctions the nonperturbational procedures included Brown's method (45–47), a general numerical procedure for solving systems of nonlinear algebraic equations, the Fletcher–Powell method (48) for extremalizing functions of several variables, and the secant-parameterization procedure, several procedures based on the RHF perturbation theory including the finite perturbation method (59–64), and two uncoupled RHF perturbation methods (57, 71, 72), the most rapidly converging was a constraint procedure based on the finite perturbation method; however, the secant-parameterization procedure, converging more slowly, required less computation and was less sensitive to numerical errors.

Therefore, the secant-parameterization method should be used to calculate constrained variational RHF wavefunctions.

The results from the method for an extensive series of constrained RHF calculations on N_2, FH, LiH, and CO are being published and analyzed (76, 77) using property expectation values, populations and electron density distribution profiles (78). The trends are very encouraging, and should advance the field from the dead-end surveyed in 1976 (79).

Appendix

Explicit expressions for Rayleigh–Schrödinger perturbation energies through seventh order

H_1 is a perturbation Hamiltonian and H_0 a zeroeth order Hamiltonian with eigenfunctions ϕ_n and energies E_n: Q_0 is the projection operator into the subspace spanned by the eigenfunctions of H_0 which are orthogonal to the eigenfunction ϕ_0 of the lowest eigenvalue E_0. The operator $Q_0/(E_0 - H_0)$ is defined so that for any operators A and B, the matrix element with respect to eigenfunctions ϕ_i and ϕ_j is

$$[4] \quad \langle\phi_i|A\frac{Q_0}{E_0 - H_0}B|\phi_j\rangle = \sum_{k\neq 0}\frac{\langle\phi_i|A|\phi_k\rangle\langle\phi_k|B|\phi_j\rangle}{E_0 - E_k}$$

Q_0 is idempotent, hence

$$[5] \quad \langle\phi_i|A\left(\frac{Q_0}{E_0 - H_0}\right)^n B|\phi_j\rangle = \langle\phi_i|A\frac{Q_0}{(E_0 - H_0)^n}B|\phi_j\rangle$$

In the Rayleigh–Schrödinger perturbation theory the perturbation expansion coefficients $E^{(n)}$ involve matrix elements which can be simplified being eqs. [4] and [5]

$$[6] \quad \langle\phi_0|H_1\frac{Q_0}{(E_0 - H_0)^{n_1}}H_1\frac{Q_0}{(E_0 - H_0)^{n_2}}H_1 \ldots H_1|\phi_0\rangle$$

For simplicity, eq. [6] is abbreviated as $\langle n_1 n_2 \ldots\rangle$.

The expressions for the $E^{(n)}$ were derived using Huby's prescription (80)

$$[7] \quad E^{(1)} = \langle\phi_0|H_1|\phi_0\rangle$$

$$[8] \quad E^{(2)} = \langle\phi_0|H_1\frac{Q_0}{E_0 - H_0}H_1|\phi_0\rangle = \langle 1\rangle$$

$$[9] \quad E^{(3)} = \langle 11\rangle - E^{(1)}\langle 2\rangle$$

$$[10] \quad E^{(4)} = \langle 111\rangle - 2E^{(1)}\langle 21\rangle + (E^{(1)})^2\langle 3\rangle - E^{(2)}\langle 2\rangle$$

$$[11] \quad E^{(5)} = \langle 1111\rangle - E^{(1)}(2\rangle 211\rangle + \langle 121\rangle) + (E^{(1)})^2(2\langle 31\rangle + \langle 22\rangle) - (E^{(1)})^3\langle 4\rangle + 2E^{(1)}E^{(2)}\langle 3\rangle - 2E^{(2)}\langle 21\rangle - E^{(3)}\langle 2\rangle$$

$$[12] \quad E^{(6)} = \langle 11111\rangle - E^{(1)}(2\langle 2111\rangle + 2\langle 1211\rangle) + (E^{(1)})^2(2\langle 221\rangle + \langle 212\rangle + 2\langle 311\rangle + \langle 131\rangle) - (E^{(1)})^3(2\langle 41\rangle + 2\langle 32\rangle) + (E^{(1)})^4\langle 5\rangle - E^{(2)}(2\langle 211\rangle + \langle 121\rangle) + E^{(1)}E^{(2)}(4\langle 31\rangle + 2\langle 22\rangle) - (E^{(1)})^2E^{(2)}\langle 4\rangle + (E^{(2)})^2\langle 3\rangle - 2E^{(3)}\langle 21\rangle + 2E^{(1)}E^{(3)}\langle 3\rangle - E^{(4)}\langle 2\rangle$$

$$[13] \quad E^{(7)} = \langle 111111\rangle - E^{(1)}(2\langle 21111\rangle + 2\langle 12111\rangle + \langle 11211\rangle) - (E^{(1)})^3(2\langle 411\rangle + 2\langle 321\rangle + 2\langle 312\rangle + 2\langle 231\rangle + \langle 222\rangle + \langle 141\rangle) + (E^{(1)})^4(2\langle 51\rangle + 2\langle 42\rangle + \langle 33\rangle) - (E^{(1)})^5\langle 6\rangle - E^{(2)}(2\langle 2111\rangle + 2\langle 1211\rangle) + (E^{(2)})^2(2\langle 31\rangle + \langle 22\rangle) + E^{(1)}E^{(2)}(4\langle 311\rangle + 4\langle 221\rangle + 2\langle 212\rangle + 2\langle 131\rangle) - (E^{(1)})^2E^{(2)}(6\langle 41\rangle + 6\langle 32\rangle) + 4(E^{(1)})^3E^{(2)}\langle 5\rangle - 3(E^{(2)})^2E^{(1)}\langle 4\rangle - E^{(3)}(2\langle 211\rangle + \langle 121\rangle) + E^{(1)}E^{(3)}(4\langle 31\rangle + 2\langle 22\rangle) - 3(E^{(1)})^2E^{(3)}\langle 4\rangle + 2E^{(2)}E^{(3)}\langle 3\rangle - 2E^{(4)}\langle 21\rangle + 2E^{(1)}E^{(4)}\langle 3\rangle - E^{(5)}\langle 2\rangle$$

The expressions were checked by repeating the LiH calculation of Chong (65). The perturbation energies and Lagrange multipliers agreed with Chong's to five places.

1-Iodoacétylènes. IV. Relations structure–réactivité pour la complexation des 1-iodoacétylènes substitués avec des bases de Lewis

CHRISTIAN LAURENCE, MICHÈLE QUEIGNEC-CABANETOS ET BRUNO WOJTKOWIAK

Laboratoire de Spectrochimie Moléculaire, U.E.R. de Chimie, Université de Nantes, 2, rue de la Houssinière, 44072 Nantes, France

Reçu le 25 mars 1982[1]

CHRISTIAN LAURENCE, MICHÈLE QUEIGNEC-CABANETOS et BRUNO WOJTKOWIAK. Can. J. Chem. **61**, 135 (1983).

Les constantes de l'équilibre de formation des complexes de Ph_3PO et Ph_3AsO avec les iodoacetylènes **1**–**8** ainsi que les déplacements des fréquences de vibration de bases de Lewis sont reliées aux constantes électroniques du substituant. Les déplacements chimiques du ^{13}C de la triple liaison constituent également des paramètres structuraux utiles pour prévoir l'acidité de Lewis des iodoalcynes.

CHRISTIAN LAURENCE, MICHÈLE QUEIGNEC-CABANETOS, and BRUNO WOJTKOWIAK. Can. J. Chem. **61**, 135 (1983).

The equilibrium constants for complex formation between the substituted 1-iodoacetylenes **1**–**8** and the vibrational frequency shifts induced by complex formation are related to the electronic substituent constants. The ^{13}C chemical shifts of the triple bond are also useful structural parameters for predicting the Lewis acidity of iodoalkynes.

Nous avons vu que l'acidité de Lewis de l'atome d'iode des 1-iodoacétylènes substitués **1**–**8** augmente considérablement en passant du substituant n-propyle au substituant cyano (1, 2). Le substituant modifie en effet le pouvoir accepteur d'électrons

$$IC{\equiv}C\ X$$

	X		X
1	n-Pr	**5**	I
2	Ph	**6**	*p*-$NO_2C_6H_4$
3	$SiEt_3$	**7**	COOEt
4	CH_2Br	**8**	CN

de l'atome d'iode par effets inductif et de résonance. Ces effets sont bien mesurés en série benzénique par les facteurs de Hammett (3) ou par les facteurs de Taft σ_I et σ_R (4). D'autres paramètres structuraux susceptibles de traduire les effets de substituant sont les déplacements chimiques $\delta^{13}C$ des carbones de la triple liaison. On a en effet souvent affirmé (5, 6) que $\delta^{13}C$ pouvait traduire les variations de densité électronique autour de l'atome de carbone.

L'objet de ce travail est d'analyser les corrélations pouvant exister entre la variation d'acidité des 1-iodoacétylènes substitués et ces deux types de paramètres structuraux. En effet l'application à la série acétylénique des facteurs σ définis en série benzénique n'a fait l'objet que de travaux limités (7) et est encore discutée (8). Par ailleurs à la lumière de la corrélation précédemment établie (9) entre l'acidité des alkylacétylènes et le déplacement chimique du carbone attaché au proton acétylénique, il semble intéressant de généraliser cette corrélation aux iodoacétylènes, substitués d'une manière plus diversifiée.

Résultats

Les propriétés corrélées sont les déplacements de fréquence $\Delta\nu$ d'un vibrateur du partenaire basique engagé dans le complexe moléculaire avec les iodoacétylènes, publiés dans un travail précédent (1), et les constantes d'équilibre de formation des complexes de Ph_3PO et Ph_3AsO avec $IC{\equiv}CX$, dont la détermination fait l'objet d'une publication séparée (2) et qui sont rappelées dans le tableau 1. Les constantes σ_I mesurant les effets inductifs des substituants X, σ_R^0 mesurant ses effets de résonance, et la constante globale[2] $\sigma_p = \sigma_I + \sigma_R^0$ sont également reportées dans ce tableau.

Les spectres de ^{13}C des iodoacétylènes **1**–**8** et des alcynes-1 correspondants (dont l'origine est indiquée dans la référence 1) ont été enregistrés sur un appareil Varian XL 100 pour des solutions approximativement molaires dans $CDCl_3$, ce solvant permettant le blocage champ-fréquence. Les déplacements des raies du ^{13}C sont mesurés à partir de la raie du TMS (référence interne) et sont comptés positivement du TMS vers les champs faibles. Ils sont rassemblés dans le tableau 2. L'influence de la concentration est pratiquement nulle pour δC_β et déplace légèrement δC_α vers les champs faibles, comme le montre le tableau 3.

Dans les spectres de 1-iodoacétylènes $IC_\alpha{\equiv}C_\beta X$ la raie C_α est toujours nettement plus intense que la raie C_β. Bien qu'une relaxation du carbone α par couplage scalaire avec le noyau quadrupolaire de l'iode soit plausible, il semble plutôt que ce fait soit lié aux conditions d'enregistrement: l'intervalle de temps (environ 3 s) séparant deux impulsions successives du champ magnétique permettrait une relaxation déjà efficace du carbone α, le temps de relaxation T_1 spin-réseau de ce carbone étant de cet ordre de grandeur. Au contraire celui du carbone β est beaucoup plus grand.[3]

Les spectres des alcynes-1 ont été enregistrés sous découplage total des protons. L'égalisation des populations des niveaux d'énergie du proton acétylénique conduit à une intensification très marquée de la raie de résonance du carbone α car la relaxation de ce carbone est dominée par un mécanisme dipôle–dipôle carbone–hydrogène.

[1]Revision reçue le 14 juillet 1982.

[2]$\sigma_p = \sigma_I + \sigma_R$ par définition. Mais pour les substituants étudiés ici $\sigma_R = \sigma_R^0$ (3).

[3]Pour $MeC{\equiv}CI$, T_1 (C_α) = 7 s et T_1 (C_β) = 33 s. On peut s'attendre dans la série $IC{\equiv}CX$ à des temps de relaxation du même ordre de grandeur.

Corrélations avec les paramètres σ

L'équation de corrélation la plus simple est celle de Hammett (3, 4, 7)

$$\log K \text{ ou } \Delta\nu = \rho(\sigma_I + \sigma_R) + h = \rho\sigma_p + h$$

où K est la constante d'équilibre de formation des complexes (Tableau 1), $\Delta\nu$ le déplacement d'un vibrateur de la base par complexation (Tableau 1 de la référence 1), ρ est le coefficient de sensibilité aux effets électroniques du substituant mesurés par σ_p et h est l'ordonnée à l'origine (voisine de log K ou $\Delta\nu$ du composé non substitué IC≡CH). Les résultats des corrélations sont reportés dans le tableau 4 et illustrés sur la figure 1. La plupart des corrélations ont un coefficient de corrélation supérieur à 0,95: pour le phénomène et l'échantillonnage de substitutants étudiés, on peut donc en conclure que les facteurs σ_p de la série benzénique (3) sont transposables en série acétylénique. Ces corrélations montrent comment croît le caractère accepteur d'électrons de l'atome d'iode des 1-iodoacétylènes substitués quand le pouvoir électroattracteur du substituant augmente. Elles permettent de prévoir qu'un des iodoacétylènes les moins acides sera $Me_2NC{\equiv}CI$ puisque $\sigma_p(NMe_2) = -0,71$ (3), qu'un des plus acides sera $IC{\equiv}CSO_2CF_3$ puisque $\sigma_p(SO_2CF_3) = +0,92$ (3) et que ce dernier formera avec Ph_3AsO des complexes plus stables (log $K_{calculé} = 8,49$) que l'iodure de cyanogène (log $K = 7,93$).

Un nombre trop limité de substituants ne permet pas de

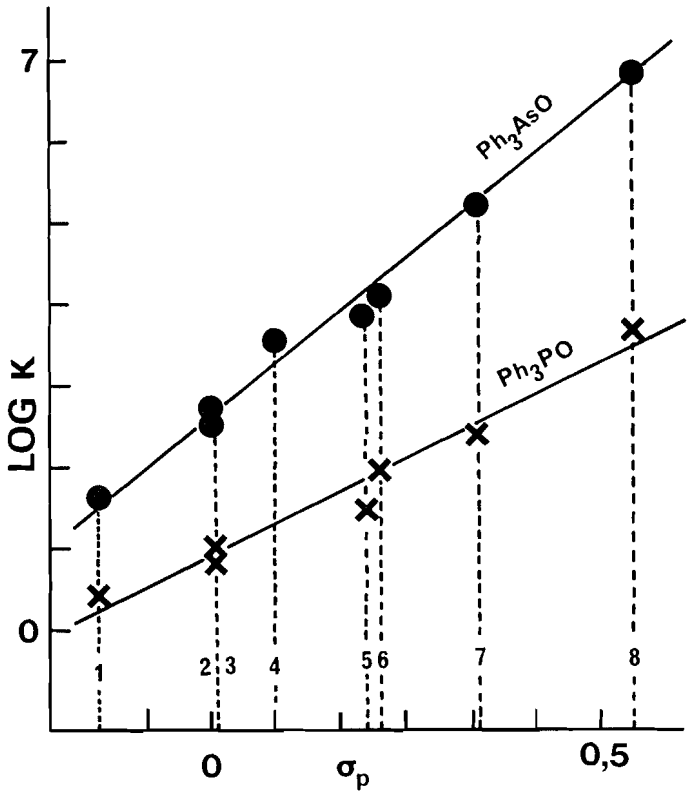

FIG. 1. Corrélation entre log K des complexes de Ph_3AsO et Ph_3PO, avec $IC\equiv CX$ et les facteurs de Hammett des substituants X. (**1**) n-Pr, (**2**) Ph, (**3**) $SiEt_3$, (**4**) CH_2Br, (**5**) I, (**6**) $C_6H_4NO_2$, (**7**) COOEt et (**8**) CN.

calculer de manière sûre les coefficients de sensibilité ρ_I et ρ_R aux effets inductif et de résonance, à l'aide de l'équation de Taft, log K ou $\Delta\nu = \rho_I\sigma_I + \rho_R\sigma_R + h$, dont l'avantage sur celle de Hammett est de ne pas imposer $\rho_I = \rho_R = \rho$ et de permettre d'utiliser diverses échelles $\sigma_R(\sigma_R^0, \sigma_R^-$ ...) selon la nature de l'interaction de résonance entre le groupe fonctionnel et le substituant.[4] On observe cependant des deplacements de

[4]Pour $IC\equiv CX$ on peut hésiter entre l'échelle σ_R^0 correspondant aux formules limites de résonance $I-{}^+C=C=\overline{X}$ ou $I-\overline{C}=C=\overset{+}{X}$ et l'échelle σ_R^- pour les substituants $-R$ correspondant à la formule limite + $I=C=C=X$ −.

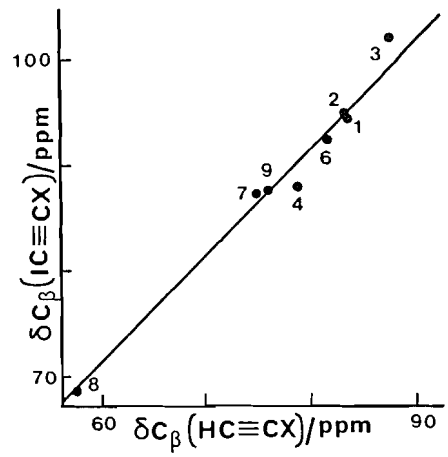

FIG. 2. Relation linéaire entre les déplacements chimiques δC_β des dérivés homologues $HC\equiv CX$ et $IC\equiv CX$. Même numérotation que Fig. 1; (**9**) COOH.

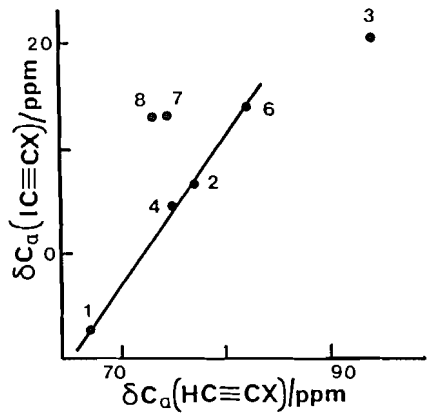

FIG. 3. Relation entre les déplacements chimiques δC_α des dérivés homologues $HC\equiv CX$ et $IC\equiv CX$. Même numérotation que Fig. 1.

fréquence (voir référence 2) et des constantes d'équilibre (Tableau 1) très voisins pour $PhC\equiv CI$ et $Et_3SiC\equiv CI$. Puisque pour les substituants Ph et Et_3Si $\sigma_I(Ph) = \sigma_R(Et_3Si)$ et $\sigma_I(Et_3Si) = \sigma_R(Ph)$, il est probable que ρ_I doit peu différer de ρ_R et que la variation de l'acidité de Lewis des iodoalcynes substituées dépend d'une manière quasiment égale des effets inductif et de résonance des substituants.

Corrélations avec les déplacements chimiques des ^{13}C de la triple liaison. Additivité des effets de substituant

Il existe une excellente relation linéaire de pente unité entre $\delta C_\beta(HC\equiv CX)$ et $\delta C_\beta(IC\equiv CX)$ (Fig. 2).

$$\delta C_\beta(IC\equiv CX) = 1{,}0(\delta C_\beta(HC\equiv CX) + 9);\ R = 0{,}986\quad n = 8$$

Cette relation prouve l'additivité des effets de l'iode et du groupement X sur δC_β (10). Cette additivité n'est plus respectée pour δC_α (Fig. 3). Une relation linéaire, déviant cependant sensiblement de l'additivité (pente 1,5 au lieu de 1), est observée pour les substituants +R (n—Pr (**1**), CH_2Br (**4**) et Ph (**2**)) et $C_6H_4NO_2$ (**6**) dont l'effet $-R$ est voisin de zéro tandis que les substituants $-R$ (CN (**8**), COOEt (**7**) et $SiEt_3$ (**3**)) dévient beaucoup plus. Cette non-additivité des effets de l'iode et des substituants X électroattracteurs sur δC_α s'explique probablement par une contribution significative des formes

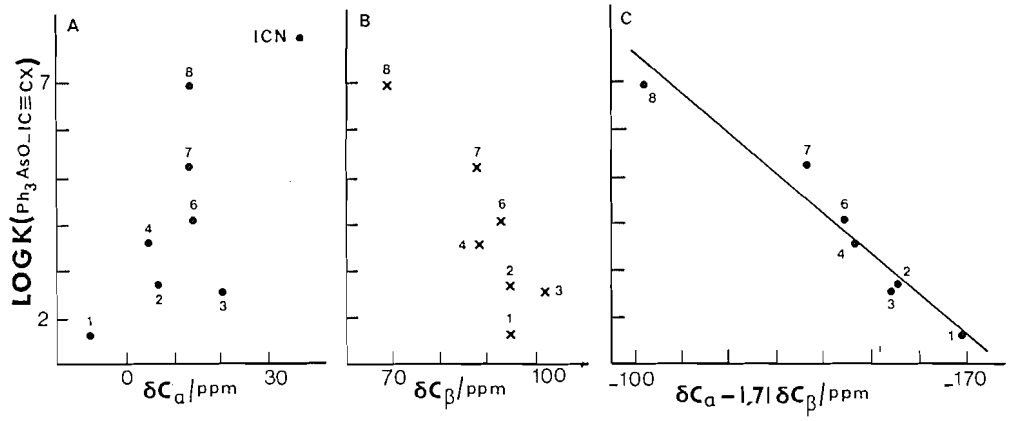

FIG. 4. Relations entre l'acidité de Lewis des iodoacétylènes et (A) δC_α, (B) δC_β et (C) une combinaison linéaire de δC_α et δC_β. Même numérotation que Fig. 1.

limites de résonance à la fonction d'onde décrivant l'environnement électronique du carbone α.

$$+ I{=}C{=}C{=}C{=}N^-, \quad + I{=}C{=}C{=}C\begin{matrix}\diagup O^- \\ \diagdown OEt\end{matrix}, \quad + I{=}C{=}C{=}\bar{S}iEt_3$$

Corrélations de δC_α et δC_β avec les constantes électroniques de substituant

Elles donnent les résultats suivants (le diiodoacétylène est exclu des corrélations):

$$\delta C_\alpha = 10 - 4\,\sigma_I + 71\,\sigma_R^0 \quad R = 0{,}90 \quad n = 7 \quad (R = 0{,}80 \text{ avec } \sigma_R^-)$$

$$\delta C_\beta = 98 - 46\,\sigma_I + 7\,\sigma_R^0 \quad R = 0{,}953 \quad n = 7$$

Elles montrent clairement que l'effet de résonance joue un rôle prédominant sur les variations de δC_α tandis que c'est l'effet inductif qui gouverne principalement les variations de δC_β. La faiblesse de notre échantillonnage de substituants (aucun halogène, aucun substituant fortement $+R$ tel que OMe et NMe_2) ne permet cependant pas de conclure définitivement. Il est en effet évident que les variations des déplacements chimiques des carbones de la triple liaison dans les iodoalcynes ne dépendent pas uniquement des effets électroniques des substituants: ainsi seulement 81% ($R^2 = 0{,}81$) de la variance de δC_α sont expliqués (64% si on remplace σ_R^0 par σ_R^-).

Corrélations entre δC_α, δC_β et l'acidité de Lewis des iodoacétylènes

δC_α et δC_β seuls ne permettent que grossièrement d'estimer la variation d'acidité des iodoacétylènes (et de ICN avec δC_α) comme le montre la figure 4. Cependant une combinaison linéaire de ces deux paramètres pourrait permettre de mieux pondérer les effets inductif et de résonance et peut-être d'éliminer partiellement les contributions non électroniques aux variations des déplacements chimiques. Les équations

$$\log K\,(Ph_3PO{-}IC{\equiv}CX) = 10 + 0{,}05\,\delta C_\alpha - 0{,}09\,\delta C_\beta \quad R = 0{,}982 \quad n = 6$$

$$\log K\,(Ph_3AsO{-}IC{\equiv}CX) = 16 + 0{,}09\,\delta C_\alpha - 0{,}15\,\delta C_\beta \quad R = 0{,}976 \quad n = 7$$

dont la seconde est illustrée sur la figure 4, sont effectivement obéies avec une précision satisfaisante et pourraient permettre de prévoir l'acidité de Lewis des iodoacétylènes à partir de leurs spectres rmn.

Remerciements

Nous remercions Mme Martin, Professeur à l'Université de Nantes, des discussions dont elle nous a fait bénéficier et M. Berry et Mme Mabon pour l'enregistrement des spectres rmn.

Rôle de l'alcool dans les microemulsions. II. Volumes et capacités calorifiques molaires apparents du système eau + dodécylsulfate de sodium + isopropanol à 298,15 K

VLADIMIR MAJER,[1] ALAIN-HENRI ROUX, GENEVIÈVE ROUX-DESGRANGES ET ANDRÉ VIALLARD

Laboratoire de Thermodynamique et Cinétique Chimique, Université de Clermont-Ferrand 2, B.P. 45-F, 63170 Aubière, France

Reçu le 4 mai 1982

VLADIMIR MAJER, ALAIN-HENRI ROUX, GENEVIÈVE ROUX-DESGRANGES et ANDRÉ VAILLARD. Can. J. Chem. **61**, 139 (1983).

Les masses volumiques et les capacités calorifiques par unité de volume du système ternaire: eau + dodécylsulfate de sodium (NaDS) + isopropanol (iPrOH) ont été mesurés en fonction de la concentration en alcool et en tensioactif à 298,15 K. Les volumes et les capacités calorifiques molaires apparents ou partiels de l'alcool dans le système ternaire en sont dérivés. Leur évolution en fonction de la composition reflète le comportement de l'alcool. En milieu dilué, il se solubilise partiellement dans les micelles et contribue à la formation de micelles mixtes. En milieu concentré, il se solubilise dans des microagrégats de nature très proche de celle de l'alcool. La variation de la capacité calorifique molaire apparente à dilution infinie de l'isopropanol en fonction de la concentration en NaDS, révèle l'existence d'une transition dans la structure micellaire vers 0,3 *m*.

VLADIMIR MAJER, ALAIN-HENRI ROUX, GENEVIÈVE ROUX-DESGRANGES, and ANDRÉ VAILLARD. Can. J. Chem. **61**, 139 (1983).

Densities and heat capacities per unit volume of the ternary system: water + sodium dodecylsulfate (NaDS) + isopropanol (iPrOH) have been measured as a function of concentration of alcohol and surfactant at 298.15 K. Apparent and partial molar volumes and heat capacities of isopropanol have been derived therefrom. These quantities reflect the behavior of alcohol in the solution. The results confirm that in the dilute region, iPrOH is partially solubilized in the micelles and contributes to the formation of mixed micelles, and that in the concentrated alcohol region, iPrOH is solubilized in microaggregates of alcohol. The variation of apparent heat capacity at infinite dilution of iPrOH as a function of NaDS concentration shows the existence of a transition in the micellar structure around 0.3 *m*.

Introduction

Depuis quelques années, un intérêt croissant est porté à l'étude des microémulsions, du fait de leurs applications dans des domaines variés (1, 2) et plus particulièrement en Récupération Assistée du Pétrole (3) et dans l'extraction d'hydrocarbures à partir des sables bitumineux (4). La présence d'un alcool est indispensable pour la formation et la stabilité de ces microémulsions, mais son rôle n'est pas encore clair.

En milieu micellaire, l'action des alcools apparaît complexe. Ils affectent la structure de l'eau et perturbent la constante diélectrique du milieu (5), mais ils se solubilisent aussi partiellement dans les micelles. De ce fait, ils interviennent sur la formation (6), la structure et la stabilité des micelles (7−12). Tous ces effets sont simultanés et difficiles à séparer (13, 14). L'étude des propriétés thermodynamiques des systèmes eau + tensioactif + alcool est un moyen d'investigation du comportement des alcools. Dans un travail précédent, nous avons étudié le système ternaire eau − dodécylsulfate de sodium − n-butanol (15).

Ce système est utilisé pour solubiliser le toluène et la microémulsion formée est une microémulsion modèle qui a déjà fait l'objet de nombreuses études (16−18), thermodynamiques entre autres (19, 20). Dans ce système ternaire, au-delà d'une certaine concentration en tensioactif, le butanol, peu soluble dans l'eau, devient totalement miscible. L'interprétation des résultats (15) conduit à considérer un partage de l'alcool entre phase aqueuse et phase micellaire et la formation de micelles mixtes alcool−tensioactif. Lorsque la concentration en alcool augmente, l'évolution des propriétés thermodynamiques permet de penser qu'il y a alors formation de "microphases" à caractère alcool proche de celui du corps pur.

Il nous a alors semblé nécessaire d'étudier le comportement d'un alcool totalement soluble dans l'eau, mais possédant un faible caractère hydrophobe. Nous avons choisi l'isopropanol qui a été particulièrement étudié dans l'eau (21). Son influence sur les propriétés des solutions micellaires reste encore controversée (22, 23). L'étude des propriétés volumiques et calorifiques du système ternaire eau + dodécylsulfate de sodium + isopropanol doit permettre de mieux comprendre les interactions de l'isopropanol avec le milieu et ses effets sur la structure micellaire.

Conditions expérimentales

Les solutions sont préparées par pesée avec de l'eau déionisée et distillée. Le dodécylsulfate de sodium (NaDS) est un produit Touzart et Matignon recristallisé deux fois dans l'éthanol et séché sous vide.[2] L'isopropanol (iPrOH) (Merck pour analyses 99,7%) conservé sur tamis moléculaires est utilisé sans purification ultérieure.

Les masses volumiques ρ des solutions sont déterminées à l'aide d'un densimètre à écoulement liquide permanent (Sodev 02D −

[1]Department of Physical Chemistry, Institute of Chemical Technology, Suchbatarova 5, 166 28 Prague 6, Czechoslovakia.

[2]La pureté du dodécylsulfate de sodium recristallisé dans les mêmes conditions a été vérifiée par des mesures de tension de surface. Aucun minimum n'apparaît au voisinage de la cmc indiquant l'absence d'impuretés. Nous remercions O. Dusart qui a bien voulu réaliser ces mesures.

*Unités: m = mol kg $^{-1}$. ρ = g cm^{-3}; $V_{\phi,3}$ = cm^3 mol^{-1}; c_p = J K^{-1} g^{-1}; $C_{\phi,3}$ = J K^{-1} mol^{-1}.

Canada) (24). Les mesures de capacités calorifiques volumiques σ sont réalisées à l'aide d'un calorimètre à écoulement pour chaleur spécifique type Picker. Cet appareil, ainsi que les procédures mises en oeuvre, ont été déjà décrits dans la littérature (25). L'appareil utilisé (Sétaram − France) est équipé de cellules en or. Les mesures sont effectuées avec une puissance de base de 21 mW, un débit liquide de 0,5 cm^3 min^{-1}, l'élévation de température est alors environ de 0,6 K. Les mesures de ρ et σ sont effectuées à 298,15 K, la température de référence est régulée à ±0,005 K et contrôlée à l'aide d'un thermomètre à quartz. Dans ces conditions, la précision des mesures est de 3×10^{-6} g cm^{-3} pour les masses volumiques et 7×10^{-5} J K^{-1} cm^{-3} pour les capacités calorifiques volumiques. Selon le domaine de concentration étudié, deux procédures de détermination de σ sont utilisées: soit par rapport à une référence fixe pour les solutions diluées, soit suivant la méthode des "références successives" pour les solutions concentrées.

Résultats

Les grandeurs expérimentales ρ et σ sont traitées sous la forme de grandeurs molaires apparentes $Y_{\phi,i}$ de la propriété Y pour un soluté i. Pratiquement, les volumes ($V_{\phi,i}$) et capacités calorifiques ($C_{\phi,i}$) molaires apparents du soluté i dans le système ternaire sont calculés à partir des différences ($\rho - \rho_0$) et ($\sigma - \sigma_0$) à l'aide des relations bien connues:

$$[1] \quad V_{\phi,i} = \frac{M_i}{\rho} - \frac{1000(\rho - \rho_0)}{m_i \rho \rho_0}$$

$$[2] \quad C_{\phi,i} = M_i c_p + \frac{1000(c_p - c_{p_0})}{m_i}$$

dans lesquelles M_i est la masse molaire du soluté i et m_i sa

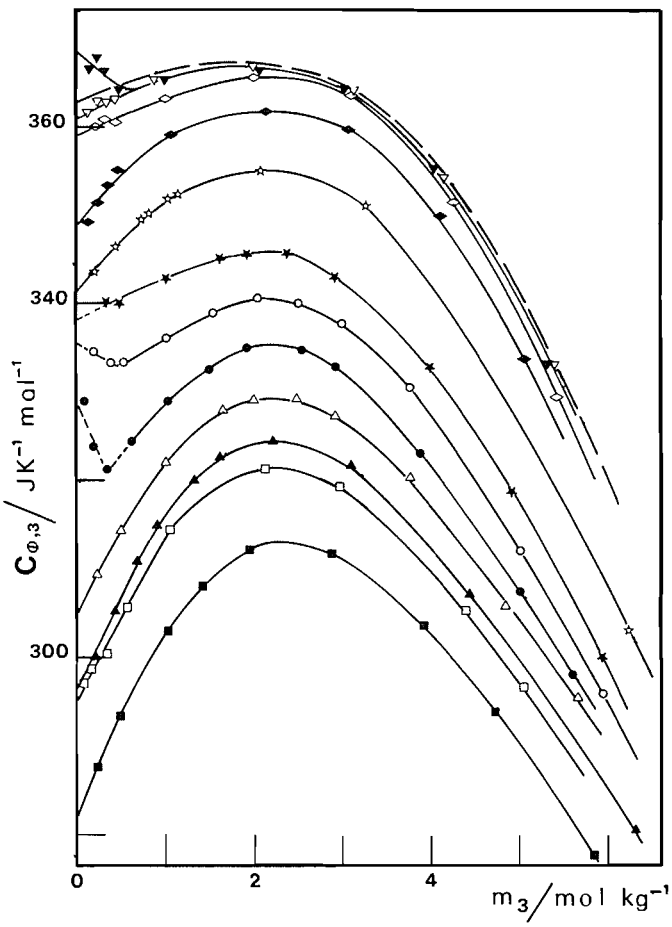

FIG. 2. Capacités calorifiques molaires apparentes de l'isopropanol à 298,15 K, en fonction de la molalité en isopropanol m_3 à différentes molalités en NaDS (m_2) du solvant mixte H_2O + NaDS:
m_2 = 0 (41) ——; 0,0029, ▽; 0,0063, ▼; 0,0100, ◇; 0,0499, ◆; 0,0985, ☆; 0,1979, ★; 0,2632, ○; 0,3064, ●; 0,3475, △; 0,3984, ▲; 0,4261, □; 0,5132, ■.

molalité par rapport au solvant de référence; ρ_0 et c_{p_0} sont les masses volumiques et capacités calorifiques du solvant de référence; dans le cas d'un système ternaire, le solvant de référence est le système binaire dans lequel est ajouté le soluté i. Les différences $(c_p - c_{p_0})$ sont calculées à partir des capacités calorifiques volumiques mesurées $(\sigma - \sigma_0)$, à l'aide de la relation:

$$[3] \quad c_p - c_{p_0} = c_{p_0}\left(\frac{\sigma - \sigma_0}{\sigma_0} + 1\right)\frac{\rho_0}{\rho} - c_{p_0}$$

dans laquelle $\sigma_0 = c_{p_0}\rho_0$ et $\sigma = c_p\rho$.

Le soluté i est l'isopropanol (i = 3), le solvant de référence est le mélange binaire H_2O (1) + NaDS (2). Les valeurs ρ_0 et c_{p_0} du binaire sont déterminées par rapport à l'eau (26, 27). Les masses volumiques et capacités calorifiques déterminées en fonction de la molalité en isopropanol, ainsi que les grandeurs apparentes $V_{\phi,3}$ et $C_{\phi,3}$ qui en résultent sont indiquées tableau 1.

Les variations de $V_{\phi,3}$ et $C_{\phi,3}$ sont représentées respectivement sur les figures 1 et 2. L'erreur estimée sur $V_{\phi,3}$ est de 0,1 cm^3 mol^{-1} à m_3 = 0,1 mol kg^{-1}, mais diminue très rapidement pour de plus fortes concentrations (elle est de 0,03 cm^3 mol^{-1} pour m_3 = 0,5 mol kg^{-1} par exemple). Pour les mêmes molalités, l'erreur sur $C_{\phi,3}$ est respectivement 1 et 0,2 J K^{-1} mol^{-1}. Les valeurs à dilution infinie $V^0_{\phi,3}$ et $C^0_{\phi,3}$ sont obtenues par extrapolation à partir des courbes $V_{\phi,3} = f(m_3)$ et $C_{\phi,3} = f(m_3)$ quand $m_3 \rightarrow 0$. Pour le domaine dilué en alcool, une équation du type Redlich–Meyer peut être utilisée pour répresenter les variations de $V_{\phi,3}$ et $C_{\phi,3}$:

$$[4] \quad Y_\phi = Y^0_\phi + A_Y m + B_Y m^2 + \ldots$$

avec $Y = V$ ou C. Une méthode de moindres carrés (premier ou second degré) permet l'évaluation des paramètres Y^0_ϕ et A_Y, ainsi que leur incertitude dans le domaine de molalité $0-m_{3,\max}$ en isopropanol. Ces différentes valeurs sont données dans le tableau 2. Cependant, pour les molalités en NaDS comprises entre 0,2 et 0,3 m, la forme particulière des courbes $C_{\phi,3} = f(m_3)$ dans leur partie initiale n'autorise pas l'utilisation d'une méthode de moindres carrés aussi simple. Les valeurs de $C^0_{\phi,3}$ et $A_{c,3}$ sont alors obtenues graphiquement; elles sont entâchées d'une erreur relativement importante.

Discussion

Les grandeurs molaires partielles ou apparentes d'un soluté sont caractéristiques de l'environnement moléculaire du soluté dans le milieu. Ces grandeurs traduisent non seulement la contribution propre du soluté, mais aussi la contribution des interactions subies par le soluté et des perturbations subies par le solvant. Ainsi, l'examen des variations des grandeurs molaires apparentes d'un soluté apporte des informations sur les change-

ments de structure de la solution qui résultent de l'addition du soluté.

A. *Evolution des grandeurs molaires apparentes de l'alcool dans le système ternaire*

1. *Examen des variations de* $V_{\phi,3}$ *et* $C_{\phi,3}$

L'allure des différentes courbes $V_{\phi,3} = f(m_3)$ (Fig. 1) d'une part, et $C_{\phi,3} = f(m_3)$ (Fig. 2) d'autre part, est comparable à celle de V_ϕ et C_ϕ de l'isopropanol dans l'eau pure (21).

Lorsque la concentration en NaDS augmente, pour une même concentration en alcool, $V_{\phi,3}$ croît et $C_{\phi,3}$ décroît. Les pentes initiales $A_{v,3}$ et $A_{c,3}$ varient peu (tableau 2). Les variations particulières observées au voisinage de la cmc (0,008 *m*), et entre 0,2 et 0,3 *m*, traduisent des changements de structure à propos desquels nous reviendrons au paragraphe B-2.

Les variations des grandeurs molaires partielles $\bar{V}_3$ et $\bar{C}_{p_3}$ sur tout le domaine de fraction molaire en isopropanol sont données (Fig. 3) pour différentes compositions du binaire H_2O + NaDS. $\bar{V}_3$ et $\bar{C}_{p_3}$ ont été déterminés à partir des variations de $V_{\phi,3}$ et $C_{\phi,3}$ selon la procédure utilisée par Desnoyers *et al.* (28). Les variations de $\bar{V}_3$ et $\bar{C}_{p_3}$ sont comparables à celles de $\bar{V}$ et $\bar{C}_p$ de l'isopropanol dans l'eau pure. Au-delà des extremums situés dans le domaine dilué, $\bar{V}_3$ et $\bar{C}_{p_3}$ tendent très rapidement vers le volume et la capacité calorifique molaire de l'isopropanol pur. Pour les fractions molaires en alcool supérieures à 0,15, quelle que soit la concentration en NaDS dans le domaine étudié, $\bar{V}_3$ et $\bar{C}_{p_3}$ apparaissent confondus avec $\bar{V}$ et $\bar{C}_p$ de l'alcool dans l'eau.

2. *Interprétation*

A l'examen de ces différentes variations, une remarque générale s'impose: le comportement de l'isopropanol en solution micellaire est similaire à son comportement dans l'eau pure.

En système binaire eau + isopropanol (21), l'isopropanol se comporte comme d'autres solutés organiques dans l'eau tels que le terbutanol (29), des alkoxyéthanols (30), des amines (21), des amines oxydes (31), etc. La similitude observée entre les variations de V_ϕ et C_ϕ en fonction de la molalité pour ces solutés et celles pour des tensioactifs vrais (32), suggère que de tels solutés ont la propriété de s'agréger pour former des microhétérogénéités dans l'eau. La formation de ces agrégats se traduit par une variation rapide de V_ϕ et C_ϕ (et surtout $\bar{V}$ et $\bar{C}_p$) dans un étroit domaine de concentration en soluté. Ensuite $\bar{V}$ et $\bar{C}_p$ ont sensiblement les valeurs du corps pur V_0 et C_{p_0}. Ceci indique que les molécules de soluté sont essentiellement localisées au sein d'un microenvironnement organique de nature proche de celui qui leur est offert dans le corps pur.

En système ternaire H_2O + NaDS + iPrOH, on constate (Figs. 1 et 2) que les variations de $V_{\phi,3}$ et $C_{\phi,3}$ en fonction de la concentration en alcool, pour différentes concentrations en tensioactif ont toutes la même allure générale, même à des concentrations élevées en tensioactif. Dans le domaine dilué en alcool, les variations de $V_{\phi,3}$ sont essentiellement représentatives des interactions soluté−soluté dans la phase aqueuse: elles traduisent les interactions hydrophobes de l'alcool. Avec l'augmentation de la concentration en tensioactif du binaire (H_2O + NaDS) à même teneur en alcool, les faibles variations de $V_{\phi,3}$ et $C_{\phi,3}$ conduisent à admettre que la quantité d'isopropanol solubilisée dans les micelles est faible. En effet, le caractère hydrophile de la molécule d'isopropanol fait qu'en solution diluée, en présence de tensioactif, il est pour l'essentiel dans la phase aqueuse. Les propriétés apparentes sont alors

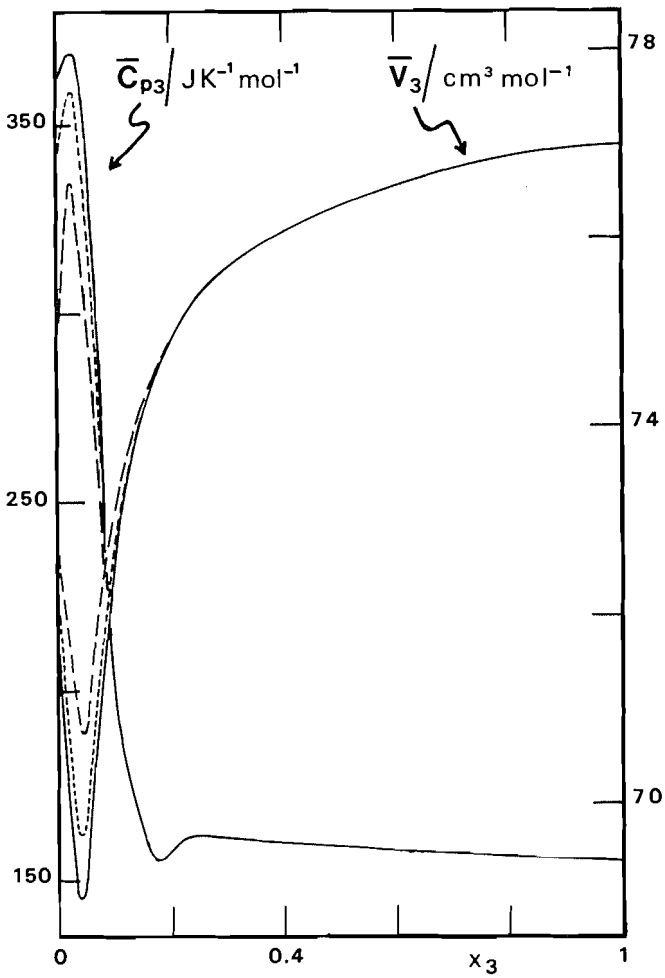

FIG. 3. Volumes et capacités calorifiques molaires partiels de l'isopropanol à 298,15 K, en fonction de la fraction molaire en isopropanol x_3, à différentes molalités en NaDS du solvant mixte H_2O + NaDS: ——— m_2 = 0 (41); --------- 0,0985; — — —, 0,3984.

assez peu différentes de celles dans l'eau pure, et ce, d'autant plus que certains auteurs (12−14) ont suggéré qu'il serait solubilisé dans la partie la plus externe de la micelle.

Dans le domaine plus concentré en alcool, au-delà du minimum de $V_{\phi,3}$ (du maximum de $C_{\phi,3}$) la contribution du phénomène d'agrégation de l'isopropanol l'emporte; le tensioactif serait susceptible de stabiliser ces agrégats sous forme de "micelles mixtes". Les variations de $V_{\phi,3}$ et $C_{\phi,3}$ traduisent la résultante des interactions entre molécules d'alcool en phase aqueuse et celle de l'alcool solubilisé dans les micelles ou sous forme d'agrégats. Pour des valeurs de x_3 supérieures à 0,15 (Fig. 3), l'alcool est presque entièrement sous forme de micro-agrégats et l'isopropanol se solubilise dans un milieu ressemblant à un milieu alcool pur. L'existence de ces micro-hétérogénéités est encore discutée, mais de récents travaux sur les systèmes eau + iPrOH + benzène (33) et eau + iPrOH + hexane (34) confortent cette hypothèse, les auteurs qualifiant même l'isopropanol de composant actif d'une "micro-émulsion sans détergent".

B. *Grandeurs à dilution infinie* $V^0_{\phi,3}$ *et* $C^0_{\phi,3}$

1. *Volumes*

La variation de $V^0_{\phi,3}$ en fonction de la molalité m_2 en NaDS est représentée (Fig. 4). $V^0_{\phi,3}$ reste constant avant la cmc, puis ensuite augmente régulièrement sur tout le domaine de concentration en NaDS étudié. Dans le domaine prémicellaire, l'isopropanol est en phase aqueuse et $V^0_{\phi,3}$ résulte des interactions de l'alcool avec les monomères de NaDS et l'eau; en milieu micellaire, comme il est réparti entre la phase aqueuse et les micelles sa propriété molaire apparente est une moyenne pondérée de celles dans chacune des deux phases. Les valeurs de $V^0_{\phi,3}$ très proches de celle de l'isopropanol à dilution infinie dans l'eau pure et la très faible variation de $V^0_{\phi,3}$ dans tout le domaine de concentration étudié montrent que la contribution de l'alcool dans la phase micellaire est très faible; l'isopropanol est donc solubilisé dans une très large proportion en phase aqueuse. Ce résultat est en accord avec ceux de Manabe *et al.* (35); ces auteurs ont étudié $V^0_{\phi,a}$ de part et d'autre de la cmc dans un étroit domaine de concentration en NaDS pour la série des alcools linéaires; ils n'observent pas de variation de cette grandeur pour les alcools inférieurs à C_4, ce qui va dans le sens d'une solubilisation de ces alcools, essentiellement en phase aqueuse. Pour des alcools à longue chaîne, peu solubles dans l'eau, $V^0_{\phi,a}$ est alors très proche du volume molaire de l'alcool pur, en raison de la solubilisation quasi totale de l'alcool dans la phase micellaire de nature organique (23, 35).

2. *Capacités calorifiques*

L'évolution de $C^0_{\phi,3}$ en fonction de la molalité m_2 en NaDS, représentée Fig. 4, apparaît plus complexe que celle de $V^0_{\phi,3}$. Au voisinage de la cmc $C^0_{\phi,3}$ semble tendre vers une valeur maximum. Pour m_2 compris entre 0,2 et 0,35 *m*, $C^0_{\phi,3}$ reste d'abord à peu près constant, puis décroît rapidement. Dans ce domaine, compte-tenu de l'incertitude sur les valeurs extrapolées de $C^0_{\phi,3}$, la forme de la courbe $C^0_{\phi,3}$ reste significative et traduit l'existence d'un phénomène réel. Ce phénomène observé à dilution infinie est encore là pour des concentrations finies en alcool, mais disparaît progressivement lorsque la concentration en alcool augmente, comme en témoigne la forme des courbes $C_{\phi,3}$ (m_2) pour différentes valeurs de m_3 (Fig. 4). Bien que le partage de l'isopropanol se fasse préférentiellement en faveur de la phase aqueuse, la contribution à $C^0_{\phi,3}$ des interactions de l'alcool solubilisé dans les micelles permet de mettre en évidence vers 0,3 *m* un changement dans la structure micellaire du binaire H_2O + NaDS. Ce changement observé lors de l'étude du binaire H_2O + NaDS (36) a aussi été mis en évidence dans l'étude du système ternaire H_2O + NaDS + n-BuOH (15). Des changements de même type ont également été observés avec des carboxylates de sodium (37) et, si l'on admet l'existence de "pseudo-phases" (37), ils correspondraient à des transitions entre des structures stables différentes.

Les variations particulières de $C^0_{\phi,3}$ au voisinage de la cmc et vers 0,3 *m* en NaDS, sont liées aux déplacements des équilibres chimiques, par suite de l'élévation de température provoquée pour l'évaluation de la capacité calorifique (38). Ainsi, les équilibres du tensioactif entre phase aqueuse et phase micellaire au voisinage de la cmc et entre les structures différentes vers 0,3 *m* sont modifiés. Il en résulte une perturbation du partage de l'alcool entre les différentes structures évoquées et, corrélativement, des valeurs de $C^0_{\phi,3}$.

C. *Grandeurs molaires apparentes relatives à NaDS en milieu eau + isopropanol*

Les mesures de masses volumiques et de capacités calorifiques réalisées dans le système ternaire permettent, au moyen d'interpolations, de calculer les grandeurs molaires apparentes $V_{\phi,2}$ et $C_{\phi,2}$ associées au tensioactif dans des solvants mixtes H_2O + iPrOH de composition donnée lorsque varie la

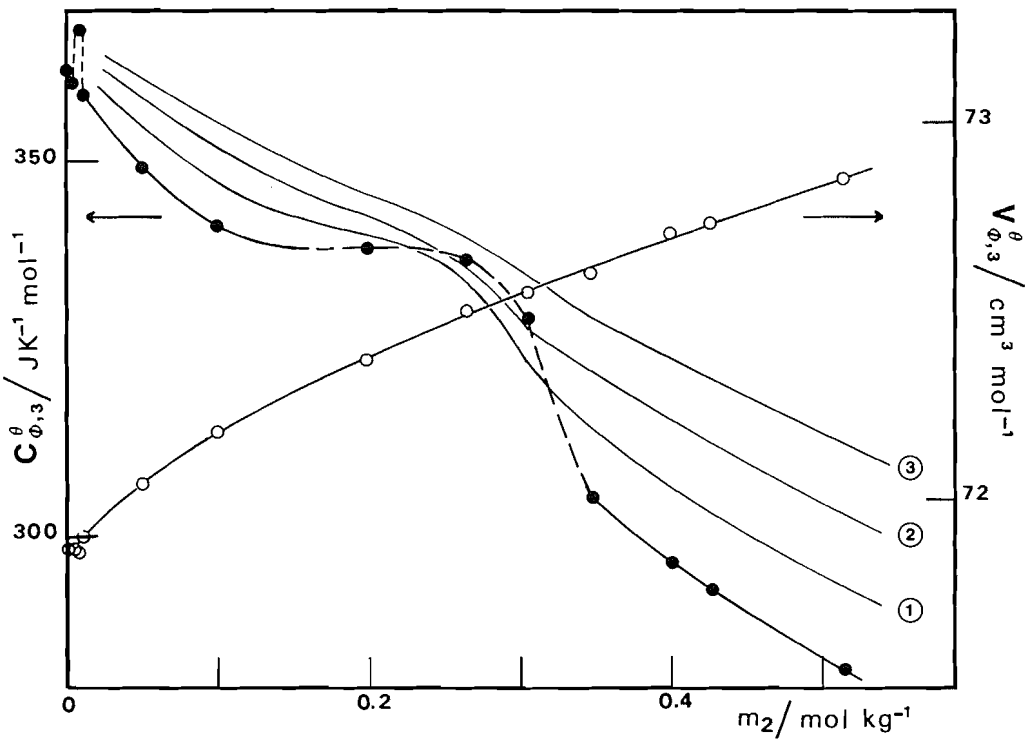

FIG. 4. Volumes et capacités calorifiques molaires apparents de l'isopropanol à 298,15 K, en fonction de la molalité en NaDS m_2 du solvant mixte H_2O + NaDS.
●○ valeurs extrapolées à dilution infinie $m_3 = 0$; ① valeurs interpolées à $m_3 = 0{,}5$; ② valeurs interpolées à $m_3 = 1$; ③ valeurs interpolées à $m_3 = 2$.

concentration en NaDS. Les courbes représentant les variations de $V_{\phi,2}$ et $C_{\phi,2}$ en fonction de m_2 pour des solutions 0,5, 1, 2, 3 et 4 *m* en iPrOH sont données respectivement figs. 5 et 6.

Il est bien connu que l'isopropanol abaisse la cmc du dodécylsulfate de sodium (11); à l'examen de ces courbes, on remarque que l'augmentation rapide de $V_{\phi,2}$ et la décroissance de $C_{\phi,2}$ se produisent pour des concentrations en tensioactif de plus en plus faibles, au fur et à mesure que la quantité d'alcool augmente dans le solvant mixte.

Dans la région prémicellaire, étant donné la très faible valeur de la cmc de NaDS ($8{,}3 \times 10^{-3}$ *m* (39)), il est difficile d'effectuer l'étude quantitative de l'influence de l'alcool sur les propriétés molaires du monomère de tensioactif, comme l'ont réalisée Vikingstad et Kvammen (14) avec la série des alcools à chaîne courte dans les solutions de décanoate de sodium ou Güveli *et al.* (40) avec les mêmes alcools dans le système H_2O – bromure de dodécyltriméthylammonium. Qualitativement, lorsque la quantité d'isopropanol augmente, on observe que le volume apparent du monomère NaDS augmente et sa capacité calorifique décroît, en accord avec les résultats précités. Ces auteurs expliquent ces variations à la fois par une diminution de l'hydratation hydrophobe de la partie hydrocarbonée du tensioactif et par une diminution de l'hydratation hydrophile de sa tête ionique, le monomère se trouvant dans un environnement de plus en plus organique.

Dans la région post-micellaire, les valeurs de $V_{\phi,2}$ augmentent et celles de $C_{\phi,2}$ diminuent lorsque la quantité de l'alcool croît dans le solvant mixte H_2O + iPrOH. L'effet de l'alcool doit être relié à des changements de la couche superficielle micellaire par suite de la solubilisation de l'alcool dans les micelles (12). Vikingstad et Kvammen (14) considèrent que l'augmentation de volume apparent du tensioactif est due à une réduction de l'électrostriction des molécules d'eau sur la surface micellaire.

Les courbes $V_{\phi,2}$ (m_2) passent par un maximum (un minimum pour $C_{\phi,2}$) puis tendent vers la valeur du volume apparent (et de la capacité calorifique apparente) de NaDS dans les micelles. Il semble que ces extremums soient d'autant plus prononcés que la composition du binaire H_2O + iPrOH est proche de celle pour laquelle il se forme des microhétérogénéités dans le binaire.

Conclusion

L'étude des volumes et capacités calorifiques du système ternaire H_2O + NaDS + iPrOH contribue à une meilleure connaissance du rôle de l'alcool dans les solutions micellaires. La nature de l'isopropanol, de par son caractère légèrement amphiphile, fait qu'il est susceptible de former des microagrégats dans l'eau, aussi certains auteurs ont-ils évoqué le "rôle actif de l'isopropanol dans les microémulsions sans détergent" (33, 34). Dans les solutions micellaires, l'isopropanol agit à la fois sur la structure du solvant et sur les propriétés micellaires provoquant un abaissement de la cmc du tensioactif. Nos résultats corroborent l'hypothèse selon laquelle l'isopropanol s'incorpore dans la micelle à l'interface micelle–solvant pour former des micelles mixtes, sans pénétrer profondément dans le coeur micellaire. En jouant un rôle d'écran entre les têtes ioniques du tensioactif, il abaisserait la densité superficielle de charge et contribuerait ainsi à stabiliser la micelle. Les alcools à plus longue chaîne, leur caractère hydrophobe augmentant, pénètrent alors plus à l'intérieur de la micelle et perturbent de façon plus importante la structure de la micelle (12, 40).

L'étude des capacités calorifiques molaires apparentes à di-

lution infinie de l'isopropanol (ou dans le domaine très dilué en alcool) a permis de mettre en évidence des changements de structure dans le binaire H_2O + NaDS. En plus de la transition correspondant à la concentration critique micellaire du tensioactif, l'existence d'une seconde transition pourrait être responsable des changements observés vers 0,3 *m* en NaDS (plus clairement mise en évidence que lors de l'étude du seul binaire H_2O + NaDS (36)). Cette transition semblerait jouer un rôle essentiel pour la solubilisation de molécules organiques telles que le butanol (15) et pour la solubilisation des hydrocarbures en milieu microémulsion (19, 20).

Remerciements

L'un de nous (V. M.) tient à exprimer ses remerciements pour l'obtention d'une bourse de la D.G.R.C.S.T., Ministère des Relations Extérieures, dans le cadre des échanges France–Tchécoslovaquie. Nous remercions aussi M. le Professeur J. E. Desnoyers (Université de Sherbrooke, Canada) pour les discussions fructueuses et l'intérêt qu'il a bien voulu porter à ce travail.

The synthesis of α-*N*,*N*-dimethyl-1′-diphenylphosphinoferrocenylethylamine and related ligands

IAN R. BUTLER AND WILLIAM R. CULLEN

Chemistry Department, University of British Columbia, Vancouver, B.C., Canada V6T 1Y6

Received July 15, 1982

IAN R. BUTLER and WILLIAM R. CULLEN. Can. J. Chem. **61**, 147 (1983).

Routes to the title compound were explored based on the cleavage of [1]-ferrocenophanes with aryllithium. Thus the cleavage of $(\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_3(CHMeNMe_2)PPh)$ with phenyllithium affords $(\eta^5\text{-}C_5H_4Li)Fe(\eta^5\text{-}C_5H_3(CHMeNMe_2)PPh_2)$ and $\eta^5\text{-}C_5H_4PPh_2)Fe(\eta^5\text{-}C_5H_3Li(CHMeNMe_2))$ in the ratio 15:85. Hydrolysis of this mixture affords the title compound **4**. The lithio-ferrocenes can be treated with XER_2 to yield other mixed ligands (E = As, P).

A route to **4** via $(\eta^5\text{-}C_5H_4PPh_2)Fe(\eta^5\text{-}C_5H_4C(O)Me)$ was also established but it is complicated by low yields and many side products such as $[(\eta^5\text{-}C_5H_4PPh_2)Fe(\eta^5\text{-}C_5H_4)]_2C{=}CH_2$.

IAN R. BUTLER et WILLIAM R. CULLEN. Can. J. Chem. **61**, 147 (1983).

On a exploré des voies d'accès au composé mentionné dans le titre qui fait appel au clivage des ferrocénophanes [*1*] avec l'aryllithium. Ainsi le clivage $(\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_3(CHMeNMe_2)PPh$ avec le phényllithium conduit au $(\eta^5\text{-}C_5H_4Li)Fe(\eta^5\text{-}C_5H_3(CHMeNMe_2)PPh_2)$ et au $(\eta^5\text{-}C_5H_4PPh_2)Fe(\eta^5\text{-}C_5H_3Li(CHMeNMe_4))$ dans un rapport de 15:85. L'hydrolyse de ce mélange permet d'obtenir le composé **4** mentionné dans le titre. On peut traiter le lithio-ferrocène avec XER_2 pour obtenir d'autres ligands mixtes (E = As, P).

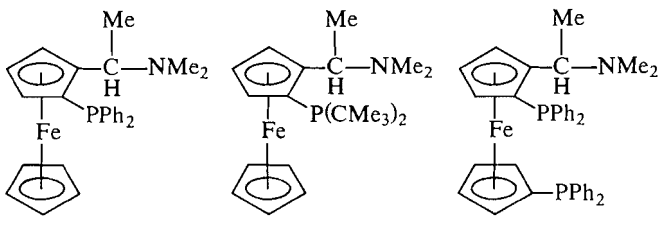
On a également établi une voie d'accès au composé **4** par l'intermédiaire de $(\eta^5\text{-}C_5H_4PPh_2)Fe(\eta^5\text{-}C_5H_4C(O)Me)$ mais dans ce cas le rendement est faible et on obtient plusieurs produits secondaires, tel le $[(\eta^5\text{-}C_5H_4PPh_2)Fe(\eta^5\text{-}C_5H_4)]_2C{=}CH_2$.

[Traduit par le journal]

Introduction

It is well known that cationic rhodium(I) complexes of formula $[Rh(L{-}L')(NBD)]^+[ClO_4]^-$ ((L—L′) = symmetrical, unsymmetrical, or asymmetric bidentate ligand; NBD = norbornadiene) are catalyst precursors for the effective hydrogenation and hydrosilylation of a range of olefins and ketones (1–3).

In our laboratories we have been particularly interested in derivatives where L—L′ is a ferrocenylphosphine such as **1** or **2** where the catalyst precursor is bound to the rhodium through both the N and P atoms (2). These ligands which possess both a chiral carbon atom and a plane of chirality can be prepared in their optically pure form reasonably easily (4). The cationic

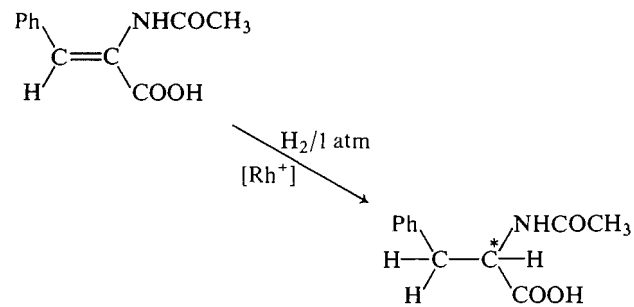


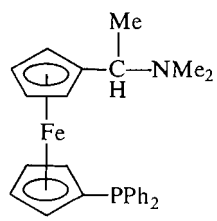
1 **2** **3**

rhodium(I) complex of **1** is an effective catalyst for the hydrogenation of amino acid precursors such as acylaminocinnamic acid in high optical yield, reaction [1].

The rhodium(I) complex of the 2-*tert*-butylphosphinoferrocenylamine **2** is also a good hydrogenation catalyst precursor with respect to reaction [1], affording higher optical yields at a faster rate than the complex of **1**. The absolute configuration of the product, however, is reversed. These results cannot be easily rationalized using any of the models currently employed to predict the course of these reactions. Thus, it is important to obtain more insight into the nature of the discrimination step. With this in mind, we have been interested in studying the effects of spatial modification of the ligand **1** and have set out to prepare 1,1′-substituted derivatives such as **4**.

[1]





4

The present paper describes the synthesis of **4** from [1]-ferrocenophanes utilizing the synthetically useful cleavage reaction of 5 with alkyl- and aryllithium reagents as reported by Seyferth and Withers (5), reaction [2]. We also show how a modification of this reaction can be applied to the preparation of new ligands related to **3** which can also afford metal complexes for further studies of catalytic hydrogenation.

Experimental

All manipulations were carried out under a nitrogen atmosphere. Solvents were predried and freshly distilled. ^{1}H nmr chemical shifts are given in ppm from TMS and were recorded on a Bruker W.P.80 operating at 80 MHz, a Varian XL100 at 100 MHz, or a Bruker WM400 at 400 MHz. Elemental analyses were performed by Mr. Peter Borda of this department and are reported in Table 1. Spectroscopic data are given in Table 2. The ferrocenophanes **5** and **14** were prepared as previously described (6, 7).

1. Preparation of 1-acetyl-1′-diphenylphosphinoferrocene, 7

The ferrocenophane **5** (2.92 g, 10 mol), in the minimum volume of ether required for dissolution, was added dropwise to an ethereal solution (100 mL) of phenyllithium (15 mmol) maintained at −78°C. The solution was warmed slowly to room temperature. A clear orange solution resulted which was then rechilled to −78°C. Acetyl chloride (1.20 g, 15.3 mmol) in ether (10 mL) was added dropwise. The solution was warmed to room temperature and was stirred for a further 10 min. Water (10 mL) was added dropwise. The ethereal layer was separated, dried over anhydrous $MgSO_4$, and the solvent volume reduced under vacuum to approximately 5 mL. The residual oil was ehromatographed on neutral alumina by eluting with progressively polar mixtures of hexane/diethyl ether. A yellow fraction which eluted first (later shown to contain a mixture of **8**, **9**, and diphenylphosphinoferrocene following a second chromatographic separation) was followed by the orange product band. The product **7** was crystallised from hexane at −20°C to give an orange crystalline solid (1.6 g, 39% yield).

2. Preparation of 1,1′-bis-(1′-diphenylphosphinoferrocenyl)ethylene, 9

The reaction of **5** (5.0 g, ~17 mmol) with phenyllithium (17 mmol) at room temperature using a similar procedure to **1** above gave 1,1′-bis-(1′-diphenylphosphinoferrocenyl) ethylene **9** as the major isolated product as a cream-coloured solid (orange in solution). This compound was isolated following column chromatography, eluting with diethyl ether (yield, 2.8 g, 43%).

3. Preparation of 1-(α-hydroxyethyl)-1′-diphenylphosphinoferrocene, 10

A solution of **7** (1.0 g, 2.92 mmol) in benzene (10 mL) was added slowly to a well-stirred suspension of $LiAlH_4$ (0.1 g, 2.7 mmol) in benzene (50 mL). After complete addition, the solution was stirred for 1 h at room temperature. Ethyl acetate (5 mL) was then added dropwise followed by water (30 mL). The organic layer was separated and dried over anhydrous $MgSO_4$. The solvent volume was reduced under vacuum to a few mL and the remaining oil was chromatographed on neutral alumina to give a single yellow band. Solvent removal under vacuum gave a yellow oil which on further drying (~50°C) *in vacuo* gave a solid product (crude yield ~95%). The solid was crystallised from hexane to give crystalline **10**, 70% yield.

4. Reaction of 10 with HBr and $HNMe_2$

Gaseous HBr was slowly bubbled through a rapidly stirred solution of **10** (0.8 g, 1.93 mmol) in benzene (50 mL). A pale yellow precipitate was observed after saturating the solution. Excess anhydrous dimethylamine was added dropwise and the precipitate, which had become orange, was filtered. The benzene solution was then treated with diethyl ether to give a pale yellow precipitate which was also filtered off. The solvent volume of the residual ether/benzene solution was reduced to a few mL and the resulting orange oil was chromatographed on neutral alumina. Two bands were isolated, the first was eluted with a 50/50 hexane/ether mixture and was identified as **4** by ^{1}H nmr spectroscopy, the second was identified as **11** by ^{1}H nmr and mass spectroscopy (Table 2). The precipitated fractions were combined and redissolved in chloroform, ether was added as a top layer, and the solution left to crystallise overnight. This gave an orange/yellow solid (0.6 g).

5. Reaction of 10 with acetic anhydride in pyridine, and acetic acid in benzene

The alcohol **10** (100 mg, 0.24 mmol) in pyridine was stirred with an excess of acetic anhydride (50 mg, 0.49 mmol) for 20 h. The solution was filtered and the solvent removed under vacuum. The residual oil was redissolved in methanol, 10 mL, and dimethylamine (50 mg, 1.1 mmol (excess)) was added. The solution was stirred for 2 h. Again the solvent was removed under vacuum and the residual oil chromatographed on neutral alumina. Two yellow bands were isolated (by elution with diethyl ether). The first was identified as unreacted **10** and the second as the product **4** (52 mg, ~49%) by ^{1}H nmr spectroscopy.

In a similar reaction **10** (300 mg, 0.725 mmol) and acetic acid (60 mg, 1.0 mmol) were refluxed in benzene (70 mL) for a 3.5 h period in an apparatus fitted with a Dean and Stark trap. After cooling, excess dimethylamine (90 mg, 2.0 mmol) was added. The reaction solution was then examined by tlc; this showed only a minor trace of product **4** with a large excess of the starting material **10**.

6. Direct preparation of 1-(α-dimethylaminoethyl)-1′-diphenylphosphinoferrocene, 4

To an ethereal solution (30 mL) of phenyllithium (0.5 mmol) maintained at −78°C, a solution of **14** (100 mg, 0.275 mmol), in the

minimum quantity of ether necessary for dissolution, was added dropwise. The solution was stirred for 5 min at −78°C before it was warmed slowly to room temperature. A clear orange solution resulted. This solution was then hydrolysed by careful dropwise addition of water (10 mL). The ethereal layer was separated, dried over anhydrous $MgSO_4$, and finally the volume was reduce to a few mL. The ^{1}H nmr spectrum of this mixture is shown in Fig. 1*c*. Column chromatography of the redissolved residual orange oil (chloroform, 2 mL) gave initially a fraction which eluted with hexane/ether, 50/50, containing **1** of known ^{1}H nmr spectrum, followed by a fraction containing **4** which eluted with diethyl ether. The solvent was removed to give the pure product, 55% yield which crystallised at −20°C from hexane over a period of 3 days to give a yellow–orange crystalline solid.

*7. Preparation of the isomers **16** and **17***

The initial procedure employed was identical with that used in the preparation of **4** but on a 10 mmol scale. Instead of hydrolysis, however, excess chlorodiphenylarsine (20 mmol) in diethyl ether was added dropwise to the chilled solution. The resulting suspension was warmed slowly to room temperature and was stirred for a further 30 min before hydrolysis (H_2O, 20 mL). The ethereal layer was separated, dried over anhydrous $MgSO_4$, and the filtered solution volume reduced to ~5 mL under vacuum. Chromatography on neutral alumina gave a single broad yellow band eluting with progressively polar mixtures of hexane and ether. On complete solvent removal a yellow oily solid remained, which when crystallised (hexane, −20°C), gave yellow nodules. ^{1}H nmr spectroscopy showed these to be a mixture of the positional isomers **16** and **17**.

These two isomers are separable by tlc (hexane eluant, aluminum backed Kieselgel plates) and preparative tlc. Long columns of alumina are required for large scale separation (there is slight decomposition on silica gel columns).

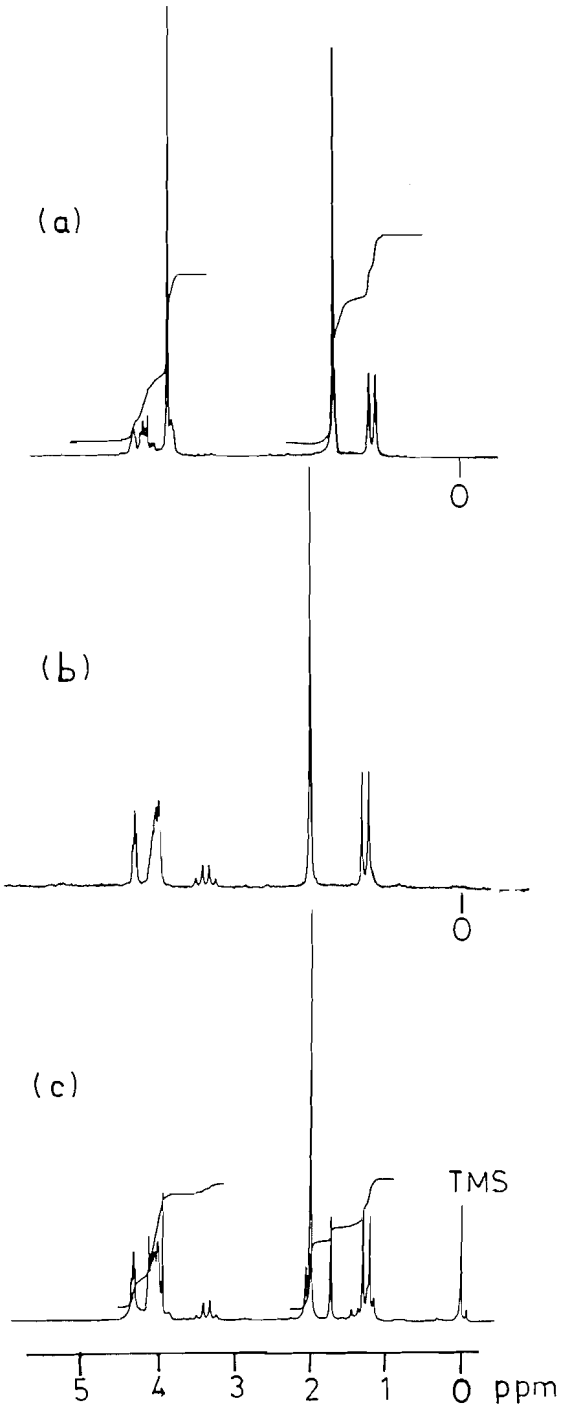

FIG. 1. The 80 MHz proton nmr spectra of (0–5 ppm) (a) PPFA **1**, (b) **4**, (c) the crude reaction mixture following reaction of **14** with phenyllithium followed by H_2O.

*8. The reaction of **14** with phenyllithium and di-*tert*-butylchlorophosphine*

To an ethereal solution (100 mL) of phenyllithium (2.0 mmol) maintained at −78°C, a solution of **14** (400 mg, 1.1 mmol) in ether was added dropwise. After warming to room temperature and recooling to −78°C an excess of di-*tert*-butylchlorophosphine (450 mg, ~2.5 mmol) was added dropwise. The solution was warmed to room temperature and was refluxed for 30 min. Following workup by an identical procedure to that in the previous preparations the resultant oil was chromatographed on Brockman Grade I neutral alumina. Two bands were isolated eluting with a mixture of diethyl ether/chloroform. The first orange band decomposed during recrystallisation and the second gave a deep-coloured oil on attempted crystallisation from hexane. This was identified as a mixture of the isomers **19** and **20** by ^{1}H nmr.

9. Reaction of 7 with phenyllithium

A solution of **7** (100 mg, 2.43 mmol) with phenyllithium (2.00 mL of 1.9 *M* solution; excess) in dry diethyl ether (10 mL) was stirred for 4 h. The solution was hydrolysed (H_2O, 5 mL) and the ethereal layer separated, dried over anhydrous $MgSO_4$. Following filtration the resultant solution was chromatographed on neutral alumina. A yellow fraction eluting with 15% diethyl ether in hexane was obtained. The solvent was removed and the ^{1}H nmr of the residual oily solid was recorded. The product was thus characterised spectroscopically as the methylphenyl alcohol derivative *7b*. A solution of the product in chloroform was observed to decompose with the formation of a small quantity of the vinyl derivative **8**.

Results and discussion

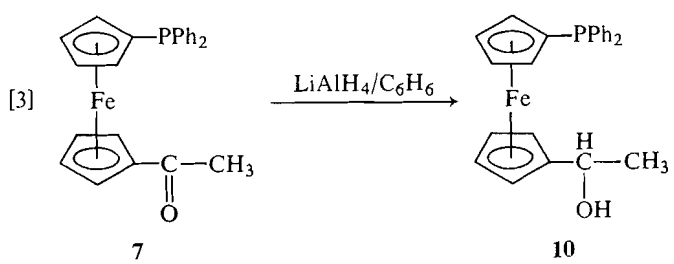
The preparation of **4** was initially approached via the ring cleavage reaction (reaction [2]) of **5** reported by Seyferth and Withers (5). The subsequent synthetic route involved the reaction of the intermediate 1′-monolithio-derivative **6** with acetyl chloride to give the 1′-acetyl derivative **7** (Scheme 1, *a*).

The procedure used was to add **5** to a solution of phenyllithium in diethyl ether since the reaction product, the 1′-monolithidiphenylphosphinoferrocene **6**, could conceivably react with **5** to give a monolithiobisferrocenyl derivative *7a*. The optimum yield of **6** is therefore achieved using an excess of phenyllithium, and a 1.5 molar excess was typically employed. On addition of acetyl chloride to the resultant solution of **6** the desired product **7** was obtained in moderate yield. However, the vinylferrocene derivative, **8**, is also produced. It is likely that the excess phenyllithium attacks the carbonyl group of **7** to give the lithium salt of the tertiary alcohol. This could give rise to **8** by acid-catalysed dehydration of an intermediate alcohol (Scheme 1, *b*) or deacetylation of the ester formed by reaction of the intermediate lithium derivative with acetyl chloride (Scheme 1, *c*).

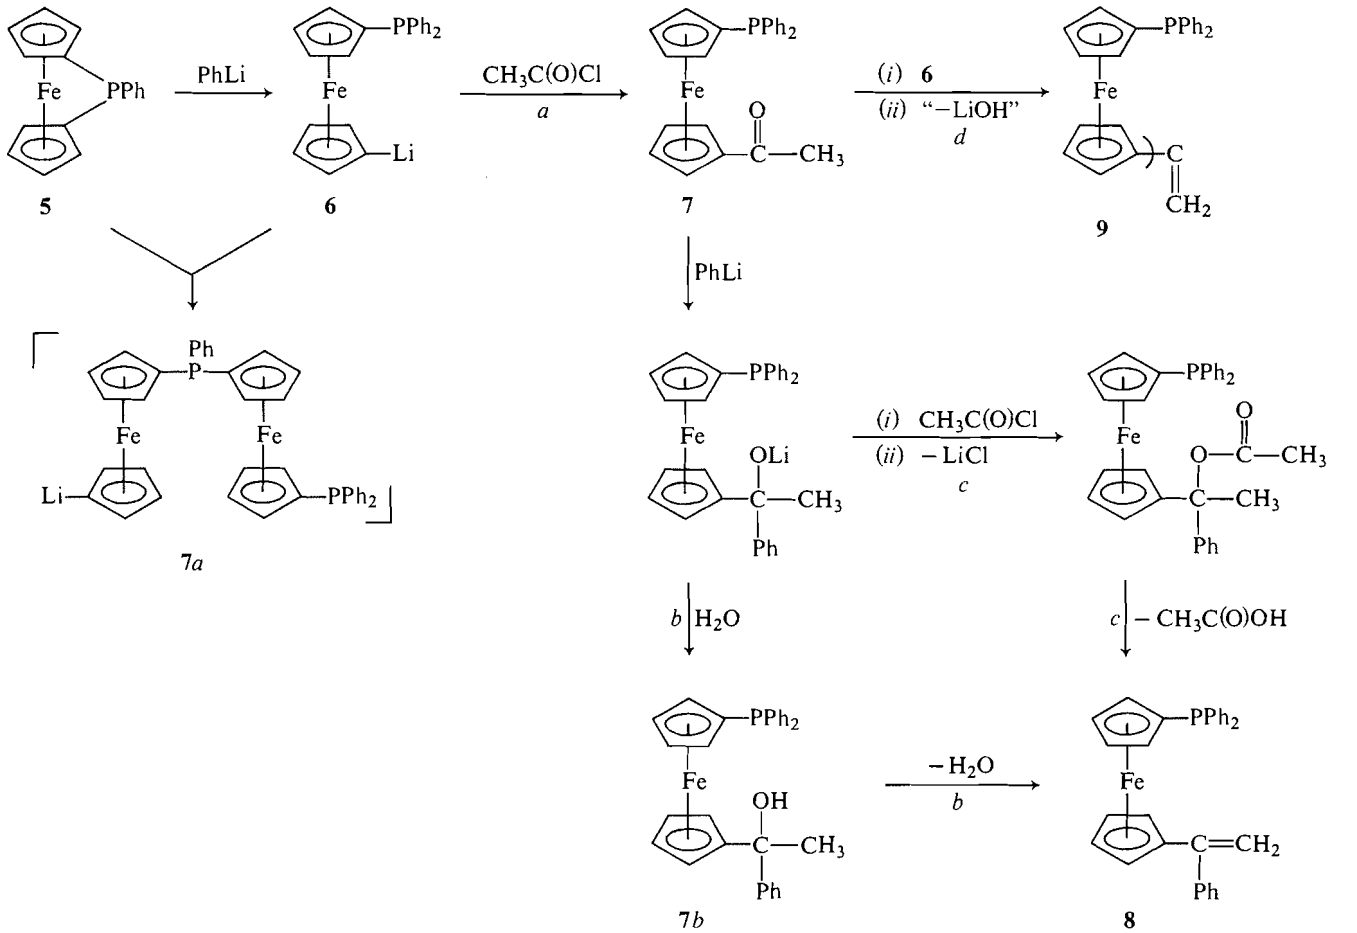
The reaction of excess phenyllithium with **7** was carried out independently. The product formed following hydrolysis was the alcohol *7b* which was observed to decompose in chloroform solution on prolonged standing to give **8**.

When a 1:1 ratio of phenyllithium to **5** is used the major isolated product is the bisferrocenylethylene derivative **9**; presumably formed by the result of an analogous sequence to the one which afforded **8**; however, in this case the lithiating agent is **6** instead of phenyllithium (Scheme 1, *d*). Column chromatography on an alumina support can be used to separate the products **7**, **8**, and **9**. All products were identified by elemental analysis and spectroscopy.

The reduction of **7** with lithium aluminum hydride in benzene gave **10** in high yield in a relatively clean reaction (reaction [3]).



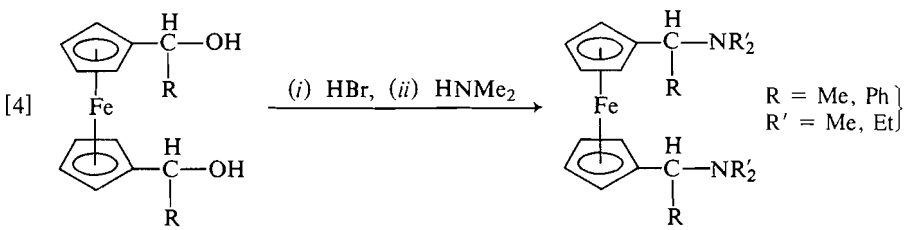
7 10



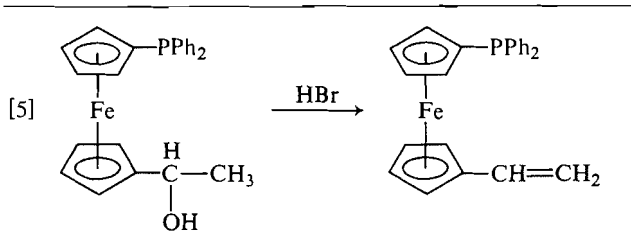
SCHEME 1

The conversion of **10** to **4** was explored by several routes: treatment of **10** with acetic anhydride in pyridine followed by the reaction of the crude product (without isolation) with dimethylamine gave **4** in approximately 50% yield although **10** was the only other compound isolated. Appreciably lower yields of **4** were obtained by a similar route using acetic acid in benzene.

The reaction of α-ferrocenylethyl alcohols with HBr followed by treatment of the crude product mixture with secondary amines is known to give the corresponding ferrocenylamines in moderate yield, reaction [4] (8).



The reaction of **10** with HBr followed by treatment of the crude reaction mixture with anhydrous dimethylamine also gave **4** but in very low yield. The major product consisted of a mixture of compounds which are probably phosphonium salts formed by the reaction of the diphenylphosphino substituent with HBr. These products were found to be difficult to obtain in a pure form, thus further study was not pursued. Another minor product obtained was the 1′-vinyl compound **11** identified by ^1H nmr and mass spectroscopy. This product is presumably formed by the acid-catalysed dehydration of **10**, reaction [5]; similar reactions are known to occur under very mild conditions (9, 10).



The overall synthetic utility of the foregoing procedures is small because of the low yields achieved. This prompted us to seek an alternate route to **4**, especially since we ultimately

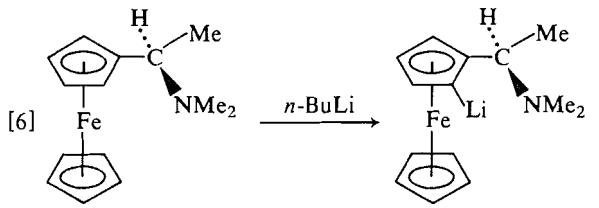
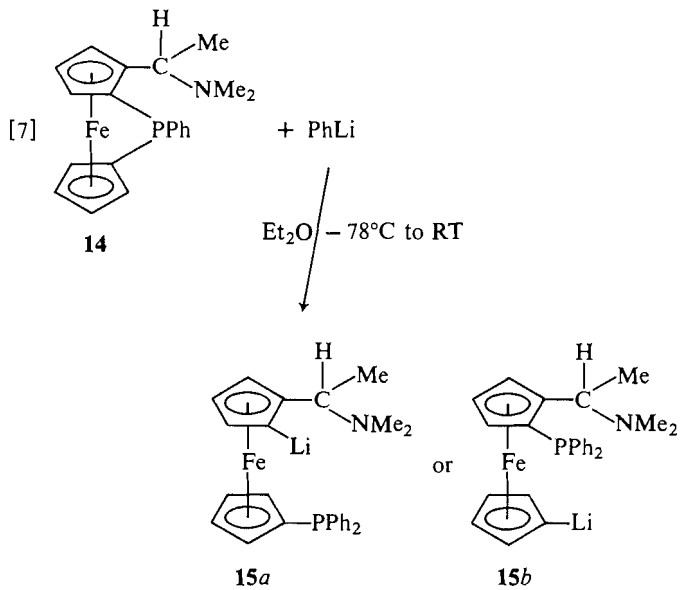
desired a resolved sample for asymmetric hydrogenation studies.[1]

The alternate preparation of **4** was approached via a synthetic pathway beginning with the easily resolvable α-*N*,*N*-dimethylferrocenylethylamine **12** (11). It is also well established that the lithiation of **12** is stereoselective (12). Thus treatment of an ethereal solution of **12** with butyllithium is known to form the 2-lithio derivative **13**. The *R*-isomer shown affords the (*R*,*S*)-isomer of **13** in 96% yield. The substitution in the ring introduces an element of planar chirality. The selectivity arises because of the stabilizing influence of the lone-pair on the adjacent nitrogen atom reaction [6]).



12 **13**

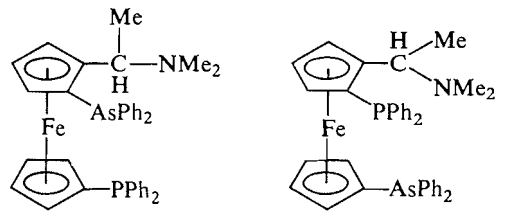
We have previously prepared the ferrocenophane **14** (7) which would be expected to undergo a cleavage reaction (reaction [2]) with phenyllithium to give predominantly the monolithio derivative **15***a* at the expense of its isomer **15***b* (reaction [7]) because **15***a* would be stabilized due to the interaction of the lithium with the adjacent amino function. Furthermore, compound **15***a* would appear to be sterically less crowded than **15***b*.



14 **15***a* **15***b*

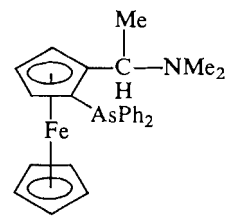
This explanation is well founded since treatment of **14** with phenyllithium at low temperatures followed by hydrolysis does give **4** as the major product. Figure 1 shows the ratio of the products **4** to **1** as 85 to 15. Treatment of **14** with phenyllithium at room temperature followed by hydrolysis was found to give substantially higher yields of **1** at the expense of **4**.

The reaction of **14** with phenyllithium at low temperature followed by treatment of the crude solution with chlorodiphenylarsine gave, on recrystallisation, approximately equal quantities of the positional isomers **16** and **17**. Presumably **17**,



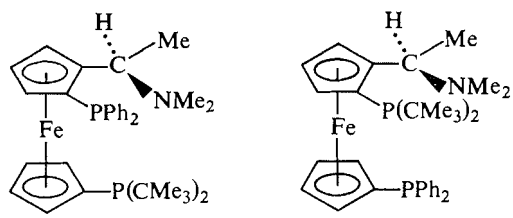
16 **17**

which should be formed in lower yield, is less soluble than **16**, and the crystals of the mixture obtained on crystallisation (hexane, −20°C) become enriched in **17**. These compounds are separable by tlc and by careful column chromatography on a neutral alumina support. They are of interest in hydrogenation reactions since the cationic rhodium(I) complex of **1**, in its resolved form, is an effective asymmetric hydrogenation catalyst precursor while its arsine analogue **18** is ineffective (2).



18

In a similar manner the reaction of **14** with phenyllithium followed by treatment with di-*tert*-butylchlorophosphine gives the isomers **19** and **20**, isolated as an oily mixture. In this case separation has not yet been achieved. This oil was found to be considerably more air-sensitive than the compounds **16** and **17** possibly because of trace impurities.



19 **20**

The preparation and use in catalytic reactions of various metal complexes of the ligands described in this paper will be the subject of a later communication.

Reactions of sydnones. Part III.[1] Bromination of 3-[*p*-(1′-pyrazolyl)]phenylsydnone

SHAMBHULING B. HAVANUR, BHARATI V. BADAMI, AND GURUBASAV S. PURANIK[2]

Department of Chemistry, Karnatak University, Pavate Nagar, Dharwad-580003, Karnataka, India

Received January 11, 1982[3]

SHAMBHULING B. HAVANUR, BHARATI V. BADAMI, and GURUBASAV S. PURANIK. Can. J. Chem. **61**, 154 (1983).

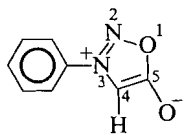
3-[*p*-(1′-Pyrazolyl)]phenylsydnone (**2**) and its derivatives have been subjected to bromination in order to study the relative reactivities of the sydnone and pyrazole moieties. The products have been confirmed by their elemental analysis and their spectral data.

SHAMBHULING B. HAVANUR, BHARATI V. BADAMI et GURUBASAV S. PURANIK. Can. J. Chem. **61**, 154 (1983).

On a bromé la [*p*-(pyrazolyl)-1′]-3 phénylsydnone (**2**) et ses dérivés dans le but d'étudier les réactivités relatives des unités sydnone et pyrazole. On a identifié des produits en faisant appel à l'analyse élémentaire et aux données de la rmn.

[Traduit par le journal]

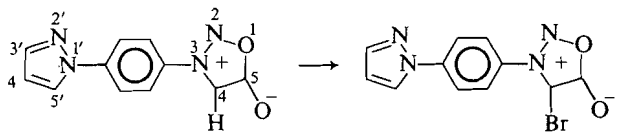
Sydnones unsubstituted at the 4-position undergo electrophilic substitution reactions and because of this behaviour they are classified as aromatic. The degree of aromaticity of the sydnone ring has been expected to be about the same order as that of the furan ring (3). In 3-phenylsydnone (**1**) the phenyl ring is less susceptible to electrophilic substitution reactions because of the positive charge, which is substantially localized on the N-3 atom (4).



1

Electrophilic substitution in 1-phenylpyrazole leads to initial attack at the 4-position of the pyrazole and hence a method was developed to prepare 5-substituted pyrazoles through 4-substituted sydnones (5).

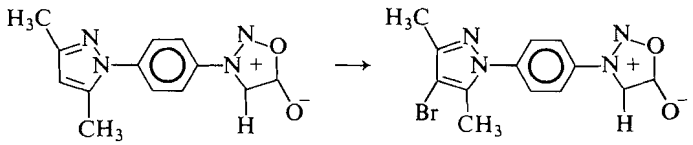
In an earlier work, 3-[*p*-(1′-pyrazolyl)]phenylsydnone (**2**) and its derivatives were synthesized to study the variation in biological properties (2, 6). Structure **2** is a combination of three aromatic moieties, viz., the phenyl, the sydnone, and the pyrazole rings, with a number of replaceable hydrogen atoms which are expected to undergo electrophilic substitution reactions.Since the phenyl ring is less susceptible to electrophilic substitution reactions in this system, it provides an opportuniy to compare the reactivities of sydnone and pyrazole rings.



2 **2*a***

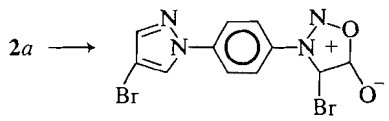
In the present study, the bromination of **2** and its derivatives has been dealt with. Bromination has been carried out with bromine in aqueous ethanol in the presence of sodium bicarbonate (7). On bromination with one mole of bromine, **2** gives 3-[*p*-(1′-pyrazolyl)]phenyl-4-bromosydnone (**2*a***).

On the other hand, when the dimethyl derivative (**3**) is brominated with one mole of bromine, the product is 3-[*p*-(4′-bromo-3′,5′-dimethyl-1′-pyrazolyl)]phenylsydnone (**3*a***).

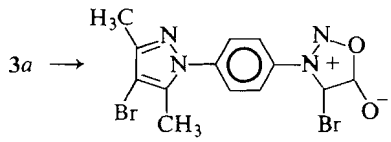


3 **3*a***

Further bromination of **2*a*** and **3*a*** gives 3-[*p*-(4′-bromo-1′-pyrazolyl)]phenyl-4-bromosydnone (**2*b***) and 3-[*p*-(4′-bromo-3′,5′-dimethyl-1′-pyrazoyl)]phenyl-4-bromosydnone (**3*b***) respectively.



2*b*



3*b*

From the above results it can be concluded that in this phenyl-linked system the sydnone ring is more reactive towards bromination than the pyrazole ring. The reactivity of the pyrazolyl-4 position is enhanced when electron-donating groups are introduced adjacent to the reactive site.

Bromination of pyrazolyl phenylsydnones with a CH_3 or C_6H_5 group in the 4-position of the sydnone ring has also been carried out to get the corresponding 4′-bromopyrazolyl phenylsydnone derivatives.

The structures of the compounds have been confirmed by elemental analysis and spectral data. The nmr data proved to be very helpful, since the sydnone-4 and pyrazole-4 protons cannot be distinguished in the infrared spectra.

The nmr spectrum of **2** shows a singlet of the sydnone-4 proton at 6.7 δ and a triplet of the pyrazolyl-4 proton at 6.5 δ. Absence of the signal at 6.7 δ in the spectrum of **2***a* confirms the bromination in the sydnone-4 position. On the other hand, in the spectrum of **3**, the sydnone-4 and pyrazolyl-4 protons appear as singlets at 6.8 δ and 6.1 δ, respectively. Disappearance of the signal at 6.1 δ in the spectrum of **3***a* suggests that the bromination has taken place at the pyrazolyl-4 position. In the case of compounds **2***b* and **3***b*, absence of both the respective signals due to the sydnone-4 and pyrazolyl-4 protons is observed. The nmr spectral details are given in Table 1.

Experimental

Melting points are uncorrected. The nmr spectra were determined at 60 MHz on a Varian A-60 nmr spectrophotometer with TMS as an internal reference.

The compounds **2**, **3**, **4***a*, **4***b*, **4***c*, and **4***d* were prepared following the procedures mentioned earlier (6).

Bromination

Bromination has been carried out with 0.005 mol of compounds **2** and **3**. In the case of **2***a*, **3***a*, **4***a*, **4***b*, **4***c*, and **4***d*, 0.0025 mol of the compound has been used.

To a suspension of the compound (0.005 mol), in 50 mL of ethanol, was added sodium bicarbonate (2.00 g, 0.024 mol) in 25 mL of water at room temperatures. The resultant cloudy solution was clarified on addition of bromine (0.005 mol) in 25 mL of ethanol. The reaction mixture was stirred further for 30 min and diluted with 200 mL of water. The separated solid was filtered and dried in air.

All of the bromo derivatives were crystallized from ethanol and the results are set out in Table 2.

Acknowledgements

Simulation of edge effects in electroanalytical experiments by orthogonal collocation. Part 3. Application to chronoamperometric experiments

BERND SPEISER AND STANLEY PONS
Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received April 5, 1982

BERND SPEISER and STANLEY PONS. Can. J. Chem. **61**, 156 (1983).

The theory of two-dimensional collocation has been employed to simulate a model describing chronoamperometric experiments under conditions where edge diffusion has to be taken into account. The influence of the dimensionless parameters, β and β′, the initial integration stepwidth, $\Delta T_0'$, the number of collocation points, N, and the kind of polynomial used to approximate the real solution are investigated and discussed. An additional transformation of the radial coordinate is introduced. The numerical values for a large number of simulations with different sets of the above parameters are compared to reference values.

BERND SPEISER et STANLEY PONS. Can. J. Chem. **61**, 156 (1983).

On a utilisé la théorie de collocation bidimensionnelle pour simuler un modèle décrivant des expériences de chronoampérométrie dans des conditions où l'on doit tenir compte de la diffusion par l'arête. On discute de l'influence des paramètres sans dimension β et β′, de l'étendue de l'intégration initiale $\Delta T_0'$, du nombre de points de collocation, N, et du type de polymère utilisé pour faire une approximation de la solution réelle. On a introduit une transformation additionnelle de la coordonnée radicale. On a comparé les valeurs numériques d'un grand nombre de simulations avec des ensembles différents des paramètres ci-dessus avec des valeurs de référence.

[Traduit par le journal]

Introduction

In parts 1 and 2 (1) of this series we derived the theory for the application of orthogonal collocation to the simulation of two-dimensional models. These are described by partial differential equations with *two independent space variables* and the time variable t. Let us consider a two-dimensional diffusion situation at a flat, circular electrode, where diffusion *not only perpendicular* to the surface may occur. This additional diffusion is called edge diffusion. The concentration c of each species is given by a partial differential equation of the form

$$[1] \quad \frac{\partial c}{\partial t} = D\left[\frac{\partial^2 c}{\partial x^2} + \frac{1}{r}\frac{\partial c}{\partial r} + \frac{\partial^2 c}{\partial r^2}\right] - f(c)$$

where x is the distance perpendicular to the surface and r is the radial distance from the centre of the electrode. The "kinetic term" $f(c)$ is determined by chemical reactions of the given species.

Our goal is to calculate c as a function of x and r at any time t under a set of initial and boundary conditions. The *initial conditions* model the experimental starting conditions, i.e. in general only the starting compound is present in a homogeneous solution. The *boundary conditions* specify the particulars of the experiment performed, e.g. chronoamperometry, cyclic voltammetry, or another electroanalytical method.

Orthogonal collocation (2, 3) approximates the real solution of partial differential equations, e.g. [1], by orthogonal polynomials, such that the differential equation is fulfilled at certain points, the collocation points. This provides a method to reduce the partial differential equations to a system of coupled ordinary differential equations.

In part 1 of this series (1) we used a product of two polynomials in x and r respectively as approximation function to the real solution of our two-dimensional model for edge effects. We solved a system of three equations of type [1] describing an EC mechanism

$$[2] \quad \mathrm{A} \underset{+ne^-}{\overset{-ne^-}{\rightleftharpoons}} \mathrm{B} \qquad E^\circ, n$$

$$[3] \quad \mathrm{B} \xrightarrow{k} \mathrm{C}$$

under the boundary conditions valid for chronoamperometric experiments.

This third part of our series demonstrates the application of the derived theory to chronoamperometry. We examine the influence of several parameters on the numerical solutions of the simulations: the dimensionless parameters β and β′, the integration stepwidth $\Delta T_0'$, the number of collocation points N, and the type of polynomial we are using to approximate the real solution. Also, we investigate the effect of choosing a different dimensionless coordinate system.

The calculations herein have been performed using only the concentration of the substrate A at the collocation points, because the current through the electrode may be calculated from the concentration profiles of A only. The concentration profiles of species B and C, however, may be calculated from the formulae in part 1 (1*a*).

We compare our numerical simulations to the results derived by an exact solution of a related problem by Oldham (4). These numbers compare very well with solutions calculated by Aoki and Osteryoung (5) and Kakihana *et al.* (6), all using different approaches to compute values for the current at a finite disc electrode under chronoamperometric conditions with consideration of edge effects. All these approaches, however, are restricted to a very simple mechanism, the reversible electron transfer. The method of orthogonal collocation on the other hand is — once derived for a specific type of model, e.g. a two-dimensional model — very easily used to simulate all possible kinds of electrode mechanism. We only have to change the kinetic terms $f(c)$ in our partial differential equations [1]. Equations describing species other than A, B, or C

are very similar in form to those already derived (1). This has been shown in part 2 of this series (*1b*) for the boundary conditions of cyclic voltammetry. Also, changes in mechanisms require only minor changes of the computer code used to calculate numerical data. Thus, orthogonal collocation proves to be a flexible method to generate simulated values for electrochemical experiments modelled by two-dimensional diffusion equations.

The dimensionless parameters β and β′

To perform the method of orthogonal collocation we have to normalize our problem into a space [0,1] in both directions x and r. Also, we have to divide the r-space into an inner and an outer segment, simulated by two different functions. We denote the new distance coordinate perpendicular to the electrode as X, and refer to the normalized inner radial segment as R while using R' for the outer coordinates. The dimensionless simulation time is T'.

After substituting the transformation equations given in part 1 (*1a*) we arrive at normalized differential equations which contain two dimensionless parameters, β and β′:

$$[4] \quad \beta = r_0^2/L^2$$

$$[5] \quad \beta' = r_0^2/(M - r_0)^2$$

Here r_0 is the radius of the electrode disc, imbedded in an insulator. The quantity L is a distance in the X-direction from the electrode at which no diffusion occurs during the simulated experiment, while M is an analogous distance in the r-direction. Thus, L and M define a region in real space which is simulated in the calculations. The real points corresponding to our N collocation points are distributed within this space. We consider two limiting cases for L. An analogous discussion may be applied to M.

First, L may be very large. Then the points corresponding to the collocation points in real space, i.e. those points at which the concentration of the species involved is calculated, are spread over a large distance. The diffusion layer in which the concentration of a species is depleted or increased, however, is very narrow in the beginning of the simulation. It increases with $t^{1/2}$. Thus, at short times, corresponding to small values of the dimensionless simulation time T', the diffusion may have reached none or only a few of the points at which the concentration is calculated. Consequently, the numerical values calculated may not represent a good approximation to the real solution of our model and yield erroneous results.

On the other hand, if L is very small, we are looking at a very narrow layer of solution in real space. Even after a short time the diffusion layer may have reached all of our points and the boundary condition that no diffusion occurs at $X = 1$ (corresponding to $x = L$) is no longer true. We are using the mathematical formulation of this boundary condition ($c_A^*(X = 1) = 1$) in our calculations and thus the numerical values may deviate from the real solution after this is happening.

We expect that the approximation solution given by orthogonal collocation is valid only in a certain time range and that this range depends on the values of β and β′ chosen.

For all calculations referred to in this paper we used the condition β = β′. We simulate a square space adjacent to the insulator, because

$$[6] \quad \beta/\beta' = 1 = (M - r_0)^2/L^2$$

or

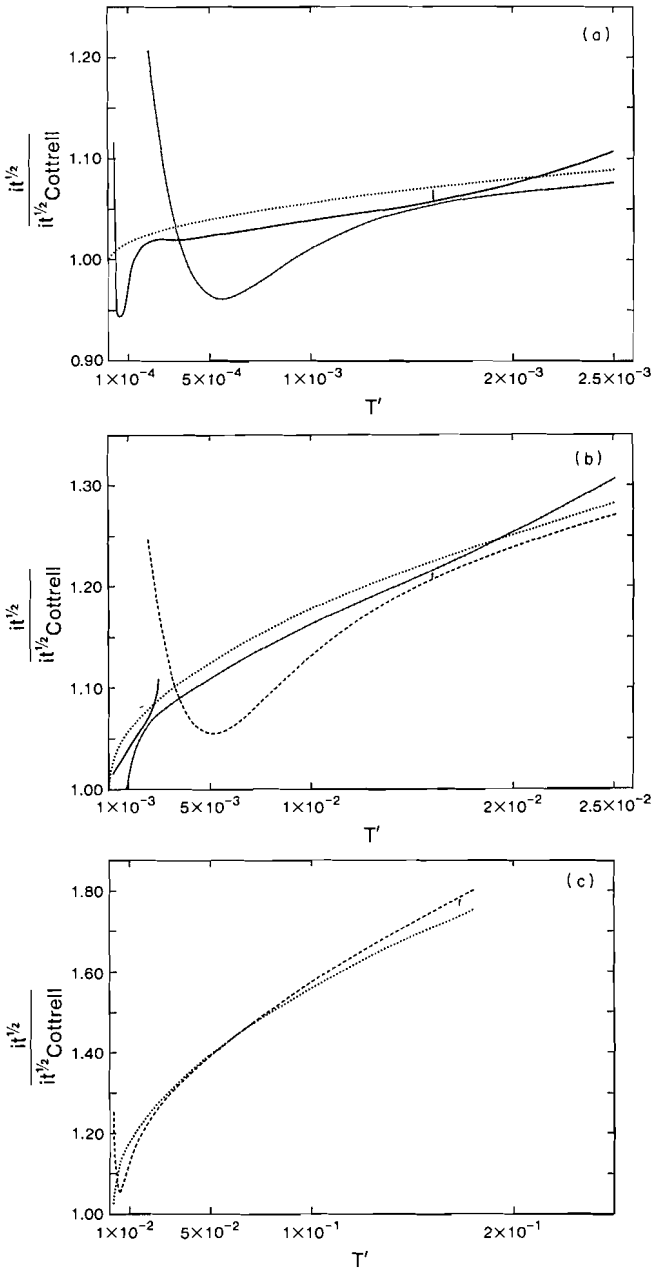

FIG. 1. Simulations of chronoamperometric experiments including edge effects with orthogonal collocation; simulation parameters: number of collocation points in each dimension $N = 6$, initial integration stepwidth $\Delta T_0' = 1 \times 10^{-4}$, Legendre polynomials in both dimensions, (—) β = 100, (·····) β = 10, (---) β = 1; (···) values calculated according to Oldham (4). The arrows indicate T', when the concentration at one of the outmost collocation points reaches 0.98.

$$[7] \quad L = (M - r_0)$$

Figure 1*a*–*c* shows calculated values for the current obtained including edge effects divided by the ideal Cottrell current. Comparing simulations using Legendre polynomials of degree $N = 6$ in both dimensions but different values for β = β′ with the reference curve given by Oldham (4), we see that the above analysis is correct. For β = 1 good agreement over a wide range of the dimensionless simulation time is found ($2 \times 10^{-2} < T' < 1.1 \times 10^{-1}$). To give a specific example ($D = 1 \times 10^{-5}$ cm²/s, $r_0 = 0.1$ cm), this range corresponds

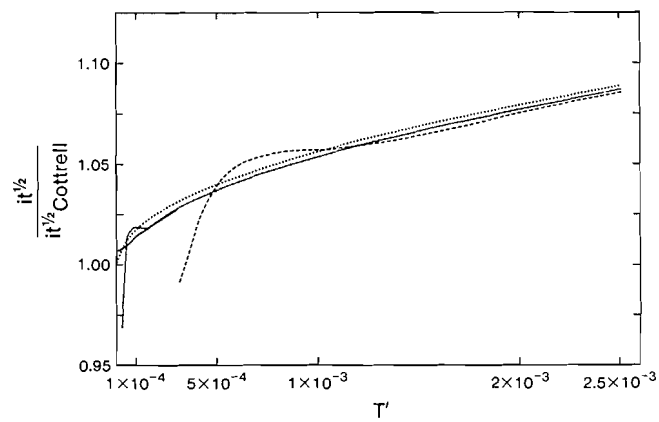

FIG. 4. Simulations of chronoamperometric experiments including edge effects with orthogonal collocation; simulation parameters: number of collocation points in each dimension $N = 15$, other parameters as in Fig. 1. The ordinate scale is expanded compared to the other figures.

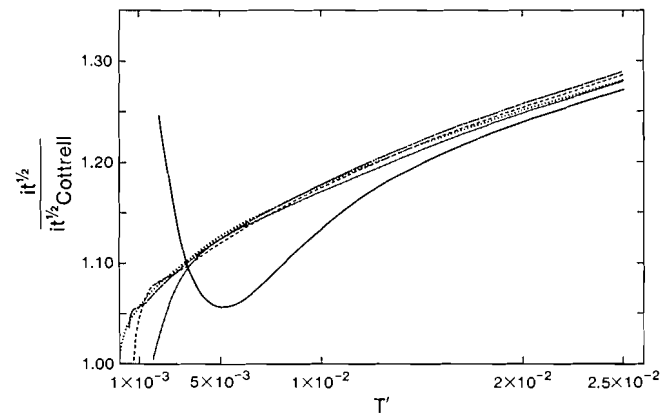

FIG. 5. Simulations of chronoamperometric experiments including edge effects with orthogonal collocation; simulation parameters: (—) $N = 6$, (·····) $N = 9$, (---) $N = 12$, (·-·-·) $N = 15$; initial integration stepwidth $\Delta T'_0 = 1 \times 10^{-4}$, Legendre polynomials in both dimensions, dimensionless parameters $\beta = \beta' = 1$, (···) values calculated according to Oldham (4).

to real times t between 2×10^1 and 1.1×10^2 s according to the transformation equation relating t and T' (1). At short times the error is considerable and it can be seen that the solution needs a number of integration steps to become stable. At longer times the collocation simulation result increases faster than Oldham's curve. This simulation needed 60 s cpu-time to calculate the entire curve ($10^{-4} \leq T' \leq 1.8 \times 10^{-1}$).

More accurate simulations for shorter times may be obtained using larger values for β. For example, with $\beta = 10$ in a range between $T' = 2 \times 10^{-3}$ and 1.2×10^{-2} good agreement with Oldham's curve is found, while $\beta = 100$ gives a reasonable approximation for $2 \times 10^{-4} \leq T' \leq 1.3 \times 10^{-3}$. In the latter cases significant deviation from Oldham's curve is seen at a time when our numerical values increase. This occurs at the same time as the calculated concentration at *one* of the outmost collocation points in the X-direction becomes smaller than about 0.98, thus confirming our conclusions drawn above. With increasing β, however, the oscillating deviations at the beginning occur in a narrower time frame, again in accordance with our analysis.

The same behavior may be seen if we use polynomials with a larger number of collocation points ($N = 9$, 12, 15; Figs. 2–4). Now the "critical concentration" at the outmost collocation points moves nearer to unity, being about 0.996 for $N = 9$. The time T' at which the deviations occur, however, is almost the same as for $N = 6$. This leads to the empirical conclusion, that the upper time limit of the simulations is only determined by β. An analogous approach has been used by Whiting and Carr (2). They defined the maximum simulation time which is accessible with a certain β as $T'_{max} \leq 0.15/\beta$. In our case we have the condition

$$[8] \quad T'_{max} \leq 0.1/\beta$$

to be within the usable time range.

The number of collocation points N

In the preceding paragraph we have seen that the number of collocation points N has a marked influence on the simulated numerical values. Thus, we compare curves obtained with different numbers N but using the same other parameters in Fig. 5.

*Values calculated by interpolation.

As N increases, the net of collocation points becomes more narrow, forcing the approximation function to fulfill the differential equation at more and more points exactly. This has two effects: first, the overall solution becomes more accurate but we also have more simulation points near the boundaries (using Legendre polynomials, the collocation points are more densely spaced near $X = 0$ and $X = 1$ than around $X = 0.5$). Thus, for short times, we have more points to represent the steep concentration profile exhibited shortly after applying the potential pulse and we expect the range within which the oscillating deviations from the reference solution occur to be more narrow. With increasing N, the overall solutions should reach a common limiting value which should be a good approximation to the real solution.

Comparing the results given in Fig. 5 we see that this is true. By increasing the number of collocation points from $N = 6$ to $N = 15$, the range in which no useful results are to be obtained because oscillations occur decreases by a factor of about 10; one gets very good approximations from $2 \times 10^{-3} - > 3 \times 10^{-2}$ dimensionless time units. The upper limit of the useful range is not affected, as Figs. 1–4 show.

Also, the results differ only little (~0.4% when increasing N from 12 to 15) with increasing N. This shows the consistency of the calculations. The "limiting" values reached are very close to Oldham's solution (4).

Increasing the number of collocation points gives more and more accurate results as is to be expected. However, the cpu-time used to perform the simulations in a given range also increases considerably. While integrating a system of $2 \times 6 \times 6 = 72$ ordinary differential equations in the case of $N = 6$ we have to deal with 162, 288, and 450 such equations if we use 9, 12, or 15 interior collocation points, respectively. The average cpu-time needed to calculate one concentration profile increases by a factor of 10 when N is increased from 6 to 15.

The integration stepwidth

The next parameter we want to discuss is the initial integration stepwidth, $\Delta T_0'$. This is an input parameter for the subroutine performing the integrations of our system of ordinary differential equations. The value chosen is used by the subroutine to calculate the first concentration profiles at $\Delta T_0'$. The subroutine DHPCGL (in the SSP library package) used by us then "decides" if sufficient accuracy is available with this value. If not, the stepwidth is divided by 2 and the calculation is repeated. Other integration subroutines, e.g. STIFF3 (3), also have the option to increase the initial stepwidth if the error is below a specific margin.

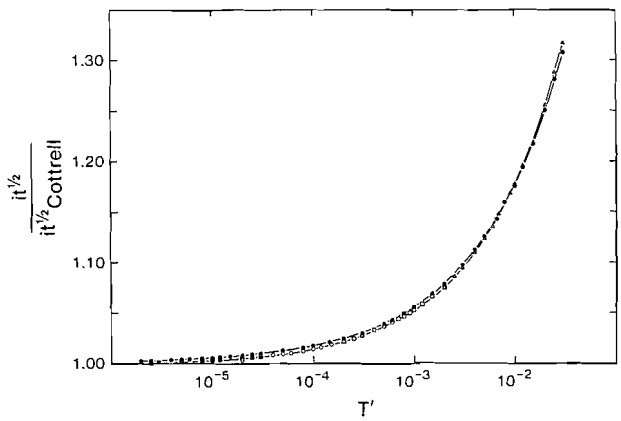

FIG. 6. Simulations pieced together from four calculations with $N = 15$ and different β compared to Oldham's solution (●); points calculated with $\beta = \beta' = 1000$ (■), $\beta = \beta' = 100$ (○), $\beta = \beta' = 10$ (□), $\beta = \beta' = 1$(Δ). The dimensionless time T covers the entire experimentally accessible range of t for an example with $D = 10^{-5}$ cm²/s and $r_0 = 0.1$ cm.

To evaluate the influence of $\Delta T_0'$ on the accuracy and performance of the edge effect calculations we run simulations with $N = 6$ and 9 using $\Delta T_0'$ values ranging from 10^{-2} to 10^{-5}. Results for $\beta = \beta' = 1$ are given in Tables 1 and 2. We see immediately that the actual value of $\Delta T_0'$ has only a very small effect on the numerical simulation results. Deviations are 0.00007 in the worst case, this corresponds to 0.007%. However, for a small $\Delta T_0'$ (10^{-5} dimensionless time units), the cpu-time needed to simulate the model up to a certain time increases considerably. The savings using $\Delta T_0'$ values $>10^{-3}$ are only about 10–20%. With large initial integration stepwidths there is not enough accuracy at the beginning of the simulation, thus causing DHPCGL to cut down $\Delta T'$ to smaller values. The actual choice of $\Delta T_0'$, however, seems not to be critical.

Complete simulations using Legendre polynomials

After discussing three of the parameters used in simulations of chronoamperometric experiments with consideration of edge

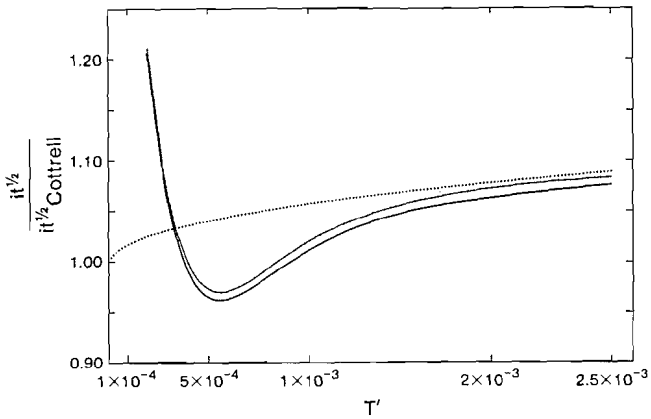

FIG. 7. Comparison of simulations using the model system given in part 1 of this series (1*a*) and the formulae derived from the transformation [13]; $N = 6$, $\beta = \beta' = 10$; (—) before transformation, (·····) after transformation, (···) Oldham's curve.

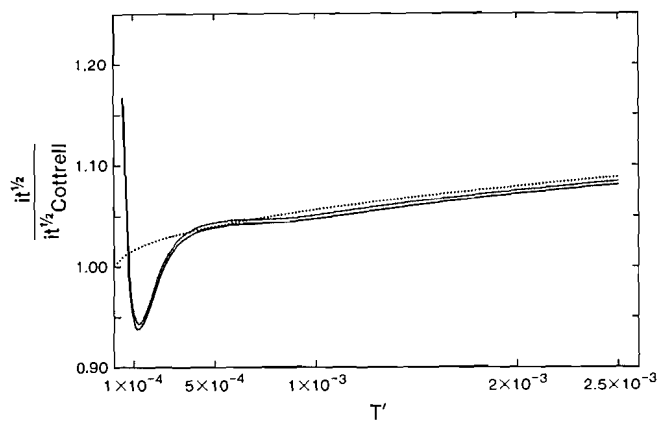

FIG. 8. Comparison of simulations using the model system given in part 1 of this series (1*a*) and the formulae derived from the transformation [13]; $N = 9$, $\beta = \beta' = 10$; (—) before transformation, (·····) after transformation, (···) Oldham's curve.

effects, we may now choose sets of parameters to obtain an approximate solution of the differential equations over a large range of the dimensionless simulation time. The number of interior collocation points will be 15. We will piece together the curve from solutions calculated with different β's, choosing the appropriate initial integration stepwidth. The trial functions will be Legendre polynomials.

The result is given in Fig. 6, where the calculated current divided by the "ideal" Cottrell current is plotted against T' (in logarithmic scale). Four different values for β (1000, 100, 10, 1) have been used and the entire curve compares very well with Oldham's results (4). The total cpu-time needed to calculate our curve was about 1340 s on an Amdahl 470/V6 computer. We cover, however, more than four orders of magnitude of the dimensionless simulation time. Using the same constants for D and r_0 as above, we simulated the response of an electrode with edge effects from 4 ms up to 30 s. At the lower limit ($T' \approx 2.5 \times 10^{-6}$) the current with edge effects deviates only by about 0.05% from the Cottrell current, while at the upper limit ($T' \approx 3 \times 10^{-2}$) the current in real experiments may be affected by convection, thus giving rise to another kind of nonideal behavior. Therefore, we can cover the entire accessible time range in which edge effects contribute to the experimental current with this simulation.

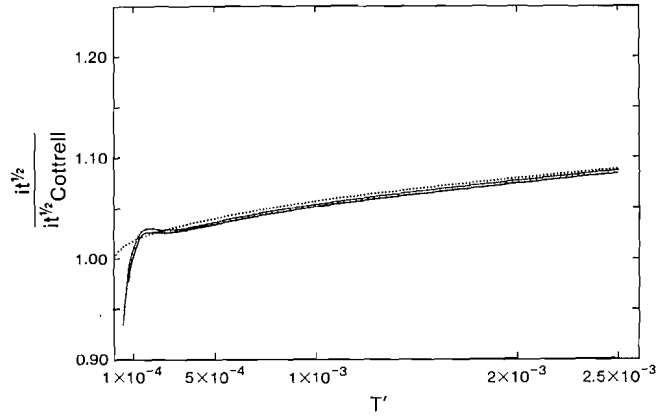

FIG. 9. Comparison of simulations using the model system given in part 1 of this series (1*a*) and the formulae derived from the transformation [13]; $N = 12$, $\beta = \beta' = 10$; (—) before transformation, (·····) after transformation, (···) Oldham's curve.

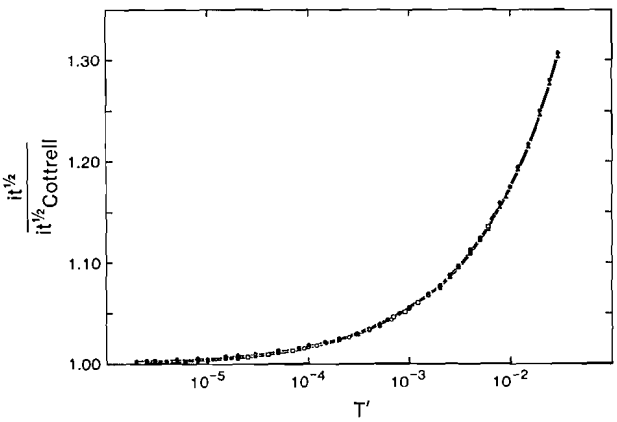

FIG. 10. Simulations to cover the entire time range $2 \times 10^{-6} < T' < 4 \times 10^{-2}$, pieced together from four calculations with $N = 15$ and different β, using the transformed system of equations, compared to Oldham's solution (●), points calculated with $\beta = \beta' = 1000$ (■), $\beta = \beta' = 100$ (○), $\beta = \beta' = 10$ (□), and $\beta = \beta' = 1$ (Δ).

Other polynomials

Orthogonal collocation may be performed using a variety of trial functions as long as we have a set of complete and linearly independent functions (7). A certain class of sets fulfilling these conditions are the Jacobi polynomials $P_N^{(\delta,\epsilon)}(x)$ given by (3)

$$[9] \quad P_N^{(\delta,\epsilon)}(x) = \sum_{i=0}^{N} (-1)^{N-i}\gamma_i x^i \qquad \gamma_0 = 1$$

with the orthogonality condition

$$[10] \quad \int_0^1 x^{\epsilon}(1-x)^{\delta} P_j(x)P_N(x)\mathrm{d}x = 0 \quad j = 0, 1, \ldots, N-1$$

The two terms x^{ϵ} and $(1-x)^{\delta}$ are "weight factors" which determine the behavior of the function at the boundaries (3). For $\epsilon \neq 0$ the function goes to zero at $x = 0$, for $\delta \neq 0$ zero is reached for $x = 1$. In our case the radial functions have nonzero values at both boundaries. Also, the x-functions in our

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

TABLE 3. Numerical values for simulation of a chronoamperometric experiment with edge effects: current with edge effects divided by Cottrell current; transformed simulation model vs. nontransformed system, $N = 15$, $\beta = \beta' = 10$, Legendre polynomials in both dimensions

T'	Oldham's solution (4)	Transformed model	Nontransformed model

4	1.0353	1.0338	1.0326
5	1.0395	1.0380	1.0367
6	1.0433	1.0416	1.0405
7	1.0468	1.0452	1.0441
8	1.0500	1.0485	1.0473
9	1.0531	1.0515	1.0504
1×10^{-3}	1.0560	1.0544	1.0534
2	1.0792	1.0776	1.0770
3	1.0970	1.0954	1.0953

outer space have a finite value at $x = 0$ (the insulator).

Thus, we would expect the best set of trial functions to be Legendre polynomials, $P_N^{(0,0)}(x)$ with $\delta = \epsilon = 0$. We used Legendre polynomials in all previous calculations in this paper, but tried also several other polynomials for the radial discretization function (e.g. $\delta = 0$, $\epsilon = 2$ which yielded good results for problems with spherical symmetry (8)).

The calculations showed that in all these cases the simulation results gave poorer agreement with Oldham's solution. We conclude therefore that the use of Jacobi type functions other than Legendre polynomials cannot be recommended in our case, due to the form of the boundary value problem.

Additional transformation of the radial variable *R*

After having simulated the concentration profile in our model we wish to calculate the current through the electrode as a function of time. In order to compare this current to the "ideal" Cottrell current we derived the expression [11] (1):

$$[11]\quad \frac{it^{1/2}}{it^{1/2}_{\text{Cottrell}}} = 2\sqrt{\beta\pi T'}\int_0^1 R\left(\frac{\partial c^*_{\text{Al}}}{\partial X}\right)_{X=0} dR$$

where we have to integrate the product of R and the flux to the electrode surface over the entire radius of the circular electrode.

This integration may be performed by a quadrature formula

$$[12]\quad \int_0^1 y(r)w_k(r)\,dr = \sum_{l=1}^{N_r+2} Q_l Y_l$$

where the Q_l's depend on the trial function used (see eq. [117] in part 1 (1*a*)).

The form of the integral in eq. [11] would suggest a trial function with $\delta = 0$ and $\epsilon = 1$. We have seen in the last paragraph, however, that the only suitable trial functions for our problem are Legendre polynomials with $\delta = \epsilon = 0$. Thus, it is desirable to bring [11] into a form with $\delta = \epsilon = 0$ by a variable transformation.

This may be done by the substitution

$$[13]\quad \mathcal{R} = R^2$$

Then

$$[14]\quad dR = \frac{1}{2\mathcal{R}^{1/2}}d\mathcal{R}$$

and

$$[15]\quad dR^2 = \frac{1}{4\mathcal{R}}d\mathcal{R}^2$$

The integral in eq. [11] reduces to

$$\frac{1}{2}\int_0^1 \left(\frac{\partial c^*_{\text{Al}}}{\partial X}\right)_{X=0} d\mathcal{R}$$

thus having a form consistent with $\delta = \epsilon = 0$.

We have to apply tranformations [13]–[15] to the differential equation describing the inner part of our model (see eq. [26], part 1 of this series (1*a*)) and to the boundary condition at $R = 1$ ($R' = 0$), where we piece together the inner and outer function (eq. [50] in part 1 (1*a*)).

The result for species A is

$$[16]\quad \frac{\partial c^*_{\text{Al}}}{\partial T'} = \beta\frac{\partial^2 c^*_{\text{Al}}}{\partial X^2} + 2\frac{\partial c^*_{\text{Al}}}{\partial \mathcal{R}} + 4\mathcal{R}\frac{\partial^2 c^*_{\text{Al}}}{\partial \mathcal{R}^2}$$

and the boundary condition changes to

$$[17]\quad \left(\frac{\partial c^*_{\text{Al}}}{\partial \mathcal{R}}\right)_{\mathcal{R}=1} = \frac{\sqrt{\beta'}}{2}\left(\frac{\partial c^*_{\text{A2}}}{\partial R'}\right)_{R'=0}$$

If we substitute these equations for eqs. [26] and [50] in part 1 (1*a*) and repeat the derivation of the discretized formulae [98] and [104] in part 1 (1*a*) we find a new, very similar system of ordinary differential equations.

In fact, we only have to change the definition of the matrix elements $E_{l,k}$ to

$$[18]\quad E_{l,k} = 2C_{l,k} + 4\mathcal{R}D_{l,k}$$

and substitute $\sqrt{\beta'/2}$ for $\sqrt{\beta'}$ in the definitions of the vector elements G_l, the matrix elements $L'_{l,k}$ and the discretized expression [98].

We calculated numerical values for this system. The results are given and compared to the nontransformed system in Figs. 7–9 for $N = 6$, 9, 12. Values for $N = 15$ are compared in Table 3, while Fig. 10 gives a curve pieced together using four calculations performed with $N = 15$ and different β values. The numerical values are consistent with changes <0.2% with N increasing by 3 in a region, where the oscillatory behavior at the beginning has stopped. Comparing to the nontransformed system and to Oldham's reference values, we find that the new equations give better values for a given number of collocation points. For $N = 15$ deviation from the reference values is in the range of 0.16% (Table 3).

Figure 10 also shows how well our numerical values compare to Oldham's model over more than four orders of magnitude in T'. While the nontransformed equations gave rise to a curve which was lower than Oldham's at shorter times and higher at longer times (Fig. 6), we see that our transformed system gives values which are slightly lower than the reference over the entire range.

This example clearly shows that the choice of trial functions and transformations has an influence on the exact numerical solutions calculated. Good approximations, however, may be available with the "standard" method also (i.e. without consideration of the type of functions used). A more detailed investigation on the effect of using different sets of trial functions is currently under way.

Conclusions

Our two-dimensional diffusion model using orthogonal col-

location has proved to provide good approximations for the current expected at a flat, circular electrode imbedded into an insulator over several orders of magnitude for the dimensionless time variable T'. The discussion of parameters in this paper shows that even with only 6 interior collocation points, i.e. a grid of $2 \times 6 \times 6 = 72$ collocation points in the entire simulation space, reliable numerical values may be obtained. With increasing number of collocation points the simulations are consistent and give even better approximations. However, longer cpu-times and costs to perform the calculations are necessary. We again like to point out that changes to different mechanisms require only the exchange or addition of a few statements in the computer code. Thus, orthogonal collocation may be recommended as a fast and powerful method to simulate edge effects at electrodes.

VICTOR M. S. GIL, ANTONIO J. C. VARANDAS, and JOHN N. MURRELL. Can. J. Chem. **61**, 163 (1983).

A critical appraisal is made of the validity of the rotational isomeric state (RIS) approximation in studies of rotational isomerism, especially as far as the determination of energy differences for the stable conformers is concerned. By using simple model potential energy functions for internal rotation appropriate to some ethane derivatives, a comparison is made between the thermodynamic parameters that can be extracted from such potential functions and those obtained by applying the RIS method to continuum averaged values of conformation dependent properties. The effects due to the form of this conformation dependence, to the features of the potential energy curve, and to the temperature are discussed. The errors can be very large for realistic situations, and variable with temperature and with the property being studied; cases for which the errors are small are usually accidental.

VICTOR M. S. GIL, ANTONIO J. C. VARANDAS et JOHN N. MURRELL. Can. J. Chem. **61**, 163 (1983).

On a fait une évaluation critique de la validité de l'approximation de l'état isomérique rotationnelle (EIR) lors de l'étude de l'isomère rotationnelle. Cette évaluation concerne surtout la détermination des différences d'énergie des conformères stables. En utilisant un modèle simple des fonctions d'énergie potentielle pour la rotation interne appropriée à quelques dérivés de l'éthane, on a comparé les paramètres thermodynamiques que l'on peut tirer de telles fonctions de potentiel avec ceux obtenus en appliquant la méthode de EIR aux valeurs moyennes du continuum des propriétés qui dépendent de la conformation. On discute des effets de la forme de cette influence de la conformation des caractéristiques de la courbe d'énergie potentielle et de la temperature. Les erreurs peuvent être très grandes pour des situations réelles; elles varient avec la température et la propriété étudiée. Les cas où les erreurs sont faibles sont habituellement acidentelles.

Introduction

Molecular properties that are conformation dependent have long been used in studies of hindered internal rotation, aiming especially at an approximate determination of the energy differences between the minima in the potential energy function for internal rotation (1, 2).

The usual procedure — often called the rotational isomeric state approximation (RIS) — consists of describing the internal rotation in terms of an equilibrium mixture of the most stable rotational isomers. Equilibrium constants are then determined, based on the observed property and its temperature dependence, and $\Delta H^{\ominus}$ and $\Delta S^{\ominus}$ values obtained.

The method obviously requires that temperature variations of medium effects are either negligible or properly accounted for (3). Even so, some recent model calculations have shown that the RIS approach can lead to quite large errors (4–7). Also, it has previously been found that when more than one type of data are available for analysis, the RIS method in its pure form may lead to inconsistent results (3, 8). Here we give a discussion of the basic sources of such discrepancies, associated with the neglect of conformations other than those of minimum energy.

Results and discussion

Two limiting situations can be identified, depending on the energy barriers to internal rotation (angle θ, potential energy $V(\theta)$), on the temperature, and on the property being measured $A(\theta)$: (*a*) The "equilibrium" is slow in the time scale of the measurement, hence distinct A values can be observed and assigned to each conformer. (*b*) The "equilibrium" is fast and only a rotational averaged A value is measured.

The terms "fast" and "slow" are defined with respect to the frequency spectrum of the observable A (9, 10)

$$[1] \quad A(\omega) = \int_0^\infty \exp(-i\omega t)\langle A(0)A(t)\rangle \, dt$$

where $\langle A(0)A(t)\rangle$ is the correlation function. This will contain periodic components with characteristic frequencies ω_i and, typically, decay components with a time constant ω_d. If ω_d is much less than all differences between frequencies ω_i, the spectrum will consist of distinguishable peaks at ω_i; if ω_d is much greater than all differences only a weighted average of the ω_i will be seen as a single frequency. We shall only examine these limiting cases. If ω_d is of the order of some ω_i differences, then a complicated (generally broadened) spectrum of A will be observed. For a criticism of the RIS method applied to dynamic properties see Vaughan (7).

In both the fast and slow cases, analysis of the data requires some knowledge about the functional form of $A(\theta)$. Even in the case of slow equilibrium this is necessary to assign separately measured properties to separate structures. Moreover, although

0008-4042/83/010163-08$01.00/0
©1983 National Research Council of Canada/Conseil national de recherches du Canada

observation may suggest slow equilibrium (case *a*), this may be due to a special form for $A(\theta)$, as Honegger and Heilbronner (5) have shown is possible for photoelectron spectral bands. The attribution of distinct A quantities to stable conformers presupposes that the distribution of A values (e.g. ionization energies (5)) is determined mainly by the conformer distribution density $P(\theta,T)$, therefore $V(\theta)$, and not by the way A varies with θ. Those authors showed that, even in the case of free rotation, multiple spectral bands may occur.

If practically only the lowest energy conformations are populated (the case of sufficiently deep potential troughs), then distinct A results can be attributed to the various rotational isomers and the ratio a_i/a_j of the intensities with which A_i and A_j occur is proportional to the equilibrium constant $K = C_i/C_j$:

$$[2] \quad a_i/a_j = \alpha_i C_i/\alpha_j C_j$$

α_k being the value of the intensity a_k for unit concentration of conformer k (e.g. molar extinction coefficient).

In general, however, such a proportionality will not hold, either because A_k may not arise entirely from conformer k or the coefficients α_k are temperature dependent and only accidentally can the ratio α_i/α_j be temperature independent. Braun and Liittke have attributed inconsistent results obtained from different ir bands of an internally rotating species to variation of α_i/α_j with temperature (8), and examined the consequences of such variation (11).

When only an averaged A value is observed, we have

$$[3] \quad \langle A \rangle = \int_0^{2\pi} A(\theta)P(\theta,T)\mathrm{d}\theta$$

with

$$[4] \quad P(\theta,T) = \exp\left[-V(\theta)/RT\right]/N$$

or

$$[5] \quad P(\theta,T) = \sum_\mu \phi_\mu^2(\theta) \exp\left(-E_\mu/RT\right)/N'$$

for the classical and quantum-mechanical approaches, respectively; N and N' are (temperature-dependent) normalizing factors and ϕ_μ is the μth torsional eigenfunction of energy E_μ.

Except when RT is much smaller than the energy barriers, [4] and [5] will be approximately identical (this has been confirmed in a few examples; see also refs. 12, 13). However, it will not in general be possible to associate a sub-set of ϕ_μ to each potential trough. Accordingly, the notion of equilibrium between any two stable conformers i, j becomes less clear. An equilibrium constant can then be defined as

$$[6] \quad K = \int_i P(\theta,T)\,\mathrm{d}\theta \Big/ \int_j P(\theta,T)\,\mathrm{d}\theta$$

where the integrals are calculated in the sub-domains of θ corresponding to troughs i and j. In a classical treatment, [6] is equal to the ratio of the partition functions for oscillations in each potential well: f_i/f_j.

The observed value $\langle A \rangle$ given by [3] can be partitioned into contributions from each well:

$$[7] \quad \langle A \rangle = \sum_k \bar{A}_k p_k$$

with

$$[8] \quad p_k = f_k/N$$

$$[9] \quad \sum_k p_k = 1$$

where $\bar{A}_k$ is the (temperature-dependent) weighted average value of $A(\theta)$ for well k. However, the usual procedure in the RIS method is to write

$$[10] \quad \langle A \rangle = \sum_k A_k^0 p_k^*$$

A_k^0 referring to the conformation of minimum energy in well k and p_k^* being an effective (temperature dependent) population (for sufficiently deep troughs, $p_k^* \approx p_k$) subject to the condition

$$[11] \quad \sum_k p_k^* = 1$$

From [7], [8], and [10] it is clear that any equilibrium constant defined by $K^* = p_i^*/p_j^*$ will differ from the true value $K = f_i/f_j = p_i/p_j$ in so far as the set of $\bar{A}_k$ values differs from the set of A_k^0 values. Such a difference depends on $V(\theta)$, T, and $A(\theta)$.

A similar discussion applies to the case when distinct A values are detected for each stable conformer. Then we can write

$$[12] \quad a_i = \alpha_i^0 C_i^* = \bar{\alpha}_i C_i$$

in parallel with [7] and [10], and $K = C_i/C_j$ will differ from $K^* = C_i^*/C_j^*$ to the extent the ratio $\bar{\alpha}_i/\bar{\alpha}_j$ differs from α_i^0/α_j^0.

But the basic criticism that can be made to the use of eqs. [10] and [11] is that, unless $\bar{A}_k \approx A_k^0$, the normalizing condition [11] does not necessarily hold. It is quite possible, for example, that all $\bar{A}_k$ values are larger (or smaller) than the corresponding A_k^0 values; therefore, in order to reproduce $\langle A \rangle$ with eq. [10], $\sum_k p_k^*$ must be greater (smaller) than 1. It may even happen that, by forcing eq. [11] to hold, negative populations are deduced. Examples of this are given further below.

As a consequence, the $(\Delta H^\ominus)^*$ and $(\Delta S^\ominus)^*$ values which are deduced from a study of K^* given by the RIS method, as a function of T^{-1}, will in general deviate from the "true" thermodynamic values as defined in terms of $K = p_i/p_j$. This will be most evident when different properties A lead to different thermodynamic parameters (3, 8).

In addition, even if $\Delta H^\ominus$ may be equated to $\Delta U^\ominus$, i.e. Δ(pressure $\times$ volume) = 0, the latter, which is a difference between weighted averages that take all possible conformations associated with each potential well into account, is not necessarily equal to the difference ΔV^0 between the corresponding minima in the potential energy function; nor, for that matter, to ΔU^0 which allows for zero-point energy. Unless the depths of the potential wells are similar and/or the temperature is sufficiently low, we expect $\Delta H_{ij}^\ominus \neq \Delta U_{ij}^0$, according to the thermodynamic relationship

$$[13] \quad \Delta H_{ij}^\ominus = \Delta U_{ij}^0 - \mathrm{d}\left[\ln f_i^0/f_j^0\right]/\mathrm{d}\,(1/T)$$

where f_k^0 are partition functions defined for each well by taking the origin of U at the respective minima.

Whereas the difference between $\Delta H^\ominus$ and ΔU^0 depends only on $V(\theta)$ and T, that between $\Delta H^\ominus$ and $(\Delta H^\ominus)^*$ depends also on the property $A(\theta)$.

We shall now consider some numerical examples in order to illustrate especially how $(\Delta H^\ominus)^*$ obtained by the RIS method can differ from the "true" $\Delta H^\ominus$ value, and how the latter differs from ΔU^0 or ΔV^0 (the quantity one usually aims to determine by the RIS method).

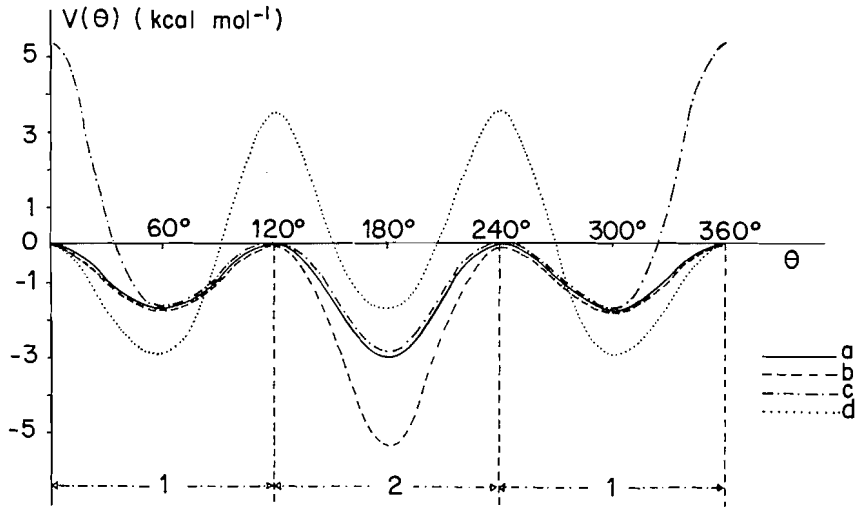

FIG. 1. Types of potential energy functions used.

(a) The difference between $(\Delta H_{ij}^{\ominus})^*$ determined by the RIS approach and the true $\Delta H_{ij}^{\ominus}$

For reasons of simplicity, we shall only deal with cases when $V(\theta)$ is a potential with three minima occurring at $\theta = 60°$, 180°, and 300°, with only one ΔV_{ij}^0 value, as shown in Fig. 1 (see also refs. 4 and 6). The troughs 0−120° and 240−360° are associated with conformer **1** and 120−240° with conformer **2**. Molecules having this type of potential function for internal rotation would, for example, be some substituted ethanes; e.g., curve *c* resembles that calculated for 1,2-dichloroethane, apart from a small displacement of the minima at 60° and 300° (16). Whereas curves *a* and *b* presuppose eclipsed conformations of equal energy, this is not the case with *c* and *d*. The actual form of $V(\theta)$ in the intervals 0−60°, 60−120°, 120−180°, etc. is that of the leading term in the potential energy function for ethane (14): proportional to $(1 - \cos 3\theta)$. The main qualitative conclusions, however, are not expected to be greatly influenced by the detailed form of $V(\theta)$ in these intervals.

As far as the θ-dependence of the property A is concerned, we have examined in particular $A(\theta) = \cos\theta$ and $A(\theta) = \cos^2\theta$. These are appropriate functions for expressing, for example, the dipole moment of $CH_2X—CH_2X$ and $CHX_2—CHX_2$ molecules as a function of θ (the squared dipole moment for each θ is proportional to $1 + \cos\theta$ provided the dipole is given as a sum of two local dipole vectors), for the square value of the distance between two vicinal nuclei (of the form $m + n\cos\theta$) and for vicinal HH nuclear spin coupling constants ($a' + b'\cos\theta + c'\cos^2\theta$ (15)). We note that any property or term varying with $\sin\theta$ gives zero with the $V(\theta)$ functions above.

The calculations have been performed for temperatures ranging from 150 to 1000 K.

For the $V(\theta)$ functions of Fig. 1, we have from [7] and [9]:

$$[14]\quad \langle A\rangle = 2p_1(\bar{A}_1 - \bar{A}_2) + \bar{A}_2$$

If [11] is assumed to be true, then from [10] and [11] we can also write

$$[15]\quad \langle A\rangle = 2p_1^*(A_1^0 - A_2^0) + A_2^0$$

Example 1

$$V(\theta) = \tfrac{1}{2}V_1^0(1 - \cos 3\theta) \qquad 0 \leqslant \theta \leqslant 120° \text{ and } 240° \leqslant \theta \leqslant 360°$$

$$= \tfrac{1}{2}V_2^0(1 - \cos 3\theta) \qquad 120° \leqslant \theta \leqslant 240°$$

$$A(\theta) = \cos\theta;\ \cos^2\theta;\ \mu\cos\theta + \lambda\cos^2\theta$$

We first take $V_1^0 = -1.8$ kcal mol^{-1} and $V_2^0 = -3.0$ kcal mol^{-1} (curve *a* in Fig. 1), noting that V^0 for ethane is ca. −3.0 kcal mol^{-1}. For $A(\theta) = \cos\theta$, [15] becomes

$$[16]\quad \langle\cos\theta\rangle = 3p_1^* - 1$$

For low temperatures, $\langle\cos\theta\rangle$ approaches −1, p_1^* and p_1 become very small, $\bar{A}_2$ tends to −1 and $\bar{A}_1$ to 1/2. As the temperature increases, so do $\langle\cos\theta\rangle$ and $\bar{A}_2$, whereas $\bar{A}_1$ decreases; p_1 and p_1^* increase and become closer ($p_1 < p_1^*$) and so do the equilibrium constants $K_{1,2}$ and $K_{1,2}^*$ ($K_{1,2} < K_{1,2}^*$). Figure 2 compares $\ln K_{1,2}$ with $\ln K_{1,2}^*$ as a function of T^{-1}. A small deviation from linearity is apparent. $\Delta H_{1,2}^{\ominus}$ is larger than $(\Delta H_{1,2}^{\ominus})^*$ but only by 5−6%. Depending on the temperature range, $\Delta H^{\ominus}$ varies from 1070 at the higher to 1210 at the lower temperatures, whereas $(\Delta H^{\ominus})^*$ goes from 1020 to 1160 cal mol^{-1}.

This difference becomes even smaller as $\Delta V_{1,2}^0$ decreases. For $\Delta V_{1,2}^0 = 0$ it vanishes, because $(\Delta H^{\ominus})^*$ and $\Delta H^{\ominus}$ are both zero. On the contrary, as the depth of trough 2 in Fig. 2 increases (curve *b*), the deviations are expected to increase, because $\bar{A}_2$ decreases and approaches A_2^0 especially at low temperatures; accordingly (see [15] and [16]), p_1^* deviates more from p_1 ($p_1 < p_1^*$). Figure 3, which is the equivalent of Fig. 2 except that trough 2 has been changed so as to make $\Delta V_{1,2}^0 = 3 \times 1.2$ kcal mol^{-1} (curve *b*, $V_1^0 = -1.8$ kcal mol^{-1}, $V_2^0 = -5.4$ kcal mol^{-1}), shows how large the difference between $(\Delta H^{\ominus})^*$ and $\Delta H^{\ominus}$ can be depending on the temperature. In particular, the variation of $-\ln K^*$ with T^{-1} is far from linear. For $\Delta H^{\ominus} = 3280 - 3580$ cal mol^{-1} $(\Delta H^{\ominus})^*$ varies from 440 cal mol^{-1} at low temperatures to 3230 cal mol^{-1} at high temperatures.

For $A(\theta) = \cos^2\theta$, $\bar{A}_1$ and $\bar{A}_2$ deviate more from A_1^0 ($\bar{A}_1 > A_1^0$) and A_2^0 ($\bar{A}_2 < A_2^0$) (see eqs. [14] and [15]) and p_1^* becomes greater than in the case $A(\theta) = \cos\theta$, hence deviating more from p_1, especially at low temperatures. For example, for $V(\theta)$ given by curve *a* (Fig. 1) and $T = 300$ K, we get $p_1 = 0.133$ and $p_1^* = 0.138$ for $A(\theta) = \cos\theta$ and $p_1^* = 0.152$ for $A(\theta) =$

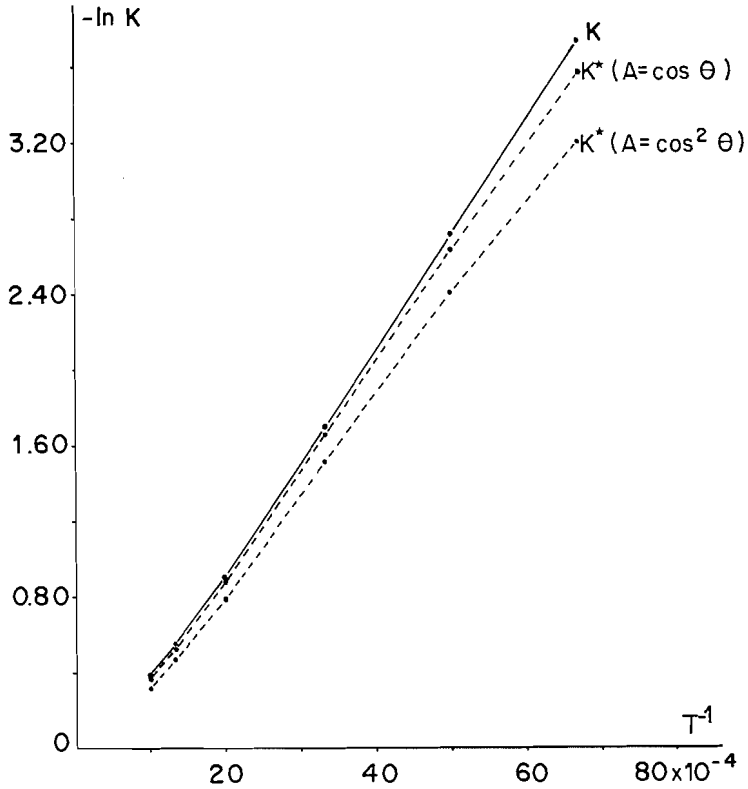

FIG. 2. Equilibrium constants – temperature plots, using $V(\theta)$ given by curve *a* in Fig. 1 (ΔV^0 = 1200 cal mol^{-1}) and $A(\theta) = \cos\theta$ (leading to $(\Delta H^{\ominus})^*$ = 1020−1160 cal mol^{-1}) and $A(\theta) = \cos^2\theta$ (leading to $(\Delta H^{\ominus})^*$ = 950−1090 cal mol^{-1}). The full line ($\Delta H^{\ominus}$ = 1070−1210 cal mol^{-1}) is obtained using eq. [6].

$\cos^2\theta$; accordingly, $K^* = 0.191$ and $K^* = 0.218$, respectively. K in comparison has the value $K = 0.182$. Again, the difference becomes more marked when $V(\theta)$ is given by curve *b*. The corresponding plots of $-\ln K^*$ against T^{-1} are shown in Figs. 2 and 3.

For $A(\theta) = \mu\cos\theta + \lambda\cos^2\theta$, p_1^* can be related to the corresponding values obtained with $A(\theta) = \cos\theta$ and $A(\theta) = \cos^2\theta$ by using [15]:

$$[17]\quad p_1^* = \left(\mu p^*_{1,\cos\theta} - \frac{\lambda}{2}\,p^*_{1,\cos^2\theta}\right) \Big/ \left(\mu - \frac{\lambda}{2}\right)$$

In Karplus' equation for HH coupling constants (15), $\lambda \gg \mu$ and the deviations are approximately those obtained with $A(\theta) = \cos^2\theta$. With $\mu = \lambda = 1$, $p_1^* = 2p^*_{1,\cos\theta} - p^*_{1,\cos^2\theta}$; since $p_1 < p^*_{1,\cos\theta} < p^*_{1,\cos^2\theta}$, p_1^* now approaches p_1. In other cases, however, the differences can be much bigger; p_1^* may even become negative. For $A(\theta) = 1.1\cos\theta + 2.0\cos^2\theta$, for example, the p_1^* values obtained for several temperatures and $V_1^0 = -1.8$, $V_2^0 = -5.4$ kcal mol^{-1}, are as follows:

T (K)	p_1^*
150	−0.0619
200	−0.0841
300	−0.124
500	−0.142
750	−0.0700
1000	+0.0160

For $A(\theta) = \cos\theta + 2\cos^2\theta$, p_1^* given by [17] would become $-\infty$! $A(\theta)$ functions like the latter giving $A_1^0 = A_2^0$ (= 1 in the present case) render the RIS method inoperative and clearly serve to demonstrate that the satisfactory results sometimes obtained with the method are purely accidental. In the case just considered, the average value $\langle A\rangle$ is not very much different from the common value $A_1^0 = A_2^0 = 1$. But in other cases when the RIS procedure is not applicable, the difference can be large. For example, with $A(\theta) = \cos 3\theta$ and T = 500 K, we have $\langle A\rangle = -0.515$ for curve *a* and −0.752 for potential *b*, whereas $A_1^0 = A_2^0 = -1$.

Example 2

$$V(\theta) = [-3.6(1 - \cos 3\theta) + 5.4] \text{ kcal mol}^{-1} \quad 0 \leqslant \theta \leqslant 60° \text{ and } 300° \leqslant \theta \leqslant 360°$$

$$= -0.9(1 - \cos 3\theta) \text{ kcal mol}^{-1} \quad 60° \leqslant \theta \leqslant 120° \text{ and } 240° \leqslant \theta \leqslant 300°$$

$$= -1.5(1 - \cos 3\theta) \text{ kcal mol}^{-1} \quad 120° \leqslant \theta \leqslant 240°$$

$A(\theta) = \cos\theta;\ \cos^2\theta$

The potential function used now is that corresponding to curve *c* in Fig. 1; it differs from curve *a* in that the energy of the conformations close to $\theta = 0°$, 360° is increased. As a consequence, for $A(\theta) = \cos\theta$, $\langle A\rangle$, p_1^*, and $\bar{A}_1$ all decrease, whereas $\bar{A}_2$ remains the same as, of course, do A_1^0 and A_2^0. According to [14] and [15], p_1^* decreases more than p_1; eventually $p_1 > p_1^*$ and $K^*_{1,2}$. This occurs at higher temperatures, because it is then that $\bar{A}_1$ obtained with curve *c* shows the greatest differences from $\bar{A}_1$ calculated using curve *a*. This is illustrated in Fig. 4. With respect to potential *a*, the difference between $\Delta H^{\ominus}$ (= 1140−1180 cal mol^{-1}) and $(\Delta H^{\ominus})^*$ (= 980−1080 cal mol^{-1}) increases and the $\Delta S^{\ominus}$ and $(\Delta S^{\ominus})^*$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

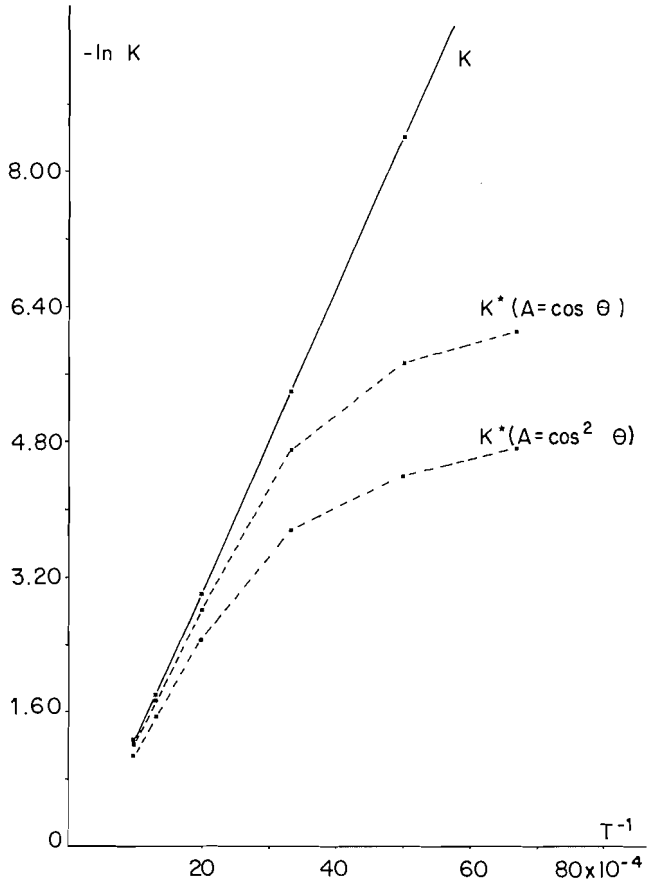

FIG. 3. The same as Fig. 2, with curve b (ΔV^0 = 3600 cal mol^{-1}); $(\Delta H^{\ominus})^*$ = 3230−440 cal mol^{-1} for $A(\theta)$ = cos θ and $(\Delta H^{\ominus})^*$ = 2780−400 cal mol^{-1} for $A(\theta)$ = cos^2 θ; $\Delta H^{\ominus}$ = 3280−3580 cal mol^{-1}.

values are now also significantly different.

For the case $A(\theta) = \cos^2\theta$, p_1^* becomes greater than for $A(\theta)$ = cos θ, as in Example 1. For example, at 300 K, p_1 = 0.105 and p_1^* = 0.103 with $A(\theta)$ = cos θ and p_1^* = 0.144 with $A(\theta) = \cos^2\theta$: accordingly, K^* = 0.129 and K^* = 0.202 respectively, in comparison with K = 0.132.

Example 3

$$V(\theta) = [-1.5(1 - \cos 3\theta)] \text{ kcal mol}^{-1} \quad 0 \leqslant \theta \leqslant 60° \text{ and } 300° \leqslant \theta \leqslant 360°$$

$$= [-3.3(1 - \cos 3\theta) + 3.6] \text{ kcal mol}^{-1} \quad 60° \leqslant \theta \leqslant 120° \text{ and } 240° \leqslant \theta \leqslant 300°$$

$$= [-2.7(1 - \cos 3\theta) + 3.6] \text{ kcal mol}^{-1} \quad 120° \leqslant \theta \leqslant 240°$$

$A(\theta)$ = cos θ; cos^2 θ

With $V(\theta)$ given by curve d, ⟨cos θ⟩ decreases from 0.519 for 150 K to 0.271 for 1000 K. $\bar{A}_2$ increases with temperature; $\bar{A}_1$ also increases up to a certain temperature and then decreases, corresponding to the population of conformations with θ approaching 120°. Both p_1 and p_1^* decrease on increasing T, with $p_1^* > p_1$. The logarithms of $K_{1,2}$ and $K_{1,2}^*$ are plotted in Fig. 5 against T^{-1}. Now $\Delta H_{2,1}^{\ominus}$ = 1320−1180 cal mol^{-1} and $(\Delta H_{2,1}^{\ominus})^* \simeq$ 1650 cal mol^{-1}; the error is 20−40%, with $(\Delta H^{\ominus})^* > \Delta H^{\ominus}$. It is noted that for T < 200 K, ⟨cos θ⟩ > A_1^0 = 0.5, hence $p_1^* > 0.5$ and p_2^* becomes negative; the higher the barrier in trough 2, the higher the temperature at which this occurs, thus making the RIS method of no value.

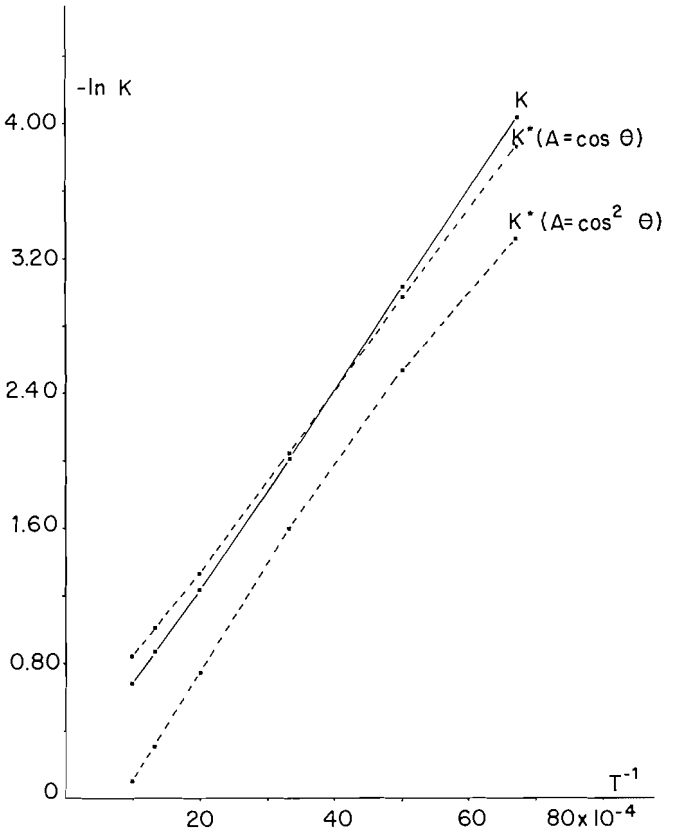

FIG. 4. The same as Fig. 2, with curve c (ΔV^0 = 1200 cal mol^{-1}); $(\Delta H^{\ominus})^*$ = 980−1080 cal mol^{-1} for $A(\theta)$ = cos θ and $(\Delta H^{\ominus})^*$ = 1290−920 cal mol^{-1} for $A(\theta) = \cos^2\theta$; $\Delta H^{\ominus}$ = 1140−1180 cal mol^{-1}.

In the case of $A(\theta) = \cos^2\theta$, $p_1^* < p_1$ especially at higher temperatures. For T = 300 K, $K_{1,2}$ = 8.57 and $K_{1,2}^*$ = 2.91; for $A(\theta)$ = cos θ, $K_{1,2}^*$ = 19.4. As seen from Fig. 5, $(\Delta H_{2,1}^{\ominus})^*$ ranges from 420 to 900 cal mol^{-1}.

(b) The difference between $\Delta H_{ij}^{\ominus}$ *and* ΔV_{ij}^0

From the plots of $-\ln K$ and $-\ln K^*$ against T^{-1}, we have obtained $\Delta H^{\ominus}$ and $(\Delta H^{\ominus})^*$ values that depend on the temperature; it was assumed that $\Delta S^{\ominus}$ and $(\Delta S^{\ominus})^*$ remain approximately constant in the temperature interval considered: 150−1000 K. Figures 2−5 show that for lower temperatures $\Delta H^{\ominus} \simeq \Delta V^0$ as would be expected. For higher temperatures, some small deviations can be observed.

In order to ascertain how big these deviations can be, we have performed analytical calculations of $\Delta H^{\ominus}$ taken equal to $\Delta U^{\ominus}$, for V-shape potentials resembling the potential curves of Fig. 1. $\Delta U_{1,2}^{\ominus}$ is defined as the difference of average values for wells 1 and 2, in a classical manner:

$$[18] \quad \Delta U_{1,2}^{\ominus} = \frac{\int_1 V(\theta) \exp[-V(\theta)/RT]d\theta}{\int_1 \exp[-V(\theta)/RT]d\theta} - \frac{\int_2 V(\theta) \exp[-V(\theta)/RT]d\theta}{\int_2 \exp[-V(\theta)/RT]d\theta}$$

(the integrals extend to all angles θ for each well).

Figure 6 shows the variation of $\Delta U^{\ominus}$ with temperature. For temperatures around 300 K and below the differences between

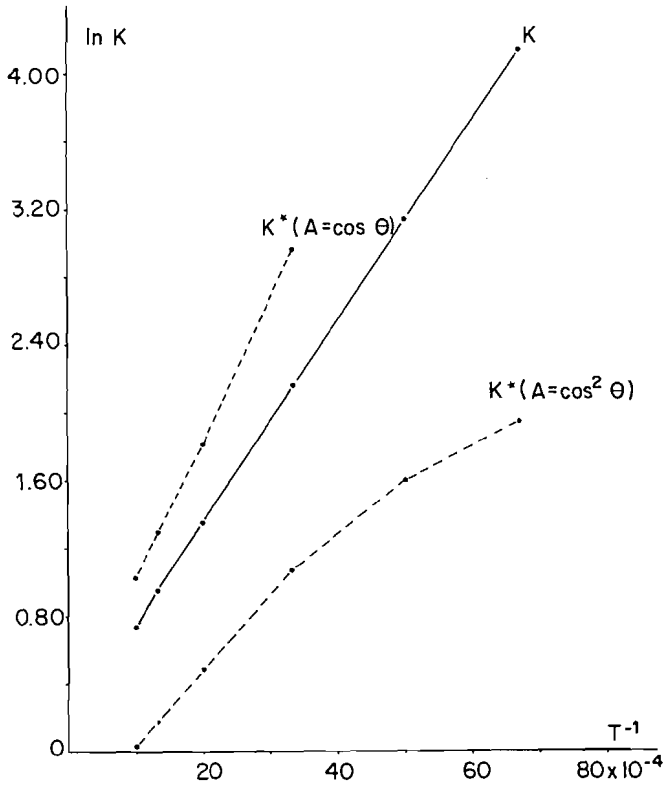

FIG. 5. The same as Fig. 2, with curve d (ΔV^0 = 1200 cal mol^{-1}); $(\Delta H^{\ominus})^*$ = 1650 cal mol^{-1} for $A(\theta) = \cos\theta$ and $(\Delta H^{\ominus})^*$ = 900−420 cal mol^{-1} for $A(\theta) = \cos^2\theta$; $\Delta H^{\ominus}$ = 1320−1180 cal mol^{-1}.

$\Delta U^{\ominus}$ and ΔV^0 are small, but for temperatures approaching 1000 K the deviations reach −25 to −30% for potentials a' and b' and +40% for curve c'. Comparing the results for potentials a' and a'' it is clear that for a given ΔV^0 value, the deviations become smaller the deeper the potential wells, as would be anticipated.

Conclusion

We have discussed two basic sources of difference between ΔV^0 for the minima in a potential energy curve appropriate to the internal rotation of ethane derivatives and the enthalpy change $(\Delta H^{\ominus})^*$ for the rotational isomers as determined by the rotational isomeric state approach. One depends only on the shape of the potential $V(\theta)$ and on the temperature; this leads to a difference between ΔV^0 and $\Delta H^{\ominus}$, $\Delta H^{\ominus}$ being the true enthalpy change. The other varies also with the conformation-dependent property $A(\theta)$ used leading to a difference between $\Delta H^{\ominus}$ and $(\Delta H^{\ominus})^*$. Other sources of error are known to exist and have been considered elsewhere (3). The following are the main conclusions:

(*1*) As would be expected, the difference between $\Delta H^{\ominus}$ and ΔV^0 depends not only on the value of ΔV^0 but also on the maxima of the potential energy function, which occur close to the eclipsed conformations. Such a difference is smaller the lower the temperature and the deeper the potential troughs. For temperatures up to 400 K and for realistic energy barriers, the deviation is ±10% at the most, increasing to about ±30% at 1000 K.

(*2*) Despite the changes of $\Delta H^{\ominus}$ with temperature, the plot of ln K against $1/T$ gives almost a straight line (passing near the origin) if K is the true equilibrium constant. However, when the equilibrium constant K^* given by the RIS method is used, a substantial and consistent deviation from linearity can be observed, especially at intermediate and low temperatures. We note that: (*a*) If the eclipsed conformations have approximately the same energy, then K and K^* approach each other at high temperatures. At low temperature, the deviation is more marked for a property varying as $A(\theta) = a \pm b\cos^2\theta$ than for $A(\theta) = c \pm d\cos\theta$ and it increases with ΔV^0. With the first $A(\theta)$ function and in the temperature range 200−300 K, $(\Delta H^{\ominus})^*$ is smaller than ΔH^0 by about 10% for ΔV^0 = 1.2 kcal mol^{-1} and up to 80% for ΔV^0 = 3.6 kcal mol^{-1}. (*b*) If the eclipsed conformations have different energies K^* can be very different from K at any temperature. This is particularly true for $A(\theta) = a \pm b\cos^2\theta$, and a significant apparent $(\Delta S^0)^*$ results.

For a system like 1,2-dichloroethane (potential of type c in Fig. 1 (16)), both $A(\theta)$ functions lead to $(\Delta H^{\ominus})^*$ in the interval 200−300 K that is only ca. 10% less than $\Delta H^{\ominus}$. This (together with conclusion 1 above) explains why Mark and Sutton (16) found good agreement between the dipole moments calculated using the continuum average and the RIS method for this compound (see also ref. 5). However, for systems in which the least stable staggered conformation occurs at θ = 180° and the least stable eclipsed conformations are those for θ = 120°, 240°, the results are quite different. In fact, for potential d in Fig. 1, the $(\Delta H^{\ominus})^*$ values at room temperature deviate in magnitude from $\Delta H^{\ominus}$ by +40% with $A(\theta) = c \pm d\cos\theta$ and by −35% with $A(\theta) = a \pm b\cos^2\theta$. Systems to which this conclusion is likely to apply semi-quantitatively are 1,2-difluoroethane (17, 18) and 1,1,2,2-tetrachloroethane (in solution or as pure liquid) (3). It is therefore anticipated that the $(\Delta H^{\ominus})^*$ values obtained, in the same conditions, from dipole moments and from HH spin couplings will be very different, the former being larger and the latter smaller than the true $\Delta H^{\ominus}$. We could not find data to confirm this prediction, but it is interesting that the RIS method based on nuclear spin coupling constants for 1,2-difluoroethane vapour gives 0.6 kcal mol^{-1} (19) whereas the value obtained from electron diffraction is 0.93 kcal mol^{-1} (17). For the pure liquid the estimated $(\Delta H^{\ominus})^*$ value is 2 kcal mol^{-1} (19), the conformation for θ = 180° being the least stable of the staggered conformations.

(*3*) The relative energies of eclipsed conformations cannot be ignored. This is demonstrated by the points (*a*) and (*b*) above. It is also a possible explanation for the unexpected stability of some conformations deduced from the RIS method. For example, succinic acid and its salts (20) and also methylsuccinic acid and its esters (21) show a surprisingly high stability of the *syn−clinal* conformations when the RIS method is applied to HH nuclear spin coupling constants. This result may just reflect the high energies of the *cis* conformations. In particular, the pair of vicinal H nuclei, for which a curve of type c (Fig. 1) would be expected to apply, should show a smaller coupling than if all eclipsed conformations had approximately the same energy.

(*4*) Cases may occur for which the RIS approach would lead to negative populations for the higher energy conformers.

Although, according to our calculations, some of the ΔV^0 values obtained by the RIS method may be approximately correct (e.g. 1,2-dichloroethane, perhaps the most studied ethane derivative from the point of view of conformation and internal rotation), many others may be in substantial error due to the interpretation of observed properties in terms of the

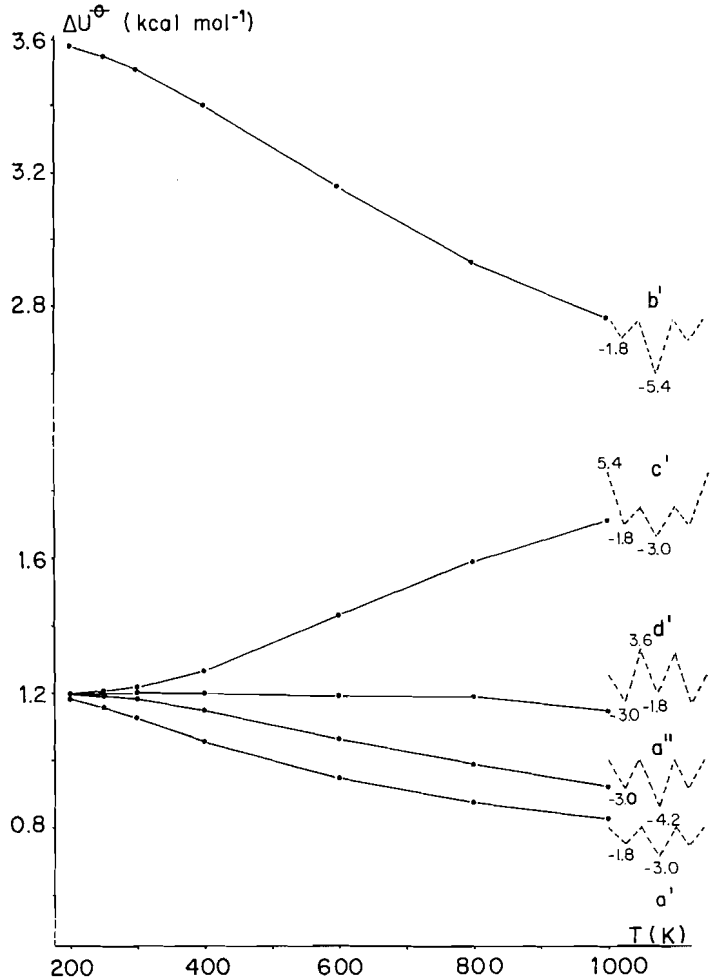

FIG. 6. Plot of $\Delta U^{\ominus}$ given by eq. [18] as a function of T for V-shape functions related to those of Fig. 1.

stable conformers only. Provided some knowledge exists on the type of potential function for internal rotation, it is possible to estimate the sign and roughly the magnitude of such errors and to decide on the conditions, namely the temperature range, for which the errors are minimized. For example, if all eclipsed conformations have approximately the same energy, then for lower temperatures the deviation between $(\Delta H^{\ominus})^*$ and $\Delta H^{\ominus}$ increases. On the other hand, for high temperatures it is the difference between ΔV^0 and $\Delta H^{\ominus}$ that is large. There will then be a minimum deviation, not necessarily negligible, between $(\Delta H^{\ominus})^*$ and ΔV^0 at some intermediate temperature. This, apart from an entropy factor which was deliberately ignored, was found by Gil and Varandas in previous calculations using vicinal HH nuclear spin coupling constants (4) and electric dipole moments (6) as conformation-dependent properties. They actually compared directly ΔV^0 with a $\Delta E'$ value which is, in fact, $(\Delta G^{\ominus})^*$.

An approximate correction to the ΔV^0 value given by the RIS approach is helpful if one is trying to fit the parameters of a potential energy function to observed properties and their temperature dependence. Obviously the study will gain much from using more than one conformation-dependent property. Apart from the values of the various energy barriers, a parameter that may be of some importance is the exact position of the minima (eventually also the maxima) in the potential energy curve (16). Work is in progress along these lines including an extension to non-symmetrical potentials.

Information on energy differences between rotational isomers can also be obtained from data in various solvents coupled with a theory of solvent effects on ΔV^0 values. This has been developed with some success by Abraham and co-workers (3). We note that, when fitting experimental data for variable dielectric constants (e.g. nuclear spin coupling constants), in terms of ΔV^0 for the vapour (in fact $\Delta G^{\ominus}$) and the coupling constants of the rotational isomers, these are effective averaged couplings appropriate to each potential well and not just the coupling constant for a specific angle of rotation. Accordingly, the equilibrium constants and the energy differences (actually $\Delta G^{\ominus}$) determined should be approximately correct, at least in so far as the values taken for the vapour are correct. We note that the approximate constancy of those couplings in various solvents must require changes in the energy of the eclipsed conformations with solvent that offset the effect of changes in the minimum energy conformations. Also, the orientation-dependent substituent effects on coupling constants demonstrated by those studies must partly arise from the features of each potential well.

The retroaldol reaction of 3-methyl-2-butenal

J. PETER GUTHRIE[1] AND BRIAN A. DAWSON

Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received June 11, 1982

J. PETER GUTHRIE and BRIAN A. DAWSON. Can. J. Chem. **61**, 171 (1983).

In aqueous sodium hydroxide solutions at 25°C, 3-methyl-2-butenal, **1***c*, undergoes retroaldol cleavage to acetone and acetaldehyde. The kinetics of the retroaldol reaction were followed spectrophotometrically at 242 nm and showed simple first order behavior. When 3-methyl-3-hydroxybutanal, **2***c*, was added to aqueous sodium hydroxide solutions at 25°C, there was an initial increase in absorbance at 242 nm, attributed to formation of **1***c*, followed by a 20-fold slower decrease; the rate of the slow decrease matches the rate of disappearance of **1***c* under the same conditions. Analysis of the kinetics allows determination of the three rate constants needed to describe the system: $k_{hyd} = 0.00342$; $k_{dehyd} = 0.00832$; $k_{retro} = 0.0564$; all M^{-1} s^{-1}. The equilibrium constant for enone hydration is 0.41. Rate constants for the analogous reactions for acrolein and crotonaldehyde could be obtained from the literature. There is a reasonable rate–equilibrium correlation for the retroaldol step. For the enone hydration step, rate and equilibrium constants respond differently to replacement of hydrogen by methyl. It is proposed that this results from release of strain after the rate-determining step by rotation about a single bond; this decrease in strain is reflected in the equilibrium constant but not in the rate constant.

J. PETER GUTHRIE et BRIAN A. DAWSON. Can. J. Chem. **61**, 171 (1983).

Le méthyl-3 buténal-2 (**1***c*), dans des solutions aqueuses d'hydroxyde de sodium à 25°C, subit un clivage rétroaldolique conduisant à l'acétone et l'acétaldéhyde. On a suivi spectrophométriquement à 242 nm la cinétique de cette réaction simple d'ordre un. Lorsqu'on ajoute du méthyl-3 hydroxy-3 butanal (**2***c*) à des solutions aqueuses d'hydroxyde de sodium à 25°C, il y a une augmentation initiale de l'absorption à 242 nm que l'on attribue à la formation du composé **1***c* suivie d'une diminution qui est 20 fois plus lente; le taux de la faible diminution correspond au taux de disparition du produit **1***c* dans ces mêmes conditions. L'analyse des données cinétiques permet de déterminer les trois constantes de vitesse nécessaires à la description du système: $k_{hyd} = 0{,}00342$; $k_{déhyd} = 0{,}00832$; $k_{rétro} = 0{,}564$; tous M^{-1} s^{-1}. La constante d'équilibre de l'hydratation de l'énone est égale à 0,41. On peut obtenir dans la littérature les constantes de vitesse des réactions analogues de l'acroléine et du crotonaldéhyde. Il y a corrélation raisonnable entre vitesse et équilibre pour l'étape de rétroaldol. Dans l'étape d'hydratation de l'énone, les constantes de vitesse et d'équilibre répondent différemment au remplacement d'un hydrogène par un méthyle. On propose que ceci provient d'une diminution de contrainte, après l'étape déterminante, provenant de la rotation autour d'une liaison simple. Cette diminution de contrainte se réflète dans les constantes d'équilibre mais pas dans les constantes de vitesse.

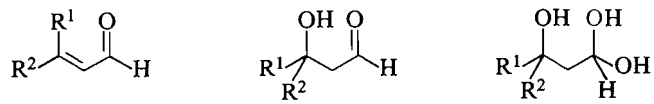
Introduction

We have reported a study (1) of the equilibrium constants for aldol condensation reactions. It seemed highly desirable to look for rate–equilibrium correlations for these synthetically important reactions, particularly since equilibrium constants were now available. However, there have been comparatively few kinetics investigations of aldol reactions. This is in large measure due to the great potential for complexity for most aldol reactions, with various modes of reaction, competing equilibria, and polymerization leading to hopelessly complicated mixtures. We have shown that much of this complexity can be avoided by studying the retroaldol reaction at low concentrations, in a study of the reaction of crotonaldehyde in dilute aqueous base (2). We now wish to report a study of a closely related compound with one additional carbon methyl group, namely 3-methyl-2-butenal, **1***c*. These new results, combined with data from the literature, allow a detailed comparison of the kinetic behavior of compounds **1***a–c*.

Results and discussion

The retroaldol reaction of **1***c* can be followed spectrophotometrically; when **1***c*, as a solution in acetonitrile, is injected into aqueous sodium hydroxide solution there is a smooth disappearance of the absorbance at 242 nm, which



1*a–c* **2***a–c* **3***a–c*

a: R' = R^2 = H
b: R' = H, R^2 = CH_3
c: R' = R^2 = CH_3

SCHEME 1

follows a simple first order rate law. Thus one can see no sign of the two stages which are believed to be essential for this reaction (eqs. [1] and [2])

$$[1]\quad (CH_3)_2C{=}CH{-}CHO \underset{k_{21}}{\overset{k_{12}}{\rightleftharpoons}} (CH_3)_2COO + CH_3{-}CHO \qquad K_1$$

$$[2]\quad (CH_3)_2COH{-}CH_2{-}CHO \underset{k_{23}}{\overset{k_{23}}{\rightleftharpoons}} (CH_3)_2CO + CH_3{-}CHO \qquad K_2$$

The two phases of the reaction are quite apparent when the aldol, 3-methyl-3-hydroxybutanal, **2***c*, is injected into aqueous sodium hydroxide solution; the absorbance at 242 nm first rises and then, about 20 times more slowly, falls again; see Fig. 1. The rate of the slow fall in absorbance is essentially identical to the rate of disappearance of the absorbance of **1***c* when the

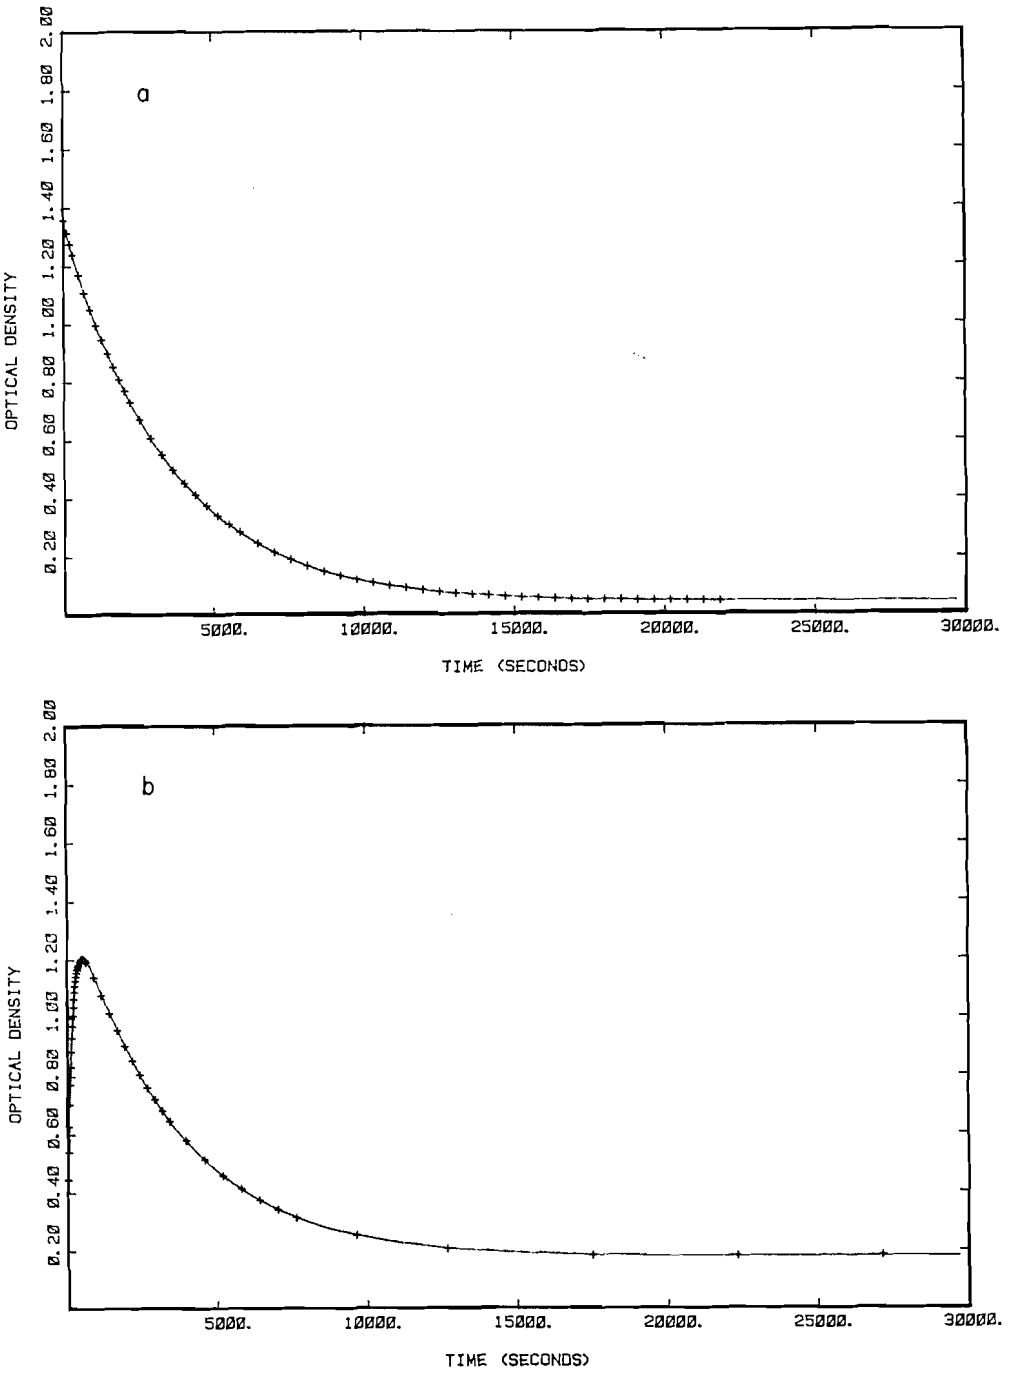

FIG. 1. Absorbance vs. time curves for reactions of 3-methyl-2-butenal (a) and 3-hydroxy-3-methylbutanal (b) with 0.1 *N* NaOH in water at 25°C. The lines are calculated using parameters determined by least squares. At the maximum in (b) 11% of the starting material had been converted to 3-methyl-2-butenal.

latter is used to initiate reaction. Analysis of the two-phase kinetics data permits evaluation of the rate constants. For the system of interest, where a low concentration of aldol product undergoes retroaldol cleavage, the rate of the second order aldol formation process, k_{32}, is negligible. A rigorous solution of the kinetics equations is possible following the procedure described in Moore and Pearson (3), and leads to eq. [3] which gives the absorbance as a function of time.

$$[3] \quad A = A_\infty + \alpha \exp(-\lambda_2 t) + \beta \exp(-\lambda_3 t)$$

where: A = absorbance, A_∞ = absorbance at infinite time, $\lambda_{2,3} = (p \pm q)/2$, $p = k_{12} + k_{21} + k_{23}$, and $q = (p^2 - 4k_{12}k_{23})^{1/2}$. When reaction starts with **1***c*,

$$\alpha = C_1^0 k_{12}\epsilon_1(\lambda_2 - k_{23})\{1 - \epsilon_2\lambda_2/\epsilon_1(\lambda_2 - k_{23}) - \epsilon_3 k_{23}/\epsilon_1(\lambda_2 - k_{23})\}/\lambda_2(\lambda_2 - \lambda_3)$$

$$\beta = C_1^0 k_{12}\epsilon_1(k_{23} - \lambda_3)\{1 - \epsilon_2\lambda_2/\epsilon_1(k_{23} - \lambda_3) - \epsilon_3 k_{23}/\epsilon_1(k_{23} - \lambda_3)\}/\lambda_3(\lambda_2 - \lambda_3)$$

When reaction starts with the aldol,

$$\alpha = C_2^0 k_{21}\epsilon_1\{-1 + \epsilon_2(\lambda_2 - k_{12})/\epsilon_1 k_{21} - \epsilon_3 k_{23}(\lambda_2 - k_{12})/\epsilon_1 k_{21}\lambda_2\}/(\lambda_2 - \lambda_3)$$

[f]Initial substrate concentration was 6.41×10^{-5} *M*.
[g]Initial substrate concentration was 8.01×10^{-5} *M*.

$$\beta = C_2^0 k_{21}\epsilon_1\{1 - \epsilon_2(\lambda_3 - k_{12})/\epsilon_1 k_{21} + \epsilon_3 k_{23}(\lambda_3 - k_{12})/\epsilon_1 k_{21}\lambda_3\}/(\lambda_2 - \lambda_3)$$

where in either case: ϵ_1 = extinction coefficient for **1***c*, ϵ_2 = extinction coefficient for aldol, ϵ_3 = extinction coefficient for the products (acetaldehyde plus acetone), and C_i^0 = initial concentration of **1***c* ($i = 1$) or aldol ($i = 2$). These equations can be usefully simplified by noting that $\epsilon_1 \gg \epsilon_2, \epsilon_3$, so that for reaction starting with **1***c*:

$$\alpha \simeq C_1^0 k_{12}\epsilon_1(\lambda_2 - k_{23})/\lambda_2(\lambda_2 - \lambda_3)$$

$$\beta \simeq C_1^0 k_{12}\epsilon_1(k_{23} - \lambda_3)/\lambda_3(\lambda_2 - \lambda_3)$$

and for reaction starting with the aldol, **2***c*:

$$\beta \simeq -\alpha \simeq C_2^0 k_{21}\epsilon_1/(\lambda_2 - \lambda_3)$$

For reactions starting with the aldol, **2***c*, the individual rate constants can now be calculated using:

$$k_{21} = (\lambda_2 - \lambda_3)\beta/C_2^0\epsilon_1$$

$$k_{23} = \{(p - k_{21}) + \sqrt{[(p - k_{21})^2 - 4\lambda_2\lambda_3]}\}/2$$

$$k_{12} = \{(p - k_{21}) - \sqrt{[(p - k_{21})^2 - 4\lambda_2\lambda_3]}\}/2$$

The equilibrium constant for the first step can be calculated using:

$$K_1 = k_{12}/k_{21}$$

We were concerned that k_{12} might be subject to error because it is the result of a subtraction of larger quantities. k_{12} can also be calculated from the steady state rate equation,

$$\lambda_3 \simeq k_{12}k_{23}/(k_{21} + k_{23})$$

which can also be derived from the above rigorous solution when $k_{12} \ll k_{21}, k_{23}$. Error analysis showed that both methods led to comparable uncertainty in k_{12} and that this uncertainty was no greater than for the other rate constants. There is of course an ambiguity in the quadratic solution, so that chemical intuition must be used to assign the identity of the larger and smaller roots. In the present case the assignment can be made as follows. The value of β is about 0.14 of the value expected if all of the aldol, **2***c*, were converted into **1***c*, requiring that k_{21} and k_{23} be in approximately this ratio. Since k_{21} is about 0.15 of the larger root of the quadratic, this larger root must be k_{23}, and the smaller root of the quadratic equation, which is smaller

TABLE 2. Second order rate constants and equilibrium constant for **1***c* extrapolated to zero hydroxide concentration[a]

Rate constant	Value
k_{12}	$3.42\pm0.05 \times 10^{-3}$[b]
k_{21}	$8.32\pm0.34 \times 10^{-3}$[b]
k_{23}	$5.64\pm0.03 \times 10^{-2}$[b]
K_1	0.413 ± 0.011[c]

[a]In aqueous solution at 25°C, μ = 0.1 (KCl).
[b]M^{-1} s^{-1}.
[c]Dimensionless; $K_1 = k_{12}/k_{21}$.

TABLE 3. pK_a results for formaldehyde hydrate

Temperature (°C)	pK_a	Reference
0	14.0	20
15	12.92	21
20	13.4	22
23	12.79	23
25	13.29	9
25	12.80	Calculated from results in ref. 6
25	12.92	Calculated from results in ref. 11
30	12.89	24
40	12.69	10
50	12.48	25

than k_{21}, must be k_{12}. That apparently single exponential kinetics were observed when reaction began with **1***c* is consistent with the rate constants derived from the analysis just described; the amplitude of the unobserved fast exponential process is calculated to be only about 5% of the amplitude of the observed slow exponential process when the rate constants derived from the analysis are substituted in eq. [3].

Table 1 shows the results of applying this analysis to the experimental data for **1***c* and the corresponding aldol, **2***c*. The rate constants refer to the *total* aldol concentration including the aldehyde, the carbonyl hydrate, and the anion of the carbonyl hydrate. The individual rate constants show the expected first order dependence upon the hydroxide concentration, but there may be a more complex dependence for some; see Fig. 2. We had previously (2) found that for crotonaldehyde, **2***b*, k_{21}, k_{23}, and $1/K_1$ showed a dependence upon hydroxide concentration of the form:

$$k_i = k_i^0/(1 + a[OH^-])$$

Similar behavior appears to be shown here, although one cannot be very confident because the variation with changing hydroxide concentration is only clearly greater than experimental error for k_{21}. Table 2 shows the second order rate constants for the individual steps evaluated in this work, corrected where appropriate to zero hydroxide ion concentration.

Another source of concern is that there appears to be a slight dependence of the second order rate constants for breakdown of **1***c* upon the hydroxide concentration. This seems most improbable because there is no obvious mechanistic path allowing two equivalents of hydroxide to be involved in the transition state. The curvature, if such there is, is slight and close to the limits of detection. The possibility that it is an artefact caused by imperfect matching of salt effects between KCl and NaOH must be kept in mind.

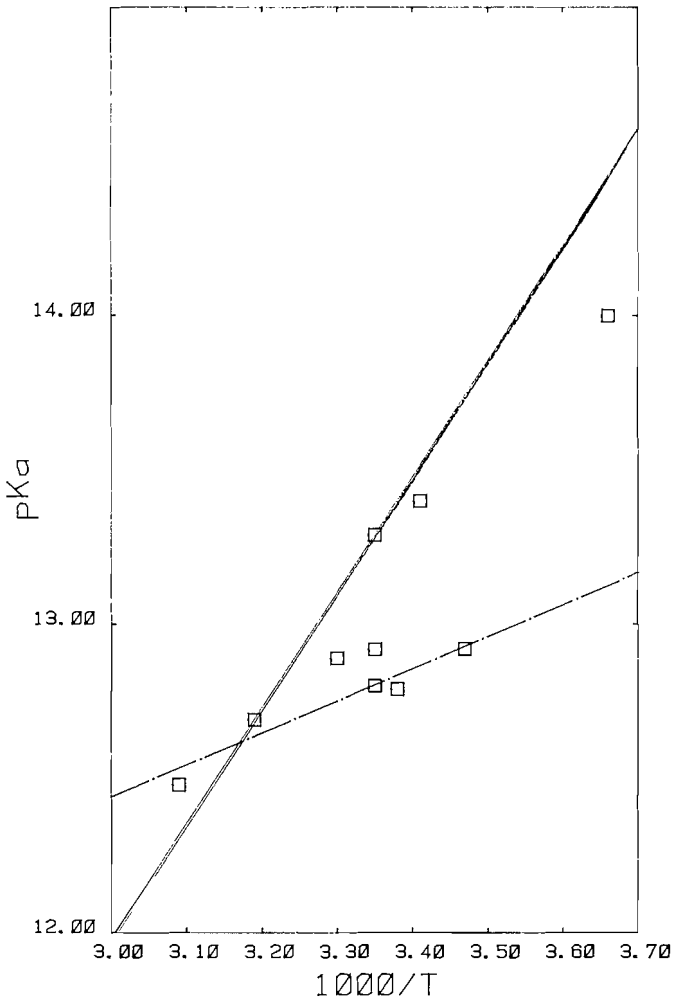

FIG. 3. Temperature dependence for the pK_a of formaldehyde hydrate (——) line based on assumption 1; (–·–·–) line based on assumption 2.

The enone hydration[2] of **1***c* has been studied in acidic solution by Lucas *et al.* (4). In experiments at 25°C and ionic strength 1.04, these authors report a hydration constant of 0.39, which is in reasonable accord with our value at ionic strength of 0.1 of 0.41.

Comparison with lower homologs

It is now possible to compare the kinetic and thermodynamic behavior of the three aldehydes of general structure **1**, with R^1, R^2 = H or CH_3. We have previously reported equilibrium constants for the aldol addition reactions and the enone dehydration steps (1). For crotonaldehyde, **1***b*, we have reported kinetics for the enone hydration, enone dehydration, and retroaldol steps (2). Ogata *et al.* (5) and Vik (6) have reported studies of the aldol addition reaction of acetaldehyde and formaldehyde, and Vik (7) has reported a study of the base catalyzed enone hydration of acrolein, **1***a*. The acid catalyzed enone hydration of acrolein had been studied earlier by Pressman and Lucas (8). From these results it has proven possible to extract the rate constants needed in the present context.

[2]We will use "carbonyl hydration" to refer to addition of water to a carbonyl group, and "enone hydration" to refer to the 1,4-addition of water to an α,β-unsaturated carbonyl compound to give the β-hydroxy carbonyl compound.

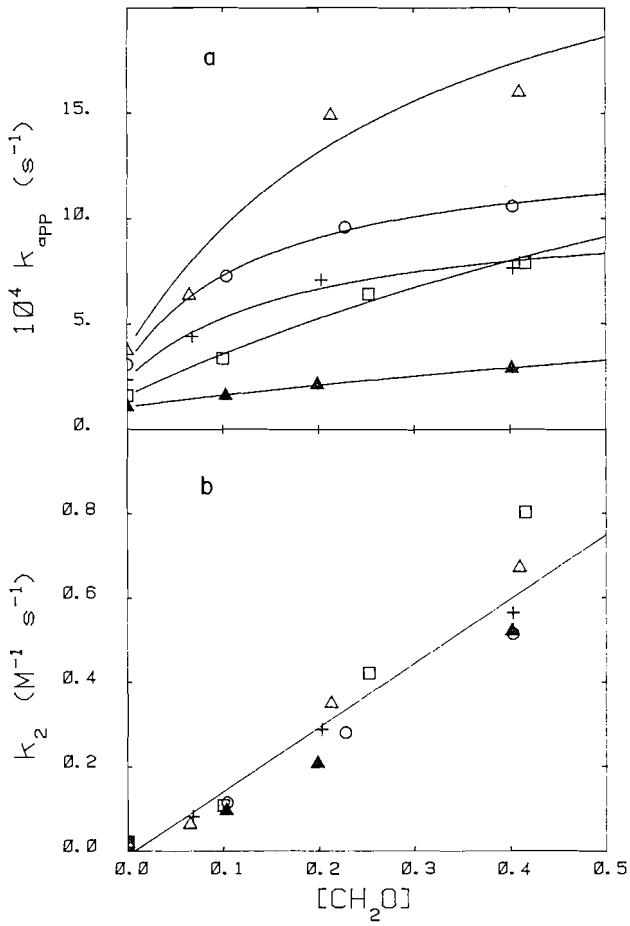

FIG. 4. Rate constants for aldol formation from formaldehyde and acetaldehyde. (a) Relationship between observed rate constants and the total formaldehyde concentration for various hydroxide concentrations: data from ref. 5, curves calculated as described in the text. (▲) 0.005 *M* NaOH; (□) 0.009 *M* NaOH; (+) 0.012 *M* NaOH; (○) 0.018 *M* NaOH; (△) 0.021 *M* NaOH. (b) Relationship between rate constants, corrected as described in the text for consumption of hydroxide by neutralization of formaldehyde hydrate, and the total formaldehyde concentration; data from ref. 5.

Unfortunately, upon critical examination of the paper by Ogata *et al.* (5), it became clear that it was necessary to reanalyse their data. Ogata *et al.* reported that the pseudo first order rate constant at fixed hydroxide concentration showed a nonlinear dependence upon formaldehyde concentration, levelling off at high formaldehyde concentration. They interpreted this as a change in rate-determining step from the aldol addition step to the proton transfer step. However, as Vik (6) had pointed out, the concentration of hydroxide in the kinetics solutions is not the same as the titrimetric concentration of base, which is what Ogata *et al.* assumed, because of partial neutralization of the weakly acidic formaldehyde hydrate (pK_a13.29 at 25°C (9). So long as the aldol addition step is rate limiting, it is the concentration of hydroxide ion, and not the total base concentration, which controls the concentration of the enolate of acetaldehyde, and thus the rate of reaction. Vik (6) carried the study to still higher formaldehyde concentrations where there was an actual decrease in apparent second order rate constant, which almost certainly indicates that there was a change in rate-determining step from addition to proton transfer. Unfortunately Vik (6) only reports apparent second order rate constants obtained by dividing the pseudo first order rate constants by the total base concentration, and does not report the base concentration used, so that the rate constants needed for our purposes cannot be extracted from his data. Since Ogata *et al.* (5) report their data in more detail it is possible to extract an approximate value of the rate constant which we require. The first step is to obtain basicity constants for formaldehyde hydrate as a function of temperature. Martin (10) has reviewed the early literature and reports a carefully determined value at 40°C. Bell and Onwood (9) report a value of 13.29 at 25°C. The data when plotted show considerable scatter; see Table 3 and Fig. 3. Bell's value, which is widely quoted in literature, is not in agreement with the trend of most values at comparable temperatures. Furthermore Vik (6) reports pH values which lead to a pK_a value of 12.8 ± 0.1 for 25°C. Other workers (11) have reported data leading to a value of 12.92.[3] To assess the uncertainty introduced by this discrepancy in pK_a values we have tried two approaches: (1) to choose Bell's value at 25°C and Martin's value at 40°C as two recent and reliable values and use them as the basis for estimates at lower temperatures; (2) to discard Bell's value at 25°C and two other discordant values and fit the remaining data by least squares. The K_b values resulting from both methods are given in Table 4, and Fig. 3 shows the relationship of the two hypotheses to the data. It should be noted that although either hypothesis leads to a similar ΔH for pK_a, the two hypotheses lead to opposite signs for the temperature dependence of pK_b. It is straightforward to derive eq. [4] which gives the true hydroxide concentration as

TABLE 4. Rate constants for aldol addition of acetaldehyde to formaldehyde[a]

[h]This work.

a function of the basicity constant K_b, the total base concentration B, and the formaldehyde concentration F.

$$[4]\quad K_b[OH^-]^2 + \{1 + K_b(F—B)\}[OH^-] - B = 0$$

This equation may readily be solved, but it must be borne in mind that the hydroxide concentrations so calculated are subject to considerable error because of the uncertainties in K_b. Nevertheless they permit a closer approximation to the actual conditions and convert the leveling off in pseudo first order rate constant with increasing formaldehyde concentration reported by Ogata to a simple linear dependence of the apparent second order rate constants upon formaldehyde concentration. Figure 4 shows the data for 20°C plotted as discussed by Ogata *et al.* (5), with curves derived by fitting Ogata's equation (eq. 14a of ref. 5) to the data at a particular hydroxide concentration, and also the second order rate constants obtained by dividing the observed pseudo first order rate constant by the calculated hydroxide concentration (hypothesis 2). The scatter is severe but there is a roughly linear correlation (r = 0.967) with no sign of a change in rate-determining step. By carrying out this procedure at each temperature for both hypotheses concerning pK_a, we obtained two sets of third order rate constants given in Table 4, each of which could be extrapolated to give a rate constant at 25°C. Of the two estimates we prefer the one based on hypothesis 2, which uses concordant data from various laboratories. Hypothesis 1 puts great weight on Bell and Onwood's value (9), which was a conductimetric determination. Although conductimetry is a very precise technique, it is subject to systematic errors if there is an unexpected ionic contaminant.

The apparent third order rate constant for hydroxide catalyzed reaction of acetaldehyde with formaldehyde, 2.10 M^{-2} s^{-1}, can now be corrected for the fraction of acetaldehyde and formaldehyde present as the hydrate, since the carbonyl compounds are the actual reactive species. The carbonyl hydration constants for compounds discussed in this paper are found in Table 5. When this is done the rate constant becomes 9900.M^{-2} s^{-1}. Then using the equilibrium constant which we evaluated for the free carbonyl species, i.e. 6×10^7 M^{-1} (1), we can calculate the rate constant for the reverse reaction, i.e. the breakdown of 3-hydroxypropanal, **2***a*, to be 2×10^{-4} M^{-1} s^{-1}. Vik (7) has reported rate constants for the enone hydration of acrolein, **1***a*, and the enone dehydration of **2***a*. The latter rate constant must be corrected for the carbonyl hydration of **2***a*; since no equilibrium constant for this carbonyl hydration has been reported, we estimate a value by use of a linear free energy relation (13) as previously reported (1); see Table 5. All of the rate constants so derived are found in Table 6.

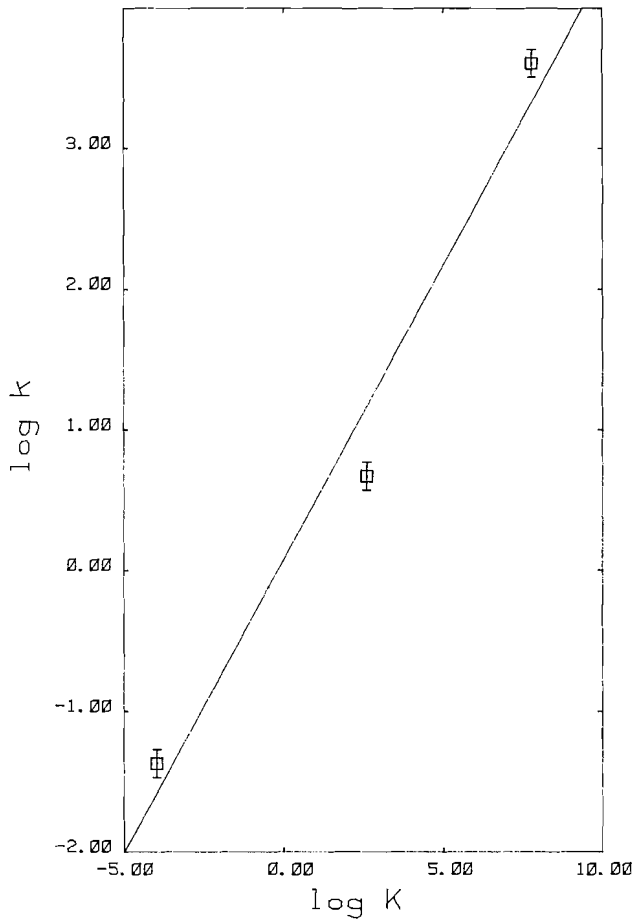

FIG. 5. Relationship between rate and equilibrium constants for the aldol addition of acetaldehyde to formaldehyde, acetaldehyde, and acetone, log k = 0.08 + 0.42 log K; r = 0.985.

The apparent rate constants for the enone hydration and retroaldol reactions of crotonaldehyde, **1***b*, have been reported (2); in a manner analogous to that just described, they can be corrected for carbonyl hydration of the aldehydes to give the values found in Table 6. Similarily the results found in this work may be corrected for aldehyde carbonyl hydration, and the corrected rate constants are given in Table 4.

Examining the results in this table we see that the aldol addition step shows the expected qualitative dependence upon reactivity of the carbonyl group to which addition takes place. Furthermore there is the expected quantitative relationship between the rate and equilibrium constants, as shown by Fig. 5.

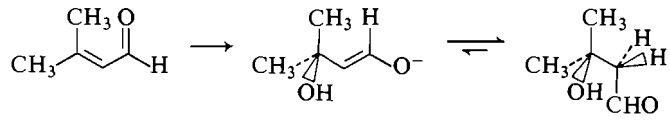
No simple interpretation can be put upon the nature of this correlation because the rate and equilibrium constants are composite quantities; the equilibrium constant includes enolate formation, the actual C—C bond-forming step, and protonation of the initially formed alkoxide ion. Assuming the C—C bond formation is rate limiting, the apparent rate constant reflects both this step and pre-equilibrium enolate formation. In fact the slope of the least-squares line ($r = 0.985$) is 0.42, which is close to the value of 0.5 expected for $\log K = 0$ on the basis of Marcus theory (14). For the three reactions considered here one expects very similar equilibrium constants for the pre- and post-equilibria, so that the observed correlation will reflect the behavior of the microscopic constants for the rate-determining step. The slope of the correlation line suggests a transition state midway along the reaction coordinate for C—C bond formation. The rate constants for enone hydration show a very regular decrease of about an order of magnitude per methyl group as the terminal hydrogens in acrolein are replaced by methyls.[4] Curiously, this regularity is less apparent in the equilibrium constants; although the first methyl group produces a tenfold decrease in the equilibrium constant for enone hydration, the second methyl produces a much more modest decrease. It is not the deviation from regularity which is curious, but the fact that it shows up only in the equilibrium constant and not in the rate constant. The second methyl would be expected to stabilize the double bond, but also introduces steric crowding; with two opposing effects, the net effect must be smaller than if only the stabilizing effect were present. The fact that the substituent effect is almost the same for rate and equilibrium constants for the first two compounds implies a late transition state; this is apparently inconsistent with the divergent behavior seen for the second methyl group. A plausible rationale is that the equilibrium constant which governs the rate constant is not that for formation of the stable conformation of the hydroxyaldehyde, but that for formation of the initial conformation of the enolate which is the immediate product. In the initial enolate corresponding to **2***c* the crowding between methyl and aldehydic hydrogen is still largely present; see Scheme 2. Thus, as far as the rate constant is concerned, thermodynamics of the enone hydration are affected only by the stabilizing effect of the methyl; the fact that a simple bond rotation will eventually offset most of this stabilization by relieving crowding is irrelevant. We see in this set of reactions an illustration of what we suspect will be a very general pattern; rate–equilibrium correlations must refer to the reactants and products of the microscopic rate-determining process and not to any more stable conformations or tautomers which may be reached by exceedingly fast transformations before or after the rate-determining step.



SCHEME 2

Experimental

Methods

Solutions of sodium hydroxide were made up starting with Fisher concentrates, diluting with glass-distilled water which had been boiled to drive out carbon dioxide. Ionic strength was maintained with KCl.

Kinetics were carried out using a Cary 210 spectrophotometer with a thermostatted 10 cm cell holder. A Neslab Exacal circulating bath was used to maintain the temperature at 25.0 ± 0.1°C. Reactions were initiated by adding a suitable amount of a solution of substrate in acetonitrile to the cell containing sodium hydroxide solution, which had been in the thermostatted cell holder for at least 15 min. Digital absorbance data were taken from the Digital Interface Port of the Cary 210 and stored in a Dynabyte BC2 controller board, which supplied time values, until the end of the experiment, when absorbance–time data were transferred to a Xitan microcomputer for permanent storage and processing. Data were fitted to the appropriate equation using weighted least squares by means of programs essentially the same as those previously described (1, 16). For every run direct, semi-log, and residual plots of the experimental data and the calculated line were drawn on an HP6225A plotter.

Preparation of 3-methyl-2-butenal, **1***c*

Oxidation of 3-methyl-2-butenol (Aldrich) was carried out using Ratcliffe's method (17). To a solution of pyridine (9.5 g) in dry methylene chloride (passed through Grade 1 neutral alumina) (150 mL) was added chromium trioxide (6 g). After stirring for ca. 15 min, 3-methyl-2-buten-1-ol (0.86 g) was added and stirring was continued for another 15 min. The organic solvent was decanted off and the tarry residue was washed with ether (2 × 100 mL). The combined organic solvents were washed with 5% NaOH (3 × 100 mL), 5% HCl (100 mL), 5% $NaHCO_3$ (100 mL), and saturated NaCl (100 mL). After drying over $MgSO_4$, the solvent was removed and the oil left behind was distilled, bulb-to-bulb, (bp 100–110°C) under nitrogen at atmospheric pressure. Proton nmr showed the product (0.7 g) to be pure 3-methyl-2-butenal.

Preparation of 3-hydroxy-3-methylbutanal, **2***c*

This compound was prepared by addition of a masked acetaldehyde equivalent to acetone using the procedure devised by Meyers *et al.* (18). To a solution of 2-methyl-2-thiazoline (2.8 g) in dry THF (Karl Fisher titration showed less than 100 μg/mL) (15 mL) at −78°C under a nitrogen atmosphere was added 14.4 mL of n-butyllithium (2.2 *M* in hexanes). After stirring for 2 hours, acetone (2.5 mL) in dry THF (15 mL) was slowly added and stirring was continued as the flask was allowed to come to room temperature (ca. 2.5 hours). The contents of the flask were poured into ice-water and acidified to ca. pH 2 with 6 *N* HCl and then extracted with ether–pentane (1:1). The aqueous layer was made alkaline by adding 20% NaOH, and then extracted with ether (3 × 50 mL). The combined ether extracts were dried over anhydrous potassium carbonate and the solvent removed to give an hydroxythiazoline compound. The proton nmr of this crude product showed that there was a small amount of impurity present.

This crude hydroxythiazoline compound was dissolved in ether which had been previously saturated with water. This solution was treated with freshly prepared aluminum-amalgam (19) (ca. 4 g) by refluxing for 2 hours. The solids were removed by filtration and washed with ether. The combined ether solutions were dried (K_2CO_3) and the ether removed. The proton nmr of this product showed two singlets (δ 1.2 and 1.4) in the region where methyl groups are expected to absorb, indicating that there was more than one product.

This crude product was dissolved in acetonitrile and the solution was slowly added to a solution of mercuric chloride in 80% acetonitrile–water. The mixture was stirred for ca. 15 min and then diluted with water and filtered. The filtrate was extracted with ether–pentane (1:1) and the organic layer was dried (K_2CO_3) and the solvent removed. This crude product was distilled, bulb-to-bulb, to give ca. 0.15 g of a clear oil which proton nmr showed to be 3-hydroxy-3-methylbutanal. A solution of this final product in $CDCl_3$ gave an nmr spectrum which changed with time, reaching an apparent equilibrium (50:50) with what is presumed to be its dimer within 20 h; no further change in the nmr spectrum was seen at 40 h.

[4]That replacement of hydrogens by alkyl groups stabilizes carbonyl groups or alkenes is a well-recognized empirical fact, for which various explanations have been offered (15).

Diazotization of *o*-aminobenzaldehyde, followed by immediate coupling of the diazonium salt with primary alkylamines, affords unstable 1-aryl-3-alkyltriazenes which immediately cyclize to the 4-hydroxy-3-alkyl-1,2,3-benzotriazines. Analogous reaction of *o*-aminobenzophenones affords stable 4-aryl-4-hydroxy-3-alkyl-1,2,3-benzotriazines. The 4-hydroxytriazine derived from *o*-anthraniloylbenzoic acid undergoes further cyclization spontaneously to a novel spiro-1,2,3-triazine-furan. Diazotization of *o*-aminopropiophenone and coupling to methylamine affords a surprisingly stable 4-alkyl-4-hydroxytriazine. Preliminary assay of the biological activity of the 4-hydroxytriazines shows significant cytotoxicity of two members of the series towards M21 melanoma cells in vitro.

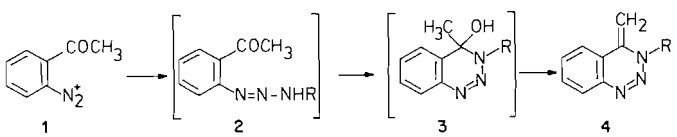
PATRICIA L. FAYE, KEITH VAUGHAN et DONALD L. HOOPER. Can. J. Chem. **61**, 179 (1983).

La diazotization du *o*-aminobenzaldéhyde, suivie par le couplage immédiat du sel de diazonium avec les alkylamines primaires, fournit les aryl-1 alkyl-3 triazènes instables qui se cyclisent immédiatement en hydroxy-4 alkyl-3 benzotriazines-1,2,3. La réaction analogue des *o*-aminobenzophénones conduit aux aryl-4 hydroxy-4 alkyl-3 benzotriazines-1,2,3 stables. L'hydroxy-4 triazine provenant de l'acide *o*-anthranylbenzoïque subit spontanément une cyclisation plus poussée en un nouveau spiro-triazine-1,2,3 furanne. La diazotization de l'*o*-aminopropiophénone et le couplage avec la méthylamine donne d'une façon surprenante l'alkyl-4 hydroxy-4 triazine stable. Un essai préliminaire de l'activité biologique des hydroxy-4 triazines montre une cytoxicité *in vitro* significative de deux composés de la série vis-à-vis les cellules mélanoma M21.

[Traduit par le journal]

Introduction

The coupling reaction of arenediazonium salts with primary alkylamines affords good yields of the monoalkyltriazenes (ArN=N·NHR) (1), which have attracted wide interest not only because of their chemistry, but also for their pharmacological importance (2). 1-Aryl-3-alkyltriazenes, with reactive substituents in the *ortho*-position of the aryl nucleus, are useful precursors of a variety of heterocyclic triazines (3). For example, coupling the diazonium salt (**1**) derived from *o*-aminoacetophenone with alkylamines leads to the novel 4-methylene-1,2,3-benzotriazines (**4**) (4). The 4-methylenetriazines presumably arise by spontaneous cyclization of the triazene (**2**) and dehydration of the intermediate 4-hydroxytriazine (**3**); neither **2** or **3** could be isolated from this reaction. The instability of the intermediate hydroxytriazine (**3**) derives from the presence of protons on the 4-methyl carbon, which are suitably situated for β-elimination to give the methylenetriazine (**4**).



The apparent ease of cyclization of the *o*-acetylphenyltriazenes (**2**) suggests that 4-hydroxytriazines of type **3** might be isolable and stable if the dehydration step **3** → **4** could be prevented. Stable 4-hydroxytriazines analogous to **3** would be expected to arise from *o*-triazenoaryl carbonyl compounds without α-hydrogens, in which case the final dehydration step is structurally impossible. This paper describes this approach to the synthesis of such 4-hydroxy-1,2,3-triazines using *o*-aminobenzophenones and *o*-aminobenzaldehyde as starting materials.

Experimental

Melting points were obtained on a hot-stage apparatus and are uncorrected. Infrared spectra were recorded with liquid paraffin mulls on a Perkin–Elmer Model 299 spectrophotometer. Nuclear magnetic resonance spectra were recorded in deuteriochloroform or dimethyl sulfoxide-d_6, using tetramethylsilane as internal standard, with Varian EM360 and CFT-20 spectrometers. Microanalysis was performed by the Canadian Microanalytical Laboratory, Vancouver, B.C. *o*-Aminobenzophenones and *o*-nitrobenzaldehyde were obtained from Aldrich Chemical Company and were used without further purification.

4-Hydroxy-3-alkyl (aryl)-1,2,3(4H)-benzotriazines (7)

General procedure

o-Aminobenzaldehyde (**5**) was prepared immediately before use by reduction of *o*-nitrobenzaldehyde with ammonia and ferrous sulphate according to the method of Smith and Opie (5).

o-Aminobenzaldehyde (1.44 g, 0.012 mol) was ground in a mortar with solid sodium nitrite (0.83 g, 0.012 mol) to a fine homogeneous powder. The solid mixture was slurried with water (4 mL) and added slowly with constant agitation to a mixture of concentrated hydrochloric acid (2.1 mL) and ice (5 g). Transfer of the slurry to the acid/ice mixture was facilitated by several washings with small amounts of water (total volume 10 mL). The temperature of the mixture was maintained below 5°C during this process. The mixture was filtered onto ice (~8 g) and the clear filtrate/ice mixture (containing the diazonium salt) was mixed with a cold solution of the appropriate amine (0.025 mol) in water (2 mL) or 2 *M* hydrochloric acid

[a]All compounds gave satisfactory C, H, and N analyses (±0.3%).

(12 mL). The resulting mixture was stirred in the cold for 2.5 h and then filtered to afford the solid product, which was recrystallized from hexane/benzene mixture. The yields and physical data of these 4-hydroxytriazines are given in Table 1.

*4-Aryl-4-hydroxy-3-methyl-1,2,3-benzotriazines (**9**)*

General procedure

The *o*-aminobenzophenone (**8**) (0.01 mol) was suspended in 2 *M* hydrochloric acid (24 mL) and the mixture heated to boiling. Concentrated hydrochloric acid (1.6 mL) was added to take the amine into solution, which was then diluted with water (32 mL) and cooled to below 5°C, whereupon the hydrochloride salt precipitated. The cold slurry was diazotized with sodium nitrite (0.77 g) in water (10 mL) and stirred until a clear solution was obtained (usually no more than 1 h). Aqueous methylamine (40%, 7.2 mL) was added in one portion to the cold diazonium salt solution, which raised the pH of the mixture to approximately 9–10. The product precipitated immediately and was filtered, usually at once, dried, and recrystallized from an appropriate solvent to afford the 4-aryl-4-hydroxy-3-methylbenzo-1,2,3-triazine (**9**) (Table 2). *Note:* In some instances, the *o*-aminobenzophenone did not dissolve readily in hot hydrochloric acid, resulting in low yields. In the case of 2-amino-2′,5-dichlorobenzophenone, the diazotization was carried out in concentrated nitric acid without diffuculty and the remaining procedure carried out as described above. Diazotization of 2-amino-3-nitrobenzophenone was also carried out in nitric acid, but coupling with methylamine was only partially successful; in one instance a violent reaction occurred when methylamine was added to the diazonium salt in one portion and in another, under more controlled conditions, a low yield of a very impure product was obtained.

*3′,4′-Benzo-5,6-benzo-3-methyl-5′-oxo-spiro[1,2,3-triazine-4,2′-furan] (**12**)*

o-Anthraniloylbenzoic acid (**10**) (2.47 g) was suspended in 2 *M* hydrochloric acid (24 mL) and concentrated hydrochloric acid (4.2 mL) was added. The mixture was diluted with water (32 mL), and then cooled to below 5°C. The suspension was diazotized with sodium nitrite (0.71 g) in a minimum volume of water and stirred for 1 h. The mixture was filtered and the clear filtrate (diazonium salt solution) was treated with 40% aqueous methylamine (7.4 mL) in one portion. The pH of the solution rose to ~10 and an off-white precipitate appeared almost immediately. The product was filtered and recrystallized from absolute alcohol to afford the spiro-lactone (**12**) (yield 0.47 g, 17.5%), mp 175–176°C (EtOH) (buff needles); ν_{max}: 1765 cm^{-1}; δ($CDCl_3$): 3.3 (s, 3H), 6.5–8.2 (m, 8H). *Anal.* calcd. for $C_{15}H_{11}N_3O_3$: C 67.92, H 4.18, N 15.84%; found: C 67.69, H 4.33, N 15.76.

*4-Ethyl-4-hydroxy-3-methyl-1,2,3-benzotriazine (**14**)*

o-Nitropropiophenone was prepared by nitration of propiophenone according to the method of Zenitz and Hartung (6). Reduction of the *o*-nitropropiophenone by a modification of the method of Simpson *et al.* (7) afforded a good yield of *o*-aminopropiophenone, which was purified by steam distillation before use.

o-Aminopropiophenone (**13**) (1.5 g) was dissolved in 2*M* hydrochloric acid (24 mL), to which concentrated hydrochloric acid (1.6 mL) was added to facilitate dissolution. The solution was diluted with water (32 mL) and then cooled to 0°C in an ice/salt bath. The cold solution was stirred while a solution of sodium nitrite (0.75 g) in water was added slowly with constant stirring. The mixture was stirred in the cold for 0.75 h and the resulting diazonium salt solution treated with a cold solution of methylamine (40%, 6.8 mL), stirred in the cold for a further 0.75 h, and filtered to afford the 4-ethyl-4-hydroxy-3-methyl-1,2,3-benzotriazine (**14**), 1.4 g (80%), mp 108°C (from benzene): ν_{max}: 2600–3300 cm^{-1}; δ (DMSO d_6): 0.65 (3H, t, J = 7.4 Hz, C—CH_3), 2.20 (2H, q, J = 7.4 Hz, —CH_2-), 3.59 (3H, s, N—CH_3), 6.84 (1H, s, OH), and 7.3–7.6 (4H, m, aromatic). *Anal.* calcd. for $C_{10}H_{13}N_3O$: C 62.81, H 6.85, N 21.97%; found: C 62.93, H 6.76, N 22.12%.

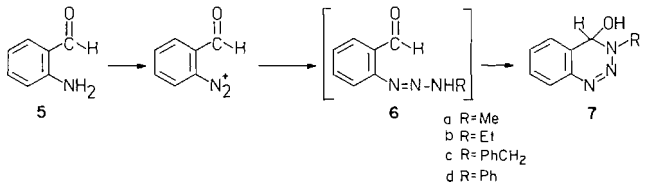
Discussion

A minor problem encountered in the experimental approach to the 4-hydroxytriazines was the diazotization of *o*-aminobenzaldehyde (**5**). The tendency of *o*-aminobenzaldehydes to form polymeric products when treated with acid (8) makes diazotization by addition of aqueous sodium nitrite to an acidic solution of the amine (**5**) unfeasible. Successful



diazotization of **5** has been achieved by slurrying a solid mixture of the amine and sodium nitrite in water and treating the slurry with hydrochloric acid and ice (9). The latter method has been employed in the present work to prepare the diazonium salt of **5**. However, significant material loss results during the filtration step necessary to achieve a clear solution of diazonium salt before further treatment, which probably accounts for the poor yields of the final products.

Treatment of the diazonium salt of **5** with an aqueous solution of the primary alkylamine affords the 4-hydroxy-3-alkyl-1,2,3-benzotriazine (**7**). The spectroscopic properties of the products of these reactions are consistent with the cyclic benzotriazine structure (**7**) rather than the open-chain triazene valence tautomer (**6**). The cyclization of the diazonium-coupling product (**6**) appears to be spontaneous and the cyclic hydroxytriazines (**7**) are stable crystalline solids. The method is equally applicable to the synthesis of 3-alkyl- and 3-aryl-4-hydroxytriazines. A significant feature of the ir spectra of these 4-hydroxy triazines (**7**) is the absence of carbonyl absorption, which rules out the open-chain structure (**6**) in favour of **7**. The cyclic structure is further corroborated by the presence in the ir spectra of hydroxyl absorption in the range 3100–3180 cm^{-1}; these OH bands are relatively sharp and readily observed in Nujol mulls. Aside from the characteristic hydroxyl band, the ir spectra show no other outstanding features.

The nmr spectra (Table 1) of the 4-hydroxytriazines in DMSO-d_6 provide unequivocal evidence of the cyclic triazine structure (**7**). All compounds exhibit an aromatic multiplet in the range 7.20–7.90 ppm and the predicted signals for the alkyl group at N-3: a singlet at 3.60 ppm for the N—Me group of **7***a*; a triplet at 1.35 ppm and quartet at 3.95 ppm for the N—Et group of **7***b*; and a singlet at 5.20 ppm for the benzylic *N*-methylene group of **7***c*. The most striking features of these spectra are the two one-proton doublets arising from the vicinal coupling (J = 8–8.5 Hz) between the methine proton at C-4 and the hydroxylic proton of the OH group attached to C-4. The hydroxylic proton is observed at 6.65 ppm in the spectra of the *N*-methyl (**7***a*) and *N*-ethyl (**7***b*) derivatives and is shifted downfield to 6.87 ppm in the *N*-benzyl derivative (**7***c*) and to 6.97 ppm in the *N*-phenyl analogue (**7***d*). The C-4 methine proton appears in the range 5.7–5.9 ppm in the *N*-alkyl triazines (**7***a*, *b*, and *c*) and is also shifted downfield to 6.53 ppm in the *N*-phenyl triazine (**7***d*). In each case (**7***a–d*) the addition of D_2O to the DMSO-d_6 solution resulted in the disappearance of the OH resonance and the collapse of the C-4 methine proton doublet to a singlet, providing confirmation of the assignments of these signals.

Diazotization of the *o*-aminobenzophenones (**8**) by addition

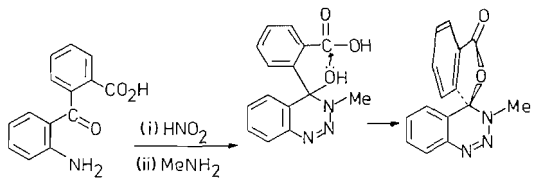
4-hydroxy-1,2,3 (4*H*)-triazines (**7**), the 4-aryl-4-hydroxytriazines (**9**) are apparently formed by spontaneous, irreversible cyclization of the intermediate monomethyltriazenes, which could not be isolated or observed. The cyclic products are stable crystalline solids which show spectroscopic features consistent with the assigned triazine structure (**9**). The ir spectra show similar characteristics to the C-4 unsubstituted analogues (**7**). Carbonyl absorption is absent in the spectra of compounds **9***a*–*e* and hydroxyl absorption is evident, but much broader (2560–3400 cm^{-1}) than in the spectra of compounds **7***a*–*d*.

The nmr spectra of **9** provide further evidence for the assigned cyclic structure. The aromatic multiplets, in the range 6.8–8.4 ppm, integrate for the respective number of aromatic protons depending on the number of aryl substituents; the *p*-tolyl derivative (**9***d*) exhibits a signal at 2.30 ppm arising from the protons of the *C*-methyl group. The *N*-methyl protons consistently give rise to a signal in the range 3.15–3.27 ppm. The hydroxylic proton, in the range 7.40–7.90, was in each case partially obscured by a component of the aromatic multiplet, but the assignment was confirmed by addition of D_2O to the DMSO-d_6 solution, which caused the OH resonance to disappear from the multiplet and the HOD signal at ca. 4.10 ppm to appear.

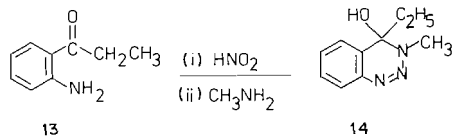
A further confirmation of the assignment of the 4-hydroxytriazine structure (**9**) to these products came somewhat unexpectedly from the analogous reaction of *o*-anthraniloylbenzoic acid (**10**). Diazotization of **10** was accomplished by the



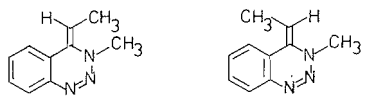
10 11 12

normal procedure and coupling with methylamine afforded a low yield of a crystalline product, which was identified as the spiro-triazinofuran (**12**) on the basis of elemental analysis and spectroscopic data. The nmr spectrum of **12** shows an N—Me group at 3.3 ppm and an eight-proton aromatic multiplet at 6.5–8.2 ppm. The infrared spectrum is devoid of absorption in the NH or OH stretching region but shows a strong band at 1765 cm^{-1} confirming the presence of the lactone carbonyl group. The formation of the lactone presumably arises from spontaneous cyclization of the intermediate 4-hydroxytriazine (**11**) and provides further striking evidence for the 4-hydroxytriazine structures (**7** and **9**) proposed above.

A surprising result was observed when the diazonium salt from *o*-aminopropiophenone (**13**) was treated with methylamine. A stable, white, crystalline product was obtained which



13 14



15 16

displays spectroscopic properties of the 4-hydroxy-4-ethyl-1,2,3-triazine (**14**). The surprising feature of this compound is not its formation, presumably via an acyclic methyltriazene, but that it survives the reaction and recrystallization conditions without undergoing dehydration to a methylenetriazine (e.g. **15** or the geometric isomer **16**). By analogy with our previously reported observations of the same reaction with *o*-aminoacetophenone (4), the dehydration of **14** would be expected to be relatively facile. The stability of **14** contradicts the apparent instability of the intermediate **3** in the conversion **1** → **4**. A possible explanation for this different behaviour may be the greater barrier to dehydration as a result of the steric hindrance introduced by the ethyl group at C-4.

However, the stability of **14** may not extend to prolonged exposure in solution. The ^1H nmr spectrum of a fresh solution of **14** in DMSO-d_6 shows that this compound exists exclusively as the ring-closed form (**14**); the C-4 ethyl group gives rise to signals at 0.65 (triplet) and 2.20 (quartet) ppm as expected and the *N*-methyl group resonance is observed at 3.59 ppm. In addition to the aromatic multiplet at ca. 7.5 ppm, a sharp singlet at 6.84 ppm arises from the hydroxylic proton; this assignment was confirmed by the disappearance of the OH signal upon the addition of D_2O. When the solution of **14** in DMSO-d_6 is left standing, additional signals grow into the spectrum which suggest that dehydration to the methylene triazine (**15**) is occurring in the solution. The additional signals are observed at 2.03 (3H, d, J = 7.4 Hz), 3.40 (3H, s), and 5.07 (1H, q, J = 7.4 Hz) ppm, consistent with the vinylic $=C\begin{matrix}H\\CH_3\end{matrix}$ system in **15**. The observation of only one set of signals suggests a preference during the dehydration of **14** to give the less sterically hindered methylenetriazine, i.e. **15**.

A more complex situation prevails when a freshly prepared $CDCl_3$ solution of **14** is examined by ^1H nmr, with no less than six different C—CH_3 signals observed. Two of these signals at 1.95 (d, J = 8.0 Hz) and 1.92 (d, J = 7.9 Hz) ppm are assigned to the *C*-methyl groups of the dehydration products, the methylenetriazine geometric isomers (**15** and **16**). Two others at 1.18 (t, J = 7.3 Hz) and 1.11 (t, J = 7.4 Hz) ppm are assigned to the tautomeric forms of the linear triazene ($ArN{=}N{-}NHCH_3 \rightleftharpoons ArNH{-}N{=}N{-}CH_3$; Ar = *o*-$CH_3CH_2CO\cdot C_6H_4$); tautomerism of this nature in $CDCl_3$ has been well defined (10). This observation of ring opening of **14** in chloroform is clearly an effect of the solvent and not due to the presence of impurities; in other respects (i.e. mp, ir spec-

For personal use only.

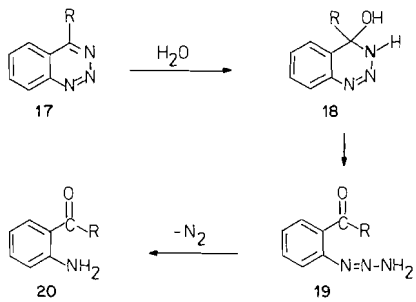
trum, and tlc) compound **14** exhibits properties of a single species, the heterocyclic 4-hydroxytriazine. The two remaining C—CH_3 signals in the $CDCl_3$ spectrum of **14**, 0.61 (t, J = 7.5 Hz) and 0.76 (t, J = 7.6 Hz) ppm, have chemical shifts close to that observed for the ring-closed form **14** in DMSO-d_6 solution. However, it is difficult to envisage different diastereomeric forms of **14**, since this would require postulation of slow inversion at a ring nitrogen, in contrast with the expected rapid inversion at such centres.

These observations of the transformations of **14** in solution in dimethyl sulfoxide and chloroform suggest that further studies of the chemistry of **14** may be fruitful on a preparative scale, and encourage a further study of the resolution of the stereoisomers of the 4-hydroxytriazines (**7**, **9**, and **14**) and the spiro triazine (**12**) reported here; all these compounds have a chiral centre at C-4 of the triazine ring. A second promising extension of the work reported here will be the preparative conversion of **14** to the novel methylenetriazines (**15** and **16**); the separation of these geometric isomers is a challenging prospect.

Aside from the previous preliminary report of the 4-phenyl-4-hydroxytriazine (**9***a*) (4), this paper is the first account of the general synthesis of 4-hydroxytriazines of types **7** and **9**. The stability of these 4-hydroxytriazines is significant and relevant to the chemistry of the parent 4-alkyl- and 4-aryltriazines (**17**), which have been extensively studied by



Rees and co-workers (11). Hydrolysis of **17** results in degradation to the respective *o*-aminophenyl ketone or aldehyde (**20**); the proposed mechanism of hydrolysis involves nucleophilic addition at C-4 of **17** to give the unstable 4-hydroxytriazine (**18**), which undergoes ring opening to the triazine (**19**) followed by N_2 elimination to give **20**. The intermediate **18** is the N-3 unsubstituted parent compound of the series of 4-hydroxytriazines (**7** and **9**) reported here.

In addition to the wealth of chemistry associated with these 4-hydroxytriazines, there is considerable potential in this ring system for pharmacological application. This potential derives from the antineoplastic properties of arylmonoalkyl triazenes (Ar·N=N·NHR) (12); the monomethyltriazenes have been implicated as the active metabolites of the extensively studied anti-tumour dimethyltriazenes (Ar·N=N·NMe_2) (2). Although the 4-hydroxytriazines exist almost exclusively in the ring-closed form, it is feasible that these compounds would undergo enzymatic or nonenzymatic ring-opening in vivo, or intracellularly, and thereby act as pro-drugs for the potentially cytotoxic open-chain triazene, e.g. **6**.

We have recently developed an assay for assessing the cytotoxicity of various triazenes against the M21 melanoma cell line in culture (in vitro) (13). A prepliminary assay of two of the 4-hydroxytriazines reported here indicates significant biological activity. 4-Hydroxy-3-methyl-4-phenyl-1,2,3-benzotriazine (**9***a*) was administered to M21 cells in culture at a dose of 50 μg/mL; the rate of growth of cells was inhibited by 58% compared to controls. The inhibitory effect of 4-hydroxy-3-methyl-1,2,3(4*H*)-benzotriazine (**7***a*) was even more striking; **7***a* was administered at a dose of 100 μg/mL (**7***a* is more soluble in the cell-growth medium than **9***a*; **9***a* precipitates out at concentrations above 50 μg/mL) and inhibition of cell growth was virtually 100%. Within 48 hours of addition of **7***a* to the cell culture, almost all the cells had become detached from the cell culture dishes and had ceased to divide. Further studies are underway to determine definitive inhibitory properties of the 4-hydroxytriazines and to assess their in vivo antitumour activity.

Received June 7, 1982

T. Stanley Cameron, Osvald Knop, and Laura Ann Macdonald. Can. J. Chem. **61**, 184 (1983).

Hydrazonium(2+) hexafluorosilicate, $N_2H_6SiF_6$, at room temperature has an orthorhombic (*Pbca*, $Z = 4$), pseudotetragonal unit cell ($a = 7.605(1)$ Å, $b = 7.586(2)$ Å, $c = 8.543(1)$ Å). The structure consists of centrosymmetric $N_2H_6^{2+}$ and SiF_6^{2-} ions arranged in a NaCl-type packing and connected by hydrogen bonds to two-dimensional $N_2H_6-SiF_6$ layers parallel to (001). All H atoms are engaged in hydrogen bonding. Four of the six H···F bonds to each cation are normal but significantly bent; the other two are trifurcated, N—H···3 F, but the out-of-layer component of the trifurcated bond is relatively unimportant. The $N_2H_6SiF_6$ structure is compared in some detail with the structures of other hydrazonium(2+) salts, with particular attention to the N—N bond length, to the "effective" size of the $N_2H_6^{2+}$ ion, and to the tendency of this ion to form bent hydrogen bonds.

T. Stanley Cameron, Osvald Knop et Laura Ann Macdonald. Can. J. Chem. **61**, 184 (1983).

A la température ambiante l'hexafluorosilicate d'hydrazonium(2+), $N_2H_6SiF_6$, a une maille élémentaire orthorhombique (*Pbca*, $Z = 4$), pseudotétragonale ($a = 7{,}605(1)$ Å, $b = 7{,}586(2)$ Å, $c = 8{,}543(1)$ Å). La structure consiste en des ions $N_2H_2^{2+}$ et SiF_6^{2-} centrosymétriques disposés selon un arrangement identique à celui du NaCl et reliés par des liaisons hydrogène à des couches bidimensionnelles de N_2H_6—SiF_6 parallèles à (001). Tous les atomes hydrogène participent dans les liaisons hydrogène. Quatre des six liaisons H···F de chaque cation sont normales mais assez coude'es. Les deux autres liaisons sont trifurquées, N—H···3F, mais la composante hors couche de la liaison trifurquée est relativement peu importante. On a comparé en détail la structure du $N_2H_6SiF_6$ avec celles d'autres sels d'hydrazonium (2+) en s'attardant particulièrement sur la longueur de liaison N—N, sur la dimension effective de l'ion $N_2H_6^{2+}$ et sur la tendance de cet ion à former des liaisons hydrogène coude'es.

[Traduit par le journal]

There are very few inorganic cations that can act as effective donors to form hydrogen bonds: $H(H_2O)_n^+$ ($n \leq 4$), NH_4^+, PH_4^+, $HONH_3^+$, $N_2H_5^+$, $N_2H_6^{2+}$. Of these, $N_2H_6^{2+}$ (abbreviated in the following to Hy) is the only such cation carrying a double charge.[2] At the same time it is a counterpart of NH_4^+ as regards the equivalence of all its hydrogens (at maximum symmetry) and their ability simultaneously to engage in hydrogen bonding. Thus if NH_4^+ may be viewed, from the point of view of crystal chemistry of ionic solids, as a size match of Rb^+ with hydrogen-bonding ability added, Hy might be considered as the corresponding companion of a large divalent simple ion, say Ba^{2+}. This analogy is given credence, albeit only within the very limited scope of the structural information available to date, when the Hy salts listed in Table 1 are compared with the corresponding Ba compounds and features specific to the cation structure and the presence of hydrogen bonding in the former are disregarded.

Table 1 presents crystallographic data of all the Hy compounds we have been able to find in the literature. This set contains only 14 compounds, the selection of which owes more to accidents of history than to premeditation, and the quality of the structural information varies widely from compound to compound. Nevertheless, the *symmetry* of the Hy ion[3] in the crystals can be ascertained (uniquely except in two cases) regardless of the details and accuracy of the structure determination, simply by comparing Z with the equipoint multiplicities of the respective space group, provided only that Z and the space group are correct.

Examination of Table 1 reveals a remarkable variety of Hy symmetries in this handful of compounds: $\bar{3}\,m$ (the maximum point group of the ion) and five of its nine subgroups are represented. This variety in turn is reflected in a diversity of hydrogen-bonding situations, characterized by the occurrence of highly-bent, bifurcated or trifurcated N—H···X bonds. The present study was undertaken to explore further the full extent of the structural behaviour of the Hy ion, the available information being quite inadequate compared with what is known, for example, about the NH_4^+ ion in crystals.

$HySiF_6$ was chosen in part to clear up the *a priori* uncertainty about the cation/anion packing in this compound. If the composite nature of Hy is disregarded, $HyTiF_6$ (and almost certainly also $HyTcF_6$, $HyReF_6$, and $HyMoF_6$) is isostructural with $KSbF_6$ and $AgSbF_6$, both reported (29, 30) to be superstructure variants (*Ia*3, $Z = 8$) of the CsCl arrangement found in $BaTiF_6$ and $BaSiF_6$ ($TlSbF_6$ type, $R\bar{3}\,m$, $Z = 1$).[4] This would suggest that the packing in $HySiF_6$, too, is of this type. However, a survey of the known ABF_6 structures (Fig. 1) shows that for a BF_6^{2-} ion as small as SiF_6^{2-} a NaCl-type packing is a distinct possibility.

[1]To whom all correspondence should be addressed.

[2]And in fact one of the very few doubly-charged composite cations, if one disregards doubly protonated amines (although Hy itself may be considered to be the initial member of the $^+H_3N(CH_2)_nNH_3^+$ series). As for the hypothetical tetrahedral H_4O^{2+} ion, *ab initio* MO calculations at the 6-31G* level (R. J. Boyd, unpublished results) predict that the isolated ion is unstable with respect to loss of a proton by about 59 kcal/mol; a more elaborate treatment might reduce this estimate by possibly as much as 15 kcal/mol. Similar calculations predict that the removal of a proton from an isolated H_3O^+ ion would require ca. 175 kcal/mol. Conditions can be envisaged under which H_4O^{2+} might be stabilized by the electrostatic potential at a crystal site.

[3]I.e. the symmetry at the midpoint of the N—N bond.

[4]It is noteworthy than no $M^{2+}X^{2-}$ compound of the CsCl type is known for simple M and X ions.

[a]Where two sets of references are given, the first set concerns crystallographic information, the second set refers to other physical measurements. In addition to the compounds listed in the table, a ^1H nmr study of $Hy(NO_3)_2$ is reported in ref. 21; $HyBr_2$ and $HyPF_6$ have been studied by inelastic neutron scattering (5); and normal coordinate analysis of Hy has been reported (25). $HyBr_2$ is probably isostructural with $HyCl_2$ (5).

[b]These three fluorides have been reported as bcc, a = 10.48–10.55 Å. It is probable that they are isostructural with $HyTiF_6$.

[c]Neutron diffraction.

[d]X-ray diffraction.

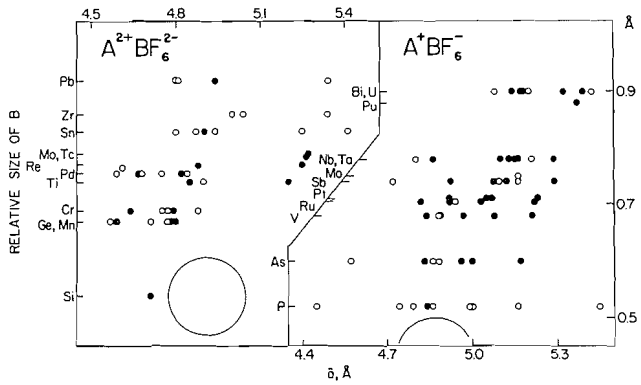

FIG. 1. Distribution of the NaCl- and CsCl-type packing arrangements among the hexafluorometallates ABF_6 (room-temperature structures; data assembled from refs. 26–28). $\bar{a}$ is the mean linear unit-cell dimension $(V/Z)^{1/3}$; the relative size of B = Shannon's crystal radius of B for 6-coordination. Open circles, NaCl type; full circles, CsCl type. On estimates from size similarity the point for $HySiF_6$ would be expected to fall within the circled areas, where the packing type is difficult to predict.

Experimental

Preparation

A calculated amount of anhydrous hydrazine was added dropwise to a vigorously stirred 23% aqueous solution (commercial) of H_2SiF_6 in a teflon beaker. Well-developed colourless crystals of the salt began to form even before the addition was completed. On removal from the saturated mother liquor the crystals were pressed between layers of filter paper, washed quickly with 95% EtOH, and dried in air. They showed pronounced cleavage. The compound is very soluble in water, somewhat soluble in EtOH.

Crystal data

$F_6H_6N_2Si$ fw = 176.14

Orthorhombic, *Pbca* (systematic absences: $0kl$, $k = 2n + 1$; $h0l$, $l = 2n + 1$; $hk0$, $h = 2n + 1$); a = 7.605(1) Å, b = 7.586(2) Å, c = 8.543(1) Å, V = 492.8 Å^3, Z = 4, ρ_c = 2.374 g/cm^3; Mo $K\alpha_1$, λ = 0.70926 Å (graphite monochromator), μ_{Mo} = 9.07 cm^{-1}, $F(000)$ = 704 e.

Structure determination

The crystal used in the determination was 0.3 × 0.3 × 0.6 mm^3 in size. A total of 870 reflections in the range $2° < \theta < 28°$ were measured on a CAD-4 four-circle diffractometer; of the 718 unique reflections 591 had $I > 3\sigma(I)$ and were used in the refinements. The unit-cell dimensions were determined from 25 general reflections with $14° < \theta < 24°$.[5] The intensities were reduced by routine procedures (31). Lorentz and polarization corrections were applied but no absorption or extinction corrections. The scattering factors for neutral atoms were taken from ref. 32. The structure was solved by the heavy atom method using the SHELX system (33).

Full-matrix least-squares ($u\Delta F^2$ = min.) refinement was carried out with isotropic temperature factors on heavy atoms until R = 0.06. The hydrogen atoms were clearly visible in a difference Fourier map calculated at this stage. The N—H bond lengths were constrained to 1.06 ± 0.02 Å and the HNH angles to tetrahedral (through a constraint on the H···H distances, 1.68 ± 0.03 Å), and refinement was continued with anisotropic temperature factors on the nonhydrogen atoms and isotropic factors on the hydrogens until R = 0.029, based on all 591 reflections. The least-squares weights were calculated from $w^{-1} = \sigma^2|F_o| + 0.000381F_o^2$, where σ is the weight for an individual reflection derived from the diffractometer counting statistics. The atomic and thermal parameters are given in Table 2, interatomic distances and bond angles in Tables 3 and 4.[6]

Description of the structure

Space-group constraints require both ions to be centrosymmetric. The centres of the cations are in equipoint 4(a) and those of the anions in equipoint 4(b) of *Pbca*. Each set thus constitutes a lattice complex *Fmmm*, the two complexes being displaced by $(\boldsymbol{a} + \boldsymbol{b} + \boldsymbol{c})/2$. Since *Pbca* ⊂ *Pa*3, the complex *Fmmm* is an orthorhombic distortion of the cubic complex *Fm*3*m*, i.e. the packing of Hy and SiF_6 is of the NaCl type (Fig. 2), the first such packing to be reported for a Hy compound.

[5]It was necessary to go to a high angle along one axis in order to find a reflection suitable for determining the unit-cell dimension.

[6]Copies of Table 5 (structure factors) are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

[a]To 3.5 Å; esd = 0.004 Å.
[b]To 2.7 Å; esd = 0.024 Å.
[c]esd = 1°.
[d]Symmetry code: B, $\bar{x}$, ½ + y, ½ − z;
B′, 1 − x, ½ + y, ½ − z;
C, ½ − x, $\bar{y}$, ½ + z;
C′, x, 1 − y, ½ + z;
D, $\bar{x}$, $\bar{y}$, $\bar{z}$;
F, x, ½ − y, ½ + z;
G, ½ + x, y, ½ − z.

The closeness of the distortion to tetragonal, with $2c/(a + b) \sim 1.12$, is a consequence of the orientation of the N—N groups. They are almost parallel to the c-axis, so that the dimension effective in determining the a and b values is the *smallest* dimension of the Hy ion. If the SiF_6 groups were assumed spherical and in contact, the effective size of the Hy ion normal to the N—N bond would be of the order of 1.1 Å; taking the effective length of the ion to be twice the N—N distance, 2.86 Å, the $2c/(a + b)$ ratio would be 1.08, in reasonable agreement with observation. This means the the effective size of Hy in a crystal would be within the limits 1.1−2.9 Å, depending on the orientation of the ion. The mean $(2.86 + 2 \times 1.1)/3 \sim 1.7$ Å would indicate a rough size similarity to the Ba^{2+} ion in 12-coordination, $r^{xii}(Ba^{2+}) \sim 1.61$ Å (Shannon).

Viewed as an assembly of spherical SiF_6 and elongated N—N groups the packing arrangement in $HySiF_6$ shows formal similarity to the *Pbca* structures of PdS_2 and β-HgO (both related to the *Pa*3 pyrite structure), and an even closer similarity to the tetragonal CaC_2-type structure, in which the c/a ratio (for MO_2 peroxides) ranges from 1.15 to 1.31. Still more conspicuous is the similarity to the tetragonal $MeNH_3Br$ and $MeNH_3I$ structures, with $c/a = 1.22$ and 1.24 respectively (34, 35). The only essential difference between these two halides and $HySiF_6$ is in the hydrogen-bonding scheme: Hy can engage in hydrogen bonding at both ends of the ion but $MeNH_3^+$ only at one end.[7]

The hydrogen bonds in $HySiF_6$ are shown in Fig. 2 and in more detail in Fig. 3. All hydrogens are bonded to F atoms. The H(1)···F(1) and H(2)···F(2) bonds are normal (i.e. to a single F each) but appreciably bent (Table 4). H(3) participates in an asymmetrically trifurcated N—H···3 F bond to F(1), F(2), and F(3) (Fig. 3), the mean H···F being 2.13(4) Å and the mean NHF angle, 126(4)°. With the exception of H(3)···F(2) the H···F bond vectors are practically parallel to (001). They are located within slabs about 0.4 Å thick, one such slab being at a mean distance of about 1 Å on each side of a layer of Si atoms parallel to (001). The hydrogen bonds thus form two-dimensional networks parallel to (001), with only a minor interlayer component H(3)···F (2), which corresponds to the longest H···F distance in the structure that may still be considered as involved in hydrogen bonding, 2.25(3) Å, N—H(3)—F(2) = 116(1)°. The NaCl packing of ions in $HySiF_6$ is thus associated with an unusual feature, viz. a layer-type hydrogen-bonding scheme reflected in the pseudotetragonal symmetry of the structure and a most pronounced cleavage along (001).

The formation of two normal but bent and one quasi-

[7]The spectroscopic and other consequences of this contrast have been explored in a number of investigations (see for example refs. 5 and 36).

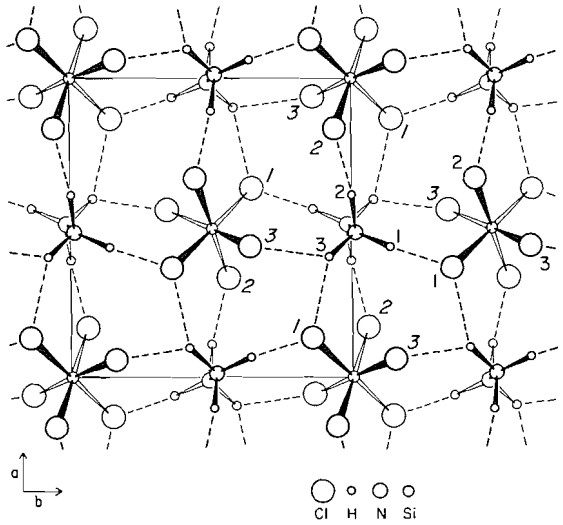

FIG. 2. Projection of the lower half of the $HySiF_6$ unit cell on (001). The Si atoms are at $z = 0$. F and H atoms with the Roman numerals have coordinates as in Table 2; the numbers in italic designate the *type* of F atom. The origin is in the lower right-hand corner of the unit-cell outline.

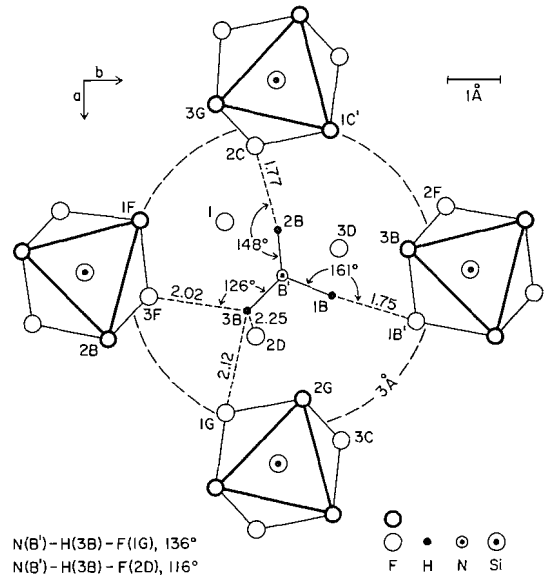

FIG. 3. Environment of a nitrogen atom in $HySiF_6$. The H···F distances (up to 2.3 Å) and NHF angles of the hydrogen bonds are shown. For longer H···F distances and symmetry code, see Table 4.

bifurcated hydrogen bond may appear surprising. In fact, this is the normal situation. In $HySiF_6$ the triplet of H atoms bonded to a nitrogen may be viewed as approximately coplanar and concentric with a quadrangle of F acceptor atoms (1B′, 1G, 2C, and 3F in Fig. 3). In an equilibrium configuration of minimum energy of an equilateral triangle of positive unit charges located within a coplanar, concentric square of negative unit charges one of the vertices of the triangle is on the bisector of a side of the square. If the positive charges are represented by H atoms at 1 Å from the centre *C* and the negative charges by fluorines at 2.8 Å (the mean of the observed N···F distances involving the four F) from *C*, the two normal H···F bonds in an equilibrium configuration will have a length of ca. 1.9 Å each, with a *C*HF angle of ca. 157°, and the symmetrically bifurcated bond will have an H···F distance of ca. 2.2 Å, with a *C*HF angle of ca. 117°. While in $HySiF_6$ these assumptions are realized only very approximately, this model accounts for the geometry actually observed better than qualitatively.[8] It is also of interest to note that much the same local hydrogen-bonding geometry as in $HySiF_6$ is observed for N(1) in $HyBeF_4$ (17) and also in $Hy(NbOF_5)(H_2O)$ (16), except that in the latter one of the two normal bonds is to an H_2O oxygen and the trifurcated bond is to two fluorines and an anion oxygen; the H···X distances and NHX angles are very similar to those in $HySiF_6$.

The two shortest H···F distances in $HySiF_6$, 1.75(3) and 1.77(3) Å, are appreciably larger than the H···F distances in HyF_2, 1.54(1) Å (3),[5] but comparable to the shortest H···F distances in $HyBeF_4$, 1.70(7) and 1.77(7) Å (19), and in $Hy(NbOF_5)(H_2O)$, 1.70(1) Å (16). They are also of the same order as the H···O distances in the last-named compound, 1.77 (1) Å, and in $HySO_4$, 1.642(4), 1.715(5), and 1.774(5) Å (20). A feature common to all these normal N—H···X bonds is the fairly constant deviation of about 15° of the NHX angle from 180°; in this the N—H(2)···F(2) bond, with its unusually small NHF angle of 150°, is an exception.

Apart possibly from $HyCl_2$ and $HyBr_2$, HyF_2 to date appears to be the only Hy compound in which the NHX angle is close to 180°. The bent normal N—H···X bonds in Hy salts are evidently the result of the staggered cation adopting the energetically most favourable orientation, with respect to hydrogen bonding, in an acceptor environment generally of unfavourable geometry forced upon the cation by the Coulombic forces which dominate the structure of the ionic crystal. It is difficult to say to what extent linearity of a normal N—H···F bond is affected by the presence of acceptor atoms at H···F distances greater than say 2.3 Å (cf. Fig. 3 and Table 4).

The N—H bond length in $HySiF_6$, 1.428(2) Å, is indistinguishable from the weighted mean of the nine d(N—N) values of Table 1, 1.426(13) Å (1.427(10) Å if $HySiF_6$ is included). This raises the question of the validity of the unusually high d(N—N) value reported for $HyTiF_6$, this value being 0.047(12) Å larger than the mean, i.e. 0.01 Å outside 3σ and 0.027 Å if $HyTiF_6$ is not included in the mean. Aware of the difficulty, the authors (10) suggest that the lengthening may be due to the strength of the six N—H···F bonds, N···F = 2.612(6) Å (as against ≥2.71 Å in $HySiF_6$). However, this may not be the explanation. In HyF_2 the six equivalent N···F distances are of comparable length, 2.62(2) Å, as found by X-ray diffraction (1) and nmr (3); assuming N, H, and F to be collinear, the H···F distance obtained from the ^{19}F resonance spectrum is 1.542(10) Å. It is unlikely that the hydrogen bonding to F^- in HyF_2 would be weaker than in $HyTiF_6$, yet d(N—N) in the fluoride is quoted as 1.42(2) Å (1).[9]

[8]It should be possible to verify the validity of this model by locating the N-hydrogens in the tetragonal $MeNH_3X$ (X = Cl, Br, I) structures, in which the model requirements are more closely satisfied. In the chloride at room temperature (34, 37) the calculated approximate H···Cl distances and NHCl angles would be 2.16 Å and 166° for the normal and 2.51 Å and 123° for the symmetrically bifurcated N—H···Cl bonds; in the bromide (35) the corresponding values would be 2.45 Å and 159°, and 2.86 Å and 120°, respectively. Nuclear magnetic resonance studies (38–40) suggest that the NH_3 triplet in the room-temperature phases undergoes spontaneous reorientations, by 90° rotations about the N—C (= C_4) axis, between the four equivalent positions resulting from the tetragonal symmetry of the non-hydrogen portion of the crystal structure.

[9]This value may be too low (cf. ref. 5).

In spite of the low overall symmetry of the structure the SiF_6 octahedron in $HySiF_6$ is only very slightly distorted (Table 3). The mean Si—F bond length, 1.678(2) Å, is shorter than the Si—F distance in $BaSiF_6$, 1.71 Å (41). However, the accuracy of this early determination is uncertain: a decrease of the stated x(F) and z(F) by 0.002 would be sufficient to reproduce the mean d(Si—F) in $HySiF_6$.

It is not clear at present why $HySiF_6$ adopts the NaCl-type and $HyTiF_6$ the CsCl-type packing. If anion size is a factor, the difference of about 0.2 Å between the Si—F and Ti—F distances must be critical, which invites examination of $HyGeF_6$.

ZHENNAN WU, NORMAN V. KLASSEN, HUGH A. GILLIS, and GEORGE G. TEATHER. Can. J. Chem. **61**, 189 (1983).

The yield and reaction kinetics of trapped electrons, e^-_{ir} and e^-_{vis}, in several ethylene glycol/D_2O glasses have been studied from 6–72 K by pulse radiolysis. An increased D_2O concentration is believed to increase the concentration of IR-traps thereby leading to a greater $G(e^-_{ir})$ and to decrease the concentration of VIS-traps thereby increasing the stability of e^-_{ir}. The yield and stability of e^-_{ir} are also increased by lowering the temperature. A redetermination of $\epsilon(e^-_{ir})$ ($1.3 \times 10^4\ M^{-1}\ cm^{-1}$ at 1800 nm) confirms earlier values.

ZHENNAN WU, NORMAN V. KLASSEN, HUGH A. GILLIS et GEORGE G. TEATHER. Can. J. Chem. **61**, 189 (1983).

Le rendement et les cinétiques des électrons piegés, e^-_{ir} ct e^-_{vis}, dans quelques verres de glycol d'éthylène/D_2O ont été étudiés de 6–72 K par radiolyse pulsée. Une augmentation en concentration de D_2O augmente la concentration des pièges-IR, qui entraine une valeur plus elevée pour $G(e^-_{ir})$, et baisse la concentration des pièges-VIS augmentant la stabilité de e^-_{ir}. Le rendement et la stabilité de e^-_{ir} sont aussi augmenté par une baisse de température. Une redétermination de $\epsilon(e^-_{ir})$ ($1.3 \times 10^4\ M^{-1}\ cm^{-1}$ à 1800 nm) confirme la valeur précédente.

Introduction

Aqueous ethylene glycol glass has proven to be a useful matrix in which to study the behaviour of infrared-absorbing trapped electrons, e^-_{ir}, and visible-absorbing trapped electrons, e^-_{vis} (1–7). The pulse radiolysis of pure ethylene glycol (EG) glass, even at 6 K, shows no evidence of e^-_{ir} whereas both e^-_{ir} and e^-_{vis} are produced in 50/50 (vol/vol) EG/D_2O and EG/H_2O glasses (3, 4). Thus the presence of water permits the production of e^-_{ir}.

In publications from this laboratory, pulse radiolysis experiments have been interpreted as indicating that e^-_{ir} and e^-_{vis} are electrons trapped in two distinctly different molecular environments both in certain aqueous glasses (1–4, 8, 9) and in crystalline ice (10, 11), although the conversion of e^-_{ir} into e^-_{vis} is readily observable in some aqueous glasses (1, 8, 12) including aqueous EG glasses (1). Dolivo and Kevan (13), on the other hand, have argued that the essential difference between the two types of electron is that e^-_{ir} has a first solvation shell of water molecules which are not at equilibrium, whereas the water molecules immediately adjacent to e^-_{vis} are at equilibrium. The present results continue to favour two distinctly different molecular environments for e^-_{ir} and e^-_{vis}.

In this study, the pulse radiolysis of EG/D_2O glasses of varied composition provides new insight into the production and decay of e^-_{ir} and e^-_{vis} and the interdependence of the two species. A redetermination of $\epsilon(e^-_{ir})$ was made to insure the reliability of the calculated values of $G(e^-_{ir})$ and $G(e^-_{vis})$.

Experimental

Ethylene glycol and sodium salicylate (NaSal) (Fisher Certified), D_2O (99.7 atom % Merck, Sharp and Dohme), and argon (Airco Superpurified) were used as received. EG/D_2O glasses are designated by the parts by volume used to make up the solution, e.g. 45/55 EG/D_2O, as well as by mol% D_2O. In practice all solutions were made by weighing because of the extreme sensitivity of $G(e^-_{ir})/G(e^-_{vis})$ to glass composition and the difficulty in accurately pipetting EG.

Windowless, crack-free glasses with a 3 mm optical path were prepared from argon-saturated solutions (4). Samples were irradiated between 6 K and 72 K in a Janis model 8DT liquid helium cryostat with a temperature control of ±1 K or at 72 K in liquid nitrogen (helium bubbled) in a quartz dewar (2). Optical windows were Suprasil.

Irradiations were carried out with single 40 ns pulses of 35 MeV electrons from a linear accelerator. The dose per pulse was about 8 krad. Dosimetry was based on oxygen-saturated $5 \times 10^{-3}\ M$ KSCN for which $OD(SCN)_2^-$ was extrapolated to mid-pulse and $G\epsilon_{475}$ was taken to be 2.2×10^4. Each pulse was monitored with a secondary emission chamber.

Optical absorption measurements were made at $350 \leq \lambda \leq 800$ nm with a Philips XP-1003 photomultiplier, at $450 \leq \lambda \leq 1000$ nm with an EG&G SHS-100 Si photodiode and at $\lambda \geq 900$ nm with a Barnes A-100 InAs detector (14). Spectra were measured by the split light beam technique. Measurements were made and stored with a Tektronix R7912/computer system (15).

Results

Spectra and kinetics of e^-_{ir} and e^-_{vis} at 72 K and 6 K

The 100 ns spectra for 45/55, 50/50, and 55/45 EG/D_2O are shown in Fig. 1 for 72 K and in Fig. 2 for 6 K. The band due to e^-_{vis} has $\lambda_{max} \simeq 650$ nm but the apparent maximum shifts to higher wavelengths for spectra dominated by the infrared band due to e^-_{ir}. The maximum for e^-_{ir} has been estimated to be 3600 nm in $MgCl_2/D_2O$ (1).

By taking $\epsilon_{max}(e^-_{vis}) = 2.0 \times 10^4$ and $\epsilon_{1800}(e^-_{ir}) = 1.3 \times 10^4$ (see below) the values of $G(e^-_{vis})$ and $G(e^-_{ir})$ were calculated for 100 ns, 400 ns, and 835 ns and for the extrapolation to mid-pulse. These data are given in Table 1.

Where it is indicated that the irradiation was done at 6 K the temperature of the sample was stabilized at 6 (±1) K before the electron pulse. The analyzing light and the electron pulse may have caused a substantial (but undetermined) rise in the temperature of the sample. All experiments were carried out in the same manner so that the temperature rise was similar each time. The spectrum labeled "6 K" is clearly very different from the 72 K spectrum but is similar to the spectrum determined by γ-radiolysis of EG/H_2O at 4 K (6). The discussion of these results does not depend on knowing accurately the temperature of the "6 K" sample.

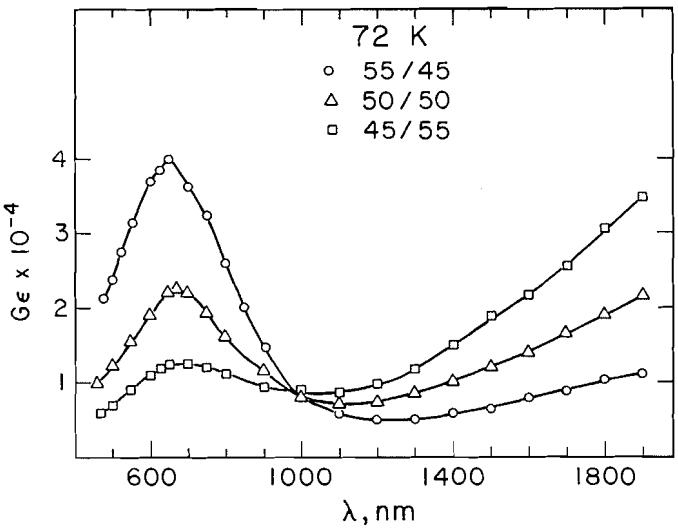

FIG. 1. The 100 ns spectra of EG/D_2O glasses at 72 K.

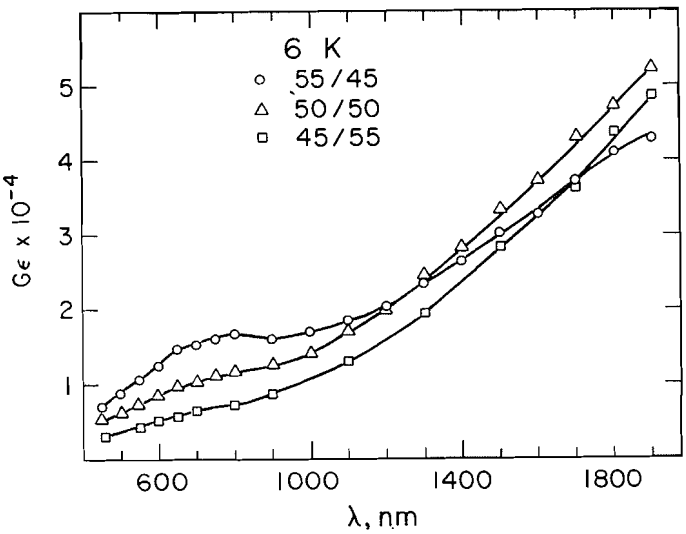

FIG. 2. The 100 ns spectra of EG/D_2O glasses at 6 K.

Determination of $\epsilon_{1800}(e_{ir}^-)$

Both the yield and stability of e_{ir}^- are increased by high D_2O concentrations and low temperatures. Advantage was taken of these factors to redetermine $\epsilon(e_{ir}^-)$. Sodium salicylate was used to scavenge electrons according to the reaction:

$$Sal^- + e^- \rightarrow Sal^{2-}$$

EG/D_2O glasses containing Sal^- were irradiated and the absorption at 460 nm and 650 nm (due to Sal^{2-}, e_{vis}^-, and e_{ir}^-) and at 1800 nm (due to e_{ir}^-) was measured and compared to the absorption in the absence of Sal^-. $G(Sal^{2-})$ was equated to the reduction of $G(e_{ir}^- + e_{vis}^-)$ estimated at mid-pulse.

The spectrum of Sal^{2-} was measured at 8 μs, 72 K, for 50/50 EG/D_2O containing 0.3 *M* Sal^-. It was found to be very similar to that reported by Singh, Chase, and Hunt (16) for Sal^{2-} in a room-temperature D_2O solution of 2 *M* NaSal (λ_{max} = 460 nm). Accordingly we adopted their value of $\epsilon_{460}(Sal^{2-}) = 4500$. Other ε's and ratios of ε's that were used are as follows: (*a*) $\epsilon_{460}(Sal^{2-})/\epsilon_{650}(Sal^{2-}) = 6.0$ from our spectrum of Sal^{2-}; (*b*) $\epsilon_{460}(e_{vis}^-)/\epsilon_{650}(e_{vis}^-) = 0.5$ from the spectrum for 55/45 EG/D_2O at 72 K (Fig. 1); (*c*) $\epsilon_{650}(e_{vis}^-) = 2.0 \times 10^4$ from ref. 17; (*d*) $\epsilon_{650}(e_{ir}^-)/\epsilon_{1800}(e_{ir}^-) = 0.08$ and $\epsilon_{460}(e_{ir}^-)/\epsilon_{1800}(e_{ir}^-) = 0.05$ estimated from the spectrum for 45/55 EG/D_2O at 6 K (Fig. 2). Absorption measurements were made at 460, 650, and 1800 nm from 100 ns to 835 ns and the concentrations of e_{ir}^-, e_{vis}^-, and Sal^{2-} at mid-pulse were estimated. The extrapolation to mid-pulse was larger for e_{ir}^- than for e_{vis}^- or Sal^{2-} but more straightforward since only e_{ir}^- absorbs at 1800 nm whereas all three species absorb at 650 and 460 nm. The uncertainty due to these extrapolations results in a large uncertainty in the calculated values of $\epsilon(e_{ir}^-)$.

The calculated values of $\epsilon_{1800}(e_{ir}^-)$ are 1.2×10^4 and $1.7 \times 10^4\ M^{-1}\ cm^{-1}$ for 45/55 EG/D_2O containing 0.01 *M* Sal^- at 6 K and 72 K, respectively, and $1.5 \times 10^4\ M^{-1}\ cm^{-1}$ for 50/50 EG/D_2O containing 0.02 *M* Sal^- at 6 K. The 45/55 matrix with 0.01 *M* Sal^- at 6 K was probably best suited for this determination because $G(e_{vis}^-)/G(e_{ir}^-)$ is small, the ratio of the extrapolated mid-pulse yield of e_{ir}^- to the yield at 100 ns is relatively small at 1.33, and because it involves the lower of the two Sal^- concentrations (which reduces the risk that Sal^- scavenges electrons which otherwise would have recombined very rapidly and therefore would not have been accounted for in the extrapolated yields of e_{ir}^- and e_{vis}^- in the absence of Sal^-). We take $\epsilon_{1800}(e_{ir}^-) = 1.3\ (\pm 0.3) \times 10^4\ M^{-1}\ cm^{-1}$ as the best value.

Concentration dependence of $G(e_{ir}^-)$ *and* $G(e_{vis}^-)$

In order to present as complete a picture as possible of the role of matrix composition on the distribution of trapped electrons at early times, measurements were made on EG/D_2O matrices at 6 K over the whole range of concentrations which were easily glassed. These results, extrapolated to mid-pulse, are plotted in Fig. 3.

Accuracy of the data

The absolute values of $G\epsilon$ reported here are believed to be accurate to ±10%. Each value is the result of several determinations on different days. Scatter in the results can result from our inability to reproduce exactly the sample composition, position, temperature, and structure (e.g. strains, which develop during glassing) as well as electron beam wander and many other parameters common to pulse radiolysis experiments. There are, however, three types of results presented here which are internally consistent to better than ±10%. They are the spectral shapes (Figs. 1 and 2), the decays (Table 1), and the relative yields at 72 K and 6 K for the same composition (Table 1). Spectra were measured by the split light beam technique in which the analyzing light is split into two beams with a partially reflecting mirror after passing through the sample. With one beam $G\epsilon_{ref}$ is measured at a reference wavelength for each pulse. The other beam is used to measure $G\epsilon_\lambda$ at different wavelengths. A spectrum made up from $G\epsilon_\lambda/G\epsilon_{ref}$ is much less sensitive to many of the experimental variables than is the absolute value of $G\epsilon$. No significant effect of accumulated dose on $G\epsilon(e_{vis}^-)$ and $G\epsilon(e_{ir}^-)$ was noticed. The decays given in Table 1 are much more accurate than ±10% because each corresponds to the same electron pulse. In addition, the decays were verified by similar results obtained on several occasions. The values of $G\epsilon_{72K}/G\epsilon_{6K}$ for a given sample composition (Table 1) are more accurate than ±10% because they were determined on the same sample after changing only the temperature.

Discussion

The values of $G(e_{ir}^-)$ and $G(e_{vis}^-)$ in this report have been calculated using a single value for $\epsilon_{1800}(e_{ir}^-)$ of $1.3 \times 10^4\ M^{-1}$

TABLE 1. Yields of e_{ir}^- and e_{vis}^- in EG/D_2O glasses at 6, 72 K[a]

Glass	T (K)	Species	G Mid-pulse[b]	G 100 ns	G 400 ns	G 835 ns
45/55	72	e_{ir}^-	2.95	2.35	1.98	1.79
		e_{vis}^-	0.38	0.49	0.57	0.63
		$e_{ir}^- + e_{vis}^-$	3.33	2.84	2.55	2.42
50/50	72	e_{ir}^-	2.38	1.65	1.20	1.02
		e_{vis}^-	0.97	1.10	1.24	1.30
		$e_{ir}^- + e_{vis}^-$	3.35	2.75	2.44	2.32
55/45	72	e_{ir}^-	1.44	0.80	0.48	0.38
		e_{vis}^-	1.92	2.01	2.09	2.14
		$e_{ir}^- + e_{vis}^-$	3.36	2.81	2.57	2.52
45/55	6	e_{ir}^-	3.56	3.36	3.23	3.13
		e_{vis}^-	0.20	0.12	0.07	0.06
		$e_{ir}^- + e_{vis}^-$	3.76	3.48	3.30	3.19
50/50	6	e_{ir}^-	3.88	3.62	3.35	3.24
		e_{vis}^-	0.31	0.30	0.29	0.27
		$e_{ir}^- + e_{vis}^-$	4.19	3.92	3.64	3.51
55/45	6	e_{ir}^-	3.48	3.16	2.90	2.78
		e_{vis}^-	0.50	0.58	0.60	0.60
		$e_{ir}^- + e_{vis}^-$	3.98	3.74	3.50	3.38

[a]Values of $G(e_{ir}^-)$ and $G(e_{vis}^-)$ are quoted here to a precision greater than warranted for their absolute yields in order to show the changes which occur with time which do warrant the precision indicated.

[b]Values of G at mid-pulse were estimated by extrapolation.

cm^{-1} and a single value for $\epsilon_{max}(e_{vis}^-)$ of $2.0 \times 10^4\ M^{-1}\ cm^{-1}$ regardless of glass composition, temperature, or time after the pulse. This is clearly an approximation since $\lambda_{max}(e_{vis}^-)$ in EG/H_2O glasses is known to depend on the temperature (6) and on the composition of the glass (18). After γ-radiolysis of EG/H_2O glasses at 77 K, $\lambda_{max}(e_{vis}^-)$ varies from 502 nm for the 100/0 glass to 585 nm for 20/80 EG/H_2O (18). However, there are no strong reasons to believe that $\epsilon_{max}(e_{vis}^-)$ changes significantly over the range of conditions in this report. Spectral variations of e_{ir}^- are difficult to assess since all measurements have been limited to wavelengths below λ_{max} due to strong absorption bands of water. We have used D_2O, rather than H_2O, to extend our measurements as far as practical into the infrared. Table 2 lists values of $\epsilon_{1900}/\epsilon_{1500}$ at 100 ns for EG/D_2O glasses at 6 and 72 K. If the spectrum of e_{ir}^- were constant and if e_{vis}^- did not contribute to the absorption above 1500 nm, all the values in Table 2 would be the same (at 72 K the differences are close to the estimated experimental uncertainties). Two trends are indicated; the ratio $\epsilon_{1900}/\epsilon_{1500}$ decreases with decreasing temperature and with decreasing yield of e_{ir}^-. These effects could be partly accounted for by a long wavelength tail of e_{vis}^- extending into the infrared at 6 K. For example, the 100 ns spectrum of trapped electrons in 8 M NaOD/D_2O glass at 6 K shows no prominent band due to e_{ir}^- but e_{vis}^- seems to have a very broad spectrum with $G\epsilon_{1500}/G\epsilon_{650} = 0.30$ and $G\epsilon_{1900}/G\epsilon_{650} = 0.26$ (19). On the other hand, $G\epsilon_{1900}/G\epsilon_{650}$ is only 0.05 at 100 ns 6 K for pure EG glass. We conclude that there may be a significant variation in $\epsilon_{1800}(e_{ir}^-)$ over the range of temperature and EG/D_2O concentrations in this study but no reasonable alternative to adopting a single value for the present calculations is evident.

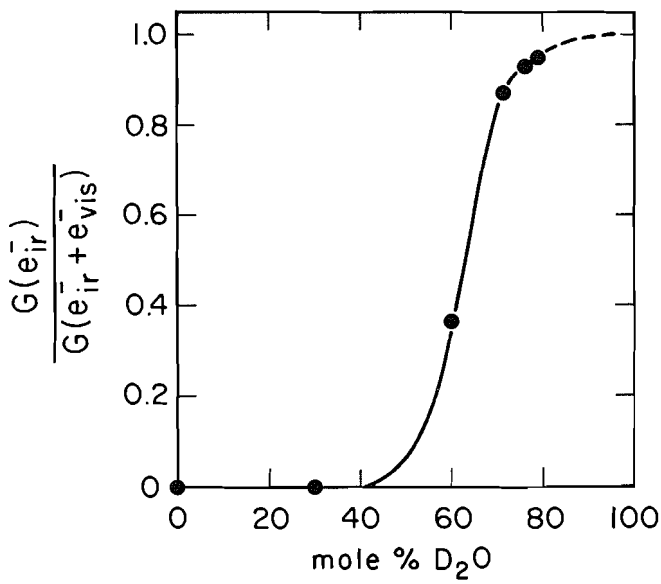

FIG. 3. The variation of $G(e_{ir}^-)/G(e_{vis}^- + e_{ir}^-)$ with EG/D_2O composition at 6 K as calculated for mid-pulse.

In this study we determined $\epsilon_{1800}(e_{ir}^-)$ to be 1.3 (±0.3) × $10^4\ M^{-1}\ cm^{-1}$ using Sal^- as an electron scavenger. We were able to take advantage of the large yield of e_{ir}^- in 45/55 EG/D_2O and its slow decay at 6 K. A previous measurement using Ag^+ as an electron scavenger in 50/50 EG/D_2O at 72 K yielded $\epsilon_{1400}(e_{ir}^-) = 0.57\ (\pm 0.08) \times 10^4\ M^{-1}\ cm^{-1}$ (1) which becomes $\epsilon_{1800}(e_{ir}^-) = 1.08\ (\pm 0.15) \times 10^4\ M^{-1}\ cm^{-1}$ when applied to the 50/50 EG/D_2O spectrum in Fig. 1. Another determination (2),

TABLE 2. Effect of temperature and matrix on the spectrum of e_{ir}^-

	$\frac{\epsilon_{1900}}{\epsilon_{1500}}$, 100 ns	
EG/D_2O	6 K	72 K
45/55	1.71±0.06	1.86±0.06
50/50	1.57±0.06	1.79±0.07
55/45	1.41±0.06	1.72±0.08

$\epsilon_{2500}(e_{ir}^-) = 3.5 \times 10^4\ M^{-1}\ cm^{-1}$ in 9.5 M $LiCl/D_2O$ containing 10^{-4} M tryptophan, is convertible into $\epsilon_{1800}(e_{ir}^-) = 1.3 \times 10^4$.

We believe that the spectrum reported for trapped electrons in 50/50 EG/H_2O after γ-radiolysis at 4 K with $OD_{1900}/OD_{700} = 1.4$ (6) had probably evolved considerably from its initial value when we compare it to the 100 ns spectrum of 50/50 EG/D_2O at 6 K, for which $OD_{1900}/OD_{700} = 5$ (Fig. 2). The evolution was probably due largely to decay of e_{ir}^- (see Table 1).

Figures 1–3 and Table 1 show that at both 6 and 72 K, $G(e_{ir}^-)$ increases with the concentration of D_2O in the matrix. A small extrapolation of the data in Fig. 3 (see dashed line) indicates that in a pure D_2O glass at 6 K probably all of the trapped electrons would be e_{ir}^- initially. These observations are qualitatively similar to the finding (9) that for $LiCl/D_2O$ glasses at 72 K electron yields fit the expression

$$\frac{G(e_{ir}^-)}{G(e_{vis}^-)} \propto \frac{[\text{Free } D_2O]}{[LiCl \cdot 4D_2O]}$$

This expression implies that e_{vis}^- is an electron trapped in a cluster of $LiCl \cdot 4D_2O$ molecules, whereas e_{ir}^- resides in an environment of only water molecules, which are thought to be incorporated interstitially at the interfaces between the clusters of $LiCl \cdot 4D_2O$ (20). Similarly the trapped electron yields for BeF_2/D_2O glasses (12) and the present results for EG/D_2O glasses suggest that e_{vis}^- is an electron trapped in clusters of $BeF_2 \cdot nD_2O$ or in clusters of $EG \cdot nD_2O$, respectively, and that e_{ir}^- is found in a pure D_2O environment. It is important to note that, at least in LiCl glasses and probably also in BeF_2 and EG glasses, the water molecules are packed differently than in ice (20, 21), so the conclusion that e_{vis}^- is found in clusters of $LiCl \cdot 4D_2O$ (or $BeF_2 \cdot nD_2O$ or $EG \cdot nD_2O$) molecules is not inconsistent with the observation that irradiation of crystalline ice at low temperatures results in a significant yield of e_{vis}^- as well as large yields of e_{ir}^- (10).

On the basis of the above picture one might expect the ratio $G(e_{ir}^-)/G(e_{vis}^-)$ to remain constant with temperature below the glass transition temperature since the structure of the glass and therefore the ratio of concentrations of the two kinds of traps should not change with temperature. However, Figs. 1 and 2 and Table 1 indicate that this ratio increases considerably for EG/D_2O glasses when the temperature is lowered from 72 to 6 K. Similarly, for $LiCl/D_2O$ glasses $G(e_{ir}^-)/G(e_{vis}^-)$ increases as the temperature is lowered from 72 to 6 K, especially for 12 and 14 M glasses in which very little free D_2O is expected (22). This could be due at least in part to a slightly higher activation energy for the process of trapping to give e_{vis}^- than for trapping to give e_{ir}^-, so that at 6 K the rate constant for trapping to give e_{ir}^- is much greater than for trapping to give e_{vis}^-. This possibility has been suggested earlier for alcohols (23–25) and for EG/D_2O (4) and EG/H_2O glasses (5).

Recently, Bartczak, Hilczer, and Kroh (26) have offered an explanation for the correlation between D_2O concentration and the ratio $G(e_{ir}^-)/G(e_{vis}^-)$ for $LiCl/D_2O$ glasses at 72 K which is very different than the one discussed above; they regard the $LiCl/D_2O$ glass as a distorted crystal lattice and suggest that e_{ir}^- and e_{vis}^- are electrons trapped in cation and anion vacancies, respectively. As the authors have stated, this treatment obviously cannot be extended to EG/D_2O glasses.

Recently, experiments were reported of a study of both temperature and concentration effects in ethanol/water glasses (27). As the water concentration was increased, the measured spectra became less like pure ethanol and more like the e_{vis}^- plus e_{ir}^- spectra of $LiCl/D_2O$ and EG/D_2O. At the highest water concentration reported (26 mol%) e_{vis}^- decreased and e_{ir}^- increased as the temperature was lowered from 72 K to 6 K. This result parallels those for $LiCl/D_2O$ and EG/D_2O. The similar results for these three systems suggest that the mechanism responsible for the proportions of e_{ir}^- and e_{vis}^- are also similar. If so, this argues against the explanation of Bartzcak, Hilczer, and Kroh, which can apply only to $LiCl/D_2O$.

An nmr study of ethanol/water solutions at 20°C (28) showed that ethanol present in small amounts is structure-making whereas, above 20 mol%, ethanol hinders the water molecules from organizing into three dimensional structures and, instead, water–ethanol hydrogen bonds are formed. Li and Kevan (29) have shown that silver ions in frozen ethanol/H_2O solutions exist in a water environment from 0–13 mol% ethanol, but above 13 mol% ethanol there is an abrupt change to an ethanol environment. It may be that above ~20 mol% EG three dimensional water structures are replaced by hydrogen bonded water–EG so that trapping sites for e_{ir}^- are replaced by trapping sites for e_{vis}^-.

The results of this study are more consistent with the model in which e_{ir}^- and e_{vis}^- are trapped in two distinctly different molecular environments than the model of Dolivo and Kevan (13) in which e_{ir}^- is the presolvated form of e_{vis}^-, with e_{ir}^- having a nonequilibrium orientation of first solvent shell molecules and e_{vis}^- having an equilibrium orientation of first solvent shell molecules. The spectra in Fig. 1 show no sign of any intermediate states between e_{ir}^- and e_{vis}^- as would be expected from the latter model. In an earlier publication (4) we showed that some published results of γ-radiolysis experiments were incorrectly interpreted in favour of the latter model.

Within the limitations of the accuracy placed on the absolute values of $G\epsilon$ reported here there are two clear trends in Table 1. They are: (*1*) $G(e_{vis}^- + e_{ir}^-)$ at a given time and temperature does not change with changes in EG/D_2O sufficient to cause large variations in $G(e_{vis}^-)/G(e_{ir}^-)$; (*2*) $G(e_{vis}^- + e_{ir}^-)$ increases on going from 72 K to 6 K. Trend (*1*) also holds for $LiCl/D_2O$ glasses as well as trend (*2*) which is less pronounced (9). As can be seen from Table 1, the most important factor in maintaining $G(e_{ir}^- + e_{vis}^-)$ independent of the matrix from mid-pulse to 835 ns is that the absolute decay of e_{ir}^-, $\Delta G(e_{ir}^-)$, is independent of the matrix. Also there is a delicate balance between the decay of e_{ir}^- and e_{vis}^- and the conversion of e_{ir}^- into e_{vis}^-. The conversion of e_{ir}^- into e_{vis}^- represents about 23% of the e_{ir}^- decay from mid-pulse to 835 ns in all three matrices at 72 K if e_{vis}^- is assumed not to decay at all. If we assume the concentration of visible traps to be proportional to $G(e_{vis}^-)$ at 6 K, mid-pulse, which implies no decay of e_{vis}^- before mid-pulse at 6 K, we find that the absolute decay of e_{ir}^-, $\Delta G(e_{ir}^-)$, between 100 ns and 400 ns can be described by

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

$$\Delta G(e_{ir}^-) = k[e_{ir}^-][\text{visible traps}]$$

where k varies by ±5% over the three glasses. Thus, it seems that the decay rate of e_{ir}^- at 72 K is proportional to the concentration of visible traps or the structure in which they exist. This implies that the species (or structures) with which e_{ir}^- reacts at 72 K (including the 23% converted into e_{vis}^-) are also to be found mostly in the region containing visible traps. Perhaps ethylene glycol molecules scavenge D_2O^+ and OD efficiently to produce ethylene glycol cations and free radicals which might then become the major electron scavengers. $G(e_{ir}^- + e_{vis}^-)$ at 100 ns, 6 K, averages 3.7 for 45/55, 50/50, and 55/45 EG/D_2O (Table 1). Thus EG/D_2O matrices trap electrons very efficiently. This might be due in part to rapid reaction of EG with D_2O^+ which is potentially a very mobile species.

Changing EG/D_2O at 72 K or at 6 K has little effect on the overall efficiency for trapping electrons. However, the increase in $G(e_{ir}^- + e_{vis}^-)$ at mid-pulse on going from 72 K to 6 K suggests that the trapping efficiency, relative to competing electron reactions, increases with decreasing temperatures.

At 6 K (Table 1) a decay of e_{vis}^- was observed in 45/55 and 50/50 glasses but a growth was measured in the 55/45 glass. This suggests that e_{vis}^- reacts on the 10^{-8} to 10^{-7} s time scale but that a net growth of e_{vis}^- is observed when a sufficiently high rate of conversion of e_{ir}^- into e_{vis}^- occurs as is found in the 55/45 matrix.

The hydrogen-bonded interactions by water and methanol in the first solvation shell of 2-aminopyrimidine, 2-, 3-, and 4-aminopyridine were determined by calorimetric analysis. The aminopyridines are enthalpically more stable in methanol than in water. This is due to methanol interactions at the amino nitrogen which do not seem to occur in water. The transfer enthalpies from water to methanol are determined primarily by the making and breaking of hydrogen bonds in the two solvents.

J. N. SPENCER, S. W. BARTON, K. A. SMITH, W. S. WOLBACH, J. F. POWELL, M. R. KIRSHENBAUM et D. W. FIRTH. Can. J. Chem. **61**, 194 (1983).

Faisant appel à l'analyse calorimétrique, on a déterminé les interactions de liaisons d'hydrogène avec l'eau et le méthanol dans la première couche de solvatation de l'amino-2 pyrimidine, des amino-2, amino-3 et amino-4 pyridines. Les aminopyridines sont enthalpiquement plus stables dans le méthanol que dans l'eau. Ceci est dû aux interactions entre le méthanol et l'azote du groupe amino qui ne semblent pas se manisfester dans l'eau. On a déterminé initialement les enthalpies de transfert de l'eau au méthanol principalement par la formation et la suppression des liaisons hydrogène dans les deux solvants.

[Traduit par le journal]

Introduction

A previous article (1) reported the solvation of heterocyclic nitrogen-containing compounds by water and methanol. The present work is a continuation of that study for the aminopyridines and 2-aminopyrimidine. Of particular interest is the interaction of the amino group of these compounds with solvent water. These amino–water solvation interactions may be used as a model for the solvation of amino groups on more complex compounds such as adenine and guanine.

Experimental

The calorimeters and methods of analysis have been previously described (2, 3). Purifications of water and methanol have been reported (1). The aminopyridines, 2- and 4-dimethylaminopyridine, and 2-aminopyrimidine were Aldrich Analyzed compounds and were vacuum sublimed. Chloroform was refluxed over P_2O_5 and fractionally distilled under nitrogen atmosphere. No absorption in the hydroxyl stretching region was observed.

Spectra were recorded on a Beckman 5240 UV-VIS-near IR spectrophotometer. For the pure base calorimetric analysis, 4-dimethylaminopyridine and 2-dimethylaminopyridine were used as model compounds for 4-aminopyridine and 2-aminopyridine, respectively.

Results

Enthalpies of solution are given in Table 1. Enthalpies of hydrogen bond formation by the amino group of 4-aminopyridine with water and methanol, and the hydrogen bond enthalpy of the amino group of 2-aminopyridine with methanol were calculated by the pure base calorimetric method (4) and are given in Table 2.

Pure base method calculations for the hydrogen bonding of the amino groups of 2-aminopyridine and 4-aminopyridine with methanol gave -3.5 and -4.0 kcal mol^{-1} of the pyridine, respectively. The frequency shifts for the 2- and 4-aminopyridine amino groups hydrogen bonded to dimethylformamide in chloroform solvent are 165 and 192 cm^{-1}, respectively. These shifts show that in agreement with the pure base calculations, the amino group of 4-aminopyridine is a better proton donor than that of 2-aminopyridine. The corresponding frequency shift for 3-aminopyridine is 174 cm^{-1} which gives an enthalpy of hydrogen bond formation for the amino group of 3-aminopyridine with methanol to be -3.7 kcal mol^{-1}. It was not possible to use the pure base method to calculate this enthalpy for 3-aminopyridine because a suitable model compound for use in the pure base calculations was not available.

The interactions of the amino groups with water of 2- and 3-aminopyridine could not be determined by the pure base method for reasons just noted for 3-aminopyridine and because of the insolubility of the model compound for 2-aminopyridine in water. The ratio of the enthalpies in water and methanol for 4-aminopyridine was used to calculate the interaction enthalpy for 2- and 3-aminopyridine in water. It was assumed that the relative strengths of the hydrogen bonds formed by the amino groups with water and methanol by 2- and 3-aminopyridine would be the same as the relative strengths of the hydrogen bonds formed by 4-aminopyridine with water and methanol. Thus the hydrogen bonds formed with methanol by the amino group were taken to be 1.25 times as strong as the hydrogen bonds to water. The results of these calculations are given in Table 2.

The enthalpy of vaporization of 2-dimethylaminopyridine (5), 12.26 kcal mol^{-1}, was combined with the enthalpy of solution of 2-dimethylaminopyridine in methanol to give the enthalpy of solvation of this compound. Corrections for the enthalpy due to interactions at the two methyl groups attached to the amino nitrogen were made (1, 4) and the enthalpy of solvation of 2-dimethylaminopyridine was compared to the enthalpy of solvation of pyridine (1). These transfers from gas phase to methanol give the interaction at the ring nitrogen of 2-aminopyridine to be -3.2 kcal mol^{-1}. Previous work (1) has shown a correlation between the proton affinity of the ring nitrogens of pyridine and the diazines with enthalpies due to interactions at the ring nitrogens. The proton affinities of pyridine, 2-, 3-, and 4-aminopyridine are 222, 228, 225, and 234 respectively (6, 7). These proton affinities were used with the

interaction enthalpies of pyridine (1) (Table 2) and 2-aminopyridine to assign enthalpies due to interactions by methanol at the ring nitrogens for 3- and 4-aminopyridine. These enthalpies are given in Table 2. Frequency shifts, determined in CCl_4 solvent, for pyridine, 2-dimethylaminopyridine, and 4-dimethylaminopyridine complexing with methanol were used to derive a $\Delta H-\Delta\nu$ relation. The enthalpy calculated for the interaction at the ring nitrogen of 4-dimethylaminopyridine was identical to that estimated from the proton affinities for 4-aminopyridine.

Enthalpies due to interactions with water by the ring nitrogen of 2- and 3-aminopyridine were determined by using transfer enthalpies. The transfer enthalpies of the ring nitrogens of pyridine, 1,2-diazine, 1,3-diazine, and 1,4-diazine from water to methanol were found to be +1.4 kcal mol^{-1} (1). It was assumed that the ring nitrogen of 3-aminopyridine would transfer from water to methanol as +1.4 kcal mol^{-1}. Furthermore, because transfer enthalpies of 2- and 3-aminopyridine, −1.01 and −1.15 kcal mol^{-1}, respectively, are nearly the same, the thermodynamic states of 2-aminopyridine and 3-aminopyridine must be comparable in water and methanol. Thus a transfer enthalpy of +1.4 kcal mol^{-1} for the ring nitrogen was also assumed for 2-aminopyridine. These assumptions then allow a calculation of the interaction enthalpy of water at the ring nitrogens of 2-aminopyridine and 3-aminopyridine. The interaction enthalpies at the ring nitrogens for 2- and 3-aminopyridine were found to be −4.6 and −4.5 kcal mol^{-1} respectively.

In a previous study, the interaction of water with N_3 of imidazole was found to be −4.3 kcal mol^{-1}; the same interaction enthalpy was found for the pyridine nitrogen interaction with water (1). The interaction of the imidazole N_1 and N_3 nitrogens with methanol was found to be −4.1 kcal mol^{-1} relative to pyrrole (1). The pyrrole nitrogen − methanol interaction was taken to be −0.4 kcal mol^{-1}. Thus, an interaction by methanol at the amino nitrogen seems likely. All interaction enthalpies except those which might be due to methanol interactions at the amino group nitrogen have now been assigned. These assigned enthalpies and transfer enthalpies may be used to identify and quantify any interactions not accounted for. The transfer enthalpy of 2-aminopyridine from water to methanol is −1.01 kcal mol^{-1}. This transfer is considered to be made up of the following group contributions:

$$\Delta H_{tr} = \Delta H_{tr}^{NH_2} + \Delta H_{tr}^{N_1} + \Delta H_{tr}^{C_4\text{—}N}$$

where subscripts refer to the group being transferred. $\Delta H_{tr}^{N_1}$ was taken to be +1.4 kcal mol^{-1} and $\Delta H_{tr}^{NH_2}$ to be −0.7 (Table 2), which then gives $\Delta H_{tr}^{C_4\text{—}N} = -1.7$ kcal mol^{-1}. For reasons to be discussed later, the enthalpy of interaction with methanol at the amino nitrogen of 2-aminopyridine was taken to be −1.7 kcal mol^{-1}. This means that no corresponding interaction at the amino group nitrogen is considered to occur with water. Similar calculations gave −1.9 kcal mol^{-1} for the interaction of the amino group nitrogen of 3-aminopyridine with methanol.

The interaction enthalpies assigned to each group should be consistent with the interactions for similar groups on other compounds. The transfer enthalpy from water to methanol for 2-aminopyrimidine is +0.41 kcal mol^{-1}. This transfer is considered to consist of the sum of group transfers:

$$\Delta H_{tr} = \Delta H_{tr}^{NH_2} + \Delta H_{tr}^{C_2\text{—}N} + \Delta H_{tr}^{N_3} + \Delta H_{tr}^{N_1}$$

By using the group transfers for 2-aminopyridine found from data given in Table 2, ΔH_{tr} is found to be:

$$\Delta H_{tr} = -0.7 - 1.7 + 1.4 + 1.4 = +0.4 \text{ kcal mol}^{-1}$$

Thus it appears that the group contributions for the aminopyridines will give reasonable estimates for similar interactions

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/06/12
For personal use only.

by other compounds.

The parameters given in Table 2 may be used with the transfer enthalpy to calculate the interaction enthalpy at the amino nitrogen of 4-aminopyridine. This interaction is −3.0 kcal mol^{-1}, about twice as large as the corresponding interactions for the 2- and 3-aminopyridines. The transfer of 4-dimethylaminopyridine, when corrected for the transfer enthalpy of the two methyl groups and the ring nitrogen, gives the interaction enthalpy for the amino group nitrogen to be −3.3 kcal mol^{-1}, which is in reasonable agreement with that assigned in Table 2.

Discussion

The tautomeric imino and amino forms of these pyridines were considered, but no consistent interpretation of the data could be found if imino forms were assumed to be present. All pyridines were assumed to exist as the amino form.

The transfer enthalpy for benzene from water to methanol is −0.13 kcal mol^{-1} (1). This small transfer enthalpy indicates that the cavity and interaction terms for benzene in these two solvents must nearly cancel. If the benzene transfer is taken as a model for the transfer of the ring portion of the pyridines of this study, it must be concluded that the transfers of these pyridines are primarily determined by the solvent interactions at the ring nitrogens and amino groups. These interactions are largely due to hydrogen bonding, thus the transfer enthalpies of the compounds of this study are determined by the making and breaking of hydrogen bonds of the first solvation shell.

The methanol interactions at the amino nitrogen of these pyridines is probably due to hydrogen bonding. The site of interaction is most likely from above and below the plane of the ring. The larger interaction enthalpy found for the amino nitrogen of 4-aminopyridine in methanol may involve two methanol molecules while only one may bond to the amino nitrogen of the 2- and 3-aminopyridine. The interaction by methanol at the amino nitrogen site was assigned by considering that no hydrogen bonding by water occurred at this site. This may not be the case but these interactions, if they occur in both solvents, are nearly 2 kcal mol^{-1} more exothermic with methanol than with water. Because water is a better proton donor than methanol (1), it does not seem likely that such interactions occur at the amino nitrogen by water. The transfer enthalpies of pyridine, 1,2-diazine, 1,3-diazine, and 1,4-diazine from water to methanol are all positive and in excess of 1 kcal mol^{-1} (1). The pyrrole, imidazole, and aminopyridine transfer enthalpies are all more negative than 1 kcal mol^{-1}. The better proton-accepting ability of methanol over water accounts for some of the heat observed in the transfer process but only about 1 kcal mol^{-1} can be attributed to stronger N—H hydrogen bonding in methanol. The additional heat found for the solvation of the aminopyridines, over that of pyridine, and the diazines must result from the formation of more hydrogen bonds with methanol than with water. Absolute values of the interaction enthalpies for the ring nitrogen of 4-aminopyridine with methanol and water are different from those for the pyridine nitrogen but the transfer enthalpy of the ring nitrogen from water to methanol should be quite similar for 4-aminopyridine and pyridine. The large exothermic transfer of 4-aminopyridine can best be rationalized by strong interactions by methanol at the amino nitrogen.

The transfer enthalpies for the aminopyridines are exothermic, meaning that the aminopyridines are enthalpically more stable in methanol than in water. Methanol is a better proton acceptor than water and correspondingly the amino group is enthalpically stabilized in methanol relative to water. Water, however, is a better proton donor than methanol and the ring nitrogens correspondingly interact with water more strongly than with methanol. For 2-aminopyrimidine the methanol interaction enthalpies at the ring and amino nitrogen sites are not sufficient to compensate for the stronger water interactions at the N_1 and N_3 positions. Hence the transfer enthalpy of 2-aminopyrimidine is positive.

Charge distributions and chemical effects. XXXI. Molecular energies of ethylenic compounds

M.-T. BÉRALDIN AND S. FLISZÁR
Department of Chemistry, University of Montreal, Montreal, P.Q., Canada H3C 3V1

Received May 27, 1982

M.-T. BÉRALDIN and S. FLISZÁR. Can. J. Chem. **61**, 197 (1983).

The energy formula describing bond contributions in terms of the charges carried by the bond-forming atoms is applied to ethylenic compounds. It is shown in what manner σ and π electrons can be treated within the framework of the bond energy theory giving the atomization energy of the vibrationless molecule at 0 K. Proper consideration of zero-point and thermal vibrational energies leads to standard enthalpies of formation. These calculations, which are carried out on the basis of ^{13}C nuclear magnetic resonance spectra, agree with their experimental counterparts, within experimental uncertainties (~0.3 kcal mol^{-1} average deviation).

M.-T. BÉRALDIN et S. FLISZÁR. Can. J. Chem. **61**, 197 (1983).

La formule décrivant l'énergie contribuée par un lien chimique en fonction des charges portées par les atomes du lien est appliquée à une série d'éthyléniques. Le traitement des électrons σ et π est illustré dans le cadre de la théorie conduisant à l'énergie d'atomisation de la molécule à 0 K, sans énergie vibrationnelle. Une considération des énergies vibrationnelles conduit aux enthalpies de formation standard. Ces calculs, entièrement basés sur les spectres de résonance magnétique nucléaire du ^{13}C, sont en accord avec leurs contreparties expérimentales, avec une déviation moyenne de 0.3 kcal mol^{-1}.

Introduction

The energy of a molecule in its hypothetical vibrationless state at 0 K is conveniently described in terms of bond energy contributions depending on the charges of the bond-forming atoms (1). The appropriate expressions were successfully tested (1–3) in comparisons with experimental atomization energies, ΔE^*_a, given by eq. [1] (see Appendix I: glossary).

$$[1] \quad \Delta E^*_a = \Sigma_i n_i[\Delta H^0_f(A_i) - 5\,RT/2] + \mathrm{ZPE} + H_T - H_0 - \Delta H^0_f$$

These verifications were made for linear and branched paraffins, including saturated hydrocarbons constructed from chair and/or boat cyclohexane rings (1, 2), as well as for ethers, aldehydes, and ketones (3). The present study offers a test for simple alkenes C_nH_{2n}.

The basic formula

$$[2] \quad \epsilon_{ij} = \epsilon^0_{ij} + a_{ij}\Delta q_i + a_{ji}\Delta q_j$$

gives the energy contribution of an *ij* bond to ΔE^*_a. Neglecting the nonbonded contributions (in the usual chemical sense), which are very small indeed (1–3), we use the approximation $\Delta E^*_a \simeq \Sigma\epsilon_{ij}$, i.e.,

$$[3] \quad \Delta E^*_a \simeq \Sigma\epsilon^0_{ij} + \Sigma_i\Sigma_j a_{ij}\Delta q_i$$

in which the $\Sigma_i\Sigma_j a_{ij}\Delta q_i$ term is responsible for the energy differences between structural isomers. The ϵ^0_{ij}'s are reference bond energies (1) (Appendix II) in kcal mol^{-1},

$\epsilon^0_{CH} = 106.806$ (CH in ethane)

$\epsilon^0_{CC} = 69.633$ (CC in ethane)

$\epsilon^0_{C=C} = 139.27$ (C=C in ethylene)

and Δq_i is the increment in net charge at atom *i* relative to the charge in the molecule selected for defining ϵ^0_{ij}. The reference net charges are (1) (Appendix III), in me = 10^{-3} electron units,

$q^0_C = 35.1$ me (C atom in ethane)

$q^0_H = -11.7$ me (H atom in ethane)

$q^0_{C\alpha} = 7.7$ me (C atom in ethylene)

Finally, the a_{ij}'s are given by the expression (1) (Appendix I)

$$a_{ij} = \frac{1}{\nu_i}\frac{K^{mol}_{Av}}{K^{mol}_i}\left[\left(\frac{\partial E^{vs}_i}{\partial N_i}\right)^0 - \frac{1}{2}\left(\frac{\partial^2 E^{vs}_i}{\partial N_i^2}\right)^0 \Delta q_i\right] - K^{mol}_{Av}\, Z^{eff}_j \langle r^{-1}_{ij}\rangle^0$$

which enables their theoretical evaluation. The second-order derivative can be safely neglected in the present case because the Δq_i's turn out to be sufficiently small. The a_{ij}'s required in this study and the parameters from which they were derived are indicated in Table 1.

For the CH and CC bonds involving sp^3 carbon atoms, the average inverse distance between nucleus *i* and the center of electronic charge on atom *j* (i.e., $\langle r^{-1}_{ij}\rangle^0$) is approximated in the usual manner (1) by the inverse of the internuclear distance, $r_{CH} = 1.08$ and $r_{CC} = 1.53$ Å. This approximation locates the centroids of σ charges at the nuclear positions. For sp^2 carbons, however, we consider that the center of π atomic charge is shifted by ~0.04 Å from the center of σ charge, toward the other carbon engaged in the double bond. The corresponding $\langle r^{-1}_{ij}\rangle^0$ parameters (Table 1) reflect this hypothesis which is justified *a posteriori* by the results obtained in this fashion.

A complication arises when atomic electron populations vary at different energy levels. Consider, for example, vinyl carbons with charges varying at the σ and π levels, i.e.,

$$\Delta q_i = \Delta q_{i\sigma} + \Delta q_{i\pi}$$

In this case, the term $a_{ij}\Delta q_i$ of eq. [2] becomes

$$a_{ij}\Delta q_i = a^\sigma_{ij}\Delta q_{i\sigma} + a^\pi_{ij}\Delta q_{i\pi}$$

indicating that a_{ij} represents now the appropriately weighted average of a^σ_{ij} and a^π_{ij}, i.e.,

$$a_{ij} = (a^\sigma_{ij}\Delta q_{i\sigma} + a^\pi_{ij}\Delta q_{i\pi})/(\Delta q_{i\sigma} + \Delta q_{i\pi})$$

TABLE 1. Calculation of a_{ij} (eq. [4])[a]

Atom	$(\partial E_i^{vs}/\partial N_i)^0$ (au)	r_{ij} (Å)	a_{ij} (au)
H(1*s*)	−0.195	1.08 (CH)	$a_{HC} = -1.007$
C(2*s*)	−0.735	1.08 (CH)	$a_{CH} = -0.394$ (sp^3—H)
		1.53 (CC)	$a_{CC} = -0.777$ (sp^3—sp^3)
C_σ	−0.375	1.34 (C=C)	$a^{\sigma}_{C=C} = -0.802$ (sp^2—sp^2)
C_π	−0.244	1.30 (C=C)	$a^{\pi}_{C=C} = -0.779$ (sp^2—sp^2)
C_σ	−0.375	1.08 (CH)	$a^{\sigma}_{C\alpha H} = -0.335$ (sp^2—H)
C_π	−0.244	1.10 (CH)	$a^{\pi}_{C\alpha H} = -0.2874$ (sp^2—H)
C_σ	−0.375	1.53 (CC)	$a^{\sigma}_{C\alpha C} = -0.718$ (sp^2—sp^3)
C_π	−0.244	1.55 (CC)	$a^{\pi}_{C\alpha C} = -0.666$ (sp^2—sp^3)

[a] We sincerely thank Professor D. Salahub and Drs. B. N. McMaster and N. A. Baykara for carrying out the SCF-Xα calculations of the derivatives. They were made as indicated in ref. 1, using α = 0.686 for H and α = 0.75928 for carbon. The results for σ and π electrons are deduced from a calculation of ethylene.

Taking advantage of the relationship $\Delta q_\sigma = m\Delta q_\pi$ ($-1 < m < 0$) describing the inverse variations in σ and π charges at vinyl carbon atoms (4), it appears that the appropriate average is simply

$$[5] \quad a_{ij} = (ma^{\sigma}_{ij} + a^{\pi}_{ij})/(m + 1)$$

The difficulty comes from the fact that calculated σ charges are considerably more basis set dependent than π charges, rendering a reliable theoretical evaluation of *m* illusory. Present numerical analyses suggest that $m \simeq -0.955$, a value which is consistent with the general conclusions drawn from the study of correlations between ^{13}C nuclear magnetic resonance shifts and atomic charges of sp^2 carbons (4). So far we have collected the theoretical information required for using eq. [3]. Now we can look at the olefins and inquire about the appropriate charges for use in this energy expression.

Charge normalization

The total (σ + π) net charge $q^0_{C\alpha}$ of the ethylene-C atom (relative to 6 e) is also its net σ charge (relative to 5 e) because its net π charge (relative to 1 e) is 0. Hence, a vinyl carbon whose net σ and π charges are q_σ and q_π, respectively, differs from the ethane carbon by $\Delta q_C = q_\sigma + q_\pi - q^0_C = (q_\sigma - q^0_{C\alpha}) + (q^0_{C\alpha} - q^0_C) + (q_\pi - 0)$, i.e.,

$$[6] \quad \Delta q_C = \Delta q_\sigma + \Delta q_\pi + \Delta q^0_{C\alpha}$$

where

$$[7] \quad \Delta q^0_{C\alpha} = q^0_{C\alpha} - q^0_C = -27.4 \text{ me}$$

is the difference in net charge between the ethylene and the ethane carbon atoms. The ethylene net charge ($q^0_{C\alpha}$), of course, is used in the evaluation of C=C double bonds, i.e.,

$$\epsilon_{C=C} = \epsilon^0_{C=C} + a_{C=C}\Sigma\Delta q_{C\alpha}$$

where $\Delta q_{C\alpha} = q_{C\alpha} - q^0_{C\alpha}$ refers to sp^2 carbons, relative to ethylene. The CH and CC simple bonds, however, *including those formed by the* sp^2 *carbon atoms* (identified as α-carbons), are expressed with reference to the ethane CH and CC bond energies. This implies that the charge increments $\Delta q_H = q_H - q^0_H$ and $\Delta q_C = q_C - q^0_C$ are also to be taken relative to the ethane net charges, namely, $q^0_C = 35.1$ me for carbon.

The hydrogen net charges appear in the final result (from eq. [3]) as the sum $\Sigma\Delta q_H$. The calculation of $\Sigma\Delta q_H = \Sigma q_H - 2nq^0_H$ is straightforward. From charge normalization, i.e., $\Sigma q_H = -(\Sigma q_{C\alpha} + \Sigma q_{C\neq\alpha})$, it follows that

$$[8] \quad \Sigma\Delta q_H = -(\Sigma\Delta q_{C\neq\alpha} + \Sigma\Delta q_{C\alpha}) - 2\Delta q^0_{C\alpha} + nq^0_H$$

where *n* is the number of C atoms in the C_nH_{2n} alkene. In this fashion, it becomes possible to express ΔE^*_a (eq. [3]) by means of a general formula requiring only the charges of the carbon atoms.

General formula for C_nH_{2n} alkenes

The sum of the $\Sigma_i\Sigma_j a_{ij}\Delta q_i$ terms (eq. [3]) referring to CC bonds gives

$$\sum_i^{\text{CC bonds}}\sum_j a_{ij}\Delta q_i = a_{CC}\Sigma N_{CC}\Delta q_{C\neq\alpha} + a_{C=C}\Sigma\Delta q_{C\alpha} + a_{C\alpha C}\Sigma N_{C\alpha C}\Delta q_C$$

Similarly, we find for the CH bonds that

$$\sum_i^{\text{CH bonds}}\sum_j a_{ij}\Delta q_i = 4a_{CH}\Sigma\Delta q_{C\neq\alpha} - a_{CH}\Sigma N_{CC}\Delta q_{C\neq\alpha} + 2a_{C\alpha H}\Sigma\Delta q_C - a_{C\alpha H}\Sigma N_{C\alpha C}\Delta q_C + a_{HC}\Sigma\Delta q_H$$

A distinction is made between CC and CH bonds involving sp^3 carbons (≠ α, described by a_{CC} and a_{CH}) and bonds formed by sp^2 carbons (α-C, described by $a_{C\alpha C}$ and $a_{C\alpha H}$, respectively). Similarly, $N_{C\alpha C}$ is the number of CC bonds formed by α carbons with

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

sp^3 C atoms and N_{CC} is the number of CC bonds formed by sp^3 carbon atoms. Using now eq. [8], the final sum over all the CC and CH bonds becomes

$$[9]\quad \Sigma_i\Sigma_j a_{ij}\Delta q_i = \lambda_1 \Sigma N_{CC}\Delta q_{C\neq\alpha} + \lambda_2 \Sigma \Delta q_{C\neq\alpha} + n a_{HC} q_H^0 + (a_{C=C} - a_{HC})\,\Sigma\Delta q_{C\alpha} + (a_{C\alpha C} - a_{C\alpha H})\sum^{\alpha} N_{C\alpha C}\Delta q_C + 2a_{C\alpha H}\sum^{\alpha}\Delta q_C - 2a_{HC}\Delta q_{C\alpha}^0$$

where

$$\lambda_1 = a_{CC} - a_{CH} = -0.383 \text{ au}$$

$$\lambda_2 = 4a_{CH} - a_{HC} = -0.569 \text{ au}$$

The $\lambda_1 \Sigma N_{CC}\Delta q_{C\neq\alpha} + \lambda_2 \Sigma \Delta q_{C\neq\alpha} + n a_{HC} q_H^0$ part of eq. [9] is well known from the study of saturated hydrocarbons (1). By means of the charge – ^{13}C nmr shift correlation $\Delta q_C = -0.148\delta_C$ me (1) we can write this part in terms of nmr shifts relative to ethane (taken at ~5.8 ppm from TMS), i.e. (with 1 au = 627.51 kcal mol^{-1}), $0.0356\Sigma N_{CC}\delta_C + 0.0529\Sigma\delta_C + 7.393n$ kcal mol^{-1}. The term in $\Sigma\Delta q_{C\alpha}$ creates no problem because the charges are expressed with respect to ethylene and can be easily resolved. The terms in Δq_C, however, which are for vinyl carbons with respect to that of ethane, require special attention.

Let us first consider the term $F = (a_{C\alpha C} - a_{C\alpha H})\sum^{\alpha} N_{C\alpha C}\Delta q_C$ of eq. [9]. The difference $a_{C\alpha C} - a_{C\alpha H}$ is λ_1^σ or λ_1^π, depending on whether it relates to σ or to π charge variations at the vinyl carbons. Of course, λ_1^σ is simply the λ_1 value indicated above and $\lambda_1^\pi = a_{C\alpha C}^\pi - a_{C\alpha H}^\pi = -0.379$ au is deduced from Table 1. Instead of using net charges, $q = Z - N$, we begin this calculation in terms of the numbers of electrons, remembering that $\Delta N = -\Delta q$. The $\sigma - \pi$ separation gives

$$F = -\lambda_1^\sigma \sum^{\alpha} N_{C\alpha C}\,(N_{\sigma v} - N_{\sigma e}) - \lambda_1^\pi \sum^{\alpha} N_{C\alpha C}(N_{\pi v} - N_{\pi e})$$

where the subscripts v and e stand for vinyl and ethane carbon, respectively. The following transformations are self-explanatory, remembering that σ net charges are expressed with respect to 5, viz. 6 e for vinyl and sp^3 carbons, respectively, while π net charges are expressed relative to 1 electron.

$$\begin{aligned}
F &= -\lambda_1^\sigma \sum^{\alpha} N_{C\alpha C}(N_{\sigma v} - 5 - 1 + 6 - N_{\sigma e}) - \lambda_1^\pi \sum^{\alpha} N_{C\alpha C}(N_{\pi v} - 1 + 1 - 0)\\
&= -\lambda_1^\sigma \sum^{\alpha} N_{C\alpha C}(-q_\sigma - 1 + q_C^0) - \lambda_1^\pi \sum^{\alpha} N_{C\alpha C}(-q_\pi + 1)\\
&= -\lambda_1^\sigma \sum^{\alpha} N_{C\alpha C}(-q_\sigma + q_{C\alpha}^0 - q_{C\alpha}^0 + q_C^0 - 1) - \lambda_1^\pi \sum^{\alpha} N_{C\alpha C}(-q_\pi + 1)\\
&= -\lambda_1^\sigma \sum^{\alpha} N_{C\alpha C}(-\Delta q_\sigma - \Delta q_{C\alpha}^0 - 1) - \lambda_1^\pi \sum^{\alpha} N_{C\alpha C}(-\Delta q_\pi + 1)\\
&= \lambda_1^\sigma \sum^{\alpha} N_{C\alpha C}\Delta q_\sigma + \lambda_1^\pi \sum^{\alpha} N_{C\alpha C}\Delta q_\pi + (\lambda_1^\sigma \Delta q_{C\alpha}^0 + \lambda_1^\sigma - \lambda_1^\pi)\sum^{\alpha} N_{C\alpha C}
\end{aligned}$$

The first two terms of this last expression combine to give $\lambda_{1_\alpha}\Sigma N_{C\alpha C}\Delta q_{C\alpha}$, with λ_{1_α} defined as follows, from eq. [5],

$$[10]\quad \lambda_{1_\alpha} = (m\lambda_1^\sigma + \lambda_1^\pi)/(m+1)$$

On the other hand, using the results given in Table 1, it is found that

$$(\lambda_1^\sigma \Delta q_{C\alpha}^0 + \lambda_1^\sigma - \lambda_1^\pi)\sum^{\alpha} N_{C\alpha C} = 4.19 \sum^{\alpha} N_{C\alpha C} \text{ kcal mol}^{-1}$$

With these results, we can now write eq. [9] as follows, in kcal mol^{-1},

$$[11]\quad \Sigma_i\Sigma_j a_{ij}\Delta q_i = 0.0356\,\Sigma N_{CC}\delta_C + 0.0529\,\Sigma\delta_C + 7.393n + (a_{C=C} - a_{HC})\,\Sigma\Delta q_{C\alpha} + \lambda_{1_\alpha}\sum^{\alpha} N_{C\alpha C}\Delta q_{C\alpha} + 4.19\sum^{\alpha} N_{C\alpha C} + 2a_{C\alpha H}\sum^{\alpha}\Delta q_C - 2a_{HC}\Delta q_{C\alpha}^0$$

The calculation of $(a_{C\alpha C} - a_{C\alpha H})\sum^{\alpha} N_{C\alpha C}\Delta q_C$ has presented no difficulty because λ_1^σ and λ_1^π are constants, depending only upon molecular geometry and the location of the centers of charge. The important point is that the derivatives $(\partial E_i^{vs}/\partial N_i)^0$ which are part of the a_{ij}'s (eq. [4]) cancel exactly in λ_1^σ and λ_1^π. This is no longer the case with the $2a_{C\alpha H}\sum^{\alpha}\Delta q_C$ term of eq. [11].

The $\sigma-\pi$ separation of $a_{C\alpha H}\sum^{\alpha}\Delta q_C$ gives, by means of eq. [6],

$$a_{C\alpha H}^\sigma \sum^{\alpha}\Delta q_\sigma + a_{C\alpha H}^\pi \sum^{\alpha}\Delta q_\pi + 2\langle a_{C\alpha H}\rangle \Delta q_{C\alpha}^0$$

The first two terms are now well defined with reference to ethylene, and enter the final sum as $2a_{C\alpha H}^\sigma\sum^{\alpha}\Delta q_\sigma + 2a_{C\alpha H}^\pi\sum^{\alpha}\Delta q_\pi$. The $a_{C\alpha H}^\sigma$ and $a_{C\alpha H}^\pi$ values can be calculated from eq. [4] and are indicated in Table 1. The $\langle a_{C\alpha H}\rangle$ parameter, however, represented here loosely as an appropriately chosen average, remains to be clarified. On the physical side, $\langle a_{C\alpha H}\rangle \Delta q_{C\alpha}^0$ appears to describe the gain

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

in stability of a CH bond in going from ethane to ethylene due to (*i*) an increase in electron population of 27.4 me and (*ii*) to the shift of the center of charge (by ~0.04 Å along the C=C axis) for 1 electron, which destabilizes the CH bond by $\sim(3/7)0.529[(1/1.08) - (1/1.10)]$ au $\simeq$ 2.395 kcal mol^{-1}. As regards the gain in electronic charge in going from ethane to ethylene, the appropriate a_{CH} values are (from Table 1) −0.394 au for ethane and −0.335 au for ethylene. Tentatively taking the average of these values, we obtain in this approximation that

$$[12]\quad \langle a_{C\alpha H}\rangle \Delta q^0_{C\alpha} = [(a_{CH} + a^{\sigma}_{C\alpha H})/2]\Delta q^0_{C\alpha} - (3/7)0.529[(1/1.08) - (1/1.10)] \text{ au}$$
$$= 3.872 \text{ kcal mol}^{-1}$$

The validity of this estimate can be evaluated as follows. The 3.872 term represents the gain in stability of a CH bond due to the change C(sp^3) → C(sp^2) from ethane to ethylene. Leaving the ethane-H charge as reference for the $a_{HC}\Delta q_H$ part, the new ϵ^0_{CH} (sp^2-H) reference energy becomes 106.806 + 3.872 = 110.68 kcal mol^{-1}. Using now the ethylene-H net charge, −3.85 me (corresponding to its C charge of 7.7 me), i.e., Δq_H = 7.85 me, it results that $a_{HC}\Delta q_H$ = −4.96 and ϵ_{CH} = 105.72 kcal mol^{-1}. Four of these CH bonds plus the theoretical $\epsilon^0_{C=C}$ = 139.27 double bond contribution lead to ΔE^*_a(ethylene) = 562.15 kcal mol^{-1}, which compares favorably with its experimental counterpart, 562.22 kcal mol^{-1}. Similarly, remembering that the gain for a C(sp^2)—C(sp^3) bond is 4.19 kcal mol^{-1} larger than that for a C(sp^2)—H bond, i.e., $\langle a_{C\alpha C}\rangle \Delta q^0_{C\alpha} = \langle a_{C\alpha H}\rangle \Delta q^0_{C\alpha}$ + 4.19 kcal mol^{-1}, we can define a new ϵ^0_{CC} (sp^2–sp^3) reference as 69.633 + 3.872 + 4.19 = 77.70 kcal mol^{-1}, where the Δq_C's are taken relative to ethylene and ethane for the sp^2 and sp^3 carbons, respectively.

The $\langle a_{C\alpha H}\rangle \Delta q^0_{C\alpha}$ term appears twice for $a_{C\alpha H}\overset{\alpha}{\Sigma}\Delta q_C$ which, in turn, enters eq. [11] with a factor 2. Hence, taking now also into account the $-2a_{HC}\Delta q^0_{C\alpha}$ term of eq. [11], the constant term appearing in this equation is

$$[13]\quad 4\langle a_{C\alpha H}\rangle \Delta q^0_{C\alpha} - 2a_{HC}\Delta q^0_{C\alpha} = -19.14 \text{ kcal mol}^{-1}$$

In comparisons with experimental atomization energies deduced from eq. [1], this result, combined with the theoretical $\epsilon^0_{C=C}$ = 139.27 kcal mol^{-1} energy, leads to a systematic deviation of ~0.08 kcal mol^{-1}. Of course, it is not possible to decide which of eq. [13] or $\epsilon^0_{C=C}$ is "wrong" because each term appears once for a C=C double bond system. At this level of accuracy, however, this question is academic.[1] Tentatively, assuming the $\epsilon^0_{C=C}$ value to be correct, we modify the result indicated in eq. [13] from −19.14 to −19.06 kcal mol^{-1}. Incidentally, it is noteworthy that the location of the π center of charge which has been postulated affects both the result given in eq. [13] and the 4.19 kcal mol^{-1} coefficient of $\overset{\alpha}{\Sigma}N_{C\alpha C}$. Moreover, it enters the calculation of $a_{C=C}$. This ~0.04 Å parameter satisfies thus three numerical values which play important roles in the final energy formula.[2]

This analysis of the $a^{\sigma}_{C\alpha H}\overset{\alpha}{\Sigma}\Delta q_C$ term still leaves us with $2a^{\sigma}_{C\alpha H}\overset{\alpha}{\Sigma}\Delta q_\sigma + 2a^{\pi}_{C\alpha H}\overset{\alpha}{\Sigma}\Delta q_\pi$ which are part of eq. [11]. Combining now these terms with $(a_{C=C} - a_{HC})\overset{\alpha}{\Sigma}\Delta q_{C\alpha}$ which is easily separated to give $(a^{\sigma}_{C=C} - a_{HC})\overset{\alpha}{\Sigma}\Delta q_\sigma + (a^{\pi}_{C=C} - a_{HC})\overset{\alpha}{\Sigma}\Delta q_\pi$, we define

$$\lambda^{\sigma}_3 = a^{\sigma}_{C=C} + 2a^{\sigma}_{C\alpha H} - a_{HC} = -0.465 \text{ au}$$
$$\lambda^{\pi}_3 = a^{\pi}_{C=C} + 2a^{\pi}_{C\alpha H} - a_{HC} = -0.347 \text{ au}$$

and obtain from eq. [5] that

$$[14]\quad \lambda_3 = (m\lambda^{\sigma}_3 + \lambda^{\pi}_3)/(m + 1)$$

In this manner, eq. [11] reduces to

$$[15]\quad \Sigma_i\Sigma_j a_{ij}\Delta q_i = 0.0356\Sigma N_{CC}\delta_C + 0.0529\Sigma\delta_C + \lambda_{1_\alpha}\overset{\alpha}{\Sigma}N_{C\alpha C}\Delta q_{C\alpha}$$
$$+ \lambda_3\Sigma\Delta q_{C\alpha} + 4.19\overset{\alpha}{\Sigma}N_{C\alpha C} + 7.393n - 19.06 \text{ kcal mol}^{-1}$$

The important point is that the $\Delta q_{C\alpha}$'s are expressed with respect to the proper reference, which is ethylene, in terms of increments in total (σ + π) net charge. Moreover, the participation of σ and π charges is also accounted for in eq. [15].

The final step consists in translating this formula into an equivalent one in which the $\Delta q_{C\alpha}$'s are expressed in terms of ^{13}C nmr shifts relative to ethylene. Recent studies (4, 5) indicate that, indeed, this is possible. If we write for vinyl carbons

$$\delta_{C\alpha} = k\Delta q_{C\alpha}$$

[1]Moreover, it must be considered that this type of uncertainty may possibly be due to a systematic error in the estimates of the zero-point plus heat content energies which are described further below.

[2]Overlapping *p* electrons forming a π bond are expected, in keeping with current views, to displace their respective centers of charge inwards, as bonding orbitals tend to collect the charge between the bonded atoms, whereas populated corresponding antibonding orbitals would have the opposite effect. It is, therefore, fair to say that the proposed model is certainly in qualitative accord with the accepted understanding of π bonds. It remains that the shift of ~0.04 Å which is assumed here is a product of trial and error analysis. Its appropriateness can be illustrated as follows. If no shift is considered (which would clearly represent an arbitrary assumption), the coefficient $\lambda^{\sigma}_1\Delta q^0_{C\alpha} + \lambda^{\sigma}_1 - \lambda^{\pi}_1$ of $\overset{\alpha}{\Sigma}N_{C\alpha C}$ and the constant term (eq. [13]) would amount to 6.59 and −9.56 kcal mol^{-1}, respectively. With a shift of 0.06, instead of 0.04 Å, these two parameters would become 2.87 and −23.80 kcal mol^{-1}, respectively. These examples and inspection of eq. [16] indicate that any choice other than ~0.04 Å leads to two distinct and important sources of systematic errors. While, of course, we would prefer to obtain this result from strict theoretical considerations, it is obvious from the present calculations that there is not much room left for error in locating the "effective" center of charge of *p* electrons engaged in a vinyl π bond.

TABLE 2. Zero-point and $H_T - H_0$ energies of selected olefins (kcal mol^{-1})[a]

Molecule	ZPE (References)	$H_T - H_0$
Ethene	30.83 (8)	2.53
	30.54 (9)	
Propene	48.58 (10)	3.24
1-Butene	65.62 (11)	4.11
2-Butene *cis*	65.97 (10)	3.94
2-Butene *trans*	65.51 (10)	4.19
Isobutene	65.57 (10, 12)	4.08
	65.41 (13)	

[a]The $H_T - H_0$ values are taken from ref. 7. The ZPE values are deduced from vibrational analyses given, references in parentheses.

and use the relationships $\Delta q_\sigma = m\Delta q_\pi$ and $\Delta q_{C\alpha} = \Delta q_\sigma + \Delta q_\pi = (m + 1)\Delta q_\pi$ it follows that

$$d\delta_{C\alpha}/dq_\alpha = k(m + 1)$$

Consequently, it is (4)

$$\Delta q_{C\alpha} = [(m + 1)/(d\delta_{C\alpha}/dq_\pi)]\delta_{C\alpha}$$

It is now possible to express λ_{I_α} (eq. [10]) and λ_3 (eq. [14]) in kcal mol^{-1} ppm^{-1} units, using also the conversion factor 1 au = 627.51 kcal mol^{-1}. In this manner we obtain

$$\lambda_{I_\alpha} = (m\lambda_I^\sigma + \lambda_I^\pi)627.51/(d\delta_{C\alpha}/dq_\pi) \text{ kcal mol}^{-1} \text{ ppm}^{-1}$$

$$\lambda_3 = (m\lambda_3^\sigma + \lambda_3^\pi)627.51/(d\delta_{C\alpha}/dq_\pi) \text{ kcal mol}^{-1} \text{ ppm}^{-1}$$

where λ_I^σ, λ_I^π, λ_3^σ, and λ_3^π are in atomic units and the derivative in ppm/electron. Within the limits of validity of the charge shift relationship, eq. [15] becomes

[16] $$\Sigma_i\Sigma_j a_{ij}\Delta q_i = 0.0356\Sigma N_{CC}\delta_C + 0.0529\Sigma\delta_C + \lambda_{I_\alpha}\Sigma N_{C\alpha C}\delta_{C\alpha} + \lambda_3\Sigma\delta_{C\alpha} + 4.19\Sigma N_{C\alpha C} + 7.393n - 19.06 \text{ kcal mol}^{-1}$$

The real difficulty rests with the "true" values of m and $d\delta_{C\alpha}/dq_\pi$ because atomic charges calculated from Mulliken's scheme are strongly basis set dependent, particularly as regards σ charges. Charge separations are invariably larger when increasingly larger basis sets are used in *ab initio* calculations, to the point that unrealistic results are obtained (6). Charge analyses carried out at the STO-3G level (5) suggest a value of ~250 ppm/e for the $d\delta_{C\alpha}/dq_\pi$ slope, which is probably also a result of slightly overestimated π charges. In selecting tentatively $d\delta_{C\alpha}/dq_\pi \simeq 300$ ppm/e for vinyl C atoms, we regard this value only as a reasonable estimate but cannot attach any precision to it. This holds also for the $m \simeq -0.955$ value which is tentatively selected. With these premises, we deduce $\lambda_{I_\alpha} \simeq -0.028$ and $\lambda_3 \simeq 0.20$ kcal mol^{-1} ppm^{-1}, but it is clear that similar values can also be obtained from alternate choices for m and $d\delta_{C\alpha}/dq_\pi$. The important point is that λ_{I_α} is small and negative, whereas λ_3 is relatively large and positive. The approximate validity of our rough estimates for m and $d\delta_{C\alpha}/dq_\pi$ is best illustrated by comparisons with experimental results. Indeed, using $\lambda_{I_\alpha} = -0.028$ and $\lambda_3 = 0.20$ kcal mol^{-1} ppm^{-1} in applications of eq. [16], it turns out that ethylene, 1-alkenes, *trans*-alkenes, and tetramethylethylene are calculated with an average error of ~0.2 kcal mol^{-1}. Numerical applications indicate that the following simplified expression (eq. [17]), in which $\lambda_{I_\alpha} = 0$, gives equally satisfactory results, within the limits of uncertainties set by the precision of the experimental data. This simplification seems reasonable, considering the uncertainties associated with λ_{I_α} and λ_3.

[17] $$\Sigma_i\Sigma_j a_{ij}\Delta q_i = 0.0356\Sigma N_{CC}\delta_{C\neq\alpha} + 0.0529\Sigma\delta_{C\neq\alpha} + 0.18\Sigma\delta_{C\alpha} + 7.393n + 4.19\Sigma N_{C\alpha C} - 19.06 \text{ kcal mol}^{-1}$$

This is the basic formula which is used in the forthcoming comparisons with experimental results.

Comparison with experimental energies

The atomization energies of olefins can now be readily deduced from their ^{13}C nmr spectra, using eqs. [3] and [17]. The calculation of the corresponding enthalpies of formation, however, also requires a realistic estimate of zero-point and heat-content energies, i.e., of ZPE + $H_T - H_0$, for use in eq. [1]. Spectroscopic information is unfortunately scarce for this class of compounds. The appropriate ZPE's, calculated in the harmonic oscillator approximation (ZPE = $\Sigma_i h\nu_i/2$) from literature data are indicated in Table 2. Fortunately, however, we can profit from a detailed study on a representative variety of saturated hydrocarbons indicating, namely, that one CH_2 added to an alkyl group increases ZPE + $H_T - H_0$ by 18.213 kcal mol^{-1} whereas branching lowers this energy by 0.343 kcal mol^{-1} (2). (Situations of extreme steric crowding, such as those arising with the presence of two *tert*-butyl groups attached to a same carbon atom are not represented by these rules.) It seems reasonable to assume a similar pattern for the normal and branched ethylenic hydrocarbons. This approximation is expressed by eq. [18].

[18] $$\text{ZPE} + H_T - H_0 \simeq 33.35 + 18.213(n - 2) - 0.343n_{\text{branch}}$$

The experimental results given in Table 2 certainly support eq. [18] although, evidently, additional vibrational energy data would

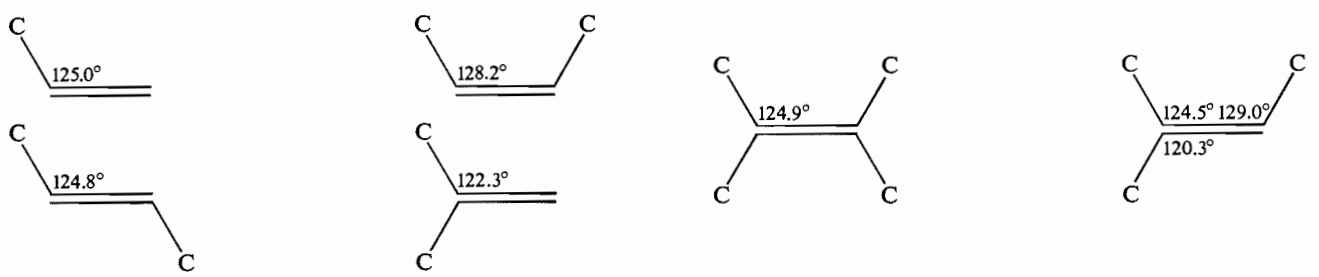
be desirable. It is noteworthy, in any case, that numerous enthalpies of formation calculated from the appropriate ΔE_a^* atomization energies (eqs. [3] and [13]), and eqs. [1] and [18], are in satisfactory agreement with their experimental counterparts, as indicated in Table 3.

The results deduced from eq. [17] concern only monoalkyl-, *trans*-dialkyl-substituted ethylenes and tetramethylethylene. They agree within ~0.2 kcal mol^{-1} (average deviation) with their experimental counterparts. Before proceeding with the study of *cis* and *gem* disubstituted and of trialkyl-substituted ethylenes, it becomes important to examine the geometries of the compounds investigated here. *Ab initio* calculations (5) indicate the results given below.



These results correspond well to what one would anticipate in a first place and it appears reasonable to assume that the hybridization of the sp^2 carbons is the same (or nearly so) in all the compounds described by eq. [17]. Indeed, a change in local geometry about the vinyl carbons would cause an additional difficulty linked to the $\sigma-\pi$ charge separation, affecting the relationship (4) $q_\sigma = mq_\pi$ + constant. This point must be considered in the evaluation of *cis* olefins. If we write $q_\sigma^{cis} = mq_\pi^{cis} + c^{cis}$ for the latter and describe their Δq_σ and Δq_π charge increments with respect to reference charges taken from the relationship $q_\sigma^{trans} = mq_\pi^{trans} + c^{trans}$ (which describes *trans*- or 1-olefins), a nonzero difference $c^{cis} - c^{trans}$ introduces a modification in the coefficient of $\Sigma N_{C\alpha C}$ and in the constant term of eq. [17]. Small effects of this sort resist their theoretical evaluation because $c^{cis} - c^{trans}$ cannot be evaluated in a reliable manner. On the other hand, an empirical assessment is presently also difficult because it is not known how accurately eq. [18] approximates the ZPE + $H_T - H_0$ values of *cis* olefins. It appears, however, that the approximation

[19] $\Sigma_i\Sigma_j a_{ij}\Delta q_i \simeq 0.0356\Sigma N_{CC}\delta_{C\neq\alpha} + 0.0529\Sigma\delta_{C\neq\alpha} + 0.18\Sigma\delta_{C\alpha} + 7.393n + 4.0\Sigma N_{C\alpha C} - 18.12$ kcal mol^{-1}

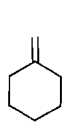
combined with eqs. [18] and [1] yields satisfactory standard enthalpies of formation for *cis* olefins. The results for trisubstituted ethylenes are deduced in the same manner (Table 3). The overall average deviation (0.30 kcal mol^{-1}) is certainly acceptable and it appears fair to conclude that, in spite of some difficulties and uncertainties, the charge dependence of the bond energy contributions which is predicted by theory has been verified at a very demanding level, that of experimental accuracy.

Conclusions

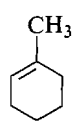
In a first place it is appropriate to assess the significance of the final results used in comparisons between theory and experiment. For saturated hydrocarbons (1), the "experimental" ΔE_a^* results were deduced entirely from experimental data, namely, the ZPE, $H_T - H_0$, and ΔH_f^0 energies required for solving eq. [1]. Nonbonded interaction energies, whose sums turn out to be small at the molecular level, were also estimated, thus permitting comparisons between theory and experiment at the best possible level (average deviation = 0.16 kcal mol^{-1}). It has appeared that *differences in nonbonded interactions cannot be made responsible for energy differences between isomers*. An approximation (2) not requiring the explicit calculation of nonbonded interactions suffers only a small loss in precision (average deviation = 0.23 kcal mol^{-1}). This approximation is exploited in ref. 2 leading eventually to simple rules for evaluating reliable ZPE + $H_T - H_0$ energies in hydrocarbons, except in situations of extreme steric crowding. Application of these rules to ethylenic compounds, for which only scarce spectroscopic information is presently available, enables a reasonable evaluation of numerous ΔE_a^* energies of olefins from their enthalpies of formation and "constructed" ZPE + $H_T - H_0$ energies. The quality of the comparisons offered for the olefins (Table 3) should be judged accordingly, also keeping in mind that nonbonded energies were not calculated explicitly. Results derived from the group additivity scheme for the estimation of thermochemical properties, as originally proposed by Benson and Buss (17), are also indicated. The quality of this additivity scheme certainly justifies Benson's statement that sufficient data are available for hydrocarbons to render suspect any data which deviate from the value predicted by the scheme, by more than ~1 kcal mol^{-1} in ΔH_f^0. It is noteworthy that in the four cases showing the largest discrepancies (0.71–1.26 kcal mol^{-1}) between our theoretical ΔH_f^0's and their experimental counterparts, Benson's values are, indeed, very similar to the present theoretical results. Under these circumstances it appears fair to conclude that the overall agreement (0.30 kcal mol^{-1} average deviation) between theory and experiment is similar in quality to that relating to the saturated hydrocarbons.

The $\lambda_1\Sigma N_{CC}\Delta q_C + \lambda_2\Sigma\Delta q_C$ term, which plays the leading role in the calculation of saturated hydrocarbons and differentiates isomers from one another, appears in the calculation of any molecule containing alkyl substituents. Its precise evaluation is, therefore, most important in all cases involving large alkyl parts. In kcal mol^{-1} ppm^{-1} units, both λ_1 and λ_2 are positive quantities. Since ^{13}C shifts of saturated hydrocarbon-C atoms are farther downfield as carbon atoms are closer to electroneutrality (i.e., have gained electronic charge), we can express the overall conclusion as a thumb rule: "*in comparisons between isomers, the more stable compound is one whose carbon skeleton best approaches electroneutrality, i.e., gains electronic charge from the hydrogen atoms, which is reflected by larger (downfield)* δ_C *values*". This, of course, is the echo of a conclusion reached earlier (1–3) describing alkyl hydrogen atoms as electron reservoirs releasing electrons toward carbon in isomerizations leading to more stable compounds. On the other hand, the fact that λ_3 is positive (as it is the case for λ_1 and λ_2) indicates that *downfield* ^{13}C *shifts at* sp^2 *carbons also reflect in a gain in molecular stability*. Contrasting with sp^3 carbons, however, a downfield shift observed for a sp^2 carbon indicates a decrease of its total electron population. Now we know (4) that such a decrease consists in a lowering in π population prevailing over an almost equally important increase in σ population. *The gain in stability accompanying downfield shifts at* sp^2 *carbons is thus traced back to a prevailing role of* σ *charges,* whose population increases, *in promoting the stability of an alkene molecule.*

Finally, *the 4.19* $\Sigma N_{C\alpha C}$ *term indicates an* a priori *gain in stability of 4.19 kcal mol*$^{-1}$ *for each CC bond formed by a vinyl carbon, in replacement for a CH bond*. This aspect is, of course, included in the calculations presented in Table 3. It appears, however, that *this gain in stability is somewhat reduced by electron redistributions*. For example, in going from 2-Me-1-pentene ($\Sigma N_{C\alpha C} = 2$) to 3-Me-1-pentene ($\Sigma N_{C\alpha C} = 1$), the decrease in ΔE_a^* is not 4.19 but only 2.6 kcal mol^{-1} because of compensating electronic rearrangements, but the leading term is clearly given by $4.19\Sigma N_{C\alpha C}$. On these grounds it is easy to predict that methylenecyclohexane ($\Sigma N_{C\alpha C} = 2$) is less stable than 1-methylcyclohexene ($\Sigma N_{C\alpha C} = 3$).



Methylenecyclohexane
ΔH_f^0(298.15, gas) = −7.2 kcal mol^{-1} (15). Calcd. (15) −8.1 kcal mol^{-1}.

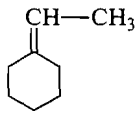


1-Methylcyclohexene
ΔH_f^0(298.15, gas) = −10.0 kcal mol^{-1} (15). Calcd. (15) −9.7 kcal mol^{-1}.

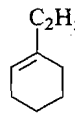
This rationale is relevant in the discussion of the relative thermochemical stabilities of *exo*- vs. *endo*-cyclic double bonds. Of course, the fact alone that a double bond is exocyclic does

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

not necessarily imply a loss in stability. For example, ethylidenecyclohexane and 1-ethylcyclohexene, for which $\Sigma N_{C\alpha C} = 3$ in both cases, are similar as regards their thermochemical stabilities.



Ethylidenecyclohexane
ΔH_f^0(298.15, gas) = −14.7 kcal mol^{-1} (18).



1-Ethylcyclohexene
ΔH_f^0(298.15, gas) = −15.0 kcal mol^{-1} (15). Calcd. (15) −14.5 kcal mol^{-1}.

These theoretical expectations, based on the $4.19\Sigma N_{C\alpha C}$ term, fully confirm similar views expressed by Fuchs and Peacock (18), suggesting that the cyclic compounds differ in double bond substitution rather than conformational stability. These aspects are currently under detailed investigation.

It is certainly pleasing that this insight is gained from basic and clearly identified physical concepts, namely from a reduction of the problem of molecular energies to its electrostatic aspects, featuring the role of local charges (1). It is also clear, however, that efforts in the study of atomic charges are worth pursuing because, so far, we had to carry on with barely the minimum of information as regards sp^2 carbons.

Appendix I
Glossary

ΔE_a^*	Atomization energy of a molecule in its vibrationless state at 0 K
$\Delta H_f^0(A_i)$	Standard enthalpy of formation of atom A_i: ΔH_f^0(C) = 170.89, ΔH_f^0(H) = 52.09 kcal mol^{-1} (19)
ΔH_f^0	Standard enthalpy of formation of the molecule (gas, 298.15 K)
ZPE	Zero-point energy
$H_T - H_0$	Heat content
K_i^{at}	Constant for an isolated atom = total/nuclear-electronic energy. $K_H^{at} = 1/2$, $K_C^{at} = 0.4276$ (20)
K_i^{mol}	Constant for an atom in a molecule, similar to K_i^{at}. $K_H^{mol} = 1/2$, $K_C^{mol} = 0.4287$ (20)
K_{Av}^{mol}	Molecular average of the K_i's, approximated as 3/7 (refs. 1, 20, and references therein)
ν_i	Number of atoms attached to atom i
$(\partial E_i^{vs}/\partial N_i)^0$	Derivative of the total energy of atom i, considered in its valence state, with respect to its electron population
Z_i^{eff}	Effective nuclear charge of atom i, e.g., 1 for H and 4 for carbon (ref. 1 and references therein)
$\langle r_{ij}^{-1}\rangle^0$	Average inverse distance between nucleus i and the center of charge of the N_j electrons allocated to atom j

Appendix II

The total (nuclear–electronic and nuclear–nuclear) potential energies V(C, mol) were derived from Hartree–Fock calculations at the $(9s5p|6s) \rightarrow [5s3p|3s]$ level for methane (−88.5540), ethane (−88.4670), and ethylene (−88.4168 au) as well as the nuclear potential energy V_{ne}(C, at) = −87.9315 au for the isolated carbon atom. From the equation (1)

$$V_{ne}(\text{C, at}) - V(\text{C, mol}) = Z_C \Sigma_j (\partial \epsilon_{Cj}/\partial Z_C)$$

in which Z_C is the nuclear charge of carbon and ϵ_{Cj} the energy associated with the bond C forms with atom j, we obtain $\partial \epsilon_{CH}/\partial Z_C \simeq 0.026$ au. Using this result and the V(C, mol)'s given above, we calculate $\partial \epsilon_{CC}/\partial Z_C$ for the ethane and the ethylene carbon–carbon bonds. In this fashion we obtain from the equation (1)

$$\epsilon_{ij} = K_i^{mol} Z_i \frac{\partial \epsilon_{ij}}{\partial Z_i} + K_j^{mol} Z_j \frac{\partial \epsilon_{ij}}{\partial Z_j} + (K_i^{at} - K_i^{mol})\, V_{ne}(\text{at. } i)/\nu_i + (K_j^{at} - K_j^{mol})\, V_{ne}(\text{at. } j)/\nu_j$$

that ϵ_{CC} = 66.7 for ethane and 133.7 kcal mol^{-1} for ethylene, i.e., a ratio of 1:2.00. While this basis cannot match experimental accuracy, it remains that comparisons on a relative scale can be regarded as being meaningful. Using, therefore, the value 69.633 kcal mol^{-1} determined earlier (1) for ethane we can estimate ϵ_{CC} = 139.27 kcal mol^{-1} for the ethylene CC bond. A rescaling of the potential and Hartree–Fock energies along the lines given in ref. 1 gives $\partial \epsilon_{C=C}/\partial Z_C \simeq 0.0305$ au and $\epsilon_{C=C}$ = 139.20 kcal mol^{-1}.

Appendix III

The ethylene-C net charge, $q_{C\alpha}^0$, is best evaluated using tetramethylethylene as a starter. Its methyl-C nmr shift is 14.3 ppm from ethane, giving (1) $\Delta q_C = -0.148\delta_C = -2.12$ me relative to the ethane carbon atom, i.e., $q_C = 35.1 - 2.12 = 32.98$ me. From the correlation (described in ref. 3, Appendix

II) between q_H and q_C in methyl groups, q_H is estimated at -12.29 me. The net charge of the methyl group is, therefore, -3.89 me and that of the sp^2 carbon is 7.77 me. Assuming $m = -0.955$ and $d\delta_{C\alpha}/dq_\pi \simeq 300$ ppm/e, as described in the text, we find $\Delta q_{C\alpha} \simeq 0.15\delta_{C\alpha}$ me. Tetramethylethylene (δ 123.2 ppm from TMS) and ethylene (δ 122.8 ppm from TMS) differ only by ~0.4 ppm, so that the difference in net charge is ~0.06 me, ethylene being thus only marginally electron-richer than tetramethylethylene. The final estimate is $q^0_{C\alpha} \simeq 7.7$ me and, of course, $q_H \simeq -3.85$ me.

Structural studies of organoboron compounds. XIII.[1] Preparation and crystal and molecular structure of bis[(salicylaldoximato(2−))phenylboron]

STEVEN J. RETTIG AND JAMES TROTTER

Department of Chemistry, University of British Columbia, 2036 Main Mall, Vancouver, B.C., Canada, V6T 1Y6

Received July 6, 1982

STEVEN J. RETTIG and JAMES TROTTER. Can. J. Chem. **61**, 206 (1983).

The reaction of $(C_6H_5)_2BOH$ with salicylaldoxime yielded $[(C_7H_5NO_2)BC_6H_5]_2$ via a boron−carbon bond cleavage reaction. Crystals of bis[(salicylaldoximato(2−))phenylboron] are triclinic, a = 9.219(1), b = 11.240(1), c = 12.086(1) Å, α = 100.682(7), β = 112.224(6), γ = 92.189(7)°, Z = 2, space group $P\bar{1}$. The structure was solved by direct methods and was refined by full-matrix least-squares procedures to R = 0.036 and R_w = 0.049 for 3433 reflections with $I \geq 3\sigma(I)$. The molecule, which has approximate C_2 symmetry, contains a system of five fused six-membered rings including the first crystallographically characterized $B_2N_2O_2$ ring. The compound is stabilized both by intramolecular N → B coordination and by resonance delocalization and contains boron atoms in a distorted tetrahedral environment. Bond lengths (corrected for libration) are: O—B, 1.469(2)−1.488(2), N—B, 1.602(2) and 1.575(2), C—B, 1.598(2) and 1.599(2) Å.

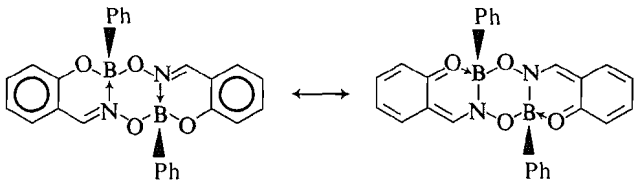
STEVEN J. RETTIG et JAMES TROTTER. Can. J. Chem. **61**, 206 (1983).

La réaction du $(C_6H_5)_2BOH$ avec la salicylaldoxime conduit au composé $[(C_7H_5NO_2)BC_6H_5]_2$ via une réaction de clivage de la liaison bore−carbone. Les cristaux de bis[(salicylaldoximato(2−))phénylbore] sont tricliniques, a = 9,219(1), b = 11,240(1), c = 12,086(1) Å, α = 100,682(7), β = 112,224(6), γ = 92,189(7)°, Z = 2, groupe d'espace $P\bar{1}$. On a résolu la structure par des méthodes directes et on l'a affinée par la méthode des moindres carrés (matrice complète) jusqu'à des valeurs de R = 0,036 et de R_w = 0,049 pour 3433 réflexions avec $I \geq 3\sigma(I)$. La molécule qui a approximativement une symétrie C_2 contient un système de 5 cycles à 6 chaînons condensés incluant le premier cycle $B_2N_2O_2$ caractérisé par cristallographie. Le composé est stabilisé à la fois par une coordination intramoléculaire N → B et par une délocalisation de la résonance et contient des atomes de bore dans un environnement tétraédrique déformé. Les longueurs de liaison (corrigées pour la libration) sont: O—B, 1,469(2)−1,488(2), N—B, 1,602(2) et 1,575(2), C—B, 1,598(2) et 1,599(2) Å.

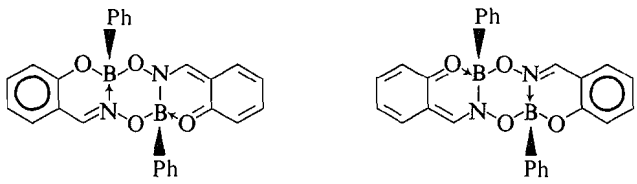
[Traduit par le journal]

Introduction

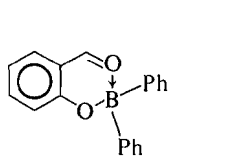
Organoboron compounds containing four-coordinate boron and stabilized by intramolecular N→B or O→B interactions have been extensively studied for the past 30 years (e.g. refs. 2, 3). In addition to the unusual hydrolytic and oxidative stability of these compounds, which prompted much of the earlier work, many of these molecules have biologically and medically useful applications (ref. 3, pp. 223, 224). As part of a continuing study[1] of the molecular structures of compounds of this type, we report here the isolation and molecular structure of bis[(salicylaldoximato(2−))phenylboron], **1**.



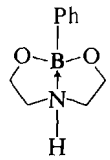
1*a* **1***b*



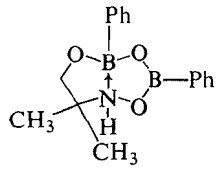
1*c* **1***d*



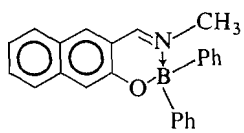
2



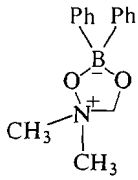
3



4



5



6

An attempt to prepare the salicylaldoxime ester of diphenylborinic acid (in which there are several possible modes of chelation to the Ph_2B moiety) by a procedure analogous to that employed for related esters (4) resulted in the isolation of **1**. The overall reaction

$$2C_7H_7NO_2 + 2(C_6H_5)_2BOH \rightarrow [(C_7H_5NO_2)BC_6H_5]_2 + 2C_6H_6 + 2H_2O$$

proceeds via a carbon−boron bond cleavage reaction (3, 5−7) to produce the dimeric ester of phenylboronic acid. The above stoichiometry indicates that the same product could be obtained by a reaction of phenylboronic acid with salicylaldoxime.

Experimental

A solution of salicylaldoxime (0.34 g, 2.5 mmol) in 50 mL of ethanol was added to a solution of diphenylborinic acid (from the acid hydrolysis of 2-aminoethyldiphenylborinate, 0.59 g, 2.6 mmol) in

ethanol/diethyl ether. A fine white powder began to precipitate almost immediately. The reaction mixture was refluxed for 6 h, allowed to cool, filtered, and was washed with water and then with ethanol. The product was dried, yielding 0.72 g (1.61 mmol, 65% yield) of product. *Anal.* calcd. for $[(C_7H_5NO_2)BC_6H_5]_2$: C 70.01, H 4.52, N 6.28; found: C 69.96, H 4.54, N 6.31. Mp (decomp.) 254−256°C.

Crystals suitable for X-ray analysis were obtained by recrystallization from a large (500 mL) volume of acetone. A crystal ca. 0.22 × 0.26 × 0.31 mm in size was mounted in a general orientation. Unit-cell parameters were refined by least-squares on 2 sin θ/λ values for 50 reflections measured on a diffractometer with Mo-Kα_1 radiation (λ = 0.70930 Å). Crystal data at 22°C are:

$C_{26}H_{20}B_2N_2O_4$ fw = 446.08

Triclinic, a = 9.219(1), b = 11.240(1), c = 12.086(1) Å, α = 100.682(7), β = 112.224(6), γ = 92.189(7)°, V = 1131.0(2) Å^3,

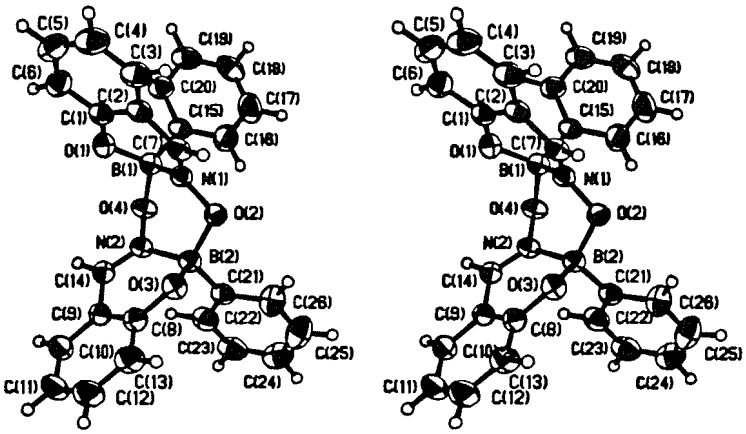

FIG. 1. Stereoscopic view of the bis[(salicylaldoximato(2−))phenylboron] molecule, 50% thermal ellipsoids are shown for the non-hydrogen atoms.

ρ_m = 1.30 (by flotation in aqueous KI), Z = 2, ρ_c = 1.310 g cm^{-3}, $F(000)$ = 464, μ(Mo-Kα) = 0.81 cm^{-1}. Absent reflections: none, space group $P\bar{1}$ (C_i^1, No. 2, reduced cell) from structure analysis. The crystal was bounded by the 6 faces: (0 ±1 0), (±1 0 0), and (0 0 ±1) (in order of increasing separation of the parallel faces).

Intensities were measured with graphite-monochromated Mo-Kα radiation (λ = 0.71073 Å) on an Enraf-Nonius CAD4-F diffractometer. An ω−1.33θ scan at 1.12−6.71° min^{-1} over a range of (0.58 + 0.35 tan θ) degrees in ω (extended by 25% on both sides for background measurement) was employed. Data were measured to 2θ = 55°. The intensities of three check reflections, measured every 3600 s throughout the data collection, remained constant to within 3%. After data reduction,[2] no absorption correction was made in view of the low value of μ. Of the 5169 independent reflections measured, 3433 (66.4%) had intensities greater than $3\sigma(I)$ above background where $\sigma^2(I) = S + 2B + (0.04(S - B))^2$ with S = scan count and B = background count.

The centrosymmetric space group $P\bar{1}$ was chosen on the basis of the E-statistics. The structure was solved by direct methods, the positions of all non-hydrogen atoms being determined from an E-map. After full-matrix least-squares refinement of the non-hydrogen atoms with anisotropic thermal parameters to R = 0.077, all 20 hydrogen atoms were positioned from a difference map and were refined with isotropic thermal parameters in subsequent least-squares cycles. The scattering factors of ref. 8 were used for non-hydrogen atoms and those of ref. 9 for hydrogen atoms. The weighting scheme, $w = 1/\sigma^2(F)$, where $\sigma^2(F)$ is derived from the previously defined $\sigma^2(I)$ gave uniform average values of $w(|F_o| - |F_c|)^2$ over ranges of both $|F_o|$ and sin θ/λ and was employed in the final stages of refinement. Convergence was reached at R = 0.036 and R_w = 0.049 for 3433 reflections with $I \geq 3\sigma(I)$. For all 5169 reflections R = 0.065. The function minimized was $\Sigma w(|F_o| - |F_c|)^2$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ and $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$.

On the final cycle of refinement the mean and maximum parameter shifts corresponded to 0.16 and 0.94σ respectively. The maximum parameter shift was associated with the temperature factor of a hydrogen atom. The mean error in an observation of unit weight was 1.696. A final difference map showed no unusual features. The final positional and thermal parameters appear in Tables 1 and 2[3] respectively. Measured and calculated structure factors have been placed in the Depository of Unpublished Data.[3]

The ellipsoids of thermal motion for the non-hydrogen atoms are shown in Fig. 1. The thermal motion has been analysed in terms of the rigid-body modes of translation, libration, and screw motion (10). The rms standard error in the temperature factors σU_{ij} (derived from the least-squares analysis) is 0.0009 Å^2. Analysis of all 34 non-hydrogen atoms gave rms ΔU_{ij} = 0.0058 Å^2 and indicated significant independent motion of the phenyl groups. Three separate smaller fragments of the molecule were analysed, the two C_6H_5B groups and the five fused rings plus the two phenyl carbon atoms bonded to B (rms ΔU_{ij} = 0.0014, 0.0018, and 0.0038 Å^2 respectively). The appropriate bond distances have been corrected for libration (10, 11), using shape parameters q^2 of 0.08 for all atoms involved. Corrected bond lengths appear in Table 3 along with the uncorrected values; corrected bond angles do not differ by more than 1σ from the uncorrected values given in Table 4. Intra-annular torsion angles defining the conformations of six-membered heterocyclic rings are listed in Table 5. Bond lengths and angles involving hydrogen and a complete listing of torsion angles (Tables 6−8) are included as supplementary material.

Results and discussion

The boron atoms in **1** are chiral, the crystal structure consisting of *RR* and *SS* pairs linked across centres of symmetry by weak C—H···O interactions (C(7)—H(7)···O(3) (1 − x, 2 − y, 1 − z), H···O = 2.35(2), C···O = 3.267(2) Å, C—H···O = 159(1)°). All other intermolecular distances correspond to normal van der Waals contacts. No attempt has been or will be made ro resolve the racemic modification. The presence of a *meso* form has not been verified although during the recrystallization only part of the material used was recovered in a crystalline state. It is quite possible that the initial product was a mixture of the *rac* and *meso* forms.

The molecule (Fig. 1) contains a linear system of five fused six-membered rings, including two C_3BNO rings and the first crystallographic example of a $B_2O_2N_2$ ring although others are known (12−14). The central $B_2N_2O_2$ ring has a slightly distorted twist-boat conformation while the two C_3BNO rings each have distorted B-envelope conformations (see Table 5), the boron atoms being displaced from the approximate planes de-

[2]The computer programs used include locally written programs for data processing and locally modified versions of the following: MULTAN 80, multisolution program by P. Main, M. M. Woolfson, L. Lessinger, G. Germain, and J. P. Declerq; ORFLS, full-matrix least-squares, and ORFFE, function and errors, by W. R. Busing, K. O. Martin, and H. A. Levy; FORDAP, Patterson and Fourier syntheses, by A. Zalkin; ORTEP II, illustrations, by C. K. Johnson.

fined by the remaining ring atoms. The C_3BNO ring conformations are very similar to that observed in the related C_3BO_2 rings of (salicylaldehydato)diphenylboron, **2** (15), and (acetylacetonato)diphenylboron (1). Each of the four aromatic rings displays statistically, but not chemically, significant deviations from planarity (maximum deviation from mean plane = 0.015 Å). The geometry of the B-substituted phenyl rings is as expected (16, 17).

The molecule has approximate C_2 symmetry, all symmetry-related bond lengths and angles except those involving B and N atoms being equal within experimental error. The molecule is stabilized both by intramolecular N→B coordination and by

resonance delocalization, the molecular geometry indicating that forms **1***a*−*d* are the major contributors to the structure.

The boron atoms are tetrahedrally coordinated, bond angles ranging from 104.6(1)−115.4(1)° (see Table 4). Both of the two significantly different N—B distances (1.575(2) and 1.602(2) Å) are considerably shorter than those in the closely related molecules **3** (18) and **4** (19) (N—B = 1.666(3) and 1.692(2) Å respectively). The N—B bonds in **1** occur at the junction of two six-membered rings while those in **3** and **4** occur at the junction of two five-membered rings and are subject to a greater degree of ring strain. The N(sp^3)—B bonds in **3** and **4** are expected to be longer than the N(sp^2)—B bonds in **1** as a result of hybridization effects. The longer N—B bond in **1**, 1.602(2) Å, is the same as the corresponding N(sp^2)—B distance of 1.601(4) Å in **5** (20) while the shorter N—B bond of 1.575(2) Å is the shortest yet observed in this type of compound. The four O—B distances also differ significantly, ranging from 1.469(2) to 1.488(2) Å, the two chemically different types of O—B bond being roughly of the same strength. The mean[4] O—B distance of 1.478(8) Å is in agreement with the mean O—B distance of 1.477(5) Å observed in the ethanolamine esters of diarylborinic acids (15, 21, 22), but slightly longer than the corresponding value of 1.463(9) Å in **3** and **4** (which compensates for the longer N—B distances in **3** and **4**). The phenolic O—B distances of 1.500(4) and 1.506(3) Å in **2** and **5** respectively as well as those of 1.530(2)−1.565(2) Å in the acetylacetone and tropolone esters of diphenylborinic acid (1) are significantly longer than those in **1**. The two equal C—B distances (mean 1.599(1) Å) are the same as that in **4** (1.599(2) Å), but shorter than those in other compounds containing tetrahedral boron, which range from 1.603(5) Å in **2** to 1.639(8) Å in **6** (23). The bonds C(2)—C(7), C(9)—C(14), C(1)—O(1), and C(8)—O(3) are all significantly longer than their counterparts in **2** and **5** indicating a lesser contribution from resonance form **1***b* than from comparable forms contributing to the structures of **2** and **5**.

[4]Here and elsewhere in this report mean values refer to weighted means with rms deviations from the mean in parentheses.

The statistically significant differences in corresponding C_2 related N—B and O—B bond lengths noted above must arise from asymmetric perturbation of the central part of the molecule. σ-Hybridization effects arise from the deviation of the molecule from true C_2 symmetry; calculations (24) predicting equivalence of the N—O and B—O bond lengths in the central ring, and that B(1)—O(1) < B(2)—O(3) and B(1)—N(1) > B(2)—N(2), both by 0.01 Å. In addition to the possible contribution of resonance forms to the overall structure in which the B, N, and O atoms are not equivalent; such a perturbation may also be attributed to the C—H···O interaction which is the only non-bonded interaction of any significance. The B(1)—O(1) distance of 1.469(2) Å is significantly shorter than the B(2)—O(3) distance of 1.488(2) Å, the latter bond being involved in the C—H···O interaction.

Crystal structure of *N,N'*-dimethyl-2-imidazolidinethione, a by-product from the reaction of $Na_2(CH_2N(CH_3)CS_2)_2$ and $HgCl_2$

CHUNG CHIEH AND SING KWEN CHEUNG

Guelph-Waterloo Centre for Graduate Work in Chemistry, University of Waterloo, Waterloo, Ont., Canada N2L 3G1

Received June 9, 1981[1]

CHUNG CHIEH and SING KWEN CHEUNG. Can. J. Chem. **61**, 211 (1983).

The reaction between mercury (II) chloride and *N,N'*-dimethylethylenebisdithiocarbamate gave a white precipitate. In an attempted recrystallization from an aqueous–ethanol solution, a cyclic thiourea-type compound, *N,N'*-dimethyl-2-imidazolidinethione, was obtained. The crystals of this compound are monoclinic, $a = 10.388(2)$, $b = 6.139(1)$, $c = 12.291(4)$ Å, $\beta = 118.64(2)$, and space group $P2_1/c$. The non-hydrogen atoms of the molecule are planar and the C=S bond length is 1.673(4) Å. The structure was refined by full-matrix least-squares from 642 independent reflections measured on an automatic diffractometer to R and R_w of 0.053 and 0.068, respectively.

CHUNG CHIEH et SING KWEN CHEUNG. Can. J. Chem. **61**, 211 (1983).

Le chlorure mercurique réagit avec le *N,N'*-diméthyléthylènebisdithiocarbamate en donnant un précipité blanc. En essayant de recristallisé le produit obtenu dans une solution aqueuse d'éthanol on obtient un composé de type thiourée cyclique, la *N,N'*-diméthylimidazolinethione-2. Les cristaux de ce composé sont monocliniques et appartiennent au groupe d'espace $P2_1/c$ avec $a = 10{,}388(2)$, $b = 6{,}139(1)$, $c = 12{,}291(4)$ Å, $\beta = 118{,}64(2)$. Les atomes de la molécule qui ne sont pas des atomes d'hydrogène, sont plans et la longueur de liaison C=S est de 1,673(4) Å. On a affiné la structure par la méthode des moindres carrés (matrice entière) jusqu'à des valeurs de R et de R_w de 0,053 et 0,068 respectivement pour 642 réflexions mesurées à l'aide d'un diffractromère automatique.

[Traduit par le journal]

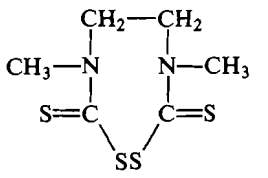
Introduction

For the study of complexation between dithiocarbamates and metal ions, *N,N'*-dimethylethylenebisdithiocarbamate was prepared (1). However, the reaction between this bisdithiocarbamate and mercury(II) chloride led to a cyclic by-product *N,N'*-dimethyl-2-imidazolidinethione. Its crystal structure as determined by X-ray method and the possible reason for its formation are reported.

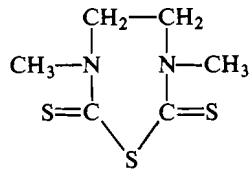
Result and discussion

The *N,N'*-dimethylethylenebisdithiocarbamate were prepared by the reaction of *N,N'*-dimethylethylenediamine and carbon disulfide in the presence of NaOH by methods similar to the one given in ref. 2. This bisdithiocarbamate reacted with mercury(II) chloride in an aqueous-ethanol solution giving a white precipitate. This precipitate turned to a creamy color on standing. In an attempt to recrystallize this product, the precipitate was stirred in an aqueous-ethanol solution for an hour to obtain a saturated solution so that the filtrate would yield crystals suitable for structural analysis. This filtrate was allowed to evaporate in a cold room (273 K) giving colorless crystals, whose nmr spectrum and elemental analysis suggested a thiourea-type compound, *N,N'*-dimethyl-2-imidazolidinethione. Furthermore, the X-ray structure determination confirmed the same result.

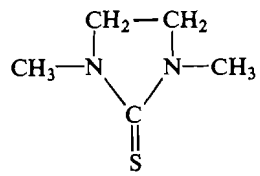
Spectroscopic evidences showed that the bisdithiocarbamate sample was pure, and the slow color change of the precipitate when $HgCl_2$ was added might be due to the elemental sulfur generated during the reaction. Although the oxidation of the bisdithiocarbamate might lead to these products:



I



II



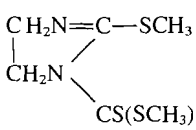
III

only **III** has been detected and confirmed as a by-product. The lack of a detectable amount of **I** or **II** is probably due to the instability of the 8- or 7-membered ring respectively. However, a compound with H instead of CH_3 in **II** was obtained by vigorous aeration of dilute solutions of disodium ethylenebisdithiocarbamate (3).

The reaction leading to **III** can be formulated as:

$$Na_2(CH_2N(CH_3)CS_2)_2 \rightarrow (CH_2N(CH_3))_2CS + CS_2 + S + 2Na^+$$

via a ring-closure mechanism. Similar ring-opening or -closure reactions were reported for many cyclic thiourea-type compounds (4), for example $(CH_2NH)_2CS$ was reported to give an orange crystal adduct



which, when treated by dry H_2S in an ethanol solution, gave

two products, one as a bisdithiocarbamate, a ring-opening process, and the other the original cyclic thiourea, a reverse reaction from the adduct. Apparently, the addition of —CS—SCH_3 to the cyclic thiourea is promoted by the *n*-C_4H_9Li, and $HgCl_2$ seems related to the ring closure in the formation of **III** from the bisdithiocarbamate.

One of the referees pointed out that a non-oxidation process could lead to the formation of **III** by

$$Na_2\begin{matrix}CH_2—N(CH_3)CS_2\\ |\\ CH_2—N(CH_3)CS_2\end{matrix} \rightarrow \begin{matrix}CH_2—N(CH_3)\\ |\quad\quad >CS\\ CH_2—N(CH_3)\end{matrix} + CS_2 + Na_2S$$

but the Na_2S would react with Hg^{2+} to give a black product; such was not the case as indicated by tests even on partially decomposed solutions of disodium *N,N'*-dimethylethylenebisdithiocarbamate.

The synthesis and properties of **III** were reported by Sakai, Fujimura, and Ishii (5) by the reaction of 1,3-dimethyl-2,2-dibutyl-1,3-diaza-2-stannacyclopentane and carbon disulfide at 273 K. The Zn(II) and Cd(II) complexes of the title compound were studied by Devillanova and Verani (6), but there has not been any structural study of **III**.

Crystal data

$C_5H_{10}N_2S$ fw = 130.8

Monoclinic, a = 10.388(2), b = 6.139(1), c = 12.291(4) Å, β = 118.64(2)°. V = 688(1) Å^3, space group $P2_1/c$ (from systematic absences), Z = 4, D_c = 1.262, D_m = 1.265 g cm^{-3} (by flotation), $F(000)$ = 280. μ(Mo Kα) = 3.60 cm^{-1}, (Mo Kα) = 0.71069 Å.

The non-hydrogen atoms of the molecule lie in a plane with a maximum deviation (N(2)) of 0.05 Å. Bond lengths and angles are shown in Fig. 1; the value of 1.673(4) Å for C=S is in agreement with those of similar compounds, for example 1.673 and 1.702 Å for dithiobiurea (7). The average angle for a regular pentagon is 108°; however, the two CNC angles of the 5-membered ring are significantly larger than the NCN or NCC angles. This may result from the partial double bond character of the (S=)C—N bonds, in agreement with their lengths. However, there are significant differences between the observed values and those composed purely from theoretical considerations in a recent CNDO/S calculation for the interpretation of $\pi-\pi^*$ transition (8).

Only van der Waals force is present in the intermolecular packing diagram shown in Fig. 2. The methyl hydrogens were not located from the difference Fourier map, but the small circles are the methylene hydrogens. The four molecules in the unit cell can be divided into two pairs, each consists of two molecules related by a center of symmetry.

Experimental

Preparation of disodium N,N'*-dimethylethylenebisdithiocarbamate*

To 30 mL aqueous solution containing 0.03 mol *N,N'*-dimethylethylenediamine, 0.06 mol (3.7 mL) of carbon disulfide and 20 mL aqueous solution of 0.06 mol NaOH were added dropwise. The mixture was stirred at 315 K until all CS_2 had reacted (~3 h). After the solvent evaporated, the solid was collected and recrystallized from water to afford a white powder. The yield was 54% and the mp, 613 K. *Anal.* Calcd. for $Na_2C_6H_{10}N_2S_4$: C 24.74, H 4.17, N 9.72; found: C 25.35, H 3.55, N 9.86. The ^{1}H nmr (60 MHz, D_2O) spectrum consisted of $\delta(CH_3$, s), 3.5 and $\delta(CH_2$, s), 4.45 ppm.

In another preparation, 15 mL of the THF was used instead of water, a precipitate immediately formed after CS_2 was added. This solid was filtered and washed with THF and then recrystallized from water.

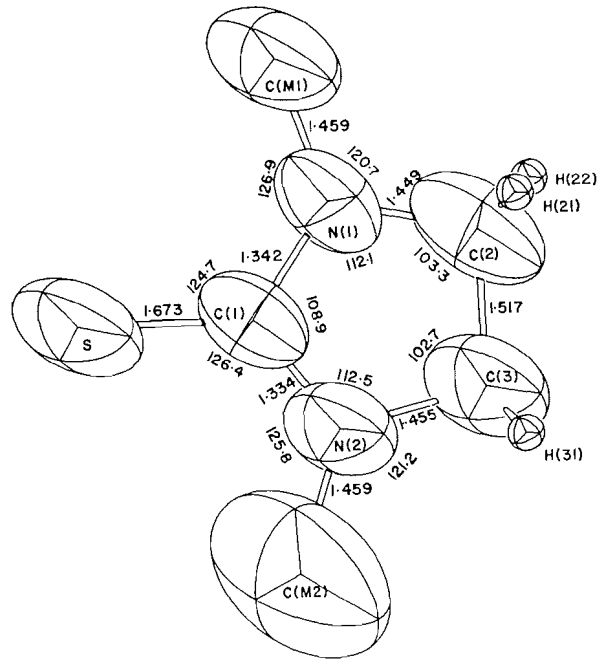

FIG. 1. An OETEP plot of the molecule with atomic numbering, bond lengths, and angles (standard deviations for bond lengths, 0.005 Å and angles 0.4°).

Reaction of disodium N,N'*-dimethylethylenebisdithiocarbamate and mercury(II) chloride*

When 20 mL ethanol solution containing 1 m*M* $HgCl_2$ was added to 20 mL aqueous-ethanol solution of 1 m*M* bisdithiocarbamate, a white precipitate immediately formed. This precipitate turned to a creamy color gradually and the solid was collected by filtration. It was then stirred in an aqueous-ethanol solution for an hour; the clear filtrate from this evaporated in a cold room (273 K) and gave colorless crystals. *Anal.* Calcd. for $C_5H_{10}N_2S$: C 46.15, H 7.62, N 21.15; found: C 45.12, H 7.81, N 21.61. The ^{1}H nmr (60 MHz, D_2O) consisted of $\delta(CH_3$, s) 3.05 and $\delta(CH_2$, s) 3.6 ppm.

Further tests indicated that a 1:1 complex was formed between $HgCl_2$ and the bisdithiocarbamate. and the creamy colored solid formed was not soluble in DMSO, DMF, pyridine, acetone, chloroform, or ethanol. The ir spectrum of this solid showed characteristic peaks of the bisdithiocarbamate, but none of the solvents mentioned above dissolved enough of the complex to give an nmr spectrum, other than that of the thione as indicated above.

Crystallographic study

Crystals of *N,N'*-dimethyl-2-imidazolidinethione are colorless and preliminary X-ray photographs gave estimates of cell constants and space group. A cubic crystal with edges of ~0.2 mm was then selected and mounted on a Syntex $P2_1$ automatic diffractometer, on which 642 independent reflections, ($\pm h$, k, l), with $2\theta \leq 40°$ were collected and the structure factor amplitudes were derived by applying the Lorentz and polarization but not the absorption corrections. Structural analysis was carried out by using the SHELX system (7). The methylene hydrogen positions were found in a difference Fourier which had no clear indication of the methyl hydrogen atoms. Anisotropic thermal parameters were given to all non-hydrogen atoms and isotropic thermal parameters were assumed for the H atoms. These were refined as well as their positions with a total of 89 variables. Using all reflections, the final R and R_w were 0.053 and 0.068 respectively, the weighting scheme being $1/(\sigma^2(F) + 0.0001F^2)$ in the function, $\sum w(|F_o| - |F_c|)^2$, minimized. The difference Fourier at the end had

COMMUNICATION

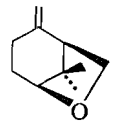
Stereoselective cyclization of epoxy allylsilanes. A synthesis of karahana ether

ROSEMARY J. ARMSTRONG AND LARRY WEILER[1]
Department of Chemistry, University of British Columbia, Vancouver, B.C., Canada V6T 1Y6

Received October 1, 1982

ROSEMARY J. ARMSTRONG and LARRY WEILER. Can. J. Chem. **61**, 214 (1983).

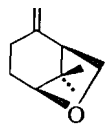
Epoxy allylsilanes can be cyclized with Lewis acids to give cyclic alcohols in a biomimetic synthesis of mono and bicyclic compounds. The allylsilane has a pronounced effect on activating an olefin in this cyclization and producing the exocyclic methylene regioselectively. A short synthesis of karahana ether (**5**) is reported.



5

ROSEMARY J. ARMSTRONG et LARRY WEILER. Can. J. Chem. **61**, 214 (1983).

On peut cycliser les époxyallylsilanes avec des acides de Lewis pour obtenir des alcools cycliques dans une synthèse biomimétique de composés mono- et bicycliques. L'allylsilane a un effet marqué en activant l'oléfine dans cette cyclisation et en produisant d'une façon régiosélective le méthylène exocyclique. On rapporte une courte synthèse de l'éther karahana (**5**).
[Traduit par le journal]



5

In 1955, Stork and Burgstahler (1) and Eschenmoser *et al.* (2) independently developed the hypothesis that many cyclic terpenoid natural products may arise via electrophilic cyclization of appropriate polyolefins. Both groups illustrated the hypothesis with laboratory examples. Since then several groups have extended and applied the cyclization of polyolefins in natural products chemistry. Most notable have been the contributions from W. S. Johnson's laboratory (3). In these cases cyclization is initiated by either protons or Lewis acids to produce products with few, if any, functional groups other than alkenes.

Following the pioneering work by Goldsmith (4*a*), several groups recognized that terminal epoxides of polyolefins might well serve as precursors in electrophilic cyclizations (4*b*). In 1966, Corey *et al.* (5) and van Tamelen *et al.* (6) showed that squalene 2,3-oxide was efficiently converted into cholesterol *in vivo*. However, *in vitro* experiments using acid catalyzed cyclizations of epoxyolefins and epoxypolyolefins usually were much less efficient. These cyclizations frequently produced a plethora of products which detracted from the synthetic utility of this reaction.[2]

In 1976, Fleming *et al.* (8) found that an allylsilane can have a dramatic effect in controlling the regiochemistry of olefin cyclizations and several groups since have reported the synthetic utility of allylsilane cyclizations (9). Recently we described the electrophilic cyclization of polyolefin allylsilanes (10). We would now like to report that the incorporation of an allylsilane moiety in an epoxyolefin has a marked effect on the cyclization of these compounds. The diene **1** can be regioselectively epoxidized in good yield to give the epoxy allylsilane **2** (Scheme 1). We found that cyclization of **2** with two equivalents of boron trifluoride etherate in *dry* methylene chloride gave a good yield of cyclized material. Vapor phase chromatographic analysis indicated that the crude product contained approximately 80% of **3**, 10% of **2**, and 10% of two other products. We did experience some losses in the column chromatographic purification of **3**. However, when the crude cyclization mixture was treated with lithium aluminum hydride, the diol **4** could be isolated in 68% yield from **2**. The spectral and chromatographic properties of **3** and **4** indicated that each was a single diastereomer. The spectral properties of the diol **4** were identical to those reported by Coates and Melvin (11). Finally, the structure and stereochemistry of the diol **4** was confirmed by its conversion to (±)-karahana ether (**5**) (12) following the procedure of Coates and Melvin (11). Two other syntheses of karahana ether (**5**) have recently been reported (13).

The trimethylsilyl group again had a marked effect on activating the olefin in this electrophilic cyclization and in controlling the regiochemistry of the product to yield the exocyclic olefin (8, 10). This is one of the first examples of an efficient

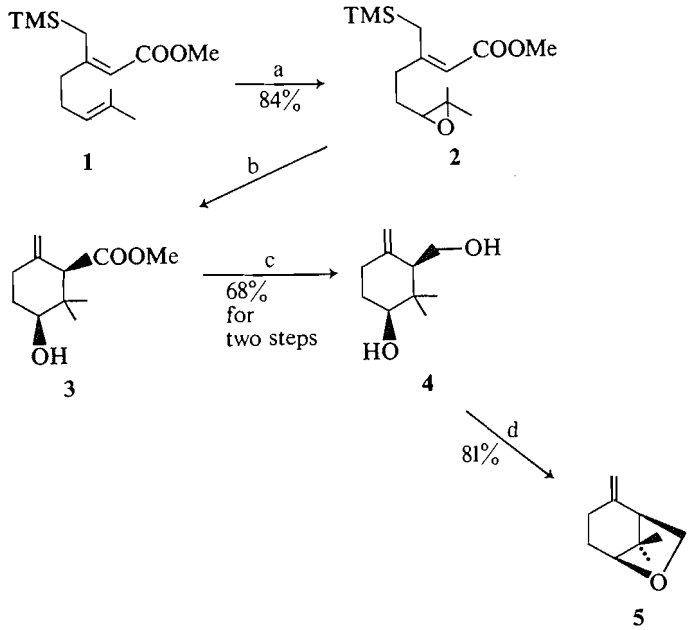
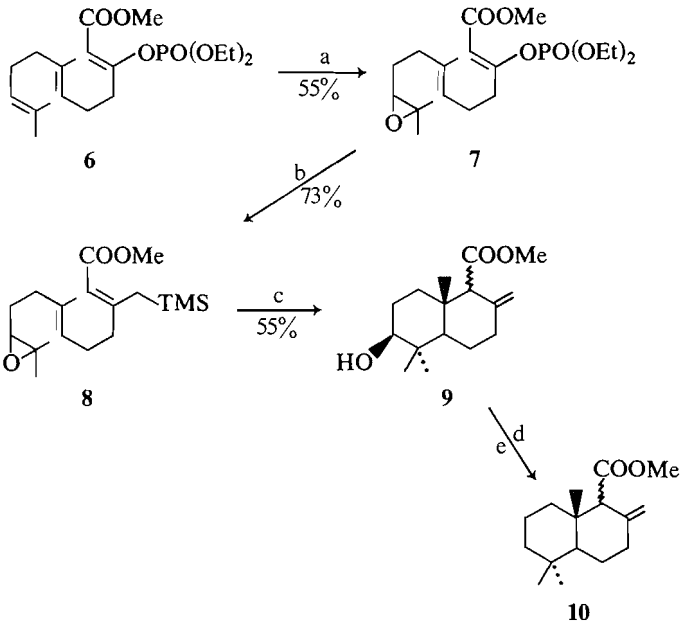


SCHEME 1. (a) MCPBA, CH_2Cl_2, 0°C; (b) 2 equiv. $BF_3 \cdot Et_2O$, dry CH_2Cl_2, −56°C; (c) $LiAlH_4$, Et_2O, 0° → 25°C; (d) TsCl, py, 0° → 25°C, 5 h.



SCHEME 2. (a) MCPBA, CH_2Cl_2, −50° → 0°C; (b) $TMSCH_2MgCl$, $Ni(acac)_2$, Et_2O; (c) $SnCl_4$, CH_2Cl_2, 0 → 25°C; (d) PCC, NaOAC, 4 Å sieves, CH_2Cl_2; (e) $TsNHNH_2$ then  , $CHCl_3$, 0°C.

cyclization of an olefinic epoxide and it illustrates the utility of an allylsilane in cyclizations of epoxyolefins. The stereochemistry of **3** can be interpreted as the outcome of a chair-like transition state for cyclization (1−4, 14).

We have also extended this cyclization to bicyclic systems as shown in Scheme 2. The triene **6** (10) was epoxidized with fair regioselectivity (C-10,11/C-6,7 ≃ 4:1) using *m*-chloroperbenzoic acid. The enol phosphate **7** was coupled with trimethylsilylmethylmagnesium chloride (10) to give **8** which was cyclized with stannic chloride to give a 55% yield of two products in a ratio of ca. 2:1 after purification (15). The two products **9** were shown to be epimeric at C-9 by oxidation of the C-3 alcohol (16), conversion to the tosyl hydrazone, and reduction with catecholborane (17) to give the 9α- and 9β-isomers of **10** (10) in the same ratio as the products in the cyclization step. The 9β-isomer is the major product. Thus the path appears open to utilize the cyclization of epoxy allylsilanes in the synthesis of functionalized polycyclic compounds.

Synthèse de cyclopropanes électrophiles à fonction aldéhyde libre ou masquée[1]

HASSAN ABDALLAH,[2] RENÉ GRÉE ET ROBERT CARRIÉ

Groupe de Recherches de Physicochimie Structurale, ERA n° 389 au C.N.R.S., Laboratoire n° 3, Université de Rennes, 35042 Rennes Cedex, France

Reçu le 3 mai 1982

HASSAN ABDALLAH, RENÉ GRÉE et ROBERT CARRIÉ. Can. J. Chem. **61**, 217 (1983).

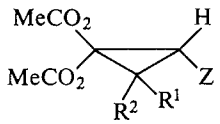
Le diméthylacétal du diazoacétaldéhyde **2** d'une part et l'oléfine **3** d'autre part permettent l'accès, dans d'excellentes conditions, à des cyclopropanes électrophiles possédant une fonction aldéhyde supplémentaire.

HASSAN ABDALLAH, RENÉ GRÉE, and ROBERT CARRIÉ. Can. J. Chem. **61**, 217 (1983).

Electrophilic cyclopropanes **1** bearing an extra aldehyde function are conveniently prepared starting either from the diazoacetal **2** or from the olefin **3**.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.105 on 09/06/12
For personal use only.

Les cyclopropanes électrophiles sont des intermédiaires très utiles en synthèse organique et il semble que de nouvelles voies d'accès à ces composés méritent d'être développées (2). Dans le cadre de travaux concernant l'utilisation en synthèse de la réaction de cycloaddition 1,3 dipolaire, nous nous sommes intéressés à la préparation des cyclopropanes électrophiles **1** possédant en outre une fonction aldéhyde supplémentaire, ce



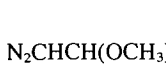
Z = CHO ou $CH(OCH_3)_2$

1

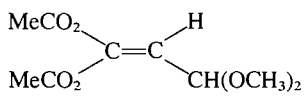
qui offre de nouvelles potentialités synthétiques notamment pour la préparation de produits naturels ou de leurs analogues (2).

Différents cyclopropanes de type **1** ont déjà été préparés par action de bromomalonates sur des aldéhydes insaturés, en présence de base (3) ou dans les conditions de catalyse par transfert de phase (4, 5). Cette réaction présente un certain nombre de limitations car l'oléfine utilisée doit être suffisamment électrophile et peu encombrée (4).

L'objet de ce mémoire est de montrer que l'utilisation du diméthylacétal du diazoacétaldéhyde **2** d'une part et de l'oléfine **3** d'autre part permet d'obtenir, dans d'excellentes conditions, les cyclopropanes recherchés **1**.



2



3

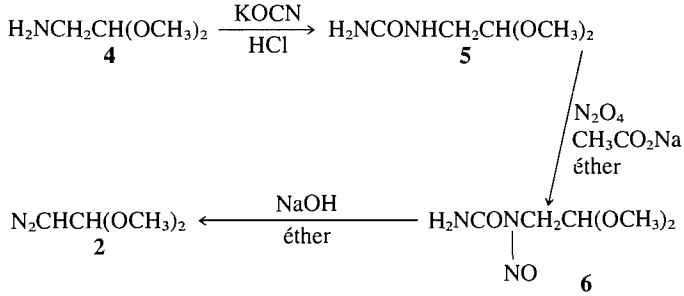
I. Synthèse et réactions du diméthylacétal du diazoacétaldehyde 2

Deux diazoacétals ont été préparés par Kirmse et Buschhoff afin d'étudier les aptitudes migratrices des groupes OR dans les carbènes correspondants (6) mais, à notre connaissance, aucune étude de ces composés en tant que dipôles 1,3 n'a été effectuée.

Le diazoacétal **2** utilisé au cours de ce travail présente un certain nombre d'avantages qui lui permettent d'occuper, tant par ses propriétés physiques que chimiques, une place assez unique dans la chimie des diazocomposés: il est assez facile d'accès et peut être isolé; il présente une bonne stabilité thermique et également une excellente réactivité en cycloaddition dipolaire 1,3; enfin, les pyrazolines-1 obtenues ne s'isomérisent pas en pyrazolines-2 par migration de l'hydrogène en α du groupe acétal.

A. Synthèse de 2

Le diazoacétal **2** est préparé selon la méthode décrite pour son homologue diéthylique (6). L'aminoacétal **4**, commercial, conduit de façon pratiquement quantitative à l'urée **5** qui est



ensuite nitrosée pour donner **6**. Le traitement de cette nitrosourée par la soude diluée conduit au diazoacétal **2**. Le diazocomposé brut obtenu peut être utilisé directement pour les cycloadditions ultérieures. Il est également possible de le distiller sous pression réduite (distillation "trap to trap": $E_{0,05}$ = 15−20°C). Le rendement global en diazoacétal **2** par rapport à **4** est de 45%. Le composé **2** peut être conservé plusieurs mois à −15°C sous atmosphère inerte.

B. Synthèse des cyclopropanes électrophiles

Le diazocomposé **2** réagit avec les oléfines **7**, en quelques heures, dans l'éther à 0°C, pour conduire de façon quasi quantitative aux pyrazolines **8** caractérisées à l'aide de la rmn (un seul diastéréoisomère dans chaque cas). Par photolyse (en solution dans le toluène à température ambiante, avec un filtre Pyrex) ces pyrazolines conduisent aux cyclopropanes **9** qui après traitement à l'acide formique pur (7) donnent les formylcyclopropanes **10** (un seul diastéréoisomère, contrôle rmn).

[1]Une partie de ce travail a fait l'objet d'une communication préliminaire (1).

[2]Boursier du Conseil National de la Recherche Scientifique Libanais.

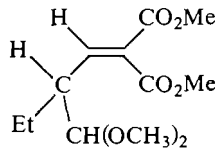
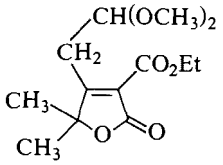
SCHÉMA 1

Toutes ces étapes ont des rendements excellents puisque les cyclopropanes **10** ont été obtenus purs après distillation au four tubulaire avec des rendements compris entre 65 et 94% à partir des oléfines **7**. Lors de la photolyse de **8***c* on observe à côté de **9***c* la formation de 15% de **11***c*; de même à partir de **8***d*, 18% de **11***d* sont obtenus. Dans les deux cas, ces composés sont



11*c*

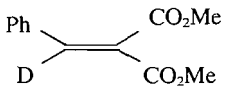


11*d*

séparés par chromatographie sur gel de silice. Les caractéristiques spectroscopiques des composés **8** à **10** figurent aux tableaux 1, 2 et 3.

(a) Structure des pyrazolines 8

L'étude rmn apporte les éléments suivants. (*i*) La multiplicité des signaux correspondant aux différents protons cycliques confirme l'orientation des cycloadditions. (*ii*) L'attribution des signaux correspondant à H_a et H_c a été effectuée sans ambiguité dans le cas de **8***a* après utilisation de l'oléfine deutériée **7***'a*. Pour les autres pyrazolines, l'attribution a été effectuée par analogie: le déplacement chimique de H_a variant

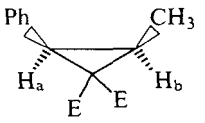


7*'a*

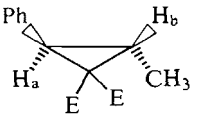
peu avec la structure. (*iii*) Sauf pour **8***d* (J_{bc} = 3,0 Hz; H_b et H_c en *trans*) la configuration relative au niveau des atomes de carbone 4 et 5 n'est pas établie: les constantes de couplage observées peu différentes de 7 Hz ne pouvant être considérées comme caractéristiques (8).

(b) Structure des cyclopropanes 9

La détermination de la configuration relative des carbones 2 et 3 des cyclopropanes électrophiles pose un problème généralement délicat en raison des valeurs élevées observées pour les constantes de couplage: elles sont par exemple de 9,2 Hz et



12

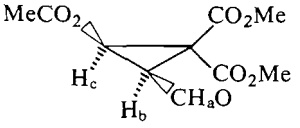


13

E = CO_2Me

8,0 Hz pour le couple de diastéréoisomères **12** et **13** (9).

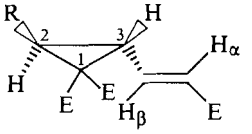
Nous avons attribué aux cyclopropanes **9** et **10** obtenus une stéréochimie *trans* sur la base des éléments suivants. Pour les composés bicycliques **9***d* et **10***d*, les constantes de couplage observées (4,7 et 4,1 Hz) indiquent sans ambiguité une position *trans* des deux protons cycliques.[3] Dans le cas de **10***b*, son diastéréoisomère **14***a* a été préparé par une autre voie et une constante J_{bc} = 9,0 Hz a été observée (10). La stéréochimie



14

des autres composés **9***a*, **9***c*, **10***a* et **10***c* a été attribuée par analogie; leurs constantes J_{bc} étant proches de celles de **9***b* et **10***b*.

Remarque: Ces formylcyclopropanes présentent une bonne réactivité. Par action du carbomethoxymethylenetriphénylphosphoranne dans le benzène à température ambiante on obtient les vinylcyclopropanes **15***a* (Rdt 68%) et **15***b* (Rdt 80%).



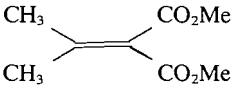
a R = Ph
b R = E = CO_2Me

15

Un seul isomère, de stéréochimie *E*, est obtenu ($J_{\alpha\beta}$ = 15,0 et 16,0 Hz).

II. Synthèse et réactions de l'oléfine 3

L'oléfine **3**, dont nous avons mis au point la synthèse, offre une voie d'accès complémentaire aux cyclopropanes électrophiles **1**. Le diazoacétal **2** est très peu réactif vis à vis d'oléfines tétrasubstituées telles que **16**; seule l'utilisation du composé **3**



16

[3]Le cyclopropane analogue à **9***d* et **10***d* pour lequel le groupement acétal (ou aldéhyde) est remplacé par un hydrogène (J. Martelli et R. Grée, travaux non publiés) présente des constantes ^3J = 7,9 et 5,5 Hz respectivement attribuables à J_{cis} et J_{trans}.

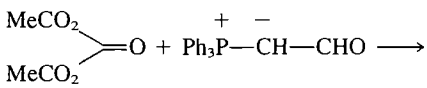
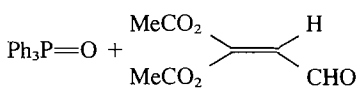
permet la préparation, dans de bonnes conditions, des cyclopropanes **1** disubstitués sur le carbone 2 (R^1 et $R^2 \neq H$).

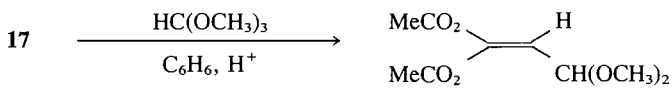
*A. Synthèse de **3***

Elle s'effectue en deux étapes (11): l'aldéhyde **17** est préparé par condensation du mésoxalate de méthyle avec le formylméthylène triphénylphosphoranne.





17



3

Cette oléfine, fragile, est isolée par distillation sous vide poussé (Rdt 70%).[4] L'acétalisation de **17** au moyen de l'orthoformiate de méthyle et à la température ambiante, conduit à l'oléfine **3** avec un rendement de 84%.[5]

B. Synthèse des cyclopropanes disubstitués en position 2

Les principaux résultats sont résumés dans le schéma 2: la

[4]Cette oléfine constitue en outre un intermédiaire clef pour la synthèse de cyclopropanes chiraux (12).

[5]Cette oléfine, ainsi que le cyclopropane **18**, ont étés préparés indépendamment par le Professeur Krief, en utilisant d'autres réactions (13).

SCHÉMA 2

TABLEAU 4. Caractéristiques rmn ($CDCl_3$) des produits de réaction de **3** avec l'isopropylidène phosphoranne ou le diphényldiazométhane

	$\delta(H_a)$	$\delta(H_b)$	$\delta(OCH_3)$	$\delta(C(CH_3)_2)$ ou $\delta(C(C_6H_5)_2)$	J_{ab}
18	4,51	2,05	3,75 et 3,37	1,40 et 1,20	7,8
19	9,57	2,58	3,79 et 3,77	1,49 et 1,34	4,5
20	4,10 et 3,85		3,82 3,24 3,78 2,67	7,85–6,85	8,8
21	4,52 (d)	3,21 (d)	3,62 3,40 3,47 3,33	7,55–7,05	8,0
22	9,37 (d)	3,45 (d)	3,71 3,41	7,55–7,05	6,0

réaction de l'isopropylidène phosphoranne (13) sur **3** conduit au cyclopropane **18**, puis après formolyse à **19** (Rdt 75% par rapport à **3**). Avec le diphényldiazométhane en solution éthérée à température ambiante, les cyclopropanes **21** puis **22** (Rdt 90% par rapport à **3**) sont obtenus.

La pyrazoline intermédiaire **20** peut être isolée et caractérisée à l'aide de la rmn mais elle évolue lentement dès la température ambiante pour conduire à **21**. L'orientation de la cycloaddition 1,3 dipolaire est établie à l'aide de la rmn ^{13}C: le déplacement chimique du carbone 4 qui porte un hydrogène (47,9 ppm) est nettement différent de ceux des carbones quaternaires 3 et 5 (106,0 et 104,7). Les caractéristiques spectroscopiques des composés **18** à **22** figurent au tableau 4.

C. Réaction de 3 avec le diazoacétal 2

Elle permet la préparation de cyclopropanes électrophiles possédant cette fois deux fonctions aldéhydes (schéma 3).

La cycloaddition de **2** au composé **3** conduit quantitativement (contrôle rmn) à la pyrazoline **23** qui par photolyse donne le cyclopropane **24** (rendement 93% à partir de **3**). Le traitement de **24** par HCO_2H pur en excès conduit au cyclopropane bisaldéhyde **25**. Il est possible de libérer sélectivement l'une des fonctions aldéhydes; par traitement avec de l'acide trifluoroacétique (4 équivalents) dans le chloroforme pendant 20 heures à température ambiante, on obtient un mélange 70:30 (intégration rmn) de **26** et **25**. Les caractéristiques spectroscopiques de ces différents composés figurent au tableau 5.

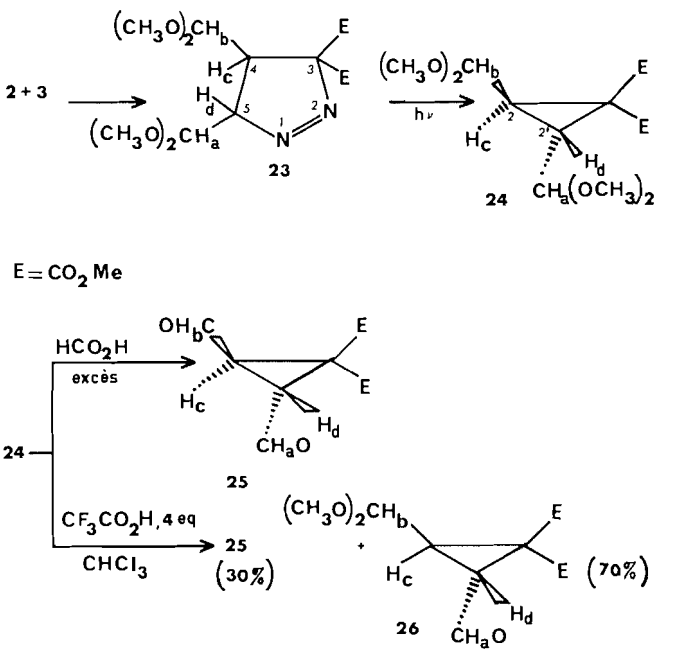

SCHÉMA 3

(a) Structure de la pyrazoline 23

La multiplicité des signaux en rmn (double doublets pour H_4 et H_5) permet de connaître l'orientation de la cycloaddition. Par

For personal use only.

TABLEAU 5. Caractéristiques rmn ($CDCl_3$) des composés obtenus à partir de **2** et **3**

	$\delta(H_a)$	$\delta(H_b)$	$\delta(H_c)$	$\delta(H_d)$	$\delta(OCH_3)$	J_{ad}	J_{bc}	J_{cd}
23	4,67	4,41	3,50	5,33	3,56 3,20 3,51 3,17 3,25 3,12	3,0	6,6	4,1
24	4,40 (2H)		2,45 (2H)		3,80 (6H) 3,38 (6H) 3,36 (6H)		Système non analysé	
25	9,52 (2H)		3,36 (2H)		3,83 (6H)		Système non analysé	
26	9,40	4,45	2,76	3,01	3,37 3,33	4,0	5,1	7,0

ailleurs, l'attribution du signal à 5,31 ppm au proton H_d a été confirmée par l'utilisation du diazocomposé deutérié **2'**; ceci permet donc une attribution non ambigüe de la constante de couplage J_{45} = 4,1 Hz. Cette faible valeur indique que les deux protons 4 et 5 sont en position *trans* (8).

(b) Structure des cyclopropanes

Nous avons attribué pour ces composés **24** et **25** une position relative *trans* des hydrogènes H_c et H_d en raison de l'équivalence des deux groupements esters, observée à l'aide des rmn ^1H et ^{13}C.

Les caractéristiques de **26** sont identiques à celles d'un échantillon préparé au laboratoire par une autre voie (12) et très voisines de celles décrites par Kucherov et coll. (5) (esters éthyliques).

Conclusion

L'utilisation du diazoacétal **2** ou de l'oléfine acétal **3** permet de préparer avec d'excellents rendements et de façon stéréospécifique les cyclopropanes électrophiles fonctionnalisés recherchés **1**. Ces composés apparaissent comme des intermédiaires susceptibles d'être très intéressants pour la synthèse de produits élaborés tels que les produits naturels.

Partie expérimentale

Indications générales

Les points de fusion, non corrigés, sont déterminés au banc chauffant Kofler. Les spectres ir ont été enregistrés sur spectrophotomètre Perkin–Elmer 225 en suspension dans le Nujol ou en film liquide. Les fréquences d'absorption sont exprimées en cm^{-1}. Les spectres de rmn ^1H ont été enregistrés à 100 MHz sur un appareil JEOL MH 100 ou à 80 MHz sur un appareil Bruker WP 80. Les spectres de rmn ^{13}C sont enregistrés à 20,115 MHz sur un appareil à transformée de Fourier Bruker WP 80 DS. Les déplacements chimiques δ sont donnés en ppm (référence interne TMS); les constantes de couplage sont en Hz. Les chromatographies sur colonne ont été effectuées avec du gel de silice 60 Merck (230–400 mesh). Les chromatographies sur couches minces (épaisseur 2 mm) sont effectuées avec du gel de silice 60 G Merck. Les photolyses sont effectuées dans une cellule en Pyrex à refroidissement par circulation d'eau. La lampe utilisée est une Hanau HQ 80 (puissance 80 W); après dégazage de la solution par barbottage d'azote, les produits sont irradiés en solution (température 25–30°C) dans le benzène ou le toluène anhydres (200 cm^3). Les analyses sont effectuées au laboratoire central de Microanalyses du C.N.R.S. (Lyon).

Urée 5

Elle est préparée selon la méthode décrite pour son homologue diéthylique (15). Composé **5** (huile), ir (film liquide): 3340 (NH), 1650 (C=O); rmn ($CDCl_3$) δ: 6,16 (t, N*H*, J = 5,7), 5,31 (s, NH_2), 4,36 (t, C*H* $(OCH_3)_2$, J = 5,1), 3,37 (s, 6H, OCH_3), 3,30 (m, CH_2).

N-*nitrosourée 6 et diazoacétal 2*

Ils sont préparés selon la méthode décrite pour leurs homologues diéthyliques (6). Composé **6**, F = 68–69°C (éther); ir (Nujol): 3329–3395 et 3177–3230 (NH), 1732 (C=O), 1602 (NO); rmn ($CDCl_3$) δ: 6,80 (s large, NH_2), 4,52 (t, C*H*, J = 5,7), 4,00 (d, CH_2), 3,30 (s, 6H, OCH_3). *Anal.* calc. pour $C_5H_{11}N_3O_4$: C 33,90, H 6,21, N 23,73; trouvé: C 33,6, H 6,3, N 23,9. Composé **2** (huile), ir (film liquide): 2078 (C=N_2); rmn (C_6D_6) δ: 4,90 (d, $(CH_3O)_2CH$, J = 2,7), 3,21 (d, N_2CH), 3,02 (s, 6H, OCH_3).

Diazoacétal deutérié 2'

Dans un Erlenmeyer, on introduit une solution de 200 mg de K_2CO_3 dans 5 cm^3 de D_2O. Sous agitation magnétique et à 0°C, on ajoute une solution de 300 mg de diazoacétal **2** dans 10 cm^3 d'éther anhydre. On abandonne 6 heures à 0°C, la phase éthérée est alors décantée, séchée sur pastilles de KOH. Après distillation du solvant, on obtient le diazoacétal deutérié (200 mg). Le taux de deutériation est supérieur à 90% (contrôle rmn).

Pyrazolines-1 8

À une solution de 10^{-2} mol d'oléfine dans 15 cm^3 d'éther anhydre, on ajoute à 0°C un léger excès (1,1 équivalent) de diazoacétal. Après 6 heures, les réactions sont terminées et l'éther est distillé sous pression réduite. La rmn montre la présence d'un seul isomère.

Les caractéristiques de rmn ^{13}C (C_6D_6) du composé **8***a* confirment l'orientation: 166,7 (m, CO_2CH_3, J = 3 et 4), 164,9 (m, CO_2CH_3, J = 4 et 5), 137, 1–127,0 (m, C_6H_5), 107,2 (d, C_3, J = 5), 103,8 (d.m, $CH(OCH_3)_2$, ^1J = 162, ^3J = 5), 98,4 (d, C_5, ^1J = 139), 55,6 et 55,3 (2q.d, $CH(OCH_3)_2$, ^1J = 143 et 142, ^3J = 6 et 5), 53,4 et 52,8 (2q, $COCH_3$, ^1J = 148), 44,6 (dd, C_4, ^1J = 137 et J = 3).

À l'exception de **8***d* qui cristallise et peut être purifiée, la photolyse est effectuée avec les produits bruts de cycloaddition. Composé **8***d*, F = 95°C (éther); ir (Nujol): 1720 et 1760 (C=O). *Anal.* calc. pour $C_{13}H_{20}N_2O_6$: C 52,00, H 6,67, N 9,33, trouvé: C 51,8, H 6,9, N 9,6.

Le composé **7***'a* est préparé par condensation du benzaldéhyde deutérié (16) avec le malonate de méthyle; **7***b* est préparé selon la référence 11 ou 17.

Cyclopropanes 9

On photolyse pendant 18 h une solution de 10^{-2} mol de pyrazoline dans 200 cm^3 de benzène ou toluène anhydre. Le solvant est ensuite distillé sous pression réduite.

(a) Composé **9***a* 66°C (éther); ir (Nujol): 1736 et 1723 (C=O). *Anal.* calc. pour $C_{16}H_{20}O_6$: C 62,34, H 6,49; trouvé: C 62,2, H 6,6.

(b) Le composé **9***b* est distillé au four tubulaire: 105°C (0,01 Torr); ir (film liquide): 1732 (large) (C=O). *Anal.* calc. pour $C_{12}H_{18}O_8$: C 49,65, H 6,21; trouvé: C 49,8, H 6,1.

(c) Le cyclopropane **9***c* et l'oléfine **11***c* sont séparés par chromatographie sur couche mince (SiO_2, éluant éther – éther de pétrole 2:3, 2 élutions). Les R_f sont respectivement de 0,65 et 0,60. Ces deux composés sont purifiés par distillation au four tubulaire. Composé **9***c* 100°C (0,05 Torr); ir (film liquide): 1728 (large) C=O. *Anal.* calc. pour $C_{12}H_{20}O_6$: C 55,38, H 7,69; trouvé: C 55,5, H 7,7. Composé **11***c* 95°C (0,003 Torr); ir (film liquide): 1724 (C=O) et 1640 (C=C); rmn ($CDCl_3$) δ: 6,87 (d, *H*C=, J = 10,8), 4,23 (d, $(CH_3O)_2CH$,

J = 5,6), 3,80 (3H), 3,76 (3H), 3,32 (6H) (OCH_3), 2,79 (m, $HC—C_2H_5$), 1,49 (m, $CH_2—CH_3$), 0,84 (t, $CH_2—CH_3$). *Anal.* calc. pour $C_{12}H_{20}O_6$: C 55,38, H 7,69; trouvé: C 55,3, H 7,7.

(d) Le cyclopropane **9***d* et l'oléfine **11***d* sont également séparés par chromatographie sur couche mince (SiO_2, éluant éther − éther de pétrole 1:1, 2 élutions). R_f = 0,3 pour **9***d* et 0,25 pour **11***d*. Ces deux composés sont purifiés par distillation au four tubulaire. Composé **9***d* 125°C (0,05 Torr); ir (film liquide): 1768 et 1728 (C=O). *Anal.* calc. pour $C_{13}H_{20}O_6$: C 57,35, H 7,35; trouvé: C 57,1, H 7,4. Composé **11***d* (également obtenu quantitativement par thermolyse de **8***d*, deux heures dans le toluène à reflux); 130°C (0,004 Torr); ir (film liquide): 1766 et 1714 (C=O); rmn ($CDCl_3$) δ: 4,69 (t, $(CH_3O)_2CH$, J = 5,6), 4,34 (q, OCH_2CH_3), 3,37 (s, 6H (OCH_3)$_2$), 2,92 (d, $—CH_2—C=$), 1,50 (s, 6H, $(CH_3)_2C$), 1,36 (t, $OCH_2—CH_3$). *Anal.* calc. pour $C_{13}H_{20}O_6$: C 57,35, H 7,35; trouvé: C 57,1, H 7,2.

Cyclopropanes ***10***

À 10^{-2} mol du cyclopropane acétal brut, on ajoute le même poids d'acide formique pur. On abandonne une nuit à température ambiante. Après distillation sous vide (15 Torr) de HCO_2H et HCO_2CH_3, les formylcyclopropanes sont purifiés par distillation au four tubulaire. Les rendements indiqués correspondent aux cyclopropanes distillés; ils sont calculés par rapport aux oléfines de départ **7**. Composé **10***a* 145°C (0,05 Torr). Rendement 94%; ir (film liquide): 1732 et 1712 (C=O). *Anal.* calc. pour $C_{14}H_{14}O_5$: C 64,12, H 5,34; trouvé: C 64,4, H 5,4. Composé **10***b* 145°C (0,05 Torr). Rendement 93%; ir (film liquide): 1736 (large) (C=O). *Anal.* calc. pour $C_{10}H_{12}O_7$: C 49,18, H 4,92; trouvé: C 48,9, H 5,0. Composé **10***c* 90°C (0,05 Torr). Rendement 80%; ir (film liquide): 1728 et 1708 (C=O). *Anal.* calc. pour $C_{10}H_{14}O_5$: C 56,07, H 6,54; trouvé: C 55,9, H 6,7. Composé **10***d* 130°C (0,05 Torr). Rendement 65%; ir (film liquide): 1772, 1720 et 1712 (C=O). *Anal.* calc. pour $C_{11}H_{14}O_5$: C 58,41, H 6,19; trouvé: C 58,2, H 6,1.

Vinylcyclopropanes ***15***

À 10^{-2} mol des cyclopropanes **10***a* ou **10***b* dissous dans 15 cm^3 de benzène anhydre sous azote, on ajoute un équivalent de carbométhoxyméthylène triphénylphosphoranne. Après 4 heures à température ambiante, le solvant est distillé sous vide. La majeure partie de l'oxyde de phosphine est d'abord précipité par addition d'éther au réfrigérateur. Le reste est éliminé par chromatographie sur une courte colonne de gel de silice (éluant: éther − éther de pétrole 1:1). Composé **15***a*, F = 72−73°C (méthanol). Rendement 68%; ir (Nujol): 1725 (C=O), 1644 (C=C); rmn ($CDCl_3$) δ: 7,30 (5H, arom), 6,80 (H_β, dd, $J_{\beta\alpha}$ = 16,0, $J_{\beta 3}$ = 8,2), 6,25 (d, H_α), 3,86 (3H), 3,78 (3H), 3,49 (3H) (OCH_3), 3,60 à 3,40 (m, H_2, H_3). *Anal.* calc. pour $C_{17}H_{18}O_6$: C 64,15, H 5,66; trouvé: C 64,2, H 5,7. Le composé **15***b* est purifié par distillation au four tubulaire 155°C (0,01 Torr). Rendement 80%. ir (film liquide): 1730 (C=O) et 1650 (C=C); rmn ($CDCl_3$) δ: 6,60 (H_β, dd, $J_{\beta\alpha}$ = 15,0, $J_{\beta 3}$ = 8,0), 6,10 (H_α, d), 3,75 (s, 3H), 3,73 (s, 3H), 3,70 (s, 6H) (OCH_3), 3,03 (H_3, dd, J_{23} = 6,8), 2,98 (H_2, d). *Anal.* calc. pour $C_{13}H_{16}O_8$: C 52,00, H 5,33; trouvé: C 52,2, H 5,6.

Oléfine 17

Dans un tricol de 100 cm^3 on introduit sous azote 4,4 g (3×10^{-2} mol) de mésoxalate de méthyle (18) dissous dans 60 cm^3 de benzène anhydre. A cette solution, refroidie dans un bain d'eau glacée, on ajoute par petites fractions sous agitation magnétique et sous courant d'azote un équivalent (9,1 g) de formylméthylènetriphénylphosphoranne (19). La réaction est instantanée. Après distillation sous vide du benzène, l'oxyde de triphénylphosphine est précipité par addition d'éther à 0°C. Il est séparé par filtration et l'éther est distillé; l'huile obtenue est ensuite fractionnée sous vide. On obtient 3,63 g de **17**, $Eb_{0,0005}$ = 60−65°C. Rendement 70%. Ce composé fragile doit être utilisé rapidement. Ses caractéristiques sont les suivantes: ir (film liquide): 1686 et 1726 (C=O), 1622 (C=C); rmn ($CDCl_3$) δ: 9,96 (d, J = 6,7, CHO), 6,86 (d, $HC=$), 3,92 et 3,86 (s, OCH_3).

Oléfine 3

À 1,70 g (10^{-2} mol) de l'oléfine **17** dissoute dans 20 cm^3 de benzène anhydre et refroidie dans un bain d'eau froide on ajoute quelques cristaux d'acide paratoluène sulfonique (~100 mg) puis un léger excès (1,2 g) d'orthoformiate de méthyle. Il y a décoloration quasi immédiate de la solution; on ajoute quelques grains de tamis moléculaire 3 Å. Un contrôle à l'aide de la rmn montre que la réaction est terminée. Après une filtration rapide sur une courte colonne de silice, le solvant est distillé. L'oléfine est purifiée par distillation au four tubulaire, 100°C (0,05 Torr); 1,83 g, rendement 84%, ir (film liquide): 1726 (C=O) et 1648 (C=C); rmn ($CDCl_3$) δ: 6,82 (d, J = 4,8, $=CH$), 5,15 (d, $CH(OCH_3)_2$), 3,84 (s, 3H) et 3,81 (s, 3H) (CO_2CH_3), 3,35 (s, 6H, $CH(OCH_3)_2$). *Anal.* calc. pour $C_9H_{14}O_6$: C 49,54, H 6,42; trouvé: C 49,5, H 6,5.

Le composé **3** peut être préparée sans isoler l'oléfine intermédiaire **17**: le produit brut de la réaction conduite à partir de 2,2 g de mésoxalate de méthyle et de 4,58 g de phosphoranne est traité par un excès (2,0 équivalents) d'orthoformiate de méthyle avec 350 mg d'acide paratoluène sulfonique et du tamis moléculaire 3 Å. Le mélange réactionnel est porté 1 heure à 45°C. Après distillation du benzène, l'oxyde de phosphine est précipité avec de l'éther. Après filtration sur une courte colonne de silice (éluant éther − éther de pétrole 2:3) l'oléfine **3** est purifiée par distillation. On obtient 2,63 g de produit (rendement 80% par rapport au mésoxalate de méthyle).

Cyclopropanes ***18*** *et* ***19***

À une solution de 2,18 g (10^{-2} mol) de **3** dans 20 cm^3 de THF anhydre on ajoute goutte à goutte et sous agitation magnétique un équivalent d'isopropylidènephosphoranne (14) dissous dans 50 cm^3 de THF. La réaction est effectuée sous atmosphère d'azote à température ambiante. L'addition terminée l'agitation est maintenue pendant une heure. Après distillation du THF sous pression réduite, le produit brut cristallisé est repris avec 60 cm^3 de chloroforme et porté à reflux pendant une heure. Après distillation sous vide du solvant, le résidu est chromatographié sur gel de silice: l'élution avec un mélange CH_2Cl_2 − éther de pétrole 3:1 donne la triphénylphosphine. On élue ensuite avec un mélange éther − éther de pétrole 1:1, ce qui permet d'isoler **18**. Ce cyclopropane est purifié par distillation au four tubulaire 100°C (0,02 Torr); 2,10 g, rendement 81%; ir (film liquide): 1724 (C=O). *Anal.* calc. pour $C_{12}H_{20}O_6$: C 55,38, H 7,69; trouvé: 55,4, H 7,7.

Ce cyclopropane, traité avec un large excès (10 equiv.) d'acide formique pur pendant 3 heures à la température ambiante conduit au cyclopropane **19** purifié par distillation au four tubulaire 105°C (0,02 Torr); 1,61 g (rendement 75% par rapport à **3**); ir (film liquide): 1728 et 1702 (C=O). *Anal.* calc. pour $C_{10}H_{14}O_5$: C 56,07, H 6,54; trouvé: C 56,3, H 6,5.

Cyclopropanes ***21*** *et* ***22***

À 2,18 g (10^{-2} mol) d'alcène **3** dissous dans 3 cm^3 d'éther anhydre, on ajoute un équivalent (1,95 g) de diphényldiazométhane. Le mélange réactionnel est abandonné à température ambiante à l'abri de la lumière. Après deux jours on obtient des cristaux de pyrazoline **20**, F = 106−107°C (déc.); ir (Nujol): 1744 et 1722 (C=O), 1590 et 1560 (N=N, C_6H_5); rmn ^{13}C ($CDCl_3$) δ: 166,5 (m, ^3J = 4) et 165,8 (m, ^3J = 4, $—CO_2CH_3$); 141,2 à 127,3 (m, C_6H_5); 106,0 (m, ^3J = 3, $C(CO_2CH_3)_2$), 104,7 (d, ^3J = 4, C $(C_6H_5)_2$), 102,1 (d.m, ^1J = 168, ^3J = 4−5, $CH(OCH_3)_2$), 55,8 (d.q, ^1J = 143, ^3J = 4) et 50,9 (d.q., ^1J = 143, ^3J = 6, $CH—OCH_3$), 53,9 (q, ^1J = 148) et 53,4 (q, ^1J = 148, $CO_2—CH_3$), 47,9 (d, ^1J = 136, $HC—CH(OCH_3)_2$).

La photolyse de cette pyrazoline pendant 16 h conduit quantitativement au cyclopropane **21**, F = 128−129°C (éther); ir (Nujol): 1754 et 1722 (C=O). *Anal.* calc. pour $C_{22}H_{24}O_6$: C 68,75, H 6,25; trouvé: C 68,5, H 6,3.

Abandonné durant quatre semaines à la température ambiante, **20** conduit également quantitativement à **21**.

Ce cyclopropane (1,9 g) traité par 2,3 g (10 équiv.) d'acide formique pur sans solvant à température ambiante (5 h) conduit quasi quantitativement à **22** purifié par distillation au four tubulaire 185°C (5×10^{-4} Torr); ir (film liquide): 1728, 1712, 1696 (C=O). *Anal.* calc. pour $C_{20}H_{18}O_5$: C 71,01; H 5,33; trouvé: C 71,3, H 5,5.

Dans les conditions décrites ci-dessus: cycloaddition, évolution

thermique de la pyrazoline puis traitement à l'acide formique du produit brut de réaction, on obtient après distillation l'aldéhyde **22** avec un rendement de 90% par rapport à l'oléfine **3**.

Cyclopropanes 24, 25 et 26

A 2,18 g (10^{-2} mol) de **3** dissous dans 15 cm^3 d'éther anhydre à 0°C, on ajoute un léger excès (1,2 g) de diazoacétal **2**. La réaction est pratiquement immédiate. Après distillation du solvant, on obtient la pyrazoline **23** sous forme d'une huile. Celle-ci est photolysée pendant 20 h. Après distillation du toluène, le cyclopropane **24** est purifié par distillation au four tubulaire 140°C (0,05 Torr); 2,88 g (rendement 94% par rapport à **3**); ir (film liquide): 1724 (C=O). *Anal.* calc. pour $C_{13}H_{22}O_8$: C 50,98, H 7,19; trouvé: C 51,2, H 7,3.

On traite 1,5 g de **24** par 10 équivalents d'acide formique pur (2,3 g) sans solvant pendant une nuit à température ambiante. Après distillation de l'acide formique et du formiate de méthyle, **25** est purifié par distillation au four tubulaire: 120°C (0,05 Torr); 1,0 g, rendement 96% par rapport à **24**; ir (film liquide): 1728, 1708 (C=O). *Anal.* calc. pour $C_9H_{10}O_6$: C 50,47, H 4,67; trouvé: C 50,7, H 4,8.

Le traitement de **24** par l'acide trifluoroacétique (4 équiv.) dans le chloroforme (20 h, temp. amb.) conduit au mélange 30:70 (intégration rmn) de **25** et **26**. Ce dernier composé a été caractérisé uniquement à l'aide de la rmn. Les différents essais de séparation de **25** et **26** par chromatographie sur couche mince ont échoué.

The probable planarity of 1,2-dimethoxybenzene in solution

TED SCHAEFER AND REINO LAATIKAINEN[1]
Department of Chemistry, University of Manitoba, Winnipeg, Man., Canada R3T 2N2

Received June 7, 1982

TED SCHAEFER and REINO LAATIKAINEN. Can. J. Chem. **61**, 224 (1983).

A precise analysis of the ^{1}H nmr spectrum of 1,2-dimethoxybenzene in benzene solution yields an accurate value for the proximate spin–spin coupling constant, $^5J_o^{H,CH_3}$, between the *ortho* ring proton and the methyl protons. The latter also couple to other ring protons and these couplings are assessed. Comparison with some values in other anisole derivatives and with a variety of INDO MO FPT calculations of $^5J_o^{H,CH_3}$ strongly implies the predominance of a planar conformation in solution. This implication disagrees with the interpretation of some other experimental and theoretical data. The mechanism of this proximate coupling is examined by the procedure of Barfield. It seems that the magnitude of the coupling is dominated by interactions involving the orbitals on the carbon atom of the methyl group.

TED SCHAEFER et REINO LAATIKAINEN. Can. J. Chem. **61**, 224 (1983).

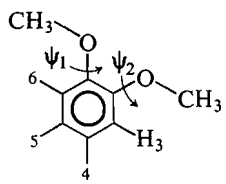
Une analyse précise du spectre de rmn du diméthoxy-1,2 benzène en solution dans le benzène donne une valeur exacte de la constante de couplage de spin voisin $^5J_o^{H,CH_3}$ entre le proton en position *ortho* du cycle et les protons du méthyle. Ces derniers se couplent également avec les autres protons du cycle et on a évalué ces couplages. La comparaison avec certaines valeurs obtenues pour d'autres dérivés de l'anisole et avec différents calculs du type INDO, OM, FPT de $^5J_o^{H,CH_3}$ laisse supposer la prédominance d'un conformation plane en solution. Cette supposition ne s'accorde pas avec l'interprétation de certaines autres données expérimentales et théoriques. On examine le mécanisme de ce couplage voisin selon le procédé de Barfield. Il semble que l'ordre de grandeur de ce couplage est influencé par les interactions qui font intervenir les orbitales de l'atome de carbone du groupe méthyle.

[Traduit par le journal]

Introduction

The conformational preferences of the methoxy groups in 1,2-dimethoxybenzene (*o*-DMB) and its derivatives have been discussed in detail (1, 2), perhaps because the psychotomimetic activity of some of these compounds is related to the orientations of the methoxy groups relative to the benzene plane. Aromatic 1,2-dimethoxy substituents are fairly common in natural products, for example, in isoquinoline alkaloids (2*b*).

In the solid state, *o*-DMB prefers a planar orientation of the heavy atoms, possibly due to crystal packing forces. In the vapor phase, the photoelectron spectrum can be interpreted as arising from a conformation in which one methoxy group is planar and the other is perpendicular with respect to the benzene plane. Partial geometry optimization procedures in MO



1

STO 3G calculations (1) for **1** find that the conformations defined by $\psi_1 = \psi_2 = 0°$ and by $\psi_1 = 0°$, $\psi_2 = 90°$ differ by only 0.1 kJ/mol in energy. In that situations, entropy terms will favor the nonplanar forms in the conformational equilibrium. The STO 3G results also imply unfavorable electronic, rather than steric, interactions in the planar form, as the reason for the nonplanar preferences.

In solution the observed dipole moment, partition coefficients, and dielectric relaxation times apparently require nonplanar forms of *o*-DMB. It has been suggested (1) that ^{1}H (3) and ^{13}C (4) nmr chemical shifts may have similar implications, but it seems that the ^{13}C shifts are also consistent with a planar conformation of the methoxy group if it has only one *ortho* substituent. Spin-lattice relaxation times of the carbon nuclei in the methoxy groups of some *o*-DMB derivatives (2) provide evidence for planar conformations of two *ortho* methoxy substituents.

One observable, whose potential as a conformational indicator has not been fully exploited, is $^5J_o^{H,CH_3}$ in **1**. Early measurements (5) of this long-range spin–spin coupling constant between the methoxy protons and the *ortho* ring protons yielded a magnitude of 0.30 ± 0.03 Hz for 2-X-anisoles (X = Cl, Br, I, NO_2). For X = OH or OCH_3 the coupling was not resolved, suggesting a small magnitude and perhaps a rotational averaging process (5). The determination of $^5J_o^{H,CH_3}$, as −0.33 (2) Hz in 2,4-dibromoanisole (6) stimulated the suggestion of a proximate or through-space mechanism for this coupling, arising from overlap of orbitals centered on the proximate nuclei and on the carbon atoms to which the protons are bonded. INDO-MO-FPT calculations on anisole (7) reproduced the sign of $^5J_o^{H,CH_3}$, and emphasized its sensitivity to internuclear distances. Furthermore, a complete analysis of the ^{1}H spectrum of 2-hydroxyanisole in benzene solution (8) gave $^5J_o^{H,CH_3}$, as (−)0.29 Hz.[2] The observed $^5J_m^{H,OH}$ indicated that the intramolecularly hydrogen bonded form existed to the extent of at least 95% in CCl_4 or C_6D_6 solution at 305 K, implying that the methyl group lies *trans* to the hydroxyl group.

Recent INDO MO FPT calculations of $^5J_o^{H,CH_3}$ confirm the through-space mechanism and the sensitivity to interproton

[2]In CCl_4 solution the chemical shift between H-3 and H-4 is only 0.02 ppm (8). This tight coupling probably accounts for the observations at 60 MHz (5).

distances (9*a*). In this paper, a complete analysis of the ten-spin ^{1}H nmr spectrum of *o*-DMB in benzene solution yields a reliable value of $^5J_o^{H,CH_3}$. Its conformational implications are discussed in connection with further INDO MO FPT computations and with the coupling observed in related compounds.

Experimental

A 10 mol% solution of *o*-dimethoxybenzene (K & K Laboratories) in benzene-d_6 was degassed by the freeze–pump–thaw method and was flame-sealed into a 5 mm od nmr sample tube, which also contained a small amount of tetramethylsilane (TMS). In the same way, 5 mol% solutions in CCl_4 of 3,5-dichloroanisole, 1,2,4-trimethoxybenzene, 1,2-dimethoxy-4-formylbenzene, and 1,2,3-trimethoxybenzene (all from Aldrich) were prepared as samples for nmr measurements. A 10 mol% solution of the formyl compound in benzene-d_6 was also prepared.

The ^{1}H nmr spectra of the latter four samples were calibrated on an HA100 spectrometer at a probe temperature of 305 K in the manner described recently in detail (9*b*). The ^{1}H nmr spectrum of 1,2-dimethoxybenzene was obtained on a WH90 (^{2}H internal lock), again at 305 K and in the manner described before (9*b*) for another molecule (see also the caption to Fig. 1).

Results and discussion

Spectral analyses

In CCl_4 solution, the ring protons of *o*-DMB resonate within 0.02 ppm of each other, thereby accounting for the small reported $^5J_o^{H,CH_3}$ (5). In benzene solution the internal shift increases to about 0.1 ppm and a proper 10-spin analysis becomes feasible with the program NUMARIT (10). There is no doubt that the methyl protons are coupled to all the ring protons. Most of these couplings are rather small but they do influence the spectral appearance. The spectrum was analyzed by iteration for all coupling larger than 0.1 Hz in magnitude, followed by visual optimization of the smaller couplings. When these smaller couplings were varied, the other couplings were always optimized. The number of calculated transitions with observable intensity was ca. 850 in the ring region and ca. 550 in the methyl proton region, while the number of non-degenerate transitions (separated by more than 0.002 Hz) was 250 and 46, respectively. The number of observed peaks or shoulders was only 55 and 3 in the two regions. These complications necessitated the procedure above. The very small couplings were varied in a systematic way in a series of some 90 trials. With hindsight it was clear that a seven-spin analysis (four ring protons and three sidechain protons), based on the six-line multiplet at high field and a few singlets at lower field, would yield the correct magnitude of $^5J_o^{H,CH_3}$. However, this analysis could not reproduce the detailed appearance of the whole spectrum.

The final parameters are given in Table 1. In Figs. 1 and 2 some calculated and observed spectra are displayed.

The 5 mol% solution of 3,5-dichloroanisole in CCl_4 had $^5J_o^{H,CH_3}$ as (−)0.158(7) Hz by a MAOCOON analysis (11). The actual observed splittings were 0.144 Hz, but a correction[3] for incomplete resolution was applied.

The 5 mol% solution of 1,2,4-trimethoxybenzene gave $^5J_o^{H,CH_3(1)}$, $^5J_o^{H,CH_3(2)}$, $^5J_o^{H,CH_3(4)}$, and $^5J_o^{H,CH_3(4)}$ as −0.232(5), −0.281(5), −0.120(20), and as −0.170(20) Hz, respectively.

TABLE 1. The ^{1}H nmr spectral parameters for 1,2-dimethoxybenzene, *o*-DMB, as a 10 mol% solution in benzene-d_6 and 305 K

Parameter	Value	Parameter	Value
ν_{CH_3}[a]	3.454(1)	$^5J_o^{H,CH_3}$	−0.280(10)
ν_3	6.6691(1)	$^6J_m^{H_4,OCH_3}$	0.060(10)[b]
ν_4	6.8305(1)	$^6J_m^{H_6,OCH_3}$	−0.010(10)[b]
$^3J_{34}$	8.005(4)	$^7J_p^{H,OCH_3}$	−0.009(10)[b]
$^3J_{45}$	7.547(4)	$^7J_p^{CH_3,CH_3}$	0.000(10)[c]
$^4J_{35}$	1.520(4)		
$^5J_{36}$	0.235(6)	Root mean square error	0.018

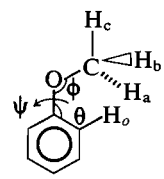
[a]In ppm from internal tetramethylsilane at 90.020 MHz, centerband.
[b]A fit to the spectrum demands nonzero magnitudes, i.e., these couplings *cannot* be set to zero.
[c]The spectrum was relatively insensitive to this parameter but appeared to be most compatible with a zero coupling.

Again, a 10 mol% solution of 1,2-dimethoxy-4-formylbenzene in benzene-d_6 had $^5J_o^{H,CH_3(1)}$ as −0.292(15) Hz and $^5J_o^{H,CH_3(2)}$ as −0.308(5) Hz, somewhat larger in magnitude than those recently reported (9).

For 1,2,3-trimethoxybenzene in CCl_4, $^5J_o^{H,CH_3}$ was −0.250(20) Hz and $^6J_m^{H_5,OCH_3}$ was 0.075(10) Hz. The peak arising from the methoxy protons at position 2 was sharp. Irradiation of this peak did not lead to a noticeable decrease in linewidth of the peaks from the ring protons.

The dihedral angle dependence of $^5J_o^{H,CH_3}$

Previous INDO MO FPT calculations (7, 9) encourage the belief that $^5J_o^{H,CH_3}$ is a proximate coupling whose magnitude has a strong dependence on the distance between the methyl and the *ortho* ring protons. The present detailed computations are based on the following geometry.



$\phi = 112° + 3.0°|\cos\psi|$
$\theta = 125° + 5.0°\cos\psi$
$r(O—CH_3) = 142.5$ pm
$r(O\text{-}C_1) = 136.0$ pm

2

The benzene fragment had a standard geometry (12), while the other bond lengths and bond angles were assigned on the basis of X-ray data[4] and of extensive MO STO 3G calculations (1, 13, and footnote 5). The torsion angle ψ is zero for the indicated "planar" conformation, **2**. The ψ dependence of the bond angles θ and ϕ is theoretical and the C—O bond lengths were kept constant. Because $^5J_o^{H,CH_3}$ is appreciable only for small values of ψ, the constancy of the C—O bond lengths is not a critical assumption.

The chosen geometry yields the following couplings in Hz for ψ = 0°, 90°, and 180°:

	ψ=0°	ψ=90°	ψ=180°
$^5J(H,OCH_a)$	−0.338	0.023	−0.010
$^5J(H,OCH_b)$	−0.338	0.087	−0.010
$^5J(H,OCH_c)$	−0.199	−0.002	0.132

[3]Tables of correction factors for overlapping lorentzians are available from R.L.

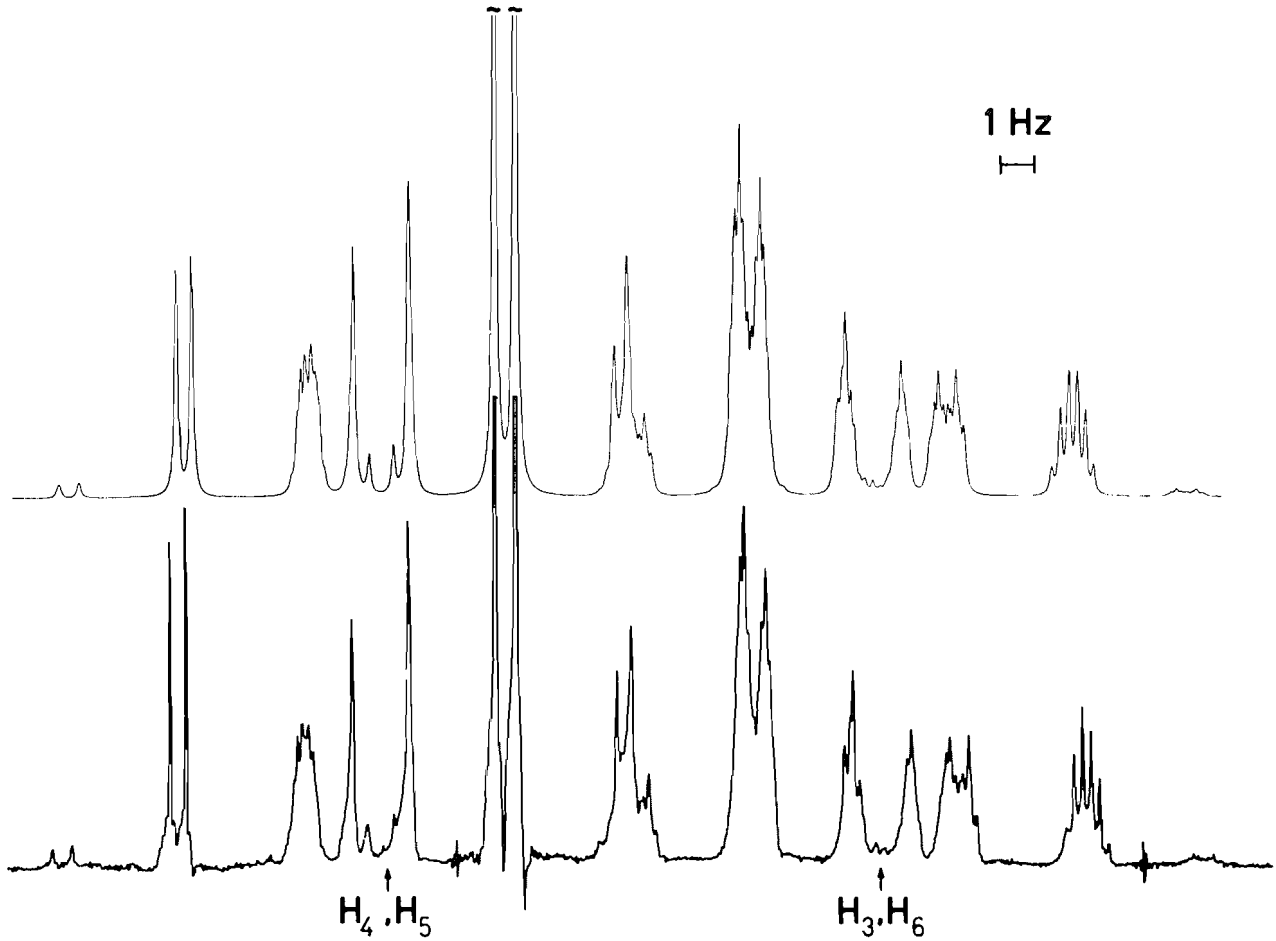

FIG. 1. The calculated and observed ring ^{1}H nmr spectra at 90 MHz of a 10 mol% solution of 1,2-dimethoxybenzene in benzene-d_6 at 305 K. The calculated spectrum assumes the parameters in Table 1 and a linewidth at half-heights of 0.10 Hz. The experimental spectrum contains some distortions near the baseline in some regions, particularly near the arrow indicating the chemical shifts of H-4 and H-5. It was accumulated with twelve free induction decays with an acquisition time of 35 s and 45° pulses.

For the planar form, **2**, the average value is −0.292 Hz. In these calculations the methyl group was not rotated about the O—CH_3 bond.

More detailed sets of computations were also undertaken, involving many more choices of the torsion angle ψ. In one set the CH_3 group was not rotated about the O—C(H_3) bond. In a second set the H_a—H_o and H_b—H_o distances were kept constant by allowing a torsion about this bond. This correlated torsion reduced the total energy relative to the first set up to ψ = 45°, after which the noncorrelated motion appeared to be favored.

The calculations of the first set were repeated in a manner first described by Barfield (14). In order to assess the importance of "coupling paths", off-diagonal elements of Fock matrices associated with orbitals centered on certain *nonbonded* atoms were set equal to zero. This procedure prevented the transmission of spin–spin coupling via overlap of those orbitals. In particular, in one calculational sequence all matrix elements involving *s* orbitals of H_o and CH_3 moiety were forced to vanish, yielding a rough estimate of the coupling transmitted via the intervening five-bond path. In another sequence, this was done for *all* orbitals centered on the coupled protons. In the last sequence, the elements involving the *s* orbitals of H_o and of the *carbon* atom of the methyl group were set equal to zero. The results of the calculations are summarized in Table 2 and Fig. 3.

Conformational deductions from $^5J_o^{H,CH_3}$

The striking aspect of the standard INDO calculations of $^5J_o^{H,CH_3}$ in Table 2 is the strong dependence of its magnitude on the torsional angle, ψ, for both the correlated and uncorrelated torsional motions. On the basis of these numbers and the relative energies of the partially optimized STO 3G conformations in ref. 1 the average $^5J_o^{H,CH_3}$ in *o*-DMB can be calculated as in Table 3. The average is -0.14_6 Hz. The planar conformation is only 10% abundant according to the STO 3G energies for the isolated molecule. In other words, the observed and calculated $^5J_o^{H,CH_3}$ values for *o*-DMB suggest negligible populations of nonplanar conformations in solution. Of course, the molecule is not rigid and some torsional motions occur (15). These can be as large as 20° in ψ without altering substantially the predicted $^5J_o^{H,CH_3}$.

If the planar form of anisole is predominant in solution, then the numbers in Table 2 suggest $^5J_o^{H,CH_3}$ in anisole as (−0.292 + 0.037)/2 or −0.13 Hz, i.e., the mean of the values for ψ = 0° and 180°. In 3,5-dichloroanisole $^5J_o^{H,CH_3}$ is (−)0.16(1) Hz, providing support for the quantitative reliability of the computed numbers and consistent with a substantial barrier to internal rotation, so that the methyl carbon atom does not sample substantially the out-of-plane conformations at 305 K. Judging from calculations for 3-fluorophenol (16), the internal barrier in 3,5-dichloranisole is larger than in anisole.

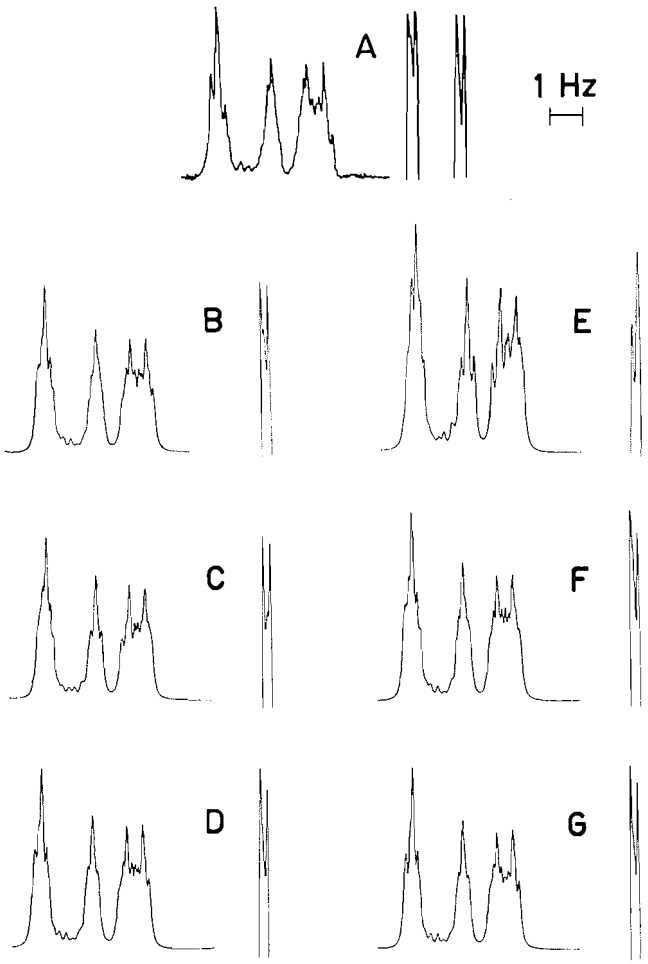

FIG. 2. In A the observed ring proton region near the chemical shifts of H-3 and H-6 (Fig. 1) and the methoxy ^{1}H nmr are displayed. The two methoxy signals are obtained by the use of different window compositions and are, of course, obtained from the same free induction decay. In B the calculated spectrum arises from the preferred spectral parameters of Table 1. In C all the long-range couplings, except for $^5J_o^{H,CH_3}$, are set equal to zero. In D all couplings less than 0.1 Hz in magnitude are zero, except for $^6J_m^{H_4,OCH_3} = {}^6J_m^{H_5,OCH_3} = +0.060$ Hz. In E the parameters in Table 1 are used except that $^6J_m^{H_4,OCH_3} = {}^6J_m^{H_5,OCH_3} = -0.060$ Hz. In F the signs of $^6J_m^{H_6,OCH_3}$ and $^6J_m^{H_3,OCH_3}$ have been changed to give +0.01 Hz. In G the values of $^7J_p^{H,OCH_3}$ have been changed to +0.01 Hz. The spectrum is *relatively* insensitive to $^7J^{CH_3,CH_3}$ but appears to be most compatible with a zero magnitude.

Because the formyl substituent has a π-electron-acceptor ability comparable to that of the nitro group (17), one might expect somewhat increased magnitudes for $^5J_o^{H,CH_3}$ in the 4-formyl derivative of *o*-DMB (smaller out-of-plane torsions). In CCl_4 solution, both $^5J_o^{H,CH_3}$ magnitudes do appear to be *somewhat* larger than in *o*-DMB. In the corresponding 4-methoxy derivative, the concomitant decrease in conjugation of the 1-methoxy group could be adduced as the reason for its $^5J_o^{H,CH_3}$ of −0.23 Hz; indeed smaller in magnitude than in *o*-DMB, whereas $^5J_o^{H,CH_3}$ for the 2-methoxy group is −0.28 Hz, the same as in *o*-DMB. The sum of the two unequal $^5J_o^{H,CH_3}$ values involving the 4-methoxy substituent is −0.29(4) Hz. The individual values are somewhat uncertain, yet their difference is large enough to suggest that the 4-methoxy group prefers the orientation remote from the 2-methoxy substituent to some extent.

$^5J_o^{H,CH_3}$ is −0.25(2) Hz in 1,2,3-trimethoxybenzene and indicates preferred planar conformations for the 1,3-methoxy substituents, whose preference for planarity, however, may be somewhat smaller than in *o*-DMB. The central methoxy group no doubt takes up a nonplanar conformation (2) and the absence of any observable coupling to the ring protons in the *meta* or *para* positions may prove useful as a conformational hint.

More indirect evidence for the ψ dependence of $^5J_o^{H,CH_3}$ comes from its sign and magnitude in 2,5-dichlorothioanisole (18) and 2-hydroxythioanisole (19). In the former, $^5J_o^{H,CH_3}$ is −0.35(1) Hz and is very likely a proximate coupling (19). In the latter, a stereospecific OH···S hydrogen bond constrains the methyl group to a plane roughly perpendicular to the benzene ring and $^5J_o^{H,CH_3}$ is ≤ 0.02 Hz in magnitude. These data are consistent with a very small $^5J_o^{H,CH_3}$ when ψ lies near 90°, as given by the INDO calculations on the analogous molecule, anisole.

Coupling mechanisms for $^5J_o^{H,CH_3}$

The rapid decrease in the magnitude of $^5J_o^{H,CH_3}$ as ψ increases, in the standard INDO calculations in Table 2, implies the importance of the proximity of the bonds containing the coupled nuclei. When the Fock matrix elements involving overlap of the *s* orbitals on H_o and on the atoms of the methyl group are set equal to zero, what remains of $^5J_o^{H,CH_3}$ in Table 2 might be termed the through-bond contribution. This contribution is ca. +0.1 Hz for ψ > 45° (see Table 2 and Fig. 3). Again, when only the *s* orbital overlaps between H_o and the hydrogen atoms of the methyl group are eliminated, one has $TS(H,H) = {}^5J^I - {}^5J(H, CH_3)$ as given in Table 2 ($^5J^I$ is the standard INDO value) and plotted in Fig. 3. In other words, the two calculations yield very similar numbers (their difference is near zero), indicating that direct overlap of *s* orbitals on the hydrogen atoms does not give rise to a negative coupling. However, if direct interaction between *s* orbitals on H_o and on the *carbon* atom of the methyl group is prevented, then $TS(H, CH) = {}^5J^I - {}^5J(H, CH_3)$. The substantial negative numbers between ψ = 0° and ψ = 60° imply a negative proximate contribution to $^5J_o^{H,CH_3}$ via the carbon orbitals. As pointed out by Barfield (14), even though certain elements of the Fock matrices are kept zero, interactions with other atoms can still lead to transmission of coupling by a particular atom (alternative coupling pathways). That is, the calculated results need not be precisely additive. Nevertheless, the present calculations may be taken to mean that it is proximate interactions via the methyl carbon atom which determine the sign of $^5J_o^{H,CH_3}$ and that they dominate over positive contributions from proximate interactions between the hydrogen atoms themselves. It may also be noted that choosing certain nonbonded interactions as zero in these calculations will not drastically alter the electronic structure of the molecule.

Calculations of $\partial(^5J)/\partial X$, where *X* is a bond length or bond angle, were done for ψ = 0°, 90°, 180° on **2**. This quantity was negligible for ψ = 90° and 180° for all reasonable changes in *X*. For ψ = 0°, changes of 1 pm in the C_1—O, O—$C(H_3)$, and C—H bond lengths cause ≤0.005 Hz changes in $^5J_o^{H,CH_3}$. A decrease of φ by 1° causes a decrease in $^5J_o^{H,CH_3}$ of 0.018 Hz. If θ decreases by 1°, the coupling decreases by 0.031 Hz, whereas it increases by 0.025 Hz if θ increases by 1°. A torsion of 10° about the O—$C(H_3)$ bond decreases $^5J_o^{H,CH_3}$ by 0.02 Hz. In other words, as expected for a proximate coupling, com-

[a]The anisole geometry is given in **2**, see text.
[b]As the O—C(H_3) bond twists out-of-plane there is no rotation of the methyl group.
[c]As the O—C(H_3) bond twists the methyl group rotates so as to keep two H—H_{ortho} distances equal (correlated rotation).
[d]All Fock matrix elements between H_o and the *s* orbitals of the atoms in the methyl group are set equal to zero, in the manner of Barfield (14).
[e]All direct interactions involving the *s* orbitals of the four hydrogen atoms are made to vanish. The ensuing ^5J values are subtracted from the standard INDO MO FPT numbers in the second column.
[f]As in [c] but for the *s* orbitals on H_o and the carbon atom of the methyl group.
[g]The value of ΔE is $E(\psi = 90°) - E(\psi = 0°)$.

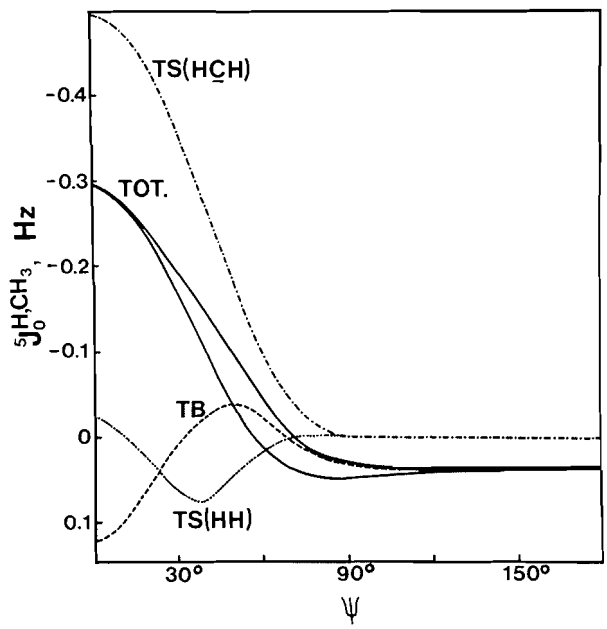

FIG. 3. $^5J_o^{H,CH_3}$ in anisole, as computed by INDO MO FPT, is shown for the standard calculation, column 2 of Table 1, for a calculation in which the methoxy group is rotated about the C_1—O bond by angle ψ (upper solid line). The lower solid line represents the data of column 3 of Table 2 for correlated rotation, in which the distance between the *ortho* hydrogen atom and two methyl hydrogen atoms is kept constant as ψ increases. The curve marked TB (through-bond) is that calculated by the method of Barfield (14) and described in the text. The curve marked TS(HH) (through-space) represents what remains of the solid curves when the coupling, obtained by elimination of interactions between the hydrogen atoms containing the coupled protons, is subtracted. Similarly, the curve marked TS(H*C*H) is obtained by subtraction of the coupling, calculated in the absence of interactions between the *ortho* hydrogen *s* orbital and the methyl carbon *s* orbital, from the solid curve.

TABLE 3. Calculations for $^5J_o^{H,CH_3}$ in *o*-dimethoxybenzene for the partially optimized conformations according to STO 3G computations (1)

Conformer	ψ_1°	ψ_2°	E (kJ/mol)	g_i[b]	P_i[c]	J_i[d,e]
1[a]	0	90	0	4	0.438	−0.128
2	0	0	0.13	1	0.100	−0.292
3	90	90	0.92	2	0.153	0.036
4	0	30	1.92	4	0.206	−0.237
5	0	60	3.68	4	0.103	−0.172

[a]The torsional angles ψ_1 and ψ_2 refer to rotation about the C_1—O and C_1—O bonds; $\psi_1 = \psi_2 = 0$ is the planar conformation, $\psi_1 = \psi_2 = 90°$ has the CH_3 groups on opposite sides of the benzene plane.
[b]Degeneracy of the conformation.
[c]Calculated from $P_i = g_i \exp(-\Delta E/RT) / \sum_i g_i \exp(-\Delta E/RT)$.
[d]According to column 1 of Table 2. The proviso, that conformational interconversion is rapid on this time scale, yields $\langle J \rangle = \sum P_i J_i = -0.14_6$ Hz as the predicted coupling for *o*-DMB.
[e]The calculated dipole moments of the nonplanar conformers 1, 4, and 5 are larger than that of the planar form, 2. Accordingly, dielectric solvent interactions would be expected to increase their relative populations, leading to larger discrepancies between observed and calculated couplings in *d*. The dipole moments of 1 to 5 are 2.06, 0.96, 0.43, 1.29, and 1.75 D in that order (1).

pression of the geometry around the methoxy group and the *ortho* C—H bond in **2** increases the magnitude of $^5J_o^{H,CH_3}$.

Summary and conclusions

The magnitude and sign of $^5J_o^{H,CH_3}$ in 1,2-dimethoxybenzene, when compared with some model compounds, imply a predominantly planar conformation in solution. The strong computed dependence of $^5J_o^{H,CH_3}$ on the torsion angle, ψ, about the C_1—O bond indicates that, if the expectation value, $\langle\psi\rangle$, were much larger than about 20°, then the magnitude of $^5J_o^{H,CH_3}$ would be much smaller than observed, suggesting in turn that the planar conformation is preferred by an energy substantially larger than kT (15).

Again, if 3,5-dichloroanisole is predominantly planar in solution, then the observed $^5J_o^{H,CH_3}$ is explicable in terms of its calculated ψ dependence. Similar remarks hold for 1,2,4-trimethoxybenzene and for 1,2-dimethoxy-4-formylbenzene.

The available T_1 data are consistent with these conclusions. In our opinion, chemical shift data need not disagree with these conclusions because nonadditivity exists for many *ortho* substituted benzene derivatives, not only for those in which the substituents are free to take on a number of orientations. We cannot judge the cogency of other physical data cited as evidence for nonplanar conformations in solution.

Recently, Caillet (20) has computed crystal lattice energies for some *o*-DMB derivatives and suggests that planar conformations exist due to steric interactions, arising when nonplanar molecules are stacked. Our results are for dilute solutions of *o*-DMB in benzene (the spectrum is very tightly coupled in other solvents). It may be that nonplanar solvent molecules would give a different result, but we doubt that. It may also be relevant that the STO 3G calculations refer to the gas phase, of course, and give a barrier of only 6 to 7 kJ for the rotation about the C—O bond in anisole. In a series of preliminary experiments on anisole in solution we have shown that this barrier can hardly be smaller than about 15 kJ (the measurements involve long-range coupling constants, T_2 and $T_{1\rho}$, and will be reported in due course). Perhaps, then, the planarity of *o*-DMB in solution arises from solvent-induced changes in the C—O barrier.

Received September 21, 1981[2]

J. V. SINISTERRA, J. M. MARINAS, and A. LLOBERA. Can. J. Chem. **61**, 230 (1983).

The Hammett equation has for the first time been applied to the esterification in the gas phase of *m*-MeO, *p*-MeO, *m*-Me, *p*-Me, H, *m*-NO_2, *m*-Cl, and *m*-Br benzoic acids, catalyzed by $AlPO_4$ of the F type. It is shown that the Hammett equation could be applied to the adsorption equilibrium constant, K_A, and to the apparent kinetic constant, $\vec{K}$. The K_A and $\vec{K}$ values used in this paper have been taken from a study by the same authors. The *m*-NO_2 benzoic acid is in disagreement with the general behavior of the other acids in the application of the Hammett equation to the adsorption process. The *p*-MeO benzoic acid is in disagreement with the behavior of the acids in the application of the equation to the surface reaction. In these cases, the ρ values were negative. It can be deduced that a positive charge is generated in the adsorption process and in the surface reaction. The $A_{Ac}2$ mechanism is discussed according to the values of ρ, and a more detailed mechanism is proposed. The separation of the enthalpic and entropic contributions to the substituent effect is carried out. $\bar{\rho}_s$ and $\bar{\rho}_H$ are nearly 50% in the adsorption process. In the surface reaction, the entropic contribution is greater (72.5%) than the enthalpic (27.5%).

J. V. SINISTERRA, J. M. MARINAS et A. LLOBERA. Can. J. Chem. **61**, 230 (1983).

On a appliqué pour la première fois l'équation de Hammett à l'estérification en phase gazeuse des acides *m*-MeO, *p*- MeO, *m*-Me, *p*-Me, H, *m*-NO_2, *m*-Cl et *m*-Br benzoïques catalysées par le $AlPO_4$ de type F. On a montré que l'équation de Hammett peut s'appliquer à la constante d'équilibre d'adsorption K_A et à la constante cinétique apparente $\vec{K}$. Les valeurs de K_A et de $\vec{K}$ utilisées proviennent d'une étude que nous avons réalisée antérieurement. L'acide *m*-NO_2 benzoïque se distingue du comportement général des autres acides lorsqu'on applique l'équation de Hammett au processus d'adsorption. L'acide *p*-MeO benzoïque se distingue des autres acides lorsqu'on applique l'équation à la réaction de surface. Dans ces cas, les valeurs de ρ sont négatives. On peut déduire qu'il y a production d'une charge positive dans le processus d'adsorption et dans la réaction de surface. On discute du mécanisme $A_{Ac}2$ selon la valeur de ρ et on propose un mécanisme plus détaillé. On a effectué une séparation de la contribution de l'enthalpie et de l'entropie à l'effet de substituant. Les valeurs de $\bar{\rho}_s$ et de $\bar{\rho}_H$ sont voisines de 50% dans le processus d'adsorption. Dans la réaction de surface, la contribution de l'entropie est supérieure (72,5%) à celle de l'enthalpie (27,5%).

[Traduit par le journal]

Introduction

A problem that has challenged chemists for years is the determination of the electronic influence that substituents exert on the rate and stereochemistry of a reaction. This problem (structure–reactivity relationship) is usually discussed by organic chemists within the context of the lineal free energy relationship (LFER). The most popular example of LFER in organic chemistry is the Hammett equation (1). It has been used in many organic reactions in homogeneous media, e.g. bromination of monosubstituted benzenes or esterification of monosubstituted benzoic acids. It has been used rarely, however, in reactions of aromatic compounds in the heterogeneous phase, e.g. intrinsic acidities of substituted benzoic acids (2), and in the adsorption of arenes on $AlPO_4$ and $AlPO_4$–SiO_2 catalysts (3).

We have recently studied the esterification of substituted benzoic acids with ethanol (4) in the vapour phase along the lines of investigation followed for the application of $AlPO_4$ to the different organic reactions: catalytic cracking, Beckmann rearrangement, etc. The kinetic runs were carried out in this study in order to elucidate the mechanism of the esterification of these acids on $AlPO_4$. We concluded that the pathway was a typical bimolecular acyl–oxygen cleavage mechanism ($A_{Ac}2$) in all cases. The rate-controlling step was not the adsorption process but the surface reaction between an adsorbed molecule of acid on the catalyst and a nonadsorbed molecule of alcohol. The application of the Hammett equation to the esterification of these acids in the vapour phase is studied in the present paper. The separation of enthalpic and entropic contributions to the substituent effect is also analyzed. The mechanism of the esterification of the substituted benzoic acids catalyzed by means of $AlPO_4$ is discussed according to the kinetic runs (4) and the Hammett equation.

Experimental

The method of synthesis, in ammoniacal medium, of the catalyst called F(100% $AlPO_4$) used in this work has been published in a previous paper (5). From adsorption–desorption isotherms of nitrogen at liquid nitrogen temperature, the surface area (S_{BET}) and accumulated pore volume (ΣV_p) were determined by the BET method (6). The results obtained were: S_{BET} = (109 ± 4) m^2/g, ΣV_p = (0.23 ± 0.09) mL/g. The acidity of the catalyst and the density of acidic sites were measured by titration in nonaqueous medium by applying the alteration to the original method (7) proposed by Balikova (8) using n-butylamine (0.0253 *M* in benzene) as the titrating agent and *p*-dimethylaminoazobenzene as the Hammett indicator (pK_a = +3.3).

m-Br	53±4	7.6±0.6	9.3±0.9	−54±5	35±3

[a]T = 200°C, W = 0.3 g of catalyst, $F_{N_2} = 5.6 \times 10^{-5}$ mol s^{-1} (carrier gas flow).

In this way the results were: total acidity = (0.49 ± 0.04) mequiv/g and density of acidic sites = (4.5 ± 0.4) × 10^{-3} mequiv/m^2. Ethanol, benzoic acid, and *m*-Me, *p*-Me, *m*-NO_2, *m*-MeO, *p*-MeO, *m*-Cl, and *m*-Br-benzoic acid were provided by Merck. Panreac anhydrous dioxane (99.98% purity) was used as an inert solvent to dissolve the reagents. This product vaporizes quickly at reaction temperature and it is inert in the reaction (4).

The kinetic runs were carried out in a conventional fixed bed reactor. The experimental results are described in the literature (4).

Results and discussion

In a previous study (4) we have shown that the esterification of substituted benzoic acids on $AlPO_4$ in the gas phase is carried out by a typical $A_{Ac}2$ mechanism where A is an active site of the catalyst (Lewis or Brönsted) (see Scheme 1).

The rate-controlling step is the surface reaction between an adsorbed molecule of acid and an unadsorbed ethanol molecule. The kinetic equation of the process is [1]

$$[1] \quad r_0 = \frac{\vec{k} \cdot s \cdot L \cdot K_A}{(1 + K_A P_{Ac})^2} P_{Ac} P_{Al}$$

where r_0 = initial reaction rate, S = number of adjacent active sites that act in the rate-controlling step, L = total number of active sites, P_{Ac} = acid pressure, and P_{Al} = alcohol pressure. From the kinetic runs, Langmuir's adsorption constants, K_A (atm^{-1}), apparent kinetic constants $\vec{K} = \vec{k} \cdot s \cdot L$(mol atm^{-1} g^{-1} s^{-1}), and the activation parameters ΔH (kcal mol^{-1}), ΔS^* (cal mol^{-1} K^{-1}), and ΔG^* (kcal mol^{-1}) were obtained for each substituent studied. Results are shown in Table 1. The adsorption parameters, ΔH^*_{ads}, ΔS^*_{ads}, and ΔG^*_{ads} were not accessible from the kinetic runs because the Yang and Hougen method (9) was used. In this method we must suppose that the adsorption constant, K_A, does not change within the range of temperatures used (160−240°C) and this is not exactly true. For this reason the precision of the constants K_A and $\vec{K}$ is not great (Table 1) but it is enough to get the sign of the slope of the Hammett equation and to study the mechanism of the organic reaction in a qualitative manner.

TABLE 2. Values of σ constants for the substituted benzoic acids studied

R—C_6H_4—CO_2H R	σ(10)	σ_H(15)	σ_S(15)
H	0.000	0.000	0.000
m-CH_3	−0.069	0.029	−0.077
p-CH_3	−0.170	−0.103	−0.055
m-NO_2	0.170	−0.198	0.942
m-OCH_3	0.115	0.045	0.068
p-OCH_3	−0.268	−0.359	0.079
m-Cl	0.373	−0.066	0.437
m-Br	0.391	−0.051	0.446

Application of the Hammett equation to the adsorption process

The values of the σ constants (10) are given in Table 2. In Fig. 1 the fitting of the experimental data with the Hammett equation, [2], for the σ constant is shown. The equation obtained was [3]

$$[2] \quad \log K_{ARBZ} = \rho\sigma \pm \log K_{AHBZ}$$

$$[3] \quad \log K_{ARBZ} = -(0.58 \pm 0.012)\,\sigma + (1.9 \pm 0.4) \quad (>99\%)$$

for r = 0.90, s = 0.078, and $F_{1,5}$ = 21.4.[3] K_{AHBZ} is the adsorption constant for benzoic acid, while K_{ARBZ} is the same

[3]Theoretical values of Snedecor's F constant: $F_{1,5}$ = 6.61 (α = 0.05); $F_{1,5}$ = 16.3 (α = 0.01).

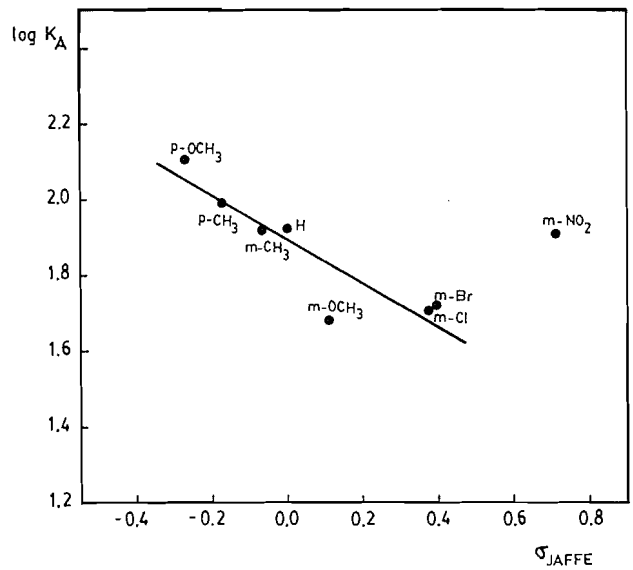

FIG. 1. Hammett plot for the Langmuir adsorption constant, catalyst $AlPO_4(F)$; $T = 200°C$.

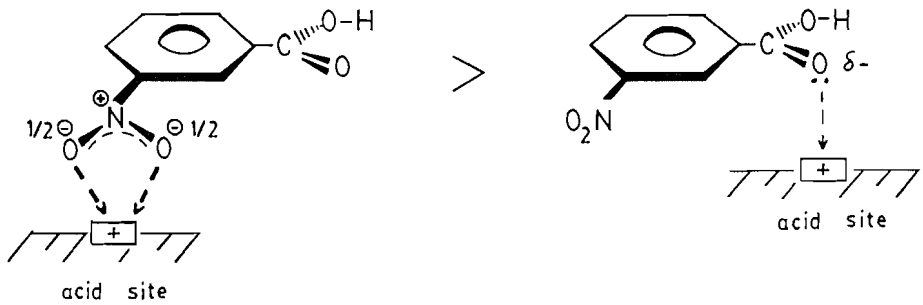
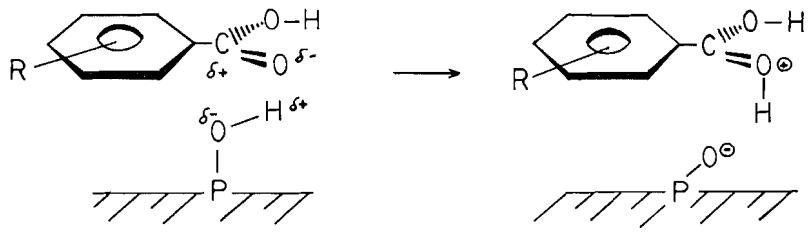
constant for the substituted benzoic acid. The value for the m-NO_2 is in disagreement with the general trend and it has not been included in the fitting of the experimental data to the Hammett equation [2]. This disagreement could be explained considering that this molecule will be adsorbed for the NO_2 group better than for the CO_2H group because of the greater negative charge of the NO_2 group. Thus the fundamental adsorption of this molecule[4] will not drive the esterification process to completion and the adsorption constant determined by the Yang and Hougen method will not be the true adsorption constant of this acid by the oxygen of the C=O bond (Scheme 2).

The negative sign of the ρ constant (−0.58) obtained indicates that a positive charge is produced on the substituted benzoic acid when the adsorption takes place. Because of this, the electron-donating groups favour the adsorption process: $K_{p\text{-MeO}} > K_{p\text{-Me}} > K_{m\text{-Me}} > K_H$, and electron-withdrawing groups do not favour the adsorption: $K_{m\text{-Cl}} < K_{m\text{-Br}} < K_{m\text{-MeO}} < K_H$. This agrees with the assumption that the adsorption process takes place on an acid site of the catalyst by means of a polar interaction between this active site and the point of greatest negative charge of the acid, the oxygen of the C=O group of carboxylic acid, except in the case of the m-NO_2 benzoic acid.



SCHEME 2



SCHEME 3

This kind of adsorption could describe the "activated adsorption" of carboxylic acid on the active site of the $AlPO_4$, probably a σ^*_{OH} bond of a P—OH alone (11). $AlPO_4$ would transfer a H^+ to the oxygen of C=O. The positive charge of this atom would be transmitted by the π conjugation to the aromatic ring. This would agree with the negative sign of the constant ρ. Thus, the adsorption process of these acids on $AlPO_4$ may be written as in Scheme 3.

Application of the Hammett equation to the surface reaction

The values of the apparent kinetic constant, $\vec{K}$, (Table 1) were adjusted to σ values of Table 2. The equation obtained was [4]

$$[4] \quad \log \vec{K}_{RBZ} = -(0.21 \pm 0.04)\,\sigma - (3.02 \pm 0.52) \quad (>99\%)$$

for $r = 0.93$, $s = 0.028$, and $F_{1,5} = 31.9$.[3] The Hammett plot is shown in Fig. 2. The p-MeO group is in disagreement with the other acids. Thus it has not been considered in the fit. This discordance could be explained by the strong +K effect of the group which makes it different from the other substituents studied. Its behaviour as an "abnormal" group has been reported in the organic literature for several reactions in homogeneous phase (12). Another explanation could be according to Yamdagni *et al.* (2) that the structure (I) (Scheme 4), being charge-separated, could be important in the "normal" solvents where the σ values are obtained. Therefore it cannot be important in the adsorbed state on the catalyst surface, where the separation of charges will probably be hindered by the electrical structure of the $AlPO_4$ catalytic surface. The σ constant of this group, for this reason, cannot be used in the gas phase.

The values of the ρ constant (−0.21) is smaller than the values obtained by the other workers in the esterification of

[4]This has been proved by F.O. theory (4).

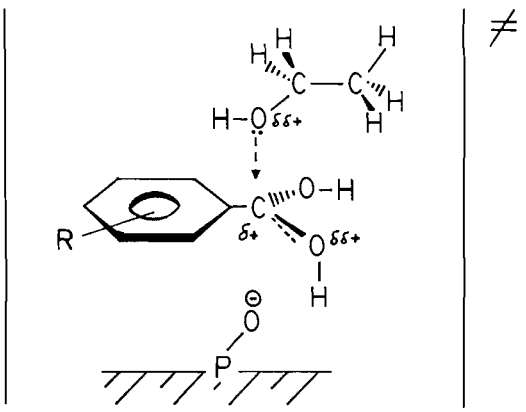
substituted benzoic acids with several alcohols, e.g. −0.58 with MeOH and HCl as the catalyst (13) and −0.48 with F_3B as the catalyst (14). This low value indicates that in our case the transition state is nearer the initial state (adsorbed acid) than the tetrahedral intermediate of a $A_{Ac}2$ mechanism. The negative sign of the ρ constant indicates that a positive charge is produced on the substituted benzoic acid when the surface reaction takes place and the activating groups: *p*-Me, *m*-Me, etc. favour the process. It only can be explained by means of an $A_{Ac}2$ mechanism if the electron donation from the lone oxygen pair of alcohol is very poor and if the C=O bond is practically broken by means of the $AlPO_4$ in the transition state. In this



SCHEME 5

case the positive charge of the carbon of the CO_2H group would increase and this positive charge would be transferred to the aromatic ring. This supposition is in agreement with the mechanism proposed from the kinetic data (4) where the rate-controlling step is the surface reaction between an adsorbed molecule of benzoic acid and an unadsorbed alcohol molecule. This also agrees with the postulates of the Frontier Orbital theory (F.O.) that say a small value of ρ indicates a very poor gap between the HOMO of the ethanol and the LUMO of the adsorbed acid. So, the transition state must be near the initial state. The transition state of the esterification of substituted benzoic acids with ethanol in the vapour phase, catalyzed by $AlPO_4$, may be pictured as in Scheme 5.

Separation of enthalpic and entropic contributions to substituent effects

In order to know if the separation of enthalpic and entropic contributions to substituent effects could be valid in a reaction in the gas phase, the Krygowski equation [5], (ref. 15), was applied

$$[5] \quad \log K = \log K_0 + \rho_H\sigma_H + \rho_S\sigma_S$$

where σ_H and σ_S are independent substituent constants for the enthalpic and entropic contributions (Table 2), ρ_H and ρ_S are the corresponding reaction constants, and K can be K_A or $\vec{K}$ according to the process under study.

The values of K_A and $\vec{K}$ (Table 1) were fitted to eq. [5]

$$[6] \quad \log K_{ARBZ} = 1.87 - 0.83\,\sigma_H - 0.49\,\sigma_S \quad (<70\%) \quad (<70\%)$$

for r = 0.93, s = 0.064, and $F_{2,4}$ = 14.0

$$[7] \quad \log \vec{K}_{RBZ} = -3.02_5 - 0.38_5\sigma_H - 0.23\sigma_S \quad (<30\%) \quad (<70\%)$$

for r = 0.93, s = 0.024, and $F_{2,4}$ = 17.5.[5] As in the Hammett equation, the *m*-NO_2 group was not considered in the adsorption process and the *p*-MeO was not considered in the surface reaction. The fit of the experimental data is acceptable but the significance level is minor compared to the other cases (only 95%), see Snedecor's F constant.

The ρ_s and ρ_H values were negative in both cases because a positive charge is created in the aromatic compound. The values of ρ_s(−0.49 and −0.23) are approximately equal to the Hammett reaction constants (−0.58 [3] and −0.21 [4]) according to the literature (15). The percentage of the enthalpic and entropic contributions $\bar{\rho}_H$ and $\bar{\rho}_S$ (15), respectively, to the substituent effect, was determined. The values obtained were by the adsorption process

$$\bar{\rho}_H = 51\% \qquad \bar{\rho}_S = 49\%$$

and by the reaction on the surface of the catalyst

$$\bar{\rho}_H = 27.5\% \quad \bar{\rho}_S = 72.5\%$$

We can say then that in the adsorption process the enthalpic and entropic contributions are equal, but not in the surface reaction, where $\bar{\rho}_S$ is greater than $\bar{\rho}_H$. These results confirm that there is a high interaction in the rate-controlling step between the molecule of benzoic acid and the environment (in our case the active surface of the catalyst $AlPO_4$). This is in agreement with the mechanism proposed in which the benzoic acid is adsorbed on the catalytic surface before the rate-controlling step.

Conclusions

From the results of this work we can deduce that the Hammett equation can be applied to the esterification process of

[5] Theoretical values of Snedecor's F constant: $F_{2,4}$ = 6.94 (α = 0.05); $F_{2,4}$ = 18 (α = 0.01).

substituted benzoic acids with ethanol in the vapour phase by means of $AlPO_4$ as catalyst.

On the other hand, the Hammett equation has been used to analyze the mechanism of the organic reaction. The mechanism, $A_{Ac}2$, seems to be the same for all substituted benzoic acids. The adsorption process and the rate-controlling step (surface reaction) take place creating a positive charge on the aromatic compound ($\rho < 0$). The small value of the ρ constant indicates a poor HOMO/LUMO gap and a preponderance of the electrostatic interaction in both processes. On the other hand, we could say that the transition state of the esterification of all acids studied is nearer the adsorption state than the tetrahedral state of the $A_{Ac}2$ mechanism, due to the small value of the ρ constant in the surface reaction. This is in agreement with the mechanism where the rate-controlling step is the reaction between an adsorbed molecule of acid and an unadsorbed ethanol molecule.

Betylates. 4. The synthesis and preparative nucleophilic substitution reactions of alkyl *S*-[3]betylates[1]

JAMES FREDERICK KING, STANISLAW SKONIECZNY,[2] AND GARY ALLAN POOLE
Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received August 18, 1982

JAMES FREDERICK KING, STANISLAW SKONIECZNY, and GARY ALLAN POOLE. Can. J. Chem. **61**, 235 (1983).

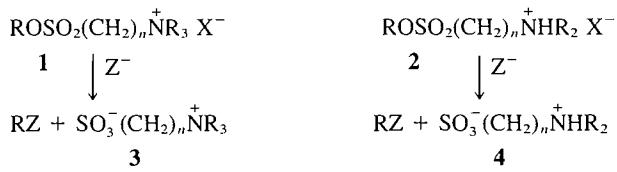
Alkyl *S*-[3]betylates (*S*,*S*-dialkyl-*S*-3[(alkyloxy)sulfonyl]propylsulfonium salts), the first examples of *S*-betylates (sulfonioalkanesulfonic esters), have been synthesized by two routes, and their suitability as intermediates in the transformation of alcohols by nucleophilic substitution reactions examined. They have been found to react readily in stoichiometric phase transfer processes, including substrate–reagent ion-pair reactions, like their previously studied nitrogen analogues, with the following particular features: (a) they may be used with basic nucleophiles (unlike [2]betylates), (b) they are more simply made from commercially available starting materials than [3]betylates, and (c) they can be made by a route that avoids a final alkylation step.

JAMES FREDERICK KING, STANISLAW SKONIECZNY et GARY ALLAN POOLE. Can. J. Chem. **61**, 235 (1983).

On a utilisé deux méthodes pour synthétiser les *S*-[3]bétylates d'alkyles, les sels de *S*,*S*-dialkyl-*S*[(alkyloxy)sulfonyl]-3-propylsulfonium, les premiers exemples de *S*-bétylates (esters de l'acide sulfonioalcanesulfonique) et on a étudié leur utilité comme intermédiaire lors de la transformation des alcools par des réactions de substitutions nucléophiles. On a trouvé qu'ils réagissent facilement par des processus de transfert de phase stoechiométriques, incluant des réactions de paire d'ions substrat–réactif, comme ceux de leurs analogues azotés étudiés antérieurement, ayant les caractéristiques particulières suivantes: (a) ils peuvent être utilisés avec des nucléophiles basiques (contrairement aux [2]bétylates), (b) ils sont obtenus plus facilement à partir de produits de départ disponibles commercialement que les [3]bétylates et (c) ils peuvent être préparés par une méthode qui évite l'étape finale d'alkylation.

[Traduit par le journal]

We have recently pointed to the merits of betylates (**1**) and norbetylates (**2**) as intermediates in the conversion of alcohols into other classes of compounds by way of nucleophilic substitution (1–5). Their application was illustrated by examples



involving ten primary or secondary alkyl groups and more than thirty different nucleophiles, leading to such varied products as halides, azides, thiocyanates, sulfonium salts, and carboxylate, sulfonate, and perchlorate esters. The particular advantages of betylates stem largely from their ability to undergo stoichiometric phase transfer, either in the form of (a) substrate phase transfer in two-phase aqueous–organic or simple aqueous systems, or (b) substrate–reagent ion-pair (SRIP) reactions in nonpolar media. One difficulty with [2]betylates (**1**, $n = 2$), however, is that under basic conditions, instead of undergoing nucleophilic displacement with formation of RZ and the betaine (**3**), they are converted back to the alkyl ethenesulfonate, which may either fail to react or simply give a product other than RZ. In practice this reaction is observed in aqueous solution when the pH is greater than about 6.5, or, in nonaqueous media with such reagents as alkylamines, alkoxides, and thiophenoxides. [3]Betylates (**1**, $n = 3$) do not suffer from this difficulty but at present their preparation from commercially available materials is rather inconvenient. In addition, current syntheses of [2]- and [3]betylates (**1**, $n = 2$ and 3, respectively) require quaternization of a tertiary amine as their final step, a procedure which may not be suitable if certain reactive groups (e.g. tertiary amino functions) are present in the original alcohol component. The formation of norbetylates (**2**), of course, does not require this alkylation step, but since these species are readily deprotonated by bases they too are obviously unsuited for general use with such reagents. Accordingly, in the hope of finding a betylate species which (a) could be used with basic reagents, (b) could be made readily from commercially available materials, and (c) did not require an alkylation step after the esterification of the alcohol, we explored – and now describe – the preparation and reactions of "*S*-[3]betylates" (**11**–**15**), the sulfur analogues of [3]betylates (**1**, $n = 3$).

S-[3]Betylates are prepared from the commercially available sultone (**5**) by either of the two routes shown in Scheme 1. All steps can be carried out in good yield, with the conversion of the alcohol (ROH) to the desired *S*-[3]betylate (**12**, **13**, **14**, or **15**) giving better than 85% yields based on the alcohol. Elemental analyses or an exact mass value were obtained for compounds **6** and **7** and representative esters (**10***b* and *e*, and **15***a*, $X^- =$ picrate), but the properties of the sulfonyl chlorides prevented full characterization; their nmr and infrared spectra taken with their mode of synthesis and conversion to esters clearly establish their identity. 3-Ethylthio-1-propanesulfonyl chloride (**8**) was readily prepared from **6** by *brief*, mild treatment with thionyl chloride in carbon tetrachloride; longer reactions times or more vigorous conditions led to poorer yields. The sulfonyl chloride (**8**) is reasonably stable in solution, showing significant decomposition only after more than two weeks at room temperature; it is distillable ($bp_{0.001}$ 62–63°C) but even with a good vacuum a good deal of decomposed stillpot residue is formed and the neat distillate so obtained turns brown after only a few hours at room temperature. Because of the short

SCHEME 1

shelf-life of the neat sulfonyl chloride (**8**), the preparation of 3-ethylthio-1-propanesulfonate esters (**10**) was carried out by using a freshly prepared solution of **8**, which is readily obtained from **6** in about 30 min in a laboratory scale preparation. The use of excess alcohol, excess sulfonyl chloride, and equimolar amounts of each, has been tried and found to give satisfactory results in all cases. The esters (**10**) so obtained appear to behave as conventional sulfonic esters. Whereas the analogous esters of aminosulfonic acids are rapidly converted by intermolecular alkyl transfer to betaines (6, 7),

$$R'_2N(CH_2)_nSO_2OR \longrightarrow RR'^{+}_2N(CH_2)_nSO_3^-$$

the corresponding reaction of the sulfide-esters (**10**) is evidently slow, distillation of the butyl ester (**10**, R = butyl) at 83–84°C (0.001 Torr) having been carried out with >80% recovery. Fortunately, however, alkylation of the sulfide

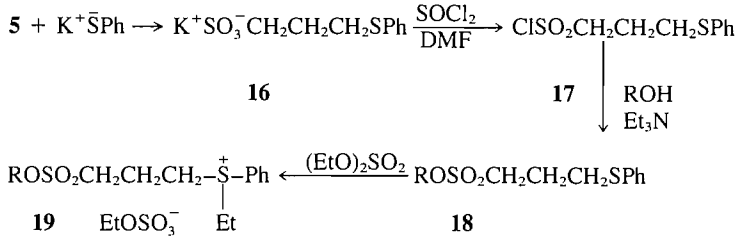
grouping in **10** to form the *S*-betylates (**12**) and (**13**) is effected in good yield by using the somewhat more reactive alkyl transfer agents diethyl and dimethyl sulfate at somewhat higher temperatures, respectively 110°C (for 1 h) and 100°C (for 0.5 h).

The alternative route to *S*-[3]betylates proceeds by way of "*S*-[3]betyl chloride" (**9**) which was obtained as an oil which in our hands did not crystallize, but which appeared from its ^{1}H nmr spectrum to be reasonably pure. A freshly prepared solution of **9** in D_2O showed no sign of the betaine (**7**) in its nmr spectrum, but after a short time peaks due to **7** appeared and those due to **9** diminished; a half-life of about 40 min (at 37°C) indicates a rate constant[3] of roughly 3×10^{-4} s^{-1}. Under ordinary storage conditions, neat **9**, in contrast to **8**, appears to keep about as well as other liquid sulfonyl chlorides. In refluxing acetonitrile **9** is converted to **8**, with ethyl chloride the presumed coproduct; such SRIP reactions of sulfonium halides are well-precedented (10).

Conversion of the *S*-betyl chloride (**9**) to hexadecyl *S*-[3]betylate chloride (**11**) was easily effected by reaction of an excess of **9** with the alcohol in the presence of triethylamine. The betylate chloride (**11**) was converted by ion extraction to the betylate picrate and camphor-10-sulfonate (**15**, X^- = picrate and camphor-10-sulfonate), the yields based on the alcohol being 97% and 88% respectively. To avoid contamination of the final product with the alkyl chloride it is apparently prudent to remove all unreacted thionyl chloride from the sulfonyl chloride (**9**) and to avoid heating of the betylate chloride (**11**) (see Experimental for details).

The reactions of some *S*-[3]betylates with a number of nucleophiles are summarized in Table 1. These reactions were found to occur under mild conditions to give clean products in respectable yields. With respect to reactions with such basic reagents as sodium ethoxide, sodium thiophenoxide, methylamine, and potassium cyanide, the behavior of *S*-[3]betylates was like that of their nitrogen analogues, the [3]betylates (**1**, $n = 3$), and much more satisfactory from a preparative viewpoint than that of the [2]betylates (**1**, $n = 2$).

Perhaps the chief difficulty with *S*-[3]betylates derives from the ease with which sulfonium salts transfer alkyl groups to nucleophiles; this reaction has already been encountered in the formation of **8** from **9** and is illustrated with *S*-[3]betylates by the SRIP reaction of the methyl ethyl picrate **14***a* (X^- = picrate). The product contained, in addition to the expected hexadecyl picryl ether, about 15% of a material which appeared from its ^{1}H nmr spectrum to be methyl picryl ether. As would be expected from the lower S_N2 reactivity of ethyl vs. methyl groups, the use of the diethyl sulfonium picrate (**15***a*, X^- = picrate) gave hexadecyl picryl ether with no sign of any ethyl picryl ether. But the alkyl transfer capability of an alkylsulfonium salt is still present even with the diethyl salts (**15**) and shows up when the alkyl group, R, is relatively unreactive; **13***c*, on treatment with sodium thiophenoxide gave roughly equivalent amounts of thiophenetole (PhSEt) and the ethylthio ester (**10***b*) together with a smaller amount of a previously unknown compound, neopentyl 3-phenylthio-1-propanesulfonate (**18***b*), the identity of which was shown by independent synthesis from **5** by the standard route (Scheme 2). Thio-



a) R = hexadecyl
b) R = neopentyl

SCHEME 2

phenetole and **10** were obviously formed by transfer of one of the *S*-ethyl groups, whereas **18** presumably arose (along with an equivalent amount of diethyl sulfide which evaporated during work-up) by reaction at the remaining carbon attached to the positively charged sulfur, i.e. C-1 of the propylsulfonium system. The comparative ease of this latter substitution at C-1 is of interest because it shows that regardless of the nature of the other two alkyl groups on the sulfonio sulfur, the undesired *S*-dealkylation will compete with *O*-alkyl transfer in the simple *S*-[3]betylate system when difficultly transferable alkyl groups such as neopentyl are attached to the sulfonyl oxygen.

The preparation of **17** and **18***b* as in Scheme 2 prompted us to take a brief look at the properties of an arylalkylsulfonic betylate (**19**) to see if such *S*-betylates possessed any advantages over their diethyl analogues (**15**). Arylalkyl sulfides are known to be more difficult to alkylate than dialkyl sulfides (11), presumably because of delocalization of the nonbonded electrons on the sulfur into the aromatic system, and we found in fact that the formation of **19***a* from **18***a* was distinctly less conveniently carried out than the preparation of **13** from **10**; after 2.5 h the reaction of **10***a* with diethyl sulfate at 80°C was nearly finished whereas that of **18***a* was less than 20% complete. By the same token, ethyl transfer *from* the positively charged sulfur was faster from **19***a* than from **13***a*; whereas the latter with aqueous sodium thiophenoxide gave phenyl hexadecyl sulfide in 81% yield, **19***a* afforded little or none of this product but rather almost entirely reverted to **18***a* (see Table 1). Evidently incorporation of one aryl group into the sulfonic grouping leads to a betylate which is less useful for the synthetic purposes studied in this paper than the dialkyl analogues **14** and **15**. A second aryl group, as in $Ar_2\overset{+}{S}CH_2CH_2CH_2SO_2OR$ X^-, would presumably not be any better since it would proba-

[3]For the corresponding hydrolysis of methanesulfonyl chloride (37°C, D_2O) a rate constant of 4.4×10^{-4} s^{-1} may be estimated from the work of Robertson and Laughton (8, 9) and the assumption that the kinetic solvent isotope effect is much the same at 37° and 20°C.

[a]Procedures: A, a suspension (or solution) of the substrate was stirred with an aqueous solution of the reagent used in tenfold excess; B, a solution of the substrate in CH_2Cl_2 (50 mL) is stirred with an aqueous solution of the reagent (50 mL); C, reaction in the organic solvent; D, reflux in toluene with no other reagents added (SRIP reaction).

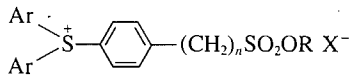
[b]Yields without parentheses refer to isolated products; those within parentheses were estimated from nmr spectra.

[c]Reaction was carried out under nitrogen. In the presence of oxygen Ph—S—S—Ph was formed (as judged by tlc).

[d]50 mL of 1,2-dimethoxyethane and 4 mL of 40% aqueous $MeNH_2$.

[e]Product composition was determined by comparison of nmr spectrum with that of an authentic mixture; in addition peaks at 1.03 (s), 3.25 (s), and 7.1–7.2 (m) are consistent with the presence of a small amount (~6%) of neopentyl phenyl sulfide.

bly suffer attack at C-1 of the propylsulfonium system analogous to the formation of **18***b* from **13***c*. Alkyl transfer from sulfur could, of course, be avoided with **20**, for example, but the preparation and reactions of such materials, in our view, constitute another project,



20 (n = 0, 1, 2 ...)

The conclusion of this initial exploration is that *S*-[3]-betylates are (a) good alkyl transfer agents for unhindered primary and secondary alkyl groups, and (b) readily prepared from a stable species (**6** or **7**) which is in turn easily made from a commercially available starting material (**5**). As such they should find, in conjunction with the other betylates (**1**) and the norbetylates (**2**), a useful part in the transformation of alcohols into other species.

Experimental

Reagent grade chemicals and solvents were used without additional purification unless otherwise noted. Melting points are uncorrected and were determined on a Kofler Hot Stage. Infrared spectra were obtained with Perkin–Elmer 621 Grating and Beckman 4250 spectrophotometers and unless otherwise noted refer to $CHCl_3$ solutions in 0.1 mm cells. Proton magnetic resonance spectra were obtained using Varian T60 and Varian XL100 spectrometers; all chemical shifts reported were obtained with the latter instrument; the ^{13}C nmr spectrum was determined on a Varian XL 200 instrument.

Potassium 3-ethylthio-1-propanesulfonate (6)

1,3-Propane sultone (**5**) (Aldrich, purified by distillation, $bp_{0.3}$ 94°C, 12.2 g, 100 mmol) in absolute ethanol (70 mL) was added dropwise during 20 min to a solution of ethanethiol (11.16 g, 180 mmol) and KOH (8.4 g, 150 mmol) in absolute ethanol (150 mL). Heat was evolved and a white precipitate formed immediately. After 1 h the reaction mixture was cooled in ice and the crystalline product **6** (20.0 g, 91%) collected by filtration; concentration of the filtrate gave a second crop (0.67 g, 3%). Recrystallization from absolute ethanol yielded white, hygroscopic crystals which decomposed without melting at 250–260°C; ir (KBr) ν_{max}: 2950 (m), 2900 (m), 1440 (m), 1410 (w), 1250 (s), 1185 (vs, br), 1040 (s) cm^{-1}; ^1H nmr (D_2O)δ: 1.24 (t, 3H), 2.02 (quintet, 2H), 2.68 (quartet, 2H), 2.74 (t, 2H), 3.02 (t, 2H). *Anal.* calcd. for $C_5H_{11}O_3S_2K$: C 27.03, H 4.95, S 28.83; found: C 27.21, H 5.02, S 28.61.

3-Ethylthio-1-propanesulfonyl chloride (8)

Recrystallized potassium 3-ethylthio-1-propanesulfonate (**6**) (4.44 g, 20 mmol) was suspended in carbon tetrachloride (20 mL). Thionyl chloride (22 mL) was added dropwise with stirring. After about 15 min of stirring at room temperature all the substrate had dissolved. After another 15 min the solution was diluted with CCl_4 (20 mL) and poured onto ice. The organic layer was washed with ice-water (100 mL) and then with five 100 mL portions of water. Each water portion was additionally washed with 5 mL of CCl_4. The organic layer was then dried with anhydrous $MgSO_4$ and the solvent evaporated giving **8** as a colourless oil (3.52 g, 87%); $bp_{0.001}$ 62–63°C. The purified compound **8** decomposed in a few hours at room temperature but was found to be stable in CCl_4 solution for at least 2 weeks; ir ν_{max}: 2960 (m), 2920 (m), 1450 (m), 1375 (vs), 1345 (m), 1300 (w), 1165 (vs), 1050 (w), 995 (w), and 840 (w) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.27 (5, 3H), 2.30 (quintet, 2H), 2.58 (quartet, 2H), 2.74 (t, 2H), 3.88 (t, 2H); ^{13}C nmr ($CDCl_3$) δ: 14.61, 23.96, 25.54, 28.91, 63.84.

Alkyl 3-ethylthio-1-propanesulfonates (10)

(a) *Hexadecyl 3-ethylthio-1-propanesulfonate (10a)*

A solution of triethylamine (5.05 g, 50 mmol) in CCl_4 (100 mL) was added dropwise during 45 min (very slowly at the beginning) to a solution of 3-ethylthio-1-propanesulfonyl chloride (**8**) (3.64 g, 18 mmol) and 1-hexadecanol (3.0 g, 12.4 mmol) in CCl_4 (100 mL). The mixture was stirred at room temperature for 0.5 h longer and washed, twice with 100 mL portions of 1 *M* HCl, 100 mL of H_2O, 100 mL of 5% Na_2CO_3, and three other 100 mL portions of H_2O. The water layer was washed each time with an additional 5 mL of CCl_4. The organic layer was then dried over $MgSO_4$ and the solvent evaporated under reduced pressure yielding 4.7 g (94%) of the product (**10***a*) which was recrystallized from pentane (50 mL) at −20°C. The white needles were collected by filtration and washed with cold pentane, mp 40°C; ir ν_{max}: 3020 (w), 2920 (vs), 2850 (s), 1465 (w), 1450 (w), 1355 (m), 1340 (m), 1160 (s), and 940 (m) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (t, 3H), 1.19–1.33 (m, 29H), 1.75 (t, 2H), 2.14 (quintet, 2H), 2.55 (quartet, 2H), 2.68 (t, 2H), 3.26 (t, 2H), 4.23 (t, 2H). *Anal.* calcd. for $C_{21}H_{44}O_3S_2$: C 61.66, H 10.77, S 15.66; found: C 61.63, H 10.80, S 15.70. The following esters were prepared similarly.

(b) *Butyl 3-ethylthio-1-propanesulfonate (10b)*

3-Ethylthio-1-propanesulfonyl chloride (**8**) (3.04 g, 15 mmol) and 1-butanol (1.11 g, 150 mmol) in 80 mL of CCl_4 and triethylamine (4.04 g, 40 mmol) in 80 mL of CCl_4 gave a colourless liquid (3.45 g, 96%) which was purified by distillation at reduced pressure, $bp_{0.001}$ 83–84°C (2.81 g, 78%); ir ν_{max}: 2960 (vs), 2930 (vs), 2875 (s), 1450 (s), 1410 (m), 1350 (vs, br), 1300 (s), 1260 (s), 1165 (vs), 1055 (m), 1010 (s), 990 (s), 950 (vs, br), 885 (vs), 850 (s), and 820 (s) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.96 (t, 3H), 1.27 (t, 3H), 1.38–1.92 (m, 4H), 2.14 (m, 2H), 2.44–2.80 (m, 4H), 3.28 (t, 2H), 4.26 (t, 2H); ms M^+ calcd.: 240.0854; found: 240.0857.

(c) *Neopentyl 3-ethylthio-1-propanesulfonate (10c)*

3-Ethylthio-1-propanesulfonyl chloride (**8**) (6.1 g, 30 mmol) and neopentyl alcohol (2.2 g, 25 mmol) in 150 mL of CCl_4 and triethylamine (8.08 g, 80 mmol) in 100 mL of CCl_4 gave a slightly yellow liquid (6.05 g, 95%). The compound **10***c* was recrystallized from pentane in Dry Ice to give white needles, mp ~0°C; ir (neat) ν_{max}: 2950 (vs), 2910 (s), 2855 (m), 1470 (m), 1445 (m), 1350 (vs), 1335 (s), 1260 (w), 1160 (vs), 955 (vs), 930 (s), 850 (m), and 825 (m) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.00 (s, 9H), 1.26 (t, 3H), 2.12 (quintet, 2H), 2.54 (quartet, 2H), 2.68 (t, 2H), 3.27 (t, 2H), 3.87 (s, 2H).

(d) *3-Buten-1-yl 3-ethylthio-1-propanesulfonate (10d)*

3-Ethylthio-1-propanesulfonyl chloride (**8**) (2.43 g, 12 mmol) and 3-buten-1-ol (0.86 g, 12 mmol) in CCl_4 (50 mL) and triethylamine (4.04 g, 40 mmol) in CCl_4 (80 mL) gave a colourless liquid (2.5 g, 89%); ir (neat) ν_{max}: 3070 (w), 2960 (s), 2920 (s), 2860 (m), 1640 (w), 1445 (m), 1425 (m), 1355 (vs), 1340 (vs), 1265 (s), 1165 (vs), 950 (vs, br), 900 (vs), and 845 (m) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.25 (t, 3H), 2.06 (quintet, 2H), 2.38–2.71 (m, 6H), 3.22 (t, 2H), 4.22 (t, 2H), 5.07–5.27 (m, 2H), 5.60–6.00 (m, 1H).

(e) *1-Methylheptyl 3-ethylthio-1-propanesulfonate (10e)*

3-Ethylthio-1-propanesulfonyl chloride (**8**) (2.43 g, 12 mmol) and 2-octanol (1.56 g, 12 mmol) in CCl_4 (50 mL) and triethylamine (3.03 g, 30 mmol) in CCl_4 (60 mL) gave a colourless liquid (3.25 g, 91%); ir ν_{max}: 2960–2910 (vs), 2860 (vs), 1460–1450 (s), 1370–1320 (br, vs), 1265 (m), 1170–1160 (vs), 1115 (m), 1025 (w), 960 (m), 910 (vs), and 875 (s) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.89 (t, 3H), 1.18–1.64 (m, 16H), 2.13 (quintet, 2H), 2.55 (quartet, 2H), 2.68 (t, 2H), 3.23 (t, 2H), 4.74–4.92 (m, 1H); ms M^+ calcd.: 269.1479; found: 269.1478.

S-Ethyl-S-3-[(hexadecyloxy)sulfonyl] propyl-S-methylsulfonium methylsulfate (12a)

Hexadecyl 3-ethylthio-1-propanesulfonate (**10***a*) (2.04 g, 5 mmol) was dissolved in dimethyl sulfate (10 mL, BDH, redistilled, bp_2 56°C), heated for 0.5 h at 100°C, cooled to 60°C, and the excess of Me_2SO_4 distilled off under reduced pressure. The residue was dissolved in anhydrous ether (15 mL), stirred for 5 min, and cooled to give **13***a* as white hygroscopic crystals. The recrystallization from

anhydrous ether was repeated several times. Yield 2.40 g (90%); ir ν_{max}: 2970 (s), 2930 (s), 1700 (w, br), 1635 (w), 1445 (w), 1415 (w), 1385 (w), 1340 (s), 1250–1200 (vs, br), 1160 (vs), 1005 (vs), 950 (w) and 910 (vs) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (t, 3H), 1.26 (s, 26H), 1.50 (t, 3H), 1.64–1.73 (m, 2H), 2.34 (quintet, 2H), 2.99 (s, 3H), 3.42–3.56 (m, 6H), 3.70 (s, 3H), 4.25 (t, 2H).

S-*Ethyl*-S-*methyl*-S-*3-[(neopentyloxy)sulfonyl] propylsulfonium methylsulfate (**12**c)*

Neopentyl 3-ethylthio-1-propanesulfonate (**10***c*) (1.02 g, 4 mmol) was methylated with 10 mL of dimethylsulfate as described for the preparation of **12***a* yielding 1.44 g (96%) of **12***c*; ir (neat) ν_{max}: 2950 (vs), 2865 (m), 1480 (w), 1455 (w), 1425 (w), 1350 (vs), 1240 (vs), 1220 (vs), 1165 (vs), 1055 (m), 1005 (s), 955 (s), 930 (s), 910 (vs), and 855 (m) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.99 (s, 9H), 1.51 (t, 3H), 2.35 (quintet, 2H), 3.01 (s, 3H), 3.42–3.57 (m, 6H), 3.68 (s, 3H), 3.93 (s, 2H).

S-*3-[(3-Buten-1-yl)oxysulfonyl] propyl*-S-*ethyl*-S-*methylsulfonium methylsulfate (**12**d)*

Compound **10***d* (2.4 g, 10 mmol) was methylated with 8 mL of dimethyl sulfate as described for the preparation of **12***a* yielding 2.83 g (79%) of **12***d*; ir (neat) ν_{max}: 2970 (s), 2930 (s), 1700 (w, br), 1635 (w), 1445 (w), 1415 (w), 1385 (w), 1340 (s), 1250–1200 (vs, br), 1160 (vs), 1005 (vs), 950 (w), and 910 (vs) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.51 (t, 3H), 2.28–2.60 (m, 4H), 3.00 (s, 3H), 3.44–3.57 (m, 6H), 3.69 (s, 3H), 4.32 (t, 2H), 5.08–5.29 (m, 2H), 5.61–6.02 (m, 1H).

S,S-*Diethyl*-S-*3-[(hexadecyloxy)sulfonyl] propylsulfonium ethylsulfate (**13**a)*

Hexadecyl 3-ethylthio-1-propanesulfonate (**10***a*) (3.3 g, 8 mmol) was dissolved in 10 mL of diethyl sulfate (BDH, redistilled, $bp_{0.2}$ 95°C), heated for 1 h at 110°C, and the excess of Et_2SO_4 distilled off under reduced pressure. The residue was dissolved in anhydrous ether and cooled. White crystals were precipitated and washed several times with anhydrous ether at −20°C to yield 4.4 g (99%) of **13***a*; ir ν_{max}: 3000 (vs), 2920 (vs), 2850 (m), 1455 (m), 1420 (w), 1385 (m), 1370 (m), 1345 (s), 1250–1200 (vs, br), 1165 (vs), 1105 (m), 1055 (m), 1015 (vs), and 915 (vs) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (t, 3H), 1.14–1.34 (m, 3H), 1.27 (s, 26H), 1.43 (t, 6H), 1.48–1.67 (m, 2H), 2.36 (quintet, 2H), 3.46–3.72 (m, 8H), 4.04 (quartet, 2H), 4.26 (t, 2H).

S-*3-(Butoxysulfonyl) propyl*-S,S-*diethylsulfonium ethylsulfate (**13**b)*

Butyl 3-ethylthio-1-propanesulfonate (**10***b*) (0.24 g, 1 mmol) was ethylated with diethyl sulfate (20 mL, 153 mmol) as described for the preparation of **13***a*, yielding **13***b* as a clear colourless liquid (0.33 g, 84%); ir ν_{max}: 2965 (vs), 2940 (vs), 2880 (s), 1455 (s), 1420 (m), 1350 (vs), 1260 (vs, br), 1160 (vs, br), 1055 (s), 1010 (vs), 940 (vs, br), 885 (s), 860 (s), and 830 (s) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.95 (t, 3H), 1.1–1.9 (m, 13H), 2.37 (m, 2H), 3.57 (m, 8H), 4.3 (m, 4H).

S,S-*Diethyl*-S-*3-[(neopentyloxy)sulfonyl] propylsulfonium ethylsulfate (**13**c)*

Neopentyl 3-ethylthio-1-propanesulfonate (**10***c*) (1 g, 4 mmol) was ethylated with diethyl sulfate (10 mL, 75 mmol) as described for the preparation of **13***a* to yield **13***c* as a viscous liquid (1.435 g, 89%); ir (neat) ν_{max}: 2960 (vs), 2865 (m), 1480 (w), 1455 (w), 1425 (w), 1350 (vs), 1240 (vs), 1220 (vs), 1165 (vs), 1055 (m), 1005 (s), 995 (s), 930 (s), 910 (vs), and 855 (m) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.99 (s, 9H), 1.28 (t, 3H), 1.53 (t, 6H), 2.38 (quintet, 2H), 3.41–3.79 (m, 8H), 3.94 (s, 2H), 4.04 (quartet, 2H).

S,S-*Diethyl*-S-*3-[(1-methylheptyloxy)sulfonyl]propylsulfonium ethylsulfate (**13**e)*

1-Methylheptyl 3-ethylthio-1-propanesulfonate (**10***e*) (2.96 g, 10 mmol) was ethylated with diethyl sulfate (15 mL, 110 mmol) as described for the preparation of **13***a* to yield **13***d* as a viscous liquid (3.96 g, 82%); ir ν_{max}: 2940–2900 (br, vs), 2840 (s), 1340–1310 (br, s), 1270–1135 (br, vs), 1000 (vs), and 900 (vs) cm^{-1}; ^1H nmr (CD_3CN) δ: 1.19–1.60 (m, 25H), 2.38 (quintet, 2H), 3.21 (t, 2H), 3.32–3.60 (m, 6H), 4.07 (quartet, 2H), 4.15–4.45 (m, 1H).

3-(Diethylsulfonio)propane-1-sulfonate (7)

1,3-Propane sultone (**5**) (Aldrich, purified by distillation $bp_{0.3}$ 94°C, 12.2 g, 0.1 mol) was refluxed with diethyl sulfide (45 g, 0.5 mol) for 40 min, cooled, and the abundant white precipitate filtered off (16.1 g, 76%). The filtrate was refluxed for an additional 2 h yielding 2.2 g (10%) of a second crop. The betaine (**7**) was recrystallized from absolute ethanol–ether, mp 260°C (dec.); ir (KBr) ν_{max}: 2970 (s), 2950 (s), 2920 (s), 1450 (s), 1425 (m), 1385 (m), 1305 (m), 1290 (s), 1265 (m), 1215 (vs), 1200–1180 (vs, br), 1055 (m), 1030 (vs) cm^{-1}; ^1H nmr (D_2O) δ: 1.45 (t, 6H), 2.26 (quintet, 2H), 3.09 (t, 2H), 3.36 (quartet, 4H), 3.47 (t, 2H). *Anal.* calcd. for $C_7H_{16}O_3S_2$: C 39.60, H 7.60, S 30.20; found: C 39.61, H 7.71, S 30.11.

S,S-*Diethyl*-S-*3-(chlorosulfonyl)propylsulfonium chloride (**9**)*

3-(Diethylsulfonio)propane-1-sulfonate (**7**) (1.06 g, 5 mmol) was dissolved in thionyl chloride (15 mL) and refluxed gently for 8–10 min. Most of the excess $SOCl_2$ was then evaporated under reduced pressure. Residual $SOCl_2$ was removed as follows. The residue was dissolved in freshly dried acetonitrile (20 mL) and evaporated; CH_3CN (20 mL) was again added and evaporated; freshly dried nitromethane (20 mL) was added and evaporated. The oily product **9** dissolves easily in water ($t_{1/2}$ for hydrolysis ~40 min at 37°C, with betaine (**7**) being the product), easily in CH_3NO_2 and in CH_3CN, and slightly in CH_2Cl_2; ir (neat) ν_{max}: 2960 (s), 2920 (s), 1445 (s), 1415 (m), 1370 (vs, br), 1270 (s), 1160 (vs), 1030 (s), 970 (m) cm^{-1}; ^1H nmr (CD_3CN) δ: 1.40 (t, 6H), 2.46 (quintet, 2H), 3.48 (quartet, 4H), 3.67 (t, 2H), 4.34 (t, 2H); ^1H nmr (D_2O) δ: 1.44 (t, 6H), 2.55 (quintet, 2H), 3.42 (quartet, 4H), 3.53 (t, 2H), 4.26 (t, 2H).

A separate nmr experiment showed that the maximum amount of the product **9** (ca. 80%) was observed after 10 min of gentle reflux of **7** in $SOCl_2$. The formation of **9** was accompanied by decomposition so that after 20 min of the reflux only ca. 50% of **9** was observed and after another 20 min almost 90% of the product was gone. In another nmr experiment purified **9** was refluxed in freshly dried acetonitrile for 10 h and the spectrum showed the product to be entirely **8**. In the presence of $SOCl_2$, however, no signals characteristic of **8** were observed.

S,S-*Diethyl*-S-*3-[(hexadecyloxy)sulfonyl] propylsulfonium chloride (**11**a)*

S,S-Diethyl-*S*-3-(chlorosulfonyl)propylsulfonium chloride (**9**) (1.34 g, 5 mmol) dissolved in freshly dried acetonitrile (15 mL) was cooled in a CCl_4 – Dry Ice bath (−23°C) and 1-hexadecanol (315 mg, 1.3 mmol) in dried methylene chloride (25 mL) added. A cold solution of freshly dried triethylamine (0.6 g, 6 mmol) in CH_2Cl_2 (20 mL) was then added dropwise (very slowly at the beginning). When the addition was complete (30–40 min) the solution was stirred for another 0.5 h while the temperature of the reaction mixture was allowed to rise to 0°C. The excess of NEt_3 was then washed out with two portions of dilute hydrochloric acid (1 *M*, 50 mL) with some ice added to bring the temperature of the solution to ca. 0°C and the organic solution was washed three times with water (50 mL each). A small sample of the reaction mixture was taken and the solution evaporated under reduced pressure at as low a temperature as possible. The ^1H nmr spectrum of the crude product showed peaks at 0.89 (t, 3H), 1.27 (s, 26H), 1.54 (t, 6H), 1.6–1.8 (m, 2H), 2.44 (quintet, 2H), 3.50 (t, 2H), 3.58 (quartet, 4H), 3.81 (t, 2H), 4.26 (t, 2H), characteristic of **11***a*.

S,S-*Diethyl*-S-*3-[(hexadecyloxy)sulfonyl] propylsulfonium picrate (**15**a, X^- = picrate)*

The CH_2Cl_2–CH_3CN solution of **11***a* was extracted twice with potassium picrate (1.1 g, 4 mmol, 150 mL of H_2O) and the excess of potassium picrate washed out with water (5–7 portions, 100 mL each). Each water layer was additionally washed with CH_2Cl_2 (10 mL); compound **15***a*, X^- = picrate, was found to be partly soluble in H_2O making the aqueous solutions milky. The organic layer was then

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

filtered twice through a paper filter and the solvent evaporated yielding an orange crude product **15***a* (X^- = picrate) (819 mg, 97%). The product was recrystallized from ethanol giving sticky crystals (730 mg, 86%), mp 82–85°C; ir (KBr) ν_{max}: 2900 (vs), 2835 (s), 1625 (m), 1605 (w), 1545 (w), 1460 (w), 1340 (s), 1300 (m), 1255 (m), 1230 (m), 1205 (m), 1155 (m) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (t, 3H), 1.27 (s, 26H), 1.55 (t, 6H), 1.6–1.8 (m, 2H), 2.42 (quintet, 2H), 3.49 (t, 2H), 3.57 (quartet, 4H), 3.81 (t, 2H), 4.26 (t, 2H), 8.79 (s, 2H). *Anal.* calcd. for $C_{29}H_{51}O_{10}S_2N_3$: C 52.33, H 7.67, S 9.62, N 6.32; found: C 52.48, H 7.83, S 9.62, N 6.31.

Compound **15***a* (X^- = picrate) was also obtained in the same manner in 83% yield from **13***a*.

S,S-*Diethyl*-S-*3-[(hexadecyloxy)sulfonyl] propylsulfonium camphor-10-sulfonate (15*a, *X^- = camphor-10-sulfonate)*

d,l-Camphor-10-sulfonic acid (0.93 g, 4 mmol, 100 mL) was used to obtain **15***a* (X^- = camphor-10-sulfonate) from a similar amount of the CH_2Cl_2–CH_3CN solution of **11***a* and using the same work-up as described for preparation of **15***a* (X^- = picrate). White sticky crystals of **15***a* (X^- = camphor-10-sulfonate) were obtained (768 mg, 88%); ir ν_{max}: 2970 (vs), 2850 (s), 1730 (m), 1350 (vs), 1240 (vs), 1165 (vs), 1045 (m), 950 (s), and 910 (vs) cm^{-1}; nmr ($CDCl_3$) δ: 0.82 (s, 3H), 0.88 (t, 3H), 1.07 (s, 3H), 1.26 (s, 26H), 1.49 (t, 6H), 1.43–3.40 (m, 15H), 3.55 (quartet, 4H), 3.52–4.00 (m, 2H), 4.28 (t, 2H).

S,S-*Diethyl*-S-*3-[(hexadecyloxy)sulfonyl] propylsulfonium fluoride (15*a, *X = F)*

A modification of the literature procedure (16) was used to prepare the F^--resin: Rexyn 203(OH) resin (7 g, 6.3 mequiv./g, 44 mmol) was treated with an excess of hydrofluoric acid (49.2% HF, 10 mL, diluted with H_2O, 190 mL) and the excess of aqueous HF was washed out with excess of distilled water to make the resin neutral and then the resin was washed with methanol (100 mL). A solution of **12***a* (2.3 g, 4 mmol) in methanol (50 mL) was then passed through the column (30 drops a minute) and the column washed with 100 mL of methanol; the methanol fractions were collected and the solvent evaporated under reduced pressure at ca. 0°C. Compound **15***a* (X = F) was found to be very hygroscopic and fragile so even gentle warming gave a product which showed, among other peaks, a doublet of triplets at δ 4.4 (J_{HF} = 48 Hz) in the ^1H nmr spectrum, characteristic of 1-fluorohexadecane. This decomposition product was easily washed out with cold hexane.

Reactions of S-*[3]betylates*

Reactants, quantities, reaction conditions, and yields are summarized in Table 1 and the spectra and mode of identification of products in Table 2. Examples of each of the four procedures referred to in Table 1 are given below.

Procedure A

S,S-Diethyl-3-[(hexadecyloxy)sulfonyl]propylsulfonium picrate (**15***a*, X^- = picrate; 1.33 g, 2 mmol) was suspended in water (50 mL) and potassium cyanide added (1.3 g, 20 mmol). A white precipitate (apparently **15***a*, X = CN) was formed after a few minutes; the suspension was heated at 80°C for 2 h. After cooling, the reaction mixture was extracted three times with methylene chloride (50 mL each), the organic layers pooled, dried over $MgSO_4$, and the solvent evaporated. The residue was dissolved in benzene (30 mL) and purified by filtration through a short column of silica gel; evaporation of the solvent gave hexadecyl cyanide as a colourless oil (381 mg, 76%) (see Table 2).

Procedure B

S,S-Diethyl-*S*-3-[(hexadecyloxy)sulfonyl]propylsulfonium ethylsulfate (**13***a*, 0.84 g, 1.5 mmol) was dissolved in methylene chloride (50 mL) and added to a solution of sodium azide (0.98 g, 15 mmol) in water (50 mL) and stirred at room temperature for 18 h. The organic layer was separated and the aqueous phase extracted with another portion of CH_2Cl_2 (30 mL); the organic solutions were pooled, dried over $MgSO_4$, the solvent evaporated, the residue dissolved in benzene (30 mL) and purified by filtration through a short column of silica gel to give hexadecyl azide as a colourless oil (332 mg, 83%) (see Table 2).

Procedure C

Sodium metal (560 mg, 20 mmol) was dissolved in absolute ethanol (20 mL) and then *S*-ethyl-*S*-methyl-*S*-3-[(hexadecyloxy) sulfonyl]propylsulfonium methylsulfate (**12***a*, 535 mg, 1 mmol) was added and the mixture stirred at room temperature for 1.5 h. The reaction mixture was then diluted with CCl_4 (40 mL) and washed with 3 portions of water (50 mL each). The organic layer was dried over sodium sulfate and the solvent evaporated to give ethyl hexadecyl ether as a colourless oil (240 mg, 90%) (see Table 2).

Procedure D

A sample of *S,S*-diethyl-3-[(hexadecyloxy)sulfonyl]propylsulfonium picrate (**15***a*, X^- = picrate; 665 mg, 1 mmol) was refluxed in toluene (15 mL) for 8 h. On cooling, a white precipitate of betaine was formed. This was filtered off and the toluene solution diluted with methylene chloride (50 mL), washed with water (three times, 50 ml each), dried over $MgSO_4$, and the solvent evaporated to dryness giving yellowish crystals of crude product (492 mg), which after two recrystallizations from petroleum ether gave hexadecyl picryl ether as white crystals, mp 64–65°C, 319 mg, 70% (see Table 2).

Potassium 3-phenylthio-1-propanesulfonate (16)

1,3-Propane sultone (**5**) (6.1 g, 50 mmol) in absolute ethanol (40 mL) was added dropwise during 15 min to a solution of benzenethiol (7.7 g, 70 mmol) and KOH (4 g, 70 mmol) in absolute ethanol (80 mL). After 0.5 h the precipitate was filtered off (12.7 g; 94%) and recrystallized from ethanol giving white fine crystals (11.5 g, 85%), mp 280°C (dec.); ir (KBr) ν_{max}: 3040 (w), 2940 (m), 2900 (w), 1565 (w), 1470 (m), 1430 (m), 1255–1245 (s), 1220–1200 (vs), 1180–1170 (vs), 1150 (m), 1090 (m), and 1045 (vs) cm^{-1}; ^1H nmr (D_2O) δ: 2.03 (quintet, 2H), 3.03 (2t, 4H), 7.18 (m, 5H).

3-Phenylthio-1-propanesulfonyl chloride (17)

Recrystallized potassium 3-phenylthio-1-propanesulfonate (**16**), (5.4 g, 20 mmol) was suspended in thionyl chloride (20 mL) and one drop of DMF was added. The suspension was refluxed for 10 min, cooled, diluted with methylene chloride (50 mL), and poured onto ice. The organic layer was washed with ice-water and then with five 100 mL portions of water. Each water portion was additionally washed with 5 mL of CH_2Cl_2. The organic layer was then dried with anhydrous $MgSO_4$ and the solvent evaporated to give an oily product (4.8 g, 96%) which was stable for at least 2 weeks at room temperature in the neat state and 1 month in $CDCl_3$ solution; ir ν_{max}: 3060 (m), 3050 (m), 2950 (s), 1580 (s), 1480 (s), 1435 (s), 1375–1350 (br, vs), 1300 (s), 1255 (s), 1170–1150 (br, vs), 1090 (m), 1020 (s), and 1000 (m) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 2.30 (quintet, 2H), 3.09 (t, 2H), 3.86 (t, 2H), 7.26–7.42 (m, 5H).

Alkyl 3-phenylthio-1-propanesulfonates (18)

The following esters were obtained following the general procedure for preparing **10***a*.

(a) *Hexadecyl 3-phenylthio-1-propanesulfonate (18*a*)*

3-Phenylthio-1-propanesulfonyl chloride (**17**) (5.01 g, 20 mmol) and 1-hexadecanol (4.36 g, 18 mmol) in CCl_4 (150 mL) and triethylamine (4.04 g, 40 mmol) in 80 mL of CCl_4 gave a white solid (7.76 g, 95%), which was recrystallized from pentane, mp 40°C; ir ν_{max}: 2910 (s), 2840 (s), 1465 (w), 1430 (w), 1345 (m), 1150 (s), and 955 (w) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (t, 3H), 1.26 (s, 26H), 1.45–1.76 (m, 2H), 2.15 (quintet, 2H), 3.07 (t, 2H), 3.27 (t, 2H), 4.19 (t, 2H), 7.27–7.41 (m, 5H); ms M^+ calcd.: 456.2731; found: 456.2723.

(b) *Neopentyl 3-phenylthio-1-propanesulfonate (18*b*)*

3-Phenylthio-1-propanesulfonyl chloride (**17**), (5.01 g, 20 mmol) and neopentyl alcohol (1.32 g, 15 mmol) in 150 mL of CCl_4 and triethylamine (6.06 g, 60 mmol) in 80 mL of CCl_4 gave slightly brown liquid (4.4 g, 97%); ir ν_{max}: 3040 (w), 2945 (br, vs), 2850 (m),

S-*Ethyl*-S-*3*-[*(hexadecyloxy)sulfonyl*]*propyl*-S-*phenylsulfonium ethylsulfate (**19**a)*

Hexadecyl 3-phenylthio-1-propanesulfonate (**18***a*) (4.56 g, 10 mmol) was dissolved in diethyl sulfate (20 mL, freshly redistilled), heated for 10 h at 85°C, and the excess of Et_2SO_4 distilled off under reduced pressure. The residue was dissolved in anhydrous ether (20 mL), stirred for a few minutes, and cooled at −20°C to give **19***a* as white hygroscopic crystals. The recrystallization from anhydrous ether was repeated 3 times. Yield 3.1 g (52%); ir ν_{max}: 3000–2980 (m), 2930 (s), 2860 (m), 1445 (m), 1350 (m), 1265–1230 (s), 1170 (vs), 1050 (br, m), 1010–1000 (s), and 915 (s) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (t, 3H), 1.13–1.68 (m, 34H), 2.18 (quintet, 2H), 3.38–4.46 (m, 10H), 7.74–7.78 (m, 2H), 8.04–8.15 (m, 3H).

Setchenow coefficients for naphthols by distribution method

M. BALÓN ALMEIDA, A. MAESTRE ALVAREZ,[1] E. MUÑOZ DE MIGUEL, AND E. SORIA DEL HOYO
Departamento de Química Física, Facultad de Ciencias Químicas, Universidad de Sevilla, Sevilla, Spain

Received December 11, 1981[2]

M. BALÓN ALMEIDA, A. MAESTRE ALVAREZ, E. MUÑOZ DE MIGUEL, and E. SORIA DEL HOYO. Can. J. Chem. **61**, 244 (1983).

Salting constant measurements have been made on 1-naphthol, 2-naphthol, and 1-NO-2-naphthol using a distribution method at 298 K. In general, the order of the salting effect is similar to that for other acidic nonelectrolytes. However, a net salting-in is observed in the pair 1-NO-2-naphthol − NaF, and such an effect is interpreted by postulating hydrogen bonding. A comparison of results with those found for benzene, naphthalene, phenol, etc..., reveals that salt effects for organic nonelectrolytes depend upon the solute size for a given salt.

Experimental k_s are compared with those calculated using various salting theories. The agreement is not quantitative.

M. BALÓN ALMEIDA, A. MAESTRE ALVAREZ, E. MUÑOZ DE MIGUEL et E. SORIA DEL HOYO. Can. J. Chem. **61**, 244 (1983).

Utilisant une méthode de distribution à 298 K, on a déterminé les constantes de salage du naphtol-1, du naphtol-2 et du NO-1 naphtol-2. En général, l'ordre de l'effet de sel est semblable à celui des autres acides non électrolytes Cependant on observe un relargage inverse net de la paire NO-1 naphtol-2 − NaF et on interprète un tel effet en supposant l'existence de liaisons hydrogène. Une comparaison des résultats avec ceux trouvés pour le benzène, la naphtalène, le phénol etc..., révèle que les effets de sel pour les non électrolytes organiques dépendent de la dimension de soluté pour un sel donné.

On a comparé les k_s expérimentaux avec ceux calculés en utilisant diverse théories de sel. L'accord n'est pas quantitatif.

[Traduit par le journal]

Introduction

A great amount of work has been done on the behavior of nonelectrolytes in aqueous electrolyte solutions (1−6). At present, the interest in the influence of electrolytes on the activity coefficients of nonelectrolytes in water and mixed solvents continues because of the increasing interest in the structural behavior of water and related problems (ion−nonelectrolyte−solvent interactions). The Setchenow coefficients, or salting constants, k_s, quantify direct interactions between the nonelectrolyte and the added salt (7).

A variety of theories have been used to calculate k_s (8); the McDevit and Long theory (MLT) and the scaled particle theory (SPT) have been the most useful in this context. The MLT and SPT were developed to describe salting effects of nonpolar solutes. Cross (9, 10) has expanded upon MLT to calculate activity coefficients of polar nonelectrolytes in salt solutions with reasonable success. For practical and theoretical reasons, most of the nonelectrolytes employed have been nonpolar solutes, but recent studies on the salting behavior of alcohols (11), tetrahydrofuran and acetonitrile (12), and cyclohexanone (13) have shown that SPT is actually the most successful theory for the prediction of the Setchenow constant of a polar solute in an inorganic salt solution.

It seemed interesting to us to study the salting effect in a series of naphthols because they present a polar character, great size, and a considerable hydrophobic group. Their comparison with benzene and naphthalene would help us to understand ion−nonelectrolyte−solvent interactions a little better. A comparison between experimental values and those predicted by the above theories may be interesting.

Experimental

The nonelectrolytes, 1-naphthol, 2-naphthol and 1-NO-2-naphthol were of the best commercially available quality (Merck, p.a., min. 99% GC) and they were purified by repeated recrystallization from water−methanol (mp, 1-naphthol 95−97°C, 2-naphthol 122−123°C, 1-NO-2-naphthol 106−108°C).

The salts employed LiCl, NaCl, KCl, NH_4Cl, HCl, Me_4NCl, $MgCl_2$, $BaCl_2$, NaF, KF, NaBr, NaI, and KI were purchased from Merck (p.a.) or Fluka (p.a.). They were purified by standard recrystallization procedures and kept in a vacuum desiccator. The organic solvents (extractants) were purchased from Merck (p.a.) and employed without being purified. Doubly distilled water was used in every experiment.

Distribution measurements

Distribution ratios of naphthols between water or salt solutions and inert organic solvent were determined by vigorous agitation of small aliquots. After equilibrium had been reached (15 min) the agitation was stopped and the systems were left in the bath for at least 2 hours. Aliquots of the aqueous phase were taken and after suitable dilution the concentrations of 1-naphthol, 2-naphthol, and 1-NO-2-naphthol were determined by measuring the optical density at 295, 320, and 380 nm respectively on a Beckman DBGT spectrophotometer equipped with digital readout. At each salt concentration 3−4 concordant replicate experiments were performed. All measurements were done at 25 ± 0.1°C.

The distribution method makes the study of very dilute solutions under identical conditions of both sparingly and readily soluble substances possible. Korenman proposed this method to obtain true Setchenow coefficients (14).

Results and discussion

The salt effect at high dilution can be estimated from the distribution of a nonelectrolyte between water, or aqueous electrolyte solutions, and an immiscible solvent (extractant) from the Setchenow equation:

$$[1] \quad \log \frac{K}{K_0} = k_s C_s$$

where K_0 and K are distribution constants of nonelectrolyte in water and aqueous electrolyte solutions respectively, C_s is the concentration of the salt, and k_s the Setchenow coefficient.

In Table 1, k_s values obtained by the solubility and distribution methods for 1-naphthol are compared. We observe that the distribution method produces a smaller k_s value than the solubility method. In the solubility method the concentration of 1-naphthol is 9.39×10^{-2} M and in the distribution method the concentration employed is 10^{-4} M. In a saturated solution solute−solute interactions may be observed; on the contrary, if the distribution method is used, we work with very dilute solutions and self-interaction may be avoided. Differences in k_s when applying the solubility and distribution methods have been observed for other solutes (1*a*). In Table 1 the effect on k_s when the organic solvent is changed in a given nonelectrolyte system is also shown. It seems that extractant does not affect the salting constants. In Table 2 the k_s values for 1-naphthol, 2-naphthol, and 1-NO-2-naphthol with various salts are given. In Figs. 1, 2, and 3 values of log K/K_0 are plotted against C_s. The slopes of the lines on these plots give the Setchenow constants for the various salts used.

A comparison of the k_s values (Table 1) shows that the salt orders for 1-naphthol are:

(*a*) $Ba^{2+} > Mg^{2+} > Na^+ > Li^+ > K^+ > NH_4^+ > H^+ > Me_4N^+$ (as chlorides)

(*b*) $F^- > Cl^- > I^- > Br^-$ (sodium and potassium)

These sequences reveal a behavior similar to other acidic nonelectrolytes (1). Setchenow coefficients for a series of nonelectrolytes are given in Table 3. Several comments can be made on various aspects: k_s increases with increasing size of the solutes (increase in hydrophobicity) for a given salt. So the

pairs benzene−naphthalene, naphthalene−biphenyl, and phenol − 1-naphthol exhibit this behavior. In this sense, Treiner (15) has recently observed for some organic solutes (nonpolar and polar) that the k_s is a monotonic function of the solute size and the nonelectrolyte dipole moment plays no role. Korenman and Bortnikova (16) have found identical results in a series of alkylphenols in various salt solutions (k_s increases systematically with the number of carbon atoms in the alkyl group). The inclusion of an OH group in benzene (Table 3) leads to more negative Setchenow coefficients, the salting-in becoming more favorable. The same pattern is observed in the pair naphthalene − 1-naphthol or 2-naphthol. The salting constants for naphthols depend on the position of the hydroxyl group. It is a general phenomenon that the location and kind of substituent in an isomer series affect k_s in different ways. Table 3 shows how k_s is affected by different salts in a mononitrophenol series; with all the salts studied, k_s diminishes in the sequence *para* > *ortho* > *meta*. This decrease could even produce a net salting-in on *meta*-nitrophenol with alkali metal chlorides and bromides. The inclusion of a NO group in the 2-naphthol molecule leads to more negative Setchenow coefficients (Table 2). It is known that the interaction of organic compounds in water or salt solutions is essentially an entropic phenomenon (8). This interaction may involve an increase or decrease of entropy depending on whether hydrophilic or hydrophobic interactions predominate. The lowering of k_s for 1-NO-2-naphthol in relation to other naphthols studied could be interpreted as a balance between hydrophilic and hydrophobic groups in each particular molecule. The NO group will be able to increase the hydrophilic interactions to a greater extent than other naphthols will. This effect produces an increase of entropy greater than other naphthols do, and, therefore, k_s will be more negative.

The large salting-in effect of Me_4NCl on 1-naphthol and 2-naphthol is remarkable. The hydrophobic interactions are important when tetraalkylammonium salts are involved (17). These interactions will be more important when the solutes are large nonelectrolytes with a predominantly hydrophobic exterior, and this is the present case. At this point, we note the influence of NaF on 1-NO-2-naphthol. This salt exhibits a large salting-out with organic solutes, but its anomalous salting-in in the present case could involve hydrogen bonding to a fluoride ion by the hydroxyl group of the 1-NO-2-naphthol, because the NO group in the molecule weakens the adjacent OH bond and this makes hydrogen bonding easier. This increases the solubility of 1-NO-2-naphthol and produces a net salting-in effect.

It is interesting to consider theoretical values of k_s. McDevit and Long (18) proposed a theory based on a thermodynamic approach that relates the changes in solubility of nonelectrolytes to the electrostriction of the solvent and the partial molal volume of the nonelectrolytes. The expression given for k_s is:

$$[2] \quad k_s = \lim_{C_s \to 0} \frac{V_i^0 \, dP_e}{2.3RT \, dC_s} = \frac{V_i^0 (V_s - V_s^0)}{2.3RT \, \beta_0}$$

where V_i^0 is the partial molar volume of the solute at infinite dilution and may reasonably be taken as the molar volume of the pure solute, V_m, when V_i^0 data are lacking, since V_i^0 and V_m are frequently similar in magnitude. V_s^0 is the partial molar volume of the salt at infinite dilution, V_s is the volume occupied by the salt as a liquid (the intrinsic volume). The difference, $V_s - V_s^0$ is the electrostriction of the solvent caused by the salt and is proportional to the effective pressure, P_e, exerted by the salt in solution; β_0 is the compressibility of water. We will limit our study to 1-naphthol. For this nonelectrolyte, V_i^0 is taken as V_m which we have determined from the molecular weight M and the density ρ of the crystal (19). We have calculated k_s using effective pressure, P_e, of the electrolytes where these are known (18) and $V_s - V_i^0$ for those where P_e, is lacking (18) (KBr and $MgCl_2$). In the case of Me_4NCl and KI, V_s has been equated to the molar volume of the crystalline salt and V_i^0 is taken from ref. 20. The values of k_s calculated are compared with experimental values in Table 4.

The scaled-particle theory (SPT) has been applied to some systems to calculate Setchenow coefficients in order to predict the salting effect of nonpolar solutes in aqueous solutions (3). However, a few researchers have applied the SPT to salting effects on polar solutes with reasonable agreement (11, 13). Desrosiers and Desnoyers (21) have applied it to the transfer functions of But_4N^+ from water to *tert*-butylalcohol + water and urea + water mixtures and the agreement with experiment is good.

We have employed the equations of Masterton and Lee (3) to calculate k_s. In order to find k_s it is necessary to know diameters, σ, of nonelectrolytes, cation, and anion and polarizabilities, α, of nonelectrlytes, cation, and anion as well as the apparent molal volume, ϕ_v^0, of the salt at infinite dilution and the energy parameter of the nonelectrolyte (ϵ/k). These parameters are given in Table 5 and the calculated k_s values for 1-naphthol are reported in Table 4.

[a]Values for σ from P = Pauling; W = Waddington; G = Goldsmidt; G−A = Gourary and Adrian; ref. 27.
[b]Reference 10.

From Table 4 we see that the values calculated from MLT are too large. In general, this is observed in many systems with MLT. However, the theory is able to predict the salting-in of Me_4NCl and gives the qualitative order of the salt effect. The values for k_s from SPT agree better with the experimental values than those from MLT, except for NH_4Cl. But SPT is very dependent on the various parameters chosen, particularly σ (cation and anion). In Table 6 we have calculated k_s for 1-naphthol with NaCl employing various σ from different sources. It is clear from Table 6 that the quantitative agreement may be very sensitive to σ.

Cross and McTigue (10) have extended the MLT to enable the calculation of activity coefficients of polar nonelectrolyte solutions. The relative mole fraction activity coefficients for the distribution of a nonelectrolyte between an organic phase and an aqueous phase are given by

For personal use only.

$$[3]\quad \lim_{\eta_{nc}\to 0}(\log f_{nc}) = \frac{V_m \cdot C_s(V_s - \phi_s)}{2.3\,RT\,\beta} \times \left[1 - \frac{C_s}{2}(V_s - \phi_s) - \frac{C_s^2}{3}(V_s - \phi_s)^2 - \ldots\right] \frac{r_h}{r_h + r_{nc}}$$

where: ϕ_s = apparent molar volume of salt in C_s molar salt solution; β = isothermal compressibility of a C_s molar salt solution: r_h = distance of closest approach to the non-electrolyte molecule. We have calculated log γ_{nc} (molar scale) at various concentrations of salt for LiCl, NaCl, and KBr and we have then obtained k_s from the plot of log γ_{nc} vs. C_s. The parameters used in eq. [3] in testing this approximation were taken in the following manner: V_m was taken at the same value as in MLT, ϕ_s from ref. 27, β from refs. 28 and 29, V_s from ref. 30, r_{nc} values have been calculated from $V_m = 4/3\pi r_{nc}^3$, and r_h were calculated from the individual ion radii, as determined from density measurements and tabulated in ref. 31.

The results obtained from eq. [3] are compiled in Table 4. Equation [3] produces the best agreement with the experimental values. It is important to notice that the values calculated from eq. [3] are also dependent on the V_s chosen. In Table 6 we have calculated k_s for the 1-naphthol − NaCl system employing various V_s. The possible general utility of eq. [3] lies in the prediction of activity coefficients, or k_s, for polar nonelectrolytes in salt solutions if an appropriate value of V_s has been found. Moreover, the treatment requires no precise mathematical description of interaction between particles or structural aspects of water.

In short, all present theories on salt effect give no quantitative agreement with experimental values. It is evident that more theoretical and practical work must be done on this problem.

Extrapolation from concentrated to dilute aqueous acids

A. J. KRESGE,[1] H. J. CHEN, G. L. CAPEN, AND M. F. POWELL

Department of Chemistry, University of Toronto, Scarborough College, West Hill, Ont., Canada M1C 1A4 and Department of Chemistry, Illinois Institute of Technology, Chicago, IL 60616, U.S.A.

Received June 15, 1981[2]

A. J. KRESGE, H. J. CHEN, G. L. CAPEN, and M. F. POWELL. Can. J. Chem. **61**, 249 (1983).

The location and the manner of union of the H_0 and H_R acidity functions with $-\log C_{H^+}$ have been determined for aqueous $HClO_4$, HCl, and H_2SO_4 (H_0 only) through particularly careful and extensive indicator measurements in dilute and moderately concentrated solutions of these acids. These data were also used to evaluate and compare a number of different ways of extrapolating measurements made in concentrated acids down to dilute solution; over the limited range of acidity investigated, the traditional acidity function method, as commonly applied in the absence of an appropriate acidity function (i.e. in the form of mH_0), was found to be the least satisfactory of these extrapolative methods, and the Cox–Yates technique was found to be the best.

A. J. KRESGE, H. J. CHEN, G. L. CAPEN et M. F. POWELL. Can. J. Chem. **61**, 249 (1983).

On a déterminé la position et le mode d'union des fonctions d'acidité de H_0 et de H_R avec $-\log C_{H^+}$ pour des solutions aqueuses de $HClO_4$, de HCl et de H_2SO_4 (H_0 seulement); on a effectué ces déterminations avec un soin particulier grâce à des mesures extensives d'indicateurs dans des solutions diluées et modérément concentrées de ces acides. On a également utilisé ces données pour évaluer et comparer un nombre de méthodes différentes de mesures par extrapolation faites à partir de solutions concentrées d'acide jusqu'à des solutions diluées dans les limites de l'intervalle d'acidité étudié. On a trouvé que la méthode traditionnelle de fonction d'acidité, i.e. telle qu'appliquée couramment en l'absence d'une fonction appropriée d'acidité sous la forme de mH_0, est la moins satisfaisante des méthodes par extrapolation et on a trouvé que la technique de Cox–Yates est la meilleure.

[Traduit par le journal]

One of the principal uses of acidity functions is to provide a means of extrapolating measurements made in concentrated acids down to dilute solution. For example, when the quantity of interest is the ratio of protonated to unprotonated forms of a weak base, C_{BH^+}/C_B ($\equiv I$), this operation gives I in a medium within the normal pH region from which a dilute solution pK_a may readily be estimated.

Such extrapolations have traditionally been performed on the assumption that $\log I$ is directly proportional to an appropriate acidity function, H_x, eq. [1] (1).

$$[1] \quad \log I = a + H_x$$

When the correct acidity function is not available, the further assumption that different acidity functions are linearly related to one another (2), and therefore to H_0, $H_x = mH_0$, is sometimes made, and the extrapolation is then performed down mH_0, eq. [2].

$$[2] \quad \log I = a + mH_0$$

This method, however, runs into the difficulty that m, though different from unity in concentrated acid solutions, must eventually become one when the H_x acidity function joins the $-\log C_{H^+}$ scale. This makes accurate extrapolation difficult, for the way in which m changes is not generally known.

An alternative method of extrapolation which avoids this problem was proposed some time ago by Bunnett and Olsen (3), who assumed that activity coefficient (f) functions of the form $\log (f_B f_{H^+}/f_{BH^+})$ rather than acidity functions are proportional to one another, eq. [3].

$$[3] \quad \log (f_B f_{H^+}/f_{BH^+}) = (1-\phi) \log (f_{B'} f_{H^+}/f_{B'H^+})$$

This hypothesis leads to the expression shown as eq. [4], which has the advantage that the extrapolation is now made down a

$$[4] \quad \log I + H_0 = pK_a + \phi(H_0 + \log C_{H^+})$$

quantity, $H_0 + \log C_{H^+}$, which becomes zero in dilute acids; this provides a simple solution to the problem of where the extrapolation should be terminated. Equation [4] was tested extensively by Bunnett and Olsen (3) and also by Marziano and Passerini (4) and was found to be generally valid. Marziano and Passerini also used the hypothesis of linearly proportional activity coefficient terms (eq. [3]) to construct a generalized activity coefficient function based upon a large number of different kinds of indicators, M_c, whose use they advocated in eq. [4] in place of ($H_0 + \log C_{H^+}$). More recently this method was extended to an even larger data base with further mathematical refinements by Cox and Yates, who called their result the excess acidity function, X (5).

We have for some time been concerned with accurate extrapolation of both kinetic and equilibrium data from concentrated to dilute acid solution. A number of years ago we therefore made extensive and careful determinations of the H_0 and H_R acidity functions in dilute and moderately concentrated aqueous acids. These data, which we present here in full,[3] show how these two acidity functions run into the $-\log C_{H^+}$ scale, and they also allow comparison of the newly developed methods of extrapolation.[4]

Results

Three H_0 indicators and three H_R indicators, chosen to give good regions of overlap, were used in this study. Extents of protonation of these indicators were measured spec-

[a]Error limits are standard deviations of mean values based upon experimental deviations; as such, they are an index of precision only and probably overestimate the accuracy.

[b]The pK_a of the most basic indicator, 4-nitroaniline, could not be determined by extrapolation in this medium because H^+ concentrations of sulfuric acid solutions are not known accurately enough. The pK_a of this indicator was therefore taken to be the average of the values determined in $HClO_4$ and HCl solutions, and this was used with the method of overlap to determine pK_a's for the two remaining indicators in H_2SO_4 solution.

trophotometrically, making use of the large changes in ultraviolet or visible spectra which accompany their protonation. Measurements were made with both sets of indicators in perchloric and hydrochloric acids and with the H_0 indicators only in sulfuric acid. For each acid–indicator combination, values of log I were determined in triplicate at three different wavelengths for 20 to 40 solutions whose concentrations were chosen to distribute the log I values evenly over the interval log $I = -1.5$ to $+1.5$, which is the range where this quantity can be determined most accurately (8). These log I values were then transformed into H_0 and H_R functions using the wholly analytical method which we developed in constructing an H_0 function for ethanolic sulfuric acid (9). In this method the usual graphical techniques for extrapolating to infinitely dilute solution and interpolating in regions of overlap are replaced by the more objective and accurate evaluation of analytical functions generated by weighted least-squares fitting of the data to appropriate mathematical expressions.[5]

The indicator pK_a's obtained in this way are listed in Table 1. The values for the most basic indicator in each set, 4-nitroaniline and 4,4′,4″-trimethoxyphenylmethanol, are based upon extrapolation to infinite dilution; the others are averages of pK_a's determined by such extrapolation and by overlap with more basic indicators. The results obtained for 4-nitroaniline in the two acids in which the pK_a of this indicator was determined are in good agreement; the pK_a's of the other indicators, however, show differences from acid to acid.[6] These differences increase with decreasing indicator basic strength, and therefore with increasing concentration of the acid in which the measurements were made, which suggests that they are the result of different medium effects, i.e. different interactions of the indicator base and its conjugate acid with the different acid solvents. This implies a breakdown of the extrapolative and comparative procedures upon which acidity functions are based. Effects of this kind are not uncommon among bases of different structure, but they are somewhat more rare for indicators belonging to structurally homogeneous classes (see, however, refs. 4, 5, and 10).

Since there is no reason to expect medium effects to be the same in different acids, these pK_a differences were retained in constructing the present H_0 and H_R scales, i.e. the pK_a's determined in a given acid were used to build the acidity function for that acid. Representative H_0 and H_R values over the regions of acid concentration covered in this study are listed in Table 2.

TABLE 2. Acidity function values determined in this study (25°C)

wt% acid	H_0			H_R

24.00	—	—	−1.34	−2.46	—

These new results compare well, on the whole, with previous determinations. For example, the Long and Paul (11) – Jorgenson and Hartter (12) H_0 scale for H_2SO_4 as compiled by Boyd (1*b*) is only 0.10 more positive than ours, and the Bascombe and Bell (13) H_0 scale for H_2SO_4 is also more positive but by a smaller amount: 0.02 to 0.05. More recent determinations of H_0 in H_2SO_4 were made by Tickle, Briggs, and Wilson (14), whose scale is 0.07 to 0.14 more positive than ours, and also by Johnson, Katritzky, and Shapiro (15), whose scale is 0.01 and 0.07 more positive than ours.

Fewer determinations of H_0 in other acids have been made, but here again agreement of modern work with the present results is good. This is especially true of the Arnett and Mach (16) H_0 scale for HCl, which never differs from ours by more than 0.01. The Yates and Wai (17) H_0 scale for $HClO_4$, as well as the closely similar Attiga and Rochester (18) scale, are also

[5]Tables of the complete log I values determined here are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

[6]A referee has asked us to emphasize that these differences impair the thermodynamic significance of these pK_a's.

For personal use only.

consistent with ours; the former runs 0.05 to 0.13 more negative than ours.

The literature contains only one determination of H_R for each of the two acids studied with this kind of indicator here. The Arnett and Mach (16) H_R scale for HCl is only 0.10 to 0.13 more positive than ours from 0.1 to 8 wt% acid, but the difference then jumps to 0.20 at 10 wt% and 0.26 at 14 wt%. For $HClO_4$, the present scale is in essential agreement with the early work of Deno, Barkheimer, Evans, and Peterson (19) at 0.5 wt% acid, but above that point the latter runs progressively more negative than our scale until at 20 wt% acid the difference amounts to 0.47.

The present results cover only a limited range of acid concentrations, and they were therefore fused with selected literature scales to provide more extensive acidity functions in the following more or less arbitrary way. Because the Johnson, Katritzky, and Shapiro (15) H_0 scale for H_2SO_4 agrees with ours to within 0.01 over the region 20–22 wt% acid, we simply joined these two scales at this point, i.e. the resulting H_0 scale for H_2SO_4 uses our values for 0.25 to 22 wt% acid and the Johnson, Katritzky, and Shapiro data from 22 to 95 wt% acid. We also joined the Arnett and Mach (16) H_0 scale for HCl to ours in the same way, i.e. with no adjustment, since it also agrees with ours to within 0.01. The Yates and Wai (17) H_0 scale for $HClO_4$, however, is more negative than ours by 0.06 at 20 wt% acid, and we therefore used our scale up to this point and the Yates and Wai scale plus 0.06 from 20 to 78 wt% acid. We also made adjustments to literature H_R scales in joining them to our results. For H_R in HCl, we used our scale up to 14 wt% acid and the Arnett and Mach (16) scale minus 0.26 from 14 to 38 wt% acid, and for H_R in $HClO_4$, we used our scale up to 24 wt% and then the Deno, Berkheimer, Evans, and Peterson (19) scale plus 0.50 from 24 to 60 wt%.

We have not supplied tables of the resulting acidity functions because we find it more convenient to store values in mathematical form. We have found that an acidity function can usually be represented quite well, to 0.01 to 0.02, by a sixth order polynomial plus a logarithmic term, eq. [5], and we therefore fitted our data to such functions by least-squares pro-

$$[5]\quad H_x = a_1 \ln x + a_2 + a_3x + a_4x^2 + a_5x^3 + a_6x^4 + a_7x^5 + a_8x^6;\ x = \text{wt\% acid}$$

cedures. The coefficients of such expressions for H_0 in $HClO_4$ and HCl[7] and for H_R in $HClO_4$ and HCl are listed in Table 3 together with those of other functions which interconvert wt% and molar concentration scales for these acids. These functions are easily programmed into small calculators and therefore provide an especially useful way of retrieving and interpolating data.

[a]Coefficients of the function $y = a_1 \ln X + a_2 + a_3x + a_4x^2 + a_5x^3 + a_6x^4 + a_7x^5 + a_8x^6$; the last two digits of a coefficient and the sign preceding them denote the power of ten. These equations reproduce wt% acid to 1/1000, M to 0.01 and H_0 and H_R to 0.01–0.02. The relationships between M and wt% are based on densities given by ref. 22*a* for $HClO_4$, ref. 22*b*, p. 54 for HCl, and p. 56 for H_2SO_4.
[b]An additional term in $(\text{wt\%})^7$ is needed whose coefficient is −2.179−13.

Discussion

Union of H_x *and* $-log\ C_{H^+}$ *scales*

Examination of Table 4, in which the presently determined H_0 and H_R scales are compared with $-\log C_{H^+}$, shows that sizeable differences exist between these acidity functions and $-\log C_{H^+}$ at the point where the latter is equal to zero (C_{H^+} =

[7]We could not find a set of coefficients which reproduced the H_0 data for H_2SO_4 well, and we therefore do not include an expression for this scale in Table 3. Our scale for this acid from 0.25 to 24 wt% is listed in Table 2; above 24 wt% acid we recommend the values of ref. 15.

[a]Interpolated using the data of Table II in ref. 5.

1.00 *M*) for all three acids investigated. These differences diminish as C_{H^+} drops through the region where the acidity functions themselves pass through zero, but even at C_{H^+} = 0.100 the differences are still significant; for example H_R measures 0.100 *M* $HClO_4$ as 0.08 more acidic than does $-\log C_{H^+}$, and H_0 measures 0.78 wt% H_2SO_4 (0.079 *M*), in which C_{H^+} = 0.100 *M*, to be 0.09 more acidic than does $-\log C_{H^+}$. These, of course, are differences on a logarithmic scale; their antilogs correspond to factors of 1.20 and 1.23, respectively. It is not until C_{H^+} drops to ca. 0.025 *M* that differences between H_0 and H_R and $-\log C_{H^+}$ reach a value, 0.01, which is experimentally indistinguishable from zero.

This point of union of H_x with $-\log C_{H^+}$ is understandable in terms of the definition of H_x, eq. [6], and the behavior of activity coefficients as represented, for example, by the Debye–Hückel equation, eq. [7]. In the Debye–Hückel formulation, activity coefficients of different ions have dissimilar

$$[6] \quad H_x = -\log C_{H^+} - \log f_x f_{H^+}/f_{xH^+}$$

$$[7] \quad -\log f = A\sqrt{\mu}/(1 + aB\sqrt{\mu})$$

values at the same ionic strength, μ, because of differences in the ion-size parameter, *a*. The H^+ ion, because it is so strongly hydrated in aqueous solution, has an unusually large value of this parameter: 8–9 Å; *a* for other ions is generally much smaller (20). This difference gives the quantity $\log f_{H^+}/f_{xH^+}$ a non-zero value and makes H_x different from $-\log C_{H^+}$ in moderately concentrated acids. The difference, however, diminishes as ionic strength decreases, and, with values of *a* recommended by Bates (20) and the condition that f_x = 1.00, the activity coefficient term $\log f_x f_{H^+}/f_{xH^+}$ drops to within 0.01 of unity when μ = ca. 0.025 *M*.

Extrapolation to dilute solution

As the data of Table 4 show, the union of H_0 and H_R with $-\log C_{H^+}$ is achieved only very gradually. This means that the coefficient *m* in the expression relating one acidity function to another, $H_x = mH_0$, begins to change from its constant concentrated-solution value in acids which are still not very dilute. This makes extrapolation down an "inappropriate" acidity function in the manner of eq. [2] difficult.

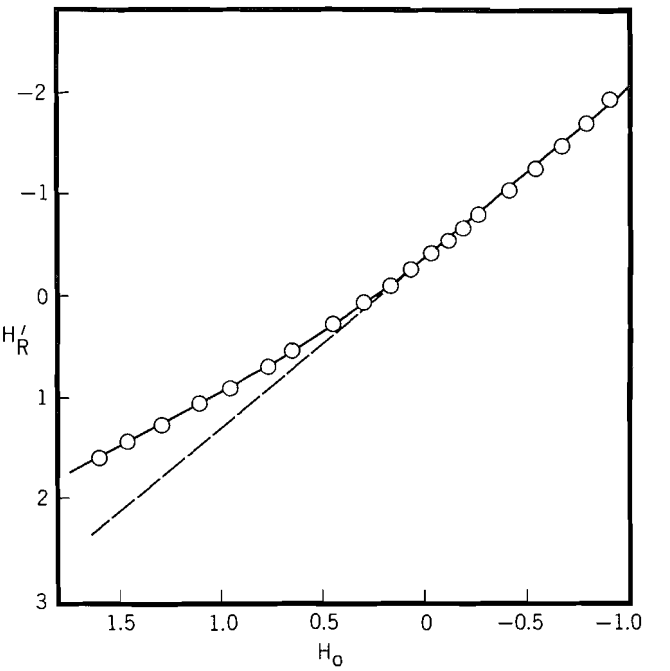

FIG. 1. Relationship between H_0 and H'_R acidity functions in aqueous $HClO_4$ at 25°C.

For example, an H'_R scale constructed from our H_R function[8] for $HClO_4$ is a good linear function of H_0 over the region 5–20 wt% acid (Fig. 1): $H'_R = (-0.343 \pm 0.009) + (1.654 \pm 0.018)H_0$; *r*(correlation coefficient) = 0.9995.[9] At 5% acid (0.51 *M*), however, *m* begins to decrease gradually, dropping from 1.654 to its dilute solution value of unity, which it reaches in 0.025 wt% $HClO_4$. This means that linear extrapolations from acids more concentrated than 5 wt% down to dilute solution (down the broken line of Fig. 1) will produce erroneous values of the quantity extrapolated. Take, for example, the case of a hypothetical H'_R base with $pK_a = 0.00$, $K_a = 1.00$, for which, by definition, $\log I = -H'_R$. Extrapolation of the linear relationship $H_R = -0.343 + 1.654H_0$ down to 0.25 wt% acid, the point where H_0 and H'_R unite with $-\log C_{H^+}$ and all three quantities have the value 1.60, gives $\log I = -2.30$. This, when combined with $\log C_{H^+}$ according to eq. [8], coupled with

$$[8] \quad pK_a = \log I + H_R = \log I - \log C_{H^+} + -\log f_x f_{H^+}/f_{xH^+}$$

the condition that in 0.25 wt% $HClO_4$ $\log f_x f_{H^+}/f_{xH^+} = 0$, produces $pK_a = -0.70$. This result differs from the true value $pK_a = 0.00$ by 0.70 log unit, which corresponds to a factor of 5 in K_a. Similar treatment of the data for HCl gives $pK_a = -0.96$, which corresponds to an acidity constant that is too high by a factor of 9.

Linear extrapolations continued to more dilute solutions lead

[8]Because H_R indicators ionize by combining with a molecule of water, $R^+ + H_2O \rightleftarrows ROH + H^+$, the H_R function differs from other acidity functions by an activity of water term: $H_R = -\log (A_{H^+} f_{ROH}/f_{R^+}) + \log (A_{H_2O})$ whereas $H_x = -\log (A_{H^+} f_B/f_{BH^+})$; conversion to H'_R removes this difference: $H'_R = H_R - \log (A_{H_2O})$.

[9]A similar good linear relationship exists in HCl from 4 to 12 wt% acid: $H'_R = (-0.145 \pm 0.012) + (1.680 \pm 0.014)H_0$, $r = 0.9997$.

to even greater errors. Extrapolations terminated in less dilute acids, on the other hand, would give better values of log I, but they would run into the additional difficulty that in these media $\log f_x f_{H^+}/f_{xH^+}$ is not zero and pK_a is therefore no longer simply equal to log I − log C_{H^+}. For example, the least concentrated $HClO_4$ solution in which the linear relationship between H_R and H_0 still holds reasonably well is 5 wt% acid with $C_{H^+} = 0.51$ M and $H_0 = +0.16$. In this medium, a pK_a estimated from the linear relationship and log I − log C_{H^+} has the value 0.37, which corresponds to an acidity constant, $K_a = 0.43$, lower than the true value of unity by a factor of 2.3. At the ionic strength of this medium, 0.51 M, estimation of the activity coefficient term needed to obtain a better value, $\log f_x f_{H^+}/f_{xH^+}$, would of course be very difficult.

The pK_a's of bases which protonate only in concentrated acids may of course be calculated without extrapolating to dilute solution by using the relationshiop log I = pK_a − H_x, which leads to the condition p$K_a = H_x$ at the point where log $I = 0$. In the event that the acidity function appropriate to the base under consideration is not available, H_x may be replaced by mH_0, but the present data show that this technique is not entirely satisfactory either. For our H'_R base with p$K_a = 0.00$, log I will be zero when $H'_R = 0.00$. In $HClO_4$ solution, this occurs at 4.5% acid where $H_0 = 0.22$ and $mH_0 = 1.654 \times 0.22 = 0.36$; this corresponds to $K_a = 0.43$, which is low by a factor of 2.3. Similar treatment of the data for HCl gives p$K_a = 0.25$, which corresponds to an acidity constant too low by a factor of 1.8. These erroneous results may be traced back to the fact that deviations from ideal behavior, i.e. from $H'_R = H_0 = -\log C_{H^+}$, begin to occur in solutions more dilute than $C_{H^+} = 1.00$ M, and that these deviations are different for different acidity functions; H_0 is consequently not equal to zero when $H'_R = 0$.

The problem of where extrapolations from concentrated to dilute acids should be terminated does not arise in the Bunnett–Olsen method and its derivatives, for here the quantity down which the extrapolation is made, $H_0 + \log C_{H^+}$, M_c, or X, becomes zero in dilute solution. These methods, however, still require the extrapolations to be truly linear. This assumption has been tested and has been found to be generally valid (3–5). However, the presently determined highly accurate values of H_0 and H'_R allow a more detailed examination of this point than was possible before.

For our hypothetical H'_R base with p$K_a = 0.00$, log I is equal to $-H'_R$ and the Bunnett–Olsen expression, eq. [4], becomes $H_0 - H'_R = \phi(H_0 + \log C_{H^+})$. Figure 2 shows that the present data for $HClO_4$ solution conform to this expression only moderately well: there are systematic deviations which suggest that the relationship between the two variables is actually curved rather than linear. The best straight line through all of the data, however, does produce a good pK_a: least-squares analysis gives $(H_0 - H'_R) = (0.024 \pm 0.009) - (1.733 \pm 0.037)(H_0 + \log C_{H^+})$, $r = 0.9960$, and this leads to p$K_a = -0.02$ and $K_a = 0.95$ which differs from the true value by only 5%. The data for the more concentrated solutions (10–20 wt% $HClO_4$) give a much better straight line, $(H_0 - H'_R) = (0.127 \pm 0.008) - (1.477 \pm 0.019)(H_0 + \log C_{H^+})$, $r = 0.9996$, but now p$K_a = -0.13$ and $K_a = 0.75$ which is 25% too low (Fig. 2, broken line). The situation in HCl is much the same: the data over the entire range investigated give a curved relationship in the manner of Fig. 2 but they produce a good acidity constant, $K_a = 1.02$, whereas the data for the more concentrated solutions (5–12 wt%) are more nearly linear but give the poorer acidity constant $K_a = 0.80$.

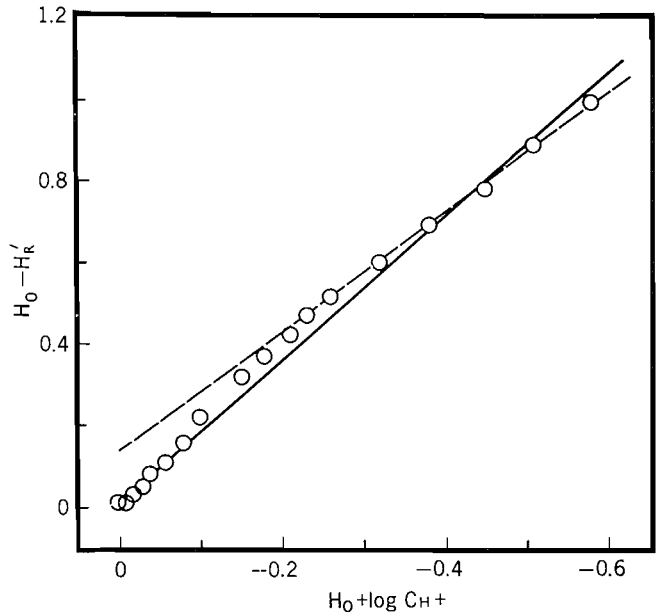

FIG. 2. Bunnett–Olsen plot for a hypothetical H'_R base with pK_a = 0.00 in $HClO_4$ at 25°C.

In the Marziano–Passerini and Cox–Yates methods, (log I − log C_{H^+}) rather than (log $I - H_0$) is used as the independent variable, and this is plotted against either M_c or X. There is an alternative formulation of the Bunnett–Olsen method which uses the same independent variable. This leads to the relationship of eq. [9], whose right-hand side differs from that of the previous Bunnett–Olsen expression, eq. [4], only in that

$$[9] \quad \log I - \log C_{H^+} = pK_a + (\phi - 1)(H_0 + \log C_{H^+})$$

the slope parameter is now $\phi - 1$ rather than ϕ. Such a Bunnett–Olsen plot using the present data for $HClO_4$ is shown in Fig. 3, for the purpose of comparison with Marziano–Passerini and Cox–Yates plots using the same data to be shown below. It is gratifying that least-squares analysis of this plot gives intercepts which are the same as those obtained with eq. [4] (Fig. 2) and slopes which are exactly one unit lower, as demanded by mathematics: from 0–20 wt% $HClO_4$, $(-H'_R - \log C_{H^+}) = (0.024 \pm 0.009) - (2.733 \pm 0.037)(H_0 + \log C_{H^+})$, $r = 0.9960$; from 10–20 wt% $HClO_4$, $(-H'_R - \log C_{H^+}) = (0.127 \pm 0.008) - (2.477 \pm 0.019)(H_0 + \log C_{H^+})$, $r = 0.9998$.

Figure 4 shows that a Marziano–Passerini plot using the present data for $HClO_4$ solutions is somewhat curved in the same manner as the Bunnett–Olsen plots. Again, the best straight line through all of the data, $(-H'_R - \log C_{H^+}) = (0.040 \pm 0.012) + (1.529 \pm 0.027)M_c$, $r = 0.9972$, gives a reasonably good estimate of the acidity constant, $K_a = 0.91$, and a better straight line through the points for the more concentrated solutions, $(-H'_R - \log C_{H^+}) = (0.144 \pm 0.010) + (1.377 \pm 0.015)M_c$, $r = 0.9984$, gives the poorer acidity constant $K_a = 0.71$.

A Cox–Yates plot using the present $HClO_4$ data is even more strongly curved, Fig. 5, and the best line through all of the points, $(-H'_R - \log C_{H^+}) = (0.089 \pm 0.022) + (2.798 \pm 0.097)X$, $r = 0.9895$, affords an acidity constant, $K_a = 0.81$, which is only moderately good. The better straight line through the data for the more concentrated solutions, $(-H'_R - \log C_{H^+}) = (0.319 \pm 0.012) + (2.199 \pm 0.029)X$, $r = 0.9996$ gives $K_a = 0.48$, which is a factor of two too low. Very recently,

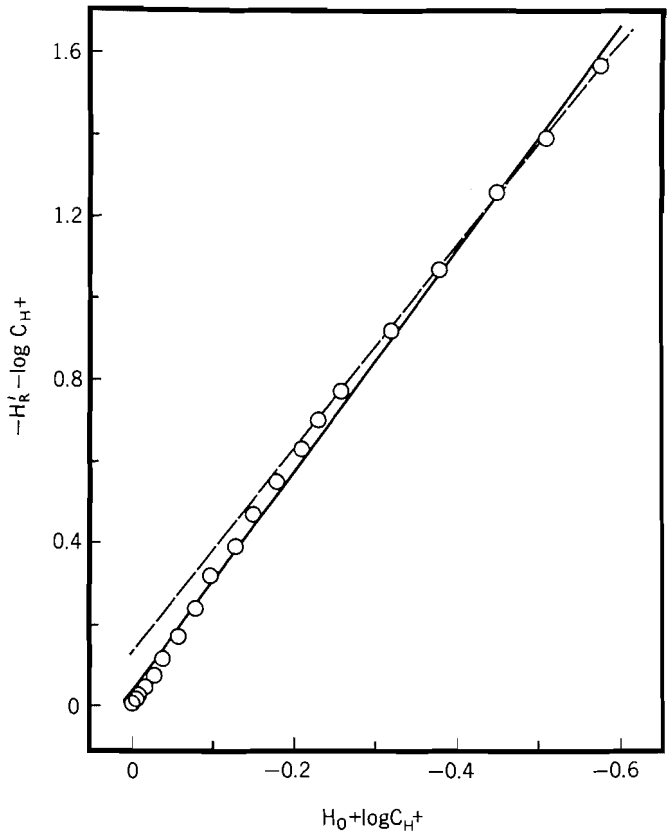

FIG. 3. Alternative formulation of the Bunnett–Olsen relationship for a hypothetical H'_R base with $pK_a = 0.00$ in $HClO_4$ at 25°C.

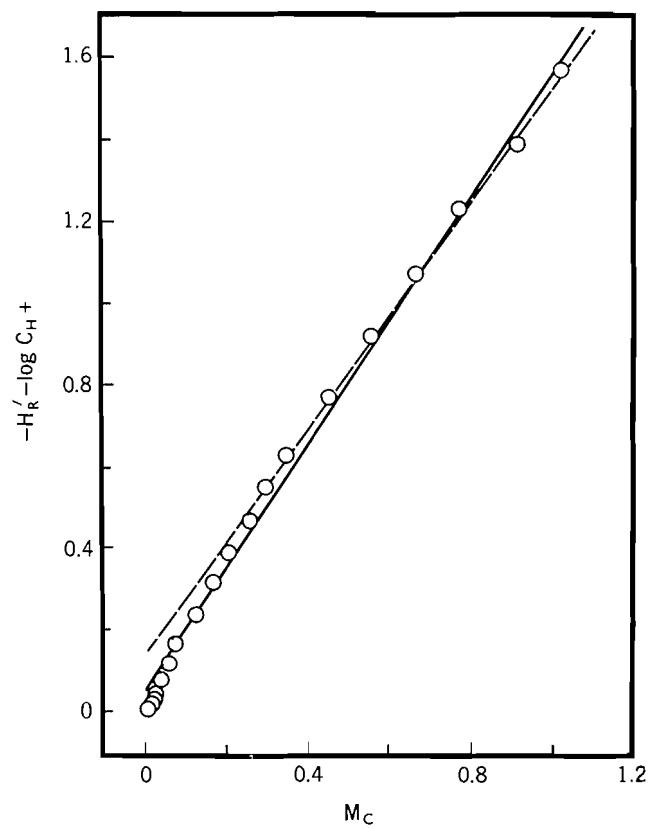

FIG. 4. Marziano–Passerini plot for a hypothetical H'_R base with $pK_a = 0.00$ in $HClO_4$ at 25°C.

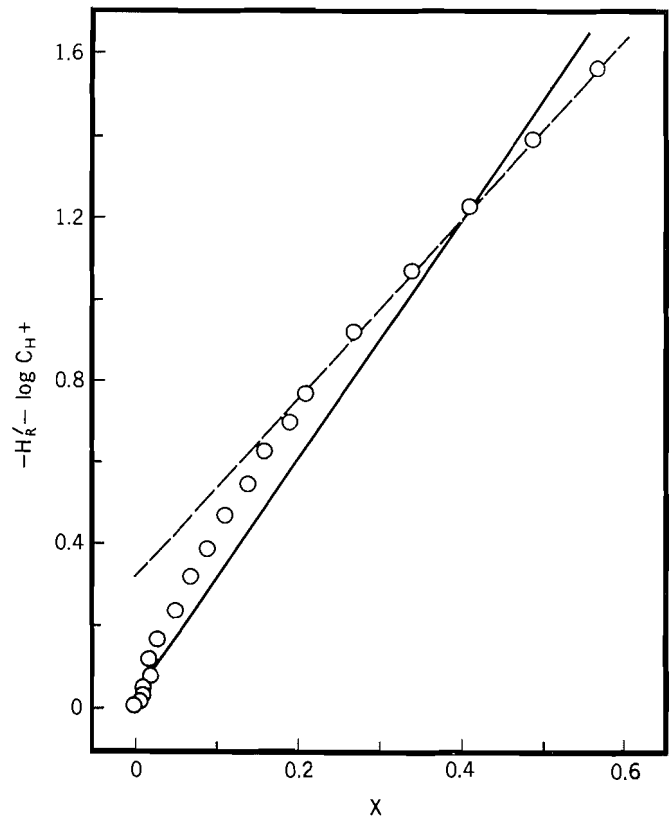

FIG. 5. Cox–Yates plot using the excess acidity function X for a hypothetical H'_R base with $pK_a = 0.00$ in $HClO_4$ at 25°C.

however, Cox and Yates have produced a revised excess acidity function for $HClO_4$ based on primary aniline indicators only, X_0 (5*b*), and this scale correlates the present data very well. As Fig. 6 shows, the Cox–Yates plot using X_0 is accurately linear over the entire range of the present data, $(-H'_R - \log C_{H^+}) = -(0.022 \pm 0.005) + (2.854 \pm 0.020)X_0$, $r = 0.9996$, and it also gives a good value of the acidity constant, $K_a = 1.05$. In HCl solution, on the other hand, Cox–Yates plots using the X and X_0 functions are equally good; both plots show only a slight hint of curvature, and the best straight lines in both cases, $(-H'_R - \log C_{H^+}) = (0.024 \pm 0.012) + (2.005 \pm 0.028)X$, $r = 0.9985$ and $(-H'_R - \log C_{H^+}) = (0.030 \pm 0.014) + (2.654 \pm 0.044)X_0$, $r = 0.9979$, give respectably good acidity constants: $K_a = 0.95$ and 0.93 using X and X_0 respectively.

Conclusions

Of the four techniques for extrapolating data from concentrated acids down to dilute solution considered here, the traditional acidity function method as applied when an appropriate acidity function is not available (eq. [2]) gives the poorest results; it produces significant errors, several fold large in the quantity extrapolated, when the extrapolation is terminated at $C_{H^+} = 0.025\ M$, the point at which H_0 first becomes equal to $-\log C_{H^+}$. Better results are obtained with protonation equilibrium data if the pK_a is taken to be equal to mH_0 at the point where $\log I = 0$, but even so errors of the order of a factor of two are produced, and the method cannot be used with kinetic data. These shortcomings of course do not apply when the appropriate acidity function is available and is used in the manner of eq. [1].

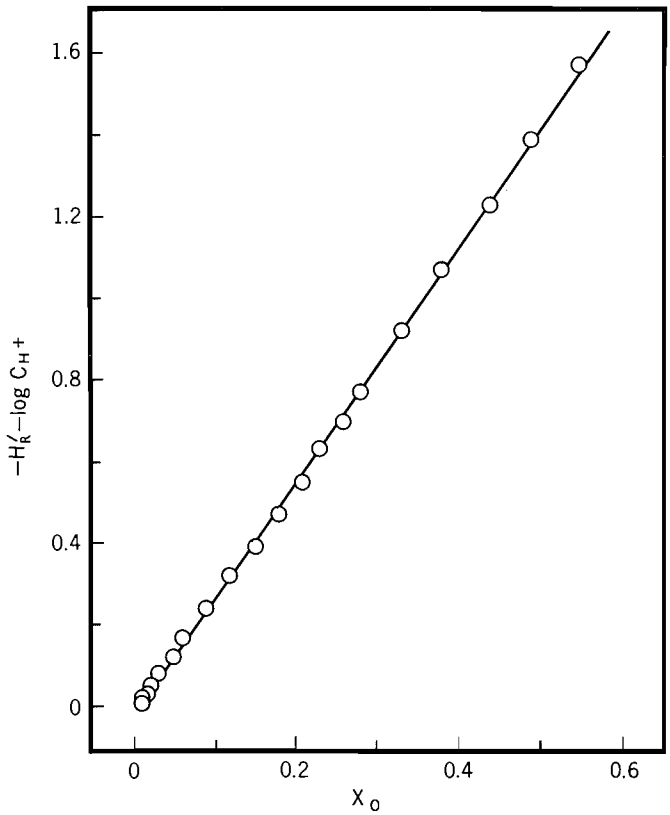

FIG. 6. Cox–Yates plot using the excess acidity function X_0 for a hypothetical H_R' base with $pK_a = 0.00$ in $HClO_4$ at 25°C.

The other three methods produce consistently better results, although the data often do give gently curved relationships where linear correlations are to be expected. Plots using the newly produced Cox–Yates function X_0 for $HClO_4$ are a notable exception: here the data are accurately linear over the entire range studied and give an extrapolated value in dilute solution which is correct to 5%. The Cox–Yates method also affords the best results in HCl solution from the point of view of both providing linear correlations and giving good extrapolated values; here, however, the functions X and X_0 appear to be equally effective.

Experimental

Materials

Triarylmethanols were prepared by standard methods and were purified as their picrates (21). Although the nmr spectra of these preparations showed no detectable impurities, only 4,4′,4″-trimethoxytriphenylmethanol could be obtained in crystalline form. The carbinols were therefore converted to their solid perchlorate salts and these were used for the indicator measurements.

The aniline indicators were obtained commercially and were purified by recrystallization until their melting points were constant and in agreement with literature values. The nmr spectra of these materials were consistent with their structures.

Acid solutions were prepared from reagent grade acids and deionized water which had been purified further by distillation from alkaline potassium permanganate. Acid concentrations were determined by titration of weighed amounts with standard sodium hydroxide.

Indicator measurements

Absorbance determinations for a given indicator–acid pair were made on series of solutions of varying acidity but accurately constant total indicator concentration. These solutions were prepared in two ways: (*1*) by combining carefully pipetted 10.00-mL aliquots of wholly aqueous stock indicator solution with similarly obtained aliquots of acid solutions of appropriate concentration, or (*2*) by adding 10.00-mL aliquots of indicator solution to 25.00-mL volumetric flasks and making up to the mark with acid and water. The second method was always used for the more strongly acidic solutions where there was danger that simple mixing of indicator and acid solutions might produce a density change and result in a final volume which was not accurately the sum of the volumes of the two pipetted aliquots. Pipetting was always done with the same pipette throughout a given series of measurements.

Since the triarylcarbinols used here are only very sparingly soluble in water, special care was taken in preparing their stock solutions. Excess carbinols or their perchlorate salts were shaken with water overnight, the saturated solutions were filtered twice, and the second filtrate was then diluted with additional water to about 90% saturation.

All volumetric manipulations were done on solutions which had equilibrated with a 25.0°C constant temperature bath, and the cell compartments of the spectrometers were also thermostatted at 25.0 ± 0.05°C. Measurements on the aniline indicators were made with a Beckman DK-2 instrument and those on the triarylcarbinols with a Cary 16 spectrometer. Reduced absorbance scales were used for the measurements with triarylcarbinols on the Cary instrument (0.06 to 0.2 *A* full scale deflection), but the greater solubility of the aniline indicators allowed the standard 0–1 *A* scale to be used for measurements with these indicators on the Beckman instrument. All measurements were made in the differential mode using reference solutions prepared exactly as the sample solutions except that pure water was substituted for the stock indicator solution.

Absorbance readings were made three times for each solution at three different wavelengths: at the absorption maximum and at wavelengths 5 nm to either side of the maximum. These nine values were then averaged and indicator ratios were calculated using the formula $I = (A_B - A)/(A - A_{BH^+})$. Absorbances of the basic forms of the indicators, A_B, were measured either in pure water or dilute alkali, and absorbances of the acidic forms, A_{BH^+} were measured in solutions whose acidity function values, H_0 or H_R as appropriate, were at least three units more acidic than the indicator pK_a's. Complete tables of all of the indicator data so obtained are available from the Depository of Unpublished Data.[5]

Structural studies of steric effects in phosphine complexes. Part XI.[1,2] Synthesis, characterization, crystal and molecular structure of the dinitrato(trimesitylarsine)mercury(II) dimer

ELMER C. ALYEA, SHELTON A. DIAS, GEORGE FERGUSON, AND PIK Y. SIEW

Guelph-Waterloo Centre for Graduate Work in Chemistry, Guelph Campus, Department of Chemistry, University of Guelph, Guelph, Ont., Canada N1G 2W1

Received July 23, 1982

ELMER C. ALYEA, SHELTON A. DIAS, GEORGE FERGUSON, and PIK Y. SIEW. Can. J. Chem. **61**, 257 (1983).

The synthesis and crystal and molecular structure of the dinitrato(trimesitylarsine)mercury(II) dimer are reported. The compound $[HgAs(mesityl)_3(NO_3)_2]_2$ belongs to the monoclinic space group $P2_1/c$ (C_2^5h, No. 14) with $a = 20.001(2)$, $b = 17.591(5)$, $c = 16.553(2)$, $\beta = 99.991(6)$, and $Z = 4$; the asymmetric unit contains two independent half dimers. The structure was refined to a final R of 0.0458 for 2631 observed reflections measured by diffractometer with $2 < \theta < 20°$. The crystal structure consists of discrete centrosymmetric dimeric molecules of $[HgAs(mesityl)_3(NO_3)_2]_2$ separated by normal van der Waals distances. The mercury coordination in both dimers **I** and **II** is characterized by three strong, nearly coplanar bonds (in **I** Hg—As 2.476(3), Hg—O 2.41(2) and 2.20(2), and in **II** Hg—As 2.482(3), Hg—O 2.28(2) and 2.39(2), and three weaker Hg—O bonds in the range 2.55–2.90 Å. Both independent trimesitylarsine ligands have the same regular propeller conformation (Hg—As—C—C torsion angles of 45 to 50°) and the largest C—As—C angles (mean value 112.5(8)°) yet determined. The As(mesityl)$_3$ cone angle is 202°. The two independent dimers differ primarily in the orientation of the non-bridging nitrato groups. Nitrato vibrational and arsine ^{1}H nmr data are also presented for $[HgAs(mesityl)_3(NO_3)_2]_2$, which becomes monomeric in dichloroethane solution.

ELMER C. ALYEA, SHELTON A. DIAS, GEORGE FERGUSON et PIK Y. SIEW. Can. J. Chem. **61**, 257 (1983).

On rapporte la synthèse et les structures cristalline moléculaire du dimère du dinitrano(trimésitylarsine)mercure(II). Le composé $[HgAs(mésityl)_3(NO_3)_2]_2$ appartient au groupe d'espace monoclinique $P2_1/c$ (C_2^5h, No. 14) avec $a = 20,001(2)$, $b = 17,591(5)$, $c = 16,553(2)$, $\beta = 99,991(6)$ et $Z = 4$. L'unité asymétrique contient deux demi dimères indépendants. On a affiné la structure jusqu'à une valeur finale de $R = 0,0458$ pour 2631 réflexions observées et mesurées à l'aide d'un diffractomètre avec $2 < \theta < 20°$. La structure du cristal consiste en des molécules dimères centrosymétriques discrètes de $[HgAs(mesityl)_3(NO_3)_2]_2$ séparées par des distances normales de van der Waals. La coordination du mercure dans les deux dimères **I** et **II** est caractérisée par trois liaisons quasi coplanaires fortes (dans **I**, Hg—As = 2,476(3), Hg—O = 2,41(2) et 2,20(2), dans **II**, Hg—As = 2,482(3), Hg—O = 2,28(2) et 2,39(2) et trois liaisons Hg—O plus faibles de l'ordre de 2,55 à 2,90 Å. Les deux ligands trimésitylarsine indépendants ont la même conformation du type hélice régulière (Hg—As—C—C angles de torsion de 45 à 50°) et les plus grands angles C—As—C (valeur moyenne 112,5(8)°) observés jusqu'à maintenant. L'angle du cone As(mésityl)$_3$ est de 202°. Deux dimères indépendants diffèrent initialement par l'orientation des groupes nitrato qui ne sont pas en position de pont. On présente également les données relatives à la vibration du groupe nitrato et à la rmn du ^{1}H de l'arsine pour le composé $[HgAs(mesityl)_3(NO_3)_2]_2$ qui devient un monomère en solution dans le dichloroéthane.

[Traduit par le journal]

Introduction

A systematic study of metal complexes of tertiary phosphines containing bulky substituents is in progress in our laboratories (1). X-ray analysis of complexes of tricyclohexylphosphine, tris(*tert*-butyl)phosphine, tri(*o*-tolyl)phosphine, and trimesitylphosphine have provided a range of experimental cone angle values (2) in good agreement with those estimated from space-filling molecular models (3). The development of the concept of a "ligand profile" (2) allowed precise comparison of the conformations of the groups bonded to phosphorus. As an extension of the use of maximum cone angles and ligand profiles derived from X-ray structural data in describing the steric effects of bulky ligands we have chosen to study an arsine with sterically demanding substituents. This paper reports the preparation, characterization, crystal and molecular structure determination of $[HgAs(mesityl)_3(NO_3)_2]_2$ (mesityl = $C_6H_2(CH_3)_3$), the first complex of trimesitylarsine to be so characterized. The compound is isomorphous with the corresponding phosphine complex (4).

[1]For Part X, see ref. 1.

[2]Presented in part at the International Conference on Phosphorus Chemistry, Durham, NC, June 1–5, 1981, Abstract 235.

Experimental

Spectroscopic and other physical measurements were performed as previously described (5). Trimesitylarsine was prepared by an appropriate modification of the literature method for trimesitylphosphine (6).

Preparation of the dinitrato(trimesitylarsine)mercury(II) dimer, $[HgAs(mesityl)_3(NO_3)_2]_2$

A solution of As(mesityl)$_3$ (0.433 g, 1.00 mmol) in absolute ethanol (50 mL) was added to a suspension of $Hg(NO_3)_2 \cdot H_2O$ (0.343 g, 1.00 mmol) in the same solvent (25 mL). The mixture was refluxed under dinitrogen for 0.5 h, giving a clear solution, from which a white crystalline solid was deposited on cooling to room temperature. The product was isolated by filtration, washed with dry ether, and dried *in vacuo*. Recrystallization from absolute ethanol afforded suitable crystals for X-ray analysis; yield 56%; mp 181–183 (decomp.). *Anal.* calcd. for $[HgAs(mesityl)_3(NO_3)_2]_2$: C 42.84, H 4.39, N 3.70; found: C 42.31, H 4.23, N 3.66.

X-ray crystallographic analysis

Weissenberg and precession photographs provided approximate unit cell dimensions; accurate lattice parameters were obtained by a least-squares treatment of the diffractometer setting angles for 12 reflections for which θ_{hkl} (Mo-K_α) was between 10 and 20°. Crystal data (at 21°C) are

$C_{54}H_{66}As_2Hg_2N_4O_{12}$ fw = 1514.2
Monoclinic, $a = 20.001(2)$, $b = 17.591(5)$, $c = 16.553(2)$, $\beta = 99.991(6)$, $V = 5735.6$ Å^3, $Z = 4$, $D_c = 1.75$ g cm^{-3}, $F(000) = 2960$, μ(Mo-K$_\alpha$) = 44.8 cm^{-1}. On the basis of systematic absences ($h0l$, l odd; and $0k0$, k odd) the crystals were uniquely assigned to space group $P2_1/c$ (C_2^5h, No. 14).

The intensity data for a unique quadrant within the limit $2 < \theta < 20$ were collected with a small crystal (0.21 × 0.21 × 0.25 mm) as described for the isomorphous phosphine complex (4), and were corrected for Lorentz and polarization factors and a numerical absorption correction was applied. Maximum and minimum values of transmission coefficients are 0.39 and 0.23 respectively. Of the 5377 measured reflections, 2631 reflections with $I > 3\sigma(I)$ were used in the final refinement of the structure parameters.

The asymmetric unit consists of two independent half dimers situated about independent symmetry centres. A first Fourier summation was phased with mercury and arsenic atom contributions, their coordinates being obtained from the phosphine complex. All non-hydrogen atoms were located in this first electron density map. The structure was then refined by full-matrix least-squares calculations with anisotropic thermal parameters for the Hg and As atoms and isotropic for the remaining non-hydrogen atoms to a final R value of 0.046. Unit weights were used in the refinement and scattering factors were taken from ref. 7 and anomalous dispersion corrections were applied (8) for Hg and As atoms. A final difference synthesis showed a few peaks in positions expected for some of the protons and no other chemically significant features.

The maximum shift/error ratios in the final cycle were 0.080 (for the z-coordinate of C(239)), and 0.028 (for U_{iso} of C(218)). The final fractional coordinates with estimated standard deviations are given in Table 1 and selected molecular dimensions are in Table 2. A listing of the observed and calculated structure factors has been deposited in the Depository of Unpublished Data.[3]

The mercury coordination and our numbering scheme are shown in

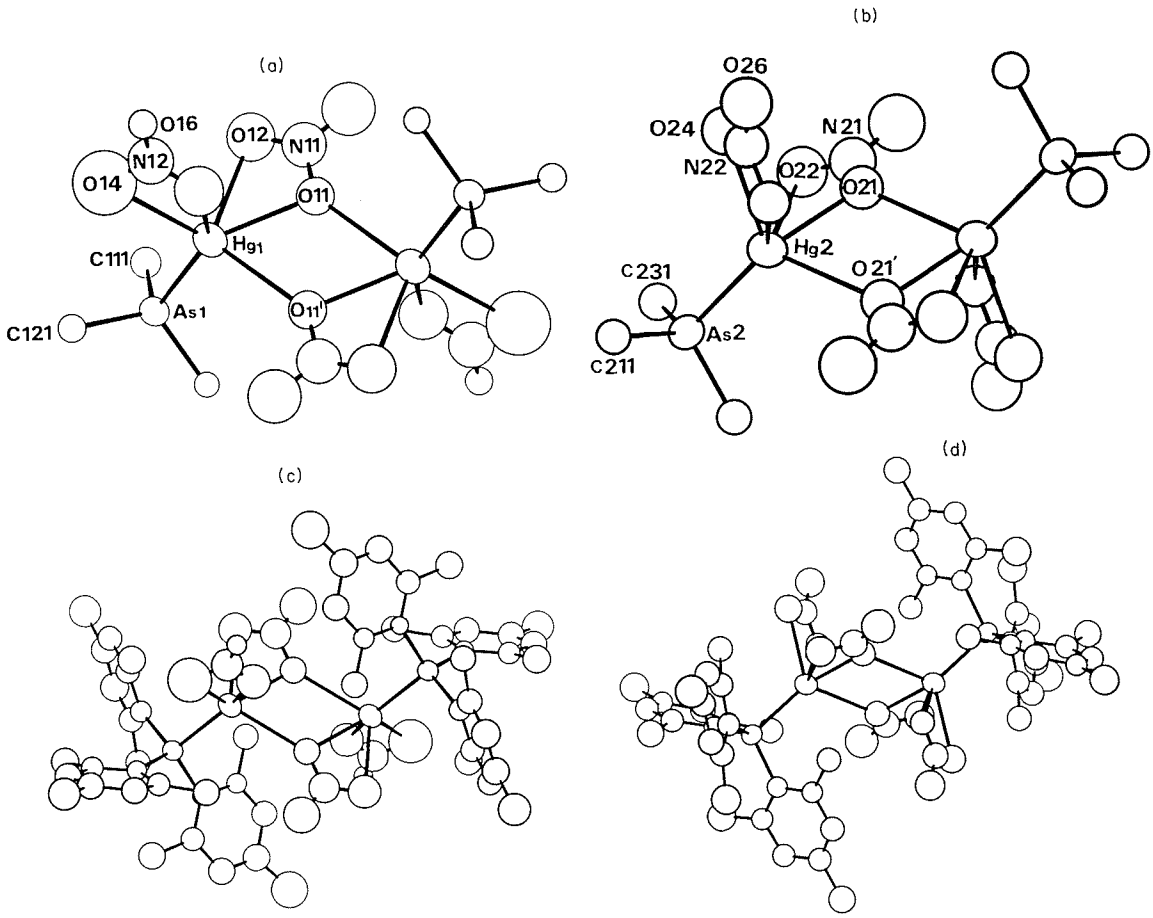

FIG. 1. Views with 50% probability ellipsoids of (*a*) and (*c*) dimer **I**, and (*b*) and (*d*) dimer **II**, of $[HgAs(mesityl)_3(NO_3)_2]_2$ showing molecular geometry and details of our numbering schemes. For simplicity, only the mesityl carbons bonded to arsenic are shown in (*a*) and (*b*).

Fig. 1 for both dimers; for simplicity only the mesityl carbons bonded to arsenic are shown in Fig. 1 *a* and *b*. The orientations of the mesityl groups may be seen in Fig. 1 *c* and *d*.

Discussion

Description of the steric effects of phosphorus ligands in terms of cone angles has found wide applicability (3) but the concept has not been developed for other ligands. In order to extend our use (1, 2) of a "ligand profile" to yield precise maximum cone angle data based on X-ray structural results, we wished to examine an arsine complex. The title compound involving the bulkiest known arsine ligand allows a direct comparison with the previously characterized analogous $P(mesityl)_3$ complex (4).

$[HgAs(mesityl)_3(NO_3)_2]_2$ has a molecular weight by osmometry in dichloroethane (ca. 10^{-3} *M* solution) of 757, which corresponds to the monomer. The complex is a non-electrolyte in dichloroethane, and the slight conductance in nitromethane (Λ26.0 ohm^{-1} cm^2 mol^{-1}, 10^{-3} mol dm^{-3}) can be attributed to partial dissociation. The ^1H nmr spectrum of the complex for a $CDCl_3$ solution at ambient temperature showed a pseudosinglet at δ2.26 ppm due to the methyl groups and a singlet at δ6.93 ppm assigned to the aromatic protons. For the free arsine, a $CDCl_3$ solution shows methyl resonances at 2.13 and 2.23 ppm in a 2:1 ratio and an aromatic proton resonance at 6.85 ppm. In contrast, splitting of both types of resonance peaks in the case of the analogous $P(mesityl)_3$ complex attested to the restricted rotation of the mesityl groups (4).

The vibrational spectrum of $[HgAs(mesityl)_3(NO_3)_2]_2$ clearly shows the absence of ionic nitrate and the presence of more than one kind of coordinated nitrato group in the solid state. Nitrato infrared spectral bands (in cm^{-1}, Nujol mull) can be identified at 1498(vs), 1265(vs), 1250(s, sh), 1080(m, br), 1040(m), 1015(s), 980(m), 922(mw), 835(m), 829(m), 810(m), 735(m), 715(mw), and 705(m). The large number of ir nitrato bands and the observation of two Raman spectral bands at 1013 cm^{-1} (s) and 1023 cm^{-1} (s, sh) attributable to the symmetric stretching mode of the nitrato group suggest the presence of at least two types of coordinated nitrato group. By analogy with our previous assignments (4, 5, 9), Raman bands at 76 cm^{-1} (vs) and 152, 176 cm^{-1} (m) might tentatively be assigned to ν(Hg—As) and ν(Hg—O), respectively.

The crystal structure contains discrete well-resolved molecules of $[HgAs(mesityl)_3(NO_3)_2]_2$, with the unit cell having four dimeric molecules, half of each of the dimers **I** and **II** corresponding to the asymmetric unit. The two independent centrosymmetric dimers differ from each other in the orientations of the nitrato groups and the configuration of the trimesityl arsine moieties at each mercury.

In both dimers (Fig. 1) the mercury coordination is essentially trigonal planar with three strong bonds (Hg—As 2.476(3) in **I** and 2.482(3) Å in **II**, Hg—O 2.41(2) and 2.20(2) in **I** and 2.28(2) and 2.39(2) Å in **II**); similar geometries are found in $[HgPCy_3(OAc)_2]_2$, $[HgP(o\text{-tolyl})_3(OAc)_2]_2$ (10), and

TABLE 3. Mean plane equations and dihedral angles (deg) within $[HgAs(mesityl)_3(NO_3)_2]_2$

Plane	Atoms in plane	Equation
1	Hg(1), As(1), C(111)	$0.085x + 0.980y + 0.181z = 1.784$

11,12	47.2

$[HgP(mesityl)_3(NO_3)_2]_2$ (4). Centrosymmetric dimer formation involves oxygen atoms O(11) in **I** and O(21) in **II** making longer contacts (2.78 and 2.72 Å respectively) with adjacent mercury atoms. Each mercury completes its six-fold coordination by virtue of two further weak contacts involving the nitrato oxygen atoms (Hg—O 2.55–2.90 Å).

The nitrato groups have N—O bond lengths in the range 1.20(4)–1.29(5), which are not significantly different but the groups differ markedly in their orientations (Fig. 1). The Hg—O distances (Table 2) show the same degree of asymmetry as was found in the phosphine complex (4).

The coordination about arsenic is distorted tetrahedral in both dimers with Hg—As—C angles averaging 106.1 and 106.5(6)° and C—As—C angles 112.7(7) and 112.2(8) in **I** and **II** respectively. In the free $As(mesityl)_3$ (11) the C—As—C angles are 107.6(2)°. The Hg—As—C and C—As—C angles show slightly less distortion from tetrahedral than the analogous angles found in the isostructural $P(mesityl)_3$ dimers (105.2, 105.6(4) and 113.3, 113.1(5)° respectively (4) but are comparable to the Hg—P—C and C—P—C angles (106.8 and 112.0(7)°) found in $HgP(t\text{-}Bu)_3(OAc)_2$ (12). The Hg—As bond lengths (2.476 and 2.482(3) Å) are about 0.08 Å longer than the Hg—P bond distances found in the related isostructural phosphine complexes (4, 10), which corresponds to the difference in covalent radii of P and As atoms (13). There are few structural comparisons possible for mercury complexes of arsines; for example, Hg—As (2.557 Å) in trigonal $Hg(SCN)_2AsPh_3$ (14) and Hg—As (2.60, 2.82 Å) in tetrahedral $HgBr_2QAS$ (QAS = tris(diphenylarsino)phenylarsine) (15). The mean bond lengths As—C (1.94(2) Å), aromatic C—C (1.39(2) Å and CH_3—C(sp^2) (1.54(3) Å) are in agreement with values found for the free arsine (11).

Steric crowding in the bulky $As(mesityl)_3$ moieties is relieved by out-of-plane displacements of arsenic and methyl groups and by increases of (As)C—Ĉ—CH_3 angles. The angle deformations at the *o*-methyl groups are similar to those reported for the mesityl groups in $As(mesityl)_3$ (11) and in $[HgP(mesityl)_3(NO_3)_2]_2$ (4). To gauge the steric bulk of the $As(mesityl)_3$ ligands we have prepared ligand profile diagrams and computed maximum semi-cone angles θ/2 as described previously (2, 4). In dimer **I** maximum θ/2 values are 101.3, 103.4, and 100.1° with a mean value of 101.6° leading to a maximum cone angle θ of 203°. For dimer **II** equivalent θ/2 values are 100.2, 101.5, and 100.0°, giving θ = 201°. As anticipated, the calculated cone angles are less than that found (208° (4)) for P(mesityl) in the isostructural $[HgP(mesityl)_3(NO_3)_2]_2$ as a result of the longer Hg—As bond lengths. A similar decrease (5°) in cone angle has been previously noted (16) for the PPh_3 and $AsPh_3$ moieties (cone angles 145 and 140° respectively). One consequence of the lower steric bulk of the arsine ligand is its lower rate of metallation with palladium and platinum (17). Both $As(mesityl)_3$ ligands adopt regular propeller conformations with dihedral angles between the appropriate Hg—As—C and mesityl plane in the range 45–50° (Table 3).

Force field of acetic acid: use of CNDO/force calculations

A. ANNAMALAI AND SURJIT SINGH[1]

Structural Chemistry Group, Department of Chemistry, Indian Institute of Technology, Madras 600 036, India

Received May 25, 1982

A. ANNAMALAI and SURJIT SINGH. Can. J. Chem. **61**, 263 (1983).

The redundancy-free internal valence force field of monomeric acetic acid is evaluated using CNDO/force calculations and least-squares refinement. The initial force field is set up by taking the interaction and bending force constants from CNDO force field and transferring the stretching force constants from the force fields of chemically related molecules. Vibrational frequencies of monomeric CH_3COOH, CH_3COOD, CD_3COOH, and CD_3COOD are used to refine the force constants. The experimental force field thus obtained is found to be reasonable when compared to the force fields of related molecules as well as on the basis of the frequency fits and potential energy distributions.

A. ANNAMALAI et SURJIT SINGH. Can. J. Chem. **61**, 263 (1983).

Utilisant des calculs de force/CNDO et des ajustements par la méthode des moindres carrés, on a évalué le champ de force de valence interne sans répétition de l'acide acétique sous forme monomère. On a établi le champ de force initial en prenant l'interaction et les constantes de force de courbure du champ de force CNDO et en transferrant les constantes de force de tension à partir des champs de force de molécules chimiquement apparentées. On a utilisé les préférences de vibration des acides monomères: CH_3COOH, CH_3COOD, CD_3COOH et CD_3COOD pour ajuster les constantes de force. On a trouvé que le champ de force expérimental ainsi obtenu est raisonnable quand lon le compare aux champs de force des molécules apparentées ainsi que sur la base des agréments des fréquences et des distributions d'énergie potentielle.

Introduction

A number of papers (1–7) deal with the ir and Raman spectroscopic studies of acetic acid monomer and its deuterated derivatives. Considering point mass models, force field calculations were carried out by Thomas (8), and Nakamoto and Kishida (9). Other force field calculations for acetic acid were carried out by Fukushima and Zwolinski (10) using a modified Urey–Bradley force field, and by Brooks and Haas (11), Alfheim and Cyvin (12), and Meyer *et al.* (5) using valence force fields. In the widely used least-squares method of force field refinement, an initial force field matrix ($\mathbf{F}_0$) is set up by transferring the force constants from chemically related molecules, and then refined using experimental data such as vibrational frequencies. The diagonal force constants can reasonably be transferred among chemically related molecules but in the case of interaction force constants, such a transfer is not justified as it very much depends on the geometry of the molecule. In the previous studies (13–17) it is found that the CNDO/force MO calculations predict reasonably well the signs of interaction force constants. The magnitudes of bending as well as stretch–bend and bend–bend interaction force constants are also reasonably estimated by these calculations. The stretch–stretch interaction constants are about 50% higher than the experimental values and the stretching force constants are overestimated by a factor of 2 to 3.5. CNDO/force calculations provide us with a reasonable way of choosing the bending and interaction force constants for the $\mathbf{F}_0$ matrix in order to perform least-squares refinement. It was pointed out by IUPAC (18) that the force constants corresponding to the coordinates expressed by redundancy conditions are indeterminate and recommendations were made that redundancy-free coordinates should be used in order to have meaningful force fields. In the present work, initial force field is set up by taking interaction and bending force constants from CNDO force field and transferring stretching force constants from the force fields of chemically related molecules from literature. Redundancy-free internal valence force field (RFIVFF) is then calculated by refining this force field using vibrational frequency data on various isotopic species of acetic acid.

Computational details and results

The CNDO/force calculations are carried out using a modified form (15) of Pople's computer program CNINDO (19). The molecular geometry is optimised as described earlier (13, 15) using the steepest descent method. The forces are then calculated by distorting the molecule from the optimised reference geometry in the positive and negative directions of redundancy-free internal coordinates. The distortions considered are 1 pm, 1°, and 2° respectively for stretching, bending, and torsional coordinates. The CNDO force constants are then derived from the forces using the relationships given earlier (15). The redundancy-free internal coordinates[2] are expressed below in terms of the internal coordinates given in Fig. 1. The CNDO/force field is given in Table 1.

In-plane:

1. $\nu_{C=O} = R$
2. $\nu_{C-C} = D$
3. $\nu_s(CH_3) = (1/\sqrt{3})\,(r_1 + r_2 + r_3)$
4. $\nu_s'(CH_3) = (1/\sqrt{6})\,(2r_1 - r_2 - r_3)$
5. $\nu_{C-O} = L$
6. $\nu_{O-H} = d$
7. $\delta_{C-C-O} = (1/\sqrt{6})\,(2\delta_1 - \delta_2 - \delta_3)$
8. $\rho_{C=O} = (1/\sqrt{2})\,(\delta_2 - \delta_3)$
9. $\delta_s(CH_3) = [3(1 + b^2)]^{-1/2}[b(\alpha_1 + \alpha_2 + \alpha_3) - (\beta_1 + \beta_2 + \beta_3)]$
   $(b = -3 \sin\beta \cos\beta/\sin\alpha)$

[1]To whom all correspondence should be addressed.

[2]The corresponding redundancy coordinates are $(1/\sqrt{3})\,(\delta_1 + \delta_2 + \delta_3)$ and $[3(1 + b^2)]^{-1/2}[(\alpha_1 + \alpha_2 + \alpha_3 + b(\beta_1 + \beta_2 + \beta_3)]$, where $b = -3\sin\beta \cos\beta/\sin\alpha$.

0008-4042/83/020263-04$01.00/0

©1983 National Research Council of Canada/Conseil national de recherches du Canada

10. $\delta_s'(CH_3) = (1/\sqrt{6})\,(2\alpha_1 - \alpha_2 - \alpha_3)$
11. $\rho_{\parallel}(CH_3) = (1/\sqrt{6})\,(2\beta_1 - \beta_2 - \beta_3)$
12. $\delta_{C-O-H} = \theta$

Out-of-plane:

13. $\nu_a(CH_3) = (1/\sqrt{2})\,(r_2 - r_3)$
14. $\delta_a(CH_3) = (1/\sqrt{2})\,(\alpha_2 - \alpha_3)$
15. $\rho_{\perp}(CH_3) = (1/\sqrt{2})\,(\beta_2 - \beta_3)$
16. $\gamma_{C=O} = \phi$
17. $\tau(CH_3) = (1/\sqrt{6})\,(\tau_1 + \tau_2 + \tau_3 + \tau_1' + \tau_2' + \tau_3')$
18. $\tau(OH) = (1/\sqrt{2})\,(\tau_4 + \tau_5)$

The initial force field is constructed according to the procedure given above. The stretch–stretch interaction force constants of the CNDO force field are scaled down by a factor of 0.65 (17) before being included in the $\mathbf{F}_0$ matrix. Schachtschneider's FPERT program (20) is used to carry out the refinement after including the damped least-squares subroutines. The force field is refined using absolute weighting factors (21) for the frequency parameters. All the calculations were performed on an IBM 370/155 computer. The vibrational frequencies of CH_3COOH, CH_3COOD, CD_3COOH, and CD_3COOD listed by Meyer *et al.* (5) with the revised assignments for a few bands are employed in the calculations. Since the CH and OH stretching frequencies were not given by Meyer *et al.*, they are taken from ref. 4. The **G** matrices are calculated on the basis of the geometry obtained by Derissen (22) from the electron diffraction data. The bond angles around the methyl C atom are assumed to be 109.47°. Based on C_s symmetry of acetic acid the 18 fundamental modes can be distributed as $12A' + 6A''$ vibrations. Calculations for A' and A'' vibrations were carried out separately. Since the number of independent force constants of acetic acid exceeds the number of available vibrational frequencies, some reasonable constraints on the force field are imposed. For the experimental force fields 38 significant parameters were considered for A' species whereas 9 force constants were considered for A'' species. The force constants are refined using 46 frequencies for A' species and 19 frequencies for A'' species. In the case of A' vibrations, the parameters *F8,9* and *F8,11* corresponding to the interactions $\rho_{C=O}/\delta_s(CH_3)$ and $\rho_{C=O}/\rho_{\parallel}(CH_3)$ respectively are constrained to zero, since the trial calculations carried out indicate negligibly small values for these constants. The force constant *F17,17* corresponding to the methyl group torsional mode is kept fixed at 0.004×10^{-18} N m rad^{-2} based on similar values obtained for acetaldehyde and acetone (17). The experimental force field obtained is also included in Table 1. In Table 2 the calculated and observed frequencies are given along with the potential energy distributions (PED).

Discussion

The force field reported in this work is rather too elaborate and includes all the diagonal and off-diagonal force constants. Meyer *et al.* (5) reported a value of 8.048×10^2 N m^{-1} for the carbonyl stretching force constant ($F_{C=O}$) of acetic acid which is considerably different from the present value (12.692×10^2 N m^{-1}). In a redundancy valence force field obtained by Ha, Meyer, and Gunthard (23) employing the *ab initio* results as the initial force constants and refining the force field using vibrational frequency data, the $F_{C=O}$ of formic acid was found to be 13.05×10^2 N m^{-1}. The estimate of Meyer *et al.* for acetic acid makes a difference of 5×10^2 N m^{-1} between the $F_{C=O}$ values of formic acid and acetic acid. For these two acids, the

[a]Units: stretch–stretch, 10^2 N m^{-1} (mdyn Å^{-1}), stretch–bend, 10^{-8} N rad^{-1} (mdyn rad^{-1}), and bend–bend, 10^{-18} N m rad^{-2} (mdyn Å rad^{-2}).
[b]Constrained force constant values.

$F_{C=O}$ values obtained using CNDO/force calculations are found to differ only by about 1.6×10^2 N m^{-1} (24). Hence, it is felt that the value of $F_{C=O}$ reported in the present work for acetic acid is more reasonable. The almost insignificant decrease in $F_{C=O}$ value ($\sim 0.04 \times 10^2$ N m^{-1}) from formic acid to acetic acid due to the substituent CH_3 is parallel to the similar observations made when the $F_{C=O}$ values of formaldehyde,

[a]Values in parentheses are estimated by Meyer *et al.* (5).

acetaldehyde, and acetone are considered (17). Force constants of C—O and O—H stretching, and COH bending modes of acetic acid are very close to the corresponding force constants of formic acid (23). The C=O/C—O interaction force constant obtained in this work (1.327×10^2 N m^{-1}) is in good agreement with the *ab initio* value reported by Ha *et al.* (23) for formic acid (1.3×10^2 N m^{-1}). The C—O stretching force constant of acetic acid (6.065×10^2 N m^{-1}) is greater than the corresponding force constants of methyl alcohol (5.4×10^2 N m^{-1}) (25) and diethyl ether (5.04×10^2 N m^{-1}) (26). In both the studies (25, 26), the initial force fields were transferred from chemically related molecules and not obtained from MO calculations and whereas the force field obtained for methanol was redundancy free, the force field for ether had redundant force constants. However, a greater C—O stretching force constant in acetic acid in comparison to methyl alcohol and ether, to some extent, may be in order because of π electron delocalisation in acetic acid. This is also reflected in the C=O/C—O interaction force constant which has a very high positive value in the case of acetic acid. The force constants corresponding to the methyl group vibrations do not differ significantly from those obtained for acetaldehyde and acetone in similar calculations (17). The observed frequencies are well reproduced by the calculated force field. The potential energy

Conductimetric studies on aqueous solutions of electrolytes. I. Conductivities of copper sulphate

VICTOR HUGO ACEVEDO, JUANA ALBARRACÍN DE MORÁN, AND LEOPOLDO ARMANDO SALES
Instituto de Química Inorgánica, Facultad de Bioquímica, Química y Farmacia, Universidad Nacional de Tucumán, Ayacucho 491, 4000-Tucumán, República Argentina

Received December 11, 1981[1]

VICTOR HUGO ACEVEDO, JUANA ALBARRACÍN DE MORÁN, and LEOPOLDO ARMANDO SALES. Can. J. Chem. **61**, 267 (1983).

The specific conductivities and pH values of copper sulphate solutions in water were measured in the temperature range from 10°C to 50°C. The data, previously corrected by hydrolysis, were analyzed by means of the Lee Wheaton theory.

This fit, for the evaluation of Λ_0, R, and K_A parameters, is quite satisfactory up to a maximum concentration of 25×10^{-4} mol dm^{-3} and the agreement between experimental data and the literature value for 25°C is acceptable.

VICTOR HUGO ACEVEDO, JUANA ALBARRACÍN DE MORÁN et LEOPOLDO ARMANDO SALES. Can. J. Chem. **61**, 267 (1983).

On a mesuré les conductivités spécifiques et le pH de solutions de sulfate de cuivre dans l'eau dans un intervalle de température allant de 10 à 50°C. Utilisant la théorie de Lee Wheaton, on a analysé les données, corrigées antérieurement par hydrolyse. Cet ajustement, pour l'évaluation des paramètres Λ_0, R et k_A, est assez satisfaisant jusqu'à une concentration maximum de 25×10^{-4} mol.dm^{-3} et l'accord entre les données expérimentales et celles de la littérature à 25° est acceptable.

[Traduit par le journal]

Introduction

For high charge electrolytes such as $CuSO_4$, the dual effects of hydrolysis and strong ion association makes the detailed interpretations of the conductance data rather difficult. The 2:2 sulphates, by contrast with 1:1 salts, show large, although non-specific negative deviations from the Debye Onsager limiting law. These deviations are usually ascribed to the formation of non-conducting ion pairs between oppositely charged ions which have approached each other quite closely. The K_A calculated for $CuSO_4$ is very strongly dependent on the particular theory applied and markedly dependent on the parameters used in the data fitting (1).

As part of an extensive investigations of the conductance of aqueous solutions of salts, we have obtained precise data for $CuSO_4$, up to a maximum concentration of 25×10^{-4} mol dm^{-3}, in the temperature range 10°C to 50°C.

In this paper we discuss the fitting of these data to the Lee Wheaton equation (2).

Experimental

The techniques used including the preparation of high purity conductivity water have been described elsewhere (3). Merck reagent grade copper sulphate pentahydrate was recrystallized three times from conductivity water. The purified salt was dried over a mixture of the penta- and trihydrates. All solutions were made up in volumetric flasks by weight. Taking into account the temperature dependence of the concentration, the weights of solute and solvent were calculated on the basis of the $d = f(c,t)$ values. The corresponding demalities were checked by gravimetric analysis.

For measurement of electrical conductivity, the Digital Conductimeter Tacussel CD 78 and immersion type cells with smooth Pt electrodes calibrated (for the different temperatures of the programme) with KCl solutions were used. Each concentration was measured at four frequencies and the conductivity extrapolated to infinite frequency.

For pH measurements the Orion 701 A Digital pH-meter with an accuracy of ±0.001 pH units was used.

The temperature of the bath was checked against two N.P.L. calibrated thermometers and was held constant to 0.005°C. In order to attain temperature equilibrium rapidly and avoid the polarization effect during measurements, the solution in the cell was stirred.

The computer analysis of the conductance data was performed in a TI 59 Microcomputer.

Results

The variation of the pH with total salt concentration is due to hydrolysis of Cu^{2+} ion, and can be expressed as follows:

[1] $Cu^{2+} + H_2O \leftrightarrow Cu(OH)^+ + H^+$

[2] $SO_4^{2-} + H_2O \leftrightarrow HSO_4^- + OH^-$

The formation of H_2SO_4 and $Cu(OH)_2$ was assumed to be negligible in dilute solutions.

The hydrolysis correction was carried out in the usual way (4), taking into account the activity coefficients and temperature dependence of the equilibrium constants.

The limiting ionic conductances for H^+, and the dissociation constants for H_2SO_4 were taken from the literature (5) while the values of conductances for $Cu(OH)^+$ and HSO_4^- and of hydrolysis constant were based on our data (9). The corrected conductivities of $CuSO_4$ solutions are given in Table 1.

Values of the molar conductivity, Λ, are quoted for the (1/2 $CuSO_4$) molar unit and in international ohms. Concentrations are given in terms of the $CuSO_4$ molar unit.

Discussion

The best-known conductance equations are one due to Pitts (6) (P equation) and those due to Fuoss (7, 8) (F 75, F 78). Lee and Wheaton have proposed, in 1978, a new conductance equation (L.W.), based on the Gurney co-sphere model, which describes charge transport in solutions containing any number of ionic species, of any valence type. For the specific case of solutions containing only a single symmetrical electrolyte, this equation has the general form:

[3] $\Lambda = f(\Lambda_0, R, K_A)$

where Λ_0 is the equivalent conductance at infinite dilution, K_A

*R = 9.64 Å; $\sigma(\Lambda) = 0.04$, $C_{max} = 25 \times 10^{-4}$ mol dm^{-3}.

the pairwise ion association constant, and R the distance parameter.

The simplified equation could be put into the form:

$$[4]\quad \Lambda = \gamma\Lambda_0[1 + C_1(\beta\kappa) + C_2(\beta\kappa)^2 + C_3(\beta\kappa)^3] - \frac{(\rho\kappa)}{(1 + KR)}[1 + C_4(\beta\kappa) + C_5(\beta\kappa)^2 + KR/12]$$

where C_1–C_5 are complex functions of (K,R), $\rho = |z|Fe/(299.79 \times 3\pi n)$, $\beta = z^2e^2/DkT$, R is the distance parameter, and all other symbols have their usual meanings.

Here,

$$[5]\quad K_A = \frac{1 - \alpha}{\alpha^2 c f_{\pm}^2}$$

and the Debye Hückel equation is used for the activity coefficient of dissociated species.

Table 2 shows the parameters obtained when fitting our results with the Lee–Wheaton equation. For low concentration results the equation provides a good fit of data. This is reflected in the standard deviation for data up to a maximum concentration of 25×10^{-4} mol dm^{-3} ($\sigma_\Lambda\% \cong 0.04$). When all data below a concentration of 50×10^{-4} mol dm^{-3} are analysed, $\sigma_\Lambda\%$ rises to 0.065.

The R value obtained is very reasonable in terms of the model proposed. It indicates that copper and sulphate ions separated by two water molecules or less should be treated as paired.

Finally we have analysed the equilibrium constant. Using the Fuoss nomenclature (7, 8) the ion pairs are divided as below,

TABLE 3. Corrected conductivities at 25°C

$C \times 10^3$ (mol dm^{-3})	Conductivity
3	91.06
3.5	88.3
4	86.22
4.5	84.21
5	82.40

with two equilibrium constants

$$[6]\quad K_A = K_R(1 + K_S)$$

$$[7]\quad K_R = (1 - \alpha)(1 - \gamma)/c\gamma^2 f^2 = (4\pi NR^3/3000)\exp(z^2e^2/D\kappa TR)$$

K_R is the association constant for the formation of solvent separated ion pairs. γc is the concentration of unpaired ions,

$$[8]\quad K_S = \alpha/(1 - \alpha)$$

is the association constant for the formation of contact ion pairs.

For this system, at 25°C the results are the following: $K_S = 5.68$, $\alpha = 8.5 \times 10^{-1}$, $K_R = 46.12$. For the lowest concentration (2×10^{-4} M), the proportion of the solvent-separated pairs would be very small: 0.88% at 25°C. However, the validity of applying these theoretical calculations is still questionable.

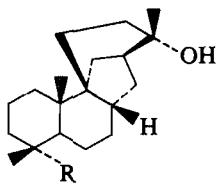
On décrit des synthèse totales stéréospécifiques de la (±) désoxy-2 stémodinone, de la (+) désoxy-2 stémodinone et du (±) stémodinol. On décrit également l'isolation de la (+) désoxy-2 stémodinone à partir de la *S. maritima* ainsi que sa caractérisation. On trace une stratégie pour l'élaboration des systèmes cycliques C/D du diterpène stémodane, de la stémarine et de l'aphidicoline à partir d'un système commun, l'hydroxy-6-bicyclo[2.2.2] octanone-2, et on prouve son efficacité par la synthèse des diterpènes stémodanes et par notre synthèse antérieure de la stémarine.

[Traduit par le journal]

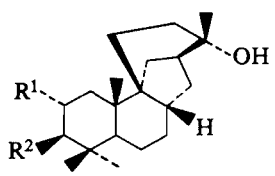
Introduction

By virtue of their unique carbon skeleton and alleged medicinal properties of *Stemodia maritma* L. from which they have been isolated (1), the stemodane group of diterpenoids has received considerable attention as targets for syntheses. Recently, three brief reports of total syntheses of representatives of this group have appeared, viz. the synthesis of stemodin (**3**) and stemodinone (**4**) (2*a*), the synthesis of maritimol (**5**) (2*b*), and the synthesis of 2-desoxystemodinone (**1**) and stemodinol (**2**) (3).

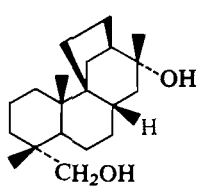
More than two years ago we revealed (ref. 4, see also ref. 3) a simple strategy for the construction of the C/D ring systems of the diterpenoids of the stemodane group (**1**–**5**) (1, 5), stemarin **6** (5), and aphidicolin (**7**) (6) from a common, readily obtainable 6-hydroxybicyclo[2.2.2]octan-2-one system represented by **8**. We proposed that the functionality of **8** could be modified to give intermediates such as **9**, **10**, and **11** (L = leaving group) which could be induced to undergo skeletal rearrangement to **12**, **13**, and **14** possessing the C/D ring systems of the stemodane diterpenoids, stemarin and aphidicolin, respectively. In each case, the leaving group (L) is aligned *anti* and periplanar to the migrating bond so that the desired C/D ring system should result from a Wagner-type rearrangement (Scheme 1). It should be pointed out that the rearrangement of bicyclo[2.2.2]octane systems to bicyclo-[3.2.1]octane systems has been employed by Wiesner *et al.* (7) in the synthesis of the delphinine and aconite alkaloids and by van Tamelen *et al.* (2*b*) in a recently reported synthesis of maritimol (**5**).



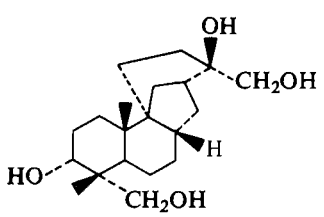
1 R = CH_3
2 R = CH_2OH
2a R = CH_2OTs



3 R^1 = OH; R^2 = H
4 R^1 = O; R^2 = H
5 R^1 = H; R^2 = OH



6



7

We have demonstrated the efficacy of our strategy by the completion of total syntheses of (±)-stemarin (**6**) (4), (±)-stemodinol (**2**) (3), (±)-2-desoxystemodinone (**1**) (3), and the naturally occurring enantiomer (+)-2-desoxystemodinone (**1**) (described in this article). The essential features of this strategy were adopted very recently by others (8) in some model studies which resulted in the synthesis of noraphidicolane and norstemodane skeleta but not in the synthesis of any naturally occurring diterpenoids.

We now wish to present the details of our syntheses of the stemodane type diterpenoids. We also wish to take this opportunity to describe the isolation of (+)-2-desoxystemodinone from *Stemodia maritima* L., the structure of which was deduced by spectral means (5) and confirmed by correlation with stemodinone (**4**) (see Experimental); the structure of the latter

was unambiguously determined by single crystal X-ray analysis (1*a*).

Discussion and results[1]

Total synthesis of (±)-2-desoxystemodinone and (±)-stemodinol

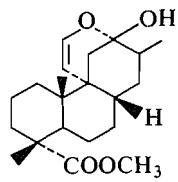
An outline of the synthesis of these racemic diterpenoids is given in Scheme 2 (Series *a*). With the possible exception of steps where stereospecificity was of no consequence, the synthesis proceeds stereospecifically from the starting material (**15***a*) to the final products.

Photoaddition of allene to the totally synthetic (9) racemic unsaturated ketone **15***a* afforded, as expected (10), the adduct **16***a* in 78% yield.[1] The configuration of **16***a* was assigned on the basis of Wiesner's (10) definitive studies on the stereochemical course of such photoadditions; the eventual conversion of **16***a* into 2-desoxystemodinone (**1**) provides yet another example of the validity of his deductions in this regard. Treatment of the adduct **16***a* with CH_3I in THF in the presence of LDA gave the methylated ketone **17***a* (74%) which was converted to the ketal **18***a* in 90% yield.

Oxidation of **18***a* with OsO_4/IO_4^- (11) gave the cyclobutanone **19***a* (77%) which was reduced quantitatively with $NaBH_4$ to the cyclobutanol **20***a*.

Having obtained the cyclobutanol **20**, we had arrived at the stage for the execution of the first two skeletal rearrangements featured in this synthetic sequence. The rearrangement, for which there is ample precedent (7, 12) was achieved by refluxing **20***a* with HCl in aqueous THF, whereupon it underwent deketalization followed by retroaldolization, then spontaneous aldol condensation to produce the keto alcohol **21***a* (72%) and its C-12 epimer (23%). The major epimer, which was chosen for the continuation of the synthetic sequence for stereochemical reasons (*vide infra*) was assigned (4) the configuration shown in **21***a* which, unlike its C-12 epimer, permits stabilization by hydrogen bonding between the OH group and the ketone (7).

We now disgress briefly to report a phenomenon of ancillary interest which was encountered with regard to the rearrangement of **20***a* (*vide supra*). When **20***a* was treated with HCl in aqueous THF under mild conditions (room temperature, 3 h) there was obtained a crystalline compound in 60% yield whose spectral properties were inconsistent with those of the expected products, **21***a* and its C-12 epimer.The ir spectrum was devoid of a band attributable to a ketone function and, furthermore, the nmr spectrum exhibited a 3-proton doublet at δ 1.00 due to a secondary methyl and two one-proton doublets (J = 6.0 Hz for each) at δ 4.76 (secondary splitting) and δ 6.42. These spectral properties prompted us to assign to this compound the unsaturated hemiacetal structure **28**. This assignment was corroborated by the discovery that the compound in question could be



28

converted quantitatively into the same mixture of **21***a* and its C-12 epimer as was obtained above by subjecting it to the more vigorous acidic conditions employed in the direct rearrangement of **20***a* (*vide supra*).

Returning to the main theme, we now describe the transformation of the keto alcohol **21***a* into the skeletally rearranged olefin **25***a*, thence to (±)-stemodinol (**2**) and (±)-2-desoxystemodinone (**1**). Accordingly, **21***a* was converted quantitatively into the thioketal **22***a* which was reduced in 97% yield to the alcohol **23***a*. This alcohol was converted into the tosylate **24***a* in which the tosylate group (leaving group) was aligned *anti* and periplanar to bond (m), the required stereoalignment for the subsequent rearrangement which was now performed as follows. The tosylate (**24***a*) was heated at 60°C in DMSO in the presence of methyl sulfinyl carbanion (13) whereupon it was transformed, by migration of bond (m) and elimination of hydrogen, into the olefin **25***a* (60% from **23***a*). Thus, the second skeletal rearrangement was achieved to produce an intermediate possessing the stemodane carbon skeleton.

The ester group of **25***a* was reduced quantitatively with $LiAlH_4$ to provide the olefinic alcohol **26***a*. The latter, on oxidation with *m*-chloroperbenzoic acid, afforded the epoxide **27***a* which, finally, was reduced with $LiAlH_4$ to stemodinol (**2**).[2]

The synthetic diterpenoid **2** was clearly *not identical* to a

[1]Yields refer to compounds which were uncontaminated as judged by silica gel tlc and which, in the majority of cases, had been purified by column chromatography. No special effort was made to optimize yields.

[2]This synthesis of stemodinol was included as part of a plenary lecture given by R. B. K. on September 30, 1980 at the IUPAC 12th International Symposium on the Chemistry of Natural Products at Puerto de la Cruz, Tenerife, Canary Islands.

Series *b* refers to the synthesis of (+)-2-desoxystemodinone from podocarpic acid

SCHEME 2

sample of "stemodinol" obtained from natural sources. Eventually it was discovered, by comparison with an authentic sample of stemarin, that the sample of naturally occurring stemodinol which we received was in fact stemarin (**6**) to which structure **2** had been erroneously assigned in the literature (1*b*). To the best of our knowledge, the diterpenoid having structure **2** has not been isolated from natural sources.[3]

We were now faced with the problem of demonstrating the validity of structure **2** for our synthetic diterpenoid. This task was complicated by our inability, despite the expenditure of a great deal of time and effort, to produce crystals of **2** or its derivatives amenable to X-ray crystallographic analysis. Eventually a solution was realized in the following manner. The tosylate **2***a* of **2** was reduced with $LiAlH_4$ and the product was shown to be identical (ir, nmr, ms, and silica gel tlc) to an authentic sample of the naturally occurring (5) 2-desoxystemodinone, the structure of which has been unequivocally shown to be (**1**) (*vide supra*). The assignment of the CH_2OH group in **2** to the α-orientation follows from the fact that **2** and stemarin (**6**) have been synthesized from common intermediates (4). Thus, the conversion of **2** into **1** proves that structure **2** is correct for our synthetic diterpenoid (stemodinol) and constitutes a stereospecific total synthesis of 2-desoxystemodinone (**1**).

[3]Professor C. D. Hufford, University of Mississippi, University, Mississippi, concurs with these conclusions.

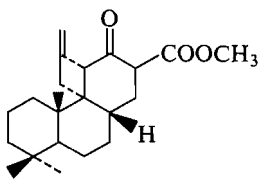
Synthesis of (+)-2-desoxystemodinone from podocarpic acid

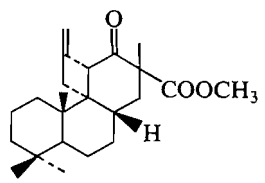
While searching for a means of resolving the difficulties surrounding our synthesis of stemodinol (**2**) (*vide supra*), we embarked upon a synthesis of the naturally occurring (+)-2-desoxystemodinone (**1**) from podocarpic acid. This synthesis was undertaken to demonstrate conclusively that the strategy described in the Introduction could be applied efficiently and stereospecifically to the synthesis of the stemodane group of diterpenoids. This objective was realized by the completion of the synthesis of **1** as described in the sequel and outlined in Scheme 2 (Series *b*).

The unsaturated ketone **15***b* was prepared in 43% overall yield from podocarpic acid by previously described procedures (14). Photoaddition of allene to **15***b* afforded the adduct **16***b*, the configuration of which was assigned as explained in the previous section.

Methylation of the photoadduct **16***b* was accomplished by a procedure different from that used in the previous synthesis. Thus, treatment of the adduct with NaH in dioxane followed by dimethylcarbonate gave the methyl ester **29** (97%) which, on treatment with NaH followed by CH_3I in dioxane, gave **30** in 90% yield. Saponification of the ester **30** with concomitant



29



30

decarboxylation produced, in 89% yield, the methylated photoadduct **17***b*.

The sequence from **17***b* to the olefin 25*b* now paralleled exactly that employed in the preceding section (**17***a* → **25***a*). Consequently, a full amount of this portion of the present synthesis would be unnecessarily repititious and will not be given here: details are given in the experimental section. A few comments, however, are in order.

From the intermediate (**15***b*) to the synthetic diterpenoid (**1**), the synthesis required fourteen steps, eight of which were achieved in yields of over 80% and three in yields of 75% to 80%. Since skeletal rearrangements are important features of this synthesis, it should be mentioned here that the first rearrangement (**20***b* → **21***b*) yielded 76% of the desired keto alcohol **21***b* along with 20% of its C-12 epimer. It should also be mentioned that the second rearrangement proceeded smoothly to give the olefin **25***b* in 70% yield (**23***b* → **24***b* → **25**b).

In the penultimate step, the olefin **25***b* was converted into the epoxide **27***b* by oxidation with *m*-chloroperbenzoic acid. Finally, reduction of **27***b* with $LiAlH_4$ afforded the diterpenoid **1** in 75% yield. The synthetic diterpenoid **1** was identical to a sample of (+)-2-desoxystemodinone obtained from *Stemodia maritima* L. (mixture mp (145°C); nmr, ir, and mass spectra, silica gel tlc). Since a synthesis of (+)-podocarpic acid, the starting material, has been accomplished (15), the completion of this synthesis represents a formal, stereospecific synthesis of (+)-2-desoxystemodinone, the naturally occurring enantiomer; it also confirms the absolute stereochemistry of the stemodane group of diterpenoids which had been assigned on the basis of optical rotatory dispersion and circular dichroism studies (1*a*).

Experimental

Instrumentation, methods, and materials

Melting points were determined on a Fisher–Johns apparatus and are uncorrected.

Unless otherwise stated, ir spectra were determined as Nujol mulls with either a Digilab FTS-14 instrument or a Perkin–Elmer 297 instrument. Proton nmr were recorded in $CDCl_3$ on either a Varian XL-100 instrument or a Varian T-60 instrument; chemical shifts are expressed in ppm (δ-values) relative to TMS as an internal standard. The ms were recorded on a Vacuum Generator VG-ZAB-1F instrument.

Silica gel G-60 was used for column chromatography and silica gel GF-240 for tlc (E. Merck, Darmstadt.). The neutral alumina used for column chromatography was Brockman Act. II aluminum oxide (Camag).

Petroleum ether refers to the fraction with boiling point range 30–60°C. Brine refers to a saturated solution of NaCl.

*Photoadduct 16*a

A solution of 1.31 g of **15***a* and 14.5 g of allene in 500 mL of CH_2Cl_2 was irradiated at −70°C for 2 h, then left at room temperature overnight to allow excess allene to escape. Evaporation of the solvent *in vacuo*, crystallization of the residue from ether – petroleum ether, and chromatography of the mother liquor on 100 g of neutral alumina in ether – petroleum ether afforded 1.17 g (78%) of **16***a*, mp 121°C; ir: 1720 (ester), 1695 (ketone), 1662 and 900 (olefin) cm^{-1}; nmr δ: 0.88 and 1.14 (3-proton singlets, tertiary methyls), 3.63 (s, 3H, OCH_3), and 4.90 (m, 2H, exocyclic methylene). *Anal.* calcd. for $C_{21}H_{33}O_3$: C 76.33 H 9.15; found: C 76.44, H 9.16.

*Methylated photoadduct 17*a

The following reaction was carried out in a dry nitrogen atmosphere. A solution of 0.30 mL of disopropylamine in 2.4 mL of dry THF was cooled to 0°C and treated with 1.54 mL of a 1.5 M hexane solution of n-butyllithium. A solution of 668 mg of **16***a* in 3.5 mL of THF was then added to the cooled solution over 5 min. The resulting solution was cooled to −10°C, treated with 0.14 mL of CH_3I, and allowed to come to room temperature over 1 h. The reaction solution was diluted with 50 mL of benzene and washed with 25 mL of water and two 25-mL portions of brine. The aqueous washings were extracted with two 75-mL portions of ether. The combined extracts were dried over $MgSO_4$ and evaporated *in vacuo*. Separation of the product from unreacted starting material on 76 g of neutral alumina in ether–petroleum ether and recyclization of the latter afforded 518 mg (74%) of **17***a*, mp 124°C; ir: 1715 (ester), 1695 (ketone), 1665 and 890 (olefin) cm^{-1}: nmr δ: 0.88 and 1.13 (3-proton singlets, tertiary methyls), 1.16 (d, J = 6.5 Hz, 3H, secondary methyl), 3.65 (s, 3H, OCH_3), and 4.90 (m, 2H, exocyclic methylene). *Anal.* calcd. for $C_{22}H_{32}O_3$: C 76.70 H 9.36; found: C 76.63, H 9.52.

*Ketal 18*a

Under a nitrogen atmosphere, a toluene (250 mL) solution of 1.01 g of **17***a*, 80 mg of *p*-toluenesulfonic acid monohydrate, and 2.2 mL of ethylene glycol was refluxed for 5 h. During this period water was separated in a Dean–Stark adaptor and hourly additions of 1.0-mL portions of ethylene glycol were made. The cooled solution was washed with 100 mL of cold saturated Na_2CO_3 solution and 100 mL of cold brine and the aqueous washings were extracted with three 300-mL portions of ether. The combined extracts were dried over Na_2SO_4 and evaporated *in vacuo*. Crystallization of the residue from ether – petroleum ether, followed by chromatography of the mother liquor on 37 g of neutral alumina in ether – petroleum ether, afforded 1.03 g (90%) of **18***a*, mp 131°C; ir: 1732 (ester), 1675 and 913 (olefin) cm^{-1}; nmr δ: 0.91 (d, J = 6.5 Hz, 3H, secondary methyl), 0.95 and 1.14 (3-proton singlets, tertiary methyls), 3.97 (br s, 4H, ethylene of ketal), and 4.89 (m, 2H, exocyclic methylene). *Anal.* calcd. for $C_{24}H_{36}O_4$: C 74.19, H 9.34; found: C 74.18, H 9.13.

*Cyclobutanone 19*a

A solution of 58 mg of OsO_4, 1.9 mL of pyridine, and 3.9 mL of

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

water was treated with a solution of 572 mg of **18***a* in 48 mL of dioxane. After stirring in the dark for 15 min, the solution was treated dropwise over 1 h with a solution of 546 mg of $NaIO_4$ in 5.5 mL of water and the resulting mixture was stirred in the dark for 45 h. Solid material was removed by filtration and the filtrate was diluted with ether and washed with two 37-mL portions of cold 10% Na_2S solution and 75 mL of cold water. The aqueous washings were extracted with three 225-mL portions of ether. The extracts were dried over K_2CO_3 and evaporated *in vacuo*. Crystallization of the residue from ether – petroleum ether, followed by chromatography of the mother liquor on 10 g of neutral alumina in ether – petroleum ether, afforded 442 mg (77%) of **19***a*, mp 155°C; ir: 1779 (cyclobutanone) and 1733 (ester) cm^{-1}; nmr δ: 0.88 (d, J = 6.5 Hz, 3H, secondary methyl), 1.05 and 1.17 (3-proton singlets, tertiary methyls), 3.63 (s, 3H, OCH_3), and 3.96 (m, 4H, ethylene of ketal). *Anal.* calcd. for $C_{23}H_{34}O_5$: C 70.74, H. 8.78; found: C 70.85, H 9.13.

Cyclobutanol ***20***a

A solution of 282 mg of **19***a* in 17 mL of ethanol was treated with 172 mg of $NaBH_4$. After stirring for 1 h the reaction mixture was filtered and the filtrate was evaporated *in vacuo*. The residue was dissolved in 100 mL of ether and the solution was washed with two 75-mL portions of brine. The aqueous washings were extracted with two 100-mL portions of ether. The combined extracts were dried ($MgSO_4$) and evaporated *in vacuo* to give 283 mg (quantitative yield) of **20***a*, mp 164°C; ir: 3450 (OH) and 1722 (ester) cm^{-1}; nmr δ: 0.86 (d, J = 6.5 Hz, 3H, secondary methyl), 0.87 and 1.12 (3-proton singlets, tertiary methyls), 3.60 (s, 3H, OCH_3), 3.86 (m, 4H, ethylene of ketal), and 4.22 (m, 1H, *H*C—OH). *Anal.* calcd. for $C_{23}H_{36}O_5$: C 70.38, H 9.24; found: C 70.47, H 9.31.

Keto alcohol ***21***a *and its C-12 epimer*

Directly from ***20***a

A solution of 98 mg of **20***a* in 10 mL of THF containing 5 mL of 1 *M* aqueous HCl was refluxed under nitrogen for 20.5 h. The cooled reaction solution was diluted with 100 mL of ether and the ethereal solution was worked up with 50 mL of saturated aqueous $NaHCO_3$ solution, then with two 40-mL portions of brine. The aqueous washings were extracted with two 100-mL portions of ether. The combined extracts were dried ($MgSO_4$), evaporated *in vacuo*, and the residue was chromatographed on 10 g of silica gel in ether – petroleum ether.

The first fraction eluted from the column comprised 20 mg (23%) of the *C-12 epimer* of **21***a*, mp 197°C: ir: 3520 (OH), 1718 (ester) and 1700 (ketone) cm^{-1}; nmr δ: 0.98 (s, 6H, superimposed signals for two tertiary methyls), 1.20 (s, 3H, tertiary methyl), 3.63 (S, 3H, OCH_3), and 3.65 (m, 1H, *H*C—OH). *Anal.* calcd. for $C_{21}H_{32}O_4$: C 72.38, H 9.26; found: C 72.16, H 9.23.

The slower moving fraction from the column afforded 63 mg (72%) of **21***a*, mp 192°C; ir: 3498 (OH), 1720 (ester), and 1702 (ketone) cm^{-1}; nmr δ: 1.01 (s, 6H, superimposed signals for two tertiary methyls), 1.21 (s, 3H, tertiary methyl), 3.63 (s, 3H, OCH_3), 3.73 and 3.88 (dd, J = 3.5 Hz, 1H, *H*C—OH).

From the unsaturated hemiacetal ***28***

The unsaturated hemiacetal **28** (*vide infra*) was converted into **21***a* (80%) and its C-12 epimer (20%) by the procedure detailed above. The two epimers were identical (mixture mp, ir, and nmr spectra, silica gel tlc) to the corresponding epimers obtained directly from **20***a* (*vide supra*).

Unsaturated hemiacetal **28**

A solution of 75 mg of **20***a* in the 5 mL of THF and 4 mL of 1 *M* aqueous HCl was stirred in a nitrogen atmosphere at room temperature for 3 h. The reaction solution was diluted with 50 mL of brine and extracted with the three 50-mL portions of chloroform. The extracts were washed with 50 mL of saturated $NaHCO_3$ solution and 50 mL of brine, combined, dried over $MgSO_4$, and evaporated *in vacuo*. Column chromatography on 7.0 g of silica gel in ether – petroleum ether afforded 40 mg (60%) of **28**, mp 146°C; ir: 3340 (OH), 1725 (ester) and 1640 (olefin) cm^{-1}; nmr δ: 1.00 (d, J = 6.5 Hz, 3H, secondary methyl), 1.06 and 1.22 (3-proton singlets, tertiary methyls), 3.63 (s, 3H, OCH_3), 4.76 and 6.42 (doublets, J = 6.0 Hz, 1H each, vinylic protons). *Anal.* calcd. for $C_{21}H_{32}O_4$: C 72.38, H 9.26; found: C 72.38, H 9.24.

Thioketal ***22***a

Under a nitrogen atmosphere, a solution of 180 mg of **21***a* in 1 mL of ethane dithiol was cooled to 0°C and treated with 0.41 mL of boron trifluoride etherate. After stirring 9 min, a cold mixture of 50 mL each of CH_2Cl_2 and 1 *M* aqueous NaOH was added and the organic phase was separated and washed with two 100-mL portions of 1 *M* NaOH. The aqueous phases were extracted with three 100-mL portions of CH_2Cl_2. Evaporation *in vacuo* of the combined and dried ($MgSO_4$) extracts afforded 219 mg (quantitative yield) of **22***a*, mp 177–178°C; ir: 3435 (OH) and 1718 (ester) cm^{-1}; nmr δ: 0.90, 1.12 and 1.17 (3-proton singlets, tertiary methyls), 3.17 (m, 4H, ethylene of ketal), 3.61 (s, 3H, OCH_3), and 3.76 (m, 1H, *H*C—OH). *Anal.* calcd. for $C_{23}H_{36}S_2O_3$: C 65.05, H. 8.54; found: C 65.02, H 8.55.

Alcohol ***23****a*

A solution of 165 mg of **22**a in 70 mL of absolute alcohol was stirred with 3.0 g of Raney nickel, W-2 (16), under a nitrogen atmosphere for 22 h. The catalyst was removed by filtration, the alcohol was evaporated *in vacuo*, and the residue taken up in ether. The ether solution was filtered and evaporated *in vacuo* to give 126 mg (97%) of **23***a*, mp 130°C; ir: 3500 (OH) and 1705 (ester) cm^{-1}; nmr δ: 0.78, 0.93 and 1.20 (3-proton singlets, tertiary methyls), 3.56 (m, 1H, *H*C—OH), and 3.66 (s, 3H, OCH_3). *Anal.* calcd. for $C_{21}H_{34}O_3$: C 75.41, H 10.25; found: C 75.58, H 10.14.

Olefinic ester ***25***a

A solution of 76 mg of **23***a* in 1.1 mL of pyridine containing 134 mg of *p*-toluenesulfonyl chloride was left in the dark at 3°C for 66.5 h. The cold solution was diluted with 4 mL of ice water and, after stirring for 15 min, 50 mL of cold ether was added. The ethereal solution was washed with 50 mL of cold 2 *M* aqueous HCl solution and two 50-mL portions of cold brine. The aqueous washings were extracted with three 50-mL portions of ether. Evaporation of the combined, dried (K_2CO_3) extracts *in vacuo* afforded 106 mg of the tosylate **24***a* which was used immediately for the next step.

The following reaction was performed under a dry nitrogen atmosphere. A solution of 106 mg of **24***a* in 2.3 mL of dry DMSO was treated with 0.59 mL of a 0.5 *M* DMSO solution of methylsulfinyl carbanion (13). The resulting solution was stirred at 60°C for 1.5 h, then cooled, treated with 1 mL of water, and diluted with 50 mL of ether. The ethereal solution was washed with three 30-mL portions of brine and three 30-mL portions of water and the washings were extracted with five 50-mL portions of ether. Evaporation *in vacuo* of the combined, dried ($MgSO_4$) extracts and chromatography of the residue on 7.0 g of silica gel in ether – petroleum ether afforded 43 mg (60%) of the oily olefin **25***a*, ir (film): 1730 (ester) and 1650 (olefin) cm^{-1}; nmr δ: 0.97 and 1.23 (3-proton singlets, tertiary methyls), 1.55 (d, J = 2 Hz, 3H, vinylic methyl), 3.61 (s, 3H, OCH_3), and 4.94 (m, 1H, vinylic proton). *Mol. Wt.* calcd. for $C_{21}H_{32}O_2$: 316; found (ms): 316.

Olefinic alcohol ***26***a

A mixture of 43 mg of **25***a*, 100 mg of $LiAlH_4$, and 4 mL of ether was refluxed for 1 h, then treated with a few drops of saturated aqueous Na_2SO_4 solution, followed by anhydrous Na_2SO_4. Solid material was removed by filtration and washed with ether. Evaporation *in vacuo* of the combined filtrate and ether washings afforded 39 mg (quantitative yield) of oily **26***a*, ir (film): 3350.(OH) and 1625 (olefin) cm^{-1}; nmr δ: 0.83 and 1.00 (3-proton singlets, tertiary methyls), 1.62 (d, J = 2.0 Hz, 3H, vinylic methyl), 3.07 and 3.38 (dd, J = 11 Hz, 1 H each, CH_2OH), and 4.96 (m, 1H, vinylic proton). *Mol. Wt.* calcd. for $C_{20}H_{32}O$: 288; found (ms): 288.

Epoxide ***27***a

A solution of 38 mg of **26***a* in 2 mL of benzene was treated with 34 mg of *m*-chloroperbenzoic acid and stirred in the dark at room temperature for 2 h, then 10 mL of 10% aqueous Na_2SO_3 was added and stirring was continued for 10 min. Ether (60 mL) was added, the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

layers were separated, and the ether phase was washed with two 50-mL portions of 5% aqueous Na_2CO_3 and 50 mL of brine. The aqueous washings were extracted with two 60-mL portions of ether. Evaporation of the combined and dried (K_2CO_3) extracts *in vacuo* and chromatography of the residue over 5.0 g of basic alumina in ether – petroleum ether afforded 28 mg (70%) of oily **27***a*, ir (film): 3350 (OH) cm^{-1}; nmr δ: 0.97 and 0.95 (3-proton singlets, tertiary methyls), 1.27 (s, 3H, methyl attached to oxirane ring), 3.03 and 3.34 (dd, J = 11 Hz, 1 H each, CH_2—OH). *Mol. Wt.* calcd. for $C_{20}H_{32}O_2$: 304; found (ms): 304.

(±)-Stemodinol (**2**)

A mixture of 21 mg of **27***a*, 80 mg of $LiAlH_4$, and 4 mL of THF was refluxed for 2 h. A few drops of saturated aqueous Na_2SO_4 solution was added to the cooled reaction mixture, followed by anhydrous Na_2SO_4. The solid material was removed by filtration and washed with CH_2Cl_2. Evaporation of the combined filtrate and washings afforded 17 mg (63%) of **2**, mp 160°C; ir: 3510 and 3350 (OH) cm^{-1}; nmr δ: 0.82, 1.00 and 1.11 (3-proton singlets, tertiary methyls), 3.07 and 3.37 (dd, J = 11 Hz, 1 H each, CH_2OH). *Anal.* calcd. for $C_{20}H_{34}O_2$: C 78.38, H 11.18; found: C 78.21, H 11.32.

Photoadduct **16**b

The unsaturated ketone **15***b* (14) was converted into the photoadduct **16***b* by the procedure described above for the preparation of **16***a*. From 2.04 g of **15***b* there was obtained 2.03 g (86%) of **16***b*, mp 90°C; ir: 1700 (ketone), 1672 and 895 (olefin) cm^{-1}; nmr δ: 0.83 (s, 3H, tertiary methyl), 0.85 (s, 6H, superimposed signals for two tertiary methyls), and 4.82 (m, 2H, exocyclic methylene). *Anal.* calcd. for $C_{20}H_3O$: C 83.85, H 10.56; found: C 84.06, H 10.64.

Ester **30**

The following reactions were performed under a dry nitrogen atmosphere. To a well-stirred mixture of 432 mg of NaH, 3.24 g of dimethylcarbonate, and 5 mL of dry dioxane at 80–85°C there was added a solution of 2.05 g of **16***b* in 10 mL of dry dioxane over 2 h. Stirring was continued at the elevated temperature for a further 2.5 h. The reaction mixture was cooled on an ice bath, acidified with 1 *M* HCl, and extracted with three 150-mL portions of ether. The ether extracts were washed with three 10-mL portions of brine and 10 mL of water, combined, dried ($MgSO_4$), and evaporated *in vacuo*. The residue was chromatographed on 55 g of silica gel in ether – petroleum ether to give 2.39 g (97%) of **29** as an oil, ir (film): 1660 and 1615 (enolized β-keto ester) cm^{-1}.

To a stirred mixture of 432 mg of NaH and 6 mL of dry dioxane there was added over 20 min a solution of 2.50 g of **29** in 10 mL of dioxane. After a further 10 min, 2.5 mL of CH_3I was added and the reaction solution was kept at 40°C for 2.5 h, then cooled on an ice bath and acidified with 1 *M* HCl. The resulting acidic mixture was extracted with three 150-mL portions of ether and the extracts were washed with 10 mL of saturated aqueous $NaHCO_3$, then with two 15-mL portions of brine. The extracts were combined, dried over $MgSO_4$, and evaporated *in vacuo*. Chromatography of the residue over 45 g of silica gel in ether – petroleum ether afforded 2.33 g (90%) of **30**, mp 101°C; ir: 1705 (ketone) and 1745 (ester) cm^{-1}; nmr δ: four methyl singlets between 0.80 and 0.84 and 4.88 (m, 2H, exocyclic methylene). *Anal.* calcd. for: $C_{23}H_{34}O_3$: C 77.05, H 9.56; found: C 77.12, H 9.65.

Methylated photoadduct **17**b

A mixture of 2.33 g of **30**, 35 mL of 10% aqueous KOH, and 12 mL of ethanol was refluxed under nitrogen for 5.5 h. The cooled solution was acidified with 1 *N* HCl and extracted with three 200-mL portions of ether. The extracts were washed with 10 mL of saturated aqueous $NaHCO_3$ solution, then with two 15-mL portions of brine. The combined extracts were dried over $MgSO_4$ and evaporated *in vacuo*. Chromatography of the residue over 45 g of silica gel in ether – petroleum ether gave 1.73 g (89%) of **17***b*, low melting; ir (film): 1700 (ketone), 1675 and 890 (olefin) cm^{-1}; nmr δ: 0.81 (s, 3H, tertiary methyl), 0.85 (s, 6H, superimposed signals for two tertiary methyls), 1.03 and 1.15 (doublets, secondary epimeric methyls). *Anal.* calcd. for $C_{21}H_{32}O$: C 83.94, H 10.74; found: C 83.58, H 10.57.

Ketal **18**b

The ketone **17***b* was converted into the ketal **18***b* by the procedure described above for the preparation of **18***a*. From 1.05 g of **17***b* there was obtained 1.06 g (87%) of **18***b*, mp 139°C; ir: devoid of bands attributable to carbonyl; nmr δ: 0.81, 0.83 and 0.92 (3-proton singlets, tertiary methyls), 0.88 (d, J = 6.5 Hz, 3H, secondary methyl), 3.98 (m, 4H, ethylene of ketal), and 4.90 (m, 2H, exocyclic methylene). *Anal.* calcd. for $C_{23}H_{36}O_2$: C 80.18, H 10.53; found: C 79.90, H 10.53.

Cyclobutanone **19**b

The ketal **18***b* was converted into the cyclobutanone **19***b* by the procedure described above for the preparation of **19***a*. From 1.00 g of **18***b* there was obtained 777 mg (77%) of **19***b*, mp 157°C, ir: 1773 (cyclobutanone) cm^{-1}; nmr δ: 0.83, 0.85 and 1.01 (3-proton singlets, tertiary methyls), 1.00 (d, J = 6.5, 3H, secondary methyl), and 3.96 (m, 4H, ethylene of ketal). *Anal.* calcd. for $C_{22}H_{34}O_3$: C 76.26, H 9.89; found: C 76.01, H 9.87.

Cyclobutanol **20**b

The cyclobutanone **19***b* was converted into the cyclobutanol **20***b* by the procedure described above for the preparation of **20***a*. From 537 mg of **19***b* there was obtained 537 mg (99%) of **20***b*, mp 149°C; ir: 3350 (OH) cm^{-1}; nmr δ: 0.83 (br s, 9H, three tertiary methyls), 0.95 (d, J = 6.5 Hz, 3H, secondary methyl), 4.08 (dd, 1H, J = 8 Hz, *H*C—OH), and 3.91 (m, 4H, ethylene of ketal). *Anal.* calcd. for $C_{22}H_{36}O_3$: C 75.81, H 10.41; found: C 76.10, H 10.63.

Keto alcohol **21**b *and its C-12 epimer*

The cyclobutanol **20***b* was converted into the keto alcohol **21***b* and its C-12 epimer by the procedure described above for the preparation of **21***a* and its epimer. From 700 mg of **20***b* there was obtained 126 mg (20%) of the epimer, mp 215°C; spectral properties similar to **21***b*. There also was obtained 468 mg (76%) of **21***b*, mp 149°C; ir: 3420 (OH) and 1690 (ketone) cm^{-1}; nmr δ: 0.89 (s, 6H, superimposed singlets for two tertiary methyls), 1.00 (s, 3H, tertiary methyl), and 3.80 (dd, J = 3 Hz, 1H, *H*C—OH). *Anal.* calcd. for $C_{20}H_{32}O_2$: C 78.89, H 10.60; found: C 78.74, H 10.64.

Thioketal **22**b

The keto alcohol **21***b* was converted into the thioketal **22***b* by the procedure described above for the preparation of **22***a*. From 200 mg of **21***b* there was obtained 212 mg (85%) of **22***b*, mp 142°C; ir: 3500 (OH) cm^{-1}; nmr δ: 0.84 (s, 6H, superimposed singlets for two tertiary methyls), 0.91 and 1.13 (singlets, 3H each, tertiary methyls), 3.20 (m, 4H, ethylene of ketal), and 3.68 (m, 1H, *H*C—OH). *Anal.* calcd. for $C_{32}H_{36}S_2O$: C 69.41, H 9.53; found: C 69.67, H 9.65.

Alcohol **23**b

The thioketal **22***b* was converted into the alcohol **23***b* by the procedure described above for the preparation of **23***a*. From 150 mg of **22***b* there was obtained 94 mg (83%) of **23***b*, mp 128°C; ir: 3350 cm^{-1}; nmr δ: 0.78 and 0.91 (singlets, 3H each, tertiary methyls), 0.85 (s, 6H, superimposed singlets for two tertiary methyls), and 3.54 (m, 1H, *H*C—OH). *Anal.* calcd. for $C_{20}H_{34}O$: C 82.69, H 11.80; found: C 82.80; H 11.89.

Olefin **25**b

The alcohol **23***b* was converted into the olefin **25***b* via the tosylate **24***b* by the procedure described above for the preparation of **25***a*. From 61 mg of **23***b* there was obtained 40 mg (70%) of **25***b* as an oil having spectral properties (nmr δ: 1.60 (s, 3H, vinylic methyl and 5.00 (m, 1H, vinylic proton)) identical to those reported for the same olefin obtained from stemodinone (**1***a*).

Epoxide **27**b

The olefin **25***b* was converted into the epoxide **27***b* by the procedure described above for the preparation of **27***a*. From 28 mg of **25***b* there was obtained 21 mg (75%) of **27***b* as an oil, nmr δ: 0.87 (s, 6H, superimposed singlets for two tertiary methyls), 1.21 (s, 3H, methyl attached to oxirane ring), and 2.73 (m, 1H, proton attached to oxirane

ring). *Mol. Wt.* calcd. for $C_{20}H_{32}O$: 288; found (ms): 288.

(+)-2-Desoxystemodinone (1)

A mixture of 28 mg of **27***b*, 100 mg of $LiAlH_4$, and 10 mL of THF was refluxed under nitrogen for 2 h. The cooled mixture was treated with a few drops of saturated aqueous Na_2SO_4 solution, followed by anhydrous Na_2SO_4. The mixture was filtered and the solid material was washed with 100 mL each of ether and CH_2Cl_2. The combined filtrate and washings were evaporated *in vacuo* and the residue was chromatographed on 5 g of silica gel in ether – petroleum ether to give 21 mg (75%) of **1**. The synthetic diterpenoid was identical with a sample of (+)-2-desoxystemodinone obtained from *Stemodia maritima* L. (mixture mp (145°C), nmr and ir spectra, ms and silica gel tlc).

(±)-2-Desoxystemodinone (1) from (±)-stemodinol (2)

A solution of 7 mg of **2** in 1 mL of pyridine was treated with 7 mg of *p*-toluenesulfonyl chloride and left at room temperature overnight. The solution was diluted with 10 mL of cold 0.1 *M* HCl and extracted twice with 20-mL portions of ethyl acetate. The extracts were washed with brine, dried over $MgSO_4$, and evaporated to give 9 mg of the tosylate **2***a* as a gum. This was immediately refluxed for 4 h in 10 mL of THF containing 10 mg of $LiAlH_4$. The reaction mixture was cooled to 0°C, acidified with 10 mL of 0.1 *M* HCl and extracted with two 15-mL portions of ethyl acetate. The combined extracts were dried over $MgSO_4$ and evaporated *in vacuo* to a gum which was purified by silica gel tlc with 20% ethyl acetate in hexane as solvent. There was obtained 4.5 mg of amorphous, racemic **1**, identical to 2-desoxystemodinone (5) isolated from *Stemodia maritima* L. (tlc, ir, nmr, and mass spectra).

Isolation of (+)-2-desoxystemodinone (1) from Stemodia maritima *L.*

Dried leaves (1.50 kg) of *S. maritima* (17), collected along the Palisadoes Peninsula of Jamaica in August 1973, were steeped in 10.0 L of hexane for 65 h. The mixture was filtered and the filtrate was concentrated to 1.50 L, diluted with 1.50 L of 95% methanol, and stirred at 50°C for 3 h. The hexane layer was separated and evaporated *in vacuo* to a yellow gum (11.3 g) which was dissolved in 50 mL of hexane and left overnight at 0°C. Crystalline stemodin (**3**) (1*a*) which had precipitated (1.6 g) was collected by filtration and the filtrate was evaporated *in vacuo*. The residue was chromatographed on 250 g of neutral alumina with 15% of ethyl acetate in hexane as eluent. Fractions containing **1**, as ascertained by silica gel tlc with the same solvent, were combined and evaporated *in vacuo*. Rechromatography of the residue on 40 g of neutral alumina as above afforded 173 mg of material which, on crystallization from aqueous methanol at 0°C, afforded 130 mg of **1**, mp 140–142°C; $[\alpha]_D^{25}$ + 6.5° (*c* 1.0, $CHCl_3$); ir ($CHCl_3$): 3590 and 3430 (OH) cm^{-1}; nmr δ: 0.88 (s, 6H, superimposed singlets for two tertiary methyls), 0.96 and 1.12 (singlets, 3H each, tertiary methyls). *Anal.* calcd. for $C_{20}H_{30}O$: C 82.76, H 11.72; found: C 82.81, H 11.67.

This material was identical to the product obtained by Huang–Minlon reduction of stemodinone (**4**) (1*a*) (mixture mp, optical rotation, ir, nmr, and mass spectra).

Selective transformations of secologanin: epoxidation

GAVIN N. SAUNDERS, JOHN R. PURDY, AND STEWART MCLEAN
Department of Chemistry, University of Toronto, Toronto, Ont., Canada M5S 1A1

Received August 24, 1982

GAVIN N. SAUNDERS, JOHN R. PURDY, and STEWART MCLEAN. Can. J. Chem. **61**, 276 (1983).

The oxidation of tetraacetylsecologanin dimethyl acetal (**7**) by *m*-chloroperbenzoic acid has been studied and the results have been compared with those obtained when tetraacetylsweroside was oxidized by the same reagent. Complete site selectivity for the vinyl side chain and a relatively low stereoselectivity leading to the formation of a small excess (7:2) of the epoxide with the 3-*R* configuration was observed with the sweroside derivative. These results parallel those in the osmium tetraoxide oxidation, and the configurations of the glycols produced have been correlated chemically with those of the epoxides. In contrast, there is little site selectivity in the oxidation of the secologanin derivative; in fact, it is the β-alkoxyacrylate site that appears to be oxidized faster to produce an epoxide (**9**) that then undergoes a second epoxidation at the vinyl side chain. Stereoselectivity is complete in the first epoxidation and is high in the epoxidation of the vinyl side chain, leading to the isomer with the 3-*R* configuration as the major product. The site selectivity appears to parallel that observed in dihydroxylation of the secologanin derivative, but the stereoselectivity of oxidations at the vinyl side chain is opposite in the two series; the configurations of the glycols and epoxides have been correlated chemically. A rational explanation can be advanced for the observed stereoselectivity in every case, but no convincing argument to explain the observed differences in site selectivity has been found.

GAVIN N. SAUNDERS, JOHN R. PURDY et STEWART MCLEAN. Can. J. Chem. **61**, 276 (1983).

On a étudié l'oxydation de l'acétal diméthylique de la tétraacétylsécologanine (**7**) par l'acide *m*-chloroperbenzoique et on a comparé les résultats avec ceux obtenus lorsqu'on oxyde la tétraacétylswéroside avec le même réactif. Dans le cas du dérivé de la swéroside, on a observé une sélectivité de site complète pour la chaîne latérale vinylique et une stéréosélectivité relativement faible conduisant à la formation d'un léger excès (7:2) d'époxyde avec une configuration 3-*R*. Ces résultats rejoignent ceux obtenus lors de l'oxydation par le tétraoxyde d'osmium et permet de faire une corrélation chimique de la configuration des glycols obtenus avec celle des époxydes. Dans le cas de l'oxydation du dérivé de la sécologanine, au contraire, il y a peu de sélectivité de site; en fait c'est le site β-alkoxyacrylate qui semble s'oxyder plus rapidement en produisant un époxyde (**9**) qui subit alors une deuxième oxydation au niveau de la chaîne latérale vinylique. La stéréosélectivité est complète lors de la première oxydation et elle est élevée lors de l'époxydation de la chaîne latérale vinylique, conduisant à l'isomère avec la configuration 3-*R* comme produit majoritaire. La sélectivité de site semble rejoindre celle observée lors de la déhydroxylation du dérivé de la sécologanine, mais la stéréosélectivité des oxydations au niveau de la chaîne latérale vinylique est opposée dans les deux séries; on a établi une corrélation chimique entre les configurations des glycols et celles des époxydes. On peut avancer une explication rationnelle pour la stéréosélectivité observée dans chaque cas, mais on n'a pas trouvé d'argument convaincant pour expliquer les différences observées dans la sélectivité de site.

[Traduit par le journal]

We have been studying selective chemical transformations of the biosynthetically important iridoid glycoside secologanin (**1**), and we have previously reported (1) on the dihydroxylation reaction resulting from oxidation with osmium tetraoxide. We report now on the epoxidation by *m*-chloroperbenzoic acid (MCPBA).

In the early stages of our investigation we had assumed that the closely related iridoid sweroside (**2***a*) would serve as a useful model compound in these studies, but we learned from the dihydroxylation study that the reactions of the two series differed in site selectivity and stereoselectivity, and we have now found that the secologanin and sweroside derivatives also behave quite differently on treatment with MCPBA. Inouye *et al.* (2) had previously reported that the MCPBA oxidation of tetraacetylsweroside (**2***b*) produced a single epoxide, **3**, in a yield of about 35%. In our hands this oxidation led to a 52% yield of a product that was shown to be a mixture of the epimeric epoxides **3** and **4** in a ratio of about 7:2 based on its ^{1}Hmr spectrum. The mixture was not separated, but each epimer was prepared separately from the corresponding glycol (**5***a*, **6***a*) obtained by dihydroxylation of **2***b* (1). Each glycol was monotosylated at the primary hydroxyl and the tosylates **5***b* and **6***b* were converted to the epoxides **3** and **4**, respectively, by the action of potassium carbonate in dimethylformamide. This procedure, in which configuration at C-3 is retained, correlates the configurations of the dihydroxylation and epoxidation products, major epimer with major epimer and minor with minor. No evidence for the oxidation of the β-alkoxyacrylate moiety was seen, even on prolonged treatment with MCPBA, of any of these sweroside derivatives, or of any others examined, such as the 3,4-dihydro derivative. The MCPBA and osmium tetraoxide oxidations of tetraacetylsweroside show the same site selectivity for the vinyl side chain; stereoselectivity is not high in either oxidation, but both show some preference for forming the product with the 3-*R* configuration, and this preference is higher in epoxidation (7:2) than in dihydroxylation (3:2).

When tetraacetylsecologanin dimethyl acetal (**7**) was treated with MCPBA under the same conditions, oxidation took place more rapidly, and three identifiable products were obtained. The most abundant product, mp 167.5–169.5°C, isolated in 44% yield after chromatography and careful recrystallization, had the formula $C_{27}H_{38}O_{17}$, corresponding to a dioxide of **7**. Its spectroscopic properties indicated that both carbon–carbon double bonds (3,4 and 8,9) had been oxidized, and the data were compatible with the assignment of a bisepoxide structure to this product. The epoxidation of the vinyl side chain was, of course, expected, but the epoxidation of the β-alkoxyacrylate

moiety had little precedent; the only example we have found of an epoxidized β-alkoxyacrylate appeared in a recent report (3), where it was obtained unexpectedly from the related unsaturated ketone which underwent both Baeyer–Villiger oxidation and epoxidation when treated with MCPBA. Because it would be difficult to adduce unequivocal chemical evidence for the bisepoxide structure, and because a rigorous definition of its stereochemistry was of particular importance to us, the product was subjected to X-ray crystal structure analysis (4). This analysis established that the product was, indeed, the proposed bisepoxide, and that its configuration, both relative and absolute (by internal reference to the glucose moiety), is represented by **8**.

The second product of MCPBA oxidation of **7**, isolated in 19% yield as crystals, mp 137–139.5°C, proved to be the monoepoxide **9**. The ^{1}Hmr spectrum showed that the vinyl side chain was still intact, but that the characteristic signal of the proton at C-9 (near τ 2.6) had been replaced by a singlet at τ 5.20, and the uv spectrum confirmed that the β-alkoxyacrylate chromophore was no longer present. Further MCPBA oxidation of **9** produced bisepoxide **8**, establishing the structure and stereochemistry of the monoepoxide. The third product of oxidation of **7** was not isolated from this source, but was shown from the ^{1}Hmr spectrum to be a minor constituent (~9%) of the chromatographic fraction that afforded the bisepoxide **8**; in the same way it was found in the same abundance in the product of MCPBA oxidation of **9**. It was shown to be the bisepoxide **10**, the C-3 epimer of **8**, by synthesis.

Dihydroxylation of **7** produces the glycol **11***a* with a high degree of stereoselectivity (1). This glycol was converted to the monoepoxide **12**, mp 84–86°C, by the route through the monotosylate **11***b* described for the sweroside derivatives **3** and **4**; the modification of employing DBU in benzene as the base for the final step was found to be much superior. It is pertinent to note that, while it was presumed that monotosylation of the glycols took place selectively at the primary hydroxyl group, in keeping with well-established precedents, none of the tosylates (**5***b*, **6***b*, **11***b*) was stable enough to be characterized completely; however, **11***b* was readily converted by the action of acid to a product from which the crystalline cyclic acetal **13** was isolated, and characterization of **13** confirmed the expected site selectivity of the tosylation reaction. Oxidation of the monoepoxide **12** with MCPBA converted it in 76% yield to the bisepoxide **10**, mp 154–156°C. The ^{1}Hmr and ^{13}Cmr spectra and the tlc characteristics of **10** prepared in this manner were identical with those of the minor component of the mixture of bisepoxides obtained by MCPBA oxidation of **7** or **9**. Furthermore, when a sample of a 6:1 mixture of the glycols **11***a* and its C-3 epimer (1) was subjected to the same sequence of reactions, the intermediate monoepoxides **12** and its C-3 epimer were obtained in a 6:1 ratio (based on the ^{1}Hmr spectrum), and MCPBA oxidation of this mixture led to a 6:1 mixture of the same epoxides obtained by direct MCPBA oxidation of **7** or **9**, but with the major epimer from one sequence being the

minor epimer from the other. These results establish that the bisepoxides **8** and **10** differ only in the configuration at C-3; they also confirm our previous assignment (1) of the stereochemistry of glycol **11** (as well as the sweroside and secogalioside derivatives with which it has been correlated (1)), and place the relative and absolute configuration of **11** on the secure foundation of the X-ray analysis of **8** and the demonstrated relationship of **8** with **11**. This result is of importance to us since we have used **11** as a key intermediate in the synthesis of the dihydrocadambine alkaloids (5).

The results of our studies of the oxidation of sweroside and secologanin derivatives can now be summarized and, to a considerable extent, rationalized. Both dihydroxylation (1) and epoxidation show complete site selectivity for the vinyl side chain in the sweroside series. Stereoselectivity is not high in either oxidation, but the formation of a product with the 3-*R* configuration is favored in both. In contrast, in the secologanin series the oxidations showed little site selectivity; this could only be deduced (1) from the study of osmium tetraoxide oxidation of **7**, since products of oxidation at the β-alkoxyacrylate site could not be characterized, but the present study explicitly shows that both olefinic sites undergo epoxidation. In fact, it appears that the β-alkoxyacrylate site reacted faster than the vinyl side chain since substantial amounts of the monoepoxide **9** were isolated after a relatively short reaction period, but no monoepoxides resulting from oxidation of the side chain were observed in this reaction. The stereoselectivity of the dihydroxylation reaction was much higher in the secologanin series than in the sweroside series, and led preferentially to the glycol with the 3-*S* configuration, opposite to that of the major sweroside glycol. The stereoselectivity of epoxidation of the side chain is also high, but the major product has the 3-*R* configuration; however, as we have just pointed out, it is almost certainly the epoxidation of the monoepoxide **9**, not the precursor **7**, that shows this stereoselectivity. The stereoselectivity of epoxidation at the β-alkoxyacrylate centre, leading to **9** as the immediate product, appears to be complete since we have seen no evidence for the formation of any epoxidation product differing in the stereochemistry at this site.

We previously rationalized (1) that the difference between the sweroside and secologanin series in the stereoselectivity of the dihydroxylation reaction at the vinyl side chain could be attributed to a difference between the two series in conformational mobility. Sweroside adopts a conformation with the vinyl side chain axial, and this does not change in derivatives in which the bulk of this two-carbon unit has been increased; in contrast, secologanin is more conformationally mobile and, when the bulk of the side chain is increased, a conformation with this side chain equatorial becomes dominant. These conformations are most easily recognized from the value of the coupling constant, $J_{1,2}$, between the protons at C-1 and C-2. Models indicate that the dominant rotamer for an axial

vinyl substituent should be that with C-3 → C-4 pointing away from the ring, and the large $J_{2,3}$ values observed support this proposal. In this conformation of a sweroside derivative there is relatively little difference between the two faces of the olefin with respect to steric hindrance to the approach of the oxidizing agent, but what there is favors approach from the face that leads to a 3-*R* product; this is what is observed in dihydroxylation and epoxidation, and steric interactions appear to have a somewhat greater directing influence on epoxidation than on dihydroxylation. It has been shown that, in the reaction of osmium tetraoxide with an alkene, the formation of the osmate ester is preceded by a series of complexes formed reversibly between the alkene and the osmium reagent (6). Consequently, steric hindrance to approach of the reagent is not the only factor determining the stereoselectivity, and it is in dihydroxylation in the secologanin series that this point is clearly demonstrated. Here, as soon as the vinyl side chain forms the initial complex with the osmium reagent, the increased bulk forces the side chain to become equatorial, and in this conformation, with the bulky glucose moiety also equatorial, there is a clear steric preference for the productive development of the complex into the osmate ester on that face of the side chain that leads finally to the observed 3-*S* glycol. Since a corresponding reversible complexation is not believed to occur in epoxidation and direct steric factors control the stereoselectivity, it would have been of considerable interest to compare the outcome of the epoxidation and dihydroxylation at the same vinyl side chain in the secologanin series. However, our evidence shows that epoxidation at the vinyl side chain of **7**, the substrate in the dihydroxylation reaction, is not observed since the monoepoxide **9** is formed first, and it is the side chain of **9** that is subsequently epoxidized. The presence of an 8,9 epoxide very considerably alters the conformational preference of the iridoid ring, and forces the two-carbon side chain at C-2 to become axial; the X-ray study (4) shows this clearly in the case of the crystalline bisepoxide **8**, the $J_{1,2}$ value of 1.8 Hz shows that this is also the conformation of **8** in solution and, wherever they can be compared, the spectroscopic properties of **8** and **9** show that they both have the same conformation. The axial vinyl group of **9** has a steric environment similar to that of the side chain of sweroside except that the steric hindrance to approach to the more hindered face is markedly increased by the presence of the 8,9 epoxide and by the effect of the side chain at C-7 which is not tied back in a lactone, as in sweroside. The MCPBA oxidation consequently leads preferentially to the formation of the epoxide with the 3-*R* configuration, as it does in the sweroside case, but with a significantly higher degree of stereoselectivity.

It is difficult to find a convincing explanation for the difference between the two series of compounds in the site selectivity of the oxidations. It seems clear that it results from the difference in reactivity of the two β-alkoxyacrylate moieties and that it has its origin in the unusually high reactivity of the secologanin derivative. In simplest terms, the olefinic double bond is activated towards electrophilic attack by the presence of oxygen at C-9 and deactivated by the carbonyl at C-8. The latter effect is greatest when the carbonyl and olefin components are coplanar, and this condition is more closely met in sweroside by the constraints of the fused lactone ring than in secologanin where steric effects tend to cause the carbomethoxyl group to rotate. This argument places the two series in the correct order of reactivity, but we feel that it is not sufficient to explain the magnitude of the difference. We have looked for other arguments that would predict an augmented

difference in reactivity, but have found none without flaws. We feel intuitively that the complete stereoselectivity observed in the epoxidation of the β-alkoxyacrylate site in the secologanin derivative **7** should be related to the unusual reactivity of the site, but we can not point to a feature that should both facilitate the reaction and direct the approach of the reagent. The steric constraints associated with epoxidation by peracids are generally conceded to be severe, and it might be supposed that these might be felt most strongly in the approach of MCPBA to the relatively rigid sweroside derivative with axial substituents at C-1 and C-2, while the more mobile secologanin derivative could react through the alternative conformation with these substituents equatorial. However, the available evidence shows that the preferred conformation of the secologanin derivative **7** has these substituents axial (1) and that they remain axial in the product epoxide **9**, so it appears probable that this conformation is at least approximated in the transition state. The experimental evidence shows that MCPBA has avoided approach from the side of the iridoid ring carrying the bulky glucoside moiety and, provided that epoxidation from this side of the molecule had the same conformational requirements as those above, the unfavorable steric interaction between the MCPBA and the glucoside unit as the transition state is approached could provide an explanation for the failure of the molecule to undergo epoxidation from this side and so account for the observed stereoselectivity. However, this proposal can not be extended to explain the increased rate of epoxidation at the other side of the molecule (relative to sweroside), and so fails to account for the site selectivity.

Experimental

Melting points were determined on a calibrated Thomas–Kofler micro hot stage. Infrared spectra were measured on a Unicam SP. 1000 spectrometer; the wavelengths (μ) of selected absorption peaks of solutions in chloroform are reported. Ultraviolet spectra were measured on a Unicam SP.800A spectrometer; the λ_{max} values (nm) of peaks followed by the log ε values in parentheses for solutions in methanol are reported; where end absorption was observed, log ε at 215 nm is reported. Proton nmr spectra were recorded on a Bruker WH-400 or a Varian XL-100 spectrometer; solutions in $CDCl_3$ were used, and data showing chemical shifts (τ scale) and apparent multiplicities and coupling constants are collected in Table 1.

Sweroside derivatives

Epoxide 3

The glycol **5***a* (600 mg; 1.07 mmol) (1) and *p*-toluenesulfonyl chloride (227 mg; 1.19 mmol) were dissolved in 30 mL of dry pyridine and stirred with 2 g of freshly activated 4A molecular sieves for 36 h at room temperature. The mixture was poured into water, and extracted with chloroform; the extract was washed with water, dried, and evaporated to dryness. Chromatography of the residue (silica gel with 10:1 ether–methanol) afforded the amorphous tosylate **5***b* (263 mg; 0.37 mmol); unchanged **5***a* (120 mg) was also recovered. The tosylate was dissolved in 5 mL of anhydrous dimethylformamide and stirred with anhydrous potassium carbonate (100 mg) for 58 h at room temperature. The mixture was poured into water and extracted with chloroform; the extract afforded an oil that was chromatographed (silica gel with 12:1 ether–methanol) and epoxide **3** (118 mg; 0.22 mmol) was obtained, after recrystallization from ethanol, as crystals, mp 199–203°C; ir: 5.70, 5.85, 6.15; uv: 241 (3.95). *Anal.* calcd. for $C_{24}H_{30}O_{14}$: C 53.14, H 5.57; found: C 53.28, H 5.42.

Epoxide 4

In the manner just described, the glycol **6***a* (295 mg; 0.53 mmol) (1) was converted through its tosylate **6***b* (135 mg; 0.19 mmol) to epoxide **4** (56 mg; 0.10 mmol), which was obtained from ethanol as crystals, mp. 154–156°C; ir: 5.70, 5.85, 6.15. *Anal.* calcd. for $C_{24}H_{30}O_{14}$: C 53.14, H 5.57; found: C 53.31, H 5.68.

*MCPBA epoxidation of tetraacetylsweroside 2*b

A solution of tetraacetylsweroside (75 mg; 0.14 mmol) and purified MCPBA (20 mg; 0.12 mmol) in 2 mL of dry benzene was stirred at 50°C under argon for 48 h. Further MCPBA (20 mg) was added and the conditions were maintained for a further 24 h. The solution was cooled, diluted with 50 mL of chloroform, washed with 5% aqueous sodium hydroxide, then brine, and dried. Evaporation afforded a crystalline material (58 mg), which was subjected to flash chromatography (silica gel with 3:2 ether–dichloromethane). Unchanged starting material (12 mg; 0.02 mmol) was recovered from early fractions; subsequent fractions afforded a crystalline material (31 mg; 0.06 mmol), mp 174–177°C, that appeared to correspond to the material described by Inouye *et al.* (2). The ^{1}Hmr spectrum of this material showed that it consisted of a 7:2 mixture of epoxides **3** and **4** (see above).

Secologanin derivatives

MCPBA epoxidation of 7

A solution of **7** (500 mg; 0.83 mmol) and purified MCPBA (428 mg; 2.48 mmol) in 5 mL of dry benzene was stirred at 50°C under argon for 6 h. The mixture was poured into aqueous sodium bicarbonate and extracted with dichloromethane. The extract afforded an oil (586 mg) which was subjected to flash chromatography (silica gel with ether). The first major fraction (252 mg; 0.40 mmol) consisted of a crystalline mixture of the bisepoxides **8** and **10** in a 10:1 ratio (based on ^{1}Hmr spectrum). Repeated recrystallization of this material from ether–dichloromethane provided a pure sample of bisepoxide **8**, mp 167.5–169.5°C (used for X-ray analysis (4)); ir: 5.70, 5.73 (sh); uv end absorption (2.20). *Anal.* calcd. for $C_{27}H_{38}O_{17}$: C 51.10, H 6.04; found: C 51.08, H 6.09. The second major chromatographic fraction (95 mg; 0.16 mmol) consisted of the epoxide **9**, which, on recrystallization from ethanol, was obtained as crystals, mp 137–139.5°C; ir: 5.70, 5.75; uv end absorption (2.44). *Anal.* calcd. for $C_{27}H_{38}O_{16}$: C 52.42, H 6.19; found: C 52.37, H 5.90.

Further treatment of **9** with MCPBA under the conditions described converted it to the 10:1 mixture of **8** and **10**.

Epoxide 12

In the manner described above for **3**, glycol **11***a* (4.93 g; 7.75 mmol) was converted to its amorphous monotosylate **11***b* (4.46 g; 5.65 mmol), which was dissolved in 25 mL of benzene containing 1,5-diazobicyclo[5.4.0]undec-5-ene (2.57 g; 16.9 mmol) and stirred at room temperature for 2.5 h. The mixture was poured into water and extracted with dichloromethane; the extract was washed with *N* hydrochloric acid and then worked up. Epoxide **12** (3.42 g; 5.53 mmol) was obtained and recrystallized from ether, to provide material mp 84–86°C; ir: 5.70, 5.85, 6.15; uv: 230 (3.91). *Anal.* calcd. for $C_{27}H_{38}O_{16}$: C 52.42, H 6.19; found: C 52.38, H 6.23. A sample recrystallized from toluene–hexane formed crystals, mp 42.5–44.5°C. *Anal.* calcd. for $C_{27}H_{38}O_{16}\cdot 0.5(C_7H_8)$: C 55.11, H 6.37; found: C 55.49, H 6.16. (The ^{1}Hmr spectrum confirmed the presence of one-half of an equivalent of toluene).

When a 6:1 mixture of the glycol **11** and its C-3 epimer was carried through this sequence the ^{1}Hmr spectrum showed that the product was a 6:1 mixture of **12** and its C-3 epimer.

Bisepoxide 10

A solution of the monoepoxide **22** (343 mg; 0.55 mmol) and purified MCPBA (190 mg; 1.10 mmol) in 10 mL of benzene was stirred at 50°C; after 2 h and 10 h further MCPBA (2 × 190 mg) was added and heating was continued for a total of 14 h. The mixture was worked up as before and bisepoxide **10** (267 mg; 0.42 mmol) was obtained, on recrystallization from ethanol, as crystals, mp 154–156°C; ir: 5.70, 5.73 (sh); uv end absorption (2.19). *Anal.* calcd. for $C_{27}H_{38}O_{17}$: C 51.10, H 6.04; found: C 51.31, H 6.05.

When the 6:1 mixture of **12** and its C-3 epimer described above was carried through this epoxidation, the ^{1}Hmr spectrum of the product showed it to be a 6:1 mixture of the bisepoxides **10** and **8**.

Cyclic acetal tosylate ***13***

Glycol **11***a* (1.58 g; 2.48 mmol) was tosylated in the manner described for **3** except that the reaction mixture was poured into *N* hydrochloric acid (instead of into water) before extraction with chloroform. The extract provided a product which was chromatographed and recrystallized from ethanol to afford **13** (670 mg; 0.88 mmol), mp 123.5–125.5°C; ir: 5.70, 5.85, 6.13. *Anal.* calcd. for $C_{33}H_{42}O_{18}S$: C 52.24, H 5.58, S 4.23; found: C 52.16, H 5.56, S 4.11.

The structure and absolute configuration of a bisepoxide (**2**) produced by oxidation of tetraacetylsecologanin dimethyl acetal (**1**) with *m*-chloroperbenzoic acid have been established by X-ray crystal structure analysis. Epoxidation of the vinyl side chain is unexceptional; epoxidation of the β-alkoxyacrylate moiety is novel. This determination represents a valuable bench mark for configurational assignments, since the bisepoxide has been correlated by chemical transformations with a number of synthetic and naturally-occurring derivatives of secologanin.

STANLEY C. NYBURG, PIK Y. SIEW, GAVIN N. SAUNDERS, JOHN R. PURDY et STEWART MCLEAN. Can. J. Chem. **61**, 282 (1983).

Faisant appel à la diffraction des rayons-X, on a établi la structure et la configuration absolue du bisépoxyde (**2**) produit lors de l'oxydation du diméthylacétal de tétraacétylsécologanine (**1**) par l'acide *m*-chloroperbenzoique. L'époxydation de la chaîne latérale vinylique est normale; toutefois l'époxydation de la portion β-alkoxyacrylate est nouvelle. Cette détermination est une étape importante dans les attributions de configuration, puisque des transformations chimiques ont permis d'établir une corrélation entre le bisépoxyde et un certain nombre de dérivés synthétiques et d'origine naturelle de la sécologanine.

As part of our study of selective oxidations of derivatives of the biosynthetically important iridoid secologanin (1, 2), we investigated the reaction of *m*-chloroperbenzoic acid wth tetraacetylsecologanin dimethyl acetal (**1**). Oxidation took place readily, and a substance, mp 167.5−169.5°C, was the principal product isolated (2). The molecular formula, $C_{27}H_{38}O_{17}$, showed it to be the dioxide of the precursor **1**, and spectroscopic evidence indicated that both olefinic double bonds had undergone reaction. The data were compatible with the assignment of a bisepoxide structure to this product; however, while the epoxidation of the vinyl side chain was expected, the epoxidation of the β-alkoxyacrylate unit was not. Normally, such a unit is expected to resist electrophilic attack by oxidizing agents, and our own study of the closely related iridoid sweroside shows that it fails to undergo oxidation at its β-alkoxyacrylate site under the same conditions; in fact, the only example we have found of an epoxidized β-alkoxyacrylate was reported recently (3), and this was obtained unexpectedly when the corresponding ketone underwent both Baeyer−Villiger oxidation and epoxidation when treated with *m*-chloroperbenzoic acid.

Besides the structural question arising from the novel oxidation of the β-alkoxyacrylate centre, there is a stereochemical question of considerable interest to us concerning the epoxidation of the vinyl side chain. There are obvious difficulties in investigating these questions by ordinary chemical and spectroscopic methods, but both the structure and stereochemistry of the product can be established simultaneously and unambiguously by the X-ray method. Furthermore, this method would establish the stereochemistry of the whole molecule, not merely the configuration induced in the oxidized side chain, and define its absolute configuration by internal reference to the glucosidic moiety. Consequently, an X-ray crystal structure analysis of the oxidation product was undertaken.

Experimental

The oxidation of the secologanin derivative **1** has been described (2); the dioxide, mp 167.5−169.5°C, was obtained as colorless rectangular plates from hexane−dichloromethane. A 0.25 × 0.17 × 0.15-mm specimen was used for structure analysis. Unit cell dimensions were obtained from eleven reflections centred on the diffractometer. *Crystal data*:

$C_{27}H_{28}O_{17}$ M = 634.60

Monoclinic, $P2_1$, a = 11.29(3), b = 12.86(2), c = 11.2(3) Å, β = 97.50(5)°, U = 1600(6) Å^3, D_c (Z = 2) = 1.33 g cc^{-1}; μ(MoKα) = 1.20 cm^{-1}.

Intensity data were collected on the automated Picker four-circle diffractometer using Zr-filtered MoKα radiation. Reflections were measured in θ−2θ scan mode at 2° min^{-1} out to 2θ = 50°. The sample was stable to X-irradiation. Of 2960 unique reflections recorded, 1878 had $F_o > 2\sigma(F)$ and were used for structure refinement; $\sigma(F)$ was taken as $\{[\sigma(I)\cdot Lp]^2 + 0.02F_o^4\}^{\frac{1}{2}}/2F_o$, where $\sigma(I)$ = (scan + Σbackground)$^{\frac{1}{2}}$ and Lp is the Lorentz-polarization factor. No absorption corrections were applied.

The structure was solved by direct methods using 470 $|E|$ values >1.3 as input to the SHELX package (4). The first pass revealed the glucose fragment and the remaining atoms were found from the ΔF map. Most of the hydrogen atoms were found in the final ΔF map. These were included in the refinement in calculated positions (C-H, 1.08 Å) with a refined overall temperature factor. Full matrix least-squares refinement gave weighted and unweighted residuals of 0.074 and 0.087 respectively. Fractional atomic coordinates are listed in Tables 1(a) and (b). Bond lengths and angles have been deposited;[1] none deserve special comment. Figure 1 shows the molecule and the atomic numbering system used here.[2] The absolute configuration shown is that which assigns the β-D-glucose unit its correct configuration. The chirality at C(3), introduced by epoxidation of the side chain, was established by unambiguously identifying the attached atoms; not only were the hydrogen atoms associated with C(4) found

[1]These tables, along with tables of observed and calculated structure factors and of temperature factors are available, at a nominal charge, from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

[2]This numbering system is arbitrary and does not correspond to that normally used for secologanin derivatives.

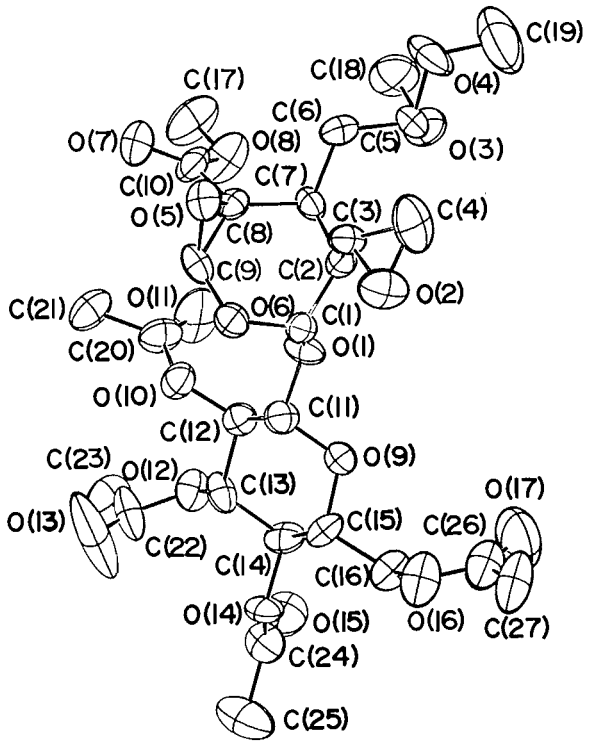

Fig. 1. ORTEP plot of molecule **2** showing atomic numbering.

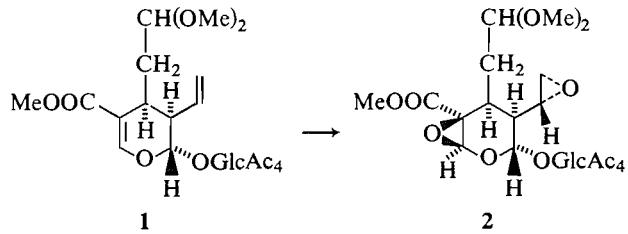
on the ΔF map, but also it was demonstrated that, if two hypothetical hydrogen atoms were assigned to O(2) as if it were part of a methylene group, one of these hypothetical atoms clashed badly with a hydrogen atom attached to C(23) of another molecule.

Results and discussion

It can be seen from Scheme 1 that the oxidation product is the bisepoxide **2**, incorporating the novel epoxidized β-alkoxyacrylate component. The relative configuration follows unequivocally from the X-ray analysis and the absolute configuration can be assigned with confidence since there is no doubt that the integrity of the β-D-glucose moiety is maintained in the synthesis of **2**.

We have now a valuable bench mark for configurational



SCHEME I

assignments to related compounds. We have correlated **2** by chemical methods with the glycols derived from **1** (2), one of which was a key intermediate in the synthesis of the dihydrocadambine alkaloids (5). We had previously assigned the configuration of this glycol by chemical correlation with a glycol derived from sweroside (1), which had in turn been correlated with the iridoid secologanin, the configuration of which depended ultimately on a nuclear Overhauser enhancement experiment (6). Reciprocally now, the configuration of all of these synthetic intermediates and natural products (and of any others that can be correlated with them) are placed on the secure basis of an X-ray crystal structure analysis by their demonstrated relationship with **2**.

Received August 24, 1982

RAYMOND G. HAMILTON, GAVIN N. SAUNDERS, and STEWART MCLEAN. Can. J. Chem. **61**, 284 (1983).

Secologanin, protected as the dimethyl acetal of its tetraacetate, had previously been dihydroxylated at the vinyl side chain with high stereoselectivity to provide the glycol (**4**) of the correct configuration for the synthesis of 3α- and 3β-dihydrocadambine. The glycol was converted to the cyclic acetal **5** to protect the secondary alcohol, the primary alcohol was oxidized to provide the aldehyde **6**, and this was reductively coupled with tryptamine. Treatment of the coupled intermediate (**8**) with 90% formic acid followed by deacetylation of the glycoside led to the formation of a mixture of 3α- and 3β-dihydrocadambine (40% and 33%, respectively). The synthesis confirms the structure assigned to these alkaloids, and establishes the configuration, relative and absolute, at all centres except C-3 (where it provides no new stereochemical information).

RAYMOND G. HAMILTON, GAVIN N. SAUNDERS et STEWART MCLEAN. Can. J. Chem. **61**, 284 (1983).

On a antérieurement dihydroxylé avec une haute stéréosélectivité la chaîne latérale vinylique de la sécologanine, protégée sous forme d'acétate diméthylique de son tétraacétate, pour obtenir le glycol (**4**) ayant la bonne configuration en vue de la synthèse des 3α- et 3β-dihydrocadambines. On a transformé le glycol en l'acétal cyclique (**5**) pour protéger l'alcool secondaire, et on a oxydé l'alcool primaire pour obtenir l'aldéhyde (**6**) et on a couplé ce dernier de façon réductrice avec la tryptamine. Le traitement de l'intermédiaire couplé (**8**) par l'acide formique à 90% suivi de la désacétylation du glycoside conduit à la formation d'un mélange de 3α- et de 3β-déhydrocadambine (40% et 33% respectivement). La synthèse confirme la structure attribuée à ces alcaloides et établit la configuration relative et absolue de tous les centres à l'exception de C-3 (où elle ne fournit aucune nouvelle information stéréochimique).

[Traduit par le journal]

We assigned the structure and relative configuration **1***a* to an alkaloid of *Nauclea diderrichii* (1); the same alkaloid was isolated from *Anthocephalus cadamba* by Brown and Fraser (2), who named it 3α-dihydrocadambine and independently assigned structure **1***a* to the alkaloid, citing circular dichroism studies of the alkaloid and its congener, cadambine (**2**), and biogenetic considerations as evidence that the relative and absolute configuration is that shown in **1***a*. Subsequently, Brown and Chapple (3) isolated the isomeric alkaloid 3β-dihydrocadambine (**1***b*), from the same extract, and demonstrated its relationship to **1***a* and **2**.

A reasonable hypothesis for the biogenesis of the dihydrocadambines involves the stereospecific oxidation of the vinyl side chain of strictosidine or vincoside to an epoxide or its equivalent, followed by internal opening of the epoxide by the nitrogen of the secondary amine, closing the seven-membered ring, and producing the secondary alcohol. Strictosidine and vincoside are, themselves, products of the biosynthetic equivalent of a Pictet–Spengler condensation of a tryptamine unit and secologanin (**3**). We have undertaken to synthesize the alkaloids from these precursors, tryptamine and secologanin, but we felt that a completely biomimetic strategy would face severe difficulties in vitro at the step requiring internal opening of the epoxide, both because the regioselectivity of this reaction is uncertain and because it can be expected that the nitrogen would more readily attack the carbomethoxy group and form a stable lactam. We chose, therefore, a strategy which essentially reverses the order of bond-forming reactions. A preliminary report of the synthesis of **1***a* has been communicated (4); more recently, improvements in our experimental procedure have significantly improved the yield of **1***a* and have also led to the isolation of its 3β epimer, **1***b*, in comparable yield.

The glycol **4**, which we prepared stereoselectively from secologanin (5), was quantitatively converted by the action of Amberlite IR 120 resin in methanol at room temperature to a crystalline substance,[1] mp 145–146°C, which was shown to be, at least in solution, a 5:2 mixture of the epimeric acetals **5**. (The configuration at C-5 is not of synthetic significance since its chirality is lost in a subsequent step.) Both **4** and **5** formed the same bridged bicyclic acetal **6** if treated with dilute acid. With the cyclic acetal function of **5** serving to protect both the aldehyde and secondary hydroxyl groups, the primary alcohol was selectively oxidized with pyridinium chlorochromate on Celite in dichloromethane with sodium acetate present (6) to provide the aldehyde **7**. The progress of the reaction was followed by ^{1}Hmr spectroscopy but **7** was not completely characterized because of its instability. As soon as it was isolated, **7** was reductively coupled with tryptamine hydrochloride in the presence of sodium cyanoborohydride without further characterization. The product **8** was isolated as a 5:2 mixture of epimers, from which the major isomer was separated chromatographically for characterization purposes.

The operations now required to complete the synthesis of the alkaloidal framework are the deprotection of the aldehyde function at C-5 and its coupling with the tryptamine moiety in an intramolecular Pictet–Spengler reaction. Both operations require acidic conditions, but it is clear that these conditions must provide a high degree of selectivity since the C-5 acetal is to be hydrolyzed in the presence of a dense array of sensitive functional groups, including several cryptoaldehydes; furthermore, there is ample evidence to indicate that hydrolysis of the acetal will be more difficult in the presence of the neighboring basic nitrogen. There was also some question concerning the effec-

[1]In preparative runs, since it was difficult to separate **4** from the small amount of its C-3 epimer produced in the dihydroxylation step (5), the mixture of epimers was carried through to this stage, where purification was more conveniently carried out.

tiveness of the Pictet–Spengler step since, although there is some precedent for such a reaction (7), comment has been made (8) about the possible difficulty of forming a seven-membered ring in a Pictet–Spengler reaction. The final question concerned the stereochemical outcome of the Pictet–Spengler condensation; we had maintained stereochemical control at all of the chiral centres up to this point, but we could see no good reason for anticipating stereoselectivity in this condensation and the generation of the 3α and 3β configurations in the alkaloids seemed equally probable.

Most of these concerns or reservations proved, in fact, to be well founded. We investigated the effect of many acidic systems on **8**, and found that either the starting material was recovered or an uncharacterizable mixture, apparently of degradation products, was obtained. We were delighted, therefore, to find that, when **7** was treated with 90% formic acid, derivatives of the target alkaloid were recognized in the product mixture. Optimization of the reaction conditions (95°C for 18 hours) and isolation procedure (deacetylation with potassium carbonate in methanol and chromatography) eventually gave very satisfactory yields of both 3α- and 3β-dihydrocadambine (40% of **1***a* and 33% of **1***b*). Clearly the Pictet–Spengler reaction has formed the seven-membered ring in good yield, but with little stereoselectivity. For characterization purposes, the alkaloids were converted to their pentaacetates **1***c* and **1***d*, which were identical in every respect, including optical activity, with materials prepared from the natural alkaloids.

This synthesis serves to confirm the structure assigned to 3α- and 3β-dihydrocadambine (1–3) and, more importantly, it provides unequivocal proof for the configurational assignments, both relative and absolute, at all centres except C-3, where it adds nothing to the evidence available from the natural alkaloids themselves. We note that the original assignments of relative configurations were based on ^{1}Hmr coupling constants (a procedure not without hazards, particularly when applied to a flexible molecule incorporating a seven-membered ring), while absolute configurations were assigned on the basis of circular dichroism and biogenetic assumptions.

Since our stereochemical conclusions are of significance, it is appropriate that we should provide more detail concerning the stereochemistry of our synthetic intermediates. It is clear that the alkaloids have the same relative and absolute configuration as secologanin at all of the chiral centres that they have in common, since none of the synthetic steps introduced the risk of isomerizing any of these centres. The configuration at C-19 in the synthetic alkaloids had its origin in the stereoselective dihydroxylation that led to **4**. We assigned (5) the configuration at C-3 of **4** by chemical correlation with the corresponding sweroside glycol, which in turn had been correlated with secogalioside, the configurational assignment of which ultimately rested on a nuclear Overhauser enhancement experiment (9). More recently we have provided conclusive proof for the stereochemistry of **4** by correlation (10) with a derivative, the structure and stereochemistry of which has been established by an X-ray crystal structure analysis (11); this procedure unequivocally establishes the relative configuration

at all chiral centres, including C-3, and provides the absolute configuration by internal reference to the glucose moiety.

Even though the configuration at all centres in **4** is secure, the possibility remains that the configuration at C-3 could undergo change during the formation or subsequent reaction of **7**, while C-4 is at the oxidation level of an aldehyde, but careful examination of the intermediates provides evidence against this. We have noted previously (5) that the dihydropyran ring of secologanin and a number of its derivatives is conformationally mobile and that the coupling constant, $J_{1,2}$, between the protons at C-1 and C-2 provides valuable information regarding the conformation of the ring. The cyclic acetals **5** have intermediate values of $J_{1,2}$ (see Table 1), indicating that they have sufficient conformational mobility to make $J_{2,3}$ values of little value for assigning the relative configuration at C-3; the appearance of the signal associated with the C-5 proton, an apparent triplet (5 Hz spacings) in the major isomer, indicates that the methoxyl group is axial at this centre, while the minor epimer has an equatorial methoxyl group. Only one bridged bicyclic acetal, **6**, was obtained; here the $J_{1,2}$ value of 9.2 Hz shows that the bridged system has reduced conformational mobility and that the molecule adopts the conformation with the corresponding protons diaxial. (In cadambine, **2**, with a similar bridged bicyclic structure, the corresponding coupling constant is 9.5 Hz, indicating a very similar rigid conformation (2), while the dihydrocadambines are more flexible.) The configuration at C-3 can not be deduced with confidence from the $J_{2,3}$ value associated with **6**, but the configuration at this centre in both **5** and **6** is secure since it can not have undergone epimerization under the reaction conditions used up to this stage. (Tietze and Henke (12) have assigned the structure and configuration **6** to a compound produced in a similar manner.) The decisive configurational question now concerns **8**, the first characterized derivative following oxidation at C-4. In this case the mixture of C-5 epimers was separated, and the ^{1}Hmr spectrum of the major isomer was examined carefully. The conformational preference of this compound is distinctly different from that of its precursors since the $J_{1,2}$ value of 2.5 Hz indicates that the corresponding protons are diequatorial on the dihydropyran ring. Although the configuration at C-5 is not of significance with respect to the configuration of the target alkaloids, it is of interest to note that the C-5 methoxyl group is equatorial in this isomer (the C-5 proton shows coupling constants of 9.2 and 1.8 Hz) and axial in the minor isomer, and that these epimers were formed in the same ratio (5:2 as judged by ^{1}Hmr spectra) that existed in the precursor **5**. The dominance of the epimer with an axial methoxyl group in **5**, formed under equilibrating conditions, probably results from an anomeric effect, while the change to an equatorial methoxyl group in the major epimer of **8** indicates that no equilibration at C-5 took place in its formation, so that the configuration at C-5 is unchanged, but the conformation of the ring is inverted. It appears that the conformation of **8** is governed by the requirement that the extended substituent at C-3 be equatorial to the tetrahydropyran ring. This leads to the fortunate result that the C-3 hydrogen is axial to this ring, as is the C-2 hydrogen, and the $J_{2,3}$ value of 9 Hz (confirmed by decoupling experiments) clearly establishes their *trans*-diaxial

relationship. The relative configuration at C-3 is, therefore, established, and the formation of **8** from **5** with retention of configuration at C-3 is thus verified; there is no doubt that the configuration is also retained at this centre, which becomes C-19 in the alkaloids, under the reaction conditions used to convert **8** to **1***a* and *b*. Consequently, the synthesis provides unequivocal confirmation for the assignment (1−3) of all structural and stereochemical features depicted by **1***a* and *b* (apart from the configuration at the centre where they are epimeric) to 3α- and 3β-dihydrocadambine.

Experimental

Melting points were determined on a calibrated Thomas−Kofler micro hot stage. Infrared spectra were measured on a Perkin−Elmer 337 spectrometer; the wavelengths (μ) of selected absorptions of solutions in chloroform are reported. Ultraviolet spectra were measured on a Unicam SP. 800A spectrometer; the λ_{max} values (nm) followed by the log ε values in parentheses for solutions in methanol are reported. Proton nmr spectra were recorded on a Nicolet 360 (at 360 MHz) or a Bruker WH-400 (at 400 MHz) spectrometer; solutions in $CDCl_3$ were used, and data showing chemical shifts (τ scale) and apparent multiplicities and coupling constants are collected in Table 1.

The cyclic acetals ***5***

A solution of the epimeric glycols (90 mg; ~90% **4**) described previously (5) in 4 mL of methanol was stirred at room temperature with 300 mg of Amberlite IR 120 resin for 12 h. The resin was removed by filtration and the solvent was evaporated providing a quantitative yield of the acetals. Recrystallization from ether provided crystalline **5**, mp 145−146°C; ir: 5.68, 5.85, 6.12; uv: 233 (3.78). *Anal.* calcd. for $C_{26}H_{36}O_{16}$: C 51.65, H 5.99; found: C 51.73, H 5.94.

The bicyclic acetal ***6***

A solution of **5** (59 mg; 0.09 mmol) in 7 mL of tetrahydrofuran containing 60 mg of concentrated hydrochloric acid was stirred at room temperature for 16 h. The solvent was removed under vacuum, and the residue was purified by chromatography on silica gel with elution by ether. The product **6** (37 mg; 0.06 mmol) was obtained as a glass; ir: 5.68, 5.85, 6.10.

The tryptamine-coupled product ***8***

A mixture of pyridinium chlorochromate (1.4 g; 6.5 mmol), sodium acetate (135 mg; 1.65 mmol), and 5 g of Celite (6) was dried at 100°C under vacuum for 2 h. The dried powder was slurried with 30 mL of dry dichloromethane, a solution of **5** (1.00 g; 1.66 mmol) in 10 mL of dichloromethane was added, and the mixture was stirred at room temperature for 14 h. The solvent was removed on a rotary evaporator, and the powder that remained was loaded on a silica gel chromatography column and eluted with dichloromethane. The aldehyde **7** was obtained as an unstable orange oil (ca. 730 mg; 1.2 mmol) which was dissolved in a mixture of 20 mL of methanol and 5 mL of tetrahydrofuran. Tryptamine hydrochloride (570 mg; 2.9 mmol), sodium cyanoborohydride (75 mg; 1.2 mmol), and 10 g of 4 Å molecular sieves were added, and the mixture was stirred at room temperature for 14 h. Solid material was removed on a rotary evaporator, and the residue was well triturated with dichloromethane. The dichloromethane solution was filtered and the solvent was removed by evaporation. The residue was chromatographed on silica gel with elution by 5:1 chloroform−methanol and the oily product **8** (581 mg; 0.78 mmol) was obtained as a 5:2 mixture of epimers. An aliquot was subjected to further chromatography on silica gel with elution by 9:1 dichloromethane−methanol and the major epimer was isolated from early fractions as an amorphous but homogeneous substance; ir: 2.87, 5.70, 5.85, 6.13; uv: 225 (4.39). *Anal.* calcd. for $C_{36}H_{46}O_{15}N_2$: C 57.90, H 6.20; found: C 57.81, H 6.18.

*The 3α- and 3β-dihydrocadambines (***1***a, b)*

A solution of the epimeric compounds **8** (164 mg; 0.22 mmol) in 10 mL of 90% formic acid was heated to 95°C for 18 h. The solvent was removed by vacuum distillation, and the residue (165 mg) was stirred with potassium carbonate (20 mg) in 5 mL of methanol at room temperature for 1 h, and then filtered. The solvent was removed on a rotary evaporator, and the residue was chromatographed on silica gel with methanol−chloroform elution. 3α-Dihydrocadambine (48 mg; 0.088 mmol) was eluted first, followed by the 3β isomer (40 mg; 0.073 mmol); other fractions afforded material (13 mg) that was a mixture of at least five uncharacterized compounds. The 3α-dihydrocadambine (**1***a*) was recrystallized from ether−chloroform, and obtained as crystals, mp 182−187°C (dec.), which showed spectroscopic characteristics (ir, uv, ^{1}Hmr) and tlc behavior identical with those of the natural alkaloid (1). Acetylation of the synthetic alkaloid provided a pentaacetate (**1***c*), mp 193−195°C (lit. (2) mp 197−199°C), recrystallized from hexane−acetone; this material was identical in every respect, including optical activity (cd in methanol, 350−205 nm), with a sample of **1***c* prepared from natural 3α-dihydrocadambine. Synthetic 3β-dihydrocadambine (**1***b*) was not obtained crystalline; it was characterized as its amorphous pentaacetate (**1***d*), which was identical with a sample of **1***d* (amorphous) derived from natural **1***b* (amorphous) (2) in spectroscopic characteristics (ir, uv, ^{1}Hmr), tlc behavior, and optical activity (cd in methanol, 350−205 nm).

Acknowledgements

We are grateful to Dr. R. T. Brown, University of Manchester, for kindly providing the reference sample of authentic pentaacetyl-3β-dihydrocadambine. We thank Dr. K. J. Dorrington, University of Toronto, for cd measurements. The nmr spectra were obtained at the Southwestern Ontario N.M.R. Center, funded by a Major Installation grant from the Natural Sciences and Engineering Research Council of Canada, and at the Toronto Biomedical NMR Centre, supported by a grant from the Medical Research Council of Canada. This research received financial support from the Natural Sciences and Research Council of Canada.

Received July 5, 1982

EDWARD PIERS, CHEUK KUN LAU, and ISAO NAGAKURA. Can. J. Chem. **61**, 288 (1983).

Treatment of the 2-(iodomethylene)cycloalkanones **10** and **11** with lithium (phenylthio)(cyclopropyl)cuprate provided good yields of the corresponding β-cyclopropyl enones **12** and **13**, respectively. Thermolysis of the latter substances produced relatively poor yields of the desired spiro-annulation products **14** and **15**. However, conversion of **12** and **13** into the corresponding enol silyl ethers **24** and **25**, followed by thermal rearrangement of the latter materials and acid hydrolysis of the resulting products, provided synthetically useful yields of the spiro enones **14** and **15**. Cuprous iodide-catalyzed addition of methyl magnesium iodide to 2-cyclohexen-1-one, followed by trapping of the resultant enolate anion with cyclopropanecarboxaldehyde, provided the ketols **38**, which could be converted readily into the mixture of enol silyl ethers **34** and **35**. Thermal rearrangement of the latter substances gave, after acid hydrolysis of the crude thermolysate, the spiro enones **42** and **43** in a ratio of ~2.5:1 (57% yield). Treatment of **42** with methyllithium in ether gave the tertiary alcohols **44** and **45** (ratio ~4:1). Hydroboration (disiamylborane, tetrahydrofuran; H_2O_2, NaOH) of **44**, followed by oxidation of the resultant diol **46** with pyridinium chlorochromate, provided the ketol **47**. A similar sequence of reactions converted the olefinic alcohol **45** into the ketol **49**. Dehydration (*p*-toluenesulfonic acid in benzene) of **47** gave the spiro enones **28** and **48**, in a ratio of ~9:1. Compound **28**, also prepared previously from the ketol **49**, had been converted earlier into the spirovetivane-type sesquiterpenoids (±)-α-vetispirene (**29**), (±)-β-vetivone (**30**), (±)-hinesol (**31**), (±)-hinesol acetate (**32**), and (±)-agarospirol (**33**).

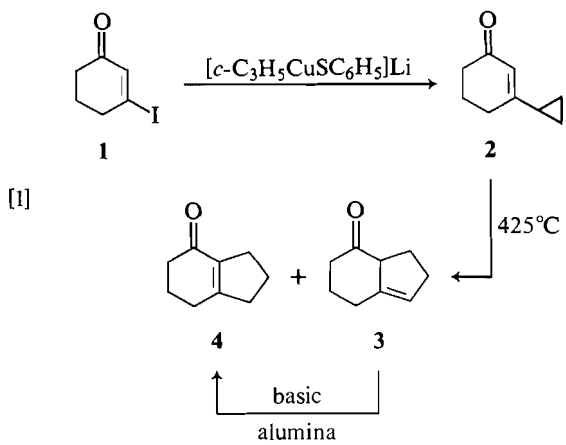
EDWARD PIERS, CHEUK KUN LAU et ISAO NAGAKURA. Can. J. Chem. **61**, 288 (1983).

Les (iodométhylène)-2 cycloalcanones **10** et **11** réagissent avec le (phénylthio)(cyclopropyle)cuprate de lithium en donnant respectivement les β cyclopropylénones **12** et **13** avec de bons rendements. La thermolyse de ces derniers composés permet d'acéder aux produits de spiro-annellation **14** et **15** attendus mais avec des rendements relativement faibles. Cependant la transformation des composés **12** et **13** en éthers énoliques silylés **24** et **25** correspondants suivie d'une transposition thermique de ces derniers et d'une hydrolyse acide des produits résultants conduit aux spiro énones **14** et **15** avec des rendements intéressants pour la synthèse. L'addition d'iodure de méthyle magnésium, catalysée par l'iodure cuivreux, sur la cyclohexène-2 one-1, suivie du piégeage de l'anion énolate résultant par le cyclopropanecarboxaldéhyde permet d'obtenir les cétols **38** que l'on peut transformer rapidement en un mélange d'éthers énoliques silylés, **34** et **35**. La transposition thermique de ces éthers, suivie de l'hydrolyse acide des produits bruts de thermolyse donne les spiro énones **42** et **43** dans un rapport d'environ 2.5:1 (rendement de 57%). Le composé **42** réagit avec le méthyllithium dans l'éther en donnant les alcools tertiaires **44** et **45** (rapport de 4:1). L'hydroboration (disiamylborane, tétrahydrofuranne; H_2O_2, NaOH) du composé **44** suivie de l'oxydation du diol **46** qui en résulte par le chlorochromate de pyridinium conduit au cétol **47**. Par une série analogue de réactions, l'alcool oléfinique **45** donne le cétol **49**. La déshydratation (acide *p*-toluènesulfonique dans le benzène) du composé **47** permet d'obtenir les spiro énones **28** et **48**, dans un rapport d'environ 9:1. Antérieurement on a transformé le composé **28** préparé à partir du cétol **49**, en sesquiterpènes du type spirovétivane, soit le (±)-α-vétispirène **29**, la (±)-β-vétivone **30**, le (±)-hinésol (**31**), l'acétate du (±)-hinésol (**32**) et le (±)-agarospirol (**33**).

[Traduit par le journal]

Introduction

A recent paper from this laboratory (1) described a new five-membered ring annulation method based on the preparation and thermal rearrangement of β-cyclopropyl α,β-unsaturated ketones.[1] For example, treatment of 3-iodo-2-cyclohexen-1-one (**1**) with lithium (phenylthio)(cyclopropyl)cuprate[2] provided efficiently the corresponding β-cyclopropyl enone **2** which, upon thermolysis at ~425°C, followed by elution of the crude thermolysate (containing mainly the isomeric enones **3** and **4**) through a column of the basic alumina, provided the annulation product **4** in 72% overall yield (eq. [1]). Similarly, thermolytic rearrangement of



[1]

3-(1-methylcyclopropyl)-2-cyclohexen-1-one (**5**) afforded, in 87% yield, the bicyclic enone **6** which served as a convenient

5 **6** **7**

starting material for a new formal total synthesis of the tricyclic sesquiterpenoid (±)-zizaene (**7**) (eq. [2]).

In an earler report (3) we had described, *inter alia*, efficient conversions of 2-(hydroxymethylene)cyclohexanone (**8**) and the analogous cyclopentanone derivative **9** into the corresponding (*E*)-2-(iodomethylene)cycloalkanones **10** and **11**, respectively. It is clear that successful use of the latter substances as starting materials in a sequence of reactions similar to that outlined in eq. [1] would constitute a new five-membered ring

[3] 
8 *n* = 2
9 *n* = 1

10 *n* = 2
11 *n* = 1

14 *n* = 2
15 *n* = 1

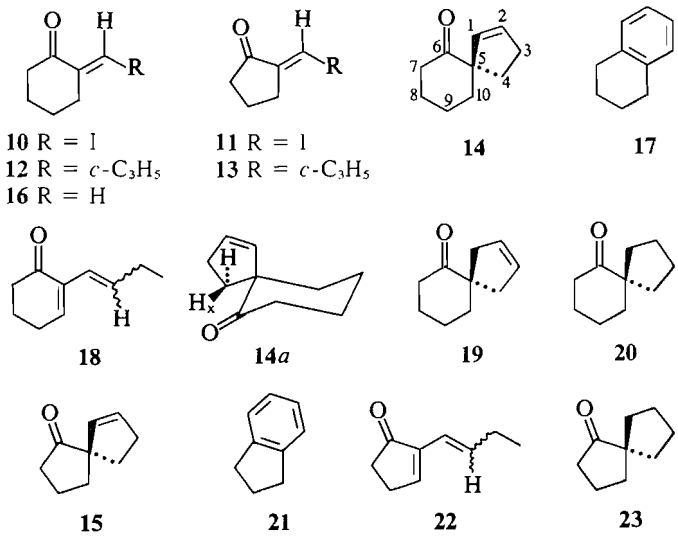
12 *n* = 2
13 *n* = 1

spiro-annulation method (see eq. [3]). Thus, treatment of compounds **10** and **11** with lithium (phenylthio)(cyclopropyl)-cuprate should provide the β-cyclopropyl enones **12** and **13** which, upon successful subjection to thermal vinylcyclopropane → cyclopentene rearrangement, would afford the spiro olefinic ketones **14** and **15**, respectively. Since spiro ring systems are quite commonly found in natural products, particularly in the sesquiterpenoid family, we wished to extend our earlier studies (1) in order to determine whether or not the spiro-annulation sequences outlined in eq. [3] are viable processes.[3] This paper describes the results of this investigation. In addition, we report the application of this new annulation method to a formal total synthesis of a number of spirovetivane sesquiterpenoids.[4]

Results and discussion

(a) *Preparation and thermal rearrangement of* (E)*-2-(cyclopropylmethylene)cyclohexanone (12) and* (E)*-2-(cyclopropylmethylene)cyclopentanone (13) (see Chart 1)*

As expected on the basis of our earlier work (1), the β-cyclopropyl enones **12** and **13** could be prepared smoothly and efficiently from the corresponding β-iodo enones **10** and **11**



10 R = I
12 R = *c*-C_3H_5
16 R = H

11 R = I
13 R = *c*-C_3H_5

CHART 1

(3). Thus, when the latter substances were allowed to react with lithium (phenylthio)(cyclopropyl)cuprate in ether–tetrahydrofuran (THF), the desired compounds **12** and **13** were obtained in yields of 82 and 65%, respectively. The stereochemistry of these products was shown to be as indicated on the basis of proton nuclear magnetic resonance (^{1}H nmr) spectroscopy. The chemical shifts of the two olefinic protons of 2-methylenecyclohexanone (**16**) have been shown to be δ 5.04 (proton *trans* to carbonyl) and δ 5.72 (proton *cis* to carbonyl) (11). Since the olefinic protons of the enones **12** and **13** resonate at δ 6.04 and 5.95, respectively, it seems appropriate to conclude that these protons are geometrically *cis* to the carbonyl group. Furthermore, in work to be described in a subsequent section of this paper (*vide infra*), we isolated the two geometric isomers of 2-(cyclopropylmethylene)-3-methylcyclohexanone. The alkene proton of the (*Z*) isomer resonated at δ 4.84, while the signal of the corresponding proton of the (*E*) isomer appeared at δ 5.98. These data unambiguously show that compounds **12** and **13** both possess the (*E*) geometry and since the stereochemistry of the starting materials (β-iodo enones **10** and **11**) had also been established (3), it is clear that, in an overall sense, the substitution reactions **10** → **12** and **11** → **13** had occurred with retention of configuration.

Thermolysis of the β-cyclopropyl enone **12** was carried out by passing a *n*-hexane solution of this material through a vertically-held, heated (~450°C) glass tube (1.2 × 32 cm) filled with glass helices. Gas–liquid chromatographic analysis of the distilled thermolysate, obtained in 74% yield, showed that it consisted of a mixture of three main components, the desired spiro ketone **14** (~44%), tetralin (**17**) (~38%), and the dienones **18** (~9%, mixture of geometric isomers), along with a number of very minor, unidentified compounds. A small sample of each of the major components was obtained by preparative glc. Tetralin was identified by comparison with commercially available material. Only a small amount of the mixture of dienones **18** was obtained and full characterization of the individual substances was not carried out. However, the fact that this material consisted of a mixture of geometric isomers was shown by the ^{1}H nmr spectrum which exhibited two signals (triplets) at high field due to the terminal methyl groups. Hydrogenation (H_2, Pd–C, methanol) of the two double bonds present in **18** afforded 2-*n*-butylcyclohexanone, which exhibited spectra identical with those of an authentic sample.

The ^{1}H nmr spectrum of the major thermolysis product, the desired spiro[4.5]dec-1-en-6-one (**14**), was deceptively simple. Although the high field region of the spectrum (7-proton and 5-proton multiplets at δ 1.40–2.03 and δ 2.18–2.60, respectively)[5] was relatively unexceptional, one might well have expected the olefinic protons of **14** to be magnetically nonequivalent. In fact, however, the alkene region of the ^{1}H nmr spectrum exhibited only a 2-proton singlet at δ 5.76.[6] On the other hand, when the spectrum was taken in the presence of an appropriate amount of the shift reagent Eu(FOD)$_3d_{27}$, the two olefinic protons did exhibit different chemical shifts (δ 6.06, 6.42) and each gave rise to a doublet of triplets with coupling constants of 6 Hz and ~2 Hz. Furthermore, the 5-proton multiplet (δ 2.18–2.60) had been transformed into two distinct signals, a 3-proton multiplet at δ 3.16–3.56 and a 2-proton multiplet at δ 2.50–2.86. In a decoupling experiment (in the presence of the shift reagent), irradiation at δ 2.70 (allylic methylene signal) caused the signals due to the olefinic protons to collapse to an AB pair of doublets (J = 6 Hz).

The proton decoupled ^{13}C nmr spectrum of the spiro ketone **14** exhibited the presence of two nonequivalent olefinic carbon atoms (δ 132.5 and 133.4). Other signals appeared at δ 211.5 (carbonyl carbon), 64.1 (quaternary carbon), 39.9 (2 carbon atoms), 32.3, 31.3, 27.7, and 23.0.

In order to obtain conclusive chemical evidence for the fact that the major thermolysis product did indeed possess the desired carbon skeleton, compound **14** was subjected to hydrogenation over palladium-on-carbon in methanol. The spectra (infrared, ^{1}H nmr) of the product, spiro[4.5]decan-6-one (**20**), were identical with those obtained from an authentic sample of this material, prepared by the method of Naro and Dixon (13).

Thermal rearrangement of (*E*)-2-(cyclopropylmethylene)-cyclopentanone (**13**) under conditions similar to those employed for the cyclohexanone analog **12** gave, in 90% yield, a colorless oil (distilled). Analysis of this material by glc revealed the presence of a number of components. Spectral data derived from small samples of the major products (collected by preparative glc) showed that they were the desired spiro[4.4]non-6-en-1-one (**15**) (~29% of the mixture), indan (**21**) (~11%), and a mixture of the geometrically isomeric dienones **22** (~44%). The olefinic region of the ^{1}H nmr spectrum of the spiro ketone **15**, in contrast to that of the homolog **14**, was found to be "normal", exhibiting two distinct multiplets at δ 5.30–5.53 and 5.73–5.97. Subjection of **15** and the mixture of dienones **22** to hydrogenation over palladium-on-carbon in methanol provided spiro[4.4]nonan-1-one (**23**) (14) and 2-*n*-butylcyclopentanone, respectively.

Although thermolysis of the β-cyclopropyl enones **12** and **13** did produce the spiro-annulation products **14** and **15**, respectively, the results summarized above show that the yields of these desired products are, from a synthetic point of view, less than satisfactory. However, even without going into a detailed mechanistic discussion, it is clear that the formation of the aromatic side products tetralin (**17**) and indan (**21**) involves, in each case, chemical reaction of the carbonyl group. Furthermore, it is not unreasonable to propose that the carbonyl groups in **12** and **13** also assist in the formation of the other major side products of these thermolysis reactions, the dienones **18** and **22**, respectively. That is to say, if the transition states involved in hydrogen migration from the C-3 carbons of **12** and **13** to produce the α,β-unsaturated ketone systems present in **18** and **22** have any degree of product-like character, they might well be expected to experience stabilization from the presence of the carbonyl groups. This mode of reasoning led us to attempt the conversion of **12** and **13** into the spiro-annulation products **14** and **15**, respectively, via thermolysis of derivatives of **12** and **13** in which the carbonyl groups were masked. The results of this study are described in the next section of this paper.

(b) *Preparation and thermal rearrangement of the enol silyl ethers 24 and 25 (see Chart 2)*

Treatment of the β-cyclopropyl enone **12** with lithium diisopropylamide in dimethoxyethane, followed by trapping of the resultant enolate anion with trimethylsilyl chloride, provided in 91% yield the enol silyl ether **24**. In identical fashion, (*E*)-2-(cyclopropylmethylene)cyclopentanone (**13**) was transformed into the enol silyl ether **25** (90% yield).

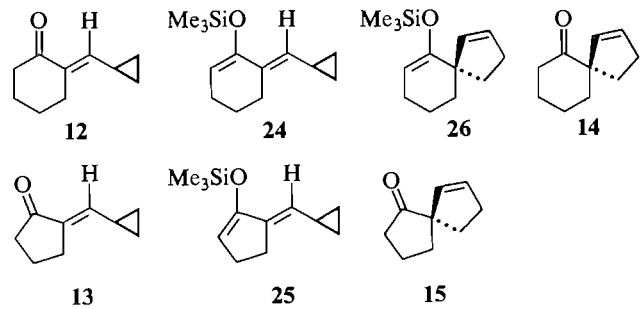

CHART 2

Rearrangement of compounds **24** and **25** was carried out via a procedure similar to that employed for the parent enones **12** and **13**, with the main differences being that the glass thermolysis tube was longer (100 cm instead of 32 cm) and the thermolysis temperature was slightly lower (~425°C instead of ~450°C).[7] In each case, the product mixture was much "cleaner" than that acquired from direct rearrangement of the corresponding β-cyclopropyl enone **12** or **13**. Thus, gas–liquid chromatographic analysis of the distilled product obtained in 85% yield from thermolysis of **24** showed that it consisted very largely (~84%) of one component, along with a number of minor unidentified materials. A small sample of the major product, collected by preparative glc, provided spectral data in accord with that expected from the spiro compound **26**. In practice, it was more convenient to subject the crude thermolysate to hydrolysis (hydrochloric acid, methanol) and purify the resultant material by column chromatography on silica gel. By means of this procedure, pure spiro[4.5]dec-1-en-6-one (**14**) could be obtained from **24** in overall yields of 50–60%.[8]

Although the distilled product obtained by sequential thermolysis and hydrolysis of the enol ether **25** consisted largely of

[5]The 5-proton multiplet at δ 2.18–2.60 presumably includes the allylic protons at C-3, the methylene protons at C-7, and one of the methylene protons at C-4. In the most stable conformation of **14** (cf. **14***a*), the C-4 proton which is *cis* to the carbonyl carbon (H_x in **14***a*) is in an orientation in which it would be expected to experience notable deshielding from the carbonyl group.

[6]It should be noted that the olefinic protons of the symmetrical, isomeric spiro[4.5]dec-2-en-6-one (**19**), kindly supplied by Dr. R. D. Sands (see ref. 12), gave rise to a singlet at δ 5.50.

[7]When the enone **13** was rearranged under these somewhat modified conditions, the results were very similar to those described previously.

[8]The fact that these yields were not higher was probably due at least in part to mechanical losses related to the volatile nature of the products.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

one component, the yield (56%) was not particularly high.[8] Purification of this material by column chromatography on silica gel allowed for the isolation of pure spiro[4.4]non-6-en-1-one (**15**) in an overall yield of 40%.[8]

The results summarized above indicate that 2-(cyclopropylmethylene)cycloalkanones can indeed serve as convenient starting materials for a new spiro-annulation sequence, based on thermal vinylcyclopropane → cyclopentene rearrangement of derived enol silyl ethers. The next section of this paper describes an application of this method to the formal total synthesis of some spirovetivane-type sesquiterpenoids.

(c) *Formal total synthesis of some spirovetivane-type sesquiterpenoids*

The spirovetivane-type sesquiterpenoids possess the substituted spiro[4.5]decane carbon skeleton **27** (see Chart 3).[9] Members of this family of terpenoids have been isolated from a variety of sources and some of them have been shown to possess interesting biological activity. The latter fact, along with the structural novelty associated with the spirovetivanes, has led to a great deal of activity related to the synthesis of a number of these natural products. Indeed, since the important pioneering work in this area by Marshall *et al.* (16), a fairly large number of reports have appeared in the literature (17–34).[10]

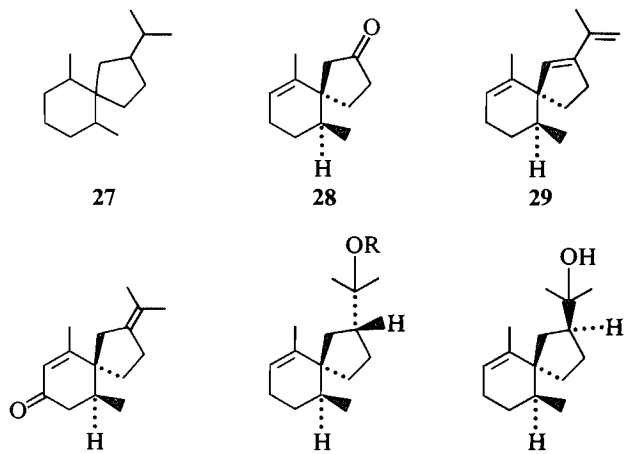

CHART 3

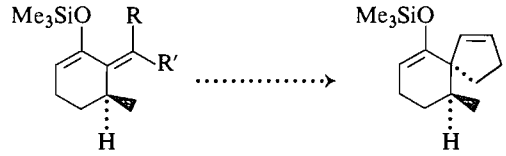
Of the impressive number of elegant synthetic routes which have been employed to prepare various members of the spirovetivane family of sesquiterpenoids, those described by Caine *et al.* (19), Buchi *et al.* (27), and Inubushi and co-workers (31)[11] have involved the use of the spiro enone **28** as a key synthetic intermediate. Thus far, the latter substance has been converted into (±)-α-vetispirene (**29**) (19), (±)-β-vetivone (**30**) (27, 31), (±)-hinesol (**31**) (31), (±)-hinesol acetate (**32**) (27), and (±)-agarospirol (**33**) (31).

Taking into account the work outlined in the previous section of this discussion, it seemed reasonable to propose that the new spiro-annulation method might serve as a convenient vehicle for a synthesis of the spiro enone **28** quite different from those reported previously (19, 27). More explicitly, our plan called for the synthesis and thermal rearrangement of the enol silyl ethers **34** and/or **35** (see eq. [4]). On the basis of steric considerations, it seemed likely that the secondary methyl group on the six-membered ring of **34** and/or **35** would, during the thermal rearrangement, direct bond formation at the adjacent center in the required stereochemical sense. Thus, one might expect the stereoselective formation of the desired spiro diene **36**. Conversion of the latter substance into the target molecule **28** would appear to be straightforward.

[4]



34 R = H, R′ = *c*-C_3H_5
35 R = *c*-C_3H_5, R′ = H
36

Cuprous iodide-catalyzed addition of methyl magnesium iodide to 2-cyclohexene-1-one (**37**) in ether at 0°C, followed by trapping (35) of the resultant enolate anion with cyclopropanecarboxaldehyde (36) afforded, after appropriate work-up, the ketol **38** which appeared to be a mixture of two diastereomers (97% yield)[12] (see Scheme 1). It should be noted that, when the aldehyde was added to the solution of enolate anion, a precipitate formed immediately. Presumably this material consisted of the magnesium alkoxides of the aldol products and the high regioselectivity and efficiency of this reaction can thus be attributed at least partially to the insolubility of these intermediates.

Dehydration of the ketols **38** could be accomplished by treatment of this mixture with a small amount of *p*-toluenesulfonic acid in refluxing benzene. Interestingly, monitoring of the progress of the reaction by thin-layer chromatography (tlc) revealed that one of the diastereomers of **38** dehydrated more rapidly than the other. When the reaction was allowed to proceed until the starting materials had been totally consumed, it was found that the yield of the desired β-cyclopropyl enones **39** and **40** was only 58%. Also isolated was a considerable amount (26%) of 3-methylcyclohexanone, clearly formed as the result of a retro-aldol process. The ^{1}H nmr spectra obtained from small samples of the geometrically isomeric enones **39** and **40** (isolated by preparative glc) clearly corroborated the stereochemical assignments. Thus, the signal due to the alkene proton of the (*E*) isomer **39** appeared, as expected, at lower field (δ 5.98) than the analogous resonance (δ 4.84) of the (*Z*) isomer.

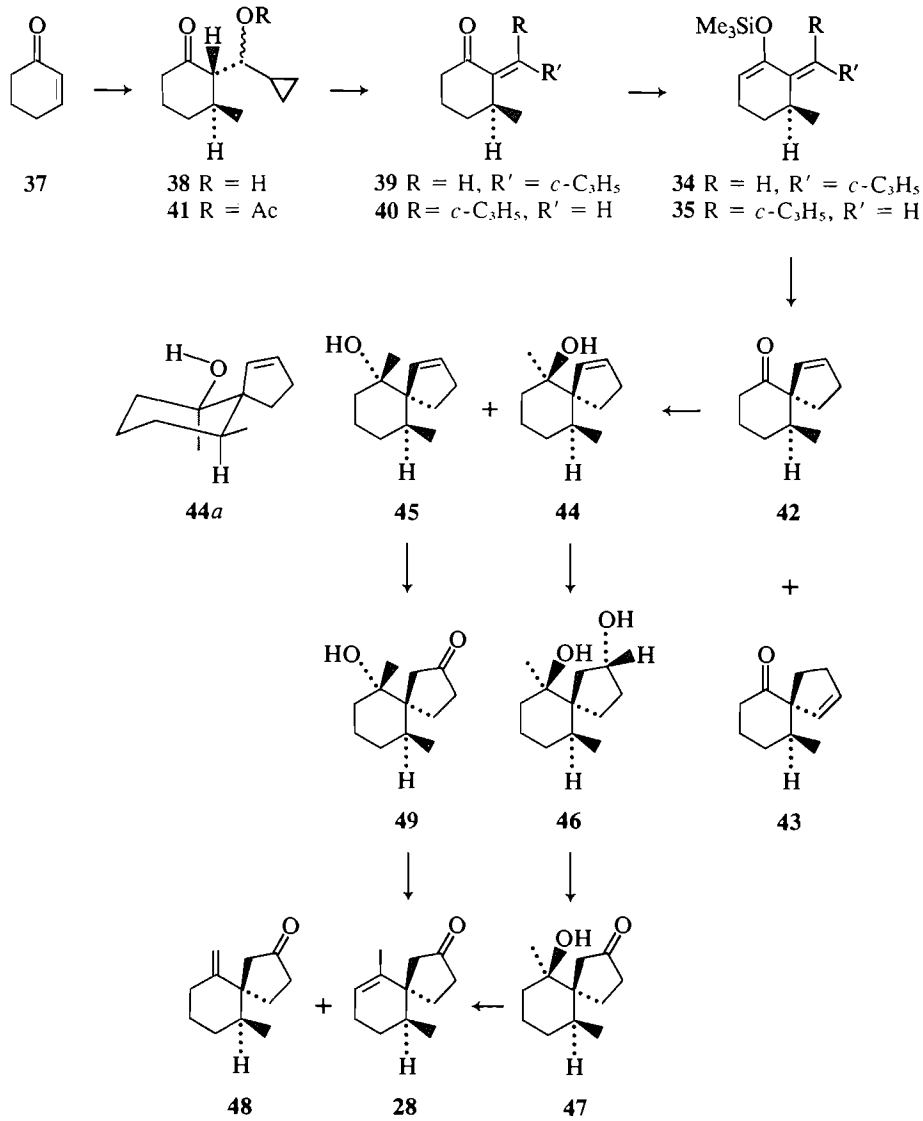
In attempts to improve the efficiency of the conversion of **38** into **39** and/or **40**, it was found that transformation (acetic anhydride, pyridine) of the ketols **38** into the corresponding

[9] For an excellent review, see ref. 15.

[10] For citations related to the structural eludication of the increasing number of spirovetivane-type sesquiterpenoids, see refs. 15–34, inclusive.

[11] The work of Inubushi and co-workers (31) was published after the appearance of our preliminary report (10).

[12] Attempted trapping (cyclopropanecarboxaldehyde) of the enolate anion derived from the addition of lithium dimethylcuprate to **37** failed to provide the regioisomerically correct product(s). The cyclopropane-containing products in this case were the two geometric isomers of 2-(cyclopropylmethylene)-5-methylcyclohexanone, both of which were different from the desired products **39** and/or **40**. A number of alternative potential methods for conversion of 2-cyclohexene-1-one (**37**) into the β-cyclopropyl enones **39** and/or **40** were investigated, but all proved to be unsatisfactory. For details of these attempts, see ref. 37.



SCHEME 1

acetates **41**, followed by treatment of the latter substances with 1,5-diazabicyclo[4.3.0]non-5-ene in refluxing benzene, afforded, in 78% yield, a mixture of the desired enones **39** and **40**, in a ratio of ~13:1, respectively.

The mixture of enones **39** and **40** was converted (lithium diisopropylamide, dimethoxyethane; trimethylsilyl chloride) into a mixture of the corresponding enol silyl ethers **34** and **35**. Thermolysis of the latter material at 380°C, followed by acid hydrolysis of the resulting crude product afforded, in 57% yield, a mixture of the two spiro enones **42** and **43**, in a ratio of ~2.5:1, respectively. Thus, although the major product **42** (mp 35–38°C) of this key step did possess the desired stereochemistry (*vide infra*), the stereoselectivity of the rearrangement process was not particularly high.[13] Nevertheless, the two diastereomeric products could be separated quite readily by column chromatography on silica gel, and, therefore, the overall sequence of reactions involving the conversion of **37** into **42** + **43** provides a convenient route for the acquisition of appreciable quantities of the desired substance **42**.

Treatment of the spiro enone **42** with methyllithium in ether at 0°C gave a mixture of epimeric alcohols **44** and **45** (ratio ~4:1, respectively), which could be separated by column chromatography on silica gel. The major isomer **44** was found to be identical with a sample of the same alcohol prepared earlier by Buchi *et al.* (27).[14] Hydroboration of compound **44** with disiamylborane in THF, followed by oxidation of the resultant trialkylborane with alkaline hydrogen peroxide, provided a single crystalline diol **46** in 77% yield. The stereochemistry of this substance, although not of crucial importance to the overall synthetic scheme, was assigned on the basis of steric considerations. In the most stable conformation of **44** (cf. **44***a*), the double bond is "protected" on one side by the rather small hydroxyl function and on the other side by the more bulky methyl group. Therefore, if the hydroboration process takes place by way of conformation **44***a*, the reagent should

[13] Although different samples of **34** + **35**, containing varying relative amounts of the two geometric isomers, were subjected to thermolysis, the ratio of products was essentially invariant. Thus, in this rearrangement, there does not appear to be a relationship between the stereochemistry of the reactants (**34**, **35**) and that of the products (**42**, **43**).

[14] We are very grateful to Professor G. Buchi for small samples of the alcohol **44** and the enone **28**, and to Professor D. S. Caine for copies of ir and ^{1}H nmr spectra of compounds **28** and **49**.

For personal use only.

approach the double bond from the less hindered side to produce, predominantly, the spiro diol **46**.

Oxidation of the diol **46** with pyridinium chlorochromate in methylene chloride afforded the crystalline keto alcohol **47** (27) in 88% yield. Dehydration of this material by treatment with *p*-toluenesulfonic acid in refluxing benzene provided, in 90% yield, a mixture of the two spiro enones **28** and **48**, in a ratio of ~9:1, respectively. A pure sample of the major product **28**, obtained by means of preparative tlc, was shown to be spectrally identical with the same substance prepared earlier by Caine *et al.* (19)[14] and by Buchi *et al.* (27).[14] As mentioned previously, compound **28** has been converted into (±)-α-vetispirene (**29**) (19), (±)-β-vetivone (**30**) (27, 31), (±)-hinesol (**31**) (31) (±)-hinesol acetate (**32**) (27), and (±)-agarospirol (**33**) (31) and, therefore, our preparation of this intermediate constitutes a new formal total synthesis of these natural products.

The olefinic alcohol **45** can also serve as a precursor for the spiro enone **28**. Thus, subjection of **45** to hydroboration–oxidation gave a crude diol which, upon treatment with pyridinium chlorochromate in methylene chloride, provided the keto alcohol **49** (19).[14] The latter substance had previously been converted into the spiro enone **28** (19).

Experimental

General

Melting points and distillation temperatures are uncorrected. Ultraviolet (uv) spectra were recorded on a Cary 15 spectrophotometer, while infrared (ir) spectra were taken on Perkin–Elmer models 710 or 710 B spectrophotometers. Proton magnetic resonance (^{1}H nmr) spectra (deuterochloroform solution) were measured using Varian Associates spectrometers, models T-60 and/or HA-100 or XL-100. Tetramethylsilane was employed as the internal standard. High resolution mass spectrometric measurements were recorded on a Kratos MS-50 mass spectrometer. Gas–liquid chromatography (glc) was carried out with a Hewlett–Packard model 5832 A gas chromatograph (analytical) or with a Varian Aerograph model 90-P instrument (preparative). Microanalyses were performed by Mr. P. Borda, Microanalytical Laboratory, University of British Columbia, Vancouver, B.C.

(E)-2-(Cyclopropylmethylene)cyclohexanone (12)

A stirred slurry of phenylthiocopper (38) (779 mg, 4.5 mmol) in dry THF (30 mL), under an atmosphere of argon, was cooled to −78°C and a solution of freshly prepared cyclopropyllithium (39, 40) (4.5 mmol) in ether was added. The mixture was warmed to −20°C and stirred at this temperature for 20 min. The resulting light brown solution of lithium (phenylthio)(cyclopropyl)cuprate was cooled to −78°C and a solution of (*E*)-2-(iodomethylene)cyclohexanone (**10**) (3) (708 mg, 3.0 mmol) in 6 mL of dry THF was added. The reaction mixture was allowed to warm to 0°C and was stirred at this temperature for 2.5 h. After addition of methanol (2 mL) and ether (20 mL), the mixture was warmed to room temperature and then was filtered through a short column of Florisil (30 g, 80–100 mesh). The column was eluted with an additional 300 mL of ether. Removal of the solvent from the combined eluate, followed by distillation (air-bath temperature ~80°C/0.2 Torr) of the residual oil, gave 369 mg(82%) of a colorless oil which, on the basis of analysis by glc, consisted very largely (>96%) of one component. An analytical sample of the β-cyclopropyl enone **12**, obtained by preparative glc, exhibited mp ~15°C; uv (methanol) λ_{max}: 265 nm (ε 11 750); ir (film): 1680, 1600 cm^{-1}; ^{1}H nmr δ: 0.49–1.10 (m, 4H), 1.18–2.03 (m, 5H), 2.26–2.50 (m, 2H), 2.50–2.76 (m, 2H), 6.04 (d of t, 1H, J = 11, 2 Hz). *Anal.* calcd. for $C_{10}H_{14}O$: C 79.96, H 9.39; found: C 79.69, H 9.35.

(E)-2-(Cyclopropylmethylene)cyclopentanone (13)

This compound was prepared via a procedure identical with that described above, except that the reaction was carried out at −78°C for 1 h and then at −20°C for an additional 2.5 h. From 666 mg (3 mmol) of (*E*)-2-(iodomethylene)cyclopentanone (**11**) (3) there was obtained a crude product which, upon distillation (air-bath temperature ~90°C/0.35 Torr) afforded 265 mg (65%) of a colorless oil which was shown by gas–liquid chromatographic analysis to consist very largely (~95%) of one component. An analytical sample of compound **13**, obtained by preparative glc, exhibited mp ~18°C; uv (methanol) λ_{max}: 267 nm (ε 14 800); ir (film): 1706, 1640 cm^{-1}; ^{1}H nmr δ: 0.54–1.10 (m, 4H), 1.16–1.70 (m, 1H), 1.76–2.14 (m, 2H), 2.18–2.42 (m, 2H), 2.58–2.82 (m, 2H), 5.95 (d of t, 1H, J = 11, 2.5 Hz). *Exact Mass* calcd. for $C_9H_{12}O$: 136.0887; found: 136.0902.

Preparation of the enol silyl ether 24

To a stirred, cold (0°C) solution of lithium diisopropylamide (4.0 mmol) in dry dimethoxyethane (4 mL) was added 450 mg (3.0 mmol) of (*E*)-2-(cyclopropylmethylene)cyclohexanone (**12**). Meanwhile, a mixture prepared by addition of 0.2 mL (~2 mmol) of triethylamine and 0.6 mL (5.1 mmol) of trimethylsilyl chloride to 2 mL of dry dimethoxyethane was centrifuged to remove any insoluble triethylamine hydrochloride. By means of a dry syringe, the resultant solution was added rapidly to the cold (0°C) solution containing the enolate anion of **12**. The resulting mixture (containing a precipitated white solid) was stirred at 0°C for 15 min, and then was treated with saturated aqueous sodium bicarbonate (10 mL) and pentane (30 mL). The aqueous layer was extracted with three 30-mL portions of pentane and the combined organic extract was dried over anhydrous magnesium sulfate. Removal of the solvent, followed by distillation (air-bath temperature ~125°C/16 Torr) of the crude oil, gave 606 mg (91%) of the enol silyl ether **24**; ir (film): 1620 cm^{-1}; ^{1}H nmr δ: 0.13 (s, 9H), 0.26–0.48 (m, 2H), 0.56–1.05 (m, 2H), 1.36–1.80 (m, 4H), 2.04–2.28 (m, 2H), 2.36–2.60 (m, 1H), 4.96 (t, 1H, J = 4.5 Hz), 5.08 (d, 1H, J = 9.5 Hz). *Exact Mass* calcd. for $C_{13}H_{22}OSi$: 222.1439; found: 222.1438.

Preparation of the enol silyl ether 25

This compound was prepared from (*E*)-2-(cyclopropylmethylene)-cyclopentanone (**13**) via a procedure identical with that decribed for the conversion of **12** into **14** (see above). From 408 mg (3 mmol) of **13** there was obtained, after distillation (air-bath temperature ~90–100°C/14 Torr) of the crude product, 562 mg (90%) of the enol silyl ether **25**; ir (film): 1615 cm^{-1}; ^{1}H nmr δ: 9.86 (s, 9H), 2.2–2.8 (m, 4H), 4.7–5.1 (m, 2H). Due to the instability of this material, it was subjected to thermolysis without further characterization.

Thermal rearrangement of (E)-2-(cyclopropylmethylene)-cyclohexanone (12)

A vertically held Pyrex tube (1.2 × 32 cm), filled with glass helices and placed inside a vertical, tubular furnace, was washed successively with saturated aqueous sodium bicarbonate, water, acetone, and *n*-hexane. The tube was heated to ~450°C and kept at this temperature for ~3 h. During this time, the tube was thoroughly purged with a stream of nitrogen. A solution of (*E*)-2-(cyclopropylmethylene)cyclohexanone (**12**) (200 mg) in *n*-hexane (20 mL) was added dropwise to the top of the heated tube. During this time, a slow flow of nitrogen (~3–5 mL/min) was passed through the tube. The thermolysate was passed through a water condensor and collected in a cold (−78°C) two-necked flask equipped with a drying tube. After the solution of **12** had been added, the hot tube was treated slowly with an additional 30 mL of *n*-hexane. Removal of the solvent from the combined thermolysate, followed by distillation (air-bath temperature ~110°C/16 Torr) of the residual oil, gave 148 mg (74%) of a colorless oil. Gas–liquid chromatographic analysis of this material showed that it contained, in addition to a number of minor unidentified components, spiro[4.5]dec-1-en-6-one (**14**) (~44%), tetralin (**17**) (~38%), and the dienones **18** (~9%). A small sample of each of these substances was obtained by preparative glc.

Tetralin (**17**) was identified by comparison (ir, ^{1}H nmr) with a sample of commercially available material.

Dienones **18**: ir (film): 1678, 1610 cm^{-1}. The fact that this material

consisted of a mixture of geometric isomers was shown by the ^{1}H nmr spectrum, which exhibited two triplets (δ 0.98, 1.01, J = 7 Hz in each case) due to terminal methyl groups and a series of multiplets between δ 5.46 and 7.04 due to the olefinic protons. Hydrogenation (10% Pd–C, methanol, room temperature, atmospheric pressure) of this material gave 2-*n*-butylcyclohexanone.

Spiro[4.5]dec-1-en-6-one (**14**): ir (film): 1710 cm^{-1}; ^{1}H nmr δ: 1.40–2.03 (m, 7H), 2.18–2.60 (m, 5H), 5.76 (s, 2H, $w_{1/2}$ = 2 Hz); ^{1}H nmr after addition of 20 mg of the shift reagent Eu(FOD)$_3$, δ: 1.82–2.38 (m, 7H), 2.50–2.86 (m, 2H), 3.16–3.56 (m, 3H), 6.06 (d of t, 1H, J = 6, 2 Hz), 6.42 (d of t, 1H, J = 6, 2 Hz). In a decoupling experiment, irradiation at δ ~2.70 caused the two signals due to the olefinic protons (δ 6.06, 6.42) to collapse to an AB pair of doublets with J = 6 Hz; ^{13}C nmr (proton decoupled) δ: 23.0, 27.7, 31.3, 32.3, 39.9 (2 carbons), 64.1, 132.5, 133.4, 211.5. *Exact Mass* calcd. for $C_{10}H_{14}O$: 150.1044; found: 150.1027.

Hydrogenation (10% Pd–C, methanol, room temperature, atmospheric pressure) of compound **14** gave spiro[4.5]decan-6-one (**20**), which was shown by ir and ^{1}H nmr spectra to be identical with an authentic sample of **20** prepared by the method of Naro and Dixon (13).

*Thermal rearrangement of (*E*)-2-(cyclopropylmethylene)cyclo-pentanone (13)*

Thermolysis of compound **13** was carried out under conditions very similar to those described above. From 400 mg of **13** (added to the heated tube as a solution in 20 mL of *n*-hexane) there was obtained, upon distillation (air-bath temperature ~110°C/12 Torr) of the crude product, 360 mg (90%) of a pale yellow oil. Gas–liquid chromatographic analysis of this material showed the presence of a number of components. Small samples of the major products were collected by preparative glc.

Indan (**21**), ~11% of the mixture, was identified by comparison with a sample of commercially available material.

Dienones **22** constituted ~44% of the mixture. The ^{1}H nmr spectrum of this material clearly showed the presence of two geometric isomers, in a ratio of ~2:1 (*E* isomer predominant). At high field, the terminal methyl groups gave rise to two triplets (δ 1.01, 1.03, J = 6.5 Hz in each case), while the low-field region of the spectrum (δ 5.60–7.54) exhibited a series of signals due to the olefinic protons. *Exact Mass* calcd. for $C_9H_{12}O$: 136.0887; found: 136.0891.

Hydrogenation (10% Pd–C, methanol, room temperature, atmospheric pressure) of the dienones **22** produced 2-*n*-butylcyclopentanone.

Spiro[4.4]non-6-en-1-one (**15**), ~29% of the mixture, exhibited ir (film): 1740 cm^{-1}; ^{1}H nmr δ: ~1.3–2.7 (diffuse m, 10H), 5.30–5.53 (m, 1H), 5.73–5.97 (m 1H). *Exact Mass* calcd. for $C_9H_{12}O$: 136.0887; found: 136.0901.

Hydrogenation (10% Pd–C, methanol, room temperature, atmospheric pressure) of compound **15** gave spiro[4.4]nonan-1-one (**23**), the 2,4-dinitrophenylhydrazone derivative of which exhibited mp 153–155°C (lit. (14) mp 155–157°C).

Thermal rearrangement of the enol silyl ether 24

(a) *With isolation of the spiro enol ether 26*

Thermolysis of compound **24** was carried out under conditions similar to those described above, except that the thermolysis tube was longer (100 cm), the tube was heated by means of a heating tape rather than a tubular furnace, the "carrier gas" was argon instead of nitrogen, and the thermolysis temperature was ~425°C rather than ~450°C. From 200 mg of the enol silyl ether **24**, added to the heated tube as a solution in 20 mL of *n*-hexane, there was obtained, upon distillation (air-bath temperature ~105°C/56 Torr) of the crude thermolysate, 170 mg (85%) of a colorless oil. Analysis of this liquid by glc showed that it consisted very largely (~84%) of one component, along with a number of minor, unidentified compounds. A small sample of the major product **26**, obtained by preparative glc, exhibited ir (film): 1655 cm^{-1}; ^{1}H nmr δ: 0.09 (s, 9H), 1.46–1.68 (m, 6H), 1.90–2.12 (m, 2H), 2.14–2.44 (m, 2H), 4.75 (t, 1H, J = 4 Hz), 5.44–5.56 (m, 1H), 5.66–5.79 (m, 1H). *Exact mass* calcd. for $C_{13}H_{22}OSi$: 222.1440; found: 222.1443.

(b) *Followed by direct hydrolysis of the crude thermolysis product*

The crude thermolysis product obtained from 1.0 g of the enol silyl ether **24** (added to the heated tube as a solution in 100 mL of *n*-hexane) was dissolved in a mixture of methanol (2.5 mL) and 1 *N* hydrochloric acid (2.5 mL) and the resulting solution was stirred at room temperature for 30 min. The mixture was diluted with water and thoroughly extracted with pentane. The combined extract was dried over anhydrous magnesium sulfate. Removal of the solvent gave an oil which was subjected to column chromatography on silica gel (50 g, 70–270 mesh). Elution of the column with pentane, followed by distillation (air-bath temperature ~100°C/14 Torr) of the oil derived from the appropriate fractions gave 340 mg (50%) of pure spiro[4.5]dec-1-en-6-one (**14**), the spectra of which were identical with those recorded previously.

Thermal rearrangement of the enol silyl ether 25

Thermolysis of compound **25** was carried out under conditions identical with those described above for the rearrangement of **24**. The crude thermolysate obtained from 200 mg of **25** (added to the heated tube as a solution in 20 mL of *n*-hexane) was subjected to acid hydrolysis as described under (b), above. Distillation (air-bath temperature ~90°C/16 Torr) of the crude hydrolysis product gave 87 mg of colorless oil which was subjected to column chromatography on silica gel (10 g, 70–270 mesh). Elution of the column with 9:1 *n*-hexane–ether, followed by distillation of the oil obtained from the appropriate fractions, gave 52 mg (40%) of pure spiro-[4.4]non-6-en-1-one (**15**), which was spectrally identical with the material isolated previously (*vide supra*).

Preparation of the keto alcohols 38

To a cold (0°C) stirred solution of methyl magnesium iodide (18 mmol) in 25 mL of dry ether was added 60 mg (0.3 mmol) of cuprous iodide and the resulting mixture was stirred at 0°C for 5 min. After addition of 2-cyclohexen-1-one (**37**) (1.44 g, 15 mmol), the reaction mixture was stirred at 0°C for 30 min, and then was cooled to −78°C. Cyclopropanecarboxaldehyde (1.05 g, 15 mmol) was added dropwise, whereupon a gummy precipitate formed. The mixture was stirred at −78°C for an additional 10 min, at 0°C for 30 min, and at room temperature for 30 min. After addition of saturated aqueous ammonium chloride (30 mL), the mixture was stirred for 5 min, the layers were separated, and the aqueous solution was washed with four 30-mL portions of ether. The combined extract was washed twice with brine and dried over anhydrous magnesium sulfate. Removal of the solvent gave 2.65 g (97%) of the keto alcohols **38** which, on the basis of analysis by tlc, consisted of two diastereomers. This material exhibited ir (film): 3470, 1700 cm^{-1} and, upon attempted distillation, underwent partial decomposition (dehydration, retro-aldol reaction). Therefore, further purification and characterization was not carried out.

Preparation of the β-cyclopropyl enones 39 and 40

(a) *By direct dehydration of the ketol alcohols 38*

A solution of the crude ketols **38** (2.65, 14.6 mmol) in benzene (60 mL) containing 33 mg of *p*-toluenesulfonic acid was refluxed under a Dean–Stark water separator. The progress of the dehydration reaction was monitored by thin-layer chromatographic analysis of aliquots taken from the reaction mixture. It was found that one of the diastereomers of **38** had reacted completely within 3 h, while the other was completely transformed into product(s) only after a period of ~18 h. The cooled benzene solution was washed with saturated aqueous sodium bicarbonate and dried over anhydrous magnesium sulfate. Removal of the solvent, followed by distillation of the residual oil, gave two distinct fractions. The first (air-bath temperature up to ~50°C/0.3 Torr, 426 mg, 26%) was shown by ir and ^{1}H nmr spectra to be 3-methylcyclohexanone, while gas–liquid chromatographic analysis of the second fraction (air-bath temperature ~80°C/0.3 Torr, 1.40 g, 58%) showed that it consisted of two components in ratio of

~6:1. A small sample of each of these materials was collected by preparative glc. The major and minor components were shown to be the β-cyclopropyl enones **39** and **40**, respectively.

Enone **39**: uv (methanol) λ_{max}: 265 nm (ε 11 400); ir (film): 1680, 1600 cm^{-1}; ^1H nmr δ: 0.50–2.52 (diffuse m, 11H), 1.04 (d, 3H, J = 7 Hz), 3.02–3.42 (m, 1H), 5.98 (d of d, 1H, J = 11, 1 Hz). *Exact Mass* calcd. for $C_{11}H_{16}O$: 164.1201; found: 164.1205.

Enone **40**: uv (methanol) λ_{max}:263 nm (ε 11 700); ir (film): 1685, 1610 cm^{-1}; ^1H nmr δ: 0.20–2.70 (diffuse m, 12H), 1.04 (d, 3H, J = 7 Hz), 4.84 (d of d, 1H, J = 10.5, 2 Hz). *Exact Mass* calcd. for $C_{11}H_{16}O$: 164.1201; found: 164.1206.

(b) *By elimination of acetic acid from the keto acetates* ***41***

A solution of the crude ketols **38** (1.1 g, 6 mmol) in a mixture of pyridine (20 mL) and acetic anhydride (6 mL) was stirred at room temperature under an atmosphere of argon for 17 h. Ether (200 mL) and water (30 mL) were added and the mixture was stirred for 5 min. The ether layer was separated and washed successively with three 20-mL portions of 1 *N* hydrochloric acid, 20 mL of brine, two 30-mL portions of saturated sodium bicarbonate and 20 mL of brine, and then was dried over anhydrous sodium sulfate. Removal of the solvent (water aspirator, followed by vacuum pump) afforded 1.3 g (98%) of the keto acetates **41**, the ^1H nmr spectrum of which exhibited two signals (δ 2.02, 2.04) due to acetate methyl groups.

To a solution of the crude acetates **41** in 95 mL of dry benzene was added 1.1 g (0.9 mmol) of 1,5-diazabicyclo[4.3.0]non-5-ene and the resulting mixture was refluxed under an atmosphere of argon for 17 h. Ether (250 mL) was added to the cooled reaction mixture, the solution was washed successively with ice-cold 1 *N* hydrochloric acid (30 mL) and brine (20 mL) and then was dried over anhydrous magnesium sulfate. Removal of the solvent, followed by distillation (air-bath temperature 75–90°C/0.4 Torr) of the residual oil, provided 770 mg (78% from the ketols **38**) of a colorless oil. Analysis of this material showed that it was a mixture of the two β-cyclopropyl enones **39** and **40** (ratio ~13:1, respectively) along with a number of very minor impurities. Small samples of the two major products, collected by preparative glc, produced spectra identical with those obtained previously.

Preparation of the enol silyl ethers ***34*** *and* ***35***

Conversion of the mixture of enones **39** and **40** into the corresponding enol silyl ethers **34** and **35**, respectively, was carried out via a procedure identical with that described for the transformation of the enone **12** into the enol silyl ether **24** (*vide supra*). From 492 mg (3 mmol) of **39** + **40** (ratio ~6:1) there was obtained 670 mg (95%) of a mixture of the enol ethers **34** and **35**, which exhibited ir (film): 1650, 1625 cm^{-1}; ^1H nmr δ: 1.03 (d, 3H, J = 7 Hz), 2.88–3.24 (m, 1H), 4.89 (t, 1H, J = 3 Hz), 5.02 (d, 1H, J = 10 Hz). This material was quite unstable and therefore was used immediately for the next step.

Thermolysis of the enol silyl ethers ***34*** *and* ***35***. *Preparation of the spiro enones* ***42*** *and* ***43***

The thermal rearrangement of the mixture of enol silyl ethers **34** and **35** was carried out under conditions described previously for the conversion of **24** into **26**, except that the thermolysis tube was heated at ~380°C instead of at ~425°C. The crude thermolysate obtained from 8.44 g of **34** + **35** (added to the hot tube as a solution in 200 mL of *n*-hexane) was subjected to acid hydrolysis (20 mL 1 *N* hydrchloric acid, 20 mL methanol, room temperature, 30 min) as described previously. Distillation (air-bath temperature 70–80°C/0.4 Torr) of the crude hydrolysis product gave 4.8 g of an oil which, on the basis of analysis by glc, consisted of a mixture of the spiro enones **42** and **43** (ratio ~2.5:1) along with a number of minor unidentified components (~15% of the mixture). This material was subjected to column chromatography on silica gel (350 g). Elution of the column with 10% ether in hexane afforded 2.03 g (35%) of the spiro enone **42**, 0.85 g (14%) of the spiro enone **43**, and 0.47 g (8%) of a mixture of **42** and **43**.

Spiro enone **42**: ir (chloroform): 1705 cm^{-1}; ^1H nmr δ: 0.90 (d, 3H, J = 6 Hz), 1.40–2.84 (diffuse m, 11H), 5.62–5.98 (m, 2H). *Exact Mass* calcd. for $C_{11}H_{16}O$: 164.1201; found: 164.1212.

Spiro enone **43**: ir (film): 1705 cm^{-1}; ^1H nmr δ: 0.86 (d, 3H, J = 6 Hz), 1.40–2.20 (diffuse m, 7H), 2.20–2.57 (diffuse m, 4H), 5.60–5.80 (m, 1H), 5.80–5.98 (m, 1H). *Exact Mass* cacld. for $C_{11}H_{16}O$: 164.1201; found: 164.1195.

Reaction of the ketone ***42*** *with methyllithium. Preparation of the epimeric alcohols* ***44*** *and* ***45***

To a cold (0°C) solution of the spiro enone **42** (492 mg, 3 mmol) in dry ether (25 mL) was added dropwise a solution of methyllithium (4.5 mmol) in ether. The mixture was stirred at 0°C for 1 h and at room temperature for 1 h. After addition of brine (20 mL), the layers were separated and the aqueous solution was extracted with ether (3 × 30 mL). The combined extract was washed with brine and dried over anhydrous magnesium sulfate. Removal of the solvent, followed by distillation (air-bath temperature ~75°C/0.4 Torr) of the residual oil gave 513 mg (95%) of a colorless oil. Analysis of this material by glc indicated the presence of two components in a ratio of ~4:1. Separation was achieved by means of column chromatrography on silica gel (50 g). Elution of the column with hexane containing 15% ether provided 286 mg (53%) of the alcohol **44**, 78 mg (14.5%) of a mixture of **44** and **45**, and 62 mg (11.5%) of the alcohol **45**.

Olefinic alcohol **44**: ir (film): 3500 cm^{-1}; ^1H nmr δ: 0.58 (d, 3H, J = 6 Hz), 1.22 (s, 3H), 1.12–1.88 (diffuse m, 9H), 2.00–2.48 (diffuse m, 3H), 5.72 (d of t, 1H, J = 6, 2 Hz), 6.07 (d of t, 1H, J = 6, 2 Hz). *Exact Mass* calcd. for $C_{12}H_{20}O$: 180.1515; found: 180.1556. This compound exhibited spectra identical with those of a sample of the same substance obtained from Professor G. Buchi (see footnote 14).

Olefinic alcohol **45**: ir (film): 3490 cm^{-1}; ^1H nmr δ: 0.75 (d, 3H, J = 6.5 Hz), 1.04 (s, 3H), 1.34–2.46 (diffuse m, 12H), 5.52 (d of t, 1H, J = 6, 2 Hz), 5.81 (d of t, 1H, J = 6, 2 Hz). *Exact Mass* cacld. for $C_{12}H_{20}O$: 180.1515; found: 180.1515.

Hydroboration of the olefinic alcohol ***44***. *Preparation of the diol* ***46***

To a cold (0°C) solution of disiamylborane (10 mmol) in 10 mL of dry tetrahydrofuran was added 180 mg (1 mmol) of the olefinic alcohol **44**. The mixture was stirred at 0°C for 1 h and then at room temperature for 21 h. After the reaction mixture had been cooled to 0°C, it was treated successively with ethanol (1 mL), 3 *N* aqueous sodium hydroxide (7 mL), and 30% aqueous hydrogen peroxide (4 mL). The resulting mixture was heated under reflux for 2 h, cooled, treated with brine (5 mL), and extracted thoroughly with ether. The combined extract was washed with brine and dried over anhydrous magnesium sulfate. Removal of the solvent, followed by recrystallization (ether–hexane) of the resultant yellow solid, gave 153 mg (77%) of the diol **46** as white crystals which exhibited mp 153–155°C; ir (chloroform): 3640, 3480 cm^{-1}; ^1H nmr δ: 0.93 (d, 3H, J = 6 Hz), 1.18 (s, 3H), 1.10–2.16 (diffuse m, 15H), 4.05–4.45 (m, 1H). *Anal.* calcd. for $C_{12}H_{22}O_2$: C 72.68, H 11.18; found: C 72.54, H 11.10.

Oxidation of the diol ***46***. *Preparation of the keto alcohol* ***47***

To a slurry of pyridinium chlorochromate (324 mg, 1.5 mmol) in dry methylene chloride (3 mL) was added a solution of the diol **46** (198 mg, 1 mmol) in 10 mL of dry methylene chloride and the resulting red solution was stirred at room temperature for 1 h. After addition of ether (20 mL), the mixture was filtered through a short column of Florisil (10 g, 80–100 mesh). The column was eluted with a further 50 mL of ether. Removal of the solvent from the combined eluate, followed by distillation (air-bath temperature ~120°C/0.2 Torr) of the residual oil, afforded 176 mg (88%) of a colorless oil which crystallized in a refrigerator. Recrystallization of a small amount of this material from ether–hexane gave an analytical sample of the keto alcohol **47** (27), which exhibited mp 51–52°C; ir (chloroform): 3660, 3500, 1730 cm^{-1}; ^1H nmr δ: 0.82 (d, 3H, J = 6.5 Hz), 1.28 (s, 3H), 1.04–2.48 (diffuse m, 12H), 2.16, 2.64 (AB pair of d, 1H each, J = 19 Hz). *Anal.* calcd. for $C_{12}H_{20}O_2$: C 73.43, H 10.27; found: C 73.53, H 10.17.

Dehydration of the keto alcohol ***47****. Preparation of the olefinic ketones* ***28*** *and* ***48***

To a solution of the keto alcohol **47** (118 mg, 0.6 mmol) in benzene (20 mL) was added 15 mg of *p*-toluenesulfonic acid and the resulting solution was heated under reflux for 87 h. The solution was cooled, washed successively with saturated aqueous sodium bicarbonate (5 mL) and brine (5 mL), and dried over anhydrous magnesium sulfate. Removal of the solvent, followed by distillation (air-bath temperature 60–65°C/0.4 Torr) of the residual material gave 96 mg (90%) of a colorless oil. This material exhibited two spots by thin-layer chromatographic analysis and, on the basis of the ^{1}H nmr analysis, appeared to consist of a mixture of the olefinic ketones **28** and **48** (ratio ~9:1, respectively). A small sample of the major component **28**, obtained from the mixture by preparative tlc, exhibited ir (film): 1740 cm^{-1}; ^{1}H nmr δ: 0.88 (d, 3H, J = 6.5 Hz), 1.2–2.5 (diffuse m,11H), 1.66 (m, 3H, $w_{1/2} \approx 4$ Hz), 5.44 (m, 1H, $w_{1/2} \approx 8$ Hz). *Exact Mass* calcd. for $C_{12}H_{18}O$: 178.1358; found: 178.1360. Compound **28** exhibited spectra identical with those of the same compound prepared previously by Caine *et al.* (19) and by Buchi *et al.* (27) (see footnote 14).

Conversion the the alcohol ***45*** *into the keto alcohol* ***49***

Hydroboration of the olefinic alcohol **45** (72 mg) under conditions identical with those described above (hydroboration of **44**) provided a crude product which, on the basis of analysis by glc, contained ~30% of the starting material **45**. Distillation (air-bath temperature up to ~80°C/0.4 Torr) removed the latter substance (~15 mg). The residual material was subjected to oxidation with pyridinium chlorochromate in dichloromethane (see above, oxidation of diol **46**). Distillation (air-bath temperature ~120°C/1 Torr) of the crude product afforded 30 mg (48% based on unrecovered **45**) of the keto alcohol **49**, which exhibited ir (film): 3500, 1730 cm^{-1}; ^{1}H nmr δ: 0.84 (d, 3H, J = 6.5 Hz), 1.16 (s, 3H), 1.02–2.48 (diffuse m, 14H). This compound exhibited spectra identical with those obtained from a sample of the same material prepared earlier by Caine *et al.* (19) (see footnote 14). Conversion of **49** into the olefinic ketone **28** has been described by Caine *et al.* (19).

Spin trapping of hydroxyl in water: decay kinetics for the ·OH and CO_2^- adducts to 5,5-dimethyl-1-pyrroline-*N*-oxide[1]

ARLINDO L. CASTELHANO, M. JOHN PERKINS,[2] AND DAVID GRILLER
Division of Chemistry, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received May 14, 1982

ARLINDO L. CASTELHANO, M. JOHN PERKINS, and DAVID GRILLER. Can. J. Chem. **61**, 298 (1983).

A spin-trapping technique for distinguishing between free and "bound hydroxyl" radicals has been proposed in the literature. This technique relied upon observations of the steady-state concentrations of the spin-adducts of ·OH and CO_2^- (from formate) to 5,5-dimethyl-1-pyrroline-*N*-oxide. In the present work, it is shown that the steady-state approach was only qualitatively correct. An alternative procedure is demonstrated which involves monitoring the growth of the spin-adducts after the start of radical generation. The latter approach is found to be quantitative.

ARLINDO L. CASTELHANO, M. JOHN PERKINS et DAVID GRILLER. Can. J. Chem. **61**, 298 (1983).

Une technique de piégeage de spin a été proposée antérieurement pour distinguer les radicaux hydroxyles libres et les radicaux "hydroxyles liés". Cette technique est reliée aux observations des concentrations de l'état stationnaire des adduits de spin de ·OH et de CO_2^- (à partir du formiate) sur le *N*-oxyde de la diméthyl-pyrrolinne-1. Dans ce travail, on montre que l'approche de l'état stationnaire n'est que qualitativement correcte. On propose une méthode alternative qui fait intervenir l'enregistrement de l'augmentation des adduits de spin après le début de la génération du radical. On a trouvé que la dernière approche est quantitative.

[Traduit par le journal]

In a recent publication (1) Lown and Chen used the spin-trap 5,5-dimethyl-1-pyrroline-*N*-oxide (DMPO), (1–12), to distinguish between the reactions of the free hydroxyl radical and those of radicals which behave as hydroxylating reagents. The latter were referred to as "bound hydroxyl". Their scheme is summarized in equations [1–3], where X· represents ·OH or "bound hydroxyl".

[1] $X\cdot + DMPO \xrightarrow{k_1}$ 
1

[2] $X\cdot + HCO_2^- \xrightarrow{k_2} CO_2^- + XH$

[3] $CO_2^- + DMPO \xrightarrow{k_3}$ 
2

In principle, there should be a difference in the ratio k_1/k_2 between those cases where X· is free hydroxyl and those where it is "bound". Accordingly, in their experiments, Lown and Chen adjusted the concentrations of DMPO and HCO_2^- until the concentration of the spin-adducts **1** and **2** were equal (1). This was taken as evidence that the rates of formation of **1** and **2** were equal and hence, (1),

[4] $k_1[X\cdot][DMPO] = k_2[X\cdot][HCO_2^-]$

[5] $k_1/k_2 = [HCO_2^-]/[DMPO]$

Variations in the ratio k_1/k_2 were used to differentiate "bound" and free hydroxyl. However, this analysis could only have been correct if the rates of loss of **1** and **2** from the systems under study were *exactly* equal, since the steady-state radical concentrations observed depended not only upon the rates of formation of **1** and **2** but also upon their rates of destruction.

A suggestion that this kinetic scheme was flawed comes from the fact that $k_1/k_2 = 0.23 \pm 0.12$ for the case where free hydroxyl was generated by photolysis of hydrogen peroxide at pH 7. By contrast, measured values of the individual rate constants give $k_1 = k_2 = 2.7 \times 10^9\ M^{-1}\ s^{-1}$ and hence, $k_1/k_2 = 1.0$ (7, 13).

To resolve these problems, we have studied the decay kinetics of the spin-adducts **1** and **2**. In addition, we have measured k_1/k_2 for "free hydroxyl" using an approach which does not involve assumptions about the decay kinetics of these spin-adducts.

The methods used for sample preparation, measurement of radical concentrations, and kinetic analysis have been described in detail elsewhere (7).

Photolysis of an aqueous solution (pH 7.0; phosphate buffer) of hydrogen peroxide (1% v/v), containing DMPO (~0.1 *M*), in the cavity of an epr spectrometer gave a clean spectrum of radical **1**. Once a concentration of $2 \times 10^{-4}\ M$ had been attained, photolysis was stopped and the decay of the radical was followed with time. The decay followed second order kinetics until a concentration of $\sim 4 \times 10^{-5}\ M$ was reached. The rate constant for the second order decay, $2k_6$ (**1**), was found to be $17 \pm 3\ M^{-1}\ s^{-1}$. The decay process became first order below the concentration of $\sim 4 \times 10^{-5}\ M$ and the rate constant for this decay process, k_7 (**1**), was found to be $(8.4 \pm 1.0) \times 10^{-4}\ s^{-1}$, in exact agreement with the value of $8.4 \times 10^{-4}\ s^{-1}$ reported previously (7).

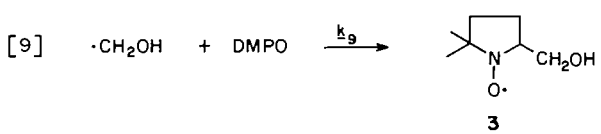
to that used to obtain **1** with the exception that it contained sodium formate, reactions [2 and 3]. The decay of **2** was second order in the concentration range $3 \times 10^{-4} \geq [\mathbf{2}] \geq 7 \times 10^{-5}$ *M* and $2k_6$ (**2**) = 12 ± 3 M^{-1} s^{-1}. Below a concentration of 7×10^{-5} *M* the decay became first order with $k_7 = (3.0 \pm 0.5) \times 10^{-4}$ s^{-1}.

These results show that the decay kinetics for radicals **1** and **2** are quite similar. Hence, the approach used by Lown and Chen is unlikely to be seriously in error if the reactions under study were carried out for the same lengths of time and the same absolute radical concentrations were obtained in each experiment. The fact that these conditions are unlikely to be realized probably accounts for the spread of a factor of 5 in the data obtained by Lown and Chen for the ratio k_1/k_2.

A more satisfactory approach to the measurement of rate constants for spin-trapping is to measure the growth of the spin-adducts from the time at which radical generation is started. We have used this approach to obtain an independent measure of the ratio k_1/k_2. The rate constant for attack by hydroxyl at methanol, reaction [8], was used as a standard so that k_1 and k_2 could be determined separately.



3

To measure the rates of growth of the spin-adducts, the light intensity at the sample was adjusted so that the radical concentrations grew over a convenient timescale for recording the spectra (ca. 3 min). This timescale was substantially shorter than that for the first order decay of the spin-adducts and the radical concentrations were sufficiently low that second order decay was insignificant. Under these conditions eq. [10] applied, subject to the further proviso that both $\cdot CH_2OH$ and $CO_2^{\cdot-}$ were efficiently trapped by DMPO, reactions [3 and 9].

$$[10] \quad \frac{k_2}{k_8} = \frac{d[\mathbf{2}]/dt}{d[\mathbf{3}]/dt} \cdot \frac{[CH_3OH]}{[HCO_2^-]}$$

Photolysis of an aqueous solution at pH 7 containing sodium formate (0.2 *M*), methanol (0.94 *M*), hydrogen peroxide (0.1 *M*), and DMPO (0.08 *M*) gave rise to the growth of spin-adducts **2** and **3**, Fig. 1. The ratio of the initial slopes, i.e. $(d[\mathbf{2}]/dt)/(d[\mathbf{3}]/dt)$, was 1.28 and hence $k_2/k_8 = 6.0$, eq. [10]. Taking $k_8 = 4.8 \times 10^8$ M^{-1} s^{-1} (13) yields $k_2 = 2.9 \times 10^9$ M^{-1} s^{-1}, in good agreement with the literature value of 2.7×10^9 M^{-1} s^{-1}. In a similar experiment k_1/k_8 was found to be 5.4 and hence $k_1 = 2.6 \times 10^9$ M^{-1} s^{-1}, which again is in excellent agreement with the value of 2.7×10^9 M^{-1} s^{-1} previously reported (7). Hence the ratio $k_1/k_2 = 0.90$ obtained in this work is in good agreement with the ratio of 1.0 obtained from literature data (7, 13), and is at variance with the value of 0.23 obtained by Lown and Chen in their steady-state approach.

To summarize, our results indicate that the ratio of rate constants for ·OH trapping by DMPO with respect to that for the reaction of ·OH with HCO_2^-, i.e. k_1/k_2, cannot be accurately determined by the steady-state technique (1). By contrast, an approach in which the growth of spin adducts as monitored directly gave a value for k_1/k_2 which was in excellent agreement with literature data.

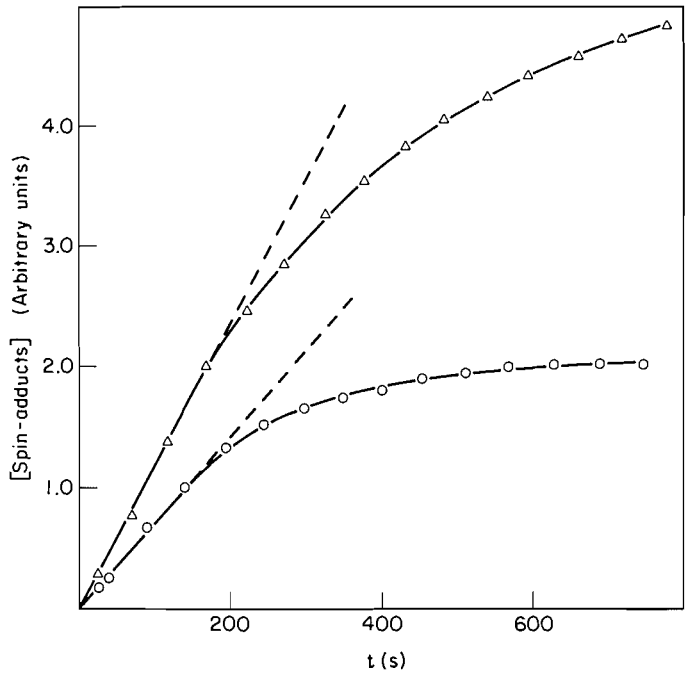


FIG. 1. Plots of the growth in concentration of spin adducts **2** (△) and **3** (○) vs. time after the start of radical generation ($t = 0$).

Photochromism of spiroindolinonaphthoxazine. I. Photophysical properties

NORI Y. C. CHU

Research and Development Laboratories, Vision Care and Safety Products Division, American Optical Corporation, Southbridge, MA 01550, U.S.A.

Received June 15, 1982

NORI Y. C. CHU. Can. J. Chem. **61**, 300 (1983).

A solution of spiroindolinonaphthoxazine in a common organic solvent shows profound photochromic effect. The colorless form in ethanol displays three absorption bands (~320, 235, 203 nm) in the ultraviolet region of the spectrum. The absorption spectrum of the colored metastable form shows two prominent absorption peaks at 612 and 578 nm. The triplet state energy level of the colorless form is estimated to be in the range from 2.4×10^4 to 2.1×10^4 cm^{-1} by the triplet–triplet energy-transfer method. There exists a thermal equilibrium between the colorless and colored forms. From the measurement of absorbance of the colored form at different temperatures, the standard enthalpy of equilibrium is obtained ($\Delta H^0 = 1500$ cm^{-1}). The thermal decay of the colored form to the colorless form depends strongly on temperature. The decay rate increases three times for every 10°C increase in temperature. From these temperature dependence studies of the thermal decay rate, the thermal energy barrier for the colored metastable state to decay to the colorless form is determined to be 6.9×10^3 cm^{-1}.

NORI Y. C. CHU. Can. J. Chem. **61**, 300 (1983).

La spiroindolinonaphthoxazine en solution dans un solvant organique ordinaire montre un effet photochimique marqué. La forme incolore dans l'éthanol présente trois bandes d'absorption (~320, 235, 203 nm) dans l'ultraviolet. Le spectre d'absorption de la forme métastable colorée montre deux pics de forte intensité à 612 et 578 nm. On évalue que le niveau d'énergie de l'état triplet de la forme incolore est de l'ordre de $2{,}4 \times 10^4$ à $2{,}1 \times 10^4$ cm^{-1} selon la méthode de transfert d'énergie triplet–triplet. Il existe un équilibre thermique entre les formes incolore et colorée. A partir des mesures d'absorption de la forme colorée à différentes températures, on obtient l'enthalpie standard d'équilibre ($\Delta H^0 = 1500$ cm^{-1}). La désintégration thermique de la forme colorée en la forme incolore dépend fortement de la température. La vitesse de désintégration augmente par un facteur de 3 pour chaque augmentation de température de 10°C. A partir des études de l'influence de la température sur la vitesse de désintégration thermique, on a déterminé la barrière d'énergie thermique de la désintégration de la forme métastable colorée en la forme incolore. Cette barrière est de $6{,}9 \times 10^3$ cm^{-1}.

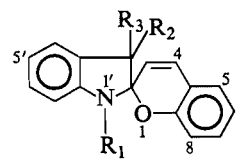
Introduction

The photochromism of spiroindolinobenzopyrans, **1**, is well known and has been thoroughly documented in a comprehensive review article by Bertelson (1). This review article integrates scattered information existing in technical reports, patent literature, and scientific journals to give a unified picture of the photochromism of spiroindolinobenzopyrans up to 1969. Since then, further understanding of the detailed mechanism of photocoloration has been greatly advanced by Russian workers (2, 3).

In contrast to spiroindolinobenzopyrans, of which hundreds have been synthesized, there is almost no information existing on a very closely related class of compound — spiro[indoline-2,3′-[3*H*]naphth[2,1-*b*][1,4]oxazine], **2**. The photochromism of this class of compound was first reported by Fox (4). He observed that the toluene solution of the parent compound — 1,3,3-trimethylspiro[indoline-2,3′-[3*H*]naphth[2,1-*b*][1,4]oxazine], **3** — and its 5-chloro derivative becomes blue in color upon irradiation by ultraviolet (uv) light at 10°C. Subsequently, 5-methyl, 5-methoxy, 1-carboxyethyl, and 1-cyanopropyl derivatives were reported to be photochromic in two patents by Ono *et al.* (5, 6).

The present work was undertaken with the aim of elucidation of the spectral properties and the electronic energy levels of **3** both in the colorless and colored form, the kinetics of the thermal decay of the colored form, and the thermodynamic parameters of **3**.



1, $R_1 = R_2 = R_3 = H$

Experimental section

Materials

Compound **3** was prepared by reacting 1-nitroso-2-naphthol (18 g; Fisher) in MeOH (200 mL) under reflux with a solution of 1,3,3-trimethyl-2-methyleneindoline (17 g; Eastman) in MeOH (50 mL) which was added over a period of 10 min. After refluxing for 1 h, the reaction mixture was cooled. A brown solid precipitated, which was filtered and washed with plenty of methanol and yielded 15 g of product. The product was purified by repeated charcoal treatment and recrystallization from acetone, mp 124–125°C (lit. 122–124°C) (4);

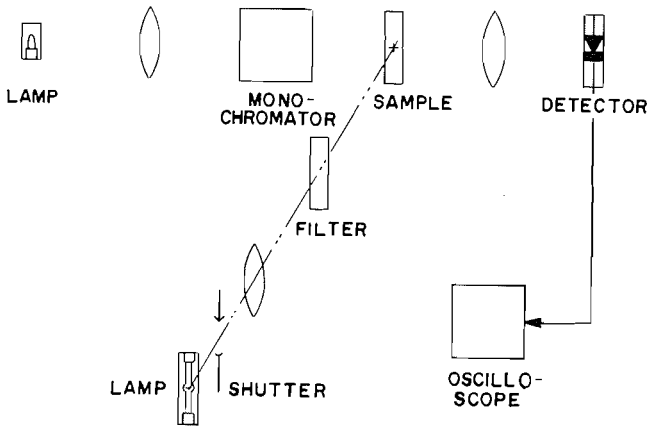

FIG. 1. Schematic diagram of the apparatus used for the kinetics measurements.

ir (KBr): 3054, 2961, 1619, 1605, 1589, 1506, 1484, 1452, 1438, 1421, 1381, 1358, 1297, 1271, 1242, 1073, 1028, 1000, 962, 813, 751, 740 cm^{-1}.

All the solvents used were either reagent or spectroscopy grade and were used without further purification.

The set-up for kinetics measurements

A schematic representation of the basic set-up is illustrated in Fig. 1. The light from the monitoring lamp (a 15 W microscope lamp) passed through a monochromator (Bausch & Lomb, 33-86-02) with the slit set at 610 nm for the maximum absorption of the colored form of **3**. The uv light from a 100 W Hg lamp was selected by using a Corning 7-37 glass filter and was used to activate the photocoloration of the photochromic solution. The variation in the monitoring light intensity due to the absorption by the colored form was detected by a Si photodiode. The output of the photodiode was displayed on an oscilloscope (Tektronix, Type 535A). The temperature of the sample in the water-jacketed cell was regulated by a Haake constant temperature bath unit.

General

The absorption spectra were recorded on a Cary 14 spectrophotometer. For low temperature measurements, either a Dry Ice – CH_2Cl_2 slush or liquid nitrogen was used. The absorption spectrum of the colored form was obtained by first irradiating the sample at low temperature with the uv from a 100 W Hg lamp filtering through a Corning 7-37 glass filter and then recorded the spectrum of the irradiated sample on a Cary 14 spectrophotometer. No error was introduced by this method since the thermal decay rate of the colored form at the Dry Ice – CH_2Cl_2 slush temperature (or lower) was negligible.

The infrared spectrum was recorded on a Perkin-Elmer 180 spectrophotometer and the melting point was determined on a Fisher-Johns melting point apparatus. The emission measurements were made on a Perkin-Elmer spectrophosphorimeter MPF-44B. In the determination of the triplet state energy levels of **3** by the triplet state sensitization, all the samples were degassed by the freeze–pump–thaw method.

Results

Absorption spectrum of the colorless form

A 3.26×10^{-5} *M* solution of **3** in ethanol is colorless and shows three groups of absorption bands in the ultraviolet region which are shown in Fig. 2. The first group in the region from 380 nm to 280 nm has moderate absorption intensity. There are three absorption peaks in this region: 345 nm ($\epsilon = 4.76 \times 10^3\ M^{-1}\ cm^{-1}$), 317 nm ($\epsilon = 6.78 \times 10^3\ M^{-1}\ cm^{-1}$), and 297 nm ($\epsilon = 6.53 \times 10^3\ M^{-1}\ cm^{-1}$). The other two absorption groups in the far ultraviolet reigon are very intense. The molar absorptivity of the absorption peak at 235 nm is $5.43 \times 10^4\ M^{-1}\ cm^{-1}$ and is $4.41 \times 10^4\ M^{-1}\ cm^{-1}$ for the peak at 203 nm.

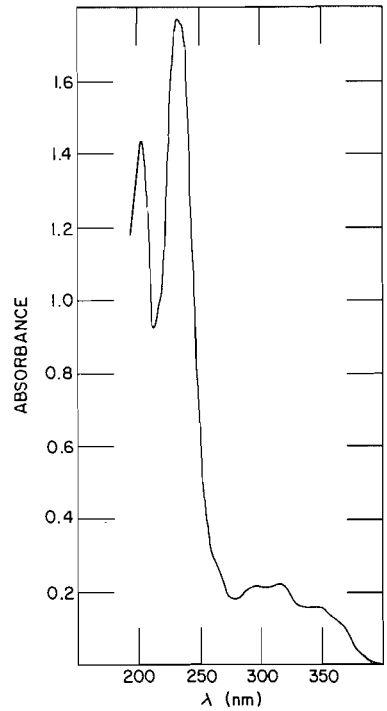

FIG. 2. The absorption spectrum of a 3.26×10^{-5} *M* solution of **3** in ethanol.

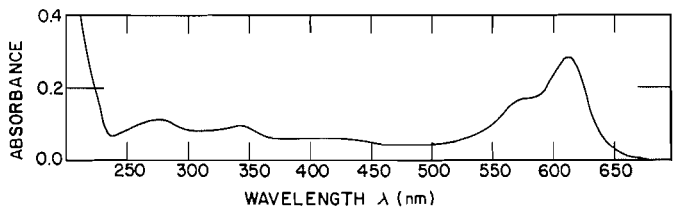

FIG. 3. The absorption spectrum of the colored form of **3** in ethanol at −75°C (3.47×10^{-6} *M*).

The positions of these absorption peaks do not change when a nonpolar solvent such as 3-methylpentane is used. On cooling to 77 K, the absorption spectrum does not show much increase in structure.

Absorption spectrum of the colored form

It is difficult to measure the complete absorption spectrum of the colored form at room temperature since its thermal decay is fairly rapid. Besides, the concentration of this metastable colored form cannot be measured. Fortunately, the thermal decay of the colored form decreases rapidly as the temperature is lowered. The decay can be completely stopped at a temperature below −60°C. Thus, a 3.47×10^{-6} *M* solution of **3** in ethanol was cooled by a Dry Ice – CH_2Cl_2 bath in a Dewar to −75°C. The solution was irradiated by a 100 W Hg lamp equipped with a Corning 7-37 glass filter for a period of 15 min to ensure the full conversion to the colored form. The measured absorption spectrum is given in Fig. 3.

The most prominent absorption peaks are at 612 nm and 578 nm with molar absorptivity of $8.1 \times 10^4\ M^{-1}\ cm^{-1}$ and $4.9 \times 10^4\ M^{-1}\ cm^{-1}$, respectively. In addition, three absorption bands at 410 nm ($\epsilon = 1.8 \times 10^4\ M^{-1}\ cm^{-1}$), 343 nm ($\epsilon = 2.7 \times 10^4\ M^{-1}\ cm^{-1}$), and 277 nm ($\epsilon = 3.2 \times 10^4\ M^{-1}\ cm^{-1}$) have been measured.

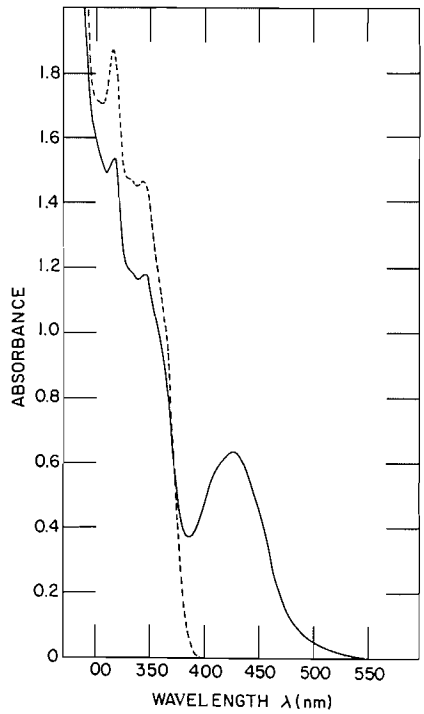

FIG. 4. The absorption spectrum of a degassed solution of **3** (1.79×10^{-4} *M*) in cyclohexane containing 2.24×10^{-3} *M* benzophenone before (- - -) and after (—) uv irradiation.

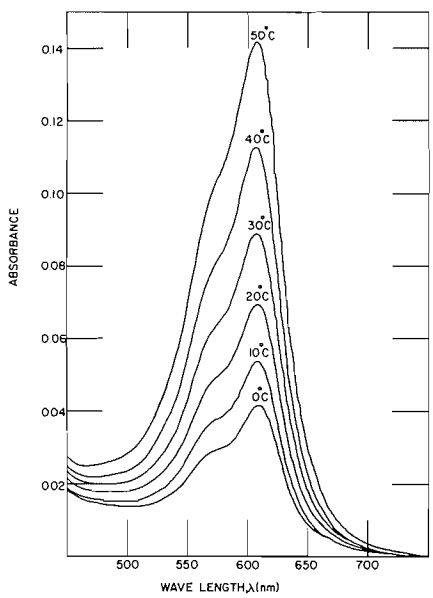

FIG. 5. The absorption spectrum of the colored form of **3** in ethanol (6.2×10^{-3} *M*) at several temperatures.

Triplet state desensitization

In a photosensitization experiment by the energy-transfer method, it was surprising to find that a degassed 1.79×10^{-4} *M* solution of **3** in cyclohexane containing 2.24×10^{-3} *M* benzophenone showed an additional absorption peak at 428 nm after 20 min uv irradiation by a 200 W Hg lamp filtered through a Corning 7-37 filter. This is shown in Fig. 4. In the meantime, the absorption peak height of **3** decreased. This new absorption peak at 428 nm was due to the photosensitized decomposition product of **3** by benzophenone since a control experiment containing either **3** or benzophenone alone did not show this additional peak under the same experimental conditions. As a matter of fact, no change in the absorption spectrum was observed for a solution of **3** or benzophenone in cyclohexane even after 8 h of irradiation. This photosensitized decomposition could still be observed even if the concentration of benzophenone was decreased by a factor of 10 to 2×10^{-4} *M*.

However, no photosensitized decomposition was observed when 2′-acetonaphthone (1.11×10^{-3} *M*) was used even after several hours of uv irradiation.

The compound responsible for the 428 nm absorption peak was a photosensitized decomposition product of **3**. This interpretation is further supported by the fact, that, besides the control experiment aforementioned, the peak height of the 428 nm absorption band increases in proportion to the decrease in height of the absorption peaks of **3**. Work is in progress trying to determine the precise nature of this compound and this will be reported in future.

Temperature dependence of the absorption of the colored form

There exists a thermal equilibrium between the ground states of the colorless and colored form. This is evident from the fact that the solution of **3** in ethanol becomes progressively bluer in color as the concentration is increased. Moreover, this thermal equilibrium is strongly temperature dependent. Thus, the ethanol solution of **3** is not only photochromic but also thermochromic. This thermochromic effect is illustrated in Fig. 5.

Kinetics of the thermal decay

The kinetics of photocoloration and thermal decay was measured by placing 0.50 mL solution of **3** in ethanol (1.35×10^{-4} *M*) in a 1 cm water-jacketed cell. By setting the slit of the monochromator at the maximum absorption of the colored form (610 nm), the change in the monitoring light intensity was easily followed by an oscilloscope. Before photocoloration, the zero absorption was recorded since the absorption of the colored form due to thermal equilibration at this concentration was negligible. Upon activation by the uv light of a Hg lamp, the absorption of the colored form increased and thus, decreased the monitoring light intensity. The thermal decay was then recorded after the photoequilibration was obtained by closing the shutter. An oscillograph representing a typical photocoloration and the thermal decay is shown in Fig. 6.

Discussion

The position of low-lying electronic excited states

The absorption spectrum of the colorless form of **3** in ethanol as displayed in Fig. 2 shows three major absorption bands. From the value of the molar absorptivity of these bands, they can be safely assigned as $\pi^* \leftarrow \pi$ transitions. This is supported by the fact that the absorption of the colorless form of III is very similar to that of 1,3,3-trimethylspiro[indoline-2,3′-[3]-naphtho-[2,1-*b*]pyran], **4**, the precise counterpart in the spiropyran series. The absorption transitions of **4** have been assigned by Tyer and Becker by comparing the spectral data of **4** with those of the appropriate chromene and indoline models (7). As in the case of **4**, the absorption peaks at 345 nm and 317 nm can be assigned to transitions localized on the oxazine half of the molecule. However, the transition at 297 nm could well have contributions from both oxazine and indoline halves of the molecule. Due to their high molar absorptivity and similarity to the indoline absorption, the transitions at 235 nm and

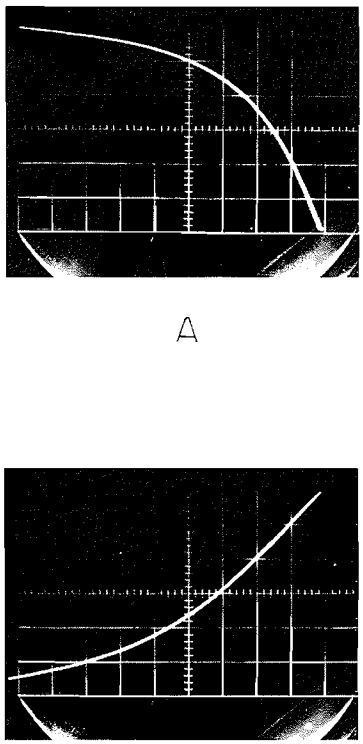

FIG. 6. The kinetics of photocoloration, *A*, and thermal decay, *B*, of a 1.35×10^{-4} *M* solution of **3** in ethanol at 20°C (20 mV/div, 1 s/div, V_0 = 270 mV).

203 nm are characteristically indoline transitions.

The absorption spectrum of the colored form of **3** in ethanol at −75°C is given in Fig. 3. The molar absorptivity of the 612 nm peak is 8.1×10^4 M^{-1} cm^{-1} (based on concentration measured at 20°C). If the contraction in volume of ethanol is corrected, then the molar absorptivity becomes 7.3×10^4 M^{-1} cm^{-1}. This is in good agreement with 6.7×10^4 M^{-1} cm^{-1} obtained for **4** (8). Upon further cooling to −196°C, the absorption spectrum of the colored form of **3** does not show any change. This is in contrast to **4** and many spiropyrans which show three distinct colored modification absorptions at low temperature (1, 9).

It is interesting to note that a hypsochromic effect of shifting the absorption maximum of the colored form of III to 555 nm occurs when cyclohexane is used as a solvent.

A well purified and freshly prepared sample of **3** in ethanol does not show any luminescence. Even at −77 K, the conversion to the colored form proceeds efficiently. Thus the location of the lowest triplet state cannot be directly measured. However, we are able to roughly measure the position of the triplet state of the colorless form from energy-transfer experiments. In a photosensitization experiment, it was surprisingly found that benzophenone (2.24×10^{-3} *M* in cyclohexane) catalyzes the photodecomposition of **3** drastically. However, no photosensitized decomposition can be detected when 2′-acetonaphthone (1.11×10^{-3} *M* in cyclohexane) is used, even after prolonged uv irradiation. Thus, the triplet state of the colorless form of **3** lies between 2.4×10^4 cm^{-1} and 2.1×10^4 cm^{-1} since the triplet state energy for benzophenone in a nonpolar solvent is 2.4×10^4 cm^{-1} and is 2.1×10^4 cm^{-1} for 2′-acetonaphthone (10).

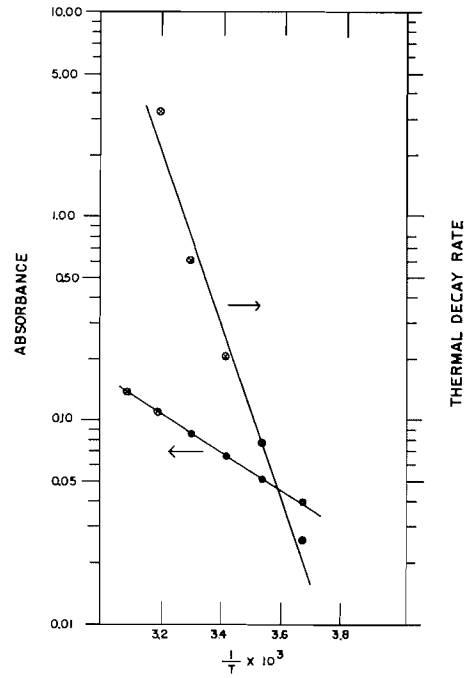

FIG. 7. A plot of the absorbance of the thermal equilibrated colored form and the thermal decay rate versus $1/T$.

The energy of the lowest triplet state of the colorless form of **4** is not known. An emission located at 720 nm from a solution of **4** in EPA at 77 K was assigned to a π,π^* triplet state of the colorless form of **4** (11), but later was reported to be a spurious one arising from an impurity (12).

The phosphorescence of 1′,3′,3′-trimethylspiro[2*H*-1-benzopyran-2,2′-indoline], **5**, in polystyrene and poly(methyl methacrylate), PMMA, has been observed and found to be located at 2.29×10^4 cm^{-1} in PMMA and 2.03×10^4 cm^{-1} in polystyrene (13). Since there is a bathochromic shift of 3.6×10^3 cm^{-1} of the singlet state energy when the conjugation is extended from **5** to **4**, the corresponding shift in the triplet state energy should not be greater than this amount. Therefore, the lowest triplet state of **3** and **4** is likely to be located in the vicinity of 2.0×10^4 cm^{-1}. This is a reasonable estimate since **3** and **4** are a perturbed phenanthrene system.

The energy diagram of the ground states

There exists a thermal equilibrium between the colorless form and the colored form of **3**. This is evident from the fact that a relatively concentrated solution of **3** is bluish in color, i.e. shows a colored form absorption. Furthermore, the intensity of the blue color increases as the temperature of the solution is increased. This phenomenon is shown in Fig. 5.

According to the law of thermodynamics, the standard enthalpy of this equilibrium reaction can be calculated using the following equation:

$$[1] \quad \log K_{eq}(T_2) - \log K_{eq}(T_1) = -\frac{\Delta H}{2.3R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$

A straight line should be obtained when the absorbance of the colored form is plotted against $1/T$ as shown in Fig. 7. In Table 1, the value of the absorbance at different temperatures is reported and from the least-square fitting the standard enthalpy of reaction, ΔH^0, is calculated to be 1.5×10^3 cm^{-1}.

By virtue of its photochromism, the metastable colored form

reverts to the colorless form upon removing the activating uv light. This is clearly illustrated in Fig. 6. This thermal decay follows a first order kinetics as shown in Fig. 8. The calculated

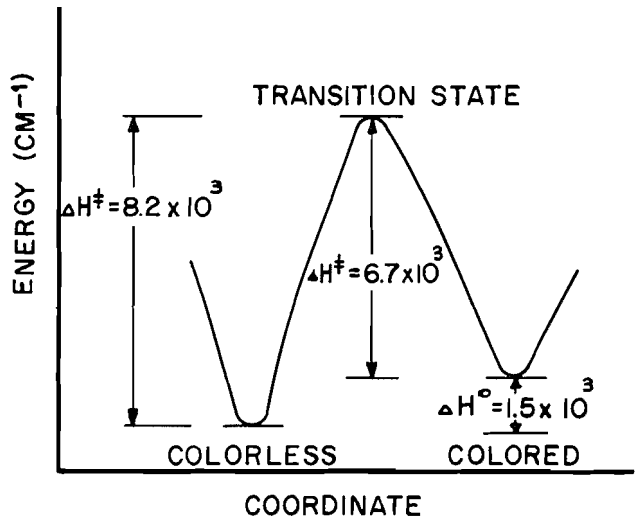

FIG. 9. The energy diagram of the ground states of **3**.

least-square fitting values at different temperatures are given in Table 1.

According to the Arrhenius Equation

$$[2] \quad \log k = -\frac{E_a}{2.3R}\left(\frac{1}{T}\right) + \log A$$

the activation energy for the transition, E_a, can be calculated. In eq. [2], A is the frequency factor. A plot of the thermal decay rate k versus $1/T$ is shown in Fig. 7. The calculated thermal barrier for this transition is 6.9×10^3 cm^{-1}.

The activation energy E_a is related to the activation enthalpy $\Delta H^{\ddagger}$ by the equation

$$[3] \quad \Delta H^{\ddagger} = E_a - RT$$

Thus, at $T = 293$ K, $\Delta H^{\ddagger} = 6.7 \times 10^3$ cm^{-1}.

In Fig. 9, an energy diagram of the ground states of the colored and colorless forms is given to illustrate their interrelations.

Finally, a comparison of the photophysical properties and thermodynamic functions of **3** and **4** is given in Table 2.

TABLE 2. The photophysical properties and thermodynamic functions of **3** and **4**

Compound	S_{Cl}^{1} [a]	S_{Cl}^{2} [a]	T_{Cl}^{1} [a]	S_{C}^{1} [a]	ΔH^{0}	E_a	k (s^{-1})

The use of localized and delocalized orbitals in a Rydberg expanded correlation analysis of the cycloaddition of ethylene

EARL M. EVLETH AND EMIL KASSAB

Centre de Mécanique Ondulatoire Appliquée, 23 rue du Maroc, Paris 75019, France

Received August 31, 1981[1]

EARL M. EVLETH and EMIL KASSAB. Can. J. Chem. **61**, 306 (1983).

Rydberg expanded orbital and state correlation diagrams are shown for the classical cycloaddition of ethylene. The diagrams are first developed at the localized valence MO level and the origins of the S^{**}-bitriplet correlations are shown. When extended to the Rydberg level, the localized state correlation diagram shows that the $\pi 3s$ Rydberg singlet state of ethylene can interact with the ground state of another ethylene to directly yield the same S^{**} surface as found in the valence-level-only diagram. In this manner the Rydberg state eventually derydbergizes.

EARL M. EVLETH et EMIL KASSAB. Can. J. Chem. **61**, 306 (1983).

Les diagrammes de corrélation des OM et ceux des états étendus au niveaux Rydberg sont montrés pour la cycloaddition classique de l'éthylène. Les diagrammes sont d'abord developpés au niveaux des OM localisées de valence et les origines de la corrélation de bitriplet-S^{**} sont montrées. Lorsque le diagramme des états est étendu aux états Rydberg, on montre que l'état Rydberg $\pi 3s$ de l'éthylène peut interagir avec l'état fondamental de l'éthylène à travers la même surface S^{**} produit directement et finira par acquérir un caractère de valence.

Introduction

Recently, there has been an expanded interest in theoretically rationalizing the photochemistry of small molecules whose lowest excited states are Rydberg in character (1–5). The theoretical methods used in these analyses are both computational and descriptive. Because of the expanded valence and Rydberg basis sets needed to adequately computationally treat excited state surfaces, *ab initio* computations are presently limited to small systems. To date, semi-empirical methods (6–8) either have failed to duplicate the known Rydberg characters of the excited states of small molecules (e.g. NH_3) or indicate (9) that there may not be a broadly applicable parameterization scheme extendable to large systems. Therefore, it is important to develop descriptive methods using Rydberg extended correlation diagrams which will permit analyzing systems too large for reliable computations. Even in those cases where computations are realizable, such analyses will permit establishing, *a priori*, the minimal Rydberg basis sets necessary to correlatively treat a particular excited state surface.

Here, we will develop the Rydberg extended correlation diagrams for the classic case of the $2s + 2s$ cycloaddition of two ethylenes to give cyclobutane. There are several reasons for this choice. First of all, the system is classic and familiar to both theoretical and non-theoretical chemists. Therefore, any Rydberg extension of orbital and state correlation diagrams will build on that previous knowledge. Secondly, we will demonstrate that in spite of previous work in this area, the actual relationship between the classical correlation diagrams and the real experimental situation needs considerable clarification. Thirdly, since Rydberg states are or may be the lowest lying singlet states for ethylene (10) and cyclobutane (1), it is obvious that the correlation diagrams must be Rydberg expanded if they are to contain some reality component at the final state level.

With regard to the general area of Rydberg extended correlation diagrams we recommend that the reader thoroughly study the simple but conceptually and methodologically complex NH bond rupture surfaces in the excited states of NH_3 (3, 4, 11, 12). In particular, the introduction of Rydberg orbitals into either computations or correlation diagrams generates a situation in which, depending on the symmetry of the molecular transformation, certain reactant Rydberg MO's (or molecular states) will evolve to product valence MO's (or molecular states). The MO derydbergizations (13) are an intrinsic feature of the united atom correlation diagrams (14). The concept of derydbergization is central in the rationalization of how a Rydberg excited reactant state adiabatically relaxes to a product valence excited or ground state.

We will develop our subject in the following manner. We will first review the known photochemical, energetic, and theoretical factors. Secondly, we will detail the conceptual traps that exist in the classical valence-level-only delocalized MO and state correlation diagrams. Next, we will show how these traps are avoided using localized MO's and how this modifies the state correlation diagrams. Finally, we will Rydberg expand both delocalized and localized MO diagrams and show a first order modification of the state correlation diagrams.

I. Known photochemical, energetic, and theoretical factors

We will mainly develop the subject from the viewpoint of the singlet photocycloaddition of two ethylenes (or simple olefins) to yield cyclobutane. In experimental fact, cyclobutanes represent a minor photoproduct in both the gas (especially) and condensed phase direct photolysis of ethylene and simple olefins (15–17). In the 2-butenes (18) the minor but stereospecific formation of various cyclobutanes is strongly perturbed by minor dilution of the neat systems. This indicates that the competitive photoprocesses are dominating these systems. In fact, the condensed phase photochemistry of a number of simple olefins is dominated by monomolecular events: *cis–trans* isomerization, 1,3-sigmatropic shifts, carbene formation, etc. (16).

In ethylene, experimental and theoretical work show that of the first two Franck–Condon singlet excited states to have $\pi 3s$ and $\pi\pi^*$ characters, respectively (7.1 and 7.4 eV (10, 19). The

lowest state is fully Rydberg in character and even the classical $\pi\pi^*$ state has to be theoretically characterized as being partially Rydberg (intravalent (20)). Likewise, there are a series of $\pi 3p_{x,y,z}$ Rydberg states at only slightly higher energies (ca. 8 eV) (21, 22). Theoretically, there is an infinite number of Rydberg states merely in the energy region between these states and the ionization potential of the molecule. The possible role of any other valence excited states in this energy region becomes problematic since they may not theoretically exist, being submerged in a Rydberg sea. In any case, for practical reasons we will limit our discussion to the $\pi 3s$ and $\pi\pi^*$ monomer states. There is, however, an infinite separation dimer state which lies in the same energy region being conceptually described as two $\pi\pi^*$ triplets. Its Franck–Condon energy can also be estimated to be in the 8 eV region (23). Although the $\pi 3s$ state will retain near-planar geometry, both the $\pi\pi^*$ singlet and triplet states will relax to their more stable 90° twist configurations, having energies in the 5.6 and 2.8 eV regions, respectively (24). Therefore, for ultimate correlation purposes, the relaxed $\pi\pi^*$ singlet and bitriplet states have about the same energy.

Previous computational and correlative treatments (24–27) of the cycloaddition of ethylene have rationalized the photodimerization reaction in the following manner. The initial step, after photoexcitation of the monomer, yields the formation of an exciplex: $E_1^* + E_2 = S^*$, where E_1^* and E_2 represent the planar $\pi\pi^*$ excited state of ethylene 1 and the ground state on ethylene 2. The S^* potential energy surface eventually crosses with another "doubly excited" S^{**} exciplex surface which has a deep minimum in the region of the HOMO–LUMO crossing region (24). In this region, the ground state S_0 and the S^{**} state are probably in close proximity. These states also have the same symmetry and configurational properties and ought to be strongly coupled by the nuclear kinetic energy operator (27, 28). Therefore, it is in the HOMO–LUMO crossing region that the non-adiabatic excited state – ground state relaxation should take place (29, 30). The allowed Woodward–Hoffmann photocycloaddition depends on the existence of the S^{**} minimum and not on any possible direct overall correlation between the excited ethylene state and the excited cyclobutane state. A required feature in such a rationalization is that the energy of the S^{**} minimum lies below that of the excited ethylene monomer, E_1^*. However, knowledge of the shapes of the surfaces leading to the S^{**} minimum is also necessary. Unfortunately, calculations in this area (27) were not sufficiently accurate to state with any confidence the relative energies of the S^{**} minimum and the E_1^* state. Based on the above-discussed photochemistry of ethylene and simple olefins, we suspect that the S^{**} minimum is kinetically inaccessible from the 90° energy relaxed form of excited ethylene (31) either because the $S^{**} >$ 5.6 eV or the potential surface leading to S^{**} has a barrier and other monomolecular kinetic events dominate the relaxation. Therefore, one must hypothesize that the photodimerization surface is initiated from species having geometries and energies close to the Franck–Condon values.

This above hypothesis yields several additional complicating factors. First of all, in competition with extremely rapid monomolecular photochemical processes, the bimolecular photodimerization of olefins can only proceed in the condensed phase at very high concentrations (preferably neat). In the condensed phase, any energetic analysis based on gas phase spectroscopic measurements or isolated molecule computations, at whatever theoretical level, will be questionable. This is particularly true as to what are the characteristics of the $\pi 3s$ Rydberg states of olefins in condensed phase. Full resolution of these problems appears experimentally and theoretically inaccessible at this time. Even an adequate valence and Rydberg basis set CISD computation of critical portions of the dimer excited state surfaces, under partial geometry optimization, is not financially feasible at this time. However, given the possible role of $\pi 3s$ Rydberg states in the condensed phase photochemistry of olefins (16), a Rydberg extended correlation analysis of this system is a minimum necessity.

II. Comparison of the valence orbital delocalized and localized correlation diagrams

A. The delocalized view

There exists a major conceptual problem in attempting to visualize the photodimerization of ethylene in delocalized valence orbital terms. At large ethylene(E_1) – ethylene(E_2) separations four delocalized π-orbitals can be written using the localized π_1 and π_2 MO's. These are: $\pi_1 + \pi_2$, $\pi_1 - \pi_2$, $\pi_1^* + \pi_2^*$, and $\pi_1^* - \pi_2^*$, these having symmetries SS', SA', AS', and AA' in classical Woodward–Hoffmann terms (24). At large E_1–E_2 separations, the first two MO pairs are degenerate, as are the last two. Likewise, the monoexcited configurations that one can construct also *appear* diagramatically degenerate (24). Two separate state biconfigurational wavefunctions having different symmetries can be generated:

$$\Psi(AA') = c_1[SA' \rightarrow AS'] + c_2[SS' \rightarrow AA']$$

and

$$\Psi(AS') = c_3[SA' \rightarrow AA'] + c_4[SS' \rightarrow AS']$$

The total SS' state polyconfigurational function is even more complex

$$\Psi(SS') = c_1'[SS'^2SA'^2] + c_2'[SS'^2AS'^2] + c_3'[SA'^2AS'^2] + c_4'[SS'^2AA'^2] + c_5'[SA'^2AA'^2] + c_6''[SS'SA'AS'AA'] + c_6^b[SS'SA'AS'AA']$$

where c_6^a and c_6^b are two determinately different forms of the same four open shell configuration. At large E_1–E_2 separations the configurations c_2' through c_6^b all appear (deceptively) degenerate in a delocalized orbital correlation diagram. These pseudo-degeneracies all disappear as the distance between E_1 and E_2 diminishes. In the region of the HOMO–LUMO crossing ($SA' \rightleftarrows AS'$) the configurational form of the lowest singly excited surface, S^* (AA') is simple ($c_1 \rightarrow 1$) while the ground and "doubly" excited surfaces, S_0 and S^{**}, are the biconfigurational pairs: $c_1'[SS'^2SA'^2] \mp c_2'[SS'^2AS'^2]$, $c_1' = c_2'$.

There is no conceptual problem with the delocalized model at small E_1–E_2 distances. However, at large E_1–E_2 distances the delocalized model does not, without further analysis, indicate how the S^* and S^{**} surfaces correlate with real monomer or dimer states of excited ethylene. Furthermore, if the diagrams are to be used as computational guides, there are certain technical factors to consider if one wishes to impose delocalized symmetry orbitals on a particular system at large separations. Finally, from an aesthetic standpoint, one might wish to begin the analysis of this system from the standpoint of a localized excited ethylene initiating its interaction with a ground state ethylene at large distances and following the surface evolutions from this standpoint. Such an approach is computationally possible (27) by merely allowing the initial geometries of E_1 and E_2 to be different. In this case, the $2s + 2s$

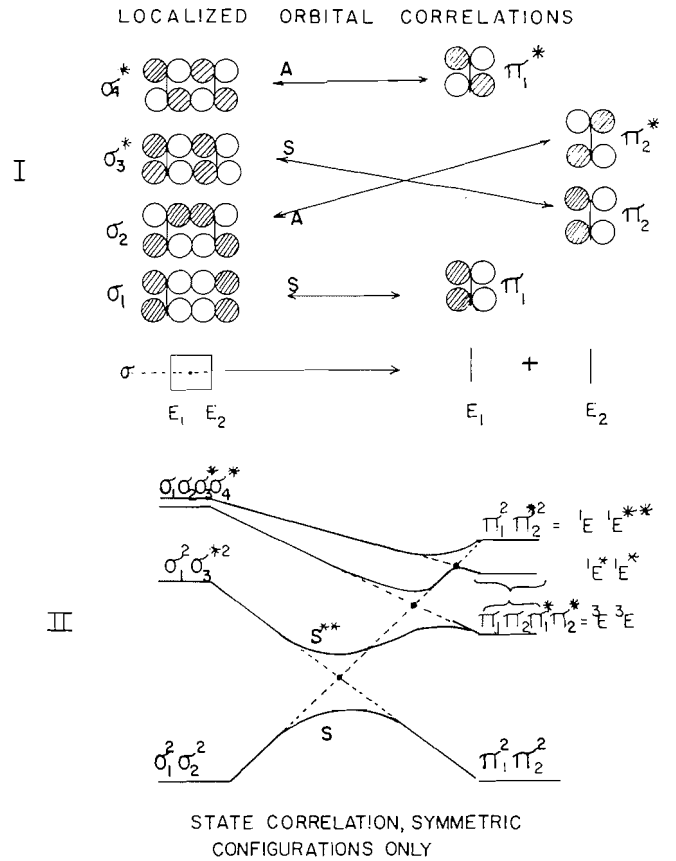

FIG. 1. I. Correlation between the delocalized cyclobutane and localized two ethylene molecular orbitals. See ref. 24 for the delocalized–delocalized correlation. II. Symmetric states only correlation diagram showing that the S^{**} state eventually terminates as two ethylene triplets by a second avoided crossing (•).

face-to-face cycloaddition would be initiated in C_{2v} symmetry at large E_1–E_2 separations, reach D_{2h} symmetry in the HOMO–LUMO crossing region, and terminate as D_{4h} at the planar cyclobutane configuration. This would require a passage from a localized to a delocalized model ($C_{2v} \rightarrow D_{2h}$) which we will now discuss.

B. The localized view

The localization procedure is a simple one and merely assumes that the CC distance in E_1 is smaller than E_2 at large E_1–E_2 separations. On the other hand, delocalized orbitals are retained on cyclobutane. This procedure will produce the following localizations at the E_1–E_2 large separation limit: $\pi_1 + \pi_2 \rightarrow \pi_1$, $\pi_1 - \pi_2 \rightarrow \pi_2$, $\pi_1^* + \pi_2^* \rightarrow \pi_2^*$, and $\pi_1^* - \pi_2^* \rightarrow \pi_1^*$. This localization will computationally occur because the absolute values of MO coefficients mixing the various localized π-orbitals will no longer be the same by symmetry (e.g. $c_1\pi_1 + c_2\pi_2$). The overall cyclobutane localized two ethylene MO correlation diagram is shown in Fig. 1, I. This MO correlation diagram appears similar to that obtained in the delocalized one in showing a required HOMO–LUMO inversion. It should be first noted under this localization procedure, all single excited configurations belong to the same representation, A. The general state function becomes: $\Psi(A) + c_1[\pi_1 \rightarrow \pi_1^*] + c_2[\pi_2 \rightarrow \pi_2^*] + c_3[\pi_1 \rightarrow \pi_2^*] + c_4[\pi_2 \rightarrow \pi_1^*]$. It is now clear that the four-fold-appearing diagrammatic degeneracy in the AA' and AS' delocalized states is deceptive. Actually two of these states are charge transfer pairs, $E_1^+E_2^- \mp E_1^-E_2^+$, which will lie at considerably higher energies than the excimer pairs, $E_1^*E_2 \mp E_1E_2^*$. The localized modified description of these excimer pairs merely decouples the two functions, giving $c_1E_1^*E_2 + c_2E_1E_2^*$. The amount of excitation localization on one of the ethylenes depends on the geometry difference between E_1 and E_2 and their separation distance. The most stable excimer state (B_{1g} in D_{2h}) results from a head-to-tail orientation of the individual ethylenes $\pi\pi^*$ transition dipoles ($\Updownarrow$). This excimer state is the one which eventually evolves along the S^* surface (27). The localized and delocalized views of the collapse of excited ethylene to the S^* exciplex are sufficiently similar that an overall state correlation diagram has not been displayed.

The diagrammatic behavior of the symmetric state surface is considerably modified at the large E_1–E_2 separation limit using the localized model. First of all, the lowest symmetric state of the dimer has a four open shell bitriplet configuration, $\pi_1\pi_2\pi_2^*\pi_1^*$, ($^3E_1{}^3E_2$), as shown in Fig. 1, II. The S^{**} surface must display two avoided crossings, one of which is that previously observed in delocalized diagram (24) between the $\sigma_1^2\sigma_2^2 \leftrightarrow \pi_1^2\pi_2^{*2}$ and $\sigma_1^2\sigma_3^{*2} \leftrightarrow \pi_1^2\pi_2^2$ correlations. The other avoided crossing exists between the former correlation and the $\sigma_1\sigma_2\sigma_3^*\sigma_4^* \leftrightarrow \pi_1\pi_2\pi_2^*\pi_1^*$ correlation. The overall first order configurational wavefunction of the S^{**} surface is tri- not bi- or polyconfigurational as implied either by a 2 × 2 CI (32) or the above-discussed diagrammatically deceptive delocalized SS' function. This triconfigurational form is:

$$\Psi(S, S^{**}) = c_1[H^2] + c_2[L^2] + c_3[(H\text{-}1)\cdot(H)\cdot(L)\cdot(L\text{-}1)]$$

where H = HOMO, L = LUMO. In the region of the HOMO–LUMO inversion, $|c_1| = |c_2|$, $c_3 \simeq 0$, while at the large separation limit, $c_3 \simeq 1$, c_1, $c_2 \simeq 0$. The ground state surface, S_0, will retain biconfigurational form in the region of the HOMO–LUMO crossing but is essentially monoconfigurational at either the cyclobutane or two ethylene limit. There are several additional nuances to the symmetric state correlation diagram shown in Fig. 1. All the features shown do not have to be physically real. None of the doubly excited cyclobutane configurations shown need to have real corresponding states, their diagrammatic role being to serve as correlation targets for other real states of the system. These real states are the ground state of cyclobutane, ethylene, and the bitriplet state. At the state correlation level, other avoided crossings can be proposed (e.g. with a bisinglet state $^1E_1^*{}^1E_2^*$). However, these other crossings are not of fundamental interest in determining the behavior of the S^{**} surface in either the HOMO–LUMO crossing region or at the E_1–E_2 separation limit. As we will now demonstrate, Rydberg additions to this state correlation will modify the S^{**} surface in an important manner.

III. A Rydberg expanded analysis

A. Construction of the orbital correlation diagrams

Because of the potentially infinite number of Rydberg product and reactant states, the construction of both the orbital and state correlation diagrams must be kept to as simple a level as possible to solve the problem raised. We will concentrate on the diagrammatic fate of the $\pi 3s$ monomer state of ethylene but will expand the subsequent discussion to include other Rydberg states. It is first stressed that the method used in the construction of Rydberg extended polyatomic MO correlation diagrams does not differ essentially from that employed in the united atom diagrams at either the diatomic or polyatomic level (14).

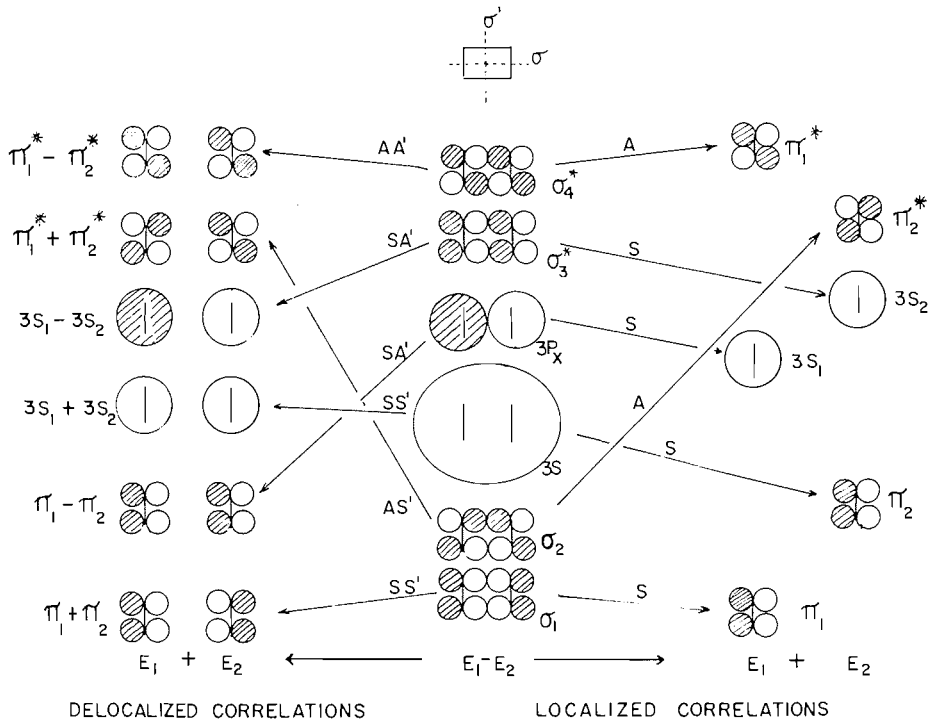

FIG. 2. Rydberg expanded delocalized and localized molecular orbital correlations. The right hand portion of this figure may be compared to Fig. 1, part I.

A recommended first step is to construct a conventional valence-orbital-only Woodward–Hoffmann type MO correlation diagram and subsequently analyze the behavior of the valence-orbital-only state correlation diagram. Next, add the Rydberg components as desired and repeat the sequence, examining the behavior of the state correlation diagram with respect to the real expected reactant and product states of interest. The added Rydberg components must be kept to a minimum, otherwise undue diagrammatic complications appear. In the case examined here, we have decided to keep the detailed analysis at the $3s$ Rydberg orbital level only. However, we will discuss the problem of variance of the diagrammatic behavior with Rydberg basis set.

The previous Rydberg extended orbital delocalized correlation diagram proposed for this system was developed by Wittel (33). Sandorfy did not specifically include Rydberg orbitals in the Woodward–Hoffmann delocalized MO correlation diagram but discussed the consequence of doing so (34). Neither authors constructed state correlation diagrams. At the minimal correlative and computational level, $3s$ orbital are placed on each ethylene, $3s_1$, $3s_2$. However, at the cyclobutane limit this basis set will generate two Rydberg MO's, $3s_1 + 3s_2$ and $3s_1 - 3s_2$, being, $3s$ and $3p_x$ by symmetry. An alternative decision to place only one $3s$ orbital at the molecular center of cyclobutane is insufficient since no Rydberg ethylene states can be generated at infinite separation. The placing of one $3s$ AO at each carbon atom will add a total of four Rydberg MO's ($3s$, $3p_{x,y}$, and $3d_{x,y}$) to the correlation diagram. Likewise, the specific addition of both $3s$ and $3p_{x,y,z}$ base orbitals will produce certain redundancies and overly complicate the final MO and, expecially, the state correlation diagrams. Finally, we have selected to diagrammatically place any Rydberg MO's energetically in between the valence bonding and antibonding MO's. This is generally what is encountered in any MO calculation on smaller systems. Rydberg MO's can be considered as having near-zero orbital energies, either at the closed shell or open shell RHF level of treatment (i.e. conceptually neither bonding nor antibonding.) Therefore our delocalized MO correlation diagram differs from that of Wittel in placing the cyclobutane $3p_x$ MO below the σ_3^* MO (Fig. 2). This placement is crucial in the sense that Wittel's diagram shows only direct Rydberg reactant – Rydberg product correlations without taking into account the possible derydbergization in the correlation diagrams, a factor which we will show is certainly important in the localized correlation.

The most important feature of Fig. 2 is that in both the delocalized and localized MO correlations certain MO's change Rydberg character in evolving from cyclobutane to two ethylenes ($3p_x \rightarrow \pi_1 - \pi_2$, $\sigma_3 \rightarrow 3s_1 - 3s_2$ or $3s \rightarrow \pi_2$, $3p_x \rightarrow 3s_1$, respectively). These Rydbergizations–derydbergizations are not diagrammatic artifacts and will also occur computationally (11, 12). For example, the MO function for the SA' delocalized correlation $3p_x \rightarrow \pi_1 - \pi_2$ will have the overall approximate form: $c_1 [2p_{1a} + 2p_{1b} - 2p_{2c} - 2p_{2d}] + c_2 [3s_1 - 3s_2]$, where the $2p$ valence orbitals are associated with carbons a and b on E_1 and c and d on E_2. At the cyclobutane configuration, $c_2 \gg c_1$ (i.e. the MO is Rydberg in character) and at the two ethylene limit, $c_1 \gg c_2$ (i.e. the same MO is valence in character). Such MO Rydbergizations are well-recognized phenomena in united atom correlation diagrams (14).

An important problem that must be pointed out is that certain portions of Rydberg expanded MO correlation diagrams may not be invariant with additional Rydberg components. For instance, if one decided to add another pair of higher energy $3p_y$ ethylene components, our previous orbital placement rules indicated that this would be inserted between the $3s_1 - 3s_2$ and the $\pi_1^* + \pi_2^*$ components. The two ethylene components would produce $3p_{y1} + 3p_{y2}$ ($3p_y$, AS'), and $3p_{y1} - 3p_{y2}$ ($3d$, AA'), in plane components. The $3p_y$ MO will correlate with σ_2 on

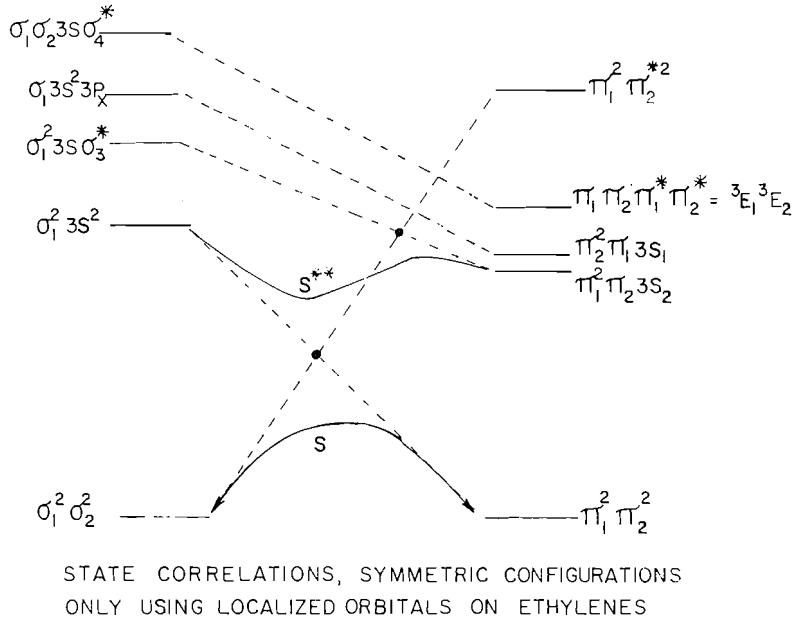

FIG. 3. Symmetric states only correlations showing that the S^{**} may correlate with a Rydberg state of the ethylene dimer.

cyclobutane. On the other hand, the additional higher energy Rydberg components will not affect the cyclobutane $3s$ localized or delocalized MO correlations. Similar variances and invariances are observed in normal united atom correlation diagrams. In a certain sense, it would appear that Fig. 2 is incomplete in not having included the $3p_{y1} + 3p_{y2} \rightarrow \sigma_2$ correlation. The AS' MO is involved in the HOMO–LUMO inversion and will eventually give rise, on the state correlation diagram, to the avoided crossing of the S_0 and S^{**} surfaces. However, this view is deceptive, since in the region of the HOMO–LUMO crossing the AS' MO will be valence and not Rydberg in character (having derydbergized before reaching this geometrical configuration). The AS' correlative behavior in this inversion region will be as if no Rydberg components had been added and the classical valence-orbital-only diagram was valid. Any interest in the Rydberg character of this AS' MO correlation would have to be retained, however, if we were interested in ethylene excited states having $3p_y$ (C—C axis directed) character. We will return to this point later.

B. Construction of the Rydberg expanded state correlation diagrams

Since, as we will show, the critical and most interesting part of the state correlation diagrams occurs using the localized Rydberg expanded MO correlation (Fig. 2) we will give a detailed discussion of Fig. 3. As is evident in Fig. 2, the lowest energy localized excitation has a $\pi 3s$ configuration. As in the previously discussed $\pi\pi^*$ valence-level-only diagram the excimer Rydberg excited states will be paired: $c_1\,[\pi_1^2\pi_2 3s_2] + c_2\,[\pi_2^2\pi_1 3s_1]$. The lowest energy excimer state will have a $\rightarrow\rightarrow$ orientation of the individual $\pi \rightarrow 3s$ transition dipoles (perpendicular to the ethylene plane). The symmetry of this state is S in the localized picture (A_1 in C_{2v}). In Fig. 3, the state configurations shown for these excimer states are considered real states as is the previously discussed bitriplet. However, on the cyclobutane part of the diagram, these doubly excited configurations do not represent real states and merely serve as correlation targets. As discussed just above, the doubly excited cyclobutane configuration, $\sigma_1^2 3s^2$, will derydbergize before reaching the minimum of the S^{**} surface, the avoided crossing region having a behavior just as if there were no Rydberg components in the correlation diagram.

The most important feature in Fig. 3 is that now the S^{**} surface evolves by a series of avoided crossings to the ethylene Rydberg monomer state, $\pi_1^2\pi_2 3s$. In the reverse direction, an ethylene $\pi 3s$ excited state will interact with an ethylene ground state to lead the system automatically onto the S^{**} surface. The critical early avoided crossing shown in Fig. 3 will be described by a configurational function having the conceptual form:

$$c_1[\pi_1^2\pi_2 3s_2] + c_2[\pi_2^2\pi_1 3s_1] + c_3[\pi_1\pi_2\pi_1^*\pi_2^*]$$

In this view, the initial portions of the S^{**} surface will have ethylene $\pi 3s$ character, the overall S^{**} surface wavefunction will derydbergize before reaching the S^{**} minimum. There is, therefore, no conceptual problem in rationalizing how an ethylene Rydberg state adiabatically evolves to the S^{**} minimum.

Analysis of the diagrammatic fate of a possible cyclobutane Rydberg state requires a further Rydberg expanded correlation diagram which we will not detail. However, the lowest A_g excited Rydberg cyclobutane state would probably have a $\sigma(e_u) \rightarrow 3p_{x,y}(e_u)$ configuration and not a doubly excited configuration A_g indicated in the classical correlation diagram. The Rydberg correlation would correlate upwards in energy and cross with the classical $\sigma_1^2\sigma_3^{*2}$ doubly excited configuration. These crossings would be avoided, and this initial cyclobutane $3p$ Rydberg state would also eventually adiabatically evolve into the S^{**} minimum.

Finally, it must be pointed out that attempts to analyze the correlative state behavior using the Rydberg expanded delocalized MO correlation diagram will lead to the same traps at the large E_1–E_2 separation that we discussed with regard to Fig. 1. Some avoidance of these conceptual traps can be accomplished by realizing that for each real monomer state there are pairs of excimer states. Even if one considers only the ethylene singlet monomer state, $\pi 3s$, $\pi\pi^*$, $\pi 3p_{x,y,z}$, this will generate 10 singlet dimer surfaces (plus the bitriplet dimer) having, initially, Franck–Condon energies all in the same energy region (7–8.5 eV). Our analysis indicates that one can limit the analysis to a simpler level in considering the probable evolution of only the S^{**} surface. Evolutions of the S^{**} hyper-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.6 on 09/06/12
For personal use only.

surfaces, however, will be made complicated by the fact that besides ending up in the region of the HOMO–LUMO minimum the system could also relax to give either the energy-relaxed 90° configuration of the singlet $\pi\pi^*$ state or two triplets. The latter relaxation, if it were efficient, would lead to *cis–trans* isomerization quantum yields in excess of unity.

Conclusions

We have demonstrated the utility of localized orbital and state correlation diagrams both at the valence and Rydberg extended level. The addition of Rydberg components to conventional Woodward–Hoffmann diagrams requires care because of the potentially large number of components that can be added and the redundancies in doing so. Finally, we have shown how a molecular Rydberg state can adiabatically evolve to a valence-excited state of the system.

Chiral transformations of D-ribose to 2-(β-D-ribofuranosyl)-L and D-glycine and an anhydroallose hemiacetal used in C-nucleoside synthesis

MORRIS J. ROBINS AND J. M. ROBERT PARKER
Department of Chemistry, The University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received May 19, 1982

MORRIS J. ROBINS and J. M. ROBERT PARKER. Can. J. Chem. **61**, 312 (1983).

Conversion of D-ribose to the epimeric 3,6-anhydro-4,5,7-tri-*O*-benzyl-D-*glycero*-D-(*allo* and *altro*)-heptonamides (**5**) followed published methods. Mesylation of **5** allowed convenient separation of the 2-*O*-methanesulfonyl D-*allo* (**6***a*) and D-*altro* (**6***b*) diasteromers. Individual treatment of **6***a* and *b* with lithium azide in DMF provided the inverted 2-azido D-*altro* (**7***a*) and D-*allo* (**7***b*) products. Acid catalyzed hydrolysis of the amide funciton of **7***a* and *b* followed by catalytic hydrogenolysis of the benzyl protecting and azide groups gave the target glycosyl amino acids, 2-(β-D-ribofuranosyl)-L-glycine (2-amino-3,6-anhydro-2-deoxy-D-*glycero*-D-*altro*-heptonic acid) (**9***a*) and its D-glycine (D-*allo*) epimer (**9***b*).

Deacylation of the known 2-(5-*O*-benzoyl-2,3-*O*-isopropylidene-β-D-ribofuranosyl)-1,3-diphenylimidazolidine (**10***a*) followed by mild acid catalyzed deprotection of the masked aldehyde function of **10***b* gave 3,4-*O*-isopropylidene-2,5-anhydro-D-allose (**11**), a compound prepared previously in racemic form and used in C-nucleoside synthesis.

MORRIS J. ROBINS et J. M. ROBERT PARKER. Can. J. Chem. **61**, 312 (1983).

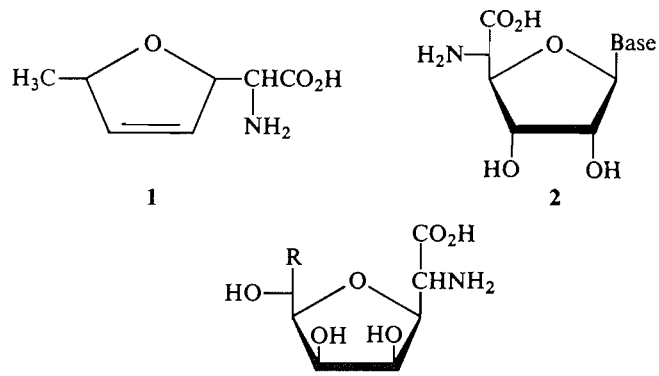
Faisant appel à des méthodes connues, on a effectué la transformation du D-ribose en anhydro-3,6 tri-*O*-benzyl-4,5,7 D-*glycéro* D-(*allo* et *altro*) heptonamides (**5**). La mésylation du composé **5** permet une séparation convenable des diastéréoisomères *O*-méthanesulfonyl-2 D-*allo* (**6***a*) et D-*altro* (**6***b*). Les dérivés **6***a* et **6***b* réagissent chacun avec l'azoture de lithium dans le DMF en conduisant aux produits inversés azido-2 D-*altro* (**7***a*) et D-*allo* (**7***b*). L'hydrolyse de la fonction amide des composés **7***a* et **7***b*, catalysée par un acide, suivie de l'hydrogénolyse catalytique des groupes protecteurs benzyle et azoture permet d'accéder aux acides aminés glycosylés recherchés, soit l'acide (β-D-ribofurannosyl)-2 L-glycine (amino-2-anhydro-3,6 déoxy-2 D-*glycéro* D-*altro*-heptonique (**9***a*) et à son épimère, D-glycine (D-*allo*) (**9***b*).

L'élimination du groupe acyle de la (*O*-benzoyl-5 *O*-isopropylidène-2,3, β-D-ribofurannosyl)-2 diphényl-1,3 imidazolidine (**10***a*) connue, suivie de l'élimination acido catalysée du groupe protecteur de la fonction aldéhyde du composé **10***b*, donne le *O*-isopropylidène-3,4 anhydro-2,5 D-allose (**11**), un composé préparé antérieurement sous forme de mélange racémique et qui est utilisé dans la synthèse du nucléoside-C.

[Traduit par le journal]

A novel amino acid antibiotic named furanomycin (**1**) (see Scheme 1) was reported in 1967 (1). Assignment of the 2,5-*cis* stereochemistry for the glycyl and methyl substituents on the 2,5-dihydrofuran ring was made from ^{1}H nmr coupling constants. Circular dichroism data indicated an L configuration for the α-amino acid fragment. A multistep synthesis of racemic furanomycin that purported to confirm the proposed structure of the antibiotic was communicated in 1975 (2). However, no conclusions regarding the complete absolute configuration of the natural product were reached. We became interested in employing D-ribose as a chiral precursor to effect a stereodefined synthesis of the suggested *cis*-2(*R*),5(*R*)-dihydrofuran structure.

A modified Strecker-type synthesis of C-glycosyl amino acids was reported (3) for the preparation of the basic skeleton of the polyoxin group of nucleoside antibiotics (4) that have a C4′ derivatized sugar component (**2**). Other approaches were used to prepare carbohydrate analogues with an amino acid side chain at C3 (5) and C2 (6). Di-*O*-isopropylidene-D-mannono-1,4-lactone was treated with ethyl isocyanoacetate in the first step of the synthesis of the C1 linked β-D-mannofuranosylglycines (**3***a*) and β-D-lyxofuranosylglycines (**3***b*) (7). Treatment of acetobromoglucose and 3,4,6-tri-*O*-benzoyl-2,5-anhydro-D-allose with 2-phenyloxazolin-5-one gave intermediates that were converted to 2-(β-D-glucopyranosyl)-D,L-glycine and 3-(β-D-ribofuranosyl)-D,L-alanine, respectively (8). We now wish to report applications of the Strecker-type approach developed by Moffatt and coworkers to the synthesis of 2-(β-D-ribofuranosyl)-L-glycine, its



SCHEME 1

D-glycine epimer, and 3,4-*O*-isopropylidene-2,5-anhydro-D-allose.

Acid catalyzed deprotection of 2-(2,3,5-tri-*O*-benzyl-β-D-ribofuranosyl)-1,3-diphenylimidazolidine (**4**) (9) was followed immediately by *in situ* treatment of the resulting aldehyde with aqueous sodium cyanide/potassium carbonate, and then hydrogen peroxide as described (9, 10). The epimeric α-hydroxy amide products (**5**) were obtained in ~90% yield (see Scheme 2). Treatment of **5** with methanesulfonyl chloride in pyridine gave the diastereomeric 2-*O*-mesyl derivatives (**6**) as a solid. Trituration of this mixture with warm ether resulted

in fractionation of the epimers. The insoluble residue (43%) was the more rapidly migrating isomer on thin layer chromatography (tlc, chloroform/ethyl acetate, 1:1, $R_f \sim 0.50$) and was later correlated as the 2(*R*) isomer (**6***a*). Chromatography of the ether supernatant solution gave **6***b* (38%, $R_f \sim 0.47$) contaminated with ~5% of **6***a*. These epimers were distinguished readily by ^{1}H nmr spectroscopy. The signal for the mesyl group appeared at δ 2.91 for **6***a* and 2.86 for **6***b*. The signal for H2 was centered at δ 4.90 (J_{2-3} = 5 Hz) for **6***a* and 4.91 (J_{2-3} = 4 Hz) for **6***b*. These H2 resonances were shifted downfield from those of their 2-hydroxy precursors (**5**). The pseudooctet centered at δ ~ 3.57 for the H7,7′ protons of **6***a* was clearly different from the corresponding multiplet at ~3.55 for **6***b* (see the Experimental).

Infrared (ir) spectra of **6***a* or *b* and all of the subsequently obtained α-substituted amides had the characteristic amide carbonyl stretching band at ~1650 cm^{-1}. Mass spectral fragmentation patterns for **6***a* and *b* were similar with parent ions at *m/z* 555 (M^+) and 556 (M + 1). The M + 1 ion was present in spectra of most of the other α-substituted amide derivatives. Other characteristic ions for **6***a*, *b* appeared at *m/z* 476 (M − SO_2CH_3) and 464 (M − $CH_2C_6H_5$).

Independent treatment of **6***a* and *b* with lithium azide[1] in hot *N*,*N*-dimethyl formamide (DMF) gave the diastereomeric α-azido amides **7***a* and *b* in ~90% yields. Moffatt and co-workers had utilized a parallel sequence in their synthesis of polyoxin compounds (3). They presented a chemical proof of inversion of configuration for the complementary α-azido amides. Indicative evidence supports parallel inversions in the present work. Loss of the mesyl singlet was accompanied by an upfield shift of the H2 nmr signal, and a strong band at 2120 cm^{-1} (R—N_3) appeared in the ir spectra of **7***a* and *b*. The splitting patterns for the H7 and 7′ nmr multiplets of **7***a* centered at δ 3.46 and 3.57 corresponded closely to those of **6***b*, and a similar correspondence of these patterns was observed for **7***b* and **6***a*. The order of melting behavior for **6***a* (mp 173−174°C) and **6***b* (114−115°C) also was inverted for **7***a* (93−94°C) and **7***b* (155−156°C).

Solvolysis of the amide function occurred smoothly (>90% yields) upon heating **7***a* or *b* with a strong acid resin in methanol (10). However, the subsequently obtained α-amino esters were unstable at room temperature and were slowly converted to unidentified (diketopiperazine?) products.

Hydrolysis of the amides **7***a* and *b* proceeded quantitatively in hot hydrochloric acid/dioxane solution to give the syrupy α-azido acids **8***a* and *b*. Hydrogenolysis of the azido function and benzyl protecting groups was effected at 100 psi in ethanol buffered at pH ~ 5 with aqueous ammonium acetate in the presence of an equal weight of 5% palladium on carbon. Complete deprotection was dependent on the efficiency of stirring as well as the quality of the catalyst.[2] The glycosyl amino acids **9***a* and *b* were isolated (in ~50% yields from **7***a* and *b*) by application of the hydrogenolysis residue to a strong acid resin and elution with aqueous ammonia. The L-amino acid (**9***a*) crystallized as a dihydrate that was partially dehydrated by heating *in vacuo* at 56°C. The D-epimer (**9***b*) did not crystallize and was isolated as an amorphous solid. Preliminary attempts to obtain more readily crystallized hydrochloride salts resulted in hygroscopic materials.

SCHEME 2

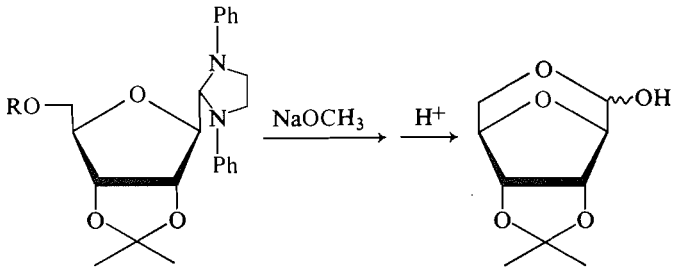
The ir spectrum of **9***a* had strong bands at 1640 (CO_2^-), 1500 (NH_3^+), and 3100−3400 cm^{-1} (OH, NH) characteristic of α-amino acids. Assignments of the L and D amino configurations were made from ord and cd curves obtained from solutions of **9***a* and *b* in 6 *N* hydrochloric acid. Epimer **9***a* had $[\phi]_{225} = +2000$ and $[\theta]_{210} = +2010$. These positive effects are characteristic for L α-amino acids (11, 12). The D epimer (**9***b*) had $[\phi]_{225} = -2300$ and $[\theta]_{210} = -1850$.

During the course of our work on synthesis of C-glycosyl amino acids related to furanomycin (13, 14), 3,4-*O*-isopropylidene-2,5-anhydro-D-allose (**11**) (see Scheme 3) was prepared as an intermediate. This product had been synthesized in racemic form by Just and co-workers beginning from a Diels−Alder reaction with furan (15). Other anhydro derivatives of D-allose have been obtained beginning with D-glucose (16) or by diazotization of 2-amino-2-deoxyaltropyranose derivatives (17). Reviews of carbohydrate precursors and their elaboration to a variety of C-nucleosides are available (18). A facile route to **11** from D-ribose follows.

The readily prepared 2-(5-*O*-benzoyl-2,3-*O*-isopropylidene-β-D-ribofuranosyl)-1,3-diphenylimidazolidine (**10***a*) reported by Moffatt and co-workers (9) was deacylated with methanolic sodium methoxide to give **10***b* in 95% yield. Treatment of **10***b* with *p*-toluenesulfonic acid monohydrate resulted in hydrolysis of the imidazolidine ring within ten minutes. Participation of the primary alcohol function in the hydrolytic displacement of the *N*,*N*′-diphenylethylenediamine protecting group (19) is likely, since analogous deprotection (3, 9) of the aldehyde

[1]Analogous treatment with sodium azide (3) was ineffective.

[2]Activation of the catalyst by stirring with 1 *N* hydrochloric acid, washing with water, and drying and storage under vacuum proved useful.



10*a* R = COPh
b R = H

11

SCHEME 3

function occurred much more slowly with the 6-*O*-benzyl or 6-*O*-benzoyl derivatives examined (13). Compound **11** was obtained in 84% yield after chromatography over silica. The tlc homogeneous solid was crystallized from chloroform/hexane to give an analytically pure product with ^{1}H nmr and mass spectral properties in agreement with the indicated structure. Exploratory reactions with **11** did not lead to promising routes for the synthesis of furanomycin (13). This sample of the epimeric hemiacetal (**11**) had a depressed melting point with respect to that of the reported racemate (15).

This study has demonstrated the convenient transformation of D-ribose to 3,4-*O*-isopropylidene-2,5-anhydro-D-allose (**11**), which was synthesized previously as a racemate and used to prepare C-nucleosides. Successful transformation of D-ribose to the target C-glycosyl amino acids 2-(β-D-ribofuranosyl)-L-glycine (2-amino-3,6-anhydro-2-deoxy-D-*glycero*-D-*altro*-heptonic acid) (**9***a*) and its 2-epimer (**9***b*) demonstrated the feasibility of this approach for the stereodefined synthesis of the structure proposed for furanomycin. Achievement of that goal and collaborative efforts that resulted in reassignment of the stereochemistry of the natural product structure are reported in the accompanying paper (14).

Experimental

General

Melting points were obtained on a Reichert microstage block and are uncorrected. Ultraviolet (uv) spectra were recorded on a Cary 15 spectrophotometer. Infrared (ir) spectra were recorded on a Nicolet 7199 FT (IR) spectrometer. Circular dichroism (cd) and optical rotatory dispersion (ord) spectra were determined on a Jasco ORD-UV-5 (CD-SS-20) spectrophotopolarimeter in H_2O or HCl/H_2O solutions. Optical rotations were measured using a Perkin–Elmer 241 polarimeter. The ^{1}H nmr spectra were recorded on a Varian HA-100 instrument by the nmr laboratory of this department using $CDCl_3$ with Me_4Si as internal standard unless otherwise specified. Mass spectra (ms) were obtained by the mass spectrometry laboratory of this department using an AEI MS-50 instrument with direct probe and computer averaging at 100–250°C and 70 eV for EI spectra or an AEI MS-12 instrument for chemical ionization (NH_3) spectra. Elemental analyses were determined by the microanalytical laboratory of this department.

All solvents were distilled prior to use. "Hexane" refers to the fraction of Skellysolve B boiling from 63–65°C. Solutions were dried over anhydrous sodium sulfate prior to filtration and evaporation using a Büchi rotary evaporator equipped with a Dewar Dry Ice condensor under water aspirator or oil vacuum pump (*in vacuo*) reduced pressure.

Thin layer chromatography (tlc) was performed on Eastman chromatogram sheets (silica gel #13181 with #6060 indicator) when uv (2537 Å) detection was used. Glass plates (coated with Merck silica gel PF-254 prepared as a slurry in $CHCl_3$) were used for detection by spraying with 5% H_2SO_4/EtOH and charring at 100–200°C. J. T. Baker #5-3405 (60–200 mesh) silica gel was used for column chromatography. J. T. Baker ANGC-244(H^+) strong acid resin was used for ion exchange chromatography and amide solvolysis catalysis. Paper chromatography (ascending) was performed on Whatman #2 Chroma sheets. Solvents used for chromatography were: (A) $CHCl_3$/EtOAc (1:1), (B) n-PrOH/H_2O (7:3), (C) n-BuOH/HOAc/H_2O (4:1:6) upper phase. The 5% palladium on carbon catalysts were purchased from Eastman or Apache Chemicals.

*3,6-Anhydro-4,5,7-tri-*O*-benzyl-*D-glycero-D-(allo *and* altro)*-heptonamide (**5**)*

A solution of *p*-toluenesulfonic acid monohydrate (5.9 g, 31 mmol) in Me_2CO (5 mL) was added to a stirred solution of 6.5 g (10.4 mmol) of 2-(2,3,5-tri-*O*-benzyl-β-D-ribofuranosyl)-1,3-diphenylimidazolidine (**4**) (9) in CH_2Cl_2 (100 mL) at 0°C. After stirring for 15 min at 0°C followed by 30 min at room temperature, an additional 500 mg of *p*-$CH_3C_6H_4SO_3H \cdot H_2O$ in Me_2CO (1 mL) was added. After a total reaction time of 1 h, the mixture was diluted with CH_2Cl_2 (100 mL), filtered using a Celite pad, washed with saturated brine (3 × 20 mL), dried, and evaporated. The residue was dissolved in dioxane, cooled to 10°C, and treated with NaCN (8.7 g) and K_2CO_3 (8.7 g) in H_2O (100 mL). After stirring at 0°C for 30 min the reaction was treated dropwise with 30% H_2O_2/H_2O (30 mL). After stirring for 1 h at 0°C the mixture was poured into H_2O (3 L). The precipitate was filtered and dried to give 4.5 g (91%) of **5** (10) contaminated with a trace impurity (tlc, A, impurity $R_f \sim 0.8$, product (**5**) $R_f \sim 0.2$).

*3,6-Anhydro-4,5,7-tri-*O*-benzyl-2-*O*-methanesulfonyl-*D-glycero-D-(allo *and* altro)*-heptonamides (**6**a *and* **6**b)*

A solution of the mixture of **5** (4.77 g, 10 mmol) in pyridine (25 mL) and CH_2Cl_2 (35 mL) at 0°C was treated dropwise with methanesulfonyl chloride (5.7 g, 4.05 mL, 50 mmol) in CH_2Cl_2 (15 mL). After 7 h at 0°C the reaction was diluted with CH_2Cl_2 (200 mL) and poured into ice-cold 1 *N* HCl/H_2O (100 mL). The organic layer was washed with 1 *N* HCl/H_2O (2 × 50 mL), saturated $NaHCO_3/H_2O$ (3 × 25 mL), saturated brine (3 × 25 mL), dried, and evaporated to a solid. This was triturated with warm Et_2O (100 mL) and filtered to give 2.4 g (43%) of **6***a* (tlc, A, $R_f \sim 0.50$). This product was recrystallized from MeOH to give 2.1 g (38%) of white needles, mp 173–174°C; $[\alpha]_D^{23}$ +65° (*c* 0.2, $CHCl_3$); ir (KBr): 1650 cm^{-1} ($CONH_2$); nmr δ: 2.91 (s, 3, SO_2CH_3), 3.44 & 3.71 (octet, $J_{7-7'} = 10$ Hz, $J_{7-6} = 3$ Hz, $J_{7'-6} = 2.5$ Hz, 2, H7,7′), 3.85–4.80 (m, 10, sugar and CH_2Ph), 4.90 (d, $J_{2-3} = 5$ Hz, 1, H2), 5.7 & 6.5 (bs, 2, $CONH_2$), 7.30 (m, 15, aromatic); ms *m/z*: 555.1954 (1.0, M^+, calcd for $C_{29}H_{33}NO_8S$: 555.1927), 476.2074 (0.6, M − SO_2CH_3), 465.1409 (26, M + 1 − CH_2Ph), 464.1374 (100, M − CH_2Ph), 449.1501 (2.4, M + 1 − OCH_2Ph), 448.1416 (2.7, M − OCH_2Ph), 358.0963 (M^+ − CH_2Ph − OCH_2Ph). *Anal.* calcd. for $C_{29}H_{33}NO_8S$: C 62.69, H 5.99, N 2.52, S 5.77; found: C 62.83, H 6.07, N 2.54, S 5.78.

The residual syrup from evaporation of the ether supernatant was chromatographed on silica (40 g, 3 × 14 cm). Elution with solvent A and evaporation of solvents gave 2.1 g (38%) of **6***b* as a white solid. This slower migrating isomer was crystallized from Et_2O (50 mL) to give a product (1.2 g) that contained a trace of **6***a* (tlc) and had mp 114–115°C; $[\alpha]_D^{23}$ +30° (*c*, 0.2, $CHCl_3$); nmr δ: 2.86 (s, 3, SO_2CH_3), 3.47 & 3.62 (m, $J_{7-7'} = 11$ Hz, $J_{7-6} = 4$ Hz, $J_{7'-6} = 3.5$ Hz, 2, H7,7′), 3.80–4.70 (m, 10, sugar and CH_2Ph), 4.91 (d, $J_{2-3} = 4$ Hz, 1, H2), 5.9 & 6.4 (bs, 2, $CONH_2$), 7.25 (m, 15, aromatic); ms *m/z*: 555.1928 (0.3, M^+, calcd. for $C_{29}H_{33}NO_8S$: 555.1927), 476.2049 (0.1, M − SO_2CH_3), 465.1426 (11; M + 1 − CH_2Ph), 464.1392 (42, M − CH_2Ph), 449.1481 (0.8, M + 1 − OCH_2Ph).

*3,6-Anhydro-2-azido-2-deoxy-4,5,7-tri-*O*-benzyl-*D-glycero-D-(altro *and* allo)*-heptonamides (**7**a *and* **7**b)*

A solution of **6***a* or **6***b* (1.11 g, 2 mmol) and LiN_3 (245 mg, 5 mmol) in DMF (40 mL) was heated at 100°C for 6 h, cooled, and poured into Et_2O (100 mL) and 5% $NaCl/H_2O$ (25 mL). The aqueous layer was extracted with Et_2O (3 × 25 mL). The combined organic layers were evaporated to a syrup and purified by chromatography on silica (20 g, 12 × 2.2 cm). Elution with solvent A gave the desired product.

"Faster" isomer (7a)

The yield after chromatography was 980 mg (98%). This solid was crystallized from EtOH with 50–70% recovery; mp 93–94°C; $[\alpha]_D^{23}$ +13° (*c* 0.2, $CHCl_3$); ir (KBr): 1670 ($CONH_2$), 2110 cm^{-1} (R—N_3); nmr δ3.46 & 3.57 (m, $J_{7-7'}$ = 10 Hz), J_{7-6} = 4 Hz, $J_{7'-6}$ = 3.5 Hz, 2, H7,7'), 3.80–4.20 (m, 11, sugar and CH_2Ph), 5.8 & 6.3 (bs, 2, $CONH_2$), 7.3 (s, 15, aromatic); ms *m/z*: 474.2157 (4.8, $M^+ - N_2$, calcd. for $C_{28}H_{30}N_2O_5$: 474.2155), 384.1646 (1.2, M + 1 − N_2 − CH_2Ph), 383.1610 (4.6, M − N_2 − CH_2Ph), 368.1734 (2.2, M + 1 − N_2 − OCH_2Ph). *Anal.* calcd. for $C_{28}H_{30}N_4O_5$: C 66.92, H 6.02, N 11.15; found: C 66.57, H 6.06, N 11.11.

"Slower" isomer (7b)

The yield after chromatography was 920 mg (92%). This solid was crystallized from Et_2O/hexane with ~70% recovery, mp 155–156°C; $[\alpha]_D^{23}$ +10° (*c* 0.2, $CHCl_3$); nmr δ: 3.92 & 3.60 (octet, $J_{7-7'}$ = 10 Hz, J_{7-6} = 3.5 Hz, $J_{7'-6}$ = 4 Hz, 2, H7,7'), 3.80–4.70 (m, 11, sugar and CH_2Ph), 6.0 & 6.4 (bs, 2, $CONH_2$), 7.3 (s, 15, aromatic); ms *m/z*: 503.2268 (2.1, M + 1), 502.2179 (0.2, M^+, calcd. for $C_{28}H_{30}N_4O_5$: 502.2189), 475.2211 (6.7, M + 1 − N_2), 474.2147 (11, M − N_2), 384.1645 (1.8, M − N_2 − CH_2Ph). *Anal.* calcd. for $C_{28}H_{30}N_4O_5$: C 66.92, H 6.02, N 11.15; found: C 66.96, H 6.11, N 10.97.

2-(β-D-Ribofuranosyl)-(L and D)-glycines or 2-amino-3,6-anhydro-2-deoxy-D-glycero-D-(altro and allo)-heptonic acids (9a and 9b)

A solution of **7***a* or **7***b* (502 mg, 1 mmol) in dioxane (10 mL) and 6 *N* HCl/H_2O (2 mL) was stirred at 80°C for 18 h, cooled, diluted with H_2O (20 mL), and extracted with $CHCl_3$ (3 × 20 mL). The combined organic layers were washed with saturated brine (3 × 10 mL), dried, and evaporated to give 510 mg (quantitative) of **8***a* or **8***b* as a colorless stiff syrup. This was dissolved in EtOH (40 mL) and 1 *M* NH_4OAc/H_2O (10 mL, adjusted to pH = 5 with HOAc) and hydrogenated over 5% Pd–C (500 mg) at 100 psi with vigorous stirring for 48 h. The mixture was filtered using a Celite pad and the filter cake was washed with 95% EtOH (25 mL) and H_2O (25 mL). The combined filtrate was evaporated to a syrup, dissolved in a small volume of H_2O, and applied to a column of ANGC(H^+) resin (20 g). The column was washed with H_2O until the eluate was neutral, followed by 0.5 *N* NH_3/H_2O. The ninhydrin positive fractions were collected and evaporated *in vacuo* to give ~110 mg (53%) of **9***a* or **9***b* as a tan colored solid that was homogeneous on paper chromatography (B, R_f 0.25; C, R_f 0.07). Crystallization of **9***a* from EtOH/H_2O gave fine colorless needles that gave analytical data in agreement with a dihydrate. This sample was dried *in vacuo* at 56°C for 3 days to give crystals that softened at ~125–130°C and melted with decomposition at ~208–210°C; $[\alpha]_D^{23}$ −12° (*c* 0.1, H_2O); ir (KBr): 1500 (NH_3^+), 1640 (CO_2^-), 3100–3400 cm^{-1} (OH, NH); ord (6 *N* HCl) $[\phi]_{225}$ = +2000; cd (6 *N* HCl) $[\theta]_{210}$ = +2010. *Anal.* calcd. for $C_7H_{13}NO_6 \cdot 0.75\ H_2O$: C 38.10, H 6.62, N 6.35; found: C 38.05, H 6.57, N 6.10.

The D-isomer (**9***b*) was isolated as an amorphous solid; mp ~120°C (dec.); $[\alpha]_D^{23}$ −4° (*c* 0.1, H_2O); ord (6 *N* HCl) $[\phi]_{225}$ = −2300; cd (6 *N* HCl) $[\theta]_{210}$ = −1850.

1,3-Diphenyl-2-(2,3-O-isopropylidene-β-D-ribofuranosyl)-imidazolidine (10b)

A solution of 10 g (20 mmol) of the 5-*O*-benzoyl derivative (**10***a*) (9) in $CHCl_3$ (150 mL) was added to a stirred solution of 0.1 *N* NaOMe/MeOH (150 mL) at room temperature. After 2.5 h the solution was poured into $CHCl_3$ (200 mL) and saturated NH_4Cl/H_2O (200 mL). The aqueous layer was extracted with $CHCl_3$ (3 × 25 mL). The combined organic layers were washed with saturated brine (3 × 20 mL), dried, and evaporated to a white solid. This residue was dissolved in hot MeOH (150 mL) and allowed to crystallize at room temperature to give 7.5 g (95%) of **10***b*, mp 170–171°C; $[\alpha]_D^{23}$ −50° (*c* 0.2, $CHCl_3$); uv (MeOH) max: 253 & 293 nm (ε 34 700 & 4400); nmr δ: 1.26 & 1.35 (s & s, 3 & 3, $C(CH_3)_2$), 2.2 (bs, 1, OH), 3.3–4.7 (m, 10, sugar and CH_2CH_2), 5.65 (s, 1, H1), 6.7–7.3 (m, 10, aromatic); ms *m/z*: 398.2159 (1.3, M + 2), 397.2124 (4.1, M + 1, calcd. for $C_{23}H_{29}N_2O_4$: 397.2127), 396.2029 (1.2, M^+), 395.1971 (2.4, *M* − 1), 382.1857 (0.9, M + 1 − CH_3), 381.1820 (3.0, M − CH_3). *Anal.* calcd. for $C_{23}H_{28}N_2O_4$: C 69.67, H 7.12, N 7.07; found: C 69.53, H 7.00, N 7.09.

2,5-Anhydro-3,4-O-isopropylidene-D-allose (11)

A stirred solution of **10***b* (396 mg, 1 mmol) in CH_2Cl_2 (15 mL) at room temperature was treated with *p*-toluenesulfonic acid monohydrate (570 mg, 3 mmol) in Me_2CO (1 mL). After 15 min the dense white mixture was diluted with Et_2O (25 mL) and filtered using a Celite pad. The filtrate was concentrated to a white gum, dissolved in EtOAc (25 mL), and washed with a small volume of saturated brine (5 mL). The aqueous layer was extracted with EtOAc (3 × 5 mL). The combined organic layers were dried and evaporated to a white solid (210 mg, quantitative). This product was rapidly chromatographed on silica gel with EtOAc/hexane (2:1) to give 170 mg (84%) of a white solid. An analytical sample was crystallized from $CHCl_3$/hexane to give **11** with mp 168–170°C (lit. (15) mp 185–186°C (racemate)); $[\alpha]_D^{23}$ +12° (*c* 1.0, $CHCl_3$); nmr (Me_2CO-d_6) δ: 1.30 & 1.38 (s & s, 3 & 3, $C(CH_3)_2$), 3.2–4.2 (m, 4, sugar protons), 4.6–5.0 (m, 3, sugar protons), 5.4 & 6.0 (d & d, 1, epimeric OH); ms *m/z*: 202.0843 (1.4, M^+, calcd. for $C_9H_{14}O_5$: 202.0841), 187.0608 (100, M − CH_3), 185.0815 (5.4, M − OH), 173.0813 (6.1, M − OH − CH_3). *Anal.* calcd. for $C_9H_{14}O_5$: C 53.46, H 6.98, O 39.56; found: C 53.24, H 7.00, O 39.69.

Chiral transformations of D-ribose to 2(*S*)-amino-2-[2,5-dihydro-5(*R*)-methylfuran-2(*R*)-yl]ethanoic acid, a diastereomer of the antibiotic (+)-furanomycin

MORRIS J. ROBINS AND J. M. ROBERT PARKER
Department of Chemistry, The University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received May 19, 1982

MORRIS J. ROBINS and J. M. ROBERT PARKER. Can. J. Chem. **61**, 317 (1983).

The chain-extended 2-(2,3-*O*-isopropylidene-β-D-ribofuranosyl)-1,3-diphenylimidazolidine derivative (**3***a*) was prepared by a known sequence from D-ribose. Benzylation of the primary alcohol function of **3***a*, deprotection of the masked aldehyde, chain extension using a modified Strecker-type synthesis, and acetylation of the resulting epimeric 2-hydroxyl groups gave the appropriately blocked seven-carbon 3,6-anhydro compounds (**5***a*, *b*). The primary alcohol function was deprotected and then removed by mesylation, iodide replacement, and hydrogenolysis. The 2-hydroxyl group was deprotected, mesylated, and replaced by azide. Methanolysis of the amide and isopropylidene groups gave the α-azido ester diols (**13***a*, *b*). Treatment of **13***a* with thiocarbonyldiimidazole followed by the Corey–Winter reaction with trimethylphosphite effected concomitant reduction of the azide function and reductive elimination of the cyclic thionocarbonate group. Saponification of the ester intermediate gave the target α-amino acid, 2(*S*)-amino-2-[2,5-dihydro-5(*R*)-methylfuran-2(*R*)-yl]ethanoic acid (**1**). Comparison of the properties of **1** and (+)-furanomycin confirmed the necessity of revision of stereochemistry for the antibiotic.

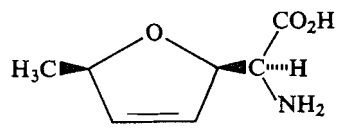
MORRIS J. ROBINS et J. M. ROBERT PARKER. Can. J. Chem. **61**, 317 (1983).

Partant du D-ribose, on a allongé la chaîne par une série connue de réactions pour obtenir le dérivé (*O*-isopropylidène-2,3 β-D-ribofurannosyl)-2 diphényl-1,3 imidazolidine (**3***a*). La benzylation de la fonction alcool primaire du composé **3***a*, la déprotection de la fonction aldéhyde bloquée, l'extension de chaîne utilisant une synthèse modifiée de type Strecker et l'acétylation des groupes hydroxyle-2 épimères qui en résulte donne les composés anhydro-3,6 (**5***a*, *b*) à sept carbones protégés adéquatement. On a déprotégé la fonction alcool primaire et on l'a enlevé par une mésylation, suivie d'une substitution par l'iode et d'une hydrogénolyse. On a déprotégé le groupe hydroxyle-2 que l'on a mésylé puis substitué par un azide. La méthanolyse des groupes amides et isopropylidène donne les diols esters α-azido (**13***a*, *b*). Le traitement du composé **13***a* avec le thiocarbonyldiimidazole, suivi de la réaction de Corey–Winter avec le triméthylphosphite, conduit à une réduction concomitante de la fonction azide et à une élimination réductrice du groupe thiocarbonate cyclique. La saponification de l'ester intermédiaire permet d'obtenir l'acide α-aminé désiré: l'acide amino-2(*S*) [dihydro-2,5 méthyl-5(*R*) furannyl-2(*R*)]-2 éthanoique (**1**). La comparaison des propriétés du composé **1** avec celles de la (+)-furannomycine a confirmé la nécessité de revoir la stéréochimie de l'antibiotique.

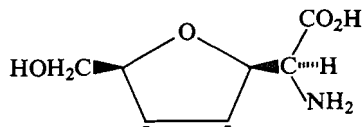
[Traduit par le journal]

A new α-amino acid antibiotic, (+)-furanomycin, was reported by Katagiri and co-workers in 1967 (1). Chemical degradation and spectroscopic studies indicated an α-(5-methyl-2,5-dihydrofuran-2-yl)glycine structure. It was concluded from the large H2 to H5 proton coupling constant that the orientation of the methyl and glycyl substituents was *cis* on the dihydrofuran ring. The positive Cotton effects in circular dichroism spectra of the antibiotic and its dihydro derivative allowed assignment of the α-amino configuration. It was concluded that the natural product was "(+)-α(*R*)-amino(2,5-dihydro-5(*R*)-methyl)furan-2(*R*)-acetic acid or one of its [*cis*] diastereomers" (1).[1] In 1975 Masamune and Ono reported a multistep synthesis of racemic furanomycin. Their product, derived from an initial limited Birch reduction of 5-methyl-2-furoic acid, was assigned a *cis*-2,5-dihydrofuran structure that was "identical with the natural sample" (2). Since no data were presented to define the absolute stereochemistry of the antibiotic, we began studies involving chiral conversions of D-ribose to give 2(*S*)-amino-2-[2,5-dihydro-5(*R*)-methylfuran-2(*R*)-yl]ethanoic acid (**1**), the structure originally proposed (1).[1]

Modified Strecker-type syntheses of C-glycosyl glycine precursors were reported by Moffatt and co-workers in their preparation of the basic skeleton of the polyoxin group of



1



2

nucleoside antibiotics (3) and intermediates used in C-nucleoside syntheses (4). We successfully applied that approach to the construction of a 2-(β-D-ribofuranosyl)-L-glycine (**2**) model for furanomycin that possessed the requisite amino acid unit at position 2, a single carbon unit at position 5, and diol functionality at positions 3 and 4 suitable for elaboration to the target 2,5-dihydrofuran structure (**1**) (5, 6). Although conversion of **2** to **1** is presumably possible, the multifunctional hydrophilic nature of **2** suggested that a new approach from D-ribose using appropriately selected protecting groups would be more profitable. One sequence was pursued with tritylation of the primary alcohol, benzylation of the secondary alcohols, protection of the chain extended aldehyde with 1,2-di-(*N*-

[1]On page 1150 of ref. 1 it is stated that "these α-amino acids belong to the L-series." Therefore, their α(*R*) designation should have been α(*S*).

SCHEME I

anilino)ethane (7), and the derived α-hydroxy amide unit as a mixed *N,O*-isopropylidene derivative (5). We were concerned with the possible lability of the target dihydrofuran ring relative to strong acid conditions needed for hydrolysis of an α-substituted amide, and nucleophilic displacement of methanesulfonate by azide was unsuccessful with α-methanesulfonyloxy ester intermediates (5). Therefore, another sequence of reactions with different protecting groups was selected.

Benzylation of the primary hydroxyl function of 2-(2,3-*O*-isopropylidene-β-D-ribofuranosyl)-1,3-diphenylimidazolidine (**3***a*) (6) (see Scheme 1) gave the suitably protected precursor **3***b* (91%). Treatment of **3***b* under controlled acidic conditions (6, 8) unmasked the aldehyde function selectively. Immediate *in situ* treatment with aqueous sodium cyanide/potassium carbonate followed by 30% hydrogen peroxide to hydrolyze the cyanohydrin (3, 4) gave 3,6-anhydro-7-*O*-benzyl-4,5,-*O*-isopropylidene-D-*glycero*-D-(*allo* and *altro*)-heptonamides (**4***a* and *b*) in 86% yield from **3***b*. The more chromatographically mobile diastereomer crystallized selectively from ether solution (43% yield) and was later indicated to have been the *allo*-epimer **4***a*, based on the derived stereochemistry and analogy with prior studies (3, 6). Chromatography of the mother liquor on silica gave **4***b* (containing variable minor amounts of **4***a*) as a syrup (43%). Infrared and ^1H nmr spectral data were in harmony with the α-hydroxy amide structures of **4***a* and *b*, and a molecular ion was present in the mass spectrum of **4***a*. Each diastereomer was reacted independently in the parallel sequences that follow.

Acetylation of **4***a* and *b* in the usual manner gave the 2-*O*-acetyl derivatives (**5***a* and *b*) as viscous syrups in quantitative yields. These epimers were distinguished readily by ^1H nmr spectroscopy (see the Experimental). Hydrogenolysis of the 7-*O*-benzyl ether function from **5***a* and *b* occurred quantitatively at 60 psi over 5% palladium on carbon to give **6***a* and *b*. Mesylation of **6***a* and *b* gave the 7-*O*-methanesulfonyl products (**7***a* and *b*) in 88% yields after chromatographic purification. The more chromatographically mobile epimer **7***a* crystallized from chloroform/ether and was completely characterized.

Treatment of **7***a* and *b* with sodium iodide in hot 2-butanone gave the 7-iodo-7-deoxy compounds (**8***a* and *b*) in quantitative yields as colorless syrups that gave a characteristic mass spec-

For personal use only.

tral fragmentation ion in high relative abundance. Hydrogenolysis of the iodo function gave the chromatographically purified 7-deoxy epimers (**9***a* and *b*) in over 90% yields. The ^{1}H nmr peak for the 7-protons appeared as the expected methyl doublet at δ 1.27 (**9***a*) and 1.33 (**9***b*).

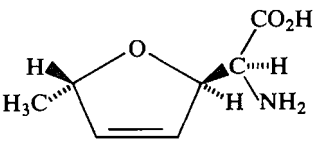
Deacetylation of **9***a* and *b* with methanolic ammonia proceeded quantitatively. The resulting deprotected α-hydroxy amide products (**10***a* and *b*) were crystallized from chloroform/ether/hexane in over 80% yields and were fully characterized. Mesylation of **10***a* and *b* gave the crystalline 2-*O*-methanesulfonyl derivatives (**11***a* and *b*). Treatment of **11***a* and *b* with lithium azide in hot *N*,*N*-dimethylformamide (DMF) resulted in smooth displacement of the mesylate function (6) to give the chromatographically purified α-azido amides (**12***a* and *b*) in ~93% yields. These products were crystallized and fully characterized. It was assumed that the usual inversion of configuration had occurred at C2 (3, 6). Solvolysis of the amide function with concomitant removal of the isopropylidene group was effected by treatment of **12***a* and *b* with strong acid resin in hot methanol. The α-azido esters **13***a* and *b* were obtained as stiff syrups in 85% yields after chromatographic purification and were characterized by spectral properties.

Model reactions had demonstrated the feasibility of using the Corey–Winter (9) decomposition of furanose *cis*-glycol cyclic thionocarbonates to 2,5-dihydrofurans (5). We also anticipated that concomitant reductive displacement of dinitrogen from the α-azido function would be effected by heating in trimethylphosphite (10) to give the α-amino group after hydrolysis. Treatment of the α-azido esters (**13***a* and *b*) with *N*,*N*′-thiocarbonyldiimidazole in acetone at room temperature resulted in conversion to the cyclic thionocarbonates (**14***a* and *b*) in 92% purified yields. Epimer **14***a* was crystallized and both isomers were characterized by their spectroscopic properties. Compounds **14***a* and *b* were heated at reflux in trimethylphosphite for 14 hours followed by saponification of the resulting intermediates. The target 2(*S*)-amino-2-[2,5-dihydro-5(*R*)-methylfuran-2(*R*)-yl]ethanoic acid (**1**) and its 2(*R*) epimer (**15**) were isolated from a strong acid resin column in ~30% yields.

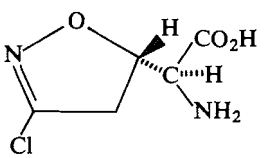
Comparison of the melting point, ^{1}H nmr, optical rotation, and circular dichroism (cd) data of compound **1** with those reported for (+)-furanomycin clearly revealed that the two were not identical. Compound **1** had a cd maximum with $[\theta]_{216} = +2200$ which was but slightly lowered by hydrogenation of the double bond to give the tetrahydrofuran product ($[\theta]_{215} = +2000$). In contrast, (+)-furanomycin was reported to have $[\theta]_{210} = +26\,000$ and its reduced product $[\theta]_{215} = +5000$ (1).

Simultaneously with completion of this sequence (5), a preliminary presentation alerted us to work by Joullié and coworkers (11) on the synthesis of *trans* diastereomers of **1**. Direct comparisons of chiroptical properties, high-field ^{1}H nmr spectra and chromatographic mobilities were made with our products and samples kindly provided by Professor M. M. Joullié. In their work (12), 2(*S*)-amino-2-[2,5-dihydro-5(*S*)-methylfuran-2(*R*)-yl]ethanoic acid (**16**) and its 2(*R*)-amino epimer were prepared by transformation chemistry from D-glucose. The value of the ellipticity measured at an inflection in the cd spectrum of **16** at 210 nm was $[\theta]_{210} = +26\,000$, in agreement with that reported for (+)-furanomycin ($[\theta]_{210} = +26\,000$) (1) and in marked contrast with those maxima measured for our *cis* isomers **1** ($[\theta]_{216} = +2200$) and **15** (calculated $[\theta]_{216} \sim -2500$). Our comparisons (5) also allowed assignment of absolute configurations for certain *cis* stereoisomers cleverly synthesized by Joullié and co-workers (13) from racemic 5-methyl-2,5-dihydrofurfural using the Ugi "four-component-condensation" approach to α-amino acids (14). Shiro *et al.* then reported an X-ray crystal structure of the *N*-acetyl derivative of (+)-furanomycin that corroborated the 2(*S*)-[5(*S*),2(*R*)] stereochemistry of **16** (15). Owing to the length of our classical Strecker-type approach and the demonstration that the natural product possessed the revised stereochemistry (**16**), the small quantities of compounds **1** and **15** obtained were characterized spectroscopically. No attempt was made to improve the rather poor yields of the last step (**14***a*, *b* → **1**, **15**) in our sequence.

It is interesting that (+)-furanomycin (**16**), isolated from a *Streptomyces* L-803 culture, has antibiotic activity against *Escherichia coli* H that is reversed by L-isoleucine (1). Some time ago racemic 2-amino-2-cyclopentylethanoic acid (cyclopentaneglycine) (16) and 2-amino-2-(cyclohex-3-enyl)-ethanoic acid (3-cyclohexene-1-glycine) (17) were prepared and also found to be isoleucine antagonists in *E. coli* cultures.



16



17

It was suggested that the planar rings attached to the α-carbon of glycine could approximate the β-branched alkyl chain of isoleucine (17). More recently another α-(heterocycle-substituted)glycine, 2(*S*)-amino-2-[3-chloro-4,5-dihydroisoxazol-5(*S*)-yl]ethanoic acid (**17**), was isolated from a *Streptomyces sviceus* culture (18) and synthesized (19) by the Upjohn group. Compound **17** was found to have significant activity against L1210 murine leukemia (20) and to inhibit a number of enzymes that catalyze amido transfer from L-glutamine (21). The activity of **17** was not reversed by L-isoleucine. Furanomycin was also detected in *Streptomyces* cultures examined by the Upjohn group and was found to have activity against the Walker 256 tumor (20). The Upjohn antibiotic (**17**) has a *threo*-α(*S*),β(*S*) configuration like L-*O*-methylallothreonine, whereas (+)-furanomycin (**16**) has the *erythro*-α(*S*),β(*R*) stereochemistry of L-*O*-methylthreonine. Incorporation of L-isoleucine into proteins of Ehrlich acites carcinoma was found to be inhibited by L-*O*-methylthreonine, but not by its α(*S*),β(*S*) *allo* diastereomer (22).

The present study has further demonstrated the viability of the modified Strecker-type approach for the stereodefined synthesis of *C*-glycosyl amino acids. The Corey–Winter conversion of furanose *cis*-glycol systems to 2,5-disubstituted-2,5-dihydrofurans of defined stereochemistry proceeds smoothly in most cases (5). The 2(*S*)-amino-2-[2,5-dihydro-5(*R*)-methylfuran-2(*R*)-yl]ethanoic acid (**1**) structure proposed for (+)-furanomycin (1) was synthesized. Collaborative efforts with Professor M. M. Joullié clearly demonstrated that a revised 2(*S*)-[5(*S*),2(*R*)] stereochemistry (**16**) exists for the natural antibiotic. No inhibition of proliferation of L1210 cells was observed with 2-(*S*)-amino-2-(β-D-ribofuranosyl)ethanoic acid (**2**) (6) at 0.1 m*M* concentration.[2] Biological evaluation of

[2]Private communication from Professor C. E. Cass, McEachern Cancer Research Laboratory, University of Alberta.

other diastereomers and analogues of furanomycin was pursued by Professor Joullié.

Experimental

General

Most general procedures are described in ref. 6 (and in more detail in ref. 5). The ^1H nmr spectra were determined at 100 MHz using $CDCl_3$ with Me_4Si as internal standard unless otherwise specified. High field (200 MHz) ^1H nmr spectra were determined on a Bruker WH200 instrument and the ^{13}C nmr spectra on a Bruker HFX90 spectrometer by the nmr laboratory of this department. Solvents used for chromatography are solvent A: hexane/ethyl acetate (1:1); solvent B: hexane/ethyl acetate (5:1).

*2-(5-O-Benzyl-2,3-O-isopropylidene-β-D-ribofuranosyl)-1,3-diphenylimidazolidine (**3**b)*

A solution of 2-(2,3,-*O*-isopropylidene-β-D-ribofuranosyl)-1,3-diphenylimidazolidine (**3***a*) (6) (3.96 g, 10 mmol) in DMF (20 mL) was added to a stirred suspension of NaH (960 mg, 50% oil suspension, 20 mmol) in DMF (5 mL) at 0°C under N_2. After 1 h at room temperature the solution was cooled to 0°C and treated dropwise with benzyl bromide (2.38 mL, 3.4 g, 20 mmol) in DMF (10 mL). The mixture was stirred at room temperature for 3 h, quenched with MeOH (2 mL), and poured into a mixture of CH_2Cl_2 (50 mL) and H_2O (50 mL). The aqueous layer was extracted with CH_2Cl_2 (3 × 25 mL). The combined organic phase was washed with saturated brine (10 mL), dried, and evaporated to a white solid. This solid was crystallized from MeOH/$CHCl_3$ to give 4.45 g (91%) of **3***b*, mp 148–149°C; $[\alpha]_D^{23}$ −14° (*c* 0.11, $CHCl_3$); uv (MeOH) max: 253 nm (ε 31 800), 293 (sh) (ε 4100); nmr δ: 1.24 & 1.38 (s & s, 3 & 3, $C(CH_3)_2$), 3.40–4.80 (m, 6, CH_2CH_2 and H6, H6′), 4.05 (q, $J_{5-6,6'}$ = 5 Hz, 1, H5), 4.25–4.40 (m, 2, H2 & H4), 4.50 (s, 2, CH_2Ph), 4.63 (d of d, *J* = 5 Hz, *J* = 6.5 Hz, 1, H3), 5.58 (d, J_{1-2} = 2 Hz, 1, H1), 6.60–7.40 (m, 15, aromatic); ms *m/z*: 486.2525 (0.5, M^+, calcd. for $C_{30}H_{34}N_2O_4$: 486.2518), 471 (M − CH_3), 380 (M − CH_3 − NPh). *Anal.* calcd. for $C_{30}H_{34}N_2O_4$: C 74.05, H 7.04, N 5.76; found: C 74.21, H 7.21, N 5.80.

*3,6-Anhydro-7-O-benzyl-4,5-O-isopropylidene-D-glycero-D-(allo and altro)-heptonamides (**4**a and **4**b)*

A stirred solution of **3***b* (12.15 g, 25 mmol) in CH_2Cl_2 (250 mL) at 0°C was treated with *p*-toluenesulfonic acid monohydrate (14.25 g, 75 mmol) in Me_2CO (20 mL). After 15 min an additonal 1 g of the acid in Me_2CO (5 mL) was added. After a total reaction time of 20 min the mixture was diluted with CH_2Cl_2 (200 mL) and filtered using a Celite pad. The filtrate was treated with solid $NaHCO_3$ (25 g), refiltered using Celite, and evaporated to a syrup. This residue was dissolved in dioxane (250 mL), cooled to 5°C, and treated with NaCN (18 g) and K_2CO_3 (18 g) in H_2O (250 mL). After 30 min at room temperature the solution was cooled to 0°C and treated dropwise with 30% H_2O_2/H_2O (125 mL) over a period of 30 min. The mixture was stirred at 0°C for an additional 30 min (the reaction temperature slowly rose to 35°C then subsided) and was then diluted with H_2O (600 mL) and EtOAc (250 mL). The aqueous phase was saturated with NaCl and extracted with EtOAc (3 × 50 mL). The combined organic phase was washed with saturated brine (3 × 20 mL), dried, concentrated to approximately 10 mL, and diluted with Et_2O (100 mL). The solid that crystallized was filtered to give 3.65 g (43%) of **4***a* (faster migrating isomer by tlc), mp 133–135°C; $[\alpha]_D^{23}$ +39° (*c* 0.1, $CHCl_3$); ir (KBr): 1650 cm^{-1} ($CONH_2$), 3300–3500 cm^{-1} (OH, NH_2); nmr δ: 1.31 & 1.50 (s & s, 3 & 3, $C(CH_3)_2$), 3.53 & 3.73 (ABX octet, J_{6-7} = 3.2 Hz, $J_{6-7'}$ = 2.7 Hz, $J_{7-7'}$ = 12 Hz, 2, H7 & H7′), 4.10–4.75 (m, 8, sugar and CH_2Ph), 5.7 & 6.7 (bs, 2, $CONH_2$), 7.3 (s, 5, Ph); ms *m/z*: 338.1599 (0.8, M + 1, calcd. for $C_{17}H_{24}NO_6$: 338.1604), 337.1539 (2.3, M^+), 323.1341 (1.6, M + 1 − CH_3), 322.1308 (7.5, M − CH_3), 263.1290 (12.2, M − $C_2H_4NO_2$). *Anal.* calcd. for $C_{17}H_{23}NO_6$: C 60.52, H 6.87, N 4.15; found: C 60.35, H 6.93, N 3.93.

The mother liquors were concentrated and purified by chromatography on silica (50 g, 3 × 15 cm). Elution with solvent A followed by EtOAc gave 3.67 g (44%) of **4***b* (as a syrup that contained a minor amout of **4***a*), $[\alpha]_D^{23}$ −10° (*c* 0.1, $CHCl_3$); nmr δ: 1.32 & 1.52 (s & s, 3 & 3, $C(CH_3)_2$), 3.56 & 3.76 (ABX octet, J_{6-7} = 3 Hz, $J_{6-7'}$ = 3 Hz, $J_{7-7'}$ = 12 Hz, 2, H7 & H7′), 4.10–4.75 (m, 8, sugar and CH_2Ph), 6.3 & 6.7 (bs, 2, $CONH_2$), 7.3 (s, 5, Ph).

*2-O-Acetyl-3,6-anhydro-7-O-benzyl-4,5-O-isopropylidene-D-glycero-D-(allo and altro)-heptonamides (**5**a and **5**b)*

A solution of **4***a* or **4***b* (11.8 g, 35 mmol) in pyridine (200 mL) at 0°C was treated with acetic anhydride (10 mL, 9.26 g, 91 mmol). After 1 h the solution was allowed to warm to room temperature for 12 h, treated with ice, and diluted with CH_2Cl_2 (250 mL). The organic phase was washed with 1 *N* HCl/H_2O, 5% $NaHCO_3/H_2O$, saturated brine (3 × 25 mL), dried, and evaporated to give **5***a* or **5***b* (13.6 g, quantitative).

The faster migrating isomer (**5***a*) was obtained as a viscous syrup, $[\alpha]_D^{23}$ −14° (*c* 0.1, $CHCl_3$); ir (film): 1700 cm^{-1} ($CONH_2$), 1750 cm^{-1} (OAc), 3300 cm^{-1} (NH_2); nmr δ: 1.33 & 1.52 (s & s, 3 & 3, $C(CH_3)_2$), 2.06 (s, 3, $COCH_3$), 3.48 & 3.69 (ABX multiplet, J_{6-7} = 5 Hz, $J_{6-7'}$ = 3.7 Hz, $J_{7-7'}$ = 11 Hz, 2, H7 & H7′), 4.05–4.30 (m, 1, H6), 4.28 & 4.33 (d of d, J_{3-2} = 5.5 Hz, J_{3-4} = 3.2 Hz, 1, H3), 4.52 (s, 2, CH_2Ph), 4.50–4.65 (d of d, J_{5-4} = 3.5 Hz, 1, H5), 4.78 & 4.81 (d of d, J_{4-3} = 3.2 Hz, J_{4-5} = 3.5 Hz, 1, H4), 5.23 (d, J_{2-3} = 5.5 Hz, 1, H2), 6.00–6.50 (bd, 2, $CONH_2$), 7.30 (s, 5, Ph); ms *m/z*: 379.1639 (0.3, M^+, calcd. for $C_{19}H_{25}NO_7$: 379.1631), 364.1393 (5.1, M − CH_3). *Anal.* calcd. for $C_{19}H_{25}NO_7$: C 60.15, H 6.64, N 3.69; found: C 59.91, H 6.57, N 3.62.

Isomer **5***b* was obtained as a viscous syrup, $[\alpha]_D^{23}$ +21° (*c* 0.1, $CHCl_3$); nmr δ: 1.33 & 1.52 (s & s, 3 & 3, $C(CH_3)_2$), 2.08 (s, 3, $COCH_3$), 3.00 (d, J_{6-7} = 4 Hz, 2, H7 & H7′), 4.00–4.25 (m, 1, H6), 4.20–4.40 (m, 1, H3), 4.52 (s, 2, CH_2Ph), 4.60–4.68 (m, 2, H4 & H5), 5.25 (d, J_{2-3} = 4.5 Hz, 1, H2), 5.90–6.40 (bd, 2, $CONH_2$), 7.31 (s, 5, Ph).

*2-O-Acetyl-3,6-anhydro-4,5-O-isopropylidene-D-glycero-D-(allo and altro)-heptonamides (**6**a and **6**b)*

A solution of **5***a* or **5***b* (4.0 g, 10.5 mmol) in 98% ethanol (100 mL) was hydrogenated over 5% Pd–C (2 g) at 60 psi. The reaction was monitored by tlc (EtOAc, **5***a*, *b*, R_f ~ 0.75; **6***a*, *b*, R_f ~ 0.25). After 8 h the mixture was filtered and evaporated to give 3.1 g (quantitative) of **6***a* or **6***b*, homogeneous by tlc, ms *m/z*: 290.1244 (3.5, M^+, calcd. for $C_{12}H_{20}NO_7$: 290.1248), 275.0966 (14.0, M + 1 − CH_3), 274.0933 (100, M − CH_3), 232.0824 (24.3, M + 1 − CH_3 − $COCH_3$).

*2-O-Acetyl-3,6-anhydro-4,5-O-isopropylidene-7-O-methanesulfonyl-D-glycero-D-(allo and altro)-heptonamides (**7**a and **7**b)*

A solution of **6***a* or **6***b* (5.0 g, 17.2 mmol) in pyridine (30 mL) and CH_2Cl_2 (30 mL) at 0°C, was treated dropwise with methanesulfonyl chloride (4.0 g, 35 mmol) in CH_2Cl_2 (10 mL). The solution was left at 0°C for 8 h, diluted with CH_2Cl_2, and poured into ice-water (25 mL). The organic phase was washed with saturated brine (3 × 10 mL), dried, and evaporated. This residue was chromatographed on silica (50 g, 3 × 20 cm). Elution with solvent A followed by EtOAc gave 5.6 g (89%) of **7***a* or **7***b* as a white foam. An analytical sample of the faster migrating isomer (**7***a*) was crystallized from $CHCl_3/Et_2O$. The slower isomer (**7***b*) was obtained as a white solid foam.

Isomer **7***a* had mp 133–134°C; $[\alpha]_D^{23}$ −11° (*c* 0.1, $CHCl_3$); ir (KBr): 1180, 1260 cm^{-1} (SO_2CH_3), 1750 cm^{-1} (OAc), 3400 cm^{-1} (NH_2); nmr δ: 1.35 & 1.54 (s & s, 3 & 3, $C(CH_3)_2$), 2.20 (s, 3, $COCH_3$), 3.06 (s, 3, SO_2CH_3), 4.10–4.40 (m, 4, H3, H6, H7, H7′), 4.58 (d of d, J_{5-6} = 4.5 Hz, J_{4-5} = 6.5 Hz, 1, H5), 4.93 (d of d, J_{4-5} = 6.5 Hz, J_{4-3} = 4 Hz, 1, H4), 5.32 (d, J_{2-3} = 4 Hz, 1, H2), 6.0–6.5 (bd, 2, $CONH_2$); ms *m/z*: 368.1006 (1.0, M + 1, calcd. for $C_{13}H_{22}NO_9S$: 368.1015), 352.0706 (100, *M* − 15), 323.0791 (0.9, M − $CONH_2$), 310.0604 (13.0, M + 1 − CH_3 − $COCH_3$), 308.0809 (3.5, M − CH_3 − $CONH_2$). *Anal.* calcd. for $C_{13}N_2NO_9S$: C 42.50, H 5.76, N

3.81, S 8.73; found: C 42.54, H 5.75, N 3.92, S 8.81.

Isomer **7***b* had $[\alpha]_D^{23}$ +14° (*c* 0.1, $CHCl_3$); nmr δ: 1.35 & 1.54 (s & s, 3 & 3, $C(CH_3)_2$), 2.18 (s, 3, $COCH_3$), 3.04 (s, 3, SO_2CH_3), 4.10–4.70 (m, 6, sugar), 5.22 (d, J_{2-3} = 4 Hz, 1, H2), 6.05–6.40 (bd, 2, $CONH_2$).

*2-O-Acetyl-3,6-anhydro-7-deoxy-4,5-*O*-isopropylidene-*D-glycero-D-(allo *and* altro)*-heptonamides (**9**a and **9**b)*

A solution of **7***a* or **7***b* (5.0 g, 13.6 mmol) in 2-butanone (200 mL) was treated with NaI (4.08 g, 27.2 mmol), stirred under N_2 at reflux for 2 h, cooled, and evaporated to a yellow paste. This residue was dissolved in EtOAc (200 mL) and 5% $NaHCO_3/H_2O$ (25 mL). The organic phase was washed with saturated brine (25 mL), dried, and evaporated to give 5.5 g (quantitative) of the 7-iodo-7-deoxy product (**8***a* or **8***b*) as a colorless syrup, ms *m/z*: 383.9952 (54.4, M − CH_3, calcd. for $C_{11}H_{15}INO_6$: 383.9946).

This syrup was dissolved in 98% ethanol (200 mL), treated with triethylamine (5 mL) and a chip of Dry Ice, and hydrogenated over 5% Pd–C (2.5 g) at 20 psi. After 10 h the reaction was filtered using a Celite pad and evaporated. The residue was dissolved in EtOAc (200 mL) and washed with saturated brine (25 mL) containing $NaHSO_3$ (500 mg). The aqueous phase was extracted with EtOAc (3 × 20 mL). The combined organic phase was dried, evaporated, and purified by chromatography on silica (50 g, 3 × 20 cm). Elution with solvent A followed by EtOAc gave the desired product as a syrup after removal of solvents.

The yield of "faster" isomer **9***a* was 3.5 g (94%), $[\alpha]_D^{23}$ −30° (*c* 0.1 $CHCl_3$); nmr δ: 1.27 (d, J_{7-6} = 6 Hz, 3, H7's), 1.36 & 1.56 (s & s, 3 & 3, $C(CH_3)_2$), 2.16 (s, 3, $COCH_3$), 3.98 (q, J_{6-7} = 6 Hz, J_{6-5} = 5 Hz, 1, H6), 4.10–4.30 (m, J_{5-6} = 5 Hz, J_{5-4} = 6.5 Hz, J_{3-2} = 4 Hz, J_{3-4} = 3.5 Hz, 2, H5 & H3), 4.88 (d of d, J_{4-5} = 6.5 Hz, J_{4-3} = 3.5 Hz, 1, H4), 5.28 (d, J_{2-3} = 4 Hz, 1, H2), 6.3–6.6 (bs, 2, $CONH_2$); ms *m/z*: 274.1290 (1.2, M + 1, calcd. for $C_{12}H_{20}NO_6$: 274.1292), 259.1015 (9.9, M + 1 − CH_3), 285.0981 (79.7, M − CH_3), 216.0874 (5.8, M + 1 − CH_3 − $COCH_3$), 215.0787 (5.4, M − CH_3 − $COCH_3$). *Anal.* calcd. for $C_{12}H_{19}NO_6$: C 52.74, H 7.00, N 5.13; found: C 52.37, H 7.11, N 4.80.

The yield of **9***b* was 3.4 g (91%), $[\alpha]_D^{23}$ −5° (*c* 0.1 $CHCl_3$); nmr δ: 1.33 (d, J_{7-6} = 6 Hz, 3, H7's), 1.36 & 1.56 (s & s, 3 & 3, $C(CH_3)_2$), 2.20 (s, 3, $COCH_3$), 4.00 (q, J_{6-7} ~ 6 Hz, J_{6-5} ~ 5 Hz, 1, H6), 4.15–4.35 (m, 2, H3 & H5), 4.64 (d of d, J_{4-5} ~ 6 Hz, J_{4-3} ~ 3 Hz, 1, H4), 5.25 (d, J_{2-3} = 4 Hz, 1, H2), 6.1–6.5 (bs, 2, $CONH_2$).

*3,6-Anhydro-7-deoxy-4,5-*O*-isopropylidene-*D-glycero-D-(allo *and* altro)*-heptonamides (**10**a and **10**b)*

A solution of **9***a* or **9***b* (4.0 g, 14.6 mmol) in MeOH (100 mL) was treated with saturated NH_3/MeOH (100 mL), left at 0°C for 16 h, and then evaporated to give 3.4 g (quantitative) of a white solid, homogeneous by tlc (EtOAc, **9***a*, *b*, R_f ~ 0.5; **10***a*, R_f ~ 0.26; **10***b*, R_f ~ 0.24).

The faster migrating product was crystallized from MeOH/hexane to give 2.95 g (87%) of **10***a*, mp 174–175°C; $[\alpha]_D^{23}$ −10° (*c* 0.1, $CHCl_3$); nmr (Me_2SO-d_6) δ: 1.19 (d, J_{7-6} ~ 7 Hz, 3, H7's), 1.22 & 1.41 (s & s, 3 & 3, $C(CH_3)_2$), 3.7–4.8 (m, 5, sugar), 5.70 (d, 1, OH), ~7.25 (bs, 2, $CONH_2$); ms *m/z*: 232.1186 (1.9, M + 1, calcd. for $C_{10}H_{18}NO_5$: 232.1185), 231.1111 (0.8, M^+), 217.0908 (8.9, M + 1 − CH_3), 216.0874 (84.2, M − CH_3), 188.1009 (2.5, M + 1 − $CONH_2$), 187.0978 (23.1, M − $CONH_2$). *Anal.* calcd. for $C_{10}H_{17}NO_5$: C 51.94; H 7.41, N 6.06; found: C 51.49, H 7.26, N 5.71.

The slower migrating product was crystallized from $CHCl_3$/hexane to give 2.76 g (82%) of **10***b*, mp 102–103°C; $[\alpha]_D^{23}$ −15° (*c* 0.1, $CHCl_3$); nmr (Me_2SO-d_6) δ: 1.16 (d, J_{7-6} ~ 7 Hz, 3, H7's), 1.24 & 1.42 (s & s, 3 & 3, $C(CH_3)_2$), 3.7–4.8 (m, 5, sugar), 5.5 (d, 1, OH), ~7.15 (bs, 2, $CONH_2$). *Anal.* calcd. for $C_{10}H_{17}NO_5$: C 51.94, H 7.41, N 6.06; found: C 51.90, H 7.63, N 5.99.

*3,6-Anhydro-7-deoxy-4,5-*O*-isopropylidene-2-*O*-methanesulfonyl-*D-glycero-D-(allo *and* altro)*-heptonamides (**11**a and **11**b)*

A solution of **10***a* or **10***b* (2.31 g, 10 mmol) in pyridine (25 mL) and CH_2Cl_2 (10 mL) at 0°C was treated dropwise with methanesulfonyl chloride (5.7 g, 50 mmol) in CH_2Cl_2 (10 mL). After 4 h at 0°C the solution was treated with a chip of ice, diluted with EtOAc (150 mL), washed with saturated brine (3 × 10 mL), dried, and evaporated to a syrup. This residue was chromatographed on silica (50 g, 3 × 20 cm). Elution with solvent B followed by EtOAc gave 2.6 g (84%) of **11***a* or **11***b*.

The faster migrating residue was crystallized from Et_2O/hexane to give 2.15 g (70%) of **11***a*, mp 104–105°C; $[\alpha]_D^{23}$ +9° (*c* 0.1, $CHCl_3$); nmr δ: 1.32 (d, J_{7-6} = 6 Hz, 3, H7's), 1.36 & 1.52 (s & s, 3 & 3, $C(CH_3)_2$), 3.15 (s, 3, SO_2CH_3), 4.00 (q, J_{6-7} ~ J_{6-5} ~ 6 Hz, 1, H6), 4.15–4.95 (m, 2, H3 & H5), 4.81 (d of d, J_{4-5} = 6.5 Hz, J_{4-3} = 4 Hz, 1, H4), 5.13 (d, J_{2-3} = 3.5 Hz, 1, H2), 6.25 & 6.7 (bs, 2, $CONH_2$); ms *m/z*: 295.0677 (10.3, M + 1 − CH_3, calcd. for $C_{10}H_{17}NO_7S$: 295.0716), 294.0651 (83.7, M − CH_3), 157.0860 (16.4, M − $C_3H_6NO_4S$). *Anal.* calcd. for $C_{11}H_{19}NO_7S$: C 42.71, H 6.19, N 4.53, S 10.36; found: C 42.60, H 6.08, N 4.27, S 10.25.

The slower migrating product was crystallized as above to give 2.4 g (78%) of **11***b*, mp 143–144°C; $[\alpha]_D^{23}$ −35° (*c* 0.1 $CHCl_3$); nmr δ: 1.32 (d, J_{7-6} = 6 Hz, 3, H7's), 1.36 & 1.52 (s & s, 3 & 3, $C(CH_3)_2$), 3.17 (s, 3, SO_2CH_3), 4.02 (m, J_{6-7} ~ J_{6-5} ~ 6 Hz, 1, H6), 4.20–4.35 (m, 2, H3 & H5), 4.80 (d of d, J_{4-5} = 6.5 Hz, J_{4-3} = 4 Hz, 1, H4), 5.00 (d, J_{2-3} = 4 Hz, 1, H2), 6.25 & 6.7 (bs, 2, $CONH_2$).

*3,6-Anhydro-2-azido-2,7-dideoxy-4,5-*O*-isopropylidene-*D-glycero-D-(altro *and* allo) *heptonamides (**12**a and **12**b)*

A solution of **11***a* or **11***b* (2.31 g, 7.5 mmol) in DMF was treated with LiN_3 (1.85 g, 38 mmol) and stirred at 80°C for 5 h. The mixture was concentrated to a yellow paste, dissolved in EtOAc (100 mL), washed with saturated brine (3 × 10 mL), dried, and evaporated. The residue was chromatographed on silica (25 g, 2.2 × 18 cm). Elution with solvent A followed by EtOAc gave the desired product.

The yield of the purified faster migrating isomer was 1.77 g (92%). A sample was crystallized from Et_2O/hexane to give **12***a*, mp 126–127°C; $[\alpha]_D^{23}$ −32° (*c* 0.1, $CHCl_3$); ir (KBr): 1600 cm^{-1} ($CONH_2$), 2120 cm^{-1} (RN_3), 3300–3400 cm^{-1} (NH_2); nmr δ: 1.31 (d, J_{7-6} = 6.5 Hz, 3, H7's), 1.34 & 1.52 (s & s, 3 & 3, $C(CH_3)_2$), 4.00 (q, J_{6-7} ~ J_{6-5} ~ 6.5 Hz, 1, H6), 4.26 (d, J_{2-3} = 4 Hz, 1, H2), 4.27 (t, J_{5-6} ~ J_{5-4} ~ 6.5 Hz, 1, H5), 4.42 (t, J_{3-2} ~ J_{3-4} = 4 Hz, 1, H3), 4.60 (d of d, J_{4-5} ~ 6.5 Hz, J_{4-3} ~ 4 Hz, 1, H4); ms *m/z*: 241.0934 (64.4, M − CH_3, calcd. for $C_9H_{13}N_4O_4$: 241.0937), 214.1081 (48.1, M − N_3), 199.0836 (1.2, M − N_3 − CH_3), 157.0863 (94, M − $C_2H_3N_4O$). *Anal.* calcd. for $C_{10}H_{16}N_4O_4$: C 46.87, H 6.29, N 21.86; found: C 46.59, H 6.50, N 22.06.

The slower migrating isomer was crystallized from Et_2O to give 1.8 g (94%) of **12***b*, mp 114–116°C. An analytical sample was recrystallized from Et_2O to give **12***b*, mp 119–120°C; $[\alpha]_D^{23}$ −84° (*c* 0.1, $CHCl_3$); nmr δ: 1.36 (d, J_{7-6} = 6.5 Hz, 3, H7's), 1.34 & 1.51 (s & s, 3 & 3, $C(CH_3)_2$), 3.90–4.90 (m, 4, H2, H3, H5, H6), 4.79 (d of d, J_{4-5} ~ 6.5 Hz, J_{4-3} ~ 3 Hz, 1, H4), 6.0 & 6.4 (bs & s, 2, $CONH_2$). *Anal.* calcd. for $C_{10}H_{16}N_4O_4$: C 46.87, H 6.29, N 21.86; found: C 47.23, H 6.55, N 21.50.

*Methyl 3,6-anhydro-2-azido-2,7-dideoxy-*D-glycero-D-(altro *and* allo)*-heptonamides (**13**a and **13**b)*

A solution of **12***a* or **12***b* (1.5 g, 5.9 mmol) in MeOH (50 mL, dried and distilled) was stirred at reflux with ANGC(H^+) resin (5 g). After 4.5 h an additional portion of resin (5 g) was added to the refluxing mixture. After a total reflux time of 9 h the mixture was filtered using a Celite pad, evaporated, and chromatographed over silica (20 g, 2.3 × 12 cm). Elution with solvent A followed by EtOAc gave 1.15 g (85%) of **13***a* or **13***b* as a stiff syrup.

The faster migrating isomer (**13***a*) had $[\alpha]_D^{23}$ −62° (*c* 0.1, $CHCl_3$); ir (film: 1740 cm^{-1} (CO_2CH_3), 2120 cm^{-1} (RN_3); nmr δ: 1.31 (d, J_{7-6} = 6 Hz, 3, H7's), 3.5–4.4 (m, 7, sugar, OH), 3.84 (s, 3, CO_2CH_3); ms *m/z*: 213.0749 (2.4, M − H_2O, calcd. for $C_8H_{11}N_3O_4$: 213.0749), 117.0549 (98.4, M − $C_3H_4N_3O_2$). *Anal.* calcd. for $C_8H_{13}N_3O_5$: C 41.56, H 5.67, N 18.17; found: C 41.08, H 5.72, N 18.08.

Isomer **13***b* had $[\alpha]_D^{23}$ +4° (*c* 0.1, $CHCl_3$); nmr δ: 1.31 (d, J_{7-6} = 6 Hz, 3, *H*7's), 3.5–4.4 (m, 7, sugar, OH), 3.82 (s, 3, CO_2CH_3).

*Methyl 3,6-anhydro-2-azido-2,7-dideoxy-4,5-*O*-thiocarbonato-*D-glycero-D-*(*altro *and* allo*)-heptonoates (**14***a and **14***b)*

A solution of **13***a* or **13***b* (1.15 g, 5 mmol) in Me_2CO (50 mL) was treated with *N*,*N*′-thiocarbonyldiimidazole (23) (1.78 g, 10 mmol) and stirred at room temperature. After 12 h, tlc (solvent A, **13***a*, *b*, R_f ~ 0.5; **14***a*, *b*, R_f ~ 0.7) indicated that reaction was complete. Solvent was evaporated, the residue was dissolved in EtOAc (100 mL) and washed with 1 N HCl/H_2O (2 × 10 mL), saturated brine (3 × 20 mL), dried, and evaporated. This residue was dissolved in Et_2O (50 mL) and rapidly filtered through silica (5 g). The silica was washed with Et_2O (20 mL) and the combined eluates were evaporated to give 1.25 g (91%) of **14***a* or **14***b*. The faster migrating isomer was isolated as a solid and was crystallized from Et_2O/hexane to give **14***a* with mp 95–96°C; ir (KBr): 1750 cm^{-1} (CO_2Me), 2120 cm^{-1} (RN_3); uv (MeOH) max: 238 nm; nmr δ: 1.43 (d, J_{7-6} = 6 Hz, 3, H7's), 3.84 (s, 3, CO_2CH_3), 4.07 (d, J_{2-3} ~ 3.5 Hz, 1, H2), 4.13 (m, J_{6-7} ~ J_{6-5} ~ 6 Hz, 1, H6), 4.55 (t, J_{3-4} = 3.0 Hz, J_{3-2} ~ 3.5 Hz, 1, H3), 4.85 (d of d, J_{5-4} = 8 Hz, J_{5-6} = 6.0 Hz, 1, H5), 5.32 (d of d, J_{4-5} = 8 Hz, J_{4-3} = 3.0 Hz, H4); ms *m*/*z*: 273.0420 (100, M^+, calcd. for $C_9H_{11}N_3O_5S$: 273.0420).

Isomer **14***b* was isolated as a viscous syrup with ir (Nujol): 1745 cm^{-1} (CO_2CH_3), 2120 cm^{-1} (RN_3); uv (MeOH) max: 238 nm; nmr δ: 1.44 (d, J_{7-6} = 6 Hz, 3, H7's), 3.84 (s, 3, CO_2CH_3), 4.14 (q, J_{6-7} ~ J_{6-5} ~ 6 Hz, 1, H6), 4.38 (d, J_{2-3} ~ 3.5 Hz, 1, H2), 4.51 (t, J_{3-4} = 3.0 Hz, J_{3-2} ~ 3.5 Hz, 1, H3), 4.82 (d of d, J_{3-4} = 8 Hz, J_{5-6} = 6.0 Hz, 1, H5), 5.34 (d of d, J_{4-5} = 8 Hz, J_{4-3} = 3.0 Hz, 1, H4); ms *m*/*z*: 273.0422 (100, M^+, calcd. for $C_9H_{11}N_3O_5S$: 273.0420).

*2(*S *and* R*)-amino-2-[2,5-dihydro-5(*R*)-methylfuran-2(*R*)-yl]ethanoic acids (**1** and **15**)*

A solution of **14***a* or **14***b* (273 mg, 1 mmol) in trimethylphosphite (25 mL) was stirred at reflux for 14 h under N_2, cooled, and evaporated to a syrup. This residue was saponified with 1 *N* $NaOH/H_2O$ (20 mL) at 90°C for 0.5 h, cooled to 0°C, and acidified to pH 2 with 1 *N* HCl/H_2O. This solution was applied to a column of ANGC(H^+) resin (20 g) and the column was washed with 0.1 *N* HCl/H_2O (100 mL) followed by H_2O (200 mL). The product was eluted with 0.5 *N* NH_3/H_2O and the ninhydrin positive fractions were collected and evaporated to give 50 mg (32%) of **1** or **15**. A solution of **1** in acetonitrile/MeOH was allowed to evaporate slowly to give a white microcrystalline solid with mp 175–178°C (dec.); $[\alpha]_D^{23}$ −50° (*c* 0.1, H_2O), $[\alpha]_D^{23}$ −8° (*c* 0.1, 1 *N* HCl/H_2O); ir (Nujol): 3000 cm^{-1} (NH_3^+), 1630 cm^{-1} (CO_2^-), 1590, 1460, and 1380 cm^{-1}; cd (*c* 1 mg/mL, 1 *N* or 6 *N* HCl/H_2O) $[\theta]_{216}$ = +2200; ord (*c* ~1 mg/mL), 6 *N* HCl/H_2O), $[\phi]_{210}$ = +1100; ^1H nmr (200 MHz) (D_2O) δ: 1.34 (d, J_{7-6} = 6.5 Hz, 3, H7's), 3.81 (d, J_{2-3} = 3 Hz, 1, H2), 4.95 (m, J_{6-7} = 6.5 Hz, J_{6-5} = 2 Hz, J_{6-4} = 0.5 Hz, J_{6-3} = 4.5 Hz, J_{6-2} ~ 0 Hz, 1, H6), 5.24 (m, J_{3-2} = 3.0 Hz, J_{3-4} = 2.5 Hz, J_{3-5} = 1 Hz, J_{3-6} = 4.5 Hz, 1 H3), 5.82 & 6.10 (ABX, J_{4-5} = 6 Hz, J_{4-3} = 2.5 Hz, J_{5-6} = 2 Hz, 2, H4 & H5); ^{13}C nmr (D_2O) δ: 21.2 (C7), 57.4 (C2), 83.6, 84.6 (C3, C6), 125.1, 136.0 (C4, C5), 172.0 (CO_2H).

Diastereomer **15** was recovered as a tan-colored solid with mp 185–190°C; $[\alpha]_D^{23}$ +21° (*c* 0.1, 1 *N* HCl/H_2O) (optical rotation calculated (5) for this particular mixture estimated from nmr to contain: **15** (82%) and **1** (18%) = +27°); cd (*c* ~ 1 mg/mL, 1 *N* HCl/H_2O) $[\theta]$ = −1700; ^1H nmr (200 MHz) (D_2O) δ: 1.28 (d, J_{7-6} = 7 Hz, 3 H7's), 3.99 (d, J_{2-3} = 4 Hz, 1, H2), 5.00 (m, J_{6-7} = 7 Hz, J_{6-5} = 2.5 Hz, J_{6-4} = 1 Hz, J_{6-3} = 4.5 Hz, J_{6-2} ~ 0 Hz, 1, H6), 5.30 (m, J_{3-2} = 4 Hz, J_{3-4} = 3 Hz, J_{3-5} = 1 Hz, J_{3-6} = 4.5 Hz, 1, H3), 5.70 & 6.12 (ABX, J_{4-5} = 6.5 Hz, J_{4-3} = 3 Hz, J_{5-6} = 2.5 Hz, 2, H4 & H5); ^{13}C nmr (D_2O) δ: 20.9 (C7), 56.9 (C2), 83.6, 84.0 (C3, C6), 122.9, 136.3 (C4, C5).

*2(*S*)-Amino-2-[tetrahydro-5(*R*)-methylfuran-2(*R*)-yl]ethanoic acid*

A solution of **1** (5mg) in H_2O (5 mL) was hydrogenated over 5% Pd–C (5 mg) at atmospheric pressure for 10 h, filtered using a Celite pad, and evaporated to give 5 mg of a solid with cd (*c* ~2 mg/mL, 6 *N* HCl/H_2O) $[\theta]_{215}$ = +2000; ^1H nmr (200 MHz) (D_2O) δ: 1.22 (d, 3, H7's), 1.40–2.20 (m, 4, H4's, H5's), 3.65 (d, 1, H2), 3.70–4.50 (m, 2, H3, H6).

Received May 17, 1982

JOHN A. FINDLAY, JIA-SEN LIU, and LAJOS RADICS. Can. J. Chem. **61**, 323 (1983).

Full spectral details in support of the earlier proposed structure **1***a* for the antitumor antibiotic ravidomycin are presented together with an account of chemical degradation products. A complete corroboration of structure is provided by cross correlation of ^{1}H and ^{13}C nmr for ravidomycin and its diacetate **1***b*.

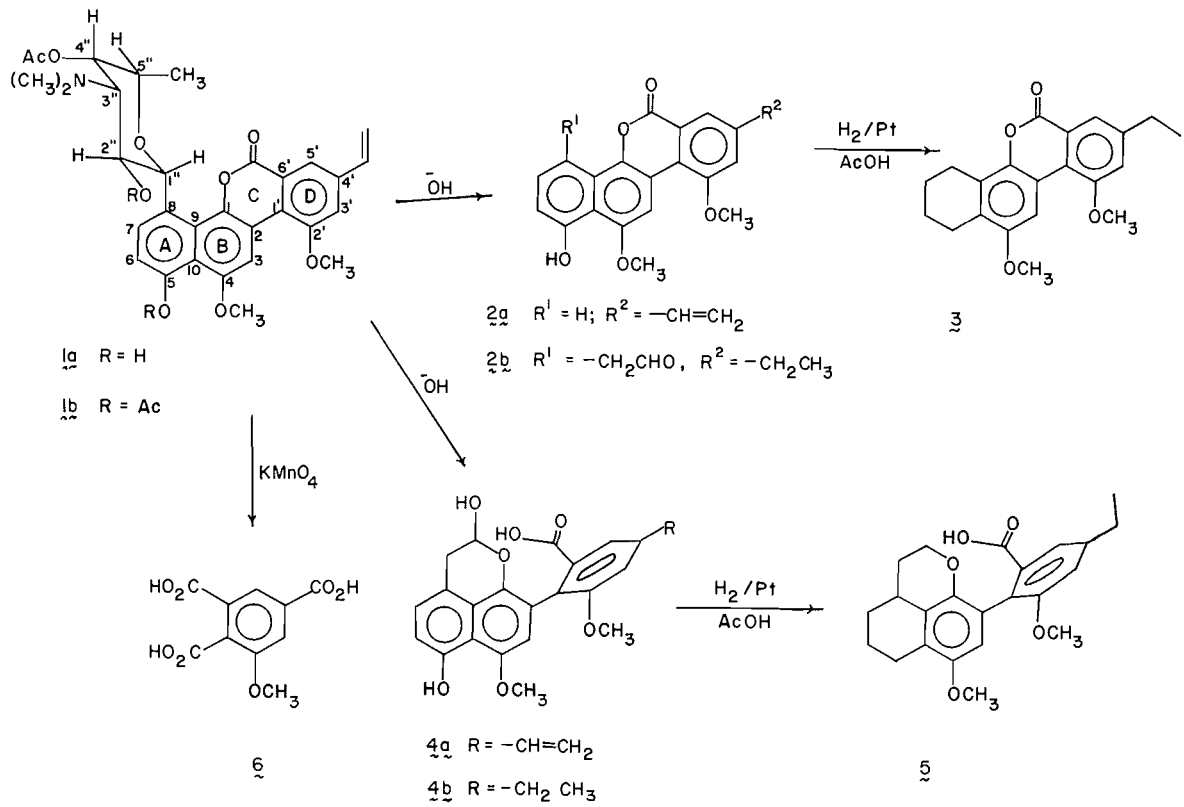
JOHN A. FINDLAY, JIA-SEN LIU et LAJOS RADICS. Can. J. Chem. **61**, 323 (1983).

On présente toutes les données spectrales qui confirment la structure **1***a* proposé pour la ravidomycine l'antibiotique antituméreux, ainsi qu'une analyse des produits de dégradation. On obtient une corroboration complète de structure grâce à une corrélation croisée de la rmn du ^{1}H et du ^{13}C de la ravidomycine et de son diacétate **1***b*.

[Traduit par le journal]

In a recent preliminary report (1) we proposed structure **1***a* for ravidomycin, an antitumor antibiotic isolated (2) from the fermentation broth of *Streptomyces ravidus*. This proposal was based on analysis of ^{1}H nmr, infrared, and ultraviolet spectral data on **1***a*, its diacetate **1***b*, the alkali fusion derived aglycone **2***a* and tranformation products **3**, **4***a*, **4***b*, and **5**. We now provide full spectral characteristics for the latter together with appropriate mechanistic rationale for their formation. In addition, a detailed corroboration of structure is forthcoming from cross correlation of the ^{1}H and ^{13}C nmr spectra of ravidomycin **1***a* and ravidomycin diacetate **1***b*.

In our structural elucidation of ravidomycin the key chemical degradative products were the aglycone **2***a* and the optically inactive diastereomeric mixture (1 : 1) of hemiacetal carboxylic acids **4***a* which were obtained in 13% and 45% yield, respectively, from alkaline fusion of **1***a* in 50% KOH at reflux temperature for 6 h. Since our conclusions about the structures of these compounds led directly to the placement of the relative positions of the *C*-glycosidic moiety and the lactone ring ether oxygen on the phenyl naphthalene skeleton it is appropriate to account for their generation. Scheme 1 portrays a mechanistic proposal to rationalize the formation of aglycone **2***a* via a



1*a* R = H
1*b* R = Ac

2*a* R^1 = H; R^2 = −CH=CH_2
2*b* R^1 = $-CH_2CHO$, R^2 = $-CH_2CH_3$

3

4*a* R = −CH=CH_2
4*b* R = $-CH_2CH_3$

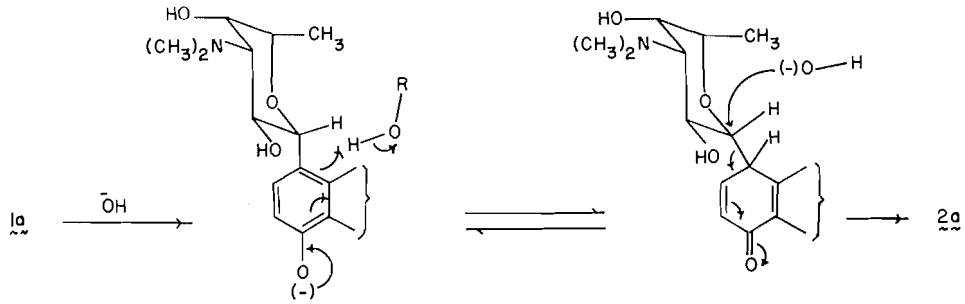
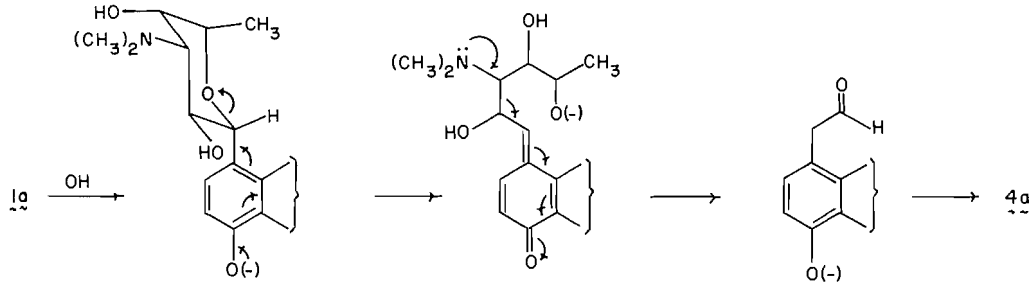


SCHEME 1



SCHEME 2

reverse electrophilic aromatic substitution in which the phenol is dealkylated at the *para* position via a quinonoid sigma complex. A possible mode of generation of the masked aldehyde **4***a* is portrayed in Scheme 2 in which the essential cleavage of the *C*-glycoside ether bond is accomplished by base catalysed generation of quinone methine **7** and followed by the rupture of the vinylogous β-aminoketone to provide the free aldehyde group which interacts with the B ring phenolate to produce the diastereomeric hemiacetals **4***a*.

The dihydro derivatives **4***b* were obtained from **4***a* in quantitative yield by catalytic (PtO) hydrogenation in ethanol and this mixture was transformed in 50% yield to the achiral isomeric lactone aldehyde **2***b* by heating in quinoline at 180°C in the presence of copper powder. The ir spectrum (KBr) of the latter gave no evidence of a carboxyl group but a strong absorption centred at 1710 cm^{-1} due to the conjugated lactone and aldehyde, while the ^1H nmr spectrum ($CDCl_3$) displayed the aldehyde proton as a singlet at δ 10.17 ppm.

It may be noted that the ready oxidative degradation of ravidomycin **1***a* to the known (5) anisole 2,3,5-tricarboxylic acid **6**, which affords corroboration of the juxtaposition of groups in ring D, is paralleled in the behaviour towards alkaline permanganate of the structurally related *C*-glycoside toromycin (3) which possesses the same aglycone as **1***a* but is devoid of nitrogen in its sugar moiety.

Complete corroborative evidence for the formulation of ravidomycin and its diacetate as in **1***a* and **1***b* is now available from our complementary ^{13}C nmr spectral analyses. The results are summarized in Table 1. To obtain these data, the following experiments were carried out. Broad band decoupled and off-resonance decoupled $^{13}C-\{^1H\}$ spectra were recorded to yield carbon chemical shifts and cross-correlations between proton-bearing carbons and their respective hydrogen atoms. The assignment of quaternary carbon signals was deduced from a series of single frequency selective (low power) $^{13}C-\{^1H\}$ double resonance experiments (correlating the quaternary carbon multiplets with individual protons in terms of long-range carbon–proton coupling constants), observed acetylation shifts, and the substantial differences in the $^{13}C-\{^1H\}$ (non-selective) nOe values of signals due to quaternary carbon atoms with and without proton(s) in *ortho* position (high and reduced nOe, respectively). Distinction between two-bond and three-bond coupling interactions (geminal vs. vicinal carbon–proton couplings) was usually based on the magnitude of the observed splittings (typical values: ^2J = 1 to 2 Hz and ^3J = 7 to 10 Hz). For couplings with 3 to 4.5 Hz moduli, the nature of the interaction was inferred either from SPT (selective population transfer) measurements (by selective inversion of one of the components of the pertinent proton satellites) affording the sign of the pertinent long-range coupling, or from the occurrence or absence of a selective $^{13}C-\{^1H\}$ nOe during selective proton decoupling experiments (the former case being characteristic of geminal coupling).

The formulation of the polycyclic backbone rests on the following evidence.

Single frequency selective $^{13}C-\{^1H\}$ decoupling experiments disclosed that the doublet splitting of the carbonyl carbon resonance of **1***b* at 160.3 ppm arises from three-bond coupling to H5′ (+4.2 Hz) and the *only* coupling exhibited by the quaternary carbon atom bearing the lactone oxygen (C1) was due to its three-bond spin–spin interaction (8.6 Hz) with H3. Selective decoupling experiments, furthermore, showed that C1′ was vicinally coupled to H5′, H3′, and H3. These findings, combined with other pertinent carbon-13 data (see Table 1), confirm that the arrangement of rings A, B, C, and D of the aglycone (as well as their respective patterns of substitution) must be as in formula **1***b*.

Low power selective irradiation of C4-OMe protons caused the C4 multiplet to collapse into a doublet due to the two-bond interaction with H3 (−4.5 Hz). This indicated the absence of vicinal interaction with ring A protons. Since the same conclusion has been reached for C1 (*vide supra*), both *peri* positions of ring A (i.e. C5 and C8) must be substituted.

Selective irradiation of the lower field *ortho*-coupled proton resonance (7.98 ppm, H-7 in **1***b*) caused the 8.4 Hz coupling of the signal at 125.16 ppm (C-9) to collapse, which showed the

[a]Chemical shifts are in delta ppm relative to internal TMS, $CDCl_3$.
[b]Capital letters refer to multiplicity resulting from directly bonded protons and small letters to long range ^{13}C, ^1H couplings.
[c]Coupling constants (±0.2 Hz) were obtained from first-order treatment of the SFSD and undecoupled spectra run at 50.32 MHz. Four-bond and two-bond couplings with nearly zero moduli are not reported.
[d]Multiplet pattern not analyzed.
[e]Resonance with highly reduced nOe indicating the absence of α-CH proton(s).
[f]Assignments may be interchanged.

existence of a three-bond interaction between these nuclei. The lack of appreciable acetylation shift, on the other hand, indicated a *meta* relationship between this (low nOe) carbon and the C5-OAc (OH) substituent. Further selective decoupling experiments involving ring A and B protons revealed that the multiplet at 116.0 (ravidomycin) or 120.89 (diacetate) was due to the (low nOe) quaternary carbon atom (C10) which was vicinally coupled to H3 *and* the higher field (H6) ring A proton (7.22 ppm in **1***b*). The observed +5 ppm acetylation shift attested to the *ortho* relationship between the C10 carbon atom and the OAc (OH) function.

The ^{13}C chemical shift assignments for the ravidomycin nucleus are in close agreement with those of Takashima *et al.* (4) for the structurally related antitumor antibiotic gilvogarcin which possesses the same aglycone linked to a furanose moiety. In view of this the assignment of ^{13}C signals in the published inventory of chemical shifts for carbon atoms in the toromycin (3) aglycone is facilitated.

Experimental

All melting points were determined on a Kofler hot stage apparatus and are uncorrected.

High resolution mass spectra were recorded on an AE1 MS-50 spectrometer at the Mass Spectrometry Lab., University of Alberta. Low resolution mass spectra were recorded on an Hitachi Perkin–Elmer RMU-6D spectrometer. The infrared spectra were measured on a Perkin–Elmer 727B or 598 infrared spectrophotometer and ultraviolet spectra were obtained with a Beckman 25 instrument.

The ^1H spectra of compounds **2***a* to **6** inclusive were determined on a Nicolet NIC-360 spectrometer at Toronto Biomedical NMR Centre while ^1H and ^{13}C spectra of ravidomycin **1***a* and ravidomycin diacetate **1***b* were recorded on a disk-augmented Varian XL-100/15FT instrument. Proton-coupled and single frequency (low-power) selective ^{13}C–{^1H} double resonance spectra were run at 50.32–{200.13} MHz using a Bruker WP 200/SY spectrometer. The amplitude of the decoupling field in the SFSD experiments varied from 2.5 to 10 Hz and the decoupler power employed in selective population transfer measurements runs for relative sign determination was usually set to 2 Hz.

Purification of ravidomycin **1**a

The ravidomycin (1.1 g), supplied by Ayerst Research Laboratories, was dissolved in chloroform (10 mL) and applied to the top of a dry column of silica gel G (polyethylene pellicle column 2.6 × 46 cm), which was developed with choroform/methanol (8:1). As soon as the solvent reached the bottom of the column, the main yellow band was cut out of the column and eluted with chloroform/methanol (5:1) immediately . The eluate was concentrated and the residue was crystallized from ethyl acetate. Fine needles were obtained, mp 248–250°C; $[\alpha]_D$ −105.5° (*c* 0.20, $CHCl_3$); ir (KBr) ν_{max}: 3380 (OH), 1740, 1240 (acetate), 1720 (lactone), 1620, 1600, 1580 (aromatic ring) cm^{-1}; uv (MeOH)λ_{max} nm (log ϵ): 244 (4.68), 263 (4.54, sh), 277 (4.60), 285 (4.65), 308 (4.33), 320 (4.30), 335 (4.20), 350 (4.08), 392 (4.24); uv ($CHCl_3$) λ_{max} nm: 246, 265, 278, 288, 308, 322, 334, 350, 395; ms *m/e*: 563.2148 (52.09%, calcd. for $C_{31}H_{33}NO_9$: 563.2155, M^+); cd (*c* = 0.0081, $CHCl_3$) $[\theta]^{26}$ nm: −2659 (245), −1095 (264), −1877 (275), −2502 (288), −1870 (300), −1877 (310), −1880 (320), −1408 (330), −1410 (340), −1870 (400).

Ravidomycin acetate **1**b

Ravidomycin (20 mg) was acetylated in pyridine (1.5 mL) and acetic anhydride (1.5 mL) at room temperature for 2 days, affording its diacetate **1***b* in quantitative yield, a colloidal solid from dichloromethane/methanol, mp 238–239°C; $[\alpha]_D^{26}$ + 33.3° (*c* 0.072, $CHCl_3$); ir ($CHCl_3$) ν_{max}: 1740 (acetyl), 1725 (lactone), 1610, 1590 (aromatic ring) cm^{-1}, no hydroxyl; uv (MeOH) λ_{max} nm (log ϵ): 245 (4.50), 278 (4.48), 285 (4.51), 306 (4.17, sh), 323 (4.08), 335 (4.06), 346 (4.01, sh), 383 (4.13); ms *m/e*: 647.2361 (3.77%, calcd. for $C_{35}H_{37}NO_{11}$: 647.2367, M^+).

Aglycone **2**a *and hemiacetals* **4**a

Ravidomycin (0.5 g) in 50% potassium hydroxide (8 mL) was refluxed for 6 h under nitrogen. The reaction mixture was acidified with concentrated hydrochloric acid in an ice bath, and provided the yellow products which were chromatographed on a silica gel column eluting with chloroform, then chloroform/methanol (20:1). The early fractions eluted by chloroform gave the aglycone **2***a* (40 mg), yellow needles from chloroform/methanol, mp 265–266°C $[\alpha]_D^{20}$ 0° (*c* 0.50, $CHCl_3$). The middle fraction eluted by chloroform/methanol (20:1) yielded the yellow granular crystals (160 mg) **4***a*, mp 227–230°C after recrystallization with chloroform/methanol; $[\alpha]_D^{20}$ 0° (*c* 1.00, $CHCl_3$). The ^1H nmr spectrum indicates a mixture (1:1) of diastereomers.

Aglycone **2***a*: ir (KBr) ν_{max}: 3350 (br, OH), 1720 (lactone), 1625, 1600, 1580 (aromatic ring) cm^{-1}; uv (MeOH) λ_{max} nm (log ϵ): 243 (4.66), 263 (4.50), 273 (4.55), 283 (4.54), 307 (4.26), 386 (4.21); ^1H nmr ($CDCl_3/CD_3OD$) δ_{TMS}: 3.51 (br, 1H, OH), 4.12 (s, 6H, OCH_3 × 2), 5.47 (d, 1H, J_{cis} = 11.0 Hz, ), 5.96 (d, 1H, J_{trans} = 17.4 Hz, ), 6.81 (dd, 1H, J_{cis} = 11.0 Hz, J_{trans} = 17.4 Hz, ), 7.00 (dd, 1H, $J_{6,7}$ = 8.0 Hz, $J_{6,8}$ = 0.8 Hz, H-6), 7.36 (d, 1H, $J_{3,5}$ = 1.6 Hz, H-3′), 7.50 (dd, $J_{6,7}$ = 8.0 Hz, $J_{7,8}$ = 8.0 Hz, H-7), 8.04 (dd, 1H, $J_{7,8}$ = 8.0 Hz, $J_{6,8}$ = 0.8 Hz, H-8), 8.10 (d, 1H, $J_{3',5'}$ = 1.6 Hz, H-5′), 8.31 (s, 1H, H-3); ms *m/e*: 348.0997 (100.00%, calcd. for $C_{21}H_{16}O_5$: 348.0998, M^+).

Hemiacetals **4***a*: ir (KBr) ν_{max}: 3600–2500, 1700 (OH, COOH), 1620, 1600, 1570 (aromatic ring) cm^{-1}; uv (MeOH) λ_{max} nm (log ϵ): 228 (4.76), 260 (4.38), 308 (4.07), 336 (4.01), 353 (4.11); ^1H nmr ($CDCl_3/CD_3OD$) δ_{TMS}: 2.82 (br, 3H, COOH, OH × 2), 3.00–3.30 (m, 2H, Ar-CH_2), 3.80, 3.79 (s, each 1.5 H, OCH_3-2′), 4.01 (s, 3H, OCH_3-4), 5.38 (dd, 0.5 H, *J* = 3.0/7.2 Hz, axial hemiacetal proton), 5.67 (dd, 0.5 H, *J* = 3.0/3.0 Hz, equatorial hemiacetal proton), 5.37 (d, 1H, J_{cis} = 11.0 Hz, ), 5.86 (d, 1H, J_{trans} = 17.7 Hz, ), 6.77, 6.76 (dd, each 0.5 H, J_{trans} = 17.7 Hz, J_{cis} = 11.0 Hz, ), 6.73, 6.69 (s, each 0.5 H, H-3), 6.82 and 6.83, 7.08 and 7.10 (two pair of AB, each 0.5 H, $J_{6,7}$ = 8.0 Hz, H-7, H-6), 7.18, 7.19 (d, each 0.5 H, $J_{3',5'}$ = 1.5 Hz, H-3′), 7.51, 7.55 (d, each 0.5 H, $J_{3',5'}$ = 1.5 Hz, H-5′); ms *m/e*: 408.1205 (10.0%, calcd. for $C_{23}H_{20}O_7$: 408.1209, M^+).

Compound **3**

The aglyone **2***a* (5 mg) in acetic acid (20 mL) was hydrogenated in the presence of platinum oxide (20 mg) at 70–75°C for 4 h, giving colorless needles (3 mg) which were crystallized from methanol, mp 190–192°C; ir (KBr) ν_{max}: 1710 (lactone), 1610, 1585 (aromatic ring) cm^{-1}, no hydroxyl; uv (MeOH) λ_{max} nm (log ϵ): 212 (4.58, sh), 221 (4.61, sh), 232 (4.69, sh), 238 (4.70), 262 (4.29, infl), 274 (4.29), 350 (4.16); ^1H nmr ($CDCl_3$) δ_{TMS}: 1.30 (t, 3H, *J* = 7.6 Hz, CH_2CH_3), 2.78 (q, 2H, *J* = 7.6 Hz, CH_2CH_3), 1.82 (m, 4H, —CH_2—CH_2—), 2.73, 2.96 (m, each 2H, Ar-CH_2 × 2), 3.90 (s, 3H, OCH_3-4), 4.07 (s, 3H, OCH_3-2′), 7.16 (d, $J_{3',5'}$ = 1.5 Hz, H-3′), 7.95 (d, $J_{3',5'}$ = 1.5 Hz, H-5′), 8.30 (s, 1H, H-3); ms *m/e*: 338.1512 (100.00%, calcd. for $C_{21}H_{22}O_4$: 338.1518, M^+).

Compound **5**

The mixture of hemiacetals **4***a* (5 mg) was hydrogenated by the above-mentioned method and the reaction product was separated on tlc (solvent system: chloroform/methanol 30:1). The main product **5** was crystallized from methanol, plates (2 mg), mp 224–226°C; ir (KBr) ν_{max}: 3600–2500, 1690, 1670 (COOH), 1600 (aromatic ring) cm^{-1}; uv (MeOH) λ_{max} nm (log ϵ): 209 (4.60), 300 (3.78); ^1H nmr ($CDCl_3/CD_3OD$) δ_{TMS}: 1.29 (t, 3H, *J* = 7.5 Hz, CH_2CH_3), 2.70 (q, 2H, *J* = 7.5 Hz, CH_2CH_3), 1.60–2.05 (m, 7H, aliphatic CH_2 × 3 and COOH, covered), 2.50–2.90 (m, 3H, Ar-CH × 3), 3.73 (s, 3H, OCH_3-4), 3.76, 3.77 (s, each 1.5 H, OCH_3-2′), 4.05 (m, 1H, axial α-hydropyran proton), 4.24 (m, 1H, equatorial α-hydropyran proton), 6.55, 6.57 (s, each 0.5 H, H-3), 6.94 (d, 1H, $J_{3',5'}$ = 1.4 Hz, H-3′), 7.27 (d, $J_{3',5'}$ = 1.4, H-5′); ms *m/e*: 382.1780 (100.00%, calcd. for $C_{23}H_{26}O_5$: 382.1780, M^+).

4-Carboxyl-6-methoxyphthalic acid **6**

Ravidomycin (100 mg) in 1% potassium hydroxide (15 mL) was oxidized with an aqueous solution of potassium permanganate under stirring and refluxing until persistence of the pink color for half an hour. After filtration of the manganese dioxide the solution was concentrated in vacuum and then acidified with concentrated hydrochloric acid to pH 1 and extracted by ethyl acetate. The evaporated extract was chromatographed on silica gel with chloroform/methanol/acetic acid (6:1:1). The early fraction yielded 4-carboxyl-6-methoxylphthalic acid (25 mg), plates from dilute hydrochloric acid, mp 240–241°C, which were identical in ir spectra and mixture melting point with the authentic sample of **6** synthesized according to a known procedure (5). The acid was methylated in methanol with diazomethane, giving trimethyl ester, plates from chloroform/methanol, mp 145°C.

4-Carboxyl-6-methoxylphthalic acid: ir (KBr) ν_{max}: 3500–2500, 1700 (COOH), 1600, 1575 (aromatic ring) cm^{-1}; ^2H nmr (unisol) δ_{TMS}: 4.00 (s, 3H, OCH_3), 7.90 (d, 1H, *J* = 1.0 Hz, H-5), 8.25 (d, 1H, *J* = 1.0 Hz, H-3); ms *m/e*: 222 (M − H_2O), 194 (M − H_2O − CO), 164 (M-COOH-OCH_3).

Trimethyl ester: ir (KBr) ν_{max}: 1740, 1730, 1720 (—$COOCH_3$), 1600, 1580 (aromatic ring) cm^{-1}, no carboxyl; ^1H nmr ($CDCl_3$) δ_{TMS}: 3.97, 4.00 (s, each 6H, OCH_3, $COOCH_3$ × 3), 7.83 (d, 1H, *J* = 1.0 Hz, H-5), 8.30 (s, 1H, *J* = 1.0 Hz, H-3); ms *m/e*: 282 (M^+), 251 (M-OCH_3), 223 (M-$COOCH_3$), 192 (M-$COOCH_3$-OCH_3), 165.

Compound **4**b

The diastereomer mixture **4***a* (50 mg) in ethanol (10 mL) was hy-

drogenated in the presence of platinum oxide (20 mg) at room temperature, affording dihydro derivative **4***b* (45 mg), which was crystallized as yellow plates from methanol, mp 220–222°C; ir (KBr) ν_{max}: 3540 (OH), 3500–2400, 1690 (COOH), 1615, 1595 (aromatic ring) cm^{-1}; uv (MeOH) λ_{max} nm (log ϵ): 227 (4.63), 248 (sh, 4.22), 288–300 (plateau, 3.82), 317 (3.86), 336 (3.90), 351 (3.97); ^1H nmr ($CDCl_3/CD_3OD$) δ_{TMS}: 1.32, 1.33 (t, each 1.5 H, J = 7.5 Hz, $—CH_2—CH_3$), 2.74, 2.75 (q, each 1H, J = 7.5 Hz, $—CH_2CH_3$), 3.00–3.30 (m, 2H, Ar-CH_2), 3.76, 3.77 (s, each 1.5 H, OCH_3-2′), 4.00, 4.01 (s, each 1.5 H, OCH_3-4), 5.37 (dd, 0.5 H, J = 7.4/3.0 Hz, axial hemiacetal proton), 5.64 (dd, 0.5 H, J = 3.0/3.0 Hz, equatorial hemiacetal proton), 6.69, 6.73 (s, each 0.5 H, H-3), 6.80 and 6.81, 7.07 and 7.09 (two pair of AB, each 0.5 H, J = 7.9 Hz, H-7, H-6), 7.00, 7.01 (d, each 0.5 H, J = 1.4 Hz, H-3′), 7.31, 7.34 (d, each 0.5 H, J = 1.4 Hz, H-5′); ms m/e: 410.1367 (72.22%, calcd. for $C_{23}H_{22}O_7$: 410.1365, M^+).

Aldehyde lactone **2**b

The dihydro derivative **4***b* (100 mg) in quinoline (2 mL, freshly distilled) was heated at 180°C for 10 min in the presence of copper powder (250 mg) with stirring. After removal of copper powder, the reaction solution was mixed with ether (15 mL), then extracted with 1.5 *N* HCL and washed with water. The residue from the ethereal layer was chromatographed on a silica gel column eluting with chloroform and chloroform/methanol (20:1) in turn. The fractions eluted with chloroform/methanol gave the aldehyde lactone **2***b* (50 mg), which crystallized as yellow needles from chloroform/methanol, mp 220–222°C; ir (KBr) ν_{max}: 3300 (OH), 1715 (>C=O), 1620, 1610, 1590 (aromatic ring) cm^{-1}, no carboxyl; ^1H nmr ($CDCl_3$) δ_{TMS}: 10.17 (s, 1H, aldehyde proton), 9.73 (s, 1H, exchangeable with D_2O, OH), 8.47 (s, 1H, H-3), 7.92 (d, 1H, J = 1.5 Hz, H-5′), 7.22, 6.95 (AB, each 1H, J = 8.0 Hz, H-7, H-6), 7.19 (d, 1H, J = 1.5 Hz, H-3′), 4.50 (s, 2H, Ar-CH_2—CO—), 4.13, 4.08 (s, each 3H, OCH_3-2′, OCH_3-4), 2.80 (q, 2H, J = 7.6 Hz, $CH_3—CH_2$), 1.34 (t, 3H, J = 7.6 Hz, $CH_3—CH_2$); ms m/e: 392 (M^+), 363 (M − CHO).

Acknowledgements

The assistance of Ayerst Research Laboratories (Montreal) in providing ravidomycin and some financial support for this study is gratefully acknowledged. The authors are grateful to Dr. L. Szilágyi (Institute of Organic Chemistry, University of Debrecen, Hungary) for kind permission to use his WP-200/SY instrument. This work was supported, in part, by a grant from the Natural Sciences and Engineering Research Council of Canada.

Basicité et structure de phosphoramides aliphatiques: dosage protométrique en solvants non-aqueux

JEAN-CLAUDE BOLLINGER, RENÉ FAURE ET THÉOPHILE YVERNAULT

Laboratoire de Chimie Générale et Analytique, Faculté des Sciences, 123 avenue Albert-Thomas, 87060 Limoges Cédex, France

Reçu le 25 juin 1982

JEAN-CLAUDE BOLLINGER, RENÉ FAURE et THÉOPHILE YVERNAULT. Can. J. Chem. **61**, 328 (1983).

Par des dosages potentiométriques à 25°C dans le nitrométhane ou le mélange sulfolane/benzène 98:2 p/p, on a déterminé la basicité selon Brönsted (potentiels de demi-neutralisation) de 19 phosphoramides aliphatiques OPXYZ, avec X, Y ou Z = Me; OEt; NMe_2; NEt_2; NHEt; $N(CH_2)_n$ (n = 3 ou 4); ou X + Y = —NMe—$(CH_2)_2$—NMe—. Ce sont des bases faibles, dont la plupart présentent un phénomène d'homoliaison hydrogène. Ceux qui contiennent des substituants Me ou $N(CH_2)_3$ se décomposent en milieu acide, ce qui a été confirmé par dosage en retour et par mesure de $E = f$(temps) au point équivalent. On compare les résultats dans les deux solvants, et on discute l'influence de la nature des substituants X, Y, Z sur les potentiels de demi-neutralisation et sur l'instabilité en milieu acide.

JEAN-CLAUDE BOLLINGER, RENÉ FAURE, and THÉOPHILE YVERNAULT. Can. J. Chem. **61**, 328 (1983).

Brönsted basicities (as half-neutralization potentials) have been determined at 25°C by potentiometric titrations in nitromethane or in the mixture sulfolane/benzene 98:2 p/p for 19 aliphatic phosphoramides OPXYZ, with X, Y, or Z = Me; OEt; NMe_2; NEt_2; NHEt; $N(CH_2)_n$ (n = 3 or 4); or X + Y = —NMe—$(CH_2)_2$—NMe—. Almost all of these weak bases give an homohydrogen bonding. Those with an Me or $N(CH_2)_3$ substituent are not stable in acidic medium, which is confirmed by back-titration and measure of E vs. time at the equivalent point. After comparing the results obtained in the two solvents, the effect of the nature of the substituents X, Y, Z on half-neutralization potentials and instability in acidic medium is analyzed.

Introduction

On sait que l'hexaméthylphosphotriamide $OP(NMe_2)_3$ ou HMPT est, parmi les solvants dipolaires aprotiques usuels, un des plus basiques au sens de Lewis; par contre il est une base de Brönsted très faible: non dosable par un acide fort dans l'eau, il se comporte comme l'urée ou le diméthylacétamide dans l'acide acétique (1), mais peut cependant être titré dans l'anhydride acétique (2); la valeur $pK_a = 0{,}15 \pm 0{,}10$ dans l'eau a été récemment déterminée par spectrophotométrie (3), et $pK_a = 7{,}0 \pm 0{,}1$ dans l'oxydipropionitrile par potentiométrie (4), à comparer à pK_a (H_2O) = −1,23 dans H_2O + H_2SO_4 par rmn du proton (5).

Depuis plusieurs années, notre laboratoire a entrepris des études en vue de mieux comprendre l'influence de la structure des composés organiques du phosphore(V) OPXYZ sur leur basicité et le mécanisme de leur coupure en milieu acide; nous avons ici utilisé une méthode de dosage potentiométrique pour évaluer la basicité selon Brönsted d'une série de phosphoramides voisins du HMPT (voir Tableau 1), en solvants non-aqueux.

Dans le nitrométhane, divers auteurs (6−11) ont étudié le dosage potentiométrique de composés organophosphorés de structures variées par une solution d'acide perchlorique. Nous avons utilisé les mêmes conditions pour doser nos phosphoramides; mais les propriétés acide−base du nitrométhane limitent son domaine d'utilisation (12, 13) et d'autre part le titrant y est partiellement aqueux.

C'est pourquoi nous avons adopté un solvant dipolaire aprotique, ni acide ni basique, le sulfolane; nous avons montré précédemment (14) que son mélange avec 2% pds de benzène permet d'obtenir à 25°C des caractéristiques très voisines de celles du sulfolane pur à 30°C (température habituellement utilisée) et qu'il convient bien pour le dosage de bases faibles, seules ou en mélanges, par le titrant $HClO_4$ dans le même mélange solvant. Les résultats du dosage de phosphoramides dans ce système sont plus particulièrement présentés dans ce mémoire, ainsi que les conclusions que l'on peut en tirer sur les basicités comparées de ces corps.

Partie expérimentale

L'origine, la purification et les propriétés physiques de plusieurs composés organophosphorés OPXYZ étudiés ici (voir Tableau 1) ont été précédemment décrites dans les références 15 (pour les composés **1** à **4**), 16 (pour **5** à **13**) et 17 (pour **17** à **21**).[1]

Les composés $OPMe(NMe_2)_2$, **23**, et $OPMe(NEt_2)_2$, **24**, ont été préparés à partir de $OPMeCl_2$[2] par action de l'amine correspondante, en solution benzénique en présence de triéthylamine, selon une méthode classique (16). Le mélange est laissé ensuite à température ambiante, 24 h pour **23** et 48 h pour **24** dont la formation est plus lente. Après élimination du sel précipité et évaporation du solvant, une première distillation sous pression réduite donne un produit riche en ions Cl^- et assez conducteur. Une deuxième distillation est effectuée en présence de soude aqueuse saturée (environ 1 mL pour 40 g) (16); on obtient alors des produits ne contenant plus d'ions Cl^- et ayant une résistivité de $10^5\ \Omega^{-1}$ cm environ. Rendements en produits purifiés: 59% pour **23**, 52% pour **24**.

On a observé les caractéristiques physiques suivants: $OPMe(NMe_2)_2$, **23**, $Eb_{0.8}$ = 60°C; F = −1,5°C; d^4_{25} = 1,016 (à comparer avec les valeurs assez nombreuses et peu concordantes de la littérature pour la température d'ébullition: réfs. 18−22); $OPMe(NEt_2)_2$, **24**, Eb_9 = 132°C (litt. (18) Eb_1 = 91°C); d^4_{25} = 0,960.

Les temps de rétention t_R ont été mesurés par chromatographie en phase gazeuse sur Carbowax 20M à 190°C, par comparaison avec HMPT, **1**: t_R(**23**) ≠ t_R(**1**); t_R(**24**) = 1,64 × t_R(**1**).

Pour les mesures dans le nitrométhane, nous avons utilisé un pH-mètre digital Beckman PHasar I (indiquant les potentiels à ±1 mV),

[1]Dans un souci de cohérence, nous avons adopté ici la même numérotation que celle utilisée dans notre précédent mémoire (17) consacré aux nombres donneurs d'une série de phosphoramides.

[2]Produit gracieusement fourni par le Prof. Dr. Klaus Weissermel (Hoechst A. G., Frankfurt/Main), à qui nous exprimons notre gratitude.

[a]Mesures à l'état surfondu.

équipé d'une électrode combinée verre/calomel (KCl 3 *M*) Metrohm EA121. Le pH-mètre est standardisé avant et après chaque dosage à l'aide de solutions tampons aqueuses pH = 4 et pH = 7 (ampoules Titrisol Merck). On opère dans une cellule thermostatée à 25°C où le titrant est introduit à l'aide d'une burette à piston Metrohm (au 1/100 mL).

Le nitrométhane Merck pour synthèse contient vraisemblablement comme impuretés principales, de l'eau et du propionitrile (23). Dans la mesure où le réactif titrant contiendra de l'eau (cf. ci-dessous), l'élimination de cette impureté n'a pas besoin d'être très poussée. C'est pourquoi nous avons simplement procédé à une distillation sous pression atmosphérique (Eb = 100°C).

Le titrant est une solution d'acide perchlorique $\simeq$ 0,1 *M* dans le nitrométhane (6, 9, 24−26) préparée à partir du produit RP p. anal. Prolabo (72% $HClO_4$ en poids). Son titre exact est déterminé selon la référence 27.

Les mesures conductométriques sont effectuées avec un conductomètre Tacussel CD7A, équipé d'électrodes en platine platiné.

Les techniques de purification et de récupération du sulfolane, la préparation du titrant ($HClO_4$ anhydre dans sulfolane/benzène 98:2 p/p) sont détaillés dans un précédent mémoire (14). Les mesures potentiométriques sont réalisées avec une électrode de verre Metrohm EA 109 et une électrode de référence Ag/$AgClO_4$ 0,05 *M*; $NaClO_4$ 0,05 *M* dans le mélange solvant; la réponse de l'électrode de verre et sa fatigue dans ce milieu, le comportement de $HClO_4$ ont également été précisés (14). Les dosages en retour sont réalisés avec une solution de pipéridine Fluka "puriss." dans le mélange solvant, dont le titre est déterminé par dosage potentiométrique avec $HClO_4$.

Résultats

Mesures dans le nitrométhane (NM)

Etant donné que le titrant ($HClO_4$ env. 0,1 *M* dans NM) n'est pas anhydre (au moins 4 g/L d'eau), nous avons étudié son comportement en suivant la variation de sa conductibilité équivalente Λ en fonction de la concentration. La courbe $\Lambda = f(\sqrt{C})$ n'est pas une droite, ce qui indique un comportement d'électrolyte faible; on en déduit, par la méthode de Fuoss et Kraus (28):

$$\Lambda_0 = 132{,}1\ \Omega^{-1}\ cm^2\ mol^{-1};\ pK_a = 2{,}40$$

Ces résultats sont comparables à ceux de la littérature (Λ_0 = 127 (29); pK_a = 2,23 (26*b*), 2,15 (cité par 13)), toutefois Wright *et al.* (29) affirment que $HClO_4$ est un électrolyte fort pour des concentrations inférieures à 10^{-3} *M* dans NM.

Afin de vérifier le bon fonctionnement de notre dispositif expérimental, nous avons effectué les dosages potentiométriques de quelques bases faibles (Fig. 1, Tableau 2); nous avons observé chaque fois que le saut de potentiel correspond bien à 100% de neutralisation. Dans le cas de la diphénylguanidine, la position du point équivalent a également été vérifiée par dosage conductométrique.

On doit signaler que, si la réponse de l'électrode de verre combinée est rapide lors de tous les dosages effectués, les potentiels mesurés sont instables dès que le milieu est acide, ce qui confirme les indications de Matrosov *et al.* (26*a*).

Nous avons ensuite opéré de façon similaire pour divers composés organophosphorés (Fig. 2; Tableaux 1 et 2). Ainsi que l'ont déjà indiqué divers auteurs (6−11), nous observons deux sauts de potentiel, correspondant à 50% et 100% de neutralisation (Fig. 2).

Ce phénomène met en évidence l'existence d'une homoliaison hydrogène[3] d'après le schéma réactionnel suivant (B = base organophosphorée):

[3]Selon la suggestion de Bordwell *et al.* (30), nous utilisons ce terme plutôt que "homoconjugaison", habituellement employé.

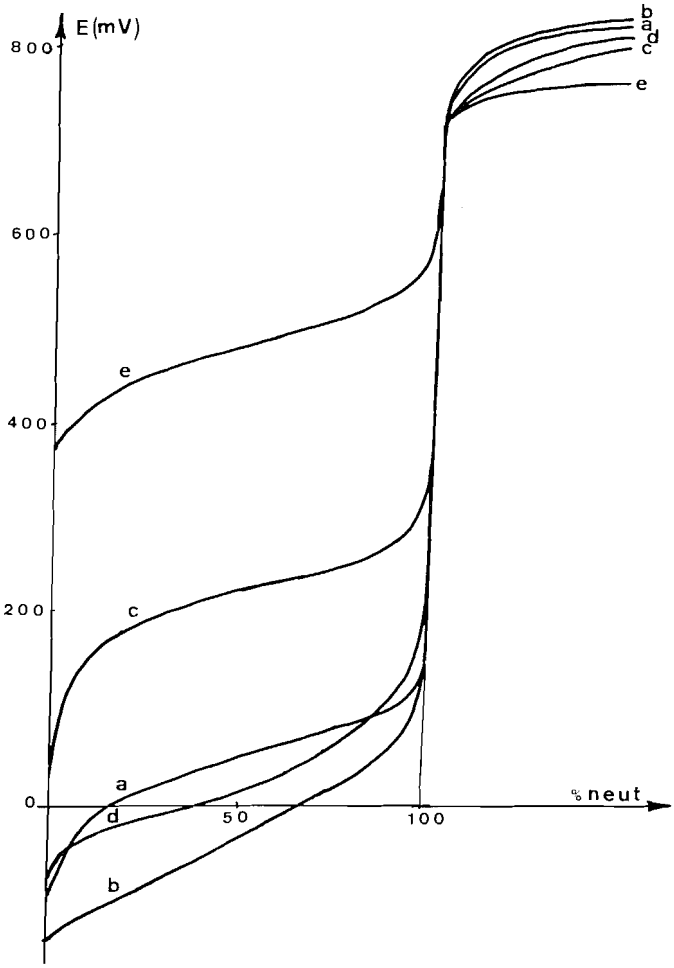

FIG. 1. Dosages protométriques de bases par $HClO_4$ 0,1 *M* dans le nitrométhane à 25°C. a: diphénylguanidine; b: triéthylamine; c: pyridine; d: morpholine; e: tétraméthylurée.

$$2\,B + H^+ \leftrightarrows BHB^+ \qquad K_1 = [B]^2[H^+]/[BHB^+]$$

$$H^+ + BHB^+ \leftrightarrows 2\,BH^+ \qquad K_2 = [BHB^+][H^+]/[BH^+]^2$$

$$2B + 2H^+ \leftrightarrows 2\,BH^+ \qquad K = [B][H^+]/[BH^+] = \sqrt{K_1 \cdot K_2}$$

Les calculs montrent (6, 26*b*) que l'on a alors, avec C = concentration stoechiométrique en base B, au quart de la neutralisation: $pH_{1/4} = pK_1 + \log C_{1/4}$; aux trois-quarts de la neutralisation: $pH_{3/4} = pK_2 - \log C_{3/4}$; à la demi-neutralisation: $pH = (pK_1 + pK_2)/2 \neq (pH_{1/4} + pH_{3/4})/2$ si la variation de la dilution est négligeable.

Quand le potentiel mesuré est fonction linéaire du pH:

$$E = E^0 + k \cdot pH$$

il vient:

$$E_{1/2} = (E_{1/4} + E_{3/4})/2 = E^0 + k \cdot pK$$

Ainsi, l'étalonnage de l'échelle des pK dans le NM n'est pas nécessaire pour comparer la basicité d'une série de composés donnant lieu à un phénomène d'homoliaison hydrogène, les potentiels de demi-neutralisation conviennent.

L'examen des courbes de dosage permet de constater qu'il est difficile d'avoir une bonne précision sur la valeur de $E_{1/2}$; il est donc préférable de la déduire des valeurs de $E_{1/4}$ et $E_{3/4}$, plus précises.

TABLEAU 2. Potentiels de demi-neutralisation de bases diverses par $HClO_4$ dans le nitrométhane à 25°C

Produits	$E_{1/4}$ (mV)	$E_{3/4}$ (mV)	$E_{1/2}$ (mV)

ou $N\langle\rangle$ augmente la basicité.

Mesures dans le mélange sulfolane/benzène 98:2 (p/p)

Nous avons suivi par potentiométrie le dosage de plusieurs phosphoramides OPXYZ par une solution d'acide perchlorique env. 0,4 *M*, dans le mélange solvant sulfolane/benzène 98:2 (p/p) (par la suite abrégé en S/B). Le point de neutralisation se manifeste par un brusque saut de potentiel et nous avons vérifié à chaque fois que ce point expérimental correspondait bien au point de neutralisation théorique (erreur inférieure à 2%). Dans le cas du HMPT, **1**, nous avons vérifié par conductométrie que le perchlorate formé est un électrolyte faible: $\Lambda_0 = 10{,}9\ \Omega^{-1}\ cm^2\ mol^{-1}$, $pK_a = 1{,}1$ selon la méthode (28).

En outre, comme dans le NM, la plupart des produits étudiés présentent un saut de potentiel intermédiaire à la demi-neutralisation, mettant ici encore en évidence l'existence d'une homoliaison hydrogène (Fig. 3).

Comme il a été montré dans notre précédent mémoire (14), il existe pour de nombreuses bases une relation linéaire entre le pK_a (H_2O) et le potentiel de demi-neutralisation $E_{1/2}$ dans S/B. Toutefois, les différentes catégories de bases étudiées (amines; pyridine *N*-oxydes) se placent sur des droites différentes; or nous ne disposons pas de valeurs de pK_a (H_2O) connues avec précision pour des composés OPXYZ, ce qui rend aléatoire toute estimation.

[a]Présence d'homoliaison hydrogène: $E_{1/2} = \frac{E_{1/4} + E_{3/4}}{2}$

[b]Pas d'homoliaison hydrogène.

Nous ne donnerons donc que des résultats en potentiels de demi-neutralisation dans S/B, ceux-ci variant dans le même sens que le pK_a. Les déterminations dans ce mélange solvant S/B sont rapportées aux potentiels de demi-neutralisation de la pyridine ($E_{1/2} = -415$ mV) et de la *p*-nitroaniline ($E_{1/2} = -70$ mV) (14).

Les résultats obtenus sont rassemblés dans le Tableau 3.

Dosage de composés instables en milieu acide

Lors du dosage du certains composés tels que **17**, **18**, **19** ou **23**, par $HClO_4$ 0,4 *M* dans S/B, les potentiels mesurés après chaque addition de titrant augmentent, puis diminuent et se stabilisent, donnant une courbe de dosage qui a toutefois l'allure habituelle.

Ce comportement est lié à une décomposition en milieu acide, qui vient d'être également signalée dans le cas de $OPMe(NMe_2)_2$, **23**, et de $OPMe_2NMe_2$, mais en solution dans NM (37). Pour notre part, afin de mettre en évidence cette décomposition, nous avons effectué des dosages en retour par une solution de base forte (pipéridine) dans S/B.

Pour le HMPT, **1**, le point équivalent correspond à celui du dosage direct, et on observe à nouveau le présence de l'homoliaison hydrogène (Fig. 4).

Par contre pour **23**, les deux points de neutralisation ne correspondent plus au dosage direct. Nous avons ici la preuve de la décomposition du produit initial (Fig. 5, courbes a, a'), ce qui est en accord avec les résultats récents de Matrosov *et al.* (37); Lelièvre et Plichon (20) avaient déjà noté que la dégradation de **23** dans l'acide acétique en présence de $HClO_4$ est suffisamment rapide pour empêcher toute détermination quantitative. Cette réaction est vraisemblablement une coupure de la liaison P—N (37) et libère de la diméthylamine qui est une

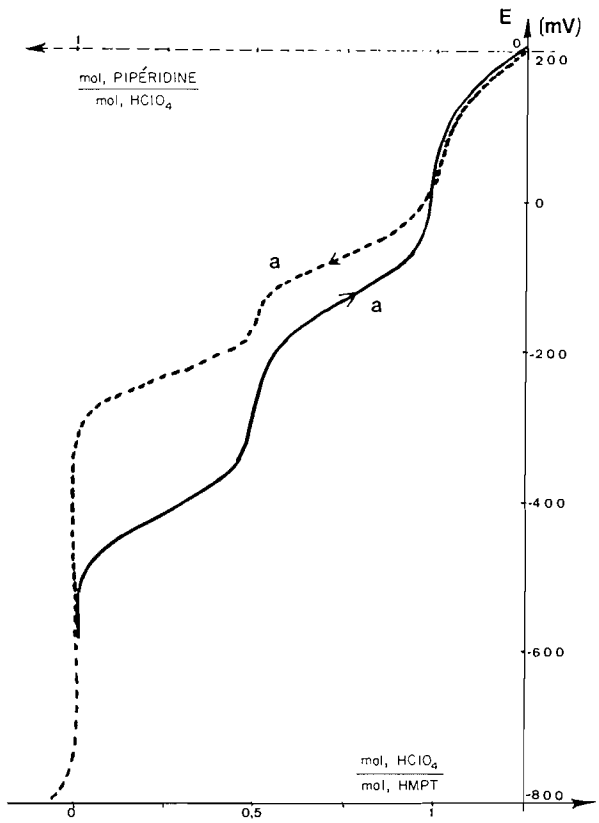

FIG. 4. Dosage protométrique direct (a: par $HClO_4$) et en retour (a': par la pipéridine) de $OP(NMe_2)_3$ **1** dans S/B à 25°C.

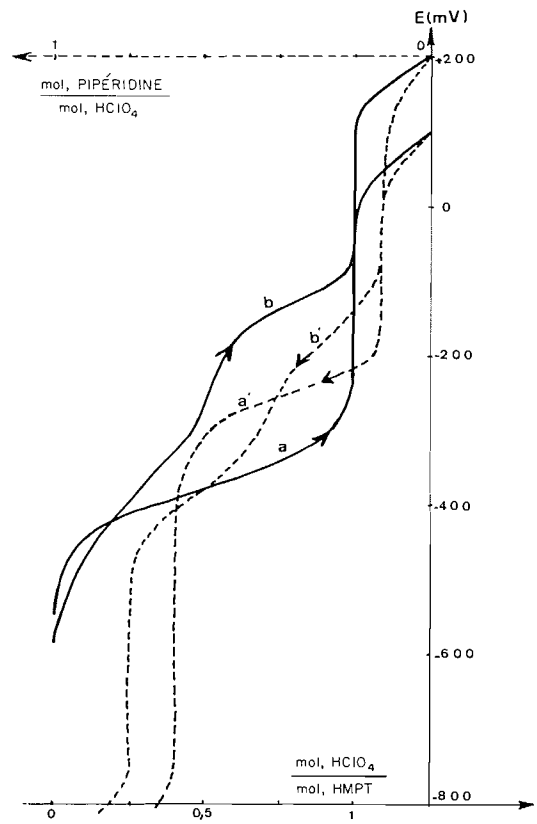

FIG. 5. Dosages protométriques directs (par $HClO_4$: a, b) et en retour (par la pipéridine: a', b') dans S/B à 15°C. a, a': $OPMe(NMe_2)_2$ **23**; b, b': $OP(NMe_2)_2$ (N◇) **17**.

base, ce qui explique le décalage entre le dosage direct et le dosage en retour.

Nous retrouvons le même phénomène de décomposition pour les dérivés azétidinylés **17**, **18** et **19** (cf. courbes bb', Fig. 5). Pour le composé **24** $OPMe(NEt_2)_2$, la décomposition est assez faible, ce qui permet de donner la valeur $E_{1/2} \simeq -384$ mV.

Cette décomposition en présence d'acide est confirmée par l'évolution du potentiel en fonction du temps, lorsque l'on mélange rapidement les deux réactifs (OPXYZ et $HClO_4$) en quantités stoechiométriques; la courbe $E = f(t)$ présente un maximum immédiatement après le mélange, puis le potentiel tend vers une valeur limite.[4]

Discussion

Comparaison des comportements dans NM et dans S/B

On peut tout d'abord constater (Tableaux 2 et 3) que, si la variation de la basicité se fait dans le même sens pour certains composés:

$$\left.\begin{array}{l} \mathbf{2 < 1 < 8 < 9 < 10} \\ \mathbf{1 < 6 < 5 < 7} \end{array}\right\} \quad \text{dans NM et S/B}$$

On a cependant plusieurs inversions dans les diverses "familles" d'organophosphorés OPXYZ:

$$\begin{cases} \mathbf{13 < 12 = 10 < 11} & \text{dans NM} \\ \mathbf{12 < 11 < 10 < 13} & \text{dans S/B} \end{cases}$$

$$\begin{cases} \mathbf{1 < 8 < 6 < 7 < 10 < 11} & \text{dans NM} \\ \mathbf{1 < 8 = 11 < 10 < 6 \ll 7} & \text{dans S/B} \end{cases}$$

Le NM est un solvant aprotique dipolaire faiblement protogène (12, 13); ce caractère, renforcé ici par la présence d'un nombre important de molécules d'eau, surtout en milieu $HClO_4$ (voir ci-dessus), facilite la formation de paires d'ions et la liaison-hydrogène entre acide et base conjugués. De fait, pour le composé **21** il y a bien présence d'homoliaison hydrogène, qui apparaît de façon éphémère si le dosage est assez rapide; mais le produit se décompose, vraisemblablement par ouverture du cycle en milieu acide. De même, le composé **2** présente le phénomène d'homoliaison hydrogène mais le composé **3** n'est pas dosable dans ce solvant.

Par contre dans le mélange S/B, qui présente un caractère dipolaire aprotique faiblement protophile, deux phénomènes nouveaux apparaissent: d'une part les composés **21** et **3** sont dosables, et d'autre part pour les composés **21**, **2** et **3** l'homoliaison hydrogène n'apparaît pas.

Influence de la structure de OPXYZ sur la coupure P—N en milieu acide dans S/B

Nous avons mis en évidence la décomposition de certains produits, par dosage en retour par une solution de base forte.

Pour les composés **17**, **18** et **19**, il s'agit probablement d'une réaction dûe à l'instabilité du cycle azétidine N◇;

[4]L'étude détaillée de cette réponse de l'électrode de verre en fonction du temps figure dans la Thèse de Doctorat de 3e Cycle de R. Faure (Poitiers, 19 Novembre 1982, no. d'ordre 861). Ce document sera envoyé aux personnes intéressées qui en feront la demande aux auteurs.

de même, les composés contenant des cycles aziridine: $OP(NMe_2)_x(N\langle\rangle)_{3-x}$ (x = 0, 1, 2) sont instables en milieu acide (31) et ne sont pas dosables dans S/B.

D'autre part, l'introduction d'un groupement méthyle parmi les substituants du phosphore(V) provoque une fragilité des liaisons P—N en milieu acide (voir ci-dessus, comportement du composé **23**). Ceci contraste avec la grande stabilité de la liaison P—N des phosphoramidates $OP(OR)_x(NMe_2)_{3-x}$ (x = 1, 2) en milieu acide, notée par Modro et coll. (32, 33) dans différents solvants et observée ici également (composés **2** et **3**). On peut rapprocher ces résultats de la diminution importante de la constante de force de la liaison de valence P—N et de l'ordre de liaison P—N quand on passe de $OP(NMe_2)_3$ à $OPMe(NMe_2)_2$ (21).

Toutefois **24** est nettement plus stable que **23**; cela peut être rapproché de la constatation que $OPCl(NEt_2)_2$ réagit beaucoup plus difficilement sur HNR_2 que $OPCl(NMe_2)_2$ (16, 34) et que HEPT **13** ne réagit pas sur $COCl_2$ ou $OPCl_3$ dans les mêmes conditions que HMPT (35).

Conclusion

Dans le mélange sulfolane/benzène 98:2 (p/p), le dosage potentiométrique des phosphoramides par une solution d'acide perchlorique est possible dans un domaine plus étendu que dans le nitrométhane. Ces composés organophosphorés se comportent comme des bases faibles, et donnent très souvent lieu à un phénomène d'autoassociation par liaison hydrogène avec l'acide conjugué.

Dans certains cas, et en particulier pour $OPMe(NMe_2)_2$, nous avons mis en évidence, notamment par dosages en retour, une décomposition du composé organophosphoré, probablement par coupure de la liaison P—N.

Toutefois, si nos mesures nous permettent de classer ces bases selon leur force, par les potentiels de demi-neutralisation dans chaque solvant, nous ne pouvons pas actuellement relier ces valeurs aux pK (H_2O). Rien ne nous permet non plus de préciser si cette protonation a lieu sur l'oxygène ou sur un atome d'azote; il est cependant généralement admis que la mono-protonation des phosphoramides se fait sur l'oxygène (36, 37), et donc la correction statistique qui serait nécessaire en cas de N-protonation n'a pas à être envisagée.

On ne peut mettre en évidence aucun incrément caractéristique des substituants; d'autre part, il n'y a pas de corrélation apparente entre les potentiels de demi-neutralisation dans NM et dans S/B. Ceci semble bien confirmer le fait que l'action spécifique des substituants n'est pas le facteur le plus important: la conformation, résultant de la rotation autour des liaisons P—N, et dans laquelle intervient également la nature du solvant, doit jouer un rôle prépondérant. Des conclusions analogues avaient été obtenues à partir de l'étude des propriétés diélectriques et de calculs CNDO/2 (31) ainsi que de la détermination calorimétrique des nombres donneurs (17).

Synthesis and physical properties of the six furylpyridines

PIERRE RIBEREAU AND GUY QUEGUINER[1]

Laboratoire de Chimie Organique Hétérocyclique, Institut National Supérieur de Chimie Industrielle de Rouen, Faculté des Sciences et des Techniques de Rouen, 76130 Mont Saint Aignan, France

Received April 6, 1982[2]

PIERRE RIBEREAU and GUY QUEGUINER. Can. J. Chem. **61**, 334 (1983).

The 3-step synthesis of furylpyridines is described, using ethyl pyridinoylacetates as starting materials for 2-furyl compounds and chloroacetylpyridines for 3-furyl isomers. Furthermore, thesc last compounds were prepared by a convenient new method for 3-substituted furan synthesis. This synthesis starts from bromopyridines and proceeds through the key intermediates (2,2-diethoxyacetyl)pyridines and methyl 2-(*x*-pyridyl)-4,4-diethoxy-2-methoxy-2-butenoates. The physical properties of the furylpyridines have been determined. Structures and interactions between furan and pyridine rings have been discussed by comparing their uv spectra, basicity constants, and dipole moments with those of phenyl and thienylpyridines.

PIERRE RIBEREAU et GUY QUEGUINER. Can. J. Chem. **61**, 334 (1983).

Nous décrivons la synthèse des furylpyridines en trois étapes à partir des pyridoylacétates d'éthyle pour les dérivés en 2 du furanne et à partir des chloroacétylpyridines dans le cas des isomères en 3. Nous décrivons une nouvelle voie d'accès aux dérivés du furanne substitué en 3. La synthèse est réalisée à partir de bromopyridines et procède par l'intermédiaire des (diéthoxy-2,2 acétyl)pyridines et pyridyl-2 diéthoxy-4,4 méthoxy-2 butène-2 oates de méthyle. Les propriétés physiques des furylpyridines ont été déterminées. Leur structure et l'intéraction entre les cycles furanne et pyridine sont discutées en comparant leurs spectres uv, constantes de basicité et moments dipolaires avec ceux des phényl et thiénylpyridines.

In the last decade much interest has focussed on the properties and reactivity of biheterocycles which result from linking of "electrophilic" and "nucleophilic" rings (1).

A 2-(3-furyl)pyridine derivative was prepared as precursor in the synthesis of nupharamine (2). Derivatives of such naturally occurring compounds isolated from Nuphar and Castoreum (3) have been employed in pharmaceutical preparations (4). Furthermore, a methiodide derivative of 4-(3-furyl)pyridine has been found to display hypoglycemic activity (5). However, only a small number of papers dealing with the synthesis and the properties of furylpyridines have been published. Most routes adopted for the preparation of 3-(2-furyl)pyridine (6−10), 2-(2-furyl)pyridine (11), and 4-(3-furyl)pyridine (5) were either the construction of the nitrogen ring starting from furan derivatives, or the linkage of the two heterocycle units. But these syntheses gave rather low yields or can only be used for the preparation of one isomer. It seemed of interest to prepare furylpyridines by an improved general method. The synthesis of these compounds will be described, using a pyridine derivative as a substrate through the construction of the oxygen ring, as reported in a previous paper (12).

Furthermore, we describe a new synthetic procedure for 3-substituted furans, which are compounds of interest in the field of natural products but not easily accessible.

Synthesis of x-*(2-furyl)pyridines*

These have been prepared according to the method established by Lions and Ritchie (6) for the synthesis of 3-(2-pyrrolyl)pyridine. The cyclization step was modified to improve the yield of furyl derivative. Finally, the best yields of furan esters **3** were obtained when ethyl pyridoylacetates **1** were treated with 1,2-dichloroethyl acetate and 10% aqueous ammonia. In fact, thermolysis of the first reaction product was necessary in order to aromatize the compound. The intermediate product **2** was isolated under mild conditions and its structure was inferred from the spectral analyses. Its ir spectrum exhibits the characteristic absorption bands of the alcohol function at 3140 and 1100 cm^{-1}. The ^1H nmr spectrum presents a deshielded doublet of doublets at δ 5.37 ppm (J = 4 and 5.5 Hz) which is the resonance of a proton attached to an hydroxyl-bearing carbon of dihydrofuran (13, 14). The ^{13}C nmr spectrum of compound **2** presents no cyclic hemiacetal type carbon (about 100 ppm). In view of these observations, we identified compound **2** as ethyl 5-(*x*-pyridyl)-3-hydroxy-2,3-dihydro-4-furoate. Formation of this nondehydrated precursor of the furyl ring can be explained by a ketolization reaction between ketoester **1** and chloroacetaldehyde resulting from the hydrolysis of 1,2-dichloroethyl acetate. Subsequent cyclization gives a dihydrofuran derivative **2**. Thermolysis of this compound produced furan ester **3**. After saponification of the ester and decarboxylation of the acid **4** at 160−220°C the furylpyridine **5** was obtained. By this route 2-, 3-, and 4-(2-furyl)-pyridines were prepared in satisfactory overall yields, namely 40%, 50%, and 34%, respectively. These results compare favorably with the yields of the syntheses previously described (6, 11).

Synthesis of x-*(3-furyl)pyridines by cyclization of epoxyalkyne*

Among the several methods described in the literature to achieve the synthesis of 3-substituted furan, the only one which offered some interest was the route proceeding through an epoxide according to the sequence established by Miller (15) for the preparation of 3-phenylfuran. Following this method, chloroacetylpyridine hydrochlorides **6** (16) react with ethynylmagnesium bromide in tetrahydrofuran and give chlorhydrins **7**. The reaction of these compounds with sodium hydroxide proceeds smoothly to give the corresponding 3,4-epoxy-3-(*x*-pyridyl)-1-butynes **8**. Because of their instability, compounds **7** and **8** were not purified. They exhibited spectral data in accordance with their structural assignments and they were shown to have a purity of at least 95% by nmr.

When acetylenic α,β-epoxides **8***b* and **8***c* were heated with 2 *N* sulfuric acid containing a catalytic amount of mercuric

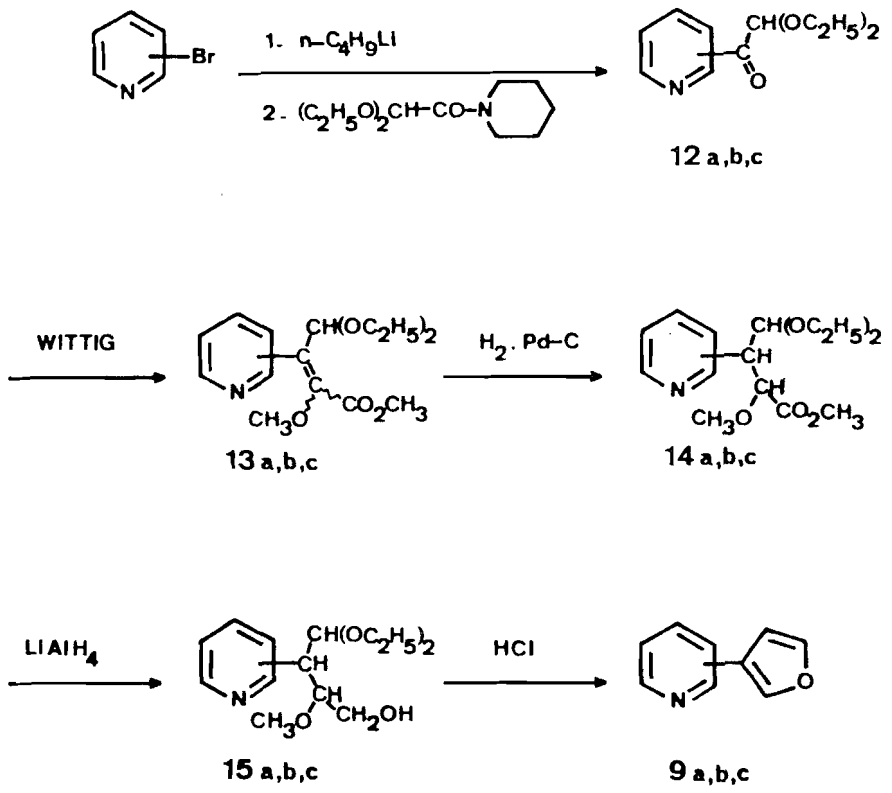

SCHEME 3

sulfate, cyclization occurred and gave furylpyridines **9***b* and **9***c* in rather low yields, 15% and 21%, respectively, from the corresponding chloroketones **6**. However under the same conditions, cyclization failed with the 2-pyridyl derivative. The acetylenic epoxide **8***a* also reacted but no 2-(3-furyl)pyridine could be isolated. Alternatively, this compound was prepared by a base-induced cyclization. The epoxide ring of compound **8***a* was opened with perchloric acid in ethanol to give 3-ethoxy-3-(2-pyridyl)-1-butyn-4-ol **10**. The structure was deduced from spectroscopic data similar to those of 3-ethoxy-3-phenyl-1-butyn-4-ol (15). Treatment of alcohol **10** with sodium ethoxide at 80°C gave the cyclized product **11** whose ir spectrum showed no hydroxy or acetylenic functions. The ^{1}H nmr spectrum exhibited two doublets at δ 6.70 and 5.21 ppm (J = 2.5 Hz) which were assigned to H-5 and H-4. The two protons on carbon 2 appeared as two singlets at δ 4.59 and 4.61 ppm. A base-induced intramolecular attack of oxygen on the acetylenic bond can easily explain this result. Such a reaction was previously used for cyclization of acetylenic diols (17) and enyne alcohols (18). Subsequent treatment of dihydrofuran derivative **11** with acid gave the expected 2-(3-furyl)pyridine (**9***a*) in a very low overall yield (9%) from chloroketone **6***a*. Since this method necessitates the prior synthesis of hard-to-obtain chloroacetylpyridines and since the yields were low, we sought another route to *x*-(3-furyl)pyridines. This new synthetic procedure was carried out using bromopyridines as starting material.

Synthesis of x-*(3-furyl)pyridines by cyclization of hydroxyacetal*

Lithiopyridines (19) were obtained from bromopyridines and n-butyllithium. The subsequent reaction with 1-(2,2-diethoxyacetyl)piperidine (20) at −70°C yields diethoxyacetylpyridines **12**. When methyl diethoxyphosphinylmethoxyacetate (21) was used in the Wittig–Horner reaction with ketones **12**, equivalent amounts of geometrical isomers of esters **13** were formed (nmr). The ethoxymethoxy series was chosen here because it offered the advantage of simple interpretation of nmr spectra of intermediates in the synthesis. Reduction of the ethylenic double bond with hydrogen and palladium catalyst provided the desired saturated esters **14**. The carbethoxy group was reduced to the hydroxymethyl group with lithium aluminium hydride. Finally, treatment of the alcohols **15** with hydrochloric acid in toluene gave the *x*-(3-furyl)pyridines. These compounds were obtained with an overall yield of 49%, 40%, and 42% from ketoacetals **12**. This easy access to the 3-furyl compounds offers an interesting potential entry to products of interest in biological or pharmaceutical problems.

Physical properties of furylpyridines

Because reactions carried out on these compounds gave results somewhat different from those obtained with analogues like thienyl and phenylpyridines (1), we have made some physical studies to clarify the interactions between the two rings.

The ultraviolet spectra of furylpyridines were obtained with absolute ethanol solution (see Table 1). 2-(2-Furyl)pyridine displays an absorption maximum at a longer wavelength than the other isomers, indicating that conjugation should be greater in this compound. From earlier studies (22–24), there is evidence that the differences between the characteristic spectral behaviour of arylpyridines and those of the corresponding pyridinium ions are related to the electronic interaction between the two rings. When the higher maximum wavelength of furyl, thienyl, and phenylpyridines (23) is compared with that of their

protonated species, a bathochromic shift is apparent: 18 to 31 nm, −14 to 9 nm, and 32 to 40 nm for 2-, 3-, and 4-pyridyl derivatives respectively. These results show, as expected, that the interaction between the pyridine nuclei and the other aryl ring is weaker in the case of 3-substituted pyridines.

Acidity constants of furylpyridines are reported in Table 1. 4-Arylpyridines have similar pK_a and they are stronger bases than pyridine. This first result suggests that the mesomeric effect (+M) for all furyl, thienyl, and phenyl groups makes electrons available in the same order of magnitude. 3-Arylpyridines are slightly weaker bases than pyridine. This can be explained by the lack of conjugative interaction for the 3-substituted pyridines and by the weak electron-withdrawing due to the inductive effect of the aryl groups. For all the 2-substituted pyridines, the basicity is weaker than that of pyridine. It is evident that the +M effect of the aryl group is diminished by its greater hindrance and by the increased importance of its inductive effect. The pK_a values of 2-(3-furyl), 2-(3-thienyl), and 2-phenylpyridines are similar (24, 25), indicating that steric hindrance of the aryl groups is about the same because, as we have seen above, the mesomeric and inductive effects are of the same order of magnitude. 2-(2-Furyl)pyridine is a stronger base than 2-(2-thienyl)pyridine (**16**) and, apart from the −I effect which is presumed to be more important for oxygen than for sulfur, other parameters must influence the stability of the protonated species (coordination of the proton by the oxygen of the furyl compound may increase the stability of the protonated form).

The experimental dipole moments of furylpyridines are reported in Table 1. Ultraviolet spectra and basicity studies have shown that electron displacements within the molecules are similar in furyl, thienyl, and phenylpyridines. Thus there are good reasons to believe that the mesomeric moment induced in the furyl or thienyl groups by the primary moment associated with the pyridine ring is not so different from the dipole moment induced in the phenyl group of phenylpyridines (26). From the dipole moments of the unsubstituted parent compounds (26, 27) and the mesomeric moments deduced from phenylpyridine studies (26), we have determined, by vector analysis, a calculated moment for *trans*-planar (α = 0°) and *cis*-planar (α = 180°) conformations of furylpyridines (Table 1).

4-(2-Furyl)pyridine and 4-(3-furyl)pyridine yield calculated moments irrespective of the angle between the planes of the two rings and consistent with the experimentally determined values. These results show that the use of mesomeric moments of phenylpyridines is significant in the case of furylpyridines. 2-(2-Furyl)pyridine shows an experimental dipole moment in good agreement with the calculated value for the *trans*-planar geometry. The most preferred conformation of this compound is thus presumed to be planar. The other isomers of the series do not exhibit such an agreement. For these substances, the experimental dipole moments lie between the values calculated for *s-cis* and *s-trans* conformations, and suggest that the two rings are not coplanar. On the basis of the calculated and measured values of the dipole moment, 2-(2-thienyl)pyridine also appears to have a twisted equilibrium conformation (28), an indication of the difference between this compound and the corresponding furan derivative, as already implied from pK_a measurement. These physical properties of furylpyridines

show that interaction between the two rings is mainly inductive and steric in nature.

All of the furylpyridines show very similar mass spectra, with an intense peak for the molecular ion m/e = 145 and the same degradation fragments. Hydrogen abstraction leads to a fragmentation peak $M - 1$ with an intensity of 29% in the spectrum of 2-(2-furyl)pyridine and of only 10% in the case of 2-(3-furyl)pyridine (the results are somewhat different in the thiophene series (29)).

Experimental

Boiling points are uncorrected. Infrared (ir) spectra were determined on a Beckman IR 4250 grating infrared spectrometer. Ultraviolet (uv) spectra were obtained on a Beckman DK-2 spectrophotometer. Proton nuclearmagnetic resonance (^{1}H nmr) spectra were recorded using a Varian A 60 spectrometer and chemical shifts are reported as δ values in ppm relative to Me_4Si as internal standard; ^{13}C nmr spectra were obtained on a Brucker WH 90 spectrometer at 22.69 MHz and chemical shifts are reported in ppm downfield from internal Me_4Si. Mass spectra were recorded on a JEOL JMS D 100 spectrometer.

*Preparation of ethyl 2-(*x*-pyridyl)-3-furoates (**3**a–c)*

To a stirred and cooled (−5 to 0°C) solution of 116 g (0.6 mol) of ethyl 3-(*x*-pyridyl)-3-oxopropanoate (30) in 1 L of CH_2Cl_2 was added 300 mL of 10% aqueous ammonia. A solution of 100 g (0.64 mol) of 1,2-dichloroethyl acetate in 200 mL of CH_2Cl_2 was added over a 30 min period. The reaction mixture was stirred for an additional 2 h at 0°C and then allowed to come to room temperature overnight. After acidification with concentrated hydrochloric acid, the aqueous layer was extracted with $CHCl_3$. After removal of the solvents, the resulting oil was distilled, giving compounds **3***a*–*c* (Table 2).

*Ethyl 5-(3-pyridyl)-3-hydroxy-2,3-dihydro-4-furoate (**2**b)*

A solution of ketoester **1***b* was treated as described above in the preparation of compounds **3**. Decantation of the organic layer and removal of the solvent, at a temperature below 40°C to avoid dehydration, gave a residue which was recrystallized in CCl_4, giving 65 g (46%) of white crystals, mp 116°C; ir (KBr): 3140 (OH), 1690 (C=O), 1415, 1290, 1100 (OH) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 1.12 (t, 3H, CH_3), 4.0 (m, 1H, OH), 4.11 (q, 2H, CH_2), 4.52 (d, 1H, J = 4 Hz, one H of CH_2—O), 4.53 (d, 1H, J = 5.5 Hz, one H of CH_2—O), 5.37 (2 doublets, 1H, HC(OH)), 7.25 (m, 1H, pyridyl H-5), 7.7 (m, 2H, pyridyl H-3 and H-4), 8.6 (m, 1H, pyridyl H-6); ^{13}C nmr ($CDCl_3$) δ: 13.7 (CH_3), 59.9 (CH_2—O), 73.5 (C—OH), 77.2 (ring CH_2—O), 122.2 (pyridyl C-5), 136.7 (pyridyl C-4), 149.9 (pyridyl C-2), 150.9 (pyridyl C-6). *Anal.* calcd. for $C_{12}H_{13}NO_4$: C 61.28, H 5.53, N 5.95; found: C 61.5, H 5.3, N 6.1.

*Preparation of 2-(*x*-pyridyl)-3-furoic acids (**4**a–c)*

To a stirred solution of 72 g (0.78 mol) of KOH in 300 mL of ethanol was added 70 g (0.32 mol) of ester **3**. The mixture was heated at 80°C for 16 h. After removal of the solvent the residue was dissolved in a minium quantity of water. The aqueous solution was washed with ether and then acidified to pH 4 with an aqueous solution of HCl. The precipitate was filtered, washed with cold water, and recrystallized from ethanol affording acids **4***a*–*c* (Table 2).

Preparation of x*-(2-furyl)pyridines (**5**a–c)*

A 10 g sample of **4** was mixed thoroughly with 10 g of red copper and the mixture was heated from 160°C to 220°C at reduced pressure (12 Torr). The resulting oil was dissolved in ether. The ether solution was washed with a 10% aqueous NaOH solution, then with water, and finally worked up as usual. Distillation offered compounds **5***a*–*c* (Table 3).

*2-(2-Chloroacetyl)pyridine hydrochloride (**6**a)*

A solution of 19.6 g (0.16 mol) of picolinic acid in 120 mL of freshly distilled sulfinyl chloride was heated at 80°C for 2 h. The excess of sulfinyl chloride was distilled off and, after addition of 20

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.40 on 09/06/12
For personal use only.

mL of dry benzene, the solvents were removed under reduced pressure. A suspension of the residue in 100 mL of dry benzene was introduced in portions to a cooled (0−5°C) and stirred solution of about 22.5 g (0.54 mol) of diazomethane in 1.2 L of diethyl ether (dried 2 h on KOH pellets). The mixture was stirred and allowed to come to room temperature overnight. The solution was then filtered. In one run the solvent was removed using a rotary evaporator. Distillation of the residue afforded 20.7 g (88%) of 2-pyridyldiazoketone: bp 82°C/0.3 Torr; ir (CCl_4): 2110 (N_2), 1640 (C=O) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 6.7 (s, 1H, CHN_2), 7.4 (m, 1H, C-5 H), 7.6−8.1 (m, 2H, C-3 H and C-4 H), 8.5 (dd, 1H, C-2 H). The cooled (0°C) and stirred solution of diazo ketone in ether was treated by a dry stream of hydrogen chloride. The precipitate was filtered and washed with dry ether. Drying under reduced pressure afforded 28.9 g of hydrochloride **6***a* (94%): ^1H nmr (DMSO-d_6) δ: 5.15 (s, 2H, CH_2Cl), 7.6 (m, 1H, C-5 H), 7.8−8.0 (m, 2H, C-3 H and C-4 H), 8.6 (m, 1H, C-6 H), 12.6 (m, 1H, N^+H). *Anal.* calcd. for C_7H_8NOCl: C 43.54, H 3.69, N 7.45; found: C 43.4, H 3.8, N 7.3.

*3-(2-Chloroacetyl)pyridine hydrochloride (**6**b)*

A solution of 41 g (0.33 mol) of nicotinic acid in 240 mL of sulfinyl chloride was heated at 80°C for 2 h. The excess of sulfinyl chloride was distilled and after addition of 20 mL of dry benzene the solvents were removed under reduced pressure. To the residue was added 32 g of freshly distilled pyridine. The mixture was distilled and the fraction collected at 91−95°C/13 Torr was redistilled offering 40 g of nicotinoyl chloride (85%), bp 90°C/12 Torr. A solution of 38.2 g (0.27 mol) of acid chloride in 100 mL of dry benzene was added dropwise to a cooled solution (0−5°C) of about 22.5 g (0.54 mol) of diazomethane in 1.2 L of ether (dried 2 h on KOH pellets). The mixture was treated as described above in the preparation of **6***a*. By this method was obtained 49 g of hydrochloride **6***b* (94%); ^1H nmr (DMSO-d_6) δ: 5.3 (s, 2H, CH_2Cl), 7.9 (ddd, 1H, J_{5-2} = 1 Hz, J_{5-4} = 8 Hz, J_{5-6} = 5 Hz, C-5 H), 8.7 (ddd, 1H, J_{4-2} = 2.5 Hz, J_{4-6} = 1.5 Hz, C-4 H), 9.0 (dd, 1H, C-6 H), 9.3 (dd, 1H, C-2 H), 11.4 (m, 1H, N^+H). *Anal.* calcd. for $C_7H_8NOCl_2$: C 43.54, H 3.69, N 7.45; found: C 43.7, H 3.6, N 7.3.

*4-(2-Chloroacetyl)pyridine hydrochloride (**6**a)*

According to the above method, the following were obtained from isonicotinic acid: 39 g (83%) of isonicotinoyl chloride, bp 81°C/13 Torr, and then 29 g (95%) of compound **6***c*: ^1H nmr (DMSO-d_6) δ: 5.45 (s, 2H, CH_2Cl), 8.3 (dd, 2H, J_{3-2} = 6.5 Hz, J_{5-2} = 1.5 Hz, C-3 H and C-5 H), 9.2 (dd, 2H, C-2 H and C-6 H), 11.2 (m, 1H, N^+H). *Anal.* calcd. for $C_7H_8NOCl_2$: C 43.54, H 3.69, N 7.45; found: C 43.6, H 3.5, N 7.2.

*Preparation of 4-chloro-3-(x-pyridyl)-1-butyn-3-ols (**7**a−c)*

Ethyl magnesium bromide, prepared in tetrahydrofuran (100 mL) from 35 g (0.32 mol) of ethyl bromide and 8 g (0.33 mol) of magnesium, was converted into ethynylmagnesium bromide by dropwise addition during 1 h to a saturated solution of acetylene in 100 mL of THF, while acetylene was passed continuously through the mixture. A suspension of 57.6 g (0.3 mol) of compound **6***a*−*c* in 250 mL of THF was added in portions to the Grignard reagent at 0−5°C. The mixture was stirred for 14 h at 20°C, cooled to 0−5°C, decomposed by addition of 16 mL of saturated aqueous ammonium chloride solution, and extracted with ether. Removal of the solvents left a dark oil which was used without further purification (Table 4).

*Preparation of 3,4-epoxy-3-(x-pyridyl)-1-butynes (**8**a−c)*

To a solution of compound **7***a*−*c* in 100 mL of dry ether was added 40 g of powdered sodium hydroxide. The mixture was stirred for 14 h, filtered, and the solvent removed. The residual oil was used without further purification (Table 4).

*3-(3-Furyl)pyridine (**9**b)*

A solution of 1.6 g of mercuric sulphate in 40 mL of 2 *N* sulphuric acid was added to a solution of compound **8***b* in 100 mL of 2 *N* sulphuric acid. The mixture was stirred 1 h at 90°C, cooled to 20°C,

basified with $NaHCO_3$, and extracted with ether. Distillation afforded 7.2 g (15%) of **9***b*, bp 72°C/0.2 Torr.

*4-(3-Furyl)pyridine (**9**c)*

It was prepared as compound **9***b*. Distillation afforded 9.1 g (21%) of **9***c*, bp 80°C/0.3 Torr.

*3-Ethoxy-3-(2-pyridyl)-1-butyn-4-ol (**10**)*

To a solution of epoxide **8***a* in 50 mL of ethanol was added 0.5 mL of 70% perchloric acid. The mixture was stirred 1 h at 80°C, cooled, and treated with anhydrous sodium carbonate. After filtration, removal of the solvent left an oil which was used without further purification: ir (neat): 3650 and 3300 (O—H), 3310 (≡C—H), 2125 (C≡C) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 1.1 (t, 3H, J = 6.5 Hz, CH_3—CH_2), 2.55 (s, 1H, ≡C—H), 3.1 (q, 2H, J = 6.5 Hz, CH_2—CH_3), 3.8 (s, 2H, CH_2), 4.0 (m, 1H, HO, signal disappeared on deuteriation), 7.2 (m, 1H, C-5 H), 7.8–7.6 (m, 2H, C-3 H and C-4 H), 8.5 (m, 1H, C-6 H).

*3-Ethoxy-3-(2-pyridyl)-4,5-dihydrofuran (**11**)*

A solution of sodium ethoxide (from 0.6 g of sodium in 150 mL of ethanol) was added to a solution of compound **10** in 50 mL of ethanol. The mixture was stirred at 80°C during 6 h. The solvent was removed and the residue was extracted with ether. Evaporation of the ether afforded an oil **11**: ^{1}H nmr ($CDCl_3$) δ: 1.20 (t, 3H, J = 6.5 Hz, CH_3—CH_2), 3.47 (q, 2H, J = 6.5 Hz, CH_2—CH_3), 4.60 and 4.58 (2s, 2H, furyl C-2 H_2), 5.21 (d, 1H, J = 2.5 Hz, furyl C-4 H), 6.70 (d, 1H, J = 2.5 Hz, furyl C-5 H), 7.10 (m, 1H, pyridyl C-5 H), 7.7–7.5 (m, 2H, pyridyl C-3 H and C-4 H), 8.53 (m, 1H, pyridyl C-6 H).

*2-(3-Furyl)pyridine (**9**a)*

A solution of compound **11** in 50 mL of 2 *N* sulphuric acid was stirred 1 h at 90°C, cooled to 20°C, treated with $NaHCO_3$, and extracted with ether. Distillation afforded 4.2 g (9.6%) of **9***a*, bp 68°C/0.2 Torr.

*2-(2,2-Diethoxyacetyl)pyridine (**12**a)*

A solution of 88.4 g (0.56 mol) of 2-bromopyridine in 100 mL of dry ether was added dropwise during 1 h to a cold (−20°C) and stirred solution of 450 mL (0.675 mol) of 1.5 *N* n-butyllithiun in hexane and 1.1 L of dry ether. The mixture was stirred for an additional 0.5 h and cooled to −25°C. A solution of 120.3 g (0.56 mol) of 1-(2,2-diethoxyacetyl)piperidine in 80 mL of dry ether was added during 1 h. The mixture was stirred at −25°C for 2 h and then allowed to come to room temperature overnight. A saturated aqueous solution of NH_4Cl (100 mL) was added slowly. Ether extraction followed by distillation of the residue afforded 98 g (84%) of ketone **12***a*, bp 95°C/0.03 Torr.

*3-(2,2-Diethoxyacetyl)pyridine (**12**b)*

A solution of 3-bromopyridine was treated according to the preparation of **12***a*, but at −70°C. By that method was obtained 91 g (78%) of ketone **12***b*, bp 90°C/0.05 Torr.

*4-(2,2-Diethoxyacetyl)pyridine (**12**c)*

A freshly prepared solution of 4-bromopyridine was treated as described above in the preparation of **12***b*. By this method was obtained 91.6 g (78.5%) of ketone **12***c*, bp 82°C/0.04 Torr.

*Preparation of methyl 3-(2-pyridyl)-4,4-diethoxy-2-methoxy-2-butenoates (**13**a–c)*

A stirred suspension of 3.0 g (0.126 mol) of sodium hydride (mineral oil free) in 120 mL dry THF was treated during 0.5 h with the dropwise addition of 30.2 g (0.126 mol) of methyl diethoxyphosphinylmethoxy acetate. Following the addition, the reaction mixture was stirred for an additional 0.5 h. After cooling to 0°C, a solution of 20.9 g (0.1 mol) of ketone **12***a*–*c* in 50 mL of dry THF was added dropwise to this solution over a 30 min period. Near the end of the addition, a gummy precipitate was formed. The reaction mixture was stirred overnight at 25°C and then treated with 75 mL of water. Benzene extraction, including an aqueous ammonium chloride wash, followed by distillation of the residue afforded a mixture (1:3) of unsaturated esters **13***a*–*c* (Table 5).

*Preparation of methyl 3-(x-pyridyl)-4,4-diethoxy-2-methoxy-butanoates (**14**a–c)*

To a solution of 11.8 g (0.04 mol) of the esters **13***a*–*c* in 50 mL of absolute ethanol was added 1.1 g of 10% palladium-on-carbon catalyst. The mixture was stirred under a hydrogen atmosphere until uptake of hydrogen ceased. The time required was approximately 20 min. Then the catalyst was removed by centrifugation and washed with ethanol. The organic fractions were combined and the solvent was evaporated. Distillation of the residue afforded esters **14***a*–*c* (Table 5).

*Preparation of 3-(x-pyridyl)-4,4-diethoxy-2-methoxy-1-butanols (**15**a–c)*

To a vigorously stirred suspension of 1.82 g (0.048 mol) of lithium aluminium hydride in 120 mL of dry THF was added 11.9 g (0.04 mol) of esters **14***a*–*c* in 30 mL of dry THF over a one-hour period. Following the addition, the reaction mixture was stirred for an additional hour before the excess hydride was destroyed by addition

of ethyl acetate. After work-up according to Fieser and Fieser (31) and benzene extraction, distillation afforded alcohols **15***a*–*c* (Table 5).

Preparation of x-*(3-furyl)pyridine (***9**a–c*) from compounds* ***15***a–c

To a stirred solution of 5.4 g (0.02 mol) of alcohols **15***a*–*c* in 150 mL of dry toluene was added 15 mL of a 1.6 *N* solution of hydrogen chloride in ether. The mixture was heated at 120°C for 24 h. After cooling, the mixture was base washed and distillation afforded compounds **9***a*–*c* (Table 3).

Synthesis of 8,10- and 9,10-disubstituted camphor derivatives

WILLIAM M. DADSON, MAYDA LAM, THOMAS MONEY,[1] AND SUSAN E. PIPER
Department of Chemistry, University of British Columbia, Vancouver, B. C., Canada V6T 1Y6

Received June 3, 1982

WILLIAM M. DADSON, MAYDA LAM, THOMAS MONEY, and SUSAN E. PIPER. Can. J. Chem. **61**, 343 (1983).

Regiospecific bromination and debromination reactions have been used to provide a synthetic route from camphor to optically active 8,10- and 9,10-disubstituted camphor derivatives.

WILLIAM M. DADSON, MAYDA LAM, THOMAS MONEY et SUSAN E. PIPER. Can. J. Chem. **61**, 343 (1983).

On a utilisé des réactions de bromation et de débromation régiospécifiques pour transformer le camphre en dérivés optiquement actifs du camphre disubstitués respectivement en positions 8,10 et en position 9,10.

[Traduit par le journal]

The establishment of camphor (**1**) as a chiral starting material in natural product synthesis (1−17) is largely due to the availability of convenient methods for the regiospecific functionalization of camphor or simple derivatives at the C(5) (18), C(8) (19), C(9) (20), and C(10) (21, 22) positions. To increase the versatility of camphor as a starting material in terpenoid and steroid synthesis we have recently investigated various methods for the stereospecific synthesis of 8,10- and 9,10-disubstituted camphor derivatives.

Although 8,10-disubstituted camphor derivatives have not been described in the literature (22), Nishikawa and Hagiwara have reported (23) that treatment of 3,9-dichlorocamphor with fuming sulfuric acid yields a mixture of 6,9-dichlorocamphor and 3,9-dichlorocamphor-10-sulfonic acid while bromination ($Br_2/ClSO_3H$) provides 3,9-dichloro-10-bromocamphor. The synthetic potential of a direct C(10)-bromination process coupled with the prospect of its application to the synthesis of 8,10- and 9,10-disubstituted camphor derivatives prompted us to extend the earlier Japanese studies using the more readily available (+)-3,9-dibromocamphor (**3**) (20) in the bromination process. Treatment of **3** with bromine in chlorosulfonic acid for 5 days at room temperature produced a crystalline product (50% yield) which was identified as (+)-3,9,10-tribromocamphor (**4**) on the basis of spectroscopic evidence. Regiospecific debromination of **4** with zinc/acetic acid at 0°C provided (+)-9,10-dibromocamphor (**5**) in 62% yield. The nmr spectrum (400 MHz) of this compound indicated that the quartets normally expected for the C(9) and C(10) methylene groups overlap to a considerable extent. Confirmation for the identity of the reaction product as (+)-9,10-dibromocamphor (**5**) was obtained by X-ray crystallographic analysis.[2]

In similar fashion, (+)-3,8-dibromocamphor (**8**)[3] was converted, via the bromination/selective debromination sequence (Scheme 1), to (+)-8,10-dibromocamphor (**10**) (35% overall yield) and the structure of this compound was also confirmed by X-ray crystallographic analysis.[2] In the 270 MHz spectra of 3,8,10-tribromocamphor (**9**), one of the AB quartets expected for the C(8) and C(10) methylene groups appears as a singlet at 3.50 δ. By contrast, the C(8)-methylene groups in 8-bromocamphor (**7**), 3,8-dibromocamphor (**8**), and 8,10-dibromocamphor (**10**) appear as singlets in the 60 and 100 MHz spectra and as AB quartets (J_{AB} = 10−10.5 Hz) in the 270 MHz spectra.

The C(10)-bromination of 3,8-dibromocamphor (**8**) and 3,9-dibromocamphor (**3**) presumably occurs by a mechanism similar to that proposed to explain C(10)-sulfonation of camphor (24). Thus we presume that Wagner−Meerwein rearrangement provides an intermediate camphene derivative (**12**; X or Y = H, X or Y = Br) which can react with bromine and subsequently revert to the camphor framework (cf. Scheme 2). It is interesting to note that the reaction conditions used in this C(10)-bromination process are similar to those normally employed for stereospecific bromination of 3,3-dibromocamphor at the C(8)-position (19) and (+)-3-bromocamphor (**2**) at the C(9)-position (20). In the latter reaction the initial camphene intermediate (**12**; X = Y = H) undergoes a 2,3-*exo*-methyl shift to provide a second intermediate (**14**) which can be brominated (20*d*) (Scheme 2). Reversal of the Nametkin and Wagner−Meerwein rearrangements then produces (+)-3,9-dibromocamphor (**3**).[4] In the C(10)-bromination processes described above the presence of the C(8) or C(9)-bromomethyl group in the starting material probably inhibits the formation of intermediate (**14**) by Nametkin rearrangement (2,3-methyl shift) and therefore bromination occurs only at the C(10) position (cf. Scheme 2). In related investigations we have shown that 3,10-dibromocamphor (**17**) and 3-bromo-10-benzoyloxycamphor (**18**) do not readily brominate when treated with $Br_2/ClSO_3H$. In these cases the C(10) substituent may inhibit formation of a carbonium ion intermediate analogous to **11** (X = Y = H) (Scheme 2) and therefore C(9)-bromination does not occur.

In summary, the methodology described above provides a convenient route to a variety of optically pure 8,10- and 9,10-disubstituted camphor derivatives and the potential of these compounds as intermediates in steroid and terpenoid synthesis is currently being evaluated.

Experimental

(+)-3,9,10-Tribromocamphor (4)

A solution of bromine (5.0 mL) in chlorosulphonic acid (18 mL)

[1]Author to whom correspondence may be addressed.

[2]S. J. Rettig and J. Trotter, unpublished results.

[3](+)-3,8-Dibromocamphor (**8**) is prepared by bromination of (+)-8-bromocamphor (**7**) in acetic acid. It should be noted that earlier literature reports (22) describing "3,8-dibromocamphor" actually refer to the 3,9-isomer.

[4]In the C(8)-bromination proceeds (19) (not shown in Scheme 2) the corresponding intermediates undergo 2,3-*endo* methyl shifts (19*c*).

was added to a stirred solution of (+)-3,9-dibromocamphor (**3**) (18 g) in chloroform (16 mL) at 0°C under nitrogen and the reaction mixture was left at room temperature for 5 days. The ether extract of the reaction mixture was washed with sodium bisulfite, sodium bicarbonate, and water. Removal of solvent produced a crude solid (22 g) which was crystallized from methanol to provide (+)-3,9,10-tribromocamphor (**4**) (12 g, 50% yield), mp 100–102°C; $[\alpha]_D$ +47.5 (*c* 1.0, MeOH); ν_{max} (CCl_3): 1760 cm^{-1}; nmr ($CDCl_3$, 400 MHz), δ: 1.21 (3H, s), 3.46 and 3.68 (2H, dd, J = 11.5 Hz), 3.64 and 3.73 (2H, AB quartet, J_{AB} = 10.5 Hz), 4.57 (1H, d, J = 4.5 Hz); *m/e*: 386/388/390/392 (M^+), 307/309/311 (M − Br), 228/230. *Anal.* calcd. for $C_{10}H_{13}Br_3O$: C 30.88, H 3.37, Br 61.64; found: C 30.87, H 3.44, Br 61.46.

(+)-9,10-Dibromocamphor (5)

A stirred solution of (+)-3,9,10-tribromocamphor (**4**) (11.5 g) in glacial acetic acid (150 mL) was treated with zinc powder (6.2 g) at room temperature for 3 hours. The reaction mixture was diluted with water, filtered through Celite, and extracted with ether. Work-up in the usual way provided a pale yellow solid (6.2 g) which was crystallized from methanol to provide (+)-9,10-dibromocamphor (**5**) (5.2 g, 62% yield), mp 98–100°C; $[\alpha]_D$ +69.75 (*c* 2.0, MeOH); nmr ($CDCl_3$, 400 MHz), δ: 1.10 (s, 3H), 3.48 (d) and 3.71 (d) (2H, AB quartet, J = 12 Hz), 3.59 (d) and 3.70 (d) (2H, AB quartet, J = 10.5 Hz); *m/e*: 312/310/308 (M^+), 231/229 (M − Br). *Anal.* calcd. for $C_{10}H_{14}Br_2O$: C 38.75, H 4.55, Br 51.55; found C 38.87, H 4.69, Br 51.33.

(+)-3,8-Dibromocamphor (8)

A solution of bromine (1.0 mL) in glacial acetic acid (50 mL) was added dropwise, at 80°C, over a period of 3.0 hours to a stirred solution of (+)-8-bromocamphor (**7**) (10.0 g) in glacial acetic acid (20 mL). After 24 h at 80°C the reaction mixture was added to ice and the ether extracts washed with sodium bisulfite, sodium bicarbonate, and water. Removal of solvent afforded a yellow oil (13.2 g) which was shown by glc to contain 80–85% 3,8-dibromocamphor. Distillation of the crude oil followed by crystallization from 95% ethanol provided (+)-3,8-dibromocamphor (**8**) (9.5 g, ~71% yield), mp 62°C; $[\alpha]_D$ +133.9 (*c* 2.0, MeOH); ν_{max} (CCl_4): 1770 cm^{-1}; nmr ($CDCl_3$, 270 MHz), δ: 0.98 (3H, s), 1.27 (3H, s), 2.64 (1H, t), 3.10 (d) and 3.20 (d) (2H, AB quartet, J = 10.1 Hz) 4.62 (1H, d, J = 4.0 Hz); *m/e*: 312/310/308 (M^+), 231/229 (M − Br). *Anal.* calcd. for $C_{10}H_{14}Br_2O$: C 38.75, H 4.55, Br 51.55; found: C 38.97, H 4.60, Br 51.33.

(+)-3,8,10-Tribromocamphor (9)

Chlorosulphonic acid (15 mL) was added dropwise at 0°C to a stirred mixture of (+)-3,8-dibromocamphor (**8**) (9.2 g), bromine (16.0 g; 5.13 mL), and chloroform (10 mL). The mixture was stirred at room temperature for 8 days before adding carefully to ice and washing the combined ether extracts with aqueous sodium bisulfite, aqueous sodium bicarbonate, and saturated NaCl solution. Removal of solvent afforded a viscous yellow oil (11.4 g) which was shown by glc to contain 75% 3,8,10-tribromocamphor and which could be used without further purification.

Purification by column chromatography (silica gel; petroleum ether (30–60°C)/ether 25:1) and crystallization from $MeOH/CH_2Cl_2$ provided (+)-3,8,10-tribromocamphor (**9**) (5.3 g, 51% yield based on recovered starting material), mp 63–66°C; $[\alpha]_D$ +126.1 (*c* 4.0, MeOH); ν_{max} (CCl_4): 1760 cm; nmr ($CDCl_3$, 270 MHz), δ: 1.39

(3H, s), 2.71 (1H, t); 3.27 (d) and 3.52 (d) (2H, AB quartet, J = 10.1 Hz); 3.50 (2H, s), 4.62 (1H, d, J = 4.5 Hz); *m/e*: 392/390/388/386 (M^+), 311/309/307 (M − Br), 228/230; *Anal.* calcd. for $C_{10}H_{13}Br_3O$: C 30.88, H 3.37, Br 61.63; found: C 31.00, H 3.30, Br 61.44.

(+)-8,10-Dibromocamphor (10)

Zinc (1.0 g) was added to a stirred solution of 3,8,10-tribromocamphor (**9**) (2.0 g) in glacial acetic acid (10 mL) at 0°C. After stirring at 0°C for 10 min and at 25°C for 1 hour the mixture was added to ice. Work-up in the usual way provided 8,10-dibromocamphor (**10**) as a colorless solid (1.53 g, ~96% yield; 97% pure by glc). Crystallization from methanol yielded pure (+)-8,10-dibromocamphor (**10**), mp 76°C; $[\alpha]_D^{22}$ +63.45 (*c* 4.0, MeOH); ν_{max} (CCl_4): 1745 cm^{-1}; nmr ($CDCl_3$, 400 MHz), δ: 1.30 (3H, d, J = 1.5 Hz), 3.24 (1H, dd, J_{AB} = 10.1 Hz, J_{BX} = 1.5 Hz), 3.46 (1H, d, J_{AB} = 10.1 Hz), 3.47 (d), 3.52 (d) (2H, AB-quartet J = 10.15 Hz); *m/e*: 312/310/308 (M^+), 231/229 (M − Br). *Anal.* calcd. for $C_{10}H_{14}Br_2O$: C 38.74, H 4.55, Br 51.55; found: C 38.98, H 4.41, Br 51.38.

A series of chemically related *para*-disubstituted aromatic solutes have been dissolved in two type II DM systems. The Saupe matrix elements of order have been determined for the solutes and the degrees of order of some segments in the amphiphiles have been derived from deuterium quadrupole splittings. The comparison of deuterium quadrupole splittings in uncontaminated mesophases with those containing the solutes leads to the conclusion that four solutes are located in the bilayer disk of the component micelles of one meosphase. A consideration of the structure and alignment of the disc micelles leads to absolute sign attribution for degrees of order of detergent segments and matrix elements for solute axes. A consideration of the orientations of the solute axes with respect to the mesophase director suggests the type of molecular interactions and motions which apply to solutes.

V. R. PAOLI-MONTEIRO, M. SUZUKI, J. A. VANIN et L. W. REEVES. Can. J. Chem. **61**, 347 (1983).

On a dissous une série de solutés aromatiques disubstituées en positions *para* reliés entre eux chimiquement dans deux systèmes du type II DM. On a déterminé les éléments d'ordres des matrices de Saupe pour les solutés et on a déduit le degré d'ordre de quelques segments d'amphiphiles à partir des dédoublements quadrupolaires du deutérium. La comparaison des dédoublements quadrupolaires du deutérium dans les mésophases non contaminées avec celles contenant les solutés permet de conclure que quatre solutés sont situés dans le disque de la couche double dans les micelles composantes d'une mésophase. En prenant en considération la structure et l'alignement des disques micellaires, on aboutit à une attribution du signe absolu des degrés d'ordre des segments de détergents et des éléments de matrice pour les axes de solutés. Une comparaison des orientations des axes du soluté par rapport à la mésophase directrice suggère le type d'interactions moléculaires et les mouvements qui s'appliquent aux solutés.

Introduction

Type II DM nematic liquid crystals are used widely as a solvent matrix for small molecules (1−4) and ions (5, 6). The proton magnetic resonance spectra of the solutes in the magnetically aligned mesophase are used to determine molecular structures by standard techniques (7, 8). The interest in such studies of relative internuclear distances has, however, not been complemented in this context by considerations of the structure of the nematic solvent (8). The structure ot type II DM mesophases is now well established. It is therefore important to have some predictive notions of the location of solubilized material (9). Such knowledge of the location of solutes and the proper mesophase matrix to select is a considerable aid in achieving a high degree of order for a particular solute and in predicting the signs of the dipolar coupling constants to aid in the spectral analysis (7, 8).

The present study is designed to investigate the location and degrees of order of some simple chemically related solutes in two different mesophases. The emphasis of the work is not in the structure of the solutes because the *para*-substituted benzenes selected have rather well-known structures.

Experimental

Proton magnetic resonance spectra were detected at 100 MHz, usually in the continuous wave mode, while deuterium magnetic resonance was observed at 15.4 MHz in the Fourier transform mode; both observations were registered on a Varian XL-100 spectrometer, with the gyrocode option. Spectral analysis of the proton signals was achieved by use of the program EUAITR for both isotropic and aligned samples (10). The computer was a Burroughs model 3600 located in the electronic computer centre of the University of Sao Paulo. The spectrometer conditions were appropriately optimized in each case and accumulations for deuterium signals varied from 5000 to 30 000 transients.

1,1,9,9,10,10,10-Heptadeuteriodecylammonium chloride, 1,1-dideuterio potassium laurate, and potassium laurate-d_{23} were derived from a previous stock, the preparation of which has already been described (11). n-Decanol from J. T. Baker was twice distilled under reduced pressure. The effective pH in the lyomesophases was achieved by prior additions of hydrochloric acid or sodium hydroxide to the water utilized in their preparation. In this manner the water was mixed with other components at pH = 1 or pH = 13. In addition the water was doped with 0.1−0.5% D_2O as convenient for the mesophase under investigation. The solutes, all of analytical grade, were used without further purification. They were: parafluorobenzoic acid (Pierce Chem. Co.), parachlorobenozic acid (Eastmann), parabromobenzoic acid (B.D.H.), paraiodobenzoic acid (Eastmann), paracyanobenzoic acid (Eastmann), parahydroxybenzoic acid (B.D.H.), paraaminobenzoic acid (B.D.H.), parafluorophenol (Aldrich), parachlorophenol (Aldrich), parabromophenol (Aldrich), paraaminophenol (Aldrich), 4-pyridine carboxylic acid (B.D.H.), and paranitrophenol sodium salt (B.D.H.). In order to simplify notations these compounds have been nominated, in order, PFBA, PClBA, PBrBA, PIBA, PCNBA, POHBA, PNH_2BA, $PF\phi OH$, $PCl\phi OH$, $PBr\phi OH$, $PNH_2\phi OH$, PCaPyr, and $PNO_2\phi O^-$. Corresponding conjugate ions, present in basic media, are designated by merely adding a negative superscript, e.g. $PCNBA^-$ means paracyanobenzoate ion.

The mesophases were prepared in a manner previously reported

*A. Mole percentages of components in mesophases prepared from decylammonium chloride with different solutes. The water was acidified and kept at pH~1 before mixing the mesophase. The solutes may be identified by the numbers heading the columns as follows: 1 = PFBA, 2 = PClBA, 3 = PBrBa, 4 = PIBA, 5 = PCNBA, 6 = PNH_3^+BA (protonated form in the mesophase), 7 = POHBA, 8 = PFϕOH, 9 = PClϕOH, 10 = PBrϕOH, 11 = PNH_3^+ϕOH (protonated form in mesopahse), 12 = PNO_2ϕONa, 13 = PCaPyr (protonated form). The water also contained a small amount of D_2O.

†B. Mole percentages of components in uncontaminated DAC mesophases with varied water content. The water content increases as the columns progress to the right.

‡C. Mole percentages of components in mesophases prepared from potassium laurate with solutes. The solutes may be identified from the column heading numbers which are assigned in part A above. All solutes are in the deprotonated or conjugate base form at pH~13. DeOH = n-decanol.

§D. Mole percentages of components in uncontaminated KL mesophases with varied water content. The water content increases as columns progress to the right.

(11). The proton spectra were observed first, then the deuterium spectrum, followed by a repeat of the proton spectra to ensure an unaltered sample in each case.

For both isotropic samples and solutes in the Type II DM mesophase the spectral widths for protons varied between 100 and 500 Hz. Individual peaks were calibrated with a frequency counter and had a random error of position between 0.1 and 0.01 Hz. In a few cases the large H_2O peak did mask some transitions of the solute, but sufficient information was always available for the spectral analysis. The mol% of each component in all mesophases studied has been listed in two tables, Table 1A for phases with a host disc bilayer of decylammonium chloride (DAC) and Table 1C for a host disc bilayer of potasisum laurate (KL). Although the mole fraction of the detergent varies somewhat, as does that of the water and solute, the mesophases are considered to be dilute in solute. The maximum mole fraction of solute in the bilayer is 0.08 while the minimum is 0.03.The variation of composition is inevitable because of the range of chemical substances used as solutes and the sensitivity of the mesophase to different impurities.

This variation in water content and, to some extent, solute concentration is properly standardized by using ratios of degrees of order (12, 13), which are independent of water content (11, 12), and studying the dependence on solute, as we shall show. The Tables 1B and 1D list compositions for pure DAC and KL mesophases which were diluted with water over the range of stability of the Type II DM lyomesophase. These uncontaminated phases served as a standard for deviations in behaviour with solutes.

Results

(a) *Analysis of solute proton spectra in isotropic media*

The precise determination of the dipole–dipole "D_{ij}" direct coupling constants in anisotropic media requires good values of the corresponding scalar couplings J_{ij} and, hopefully, their sign. Solutes were dissolved in basic or acidic aqueous solution at 35°C in order to achieve the spectra required. The spectra are AA′BB′ and standard methods sufficed for the analysis. Table 2 summarizes the results. The chemical shift differences AA′ with BB′ are of course a strong function of solvent, but scalar couplings also vary, especially when comparing the present experiments with those of Cox (14) in DMSO. The signs of the coupling constants J_{ij} between the protons in the aromatic rings are positive. The pK_a values for all compounds investigated show that at pH = 1 the acid form is present and at pH = 13 the basic form predominates in at least 99% in all cases.

(b) *Analysis of proton spectra of solutes in aligned type II DM mesophases*

In DAC mesophases the pH of the component water cannot

*The solvent is water at pH specified in column 2 except for (a) where the data of Cox is used (25) and for (b) which was a concentrated micellar solution of decylammonium chloride. The chemical shift difference in the AA′BB′ spectrum is listed in parts per million while scalar couplings are denoted in Hz, subscripts following the diagram given as Fig. 1 for the positions of protons. (c) Paracarboxylpyridinium ion. (d) The couplings to the fluorine are $J_{15} = 8.6$, $J_{25} = 5.5$. (e) Couplings to the fluorine are $J_{15} = 8.2$, $J_{25} = 8.1$. (f) Coupling $J_{13} = J_{24} = 0.8$. (g) $J_{13} = J_{24} = 1.0$. (h) $J_{13} = J_{24} = 0.37$. (i) $J_{13} = J_{24} = 0.56$. (j) $J_{13} = J_{24} = 0.6$. (k) $J_{13} = J_{24} = 0.7$. (l) $J_{13} = J_{24} = 0.6$. Couplings may be taken to have errors ±0.15 Hz.

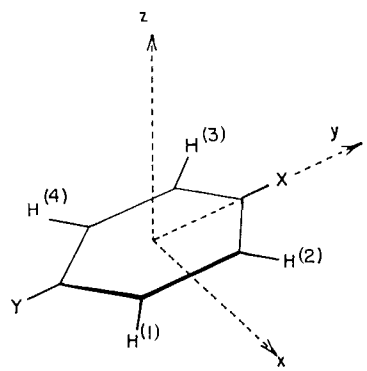

FIG. 1. The system of coordinates used for *para*-substituted benzenes. The axes, x, y, and z are equivalent to the principal axes of the order tensor 11, 22, and 33, respectively. The substituents Y are —COOH, —COO^{-}, —OH, or O while the substituents X are all other possibilities among the compounds chosen. The protons are enumerated in the diagram according to position and used as subscripts in the text, e.g. r_{12}, D_{23}, J_{24}, etc.

be raised to the basic region because the mesophase disintegrates and thus all the solutes are present in the acid form, which in the case of basic nitrogen solutes $PNH_2\phi OH$, PCaPyr, and PNH_2BA results in a protonated nitrogen. In the mesophases prepared from KL, the solutes are in the form of conjugate bases at pH = 13. The spectra of aligned solutes are also AA′BB′ except PFBA, $PFBA^{-}$, PFφOH, and $PF\phi O^{-}$ where the F-19 spin nucleus contributed to give two AA′BB′ subspectra. The values of J_{ij} obtained previously were introduced in order to compute by iteration the values D_{ij}. In the present work four spectra were averaged for the position of 10 to 12 peaks. The calculated spectra are insensitive to the relative changes of sign of D_{ij} provided a given set of parities is preserved, if the degree of order of the *para* axis is large. On the other hand, for PNH_3BA^{+} in DAC and the ions $PFBA^{-}$ and $PClBA^{-}$ in KL mesophases, the lower degree of order leads to a larger number of observable transitions and the absolute signs of D_{ij} become available from the spectral analysis. The dipole–dipole coupling $D_{14} = D_{23}$ ($D_{AA'} = D_{BB'}$) for all cases. The numbering of positions and labelling of axes are presented in Fig. 1.

The computed dipole–dipole couplings were converted into the defining ratios of distances for a rectangular arrangement of four protons (15) by using the three equations below and seeking the roots which are physically reasonable:

$$[1]\quad \left(\frac{r_{14}}{r_{23}}\right) = \left(\frac{D_{23}}{D_{14}}\right)^{1/3}$$

$$[2]\quad D_{12}\left(\frac{r_{12}}{r_{23}}\right)^{5} - D_{13}\left[\left(\frac{D_{23}}{D_{14}}\right)^{1/3} + \left(\frac{r_{12}}{r_{23}}\right)^{2}\right]^{5/2} = -D_{23}\left(\frac{D_{23}}{D_{14}}\right)^{1/3}$$

$$[3]\quad \left(\frac{r_{13}}{r_{23}}\right)^{2} = \left(\frac{D_{23}}{D_{14}}\right)^{1/3} + \left(\frac{r_{12}}{r_{23}}\right)^{2}$$

The two independent Saupe (16, 17) matrix elements of order were converted from the dipole–dipole couplings using the expressions:

$$[4]\quad S_{11} = -\frac{4\pi^2}{h\gamma_H{}^2} D_{23} r_{23}^3$$

$$[5]\quad S_{22} = -\left(\frac{4\pi^2}{h\gamma_H{}^2}\right) r_{12}^3 \left\{D_{12} - \left(\frac{D_{23}}{4}\right)\left(\frac{r_{12}}{r_{23}}\right)^{-5} \times \left[\left(\frac{D_{23}}{D_{14}}\right)^{1/3} - 1\right]^2\right\} \times \left\{1 - \frac{1}{4}\left(\frac{r_{12}}{r_{23}}\right)^{-2}\left[\left(\frac{D_{23}}{D_{14}}\right)^{1/3} - 1\right]^2\right\}^{-1}$$

*Molecular species and positive ions in mesophases of DAC.
†Negative ion solutes in KL mesophases. Random errors of measurement have a maximum of 1% and a minimum of 0.3% in the values cited.

The value of r_{12} was assumed to be 2.47 ± 0.01 Å. The third diagonal element of the order matrix was obtained by using the property that the trace is zero (17).

The results of these computations are listed in Tables 3 and 4. Table 3 lists the *ortho/meta* ratios and the *para/meta* ratios for the solutes studied in this investigation. The regular hexagon has an *ortho/meta* ratio of 0.5774 and a *para/meta* ratio 1.1547. The errors of corresponding experimental ratios for the solutes are expressed in columns 4 and 6 of Table 3. These errors arise from lack of vibrational corrections, which were not deemed important in a study which emphasizes the role of the nematic matrix. Many of the deviations are less than 1% while one result has a difference of 3.05%.

For personal use only.

Table 4 is a composite of all values of S_{11}, S_{22}, and S_{33} obtained both in the present study and some previous similar determinations. In cases where only one sign is attributed the value is absolute, while all other cases have two relative sign assignments, leaving a choice to be made based on arguments to be presented in the discussion. A study of similar compounds without reference to the mesophase structure has recently appeared (18).

(c) *Deuterium magnetic resonance spectra*

The deuterium spectra contain the quadrupole splittings from which are derived the degree of order of C—D or O—D axes for deuteriated segments of the hydrocarbon chain and the water. The asymmetry parameter η is negligible, consequently the degrees of order can be derived from experiments using:

$$[6] \quad \Delta\nu_Q = 3/2\,\nu_Q S_{ZZ}\tfrac{1}{2}(3\cos^2\Omega - 1)$$

$\Delta\nu_Q$ is the measured quadrupole splitting in Hz, ν_Q is the quadrupole coupling for C—D bonds in hydrocarbon chains assigned as 170 ± 8.5 kHz (19). S_{ZZ} is the degree of order along the C—D bond and Ω is the angle ($\pi/2$) between the magnetic field and the director. The value of S_{ZZ} is determined from eq. [6] above, along the axis of the pseudo-extended hydrocarbon chain, which oscillates about the director of the mesophase.

The quadrupole splittings evaluated are listed in Table 5 for phases prepared from DAC and KL. The sign of the derived degrees of order along the extended chain axis is positive because the location of the chain axis with respect to the mesophase director is known from the structure of the Type II DM system and the action of the director under the dual influence of sample spinning about an axis perpendicular to the static magnetic field (9).

(d) *The dilution of uncontaminated mesophases with water*

In order to preserve mesophase stability the water content of Type II DM DAC mesophases remains unaltered with the addition of solutes, while the KL mesophases are affected considerably in their range of water content by the solute additions. Water content variations have been studied extensively in previous publications (11, 12) and for the present case it is sufficient to report that degrees of order of both water and —CD_2— segments decrease as water is added, but preserve their ratios of order in the chain segments to a high degree of experimental precision. The ratios measured for all water contents give 1.569 ± 0.0221 for S_1/S_8, i.e. first divided by eighth segment, 1.960 ± 0.013 for S_1/S_9, and 8.49 ± 0.199 for S_1/S_{10} for the DAC mesophases. The ratios of order for the uncontaminated laurate mesophases are S_2/S_{3-8} = 1.1833 ± 0.0036, S_2/S_{10} = 1.4640 ± 0.0137, S_2/S_{11} = 1.9154 ± 0.0162, and S_2/S_{12} = 5.7166 ± 0.082, independent of water content. The quadrupole splittings ν_{DOH} for water (DOH) are linear with those of the α-CD_2 group ν_{C_1D} of DAC and KL. A least-squares fit to the straight line has been obtained in the form:

$$[7] \quad \nu_{C_1D} = m\nu_{DOH} + \text{const.}$$

For DAC mesophases, m = 69.85 and const. = 116.00 Hz with a correlation 0.9986 while for KL mesophases, m = 36.783 and const. = 3097.12 Hz with a correlation 0.9929. The statistical errors are small compared to the systematic uncertainty in ν_Q. In direct comparisons of degrees of order from the same parameter, only the statistical error is of significance.

Discussion

(a) *General chemical considerations*

The effect of changes in water content on a pure host mesophase has previously been well characterized (9, 12). The decrease in absolute degrees of order of water and hydrocarbon chain segments is associated with the increased motional freedom of the micelles as a unit. The increase in motional freedom is to a large extent associated with the decrease in size of micelles as water is added. An estimate of the size range of disc micelles has recently been made (20). The basis of the discussion here depends on the preservation of ratios of degrees of order along C—D bonds in different segments of the host amphiphile in uncontaminated mesophases as water content changes. We can write this simply as (9):

$$[8] \quad (S_o)_n = (S_{t/g})_n \cdot S_c$$

and

$$[9] \quad \frac{(S_o)_n}{(S_o)_m} = \frac{(S_{t/g})_n}{(S_{t/g})_m} = \text{constant} = K$$

where S_o denotes observed degree of order of the C—D bond, subscripts m and n denote arbitrary segments of the amphiphile chains, $S_{t/g}$ denotes the contribution to the observed degree of order from intramolecular *trans/gauche* equilibria, and S_c represents the contribution derived from overall motion of the pseudo-rigid almost-extended hydrocarbon chain. Equation [8] is interpreted in terms of an internal structure of the micelle, which is independent of the water content (9). The object of the present study is to determine the locale of the small quantity of solute in terms of changes in the order parameters provoked by the additions. The variations in water content necessary to preserve the integrity of the Type II DM mesophase are not important, because in uncontaminated mesophases the ratios of segment order are preserved. It is the purpose of this discussion to bring more evidence to bear with respect to relative alignment of detergent chain axis and solute axes.

The quadrupole splittings of the first —CD_2— segment in Type II DM pure mesophases of DAC are plotted against the splittings of the ninth —CD_2— segment, adjacent to the terminal —CD_3 groups. This graph is used as the standard system uncontaminated by solutes. The slope of this line has been included in the results section and deviations are less than ±0.6% (standard deviation) for individual measurements. The measurements made on contaminated systems will be compared with the standard Type II DM mesophases. The graph reproduced as Fig. 2A corresponds to the DAC system, while Fig. 2C is a replicated treatment of the data for KL mesophases. In the latter case $\nu_{C_{11}D}$ is plotted against ν_{C_2D}, where carbon 2 is the first —CD_2— segment.

In order to leave no doubt as to the relative alignment of the disc–bilayer micelles, Fig. 3 has been designed to clarify this situation with respect to the axis of the nmr tube, axis of spinning, magnetic field direction, and the normal to the disk-like micelle (9).

(b) *Relationship between the deuterium quadrupole splittings of chain segment in mesophases containing solutes*

In Fig. 2A the experimental determinations of the quadrupole splittings ν_{C_1D} and ν_{C_9D} in mesophases containing solutes for DAC phases are plotted. The water content of these phases does vary, but of course they should follow the behaviour of the uncontaminated mesophase, if there is little insertion of impurity into the micelle. The points are identified according to

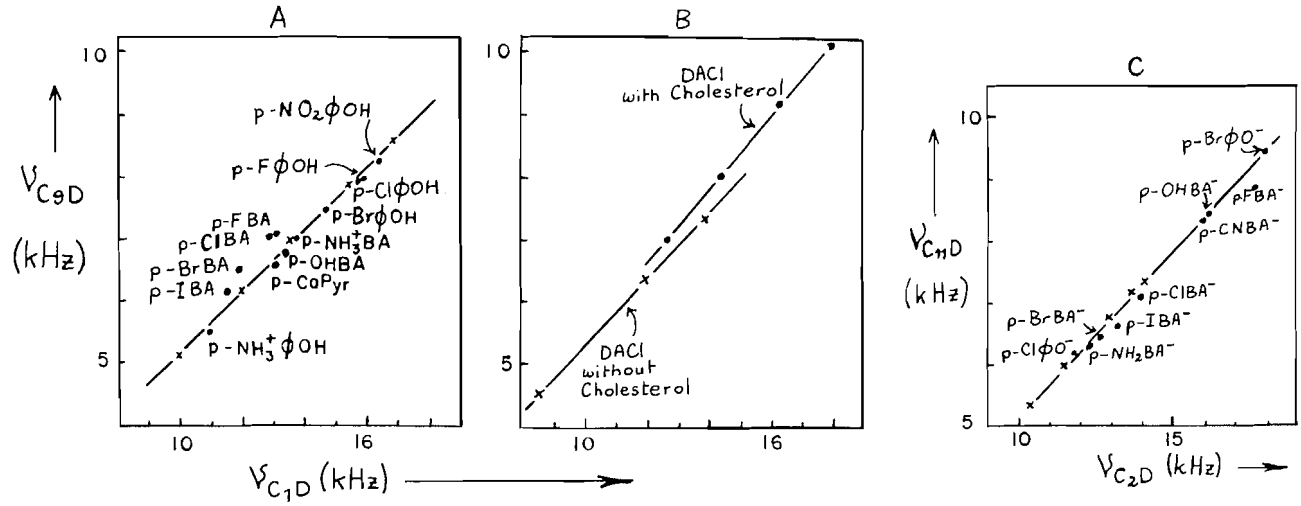

FIG. 2. A. Quadrupole splittings of the ninth segment plotted against the first segment —CD_2— for both contaminated and uncontaminated —DAC mesophases. The line corresponds to those phases which do not contain solutes or contain only solutes which do not change the ratio (ν_{C_1D}/ν_{C_9D}). Points derived from contaminated phases are identified by the name of the solute. The four points above the solid line are the four *p*-halo-substituted benzenes. Points set as crosses × are for uncontaminated mesophases. Solute points are identified by shortened names. B. Graph as in A for DAC mesophases with and without added cholesterol. Data taken from ref. 18. C. Graphs as in A for KL mesophases. Solid line corresponds to phases without solute. The mesophases which contain solutes are identified by shortened formulas given in the text.

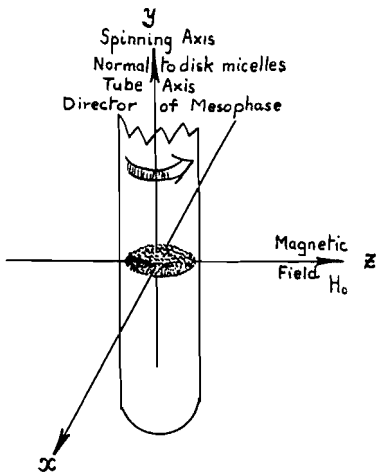

FIG. 3. The schematic arrangement of the alignments of magnetic field, disc micelle, and bilayer and the axis of the nmr tube. One micelle is diagrammatically represented at its mean position with the normal along the director of the mesophase. Relative sizes of objects are of course greatly distorted. If we take the magnetic field as a *z* axis, the director and glass tube axis as a *y* axis, then the micelle surface lies in the *xz* plane.

the impurity present and the concentrations can be obtained from the experimental section. The majority of solutes do not influence appreciably the ratio (ν_{C_1D}/ν_{C_9D}) and they give ratios which fall on or very close to the line for the mesophase without solutes. Taking the solutes, which do not perturb the ratio (ν_{C_1D}/ν_{C_9D}), i.e. PCNBA, POHBA, PNH_3BA^+, PFφOH, PClφOH, PBrφOH, $PNH_3\phi OH^+$, PCaPyr, and $PNO_2\phi O^-$, the value obtained from the experimental measurements is 1.977 ± 0.017, the deviation being given as the standard one over 9 points. This compares within the statistical error with 1.960 ± 0.013 for the same ratio over six data points for the uncontaminated mesophases reported in the experimental section. The conclusion on this evidence is clear, none of these solutes perturb (by eq. [8]) the *trans/gauche* equilibria of the host amphiphile in the micelle. This argument strongly suggests the absence of these solutes inside the micelle.

Four of the solutes do affect the ratio (ν_{C_1D}/ν_{C_9D}) appreciably and these are the chemically related *para*-halogen substituted benzoic acids. They appear in Fig. 2A above the line associated with uncontaminated phases. Although the concentrations of these perturbing solutes in the mesophase do differ, the systematic trend of their effect in increasing the ratio (ν_{D_1D}/ν_{C_9D}) qualifies their behaviour as indicating an inclusion among the solvent amphiphile chains in the micelle. The ratio of order in the first and ninth segments for the four perturbing solutes gives 1.842 for PFBA, 1.854 for PClBA, 1.836 for PBrBA, and 1.890 for PIBA. These values are substantially less than the value for standard uncontaminated phases of 1.960 ± 0.013. We conclude therefore that these solutes insert into the micelle deeper than the first —CD_2— segment but not as deep as the ninth —CD_2—. There is, of course, an equilibrium between aqueous solute and those solute molecules inserted into the micelle bilayer. The arguments above for molecular solutes in a cationic bilayer suggest that the coefficient of distribution is large compared to 1 for the solutes which perturb the host bilayer.

Since the micelle motion and other factors which influence S_c do not affect the ratios of order we can proceed to interpret changes in ratios as resulting from perturbed packing of amphiphile chains in the micelle. The ratios (ν_{C_1D}/ν_{C_9D}) are larger in uncontaminated mesophases and this indicates a larger difference in motional freedom between the head group segment and the last one (22). The interpretation of degrees of order in terms of motional freedom is complicated by constraint angle effects (23). In the present case, however, there is no ambiguity about the mean position of the pseudo-extended chains.

Having discussed the present case of solutes in DAC mesophases, it is possible to reconstruct the same argument from our previously published data (11). Cholesterol is soluble up to 9 mol% in the DAC bilayer and its location is in little doubt. In Fig. 2B the corresponding ratios of quadrupolar splittings for (ν_{C_1D}/ν_{C_9D}) are plotted as in 2A for this system. The ratio (ν_{C_1D}/ν_{C_9D}) is decreased on adding the hydrophobic solute, indicating the stiffening of solvent chains in a manner associ-

ated with biological membranes. The results from an earlier paper (11) were obtained by keeping the cholesterol content of the bilayer constant at 9.2 mol% but varying the water content (Fig. 3, ref. 18).

The results for KL mesophases are very similar (Fig. 2C). They show that no solute decreases the ratio ($\nu_{C_2D}/\nu_{C_{11}D}$) below the value 1.9154 ± 0.0162 quoted in the results section for the uncontaminated mesophase. We conclude therefore that the solutes are mostly located in the aqueous component or at the micelle interface of the liquid crystal. The values observed for the ratio ($\nu_{C_2D}/\nu_{C_{11}D}$) with solute are the following: $PFBA^-$ 1.989, $PClB^-$ 1.972, $PBrBA^-$ 1.976, PCNBA 1.922, PNH_2BA^- 1.944, $POHBA^-$ 1.903, $PCl\phi O^-$ 1.904, and $PBr\phi O^-$ 1.900. Four of these ratios are within the standard deviation for the uncontaminated mesophase, i.e. 1.915 ± 0.016, while the remaining five have somewhat higher values of the ratio. The solubility of the ionic solutes in water is of course higher than the conjugate acids and this has previously been shown to affect the deuterium quadrupole splitting of α-substituted carboxylates (21). Some small perturbation of the interface region is indicated in these cases.

(c) *Relationships between order parameters of solutes and those of detergent segments*

It is useful to consider the ratio of the matrix elements S_{11}, S_{22}, and S_{33}, defined by Saupe, for the solutes and compare them to the degree of order of the first —CD_2— segment of the detergent chains, taken along the axis of the pseudo-extended chain. This is the direction along which the included solutes will be most restricted in their motion because of the encasing bilayer. The geometry of the situation has been clarified in Fig. 3. The oscillatory motion of the pseudo-extended chain derives from both the motion of the micelle as a body and of the chain itself about the normal to the micelle interface (9). In Table 6 the ratios discussed in this section are listed. The uncertainty in the degree of order derived from the quadrupole splitting carries the uncertainty in ν_Q of eq. [6] of about ±5% but this is a systematic error which occurs in all ratios. The random error in the ratios cited may be taken to be a maximum of ±2%, these arising from the spectra AA′BB′, other errors being negligible in comparison. The direction of the axis S_{22} in the solute is the same as that of the S_{C_1D}, namely along a direction normal to the micelle disc interface if the solute is inserted into the bilayer with the *para* axis perpendicular to the plane of the disc. The magnitude of the solute degree of order along this 22 axis is always larger than the perpendicular axes, 11 and 33. The largest magnitudes of S_{22} occur for the series PFBA, PClBA, PBrBA, and PIBA in mesophases prepared from decylammonium chloride. This is consistent with the argument mounted in the last section. The ratios S_{22}/S_{C_1D} and S_{22}/S_{C_2D} in Table 6 are smaller than 1 for all other solutes, indicating greater freedom of movement for those solutes which, by previous argument, are located mainly in the aqueous layers.

The sign of the dipole–dipole coupling constant is the reverse of the sign of the degree of order, e.g. see eq. [4]. Since different relative sign combinations are possible for the different solutes used here, it is constructive to consider the implied orientations of the solutes in terms of the structure of the mesophase.

Taking into account the plane of the aromatic ring of the solute and the plane represented by the interface of the micelle, three limiting arrangements are possible. (a) The aromatic ring may lie flat on the interface, in which case the normal to the aromatic ring oscillates about the director of the mesophase. (b) The ring may be disposed with the *para* axis of substituents perpendicular to the interface, i.e. the *para* axis oscillates angularly about the mesophase director. (c) The plane of the ring may be in a plane perpendicular to the interface, with an axis perpendicular to the *para* axis oscillating about the director.

*Molecular and positive ion solutes in mesophases of DAC.

†Negative ion solutes in the KL mesophase. Errors in this ratio from random sources are ±1.0% at worst and ±0.4% at best.

The argument will be carried using the signs of the Saupe matrix elements S_{11}, S_{22}, and S_{33} since these are automatically derived from the relative signs of D_{ij}, the dipole–dipole couplings obtained by analysis of the spectra of solutes. An orientation of the benzene ring of solutes perpendicular to the mesophase director yields the following relative signs $S_{11} < 0$, $S_{22} < 0$, $S_{33} > 0$. If the aromatic ring is aligned with the *para*-substituted axis along the director, the relative signs become $S_{11} > 0$, $S_{22} < 0$, $S_{33} < 0$ while an orientation of the director in the plane of the aromatic ring along the direction perpendicular to the *para* axis leads to the sign combination $S_{11} > 0$, $S_{22} < 0$, $S_{33} < 0$.

It is important of course to understand that the degrees of order S_{11}, S_{22}, and S_{33} may be modulated by chemical exchange processes between the three fixed sites indicated and in principle others, including residence in the aqueous layer away from the interface. The residence time in the aqueous bath away from the influence of the interface does not impose orientational order on the solutes; indeed, for ions such as Cl^- or the D_2O, it has been shown that order is transferred at an adsorbed interface layer (11). The effect of residence time in the aqueous bath is to reduce the absolute degrees of order measured for the solute (9). In the sense that the degrees of order measured along the *para* axis for PFBA, PClBA, PBrBA, and PIBA exceed those of the detergent segment next to the ionic head group for DACl mesophases, we can expect negligible residence time for these species in the aqueous bath, a conclusion we have already drawn from other evidence cited earlier.

It is now interesting to suppose that the orientation of the aligned inserted species occurs in the manner with the director along the *para* axis, i.e. perpendicular to the interface of the micelle (see also Figs. 3 and 4). In this case the signs of order

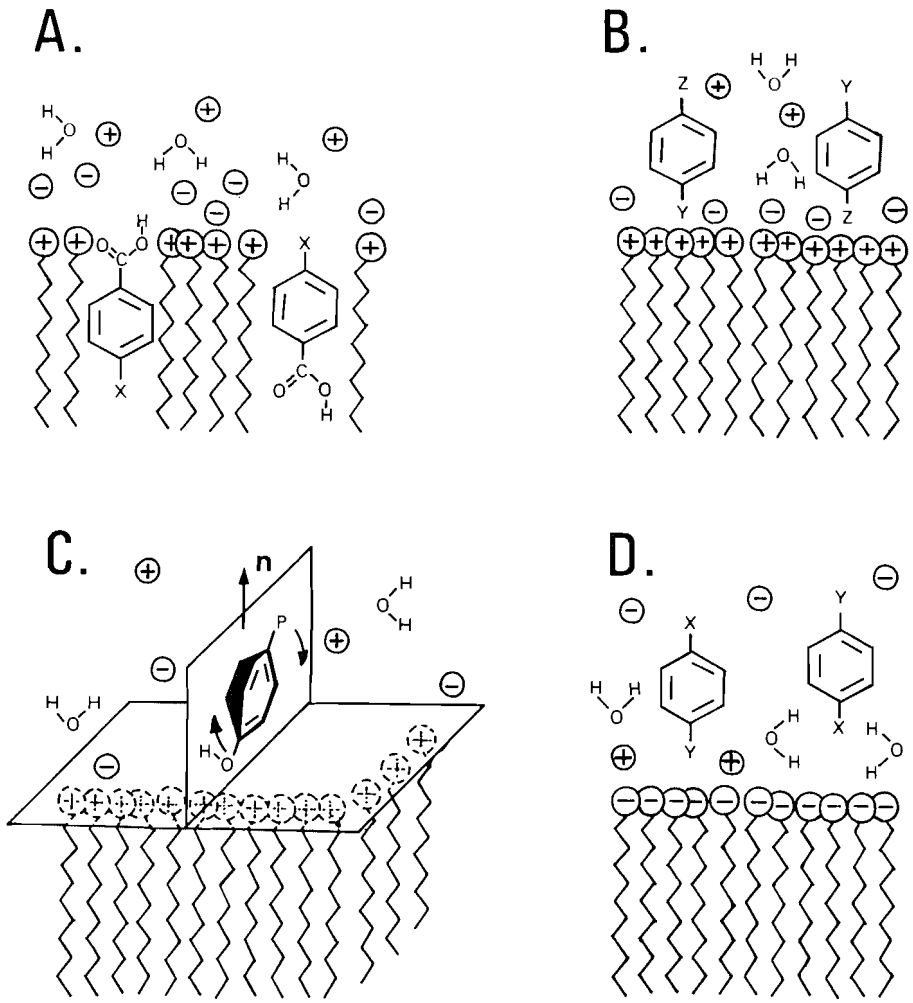

FIG. 4. A. Orientations of *para*-halobenzoic acids in the interface of the micelle following the evidence of sign attributions of S_{ii}'s and the evidence of insertion in the bilayer. The location of the carboxyl group in the interface is based on the polar chemical nature of this group. B. The two possible alignments of the compounds indicated with the alternate possibility of either *para* substituent in the interface. Some equilibrium with inserted situations in the bilayer is possible, though evidence points to attachment predominantly from the aqueous side. C. The alignment of parahydroxybenzoic acid and parafluorophenol in lyomesophases of DAC. The plane of the benzene ring is perpendicular to the interface plane of the micelle and the ring has freedom to rotate in this plane, probably with attachment to the interface by the *para*-substituted groups with water bridges. D. The alignment of *para*-substituted phenoxides and benzoates in mesophases of KL. In principle both *para* groups may attach to the ionic interface, perhaps with hydrogen bonded water bridges.

TABLE 7. Absolute signs of Saupe matrix elements determined using the mesophase structure and the relative signs available from the proton resonance spectra

Solute	S_{11}	S_{22}	S_{33}

parameters are $S_{11} < 0$, $S_{22} > 0$, and $S_{33} < 0$. This is one of the two relative sign combinations derived from the experimental results, the other possibility being $S_{11} > 0$, $S_{22} < 0$, and $S_{33} > 0$, which we now discard. This is summarized in Table 7. The sign combination in itself leaves us still with the choice of alignments as in Figs. 4A or B, but obviously the prior evidence points to A being the correct assignment with the carboxyl group acting as a polar group in the interface and the *para*-halogen substituents inserted into, and perturbing the packing of, amphiphiles in the bilayer.

The values in Tables 4 and 6 for PCNBA, PNH_3BA^+, and PClϕOH also show that the value of S_{22} is somewhat larger than S_{11} and S_{33} in magnitude but the solute is considerably less ordered than the α detergent segment along this same direction. On the other hand, there is little perturbation (not detectable) of the order ratio in the detergent segments (ν_{C_1D}/ν_{C_9D}). The relative sign combination from the experiments indicates again the choice $S_{11} < 0$, $S_{22} > 0$, $S_{33} > 0$ rather than the inverse, which has no physical reality. We propose for these three solutes, therefore, an equilibrium between orientations 4A and 4B with

the polar groups —COOH, NH_3^+ or COOH and —OH in the interface. The equilibrium evidently favours attachment to the interface from the aqueous side with little insertion into the bilayer.

The situation with PBrϕOH is uncertain because the magnitude of S_{11} is very small and any sign attribution is within experimental error. Some inclined average orientation is indicated with more than one site in a chemical exchange, S_{22} and S_{33} having opposite signs.

The sign combination $S_{33} > 0$, $S_{22} < 0$ and $S_{11} < 0$ fits the cases of POHBA and PFϕOH (Table 5). The orientation corresponds to Fig. 4C with the plane of the aromatic ring perpendicular to the plane of the micelle interface. Presumably the polar *para* groups partake in hydrogen bonding, probably with water bridges to the interface head groups. It is interesting to recall that the phenolic —OH has stable configurations in the plane of the ring, as does the carboxyl group. Rotation of the plane of the aromatic ring about its perpendicular axis, in the perpendicular plane to the interface, is rather uninhibited as shown by the low values of S_{11} for both compounds. The rotation of the ring is indicated by arrows in Fig. 4C.

The solutes in KL mesophases all present the same relative signs for degrees of order so we can propose the only acceptable combination of absolute signs as $S_{11} < 0$, $S_{22} > 0$, and $S_{33} < 0$ (q.v.). Since we have previously argued that there is no detectable perturbation of the host bilayer packing, then a preponderance of the alignment of the *para* axis perpendicular to the interface, but from the aqueous side, is indicated. This corresponds to the situation in Fig. 5D, with the point of attachment to the interface being either *para* group, in principle.

Organic solvents-induced difference spectra of bovine serum albumin

S. F. SUN, T. S. CHANG, AND G. M. LAM
Department of Chemistry, St. John's University, Jamaica, NY 11439, U.S.A.

Received July 15, 1982

S. F. SUN, T. S. CHANG, and G. M. LAM. Can. J. Chem. **61**, 356 (1983).

Difference spectra of tyrosyl residues in bovine serum albumin produced by three organic solvents (ethanol, *n*-propanol, and dioxane) have been studied at three different pH values (pH 2.2, pH 5.4–5.8, and pH 11.6). The measurements were taken at 25°C and ionic strength 0.03 and in a concentration of organic solvent from 5% to 25% by volume. The spectra are compared to those of a model chromophore, *N*-acetyl-L-tyrosine ethyl ester. Both *n*-propanol and dioxane cause a change in the conformation of the protein, while ethanol does not. Near the isoelectric point the difference spectra produced by *n*-propanol (at high concentration) and dioxane appear to be the results of a superposition of denaturation blue shifts on solvent-induced red-shifts; those produced by ethanol are characteristic of perturbation of tyrosyl and tryptophyl residues. An empirical equation which correlates $\Delta\epsilon$ (the molar difference absorption coefficient) with n (refractive index) and D (dielectric constant) is proposed to interpret the results qualitatively.

S. F. SUN, T. S. CHANG et G. M. LAM. Can. J. Chem. **61**, 356 (1983).

On a étudié à trois pH différents (pH 2,2, pH 5,4–5,8 et pH 11,6) les différences spectrales des unités tyrosyles de l'albumine du sérum de bovin produites par trois solvants organiques différents (éthanol, *n*-propanol et dioxanne). On a effectué les mesures à 25°C, à une force ionique de 0,3 et pour des concentrations de solvant organique allant de 5% à 25% en volume. On a comparé les spectres à ceux d'un chromophore modèle, l'ester éthylique de la *N*-acétyl L-tyrosine. Le *n*-propanol et le dioxanne provoquent un changement de conformation de la protéine, tandis que l'éthanol n'a aucun effet. Au voisinage du point isoélectrique, les différences dans les spectres des produits obtenus soit avec le *n*-propanol (à forte concentration) ou le dioxanne ne semblent être le résultat que de la superposition de glissements vers le bleu dû à une dénaturation sur les glissements vers le rouge induits par le solvant. Ceux produits par l'éthanol sont caractéristiques d'une perturbation des unités tyrosyle et tryptophyle. Pour interpréter qualitativement ces résultats, on propose une équation empirique qui établit une corrélation entre $\Delta\epsilon$ (le coefficient d'absorption de différence molaire) et n (indice de réfractions) et D (constante diélectrique).
[Traduit par le journal]

Introduction

Information has been accumulated through the years concerning the difference spectra of tyrosyl residues in proteins in different environments. The time seems ripe for us to draw some definite conclusions on the three major factors that influence the position, shape, and intensity of spectral lines. These factors are: burial and exposure, folding and unfolding, and ionization.

In order to achieve this goal, bovine serum albumin was selected for study. The abundance of literature on this protein (1–4) made the interpretation of data relatively simple. Bovine serum albumin is a model protein, important not only as a standard for calibration whenever a new experimental method is introduced in protein chemistry but also as a sample for testing new ideas regarding the structural properties of a protein or enzyme. Its behavior also commands attention: It is a very stable protein, easy to handle, and there is little fear of degradation. Its change in conformation as a function of pH is well known (1, 3). The three well-defined regions are: acidic region (below pH 4.3) where the protein unfolds due to ionization of glutamic and aspartic acids, basic region (above pH 10.5) where the protein almost completely unfolds due to ionization of basic groups such as lysine and arginine, and the region between 4.3 and 10.5 where the protein is in the folded, native stable state. Unless drastically disturbed, the change in conformation is reversible.

Ethanol, *n*-propanol, and dioxane were used as three probes. Both ethanol and *n*-propanol are hydroxy reagents, normally used for perturbation of tyrosyl residues in proteins. However, there is a pronounced difference between the two compounds. Although they are in the same homologous series, *n*-propanol is the first member that has a free rotational alkyl group. For that reason *n*-propanol's behavior in many ways is different from that of ethanol (5). Dioxane is known for its effect on hydrogen-bonding interactions (6–8). The presence of dioxane often causes pK shifts of charged groups in proteins (9). Even though solvent effects on differential spectra of bovine serum albumin have been reported in literature (4), the present study describes in a more conclusive way the subtle effect of environment on the physical and chemical states of aromatic residues, particularly tyrosine, in the three well-defined pH regions.

Experimental

Materials

Armour crystalline bovine serum albumin, Lot Nos. J 72003 and J 72105, was deionized by passing the concentrated aqueous solution through a mixed ion-exchange bed resin followed by dialysis against water in a cold room overnight. The model compound, *N*-acetyl-L-tyrosine ethyl ester, was purchased from the Schwartz-Mann Research Laboratories and was used as received. All the organic solvents used were reagent grade and were purified by fractionation distillation before use. Glass-distilled water was used throughout the experiments.

Preparation of solutions

A typical neutral protein solution (at a pH near the isoelectric point 5.3–5.8) was prepared as follows. To a calibrated 25-mL volumetric flask the following were added in order: 12.5 mL of 0.06 *M* KCl, 5 mL of the protein stock solution, a calculated amount of organic solvent, and water to the mark. An acid or basic protein solution was prepared in the same way as for a neutral solution, except that an additional calculated amount of KOH (0.22 *M*) or HCl (0.5 *M*) was added. To minimize the discrepancy in concentration the same two or three burets and the same two or three pipets were used for the

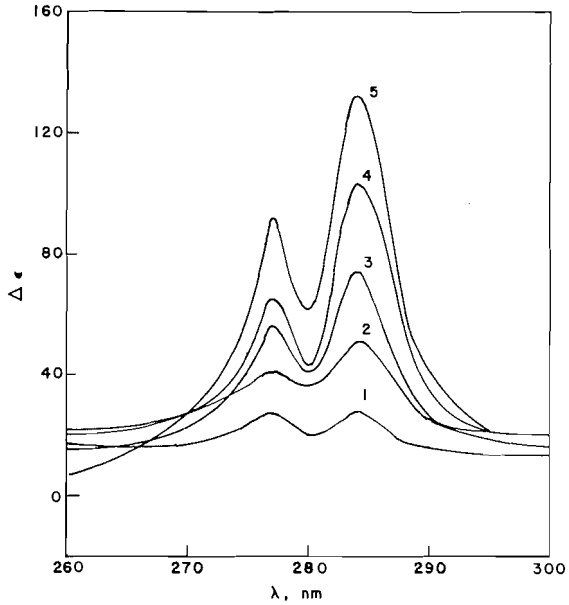

FIG. 1. Difference spectra of *N*-acetyl-L-tyrosine ethyl ester at pH 5.4, ionic strength 0.03 and 25°C produced by ethanol. Concentrations of ethanol (v/v): *1*, 5%; *2*, 10%, *3*, 15%; *4*, 20%; *5*, 25%.

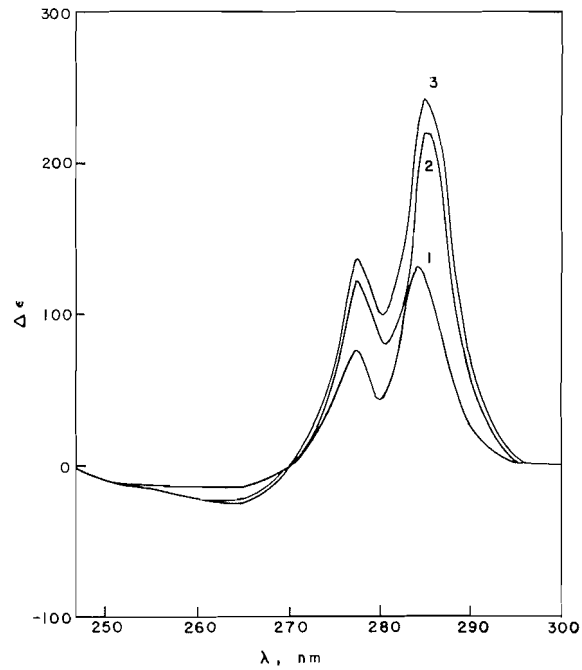

FIG. 2. Comparison of the difference spectra of *N*-acetyl-L-tyrosine ethyl ester produced by 25% organic solvent at pH 5.4–5.7, ionic strength 0.03 and 25°C. Curves: *1*, ethanol; *2*, *n*-propanol; *3*, dioxane.

preparation of all solutions. The reference solutions were prepared in the same way as the sample solutions except that no organic solvent was added. Since the ionization of acid or base in an aqueous solution is affected by the presence of an organic solvent, the amount of acid or base added to a reference solution was slightly different from that added to a sample solution. Similar methods were used for the preparation of solutions of the model compound.

Concentrations of the stock protein solution and of the model compound were determined spectrophotometrically, using $E^{1\%}_{1cm} = 6.67$ at 279 nm for albumin and 1340 for the molar extinction coefficient for tyrosyl ester at 274.5 nm. The molecular weight of bovine serum albumin used in calculations was 69 000. The protein concentrations used ranged from 2.5×10^{-5} to 3.2×10^{-5} *M*, while the concentrations of tyrosyl ester used ranged from 3.2×10^{-4} to 7.8×10^{-4} *M*.

Measurements

All the absorption measurements were done with a Cary model 14 recording spectrophotometer equipped with an expanded slide-wire in the range of 0–0.1 optical density units. A set of tandem double cells designed by Herskovits and Laskowski (10) with a 1.0 cm path length for each of the two components was used. The slit width was less than 0.2 mm for data obtained above 260 nm; it was more than 0.2 mm but not exceeding 1.0 cm for data obtained below 260 nm. We do not put much weight on the data below 260 nm. All difference spectra were obtained within 10 to 30 min after solutions were prepared. We did not find a time-dependent change in the spectrum, nor did we have any evidence for aggregation.

The pH of each solution was measured immediately after the absorption measurement with a Radiometer TTTIC equipped with a scale expander to check if the value was that planned. Usually the agreement was within 0.1 pH units. The pH values as read from the glass electrode pH meter were not corrected for the presence of organic solvent (6, 7, 9).

Results

(a) The model chromophore

Since serum albumin is rich in tyrosyl content (21 tyrosines and 2 tryptophans), only *N*-acetyl-L-tyrosine ethyl ester was used as a model. Difference spectra were obtained for the tyrosyl ester in organic solvent – water mixtures at ionic

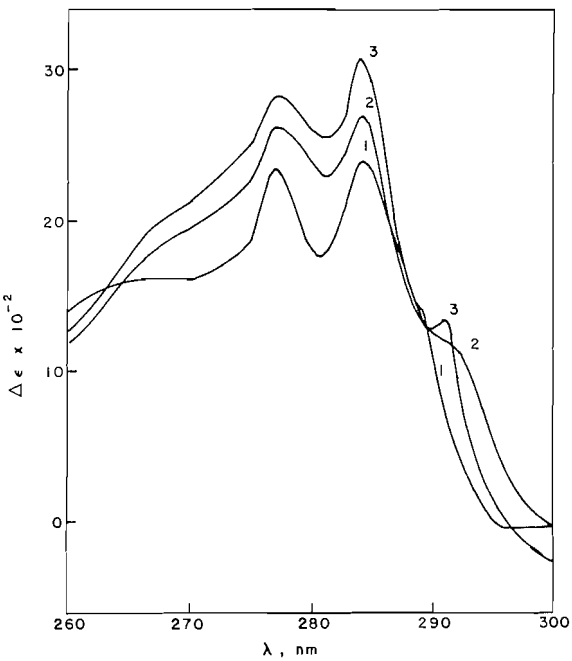

FIG. 3. Difference spectra of bovine serum albumin at pH 2.2, ionic strength 0.03 and 25°C produced by 25% organic solvent. Curves: *1*, dioxane; *2*, ethanol; *3*, *n*-propanol.

strength 0.03. The concentrations of organic solvents were selected: 5%, 10%, 15%, 20%, and 25% (v/v) respectively. Later the same concentrations were applied to serum albumin.

Figure 1 shows the representative difference spectra of tyrosyl ester produced by ethanol, curve *1* in 5% ethanol; curve *2*, 10% ethanol; curve *3*, 15% ethanol; curve *4*, 20% ethanol; and curve *5*, 25% ethanol. Each curve gives two peaks, one at 277–279 nm and the other at 284–286 nm, typical of tyrosine (11). As expected, the magnitudes of the two peaks are a linear

function of the concentration of ethanol. Similar difference spectra were obtained for tyrosyl ester produced by *n*-propanol and dioxane. For comparison, Fig. 2 gives the difference spectra of tyrosyl ester produced by 25% ethanol (curve *1*), 25% *n*-propanol (curve *2*), and 25% dioxane (curve *3*), at pH 5.4–5.7 and ionic strength 0.03. Under these experimental conditions (pH and ionic strength), the phenolic OH of tyrosine is not dissociated and the carboxylic and amino groups have no electric charge. The shapes of the three curves are almost identical. The differences lie mainly in intensities. The intensities of the two characteristic peaks reflect the strength of molecular interaction between the solvent and the solute. They are in the order: dioxane > *n*-propanol > ethanol. This is inversely proportional to the dielectric constant of the solvent medium, indicating the involvement of an electrostatic effect. The dielectric constants for the three solvents are: dioxane–water (25:75, v/v) 56.0; *n*-propanol – water (25:75, v/v), 61.5; and ethanol–water (25:75, v/v), 67.0 (12).

(b) Acidic serum albumin

The expansion of bovine serum albumin in acidic aqueous solutions reaches its maximum when the pH is 2.2 (2, 3). Our study of organic solvent effect in acidic region was, therefore, carried out at that pH value. In Fig. 3, difference spectra of serum albumin produced by three 25% organic solvents at pH 2.2 are compared: curve *1*, dioxane; curve *2*, ethanol; and curve *3*, *n*-propanol. The shapes of the three curves are similar to those of tyrosyl ester. However, the ratio of the height of the major peak at 284–286 nm over that of the minor peak at 277–278 nm is much smaller for the protein curve than for the tyrosyl ester curve. Furthermore, the values of $\Delta\epsilon$, the molar difference of absorption coefficient, at the 284–286 nm peak are in the order of *n*-propanol > ethanol > dioxane, not in correspondence with the increase or decrease of dielectric constant of the solvent medium as in the case of tyrosyl ester. Nor are they in correspondence with the increase or decrease in the refractive index of the solvent. The refractive indices of the solvents are $n_D^{25} = 1.3450$ for 25% ethanol, $n_D^{25} = 1.3499$ for 25% *n*-propanol, and $n_D^{25} = 1.3560$ for 25% dioxane. This clearly indicates that the presence of organic solvent involves more than the electrostatic effect. There must be something related to the neighboring groups of tyrosyl residues in the protein. Comparison of the difference spectra of tyrosyl residues in the protein at acidic pH with that of tyrosyl esters reveals that although the 21 tyrosyl residues are not all exposed to the surface (4), those which are exposed are completely accessible to the solvent. The estimate was based upon the choice of the model compound, the tyrosyl ester, as "100% exposed" (13).

(c) Isoelectric serum albumin

At pH near the isoelectric point, serum albumin is in its native state. Fig. 4 (*a*), (*b*), and (*c*) give the difference spectra of serum albumin as a function of the concentration of organic solvent at isoelectric pH. Concentrations of the organic solvent (v/v) in each figure are as follows: curve *1*, 5%; curve *2*, 10%; curve *3*, 15%; curve *4*, 20%; and curve *5*, 25%.

Figure 4 (*a*) shows that each curve contains the twin peaks and a shoulder. The twin peaks are unmistakably due to tyrosyls, while the shoulder is due to tryptophyls. The ratio of the heights of the two peaks increases as the concentration of ethanol increases. The values of $\Delta\epsilon$ of the major peak form a linear function with the concentration of ethanol indicating that there is no conformational change of the protein and ethanol serves as a perturbant to the tyrosyls.

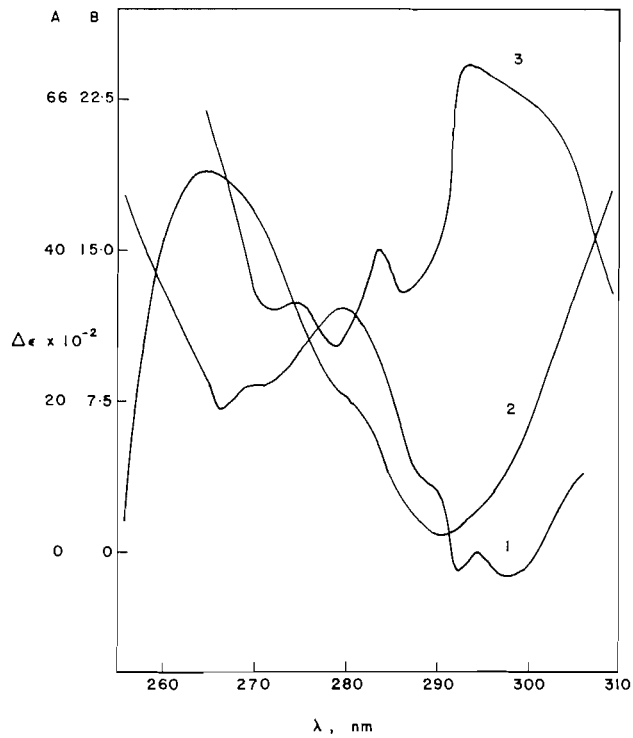

FIG. 5. Comparison of the difference spectra of bovine serum albumin at pH 11.6, ionic strength 0.03 and 25°C produced by 25% organic solvent. Curves: *1*, ethanol; *2*, dioxane; *3*, *n*-propanol. Scales: *A*, dioxane; *B*, ethanol and *n*-propanol.

The difference spectra of serum albumin produced by *n*-propanol shown in Fig. 4 (*b*) are more complicated than those shown in Fig. 4 (*a*). The curves in Fig. 4 (*b*) may be divided into two groups. The first group consists of three curves: 5%, 10%, and 15% *n*-propanol; the second group consists of two curves: 20% and 25% *n*-propanol. In the first group the values of $\Delta\epsilon$ at 284–286 nm form a linear function with the concentration of *n*-propanol as in the ethanol solutions, suggesting that *n*-propanol at these concentrations serves as a perturbant, but not as effectively as ethanol. The curves in the second group show a deep trough at 288 nm. The deep trough at 288 nm has been attributed to the red shift of the tryptophan trough and blue shift of the tyrosine trough, an indication of the change in tertiary structure of the protein (14).

Figure 4 (*c*) shows the difference spectra of serum albumin produced by dioxane at isoelectric pH. These curves are even more complicated than those produced by *n*-propanol. First, there are more peaks and troughs in the region between 240–270 nm, indicating more interference from phenylalanine residues. Second, the twin peaks of tyrosyls are obscure. There appears a deep and wide trough at 288 nm, suggesting some changes in the conformation of the protein.

(d) Basic serum albumin

The difference spectra of bovine serum albumin at pH 11.6 produced by 25% organic solvent are shown in Fig. 5. At such high pH the absorptions of chromophores interfere with each other and no peak can be assigned to a particular group unmistakably. The resolution of the *n*-propanol curve seems to be better than that of the ethanol curve. The curve of dioxane is markedly different from those of ethanol and *n*-propanol both in intensity and shape. A broad trough occurs at 290 nm and a

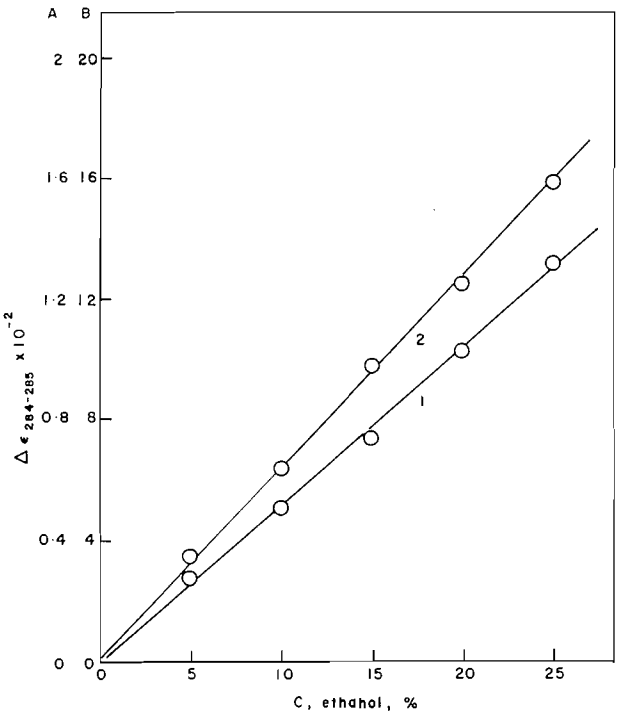

FIG. 6. Effect of the concentration of ethanol on the difference spectra of bovine serum albumin and that of *N*-acetyl-L-tyrosine ethyl ester at pH 5.4–5.7, ionic strength 0.03 and 25°C. Curve *1* and scale *A*, *N*-acetyl-L-tyrosine ethyl ester; curve *2* and scale *B*, bovine serum albumin.

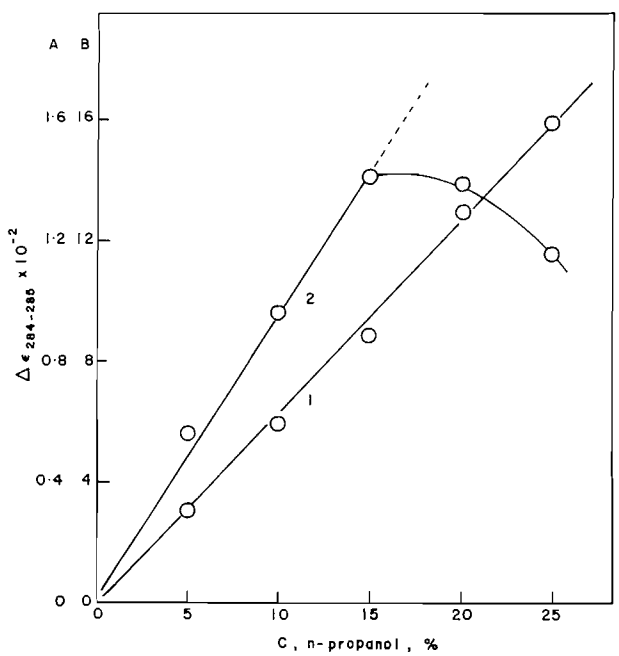

FIG. 7. Effect of the concentration of *n*-propanol on the difference spectra of bovine serum albumin and that of *N*-acetyl-L-tyrosine ethyl ester at pH 5.4–5.7, ionic strength 0.03 and 25°C. Curve *1* and scale *A*, *N*-acetyl-L-tyrosine ethyl ester; curve *2* and scale *B*, bovine serum albumin.

broad peak at 265 nm. The curve represents a complete ionization of the phenolic chromophores of bovine serum albumin (6).

Discussion

Tyrosyl residues in a protein are believed to involve three types of interactions: (*a*) tyrosyl–water interaction through hydrogen bonding, (*b*) tyrosyl–carboxylate (e.g. tyrosyl–glutamate) interaction also through hydrogen bonding (15, 16), and (*c*) the interaction between the methyl groups of non-polar side chains such as leucine or of polar side chains such as lysine and the benzene ring of tyrosine through hydrophobic bonds. The first type of interaction occurs on the surface of the protein molecule where the tyrosyl residues are accessible to the solvent. The second and third types of interaction occur in the interior of the protein molecule. The effect of an organic solvent depends on its ability to alter the relative strengths of the internal hydrogen and hydrophobic bonds in the native protein and of the hydrogen bond to water.

In acidic solution, e.g., pH 2.2, where the protein expands, the difference spectra produced by the three organic solvents are similar to those of tyrosyl esters, as shown in Figs. 2 and 3. This shows that the three organic solvents act mainly by solvent effect. However, the fact that the intensities of major peaks in the three organic solvent – water mixtures do not correlate with the dielectric constants of the solvents indicates that the polarity of the solvent is not the only factor to affect the absorption spectra. We attribute this fact to the different bonding strength of the three organic solvents. Dioxane seems to be stronger in interaction with water through hydrogen bonding than alcohols, but weaker in interaction with non-polar groups of side chains in a protein molecule than the two alcohols. Between the two alcohols, *n*-propanol is stronger than ethanol in hydrophobic bonding due to the additional alkyl group in the chain (5, 17).

At basic pH, e.g. 11.6, the protein molecule greatly expands. The value of the reduced viscosity is 3 times higher than that at pH 2.2 (3). Also, the tyrosyl residues are believed to be completely ionized. The spectral shift due to the solvent effect is cancelled by the conformational blue shift. The difference spectra we observed are a reflection of the change in pK values of the ionized tyrosyl residues. The pK shift for phenolic groups in 25% dioxane is 0.15 units (9); that in 25% *n*-propanol or in 25% ethanol is smaller than 0.15 units (our experimental results). That the spectrum in 25% ethanol is quite different from that in 25% propanol reflects the different chemical properties of the two alcohols as we described elsewhere (5).

At pH near isoelectric point (ca. 5.4), bovine serum albumin is in its native state. Here we observed the clear-cut influence of the three different environments produced by three different organic solvents on the physical and chemical states of the tyrosyl residues in a protein.

The value of $\Delta\epsilon$ (the molar difference absorption coefficient) depends upon the refractive index of the chromophore and the dielectric constant of the solvent medium. Parallel to the expression of $\Delta\nu/\nu$ (18) (where ν is the frequency of the absorption maxima), the parameter $\Delta\epsilon$ may be expressed by the equation

$$\Delta\epsilon = A + B[\mathrm{R}] + C[\mathrm{P}]$$

where

$$[\mathrm{R}] = \frac{n^2 - 1}{n^2 + 2}\frac{M}{P}$$

and

$$[\mathrm{P}] = \frac{D - 1}{D + 2}\frac{M}{P}$$

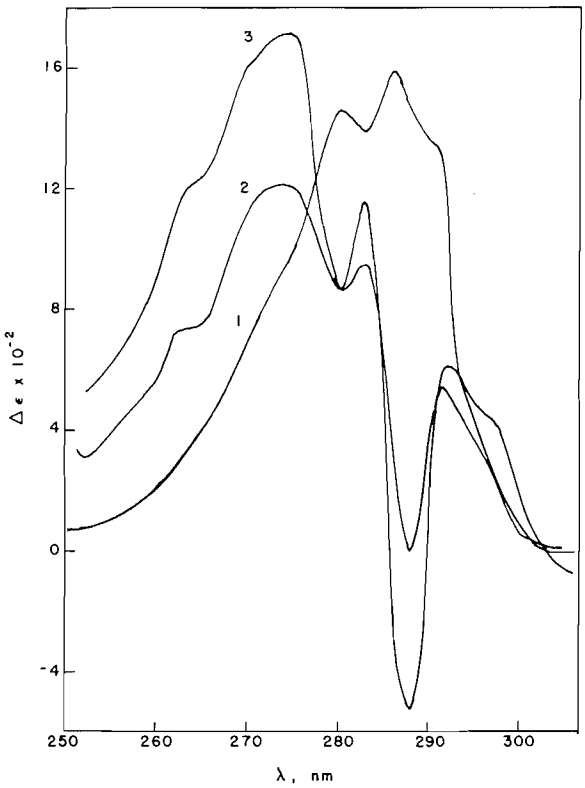

FIG. 8. Comparison of the difference spectra of bovine serum albumin at pH 5.4–5.7, ionic strength 0.03 and 25°C produced by 25% organic solvent. Curves: *1*, ethanol; *2*, dioxane; *3*, *n*-propanol.

In the above equations, n is the refractive index, M is the molecular weight, P is the density of the medium, and D is the dielectric constant. P is the molar polarization or distortion polarization which is related to the polarizability α of the chromophore by the equation $P = \frac{4}{3}\pi N\alpha$, N being the Avogadro's number. A, B, and C are constants: A is related to the dispersion force, B to the interaction between the chromophore as an oscillating dipole and the organic solvent molecule as an induced dipole, and C to the interaction between the oscillating dipole and the permanent dipole.

In Fig. 6 the values of $\Delta\epsilon$ at 284–285 nm are plotted against the concentration of ethanol for the model compound (curve *1*) and for serum albumin (curve *2*). The fact that a straight line was obtained for albumin just as it was for the model compound demonstrates that B is zero, that is, $\Delta\epsilon$ depends on the dielectric constant of the solvent medium alone. It is well known that $D = n^2$ for a molecule with no permanent dipole moment. There is obviously no change in conformation of the protein.

Figure 7 compares the values of $\Delta\epsilon$ at 284–285 nm of the tyrosyl ester with that of serum albumin as a function of the concentration of *n*-propanol. While a straight line was obtained for tyrosyl ester (curve *1*) in *n*-propanol–water mixtures as in ethanol–water mixtures, this was not so for serum albumin (curve *2*). The first three points (in 5%, 10%, and 15% *n*-propanol) are on the straight line, but the last two points (20% and 25% *n*-propanol) are off the line. This demonstrates that as the concentration of *n*-propanol increases to 20%, the conformation of the protein changes. That is, for tyrosyl residues in the protein, both B and C are not zero at higher concentrations of *n*-propanol. B is zero only for tyrosyl residues in the protein at low concentrations of *n*-propanol. It is zero for the model compound in both low and high concentrations.

Figure 8 compares difference spectra of serum albumin produced by the three organic solvents at the same concentration, 25%, and at the isoelectric pH. Among the differences are: the positions of the three peaks, the shapes of the curves, the intensities of the twin peaks of the tyrosyl residues, and the trough at 288 nm.

Spectral changes in the isoelectric pH region seem to correlate well with viscosity data. The intrinsic viscosity of bovine serum albumin in units of dl/g in 25% organic solvent – 75% H_2O, ionic strength 0.03, in the isoelectric pH region is: dioxane 0.019, *n*-propanol 0.061, and ethanol 0.037, in comparison with 0.037 when no organic solvent is present (9, 19). Thus the conformation of serum albumin remains the same in the presence of 25% ethanol, expands in the presence of 25% *n*-propanol, and shrinks in the presence of 25% dioxane.

The results lead us to the conclusion that for bovine serum albumin in its native state ethanol has no effect on the intermolecular forces that exist between tyrosyl residues and other polar or non-polar amino acid residues, but *n*-propanol and dioxane do. The presence of *n*-propanol has a strong impact on the hydrophobic region of the protein molecule. Possibly, the alkyl group in the side chain of *n*-propanol competes with the benzene ring of tyrosyl residues in forming hydrophobic bonds with the alkyl groups of polar and non-polar amino acid residues inside the protein molecule. That is, *n*-propanol has weakened the third type of interaction of tyrosyl residues, thereby causing the conformational change in protein. Dioxane has the ability of interrupting all three types of interactions of tyrosyl residues, though weaker than *n*-propanol in interrupting the third type of interaction. Because of this, the change in the conformation of the protein in the presence of dioxane is in the form of contraction (19).

Structure et réactivité. V.[1] Étude par résonance magnétique nucléaire des produits d'halogénation des *tert*-butyl-3 methoxycarbonyl-4 cyclohexènes

JEANINE BOUTEILLER-PRATI, JEAN-CLAUDE BOUTEILLER ET JEAN-PIERRE AYCARD[2]

Laboratoire de Chimie Organique Structurale, Université de Provence, Centre de Saint-Jérôme, 13 rue Henri Poincaré, 13397 Marseille Cedex 13, France

Reçu le 5 juillet 1982

JEANINE BOUTEILLER-PRATI, JEAN-CLAUDE BOUTEILLER et JEAN-PIERRE AYCARD. Can. J. Chem. **61**, 362 (1983).

Les produits de la réaction de bromation (ou de chloration) des *tert*-butyl-3 carbométhoxy-4 cyclohexènes *cis* et *trans* sont étudiés par rmn. Les résultats montrent que la réaction sur l'isomère *cis* conduit à plus de 90% de la lactone de l'acide bromo-4 (chloro-4) *trans* hydroxy-3 *cis tert*-butyl-2 *trans* cyclohexane carboxylique alors que la réaction sur l'isomère *trans* conduit au dibromo (dichloro)-1,2 *trans tert*-butyl-3- *cis* carbométhoxy-4 *trans* cyclohexane qui adopte une conformation twist. Pour le composé dibromé ce produit cinétique se transpose en dibromo-1,2 *trans tert*-butyl-3 *trans* carbométhoxy-4 *cis* cyclohexane par un rearrangement dyotropique. La formation des produits cinétiques est expliquée par l'intervention des conformères diaxiaux des dérivés cyclohexéniques de départ.

JEANINE BOUTEILLER-PRATI, JEAN-CLAUDE BOUTEILLER, and JEAN-PIERRE AYCARD. Can. J. Chem. **61**, 362 (1983).

The product of the bromination (chlorination) reaction on *cis* and *trans* 3-*tert*-butyl 4-carbomethoxy cyclohexene is studied by nmr. The results show that the reaction of the *cis* isomer gives 90% of the *trans* 4-bromo (chloro) *cis* 3-hydroxy *trans* 2-*tert*-butyl cyclohexane 1-carboxylic acid lactone and the reaction of the *trans* isomer gives *trans* 1,2-dibromo (dichloro) *cis* 3-*tert*-butyl *trans* 4-carbomethoxy cyclohexane which adopts a twist conformation. For the dibromo compound this kinetic product gives the corresponding thermodynamically more stable isomer, *trans* 1,2-dibromo *trans* 3-*tert*-butyl *cis* 4-carbomethoxy cyclohexane, by a diotropic rearrangement. The formation of the kinetic product is explained by the reaction of the less stable diaxial conformer of the cyclohexene derivative.

Il est maintenant démontré que l'existence de fortes contraintes stériques dans les dérivés du *tert*-butyl-3 cyclohexène conduit à des données structurales (2), conformationnelles (3) et réactionnelles (4) particulières.

Ainsi, l'existence d'un équilibre conformationnel pour les dérivés 3,4 disubstitués conduit lors des réactions d'addition électrophile à des stéréosélectivités qui ne peuvent être expliqué que par l'intervention de conformères de haute énergie (5).

Dans le cadre d'une étude de réactivité de molécules fortement contraintes (5, 6), nous nous sommes intéressés aux réactions d'addition du brome et du chlore au *tert*-butyl-3 méthoxycarbonyl-4 cyclohexènes *cis* et *trans*, le choix de ces substrats nous ayant été dicté par la bonne connaissance des équilibres conformationnels des dérivés cyclohexéniques de départ et par les résultats de Bellucci *et al.* sur les réactions d'addition électrophile au méthoxycarbonyl-4 cyclohexène (7) et au *tert*-butyl-3 cyclohexène (8). Enfin, les cyclohexanes obtenus présentent un intérêt structural indéniable par le cumul des fortes contraintes stériques qu'ils comportent (9, 10).

Résultats expérimentaux

Afin de pouvoir étudier par rmn du proton la stéréochimie des produits de réaction, les additions sont effectuées (cf. partie expérimentale) sur les *tert*-butyl-3 méthoxycarbonyl-4 cyclohexènes *cis* et *trans*, et à titre de comparaison sur le méthoxycarbonyl-4 cyclohexène, spécifiquement deutériés en position allylique (3). Dans ces conditions, outre les signaux des groupements *tert*-butyl et méthoxycarbonyle, les spectres rmn se composent de deux systèmes de spins (deux et trois protons) indépendants facilement analysables. Les différents paramètres ainsi obtenus sont regroupés dans le tableau 1.

Addition au tert-*butyl-3 méthoxycarbonyl-4 cyclohexène* trans

Après addition du brome le spectre de rmn du mélange réactionnel montre un mélange de deux isomères du dibromo-1,2 *tert*-butyl-3 méthoxycarbonyl-4 cyclohexane **1** et **2** dans des proportions variant avec le temps d'analyse.

Ainsi, dans le spectre réalisé dans CCl_4 immédiatement après extraction, les signaux du composé majoritaire **1** (cf. Fig. 1) se composent essentiellement d'un spectre de type AB centré à $\delta = 4{,}55$ ($J = 4{,}8$ Hz) correspondant aux protons géminés des bromes, d'un triplet d'intensité 1 centré à 2,7 ($J = 6{,}5$ Hz) et d'un doublet correspondant aux deux protons du carbone 5 centré à $\delta = 1{,}91$. Le produit minoritaire **2** présente pour les protons géminés aux bromes, un singulet à $\delta = 4{,}69$. Les trois autres protons H_4, H_{5a} et H_{5b} (cf. schéma, Tableau 1) se présentent sous forme d'un spectre AMX dont les trois massifs sont centrés respectivement à $\delta = 2{,}75$, 1,71 et 2,20.

Après 48 h à température ambiante, on observe dans le milieu que le composé **2**; l'isomère **1** produit cinétique ayant quasiment disparu (**1** <5%).

Le spectre effectué dans le benzène permet par effet d'ASIS de transformer le spectre de type A_2 des protons géminés des bromes H_1 et H_2 en un spectre de type AB centré à $\delta = 4{,}44$ ($J = 3{,}5$ Hz).

Dans ce dernier solvant, l'observation de la constante de couplage à longue distance $^4J = 1{,}5$ Hz entre le proton résonnant à $\delta = 4{,}37$ et celui résonnant à $\delta = 1{,}43$ confirme la position équatoriale de H_{5a} et permet d'attribuer H_1. La situation axiale du proton résonnant à $\delta = 2{,}25$ est confirmée par la structure triplet de son signal (deux grandes constantes de couplage).

Après addition du chlore au *tert*-butyl-3 méthoxycarbonyl-4 cyclohexène *trans* on obtient un mélange invariant de **4** et de **5** (90% et 10% respectivement). Le spectre du produit majoritaire **4** se compose essentiellement d'un spectre de type AB relatif aux protons géminés des bromes et d'un spectre de type

FIG. 1

ABX relatif aux protons H_4, H_{5a} et H_{5b}. Le proton H_4, en α du groupement fonctionnel est attribué au signal résonnant à δ = 2,59 et H_{5b} à celui présentant deux grandes constantes de couplage. Pour **5** seuls les signaux des protons géminés des bromes et du groupement méthoxycarbonyl ont pu être analysés. Pour ce composé, l'attribution de H_1 et H_2 est faite par l'observation d'un élargissement des raies vraisemblablement dû à un couplage ^4J avec le proton H_{5a}.

Addition au tert-*butyl-3 méthoxycarbonyl-4 cyclohexène* cis

Après addition du chlore ou du brome sur l'isomère *cis*, la première observation que l'on puisse effectuer sur le spectre rmn des produits de réaction est l'absence totale ou quasi totale du signal correspondant au groupement méthoxycarbonyl.

En effet lors de l'addition du brome nous obtenons un mélange essentiellement composé de **3** (>95%) et d'environ 5% d'un produit minoritaire présentant encore la fonction ester.

Dans CCl_4, le spectre de **3** est essentiellement constitué d'un doublet centré à δ = 1,91 correspondant à deux protons et d'un triplet centré à δ = 2,57 attribuable à H_1. À δ = 4,44 et δ = 4,66 apparaissent deux doublets caractéristiques d'un spectre de type AX. Les raies centrées à 4,6 présentent un élargissement correspondant à une constante de couplage à longue distance (^4J = 1,2 Hz) avec le proton H_4. Cette dernière apparaît nettement dans le spectre enregistré dans C_6D_6 et permet d'attribuer le signal du proton H_2.

L'existence de cette constante et la présence dans le spectre ir d'une vibration d'élongation $\bar{\nu}$ (C=O) à 1785 cm^{-1} permet d'attribuer à ce composé la structure d'une lactone bicyclique correspondant à l'attaque du groupement méthoxycarbonyl sur le carbone 3. Dans une telle structure de type [3.2.1.]octane, le cycle à cinq et le cycle à six chainons sont dans des conformations favorables (enveloppe et chaise respectivement) et les protons H_4 et H_2 peuvent présenter un couplage à longue distance de type W.

La faible intensité des signaux de l'ester minoritaire et le fait que ceux ci soient partiellement recouvert par ceux de **3** ne permet pas de déterminer la totalité des paramètres rmn de ce composé. Néanmoins dans le spectre enregistré dans C_6D_6 il est possible d'observer deux doublets centrés à δ = 4,2 et δ = 3,81 (J = 3,8 Hz) correspondant vraisemblablement à une structure *trans* diaxiale des bromes, et centré à δ = 2,42 (J = 3,2 Hz)

SCHÉMA 1

un triplet pouvant correspondre au signal du proton H_4 en α groupement fonctionnel.

Lors de l'addition du chlore nous n'observons qu'un seul composé **6** dont le spectre rmn est identique à celui obtenu par **3**. La présence pour ce composé d'une vibration $\bar{\nu}$(C=O) à 1785 cm^{-1} permet d'envisager pour **6** une structure de lactone bicyclique identique à celle de **3**.

Addition au carboxy-4 cyclohexène et à son ester d'éthyle

Afin de vérifier les résultats obtenus par nos molécules contraintes nous avons effectué l'addition du brome et du chlore sur l'acide carboxy-4 cyclohexène et sur son ester d'éthyle.

Nous avons ainsi obtenu en procédant selon la méthode de Bellucci *et al.* (7) la lactone **7** ou son homologue chlorée dont les paramètres rmn et ir sont comparables à ceux de **3** et **6**, alors que l'addition du brome sur l'ester conduit uniquement à l'ester **8**.

Discussion

L'obtention des lactones **3** et **6** s'explique aisément en considérant une attaque intramoléculaire du groupement méthoxycarbonyl sur l'ion bromonium ou chloronium résultant de l'entrée *anti* de l'halogène. Cette approche de l'halogène analogue à celle observée dans la réaction d'époxydation de ces dérivés (5) peut facilement s'interpréter en considérant la gène stérique engendrée par le groupement ester lors de l'entrée *syn* du chlore ou du brome.

Lors des réactions d'addition à l'ester *trans*, nous obtenons dans tous les cas un produit cinétique **1** ou **4** qui reste stable dans le cas de **4** ou qui évolue dans le cas du dérivé bromé **1** vers un produit thermodynamiquement plus stable **2**. Pour ce dernier la structure chaise à groupement méthoxycarbonyl équatorial et à bromes diaxiaux (analogue à celle de **8** et **5**) est aisément déterminée à partir des valeurs des constantes de couplage (cf. Tableau 1). Celles-ci sont en effet en tout point comparables à celles du diastéréoisomère le plus stable du *tert*-butyl-2 méthoxycarbonyl cyclohexane (11) (J_{45b} = 12 Hz et J_{45a} = 4 Hz). De plus il faut remarquer que la stéréochimie *cis* du *tert*-butyle et du brome vicinal correspond à celle du diastéréoisomère le plus stable du dibromo-1,2 *tert*-butyl-3 cyclohexane (4*b*).

Pour les produits cinétiques **1** et **4** les faibles valeurs des constantes de couplage J_{45b} et J_{12} (cf. Tableau 1) sont incompatibles avec une conformation chaise à substituants équatoriaux. Nous devons donc envisager l'existence d'un équilibre conformationnel entre cette conformation et une conformation croisée[3] analogue à celle envisagée lors de l'étude rmn des dibromo-1,2 *tert*-butyl-3 cyclohexane (10) et dont les angles dièdres sont voisins de ceux déterminés lors de l'étude cristallographique du dibromo-2 *cis*-3 *trans tert*-butyl-4 *cis* cyclohexyl *p*-nitrobenzoate (12).

Leur formation peut être envisagée à partir des quatre intermédiaires issus de l'addition *syn* ou *anti* sur les deux conformères du *tert*-butyl-3 méthoxycarbonyl-4 cyclohexène *trans* (3) (cf. Schéma 1). Dans ces conditions suivant le mécanisme généralement admis d'une addition *trans* diaxiale (13, 14), nous devons considérer que **1** (ou **4**) est issu d'une des espèces aA ou aS alors que les quelques pourcents de produits thermodynamiques obtenus proviendraient de eA ou eS (cas du chlore). Cette sélectivité est vraisemblablement due à la gène stérique des groupements *tert* butyle et carbométhoxy équitoriaux qui augmente trop l'énergie d'activation via eA ou eS.

Dans le cas des dérivés bromés le passage de **1** à **2** s'effectue suivant un mécanisme classique de transposition dyotropique des bromes (15, 16) qui minimise les interactions gauches *t*-Bu Br (4*a*).

Partie expérimentale

Toutes les synthèses ont été effectuées sur des stéréoisomères purs, préalablement séparés par chromatographie en phase gazeuse préparative. La synthèse des esters utilisés a déjà été décrite (5).

[3] D'apres les modèles Dreiding la structure la plus probable correspond à une conformation croisée possédant un pseudo axe propre d'ordre 2 entre les carbones C_2 et C_5 et ayant pour angle dièdre ϕ_{12} = +40, ϕ_{23} = +30, ϕ_{34} = −70, ϕ_{45} = +40, ϕ_{56} = +30, ϕ_{61} = −70.

Les mélanges réactionnels sont analysés par chromatographie en phase vapeur (cpv) dans les conditions suivantes: chromatographe Girdel Série 3000 équipé d'un détecteur à ionisation de flamme; gaz vecteur: azote, débit environ 10 mL/min; température du détecteur: 215°C; colonne en acier inoxydable de 1/8 po de diamètre et de 3 m de long, remplie de Chromosorb W(AW) 60/80 mesh, imprégné à 10% en poids de Réoplex 400.

Les spectres infrarouges sont effectués en solution dans CCl_4 sur un spectrographe Perkin–Elmer 577; les fréquences sont données en cm^{-1}. Les spectres rmn ont été réalisés sur un appareil Varian XL 100, en solution à 10% dans le CCl_4 avec du tétraméthylsilane comme étalon interne et avec irradiation du deutérium. Les microanalyses n'ont été effectuées que sur les composés non deutériés. Seuls les carbones et hydrogènes ont été analysés.

Les réactions de bromation ont été conduites suivant la méthode générale décrite ci-dessous.

On ajoute goutte à goutte, à 10^{-3} mol de dérivé cyclohexénique dissous dans 10 mL de tétrachlorure de carbone, $1{,}2 \times 10^{-3}$ mol de brôme provenant d'une solution 0,23 *M* de brome dans le tétrachlorure de carbone. Durant toute l'addition, puis durant 3 à 4 heures, le mélange réactionnel est maintenu à 0°C, sous agitation et à l'abri de la lumière. Puis l'excès de brôme et le solvant sont évaporés sous vide, le résidu est repris par du CCl_4, filtré sur laine de verre et évaporé de nouveau.

Bromo-4 tert-*butyl-8 one-7 oxa-6 bicyclo octane [3.2.1]*

On fait réagir 0,14 g ($0{,}7 \times 10^{-3}$ mol) de *tert*-butyl-3 carbométhoxy-4 cyclohexène *cis* avec 3,7 mL de la solution de brome ($0{,}85 \times 10^{-3}$ mol). Le rendement est de l'ordre de 97%, la lactone représentant 95% des produits formés. *Anal.* calc. pour $C_{11}H_{17}O_2Br$: C 50,59, H 6,56, Br 30,59; trouvée: C 50,31, H 6,49. On synthétise de la même manière le bromo-4 *tert*-butyl-8 one-7 oxa-6 bicyclo octane[3.2.1.] (D_3-3,3,8) à l'aide de l'ester correspondant; cpv: température 140°C, t_r: 2,70 min; ir (CCl_4) ν_{max}: 1785 (C=O), 2100 à 2200 (C—D) cm^{-1}.

Dibromo-1,2 tert-*butyl-3 méthoxycarbonyl-4 cyclohexane*

On opère sur 0,119 g ($0{,}6 \times 10^{-3}$ mol) de *tert*-butyl-3 carbométhoxy-4 cyclohexène *trans* et 3,2 mL de la solution de brôme. Rendement 96%. *Anal.* calc. pour $C_{12}H_{20}O_2Br_2$: C 40,47, H 5,66, Br 44,88; trouvée: C 40,16, H 5,52. On synthétise semblablement les dibromo-1,2 *tert*-butyl-3 méthoxy carbonyl-4 cyclohexanes (D_3-3,6,6) à partir de l'ester correspondant; cpv: température 140°C, t_r: 3,75 min; ir (CCl_4) ν_{max}: 1730 (C=O), 2100 à 2200 (C—D) cm^{-1}.

Bromo-4 one-7 oxa-6 bicyclo octane[3.2.1] (D_4*-3,3,8,8)*

On utilise la méthode décrite par Bellucci *et al.* (7) en faisant réagir 0,176 g d'acide cyclohexène carboxylique-4 (D_4-3,3,6,6). Les réactions de chloration ont été conduites de la manière suivante. Une solution de 10^{-3} mol de composé cyclohexénique dans 20 mL de tétrachlorure, maintenue à 0°C et à l'abri de la lumière, est saturée de chlore gazeux. Après une demie-heure, le mélange réactionnel est traité de la même manière que précédemment.

Chloro-4 tert-*butyl-8 one-7 oxa-6 bicyclo octane[3.2.1]*

Le rendement est de l'ordre de 98%. *Anal.* calc. pour $C_{11}H_{17}O_2Cl$: C 60,97, H 7,91, Cl 16,36; trouvée: C 60,65, H 7,80. On synthétise de la même manière le chloro-4 *tert*-butyl-8 one-7 oxa-6 bicyclo octane[3.2.1] (D_3-3,3,8); cpv: température 140°C, t_r = 1,76 min; ir (CCl_4) ν_{max}: 1735 (C=O), 2100 à 2200 (C—D) cm^{-1}.

Dichloro-1,2 tert-*butyl-3 méthoxycarbonyl-4 cyclohexane*

Anal. calc. pour $C_{12}H_{20}O_2Cl_2$: C 53,94, H 7,54, Cl 26,54; trouvée: C 53,65, H 7,42.

Dichloro-1,2 tert-*butyl-3 méthoxycarbonyl-4 cyclohexane (*D_3*-3,6,6)*

Chromatographie en phase vapeur: température 140°C, t_r: 2,35 min; ir (CCl_4) ν_{max}: 1735 (C=O), 2100 à 2200 (C—D) cm^{-1}.

VINCENZO MALATESTA, MICHAEL JENNINGS, and PETER HACKETT. Can. J. Chem. **61**, 366 (1983).

Irradiation at 300 nm of cycloalkanones in methanol gives the corresponding ketals in good yields. The results indicate that an excited state of the cycloalkanone is responsible for the facile addition of methanol to the carbonyl group.

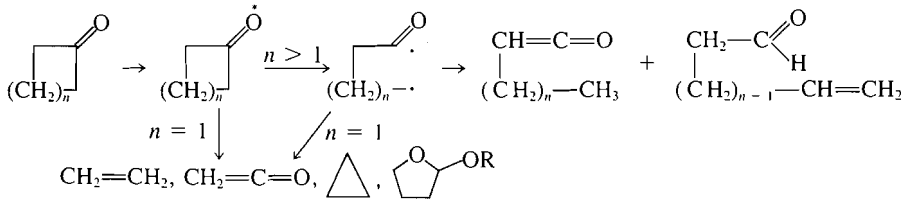
VINCENZO MALATESTA, MICHAEL JENNINGS et PETER HACKETT. Can. J. Chem. **61**, 366 (1983).

L'irradiation des cycloalcanones dans le méthanol à 300 nm donne les cétals correspondants avec de bons rendements. Les résultats indiquent qu'un état excité de la cycloalcanone est responsable de l'addition facile du méthanol sur le groupe carbonyle.

[Traduit par le journal]

The photochemistry of cycloalkanones has been dealt with in great detail in both gas phase and in solution. The Norrish type I α-cleavage has been established as the most prevalent photochemical process for non-conjugated cyclic ketones in solution (Scheme 1) (1–4). The secondary reactions of the alkylacyl diradical depend upon both structure and the conditions of the photolysis (5–8). For example, the ratio of aldehyde to ester is sensitive to conformational effects upon the transition states of enol and ketene formation (9).

When cyclobutanone is irradiated in methanol solution a moderate yield (8%) of 2-methoxytetrahydrofuran is observed in addition to those products reported from gas phase photolyses (ethylene, cyclopropane, carbon monoxide, and ketene) (10–12). We have observed a new reaction pathway. When methanolic solutions of cyclobutanone, cyclopentanone, and cyclohexanone were irradiated at 300 nm the corresponding dimethylketals were obtained in 80, 25, and 40% yield respectively. Ketals are normally prepared by acid-catalysed transketalization reactions between either orthoesters (13, 14) or 2,2-dimethoxypropane and ketones (15). The photo-induced addition of alcohols reported here could provide a useful alternative whenever acid-sensitive functional groups are present.



SCHEME 1

Typical runs involved the irradiation of 2 mL of 1.35 *M* solutions of cycloalkanones in methanol, using a Rayonet Srinivasan photochemical reactor. The reaction mixture was analysed by vpc on a 12 ft × 1/8 in., 12% OV-101 on chromasorb-WHP column, programmed between 25 and 135°C at 6°C/min. Authentic samples of the dimethylketals were prepared by acid-catalysed reaction between trimethylorthoformate and the corresponding ketones. Their nmr spectra and vpc retention times were identical to those of the reaction products.

During irradiation the presence of trace amounts of sodium acetate suppressed ketal formation. This result suggests that acetate ion removes any species responsible for acid catalysis; yet the reaction is still observed in dry, neutral methanol distilled from magnesium methoxide. Furthermore, those carboxylic acids which could form from ketenes by *in situ* reaction with moisture are not effective catalysts. This was shown in control experiments in which dark reaction between cyclobutanone and methanol in the presence of acetic acid gave only 0.5% conversion to 1,1-dimethoxycyclobutane after 1 week; this same solution rapidly yielded ketal upon irradiation. These observations all suggest that an excited state of the cycloalkanone is responsible for the facile addition of methanol to the carbonyl group, and that addition is itself acid-catalysed.

We suggest that irradiation in a protic solvent leads to carbonium ion intermediates which are susceptible to nucleophilic attack by solvent as shown in Scheme 2.

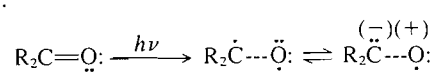
Neither the semiketal nor the enol ether are expected to absorb at the photolysing wavelength and their secondary photoreactions are hence precluded. This leads us to conclude that the final stage in ketal formation is catalysed by organic acids formed during the irradiation. The effect of acetate ion could then occur at two stages: by deprotonating the initial cation, reforming ketone; or by slowing the protonation of the hemiketal.

One might have expected that n—π* excitation of the carbonyl group would lead to decreased susceptibility to nucleophilic attack on carbon due to the influence of resonance structure **3** (16).



1 **2** **3**

However, this argument is only strictly applicable to gas phase systems (17) and may be extensively modified by hydrogen bonding in protic solvents.

Photochemically induced addition of alcohols to double bonds has been previously observed for cycloalkenones (18, 19), cyclic dienes (20–22), and olefins (23, 24). It was suggested that protonation of the triplet state of olefins (orthogonal or twisted) would relieve configurational strain, giving an intermediate with carbonium ion character (25). In the present case it is possible that protonation relieves the *ground state* ring strain and the variation in yield from cyclobutanone to cyclohexanone could reflect this.[4] However, there are many parallel reactions in these systems (cycloreversion, decarbonylation, and aldehyde and ketene formation) which complicate the mechanistic picture and make detailed interpretations premature. However, the reaction is of synthetic interest and studies of its scope and mechanism are in progress.

Syntheses of 1-trifluoromethyl-2-naphthalenols via a novel construction of the naphthalene nucleus

STEVEN FUNG, NEDUMPARAMBIL A. ABRAHAM, FRANCESCO BELLINI, AND KAZIMIR SESTANJ
Department of Chemistry, Ayerst Laboratories, P.O. Box 6115, Montreal, P.Q., Canada H3C 3J1

Received July 8, 1982

STEVEN FUNG, NEDUMPARAMBIL A. ABRAHAM, FRANCESCO BELLINI, and KAZIMIR SESTANJ. Can. J. Chem. **61**, 368 (1983).

A relatively simple and efficient synthesis of the hitherto unknown 1-trifluoromethyl-2-naphthalenols is described. Easily accessible benzenoid precursors **6** and **7** were converted to the oximino-ketones **8** and **9** by nitrosation. A novel cyclization and hydrolysis afforded surprisingly stable hydroxytetralones **12** and **13** which in turn were aromatized to the naphthalenols **1** and **15**.

STEVEN FUNG, NEDUMPARAMBIL A. ABRAHAM, FRANCESCO BELLINI et KAZIMIR SESTANJ. Can. J. Chem. **61**, 368 (1983).

On décrit une synthèse efficace relativement simple des trifluorométhyl-1 naphtalénols-2 inconnus jusqu'ici. On a transformé les précurseurs benzenoïdes **6** et **7** facilement accessibles en oximino cétones **8** et **9** par nitrosation. Une nouvelle cyclisation et une hydrolyse conduisent d'une façon surprenante aux hydroxytétralones **12** et **13** stables qui à leur tour sont aromatisés en naphtalénols **1** et **15**.

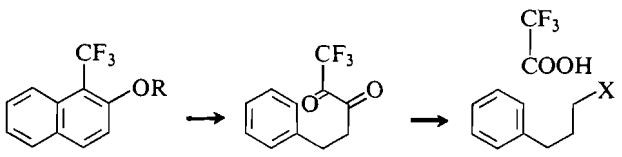
[Traduit par le journal]

We have recently been interested in general synthetic methods for the preparation of the hitherto unknown 1-trifluoromethyl-2-naphthalenol (**1**) and its congeners, which can serve as intermediates in the synthesis of compounds of potential therapeutic utility.

Demethylation of the methyl ether **2** would be the method of choice since **2** can be easily obtained from 1-iodo-2-methoxynaphthalene, iodotrifluoromethane, and copper powder under pressure (1). Unfortunately, the naphthalenol **1** belongs to a class of compounds generally known to be sensitive to demethylation reaction conditions (2, 3) and consequently has never been prepared by this route. In addition, the trifluoromethylation reaction itself becomes prohibitively expensive on a large scale due to costly trifluoromethyl iodide and special alloy pressure equipment.

Herein, we wish to report a relatively simple and efficient synthesis of the naphthalenols and their derivatives involving a *de novo* construction of the naphthalene ring and introduction of the trifluoromethyl group without application of high pressure reactions.

Our synthetic plan consisted, in principle (Retrosynthetic Scheme), of cyclization of a benzenoid precursor (**3**) containing a trifluoromethyl group and two carbonyl functions in the side chain. The percursor **3** in turn could be prepared from the inexpensive and easily available γ-halopropyl-benzene and trifluoroacetic acid.



1 R = H
2 R = CH_3

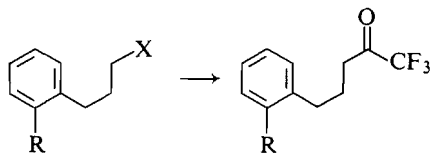
3

Retrosynthetic Scheme

Reaction of organomagnesium compounds with trifluoroacetic acid results in the formation of trifluoromethyl ketones in reasonable yields. According to Dishart and Levine (4), the reaction is best performed with a threefold excess of the organomagnesium compound.

In the execution of the synthesis we used the Grignard reagent prepared from commercially available 3-bromopropylbenzene (**4**). In order to reduce the amount of starting material required, less expensive ethylmagnesium bromide was employed for the *in situ* conversion of the trifluoroacetic acid to the bromomagnesium salt. Subsequent addition of 1.5 moles of phenylpropylmagnesium bromide to the salt gave ketone **6** in 55% yield.

Introduction of the second functional group was initially attempted by selenium dioxide oxidation of the ketone **6**. The reaction, performed in methanol, ethanol, or acetic acid, did not give the expected diketone **3**. Better results were obtained by the nitrosation with sodium nitrite in water/acetic acid giving a 42% yield of keto-oxime **8**.



4 X = Br, R = H
5 X = Cl, R = CH_3

6 R = H
7 R = CH_3

However, the conversion of **8** to the diketone **3** proved quite troublesome. Acidic hydrolysis (dilute hydrochloric or sulfuric acids) and acid catalyzed carbonyl exchange reactions (e.g. with pyruvic acid, acetone, etc.) resulted in complex mixtures from which no diketone **3** could be isolated. A surprising result was obtained by treating **8** with 85% sulfuric acid. The cyclized oxime **10** was formed as the principal reaction product (69%

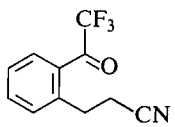
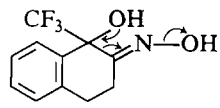
yield). Besides hydrolysis, several other reactions could be expected to occur, e.g. Beckmann rearrangement or scission between two sp^2 carbon atoms (8). Preferential cyclization in the case of **8** (and **9**) undoubtedly has to be ascribed to the presence of the strongly electronegative trifluoromethyl group. The electron deficiency of the neighbouring carbonyl carbon facilitates the intramolecular electrophilic substitution on the nearby aromatic system. Subsequent hydrolysis with concentrated hydrochloric acid gave the hydroxyketone **12** in 54% yield. Attempted conversion of **10** to **12** in the presence of sodium bisulfite effected ring cleavage to give the unwanted ketonitrile **14** (arising from a carbon–carbon bond scission and concomitant loss of water, **14***a*). Interestingly enough, the hydroxyketone **12** was not detected in the mixture of products obtained in the attempted preparation of **3** by hydrolysis of the oxime **8**.

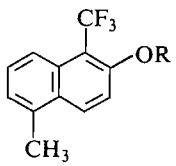
Although a vinylogous dehydration of **10** or **12**, accompanied (or preceded) by enolization of the keto- or oximino-groups (**17**), would result in the formation of a fully aromatic



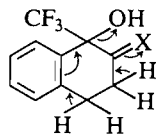
14



14*a*



15 R = H
16 R = CH_3



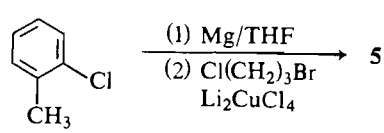
17

(**10** X = NOH
12 X = O)

system (e.g. **12** → **1**), it did not occur spontaneously or under the reaction conditions employed to prepare the compounds. Remarkable stability of the hydroaromatic system of these compounds is apparently due also to high electronegativity of the trifluoromethyl group which makes the hydroxyl tightly bound to the tertiary carbon atom. Removal of the elements of water requires more energetic treatment. The hydroxyketone **12** was thus aromatized to **1** by dehydration with either trifluoroacetic anhydride/pyridine and a catalytic amount of 4-dimethylaminopyridine at room temperature (75% yield of **1**) or with thionyl chloride/pyridine at 70°C (81% crude yield).

The applicability of the above method for the preparation of ring substituted 1-trifluoromethyl-2-naphthalenol analogs was demonstrated by the synthesis of the naphthalenol **15**. The required starting material, *o*-(3-chloropropyl)toluene (**5**) was prepared by chlorotricarbon homologation (5) of *o*-tolylmagnesium chloride with 1-bromo-3-chloropropane in excellent yield (90%).

Only a few nonessential modifications were applied in some of the steps. Instead of trifluoroacetic acid (or its halomagnesium salt), in the preparation of ketone **7**, the lithium salt



was employed (6). The yield was 85%. Nitrosation of **7** was performed with either sodium nitrite/acetic acid/isopropanol (51% yield) or with potassium nitrite/acetic acid/*tert*-butanol, giving an almost quantitative yield of the crude keto-oxime **9**. Cyclization of **9** to **11** was performed with cold concentrated sulfuric acid. Hydrolysis of **11** and dehydration of the resulting hydroxyketone **13** gave the naphthalenol **15** in an overall yield (from *o*-chlorotoluene) of 57%. The methyl ethers **2** and **16** were obtained by methylation of **1** and **15** with dimethylsulfate.

The synthesis, we believe, is one of general significance and, besides containing some new and unusual features, provides an inexpensive and efficient route to various substituted 1-trifluoromethyl-2-naphthalenols.

Experimental

Infrared spectra were recorded on a Perkin–Elmer 225 spectrophotometer, ultraviolet spectra on a Zeiss DMR-21 spectrophotometer, nmr spectra on a Varian CFT-20 spectrometer, and mass spectra on a LKB 9000S. Melting points were recorded on a Thomas Hoover capillary melting point apparatus and are uncorrected.

5-Phenyl-1,1,1-trifluoro-2-pentanone (6)

A solution of ethylmagnesium bromide (0.37 mol) in anhydrous ether (96 mL) was added dropwise under nitrogen to a stirred solution of trifluoroacetic acid (24.9 mL, 0.33 mol) in anhydrous ether (84 mL) at −5 to −10°C. The reaction mixture was allowed to warm to room temperature to produce the magnesium bromide salt of trifluoroacetic acid. A solution of 3-bromopropylbenzene (100 g, 0.50 mol, Eastman) in anhydrous ether (130 mL) was added dropwise with stirring to magnesium (13.4 g, 0.55 mol), iodine (catalytic amount), and anhydrous ether (~10 mL) at a rate to maintain a steady reflux. The mixture was refluxed until the reaction was complete (~2 h). To the resulting Grignard solution was added dropwise under nitrogen the trifluoroacetic acid salt suspension at ~5°C. The reaction mixture was stirred overnight at room temperature and cold HCl (8 *N*, 123 mL) was added dropwise at 0°C. The solid was separated by filtration and the aqueous layer extracted with ether. The organic layer was washed with brine, dried ($MgSO_4$), concentrated, and distilled (40°C/10 Torr) to give pure **6** (40 g, 55%)[1] as a colorless liquid; ir ($CHCl_3$): 1760, 1160, 1140 cm^{-1}; nmr ($CDCl_3$) δ: 7.2 (5H, m, ArH), 2.65 (4H, m, $ArCH_2$, $COCH_2$), 2.0 (2H, m, $ArCH_2CH_2$); ms *m/e*: 216 (M^+), 147, 136, 118, 104, 91 (100).

3-Oximino-5-phenyl-1,1,1-trifluoro-2-pentanone (8)

A solution of sodium nitrite (6.5 g, 94.2 mmol) in water (10 mL) was added dropwise to a stirred solution of **6** (10.0 g, 46.3 mmol) in acetic acid (10 mL) at 0°C. The reaction mixture was stirred overnight at room temperature, diluted with water, and extracted with ethyl acetate (2×). The combined organic layers were washed with brine, dried ($MgSO_4$), and concentrated under reduced pressure. Recrystallization (hexane) of the residue gave **8** as pale yellow crystals (4.75 g, 42%). An analytically pure sample of **8** was obtained as colorless prisms, mp 92–93°C by sublimation (60°C/0.05 Torr); ir ($CHCl_3$): 3540, 3350, 1730, 1160 cm^{-1}; nmr ($CDCl_3$) δ: 7.2 (5H, m, ArH), 2.85 (4H, m, CH_2); ms *m/e*: 245 (M^+), 228, 176, 148, 131, 104, 91 (100). *Anal.* calcd. for $C_{11}H_{10}F_3NO_2$: C 53.88, H 4.11, N 5.71; found: C 54.12, H 4.18, N 5.60.

1-Hydroxy-2-oximino-1-trifluoromethyl-1,2,3,4-tetrahydronaphthalene (10)

Sulfuric acid (85%, 80 mL) was added to **8** (1.6 g, 6.5 mmol), cooled in an ice–water bath. The reaction mixture was stirred and heated on a steam bath for 10 min, cooled, and extracted with ether. The ethereal extract was washed with brine, dried ($MgSO_4$), and concentrated under reduced pressure. The residue was recrystallized twice (hexane) to give **10** (1.1 g, 69%) as white crystals, mp 121–122°C; ir ($CHCl_3$): 3560, 3480, 1170 cm^{-1}; nmr ($CDCl_3$) δ: 7.75

[1]It was estimated (nmr) that the distillation forerun contained additional **6** (15.6 g).

(1H, m, ArH), 7.45 (1H, bs, OH), 7.2 (3H, m, ArH), 4.55 (1H, bs, OH), 2.9 (4H, m, CH_2); ms *m/e*: 245 (M^+), 176 (100), 158, 148, 131, 130, 103. *Anal.* calcd. for $C_{11}H_{10}F_3NO_2$: C 53.88, H 4.11, N 5.71; found: C 53.84, H 4.14, N 5.63.

1-Hydroxy-2-oxo-1-trifluoromethyl-1,2,3,4-tetrahydronaphthalene (12)

A solution of **10** (1.5 g, 6.1 mmol) in concentrated HCl (150 mL) was stirred at 65°C for 2 h. The product started to precipitate after 15 min. The reaction mixture was cooled, poured into ice, stirred, and filtered to give crude **12**. Ether extraction of the filtrate gave additional crude material. Recrystallization (hexane) of the crude product gave purified **12** (0.98 g, 70%) as pale yellow crystals, mp 87–88°C; ir ($CHCl_3$): 3460, 1730, 1175 cm^{-1}; nmr ($CDCl_3$) δ: 7.65 (1H, m, ArH), 7.25 (3H, m, ArH), 4.5 (1H, s, OH), 3.1 (4H, m, CH_2); ms *m/e*: 230 (M^+), 188, 161, 133, 119 (100), 105, 91. *Anal.* calcd. for $C_{11}H_9F_3O_2$: C 57.40, H 3.94; found: C 57.09, H 3.91.

3-(2-Trifluoroacetylphenyl)propionitrile (14)

A solution of **10** (603 mg, 2.45 mmol) and sodium bisulfite (1.02 g, 9.8 mmol) in ethanol (15 mL) and water (15 mL) was refluxed for 8 h and concentrated under reduced pressure. Water was added and the mixture extracted with chloroform. The extract was dried ($MgSO_4$) and concentrated under reduced pressure. The residue was recrystallized (hexane) to give **14** (300 mg, 54%) as flat needles, mp 48–49°C; ir ($CHCl_3$): 2240, 1715, 1185, 1150 cm^{-1}; nmr ($CDCl_3$) δ: 7.95 (1H, m, ArH), 7.5 (3H, m, ArH), 3.15 (2H, t, J = 7, $ArCH_2$), 2.7 (2H, t, J = 7, CH_2CN); ms *m/e*: 227 (M^+), 200, 187, 158 (100), 130, 103. *Anal.* calcd. for $C_{11}H_8F_3NO$: C 58.15, H 3.55, N 6.17; found: C 57.82, H 3.56, N 6.18.

1-Trifluoromethyl-2-naphthalenol (1)

Trifluoroacetic anhydride (2.0 mL, 14.2 mmol) was added dropwise under anhydrous conditions to a solution of **12** (0.4 g, 1.74 mmol) and 4-dimethylaminopyridine (5 mg) in pyridine (20 mL, 24.7 mmol). The reaction mixture was stirred overnight at room temperature, poured into ice, stirred, and extracted with ether. The ethereal extract was washed with dilute HCl, brine, sodium bicarbonate solution, and brine, dried ($MgSO_4$), and concentrated under reduced pressure. The residue was triturated with hexane and column chromatographed (silica gel, 20% ethyl acetate/toluene) to give **1** (0.28 g, 75%). An analytical sample was prepared by sublimation (25°C/0.05 Torr) to give **1** as white crystals, mp 55–56°C; ir ($CHCl_3$): 3620, 1235, 1210 cm^{-1}; uv (CH_3OH): 331 (2760), 319 (2440), 287 (3300), 276 (4470), 266 (3990), 223 nm (68 500); nmr ($CDCl_3$) δ: 7.9 (1H, m, H-8), 7.8 (1H, d, J = 9, H-4), 7.5 (3H, m, ArH), 7.05 (1H, d, J = 9, H-3); ms *m/e*: 212 (100) (M^+), 192, 170, 164. *Anal.* calcd. for $C_{11}H_7F_3O$: C 62.27, H 3.33, found: C 61.61, H 3.18.

Alternative preparation of 1

Thionyl chloride (0.20 mL, 2.74 mmol) was added dropwise to a solution of **12** (50 mg, 0.22 mmol) in pyridine (0.5 mL) at 0°C. The reaction mixture was heated at 70°C for 2 h and concentrated under reduced pressure. Ice was added and the mixture extracted with ether. The ethereal extract was washed with brine, dried ($MgSO_4$), and concentrated under reduced pressure to give **1** (37.5 mg, 81%), homogenous by tlc.

2-Methoxy-1-trifluoromethylnaphthalene (2)

A mixture of **1** (52 mg, 0.25 mmol), dimethyl sulfate (0.030 mL, 0.32 mmol), potassium carbonate (53 mg, 0.038 mmol), and acetone (1 mL) was stirred at room temperature for 20 h. The solvent was evaporated and the residue diluted with water and extracted with hexane (3×). The combined extracts were dried ($MgSO_4$) and concentrated under reduced pressure. The crude material was purified by preparative tlc (silica, 10% ethyl acetate/hexane) to give **2** as slightly yellow crystals (45 mg, 81%), mp 52–53°C; ir ($CHCl_3$); 1620, 1595, 1505, 1345, 1295, 1205, 1105, 1065 cm; uv (CH_3OH): 333 (2690), 319 (2430), 291 (3490), 279 (4455), 270 (3780), 224 nm (54 410). Compound **2** was identical (mp, tlc, ir, uv) with authentic material prepared according to ref. 1.

o-(γ-Chloropropyl)toluene (5)

A mixture of freshly distilled *o*-chlorotoluene (94.9 g, 0.75 mol), magnesium (18.23 g, 0.75 mol), and iodide (catalytic amount) was stirred in an oil bath kept at 145°C. Dry tetrahydrofuran (3 mL) was added. The reaction began within 1/2 h. More tetrahydrofuran (333 mL) was added dropwise over 2 h. The reaction temperature was not allowed to rise above 145°C by controlling the rate of addition of tetrahydrofuran. The oil bath temperature was decreased gradually to 120°C during the tetrahydrofuran addition and kept at 120°C for another 2 h. The *o*-tolylmagnesium chloride solution was decanted under anhydrous conditions into a cooled mixture (−78°C) of 1-bromochloropropane (94.4 g, 0.6 mol), Li_2CuCl_4 (0.1 *M* in tetrahydrofuran, 18 mL) (7), and tetrahydrofuran (210 mL). The mixture was stirred overnight at room temperature, cooled in ice, and a solution of NH_4Cl (30 g) in water (90 mL) was added. The mixture was extracted with ether. The organic layer was washed with brine, dried (Na_2SO_4), and concentrated under reduced pressure. The residue was distilled (58–60°C/0.05 Torr) to give **5** (91.1 g, 90%) as a colorless oil; ir ($CHCl_3$): 1600, 1490, 1455, 1440, 1375 cm^{-1}; nmr ($CDCl_3$) δ: 7.1 (4H, m, ArH), 3.55 (2H, t, J = 6, $ClCH_2$), 2.8 (2H, t, J = 7.5, $ArCH_2$), 2.35 (3H, s, CH_3), 2.05 (2H, m, $ArCH_2CH_2$); ms *m/e*: 168 (100) (M^+), 132, 117, 105.

5-(o-Tolyl)-1,1,1-trifluoro-2-pentanone (7)

The Grignard reagent was prepared from **5** (88.1 g, 0.522 mol), magnesium (12.6 g, 0.522 mol), and a catalytic amount of iodine in anhydrous ether (366 mL). It was reacted in a similar manner as described for the preparation of **6** with a suspension of lithium trifluoroacetate (50 g, 0.417 mol) (6) in anhydrous ether (366 mL) at −78°C. After the usual work-up, the crude liquid was distilled (68–70°C/1.55 Torr) to give **7**; ir ($CHCl_3$): 1760 cm^{-1}; nmr ($CDCl_3$) δ: 7.05 (4H, s, ArH), 2.65 (4H, m, $ArCH_2$, $COCH_2$), 2.3 (3H, s, CH_3), 2.0 (2H, m, $ArCH_2$—CH_2); ms *m/e*: 230 (M^+), 161, 150, 132, 118 (100), 105.

3-Oximino-5-(o-tolyl)-1,1,1-trifluoro-2-pentanone (9)

A solution of potassium nitrite (22.2 g, 261 mmol) in water (7.4 mL) was added in one portion to a stirred solution of **7** (20.0 g, 86.9 mmol) in acetic acid (25 mL) and *tert*-butanol (50 mL) at room temperature. After stirring for 2.5 h, additional potassium nitrite solution (7.5 g/2.5 mL) was added to the reaction mixture and stirred for 1.5 h. A work-up similar to that of **8** gave crude **9** as a yellow crystalline material (22.1 g, 98%). It was used as starting material for **11**. An analytically pure sample of **9** was prepared by recrystallization (hexane) to give white crystals, mp 80–81°C; ir ($CHCl_3$): 3540, 3340, 1730, 1165 cm^{-1}; nmr ($CDCl_3$) δ: 7.1 (4H, s, ArH), 2.8 (4H, s, CH_2), 2.35 (3H, s, CH_3); ms *m/e*: 259 (M^+), 242, 190, 145, 118, 105 (100). *Anal.* calcd. for $C_{12}H_{12}F_3NO_2$: C 55.60, H 4.67, N 5.40; found: C 55.41, H 4.60, N 5.42.

1-Hydroxy-5-methyl-2-oximino-1-trifluoromethyl-1,2,3,4-tetrahydronaphthalene (11)

Concentrated H_2SO_4 (12 mL) was added at 0°C to a stirred suspension of crude **9** (11.9 g, 45.9 mmol) in toluene (16 mL). The reaction mixture was allowed to warm to room temperature with stirring for 30 min. The reaction was worked up in a similar manner as described in the preparation of **10** to give crude **11** as an amber coloured solid (10.4 g, 87%). Crude **11** was used as starting material for **13**. Analytically pure **11** was prepared by recrystallization (ether/hexane) to give white crystals, mp 160.5–161.5°C; ir ($CHCl_3$): 3570, 3480, 1165, 1115 cm^{-1}; nmr ($CDCl_3$) δ: 7.6 (1H, m, ArH), 7.2 (2H, m, ArH), 4.6 (1H, bs, OH), 2.9 (4H, m, CH_2), 2.3 (3H, s, CH_3); ms *m/e*: 259 (M^+), 190 (100), 173, 172, 162, 145, 144, 117. *Anal.* calcd. for $C_{12}H_{12}F_3NO_2$: C 55.60, H 4.67, N 5.40; found: C 55.60, H 4.65, N 5.36.

1-Hydroxy-5-methyl-2-oxo-1-trifluoromethyl-1,2,3,4-tetrahydronaphthalene (13)

Concentrated HCl (220 mL) and crude **11** (10.2 g, 39.4 mmol) were employed in a similar manner as described in the preparation of **12** to

give crude **13** as a yellow solid (8.7 g, 91%). An analytically pure sample was prepared by recrystallization (hexane) to give white crystals, mp 122–123°C; ir ($CHCl_3$): 3460, 1730, 1170, 1115 cm^{-1}; nmr ($CDCl_3$) δ: 7.55 (1H, m, ArH), 7.2 (2H, m, ArH), 4.6 (1H, s, OH), 3.1 (4H, m, CH_2), 2.3 (3H, s, CH_3); ms *m/e*: 244 (M^+), 175 (100), 147, 105. *Anal.* calcd. for $C_{12}H_{11}F_3O_2$: C 59.02, H 4.54; found: C 59.22, H 4.44.

*5-Methyl-1-trifluoromethyl-2-naphthalenol (**15**)*

Thionyl chloride (0.33 mL, 4.52 mmol), **13** (1.04 g, 4.26 mmol), 4-dimethylaminopyridine (3.5 mg), and pyridine (0.73 mL) were reacted at room temperature for 30 min in a manner similar to that described in the alternative preparation of **1**. Crude **15** was obtained as yellow crystals (961 mg, 100%) homogenous by tlc. An analytically pure sample was prepared by sublimation (30–35°C/0.05 Torr) to give **15** as white crystals, mp 83–84°C; ir ($CHCl_3$): 3620, 1125 cm^{-1}; uv (CH_3OH): 335 (2770), 322 (2420), 293 (4050), 281 (4680), 222 nm (46 400); nmr ($CDCl_3$) δ: 8.05 (1H, d, J = 9, H-4), 7.85 (1H, m, H-8), 7.35 (1H, q, J = 8, H-7), 7.25 (1H, m, H-6), 7.1 (1H, d, J = 9, H-3), 6.55 (1H, m, OH), 2.65 (3H, s, CH_3); ms *m/e*: 226 (100 (M^+), 206, 178. *Anal.* calcd. for $C_{12}H_9F_3O$: C 63.72, H 4.01; found: C 63.47, H 3.96.

*2-Methoxy-5-methyl-1-trifluoromethylnaphthalene (**16**)*

In similar fashion to that described for **2**, dimethylsulfate (1.13 g, 8.75 mmol), **15** (1.8 g, 7.96 mmol), potassium carbonate (2.2 g, 15.9 mmol), and dimethylformamide (20 mL) were reacted for 2 h at room temperature. The usual work-up gave crude **16** (1.7 g, 90%). An analytical sample was prepared by trituration of the crude solid with pentane and sublimation (45°C/0.05 Torr) to give pure **16** as white crystals, mp 69–70°C; ir ($CHCl_3$): 1390, 1340, 1280, 1255, 1245, 1110, 1095, 1085, 1045 cm^{-1}; uv (CH_3OH): 336 (2910), 323 (2645), 297 (4440), 286 (4880), 236 (30 050), 224 nm (46 730); nmr ($CDCl_3$) δ: 8.1 (1H, d, J = 9, H-4), 8.0 (1H, m, H-8), 7.35 (1H, q, J = 8, H-7), 7.2 (2H, m, H-3, H-6), 3.95 (3H, s, OCH_3), 2.65 (3H, s, $ArCH_3$); ms *m/e*: 240 (100) (M^+), 225, 221, 209, 197, 171. *Anal.* calcd. for $C_{13}H_{11}F_3O$: C 65.00, H 4.62; found: C 64.90, H 4.38.

Acknowledgements

We wish to thank Mrs. S. Goulet, Mr. G. Marcoux, Ms. H. Venda, Mr. Y. S. Lin, Mr. M. Boni, Mr. P. Bouca, and Mr. M. Barron, who performed a large part of the experimental work, and Dr. G. Schilling and his staff for the analytical and spectral data. The authors would also like to thank Dr. L. Humber and Prof. Z. Valenta for their interest and support.

Received July 29, 1982

ALBERT STOESSL, C. H. UNWIN, and J. B. STOTHERS. Can. J. Chem. **61**, 372 (1983).

^{13}C nuclear magnetic resonance spectroscopy has revealed that cultures of the fungus *Alternaria solani* incorporate [1,2-$^{13}C_2$]acetate into the anthraquinone macrosporin (**3**) and the tetrahydroanthraquinones altersolanol A (**4**) and dactylariol (**6**) from a single octaketide chain. The carbon skeleton of **4**-$^{13}C_x$ was incorporated *in toto* into **3**, with **6** as a probable intermediate; there is also evidence that **4** may be a precursor of altersolanol B (**5**). The ^{2}Hmr spectra show that deuterium from [1-$^{13}C_1$,2-$^{2}H_3$]acetate is retained to a considerable extent in the C-methyl groups and the 1, 6, and 8 positions of **3** and **4** but is completely lost from the 3-position in **4**. Zinniol (**7**), also a metabolite of the fungus, is a normal tetraketide.

ALBERT STOESSL, C. H. UNWIN et J. B. STOTHERS. Can. J. Chem. **61**, 372 (1983).

La spectroscopie de la rmn du ^{13}C a révélé que les cultures du champignon *Alternaria solani* incorporent l'acétate [$^{13}C_2$-1,2] dans l'anthraquinone macrosporine (**3**) et dans les tétrahydroanthraquinones altersolanol A (**4**) et dactylariol (**6**) à partir d'une chaîne simple d'octacétide. Le squelette carboné $^{13}C_x$-**4** est incorporé *in toto* dans le composé **3** utilisant probablement le composé **6** comme intermédiaire; on a aussi des données à l'effet que le composé **4** peut être un précurseur de l'altersolanol B (**5**). Les spectres de rmn du ^{2}H montrent que le deutérium de l'acétate [$^{13}C_1$-1-$^{2}H_3$-2] est retenu dans une grande proportion dans les groupes C-méthyle et au niveau des positions 1, 6 et 8 des composés **3** et **4** mais qu'il n'y a pas de deutérium en position 3 du composé **4**. Le zinniol (**7**), un métabolite du champignon est un tétracétide normal.

The fungus *Alternaria solani* (Ell. & Mart.) Sorauer, the causative organism of early blight disease of tomato and potato (1), produces the following yellow and orange pigments: 2-methylxanthopurpurin-7-methyl ether (**1**), 7-methoxy-2-methyl-3,4,5-trihydroxyanthraquinone (**2**), macrosporin (**3**), altersolanol A (**4**), and altersolanol B (**5**) (2). The last two compounds are rare but not unique examples of naturally occurring tetrahydroanthraquinones (3, 4). Macrosporin, an anthraquinone, is known from several *Alternaria* spp. (5) and from two other, unrelated fungi, *Phomopsis juniperovora* (6) and *Dactylaria lutea* (5). It is significant that the latter fungi are also producers of **4**, and of **4** and **5**, respectively. The location of the hydroxyl group at the 3-position of macrosporin is anomalous for a polyketide-derived anthraquinone, as pointed out by Turner (7). Two further *A. solani* metabolites were discovered during the course of the present study, as reported in preliminary form (8). One is dactylariol (**6**),[3] which had been found previously as a congener of altersolanols A and B in *D. lutea* (5), and the other is zinniol (**7**), described earlier as phytotoxin from *A. zinniae* (9) and also, very recently, as a metabolite of *A. dauci* (10) and *A. carthami* (11).

The principal objective of the present study was to gain insight into the biosynthesis of these compounds by means of now well-established nmr methodology utilizing [1,2-$^{13}C_2$]- and [1-^{13}C,2-$^{2}H_3$]acetate as precursors. As a prerequisite, the

1. The specific signal assignments were made through the usual methods (12)[4] primarily including detailed examination of the coupled spectra and, in a few cases, selective decoupling experiments. The relative intensities exhibited by the non-protonated carbons in both coupled and decoupled spectra are particularly informative for specific assignments since the number of neighboring protons governs the magnitude of the nuclear Overhauser enhancement experienced by these centres. In addition, data for several closely-related anthraquinones are readily available (13–16) from which it had been established that substitution in one of the aryl rings has relatively little effect on the ^{13}C shieldings for the other ring. For example, the shieldings for C-5 through C-13 in **1***a* were found to differ, on average, by 0.2 ppm from those for the corresponding centres in 1,3-diacetoxyanthraquinone (14). The same comparison revealed a −1.9 ppm upfield shift for C-14, readily attributable to the 2-methyl group to which it is *para*. The remaining aryl assignments followed from the results for 2-methylanthraquinone (15) with C-1 and -4 readily distinguished in a coupled spectrum because of the three-bond couplings for the former with H-3 and the methyl protons (16). Similarly, the signals for C-5 through C-13 in the spectra of **2***a* and **3***a* were easily identified by comparison with the results of 1-acetoxy-3-methoxyanthraquinone (14) and the assignments completed by consideration of the effects produced by the remaining substituents. Confirmation of the assignments for macrosporin diacetate (**3***a*) was provided by the spectra of the enriched samples obtained from incorporation experiments with doubly labelled [1,2-$^{13}C_2$]acetate.

Compounds **4**–**6** are 1,2,3,4-tetrahydroanthraquinone derivatives for which the C-5 through C-12 assignments could be made by comparison with the results for the corresponding centres in 1-acetoxy-3-methoxy or 1-hydroxy-3-methoxyanthraquinone (14). Although the data for the latter are reported for $CDCl_3$ solutions, the shieldings observed for **4** and **6** in DMSO-d_6 are not greatly different as was expected from the earlier comparison of the shieldings for the 1-hydroxy and 1-methoxyanthraquinone derivatives in both $CDCl_3$ and DMSO-d_6 (14). From the remarkable similarity of the shieldings of C-5 through C-12 for **4***a*–*c* and **5***a* it is apparent that differing substitution on the tetrahydro ring has little effect at these centres. With the exception of C-11 and -12, the observed shieldings are within 1 ppm of those for the corresponding carbons in 1-acetoxy-3-methoxyanthraquinone; C-11 and -12 apparently experience upfield shifts of −1 and −2 ppm in the tetrahydro derivatives. Assignments for the sp^3-carbons in the **4***a*–*c*, **5***a*, and **6** were essentially straightforward since C-3 in each could be identified by selective decoupling as could C-1 in **4***a*–*c* and **6**. Again, these assignments were confirmed by spectra of enriched **4**, **4***a*, and **6** obtained from the incorporation experiments.

For the biosynthetic studies, labelled precursors were administered to actively growing cultures of the fungus from which the labelled metabolites were isolated after an appropriate incubation period, as detailed in the Experimental. From the first set of experiments, the ^{13}Cmr spectra of the purified products (and/or their acetates) showed that [1,2-$^{13}C_2$]acetate was incorporated into macrosporin (**3**), altersolanol A (**4**), and dactylariol (**6**). The ^{13}C—^{13}C couplings in the spectra (Table 2) were similar and proved that the molecules arise from octa-

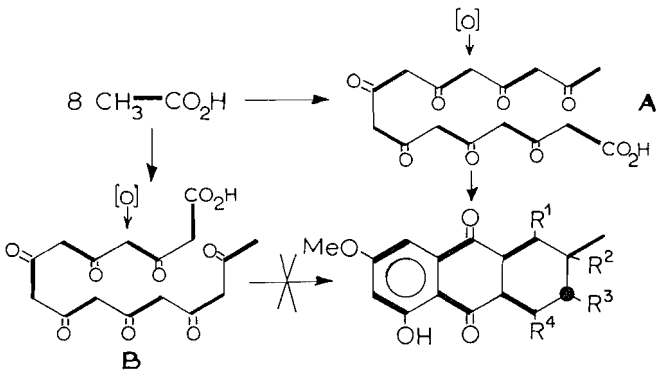
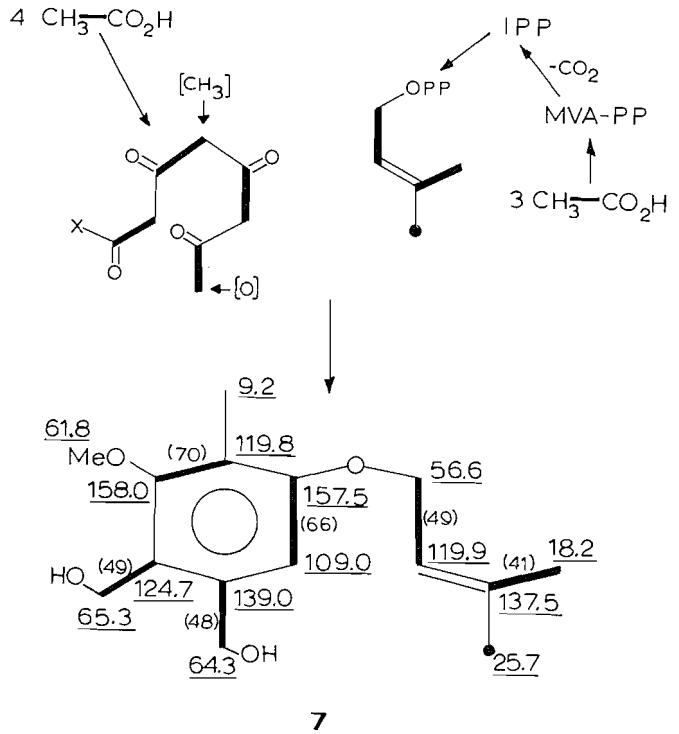


SCHEME 1. Biosynthesis of anthraquinoid metabolites.



SCHEME 2. The ^{13}Cmr parameters and biosynthesis of zinniol (**7**). The black circles denote C-2 of acetate units which have lost C-1 by decarboxylation.

ketide chains without apparent skeletal rearrangement and without cleavage of acetate units, except for the loss of carboxyl carbon from the terminal unit, giving rise to an enhanced singlet for C-3. The octaketide apparently cyclizes from the folding pattern A as in Scheme 1, and not from the alternative pattern B. Derivation from a single polyketide chain is further supported by the near equality of incorporation levels at all positions except for the expected starter effects discernible in the C-2—Me units. The general incorporation levels were about 0.7% per site and were realized without attempts to optimize incorporation conditions. Altersolanol B (**5**) was also enriched, as indicated by mass spectrometry, but too little was obtained to allow measurement of its ^{13}Cmr spectrum. Finally, the identity of **6** with dactylariol from *D. lutea* (**5**) is assured by all available data (see Experimental).

The identity of zinniol (**7**) from *A. solani* with an authentic specimen from *A. zinniae* (9) was established by a direct comparison of their diacetates (**7***a*). The ^{13}Cmr spectrum of the specimen from *A. solani* showed that the aromatic moiety was assembled from a tetraketide as indicated in Scheme 2. The direction of assembly is revealed by the orsellinic acid-type substitution pattern. The incorporation level was about 1.5% per site. The dimethylallyl group was labelled as expected for its origin from acetate via mevalonic acid. The individual shieldings (underlined) and J_{CC} values in Hz (in parentheses) are given in **7**. The aryl methyl and methoxyl carbons were unlabelled, consistent with their expected origin from methionine.

When ^{13}C-labelled altersolanol A (**4**) from these experiments was administered to cultures of *A. solani*, it was slowly metabolized. The cultures used for this purpose were of a strain, ATCC 11078, which no longer produces detectable amounts of tetrahydroanthraquinones in culture media, although very small quantities of **1** and **3** can still be found in the mycelia. However, when extracted several days after addition of **4**, the culture filtrates were found to contain very small amounts of **5** and **6**, while the mycelia yielded nearly 3 times as much **3** as did untreated controls. The ^{13}Cmr spectrum of the diacetate **3***a*, prepared from the **3**, thus obtained, showed clearly that it was ^{13}C-enriched in precisely the same pattern as the administered **4**. The degree of enrichment at each site was about 70% of that at the corresponding site in starting material **4**. These results demonstrate that **4** was incorporated into **3** without prior degradation but with some dilution by endogenously formed material.

The small amount of **6** from the amended cultures decomposed during attempted isolation; it therefore remains formally unproved that it was significantly labelled. However, there seems little doubt that it is an intermediate on the pathway from **4** to **3**. The rapidity with which the postulated dehydration step takes place in culture makes it likely that it is enzyme-mediated; nevertheless, it is relevant that on tlc evidence, pure **6** is slowly transformed into **3** on standing in methanolic solution even at room temperature.

Altersolanol B (**5**) was isolated from the amended culture as the aromatized product **1**, which was more amenable to purification. The compound was obtained in insufficient amount for a ^{13}C spectrum, but its mass spectrum indicated it to be labelled. Unfortunately, however, small amounts of **5** tend to cochromatograph and cocrystallize with **4**, in which they are detectable only with difficulty at the 1% level. Because of this circumstance, and contrary to our earlier report (8), we are not certain that the small amount of **1** isolated from the experiment (<1 mg) was derived from **4** and not from **5**, traces of which (~0.9%) were, in fact, found to be present on a careful re-examination of a sample of the **4** which had been used in the experiment. In a duplicate experiment with very carefully purified altersolanol A-$^{13}C_x$, macrosporin-$^{13}C_x$ was isolated and found to be labelled in the same manner and to the same extent as before. Traces of **5** (and **6**) were also observed but in insuf-

For personal use only.

ficient amounts to be isolable even after aromatization. Several preliminary runs with unlabelled **4** were attempted to intercept **5** and **6** at increased concentrations, by varying culture media and incubation periods, but these were unsuccessful. It is pertinent to note that very small amounts of **5** and **6** were observed in several of these experiments although the compounds could not be detected at equivalent levels in either starting material **4** or in untreated cultures. Thus, the evidence relating to the conversion of **4** to **5** remains inconclusive.

In another set of experiments [1-^{13}C,2-^{2}H$_3$]acetate was administered as the precursor and the resulting metabolites examined by both ^{13}C and ^{2}Hmr. For these doubly labelled acetate units, the ^{13}C nuclei experience upfield isotope shifts produced by their geminal deuterium neighbors. Thus, in the ^{13}C spectra of the metabolites, the presence of intact acetate units is revealed by the appearance of these shifted components accompanying the natural abundance signals. Since geminal ^{2}H—^{13}C spin coupling is very small (<1 Hz), these shifted signals are also singlets in proton-decoupled ^{13}C spectra. For acetate units in which the deuterium is lost, the ^{13}C label serves to enhance the intensity of the natural abundance signal with which it coincides. The ^{2}Hmr spectra provide a direct means for locating individual deuterium-labelled sites. The use of doubly labelled [1-^{13}C,2-^{2}H$_3$]acetate has been described for other biosynthetic studies (17).

Macrosporin (**3**-^{13}C$_x$,^{2}H$_y$) obtained from these experiments was diacetylated and the ^{13}C spectrum recorded. The signal for C-4 was significantly enhanced relative to those for the remaining protonated carbons, indicating an enrichment of ca. 7% for this centre. Isotopically shifted (0.03–0.07 ppm) components were apparent in the absorptions for C-2, -5, -7, and -13, establishing that these centres arise from intact acetate units bearing deuterium on the adjacent carbons, i.e. 2-CH$_3$, C-6, -8, and -1, respectively. Of the quinone carbonyl signals, that for C-10 was much more intense than that for C-9, while the C-12 signal was similarly enhanced relative to those for C-3 and -14. These results are fully in accord with acetate incorporation as in Scheme 1. The ^{2}Hmr spectrum of ***3a***-^{13}C$_x$,^{2}H$_y$ contained the three, expected (2*b*) aryl signals as well as methyl absorption, with the relative intensity of the aryl absorption almost equal to that for the methyl signal, indicating some deuterium loss from the methyl group (see Table 3).

The ^{13}Cmr spectra of **4**-^{13}C$_x$,^{2}H$_y$ and its pentacetate contained all of the features just described for **3**-^{13}C$_x$,^{2}H$_y$, with an additional benefit. The C-2 absorption pattern consisted of the normal signal at 81.1 ppm and three clearly resolved, isotope-shifted components at 0.05, 0.10, and 0.15 ppm higher field. This is definitive evidence for the presence of species with one, two, and three deuterium nuclei on the methyl carbon and establishes that significant deuterium loss occurred from this centre during the biogenesis of the metabolite, a feature noted for **3**-^{13}C$_x$,^{2}H$_y$ above from its ^{2}H spectrum. Unfortunately the isotope shifts are smaller in this compound and the shifted component in its C-2 absorption was too ill-defined to permit a definitive conclusion. The ^{2}Hmr spectrum of ***4a***-^{13}C$_x$,^{2}H$_y$ afforded one additional piece of evidence regarding its biosynthesis, namely, the complete absence, within the limits of detection, of deuterium at C-3. Again, the relative intensity of the absorption for deuterium at C-1, -6, and -8, an ill-resolved band because of the small shielding differences for these nuclei (2*a*), was found to be comparable to that for the methyl signal (Table 3), providing additional evidence of substantial deuterium loss from the methyl carbon. Thus during the generation of **4** there is substantial exchange at this methyl and complete loss of deuterium from C-3; the latter fact seems rather surprising, and probably has biosynthetic significance regarding the mode of oxygenation at this carbon. This aspect will require further study and experimentation.

TABLE 3. Incorporation of deuterium from [2-^{2}H$_3$-1-^{13}C]acetate into macrosporin (**3**) and altersolanol A (**4**)

		Position and enrichment[b] (atoms/mol)				
Compound[a]	Expt.	Me	1	8	6	3
3a	1[c]	Insufficient material obtained				
	2[d]	4.82	1.47	1.41	1.26	—
4a	1[c]	3.09		2.89		0
	2[d]	3.15		2.55		0

[a] Measurements were obtained after acetylation of **3** and **4** to their more soluble acetates ***3a*** and ***4a***.

[b] Calibrated by comparison to the natural abundance ^{2}H signal of the weighed solvent.

[c] Labelled acetate administered immediately after inoculation, with extraction 4 days later.

[d] Labelled acetate added 4 days after inoculation and extracted 2 days later.

Experimental

Solvents were reagent grade and redistilled before use. Ethanol was 96% EtOH. Agar was Difco Bacto-Agar; casein hydrolyzate was from ICN Pharmaceuticals, Cleveland, Ohio; V8 Juice (Campbell Soup Co.) was the canned product obtained from local groceries. Silica gel used for column chromatography was of tlc grade (Camag DF 5) but not activated. The same adsorbent, activated at 110°C, was used for preparative tlc. Analytical tlc was on precoated plates (Machery–Nagel Polygram SIL N-HR/UV$_{254}$ (0.2 mm)). Sodium [1,2-^{13}C$_2$]acetate (90% ^{13}C) and [1-^{13}C$_1$,2-^{3}H$_2$]acetate (90% ^{13}C, 98% ^{2}H) and deuterated solvents were from Merck, Sharp, and Dohme Canada Ltd., Pointe Claire – Dorval, Quebec.

Evaporations were done below 30°C at reduced pressure or under a slow stream of N_2. Ultraviolet spectra were measured on ethanolic solutions using Beckman DK 1 or Pye–Unicam SP-8000 spectrophotometers. Mass spectra were obtained with a Varian MAT 311A instrument. The ^{1}Hmr spectra were obtained with a Varian XL-100-12 system, operating in either the continuous wave or Fourier transform mode as appropriate, with TMS as internal reference and $CDCl_3$, CD_2Cl_2, or dimethylsulphoxide-d_6 as solvents. The majority of the ^{13}Cmr spectra were obtained with a Varian XL-100-15 system operating in the Fourier transform mode with either square wave modulated proton decoupling (for completely decoupled spectra) or gated decoupling for proton-coupled spectra. In the latter stages of the work, a Varian XL-200 system was employed, operating at 50.3 MHz for ^{13}C and 30.7 MHz for ^{2}H in the Fourier transform mode. In general the ^{13}C shielding data have an estimated precision of 0.05 ppm but, for the material obtained fom the [1-^{13}C,-^{2}H$_3$]acetate incorporation experiments, the precision of the isotope shifts is of the order of ± 0.01 ppm.

Fungal cultures

An altersolanol A-producing culture of *A. solani* was the gift of Dr. U. Matern, University of Freiburg, Germany. It was routinely maintained on V8-juice agar (V8 Juice, 350 mL; $CaCO_3$, 3.0 g; agar, 20 g; H_2O to 1 L) at 15°C in the dark. It has since been deposited at the American Type Culture Collection, Rockville, Maryland, as ATCC No. 44204 ("strain 44204" hereafter). This strain did not produce detectable amounts of alternaric acid (18) on the several occasions it was tested.

An alternaric acid-producing strain of the fungus, derived from one of Brian's original isolates (18), was freshly obtained from the Amer-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.5 on 09/06/12
For personal use only.

ican Type Culture Collection as ATCC No. 11078 ("strain 11078" below) and maintained similarly. In numerous experiments, liquid media supporting cultures of this strain appeared to remain free of **4** or other tetrahydroanthraquinonoid pigments. However, it should be noted that, in the earlier work in these laboratories (2*a*), substantial amounts of **4** and related pigments were obtained from cultures of the same parent strain.

Slants of these strains were used to inoculate Brian's Medium T (glucose, casein hydrolyzate, and mineral salts) (19) contained in Delong flasks (25 mL/flask; 4–6 flasks/slant) which were then incubated in the dark at 24°C. After 10–12 days, and using aseptic conditions throughout, the mycelia were collected, rinsed well with water, homogenized in water, diluted to a suitable volume, and inoculated into fresh Medium T in Roux bottles (100 mL/bottle; 3–5 bottles/flask) which were incubated as previously. Precursors were added to the cultures after the time intervals specified below, by injection of their aqueous solutions below the mycelia. Cultures were harvested by filtration through cheese cloth, the mycelia being rinsed well with H_2O. Further processing varied with the experiment. For reasons which are not understood, pigment production by *A. solani* strain 44204 has been characteristically variable both as regards quantity and timing. The timing of precursor addition was therefore decided on an *ad hoc* basis in each case.

Incorporation of sodium[1,2-$^{13}C_2$]acetate into metabolites of strain 44204

(a) Cultures of the fungus in 8 Roux bottles were supplemented 2 days after inoculation with 0.05 *M* sodium [1,2-$^{13}C_2$]acetate (10 mL/bottle) and with another 5 mL after another 5 days. The combined culture media were extracted with EtOAc (5 × 1 L) 9 days after inoculation. After evaporation, the extract (0.43 g) was distributed between $CHCl_3$/MeOH (9:1; 6 × 10 mL) and H_2O (6 × 10 mL), to furnish 6 lower phases (L1–L6) and 6 aqueous, upper phases. The latter were extracted in turn with EtOAc till almost colourless, the combined extracts evaporated, and the residue (129 mg) crystallized (EtOH) to give **4**-$^{13}C_x$ (52 mg after washing with hot EtOAc). Fractions L1 and L2 (239 mg) crystallized from EtOH to give **3**-$^{13}C_x$ (12.5 mg after washing with hot EtOAc) which was acetylated (2*a*) to the diacetate **3***a*-$^{13}C_x$. The mother liquors from the crystallizations of L1, L2, and **4** were chromatographed over a 300 g column in MeOH/$CHCl_3$/HOAc (10:90:0.1) ("solvent A") in 25-mL fractions. Fractions 24–26 were essentially pure **7**-$^{13}C_x$ (91 mg); fractions 27–30 on column rechromatography (iPrOH/MeOH/HOAc 5:95:0.1) and preparative tlc (solvent A) gave more **7** (6 mg) and **5**-$^{13}C_x$ (0.4 mg from EtOH). (The ms clearly indicated that the sample was enriched but because of the presence of impurities, the spectrum could not be quantitatively evaluated.) Fractions 34–38 and L3–L5 were rechromatographed (25 g SiO_2, solvent A), the main coloured band furnishing **6**-$^{13}C_x$ (5 mg) on recrystallization from EtOH. The compound, deep orange-red crystals, showing complex behavior on the Kofler block (rearrangement from plates to needles, 155–200°C; partial sublimation without melting, 235–290°C; decomposition, 290°C), had λ_{max}: 420, 284(sh), 269, 238, and 220 nm (ϵ 5500, 9810, 15 350, 9320, and 45 000) and *Exact Mass* calcd. for $C_{16}H_{16}O_7$: 320.0892; found (high resolution ms): 320.0892.

A direct comparison of ms and ^{1}Hmr spectra, kindly carried out by Dr. R. W. Rickards, Canberra, left no doubt that the *A. solani* metabolite and dactylariol (5) are identical. The identity of product **7** with zinniol was confirmed by treatment with Ac_2O/py (RT, 24 h) which on chromatography ($CHCl_3$) and recrystallization from light petrol gave the diacetate **7***a*, identical with an authentic specimen from *A. zinniae* (9) by tlc, ^{1}Hmr, ^{13}Cmr, mp, and mixture mp.

(b) Another 8 cultures initiated with the same inoculum were supplemented with the labelled acetate solution on day 7 only. Extraction of the cultures on day 9 and work-up as above furnished **4**-$^{13}C_x$ (28 mg).

(c) In a similar experiment, two 100-mL cultures of strain 44204 were supplemented with 0.054 *M* sodium [1,2-$^{13}C_2$]acetate (10 mL/bottle) 7 days after inoculation. The culture filtrates, collected after another 3 days and exceptionally heavily pigmented, yielded EtOAc extracts from which **4**-$^{13}C_x$ crystallized on concentration. Chromatography of the mother liquors gave **7**-$^{13}C_x$ (28 mg) and **6**-$^{13}C_x$ (2 mg; dissipated into several products upon acetylation).

The ^{13}Cmr spectra were obtained from the various samples of **4**-$^{13}C_x$ after acetylation to **4***a*. Measurements of the relative intensities of the satellites and central peaks in the absorption patterns for carbons from intact acetate units indicated general enrichment levels of 0.7–0.8% with 1.1–1.2% enrichment in the C-2 methyl group.

Incorporation of altersolanol A $^{13}C_x$ into macrosporin and altersolanol B

(d) Altersolanol A $^{13}C_x$ from (c) above was further purified by precipitation from DMSO-d_6 with H_2O and recrystallization from H_2O/EtOH. As shown by direct tlc comparison, the purified sample contained less than 1% of its weight of **5** and no detectable trace of **3**. The substance (22 mg in 8 mL EtOH) was administered in equal portions to four 11-day old cultures of strain 11078. Four similar cultures were treated with EtOH as controls. After a further 9 days' incubation, the cultures were harvested and the filtrates extracted as usual. The extracts were washed with 5% $NaHCO_3$ solution and H_2O, which removed acidic material (118 mg) consisting mostly of alternaric acid and indistinguishable by tlc from the corresponding fraction (115 mg) from the controls. The neutral fraction (55 mg; λ_{max} 402, $E^{1\%}_{1cm}$ 7.6) was chromatographed (50 g SiO_2, solvent A, 10 mL fractions) yielding 2 bands containing **5** ($\leq$1.5 mg from absorbance at λ_{max} 269 nm) and **6** respectively, the latter decomposing on attempted further purification. The fraction containing **5** was treated with $SOCl_2$ (3 microdrops) in ice-cold pyridine (0.5 mL) (2*a*) and the product chromatographed over SiO_2 (0.5 g) in $CHCl_3$ to give crystalline **1** (ca. 0.9 mg) on evaporation of the only coloured band. The neutral fraction from the controls (71 mg) had λ_{sh} 395 nm, $E^{1\%}_{1cm}$ 2.8, and contained at most a just detectable trace of **5** and no **6** (tlc; 2λ of a 5% solution).

The mycelia from the amended cultures were steeped in EtOH (200 mL) overnight, homogenized (Waring Blendor), filtered, and re-extracted similarly with EtOH (100 mL). Concentration of the filtrates till aqueous, extraction with EtOAc (3 × 50 mL), and chromatography of the extracts (300 g SiO_2, MeOH/$CHCl_3$ 5:95) gave crystalline **3**-$^{13}C_x$ (5.1 mg), identified by uv spectrum, mp and mp in admixture with an authentic specimen. This was converted into the diacetate with an enrichment level of ca. 0.8% at the C-2—Me and ca. 0.5% at the other sites (^{13}Cmr). The mycelia from the controls, on similar work-up, yielded only 1.9 mg of 3.

(e) In a similar experiment, **4**-$^{13}C_x$ (from (a)) was administered to 11-day old cultures of strain 11078 (2.5 mg/bottle), 8 of the cultures being extracted after 6, 7 after 11 days' further incubation. Altersolanol B (**5**) and dactylariol (**6**) were present in the extracts but in amounts too small to allow their isolation. Crystalline macrosporin (**3**) was isolated from the mycelia as the diacetate **3***a* (2.6 and 3.0 mg respectively) but incorporation levels were too low to allow a reliable spectroscopic comparison. After addition of a little more **3***a* from the culture filtrates, the combined material was shown by ^{13}Cmr to have an average enrichment of 0.5% with 0.8% in the C-2—Me group.

Incorporation of sodium [1-^{13}C,2-$^2H_3$]acetate into macrosporin and altersolanol A

(f) Four cultures of strain 44204 on potato-dextrose broth (100 mL/bottle) were treated with 0.05 *M* sodium [1-^{13}C,2-$^2H_3$]acetate (90%, ^{13}C; 98%, ^{2}H; 10 mL/bottle) immediately after inoculation and were extracted after 4 days, when the medium had turned orange. Another 4 cultures were treated with the acetate solution 4 days after inoculation and extracted 2 days later. Extraction of the mycelia from the first set of cultures furnished only a negligible trace of **3** but, after chromatography (solvent A), 8 mg of **3** was obtained from the second set. Direct crystallization of the EtOAc extracts from the culture filtrates afforded 20 mg of **4** from the first, and 25 mg from the second set of cultures. The ^{13}Cmr spectra of **4** were obtained in DMSO-d_6 and after acetylation, spectra of **3***a* and **4***a* were recorded in $CDCl_3$. The ^{2}Hmr spectra of **4** were measured in DMSO while **3***a* and **4***a* were examined in both $CHCl_3$ and CH_2Cl_2.

Acknowledgements

We wish to thank the Natural Sciences and Engineering Research Council of Canada for financial support of this work. We are very grateful to Dr. U. Matern for cultures of *A. solani*; Dr. R. W. Rickards for drawing our attention to the identity of dactylariol and "altersolanol C", and for comparing spectral data; Dr. A. N. Starratt for a gift of authentic zinniol diacetate; and we wish to acknowledge the skillful technical assistance of D. Hairsine, H. Schroeder, H. Bork, A. H. Hood, and G. L. Rock.

Tetrahydroaltersolanol B, a hexahydroanthronol from *Alternaria solani*[1,2]

A. STOESSL AND J. B. STOTHERS

Agriculture Canada, London Research Centre and the Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received September 13, 1982

A. STOESSL and J. B. STOTHERS. Can. J. Chem. **61**, 378 (1983).

The structure of a novel reduced anthraquinone, isolable in small amounts from culture filtrates of the fungus, *Alternaria solani*, is shown to be **6***a* mainly by spectroscopic methods. Detailed examination of the ^{1}Hmr spectra of **6***a* has defined its stereochemistry; the ^{13}Cmr spectral data for **6***a* and several derivatives are also reported.

A. STOESSL et J. B. STOTHERS. Can. J. Chem. **61**, 378 (1983).

À l'aide de méthodes spectroscopiques, on montre que la formule **6***a* correspond à la structure de la nouvelle anthraquinone réduite, isolée en petites quantités à partir du champignon *Alternaria solani*. Une étude poussée du spectre de rmn du ^{1}H a permis de définir sa stéréochimie; on rapporte également les données spectrales de la rmn du ^{13}C du composé **6***a* et de plusieurs dérivés.

As described in the preceding paper (1), the fungus *Alternaria solani* (Ell. & Mart.) Sorauer produces the polyketide metabolites **1**–**5** as well as some anthraquinones related to **1**–**3**. One of these compounds, altersolanol A (**1**), is sometimes obtained in relatively large amounts (up to 0.25 mg/mL culture filtrate) but, at other times, the yields can be very much lower. Recently, in several instances of the latter sort, the altersolanol A-containing fractions were found to deposit colorless crystals which are even less soluble in common solvents than the sparingly soluble **1**.

The constitution of this new compound was established by precise mass determination as $C_{16}H_{20}O_6$. Recrystallization from methanol-d_4 replaced four hydrogen atoms with deuterium ($\Delta M^+ = +4$), indicating the presence of four hydroxyl groups. The uv spectrum (λ_{max}: 281 (35 300), 315 (14 900)) is almost identical to that for 2,4-dihydroxyacetophenone (λ_{max}: 277 (27 400), 315 (15 200)) and the presence in the ir spectrum of strong bands at ν_{max} 1600 and 1632 cm^{-1} is indicative of an aromatic nucleus and a conjugated chelated ketone, respectively. Acetylation gave a triacetate together with a small amount of a somewhat unstable diacetate. In the ir the triacetate showed the expected bands for aryl acetate (1779 cm^{-1}), two aliphatic acetates (1750, 1755 cm^{-1}), and conjugated, but not chelated, carbonyl absorption (1689 cm^{-1}).

The proton spectrum of the new metabolite in DMSO-d_6 contained four hydroxy absorptions, two singlets (3.81 and 12.91 ppm) and two doublets (4.45 and 5.63 ppm, J = 6.5 and 7.4 Hz, respectively); these signals disappeared upon addition of D_2O, confirming their facile exchange. A pair of *meta*-coupled protons were apparent at 6.35 and 6.70 ppm with J = 2.5 Hz as well as an aromatic methoxy signal at 3.82 ppm. These are features familiar from the spectra for **1**–**3** (1–4). However, the less shielded of the aryl protons also exhibited a second splitting of 1.1 Hz, indicating a long range coupling with a *peri*-proton. A one-proton multiplet at 4.29 ppm was shown to contain this 1.1 Hz splitting by decoupling, an experiment which also established that this multiplet was coupled to

the hydroxy absorption at 5.63 ppm. In DMSO-d_6/D_2O the 4.29 ppm multiplet shifted to 4.333 ppm and was collapsed to a sharp doublet, J = 11 Hz, upon irradiation of the less-shielded aryl proton. These results indicated that the quinone carbonyl, corresponding to that at C-9 in **1**−**3**, had been reduced to a hydroxy group in accord with the absence of color for this compound. Furthermore, this carbinyl proton has a vicinal proton. Other features similar to those in the spectra of **1**−**3** were the presence of a methyl singlet (1.160 ppm) and a carbinyl proton appearing as a doublet of doublets in DMSO-d_6/D_2O at 3.360 ppm (spacings of 4.6 and 10.7 Hz). An additional splitting of 6.5 Hz was evident in this multiplet in DMSO-d_6 and was shown to be common to the hydroxy signal at 4.45 ppm. From these data the new metabolite could be assigned structure **6***a* with the di- and triacetates as **6***b* and **6***c*. The sites of acetylation followed from (a) the appearance of a chelated hydroxy signal at 12.78 ppm in the spectrum of **6***b* and the absence of an analogous signal for **6***c*; (b) characteristic acylation shifts of ca. 1.5 ppm for the carbinyl protons, and (c) upfield shifts for H-8 of ca. −0.5 ppm (**6***b*) and −0.11 ppm (**6***c*). The relatively low field position for the carbinyl proton at C-9 is consonant with its benzylic nature. Hydrolysis of **6***c* to **6***a* confirmed that acetylation proceeds without skeletal rearrangement.

The question of stereochemistry for **6***a* was resolved by more detailed examination of the higher field region of its proton spectrum. As noted, the spectrum was simplified in DMSO-d_6/D_2O by the disappearance of the couplings with the hydroxy protons apparent in the spectrum in DMSO-d_6, which permitted us to correlate the individual hydroxy signals with specific carbinyl protons. (It should be mentioned that the addition of D_2O to the DMSO-d_6 solution produced minor shifts in position of the absorption patterns.) With the assignment of the carbinyl absorption at 4.333 ppm to H-9, the doublet of doublets at 3.360 ppm must arise from H-3 and the spacings of 4.6 and 10.7 Hz indicate an axial−axial and an axial−equatorial coupling for H-3 with its vicinal neighbors. A four-line multiplet at 1.495 ppm, which could be described as a doublet of triplets with comparable coupling constants for each of its three coupling interactions, ca. 12 Hz, was assigned to the axial proton at C-4 because irradiation of H-3 at 3.360 ppm collapsed the pattern to a 1:2:1 "triplet" with spacings of 12 Hz. It follows therefore that the H-3 carbinyl proton is axial.

A doublet of doublets centred at 1.296 ppm, having spacings of 12 and 13 Hz, was unaffected by this decoupling experiment but was collapsed to a clear doublet upon irradiation at 1.965 ppm which is the centre of another multiplet, a doublet of quartets with a total width of 38.5 Hz. This decoupling experiment also collapsed the H-9 carbinyl absorption at 4.333 ppm to a doublet with J = 1.1 Hz. Hence H-13 absorbs at 1.965 ppm and is most probably axial, displaying axial−axial spin coupling with H-9 and the proton absorbing at 1.296 ppm which can be assigned to the axial proton at C-1. In addition, the irradiation at 1.965 ppm resulted in the collapse of a "doublet of triplets" (spacings of 3.7 and 12 Hz) at 2.465 ppm to a "doublet of doublets" with the same splittings. The latter multiplet could, therefore, be directly assigned to H-14; the relatively large splitting of 12 Hz indicated that H-13 and -14 are both axial. Hence, **6***a* has a *trans* ring junction. Two overlapping multiplets near 2.2 ppm exhibited informative alterations during these decoupling experiments. A doublet of doublets, with spacings of 3.3 and 13 Hz, could be assigned to the equatorial proton at C-1, as the collapse of the larger splitting upon irradiation at 1.296 ppm (axial H-1) confirmed. The four-line pattern at 1.495 ppm (axial H-4) became a "triplet" upon irradiation near 2.2 ppm, thereby locating the obscured multiplet for the equatorial H-4. Thus, the protons at C-3, -9, -13, and -14, four of the five chiral centres, could be assigned axial orientations. Since the 2- and 3-hydroxyls are α as in **2** (4) and the 3-proton is axial, **6***a* must have the stereochemistry shown in **7**, with the 3-, 9-, and 14-protons β.

The proton data are collected in Table 1. The parameters listed for the protons on the saturated ring for **6***a* in DMSO-d_6/D_2O solution were obtained by spin simulation calculations using the program supplied with the XL-200 software. The patterns for the protons at C-3, -4, and -14 were calculated, including the coupling between H-14 and -13; in a similar manner the spectrum for the protons at C-1, -9, and -13 was obtained and the two results added to give a composite spectrum for comparison with that observed. Suitable adjustments of the parameters led to a good match for the simulated and observed spectra. A complete analysis was not attempted because of the size of the spin system and the presence of several small unresolved long range couplings. Nevertheless, the coupling constants listed in Table 1 are undoubtedly close to the true values and the key coupling constants are sufficiently large to render firm stereochemical conclusions. The ^{13}Cmr spectra of these compounds were also recorded and these data are listed in Table 2. The assignments were straightforward, following from the earlier data for **1**−**3** (1), and fully corroborate the structural elucidations discussed above.

On treatment with acetone in the presence of a trace of strong acid, **6***a* furnished an acetonide **6***d*, as confirmed by the presence in the ^{13}C spectrum of two new methyl signals and a strongly dishielded quaternary carbon at 107.5 ppm (Table 2). The proton spectrum (Table 1) similarly contained two new methyl singlets together with hydroxy peaks at 1.75 and 12.65 ppm. The absorptions for H-6, -8, and -9 were similar to those for **6***a* but the pattern for the remaining carbinyl proton was significantly different, appearing as a triplet with spacings of ca. 4 Hz at 4.14 ppm. Irradiation of this multiplet showed it to be coupled to a doublet of triplets (spacings, 4 and 15 Hz) at 2.74 ppm and to an eight-line pattern, total width 28 Hz, at 1.84 ppm. The latter multiplets must arise from the equatorial and axial protons, respectively, on C-4. A more detailed analysis of the spectrum was precluded, however, by severe overlapping of the multiplets for "equat" H-1, -13, and -14 in the region 2.2−2.45 ppm and partial masking of the remaining H-1 absorption near 1.85 ppm by the methyl signals. In any event, the relatively small couplings, ≤8 Hz, for H-3 indicate the absence of an axial−axial interaction for this proton, therefore signifying a conformational change for the saturated ring in **6***d*. While it is conceivable that the acid catalysis could change the ring junction geometry by epimerization at the α-carbon, C-14, the resulting *cis*-fusion should favor the chair conformer having an axial proton at C-3, contrary to the appearance of its absorption. We conclude, therefore, that the saturated ring in **6***d* exists as a non-chair ring or as a mixture of non-chair forms. The pronounced deshielding of one of the 4-protons indicates that it lies close to the plane of the carbonyl group, suggesting that **8** may be the favored conformer for **6***d*.

It is unclear at present whether **6***a* is biosynthetically a precursor of, or a metabolite derived from, altersolanol B (**2**) or indeed whether it is formed through a different pathway. The small amounts in which both compounds accrue currently present a bar to further examination of this question.

Experimental

Materials and the general techniques employed have been described previously (1). The ^{13}Cmr spectra were measured at 50.3 MHz with a Varian XL-200 instrument using 12 KHz spectral widths, 30° pulses, and 2 s repetition rates. Comparison of spectra obtained using the APT sequence (5) with usual proton decoupled spectra allowed distinction between methyl, methylene, methine, and fully-substituted carbons. The ^{13}C shieldings are reported relative to internal TMS with estimated precisions of ±0.05 ppm. Proton spectra were recorded at 200 MHz, generally using 3 KHz spectral widths and 32 K transforms. For **6***a*, the observed spectrum was compared with that obtained using the spin simulation program provided with the G-2 software for the XL-200. Since this program cannot handle an 8-spin system, the results for two 5-spin calculations were added to give a composite spectrum for the protons on sp^3-carbons. The best match of observed and calculated spectra was obtained with the parameters listed in Table 1 for **6***a* in DMSO-d_6/D_2O.

Isolation and properties of compound **6**a

The neutral EtOAc extracts of the filtrates obtained from 21 day-old cultures of *A. solani* ATCC 44204 on Brian's medium T (28 Roux bottles; 100 mL/bottle) were evaporated and the combined residues were triturated twice with a mixture of water (12.5 mL) and MeOH/$CHCl_3$ (1:9, 12.5 mL). The material which had remained undissolved was recrystallized from MeOH to furnish **6***a*, 7.5 mg, which contained traces of a compound containing an extra oxygen atom (ms) but could be purified through its triacetate **6***c*.

In a second run, the combined crude EtOAc extracts (534 mg) from 30 similar cultures, harvested in another connection at various time intervals, were chromatographed over SiO_2 (200 g) in MeOH/$CHCl_3$/HOAc (5:95:0.1; 25 mL/fraction). Fractions 112–131 (33 mg) consisted of **1**. Fractions 91–99 (33 mg) yielded pure **6***a* (16 mg) upon a single recrystallization from MeOH; mp 256–257°C, $[\alpha]_D^{25}$ −27.2° (*c* 0.18, MeOH); *m/e*: 308, 290, 272, 246, 232, 215, 203 (100%). *Exact Mass* calculated for $C_{16}H_{20}O_6$: 308.1258; found (high resolution ms): 308.1260. After recrystallization from methanol-d_4, *m/e*: 312, 292, 273, 248, 234, 216, 205 (100%). *Exact Mass* calculated for $C_{16}{}^1H_{16}{}^2H_4O_6$: 312.1508; found (high resolution ms): 312.1526.

Acetylation (Ac_2O/pyridine at room temperature overnight followed by evaporation *in vacuo*) gave the triacetate **6***c* together with a small amount of the diacetate **6***b*, which were separated by chromatography over SiO_2 (10 g) in Et_2O, **6***b* being eluted first.

Diacetate **6***b*, a crystalline solid when first isolated, had λ_{max} 279.5 (26 000) and 316 (11 400) and the nmr data recorded in Tables 1 and 2 when first measured. Subsequent examination of the solution indicated some decomposition and/or acyl migration. This material had *m/e*: 392, 350, 332, 314, 290, and 272 (100%).

Triacetate **6***c*, mp 168°C (from light petrol/Et_2O), $[\alpha]_D^{25}$ −16.1° (*c* 0.18, $CHCl_3$), had *m/e*: 434, 392, 350, 332, 314, 290, and 272 (100%) and λ_{max} 225 (14 100) and 273 (13 300). Hydrolysis of the compound (6.1 mg) in 0.05 *M* NaOH (2 mL) at room temperature for 2 days gave crystals of **6***a* (2.1 mg; mp 250–254°C) on acidification.

Acetonide **6***d*. Treatment of **6***a* (10 mg) with acetone (0.75 mL) containing H_2SO_4 (0.4% v/v) at ice temperature for 1.5 h, and at room temperature for another 1.5 h, gave **6***d* (6.6 mg) on extraction into EtOAc from $NaHCO_3$ solution; mp 150°C after recrystallization from CCl_4; *m/e*: 348, 333, 291 (100%), 273, 260, and 245. *Exact Mass* calculated for $C_{19}H_{24}O_6$: 348.15725; found (high resolution ms): 348.15705.

Formation equilibria of silver amminocomplexes at temperatures up to 453 K

BARBARA KOŁODZIEJ

Institute of Inorganic Chemistry and Metallurgy of Rare Elements, Technical University of Wrocław 50-370 Wrocław, Poland

Received January 26, 1982[1]

BARBARA KOŁODZIEJ. Can. J. Chem. **61**, 383 (1983).

The formation equilibria of silver amminocomplexes were investigated by potentiometric method over the temperature range 333 to 453 K. On the grounds of emf measurements of a concentration cell consisting of

$Ag|AgNO_3$, NH_4NO_3 (2 *M*)$\|AgNO_3$, NH_3, NH_4NO_3 (2 *M*)$|Ag$

the equilibrium concentrations of uncomplexed silver ions $[Ag^+]$ were determined in a $Ag-NH_3-H_2O$ system. The Leden method was followed and the mean number of ligands ($\bar{N}$) per silver atom bound in amminocomplexes as well as the equilibrium concentration of free ammonia $[NH_3]$ were calculated. From the values obtained above the stability constants of silver amminocomplexes β_1 and β_2 were determined over the temperature range 333 to 453 K. The dependence of log β_1 versus temperature was described by the equation: $\log \beta_1 = 6.89 - 1.16 \times 10^{-2}T$ whereas for log β_2 the linear equation: $\log \beta_2 = 14.10 - 2.41 \times 10^{-2}T$ is satisfied only up to 413 K. Above 413 K the nature of the dependence is changed.

BARBARA KOŁODZIEJ. Can. J. Chem. **61**, 383 (1983).

On a étudié la formation des équilibres des complexes aminés de l'argent en utilisant une méthode potentiométrique dans un intervalle de température allant de 333 à 453 K. En se basant sur les mesures de la fem d'une cellule de concentration de

$Ag|AgNO_3$, NH_4NO_3 (2 *M*)$\|AgNO_3$, NH_3, NH_4NO_3 (2 *M*)$|Ag$

on a déterminé les concentrations à l'équilibre des ions argent non complexés $[Ag^+]$ d'un système $Ag-NH_3-H_2O$. On a utilisé une méthode de calcul basée sur la méthode de Leden et on a ainsi calculé le nombre moyen de ligands ($\bar{N}$) par atome d'argent lié dans les complexes aminés ainsi que la concentration à l'équilibre de l'ammoniac libre $[NH_3]$. A partir des valeurs ainsi obtenues, on a déterminé les constantes de stabilité des complexes aminés de l'argent β_1 et β_2 sur un intervalle de température allant de 333 à 453 K. On décrit l'influence de la température sur le log β_1 par l'équation: $\beta_1 = 6{,}89 - 1{,}16 \times 10^{-2}T$ alors que pour le log β_2 l'équation linéaire: $\log \beta_2 = 14{,}10 - 2{,}41 \times 10^{-2}T$ est satisfaisante uniquement jusqu'à 413 K. Au dessus de 413 K la nature de la relation change.

[Traduit par le journal]

Introduction

In the present paper the formation equilibria of silver amminocomplexes were investigated using the potentiometric method in a temperature range from 303 to 453 K using an electrolytic cell of special design (1).

Bjerrum (2), Nasanen (3), and Koch (4) applied electrochemical methods for studies of the above equilibria at standard temperatures. The stability constants of silver amminocomplexes were also determined by means of potentiometric method at temperatures up to 373 K (5, 6).

In the present paper the emf of the following concentration cell was measured at suitable temperatures:

[1] $Ag|AgNO_3$, NH_4NO_3 (2 *M*)$\|AgNO_3$, NH_3, NH_4NO_3 (2 *M*)$|Ag$

I II

emf

In both semi-cells of the concentration cell [1] the concentration of $AgNO_3$ (0.01 *M*) and ionic strength of NH_4NO_3 (2 *M*) were kept constant, only the ammonia concentration in suitable electrolytes in semi-cell II was varied. Emf measurements of cell [1] at a specific temperature in the equilibrium enabled us to determine the uncomplexed silver ion concentration $[Ag^+]$ in solutions of semi-cell II according to eq. [2].

$$[2] \quad \log [Ag^+] = \log [Ag^+]_c - \frac{F}{2.303RT}\Delta E$$

Other values necessary for determination of the stability constants of silver amminocomplexes were found by means of a modified Leden method (7).

At each specific temperature in the $Ag-NH_3-H_2O$ system an equilibrium described by eq. [3] is established:

$$[3] \quad \frac{[Ag^+][NH_3]^{\bar{N}}}{[Ag(NH_3)^+_{\bar{N}}]} = \text{constant}$$

where $\bar{N}$, the mean number of ligands per silver atom bound in the amminocomplexes, is given by expression [4]:

$$[4] \quad \bar{N} = \frac{[Ag(NH_3)^+] + 2[Ag(NH_3)_2^+]}{[Ag(NH_3)^+] + [Ag(NH_3)_2^+]}$$

whose numerator and denominator may be presented as follows:

$$[5] \quad [Ag(NH_3)^+] + 2[Ag(NH_3)_2^+] = [NH_3]_c - [NH_3]$$

$$[6] \quad [Ag(NH_3)^+] + [Ag(NH_3)_2^+] = [Ag(NH_3)_{\bar{N}}^+] = [Ag^+]_c - [Ag^+]$$

Thus, on the grounds of eqs. [4], [5], [6], the equilibrium concentration of free ammonia, $[NH_3]$, is given by eq. [7]:

$$[7] \quad [NH_3] = [NH_3]_c - \bar{N}([Ag^+]_c - [Ag^+])$$

The value which is unknown in eq. [7] and is necessary to find $[NH_3]$ is the mean number of ligands $\bar{N}$. This value was determined by transforming eq. [2] into form [8] using eqs. [3] and [7].

[1]Revision received July 20, 1982.

$$[8]\quad \Delta E = \frac{2.303RT}{F}\left\{\bar{N}\log\left[[NH_3]_c - \bar{N}([Ag^+]_c - [Ag^+])\right] + \log\frac{[Ag^+]_c}{[Ag^+]_c - [Ag^+]}\right\} + \text{constant}'$$

For the equilibrium free ion concentrations $[Ag^+]$ defined at a given temperature and determined from eq. [2] (other values in eq. [8] are present values), the trial-and-error method may be used to select such values of $\bar{N}$ so that eq. [9] would be a straight line whose slope is $2.303RT/F$.

$$[9]\quad \Delta E = f\left\{\bar{N}\log\left[[NH_3]_c - \bar{N}([Ag^+]_c - [Ag^+])\right] + \log\frac{[Ag^+]_c}{[Ag^+]_c - [Ag^+]}\right\}$$

The values of $\bar{N}$ found by this method at a given temperature together will the predetermined values of $[Ag^+]$ enable us to calculate the respective equilibrium concentrations of uncomplexed ammonia $[NH_3]$ (eq. [7]).

From the equilibrium concentrations $[Ag^+]$ and $[NH_3]$ which are established at a specific temperature in the $Ag-NH_3-H_2O$ system, one can determine the stability constants of silver amminocomplexes β_1 and β_2 defining them as coefficients of eq. [10]:

$$[10]\quad \frac{[Ag^+]_c - [Ag^+]}{[Ag^+][NH_3]} = \beta_1 + \beta_2[NH_3]$$

Equation [10] was derived from eqs. [5] and [6] taking into consideration the definitions of stability constants β_1 and β_2:

$$[11]\quad \beta_1 = [Ag(NH_3)^+]/[Ag^+][NH_3]$$

$$[12]\quad \beta_2 = [Ag(NH_3)_2^+]/[Ag^+][NH_3]^2$$

Experimental

Emf measurements of the concentration cell [1] were carried out in a specially designed and constructed electrolytic cell (1). Its design made it possible to measure the emf values at temperatures exceeding 373 K.

The electrolytic cell shown in Fig. 1 consists of a vertical cylindrical PTFE block (*1*) enclosed in a metal housing (*2*). The PTFE block contains four vertical cylindrical chambers (*3*) connected in their bottom parts through capillary holes (*4*) filled with asbestos to a profiled chamber (*5*) which, having been filled with electrolyte, acts as a salt-bridge. Cylindrical chambers (*3*) were filled completely with electrolyte solutions in order to eliminate any free space, and with electrodes installed in them, they function as respective semi-cells. Each of the four cylindrical chambers (*3*) is closed with a PTFE stopper (*6*) provided with an axially installed electrode. The holes closed with PTFE stoppers are made tight by means of sleeves (*7*) of setscrews (*8*) and (*9*). Setscrews (*8*) are screwed into a metal cover (*10*) pressed down to the metal housing by means of a nut (*11*). Chamber (*5*) for the salt-bridge solution is closed from the top by means of a PTFE stopper (*12*) tightened with a sleeve (*13*) and a screw (*14*) and from the bottom by means of a four-winged PTFE stopper (*15*) tightened with a set screw (*16*). In addition, the PTFE block is provided with four copper heating inlets (*17*) and a cylindrical hole (*18*) for a thermocouple and thermometer.

The cell was placed in an electric furnace whose temperature was adjusted by means of a thermoregulator. The temperature in the electrolytic cell was measured by means of a copper–constantan thermocouple using a KM-76 compensator and ekN/T12 recorder. After the temperature became stable, the emf of the respective cells was measured. Emf was measured by means of a KM-76 compensator accurate to 0.1 mV.

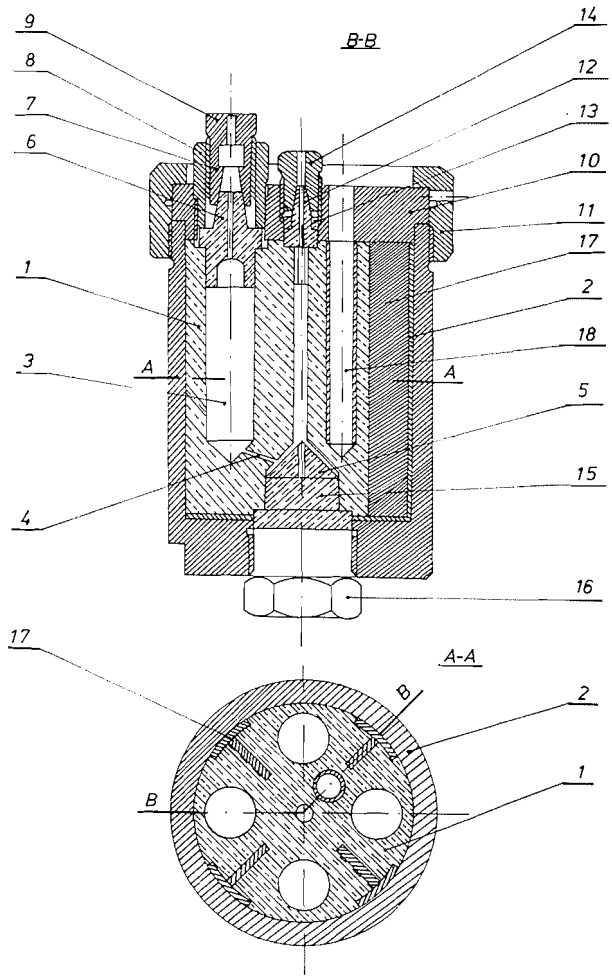

FIG. 1. Electrolytic cell for emf measurements at temperatures exceeding 373 K.

$AgNO_3$ solutions at suitable concentrations were prepared from weighed portions of crystalline silver nitrate after recrystallization of analytical grade $AgNO_3$. NH_4NO_3 solutions were prepared by the same method. Suitable ammonia solutions whose concentrations were determined by acid–base titrations were prepared by diluting concentrated NH_3 analytical grade.

Results and discussion

Emf measurements of cell [1] were carried out for the respective solutions in a temperature range from 303 to 453 K. In the solutions under investigation a constant ionic strength (2 *M* NH_4NO_3) and constant silver ion concentration $[Ag^+]_c$ was maintained. Only the concentration of ammonia $[NH_3]$ was varied.

Initial concentrations $[Ag]_c$, $[NH_3]_c$ in the electrolytes of cell [I] under investigation, their corresponding emf values at specific temperatures, and equilibrium concentrations of the uncomplexed silver ions $[Ag^+]$ calculated from eq. [2] are summarized in Table 1. In the values given, allowance was made for the change of the water density with temperature.

The values of $\bar{N}$ found for the respective temperatures by the trial-and-error method are presented in Table 2. Table 2 also contains a comparison of the slope coefficient for straight line [8] at the values of $\bar{N}$ assumed for specific temperatures with the actual value for a given temperature coefficient $2.303RT/F$. A satisfactory agreement between these coefficients enabled us, on the grounds of the selected values of $\bar{N}$, to determine the

The influence of the ionic strength on the adsorption of thiocyanate ions on mercury[1]

LUIS A. AVACA, ERNESTO R. GONZÁLEZ, AND ROMEU C. ROCHA FILHO[2]

Instituto de Física e Química de São Carlos, Universidade de São Paulo, C.P. 369, São Carlos, SP, 13560 Brasil

Received March 3, 1982

LUIS A. AVACA, ERNESTO R. GONZÁLEZ, and ROMEU C. ROCHA FILHO. Can. J. Chem. **61**, 388 (1983).

The adsorption of thiocyanate ions at mercury has been studied from aqueous solutions of two different and constant ionic strengths, namely, x *M* KSCN + $(0.5 - x)$ *M* KF and x *M* KSCN + $(1.0 - x)$ *M* KF, at 298 K. The surface excess due to thiocyanate ions was determined using the Hurwitz–Parsons analysis as well as using the surface pressure method. The amount of specifically adsorbed thiocyanate ion at a given electrode charge density and thiocyanate concentration is shown to depend on the ionic strength. For both ionic strengths, the adsorption process was found to be described by an isotherm congruent on the electrode charge density, to which virial isotherms were fitted with the following parameter values: B = 210 and 185 Å^2 ion^{-1}, and ΔG_0^0 = −93.05 and −92.88 kJ mol^{-1}, for ionic strengths 0.5 and 1.0 *M*, respectively. The properties of the inner layer are discussed based on the corresponding Christie plots.

LUIS A. AVACA, ERNESTO R. GONZÁLEZ et ROMEU C. ROCHA FILHO. Can. J. Chem. **61**, 388 (1983).

On a étudié l'adsorption des ions thiocyanates sur le mercure à partir de solutions aqueuses de deux forces ioniques différentes et constantes, soit: x *M* KSCN + $(0,5 - x)$ *M* KF et x *M* KSCN + $(1,0 - x)$ *M* KF à 298 K. On a déterminé la surface en excès due aux ions thiocyanates en utilisant l'analyse de Hurwitz–Parsons ainsi que la méthode de pression de surface. On montre que la quantité d'ions thiocyanates adsorbés spécifiquement à une densité de charge d'électrodes et à une concentration de thiocyanate données dépend de la force ionique. On a trouvé que pour les deux forces ioniques, le processus d'adsorption doit être décrit par une isotherme convergente sur la densité de charge d'électrode, sur laquelle on ajuste les isothermes viriaux à l'aide des valeurs des paramètres suivants: B = 210 et 185 Å ion^{-1} et ΔG_0^0 = 93,05 et −92,88 kJ mol^{-1} respectivement pour des forces ioniques de 0,5 et 1,0 *M*. On discute des propriétés de la couche interne en se basant sur les courbes correspondantes de Christie.

[Traduit par le journal]

Introduction

In recent years there has been a growing interest in the study of adsorption of ions at the mercury – aqueous solution interface from constant ionic strength solutions (1–6). In general, these studies included comparison with the results obtained from single salt solutions and, in some cases (3–5), comparisons between double-layer parameters for different values of the ionic strength were also carried out. Thus, Dutkiewicz (3) analyzed the adsorption of benzenesulphonate ions from solutions of 0.3 and 1.0 *M* ionic strength but, due to inherent complexities in the adsorption characteristics of this ion, the influence of the ionic strength on the adsorption process and on some electrical double-layer parameters was only partially discussed. On the other hand, Fawcett and Sellan (5) studied the adsorption of nitrate ions from 0.2 *M* ionic strength solutions and, by comparing the amounts of specifically adsorbed charges with those obtained by Payne (7) at 1.0 *M* ionic strength, were able to draw some conclusions regarding the dependence of the adsorption process on the ionic strength. A similar analysis was done previously for iodide adsorption (4).

Fawcett and Sellan (5) found that the nitrate ion is moderately adsorbed on Hg, that is, when the electrode charge density q^M is positive the interface shows an absolute value of the specifically adsorbed charge density $|q_-'|$ greater than q^M at high nitrate concentrations, while the opposite happens at low concentrations; a similar behavior was observed for azide ions (6). As a consequence, when a comparison between the specifically adsorbed charge densities obtained at two ionic strengths was carried out an interesting result was obtained: the adsorption is greater at the higher ionic strength for high nitrate concentrations, i.e., for $|q_-'| > q^M$, while the contrary becomes true at low concentrations. This behavior was explained in terms of the change in the potential at the outer Helmholtz plane (oHp), as pointed out previously by Randles (8). Studies of adsorption on mercury of the azide ion at different ionic strengths are being carried out in this laboratory to investigate further the adsorption behavior demonstrated by the nitrate ion study.

If an ion adsorbs strongly, $|q_-'|$ should be greater than q^M even at low bulk concentrations. This means that for a constant concentration of the ion its adsorption will be larger the greater the ionic strength, as has been shown by Fawcett and McCarrick (4) in the case of iodide. Previous studies of the adsorption of thiocyanate ions on mercury from single salt solutions have shown that this ion has characteristics of a pseudo-halide, with an adsorption only slightly weaker than that of iodide (10–13). Behr *et al.* (14) studied the adsorption of thiocyanate from aqueous solutions of constant ionic strength. However, as their aim was to analyze the effect of additions of acetone on the adsorption of SCN^-, a detailed study of the characteristics of the electrical double-layer was not made. The present work was undertaken to examine the influence of the ionic strength on the adsorption of a strongly adsorbing ion, thiocyanate. The influence of the ionic strength on the inner-layer properties was also analyzed. The systems studied were aqueous (KSCN + KF) solutions at 0.5 and 1.0 *M* ionic strengths.

Experimental

Data for differential capacity against electrode potential, for the

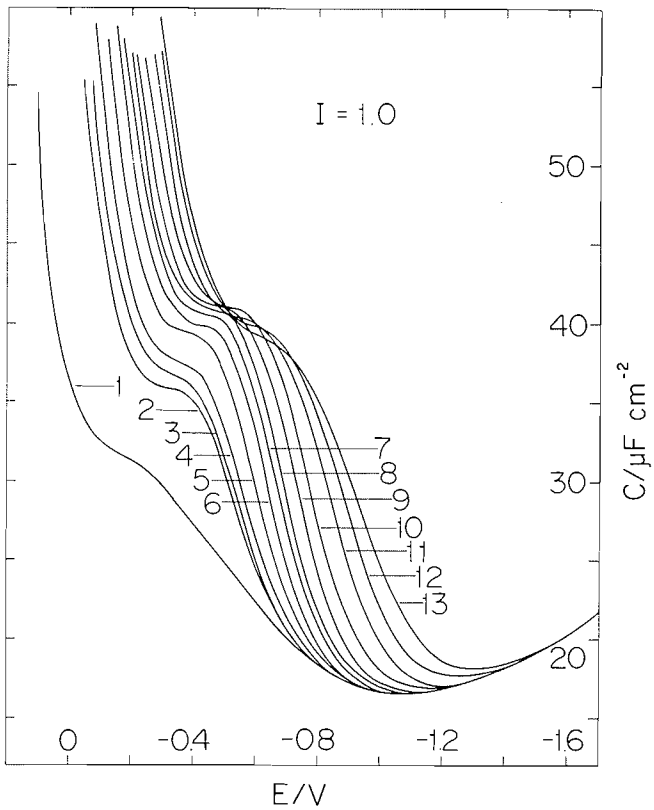

FIG. 1. Differential capacity of the electrical double layer for a mercury electrode in aqueous x *M* KSCN + $(1.0 - x)$ *M* KF solutions at 298 K. x = (*1*) 0, (*2*) 0.001, (*3*) 0.00125, (*4*) 0.0025, (*5*) 0.005, (*6*) 0.01, (*7*) 0.0175, (*8*) 0.025, (*9*) 0.05, (*10*) 0.1, (*11*) 0.25, (*12*) 0.5, (*13*) 1.0. Potentials with respect to a sce.

mercury – aqueous solution interface at 298 K, were obtained with 12 solutions of composition x *M* KSCN + $(0.5 - x)$ *M* KF, where x had the values 0, 0.001, 0.00125, 0.0025, 0.005, 0.01, 0.0175, 0.025, 0.05, 0.1, 0.25, and 0.5; and for 13 solutions of composition x *M* KSCN + $(1.0 - x)$ *M* KF, where x had the same values as before plus the additional value of 1.0. The experimental procedure has been described elsewhere (6). The calculated differential capacities were found to be independent of frequency in the range 50–800 Hz. Analytical grade salts, dried over P_2O_5, were used without further purification. The purity of KF was tested by comparing capacity curves of KF solutions at different concentrations with those from the literature (15), with good agreement. Water and mercury were purified as described previously (16). All potentials are referred to a saturated calomel electrode used as reference.

Results and discussion

Figure 1 shows the differential capacity against potential curves for an ionic strength of 1.0 *M*. As can be observed, the value of the differential capacity is independent of solution composition for potentials more negative than −1.5 V. The results obtained for the 0.5 *M* ionic strength were similar to those already shown, presenting the same behavior at large negative potentials.

The experimental values of the potential of zero charge, E^z, and the calculated values of the interfacial tension at this potential, γ^z, are shown in Table 1. The latter were calculated by back integration from the value at −1.70 V, which, in turn, was calculated through forward integration of the data for the KF electrolyte solution from the value 425.7 mN m^{-1} for γ^z (17), using a computer program described elsewhere (18).

The variation of ionic activity coefficients in mixed salt

solutions containing, for example, a single cation has been considered in theoretical treatments of adsorption from such solutions (9, 19). As shown by Fawcett and McCarrick (4), the magnitude of this variation is a function of the nature of the system and, in some cases, can be disregarded. In this work, as a first approximation, the variation of the activity coefficient with composition was not taken into account and, so, the double-layer parameters were obtained on the basis of the treatment of Dutkiewicz and Parsons (20), as already described (6). Further below, the error in the values of the specifically adsorbed charge density q_-' due to this approximation will be estimated.

The adsorption isotherm

In each of the adsorption studies done from solutions containing only thiocyanate, a different isotherm was found to describe its adsorption on mercury. Thus, Wroblowa *et al.* (11) fitted their data to the Bockris–Devanathan–Müller isotherm (21) while Minc and Andrzejczak (12), applying the surface pressure method (22), found that the isotherm was congruent in charge density and were able to fit the data to the Frumkin equation; finally, Parsons and Symons (13) analyzed their data in terms of the virial isotherm.

Although the integral form of the iostherm (in terms of surface pressures) is not very sensitive, it is useful because it avoids the errors due to the differentiation necessary to obtain the specifically adsorbed charge q_-' (23). At the same time, it allows a comparison between the values of q_-' obtained from the isotherm and those calculated through differentiation of Parsons function ($\xi = \gamma + Eq^M$) against log c. Thus, the surface pressure method (22) was applied to the data obtained here, for both ionic strengths. The surface pressure Φ vs. log c curves for all charge densities q^M in the range −8 to 14 μC cm^{-2} were found to be congruent in the charge density; the composite curves shown in Figs. 2 and 3 were obtained as a result of this analysis. Both of these curves could be fitted to a virial isotherm, which may be written as

$$[1] \quad -q_-' = xF \exp\left(\frac{-\Delta G^0}{RT} + \frac{2Bq_-'}{F}\right)$$

where ΔG^0 is the standard free energy of adsorption at zero coverage which is a function only of q^M, B the second virial

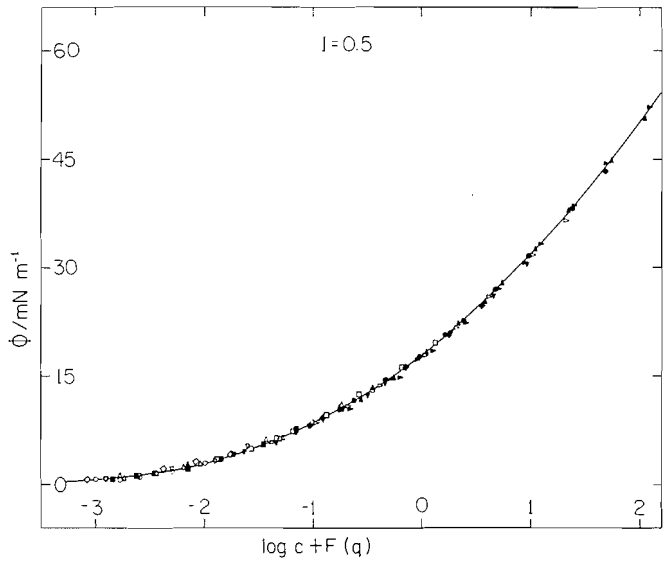

FIG. 2. Composite surface pressure curve at constant charge density for the adsorption of thiocyanate on Hg at 298 K from aqueous 0.5 M ionic strength solutions. (◇) $q^M = -8$, (▽) $q^M = -6$, (■) $q^M = -4$, (△) $q^M = -2$, (○) $q^M = 0$, (□) $q^M = 2$, (◆) $q^M = 4$, (▼) $q^M = 6$, (▷) $q^M = 8$, (●) $q^M = 10$, (▲) $q^M = 12$, (▶) $q^M = 14$ μC cm^{-2}. The solid line was calculated from a virial equation with the second virial coefficient $B = 210$ Å^2 ion^{-1}.

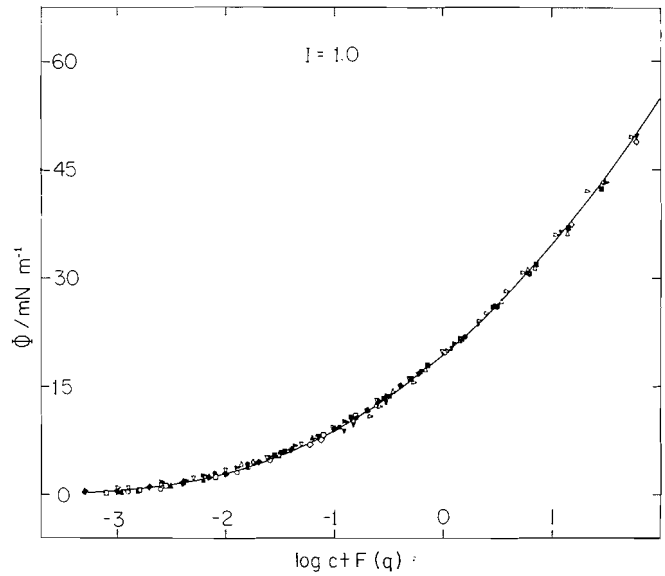

FIG. 3. Composite surface pressure curve at constant charge density for the adsorption of thiocyanate on Hg at 298 K from aqueous 1.0 M ionic strength solutions. (○) $q^M = -8$, (▲) $q^M = -6$, (□) $q^M = -4$, (◆) $q^M = -2$, (▽) $q^M = 0$, (▶) $q^M = 2$, (●) $q^M = 4$, (△) $q^M = 6$, (■) $q^M = 8$, (◇) $q^M = 10$, (▼) $q^M = 12$, (▷) $q^M = 14$ μC cm^{-2}. The solid line was calculated from a virial equation with the second virial coefficient $B = 185$ Å^2 ion^{-1}.

coefficient, x the SCN^- concentration, and R, F, and T have their usual significance.

The values found for the isotherm parameters were 210 and 185 Å^2 ion^{-1} for B, and −93.05 and −92.88 kJ mol^{-1} for the standard free energies of adsorption at zero coverage in the absence of electrical interaction between ion and electrode ΔG_0^0, for the ionic strengths 0.5 and 1.0 M, respectively. The standard states were 1 ion cm^{-2} on the surface and 1 mol L^{-1} in the solution.

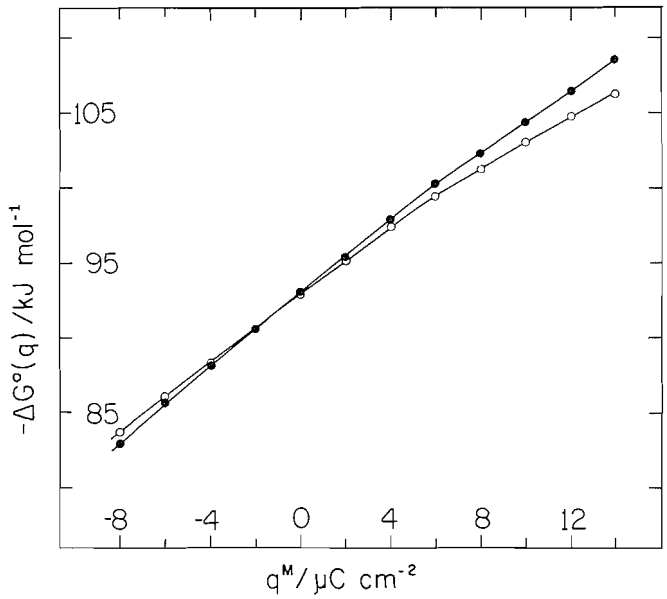

FIG. 4. Dependence of the standard free energy of adsorption at zero coverage on the electrode charge density, for the adsorption of thiocyanate on Hg at 298 K from aqueous (●) 0.5 and (○) 1.0 M ionic strength solutions.

The fact that the values of ΔG_0^0 are practically the same for both ionic strengths confirms the consistence of the analyses since this parameter should not depend on the ionic strength. Moreover, these values are very close to the one which can be estimated from the results of Minc and Andrzejczak (12) for pure KSCN solutions (−92.1 kJ mol^{-1} at 298 K). The different values of B obtained for the two ionic strengths are due to the fact that, as the ionic strength increases, the ionic atmosphere of each adsorbed SCN^- ion lowers the repulsive interaction between adsorbed SCN^- ions. Consequently, a smaller value of B is required for the isotherm which describes the adsorption process for the higher ionic strength. Parsons and Symons (13) found an apparent decrease of B from 1600 to 700 Å^2 ion^{-1} as the concentration of SCN^- increased in solutions of varying ionic strength. This variation and its range are consistent with the analysis above.

The values of the free energy of adsorption at zero coverage, ΔG^0, for each value of q^M were estimated from the displacements made along the log c axis in order to obtain the composite surface pressure curves of Figs. 2 and 3 (22). The dependence of ΔG^0 on q^M is shown in Fig. 4, for both ionic strengths. The behavior of each ionic strength is very similar in that the adsorption process becomes energetically favored as q^M increases. Starting from negative q^M values up to slightly positive ones the dependence of ΔG^0 on q^M is linear, which shows that in this range of q^M both systems behave as fixed parallel plate condensers in which one dielectric is replaced by another (24), while for high positive values of q^M this simple model no longer holds.

The specifically adsorbed charge

Figure 5 shows the specifically adsorbed charge density q_-', obtained via Parsons function, plotted against the electrode charge density for different SCN^- concentrations at the ionic strength 1.0 M. The curves are qualitatively similar to those presented by halide and pseudo halide ions in solutions of constant ionic strength, as well as in solutions containing one salt (2, 6, 13). For the 0.5 M ionic strength the results are

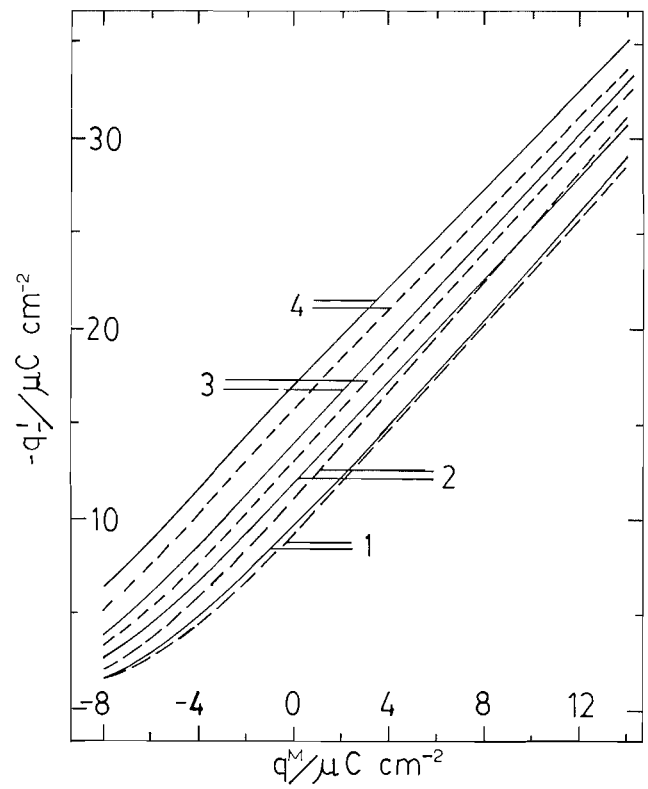

FIG. 6. Charge due to adsorbed thiocyanate ions on Hg at 298 K from aqueous x *M* KSCN + (1.0 − x) *M* KF (full lines) and x *M* KSCN + (0.5 − x) *M* KF solutions (broken lines). x = (*1*) 0.025, (*2*) 0.05, (*3*) 0.1, (*4*) 0.25.

similar to those in Fig. 5, showing smaller values of q_-' at the higher concentrations. It follows from Fig. 5 that the adsorption of SCN^- can be considered to be quite strong, since $|q_-'| > q^M$ even at low thiocyanate concentrations. This implies that the potential at the oHp, ϕ^2, should become less negative as the ionic strength is increased (8) and, consequently, for a fixed concentration of SCN^- its amount specifically adsorbed should increase accordingly. As can be seen in Fig. 6, the present results confirm this behavior, which has also been observed for iodide (4) and for nitrate ion adsorption (5) when the condition $|q_-'| > q^M$ is fulfilled. A comparison of the data in Fig. 6 with those for the adsorption of thiocyanate from pure salt solutions (11–13) again shows that for fixed concentrations of SCN^- the specifically adsorbed charge densities are larger the higher the ionic strength of the solution, as reported previously for other systems (2, 4–6). This behaviour has been qualitatively explained by Hills and Reeves (2) on the basis of charge imaging.

As mentioned before, the use of the surface pressure method to obtain the adsorption isotherm avoids the errors involved in the differentiation process to obtain the values of q_-', since they can be obtained from the isotherm by rewriting eq. [1] in the form (for standard states 1 ion cm^{-2} on the electrode surface and 1 mol L^{-1} in the solution)

$$[2] \quad \ln\left(-\frac{q_-'}{xe_0}\right) + \frac{\Delta G^0}{RT} - \frac{2Bq_-'}{e_0} = 0$$

where e_0 is the electronic charge. Once the values of ΔG^0 and B are known, eq. [2] can be used to obtain q_-' for the different values of x at different constant values of q^M. This was done iteratively, starting with the assumption that $q_-' = 0.01$ μC cm^{-2}, changing it in steps of 0.01 μC cm^{-2} up to the value for which eq. [2] was obeyed.

A comparison between the values of q_-' obtained through differentiation and those from the isotherm is shown in Fig. 7 for different concentrations of SCN^- at ionic strength 1.0 *M*. It can be seen that the two sets of values are in good agreement, except for the highest concentration (x = 0.5) and for highly positive values of q^M. The same type of behavior was observed for the results obtained at ionic strength 0.5 *M*. Before drawing any conclusions from the comparison above, it is interesting to estimate the error in q_-' obtained by differentiation without considering the variation of activity coefficients with solution composition.

Fawcett and co-workers (4, 5) have taken into account the variation of the activity coefficient with solution composition by introducing the parameter $\beta = (\beta_{KSCN} - \beta_{KF})I$, where β_{KX} is the interaction coefficient between K^+ and X^-, and I is the ionic strength. Thus, knowledge of the value of this parameter allows the calculation of q_-' through the equation (4)

$$[3] \quad \frac{F}{RT(1+\beta\mu)}\left(\frac{\partial\xi^+}{\partial \ln \mu}\right)_{q^M} = q_-' + q_-^{d}\frac{\beta\mu}{(1+\beta\mu)}$$

where q_-^d is the charge in the diffuse layer due to anions, ξ^+ the value of Parsons function for an electrode potential with respect to an electrode reversible to K^+, and $\mu = x/I$.

An examination of the values of $\gamma_\pm$(KSCN) and of $\gamma_\pm$(KF) in the literature (25), together with the works of Fawcett and McCarrick (4) and of Fawcett and Sellan (5), permits one to conclude that in the case of SCN^-, the values of q_-' obtained through differentiation without considering activity coefficient variation would be underestimated, as in the case of NO_3^- (5). One way of estimating the value of β is through the use of the equation (25)

$$[4] \quad \ln \gamma_\pm(KX) = -\frac{AI^{1/2}}{1 + BaI^{1/2}} + \beta_{KX}I$$

where A and B are the Debye–Hückel parameters, and a is the ion size parameter. This equation can be rewritten as

For personal use only.

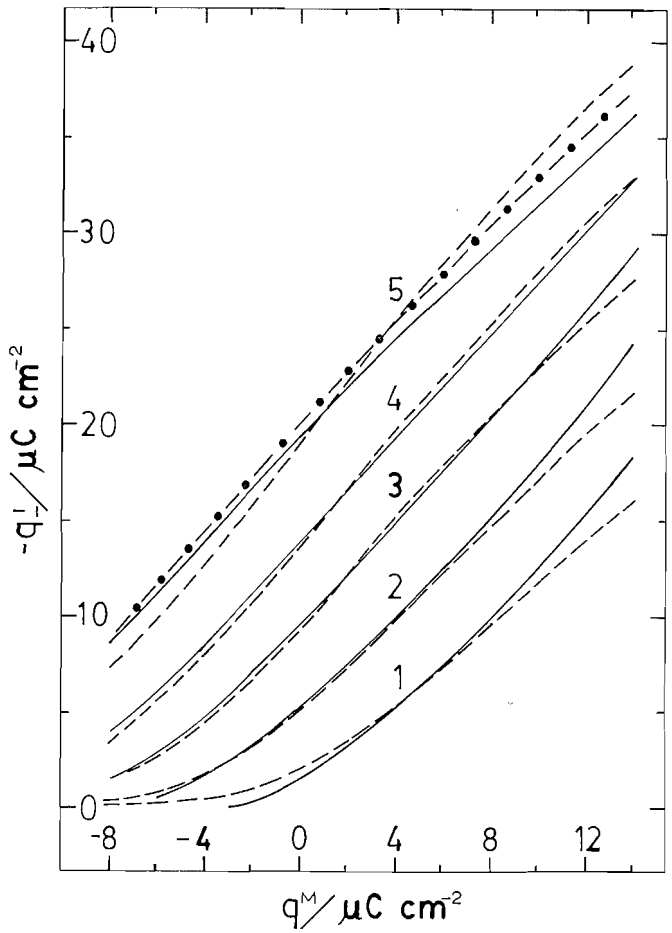

FIG. 7. Charge due to adsorbed thiocyanate ions on Hg at 298 K from aqueous x *M* KSCN + $(1.0 - x)$ *M* KF solutions. x = (*1*) 0.001, (*2*) 0.005, (*3*) 0.025, (*4*) 0.1, (*5*) 0.5. Full lines correspond to data obtained through differentiation; dashed lines correspond to data obtained from the isotherm fitted through the surface pressure method (see text); dotted dashed line corresponds to data obtained through differentiation and corrected because of activity coefficient variation (see text).

$$[5] \quad w = \ln \gamma_{\pm}(KX) + \frac{AI^{1/2}}{1 + BaI^{1/2}} = \beta_{KX} I$$

such that β_{KX} can be calculated through least squares from tabulated values of $\gamma_{\pm}(KX)$ (25), given the value of a for the salt. Least-squares fits were carried out for values of a in the range 2.5–6.0 Å, in steps of 0.1 Å, and the values of β_{KX} used to calculate β were those for the best fit (a_{KSCN} = 3.9 Å; a_{KF} = 3.9 Å). The value of β obtained was −0.072.

Assuming that this value of β is reasonable and considering that the maximum value of q_-^d is ~6 μC cm^{-2} for I = 1.0 *M* and ~4 μC cm^{-2} for I = 0.5 *M* (26), eq. [3] can be used to estimate errors in the values of q_-' of ca. 7% and 4% for μ = 1 for the ionic strengths 1.0 and 0.5 *M*, respectively. Hence, the values of q_-' for x = 0.5 and I = 1.0 *M* (full line No. 5 of Fig. 7) should be ~4% underestimated. When this is taken into consideration the dotted line No. 5 of Fig. 7 is obtained. If the following points are recalled: (*i*) the difference between the dotted line and the one for q_-' from the isotherm (dashed line No. 5 of Fig. 7) is at most ~10%; (*ii*) the values of q_-' obtained through differentiation for x = 0.5 are from one of the ends of the differentiation interval and, so, should be affected by a greater differentiation error; and (*iii*) the surface pressure

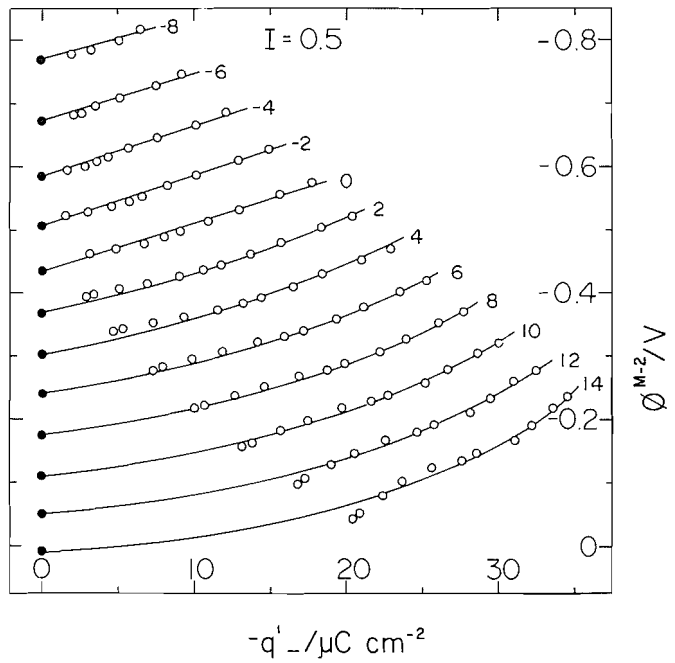

FIG. 8. Potential drop in the inner layer, ϕ^{M-2}, as a function of the specifically adsorbed charge due to SCN^-, q_-' at constant electrode charge density q^M (indicated by the integers adjacent to each curve) for adsorption from the system x *M* KSCN + $(0.5 - x)$ *M* KF. (●) values corresponding to the base solution (see text).

method lacks sensitivity (23); it seems that the difference between the two sets of values of q_-' for x = 0.5 and I = 1.0 *M* is not very significant.

Furthermore, from the value of β above, it can be concluded that there should be no significant error in the values of q_-' from the differentiation for values of $x < 0.25$ when the variation of the activity coefficient with solution composition is not taken into account. From Fig. 7 it can be seen that for $x < 0.25$ the values of q_-' from the differential and those from the isotherm are practically the same (such behavior was also found for I = 0.5 *M*). This indicates that the virial isotherms fitted to the composite surface pressure curves (Figs. 2 and 3) describe quite well the adsorption processes here studied. It would then be of interest to make the same type of comparison for other systems.

In principle, a congruent isotherm is not expected to be suitable to describe ionic adsorption, since the necessity of including a term in ϕ^2 has been demonstrated (27). However, as shown by Fawcett and Sellan (5), when ϕ^2 is small enough it can be expressed in terms of q^M and q_-'. Thus, even with a term in ϕ^2 the isotherm may still be congruent.

The inner layer

Plots of the potential drop across the inner layer, ϕ^{M-2}, against the specifically adsorbed charge density, q_-' at constant q^M (Christie plots) are usually employed to analyze the properties of the inner layer.

Such plots for the data obtained from differentiation are shown in Figs. 8 and 9 for the ionic strengths 0.5 and 1.0 *M*, respectively. From these figures it can be seen that a linear relationship between ϕ^{M-2} and q_-' exists only for $q^M \leq 0$; for positive values of q^M the plots are curvilinear. This latter type of relationship becomes clear by the inclusion of the value of ϕ^{M-2} for q_-' = 0, an important procedure previously called to attention by Fawcett and Sellan (5).

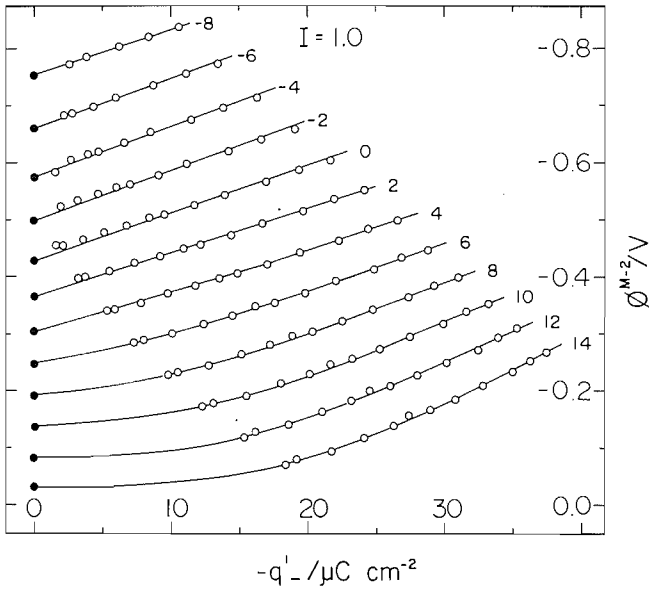

FIG. 9. Potential drop in the inner layer, ϕ^{M-2}, as a function of the specifically adsorbed charge due to SCN^-, q_-' at constant electrode charge density q^M (indicated by the integers adjacent to each curve) for adsorption from the system x *M* KSCN + $(1.0 - x)$ *M* KF. (●) values corresponding to the base solution (see text).

The potential drop across the inner layer, according to Grahame's model, is given by

$$[6] \quad \phi^{M-2} = \frac{q^M}{K_i} + \frac{q_-'}{K_2}$$

where K_i is the integral capacity of the inner layer, and K_2, that between the inner Helmholtz plane (iHp) and the oHp. If for a fixed value of q^M, K_i and K_2 are independent of q_-', then the slope of the Christie plots is equal to $1/K_2$. In general, the slope is given by

$$[7] \quad \left(\frac{\partial\phi^{M-2}}{\partial q_-'}\right)_{q^M} = \frac{1}{K_2} + q_-'\left(\frac{\partial(1/K_2)}{\partial q_-'}\right)_{q^M} + q^M\left(\frac{\partial(1/K_i)}{\partial q_-'}\right)_{q^M}$$

As the Christie plots (Figs. 8 and 9) are linear for $q^M \leq 0$ and curvilinear for $q^M > 0$, each one of these behaviors will be analyzed separately.

When the Christie plots are linear (for -8 μC cm$^{-2} \leq q^M \leq 0$), one may conclude that $\partial(1/K_2)/\partial q_-' \simeq 0$. Considering the fact that the plots are almost parallel but for $q^M = -8$ μC cm^{-2}, the contribution from the third term in eq. [7] must be small in magnitude. Hence, one may conclude that the slopes of the Christie plots are approximately equal to $1/K_2$ within the range of q^M under consideration. The values of K_2 obtained from the plots in Figs. 8 and 9 (Table 2) vary from 123 to 148 μF cm^{-2} at ionic strength 0.5 *M* and from 112 to 124 μF cm^{-2} at ionic strength 1.0 *M*. The smaller values of K_2 at the higher ionic strength may be explained by the increased adsorption which affects the nature of the predominant counter ion at the oHp and, consequently, the thickness of the inner layer. From the values of ϕ^{M-2} in the limit for $q_-' = 0$, one may calculate K_i as

$$[8] \quad K_i = \frac{q^M}{(\phi^{M-2})_{q_-' = 0}}$$

From the values so calculated (Table 2) it seems that K_i is independent of the ionic strength. The smaller variation in K_i with q^M when compared with that in K_2 can be explained by the fact that the nature of the counter ion, which changes when q^M increases, mainly affects the properties of the region of the inner layer between the iHp and oHp, and so, K_2 is expected to vary much more than K_i. If the values of K_i and K_2 here obtained for -8 μC cm$^{-2} \leq q^M < 0$ are compared with those obtained for solutions of one salt (Table 3 of ref. 12), it can be concluded that they are reasonably compatible notwithstanding the different concentration intervals studied. From this comparison it also becomes clear that K_i seems not to depend on the ionic strength.

TABLE 2. Inner-layer integral capacities in the presence of thiocyanate adsorbed on Hg from aqueous 0.5 *M* and 1.0 *M* ionic strength solutions (see text)

q^M (μC cm^{-2})	K_i (μF cm^{-2})		K_2 (μF cm^{-2})	
	I = 0.5 *M*	I = 1.0 *M*	I = 0.5 *M*	I = 1.0 *M*
−8	24	25	148	124
−6	25	26	135	112
−4	27	28	126	112
−2	28	29	123	112

Before analyzing the Christie plots for $q^M > 0$, it is of interest to compare the present results for $q^M < 0$ with those obtained for the adsorption of other ions on Hg from solutions of constant ionic strength (4, 6, 20). First, the comparison will be carried out for those ions whose adsorption was studied from solutions containing K^+ as the counter ion (4, 20) and, after, for those where Na^+ was the counter ion (4, 6), since, as Fawcett and Sellan (5) have pointed out, the nature of the counter ion determines the distance between the iHp and the oHp, χ_{ad}, thus changing the value of K_2. Dutkiewicz and Parsons (20) found K_2 to be approximately constant (60 μF cm^{-2}) in the x *M* KI + $(1.0 - x)$ *M* KF system at negative electrode charge densities ($-12 \leq q^M \leq -6$ μC cm^{-2}); Fawcett and McCarrick (4) found K_2 to be 50 μF cm^{-2} in the x *M* KI + $(0.25 - x)$ *M* KF system at $q_M = -8$ μC cm^{-2}; these values of K_2 are approximately half those obtained here, indicating that χ_{ad} decreases by approximately a factor of two when SCN^- is the adsorbing ion. Fawcett and McCarrick (4) found K_2 to be smaller than 50 μF cm^{-2} in the x *M* NaI + $(0.25 - x)$ *M* NaF system at $q^M = -8$ μC cm^{-2}; K_2 was found to be in the range $125 \leq K_2 \leq 137$ μF cm^{-2} in the x *M* NaN_3 + $(0.95 - x)$ *M* NaF system (6) at negative electrode charge densities ($-7 \leq q^M < 0$ μC cm^{-2}); again χ_{ad} decreases by approximately a factor of two. The fact that for the interfaces containing adsorbed SCN^- and N_3^-, respectively, χ_{ad} is ca. half that for the interfaces containing I^- adsorbed, strongly suggests that SCN^- as well as N_3^- behave as approximately cylindrical ions with their axes perpendicular to the electrode surface, as suggested previously in the case of SCN^- (13). Another important fact that should be pointed out is that the value of K_i for systems at constant ionic strength, besides having no dependence on the ionic strength, seems also not to depend on the nature of the system, as can be seen comparing the values presently obtained with those for I^- (20) and N_3^- (6) at $q^M = -8$ and -6 μC cm^{-2}. The value of K_i seems also not to depend on the nature of the counter ion, since N_3^- was adsorbed from constant ionic strength solutions containing Na^+ as counter ion (6) while I^- (20) and SCN^- were adsorbed from constant ionic strength solutions containing K^+ as counter ion; this same behavior was found before by Fawcett and Sellan (5) for NO_3^-. Such behavior is reasonable since K_i is calculated for $q_-' = 0$ and at $q^M < 0$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 210.87.254.42 on 09/06/12
For personal use only.

(eq. [8]); under this condition the potential drop across the inner layer seems to be very similar, independent of the nature of the cation at the oHp.

For $q^M > 0$ the Christie plots are curvilinear (Figs. 8 and 9) and present two different behaviors, i.e., their slopes decrease with increasing q^M at fixed q_-' for $|q_-'| < 20$ μC cm^{-2} and increase with increasing q^M at fixed q_-' for $|q_-'| > 20$ μC cm^{-2}. The following discussion will be made assuming that the derivatives defining changes in K_1 and K_2 with q_-' (see eq. [7]) are approximately constant for a given value of q^M (5). For $|q_-'| < 20$ μC cm^{-2}, since the slopes decrease with increasing q^M for constant q_-', it is possible to assume that $(\partial(1/K_1)/\partial q_-')_{q^M}$ is negative; thus, K_1 decreases with increasing adsorption. For $|q_-'| > 20$ μC cm^{-2}, the opposite is true; thus K_1 increases with adsorption. The fact that K_1 increases for $|q_-'| > 20$ μC cm^{-2} may be due to changes in the value of χ_{ad} or even in the value of the local dielectric constant, ϵ_i. A decrease in the value of χ_{ad} could be brought by fluoride coadsorption at the more positive electrode charge densities (28). If fluoride specific adsorption is significant, the specifically adsorbed charge density, neglecting variation of the activity coefficient with solution composition, is given by (19)

$$[9] \quad q_-' = q_-'(SCN^-) - \frac{x}{I - x} q_-'(F^-)$$

where $q_-'(SCN^-)$ and $q_-'(F^-)$ are the specifically adsorbed charge densities due to thiocyanate and fluoride ions, respectively, x is the SCN^- ion concentration, and I the ionic strength. Neglect of fluoride adsorption would result in an underestimation of $q_-'(SCN^-)$ and in the Christie plots being more curved. Furthermore, if, as suggested by Baugh and Parsons (29), fluoride ions retain their primary hydration shell when they become adsorbed at Hg, this could lead to an increase in the local dielectric constant. However, the subject of fluoride adsorption on Hg is still not settled and awaits further experimental evidence. For fixed values of q^M, the slopes of the Christie plots increase with increasing $|q_-'|$, indicating that $(\partial(1/K_2)/\partial q_-')_{q^M}$ is negative; thus, K_2 decreases with increasing adsorption.

Received April 22, 1982

SHENGZHI HU, RICHARD JAMES BARTON, KEITH JAMES JOHNSON, and BEVERLY ELLIS ROBERTSON. Can. J. Chem. **61**, 395 (1983).

Crystals of the Cu(II), Co(II), and Ni(II) β-picoline complexes ($[M(H_2O)_2(C_6H_7N)_4](ClO_4)_2$, M = Cu, Co, Ni) all showed monoclinic rhombohedral morphology and were shown by diffraction methods to be isomorphous. The structures of the Cu(II) and Co(II) complexes have been determined in detail.

Atom	a (Å)	b (Å)	c (Å)	β (deg)	D_m	D_x	Colour
Cu(II)	15.292(4)	9.672(2)	20.579(5)	94.73(2)	1.45(1)	1.467	Blue
Co(II)	15.878(12)	9.374(3)	20.661(7)	96.50(4)	1.45(1)	1.448	Pink
Ni(II)	15.7	9.3	20.4	96.5	1.44(1)		Pale blue
